## PREFACE

*Machinery's Handbook* has served as the principal reference work in metalworking, design and manufacturing facilities, and in technical schools and colleges throughout the world, for more than 90 years of continuous publication. Throughout this period, the intention of the *Handbook* editors has always been to create a comprehensive and practical tool, combining the most basic and essential aspects of sophisticated manufacturing practice. A tool to be used in much the same way that other tools are used, to make and repair products of high quality, at the lowest cost, and in the shortest time possible.

The essential basics, material that is of proven and everlasting worth, must always be included if the *Handbook* is to continue to provide for the needs of the manufacturing community. But, it remains a difficult task to select suitable material from the almost unlimited supply of data pertaining to the manufacturing and mechanical engineering fields, and to provide for the needs of design and production departments in all sizes of manufacturing plants and workshops, as well as those of job shops, the hobbyist, and students of trade and technical schools.

The editors rely to a great extent on conversations and written communications with users of the *Handbook* for guidance on topics to be introduced, revised, lengthened, shortened, or omitted. In response to such suggestions, in recent years material on logarithms, trigonometry, and sine-bar constants have been restored after numerous requests for these topics. Also at the request of users, in 1997 the first ever large-print or "desktop" edition of the *Handbook* was published, followed in 1998 by the publication of *Machinery's Handbook CD-ROM* including hundreds of additional pages of material restored from earlier editions. The large-print and CD-ROM editions have since become permanent additions to the growing family of *Machinery's Handbook* products.

Regular users of the *Handbook* will quickly discover some of the many changes embodied in the present edition. One is the combined *Mechanics and Strength of Materials* section, arising out of the two former sections of similar name; another is the *Index of Standards*, intended to assist in locating standards information. "Old style" numerals, in continuous use in the first through twenty-fifth editions, are now used only in the index for page references, and in cross reference throughout the text. The entire text of this edition, including all the tables and equations, has been reset, and a great many of the numerous figures have been redrawn. This edition contains more information than ever before, and sixty-four additional pages brings the total length of the book to 2704 pages, the longest *Handbook* ever.

The 27th edition of the *Handbook* contains significant format changes and major revisions of existing content, as well as new material on a variety of topics. The detailed tables of contents located at the beginning of each section have been expanded and fine tuned to simplify locating your topic; numerous major sections have been extensively reworked and renovated throughout, including *Mathematics*, *Mechanics and Strength of Materials*, *Properties of Materials*, *Fasteners*, *Threads and Threading*, and *Unit Conversions*. New material includes fundamentals of basic math operations, engineering economic analysis, matrix operations, disc springs, constants for metric sine-bars, additional screw thread data and information on obscure and historical threads, aerodynamic lubrication, high speed machining, grinding feeds and speeds, machining econometrics, metalworking fluids, ISO surface texture, pipe welding, geometric dimensioning and tolerancing, gearing, and EDM.

Other subjects in the *Handbook* that are new or have been revised, expanded, or updated are: analytical geometry, formulas for circular segments, construction of four-arc ellipse, geometry of rollers on a shaft, mechanisms, additional constants for measuring weight of piles, Ohm's law, binary multiples, force on inclined planes, and measurement over pins.

The large-print edition is identical to the traditional toolbox edition, but the size is increased by a comfortable 140% for easier reading, making it ideal as a desktop reference. Other than size, there are no differences between the toolbox and large-print editions.

## PREFACE

The *Machinery's Handbook 27* CD-ROM contains the complete contents of the printed edition, presented in Adobe Acrobat PDF format. This popular and well known format enables viewing and printing of pages, identical to those of the printed book, rapid searching, and the ability to magnify the view of any page. Navigation aids in the form of thousands of clickable bookmarks, page cross references, and index entries take you instantly to any page referenced.

The CD contains additional material that is not included in the toolbox or large print editions, including an extensive index of materials referenced in the Handbook, numerous useful mathematical tables, sine-bar constants for sine-bars of various lengths, material on cement and concrete, adhesives and sealants, recipes for coloring and etching metals, forge shop equipment, silent chain, worm gearing and other material on gears, and other topics.

Also new on the CD are numerous interactive math problems. Solutions are accessed from the CD by clicking an icon, located in the page margin adjacent to a covered problem, (see figure shown here). An internet connection is required to use these problems. The list of interactive math solutions currently available can be found in the *Index of Interactive Equations*, starting on page 2689. Additional interactive solutions will be added from time to time as the need becomes clear.

Those users involved in aspects of machining and grinding will be interested in the topics Machining Econometrics and Grinding Feeds and Speeds, presented in the *Machining* section. The core of all manufacturing methods start with the cutting edge and the metal removal process. Improving the control of the machining process is a major component necessary to achieve a **Lean chain** of manufacturing events. These sections describe the means that are necessary to get metal cutting processes under control and how to properly evaluate the decision making.

A major goal of the editors is to make the *Handbook* easier to use. The 27th edition of the *Handbook* continues to incorporate the timesaving thumb tabs, much requested by users in the past. The table of contents pages beginning each major section, first introduced for the 25th edition, have proven very useful to readers. Consequently, the number of contents pages has been increased to several pages each for many of the larger sections, to more thoroughly reflect the contents of these sections. In the present edition, the *Plastics* section, formerly a separate thumb tab, has been incorporated into the *Properties of Materials* section. A major task in assembling this edition has been the expansion and reorganization of the index. For the first time, most of the many Standards referenced in the *Handbook* are now included in a separate *Index Of Standards* starting on page 2677.

The editors are greatly indebted to readers who call attention to possible errors and defects in the *Handbook*, who offer suggestions concerning the omission of some matter that is considered to be of general value, or who have technical questions concerning the solution of difficult or troublesome *Handbook* problems. Such dialog is often invaluable and helps to identify topics that require additional clarification or are the source of reader confusion. Queries involving *Handbook* material usually entail an in depth review of the topic in question, and may result in the addition of new material to the *Handbook* intended to resolve or clarify the issue. The new material on the mass moment of inertia of hollow circular rings, page 248, and on the effect of temperature on the radius of thin circular rings, page 405, are good examples.

Our goal is to increase the usefulness of the *Handbook* to the greatest extent possible. All criticisms and suggestions about revisions, omissions, or inclusion of new material, and requests for assistance with manufacturing problems encountered in the shop are always welcome.

Christopher J. McCauley, Senior Editor

## ACKNOWLEDGMENTS

The editors would like to acknowledge all those who contributed ideas, suggestions, and criticisms concerning the *Handbook*.

Most importantly, we thank the readers who have contacted us with suggestions for new topics to present in this edition of the *Handbook*. We are grateful for your continuing constructive suggestions and criticisms with regard to *Handbook* topics and presentation. Your comments for this edition, as well as past and future ones are invaluable, and well appreciated.

Special thanks are also extended to current and former members of our staff, the talented engineers, recent-graduates, who performed much of the fact checking, calculations, artwork, and standards verification involved in preparing the printed and CD-ROM editions of the *Handbook*.

Many thanks to Janet Romano for her great *Handbook* cover designs. Her printing, packaging, and production expertise are irreplaceable, continuing the long tradition of *Handbook* quality and ruggedness.

Many of the American National Standards Institute (ANSI) Standards that deal with mechanical engineering, extracts from which are included in the *Handbook*, are published by the American Society of Mechanical Engineers (ASME), and we are grateful for their permission to quote extracts and to update the information contained in the standards, based on the revisions regularly carried out by the ASME.

ANSI Standards are copyrighted by the publisher. Information regarding current editions of any of these Standards can be obtained from ASME International, Three Park Avenue, New York, NY 10016, or by contacting the American National Standards Institute, West 42nd Street, New York, NY 10017, from whom current copies may be purchased. Additional information concerning Standards nomenclature and other Standards bodies that may be of interest is located on page 2079.

Several individuals in particular, contributed substantial amounts of time and information to this edition.

Mr. David Belforte, for his thorough contribution on lasers.

Manfred K. Brueckner, for his excellent presentation of formulas for circular segments, and for the material on construction of the four-arc oval.

Dr. Bertil Colding, provided extensive material on grinding speeds, feeds, depths of cut, and tool life for a wide range of materials. He also provided practical information on machining econometrics, including tool wear and tool life and machining cost relationships.

Mr. Edward Craig contributed information on welding.

Dr. Edmund Isakov, contributed material on coned disc springs as well as numerous other suggestions related to hardness scales, material properties, and other topics.

Mr. Sidney Kravitz, a frequent contributor, provided additional data on weight of piles, excellent proof reading assistance, and many useful comments and suggestions concerning many topics throughout the book.

Mr. Richard Kuzmack, for his contributions on the subject of dividing heads, and additions to the tables of dividing head indexing movements.

Mr. Robert E. Green, as editor emeritus, contributed much useful, well organized material to this edition. He also provided invaluable practical guidance to the editorial staff during the *Handbook's* compilation.

Finally, Industrial Press is extremely fortunate that Mr. Henry H. Ryffel, author and editor of *Machinery's Handbook*, continues to be deeply involved with the *Handbook*. Henry's ideas, suggestions, and vision are deeply appreciated by everyone who worked on this book.

To find the square of a given whole number, divide the number by 10 and find the row in the first column that contains the whole number portion of the result. The selected row contains the square of given number under the column corresponding to the last digit in the number.

*Example:* The square of 673, found in row labeled 67, under column labeled 3, is given as 452,929.

**CEMENT, CONCRETE, LUTES, ADHESIVES, AND SEALANTS****Cement**

The cements used in concrete construction are classified as:

- 1) Portland cements.
- 2) Natural cements.
- 3) Pozzuolanic, pozzuolan, or slag cements.

These different classes are all hydraulic cements as they will set or harden under water. When the powdered cement is mixed with water to a plastic condition, the cement sets or solidifies as the result of chemical action. After the preliminary hardening or initial set, the cement slowly increases in strength, the increase extending over months or years.

**Portland Cement.**— Portland and natural cements are the kinds most commonly used. Portland cement should be used for all structures which must withstand stresses and for masonry that is either under water or heavily exposed to water or the weather. According to the specifications of the American Society for Testing Materials, the specific gravity of Portland cement must be not less than 8:1. If the tested cement is below this requirement. A second test should be made on a sample ignited at a low red heat. The ignited cement should not lose more than four per cent of its weight. A satisfactory Portland cement must not develop initial set in less than 30 minutes; it must not develop hard set in less than 1 hour; but the time required for developing hard set must not exceed 10 hours. The minimum requirements for tensile strength in pounds, for briquettes one square inch in cross-section, should be as follows:

For cement 24 hours old in moist air, 175 pounds.

For cement 7 days old, one day in moist air and six days in water, 500 pounds.

For cement 28 days old, one day in moist air and 27 days in water, 600 pounds.

For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 200 pounds.

For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 275 pounds.

The cements must under no circumstances show a decrease in strength during the time periods specified.

**Natural Cement.**— Natural cement is used in mortar for ordinary brick work and stone masonry, street sub-pavements, as a backing or filling for massive concrete or stone masonry, and for similar purposes. Natural cement does not develop its strength as quickly and is not as uniform in composition as Portland cement. It should not be used for columns, beams, floors or any structural members which must withstand considerable stress. Natural cement is also unsuitable for work that is exposed to water. Foundations which are subjected to moderate compressive stresses may be made of natural cement, which is also satisfactory for massive masonry where weight rather than strength is the essential feature.

The American Society for Testing Materials gives the following specifications for natural cement: An initial set must not develop in less than 10 minutes, and the hard set must not develop in less than 30 minutes, but must develop in less than three hours. The minimum requirements for tensile strength in pounds, for briquettes one inch in cross-section, are as follows:

For natural cement 24 hours old in moist air, 75 pounds.

For natural cement 7 days old, one day in moist air and six days in water, 150 pounds.

For natural cement 28 days old, one day in moist air and 27 days in water, 250 pounds.

For one part of cement and three parts of standard Ottawa sand, 7 days old, one day in moist air and six days in water, 50 pounds.

For one part of cement and three parts of standard Ottawa sand, 28 days old, one day in moist air and 27 days in water, 125 pounds.

**Pozzolan or Slag Cement.**—This cement is adapted for structures which are constantly exposed to fresh or salt water and for drains, sewers, foundation work underground, etc. It is not suitable where masonry is exposed to dry air for long periods. Pozzolan cement sets slowly but its strength increases considerably with age. While this cement is relatively cheap, it is not as strong, uniform, or reliable as Portland and natural cements, and is not used extensively.

### Concrete

**Concrete.**—The principal ingredients of concrete are the matrix or mortar and the “coarse aggregate.” The matrix consists of cement and sand mixed with water, and the coarse aggregate is usually broken stone or gravel. What is known as *rubble concrete* or cyclopean masonry contains large stones which are used for reducing the cost of massive dams and walls. These rubble stones may vary from a few per cent to over one-half the volume. When concrete without much strength but light in weight is required, cinders may be used. This cinder concrete is porous and is used for light floor construction or fire-proofing.

**Concrete Mixtures.**—In the mixing of concrete, it is desirable to use as little cement as is consistent with the required strength, because the cement is much more expensive than the other ingredients. The proportioning of the ingredients is usually by volume and mixtures are generally designated by giving the amount of each ingredient in a fixed order, as 1 : 2 : 5, the first figure indicating the amount of cement by volume, the second the amount of sand, and the third the amount of broken stone or gravel.

For ordinary machine foundations, retaining walls, bridge abutments, and piers exposed to the air, a 1 : 2½ : 5 concrete is satisfactory; and for ordinary foundations, heavy walls, etc., a lean mixture of 1 : 3 : 6 may be used. For reinforced floors, beams, columns, and arches, as well as for machine foundations which are subjected to vibration, a 1 : 2 : 4 concrete is generally used. This composition is also employed when concrete is used under water. For water tanks and similar structures subjected to considerable pressure and required to be water-tight, mixtures rich in cement and composed of either 1 : 1 : 2 or 1 : 1½ : 3 concrete are used. Portland cement should preferably be used in concrete construction.

**Sand, Gravel, and Stone for Concrete.**—The sand used must be free from dust, loam, vegetable, or other organic matter; it should pass, when dry, through a screen with holes of ¼-inch mesh. The gravel should consist of clean pebbles free from foreign matter and should be of such coarseness that it will not pass through a screen of ¼-inch mesh. Gravel containing loam or clay should be washed by a hose before mixing. The broken stone should be of a hard and durable kind, such as granite or limestone. This stone should pass through a 2½-inch screen.

**Amount of Water for Mixing Concrete.**—The amount of water required to combine chemically with cement is about 16 per cent by weight, but in mixing concrete a greater amount than this must be used, because of losses and the difficulty of uniformly distributing the water. In hot weather more water is required than in cool weather because of the loss due to evaporation. The same applies when absorbent sand is used, or when the concrete is not rammed tightly. An excess of water is not desirable, because this excess will flow away and carry some of the cement with it. The water must be free from oils, acids, and impurities that would prevent a proper chemical combination with the cement. It is important to mix the ingredients thoroughly. Lime cement, sand and stone should be mixed while dry, preferably using a machine. Enough water should then be added to produce a mixture which will flow readily and fill different parts of the form.

**Reinforced Concrete.**—Concrete reinforced with steel is widely used, especially where the concrete must resist tensile as well as compressive stresses. This reinforcement may be in the form of round bars twisted square bars, corrugated bars, expanded metal, steel mesh, or wire fabric. The proportions for reinforced concrete structures are usually 1 : 2 : 4, or 1

barrel of portland cement, 2 barrels of sand, and 4 barrels of broken stone or gravel. The lateral spacing between reinforcement bars should not be less than three times the bar diameter from center to center, with a clear space between the bars of at least one inch. The distance from the side of a beam to the center of the nearest bar should be not less than two diameters.

**Strength of Concrete.**—The strength varies greatly depending upon the quality and proportions of the ingredients and the care in mixing and depositing in the forms. The compressive strength of concrete which, after having been mixed and laid, has set 28 days, varies from 1000 to 3300 pounds per square inch, according to the mixture used. If made in the proportion 1 : 3 : 6, using soft limestone and sandstone a compressive strength of only 1000 pounds per square inch may be expected, whereas a mixture of 1 : 1 : 2, made with soft limestone and sandstone, will show a strength of 2200 pounds per square inch. A mixture of 1 : 3 : 6, made from granite or trap rock, will have a compressive strength of 1400 pounds per square inch, while a mixture of 1 : 1 : 2, made from granite or trap rock, will have a strength of 3300 pounds per square inch. Other mixtures will have values between those given. The richer in cement in proportion to sand, gravel, and stone, the stronger will be the concrete. The strongest concretes are also obtained by using granite or trap rock. A medium strength is obtained by using gravel, hard limestone, or hard sandstone, whereas the least strength is obtained by using soft limestone or sandstone. Concrete may also be mixed with cinders, but, in this case, very inferior strength is obtained; the richest mixtures will only give a strength of about 800 pounds per square inch.

**Durability of Concrete in Sea Water.**—Experiments have been made to determine the durability of different mixtures of concrete when exposed to sea water. It has been found that the mixtures that give the best results are those that are richest in cement. Mixtures of 1 : 1 : 2, for example, will give much better results than mixtures of 1 : 3 : 6. Also, very wet mixtures seem to give better results than those that are comparatively dry when deposited. It has also been found that, in order to insure the permanence of Portland cement concrete in sea water, the cement must contain as little lime and alumina as possible and must also be free from sulfates, and the proportion of sand and stones in the concrete must be such that the structure is practically non-porous. Natural cement should never be used for concrete exposed to sea water.

**Waterproofing Concrete.**—Several formulas for making concrete waterproof have been successfully used but some of them are too expensive for general application. One of the simplest, cheapest, and most effective is that developed by the U.S. Geological Survey. A heavy residual mineral oil of 0.93 specific gravity, mixed with Portland cement, makes it waterproof and does not weaken when the concrete consists of, say, cement, 1 part, sand, 3 parts, and oil, not more than 10 per cent, by weight, of the cement. Concrete mixed with oil requires about fifty per cent longer time to set hard, and the compressive strength is slightly decreased but not seriously. The bond or grip of oil concrete on steel is much decreased when plain bars are used, but formed bars, wire mesh, or expanded metal act as effectively in it as in ordinary concrete.

**Resistance to Acids and Oils.**—Concrete of a good quality, that has thoroughly hardened, resists the action of acids and mineral oils as well as other building materials, but vegetable oils containing fatty acids produce injurious effects by combining with the lime in the cement and causing disintegration of the concrete.

### Lutes and Cements

Luting and cementing materials for various purposes in the laboratory and shops may be classified as follows: water- and steam-proof; oil-proof; acid-proof; proof to hydrocarbon gases; chlorine-proof; elastic; general purposes; marine glue; gaskets; machinists; leather (belting); crucible; iron; and stone.

**Water-proof Compositions.**—The asphalt fluid coatings for reservoir wall, concrete foundations, brick, wood, etc., are often of use to engineers. Asphalt only partly dissolves in petroleum naphtha, but when heated in a steam-jacketed kettle and not thinned out too much, a mixture of the two may be obtained in which the part of the asphalt not dissolved is held in suspension. Asphalt is entirely soluble in benzol or toluol, which are about the cheapest solvents for all the constituents of asphalt. Tar and pitch are sometimes used in this connection, but tar contains water, light oils and free carbon, and does not wear as well as good refined asphalt; pitch also contains free carbon, which is sometimes objectionable when it is thinned out with a solvent. Asphalt alone is somewhat pervious to water, but it can be improved in this respect by adding about one-fourth its weight of paraffin; it is also well to add a little boiled linseed oil. For thicker compositions, where body is required, asbestos, stone powder, cement, etc., may be added as fillers. Lutes of linseed oil thickened with clay, asbestos, red or white lead, etc., are waterproof if made thick enough. These are much used for steam joints. Flaxseed meal made into a paste with water is often serviceable, the oil contained serving as a binder as the water evaporates.

**Oil-proof Cements.**—The well-known “hektograph composition” is the most useful lute for small leaks, etc. It consists of the following ingredients: Good glue or gelatin, 2 parts; glycerin, 1 part; water, 7 parts. This preparation is applied warm and stiffens quickly on cooling. Another very useful composition is a stiff paste of molasses and flour. Another preparation, impervious to oil vapors, is the “flaxseed poultice,” mentioned in the preceding paragraph, which is proof to oil vapors. One of the strongest cements, and one which is really oil-proof, waterproof and acid-proof, is a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use. A mixture of plaster-of-paris and water is useful, and it is sometimes advantageous to mix straw or hair with it. A solution of silicate of soda made into a stiff paste with carbonate of lime gets hard in six to eight hours.

**Acid-proof Cements.**—The asphalt compositions already mentioned, compositions of melted sulphur with fillers of stone powder, cement, sand, etc., may be used, and also the following, which withstands hydrochloric acid vapors: rosin, 1 part; sulphur, 1 part; fireclay, 2 parts. The lute composed of boiled linseed oil and fireclay acts well with most acid vapors. The composition of glycerin and litharge previously referred to is useful in this connection, especially when made up according to the following formula: Litharge, 80 pounds; red lead, 8 pounds; “flock” asbestos, 10 pounds. It should be fed into a mixer, a little at a time, with small quantities of boiled oil (about six quarts of oil being used). Sockets in 3-inch pipes carrying nitric acid, calked with this preparation, showed no leaks in nine months.

A particularly useful cement for withstanding acid vapors, which is tough and elastic, is composed of crude rubber, cut fine, 1 part; linseed oil, boiled, 4 parts; fireclay, 6 parts. The rubber is dissolved in carbon disulphide to the consistency of molasses and is then mixed with the oil. Other acid-proof cements are as follows: “Black putty” made by carefully mixing equal portions of china-clay, gas-tar and linseed oil. The china-clay must be well dried by placing it over a boiler or by other means. Barytes cement is composed of pure, finely ground sulfate of barium, and is made into a putty with a solution of silicate of soda. This sets very hard when moderately heated, and is then proof against acids. The gravity of the silicate of soda should be between 1.2 and 1.4, 24 degrees to 42 degrees Baume. If too thin, it does not hold; and when thicker than 1.4, it expands and breaks.

**Gasket Compositions.**—Almost any cementing substance may be used with rings of asbestos, etc., for gaskets, but some are especially adapted for the purpose. Asphalt, tar, petroleum residuum and soft or hard pitch are recommended. Silicate of soda is much used, and is sometimes advantageously mixed with casein, fine sand, clay, carbonate of lime, caustic lime, magnesia, oxides of heavy metals, such as lead, zinc, iron and powdered

barytes. A few mixtures that might be selected are: Silicate of soda and asbestos; silicate of soda, asbestos and slaked lime; silicate of soda and fine sand; silicate of soda and fireclay.

**Machinists Cements.**—These are also known as red and white leads. The red lead is often diluted with an equal bulk of silica or other inert substance to make it less powdery. The best way to do this is to add rubber or gutta-percha to the oil as follows: Linseed oil, 6 parts, by weight; rubber or gutta-percha, 1 part by weight. The rubber or gutta-percha is dissolved in sufficient carbon disulphide to give it the consistency of molasses, mixed with the oil, and left exposed to the air for about twenty-four hours. The red lead is then mixed to a putty. Oxide of iron makes a less brittle cement than red lead.

**Leather Cements.**—a) Equal parts of good hide glue and American isinglass, softened in water for ten hours and then boiled with pure tannin until the whole mass is sticky. The surface of the joint should be roughened and the cement applied hot.

b) 1 pound of finely shredded gutta-percha digested over a water-bath with 10 pounds of benzol, until dissolved, and 12 pounds of linseed oil varnish stirred in.

c) 7  $\frac{1}{2}$  pounds of finely shredded india-rubber is completely dissolved in 10 pounds of carbon disulphide by treating while hot; 1 pound of shellac and 1 pound of turpentine are added, and the hot solution heated until the two latter ingredients are also dissolved.

d) another leather cement is as follows: gutta-percha, 8 ounces; pitch, 1 ounce; shellac, 1 ounce; sweet oil, 1 ounce. These are melted together.

e) still another is as follows: fish glue is soaked in water twenty-four hours, allowed to drain for a like period, boiled well, and a previously melted mixture of 2 ounces of rosin and  $\frac{1}{2}$  ounce of boiled oil is added to every two pounds of glue solution.

**Iron and Stone Cements.**—When finely divided iron, such as filings or cast iron borings that have been powdered, is mixed with an oxidizing agent, such as manganese dioxide, or a substance electro-negative to iron, such as sulphur, in a good conducting solution like salt or sal-ammoniac, galvanic action sets in very rapidly and the iron swells, by forming iron oxide, and cements the mass together. It is best diluted with Portland cement, the proportions being as follows: iron filings, 40 parts; manganese dioxide or flowers of sulphur, 10 parts; sal-ammoniac, 1 part; Portland cement, 23 to 40 parts; water to form a paste. A hard stone-like composition is made as follows: zinc oxide, 2 parts; zinc chloride, 1 part; water to make a paste. Magnesium oxide and chloride may also be used in like proportions. When used in considerable quantity, this cement is mixed with powdered stone, for reasons of economy, the proportions depending upon the character of the work.

**Cement Proof to Hydrocarbon Gases.**—Compositions of plaster and cement, the former setting more quickly, are used; also compositions of casein, such as finely powdered casein, 2 parts; fresh slaked lime, 50 parts; fine sand, 50 parts. Water is added, when used, to form a thick mass. Various mixtures of silicate of soda are employed in which the thick silicate is absorbed in some inert material such as clay, sand or asbestos.

**Cements Proof to Chlorine.**—The best and only reliable compositions are a few made with Portland cement, and the following is used for electrolytic and chemical plants: powdered glass, 1 part; Portland cement, 1 part; silicate of soda, 1 part; a small amount of powdered slate. This lute withstands acids and alkalies, as well as the influences of chlorine. Linseed oil made into a paste with fireclay serves for a time.

**Elastic Cements.**—The various cements containing rubber are elastic, if the rubber is in a predominating amount; many containing boiled linseed oil and the hektograph composition already mentioned are quite elastic. The rubber and linseed-oil cement, given in *Acid-proof Cements* on page 2906, is very tough and useful for nearly all purposes except when oil vapors are to be confined. The most useful single rubber lute is probably the so-called Hart's india-rubber cement. Equal parts of raw linseed oil and pure masticated rubber are digested together by heating, and this mixture is made into a stiff putty with fine "paper stock" asbestos. It is more convenient, however, to dissolve the rubber first in carbon disulphide, and, after mixing the oil with it, to let the solvent evaporate spontaneously.

**General Purposes.**—Plaster-of-paris, especially when mixed with straw, flush trimmings, hair, broken stone, etc., and used according to temperature strain and other conditions, is one of the most useful preparations for general purposes. A putty of flour and molasses is a good composition to keep in a works ready for quick application when needed. It serves, for a time, almost any purpose at moderate temperatures. Casein compositions have great strength. the white of an egg made into a paste with slaked lime is strong and efficient, but must be used promptly on account of its quick setting qualities.

**Marine Glue.**—This can be purchased almost as cheaply as made. It consists of crude rubber, 1 part; shellac, 2 parts; pitch, 3 parts. The rubber must first be dissolved in carbon disulphide or turpentine before mixing with the heated combination of the other two ingredients.

**Acid-proof Lining.**—A lining for protecting tanks from the influence of acids is made from a mixture consisting of 75 parts (by weight), of pitch; 9 parts plaster-of-paris; 9 parts ochre; 15 parts beeswax; and 3 parts litharge. The tanks are covered on the inside with a thick coat of this mixture.

**Cements for Pipe Joints.**—A strong cement which is oil-proof, waterproof, and acid-proof, consists of a stiff paste of glycerin and litharge. These form a chemical combination which sets in a few minutes. If a little water is added, it sets more slowly, which is often an advantage. This cement is mixed when required for use.

*Mixture for Threaded Pipe Joints:* A good material to apply to pipe threads before making up the joints, in order to obtain a tight joint that will resist the action of gases or liquids, is made of red lead mixed with pure boiled linseed oil. This mixture has been widely used and is very satisfactory. It should have a heavy fluid-like consistency, and if applied to a clean, well-cut thread will give an excellent joint.

*Shellac for Pipe Connections:* Shellac has proved to be a very satisfactory substitute for lead in sealing air and gas pipe connections. It is applied with a brush to the joints and hardens very rapidly, and being brittle, the pipes can be readily disconnected.

*Graphic, Litharge, Chalk Cement:* A good cement for use in making steam pipe joints is made in the following manner: Grind and wash in clean cold water 15 parts of chalk and 50 parts of graphite; mix the two together thoroughly and allow to dry. When dry regrind to a fine powder, to which add 20 parts of ground litharge and mix to a stiff paste with 15 parts of boiled linseed oil. The preparation may be set aside for future use, as it will remain plastic for a long time if placed in a cool place. It is applied to the joint packing as any ordinary cement.

*White and Red Lead Mixture:* Mix in ordinary white lead, enough powdered red lead to make a paste the consistency of putty. Spread this mixture on the joint, and when it hardens, the joint will be water tight. This mixture was used on stand-pipe flanges after testing all kinds of rubber gaskets without success. The mixture hardened and made a tight joint, never leaking afterward.

### Adhesives

**Adhesives Bonding.**—By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. However, besides bonding a joint, an adhesive may serve as a seal against attack by or passage of foreign materials. When an adhesive performs both bonding and sealing functions, it is usually called an adhesive sealant.

Where the design of an assembly permits, bonding with adhesives can replace bolting, welding, and riveting. When considering other fastening methods for thin cross-sections, the joint loads might be of such an unacceptable concentration that adhesives bonding may provide the only viable alternative. Properly designed adhesive joints can minimize or eliminate irregularities and breaks in the contour of an assembly. Adhesives can also serve

as dielectric insulation. An adhesive with dielectric properties can act as a barrier against galvanic corrosion when two dissimilar metals such as aluminum and magnesium are joined together. Conversely, adhesive products are available which also conduct electricity.

An adhesive can be classified as structural or non-structural. Agreement is not universal on the exact separation between both classifications. But, in a general way, an adhesive can be considered structural when it is capable of supporting heavy loads; non-structural when it cannot. Most adhesives are found in liquid, paste, or granular form, though film and fabric-backed tape varieties are available. Adhesive formulations are applied by brush, roller, trowel, or spatula. If application surfaces are particularly large or if high rates of production are required, power-fed flow guns, brushes, or sprays can be used.

The hot-melt adhesives are relatively new to the assembly field. In general, they permit fastening speeds that are much greater than water- or solvent-based adhesives. Supplied in solid form, the hot-melts liquefy when heated. After application, they cool quickly, solidifying and forming the adhesive bond. They have been used successfully for a wide variety of adherends, and can greatly reduce the need for clamping and lengths of time for curing storage.

If an adhesive bonding agent is to give the best results, time restrictions recommended by the manufacturer, such as shelf life and working life must be observed. The shelf life is considered as the period of time an adhesive can be stored after its manufacture. Working or "pot" life is the span of time between the mixing or making ready of an adhesive, on the job, and when it is no longer usable.

The actual performance of an adhesive-bonded joint depends on a wide range of factors, many of them quite complex. They include: the size and nature of the applied loads; environmental conditions such as moisture or contact with other fluids or vapors; the nature of prior surface treatment of adherends; temperatures, pressures and curing times in the bonding process.

A great number of adhesives, under various brand names, may be available for a particular bonding task. However, there can be substantial differences in the cost of purchase and difficulties in application. Therefore, it is always best to check with manufacturers' information before making a proper choice. Also, testing under conditions approximating those required of the assembly in service will help assure that joints meet expected performance.

Though not meant to be all-inclusive, the information which follows correlates classes of adherends and some successful adhesive compositions from the many that can be readily purchased.

*Bonding Metal:* Epoxy resin adhesives perform well in bonding metallic adherends. One type of epoxy formulation is a two-part adhesive which can be applied at room temperature. It takes, however, seven days at room temperature for full curing, achieving shear strengths as high as 2500 psi (17.2 MPa). Curing times for this adhesive can be greatly accelerated by elevating the bonding temperature. For example, curing takes only one hour at 160°F (71°C).

A structural adhesive-filler is available for metals which is composed of aluminum powder and epoxy resin. It is made ready by adding a catalyst to the base components, and can be used to repair structural defects. At a temperature of 140°F (60°C) it cures in approximately one hour. Depending on service temperatures and design of the joint, this adhesive-filler is capable of withstanding flexural stresses above 10,000 psi (69 MPa), tension above 5,000 psi (34 MPa), and compression over 30,000 psi (207 MPa).

Many non-structural adhesives for metal-to-metal bonding are also suitable for fastening combinations of types of materials. Polysulfide, neoprene, or rubber-based adhesives are used to bond metal foils. Ethylene cellulose cements, available in a selection of colors, are used to plug machined recesses in metal surfaces, such as with screw insets. They harden within 24 hours. Other, stronger adhesive fillers are available for the non-structural patch-

ing of defects in metallic parts. One variety, used for iron and steel castings, is a cement that combines powdered iron with water-activated binding agents. The consistency of the prepared mix is such that it can be applied with a trowel and sets within 24 hours at room temperature. The filler comes in types that can be applied to both dry and wet castings, and is able to resist the quick changes of temperature during quenching operations.

Polyester cement can replace lead and other fillers for dents and openings in sheet metal. One type, used successfully on truck and auto bodies, is a two-part cement consisting of a paste resin that can be combined with a paste or powder extender. It is brushed or trowelled on, and is ready for finishing operations in one hour.

Adhesives can be used for both structural and non-structural applications which combine metals with non-metals. Structural polyester-based adhesives can bond reinforced plastic laminates to metal surfaces. One type has produced joints, between glass reinforced epoxy and stainless steel, that have tensile strengths of over 3000 psi (21 MPa). Elevated temperature service is not recommended for this adhesive. However, it is easily brushed on and bonds under slight pressure at room temperature, requiring several days for curing. The curing process accelerates when heat is added in a controlled environment, but there results a moderate reduction in tensile strength.

Low-density epoxy adhesives are successful in structurally adhering light plastics, such as polyurethane foam, to various metals. Applied by brush or spatula, the bonds cure within 24 hours at room temperatures.

Metals can be bonded structurally to wood with a liquid adhesive made up of neoprene and synthetic resin. For the best surface coverage, the adhesive should be applied in a minimum of two coats. The joints formed are capable of reaching shear stresses of 125 psi, and can gain an additional 25 percent in shear strength with the passage of time. This adhesive also serves as a strong, general purpose bonding agent for other adherend combinations, including fabrics and ceramics.

For bonding strengths in shear over 500 psi (3.4 MPa) and at service temperatures slightly above 160°F (71°C), one- and two-part powder and jelly forms of metal-to-wood types are available.

Besides epoxy formulations, there are general purpose rubber, cellulose, and vinyl adhesives suitable for the non-structural bonding of metals to other adherends, which include glass and leather. These adhesives, however, are not limited only to applications in which one of the adherends is metal. The vinyl and cellulose types have similar bonding properties, however the vinyls are less flammable and are weaker in resistance to moisture than the comparable cellulose. Rubber-based adhesives, in turn, have good resistance to moisture and lubricating oil. They can form non-structural bonds between metal and rubber.

One manufacturer has produced an acrylic-based adhesive that is highly suitable for rapidly bonding metal with other adherends at room temperature. For some applications it can be used as a structural adhesive, in the absence of moisture and high temperature. It cures within 24 hours and can be purchased in small bottles with dispenser tips.

A two-part epoxy adhesive is commercially available for non-structural bonding of joints or for patchwork in which one of the adherends is metal. Supplied in small tubes, it performs well even when temperatures vary between -50° to 200°F (-46° to 93°C). However, it is not recommended for use on assemblies that may experience heavy vibrations.

*Bonding Plastic:* Depending on the type of resin compound used in its manufacture, a plastic material can be classified as one of two types: a thermoplastic or a thermoset.

Thermoplastic materials have the capability of being repeatedly softened by heat and hardened by cooling. Common thermoplastics are nylon, polyethylene, acetal, polycarbonate, polyvinyl chloride, cellulose nitrate and cellulose acetate. Also, solvents can easily dissolve a number of thermoplastic materials. Because of these physical and chemical characteristics of thermoplastics, heat or solvent welding may in many instances offer a better bonding alternative than adhesives.

Thermoplastics commonly require temperatures between 200° and 400°F (93° and 204°C) for successful heat welding. However, if the maximum temperature limit for a particular thermoplastic formulation is exceeded, the plastic material will experience permanent damage. Heat can be applied directly to thermoplastic adherends, as in hot-air welding. More sophisticated joining techniques employ processes in which the heat generated for fusing thermoplastics is activated by electrical, sonic, or frictional means.

In the solvent welding of thermoplastics, solvent is applied to the adherend surfaces with the bond forming as the solvent dries. Some common solvents for thermoplastics are: a solution of phenol and formic acid for nylon; methylene chloride for polycarbonate; and methyl alcohol for the cellulose.

Many adhesive bonding agents for thermoplastics are “dope” cements. Dope or solvent cements combine solvent with a base material that is the same thermoplastic as the adherend. One type is used successfully on polyvinyl chloride water (PVC) pipe. This liquid adhesive, with a polyvinyl chloride base, is applied in at least two coats. The pipe joint, however, must be closed in less than a minute after the adhesive is applied. Resulting joint bonds can resist hydrostatic pressures over 400 psi (28 MPa), for limited periods, and also have good resistance to impact.

Previously mentioned general purpose adhesives, such as the cellulose, vinyls, rubber cements, and epoxies are also used successfully on thermoplastics.

Thermoset plastics lack the fusibility and solubility of the thermoplastics and are usually joined by adhesive bonding. The phenolics, epoxies, and alkyds are common thermoset plastics. Epoxy-based adhesives can join most thermoset materials, as can neoprene, nitrile rubber, and polyester-based cements. Again, these adhesives are of a general purpose nature, and can bond both thermoplastics and thermosets to other materials which include ceramics, fabric, wood, and metal.

**Bonding Rubber:** Adhesives are available commercially which can bond natural, butyl, nitrile, neoprene, and silicone rubbers. Natural and synthetic rubber cements will provide flexible joints; some types resist lubricating and other oils. Certain general purpose adhesives, such as the acrylics or epoxies, can bond rubber to almost anything else, though joints will be rigid. Depending on the choice of adhesive as well as adherend types, the bonds can carry loadings that vary from weak non-structural to mild structural in description. One type of natural rubber with a benzene-naphtha solvent can resist shear stresses to 1252.5 psi (83 kPa).

**Bonding Wood:** Animal glues, available in liquid and powder form, are familiar types of wood-to-wood adhesives, commonly used in building laminated assemblies. Both forms, however, require heavy bonding pressures for joints capable of resisting substantial loadings. Also, animal glues are very sensitive to variations in temperature and moisture.

Casein types of adhesive offer moderate resistance to moisture and high temperature, but also require heavy bonding pressures, as much as 200 psi, for strong joints. Urea resin adhesives also offer moderate weather resistance, but are good for bonding wood to laminated plastics as well as to other wooden adherends. For outdoor service, under severe weather conditions, phenol-resorcinol adhesives are recommended.

Vinyl-acetate emulsions are excellent for bonding wood to other materials that have especially non-porous surfaces, such as metal and certain plastic laminates. These adhesives, too, tend to be sensitive to temperature and moisture, but are recommended for wooden pattern making.

Rubber, acrylic, and epoxy general-purpose adhesives also perform well with wood and other adherend combinations. Specific rubber-based formulations resist attack by oil.

**Fabric and Paper Bonding:** The general purpose adhesives, which include the rubber cements and epoxies previously mentioned, are capable of bonding fabrics together and fabrics with other adherend materials. A butadiene-acrylonitrile adhesive, suitable also for fastening metals, glass, plastic, and rubber, forms joints in fabric that are highly resistant to

oil and which maintain bonding strength at temperatures up to 160°F (70°C). This adhesive, however, requires a long curing period, the first few hours of which are at an elevated temperature.

Commonly, when coated fabric materials must be joined, the base material forming the suitable adhesive is of the same type as that protecting the fabric. For example, a polyvinyl chloride-based adhesive is acceptable for vinyl-coated fabrics; and neoprene-based cements for neoprene-coated materials.

Rubber cements, gum mucilages, wheat pastes, and wood rosin adhesive can join paper as well as fabric assemblies. Solvent-based rosins can be used on glass and wood also. Rosin adhesives can also be treated as hot-melt adhesives for rapid curing. Generally, the rosins are water resistant, but usually weak against attack by organic solvents.

### Sealants

**Sealants.**—Normally, the primary role of a sealant composition is the prevention of leakage or access by dust, fluid, and other materials in assembly structures. Nevertheless, many products are currently being manufactured that are capable of performing additional functions. For example, though a sealant is normally not an adhesive, there exists a family of adhesive sealants which in varying degrees can bond structural joints as well. Besides resisting chemical attack, some sealant surface coatings can protect against physical wear. Sealants can also dampen noise and vibration, or restrict the flow of heat or electricity. Many sealant products are available in decorative tints that can help improve the appearance of an assembly.

Most sealants tend to be limited by the operating temperatures and pressures under which they are capable of sustained performance. Also, before a suitable choice of sealant formulation is made, other properties have to be examined; these include: strength of the sealant; its degree of rigidity; ease of repair; curing characteristics; and even shelf and working life.

Dozens of manufacturers supply hundreds of sealant compounds, a number of which may fill the requirements for a particular application. The following information, however, lists common uses for sealants, along with types of compositions that have been employed successfully within each category.

*Gasket Materials:* Silicone rubber gasket compositions are supplied in tubes in a semi-liquid form ready for manual application. They can also be obtained in larger containers for power-fed applications. Suppliers offer a silicone rubber-based composition that can replace preformed paper, cork, and rubber gaskets for many manufacturing operations. This composition has performed successfully in sealing water pumps, engine filter housings, and oil pans. It can also seal gear housings and other joints that require a flexible gasket material that besides resisting shock can sustain large temperature changes. Silicone rubber compositions can withstand temperatures that vary from -100°F to 450°F (-73°C to 232°C).

Gasket tapes, ropes, and strips can also be readily purchased to fit many assembly applications. One type of sealant tape combines a pressure-sensitive adhesive with a strip of silicone-rubber sponge. This tape has good cushioning properties for vibration damping and can stick to metal, plastic, ceramic, and glass combinations.

TFE-based gasketing strips are also available. This non-stick gasketing material can perform at pressures up to 200 psi (1.4 MPa) and temperatures to 250°F (120°C). Because of the TFE base, the strip does not adhere to or gum joint surfaces.

*Sealing Pipe Joints:* Phenolic-based sealants can seal threaded joints on high-pressure steam lines. One type, that is available in liquid or paste form, resists pressure up to 1200 psi (8.3 MPa) and temperatures to 950°F (510°C). This compound is brushed on and the joint closed and tightened to a torque of 135 in.-lb. (15.3 N m). The connection is then subjected to a 24-hour cure with superheated steam.

The joining and sealing of plastic pipe is covered under the previous adhesives bonding section.

Sulfur-based compounds, though lacking the durability of caulking lead, can be used on bell and spigot sewer pipe. Available in a formulation that can resist temperatures up to 200°F (93°C), one sulfur-based sealant is applied as a hot-melt and allowed to flow into the bell and spigot connection. It quickly solidifies at room temperature, and can develop a joint tensile strength over 300 psi (2.1 MPa).

There are asphalt, coal-tar and plastic-based compositions that can be used on both cast-iron and ceramic bell and spigot pipe. Portland cement mortars also seal ceramic piping.

**SURFACE TREATMENTS FOR METALS****Coloring Metals**

**General Requirements in the Coloring of Metal Surfaces.**—Copper is more susceptible to coloring processes and materials than any of the other metals, and hence the alloys containing large percentages of copper are readily given various shades of yellow, brown, red, blue, purple, and black. Alloys with smaller percentages of copper (or none at all) can be given various colors, but not as easily as if copper were the principal ingredient, and the higher the copper content, the more readily can the alloy be colored. The shades, and even the colors, can be altered by varying the density of the solution, its temperature and the length of time the object is immersed. They can also be altered by finishing the work in different ways. If a cotton buff is used, one shade will be produced; a scratch brush will produce another, etc. Thus to color work the same shade as that of a former lot, all the data in connection with these operations must be preserved so they can be repeated with exactness.

**Cleaning Metals for Coloring.**—Metal surfaces to be colored chemically must first be thoroughly cleaned. To remove grease from small parts, dip in benzine, ether or some other solvent for the grease. Boil large pieces in a solution of one part caustic soda and ten parts water. For zinc, tin or britannia metal, do not use caustic soda, but a bath composed of one part carbonate of soda or potash and ten parts water. After boiling, wash in clean water. Do not touch the clean surfaces with the fingers, but handle the objects by the use of tongs or wires.

**Pickling Solutions or Dips for Coloring.**—The grease removal should be followed by chemical cleansing, which principally serves the purpose of removing the greenish or brownish films which form on copper, brass, bronze, etc. The composition of the bath or mixture for pickling varies for different metals. For copper and its alloys, a mixture of 100 parts concentrated sulphuric acid (66 degrees Baume and 75 parts nitric acid (40 degrees Baume is sometimes used. If the metal is to be given a luster instead of a mat or dull finish, add about 1 part common salt to 100 parts of the pickling solution, by weight. A better dip for a mat surface consists of 90 parts nitric acid (36 degrees Baume 45 parts concentrated sulphuric acid, 1 part salt, and from 1 to 5 parts of sulphate of zinc, by weight. The composition of copper-zinc alloys will produce different color tones in the same dip and will affect the results of chemical coloring. After pickling, washing in water is necessary.

Another good method of removing these films is to soak the work in a pickle composed of spent aquafortis until a black scale is formed, and then dip it for a few minutes into a solution of 64 parts water, 64 parts commercial sulphuric acid, 32 parts aquafortis, and 1 part hydrochloric acid. After that the work should be thoroughly rinsed several times with distilled water.

**Coloring Brass.**—Polished brass pieces can be given various shades from golden yellow to orange by immersing them for a certain length of time in a solution composed of 5 parts, by weight, of caustic soda, 50 parts water and 10 parts copper carbonate. When the desired shade is reached, the work must be well washed with water and dried in sawdust. Golden yellow may be produced as follows: Dissolve 100 grains lead acetate in 1 pint of water and add a solution of sodium hydrate until the precipitate which first forms is re-dissolved; then add 300 grains red potassium ferro-cyanide. With the solution at ordinary temperatures, the work will assume a golden yellow, but heating the solution darkens the color, until at 125 degrees F. it has changed to a brown.

**To Produce a Rich Gold Color.**—Brass can be given a rich gold color by boiling it in a solution composed of 2 parts, by weight, of saltpeter, 1 part common salt, 1 part alum, 24 parts water and 1 part hydrochloric acid. Another method is to apply a mixture of 3 parts alum, 6 parts saltpeter, 3 parts sulphate of zinc, and 3 parts common salt. After applying

this mixture the work is heated over a hot plate until it becomes black, after which it is washed with water, rubbed with vinegar, and again washed and dried.

**White Colors or Coatings.**—The white color or coating that is given to such brass articles as pins, hooks and eyes, buttons, etc., can be produced by dipping them in a solution made as follows: Dissolve 2 ounces fine-grain silver in nitric acid, then add 1 gallon distilled water, and put this into a strong solution of sodium chloride. The silver will precipitate in the form of chloride, and must be washed until all traces of the acid are removed. Testing the last rinse water with litmus paper will show when the acid has disappeared; then mix this chloride of silver with an equal amount of potassium bitartrate (cream of tartar), and add enough water to give it the consistency of cream. The work is then immersed in this solution and stirred around until properly coated, after which it is rinsed in hot water and dried in sawdust.

**Silvering.**—A solution for silvering, that is applicable to such work as gage or clock dials, etc., can be made by grinding together in a mortar 1 ounce of very dry chloride of silver, 2 ounces cream of tartar, and 3 ounces common salt, then add enough water to obtain the desired consistency and rub it onto the work with a soft cloth. This will give brass or bronze surfaces a dead-white thin silver coating, but it will tarnish and wear if not given a coat of lacquer. The ordinary silver lacquers that can be applied cold are the best. Before adding the water, the mixture, as it leaves the mortar, can be kept a long time if put in very dark colored bottles, but if left in the light it will decompose.

**To Give Brass a Green Tint.**—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

**Blackening Brass.**—There are many different processes and solutions for blackening brass. Trioxide of arsenic, white arsenic or arsenious acid are different names for the chemical that is most commonly used. It is the cheapest chemical for producing black on brass, copper, nickel, German silver, etc., but has a tendency to fade, especially if not properly applied, although a coat of lacquer will preserve it a long time. A good black can be produced by immersing the work in a solution composed of 2 ounces white arsenic, 5 ounces cyanide of potassium, and 1 gallon of water. This should be boiled in an enamel or agate vessel, and used hot. Another cheap solution is composed of 8 ounces of sugar of lead, 8 ounces hyposulphite of soda and 1 gallon of water. This must also be used hot and the work afterwards lacquered to prevent fading. When immersed, the brass first turns yellow, then blue and then black, the latter being a deposit of sulphide of lead.

**Preservation of Color.**—After a part has been given the desired color, it is usually washed in water and then dried with clean sawdust. The colored surfaces of alloys are commonly protected and preserved by coating with a colorless lacquer, such as japan lacquer. Small parts are coated by dipping, and large ones by rubbing the lacquer on. The lacquer is hard after drying, and insoluble in most fluids; hence, it can be washed without injury.

**Niter Process of Bluing Steel.**—The niter process of bluing iron and steel is as follows: The niter or nitrate of potash (often called saltpeter) is melted in an iron pot and heated to about 600 degrees F. The parts to be blued are cleaned and polished and then immersed in the molten niter until a uniform color of the desired shade has been obtained. This requires only a few seconds. The articles are then removed and allowed to cool, after which the adhering niter is washed off in water. Parts which will not warp may be immersed immediately after removing from the niter bath. After cleaning, dry in sawdust, and then apply some suitable oil, such as linseed, to prevent rusting. To secure uniform coloring, a pyrom-

eter should be used to gage the temperature of the niter, because a higher heat than 600 degrees F. will produce a dark color, whereas a lower heat will give a lighter shade.

**Bluing Steel by Heat-treatment.**—Polished steel parts can be given a blue color by heating in hot sand, wood ashes, or pulverized charcoal. Place the substance in an iron receptacle and stir constantly, while heating, in order to heat uniformly. Heat just hot enough to char a pine stick. The parts to be blued must be absolutely free from grease. They are placed in the heated substance until the desired color is obtained. Further coloring is then checked by immersing in oil. Small parts are sometimes heated by a Bunsen burner or by laying upon a heated plate. For a light blue color, heat in sand or wood ashes, and for a dark blue, use pulverized charcoal. The quality of the color depends largely upon the fineness of the finish. Still another method of coloring by heat is to immerse the parts in a molten bath of potassium nitrate and sodium nitrate. The coloring is then checked by plunging the work into boiling water.

**Blue-black Finish.**—To obtain a blue-black finish on small steel parts, use a mixture of 16 parts, by weight, of saltpeter and 2 parts of black oxide of manganese. This mixture is heated to a temperature of 750 degrees F. and the objects are immersed in it. The oxide of manganese is deposited on the work and must, therefore, be frequently replenished in the mixture.

**Black Finish.**—To obtain a black rust-protecting finish on hardened parts, temper, after hardening, in "heavy" cylinder oil; then immediately place the part with the oil on it in an oven having a temperature of from 300 to 350 degrees F. Remove the work in from to 8 minutes, when the black finish is baked onto it.

**Gun Metal Finish.**—Several different chemical solutions have been used successfully for giving steel a gun metal finish or black color. Among these are the following:

- 1) Bismuth chloride, one part; copper chloride, one part; mercury chloride, two parts; hydrochloric acid, six parts; and water, fifty parts.
- 2) Ferric chloride, one part; alcohol, eight parts; and water, eight parts.
- 3) Copper sulphate, two parts; hydrochloric acid, three parts; nitric acid, seven parts; and perchloride of iron, eighty-eight parts.

Other solutions have been prepared from nitric ether, nitric acid, copper sulphate, iron chloride, alcohol and water and from nitric acid, copper sulphate, iron chloride and water. The method of applying these and finishing the work is practically the same in all cases.

The surface is given a very thin coating with a soft brush or sponge that has been well squeezed, and is then allowed to dry. The work is then put in a closed retort to which steam is admitted and maintained at a temperature of about 100 degrees F., until the parts are covered with a slight rust. They are then boiled in clean water for about fifteen minutes and allowed to dry. A coating of black oxide will cover the surface, and this is scratch brushed. After brushing, the surface will show a grayish black. By repeating the sponging, steaming and brushing operations several times, a shiny black lasting surface will be obtained. For the best finishes, these operations are repeated as many as eight times.

Another process employs a solution of mercury chloride and ammonium chloride which is applied to the work three times and dried each time. A solution of copper sulphate, ferric chloride, nitric acid, alcohol and water is then applied three times and dried as before. A third solution of ferrous chloride, nitric acid and water is applied three times, and the work is boiled in clean water and dried each time. Finally, a solution of potassium chloride is applied and the work boiled and dried three times. The work is then scratch brushed and given a thin coating of oil. Ordnance for the French Government is treated in this way. The above methods are applicable to hardened and tempered steels, as a temperature of 100 degrees F. does not affect the hardness of the steel. For steels that will stand 600 degrees temperature without losing the desired hardness, better and much cheaper methods have been devised.

The American Gas Furnace Co. has developed a process employing a furnace with a revolving retort. The work is charged in this, together with well-burnt bone. A chemical solution that gasifies when it enters the furnace is then injected into this retort while the work is heated to the proper temperature. This solution has been named "Carbonia." The color does not form a coating on the outside, as with the other processes, but a thin layer of the metal itself is turned to the proper color. By varying the temperature of the furnace, the time the work is in it, and the chemical, different colors can be produced from light straw to brown, blue, purple and black, or gun metal finish. Rough or sand-blasted surfaces will have a frosted appearance, while smooth polished surfaces will have a shiny brilliant appearance.

**Browning Iron and Steel.**—A good brown color can be obtained as follows: Coat the steel with ammonia and dry it in a warm place; then coat it with muriatic or nitric acid and dry it in a warm place; then place the steel in a solution of tannin or gallic acid and again dry it. The color can be deepened by placing the work near the fire, but it should be withdrawn the minute the desired shade is reached or it will turn black.

**To Produce a Bronze Color.**—A bronze-like color can be produced by exposing iron or steel parts to the vapors of heated aquaregia, dipping them in melted petroleum jelly, and then heating them until it begins to decompose, when it is wiped off with a soft cloth. Another method of producing this bronze-brown color is to slightly heat the work, evenly cover the surfaces with a paste of antimony chloride (known as "bronzing salt"), and let the object stand until the desired color is obtained. The paste can be made more active by adding a little nitric acid.

**To Produce a Gray Color.**—A gray color on steel can be obtained by immersing the work in a heated solution of ten grains of antimony chloride, ten grains of gallic acid, 400 grains of ferric chloride and five fluid ounces of water. The first color to appear is pale blue, and this passes through the darker blues to the purple, and, finally, to the gray. If immersed long enough, the metal will assume the gray color, but any of the intermediate colors may be produced. When used cold, this is also one of the bronzing solutions.

**Mottled Coloring.**—Mottled colors on steel can be produced by heating the objects to a good cherry-red for several minutes in cyanide of potassium, then pouring the cyanide off, and placing the receptacle containing the work back on the tire for five minutes. The contents are then quickly dumped into clean water. To heighten the colors, boil afterward in water and oil.

**Coppering Solution.**—A coppering solution for coating finished surfaces in order that lay-out lines may be more easily seen, is composed of the following ingredients: To 4 ounces of distilled water (or rain water) add all the copper sulphate (blue vitriol) it will dissolve; then add 10 drops of sulphuric acid. Test by applying to a piece of steel, and, if necessary, add four or five drops of acid. The surface to be coppered should be polished and free from grease. Apply the solution with clean waste, and, if a bright copper coating is not obtained, add a few more drops of the solution; then scour the surface with fine emery cloth, and apply rapidly a small quantity of fresh solution.

**White Coatings for Laying Out Lines.**—Powdered chalk or whiting mixed with alcohol is commonly used for coating finished metal surfaces preparatory to laying out lines for machining operations. Alcohol is preferable to water, because it will dry quicker and does not tend to rust the surface. This mixture can be applied with a brush and is more convenient than a coppering solution for general work. For many purposes, the surface can be coated satisfactorily by simply rubbing dry chalk over it.

**To Produce Gray Colors.**—A solution of 1 ounce of arsenic chloride in 1 pint of water will produce a gray color on brass, but if the work is left in this solution too long it will become black. The brass objects are left in the bath until they have assumed the correct shade, and are then washed in clean warm water, dried in sawdust and finally in warm air.

**Blue and Violet Shades.**—To give brass a blue color, dissolve 1 ounce of antimony chloride in 20 ounces of water, and add 3 ounces hydrochloric acid; then warm the work and immerse it in this solution, until the desired blue is obtained. After that wash in clean water and dry in sawdust. A permanent and beautiful blue-black can be obtained by using just enough water to dissolve 2 ounces copper sulphate and then adding enough ammonia to neutralize and make it slightly alkaline. The work must be heated before immersion.

**To Give Brass a Green Tint.**—One solution that will produce the Verde antique, or rust green, is composed of 3 ounces crystallized chloride of iron, 1 pound ammonium chloride, 8 ounces verdigris, 10 ounces common salt, 4 ounces potassium bitartrate and 1 gallon of water. If the objects to be colored are large, the solution can be put on with a brush. Several applications may be required to give the desired depth of color. Small work should be immersed and the length of time it remains in the solution will govern the intensity of the color. After immersion, stippling the surface with a soft round brush, dampened with the solution, will give it the variegated appearance of the naturally aged brass or bronze.

### Etching And Etching Fluids

**Etching Fluids for Different Metals.**—A common method of etching names or simple designs upon steel is to apply a thin, even coating of beeswax or some similar substance which will resist acid; then mark the required lines or letters in the wax with a sharp-pointed scribe, thus exposing the steel (where the wax has been removed by the scribe point) to the action of an acid, which is finally applied. To apply a very thin coating of beeswax, place the latter in a silk cloth, warm the piece to be etched, and rub the pad over it. Regular coach varnish is also used instead of wax, as a "resist."

An etching fluid ordinarily used for carbon steel consists of nitric acid, 1 part; water, 4 parts. It may be necessary to vary the amount of water, as the exact proportion depends upon the carbon in the steel and whether it is hard or soft. For hard steel, use nitric acid, 2 parts; acetic acid, 1 part. For high-speed steel, nickel or brass, use nitro-hydrochloric acid (nitric, 1 part; hydrochloric, 4 parts). For high-speed steel it is sometimes better to add a little more nitric acid. For etching bronze, use nitric acid, 100 parts; muriatic acid, parts. For brass, nitric acid, 16 parts; water, 160 parts; dissolve 6 parts potassium chlorate in 100 parts of water; then mix the two solutions and apply.

A fluid which may be used either for producing a frosted effect or for deep etching (depending upon the time it is allowed to act) is composed of 1 ounce sulphate of copper (blue vitriol);  $\frac{1}{4}$  ounce alum;  $\frac{1}{2}$  teaspoonful of salt; 1 gill of vinegar, and 20 drops of nitric acid. For aluminum, use a solution composed of alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces; water, 40 ounces.

The National Twist Drill Co. employs the following method for etching on cutters and other tools: The steel is brushed with asphaltum varnish which is allowed to stand until it thickens and hardens to the right degree; then the desired inscription is pressed through the asphaltum with a rubber stamp and the etching fluid (nitrohydrochloric acid or *aquaregia*) is applied with a medicine dropper. Practice and experience are required to judge just when the varnish has dried to the right consistency. A similar method, which has been successfully used for etching names on cutlery, is to coat the surface with gum guaiacum varnish. A rubber stamp having the name or design is then coated with a thin layer of potash solution. When this stamp is applied to the work, the varnish is "cut" by the potash wherever the coated stamp comes into contact with it; the surface is then brushed lightly with water to remove the loosened varnish and expose the lettering or design, which is then etched by applying dilute nitric acid. The rubber-stamp method is a very cheap and rapid process. One method of applying the potash is to press the stamp against a pad soaked with the solution. The action of etching fluids on steels varies somewhat according to the composition, high-carbon and alloy steels being acted upon more slowly than low-carbon steel or wrought iron.

**Etching Brass Nameplates.**—Etched brass nameplates having a black background are now often used in preference to cast plates, as they are less expensive. The etched plate is produced by coating a flat and polished sheet of brass with a thin layer of bichromated albumen, and exposing it to the light for a few minutes under a glass negative upon which are a number of the desired nameplate designs. (In order to prepare the bichromated albumen, mix together 10 parts of the white of egg with 30 parts of water. A second mixture is then made consisting of 2 parts of potassium bichromate and 58 parts of water. The first mixture composed of the white of egg and water, and the second mixture containing potassium bichromate and water, are next mixed together in a dark room. The bichromated albumen thus obtained should be kept and used in the dark.) When the brass plate is developed, this removes the albumen not exposed to the light (or that which has been protected by the black portions of the negative), and leaves the brass free to be etched. The etching solution will not attack the parts protected by the albumen or “resist.”

The etching is done by a solution of perchlorate of iron, or by making the plate the anode in an acid-copper solution. When the plate has been etched to the required depth, it is washed. If the etched surface is tarnished, as it usually is after drying, a solution made of 2 parts of water and 1 part of muriatic acid should be spread over the surface to remove the stains and leave it clean and uniform. The plate should then be rinsed, but not dried. Then, without removing the resist, it is treated in some manner to produce a black background. When this has been done, the resist is removed and the sheet is cut up to form the individual nameplates, which are then lacquered.

**Producing a Black Background.**—The use of a black nickel deposit is the best method of producing a black background on etched brass name-plates. This solution does not affect any of the various kinds of resist used, and a large number of plates can be treated in a tank at one time. The black nickel bath is composed of water, 1 gallon; double-nickel salts, 8 ounces; ammonium sulpho-cyanate, 2 ounces; zinc sulphate, 1 ounce. This solution is used cold, with a weak current of about 1 volt. With a greater voltage, the deposit will be streaked and gray. As soon as the deposit is black, remove the plates, rinse, dry and cut to the desired size; then lacquer immediately in order to prevent the brownish discoloration which will otherwise form on the surface of the deposit. This solution can be used for brass, copper, bronze, etc.

**Etching Ornamental Designs in Metal.**—When metal plates having an ornamental design are required in small quantities, the etching process is sometimes used. The photographic method which is employed for nearly all intricate designs is as follows: The design is first drawn on white paper to any convenient scale, in black and white. A photographic negative is then made, or this may be procured from photo engravers who make a specialty of such work. The blacks and whites must be, respectively, opaque and transparent. This negative is used to print the design on the work to be etched, the metal, in order to take the design, being coated with a sensitized emulsion of bi-chromated albumen which has the property of remaining insoluble in water after exposure to the light. The portions corresponding to the opaque parts of the negative thus wash out in warm water, leaving the metal bare. Just prior to washing, however, the surface is coated with special lithographic ink, by means of a roller. The design is now on the metal, surrounded by a resist of a bi-chromated albumen base covered with a sticky ink. This resist is further reinforced by sprinkling the surface with dragon's blood. The latter is melted by heating and adheres to the resist, but forms a powder on the unprotected surface which can readily be blown off. This resist is effective, provided the etching is not done too deeply. For brass and copper, a strong solution of perchloride of iron is generally preferred as an etching fluid, as this does not attack the resist like strong acids, although its action is comparatively slow. Nitric acid may be used with proper resists. While etching is usually employed for cutting into the surface of the metal, the same process can be used for perforating the design in the plate.

Various acid-resisting materials are used for covering the surfaces of steel rules, etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine

and very closely spaced, as on machinists' scales which are divided into hundredths or sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent any under-cutting of the acid; the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 per cent of asphaltum, 25 per cent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; then the work is held at a slight angle and the paraffin is poured on its upper surface. The melted paraffin forms a thin protective coating.

**MANUFACTURING****Welding with Thermit**

**Thermit Process.**—This process of welding metals is effected by pouring superheated thermit steel around the parts to be united. Thermit is a mixture of finely divided aluminum and iron oxide. This mixture is placed in a crucible and the steel is produced by igniting the thermit in one spot by means of a special powder, which generates the intense heat necessary to start the chemical reaction. When the reaction is once started it continues throughout the entire mass, the oxygen of the iron being taken up by the aluminum (which has a strong affinity for it), producing aluminum oxide (or slag) and superheated thermit steel. ordinarily, the reaction requires from 35 seconds to one minute, depending upon the amount of thermit used. As soon as it ceases, the steel sinks to the bottom of the crucible and is tapped into a mold surrounding the parts to be welded. As the temperature of the steel is about 5400 degrees F., it fuses and amalgamates with the broken sections, thus forming a homogeneous weld.

It is necessary to pre-heat the sections to be welded before pouring, to prevent chilling the steel. The principal steps of the welding operation are, to clean the sections to be welded, remove enough metal at the fracture to provide for a free flow of thermit steel, align the broken members and surround them with a mold to retain the steel, pre-heat by means of a gasoline torch to prevent chilling the steel, ignite the thermit and tap the molten steel into the mold. This process is especially applicable to the welding of large sections. It has been extensively used for welding locomotive frames, broken motor casings, rudder- and stern-posts of ships, crankshafts, spokes of driving wheels, connecting rods, and heavy repair work in general. One of the great advantages of the thermit process is that broken parts can usually be welded in place. For example, locomotive frames are welded by simply removing parts that would interfere with the application of a suitable mold. Thermit is also used for pipe welding, rail welding, and in foundry practice, to prevent the "piping" of ingots.

**Preparation of Part to be Welded.**—The first step in the operation of thermit welding is to clean the fractured parts and cut away enough metal to insure an unobstructed flow of the molten thermit. The oxy-acetylene or oxy-hydrogen cutting torch is very efficient for this operation. The amount that should be cut away depends upon the size of the work. Assuming that a locomotive frame is to be welded, the space should be about  $\frac{3}{4}$  inch wide for a small frame, and 1 inch wide for a large frame. The frame sections are then jacked apart about  $\frac{1}{4}$  inch to allow for contraction of the weld when cooling; trammel marks are scribed on each side of the fracture to show the normal length. If the weld is to be made on one member of a double-bar frame, the other parallel member should be heated with a torch to equalize the expansion in both sections and prevent unequal strains.

**Mold for Thermit Welding.**—The mold surrounding the fractured part should be so arranged that the molten thermit will run through a gate to the lowest part of the mold and rise through and around the parts to be welded into a large riser. The accompanying illustration shows a mold applied to a locomotive frame that is broken between the pedestals at *A*. The thermit steel is poured through gate *B*, and rises into space *C* after passing around and between the ends of frame *F*. The mold must allow for a reinforcing band or collar of thermit steel to be cast around the ends to be welded. Space *G*, for forming this collar, and the opening between the frame ends, must be filled before ramming up the mold. Yellow wax is ordinarily used for this purpose. The shape of this band or collar should be as indicated by the view of the completed weld at *D*. The thickest part is directly over the fracture and the band overlaps the edges of the fracture at least one inch.

## WELDING WITH THERMIT

For a frame of average size, the collars are made about 4 inches wide and 1 inch thick at the center, the thickness being increased for comparatively large sections. An opening is also made at *E* for pre-heating the ends to be welded.

Patterns for the riser, pouring and heating gates can be made of wood. The riser *C* should be quite large because the steel that first enters the mold is chilled somewhat by coming into contact with the metal, even when pre-heated. This chilling effect is overcome by using enough thermit steel to force the chilled portion up into the riser and replacing it by metal which has practically the full temperature received during reaction. The mold must be made of a refractory material, owing to the intense heat. The best material is made of one part fire sand, one part fire-clay and one part ground firebrick, thoroughly mixed while dry and moistened just enough to pack well. If these ingredients cannot be obtained, one part fire-clay and one part clean, dry sand may be used. When the mold and box are filled and tamped, the wooden runner and riser patterns are withdrawn. The mold is then ready for the pre-heating and drying operation which causes the wax matrix to melt and run out.

**Thermit Required for Welding.**—The quantity of thermit required for making a weld can be determined from the cubic contents of the weld. Calculate the cubic contents of the weld and its reinforcement in cubic inches; double this amount to allow for filling the gate and riser, and multiply by 0.56 to get the number of pounds of thermit required. When wax is used for filling, the weight of the thermit can be determined as follows: Weigh the wax supply before and after filling the fracture. The difference in weight (in pounds, or the quantity used, multiplied by 32 will give the weight of thermit in pounds.

**Thermit Additions.**—When a quantity of more than 10 pounds of thermit is to be used, add 10 per cent of steel punchings (not over  $\frac{1}{2}$  inch in diameter) or steel scrap, free from grease, into the thermit powder. If the thermit exceeds 50 pounds, 15 per cent of small mild steel rivets may be mixed with it. One per cent (by weight) of pure manganese and 1 per cent of nickel - thermit should be added to increase the strength of the thermit steel.

**Pre-heating — Making a Weld.**—The ends to be welded should be red hot at the moment the thermit steel is tapped into the mold. This pre-heating is done, preferably, by a gasoline, compressed-air torch, and, as previously mentioned, it melts the wax matrix used for filling the fracture to form the pattern for the reinforcing band. When the ends have been heated red, quickly remove the torch and plug the pre-heating hole *E* with a dry sand core, backing it up with a few shovelfuls of sand, well packed. The end of the cone-shaped crucible should be directly over the pouring gate and not more than 4 inches above it. To start the reaction, place one-half teaspoonful of ignition powder on top of the thermit and ignite with a storm match. It is important that sufficient time be allowed for the completion of the thermit reaction and for fusion of the steel punchings which have been

mixed within the thermit. Within charges containing from 30 to 50 pounds of thermit, the crucible should not be tapped in less than 35 seconds; with charges containing from 50 to 75 pounds, 40 seconds; 75 to 100 pounds, 50 seconds to one minute.

When welding a frame broken as shown in the illustration previously referred to, the screw jack used for forcing the pedestals apart should be turned back somewhat to release the pressure gradually as the weld cools. After pouring, the mold should remain in place as long as possible (preferably 10 or 12 hours) to anneal the steel in the weld, and, in any case, it should not be disturbed for at least two hours after pouring.

When welding a broken spoke in a driving wheel, or a similar part, it is necessary to pre-heat the adjacent spokes in order to prevent undue strains due to expansion and contraction. If a section of a spoke is broken out, it can be cast in, but if the space is over 6 inches long, it is better to insert a piece of steel and make a weld at each end. Owing to the high temperature 5400 degrees F.) and the violent ebullition of thermit during reaction, the crucible must be lined with a very refractory material. The crucibles used for this purpose have a sheet-iron shell and are lined with magnesia.

**Filling Shrinkage Holes and Surface Flaws.**—The filling of surface flaws in castings and forgings usually requires from 2 to 10 pounds of thermit. To make a weld of this kind, place an open mold around the part to be filled, large enough to overlap it about  $\frac{1}{2}$  inch. Clean the hole thoroughly and heat to a red heat by means of a strong blow-torch. Use eighteen ounces of thermit for each cubic inch of space to be filled, but do not use less than two pounds for any one weld. Place a small amount of thermit in the crucible which, in this case, is of a small size for hand use. Ignite the thermit with ignition powder and as soon as it begins to burn, add the remainder, feeding it fast enough to keep the combustion going. When the reaction is completed, quickly pour the slag (which is about three-fourths of the total liquid) into dry sand; then pour the steel into the open mold and sprinkle loose thermit on top to prolong the reaction, as the casting, even when pre-heated, will have a chilling effect on the steel.

**Composition of Thermit Steel.**—An average analysis of thermit steel is as follows: carbon, 0.05 to 0.10 per cent; manganese, 0.08 to 0.10 per cent; silicon, 0.09 to 0.20 per cent; sulphur, 0.03 to 0.04 per cent; phosphorus, 0.04 to 0.05 per cent; aluminum, 0.07 to 0.18 per cent. The tensile strength is about 65,000 pounds per square inch.

**High- and Low-pressure Torches.**—The difference between high- and low-pressure welding and cutting torches, according to the generally accepted meaning of the term, is in the pressure of the acetylene. The first oxy-acetylene torches developed by Fouche were of the high-pressure type, using acetylene dissolved in acetone. Later, he developed a low-pressure torch, working on the injector principle, acetylene being drawn into the carburetor chamber where it mixed with the oxygen. The high pressures originally employed in the first torches could not be safely employed with the acetylene produced in generators, because the safe pressure of acetylene in volume should never exceed from 15 to 20 pounds per square inch, and the pressure is limited to 25 pounds per square inch by the Underwriters' Association in the United States: hence, the medium pressure which is in general use was developed. The proportion of oxygen to acetylene varies somewhat in the different torches. Usually from 1.04 to 1.12 times more oxygen is consumed than acetylene.

Welders and cutters should be provided with goggles or spectacles fitted with approved colored lenses that protect the eye from destructive light rays, flying sparks and globules of molten metal.

**FORGE SHOP EQUIPMENT****Hammer and Anvil**

**Blacksmiths' Anvils.**—The quality of an anvil can generally be judged by its ring, a good anvil giving out a clear, sharp sound when struck with a hammer. If soft or defective, the sound will be dull. A good anvil so mounted that it gives out a full volume of sound is easier to work upon than one having a dead ring. Anvils ordinarily vary in weight from 150 to 300 pounds. A mistake is often made in selecting anvils that are too light for the service required. A 300-pound anvil is suitable for almost any kind of machine blacksmithing, and, if of this weight or heavier, it will not move around while in use or need to be strapped to its block. The square hole in the face of an anvil for receiving the cutting and forming tools is called the "hardie hole," and the small round hole near it is called the "pritchel hole." Anvils are usually made with a wrought-iron body to which is welded a hardened steel face.

**Setting the Anvil.**—The height of an anvil should be such that when standing beside if the knuckles of the hands will just reach the top surface or face. A solid oak block set endwise in the ground is often used as a foundation, but a cast-iron mounting block is preferable as it can easily be moved. The casting should have a fairly broad base, and a pocket at the top for receiving the anvil; a flat block of wood is provided to act as a cushion. An anvil should not be strapped rigidly to its foundation, as this checks the vibration which tends to keep the face free from scales, and renders a high-grade wrought-iron anvil little better than one made of cast iron. When a wooden block is used under the anvil, it is necessary to drive in a few spikes to keep the anvil in place, but these should be so placed that they do not bear directly upon or bind against the corners.

**Steam Hammer Rating.**—The capacity of a steam hammer or its rating is the weight of the ram and its attached parts, such as the piston and rod. The steam pressure behind the piston is not considered as far as the rating is concerned. For example, a 1000-pound hammer has reciprocating parts of that weight. The steam pressures for operating hammers usually vary from 75 to 100 pounds per square inch.

**Capacity of Steam Hammers.**—Capacity of a steam hammer or the proper size to use for working iron and steel of a given cross-sectional area can be determined approximately by the following rule: Multiply the area of the largest cross-section to be worked by 80, if of steel, or 60, if of iron, and the product will be the required rating of the hammer in pounds. For example, the capacity of a hammer for working steel billets 5 inches square would be determined as follows:  $5 \times 5 = 25$ ; and  $25 \times 80 = 2000$ , which is the rating of the hammer in pounds. A hammer rated according to this rule is an economical size to use, although it can, of course, be employed for heavier work.

**Power for Operating Steam Hammers.**—The boiler horsepower for operating a steam hammer depends upon the service required and the number of hammers in use. Ordinarily, the boiler capacity can be less where there are a number of hammers, because all of the hammers are rarely, if ever, used at the same time; consequently, there is a reserve power; but with a single hammer, especially when in constant service, the boiler capacity should be proportionately greater. For average conditions, the boiler horsepower can be determined approximately by the following rule: Divide the rated capacity of the hammer in pounds by 100, and the quotient will be the boiler horsepower required for continuous operation. For example, if the hammer is rated at 2000 pounds, the boiler horsepower would equal  $2000 \div 100 = 20$  H.P. This rule is also applicable in cases where the hammer is not used continually, by estimating the amount of idle time and making suitable allowance, but the boiler capacity must not be reduced to such an extent that there is a decided diminution in the pressure during the working period.

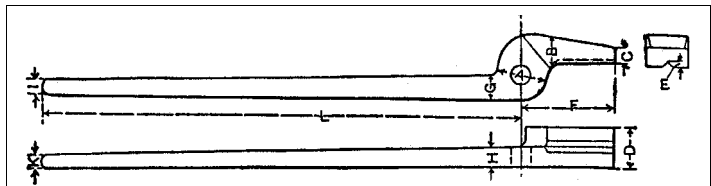

For foundations for steam hammers, see section on "Machinery and Hammer Foundations."

**Board Drop-hammers.**—This type of hammer is generally considered superior to the steam hammer for producing drop-forgings of small and medium size. When the work is heavy and requires a great deal of "breaking down" or drawing, or even when the forgings are light, but have thin sections that cool quickly, thus requiring sharp, rapid blows, the steam hammer will usually give better results than aboard drop. The capacity of most of the board drop-hammers in use varies from 800 to 1500 pounds; the steam hammers found in drop forging plants usually range from 2000 to 5000 pounds capacity, for handling average work. It does not seem practicable to build board drops larger than 3000 pounds falling weight, and where the forgings are heavy enough to require a capacity over 1500 or 2000 pounds, steam hammers are usually preferred. The latter type is also preferred in some forge shops for all classes of work. It is generally conceded that the cost of operation and repairs is greater for steam hammers, but the latter has a greater output for a given capacity.

The power required for operating board drop-hammers varies considerably with the nature of the work. Very little power is required at the point of "pick up," if the work is practically "die to die;" but when the work is soft and there is no rebound, a great deal more power is required, as the rolls have to pick up a "dead load" from rest and there is little kinetic energy in the driving pulleys. When there is a good rebound, with the knock-off properly timed, the board will be moving upward with considerable velocity when engaged by the rolls, and much less power is required. Seasoned maple boards have proved superior to any other kind for board drop-hammers. Paper fiber has been tried with fair results, but at present the cost of this material is too high.

For foundations for drop-hammers, see section on "Machinery and Hammer Foundations."

**Forging Presses.**—The power of forging presses for the average line of work is approximately as follows: For mild steel at a fair heat, a pressure of from 3 to 5 tons per square inch on the faces of the tools is generally sufficient, but when swages or dies are used, it may be necessary to double these pressures. For the very hardest steels, the pressure required may be as high as 10 or even 15 tons per square inch, but this is an exceptional case. For small forgings, including such parts as can be made from 8-inch square blooms or 12- by 6-inch flats, a press of 300 tons is sufficient, and for larger forgings, such as those used for heavy marine shafts and cranks, a 3000-ton press is generally considered sufficient and can readily handle a 60-inch ingot. The table above indicates, in a general way, the capacity of presses for handling ingots of various diameters.

Table 65. Capacity of Forging Presses

| Capacity of Press, Tons | Maximum Diam. of Ingots, Inches | Capacity of Press, Tons | Maximum Diam. of Ingots, Inches |
|-------------------------|---------------------------------|-------------------------|---------------------------------|
| 300                     | 10                              | 1500                    | 36                              |
| 500                     | 14                              | 2000                    | 48                              |
| 800                     | 20                              | 3000                    | 60                              |
| 1200                    | 27                              | 4000                    | 72                              |

A press of comparatively small capacity may, with suitable appliances, handle work that is really too heavy for it, but at some sacrifice of speed; for economical operation, there should be ample power. As is generally known, the forging press is superior to the steam hammer for comparatively large forgings, because the hammer tends to spread the surface metal without acting upon the center of the ingot to the required degree. With a press, the forging action goes right to the center of the ingot, as evidenced by the bulging that takes place at the sides, and if there is a cavity in the ingot, forging under the press closes it, whereas a hammer, by spreading the surface metal, may tend to enlarge it. As forgings diminish in size, the difference in favor of the press is less marked. Owing to the recent increase in the operating speed of forging presses, however, they now compete with power hammers in the forging of comparatively light work, and the range of presses has been greatly extended.

**Air Pressures and Pipe Sizes for Forges.**—Blacksmiths' forges require air pressures varying from  $1\frac{1}{2}$  to 6 ounces per square inch. Small forges with the blower close to them are adequately supplied with  $1\frac{1}{2}$  ounce pressure. If the blower is some distance away and a long discharge pipe with many bends leads to the forge, even though the latter be small, it may be necessary to carry 3 ounces pressure or more, to overcome the friction in the air ducts. Large forges usually require from 3 to 6 ounces pressure. The table, "Air Pressures and Pipe Sizes for Forges," gives the diameters of discharge mains for various tuyere sizes and numbers of forges.

**Table 66. Air Pressures and Pipe Sizes for Forges**

| Diam.<br>Forge Tuy-<br>ere, Inches | Number of Forges Supplied by Blower       |                |                |                |                |                |                |    |    |    |
|------------------------------------|---|----------------|----------------|----------------|----------------|----------------|----------------|----|----|----|
|                                    | 1   | 2              | 3              | 4              | 5              | 6              | 7              | 8  | 9  | 10 |

American Blower Co.

**The Cold Swaging Process.**—Cold swaging is a method of reducing or forming steel or other material while cold, by drawing to a point or reducing the diameter, as may be required. This is performed by a machine that causes the work to be struck a large number of successive blows by a pair of dies shaped to give the required form. This process is principally applied to the reduction of wires, rods and tubes, and is the only method by which rolled or plated stock can be reduced without destroying the plating or coating. For this reason, it is largely employed for jewelers' work. It is also extensively used for pointing rods or tubes which are to be drawn. The process is used in the manufacture of needles, bicycle spokes, button hooks, crochet needles, etc.

**Forging Machines.**—Some forging machines are intended especially for bolt and rivet heading, and others for more general work. The form or shape into which a part is forged is governed by dies of the required shape and also by a heading tool or plunger which bends or upsets the heated bar of metal and forces it into the die impression. The die may have a single impression, or two or three impressions may be required in order to forge the part by successive operations.

**Dies for Bolt and Rivet Forging Machines.**—Bolt and rivet dies used in forging machines are, as a rule, made from steel containing from 0.60 to 0.80 per cent carbon and are hardened and drawn. The heading tool, which must be tougher than the dies, is generally made from steel containing from 0.40 to 0.50 per cent carbon, and is drawn considerably more than the forming dies.

**Dies and Tools Used in Hot-pressed Center-feed Nut Machines.**—The dies used in hot-pressed center-feed nut machines are usually made from chilled iron castings, the dies being ground to size. It is claimed that dies made from this material will last fully eight times as long as those made from ordinary carbon steel, but as it is somewhat difficult to obtain the proper amount of chill, many manufacturers use a good grade of open-hearth crucible steel instead. A crucible steel which is found to give good results contains from 0.90 to 1.10 per cent carbon. In many cases, vanadium alloy steel is used for dies for nut forging machines. The composition of vanadium steel for dies varies. Two grades of vanadium tool steel are recommended for forging machine dies by the American Vanadium Co., of Pittsburgh, Pa. One is composed of carbon, 0.50 per cent; chromium, from 0.80 to 1.10 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment recommended for this steel is as follows: Heat to 1550 degrees F. and quench in oil; then reheat to from 1425 to 1450 degrees F., and quench in water, submerging the face of the die only.

The second kind of vanadium tool steel recommended has the following analysis: Carbon, from 0.65 to 0.75 per cent; manganese, from 0.40 to 0.60 per cent; vanadium, not less than 0.16 per cent; silicon, not more than 0.20 per cent. The heat-treatment for this steel should be as follows: Heat to 1525 degrees F. and quench in water, with only the face of the die submerged. Ordinary carbon tool steel dies should be drawn to a light straw color.

**Bulldozer Dies.**—Many of the tools or dies used on bulldozers are made of cast iron, in order to reduce the cost, and those parts of the dies which are subjected to wear are faced with hardened steel plates which may readily be replaced, if necessary. Whenever hot punching or cutting is done, high-speed self-hardening steel should be used for the working members of the tool.

**Helve Hammers.**—Power hammers of the helve type are adapted especially for relatively light forging operations, particularly when a rapid succession of blows is required. Ordinary helve hammers are usually built in sizes ranging from 15 to 200 pounds, this rating being based upon the weight of the hammer head. Some "upright helve" hammers are made in sizes up to 500 pounds.

**Vertical Power Hammers.**—Vertical power hammers of the crank- and pneumatically-operated types are used for general forging operations, especially on the lighter classes of work. Power hammers of the vertical type usually range in size from 25 pounds up to 500 pounds.

**Efficiency of Forging Hammers.**—The Heim method for determining the efficiency of forging hammers is based on the results of numerous tests conducted by allowing an ordinary drop-hammer to fall a predetermined distance upon a pure lead cylinder, the height of which is 1.5 times its diameter. The diameters of the cylinders which have been adopted for use in testing various sizes of hammers (with regard to their falling weight) are given in [Table 67](#). The following formula gives the number of foot-pounds of work done by one blow of the hammer:

$$\text{Work} = 36.75D^3 [8.85A + 13.12(A^2 + A^4)] \text{ foot-pounds}$$

Where  $D$  = Diameter of the lead cylinder;

$$A = (H - H_1) \div H$$

$H$  = Original height of the cylinder

$H_1$  = height of the cylinder after being struck by the hammer.

If the expression inside the brackets in the formula is designated by  $B$ , the formula may be expressed in the following form:

$$\text{Work} = 36.75D^3 B$$

After the lead cylinder has been struck by the hammer, the value of  $A$  is calculated and the number of foot-pounds of work developed by the hammer is then obtained by taking the value of  $B$  from Table 68 and substituting in the formula.

*Example:* Suppose a 100-kilogram (220-pound) hammer striking 180 blows per minute is allowed to strike a lead cylinder, the original dimensions of which are 50 millimeters (1.97 inch) in diameter by 75 millimeters (2.95 inches) high. After the blow has been struck, the resulting height of the cylinder is 48 millimeters (1.90 inch). From the preceding formula:

$$A = \frac{2.95 - 1.90}{2.95} = 0.35$$

$B = 4.9$ , from Table 68

Substituting the values of  $D$  and  $B$  in the formula for the work done by one blow of the hammer:

$$36.75 \times 1.97^3 \times 4.9 = 1376 \text{ foot-pounds} = \text{work done by one blow.}$$

$$\frac{1376 \times 180}{60} = 4128 \text{ foot-pounds} = \text{work done by one blow.}$$

The maximum power required to drive the hammer is 10.3 horsepower. As one horsepower is equivalent to 550 foot-pounds of work per second, the amount of power consumed by the hammer per second is:  $10.3 \times 550 = 5665$  foot-pounds. The efficiency of the is found to be:

$$\text{Efficiency} = \frac{\text{useful work}}{\text{power supplied}} = \frac{4128}{5665} = 72 \text{ percent.}$$

The Heim formula and method of testing may be applied to all types of hammers, but, when used on steam hammers, the test must be made while the hammer is running continuously and not when set to deliver a single blow.

**Table 67. Dimensions of Lead Plugs Used for Testing Various Sizes of Hammers**

| Falling Weight of Hammer |           | Diameter of Lead Cylinder <sup>a</sup> |             | Falling Weight of Hammer |           | Diameter of Lead Cylinder |             |
|--------------------------|-----------|--|-------------|--------------------------|-----------|---------------------------|-------------|
| Pounds                   | Kilograms | Inches                                 | Millimeters | Pounds                   | Kilograms | Inches                    | Millimeters |
| 66                       | 30        | 1.18                                   | 30          | 330                      | 150       | 2.36                      | 60          |
| 110                      | 50        | 1.38                                   | 35          | 506                      | 230       | 2.76                      | 70          |
| 165                      | 75        | 1.57                                   | 40          | 770                      | 350       | 3.15                      | 80          |
| 220                      | 100       | 1.97                                   | 50          | 1100                     | 500       | 3.54                      | 90          |

<sup>a</sup> Height equals  $1.5 \times$  diameter.

### Machinery and Hammer Foundations

The materials commonly used are concrete, stone, brick, and wood in conjunction with concrete for machines subjected to considerable vertical shock. The principal characteristics of these materials are briefly as follows: Concrete is an ideal foundation material, as it becomes practically one solid piece and is much cheaper than a masonry foundation. Stone, in addition to being strong and durable, has great vibrations absorbing power, but is quite costly. Brick is not so durable as stone, but is cheaper and available everywhere. In building a foundation, provision should be made for the foundation bolts, when these are necessary. Sometimes the bolts are set permanently in the foundation, or they may be placed in pipes and have pockets at the lower ends, thus permitting adjustment or removal, if necessary. The bolts are usually located in the proper position by making a wooden templet in which holes are bored to coincide with the holes in the machine base. The inclination of the sides of a foundation should vary from  $1\frac{1}{2}$  to 3 inches per foot from the vertical. The foundation pit should be excavated below the frost line of the locality.

**Concrete Foundations.**—The timber used for making the forms in which concrete foundations are molded should be about 1 inch thick, dressed on the inner side to give a smooth surface. The form should be braced externally about every  $2\frac{1}{2}$  feet, and internally about every foot in height. As the form is being filled, the inside braces can be removed. If pocket molds are used for the lower ends of the bolts, they should be soaked in water two or three hours before using, to prevent their swelling and sticking in the concrete. Do not use concrete that has been mixed over twenty minutes. Ram with hammers weighing about 1 pound per square inch of face area, the ramming being continued until water just shows at the surface.

Fig. 1.

Fig. 2.

Put down the concrete in layers about 6 inches thick and work it onto the form with a shovel, to obtain a smooth, even surface. The foundation may be partly filled with stones about the size of a man's head, placed approximately one foot apart and not less than one foot from the foundation surfaces. These stones should be wet before laying. If the work is stopped at night before completion, make grooves in the surface and when starting the next

day, sprinkle and dust over with dry cement. As soon as the concrete has set, remove the form, as it is much easier to patch when the cement is somewhat "green." Foundations are sometimes "slushed" instead of being rammed. In this case, the concrete is mixed just wet enough so that it cannot be piled up. It is then dumped into the molds and worked in them to prevent air bubbles. The first method gives a more homogeneous structure as there is no chance for the broken stones to settle. When the machine is in position, the space around the foundation bolts may be filled with liquid cement, lead or melted sulphur.

**Drop Hammer Foundations.**—The following drop-hammer foundations are recommended by the E. W. Bliss Company:

*Concrete Foundation:* Excavate a hole from 10 to 14 feet deep and from 8 to 12 feet square; build up a block of concrete with tapering sides, as shown in Fig. 63, having a top about 6 to 12 inches wider, all around, than the base of the anvil. Place the anvil in position and wedge it level; then run a thin mixture of concrete the anvil and allow it to set. Next move the wedges and build up a wall of concrete from 4 to 6 inches thick around the anvil. (See Fig. 1 and Fig. 2) This will make the use of bolts unnecessary and the anvil will set solid and will not be likely to shift. Solid concrete makes an excellent foundation that does not deteriorate, as is the case with timber when subjected to dampness from the earth or atmospheric moisture. Another advantage is that it is almost impervious to sparks or hot pieces of metal.

*Timber Concrete Foundations:* Excavate a hole somewhat larger than the anvil or base of the hammer. At the bottom lay a bed of concrete from 1 to 2 feet thick, as shown in Fig. 2. On this concrete bed place, endwise, Georgia pine timbers 12 by 12 inches by 6 to 8 feet long. These should be securely strapped together by steel bands on the outside fastened with through bolts. The timber base should preferably be a little larger than the anvil. To preserve the timbers coat them with oil of tar or creosote. The tops of the timbers should be dazed off evenly to obtain a level surface for the anvil. Another method of making a foundation of this kind, for small and medium sized hammers, is to put the timbers upon a foot or more of gravel rammed down on a hard-pan bottom. When the timbers, which are also placed endwise and bolted, are in position, the space around the sides is filled with gravel tightly rammed.

**Foundation for Steam Hammer.**—To secure the greatest efficiency from steam power hammers, the foundations on which they are mounted must be solid concrete resting upon hard-pan has given better results than the combination of heavy wooden beams and concrete often used. When making solid concrete foundations, there should be several inches of cement placed over the concrete, and a cushion of wood, at least 3 inches tuck, between the cement and base of the anvil, to give the necessary resiliency and prevent the concrete from being pulverized by the impact of the blows. In the front and rear of the hammer there should be openings down to the level of the anvil base, so that it can be leveled or adjusted by wedging and grouting with cement, in case it should sag or get out of alignment with the upper parts of the hammer. These openings can be covered with hatches set level with the floor.

### Machine and Forge Shop Floor Materials

Machine shop floors are commonly made of wood or concrete. Probably there is no floor for the machine shop as good as one made of selected hard maple, properly laid and supported, as it wears smoothly and evenly. Concrete, however, has its advantages, the most important of which is its fire-resisting qualities. There are few objections to a wooden floor, and from the standpoint of health it is generally considered superior to concrete. Where there is much heat, or large quantities of moisture or chemicals in bulk, wooden floors should not be used. In certain classes of store-rooms, or where there is a likelihood of considerable moisture, as in wash rooms, concrete floors are considered superior to wood.

**Concrete and Wooden Floors.**—The following information on shop floors and their materials is abstracted from a paper by Mr. L. C. Wason read before the American Society of Mechanical Engineers. While the factor of cost is to be considered first, very often the maintenance and adaptability for the particular Service required is of first importance. The initial cost of a granolithic floor surface is at no disadvantage compared with a wooden floor, as the cost of such a surface laid in the best manner is about equal to the cost of seven-eighths maple flooring. In addition, the granolithic surface is fire-proof and will not decay or disintegrate as the result of moisture, which is one of the weak points of the wooden floor. On the other hand, a wooden floor is more easily repaired than a granolithic surface. In making a comparison between wooden and granolithic floors, it is also necessary to consider the workmanship. With a maple top floor, the wearing quality depends comparatively little on the skill of the one who lays the floor, but with a granolithic finish, the work must be done care fully and intelligently. Among the objections to the granolithic surface, one of the most prominent is the bad effect of a concrete floor upon the health and comfort of the workmen. This is not due to the hardness of the floor, but rather to its heat conductivity. When a workman stands for hours on a concrete floor, the heat of the body is conducted to the floor quite rapidly, which tends to disarrange the circulation and cause physical ailments, such as rheumatism, etc. For men working steadily at machines, and usually in one position, this objectionable feature can be overcome by the use of insulating foot-boards or wooden gratings upon which to stand.

The dust produced by the wear of some granolithic surfaces has proved harmful to delicate machinery, whereas a wooden floor does not of itself produce a dust capable of any appreciable abrasive action. It is possible, however, by gluing battleship linoleum to concrete floors, to obtain many of the advantages of a wooden surface. Linoleum is also an effective insulation against the loss of bodily heat.

High resistance to wear and practically complete dustlessness can be secured in a granolithic surface if properly made. To secure a durable and practically dustless floor, proceed as follows: Do not use sand, as sand grains are quickly broken by abrasion and form dust. The granolithic finish should contain the highest possible proportion of tough stone aggregate. Use stone suitable for macadam road, and of a size that will pass through a half-inch round mesh screen, but use nothing smaller than that passed by a 20-mesh screen. Mix the concrete dry, and of a consistency for making blocks, so that considerable tamping will be required to bring enough water to the surface for troweling. Finally, do the troweling before the mortar sets. Prolonged troweling of a wet mixture brings to the top the "laitance" of the concrete, which is the part incapable of a true set. A top layer of laitance is therefore porous and wears down quickly. Even the fine particles of good cement should not be brought to the surface, as they form a layer which is weakly bonded to the rest of the concrete and wears away rapidly, appearing in the air as dust.

**To Prevent Dust on Concrete Floors.**—The Aberthaw Construction Co. of Boston, contracting engineers specializing in concrete, recommends the following method of curing a dusty concrete floor: Have the surface entirely dry; then paint it with a mixture of boiled linseed oil thinned with gasoline. Apply several coats, until the oil shows glossy on the top. The theory of this is that the linseed oil, having been boiled, has lost most of its volatile components and is practically permanent. The gasoline thins this down enough so that it will strike into the pores. A little experimenting will show the proper proportions. The thinner it is, the more coats will be required and the deeper it will strike in. A floor that is causing serious trouble from dust can often be cured with very little trouble and expense in this way.

**Floors for Forge Shops.**—There is considerable difference in opinion as to the best material for blacksmith shop flooring. Wood is too inflammable, bricks crack and break from the heat, cement or concrete has the same objectionable features, and asphalt is out of the question. Perhaps nothing is superior to or cheaper than dirt mixed with ashes. If kept moist by sprinkling at least once a day, it is more comfortable to stand upon than the other mate-

rials mentioned. It is easily repaired and leveled in case holes are worn in it, and is not affected by dropping heavy or hot pieces upon it. The space between the walls and forges, however, may be covered with concrete to facilitate the handle of such appliances as portable surface-plates and vises.

### Drop-Forging Dies

**Steel for Drop-forging Dies.**—Practically all drop-forging dies are made of high-grade open-hearth steel. A 60-point carbon steel is mostly used, although steel as low as 40-point and as high as 85-point carbon is employed in some cases. A special hardening treatment is required for the low-carbon steel, which more than offsets the saving in price, and, except in special cases, there is no advantage in using high-carbon steels, owing to the expense. The average 60-point carbon steel die, if properly hardened, should last for from 15,000 to 40,000 forgings, and sometimes as many as 70,000 forgings can be made from one set of dies. When making dies for large forgings, it is often thought advisable to use 80-point carbon steel, and not harden the dies. This obviates the danger from “checking” or cracking in hardening, and the un-hardened steel is hard enough to resist the tendency to stretch. A steel that is quite high in carbon should always be used for dies that are intended for making forgings from tool steel or any other hard steel.

**Allowance for Shrinkage.**—When making dies for small cold-trimmed steel forgings, the proper allowance for shrinkage is  $\frac{3}{16}$  inch to the foot, or 0.015 inch to the inch. Such forgings are finished at a bright red heat and the rate of shrinkage is considerable. When making dies for hot-trimmed steel forgings of medium and large sizes, the shrinkage allowance is  $\frac{1}{8}$  inch to the foot, or 0.010 inch to the inch. Hot-trimmed forgings receive the finishing blow while comparatively cold, and shrink a smaller amount than the cold-trimmed forgings. The foregoing allowances are used for all dimensions of the die impression, such as depth, width or length. The shrinkage allowance for dies to be used in forging bronze or copper is practically the same as that for steel.

**Draft Allowance.**—The amount of draft in a drop-forging die varies from 3 to 10 degrees. If the die is for a thin forging of uniform section, 3 degrees is ample, but if the forging is deep and has narrow ribs which are apt to stick, at least 7 degrees is necessary. If a die is used for forging a piece that is ring-shaped or has an annular part, the central plug that forms the interior of the ring should have a draft of 10 degrees, because, as the forging cools while being worked, it tends to shrink around the plug and if the draft is insufficient, it will stick in the die. With the foregoing exception, most drop-forging dies have a 7-degree draft. For convenience in laying out, it is well to remember that a 7-degree taper is approximately equal to a  $\frac{1}{8}$ -inch taper to the inch, and a 10-degree taper,  $\frac{3}{16}$  inch to the inch.

**Locating Impression in the Die.**—When laying out a drop-forging die, the impression should be located so that the heaviest end of the forging will be at the front of the die-block. This makes the forging easier to handle and also permits the use of a fairly large sprue. There should be at least  $1\frac{1}{2}$  inch left all around between the impression and the outside edge of the block. This also holds true for any part of the die, such as the edger, anvil or forming impression. If the forging has a hub or other projection that extends some distance from the main part on one side, the upper or top die should contain this deeper impression.

**Obtaining Weight of Forging from Lead Proof.**—After the upper and lower dies have been completed, shrinkage allowances and the general finish of the impressions are ordinarily tested by taking a “lead proof,” and by weighing the lead, an approximate idea of the weight of the finished forging can be obtained. Roughly speaking, the finished forging will weigh two-thirds as much as the lead proof. The shrinkage of lead is practically the same as that of steel, so that the finished forging will also measure about the same as the one made of lead. In case of dies for eye-bolts and similar work, this rule must be disregarded, because the plugs that form the central opening will prevent the lead from shrinking natu-

rally. When taking the lead proof, the die impressions are dusted with powdered chalk, and after the dies are clamped together, the molten lead is poured.

**Amount of Flash for Drop-forging Dies.**—Theoretically, there should be just enough forging metal in a die to fill the impression, and no more, but this is, of course, not practicable, as there is always some stock that must be disposed of after the impression is filled. To take care of this excess metal, dies are relieved all around the impression by milling a flat shallow recess about  $\frac{1}{64}$  inch deep and  $\frac{5}{8}$  inch wide. These dimensions are for dies of average size; in comparatively large dies this recess or “flash” would be a little deeper and wider. Both the upper and lower dies are flashed in this way. In addition, the upper die is “back-flashed,” which means that there is a deeper recess, sometimes called the “gutter,” milled around the impression at a distance of  $\frac{1}{4}$  inch from the impression at every point. This back-flash is  $\frac{3}{64}$  inch deep and acts as a relief for the excess metal after it has been squeezed from the flash proper. Only the finishing impression is provided with a flash and back-flash.

**The Break-down of Drop-forging Dies.**—The width of section used as a break-down (also known as the edger or side cut) should be enough wider than the forging to give plenty of room for the work of forging. A forging 1 inch thick should have a break-down  $1\frac{1}{2}$  inch wide, and about the same proportions should be followed for forgings of other widths. The break-down should have a section corresponding with the gate and sprue of the die impression, but it should be made slightly longer, so that the forging will not be stretched when struck in the impression.

**Hardening Drop-forging Dies.**—Dies to be carburized should always be packed for hardening in cast-iron or sheet-iron boxes containing a mixture of fresh bone and charcoal. The ordinary mixture is half bone and half charcoal. More bone gives greater hardness and more charcoal, less hardness, for a given heat; hence, the proportions should be varied according to requirements. The die should be packed face down on a one- or two-inch layer of this mixture and be settled so that the impression is filled. Sometimes the face is coated, before packing, with a thick paste of linseed oil and powdered bone-black, to protect the delicate edges from oxidation when in contact with the air. Fill the space between the sides of the die and the box with the bone and charcoal mixture, and cover over with a thick layer of wet clay paste to prevent the charcoal from burning out. Dies made of steel having less than 60-point carbon content should always be carburized. Open-hearth steel dies containing 60-point carbon or over can be hardened without carburizing.

**Heating the Die.**—An oil or gas furnace is recommended for heating, although a coal or coke-fired muffle furnace, capable of maintaining a temperature of at least 1600 degrees F., may be used, provided the temperature can be held constant. A temperature indicating device is necessary. The die should be put into the furnace as soon as the latter is lighted. If the correct quenching temperature for the steel is, say, 1500 degrees F., the furnace should be checked when the pyrometer indicates 1400 degrees, the die being allowed to “soak” at that heat for three or four hours. Then the heat should be slowly raised to 1500 degrees and held at that point one or two hours longer, according to the size of the die. Five hours is the minimum total time for heating, and seven or eight hours is much safer. A 60-point carbon die should be quenched between 1425 and 1450 degrees F.

**Cooling the Heated Die.**—When cooling, the face of the die should receive a sufficient flow of cold water to cause it to harden to the greatest possible depth. The back of the die should, at the same time, be cooled to make the shrinkage of the face and back equal, and to prevent warping. A good form of cooling tank is one having a large supply pipe extending up through the bottom for cooling the die face, and a smaller pipe above the tank to cool the back. Unless a jet of water under pressure is applied to the face of the die, the sunken parts of the impression will not harden equally with the face. Dies should not be cooled in a tank of still water, because steam forms in the die cavity which prevents the water from enter-

ing, thus causing the formation of soft spots. To overcome this, the water must be forced into the impression by pressure sufficient to overcome the resistance of the steam thus formed. Oil should not be used for hardening hammer dies, as its cooling action is not great enough to produce a sufficient depth of hardening. Hammer dies which are simply surface hardened will not withstand the heavy blows received in service. To secure a greater hardening effect, brine of about 40 per cent solution is used by some die-makers.

**Tempering Dies.**—Dies should be tempered and drawn as soon as they are cool enough to remove from the tank. The dies should be heated in an oil bath, and quenched in water or cool oil. Any high-grade cylinder oil of high flash-point is suitable. Low-grade oils smoke unpleasantly and will not stand high temperatures. The drawing temperature of die steels is about 450 degrees F., for average conditions. The corners of the die and the cut-off should be drawn to a purple color with the aid of a blow torch.

**Dies for Bronze and Copper Forgings.**—Dies for producing drop-forgings from bronze or copper differ from those used for steel or iron forgings principally in the matter of finish. Owing to the softness of copper and bronze, the metal is driven into very minute impressions in the surface of the dies; hence, these surfaces must be perfectly free from scratches, in order to insure a smooth finish on the work. Even though these metals are soft, the hammering necessary when forging is very hard on the dies, and to prevent them from dishing or spreading, tool steel is ordinarily used, unless the forgings are extra large and heavy. The shrinkage, draft and finish allowances on this class of drop-forging dies are practically the same as on dies for steel and iron.

**Trimming Dies for Drop-forgings.**—Hot-trimming dies are made of a special grade of steel known as hot-trimming die-stock. The objection to use ordinary tool steel for hot-trimming dies is that the edges of a hardened die check badly after the die has been used for a short time, and this checking is followed by a breaking away of the steel around the edges, thus rendering the die unfit for use. This special steel requires no hardening, and after the die is in use, the edges toughen and give better service than the best hardened tool steel. The usual form of punch for hot-trimming dies merely supports the forging while it is being pushed through. If the forging has a broad, flat top face, the punch need only be a little more than a flat piece that covers the forging and acts as a pusher. Such punches are commonly made of cast iron. Cold-trimming dies are made from good tool steel of from 1.00 to 1.25 per cent carbon, and hardened and drawn to a dark straw color. The punches for cold trimmers are also made of tool steel and are hardened and drawn to a very dark straw color. These punches are hardened to prevent them from upsetting at the edges. As with hot-trimming punches, the punch should fit the die loosely, but it should support the forging at every point while it is being pushed through the die. There are two instances in which trimming punches should fit the dies as closely as the average punching die for sheet metal work; first, when trimming forgings on which the fin comes at the corner of the forging; second, forgings that are formed all in one die, the other die being flat. In these two cases, unless the dies fit very well, there will be burrs at the trimmed edges.

**Standard Tolerances for Forgings.**—The tolerances adopted by the Drop Forging Association in 1937 (see accompanying [Tables 69](#) through [73](#)) apply to forgings under 100 pounds each. Forging tolerances may either be "special" or "regular." *Special tolerances* are those which are particularly noted in the specifications and may state any or all tolerances in any way as required. Special tolerances apply only to the particular dimensions noted. In all cases where special tolerances are not specified, regular tolerances apply.

**Table 69. Standard Tolerances for Forgings Adopted, 1937,  
by Drop Forging Association for Forgings under 100 Pounds Each**

| Thickness Tolerances, Inch <sup>a</sup> |            |      |       |      |                                 |            |      |       |      |
|---|------------|------|-------|------|---------------------------------|------------|------|-------|------|

|   | –          | +    | –     | +    |                                 | –          | +    | –     | +    |
| .2                                      | .008       | .024 | .004  | .012 | 20                              | .026       | .078 | .013  | .039 |
| .4                                      | .009       | .027 | .005  | .015 | 30                              | .030       | .090 | .015  | .045 |
| .6                                      | .010       | .030 | .005  | .015 | 40                              | .034       | .102 | .017  | .051 |
| .8                                      | .011       | .033 | .006  | .018 | 50                              | .038       | .114 | .019  | .057 |
| 1                                       | .012       | .036 | .006  | .018 | 60                              | .042       | .126 | .021  | .063 |
| 2                                       | .015       | .045 | .008  | .024 | 70                              | .046       | .138 | .023  | .069 |
| 3                                       | .017       | .051 | .009  | .027 | 80                              | .050       | .150 | .025  | .075 |
| 4                                       | .018       | .054 | .009  | .027 | 90                              | .054       | .162 | .027  | .081 |
| 5                                       | .019       | .057 | .010  | .030 | 100                             | .058       | .174 | .029  | .087 |
| 10                                      | .022       | .066 | .011  | .033 |                                 |            |      |       |      |

<sup>a</sup> Thickness tolerances apply to the over-all thickness. For drop-hammer forgings, they apply to the thickness in a direction perpendicular to the main or fundamental parting plane of the die. For upset forgings, they apply to the thickness in the direction parallel to the travel of the ram, but only to such dimensions as are enclosed by the actually formed by the die.

| 3                                   | .009                      | .005            | 5                          | .038                      | .019            | 13                                 | .021            | .014  |
| 4                                   | .012                      | .006            | 7                          | .041                      | .021            | 19                                 | .024            | .016  |
| 5                                   | .015                      | .008            | 9                          | .044                      | .022            | 25                                 | .027            | .018  |
| 6                                   | .018                      | .009            | 11                         | .047                      | .024            | 31                                 | .030            | .020  |

For each additional inch under shrinkage, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. For example, if length or width is 12 inches, the commercial tolerance is plus or minus 0.036 and the close tolerance plus or minus 0.018.

For each additional 2 pounds under die wear, add 0.003 to the commercial tolerance and 0.0015 to the close tolerance. Thus, if the net weight is 21 pounds, the die wear commercial tolerance is 0.062 plus or minus, and the close tolerance 0.031 plus or minus.

For each additional 6 pounds under mismatching, add 0.003 to the commercial tolerance and 0.002 to the close tolerance. Thus, if the net weight is 37 pounds, the mismatching commercial tolerance is 0.033 and the close tolerance 0.022.

| 20 - 29                   | 4                     | 2                 | 600 - 1,249               | 7                     | 3.5                 |
| 30 - 39                   | 5                     | 2                 | 1,250 - 2,999             | 6                     | 3.0                 |
| 40 - 49                   | 6                     | 3                 | 3,000 - 9,999             | 5                     | 2.5                 |
| 50 - 59                   | 7                     | 3                 | 10,000 - 39,999           | 4                     | 2.0                 |
| 60 - 69                   | 8                     | 4                 | 40,000 - 299,999          | 3                     | 1.5                 |
| 70 - 79                   | 9                     | 4                 | 300,000 up                | 2                     | 1.0                 |
| 80 - 99                   | 10                    | 5                 |                           |                       |                     |

These quantity tolerances represent the permissible over-run or under-run allowed for each release or part shipment of an order. Any shipping quantity within the limits of over-run or under-run shall be considered as completing the order.

**Table 73. Standard Tolerances for Forgings Adopted, 1937, by Drop Forging Association for Forgings under 100 Pounds Each**

| Maximum Radii of Fillets and Corners, Inch |                |                |                              |                |                |
|--|----------------|----------------|------------------------------|----------------|----------------|
| Net Weights, Pounds, up to —               | Commercial     | Close          | Net Weights, Pounds, up to — | Commercial     | Close          |
| .3   | $\frac{3}{32}$ | $\frac{3}{64}$ | 10                           | $\frac{3}{16}$ | $\frac{3}{32}$ |
| 1  | $\frac{1}{8}$  | $\frac{1}{16}$ | 30                           | $\frac{7}{32}$ | $\frac{7}{64}$ |
| 3  | $\frac{5}{32}$ | $\frac{5}{64}$ | 100                          | $\frac{1}{4}$  | $\frac{1}{8}$  |

*Regular tolerances:* are divided into two divisions — “Commercial Standard” and “Close Standard.” “Commercial Standard” tolerances are for general forging practice, but when extra close work is desired involving additional expense and care in the production of forgings, “Close Standard” may be specified. When no standard is specified, “Commercial Standard” shall apply.

Regular tolerances are applicable to 1) thickness; 2) width, including shrinkage and die wear, mismatching, and trimmed size; 3) draft angle; 4) quantity in shipment; and 5) fillets and corners.

*Thickness Tolerances:* Thickness tolerances shall apply to the overall thickness of a forging. (See [Table 69](#).)

*Width and Length Tolerances:* Width and length tolerances shall be alike and shall apply to the width or length of a forging. When applied to drop hammer forgings, they shall apply to the width or length in a direction parallel to the main or fundamental parting plane of the die, but only to such dimensions as are enclosed by and actually formed by the die. When applied to upset forgings, they shall apply to the width or length in a direction perpendicular to the direction of travel of the ramp.

Width and length tolerances consist of the three subdivisions following: a) Shrinkage and die wear tolerance; b) mismatching tolerance; and c) trimmed size tolerance.

### Welding Methods

**Classes of Welds.**—Welds are classified according to the way the ends are formed prior to making the weld. The different welds ordinarily made in hand forging practice are the scarf weld, butt weld, lap weld, cleft or split weld and jump weld. These welds are shown by the accompanying illustration. It will be seen that the surfaces, in most instances, are rounded or crowned. This is done so that when the heated ends are brought together they will unite first in the center. Any slag or dirt which may have adhered to the heated surfaces will then be forced out as the welding proceeds from the center outward. When making a lap weld, the hammering should begin at the center in order to work all the slag out, as the faces in this case are not rounded.

**Welding Heat.**—When two pieces of wrought iron or mild steel are heated until they become soft and plastic and will stick together when one is pressed or hammered against the other, they have reached what is commonly known as a welding heat. The quality of the weld depends largely upon the welding heat. If the ends to be heated are not hot enough, they will not stick together; inversely, if the work remains in the fire too long, it becomes overheated and burned, which greatly injures the metal. Iron which has been overheated has a rough, spongy appearance and is brittle. The danger of burning is increased when the air blast is too strong and the fire is oxidizing. It is important to heat the work slowly to secure a uniform temperature throughout the ends to be heated. With rapid heating, the outside may be raised to the welding temperature, while the interior is much below it; consequently, the weld will be defective.

**Fire for Welding.**—When heated iron comes into contact with the air it absorbs oxygen, thus forming a scale or oxide of iron on the surface, which prevents the formation of a good weld. A fire for heating parts to be welded should have a fairly thick bed between the tuyere and the work, so that the oxygen in the air blast will be consumed before it reaches the parts being heated. When there is only a thin bed of fuel beneath the work, or if too strong a blast is used, the excess of oxygen will pass through and oxidize the iron. The hotter the iron, the greater the formation of scale. The surface being heated can be given an additional protection by covering it with some substance that will exclude the air. (See "Fluxes for Welding.") Ordinarily, the air blast for a forge fire should have a pressure varying from 3 to 6 ounces per square inch. (See "Air Pressures and Pipe Sizes for Forges.")

**Fluxes for Welding.**—When iron is being heated preparatory to welding, the heated surfaces are oxidized to some extent or covered with oxide of iron, which forms a black scale when the hot iron comes into contact with the air. If this scale is not removed, it will cause a defective weld. Wrought iron can be heated to a high enough temperature to melt this oxide so that the latter is forced out from between the surfaces by the hammer blows; but when welding machine steel, and especially tool steel, a temperature high enough to melt the oxide would burn the steel, and it is necessary to use what is called a flux. This is a substance, such as sand or borax, having a melting temperature below the welding temperature of the work, and it is sprinkled upon the heated ends when they have reached about a yellow heat. The flux serves two purposes: It melts and covers the heated surfaces, thus protecting them from oxidation, and, when molten, aids in dissolving any oxide that may have formed, the oxide melting at a lower temperature when combined with the flux. Wrought

iron can be welded in a clean, well-kept fire without using a flux of any kind, except when the material is very thin. The fluxes commonly used are fine clean sand and borax. When borax is used, it will give better results if burned. This can be done by heating it in a crucible until reduced to the liquid state. It should then be poured onto a flat surface to form a sheet; when cold, it can easily be broken up and pulverized. The borax powder can be used plain or it can be mixed with an equal quantity of fine clean sand and about 25 per cent iron (not steel) filings. For tool steel, a flux made of one part sal-ammoniac and twelve parts borax is recommended. When pieces are put together previous to welding, as in split welds, or when taking a second heat (usually termed a "wash"), a flux that will flow easily should be used. There are many welding compounds on the market, some of which are suited for one class of welding and some for another.

**Fuels for Forge.**—Coke, coal, charcoal, oil and gas are used as fuels for heating iron and steel preparatory to forging or welding. For general work, a coke fire is the best, although bituminous coal is extensively used. With anthracite coal, it is difficult to get a hot enough fire, especially on a small forge. Coke or bituminous coal should be low in sulphur, because sulphur makes the iron "hot short" or brittle while hot. Sulphur, lead, bronze or brass must not be in the fuel or fire to be used for heating iron or steel. A weld may be spoiled by throwing brass filings into a fire before heating the work.

**Machine Welding.**—There are three common types of welds that can be made satisfactorily in a forging machine, simple examples of which are shown in the accompanying illustration.

*Lap-welding:* This is one of the most successful methods that can be used in joining pieces together in a forging machine, whenever requirements will permit. There are several applications of this type of welding: Two pieces can be joined together (as shown in the illustration) or several pieces can be welded together in one block. Machine lap-welding is also employed for enlarging the diameter of a bar, this being accomplished by welding a U-shaped piece of rectangular stock to the end, and then upsetting the mass into the shape desired. An end plunger is used to upset the bar after the latter is securely held between the opposing faces of the gripping dies.

*Pin-welding:* In order to make a pin weld, the end of the bar is reduced and inserted in a hole in the part to which it is to be joined (see illustration). The reduced end is usually made from one-quarter to one-half the diameter of the original bar. The U-shaped piece, or other part which is to be joined to it, is generally made thicker where the weld is made, in order to strengthen the weld. The welding operation is effected by a plunger in the ram of the machine, which upsets the "pin" and at the same time forms the joint.

*Butt-welding:* This method of machine welding is not as common as the other two methods referred to, but is satisfactory when properly applied. To make a butt weld, it is not necessary to prepare the stock beforehand, although the pieces should have practically the desired shape. The weld is effected by a plunger having a pointed end which is forced through the forward member to be joined, thus closely pressing together the material and insuring a solid weld (see illustration).

This method of welding is not considered as practicable as pin-welding, but when properly handled, it is satisfactory for many classes of work. Wrought iron is welded in a forging machine without using any flux but the parts to be joined must be clean and free from scale. As a rule, compressed air is used to remove the scale formed by oxidization. A small jet of air is directed against the work just before the machine is operated. For welding steel having a comparatively high carbon content, it is necessary to use a flux to make a satisfactory weld. (See "Fluxes for Welding.")

## Hydraulic Press

**Rules and Formulas for Hydraulic Press Calculations.**—To find the total pressure of a hydraulic press when the diameter of the ram in inches and the water pressure (gage pressure) in pounds per square inch are given, multiply the area of the cross-section of the ram by the pressure per square inch, and divide by 2000. The result is the capacity of the hydraulic press in tons. The same result may be obtained as follows: Multiply the square of the diameter of the ram by the pressure per square inch, and multiply this product by 0.00039. The result is the total pressure of the press in tons.

The pressure per square inch on the material under pressure in the press can be determined when the total pressure of the press and the area of the material under pressure are known. Multiply the total pressure of the press in tons by 2000, and divide the product by the area of the material to be pressed. The quotient is the pressure in pounds per square inch on the surface of the material.

Table 74. Capacity of Hydraulic Presses

| Diam. of Ram, Inches | Area of Ram, Sq. Ins. | Pressure in Pounds per Square Inch on End of Ram |      |      |      |      |      |      |      |      |      |      |
|----------------------|-----------------------|--|------|------|------|------|------|------|------|------|------|------|

When a certain pressure per square inch on the material under pressure is required, the gage pressure of the press necessary to obtain this pressure may be calculated as follows: Multiply the area of the surface under pressure by the pressure per square inch desired on the material. Divide this product by 0.7854 times the square of the diameter of the ram. The quotient will be the desired gage pressure.

Expressing these rules as formulas, let  $D$  = diameter of ram in inches;  $P$  = water pressure in pounds per square inch (gage pressure);  $C$  = total pressure or capacity of press in tons;  $A$  = area of material to be pressed, in square inches;  $P_a$  = pressure in pounds per square inch on material under pressure; then:

$$C = 0.00039D^2 \times P \quad P_a = \frac{2000C}{A} \quad P = \frac{A \times P_a}{0.7854D^2}$$

## SILENT OR INVERTED TOOTH CHAIN

Silent or inverted tooth chain consists of a series of toothed links alternately assembled either with pins or with a combination of joint components in such a way that the joints articulate between adjoining pitches. Side Guide chain has guide links which straddle the sprocket sides to control the chain laterally. Center Guide chain has guide links that run within a circumferential groove or grooves for lateral control.

### Characteristics of Silent Chain Drives

The silent or "inverted-tooth" driving chain has the following characteristics: The chain passes over the face of the wheel like a belt and the wheel teeth do not project through it; the chain engages the wheel by means of teeth extending across the full width of the under side, with the exception of those chains having a central guide link; the chain teeth and wheel teeth are of such a shape that as the chain pitch increases through wear at the joints, the chain shifts outward upon the teeth, thus engaging the wheel on a pitch circle of increasing diameter; the result of this action is that the pitch of the wheel teeth increases at the same rate as the chain pitch. The accompanying illustration shows an unworn chain to the left, and a worn chain to the right, which has moved outward as the result of wear. Another distinguishing feature of the silent chain is that the power is transmitted by and to all the teeth in the arc of contact, irrespective of the increasing pitch due to elongation. The links have no sliding action either on or off the teeth, which results in a smooth and practically noiseless action, the chain being originally designed for the transmission of power at higher speeds than are suitable for roller chains. The efficiency of the silent chain itself may be as high as 99 per cent, and for the complete drive, from 96 to 97 percent, under favorable conditions; from 94 to 96 per cent can be secured with well-designed drives under average conditions.

The life and upkeep of silent chains depend largely upon the design of the entire drive, including the provision for adjustment. If there is much slack, the whipping of the chain will greatly increase the wear, and means of adjustment may double the life of the chain. A slight amount of play is necessary for satisfactory operation. The minimum amount of sag should be about  $\frac{1}{8}$  inch. Although the silent chain shifts outward from the teeth and adjusts itself for an increase of pitch, it cannot take up the increased pitch in that portion of the chain between the wheels; therefore, the wheel must lag to the extent of the increased pitch in the straight portion of the chain.

**Standard Silent Chain Designation.**—The standard chain number or designation for  $\frac{3}{8}$ -inch pitch or larger consists of:

1) a two letter symbol SC; 2) one or two numerical digits indicating the pitch in eighths of an inch; and 3) two or three numerical digits indicating the chain width in quarter-inches.

Thus, SC302 designates a silent chain of  $\frac{3}{8}$ -inch pitch and  $\frac{1}{2}$ -inch width, while SC1012 designates a silent chain of  $1\frac{1}{4}$ -inch pitch and 3-inch width.

The standard chain number or designation for  $\frac{3}{16}$ -inch pitch consists of:

a) a two letter symbol SC; b) a zero followed by a numerical digit indicating pitch in sixteenths of an inch; and c) two numerical digits indicating the chain width in thirty-seconds of an inch. Thus, SC0309 designates a silent chain of  $\frac{3}{16}$ -inch pitch and  $\frac{9}{32}$ -inch width.

**Silent Chain Links.**—The joint components and link contours vary with each manufacturer's design. As shown in [Table 1](#) minimum crotch height and pitch have been standardized for interchangeability. Chain link designations for  $\frac{3}{8}$ -inch and larger pitch are given in [Table 1](#)

**Table 1. American National Standard Silent Chain Links\***

| Chain Number                      | Chain Pitch |       | Stamp      | Crotch Height, Min. |       |
|-----------------------------------|-------------|-------|------------|---------------------|-------|

Min. Crotch Height =  $0.062 \times \text{Chain Pitch}$ .

Link contour may vary but must engage standard sprocket tooth so that joint centers lie on pitch diameter of sprockets.

**Silent Chain Sprocket Diameters.**—The important sprocket diameters are:

- 1) outside diameter; 2) pitch diameter; 3) maximum guide groove diameter; and
- 4) over-pin diameter.

These are shown in the diagram in [Table 2](#) and the symbols and formulas for each are also given in this table. [Table 3a](#) gives values of outside diameters for sprockets with rounded teeth and with square teeth, pitch diameters, and over-pin diameters for chains of 1-inch pitch and sprockets of various tooth numbers. Values for chains of other pitches ( $\frac{3}{8}$  inch and larger) are found by multiplying the values shown by the pitch. [Table 3b](#) gives this information for  $\frac{3}{16}$ -in. pitch chains. Note that the over-pin diameter is measured over gage pins having a diameter  $D_p = 0.625P$  in. for  $\frac{3}{8}$ -in. and larger pitch and  $D_p = 0.667P$  in. for  $\frac{3}{16}$ -in. pitch chains. Over-pin diameter tolerances are given in [Table 4a](#) and [4b](#).

**Silent Chain Sprocket Profiles and Chain Widths.**—Sprocket tooth face profiles for side guide chain, center guide chain and double guide chain are shown in [Table 4c](#) and [4d](#) together with important dimensions for chains of various pitches and widths. Maximum over-all width  $M$  of the three types of chain are also given in this table for various pitches and widths. It should be noted that the sprocket tooth width  $W$  for the side guide chain is given in [Table 5](#) for one-half-inch wide chains of  $\frac{3}{8}$ -inch and  $\frac{1}{2}$ -inch pitches. No values of  $W$  for other chain sizes are specified in American National Standard B29.2M-1982 (1987).

\* For  $\frac{3}{8}$ -inch and larger pitch chains.

**Table 2. ANSI Silent Chain Sprocket Diameters (ANSI B29.2M-1982, R1987)**

- $P$  = Chain Pitch
- $PD$  = Pitch Diameter
- $OD$  = Outside Diameter
- $D_p$  = Gage Pin Diameter
- $N$  = Number of Teeth
- $E$  = Diameter to center of Topping Curve
- $OPD$  = Over Pin Diameter
- $G$  = Max. Guide Groove Diameter

$$PD = \frac{P}{\sin \frac{180^\circ}{N}}$$

$D_p = 0.625P$ , for  $\frac{3}{8}$  in. and larger pitch chain  
 [=  $0.667P$  for  $\frac{3}{16}$  in. pitch chain ]

$$OPD \text{ (For Even No. of Teeth)} = PD - 0.125P \csc \left( 30 - \frac{180^\circ}{N} \right) + 0.625P$$

$$\left[ = PD - 0.160P \csc \left( 30 - \frac{180^\circ}{N} \right) + 0.667P \right]$$

$$OPD \text{ (For Odd No. of Teeth)} = \cos \frac{90^\circ}{N} \left[ PD - 0.125P \csc \left( 30 - \frac{180^\circ}{N} \right) \right] + 0.625P$$

$$\left[ = \cos \frac{90^\circ}{N} \left[ PD - 0.160P \csc \left( 30 - \frac{180^\circ}{N} \right) \right] + 0.625P \right]$$

$$OD \text{ (For Round Teeth)} = P \left( \cot \frac{180^\circ}{N} + 0.08 \right)$$

$$\left[ OD \text{ (For Nominal Round Teeth)} = P \left( \cot \frac{180^\circ}{N} - 0.032 \right) \right]$$

$$OD \text{ (For Square Teeth)} = 2\sqrt{X^2 + L^2} - 2XL \cos \alpha$$

Where

$$X = Y \cos \alpha - \sqrt{(0.15P)^2 - (Y \sin \alpha)^2}$$

$$Y = P(0.500 - 0.375 \sec \alpha) \cot \alpha + 0.11P$$

$$L = Y + \frac{E}{2} \text{ (See Table 8A for E);}$$

$$\alpha = \left( 30 - \frac{360^\circ}{N} \right)^\circ$$

$$G(\text{max.}) = P \left( \cot \frac{180^\circ}{N} - 1.16 \right)$$

$$\left[ G(\text{max.}) = P \left( \cot \frac{180^\circ}{N} - 1.20 \right) \right]$$

Tolerance = +0, -0.030 in. (0.76 mm)

[Tolerance = +0, -0.015 in. (0.38 mm)]<sup>a</sup>

<sup>a</sup> All inside [ ] bracket applies to  $\frac{3}{16}$ -inch pitch main. All other equations apply to  $\frac{3}{8}$ -inch and larger pitch chains.

## SILENT OF INVERTED TOOTH CHAIN

**Table 3a. (Continued) American National Standard Silent Chain Sprocket Diameters ANSI B29.2M-1982, R1987**

| These diameters apply only to chain of 1-inch pitch.<br>For any other pitch ( $\frac{3}{8}$ -inch and larger) multiply the values given below by the pitch. |                |                            |                           |                                |           |                |                  |              |                   |
|---|----------------|----------------------------|---------------------------|--------------------------------|-----------|----------------|------------------|--------------|-------------------|
| No. Teeth   | Pitch Diameter | Outside Diameter           |                           | Over Pin Diameter <sup>a</sup> | No. Teeth | Pitch Diameter | Outside Diameter |              | Over Pin Diameter |
|   |                | Rounded Teeth <sup>b</sup> | Square Teeth <sup>c</sup> |                                |           |                | Rounded Teeth    | Square Teeth |                   |

<sup>a</sup> For tolerances on over-pin diameters, see table 4.<sup>b</sup> Blank diameters are 0.020 inch larger and maximum guide groove diameters G are 1.240 inches smaller than these outside diameters.<sup>c</sup> These diameters are maximum; tolerance is +0, -0.50× pitch, inches.Tolerance for maximum eccentricity (total indicator reading) of pitch diameter with respect to bore is  $0.001 \times PD$ , but not less than 0.006 nor more than 0.032 inch.

**Table 3b. American National Standard Silent Chain Sprocket Diameters for  $\frac{3}{16}$ -in. Pitch Chain ANSI B29.2M-1982, R1987**

| No. Teeth | Pitch Diameter | Outside Diameter           |                           | Over Pin Diameter <sup>a</sup> | No. Teeth | Pitch Diameter | Outside Diameter           |                           | Over Pin Diameter <sup>a</sup> |

<sup>a</sup>For tolerances on over-pin diameters, see table 4.

<sup>b</sup>Blank diameters are 0.020 inch larger and maximum guide groove diameters G are 1.240 inches smaller than these outside diameters.

<sup>c</sup>These diameters are maximum; tolerance is +0, -0.50 × pitch, inches.

Tolerance for maximum eccentricity (total indicator reading) of pitch diameter with respect to bore is 0.004 in. up to and including 4 in. diameter; and 0.008 in., over 4 in. diameter.

**Table 4a. Over-Pin Diameter Tolerances for American National Standard  $\frac{3}{8}$ -in. Pitch and Larger Silent Chain Sprocket Measurement ANSI B29.2M-1982, 1987**

| Pitch                          | Number of Teeth |       |       |       |       |       |       |         |         |        |
|--------------------------------|-----------------|-------|-------|-------|-------|-------|-------|---------|---------|--------|

<sup>a</sup>All tolerances are negative.

Grooving tool may be either square or round end but groove must be full width down to diameter of G. For values of G (max.) see footnote to Table 3a

Values of H ( $\pm 0.003$  in.) = 0.051 in. are given only for chain numbers SC302 and SC402. M = Max. overall width of chain. The maximum radius over a new chain engaged on a sprocket will not exceed the sprocket pitch radius plus 75 per cent of the chain pitch. To obtain the chain widths and sprocket face dimensions in millimeters, multiply each entry by 25.4.

**Table 4c. ANSI  $\frac{3}{8}$ - in. Pitch and Larger Silent Chain Widths and Sprocket Face Dimensions (ANSI B29.2M-1982, R1987)**

All dimensions in inches. M = Max. overall width of chain.

To obtain chain width and sprocket face dimensions in millimeters, multiply each entry by 25.4.

**Sprocket Hub Dimensions.**—The important hub dimensions are the outside diameter, the bore, and the length. The maximum hub diameter is limited by the need to clear the chain guides and is of particular importance for sprockets with low numbers of teeth. The American National Standard for inverted tooth chains and sprocket teeth ANSI B29.2M-1982 (R1987) provides the following formulas for calculating maximum hub diameters, *MHD*.

$$MHD(\text{for hobbled teeth}) = P \left[ \cot \left( \frac{180^\circ}{N} \right) - 1.33 \right]$$

$$MHD(\text{for straddle cut teeth}) = P \left[ \cot \left( \frac{180^\circ}{N} \right) - 1.25 \right]$$

Maximum hub diameters for sprockets with from 17 to 31 teeth are given in Table 5. Maximum hub diameters for other methods of cutting teeth may differ from these values. Recommended maximum bores are given in Table 6.

**Table 5. American National Standard Minimum Hub Diameters for Silent chain Sprockets (17 to 31 Teeth) ANSI B29.2M-1982, 1987**

| No. Teeth | Hob cut        | Straddle Cut | No. Teeth | Hob cut        | Straddle Cut | No. Teeth | Hob cut        | Straddle Cut |

| 21        | 5.304          | 5.384        | 26        | 6.905          | 6.985        | 31        | 8.503          | 8.583        |

All dimensions in inches.

Values shown are 1-inch pitch chain. For other pitches ( $\frac{3}{8}$ -inch and larger) multiply the values given by the pitch.

Good practice indicates that teeth of sprockets up to and including 31 teeth should have a Rockwell hardness of C50 min.

**Table 6. Recommended maximum Sprocket Bores for Silent Chains**

| Number of Teeth | Chain Pitch, Inches           |                  |                |                |                |                |                |                 |

<sup>a</sup> Range of teeth is indicated in the cutter marking.

<sup>b</sup> Suggested standard. Bores other than standard must be specified.

All dimensions in inches. To obtain values in millimeters, multiply inch values by 25.4. These data are given as supplementary information in ANSI B29.2M-1982, R1987 and are made available by the American Chain Association.

Fig. 3. Identification of Inverted Tooth Chain Hobs.

Table 9. Hobs for ANSI  $\frac{3}{8}$ -inch and larger Silent Tooth Sprocket\*

$P$  = Chain Pitch

$N$  = Number of Teeth

$$HGD = P \sqrt{\frac{1}{\sin \frac{180^\circ}{N}} + 0.5625 - \frac{1.5 \sin \left( 30 - \frac{180^\circ}{N} \right)}{\sin \frac{180^\circ}{N}}}$$

**Sprocket Design and Tooth Form.**—Except for tooth form, silent chain sprocket design parallels the general design practice of roller chain sprockets as covered in the previous section.

As shown in Tables 7a and 7b, sprockets for American National Standard silent chains have teeth with straight-line working faces. The tops of teeth for  $\frac{3}{8}$ -in. and larger pitch chains may be rounded or square. Bottom clearance below the working face is not specified but must be sufficient to clear the chain teeth. The standard tooth form for  $\frac{3}{8}$ -in. and larger pitch chains is designed to mesh with link plate contours having an included angle of 60 degrees as shown in the diagram of Table 7a. The standard tooth form for  $\frac{3}{16}$ -in. pitch chains has an included angle of 70 degrees as shown in Table 7b. It will be seen from these tables that the angle between the faces of a given tooth [ $60^\circ - 720^\circ/N$  for  $\frac{3}{8}$ -in. pitch and larger;  $70^\circ - 720^\circ/N$  for  $\frac{3}{16}$ -in. pitch] becomes smaller as the number of teeth decreases. Therefore, for a  $\frac{3}{8}$ -in. pitch or larger 12-tooth sprocket it will be zero. In other words the tooth faces will be parallel.

For smaller tooth numbers the teeth would be undercut. For best results, 21 or more teeth are recommended; less than 17 should not be used.

**Cutting Silent Chain Sprocket Teeth.**—Sprocket teeth may be cut by either a straddle cutter or a hob. Essential dimensions for straddle cutters are given in Table 8 and for hobs in Table 9 and 10. American National Standard silent chain hobs are stamped for identification as shown on page 2375.

**Design of Silent Chain Drives.**—The design of silent chain transmissions must be based not only upon the power to be transmitted and the ratio between driving and driven shafts, but also upon such factors as the speed of the faster running shaft, the available space, assuming that it affects the sprocket diameters, the character of the load and certain other factors. Determining the pitch of the chain and the number of teeth on the smallest sprocket are the important initial steps. Usually any one of several combinations of pitches and sprocket sizes may be employed for a given installation. In attempting to select the best combination, it is advisable to consult with the manufacturer of the chain to be used. Some of the more important fundamental points governing the design of silent chain transmissions will be summarized.

The design of a silent chain drive consists, primarily, of the selection of the chain size, sprockets, determination of chain length, center distance, lubrication method, and arrangement of casings.

**Pitch of Silent Chain.**—The pitch is selected with reference to the speed of the faster running shaft which ordinarily is the driver and holds the smaller sprocket. The following pitches are recommended: for a faster running shaft of 2000 to 5000 rpm,  $\frac{3}{8}$ -inch pitch; for 1500 to 2000 rpm,  $\frac{1}{2}$ -inch pitch; for 1200 to 1500 rpm,  $\frac{5}{8}$ -inch pitch, for 1000 to 1200 rpm,  $\frac{3}{4}$ -inch pitch; for 800 to 1000 rpm, 1-inch pitch; for 650 to 800 rpm,  $1\frac{1}{4}$ -inch pitch; for 300 to 600 rpm,  $1\frac{1}{2}$ -inch pitch; for 300 to 500 rpm, 2-inch pitch; and for below 300 rpm,  $2\frac{1}{2}$ -inch pitch. As the normal operating speeds increase, the allowable pitch decreases. Recommendations relating to the relationship between pitch and operating speed are intended for normal or average conditions. Speeds for a given pitch may be exceeded under favorable conditions and may have to be reduced when conditions are unfavorable. In general, smoother or quieter operation will result from using the smallest pitch suitable for a given speed and load. However, a larger pitch which might be applicable under the same conditions, will result in a narrower chain and a less expensive transmission. This relationship usually is true when there is a small speed reduction and comparatively long center distance. If there is a large speed reduction and short center distance, drives having the smaller pitches may be less expensive.

**Maximum Ratios for Silent Chain Drives.**—The maximum permissible ratios between driving and driven sprockets vary somewhat for different conditions and usually range from 6- or 7-to-1 up to 10-to-1. Some drives have even higher ratios, especially when the operating conditions are exceptionally favorable. When a large speed reduction is necessary, it is preferable as a general rule to use a double reduction or compound type of transmission instead of obtaining the entire reduction with two sprockets. Drives should be so proportioned that the angle between the two strands of a tight chain does not exceed 45 degrees. When the angle is larger, the chain does not have sufficient contact with the driving sprocket.

*Sprocket Size and Chain Speed:* A driving sprocket with not less than 17 teeth is generally recommended. For the driven sprocket, one manufacturer recommends 127 teeth as a maximum limit and less than 100 as preferable. If practicable, the sprocket sizes should be small enough to limit the chain speed to from 1200 to 1400 feet per minute. If the chain speed exceeds these figures, this may indicate that the pitch is too large or that a smaller pitch, and, consequently, a reduction in sprocket diameters (and chain speed) will result in better operating conditions. Both sprockets should preferably have a "hunting tooth ratio" relative to the number of chain links for uniform wear. See "Hunting Tooth Ratios," page 1867.

If there is a small reduction in speed between the driving and driven shafts, both sprockets may be made as small as is consistent with satisfactory operation, either to obtain a compact drive or possibly to avoid excessive chain speed in cases where the rotative speed is high for a given horsepower. Under such conditions, one manufacturer recommends driving sprockets ranging from 17 to 30 teeth, and driven sprockets ranging from 19 to 33

teeth. If the number of revolutions per minute is low for a given horsepower and the center distance comparatively long, then the recommended range for driving sprockets is from 23 to iii teeth, and driven sprockets from 27 to 129 teeth. The preferable range is from 17 to 75 teeth for the driving sprockets, and 19 to 102 teeth for the driven sprockets.

**Center Distance for Silent Chain Drives.**—If the ratio of the drive is small, it is possible to locate the sprockets so close—that the teeth just clear; however, as a general rule, the minimum center-to-center distance should equal the sum of the diameters of both sprockets. According to the Whitney Chain & Mfg. Co., if the speed ratio is not over  $2\frac{1}{2}$ -to-1, the center distance may be equal to one-half the sum of the sprocket diameters plus tooth clearance, providing this distance is not less than the minimum given in Table 11. If the speed ratio is greater than  $2\frac{1}{2}$ -to-1, the center distance should not be less than the sum of the sprocket diameters.

**Table 11. Minimum Center Distances for Various Pitches**

| Pitch, inches                    | $\frac{3}{8}$ | $\frac{1}{2}$ | $\frac{5}{8}$ | $\frac{3}{4}$ | 1  | $1\frac{1}{4}$ | $1\frac{1}{2}$ |
|----------------------------------|---------------|---------------|---------------|---------------|----|----------------|----------------|
| Minimum Center Distances, inches | 6             | 9             | 12            | 15            | 21 | 27             | 33             |

When the chain length in pitches is known, the equivalent center distance for a tight chain may be determined by the formula for roller chain found on page 2348.

In selecting chain length, factors determining length should be adjusted so that the use of offset links may be avoided wherever possible. Chain lengths of an uneven number of pitches are also to be avoided.

**Silent Tooth Chain Horsepower Capacity.**—The horsepower ratings given in Tables 12a, 12b, and 12c have been established on a life expectancy of approximately 15,000 hours under optimum drive conditions, i.e. for a uniform rate of work where there is relatively little shock or load variation throughout a single revolution of a driven sprocket. Using these horsepower ratings as a basis, engineering judgment should be exercised as to the severity of the operating conditions for the intended installation, taking into consideration the source of power, the nature of the load, and the resulting effects of inertia, strain, and shock. Thus, for other than optimum drive conditions, the specified horsepower must be multiplied by the applicable service factor to obtain a “design” horsepower value. This is the value used to enter Table 13 to obtain the required size of chain.

*Service Factors:* For a uniform type of load, a service factor of 1.0 for a 10-hour day and 1.3 for a 24-hour day are recommended. For a moderate shock load, service factors of 1.4 for a 10-hour day and 1.7 for a 24-hour day are recommended. For heavy shock loads, service factors of 1.7 for a 10-hour day and 2.0 for a 24-hour day are recommended. For extensive table of service factor applications, see supplementary information in ANSI B29.2M-1982.

**Installation of Silent Chain Drives.**—In installing chain transmissions of any kind, horizontal drives are those having driving and driven shafts in a horizontal plane. These are always preferable to vertical drives, which have a vertical center line intersecting the driving and driven shafts. If one sprocket must be higher than the other, avoid a vertical drive if possible by so locating the two sprockets that the common center line inclines from the vertical as far as is permitted by other conditions which might govern the installation. If practicable, an adjustment should be provided for the center distance between the driving and driven shafts.

*Slack Side of Chain:* As a general rule, the slack strand of a chain should be on the lower side of a horizontal drive. If the drive is not horizontal but angular or at some angle less than 90 degrees from the vertical, the slack should preferably be on that side which causes the strand to curve outward or away from the center line of the driving and driven shafts. Whenever the slack strand is on the upper side of either a horizontal or inclined drive,

adjustment for the center distance is especially important to compensate for possible chain elongation.

*Lubrication:* The life of a silent chain subjected to conditions such as are common to automobile drives, depends largely upon the wear of the joints. On account of the high speed and whipping action, it is important to have the chains well oiled. When splash lubrication is employed, the supply pipe should be placed so that the oil will be directed against the inside of the chain. It is preferable that silent chains be operated in an oil-retaining casing with provisions for lubrication. Avoid using greases of any kind. The viscosity of the oil depends on temperature, as follows:

| Ambient Temp.<br>°F   | Chain Pitch                         |                             | Ambient Temp.<br>°F   | Chain Pitch                         |                             |
|-----------------------|-------------------------------------|-----------------------------|-----------------------|-------------------------------------|-----------------------------|
|                       | $\frac{3}{16}$ & $\frac{3}{8}$ inch | $\frac{1}{2}$ inch & larger |                       | $\frac{3}{16}$ & $\frac{3}{8}$ inch | $\frac{1}{2}$ inch & larger |
| Recommended Lubricant |                                     |                             | Recommended Lubricant |                                     |                             |
| 20-40                 | SAE 10                              | SAE 20                      | 20-40                 | SAE 10                              | SAE 20                      |
| 40-100                | SAE 20                              | SAE 30                      | 40-100                | SAE 20                              | SAE 30                      |

**Double-Flexure Silent Chain.**—In double-flexure chain, the teeth of the link plates project on both sides of the chain and the chain flexes in both directions. This chain is used where the drive arrangements require that sprockets contact both sides of the chain. Neither double-flexure chain nor sprockets are covered in American National Standard ANSI B29.2M-1982.

#### **Horsepower Ratings Per Inch of Chain Width for Silent Chain Drives — 1982.**—

The following industrial standard horsepower ratings for silent chain drives have been supplied by the American Chain Association. These ratings are for American National Standard silent chain as covered by ANSI B29.2M-1982. These values may require modification by using the appropriate service factors (see page 2379). These factors, which apply to typical drives, are intended as a general guide only, and engineering judgment and experience may indicate different modifications to suit the nature of the load.

$$\text{Horsepower capacity of chain per inch of width} = \frac{\text{Rating in Table 12A, 12B}}{\text{Service Factor}}$$

$$\text{chainwidth for given total hp capacity} = \frac{\text{hp} \times \text{Service factor}}{\text{Rating per inch, Table 12A, 12B}}$$

*Lubrication:* The horsepower established from the sprocket and speed combinations of the drive under consideration will indicate a method of lubrication. This method or a better one must be used to obtain optimum chain life. The types of lubrication as indicated on the tables are: Type I, manual, brush, or oil cup; Type II, bath or disk; Type III, circulating pump.

SILENT OF INVERTED TOOTH CHAIN

**Table 12a. Horse Power Ratings per Inch of Chain Width for Silent Chain Drives—1982**

<sup>a</sup> For best results, smaller sprocket should have at least 21 teeth.

## GEARS AND GEARING

### Geometry Factors For Gear Teeth

**Contact and Bending Stresses.**—To calculate the contact and bending stresses acting between the teeth of a pair of gears meshing under load, it is necessary to include in the stress formulas a number of factors that account for the geometry of the teeth, the physical properties of the materials used, and the nature of the specific application.

AGMA 908-B89 Information Sheet\* gives equations for calculating the pitting resistance geometry factor,  $I$ , for external and internal spur and helical gears; and the bending strength geometry factor,  $J$ , for external spur and helical gears that are generated by rack-type tools (hobs, rack cutters, or generating grinding wheels) or pinion-type tools (shaper cutters). The document includes 66 tables of geometry factors,  $I$  and  $J$ , for a range of typical gear sets and tooth forms of  $14\frac{1}{2}$ -, 20-, and 25-deg pressure angles and 0-, 10-, 15-, 20-, 25-, and 30-deg helix angles.

The Information sheet was prepared to assist designers making preliminary design studies and to present data useful to those without access to computer programs. Not all tooth forms, pressure angles, and pinion and gear modifications are covered. Neither are these data applicable to all gear designs; however, the data should be helpful to the majority of gear designers. Data from this Information Sheet are used with the rating procedures described in AGMA 2001-B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, for evaluating various spur and helical gear designs produced by using a generating process (see page 1834).

**Geometry Factors for Pitting Resistance and Bending Strength.**—The AGMA Information Sheet includes a mathematical procedure to determine the pitting resistance geometry factor,  $I$ , for internal and external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical design. A mathematical procedure is also included to determine the bending strength geometry factor,  $J$ , for external gear sets of spur, conventional helical, and low-axial-contact-ratio (LACR) helical designs. The calculation procedure is valid for generated root fillets produced by both rack- and pinion-type tools.

**Exceptions to the Information Sheet Data and Procedures.**—The formulas in the Information Sheet are not valid when any of the following conditions exist:

1) Spur gears with transverse contact ratio less than one,  $m_p < 1.0$ ; 2) spur or helical gears with transverse contact ratio equal or greater than two,  $m_p \geq 2.0$ ; 3) interference exists between the tips of teeth and root fillets; 4) the teeth are pointed; 5) backlash is zero; 6) undercut exists in an area above the theoretical start of the active profile (the effect of this undercut is to move the highest point of single tooth contact, negating the assumption of this calculation method; however, the reduction in tooth thickness due to protuberance below the active profile is handled correctly by this method); 7) the root profiles are stepped or irregular (the  $J$  factor calculation uses the stress correction factors developed by Dolan and Broghamer; the factors may not be valid for root forms that are not smooth curves; for root profiles that are stepped or irregular, other stress correction factors may be appropriate); 8) where root fillets of the gear teeth are produced by a process other than generating; and 9) the helix angle at the standard (reference) diameter is greater than 50 deg.

In addition to these exceptions, it is assumed that 1) the friction effect on the direction of force is neglected; and 2) the fillet radius is smooth (it is actually a series of scallops).

**Basic Gear Geometry of Spur and Helical Gears.**—The equations that follow apply to spur and helical gears. Where double signs are used (e.g.,  $\pm$ ), the upper sign applies to exter-

\* Extracted from AGMA 908-B89, Information Sheet, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

nal gears and the lower sign to internal gears. The equations given are based on unity normal module ( $m_n = 1$ ) or unity normal diametral pitch ( $P_{nd} = 1$ ) and are valid for any consistent set of units. All angles are in radians unless otherwise specified. *In using the given equations, certain variables must be made dimensionless by dividing by the normal module  $m_n$  or multiplying by the normal diametral pitch  $P_{nd}$ .* For example, if a face width  $F$  0.5 in. and the normal diametral pitch is 4, then the value of  $F$  to be used in the equations is  $0.5 \times 4 = 2$ . The variables to be so adjusted are  $F, R_{o1}, R_{o2}, R_{oc}, R_c, h_{ao}, \delta_{ao}, \rho_{ao},$  and  $\Delta_{sn}$ .

$$\text{Gear ratio, } m_G = \frac{n_2}{n_1}, \text{ Where } n_1 \text{ and } n_2 \text{ are pinion and gear tooth numbers} \quad (1)$$

$$\text{Standard (reference) pinion pitch radius, } R_1 = \frac{n_1}{2 \cos \psi} \quad (2)$$

Where  $\psi$  = standard helix angle.

$$\text{Standard (reference) gear pitch radius, } R_2 = R_1 m_G \quad (3)$$

$$\text{Standard transverse pressure angle, } \phi = \arctan\left(\frac{\tan \phi_n}{\cos \psi}\right) \quad (4)$$

Where  $\phi_n$  = standard normal pressure angle.

$$\text{Pinion base radius, } R_{b1} = R_1 \cos \phi \quad (5)$$

$$\text{Gear base radius, } R_{b2} = R_{b1} m_G \quad (6)$$

$$\text{Operating transverse pressure angle, } \phi_r = \arccos\left(\frac{R_{b2} \pm R_{b1}}{C_r}\right) \quad (7)$$

Where  $C_r$  = Operating center distance.

$$\text{Transverse base pitch, } P_b = \frac{2\pi R_{b1}}{n_1} \quad (8)$$

$$\text{Normal base pitch, } P_N = \pi \cos \phi_n \quad (9)$$

$$\text{Base helix angle, } \psi_b = \arccos\left(\frac{P_N}{P_b}\right) \quad (10)$$

Fig. 1 shows a view of the line of action in the transverse plane of two meshing gears. The distances  $C_1$ , through  $C_6$  are derived from this figure taking into account the exceptions noted previously with regard to undercut.

$$C_6 = C_r \sin \phi_r \quad (11)$$

$$C_1 = \pm [C_6 - (R_{o2}^2 - R_{b2}^2)^{0.5}] \quad (12)$$

where  $R_{o2}$  = addendum radius of gear, for internal or external gears.

$$C_3 = \frac{C_6}{(m_G \pm 1)} \quad (13)$$

$$C_4 = C_1 + P_b \quad (14)$$

$$C_5 = (R_{o1}^2 - R_{b1}^2)^{0.50} \tag{15}$$

Where  $R_{o1}$  = addendum radius of pinion.

$$C_2 = C_5 - P_b \tag{16}$$

$$\text{Active length of line of contact, } Z = C_5 - C_1 \tag{17}$$

Distance  $C_2$  locates the lowest point of single tooth contact (LPSTC); distance  $C_4$  locates the highest point of single tooth contact (HPSTC), where  $C_r$ ,  $R_{o1}$ , and  $R_{o2}$  are values for  $m_n = 1$  or  $P_{nd} = 1$ .

Fig. 1. Transverse Plane View of the Line of Action

**Contact Ratios.**—The contact ratios are as follows:

$$\text{Transverse Contact ratio, } m_p = \frac{Z}{P_b} \tag{18}$$

$$\text{Axial pitch, } P_x = \frac{\pi}{\sin \psi} \tag{19}$$

$$\text{Axial contact ratio, } m_F = \frac{F}{P_x} \tag{20}$$

where  $F$  = effective face width at  $m_n = 1$  or  $P_{nd} = 1$ . For spur gears,  $m_F = 0$ .

**Minimum Lengths of Lines of Contact.**—For spur gears with  $m_p < 2.0$  the minimum length of contact lines,  $L_{min}$ ,

$$L_{min} = F \quad (21)$$

For helical gears, two cases must be considered:

$$\text{Case I: For } n_a \leq 1 - n_r, L_{min} = \frac{(m_p F - n_a n_r p_x)}{\cos \psi_b} \quad (22)$$

$$\text{Case II: For } n_a > 1 - n_r, L_{min} = \frac{[m_p F - (1 - n_a)(1 - n_r)p_x]}{\cos \psi_b} \quad (23)$$

where  $n_r$  = fractional part of  $m_p$ , and  $n_a$  = fractional part of  $m_F$ . For example, if  $m_p = 1.4$ , then  $n_r = 0.4$ .

**Load Sharing Ratio,  $m_N$ .**—The load sharing ratio  $m_N$  is calculated as follows:

$$\text{For helical gears, } m_N = \frac{F}{L_{min}} \quad (24)$$

$$\text{For spur gears with } m_p \leq 2.0, \text{ Eq. (21) has } L_{min} = F \text{ so that } m_N = 1.0 \quad (25)$$

For low axial contact ratio (LACR) helicals,  $m_F \leq 1.0$ . Load sharing is accommodated by the helical overlap factor  $C_\psi$  [Equation (36)]; therefore,

$$m_N = 1.0 \quad (26)$$

$$\text{Operating helix angle, } \psi_r = \arctan\left(\frac{\tan \psi_b}{\cos \phi_r}\right) \quad (27)$$

$$\text{Operating normal pressure angle, } \phi_{nr} = \arcsin(\cos \psi_b \sin \phi_r) \quad (28)$$

**Calculating the Pitting Resistance Geometry Factor,  $I$ .**—The pitting resistance geometry factor  $I$  is a dimensionless number that takes into account the effects of the radii of curvature of the gear tooth surfaces, load sharing, and the normal component of the transmitted load:

$$I = \frac{\cos \phi_r C_\psi^2}{[(1/\rho_1 + 1/\rho_2)(dm_N)]} \quad (29)$$

where

$\phi_r$  = operating transverse pressure angle [Equation (7)];

$C_\psi$  = helical overlap factor [Equation (36)];

$d$  = pinion operating pitch diameter [Equation (30)];

$m_N$  = load sharing ratio [Equation (24), (25), or (26)]; and

$\rho_1$  and  $\rho_2$  = radii of curvature of pinion and gear profiles, respectively, at point of stress calculation.

$$\text{Operating pitch diameter of pinion, } d = \frac{2c_r}{(m_G + 1)} \quad (30)$$

**Radii of Curvature of Profiles at Contact Stress Calculation Point:** For conventional helical gears ( $m_F > 1$ ) the radii of curvature are calculated at the mean radius or middle of the working profile of the pinion where

$$\text{Mean radius of pinion, } R_{m1} = \frac{1}{2}[R_{O1} \pm (C_r - R_{O2})] \quad (31)$$

where

$R_{O1}$  = addendum radius of pinion and;

$R_{O2}$  = addendum radius of gear, internal or external.

$$\text{radius of curvature of pinion profile, } \rho_1 = (R_{m1}^2 - R_{b1}^2)^{0.50} \quad (32)$$

Where  $R_{b1}$  = base radius of pinion.

$$\text{Radius of curvature of gear profile, } \rho_2 = C_6 \mp \rho_1 \quad (33)$$

For spurs and LACR helicals ( $m_F \leq 1$ ), the radii of curvature are calculated at the LPSTC:

$$\rho_1 = C_2 \quad (34)$$

$$\rho_2 = C_6 \mp \rho_1 \quad (35)$$

Helical overlap factor for LACR ( $m_F \leq 1$ ), helical gears,

$$C_\psi = \left[ 1 - m_F \left( 1 - \frac{\rho_{m1} \rho_{m2} Z}{\rho_1 \rho_2 \rho_N} \right) \right]^{0.50} \quad (36)$$

where  $Z$  = Equation (17);  $\rho_N$  = Equation (9);  $\rho_{m1}$  = Equation (37) and,  $\rho_{m2}$  = Equation (38).  
radius of curvature of pinion profile at mean radius of profile,

$$\rho_{m1} = (R_{m1}^2 - R_{b1}^2)^{0.50} \quad (37)$$

Radius of curvature of gear profile at mean radius of gear,

$$\rho_{m2} = C_6 \mp \rho_{m1} \quad (38)$$

$$\text{For spur and conventional helicals, } C_\psi = 1 \quad (39)$$

**Bending Strength Geometry Factor,  $J$ .**—The bending strength geometry factor is a dimensionless number that takes into account: 1) shape of the tooth; 2) worst load position; 3) stress concentration; and 4) load sharing between oblique lines of contact in helical gears.

Both tangential (bending) and radial (compressive) components of the tooth load are included. The equations and calculation procedures for the bending stress geometry factor are not given here, but may be found in AGMA 908-B89. The procedures apply only to external gears and must be repeated for both the pinion and the gear using the appropriate dimensions for each.

*Generating Tool Geometry:* Details of the methods for calculating the geometry of the tools used to generate tooth profiles are provided in the Information Sheet as part of the  $J$ -factor calculation procedure.

\*Included in the AGMA Information Sheet are the equations needed to write a computer program to calculate values not given in the tables of  $J$  factors.

Fig. 2. Load Angle and Load Radius

Fig. 3. Pressure Angle Where Tooth Comes to Point

*Virtual Spur Gear:* Helical gears are considered to be virtual spur gears with the following virtual geometry:

$$\text{Virtual tooth number, } n = \frac{n_1}{\cos^3 \psi} \quad (40)$$

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_n = \frac{n}{2} \quad (41)$$

$$\text{Virtual base radius, } r_{nb} = r_n \cos \phi_n \quad (42)$$

$$\text{Virtual outside radius, } r_{na} = r_n + R_{01} - R_1 \quad (43)$$

For spur gears, the virtual geometry is the same as the actual geometry:

$$n = n_1 \quad (44)$$

$$r_n = R_1 \quad (45)$$

$$r_{nb} = R_{b1} \quad (46)$$

$$r_{na} = R_{01} \quad (47)$$

**Pressure Angle at Load Application Point.**—The critical bending stress on a spur gear tooth develops when all the applied load is carried at the highest point of single tooth contact on the tooth. Spur gears having variations that prevent two pairs of teeth from sharing the load may be stressed most heavily when the load is applied at the tips of the teeth. Table 1 has been used in previous standards to establish the variation in base pitch between the

gear and pinion, which determines whether load sharing exists in steel spur gears. Values greater than those in the table require the use of tip loading in determining bending stress geometry factors described in AGMA 908-B89.

**Table 1. Maximum Allowable Variation in Action for Steel Spur Gears for Load Sharing (Variation in Base Pitch)**

| Number of Pinion Teeth | Load Pounds per Inch of Face (Newtons Per Millimeter of Face)               |                |                |                |                 |
|------------------------|---|----------------|----------------|----------------|-----------------|
|                        | 500 lb (90N)  | 1000 lb (175N) | 2000 lb (350N) | 4000 lb (700N) | 8000 lb (1400N) |
|                        | Maximum Allowable Variation in Inches and Millimeters when Teeth Share Load |                |                |                |                 |
| 15                     | 0.0004 in.  | 0.0007 in.     | 0.0014 in.     | 0.0024 in.     | 0.0042 in.      |
|                        | 0.01 mm   | 0.02 mm        | 0.04 mm        | 0.06 mm        | 0.11 mm         |
| 20                     | 0.0003 in.  | 0.0006 in.     | 0.0011 in.     | 0.0020 in.     | 0.0036 in.      |
|                        | 0.01 mm   | 0.02 mm        | 0.03 mm        | 0.05 mm        | 0.09 mm         |
| 25                     | 0.0002 in.  | 0.0005 in.     | 0.0009 in.     | 0.0017 in.     | 0.0030 in.      |
|                        | 0.01 mm   | 0.01 mm        | 0.02 mm        | 0.04 mm        | 0.08 mm         |

For helical gears and spur gears that are analyzed with the load applied at the tip of the tooth, the pressure angle at the load application point,  $\phi_{nW}$ , is found from

$$\tan \phi_{nW} = \left[ \left( \frac{r_{na}}{r_{nb}} \right)^2 - 1 \right]^{0.50} \quad (48)$$

For spur gears, where the highest bending stress occurs when the load is at the highest point of single tooth contact (HPSTC), the pressure angle is found from

$$\tan \phi_{nW} = \frac{C_4}{r_{nb}} \quad (49)$$

Equation (49) may also be used for LACR helical gears, but distance  $C_4$  must be based on the virtual spur gear. The following equations are from analogy with Equation (3), (6), (11), (12), (14), (44), and (49):

$$\text{Standard (ref) pitch radius of virtual spur gear, } r_{n2} = r_n m_G \quad (50)$$

$$\text{Virtual base radius, } r_{nb2} = r_{nb} m_G \quad (51)$$

$$\text{Virtual outside radius, } r_{na2} = r_{n2} + R_{02} - R_2 \quad (52)$$

$$\text{Sixth distance along line of action of virtual gear, } C_{n6} = (r_{nb2} + r_{nb}) \tan \phi_{nr} \quad (53)$$

$$\text{First distance along line of action of virtual gear, } C_{n1} = [C_{n6} - (r_{na2}^2 - r_{nb2}^2)^{0.50}] \quad (54)$$

$$\text{Fourth distance along line of action of virtual gear, } C_{n4} = C_{n1} + \rho_N \quad (55)$$

The pressure angle at the load application point (tip),  $\phi_{nW}$

$$\tan \phi_{nW} = \frac{C_{n4}}{r_{nb}} \quad (56)$$

**Generating-Rack Shift Coefficient.**—The generating-rack shift coefficient,  $x_g$ , applies to the completely finished teeth. It includes the rack shift for addendum modification plus the rack shift for thinning the teeth to obtain backlash:

$$x_g = x - \frac{\Delta s_n}{2 \tan \phi_n} \quad (57)$$

where  $\Delta S_n$  = amount gear tooth is thinned for backlash and  $x$  = addendum modification coefficient at zero backlash,

$$x = \frac{\left(S_n + \Delta S_n - \frac{\pi}{2}\right)}{(2 \tan \phi_n)} \quad (58)$$

where  $S_n$  = normal circular tooth thickness measured on the standard (ref) pitch cylinder,

$$S_n = \frac{\pi}{2} + 2x_g \tan \phi_n \quad (59)$$

*Load Angle and Load Radius:* Fig. 2 defines the load angle  $\phi_{nl}$  and the load radius  $r_{nl}$ . The applied load is shown at an arbitrary point  $W$  such that:

$$\phi_{nl} = \tan \phi_{nw} - \text{INV} \phi_{np} \quad (60)$$

where  $\phi_{np}$  = pressure angle where gear tooth is pointed, Fig. 3.

$$\text{INV} \phi_{np} = \text{INV} \phi_n + \frac{S_n}{2r_n} \quad (61)$$

but,

$$\text{INV} \phi_n = \tan \phi_n - \phi \quad (62)$$

and

$$2r_n = n \quad (63)$$

so that

$$\text{INV} \phi_{np} = \tan \phi_n - \phi_n + \frac{S_n}{n} \quad (64)$$

Then Equation (60) can be expressed as

$$\phi_{nl} = \tan \phi_{nw} - \tan \phi_n + \phi_n - \frac{S_n}{n} \quad (65)$$

Equation (65) gives the load angle  $\phi_{nL}$  for any load position specified by  $\tan \phi_{nw}$  found from Equation (48) and (49).

As may be seen from Fig. 3, the virtual radius is

$$r_{nl} = \frac{r_{nb}}{\cos \phi_{nL}} \quad (66)$$

**Tables of Geometry Factors,  $I$  and  $J$ .**—Included here are some of the tables of precalculated values of  $I$  and  $J$  extracted from the Information Sheet. For additional data, tables, and related information for other combinations of gear sets, tooth forms, pressure angles, helix angles, cutting tool dimensions, and addendum coefficients, refer to the Information Sheet. It should be noted that the formulas and data in the Information Sheet are not applicable to bending stresses in internal gears, since no simplified model for calculating bending stresses in internal gears is available.

**Using the Tables.**—Each of the tables in the Information Sheet and those presented here were generated for a specific tool form (basic rack) defined by whole depth factor, normal pressure (profile) angle, and tool tip radius. Only those tables applicable to spur gears are presented here; those for helical gear sets are available in the Information Sheet.

*Whole Depth:* Whole depth is expressed in the tables as a “whole depth factor” and is the whole depth of a basic rack for  $I$  normal module or  $I$  normal diametral pitch. The actual generated depths will be slightly greater due to tooth thinning for backlash

*Outside Diameter:* The tabulated values are for gears having an outside diameter (for normal module or normal diametral pitch = 1), equal to

$$D_{a1} = \frac{n_1}{\cos \psi} + 2(1 + x_1) \quad (67)$$

$$D_{a2} = \frac{n_2}{\cos \psi} + 2(1 + x_2) \quad (68)$$

where  $n_1$  and  $n_2$  are the pinion and gear tooth numbers, respectively;  $\psi$  = standard helix angle, deg.; and  $D_{a1}$  and  $D_{a2}$  are the pinion and gear addendum, respectively.

*Center Distance:* The tables apply to gearsets that operate at standard center distance. This center distance is the tight-mesh center distance for gears not yet thinned for backlash:

$$C = \frac{(n_1 + n_2)}{2 \cos \psi} \quad (69)$$

where  $C$  = standard center distance. For this center distance the sum of the addendum modification coefficients for pinion and gear is zero:

$$x_1 + x_2 = 0 \quad (70)$$

*Tooth Thickness Backlash Allowance:* Values in the tables were calculated based on a backlash allowance. The circular tooth thickness for the pinion and gear are each thinned by an amount  $\Delta s_n$ :

$$\Delta s_n = \frac{0.024}{P_{nd}} = 0.024 \text{ for } P_{nd} = 1 \quad (71)$$

If the gears being evaluated have different minimum tooth thicknesses than from Equation (71), the bending strength geometry factor,  $J$ , can be approximated by using Equation (72). The pitting resistance geometry factor,  $I$ , is unaffected by variations in tooth thickness:

$$J_1 = J_s \left( \frac{s_{n1}}{s_{ns}} \right)^2 \quad (72)$$

where  $J_1$  = adjusted geometry factor;  $J_s$  = geometry factor from table;  $s_{n1}$  = adjusted circular tooth thickness; and  $s_{ns}$  = standard tooth thickness thinned per Equation (71).

As an example, from Table 4, for 20-deg pressure angle spur gears loaded at the highest point of single tooth contact, the  $J$  factor for a 21-tooth pinion operating with a 35-tooth gear is found to be 0.31. The table values are based on a circular tooth thickness of  $\pi/2 - 0.024 = 3.1416/2 - 0.024 = 1.547$  for diametral pitch.

For a 10 normal diametral pitch pinion or gear, the equivalent circular tooth thickness would be  $1.547/10 = 0.155$ .

If a  $J$  value for a 0.010 in. thinner pinion, having a circular thickness of  $0.155 - 0.010 = 0.145$  in. is required, the approximate value is  $0.34(0.145/0.155)^2 = 0.30 = J_1$  so that a 6.5 per cent reduction in tooth thickness reduces the  $J$  factor by 12 percent.

*Undercutting:* The tables do not include geometry factors that may be needed if an undercutting condition exists in either of the two gears. Undercutting can be evaluated using Equation (73) and Fig. 4 where the generating-rack shift coefficient,  $x_g$ , must be equal to or greater than the expression in Equation (73):

$$x_{gmin} = h_{ao} - \rho_{ao}(1 - \sin \phi_n) - \left( \frac{n}{2} \right) \sin \phi_n^2 \quad (73)$$

where  $h_{ao}$  = nominal tool addendum;  $\rho_{ao}$  = tool tip radius; and  $n$  = pinion or gear tooth number.

Fig. 4. Undercutting Criteria

*Top Land:* The tables do not include geometry factors when either the pinion or the gear tooth top land is less than the value expressed in Equation (74) or (74a):

$$s_{namin} \geq \frac{0.3}{P_{nd}} \text{ in.} \tag{74}$$

$$s_{namin} \geq 0.3m_n \text{ mm} \tag{74a}$$

in which  $s_{na}$  = tooth thickness at outside diameter.

*Cutter Geometry:* The hob geometry used in the calculation of  $I$  and  $J$  is as follows: Tool tooth number,  $n_c = 10,000$ ; reference normal circular tooth thickness of tool,  $s_{no} = 1.5708$ ; addendum modification coefficient of tool,  $x_o = 0.0$ ; amount of protuberance,  $\delta_o = 0.0$ .

**Table 2. Geometry Factors  $I$  and  $J$  for Various Number Combinations for Module = 1 or Normal Diametral Pitch = 1**

The addendum modification coefficients  $x_f$  and  $x_2$  are for zero backlash gears meshing at standard center distance.

### Power-Transmitting Capacity of Spur Gears

**Modes of Failure.**—When sets of spur gears are made, installed, and lubricated properly, they normally may be subject to three primary modes of failure, as discussed below.

**Tooth Scoring:** Tooth scoring is a scuffing or welding type of tooth failure, caused by high sliding speed combined with high contact stress. Scoring is not a fatigue failure but rather a failure of the lubricant caused by increases in lubricant viscosity with pressure. The lubricant must provide cooling to the gears as well as reducing friction. Well proportioned commercial gears with a pitchline velocity of less than 7000 ft/min will normally not score if they have a reasonably good surface finish and are properly lubricated. If scoring does occur or if it is suspected to be critical in a new high speed design, the scoring temperature index should be determined by the method shown in American Gear Manufacturers Standard AGMA 217.01 or by some similar method.

**Pitting:** In surface pitting, small cracks first develop on and under the surfaces of gear teeth as a result of metal fatigue. Pieces of the surface then break away, and those that do not fall clear cause further damage or broken teeth. Vacuum-melted steels have gone far toward reducing pitting. Failure usually occurs at a point just below the pitch surface on the driving pinion and may be anticipated in the gear design by a determination of the gear set contact compressive stress.

**Tooth Breakage:** Tooth breakage is usually a tensile fatigue failure at the weakest section of the gear tooth when considered as a cantilever beam. The weakest point is normally the tensile side of the gear tooth fillet, and it may be anticipated in the gear design by determining the stress at this weakest section of the gear tooth.

**Strength Calculations for Spur and Helical Gears.**—Many standards and procedures for the design, manufacture, inspection, and application of gears have been published for the guidance of both the users and the manufacturers of gears and gear products. Among such publications, those of the American Gear Manufacturers Association (AGMA) represent an authoritative resource for information and standards on all phases of design, inspection, manufacture, application, and other aspects of gear technology.

American Gear Manufacturers Association Standard, AGMA 2001–B88, *Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth*, is a revision of, and supersedes, AGMA 218.01. The Standard presents general formulas for rating the pitting resistance and the bending strength of spur and helical involute gear teeth and is intended to establish a common base for rating various types of gears for differing applications and to encourage the maximum practical degree of uniformity and consistency between rating practices in the gear industry. Standard 2001–B88 provides the basis from which more detailed AGMA Application Standards are developed and is a means for calculation of approximate ratings in the absence of such standards. Where applicable AGMA standards exist, they should be used in preference to this Standard. Where no applicable standards exist, numerical values may be estimated for the factors used in the general equations presented in the standard. The values of these factors may vary significantly, depending on the application, system effects, gear accuracy, manufacturing practice, and definition of what constitutes gear failure. Proper evaluation of these factors is essential for realistic ratings.

Information on the geometry factors,  $I$  and  $J$ , used in pitting resistance and bending strength calculations has been amplified, and moved from the old AGMA 218.01 standard to AGMA 908–B89, *Geometry Factors for Determining the Pitting Resistance and Bending Strength of Spur, Helical, and Herringbone Gear Teeth*. AGMA Standard 908–B89 is covered on Handbook pages 1853–1866.

**Rating Formulas\*.**—AGMA 2001–B88 provides a method whereby different gear designs can be compared but it is not intended to ensure the performance of assembled gear drive systems. The formulas are applicable for rating the pitting resistance and bending strength of internal and external spur and helical involute gear teeth operating on parallel axes. Gear tooth capacity is influenced by the major factors that affect gear tooth pitting and gear tooth fracture at the fillet radius can be evaluated with these formulas.

Knowledge and judgment required to evaluate the various rating factors can be gained only from years of accumulated experience in designing, manufacturing, and operating gear units. Empirical factors given in the AGMA 2001–B88 standard are general in nature, and other AGMA application standards may use other empirical factors that are more closely suited to the particular field of application. AGMA 2001–B88 is intended for use by the experienced gear designer capable of selecting suitable values for the factors and not for use by engineers inexperienced in gear design and applications.

**Exceptions.**—The formulas in this Standard are not applicable to other types of gear tooth deterioration such as plastic yielding, wear, case crushing, and welding and are not applicable when vibratory conditions exceed the limits for the normal operation of the gears (see AGMA 6000–A88, *Specification for Measurement of Lateral Vibration on Gear Units*). The formulas are not applicable when any of the following conditions exist:

5) spur gears with transverse contact ratio less than 1.0; 6) spur or helical gears with transverse contact ratio equal to or greater than 2.0; 7) interference exists between the tips of the teeth and the root fillets; 8) the teeth are pointed; and 9) backlash is zero.

**Additional Considerations.**—When suitable test results or field data are not available, values for the rating factors should be chosen conservatively. Among other considerations, the following should be taken into account:

*Manufacturing Tolerances:* Rating factors should be evaluated on the basis of the expected variation of component parts in the production run.

*Accuracy:* Experimental data from actual gear unit measurements are seldom repeatable within a plus or minus 10 per cent band. Calculated gear ratings are intended to be conservative but the scatter in actual results may exceed 20 per cent.

*Misalignment and Deflection of Foundations:* Misalignment and deflection of foundations, on which many gear systems depend to maintain alignment of the gear mesh, will adversely affect overall performance.

*Deflection due to External Loads:* Deflection of supporting housings, shafts, and bearings, due to external overhang, transverse and thrust loads affects tooth contact across the mesh. Deflection varies with load, so it is difficult to obtain good tooth contact at different loads. Generally, deflection due to external loads reduces capacity.

*Metallurgy:* The allowable stress numbers included in the Standard are a function of melting, casting, forging, and heat treating practices. Hardness, tensile strength, and cleanliness are some of the criteria for determining allowable stress numbers; the allowable values in this Standard are based on 10,000,000 cycles of loading, 99 percent reliability, and unidirectional loading.

Variations in microstructure account for some variation in gear capacity. Higher levels of cleanliness and better metallurgical controls permit use of higher allowable stress values and, conversely, lower quality levels require the use of lower values.

*Residual Stress:* Any material having a case—core relationship is likely to have residual stresses. Properly managed, these stresses will be compressive at the surface and will enhance the bending strength performance of the gear teeth. Shot peening, case carburiz-

\*Extracted from AGMA 2001–B88, Fundamental Rating Factors and Calculation Methods for Involute Spur and Helical Gear Teeth, with the permission of the publisher, American Gear Manufacturers Association, 1500 King Street, Suite 201, Alexandria, Virginia 22314.

ing, nitriding, and induction hardening are common methods of inducing compressive prestress in the surfaces of gear teeth.

Grinding the tooth surfaces after heat treatment reduces residual compressive stresses; and grinding the tooth surfaces and the root fillet areas may introduce tensile stresses and possibly cracks in these areas if done incorrectly. Care is needed to avoid excessive reductions in hardness and changes in microstructure during the grinding process, and shot peening after grinding is often performed to ensure the presence of residual compressive stresses.

*Lubrication:* The ratings determined by the formulas in the Standard are only valid when a lubricant of proper viscosity for the load, gear-tooth surface finish, temperature, and pitchline velocity is used. Gears with pitchline velocities of less than 100 ft/min require special design considerations to avoid premature failure from inadequate lubrication.

Velocities greater than 100 ft/min but less than 1000 ft/min frequently require special design considerations even when the lubricants used conform to AGMA 250 recommendations.

With velocities in the range of 1000–0,000 ft/min, lubrication problems may be caused by high temperatures, unsuitable additives in the oil, size of the pinion, inadequate oil viscosity, or tooth finish characteristics. Problems in this speed range are not common in industrial gears but sometimes occur in aerospace and in marine gearing.

From a lubrication standpoint, the design of slower gears should be based on application criteria such as hours of life, degree of reliability needed, and acceptable increases in vibration and noise as the gear teeth wear or deform. At pitchline velocities below 100 ft/min, or 20 rpm input speed, the gear designer may allow for acceptable pitting and wear to occur during the gear life when using these rating practices for other than surface-hardened gearing. Rating of gear teeth due to wear is not covered by this Standard.

*System Dynamics:* The dynamic response of the system results in additional gear tooth loads due to the relative motions of the connected masses of the driver and the driven equipment. Application factors,  $C_a$  and  $K_a$ , are intended to account for the operating characteristics of the driving and driven equipment. However, if the operating roughness of the driver, gearbox, or driven equipment causes an excitation with a frequency near to one of the system's major natural frequencies, resonant vibrations may cause severe overloads that may be several times higher than the nominal load. For more information, refer to AGMA 427.01, *Information Sheet—Systems Considerations for Critical Service Gear Drives*.

*Corrosion:* Corrosion of the gear tooth surface can have significant detrimental effects on the bending strength and pitting resistance of the teeth. The extent of these corrosion effects is not included in the Standard.

*Cold Temperature Operation:* For gears operated at temperatures below 320F, special care must be taken to select materials that will have adequate impact properties at the operating temperature. Consideration should be given to

1) low-temperature Charpy impact specification; 2) fracture appearance transition or nil ductility temperature specification; 3) reduction of carbon content to less than 0.4 per cent; and 4) use of higher nickel alloy steels.

### Criteria for Gear Tooth Capacity

**Relationship of Pitting Resistance and Bending Strength Ratings.**—There are two major differences between the pitting resistance and the bending strength ratings. Pitting is a function of the Hertzian contact (compressive) stresses between two cylinders and is proportional to the square root of the applied load. Bending strength is measured in terms of the bending (tensile) stress in a cantilever plate and is directly proportional to this same load. The difference in the nature of the stresses induced in the tooth surface areas and at

the tooth root is reflected in a corresponding difference in allowable limits of contact and bending stress numbers for identical materials and load intensities.

Analysis of the load and stress modifying factors is similar in each instance, so many of these factors have identical numerical values. The term "gear failure" is itself subjective and a source of considerable disagreement. One observer's "failure" may be another observer's "wearing in." A more complete discussion of "failure" is given in AGMA 110.04, Nomenclature of Gear Tooth Failure Modes.

**Pitting Resistance:** In most industrial practice, corrective and nonprogressive initial pitting is not deemed serious. Initial pitting is characterized by small pits that do not extend over the entire face width or profile height of the affected teeth. The definition of acceptable pitting varies widely with gear application. Initial pitting occurs in localized, overstressed areas and tends to redistribute the load by progressively removing high contact spots. Generally, when the load has been reduced or redistributed, the pitting stops.

The pitting resistance formula aims to determine a load rating at which destructive pitting of the teeth does not occur during their design life. The ratings for pitting resistance are based on the formulas developed by Hertz for contact pressure between two curved surfaces, modified for the effect of load sharing between adjacent teeth.

**Bending Strength:** The bending strength of gear teeth is a fatigue phenomenon related to the resistance to cracking at the tooth root fillet in external gears and at the critical section in internal gears. The basic theory employed in this analysis assumes the gear tooth to be rigidly fixed at its base, thus, the critical stress occurs in the fillet. If the rim supporting the gear tooth is thin relative to the size of the tooth and the gear pitch diameter, another critical stress may occur not at the fillet but in the root area. The rim thickness factor,  $K_B$ , adjusts the calculated bending stress number for thin rimmed gears.

The strength ratings determined by this Standard are based on plate theory that is modified to consider:

- 1) the compressive stress at tooth roots caused by the radial component of tooth loading;
- 2) nonuniform moment distribution resulting from the inclined angle of the load lines on the teeth; 3) stress concentrations at the tooth root fillets; and 4) the load sharing between adjacent teeth in contact.

The intent of the AGMA strength rating formula is to determine the load that can be transmitted for the design life of the gear drive without causing cracking or failure. Occasionally, wear, surface fatigue, or plastic flow may limit bending strength due to stress concentrations around large, sharp cornered pits or wear steps on the tooth surface.

**Fundamental Rating Formulas.**—The symbols and definitions used in the pitting resistance and bending strength formulas are shown in [Table 1](#). SI units are shown in parentheses in [Table 1](#) and in the text. Where equations require a different format or constant for use with SI units, a second expression is shown after the first and with  $M$  included in the equation number at the right.

**Pitting Resistance.**—The fundamental formula for pitting resistance of gear teeth is

$$S_c = C_p \sqrt{\frac{W_t \times C_a \cdot C_s \cdot C_m \times C_f}{C_v \cdot dF \cdot I}} \quad (1)$$

where the meaning of the symbols is as shown in [Table 1](#) and,

$$d = \frac{2C}{m_G + 1.0} \quad \text{for external gears} \quad (2)$$

$$d = \frac{2C}{m_G - 1.0} \quad \text{for internal gears} \quad (3)$$

**Table 1. Symbols Used in Gear Rating Equations**

| Symbol   | Description of Symbols and Units   | Symbol   | Description of Symbols and Units                                 |
|----------|--|----------|--|
| $C$      | Operating center distance, in. (mm)  | $K_R$    | Reliability factor for bending strength                          |
| $C_a$    | Application factor for pitting resistance                                      | $K_s$    | Size factor for bending strength                                 |
| $C_c$    | Curvature factor at pitchline  | $K_{SF}$ | Service factor for bending strength                              |
| $C_e$    | Mesh alignment correction factor   | $K_T$    | Temperature factor for bending strength                          |
| $C_f$    | Surface condition factor for pitting resistance                                | $K_v$    | Dynamic factor for bending strength                              |
| $C_G$    | Gear ratio factor  | $K_y$    | Yield strength factor  |
| $C_H$    | Hardness ratio factor for pitting resistance                                   | $m$      | Metric module, nominal in plane of rotation (mm)                 |
| $C_L$    | Life factor for pitting resistance   | $m_B$    | Back up ratio  |
| $C_m$    | Load distribution factor for pitting resistance                                | $m_G$    | Gear ratio (never less than 1.0)                                 |
| $C_{ma}$ | Mesh alignment factor  | $m_N$    | Load sharing ratio   |
| $C_{mc}$ | Lead correction factor   | $m_n$    | Normal metric module, nominal (mm)                               |
| $C_{mf}$ | Face load distribution factor  | $N$      | Number of load cycles  |
| $C_{mt}$ | Transverse load distribution factor  | $N_G$    | Number of teeth in gear  |
| $C_p$    | Elastic coefficient [lb/in. <sup>2</sup> ] <sup>0.5</sup> (MPa) <sup>0.5</sup> | $N_p$    | Number of teeth in pinion  |
| $C_{pf}$ | Pinion proportion factor   | $n_p$    | Pinion speed rpm   |
| $C_{pm}$ | Pinion proportion modifier   | $P$      | Transmitted power, hp (kW)                                       |
| $C_R$    | Reliability factor for pitting resistance                                      | $P_{ac}$ | Allowable transmitted power for pitting resistance, hp (kW)      |
| $C_s$    | Size factor for pitting resistance   | $P_{at}$ | Allowable transmitted power for bending strength, hp (kW)        |
| $C_{SF}$ | Service factor for pitting resistance  | $P_d$    | Diametral pitch, nominal, in plane of rotation, in <sup>-1</sup> |
| $C_T$    | Temperature factor for pitting resistance                                      | $P_{nd}$ | Normal diametral pitch, nominal, in <sup>-1</sup>                |
| $C_v$    | Dynamic factor for pitting resistance  | $P_b$    | Transverse base pitch, in. (mm)                                  |
| $C_x$    | Contact height factor  | $P_x$    | Axial pitch, in. (mm)  |
| $C_\psi$ | Helical overlap factor   | $Q_v$    | Transmission accuracy level number                               |
| $d$      | Operating pitch diameter of pinion, in. (mm)                                   | $S$      | Bearing span, in. (mm)   |
| $E_G$    | Modulus of elasticity for gear, lb/in. <sup>2</sup> (MPa)                      | $S_l$    | Pinion offset, in. (mm)  |
| $E_p$    | Modulus of elasticity for pinion, lb/in. <sup>2</sup> (MPa)                    | $S_{ac}$ | Allowable contact stress number, lb/in. <sup>2</sup> (MPa)       |
| $e_t$    | Total lead mismatch, in. (mm)  | $S_{at}$ | Allowable bending stress number, lb/in. <sup>2</sup> (MPa)       |

**Table 1. (Continued) Symbols Used in Gear Rating Equations**

| Symbol       | Description of Symbols and Units                                      | Symbol       | Description of Symbols and Units                                      |
|--------------|---|--------------|---|
| $f_p$        | Pinion surface finish, microinches rms                                | $S_{ay}$     | Allowable yield stress number, lb/in. <sup>2</sup> (MPa)              |
| $F$          | Net face width of narrowest member, in. (mm)                          | $S_c$        | Contact stress number, lb/in. <sup>2</sup> (MPa)                      |
| $G$          | Tooth stiffness constant, lb/in. <sup>2</sup> (MPa)                   | $S_t$        | Bending stress number, lb/in. <sup>2</sup> (MPa)                      |
| $H_{BG}$     | Brinell hardness of gear  | $T$          | Transmitted pinion torque, lb-in. (N-m)                               |
| $H_{BP}$     | Brinell hardness of pinion  | $t_R$        | Gear rim thickness, in. (mm)  |
| $h_c$        | Minimum total case depth for nitrided gears, in. (mm)                 | $t_o$        | Normal tooth thickness at top land of gear, in. (mm)                  |
| $h_e$        | Minimum effective case depth for carburized gears, in. (mm)           | $U_{at}$     | Allowable unit load for bending strength, lb/in. <sup>2</sup> (MPa)   |
| $h_{e\ max}$ | Maximum effective case depth, in. (mm)                                | $U_c$        | Core hardness coefficient   |
| $h_t$        | Gear tooth whole depth, in. (mm)                                      | $U_H$        | Hardening process factor  |
| $I$          | Geometry factor for pitting resistance                                | $U_L$        | Unit load for bending strength, lb/in. <sup>2</sup> (MPa)             |
| $J$          | Geometry factor for bending strength                                  | $v_t$        | Pitch line velocity at operating pitch diameter, ft/min (m/s)         |
| $K$          | Contact load factor for pitting resistance, lb/in. <sup>2</sup> (MPa) | $v_{t\ max}$ | Pitch line velocity maximum at operating pitch diameter, ft/min (m/s) |
| $K_a$        | Application factor for bending strength                               | $W_d$        | Incremental dynamic tooth load, lb (N)                                |
| $K_{ac}$     | Allowable contact load factor, lb/in. <sup>2</sup> (MPa)              | $W_{max}$    | Maximum peak tangential load, lb (N)                                  |
| $K_B$        | Rim thickness factor  | $W_t$        | Transmitted tangential load, lb (N)                                   |
| $K_f$        | Stress correction factor  | $Y$          | Tooth form factor   |
| $K_L$        | Life factor for bending strength                                      | $Z$          | Length of action in transverse plane, in. (mm)                        |
| $K_m$        | Load distribution factor for bending strength                         | $\mu_G$      | Poisson's ratio for gear  |
|              |   | $\mu_P$      | Poisson's ratio for pinion  |
|              |   | $\phi_t$     | Operating transverse pressure angle                                   |
|              |   | $\psi_s$     | Helix angle at standard pitch diameter                                |
|              |   | $\psi_b$     | Base helix angle  |

**Allowable Contact Stress Number:** The relation of calculated contact stress number (graphed in Fig. 1) to the allowable contact stress number is

$$S_c \leq S_{ac} \frac{C_L C_H}{C_T C_R} \quad (4)$$

Fig. 1. Allowable Contact Stress Number for Steel Gears,  $S_{ac}$

**Pitting Resistance Power Rating.**—The pitting resistance power rating is given by

$$P_{ac} = \frac{n_p \times F}{12600 C_s \times C_m \times C_f \times C_a} \frac{I \times C_v}{C_p \times C_T \times C_R} \left( \frac{d \times S_{ac} C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \quad (5)$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7 C_s \times C_m \times C_f \times C_a} \frac{I \times C_v}{C_p \times C_T \times C_R} \left( \frac{d \times S_{ac} C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \quad (5a)$$

In using Formula (5) and (5a), the ratings of both pinion and gear must be calculated to evaluate differences in material properties and the number of cycles under load. The pitting resistance power rating is based on the lowest value of the product  $S_{ac} C_L C_H$  for each of the mating gears.

**Contact Load Factor,  $K$ .**—In some industries, pitting resistance is rated in terms of a  $K$  factor:

$$K = \frac{W_t}{dF} \times \frac{1}{C_G} \quad (6)$$

for external gears,  $C_G = \frac{N_G}{N_G + N_P}$  (7)

for internal gears,  $C_G = \frac{N_G}{N_G - N_P}$  (8)

In terms of this Standard, the allowable  $K$  factor is defined as

$$K_{ac} = \frac{I}{C_G C_a \times C_s \times C_m \times C_f} \frac{C_v}{C_p \times C_T \times C_R} \left( \frac{S_{ac} \times C_L \times C_H}{C_p \times C_T \times C_R} \right)^2 \quad (9)$$

The allowable contact load factor,  $K_{ac}$ , is the lowest of the ratings calculated using the different values of  $s_{ac}$ ,  $C_L$ , and  $C_H$  for pinion and gear.

**Bending Strength.**—The fundamental formula for bending stress number in a gear tooth is

$$s_t = \frac{W_t \times K_a P_d K_s \times K_m \times K_B}{K_v F J} \tag{10}$$

where  $P_d = P_{nd}$  for spur gears. For helical gears,  $P_d$  is given by Equation (11),

$$s_t = \frac{W_t \times K_a I K_s \times K_m \times K_B}{K_v F \times m J} \tag{10a}$$

where  $m = m_n$  for spur gears. For helical gears  $m$  is given by Equation (11a):

$$P_d = \frac{\pi}{p_x \tan \psi_s} = P_{nd} \cos \psi_s \tag{11}$$

$$m = \frac{P_x \times \tan \psi_s}{\pi} = \frac{m_n}{\cos \psi_s} \tag{11a}$$

where  $\psi_s$  is given by Equation (12) or (12a)

$$\psi_s = \text{asin} \left( \frac{\pi}{p_x \times P_{nd}} \right) \tag{12}$$

$$\psi_s = \text{asin} \left( \frac{\pi \times m_n}{p_x} \right) \tag{12a}$$

**Allowable Bending Stress Number.**—The relation of calculated bending stress number to allowable bending stress number is

$$S_t \leq \frac{S_{at} \times K_L}{K_T \times K_R} \tag{13}$$

Fig. 2. Allowable Bending Stress Number for Steel Gears  $s_{at}$

**Bending Strength Power Rating.**—The bending strength power rating is

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_a P_d K_s \times K_m \times K_B K_R \times K_T} \frac{F}{J} \frac{s_{at} \times K_L}{K_T} \quad (14)$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_a} \frac{F \times m \times J}{K_s \times K_m \times K_B K_R \times K_T} \frac{s_{at} \times K_L}{K_T} \quad (14a)$$

The ratings of both pinion and gear must be calculated to evaluate differences in geometry factors, number of load cycles, and material properties. The bending strength power rating is based on the lowest value of the term  $s_{at} K_L J / K_B$  for each of the mating gears.

In some industries, the bending strength is rated in terms of unit load:

$$U_L = \frac{(W_t \times P_{nd})}{F} \quad (15)$$

$$U_L = \frac{W_t}{(F \times m)} \quad (15a)$$

The allowable unit load,  $U_{at}$ , is the lowest of the ratings calculated using the different values of  $s_{at}$ ,  $K_B$ ,  $K_L$ , and  $J$  for pinion and gear in Equation (16):

$$U_{at} = \frac{J}{\cos \psi K_a \times K_m \times K_s \times K_B K_R \times K_T} \frac{K_v}{s_{at} \times K_L} \quad (16)$$

**Values for Factors Applied in Fundamental Equations.**—Values for the various factors used in the pitting resistance and bending strength rating equations are discussed and explained in greater detail in the Standard and its appendices than can be provided here. The following paragraphs are intended by the Editors to provide values for some of these factors suitable for making approximations to the ratings of pairs of mating gears without the refinements used by experienced gear designers.

**Rim Thickness Factor  $K_B$ .**—The rim thickness factor,  $K_B$ , is used to adjust the calculated bending stress number for thin rimmed gears, the value of the factor depending upon the backup ratio,

$$m_B = \frac{t_R}{h_t} \quad (17)$$

If  $m_B$  is equal to or greater than 1.2, then  $K_B$  may be taken as 1.0. For values of  $m_B$  less than 1.2, see the information in Appendix C following the Standard.

**Geometry Factors  $I$  and  $J$ .**—The geometry factors  $I$  and  $J$  for pitting resistance and bending strength, respectively, are described, along with selected typical values, beginning on page 1853.

**Transmitted Tangential Load,  $W_t$ .**—In most gear applications the torque is not constant, so the transmitted tangential load will vary. To obtain values of the operating transmitted tangential load,  $W_t$ , the values of power and speed at which the driven device will operate should be used. If the rating is calculated on the basis of uniform load, then the transmitted tangential load is

$$W_t = \frac{33000 \times P}{v_t} = \frac{2 \times T}{d} = \frac{126000 \times P}{n_p \times d} \quad (18)$$

$$W_t = \frac{1000 \times P}{v_t} = \frac{2000 \times T}{d} = \frac{1.91 \times 10^7 \times P}{n_p \times d} \quad (18a)$$

where,

$$v_t = \frac{(\pi \times n_p \times d)}{12} \quad (19)$$

$$v_t = \frac{(\pi \times n_p \times d)}{60000} \quad (19a)$$

**Nonuniform Load:** When the transmitted load is not uniform, consideration should be given not only to the peak load and its anticipated number of cycles, but also to intermediate loads and their duration. This type of load is often considered a duty cycle and may be represented by a load spectrum. The cumulative fatigue effect of the duty cycle is then considered in rating the gearset. A method of calculating the effects of the loads under such conditions is given in Appendix B of the Standard.

**Dynamic Factors,  $C_v$  and  $K_d$ .**—Dynamic factors account for internally generated gear tooth loads, which are induced by nonconjugate meshing action of the gear teeth. Even if the input torque and speed are constant, significant vibration of the gear masses, and therefore dynamic tooth forces, can exist. These forces result from the relative displacements between the gears as they vibrate in response to an excitation known as “transmission error.” Ideally, a gearset would have a uniform velocity ratio between the input and output rotation. Transmission error is defined as the departure from uniform relative angular motion of the pair of meshing gears. It is influenced by all the deviations from the ideal gear tooth form.

The dynamic factor relates the total tooth load, including internal dynamic effects, to the transmitted tangential tooth load:

$$C_v = K_v = \frac{W_t}{W_d \times W_t} \quad (20)$$

where  $W_d$  = incremental dynamic tooth load due to the dynamic response of the gear pair to the transmission error excitation, excluding the transmitted tangential load  $W_t$ .

**Excitation:** The transmission error contributing to the dynamic factors is influenced by:

- 1) Manufacturing variations such as spacing, profile, lead, and runout.
- 2) Gear mesh stiffness variation as the gear teeth pass through the meshing cycle. This source of excitation is especially pronounced in spur gears without profile modification. Spur gears with properly designed profile modification, and helical gears with axial contact ratios greater than 1.0, have a smaller stiffness variation.
- 3) Transmitted load. Since elastic deflections are load dependent, gear tooth profile modifications can be designed to give a uniform velocity ratio at only one load magnitude.
- 4) Pitchline velocity. The frequencies of the excitation depend on the pitchline velocity.
- 5) Dynamic imbalance of the gears and shafts.
- 6) Excessive wear and plastic deformation of the gear tooth profiles increase the amount of transmission error.
- 7) Shaft alignment. Gear tooth alignment is influenced by load and thermal distortions of the gears, shafts, bearings, and housings, and by manufacturing variations.
- 8) Tooth friction induced excitation.

**Dynamic Response:** The dynamic tooth forces are influenced by:

- 1) Mass of the gears, shafts, and other major internal components.
- 2) Stiffness of the gear teeth, gear blanks, shafts, bearings, and gear housings.
- 3) Damping. The principal source of coulomb or viscous damping is the shaft bearings. Generally, oil film bearings provide greater damping than rolling element bearings. Other sources of damping include the hysteresis of the gear shafts, and viscous damping at sliding interfaces and shaft couplings.

*Resonance:* When an excitation frequency coincides with a natural frequency, the resonant response is limited only by the damping, and high dynamic loads may result. The dynamic factors  $C_v$  and  $K_d$  do not apply to resonance.

*Gear Pair Resonance:* If a particular frequency of the transmission error excitation is close to the natural frequency of the gear masses, or some multiple of the natural frequency such as  $\frac{1}{2}$  or 2, a resonant vibration may cause high dynamic tooth forces due to large relative displacements of the gear masses. The dynamic factors  $C_v$  and  $K_d$  do not account for gear pair resonance and operation in this regime is to be avoided.

*Gear Blank Resonance:* Gear blanks may have natural frequencies within the operating speed range. If the gear blank is excited by a frequency that is close to one of its natural frequencies, the resonant deflections may cause high dynamic tooth loads. This phenomenon occurs more frequently in high speed, light weight gear blanks, but can also occur in other thin rimmed or thinwebbed blanks. The dynamic factors  $C_v$  and  $K_d$  do not account for gear blank resonance. A separate investigation is recommended when these conditions arise.

*System Resonance:* The gearbox is one component of a system comprised of a power source, gearbox, driven equipment, and interconnecting shafts and couplings. The dynamic response of this system depends on the distribution of the masses, stiffness, and damping. In certain designs, a system may possess a torsional natural frequency close to an excitation frequency associated with an operating speed. Under these resonant conditions the dynamic tooth loads may be high, and operation near such a system resonance is to be avoided. The dynamic factors  $C_v$  and  $K_d$  do not include considerations of the dynamic loads due to torsional vibration of the gear system. These loads must be included with other externally applied forces in the application factors  $C_a$  and  $K_a$ . For critical drives, a separate dynamic analysis of the entire system is recommended.

*Shaft Critical Speeds:* Owing to their high bending stiffness, the natural frequency of lateral vibrations of the gear shafts are usually much higher than the operating speeds. However, for high speed gears it is recommended that the critical speeds be analyzed to ensure that they are well removed from the operating speed range. The dynamic factors  $C_v$  and  $K_d$  do not account for the dynamic tooth loads due to this mode of vibration.

*Nonlinear Resonance:* Large cyclical variation in gear mesh stiffness and impact loads may lead to additional regions of resonance and instability. This problem appears primarily with lightly loaded, lightly damped spur gears that do not have profile modifications.

*Approximate Dynamic Factors:* Fig. 3 shows dynamic factors that can be used in the absence of specific knowledge of the dynamic loads. The curves of Fig. 3 are based on equations in the Standard derived from empirical data and do not account for resonance.

Choice of which of curves 5 through 11 of Fig. 3 to use should be based on transmission error. When transmission error data are unavailable, it is reasonable to use pitch (spacing) and profile accuracy.  $Q_v$  is the transmission accuracy level number. It can be the same as the quality number for the lowest quality member in the mesh from AGMA 2000–A88 when manufacturing techniques ensure equivalent transmission accuracy, or when the pitch (spacing) and profile accuracy are the same as AGMA 2000–A88 tolerances.

Owing to the approximate nature of the empirical curves and the lack of measured tolerance values at the design stage, the dynamic factor curve should be selected based on experience with the manufacturing methods and operating considerations of the design.

The curves in Fig. 3 are referenced only by spacing and profile, and actual dynamic load is influenced by many other factors, so slight variations from the selected tolerances are not considered significant to the gearset rating.

Fig. 3. Dynamic Factors,  $C_v$  and  $K_d$ 

**Very Accurate Gearing:** Where gearing is manufactured using process controls that correspond to  $Q_v \geq 12$  limits, or where the design and manufacturing techniques ensure a low transmission error equivalent to this accuracy, values of  $C_v$  and  $K_d$  between 0.90 and 0.98 may be used, depending on the specifier's experience with similar applications and the degree of accuracy actually achieved. To use these values, the gearing must be maintained in accurate alignment and adequately lubricated so that its accuracy is maintained under the operating conditions. Spur gears should have properly designed profile modification and helical gears should have an axial contact ratio greater than 1.0.

**Curves Numbered 6 through 11 on Fig. 3:** These curves are generated by equations in the Standard for values of  $Q_v$ , such that  $6 \leq Q_v \leq 11$ .

**Unity Dynamic Factor:** When the known dynamic loads (from analysis or experience) are added to the nominal transmitted load, then the dynamic factor can be taken to be 1.0.

**Application Factors,  $C_a$  and  $K_a$ .**—These application factors make allowance for any externally applied loads in excess of the nominal tangential load  $W_t$ . Application factors can only be established after considerable field experience is gained in a particular application.

In determining the application factor, consideration should be given to the fact that many prime movers develop momentary peak torques appreciably greater than those determined by the nominal ratings of either the prime mover or the driven equipment. Many possible sources of overload should be considered. Some of these are system vibrations, acceleration torques, overspeeds, variations in system operation, split path load sharing among multiple prime movers, and changes in process load conditions. When operating near a critical speed of the drive system, a careful analysis of conditions must be made.

**Service Factors,  $C_{SF}$  and  $K_{SF}$ .**—These service factors have been used to include the combined effects of  $C_L$ ,  $C_R$ ,  $C_a$  and  $K_L$ ,  $K_R$ ,  $K_a$ , respectively, in an empirically determined single factor. The mathematical contribution of each of these factors has not been established, so that, in the absence of more specific load data, a service factor may be used. When a ser-

vice factor is used, the power rating formulas [Equation (5) and (5a)] would be modified as follows:

$$P_{ac} = \frac{n_p \times F}{126000 C_{sf} \times C_s \times C_m \times C_f} \frac{I \times C_v}{C_p} \left( \frac{d \times s_{ac} C_H}{C_T} \right) \quad (21)$$

$$P_{ac} = \frac{n_p \times F}{1.91 \times 10^7 C_{sf} \times C_s \times C_m \times C_f} \frac{I \times C_v}{C_p} \left( \frac{d \times s_{ac} C_H}{C_T} \right) \quad (21a)$$

$$P_{at} = \frac{n_p \times d \times K_v}{126000 \times K_{SF} P_d K_s \times K_m \times K_B K_T} \frac{F}{J} \frac{s_{at}}{K_T} \quad (22)$$

$$P_{at} = \frac{n_p \times d \times K_v}{1.91 \times 10^7 \times K_{SF} K_s \times K_m \times K_B K_T} \frac{F \times m \times J}{s_{at}} \quad (22a)$$

where  $C_{SF}$  and  $K_{SF}$  are service factors for pitting resistance and bending strength, respectively.

Teeth of both the pinion and the gear must be checked to account for differences in material properties, geometry factors, and the number of cycles under load. The power rating is then based on the lowest values of the following expressions for each of the mating gears:

$$\text{for pitting resistance } \frac{(s_{ac} \times C_H)^2}{C_{SF}}, \text{ and for bending strength } \frac{s_{at} \times J}{K_{SF}}.$$

**Elastic Coefficient,  $C_p$ .**—The elastic coefficient,  $C_p$ , is defined by the equation

$$C_p = \sqrt{\frac{1.0}{\pi \left[ \left( \frac{1.0 - \mu_P^2}{E_P} \right) \div \left( \frac{1.0 - \mu_G^2}{E_G} \right) \right]}} \quad (23)$$

The value of  $C_p$  for a steel gear meshing with a steel pinion is 2300 [lb/in.<sup>2</sup>]<sup>0.5</sup>, or 191 (MPa)<sup>0.5</sup>, approximately. Approximate values for other combinations of materials are given in the Standard.

**Surface Condition Factor,  $C_f$ .**—The surface finish factor used only in the pitting resistance formulas has not yet been established for conditions where there is a detrimental surface finish effect. Where such effects are encountered, a surface condition factor greater than unity should be used.

**Size Factors,  $C_s$  and  $K_s$ .**—The size factor reflects nonuniformity of material properties and depends primarily on tooth size, diameter of parts, ratio of tooth size to diameter of part, face width, area of stress pattern, ratio of case depth to tooth size, and hardenability and heat treatment of materials. Size factors have not yet been established for conditions where there is a detrimental size effect, but the factor may be taken as unity for most gears provided that a proper choice of steel is made for the size of the part and its heat treatment and hardening processes.

**Load Distribution Factors,  $C_m$  and  $K_m$ .**—The load distribution factor modifies the rating equations to reflect the nonuniform distribution of the load along the lines of contact. The amount of nonuniformity of the load distribution is caused by, and is dependent on the following influences:

- 1) The gear tooth manufacturing accuracy: lead, profile, and spacing;
- 2) alignment of the axes of rotation of the pitch cylinders of the mating gear elements;

## 3000 POWER TRANSMITTING CAPACITY OF SPUR GEARS

- 3) elastic deflections of gear unit elements: shafts, bearings, housings, and foundations that support the gear elements;
- 4) bearing clearances;
- 5) Hertzian contact and bending deformations at the tooth surface;
- 6) thermal expansion and distortion due to operating temperature (especially on wide face gearing);
- 7) centrifugal deflections due to operating speed;
- 8) tooth crowning and end relief.

Any of these influences that affect a given application should be evaluated by appropriate analysis when possible.

*Values for  $C_m$  and  $K_m$ :* The load distribution factor is defined to be the peak load intensity divided by the average, or uniformly distributed load intensity; i.e., the ratio of peak to mean loading. The magnitude is influenced by two components, namely,  $C_{mf}$  = face load distribution factor and  $C_{mt}$  = transverse load distribution factor that accounts for nonuniform load sharing among load sharing teeth. The load distribution factor is affected primarily by the correctness of the profiles of mating teeth, i.e., profile modification and profile error. The value of the factor may be taken as 1.0 because the Standard has not yet established procedures to evaluate its influence. If  $C_{mt}$  is taken as 1.0, then  $C_m = K_m = C_{mf}$ .

The face load distribution factor  $C_{mf}$  accounts for the nonuniform distribution of load across the gearing face width. The magnitude of  $C_{mf}$  is defined as the peak load intensity divided by the average load intensity across the face width. Two methods of determining  $C_{mf}$  are given in the Standard, an empirical method and an analytical method. These two methods sometimes yield significantly different results.

*Empirical Method:* The empirical method requires a minimum amount of information and is recommended for relatively stiff designs that meet the following requirements:

- 1) Ratio of net face width to pinion pitch diameter is less than or equal to 2.0;
- 2) the gear elements are mounted between bearings (not overhung);
- 3) face width up to 40 in.; and
- 4) contact across full face width of narrowest member when loaded.

Other restrictions apply to the use of this method. For details of these restrictions and how the method is applied, the Standard should be consulted.

*Analytical Method:* This method is based on theoretical calculation of values of elastic tooth deformation under load and lead mismatch. Knowledge of the design, manufacturing, and mounting are required to evaluate the load distribution factor. Calculated results should be compared with past experience as it may be necessary to reevaluate other rating factors to arrive at a rating consistent with past experience. As explained in the Standard, the analytical method assumes that mismatch between the teeth is a straight line. This approach usually yields load distribution factors larger than those used in the past. Another method, using true deflection between the teeth (which is not straight line deflection), has resulted in calculated values closer to those used in the past, but it has not been demonstrated that either method is more accurate. Further study may produce other, more accurate, methods.

In using the analytical method, if high values of the gear tooth stiffness constant are used ( $G = 2,000,000$ ) or high values of total lead mismatch  $e_t$  are assumed, the  $C_{mf}$  values calculated will be much more conservative than those obtained by the empirical method. If  $C_{mf}$  values calculated are in excess of 2.0, indicating less than full face contact, it may be desirable to revise the design by improving the configuration of bearings, shaft diameters, aspect ratio, and center distance to lower  $C_{mf}$ . It may be possible to lower  $C_{mf}$  by modifying leads of the parts. The assumed values of  $e_t$  and  $G$  have a large effect on  $C_{mf}$ , so there are times when experimental verification of  $C_{mf}$  may be necessary.

The analytical method is valid for any gear design and is recommended for the following conditions:

1) ratio of net face width to pinion pitch diameter,  $F/D$ , is equal or greater than 2.0 (for double helical gears the gap is not included in the face width); 2) applications with overhanging gear elements; 3) applications with long shafts subject to large deflections or where deflections under load reduce width of contact; and 4) applications where contact does not extend across the full face of narrowest member when loaded.

For designs that have high crowns to centralize tooth contact under deflected conditions, the factors  $C_m$  and  $K_m$  may be conservatively approximated by this method. For the most commonly encountered condition, contact across the entire face width under normal operating load, the face load distribution factor expressions are

$$\text{for spur gearing: } C_{mf} = 1.0 + \frac{G \times e_t \times F}{2 \times W_t} \quad (24)$$

$$\text{and, for helical gearing: } C_{mf} = 1.0 + \frac{G \times e_t \times Z \times F}{1.8 \times W_t} \quad (25)$$

If the total contact length under normal operating load is less than the face width, the expressions for the load distribution factor are

$$\text{for spur gearing: } C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times F}{W_t}} \quad (26)$$

$$\text{and, for helical gearing: } C_{mf} = \sqrt{\frac{2.0 \times G \times e_t \times Z \times F}{W_t \times P_b}} \quad (27)$$

where  $G$  = tooth stiffness constant, lb/in./in. of face (MPa), the average mesh stiffness of a single pair of teeth in the normal direction. The usual range of this value that is compatible with this analysis is  $1.5\text{--}2.0 \times 10^6$  lb/in.<sup>2</sup> ( $1.0\text{--}1.4 \times 10^4$  MPa). The most conservative value is the highest.  $e_t$  = total lead mismatch between mating teeth, in loaded condition, in. (mm).  $Z$  = length of action in transverse plane, from Equation (17) on page 2995, in. (mm).  $P_b$  = transverse base pitch, in. (mm).

The total mismatch,  $e_p$ , is a virtual separation between the tooth profiles at the end of the face width which is composed of the static, no load separation plus a component due to the elastic load deformations. This total mismatch is influenced by all the items listed under Load Distribution Factors except the Hertzian contact stress and bending deformations of the gear teeth, which are accounted for by the tooth stiffness constant  $G$ . Evaluation of  $e_p$  is difficult but it is critical to the reliability of the analytical method. An iterative computer program may be used, but in critical applications full scale testing may be desirable.

**Allowable Stress Numbers,  $S_{ac}$  and  $S_{at}$ .**—The allowable stress numbers depend on

1) material composition and cleanliness; 2) mechanical properties; 3) residual stress; 4) hardness and; and 5) type of heat treatment, surface or through hardened.

An allowable stress number for unity application factor, 10 million cycles of load application, 99 per cent reliability and unidirectional loading, is determined or estimated from laboratory and field experience for each material and condition of that material. This stress number is designated  $S_{ac}$  and  $S_{at}$ . The allowable stress numbers are adjusted for design life cycles by the use of life factors.

The allowable stress numbers for gear materials vary with material composition, cleanliness, quality, heat treatment, and processing practices. For materials other than steel, a range is shown, and the lower values should be used for general design purposes. Data for materials other than steel are given in the Standard.

Allowable stress numbers for steel gears are established by specific quality control requirements for each material type and grade. All requirements for the quality grade must be met in order to use the stress values for that grade. Details of these quality requirements are given in the Standard.

*Reverse Loading:* For idler gears and other gears where the teeth are completely reverse loaded on every cycle, 70 per cent of the  $S_{at}$  values should be used.

Fig. 4. Effective Case Depth for Carburized Gears,  $h_e$

**Case Depth of Surface-Hardened Gears.**—The Standard provides formulas to guide the selection of minimum effective case depth at the pitchline for carburized and induction hardened teeth based on the maximum shear from contact loading.

Fig. 5. Minimum Total Case Depth for Nitrided Gears,  $h_c$

Fig. 5 shows values that have a long history of successful use for carburized gears and can be used for such gears.

For nitrided gears, case depth is specified as the total case depth  $h_c$ , which is defined as the depth below the surface at which the hardness has dropped to 10 per cent of the core hardness. Minimum total case depths for nitrided gears are shown in Fig. 5.

**Momentary Overloads.**—When the gear is subjected to less than 100 cycles of momentary overloads, the maximum allowable stress is determined by the allowable yield properties rather than the bending fatigue strength of the material. Fig. 6 shows suggested values of the allowable yield strength  $S_{ay}$  for through hardened steel. For case hardened gears, the core hardness should be used in conjunction with the table of metallurgical factors affecting the bending stress number for carburized gears shown in the Standard.

Fig. 6. Allowable Yield Strength Number for Steel Gears,  $S_{ay}$

The design should be checked to make sure that the teeth are not permanently deformed. Also, when yield is the governing stress, the stress correction factor  $K_f$  is considered ineffective and therefore taken as unity.

**Yield Strength.**—For through hardened gears up to 400 BHN, a yield strength factor  $K_y$  can be applied to the allowable yield strength taken from Fig. 6. This factor is applied at the maximum peak load to which the gear is subjected:

$$S_{ay} \times K_y \geq \frac{W_{max} \times K_a P_d K_s \times K_m}{K_v F J \times K_f} \quad (28)$$

$$S_{ay} \times K_y \geq \frac{W_{max} \times K_a \times K_s \times K_m}{K_v \times F \times m \times J \times K_f} \quad (28a)$$

For conservative practice,  $K_y$  is taken as 0.5 and for industrial practice,  $K_y$  is 0.75.

**Hardness Ratio Factor  $C_H$ .**—The hardness ratio factor depends on (1) gear ratio and (2) Brinell hardness numbers of gear and pinion. When the pinion is substantially harder than the gear, the work hardening effect increases the gear capacity. Typical values of the hard-

ness ratio factor,  $C_H$ , for through hardened gears are shown in Fig. 7. These values apply to the gear only, not to the pinion.

When surface hardened pinions (48 HRC or harder) are run with through hardened gears (180–400 BHN), a work hardening effect is achieved. The  $C_H$  factor varies with the surface finish of the pinion,  $K_p$ , and the mating gear hardness as shown in Fig. 8.

Fig. 7. Hardness Ratio Factor,  $C_H$  (Through Hardened)

**Life Factors  $C_L$  and  $K_L$ .**— These life factors adjust the allowable stress numbers for the required number of cycles of operation. In the Standard, the number of cycles,  $N$ , is defined as the number of mesh contacts under load of the gear tooth being analyzed. Allowable stress numbers are established for 10,000,000 tooth load cycles at 99 per cent reliability. The life cycle factors adjust the allowable stress numbers for design lives other than 10,000,000 cycles.

The life factor accounts for the  $S/N$  characteristics of the gear material as well as for the gradually increased tooth stress that may occur from tooth wear, resulting in increased dynamic effects and from shifting load distributions that may occur during the design life of the gearing. A  $C_L$  or  $K_L$  value of 1.0 may be used beyond 10,000,000 cycles, where justified by experience.

*Life Factors for Steel Gears:* Insufficient data exist to provide accurate life curves for every gear and gear application. However, experience suggests life curves for pitting and strength of steel gears are as shown in Figs. 9 and 10. These figures do not include data for nitrided gears. The upper portions of the shaded zones are for general commercial applications. The lower portions of the shaded zones are typically used for critical service applications where little pitting and tooth wear are permissible and where smoothness of operation and low vibration levels are required. When gear service ratings are established by the use

Fig. 8. Hardness Ratio Factor,  $C_H$  (Surface Hardened Pinions)

of service factors, life factors  $C_L$  and  $K_L$  should be set equal to 1.0 for the determination of the gear tooth rating.

**Localized Yielding.**—If the product of  $S_{at} K_L$  exceeds the allowable yield stress  $S_{ay}$  of Fig. 6, localized yielding of the teeth may occur. In some applications this yielding is not acceptable. In others, where profile and motion transmission accuracies are not critical, the yielding may be acceptable for limited life.

**Reliability Factors,  $C_R$  and  $K_R$ .**—These reliability factors account for the effect of the normal statistical distribution of failures found in materials testing. The allowable stress numbers given in the tables in the Standard are based on a statistical probability of 1 failure in 100 at 10,000,000 cycles. Table 2 contains reliability factors which may be used to modify these allowable stresses to change that probability. These numbers are based on data developed for bending and pitting failure by the U.S. Navy. Other values may be used if specific data are available.

When strength rating is based on yield strength,  $S_{ay}$  the values of  $K_y$  given in the paragraph, Yield Strength, should be used instead of  $K_R$ .

**Temperature Factors  $C_T$  and  $K_T$ .**—The temperature factor is generally taken as 1 when gears operate with temperatures of oil or gear blank not over 250°F (120°C). At temperatures above 250°F, the factors are given a value greater than 1.0 to allow for the effect of temperature on oil film and material properties. Consideration must be given to the loss of hardness and strength of some materials due to the tempering effect of temperatures over 350°F (175°C).

Fig. 9. Pitting Resistance Life Factor,  $C_L$

Fig. 10. Bending Strength Life Factor,  $K_L$

Table 2. Reliability Factors,  $C_R$  and  $K_R$

| Requirement of Application     | $C_R, K_R^a$ | Requirement of Application  | $C_R, K_R$        |
|--------------------------------|--------------|-----------------------------|-------------------|
| Fewer than 1 failure in 10,000 | 1.50         | Fewer than 1 failure in 100 | 1.00              |
| Fewer than 1 failure in 1,000  | 1.25         | Fewer than 1 failure in 10  | 0.85 <sup>b</sup> |

<sup>a</sup>Tooth breakage is sometimes considered a greater hazard than pitting. In such instances a value of  $K_R$  greater than  $C_R$  is selected.

<sup>b</sup>At this value plastic flow might occur rather than pitting.

### Worm Gearing

**Worm Gearing Classification.**—Worm gearing may be divided into two general classes, fine-pitch worm gearing, and coarse-pitch worm gearing. Fine-pitch worm gearing is segregated from coarse-pitch worm gearing for the following reasons:

- 1) Fine-pitch worms and wormgears are used largely to transmit motion rather than power. Tooth strength except at the coarser end of the fine-pitch range is seldom an important factor; durability and accuracy, as they affect the transmission of uniform angular motion, are of greater importance.
- 2) Housing constructions and lubricating methods are, in general, quite different for fine-pitch worm gearing.
- 3) Because fine-pitch worms and wormgears are so small, profile deviations and tooth bearings cannot be measured with the same accuracy as can those of coarse pitches.
- 4) Equipment generally available for cutting fine-pitch wormgears has restrictions which limit the diameter, the lead range, the degree of accuracy attainable, and the kind of tooth bearing obtainable.
- 5) Special consideration must be given to top lands in fine-pitch hardened worms and wormgear-cutting tools.
- 6) Interchangeability and high production are important factors in fine-pitch worm gearing; individual matching of the worm to the gear, as often practiced with coarse-pitch precision worms, is impractical in the case of fine-pitch worm drives.

**American Standard Design for Fine-pitch Worm Gearing (ANSI B6.9-1977).**—This standard is intended as a design procedure for fine-pitch worms and wormgears having axes at right angles. It covers cylindrical worms with helical threads, and wormgears hobbled for fully conjugate tooth surfaces. It does not cover helical gears used as wormgears.

*Hobs:* The hob for producing the gear is a duplicate of the mating worm with regard to tooth profile, number of threads, and lead. The hob differs from the worm principally in that the outside diameter of the hob is larger to allow for resharpening and to provide bottom clearance in the wormgear.

*Pitches:* Eight standard axial pitches have been established to provide adequate coverage of the pitch range normally required: 0.030, 0.040, 0.050, 0.065, 0.080, 0.100, 0.130, and 0.160 inch.

Axial pitch is used as a basis for this design standard because: 1) Axial pitch establishes lead which is a basic dimension in the production and inspection of worms; 2) the axial pitch of the worm is equal to the circular pitch of the gear in the central plane; and 3) only one set of change gears or one master lead cam is required for a given lead, regardless of lead angle, on commonly-used worm-producing equipment.

*Lead Angles:* Fifteen standard lead angles have been established to provide adequate coverage: 0.5, 1, 1.5, 2, 3, 4, 5, 7, 9, 11, 14, 17, 21, 25, and 30 degrees.

This series of lead angles has been standardized to: 1) Minimize tooling; 2) permit obtaining geometric similarity between worms of different axial pitch by keeping the same lead angle; and 3) take into account the production distribution found in fine-pitch worm gearing applications.

For example, most fine-pitch worms have either one or two threads. This requires smaller increments at the low end of the lead angle series. For the less frequently used thread numbers, proportionately greater increments at the high end of the lead angle series are sufficient.

| Outside Diameter   | $d_o = d + 2a$                  | Face Width                                     | $F_{Gmin} = 1.125 \times \sqrt{(d_o + 2c)^2 - (d_o - 4a)^2}$ |
| Safe Minimum Length of Threaded Portion of Worm <sup>b</sup> | $F_W = \sqrt{D_o^2 - D^2}$      |  |  |
| DIMENSIONS FOR BOTH WORM AND WORMGEAR                        |                                 |  |  |
| Addendum   | $a = 0.3183P_n$                 | Tooth thickness                                | $t_n = 0.5P_n$   |
| Whole Depth  | $h_t = 0.7003P_n + 0.002$       | Approximate normal pressure angle <sup>c</sup> | $\phi_n = 20$ degrees  |
| Working Depth  | $h_k = 0.6366P_n$               |  |  |
| Clearance  | $c = h_t - h_k$                 | Center distance                                | $C = 0.5(d + D)$   |

<sup>a</sup> Current practice for fine-pitch worm gearing does not require the use of throated blanks. This results in the much simpler blank shown in the diagram which is quite similar to that for a spur or helical gear. The slight loss in contact resulting from the use of non-throated blanks has little effect on the load-carrying capacity of fine-pitch worm gears. It is sometimes desirable to use topping hobs for producing wormgears in which the size relation between the outside and pitch diameters must be closely controlled. In such cases the blank is made slightly larger than  $D_o$  by an amount (usually from 0.010 to 0.020) depending on the pitch. Topped wormgears will appear to have a small throat which is the result of the hobbing operation. For all intents and purposes, the throating is negligible and a blank so made is not to be considered as being a throated blank.

<sup>b</sup> This formula allows a sufficient length for fine-pitch worms.

<sup>c</sup> As stated in the text on page 3008, the actual pressure angle will be slightly greater due to the manufacturing process.

All dimensions in inches unless otherwise indicated.

**Pressure Angle of Worm:** A pressure angle of 20 degrees has been selected as standard for cutters and grinding wheels used to produce worms within the scope of this Standard because it avoids objectionable undercutting regardless of lead angle.

Although the pressure angle of the cutter or grinding wheel used to produce the worm is 20 degrees, the normal pressure angle produced in the worm will actually be slightly greater, and will vary with the worm diameter, lead angle, and diameter of cutter or grinding wheel. A method for calculating the pressure angle change is given under the heading *Effect of Production Method on Worm Profile and Pressure Angle*.

**Pitch Diameter Range of Worms:** The minimum recommended worm pitch diameter is 0.250 inch and the maximum is 2.000 inches. Pitch diameters for all possible combinations of lead and lead angle, together with the number of threads for each lead, are given in [Table 2a](#) and [2b](#).

**Tooth Form of Worm and Wormgear:** The shape of the worm thread in the normal plane is defined as that which is produced by a symmetrical double-conical cutter or grinding wheel having straight elements and an included angle of 40 degrees.

Because worms and wormgears are closely related to their method of manufacture, it is impossible to specify clearly the tooth form of the wormgear without referring to the mating worm. For this reason, worm specifications should include the method of manufacture and the diameter of cutter or grinding wheel used. Similarly, for determining the shape of the generating tool, information about the method of producing the worm threads must be given to the manufacturer if the tools are to be designed correctly.

The worm profile will be a curve that departs from a straight line by varying amounts, depending on the worm diameter, lead angle, and the cutter or grinding wheel diameter. A method for calculating this deviation is given in the Standard. The tooth form of the wormgear is understood to be made fully conjugate to the mating worm thread.

**Proportions of Fine-pitch Worms and Wormgears.**—Hardened worms and cutting tools for wormgears should have adequate top lands. To automatically provide sufficient top lands, regardless of lead angle or axial pitch, the addendum and whole depth proportions of fine-pitch worm gearing are based on the normal circular pitch. Tooth proportions based on normal pitch for all combinations of standard axial pitches and lead angles are given in [Table 3](#). Formulas for the proportions of worms and worm gears are given in [Table 1](#).

**Example 1:** Determine the design of a worm and wormgear for a center distance of approximately 3 inches if the ratio is to be 10 to 1; axial pitch, 0.1600 inch; and lead angle, 30 degrees.

From [Table 2a](#) and [2b](#) it can be determined that there are eight possible worm diameters that will satisfy the given conditions of lead angle and pitch. These worms have from 3 to 10 threads.

To satisfy the 3-inch center distance requirement it is now necessary to determine which of these eight worms, together with its mating wormgear, will come closest to making up this center distance. One way of doing this is as follows:

First use the formula given below to obtain the approximate number of threads necessary. Then from the eight possible worms in [Table 2a](#) and [2b](#), choose the one whose number of threads is nearest this approximate value:

Approximate number of threads needed for required center distance =

$$\frac{2\pi \times \text{required center distance}}{P_x (\cot \lambda + m_G)}$$

Approximate number of threads =

$$\frac{2 \times 3.1416 \times 3}{0.1600 \times (1.7320 + 10)} = 10.04 \text{ threads}$$

Of the eight possible worms in [Table 2a](#) and [2b](#), the one having a number of threads nearest this value is the 10-thread worm with a pitch diameter of 0.8821 inch. Since the ratio of gearing is given as 10,  $N$  may now be computed as follows:  $N = 10 \times 10 = 100$  teeth (from [Table 1](#))

Other worm and wormgear dimensions may now be calculated using the formulas given in [Table](#) or may be taken from the data presented in [Table 2a](#), [2b](#), and [3](#).

$l = 1.600$  inches (from [Table 2b](#))

$$d = 0.8821 \text{ inch (from Table 2b)}$$

$$D = 100 \times 0.1600 + 3.1416 = 5.0930 \text{ inches (from Table 1)}$$

$$C = 0.5(0.8821 + 5.0930) = 2.9876 \text{ inches (from Table 1)}$$

$$P_n = 0.1386 \text{ inch (from Table 3)}$$

$$a = 0.0441 \text{ inch (from Table 3)}$$

$$h_t = 0.0990 \text{ inch (from Table 3)}$$

$$h_k = 0.6366 \times 0.1386 = 0.0882 \text{ inch (from Table 1)}$$

$$c = 0.0990 - 0.0882 = 0.0108 \text{ inch (from Table 1)}$$

$$t_n = 0.5 \times 0.1386 = 0.0693 \text{ inch (from Table 1)}$$

$$d_o = 0.8821 + (2 \times 0.0441) = 0.9703 \text{ inch (from Table 1)}$$

$$D_o = (2 \times 2.9876) - 0.8821 + (2 \times 0.0441) = 5.1813 \text{ (from Table 1)}$$

$$F_G = 1.125 \sqrt{(0.9703 + 2 \times 0.0108)^2 - (0.9703 - 4 \times 0.0441)^2} = 0.6689 \text{ inch}$$

$$F_W = \sqrt{5.1813^2 - 5.0930^2} = 0.9525 \text{ inch}$$

*Example 2:* Determine the design of a worm and wormgear for a center distance of approximately 0.550 inch if the ratio is to be 50 to 1 and the axial pitch is to be 0.050 inch.

Assume that  $n = 1$  (since most fine-pitch worms have either one or two threads). The lead of the worm will then be  $nP_x = 1 \times 0.050 = 0.050$  inch. From Table 2a and 2b it can be determined that there are six possible lead angles and corresponding worm diameters that will satisfy this lead. The approximate lead angle required to meet the conditions of the example can be computed from the following formula:

$$\text{Cotangent of approx. lead angle} = \frac{2\pi \times \text{approximate center distance required}}{\text{assumed number of threads} \times \text{axial pitch}} - m_G$$

Using letter symbols, this formula becomes:

Of the six possible worms in Table 2a and 2b, the one with the 3-degree lead angle is closest to the calculated  $2^\circ 59'$  lead angle. This worm, which has a pitch diameter of 0.3037 inch, is therefore selected.

The remaining worm and wormgear dimensions may now be determined from the data in Table 2a, 2b and 3 and by computation using the formulas given in Table 1.

$$N = 50 \times 1 = 50 \text{ teeth (from Table 1)}$$

$$d = 0.3037 \text{ inch (from Table 2b)}$$

$$D = 50 \times 0.050 \div 3.1416 = 0.7958 \text{ inch (from Table 1)}$$

$$C = 0.5(0.3037 + 0.7958) = 0.5498 \text{ inch (from Table 1)}$$

$$P_n = 0.0499 \text{ inch (from Table 3)}$$

$$a = 0.0159 \text{ inch (from Table 3)}$$

$$h_t = 0.0370 \text{ inch (from Table 3)}$$

$$h_k = 0.6366 \times 0.0499 = 0.0318 \text{ inch (from Table 1)}$$

$$c = 0.0370 - 0.0318 = 0.0052 \text{ inch (from Table 1)}$$

$$t_n = 0.5 \times 0.0499 = 0.0250 \text{ inch (from Table 1)}$$

$$d_o = 0.3037 + (2 \times 0.0159) = 0.3355 \text{ inch (from Table 1)}$$

$$D_o = (2 \times 0.5498) - 0.3037 + (2 \times 0.0159) = 5.1813 \text{ (from Table 1)}$$

$$F_{Gmin} = 1.125 \sqrt{(0.3355 + 2 \times 0.0052)^2 - (0.3355 - 4 \times 0.0159)^2} = 0.2405 \text{ inch}$$

$$F_W = \sqrt{0.8277^2 - 0.7958^2} = 0.2276 \text{ inch}$$

**Table 2a. Pitch Diameters of Fine-pitch Worms for American Standard Combinations of Lead and Lead Angle (ANSI B6.9-1977)**

**Effect of Production Method on Worm Profile and Pressure Angle.**—In worm gearing, tooth bearing is usually used as the means of judging tooth profile accuracy since direct profile measurements on fine-pitch worms or wormgears is not practical. According to AGMA 370.01, Design Manual for Fine-Pitch Gearing, a minimum of 50 per cent initial area of contact is suitable for most fine-pitch worm gearing, although in some cases, such as when the load fluctuates widely, a more restricted initial area of contact may be desirable.

Except where single-pointed lathe tools, end mills, or cutters of special shape are used in the manufacture of worms, the pressure angle and profile produced by the cutter are different from those of the cutter itself. The amounts of these differences depend on several factors, namely, diameter and lead angle of the worm, thickness and depth of the worm thread, and diameter of the cutter or grinding wheel. The accompanying diagram shows the curvature and pressure angle effects produced in the worm by cutters and grinding wheels, and how the amount of variation in worm profile and pressure angle is influenced by the diameter of the cutting tool used.

### Effect of Diameter of Cutting on Profile and Pressure Angle of Worms

*Calculating Worm Deviations and Pressure Angle Changes:* Included in American Standard ANSI B6.9-1977 is an extensive tabulation of profile deviations and pressure angle changes produced by cutters and grinding wheels of 2-inch and 20-inch diameters. These diameters represent the limits of the range commonly used, and the data given are useful in specifying worm profile tolerances. The data also aid in the selection of the method to be used in producing the worm and in specifying the hobs for wormgears. The formulas used to compute the data in the Standard are given here in slightly modified form, and may be used to calculate the profile deviations and pressure angle changes produced in the worm by cutters or grinding wheels.

$$\rho_{ni} = \frac{r \sin \phi_n}{(\sin \lambda)^2} \text{ inches} \quad (1)$$

$$\rho_n = \rho_{ni} + \frac{r \rho_{ni}}{R(\cos \lambda)^2} \text{ inches} \quad (2)$$

$$\Delta \phi = \frac{5400r(\sin \lambda)^3}{n(R(\cos \lambda)^2 + r)} \text{ minutes} \quad (3)$$

## WORM GEARING

3015

$$q = a \sec \phi_n \text{ inches} \quad (4)$$

$$y = \frac{q^2}{2\rho_n} \text{ inches} \quad (5)$$

$$s = 0.000582q\Delta\phi \text{ inches} \quad (6)$$

$$\Delta y = y_w - y_c \text{ inches} \quad (7)$$

$$\Delta s = s_c - s_w \text{ inches} \quad (8)$$

In these formulas,

$\rho_{ni}$  = radius of curvature of normal thread profile for involute thread;

$r$  = pitch radius of worm;

$\Phi_n$  = normal pressure angle of cutter or grinding wheel;

$\lambda$  = lead angle of worm;

$\rho_n$  = radius of curvature of normal thread profile;

$R$  = radius of cutter or grinding wheel;

$\Delta\Phi$  = difference between the normal pressure angle of the thread and the normal pressure angle of the cutter or grinding wheel in minutes (see diagram). Subscripts  $c$  and  $w$  are used to denote the cutter and grinding wheel diameters, respectively;

$n$  = number of threads in worm;

$a$  = addendum of worm;

$q$  = slant height of worm addendum;

$y$  = amount normal worm profile departs from a straight side (see diagram). Subscripts  $c$  and  $w$  are used to denote the cutter and grinding wheel diameters, respectively;

$s$  = effect along slant height of worm thread caused by change in pressure angle  $\Delta\Phi$

$\Delta y$  = difference in  $y$  values of two cutters or grinding wheels of different diameter (see diagram);

$\Delta s$  = effect of  $\Delta\Phi_c - \Delta\Phi_w$  along slant height of thread (see diagram).

*Example 3:* Assuming the worm dimensions are the same as in [Example 1](#), determine the corrections for two worms, one milled by a 2-inch diameter cutter, the other ground by a 20-inch diameter wheel, both to be assembled with identical wormgears.

To make identical worms when using a 2-inch cutter and a 20-inch wheel, the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to  $\Delta s$  and the profile of the cutter or wheel must be a curve which departs from a straight line by an amount  $\Delta y$ . The calculations are as follows:

For the 2-inch diameter cutter, using [Formula \(1\)](#) to [\(6\)](#),

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{1 \times 0.8660^2} = 0.9581 \text{ inch} \quad (2)$$

$$\Delta\phi_c = \frac{5400 \times 0.4410 \times 0.5000^3}{10(1 \times 0.8660^2 + 0.4410)} = 24.99 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

## WORM GEARING

$$y_c = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_c = 0.000582 \times 0.0469 \times 24.99 = 0.000682 \text{ inch} \quad (6)$$

For the 20-inch diameter wheel, using [Formula \(1\)](#) to [\(6\)](#)

$$\rho_{ni} = \frac{0.4410 \times 0.3420}{0.5000^2} = 0.6033 \text{ inch} \quad (1)$$

$$\rho_n = 0.6033 + \frac{0.4410 \times 0.6033}{10 \times 0.8660^2} = 0.6387 \text{ inch} \quad (2)$$

$$\Delta\phi_w = \frac{5400 \times 0.4410 \times 0.5000^3}{10(10 \times 0.8660^2 + 0.4410)} = 3.749 \text{ inches} \quad (3)$$

$$q = 0.0441 \times 1.0642 = 0.0469 \text{ inch} \quad (4)$$

$$y_w = \frac{0.0469^2}{2 \times 0.6387} = 0.00172 \text{ inches} \quad (5)$$

$$s_w = 0.000582 \times 0.0469 \times 3.749 = 0.000102 \text{ inch} \quad (6)$$

Applying [Formula \(7\)](#) to [\(8\)](#):

$$\Delta y = 0.00172 - 0.00115 = 0.00057 \text{ inch} \quad (7)$$

$$\Delta s = 0.000682 - 0.000102 = 0.000580 \text{ inch} \quad (8)$$

Therefore the pressure angle of either the cutter or the wheel must be corrected by an amount corresponding to a  $\Delta s$  of 0.00580 inch and the profile of the cutter or wheel must be a curve which departs from a straight line by 0.00057 inch.

**Industrial Worm Gearing.**—The primary considerations in industrial worm gearing are usually:

- 1) To transmit power efficiently;
- 2) to transmit power at a considerable reduction in velocity; and
- 3) to provide a considerable "mechanical advantage" when a given applied force must overcome a comparatively high resisting force.

Worm gearing for use in such applications is usually of relatively coarse pitch. The notation below is used in the formulas on the following pages.

|                      |  |                      |  |
|----------------------|--|----------------------|--|
| <i>a</i>             | addendum, worm thread                    | <i>m</i>             | module = 0.3183 × axial pitch  |
| <i>A</i>             | addendum, wormgear tooth                 | <i>N</i>             | revolutions per minute of wormgear                                   |
| <i>B</i>             | dedendum, wormgear tooth                 | <i>n</i>             | revolutions per minute of worm                                       |
| <i>b</i>             | dedendum, worm thread                    | <i>P</i>             | axial pitch of worm and circular pitch of wormgear                   |
| <i>C</i>             | center distance (Fig. 1, p. 1928)        | <i>P<sub>n</sub></i> | normal pitch of worm   |
| <i>c</i>             | clearance                                | <i>Q</i>             | arc length of wormgear tooth measured along root                     |
| <i>D</i>             | pitch diameter of wormgear               |                      | ratio of worm gearing = No. of wormgear teeth ÷ No. of worm threads. |
| <i>d</i>             | pitch diameter of worm                   | <i>S<sub>c</sub></i> | surface stress factor ( <a href="#">Table 4</a> )                    |
| <i>d<sub>o</sub></i> | outside diameter of worm                 | <i>S<sub>b</sub></i> | bending stress factors, lbs. per sq. in. ( <a href="#">Table 4</a> ) |
| <i>D<sub>o</sub></i> | outside or over-all diameter of wormgear | <i>T</i>             | number of teeth on wormgear  |

|       |   |                       |  |
|-------|---|-----------------------|--|
| $D_t$ | throat diameter of wormgear   | $t$                   | number of threads or "starts" and on worm-2 for double thread, 3 for triple thread, 4 for quadruple thread, etc. |
| $E$   | efficiency of worm gearing, per cent  | $U$                   | radius of wormgear throat (Fig. 11)  |
| $F$   | nominal face width of wormgear rim  | $V$                   | rubbing speed of worm in feet per minute   |
| $F_e$ | effective face width (Fig. 11, p. 1928)   | $W$                   | whole tooth depth (worm and-wormgear)  |
| $f$   | coefficient of friction   | $X_{cp}$ and $X_{cw}$ | speed factor when load rating is limited by wear (Fig. 11)   |
| $G$   | length of worm threaded section   | $X_{bp}$ and $X_{bw}$ | speed factor when load rating is limited by strength (Table 5)   |
| $H$   | horsepower rating   | $\phi$                | angle of friction ( $\tan \phi =$ coefficient of friction)   |
| $L$   | lead of worm thread = pitch $\times$ number of threads or "starts"                |                       |  |
| $L_a$ | lead angle of worm = helix angle measured from a plane perpendicular to worm axis |                       |  |
| $M$   | torque applied to wormgear, pound inches  |                       |  |

**Materials for Worm Gearing.**—Worm gearing, especially for power transmission, should have steel worms and phosphor bronze wormgears. This combination is used extensively. The worms should be hardened and ground to obtain accuracy and a smooth finish.

The phosphor bronze wormgears should contain from 10 to 12 per cent of tin. The S.A.E. phosphor gear bronze (No. 65) contains 88–90% copper, 10–12% tin, 0.50% lead, 0.50% zinc (but with a maximum total lead, zinc and nickel content of 1.0 percent), phosphorous 0.10–0.30%, aluminum 0.005%. The S.A.E. nickel phosphor gear bronze (No. 65 + Ni) contains 87% copper, 11% tin, 2% nickel and 0.2% phosphorous.

**Single-thread Worms.**—The ratio of the worm speed to the wormgear speed may range from 1.5 or even less up to 100 or more. Worm gearing having high ratios are not very efficient as transmitters of power; nevertheless high as well as low ratios often are required. Since the ratio equals the number of wormgear teeth divided by the number of threads or "starts" on the worm, single-thread worms are used to obtain a high ratio. As a general rule, a ratio of 50 is about the maximum recommended for a single worm and wormgear combination, although ratios up to 100 or higher are possible. When a high ratio is required, it may be preferable to use, in combination, two sets of worm gearing of the multi-thread type in preference to one set of the single-thread type in order to obtain the same total reduction and a higher combined efficiency.

Single-thread worms are comparatively inefficient because of the effect of the low lead angle; consequently, single-thread worms are not used when the primary purpose is to transmit power as efficiently as possible but they may be employed either when a large speed reduction with one set of gearing is necessary, or possibly as a means of adjustment, especially if "mechanical advantage" or self-locking are important factors.

**Multi-thread Worms.**—When worm gearing is designed primarily for transmitting power efficiently, the lead angle of the worm should be as high as is consistent with other requirements and preferably between, say, 25 or 30 and 45 degrees. This means that the worm must be multi-threaded. To obtain a given ratio, some number of wormgear teeth divided by some number of worm threads must equal the ratio. Thus, if the ratio is 6, combinations such as the following might be used:

WORM GEARING

$$\frac{24}{4}, \frac{30}{5}, \frac{36}{6}, \frac{42}{7}$$

The numerators represent the number of wormgear teeth and the denominators, the number of worm threads or "starts." The number of wormgear teeth may not be an exact multiple of the number of threads on a multi-thread worm in order to obtain a "hunting tooth" action.

*Number of Threads or "Starts" on Worm:* The number of threads on the worm ordinarily varies from one to six or eight, depending upon the ratio of the gearing. As the ratio is increased, the number of worm threads is reduced, as a general rule. In some cases, however, the higher of two ratios may also have a larger number of threads. For example, a ratio of  $6\frac{1}{5}$  would have 5 threads whereas a ratio of  $6\frac{5}{6}$  would have 6 threads. Whenever the ratio is fractional, the number of threads on the worm equals the denominator of the fractional part of the ratio.

**Table 4. Rules and Formulas for Worm Gearing**

| No. | To Find                 | Rule  | Formula  |
|-----|-------------------------|---|--|
| 1   | Addendum                | Addendum may be affected by lead angle. See paragraph, Addendum and Dedendum.   |  |
| 2   | Center Distance         | Add pitch diameter of wormgear to pitch diameter of worm, and divide sum by 2   | $C = \frac{D+d}{2}$  |
| 3   |                         | Divide number of worm threads by tangent lead angle, add number of wormgear teeth and multiply sum by quotient obtained by dividing pitch by 6.2832 | $C = \frac{P}{6.2832} \left( \frac{t}{\tan L_a} + T \right)$ |
| 4   | Dedendum                | Dedendum may be affected by lead angle. See paragraph, Addendum and Dedendum  |  |
| 5   | Clearance               | British Standard-multiply cosine lead angle by 0.2 times module.  | $c = 0.2m \cos L_a$  |
| 6   | Face width Wormgear     | For single and double thread worms, multiply pitch by 2.38 and add 0.25. (shell type worm.)   | $F = 2.38P + 0.25$   |
| 7   |                         | For triple and quadruple thread multiply pitch by 2.15 and add 0.2. (shell type )   | $F = 2.15P + 0.20$   |
| 8   |                         | When worm threads are integral with shaft, face width of wormgear may be equal $C^{0.875}$ divided by 3.  | $F = \frac{C^{0.875}}{3}$                                    |
| 9   | Lead of Worm thread     | Multiply pitch by number of worm threads or "starts"  | $L = 1P$   |
| 10  |                         | Multiply pitch circumference of worm by tangent of lead angle.  | $L = \pi d \times \tan L_a$                                  |
| 11  |                         | Divide pitch circumference of wormgear by ratio.  | $L = \pi D \div R$   |
| 12  | Lead Angle, Worm        | Divide lead by pitch circumference of worm; quotient is tangent of lead angle.  | $\tan L_a = \frac{L}{3.1416d}$                               |
| 13  | Outside Diam., Worm     | Add to pitch diameter twice the addendum. see paragraph, pitch diameter of worm; also Addendum and Dedendum.  | $d_0 = d + 2a$   |
| 14  | Outside Diam., Wormgear | For outside or over-all diameter of wormgear, see paragraph, outside diameter of wormgear.  |  |

Table 4. (Continued) Rules and Formulas for Worm Gearing

| No. | To Find                        | Rule   | Formula  |
|-----|--------------------------------|--|--|
| 15  | Pitch of Worm and Wormgear     | Divide lead by number of threads or "starts" on worm = axial pitch of worm and circular pitch of wormgear.   | $P = \frac{L}{t}$                                    |
| 16  |                                | Subtract the worm pitch diameter from twice the center distance. Multiply by 3.1416 and divide by number of wormgear teeth.                                    | $P = \frac{(2C - d)3.1416}{T}$                       |
| 17  | Pitch of Worm, Normal          | Multiply axial pitch by cosine of lead angle to find normal pitch.   | $P_n = P \times \cos L_a$                            |
| 18  | Pitch Diameter, Worm           | Subtract pitch diameter of worm gear from twice the center distance.   | $d = 2C - D$   |
| 19  |                                | Subtract twice the addendum from outside diameter. See Addendum and Dedendum.  | $D = d_0 - 2a$                                       |
| 20  |                                | Multiply lead by cotangent lead angle and divide product by 3.1416   | $d = \frac{L \times \cot L_a}{3.1416}$               |
| 21  | Pitch Diameter, Wormgear       | Subtract pitch diameter of worm from twice the center distance.  | $D = 2C - d$   |
| 22  |                                | Multiply number of wormgear teeth by axial pitch of worm and divide product by 3.1416.   | $D = \frac{TP}{3.1416}$                              |
| 23  | Radius of Rim Corner, Wormgear | Multiply pitch by 0.25   | Radius = 0.25P                                       |
| 24  |                                | British Standard: Radius = 0.5 × module.   | Radius = 0.50m                                       |
| 25  | Ratio                          | Divide number of wormgear teeth by by number of worm threads.  | $R = T \div t$                                       |
| 26  | Rubbing speed, ft. per minute  | Divide wormgear pitch diameter by ratio; square quotient and add to square of worm pitch diameter; multiply square root of this sum by 0.262 × R.P.M. of worm. | $V = 0.262n \sqrt{d^2 + \left(\frac{D}{4}\right)^2}$ |
| 27  |                                | Multiply 0.262 × Pitch diameter of worm by worm R.P.M. of worm; then multiply product by secant of lead angle.   | $V = 0.262dn \times \sec L_a$                        |
| 28  | Throat Diameter Wormgear       | Add twice the addendum to pitch diameter. See paragraph, Addendum and Dedendum   | $D_t = D + 2A$                                       |
| 29  | Throat Radius Wormgear         | Subtract twice the addendum from outside radius of worm.   | $U = \frac{d_0}{2} - 2a$                             |
| 30  | Total Depth                    | Whole depth equals addendum + Dedendum. See paragraph, Addendum and Dedendum   | $W = a + b \quad \text{or} \quad A + B$              |
| 31  | Worm Thread Length             | Multiply the number of wormgear teeth by 0.02, add 4.5 and multiply sum by pitch.  | $G = P(4.5 + 0.02T)$                                 |
| 32  |                                | British Standard subtract square of wormgear pitch diameter from square of outside diameter and extract square root of remainder.                              | $G = \sqrt{D_0^2 - D^2}$                             |

**Ratio for Obtaining "Hunting Tooth" Action.**—In designing wormgears having multi-thread worms, it is common practice to select a number of wormgear teeth that is not an exact multiple of the number of worm threads. To illustrate, if the desired ratio is about 5 or 6, the actual ratio might be  $5\frac{1}{6}$ ,  $5\frac{5}{6}$ ,  $5\frac{2}{3}$ ,  $6\frac{1}{5}$ , etc., so that combinations such as  $\frac{31}{6}$ ,  $\frac{35}{6}$ ,  $\frac{37}{4}$  or  $\frac{31}{5}$  would be obtained. Since the number of wormgear teeth and number of worm threads do not have a common divisor, the threads of the worm will mesh with all of the wormgear teeth in succession, thus obtaining a "hunting tooth" or self-indexing action. This progressive change will also occur during the wormgear hobbing operation, and its primary purpose is to produce more accurate wormgears by uniformly distributing among all of the teeth, any slight errors which might exist in the hob teeth. Another object is to improve the

“running-in” action between the hardened and ground worm and the phosphor bronze wormgear, but in order to obtain this advantage, the threads on the worm must be accurately or uniformly spaced by precise indexing. With a “hunting tooth ratio,” if the thread spacing of a multi-thread worm is inaccurate, load distribution on the threads will be unequal and some threads might not even make contact with the wormgear teeth. For this reason, if the indexing is inaccurate, it is preferable to avoid a hunting tooth ratio, but in that case, if the gearing is disassembled, the same worm and wormgear teeth should be mated when reassembled.

Fig. 11.

**Pitch Diameter of Worm.**—The worm must be strong enough to transmit its maximum load without excessive deflection but the diameter should be as small as is consistent with the necessary strength in order to minimize the rubbing speed. It is impracticable to give a rule or formula that is generally applicable, but the following empirical rules are based upon actual practice and may prove useful as a general guide. They apply to casehardened alloy steel worms which are integral with the shaft.

For ratios of 5, 6, or 7, the pitch diameter ranges approximately from 0.38  $C$  when center distance  $C$  is 4 inches to 0.33  $C$  when  $C$  is 20 inches.

For ratios of 8, 9, 10, the pitch diameter ranges approximately from 0.38  $C$  when center distance  $C$  is 4 inches to 0.25  $C$  when  $C$  is 30 inches.

For ratios of 10 to 20, the pitch diameter ranges approximately from 0.37  $C$  when center distance  $C$  is 4 inches to 0.24  $C$  when  $C$  is 30 inches.

For ratios of 20 to 40, the pitch diameter ranges approximately from 0.36  $C$  when center distance  $C$  is 4 inches to 0.23  $C$  when  $C$  is 30 inches.

According to another empirical formula pitch diameter  $d = C^{0.75} + 2.2$ .

**Addendum and Dedendum.**—The following A.G.M.A. formulas are applicable to industrial worm gearing. For single and double thread worms, addendum  $a = 0.318 P$  and whole depth  $W = 0.686 P$ ; for triple and quadruple threads, addendum  $a = 0.286 P$  and whole depth  $W = 0.623 P$ .

According to the British standard,  $a = \text{module } m = 0.3183 P$ ;  $b = m(2.2 \cos L_a - 1)$ ;  $A = m(2.2 \cos L_a - 1)$ ;  $B = m(1 + 0.2 \cos L_a)$ .

**Outside Diameter of Wormgear.**—Practice varies somewhat in determining the outside or over-all diameter of the wormgear, as indicated by the following formulas. For usual rim shape, see Fig. 11.

- 1) For lead angles up to about 15 or 20 degrees,  $D_o = D + (3 \times 0.3183 P)$
- 2) For lead angles over 20 degrees,  $D_o = D + (3 \times 0.3183 P \times \cos L_a)$
- 3) For single and double thread,  $D_o = D_t + 0.4775 P$
- 4) For triple and quadruple thread,  $D_o = D_t + 0.3183 P$

**Pressure Angles.**—The pressure angle (one-half the included thread angle) ranges from  $14\frac{1}{2}$  to 30 degrees. While the practice varies somewhat, the following relationship between lead angle and pressure angle may be used as a general guide.

For lead angles up to about 10 or 12 degrees, pressure angle =  $14\frac{1}{2}$  degrees.

For lead angles from 10 or 12 to about 20 or 25 degrees, pressure angle = 20 degrees.

For lead angles from 25 to about 35 degrees, pressure angle = 25 degrees.

For lead angles over 35 degrees, pressure angle = 30 degrees.

In the British Standard specifications, the recommended thread form has a normal pressure angle of 20 degrees.

**Designing Worm Gearing Relative to Center Distance and Ratio.**—In designing worm gearing, three general cases or types of problems may be encountered in establishing the proportions of the worm and wormgear.

*When Center Distance is Fixed and Ratio may be Varied:* The ratio in this case is nominal and may be varied somewhat to meet other conditions. Assume that the required center distance is 6 inches, the desired ratio is about 7, and the pitch of the worm and wormgears is to be approximately 1 inch. Combinations of wormgears and worms such as the following might be used in this case:

$$\frac{28}{4}, \frac{35}{5}, \frac{42}{6}, \frac{56}{8}, \text{ etc.}$$

Suppose we select the  $\frac{28}{4}$  combination for trial but change the number of worm-gear teeth from 28 to 29 to obtain a self-indexing or "hunting tooth" action. The ratio now equals  $\frac{29}{4}$  or 7.25. Then, for trial purposes

$$\text{Pitch diameter } D \text{ of wormgear} = \frac{T \times P}{\pi} = \frac{29 \times 1}{3.1416} = 9.231 \text{ inches}$$

$$\text{Pitch diameter } d \text{ of wormgear} = 2C - D = 2 \times 6 - 9.231 = 2.769 \text{ inches}$$

Assume that experience, tests, or calculations show that a worm of smaller diameter will have the necessary bending and torsional strength and that a pitch of 1.0625 will be satisfactory. Then the pitch diameter of the worm will be decreased to 2.192 inches and the pitch diameter of the wormgear will be increased to 9.808 inches. A check of the lead-angle will show that it equals  $31^\circ 41'$  which is conducive to high efficiency.

*When Ratio is Fixed and Center Distance may be Varied:* Assume that the required ratio is  $7\frac{1}{4}$  and that the center distance may be any value consistent with approved designing practice. This ratio may be obtained with a number of different worm and wormgear sizes. For example, in a series of commercial wormgears, the following combinations are employed for gearing having a ratio of  $7\frac{1}{4}$  with center distances varying from 4 to 8.25 inches. The number of worm threads is 4 and the number of teeth on the wormgear is 29 in all cases.

$$\text{When } C = 4 \text{ inches, } d = 1.654; D = 6.346; P = 0.6875; L_a = 27^\circ 54'$$

When  $C = 5$  inches,  $d = 1.923$ ;  $D = 8.077$ ;  $P = 0.875$ ;  $L_a = 30^\circ 5'$

When  $C = 6$  inches,  $d = 2.192$ ;  $D = 9.808$ ;  $P = 1.0625$ ;  $L_a = 31^\circ 41'$

When  $C = 7$  inches,  $d = 2.461$ ;  $D = 11.539$ ;  $P = 1.25$ ;  $L_a = 32^\circ 53'$

When  $C = 8.25$  inches,  $d = 2.942$ ;  $D = 13.558$ ;  $P = 1.4687$ ;  $L_a = 32^\circ 27'$

The horsepower rating increases considerably as the proportions of the worm gearing increase; hence if the gears are intended primarily for power transmission, the general proportions must be selected with reference to the power-transmitting capacity, and, usually the smallest and most compact design that will give satisfactory performance should be selected. The power capacity of the transmission, however, does not depend solely upon the proportions of the worm and wormgear. For example, the quality and viscosity of the lubricant is an important factor. The load transmitting capacity of the lubricant may also be increased decidedly when excessive temperature rises are prevented by special means such as forced air cooling. (See "Water and Forced-Air Cooling.")

*When Both Ratio and Center Distance are Fixed:* When both ratio and center distance are fixed, the problem usually is to obtain the best proportions of worm and wormgear conforming to these fixed values.

*Example:* The required ratio is 6 (6 to 1) and the center distance is fixed at 3.600 inches. Assume that experience or tests show that an axial pitch of 0.50 inch will meet strength requirements. If normal pitch  $P_n$  is given, change to axial pitch ( $P = P_n \div \cos L_a$ ). With a

ratio of 6, some of the combinations for trial are:  $\frac{30}{5}, \frac{36}{6}, \frac{42}{7}$

Trial calculations will show that the  $\frac{36}{6}$  combination gives the best proportions of worm and wheel for the center distance and pitch specified. Thus

$$D = \frac{TP}{\pi} = \frac{36 \times 0.5}{3.1416} = 5.729; \quad d = 2C - D = 2 \times 3.6 - 5.729 = 1.471$$

The lead angle is about 33 degrees. The effect of lead angle on efficiency is dealt with in a following paragraph. The total obtained by adding the number of worm-gear teeth to the number of worm threads, equals  $36 + 6 = 42$  (a total of 40 is a desirable minimum). With the  $\frac{42}{7}$  combination of the same pitch, the worm would be too small (0.516 inch); and with the  $\frac{30}{5}$  combination it would be too large (2.426 inches). The present trend in gear designing practice is to use finer pitches than in the past. In the case of worm gearing, the pitch may, in certain instances, be changed somewhat either to permit cutting with available equipment or to improve the proportions of worm and wheel.

*When Ratio, Pitch and Lead Angle are Fixed:* Assume that  $R = 10$ , axial pitch  $P = 0.16$  inch,  $L_a = 30$  degrees and  $C = 3$  inches, approximately.

The first step is to determine for the given ratio, pitch and lead angle, the number of worm threads  $t$  which will give a center distance nearest 3 inches.

The whole number nearest 10.04, or 10, is the required number of worm threads; hence number of teeth on wormgear equals  $R \times 10 = 100$

$$d = (L \cot L_a) \div \pi = (10 \times 0.16 \times 1.732) \div \pi = 0.8821 \text{ inches}$$

$$D = (TP) \div \pi = (100 \times 0.16) \div \pi = 5.0929 \text{ inches}$$

$$C = (D + d) \div 2 = (5.0929 + 0.8821) \div 2 = 2.9875 \text{ inches}$$

**Efficiency of Worm Gearing.**—The efficiency at a given speed, depends upon the worm lead angle, the workmanship, the lubrication, and the general design of the transmission. When worm gearing consists of a hardened and ground worm running with an accurately hobbled wormgear properly lubricated, the efficiency depends chiefly upon the lead angle

and coefficient of friction between the worm and worm-gear. In the lower range of lead angles, the efficiency increases considerably as the lead angle increases, as shown by Table 5 and . This increase in efficiency remains practically constant for lead angles between 30 and 45 degrees. Several formulas for obtaining efficiency percentage follow:  
*With worm driving:*

$$E = 100 - \frac{R}{2} \text{ (empirical rule); } E = \frac{100 \times \tan L_a}{\tan(L_a + \phi)}; E = \frac{100 \times L}{L + f\pi d}$$

*With wormgear driving*

$$E = 100 - 2R \text{ (empirical rule); } E = \frac{100 \times \tan(L_a - \phi)}{\tan L_a}$$

The efficiencies obtained by these formulas and other modifications of them differ somewhat and do not take into account bearing and oil-churning losses. The efficiency may be improved somewhat after the "running in" period.

**Table 5. Efficiency of Worm Gearing for Different Lead Angles and Frictional Coefficients**

| Coefficient of friction | Lead angle of worm in degrees |         |         |         |         |         |         |         |         |
|-------------------------|-------------------------------|---------|---------|---------|---------|---------|---------|---------|---------|
|                         | 5 Deg.                        | 10 Deg. | 15 Deg. | 20 Deg. | 25 Deg. | 30 Deg. | 35 Deg. | 40 Deg. | 45 Deg. |
| 0.01                    | 89.7                          | 94.5    | 96.1    | 97.0    | 97.4    | 97.7    | 97.9    | 98.0    | 98.0    |

<sup>a</sup> These values for different rubbing speeds are based upon the use of phosphor bronze wormgears with case-hardened ground and polished steel worms lubricated with mineral oil.

**Self-locking or Irreversible Worm Gearing.**—Neglecting friction in the bearings, worm gearing is irreversible when the efficiency is zero or negative, the lead angle being equal to or less than the angle  $\phi$  of friction ( $\tan \phi =$  coefficient of friction). When worm gearing is self-locking or irreversible, this means that the worm-gear cannot drive the worm. Since the angle of friction changes rapidly with the rubbing speed, and the static angle of friction may be reduced by external vibration, it is usually impracticable to design irreversible worm gearing with any security. If irreversibility is desired, it is recommended that some form of brake be employed.

**Worm Gearing Operating Temperatures.**—The load capacity of a worm gearing lubricant at operating temperature is an important factor in establishing the continuous power-transmitting capacity of the gearing. If the churning or turbulence of the oil generates excessive heat, the viscosity of the lubricant may be reduced below its load-supporting capacity. The temperature measured in the oil sump should not, as a rule, exceed 180 to 200 degrees F. or rise more than 120 to 140 degrees F. above a surrounding air temperature of 60 degrees F. In rear axle motor vehicle transmissions, the maximum operating temperature may be somewhat higher than the figures given and usually is limited to about 220 degrees F.

**Thermal Rating.**—In some cases, especially when the worm speed is comparatively high, the horsepower capacity of worm gearing should be based upon its thermal rating instead of the mechanical rating. To illustrate, worm gearing may have a thermal rating of, say, 60 H.P., and mechanical ratings which are considerably higher than 60 for the higher

speed ranges. This means that the gearing is capable of transmitting more than 60 H.P. so far as wear and strength are concerned but not without overheating; hence, in this case a rating of 60 should be considered maximum. Of course, if the power to be transmitted is less than the thermal rating for a given ratio, then the thermal rating may be ignored.

**Water and Forced-Air Cooling.**—One method of increasing the thermal rating of a speed-reducing unit of the worm gearing type, is by installing a water-cooling coil through which water is circulated to prevent an excessive rise of the oil temperature. According to one manufacturer, the thermal rating may be increased as much as 35 per cent in this manner. Much larger increases have been obtained by means of a forced air cooling system incorporated in the design of the speed-reducing unit. A fan which is mounted on the worm shaft draws air through a double walled housing, thus maintaining a comparatively low oil bath temperature. A fan cooling system makes it possible to transmit a given amount of power through a worm-gearing unit that is much smaller than one not equipped with a fan.

**Double-enveloping Worm Gearing.**—Contact between the worm and wormgear of the conventional type of worm gearing is theoretically a line contact; however, due to deflection of the materials under load, the line is increased to a narrow band or contact zone. In attempting to produce a double-enveloping type of worm gearing (with the worm curved longitudinally to fit the curvature of the gear as shown by illustration), the problem primarily was that of generating the worm and worm-gear in such a manner as to obtain area contact between the engaging teeth. A practical method of obtaining such contact was developed by Samuel I. Cone at the Norfolk Navy Yard, and this is known as "Cone-Drive" worm gearing. The Cone generating method makes it possible to cut the worm and wormgear without any interference which would alter the required tooth form. The larger tooth bearing area and multiple tooth contact obtained with this type of worm gearing, increases the load-carrying or horsepower capacity so that as compared with a conventional worm drive a double-enveloping worm drive may be considerably smaller in size. [Table 6](#), which is intended as a general guide, gives input horsepower ratings for Cone-Drive worm gearing for various center distances of from 2 to 12 inches. These ratings are based on AGMA specifications 341, 441, and 641. They allow for starting and momentary peak overloads of up to 300 per cent of the values shown in [Table 5](#) using a service factor of 1. Factors for various types of service are given in [Table 7](#). To obtain the mechanical horsepower rating required, multiply the appropriate rating given in [Table 6](#) by the service factor taken from [Table 7](#).

\*Horsepower ratings are for Class 1 service, using splash lubrication, except for that shown in italics, for which force feed lubrication is required. Other ratios and center distances are available.

**Table 7. Service Factors for Cone-Drive Worm Gearing**

| Hours/Day | Uniform Motion | Moderate Shock | Heavy Shock | Extreme Shock |
|-----------|----------------|----------------|-------------|---------------|
| 0.5       | 0.6            | 0.8            | 0.9         | 1.1           |
| 1         | 0.7            | 0.9            | 1           | 1.2           |
| 2         | 0.9            | 1              | 1.2         | 1.3           |
| 10        | 1              | 1.2            | 1.3         | 1.5           |
| 24        | 1.2            | 1.3            | 1.5         | 1.75          |

**Thermal Horsepower Rating:** When the operation is to be continuous, consideration must be given to the possibility of overheating. For this possibility, the thermal horsepower rating given in Ex-Cell-O Corporation, Cone Drive Operations catalog must be checked. The thermal rating defines the maximum horsepower which can be transmitted continuously (30 minutes or longer). This is based on an oil sump temperature rise of 100 deg. F above the ambient temperature. This rise must not exceed 200 deg. F. If the thermal rating is lower than the mechanical rating, the unit must be selected on the basis of the thermal rating.

**Type of Drive Connection:** If either input or output shaft is connected to driver or driven mechanism by other than a direct shaft coupling, the overhead load requirement (chain pull) must be calculated by dividing the torque demand by the pitch radius of the sprocket, sheave, spur gear, or helical gear used. The result is multiplied by the overhung load factor which is: for a chain sprocket, 1.00; for spur or helical gearing, 1.25; for a V-belt sheave, 1.50; and for a flat belt sheave, 2.50. As modified by the applicable overhung load factor, this load may not exceed the overhung load rating given in the company catalog.

**Locking Considerations:** It is a common misconception that all worm gears are self-locking or non-overhauling. Actually, wormgear ratios up 15 to 1 will overhaul quite freely. Ratios from 20:1 to 40:1 can generally be considered as overhauling with difficulty, particularly from rest. Ratios above 40:1 may or may not overhaul depending on the loading, lubrication, and amount of vibration present. Therefore it is not acceptable to rely on a wormgear to prevent movement in a system. Whenever a load must be stopped or held in place, a positive mechanical device must be incorporated into the system to prevent rotation of the gearset.

**Backdriving or Overhauling:** Applications such as wheel drives that require a brake on the motor or input shaft to decelerate a high inertial load require special attention to brake selection. Wherever possible, these applications should utilize freely overhauling ratios (15:1 or less). If higher ratios are used with a brake, the gearset can, under certain conditions, lockup during deceleration and impose severe shock loading on the reducer and driven equipment.

**Stairstepping:** Self-locking ratios (generally 40:1 and higher) are susceptible to the phenomenon of "stair stepping" when back driving or overhauling. This erratic rotation of the gear set occasionally occurs when the gear set is back driven at worm speeds less than the theoretical lockup speed of the gear set and can be amplified by the rest of the drive train creating a very undesirable operating condition. "Stair stepping" can occur on drives where there is a high inertial load at the output shaft.

**Backlash:** Defined as the amount of movement at the pitch line of the gear with the worm locked and the gear set on exact center distance, backlash normally ranges from 0.003 to 0.008 inch for a 2-inch center distance set up to 0.012 to 0.020 inch for a 12-inch center distance set. When the gear set is assembled into a machine or reducer, the assembled backlash may fall outside these limits depending upon worm and gear bearing looseness and the actual center distance used.

**Lubrication:** Lubricating oils for use in double-enveloping worm drive units should be well refined petroleum oils of high quality. They should not be corrosive to gears or bear-

ings and they must be neutral in reaction and free from grit or abrasives. They should have good defoaming properties and good resistance to oxidation. For worm gears, add up to 3 to 10 per cent of acid less tallow or similar animal fat.

The oil bath temperature should not exceed 200 degrees F. Where worm speed exceeds 3600 revolutions per minute, or 2000 feet per minute rubbing speed, a force feed lubrication may be required. Auxiliary cooling by forced air, water coils in sump, or an oil heat exchanger may be provided in a unit where mechanical horsepower rating is in excess of the thermal rating, if full advantage of mechanical capacity is to be realized. The rubbing speed ( $V$ ), in feet per minute, may be calculated from the formula:  $V = 0.262 \times \text{worm thread diameter in inches} \times \text{worm RPM} \div \cos \text{lead angle}$ .

**Worm Thread Cutting.**—Worm threads are cut either by using some form of thread-cutting lathe and a single-point tool, by using a thread milling machine and a disk type of cutter, or by using a gear-hobbing machine. Single-thread worms usually have an included angle of 29 degrees. Many worm gears used at the present time, especially for power transmission, have thread angles larger than 29 degrees because multiple-thread worms are used to obtain higher efficiency, and larger thread angles are necessary in order to avoid excessive under-cutting of the worm-wheel teeth. According to the recommended practice of the American Gear Manufacturers' Association, worms having triple and quadruple threads should have a thread angle of 40 degrees, and some manufacturers of worm gearing, especially when the helix or lead angle of the thread is quite large, use a thread angle of 60 degrees.

If the helix or lead angle of the worm thread exceeds 15 or 20 degrees, it is common practice to reduce the depth of the thread by using the normal instead of the axial pitch of the worm in the formulas. Thus, if  $P_n$  equals normal pitch, the total depth equals  $P_n \times 0.6866$  instead of  $P_n = 0.6866$ . This normal pitch  $P_n$ , equals  $P_n \times \cos$ ine of the helix angle. According to the recommended practice of the American Gear Manufacturers' Association, the whole depth for single- and double-thread worms equals  $P_n \times 0.686$ , and for triple and quadruple-thread worms equals  $P_n \times 0.623$ .

**Wormgear Hobs.**—An ideal hob would have exactly the same pitch diameter and lead angle as the worm; repeated sharpening, however, would reduce the hob size because of the form-relieved teeth. Hence, the general practice is to make hobs (especially the radial or in-feed type) "over-size" to provide a grinding allowance and increase the hob life. An over-size hob has a larger pitch diameter and smaller lead angle than the worm, but repeated sharpenings gradually reduce these differences. To compensate for the smaller lead angle of an over-size hob, the hob axis may be set 90-degrees relative to the wormgear axis plus the difference between the lead angle of the worm at the pitch line, and the lead angle of the over-size hob at its pitch line. This angular adjustment is in the direction required to increase the inclination of the wormgear teeth so that the axis of the assembled worm will be 90 degrees from the wormgear axis. ("Lead angle" is measured from a plane perpendicular to worm or hob axis.)

*Hob Diameter Formulas:* If

$D$  = pitch diameter of worm;

$D_h$  = pitch diameter of hob;

$A$  = addendum of worm and wormgear;

$C$  = clearance between worm and worm-gear;

$S$  = increase in hob diameter or "over-size" allowance for sharpening.

Outside diameter  $O$  of hob =  $D + 2A + 2C + S$

Root diameter of hob =  $D - 2A$

Pitch diameter  $D_h$  of hob =  $O - (2A + 2C)$

*Sharpening Allowance:* Hobs for ordinary commercial work are given the following sharpening allowance, according to the recommended practice of the AGMA: In this for-

mula,  $h$  = helix angle of hob at outside diameter measured from axis;  $H$  = helix angle of hob at pitch diameter measured from axis.

$$\text{Sharpening allowance} = 0.075 \times \text{normal pitch} \times \left[ \frac{16 - (h - H)}{16} \right] + 0.010$$

*Number of Flutes or Gashes in Hobs:* For finding the approximate number of flutes in a hob, the following rule may be used: Multiply the diameter of the hob by 3, and divide this product by twice the linear pitch. This rule gives suitable results for hobs for general purposes. Certain modifications, however, are necessary as explained in the following paragraph.

It is important that the number of flutes or gashes in hobs bear a certain relation to the number of threads in the hob and the number of teeth in the wormgear to be hobbled. In the first place, avoid having a common factor between the number of threads in the hob and the number of flutes; that is, if the worm is double-threaded, the number of gashes should be, say, 7 or 9, rather than 8. If it is triple threaded, the number of gashes should be 7 or 11, rather than 6 or 9. The second requirement is to avoid having a common factor between the number of threads in the hob and the number of teeth in the wormgear. For example, if the number of teeth in the wheel is 28, it would be best to have the hob triple-threaded, as 3 is not a factor of 28. Again, if there were to be 36 threads in the wormgear, it would be preferable to have 5 threads in the hob.

The cutter used in gashing hobs should be from  $\frac{1}{8}$  to  $\frac{1}{4}$  inch thick at the periphery, according to the pitch of the thread of the hob. The width of the gash at the periphery of the hob should be about 0.4 times the pitch of the flutes. The cutter should be sunk into the hob blank so that it reaches from  $\frac{3}{16}$  to  $\frac{1}{4}$  inch below the root of the thread.

**Helical Fluted Hobs.**—Hobs are generally fluted parallel with the axis, but it is obvious that the cutting action will be better if they are fluted on a helix at right angles with the thread helix. The difficulty of relieving the teeth with the ordinary backing-off attachment is the cause for using a flute parallel with the axis. Flutes cut at right angles to the direction of the thread can, however, also be relieved, if the angle of the flutes is slightly modified. In order to relieve hobs with a regular relieving attachment, it is necessary that the number of teeth in one revolution along the thread helix be such that the relieving attachment can be geared to suit it. The following method makes it possible to select an angle of flute that will make the flute come approximately at right angles to the thread, and at the same time the angle is so selected that the relieving attachment can be properly geared for relieving the hob.

Let

$C$  = pitch circumference

$T$  = developed length of thread in one turn;

$N$  = number of teeth in one turn along thread helix;

$F$  = number of flutes;

$\alpha$  = angle of thread helix.

Then  $C \div F =$  length of each small division on pitch circumference;  
 $(C \div F) \times \cos \alpha =$  length of division on developed thread;  
 $C \div \cos \alpha = T$

Hence

$$\frac{T}{(C \div F) \cos \alpha} = N = \frac{F}{\cos \alpha^2}$$

Now, if

$$\alpha = 30 \text{ degrees}, N = 1\frac{1}{3}F;$$

$$\alpha = 45 \text{ degrees}, N = 2F;$$

$$\alpha = 60 \text{ degrees}, N = 4F.$$

In most cases, however, such simple relations are not obtained. Suppose for example that  $F = 7$ , and  $\alpha = 35$  degrees. Then  $N = 10.432$ , and no gears could be selected that would relieve this hob. By a very slight change in the helix angle of the flute, however, we can change  $N$  to 10 or  $10\frac{1}{2}$ ; in either case we can find suitable gears for the relieving attachment.

The rule for finding the modified helical lead of the flute is: Multiply the lead of the hob by  $F$ , and divide the product by the difference between the desired values of  $N$  and  $F$ .

Hence, the lead of flute required to make  $N = 10$  is:

$$\text{Lead of hob} \times (7 \div 3).$$

To make  $N = 10\frac{1}{2}$ , we have:

$$\text{Lead of flute} = \text{lead of hob} \times (7 \div 3.5).$$

From this the angle of the flute can easily be found.

That the rule given is correct will be understood from the following consideration. Change the angle of the flute helix  $\beta$  so that  $AG$  contains the required number of parts  $N$  desired. Then  $EG$  contains  $N - F$  parts. But  $\cot \beta = BD \div ED$  and by the law of similar triangles,

$$BD = \frac{F}{N} \times BG, \text{ and } ED = \frac{N - F}{N} C$$

The lead of the helix of the flute, however, is  $C \times \cot \beta$ .

Hence, the required lead of the helix of the flute:

$$C \times \cot \beta = \frac{F}{N - F} L$$

This formula makes it possible always to flute hobs so that they can be conveniently relieved, and at the same time have the flutes at approximately right angles to the thread.

**Gear Shaving**

The purpose of gear shaving is to correct errors in indexing, helix angle, tooth profile, and eccentricity by removing small amounts of material from the working surfaces of gear teeth. Special shaving cutters are used and have tooth flanks with sharp-edged grooves that traverse the tooth surfaces of the gear to be corrected as the hardened, driven cutter and the softer (30-35 Rockwell C) free-running gear are rotated in mesh on crossed axes in a special machine. The crossed angle is usually between 10 and 15 degrees, or half the difference between the helix angles of cutter and gear. In conventional shaving, the gear is held between live centers on the machine table, which is moved parallel to the gear axis, and is fed into contact with the cutter at each successive stroke of the table. Cutter speeds of up to 450 surface feet/min are commonly used.

The crossed axes cause the sharp-edged grooves on the cutter to traverse the tooth surfaces on the gear as cutter and gear rotate, resulting in a shearing action that cuts fine slivers from the gear tooth surfaces. At the same time, contact between the meshing sets of teeth has a burnishing action on the gear teeth, improving the surface finish. Shaving can remove 60-80 per cent of errors in a gear, and can produce accuracies of 0.0002 in. on the involute profile, 0.0003 in. on tooth-to-tooth spacing, and 0.0002 in. on lead or parallelism.

Gear-shaving machines have built-in mechanisms that can be used to rock the table as it traverses, producing crowned gear teeth that are slightly thicker at the center than at the ends. In the faster diagonal shaving method, the traversing movement of the table is at an angle to the gear axis, so that the cutter grooves move more rapidly across the gear, increasing the shaving action.

**MISCELLANEOUS TOPICS****Mathematics**

**Catenary Curve.**—The catenary is the curve assumed by a string or chain of uniform weight hanging freely between two supports. The cables of a suspension bridge, if uniformly loaded, assume the form of the catenary curve. It has, therefore, considerable importance in structural engineering.

**Mechanics**

**Running Balance.**—When a part such as a drum, rotor, crankshaft, pulley, etc., is properly tested for balance while revolving, and any appreciable lack of balance is corrected on the basis of such test, the part is said to be in running or dynamic balance. Special balancing machines are used to determine the magnitude and location of unbalanced masses while the part is revolving; hence, the test is applied under operating conditions, which is not true of the test for static or standing balance.

**Properties of Materials**

**Copper-Clad Steel.**—A material generally used in the form of wire, in which a steel wire is covered with a coating of copper. It is produced either by alloying the copper with the surface of the metal or by welding it onto the surface. When the copper is alloyed with the surface, it is brought to a molten state before being applied, while, when welded to the surface, it is merely in a plastic state.

**Truflex.**—Thermostatic bimetal made in different types for automatically controlling temperature ranges of from —50 degrees F. to 1000 degrees F. Used for automatically controlling the operation of devices either heated or cooled by electricity, oil, or gas, as, for example: electric refrigerators, irons, toasters, gas ranges, water heaters, and domestic oil burners. Available in helical and spiral coils, rings, flat pieces, U-shapes, and in sheets up to 8 inches wide.

**Firebrick Properties.**—Brick intended for use in furnaces, flues, and cupolas, where the brickwork is subjected to very high temperatures, is generally known as "firebrick." There are several classes of firebrick, such as fireclay brick, silica brick, bauxite brick, chrome brick, and magnesia brick.

Ordinary firebricks are made from fireclay; that is, clays which will stand a high temperature without fusion, excessive shrinkage, or warping. There is no fixed standard of refractoriness for fireclay, but, as a general rule, no clay is classed as a fireclay that fuses below 2900 degrees F.

Fireclays vary in composition, but they all contain high percentages of alumina and silica, and only small percentages of such constituents as oxide of iron, magnesia, lime, soda, and potash. A great number of different kinds of firebrick are manufactured to meet the various conditions to which firebricks are subjected. Different classes of bricks are required to withstand different temperatures, as well as the corrosive action of gases, the chemical action of furnace charges, etc.

The most common firebrick will melt at a temperature ranging from 2830 to 3140 degrees F.; bauxite brick, from 2950 to 3245 degrees F.; silica brick, from 3090 to 3100 degrees F.; chromite brick, at 3720 degrees F.; and magnesia brick, at 4950 degrees F.

**Inconel.**—This heat resistant alloy retains its strength at high heats, resists oxidation and corrosion, has a high creep strength and is non-magnetic. It is used for high temperature applications (up to 2000 degrees F.) such as engine exhaust manifolds and furnace and heat treating equipment. Springs operating at temperatures up to 700 degrees F. are also made from it.

*Approximate Composition:* Nickel, 76; copper, 0.20; iron, 7.5; chromium, 15.5; silicon, 0.25; manganese, 0.25; carbon, 0.08; and sulphur, 0.007.

*Physical Properties:* Wrought Inconel in the annealed, hot-rolled, cold-drawn, and hard temper cold-rolled conditions exhibits yield strengths (0.2 per cent offset) of 35,000, 60,000, 90,000, and 110,000 pounds per square inch, respectively; tensile strengths of 85,000, 100,000, 115,000, and 135,000 pounds per square inch, respectively; elongations in 2 inches of 45, 35, 20, and 5 per cent, respectively; and Brinell hardnesses of 150, 180, 200, and 260, respectively.

**Inconel "X".**—This alloy has a low creep rate, is age-hardenable and non-magnetic, resists oxidation and exhibits a high strength at elevated temperatures. Uses include the making of bolts and turbine rotors used at temperatures up to 1500 degrees F., aviation brake drum springs and relief valve and turbine springs with low load loss or relaxation for temperatures up to 1000 degrees F.

*Approximate Composition:* Nickel, 73; copper, 0.2 maximum; iron, 7; chromium, 15; aluminum, 0.7; silicon, 0.4; manganese, 0.5; carbon, 0.04; sulphur, 0.007; columbium, 1; and titanium, 2.5.

*Average Physical Properties:* Wrought Inconel "X" in the annealed and age-hardened hot-rolled conditions exhibits yield strengths (0.2 per cent offset) of 50,000 and 120,000 pounds per square inch, respectively; tensile strengths of 115,000 and 180,000 pounds per square inch, respectively; elongations in 2 inches of 50 and 25 per cent, respectively; and Brinell hardnesses of 200 and 360, respectively.

**Lodestone.**—The most highly magnetic substances are iron and steel. Nickel and cobalt are also magnetic, but in a less degree. The name "magnet" has been derived from that of Magnesia, a town in Asia Minor, where an iron ore was found in early days which had the power of attracting iron.

This ore is known as magnetite and consists of about 72 per cent, by weight, of iron and 28 per cent of oxygen, the chemical formula being  $Fe_3O_4$ . The ore possessing this magnetic property is also known as lodestone. If a bar of hardened steel is rubbed with a piece of lodestone, it will acquire magnetic properties similar to those of the lodestone itself.

**Metallography.**—The science or study of the microstructure of metal is known by most metallurgists as "metallography." The name "crystallography" is also used to some extent. The examination of metals and metal alloys by the aid of the microscope has become one of the most effective methods of studying their properties, and it is also a valuable means of controlling the quality of manufactured metallic articles and of testing the finished product. In preparing the specimen to be examined, a flat surface is first formed by filing or grinding, and this surface is then given a high polish, which is later subjected to the action of a suitable acid or etching reagent, in order to reveal clearly the internal structure of the metal when the specimen is examined under the microscope. This process shows clearly to an experienced observer the effect of variation in composition, heat-treatment, etc., and in many cases it has proved a correct means of determining certain properties of industrial products that a chemical analysis has failed to reveal.

*Preparing Hardened Steel for Microscopic Study:* To cause the constituents of the specimen to contrast with one another as seen through the microscope is the desired end, and a reagent is used which acts differently towards these elements; generally this reagent acts on one element more than on another so that the one least affected reflects the light from the faces of its crystals while the etched part absorbs the light, and, therefore, appears dark when photographed.

In etching specimens to develop the constituents of hardened anti tempered steels, very good results are obtained with sulphurous acid that is composed of 4 parts of sulphur dioxide to 96 parts of distilled water. The specimens are immersed in this, face upward, and removed as soon as the polished surface is frosted. This takes from 7 seconds to 1 minute.

They are then rinsed with water and dried with alcohol. Very thin layers of iron sulphide are deposited on the different constituents in different thicknesses, and this gives them different colors. Austenite remains a pale brown; martensite is given a pale blue and deep blue and brown color; troostite is made very dark; sorbite is uncolored; cementite exhibits a brilliant white; and ferrite is made dark brown. When the etching has proceeded to the desired extent, the specimen is at once washed thoroughly in order to remove all trace of the etching reagent. Usually it is simply rinsed with water, but frequently the washing is done with absolute alcohol, while ether and chloroform are also sometimes used.

The apparatus used for examining the etched surfaces of metals is composed of a microscope and camera combined with an arc lamp or other means of illumination.

*Microscopic Study of Steel:* Steel, in particular, shows many changes of structure due to the mechanical and thermal treatment, so that the microscope has become a very valuable instrument with which to inspect steel. To one who understands what the different formations of crystalline structure denote, the magnified surface reveals the temperature at which the steel was hardened, or at which it was drawn, and the depth to which the hardness penetrated. It also shows whether the steel was annealed or casehardened, as well as the depth to which the carbon penetrated. The carbon content can be closely judged, when the steel is annealed, and also how much of it is in the graphitic state in the high carbon steels. The quantity of special elements that is added to steel, such as nickel, chromium, tungsten, etc., can also be estimated, when the alloy to be examined has been put through its prescribed heat-treatment. Likewise, the impurities that may be present are clearly seen, regardless of whether they are of solid or gaseous origin.

**Micarta.**—Micarta is a non-metallic laminated product of specially treated woven fabric. By means of the various processes through which it is passed, it becomes a homogenous structure with physical properties which make it especially adapted for use as gears and pinions. Micarta can be supplied either in plate form or cut into blanks. It may also be molded into rings or on metal hubs for applications such as timing gears, where quantity production is attained. Micarta may be machined in the ordinary manner with standard tools and equipment.

Micarta gears do not require shrouds or end plates except where it is desired to provide additional strength for keyway support or to protect the keyway and bore against rough usage in mounting drive fits and the like. When end plates for hub support are employed they should extend only to the root of the tooth or slightly less.

*Properties:* The physical and mechanical properties of Micarta are as follows: weight per cubic inch, 0.05 pound; specific gravity, 1.4; oil absorption, practically none; shrinkage, swelling or warping, practically none up to 100 degrees C.; coefficient of expansion per inch per degree Centigrade, 0.00002 inch in the direction parallel to the laminations (edgewise), 0.00009 inch in the direction perpendicular to the laminations (flat wise); tensile strength, edgewise, 10,000 pounds per square inch; compressive strength, flat wise, 40,000 pounds per square inch; compressive strength, edgewise, 20,000 pounds per square inch; bending strength, flatwise, 22,000 pounds per square inch; bending strength, edgewise, 20,000 pounds per square inch.

**Monel.**—This general purpose alloy is corrosion-resistant, strong, tough and has a silvery-white color. It is used for making abrasion- and heat-resistant valves and pump parts, propeller shafts, laundry machines, chemical processing equipment, etc.

*Approximate Composition:* Nickel, 67; copper, 30; iron, 1.4; silicon, 0.1; manganese, 1; carbon, 0.15; and sulphur 0.01.

*Average Physical Properties:* Wrought Monel in the annealed, hot-rolled, cold-drawn, and hard temper cold-rolled conditions exhibits yield strengths (0.2 per cent offset) of 35,000, 50,000, 80,000, and 100,000 pounds per square inch, respectively; tensile strengths of 75,000, 90,000, 100,000, and 110,000 pounds per square inch, respectively;

elongations in 2 inches of 40, 35, 25, and 5 per cent, respectively; and Brinell hardnesses of 125, 150, 190, and 240, respectively.

**“R” Monel.**—This free-cutting, corrosion resistant alloy is used for automatic screw machine products such as bolts, screws and precision parts.

*Approximate Composition:* Nickel, 67; copper, 30; iron, 1.4; silicon, 0.05; manganese, 1; carbon, 0.15; and sulphur, 0.035.

*Average Physical Properties:* In the hot-rolled and cold-drawn conditions this alloy exhibits yield strengths (0.2 per cent offset) of 45,000 and 75,000 pounds per square inch, respectively; tensile strengths of 85,000 and 90,000 pounds per square inch, respectively; elongations in 2 inches of 35, and 25 per cent, respectively; and Brinell hardnesses of 145 and 180, respectively.

**“K” Monel.**—This strong and hard alloy, comparable to heat-treated alloy steel, is age-hardenable, non-magnetic and has low-sparking properties. It is used for corrosive applications where the material is to be machined or formed, then age hardened. Pump and valve parts, scrapers, and instrument parts are made from this alloy.

*Approximate Composition:* Nickel, 66; copper, 29; iron, 0.9; aluminum, 2.75; silicon, 0.5; manganese, 0.75; carbon, 0.15; and sulphur, 0.005.

*Average Physical Properties:* In the hot-rolled, hot-rolled and age-hardened, cold-drawn, and cold-drawn and age-hardened conditions the alloy exhibits yield strengths (0.2 per cent offset) of 45,000, 110,000, 85,000, and 115,000 pounds per square inch, respectively; tensile strengths of 100,000, 150,000, 115,000, and 155,000 pounds per square inch, respectively; elongations in 2 inches of 40, 25, 25, and 20 per cent, respectively; and Brinell hardnesses of 160, 280, 210, and 290, respectively.

**“KR” Monel.**—This strong, hard, age-hardenable and non-magnetic alloy is more readily machinable than “K” Monel. It is used for making valve stems, small parts for pumps, and screw machine products requiring an age-hardening material that is corrosion-resistant.

*Approximate Composition:* Nickel, 66; copper, 29; iron, 0.9; aluminum, 2.75; silicon, 0.5; manganese, 0.75; carbon, 0.28; and sulphur, 0.005.

*Average Physical Properties:* Essentially the same as “K” Monel.

**“S” Monel.**—This extra hard casting alloy is non-galling, corrosion-resisting, non-magnetic, age-hardenable and has low-sparking properties. It is used for gall-resistant pump and valve parts which have to withstand high temperatures, corrosive chemicals and severe abrasion.

*Approximate Composition:* Nickel, 63; copper, 30; iron, 2; silicon, 4; manganese, 0.75; carbon, 0.1; and sulphur, 0.015.

*Average Physical Properties:* In the annealed sand-cast, as-cast sand-cast, and age-hardened sand-cast conditions it exhibits yield strengths (0.2 per cent offset) of 70,000, 100,000, and 100,000 pounds per square inch, respectively; tensile strengths of 90,000, 130,000, and 130,000 pounds per square inch, respectively; elongations in 2 inches of and 3, 2, and 2 per cent, respectively; and Brinell hardnesses of 275, 320, and 350, respectively.

**“H” Monel.**—An extra hard casting alloy with good ductility, intermediate strength and hardness that is used for pumps, impellers and steam nozzles.

*Approximate Composition:* Nickel, 63; copper, 31; iron, 2; silicon, 3; manganese, 0.75; carbon, 0.1; and sulphur, 0.015.

*Average Physical Properties:* In the as-cast sand-cast condition this alloy exhibits a yield strength (0.2 per cent offset) of 60,000 pounds per square inch, a tensile strength of 100,000 pounds per square inch, an elongation in 2 inches of 15 per cent and a Brinell hardness of 210.

**Nichrome.**—“Nichrome” is the trade name of an alloy composed of nickel and chromium, which is practically non-corrosive and far superior to nickel in its ability to withstand high

temperatures. Its melting point is about 1550 degrees C. (about 2800 degrees F.). Nichrome shows a remarkable resistance to sulphuric and lactic acids. In general, nichrome is adapted for annealing and carburizing boxes, heating retorts of various kinds, conveyor chains subjected to high temperatures, valves and valve seats of internal combustion engines, molds, plungers and conveyors for use in the working of glass, wire baskets or receptacles of other form that must resist the action of acids, etc. Nichrome may be used as a substitute for other materials, especially where there is difficulty from oxidation, pitting of surfaces, corrosion, change of form, or lack of strength at high temperatures. It can be used in electrically-heated appliances and resistance elements. Large plates of this alloy are used by some manufacturers for containers and furnace parts, and when perforated, as screens for use in chemical sifting and ore roasting apparatus, for services where temperatures between 1700 degrees F. and 2200 degrees F. are encountered.

*Strength of Nichrome:* The strength of a nichrome casting, when cold, varies from 45,000 to 50,000 pounds per square inch. The ultimate strength at 200 degrees F. is 94,000 pounds per square inch; at 400 degrees F., 91,000 pounds per square inch; at 600 degrees F., 59,000 pounds per square inch; and at 800 degrees F., 32,000 pounds per square inch. At a temperature of 1800 degrees F., nichrome has a tensile strength of about 30,000 pounds per square inch, and it is tough and will bend considerably before breaking, even when heated red or white hot.

*Nichrome in Cast Iron:* Because of the irregularity of the castings, the numerous cores required, and the necessity for sound castings, gray iron with a high silicon content has been the best cast iron available to the automotive industry. Attempts have been made to alloy this metal in such a way that the strength and hardness would be increased, but considerable difficulty has been experienced in obtaining uniform results. Nickel has been added to the cupola with success, but in the case of automotive castings, where a large quantity of silicon is present, the nickel has combined with the silicon in forming large flakes of graphite, which, of course, softens the product. To offset this, chromium has also been added, but it has been uncertain just what the chromium content of the poured mixture should be, as a considerable amount of the chromium oxidizes.

Nichrome (Grade B) may be added to the ladle to obtain chromium and nickel in definite controllable amounts. The analysis of this nichrome is, approximately: Nickel, 60 per cent; chromium, 12 per cent; and iron, 24 per cent. It is claimed that the process produces castings of closer grain, greater hardness, greater resistance to abrasion, increased durability, improved machinability, and decreased brittleness. Nichrome-processed iron is suitable for casting internal-combustion engine cylinders; electrical equipment, where a control of the magnetic properties is desired; cast-iron cams; iron castings of thin sections where machinability and durability are factors; electrical resistance grids; pistons; piston-rings; and water, steam, gas, and other valves.

**Nickel Alloy for Resisting Acids.**—The resistance of nickel to acids is considerably increased by an addition of tantalum. Ordinarily from 5 to 10 per cent may be added, but the resistance increases with an increasing percentage of tantalum. An alloy of nickel with 30 per cent tantalum, for example, can be boiled in aqua regia or any other acid without being affected. The alloy is claimed to be tough, easily rolled, capable of being hammered or drawn into wire. The nickel loses its magnetic quality when alloyed with tantalum. The alloy can be heated in the open air at a high temperature without oxidizing. The method of producing the alloy consists in mixing the two metals in a powdered form, compressing them at high pressure, and bringing them to a high heat in a crucible or quartz tube in a vacuum. For general purposes, the alloy is too expensive.

**Duronze.**—An alloy of high resistance to wear and corrosion, composed of aluminum, copper, and silicon, with a tensile strength of 90,000 pounds per square inch. Developed for the manufacture of valve bushings for valves that must operate satisfactorily at high pressures and high temperatures without lubrication.

**Aluminum Alloys, Wrought, Sheet.**—*Physical Properties:* In the form of sheets, the tensile strength varies from 35,000 for soft temper to 62,000 pounds per square inch for heat-treated sheets, and the elongation in 2 inches from 12 to 18 per cent. The yield strength of a heat-treated sheet is about 40,000 pounds per square inch minimum.

**Plow-steel Wire Rope.**—The name “plow” steel originated in England and was applied to a strong grade of steel wire used in the construction of very strong ropes employed in the mechanical operation of plows. The name “plow” steel, however, has become a commercial trade name, and, applied to wire, simply means a high-grade open-hearth steel of a tensile strength in wire of from 200,000 to 260,000 pounds per square inch of sectional area. A strength of 200,000 pounds per square inch is obtained in wire about 0.200 inch in diameter. Plow steel when used for wire ropes has the advantage of combining lightness and great strength. It is a tough material, but not as pliable as crucible steel. The very highest grade of steel wire used for wire rope is made from special steels ranging in tensile strength in wire from 220,000 to 280,000 pounds per square inch of sectional area. This steel is especially useful when great strength, lightness, and abrasive resisting qualities are required.

**Type Metal.**—Antimony gives to metals the property of expansion on solidification, and hence, is used in type metal for casting type for the printing trades to insure completely filling the molds. Type metals are generally made with from 5 to 25 per cent of antimony, and with lead, tin and sometimes a small percentage of copper as the other alloying metals.

The compositions of a number of type metal alloys are as follows (figures given are percentages): lead 77.5, tin 6.5, antimony 16; lead 70, tin, 10, antimony 18, copper, 2; lead 63.2, tin 12, antimony 24, copper 0.8; lead 60.5, tin 14.5, antimony 24-25, copper 0.75; lead 60, tin 35, antimony 5; and lead 55.5, tin 40, antimony 4.5.

A high grade of type metal is composed of the following percentages: lead 50; tin 25; and antimony 25.

**Vanadium Steel.**—The two most marked characteristics of vanadium steel are its high tensile strength and its high elastic limit. Another equally important characteristic is its great resistance to shocks; vanadium steel is essentially a non-fatigue metal, and, therefore, does not become crystallized and break under repeated shocks like other steels. Tests of the various spring steels show that, when subjected to successive shocks for a considerable length of time, a crucible carbon-steel spring was broken by 125,000 alternations of the testing machine, while a chrome-vanadium steel spring withstood 5,000,000 alternations, remaining unbroken. Another characteristic of vanadium steel is its great ductility. Highly-tempered vanadium-steel springs may be bent sharply, in the cold state, to an angle of 90 degrees or more, and even straightened again, cold, without a sign of fracture; vanadium-steel shafts and axles may be twisted around several complete turns, in the cold state, without fracture. This property, combined with its great tensile strength, makes vanadium steel highly desirable for this class of work, as well as for gears which are subjected to heavy strains or shocks upon the teeth. Chromium gives to steel a brittle hardness which makes it very difficult to forge, machine, or work, but vanadium, when added to chrome-steel, reduces this brittle hardness to such an extent that it can be machined as readily as an 0.40-per-cent carbon steel, and it forges much more easily. Vanadium steels ordinarily contain from 0.16 to 0.25 per cent of vanadium. Steels of this composition are especially adapted for springs, car axles, gears subjected to severe service, and for all parts which must withstand constant vibration and varying stresses. Vanadium steels containing chromium are used for many automobile parts, particularly springs, axles, driving-shafts, and gears.

**Wood's Metal.**—The composition of Wood's metal, which is a so-called “fusible metal,” is as follows: 50 parts of bismuth, 25 parts of lead, 12.5 parts of tin and 12.5 parts of cadmium. The melting point of this alloy is from 66 to 71 degrees centigrade (151 to 160 degrees F. approximately).

**Lumber.**—Lumber is the product of the saw and planing mill not further manufactured than by sawing, resawing, and passing lengthwise through a standard planing machine, cross-cutting to length and working. When not in excess of one-quarter inch thickness and intended for use as veneering it is classified as veneer. According to the Simplified Practice Recommendations promulgated by the National Bureau of Standards, lumber is classified by its principal use as: yard lumber, factory and shop lumber, and structural lumber.

*Yard lumber* is defined as lumber of all sizes and patterns which is intended for general building purposes. Its grading is based on intended use and is applied to each piece without reference to size and length when graded and without consideration to further manufacture. As classified by size it includes: strips, which are yard lumber less than 2 inches thick and less than 8 inches wide; boards, which are yard lumber less than 2 inches thick but 8 inches or more wide; dimension, which includes all yard lumber except strips, boards and timbers; and timbers, which are yard lumber of 5 or more inches in the least dimension.

*Factory and shop lumber* is defined as lumber intended to be cut up for use in further manufacture. It is graded on the basis of the percentage of the area which will produce a limited number of cuttings of a specified, or of a given minimum, size and quality.

*Structural lumber* is defined as lumber that is 2 or more inches thick and 4 or more inches wide, intended for use where working stresses are required. The grading of structural lumber is based on the strength of the piece and the use of the entire piece. As classified by size and use it includes *joists* and *planks*—lumber from 2 inches to but not including 5 inches thick, and 4 or more inches wide, of rectangular cross section and graded with respect to its strength in bending, when loaded either on the narrow face as joist or on the wide face as plank; *beams* and *stringers*—lumber of rectangular cross section 5 or more inches thick and 8 or more inches wide and graded with respect to its strength in bending when loaded on the narrow face; and *posts* and *timbers*—pieces of square or approximately square cross section 5 by 5 inches and larger and graded primarily for use as posts or columns carrying longitudinal load, but adapted to miscellaneous uses in which strength in bending is not especially important.

**Lumber, Manufactured.**—According to the Simplified Practice Recommendations promulgated by the National Bureau of Standards, lumber may be classified according to the extent which it is manufactured as:

*Rough lumber* which is lumber that is undressed as it comes from the saw.

*Surfaced lumber* which is lumber that is dressed by running it through a planer and may be surfaced on one or more sizes and edges.

*Worked lumber* which is lumber that has been run through a matching machine, sticker or molder and includes: *matched lumber* which has been worked to provide a close tongue-and-groove joint at the edges or, in the case of end-matched lumber, at the ends also; *ship-lapped lumber* which has been worked to provide a close rabbetted or lapped joint at the edges; and *patterned lumber* which has been shaped to a patterned or molded form.

**Lumber Water Content.**—The origin of lumber has a noticeable effect on its water content. Lumber or veneer (thin lumber produced usually by rotary cutting or flat slicing, sometimes by sawing), when produced from the log, contains a large proportion of water, ranging from 25 to 75 per cent of the total weight. One square foot (board measure, one inch thick) of gum lumber, weighing approximately five pounds when sawed, will be reduced to about three pounds when its water content of approximately one quart has been evaporated. Oak grown on a hillside may contain only a pint (approximately 1 lb.) and swamp gum may have from 2 to 4 pints of water per square foot, board measure. This water content of wood exists in two forms—free moisture and cell moisture. The former is readily evaporable in ordinary air drying, but the latter requires extensive air drying (several years) or artificial treatment in kilns. It is possible to use artificial means to remove the free moisture, but a simple air exposure is usually more economical.

## Dimensioning, Gaging, and Measuring

**Transfer Calipers.**—Calipers provided with an auxiliary arm which can be located so that the calipers may be opened or closed to the original setting, if required. Calipers of this type are generally used for inside measurements, and are employed for measuring recesses where it is necessary to move the caliper points in order to remove the calipers from the place where the measurement is taken.

**Wheatstone Bridge.**—The most generally used method for the measurement of the ohmic resistance of conductors is by the use of the *Wheatstone bridge*. In a simple form (See Fig. 1.) it comprises two resistance coils the ratio of the resistances of which is known, and a third, generally adjustable, resistance of known value. These are connected in circuit with the unknown resistance to be measured, a galvanometer, and a source of current, as in the diagram.

Fig. 1. Wheatstone Bridge

The adjustable resistance and the "bridge arms," if necessary, are adjusted until the galvanometer indicates no flow of current. The value of the unknown resistance is thus measured in terms of the known resistance and the known ratio of the bridge arms. In the diagram,  $R_1$ ,  $R_2$ ,  $R_3$ , and  $R_4$  are resistances;  $B$  a source of electromotive force and  $I_1$ ,  $I_2$ ,  $I_3$  and  $I_4$  currents through the resistances;  $G$  is a galvanometer. If the relation of the various resistances is such that no current flows through  $G$ , then  $I_1$  equals  $I_2$ , and  $I_3$  equals  $I_4$ ; also  $I_1R_1$  equals  $I_3R_3$ , and  $I_2R_2$  equals  $I_4R_4$ , there being no electromotive forces in the triangles  $R_1R_3G$  and  $R_2R_4G$ . It follows, therefore, that

$$\frac{I_1}{I_3} = \frac{R_3}{R_1}, \quad \text{and} \quad \frac{I_2}{I_4} = \frac{R_4}{R_2}$$

and hence, as

$$\frac{I_1}{I_3} = \frac{I_2}{I_4}, \quad \text{it follows that} \quad \frac{R_3}{R_1} = \frac{R_4}{R_2}$$

If one of these resistances,  $R_1$  for instance, is unknown, it may then be found through the equation:

$$R_1 = \frac{R_2 R_3}{R_4}$$

Wheatstone bridges are made in many forms. The three known resistances are made adjustable and are usually made of many spools of special resistance wire. The resistances are usually varied by short-circuiting a greater or smaller number of these spools.

### Tools and Tooling

**Rotary Files and Burs.**—Rotary files and burs are used with power-operated tools, such as flexible- or stationary-shaft machines, drilling machines, lathes, and portable electric or pneumatic tools, for abrading or smoothing metals and other materials. Corners can be broken and chamfered, burs and fins removed, holes and slots enlarged or elongated, and scale removed in die-sinking, metal patternmaking, mold finishing, toolmaking and casting operations.

The difference between rotary files and rotary burs, as defined by most companies, is that the former have teeth cut by hand with hammer and chisel, whereas the latter have teeth or flutes ground from the solid blank after hardening, or milled from the solid blank before hardening. (At least one company, however prefers to differentiate the two by use and size: The larger-sized general purpose tools with  $\frac{1}{4}$ -inch shanks, whether hand cut or ground, are referred to as rotary files; the smaller shanked  $\frac{1}{8}$ -inch – and correspondingly smaller-headed tools used by diesinkers and jewelers are referred to as burs.) Rotary files are made from high-speed steel and rotary burs from high-speed steel or cemented carbide in various cuts such as double extra coarse, extra coarse or rough, coarse or standard, medium, fine, and smooth. Standard shanks are  $\frac{1}{4}$  inch in diameter.

There is very little difference in the efficiency of rotary files or burs when used in electric tools and when used in air tools, provided the speeds have been reasonably well selected. Flexible-shaft and other machines used as a source of power for these tools have a limited number of speeds which govern the revolutions per minute at which the tools can be operated.

The carbide bur may be used on hard or soft materials with equally good results. The principal difference in construction of the carbide bur is that its teeth or flutes are provided with negative rather than a radial rake. Carbide burs are relatively brittle and must be treated more carefully than ordinary burs. They should be kept cutting freely, in order to prevent too much pressure, which might result in crumbling of the cutting edges.

At the same speeds, both high-speed steel and carbide burs remove approximately the same amount of metal. However, when carbide burs are used at their most efficient speeds, the rate of stock removal may be as much as four times that of ordinary burs. It has been demonstrated that a carbide bur will last up to 100 times as long as a high-speed steel bur of corresponding size and shape.

**Tooth-rest for Cutter Grinding.**—A tooth-rest is used to support a cutter while grinding the teeth. For grinding a cylindrical cutter having helical or "spiral" teeth, the tooth-rest must remain in a fixed position relative to the grinding wheel. The tooth being ground will then slide over the tooth-rest, thus causing the cutter to turn as it moves longitudinally, so that the edge of the helical tooth is ground to a uniform distance from the center, throughout its length. For grinding a straight-fluted cutter, it is also preferable to have the tooth-rest in a fixed position relative to the wheel, unless the cutter is quite narrow, because any warping of the cutter in hardening will result in inaccurate grinding, if the toothrest moves with the work. The tooth-rest should be placed as close to the cutting edge of the cutter as is practicable, and bear against the face of the tooth being ground.

### Machining Operations

**Feed Rate on Machine Tools.**— The rate of feed as applied to machine tools in general, usually indicates (1) the movement of a tool per work revolution, (2) the movement of a tool per tool revolution, (3) or the movement of the work per tool revolution.

*Rate of Feed in Turning:* The term "feed" as applied to a lathe indicates the distance that the tool moves during each revolution of the work. There are two ways of expressing the rate of feed. One is to give the actual tool movement per work revolution in thousandths of an inch. For example, the range of feeds may be given as 0.002 to 0.125 inch. This is the usual method. Another way of indicating a feed range is to give the number of cuts per inch or the number of ridges that would be left by a pointed tool after turning a length of one inch. For example, the feed range might be given as 8 to 400. In connection with turning and other lathe operations, the feed is regulated to suit the kind of material, depth of cut, and in some cases the finish desired.

*Rate of Feed in Milling:* The feed rate of milling indicates the movement of the work per cutter revolution.

*Rate of Feed in Drilling:* The rate of feed on drilling machines ordinarily indicates the feeding movement of the drill per drill revolution.

*Rate of Feed in Planing:* On planers, the rate of feed represents the tool movement per cutting stroke. On shapers, which are also machines of the planing type, the rate of feed represents the work movement per cutting stroke.

*Rate of Feed on Gear Hobbing:* The feed rate of a gear hobbing machine represents the feeding movement of the hob per revolution of the gear being hobbled.

*Feed on Grinding Machines:* The traversing movement in grinding is equivalent to the feeding movement on other types of machine tools and represents either the axial movement of the work per work revolution or the traversing movement of the wheel per work revolution, depending upon the design of the machine.

**Billet.**— A "billet," as the term is applied in rolling mill practice, is square or round in section and from 1½ inches in diameter or square to almost 6 inches in diameter or square. Rolling mills used to prepare the ingot for the forming mills are termed "blooming mills," "billet mills," etc.

**Milling Machines, Lincoln Type.**—The well-known Lincoln type of milling machine is named after George S. Lincoln of the firm then known as George S. Lincoln & Co., Hartford, Conn. Mr. Lincoln, however, did not originate this type but he introduced an improved design. Milling machines constructed along the same general lines had previously been built by the Phoenix Iron Works of Hartford, Conn., and also by Robbins & Lawrence Co., of Windsor, Vt. Milling machines of this class are intended especially for manufacturing and are not adapted to a great variety of milling operations, but are designed for machining large numbers of duplicate parts. Some milling machines which are designed along the same lines as the Lincoln type are referred to as the *manufacturing type*. The distinguishing features of the Lincoln type are as follows: The work table, instead of being carried by an adjustable knee, is mounted on the solid bed of the machine and the outer arbor support is also attached directly to the bed. This construction gives a very rigid support both for the work and the cutter. The work is usually held in a fixture or vise attached to the table, and the milling is done as the table feeds longitudinally. The table is not adjustable vertically but the spindle head and spindles can be raised or lowered as may be required.

**Saddle.**—A machine tool saddle is a slide which is mounted upon the ways of a bed, cross-rail, arm, or other guiding surfaces, and the saddle metal-cutting tools or a work-holding table. On holding either metal-cutting tools or a work-holding table. On a knee-type milling machine the saddle is that part which slides upon the knee and which supports the work-holding table. The saddle of a planer or boring mill is mounted upon the cross-rail

and supports the tool-holding slide. The saddle of a lathe is that part of a carriage which slide. The saddle of a lathe is that part of a carriage which slides directly upon the lathe bed and supports the cross-slide.

**Cold Extrusion.**—In simplest terms, cold extrusion can be defined as the forcing of unheated metal to flow through a shape-forming die. It is a method of shaping metal by plastically deforming it under compression at room temperature while the metal is within a die cavity formed by the tools. The metal issues from the die in at least one direction with the desired cross-sectional contour, as permitted by the orifice created by the tools.

Cold extrusion is always performed at a temperature well below the recrystallization temperature of the metal (about 1100 to 1300 degrees F. for steel) so that work-hardening always occurs. In hot extrusion, recrystallization eliminates the effects of work-hardening, unless rapid cooling of the extrusion prevents recrystallization from being completed.

Extrusion differs from other processes, such as drawing, in that the metal is always being pushed under compression and never pulled in tension. As a result, the material suffers much less from cracking. While coining is closely related to extrusion, it differs in that metal is completely confined in the die cavity instead of being forced through openings in the die. Some forging operations combine both coining and extrusion.

The pressure of the punch against the metal in an open die, and the resultant shaped part obtained by displacing the metal along paths of least resistance through an orifice formed between the punch and die, permits considerably higher deformation rates without tearing and large changes in the shape. Extrusion is characterized by a thorough kneading of the material. The cross-sectional shape of the part will not change due to expansion or contraction as it leaves the tool orifice. The term "cold extrusion" is not too descriptive and is not universally accepted. Other names for the same process include impact extrusion, extrusion-forging, cold forging, extrusion pressing, and heavy cold forming. Impact extrusion, however, is more frequently used to describe the production of non-ferrous parts, such as collapsible tubes and other components, while cold extrusion seems to be preferred by manufacturers of steel parts. In Germany, the practice is called *Kaltspritzen*—a literal translation of which is "cold-squirting."

One probable reason for not using impact extrusion in referring to the cold extrusion of steel is that the term implies plastic deformation by striking the metal an impact blow. Actually, the metal must be pushed through the die orifice, with pressure required over a definite period of time. One disadvantage of the terminology "cold extrusion" is the possible confusion with the older, more conventional direct extrusion process in which billets of hot metal are placed in a cylinder and pushed by a ram through a die (usually in a large, horizontal hydraulic press) to form rods, bars, tubes, or irregular shapes of considerable length.

Another possible disadvantage is the connotation of the word "cold." While the process is started with blanks, slugs, tubular sections, or pre-formed cups at room temperature, the internal, frictional resistance of the metal to plastic flow raises the surface temperature of the part to 400 degrees F. or more, and the internal temperature even higher (depending on the severity of the operation). These are still below the recrystallization temperature and the extrusions retain the advantages of improved physical properties resulting from the cold working.

**Transfer Machines.**—These specialized machine tools are used to perform various machining operations on parts or parts in fixtures as the parts are moved along on an automatic conveyor which is part of the machine tool set-up. In a set-up, the parts can move in a straight line from their entry point to their exit point, or the setup may be constructed in a U-shape so that the parts are expelled near where they start.

## Fasteners

**Stove Bolt.**— This bolt has been so named because of its use in stove building. It is made in a number of different forms, either with a round button, or flat countersunk head, the head having a slot for a screwdriver and the threaded end being provided with a square or hexagon nut.

**Flattening Test.**— This term as applied to tubing refers to a method of testing a section of tubing by flattening it until the inside walls are parallel and separated by a given distance—usually equal to three times the wall thickness for seamless tubes and five times the wall thickness for lap-welded tubes. Boiler tubes subjected to this test should show no cracks or flaws. The flattening test applied to rivets, consists in flattening a rivet head while hot to a diameter equal to  $2\frac{1}{2}$  times the diameter of the shank or body of the rivet. Good rivet steel must not crack at the edges of the flattened head.

**Rivets, Cold Formed.**— In permanently assembling various Light parts, it is often possible to greatly reduce the cost and yet secure sufficient strength by cold forming in an assembling die, the rivet or rivets as an integral part of one of the assembled sections. Figures 1a, 1b, and 1c illustrate how a steel spring is cold riveted to the heavier section. Plain round punches descend and form the rivets by forcing metal down through the holes in the spring (see Fig. 1b); the metal at the edge is then turned back by the die as shown in Fig. 1c, thus completing the riveting at one stroke of the press. In this particular case, about sixty assemblies per minute are obtained.

*Embossed Dowels and Hubs:* When dowel-pins are required to insure the accurate location of parts relative to each other, small projections or bosses may be formed directly on many die-made products, the projection being an integral part of the work and serving as a dowel-pin. Figure 1d illustrates how the dowel is formed. The method may be described as a partial punching operation, as a punch penetrate about one-half the stock thickness and forces the boss into a pocket in the die which controls the diameter and compresses the metal, thus forming a stronger projection than would be obtained otherwise. The height  $h$  of the dowel or boss should not exceed one-half of the dowel diameter  $d$  and  $h$ . should not exceed one-half of the stock thickness  $t$ . This is a practical rule which may be applied either to steel or non-ferrous metals, such as brass.

Fig. 1b.

Fig. 1c.

Fig. 1d.

**Expansion Bolt.**—When a through bolt cannot be used for attaching a pipe hanger, bracket, or other part, to a wall or ceiling of brick or concrete, what are known as *expansion bolts* are often used. The body of an expansion bolt is divided and the arrangement is such that, when the head of the bolt is turned, the sections forming the body of the bolt are forced outward and against the wall of the hole which has been drilled into the brick, concrete, or stone, as the case may be. Bolts of this type are made in quite a variety of designs. The nominal size represents the diameter of the bolt proper and not the diameter of the casing or expansion member.

Fig. 2. Expansion Bolt

**Washers.**—Plain washers are made in standard sizes to suit standard screw threads, bolts and screws. The manufacturers' regular standard, adopted in 1935, is for bolt sizes ranging from  $\frac{1}{4}$  inch up to 3 inches, inclusive. There is also an S.A.E. standard for plain washers. This includes screw and bolt sizes ranging from No. 2 machine screw up to, and including,  $1\frac{1}{2}$ -inch bolts. These washers are somewhat smaller than the manufacturers' standard and also have smaller inside diameters or clearance spaces between the bolt and washer.

### Threads and Threading

**History of Briggs Pipe Thread (NPT).**—The USA (American) Standard for Pipe Threads, originally known as the Briggs Standard, was formulated by Mr. Robert Briggs. For several years around 1862 Mr. Briggs was superintendent of the Pascal Iron Works of Morris, Tasker & Company, Philadelphia, Pa., and later engineering editor of the "Journal" of the Franklin Institute. After his death on July 24, 1882, a paper by Mr. Briggs containing detailed information regarding American pipe and pipe thread practice, as developed by him when superintendent of the Pascal Iron Works, was read before the Institution of Civil Engineers of Great Britain. This is recorded in the Excerpt Minutes, Volume LXXI, Session 1882–1883, Part 1, of that Society.

It is of interest to note that the nominal sizes (diameters) of pipe ten (10) inches and under, and the pitches of the thread were for the most part established between 1820 and 1840.

By publishing his data, based on years of practice, Mr. Briggs was the means of establishing definite detail dimensions. The Briggs formula did not provide for the internal threads or gaging requirements for making taper threaded joints. It established only the external thread on pipe, with no tolerance.

In 1886 the large majority of American manufacturers threaded pipe to practically the Briggs Standard, and acting jointly with The American Society of Mechanical Engineers they adopted it as a standard practice that year, and master plug and ring gages were made.

Later at various conferences representatives of the manufacturers and the ASME established additional sizes, certain details of gaging, tolerances, special applications of the standard, and in addition tabulated the formulas and dimensions more completely than was done by Mr. Briggs.

Until the manufacturers adopted the Briggs thread in 1886, it seems that each manufacturer of necessity threaded his pipe and fittings according to his best judgment. After 1886 there was some attempt to work toward better interchangeability. However, the need for a better gaging practice resulted in the adoption of the thin ring gage and the truncation of the plug and ring gages to gage the flanks of the thread. This practice of threading fittings and couplings which provides threads to make up joints with a wrench was standardized about 1913.

In 1913 a Committee on the Standardization of Pipe Threads was organized for the purpose of re-editing and expanding the Briggs Standard. The American Gas Association and The American Society of Mechanical Engineers served as joint sponsors. After six years of work, this committee completed the revised standard for taper pipe thread which was published in the ASME "*Transactions*" of 1919, and was approved as an American Standard by the American Engineering Standards Committee, later named the American Standards Association in December 1919. It was the first standard to receive this designation under the ASA procedure, and was later published in pamphlet form.

In the years which followed, the need for a further revision of this American Standard became evident as well as the necessity of adding to it the recent developments in pipe threading practice. Accordingly, the Sectional Committee on the Standardization of Pipe Threads, B2, was organized in 1927 under the joint sponsorship of the A.G.A. and the ASME.

During the following 15 years, several meetings were held leading to approval by the members of the Sectional Committee, of the April 1941 draft. The revision was approved by the sponsors and ASA and published as an American Standard in October, 1942.

Shortly after publication of the 1942 standard, the Committee undertook preparation of a complete revision. The text and tables were rearranged and expanded to include Dryseal pipe threads, and an extensive appendix was added to provide additional data on the application of pipe threads and to record in abbreviated form the several special methods which were established for gaging some of the various applications of pipe threads.

The resulting proposal was approved by letter ballot of the Sectional Committee. Following its acceptance by the sponsor bodies, the draft was submitted to the American Standards Association and designated an American Standard on December 11, 1945.

At a subsequent meeting of the Sectional Committee it was agreed that for the convenience of users, the standards covering Dryseal pipe threads should be published under separate cover. Consequently, the section included in ASA B2.1-1945 on Dryseal pipe threads was deleted from the 1960 revision to that standard and used as a basis for the development of a separate proposal for Dryseal pipe threads. The text and tables were expanded to completely document the various series threads and gages, and appendices covering formulas, drilled hole sizes and special series threads were added. The  $E_j$  internal diameter and the  $L_j$  hand type engagements for the  $\frac{1}{8}$  and  $\frac{1}{4}$  inch sizes were revised to correct for a disproportionate number of threads for hand tight engagement. This proposal was approved by letter ballot vote of the Sectional Committee and submitted to the A.G.A. and the ASME. Following approval by the sponsor organizations, it was approved by the American Standards Association on April 29, 1960, and designated as ASA B2.1-1960, Pipe Threads (Except Dryseal).

The present revision of this standard constitutes a general updating. In line with their current policy, the A.G.A. has withdrawn sponsorship of this standard, while remaining active in the work of the standards committee. In compliance with the rules of the United States of America Standards Institute (formerly ASA) the previously designated Sectional Committees are now called Standards Committees.

Following approval by the Standards Committee B2 and the sponsor, ASME, the revision was approved by the United States of America Standards Institute on November 29, 1968.

**Lock-Nut Pipe Thread.**—The lock-nut pipe thread is a straight thread of the largest diameter which can be cut on a pipe. Its form is identical with that of the American or Briggs standard taper pipe thread. In general, “Go” gages only are required. These consist of a straight-threaded plug representing the minimum female lock-nut thread, and a straight-threaded ring representing the maximum male lock-nut thread. This thread is used only to hold parts together, or to retain a collar on the pipe. It is never used where a tight threaded joint is required.

**Thread Grinding.**—Thread grinding is applied both in the manufacture of duplicate parts and also in connection with precision thread work in the tool-room.

*Single-edged Grinding Wheel:* In grinding a thread, the general practice in the United States is to use a large grinding wheel (for external threads) having a diameter of possibly 18 to 20 inches. The width may be  $5/16$  or  $3/8$  inch. The face or edge of this comparatively narrow wheel is accurately formed to the cross-sectional shape of the thread to be ground. The thread is ground to the correct shape and lead by traversing it relative to the grinding wheel. This traversing movement, which is equivalent to the lead of the screw thread for each of its revolutions, is obtained from a lead-screw. On one type of thread grinder, this lead-screw is attached directly to the work-spindle and has the same lead as the screw thread to be ground; hence, there is a separate lead-screw for each different lead of thread to be ground. On another design of machine, the lead-screw arrangement is similar to that on a lathe in that the required lead on the ground thread is obtained by selection of the proper change gears. The grinding wheel may have a surface speed of 7000 feet a minute, whereas the work speed may range from 3 to 10 feet per minute. The grinding wheel is inclined to suit the helix angle of the thread and either right- or left-hand threads may be ground. Provision is also made for grinding multiple threads and for relieving taps and hobs. The wheel shape is accurately maintained by means of diamond truing tools. On one type of machine, this truing is done automatically and the grinding wheel is also adjusted automatically to compensate for whatever slight reduction in wheel size may result from the truing operation.

An internal thread may also be ground with a single-edged wheel. The operation is the same in principle as external thread grinding. The single-edged wheel is used whenever the highest precision is required, grinding the work either from the solid or as a finishing operation.

*Grinding “from the Solid”:* On some classes of work, the entire thread is formed by grinding “from the solid,” especially if the time required is less than would be needed for a rough thread-cutting operation followed by finish-grinding after hardening. Grinding threads from the solid is applied to the finer pitches. In some plants, threads with pitches up to about  $1/16$  inch are always ground by this method.

*Multi-edged Grinding Wheel:* An entire screw thread, if not too long, may be ground completely in one revolution by using a multi-edged type of grinding wheel. The face of this wheel is formed of a series of annular thread-shaped ridges so that it is practically a number of wheels combined in one. The principle is the same as that of milling screw threads by the multiple-cutter method. If the length of the thread to be ground is less than the width of the wheel, it is possible to complete the grinding in practically one work revolution as in thread milling. A grinding wheel having a width of, say,  $2\frac{1}{2}$  inches, is provided

with annual ridges or threads across its entire width. The wheel is fed in to the thread depth, and, while the work makes one single revolution, the wheel moves axially a distance equal to the thread lead along the face of the work. Most threads which require grinding are not longer than the width of the wheel; hence, the thread is completed by one turn of the work.

If the thread is longer than the wheel width, one method is to grind part of the thread and then shift the wheel axially one or more times for grinding the remaining part. For example, with a wheel  $2\frac{1}{2}$  inches in width, a thread approximately 12 inches long might be ground in five successive steps. A second method is that of using a multi-edged tapering wheel which is fed axially along the work. The taper is to distribute the work of grinding over the different edges or ridges as the wheel feeds along.

**Hand Chaser.**—A hand chaser is a type of threading tool used either for cutting or chasing external or internal threads. The tool is supported upon a rest and is guided by the hand; it is used mainly on brass work, for slightly reducing the size of a thread that has been cut either by a die or threading tool. A hand chaser may also be used for truing up battered threads in repair work and for similar purposes.

**Thread-Cutting Methods.**—The two general methods of forming screw threads may be defined as the cutting method and the rolling or displacement method. The cutting methods as applied to external threads are briefly as follows:

1) By taking a number of successive cuts with a single-point tool that is traversed along the part to be threaded at a rate per revolution of the work depending upon the lead of the thread. (Common method of cutting screw threads in the engine lathe.)

2) By taking successive cuts with a multiple-point tool or chaser of the type used to some extent in conjunction with the engine lathe and on lathes of the Fox or monitor types.

3) By using a tool of the die class, which usually has four or more multiple-point cutting edges or chasers and generally finishes the thread in one cut or passage of the tool.

4) By a single rotating milling cutter, which forms the thread groove as either the cutter or the work is traversed axially at a rate depending upon the thread lead.

5) By a multiple rotating milling cutter which completes a thread in approximately one revolution of the work.

6) By a multiple rotating cutter which also has a planetary rotating movement about the work which is held stationary. See Planamilling and Planathreading.

7) By a grinding wheel having its edge shaped to conform to the groove of the screw thread.

8) By a multi-edged grinding wheel which, within certain limits as to thread length, will grind the complete thread in practically one revolution of the work.

Internal screw threads, or those in holes, may or may not be produced by the same general method that is applied to external work. There are three commercial methods of importance, namely:

1) By the use of a single-point traversing tool in the engine lathe or a multiple-point chaser in some cases.

2) By means of a tap which, in machine tapping, usually finishes the thread in one cut or passage of the tool.

3) By a rotating milling cutter of either the single or the multiple type.

Dies operated by hand are frequently used for small and medium-sized parts, especially when accuracy as to the lead of the thread and its relation to the screw axis is not essential and comparatively few parts need to be threaded at a time. When a large number of pieces must be threaded, power-driven machines equipped with dies are commonly employed. If the operation is simply that of threading the ends of bolts, studs, rods, etc., a "bolt cutter" would generally be used, but if cutting the thread were only one of several other operations necessary to complete the work, the thread would probably be cut in the same machine performing the additional operations. For instance, parts are threaded in turret lathes and automatic screw machines by means of dies and in conjunction with other operations. When

screws are required which must be accurate as to the pitch or lead of the thread, and be true relative to the axis of the work, a lathe is generally used; lathes are also employed, ordinarily, when the threaded part is comparatively long and large in diameter. Many threads which formerly were cut in the lathe are now produced by the milling process in special thread-milling machines. The method often depends upon the equipment at hand and the number of parts to be threaded. Very precise threads may be produced by grinding.

**Taps.**—A tap is an internal thread-cutting tool having teeth which conform to the shape of the thread. Taps may be classified according to the kind of thread with which they are provided, as U. S. Standard thread taps, square thread taps, and Acme thread taps, etc. The most important classification of taps, however, is according to their use.

*Hand taps:* as the name implies, are intended primarily for tapping holes by hand but are often used in machines. All taps used by hand are not termed “hand” taps as there are many special taps used by hand which are known by specific names.

*Tapper taps:* are used for tapping nuts in tapping machines. They are provided with a long chamfered part on the end of the threaded portion, and a long shank.

*Machine nut taps:* are also used for tapping nuts in tapping machines. This type is designed for more severe duty than the tapper tap and is especially adapted for tapping holes in materials of tough structure. Machine nut taps are chamfered and relieved in a different manner from tapper taps.

*Machine screw taps:* may be either hand taps or machine nut taps, but are known by the name “machine screw tap,” because they constitute a class of special taps used for tapping holes for standard machine screw sizes.

*Screw machine taps:* for tapping in the screw machine are provided with shanks fitting either the turret holes of the machine or bushings inserted in these holes. As these taps ordinarily cut threads down to the bottom of the hole, they are provided with a very short chamfer.

*Pulley taps:* are simply a special type of taps used for tapping holes which cannot be reached by ordinary hand taps, as, for instance, the set-screw or oil-cup holes in the hubs of pulleys. They are simply hand taps with a very long shank.

*Die taps:* also known as long taper die taps, are used for cutting the thread in a die in a single operation from the blank, and are intended to be followed by a sizing hob tap. Die taps are similar to machine nut taps.

*Hob taps:* are used for sizing dies. They are intended only for the final finishing of the thread and can only take a slight chip. They are made to the same dimensions as regular hand taps, but fluted differently.

*Pipe taps:* are used for tapping holes for standard pipe sizes. These taps are taper taps. There is also a special form of pipe tap termed *straight* pipe tap, which is simply a hand corresponding in diameter and number of threads per inch to standard pipe sizes.

*Pipe hobs:* are similar to pipe taps, but are intended only for sizing pipe dies after the thread has been cut either by a pipe tap or in a lathe.

*Boiler taps:* are used in steam boiler work where a steam-tight fit is required. They are made either straight or tapered. The straight boiler tap is practically only a hand tap.

*Mud or washout taps:* are used in boiler or locomotive work. They are sometimes also called arch pipe taps. Patch bolt taps are used in boiler and locomotive work. These are taper taps similar to mud or washout taps.

*Staybolt taps:* are used on locomotive boiler work. They are usually provided with a reamer portion preceding the threaded part, and have generally a long threaded portion and a long shank. A special form of staybolt tap is known as a spindle staybolt tap which revolves on a central spindle with a taper guide on the front end.

*Stove-bolt taps* and *carriage-bolt taps* are taps which have derived their names from the uses to which they were originally put. These taps have special forms of threads.

*Bit-brace taps* differ in no essential from the hand tap on the threaded portion, but are provided with a special shank for use in a bit brace.

*Blacksmiths' taper taps* are made for general rough threading and are used especially in repair work, where an accurately fitting thread is not required.

*Inserted cutter taps* may belong to any of the classes mentioned and constitute a separate type only because they are not solid, but have the cutting teeth on blades inserted and held rigidly in a tap body.

### Machine Elements

**Nordberg Key.**—This is a taper key of circular cross-section. This type of key may be used for attaching hand wheels to their shafts or for other similar light work requiring an inexpensive type of key. The Nordberg key has a taper of 1/16 inch per foot. The center of the key hole is located at the joint line between the shaft and hub. A small hole may be drilled first to prevent the larger drill from crowding over into the cast-iron hub. A general rule for determining the size of the key is to make the large key diameter equal to one-fourth the shaft diameter.

**Woodruff Keys.**—In the Woodruff key system, half-circular disks of steel are used as keys, the half-circular side of the key being inserted into the keyseat. Part of the key projects and enters into a keyway in the part to be keyed to the shaft in the ordinary way. The advantage of this method of keys is that the keyway is easily milled by simply sinking a milling cutter, of the same diameter as the diameter of the stock from which the keys are made, into the shaft. The keys are also very cheaply made, as they are simply cut off from round bar stock and milled apart in the center. Dimensions of Woodruff keys are given in engineering handbooks.

**Saddle Key.**—This form of key has parallel sides and is curved on its under side to fit the shaft. It is slightly tapered on top so that, when it is driven tightly in place, the shaft is held by frictional resistance. This key should be fitted so that it bears lightly on the sides and heavily between the shaft and hub throughout its entire length. As the drive with this type of key is not positive, it is only used where there is little power to transmit. It is an inexpensive method of keying, as the shaft does not need to be machined.

**Locomotive Development.**—The first steam locomotive which ever ran on rails was built in 1804 by Richard Trevithick, an Englishman, and the first one to be used on a commercial basis was built by Matthew Murray, another Englishman. In 1811, Blenkinsop of Leeds, had several locomotives built by Murray in order to operate a railway extending from Middletown Colliers to Leeds, a distance of three and one-half miles. Trevithick's impracticable design had a single cylinder only, but Murray used two cylinders which were utilized in driving the same shaft on which cranks were set at right angles an important arrangement common to all modern locomotives. A cog-wheel, or gear, meshing with a continuous rack laid along the road-bed was employed. These locomotives were used daily for years and were examined by George Stephenson when he began his work on locomotive development. Several years after the construction of Murray's locomotives Hedley and Stephenson demonstrated that the gear and rack method of propulsion was unnecessary, and that the frictional resistance of smooth drivers would supply adequate tractive power. Stephenson's name will always be associated with locomotive development owing to his accomplishments in perfecting the locomotive and in establishing it on a commercial basis. His first locomotive was tried on the Killingworth Railway in 1814. The first locomotive to be used in the United States was imported from England in 1829.

**Percentages of Radial and Thrust Loads.**—There are three types of bearing that are combined load carriers: First, the annular ball bearing, which is primarily designed for radial loads and has no angle of contact incorporated in its design, therefore having minimum thrust capacity (approximately 20 per cent of its radial capacity). Second, the one-direction angular contact bearing, which has a thrust capacity depending upon race design and the angle incorporated, which is generally made so that the thrust capacity is 100 per cent of the radial capacity. (This bearing, however, when used for combined loads, can

only be used in pairs, and must have a threaded or shim adjustment incorporated in the mounting design to allow for initial adjustment.) Third, the double angular type bearing which is really two of the previously mentioned bearings built as a self-contained unit. The functioning of this bearing is not dependent on any exterior adjustment, and the angle of contact is generally such that it will sustain approximately 150 per cent of its radial capacity as thrust.

**Roller Bearing.**—The load on roller bearings is supported by cylindrical or conical rollers interposed between two races, one race being mounted on the shaft and one other in the bearing proper. There are three principal designs of roller bearings. One is for straight radial loads, the lines of contact of the rollers with the races being parallel with the shaft axis, as shown by the left-hand diagram; another design is for combined radial and thrust loads (See Fig. 3b.). With this design, the rollers are tapering so that the lines of contact of the rollers with the races, and the axis of the rollers, will intersect, if extended, at the same point on the shaft axis. A third design is intended for thrust or axial loads exclusively. Bearings for radial loads may have solid rollers, or the hollow helically-wound type such as is used in the Hyatt bearing. Although anti-friction bearings have replaced a great many plain or sliding bearings, the trend is toward a much wider application, and evidently will include eventually the heaviest classes of service since modern anti-friction bearings not only greatly reduce friction losses, but lower maintenance and repair costs.

Fig. 3a. Bearing for Radial Load

Fig. 3b. Bearing for Radial and Thrust Loads

**Ball Bearing Lubrication.**—To obtain the full measure of efficiency and service from ball and roller bearing equipment, the kind and quality of the lubricant, as well as the system of applying it, must be adapted to the design of the bearing, the design of the machine, and the operating conditions.

*Operating Temperatures:* Under ordinary conditions the temperature of a bearing while running will be from 10 to 60 degrees F. above that of the room. If it exceeds 125 degrees F., ordinary greases will frequently prove unsatisfactory. They will tend to soften and flow continuously into the path of the rolling elements, causing a rise in the normal operating temperature due to the increased frictional resistance introduced. This may eventually result in the separation of the oil and soap base, with a complete loss of lubricating qualities. In some cases, greases developed for use at high temperatures may be employed. Care should be taken, however, to see that they meet all the requirements for adequate lubrication.

Mineral oil of proper physical and chemical properties is an ideal lubricant for ball and roller bearings when the housing is designed to control the quantity entering the bearing and to prevent leakage and protect the bearing from the entrance of foreign matter. A ball or roller bearing should not be subjected to temperature in excess of 300 degrees F., because of the danger of drawing the temper of the hardened steel races and balls.

*Quantity of Lubricant Required:* In no case does a ball or roller bearing require a large quantity of lubricant. On the contrary, a few drops of oil, or a corresponding amount of grease, properly distributed over the running surfaces of the bearing, will provide satisfactory lubrication for a considerable period of time. A large volume of lubricant within a

bearing will usually result in high operating temperatures, due to the working or churning of the lubricant by the rolling elements and retainer. This may seriously impair the useful life of the lubricant through oxidation or sludging of the oil or actual disintegration of greases.

*Use of Grease:* If grease is used, the housing should not be kept more than one-fourth to one-half full of the lubricant. Unlike oil, there is no way of controlling with any degree of exactness the quantity of grease in a housing, and greater care must therefore be taken to avoid overloading. A bearing that runs at too high a temperature will often return to normal temperature if some of the lubricating grease is removed.

Grease is being used successfully for the lubrication of ball bearings at high speeds, but great care is necessary, both from the standpoint of housing design and selection of the lubricant, in order to obtain satisfactory results. Any system employed must be designed to feed only a limited amount of grease to the bearing. For the average application at operating speeds up to 3600 revolutions per minute, a grease of soft consistency, such as a No. 2 grease, will usually be found satisfactory, provided it is suitable in other respects. Hard greases, such as No. 3, may be used if the grease is to serve as a packing medium around the shaft to prevent the entrance of dirt, water, or other corrosive substances.

*Sealed Bearings:* Bearings for certain classes of service must operate over long periods without relubrication, as, for example, a motor installation on an airplane beacon; hence the efforts of ball-bearing manufacturers to produce bearings so completely sealed as to enable them to retain their original charge of grease for many months. In appreciation of this requirement, the petroleum industry has developed lubricants that will maintain lubrication for a long period without change in structure, homogeneity, lubricating properties, or leakage.

**Engine Governors.**—Governors may be of a purely centrifugal type such as the fly-ball or pendulum design previously referred to, or the principle of inertia may be introduced to secure better speed regulation. Thus, there are two general classes of governors known as centrifugal and inertia governors. The method of utilizing the motion of the governing element for regulating the speed varies; as applied to steam engines, there is the general type of governor which controls the speed by operating a throttling valve which increases or diminishes the amount of steam admitted to the steam-chest, and another general type which regulates the speed by changing the point of cut-off and consequently the amount of expansion in the cylinders.

In the design of governors, the sensitiveness, effort, and stability of the governor are important factors. The sensitiveness of a fly-ball governor is indicated by the amount that the governing sleeve is displaced for a given change in speed, the displacement being relatively large for a given speed change if the governor is sensitive.

The term "effort" as applied to a governor relates to the energy it is capable of exerting upon the governing mechanism. Thus, in the case of a fly-ball governor, the effort indicates the energy exerted on the sleeve while the governor speed is increasing or diminishing. If the energy stored in a revolving governor is small, its sensitiveness will be reduced, because a larger speed change is necessary to obtain the power for operating the governing mechanism than would be required with a governor which exerts greater energy for a given speed change.

When a governor occupies a definite position of equilibrium for any speed within the range of speeds controlled by the governor, it is said to be "stable." If the load on an engine having a fly-ball governor is diminished, the balls of a stable governor will move outward to a new position as the speed increases, although there will usually be a temporary oscillating movement on each side of this new position, the oscillations gradually diminishing. If the governor were unstable (and therefore useless) the oscillations would increase until the limiting points were reached.

Fig. 1.

Fig. 2.

**Loaded or Weighted Fly-ball Governors.**—As the arms of a governor of the conical pendulum type swing outward toward the horizontal position as the result of increasing speed, the change in height  $h$  (see Fig. 1) is small for given changes in speed. For instance, if the speed is changed from 50 to 70 revolutions per minute, the difference between the values of  $h$  is nearly 7 inches, whereas if the speed changes from 200 to 300 revolutions per minute, the difference in height  $h$  for the two speeds is only about  $\frac{1}{2}$  inch. Hence, the simple pendulum governor is not suitable for the higher speeds, because then the movement which accompanies the speed changes is too small to secure proper regulation through the governing mechanism. Fly-ball governors are adapted for much higher speeds by loading them. The load may be in the form of a weight which surrounds the spindle, as illustrated by Fig. 1. This is known as a Porter governor.

In the following formula,  $w$  = the weight of one governor ball in pounds;  $c$  = the weight of the additional load;  $h$  = the height in feet indicated by the diagram, Fig. 1;  $n$  = speed of governor in revolutions per minute:

$$h = \frac{2933}{n^2} \times \frac{e + w}{w}$$

If the governor is constructed as indicated by the diagram Fig. 2, the height  $h$  is not measured from the points at which the arms or rods are suspended, but from the point where the axes of the rods intersect with the vertical center line. The outward movement of the balls may be resisted by a spring instead of a weight, as in the case of the Hartnell governor, which is known as a spring-loaded type.

**Sensitiveness and Stability of Governors.**—The sensitiveness of one governor may be compared with that of another by determining the *coefficient of speed variations*. If  $C$  = the coefficient of speed variations,  $M$  = maximum speed within limits of the governor action;  $M_1$  = minimum speed within limits of governor action;  $m$  = mean speed within these limits; then,

$$C = \frac{M - M_1}{m}$$

The minimum value of coefficient  $C$  necessary to obtain stability in a pendulum type of governor is given by the following formula in which  $y$  = distance the fly-balls move horizontally in feet;  $F$  = mean centrifugal force of fly-balls in pounds;  $H$  = indicated horsepower of engine;  $W$  = the weight of engine flywheel in pounds;  $S$  = revolutions per minute of main shaft;  $R$  = the flywheel radius in feet.

## ROPE SPLICING

$$C = 4000 \sqrt[3]{\frac{xy}{F}} \times 8 \sqrt[4]{\frac{H^2}{S^4 R^4 W^2}}$$

The factor  $x$  in this formula represents that weight which would be equivalent to the weights of the various moving parts, if it were centered at a point corresponding to the center of gravity of the fly-balls. To determine the value of  $x$ , first determine the weights of the different moving parts of the governor, such as the balls, the central weight or load (in the case of a Porter governor), the sleeve, etc.; multiply the weight of each part by the square of the distance it moves from one position to the other; add the various products thus obtained, and divide the total sum by the square of the corresponding movement of the fly-balls at right angles to the governor spindle.

**Shaft Governors.**—Shaft governors are so named because the governing mechanism is carried by the main shaft and is commonly attached in some way to the flywheel. One type is so arranged that, in the case of a steam engine, the action of centrifugal force on a pivoted and weighted lever, to which a spring is attached, changes the position of the eccentric which operates the slide valve, thus increasing or decreasing the valve travel and changing the point of cut-off. Another type is so designed that the inertia of a pivoted “weight arm” accelerates the governing action by acting in conjunction with the effect of centrifugal force, thus increasing the sensitiveness of the governor. With the inertia governor, the effort or force needed to actuate the governing mechanism increases as the rate of velocity change increases; hence this type is adapted to engines liable to sudden load changes. When the load remains practically constant, the centrifugal type of shaft governor is often employed in preference to the inertia type. The design of these governors depends upon the arrangement of the governing mechanism and upon varying factors.

**Rope Splicing.**—Splicing is the operation when two pieces of rope are joined by unlaying the strands and weaving or intertwining the strands of one end with those of the other.

*Short Splice:* The first step in making a short splice is to unlay or untwist the strands at the end of each rope. After the ropes are placed together, as shown at A, Fig. 1a, the strands on one side, as shown at  $d$ ,  $e$ , and  $f$ , are either held together by the left hand or are fastened together with twine, in case the rope is too large to be held by the hand. The splicing operation is started by taking one of the strands as at  $a$ , and passing it across or over the adjacent strand  $d$  and then under the next strand  $e$ , after having made an opening beneath strand  $e$ . The strands  $b$  and  $c$  are next treated in the same manner, first one and then the other being passed over its adjoining strand and then under the next successive one. These same operations are then repeated for the strands  $d$ ,  $e$  and  $f$  of the other rope. The splice will now appear as shown at B, Fig. 1b. In order to make it stronger and more secure, the projecting strands of each rope are again passed diagonally over the adjoining strands and under the next successive ones. The splice should then be subjected to a strong pull, in order to tighten the strands and make them more compact. The projecting ends of the strands should then be cut off, thus completing the splice as shown at C. For making the openings beneath the strands on the rope, what is known as a marlin spike is generally used. This is merely a tapering, pointed pin made of wood or iron.

Fig. 1a. Method of Making a Short Splice

Fig. 1b. Method of Making a Short Splice

Fig. 1c. Method of Making a Short Splice

**Long Splice:** When a rope has to pass through pulley blocks, or in case any increase in the size of the rope would be objectionable, the short splice is not suitable and the long splice should be employed. The diameter of a long splice is the same as that of the rope and, if the work is done carefully, the place where the ends are joined can scarcely be distinguished from the rest of the rope. The ends of each rope are first unlaied or untwisted the same as when making a short splice, but for a distance about three times as long. These ends are then placed together so that each strand lies between two strands of the other rope, the same as for a short splice. One of the strands is next unlaied and then a strand from the other rope is curled around into the groove thus made, as indicated at A Fig. 2a, strand a having been unlaied and strand b from the other rope end, put into its place. Care should be taken to twist strand b so that it will lie in its natural position into the groove previously occupied by strand a, as the neatness of the splice will depend partly upon the care with which this part of the work is done. This operation is then repeated in connection with strands c and d, strand c being unlaied and strand d twisted around to occupy the groove thus made. The splice will now be as shown at B, Fig. 2b, and the next step is that of disposing of the protruding ends of the strands. After these strands have been cut to about the length shown at B, two of the strands, as at a and b, are first reduced in size by removing about one-third of the fiber; these ends are then tied by an overhand knot as shown at e. After tightening this knot, the protruding ends may be disposed of the same as when making a short splice, or by passing them over the adjoining strand and through the rope, under the next one. By gradually removing the fiber each time the end is passed across an adjoining strand, the enlargement of the rope at this point may be made very slight and scarcely noticeable. The strands f and g which remain in their original positions in the center of the splice, and the strands c and d are disposed of in a similar manner, thus completing the splice as shown at Fig. 2c.

Fig. 2a. How a Long Splice is Made

Fig. 2b. How a Long Splice is Made

Fig. 2c. How a Long Splice is Made

*Eye-Splice:* When a loop is formed at the end of a rope by splicing the free end to the main or standing part of the rope, this is known as an *eye-splice*. The end of the rope is first unlaidd about as far as it would be for making a short splice. After bending the end around to form a loop of the required size, the middle strand *a*, Fig. 3a, is tucked under a strand on the main part of the rope. The strand *b* is next inserted from the rear side under the strand on the main part which is just above the strand under which *a* was inserted. Since strand *b* is pushed under the strand on the main part from the rear side, it will come out at the point where strand *a* went in, as Fig. 3b. The third strand *c* is now passed over the strand under which strand *a* was inserted, and then under the next successive one, as Fig. 3c. These three strands are next pulled taut and then about one-third of the fiber should be cut from them; they are next tucked away by passing a strand over its adjoining one and under the next successive strand. Cutting away part of the fiber or yarns is to reduce the size of the splice and give it a neater appearance. By gradually thinning out the fiber, the over-lapping strands may be given a gradual taper, as Fig. 3d which shows the completed eye-splice.

<sup>a</sup>Table data are based on 1 inch = 25.4 mm, exactly. Inch to millimeter conversion values are exact. Whole number millimeter to inch conversions are rounded to 9 decimal places.

<sup>b</sup>Numbers with an overbar, repeat indefinitely after the last figure, for example 0.08 $\overline{33}$  = 0.08333...

### Numbers

Numbers are the basic instrumentation of computation. Calculations are made by operations of numbers. The whole numbers greater than zero are called natural numbers. The first ten numbers 0, 1, 2, 3, 4, 5, 6, 7, 8, 9 are called numerals. Numbers follow certain formulas. The following properties hold true:

*Associative law:*  $x + (y + z) = (x + y) + z$ ,  $x(yz) = (xy)z$

*Distributive law:*  $x(y + z) = xy + xz$

*Commutative law:*  $x + y = y + x$

*Identity law:*  $0 + x = x$ ,  $1x = x$

*Inverse law:*  $x - x = 0$ ,  $x/x = 1$

**Positive and Negative Numbers.**—The degrees on a thermometer scale extending upward from the zero point may be called *positive* and may be preceded by a plus sign; thus +5 degrees means 5 degrees above zero. The degrees below zero may be called *negative* and may be preceded by a minus sign; thus, -5 degrees means 5 degrees below zero. In the same way, the ordinary numbers 1, 2, 3, etc., which are larger than 0, are called positive numbers; but numbers can be conceived of as extending in the other direction from 0, numbers that, in fact, are less than 0, and these are called negative. As these numbers must be expressed by the same figures as the positive numbers they are designated by a minus sign placed before them, thus: (-3). A negative number should always be enclosed within parentheses whenever it is written in line with other numbers; for example:  $17 + (-13) - 3 \times (-0.76)$ .

Negative numbers are most commonly met with in the use of logarithms and natural trigonometric functions. The following rules govern calculations with negative numbers.

A negative number can be added to a positive number by subtracting its numerical value from the positive number.

*Example:*  $4 + (-3) = 4 - 3 = 1$

A negative number can be subtracted from a positive number by adding its numerical value to the positive number.

*Example:*  $4 - (-3) = 4 + 3 = 7$

A negative number can be added to a negative number by adding the numerical values and making the sum negative.

*Example:*  $(-4) + (-3) = -7$

A negative number can be subtracted from a larger negative number by subtracting the numerical values and making the difference negative.

*Example:*  $(-4) - (-3) = -1$

A negative number can be subtracted from a smaller negative number by subtracting the numerical values and making the difference positive.

*Example:*  $(-3) - (-4) = 1$

If in a subtraction the number to be subtracted is larger than the number from which it is to be subtracted, the calculation can be carried out by subtracting the smaller number from the larger, and indicating that the remainder is negative.

*Example:*  $3 - 5 = -(5 - 3) = -2$

When a positive number is to be multiplied or divided by a negative numbers, multiply or divide the numerical values as usual; the product or quotient, respectively, is negative. The same rule is true if a negative number is multiplied or divided by a positive number.

*Examples:*  $4 \times (-3) = -12$   $(-4) \times 3 = -12$

$15 \div (-3) = -5$   $(-15) \div 3 = -5$

When two negative numbers are to be multiplied by each other, the product is positive. When a negative number is divided by a negative number, the quotient is positive.

Examples:  $(-4) \times (-3) = 12$ ;  $(-4) \div (-3) = 1.333$

The two last rules are often expressed for memorizing as follows: "Equal signs make plus, unequal signs make minus."

**Sequence of Performing Arithmetic Operations.**—When several numbers or quantities in a formula are connected by signs indicating that additions, subtractions, multiplications, and divisions are to be made, the multiplications and divisions should be carried out first, in the sequence in which they appear, before the additions or subtractions are performed.

Example:

$$10 + 26 \times 7 - 2 = 10 + 182 - 2 = 190$$

$$18 \div 6 + 15 \times 3 = 3 + 45 = 48$$

$$12 + 14 \div 2 - 4 = 12 + 7 - 4 = 15$$

When it is required that certain additions and subtractions should precede multiplications and divisions, use is made of parentheses ( ) and brackets [ ]. These signs indicate that the calculation inside the parentheses or brackets should be carried out completely by itself before the remaining calculations are commenced. If one bracket is placed inside another, the one inside is first calculated.

Example:

$$(6 - 2) \times 5 + 8 = 4 \times 5 + 8 = 20 + 8 = 28$$

$$6 \times (4 + 7) \div 22 = 6 \times 11 \div 22 = 66 \div 22 = 3$$

$$2 + [10 \times 6(8 + 2) - 4] \times 2 = 2 + [10 \times 6 \times 10 - 4] \times 2$$

$$= 2 + [600 - 4] \times 2 = 2 + 596 \times 2 = 2 + 1192 = 1194$$

The parentheses are considered as a sign of multiplication; for example:

$$6(8 + 2) = 6 \times (8 + 2).$$

The line or bar between the numerator and denominator in a fractional expression is to be considered as a division sign. For example,

$$\frac{12 + 16 + 22}{10} = (12 + 16 + 22) \div 10 = 50 \div 10 = 5$$

In formulas, the multiplication sign ( $\times$ ) is often left out between symbols or letters, the values of which are to be multiplied. Thus,

$$AB = A \times B \quad \text{and} \quad \frac{ABC}{D} = (A \times B \times C) \div D$$

**Ratio and Proportion.**—The *ratio* between two quantities is the quotient obtained by dividing the first quantity by the second. For example, the ratio between 3 and 12 is  $\frac{1}{4}$ , and the ratio between 12 and 3 is 4. Ratio is generally indicated by the sign (:); thus, 12 : 3 indicates the ratio of 12 to 3.

A *reciprocal*, or *inverse* ratio, is the opposite of the original ratio. Thus, the inverse ratio of 5 : 7 is 7 : 5.

In a *compound* ratio, each term is the product of the corresponding terms in two or more simple ratios. Thus, when

$$8:2 = 4 \quad 9:3 = 3 \quad 10:5 = 2$$

then the compound ratio is

$$8 \times 9 \times 10 : 2 \times 3 \times 5 = 4 \times 3 \times 2$$

$$720:30 = 24$$

*Proportion* is the equality of ratios. Thus,

$$6:3 = 10:5 \quad \text{or} \quad 6:3::10:5$$

The first and last terms in a proportion are called the *extremes*; the second and third, the *means*. The product of the extremes is equal to the product of the means. Thus,

$$25:2 = 100:8 \quad \text{and} \quad 25 \times 8 = 2 \times 100$$

If three terms in a proportion are known, the remaining term may be found by the following rules:

The first term is equal to the product of the second and third terms, divided by the fourth. The second term is equal to the product of the first and fourth terms, divided by the third. The third term is equal to the product of the first and fourth terms, divided by the second. The fourth term is equal to the product of the second and third terms, divided by the first.

*Example:* Let  $x$  be the term to be found, then,

$$x : 12 = 3.5 : 21 \quad x = \frac{12 \times 3.5}{21} = \frac{42}{21} = 2$$

$$\frac{1}{4} : x = 14 : 42 \quad x = \frac{\frac{1}{4} \times 42}{14} = \frac{1}{4} \times 3 = \frac{3}{4}$$

$$5 : 9 = x : 63 \quad x = \frac{5 \times 63}{9} = \frac{315}{9} = 35$$

$$\frac{1}{4} : \frac{7}{8} = 4 : x \quad x = \frac{\frac{7}{8} \times 4}{\frac{1}{4}} = \frac{3\frac{1}{2}}{\frac{1}{4}} = 14$$

If the second and third terms are the same, that number is the *mean proportional* between the other two. Thus,  $8 : 4 = 4 : 2$ , and 4 is the mean proportional between 8 and 2. The mean proportional between two numbers may be found by multiplying the numbers together and extracting the square root of the product. Thus, the mean proportional between 3 and 12 is found as follows:

$$3 \times 12 = 36 \quad \text{and} \quad \sqrt{36} = 6$$

which is the mean proportional.

*Practical Examples Involving Simple Proportion:* If it takes 18 days to assemble 4 lathes, how long would it take to assemble 14 lathes?

Let the number of days to be found be  $x$ . Then write out the proportion as follows:

$$4:18 = 14:x$$

$$(\text{lathes} : \text{days} = \text{lathes} : \text{days})$$

Now find the fourth term by the rule given:

$$x = \frac{18 \times 14}{4} = 63 \text{ days}$$

Thirty-four linear feet of bar stock are required for the blanks for 100 clamping bolts. How many feet of stock would be required for 912 bolts?

Let  $x$  = total length of stock required for 912 bolts.

$$34:100 = x:912$$

$$(\text{feet} : \text{bolts} = \text{feet} : \text{bolts})$$

Then, the third term  $x = (34 \times 912)/100 = 310$  feet, approximately.

*Inverse Proportion:* In an inverse proportion, as one of the items involved *increases*, the corresponding item in the proportion *decreases*, or vice versa. For example, a factory employing 270 men completes a given number of typewriters weekly, the number of working hours being 44 per week. How many men would be required for the same production if the working hours were reduced to 40 per week?

The time per week is in an inverse proportion to the number of men employed; the shorter the time, the more men. The inverse proportion is written:

$$270 : x = 40 : 44$$

(men, 44-hour basis: men, 40-hour basis = time, 40-hour basis: time, 44-hour basis)  
Thus

$$\frac{270}{x} = \frac{40}{44} \quad \text{and} \quad x = \frac{270 \times 44}{40} = 297 \text{ men}$$

*Problems Involving Both Simple and Inverse Proportions:* If two groups of data are related both by direct (simple) and inverse proportions among the various quantities, then a simple mathematical relation that may be used in solving problems is as follows:

$$\begin{aligned} & \frac{\text{Product of all directly proportional items in first group}}{\text{Product of all inversely proportional items in first group}} \\ &= \frac{\text{Product of all directly proportional items in second group}}{\text{Product of all inversely proportional items in second group}} \end{aligned}$$

*Example:* If a man capable of turning 65 studs in a day of 10 hours is paid \$6.50 per hour, how much per hour ought a man be paid who turns 72 studs in a 9-hour day, if compensated in the same proportion?

The first group of data in this problem consists of the number of hours worked by the first man, his hourly wage, and the number of studs which he produces per day; the second group contains similar data for the second man except for his unknown hourly wage, which may be indicated by  $x$ .

The labor cost per stud, as may be seen, is directly proportional to the number of hours worked and the hourly wage. These quantities, therefore, are used in the numerators of the fractions in the formula. The labor cost per stud is inversely proportional to the number of studs produced per day. (The greater the number of studs produced in a given time the less the cost per stud.) The numbers of studs per day, therefore, are placed in the denominators of the fractions in the formula. Thus,

$$\begin{aligned} \frac{10 \times 6.50}{65} &= \frac{9 \times x}{72} \\ x &= \frac{10 \times 6.50 \times 72}{65 \times 9} = \$8.00 \text{ per hour} \end{aligned}$$

**Percentage.**—If out of 100 pieces made, 12 do not pass inspection, it is said that 12 per cent (12 of the hundred) are rejected. If a quantity of steel is bought for \$100 and sold for \$140, the profit is 28.6 per cent of the selling price.

The per cent of gain or loss is found by dividing the amount of gain or loss by the *original* number of which the percentage is wanted, and multiplying the quotient by 100.

*Example:* Out of a total output of 280 castings a day, 30 castings are, on an average, rejected. What is the percentage of bad castings?

$$\frac{30}{280} \times 100 = 10.7 \text{ per cent}$$

If by a new process 100 pieces can be made in the same time as 60 could formerly be made, what is the gain in output of the new process over the old, expressed in per cent?

Original number, 60; gain  $100 - 60 = 40$ . Hence,

$$\frac{40}{60} \times 100 = 66.7 \text{ per cent}$$

Care should be taken always to use the original number, or the number of which the percentage is wanted, as the divisor in all percentage calculations. In the example just given, it

is the percentage of gain over the old output 60 that is wanted and not the percentage with relation to the new output too. Mistakes are often made by overlooking this important point.

### Fractions

**Common Fractions.**— Common fractions consist of two basic parts, a denominator, or bottom number, and a numerator, or top number. The denominator shows how many parts the whole unit has been divided into. The numerator indicates the number of parts of the whole that are being considered. A fraction having a value of  $\frac{5}{32}$ , means the whole unit has been divided into 32 equal parts and 5 of these parts are considered in the value of the fraction.

The following are the basic facts, rules, and definitions concerning common fractions.

A common fraction having the same numerator and denominator is equal to 1. For example,  $\frac{2}{2}$ ,  $\frac{4}{4}$ ,  $\frac{8}{8}$ ,  $\frac{16}{16}$ ,  $\frac{32}{32}$ , and  $\frac{64}{64}$  all equal 1.

**Proper Fraction:** A proper fraction is a common fraction having a numerator smaller than its denominator, such as  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $\frac{47}{64}$ .

**Improper Fraction:** An improper fraction is a common fraction having a numerator larger than its denominator. For example,  $\frac{3}{2}$ ,  $\frac{5}{4}$ , and  $\frac{10}{8}$ . To convert a whole number to an improper fraction place the whole number over 1, as in  $4 = \frac{4}{1}$  and  $3 = \frac{3}{1}$ .

**Reducible Fraction:** A reducible fraction is a common fraction that can be reduced to lower terms. For example,  $\frac{2}{4}$  can be reduced to  $\frac{1}{2}$ , and  $\frac{28}{32}$  can be reduced to  $\frac{7}{8}$ . To reduce a common fraction to lower terms, divide both the numerator and the denominator by the same number. For example,  $\frac{24}{32} \div \frac{8}{8} = \frac{3}{4}$  and  $\frac{6}{8} \div \frac{2}{2} = \frac{3}{4}$ .

**Least Common Denominator:** A least common denominator is the smallest denominator value that is evenly divisible by the other denominator values in the problem. For example, given the following numbers,  $\frac{1}{2}$ ,  $\frac{1}{4}$ , and  $\frac{3}{8}$ , the least common denominator is 8.

**Mixed Number:** A mixed number is a combination of a whole number and a common fraction, such as  $2\frac{1}{2}$ ,  $1\frac{7}{8}$ ,  $3\frac{15}{16}$  and  $1\frac{9}{32}$ .

To convert mixed numbers to improper fractions, multiply the whole number by the denominator and add the numerator to obtain the new numerator. The denominator remains the same. For example,

$$2\frac{1}{2} = \frac{2 \times 2 + 1}{2} = \frac{5}{2}$$

$$3\frac{7}{16} = \frac{3 \times 16 + 7}{16} = \frac{55}{16}$$

To convert an improper fraction to a mixed number, divide the numerator by the denominator and reduce the remaining fraction to its lowest terms. For example,

$$\frac{17}{8} = 17 \div 8 = 2\frac{1}{8} \text{ and } \frac{26}{16} = 26 \div 16 = 1\frac{10}{16} = 1\frac{5}{8}$$

A fraction may be converted to higher terms by multiplying the numerator and denominator by the same number. For example,  $\frac{1}{4}$  in 16ths =  $\frac{1}{4} \times \frac{4}{4} = \frac{4}{16}$  and  $\frac{3}{8}$  in 32nds =  $\frac{3}{8} \times \frac{4}{4} = \frac{12}{32}$ .

To change a whole number to a common fraction with a specific denominator value, convert the whole number to a fraction and multiply the numerator and denominator by the desired denominator value.

*Example:*  $4$  in 16ths =  $\frac{4}{1} \times \frac{16}{16} = \frac{64}{16}$  and  $3$  in 32nds =  $\frac{3}{1} \times \frac{32}{32} = \frac{96}{32}$

**Reciprocals.**— The *reciprocal*  $R$  of a number  $N$  is obtained by dividing 1 by the number;  $R = 1/N$ . Reciprocals are useful in some calculations because they avoid the use of negative characteristics as in calculations with logarithms and in trigonometry. In trigonometry, the

values *cosecant*, *secant*, and *cotangent* are often used for convenience and are the reciprocals of the *sine*, *cosine*, and *tangent*, respectively (see page 88). The reciprocal of a fraction, for instance  $\frac{3}{4}$ , is the fraction inverted, since  $1 \div \frac{3}{4} = 1 \times \frac{4}{3} = \frac{4}{3}$ .

### Adding Fractions and Mixed Numbers

*To Add Common Fractions:* 1) Find and convert to the least common denominator; 2) Add the numerators; 3) Convert the answer to a mixed number, if necessary; and 4) Reduce the fraction to its lowest terms.

*To Add Mixed Numbers:* 1) Find and convert to the least common denominator; 2) Add the numerators; 3) Add the whole numbers; and 4) Reduce the answer to its lowest terms.

*Example, Addition of Common Fractions:*

$$\begin{aligned}\frac{1}{4} + \frac{3}{16} + \frac{7}{8} &= \\ \frac{1}{4}\left(\frac{4}{4}\right) + \frac{3}{16} + \frac{7}{8}\left(\frac{2}{2}\right) &= \\ \frac{4}{16} + \frac{3}{16} + \frac{14}{16} &= \frac{21}{16}\end{aligned}$$

*Example, Addition of Mixed Numbers:*

$$\begin{aligned}2\frac{1}{2} + 4\frac{1}{4} + 1\frac{15}{32} &= \\ 2\frac{1}{2}\left(\frac{16}{16}\right) + 4\frac{1}{4}\left(\frac{8}{8}\right) + 1\frac{15}{32} &= \\ 2\frac{16}{32} + 4\frac{8}{32} + 1\frac{15}{32} &= 7\frac{39}{32} = 8\frac{7}{32}\end{aligned}$$

### Subtracting Fractions and Mixed Numbers

*To Subtract Common Fractions:* 1) Convert to the least common denominator; 2) Subtract the numerators; and 3) Reduce the answer to its lowest terms.

*To Subtract Mixed Numbers:* 1) Convert to the least common denominator; 2) Subtract the numerators; 3) Subtract the whole numbers; and 4) Reduce the answer to its lowest terms.

*Example, Subtraction of Common Fractions:*

$$\begin{aligned}\frac{15}{16} - \frac{7}{32} &= \\ \frac{15}{16}\left(\frac{2}{2}\right) - \frac{7}{32} &= \\ \frac{30}{32} - \frac{7}{32} &= \frac{23}{32}\end{aligned}$$

*Example, Subtraction of Mixed Numbers:*

$$\begin{aligned}2\frac{3}{8} - 1\frac{1}{16} &= \\ 2\frac{3}{8}\left(\frac{2}{2}\right) - 1\frac{1}{16} &= \\ 2\frac{6}{16} - 1\frac{1}{16} &= 1\frac{5}{16}\end{aligned}$$

### Multiplying Fractions and Mixed Numbers

*To Multiply Common Fractions:* 1) Multiply the numerators; 2) Multiply the denominators; and 3) Convert improper fractions to mixed numbers, if necessary.

*To Multiply Mixed Numbers:* 1) Convert the mixed numbers to improper fractions; 2) Multiply the numerators; 3) Multiply the denominators; and 4) Convert improper fractions to mixed numbers, if necessary.

*Example, Multiplication of Common Fractions:*

$$\frac{3}{4} \times \frac{7}{16} = \frac{3 \times 7}{4 \times 16} = \frac{21}{64}$$

*Example, Multiplication of Mixed Numbers:*

$$2\frac{1}{4} \times 3\frac{1}{2} = \frac{9 \times 7}{4 \times 2} = \frac{63}{8} = 7\frac{7}{8}$$

### Dividing Fractions and Mixed Numbers

*To Divide Common Fractions:* 1) Write the fractions to be divided; 2) Invert (switch) the numerator and denominator in the dividing fraction; 3) Multiply the numerators and denominators; and 4) Convert improper fractions to mixed numbers, if necessary.

*To Divide Mixed Numbers:* 1) Convert the mixed numbers to improper fractions; 2) Write the improper fraction to be divided; 3) Invert (switch) the numerator and denominator in the dividing fraction; 4) Multiplying numerators and denominators; and 5) Convert improper fractions to mixed numbers, if necessary.

*Example, Division of Common Fractions:*

$$\frac{3}{4} \div \frac{1}{2} = \frac{3 \times 2}{4 \times 1} = \frac{6}{4} = 1\frac{1}{2}$$

*Example, Division of Mixed Numbers:*

$$2\frac{1}{2} \div 1\frac{7}{8} = \frac{5 \times 8}{2 \times 15} = \frac{40}{30} = 1\frac{1}{3}$$

**Decimal Fractions.**—Decimal fractions are fractional parts of a whole unit, which have implied denominators that are multiples of 10. A decimal fraction of 0.1 has a value of 1/10th, 0.01 has a value of 1/100th, and 0.001 has a value of 1/1000th. As the number of decimal place values increases, the value of the decimal number changes by a multiple of 10. A single number placed to the right of a decimal point has a value expressed in tenths; two numbers to the right of a decimal point have a value expressed in hundredths; three numbers to the right have a value expressed in thousandths; and four numbers are expressed in ten-thousandths. Since the denominator is implied, the number of decimal places in the numerator indicates the value of the decimal fraction. So a decimal fraction expressed as a 0.125 means the whole unit has been divided into 1000 parts and 125 of these parts are considered in the value of the decimal fraction.

In industry, most decimal fractions are expressed in terms of thousandths rather than tenths or hundredths. So a decimal fraction of 0.2 is expressed as 200 thousandths, not 2 tenths, and a value of 0.75 is expressed as 750 thousandths, rather than 75 hundredths. In the case of four place decimals, the values are expressed in terms of ten-thousandths. So a value of 0.1875 is expressed as 1 thousand 8 hundred and 75 ten-thousandths. When whole numbers and decimal fractions are used together, whole units are shown to the left of a decimal point, while fractional parts of a whole unit are shown to the right.

*Example:*

|                |                   |
|----------------|-------------------|
| 10.125         |                   |
| Whole<br>Units | Fraction<br>Units |

*Adding Decimal Fractions:* 1) Write the problem with all decimal points aligned vertically; 2) Add the numbers as whole number values; and 3) Insert the decimal point in the same vertical column in the answer.

*Subtracting Decimal Fractions:* 1) Write the problem with all decimal points aligned vertically; 2) Subtract the numbers as whole number values; and 3) Insert the decimal point in the same vertical column in the answer.

*Multiplying Decimal Fractions:* 1) Write the problem with the decimal points aligned; 2) Multiply the values as whole numbers; 3) Count the number of decimal places in both multiplied values; and 4) Counting from right to left in the answer, insert the decimal point so the number of decimal places in the answer equals the total number of decimal places in the numbers multiplied.

*Example, Adding Decimal Fractions:*

$$\begin{array}{r} 0.125 \\ 1.0625 \\ 2.50 \\ \hline 0.1875 \\ 3.8750 \end{array} \quad \text{or} \quad \begin{array}{r} 1.750 \\ 0.875 \\ 0.125 \\ \hline 2.0005 \\ 4.7505 \end{array}$$

*Example, Subtracting Decimal Fractions:*

$$\begin{array}{r} 1.750 \\ -0.250 \\ \hline 1.500 \end{array} \quad \text{or} \quad \begin{array}{r} 2.625 \\ -1.125 \\ \hline 1.500 \end{array}$$

Example, Multiplying Decimal Fractions:

|             |                       |              |
|-------------|-----------------------|--------------|
| 0.75        |                       | 1.625        |
| <u>0.25</u> |                       | <u>0.033</u> |
| 375         | (four decimal places) | 4875         |
| <u>150</u>  |                       | <u>4875</u>  |
| 0.1875      |                       | 0.053625     |

**Continued Fractions.**—In dealing with a cumbersome fraction, or one which does not have satisfactory factors, it may be possible to substitute some other, approximately equal, fraction which is simpler or which can be factored satisfactorily. Continued fractions provide a means of computing a series of fractions each of which is a closer approximation to the original fraction than the one preceding it in the series.

A continued fraction is a proper fraction (one whose numerator is smaller than its denominator) expressed in the form shown at the left below; or, it may be convenient to write the left expression as shown at the right below.

$$\frac{N}{D} = \frac{1}{D_1 + \frac{1}{D_2 + \frac{1}{D_3 + \dots}}} \qquad \frac{N}{D} = \frac{1}{D_1} + \frac{1}{D_2} + \frac{1}{D_3} + \frac{1}{D_4} + \dots$$

The continued fraction is produced from a proper fraction  $N/D$  by dividing the numerator  $N$  both into itself and into the denominator  $D$ . Dividing the numerator into itself gives a result of 1; dividing the numerator into the denominator gives a whole number  $D_1$  plus a remainder fraction  $R_1$ . The process is then repeated on the remainder fraction  $R_1$  to obtain  $D_2$  and  $R_2$ ; then  $D_3, R_3$ , etc., until a remainder of zero results. As an example, using  $N/D = 2153/9277$ ,

$$\frac{2153}{9277} = \frac{2153 \div 2153}{9277 \div 2153} = \frac{1}{4 + \frac{665}{2153}} = \frac{1}{D_1 + R_1}$$

$$R_1 = \frac{665}{2153} = \frac{1}{3 + \frac{158}{665}} = \frac{1}{D_2 + R_2} \text{ etc.}$$

from which it may be seen that  $D_1 = 4, R_1 = 665/2153; D_2 = 3, R_2 = 158/665$ ; and, continuing as was explained previously, it would be found that:  $D_3 = 4, R_3 = 33/158; \dots; D_9 = 2, R_9 = 0$ . The complete set of continued fraction elements representing  $2153/9277$  may then be written as

$$\frac{2153}{9277} = \frac{1}{4 + \frac{1}{3 + \frac{1}{4 + \frac{1}{4 + \frac{1}{1 + \frac{1}{3 + \frac{1}{1 + \frac{1}{2 + \frac{1}{2}}}}}}}}}$$

$$D_1 \dots \dots \dots D_5 \dots \dots \dots D_9$$

By following a simple procedure, together with a table organized similar to the one below for the fraction  $2153/9277$ , the denominators  $D_1, D_2, \dots$  of the elements of a continued fraction may be used to calculate a series of fractions, each of which is a successively closer approximation, called a *convergent*, to the original fraction  $N/D$ .

1) The first row of the table contains column numbers numbered from 1 through 2 plus the number of elements,  $2 + 9 = 11$  in this example.

CONJUGATE FRACTIONS

2) The second row contains the denominators of the continued fraction elements in sequence but beginning in column 3 instead of column 1 because columns 1 and 2 must be blank in this procedure.

3) The third row contains the convergents to the original fraction as they are calculated and entered. Note that the fractions 1/0 and 0/1 have been inserted into columns 1 and 2. These are two arbitrary convergents, the first equal to infinity, the second to zero, which are used to facilitate the calculations.

4) The convergent in column 3 is now calculated. To find the numerator, multiply the denominator in column 3 by the numerator of the convergent in column 2 and add the numerator of the convergent in column 1. Thus,  $4 \times 0 + 1 = 1$ .

5) The denominator of the convergent in column 3 is found by multiplying the denominator in column 3 by the denominator of the convergent in column 2 and adding the denominator of the convergent in column 1. Thus,  $4 \times 1 + 0 = 4$ , and the convergent in column 3 is then  $\frac{1}{4}$  as shown in the table.

6) Finding the remaining successive convergents can be reduced to using the simple equation

$$\text{CONVERGENT}_n = \frac{(D_n)(\text{NUM}_{n-1}) + \text{NUM}_{n-2}}{(D_n)(\text{DEN}_{n-1}) + \text{DEN}_{n-2}}$$

in which  $n$  = column number in the table;  $D_n$  = denominator in column  $n$ ;  $\text{NUM}_{n-1}$  and  $\text{NUM}_{n-2}$  are numerators and  $\text{DEN}_{n-1}$  and  $\text{DEN}_{n-2}$  are denominators of the convergents in the columns indicated by their subscripts; and  $\text{CONVERGENT}_n$  is the convergent in column  $n$ .

**Convergents of the Continued Fraction for 2153/9277**

| Column Number, $n$            | 1             | 2             | 3             | 4              | 5               | 6                | 7                | 8                  | 9                  | 10                 | 11                  |
|-------------------------------|---------------|---------------|---------------|----------------|-----------------|------------------|------------------|--------------------|--------------------|--------------------|---------------------|
| Denominator, $D_n$            | —             | —             | 4             | 3              | 4               | 4                | 1                | 3                  | 1                  | 2                  | 2                   |
| Convergent, $\frac{NUM}{DEN}$ | $\frac{1}{0}$ | $\frac{0}{1}$ | $\frac{1}{4}$ | $\frac{3}{13}$ | $\frac{13}{56}$ | $\frac{55}{237}$ | $\frac{68}{293}$ | $\frac{259}{1116}$ | $\frac{327}{1409}$ | $\frac{913}{3934}$ | $\frac{2153}{9277}$ |

Notes: The decimal values of the successive convergents in the table are alternately larger and smaller than the value of the original fraction 2153/9277. If the last convergent in the table has the same value as the original fraction 2153/9277, then all of the other calculated convergents are correct.

**Conjugate Fractions.**—In addition to finding approximate ratios by the use of continued fractions and logarithms of ratios, conjugate fractions may be used for the same purpose, independently, or in combination with the other methods.

Two fractions  $a/b$  and  $c/d$  are said to be conjugate if  $ad - bc = \pm 1$ . Examples of such pairs are: 0/1 and 1/1; 1/2 and 1/1; and 9/10 and 8/9. Also, every successive pair of the convergents of a continued fraction are conjugate. Conjugate fractions have certain properties that are useful for solving ratio problems:

1) No fraction between two conjugate fractions  $a/b$  and  $c/d$  can have a denominator smaller than either  $b$  or  $d$ .

2) A new fraction,  $e/f$ , conjugate to both fractions of a given pair of conjugate fractions,  $a/b$  and  $c/d$ , and lying between them, may be created by adding respective numerators,  $a + c$ , and denominators,  $b + d$ , so that  $e/f = (a + c)/(b + d)$ .

3) The denominator  $f = b + d$  of the new fraction  $e/f$  is the smallest of any possible fraction lying between  $a/b$  and  $c/d$ . Thus, 17/19 is conjugate to both 8/9 and 9/10 and no fraction with denominator smaller than 19 lies between them. This property is important if it is desired to minimize the size of the factors of the ratio to be found.

The following example shows the steps to approximate a ratio for a set of gears to any desired degree of accuracy within the limits established for the allowable size of the factors in the ratio.

*Example:* Find a set of four change gears,  $ab/cd$ , to approximate the ratio 2.105399 accurate to within  $\pm 0.0001$ ; no gear is to have more than 120 teeth.

Step 1. Convert the given ratio  $R$  to a number  $r$  between 0 and 1 by taking its reciprocal:  $1/R = 1/2.105399 = 0.4749693 = r$ .

Step 2. Select a pair of conjugate fractions  $a/b$  and  $c/d$  that bracket  $r$ . The pair  $a/b = 0/1$  and  $c/d = 1/1$ , for example, will bracket 0.4749693.

Step 3. Add the respective numerators and denominators of the conjugates  $0/1$  and  $1/1$  to create a new conjugate  $e/f$  between 0 and 1:  $e/f = (a + c)/(b + d) = (0 + 1)/(1 + 1) = 1/2$ .

Step 4. Since 0.4749693 lies between  $0/1$  and  $1/2$ ,  $e/f$  must also be between  $0/1$  and  $1/2$ :  $e/f = (0 + 1)/(1 + 2) = 1/3$ .

Step 5. Since 0.4749693 now lies between  $1/3$  and  $1/2$ ,  $e/f$  must also be between  $1/3$  and  $1/2$ :  $e/f = (1 + 1)/(3 + 2) = 2/5$ .

Step 6. Continuing as above to obtain successively closer approximations of  $e/f$  to 0.4749693, and using a handheld calculator and a scratch pad to facilitate the process, the fractions below, each of which has factors less than 120, were determined:

| Fraction | Numerator Factors  | Denominator Factors             | Error       |
|----------|--|---------------------------------|-------------|
| 19/40    | 19   | $2 \times 2 \times 2 \times 5$  | + .000031   |
| 28/59    | $2 \times 2 \times 7$  | 59                              | - .00039    |
| 47/99    | 47   | $3 \times 3 \times 11$          | - .00022    |
| 104/219  | $2 \times 2 \times 2 \times 13$                                    | $3 \times 73$                   | - .000083   |
| 123/259  | $3 \times 41$  | $7 \times 37$                   | - .000066   |
| 142/299  | $2 \times 71$  | $13 \times 23$                  | - .000053   |
| 161/339  | $7 \times 23$  | $3 \times 113$                  | - .000043   |
| 218/459  | $2 \times 109$   | $3 \times 3 \times 3 \times 17$ | - .000024   |
| 256/539  | $2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2 \times 2$ | $7 \times 7 \times 11$          | - .000016   |
| 370/779  | $2 \times 5 \times 37$   | $19 \times 41$                  | - .0000014  |
| 759/1598 | $3 \times 11 \times 23$  | $2 \times 17 \times 47$         | - .00000059 |

Factors for the numerators and denominators of the fractions shown above were found with the aid of the Prime Numbers and Factors tables beginning on page 20. Since in Step 1 the desired ratio of 2.105399 was converted to its reciprocal 0.4749693, all of the above fractions should be inverted. Note also that the last fraction, 759/1598, when inverted to become 1598/759, is in error from the desired value by approximately one-half the amount obtained by trial and error using earlier methods.

**Using Continued Fraction Convergents as Conjugates.**—Since successive convergents of a continued fraction are also conjugate, they may be used to find a series of additional fractions in between themselves. As an example, the successive convergents 55/237 and 68/293 from the table of convergents for 2153/9277 on page 12 will be used to demonstrate the process for finding the first few in-between ratios.

#### Desired Fraction $N/D = 2153/9277 = 0.2320793$

| $ab$                      | $ef$   | $cd$                  |
|---------------------------|--|-----------------------|
| (1) $55/237 = .2320675$   | $^{a}123/530 = .2320755$ error = - .0000039  | $68/293 = .2320819$   |
| (2) $123/530 = .2320755$  | $191/823 = .2320778$ error = - .0000016      | $68/293 = .2320819$   |
| (3) $191/823 = .2320778$  | $^{a}259/1116 = .2320789$ error = - .0000005 | $68/293 = .2320819$   |
| (4) $259/1116 = .2320789$ | $327/1409 = .2320795$ error = + .0000002     | $68/293 = .2320819$   |
| (5) $259/1116 = .2320789$ | $586/2525 = .2320792$ error = - .0000001     | $327/1409 = .2320795$ |
| (6) $586/2525 = .2320792$ | $913/3934 = .2320793$ error = - .0000000     | $327/1409 = .2320795$ |

<sup>a</sup> Only these ratios had suitable factors below 120.

Step 1. Check the convergents for conjugateness:  $55 \times 293 - 237 \times 68 = 16115 - 16116 = -1$  proving the pair to be conjugate.

Step 2. Set up a table as shown above. The leftmost column of line (1) contains the convergent of lowest value,  $a/b$ ; the rightmost the higher value,  $c/d$ ; and the center column the derived value  $e/f$  found by adding the respective numerators and denominators of  $a/b$  and  $c/d$ . The error or difference between  $e/f$  and the desired value  $N/D$ ,  $\text{error} = N/D - e/f$ , is also shown.

Step 3. On line (2), the process used on line (1) is repeated with the  $e/f$  value from line (1) becoming the new value of  $a/b$  while the  $c/d$  value remains unchanged. Had the error in  $e/f$  been + instead of -, then  $e/f$  would have been the new  $c/d$  value and  $a/b$  would be unchanged.

Step 4. The process is continued until, as seen on line (4), the error changes sign to + from the previous -. When this occurs, the  $e/f$  value becomes the  $c/d$  value on the next line instead of  $a/b$  as previously and the  $a/b$  value remains unchanged.

### Powers and Roots

The *square* of a number (or quantity) is the product of that number multiplied by itself. Thus, the square of 9 is  $9 \times 9 = 81$ . The square of a number is indicated by the *exponent* (<sup>2</sup>), thus:  $9^2 = 9 \times 9 = 81$ .

The *cube* or *third power* of a number is the product obtained by using that number as a factor three times. Thus, the cube of 4 is  $4 \times 4 \times 4 = 64$ , and is written  $4^3$ .

If a number is used as a factor four or five times, respectively, the product is the fourth or fifth power. Thus,  $3^4 = 3 \times 3 \times 3 \times 3 = 81$ , and  $2^5 = 2 \times 2 \times 2 \times 2 \times 2 = 32$ . A number can be raised to any power by using it as a factor the required number of times.

The *square root* of a given number is that number which, when multiplied by itself, will give a product equal to the given number. The square root of 16 (written  $\sqrt{16}$ ) equals 4, because  $4 \times 4 = 16$ .

The *cube root* of a given number is that number which, when used as a factor three times, will give a product equal to the given number. Thus, the cube root of 64 (written  $\sqrt[3]{64}$ ) equals 4, because  $4 \times 4 \times 4 = 64$ .

The fourth, fifth, etc., roots of a given number are those numbers which when used as factors four, five, etc., times, will give as a product the given number. Thus,  $\sqrt[4]{16} = 2$ , because  $2 \times 2 \times 2 \times 2 = 16$ .

In some formulas, there may be such expressions as  $(a^2)^3$  and  $a^{3/2}$ . The first of these,  $(a^2)^3$ , means that the number  $a$  is first to be squared,  $a^2$ , and the result then cubed to give  $a^6$ . Thus,  $(a^2)^3$  is equivalent to  $a^6$  which is obtained by *multiplying* the exponents 2 and 3. Similarly,  $a^{3/2}$  may be interpreted as the cube of the square root of  $a$ ,  $(\sqrt{a})^3$ , or  $(a^{1/2})^3$ , so that, for example,  $16^{3/2} = (\sqrt{16})^3 = 64$ .

The multiplications required for raising numbers to powers and the extracting of roots are greatly facilitated by the use of logarithms. Extracting the square root and cube root by the regular arithmetical methods is a slow and cumbersome operation, and any roots can be more rapidly found by using logarithms.

When the power to which a number is to be raised is not an integer, say 1.62, the use of either logarithms or a scientific calculator becomes the only practical means of solution.

**Powers of Ten Notation.**—Powers of ten notation is used to simplify calculations and ensure accuracy, particularly with respect to the position of decimal points, and also simplifies the expression of numbers which are so large or so small as to be unwieldy. For example, the metric (SI) pressure unit pascal is equivalent to 0.0000986923 atmosphere or 0.0001450377 pound/inch<sup>2</sup>. In powers of ten notation, these figures are  $9.86923 \times 10^{-6}$

atmosphere and  $1.450377 \times 10^{-4}$  pound/inch<sup>2</sup>. The notation also facilitates adaptation of numbers for electronic data processing and computer readout.

**Expressing Numbers in Powers of Ten Notation.**—In this system of notation, every number is expressed by two factors, one of which is some integer from 1 to 9 followed by a decimal and the other is some power of 10.

Thus, 10,000 is expressed as  $1.0000 \times 10^4$  and 10,463 as  $1.0463 \times 10^4$ . The number 43 is expressed as  $4.3 \times 10$  and 568 is expressed as  $5.68 \times 10^2$ .

In the case of decimals, the number 0.0001, which as a fraction is  $\frac{1}{10,000}$  and is expressed as  $1 \times 10^{-4}$  and 0.0001463 is expressed as  $1.463 \times 10^{-4}$ . The decimal 0.498 is expressed as  $4.98 \times 10^{-1}$  and 0.03146 is expressed as  $3.146 \times 10^{-2}$ .

**Rules for Converting Any Number to Powers of Ten Notation.**—Any number can be converted to the powers of ten notation by means of one of two rules.

*Rule 1:* If the number is a whole number or a whole number and a decimal so that it has digits to the left of the decimal point, the decimal point is moved a sufficient number of places to the *left* to bring it to the immediate right of the first digit. With the decimal point shifted to this position, the number so written comprises the *first* factor when written in powers of ten notation.

The number of places that the decimal point is moved to the left to bring it immediately to the right of the first digit is the *positive* index or power of 10 that comprises the *second* factor when written in powers of ten notation.

Thus, to write 4639 in this notation, the decimal point is moved three places to the left giving the two factors:  $4.639 \times 10^3$ . Similarly,

$$431.412 = 4.31412 \times 10^2 \quad 986388 = 9.86388 \times 10^5$$

*Rule 2:* If the number is a decimal, i.e., it has digits entirely to the right of the decimal point, then the decimal point is moved a sufficient number of places to the *right* to bring it immediately to the right of the first digit. With the decimal point shifted to this position, the number so written comprises the *first* factor when written in powers of ten notation.

The number of places that the decimal point is moved to the *right* to bring it immediately to the right of the first digit is the *negative* index or power of 10 that follows the number when written in powers of ten notation.

Thus, to bring the decimal point in 0.005721 to the immediate right of the first digit, which is 5, it must be moved *three* places to the right, giving the two factors:  $5.721 \times 10^{-3}$ . Similarly,

$$0.469 = 4.69 \times 10^{-1} \quad 0.0000516 = 5.16 \times 10^{-5}$$

**Multiplying Numbers Written in Powers of Ten Notation.**—When multiplying two numbers written in the powers of ten notation together, the procedure is as follows:

1) Multiply the first factor of one number by the first factor of the other to obtain the first factor of the product.

2) Add the index of the second factor (which is some power of 10) of one number to the index of the second factor of the other number to obtain the index of the second factor (which is some power of 10) in the product. Thus:

$$(4.31 \times 10^{-2}) \times (9.0125 \times 10) = (4.31 \times 9.0125) \times 10^{-2+1} = 38.844 \times 10^{-1}$$

$$(5.986 \times 10^4) \times (4.375 \times 10^3) = (5.986 \times 4.375) \times 10^{4+3} = 26.189 \times 10^7$$

In the preceding calculations, neither of the results shown are in the conventional powers of ten form since the first factor in each has two digits. In the conventional powers of ten notation, the results would be

$38.844 \times 10^{-1} = 3.884 \times 10^0 = 3.884$ , since  $10^0 = 1$ , and  $26.189 \times 10^7 = 2.619 \times 10^8$  in each case rounding off the first factor to three decimal places.

When multiplying several numbers written in this notation together, the procedure is the same. All of the first factors are multiplied together to get the first factor of the product and all of the indices of the respective powers of ten are added together, taking into account their respective signs, to get the index of the second factor of the product. Thus,  $(4.02 \times 10^{-3}) \times (3.987 \times 10) \times (4.863 \times 10^5) = (4.02 \times 3.987 \times 4.863) \times 10^{(-3+1+5)} = 77.94 \times 10^3 = 7.79 \times 10^4$  rounding off the first factor to two decimal places.

**Dividing Numbers Written in Powers of Ten Notation.**—When dividing one number by another when both are written in this notation, the procedure is as follows:

1) Divide the first factor of the dividend by the first factor of the divisor to get the first factor of the quotient.

2) Subtract the index of the second factor of the divisor from the index of the second factor of the dividend, taking into account their respective signs, to get the index of the second factor of the quotient. Thus:

$$(4.31 \times 10^{-2}) \div (9.0125 \times 10) = \\ (4.31 \div 9.0125) \times (10^{-2-1}) = 0.4782 \times 10^{-3} = 4.782 \times 10^{-4}$$

It can be seen that this system of notation is helpful where several numbers of different magnitudes are to be multiplied and divided.

*Example:* Find the quotient of  $\frac{250 \times 4698 \times 0.00039}{43678 \times 0.002 \times 0.0147}$

*Solution:* Changing all these numbers to powers of ten notation and performing the operations indicated:

$$\frac{(2.5 \times 10^2) \times (4.698 \times 10^3) \times (3.9 \times 10^{-4})}{(4.3678 \times 10^4) \times (2 \times 10^{-3}) \times (1.47 \times 10^{-2})} = \\ = \frac{(2.5 \times 4.698 \times 3.9)(10^{2+3-4})}{(4.3678 \times 2 \times 1.47)(10^{4-3-2})} = \frac{45.8055 \times 10}{12.8413 \times 10^{-1}} \\ = 3.5670 \times 10^{1-(-1)} = 3.5670 \times 10^2 = 356.70$$

### Constants Frequently Used in Mathematical Expressions

|   |                                   |                                   |                               |
|---|-----------------------------------|-----------------------------------|-------------------------------|
| $0.00872665 = \frac{\pi}{360}$          | $0.8660254 = \frac{\sqrt{3}}{2}$  | $2.0943951 = \frac{2\pi}{3}$      | $4.712389 = \frac{3\pi}{2}$   |
| $0.01745329 = \frac{\pi}{180}$          | $1.0471975 = \frac{\pi}{3}$       | $2.3561945 = \frac{3\pi}{4}$      | $5.2359878 = \frac{5\pi}{3}$  |
| $0.26179939 = \frac{\pi}{12}$           | $1.1547005 = \frac{2\sqrt{3}}{3}$ | $2.5980762 = \frac{3\sqrt{3}}{2}$ | $5.4977871 = \frac{7\pi}{4}$  |
| $0.39269908 = \frac{\pi}{8}$            | $1.2247449 = \sqrt{\frac{3}{2}}$  | $2.6179939 = \frac{5\pi}{6}$      | $5.7595865 = \frac{11\pi}{6}$ |
| $0.52359878 = \frac{\pi}{6}$            | $1.4142136 = \sqrt{2}$            | $3.1415927 = \pi$                 | $6.2831853 = 2\pi$            |
| $0.57735027 = \frac{\sqrt{3}}{3}$       | $1.5707963 = \frac{\pi}{2}$       | $3.6651914 = \frac{7\pi}{6}$      | $9.8696044 = \pi^2$           |
| $0.62035049 = \sqrt[3]{\frac{3}{4\pi}}$ | $1.7320508 = \sqrt{3}$            | $3.9269908 = \frac{5\pi}{4}$      | $9.424778 = 3\pi$             |
| $0.78539816 = \frac{\pi}{4}$            | $2.4674011 = \frac{\pi^2}{4}$     | $4.1887902 = \frac{4\pi}{3}$      | $12.566371 = 4\pi$            |
|   |                                   |                                   | $57.29578 = \frac{180}{\pi}$  |
|   |                                   |                                   | $114.59156 = \frac{360}{\pi}$ |

### Imaginary and Complex Numbers

**Complex or Imaginary Numbers.**—Complex or imaginary numbers represent a class of mathematical objects that are used to simplify certain problems, such as the solution of polynomial equations. The basis of the complex number system is the unit imaginary number  $i$  that satisfies the following relations:

$$i^2 = (-i)^2 = -1 \quad i = \sqrt{-1} \quad -i = -\sqrt{-1}$$

In electrical engineering and other fields, the unit imaginary number is often represented by  $j$  rather than  $i$ . However, the meaning of the two terms is identical.

**Rectangular or Trigonometric Form:** Every complex number,  $Z$ , can be written as the sum of a real number and an imaginary number. When expressed as a sum,  $Z = a + bi$ , the complex number is said to be in rectangular or trigonometric form. The real part of the number is  $a$ , and the imaginary portion is  $bi$  because it has the imaginary unit assigned to it.

**Polar Form:** A complex number  $Z = a + bi$  can also be expressed in polar form, also known as phasor form. In polar form, the complex number  $Z$  is represented by a magnitude  $r$  and an angle  $\theta$  as follows:

$$Z = r \angle \theta$$

$\angle \theta$  = a direction, the angle whose tangent is  $b \div a$ , thus  $\theta = \text{atan} \frac{b}{a}$  and

$$r = \sqrt{a^2 + b^2} \text{ is the magnitude}$$

A complex number can be plotted on a real-imaginary coordinate system known as the complex plane. The figure below illustrates the relationship between the rectangular coordinates  $a$  and  $b$ , and the polar coordinates  $r$  and  $\theta$ .

Complex Number in the Complex Plane

The rectangular form can be determined from  $r$  and  $\theta$  as follows:

$$a = r \cos \theta \quad b = r \sin \theta \quad a + bi = r \cos \theta + ir \sin \theta = r(\cos \theta + i \sin \theta)$$

The rectangular form can also be written using Euler's Formula:

$$e^{\pm i\theta} = \cos \theta \pm i \sin \theta \quad \sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} \quad \cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2}$$

**Complex Conjugate:** Complex numbers commonly arise in finding the solution of polynomials. A polynomial of  $n^{\text{th}}$  degree has  $n$  solutions, an even number of which are complex and the rest are real. The complex solutions always appear as complex conjugate pairs in the form  $a + bi$  and  $a - bi$ . The product of these two conjugates,  $(a + bi) \times (a - bi) = a^2 + b^2$ , is the square of the magnitude  $r$  illustrated in the previous figure.

### Operations on Complex Numbers

**Example 1, Addition:** When adding two complex numbers, the real parts and imaginary parts are added separately, the real parts added to real parts and the imaginary to imaginary parts. Thus,

$$(a_1 + ib_1) + (a_2 + ib_2) = (a_1 + a_2) + i(b_1 + b_2)$$

$$(a_1 + ib_1) - (a_2 + ib_2) = (a_1 - a_2) + i(b_1 - b_2)$$

$$(3 + 4i) + (2 + i) = (3 + 2) + (4 + 1)i = 5 + 5i$$

*Example 2, Multiplication:* Multiplication of two complex numbers requires the use of the imaginary unit,  $i^2 = -1$  and the algebraic distributive law.

$$\begin{aligned}(a_1 + ib_1)(a_2 + ib_2) &= a_1a_2 + ia_1b_2 + ia_2b_1 + i^2b_1b_2 \\ &= a_1a_2 + ia_1b_2 + ia_2b_1 - b_1b_2\end{aligned}$$

$$\begin{aligned}(7 + 2i) \times (5 - 3i) &= (7)(5) - (7)(3i) + (2i)(5) - (2i)(3i) \\ &= 35 - 21i + 10i - 6i^2 \\ &= 35 - 21i + 10i - (6)(-1) = 41 - 11i\end{aligned}$$

Multiplication of two complex numbers,  $Z_1 = r_1(\cos\theta_1 + i\sin\theta_1)$  and  $Z_2 = r_2(\cos\theta_2 + i\sin\theta_2)$ , results in the following:

$$Z_1 \times Z_2 = r_1(\cos\theta_1 + i\sin\theta_1) \times r_2(\cos\theta_2 + i\sin\theta_2) = r_1r_2[\cos(\theta_1 + \theta_2) + i\sin(\theta_1 + \theta_2)]$$

*Example 3, Division:* Divide the following two complex numbers,  $2 + 3i$  and  $4 - 5i$ . Dividing complex numbers makes use of the complex conjugate.

$$\frac{2 + 3i}{4 - 5i} = \frac{(2 + 3i)(4 + 5i)}{(4 - 5i)(4 + 5i)} = \frac{8 + 12i + 10i + 15i^2}{16 + 20i - 20i - 25i^2} = \frac{-7 + 22i}{16 + 25} = \left(\frac{-7}{41}\right) + i\left(\frac{22}{41}\right)$$

*Example 4:* Convert the complex number  $8+6i$  into phasor form.

First find the magnitude of the phasor vector and then the direction.

$$\text{magnitude} = \sqrt{8^2 + 6^2} = 10 \quad \text{direction} = \text{atan}\frac{6}{8} = 36.87^\circ$$

$$\text{phasor} = 10 \angle 36.87^\circ$$

**Factorial.**—A factorial is a mathematical shortcut denoted by the symbol ! following a number (for example, 3! is three factorial). A factorial is found by multiplying together all the integers greater than zero and less than or equal to the factorial number wanted, except for zero factorial (0!), which is defined as 1. For example: 3! = 1 × 2 × 3 = 6; 4! = 1 × 2 × 3 × 4 = 24; 7! = 1 × 2 × 3 × 4 × 5 × 6 × 7 = 5040; etc.

*Example:* How many ways can the letters X, Y, and Z be arranged?

*Solution:* The numbers of possible arrangements for the three letters are 3! = 3 × 2 × 1 = 6.

**Permutations.**—The number of ways  $r$  objects may be arranged from a set of  $n$  elements

$$\text{is given by } {}^n P_r = \frac{n!}{(n-r)!}$$

*Example:* There are 10 people are participating in the final run. In how many different ways can these people come in first, second and third.

*Solution:* Here  $r$  is 3 and  $n$  is 10. So the possible numbers of winning number will be

$${}^{10} P_3 = \frac{10!}{(10-3)!} = \frac{10!}{7!} = 10 \times 9 \times 8 = 720$$

**Combinations.**—The number of ways  $r$  distinct objects may be chosen from a set of  $n$  elements is given by

$${}^n C_r = \frac{n!}{(n-r)!r!}$$

*Example:* How many possible sets of 6 winning numbers can be picked from 52 numbers.

*Solution:* Here  $r$  is 6 and  $n$  is 52. So the possible number of winning combinations will be

$${}^{52}C_6 = \frac{52!}{(52-6)!6!} = \frac{52!}{46!6!} = \frac{52 \times 51 \times 50 \times 49 \times 48 \times 47}{1 \times 2 \times 3 \times 4 \times 5 \times 6} = 20358520$$

### Prime Numbers and Factors of Numbers

The *factors* of a given number are those numbers which when multiplied together give a product equal to that number; thus, 2 and 3 are factors of 6; and 5 and 7 are factors of 35.

A *prime number* is one which has no factors except itself and 1. Thus, 2, 3, 5, 7, 11, etc., are prime numbers. A factor which is a prime number is called a *prime factor*.

The accompanying "Prime Number and Factor Tables," starting on page 20, give the smallest prime factor of all odd numbers from 1 to 9600, and can be used for finding all the factors for numbers up to this limit. For example, find the factors of 931. In the column headed "900" and in the line indicated by "31" in the left-hand column, the smallest prime factor is found to be 7. As this leaves another factor 133 (since  $931 \div 7 = 133$ ), find the smallest prime factor of this number. In the column headed "100" and in the line "33", this is found to be 7, leaving a factor 19. This latter is a prime number; hence, the factors of 931 are  $7 \times 7 \times 19$ . Where no factor is given for a number in the factor table, it indicates that the number is a prime number.

The last page of the tables lists all prime numbers from 9551 through 18691; and can be used to identify quickly all unfactorable numbers in that range.

For factoring, the following general rules will be found useful:

2 is a factor of any number the right-hand figure of which is an even number or 0. Thus,  $28 = 2 \times 14$ , and  $210 = 2 \times 105$ .

3 is a factor of any number the sum of the figures of which is evenly divisible by 3. Thus, 3 is a factor of 1869, because  $1 + 8 + 6 + 9 = 24 \div 3 = 8$ .

4 is a factor of any number the two right-hand figures of which, considered as one number, are evenly divisible by 4. Thus, 1844 has a factor 4, because  $44 \div 4 = 11$ .

5 is a factor of any number the right-hand figure of which is 0 or 5. Thus,  $85 = 5 \times 17$ ;  $70 = 5 \times 14$ .

Tables of prime numbers and factors of numbers are particularly useful for calculations involving change-gear ratios for compound gearing, dividing heads, gear-generating machines, and mechanical designs having gear trains.

*Example 1:* A set of four gears is required in a mechanical design to provide an overall gear ratio of  $4104 \div 1200$ . Furthermore, no gear in the set is to have more than 120 teeth or less than 24 teeth. Determine the tooth numbers.

First, as explained previously, the factors of 4104 are determined to be:  $2 \times 2 \times 2 \times 3 \times 3 \times 57 = 4104$ . Next, the factors of 1200 are determined:  $2 \times 2 \times 2 \times 2 \times 5 \times 5 \times 3 = 1200$ .

Therefore  $\frac{4104}{1200} = \frac{2 \times 2 \times 2 \times 3 \times 3 \times 57}{2 \times 2 \times 2 \times 2 \times 5 \times 5 \times 3} = \frac{72 \times 57}{24 \times 50}$ . If the factors had been com-

bined differently, say, to give  $\frac{72 \times 57}{16 \times 75}$ , then the 16-tooth gear in the denominator would

not satisfy the requirement of no less than 24 teeth.

*Example 2:* Factor the number 25078 into two numbers neither of which is larger than 200.

The first factor of 25078 is obviously 2, leaving  $25078 \div 2 = 12539$  to be factored further. However, from the last table, *Prime Numbers from 9551 to 18691*, it is seen that 12539 is a prime number; therefore, no solution exists.

## ALGEBRA AND EQUATIONS

An unknown number can be represented by a symbol or a letter which can be manipulated like an ordinary numeral within an arithmetic expression. The rules of arithmetic are also applicable in algebra.

**Rearrangement and Transposition of Terms in Formulas**

A formula is a rule for a calculation expressed by using letters and signs instead of writing out the rule in words; by this means, it is possible to condense, in a very small space, the essentials of long and cumbersome rules. The letters used in formulas simply stand in place of the figures that are to be substituted when solving a specific problem.

As an example, the formula for the horsepower transmitted by belting may be written

$$P = \frac{SVW}{33,000}$$

where  $P$  = horsepower transmitted;  $S$  = working stress of belt per inch of width in pounds;  $V$  = velocity of belt in feet per minute; and,  $W$  = width of belt in inches.

If the working stress  $S$ , the velocity  $V$ , and the width  $W$  are known, the horsepower can be found directly from this formula by inserting the given values. Assume  $S = 33$ ;  $V = 600$ ; and  $W = 5$ . Then

$$P = \frac{33 \times 600 \times 5}{33,000} = 3$$

Assume that the horsepower  $P$ , the stress  $S$ , and the velocity  $V$  are known, and that the width of belt,  $W$ , is to be found. The formula must then be rearranged so that the symbol  $W$  will be on one side of the equals sign and all the known quantities on the other. The rearranged formula is as follows:

$$\frac{P \times 33,000}{SV} = W$$

The quantities ( $S$  and  $V$ ) that were in the numerator on the right side of the equals sign are moved to the denominator on the left side, and "33,000," which was in the denominator on the right side of the equals sign, is moved to the numerator on the other side. Symbols that are not part of a fraction, like " $P$ " in the formula first given, are to be considered as being numerators (having the denominator 1).

Thus, any formula of the form  $A = B/C$  can be rearranged as follows:

$$A \times C = B \quad \text{and} \quad C = \frac{B}{A}$$

Suppose a formula to be of the form  $A = \frac{B \times C}{D}$

$$\text{Then} \quad D = \frac{B \times C}{A} \quad \frac{A \times D}{C} = B \quad \frac{A \times D}{B} = C$$

The method given is only directly applicable when all the quantities in the numerator or denominator are standing independently or are *factors of a product*. If connected by + or - signs, the entire numerator or denominator must be moved as a unit, thus,

$$\text{Given:} \quad \frac{B+C}{A} = \frac{D+E}{F}$$

To solve for  $F$ , rearrange in two steps as follows:  $\frac{F}{A} = \frac{D+E}{B+C}$  and  $F = \frac{A(D+E)}{B+C}$

A quantity preceded by a + or - sign can be transposed to the opposite side of the equals sign by changing its sign; if the sign is +, change it to - on the other side; if it is -, change it to +. This process is called *transposition* of terms.

*Example:*  $B + C = A - D$  then  $A = B + C + D$   
 $B = A - D - C$   
 $C = A - D - B$

### Principal Algebraic Expressions and Formulas

$$a \times a = aa = a^2$$

$$a \times a \times a = aaa = a^3$$

$$a \times b = ab$$

$$a^2 b^2 = (ab)^2$$

$$a^2 a^3 = a^{2+3} = a^5$$

$$a^4 \div a^3 = a^{4-3} = a$$

$$a^0 = 1$$

$$a^2 - b^2 = (a+b)(a-b)$$

$$(a+b)^2 = a^2 + 2ab + b^2$$

$$(a-b)^2 = a^2 - 2ab + b^2$$

$$ab = \left(\frac{a+b}{2}\right)^2 - \left(\frac{a-b}{2}\right)^2$$

$$\sqrt{a} \times \sqrt{a} = a$$

$$\sqrt[3]{a} \times \sqrt[3]{a} \times \sqrt[3]{a} = a$$

$$(\sqrt[3]{a})^3 = a$$

$$\sqrt[3]{a^2} = (\sqrt[3]{a})^2 = a^{2/3}$$

$$\sqrt[4]{\sqrt[3]{a}} = 4 \times \sqrt[3]{a} = \sqrt[3]{4\sqrt{a}}$$

$$\sqrt{a} + \sqrt{b} = \sqrt{a+b+2\sqrt{ab}}$$

$$\frac{a^3}{b^3} = \left(\frac{a}{b}\right)^3$$

$$\frac{1}{a^3} = \left(\frac{1}{a}\right)^3 = a^{-3}$$

$$(a^2)^3 = a^{2 \times 3} = (a^3)^2 = a^6$$

$$a^3 + b^3 = (a+b)(a^2 - ab + b^2)$$

$$a^3 - b^3 = (a-b)(a^2 + ab + b^2)$$

$$(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$$

$$(a-b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$$

$$a^3 + b^3 = (a+b)^3 - 3ab(a+b)$$

$$a^3 - b^3 = (a-b)^3 + 3ab(a-b)$$

$$\sqrt[3]{ab} = \sqrt[3]{a} \times \sqrt[3]{b}$$

$$\sqrt[3]{\frac{a}{b}} = \frac{\sqrt[3]{a}}{\sqrt[3]{b}}$$

$$\sqrt[3]{\frac{1}{a}} = \frac{1}{\sqrt[3]{a}} = a^{-1/3}$$

When  $a \times b = x$  then  $\log a + \log b = \log x$

$a \div b = x$  then  $\log a - \log b = \log x$

$a^3 = x$  then  $3 \log a = \log x$

$\sqrt[3]{a} = x$  then  $\frac{\log a}{3} = \log x$

## Equation Solving

An equation is a statement of equality between two expressions, as  $5x = 105$ . The unknown quantity in an equation is frequently designated by the letter such as  $x$ . If there is more than one unknown quantity, the others are designated by letters also usually selected from the end of the alphabet, as  $y, z, u, t$ , etc.

An equation of the first degree is one which contains the unknown quantity only in the first power, as in  $3x = 9$ . A quadratic equation is one which contains the unknown quantity in the second, but no higher, power, as in  $x^2 + 3x = 10$ .

**Solving Equations of the First Degree with One Unknown.**—Transpose all the terms containing the unknown  $x$  to one side of the equals sign, and all the other terms to the other side. Combine and simplify the expressions as far as possible, and divide both sides by the coefficient of the unknown  $x$ . (See the rules given for transposition of formulas.)

*Example:*

$$\begin{aligned} 22x - 11 &= 15x + 10 \\ 22x - 15x &= 10 + 11 \\ 7x &= 21 \\ x &= 3 \end{aligned}$$

**Solution of Equations of the First Degree with Two Unknowns.**—The form of the simplified equations is

$$\begin{aligned} a_1x + b_1y &= c_1 \\ a_2x + b_2y &= c_2 \end{aligned}$$

Then,

$$x = \frac{c_1b_2 - c_2b_1}{a_1b_2 - a_2b_1} \qquad y = \frac{a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$$

*Example:*

$$\begin{aligned} 3x + 4y &= 17 \\ 5x - 2y &= 11 \\ x &= \frac{17 \times (-2) - 11 \times 4}{3 \times (-2) - 5 \times 4} = \frac{-34 - 44}{-6 - 20} = \frac{-78}{-26} = 3 \end{aligned}$$

The value of  $y$  can now be most easily found by inserting the value of  $x$  in one of the equations:

$$5 \times 3 - 2y = 11 \qquad 2y = 15 - 11 = 4 \qquad y = 2$$

**Solution of Quadratic Equations with One Unknown.**—If the form of the equation is  $ax^2 + bx + c = 0$ , then

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

*Example:* Given the equation,  $1x^2 + 6x + 5 = 0$ , then  $a = 1$ ,  $b = 6$ , and  $c = 5$ .

$$x = \frac{-6 \pm \sqrt{6^2 - 4 \times 1 \times 5}}{2 \times 1} = \frac{(-6) + 4}{2} = -1 \quad \text{or} \quad \frac{(-6) - 4}{2} = -5$$

If the form of the equation is  $ax^2 + bx = c$ , then

$$x = \frac{-b \pm \sqrt{b^2 + 4ac}}{2a}$$

*Example:* A right-angle triangle has a hypotenuse 5 inches long and one side which is one inch longer than the other; find the lengths of the two sides.

Let  $x =$  one side and  $x + 1 =$  other side; then  $x^2 + (x + 1)^2 = 5^2$  or  $x^2 + x^2 + 2x + 1 = 25$ ; or  $2x^2 + 2x = 24$ ; or  $x^2 + x = 12$ . Now referring to the basic formula,  $ax^2 + bx = c$ , we find that  $a = 1$ ,  $b = 1$ , and  $c = 12$ ; hence,

$$x = \frac{-1 \pm \sqrt{1 + 4 \times 1 \times 12}}{2 \times 1} = \frac{(-1) + 7}{2} = 3 \quad \text{or} \quad x = \frac{(-1) - 7}{2} = -4$$

Since the positive value (3) would apply in this case, the lengths of the two sides are  $x = 3$  inches and  $x + 1 = 4$  inches.

**Factoring a Quadratic Expression.**—The method described below is useful in determining factors of the quadratic equation in the form  $ax^2 + bx + c = 0$ . First, obtain the product  $ac$  from the coefficients  $a$  and  $c$ , and then determine two numbers,  $f_1$  and  $f_2$ , such that  $f_1 \times f_2 = |ac|$ , and  $f_1 + f_2 = b$  if  $ac$  is positive, or  $f_1 - f_2 = b$  if  $ac$  is negative.

The numbers  $f_1$  and  $f_2$  are used to modify or rearrange the  $bx$  term to simplify factoring the quadratic expression. The roots of the quadratic equation can be easily obtained from the factors.

*Example:* Factor  $8x^2 + 22x + 5 = 0$  and find the values of  $x$  that satisfy the equation.

*Solution:* In this example,  $a = 8$ ,  $b = 22$ , and  $c = 5$ . Therefore,  $ac = 8 \times 5 = 40$ , and  $ac$  is positive, so we are looking for two factors of  $ac$ ,  $f_1$  and  $f_2$ , such that  $f_1 \times f_2 = 40$ , and  $f_1 + f_2 = 22$ .

The  $ac$  term can be written as  $2 \times 2 \times 2 \times 5 = 40$ , and the possible combination of numbers for  $f_1$  and  $f_2$  are (20 and 2), (8 and 5), (4 and 10) and (40 and 1). The requirements for  $f_1$  and  $f_2$  are satisfied by  $f_1 = 20$  and  $f_2 = 2$ , i.e.,  $20 \times 2 = 40$  and  $20 + 2 = 22$ . Using  $f_1$  and  $f_2$ , the original quadratic expression is rewritten and factored as follows:

$$\begin{aligned} 8x^2 + 22x + 5 &= 0 \\ 8x^2 + 20x + 2x + 5 &= 0 \\ 4x(2x + 5) + 1(2x + 5) &= 0 \\ (2x + 5)(4x + 1) &= 0 \end{aligned}$$

If the product of the two factors equals zero, then each of the factors equals zero, thus,  $2x + 5 = 0$  and  $4x + 1 = 0$ . Rearranging and solving,  $x = -\frac{5}{2}$  and  $x = -\frac{1}{4}$ .

*Example:* Factor  $8x^2 + 3x - 5 = 0$  and find the solutions for  $x$ .

*Solution:* Here  $a = 8$ ,  $b = 3$ ,  $c = -5$ , and  $ac = 8 \times (-5) = -40$ . Because  $ac$  is negative, the required numbers,  $f_1$  and  $f_2$ , must satisfy  $f_1 \times f_2 = |ac| = 40$  and  $f_1 - f_2 = 3$ .

As in the previous example, the possible combinations for  $f_1$  and  $f_2$  are (20 and 2), (8 and 5), (4 and 10) and (40 and 1). The numbers  $f_1 = 8$  and  $f_2 = 5$  satisfy the requirements because  $8 \times 5 = 40$  and  $8 - 5 = 3$ . In the second line below,  $5x$  is both added to and subtracted from the original equation, making it possible to rearrange and simplify the expression.

$$\begin{aligned} 8x^2 + 3x - 5 &= 0 \\ 8x^2 + 8x - 5x - 5 &= 0 \\ 8x(x + 1) - 5(x + 1) &= 0 \\ (x + 1)(8x - 5) &= 0 \end{aligned}$$

Solving, for  $x + 1 = 0$ ,  $x = -1$ ; and, for  $8x - 5 = 0$ ,  $x = \frac{5}{8}$ .

**Cubic Equations.**—If the given equation has the form:  $x^3 + ax + b = 0$  then

$$x = \left(-\frac{b}{2} + \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{1/3} + \left(-\frac{b}{2} - \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{1/3}$$

The equation  $x^3 + px^2 + qx + r = 0$ , may be reduced to the form  $x_1^3 + ax_1 + b = 0$  by substituting  $x_1 = x - \frac{p}{3}$  for  $x$  in the given equation.

**Solving Numerical Equations Having One Unknown.**—The Newton-Raphson method is a procedure for solving various kinds of numerical algebraic and transcendental equations in one unknown. The steps in the procedure are simple and can be used with either a handheld calculator or as a subroutine in a computer program.

Examples of types of equations that can be solved to any desired degree of accuracy by this method are

$$f(x) = x^2 - 101 = 0, \quad f(x) = x^3 - 2x^2 - 5 = 0$$

$$\text{and } f(x) = 2.9x - \cos x - 1 = 0$$

The procedure begins with an estimate,  $r_1$ , of the root satisfying the given equation. This estimate is obtained by judgment, inspection, or plotting a rough graph of the equation and observing the value  $r_1$  where the curve crosses the  $x$  axis. This value is then used to calculate values  $r_2, r_3, \dots, r_n$  progressively closer to the exact value.

Before continuing, it is necessary to calculate the first derivative,  $f'(x)$ , of the function. In the above examples,  $f'(x)$  is, respectively,  $2x$ ,  $3x^2 - 4x$ , and  $2.9 + \sin x$ . These values were found by the methods described in *Derivatives and Integrals of Functions* on page 34.

In the steps that follow,

$r_1$  is the first estimate of the value of the root of  $f(x) = 0$ ;

$f(r_1)$  is the value of  $f(x)$  for  $x = r_1$ ;

$f'(x)$  is the first derivative of  $f(x)$ ;

$f'(r_1)$  is the value of  $f'(x)$  for  $x = r_1$ .

The second approximation of the root of  $f(x) = 0$ ,  $r_2$ , is calculated from

$$r_2 = r_1 - [f(r_1)/f'(r_1)]$$

and, to continue further approximations,

$$r_n = r_{n-1} - [f(r_{n-1})/f'(r_{n-1})]$$

*Example:* Find the square root of 101 using the Newton-Raphson method. This problem can be restated as an equation to be solved, i.e.,  $f(x) = x^2 - 101 = 0$

Step 1. By inspection, it is evident that  $r_1 = 10$  may be taken as the first approximation of the root of this equation. Then,  $f(r_1) = f(10) = 10^2 - 101 = -1$

Step 2. The first derivative,  $f'(x)$ , of  $x^2 - 101$  is  $2x$  as stated previously, so that

$$f'(10) = 2(10) = 20.$$

Then,  $r_2 = r_1 - f(r_1)/f'(r_1) = 10 - (-1)/20 = 10 + 0.05 = 10.05$

$$\text{Check: } 10.05^2 = 101.0025; \text{ error} = 0.0025$$

Step 3. The next, better approximation is

$$r_3 = r_2 - [f(r_2)/f'(r_2)] = 10.05 - [f(10.05)/f'(10.05)]$$

$$= 10.05 - [(10.05^2 - 101)/2(10.05)] = 10.049875$$

$$\text{Check: } 10.049875^2 = 100.9999875; \text{ error} = 0.0000125$$

**Series.**—Some hand calculations, as well as computer programs of certain types of mathematical problems, may be facilitated by the use of an appropriate series. For example, in some gear problems, the angle corresponding to a given or calculated involute function is found by using a series together with an iterative procedure such as the Newton-Raphson method described on page 33. The following are those series most commonly used for such purposes. In the series for trigonometric functions, the angles  $x$  are in radians (1 radian =  $180/\pi$  degrees). The expression  $\exp(-x^2)$  means that the base  $e$  of the natural logarithm system is raised to the  $-x^2$  power;  $e = 2.7182818$ .

- (1)  $\sin x = x - x^3/3! + x^5/5! - x^7/7! + \dots$  for all values of  $x$ .
- (2)  $\cos x = 1 - x^2/2! + x^4/4! - x^6/6! + \dots$  for all values of  $x$ .
- (3)  $\tan x = x + x^3/3 + 2x^5/15 + 17x^7/315 + 62x^9/2835 + \dots$  for  $|x| < \pi/2$ .
- (4)  $\arcsin x = x + x^3/6 + 1 \cdot 3 \cdot x^5/(2 \cdot 4 \cdot 5) + 1 \cdot 3 \cdot 5 \cdot x^7/(2 \cdot 4 \cdot 6 \cdot 7) + \dots$  for  $|x| \leq 1$ .
- (5)  $\arccos x = \pi/2 - \arcsin x$
- (6)  $\arctan x = x - x^3/3 + x^5/5 - x^7/7 + \dots$  for  $|x| \leq 1$ .
- (7)  $\pi/4 = 1 - 1/3 + 1/5 - 1/7 + 1/9 \dots \pm 1/(2x - 1) \mp \dots$  for all values of  $x$ .
- (8)  $e = 1 + 1/1! + 2/2! + 1/3! + \dots$  for all values of  $x$ .
- (9)  $e^x = 1 + x + x^2/2! + x^3/3! + \dots$  for all values of  $x$ .
- (10)  $\exp(-x^2) = 1 - x^2 + x^4/2! - x^6/3! + \dots$  for all values of  $x$ .
- (11)  $a^x = 1 + x \log_e a + (x \log_e a)^2/2! + (x \log_e a)^3/3! + \dots$  for all values of  $x$ .
- (12)  $1/(1+x) = 1 - x + x^2 - x^3 + x^4 - \dots$  for  $|x| < 1$ .
- (13)  $1/(1-x) = 1 + x + x^2 + x^3 + x^4 + \dots$  for  $|x| < 1$ .
- (14)  $1/(1+x)^2 = 1 - 2x + 3x^2 - 4x^3 + 5x^4 - \dots$  for  $|x| < 1$ .
- (15)  $1/(1-x)^2 = 1 + 2x + 3x^2 + 4x^3 + 5x^4 + \dots$  for  $|x| < 1$ .
- (16)  $\sqrt{1+x} = 1 + x/2 - x^2/(2 \cdot 4) + 1 \cdot 3 \cdot x^3/(2 \cdot 4 \cdot 6) - 1 \cdot 3 \cdot 5 \cdot x^4/(2 \cdot 4 \cdot 6 \cdot 8) - \dots$  for  $|x| < 1$ .
- (17)  $1/(\sqrt{1+x}) = 1 - x/2 + 1 \cdot 3 \cdot x^2/(2 \cdot 4) - 1 \cdot 3 \cdot 5 \cdot x^3/(2 \cdot 4 \cdot 6) + \dots$  for  $|x| < 1$ .
- (18)  $(a+x)^n = a^n + na^{n-1}x + n(n-1)a^{n-2}x^2/2! + n(n-1)(n-2)a^{n-3}x^3/3! + \dots$  for  $x^2 < a^2$ .

**Derivatives and Integrals of Functions.**—The following are formulas for obtaining the derivatives and integrals of basic mathematical functions. In these formulas, the letters  $a$  and  $c$  denotes constants; the letter  $x$  denotes a variable; and the letters  $u$  and  $v$  denote functions of the variable  $x$ . The expression  $d/dx$  means the derivative with respect to  $x$ , and as such applies to whatever expression in parentheses follows it. Thus,  $d/dx(ax)$  means the derivative with respect to  $x$  of the product  $(ax)$  of the constant  $a$  and the variable  $x$ .

**Formulas for Differential and Integral Calculus**

| Derivative                       | Value   | Integral                  | Value                           |
|----------------------------------|---|---------------------------|---------------------------------|
| $\frac{d}{dx}(c)$                | 0   | $\int c dx$               | $cx$                            |
| $\frac{d}{dx}(x)$                | 1   | $\int 1 dx$               | $x$                             |
| $\frac{d}{dx}(x^n)$              | $nx^{n-1}$                                      | $\int x^n dx$             | $\frac{x^{n+1}}{n+1}$           |
| $\frac{d}{dx}(g(u))$             | $\frac{d}{du}g(u) \frac{du}{dx}$                | $\int \frac{dx}{ax+b}$    | $\frac{1}{a} \log ax+b $        |
| $\frac{d}{dx}(u(x) + v(x))$      | $\frac{d}{dx}u(x) + \frac{d}{dx}v(x)$           | $\int (u(x) \pm v(x)) dx$ | $\int u(x) dx \pm \int v(x) dx$ |
| $\frac{d}{dx}(u(x) \times v(x))$ | $u(x) \frac{d}{dx}v(x) + v(x) \frac{d}{dx}u(x)$ | $\int u(x)v(x) dx$        | $u(x)v(x) - \int v(x) du(x)$    |

## Formulas for Differential and Integral Calculus (Continued)

| Derivative                                   | Value  | Integral                         | Value  |

| $\frac{d}{dx}(\log \cot x)$                  | $\frac{-2}{\sin 2x}$   | $\int \frac{1}{\cos x} dx$       | $\log \tan \left( \frac{\pi}{4} + \frac{x}{2} \right)$   |
| $\frac{d}{dx}(\sqrt{x})$                     | $\frac{1}{2\sqrt{x}}$  | $\int \frac{1}{1+\cos x} dx$     | $\tan \frac{x}{2}$   |
| $\frac{d}{dx}(\log_{10} x)$                  | $\frac{\log_{10} e}{x}$                                      | $\int \log x dx$                 | $x \log x - x$   |

## GEOMETRY

### Arithmetical Progression

An arithmetical progression is a series of numbers in which each consecutive term differs from the preceding one by a fixed amount called the *common difference*,  $d$ . Thus, 1, 3, 5, 7, etc., is an arithmetical progression where the difference  $d$  is 2. The difference here is *added* to the preceding term, and the progression is called increasing. In the series 13, 10, 7, 4, etc., the difference is (-3), and the progression is called decreasing. In any arithmetical progression (or part of progression), let

$a$  = first term considered

$l$  = last term considered

$n$  = number of terms

$d$  = common difference

$S$  = sum of  $n$  terms

Then the general formulas are  $l = a + (n - 1)d$       and       $S = \frac{a + l}{2} \times n$

In these formulas,  $d$  is positive in an increasing and negative in a decreasing progression. When any three of the preceding five quantities are given, the other two can be found by the formulas in the accompanying table of arithmetical progression.

*Example:* In an arithmetical progression, the first term equals 5, and the last term 40. The difference is 7. Find the sum of the progression.

$$S = \frac{a + l}{2d}(l + d - a) = \frac{5 + 40}{2 \times 7}(40 + 7 - 5) = 135$$

### Geometrical Progression

A geometrical progression or a geometrical series is a series in which each term is derived by multiplying the preceding term by a constant multiplier called the *ratio*. When the ratio is greater than 1, the progression is increasing; when less than 1, it is decreasing. Thus, 2, 6, 18, 54, etc., is an increasing geometrical progression with a ratio of 3, and 24, 12, 6, etc., is a decreasing progression with a ratio of 1/2.

In any geometrical progression (or part of progression), let

$a$  = first term

$l$  = last (or  $n$ th) term

$n$  = number of terms

$r$  = ratio of the progression

$S$  = sum of  $n$  terms

Then the general formulas are  $l = ar^{n-1}$       and       $S = \frac{rl - a}{r - 1}$

When any three of the preceding five quantities are given, the other two can be found by the formulas in the accompanying table. For instance, geometrical progressions are used for finding the successive speeds in machine tool drives, and in interest calculations.

*Example:* The lowest speed of a lathe is 20 rpm. The highest speed is 225 rpm. There are 18 speeds. Find the ratio between successive speeds.

$$\text{Ratio } r = \sqrt[n-1]{\frac{l}{a}} = \sqrt[17]{\frac{225}{20}} = 17\sqrt{11.25} = 1.153$$

## Formulas for Arithmetical Progression

| To Find | Given               | Use Equation   |
|---------|---------------------|--|
| $a$     | $d \quad l \quad n$ | $a = l - (n - 1)d$   |
|         | $d \quad n \quad S$ | $a = \frac{S}{n} - \frac{n-1}{2} \times d$                                 |
|         | $d \quad l \quad S$ | $a = \frac{d \pm 1}{2} \sqrt{(2l + d)^2 - 8dS}$                            |
|         | $l \quad n \quad S$ | $a = \frac{2S}{n} - l$   |
| $d$     | $a \quad l \quad n$ | $d = \frac{l - a}{n - 1}$  |
|         | $a \quad n \quad S$ | $d = \frac{2S - 2an}{n(n - 1)}$  |
|         | $a \quad l \quad S$ | $d = \frac{l^2 - a^2}{2S - l - a}$   |
|         | $l \quad n \quad S$ | $d = \frac{2nl - 2S}{n(n - 1)}$  |
| $l$     | $a \quad d \quad n$ | $l = a + (n - 1)d$   |
|         | $a \quad d \quad S$ | $l = -\frac{d \pm 1}{2} \sqrt{8dS + (2a - d)^2}$                           |
|         | $a \quad n \quad S$ | $l = \frac{2S}{n} - a$   |
|         | $d \quad n \quad S$ | $l = \frac{S}{n} + \frac{n-1}{2} \times d$                                 |
| $n$     | $a \quad d \quad l$ | $n = 1 + \frac{l - a}{d}$  |
|         | $a \quad d \quad S$ | $n = \frac{d - 2a}{2d} \pm \frac{1}{2d} \sqrt{8dS + (2a - d)^2}$           |
|         | $a \quad l \quad S$ | $n = \frac{2S}{a + l}$   |
|         | $d \quad l \quad S$ | $n = \frac{2l + d}{2d} \pm \frac{1}{2d} \sqrt{(2l + d)^2 - 8dS}$           |
| $S$     | $a \quad d \quad n$ | $S = \frac{n}{2}[2a + (n - 1)d]$   |
|         | $a \quad d \quad l$ | $S = \frac{a + l}{2} + \frac{l^2 - a^2}{2d} = \frac{a + l}{2d}(l + d - a)$ |
|         | $a \quad l \quad n$ | $S = \frac{n}{2}(a + l)$   |
|         | $d \quad l \quad n$ | $S = \frac{n}{2}[2l - (n - 1)d]$   |

## Formulas for Geometrical Progression

| To Find | Given               | Use Equation   |
|---------|---------------------|--|
| $a$     | $l \quad n \quad r$ | $a = \frac{l}{r^{n-1}}$  |
|         | $n \quad r \quad S$ | $a = \frac{(r-1)S}{r^n - 1}$   |
|         | $l \quad r \quad S$ | $a = lr - (r-1)S$  |
|         | $l \quad n \quad S$ | $a(S-a)^{n-1} = l(S-l)^{n-1}$  |
| $l$     | $a \quad n \quad r$ | $l = ar^{n-1}$   |

## Analytical Geometry

**Straight Line.**—A straight line is a line between two points with the minimum distance.

*Coordinate System:* It is possible to locate any point on a plane by a pair of numbers called the coordinates of the point. If P is a point on a plane, and perpendiculars are drawn from P to the coordinate axes, one perpendicular meets the X-axis at the  $x$ -coordinate of P and the other meets the Y-axis at the  $y$ -coordinate of P. The pair of numbers  $(x_1, y_1)$ , in that order, is called the coordinates or coordinate pair for P.

Fig. 1. Coordinate Plan

*Distance Between Two Points:* The distance  $d$  between two points  $P_1(x_1, y_1)$  and  $P_2(x_2, y_2)$  is given by the formula:

$$d(P_1, P_2) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

*Example 1:* What is the distance AB between points A(4,5) and B(7,8)?

*Solution:* The length of line AB is

$$d = \sqrt{(7-4)^2 + (8-5)^2} = \sqrt{3^2 + 3^2} = \sqrt{18} = 3\sqrt{2}$$

*Intermediate Point:* An intermediate point, P( $x, y$ ) on a line between two points,  $P_1(x_1, y_1)$  and  $P_2(x_2, y_2)$ , Fig. 2, can be obtained by linear interpolation as follows,

$$x = \frac{r_1 x_1 + r_2 x_2}{r_1 + r_2} \quad \text{and} \quad y = \frac{r_1 y_1 + r_2 y_2}{r_1 + r_2}$$

where  $r_1$  is the ratio of the distance of  $P_1$  to P to the distance of  $P_1$  to  $P_2$ , and  $r_2$  is the ratio of the distance of  $P_2$  to P to the distance of  $P_1$  to  $P_2$ . If the desired point is the midpoint of line  $P_1P_2$ , then  $r_1 = r_2 = 1$ , and the coordinates of P are:

$$x = \frac{x_1 + x_2}{2} \quad \text{and} \quad y = \frac{y_1 + y_2}{2}$$

*Example 2:* What is the coordinate of point P( $x, y$ ), if P divides the line defined by points A(0,0) and B(8,6) at the ratio of 5:3.

$$\text{Solution:} \quad x = \frac{5 \times 0 + 3 \times 8}{5 + 3} = \frac{24}{8} = 3 \quad y = \frac{5 \times 0 + 3 \times 6}{5 + 3} = \frac{18}{8} = 2.25$$

*External Point:* A point,  $Q(x, y)$  on the line  $P_1P_2$ , and beyond the two points,  $P_1(x_1, y_1)$  and  $P_2(x_2, y_2)$ , can be obtained by external interpolation as follows,

$$x = \frac{r_1 x_1 - r_2 x_2}{r_1 - r_2} \quad \text{and} \quad y = \frac{r_1 y_1 - r_2 y_2}{r_1 - r_2}$$

where  $r_1$  is the ratio of the distance of  $P_1$  to  $Q$  to the distance of  $P_1$  to  $P_2$ , and  $r_2$  is the ratio of the distance of  $P_2$  to  $Q$  to the distance of  $P_1$  to  $P_2$ .

Fig. 2. Finding Intermediate and External Points on a Line

*Equation of a line  $P_1P_2$ :* The general equation of a line passing through points  $P_1(x_1, y_1)$  and  $P_2(x_2, y_2)$  is  $\frac{y - y_1}{y_1 - y_2} = \frac{x - x_1}{x_1 - x_2}$ .

The previous equation is frequently written in the form  $y - y_1 = \frac{y_1 - y_2}{x_1 - x_2}(x - x_1)$

where  $\frac{y_1 - y_2}{x_1 - x_2}$  is the slope of the line,  $m$ , and thus becomes  $y - y_1 = m(x - x_1)$  where  $y_1$  is the coordinate of the  $y$ -intercept  $(0, y_1)$  and  $x_1$  is the coordinate of the  $x$ -intercept  $(x_1, 0)$ . If the line passes through point  $(0, 0)$ , then  $x_1 = y_1 = 0$  and the equation becomes  $y = mx$ . The  $y$ -intercept is the  $y$ -coordinate of the point at which a line intersects the  $Y$ -axis at  $x = 0$ . The  $x$ -intercept is the  $x$ -coordinate of the point at which a line intersects the  $X$ -axis at  $y = 0$ . If a line  $AB$  intersects the  $X$ -axis at point  $A(a, 0)$  and the  $Y$ -axis at point  $B(0, b)$  then the equation of line  $AB$  is

$$\frac{x}{a} + \frac{y}{b} = 1$$

*Slope:* The equation of a line in a Cartesian coordinate system is  $y = mx + b$ , where  $x$  and  $y$  are coordinates of a point on a line,  $m$  is the slope of the line, and  $b$  is the  $y$ -intercept. The slope is the rate at which the  $x$  coordinates are increasing or decreasing relative to the  $y$  coordinates.

Another form of the equation of a line is the point-slope form  $(y - y_1) = m(x - x_1)$ . The slope,  $m$ , is defined as a ratio of the change in the  $y$  coordinates,  $y_2 - y_1$ , to the change in the  $x$  coordinates,  $x_2 - x_1$ ,

$$m = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$$

*Example 3:* What is the equation of a line AB between points A(4,5) and B(7,8)?

*Solution:*

$$\frac{y - y_1}{y_1 - y_2} = \frac{x - x_1}{x_1 - x_2}$$

$$\frac{y - 5}{5 - 8} = \frac{x - 4}{4 - 7}$$

$$y - 5 = x - 4$$

$$y - x = 1$$

*Example 4:* Find the general equation of a line passing through the points (3, 2) and (5, 6), and its intersection point with the y-axis.

First, find the slope using the equation above

$$m = \frac{\Delta y}{\Delta x} = \frac{6 - 2}{5 - 3} = \frac{4}{2} = 2$$

The line has a general form of  $y = 2x + b$ , and the value of the constant  $b$  can be determined by substituting the coordinates of a point on the line into the general form. Using point (3,2),  $2 = 2 \times 3 + b$  and rearranging,  $b = 2 - 6 = -4$ . As a check, using another point on the line, (5,6), yields equivalent results,  $y = 6 = 2 \times 5 + b$  and  $b = 6 - 10 = -4$ .

The equation of the line, therefore, is  $y = 2x - 4$ , indicating that line  $y = 2x - 4$  intersects the y-axis at point (0,-4), the y-intercept.

*Example 5:* Use the point-slope form to find the equation of the line passing through the point (3,2) and having a slope of 2.

$$(y - 2) = 2(x - 3)$$

$$y = 2x - 6 + 2$$

$$y = 2x - 4$$

The slope of this line is positive and crosses the y-axis at the y-intercept, point (0,-4).

*Parallel Lines:* The two lines,  $P_1P_2$  and  $Q_1Q_2$ , are parallel if both lines have the same slope, that is, if  $m_1 = m_2$ .

Fig. 3. Parallel Lines

Fig. 4. Perpendicular Lines

*Perpendicular Lines:* The two lines  $P_1P_2$  and  $Q_1Q_2$  are perpendicular if the product of their slopes equal  $-1$ , that is,  $m_1m_2 = -1$ .

*Example 6:* Find an equation of a line that passes through the point (3,4) and is (a) parallel to and (b) perpendicular to the line  $2x - 3y = 16$ ?

*Solution (a):* Line  $2x - 3y = 16$  in standard form is  $y = \frac{2}{3}x - \frac{16}{3}$ , and the equation of a line passing through (3,4) is  $y - 4 = m(x - 3)$ .

If the lines are parallel, their slopes are equal. Thus,  $y - 4 = \frac{2}{3}(x - 3)$  is parallel to line  $2x - 3y = -6$  and passes through point (3,4).

*Solution (b):* As illustrated in part (a), line  $2x - 3y = -6$  has a slope of  $\frac{2}{3}$ . The product of the slopes of perpendicular lines = -1, thus the slope  $m$  of a line passing through point (4,3) and perpendicular to  $2x - 3y = -6$  must satisfy the following:

$$m = \frac{-1}{m_1} = \frac{-1}{\frac{2}{3}} = -\frac{3}{2}$$

The equation of a line passing through point (4,3) and perpendicular to the line  $2x - 3y = -6$  is  $y - 4 = -\frac{3}{2}(x - 3)$ , which rewritten is  $3x + 2y = 17$ .

*Angle Between Two Lines:* For two non-perpendicular lines with slopes  $m_1$  and  $m_2$ , the angle between the two lines is given by

$$\tan \theta = \left| \frac{m_1 - m_2}{1 + m_1 m_2} \right|$$

*Note:* The straight brackets surrounding a symbol or number, as in  $|x|$ , stands for absolute value and means use the positive value of the bracketed quantity, irrespective of its sign.

*Example 7:* Find the angle between the following two lines:  $2x - y = 4$  and  $3x + 4y = 12$

*Solution:* The slopes are 2 and  $-\frac{3}{4}$ , respectively. The angle between two lines is given by

$$\tan \theta = \left| \frac{m_1 - m_2}{1 + m_1 m_2} \right| = \left| \frac{2 - \left(-\frac{3}{4}\right)}{1 + 2\left(-\frac{3}{4}\right)} \right| = \left| \frac{2 + \frac{3}{4}}{1 - \frac{6}{4}} \right| = \left| \frac{\frac{8 + 3}{4}}{\frac{4 - 6}{4}} \right| = \left| \frac{11}{-2} \right| = \frac{11}{2}$$

$$\theta = \text{atan} \frac{11}{2} = 79.70^\circ$$

*Distance Between a Point and a Line:* The distance between a point  $(x_1, y_1)$  and a line given by  $Ax + By + C = 0$  is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

*Example 8:* Find the distance between the point (4,6) and the line  $2x + 3y - 9 = 0$ .

*Solution:* The distance between a point and the line is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}} = \frac{|2 \times 4 + 3 \times 6 - 9|}{\sqrt{2^2 + 3^2}} = \frac{|8 + 18 - 9|}{\sqrt{4 + 9}} = \frac{17}{\sqrt{13}}$$

**Coordinate Systems.**—*Rectangular, Cartesian Coordinates:* In a Cartesian coordinate system the coordinate axes are perpendicular to one another, and the same unit of length is chosen on the two axes. This rectangular coordinate system is used in the majority of cases.

*Polar Coordinates:* Another coordinate system is determined by a fixed point O, the origin or pole, and a zero direction or axis through it, on which positive lengths can be laid off and measured, as a number line. A point P can be fixed to the zero direction line at a distance  $r$  away and then rotated in a positive sense at an angle  $\theta$ . The angle,  $\theta$ , in polar coordinates can take on values from  $0^\circ$  to  $360^\circ$ . A point in polar coordinates takes the form of  $(r, \theta)$ .

*Changing Coordinate Systems:* For simplicity it may be assumed that the origin on a Cartesian coordinate system coincides with the pole on a polar coordinate system, and its axis with the x-axis. Then, if point P has polar coordinates of  $(r, \theta)$  and Cartesian coordinates of  $(x, y)$ , by trigonometry  $x = r \times \cos(\theta)$  and  $y = r \times \sin(\theta)$ . By the Pythagorean theorem and trigonometry

$$r = \sqrt{x^2 + y^2} \quad \theta = \operatorname{atan} \frac{y}{x}$$

*Example 1:* Convert the Cartesian coordinate (3, 2) into polar coordinates.

$$r = \sqrt{3^2 + 2^2} = \sqrt{9 + 4} = \sqrt{13} = 3.6 \quad \theta = \operatorname{atan} \frac{2}{3} = 33.69^\circ$$

Therefore the point (3.6, 33.69) is the polar form of the Cartesian point (3, 2).

Graphically, the polar and Cartesian coordinates are related in the following figure

*Example 2:* Convert the polar form (5, 608) to Cartesian coordinates. By trigonometry,  $x = r \times \cos(\theta)$  and  $y = r \times \sin(\theta)$ . Then  $x = 5 \cos(608) = -1.873$  and  $y = 5 \sin(608) = -4.636$ . Therefore, the Cartesian point equivalent is  $(-1.873, -4.636)$ .

*Spherical Coordinates:* It is convenient in certain problems, for example, those concerned with spherical surfaces, to introduce non-parallel coordinates. An arbitrary point P in space can be expressed in terms of the distance  $r$  between point P and the origin O, the angle  $\phi$  that  $OP'$  makes with the x-y plane, and the angle  $\lambda$  that the projection  $OP'$  (of the segment  $OP$  onto the x-y plane) makes with the positive x-axis.

The rectangular coordinates of a point in space can therefore be calculated by the formulas in the following table.

## Relationship Between Spherical and Rectangular Coordinates

| Spherical to Rectangular  | Rectangular to Spherical  |
|---|---|
| $x = r \cos \phi \cos \lambda$<br>$y = r \cos \phi \sin \lambda$<br>$z = r \sin \phi$ | $r = \sqrt{x^2 + y^2 + z^2}$  |
|   | $\phi = \operatorname{atan} \frac{z}{\sqrt{x^2 + y^2}}$ (for $x^2 + y^2 \neq 0$ ) |
|   | $\lambda = \operatorname{atan} \frac{y}{x}$ (for $x > 0, y > 0$ )                 |
|   | $\lambda = \pi + \operatorname{atan} \frac{y}{x}$ (for $x < 0$ )                  |
|   | $\lambda = 2\pi + \operatorname{atan} \frac{y}{x}$ (for $x > 0, y < 0$ )          |

*Example 3:* What are the spherical coordinates of the point  $P(3, -4, -12)$ ?

$$r = \sqrt{3^2 + (-4)^2 + (-12)^2} = 13$$

$$\phi = \operatorname{atan} \frac{-12}{\sqrt{3^2 + (-4)^2}} = \operatorname{atan} \frac{-12}{5} = -67.38^\circ$$

$$\lambda = 360^\circ + \operatorname{atan} \frac{-4}{3} = 360^\circ - 53.13^\circ = 306.87^\circ$$

The spherical coordinates of  $P$  are therefore  $r = 13$ ,  $\phi = -67.38^\circ$ , and  $\lambda = 306.87^\circ$ .

*Cylindrical Coordinates:* For problems on the surface of a cylinder it is convenient to use cylindrical coordinates. The cylindrical coordinates  $r$ ,  $\theta$ ,  $z$ , of  $P$  coincide with the polar coordinates of the point  $P'$  in the  $x$ - $y$  plane and the rectangular  $z$ -coordinate of  $P$ . This gives the conversion formula. Those for  $\theta$  hold only if  $x^2 + y^2 \neq 0$ ;  $\theta$  is undetermined if  $x = y = 0$ .

| Cylindrical to Rectangular                            | Rectangular to Cylindrical                 |
|---|--|
| $x = r \cos \theta$<br>$y = r \sin \theta$<br>$z = z$ | $r = \frac{1}{\sqrt{x^2 + y^2}}$           |
|   | $\cos \theta = \frac{x}{\sqrt{x^2 + y^2}}$ |
|   | $\sin \theta = \frac{y}{\sqrt{x^2 + y^2}}$ |
|   | $z = z$                                    |

*Example 4:* Given the cylindrical coordinates of a point  $P$ ,  $r = 3$ ,  $\theta = -30^\circ$ ,  $z = 51$ , find the rectangular coordinates. Using the above formulas  $x = 3 \cos(-30^\circ) = 3 \cos(30^\circ) = 2.598$ ;  $y = 3 \sin(-30^\circ) = -3 \sin(30^\circ) = -1.5$ ; and  $z = 51$ . Therefore, the rectangular coordinates of point  $P$  are  $x = 2.598$ ,  $y = -1.5$ , and  $z = 51$ .

**Circle.**—The general form for the equation of a circle is  $x^2 + y^2 + 2gx + 2fy + c = 0$ , where  $-g$  and  $-f$  are the coordinates of the center and the radius is  $r = \sqrt{g^2 + f^2 - c}$ .

The center radius form of the circle equation is

$$(x - h)^2 + (y - k)^2 = r^2$$

where  $r$  = radius and point  $(h, k)$  is the center.

When the center of circle is at point  $(0,0)$ , the equation of circle reduces to  $x^2 + y^2 = r^2$  or  $r = \sqrt{x^2 + y^2}$

*Example:* Point  $(4,6)$  lies on a circle whose center is at  $(-2,3)$ . Find the circle equation?

*Solution:* The radius is the distance between the center  $(-2,3)$  and point  $(4,6)$ , found using the method of [Example 1](#) on page 39.

$$r = \sqrt{[4 - (-2)]^2 + (6 - 3)^2} = \sqrt{6^2 + 3^2} = \sqrt{45}$$

The equation of the circle is

$$\begin{aligned}(x - h)^2 + (y - k)^2 &= r^2 \\(x + 2)^2 + (y - 3)^2 &= x^2 + 4x + 4 + y^2 - 6y + 9 = 45 \\x^2 + y^2 + 4x - 6y - 32 &= 0\end{aligned}$$

**Parabola.**—A parabola is the set of all points  $P$  in the plane that are equidistant from focus  $F$  and a line called the directrix. A parabola is symmetric with respect to its parabolic axis. The line perpendicular to the parabolic axis which passing through the focus is known as latus rectum.

The general equation of a parabola is given by  $(y - k)^2 = 4p(x - h)$ , where the vertex is located at point  $(h, k)$ , the focus  $F$  is located at point  $(h + p, k)$ , the directrix is located at  $x = h - p$ , and the latus rectum is located at  $x = h + p$ .

*Example:* Determine the focus, directrix, axis, vertex, and latus rectum of the parabola

$$4y^2 - 8x - 12y + 1 = 0$$

*Solution:* Format the equation into the general form of a parabolic equation

$$4y^2 - 8x - 12y + 1 = 0$$

$$4y^2 - 12y = 8x - 1$$

$$y^2 - 3y = 2x - \frac{1}{4}$$

$$y^2 - 2y\left(\frac{3}{2}\right) + \left(\frac{3}{2}\right)^2 = 2x - \frac{1}{4} + \frac{9}{4}$$

$$\left(y - \frac{3}{2}\right)^2 = 2\left(x + \frac{1}{2}\right)$$

Parabola

Thus,  $k = \frac{3}{2}$ ,  $h = -\frac{1}{2}$  and  $p = \frac{1}{2}$ . Focus  $F$  is located at point  $(h + p, k) = (\frac{1}{2}, \frac{3}{2})$ ; the directrix is located at  $x = h - p = -1 - \frac{1}{2} = -\frac{3}{2}$ ; the parabolic axis is the horizontal line  $y = \frac{3}{2}$ ; the vertex  $V(h, k)$  is located at point  $(-\frac{1}{2}, \frac{3}{2})$ ; and the latus rectum is located at  $x = h + p = -\frac{1}{2}$ .

**Ellipse.**—The ellipse with eccentricity  $e$ , focus  $F$  and a directrix  $L$  is the set of all points  $P$  such that the distance  $PF$  is  $e$  times the distance from  $P$  to the line  $L$ . The general equation of an ellipse is

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \Big|_{AC > 0 \text{ and } A \neq C$$

The ellipse has two foci separated along the major axis by a distance  $2c$ . The line passing through the focus perpendicular to the major axis is called the latus rectum. The line passing through the center, perpendicular to the major axis, is called the minor axis. The distances  $2a$  and  $2b$  are the major distance, and the minor distance. The ellipse is the locus of points such that the sum of the distances from the two foci to a point on the ellipse is  $2a$ , thus,  $PF_1 + PF_2 = 2a$

If  $(h, k)$  are the center, the general equation of an ellipse is  $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$

The eccentricity of the ellipse,  $e = \frac{\sqrt{a^2 - b^2}}{a}$ , is always less than 1.

The distance between the two foci is  $2c = 2\sqrt{a^2 - b^2}$ .

The aspect ratio of the ellipse is  $a/b$ .

The equation of an ellipse centered at  $(0, 0)$  with foci at  $(\pm c, 0)$  is  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ , and the

ellipse is symmetric about both coordinate axes. Its  $x$ -intercepts are  $(\pm a, 0)$  and  $y$ -intercepts are  $(0, \pm b)$ . The line joining  $(0, b)$  and  $(0, -b)$  is called the minor axis. The vertices of the ellipse are  $(\pm a, 0)$ , and the line joining vertices is the major axis of the ellipse.

*Example:* Determine the values of  $h, k, a, b, c$ , and  $e$  of the ellipse

$$3x^2 + 5y^2 - 12x + 30y + 42 = 0$$

*Solution:* Rearrange the ellipse equation into the general form as follows:

$$3x^2 + 5y^2 - 12x + 30y + 42 = 3x^2 - 12x + 5y^2 + 30y + 42 = 0$$

$$3(x^2 - 4x + 2^2) + 5(y^2 + 6y + 3^2) = 15$$

$$\frac{3(x-2)^2}{15} + \frac{5(y+3)^2}{15} = \frac{(x-2)^2}{(\sqrt{5})^2} + \frac{(y+3)^2}{(\sqrt{3})^2} = 1$$

Comparing the result with the general form,  $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$ , and solving for  $c$  and  $e$  gives

$$h = 2 \quad k = -3 \quad a = \sqrt{5} \quad b = \sqrt{3} \quad c = \sqrt{2} \quad e = \sqrt{\frac{2}{5}}$$

**Four-Arc Oval that Approximates an Ellipse\*.**—The method of constructing an approximate ellipse by circular arcs, described on page 57, fails when the ratio of the major to minor diameter equals four or greater. Additionally, it is reported that the method always draws a somewhat larger minor axes than intended. The method described below presents an alternative.

An oval that approximates an ellipse, illustrated in Fig. 1, can be constructed from the following equations:

$$r = \frac{B^2 \left(\frac{A}{B}\right)^{0.38}}{2A} \quad (1)$$

where  $A$  and  $B$  are dimensions of the major and minor axis, respectively, and  $r$  is the radius of the curve at the long ends.

The radius  $R$  and its location are found from Equations (2) and (3):

$$X = \frac{\frac{A^2}{4} - Ar + Br - \frac{B^2}{4}}{B - 2r} \quad (2) \quad R = \frac{B}{2 + X} \quad (3)$$

Fig. 1.

To make an oval thinner or fatter than that given, select a smaller or larger radius  $r$  than calculated by Equation (1) and then find  $X$  and  $R$  using Equations (2) and (3).

**Hyperbola.**—The hyperbola with eccentricity  $e$ , focus  $F$  and a directrix  $L$  is the set of all points  $P$  such that the distance  $PF$  is  $e$  times the distance from  $P$  to the line  $L$ . The general equation of an hyperbola is

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \quad \left|_{AC < 0 \text{ and } AC \neq 0}\right.$$

The hyperbola has two foci separated along the transverse axis by a distance  $2c$ . Lines perpendicular to the transverse axis passing through the foci are the conjugate axis. The distance between two vertices is  $2a$ . The distance along a conjugate axis between two

\* Four-Arc Oval material contributed by Manfred K. Brueckner

## HYPERBOLA

points on the hyperbola is  $2b$ . The hyperbola is the locus of points such that the difference of the distances from the two foci is  $2a$ , thus,  $PF_2 - PF_1 = 2a$

If point  $(h, k)$  is the center, the general equation of an ellipse is  $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$

Hyperbola

The eccentricity of hyperbola,  $e = \frac{\sqrt{a^2 + b^2}}{a}$  is always less than 1.

The distance between the two foci is  $2c = 2\sqrt{a^2 + b^2}$ .

The equation of a hyperbola with center at  $(0, 0)$  and focus at  $(\pm c, 0)$  is  $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ .

*Example:* Determine the values of  $h, k, a, b, c,$  and  $e$  of the hyperbola

$$9x^2 - 4y^2 - 36x + 8y - 4 = 0$$

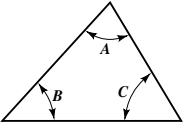

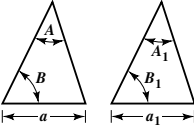

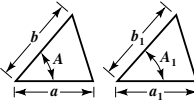

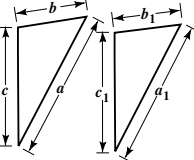

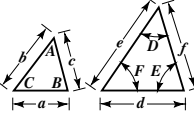

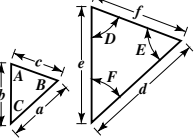

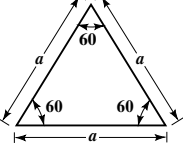

*Solution:* Convert the hyperbola equation into the general form

$$\begin{aligned} 9x^2 - 4y^2 - 36x + 8y - 4 &= (9x^2 - 36x) - (4y^2 - 8y) - 4 = 0 \\ 9(x^2 - 4x + 4) - 4(y^2 - 2y + 1) &= 36 \\ 9\frac{(x-2)^2}{36} - 4\frac{(y-1)^2}{36} &= \frac{(x-2)^2}{2^2} - \frac{(y-1)^2}{3^2} = 1 \end{aligned}$$

Comparing the results above with the general form  $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$  and calculating the eccentricity from  $e = \frac{\sqrt{a^2 + b^2}}{a}$  and  $c$  from  $c = \sqrt{a^2 + b^2}$  gives

$$h = 2 \quad k = 1 \quad a = 2 \quad b = 3 \quad c = \sqrt{13} \quad e = \frac{\sqrt{13}}{2}$$

Then, with <math>B</math> and <math>C</math> as centers and a radius longer than <math>AB</math>, draw circular arcs intersecting at <math>D</math>. Line <math>DA</math> is perpendicular to <math>BC</math> at <math>A</math>.</p>                                       |
|    | <p>To draw a perpendicular line from a point <math>A</math> at the end of a line <math>AB</math>:</p> <p>With any point <math>D</math>, outside of the line <math>AB</math>, as a center, and with <math>AD</math> as a radius, draw a circular arc intersecting <math>AB</math> at <math>E</math>. Draw a line through <math>E</math> and <math>D</math> intersecting the arc at <math>C</math>; then join <math>AC</math>. This line is the required perpendicular.</p>   |
|  | <p>To draw a perpendicular to a line <math>AB</math> from a point <math>C</math> at a distance from it:</p> <p>With <math>C</math> as a center, draw a circular arc intersecting the given line at <math>E</math> and <math>F</math>. With <math>E</math> and <math>F</math> as centers, draw circular arcs with a radius longer than one-half the distance between <math>E</math> and <math>F</math>. These arcs intersect at <math>D</math>. Line <math>CD</math> is the required perpendicular.</p>              |
|  | <p>To divide a straight line <math>AB</math> into a number of equal parts:</p> <p>Let it be required to divide <math>AB</math> into five equal parts. Draw line <math>AC</math> at an angle with <math>AB</math>. Set off on <math>AC</math> five equal parts of any convenient length. Draw <math>B-5</math> and then draw lines parallel with <math>B-5</math> through the other division points on <math>AC</math>. The points where these lines intersect <math>AB</math> are the required division points.</p> |

## Geometrical Constructions

|  |  |
|--|--|
|    | <p>To draw a straight line parallel to a given line <math>AB</math>, at a given distance from it:</p> <p>With any points <math>C</math> and <math>D</math> on <math>AB</math> as centers, draw circular arcs with the given distance as radius. Line <math>EF</math>, drawn to touch the circular arcs, is the required parallel line.</p>   |
|    | <p>To bisect or divide an angle <math>BAC</math> into two equal parts:</p> <p>With <math>A</math> as a center and any radius, draw arc <math>DE</math>. With <math>D</math> and <math>E</math> as centers and a radius greater than one-half <math>DE</math>, draw circular arcs intersecting at <math>F</math>. Line <math>AF</math> divides the angle into two equal parts.</p>  |
|    | <p>To draw an angle upon a line <math>AB</math>, equal to a given angle <math>FGH</math>:</p> <p>With point <math>G</math> as a center and with any radius, draw arc <math>KL</math>. With <math>A</math> as a center and with the same radius, draw arc <math>DE</math>. Make arc <math>DE</math> equal to <math>KL</math> and draw <math>AC</math> through <math>E</math>. Angle <math>BAC</math> then equals angle <math>FGH</math>.</p>  |
|   | <p>To lay out a 60-degree angle:</p> <p>With <math>A</math> as a center and any radius, draw an arc <math>BC</math>. With point <math>B</math> as a center and <math>AB</math> as a radius, draw an arc intersecting at <math>E</math> the arc just drawn. <math>EAB</math> is a 60-degree angle.</p> <p>A 30-degree angle may be obtained either by dividing a 60-degree angle into two equal parts or by drawing a line <math>EG</math> perpendicular to <math>AB</math>. Angle <math>AEG</math> is then 30 degrees.</p> |
|  | <p>To draw a 45-degree angle:</p> <p>From point <math>A</math> on line <math>AB</math>, set off a distance <math>AC</math>. Draw the perpendicular <math>DC</math> and set off a distance <math>CE</math> equal to <math>AC</math>. Draw <math>AE</math>. Angle <math>EAC</math> is a 45-degree angle.</p>   |
|  | <p>To draw an equilateral triangle, the length of the sides of which equals <math>AB</math>:</p> <p>With <math>A</math> and <math>B</math> as centers and <math>AB</math> as radius, draw circular arcs intersecting at <math>C</math>. Draw <math>AC</math> and <math>BC</math>. Then <math>ABC</math> is an equilateral triangle.</p>  |

## Geometrical Constructions

|   |   |
|---|---|
|    | <p>To draw a circular arc with a given radius through two given points <math>A</math> and <math>B</math>:</p> <p>With <math>A</math> and <math>B</math> as centers, and the given radius as radius, draw circular arcs intersecting at <math>C</math>. With <math>C</math> as a center, and the same radius, draw a circular arc through <math>A</math> and <math>B</math>.</p>   |
|     | <p>To find the center of a circle or of an arc of a circle:</p> <p>Select three points on the periphery of the circle, as <math>A</math>, <math>B</math>, and <math>C</math>. With each of these points as a center and the same radius, describe arcs intersecting each other. Through the points of intersection, draw lines <math>DE</math> and <math>FG</math>. Point <math>H</math>, where these lines intersect, is the center of the circle.</p> |
|    | <p>To draw a tangent to a circle from a given point on the circumference:</p> <p>Through the point of tangency <math>A</math>, draw a radial line <math>BC</math>. At point <math>A</math>, draw a line <math>EF</math> at right angles to <math>BC</math>. This line is the required tangent.</p>  |
|   | <p>To divide a circular arc <math>AB</math> into two equal parts:</p> <p>With <math>A</math> and <math>B</math> as centers, and a radius larger than half the distance between <math>A</math> and <math>B</math>, draw circular arcs intersecting at <math>C</math> and <math>D</math>. Line <math>CD</math> divides arc <math>AB</math> into two equal parts at <math>E</math>.</p>  |
|  | <p>To describe a circle about a triangle:</p> <p>Divide the sides <math>AB</math> and <math>AC</math> into two equal parts, and from the division points <math>E</math> and <math>F</math>, draw lines at right angles to the sides. These lines intersect at <math>G</math>. With <math>G</math> as a center and <math>GA</math> as a radius, draw circle <math>ABC</math>.</p>  |
|   | <p>To inscribe a circle in a triangle:</p> <p>Bisect two of the angles, <math>A</math> and <math>B</math>, by lines intersecting at <math>D</math>. From <math>D</math>, draw a line <math>DE</math> perpendicular to one of the sides, and with <math>DE</math> as a radius, draw circle <math>EFG</math>.</p>   |

**Geometrical Constructions**

|  |  |
|--|--|
|  | <p>To describe a circle about a square and to inscribe a circle in a square:</p> <p>The centers of both the circumscribed and inscribed circles are located at the point <math>E</math>, where the two diagonals of the square intersect. The radius of the circumscribed circle is <math>AE</math>, and of the inscribed circle, <math>EF</math>.</p>   |
|  | <p>To inscribe a hexagon in a circle:</p> <p>Draw a diameter <math>AB</math>. With <math>A</math> and <math>B</math> as centers and with the radius of the circle as radius, describe circular arcs intersecting the given circle at <math>D, E, F</math>, and <math>G</math>. Draw lines <math>AD, DE</math>, etc., forming the required hexagon.</p>   |
|  | <p>To describe a hexagon about a circle:</p> <p>Draw a diameter <math>AB</math>, and with <math>A</math> as a center and the radius of the circle as radius, cut the circumference of the given circle at <math>D</math>. Join <math>AD</math> and bisect it with radius <math>CE</math>. Through <math>E</math>, draw <math>FG</math> parallel to <math>AD</math> and intersecting line <math>AB</math> at <math>F</math>. With <math>C</math> as a center and <math>CF</math> as radius, draw a circle. Within this circle, inscribe the hexagon as in the preceding problem.</p>  |
|  | <p>To describe an ellipse with the given axes <math>AB</math> and <math>CD</math>:</p> <p>Describe circles with <math>O</math> as a center and <math>AB</math> and <math>CD</math> as diameters. From a number of points, <math>E, F, G</math>, etc., on the outer circle, draw radii intersecting the inner circle at <math>e, f, g</math>. From <math>E, F</math>, and <math>G</math>, draw lines perpendicular to <math>AB</math>, and from <math>e, f</math>, and <math>g</math>, draw lines parallel to <math>AB</math>. The intersections of these perpendicular and parallel lines are points on the curve of the ellipse.</p>  |
|  | <p>To construct an approximate ellipse by circular arcs:</p> <p>Let <math>AC</math> be the major axis and <math>BN</math> the minor. Draw half circle <math>ADC</math> with <math>O</math> as a center. Divide <math>BD</math> into three equal parts and set off <math>BE</math> equal to one of these parts. With <math>A</math> and <math>C</math> as centers and <math>OE</math> as radius, describe circular arcs <math>KLM</math> and <math>FGH</math>; with <math>G</math> and <math>L</math> as centers, and the same radius, describe arcs <math>FCH</math> and <math>KAM</math>. Through <math>F</math> and <math>G</math>, draw line <math>FP</math>, and with <math>P</math> as a center, draw the arc <math>FBK</math>. Arc <math>HNM</math> is drawn in the same manner.</p> |

**Geometrical Constructions**

|  |  |
|--|--|
|  | <p>To construct a parabola:</p> <p>Divide line <math>AB</math> into a number of equal parts and divide <math>BC</math> into the same number of parts. From the division points on <math>AB</math>, draw horizontal lines. From the division points on <math>BC</math>, draw lines to point <math>A</math>. The points of intersection between lines drawn from points numbered alike are points on the parabola.</p>   |
|  | <p>To construct a hyperbola:</p> <p>From focus <math>F</math>, lay off a distance <math>FD</math> equal to the transverse axis, or the distance <math>AB</math> between the two branches of the curve. With <math>F</math> as a center and any distance <math>FE</math> greater than <math>FB</math> as a radius, describe a circular arc. Then with <math>F_1</math> as a center and <math>DE</math> as a radius, describe arcs intersecting at <math>C</math> and <math>G</math> the arc just described. <math>C</math> and <math>G</math> are points on the hyperbola. Any number of points can be found in a similar manner.</p> |
|  | <p>To construct an involute:</p> <p>Divide the circumference of the base circle <math>ABC</math> into a number of equal parts. Through the division points 1, 2, 3, etc., draw tangents to the circle and make the lengths <math>D-1</math>, <math>E-2</math>, <math>F-3</math>, etc., of these tangents equal to the actual length of the arcs <math>A-1</math>, <math>A-2</math>, <math>A-3</math>, etc.</p>   |
|  | <p>To construct a helix:</p> <p>Divide half the circumference of the cylinder, on the surface of which the helix is to be described, into a number of equal parts. Divide half the lead of the helix into the same number of equal parts. From the division points on the circle representing the cylinder, draw vertical lines, and from the division points on the lead, draw horizontal lines as shown. The intersections between lines numbered alike are points on the helix.</p>   |

## Areas and Volumes

**The Prismoidal Formula.**—The prismoidal formula is a general formula by which the volume of any prism, pyramid, or frustum of a pyramid may be found. 

$A_1$  = area at one end of the body

$A_2$  = area at the other end

$A_m$  = area of middle section between the two end surfaces

$h$  = height of body

Then, volume  $V$  of the body is  $V = \frac{h}{6}(A_1 + 4A_m + A_2)$

**Pappus or Guldinus Rules.**—By means of these rules the area of any surface of revolution and the volume of any solid of revolution may be found. The area of the surface swept out by the revolution of a line  $ABC$  (see illustration) about the axis  $DE$  equals the length of the line multiplied by the length of the path of its center of gravity,  $P$ . If the line is of such a shape that it is difficult to determine its center of gravity, then the line may be divided into a number of short sections, each of which may be considered as a straight line, and the areas swept out by these different sections, as computed by the rule given, may be added to find the total area. The line must lie wholly on one side of the axis of revolution and must be in the same plane.

The volume of a solid body formed by the revolution of a surface  $FGHJ$  about axis  $KL$  equals the area of the surface multiplied by the length of the path of its center of gravity. The surface must lie wholly on one side of the axis of revolution and in the same plane.

*Example:* By means of these rules, the area and volume of a cylindrical ring or torus may be found. The torus is formed by a circle  $AB$  being rotated about axis  $CD$ . The center of gravity of the circle is at its center. Hence, with the dimensions given in the illustration, the length of the path of the center of gravity of the circle is  $3.1416 \times 10 = 31.416$  inches. Multiplying by the length of the circumference of the circle, which is  $3.1416 \times 3 = 9.4248$  inches, gives  $31.416 \times 9.4248 = 296.089$  square inches which is the area of the torus.

The volume equals the area of the circle, which is  $0.7854 \times 9 = 7.0686$  square inches, multiplied by the path of the center of gravity, which is 31.416, as before; hence,

$$\text{Volume} = 7.0686 \times 31.416 = 222.067 \text{ cubic inches}$$

**Approximate Method for Finding the Area of a Surface of Revolution.**—The accompanying illustration is shown in order to give an example of the approximate method based on Guldinus' rule, that can be used for finding the area of a symmetrical body. In the illustration, the dimensions in common fractions are the known dimensions; those in decimals are found by actual measurements on a figure drawn to scale.

The method for finding the area is as follows: First, separate such areas as are cylindrical, conical, or spherical, as these can be found by exact formulas. In the illustration  $ABCD$  is a cylinder, the area of the surface of which can be easily found. The top area  $EF$  is simply a circular area, and can thus be computed separately. The remainder of the surface generated by rotating line  $AF$  about the axis  $GH$  is found by the approximate method explained in the previous section. From point  $A$ , set off equal distances on line  $AF$ . In the illustration, each division indicated is  $\frac{1}{8}$  inch long. From the central or middle point of each of these parts draw a line at right angles to the axis of rotation  $GH$ , measure the length of these lines or diameters (the length of each is given in decimals), add all these lengths together and multiply the sum by the length of one division set off on line  $AF$  (in this case,  $\frac{1}{8}$  inch), and multiply this product by  $\pi$  to find the approximate area of the surface of revolution.

In setting off divisions  $\frac{1}{8}$  inch long along line  $AF$ , the last division does not reach exactly to point  $F$ , but only to a point 0.03 inch below it. The part 0.03 inch high at the top of the cup can be considered as a cylinder of  $\frac{1}{2}$  inch diameter and 0.03 inch height, the area of the cylindrical surface of which is easily computed. By adding the various surfaces together, the total surface of the cup is found as follows:

|   |                            |
|---|----------------------------|
| Cylinder, $1 \frac{5}{8}$ inch diameter, 0.41 inch high | 2.093 square inches        |
| Circle, $\frac{1}{2}$ inch diameter                     | 0.196 square inch          |
| Cylinder, $\frac{1}{2}$ inch diameter, 0.03 inch high   | 0.047 square inch          |
| Irregular surface                                       | <u>3.868</u> square inches |
| Total   | 6.204 square inches        |

**Area of Plane Surfaces of Irregular Outline.**—One of the most useful and accurate methods for determining the approximate area of a plane figure or irregular outline is known as *Simpson's Rule*. In applying Simpson's Rule to find an area the work is done in four steps:

- 1) Divide the area into an *even* number,  $N$ , of parallel strips of equal width  $W$ ; for example, in the accompanying diagram, the area has been divided into 8 strips of equal width.
- 2) Label the sides of the strips  $V_0, V_1, V_2, \dots, V_N$ .
- 3) Measure the heights  $V_0, V_1, V_2, \dots, V_N$  of the sides of the strips.
- 4) Substitute the heights  $V_0, V_1, \dots$ , in the following formula to find the area  $A$  of the figure:

$$A = \frac{W}{3}[(V_0 + V_N) + 4(V_1 + V_3 + \dots + V_{N-1}) + 2(V_2 + V_4 + \dots + V_N).$$

*Example:* The area of the accompanying figure was divided into 8 strips on a full-size drawing and the following data obtained. Calculate the area using Simpson's Rule.

- $W = \frac{1}{2}''$
- $V_0 = 0''$
- $V_1 = \frac{3}{4}''$
- $V_2 = 1\frac{1}{4}''$
- $V_3 = 1\frac{1}{2}''$
- $V_4 = 1\frac{5}{8}''$
- $V_5 = 2\frac{1}{4}''$
- $V_6 = 2\frac{1}{2}''$
- $V_7 = 1\frac{3}{4}''$
- $V_8 = \frac{1}{2}''$

Substituting the given data in the Simpson formula,

$$\begin{aligned} A &= \frac{1/2}{3}[(0 + 1/2) + 4(3/4 + 1\frac{1}{2} + 2\frac{1}{4} + 1\frac{3}{4}) + 2(1\frac{1}{4} + 1\frac{5}{8} + 2\frac{1}{2})] \\ &= \frac{1}{6}[(1/2) + 4(6\frac{1}{4}) + 2(5\frac{3}{8})] = \frac{1}{6}[36\frac{1}{4}] \\ &= 6.04 \text{ square inches} \end{aligned}$$

In applying Simpson's Rule, it should be noted that the larger the number of strips into which the area is divided the more accurate the results obtained.

**Areas Enclosed by Cycloidal Curves.**—The area between a cycloid and the straight line upon which the generating circle rolls, equals three times the area of the generating circle (see diagram, page 66). The areas between epicycloidal and hypocycloidal curves and the “fixed circle” upon which the generating circle is rolled, may be determined by the following formulas, in which  $a$  = radius of the fixed circle upon which the generating circle rolls;  $b$  = radius of the generating circle;  $A$  = the area for the epicycloidal curve; and  $A_1$  = the area for the hypocycloidal curve.

$$A = \frac{3.1416b^2(3a + 2b)}{a} \qquad A_1 = \frac{3.1416b^2(3a - 2b)}{a}$$

**Find the Contents of Cylindrical Tanks at Different Levels.**—In conjunction with the table *Segments of Circles for Radius = 1* starting on page 71, the following relations can give a close approximation of the liquid contents, at any level, in a cylindrical tank.

A long measuring rule calibrated in length units or simply a plain stick can be used for measuring contents at a particular level. In turn, the rule or stick can be graduated to serve as a volume gauge for the tank in question. The only requirements are that the cross-section of the tank is circular; the tank's dimensions are known; the gauge rod is inserted vertically through the top center of the tank so that it rests on the exact bottom of the tank; and that consistent English or metric units are used throughout the calculations.

$$K = Cr^2L = \text{Tank Constant (remains the same for any given tank)} \quad (1)$$

$$V_T = \pi K, \text{ for a tank that is completely full} \quad (2)$$

$$V_s = KA \quad (3)$$

$$V = V_s \text{ when tank is less than half full} \quad (4)$$

$$V = V_T - V_s = V_T - KA, \text{ when tank is more than half full} \quad (5)$$

where  $C$  = liquid volume conversion factor, the exact value of which depends on the length and liquid volume units being used during measurement: 0.00433 U.S. gal/in<sup>3</sup>; 7.48 U.S. gal/ft<sup>3</sup>; 0.00360 U.K. gal/in<sup>3</sup>; 6.23 U.K. gal/ft<sup>3</sup>; 0.001 liter/cm<sup>3</sup>; or 1000 liters/m<sup>3</sup>

$V_T$  = total volume of liquid tank can hold

$V_s$  = volume formed by segment of circle having depth =  $x$  in given tank (see diagram)

$V$  = volume of liquid at particular level in tank

$d$  = diameter of tank;  $L$  = length of tank;  $r$  = radius of tank ( $= \frac{1}{2}$  diameter)

$A$  = segment area of a corresponding unit circle taken from the table starting on page 71

$y$  = actual depth of contents in tank as shown on a gauge rod or stick

$x$  = depth of the segment of a circle to be considered in given tank. As can be seen in above diagram,  $x$  is the actual depth of contents ( $y$ ) when the tank is less than half full, and is the depth of the void ( $d - y$ ) above the contents when the tank is more than half full. From pages 71 and 74 it can also be seen that  $h$ , the height of a segment of a corresponding unit circle, is  $x/r$

*Example:* A tank is 20 feet long and 6 feet in diameter. Convert a long inch-stick into a gauge that is graduated at 1000 and 3000 U.S. gallons.

$$L = 20 \times 12 = 240 \text{ in.} \quad r = \frac{6}{2} \times 12 = 36 \text{ in.}$$

From [Formula \(1\)](#):  $K = 0.00433(36)^2(240) = 1346.80$

From [Formula \(2\)](#):  $V_T = 3.1416 \times 1347 = 4231.1$  US gal.

The 72-inch mark from the bottom on the inch-stick can be graduated for the rounded full volume "4230"; and the halfway point 36" for 4230/2 or "2115." It can be seen that the 1000-gal mark would be below the halfway mark. From [Formulas \(3\) and \(4\)](#):

$$A_{1000} = \frac{1000}{1347} = 0.7424 \text{ from the table starting on page 71, } h \text{ can be interpolated as}$$

0.5724; and  $x = y = 36 \times 0.5724 = 20.61$ . If the desired level of accuracy permits, interpolation can be omitted by choosing  $h$  directly from the table on page 71 for the value of  $A$  nearest that calculated above.

Therefore, the 1000-gal mark is graduated  $20\frac{5}{8}$ " from bottom of rod.

It can be seen that the 3000 mark would be above the halfway mark. Therefore, the circular segment considered is the cross-section of the void space at the top of the tank. From [Formulas \(3\) and \(5\)](#):

$$A_{3000} = \frac{4230 - 3000}{1347} = 0.9131; h = 0.6648; x = 36 \times 0.6648 = 23.93''$$

Therefore, the 3000-gal mark is  $72.00 - 23.93 = 48.07$ , or at the  $48\frac{1}{16}$ " mark from the bottom.

## Areas and Dimensions of Plane Figures

In the following tables are given formulas for the areas of plane figures, together with other formulas relating to their dimensions and properties; the surfaces of solids; and the volumes of solids. The notation used in the formulas is, as far as possible, given in the illustration accompanying them; where this has not been possible, it is given at the beginning of each set of formulas.

Examples are given with each entry, some in English and some in metric units, showing the use of the preceding formula.

*Square:*

$$\begin{aligned} \text{Area} = A &= s^2 = \frac{1}{2}d^2 \\ s &= 0.7071d = \sqrt{A} \\ d &= 1.414s = 1.414\sqrt{A} \end{aligned}$$

*Example:* Assume that the side  $s$  of a square is 15 inches. Find the area and the length of the diagonal.

$$\text{Area} = A = s^2 = 15^2 = 225 \text{ square inches}$$

$$\text{Diagonal} = d = 1.414s = 1.414 \times 15 = 21.21 \text{ inches}$$

*Example:* The area of a square is 625 square inches. Find the length of the side  $s$  and the diagonal  $d$ .

$$s = \sqrt{A} = \sqrt{625} = 25 \text{ inches}$$

$$d = 1.414\sqrt{A} = 1.414 \times 25 = 35.35 \text{ inches}$$

*Rectangle:*

$$\begin{aligned} \text{Area} = A &= ab = a\sqrt{d^2 - a^2} = b\sqrt{d^2 - b^2} \\ d &= \sqrt{a^2 + b^2} \\ a &= \sqrt{d^2 - b^2} = A \div b \\ a &= \sqrt{d^2 - a^2} = A \div a \end{aligned}$$

*Example:* The side  $a$  of a rectangle is 12 centimeters, and the area 70.5 square centimeters. Find the length of the side  $b$ , and the diagonal  $d$ .

$$b = A \div a = 70.5 \div 12 = 5.875 \text{ centimeters}$$

$$d = \sqrt{a^2 + b^2} = \sqrt{12^2 + 5.875^2} = \sqrt{178.516} = 13.361 \text{ centimeters}$$

*Example:* The sides of a rectangle are 30.5 and 11 centimeters long. Find the area.

$$\text{Area} = A = a \times b = 30.5 \times 11 = 335.5 \text{ square centimeters}$$

*Parallelogram:*

$$\begin{aligned} \text{Area} = A &= ab \\ a &= A \div b \\ b &= A \div a \end{aligned}$$

*Note:* The dimension  $a$  is measured at right angles to line  $b$ .

*Example:* The base  $b$  of a parallelogram is 16 feet. The height  $a$  is 5.5 feet. Find the area.

$$\text{Area} = A = a \times b = 5.5 \times 16 = 88 \text{ square feet}$$

*Example:* The area of a parallelogram is 12 square inches. The height is 1.5 inches. Find the length of the base  $b$ .

$$b = A \div a = 12 \div 1.5 = 8 \text{ inches}$$

**Right-Angled Triangle:**

$$\text{Area} = A = \frac{bc}{2}$$

$$a = \sqrt{b^2 + c^2}$$

$$b = \sqrt{a^2 - c^2}$$

$$c = \sqrt{a^2 - b^2}$$

*Example:* The sides  $b$  and  $c$  in a right-angled triangle are 6 and 8 inches. Find side  $a$  and the area

$$a = \sqrt{b^2 + c^2} = \sqrt{6^2 + 8^2} = \sqrt{36 + 64} = \sqrt{100} = 10 \text{ inches}$$

$$A = \frac{b \times c}{2} = \frac{6 \times 8}{2} = \frac{48}{2} = 24 \text{ square inches}$$

*Example:* If  $a = 10$  and  $b = 6$  had been known, but not  $c$ , the latter would have been found as follows:

$$c = \sqrt{a^2 - b^2} = \sqrt{10^2 - 6^2} = \sqrt{100 - 36} = \sqrt{64} = 8 \text{ inches}$$

**Acute-Angled Triangle:**

$$\text{Area} = A = \frac{bh}{2} = \frac{b}{2} \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2}$$

If  $S = \frac{1}{2}(a + b + c)$ , then

$$A = \sqrt{S(S-a)(S-b)(S-c)}$$

*Example:* If  $a = 10$ ,  $b = 9$ , and  $c = 8$  centimeters, what is the area of the triangle?

$$A = \frac{b}{2} \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2} = \frac{9}{2} \sqrt{10^2 - \left(\frac{10^2 + 9^2 - 8^2}{2 \times 9}\right)^2} = 4.5 \sqrt{100 - \left(\frac{117}{18}\right)^2}$$

$$= 4.5 \sqrt{100 - 42.25} = 4.5 \sqrt{57.75} = 4.5 \times 7.60 = 34.20 \text{ square centimeters}$$

**Obtuse-Angled Triangle:**

$$\text{Area} = A = \frac{bh}{2} = \frac{b}{2} \sqrt{a^2 - \left(\frac{c^2 - a^2 - b^2}{2b}\right)^2}$$

If  $S = \frac{1}{2}(a + b + c)$ , then

$$A = \sqrt{S(S-a)(S-b)(S-c)}$$

*Example:* The side  $a = 5$ , side  $b = 4$ , and side  $c = 8$  inches. Find the area.

$$S = \frac{1}{2}(a + b + c) = \frac{1}{2}(5 + 4 + 8) = \frac{1}{2} \times 17 = 8.5$$

$$A = \sqrt{S(S-a)(S-b)(S-c)} = \sqrt{8.5(8.5-5)(8.5-4)(8.5-8)}$$

$$= \sqrt{8.5 \times 3.5 \times 4.5 \times 0.5} = \sqrt{66.937} = 8.18 \text{ square inches}$$

**Trapezoid:**

$$\text{Area} = A = \frac{(a+b)h}{2}$$

*Note:* In Britain, this figure is called a *trapezium* and the one below it is known as a *trapezoid*, the terms being reversed.

*Example:* Side  $a = 23$  meters, side  $b = 32$  meters, and height  $h = 12$  meters. Find the area.

$$A = \frac{(a+b)h}{2} = \frac{(23+32)12}{2} = \frac{55 \times 12}{2} = 330 \text{ square meters}$$

**Trapezium:**

$$\text{Area} = A = \frac{(H+h)a + bh + cH}{2}$$

A trapezium can also be divided into two triangles as indicated by the dashed line. The area of each of these triangles is computed, and the results added to find the area of the trapezium.

*Example:* Let  $a = 10$ ,  $b = 2$ ,  $c = 3$ ,  $h = 8$ , and  $H = 12$  inches. Find the area.

$$\begin{aligned} A &= \frac{(H+h)a + bh + cH}{2} = \frac{(12+8)10 + 2 \times 8 + 3 \times 12}{2} \\ &= \frac{20 \times 10 + 16 + 36}{2} = \frac{252}{2} = 126 \text{ square inches} \end{aligned}$$

**Regular Hexagon:**

$$A = 2.598s^2 = 2.598R^2 = 3.464r^2$$

$$R = s = \text{radius of circumscribed circle} = 1.155r$$

$$r = \text{radius of inscribed circle} = 0.866s = 0.866R$$

$$s = R = 1.155r$$

*Example:* The side  $s$  of a regular hexagon is 40 millimeters. Find the area and the radius  $r$  of the inscribed circle.

$$A = 2.598s^2 = 2.598 \times 40^2 = 2.598 \times 1600 = 4156.8 \text{ square millimeters}$$

$$r = 0.866s = 0.866 \times 40 = 34.64 \text{ millimeters}$$

*Example:* What is the length of the side of a hexagon that is drawn around a circle of 50 millimeters radius? — Here  $r = 50$ . Hence,  $s = 1.155r = 1.155 \times 50 = 57.75$  millimeters

**Regular Octagon:**

$$A = \text{area} = 4.828s^2 = 2.828R^2 = 3.314r^2$$

$$R = \text{radius of circumscribed circle} = 1.307s = 1.082r$$

$$r = \text{radius of inscribed circle} = 1.207s = 0.924R$$

$$s = 0.765R = 0.828r$$

*Example:* Find the area and the length of the side of an octagon that is inscribed in a circle of 12 inches diameter.

Diameter of circumscribed circle = 12 inches; hence,  $R = 6$  inches.

$$A = 2.828R^2 = 2.828 \times 6^2 = 2.828 \times 36 = 101.81 \text{ square inches}$$

$$s = 0.765R = 0.765 \times 6 = 4.590 \text{ inches}$$

**Regular Polygon:**

$$A = \text{area} \quad n = \text{number of sides}$$

$$\alpha = 360^\circ \div n \quad \beta = 180^\circ - \alpha$$

$$A = \frac{nsr}{2} = \frac{ns}{2} \sqrt{R^2 - \frac{s^2}{4}}$$

$$R = \sqrt{r^2 + \frac{s^2}{4}} \quad r = \sqrt{R^2 - \frac{s^2}{4}} \quad s = 2\sqrt{R^2 - r^2}$$

*Example:* Find the area of a polygon having 12 sides, inscribed in a circle of 8 centimeters radius. The length of the side  $s$  is 4.141 centimeters.

$$\begin{aligned} A &= \frac{ns}{2} \sqrt{R^2 - \frac{s^2}{4}} = \frac{12 \times 4.141}{2} \sqrt{8^2 - \frac{4.141^2}{4}} = 24.846 \sqrt{59.713} \\ &= 24.846 \times 7.727 = 191.98 \text{ square centimeters} \end{aligned}$$

## Circle:

$$\begin{aligned} \text{Area} = A &= \pi r^2 = 3.1416r^2 = 0.7854d^2 \\ \text{Circumference} = C &= 2\pi r = 6.2832r = 3.1416d \\ r &= C \div 6.2832 = \sqrt{A \div 3.1416} = 0.564\sqrt{A} \\ d &= C \div 3.1416 = \sqrt{A \div 0.7854} = 1.128\sqrt{A} \\ \text{Length of arc for center angle of } 1^\circ &= 0.008727d \\ \text{Length of arc for center angle of } n^\circ &= 0.008727nd \end{aligned}$$

*Example:* Find the area  $A$  and circumference  $C$  of a circle with a diameter of  $2\frac{3}{4}$  inches.

$$A = 0.7854d^2 = 0.7854 \times 2.75^2 = 0.7854 \times 2.75 \times 2.75 = 5.9396 \text{ square inches}$$

$$C = 3.1416d = 3.1416 \times 2.75 = 8.6394 \text{ inches}$$

*Example:* The area of a circle is 16.8 square inches. Find its diameter.

$$d = 1.128\sqrt{A} = 1.128\sqrt{16.8} = 1.128 \times 4.099 = 4.624 \text{ inches}$$

## Circular Sector:

$$\begin{aligned} \text{Length of arc} = l &= \frac{r \times \alpha \times 3.1416}{180} = 0.01745r\alpha = \frac{2A}{r} \\ \text{Area} = A &= \frac{1}{2}rl = 0.008727r^2\alpha \\ \text{Angle, in degrees} = \alpha &= \frac{57.296 l}{r} \quad r = \frac{2A}{l} = \frac{57.296 l}{\alpha} \end{aligned}$$

*Example:* The radius of a circle is 35 millimeters, and angle  $\alpha$  of a sector of the circle is 60 degrees. Find the area of the sector and the length of arc  $l$ .

$$A = 0.008727r^2\alpha = 0.008727 \times 60 \times 35^2 = 641.41 \text{ mm}^2 = 6.41 \text{ cm}^2$$

$$l = 0.01745r\alpha = 0.01745 \times 35 \times 60 = 36.645 \text{ millimeters}$$

## Circular Segment:

$$\begin{aligned} A &= \text{area} \quad l = \text{length of arc} \quad \alpha = \text{angle, in degrees} \\ c &= 2\sqrt{h(2r-h)} \quad A = \frac{1}{2}[rl - c(r-h)] \\ r &= \frac{c^2 + 4h^2}{8h} \quad l = 0.01745r\alpha \\ h &= r - \frac{1}{2}\sqrt{4r^2 - c^2} = r[1 - \cos(\alpha/2)] \quad \alpha = \frac{57.296 l}{r} \end{aligned}$$

See also, *Circular Segments* starting on page 70.

*Example:* The radius  $r$  is 60 inches and the height  $h$  is 8 inches. Find the length of the chord  $c$ .

$$c = 2\sqrt{h(2r-h)} = 2\sqrt{8 \times (2 \times 60 - 8)} = 2\sqrt{896} = 2 \times 29.93 = 59.86 \text{ inches}$$

*Example:* If  $c = 16$ , and  $h = 6$  inches, what is the radius of the circle of which the segment is a part?

$$r = \frac{c^2 + 4h^2}{8h} = \frac{16^2 + 4 \times 6^2}{8 \times 6} = \frac{256 + 144}{48} = \frac{400}{48} = 8\frac{1}{3} \text{ inches}$$

## Cycloid:

$$\begin{aligned} \text{Area} = A &= 3\pi r^2 = 9.4248r^2 = 2.3562d^2 \\ &= 3 \times \text{area of generating circle} \\ \text{Length of cycloid} = l &= 8r = 4d \end{aligned}$$

See also, *Areas Enclosed by Cycloidal Curves* on page 61.

*Example:* The diameter of the generating circle of a cycloid is 6 inches. Find the length  $l$  of the cycloidal curve, and the area enclosed between the curve and the base line.

$$l = 4d = 4 \times 6 = 24 \text{ inches} \quad A = 2.3562d^2 = 2.3562 \times 6^2 = 84.82 \text{ square inches}$$

**Circular Ring:**

$$\begin{aligned} \text{Area} = A &= \pi(R^2 - r^2) = 3.1416(R^2 - r^2) \\ &= 3.1416(R + r)(R - r) \\ &= 0.7854(D^2 - d^2) = 0.7854(D + d)(D - d) \end{aligned}$$

*Example:* Let the outside diameter  $D = 12$  centimeters and the inside diameter  $d = 8$  centimeters. Find the area of the ring.

$$\begin{aligned} A &= 0.7854(D^2 - d^2) = 0.7854(12^2 - 8^2) = 0.7854(144 - 64) = 0.7854 \times 80 \\ &= 62.83 \text{ square centimeters} \end{aligned}$$

By the alternative formula:

$$\begin{aligned} A &= 0.7854(D + d)(D - d) = 0.7854(12 + 8)(12 - 8) = 0.7854 \times 20 \times 4 \\ &= 62.83 \text{ square centimeters} \end{aligned}$$

**Circular Ring Sector:**

$A = \text{area}$       $\alpha = \text{angle, in degrees}$

$$\begin{aligned} A &= \frac{\alpha\pi}{360}(R^2 - r^2) = 0.00873\alpha(R^2 - r^2) \\ &= \frac{\alpha\pi}{4 \times 360}(D^2 - d^2) = 0.00218\alpha(D^2 - d^2) \end{aligned}$$

*Example:* Find the area, if the outside radius  $R = 5$  inches, the inside radius  $r = 2$  inches, and  $\alpha = 72$  degrees.

$$\begin{aligned} A &= 0.00873\alpha(R^2 - r^2) = 0.00873 \times 72(5^2 - 2^2) \\ &= 0.6286(25 - 4) = 0.6286 \times 21 = 13.2 \text{ square inches} \end{aligned}$$

**Spandrel or Fillet:**

$$\text{Area} = A = r^2 - \frac{\pi r^2}{4} = 0.215r^2 = 0.1075c^2$$

*Example:* Find the area of a spandrel, the radius of which is 0.7 inch.

$$A = 0.215r^2 = 0.215 \times 0.7^2 = 0.105 \text{ square inch}$$

*Example:* If chord  $c$  were given as 2.2 inches, what would be the area?

$$A = 0.1075c^2 = 0.1075 \times 2.2^2 = 0.520 \text{ square inch}$$

**Parabola:**

$$\text{Area} = A = \frac{2}{3}xy$$

(The area is equal to two-thirds of a rectangle which has  $x$  for its base and  $y$  for its height.)

*Example:* Let  $x$  in the illustration be 15 centimeters, and  $y$ , 9 centimeters. Find the area of the shaded portion of the parabola.

$$A = \frac{2}{3} \times xy = \frac{2}{3} \times 15 \times 9 = 10 \times 9 = 90 \text{ square centimeters}$$

## Parabola:

$$l = \text{length of arc} = \frac{p}{2} \left[ \sqrt{\frac{2x}{p} \left( 1 + \frac{2x}{p} \right)} + \ln \left( \sqrt{\frac{2x}{p}} + \sqrt{1 + \frac{2x}{p}} \right) \right]$$

When  $x$  is small in proportion to  $y$ , the following is a close approximation:

$$l = y \left[ 1 + \frac{2}{3} \left( \frac{x}{y} \right)^2 - \frac{2}{5} \left( \frac{x}{y} \right)^4 \right] \text{ or } l = \sqrt{y^2 + \frac{4}{3}x^2}$$

*Example:* If  $x = 2$  and  $y = 24$  feet, what is the approximate length  $l$  of the parabolic curve?

$$\begin{aligned} l &= y \left[ 1 + \frac{2}{3} \left( \frac{x}{y} \right)^2 - \frac{2}{5} \left( \frac{x}{y} \right)^4 \right] = 24 \left[ 1 + \frac{2}{3} \left( \frac{2}{24} \right)^2 - \frac{2}{5} \left( \frac{2}{24} \right)^4 \right] \\ &= 24 \left[ 1 + \frac{2}{3} \times \frac{1}{144} - \frac{2}{5} \times \frac{1}{20,736} \right] = 24 \times 1.0046 = 24.11 \text{ feet} \end{aligned}$$

## Segment of Parabola:

$$\text{Area BFC} = A = \frac{2}{3} \text{ area of parallelogram BCDE}$$

If  $FG$  is the height of the segment, measured at right angles to  $BC$ , then:

$$\text{Area of segment BFC} = \frac{2}{3} BC \times FG$$

*Example:* The length of the chord  $BC = 19.5$  inches. The distance between lines  $BC$  and  $DE$ , measured at right angles to  $BC$ , is 2.25 inches. This is the height of the segment. Find the area.

$$\text{Area} = A = \frac{2}{3} BC \times FG = \frac{2}{3} \times 19.5 \times 2.25 = 29.25 \text{ square inches}$$

## Hyperbola:

$$\text{Area BCD} = A = \frac{xy}{2} - \frac{ab}{2} \ln \left( \frac{x}{a} + \frac{y}{b} \right)$$

*Example:* The half-axes  $a$  and  $b$  are 3 and 2 inches, respectively. Find the area shown shaded in the illustration for  $x = 8$  and  $y = 5$ .

Inserting the known values in the formula:

$$\begin{aligned} A &= \frac{8 \times 5}{2} - \frac{3 \times 2}{2} \times \ln \left( \frac{8}{3} + \frac{5}{2} \right) = 20 - 3 \times \ln 5.167 \\ &= 20 - 3 \times 1.6423 = 20 - 4.927 = 15.073 \text{ square inches} \end{aligned}$$

## Ellipse:

$$\text{Area} = A = \pi ab = 3.1416ab$$

An approximate formula for the perimeter is

$$\text{Perimeter} = P = 3.1416 \sqrt{2(a^2 + b^2)}$$

A closer approximation is

$$P = 3.1416 \sqrt{2(a^2 + b^2) - \frac{(a-b)^2}{2.2}}$$

*Example:* The larger or major axis is 200 millimeters. The smaller or minor axis is 150 millimeters. Find the area and the approximate circumference. Here, then,  $a = 100$ , and  $b = 75$ .

$$A = 3.1416ab = 3.1416 \times 100 \times 75 = 23,562 \text{ square millimeters} = 235.62 \text{ square centimeters}$$

$$P = 3.1416 \sqrt{2(a^2 + b^2)} = 3.1416 \sqrt{2(100^2 + 75^2)} = 3.1416 \sqrt{2 \times 15,625}$$

$$= 3.1416 \sqrt{31,250} = 3.1416 \times 176.78 = 555.37 \text{ millimeters} = (55.537 \text{ centimeters})$$

**Formulas and Table for Regular Polygons.**—The following formulas and table can be used to calculate the area, length of side, and radii of the inscribed and circumscribed circles of regular polygons (equal sided).

$$A = NS^2 \cot \alpha \div 4 = NR^2 \sin \alpha \cos \alpha = Nr^2 \tan \alpha$$

$$r = R \cos \alpha = (S \cot \alpha) \div 2 = \sqrt{(A \times \cot \alpha) \div N}$$

$$R = S \div (2 \sin \alpha) = r \div \cos \alpha = \sqrt{A \div (N \sin \alpha \cos \alpha)}$$

$$S = 2R \sin \alpha = 2r \tan \alpha = 2\sqrt{(A \times \tan \alpha) \div N}$$

where  $N$  = number of sides;  $S$  = length of side;  $R$  = radius of circumscribed circle;  $r$  = radius of inscribed circle;  $A$  = area of polygon; and,  $\alpha = 180^\circ \div N$  = one-half center angle of one side. See also *Regular Polygon* on page 65.

#### Area, Length of Side, and Inscribed and Circumscribed Radii of Regular Polygons

| No. of Sides | $\frac{A}{S^2}$ | $\frac{A}{R^2}$ | $\frac{A}{r^2}$ | $\frac{R}{S}$ | $\frac{R}{r}$ | $\frac{S}{R}$ | $\frac{S}{r}$ | $\frac{r}{R}$ | $\frac{r}{S}$ |
|--------------|-----------------|-----------------|-----------------|---------------|---------------|---------------|---------------|---------------|---------------|
| 3            | 0.4330          | 1.2990          | 5.1962          | 0.5774        | 2.0000        | 1.7321        | 3.4641        | 0.5000        | 0.2887        |

*Example 1:* A regular hexagon is inscribed in a circle of 6 inches diameter. Find the area and the radius of an inscribed circle. Here  $R = 3$ . From the table, area  $A = 2.5981R^2 = 2.5981 \times 9 = 23.3829$  square inches. Radius of inscribed circle,  $r = 0.866R = 0.866 \times 3 = 2.598$  inches.

*Example 2:* An octagon is inscribed in a circle of 100 millimeters diameter. Thus  $R = 50$ . Find the area and radius of an inscribed circle.  $A = 2.8284R^2 = 2.8284 \times 2500 = 7071 \text{ mm}^2 = 70.7 \text{ cm}^2$ . Radius of inscribed circle,  $r = 0.9239R = 0.9239 \times 50 = 46.195 \text{ mm}$ .

*Example 3:* Thirty-two bolts are to be equally spaced on the periphery of a bolt-circle, 16 inches in diameter. Find the chordal distance between the bolts. Chordal distance equals the side  $S$  of a polygon with 32 sides.  $R = 8$ . Hence,  $S = 0.196R = 0.196 \times 8 = 1.568$  inch.

*Example 4:* Sixteen bolts are to be equally spaced on the periphery of a bolt-circle, 250 millimeters diameter. Find the chordal distance between the bolts. Chordal distance equals the side  $S$  of a polygon with 16 sides.  $R = 125$ . Thus,  $S = 0.3902R = 0.3902 \times 125 = 48.775$  millimeters.

**Circular Segments.**—The table that follows gives the principle formulas for dimensions of circular segments. The dimensions are illustrated in the figures on pages 66 and 71. When two of the dimensions found together in the first column are known, the other dimensions are found by using the formulas in the corresponding row. For example, if radius  $r$  and chord  $c$  are known, solve for angle  $\alpha$  using Equation (13), then use Equations (14) and (15) to solve for  $h$  and  $l$ , respectively. In these formulas, the value of  $\alpha$  is in degrees between 0 and 180°.

**Formulas for Circular Segments**

| Given       | Formulas  |   |  |
|-------------|---|---|--|
| $\alpha, r$ | $c = 2r \sin \frac{\alpha}{2}$ (1)                          | $h = r \left( 1 - \cos \frac{\alpha}{2} \right)$ (2)      | $l = \frac{\pi r \alpha}{180}$ (3)   |
| $\alpha, c$ | $r = \frac{c}{2 \sin \alpha}$ (4)                           | $h = -\frac{c}{2} \tan \alpha$ (5)                        | $l = \frac{\pi c \alpha}{360 \sin \frac{\alpha}{2}}$ (6)                               |
| $\alpha, h$ | $r = \frac{h}{1 - \cos \frac{\alpha}{2}}$ (7)               | $c = \frac{2h}{\tan \frac{\alpha}{4}}$ (8)                | $l = \frac{\pi H \alpha}{180 \left( 1 - \cos \frac{\alpha}{2} \right)}$ (9)            |
| $\alpha, l$ | $r = \frac{180 l}{\pi \alpha}$ (10)                         | $c = \frac{360 l \sin \frac{\alpha}{2}}{\pi \alpha}$ (11) | $h = \frac{180 l \left( 1 - \cos \frac{\alpha}{2} \right)}{\pi \alpha}$ (12)           |
| $r, c$      | $\alpha = \arccos \left( \frac{1 - c^2}{2R^2} \right)$ (13) | $h = r - \frac{\sqrt{4r^2 - c^2}}{2}$ (14)                | $l = \frac{\pi}{90} r \sin \left( \frac{c}{2r} \right)$ (15)                           |
| $r, h$      | $\alpha = 2 \arccos \left( 1 - \frac{h}{r} \right)$ (16)    | $c = 2 \sqrt{h(2r - h)}$ (17)                             | $l = \frac{\pi}{90} r \arccos \left( 1 - \frac{h}{r} \right)$ (18)                     |
| $r, l$      | $\alpha = \frac{180 l}{\pi r}$ (19)                         | $c = 2r \sin \frac{90l}{\pi R}$ (20)                      | $h = r \left( 1 - \cos \frac{90l}{\pi r} \right)$ (21)                                 |
| $c, h$      | $\alpha = 4 \operatorname{atan} \frac{2h}{c}$ (22)          | $r = \frac{c^2 + 4h^2}{8H}$ (23)                          | $l = \pi \left( \frac{c^2 + 4h^2}{360h} \right) \operatorname{atan} \frac{2h}{c}$ (24) |

| Given  | Formula To Find   | Given  | Formula To Find  |
|--------|---|--------|--|
| $c, l$ | $\frac{360 l}{\pi c} = \frac{\alpha}{\sin \frac{\alpha}{2}}$ (25)<br>Solve Equation (25) for $\alpha$ by iteration <sup>a</sup> , then<br>$r =$ Equation (10)<br>$h =$ Equation (5) | $h, l$ | $\frac{180 l}{\pi h} = \frac{\alpha}{1 - \cos \frac{\alpha}{2}}$ (26)<br>Solve Equation (26) for $\alpha$ by iteration <sup>a</sup> , then<br>$r =$ Equation (10)<br>$c =$ Equation (11) |

<sup>a</sup>Equations (25) and (26) can not be easily solved by ordinary means. To solve these equations, test various values of  $\alpha$  until the left side of the equation equals the right side. For example, if given  $c = 4$  and  $l = 5$ , the left side of Equation (25) equals 143.24, and by testing various values of  $\alpha$  it will be found that the right side equals 143.24 when  $\alpha = 129.62^\circ$ .

Angle  $\alpha$  is in degrees,  $0 < \alpha < 180$

Formulas for Circular Segments contributed by Manfred Brueckner

**Segments of Circles for Radius = 1.**—Formulas for segments of circles are given on pages 66 and 70. When the central angle  $\alpha$  and radius  $r$  are known, the tables on this and the following page can be used to find the length of arc  $l$ , height of segment  $h$ , chord length  $c$ , and segment area  $A$ .

When angle  $\alpha$  and radius  $r$  are not known, but segment height  $h$  and chord length  $c$  are known or can be measured, the ratio  $h/c$  can be used to enter the table and find  $\alpha$ ,  $l$ , and  $A$  by linear interpolation. Radius  $r$  is found by the formula on page 66 or 70. The value of  $l$  is then multiplied by the radius  $r$  and the area  $A$  by  $r^2$ , the square of the radius.

Angle  $\alpha$  can be found thus with an accuracy of about 0.001 degree; arc length  $l$  with an error of about 0.02 per cent; and area  $A$  with an error ranging from about 0.02 per cent for the highest entry value of  $h/c$  to about 1 per cent for values of  $h/c$  of about 0.050. For lower values of  $h/c$ , and where greater accuracy is required, area  $A$  should be found by the formula on page 66.

## Diameters of Circles and Sides of Squares of Equal Area

The table below will be found useful for determining the diameter of a circle of an area equal to that of a square, the side of which is known, or for determining the side of a square which has an area equal to that of a circle, the area or diameter of which is known. For example, if the diameter of a circle is  $17\frac{1}{2}$  inches, it is found from the table that the side of a square of the same area is 15.51 inches.

| Diam. of Circle, $D$ | Side of Square, $S$ | Area of Circle or Square | Diam. of Circle, $D$ | Side of Square, $S$ | Area of Circle or Square | Diam. of Circle, $D$ | Side of Square, $S$ | Area of Circle or Square |

| 20                   | 17.72               | 314.16                   | 40                   | 35.45               | 1256.64                  | 60                   | 53.17               | 2827.43                  |

**Distance Across Corners of Squares and Hexagons.**—The table below gives values of dimensions  $D$  and  $E$  described in the figures and equations that follow.

$$D = \frac{2\sqrt{3}}{3}d = 1.154701d$$

$$E = d\sqrt{2} = 1.414214d$$

A desired value not given directly in the table can be obtained directly from the equations above, or by the simple addition of two or more values taken directly from the table. Further values can be obtained by shifting the decimal point.

*Example 1:* Find  $D$  when  $d = 2 \frac{5}{16}$  inches. From the table,  $2 = 2.3094$ , and  $\frac{5}{16} = 0.3608$ . Therefore,  $D = 2.3094 + 0.3608 = 2.6702$  inches.

*Example 2:* Find  $E$  when  $d = 20.25$  millimeters. From the table,  $20 = 28.2843$ ;  $0.2 = 0.2828$ ; and  $0.05 = 0.0707$  (obtained by shifting the decimal point one place to the left at  $= 0.5$ ). Thus,  $E = 28.2843 + 0.2828 + 0.0707 = 28.6378$  millimeters.

### Distance Across Corners of Squares and Hexagons (English and metric units)

| $d$             | $D$    | $E$    | $d$             | $D$     | $E$     | $d$ | $D$     | $E$     | $d$ | $D$     | $E$     |

## Volumes of Solids

## Cube:

$$\text{Diagonal of cube face} = d = s\sqrt{2}$$

$$\text{Diagonal of cube} = D = \sqrt{3d^2} = s\sqrt{3} = 1.732s$$

$$\text{Volume} = V = s^3$$

$$s = \sqrt[3]{V}$$

*Example:* The side of a cube equals 9.5 centimeters. Find its volume.

$$\text{Volume} = V = s^3 = 9.5^3 = 9.5 \times 9.5 \times 9.5 = 857.375 \text{ cubic centimeters}$$

*Example:* The volume of a cube is 231 cubic centimeters. What is the length of the side?

$$s = \sqrt[3]{V} = \sqrt[3]{231} = 6.136 \text{ centimeters}$$

## Square Prism:

$$\text{Volume} = V = abc$$

$$a = \frac{V}{bc} \quad b = \frac{V}{ac} \quad c = \frac{V}{ab}$$

*Example:* In a square prism,  $a = 6$ ,  $b = 5$ ,  $c = 4$ . Find the volume.

$$V = a \times b \times c = 6 \times 5 \times 4 = 120 \text{ cubic inches}$$

*Example:* How high should a box be made to contain 25 cubic feet, if it is 4 feet long and  $2\frac{1}{2}$  feet wide? Here,  $a = 4$ ,  $c = 2.5$ , and  $V = 25$ . Then,

$$b = \text{depth} = \frac{V}{ac} = \frac{25}{4 \times 2.5} = \frac{25}{10} = 2.5 \text{ feet}$$

## Prism:

$$V = \text{volume}$$

$$A = \text{area of end surface}$$

$$V = h \times A$$

The area  $A$  of the end surface is found by the formulas for areas of plane figures on the preceding pages. Height  $h$  must be measured perpendicular to the end surface.

*Example:* A prism, having for its base a regular hexagon with a side  $s$  of 7.5 centimeters, is 25 centimeters high. Find the volume.

$$\text{Area of hexagon} = A = 2.598s^2 = 2.598 \times 56.25 = 146.14 \text{ square centimeters}$$

$$\text{Volume of prism} = h \times A = 25 \times 146.14 = 3653.5 \text{ cubic centimeters}$$

## Pyramid:

$$\text{Volume} = V = \frac{1}{3}h \times \text{area of base}$$

If the base is a regular polygon with  $n$  sides, and  $s =$  length of side,  $r =$  radius of inscribed circle, and  $R =$  radius of circumscribed circle, then:

$$V = \frac{nsrh}{6} = \frac{ns}{6} \sqrt{R^2 - \frac{s^2}{4}}$$

*Example:* A pyramid, having a height of 9 feet, has a base formed by a rectangle, the sides of which are 2 and 3 feet, respectively. Find the volume.

$$\text{Area of base} = 2 \times 3 = 6 \text{ square feet; } h = 9 \text{ feet}$$

$$\text{Volume} = V = \frac{1}{3}h \times \text{area of base} = \frac{1}{3} \times 9 \times 6 = 18 \text{ cubic feet}$$

*Frustum of Pyramid:*

$$\text{Volume} = V = \frac{h}{3}(A_1 + A_2 + \sqrt{A_1 \times A_2})$$

*Example:* The pyramid in the previous example is cut off  $4\frac{1}{2}$  feet from the base, the upper part being removed. The sides of the rectangle forming the top surface of the frustum are, then, 1 and  $1\frac{1}{2}$  feet long, respectively. Find the volume of the frustum.

$$\text{Area of top} = A_1 = 1 \times 1\frac{1}{2} = 1\frac{1}{2} \text{ sq. ft.} \quad \text{Area of base} = A_2 = 2 \times 3 = 6 \text{ sq. ft.}$$

$$V = \frac{4.5}{3}(1.5 + 6 + \sqrt{1.5 \times 6}) = 1.5(7.5 + \sqrt{9}) = 1.5 \times 10.5 = 15.75 \text{ cubic feet}$$

*Wedge:*

$$\text{Volume} = V = \frac{(2a + c)bh}{6}$$

*Example:* Let  $a = 4$  inches,  $b = 3$  inches, and  $c = 5$  inches. The height  $h = 4.5$  inches. Find the volume.

$$V = \frac{(2a + c)bh}{6} = \frac{(2 \times 4 + 5) \times 3 \times 4.5}{6} = \frac{(8 + 5) \times 13.5}{6} \\ = \frac{175.5}{6} = 29.25 \text{ cubic inches}$$

*Cylinder:*

$$\text{Volume} = V = 3.1416r^2h = 0.7854d^2h$$

$$\text{Area of cylindrical surface} = S = 6.2832rh = 3.1416dh$$

Total area  $A$  of cylindrical surface and end surfaces:

$$A = 6.2832r(r + h) = 3.1416d(\frac{1}{2}d + h)$$

*Example:* The diameter of a cylinder is 2.5 inches. The length or height is 20 inches. Find the volume and the area of the cylindrical surface  $S$ .

$$V = 0.7854d^2h = 0.7854 \times 2.5^2 \times 20 = 0.7854 \times 6.25 \times 20 = 98.17 \text{ cubic inches}$$

$$S = 3.1416dh = 3.1416 \times 2.5 \times 20 = 157.08 \text{ square inches}$$

*Portion of Cylinder:*

$$\text{Volume} = V = 1.5708r^2(h_1 + h_2)$$

$$= 0.3927d^2(h_1 + h_2)$$

$$\text{Cylindrical surface area} = S = 3.1416r(h_1 + h_2)$$

$$= 1.5708d(h_1 + h_2)$$

*Example:* A cylinder 125 millimeters in diameter is cut off at an angle, as shown in the illustration. Dimension  $h_1 = 150$ , and  $h_2 = 100$  mm. Find the volume and the area  $S$  of the cylindrical surface.

$$V = 0.3927d^2(h_1 + h_2) = 0.3927 \times 125^2 \times (150 + 100)$$

$$= 0.3927 \times 15,625 \times 250 = 1,533,984 \text{ cubic millimeters} = 1534 \text{ cm}^3$$

$$S = 1.5708d(h_1 + h_2) = 1.5708 \times 125 \times 250$$

$$= 49,087.5 \text{ square millimeters} = 490.9 \text{ square centimeters}$$

*Portion of Cylinder:*

$$\text{Volume} = V = \left(\frac{2}{3}a^3 \pm b \times \text{area } ABC\right) \frac{h}{r \pm b}$$

$$\text{Cylindrical surface area} = S = (ad \pm b \times \text{length of arc } ABC) \frac{h}{r \pm b}$$

Use + when base area is larger, and - when base area is less than one-half the base circle.

*Example:* Find the volume of a cylinder so cut off that line AC passes through the center of the base circle — that is, the base area is a half-circle. The diameter of the cylinder = 5 inches, and the height  $h = 2$  inches.

In this case,  $a = 2.5$ ;  $b = 0$ ;  $\text{area } ABC = 0.5 \times 0.7854 \times 5^2 = 9.82$ ;  $r = 2.5$ .

$$V = \left(\frac{2}{3} \times 2.5^3 + 0 \times 9.82\right) \frac{2}{2.5 + 0} = \frac{2}{3} \times 15.625 \times 0.8 = 8.33 \text{ cubic inches}$$

*Hollow Cylinder:*

$$\begin{aligned} \text{Volume} = V &= 3.1416h(R^2 - r^2) = 0.7854h(D^2 - d^2) \\ &= 3.1416ht(2R - t) = 3.1416ht(D - t) \\ &= 3.1416ht(2r + t) = 3.1416ht(d + t) \\ &= 3.1416ht(R + r) = 1.5708ht(D + d) \end{aligned}$$

*Example:* A cylindrical shell, 28 centimeters high, is 36 centimeters in outside diameter, and 4 centimeters thick. Find its volume.

$$\begin{aligned} V &= 3.1416ht(D - t) = 3.1416 \times 28 \times 4(36 - 4) = 3.1416 \times 28 \times 4 \times 32 \\ &= 11,259.5 \text{ cubic centimeters} \end{aligned}$$

*Cone:*

$$\text{Volume} = V = \frac{3.1416r^2h}{3} = 1.0472r^2h = 0.2618d^2h$$

$$\begin{aligned} \text{Conical surface area} = A &= 3.1416r\sqrt{r^2 + h^2} = 3.1416rs \\ &= 1.5708ds \end{aligned}$$

$$s = \sqrt{r^2 + h^2} = \sqrt{\frac{d^2}{4} + h^2}$$

*Example:* Find the volume and area of the conical surface of a cone, the base of which is a circle of 6 inches diameter, and the height of which is 4 inches.

$$V = 0.2618d^2h = 0.2618 \times 6^2 \times 4 = 0.2618 \times 36 \times 4 = 37.7 \text{ cubic inches}$$

$$\begin{aligned} A &= 3.1416r\sqrt{r^2 + h^2} = 3.1416 \times 3 \times \sqrt{3^2 + 4^2} = 9.4248 \times \sqrt{25} \\ &= 47.124 \text{ square inches} \end{aligned}$$

*Frustum of Cone:*

$$V = \text{volume} \quad A = \text{area of conical surface}$$

$$V = 1.0472h(R^2 + Rr + r^2) = 0.2618h(D^2 + Dd + d^2)$$

$$A = 3.1416s(R + r) = 1.5708s(D + d)$$

$$a = R - r \quad s = \sqrt{a^2 + h^2} = \sqrt{(R - r)^2 + h^2}$$

*Example:* Find the volume of a frustum of a cone of the following dimensions:  $D = 8$  centimeters;  $d = 4$  centimeters;  $h = 5$  centimeters.

$$\begin{aligned} V &= 0.2618 \times 5(8^2 + 8 \times 4 + 4^2) = 0.2618 \times 5(64 + 32 + 16) \\ &= 0.2618 \times 5 \times 112 = 146.61 \text{ cubic centimeters} \end{aligned}$$

## Sphere:

$$\text{Volume} = V = \frac{4\pi r^3}{3} = \frac{\pi d^3}{6} = 4.1888r^3 = 0.5236d^3$$

$$\text{Surface area} = A = 4\pi r^2 = \pi d^2 = 12.5664r^2 = 3.1416d^2$$

$$r = \sqrt[3]{\frac{3V}{4\pi}} = 0.6204\sqrt[3]{V}$$

*Example:* Find the volume and the surface of a sphere 6.5 centimeters diameter.

$$V = 0.5236d^3 = 0.5236 \times 6.5^3 = 0.5236 \times 6.5 \times 6.5 \times 6.5 = 143.79 \text{ cm}^3$$

$$A = 3.1416d^2 = 3.1416 \times 6.5^2 = 3.1416 \times 6.5 \times 6.5 = 132.73 \text{ cm}^2$$

*Example:* The volume of a sphere is 64 cubic centimeters. Find its radius.

$$r = 0.6204\sqrt[3]{64} = 0.6204 \times 4 = 2.4816 \text{ centimeters}$$

## Spherical Sector:

$$V = \frac{2\pi r^2 h}{3} = 2.0944r^2 h = \text{Volume}$$

$$A = 3.1416r(2h + \frac{1}{2}c)$$

= total area of conical and spherical surface

$$c = 2\sqrt{h(2r-h)}$$

*Example:* Find the volume of a sector of a sphere 6 inches in diameter, the height  $h$  of the sector being 1.5 inch. Also find the length of chord  $c$ . Here  $r = 3$  and  $h = 1.5$ .

$$V = 2.0944r^2 h = 2.0944 \times 3^2 \times 1.5 = 2.0944 \times 9 \times 1.5 = 28.27 \text{ cubic inches}$$

$$c = 2\sqrt{h(2r-h)} = 2\sqrt{1.5(2 \times 3 - 1.5)} = 2\sqrt{6.75} = 2 \times 2.598 = 5.196 \text{ inches}$$

## Spherical Segment:

$$V = \text{volume} \quad A = \text{area of spherical surface}$$

$$V = 3.1416h^2\left(r - \frac{h}{3}\right) = 3.1416h\left(\frac{c^2}{8} + \frac{h^2}{6}\right)$$

$$A = 2\pi rh = 6.2832rh = 3.1416\left(\frac{c^2}{4} + h^2\right)$$

$$c = 2\sqrt{h(2r-h)}; \quad r = \frac{c^2 + 4h^2}{8h}$$

*Example:* A segment of a sphere has the following dimensions:  $h = 50$  millimeters;  $c = 125$  millimeters. Find the volume  $V$  and the radius of the sphere of which the segment is a part.

$$V = 3.1416 \times 50 \times \left(\frac{125^2}{8} + \frac{50^2}{6}\right) = 157.08 \times \left(\frac{15,625}{8} + \frac{2500}{6}\right) = 372,247 \text{ mm}^3 = 372 \text{ cm}^3$$

$$r = \frac{125^2 + 4 \times 50^2}{8 \times 50} = \frac{15,625 + 10,000}{400} = \frac{25,625}{400} = 64 \text{ millimeters}$$

## Ellipsoid:

$$\text{Volume} = V = \frac{4\pi}{3}abc = 4.1888abc$$

In an ellipsoid of revolution, or spheroid, where  $c = b$ :

$$V = 4.1888ab^2$$

*Example:* Find the volume of a spheroid in which  $a = 5$ , and  $b = c = 1.5$  inches.

$$V = 4.1888 \times 5 \times 1.5^2 = 47.124 \text{ cubic inches}$$

**Spherical Zone:**

$$\text{Volume} = V = 0.5236h \left( \frac{3c_1^2}{4} + \frac{3c_2^2}{4} + h^2 \right)$$

$$A = 2\pi rh = 6.2832rh = \text{area of spherical surface}$$

$$r = \sqrt{\frac{c_2^2}{4} + \left( \frac{c_2^2 - c_1^2 - 4h^2}{8h} \right)^2}$$

*Example:* In a spherical zone, let  $c_1 = 3$ ;  $c_2 = 4$ ; and  $h = 1.5$  inch. Find the volume.

$$V = 0.5236 \times 1.5 \times \left( \frac{3 \times 3^2}{4} + \frac{3 \times 4^2}{4} + 1.5^2 \right) = 0.5236 \times 1.5 \times \left( \frac{27}{4} + \frac{48}{4} + 2.25 \right) = 16.493 \text{ in}^3$$

**Spherical Wedge:**

$$V = \text{volume} \quad A = \text{area of spherical surface}$$

$$\alpha = \text{center angle in degrees}$$

$$V = \frac{\alpha}{360} \times \frac{4\pi r^3}{3} = 0.0116\alpha r^3$$

$$A = \frac{\alpha}{360} \times 4\pi r^2 = 0.0349\alpha r^2$$

*Example:* Find the area of the spherical surface and the volume of a wedge of a sphere. The diameter of the sphere is 100 millimeters, and the center angle  $\alpha$  is 45 degrees.

$$V = 0.0116 \times 45 \times 50^3 = 0.0116 \times 45 \times 125,000 = 65,250 \text{ mm}^3 = 65.25 \text{ cm}^3$$

$$A = 0.0349 \times 45 \times 50^2 = 3926.25 \text{ square millimeters} = 39.26 \text{ cm}^2$$

**Hollow Sphere:**

$V =$  volume of material used  
to make a hollow sphere

$$V = \frac{4\pi}{3}(R^3 - r^3) = 4.1888(R^3 - r^3)$$

$$= \frac{\pi}{6}(D^3 - d^3) = 0.5236(D^3 - d^3)$$

*Example:* Find the volume of a hollow sphere, 8 inches in outside diameter, with a thickness of material of 1.5 inch.

Here  $R = 4$ ;  $r = 4 - 1.5 = 2.5$ .

$$V = 4.1888(4^3 - 2.5^3) = 4.1888(64 - 15.625) = 4.1888 \times 48.375 = 202.63 \text{ cubic inches}$$

**Paraboloid:**

$$\text{Volume} = V = \frac{1}{2}\pi r^2 h = 0.3927d^2 h$$

$$\text{Area} = A = \frac{2\pi}{3} p \left[ \sqrt{\left( \frac{d^2}{4} + p^2 \right)^3} - p^3 \right]$$

$$\text{in which } p = \frac{d^2}{8h}$$

*Example:* Find the volume of a paraboloid in which  $h = 300$  millimeters and  $d = 125$  millimeters.

$$V = 0.3927d^2 h = 0.3927 \times 125^2 \times 300 = 1,840,781 \text{ mm}^3 = 1,840.8 \text{ cm}^3$$

*Paraboloidal Segment:*

$$\begin{aligned} \text{Volume} = V &= \frac{\pi}{2}h(R^2 + r^2) = 1.5708h(R^2 + r^2) \\ &= \frac{\pi}{8}h(D^2 + d^2) = 0.3927h(D^2 + d^2) \end{aligned}$$

*Example:* Find the volume of a segment of a paraboloid in which  $D = 5$  inches,  $d = 3$  inches, and  $h = 6$  inches.

$$\begin{aligned} V &= 0.3927h(D^2 + d^2) = 0.3927 \times 6 \times (5^2 + 3^2) \\ &= 0.3927 \times 6 \times 34 = 80.11 \text{ cubic inches} \end{aligned}$$

*Torus:*

$$\begin{aligned} \text{Volume} = V &= 2\pi^2 Rr^2 = 19.739Rr^2 \\ &= \frac{\pi^2}{4}Dd^2 = 2.4674Dd^2 \end{aligned}$$

$$\begin{aligned} \text{Area of surface} = A &= 4\pi^2 Rr = 39.478Rr \\ &= \pi^2 Dd = 9.8696Dd \end{aligned}$$

*Example:* Find the volume and area of surface of a torus in which  $d = 1.5$  and  $D = 5$  inches.

$$V = 2.4674 \times 5 \times 1.5^2 = 2.4674 \times 5 \times 2.25 = 27.76 \text{ cubic inches}$$

$$A = 9.8696 \times 5 \times 1.5 = 74.022 \text{ square inches}$$

*Barrel:*

$V =$  approximate volume.

If the sides are bent to the arc of a circle:

$$V = \frac{1}{12}\pi h(2D^2 + d^2) = 0.262h(2D^2 + d^2)$$

If the sides are bent to the arc of a parabola:

$$V = 0.209h(2D^2 + Dd + \frac{3}{4}d^2)$$

*Example:* Find the approximate contents of a barrel, the inside dimensions of which are  $D = 60$  centimeters,  $d = 50$  centimeters;  $h = 120$  centimeters.

$$\begin{aligned} V &= 0.262h(2D^2 + d^2) = 0.262 \times 120 \times (2 \times 60^2 + 50^2) \\ &= 0.262 \times 120 \times (7200 + 2500) = 0.262 \times 120 \times 9700 \\ &= 304,968 \text{ cubic centimeters} = 0.305 \text{ cubic meter} \end{aligned}$$

*Ratio of Volumes:*

If  $d =$  base diameter and height of a cone, a paraboloid and a cylinder, and the diameter of a sphere, then the volumes of these bodies are to each other as follows:

$$\text{Cone:paraboloid:sphere:cylinder} = \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$$

*Example:* Assume, as an example, that the diameter of the base of a cone, paraboloid, and cylinder is 2 inches, that the height is 2 inches, and that the diameter of a sphere is 2 inches. Then the volumes, written in formula form, are as follows:

$$\frac{\text{Cone}}{12} \times 2^2 \times 2 : \frac{\text{Paraboloid}}{8} \times (2p)^2 \times 2 : \frac{\text{Sphere}}{6} \times 2^3 : \frac{\text{Cylinder}}{4} \times 2^2 \times 2 = \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$$

## Packing Circles in Circles and Rectangles

**Diameter of Circle Enclosing a Given Number of Smaller Circles.**—Four of many possible compact arrangements of circles within a circle are shown at A, B, C, and D in Fig. 1. To determine the diameter of the smallest enclosing circle for a particular number of enclosed circles all of the same size, three factors that influence the size of the enclosing circle should be considered. These are discussed in the paragraphs that follow, which are based on the article "How Many Wires Can Be Packed into a Circular Conduit," by Jacques Dutka, *Machinery*, October 1956.

1) *Arrangement of Center or Core Circles:* The four most common arrangements of center or core circles are shown cross-sectioned in Fig. 1. It may seem, offhand, that the "A" pattern would require the smallest enclosing circle for a given number of enclosed circles but this is not always the case since the most compact arrangement will, in part, depend on the number of circles to be enclosed.

Fig. 1. Arrangements of Circles within a Circle

2) *Diameter of Enclosing Circle When Outer Layer of Circles Is Complete:* Successive, complete "layers" of circles may be placed around each of the central cores, Fig. 1, of 1, 2, 3, or 4 circles as the case may be. The number of circles contained in arrangements of complete "layers" around a central core of circles, as well as the diameter of the enclosing circle, may be obtained using the data in Table 1. Thus, for example, the "A" pattern in Fig. 1 shows, by actual count, a total of 19 circles arranged in two complete "layers" around a central core consisting of one circle; this agrees with the data shown in the left half of Table 1 for  $n = 2$ .

To determine the diameter of the enclosing circle, the data in the right half of Table 1 is used. Thus, for  $n = 2$  and an "A" pattern, the diameter  $D$  is 5 times the diameter  $d$  of the enclosed circles.

3) *Diameter of Enclosing Circle When Outer Layer of Circles Is Not Complete:* In most cases, it is possible to reduce the size of the enclosing circle from that required if the outer layer were complete. Thus, for example, the "B" pattern in Fig. 1 shows that the central core consisting of 2 circles is surrounded by 1 complete layer of 8 circles and 1 partial, outer layer of 4 circles, so that the total number of circles enclosed is 14. If the outer layer were complete, then (from Table 1) the total number of enclosed circles would be 24 and the diameter of the enclosing circle would be  $6d$ ; however, since the outer layer is composed of only 4 circles out of a possible 14 for a complete second layer, a smaller diameter of enclosing circle may be used. Table 2 shows that for a total of 14 enclosed circles arranged in a "B" pattern with the outer layer of circles incomplete, the diameter for the enclosing circle is  $4.606d$ .

Table 2 can be used to determine the smallest enclosing circle for a given number of circles to be enclosed by direct comparison of the "A," "B," and "C" columns. For data outside the range of Table 2, use the formulas in Dr. Dutka's article.

**Table 1. Number of Circles Contained in Complete Layers of Circles and Diameter of Enclosing Circle (English or metric units)**

| No. Complete Layers Over Core, <i>n</i> | Number of Circles in Center Pattern                   |          |          |   |             |             |                 |                 |
|---|---|----------|----------|---|-------------|-------------|-----------------|-----------------|
|   | 1   | 2        | 3        | 4   | 1           | 2           | 3               | 4               |
|   | Arrangement of Circles in Center Pattern (see Fig. 1) |          |          |   |             |             |                 |                 |
|   | "A"   | "B"      | "C"      | "D"   | "A"         | "B"         | "C"             | "D"             |
| Number of Circles, <i>N</i> , Enclosed  |   |          |          | Diameter, <i>D</i> , of Enclosing Circle <sup>a</sup> |             |             |                 |                 |
| 0                                       | 1   | 2        | 3        | 4   | <i>d</i>    | <i>2d</i>   | 2.155 <i>d</i>  | 2.414 <i>d</i>  |
| 1                                       | 7   | 10       | 12       | 14  | 3 <i>d</i>  | 4 <i>d</i>  | 4.055 <i>d</i>  | 4.386 <i>d</i>  |
| 2                                       | 19  | 24       | 27       | 30  | 5 <i>d</i>  | 6 <i>d</i>  | 6.033 <i>d</i>  | 6.379 <i>d</i>  |
| 3                                       | 37  | 44       | 48       | 52  | 7 <i>d</i>  | 8 <i>d</i>  | 8.024 <i>d</i>  | 8.375 <i>d</i>  |
| 4                                       | 61  | 70       | 75       | 80  | 9 <i>d</i>  | 10 <i>d</i> | 10.018 <i>d</i> | 10.373 <i>d</i> |
| 5                                       | 91  | 102      | 108      | 114   | 11 <i>d</i> | 12 <i>d</i> | 12.015 <i>d</i> | 12.372 <i>d</i> |
| <i>n</i>                                | <i>b</i>  | <i>b</i> | <i>b</i> | <i>b</i>  | <i>b</i>    | <i>b</i>    | <i>b</i>        | <i>b</i>        |

<sup>a</sup>Diameter *D* is given in terms of *d*, the diameter of the enclosed circles.

<sup>b</sup>For *n* complete layers over core, the number of enclosed circles *N* for the "A" center pattern is  $3n^2 + 3n + 1$ ; for "B,"  $3n^2 + 5n + 2$ ; for "C,"  $3n^2 + 6n + 3$ ; for "D,"  $3n^2 + 7n + 4$ . The diameter *D* of the enclosing circle for "A" center pattern is  $(2n + 1)d$ ; for "B,"  $(2n + 2)d$ ; for "C,"  $(1 + 2\sqrt{n^2 + n + \frac{1}{2}})d$  and for "D,"  $(1 + \sqrt{4n^2 + 5.644n + 2})d$ .

**Table 2. Factors for Determining Diameter, *D*, of Smallest Enclosing Circle for Various Numbers, *N*, of Enclosed Circles (English or metric units)**

| No. <i>N</i> | Center Circle Pattern    |       |       | No. <i>N</i> | Center Circle Pattern    |       |       | No. <i>N</i> | Center Circle Pattern    |        |        |
|--------------|--------------------------|-------|-------|--------------|--------------------------|-------|-------|--------------|--------------------------|--------|--------|
|              | "A"                      | "B"   | "C"   |              | "A"                      | "B"   | "C"   |              | "A"                      | "B"    | "C"    |
|              | Diameter Factor <i>K</i> |       |       |              | Diameter Factor <i>K</i> |       |       |              | Diameter Factor <i>K</i> |        |        |
| 2            | 3                        | 2     | ...   | 34           | 7.001                    | 7.083 | 7.111 | 66           | 9.718                    | 9.545  | 9.327  |
| 3            | 3                        | 2.733 | 2.155 | 35           | 7.001                    | 7.245 | 7.111 | 67           | 9.718                    | 9.545  | 9.327  |
| 4            | 3                        | 2.733 | 3.310 | 36           | 7.001                    | 7.245 | 7.111 | 68           | 9.718                    | 9.545  | 9.327  |
| 5            | 3                        | 3.646 | 3.310 | 37           | 7.001                    | 7.245 | 7.430 | 69           | 9.718                    | 9.661  | 9.327  |
| 6            | 3                        | 3.646 | 3.310 | 38           | 7.929                    | 7.245 | 7.430 | 70           | 9.718                    | 9.661  | 10.019 |
| 7            | 3                        | 3.646 | 4.056 | 39           | 7.929                    | 7.558 | 7.430 | 71           | 9.718                    | 9.889  | 10.019 |
| 8            | 4.465                    | 3.646 | 4.056 | 40           | 7.929                    | 7.558 | 7.430 | 72           | 9.718                    | 9.889  | 10.019 |
| 9            | 4.465                    | 4     | 4.056 | 41           | 7.929                    | 7.558 | 7.430 | 73           | 9.718                    | 9.889  | 10.019 |
| 10           | 4.465                    | 4     | 4.056 | 42           | 7.929                    | 7.558 | 7.430 | 74           | 10.166                   | 9.889  | 10.019 |
| 11           | 4.465                    | 4.606 | 4.056 | 43           | 7.929                    | 8.001 | 8.024 | 75           | 10.166                   | 10     | 10.019 |

The diameter  $D$  of the enclosing circle is equal to the diameter factor,  $K$ , multiplied by  $d$ , the diameter of the enclosed circles, or  $D = K \times d$ . For example, if the number of circles to be enclosed,  $N$ , is 12, and the center circle arrangement is "C," then for  $d = 1\frac{1}{2}$  inches,  $D = 4.056 \times 1\frac{1}{2} = 6.084$  inches. If  $d = 50$  millimeters, then  $D = 4.056 \times 50 = 202.9$  millimeters.

*Approximate Formula When Number of Enclosed Circles Is Large:* When a large number of circles are to be enclosed, the arrangement of the center circles has little effect on the diameter of the enclosing circle. For numbers of circles greater than 10,000, the diameter of the enclosing circle may be calculated within 2 per cent from the formula  $D = d(1 + \sqrt{N \div 0.907})$ . In this formula,  $D$  = diameter of the enclosing circle;  $d$  = diameter of the enclosed circles; and  $N$  is the number of enclosed circles.

An alternative approach relates the area of each of the same-sized circles to be enclosed to the area of the enclosing circle (or container), as shown in Figs. 1 through 27. The table shows efficient ways for packing various numbers of circles  $N$ , from 2 up to 97.

In the table,  $D$  = the diameter of each circle to be enclosed,  $d$  = the diameter of the enclosing circle or container, and  $\Phi = Nd^2/D^2$  = ratio of the area of the  $N$  circles to the area of the enclosing circle or container, which is the packing efficiency. Cross-hatching in the diagrams indicates loose circles that may need packing constraints.

Data for Numbers of Circles in Circles

| $N$ | $D/d$  | $\Phi$ | Fig. | $N$ | $D/d$   | $\Phi$ | Fig. |

Packing of large numbers of circles, such as the 97 in Fig. 27, may be approached by drawing a triangular pattern of circles, as shown in Fig. 28, which represents three circles near the center of the array. The point of a compass is then placed at  $A$ ,  $B$ , or  $C$ , or anywhere within triangle  $ABC$ , and the radius of the compass is gradually enlarged until it encompasses the number of circles to be enclosed. As a first approximation of the diameter,  $D = 1.14d\sqrt{N}$  may be tried.

**Circles within Rectangles.**—For small numbers  $N$  of circles, packing (for instance, of cans) is less vital than for larger numbers and the number will usually govern the decision whether to use a rectangular or a triangular pattern, examples of which are seen in Figs. 29 and 30.

Fig. 29. Rectangular Pattern ( $r = 4, c = 5$ )

Fig. 30. Triangular Pattern ( $r = 3, c = 7$ )

If  $D$  is the can diameter and  $H$  its height, the arrangement in Fig. 29 will hold 20 circles or cans in a volume of  $5D \times 4D \times H = 20D^2 H$ . The arrangement in Fig. 30 will pack the same 20 cans into a volume of  $7D \times 2.732D \times H = 19.124D^2 H$ , a reduction of 4.4 per cent. When the ratio of  $H/D$  is less than 1.196:1, the rectangular pattern requires less surface area (therefore less material) for the six sides of the box, but for greater ratios, the triangular pattern is better. Some numbers, such as 19, can be accommodated only in a triangular pattern.

The following table shows possible patterns for 3 to 25 cans, where  $N$  = number of circles,  $P$  = pattern ( $R$  rectangular or  $T$  triangular), and  $r$  and  $c$  = numbers of rows and columns, respectively. The final table column shows the most economical application, where  $V$  = best volume,  $S$  = best surface area (sometimes followed by a condition on  $H/D$ ). For the rectangular pattern, the area of the container is  $rD \times cD$ , and for the triangular pattern, the area is  $cD \times [1 + (r - 1)\sqrt{3}/2]D$ , or  $cD^2[1 + 0.866(r - 1)]$ .

**Numbers of Circles in Rectangular Arrangements**

| $N$ | $P$ | $r$ | $c$ | Application           | $N$ | $P$ | $r$ | $c$                   | Application                |

**Rollers on a Shaft\*.**—The following formulas illustrate the geometry of rollers on a shaft. In Fig. 31,  $D$  is the diameter of the center line of the roller circle,  $d$  is the diameter of a roller,  $D_S = D - d$  is the shaft diameter, and  $C$  is the clearance along the center line of the roller circle. In the equations that follow,  $N$  is the number of rollers, and  $N > 3$ .

Equation (1a) applies when the clearance  $C = 0$

$$D = \frac{d}{\sin\left(\frac{180}{N}\right)} \quad (1a)$$

Equation (1b) applies when clearance  $C > 0$  then

$$C = D \sin\left(180^\circ - (N - 1) \operatorname{asin}\left(\frac{d}{D}\right)\right) - d \quad (1b)$$

Fig. 31.

*Example:* Forty bearings are to be placed around a 3-inch diameter shaft with no clearance. What diameter bearings are needed?

*Solution:* Rearrange Equation (1a), and substitute in the value of  $N$ . Use the result to eliminate  $d$ , using  $D_S = D - d$ . Finally, solve for  $D$  and  $d$ .

$$d = D \sin\left(\frac{180}{N}\right) = D \sin\left(\frac{180}{40}\right) = 0.078459D$$

$$D = D_S + d = 3 + 0.078459D$$

$$D = \frac{3}{0.92154} = 3.2554$$

$$d = D - D_S = 0.2554$$

## SOLUTION OF TRIANGLES

Any figure bounded by three straight lines is called a triangle. Any one of the three lines may be called the base, and the line drawn from the angle opposite the base at right angles to it is called the height or altitude of the triangle.

If all three sides of a triangle are of equal length, the triangle is called *equilateral*. Each of the three angles in an equilateral triangle equals 60 degrees. If two sides are of equal length, the triangle is an *isosceles* triangle. If one angle is a right or 90-degree angle, the triangle is a *right* or *right-angled* triangle. The side opposite the right angle is called the *hypotenuse*.

If all the angles are less than 90 degrees, the triangle is called an *acute* or *acute-angled* triangle. If one of the angles is larger than 90 degrees, the triangle is called an *obtuse-angled* triangle. Both acute and obtuse-angled triangles are known under the common name of *oblique-angled* triangles. The sum of the three angles in every triangle is 180 degrees.

The sides and angles of any triangle that are not known can be found when: 1) all the three sides; 2) two sides and one angle; and 3) one side and two angles are given.

In other words, if a triangle is considered as consisting of six parts, three angles and three sides, the unknown parts can be determined when any three parts are given, provided at least one of the given parts is a side.

## Functions of Angles

For every right triangle, a set of six ratios is defined; each is the length of one side of the triangle divided by the length of another side. The six ratios are the trigonometric (trig) functions sine, cosine, tangent, cosecant, secant, and cotangent (abbreviated sin, cos, tan, csc, sec, and cot). Trig functions are usually expressed in terms of an angle in degree or radian measure, as in  $\cos 60^\circ = 0.5$ . "Arc" in front of a trig function name, as in arcsin or arccos, means find the angle whose function value is given. For example,  $\arcsin 0.5 = 30^\circ$  means that  $30^\circ$  is the angle whose sin is equal to 0.5. Electronic calculators frequently use  $\sin^{-1}$ ,  $\cos^{-1}$ , and  $\tan^{-1}$  to represent the arc functions.

*Example:*  $\tan 53.1^\circ = 1.332$ ;  $\arctan 1.332 = \tan^{-1} 1.332 = 53.1^\circ = 53^\circ 6'$

The *sine* of an angle equals the opposite side divided by the hypotenuse. Hence,  $\sin B = b \div c$ , and  $\sin A = a \div c$ .

The *cosine* of an angle equals the adjacent side divided by the hypotenuse. Hence,  $\cos B = a \div c$ , and  $\cos A = b \div c$ .

The *tangent* of an angle equals the opposite side divided by the adjacent side. Hence,  $\tan B = b \div a$ , and  $\tan A = a \div b$ .

The *cotangent* of an angle equals the adjacent side divided by the opposite side. Hence,  $\cot B = a \div b$ , and

$\cot A = b \div a$ .

The *secant* of an angle equals the hypotenuse divided by the adjacent side. Hence,  $\sec B = c \div a$ , and  $\sec A = c \div b$ .

The *cosecant* of an angle equals the hypotenuse divided by the opposite side. Hence,  $\csc B = c \div b$ , and  $\csc A = c \div a$ .

It should be noted that the functions of the angles can be found in this manner only when the triangle is right-angled.

If in a right-angled triangle (see preceding illustration), the lengths of the three sides are represented by  $a$ ,  $b$ , and  $c$ , and the angles opposite each of these sides by  $A$ ,  $B$ , and  $C$ , then the side  $c$  opposite the right angle is the hypotenuse; side  $b$  is called the *side adjacent* to angle  $A$  and is also the *side opposite* to angle  $B$ ; side  $a$  is the side adjacent to angle  $B$  and the

side opposite to angle  $A$ . The meanings of the various functions of angles can be explained with the aid of a right-angled triangle. Note that the cosecant, secant, and cotangent are the reciprocals of, respectively, the sine, cosine, and tangent.

The following relation exists between the angular functions of the two acute angles in a right-angled triangle: The sine of angle  $B$  equals the cosine of angle  $A$ ; the tangent of angle  $B$  equals the cotangent of angle  $A$ , and *vice versa*. The sum of the two acute angles in a right-angled triangle always equals 90 degrees; hence, when one angle is known, the other can easily be found. When any two angles together make 90 degrees, one is called the *complement* of the other, and the sine of the one angle equals the cosine of the other, and the tangent of the one equals the cotangent of the other.

**The Law of Sines.**—In any triangle, any side is to the sine of the angle opposite that side as any other side is to the sine of the angle opposite that side. If  $a$ ,  $b$ , and  $c$  are the sides, and  $A$ ,  $B$ , and  $C$  their opposite angles, respectively, then:

$$\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}, \quad \text{so that:}$$

$$a = \frac{b \sin A}{\sin B} \quad \text{or} \quad a = \frac{c \sin A}{\sin C}$$

$$b = \frac{a \sin B}{\sin A} \quad \text{or} \quad b = \frac{c \sin B}{\sin C}$$

$$c = \frac{a \sin C}{\sin A} \quad \text{or} \quad c = \frac{b \sin C}{\sin B}$$

**The Law of Cosines.**—In any triangle, the square of any side is equal to the sum of the squares of the other two sides minus twice their product times the cosine of the included angle; or if  $a$ ,  $b$  and  $c$  are the sides and  $A$ ,  $B$ , and  $C$  are the opposite angles, respectively, then:

$$a^2 = b^2 + c^2 - 2bc \cos A$$

$$b^2 = a^2 + c^2 - 2ac \cos B$$

$$c^2 = a^2 + b^2 - 2ab \cos C$$

These two laws, together with the proposition that the sum of the three angles equals 180 degrees, are the basis of all formulas relating to the solution of triangles.

Formulas for the solution of right-angled and oblique-angled triangles, arranged in tabular form, are given on the following pages.

**Signs of Trigonometric Functions.**—The diagram, Fig. 1 on page 98, shows the proper sign (+ or -) for the trigonometric functions of angles in each of the four quadrants, 0 to 90, 90 to 180, 180 to 270, and 270 to 360 degrees. Thus, the cosine of an angle between 90 and 180 degrees is negative; the sine of the same angle is positive.

**Trigonometric Identities.**—Trigonometric identities are formulas that show the relationship between different trigonometric functions. They may be used to change the form of some trigonometric expressions to simplify calculations. For example, if a formula has a term,  $2\sin A \cos A$ , the equivalent but simpler term  $\sin 2A$  may be substituted. The identities that follow may themselves be combined or rearranged in various ways to form new identities.

**Basic**

$$\tan A = \frac{\sin A}{\cos A} = \frac{1}{\cot A} \quad \sec A = \frac{1}{\cos A} \quad \csc A = \frac{1}{\sin A}$$

**Negative Angle**

$$\sin(-A) = -\sin A \quad \cos(-A) = \cos A \quad \tan(-A) = -\tan A$$

**Pythagorean**

$$\sin^2 A + \cos^2 A = 1 \quad 1 + \tan^2 A = \sec^2 A \quad 1 + \cot^2 A = \csc^2 A$$

**Sum and Difference of Angles**

$$\tan(A + B) = \frac{\tan A + \tan B}{1 - \tan A \tan B} \quad \tan(A - B) = \frac{\tan A - \tan B}{1 + \tan A \tan B}$$

$$\cot(A + B) = \frac{\cot A \cot B - 1}{\cot B + \cot A} \quad \cot(A - B) = \frac{\cot A \cot B + 1}{\cot B - \cot A}$$

$$\sin(A + B) = \sin A \cos B + \cos A \sin B \quad \sin(A - B) = \sin A \cos B - \cos A \sin B$$

$$\cos(A + B) = \cos A \cos B - \sin A \sin B \quad \cos(A - B) = \cos A \cos B + \sin A \sin B$$

**Double-Angle**

$$\cos 2A = \cos^2 A - \sin^2 A = 2 \cos^2 A - 1 = 1 - 2 \sin^2 A$$

$$\sin 2A = 2 \sin A \cos A \quad \tan 2A = \frac{2 \tan A}{1 - \tan^2 A} = \frac{2}{\cot A - \tan A}$$

**Half-Angle**

$$\sin \frac{1}{2}A = \sqrt{\frac{1 - \cos A}{2}} \quad \cos \frac{1}{2}A = \sqrt{\frac{1 + \cos A}{2}}$$

$$\tan \frac{1}{2}A = \frac{\sqrt{1 - \cos A}}{\sqrt{1 + \cos A}} = \frac{1 - \cos A}{\sin A} = \frac{\sin A}{1 + \cos A}$$

**Product-to-Sum**

$$\sin A \cos B = \frac{1}{2}[\sin(A + B) + \sin(A - B)]$$

$$\cos A \cos B = \frac{1}{2}[\cos(A + B) + \cos(A - B)]$$

$$\sin A \sin B = \frac{1}{2}[\cos(A - B) - \cos(A + B)]$$

$$\tan A \tan B = \frac{\tan A + \tan B}{\cot A + \cot B}$$

**Sum and Difference of Functions**

$$\sin A + \sin B = 2[\sin \frac{1}{2}(A + B) \cos \frac{1}{2}(A - B)]$$

$$\sin A - \sin B = 2[\sin \frac{1}{2}(A - B) \cos \frac{1}{2}(A + B)]$$

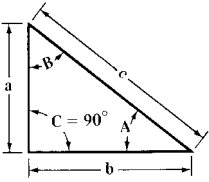

$$\cos A + \cos B = 2[\cos \frac{1}{2}(A + B) \cos \frac{1}{2}(A - B)]$$

$$\cos A - \cos B = -2[\sin \frac{1}{2}(A + B) \sin \frac{1}{2}(A - B)]$$

$$\tan A + \tan B = \frac{\sin(A + B)}{\cos A \cos B} \quad \tan A - \tan B = \frac{\sin(A - B)}{\cos A \cos B}$$

$$\cot A + \cot B = \frac{\sin(B + A)}{\sin A \sin B} \quad \cot A - \cot B = \frac{\sin(B - A)}{\sin A \sin B}$$

## Solution of Right-Angled Triangles
