**Nitriding High-Speed Steel Tools.**—Nitriding is applied to high-speed steel for the purpose of increasing tool life by producing a very hard skin or case, the thickness of which ordinarily is from 0.001 to 0.002 inch. Nitriding is done after the tool has been fully heat treated and finish-ground. (The process differs entirely from that which is applied to surface harden certain alloy steels by heating in an atmosphere of nitrogen or ammonia gas.) The temperature of the high-speed steel nitriding bath, which is a mixture of sodium and potassium cyanides, is equal to or slightly lower than the tempering temperature. For ordinary tools, this temperature usually varies from about 1025 to 1050 deg. F; but if the tools are exceptionally fragile, the range may be reduced to 950 or 1000 deg. F. Accurate temperature control is essential to prevent exceeding the final tempering temperature. The nitriding time may vary from 10 or 15 minutes to 30 minutes or longer, and should be determined by experiment. The shorter periods are applied to tools for iron or steel, or any shock-resisting tools, and the longer periods are for tools used in machining nonferrous metals and plastics. This nitriding process is applied to tools such as hobs, reamers, taps, box tools, form tools, and milling cutters. Nitriding may increase tool life 50 to 200 per cent, or more, but it should always be preceded by correct heat treatment.

*Nitriding Bath Mixtures and Temperatures:* A mixture of 60 per cent sodium cyanide and 40 per cent potassium cyanide is commonly used for nitriding. This mixture has a melting point of 925 deg. F, which is gradually reduced to 800 deg. F as the cyanate content of the bath increases. A more economical mixture of 70 per cent sodium cyanide and 30 per cent potassium cyanide may be used if the operating temperature of the bath is only 1050 deg. F. Nitriding bath temperatures should not exceed 1100 deg. F because higher temperatures accelerate the formation of carbonate at the expense of the essential cyanide. A third mixture suitable for nitriding consists of 55 per cent sodium cyanide, 25 per cent potassium chloride, and 20 per cent sodium carbonate. This mixture melts at 930 deg. F.

**Equipment for Hardening High-Speed Steel.**—Equipment for hardening high-speed steel consists of a hardening furnace capable of maintaining a temperature of 2350 to 2450 deg. F; a preheating furnace capable of maintaining a temperature of 1700 to 1800 deg. F, and of sufficient size to hold a number of pieces of the work; a tempering (drawing) furnace capable of maintaining a temperature of 1000 to 1200 deg. F as a general rule; and a water-cooled tank of quenching oil.

High-speed steels usually are heated for hardening either in some type of electric furnace or in a gas-fired furnace of the muffle type. The small furnaces used for high-speed steel seldom are oil-fired. It is desirable to use automatic temperature control and, where an oven type of furnace is employed, a controlled atmosphere is advisable because of the variations in cutting qualities caused by hardening under uncontrolled conditions. Some furnaces of both electric and fuel-fired types are equipped with a salt bath suitable for high-speed steel hardening temperatures. Salt baths have the advantage of providing protection against the atmosphere during the heating period. A type of salt developed for commercial use is water-soluble, so that all deposits from the hardening bath may be removed by

immersion in water after quenching in oil or salt, or after air cooling. One type of electric furnace heats the salt bath internally by electrodes immersed in it. The same type of furnace is also applied to various heat-treating operations, such as cyanide hardening, liquid carburizing, tempering, and annealing.

An open-forge fire has many disadvantages, especially in hardening cutters or other tools that cannot be ground all over after hardening. The air blast decarburizes the steel and lack of temperature control makes it impossible to obtain uniform results. Electric and gas furnaces provide continuous uniform heat, and the temperature may be regulated accurately, especially when pyrometers are used. In shops equipped with only one furnace for carbon steel and one for high-speed steel, the tempering can be done in the furnace used for hardening carbon steel after the preheating is finished and the steel has been removed for hardening.

**Heating High-Speed Steel for Forging.**—Care should be taken not to heat high-speed steel for forging too abruptly. In winter, the steel may be extremely cold when brought into the forge shop. If the steel is put directly into the hot forge fire, it is likely to develop cracks that will show up later in the finished tool. The steel, therefore, should be warmed gradually before heating for forging.

### Subzero Treatment of Steel

Subzero treatment consists of subjecting the steel, after hardening and either before or after tempering, to a subzero temperature (that usually ranges from  $-100$  to  $-120$  deg. F) and for a period of time varying with the size or volume of the tool, gage, or other part. Commercial equipment is available for obtaining these low temperatures.

The subzero treatment is employed by most gage manufacturers to stabilize precision gages and prevent subsequent changes in size or form. Subzero treatment is also applied to some high-speed steel cutting tools. The object here is to increase the durability or life of the tools; however, up to the present time, the results of tests by metallurgists and tool engineers often differ considerably and in some instances are contradictory. Methods of procedure also vary, especially with regard to the order and number of operations in the complete heat-treating and cooling cycle.

**Changes Resulting From Subzero Treatment.**—When steel is at the hardening temperature it contains a solid solution of carbon and iron known as *austenite*. When the steel is hardened by sudden cooling, most of the austenite, which is relatively soft, tough, and ductile even at room temperatures, is transformed into martensite, a hard and strong constituent. If all the austenite were changed to martensite upon reaching room temperature, this process would be an ideal hardening operation, but many steels retain some austenite. In general, the higher the carbon and alloy contents and the higher the hardening temperature, the greater the tendency to retain austenite. When steel is cooled to subzero temperatures, the stability of the retained austenite is reduced so that it is more readily transformed. To obtain more complete transformation, the subzero treatment may be repeated. The ultimate transformation of austenite to martensite may take place in carbon steel without the aid of subzero treatment, but this natural transformation might require 6 months or longer, whereas by refrigeration this change occurs in a few hours.

The thorough, uniform heating that is always recommended in heat-treating operations should be accompanied by thorough, uniform cooling when the subzero treatment is applied. To ensure uniform cooling, the subzero cooling period should be increased for the larger tools and it may range from 2 to 6 hours. The tool or other part is sometimes surrounded by one or more layers of heavy wrapping or asbestos paper to delay the cooling somewhat and ensure uniformity. After the cooling cycle is started, it should continue without interruption.

Subzero treatment may sometimes cause cracking. Normally, the austenite in steel provides a cushioning effect that may prevent cracking or breakage resulting from treatments

involving temperature and dimensional changes; but if this cushioning effect is removed, particularly at very low temperatures as in subzero treatments, there may be danger of cracking, especially with tools having large or irregular sections and sharp corners offering relatively low resistance to stresses. This effect is one reason why subzero treatments may differ in regard to the cooling and tempering cycle.

**Stabilizing Dimensions of Gages or Precision Parts by Subzero Cooling.**—Transformation of austenite into martensite is accompanied by an increase in volume; consequently, the transformation of austenite, that may occur naturally over a period of months or years, tends to change the dimensions and form of steel parts, and such changes may be serious in the case of precision gages, close-fitting machine parts, etc. To prevent such changes, the subzero treatment has proved effective. Gage-blocks, for example, may be stabilized by hardening followed by repeated cycles of chilling and tempering, to transform a large percentage of the austenite into martensite.

*Order of Operations for Stabilizing Precision Gages:* If precision gages and sine-bars, are heat-treated in the ordinary manner and then are finished without some stabilizing treatment, dimensional changes and warpage are liable to occur. Sub-zero cooling provides a practical and fairly rapid method of obtaining the necessary stabilization by transforming the austenite into martensite. In stabilization treatments of this kind, tempering is the final operation. One series of treatments that has been recommended after hardening and rough-grinding is as follows:

a) Cool to  $-120$  degrees F. (This cooling period may require from one to six hours, depending on the size and form of the gage.)

b) Place gage in boiling water for two hours (oil or salt bath may also be used).

Note: Steps (a) and (b) may be repeated from two to six times, depending on the size and form of the gage. These repeated cycles will eventually transform practically all the austenite into martensite. Two or three cooling and drawing operations usually are sufficient for such work as thread gages and gage-blocks.

c) Follow with regular tempering or drawing operation and finish gage by lapping.

*Series of Stabilizing Treatments for Chromium Steel:* The following series of treatments has proved successful in stabilizing precision gage-blocks made from SAE 52100 chromium steel.

a) Preheat to 600 degrees F and then heat to 1575 degrees F for a period of four minutes.

b) Quench in oil at 85 degrees F. (Uniform quenching is essential.)

c) Temper at 275 degrees F for one hour.

d) Cool in tempering furnace to room temperature.

e) Continue cooling in atmosphere of industrial refrigerator for six hours with temperature of atmosphere at  $-120$  degrees F.

f) Allow gage-blocks to return to room temperature and again temper.

Note: The complete treatment consists of six subzero cooling periods, each followed by a tempering operation. The transformation to martensite is believed to be complete even after the fifth cooling period. The hardness is about 66 Rockwell C. Transformation is checked by magnetic tests based upon the magnetism of martensite and the nonmagnetic qualities of austenite.

**Stabilizing Dimensions of Close-Fitting Machine Parts.**—Subzero treatment will always cause an increase in size. Machine parts subjected to repeated and perhaps drastic changes in temperature, as in aircraft, may eventually cause trouble due to growth or warpage as the austenite gradually changes to martensite. In some instances, the sizes of close-fitting moving parts have increased sufficiently to cause seizure. Such treatment, for example, may be applied to precision bearings made from SAE 52100 or alloy carburizing steels for stabilizing or aging them. *Time* aging of 52100 steels after hardening has been found to cause changes as large as 0.0025 inch in medium size sections. A practical remedy is to apply the subzero treatment before the final grinding or other machining operation.

**Subzero Treatment of Carburized Parts to Improve Physical Properties.**—The subzero treatment has been applied to carburized machine parts. For example, the amount of retained austenite in carburized gears may be sufficient to reduce the life of the gears. In one component, the Rockwell hardness was increased from 55 C to 65 C without loss of impact resistance qualities; in fact, impact and fatigue resistance may be increased in some examples.

**Application of Subzero Treatments to High-Speed Steel.**—The subzero treatment has been applied to such tools as milling cutters, hobs, taps, broaches, and drills. It is applicable to different classes of high-speed steels, such as the 18–4–1 tungsten, 18–4–14 cobalt, and the molybdenum high-speed steels. This *cold* treatment is applied preferably in conjunction with the heat treatment, both being combined in a continuous cycle of operations. The general procedure is either to harden the steel, cool it to a subzero temperature, and then temper; or, especially if there is more than one tempering operation, the first one may *precede* subzero cooling. The cooling and tempering cycle may be repeated two or more times. The number and order of the operations, or the complete cycle, may be varied to suit the class of work and, to minimize the danger of cracking, particularly if the tool has large or irregular sections, sharp corners or edges, or a high cobalt content. A subzero treatment of some kind with a final tempering operation for stress relief, is intended to increase strength and toughness without much loss in hardness; consequently, if there is greater strength at a given hardness, tools subjected to subzero treatment can operate with a higher degree of hardness than those heat treated in the ordinary manner, or, if greater toughness is preferred, it can be obtained by tempering to the original degree of hardness.

**Order of Cooling and Tempering Periods for High-speed Steel.**—The order or cycle for the cooling and tempering periods has not been standardized. The methods that follow have been applied to high-speed steel tools. They are given as examples of procedure and are subject to possible changes due to subsequent developments. The usual ranges of preheating and hardening temperatures are given; but for a particular steel, the recommended temperatures should be obtained from the manufacturer.

- 1) *Double Subzero Treatment:* (For rugged simple tool forms without irregular sections, sharp corners or edges where cracks might develop during the subzero treatment).
  - a) Preheat between 1400 and 1600 degrees F (double preheating is preferable, the first preheating ranging from 700 to 1000 degrees F).
  - b) Heat to the hardening temperature. (*Note:* Tests indicate that the effect of subzero treatment on high-speed steel may be influenced decidedly by the hardening temperature. If this temperature is near the lower part of the range, the results are unsatisfactory. Effective temperatures for ordinary high-speed steels appear to range from 2300 to 2350 degrees F).
  - c) Quench in oil, salt, lead, or air, down to a workpiece temperature of 150–200 degrees F. (*Note:* One method is to quench in oil; a second method is to quench in oil to about 200–225 degrees F and then air cool; a third method is to quench in salt bath at 1050–1100 degrees F and then air cool.)
  - d) Cool in refrigerating unit to temperature of –100 to –120 degrees F *right after quenching.* (*Note:* Tests have shown that a delay of one hour has a detrimental effect, and in ten hours the efficiency of the subzero treatment is reduced 50 per cent. This is because the austenite becomes more and more stabilized when the subzero treatment is delayed; consequently, the austenite is more difficult to transform into martensite.) The refrigerating period usually varies from two to six hours, depending on the size of the tool. Remove the tool from the refrigerating unit and allow it to return to room temperature.
  - e) Temper to required hardness for a period of two and one-half to three hours. The tempering temperature usually varies from a minimum of 1000 to 1100 degrees F for ordinary high-speed steels. Tests indicate that if this first tempering is less than two and one-half hours at 1050 degrees F, there will not be sufficient precipitation of car-

bides at the tempering temperature to allow complete transformation of the retained austenite on cooling, whereas more than three hours causes some loss in room temperature hardness, hot hardness, strength, and toughness.

- f) Repeat subzero treatment, step (d).
  - g) Repeat the tempering operation, step (e). (*Note:* The time for the second tempering operation is sometimes reduced to about one-half the time required for the first tempering.)
- 2) *Single Subzero Treatment:* This treatment is the same as procedure (1) except that a second subzero cooling is omitted; hence, the cycle consists of hardening, subzero cooling, and double tempering. Procedure (3), which follows, also has one subzero cooling period in the cycle, but this *follows* the first tempering operation.
- 3) *Tempering Followed by Subzero Treatment:* This treatment is for tools having irregular sections, sharp corners, or edges where cracks might develop if the hardening operation were followed immediately by subzero cooling.
- a) Preheat and heat for hardening.
  - b) Preheat and heat for hardening.
  - c) Quench as described under procedure (1).
  - d) Temper to required hardness.
  - e) Cool to subzero temperature  $-100$  to  $-120$  degrees F and then allow the tool to return to room temperature.
  - f) Repeat tempering operation.

### Testing the Hardness of Metals

**Brinell Hardness Test.**—The Brinell test for determining the hardness of metallic materials consists in applying a known load to the surface of the material to be tested through a hardened steel ball of known diameter. The diameter of the resulting permanent impression in the metal is measured and the Brinell Hardness Number (BHN) is then calculated from the following formula in which  $D$  = diameter of ball in millimeters,  $d$  = measured diameter at the rim of the impression in millimeters, and  $P$  = applied load in kilograms.

$$\text{BHN} = \frac{\text{load on indenting tool in kilograms}}{\text{surface area of indentation in sq. mm.}} = \frac{P}{\frac{\pi D}{2}(D - \sqrt{D^2 - d^2})}$$

If the steel ball were not deformed under the applied load and if the impression were truly spherical, then the preceding formula would be a general one, and any combination of applied load and size of ball could be used. The impression, however, is not quite a spherical surface because there must always be some deformation of the steel ball and some recovery of form of the metal in the impression; hence, for a standard Brinell test, the size and characteristics of the ball and the magnitude of the applied load must be standardized. In the standard Brinell test, a ball 10 millimeters in diameter and a load of 3000, 1500, or 500 kilograms is used. It is desirable, although not mandatory, that the test load be of such magnitude that the diameter of the impression be in the range of 2.50 to 4.75 millimeters. The following test loads and approximate Brinell numbers for this range of impression diameters are: 3000 kg, 160 to 600 BHN; 1500 kg, 80 to 300 BHN; 500 kg, 26 to 100 BHN. In making a Brinell test, the load should be applied steadily and without a jerk for at least 15 seconds for iron and steel, and at least 30 seconds in testing other metals. A minimum period of 2 minutes, for example, has been recommended for magnesium and magnesium alloys. (For the softer metals, loads of 250, 125, or 100 kg are sometimes used.)

According to the American Society for Testing and Materials Standard E10-66, a steel ball may be used on material having a BHN not over 450, a Hultgren ball on material not over 500, or a carbide ball on material not over 630. The Brinell hardness test is not recommended for material having a BHN over 630.

**Rockwell Hardness Test.**—The Rockwell hardness tester is essentially a machine that measures hardness by determining the depth of penetration of a penetrator into the specimen under certain fixed conditions of test. The penetrator may be either a steel ball or a diamond spheroconical penetrator. The hardness number is related to the depth of indentation and the number is higher the harder the material. A minor load of 10 kg is first applied, causing an initial penetration; the dial is set at zero on the black-figure scale, and the major load is applied. This major load is customarily 60 or 100 kg when a steel ball is used as a penetrator, but other loads may be used when necessary. The ball penetrator is  $\frac{1}{16}$  inch in diameter normally, but other penetrators of larger diameter, such as  $\frac{1}{8}$  inch, may be employed for soft metals. When a diamond spheroconical penetrator is employed, the load usually is 150 kg. Experience decides the best combination of load and penetrator for use. After the major load is applied and removed, according to standard procedure, the reading is taken while the minor load is still applied.

**The Rockwell Hardness Scales.**—The various Rockwell scales and their applications are shown in the following table. The type of penetrator and load used with each are shown in Tables 1 and 2, which give comparative hardness values for different hardness scales.

| Scale               | Testing Application   |
|---------------------|---|
| A                   | For tungsten carbide and other extremely hard materials. Also for thin, hard sheets.              |
| B                   | For materials of medium hardness such as low- and medium-carbon steels in the annealed condition. |
| C                   | For materials harder than Rockwell B-100.   |
| D                   | Where a somewhat lighter load is desired than on the C scale, as on case-hardened pieces.         |
| E                   | For very soft materials such as bearing metals.   |
| F                   | Same as the E scale but using a $\frac{1}{16}$ -inch ball.  |
| G                   | For metals harder than tested on the B scale.   |
| H & K               | For softer metals.  |
| 15-N; 30-N;<br>45-N | Where a shallow impression or a small area is desired. For hardened steel and hard alloys.        |
| 15-T; 30-T;<br>45-T | Where a shallow impression or a small area is desired for materials softer than hardened steel.   |

**Shore's Scleroscope.**—The scleroscope is an instrument that measures the hardness of the work in terms of elasticity. A diamond-tipped hammer is allowed to drop from a known height on the metal to be tested. As this hammer strikes the metal, it rebounds, and the harder the metal, the greater the rebound. The extreme height of the rebound is recorded, and an average of a number of readings taken on a single piece will give a good indication of the hardness of the work. The surface smoothness of the work affects the reading of the instrument. The readings are also affected by the contour and mass of the work and the depth of the case, in carburized work, the soft core of light-depth carburizing, pack-hardening, or cyanide hardening, absorbing the force of the hammer fall and decreasing the rebound. The hammer weighs about 40 grains, the height of the rebound of hardened steel is in the neighborhood of 100 on the scale, or about  $6\frac{1}{4}$  inches, and the total fall is about 10 inches or 255 millimeters.

**Vickers Hardness Test.**—The Vickers test is similar in principle to the Brinell test. The standard Vickers penetrator is a square-based diamond pyramid having an included point angle of 136 degrees. The numerical value of the hardness number equals the applied load in kilograms divided by the area of the pyramidal impression: A smooth, firmly supported, flat surface is required. The load, which usually is applied for 30 seconds, may be 5, 10, 20, 30, 50, or 120 kilograms. The 50-kilogram load is the most usual. The hardness number is based upon the diagonal length of the square impression. The Vickers test is considered to

be very accurate, and may be applied to thin sheets as well as to larger sections with proper load regulation.

**Knoop Hardness Numbers.**—The Knoop hardness test is applicable to extremely thin metal, plated surfaces, exceptionally hard and brittle materials, very shallow carburized or nitrided surfaces, or whenever the applied load must be kept below 3600 grams. The Knoop indenter is a diamond ground to an elongated pyramidal form and it produces an indentation having long and short diagonals with a ratio of approximately 7 to 1. The longitudinal angle of the indenter is 172 degrees, 30 minutes, and the transverse angle 130 degrees. The Tukon Tester in which the Knoop indenter is used is fully automatic under electronic control. The Knoop hardness number equals the load in kilograms divided by the projected area of indentation in square millimeters. The indentation number corresponding to the long diagonal and for a given load may be determined from a table computed for a theoretically perfect indenter. The load, which may be varied from 25 to 3600 grams, is applied for a definite period and always normal to the surface tested. Lapped plane surfaces free from scratches are required.

**Monotron Hardness Indicator.**—With this instrument, a diamond-ball impressor point  $\frac{3}{4}$  mm in diameter is forced into the material to a depth of  $\frac{1}{500}$  inch and the pressure required to produce this constant impression indicates the hardness. One of two dials shows the pressure in kilograms and pounds, and the other shows the depth of the impression in millimeters and inches. Readings in Brinell numbers may be obtained by means of a scale designated as *M-1*.

**Keep's Test.**—With this apparatus, a standard steel drill is caused to make a definite number of revolutions while it is pressed with standard force against the specimen to be tested. The hardness is automatically recorded on a diagram on which a dead soft material gives a horizontal line, and a material as hard as the drill itself gives a vertical line, intermediate hardness being represented by the corresponding angle between 0 and 90 degrees.

**Comparison of Hardness Scales.**—Tables 1 and 2 show comparisons of various hardness scales. All such tables are based on the assumption that the metal tested is homogeneous to a depth several times that of the indentation. To the extent that the metal being tested is not homogeneous, errors are introduced because different loads and different shapes of penetrators meet the resistance of metal of varying hardness, depending on the depth of indentation. Another source of error is introduced in comparing the hardness of different materials as measured on different hardness scales. This error arises from the fact that in any hardness test, metal that is severely cold-worked actually supports the penetrator, and different metals, different alloys, and different analyses of the same type of alloy have different cold-working properties. In spite of the possible inaccuracies introduced by such factors, it is of considerable value to be able to compare hardness values in a general way.

The data shown in Table 1 are based on extensive tests on carbon and alloy steels mostly in the heat-treated condition, but have been found to be reliable on constructional alloy steels and tool steels in the as-forged, annealed, normalized, quenched, and tempered conditions, providing they are homogeneous. These hardness comparisons are not as accurate for special alloys such as high manganese steel, 18-8 stainless steel and other austenitic steels, nickel-base alloys, constructional alloy steels, and nickel-base alloys in the cold-worked condition.

The data shown in Table 2 are for hardness measurements of unhardened steel, steel of soft temper, grey and malleable cast iron, and most nonferrous metals. Again these hardness comparisons are not as accurate for annealed metals of high Rockwell B hardness such as austenitic stainless steel, nickel and high nickel alloys, and cold-worked metals of low B-scale hardness such as aluminum and the softer alloys.

HARDNESS TESTING

**Table 1. Comparative Hardness Scales for Steel**

| Rockwell C-Scale Hardness Number | Diamond Pyramid Hardness Number Vickers | Brinell Hardness Number 10-mm Ball, 3000-kgf Load |               |                       | Rockwell Hardness Number             |                                       | Rockwell Superficial Hardness Number Superficial Diamond Indenter |                        |                        | Shore Scleroscope Hardness Number |
|----------------------------------|---|---|---------------|-----------------------|--------------------------------------|---------------------------------------|---|------------------------|------------------------|-----------------------------------|
|                                  |   | Standard Ball                                     | Hultgren Ball | Tungsten Carbide Ball | A-Scale 60-kgf Load Diamond Indenter | D-Scale 100-kgf Load Diamond Indenter | 15-N Scale 15-kgf Load  | 30-N Scale 30-kgf Load | 45-N Scale 45-kgf Load |                                   |
| 68                               | 940                                     | ...   | ...           | ...                   | 85.6                                 | 76.9                                  | 93.2  | 84.4                   | 75.4                   | 97                                |
| 67                               | 900                                     | ...   | ...           | ...                   | 85.0                                 | 76.1                                  | 92.9  | 83.6                   | 74.2                   | 95                                |

Note: The values in this table shown in **boldface** type correspond to those shown in American Society for Testing and Materials Specification E140-67.

Values in ( ) are beyond the normal range and are given for information only.

**Turner's Sclerometer.**—In making this test a weighted diamond point is drawn, once forward and once backward, over the smooth surface of the material to be tested. The hardness number is the weight in grams required to produce a standard scratch.

**Mohs's Hardness Scale.**—Hardness, in general, is determined by what is known as Mohs's scale, a standard for hardness that is applied mainly to nonmetallic elements and minerals. In this hardness scale, there are ten degrees or steps, each designated by a mineral, the difference in hardness of the different steps being determined by the fact that any member in the series will scratch any of the preceding members. This scale is as follows:

- 1) talc; 2) gypsum; 3) calcite; 4) fluor spar; 5) apatite; 6) orthoclase; 7) quartz;  
8) topaz; 9) sapphire or corundum; and 10) diamond.

These minerals, arbitrarily selected as standards, are successively harder, from talc, the softest of all minerals, to diamond, the hardest. This scale, which is now universally used for nonmetallic minerals, is not applied to metals.

**Relation Between Hardness and Tensile Strength.**—The approximate relationship between the hardness and tensile strength is shown by the following formula:

Tensile strength =  $Bhn \times 515$  (for Brinell numbers up to 175).

Tensile strength =  $Bhn \times 490$  (for Brinell numbers larger than 175).

The above formulas give the tensile strength in pounds per square inch for steels. These approximate relationships between hardness and tensile strength do not apply to nonferrous metals with the possible exception of certain aluminum alloys.

**Durometer Tests.**—The durometer is a portable hardness tester for measuring hardness of rubber, plastics, and some soft metals. The instrument is designed to apply pressure to the specimen and the hardness is read from a scale while the pressure is maintained. Various scales can be used by changing the indenter and the load applied.

**Table 2. Comparative Hardness Scales for Unhardened Steel, Soft-Temper Steel, Grey and Malleable Cast Iron, and Nonferrous Alloys**

| Rockwell Hardness Number       |                          |                           | Rockwell Superficial Hardness Number |                             |                             | Rockwell Hardness Number      |                           |                           | Brinell Hardness Number  |                     |                 |

Not applicable to annealed metals of high B-scale hardness such as austenitic stainless steels, nickel and high-nickel alloys nor to cold-worked metals of low B-scale hardness such as aluminum and the softer alloys. (Compiled by Wilson Mechanical Instrument Co.)

## NONFERROUS ALLOYS

## Strength Data for Nonferrous Metals

The ultimate tensile, shear, and yield strengths and moduli of elasticity of many nonferrous metals are given in Table 1. Values for the most part are given in ranges rather than as single values because of differences in composition, forms, sizes, and shapes for the aluminum alloys plus differences in heat treatments undergone for the other nonferrous metals. The values in the table are meant to serve as a guide, not as specifications. More specific data should be obtained from the supplier.

Table 1. Strength Data for Nonferrous Metals

| Material                  | Ultimate Strength, kpsi |          | Yield Strength, kpsi<br>(0.2% offset) | Modulus of Elasticity, 10 <sup>6</sup> psi |                    |
|---------------------------|-------------------------|----------|---------------------------------------|--|--------------------|
|                           | in Tension              | in Shear |                                       | in Tension, <i>E</i>                       | in Shear, <i>G</i> |

### Copper and Copper Alloys

Pure copper is a reddish, highly malleable metal, and was one of the first to be found and utilized. Copper and its alloys are widely used because of their excellent electrical and thermal conductivities, outstanding resistance to corrosion, ease of fabrication, and broad ranges of obtainable strengths and special properties. Almost 400 commercial copper and copper-alloy compositions are available from mills as wrought products (rod, plate, sheet, strip, tube, pipe, extrusions, foil, forgings, and wire) and from foundries as castings.

Copper alloys are grouped into several general categories according to composition:

- coppers and high-copper alloys
- brasses
- bronzes
- copper nickels
- copper–nickel–zinc alloys (nickel silvers)
- leaded coppers
- special alloys

The designation system originally developed by the U.S. copper and brass industry for identifying copper alloys used a three-digit number preceded by the letters CA. These designations have now been made part of the Unified Numbering System (UNS) simply by expanding the numbers to five digits preceded by the letter C. Because the old numbers are embedded in the new UNS numbers, no confusion results. UNS C10000 to C79999 are assigned to wrought compositions, and UNS C80000 to C99999 are assigned to castings. The designation system is not a specification, but a method for identifying the composition of mill and foundry products. The precise technical and quality assurance requirements to be satisfied are defined in relevant standard specifications issued by the federal government, the military, and the ASTM.

#### Classification of Copper and Copper Alloys

| Family                         | Principal Alloying Element | UNS Numbers <sup>a</sup>                    |
|--------------------------------|----------------------------|---|
| Coppers, high-copper alloys    |                            | C1xxxx                                      |
| Brasses                        | Zn                         | C2xxxx, C3xxxx, C4xxxx,<br>C66400 to C69800 |
| Phosphor bronzes               | Sn                         | C5xxxx                                      |
| Aluminum bronzes               | Al                         | C60600 to C64200                            |
| Silicon bronzes                | Si                         | C64700 to C66100                            |
| Copper nickels, nickel silvers | Ni                         | C7xxxx                                      |

<sup>a</sup> Wrought alloys.

**Cast Copper Alloys.**—Generally, casting permits greater latitude in the use of alloying elements than in the fabrication of wrought products, which requires either hot or cold working. The cast compositions of coppers and high-copper alloys have a designated minimum copper content and may include other elements to impart special properties. The cast brasses comprise copper–zinc–tin alloys (red, semired, and yellow brasses); manganese bronze alloys (high-strength yellow brasses); leaded manganese bronze alloys (leaded high-strength yellow brasses); and copper–zinc–silicon alloys (silicon brasses and bronzes).

The cast bronze alloys have four main families: copper–tin alloys (tin bronzes); copper–tin–lead alloys (leaded and high leaded tin bronzes); copper–tin–nickel alloys (nickel–tin bronzes); and copper–aluminum alloys (aluminum bronzes).

The cast copper–nickel alloys contain nickel as the principal alloying element. The leaded coppers are cast alloys containing 20 per cent or more lead.

Table 2 lists the properties and applications of common cast copper alloys.

**Table 2. Properties and Applications of Cast Coppers and Copper Alloys**

| UNS Designation    | Nominal Composition (%)                                      | Typical Mechanical Properties, as Cast or Heat Treated <sup>a</sup> |                      |                         |                                   | Typical Applications   |
|--------------------|--|---|----------------------|-------------------------|-----------------------------------|--|
|                    |  | Tensile Strength (ksi)  | Yield Strength (ksi) | Elongation in 2 in. (%) | Machinability Rating <sup>b</sup> |  |
| Copper Alloys      |  |   |                      |                         |                                   |  |
| C80100             | 99.95 Cu + Ag min, 0.05 others max                           | 25  | 9                    | 40                      | 10                                | Electrical and thermal conductors; corrosion and oxidation-resistant applications.   |

| C90200                  | 93 Cu, 7 Sn                               | 38  | 16                   | 30                      | 20                                | Bearings and bushings.   |
| C90300                  | 88 Cu, 8 Sn, 4 Zn                         | 45  | 21                   | 30                      | 30                                | Bearings, bushings, pump impellers, piston rings, valve components, seal rings, steam fittings, gears.                           |
| C90500                  | 88 Cu, 10 Sn, 2 Zn                        | 45  | 22                   | 25                      | 30                                | Bearings, bushings, pump impellers, piston rings, valve components, steam fittings, gears.                                       |
| C90700                  | 89 Cu, 11 Sn                              | 44 (55)   | 22 (30)              | 20 (16)                 | 20                                | Gears, bearings, bushings.   |
| C90900                  | 87 Cu, 13 Sn                              | 40  | 20                   | 15                      | 20                                | Bearings and bushings.   |
| C91000                  | 85 Cu, 14 Sn, 1 Zn                        | 32  | 25                   | 2                       | 20                                | Piston rings and bearings.   |
| C91100                  | 84 Cu, 16 Sn                              | 35  | 25                   | 2                       | 10                                | Piston rings, bearings, bushings, bridge plates.   |
| C91300                  | 81 Cu, 19 Sn                              | 35  | 30                   | 0.5                     | 10                                | Piston rings, bearings, bushings, bridge plates, bells.  |
| C91600                  | 88 Cu, 10.5 Sn, 1.5 Ni                    | 44 (60)   | 22 (32)              | 16 (16)                 | 20                                | Gears.   |
| C91700                  | 86.5 Cu, 12 Sn, 1.5 Ni                    | 44 (60)   | 22 (32)              | 16 (16)                 | 20                                | Gears.   |
| Leaded Tin Bronzes      |   |   |                      |                         |                                   |  |
| C92200                  | 88 Cu, 6 Sn, 1.5 Pb, 4.5 Zn               | 40  | 20                   | 30                      | 42                                | Valves, fittings, and pressure-containing parts for use up to 550°F.   |
| C92300                  | 87 Cu, 8 Sn, 4 Zn                         | 40  | 20                   | 25                      | 42                                | Valves, pipe fittings, and high-pressure steam castings. Superior machinability to C90300.                                       |
| C92500                  | 87 Cu, 11 Sn, 1 Pb, 1 Ni                  | 44  | 20                   | 20                      | 30                                | Gears, automotive synchronizer rings.  |
| C92600                  | 87 Cu, 10 Sn, 1 Pb, 2 Zn                  | 44  | 20                   | 30                      | 40                                | Bearings, bushings, pump impellers, piston rings, valve components, steam fittings, and gears. Superior machinability to C90500. |
| C92700                  | 88 Cu, 10 Sn, 2 Pb                        | 42  | 21                   | 20                      | 45                                | Bearings, bushings, pump impellers, piston rings, and gears. Superior machinability to C90500.                                   |
| C92800                  | 79 Cu, 16 Sn, 5 Pb                        | 40  | 30                   | 1                       | 70                                | Piston rings.  |
| C92900                  | 82 Cu min, 9 Sn min, 2 Pb min, 2.8 Ni min | 47 (47)   | 26 (26)              | 20 (20)                 | 40                                | Gears, wear plates, guides, cams, parts requiring machinability superior to that of C91600 or 91700.                             |
| High-Leaded Tin Bronzes |   |   |                      |                         |                                   |  |
| C93200                  | 83 Cu, 6.3 Sn min, 7 Pb, 3 Zn             | 35  | 18                   | 20                      | 70                                | General-utility bearings and bushings.   |
| C93400                  | 84 Cu, 8 Sn, 8 Pb                         | 32  | 16                   | 20                      | 70                                | Bearings and bushings.   |
| C93500                  | 85 Cu, 5 Sn, 9 Pb                         | 32  | 16                   | 20                      | 70                                | Small bearings and bushings, bronze backing for rabbit-lined automotive bearings.  |
| C93700                  | 80 Cu, 10 Sn, 10 Pb                       | 35  | 18                   | 20                      | 80                                | Bearings for high speed and heavy pressures, pumps, impellers, corrosion-resistant applications, pressure tight castings.        |
| C93800                  | 78 Cu, 7 Sn, 15 Pb                        | 30  | 16                   | 18                      | 80                                | Bearings for general service and moderate pressure, pump impellers, and bodies for use in acid mine water.                       |
| C93900                  | 79 Cu, 6 Sn, 15 Pb                        | 32  | 22                   | 7                       | 80                                | Continuous castings only. Bearings for general service, pump bodies, and impellers for mine waters.                              |
| C94300                  | 70 Cu, 5 Sn, 25 Pb                        | 27  | 13                   | 15                      | 80                                | High-speed bearings for light loads.   |
| C94400                  | 81 Cu, 8 Sn, 11 Pb, 0.35 P                | 32  | 16                   | 18                      | 80                                | General-utility alloy for bushings and bearings.   |
| C94500                  | 73 Cu, 7 Sn, 20 Pb                        | 25  | 12                   | 12                      | 80                                | Locomotive wearing parts; high-low, low-speed bearings.  |

**Table 2. (Continued) Properties and Applications of Cast Coppers and Copper Alloys**

| UNS Designation    | Nominal Composition (%)                         | Typical Mechanical Properties, as Cast or Heat Treated <sup>a</sup> |                      |                         |                                   | Typical Applications  |
|--------------------|---|---|----------------------|-------------------------|-----------------------------------|---|
|                    |   | Tensile Strength (ksi)  | Yield Strength (ksi) | Elongation in 2 in. (%) | Machinability Rating <sup>b</sup> |   |
| Nickel-Tin Bronzes |   |   |                      |                         |                                   |   |
| C94700             | 88 Cu, 5 Sn, 2 Zn, 5 Ni                         | 50 (85)   | 23 (60)              | 35 (10)                 | 30 (20)                           | Valve stems and bodies, bearings, wear guides, shift forks, feeding mechanisms, circuit breaker parts, gears, piston cylinders, nozzles.                      |
| C94800             | 87 Cu, 5 Sn, 5 Ni                               | 45 (60)   | 23 (30)              | 35 (8)                  | 50 (40)                           | Structural castings, gear components, motion-translation devices, machinery parts, bearings.  |
| Aluminum Bronzes   |   |   |                      |                         |                                   |   |
| C95200             | 88 Cu, 3 Fe, 9 Al                               | 80  | 27                   | 35                      | 50                                | Acid-resisting pumps, bearing, gears, valve seats, guides, plungers, pump rods, bushings.   |
| C95300             | 89 Cu, 1 Fe, 10 Al                              | 75 (85)   | 27 (42)              | 25 (15)                 | 55                                | Pickling baskets, nuts, gears, steel mill slippers, marine equipment, welding jaws.   |
| C95400             | 85 Cu, 4 Fe, 11 Al                              | 85 (105)  | 35 (54)              | 18 (8)                  | 60                                | Bearings, gears, worms, bushings, valve seats and guides, pickling hooks.   |
| C95500             | 81 Cu, 4 Ni, 4 Fe, 11 Al                        | 100 (120)   | 44 (68)              | 12 (10)                 | 50                                | Valve guides and seats in aircraft engines, corrosion-resistant parts, bushings, gears, worms, pickling hooks and baskets, agitators.                         |
| C95600             | 91 Cu, 7 Al, 2 Si                               | 75  | 34                   | 18                      | 60                                | Cable connectors, terminals, valve stems, marine hardware, gears, worms, pole-line hardware.  |
| C95700             | 75 Cu, 2 Ni, 3 Fe, 8 Al, 12 Mn                  | 95  | 45                   | 26                      | 50                                | Propellers, impellers, stator clamp segments, safety tools, welding rods, valves, pump casings.   |
| C95800             | 81 Cu, 5 Ni, 4 Fe, 9 Al, 1 Mn                   | 95  | 38                   | 25                      | 50                                | Propeller hubs, blades, and other parts in contact with salt water.   |
| Copper-Nickels     |   |   |                      |                         |                                   |   |
| C96200             | 88.6 Cu, 10 Ni, 1.4 Fe                          | 45 min  | 25 min               | 20 min                  | 10                                | Components of items being used for seawater corrosion resistance.   |
| C96300             | 79.3 Cu, 20 Ni, 0.7 Fe                          | 75 min  | 55 min               | 10 min                  | 15                                | Centrifugally cast tailshaft sleeves.   |

**Wrought Copper Alloys.**—Wrought copper alloys can be utilized in the annealed, cold-worked, stress-relieved, or hardened-by-heat-treatment conditions, depending on composition and end use. The “temper designation” for copper alloys is defined in ASTM Standard Recommended Practice B601, which is applicable to all product forms.

Wrought copper and high-copper alloys, like cast alloys, have a designated minimum copper content and may include other elements to impart special properties. Wrought brasses have zinc as the principal alloying element and may have other designated elements. They comprise the copper–zinc alloys; copper–zinc–lead alloys (leaded brasses); and copper–zinc–tin alloys (tin brasses).

Wrought bronzes comprise four main groups; copper–tin–phosphorus alloys (phosphor bronze); copper–tin–lead–phosphorus alloys (leaded phosphor bronze); copper–aluminum alloys (aluminum bronzes); and copper–silicon alloys (silicon bronze).

Wrought copper–nickel alloys, like the cast alloys, have nickel as the principal alloying element. The wrought copper–nickel–zinc alloys are known as “nickel silvers” because of their color.

Table 3 lists the nominal composition, properties, and applications of common wrought copper alloys.

**Table 3. Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number  | Nominal Composition (%)         | Strength (ksi) |       | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications   |
|--|---------------------------------|----------------|-------|-------------------------|-----------------------------------|--|
|  |                                 | Tensile        | Yield |                         |                                   |  |
| C10100<br>Oxygen-free electronic                                       | 99.99 Cu                        | 32–66          | 10–53 | 55                      | 20                                | Excellent hot and cold workability; good forgeability. Fabricated by blanking, coining, copper-smithing, drawing and upsetting, hot forging and pressing, spinning, swaging, stamping. Uses: busbars, bus conductors, waveguides, hollow conductors, lead-in wires and anodes for vacuum tubes, vacuum seals, transistor components, glass to metal seals, coaxial cables and tubes, klystrons, microwave tubes, rectifiers. |
| C10200<br>Oxygen-free copper   | 99.95 Cu                        | 32–66          | 10–53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: busbars, waveguides.   |
| C10300<br>Oxygen-free, extra-low phosphorus                            | 99.95 Cu,<br>0.003 P            | 32–55          | 10–50 | 50                      | 20                                | Fabricating characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring good conductivity and welding or brazing properties.   |
| C10400, C10500,<br>C10700<br>Oxygen-free, silver-bearing               | 99.95 Cu                        | 32–66          | 10–53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: auto gaskets, radiators, busbars, conductivity wire, contacts, radio parts, winding, switches, terminals, commutator segments; chemical process equipment, printing rolls, clad metals, printed-circuit foil.  |
| C10800<br>Oxygen-free, low phosphorus                                  | 99.95 Cu,<br>0.009 P            | 32–55          | 10–50 | 50                      | 20                                | Fabricating characteristics same as C10100. Uses: refrigerators, air conditioners, gas and heater lines, oil burner tubes, plumbing pipe and tube, brewery tubes, condenser and heat-exchanger tubes, dairy and distiller tubes, pulp and paper lines, tanks; air, gasoline, and hydraulic lines.  |
| C11000<br>Electrolytic tough pitch copper                              | 99.90 Cu,<br>0.04 O             | 32–66          | 10–53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: downspouts, gutters, roofing, gaskets, auto radiators, busbars, nails, printing rolls, rivets, radio parts.  |
| C11000<br>Electrolytic tough pitch, anneal-resistant                   | 99.90 Cu,<br>0.04 O,<br>0.01 Cd | 66             | ...   | ...                     | 20                                | Fabricated by drawing and stranding, stamping. Uses: electrical power transmission where resistance to softening under overloads is desired.   |
| C11300,<br>C11400, C11500,<br>C11600 Silver-bearing tough pitch copper | 99.90 Cu,<br>0.04 O,<br>Ag      | 32–66          | 10–53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: gaskets, radiators, busbars, windings, switches, chemical process equipment, clad metals, printed-circuit foil.  |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number   | Nominal Composition (%)                         | Strength (ksi) |       | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications   |
|---|---|----------------|-------|-------------------------|-----------------------------------|--|
|   |   | Tensile        | Yield |                         |                                   |  |
| C12000, C12100<br>Phosphorus deoxidized, low residual phosphorus                  | 99.9 Cu   | 32-57          | 10-53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring welding or brazing.  |
| C12200, C12210<br>Phosphorus deoxidized copper, high residual phosphorus          | 99.90 Cu,<br>0.02 P                             | 32-55          | 10-53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: gas and heater lines; oil burner tubing; plumbing pipe and tubing; condenser, evaporator, heat exchanger, dairy, and distiller tubing; steam and water lines; air, gasoline, and hydraulic lines.  |
| C12500, C12700,<br>C12800, C12900,<br>C13000 Fire-refined tough pitch with silver | 99.88 Cu  | 32-66          | 10-53 | 55                      | 20                                | Fabricating characteristics same as C10100. Uses: same as C11000, Electrolytic tough pitch copper.   |
| C14200<br>Phosphorus deoxidized, arsenical  | 99.68 Cu,<br>0.3 As,<br>0.02 P                  | 32-55          | 10-50 | 45                      | 20                                | Fabricating characteristics same as C10100. Uses: staybolts, heat-exchanger and condenser tubes.   |
| C14300, C14310<br>Cadmium copper, deoxidized                                      | 99.9 Cu,<br>0.1 Cd                              | 32-58          | 11-56 | 42                      | 20                                | Fabricating characteristics same as C10100. Uses: anneal-resistant electrical applications requiring thermal softening and embrittlement resistance, lead frames, contacts, terminals, solder-coated and solder-fabricated parts, furnace-brazed assemblies and welded components, cable wrap.   |
| C14500, C14510,<br>C14520<br>Tellurium bearing                                    | 99.5 Cu,<br>0.50 Te,<br>0.008 P                 | 32-56          | 10-51 | 50                      | 85                                | Fabricating characteristics same as C10100. Uses: Forgings and screw-machine products, and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these; electrical connectors, motor and switch parts, plumbing fittings, soldering coppers, welding torch tips, transistor bases, and furnace-brazed articles.                                    |
| C14700, C14710,<br>C14720<br>Sulfur bearing                                       | 99.6 Cu,<br>0.40 S                              | 32-57          | 10-55 | 52                      | 85                                | Fabricating characteristics same as C10100. Uses: screw-machine products and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these; electrical connectors, motor and switch components, plumbing fittings, cold-headed and machined parts, cold forgings, furnace-brazed articles, screws, soldering coppers, rivets and welding torch tips. |
| C15000<br>Zirconium copper  | 99.8 Cu,<br>0.15 Zr                             | 29-76          | 6-72  | 54                      | 20                                | Fabricating characteristics same as C10100. Uses: switches, high-temperature circuit breakers, commutators, stud bases for power transmitters, rectifiers, soldering welding tips.   |
| C15500  | 99.75 Cu,<br>0.06 P,<br>0.11 Mg,<br>Ag          | 40-80          | 18-72 | 40                      | 20                                | Fabricating characteristics same as C10100. Uses: high-conductivity light-duty springs, electrical contacts, fittings, clamps, connectors, diaphragms, electronic components, resistance-welding electrodes.   |
| C15715  | 99.6 Cu,<br>0.13 Al <sub>2</sub> O <sub>3</sub> | 52-88          | 44-84 | 27                      | 20                                | Excellent cold workability. Fabricated by extrusion, drawing, rolling, heading, swaging, machining, blanking, roll threading. Uses: integrated-circuit lead frames, diode leads; vacuum, microwave, and x-ray tube components; electrical components; brush springs; commutators, electric generator and motor components.   |
| C15720  | 99.5 Cu,<br>0.18 Al <sub>2</sub> O <sub>3</sub> | 64-98          | 54-96 | 25                      | ...                               | Excellent cold workability. Fabricated by extrusion, drawing, rolling, heading, swaging, machining, blanking. Uses: relay and switch springs, lead frames, contact supports, heat sinks, circuit breaker parts, rotor bars, resistance-welding electrodes and wheels, connectors, soldering gun tips.  |

| Name and Number                                    | Nominal Composition (%)                         | Strength (ksi) |        | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications  |
|--|---|----------------|--------|-------------------------|-----------------------------------|---|
|  |   | Tensile        | Yield  |                         |                                   |   |
| C15760   | 98.8 Cu,<br>0.58 Al <sub>2</sub> O <sub>3</sub> | 70-90          | 65-87  | 22                      | ...                               | Excellent cold workability. Fabricated by extrusion and drawing. Uses: resistance-welding electrodes, soldering gun tips, MIG welding contact tips, continuous-casting molds.   |
| C16200, C16210<br>Cadmium copper                   | 99.0 Cu,<br>1.0 Cd                              | 35-100         | 7-69   | 57                      | 20                                | Excellent cold workability; good hot formability. Uses: trolley wires, heating pads, electric-blanket elements, spring contacts, railbands, high-strength transmission lines, connectors, cable wrap, switch-gear components, and waveguide cavities.   |
| C16500   | 98.6 Cu,<br>0.8 Cd,<br>0.6 Sn                   | 40-95          | 14-71  | 53                      | 20                                | Fabricating characteristics same as C16200. Uses: electrical springs and contacts, trolley wire, clips, flat cable, resistance-welding electrodes.  |
| C17000<br>Beryllium copper                         | 98.3 Cu,<br>1.7 Be,<br>0.20 Co                  | 70-190         | 32-170 | 45                      | 20                                | Fabricating characteristics same as C16200. Commonly fabricated by blanking, forming and bending, turning, drilling, tapping. Uses: bellows, Bourdon tubing, diaphragms, fuse clips, fasteners, lock-washers, springs, switch parts, roll pins, valves, welding equipment.  |
| C17200<br>Beryllium copper                         | 98.1 Cu,<br>1.9 Be,<br>0.20 Co                  | 68-212         | 25-195 | 48                      | 20                                | Similar to C17000, particularly for its nonsparking characteristics.  |
| C17300<br>Beryllium copper                         | 98.1 Cu,<br>1.9 Be,<br>0.40 Pb                  | 68-212         | 25-195 | 48                      | 50                                | Combines superior machinability with good fabricating characteristics of C17200.  |
| C17500, C17510<br>Beryllium copper                 | 96.9 Cu,<br>2.5 Co,<br>0.6 Be                   | 45-115         | 25-110 | 28                      | ...                               | Fabricating characteristics same as C16200. Uses: fuse clips, fasteners, springs, switches and relay parts, electrical conductors, welding equipment.   |
| C18200, C18400,<br>C18500<br>Chromium copper       | 99.2 Cu   | 34-86          | 14-77  | 40                      | 20                                | Excellent cold workability, good hot workability. Uses: resistance-welding electrodes, seam-welding wheels, switch gear, electrode holder jaws, cable connectors, current-carrying arms and shafts, circuit-breaker parts, molds, spot-welding tips, flash-welding electrodes, electrical and thermal conductors requiring strength, switch contacts.                 |
| C18700<br>Leaded copper                            | 99.0 Cu,<br>1.0 Pb                              | 32-55          | 10-50  | 45                      | 85                                | Good cold workability; poor hot formability. Uses: connectors, motor and switch parts, screw-machine parts requiring high conductivity.   |
| C18900   | 98.7 Cu,<br>0.8 Sn,<br>0.3 Si,<br>0.20 Mn       | 38-95          | 9-52   | 48                      | 20                                | Fabricating characteristics same as C10100. Uses: welding rod and wire for inert gas tungsten arc and metal arc welding and oxyacetylene welding of copper.   |
| C19000<br>Copper-nickel-phosphorus alloy           | 98.6 Cu,<br>1.1 Ni,<br>0.3 P                    | 38-115         | 20-81  | 50                      | 30                                | Fabricating characteristics same as C10100. Uses: springs, clips, electrical connectors, power tube and electron tube components, high-strength electrical conductors, bolts, nails, screws, cotter pins, and parts requiring some combination of high strength, high electrical or thermal conductivity, high resistance to fatigue and creep, and good workability. |
| C19100<br>Copper-nickel-phosphorus-tellurium alloy | 98.2 Cu,<br>1.1 Ni,<br>0.5 Te,<br>0.2 P         | 36-104         | 10-92  | 27                      | 75                                | Good hot and cold workability. Uses: forgings and screw-machine parts requiring high strength, hardenability, extensive machining, corrosion resistance, copper color, good conductivity, or a combination of these; bolts, bushings, electrical connectors, gears, marine hardware, nuts, pinions, tie rods, turnbuckle barrels, welding torch tips.                 |
| C19200   | 99 Cu,<br>1.0 Fe,<br>0.03 P                     | 37-77          | 11-74  | 40                      | 20                                | Excellent hot and cold workability. Uses: automotive hydraulic brake lines, flexible hose, electrical terminals, fuse clips, gaskets, gift hollow ware, applications requiring resistance to softening and stress corrosion, air-conditioning and heat-exchanger tubing.  |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number   | Nominal Composition (%)                              | Strength (ksi) |       | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications  |
|---|--|----------------|-------|-------------------------|-----------------------------------|---|
|   |  | Tensile        | Yield |                         |                                   |   |
| C19400  | 97.4 Cu,<br>2.4 Fe,<br>0.13 Zn,<br>0.04 P            | 45–76          | 24–73 | 32                      | 20                                | Excellent hot and cold workability. Uses: circuit-breaker components, contact springs, electrical clamps, electrical springs, electrical terminals, flexible hose, fuse clips, gaskets, gift hollow ware, plug contacts, rivets, and welded condenser tubes.              |
| C19500  | 97.0 Cu,<br>1.5 Fe,<br>0.6 Sn,<br>0.10 P,<br>0.80 Co | 80–97          | 65–95 | 15                      | 20                                | Excellent hot and cold workability. Uses: electrical springs, sockets, terminals, connectors, clips, and other current-carrying parts requiring strength.   |
| C21000<br>Gilding, 95%                                    | 95.0 Cu,<br>5.0 Zn                                   | 34–64          | 10–58 | 45                      | 20                                | Excellent cold workability, good hot workability for blanking, coining, drawing, piercing and punching, shearing, spinning, squeezing and swaging, stamping. Uses: coins, medals, bullet jackets, fuse caps, primers, plaques, jewelry base for gold plate.               |
| C22000<br>Commercial bronze,<br>90%                       | 90.0 Cu,<br>10.0 Zn                                  | 37–72          | 10–62 | 50                      | 20                                | Fabricating characteristics same as C21000, plus heading and up-setting, roll threading and knurling, hot forging and pressing. Uses: etching bronze, grillwork, screen cloth, weatherstripping, lipstick cases, compacts, marine hardware, screws, rivets.               |
| C22600<br>Jewelry bronze, 87.5%                           | 87.5 Cu,<br>12.5 Zn                                  | 39–97          | 11–62 | 46                      | 30                                | Fabricating characteristics same as C21000, plus heading and up-setting, roll threading and knurling. Uses: angles, channels, chain, fasteners, costume jewelry, lipstick cases, powder compacts, base for gold plate.  |
| C23000<br>Red brass, 85%                                  | 85.0 Cu,<br>15.0 Zn                                  | 39–105         | 10–63 | 55                      | 30                                | Excellent cold workability; good hot formability. Uses: weather-stripping, conduit, sockets, fasteners, fire extinguishers, condenser and heat-exchanger tubing, plumbing pipe, radiator cores.   |
| C24000<br>Low brass, 80%                                  | 80.0 Cu,<br>20.0 Zn                                  | 42–125         | 12–65 | 55                      | 30                                | Excellent cold workability. Fabricating characteristics same as C23000. Uses: battery caps, bellows, musical instruments, clock dials, pump lines, flexible hose.   |
| C26000, C26100,<br>C26130, C26200<br>Cartridge brass, 70% | 70.0 Cu,<br>30.0 Zn                                  | 44 –<br>130    | 11–65 | 66                      | ...                               | Excellent cold workability. Uses: radiator cores and tanks, flashlight shells, lamp fixtures, fasteners, screws, springs, grillwork, stencils, plumbing accessories, plumbing brass goods, locks, hinges, ammunition components, plumbing accessories, pins, rivets.      |
| C26800, C27000<br>Yellow brass                            | 65.0 Cu,<br>35.0 Zn                                  | 46–128         | 14–62 | 65                      | 30                                | Excellent cold workability. Fabricating characteristics same as C23000. Uses: same as C26000 except not used for ammunition.  |
| C28000<br>Muntz metal, 60%                                | 60.0 Cu,<br>40.0 Zn                                  | 54–74          | 21–55 | 52                      | 40                                | Excellent hot formability and forgeability for blanking, forming and bending, hot forging and pressing, hot heading and upsetting, shearing. Uses: architectural, large nuts and bolts, brazing rod, condenser plates, heat-exchanger and condenser tubing, hot forgings. |
| C31400<br>Leaded commercial<br>bronze                     | 89.0 Cu,<br>1.9 Pb,<br>0.1 Zn                        | 37–60          | 12–55 | 45                      | 80                                | Excellent machinability. Uses: screws, machine parts, pickling crates.  |
| C31600<br>Leaded commercial<br>bronze, nickel-bearing     | 89.0 Cu,<br>1.9 Pb,<br>1.0 Ni,<br>8.1 Zn             | 37–67          | 12–59 | 45                      | 80                                | Good cold workability; poor hot formability. Uses: electrical connectors, fasteners, hardware, nuts, screws, screw-machine parts.   |
| C33000<br>Low-leaded brass tube                           | 66.0 Cu,<br>0.5 Pb,<br>33.5 Zn                       | 47–75          | 15–60 | 60                      | 60                                | Combines good machinability and excellent cold workability. Fabricated by forming and bending, machining, piercing and punching. Uses: pump and power cylinders and liners, ammunition primers, plumbing accessories.   |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number                        | Nominal Composition (%)        | Strength (ksi)     |       | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications   |
|--|--------------------------------|--------------------|-------|-------------------------|-----------------------------------|--|
|  |                                | Tensile            | Yield |                         |                                   |  |
| C33200<br>High-leaded brass tube       | 66.0 Cu,<br>2.0 Pb,<br>32.0 Zn | 47–75              | 15–60 | 50                      | 80                                | Excellent machinability. Fabricated by piercing, punching, and machining. Uses: general-purpose screw-machine parts.   |
| C33500<br>Low-leaded brass             | 63.5 Cu,<br>0.5 Pb,<br>36 Zn   | 46–74              | 14–60 | 65                      | 60                                | Similar to C33200. Commonly fabricated by blanking, drawing, machining, piercing and punching, stamping. Uses: butts, hinges, watch backs.   |
| C34000<br>Medium-leaded brass          | 63.5 Cu,<br>1.0 Pb,<br>35.5 Zn | 47–88              | 15–60 | 60                      | 70                                | Similar to C33200. Fabricated by blanking, heading and upsetting, machining, piercing and punching, roll threading and knurling, stamping. Uses: butts, gears, nuts, rivets, screws, dials, engravings, instrument plates.                                     |
| C34200<br>High-leaded brass            | 63.5 Cu,<br>2.0 Pb,<br>34.5 Zn | 49–85              | 17–62 | 52                      | 90                                | Combines excellent machinability with moderate cold workability. Uses: clock plates and nuts, clock and watch backs, gears, wheels and channel plate.  |
| C35000<br>Medium-leaded brass          | 62.5 Cu,<br>1.1 Pb,<br>36.4 Zn | 45–95              | 13–70 | 66                      | 70                                | Fair cold workability; poor hot formability. Uses: bearing cages, book dies, clock plates, gears, hinges, hose couplings, keys, lock parts, lock tumblers, meter parts, nuts, sink strainers, strike plates, templates, type characters, washers, wear plates. |
| C35300<br>High-leaded brass            | 61.5 Cu,<br>2.8 Pb,<br>36.5 Zn | 49–85              | 17–62 | 52                      | 90                                | Similar to C34200.   |
| C35600<br>Extra-high-leaded brass      | 61.5 Cu,<br>2.5 Pb,<br>36 Zn   | 47–97              | 17–87 | 60                      | 100                               | Excellent machinability. Fabricated by blanking, machining, piercing and punching, stamping. Uses: clock plates and nuts, clock and watch backs, gears, wheels, and channel plate.   |
| C36000<br>Free-cutting brass           | 61.5 Cu,<br>3.1 Pb,<br>35.4 Zn | 49–68              | 18–45 | 53                      | 100                               | Excellent machinability. Fabricated by machining, roll threading, and knurling. Uses: gears, pinions, automatic high-speed screw-machine parts.  |
| C36500 to C36800<br>Leaded Muntz metal | 59.5 Cu,<br>0.5 Pb,<br>40.0 Zn | 54 (As hot rolled) | 20    | 45                      | 60                                | Combines good machinability with excellent hot formability. Uses: condenser-tube plates.   |
| C37000<br>Free-cutting Muntz metal     | 60.0 Cu,<br>1.0 Pb,<br>39.0 Zn | 54–80              | 20–60 | 40                      | 70                                | Fabricating characteristics similar to C36500 to 36800. Uses: automatic screw-machine parts.   |
| C37700<br>Forging brass                | 59.5 Cu,<br>2.0 Pb,<br>38.0 Zn | 52 (As extruded)   | 20    | 45                      | 80                                | Excellent hot workability. Fabricated by heading and upsetting, hot forging and pressing, hot heading and upsetting, machining. Uses: forgings and pressings of all kinds.   |
| C38500<br>Architectural bronze         | 57.0 Cu,<br>3.0 Pb,<br>40.0 Zn | 60 (As extruded)   | 20    | 30                      | 90                                | Excellent machinability and hot workability. Fabricated by hot forging and pressing, forming, bending, and machining. Uses: architectural extrusions, store fronts, thresholds, trim, butts, hinges, lock bodies, and forgings.                                |
| C40500                                 | 95 Cu,<br>1 Sn,<br>4 Zn        | 39–78              | 12–70 | 49                      | 20                                | Excellent cold workability. Fabricated by blanking, forming, and drawing. Uses: meter clips, terminals, fuse clips, contact and relay springs, washers.  |
| C40800                                 | 95 Cu,<br>2 Sn,<br>3 Zn        | 42–79              | 13–75 | 43                      | 20                                | Excellent cold workability. Fabricated by blanking, stamping, and shearing. Uses: electrical connectors.   |
| C41100                                 | 91 Cu,<br>0.5 Sn,<br>8.5 Zn    | 39–106             | 11–72 | 43                      | 20                                | Excellent cold workability, good hot formability. Fabricated by blanking, forming and bending, drawing, piercing and punching, shearing, spinning, and stamping. Uses: bushings, bearing sleeves, thrust washers, flexible metal hose.                         |
| C41300                                 | 90.0 Cu,<br>1.0 Sn,<br>9.0 Zn  | 41–105             | 12–82 | 45                      | 20                                | Excellent cold workability; good hot formability. Uses: plater bar for jewelry products, flat springs for electrical switchgear.   |

|  |   | Tensile        | Yield |                         |                                   |   |
| C41500   | 91 Cu,<br>1.8 Sn,<br>7.2 Zn               | 46–81          | 17–75 | 44                      | 30                                | Excellent cold workability. Fabricated by blanking, drawing, bending, forming, shearing, and stamping. Uses: spring applications for electrical switches.   |
| C42200   | 87.5 Cu,<br>1.1 Sn,<br>11.4 Zn            | 43–88          | 15–75 | 46                      | 30                                | Excellent cold workability; good hot formability. Fabricated by blanking, piercing, forming, and drawing. Uses: sash chains, fuse clips, terminals, spring washers, contact springs, electrical connectors.   |
| C42500   | 88.5 Cu,<br>2.0 Sn,<br>9.5 Zn             | 45–92          | 18–76 | 49                      | 30                                | Excellent cold workability. Fabricated by blanking, piercing, forming, and drawing. Uses: electrical switches, springs, terminals, connectors, fuse clips, pen clips, weather stripping.  |
| C43000   | 87.0 Cu,<br>2.2 Sn,<br>10.8 Zn            | 46–94          | 18–73 | 55                      | 30                                | Excellent cold workability; good hot formability. Fabricated by blanking, coining, drawing, forming, bending, heading, and upsetting. Uses: same as C42500.   |
| C43400   | 85.0 Cu,<br>0.7 Sn,<br>14.3 Zn            | 45–90          | 15–75 | 49                      | 30                                | Excellent cold workability. Fabricated by blanking, drawing, bonding, forming, stamping, and shearing. Uses: electrical switch parts, blades, relay springs, contacts.  |
| C43500   | 81.0 Cu,<br>0.9 Sn,<br>18.1 Zn            | 46–80          | 16–68 | 46                      | 30                                | Excellent cold workability for fabrication by forming and bending. Uses: Bourdon tubing and musical instruments.  |
| C44300, C44400,<br>C44500<br>Inhibited admiralty | 71.0 Cu,<br>28.0 Zn,<br>1.0 Sn            | 48–55          | 18–22 | 65                      | 30                                | Excellent cold workability for forming and bending. Uses: condenser, evaporator and heat-exchanger tubing, condenser tubing plates, distiller tubing, ferrules.   |
| C46400 to C46700<br>Naval brass                  | 60.0 Cu,<br>39.2 Zn,<br>0.8 Sn            | 55–88          | 25–66 | 50                      | 30                                | Excellent hot workability and hot forgeability. Fabricated by blanking, drawing, bending, heading and upsetting, hot forging, pressing. Uses: aircraft turnbuckle barrels, balls, bolts, marine hardware, nuts, propeller shafts, rivets, valve stems, condenser plates, welding rod.                         |
| C48200<br>Naval brass, medium-leaded             | 60.5 Cu,<br>0.7 Pb,<br>0.8 Sn,<br>38.0 Zn | 56–75          | 25–53 | 43                      | 50                                | Good hot workability for hot forging, pressing, and machining operations. Uses: marine hardware, screw-machine products, valve stems.   |
| C48500<br>Leaded naval brass                     | 60.0 Cu,<br>1.8 Pb,<br>37.5 Zn,<br>0.7 Sn | 57–75          | 25–53 | 40                      | 70                                | Combines good hot forgeability and machinability. Fabricated by hot forging and pressing, machining. Uses: marine hardware, screw-machine parts, valve stems.   |
| C50500<br>Phosphor bronze,<br>1.25% E            | 98.7 Cu,<br>1.3 Sn,<br>trace P            | 40–79          | 14–50 | 48                      | 20                                | Excellent cold workability; good hot formability. Fabricated by blanking, bending, heading and upsetting, shearing and swaging. Uses: electrical contacts, flexible hose, pole-line hardware.   |
| C51000<br>Phosphor bronze,<br>5% A               | 94.8 Cu,<br>5.0 Sn,<br>trace P            | 47–140         | 19–80 | 64                      | 20                                | Excellent cold workability. Fabricated by blanking, drawing, bending, heading and upsetting, roll threading and knurling, shearing, stamping. Uses: bellows, Bourdon tubing, clutch discs, cotter pins, diaphragms, fasteners, lock washers, wire brushes, chemical hardware, textile machinery, welding rod. |
| C51100   | 95.6 Cu,<br>4.2 Sn,<br>0.2 P              | 46–103         | 50–80 | 48                      | 20                                | Excellent cold workability. Uses: bridge bearing plates, locator bars, fuse clips, sleeve bushings, springs, switch parts, truss wire, wire brushes, chemical hardware, perforated sheets, textile machinery.   |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number                     | Nominal Composition (%)                    | Strength (ksi)       |         | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications   |
|-------------------------------------|--|----------------------|---------|-------------------------|-----------------------------------|--|
|                                     |  | Tensile              | Yield   |                         |                                   |  |
| C52100<br>Phosphor bronze,<br>8% C  | 92.0 Cu,<br>8.0 Sn,<br>trace P             | 55-140               | 24-80   | 70                      | 20                                | Good cold workability for blanking, drawing, forming and bending, shearing, stamping. Uses: generally for more severe service conditions than C51000.  |
| C52400<br>Phosphor bronze,<br>10% D | 90.0 Cu,<br>10.0 Sn,<br>trace P            | 66-147               | 28      | 70                      | 20                                | Good cold workability for blanking, forming and bending, shearing. Uses: heavy bars and plates for severe compression, bridge and expansion plates and fittings, articles requiring good spring qualities, resilience, fatigue resistance, good wear and corrosion resistance. |
| C54400                              | 88.0 Cu,<br>4.0 Pb,<br>4.0 Zn,<br>4.0 Sn   | 44-75                | 19-63   | 50                      | 80                                | Excellent machinability; good cold workability. Fabricated by blanking, drawing, bending, machining, shearing, stamping. Uses: bearings, bushings, gears, pinions, shafts, thrust washers, valve parts.  |
| C60800                              | 95.0 Cu,<br>5.0 Al                         | 60                   | 27      | 55                      | 20                                | Good cold workability; fair hot formability. Uses: condenser, evaporator and heat-exchanger tubes, distiller tubes, ferrules.  |
| C61000                              | 92.0 Cu,<br>8.0 Al                         | 52-60                | 17-27   | 45                      | 20                                | Good hot and cold workability. Uses: bolts, pump parts, shafts, tie rods, overlay on steel for wearing surfaces.   |
| C61300                              | 90.3 Cu,<br>0.35 Sn,<br>6.8 Al,<br>0.35 Sn | 70-85                | 30-58   | 42                      | 30                                | Good hot and cold formability. Uses: nuts, bolts, corrosion resistant vessels and tanks, structural components, machine parts, condenser tube and piping systems, marine protective sheathing and fasteners, munitions mixing troughs and blending chambers.                   |
| C61400<br>Aluminum bronze, D        | 91.0 Cu,<br>7.0 Al,<br>2.0 Fe              | 76-89                | 33-60   | 45                      | 20                                | Similar to C61300.   |
| C61500                              | 90.0 Cu,<br>8.0 Al,<br>2.0 Ni              | 70-145               | 22-140  | 55                      | 30                                | Good hot and cold workability. Fabricating characteristics similar to C52100. Uses: hardware, decorative metal trim, interior furnishings and other articles requiring high tarnish resistance.  |
| C61800                              | 89.0 Cu,<br>1.0 Fe,<br>10.0 Al             | 80-85                | 39-42.5 | 28                      | 40                                | Fabricated by hot forging and hot pressing. Uses: bushings, bearings, corrosion-resistant applications, welding rods.  |
| C61900                              | 86.5 Cu,<br>4.0 Fe,<br>9.5 Al              | 92-152               | 49-145  | 30                      | ...                               | Excellent hot formability for fabricating by blanking, forming, bending, shearing, and stamping. Uses: springs, contacts, and switch components.   |
| C62300                              | 87.0 Cu,<br>3.0 Fe,<br>10.0 Al             | 75-98                | 35-52   | 35                      | 50                                | Good hot and cold formability. Fabricated by bending, hot forging, hot pressing, forming, and welding. Uses: bearings, bushings, valve guides, gears, valve seats, nuts, bolts, pump rods, worm gears, and cams.   |
| C62400                              | 86.0 Cu,<br>3.0 Fe,<br>11.0 Al             | 90-105               | 40-52   | 18                      | 50                                | Excellent hot formability for fabrication by hot forging and hot bending. Uses: bushings, gears, cams, wear strips, nuts, drift pins, tie rods.  |
| C62500                              | 82.7 Cu,<br>4.3 Fe,<br>13.0 Al             | 100<br>(As extruded) | 55      | 1                       | 20                                | Excellent hot formability for fabrication by hot forging and machining. Uses: guide bushings, wear strips, cams, dies, forming rolls.  |
| C63000                              | 82.0 Cu,<br>3.0 Fe,<br>10.0 Al,<br>5.0 Ni  | 90-118               | 50-75   | 20                      | 30                                | Good hot formability. Fabricated by hot forging and forging. Uses: nuts, bolts, valve seats, plunger tips, marine shafts, valve guides, aircraft parts, pump shafts, structural members.   |
| C63200                              | 82.0 Cu,<br>4.0 Fe,<br>9.0 Al,<br>5.0 Ni   | 90-105               | 45-53   | 25                      | 30                                | Good hot formability. Fabricated by hot forming and welding. Uses: nuts, bolts, structural pump parts, shafting requiring corrosion resistance.  |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number                     | Nominal Composition (%)                              | Strength (ksi) |         | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications   |
|-------------------------------------|--|----------------|---------|-------------------------|-----------------------------------|--|
|                                     |  | Tensile        | Yield   |                         |                                   |  |
| C63600                              | 95.5 Cu,<br>3.5 Al,<br>1.0 Si                        | 60–84          | ...     | 64                      | 40                                | Excellent cold workability; fair hot formability. Fabricated by cold heading. Uses: components for pole-line hardware, cold-headed nuts for wire and cable connectors, bolts and screw products.   |
| C63800                              | 95.0 Cu,<br>2.8 Al,<br>1.8 Si,<br>0.40 Co            | 82–130         | 54–114  | 36                      | ...                               | Excellent cold workability and hot formability. Uses: springs, switch parts, contacts, relay springs, glass sealing, and porcelain enameling.  |
| C64200                              | 91.2 Cu,<br>7.0 Al,<br>1.8 Si                        | 75–102         | 35–68   | 32                      | 60                                | Excellent hot formability. Fabricated by hot forming, forging, machining. Uses: valve stems, gears, marine hardware, pole-line hardware, bolts, nuts, valve bodies, and components.  |
| C65100<br>Low-silicon bronze, B     | 98.5 Cu,<br>1.5 Si                                   | 40–105         | 15–71   | 55                      | 30                                | Excellent hot and cold workability. Fabricated by forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, squeezing and swaging. Uses: hydraulic pressure lines, anchor screws, bolts, cable clamps, cap screws, machine screws, marine hardware, nuts, pole-line hardware, rivets, U-bolts, electrical conduits, heat-exchanger tubing, welding rod. |
| C65500<br>High-silicon bronze, A    | 97.0 Cu,<br>3.0 Si                                   | 56–145         | 21–71   | 63                      | 30                                | Excellent hot and cold workability. Fabricated by blanking, drawing, forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, shearing, squeezing and swaging. Uses: similar to C65100 including propeller shafts.   |
| C66700<br>Manganese brass           | 70.0 Cu,<br>28.8 Zn,<br>1.2 Mn                       | 45.8–100       | 12–92.5 | 60                      | 30                                | Excellent cold formability. Fabricated by blanking, bending, forming, stamping, welding. Uses: brass products resistance welded by spot, seam, and butt welding.   |
| C67400                              | 58.5 Cu,<br>36.5 Zn,<br>1.2 Al,<br>2.8 Mn,<br>1.0 Sn | 70–92          | 34–55   | 28                      | 25                                | Excellent hot formability. Fabricated by hot forging and pressing, machining. Uses: bushings, gears, connecting rods, shafts, wear plates.   |
| C67500<br>Manganese bronze, A       | 58.5 Cu,<br>1.4 Fe,<br>39.0 Zn,<br>1.0 Sn,<br>0.1 Mn | 65–84          | 30–60   | 33                      | 30                                | Excellent hot workability. Fabricated by hot forging and pressing, hot heading and upsetting. Uses: clutch discs, pump rods, shafting, balls, valve stems and bodies.  |
| C68700<br>Aluminum brass, arsenical | 77.5 Cu,<br>20.5 Zn,<br>2.0 Al,<br>trace As          | 60             | 27      | 55                      | 30                                | Excellent cold workability for forming and bending. Uses: condenser, evaporator- and heat-exchanger tubing, condenser tubing plates, distiller tubing, ferrules.   |
| C68800                              | 73.5 Cu,<br>22.7 Zn,<br>3.4 Al,<br>0.40 Co           | 82–129         | 55–114  | 36                      | ...                               | Excellent hot and cold formability. Fabricated by blanking, drawing, forming and bending, shearing and stamping. Uses: springs, switches, contacts, relays, drawn parts.   |
| C69000                              | 73.3 Cu,<br>3.4 Al,<br>0.6 Ni,<br>22.7 Zn            | 82–130         | 52–117  | 35                      | ...                               | Fabricating characteristics same as C68800. Uses: contacts, relays, switches, springs, drawn parts.  |
| C69400<br>Silicon red brass         | 81.5 Cu,<br>14.5 Zn,<br>4.0 Si                       | 80–100         | 40–57   | 25                      | 30                                | Excellent hot formability for fabrication by forging, screw-machine operations. Uses: valve stems where corrosion resistance and high strength are critical.   |
| C70400<br>Copper nickel, 5%         | 92.4 Cu,<br>1.5 Fe,<br>5.5 Ni,<br>0.6 Mn             | 38–77          | 40–76   | 46                      | 20                                | Excellent cold workability; good hot formability. Fabricated by forming, bending, and welding. Uses: condensers, evaporators, heat exchangers, ferrules, salt water piping, lithium bromide absorption tubing, shipboard condenser intake systems.   |

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

| Name and Number                | Nominal Composition (%)                         | Strength (ksi) |        | Elongation in 2 in. (%) | Machinability Rating <sup>a</sup> | Fabricating Characteristics and Typical Applications  |
|--------------------------------|---|----------------|--------|-------------------------|-----------------------------------|---|
|                                |   | Tensile        | Yield  |                         |                                   |   |
| C70600<br>Copper nickel, 10%   | 88.6 Cu,<br>1.4 Fe,<br>10.0 Ni                  | 44–60          | 16–57  | 42                      | 20                                | Good hot and cold workability. Fabricated by forming and bending, welding. Uses: condensers, condenser plates, distiller tubing, evaporator and heat-exchanger tubing, ferrules.  |
| C71000<br>Copper nickel, 20%   | 79.0 Cu,<br>21.0 Ni                             | 49–95          | 13–85  | 40                      | 20                                | Good hot and cold formability. Fabricated by blanking, forming and bending, welding. Uses: communication relays, condensers, condenser plates, electrical springs, evaporator and heat-exchanger tubes, ferrules, resistors.  |
| C71500<br>Copper nickel, 30%   | 69.5 Cu,<br>30.0 Ni,<br>0.5 Fe                  | 54–75          | 20–70  | 45                      | 20                                | Similar to C70600.  |

**Copper-Silicon and Copper-Beryllium Alloys**

**Everdur.**—This copper-silicon alloy is available in five slightly different nominal compositions for applications that require high strength, good fabricating and fusing qualities, immunity to rust, free-machining and a corrosion resistance equivalent to copper. The following table gives the nominal compositions and tensile strengths, yield strengths, and per cent elongations for various tempers and forms.

**Table 4. Nominal Composition and Properties of Everdur**

| Desig. No. | Nominal Composition |      |      |      |      | Temper <sup>a</sup> | Strength      |             | Elongation (%)       |
|------------|---------------------|------|------|------|------|---------------------|---------------|-------------|----------------------|
|            | Cu                  | Si   | Mn   | Pb   | Al   |                     | Tensile (ksi) | Yield (ksi) |                      |
| 655        | 95.80               | 3.10 | 1.10 | ...  | ...  | A                   | 52            | 15          | 35 <sup>b</sup>      |

|            |                     |      |      |      |      | A                   | 75 to 90      | 37.5 to 45  | 12 to 9 <sup>b</sup> |

<sup>a</sup> Symbols used are: HRA for hot-rolled and annealed tank plates; CRA for cold-rolled sheets and strips; CRHH for cold-rolled half hard strips; abd CRH for cold-rolled hard strips. For round, square, hexagonal, and octagonal rods: A for annealed; H for hard; and XHB for extra-hard bolt temper (in coils for cold-heading). For pipe and tube: AP for annealed; and HP for hard. For castings: AC for as cast.

<sup>b</sup> Per cent elongation in 4 times the diameter or thickness of the specimen. All other values are per cent elongation in 2 inches.

Designation numbers are those of the American Brass Co.

The values given for the tensile strength, yield strength, and elongation are all minimum values. Where ranges are shown, the first values given are for the largest diameter or largest size specimens. Yield strength values were determined at 0.50 per cent elongation under load.

**Copper-Beryllium Alloys.**—Alloys of copper and beryllium present health hazards. Particles produced by machining may be absorbed into the body through the skin, the mouth, the nose, or an open wound, resulting in a condition requiring immediate medical attention. Working of these alloys requires protective clothing or other shielding in a monitored environment. Copper-beryllium alloys involved in a fire give off profuse toxic fumes that must not be inhaled.

These alloys contain copper, beryllium, cobalt, and silver, and fall into two groups. One group whose beryllium content is greater than one per cent is characterized by its high strength and hardness and the other, whose beryllium content is less than one per cent, by its high electrical and thermal conductivity. The alloys have many applications in the electrical and aircraft industries or wherever strength, corrosion resistance, conductivity, non-magnetic and nonsparking properties are essential. Beryllium copper is obtainable in the form of strips, rods and bars, wire, platers, bars, billets, tubes, and casting ingots.

*Composition and Properties:* Table 5 lists some of the more common wrought alloys and gives some of their mechanical properties.

**Table 5. Wrought Copper-Beryllium Properties**

| Alloy <sup>a</sup> | Form                               | Temper <sup>b</sup> | Heat Treatment                     | Tensile Strength (ksi) | Yield Strength 0.2% Offset (ksi) | Elongation in 2 in. (%) |
|--------------------|------------------------------------|---------------------|------------------------------------|------------------------|----------------------------------|-------------------------|
| 25                 | Rod, Bar, and Plate                | A                   | ...                                | 60-85                  | 20-30                            | 35-60                   |
|                    |                                    | ½ H or H            | ...                                | 85-130                 | 75-105                           | 10-20                   |
|                    |                                    | AT                  | 3 hr at 600°F or mill heat treated | 165-190                | 145-175                          | 3-10                    |
|                    |                                    | ½ HT or HT          | 2 hr at 600°F or mill heat treated | 175-215                | 150-200                          | 2-5                     |
|                    | Wire                               | A                   | ...                                | 58-78                  | 20-35                            | 35-55                   |
|                    |                                    | ¼ H                 | ...                                | 90-115                 | 70-95                            | 10-35                   |
|                    |                                    | ½ H                 | ...                                | 110-135                | 90-110                           | 5-10                    |
|                    |                                    | ¾ H                 | ...                                | 130-155                | 110-135                          | 2-8                     |
|                    |                                    | AT                  | 3 hr at 600°F                      | 165-190                | 145-175                          | 3-8                     |
|                    |                                    | ¼ HT                | 2 hr at 600°F                      | 175-205                | 160-190                          | 2-5                     |
|                    |                                    | ½ HT                | 2 hr at 600°F                      | 190-215                | 175-200                          | 1-3                     |
|                    |                                    | ¾ HT                | 2 hr at 600°F                      | 195-220                | 180-205                          | 1-3                     |
|                    |                                    | XHT                 | Mill heat treated                  | 115-165                | 95-145                           | 2-8                     |
|                    |                                    | 165                 | Rod, Bar, and Plate                | A                      | ...                              | 60-85                   |
| ½ H or H           | ...                                |                     |                                    | 85-130                 | 75-105                           | 10-20                   |
| AT                 | 3 hr at 650°F or mill heat treated |                     |                                    | 150-180                | 125-155                          | 4-10                    |
| ½ HT or HT         | 2 hr at 650°F or mill heat treated |                     |                                    | 165-200                | 135-165                          | 2-5                     |
| 10                 | Rod, Bar, and Plate                | A                   | ...                                | 35-55                  | 20-30                            | 20-35                   |
|                    |                                    | ½ H or H            | ...                                | 65-80                  | 55-75                            | 10-15                   |
|                    |                                    | AT                  | 3 hr at 900°F or mill heat treated | 100-120                | 80-100                           | 10-25                   |
|                    |                                    | ½ HT or HT          | 2 hr at 900°F or mill heat treated | 110-130                | 100-120                          | 8-20                    |
| 50                 | Rod, Bar, and Plate                | A                   | ...                                | 35-55                  | 20-30                            | 20-35                   |
|                    |                                    | ½ H or H            | ...                                | 65-80                  | 55-75                            | 10-15                   |
|                    |                                    | AT                  | 3 hr at 900°F or mill heat treated | 100-120                | 80-100                           | 10-25                   |
|                    |                                    | ½ HT or HT          | 2 hr at 900°F or mill heat treated | 110-130                | 100-120                          | 8-20                    |
| 35                 | Rod, Bar, and Plate                | A                   | ...                                | 35-55                  | 20-30                            | 20-35                   |
|                    |                                    | ½ H or H            | ...                                | 65-80                  | 55-75                            | 10-15                   |
|                    |                                    | AT                  | 3 hr at 900°F or mill heat treated | 100-120                | 80-100                           | 10-25                   |
|                    |                                    | ½ HT or HT          | 2 hr at 900°F or mill heat treated | 110-130                | 100-120                          | 8-20                    |

<sup>a</sup> Composition (in per cent) of alloys is as follows: alloy 25: 1.80-2.05 Be, 0.20-0.35 Co, balance Cu; alloy 165: 1.6-1.8 Be, 0.20-0.35 Co, balance Cu; alloy 10: 0.4-0.7 Be, 2.35-2.70 Co, balance Cu; alloy 50, 0.25-0.50 Be, 1.4-1.7 Co, 0.9-1.1 Ag, balance Cu; alloy 35, 0.25-0.50 Be, 1.4-1.6 Ni, balance Cu.

<sup>b</sup> Temper symbol designations: A, solution annealed; H, hard; HT, heat-treated from hard; At, heat-treated from solution annealed.

**Aluminum and Aluminum Alloys**

Pure aluminum is a silver-white metal characterized by a slightly bluish cast. It has a specific gravity of 2.70, resists the corrosive effects of many chemicals, and has a malleability approaching that of gold. When alloyed with other metals, numerous properties are obtained that make these alloys useful over a wide range of applications.

Aluminum alloys are light in weight compared with steel, brass, nickel, or copper; can be fabricated by all common processes; are available in a wide range of sizes, shapes, and forms; resist corrosion; readily accept a wide range of surface finishes; have good electrical and thermal conductivities; and are highly reflective to both heat and light.

**Characteristics of Aluminum and Aluminum Alloys.**—Aluminum and its alloys lose part of their strength at elevated temperatures, although some alloys retain good strength at temperatures from 400 to 500 degrees F. At subzero temperatures, however, their strength increases without loss of ductility so that aluminum is a particularly useful metal for low-temperature applications.

When aluminum surfaces are exposed to the atmosphere, a thin invisible oxide skin forms immediately that protects the metal from further oxidation. This self-protecting characteristic gives aluminum its high resistance to corrosion. Unless exposed to some substance or condition that destroys this protective oxide coating, the metal remains protected against corrosion. Aluminum is highly resistant to weathering, even in industrial atmospheres. It is also corrosion resistant to many acids. Alkalis are among the few substances that attack the oxide skin and therefore are corrosive to aluminum. Although the metal can safely be used in the presence of certain mild alkalis with the aid of inhibitors, in general, direct contact with alkaline substances should be avoided. Direct contact with certain other metals should be avoided in the presence of an electrolyte; otherwise, galvanic corrosion of the aluminum may take place in the contact area. Where other metals must be fastened to aluminum, the use of a bituminous paint coating or insulating tape is recommended.

Aluminum is one of the two common metals having an electrical conductivity high enough for use as an electric conductor. The conductivity of electric-conductor (EC) grade is about 62 per cent that of the International Annealed Copper Standard. Because aluminum has less than one-third the specific gravity of copper, however, a pound of aluminum will go almost twice as far as a pound of copper when used as a conductor. Alloying lowers the conductivity somewhat so that wherever possible the EC grade is used in electric conductor applications. However, aluminum takes a set, which often results in loosening of screwed connectors, leading to arcing and fires. Special clamping designs are therefore required when aluminum is used for electrical wiring, especially in buildings.

Aluminum has nonsparking and nonmagnetic characteristics that make the metal useful for electrical shielding purposes such as in bus bar housings or enclosures for other electrical equipment and for use around inflammable or explosive substances.

Aluminum can be cast by any method known. It can be rolled to any desired thickness down to foil thinner than paper and in sheet form can be stamped, drawn, spun, or roll-formed. The metal also may be hammered or forged. Aluminum wire, drawn from rolled rod, may be stranded into cable of any desired size and type. The metal may be extruded into a variety of shapes. It may be turned, milled, bored, or otherwise machined in equipment often operating at their maximum speeds. Aluminum rod and bar may readily be employed in the high-speed manufacture of parts made on automatic screw-machine.

Almost any method of joining is applicable to aluminum—riveting, welding, or brazing. A wide variety of mechanical aluminum fasteners simplifies the assembly of many products. Resin bonding of aluminum parts has been successfully employed, particularly in aircraft components.

For the majority of applications, aluminum needs no protective coating. Mechanical finishes such as polishing, sandblasting, or wire brushing meet the majority of needs. When

additional protection is desired, chemical, electrochemical, and paint finishes are all used. Vitreous enamels have been developed for aluminum, and the metal may also be electroplated.

**Temper Designations for Aluminum Alloys.**—The temper designation system adopted by the Aluminum Association and used in industry pertains to all forms of wrought and cast aluminum and aluminum alloys except ingot. It is based on the sequences of basic treatments used to produce the various tempers. The temper designation follows the alloy designation, being separated by a dash.

Basic temper designations consist of letters. Subdivisions of the basic tempers, where required, are indicated by one or more digits following the letter. These digits designate specific sequences of basic treatments, but only operations recognized as significantly influencing the characteristics of the product are indicated. Should some other variation of the same sequence of basic operations be applied to the same alloy, resulting in different characteristics, then additional digits are added.

The basic temper designations and subdivisions are as follows:

–*F*, as fabricated: Applies to products that acquire some temper from shaping processes not having special control over the amount of strain-hardening or thermal treatment. For wrought products, there are no mechanical property limits.

–*O*, annealed, recrystallized (*wrought products only*): Applies to the softest temper of wrought products.

–*H*, strain-hardened (*wrought products only*): Applies to products that have their strength increased by strain-hardening with or without supplementary thermal treatments to produce partial softening.

The –*H* is always followed by two or more digits. The first digit indicates the specific combination of basic operations, as follows:

–*H1*, strain-hardened only: Applies to products that are strain-hardened to obtain the desired mechanical properties without supplementary thermal treatment. The number following this designation indicates the degree of strain-hardening.

–*H2*, strain-hardened and then partially annealed: Applies to products that are strain-hardened more than the desired final amount and then reduced in strength to the desired level by partial annealing. For alloys that age-soften at room temperature, the –*H2* tempers have approximately the same ultimate strength as the corresponding –*H3* tempers. For other alloys, the –*H2* tempers have approximately the same ultimate strengths as the corresponding –*H1* tempers and slightly higher elongations. The number following this designation indicates the degree of strain-hardening remaining after the product has been partially annealed.

–*H3*, strain-hardened and then stabilized: Applies to products which are strain-hardened and then stabilized by a low-temperature heating to slightly lower their strength and increase ductility. This designation applies only to the magnesium-containing alloys that, unless stabilized, gradually age-soften at room temperature. The number following this designation indicates the degree of strain-hardening remaining after the product has been strain-hardened a specific amount and then stabilized.

The second digit following the designations –*H1*, –*H2*, and –*H3* indicates the final degree of strain-hardening. Numeral 8 has been assigned to indicate tempers having a final degree of strain-hardening equivalent to that resulting from approximately 75 per cent reduction of area. Tempers between –*O* (annealed) and 8 (full hard) are designated by numerals 1 through 7. Material having an ultimate strength about midway between that of the –*O* temper and that of the 8 temper is designated by the numeral 4 (half hard); between –*O* and 4 by the numeral 2 (quarter hard); and between 4 and 8 by the numeral 6 (three-quarter hard). (*Note:* For two-digit –*H* tempers whose second figure is odd, the standard limits for ultimate strength are exactly midway between those for the adjacent two-digit –*H* tempers whose second figures are even.) Numeral 9 designates extra-hard tempers.

The third digit, when used, indicates a variation of a two-digit -H temper, and is used when the degree of control of temper or the mechanical properties are different from but close to those for the two-digit -H temper designation to which it is added. (*Note:* The minimum ultimate strength of a three-digit -H temper is at least as close to that of the corresponding two-digit -H temper as it is to the adjacent two-digit -H tempers.) Numerals 1 through 9 may be arbitrarily assigned and registered with the Aluminum Association for an alloy and product to indicate a specific degree of control of temper or specific mechanical property limits. Zero has been assigned to indicate degrees of control of temper or mechanical property limits negotiated between the manufacturer and purchaser that are not used widely enough to justify registration with the Aluminum Association.

The following three-digit -H temper designations have been assigned for wrought products in all alloys:

-H111: Applies to products that are strain-hardened less than the amount required for a controlled H11 temper.

-H112: Applies to products that acquire some temper from shaping processes not having special control over the amount of strain-hardening or thermal treatment, but for which there are mechanical property limits, or mechanical property testing is required.

The following three-digit H temper designations have been assigned for wrought products in alloys containing more than a normal 4 per cent magnesium.

-H311: Applies to products that are strain-hardened less than the amount required for a controlled H31 temper.

-H321: Applies to products that are strain-hardened less than the amount required for a controlled H32 temper.

-H323: Applies to products that are specially fabricated to have acceptable resistance to stress-corrosion cracking.

-H343: Applies to products that are specially fabricated to have acceptable resistance to stress-corrosion cracking.

The following three-digit -H temper designations have been assigned for

| Patterned or Embossed Sheet | Fabricated Form                       |
|-----------------------------|---------------------------------------|
| -H114                       | -O temper                             |
| -H124, -H224, -H324         | -H11, -H21, -H31 temper, respectively |
| -H134, -H234, -H334         | -H12, -H22, -H32 temper, respectively |
| -H144, -H244, -H344         | -H13, -H23, -H33 temper, respectively |
| -H154, -H254, -H354         | -H14, -H24, -H34 temper, respectively |

-W, *solution heat-treated*: An unstable temper applicable only to alloys that spontaneously age at room temperature after solution heat treatment. This designation is specific only when the period of natural aging is indicated.

-T, *thermally treated to produce stable tempers other than -F, -O, or -H*: Applies to products that are thermally treated, with or without supplementary strain-hardening, to produce stable tempers. The -T is always followed by one or more digits. Numerals 2 through 10 have been assigned to indicate specific sequences of basic treatments, as follows:

-T1, *naturally aged to a substantially stable condition*: Applies to products for which the rate of cooling from an elevated temperature-shaping process, such as casting or extrusion, is such that their strength is increased by room-temperature aging.

–T2, *annealed (cast products only)*: Designates a type of annealing treatment used to improve ductility and increase dimensional stability of castings.

–T3, *solution heat-treated and then cold-worked*: Applies to products that are cold-worked to improve strength, or in which the effect of cold work in flattening or straightening is recognized in applicable specifications.

–T4, *solution heat-treated and naturally aged to a substantially stable condition*: Applies to products that are not cold-worked after solution heat treatment, or in which the effect of cold work in flattening or straightening may not be recognized in applicable specifications.

–T5, *artificially aged only*: Applies to products that are artificially aged after an elevated-temperature rapid-cool fabrication process, such as casting or extrusion, to improve mechanical properties or dimensional stability, or both.

–T6, *solution heat-treated and then artificially aged*: Applies to products that are not cold-worked after solution heat-treatment, or in which the effect of cold work in flattening or straightening may not be recognized in applicable specifications.

–T7, *solution heat-treated and then stabilized*: Applies to products that are stabilized to carry them beyond the point of maximum hardness, providing control of growth or residual stress or both.

–T8, *solution heat-treated, cold-worked, and then artificially aged*: Applies to products that are cold-worked to improve strength, or in which the effect of cold work in flattening or straightening is recognized in applicable specifications.

–T9, *solution heat-treated, artificially aged, and then cold-worked*: Applies to products that are cold-worked to improve strength.

–T10, *artificially aged and then cold-worked*: Applies to products that are artificially aged after an elevated-temperature rapid-cool fabrication process, such as casting or extrusion, and then cold-worked to improve strength.

Additional digits may be added to designations –T1 through –T10 to indicate a variation in treatment that significantly alters the characteristics of the product. These may be arbitrarily assigned and registered with The Aluminum Association for an alloy and product to indicate a specific treatment or specific mechanical property limits.

These additional digits have been assigned for wrought products in all alloys:

–T\_\_51, *stress-relieved by stretching*: Applies to products that are stress-relieved by stretching the following amounts after solution heat-treatment:

|                     |                                 |
|---------------------|---------------------------------|
| Plate               | 1½ to 3 per cent permanent set  |
| Rod, Bar and Shapes | 1 to 3 per cent permanent set   |
| Drawn tube          | 0.5 to 3 per cent permanent set |

Applies directly to plate and rolled or cold-finished rod and bar.

These products receive no further straightening after stretching.

Applies to extruded rod and bar shapes and tube when designated as follows:

–T\_\_510 : Products that receive no further straightening after stretching.

–T\_\_511: Products that receive minor straightening after stretching to comply with standard tolerances.

–T\_\_52, *stress-relieved by compressing*: Applies to products that are stress-relieved by compressing after solution heat-treatment, to produce a nominal permanent set of 2½ per cent.

–T\_\_54, *stress-relieved by combined stretching and compressing*: Applies to die forgings that are stress relieved by restriking cold in the finish die.

The following two-digit –T temper designations have been assigned for wrought products in all alloys:

–T42: Applies to products solution heat-treated and naturally aged that attain mechanical properties different from those of the –T4 temper.

–T62: Applies to products solution heat-treated and artificially aged that attain mechanical properties different from those of the –T6 temper.

**Aluminum Alloy Designation Systems.**—Aluminum casting alloys are listed in many specifications of various standardizing agencies. The numbering systems used by each differ and are not always correlatable. Casting alloys are available from producers who use a commercial numbering system and this numbering system is the one used in the tables of aluminum casting alloys given in this section.

Table 6a lists the nominal composition of commonly used aluminum casting alloys, and Tables 6b and 6c list the typical tensile properties of separately cast bars.

**Table 6a. Nominal Compositions (in per cent) of Common Aluminum Casting Alloys (AA/ANSI)**

| Alloy  | Producer <sup>a</sup> | Si        | Fe               | Cu        | Mn                | Mg        | Cr        | Ni      | Zn      | Ti        | Others            |       |
|--------|-----------------------|-----------|------------------|-----------|-------------------|-----------|-----------|---------|---------|-----------|-------------------|-------|
|        |                       |           |                  |           |                   |           |           |         |         |           | Each              | Total |

<sup>a</sup> S = sand cast; P = permanent mold cast. The sum of those "Others" metallic elements 0.010 per cent or more each, expressed to the second decimal before determining the sum. Source: *Standards for Aluminum Sand and Permanent Mold Castings*, courtesy of the Aluminum Association.

<sup>b</sup> Also contains 0.40–1.0 per cent silver.

<sup>c</sup> Also contains 0.05 max. per cent tin.

<sup>d</sup> If iron exceeds 0.45 per cent, manganese content should not be less than one-half the iron content.

<sup>e</sup> Also contains 0.04–0.07 per cent beryllium.

<sup>f</sup> Also contains 5.5–7.0 per cent tin.

**Table 6b. Mechanical Property Limits for Separately Cast Test Bars of Commonly Used Aluminum Sand Casting Alloys**

| Alloy  | Temper <sup>a</sup> | Minimum Properties     |       |                            | Typical Brinell Hardness (500 kgf load, 10-mm ball) |

Source: Standards for Aluminum Sand and Permanent Mold Castings, courtesy of the Aluminum Association.

<sup>a</sup>F indicates "as cast" condition.

<sup>b</sup>Mechanical properties for these alloys depend on the casting process. For further information consult the individual foundries.

<sup>c</sup>The T4 temper of Alloy 520.0 is unstable; significant room temperature aging occurs within life expectancy of most castings. Elongation may decrease by as much as 80 percent.

**Table 6c. Mechanical Property Limits for Separately Cast Test Bars of Commonly Used Aluminum Permanent Mold Casting Alloys**

| Alloy  | Temper <sup>a</sup> | Minimum Properties     |       |                            | Typical Brinell Hardness (500 kgf load, 10-mm ball) |
|--------|---------------------|------------------------|-------|----------------------------|---|
|        |                     | Tensile Strength (ksi) |       | Elongation In 2 inches (%) |   |
|        |                     | Ultimate               | Yield |                            |   |

<sup>a</sup>F indicates "as cast" condition.

A system of four-digit numerical designations for wrought aluminum and wrought aluminum alloys was adopted by the Aluminum Association in 1954. This system is used by the commercial producers and is similar to the one used by the SAE; the difference being the addition of two prefix letters.

The first digit of the designation identifies the alloy type: 1) indicating an aluminum of 99.00 per cent or greater purity; 2) copper; 3) manganese; 4) silicon; 5) magnesium; 6) magnesium and silicon; 7) zinc; 8) some element other than those aforementioned; and 9) unused (not assigned at present).

If the second digit in the designation is zero, it indicates that there is no special control on individual impurities; integers 1 through 9 indicate special control on one or more individual impurities.

In the 1000 series group for aluminum of 99.00 per cent or greater purity, the last two of the four digits indicate to the nearest hundredth the amount of aluminum above 99.00 per cent. Thus designation 1030 indicates 99.30 per cent minimum aluminum. In the 2000 to 8000 series groups the last two of the four digits have no significance but are used to identify different alloys in the group. At the time of adoption of this designation system most of the existing commercial designation numbers were used for these last two digits, as for example, 14S became 2014, 3S became 3003, and 75S became 7075. When new alloys are developed and are commercially used these last two digits are assigned consecutively beginning with -01, skipping any numbers previously assigned at the time of initial adoption.

Experimental alloys are also designated in accordance with this system but they are indicated by the prefix X. The prefix is dropped upon standardization.

Table 7a shows the product forms and nominal compositions of common wrought aluminum alloys, and Table 7b lists typical mechanical properties of wrought aluminum alloys.

**Table 7a. Nominal Compositions of Common Wrought Aluminum Alloys**

<sup>a</sup> Based on 500,000,000 cycles of completely reversed stress using the R. R. Moore type of machine and specimen.

<sup>b</sup> 1350-O wire should have an elongation of approximately 23 per cent in 10 inches.

<sup>c</sup> 1350-H19 wire should have an elongation of approximately 1.5 per cent in 10 inches.

<sup>d</sup> Tempers T361 and T861 were formerly designated T36 and T86, respectively.

<sup>e</sup> Based on  $10^7$  cycles using flexural type testing of sheet specimens.

<sup>f</sup> T7451, although not previously registered, has appeared in the literature and in some specifications as T73651.

The data given in this table are intended only as a basis for comparing alloys and tempers and should not be specified as engineering requirements or used for design purposes. The indicated typical mechanical properties for all except O temper material are higher than the specified minimum properties. For O temper products, typical ultimate and yield values are slightly lower than specified (maximum) values.

**Heat-treatability of Wrought Aluminum Alloys.**—In high-purity form, aluminum is soft and ductile. Most commercial uses, however, require greater strength than pure aluminum affords. This extra strength is achieved in aluminum first by the addition of other elements to produce various alloys, which singly or in combination impart strength to the metal. Further strengthening is possible by means that classify the alloys roughly into two categories, non-heat-treatable and heat-treatable.

*Non-heat-treatable alloys:* The initial strength of alloys in this group depends upon the hardening effect of elements such as manganese, silicon, iron and magnesium, singly or in

various combinations. The non-heat-treatable alloys are usually designated, therefore, in the 1000, 3000, 4000, or 5000 series. These alloys are work-hardenable, so further strengthening is made possible by various degrees of cold working, denoted by the "H" series of tempers. Alloys containing appreciable amounts of magnesium when supplied in strain-hardened tempers are usually given a final elevated-temperature treatment called *stabilizing* for property stability.

*Heat-treatable alloys:* The initial strength of alloys in this group is enhanced by the addition of alloying elements such as copper, magnesium, zinc, and silicon. These elements singly or in various combinations show increasing solid solubility in aluminum with increasing temperature, so it is possible to subject them to thermal treatments that will impart pronounced strengthening.

The first step, called *heat-treatment* or *solution heat-treatment*, is an elevated-temperature process designed to put the soluble element in solid solution. This step is followed by rapid quenching, usually in water, which momentarily "freezes" the structure and for a short time renders the alloy very workable. Some fabricators retain this more workable structure by storing the alloys at below freezing temperatures until they can be formed. At room or elevated temperatures the alloys are not stable after quenching, however, and precipitation of the constituents from the supersaturated solution begins. After a period of several days at room temperature, termed *aging* or *room-temperature precipitation*, the alloy is considerably stronger. Many alloys approach a stable condition at room temperature, but some alloys, particularly those containing magnesium and silicon or magnesium and zinc, continue to age-harden for long periods of time at room temperature.

Heating for a controlled time at slightly elevated temperatures provides even further strengthening and properties are stabilized. This process is called *artificial aging* or *precipitation hardening*. By application of the proper combination of solution heat-treatment, quenching, cold working and artificial aging, the highest strengths are obtained.

**Clad Aluminum Alloys.**—The heat-treatable alloys in which copper or zinc are major alloying constituents are less resistant to corrosive attack than the majority of non-heat-treatable alloys. To increase the corrosion resistance of these alloys in sheet and plate form they are often clad with high-purity aluminum, a low magnesium-silicon alloy, or an alloy containing 1 per cent zinc. The cladding, usually from 2½ to 5 per cent of the total thickness on each side, not only protects the composite due to its own inherently excellent corrosion resistance but also exerts a galvanic effect that further protects the core material.

Special composites may be obtained such as clad non-heat-treatable alloys for extra corrosion protection, for brazing purposes, or for special surface finishes. Some alloys in wire and tubular form are clad for similar reasons and on an experimental basis extrusions also have been clad.

**Aluminum Alloys, Wrought, Sheet.**—*Physical Properties:* In the form of sheets, the tensile strength varies from 35,000 for soft temper to 62,000 pounds per square inch for heat-treated sheets, and the elongation in 2 inches from 12 to 18 per cent. The yield strength of a heat-treated sheet is about 40,000 pounds per square inch minimum.

**Characteristics of Principal Aluminum Alloy Series Groups.**—*1000 series:* These alloys are characterized by high corrosion resistance, high thermal and electrical conductivity, low mechanical properties and good workability. Moderate increases in strength may be obtained by strain-hardening. Iron and silicon are the major impurities.

*2000 series:* Copper is the principal alloying element in this group. These alloys require solution heat-treatment to obtain optimum properties; in the heat-treated condition mechanical properties are similar to, and sometimes exceed, those of mild steel. In some instances artificial aging is employed to further increase the mechanical properties. This treatment materially increases yield strength, with attendant loss in elongation; its effect on tensile (ultimate) strength is not as great. The alloys in the 2000 series do not have as good corrosion resistance as most other aluminum alloys and under certain conditions they

may be subject to intergranular corrosion. Therefore, these alloys in the form of sheet are usually clad with a high-purity alloy or a magnesium-silicon alloy of the 6000 series which provides galvanic protection to the core material and thus greatly increases resistance to corrosion. Alloy 2024 is perhaps the best known and most widely used aircraft alloy.

*3000 series:* Manganese is the major alloying element of alloys in this group, which are generally non-heat-treatable. Because only a limited percentage of manganese, up to about 1.5 per cent, can be effectively added to aluminum, it is used as a major element in only a few instances. One of these, however, is the popular 3003, used for moderate-strength applications requiring good workability.

*4000 series:* The major alloying element of this group is silicon, which can be added in sufficient quantities to cause substantial lowering of the melting point without producing brittleness in the resulting alloys. For these reasons aluminum-silicon alloys are used in welding wire and as brazing alloys where a lower melting point than that of the parent metal is required. Most alloys in this series are non-heat-treatable, but when used in welding heat-treatable alloys they will pick up some of the alloying constituents of the latter and so respond to heat-treatment to a limited extent. The alloys containing appreciable amounts of silicon become dark gray when anodic oxide finishes are applied, and hence are in demand for architectural applications.

*5000 series:* Magnesium is one of the most effective and widely used alloying elements for aluminum. When it is used as the major alloying element or with manganese, the result is a moderate to high strength non-heat-treatable alloy. Magnesium is considerably more effective than manganese as a hardener, about 0.8 per cent magnesium being equal to 1.25 per cent manganese, and it can be added in considerably higher quantities. Alloys in this series possess good welding characteristics and good resistance to corrosion in marine atmospheres. However, certain limitations should be placed on the amount of cold work and the safe operating temperatures permissible for the higher magnesium content alloys (over about 3½ per cent for operating temperatures over about 150 deg. F) to avoid susceptibility to stress corrosion.

*6000 series:* Alloys in this group contain silicon and magnesium in approximate proportions to form magnesium silicide, thus making them capable of being heat-treated. The major alloy in this series is 6061, one of the most versatile of the heat-treatable alloys. Though less strong than most of the 2000 or 7000 alloys, the magnesium-silicon (or magnesium-silicide) alloys possess good formability and corrosion resistance, with medium strength. Alloys in this heat-treatable group may be formed in the -T4 temper (solution heat-treated but not artificially aged) and then reach full -T6 properties by artificial aging.

*7000 series:* Zinc is the major alloying element in this group, and when coupled with a smaller percentage of magnesium, results in heat-treatable alloys of very high strength. Other elements such as copper and chromium are usually added in small quantities. A notable member of this group is 7075, which is among the highest strength aluminum alloys available and is used in air-frame structures and for highly stressed parts.

**Type Metal.**—Antimony gives to metals the property of expansion on solidification, and hence, is used in type metal for casting type for the printing trades to insure completely filling the molds. Type metals are generally made with from 5 to 25 per cent of antimony, and with lead, tin and sometimes a small percentage of copper as the other alloying metals.

The compositions of a number of type metal alloys are as follows (figures given are per-centages): lead 77.5, tin 6.5, antimony 16; lead 70, tin, 10, antimony 18, copper, 2; lead 63.2, tin 12, antimony 24, copper 0.8; lead 60.5, tin 14.5, antimony 24–25, copper 0.75; lead 60, tin 35, antimony 5; and lead 55.5, tin 40, antimony 4.5.

A high grade of type metal is composed of the following percentages: lead 50; tin 25; and antimony 25.

### Magnesium Alloys

**Magnesium Alloys.**—Magnesium is the lightest of all structural metals. Silver-white in color, pure magnesium is relatively soft, so is rarely used for structural purposes in the pure state. Principal metallurgical uses for pure magnesium are as an alloying element for aluminum and other metals; as a reducing agent in the extraction of such metals as titanium, zirconium, hafnium, and uranium; as a nodularizing agent in the manufacture of ductile iron; and as a sulfur removal agent in steel manufacture. Magnesium alloys are made by alloying up to about 10 per cent of other metals and have low density and an excellent combination of mechanical properties, as shown in [Table 8a](#), resulting in high strength-to-weight ratios.

Magnesium alloys are the easiest of all the structural metals to machine, and these alloys have very high weld efficiencies. Magnesium is readily processed by all the standard casting and fabrication techniques used in metalworking, especially by pressure die casting. Because the metal work hardens rapidly, cold forming is limited to mild deformation, but magnesium alloys have excellent working characteristics at temperatures between 300 and 500 degrees F.

These alloys have relatively low elastic moduli, so they will absorb energy with good resistance to dents and high damping capacities. Fatigue strength also is good, particularly in the low-stress, high-cycle range. The alloys can be precipitation hardened, so mechanical properties can be improved by solution heat treatment and aging. Corrosion resistance was greatly improved recently, when methods were found to limit heavy metal impurities to "parts per million."

**Applications of Magnesium Alloys.**—Magnesium alloys are used in a wide variety of structural applications including industrial, materials handling, automotive, consumer-durable, and aerospace equipment. In industrial machinery, the alloys are used for parts that operate at high speeds, which must have light weight to allow rapid acceleration and minimize inertial forces. Materials handling equipment applications include hand trucks, dockboards, grain shovels, and gravity conveyors. Automotive applications include wheels, gearboxes, clutch housings, valve covers, and brake pedal and other brackets. Consumer durables include luggage, softball bats, tennis rackets, and housings for cameras and projectors. Their high strength-to-weight ratio suits magnesium alloys to use in a variety of aircraft structures, particularly helicopters. Very intricate shapes that are uneconomical to produce in other materials are often cast in magnesium, sometimes without draft. Wrought magnesium alloys are made in the form of bars, forgings, extrusions, wire, sheet, and plate.

**Alloy and Temper Designation.**—Magnesium alloys are designated by a standard four-part system established by the ASTM, and now also used by the SAE, that indicates both chemical composition and temper. Designations begin with two letters representing the two alloying elements that are specified in the greatest amount; these letters are arranged in order of decreasing percentage of alloying elements or alphabetically if they are present in equal amounts. The letters are followed by digits representing the respective composition percentages, rounded off to whole numbers, and then by a serial letter indicating some variation in composition of minor constituents. The final part, separated by a hyphen, consists of a letter followed by a number, indicating the temper condition. The letters that designate the more common alloying elements are A, aluminum; E, rare earths; H, thorium; K, zirconium; M, manganese; Q, silver; S, silicon; T, tin; Z, zinc.

The letters and numbers that indicate the temper designation are: F, as fabricated; O, annealed; H10, H11, strain hardened; H23, H24, H26, strain hardened and annealed; T4, solution heat treated; T5, artificially aged; T6, solution heat treated and artificially aged; and T8, solution heat treated, cold-worked, and artificially aged.

The nominal composition and typical properties of magnesium alloys are listed in [Tables 8a](#) and [8b](#).

**Table 8a. Nominal Compositions of Magnesium Alloys**

| Alloy  | Al   | Zn  | Mn <sup>a</sup> | Si  | Zr   | Ag  | Th  | Y   | Rare Earth |

<sup>a</sup> All manganese values are minimum.<sup>b</sup> High-purity alloy, Ni, Fe, and Cu severely restricted.<sup>c</sup> 0.30 per cent maximum residual copper is allowed.<sup>d</sup> For battery applications.Source: *Metals Handbook*, 9th edition, Vol. 2, American Society for Metals.

**Table 8b. Typical Room-Temperature Mechanical Properties of Magnesium Alloys**

| Alloy  | Tensile Strength (ksi) | Yield Strength |                   |               | Elongation in 2 in. (%) | Shear Strength (ksi) | Hardness Rockwell B <sup>a</sup> |
|--|------------------------|----------------|-------------------|---------------|-------------------------|----------------------|----------------------------------|
|  |                        | Tensile (ksi)  | Compressive (ksi) | Bearing (ksi) |                         |                      |                                  |

<sup>a</sup> 500 kg load, 10-mm ball.<sup>b</sup> High-purity alloy, Ni, Fe, and Cu severely restricted.<sup>c</sup> 0.30 per cent maximum residual copper is allowed.<sup>d</sup> For battery applications.Source: *Metals Handbook*, 9th edition, Vol. 2, American Society for Metals.

### Nickel and Nickel Alloys

**Characteristics of Nickel and Nickel Alloys.**—Nickel is a white metal, similar in some respects to iron but with good oxidation and corrosion resistances. Nickel and its alloys are used in a variety of applications, usually requiring specific corrosion resistance or high strength at high temperature. Some nickel alloys exhibit very high toughness; others have very high strength, high proportional limits, and high moduli compared with steel. Commercially, pure nickel has good electrical, magnetic, and magnetostrictive properties. Nickel alloys are strong, tough, and ductile at cryogenic temperatures, and several of the so-called nickel-based superalloys have good strength at temperatures up to 2000 degrees F.

Most wrought nickel alloys can be hot and cold-worked, machined, and welded successfully; an exception is the most highly alloyed nickel compound—forged nickel-based superalloys—in which these operations are more difficult. The casting alloys can be machined or ground, and many can be welded and brazed.

There are five categories into which the common nickel-based metals and alloys can be separated: the pure nickel and high nickel (over 94 per cent Ni) alloys; the nickel–molybdenum and nickel–molybdenum–chromium superalloys, which are specifically for corrosive or high-temperature, high-strength service; the nickel–molybdenum–chromium–copper alloys, which are also specified for corrosion applications; the nickel–copper (Monel) alloys, which are used in actively corrosive environments; and the nickel–chromium and nickel–chromium–iron superalloys, which are noted for their strength and corrosion resistance at high temperatures.

Descriptions and compositions of some commonly used nickel and high nickel alloys are shown in [Table 9](#).

### Titanium and Titanium Alloys

Titanium is a gray, light metal with a better strength-to-weight ratio than any other metal at room temperature, and is used in corrosive environments or in applications that take advantage of its light weight, good strength, and nonmagnetic properties. Titanium is available commercially in many alloys, but multiple requirements can be met by a single grade of the commercially pure metal. The alloys of titanium are of three metallurgical types: alpha, alpha–beta, and beta, with these designations referring to the predominant phases present in the microstructure.

Titanium has a strong affinity for hydrogen, oxygen, and nitrogen gases, which tend to embrittle the material; carbon is another embrittling agent. Titanium is outstanding in its resistance to strongly oxidizing acids, aqueous chloride solutions, moist chlorine gas, sodium hypochlorite, and seawater and brine solutions. Nearly all nonaircraft applications take advantage of this corrosion resistance. Its uses in aircraft engine compressors and in airframe structures are based on both its high corrosion resistance and high strength-to-weight ratio.

Procedures for forming titanium are similar to those for forming stainless steel. Titanium and its alloys can be machined and abrasive ground; however, sharp tools and continuous feed are required to prevent work hardening. Tapping is difficult because the metal galls.

Titanium castings can be produced by investment or graphite mold methods; however, because of the highly reactive nature of the metal in the presence of oxygen, casting must be done in a vacuum.

Generally, titanium is welded by gas-tungsten arc or plasma arc techniques, and the key to successful welding lies in proper cleaning and shielding. The alpha–beta titanium alloys can be heat treated for higher strength, but they are not easily welded. Beta and alpha–beta alloys are designed for formability; they are formed in the soft state, and then heat treated for high strength.

The properties of some wrought titanium alloys are shown in [Table 10](#).

**Table 9. Common Cast and Wrought Nickel and High Nickel Alloys — Designations, Compositions, Typical Properties, and Uses**

| UNS Designation | Description and Common Name               | Nominal Composition (Weight %)                      | Typical Room-Temperature Properties |                  |            | Form           | Typical Uses   |
|-----------------|---|---|-------------------------------------|------------------|------------|----------------|--|
|                 |   |   | Tensile (ksi)                       | 0.2% Yield (ksi) | Elong. (%) |                |  |
| N02200          | Commercially pure Ni (Nickel 200)         | 99.5 Ni   | 67                                  | 22               | 47         | Wrought        | Food processing and chemical equipment.  |
| N04400          | Nickel-copper alloy (Monel 400)           | 65 Ni, 32 Cu, 2 Fe                                  | 79                                  | 30               | 48         | Wrought        | Valves, pumps, shafts, marine fixtures and fasteners, electrical and petroleum refining equipment. |
| N05500          | Age-hardened Ni-Cu alloy (Monel K 500)    | 65 Ni, 30 Cu, 2 Fe, 3 Al + Ti                       | 160                                 | 111              | 24         | Wrought        | Pump shafts, impellers, springs, fasteners, and electronic and oil well components.                |
| N06002          | Ni-Cr Alloy (Hastelloy X)                 | 60 Ni, 22 Cr, 19 Fe, 9 Mo, 0.6 W                    | 114                                 | 52               | 43         | Wrought        | Turbine and furnace parts, petrochemical equipment.  |

## PLASTICS

## PLASTICS

## Properties of Plastics

## Characteristics of Important Plastics Families

|  |  |
|--|--|
| ABS<br>(acrylonitrile-butadiene-styrene) | Rigid, low-cost thermoplastic, easily machined and thermo-formed.  |
| Acetal                                   | Engineering thermoplastic with good strength, wear resistance, and dimensional stability. More dimensionally stable than nylon under wet and humid conditions.   |
| Acrylic                                  | Clear, transparent, strong, break-resistant thermoplastic with excellent chemical resistance and weatherability.   |
| CPVC<br>(chlorinated PVC)                | Thermoplastic with properties similar to PVC, but operates to a 40-60°F higher temperature.  |
| Fiberglass                               | Thermosetting composite with high strength-to-weight ratio, excellent dielectric properties, and unaffected by corrosion.  |
| Nylon                                    | Thermoplastic with excellent impact resistance, ideal for wear applications such as bearings and gears, self-lubricating under some circumstances.   |
| PEEK<br>(polyetheretherketone)           | Engineering thermoplastic, excellent temperature resistance, suitable for continuous use above 500°F, excellent flexural and tensile properties.   |
| PET<br>(polyethylene-terephthalate)      | Dimensionally stable thermoplastic with superior machining characteristics compared to acetal.   |
| Phenolic                                 | Thermosetting family of plastics with minimal thermal expansion, high compressive strength, excellent wear and abrasion resistance, and a low coefficient of friction. Used for bearing applications and molded parts. |
| Polycarbonate                            | Transparent tough thermoplastic with high impact strength, excellent chemical resistance and electrical properties, and good dimensional stability.  |
| Polypropylene                            | Good chemical resistance combined with low moisture absorption and excellent electrical properties, retains strength up to 250°F.  |
| Polysulfone                              | Durable thermoplastic, good electrical properties, operates at temperatures in excess of 300°F.  |
| Polyurethane                             | Thermoplastic, excellent impact and abrasion resistance, resists sunlight and weathering.  |
| PTFE<br>(polytetrafluoroethylene)        | Thermoplastic, low coefficient of friction, withstands up to 500°F, inert to chemicals and solvents, self-lubricating with a low thermal-expansion rate.   |
| PVC<br>(polyvinyl chloride)              | Thermoplastic, resists corrosive solutions and gases both acid and alkaline, good stiffness.   |
| PVDF<br>(polyvinylidene-fluoride)        | Thermoplastic, outstanding chemical resistance, excellent substitute for PVC or polypropylene. Good mechanical strength and dielectric properties.   |

**Plastics Materials.**—Plastics materials, often called resins, are made up of many repeating groups of atoms or molecules linked in long chains (called polymers) that combine such elements as oxygen, hydrogen, nitrogen, carbon, silicon, fluorine, and sulfur. Both the lengths of the chains and the mechanisms that bond the links of the chains together are related directly to the mechanical and physical properties of the materials. There are two main groups: thermoplastics and thermosets.

*Thermoplastic materials* become soft and moldable when heated, and change back to solids when allowed to cool. Examples of thermoplastics are acetal, acrylic, cellulose acetate, nylon, polyethylene, polystyrene, vinyl, and nylon. Thermoplastic materials that are flexible even when cool are known as thermoplastic elastomers or TPEs. When thermoplastic materials are heated, the linked chains of molecules can move relative to each other, allowing the mass to flow into a different shape. Cooling prevents further flow. Although the heating/cooling cycle can be repeated, recycling reduces mechanical properties and appearance.

*Thermoset plastics* such as amino, epoxy, phenolic, and unsaturated polyesters, are so named because they are changed chemically during processing and become hard solids. Although the structures of thermoset materials are similar to those of thermoplastic materials, processing develops cross-links between adjacent molecules, forming complex networks that prevent relative movement between the chains at any temperature. Many rubbers that are processed by vulcanizing, such as butyl, latex, neoprene, nitrile, polyurethane, and silicone, also are classified as thermosets. Heating a thermoset degrades the material so that it cannot be reprocessed satisfactorily.

*Elastomers* are flexible materials that can be stretched up to about double their length at room temperature and can return to their original length when released. Thermoplastic elastomers are often used in place of rubber, and may also be used as additives to improve the impact strength of rigid thermoplastics.

**Structures.**—Thermoplastics can be classified by their structures into categories such as amorphous (noncrystalline), crystalline, and liquid crystalline polymers (LCP). Amorphous thermoplastics include polycarbonate, polystyrene, ABS (acrylonitrile-butadiene-styrene), SAN (styrene-acrylonitrile), and PVC (polyvinylchloride). Crystalline thermoplastics have polymer chains that are packed together in an organized way, as distinct from the unorganized structures of amorphous plastics, and include acetal, nylon, polyethylene, polypropylene, and polyester. The organized regions in crystalline thermoplastics are joined by noncrystalline (amorphous) zones, and the structures are such that the materials are stronger and stiffer, though less resistant to impact, than completely noncrystalline materials. Crystalline thermoplastics have higher melting temperatures and higher shrinkage and warpage factors than amorphous plastics. Liquid crystalline plastics are polymers with highly ordered rod-like structures and have high mechanical property values, good dimensional stability and chemical resistance, and are easy to process, with melting temperatures similar to those of crystalline plastics. Unlike amorphous and crystalline plastics, liquid crystalline plastics retain significant order in the melt phase. As a result, they have the lowest shrinkage and warpage of the three types of thermoplastics.

**Mixtures.**—Characteristics of plastics materials can be changed by mixing or combining different types of polymers and by adding nonplastics materials. Particulate fillers such as wood flour, silica, sand, ceramic and carbon powder, tiny glass balls, and powdered metal are added to increase modulus and electrical conductivity, to improve resistance to heat or ultraviolet light, and to reduce cost, for example. Plasticizers may be added to decrease modulus and increase flexibility. Other additives may be used to increase resistance to effects of ultraviolet light and heat or to prevent oxidation, and for a variety of other purposes.

*Reinforcing fibers* of glass, carbon, or Aramid (aromatic polyamide fibers having high tensile strength, a range of moduli, good toughness, and stress-strain behavior similar to

that of metals) are added to improve mechanical properties. Careful design and process selection must be used to position the fibers so that they will provide the required strength where it is needed. Continuous fiber may be positioned carefully in either a thermoplastics or thermoset matrix to produce basic parts generally called composites, which have the highest mechanical properties and cost of the reinforced plastics.

*Copolymers* embody two or more different polymers and may have properties that are completely different from those of the individual polymers (homopolymers) from which they are made. An approach known as alloying consists of pure mechanical blending of two or more different polymers, often with special additives to make them compatible. These "alloys" are compounded so as to retain the most desirable characteristics of each constituent, especially in impact strength and flame resistance. However, properties usually are intermediate between those of the constituent materials.

**Physical Properties.**—Almost all proposed uses of plastics require some knowledge of the physical properties of the materials, and this information is generally readily available from manufacturers. Properties such as density, ductility, elasticity and plasticity, homogeneity, uniformity of composition, shrinkage during cooling from the molding temperature, transmittal of light, toughness (resistance to impact), brittleness, notch sensitivity, isotropy (properties that are the same when measured in any direction) and anisotropy (properties that vary when measured in different directions), and lubricity (load-bearing characteristics under relative motion) may all need consideration when a material suitable for a specific application is to be specified.

Most of the terms used to describe the physical characteristics of metals, such as density, ductility, brittleness, elasticity, notch sensitivity, specific gravity, and toughness, have similar meanings when they are applied to plastics, but different measures are often used with plastics. Like cast metals, many plastics are isotropic so that their characteristics are the same measured in any direction. Properties of rolled metals and extruded plastics vary when measured in the longitudinal and transverse directions, so these materials are anisotropic.

*Density* is a measure of the mass per unit volume, usually expressed in lb/in.<sup>3</sup> or g/cm<sup>3</sup> at a temperature of 73.4 degrees F (23 degrees C). Density information is used mainly to calculate the amount of material required to make a part of a given volume, the volume being calculated from drawing dimensions.

*Specific gravity* is the ratio of the mass of a given volume of a material to the mass of the same volume of water, both measured at 73.4 degrees F (23 degrees C). The ratio is dimensionless so is useful for comparing different materials, and is used in cost estimating and quality control.

*Shrinkage* is the ratio of the dimension of the plastics molding to the corresponding dimension of the mold, expressed in in./in. or cm/cm, both at room temperature. As with a die casting die, the moldmaker uses this ratio to determine mold cavity measurements that will produce a part of the required dimensions. Shrinkage in a given material can vary with wall thickness, direction of flow of the plastics in the mold, and molding conditions. Amorphous and liquid crystalline thermoplastics have lower shrinkage ratios than crystalline thermoplastics. Glass-reinforced and filled materials have lower shrinkage than unfilled materials.

*Water absorption* is the amount of increase in weight of a material due to absorption of water, expressed as a percentage of the original weight. Standard test specimens are first dried for 24 hr, then weighed before and after immersion in water at 73.4 degrees F (23 degrees C) for various lengths of time. Water absorption affects both mechanical and electrical properties and part dimensions. Parts made from materials with low water absorption rates tend to have greater dimensional stability.

*Opacity (or transparency)* is a measure of the amount of light transmitted through a given material under specific conditions. Measures are expressed in terms of haze and

luminous transmittance. Haze measurements indicate the percentage of light transmitted through a test specimen that is scattered more than 2.5 degrees from the incident beam. Luminous transmittance is the ratio of transmitted light to incident light.

*Elasticity* is the ability of a material to return to its original size and shape after being deformed. Most plastics have limited elasticity, although rubber and materials classified as thermoplastic elastomers (TPEs) have excellent elasticity.

*Plasticity* is the inverse of elasticity, and a material that tends to stay in the shape or size to which it has been deformed has high plasticity. Some plastics can be formed cold by being stressed beyond the yield point and such plastics then exhibit plasticity. When thermoplastics are heated to their softening temperature, they have almost perfect plasticity.

*Ductility* is the ability of a material to be stretched, pulled, or rolled into shape without destroying the integrity of the material.

*Toughness* is a measure of the ability of a material to absorb mechanical energy without cracking or breaking. Tough material can absorb mechanical energy with either elastic or plastic deformation. High-impact unfilled plastics generally have excellent toughness, and low- or moderate-impact materials may also be tough if their ultimate strength is high enough (see *Typical Stress–Strain Curves* on page 598). The area under the stress–strain curve is often used as the measure of toughness for a particular plastics material.

*Brittleness* is the lack of toughness. Brittle plastics frequently have low impact and high stiffness properties. Many glass-reinforced and mineral-filled materials are brittle.

*Notch sensitivity* is a measure of the ease with which a crack progresses through a material from an existing notch, crack, or sharp corner.

*Lubricity* describes the load-bearing characteristics of a material under relative motion. Plastics with good lubricity have low coefficients of friction with other materials (or sometimes with themselves) and no tendency to gall.

*Homogeneous* means uniform. The degree of homogeneity indicates the uniformity of composition of a material throughout its mass. In a completely homogeneous body, the smallest sample has the same physical properties as the body. An unfilled thermoplastics is a reasonably homogeneous material.

*Heterogeneous* means varying. In a heterogeneous body, for example, a glass-reinforced material, the composition varies from point to point. Many heterogeneous materials are treated as homogeneous for design purposes because a small sample of the material has the same properties as the body.

*Isotropy* means that the properties at any point in a body are the same, regardless of the direction in which they are measured.

*Anisotropy* means that the physical properties of a material depend on the direction of measurement. Various degrees of anisotropy exist, depending on the amount of symmetry of the material or component shape. For example, cast metals and plastics tend to be isotropic so that samples cut in any direction within a cast body tend to have the same physical properties. However, rolled metals tend to develop crystal orientation in the direction of rolling so that they have different mechanical properties in the rolling and transverse-to-rolling directions.

Extruded plastics film also may have different properties in the extruding and transverse directions so that these materials are oriented biaxially and are anisotropic. Composite materials that have fiber reinforcements carefully oriented in the direction of applied loads, surrounded by a plastics matrix, have a high degree of property orientation with direction at various points in the structure and are anisotropic.

As another example, wood, page 411, is an anisotropic material with distinct properties in three directions and is very stiff and strong in the direction of growth. Fair properties are also found in one direction perpendicular to the growth direction, but in a third direction at right angles to the other two directions, the mechanical properties are much lower.

The preceding examples involve mechanical properties, but anisotropy is also used in referring to the way a material shrinks in the mold. Anisotropic shrinkage is important in molding crystalline and glass-fiber-reinforced materials for which shrinkage values are usually listed for the flow direction and the cross-flow direction. These values are of most concern to the tool designer and molder, but the existence of anisotropy and its severity must be considered when a material is chosen for a part having tight tolerances.

*Significance of Elasticity, Homogeneity, and Isotropy:* Structural analysis during design of components uses two independent constants, Young's modulus ( $E$ ) and Poisson's ratio ( $\nu$ ), but two constants are sufficient only for elastic, isotropic materials that respond linearly to loads (when load is proportional to deformation). Designers often use the same values for these constants everywhere in the structure, which is correct only if the structure is homogeneous.

Assumptions of linear elasticity, isotropy, and homogeneity are reasonable for many analyses and are a good starting point, but use of these assumptions can lead to significant design errors with plastics, particularly with glass-reinforced and liquid crystalline polymers, which are highly anisotropic. In the following, plastics are assumed to be linearly elastic, homogeneous, and isotropic to allow a simpler presentation of mechanical properties in line with the data provided in plastics manufacturers' marketing data sheets. The standard equations of structural analysis (bending, torsion, pressure in a pipe, etc.) also require these assumptions.

As the degree of anisotropy increases, the number of constants or moduli required to describe the material also increases, up to a maximum of 21. Uncertainty about material properties and the questionable applicability of the simple analysis techniques employed point to the need for extensive end-use testing of plastics parts before approval of a particular application. A partial solution to this problem lies in the use of finite-element-analysis (FEA) methods. The applicability of FEA methods requires good understanding of the anisotropic nature of plastics materials.

**Mechanical Properties.**—Almost all end-use applications involve some degree of loading, so mechanical properties are of prime importance in designing with plastics. Material selection is usually based on manufacturers' marketing data sheets listing tensile strength, modulus of elasticity ( $E$ ), elongation, impact strength, stress and strain behavior, and shear strength. Suppliers' data often are generated under standard test conditions so may not be directly transferable to the components produced. Because of the somewhat lower modulus of elasticity of plastics materials ( $10^5$  for plastics compared with  $10^6$  lb<sub>f</sub>/in<sup>2</sup> for metals), different units of measure are used to express the results.

Determination of the true meaning of mechanical properties and their relation to end-use requirements is of vital importance in design. In practical applications, materials are seldom subjected to steady deformation without the influence of other factors such as environment and temperature. A thorough understanding of mechanical properties and tests used to determine such properties, and the effects of adverse or beneficial conditions on mechanical properties over long time periods, is extremely important. Some manufacturers offer design and technical advice to customers who do not possess this understanding.

*Stress:* A three-dimensional body having a balanced system of external forces  $F_1$  through  $F_5$  acting on it, such that the body is at rest, is shown in Fig. 1. Such a body develops internal forces to transfer and distribute the external loads. If the body is cut at an arbitrary cross-section and one part is removed, as shown at the right in Fig. 1, a new system of

forces acting on the cut surface is developed to balance the remaining external forces. Similar forces (stresses) exist within the uncut body.

Fig. 1. Internal Forces and Stresses in a Body

Fig. 2. Simple Tension Load

Stresses must be defined with both magnitude and direction. The stress  $S$  acting in the direction shown in Fig. 1, on the point  $P$  of the cut surface, has two stress components. One of these components,  $\sigma$ , acts perpendicular to the surface and is called a normal or direct stress. The other stress,  $\tau$ , acts parallel to the surface and is called a shear stress.

*Normal stress* is illustrated by the simple tension test shown in Fig. 2, where the direct stress is the ratio of applied load to the original cross-sectional area in lb<sub>f</sub>/in<sup>2</sup>. In the Système International (SI or metric system, see pages 2544, and starting on page 2576) the stress,  $\sigma$ , is expressed in newtons/meter<sup>2</sup> (N/m<sup>2</sup>).

$$\text{Stress} = \frac{\text{Load}}{\text{Area}} \text{ or } \sigma = \frac{F}{A} \quad (1)$$

If the load is applied as shown in Fig. 2, the test piece is in tension, and if reversed, it is in compression.

*Normal strain* is also illustrated by the diagram in Fig. 2, where the load or stress applied to the test piece causes it to change its length. If the bar has an original length  $L$ , and changes its length by  $\Delta L$ , the strain,  $\epsilon$ , is defined as

$$\text{Strain} = \frac{\text{Change of Length}}{\text{Original Length}} \text{ or } \epsilon = \frac{\Delta L}{L} \quad (2)$$

Strain is the ratio between the amount of deformation of the material and its original length and is a dimensionless quantity. Extensions of most materials under load are generally very small. Strain ( $\mu\epsilon$  or microstrain in most metals) is measured and expressed in microinches (millionths of an inch) per inch, or  $10^{-6}$  in./in. ( $10^{-6}$  cm/cm). Alternatively, strain is expressed as a percentage. The three methods compare as follows:

$$1000\mu\epsilon = 0.001 = 0.1 \text{ per cent strain}$$

$$10000\mu\epsilon = 0.010 = 1 \text{ per cent strain}$$

*Modulus of Elasticity:* Most metals and plastics have deformations that are proportional to the imposed loads over a range of loads. Stress is proportional to load and strain is proportional to deformation, so stress is proportional to strain and is expressed by Hooke's law:

$$\frac{\text{Stress}}{\text{Strain}} = \text{Constant} = E \quad (3)$$

The constant  $E$  is called the modulus of elasticity, Young's modulus, or, in the plastics industry, tensile modulus. Referring to Fig. 2, tensile modulus is given by the formula:

$$E = \frac{\sigma}{\epsilon} = \frac{F/A}{\Delta L/L} = \frac{FL}{A\Delta L} \quad (4)$$

Thus, the modulus is the slope of the initial portion of the stress-strain curve. An elastic material does not necessarily obey Hooke's law, since it is possible for a material to return to its original shape without the stress being proportional to the strain. If a material does obey Hooke's law, however, it is elastic.

The straight portion of the stress-strain curve for many plastics is difficult to locate, and it is necessary to construct a straight line tangent to the initial portion of the curve to use as a modulus. The shape of a line so obtained is called the initial modulus. In some plastics, the initial modulus can be misleading, owing to the nonlinear elasticity of the material. Some suppliers therefore provide the so-called 1 per cent secant modulus, which is the ratio of stress to strain at 1 per cent strain on the stress-strain curve. In the illustration of typical stress-strain curves in Fig. 3, the secant modulus at the point *E* is the slope of the line *OE*.

Fig. 3. Typical Stress-Strain Curves

For metals, Young's modulus is expressed in terms of  $10^6$  lb<sub>f</sub>/in.<sup>2</sup>, N/m<sup>2</sup>, or Pa, as convenient (see starting on page 2576). For plastics, tensile modulus is expressed as  $10^5$  lb<sub>f</sub>/in.<sup>2</sup> or in GPa (1 GPa = 145,000 lb<sub>f</sub>/in.<sup>2</sup>).

*Secant modulus* is the ratio of stress to corresponding strain at any point on the stress-strain curve (see *Modulus of Elasticity*).

*Proportional limit* is the greatest stress at which a material is capable of sustaining the applied load without losing the proportionality of stress to strain. This limit is the point on the stress-strain curve where the slope begins to change, as shown at *A* on each of the curves in Fig. 3. Proportional limit is expressed in lb<sub>f</sub>/in.<sup>2</sup> (MPa or GPa).

*Yield point* is the first point on the stress-strain curve where an increase in strain occurs without an increase in stress, and is indicated by *B* on some of the curves in Fig. 3. The slope of the curve is zero at this point; however, some materials do not have a yield point.

*Ultimate strength* is the maximum stress a material withstands when subjected to a load, and is indicated by *C* in Fig. 3. Ultimate strength is expressed in lb<sub>f</sub>/in.<sup>2</sup> (MPa or GPa).

*Elastic limit* is indicated by the point *D* on the stress-strain curve in Fig. 3, and is the level beyond which the material is permanently deformed when the load is removed. Although many materials can be loaded beyond their proportional limit and still return to zero strain when the load is removed, some plastics have no proportional limit in that no region exists where the stress is proportional to strain (i.e., where the material obeys Hooke's law).

*Yield strength* is the stress at which a material shows a specified deviation from stress to strain proportionality. Some materials do not show a yield strength clearly, and it may be desirable to choose an arbitrary stress level beyond the elastic limit, especially with plas-

tics that have a very high strain at the yield point, to establish a realistic yield strength. Such a point is seen at  $F$  on some of the curves in Fig. 3, and is defined by constructing a line parallel to  $OA$  at a specified offset strain,  $H$ . The stress at the intersection of the line with the stress-strain curve at  $F$  would be the yield strength at  $H$  offset. If  $H$  were at 2 per cent strain,  $F$  would be described as the yield strength at a 2 per cent strain offset.

*Poisson's ratio* is defined on page 204. Under a tensile load, a rectangular bar of length  $L$ , with sides of widths  $b$  and  $d$ , lengthens by an amount  $\Delta L$ , producing a longitudinal strain of

$$\epsilon = \frac{\Delta L}{L} \quad (5)$$

The bar is reduced in its lateral dimensions and the associated lateral strains will be opposite in sign, resulting in

$$\epsilon = -\frac{\Delta b}{b} = -\frac{\Delta d}{d} \quad (6)$$

If the deformation is within the elastic range, the ratio (Poisson's ratio  $\nu$ ) of the lateral to the longitudinal strains will be constant. The formula is:

$$\nu = \frac{\text{Lateral Strain}}{\text{Longitudinal Strain}} = \frac{\Delta d/d}{\Delta L/L} \quad (7)$$

Values of  $\nu$  for most engineering materials lie between 0.20 and 0.40, and these values hold for unfilled rigid thermoplastics. Values of  $\nu$  for filled or reinforced rigid thermoplastics fall between 0.10 and 0.40 and for structural foam between 0.30 and 0.40. Rigid thermoset plastics have Poisson's ratios between 0.20 and 0.40, whether filled or unfilled, and elastomers can approach 0.5.

*Shear stress* is treated on page 215. Any block of material is subject to a set of equal and opposite shearing forces  $Q$ . If the block is envisaged as an infinite number of infinitesimally thin layers as shown diagrammatically in Fig. 4, it is easy to imagine a tendency for one layer subject to a force to slide over the next layer, producing a shear form of deformation or failure. The shear stress  $\tau$  is defined as

$$\tau = \frac{\text{Shear Load}}{\text{Area Resisting Load}} = \frac{Q}{A} \quad (8)$$

Shear stress is always tangential to the area on which it acts. Shearing strain is the angle of deformation  $\gamma$  and is measured in radians.

Fig. 4. Shear Stress is Visualized as a Force  $Q$  Causing Infinitely Thin Layers of a Component to Slide Past Each Other, Producing a Shear Form of Failure

*Shear modulus* is a constant  $G$ , otherwise called the modulus of rigidity, and, for materials that behave according to Hooke's law, is directly comparable to the modulus of elasticity used in direct stress calculations. The constant is derived from

$$G = \frac{\text{Shear Stress}}{\text{Shear Strain}} = \frac{\tau}{\gamma} \quad (9)$$

*Relating Material Constants:* Although only two material constants are required to characterize a material that is linearly elastic, homogeneous, and isotropic, three such constants have been introduced here. These three constants are tensile modulus  $E$ , Poisson's ratio  $\nu$ , and shear modulus  $G$ , and they are related by the following equation, based on elasticity principles:

$$\frac{E}{G} = 2(1 + \nu) \quad (10)$$

This relationship holds for most metals and is generally applicable to injection-moldable thermoplastics. It must be remembered, however, that most plastics, and particularly fiber-reinforced and liquid crystalline materials, are inherently either nonlinear, or anisotropic, or both.

*Direct shear* refers to a shear strength test much used in the plastics industry with a setup similar to that shown in Fig. 5, and the results of such tests are often described in manufacturers' marketing data sheets as the shear strength of the material. The shear strength reported from such a test is not a pure shear strength because a considerable part of the load is transferred by bending or compressing, or both, rather than by pure shear, and results can be affected by the susceptibility of the material to the sharpness of the load faces in the test apparatus. Thus, the test cannot be used to develop shear stress–strain curves or to determine the shear modulus.

When analyzing plastics in a pure shear situation or when the maximum shear stress is calculated in a complex stress environment, designers often use a shear strength value of about half the tensile strength, or the direct shear strength obtained from the test referred to above, whichever is least.

Fig. 5. Direct Shear Test Used in the Plastics Industry

*True stress and true strain* are terms not in frequent use. In Fig. 2, the stress, sometimes called the engineering stress, is calculated from an increasing load  $F$ , acting over a constant area  $A$ . Because the cross-sectional area is reduced with most materials, use of that smaller cross-sectional area in the calculation yields what is called the "true stress." In addition, the direct strain referred to earlier, that is, the total change in length divided by the original length, is often called the "engineering strain." The true strain would be the instantaneous deformation divided by the instantaneous length. Therefore, the shape of such a stress–strain curve would not be the same as a simple stress–strain curve. Modulus values and stress–strain curves are almost universally based on engineering stress and strain.

**Other Measures of Strength and Modulus.**—Tensile and compression properties of many engineering materials, which are treated as linearly elastic, homogeneous, and isotropic, are often considered to be identical, so as to eliminate the need to measure properties in compression. Also, if tension and compression properties are identical, under standard beam bending theory, there is no need to measure the properties in bending. In a concession to the nonlinear, anisotropic nature of most plastics, these properties, particularly flexural properties, are often reported on manufacturers' marketing data sheets.

*Compression Strength and Modulus:* Because of the relative simplicity of testing in tension the elastic modulus of a material is usually measured and reported as a tension value. For design purposes it often is necessary to know the stress-strain relationship for compression loading. With most elastic materials at low stress levels, the tensile and compressive stress-strain curves are nearly equivalent. At higher stress levels, the compressive strain is less than the tensile strain. Unlike tensile loading, which usually results in a clear-cut failure, stressing in compression produces a slow and indefinite yielding that seldom leads to failure. Because of this phenomenon, compressive strength is customarily expressed as the stress in lb/in.<sup>2</sup> (Pa) required to deform a standard plastics test specimen to a certain strain. Compression modulus is not always reported, because defining a stress at a given strain is equivalent to reporting a secant modulus. If a compression modulus is given, it is usually an initial modulus.

*Bending Strength and Modulus:* When material of rectangular cross-section is bent, it is apparent that one surface is stretched in tension and the other side is compressed. Within the material is a line or plane of zero stress called the neutral axis. Simple beam bending theory makes the following assumptions: that the beam is initially straight, unstressed, and symmetric; the material is linearly elastic, homogeneous, and isotropic; the proportional limit is not exceeded; Young's modulus for the material is the same in tension and compression; and all deflections are small so that planar cross-sections remain planar before and after bending.

In these conditions, the formula for bending stress  $\sigma$  is

$$\sigma = \frac{3FL}{2bh^2} \quad (11)$$

the formula for bending or flexural modulus  $E$  is

$$E = \frac{FL^3}{4bh^3Y} \quad (12)$$

and the formula for deflection  $Y$  is

$$Y = \frac{FL^3}{4Ebh^3} \quad (13)$$

where  $F$ , the force in pounds, is centered between the specimen support points,  $L$  is the distance in inches between the support points,  $b$  and  $h$  are the width and thickness of the test specimen in inches, and  $Y$  is the deflection in inches at the central load point.

Using the preceding relationships, the flexural strength and flexural modulus (of elasticity) for any material can be determined in the laboratory. The flexural modulus reported is usually the initial modulus from the load deflection curve. Most plastics parts must be analyzed in bending, so use of flexural values should give more accurate results than corresponding tensile values.

*Rate Dependence of Mechanical Properties:* Tensile and flexural data in manufacturers' literature are measured at specific displacement rates. These rates are usually not consistent with the loading environment encountered in use of the product. The same plastics material, under differing rates or in other environmental conditions, can produce different stress-strain curves. Designers should be aware of the loading rates in specific applica-

tions and request the appropriate data. End-use testing must always be considered, but particularly when adequate data are not available.

**Time-Related Mechanical Properties.**—Mechanical properties discussed previously were related to loads applied gradually and applied for short periods. Long-term and very short-term loading may give somewhat different results. With high-performance thermoplastics it is important to consider creep, impact, fatigue, and related issues. Even the best laboratory test methods do not always predict structural response of production parts accurately, and other factors may also affect results.

*Creep* is defined as increasing strain over time in the presence of a constant stress when deformation continues without increases in load or stress. The rate of creep for a given material depends on applied stress, temperature, and time.

Creep behavior of a material is important, and a crucial issue with plastics, where parts are to be subjected to loads for extended periods and where the maximum deflection is critical. To determine the creep behavior, test samples may be loaded in tension, compression, or flexure in a constant-temperature environment. Under constant loads, deflection is recorded at regular intervals over suitable periods. Results are generally obtained for four or more stress levels and recorded as creep curves of strain versus time on a logarithmic scale. In general, crystalline materials have lower creep rates than amorphous plastics. Glass reinforcement generally improves the creep resistance.

*Apparent or Creep Modulus:* If the deflection of a part subjected to continuous loading is calculated by using the modulus of elasticity  $E$ , results are likely to be inaccurate because the effects of creep have not been considered. If the stress level and temperature are known and creep curves are available for the temperature in question, an apparent or creep modulus  $E_{app}$  can be calculated from the creep curves by the formula:  $E_{app} = \sigma / \epsilon_c$ , where  $\sigma$  is the calculated stress level and  $\epsilon_c$  is the strain from the creep curve at the expected time and temperature.

This value  $E_{app}$  can be used instead of  $E$  in predicting the maximum deflection, using the methods described subsequently (page 602).

Manufacturers' data often include curves of creep modulus (or log creep modulus) versus log time at either constant stress or constant strain, derived from creep data. This information may also be provided as tables of values at constant stress and temperature for various time periods. Some manufacturers provide creep data in the form of creep modulus figures rather than curves.

*Creep rupture* data are obtained in the same manner as creep data except that higher stresses are used and time is measured to failure. Such failures may be brittle or ductile with some degree of necking. Results are generally plotted as log stress versus log time to failure.

*Stress relaxation* occurs when plastics parts are assembled into a permanent deflected condition, as in a press fit, a bolted assembly, or some plastics springs. Under constant strain over a period of time, the stress level decreases due to the same internal molecular movement that produces creep. Stress relaxation is important with such applications as bolt preloading and springs, where loading must be maintained. The relaxation can be assessed by applying a fixed strain to a sample and measuring the load over time. A relaxation modulus similar to the creep modulus can be derived from the relaxation data. Relaxation data are not as readily available as creep data, but the decrease in load due to stress relaxation can be approximated by using the creep modulus  $E_{app}$  calculated from the creep curves.

Plastics parts often fail due to imposition of excessive fixed strains over extended periods of time, for example, a plastics tube that is a press fit over a steel shaft. No relaxation rupture equivalent to creep rupture exists, so for initial design purposes a strain limit of 20 percent of the strain at the yield point or yield strength is suggested for high-elongation plas-

tics. For low-elongation brittle plastics that have no yield point, 20 per cent of the elongation at break is also recommended. These figures should be regarded only as guidelines for development of initial design concepts; prototype parts should be thoroughly tested under end-use conditions to confirm the suitability of the design. Higher or lower property limits may also be indicated in manufacturers' data on specific materials.

*Extrapolating creep and relaxation data* must be done with caution. When creep and relaxation data are plotted as log property against log time, the curves are generally less pronounced, facilitating extrapolation. This procedure is common practice, particularly with creep modulus and creep rupture data. Extrapolation should not exceed one unit of log time, and the strain limit of 20 per cent of the yield or ultimate strength mentioned above should not be exceeded.

*Impact loading* describes a situation in which a load is imposed rapidly. Any moving body has kinetic energy and when the motion is stopped by a collision, the energy is dissipated. Ability of a plastics part to absorb energy is determined by the shape, size, thickness, and type of material. Impact testing methods now available do not provide designers with information that can be used analytically. The tests can be used for comparing relative notch sensitivity or relative impact resistance, so can be useful in choosing a series of materials to be evaluated for an application or in grading materials within a series.

*Impact testing* by the Izod and Charpy methods, in which a pendulum arm is swung from a certain height to impact a notched test specimen, is the most widely used for measuring impact strength. Impact with the test specimen reduces the energy remaining in the arm, and this energy loss is recorded in ft-lb (J). The value of such tests is that they permit comparison of the relative notch toughness of two or more materials under specific conditions.

*Tensile impact* tests mount the test specimen on the swinging arm. Attached to the test specimen is a cross piece that is arrested by a notched anvil as the bar swings down, allowing the energy stored in the arm to break the specimen under tension as it passes through the notch. Another impact test used for plastics allows a weighted, round-ended cylindrical "dart" to fall on a flat disk of the plastics to be tested. This test is good for ranking materials because it represents conditions that are encountered by actual parts in certain applications.

*Fatigue tests* are designed to measure the relative ability of plastics materials to withstand repeated stresses or other cyclic phenomena. For example, a snap-action, or snap-fit latch that is continually opened and closed, a gear tooth, a bearing, a structural component subject to vibration or to repeated impacts. Cyclic loading can cause mechanical deterioration and progressive fracture, leading to failure in service. Typical fatigue tests are carried out on machines designed to subject a cantilever test piece to reversing flexural loading cycles at different stress levels. Numbers of cycles before failure are recorded for each stress level. Data are normally presented in plots of log stress versus log cycles called *S-N* curves for specific cycle rates and environmental temperatures. With thermoplastics materials there is the added complication that heat built up by the frequency of the cyclic stress may contribute to failure. Significantly different *S-N* curves can be produced for the same materials by testing at different frequencies, mean stresses, waveforms, and methods, such as testing in tension rather than in bending. Testing usually cannot reproduce the conditions under which components will work. Only tests on the end product can determine whether the design is suitable for the purpose to be served.

**Thermal Properties.**—Melting temperatures of crystalline thermoplastics are sharp and clearly defined, but amorphous and liquid crystalline materials soften and become more fluid over wider temperature ranges. Melting points have greater significance in molding and assembly operations than in product design, which usually deals with the product's temperatures.

*Glass transition temperature* is a level at which a plastics material undergoes a significant change in properties. Below this temperature  $T_g$ , the material has a stiff, glassy, brittle response to loads. Above  $T_g$  the material has a more ductile, rubbery response.

*Vicat softening point* is the temperature at which a small, circular, lightly gravity-loaded, heated probe penetrates a specific distance into a thermoplastics test specimen. This test measures the ability of a thermoplastics material to withstand a short-term contact with a heated surface, and is most useful for crystalline plastics. Amorphous thermoplastics materials tend to creep during the test, which reduces its usefulness for such materials.

*Deflection temperature under load* (DTUL) is the temperature at which a test bar of 0.5 in. thickness, loaded to a specified bending stress, will deflect by 0.010 in. This test is run at bending stresses of 66 lb<sub>f</sub>/in.<sup>2</sup> or 264 lb<sub>f</sub>/in.<sup>2</sup> or both. The value obtained is sometimes referred to as the heat distortion temperature (HDT), and is an indication of the ability of the material to perform at elevated temperatures under load. Both stress and deflection for a specific design of test bar are given so the test may be regarded as establishing the temperature at which the flexural modulus is reduced to particular values, 35,200 lb<sub>f</sub>/in.<sup>2</sup> at 66 lb<sub>f</sub>/in.<sup>2</sup> stress, and 140,000 lb<sub>f</sub>/in.<sup>2</sup> at 264 lb<sub>f</sub>/in.<sup>2</sup> stress.

*Linear thermal expansion:* Like metals, thermoplastic materials expand when heated and contract when cooled. For a given temperature range, most plastics change dimensions much more than metals. The coefficient of linear thermal expansion (CLTE) is the ratio of the change in a linear dimension to the original dimension for a unit change of temperature and is expressed as in/in/degree F, or cm/cm/degree C. Typical average values for common materials are shown in the table on page 402. These values do not take account of grades, molding conditions, wall thickness, or direction of flow in molding.

*Thermal conductivity* is the rate at which a material conducts heat energy along its length or through its thickness.

*Aging at elevated temperatures* may affect physical, mechanical, electrical, or thermal properties of plastics materials. Data from tests on specimens stored at specific temperatures for suitable periods are presented as plots of properties versus aging time at various temperatures, and may be used as an indication of thermal stability of the material.

*Temperature index* is a rating by Underwriters Laboratories (UL) of electrical and mechanical properties (with and without effects of impacts) of plastics materials used in electrical equipment for certain continuous operating conditions.

*Flammability ratings* also are produced by Underwriters Laboratories. UL tests measure the ability to continue burning after a flame is removed, and the percentage of oxygen needed for the material to continue burning. Other tests measure combustibility, ignition temperatures, and smoke generation.

**Effect of Temperature on Mechanical Properties.**—The inverse relationship between strain rate and temperature must be kept in mind when designing with plastics materials. Stress/strain curves for tests performed with one strain rate at several temperatures are similar to those for tests with one temperature and several strain rates. Therefore, very high strain rates and very low temperatures produce similar responses in materials. Conversely, the effects of very low strain rates, that is, creep effects, can be determined more quickly by testing at elevated temperatures. Testing at temperatures near or above the highest values expected in everyday use of a product helps the designer estimate long-term performance of components.

Strength, modulus, and elongation behavior are similar for tensile, compressive, flexural, and shear properties. Generally, strength and modulus decrease with increasing temperature. The effect of temperature increases is shown by the curves in Fig. 6 for crystalline and amorphous materials, where a gradual drop in modulus is seen as the glass transition temperature  $T_g$  is approached. Above the glass transition temperature, amorphous materi-

als have a rapid loss of modulus, and even with glass-fiber reinforcement they display a rapid drop in modulus above the glass transition temperature. Crystalline materials maintain a significant usable modulus at temperatures approaching the crystalline melting point, and glass-fiber reinforcement can significantly improve the modulus of crystalline materials between the glass transition and melting temperatures. Generally, strength versus temperature curves are similar to modulus curves and elongation increases with rising temperatures.

Fig. 6. Modulus Behavior of Crystalline and Amorphous Plastics Showing  $T_g$  and Melt Temperatures and the Effect of Reinforcement on Deflection Temperature Under Load (DTUL)

Isochronous stress and isometric stress curves are taken from measurements made at fixed temperatures, although sometimes curves are available for other-than-ambient temperatures. Creep rupture and apparent modulus curves also are often plotted against the log of time, with temperature as a parameter. Refer to sections on creep, creep modulus, and creep rupture beginning on page 602.

As temperatures drop significantly below ambient, most plastics materials lose much of their room temperature impact strength, although a few materials show only a gradual decrease. Plastics reinforced with long glass fibers have relatively high Izod impact values at room temperature, and retain these values at  $-40$  degrees F ( $-40$  degrees C).

**Electrical Properties.**—The most notable electrical property of plastics is that they are good insulators, but there are many other electrical properties that must be considered in plastics part design.

*Conductivity* in solids depends on the availability and mobility of movable charge carriers within the material. Metals are good conductors because the metal atom has a loosely held, outermost electron, and the close proximity of the atoms allows these outer electrons to break free and move within the lattice structure. These free electrons give metals the ability to conduct large currents, even at low voltages. Outer electrons in materials such as glass, porcelain, and plastics are tightly bound to the atoms or molecules so there are no free electrons. Electrical current cannot be conducted and the materials act as insulators.

*Volume resistivity* is the electrical resistance of a material when a current is applied to it. The resistance is measured in ohm-cm. Materials having values above  $10^8$  ohm-cm are considered to be insulators, and materials with values between  $10^8$  and  $10^3$  ohm-cm are considered to be partial conductors. Most plastics have volume resistivity in the range of  $10^{12}$  to  $10^{18}$  ohm-cm.

*Surface resistivity* is a measure of the susceptibility of a material to surface contamination, particularly moisture. The tests use electrodes that are placed on the same side of the material.

*Dielectric strength* is a measure of the voltage required to cause an insulator to break down and allow an electric current to pass and is expressed in volts per 0.001 in. of thickness. Variables that may affect test results include temperature, sample thickness and condition, rate of voltage increase and duration of test, sample contamination, and internal voids.

*Dielectric constant or permittivity* is a dimensionless constant that indicates how easily a material can become polarized by imposition of an electrical field on an insulator. Reversal of the direction of flow of the current results in reversal of the polarization. The dielectric constant is the ratio of the permittivity of the material in normal ambient conditions to the permittivity of a vacuum. Permittivity is important when plastics are used as insulating materials in high-frequency electrical apparatus. Changes in temperature, moisture levels, electrical frequency, and part thickness may affect the dielectric constant.

*Heat dissipation factor* is a measure of heat energy dissipated by rapidly repeated reversals of polarization, as with an alternating current. The dissipation factor may also be thought of as the ratio of heat energy lost compared to that transmitted at a given frequency, often 1 MHz ( $10^6$  cycles/sec). Some dielectric constants and heat dissipation factor values are shown in Table 1.

Arc resistance is the length of time required for an electric arc imposed on the surface of an insulating material to develop a conductive path. Materials that resist such a development are preferred for parts of switchgear and other high-voltage apparatus. Tests are used mostly for thermosetting materials because conductive paths can be formed on such materials from the decomposition products resulting from heating by an electric arc.

**Table 1. Typical Values of Dielectric Constants and Heat Dissipation Factors for Various Thermoplastics at Room Temperature**

| Material      | Dielectric Constant | Heat Dissipation Factor | Material              | Dielectric Constant | Heat Dissipation Factor |
|---------------|---------------------|-------------------------|-----------------------|---------------------|-------------------------|
| Acetal        | 3.7–3.9             | 0.001–0.007             | Polypropylene         | 2.3–2.9             | 0.003–0.014             |
| Acrylic       | 2.1–3.9             | 0.001–0.060             | Polysulfone           | 2.7–3.8             | 0.0008–0.009            |
| ABS           | 2.9–3.4             | 0.006–0.021             | Modified PPO          | 2.4–3.1             | 0.0002–0.005            |
| Nylon 6/6     | 3.1–8.3             | 0.006–0.190             | Polyphenylene sulfide | 2.9–4.5             | 0.001–0.002             |
| Polycarbonate | 2.9–3.8             | 0.0006–0.026            | Polyarylate           | 2.6–3.1             | 0.001–0.022             |
| TP Polyester  | 3.0–4.5             | 0.0012–0.022            | Liquid crystal        | 3.7–10              | 0.010–0.060             |

*Comparative tracking index (CTI)* is another UL test that is similar to the arc resistance test except that the surface to be tested is precoated with an ammonium chloride electrolyte. The test measures the voltage required to cause a conductive path to form between the electrodes, and indicates the arc resistance of a contaminated surface, often found in electrical and electronic equipment.

**End-Use Environmental Considerations.**—The environment that will be encountered by the product is a prime consideration at the design stage. Problems with cracking, crazing, discoloration, loss of properties, melting, or dissolving can be encountered in the presence of high or low temperatures, chemical substances, energy sources, and radiation. Plastics components also are often subjected to processing, assembly, finishing, and cleaning operations before reaching their ultimate environment.

The stress level in the plastics product greatly affects performance. Generally, increased stress levels resulting from injection molding, forming, assembly work, and end-use forces reduce resistance to environmental factors. Although many plastics are hygroscopic and absorption of water results in dimensional and property changes, plastics are widely accepted because of their relative compatibility with the environment compared with metals. Some chemicals attack the polymer chain directly by reaction, resulting in a progres-

sive lowering of the molecular weight of the polymer and changes in the short-term mechanical properties. Others dissolve the material, although high-molecular-weight plastics dissolve very slowly. Swelling, changes in weight and dimensions, and loss of properties are evidence of solvation.

Plasticization may result if the chemical is miscible with the polymer, resulting in loss of strength, stiffness, and creep resistance, and increased impact resistance. The material may swell and warp due to relaxation of molded-in stresses. Environmental stress cracking may cause catastrophic failure when plastics are stressed, even when the product appears to be unaffected by exposure to a chemical.

Chemical compatibility data are obtained from standard test bars exposed to or placed in the chemical of study and tested as previously described for such properties as tensile strength, flexural modulus, dimensional change, weight, and discoloration. Chemical resistance from some commonly used thermoplastics materials are shown in [Table 2](#), but are only general guidelines and cannot substitute for tests on the end product. More extensive tests expose samples to a chemical in the presence of fixed stress or fixed strain distribution along its length, followed by examination for the stress or strain location at which damage begins.

The preceding tests may provide data about chemical compatibility but do not generate reliable information on performance properties for design purposes. The only test that provides such information is the creep rupture test, conducted at appropriate temperatures in the environment that will be encountered by the product, preferably on prototype parts. Plastics are degraded to varying degrees by ultraviolet light, which causes fading, chalking, and embrittlement. Plastics that will resist the action of ultraviolet rays are available on the market.

### Design Analysis

**Structural Analysis.**—Even the simplest plastics parts may be subjected to stresses caused by assembly, handling, temperature variations, and other environmental effects. Simple analysis using information in *Moment of Inertia* starting on page [236](#) and *Beam Calculations* on page [260](#) can be used to make sure that newly designed parts can withstand these stresses. These methods may also be used for product improvement, cost reduction, and failure analysis of existing parts.

**Safety Factors:** In setting safety factors for plastics parts there are no hard and fast rules. The most important consideration is the consequence of failure. For example, a little extra deflection in an outside wall or a crack in one of six internal screw bosses may not cause much concern, but the failure of a pressure vessel or water valve might have serious safety or product liability implications. Tests should be run on actual parts at the most extreme operating conditions that could possibly be encountered before any product is marketed. For example, maximum working load should be applied at the maximum temperature and in the presence of any chemicals that might be encountered in service. Loads, temperatures, and chemicals to which a product may be exposed prior to its end use also should be investigated. Impact loading tests should be performed at the lowest temperature expected, including during assembly and shipping. Effects of variations in resin lots and molding conditions must also be considered.

Failures in testing of preproduction lots often can be corrected by increasing the wall thickness, using ribs or gussets, and eliminating stress concentrations. Changing the material to another grade of the same resin or to a different plastics with more suitable mechanical properties is another possible solution. Reviews of product data and discussions with experienced engineers suggest the design stresses shown in [Table 3](#) are suitable for use with the structural analysis information indicated above and the equations presented here, for preliminary design analysis and evaluating general product dimensions. Products designed under these guidelines must be thoroughly tested before being marketed.

**Table 2. Chemical Resistance of Various Materials by Chemical Classes**

|                                     | Polyarylate                   |   |   |   |   |   |   |   |   |   | Polycarbonate                |   |   |   |   |   |   |   |   |  |
|-------------------------------------|-------------------------------|---|---|---|---|---|---|---|---|---|------------------------------|---|---|---|---|---|---|---|---|--|
|                                     | Polyphenylene Sulfide*        |   |   |   |   |   |   |   |   |   | Polysulfone*                 |   |   |   |   |   |   |   |   |  |
|                                     | Liquid Crystal Polymer*       |   |   |   |   |   |   |   |   |   | Modified Polyphenylene Oxide |   |   |   |   |   |   |   |   |  |
|                                     | Polyester Elastomer           |   |   |   |   |   |   |   |   |   | Polypropylene                |   |   |   |   |   |   |   |   |  |

This information is presented for instructional purposes and is not intended for design. The data were extracted from numerous sources making consistent rating assignments difficult. Furthermore, the response of any given material to specific chemicals in any one class can vary significantly. Indeed, during the preparation of the table, the effect on one plastics of various chemicals in the same category ranged from essentially no effect to total dissolution. Therefore, an "A" rating for a particular plastics exposed to a particular class of chemicals should not be interpreted as applying to all chemicals in that class. The rating simply means that for the chemicals in that class found in the literature reviewed, the rating was generally an "A." There may be other chemicals in the same class for which the rating would be "C." Finally, the typical chemicals listed do not necessarily correspond to the ones on which the individual ratings are based.

A—minimal effect; B—some effect; C—generally not recommended.  
 Room temperature except for hot water, steam, and materials marked with a \* = 200°. Generally, extended exposure (more than a week) data were used.

**Table 3. Design Stresses for Preliminary Part Designs Expressed as a Percentage of Manufacturers' Data Sheet Strength Values**

|                                   | Failure Not Critical | Failure Critical |
|-----------------------------------|----------------------|------------------|
| Intermittent (Nonfatigue) loading | 25–50                | 10–25            |
| Continuous loading                | 10–25                | 5–10             |

*Failure Criteria:* Setting of failure criteria is beyond the scope of this section, which is intended to give only basic general information on plastics. Designers who wish to rationalize complex stress states and analyses might investigate the maximum shear theory of failure (otherwise known as Coulomb or Tresca theory). It is further suggested that the shear strength be taken as the manufacturer's published shear strength, or half the tensile strength, whichever is lower. Better still, use half the stress at the elastic limit, if known.

*Pressure Vessels:* The most common plastics pressure vessel takes the form of a tube with internal pressure. In selecting a wall thickness for the tube, it is convenient to use the thin-wall hoop stress equation:

$$\text{hoop stress } \sigma = \frac{Pd}{2t} \quad (14)$$

where  $P$  = the uniform internal pressure in the tube,  $d$  = inside diameter of the tube, and  $t$  = the tube wall thickness. This equation is reasonably accurate for tubes where the wall thickness is less than 0.1 of the inside diameter of the tube. As the wall thickness increases, the error becomes quite large.

For thick-walled tubes the maximum hoop stress on the wall surface inside the tube can be calculated from

$$\text{hoop stress } \sigma = P \frac{1+R}{1-R} \quad (15)$$

where  $R = (d_i/d_o)^2$ , and  $d_i$  and  $d_o$  are the inside and outside diameters of the tube, respectively.

*Press Fits:* Press fits are used widely in assembly work for speed and convenience, although they sometimes are unsatisfactory with thermoplastics parts. Common applications are to a plastics hub or boss accepting a plastics or metal shaft or pin. Forcing the pin into the hole expands the hub, creating a tensile or hoop stress.

If the interference is too great, very high strain and stress develop and the plastics part will: a) fail immediately by developing a crack parallel to the hub axis to relieve the stress, a typical hoop stress failure; b) survive assembly but fail prematurely due to creep rupture caused by the high induced-stress levels; and c) undergo stress relaxation sufficient to reduce the stress to a level that can be sustained.

For a typical press fit, the allowable design stress depends on the particular plastics material, temperature, and other environmental considerations. Hoop stress equations for such a design make use of a geometry factor  $\gamma$ :

$$\gamma = \frac{1 + (d_s/d_o)^2}{1 - (d_s/d_o)^2} \quad (16)$$

where  $d_s$  = diameter of the pin to be inserted and  $d_o$  = outside diameter of the boss.

When both the shaft and the hub are of the same, or essentially the same, materials, the hoop stress  $\sigma$ , given the diametral interference,  $i = d_s - d_i$ , is

$$\sigma = \frac{i}{d_s} E_p \frac{\gamma}{\gamma + 1} \quad (17)$$

and the allowable interference  $i_a$ , given the permissible design stress  $\sigma_a$ , is

$$i_a = d_s \frac{\sigma_a}{E_p} \frac{\gamma + 1}{\gamma} \quad (18)$$

When the shaft is metal and the hub is plastics, the hoop stress, given  $i$ , is obtained from

$$\sigma = \frac{i}{d_s} E_p \frac{\gamma}{\gamma + \nu_p} \quad (19)$$

and the allowable interference  $i_a$ , given the permissible design stress for plastics  $\sigma_a$ , is

$$i_a = d_s \frac{\sigma_a}{E_p} \frac{\gamma + \nu_p}{\gamma} \quad (20)$$

where  $E_p$  = modulus of elasticity of plastics and  $\nu_p$  = Poisson's ratio for plastics.

**Pipe Threads:** Pipe threads on plastics pipes and other parts used in plastics plumbing and pneumatic assemblies require only hand tight assembly to effect a good seat, especially if a compatible sealant tape or compound is used. Assembling a tapered male pipe thread into a mating female thread in a plastics part is analogous to driving a cone into a round hole and may result in a split boss. Sometimes straight threads and an O-ring seal can avoid the need for pipe threads. When pipe threads must be used, torque control is essential.

When mating metal to plastics pipe threads, the threaded plastics component should be the male member, so that the plastics are in compression. If torque can be controlled during assembly, use fluoroplastics tape on female plastics pipe threads. If torque cannot be controlled, consider using an external hoop ring, either pressed on or molded in. Do not design flats into plastics parts for assembly purposes, because they will encourage overtightening. If some provision for improved gripping must be made, use wings or a textured surface. An approximate formula for the hoop stress  $\sigma$  produced in a plastics boss with internal pipe threads is

$$\sigma = \frac{3T}{tdL} \quad (21)$$

where  $T$  = torque in in.-lb,  $t$  = wall thickness of the plastics boss in in.,  $d$  = pipe outside diameter in in., and  $L$  = length of thread engagement in in.

This equation assumes certain geometric relationships and a coefficient of friction of 0.15. If compatible thread lubricants are used during assembly, the torque must be reduced. To ensure safety and reliability, all threaded assemblies must be subjected to long-term testing under operating pressures, temperatures, and stresses caused by installation procedures exceeding those likely to be encountered in service.

**Thermal Stresses.**—When materials with different coefficients of thermal expansion are bolted, riveted, bonded, crimped, pressed, welded, or fastened by any method that prevents relative movement between the parts, there is potential for thermal stress to exist. Typical examples are joining of nonreinforced thermoplastics parts with materials such as metals, glass, or ceramics that usually have much lower coefficients of thermal expansion. The basic relationship for thermal expansion is

$$\Delta L = \alpha L \Delta T \quad (22)$$

where  $\Delta L$  = change in length,  $\alpha$  = coefficient of thermal expansion (see page 402),  $L$  = linear dimension under consideration (including hole diameters), and  $\Delta T$  = temperature change.

If the plastics component is constrained so that it cannot expand or contract, the strain  $\epsilon_T$ , induced by a temperature change, is calculated by

$$\epsilon_T = \frac{\Delta L}{L} = \alpha \Delta T \tag{23}$$

The stress can then be calculated by multiplying the strain  $\epsilon_T$  by the tensile modulus of the material at the temperature involved. A typical example is of a plastics part to be mounted to a metal part, such as a window in a housing. Both components expand with changes in temperature. The plastics imposes insignificant load to the metal but considerable stress is generated in the plastics. For such an example, the approximate thermal stress  $\sigma_T$  in the plastics is given by

$$\sigma_T = (\alpha_m - \alpha_p) E_p \Delta T \tag{24}$$

where  $\alpha_m$  = coefficient of thermal expansion of the metal,  $\alpha_p$  = coefficient of thermal expansion of the plastics, and  $E_p$  = tensile modulus of the plastics at the temperature involved.

Other equations for thermal expansion in various situations are shown in Fig. 7.

Most plastics expand more than metals with temperature increases and their modulus drops. The result is a compressive load in the plastics that often results in buckling. Conversely, as the temperature drops, the plastics shrinks more than the metal and develops an increased tensile modulus. These conditions can cause tensile rupture of the plastics part. Clearances around fasteners, warpage, creep, or failure, or yield of adhesives tend to relieve the thermal stress. Allowances must be made for temperature changes, especially with large parts subjected to wide variations. Provision is often made for relative motion  $\Delta L_{rel}$ , between two materials, as illustrated in Fig. 7:

$$\Delta L_{rel} = (\alpha_p - \alpha_m) L \Delta T \tag{25}$$

Fig. 7. Thermal Expansion Equations for Various Combinations of Materials and Situations

**Design for Injection Moldings.**—Injection molding uses equipment similar to that for die casting, in that a precision steel mold is clamped shut, and melted material (here, plasticized plastics) is forced into the cavity between the mold components. The pelletized plastics material is fed into a heated chamber, or barrel, by a large, slowly rotating screw,

and is melted. When a sufficient quantity to fill the cavity has been prepared, the screw is moved axially under high pressure to force the material into the cavity. The mold has channels through which coolant is circulated to remove heat and to chill the plastics. When the plastics has cooled sufficiently, the mold is unclamped and opened, and the molding is forced out by strategically located ejectors. During cooling and removal, material for the next part is plasticized within the barrel, ready for the cycle to be repeated.

Product analysis provides a good approach to design for plastics molding. A basic principle of plastics molding design, when moldings are being substituted for parts made by other means, is to incorporate as many functions into the molding as possible, especially those requiring nuts, bolts, and washers, for instance. Material should be selected that fulfills the maximum requirements, such as the functions mentioned, as well as insulation from the passage of heat or electricity, and allows use of the minimum amount of material.

Important material selection criteria include ability to withstand the heat of assembly, finishing, shipping, operating, and heat from internal sources. Effects of chemicals in the environment and approvals of government and other agencies also should be checked. Many such approvals specify wall thicknesses, color additives, fillers, and operating temperatures. Plans for assembly by bonding may dictate use of certain materials, and the question of painting, plating, or other surface coatings must be considered. Cost of candidate materials compared with the alternatives must be weighed, using the formula for cost per in.<sup>3</sup> = 0.0361 × specific gravity × material cost per lb. Material cost required for a part is obtained by multiplying the cost per in.<sup>3</sup> by the part volume. A rough estimate of likely part cost is double the cost of material for the part.

**Wall Thicknesses:** The thickness of material used in a plastics molding is of the greatest importance, and should be settled before the mold is made, since modifications are costly. In general, wall thicknesses should be kept as thin as practical and as uniform as possible. Ideally, the flow of molding material should be so arranged that it moves through thicker sections into thinner ones rather than the reverse. Geometric, structural, or functional needs may prevent ideal design, but examination of alternatives can often prevent problems from arising. Most injection-molded plastics parts range in thickness from  $\frac{1}{32}$  to  $\frac{3}{16}$  in. (0.8 to 4.8 mm) with the dimensions within that range related to the total size of the part.

**Impact Resistance:** The impact resistance of a plastics part is directly related to its ability to absorb mechanical energy without fracture or deformation, and this ability depends on the material properties and the part geometry. Increasing wall thickness may improve the impact resistance but may also hurt impact resistance by making the part too stiff so that it is unable to deflect and distribute the force.

Fig. 8. Typical Spiral-Flow Curves for (1) Nylon 6/6, (2) Polyester Thermoplastics PBT, Liquid-Crystal-Glass-Reinforced, and Polyphenylene-Sulfide-Glass-Reinforced, (3) Acetal Copolymer, and (4) PBT-Glass-Reinforced Plastics Materials

Design engineers must also have some knowledge of mold design and, in determining wall thickness, should consider the ability of plastics to flow into the narrow mold channels. This flowability depends on temperature and pressure to some extent, but varies for different materials, as shown in Fig. 8.

Table 4 shows typical nominal wall thicknesses for various types of thermoplastics.

**Table 4. Typical Nominal Wall Thicknesses for Various Classes of Thermoplastics**

| Thermoplastics Group                  | Typical Working Range (in.) | Thermoplastics Group        | Typical Working Range (in.) |
|---------------------------------------|-----------------------------|-----------------------------|-----------------------------|
| Acrylonitrile-butadiene-styrene (ABS) | 0.045–0.140                 | Polyester elastomer         | 0.025–0.125                 |
| Acetal                                | 0.030–0.120                 | Polyethylene                | 0.030–0.200                 |
| Acrylic                               | 0.025–0.150                 | Polyphenylene sulfide       | 0.020–0.180                 |
| Liquid-crystal polymer                | 0.008–0.120                 | Polypropylene               | 0.025–0.150                 |
| Long-fiber-reinforced plastics        | 0.075–1.000                 | Polystyrene                 | 0.035–0.150                 |
| Modified polyphenylene ether          | 0.045–0.140                 | Polysulfone                 | 0.050–0.150                 |
| Nylon                                 | 0.010–0.115                 | Polyurethane                | 0.080–0.750                 |
| Polyarylate                           | 0.045–0.150                 | Polyvinyl chloride (PVC)    | 0.040–0.150                 |
| Polycarbonate                         | 0.040–0.150                 | Styrene-acrylonitrile (SAN) | 0.035–0.150                 |
| Polyester                             | 0.025–0.125                 | ...                         | ...                         |

If the plastics part is to carry loads, load-bearing areas should be analyzed for stress and deflection. When stress or deflection is too high, solutions are to use ribs or contours to increase section modulus; to use a higher-strength, higher-modulus (fiber-reinforced) material; or to increase the wall thickness if it is not already too thick. Where space allows, adding or thickening ribs can increase structural integrity without thickening walls.

Equations (11), (12), and (13) can be related to formulas using the section modulus and moment of inertia on page 261, where Case 2, for (i), stress at the beam center is given by  $\sigma = -W/4Z$ .

On page 260, note that  $Z = I \div$  distance from neutral axis to extreme fiber ( $h \div 2$  in the plastics example). The rectangular beam section diagrammed on page 239 gives the equivalent of  $I = bh^3/12$  for the rectangular section in the plastics example. Therefore,

$$Z = \frac{I}{h/2} = \frac{bh^3}{12} \times \frac{2}{h} = \frac{bh^2}{6}$$

In  $\sigma = -W/4Z$ , the (–) sign indicates that the beam is supported at the ends, so that the upper fibers are in compression and the lower fibers are in tension. Also,  $W = F$  and  $l = L$  in the respective equations, so that stress,  $\sigma = FL/4(bh^2)/6$ , and  $\sigma = 3FL/2bh^2$ .

To calculate (ii) maximum deflection  $Y$  at load, use  $Y = Wl^3/48EI$  from page 261, where  $W = F$ ,  $l = L$ ,  $E = E$ , from Equation (12) and  $I = bh^3/12$ . Therefore,

$$Y = \frac{FL^3}{48E(bh^2/12)} = \frac{FL^3}{4Ebh^3}$$

As an example, assume that a beam as described in connection with Equations (11), (12), and (13) is 0.75 in. wide, with a constant wall thickness of 0.080 in., so that the cross-sectional area is 0.060 in.<sup>2</sup>, and there is a central load  $W$  of 5 lb. Based on a bending or flexural modulus of 300,000 lb/in.<sup>2</sup>, the maximum stress is calculated at 6250 lb/in.<sup>2</sup> and the maximum deflection at 0.694 in. Both the stress and the deflection are too high, so a decision is made to add a rib measuring 0.040 in. thick by 0.400 in. deep, with a small draft of  $\frac{1}{2}$  degree per side, to reinforce the structure.

The equations on page 261, the drawing page 245 representing the ribbed section (neglecting radii), and the accompanying formulas, permit calculation of the maximum stress and deflection for the ribbed section.

With the new cross-sectional area only slightly larger at 0.0746 in.<sup>2</sup>, the calculated stress is reduced to 2270 lb/in.<sup>2</sup>, and the deflection goes down to 0.026 in., which is acceptable for both the material and the application. To achieve the same result from a heavier beam would require a thickness of 0.239 in., tripling the weight of the beam and increasing molding difficulties. The rib adds only 25 percent to the total section weight.

Use of ribs allows the structural characteristics of a part to be tailored to suit its function, but ribs can cause warping and appearance problems, so are best avoided if they are not structurally necessary. If the first parts produced require strengthening, ribs can be added or thickened without high cost after the tool is finished because the work consists only of removing steel from the mold. In general, ribs should have a base thickness of about half the thickness of the adjacent wall, and be kept as thin as possible where they are positioned near faces that need to have a good appearance.

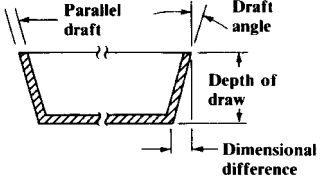

Where structural strength is more important than appearance, or when using materials that have low shrinkage, ribs can be made 75 or 100 per cent of the wall thickness. However, where the rib base joins the main molding there is an increase in thickness forming a heavy mass of material. Shrinkage of this mass can produce a cavity or void, a hollow area or sink, or can distort the molding. If the mass is very large, cooling time may be prolonged, leading to low output from the machine. Large masses of material in other parts of a molding are also best avoided. These problems can usually be addressed by good mold design.

Ribs need not be of constant height or width, and are often varied in proportions to suit the stress distribution in the part. All ribs should have a minimum of  $\frac{1}{2}$  degree of draft per side for ease of removal from the mold, and a minimum radius of 0.005 in. at the base to avoid stress-raising corners. Draft and thickness requirements will usually limit the height of the rib, which can be from 1.5 to 5 times the base thickness, and several evenly spaced ribs are generally preferred to a single large one. Smooth transitions should be made to other structural features such as bosses, walls, and pads.

Other ways to improve section properties include use of top-hat and corrugated sections, crowning or doming of some areas, and reinforcement with metal or other inserts that are placed in the mold before it is closed. To keep molded parts uniform in wall thickness, cores or projections may be provided in the mold to prevent a space being filled with molding material. Blind holes can be cored by pins that are supported on only one side of the mold and through holes by pins that pass through both sides. The length to width ratio should be kept as low as possible to prevent bending or breakage under the high pressures used in the injection molding process.

Agency approvals for resistance to flammability or heat, electrical properties, or other characteristics are usually based on specific wall thicknesses. These restrictions sometimes necessitate thicker walls than are required for structural strength purposes.

**Draft:** Most molded parts have features that must be cut into the mold perpendicular to the parting line. Removal of these parts from the mold is easier if they are tapered in the direction of mold opening. This taper is called draft in the line of draw or mold movement, and it allows the part to break free of the mold by creating a clearance as soon as the mold starts to open. Plastics materials shrink as they cool, so they grip mold projections very tightly and ejection can be difficult without sufficient draft. A draft of  $\frac{1}{2}$  degree on each side of a projection on the part is generally considered as a minimum, although up to 3 degrees per side is often used. Draft angles in degrees for various draw depths, and the resulting dimensional changes per side in inches (rounded to three decimal places), between the dimensions at the base and at the top of a projection are shown in [Table 5](#). A rule of thumb is that 1 degree of draft yields 0.017 in. of difference in dimension per inch of draw length. Where a minimum of variation in wall thickness is needed to produce walls that are perpendicular to the direction of draw, the mold sometimes can be designed to produce parallel draft, as seen at the left in [Table 5](#). The amount of draft required also depends

**Table 5. Dimensional Changes for Various Combinations of Draft Angles and Draw Depths (Values to Nearest 0.001 in.)**

The diagram illustrates a tapered cylindrical part. The top surface is labeled 'Parallel draft'. The angle between the vertical axis and the slanted side is labeled 'Draft angle'. The vertical height of the part is labeled 'Depth of draw'. The horizontal distance between the top and bottom edges of the part is labeled 'Dimensional difference'.

| Draw Depth (in) | Draft Angle (degrees) |               |               |       |       |       |       |       |
|-----------------|-----------------------|---------------|---------------|-------|-------|-------|-------|-------|
|                 | $\frac{1}{8}$         | $\frac{1}{4}$ | $\frac{1}{2}$ | 1     | 2     | 3     | 4     | 5     |
| 1               | 0.002                 | 0.004         | 0.009         | 0.017 | 0.035 | 0.052 | 0.070 | 0.080 |
| 2               | 0.004                 | 0.009         | 0.017         | 0.035 | 0.070 | 0.105 | 0.140 | 0.175 |
| 3               | 0.007                 | 0.013         | 0.026         | 0.053 | 0.105 | 0.157 | 0.210 | 0.263 |
| 4               | 0.009                 | 0.018         | 0.035         | 0.070 | 0.140 | 0.210 | 0.280 | 0.350 |
| 5               | 0.011                 | 0.022         | 0.044         | 0.088 | 0.175 | 0.262 | 0.350 | 0.437 |
| 6               | 0.013                 | 0.026         | 0.052         | 0.105 | 0.209 | 0.314 | 0.420 | 0.525 |
| 7               | 0.015                 | 0.031         | 0.061         | 0.123 | 0.244 | 0.367 | 0.490 | 0.612 |
| 8               | 0.018                 | 0.035         | 0.070         | 0.140 | 0.279 | 0.419 | 0.559 | 0.700 |
| 9               | 0.020                 | 0.040         | 0.078         | 0.158 | 0.314 | 0.472 | 0.629 | 0.787 |
| 10              | 0.022                 | 0.044         | 0.087         | 0.175 | 0.349 | 0.524 | 0.699 | 0.875 |

on the surface finish of the mold walls. Any surface texture will increase the draft requirement by at least 1 degree per side for every 0.001 in. of texture depth.

**Fillets, Radii, and Undercuts:** Sharp corners are always to be avoided in injection-molded part designs because they represent points of stress concentration. Sharp corners in metal parts often are less important because the stresses are low compared with the strength of the material or because local yielding redistributes the loads. Sharp inside corners are particularly to be avoided in moldings because severe molded-in stresses are generated as the material shrinks onto the mold corner. Sharp corners also cause poor material flow patterns, reduced mechanical properties, and increased tool wear. Therefore, inside corner radii should be made equal to half the nominal wall thickness, with a minimum of 0.020 in. for parts subject to stress and 0.005 in. radius for stress-free parts. Outside corners should have a radius equal to the inside corner radius plus the wall thickness.

With an inside radius of half the wall thickness, a stress concentration of 1.5 is a reasonable assumption, and for radii down to 0.1 times the wall thickness, a stress concentration of 3 is likely. More information on stress concentrations is found in *Working Stress* on page 208, *Stress Concentration Factors* on page 209, and in the charts pages 209 through 212. A suitable value for  $q$  in Equation (8) on page 209, for plastics materials, is 1. Most plastics parts are so designed that they can be ejected parallel with the direction of mold parting. Complex parts with undercuts may require mold designs with cavity-forming projections that must move at an angle to the direction of opening. Between these two extremes lie such items as "windows," or simple openings in the side of a molding, which can be produced by the normal interaction of the two main parts of the mold.

**Design for Assembly.**—An advantage of the flexibility of plastics parts is that they can often be designed for assembly by means of molded-in snap-fit, press-fit, pop-on, and thread fasteners, so that no additional fasteners, adhesives, solvents, or special equipment is required. Improper assembly can be minimized, but tooling is often made more complex and disassembly may be difficult with these methods.

*Chemical bonding* involves fixtures, substances, and safety equipment, is suited to applications that must be leak-tight, and does not create stresses. However, adhesives and solvents can be dangerous and preparation and cure times can be prolonged.

*Thermal welding* methods include ultrasonic, hot-plate, spin, induction, and radio-frequency energy and require special equipment. Thermal methods are also used for staking, swaging, and other heat deformation procedures. Materials must be compatible and have similar melting temperatures.

*Mechanical fasteners* designed for metals are generally usable with plastics, and there are many other fasteners designed specifically for plastics. Typical are bolts, self-tapping and thread-forming screws, rivets, threaded inserts, and spring clips. Care must be taken to avoid overstressing the parts. Creep can result in loss of preload in poorly designed systems.

*Snap-fit* designs are widely used, a typical application being to battery compartment covers. All snap-fit designs have a molded part that must flex like a spring, usually past a designed-in interference, then return to its unflexed position to hold the parts together. There must be sufficient holding power without exceeding the elastic or fatigue limits of the material. With the typical snap-fit designs in Fig. 9, beam equations can be used to calculate the maximum strain during assembly. If the stress is kept below the yield point of the material, the flexing finger returns to its original position.

Fig. 9. Snap-fit Designs for Cantilever Beams with Rectangular Cross Sections

With some materials the calculated bending stress can exceed the yield point stress considerably if the movement is done rapidly. In other words, the flexing finger passes through its maximum deflection or strain and the material does not respond as it should if the yield stress has been greatly exceeded. It is common to evaluate snap-ins by calculating strain instead of stress.

Dynamic strain  $\epsilon$ , for the straight beam, is calculated from

$$\epsilon = \frac{3Yh_0}{2L^2} \quad (26)$$

and for the tapered beam, from

$$\epsilon = \frac{3Yh_o}{2L^2K} \quad (27)$$

The derived values should be compared with the permissible dynamic strain limits for the material in question, if known. A tapered finger provides more-uniform stress distribution and is recommended where possible. Sharp corners or structural discontinuities that will cause stress concentrations on fingers such as those shown must be avoided.

Snap-in arrangements usually require undercuts produced by a sliding core in the mold as shown in Fig. 10a. Sometimes the snap finger can be simply popped off when the mold is opened. An alternative to the sliding core is shown in Fig. 10b, which requires an opening in the molding at the base of the flexing finger. Other snap-in assembly techniques that take advantage of the flexibility of plastics are shown in Fig. 11.

Molded-in threads in holes usually are formed by cores that require some type of unscrewing or collapsing mechanism leading to tooling complications. External threads can often be molded by positioning them across the parting plane of the mold. Molding of threads finer than 28 to the inch is generally not practical.

Fig. 10. (left) (a) Arrangement for Molding an Undercut on the End of a Flexible Finger Using a Sliding Core; (b) With the Undercut Formed by a Mold Projection, the Sliding Core is Eliminated.

Fig. 11. (right) Examples of Snap-In and Snap-On Arrangements

Chemical bonding may use solvents or adhesives. Use of solvents is limited to compatible materials that can be dissolved by the same solvent. Chemical resistance of many plastics, especially crystalline materials, limits the use of this method. Safety precautions must also be considered in handling the solvents to protect workers and for solvent recovery.

With adhesive bonding, a third adhesive substance is introduced at the interface between the parts to be joined. Adhesives can join plastics, metals, ceramics, glass, wood, or other bondable substances.

Typical adhesives used for thermoplastics are epoxies, acrylics, polyurethanes, phenolics, rubbers, polyesters, and vinyls. Cyanoacrylates are often used because of their rapid adhesion to many materials. Manufacturers' recommendations should be sought because many adhesives contain solvents that partially dissolve the plastics surfaces, giving improved adhesion. However, some adhesives can attack certain plastics, leading to deterioration and failure. The main disadvantages of adhesives are that they are slow, use long clamp times, require fixtures, and may involve special ovens or curing conditions. Surface preparation also may be difficult because the presence of grease, oil, mold-release material, or even a fingerprint can spoil a bond. Some materials may need surface preparation such as chemical etching or mechanical roughening to improve joint strength.

Ultrasonic welding is frequently used for joining parts of similar material, of small and medium size, is rapid, and can be automated. High-frequency (20–40 kHz) vibrational energy is directed to the interfaces to be joined, creating localized molecular excitation that causes the plastics to melt. With proper joint designs, welds can be made in only 2 seconds that are as strong as the base materials. When the energy is switched off, the plastics solidifies immediately. Parts to be welded ultrasonically must be so designed that the energy is concentrated in an initially small contact area, creating rapid melting and melt flow that progresses along the joint as the parts are pressed together. The lower part of the assembly is supported in a rigid nest fixture and the upper part is aligned, usually by the joint design. This upper part has freedom to couple acoustically when it is in contact with the horn through which the ultrasonic energy is transmitted.

Fig. 12. (left) Energy Director Types of Ultrasonic Weld Joint Designs for Assembly of Plastics Moldings, and (right) Typical Shear Interference

Typical joint designs are shown in Fig. 12, where the example at the left is of a simple butt-type energy director design that works well with amorphous materials. The inverted V-projection, known as an energy director, concentrates the energy in a small area on both sides of the joint. This area melts quickly and the material flows as the parts are pressed together. A basic shear interference joint is seen at the right in Fig. 12. Melting of both components starts at the small initial contact area and flow continues along the near-verti-

cal wall as the parts are pressed together, creating a continuous, leakproof joint with a strength that often exceeds that of the parts joined.

This design is preferred with liquid crystal polymers and crystalline materials such as nylon, acetal, and thermoplastics polyester, and for any application of these materials where high strength and a hermetic seal are required. Many variations of these basic designs are possible and manufacturers of materials and ultrasonic equipment offer literature and design assistance. Ultrasonic vibrations may also be used for staking, swaging, and spot-welding in assembly of plastics parts.

With hygroscopic materials, welding should be completed as soon as possible after molding because moisture can cause weaker bonds. Drying may be advisable immediately before welding. Drawbacks with ultrasonic welding are that design, quality control, equipment maintenance, and settings are of critical importance for consistent, high-strength welds; the equipment is costly; the process uses large amounts of electric power especially with large parts; and parts to be joined must be of the same or similar materials. Filled and reinforced materials also present difficulties with compatibility.

Operating frequencies used in ultrasonic welding are in the range of 20–40 kHz, above the range detectable by the ear. However, discomforting sounds may be generated when plastics parts vibrate at lower frequencies, and may make sound-proofing necessary.

Vibration welding resembles ultrasonic welding except that the parts to be joined are rubbed together to produce heat to melt the joint faces by friction. The energy is transferred in the form of high-amplitude, low-frequency, reciprocating motion. When the vibration stops, the weld area cools and the parts remain joined in the alignment provided by the welding fixture. Typical frequencies used are 120–240 Hz and amplitudes range between 0.10 and 0.20 in. of linear displacement. When the geometry or assembly design prevents linear movement, vibration-welding equipment can be designed to produce angular displacement of parts.

Like ultrasonic welding, vibration welding produces high-strength joints and is better suited to large parts and irregular joint faces. Moisture in hygroscopic materials such as nylon has less effect on the joint strength than it does with ultrasonic methods.

Spin welding is a rapid and economical method of joining parts that have circular joint interfaces. The process usually is completed in about 3 seconds and can be automated easily. Frictional heat for welding is generated by rotating one part against the other (usually fixed) with a controlled pressure. When the rotation is stopped, pressure is maintained during cooling and solidification of the melted material. Simple equipment such as a drill press is often sufficient for this process.

Radio-frequency welding, often called heat sealing, is widely used with flexible thermoplastics films and sheets of materials such as vinyl (plasticized PVC) and polyurethane, and for joining injection-molded parts, usually to film. Heat for welding is generated by a strong radio-frequency field to the joint region through a metal die formed to suit the joint shape. The die also applies the pressure required to complete the weld. Some plastics are transparent to radio frequency, so cannot be welded by this method.

Electromagnetic or induction welding uses inductive heating to generate fusion temperatures in thermoplastics materials as shown at the top in Fig. 13. Fine, magnetizable particles embedded in a gasket, preform, filament, ribbon, adhesive, coextruded film, or molded part are excited by the radio frequency and are thus heated to welding temperatures. The heated parts are pressed together, and as the temperature rises, the material of the particle carrier flows under pressure through the joint interface, filling voids and cavities and becoming an integral part of the weld. Ideally, the melted material should be contained and subjected to an internal pressure by the surrounding component surfaces. Proper joint design is essential to successful welding and some basic designs are also shown in Fig. 13.

Requirements of the preform often add cost to this welding method but the cost is offset by low reject rates resulting from good reliability of the welds. Structural, hermetic welds

can be produced in most thermoplastics materials and automation can be used for large-volume production. The process also offers great latitude in joint size, configuration, tolerance requirements, and ability to bond some dissimilar materials. A disadvantage is that no metal can be near the joint line during energization of the inductor coil. All components of an assembly to be induction-welded must therefore be nonmetallic, or metallic components must be placed where they will not be subjected to the radio-frequency field from the inductor.

**Assembly with Fasteners.**—Metal fasteners of high strength can overstress plastics parts, so torque-controlled tightening or special design provisions are needed. Examples of poor and preferred designs are shown in Fig. 14. Where torque cannot be controlled, even with a shoulder screw, various types of washers can be used to spread the compression force over wider areas.

Fig. 13. Typical Joint Designs Used in Induction Welding of Plastics Materials

Metal inserts are available in a wide range of shapes and sizes for permanent installation of metal threads or bushings in plastics parts. Inserts are typically installed in molded bosses, designed with holes to suit the insert to be used. Some inserts are pressed into place and others are installed by methods designed to limit stress and increase strength. Generally, the outside of the insert is provided with projections of various configurations that penetrate the plastics and prevent movement under normal forces exerted during assem-

bly. Inserts can also be installed with equipment similar to that used for ultrasonic welding, the plastics being melted to enhance contact with the metal and reduce insertion stresses.

Thread-cutting and -forming screws are widely used with plastics parts. Information on standard self-threading screws is found in *SELF-THREADING SCREWS* starting on page 1639. Thread-forming screws must be used carefully with high-modulus, low-creep materials, as high hoop stresses can be generated during insertion. Screws with multiple lobes and screws with alternating low and high threads have excellent holding power in plastics. Molded holes must have sufficient depth to prevent bottoming, and boss walls must be thick enough to resist stresses. A rule of thumb is that the outside diameter of the boss should be double the major diameter of the screw.

Hollow aluminum or other metal rivets are often used in plastics assembly, as are stamped sheet metal components, especially push-on or -in designs. Molded plastics fasteners also are frequently used.

Fig. 14. Examples of Poor and Good Designs Used for Assembly of Plastics Parts with Metal Fasteners

**Machining Plastics.**—Plastics can be molded into complex shapes so do not usually need to be machined. However, machining is sometimes more cost-effective than making a complex tool, especially when requirements are for prototype development, low-volume production, undercuts, angular holes, or other openings that are difficult to produce in a mold. Specialized methods for development of prototypes are discussed later. All machin-

ing of plastics requires dust control, adequate ventilation, safety guards, and eye protection.

Like some metals, plastics may need to be annealed before machining to avoid warpage. Specific annealing instructions can be obtained from plastics suppliers. The modulus of elasticity of plastics is 10–60 times smaller than for metals, and this resilience permits much greater deflection of the work material during cutting. Thermoplastics materials must be held and supported firmly to prevent distortion, and sharp tools are essential to keep cutting forces to a minimum.

Plastics recover elastically during and after machining so that drilled or tapped holes often end up tapered or of smaller diameter than the tool. Turned diameters also can end up larger than the dimensions measured immediately after the finishing cut. The low thermal conductivity of plastics causes most of the heat generated in cutting to be absorbed by the tool. Heat in the plastics tends to stay at the surface. The heat must be removed by an air blast or a liquid coolant for good results in machining.

Plastics have thermal expansion coefficients some 10 times higher than those of metals, so that more heat is generated during machining than with metals. Adequate tool clearances must be provided to minimize heating. Compared with metals, temperatures at which plastics soften, deform and degrade are quite low. Allowing frictional heat to build up causes gumming, discoloration, poor tolerance control, and rough finishes. These effects are more pronounced with plastics such as polystyrene and polyvinyl chloride, having low melting points, than with plastics having higher melting points such as nylon, fluoroplastics, and polyphenylene sulfide. Sufficient clearances must be provided on cutting tools to prevent rubbing contact between the tool and the work. Tool surfaces that will come into contact with plastics during machining must be polished to reduce frictional drag and resulting temperature increases. Proper rake angles depend on depth of cut, cutting speed, and type of plastics being cut. Large rake angles should be used to produce continuous-type cuttings, but they should not be so large as to cause brittle fracture of the work, and resulting discontinuous chips. A discussion of machining techniques follows.

*Turning and Cutting Off:* High speed steel and carbide tools are commonly used with cutting speeds of 200–500 and 500–800 ft/min, respectively. Water-soluble coolants can be used to keep down temperatures at the shear zone and improve the finish, except when they react with the work material. Chatter may result from the low modulus of elasticity and can be reduced by close chucking and follow rests. Box tools are good for long, thin parts. Tools for cutting off plastics require greater front and side clearances than are needed for metal. Cutting speeds should be about half those used for turning operations.

*Drilling:* Chip flow in drilling is poor, the rake angles are insufficient and cutting speeds vary from the center to the periphery of the drill, so that drilling imposes severe loading on the workpiece. Drills of high speed steel or premium high speed steel (T15, M33, or M41–M47) are recommended, with low helix angles, point angles of 70–120 deg, and wide, highly polished flutes to ease chip exit. Normal feed rates are in the range of 0.001–0.012 in./rev for holes of  $\frac{1}{16}$  to 2 in. diameter, with speeds of 100–250 ft/min, using lower speeds for deep and blind holes. Point angles of 60–90 deg (included) are used for many plastics, but an angle of 120 deg should be used for rigid polyvinyl chloride and acrylic (polymethyl methacrylate).

Clearance angles of 9–15 deg are usually sufficient to prevent the drill flanks from rubbing in the bottom of the hole, but acrylic materials require angles of 12–20 deg. Tests may be needed to determine the drill diameter for accurately sized holes, taking thermal expansion and elastic recovery into account. Reaming may be used to size holes accurately, but diameters produced may also be affected by thermal expansion of the plastics. Close-fitting bushings in drill jigs may increase friction on the drill and cause chips to plug up the drill flutes. For positioning accuracy, removable templates may be used to spot the hole position, then removed for the drilling to be completed. Pilot holes are not necessary,

except when the hole is to be reamed or counterbored. Peck feeds to remove chips and compressed air cooling may be needed, especially for deep holes.

Drilling and reaming speed and feed recommendations for various materials are shown in Table 6.

These speeds and feeds can be increased where there is no melting, burning, discoloration, or poor surface finish. Drilling is best done with commercially available drills designed for plastics, usually having large helix angles, narrow lands, and highly polished or chromium-plated flutes to expel chips rapidly and minimize frictional heating. Circle cutters are often preferred for holes in thin materials. Deep holes may require peck feeds. Drills must be kept sharp and cool, and carbide tools may be needed in high production, especially with glass-reinforced materials. Cool with clean compressed air to avoid contamination. Use aqueous solutions for deep drilling because metalcutting fluids and oils may degrade or attack the plastics and may cause a cleaning problem. Hold plastics parts firmly during drilling to counter the tendency for the tooling to grab and spin the work.

**Table 6. Speeds and Feeds for Drilling Holes of 0.25 to 0.375 in. Diameter in Various Thermoplastics**

| Material                | Speed (rpm) | Feed <sup>a</sup> | Comments                     |
|-------------------------|-------------|-------------------|------------------------------|
| Polyethylene            | 1,000–2,000 | H                 | Easy to machine              |
| Polyvinyl chloride      | 1,000–2,000 | M                 | Tends to become gummy        |
| Acrylic                 | 500–1,500   | M–H               | Easy to drill with lubricant |
| Polystyrene             | 500–1,500   | H                 | Must have coolant            |
| ABS                     | 500–1,000   | M–H               |                              |
| Polytetrafluoroethylene | 1,000       | L–M               | Easy to drill                |
| Nylon 6/6               | 1,000       | H                 | Easy to drill                |
| Polycarbonate           | 500–1,500   | M–H               | Easy to drill, some gumming  |
| Acetal                  | 1,000–2,000 | H                 | Easy to drill                |
| Polypropylene           | 1,000–2,000 | H                 | Easy to drill                |
| Polyester               | 1,000–1,500 | H                 | Easy to drill                |

<sup>a</sup> H = high; M = medium; L = low.

*Tapping and Threading of Plastics:* Many different threaded fasteners can be used with plastics, including thread-tapping and -forming screws, threaded metal inserts, and molded-in threads, but threads must sometimes be machined after molding. For tapping of through-holes in thin cast, molded, or extruded thermoplastics and thermosets, a speed of 50 ft/min is appropriate. Tapping of filled materials is done at 25 ft/min. These speeds should be reduced for deep or blind holes, and when the percentage of thread is greater than 65–75 per cent. Taps should be of M10, M7, or M1, molybdenum high-speed steel, with finish-ground and -polished flutes. Two-flute taps are recommended for holes up to 0.125 in. diameter. Oversize taps may be required to make up for elastic recovery of the plastics. The danger of retapping on the return stroke can be reduced by blunting the withdrawal edges of the tool.

*Sawing Thermoset Cast or Molded Plastics:* Circular or band saws may be used for sawing. Circular saws provide smoother cut faces than band saws, but band saws run cooler so are often preferred even for straight cuts. Projection of the circular saw above the table should be minimized. Saws should have skip teeth or buttress teeth with zero front rake and a raker set. Precision-tooth saw blades should be used for thicknesses up to 1 in., and saws with buttress teeth are recommended for thicknesses above 1 in. Dull edges to the teeth cause chipping of the plastics and may cause breakage of the saw. Sawing speeds and other recommendations for using blades of high-carbon steel are shown in the accompanying table.

### Speeds and Numbers of Teeth for Sawing Plastics Materials with High-Carbon Steel Saw Blades

| Material Thickness (in.) | Number of Teeth on Blade | Peripheral Speed (ft/min)         |   |
|--------------------------|--------------------------|-----------------------------------|---|
|                          |                          | Thermoset Cast or Molded Plastics | Thermoplastics (and Epoxy, Melamine, Phenolic and Allyl Thermosets) |
| 0–0.5                    | 8–14                     | 2000–3000                         | 4000–5000   |
| 0.5–1                    | 6–8                      | 1800–2200                         | 3500–4300   |
| 1–3                      | 3                        | 1500–2200                         | 3000–3500   |
| >3                       | >3                       | 1200–1800                         | 2500–3000   |

*Milling of Plastics:* Peripheral cutting with end mills is used for edge preparation, slotting and similar milling operations, and end cutting can also be used for facing operations. Speeds for milling range from 800 to 1400 ft/min for peripheral end milling of many thermoplastics and from 400 to 800 ft/min for many thermosets. However, slower speeds are generally used for other milling operations, with some thermoplastics being machined at 300–500 ft/min, and some thermosets at 150–300 ft/min. Adequate support and suitable feed rates are very important. A table feed that is too low will generate excessive heat and cause surface cracks, loss of dimensional accuracy, and poor surface finish. Too high a feed rate will produce a rough surface. High-speed steel tools (M2, M3, M7, or T15) are generally used, but for glass-reinforced nylon, silicone, polyimide, and allyl, carbide (C2) is recommended.

*New Techniques:* Lasers can be used for machining plastics, especially sheet laminates, although their use may generate internal stresses. Ultrasonic machining has no thermal, chemical, or electrical reaction with the workpiece and can produce holes down to 0.003 in. diameter, tight tolerances (0.0005 in.), and very smooth finishes (0.15  $\mu$ m. with No. 600 boron carbide abrasive powder). Water-jet cutting using pressures up to 60,000 lb/in.<sup>2</sup> is widely used for plastics and does not introduce stresses into the material. Tolerances of  $\pm$  0.004 in. can be held, depending on the equipment available. Process variables, pressures, feed rates, and the nozzle diameter depend on the material being cut. This method does not work with hollow parts unless they can be filled with a solid core.

**Development of Prototypes.**—Prototypes are made for testing of properties such as stress and fatigue resistance, to find ways to improve quality and reliability, to improve tooling, and to reduce time to market. Prototyping may answer questions about finish, sink marks that result from contraction, witness lines from mold joints, ejector pin marks, knit or weld lines, texturing, moldability, shrinkage, mechanical strength, pull-out resistance of inserts, electrical properties, and problems of mating with other parts.

Prototypes of moldings are made in five major steps including design; refining the design; making a model (physical or computer); making a mold; and producing parts. The model may be made from wood, plaster, plastics (by machining), or a metal. Some 90 per cent of prototypes are made by modern CAD/CAM methods that allow holding of dimensional tolerances of 2–3 per cent of drawing specifications.

Prototypes can also be made by a process called stereo lithography that uses a tank of photosensitive liquid polymer, an x-y scanning, ultraviolet laser with a beam diameter of 0.010 in., a z-axis elevator platform, and a controlling computer. The platform height is adjusted so that a suitable thickness of liquid polymer covers its surface. The laser beam is focused on the liquid surface and hardens the polymer at this point by heating.

The CAD representation of the prototype is described by a model in which thin (0.005–0.020 in.) cross sections can be isolated. Data representing the lowest level of the prototype are used to move the platform so that a layer of the polymer corresponding to the lowest “slice” is hardened. The platform is then lowered, the liquid polymer flows over the hard-

ened layer, and the platform is again raised, less an amount equal to the next "slice." The process is repeated for successive "slices" of the prototype, which is thus built up gradually to form a hollow, three-dimensional shape corresponding to the model in the CAD program. The part thus produced is fairly brittle but can be used for visual examination, design verification, and marketing evaluation, and can be replicated from other materials such as plastics or metals by casting or other methods.

Finishing and decorating methods used for plastics parts include spray painting, vacuum metallizing, hot stamping, silk screening, and plating. Conductive coatings may be applied to inside surfaces, usually by flame- or arc-spraying, to dissipate static electricity and provide electromagnetic shielding. Thorough cleaning is essential. Materials such as polyethylene, polypropylene, and acetal have waxlike surfaces that may not be painted easily or may need pretreatment or special primers. Many amorphous plastics are easy to paint. Suitable coatings include polyurethane-, epoxy-, acrylic-, alkyd-, and vinyl-based paints. Oven curing may distort parts made from non-heat-resistant materials.

Vacuum metallizing and sputter-plating require application of a special base coat and a protective clear top coat before and after treatment. Resistance heating or an electron beam can be used to melt the metallizing materials such as aluminum, silver, copper, and gold, which usually are pure elements. Sputter plating uses a plasma to produce the metallic vapor and can use brass as well as the metals mentioned. Chromium plating requires etched surfaces to ensure good adhesion.

Plastics may be polished by buffing methods similar to those used on metals, but experiments to determine the effect of frictional heat are recommended. Surfaces can be heated to 300–400 deg. F by buffing, and some plastics soften and melt at these temperatures. Heating sometimes causes plastics to give off toxic gases, so masks should be worn to filter out such gases and dust. Parting lines, imperfections, scratches, saw lines, and scars resulting from fabrication can be treated with abrasives prior to buffing. Wet or dry abrasives such as silicon carbide or aluminum oxide are generally used, in grain sizes of 60 to as fine as 320. Some buffing compounds are ineffective on plastics. Scratch lines should be presented at a slight angle to the buff surface for best results. Light, tallow-free grease will help keep the abrasive surface free from buildup, and speeds of 5,000 to 6,000 surface feet per minute are recommended.

For low-melting point plastics, soft cotton buffs are best, with surface speeds of 4,000 to 5,000 feet per minute, using a wet or greasy tripoli or silica compound. For finishing, only rouge may be needed for a satisfactory finish. If a cleaning solvent is used it should be checked to see that it does not dissolve the plastics, and it should be used only in a well-ventilated area. Acrylics such as Acrylite or Plexiglass may also be 'flame polished,' under advice from the materials supplier.

**Plastics Gearing.**—Plastics gears may be cut from blanks, as with metal gears, or molded to shape in an injection-molding machine, for lower production costs, though tooling may cost more. Cut plastics gears may be of similar design to their metal counterparts, but molded gears are usually of modified form to suit the material characteristics. Plastics materials also may be preferred for gears because of superior sliding properties with reduced noise and need for lubrication, chemical or electrical properties, or resistance to wear. However, plastics gear teeth slide more smoothly and easily against metal teeth than do plastics against plastics, and wear is less. For power transmission, plastics gear teeth are usually of involute form. See also *Non-metallic Gearing* on page 2149.

Most plastics gears are made from nylons and acetals, although acrylonitrile-butadiene-styrenes (ABS), polycarbonates, polysulfones, phenylene oxides, poly-urethanes, and thermoplastic polyesters can also be used. Additives used in plastics gears include glass fiber for added strength, and fibers, beads, and powders for reduced thermal expansion and improved dimensional stability. Other materials, such as molybdenum disulfide, tetrafluoroethylene (TFE), and silicones, may be added as lubricants to improve wear resistance.

Choice of plastics gear material depends on requirements for size and nature of loads to be transmitted, speeds, required life, working environment, type of cooling, lubrication, and operating precision. Because of cost, plastics gears are sometimes not enclosed in sealed housings, so are often given only a single coating of lubricant grease. Overloading of lubricated plastics gear teeth will usually cause tooth fracture, and unlubricated teeth often suffer excessive wear. Thermoplastics strength varies with temperature, with higher temperatures reducing root stress and permitting tooth deformation. In calculating power to be transmitted by spur, helical, and straight bevel gearing, the following formulas should be used with the factors given in Tables 7, 8, and 9.

For internal and external spur gears,

$$HP = \frac{S_s FYV}{55(600 + V)PC_s} \quad (28)$$

For internal and external helical gears,

$$HP = \frac{S_s FYV}{423(78 + \sqrt{V})P_n C_s} \quad (29)$$

For straight bevel gears,

$$HP = \frac{S_s FYV(C - F)}{55(600 + V)PCC_s} \quad (30)$$

where  $S_s$  = safe stress in bending (from Table 8);  $F$  = face width in inches;  $Y$  = tooth form factor (from Table 7);  $C$  = pitch cone distance in inches;  $C_s$  = service factor (from Table 9);  $P$  = diametral pitch;  $P_n$  = normal diametral pitch; and  $V$  = velocity at pitch circle diameter in ft/min.

**Table 7. Tooth Form Factors  $Y$  for Plastics Gears**

| Number of Teeth | 14½-deg Involute or Cycloidal | 20-deg Full Depth Involute | 20-deg Stub Tooth Involute | 20-deg Internal Full Depth |       |
|-----------------|-------------------------------|----------------------------|----------------------------|----------------------------|-------|
|                 |                               |                            |                            | Pinion                     | Gear  |
| 12              | 0.210                         | 0.245                      | 0.311                      | 0.327                      | ...   |
| 13              | 0.220                         | 0.261                      | 0.324                      | 0.327                      | ...   |

| 300             | 0.383                         | 0.471                      | 0.534                      | 0.478                      | 0.534 |
| Rack            | 0.390                         | 0.484                      | 0.550                      | ...                        | ...   |

These values assume a moderate temperature increase and some initial lubrication. With bevel gearing, divide the number of teeth by the cosine of the pitch angle and use the data in the table. For example, if a 20-deg PA bevel gear has 40 teeth and a pitch angle of 58 deg, 40 divided by the cosine of 58 deg =  $40 \div 0.529919 \sim 75$ , and  $Y = 0.434$ .

**Table 8. Safe Bending Stress (lb/in<sup>2</sup>) Values for Plastics Gears**

| Plastics Type | Safe Stress |              |
|---------------|-------------|--------------|
|               | Unfilled    | Glass-filled |
| ABS           | 3,000       | 6,000        |
| Acetal        | 5,000       | 7,000        |
| Nylon         | 6,000       | 12,000       |
| Polycarbonate | 6,000       | 9,000        |
| Polyester     | 3,500       | 8,000        |
| Polyurethane  | 2,500       | ...          |

**Table 9. Service Factors for Plastics Gears**

| Type of Load | 8–10 Hr/Day | 24 Hr/Day | Intermittent, 3 Hr/Day | Occasional, ½ Hr/Day |
|--------------|-------------|-----------|------------------------|----------------------|
| Steady       | 1.00        | 1.25      | 0.80                   | 0.50                 |
| Light shock  | 1.25        | 1.5       | 1.00                   | 0.80                 |
| Medium shock | 1.5         | 1.75      | 1.25                   | 1.00                 |
| Heavy shock  | 1.75        | 2.00      | 1.5                    | 1.25                 |

*Example:* As an example, assume that a material is to be selected for a spur gear that must transmit  $\frac{1}{8}$  hp at 350 rpm, for 8 hrs/day under a steady load. The gear is to have 75 teeth, 32 diametral pitch, 20 deg pressure angle, 0.375 in. face width, and a pitch diameter of 2.3438 in. Using Equation (28),

$$HP = \frac{S_s FYV}{55(600 + V)PC_s} \quad \text{or} \quad S_s = \frac{55(600 + V)PC_s HP}{FYV}$$

$$\text{hp} = 0.125, \quad Y = 0.434 \quad \text{and}$$

$$V = \frac{\text{rpm} \times \pi \times D}{12} = \frac{350 \times 3.1416 \times 2.3438}{12} = 215 \text{ ft/min}$$

therefore,

$$S_s = \frac{55(600 + 215)32 \times 1.00 \times 0.125}{0.375 \times 0.434 \times 215} = 5,124 \text{ lb/in.}^2$$

From Table 8 it is apparent that the gear could be molded from several materials. Available physical and chemical characteristics must now be considered in relation to the operating environment for the gear. Strengths of plastics materials decrease with increasing temperatures and not all plastics resist the effects of some liquids, including some lubricants. Some plastics deteriorate when in sunlight for long periods; some are more dimensionally stable than others; and wear resistance varies from one to another. Manufacturers' data sheets will answer some of these questions.

**Backlash:** Plastics gears should be so dimensioned that they will provide sufficient backlash at the highest temperatures likely to be encountered in service. Dimensional allowances must also be made for gears made of hygroscopic plastics that may be exposed to damp service conditions. Teeth of heavily loaded gears usually have tip relief to reduce effects of deflection, and have full fillet radii to reduce stress concentrations. Such modifications to tooth form are also desirable in plastics gears. If the pinion in a pair of gears has a small number of teeth, undercutting may result. Undercutting weakens teeth, causes undue wear, and may affect continuity of action. The undercutting can be reduced by using the long-short addendum system, which involves increasing the addendum of the pinion teeth and reducing that of the gear teeth. The modified addendum method will also reduce the amount of initial wear that takes place during the initial stages of contact between the teeth.

**Accuracy:** The Gear Handbook, AGMA 390-03a-1980, Part 2, Gear Classification, provides a system whereby results of gear accuracy measurements are expressed in terms of maximum tooth-to-tooth and composite tolerances. This system uses AGMA quality numbers related to maximum tolerances, by pitch and diameter, and is equally applicable to plastics gears as to metal gears. AGMA quality numbers must be chosen for a pair of mating gears early in the design process, and the finished gears must be inspected by being run in close mesh with a master gear in a center-distance measuring instrument to make sure that the errors do not exceed the specified tolerances.

To prevent failure from fatigue and wear caused by excessive flexing of the teeth, plastics gears must be made to the same standards of accuracy as metal gears. Solidification shrinkage of plastics requires that dimensions of molds for gears be larger than the dimensions of the parts to be produced from them. The amount of the shrinkage is usually added to the mold dimension (with the mold at operating temperature). However, this procedure cannot be followed for the tooth profile as it would introduce large errors in the pressure angle. Increases in pressure angle cause gear teeth to become wider at the root and more pointed. Sliding conditions are improved and the teeth are stronger, so that higher loading values can be used.

Shrinkage allowances have the greatest effect on the accuracy of the molded gears, so tooth profiles must be calculated extremely carefully in terms of mold profile. If a tooth is merely made larger by using a standard hobbing cutter to cut the tool whereby the teeth in the mold are electroeroded, differential shrinkage caused by the molded tooth being thicker at the root than at the tip will distort the shape of the molded tooth, making it thinner at the tip and thicker at the root. With two mating gears, these faulty shapes will affect the pressure angle resulting in binding, wear, and general malfunction. If the tooth thickness limits for a molded gear are to be held to +0.000 in., -0.001 in., the outside diameter must be permitted to vary up to 0.0027 in. for 20-deg, and 0.0039 in. for 14½-deg pressure angle gears. All high-accuracy gears should be specified with AGMA quality numbers and inspected with center-distance measuring machines if the required accuracy is to be achieved.

## DRAFTING PRACTICES

## American National Standard Drafting Practices

Several American National Standards for use in preparing engineering drawings and related documents are referred to for use.

**Sizes of Drawing Sheets.**—Recommended trimmed sheet sizes, based on ANSI Y14.1-1980 (R1987), are shown in the following table.

| Size, inches |         |   |         | Metric Size, mm |            |    |           |
|--------------|---------|---|---------|-----------------|------------|----|-----------|
| A            | 8½ × 11 | D | 22 × 34 | A0              | 841 × 1189 | A3 | 297 × 420 |
| B            | 11 × 17 | E | 34 × 44 | A1              | 594 × 841  | A4 | 210 × 297 |
| C            | 17 × 22 | F | 28 × 40 | A2              | 420 × 594  |    |           |

The standard sizes shown by the left-hand section of the table are based on the dimensions of the commercial letter head, 8½ × 11 inches, in general use in the United States. The use of the basic sheet size 8½ × 11 inches and its multiples permits filing of small tracings and folded blueprints in commercial standard letter files with or without correspondence. These sheet sizes also cut without unnecessary waste from the present 36-inch rolls of paper and cloth.

For drawings made in the metric system of units or for foreign correspondence, it is recommended that the metric standard trimmed sheet sizes be used. (Right-hand section of table.) These sizes are based on the width-to-length ratio of 1 to  $\sqrt{2}$ .

**Line Conventions and Drawings.**—American National Standard Y14.2M-1979 (R1987) establishes line and lettering practices for engineering drawings. The line conventions and the symbols for section lining are as shown on [Tables 1](#) and [2](#).

Approximate width of THICK lines for metric drawings are 0.6 mm, and for inch drawings, 0.032 inch. Approximate width of THIN lines for metric drawings are 0.3 mm, and for inch drawings, 0.016 inch. These approximate line widths are intended to differentiate between THICK and THIN lines and are not values for control of acceptance or rejection of the drawings.

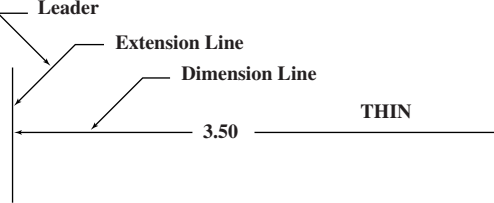

**Surface-Texture Symbols.**—A detailed explanation of the use of surface-texture symbols from American National Standard Y14.36M-1996 begins on page [731](#).

**Geometric Dimensioning and Tolerancing.**—ANSI/ASME Y14.5M-1994, “Dimensioning and Tolerancing,” covers dimensioning, tolerancing, and similar practices for engineering drawings and related documentation. The mathematical definitions of dimensioning and tolerancing principles are given in the standard ANSI/ASME Y14.5.1M-1994. ISO standards ISO 8015 and ISO 26921 contain a detailed explanation of ISO geometric dimensioning and tolerancing practices.

Geometric dimensioning and tolerancing provides a comprehensive system for symbolically defining the geometrical tolerance zone within which features must be contained. It provides an accurate transmission of design specifications among the three primary users of engineering drawings; design, manufacturing and quality assurance.

Some techniques introduced in ANSI/ASME Y14.5M-1994 have been accepted by ISO. These techniques include projected tolerance zone, three-plane datum concept, total runout tolerance, multiple datums, and datum targets. Although this Standard follows ISO practice closely, there are still differences between ISO and U.S. practice. (A comparison of the symbols used in ISO standards and Y14.5M is given on page [633](#).)

<sup>a</sup> Arrowheads may be filled in.

One major area of disagreement is the ISO "principle of independency" versus the "Taylor principle." Y14.5M and standard U.S. practice both follow the Taylor principle, in which a geometric tolerancing zone may not extend beyond the boundary (or envelope) of perfect form at MMC (maximum material condition). This boundary is prescribed to control variations as well as the size of individual features. The U.S. definition of independency further defines features of size as being independent and not required to maintain a perfect relationship with other features. The envelope principle is optional in treatment of these principles. A summary of the application of ANSI/ASME geometric control symbols and their use with basic dimensions and modifiers is given in Table 1.

**Table 1. Application of Geometric Control Symbols**

| Type        | Geometric Characteristics | Pertains To       | Basic Dimensions          | Feature Modifier                        | Datum Modifier                          |
|-------------|---------------------------|-------------------|---------------------------|---|---|
| Form        |                           | Straightness      |                           | Modifier not applicable                 | NO datum                                |
|             |                           | Circularity       |                           |   |   |
|             |                           | Flatness          |                           |   |   |
|             |                           | Cylindricity      |                           |   |   |
| Profile     |                           | Profile (Line)    | Individual or related     | Yes if related                          | RFS implied unless MMC or LMC is stated |
|             |                           | Profile (Surface) |                           |   |   |
| Orientation |                           | Angularity        | ALWAYS related feature(s) | Yes                                     |   |
|             |                           | Perpendicularity  |                           | RFS implied unless MMC or LMC is stated |   |
|             |                           | Parallelism       |                           |   |   |
| Location    |                           | Position          |                           | Yes                                     |   |
|             |                           | Concentricity     |                           | Only RFS                                |   |
|             |                           | Symmetry          |                           |   |   |
| Runout      |                           | Circular Runout   |                           | Only RFS                                | Only RFS                                |
|             |                           | Total Runout      |                           |   |   |

Five types of geometric control, when datums are indicated, when basic dimensions are required, and when MMC and LMC modifiers may be used.

ANSI/ASME Y14.5M features metric SI units (the International System of Units), but customary units may be used without violating any principles. On drawings where all dimensions are either in millimeters or in inches, individual identification of linear units is not required. However, the drawing should contain a note stating UNLESS OTHERWISE SPECIFIED, ALL DIMENSIONS ARE IN MILLIMETERS (or IN INCHES, as applicable). According to this Standard, all dimensions are applicable at a temperature of 20 C (68 F) unless otherwise specified. Compensation may be made for measurements taken at other temperatures.

Angular units are expressed in degrees and decimals of a degree (35.4) or in degrees ( $^{\circ}$ ), minutes ( $'$ ), and seconds ( $''$ ), as in  $35^{\circ} 25' 10''$ . A 90-degree angle is implied where center lines and depicting features are shown on a drawing at right angles and no angle is specified. A 90-degree BASIC angle applies where center lines of features in a pattern or surface shown at right angles on a drawing are located or defined by basic dimensions and no angle is specified.

**Definitions.**—The following terms are defined as their use applies to ANSI/ASME Y14.5M.

*Datum Feature:* The feature of a part that is used to establish a datum.

*Datum Identifier:* The graphic symbol on a drawing used to indicate the datum feature.

Fig. 1. Datum Feature Symbol

**Datum Plane:** The individual theoretical planes of the reference frame derived from a specified datum feature. A datum is the origin from which the location or other geometric characteristics of features of a part are established.

**Datum Reference Frame:** Sufficient features on a part are chosen to position the part in relationship to three planes. The three planes are mutually perpendicular and together called the datum reference frame. The planes follow an order of precedence and allow the part to be immobilized. This immobilization in turn creates measurable relationships among features.

**Datum Simulator:** Formed by the datum feature contacting a precision surface such as a surface plate, gage surface or by a mandrel contacting the datum. Thus, the plane formed by contact restricts motion and constitutes the specific reference surface from which measurements are taken and dimensions verified. The datum simulator is the practical embodiment of the datum feature during manufacturing and quality assurance.

**Datum Target:** A specified point, line, or area on a part, used to establish a datum.

**Degrees of Freedom:** The three directions of movement or translation are called degrees of freedom in a three-dimensional environment. They are up-down, left-right, fore-aft, roll, pitch and yaw.

Fig. 2. Degrees of Freedom (Movement) That Must be Controlled, Depending on the Design Requirements.

**Dimension, Basic:** A numerical value used to describe the theoretically exact size, orientation, location, or optionally, profile, of a feature or datum or datum target. Basic dimensions are indicated by a rectangle around the dimension and are not tolerated directly or by default. The specific dimensional limits are determined by the permissible variations as established by the tolerance zone specified in the feature control frame. A dimension is only considered basic for the geometric control to which it is related.

Fig. 3. Basic Dimensions

**Dimension Origin:** Symbol used to indicate the origin and direction of a dimension between two features. The dimension originates from the symbol with the dimension tolerance zone being applied at the other feature.

Fig. 4. Dimension Origin Symbol

**Dimension, Reference:** A dimension, usually without tolerance, used for information purposes only. Considered to be auxiliary information and not governing production or inspection operations. A reference dimension is a repeat of a dimension or is derived from a calculation or combination of other values shown on the drawing or on related drawings.

**Feature Control Frame:** Specification on a drawing that indicates the type of geometric control for the feature, the tolerance for the control, and the related datums, if applicable.

Fig. 5. Feature Control Frame and Datum Order of Precedence

**Feature:** The general term applied to a physical portion of a part, such as a surface, hole, pin, tab, or slot.

**Least Material Condition (LMC):** The condition in which a feature of size contains the least amount of material within the stated limits of size, for example, upper limit or maximum hole diameter and lower limit or minimum shaft diameter.

**Limits, Upper and Lower (UL and LL):** The arithmetic values representing the maximum and minimum size allowable for a dimension or tolerance. The upper limit represents the maximum size allowable. The lower limit represents the minimum size allowable.

**Maximum Material Condition (MMC):** The condition in which a feature of size contains the maximum amount of material within the stated limits of size. For example, the lower limit of a hole is the minimum hole diameter. The upper limit of a shaft is the maximum shaft diameter.

**Position:** Formerly called true position, position is the theoretically exact location of a feature established by basic dimensions.

**Regardless of Feature Size (RFS):** The term used to indicate that a geometric tolerance or datum reference applies at any increment of size of the feature within its tolerance limits. RFS is the default condition unless MMC or LMC is specified. The concept is now the default in ANSI/ASME Y14.5M-1994, unless specifically stated otherwise. Thus the symbol for RFS is no longer supported in ANSI/ASME Y14.5M-1994.

**Size, Actual:** The term indicating the size of a feature as produced.

**Size, Feature of:** A feature that can be described dimensionally. May include a cylindrical or spherical surface, or a set of two opposed parallel surfaces associated with a size dimension.

**Tolerance Zone Symmetry:** In geometric tolerancing, the tolerance value stated in the feature control frame is always a single value. Unless otherwise specified, it is assumed that the boundaries created by the stated tolerance are bilateral and equidistant about the perfect form control specified. However, if desired, the tolerance may be specified as unilateral or unequally bilateral. (See Figs. 6 through 8)

**Tolerance, Bilateral:** A tolerance where variation is permitted in both directions from the specified dimension. Bilateral tolerances may be equal or unequal.

**Tolerance, Geometric:** The general term applied to the category of tolerances used to control form, profile, orientation, location, and runout.

**Tolerance, Unilateral:** A tolerance where variation is permitted in only one direction from the specified dimension.

**True Geometric Counterpart:** The theoretically perfect plane of a specified datum feature.

**Virtual Condition:** A constant boundary generated by the collective effects of the feature size, its specified MMC or LMC material condition, and the geometric tolerance for that condition.

**Bilateral zone with 0.1 of the 0.25 tolerance outside perfect form.**

Fig. 6. Application of a bilateral geometric tolerance

Fig. 7. Application of a unilateral geometric tolerance zone outside perfect form

Fig. 8. Application of a unilateral geometric tolerance zone inside a perfect form

**Datum Referencing.**—A datum indicates the origin of a dimensional relationship between a toleranced feature and a designated feature or features on a part. The designated feature serves as a datum feature, whereas its true geometric counterpart establishes the datum plane. Because measurements cannot be made from a true geometric counterpart, which is theoretical, a datum is assumed to exist in, and be simulated by the associated processing equipment.

For example, machine tables and surface plates, although not true planes, are of such quality that they are used to simulate the datums from which measurements are taken and dimensions are verified. When magnified, flat surfaces of manufactured parts are seen to have irregularities, so that contact is made with a datum plane formed at a number of surface extremities or high points.

Sufficient datum features, those most important to the design of the part, are chosen to position the part in relation to a set of three mutually perpendicular planes, the datum reference frame. This reference frame exists only in theory and not on the part. Therefore, it is necessary to establish a method for simulating the theoretical reference frame from existing features of the part. This simulation is accomplished by positioning the part on appropriate datum features to adequately relate the part to the reference frame and to restrict the degrees of freedom of the part in relation to it.

These reference frame planes are simulated in a mutually perpendicular relationship to provide direction as well as the origin for related dimensions and measurements. Thus, when the part is positioned on the datum reference frame (by physical contact between each datum feature and its counterpart in the associated processing equipment), dimensions related to the datum reference frame by a feature control frame are thereby mutually perpendicular. This theoretical reference frame constitutes the three-plane dimensioning system used for datum referencing.

Fig. 9. Datum target symbols

Depending on the degrees of freedom that must be controlled, a simple reference frame may suffice. At other times, additional datum reference frames may be necessary where physical separation occurs or the functional relationship. Depending on the degrees of freedom that must be controlled, a single datum of features require that datum reference frames be applied at specific locations on the part. Each feature control frame must contain the datum feature references that are applicable.

**Datum Targets:** Datum targets are used to establish a datum plane. They may be points, lines or surface areas. Datum targets are used when the datum feature contains irregularities, the surface is blocked by other features or the entire surface cannot be used. Examples where datum targets may be indicated include uneven surfaces, forgings and castings, weldments, non-planar surfaces or surfaces subject to warping or distortion. The datum target symbol is located outside the part outline with a leader directed to the target point, area or line. The targets are dimensionally located on the part using basic or toleranced dimensions. If basic dimensions are used, established tooling or gaging tolerances apply. A solid leader line from the symbol to the target is used for visible or near side locations with a dashed leader line used for hidden or far side locations. The datum target symbol is divided horizontally into two halves. The top half contains the target point area if applicable; the bottom half contains a datum feature identifying letter and target number. Target

numbers indicate the quantity required to define a primary, secondary, or tertiary datum. If indicating a target point or target line, the top half is left blank. Datum targets and datum features may be combined to form the datum reference frame, Fig. 9.

**Datum Target points:** A datum target point is indicated by the symbol "X," which is dimensionally located on a direct view of the surface. Where there is no direct view, the point location is dimensioned on multiple views.

**Datum Target Lines:** A datum target line is dimensionally located on an edge view of the surface using a phantom line on the direct view. Where there is no direct view, the location is dimensioned on multiple views. Where the length of the datum target line must be controlled, its length and location are dimensioned.

**Datum Target Areas:** Where it is determined that an area or areas of flat contact are necessary to ensure establishment of the datum, and where spherical or pointed pins would be inadequate, a target area of the desired shape is specified. Examples include the need to span holes, finishing irregularities, or rough surface conditions. The datum target area may be indicated with the "X" symbol as with a datum point, but the area of contact is specified in the upper half of the datum target symbol. Datum target areas may additionally be specified by defining controlling dimensions and drawing the contact area on the feature with section lines inside a phantom outline of the desired shape.

**Positional Tolerance.**—A positional tolerance defines a zone within which the center, axis, or center plane of a feature of size is permitted to vary from true (theoretically exact) position. Basic dimensions establish the true position from specified datum features and between interrelated features. A positional tolerance is indicated by the position symbol, a tolerance, and appropriate datum references placed in a feature control frame.

**Modifiers:** In certain geometric tolerances, modifiers in the form of additional symbols may be used to further refine the level of control. The use of the MMC and LMC modifiers has been common practice for many years. However, several new modifiers were introduced with the 1994 U.S. national standard. Some of the new modifiers include free state, tangent plane and statistical tolerancing, Fig. 10.

|            |     |     |               |                          |                       |
|------------|-----|-----|---------------|--------------------------|-----------------------|
| ⓕ          | Ⓜ   | Ⓛ   | Ⓣ             | Ⓟ                        | ⓈⓉ                    |
| Free State | MMC | LMC | Tangent Plane | Projected Tolerance Zone | Statistical Tolerance |

Fig. 10. Tolerance modifiers

**Projected Tolerance Zone:** Application of this concept is recommended where any variation in perpendicularity of the threaded or press-fit holes could cause fasteners such as screws, studs, or pins to interfere with mating parts. An interference with subsequent parts can occur even though the hole axes are inclined within allowable limits. This interference occurs because, without a projected tolerance zone, a positional tolerance is applied only to the depth of threaded or press-fit holes. Unlike the floating fastener application involving clearance holes only, the attitude of a fixed fastener is restrained by the inclination of the produced hole into which it assembles.

Fig. 11. Projected tolerance zone callout

With a projected tolerance zone equal to the thickness of the mating part, the inclinational error is accounted for in both parts. The minimum extent and direction of the projected tolerance zone is shown as a value in the feature control frame. The zone may be shown in a drawing view as a dimensioned value with a heavy chain line drawn closely adjacent to an extension of the center line of the hole.

Fig. 12. Projected tolerance zone application

**Statistical Tolerance:** The statistical tolerancing symbol is a modifier that may be used to indicate that a tolerance is controlled statistically as opposed to being controlled arithmetically. With arithmetic control, assembly tolerances are typically divided arithmetically among the individual components of the assembly. This division results in the assumption that assemblies based on “worst case” conditions would be guaranteed to fit because the worst case set of parts fit — so that anything better would fit as well.

When this technique is restrictive, statistical tolerancing, via the symbol, may be specified in the feature control frame as a method of increasing tolerances for individual parts. This procedure may reduce manufacturing costs because its use changes the assumption that statistical process control may make a statistically significant quantity of parts fit, but not absolutely all. The technique should only be used when sound statistical methods are employed.

**Tangent Plane:** When it is desirable to control the surface of a feature by the contacting or high points of the surface, a tangent plane symbol is added as a modifier to the tolerance in the feature control frame, Fig. 13.

Fig. 13. Tangent plane modifier

**Free State:** The free state modifier symbol is used when the geometric tolerance applies to the feature in its "free state," or after removal of any forces used in the manufacturing process. With removal of forces the part may distort due to gravity, flexibility, spring back, or other release of internal stresses developed during fabrication. Typical applications include parts with extremely thin walls and non-rigid parts made of rubber or plastics. The modifier is placed in the tolerance portion of the feature control frame and follows any other modifier.

The above examples are just a few of the numerous concepts and related symbols covered by ANSI/ASME Y14.5M-1994. Refer to the standard for a complete discussion with further examples of the application of geometric dimensioning and tolerancing principles.

**Checking Drawings.**—In order that the drawings may have a high standard of excellence, a set of instructions, as given in the following, has been issued to the checkers, and also to the draftsmen and tracers in the engineering department of a well-known machine-building company.

**Inspecting a New Design:** When a new design is involved, first inspect the layouts carefully to see that the parts function correctly under all conditions, that they have the proper relative proportions, that the general design is correct in the matters of strength, rigidity, bearing areas, appearance, convenience of assembly, and direction of motion of the parts, and that there are no interferences. Consider the design as a whole to see if any improvements can be made. If the design appears to be unsatisfactory in any particular, or improvements appear to be possible, call the matter to the attention of the chief engineer.

**Checking for Strength:** Inspect the design of the part being checked for strength, rigidity, and appearance by comparing it with other parts for similar service whenever possible, giving preference to the later designs in such comparison, unless the later designs are known to be unsatisfactory. If there is any question regarding the matter, compute the stresses and deformations or find out whether the chief engineer has approved the stresses or deformations that will result from the forces applied to the part in service. In checking parts that are to go on a machine of increased size, be sure that standard parts used in similar machines and proposed for use on the larger machine, have ample strength and rigidity under the new and more severe service to which they will be put.

**Materials Specified:** Consider the kind of material required for the part and the various possibilities of molding, forging, welding, or otherwise forming the rough part from this material. Then consider the machining operations to see whether changes in form or design will reduce the number of operations or the cost of machining.

See that parts are designed with reference to the economical use of material, and whenever possible, utilize standard sizes of stock and material readily obtainable from local

dealers. In the case of alloy steel, special bronze, and similar materials, be sure that the material can be obtained in the size required.

*Method of Making Drawing:* Inspect the drawing to see that the projections and sections are made in such a way as to show most clearly the form of the piece and the work to be done on it. Make sure that any worker looking at the drawing will understand what the shape of the piece is and how it is to be molded or machined. Make sure that the delineation is correct in every particular, and that the information conveyed by the drawing as to the form of the piece is complete.

*Checking Dimensions:* Check all dimensions to see that they are correct. Scale all dimensions and see that the drawing is to scale. See that the dimensions on the drawing agree with the dimensions scaled from the lay-out. Wherever any dimension is out of scale, see that the dimension is so marked. Investigate any case where the dimension, the scale of the drawing, and the scale of the lay-out do not agree. All dimensions not to scale must be underlined on the tracing. In checking dimensions, note particularly the following points:

See that all figures are correctly formed and that they will print clearly, so that the workers can easily read them correctly.

See that the overall dimensions are given.

See that all witness lines go to the correct part of the drawing.

See that all arrow points go to the correct witness lines.

See that proper allowance is made for all fits.

See that the tolerances are correctly given where necessary.

See that all dimensions given agree with the corresponding dimensions of adjacent parts.

Be sure that the dimensions given on a drawing are those that the machinist will use, and that the worker will not be obliged to do addition or subtraction to obtain the necessary measurements for machining or checking his work.

Avoid strings of dimensions where errors can accumulate. It is generally better to give a number of dimensions from the same reference surface or center line.

When holes are to be located by boring on a horizontal spindle boring machine or other similar machine, give dimensions to centers of bored holes in rectangular coordinates and from the center lines of the first hole to be bored, so that the operator will not be obliged to add measurements or transfer gages.

*Checking Assembly:* See that the part can readily be assembled with the adjacent parts. If necessary, provide tapped holes for eyebolts and cored holes for tongs, lugs, or other methods of handling.

Make sure that, in being assembled, the piece will not interfere with other pieces already in place and that the assembly can be taken apart without difficulty.

Check the sum of a number of tolerances; this sum must not be great enough to permit two pieces that should not be in contact to come together.

*Checking Castings:* In checking castings, study the form of the pattern, the methods of molding, the method of supporting and venting the cores, and the effect of draft and rough molding on clearances.

Avoid undue metal thickness, and especially avoid thick and thin sections in the same casting.

Indicate all metal thicknesses, so that the molder will know what chaplets to use for supporting the cores.

See that ample fillets are provided, and that they are properly dimensioned.

See that the cores can be assembled in the mold without crushing or interference.

See that swelling, shrinkage, or misalignment of cores will not make trouble in machining.

See that the amount of extra material allowed for finishing is indicated.

See that there is sufficient extra material for finishing on large castings to permit them to be "cleaned up," even though they warp. In such castings, make sure that the metal thickness will be sufficient after finishing, even though the castings do warp.

Make sure that sufficient sections are shown so that the pattern makers and molders will not be compelled to make assumptions about the form of any part of the casting. These details are particularly important when a number of sections of the casting are similar in form, while others differ slightly.

*Checking Machined Parts:* Study the sequences of operations in machining and see that all finish marks are indicated.

See that the finish marks are placed on the lines to which dimensions are given.

See that methods of machining are indicated where necessary.

Give all drill, reamer, tap, and rose bit sizes.

See that jig and gage numbers are indicated at the proper places.

See that all necessary bosses, lugs, and openings are provided for lifting, handling, clamping, and machining the piece.

See that adequate wrench room is provided for all nuts and bolt heads.

Avoid special tools, such as taps, drills, reamers, etc., unless such tools are specifically authorized.

Where parts are right- and left-hand, be sure that the hand is correctly designated. When possible, mark parts as symmetrical, so as to avoid having them right- and left-hand, but do not sacrifice correct design or satisfactory operation on this account.

When heat-treatment is required, the heat-treatment should be specified.

Check the title, size of machine, the scale, and the drawing number on both the drawing and the drawing record card.

**Tapers for Machine Tool Spindles.**—Various standard tapers have been used for the taper holes in the spindles of machine tools, such as drilling machines, lathes, milling machines, or other types requiring a taper hole for receiving either the shank of a cutter, an arbor, a center, or any tool or accessory requiring a tapering seat. The Morse taper represents a generally accepted standard for drilling machines.

#### Morse Tapers

| Morse Taper | Taper per Foot | Morse Taper | Taper per Foot | Morse Taper | Taper per Foot |
|-------------|----------------|-------------|----------------|-------------|----------------|
| 0           | 0.62460        | 2           | 0.59941        | 4           | 0.62326        |
| 1           | 0.59858        | 3           | 0.60235        | 5           | 0.63151        |

The headstock and tailstock spindles of lathes also have the Morse taper in most cases; but the Jarno, the Reed (which is the short Jarno), and the Brown & Sharpe have also been used. Milling machine spindles formerly had Brown & Sharpe tapers in most cases.

In 1927, the milling machine manufacturers of the National Machine Tool Builders' Association adopted a standard taper of  $3\frac{1}{2}$  inches per foot. This comparatively steep taper has the advantage of insuring instant release of arbors or adapters.

#### National Machine Tool Builders' Association Tapers

| Taper Number <sup>a</sup> | Large End Diameter | Taper Number <sup>a</sup> | Large End Diameter |
|---------------------------|--------------------|---------------------------|--------------------|
| 30                        | $1\frac{1}{4}$     | 50                        | $2\frac{3}{4}$     |
| 40                        | $1\frac{3}{4}$     | 60                        | $4\frac{1}{4}$     |

<sup>a</sup>Standard taper of  $3\frac{1}{2}$  inches per foot

The British Standard for milling machine spindles is also  $3\frac{1}{2}$  inches taper per foot and includes these large end diameters:  $1\frac{3}{8}$  inches,  $1\frac{3}{4}$  inches,  $2\frac{3}{4}$  inches, and  $3\frac{1}{4}$  inches.

## ALLOWANCES AND TOLERANCES FOR FITS

### Limits and Fits

Fits between cylindrical parts, i.e., cylindrical fits, govern the proper assembly and performance of many mechanisms. Clearance fits permit relative freedom of motion between a shaft and a hole—axially, radially, or both. Interference fits secure a certain amount of tightness between parts, whether these are meant to remain permanently assembled or to be taken apart from time to time. Or again, two parts may be required to fit together snugly—without apparent tightness or looseness. The designer's problem is to specify these different types of fits in such a way that the shop can produce them. Establishing the specifications requires the adoption of two manufacturing limits for the hole and two for the shaft, and, hence, the adoption of a manufacturing tolerance on each part.

In selecting and specifying limits and fits for various applications, it is essential in the interests of interchangeable manufacturing that 1) standard definitions of terms relating to limits and fits be used; 2) preferred basic sizes be selected wherever possible to reduce material and tooling costs; 3) limits be based upon a series of preferred tolerances and allowances; and 4) a uniform system of applying tolerances (preferably unilateral) be used. These principles have been incorporated in both the American and British standards for limits and fits. Information about these standards is given beginning on page 651.

**Basic Dimensions.**—The basic size of a screw thread or machine part is the theoretical or nominal standard size from which variations are made. For example, a shaft may have a *basic* diameter of 2 inches, but a maximum variation of minus 0.010 inch may be permitted. The minimum hole should be of basic size wherever the use of standard tools represents the greatest economy. The maximum shaft should be of basic size wherever the use of standard purchased material, without further machining, represents the greatest economy, even though special tools are required to machine the mating part.

**Tolerances.**—Tolerance is the amount of variation permitted on dimensions or surfaces of machine parts. The tolerance is equal to the difference between the maximum and minimum limits of any specified dimension. For example, if the maximum limit for the diameter of a shaft is 2.000 inches and its minimum limit 1.990 inches, the tolerance for this diameter is 0.010 inch. The extent of these tolerances is established by determining the maximum and minimum clearances required on operating surfaces. As applied to the fitting of machine parts, the word tolerance means the amount that duplicate parts are allowed to vary in size in connection with manufacturing operations, owing to unavoidable imperfections of workmanship. Tolerance may also be defined as the amount that duplicate parts are permitted to vary in size to secure sufficient accuracy without unnecessary refinement. The terms “tolerance” and “allowance” are often used interchangeably, but, according to common usage, *allowance* is a difference in dimensions prescribed to secure various classes of fits between different parts.

**Unilateral and Bilateral Tolerances.**—The term “unilateral tolerance” means that the total tolerance, as related to a basic dimension, is in *one* direction only. For example, if the basic dimension were 1 inch and the tolerance were expressed as 1.000–0.002, or as 1.000 + 0.002, these would be unilateral tolerances because the total tolerance in each is in one direction. On the contrary, if the tolerance were divided, so as to be partly plus and partly minus, it would be classed as “bilateral.”

Thus,  $1.000 \begin{matrix} +0.001 \\ -0.001 \end{matrix}$

is an example of bilateral tolerance, because the total tolerance of 0.002 is given in two directions—plus and minus.

When unilateral tolerances are used, one of the three following methods should be used to express them:

- 1) Specify, limiting dimensions only as  
Diameter of hole: 2.250, 2.252  
Diameter of shaft: 2.249, 2.247
  - 2) One limiting size may be specified with its tolerances as  
Diameter of hole: 2.250 + 0.002, -0.000  
Diameter of shaft: 2.249 + 0.000, -0.002
  - 3) The nominal size may be specified for both parts, with a notation showing both allowance and tolerance, as  
Diameter of hole:  $2\frac{1}{4} + 0.002, -0.000$   
Diameter of shaft:  $2\frac{1}{4} - 0.001, -0.003$
- Bilateral tolerances should be specified as such, usually with plus and minus tolerances of equal amount. An example of the expression of bilateral tolerances is

$$2 \pm 0.001 \quad \text{or} \quad 2 \begin{array}{l} +0.001 \\ -0.001 \end{array}$$

**Application of Tolerances.**—According to common practice, tolerances are applied in such a way as to show the permissible amount of dimensional variation in the direction that is less dangerous. When a variation in either direction is equally dangerous, a bilateral tolerance should be given. When a variation in one direction is more dangerous than a variation in another, a unilateral tolerance should be given in the less dangerous direction.

For nonmating surfaces, or atmospheric fits, the tolerances may be bilateral, or unilateral, depending entirely upon the nature of the variations that develop in manufacture. On mating surfaces, with few exceptions, the tolerances should be unilateral.

Where tolerances are required on the distances between holes, usually they should be bilateral, as variation in either direction is normally equally dangerous. The variation in the distance between shafts carrying gears, however, should always be unilateral and plus; otherwise, the gears might run too tight. A slight increase in the backlash between gears is seldom of much importance.

One exception to the use of unilateral tolerances on mating surfaces occurs when tapers are involved; either bilateral or unilateral tolerances may then prove advisable, depending upon conditions. These tolerances should be determined in the same manner as the tolerances on the distances between holes. When a variation either in or out of the position of the mating taper surfaces is equally dangerous, the tolerances should be bilateral. When a variation in one direction is of less danger than a variation in the opposite direction, the tolerance should be unilateral and in the less dangerous direction.

**Locating Tolerance Dimensions.**—Only one dimension in the same straight line can be controlled within fixed limits. That dimension is the distance between the cutting surface of the tool and the locating or registering surface of the part being machined. Therefore, it is incorrect to locate any point or surface with tolerances from more than one point in the same straight line.

Every part of a mechanism must be located in each plane. Every operating part must be located with proper operating allowances. After such requirements of location are met, all other surfaces should have liberal clearances. Dimensions should be given between those points or surfaces that it is essential to hold in a specific relation to each other. This restriction applies particularly to those surfaces in each plane that control the location of other component parts. Many dimensions are relatively unimportant in this respect. It is good practice to establish a common locating point in each plane and give, as far as possible, all such dimensions from these common locating points. The locating points on the drawing, the locating or registering points used for machining the surfaces and the locating points for measuring should all be identical.

The initial dimensions placed on component drawings should be the exact dimensions that would be used if it were possible to work without tolerances. Tolerances should be

given in that direction in which variations will cause the least harm or danger. When a variation in either direction is equally dangerous, the tolerances should be of equal amount in both directions, or bilateral. The initial clearance, or allowance, between operating parts should be as small as the operation of the mechanism will permit. The maximum clearance should be as great as the proper functioning of the mechanism will permit.

**Direction of Tolerances on Gages.**—The extreme sizes for all plain limit gages shall not exceed the extreme limits of the part to be gaged. All variations in the gages, whatever their cause or purpose, shall bring these gages within these extreme limits.

The data for gage tolerances on page 678 cover gages to inspect workpieces held to tolerances in the American National Standard ANSI B4.4M-1981.

**Allowance for Forced Fits.**—The allowance per inch of diameter usually ranges from 0.001 inch to 0.0025 inch, 0.0015 being a fair average. Ordinarily the allowance per inch decreases as the diameter increases; thus the total allowance for a diameter of 2 inches might be 0.004 inch, whereas for a diameter of 8 inches the total allowance might not be over 0.009 or 0.010 inch. The parts to be assembled by forced fits are usually made cylindrical, although sometimes they are slightly tapered. The advantages of the taper form are that the possibility of abrasion of the fitted surfaces is reduced; that less pressure is required in assembling; and that the parts are more readily separated when renewal is required. On the other hand, the taper fit is less reliable, because if it loosens, the entire fit is free with but little axial movement. Some lubricant, such as white lead and lard oil mixed to the consistency of paint, should be applied to the pin and bore before assembling, to reduce the tendency toward abrasion.

**Pressure for Forced Fits.**—The pressure required for assembling cylindrical parts depends not only upon the allowance for the fit, but also upon the area of the fitted surfaces, the pressure increasing in proportion to the distance that the inner member is forced in. The approximate ultimate pressure in tons can be determined by the use of the following formula in conjunction with the accompanying table of *Pressure Factors for Forced Fits*. Assuming that  $A$  = area of surface in contact in "fit";  $a$  = total allowance in inches;  $P$  = ultimate pressure required, in tons;  $F$  = pressure factor based upon assumption that the diameter of the hub is twice the diameter of the bore, that the shaft is of machine steel, and that the hub is of cast iron:

$$P = \frac{A \times a \times F}{2}$$

**Pressure Factors for Forced Fits**

| Diameter, Inches | Pressure Factor | Diameter, Inches | Pressure Factor | Diameter, Inches | Pressure Factor | Diameter, Inches | Pressure Factor | Diameter, Inches | Pressure Factor |
|------------------|-----------------|------------------|-----------------|------------------|-----------------|------------------|-----------------|------------------|-----------------|
| 1                | 500             | 3½               | 132             | 6                | 75              | 9                | 48.7            | 14               | 30.5            |
| 1¼               | 395             | 3¾               | 123             | 6¼               | 72              | 9½               | 46.0            | 14½              | 29.4            |
| 1½               | 325             | 4                | 115             | 6½               | 69              | 10               | 43.5            | 15               | 28.3            |
| 1¾               | 276             | 4¼               | 108             | 6¾               | 66              | 10½              | 41.3            | 15½              | 27.4            |
| 2                | 240             | 4½               | 101             | 7                | 64              | 11               | 39.3            | 16               | 26.5            |
| 2¼               | 212             | 4¾               | 96              | 7¼               | 61              | 11½              | 37.5            | 16½              | 25.6            |
| 2½               | 189             | 5                | 91              | 7½               | 59              | 12               | 35.9            | 17               | 24.8            |
| 2¾               | 171             | 5¼               | 86              | 7¾               | 57              | 12½              | 34.4            | 17½              | 24.1            |
| 3                | 156             | 5½               | 82              | 8                | 55              | 13               | 33.0            | 18               | 23.4            |
| 3¼               | 143             | 5¾               | 78              | 8½               | 52              | 13½              | 31.7            | ...              | ...             |

**Allowance for Given Pressure.**—By transposing the preceding formula, the approximate allowance for a required ultimate tonnage can be determined. Thus,  $a = \frac{2P}{AF}$ . The

average ultimate pressure in tons commonly used ranges from 7 to 10 times the diameter in inches.

**Expansion Fits.**—In assembling certain classes of work requiring a very tight fit, the inner member is contracted by sub-zero cooling to permit insertion into the outer member and a tight fit is obtained as the temperature rises and the inner part expands. To obtain the sub-zero temperature, solid carbon dioxide or “dry ice” has been used but its temperature of about 109 degrees F. below zero will not contract some parts sufficiently to permit insertion in holes or recesses. Greater contraction may be obtained by using high purity liquid nitrogen which has a temperature of about 320 degrees F. below zero. During a temperature reduction from 75 degrees F. to -321 degrees F., the shrinkage per inch of diameter varies from about 0.002 to 0.003 inch for steel; 0.0042 inch for aluminum alloys; 0.0046 inch for magnesium alloys; 0.0033 inch for copper alloys; 0.0023 inch for monel metal; and 0.0017 inch for cast iron (not alloyed). The cooling equipment may vary from an insulated bucket to a special automatic unit, depending upon the kind and quantity of work. One type of unit is so arranged that parts are precooled by vapors from the liquid nitrogen before immersion. With another type, cooling is entirely by the vapor method.

**Shrinkage Fits.**—General practice seems to favor a smaller allowance for shrinkage fits than for forced fits, although in many shops the allowances are practically the same for each, and for some classes of work, shrinkage allowances exceed those for forced fits. The shrinkage allowance also varies to a great extent with the form and construction of the part that has to be shrunk into place. The thickness or amount of metal around the hole is the most important factor. The way in which the metal is distributed also has an influence on the results. Shrinkage allowances for locomotive driving wheel tires adopted by the American Railway Master Mechanics Association are as follows:

|                         |       |       |       |       |       |       |
|-------------------------|-------|-------|-------|-------|-------|-------|
| Center diameter, inches | 38    | 44    | 50    | 56    | 62    | 66    |
| Allowances, inches      | 0.040 | 0.047 | 0.053 | 0.060 | 0.066 | 0.070 |

Whether parts are to be assembled by forced or shrinkage fits depends upon conditions. For example, to press a tire over its wheel center, without heating, would ordinarily be a rather awkward and difficult job. On the other hand, pins, etc., are easily and quickly forced into place with a hydraulic press and there is the additional advantage of knowing the exact pressure required in assembling, whereas there is more or less uncertainty connected with a shrinkage fit, unless the stresses are calculated. Tests to determine the difference in the quality of shrinkage and forced fits showed that the resistance of a shrinkage fit to slippage for an axial pull was 3.66 times greater than that of a forced fit, and in rotation or torsion, 3.2 times greater. In each comparative test, the dimensions and allowances were the same.

**Allowances for Shrinkage Fits.**—The most important point to consider when calculating shrinkage fits is the stress in the hub at the bore, which depends chiefly upon the shrinkage allowance. If the allowance is excessive, the elastic limit of the material will be exceeded and permanent set will occur, or, in extreme conditions, the ultimate strength of the metal will be exceeded and the hub will burst. The intensity of the grip of the fit and the resistance to slippage depends mainly upon the thickness of the hub; the greater the thickness, the stronger the grip, and *vice versa*. Assuming the modulus of elasticity for steel to be 30,000,000, and for cast iron, 15,000,000, the shrinkage allowance per inch of nominal diameter can be determined by the following formula, in which  $A$  = allowance per inch of diameter;  $T$  = true tangential tensile stress at inner surface of outer member;  $C$  = factor taken from one of the accompanying Tables 1, 2, and 3.

For a cast-iron hub and steel shaft:

$$A = \frac{T(2 + C)}{30,000,000} \quad (1)$$

When both hub and shaft are of steel:

$$A = \frac{T(1 + C)}{30,000,000} \quad (2)$$

If the shaft is solid, the factor  $C$  is taken from [Table 1](#); if it is hollow and the hub is of steel, factor  $C$  is taken from [Table 2](#); if it is hollow and the hub is of cast iron, the factor is taken from [Table 3](#).

**Table 1. Factors for Calculating Shrinkage Fit Allowances for Steel Shafts and Steel or Cast Iron Hubs**

| Ratio of Diameters<br>$\frac{D_2}{D_1}$ | Steel Hub | Cast-iron Hub | Ratio of Diameters<br>$\frac{D_2}{D_1}$ | Steel Hub | Cast-iron Hub |
|---|-----------|---------------|---|-----------|---------------|
|   | $C$       |               |   | $C$       |               |
| 1.5                                     | 0.227     | 0.234         | 2.8                                     | 0.410     | 0.432         |
| 1.6                                     | 0.255     | 0.263         | 3.0                                     | 0.421     | 0.444         |
| 1.8                                     | 0.299     | 0.311         | 3.2                                     | 0.430     | 0.455         |
| 2.0                                     | 0.333     | 0.348         | 3.4                                     | 0.438     | 0.463         |
| 2.2                                     | 0.359     | 0.377         | 3.6                                     | 0.444     | 0.471         |
| 2.4                                     | 0.380     | 0.399         | 3.8                                     | 0.450     | 0.477         |
| 2.6                                     | 0.397     | 0.417         | 4.0                                     | 0.455     | 0.482         |

Values of factor  $C$  for solid steel shafts of nominal diameter  $D_1$ , and hubs of steel or cast iron of nominal external and internal diameters  $D_2$  and  $D_1$ , respectively.

*Example 1:* A steel crank web 15 inches outside diameter is to be shrunk on a 10-inch solid steel shaft. Required the allowance per inch of shaft diameter to produce a maximum tensile stress in the crank of 25,000 pounds per square inch, assuming the stresses in the crank to be equivalent to those in a ring of the diameter given.

The ratio of the external to the internal diameters equals  $15 \div 10 = 1.5$ ;  $T = 25,000$  pounds; from [Table 1](#),  $C = 0.227$ . Substituting in [Formula \(2\)](#):

$$A = \frac{25,000 \times (1 + 0.227)}{30,000,000} = 0.001 \text{ inch}$$

*Example 2:* Find the allowance per inch of diameter for a 10-inch shaft having a 5-inch axial through hole, other conditions being the same as in [Example 1](#).

The ratio of external to internal diameters of the hub equals  $15 \div 10 = 1.5$ , as before, and the ratio of external to internal diameters of the shaft equals  $10 \div 5 = 2$ . From [Table 2](#), we find that factor  $C = 0.455$ ;  $T = 25,000$  pounds. Substituting these values in [Formula \(2\)](#):

$$A = \frac{25,000(1 + 0.455)}{30,000,000} = 0.0012 \text{ inch}$$

The allowance is increased, as compared with [Example 1](#), because the hollow shaft is more compressible.

*Example 3:* If the crank web in [Example 1](#) is of cast iron and 4000 pounds per square inch is the maximum tensile stress in the hub, what is the allowance per inch of diameter?

$$\frac{D_2}{D_1} = 1.5 \quad T = 4000$$

In [Table 1](#), we find that  $C = 0.234$ . Substituting in [Formula \(1\)](#), for cast-iron hubs,  $A = 0.0003$  inch, which, owing to the lower tensile strength of cast iron, is about one-third the shrinkage allowance in [Example 1](#), although the stress is two-thirds of the elastic limit.

**Temperatures for Shrinkage Fits.**—The temperature to which the outer member in a shrinkage fit should be heated for clearance in assembling the parts depends on the total

<sup>a</sup> Values of factor  $C$  for hollow steel shafts and cast-iron hubs. Notation as in Table 2.

expansion required and on the coefficient  $\alpha$  of linear expansion of the metal (i.e., the increase in length of any section of the metal in any direction for an increase in temperature of 1 degree F). The total expansion in diameter that is required consists of the total allowance for shrinkage and an added amount for clearance. The value of the coefficient  $\alpha$  is, for nickel-steel, 0.000007; for steel in general, 0.0000065; for cast iron, 0.0000062. As an example, take an outer member of steel to be expanded 0.005 inch per inch of internal diameter, 0.001 being the shrinkage allowance and the remainder for clearance. Then

$$\alpha \times t^{\circ} = 0.005$$

$$t = \frac{0.005}{0.0000065} = 769 \text{ degrees F}$$

The value  $t$  is the number of degrees F that the temperature of the member must be raised above that of the room temperature.

### ANSI Standard Limits and Fits

This American National Standard for Preferred Limits and Fits for Cylindrical Parts, ANSI B4.1-1967 (R1999), presents definitions of terms applying to fits between plain (non threaded) cylindrical parts and makes recommendations on preferred sizes, allowances, tolerances, and fits for use wherever they are applicable. This standard is in accord with the recommendations of American-British-Canadian (ABC) conferences up to a diameter of 20 inches. Experimental work is being carried on with the objective of reaching agreement in the range above 20 inches. The recommendations in the standard are presented for guidance and for use where they might serve to improve and simplify products, practices, and facilities. They should have application for a wide range of products.

As revised in 1967, and reaffirmed in 1999, the definitions in ANSI B4.1 have been expanded and some of the limits in certain classes have been changed.

**Factors Affecting Selection of Fits.**—Many factors, such as length of engagement, bearing load, speed, lubrication, temperature, humidity, and materials must be taken into consideration in the selection of fits for a particular application, and modifications in the ANSI recommendations may be required to satisfy extreme conditions. Subsequent adjustments may also be found desirable as a result of experience in a particular application to suit critical functional requirements or to permit optimum manufacturing economy.

**Definitions.**—The following terms are defined in this standard:

*Nominal Size:* The nominal size is the designation used for the purpose of general identification.

*Dimension:* A dimension is a geometrical characteristic such as diameter, length, angle, or center distance.

*Size:* Size is a designation of magnitude. When a value is assigned to a dimension, it is referred to as the size of that dimension. (It is recognized that the words "dimension" and "size" are both used at times to convey the meaning of magnitude.)

*Allowance:* An allowance is a prescribed difference between the maximum material limits of mating parts. (See definition of *Fit*). It is a minimum clearance (positive allowance) or maximum interference (negative allowance) between such parts.

*Tolerance:* A tolerance is the total permissible variation of a size. The tolerance is the difference between the limits of size.

*Basic Size:* The basic size is that size from which the limits of size are derived by the application of allowances and tolerances.

*Design Size:* The design size is the basic size with allowance applied, from which the limits of size are derived by the application of tolerances. Where there is no allowance, the design size is the same as the basic size.

*Actual Size:* An actual size is a measured size.

*Limits of Size:* The limits of size are the applicable maximum and minimum sizes.

**Maximum Material Limit:** A maximum material limit is that limit of size that provides the maximum amount of material for the part. Normally it is the maximum limit of size of an external dimension or the minimum limit of size of an internal dimension.\*

**Minimum Material Limit:** A minimum material limit is that limit of size that provides the minimum amount of material for the part. Normally it is the minimum limit of size of an external dimension or the maximum limit of size of an internal dimension.\*

**Tolerance Limit:** A tolerance limit is the variation, positive or negative, by which a size is permitted to depart from the design size.

**Unilateral Tolerance:** A unilateral tolerance is a tolerance in which variation is permitted in only one direction from the design size.

**Bilateral Tolerance:** A bilateral tolerance is a tolerance in which variation is permitted in both directions from the design size.

**Unilateral Tolerance System:** A design plan that uses only unilateral tolerances is known as a Unilateral Tolerance System.

**Bilateral Tolerance System:** A design plan that uses only bilateral tolerances is known as a Bilateral Tolerance System.

**Fits.—Fit:** Fit is the general term used to signify the range of tightness that may result from the application of a specific combination of allowances and tolerances in the design of mating parts.

**Actual Fit:** The actual fit between two mating parts is the relation existing between them with respect to the amount of clearance or interference that is present when they are assembled. (Fits are of three general types: clearance, transition, and interference.)

**Clearance Fit:** A clearance fit is one having limits of size so specified that a clearance always results when mating parts are assembled.

**Interference Fit:** An interference fit is one having limits of size so specified that an interference always results when mating parts are assembled.

**Transition Fit:** A transition fit is one having limits of size so specified that either a clearance or an interference may result when mating parts are assembled.

**Basic Hole System:** A basic hole system is a system of fits in which the design size of the hole is the basic size and the allowance, if any, is applied to the shaft.

**Basic Shaft System:** A basic shaft system is a system of fits in which the design size of the shaft is the basic size and the allowance, if any, is applied to the hole.

**Preferred Basic Sizes.—**In specifying fits, the basic size of mating parts shall be chosen from the decimal series or the fractional series in [Table 4](#).

**Preferred Series for Tolerances and Allowances.—**All fundamental tolerances and allowances of all shafts and holes have been taken from the series given in [Table 5](#).

**Standard Tolerances.—**The series of standard tolerances shown in [Table 6](#) are so arranged that for any one grade they represent approximately similar production difficulties throughout the range of sizes. This table provides a suitable range from which appropriate tolerances for holes and shafts can be selected and enables standard gages to be used. The tolerances shown in [Table 6](#) have been used in the succeeding tables for different classes of fits.

[Table 7](#) graphically illustrates the range of tolerance grades that various machining processes may produce under normal conditions.

**ANSI Standard Fits.—**[Tables 8a](#) through [12](#) inclusive show a series of standard types and classes of fits on a unilateral hole basis, such that the fit produced by mating parts in any one class will produce approximately similar performance throughout the range of sizes. These tables prescribe the fit for any given size, or type of fit; they also prescribe the

\* An example of exceptions: an exterior corner radius where the maximum radius is the minimum material limit and the minimum radius is the maximum material limit.

standard limits for the mating parts that will produce the fit. The fits listed in these tables contain all those that appear in the approved American-British-Canadian proposal.

**Selection of Fits:** In selecting limits of size for any application, the type of fit is determined first, based on the use or service required from the equipment being designed; then the limits of size of the mating parts are established, to insure that the desired fit will be produced.

Theoretically, an infinite number of fits could be chosen, but the number of standard fits shown in the accompanying tables should cover most applications.

**Designation of Standard Fits:** Standard fits are designated by means of the following symbols which, facilitate reference to classes of fit for educational purposes. The symbols are not intended to be shown on manufacturing drawings; instead, sizes should be specified on drawings.

STANDARD FITS

The letter symbols used to designate standard fits are as follows:

- RC = Running or Sliding Clearance Fit    LC = Locational Clearance Fit
- LT = Transition Clearance or Interference Fit
- LN = Locational Interference Fit
- FN = Force or Shrink Fit

These letter symbols are used in conjunction with numbers representing the class of fit; thus FN 4 represents a Class 4, force fit.

Each of these symbols (two letters and a number) represents a complete fit for which the minimum and maximum clearance or interference and the limits of size for the mating parts are given directly in the tables.

**Description of Fits.**—The classes of fits are arranged in three general groups: running and sliding fits, locational fits, and force fits.

*Running and Sliding Fits (RC):* Running and sliding fits, for which limits of clearance are given in [Table 8a](#), are intended to provide a similar running performance, with suitable lubrication allowance, throughout the range of sizes. The clearances for the first two classes, used chiefly as slide fits, increase more slowly with the diameter than for the other classes, so that accurate location is maintained even at the expense of free relative motion.

These fits may be described as follows:

RC 1 *Close sliding fits* are intended for the accurate location of parts that must assemble without perceptible play.

RC 2 *Sliding fits* are intended for accurate location, but with greater maximum clearance than class RC 1. Parts made to this fit move and turn easily but are not intended to run freely, and in the larger sizes may seize with small temperature changes.

RC 3 *Precision running fits* are about the closest fits that can be expected to run freely, and are intended for precision work at slow speeds and light journal pressures, but are not suitable where appreciable temperature differences are likely to be encountered.

RC 4 *Close running fits* are intended chiefly for running fits on accurate machinery with moderate surface speeds and journal pressures, where accurate location and minimum play are desired.

RC 5 and RC 6 *Medium running fits* are intended for higher running speeds, or heavy journal pressures, or both.

RC 7 *Free running fits* are intended for use where accuracy is not essential, or where large temperature variations are likely to be encountered, or under both these conditions.

RC 8 and RC 9 *Loose running fits* are intended for use where wide commercial tolerances may be necessary, together with an allowance, on the external member.

*Locational Fits (LC, LT, and LN):* Locational fits are fits intended to determine only the location of the mating parts; they may provide rigid or accurate location, as with interference fits, or provide some freedom of location, as with clearance fits. Accordingly, they are divided into three groups: clearance fits (LC), transition fits (LT), and interference fits (LN).

These are described as follows:

LC *Locational clearance fits* are intended for parts which are normally stationary, but that can be freely assembled or disassembled. They range from snug fits for parts requiring accuracy of location, through the medium clearance fits for parts such as spigots, to the looser fastener fits where freedom of assembly is of prime importance.

LT *Locational transition fits* are a compromise between clearance and interference fits, for applications where accuracy of location is important, but either a small amount of clearance or interference is permissible.

LN *Locational interference fits* are used where accuracy of location is of prime importance, and for parts requiring rigidity and alignment with no special requirements for bore pressure. Such fits are not intended for parts designed to transmit frictional loads from one part to another by virtue of the tightness of fit. These conditions are covered by force fits.

*Force Fits: (FN):* Force or shrink fits constitute a special type of interference fit, normally characterized by maintenance of constant bore pressures throughout the range of sizes. The interference therefore varies almost directly with diameter, and the difference

between its minimum and maximum value is small, to maintain the resulting pressures within reasonable limits.

These fits are described as follows:

FN 1 *Light drive fits* are those requiring light assembly pressures, and produce more or less permanent assemblies. They are suitable for thin sections or long fits, or in cast-iron external members.

FN 2 *Medium drive fits* are suitable for ordinary steel parts, or for shrink fits on light sections. They are about the tightest fits that can be used with high-grade cast-iron external members.

FN 3 *Heavy drive fits* are suitable for heavier steel parts or for shrink fits in medium sections.

FN 4 and FN 5 *Force fits* are suitable for parts that can be highly stressed, or for shrink fits where the heavy pressing forces required are impractical.

**Graphical Representation of Limits and Fits.**—A visual comparison of the hole and shaft tolerances and the clearances or interferences provided by the various types and classes of fits can be obtained from the diagrams on page 657. These diagrams have been drawn to scale for a nominal diameter of 1 inch.

**Use of Standard Fit Tables.**—*Example 1:* A Class RC 1 fit is to be used in assembling a mating hole and shaft of 2-inch nominal diameter. This class of fit was selected because the application required accurate location of the parts with no perceptible play (see *Description of Fits*, RC 1 close sliding fits). From the data in [Table 8a](#), establish the limits of size and clearance of the hole and shaft.

Maximum hole =  $2 + 0.0005 = 2.0005$ ; minimum hole = 2 inches

Maximum shaft =  $2 - 0.0004 = 1.9996$ ; minimum shaft =  $2 - 0.0007 = 1.9993$  inches

Minimum clearance = 0.0004; maximum clearance = 0.0012 inch

**Modified Standard Fits.**—Fits having the same limits of clearance or interference as those shown in [Tables 8a to 12](#) may sometimes have to be produced by using holes or shafts having limits of size other than those shown in these tables. These modifications may be accomplished by using either a *Bilateral Hole System (Symbol B)* or a *Basic Shaft System (Symbol S)*. Both methods will result in nonstandard holes and shafts.

*Bilateral Hole Fits (Symbol B):* The common situation is where holes are produced with fixed tools such as drills or reamers; to provide a longer wear life for such tools, a bilateral tolerance is desired.

The symbols used for these fits are identical with those used for standard fits except that they are followed by the letter B. Thus, LC 4B is a clearance locational fit, Class 4, except that it is produced with a bilateral hole.

The limits of clearance or interference are identical with those shown in [Tables 8a to 12](#) for the corresponding fits.

The hole tolerance, however, is changed so that the plus limit is that for one grade finer than the value shown in the tables and the minus limit equals the amount by which the plus limit was lowered. The shaft limits are both lowered by the same amount as the lower limit of size of the hole. The finer grade of tolerance required to make these modifications may be obtained from [Table 6](#). For example, an LC 4B fit for a 6-inch diameter hole would have tolerance limits of  $+4.0, -2.0$  ( $+0.0040$  inch,  $-0.0020$  inch); the shaft would have tolerance limits of  $-2.0, -6.0$  ( $-0.0020$  inch,  $-0.0060$  inch).

*Basic Shaft Fits (Symbol S):* For these fits, the maximum size of the shaft is basic. The limits of clearance or interference are identical with those shown in [Tables 8a to 12](#) for the corresponding fits and the symbols used for these fits are identical with those used for standard fits except that they are followed by the letter S. Thus, LC 4S is a clearance locational fit, Class 4, except that it is produced on a basic shaft basis.

The limits for hole and shaft as given in Tables 8a to 12 are increased for clearance fits (decreased for transition or interference fits) by the value of the upper shaft limit; that is, by the amount required to change the maximum shaft to the basic size.

**Graphical Representation of ANSI Standard Limits and Fits**  
ANSI B4.1-1967 (R1999)

Diagrams show disposition of hole and shaft tolerances (in thousandths of an inch) with respect to basic size (0) for a diameter of 1 inch.

Table 8a. American National Standard Running and Sliding Fits ANSI B4.1-1967 (R1999)

| Nominal<br>Size Range,<br>Inches | Class RC 1                                       |                           |                | Class RC 2             |                           |                | Class RC 3             |                           |               | Class RC 4             |                           |              |

<sup>a</sup> Pairs of values shown represent minimum and maximum amounts of clearance resulting from application of standard tolerance limits.

Tolerance limits given in body of table are added to or subtracted from basic size (as indicated by + or - sign) to obtain maximum and minimum sizes of mating parts.

All data above heavy lines are in accord with ABC agreements. Symbols H5, g4, etc. are hole and shaft designations in ABC system. Limits for sizes above 19.69 inches are also given in the ANSI Standard.

Table 9a. American National Standard Clearance Locational Fits ANSI B4.1-1967 (R1999)

<sup>a</sup> Pairs of values shown represent minimum and maximum amounts of interference resulting from application of standard tolerance limits.

Tolerance limits given in body of table are added or subtracted to basic size (as indicated by + or - sign) to obtain maximum and minimum sizes of mating parts. All data above heavy lines are in accordance with American-British-Canadian (ABC) agreements. Symbols H6, H7, s6, etc. are hole and shaft designations in ABC system. Limits for sizes above 19.69 inches are not covered by ABC agreements but are given in the ANSI Standard.

<sup>a</sup>Pairs of values shown represent maximum amount of interference (–) and maximum amount of clearance (+) resulting from application of standard tolerance limits. All data above heavy lines are in accord with ABC agreements. Symbols H7, js6, etc., are hole and shaft designations in the ABC system.

<sup>a</sup> Pairs of values shown represent minimum and maximum amounts of interference resulting from application of standard tolerance limits.

All data above heavy lines are in accordance with American-British-Canadian (ABC) agreements. Symbols H6, H7, s6, etc., are hole and shaft designations in the ABC system. Limits for sizes above 19.69 inches are not covered by ABC agreements but are given in the ANSI standard.

All data in this table are in accordance with American-British-Canadian (ABC) agreements.

Limits for sizes above 19.69 inches are not covered by ABC agreements but are given in the ANSI Standard.

Symbols H7, p6, etc., are hole and shaft designations in the ABC system.

Tolerance limits given in body of table are added or subtracted to basic size (as indicated by + or – sign) to obtain maximum and minimum sizes of mating parts.

### American National Standard Preferred Metric Limits and Fits

This standard ANSI B4.2-1978 (R1999) describes the ISO system of metric limits and fits for mating parts as approved for general engineering usage in the United States.

It establishes: 1) the designation symbols used to define dimensional limits on drawings, material stock, related tools, gages, etc.; 2) the preferred basic sizes (first and second choices); 3) the preferred tolerance zones (first, second, and third choices); 4) the preferred limits and fits for sizes (first choice only) up to and including 500 millimeters; and 5) the definitions of related terms.

The general terms “hole” and “shaft” can also be taken to refer to the space containing or contained by two parallel faces of any part, such as the width of a slot, or the thickness of a key.

**Definitions.**—The most important terms relating to limits and fits are shown in Fig. 1 and are defined as follows:

*Basic Size:* The size to which limits of deviation are assigned. The basic size is the same for both members of a fit. For example, it is designated by the numbers 40 in 40H7.

*Deviation:* The algebraic difference between a size and the corresponding basic size.

*Upper Deviation:* The algebraic difference between the maximum limit of size and the corresponding basic size.

*Lower Deviation:* The algebraic difference between the minimum limit of size and the corresponding basic size.

*Fundamental Deviation:* That one of the two deviations closest to the basic size. For example, it is designated by the letter H in 40H7.

*Tolerance:* The difference between the maximum and minimum size limits on a part.

*Tolerance Zone:* A zone representing the tolerance and its position in relation to the basic size.

Fig. 1. Illustration of Definitions

*International Tolerance Grade (IT):* A group of tolerances that vary depending on the basic size, but that provide the same relative level of accuracy within a given grade. For example, it is designated by the number 7 in 40H7 or as IT7.

*Hole Basis:* The system of fits where the minimum hole size is basic. The fundamental deviation for a hole basis system is H.

*Shaft Basis:* The system of fits where the maximum shaft size is basic. The fundamental deviation for a shaft basis system is h.

*Clearance Fit:* The relationship between assembled parts when clearance occurs under all tolerance conditions.

*Interference Fit:* The relationship between assembled parts when interference occurs under all tolerance conditions.

*Transition Fit:* The relationship between assembled parts when either a clearance or an interference fit can result, depending on the tolerance conditions of the mating parts.

**Tolerances Designation.**—An “International Tolerance grade” establishes the magnitude of the tolerance zone or the amount of part size variation allowed for external and internal dimensions alike (see Fig. 1). Tolerances are expressed in grade numbers that are consistent with International Tolerance grades identified by the prefix IT, such as IT6, IT11, etc. A smaller grade number provides a smaller tolerance zone.

A fundamental deviation establishes the position of the tolerance zone with respect to the basic size (see Fig. 1). Fundamental deviations are expressed by tolerance position letters. Capital letters are used for internal dimensions and lowercase or small letters for external dimensions.

**Symbols.**—By combining the IT grade number and the tolerance position letter, the tolerance symbol is established that identifies the actual maximum and minimum limits of the part. The toleranced size is thus defined by the basic size of the part followed by a symbol composed of a letter and a number, such as 40H7, 40f7, etc.

A fit is indicated by the basic size common to both components, followed by a symbol corresponding to each component, the internal part symbol preceding the external part symbol, such as 40H8/f7.

Some methods of designating tolerances on drawings are:

$$40H8 \qquad 40H8 \begin{pmatrix} 40.039 \\ 40.000 \end{pmatrix} \qquad \begin{pmatrix} 40.039 \\ 40.000 \end{pmatrix} 40H8$$

The values in parentheses indicate reference only.

**Preferred Metric Fits.**—First-choice tolerance zones are used to establish preferred fits in ANSI B4.2, *Preferred Metric Limits and Fits*, as shown in Figs. 2 and 3. A complete listing of first-, second-, and third- choice tolerance zones is given in the Standard.

Hole basis fits have a fundamental deviation of H on the hole, and shaft basis fits have a fundamental deviation of *h* on the shaft and are shown in Fig. 2 for hole basis and Fig. 3 for shaft basis fits. A description of both types of fits, that have the same relative fit condition, is given in Table 1. Normally, the hole basis system is preferred; however, when a common shaft mates with several holes, the shaft basis system should be used.

The hole basis and shaft basis fits shown in the table *Description of Preferred Fits* on page 669 are combined with the first-choice preferred metric sizes from Table 1 on page 690, to form Tables 2, 3, 4, and 5, in which specific limits as well as the resultant fits are tabulated.

If the required size is not found tabulated in Tables 2 through 5 then the preferred fit can be calculated from numerical values given in an appendix of ANSI B4.2-1978 (R1999). It is anticipated that other fit conditions may be necessary to meet special requirements, and a preferred fit can be loosened or tightened simply by selecting a standard tolerance zone as given in the Standard. Information on how to calculate limit dimensions, clearances, and interferences, for nonpreferred fits and sizes can be found in an appendix of this Standard.

*Conversion of Fits:* It may sometimes be necessary or desirable to modify the tolerance zone on one or both of two mating parts, yet still keep the total tolerance and fit condition the same. Examples of this appear in Table 1 on page 669 when converting from a hole basis fit to a shaft basis fit. The corresponding fits are identical yet the individual tolerance zones are different.

To convert from one type of fit to another, reverse the fundamental deviations between the shaft and hole keeping the IT grade the same on each individual part. The examples below represent preferred fits from Table 1 for a 60-mm basic size. These fits have the same maximum clearance (0.520) and the same minimum clearance (0.140).

Hole basis, loose running fit, values from Table 2

$$\text{Hole } 60H11 \begin{pmatrix} 60.190 \\ 60.000 \end{pmatrix} \qquad \text{Shaft } 60c11 \begin{pmatrix} 59.860 \\ 59.670 \end{pmatrix} \qquad \text{Fit } 60H11/c11 \begin{pmatrix} 0.520 \\ 0.140 \end{pmatrix}$$

Hole basis, loose running fit, values from Table 4

$$\text{Hole } 60C11 \begin{pmatrix} 60.330 \\ 60.140 \end{pmatrix} \qquad \text{Shaft } 60h11 \begin{pmatrix} 60.000 \\ 59.810 \end{pmatrix} \qquad \text{Fit } 60C11/h11 \begin{pmatrix} 0.520 \\ 0.140 \end{pmatrix}$$

PREFERRED METRIC FITS

<sup>a</sup>The sizes shown are first-choice basic sizes (see Table 1). Preferred fits for other sizes can be calculated from data given in ANSI B4.2-1978 (R1999).

<sup>b</sup>All fits shown in this table have clearance.

All dimensions are in millimeters.

**Table 3. American National Standard Preferred Hole Basis Metric Transition and Interference Fits ANSI B4.2-1978 (R1999)**

| Basic Size <sup>a</sup> |     | Locational Transition |          |                  | Locational Transition |          |                  | Locational Interference |          |                  | Medium Drive |          |                  | Force   |          |                  |

<sup>a</sup>The sizes shown are first-choice basic sizes (see Table 1). Preferred fits for other sizes can be calculated from data given in ANSI B4.2-1978 (R1999).

<sup>b</sup>A plus sign indicates clearance; a minus sign indicates interference.

All dimensions are in millimeters.

Table 4. American National Standard Preferred Shaft Basis Metric Clearance Fits ANSI B4.2-1978 (R1999)

| Basic Size <sup>a</sup> |     | Loose Running |           |                  | Free Running |          |                  | Close Running |          |                  | Sliding |          |                  | Locational Clearance |          |                  |
|-------------------------|-----|---------------|-----------|------------------|--------------|----------|------------------|---------------|----------|------------------|---------|----------|------------------|----------------------|----------|------------------|

<sup>a</sup>The sizes shown are first-choice basic sizes (see Table 1). Preferred fits for other sizes can be calculated from data given in ANSI B4.2-1978 (R1999).

<sup>b</sup>All fits shown in this table have clearance.

All dimensions are in millimeters.

Table 5. American National Standard Preferred Shaft Basis Metric Transition and Interference Fits ANSI B4.2-1978 (R1999)

<sup>a</sup>The sizes shown are first-choice basic sizes (see Table 1). Preferred fits for other sizes can be calculated from data given in ANSI B4.2-1978 (R1999).

<sup>b</sup>A plus sign indicates clearance; a minus sign indicates interference.

All dimensions are in millimeters.

All dimensions are in millimeters. For closer gagemakers tolerance classes than Class XXXM, specify 5 per cent of IT5, IT4, or IT3 and use the designation 0.05 IT5, 0.05 IT4, etc.

Fig. 4. Relationship between Gagemakers Tolerance, Wear Allowance and Workpiece Tolerance

**Applications.**—Many factors such as length of engagement, bearing load, speed, lubrication, operating temperatures, humidity, surface texture, and materials must be taken into account in fit selections for a particular application.

Choice of other than the preferred fits might be considered necessary to satisfy extreme conditions. Subsequent adjustments might also be desired as the result of experience in a particular application to suit critical functional requirements or to permit optimum manufacturing economy. Selection of a departure from these recommendations will depend upon consideration of the engineering and economic factors that might be involved; however, the benefits to be derived from the use of preferred fits should not be overlooked.

A general guide to machining processes that may normally be expected to produce work within the tolerances indicated by the IT grades given in ANSI B4.2-1978 (R1999) is shown in Table 8. Practical usage of the various IT tolerance grades is shown in Table 9.

**Table 8. Relation of Machining Processes to IT Tolerance Grades**

### British Standard for Metric ISO Limits and Fits

Based on ISO Recommendation R286, this British Standard BS 4500:1969 is intended to provide a comprehensive range of metric limits and fits for engineering purposes, and meets the requirements of metrication in the United Kingdom. Sizes up to 3,150 mm are covered by the Standard, but the condensed information presented here embraces dimensions up to 500 mm only. The system is based on a series of tolerances graded to suit all classes of work from the finest to the most coarse, and the different types of fits that can be obtained range from coarse clearance to heavy interference. In the Standard, only cylindrical parts, designated holes and shafts are referred to explicitly, but it is emphasized that the recommendations apply equally well to other sections, and the general term *hole* or *shaft*

can be taken to mean the space contained by or containing two parallel faces or tangent planes of any part, such as the width of a slot, or the thickness of a key. It is also strongly emphasized that the grades series of tolerances are intended for the most general application, and should be used wherever possible whether the features of the component involved are members of a fit or not.

**Definitions.**—The definitions given in the Standard include the following:

*Limits of Size:* The maximum and minimum sizes permitted for a feature.

*Basic Size:* The reference size to which the limits of size are fixed. The basic size is the same for both members of a fit.

*Upper Deviation:* The algebraical difference between the maximum limit of size and the corresponding basic size. It is designated as ES for a hole, and as es for a shaft, which stands for the French term *écart supérieur*.

*Lower Deviation:* The algebraical difference between the minimum limit of size and the corresponding basic size. It is designated as EI for a hole, and as ei for a shaft, which stands for the French term *écart inférieur*.

*Zero Line:* In a graphical representation of limits and fits, the straight line to which the deviations are referred. The zero line is the line of zero deviation and represents the basic size.

*Tolerance:* The difference between the maximum limit of size and the minimum limit of size. It is an absolute value without sign.

*Tolerance Zone:* In a graphical representation of tolerances, the zone comprised between the two lines representing the limits of tolerance and defined by its magnitude (tolerance) and by its position in relation to the zero line.

*Fundamental Deviation:* That one of the two deviations, being the one nearest to the zero line, which is conventionally chosen to define the position of the tolerance zone in relation to the zero line.

*Shaft-Basis System of Fits:* A system of fits in which the different clearances and interferences are obtained by associating various holes with a single shaft. In the ISO system, the basic shaft is the shaft the upper deviation of which is zero.

*Hole-Basis System of Fits:* A system of fits in which the different clearances and interferences are obtained by associating various shafts with a single hole. In the ISO system, the basic hole is the hole the lower deviation of which is zero.

**Selected Limits of Tolerance, and Fits.**—The number of fit combinations that can be built up with the ISO system is very large. However, experience shows that the majority of fits required for usual engineering products can be provided by a limited selection of tolerances. Limits of tolerance for selected holes are shown in [Table 1](#), and for shafts, in [Table 2](#). Selected fits, based on combinations of the selected hole and shaft tolerances, are given in [Table 3](#).

**Tolerances and Fundamental Deviations.**—There are 18 tolerance grades intended to meet the requirements of different classes of work, and they are designated IT01, IT0, and IT1 to IT16. (IT stands for ISO series of tolerances.) [Table 4](#) shows the standardized numerical values for the 18 tolerance grades, which are known as standard tolerances. The system provides 27 fundamental deviations for sizes up to and including 500 mm, and [Tables 5a](#) and [5b](#) contain the values for shafts and [Tables 6a](#) and [6b](#) for holes. Uppercase (capital) letters designate hole deviations, and the same letters in lower case designate shaft deviations. The deviation  $j_s$  ( $J_s$  for holes) is provided to meet the need for symmetrical bilateral tolerances. In this instance, there is no fundamental deviation, and the tolerance zone, of whatever magnitude, is equally disposed about the zero line.

**Calculated Limits of Tolerance.**—The deviations and fundamental tolerances provided by the ISO system can be combined in any way that appears necessary to give a required fit. Thus, for example, the deviations H (basic hole) and f (clearance shaft) could be associated, and with each of these deviations any one of the tolerance grades IT01 to IT16 could

be used. All the limits of tolerance that the system is capable of providing for sizes up to and including 500 mm can be calculated from the standard tolerances given in [Table 4](#), and the fundamental deviations given in [Tables 5a](#), [5b](#), [6a](#) and [6b](#). The range includes limits of tolerance for shafts and holes used in small high-precision work and horology.

The system provides for the use of either hole-basis or shaft-basis fits, and the Standard includes details of procedures for converting from one type of fit to the other.

The limits of tolerance for a shaft or hole are designated by the appropriate letter indicating the fundamental deviation, followed by a suffix number denoting the tolerance grade. This suffix number is the numerical part of the tolerance grade designation. Thus, a hole tolerance with deviation H and tolerance grade IT7 is designated H7. Likewise, a shaft with deviation p and tolerance grade IT6 is designated p6. The limits of size of a component feature are defined by the basic size, say, 45 mm, followed by the appropriate tolerance designation, for example, 45 H7 or 45 p6. A fit is indicated by combining the basic size common to both features with the designation appropriate to each of them, for example, 45 H7-p6 or 45 H7/p6.

When calculating the limits of size for a shaft, the upper deviation  $e_s$ , or the lower deviation  $e_i$ , is first obtained from [Tables 5a](#) or [5b](#), depending on the particular letter designation, and nominal dimension. If an upper deviation has been determined, the lower deviation  $e_i = e_s - IT$ . The IT value is obtained from [Table 4](#) for the particular tolerance grade being applied. If a lower deviation has been obtained from [Tables 5a](#) or [5b](#), the upper deviation  $e_s = e_i + IT$ . When the upper deviation ES has been determined for a hole from [Tables 6a](#) or [6b](#), the lower deviation EI = ES - IT. If a lower deviation EI has been obtained from [Table 6a](#), then the upper deviation ES = EI + IT.

The upper deviations for holes K, M, and N with tolerance grades up to and including IT8, and for holes P to ZC with tolerance grades up to and including IT7 must be calculated by adding the delta ( $\Delta$ ) values given in [Table 6b](#) as indicated.

*Example 1:* The limits of size for a part of 133 mm basic size with a tolerance designation g9 are derived as follows:

From [Table 5a](#), the upper deviation ( $e_s$ ) is  $-0.014$  mm. From [Table 4](#), the tolerance grade (IT9) is 0.100 mm. The lower deviation ( $e_i$ ) =  $e_s - IT = 0.114$  mm, and the limits of size are thus 132.986 and 132.886 mm.

*Example 2:* The limits of size for a part 20 mm in size, with tolerance designation D3, are derived as follows: From [Table 6a](#), the lower deviation (EI) is  $+0.065$  mm. From [Table 4](#), the tolerance grade (IT3) is 0.004 mm. The upper deviation (ES) =  $EI + IT = 0.069$  mm, and thus the limits of size for the part are 20.069 and 20.065 mm.

*Example 3:* The limits of size for a part 32 mm in size, with tolerance designation M5, which involves a delta value, are obtained as follows: From [Table 6a](#), the upper deviation ES is  $-0.009$  mm +  $\Delta = -0.005$  mm. (The delta value given at the end of [Table 6b](#) for this size and grade IT5 is 0.004 mm.) From [Table 4](#), the tolerance grade (IT5) is 0.011 mm. The lower deviation (EI) =  $ES - IT = -0.016$  mm, and thus the limits of size for the part are 31.995 and 31.984 mm.

Where the designations h and H or  $j_s$  and  $J_s$  are used, it is only necessary to refer to [Table 4](#). For h and H, the fundamental deviation is always zero, and the disposition of the tolerance is always negative ( - ) for a shaft, and positive ( + ) for a hole.

*Example 4:* The limits for a part 40 mm in size, designated h8 are derived as follows: From [Table 4](#), the tolerance grade (IT8) is 0.039 mm, and the limits are therefore 40.000 and 39.961 mm.

*Example 5:* The limits for a part 60 mm in size, designated  $j_s7$  or  $J_s7$  are derived as follows: From [Table 4](#), the tolerance grade (IT7) is 0.030 mm, and this value is divided equally about the basic size to give limits of 60.015 and 59.985 mm.

**Table 1. British Standard Limits of Tolerance for Selected Holes (Upper and Lower Deviations) BS 4500:1969**

| Nominal Sizes, mm |                     | H7   |    | H8   |    | H9   |    | H11  |    |

The dimensions are given in 0.001 mm, except for the nominal sizes, which are in millimeters.

Minus (-) sign indicates negative clearance, i.e., interference.

<sup>a</sup>Not applicable to sizes up to 1 mm.

<sup>b</sup>In grades 7 to 11, the two symmetrical deviations ±IT/2 should be rounded if the IT value in micrometers is an odd value by replacing it with the even value immediately below. For example, if IT = 175, replace it by 174.

Table 5b. British Standard Fundamental Deviations for Shafts BS 4500:1969

<sup>a</sup> Special case: for M6, ES = -9 for sizes from 250 to 315 mm, instead of -11.

<sup>b</sup> Not applicable to sizes up to 1 mm.

<sup>c</sup> In grades 7 to 11, the two symmetrical deviations ±IT/2 should be rounded if the IT value in micrometers is an odd value, by replacing it with the even value below. For example, if IT = 175, replace it by 174.

<sup>d</sup> When calculating deviations for holes K, M, and N with tolerance grades up to and including IT8, and holes F to ZC with tolerance grades up to and including IT7, the delta (Δ) values are added to the upper deviation ES. For example, for 25 P7, ES = -0.022 + 0.008 = -0.014 mm.

| 450               | 500 | -68  | -132  | -252 | -360 | -540 | -660 | -820 | -1000 | -1250 | -1600 | -2100 | -2600 | 5     | 5  | 7   | 13 | 23 | 34 |    |   |

The dimensions are given in 0.001 mm, except the nominal sizes, which are in millimeters.

### Preferred Numbers

Preferred numbers are series of numbers selected to be used for standardization purposes in preference to any other numbers. Their use will lead to simplified practice and they should be employed whenever possible for individual standard sizes and ratings, or for a series, in applications similar to the following:

1) Important or characteristic linear dimensions, such as diameters and lengths, areas, volume, weights, capacities.

2) Ratings of machinery and apparatus in horsepower, kilowatts, kilovolt-amperes, voltages, currents, speeds, power-factors, pressures, heat units, temperatures, gas or liquid-flow units, weight-handling capacities, etc.

3) Characteristic ratios of figures for all kinds of units.

**American National Standard for Preferred Numbers.**—This ANSI Standard Z17.1-1973 covers basic series of preferred numbers which are independent of any measurement system and therefore can be used with metric or customary units.

The numbers are rounded values of the following five geometric series of numbers:  $10^{N/5}$ ,  $10^{N/10}$ ,  $10^{N/20}$ ,  $10^{N/40}$ , and  $10^{N/80}$ , where  $N$  is an integer in the series 0, 1, 2, 3, etc. The designations used for the five series are respectively R5, R10, R20, R40, and R80, where R stands for Renard (Charles Renard, originator of the first preferred number system) and the number indicates the root of 10 on which the particular series is based.

The R5 series gives 5 numbers approximately 60 per cent apart, the R10 series gives 10 numbers approximately 25 per cent apart, the R20 series gives 20 numbers approximately 12 per cent apart, the R40 series gives 40 numbers approximately 6 per cent apart, and the R80 series gives 80 numbers approximately 3 per cent apart. The number of sizes for a given purpose can be minimized by using first the R5 series and adding sizes from the R10 and R20 series as needed. The R40 and R80 series are used principally for expressing tolerances in sizes based on preferred numbers. Preferred numbers below 1 are formed by dividing the given numbers by 10, 100, etc., and numbers above 10 are obtained by multiplying the given numbers by 10, 100, etc. Sizes graded according to the system may not be exactly proportional to one another due to the fact that preferred numbers may differ from calculated values by +1.26 per cent to -1.01 per cent. Deviations from preferred numbers are used in some instances — for example, where whole numbers are needed, such as 32 instead of 31.5 for the number of teeth in a gear.

#### Basic Series of Preferred Numbers ANSI Z17.1-1973

| Series Designation |      |      |      |      |      |      |      |      |

**Preferred Metric Sizes.**—American National Standard ANSI B32.4M-1980 (R1994), presents series of preferred metric sizes for round, square, rectangular, and hexagonal metal products. Table 1 gives preferred metric diameters from 1 to 320 millimeters for round metal products. Wherever possible, sizes should be selected from the Preferred Series shown in the table. A Second Preference series is also shown. A Third Preference Series not shown in the table is: 1.3, 2.1, 2.4, 2.6, 3.2, 3.8, 4.2, 4.8, 7.5, 8.5, 9.5, 36, 85, and 95.

Most of the Preferred Series of sizes are derived from the American National Standard "10 series" of preferred numbers (see *American National Standard for Preferred Numbers* on page 689). Most of the Second Preference Series are derived from the "20 series" of preferred numbers. Third Preference sizes are generally from the "40 series" of preferred numbers.

For preferred metric diameters less than 1 millimeter, preferred across flat metric sizes of square and hexagon metal products, preferred across flat metric sizes of rectangular metal products, and preferred metric lengths of metal products, reference should be made to the Standard.

**Table 1. American National Standard Preferred Metric Sizes**  
*ANSI B4.2-1978 (R1999)*

| Basic Size, mm |            | Basic Size, mm |            | Basic Size, mm |            | Basic Size, mm |            |

**British Standard Preferred Numbers and Preferred Sizes.**—This British Standard, PD 6481:1977 1983, gives recommendations for the use of preferred numbers and preferred sizes for functional characteristics and dimensions of various products.

The preferred number system is internationally standardized in ISO 3. It is also referred to as the Renard, or R, series (see *American National Standard for Preferred Numbers*, on page 689).

The series in the preferred number system are geometric series, that is, there is a constant ratio between each figure and the succeeding one, within a decimal framework. Thus, the R5 series has five steps between 1 and 10, the R10 series has 10 steps between 1 and 10, the R20 series, 20 steps, and the R40 series, 40 steps, giving increases between steps of approximately 60, 25, 12, and 6 per cent, respectively.

The preferred size series have been developed from the preferred number series by rounding off the inconvenient numbers in the basic series and adjusting for linear measurement in millimeters. These series are shown in Table 2.

After taking all normal considerations into account, it is recommended that (a) for ranges of values of the primary *functional* characteristics (outputs and capacities) of a series of

products, the preferred number series R5 to R40 (see page 689) should be used, and (b) whenever linear sizes are concerned, the preferred sizes as given in the following table should be used. The presentation of preferred sizes gives designers and users a logical selection and the benefits of rational variety reduction.

The second-choice size given should only be used when it is not possible to use the first choice, and the third choice should be applied only if a size from the second choice cannot be selected. With this procedure, common usage will tend to be concentrated on a limited range of sizes, and a contribution is thus made to variety reduction. However, the decision to use a particular size cannot be taken on the basis that one is first choice and the other not. Account must be taken of the effect on the design, the availability of tools, and other relevant factors.

**Table 2. British Standard Preferred Sizes, PD 6481: 1977 (1983)**

| Choice |     |     | Choice |     |     | Choice |     |     | Choice |     |     | Choice |     |     | Choice |     |     |
|--------|-----|-----|--------|-----|-----|--------|-----|-----|--------|-----|-----|--------|-----|-----|--------|-----|-----|
| 1st    | 2nd | 3rd | 1st    | 2nd | 3rd | 1st    | 2nd | 3rd | 1st    | 2nd | 3rd | 1st    | 2nd | 3rd | 1st    | 2nd | 3rd |
| 1      |     |     |        |     | 5.2 |        |     | 23  | 65     |     |     |        |     | 122 |        |     | 188 |
|        | 1.1 |     |        | 5.5 |     |        |     | 24  |        |     | 66  |        | 125 |     | 190    |     |     |
| 1.2    |     |     |        | 5.8 | 25  |        |     | 26  | 70     | 68  |     | 130    |     | 128 |        | 195 | 192 |
|        | 1.4 |     | 6      |     |     | 28     |     |     |        | 72  |     |        |     | 132 |        |     | 198 |
|        |     | 1.3 |        | 6.2 |     |        |     |     |        |     | 74  |        | 135 |     | 200    |     |     |
| 1.6    |     |     |        | 6.5 | 30  |        |     |     | 75     |     | 76  |        | 140 |     | 210    |     | 205 |
|        |     | 1.5 |        | 6.8 |     | 32     |     | 34  |        |     |     |        |     | 138 |        |     |     |
|        | 1.8 |     |        | 7   |     |        |     |     |        | 78  |     |        |     | 142 |        |     | 215 |
|        |     | 1.9 | 8      |     |     |        |     |     | 80     |     |     |        | 145 |     | 220    |     |     |
| 2      |     |     |        | 8.5 |     |        | 38  |     |        |     |     |        |     | 148 |        |     | 225 |
|        |     | 2.1 |        | 9   |     |        | 40  |     |        | 85  |     | 150    |     | 152 |        | 230 |     |
|        | 2.2 |     |        | 9.5 |     |        | 42  |     |        |     | 88  |        |     | 155 |        |     | 235 |
|        |     | 2.4 | 10     |     |     |        |     | 44  | 90     |     |     |        |     | 158 |        | 240 |     |
| 2.5    |     |     |        | 11  |     |        | 45  |     |        |     | 92  |        |     | 160 |        |     | 245 |
|        |     | 2.6 |        | 12  |     |        |     | 46  |        | 95  |     | 165    |     | 162 |        | 250 |     |
| 2.8    |     |     |        | 13  |     |        | 48  |     |        |     |     |        |     | 166 |        |     | 255 |
| 3      |     |     |        | 14  |     |        | 50  |     | 100    |     |     |        |     | 168 |        | 260 |     |
|        |     | 3.2 |        | 15  |     |        |     | 52  |        |     |     |        |     | 170 |        |     | 265 |
|        | 3.5 |     | 16     |     |     |        |     | 54  | 105    |     |     |        | 175 |     |        | 270 |     |
|        |     | 3.8 |        | 17  | 55  |        |     | 56  |        | 110 |     |        |     | 172 |        |     | 275 |
| 4      |     |     |        | 18  |     |        |     | 58  |        |     |     |        | 177 |     | 280    |     |     |
|        |     | 4.2 |        | 19  |     |        |     | 59  |        |     |     |        | 178 |     |        |     | 285 |
|        | 4.5 |     | 20     |     |     |        | 60  |     |        | 115 |     | 180    |     | 182 |        | 290 |     |
|        |     | 4.8 |        | 21  |     |        | 62  |     |        |     | 118 |        |     | 185 |        |     | 295 |
| 5      |     |     |        | 22  |     |        |     | 64  | 120    |     |     |        |     |     | 300    |     |     |

For dimensions above 300, each series continues in a similar manner, i.e., the intervals between each series number are the same as between 200 and 300.

## MEASURING INSTRUMENTS AND INSPECTION METHODS

## Verniers and Micrometers

**Reading a Vernier.**—A general rule for taking readings with a vernier scale is as follows: Note the number of inches and sub-divisions of an inch that the zero mark of the vernier scale has moved along the true scale, and then add to this reading as many thousandths, or hundredths, or whatever fractional part of an inch the vernier reads to, as there are spaces between the vernier zero and that line on the vernier which coincides with one on the true scale. For example, if the zero line of a vernier which reads to thousandths is slightly beyond the 0.5 inch division on the main or true scale, as shown in Fig. 1, and graduation line 10 on the vernier exactly coincides with one on the true scale, the reading is  $0.5 + 0.010$  or 0.510 inch. In order to determine the reading or fractional part of an inch that can be obtained by a vernier, multiply the denominator of the finest sub-division given on the true scale by the total number of divisions on the vernier. For example, if one inch on the true scale is divided into 40 parts or fortieths (as in Fig. 1), and the vernier into twenty-five parts, the vernier will read to thousandths of an inch, as  $25 \times 40 = 1000$ . Similarly, if there are sixteen divisions to the inch on the true scale and a total of eight on the vernier, the latter will enable readings to be taken within one-hundred-twenty-eighths of an inch, as  $8 \times 16 = 128$ .

Fig. 1.

Fig. 2.

If the vernier is on a protractor, note the whole number of degrees passed by the vernier zero mark and then count the spaces between the vernier zero and that line which coincides with a graduation on the protractor scale. If the vernier indicates angles within five minutes or one-twelfth degree (as in Fig. 2), the number of spaces multiplied by 5 will, of course, give the number of minutes to be added to the whole number of degrees. The reading of the protractor set as illustrated would be 14 whole degrees (the number passed by the zero mark on the vernier) plus 30 minutes, as the graduation 30 on the vernier is the only one to

the right of the vernier zero which exactly coincides with a line on the protractor scale. It will be noted that there are duplicate scales on the vernier, one being to the right and the other to the left of zero. The left-hand scale is used when the vernier zero is moved to the left of the zero of the protractor scale, whereas the right-hand graduations are used when the movement is to the right.

**Reading a Metric Vernier.**—The smallest graduation on the bar (true or main scale) of the metric vernier gage shown in Fig. 1, is 0.5 millimeter. The scale is numbered at each twentieth division, and thus increments of 10, 20, 30, 40 millimeters, etc., are indicated. There are 25 divisions on the vernier scale, occupying the same length as 24 divisions on the bar, which is 12 millimeters. Therefore, one division on the vernier scale equals one twenty-fifth of 12 millimeters =  $0.04 \times 12 = 0.48$  millimeter. Thus, the difference between one bar division (0.50 mm) and one vernier division (2.48 mm) is  $0.50 - 0.48 = 0.02$  millimeter, which is the minimum measuring increment that the gage provides. To permit direct readings, the vernier scale has graduations to represent tenths of a millimeter (0.1 mm) and fiftieths of a millimeter (0.02 mm).

Fig. 1.

To read a vernier gage, first note how many millimeters the zero line on the vernier is from the zero line on the bar. Next, find the graduation on the vernier scale which exactly coincides with a graduation line on the bar, and note the value of the vernier scale graduation. This value is added to the value obtained from the bar, and the result is the total reading.

In the example shown in Fig. 1, the vernier zero is just past the 40.5 millimeters graduation on the bar. The 0.18 millimeter line on the vernier coincides with a line on the bar, and the total reading is therefore  $40.5 + 0.18 = 40.68$  mm.

**Dual Metric-Inch Vernier.**—The vernier gage shown in Fig. 2 has separate metric and inch 50-division vernier scales to permit measurements in either system.

A 50-division vernier has more widely spaced graduations than the 25-division vernier shown on the previous pages, and is thus easier to read. On the bar, the smallest metric graduation is 1 millimeter, and the 50 divisions of the vernier occupy the same length as 49 divisions on the bar, which is 49 mm. Therefore, one division on the vernier scale equals one-fiftieth of 49 millimeters =  $0.02 \times 49 = 0.98$  mm. Thus, the difference between one bar division (1.0 mm) and one vernier division (0.98 mm) is 0.02 mm, which is the minimum measuring increment the gage provides.

The vernier scale is graduated for direct reading to 0.02 mm. In the figure, the vernier zero is just past the 27 mm graduation on the bar, and the 0.42 mm graduation on the vernier coincides with a line on the bar. The total reading is therefore 27.42 mm.

The smallest inch graduation on the bar is 0.05 inch, and the 50 vernier divisions occupy the same length as 49 bar divisions, which is 2.45 inches. Therefore, one vernier division

equals one-fiftieth of 2.45 inches =  $0.02 \times 2.45 = 0.049$  inch. Thus, the difference between the length of a bar division and a vernier division is  $0.050 - 0.049 = 0.001$  inch. The vernier scale is graduated for direct reading to 0.001 inch. In the example, the vernier zero is past the 1.05 graduation on the bar, and the 0.029 graduation on the vernier coincides with a line on the bar. Thus, the total reading is 1.079 inches.

Fig. 2.

**Reading a Micrometer.**—The spindle of an inch-system micrometer has 40 threads per inch, so that one turn moves the spindle axially  $0.025$  inch ( $1 \div 40 = 0.025$ ), equal to the distance between two graduations on the frame. The 25 graduations on the thimble allow the  $0.025$  inch to be further divided, so that turning the thimble through one division moves the spindle axially  $0.001$  inch ( $0.025 \div 25 = 0.001$ ). To read a micrometer, count the number of whole divisions that are visible on the scale of the frame, multiply this number by 25 (the number of thousandths of an inch that each division represents) and add to the product the number of that division on the thimble which coincides with the axial zero line on the frame. The result will be the diameter expressed in thousandths of an inch. As the numbers 1, 2, 3, etc., opposite every fourth sub-division on the frame, indicate hundreds of thousandths, the reading can easily be taken mentally. Suppose the thimble were screwed out so that graduation 2, and three additional sub-divisions, were visible (as shown in Fig. 3), and that graduation 10 on the thimble coincided with the axial line on the frame. The reading then would be  $0.200 + 0.075 + 0.010$ , or  $0.285$  inch.

Fig. 3. Inch Micrometer

Fig. 4. Inch Micrometer with Vernier

Some micrometers have a vernier scale on the frame in addition to the regular graduations, so that measurements within  $0.0001$  part of an inch can be taken. Micrometers of this type are read as follows: First determine the number of thousandths, as with an ordinary micrometer, and then find a line on the vernier scale that exactly coincides with one on the thimble; the number of this line represents the number of ten-thousandths to be added to the number of thousandths obtained by the regular graduations. The reading shown in the illustration, Fig. 4, is  $0.270 + 0.0003 = 0.2703$  inch.

Micrometers graduated according to the English system of measurement ordinarily have a table of decimal equivalents stamped on the sides of the frame, so that fractions such as sixty-fourths, thirty-seconds, etc., can readily be converted into decimals.

**Reading a Metric Micrometer.**—The spindle of an ordinary metric micrometer has 2 threads per millimeter, and thus one complete revolution moves the spindle through a distance of 0.5 millimeter. The longitudinal line on the frame is graduated with 1 millimeter divisions and 0.5 millimeter sub-divisions. The thimble has 50 graduations, each being 0.01 millimeter (one-hundredth of a millimeter).

To read a metric micrometer, note the number of millimeter divisions visible on the scale of the sleeve, and add the total to the particular division on the thimble which coincides with the axial line on the sleeve. Suppose that the thimble were screwed out so that graduation 5, and one additional 0.5 sub-division were visible (as shown in Fig. 5), and that graduation 28 on the thimble coincided with the axial line on the sleeve. The reading then would be  $5.00 + 0.5 + 0.28 = 5.78$  mm.

Some micrometers are provided with a vernier scale on the sleeve in addition to the regular graduations to permit measurements within 0.002 millimeter to be made. Micrometers of this type are read as follows: First determine the number of whole millimeters (if any) and the number of hundredths of a millimeter, as with an ordinary micrometer, and then find a line on the sleeve vernier scale which exactly coincides

Fig. 5. Metric Micrometer

with one on the thimble. The number of this coinciding vernier line represents the number of two-thousandths of a millimeter to be added to the reading already obtained. Thus, for example, a measurement of 2.958 millimeters would be obtained by reading 2.5 millimeters on the sleeve, adding 0.45 millimeter read from the thimble, and then adding 0.008 millimeter as determined by the vernier.

*Note:* 0.01 millimeter = 0.000393 inch, and 0.002 millimeter = 0.000078 inch (78 millionths). Therefore, metric micrometers provide smaller measuring increments than comparable inch unit micrometers—the smallest graduation of an ordinary inch reading micrometer is 0.001 inch; the vernier type has graduations down to 0.0001 inch. When using either a metric or inch micrometer, without a vernier, smaller readings than those graduated may of course be obtained by visual interpolation between graduations.

### Sine-bar

The sine-bar is used either for very accurate angular measurements or for locating work at a given angle as, for example, in surface grinding templets, gages, etc. The sine-bar is especially useful in measuring or checking angles when the limit of accuracy is 5 minutes or less. Some bevel protractors are equipped with verniers which read to 5 minutes but the setting depends upon the alignment of graduations whereas a sine-bar usually is located by positive contact with precision gage-blocks selected for whatever dimension is required for obtaining a given angle.

**Types of Sine-bars.**—A sine-bar consists of a hardened, ground and lapped steel bar with very accurate cylindrical plugs of equal diameter attached to or near each end. The form illustrated by Fig. 3 has notched ends for receiving the cylindrical plugs so that they are held firmly against both faces of the notch. The standard center-to-center distance *C* between the plugs is either 5 or 10 inches. The upper and lower sides of sine-bars are parallel to the center line of the plugs within very close limits. The body of the sine-bar ordi-

narily has several through holes to reduce the weight. In the making of the sine-bar shown in Fig. 4, if too much material is removed from one locating notch, regrinding the shoulder at the opposite end would make it possible to obtain the correct center distance. That is the reason for this change in form. The type of sine-bar illustrated by Fig. 5 has the cylindrical disks or plugs attached to one side. These differences in form or arrangement do not, of course, affect the principle governing the use of the sine-bar. An accurate surface plate or master flat is always used in conjunction with a sine-bar in order to form the base from which the vertical measurements are made.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

**Setting a Sine-bar to a Given Angle.**—To find the vertical distance  $H$ , for setting a sine-bar to the required angle, convert the angle to decimal form on a pocket calculator, take the sine of that angle, and multiply by the distance between the cylinders. For example, if an angle of 31 degrees, 30 minutes is required, the equivalent angle is 31 degrees plus  $\frac{30}{60} = 31 + 0.5$ , or 31.5 degrees. (For conversions from minutes and seconds to decimals of degrees and vice versa, see page 96). The sine of 31.5 degrees is 0.5225 and multiplying this value by the sine-bar length gives 2.613 in. for the height  $H$ , Fig. 1 and 3, of the gage blocks.

**Finding Angle when Height  $H$  of Sine-bar is Known.**—To find the angle equivalent to a given height  $H$ , reverse the above procedure. Thus, if the height  $H$  is 1.4061 in., dividing by 5 gives a sine of 0.28122, which corresponds to an angle of 16.333 degrees, or 16 degrees 20 minutes.

**Checking Angle of Templet or Gage by Using Sine-bar.**—Place templet or gage on sine-bar as indicated by dotted lines, Fig. 1. Clamps may be used to hold work in place. Place upper end of sine-bar on gage blocks having total height  $H$  corresponding to the required angle. If upper edge  $D$  of work is parallel with surface plate  $E$ , then angle  $A$  of work equals angle  $A$  to which sine-bar is set. Parallelism between edge  $D$  and surface plate may be tested by checking the height at each end with a dial gage or some type of indicating comparator.

**Measuring Angle of Templet or Gage with Sine-bar.**—To measure such an angle, adjust height of gage blocks and sine-bar until edge  $D$ , Fig. 1, is parallel with surface plate  $E$ ; then find angle corresponding to height  $H$ , of gage blocks. For example, if height  $H$  is

2.5939 inches when  $D$  and  $E$  are parallel, the calculator will show that the angle  $A$  of the work is 31 degrees, 15 minutes.

**Checking Taper per Foot with Sine-bar.**—As an example, assume that the plug gage in Fig. 2 is supposed to have a taper of  $6\frac{1}{8}$  inches per foot and taper is to be checked by using a 5-inch sine-bar. The table of *Tapers per Foot and Corresponding Angles* on page 714 shows that the included angle for a taper of  $6\frac{1}{8}$  inches per foot is 28 degrees 38 minutes 1 second, or 28.6336 degrees from the calculator. For a 5-inch sine-bar, the calculator gives a value of 2.396 inch for the height  $H$  of the gage blocks. Using this height, if the upper surface  $F$  of the plug gage is parallel to the surface plate the angle corresponds to a taper of  $6\frac{1}{8}$  inches per foot.

**Setting Sine-bar having Plugs Attached to Side.**—If the lower plug does not rest directly on the surface plate, as in Fig. 3, the height  $H$  for the sine-bar is the difference between heights  $x$  and  $y$ , or the difference between the heights of the plugs; otherwise, the procedure in setting the sine-bar and checking angles is the same as previously described.

**Checking Templets Having Two Angles.**—Assume that angle  $a$  of templet, Fig. 4, is 9 degrees, angle  $b$  12 degrees, and that edge  $G$  is parallel to the surface plate. For an angle  $b$  of 12 degrees, the calculator shows that the height  $H$  is 1.03956 inches. For an angle  $a$  of 9 degrees, the difference between measurements  $x$  and  $y$  when the sine-bar is in contact with the upper edge of the templet is 0.78217 inch.

**Using Sine-bar Tables to Set 5-inch and 100-mm Sine-bars to Given Angle.**—The table starting on page 699 gives constants for a 5-inch sine-bar, and starting on page 706 are given constants for a 100-mm sine-bar. These constants represent the vertical height  $H$  for setting a sine-bar of the corresponding length to the required angle.

**Using Sine-bar Tables with Sine-bars of Other Lengths.**—A sine-bar may sometimes be preferred that is longer (or shorter) than that given in available tables because of its longer working surface or because the longer center distance is conducive to greater precision. To use the sine-bar tables with a sine-bar of another length to obtain the vertical distances  $H$ , multiply the value obtained from the table by the fraction (length of sine-bar used  $\div$  length of sine-bar specified in table).

*Example:* Use the 5-inch sine-bar table to obtain the vertical height  $H$  for setting a 10-inch sine-bar to an angle of  $39^\circ$ . The sine of  $39^\circ$  is 0.62932, hence the vertical height  $H$  for setting a 10-inch sine-bar is 6.2932 inches.

*Solution:* The height  $H$  given for  $39^\circ$  in the 5-inch sine-bar table (page 703) is 3.14660. The corresponding height for a 10-inch sine-bar is  $\frac{10}{5} \times 3.14660 = 6.2932$  inches.

**Using a Calculator to Determine Sine-bar Constants for a Given Angle.**—The constant required to set a given angle for a sine-bar of any length can be quickly determined by using a scientific calculator. The required formulas are as follows:

a) angle  $A$  given in degrees and calculator is set to measure angles in radian

or

a) angle  $A$  is given in radian, or  
b) angle  $A$  is given in degrees and calculator is set to measure angles in degrees

$$H = L \times \sin\left(A \times \frac{\pi}{180}\right)$$

$$H = L \times \sin(A)$$

where  $L$  = length of the sine-bar  $A$  = angle to which the sine-bar is to be set

$H$  = vertical height to which one end of sine-bar must be set to obtain angle  $A$

$$\pi = 3.141592654$$

In the previous formulas, the height  $H$  and length  $L$  must be given in the same units, but may be in either metric or US units. Thus, if  $L$  is given in mm, then  $H$  is in mm; and, if  $L$  is given in inches, then  $H$  is in inches.

**Measuring Tapers with Vee-block and Sine-bar.**—The taper on a conical part may be checked or found by placing the part in a vee-block which rests on the surface of a sine-plate or sine-bar as shown in the accompanying diagram. The advantage of this method is that the axis of the vee-block may be aligned with the sides of the sine-bar. Thus when the tapered part is placed in the vee-block it will be aligned perpendicular to the transverse axis of the sine-bar.

The sine-bar is set to angle  $B = (C + A/2)$  where  $A/2$  is one-half the included angle of the tapered part. If  $D$  is the included angle of the precision vee-block, the angle  $C$  is calculated from the formula:

$$\sin C = \frac{\sin(A/2)}{\sin(D/2)}$$

If dial indicator readings show no change across all points along the top of the taper surface, then this checks that the angle  $A$  of the taper is correct.

If the indicator readings vary, proceed as follows to find the actual angle of taper: 1) Adjust the angle of the sine-bar until the indicator reading is constant. Then find the new angle  $B'$  as explained in the paragraph *Measuring Angle of Templet or Gage with Sine-bar* on page 696; and 2) Using the angle  $B'$  calculate the actual half-angle  $A'/2$  of the taper from the formula:

$$\tan \frac{A'}{2} = \frac{\sin B'}{\csc \frac{D}{2} + \cos B'}$$

The taper per foot corresponding to certain half-angles of taper may be found in the table on page 714.

**Dimensioning Tapers.**—At least three methods of dimensioning tapers are in use.

*Standard Tapers:* Give one diameter or width, the length, and insert note on drawing designating the taper by number.

*Special Tapers:* In dimensioning a taper when the slope is specified, the length and only one diameter should be given or the diameters at both ends of the taper should be given and length omitted.

*Precision Work:* In certain cases where very precise measurements are necessary the taper surface, either external or internal, is specified by giving a diameter at a certain distance from a surface and the slope of the taper.

## 5-INCH SINE-BAR CONSTANTS

## Constants for 5-inch Sine-bar

## Constants for Setting a 5-inch Sine-bar for 1° to 7°

### Accurate Measurement of Angles and Tapers

When great accuracy is required in the measurement of angles, or when originating tapers, disks are commonly used. The principle of the disk method of taper measurement is that if two disks of unequal diameters are placed either in contact or a certain distance apart, lines tangent to their peripheries will represent an angle or taper, the degree of which depends upon the diameters of the two disks and the distance between them.

The gage shown in the accompanying illustration, which is a form commonly used for originating tapers or measuring angles accurately, is set by means of disks. This gage consists of two adjustable straight edges  $A$  and  $A_1$ , which are in contact with disks  $B$  and  $B_1$ . The angle  $\alpha$  or the taper between the straight edges depends, of course, upon the diameters of the disks and the center distance  $C$ , and as these three dimensions can be measured accurately, it is possible to set the gage to a given angle within very close limits. Moreover, if a record of the three dimensions is kept, the exact setting of the gage can be reproduced quickly at any time. The following rules may be used for adjusting a gage of this type, and cover all problems likely to arise in practice. Disks are also occasionally used for the setting of parts in angular positions when they are to be machined accurately to a given angle; the rules are applicable to these conditions also.

**Measuring Dovetail Slides.**—Dovetail slides that must be machined accurately to a given width are commonly gaged by using pieces of cylindrical rod or wire and measuring as indicated by the dimensions  $x$  and  $y$  of the accompanying illustrations.

The rod or wire used should be small enough so that the point of contact  $e$  is somewhat below the corner or edge of the dovetail.

To obtain dimension  $x$  for measuring male dovetails, add 1 to the cotangent of one-half the dovetail angle  $\alpha$ , multiply by diameter  $D$  of the rods used, and add the product to dimension  $a$ .

$$x = D(1 + \cot \frac{1}{2}\alpha) + a \quad c = h \times \cot \alpha$$

To obtain dimension  $y$  for measuring a female dovetail, add 1 to the cotangent of one-half the dovetail angle  $\alpha$ , multiply by diameter  $D$  of the rod used, and subtract the result from dimension  $b$ . Expressing these rules as formulas:

$$y = b - D(1 + \cot \frac{1}{2}\alpha)$$

## Tapers per Foot and Corresponding Angles

| Taper per Foot  | Included Angle |    |        | Angle with Center Line |        |  | Taper per Foot   | Included Angle |    |        | Angle with Center Line |        |  |

Taper per foot represents inches of taper per foot of length. For conversions into decimal degrees and radians see *Conversion Tables of Angular Measure* on page 96.

## Rules for Figuring Tapers

| Given   | To Find   | Rule   |
|---|---|--|
| The taper per foot.   | The taper per inch.                             | Divide the taper per foot by 12.   |
| The taper per inch.   | The taper per foot.                             | Multiply the taper per inch by 12.   |
| End diameters and length of taper in inches.                      | The taper per foot.                             | Subtract small diameter from large; divide by length of taper; and multiply quotient by 12.          |
| Large diameter and length of taper in inches, and taper per foot. | Diameter at small end in inches                 | Divide taper per foot by 12; multiply by length of taper; and subtract result from large diameter.   |
| Small diameter and length of taper in inches, and taper per foot. | Diameter at large end in inches.                | Divide taper per foot by 12; multiply by length of taper; and add result to small diameter.          |
| The taper per foot and two diameters in inches.                   | Distance between two given diameters in inches. | Subtract small diameter from large; divide remainder by taper per foot; and multiply quotient by 12. |
| The taper per foot.   | Amount of taper in a certain length in inches.  | Divide taper per foot by 12; multiply by given length of tapered part.                               |

To find angle  $\alpha$  for given taper  $T$  in inches per foot.—

*Example:* What angle  $\alpha$  is equivalent to a taper of 1.5 inches per foot?

$$\alpha = 2 \times \arctan(1.5/24) = 7.153^\circ$$

To find taper per foot  $T$  given angle  $\alpha$  in degrees.—

$$T = 24 \tan(\alpha/2) \text{ inches per foot}$$

*Example:* What taper  $T$  is equivalent to an angle of  $7.153^\circ$ ?

$$T = 24 \tan(7.153/2) = 1.5 \text{ inches per foot}$$

To find angle  $\alpha$  given dimensions  $D$ ,  $d$ , and  $C$ .— Let  $K$  be the difference in the disk diameters divided by twice the center distance.  $K = (D - d)/(2C)$ , then  $\alpha = 2 \arcsin K$

*Example:* If the disk diameters  $d$  and  $D$  are 1 and 1.5 inches, respectively, and the center distance  $C$  is 5 inches, find the included angle  $\alpha$ .

$$K = (1.5 - 1)/(2 \times 5) = 0.05 \quad \alpha = 2 \times \arcsin 0.05 = 5.732^\circ$$

To find taper  $T$  measured at right angles to a line through the disk centers given dimensions  $D$ ,  $d$ , and distance  $C$ .— Find  $K$  using the formula in the previous example, then  $T = 24K/\sqrt{1 - K^2}$  inches per foot

*Example:* If disk diameters  $d$  and  $D$  are 1 and 1.5 inches, respectively, and the center distance  $C$  is 5 inches, find the taper per foot.

$$K = (1.5 - 1)/(2 \times 5) = 0.05 \quad T = \frac{24 \times 0.05}{\sqrt{1 - (0.05)^2}} = 1.2015 \text{ inches per foot}$$

**To find center distance  $C$  for a given taper  $T$  in inches per foot.—**

$$C = \frac{D-d}{2} \times \frac{\sqrt{1+(T/24)^2}}{T/24} \text{ inches}$$

*Example:* Gage is to be set to  $\frac{3}{4}$  inch per foot, and disk diameters are 1.25 and 1.5 inches, respectively. Find the required center distance for the disks.

$$C = \frac{1.5-1.25}{2} \times \frac{\sqrt{1+(0.75/24)^2}}{0.75/24} = 4.002 \text{ inches}$$

**To find center distance  $C$  for a given angle  $\alpha$  and dimensions  $D$  and  $d$ .—**

$$C = (D-d)/2 \sin(\alpha/2) \text{ inches}$$

*Example:* If an angle  $\alpha$  of  $20^\circ$  is required, and the disks are 1 and 3 inches in diameter, respectively, find the required center distance  $C$ .

$$C = (3-1)/(2 \times \sin 10^\circ) = 5.759 \text{ inches}$$

**To find taper  $T$  measured at right angles to one side.—**When one side is taken as a base line and the taper is measured at right angles to that side, calculate  $K$  as explained above and use the following formula for determining the taper  $T$ :

$$T = 24K \frac{\sqrt{1-K^2}}{1-2K^2} \text{ inches per foot}$$

*Example:* If the disk diameters are 2 and 3 inches, respectively, and the center I distance is 5 inches, what is the taper per foot measured at right angles to one side?

$$K = \frac{3-2}{2 \times 5} = 0.1 \quad T = 24 \times 0.1 \times \frac{\sqrt{1-(0.1)^2}}{1-[2 \times (0.1)^2]} = 2.4367 \text{ in. per ft.}$$

**To find center distance  $C$  when taper  $T$  is measured from one side.—**

$$C = \frac{D-d}{\sqrt{2-2/\sqrt{1+(T/12)^2}}} \text{ inches}$$

*Example:* If the taper measured at right angles to one side is 6.9 inches per foot, and the disks are 2 and 5 inches in diameter, respectively, what is center distance  $C$ ?

$$C = \frac{5-2}{\sqrt{2-2/\sqrt{1+(6.9/12)^2}}} = 5.815 \text{ inches.}$$

**To find diameter  $D$  of a large disk in contact with a small disk of diameter  $d$  given angle  $\alpha$ .—**

$$D = d \times \frac{1 + \sin(\alpha/2)}{1 - \sin(\alpha/2)} \text{ inches}$$

*Example:* The required angle  $\alpha$  is  $15^\circ$ . Find diameter  $D$  of a large disk that is in contact with a standard 1-inch reference disk.

$$D = 1 \times \frac{1 + \sin 7.5^\circ}{1 - \sin 7.5^\circ} = 1.3002 \text{ inches}$$

### Measurement over Pins and Rolls

**Measurement over Pins.**—When the distance across a bolt circle is too large to measure using ordinary measuring tools, then the required distance may be found from the distance across adjacent or alternate holes using one of the methods that follow:

Fig. 1a.

Fig. 1b.

Fig. 1c.

**Even Number of Holes in Circle:** To measure the unknown distance  $x$  over opposite plugs in a bolt circle of  $n$  holes ( $n$  is even and greater than 4), as shown in Fig. 1a, where  $y$  is the distance over alternate plugs,  $d$  is the diameter of the holes, and  $\theta = 360^\circ/n$  is the angle between adjacent holes, use the following general equation for obtaining  $x$ :

$$x = \frac{y-d}{\sin \theta} + d$$

**Example:** In a die that has six  $3/4$ -inch diameter holes equally spaced on a circle, where the distance  $y$  over alternate holes is  $4\frac{1}{2}$  inches, and the angle  $\theta$  between adjacent holes is  $60^\circ$ , then

$$x = \frac{4.500 - 0.7500}{\sin 60^\circ} + 0.7500 = 5.0801$$

In a similar problem, the distance  $c$  over adjacent plugs is given, as shown in Fig. 1b. If the number of holes is even and greater than 4, the distance  $x$  over opposite plugs is given in the following formula:

$$x = 2(c-d) \left( \frac{\sin \left( \frac{180-\theta}{2} \right)}{\sin \theta} \right) + d$$

where  $d$  and  $\theta$  are as defined above.

**Odd Number of Holes in Circle:** In a circle as shown in Fig. 1c, where the number of holes  $n$  is odd and greater than 3, and the distance  $c$  over adjacent holes is given, then  $\theta$  equals  $360/n$  and the distance  $x$  across the most widely spaced holes is given by:

$$x = \frac{c-d}{\sin \frac{\theta}{4}} + d$$

**Checking a V-shaped Groove by Measurement Over Pins.**—In checking a groove of the shape shown in Fig. 2, it is necessary to measure the dimension  $X$  over the pins of radius  $R$ . If values for the radius  $R$ , dimension  $Z$ , and the angles  $\alpha$  and  $\beta$  are known, the problem is

to determine the distance  $Y$ , to arrive at the required overall dimension for  $X$ . If a line  $AC$  is drawn from the bottom of the  $V$  to the center of the pin at the left in Fig. 2, and a line  $CB$  from the center of this pin to its point of tangency with the side of the  $V$ , a right-angled triangle is formed in which one side,  $CB$ , is known and one angle  $CAB$ , can be determined. A line drawn from the center of a circle to the point of intersection of two tangents to the circle bisects the angle made by the tangent lines, and angle  $CAB$  therefore equals  $\frac{1}{2}(\alpha + \beta)$ . The length  $AC$  and the angle  $DAC$  can now be found, and with  $AC$  known in the right-angled triangle  $ADC$ ,  $AD$ , which is equal to  $Y$  can be found.

Fig. 2.

The value for  $X$  can be obtained from the formula

$$X = Z + 2R \left( \csc \frac{\alpha + \beta}{2} \cos \frac{\alpha - \beta}{2} + 1 \right)$$

For example, if  $R = 0.500$ ,  $Z = 1.824$ ,  $\alpha = 45$  degrees, and  $\beta = 35$  degrees,

$$X = 1.824 + (2 \times 0.5) \left( \csc \frac{45^\circ + 35^\circ}{2} \cos \frac{45^\circ - 35^\circ}{2} + 1 \right)$$

$$X = 1.824 + \csc 40^\circ \cos 5^\circ + 1$$

$$X = 1.824 + 1.5557 \times 0.99619 + 1$$

$$X = 1.824 + 1.550 + 1 = 4.374$$

**Checking Radius of Arc by Measurement Over Rolls.**—The radius  $R$  of large-radius concave and convex gages of the type shown in Figs. 3a, 3b and 3c can be checked by measurement  $L$  over two rolls with the gage resting on the rolls as shown. If the diameter of the rolls  $D$ , the length  $L$ , and the height  $H$  of the top of the arc above the surface plate (for the concave gage, Fig. 3a) are known or can be measured, the radius  $R$  of the workpiece to be checked can be calculated trigonometrically, as follows.

Referring to Fig. 3a for the concave gage, if  $L$  and  $D$  are known,  $cb$  can be found, and if  $H$  and  $D$  are known,  $ce$  can be found. With  $cb$  and  $ce$  known,  $ab$  can be found by means of a diagram as shown in Fig. 3c.

In diagram Fig. 3c,  $cb$  and  $ce$  are shown at right angles as in Fig. 3a. A line is drawn connecting points  $b$  and  $e$  and line  $ce$  is extended to the right. A line is now drawn from point  $b$  perpendicular to  $be$  and intersecting the extension of  $ce$  at point  $f$ . A semicircle can now be drawn through points  $b$ ,  $e$ , and  $f$  with point  $a$  as the center. Triangles  $bce$  and  $bef$  are similar and have a common side. Thus  $ce:bc::bc:cf$ . With  $ce$  and  $bc$  known,  $cf$  can be found from this proportion and hence  $ef$  which is the diameter of the semicircle and radius  $ab$ . Then  $R = ab + D/2$ .

Fig. 3a.

Fig. 3b.

Fig. 3c.

The procedure for the convex gage is similar. The distances  $cb$  and  $ce$  are readily found and from these two distances  $ab$  is computed on the basis of similar triangles as before. Radius  $R$  is then readily found.

The derived formulas for concave and convex gages are as follows:

Formulas:

$$R = \frac{(L-D)^2}{8(H-D)} + \frac{H}{2} \quad (\text{Concave gage Fig. 3a})$$

$$R = \frac{(L-D)^2}{8D} \quad (\text{Convex gage Fig. 3b})$$

For example: For Fig. 3a, let  $L = 17.8$ ,  $D = 3.20$ , and  $H = 5.72$ , then

$$R = \frac{(17.8 - 3.20)^2}{8(5.72 - 3.20)} + \frac{5.72}{2} = \frac{(14.60)^2}{8 \times 2.52} + 2.86$$

$$R = \frac{213.16}{20.16} + 2.86 = 13.43$$

For Fig. 3b, let  $L = 22.28$  and  $D = 3.40$ , then

$$R = \frac{(22.28 - 3.40)^2}{8 \times 3.40} = \frac{356.45}{27.20} = 13.1$$

### Checking Shaft Conditions

**Checking for Various Shaft Conditions.**—An indicating height gage, together with V-blocks can be used to check shafts for ovality, taper, straightness (bending or curving), and concentricity of features (as shown exaggerated in Fig. 4). If a shaft on which work has

been completed shows lack of concentricity. It may be due to the shaft having become bent or bowed because of mishandling or oval or tapered due to poor machine conditions. In checking for concentricity, the first step is to check for ovality, or out-of-roundness, as in Fig. 4a. The shaft is supported in a suitable V-block on a surface table and the dial indicator plunger is placed over the workpiece, which is then rotated beneath the plunger to obtain readings of the amount of eccentricity.

This procedure (sometimes called clocking, owing to the resemblance of the dial indicator to a clock face) is repeated for other shaft diameters as necessary, and, in addition to making a written record of the measurements, the positions of extreme conditions should be marked on the workpiece for later reference.

Fig. 4.

To check for taper, the shaft is supported in the V-block and the dial indicator is used to measure the maximum height over the shaft at various positions along its length, as shown in Fig. 4b, without turning the workpiece. Again, the shaft should be marked with the reading positions and values, also the direction of the taper, and a written record should be made of the amount and direction of any taper discovered.

Checking for a bent shaft requires that the shaft be clocked at the shoulder and at the farther end, as shown in Fig. 4c. For a second check the shaft is rotated only  $90^\circ$  or a quarter turn. When the recorded readings are compared with those from the ovality and taper checks, the three conditions can be distinguished.

To detect a curved or bowed condition, the shaft should be suspended in two V-blocks with only about  $\frac{1}{8}$  inch of each end in each vee. Alternatively, the shaft can be placed between centers. The shaft is then clocked at several points, as shown in Fig. 4d, but preferably not at those locations used for the ovality, taper, or crookedness checks. If the single element due to curvature is to be distinguished from the effects of ovality, taper, and crookedness, and its value assessed, great care must be taken to differentiate between the conditions detected by the measurements.

Finally, the amount of eccentricity between one shaft diameter and another may be tested by the setup shown in Fig. 4e. With the indicator plunger in contact with the smaller diameter, close to the shoulder, the shaft is rotated in the V-block and the indicator needle position is monitored to find the maximum and minimum readings.

Curvature, ovality, or crookedness conditions may tend to cancel each other, as shown in Fig. 5, and one or more of these degrees of defectiveness may add themselves to the true eccentricity readings, depending on their angular positions. Fig. 5a shows, for instance, how crookedness and ovality tend to cancel each other, and also shows their effect in falsifying the reading for eccentricity. As the same shaft is turned in the V-block to the position shown in Fig. 5b, the maximum curvature reading could tend to cancel or reduce the maximum eccentricity reading. Where maximum readings for ovality, curvature, or crookedness occur at the same angular position, their values should be subtracted from the eccentricity reading to arrive at a true picture of the shaft condition. Confirmation of eccentricity readings may be obtained by reversing the shaft in the V-block, as shown in Fig. 5c, and clocking the larger diameter of the shaft.

Fig. 5.

**Out-of-Roundness—Lobing.**—With the imposition of finer tolerances and the development of improved measurement methods, it has become apparent that no hole, cylinder, or sphere can be produced with a perfectly symmetrical round shape. Some of the conditions are diagrammed in Fig. 6, where Fig. 6a shows simple ovality and Fig. 6b shows ovality occurring in two directions. From the observation of such conditions have come the terms lobe and lobing. Fig. 6c shows the three-lobed shape common with centerless-ground components, and Fig. 6d is typical of multi-lobed shapes. In Fig. 6e are shown surface waviness, surface roughness, and out-of-roundness, which often are combined with lobing.

## OUT OF ROUNDNESS, LOBING

Fig. 6.

In Figs. 6a through 6d, the cylinder (or hole) diameters are shown at full size but the lobes are magnified some 10,000 times to make them visible. In precision parts, the deviation from the round condition is usually only in the range of millionths of an inch, although it occasionally can be 0.0001 inch, 0.0002 inch, or more. For instance, a 3-inch-diameter part may have a lobing condition amounting to an inaccuracy of only 30 millionths (0.000030 inch). Even if the distortion (ovality, waviness, roughness) is small, it may cause hum, vibration, heat buildup, and wear, possibly leading to eventual failure of the component or assembly.

Plain elliptical out-of-roundness (two lobes), or any even number of lobes, can be detected by rotating the part on a surface plate under a dial indicator of adequate resolution, or by using an indicating caliper or snap gage. However, supporting such a part in a V-block during measurement will tend to conceal roundness errors. Ovality in a hole can be detected by a dial-type bore gage or internal measuring machine. Parts with odd numbers of lobes require an instrument that can measure the envelope or complete circumference. Plug and ring gages will tell whether a shaft can be assembled into a bearing, but not whether there will be a good fit, as illustrated in Fig. 6e.

A standard, 90-degree included-angle V-block can be used to detect and count the number of lobes, but to measure the exact amount of lobing indicated by  $R-r$  in Fig. 7 requires a V-block with an angle  $\alpha$ , which is related to the number of lobes. This angle  $\alpha$  can be calculated from the formula  $2\alpha = 180^\circ - 360^\circ/N$ , where  $N$  is the number of lobes. Thus, for a three-lobe form,  $\alpha$  becomes 30 degrees, and the V-block used should have a 60-degree included angle. The distance  $M$ , which is obtained by rotating the part under the comparator plunger, is converted to a value for the radial variation in cylinder contour by the formula  $M = (R - r)(1 + \csc \alpha)$ .

Fig. 7.

Using a V-block (even of appropriate angle) for parts with odd numbers of lobes will give exaggerated readings when the distance  $R - r$  (Fig. 7) is used as the measure of the amount of out-of-roundness. The accompanying table shows the appropriate V-block angles for various odd numbers of lobes, and the factors  $(1 + \csc \alpha)$  by which the readings are increased over the actual out-of-roundness values.

**Table of Lobes, V-block Angles and Exaggeration Factors in Measuring Out-of-round Conditions in Shafts**

| Number of Lobes | Included Angle of V-block (deg) | Exaggeration Factor<br>( $1 + \csc \alpha$ ) |
|-----------------|---------------------------------|--|
| 3               | 60                              | 3.00   |
| 5               | 108                             | 2.24   |
| 7               | 128.57                          | 2.11   |
| 9               | 140                             | 2.06   |

Measurement of a complete circumference requires special equipment, often incorporating a precision spindle running true within two millionths (0.000002) inch. A stylus attached to the spindle is caused to traverse the internal or external cylinder being inspected, and its divergences are processed electronically to produce a polar chart similar to the wavy outline in Fig. 6e. The electronic circuits provide for the variations due to surface effects to be separated from those of lobing and other departures from the "true" cylinder traced out by the spindle.

### Measurements Using Light

**Measuring by Light-wave Interference Bands.**—Surface variations as small as two millionths (0.000002) inch can be detected by light-wave interference methods, using an optical flat. An optical flat is a transparent block, usually of plate glass, clear fused quartz, or borosilicate glass, the faces of which are finished to extremely fine limits (of the order of 1 to 8 millionths [0.000001 to 0.000008] inch, depending on the application) for flatness. When an optical flat is placed on a "flat" surface, as shown in Fig. 8, any small departure from flatness will result in formation of a wedge-shaped layer of air between the work surface and the underside of the flat.

Light rays reflected from the work surface and the underside of the flat either interfere with or reinforce each other. Interference of two reflections results when the air gap measures exactly half the wavelength of the light used, and produces a dark band across the work surface when viewed perpendicularly, under monochromatic helium light. A light band is produced halfway between the dark bands when the rays reinforce each other. With the 0.0000232-inch-wavelength helium light used, the dark bands occur where the optical flat and the work surface are separated by 11.6 millionths (0.0000116) inch, or multiples thereof.

Fig. 8.

For instance, at a distance of seven dark bands from the point of contact, as shown in Fig. 8, the underface of the optical flat is separated from the work surface by a distance of  $7 \times 0.0000116$  inch or 0.0000812 inch. The bands are separated more widely and the indications become increasingly distorted as the viewing angle departs from the perpendicular. If the bands appear straight, equally spaced and parallel with each other, the work surface is flat. Convex or concave surfaces cause the bands to curve correspondingly, and a cylindrical tendency in the work surface will produce unevenly spaced, straight bands.

**SURFACE TEXTURE****American National Standard Surface Texture  
(Surface Roughness, Waviness, and Lay)**

American National Standard ANSI/ASME B46.1-1995 is concerned with the geometric irregularities of surfaces of solid materials, physical specimens for gaging roughness, and the characteristics of stylus instrumentation for measuring roughness. The standard defines surface texture and its constituents: roughness, waviness, lay, and flaws. A set of symbols for drawings, specifications, and reports is established. To ensure a uniform basis for measurements the standard also provides specifications for Precision Reference Specimens, and Roughness Comparison Specimens, and establishes requirements for stylus-type instruments. The standard is not concerned with luster, appearance, color, corrosion resistance, wear resistance, hardness, subsurface microstructure, surface integrity, and many other characteristics that may be governing considerations in specific applications.

The standard is expressed in SI metric units but U.S. customary units may be used without prejudice. The standard does not define the degrees of surface roughness and waviness or type of lay suitable for specific purposes, nor does it specify the means by which any degree of such irregularities may be obtained or produced. However, criteria for selection of surface qualities and information on instrument techniques and methods of producing, controlling and inspecting surfaces are included in Appendixes attached to the standard. The Appendix sections are not considered a part of the standard: they are included for clarification or information purposes only.

Surfaces, in general, are very complex in character. The standard deals only with the height, width, and direction of surface irregularities because these characteristics are of practical importance in specific applications. Surface texture designations as delineated in this standard may not be a sufficient index to performance. Other part characteristics such as dimensional and geometrical relationships, material, metallurgy, and stress must also be controlled.

**Definitions of Terms Relating to the Surfaces of Solid Materials.**—The terms and ratings in the standard relate to surfaces produced by such means as abrading, casting, coating, cutting, etching, plastic deformation, sintering, wear, and erosion.

*Error of form* is considered to be that deviation from the nominal surface caused by errors in machine tool ways, guides, insecure clamping or incorrect alignment of the workpiece or wear, all of which are not included in surface texture. Out-of-roundness and out-of-flatness are examples of errors of form. See ANSI/ASME B46.3.1-1988 for measurement of out-of-roundness.

*Flaws* are unintentional, unexpected, and unwanted interruptions in the topography typical of a part surface and are defined as such only when agreed upon by buyer and seller. If flaws are defined, the surface should be inspected specifically to determine whether flaws are present, and rejected or accepted prior to performing final surface roughness measurements. If defined flaws are not present, or if flaws are not defined, then interruptions in the part surface may be included in roughness measurements.

*Lay* is the direction of the predominant surface pattern, ordinarily determined by the production method used.

*Roughness* consists of the finer irregularities of the surface texture, usually including those irregularities that result from the inherent action of the production process. These irregularities are considered to include traverse feed marks and other irregularities within the limits of the roughness sampling length.

*Surface* is the boundary of an object that separates that object from another object, substance or space.

*Surface, measured* is the real surface obtained by instrumental or other means.

Fig. 1. Pictorial Display of Surface Characteristics

*Surface, nominal* is the intended surface contour (exclusive of any intended surface roughness), the shape and extent of which is usually shown and dimensioned on a drawing or descriptive specification.

*Surface, real* is the actual boundary of the object. Manufacturing processes determine its deviation from the nominal surface.

*Surface texture* is repetitive or random deviations from the real surface that forms the three-dimensional topography of the surface. Surface texture includes roughness, waviness, lay and flaws. Fig. 1 is an example of a unidirectional lay surface. Roughness and waviness parallel to the lay are not represented in the expanded views.

*Waviness* is the more widely spaced component of surface texture. Unless otherwise noted, waviness includes all irregularities whose spacing is greater than the roughness sampling length and less than the waviness sampling length. Waviness may result from

such factors as machine or work deflections, vibration, chatter, heat-treatment or warping strains. Roughness may be considered as being superposed on a 'wavy' surface.

**Definitions of Terms Relating to the Measurement of Surface Texture.**—Terms regarding surface texture pertain to the geometric irregularities of surfaces and include roughness, waviness and lay.

*Profile* is the contour of the surface in a plane measured normal, or perpendicular, to the surface, unless another other angle is specified.

*Graphical centerline.* See Mean Line.

*Height ( $z$ )* is considered to be those measurements of the profile in a direction normal, or perpendicular, to the nominal profile. For digital instruments, the profile  $Z(x)$  is approximated by a set of digitized values. Height parameters are expressed in micrometers ( $\mu\text{m}$ ).

*Height range ( $z$ )* is the maximum peak-to-valley surface height that can be detected accurately with the instrument. It is measurement normal, or perpendicular, to the nominal profile and is another key specification.

*Mean line ( $M$ )* is the line about which deviations are measured and is a line parallel to the general direction of the profile within the limits of the sampling length. See Fig. 2. The mean line may be determined in one of two ways. The filtered mean line is the centerline established by the selected cutoff and its associated circuitry in an electronic roughness average measuring instrument. The least squares mean line is formed by the nominal profile but by dividing into selected lengths the sum of the squares of the deviations minimizes the deviation from the nominal form. The form of the nominal profile could be a curve or a straight line.

*Peak* is the point of maximum height on that portion of a profile that lies above the mean line and between two intersections of the profile with the mean line.

*Profile measured* is a representation of the real profile obtained by instrumental or other means. When the measured profile is a graphical representation, it will usually be distorted through the use of different vertical and horizontal magnifications but shall otherwise be as faithful to the profile as technically possible.

*Profile, modified* is the measured profile where filter mechanisms (including the instrument datum) are used to minimize certain surface texture characteristics and emphasize others. Instrument users apply profile modifications typically to differentiate surface roughness from surface waviness.

*Profile, nominal* is the profile of the nominal surface; it is the intended profile (exclusive of any intended roughness profile). Profile is usually drawn in an x-z coordinate system. See Fig. 2.

Fig. 2. Nominal and Measured Profiles

*Profile, real* is the profile of the real surface.

*Profile, total* is the measured profile where the heights and spacing may be amplified differently but otherwise no filtering takes place.

*Roughness profile* is obtained by filtering out the longer wavelengths characteristic of waviness.

*Roughness spacing* is the average spacing between adjacent peaks of the measured profile within the roughness sampling length.

*Roughness topography* is the modified topography obtained by filtering out the longer wavelengths of waviness and form error.

*Sampling length* is the nominal spacing within which a surface characteristic is determined. The range of sampling lengths is a key specification of a measuring instrument.

*Spacing* is the distance between specified points on the profile measured parallel to the nominal profile.

*Spatial ( $x$ ) resolution* is the smallest wavelength which can be resolved to 50% of the actual amplitude. This also is a key specification of a measuring instrument.

*System height resolution* is the minimum height that can be distinguished from background noise of the measurement instrument. Background noise values can be determined by measuring approximate rms roughness of a sample surface where actual roughness is significantly less than the background noise of the measuring instrument. It is a key instrumentation specification.

*Topography* is the three-dimensional representation of geometric surface irregularities.

*Topography, measured* is the three-dimensional representation of geometric surface irregularities obtained by measurement.

*Topography, modified* is the three-dimensional representation of geometric surface irregularities obtained by measurement but filtered to minimize certain surface characteristics and accentuate others.

*Valley* is the point of maximum depth on that portion of a profile that lies below the mean line and between two intersections of the profile with the mean line.

*Waviness, evaluation length ( $L$ )*, is the length within which waviness parameters are determined.

*Waviness, long-wavelength cutoff ( $lcw$ )* the spatial wavelength above which the undulations of waviness profile are removed to identify form parameters. A digital Gaussian filter can be used to separate form error from waviness but its use must be specified.

*Waviness profile* is obtained by filtering out the shorter roughness wavelengths characteristic of roughness and the longer wavelengths associated with the part form parameters.

*Waviness sampling length* is a concept no longer used. See waviness long-wavelength cutoff and waviness evaluation length.

*Waviness short-wavelength cutoff ( $lsw$ )* is the spatial wavelength below which roughness parameters are removed by electrical or digital filters.

*Waviness topography* is the modified topography obtained by filtering out the shorter wavelengths of roughness and the longer wavelengths associated with form error.

*Waviness spacing* is the average spacing between adjacent peaks of the measured profile within the waviness sampling length.

**Sampling Lengths.**—Sampling length is the normal interval for a single value of a surface parameter. Generally it is the longest spatial wavelength to be included in the profile measurement. Range of sampling lengths is an important specification for a measuring instrument.

Fig. 3. Traverse Length

*Roughness sampling length ( $l$ )* is the sampling length within which the roughness average is determined. This length is chosen to separate the profile irregularities which are des-

ignated as roughness from those irregularities designated as waviness. It is different from evaluation length ( $L$ ) and the traversing length. See Fig. 3.

*Evaluation length ( $L$ )* is the length the surface characteristics are evaluated. The evaluation length is a key specification of a measuring instrument.

*Traversing length* is profile length traversed to establish a representative evaluation length. It is always longer than the evaluation length. See Section 4.4.4 of ANSI/ASME B46.1-1995 for values which should be used for different type measurements.

*Cutoff* is the electrical response characteristic of the measuring instrument which is selected to limit the spacing of the surface irregularities to be included in the assessment of surface texture. Cutoff is rated in millimeters. In most electrical averaging instruments, the cutoff can be user selected and is a characteristic of the instrument rather than of the surface being measured. In specifying the cutoff, care must be taken to choose a value which will include all the surface irregularities to be assessed.

*Waviness sampling length ( $l$ )* is a concept no longer used. See waviness long-wavelength cutoff and waviness evaluation length.

**Roughness Parameters.**—Roughness is the fine irregularities of the surface texture resulting from the production process or material condition.

*Roughness average ( $R_a$ )*, also known as arithmetic average (AA) is the arithmetic average of the absolute values of the measured profile height deviations divided by the evaluation length,  $L$ . This is shown as the shaded area of Fig. 4 and generally includes sampling lengths or cutoffs. For graphical determinations of roughness average, the height deviations are measured normal, or perpendicular, to the chart center line.

Fig. 4.

Roughness average is expressed in micrometers ( $\mu\text{m}$ ). A micrometer is one millionth of a meter (0.000001 meter). A microinch ( $\mu\text{in}$ ) is one millionth of an inch (0.000001 inch). One microinch equals 0.0254 micrometer ( $1 \mu\text{in} = 0.0254 \mu\text{m}$ ).

*Roughness Average Value ( $R_a$ ) From Continuously Averaging Meter Reading* may be made of readings from stylus-type instruments of the continuously averaging type. To ensure uniform interpretation, it should be understood that the reading that is considered significant is the mean reading around which the needle tends to dwell or fluctuate with a small amplitude.

Roughness is also indicated by the root-mean-square (rms) average, which is the square root of the average value squared, within the evaluation length and measured from the mean line shown in Fig. 4, expressed in micrometers. A roughness-measuring instrument calibrated for rms average usually reads about 11 per cent higher than an instrument calibrated for arithmetical average. Such instruments usually can be recalibrated to read arithmetical average. Some manufacturers consider the difference between rms and AA to be small enough that rms on a drawing may be read as AA for many purposes.

*Roughness evaluation length ( $L$ )*, for statistical purposes should, whenever possible, consist of five sampling lengths ( $l$ ). Use of other than five sampling lengths must be clearly indicated.

**Waviness Parameters.**—Waviness is the more widely spaced component of surface texture. Roughness may be thought of as superimposed on waviness.

*Waviness height* ( $Wt$ ) is the peak-to-valley height of the modified profile with roughness and part form errors removed by filtering, smoothing or other means. This value is typically three or more times the roughness average. The measurement is taken normal, or perpendicular, to the nominal profile within the limits of the waviness sampling length.

*Waviness evaluation length* ( $Lw$ ) is the evaluation length required to determine waviness parameters. For waviness, the sampling length concept is no longer used. Rather, only waviness evaluation length ( $Lw$ ) and waviness long-wavelength cutoff ( $lew$ ) are defined. For better statistics, the waviness evaluation length should be several times the waviness long-wavelength cutoff.

**Relation of Surface Roughness to Tolerances.**—Because the measurement of surface roughness involves the determination of the average linear deviation of the measured surface from the nominal surface, there is a direct relationship between the dimensional tolerance on a part and the permissible surface roughness. It is evident that a requirement for the accurate measurement of a dimension is that the variations introduced by surface roughness should not exceed the dimensional tolerances. If this is not the case, the measurement of the dimension will be subject to an uncertainty greater than the required tolerance, as illustrated in Fig. 5.

Fig. 5.

The standard method of measuring surface roughness involves the determination of the average deviation from the mean surface. On most surfaces the total profile height of the surface roughness (peak-to-valley height) will be approximately four times ( $4\times$ ) the measured average surface roughness. This factor will vary somewhat with the character of the surface under consideration, but the value of four may be used to establish approximate profile heights.

From these considerations it follows that if the arithmetical average value of surface roughness specified on a part exceeds one eighth of the dimensional tolerance, the whole tolerance will be taken up by the roughness height. In most cases, a smaller roughness specification than this will be found; but on parts where very small dimensional tolerances are given, it is necessary to specify a suitably small surface roughness so useful dimensional measurements can be made. The tables on pages 652 and 679 show the relations between machining processes and working tolerances.

Values for surface roughness produced by common processing methods are shown in Table 1. The ability of a processing operation to produce a specific surface roughness depends on many factors. For example, in surface grinding, the final surface depends on the peripheral speed of the wheel, the speed of the traverse, the rate of feed, the grit size, bonding material and state of dress of the wheel, the amount and type of lubrication at the

**Table 1. Surface Roughness Produced by Common Production Methods**

| Process                | Roughness Average, $R_a$ – Micrometers $\mu\text{m}$ (Microinches $\mu\text{in.}$ ) |              |               |              |              |             |              |              |             |             |             |              |                |
|------------------------|---|--------------|---------------|--------------|--------------|-------------|--------------|--------------|-------------|-------------|-------------|--------------|----------------|

point of cutting, and the mechanical properties of the piece being ground. A small change in any of the above factors can have a marked effect on the surface produced.

**Instrumentation for Surface Texture Measurement.**—Instrumentation used for measurement of surface texture, including roughness and waviness generally falls into six types. These include:

*Type I, Profiling Contact Skidless Instruments:* Used for very smooth to very rough surfaces. Used for roughness and may measure waviness. Can generate filtered or unfiltered profiles and may have a selection of filters and parameters for data analysis. Examples include: 1) skidless stylus-type with LVDT (linear variable differential transformer) vertical transducers; 2) skidless-type using an interferometric transducer; 3) skidless stylus-type using capacitance transducer.

*Type II, Profiling Non-contact Instruments:* Capable of full profiling or topographical analysis. Non-contact operation may be advantageous for softness but may vary with sample type and reflectivity. Can generate filtered or unfiltered profiles but may have difficulty with steeply inclined surfaces. Examples include: 1) interferometric microscope; 2) optical focus sensing; 3) Nomarski differential profiling; 4) laser triangulation; 5) scanning electron microscope (SEM) stereoscopy; 6) confocal optical microscope.

*Type III, Scanned Probe Microscope:* Feature high spatial resolution (at or near the atomic scale) but area of measurement may be limited. Examples include: 1) scanning tunneling microscope (STM) and 2) atomic force microscope (AFM).

*Type IV, Profiling Contact Skidded Instruments:* Uses a skid as a datum to eliminate longer wavelengths; thus cannot be used for waviness or errors of form. May have a selection of filters and parameters and generates an output recording of filtered and skid-modified profiles. Examples include: 1) skidded, stylus-type with LVDT vertical measuring transducer and 2) fringe-field capacitance (FFC) transducer.

*Type V, Skidded Instruments with Parameters Only:* Uses a skid as a datum to eliminate longer wavelengths; thus cannot be used for waviness or errors of form. Does not generate a profile. Filters are typically 2RC type and generate Ra but other parameters may be available. Examples include: 1) skidded, stylus-type with piezoelectric measuring transducer and 2) skidded, stylus-type with moving coil measuring transducer.

*Type VI, Area Averaging Methods:* Used to measure averaged parameters over defined areas but do not generate profiles. Examples include: 1) parallel plate capacitance (PPC) method; 2) total integrated scatter (TIS); 3) angle resolved scatter (ARS)/bi-directional reflectance distribution function (BRDF).

**Selecting Cutoff for Roughness Measurements.**—In general, surfaces will contain irregularities with a large range of widths. Surface texture instruments are designed to respond only to irregularity spacings less than a given value, called cutoff. In some cases, such as surfaces in which actual contact area with a mating surface is important, the largest convenient cutoff will be used. In other cases, such as surfaces subject to fatigue failure only the irregularities of small width will be important, and more significant values will be obtained when a short cutoff is used. In still other cases, such as identifying chatter marks on machined surfaces, information is needed on only the widely spaced irregularities. For such measurements, a large cutoff value and a larger radius stylus should be used.

The effect of variation in cutoff can be understood better by reference to Fig. 6. The profile at the top is the true movement of a stylus on a surface having a roughness spacing of about 1 mm and the profiles below are interpretations of the same surface with cutoff value settings of 0.8 mm, 0.25 mm and 0.08 mm, respectively. It can be seen that the trace based on 0.8 mm cutoff includes most of the coarse irregularities and all of the fine irregularities of the surface. The trace based on 0.25 mm excludes the coarser irregularities but includes the fine and medium fine. The trace based on 0.08 mm cutoff includes only the very fine irregularities. In this example the effect of reducing the cutoff has been to reduce the roughness average indication. However, had the surface been made up only of irregularities as fine as those of the bottom trace, the roughness average values would have been the same for all three cutoff settings.

In other words, all irregularities having a spacing less than the value of the cutoff used are included in a measurement. Obviously, if the cutoff value is too small to include coarser irregularities of a surface, the measurements will not agree with those taken with a larger cutoff. For this reason, care must be taken to choose a cutoff value which will include all of the surface irregularities it is desired to assess.

To become proficient in the use of continuously averaging stylus-type instruments the inspector or machine operator must realize that for uniform interpretation, the reading which is considered significant is the mean reading around which the needle tends to dwell or fluctuate under small amplitude.

**Drawing Practices for Surface Texture Symbols.**—American National Standard ANSI/ASME Y14.36M-1996 establishes the method to designate symbolic controls for surface texture of solid materials. It includes methods for controlling roughness, waviness, and lay, and provides a set of symbols for use on drawings, specifications, or other documents. The standard is expressed in SI metric units but U.S. customary units may be used without prejudice. Units used (metric or non-metric) should be consistent with the other units used on the drawing or documents. Approximate non-metric equivalents are shown for reference.

Fig. 6. Effects of Various Cutoff Values

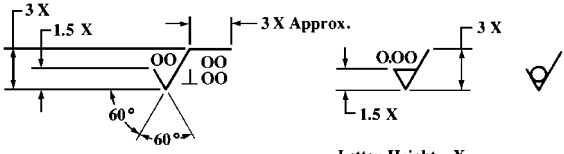

**Surface Texture Symbol.**—The symbol used to designate control of surface irregularities is shown in Fig. 7b and Fig. 7d. Where surface texture values other than roughness average are specified, the symbol must be drawn with the horizontal extension as shown in Fig. 7f.

*Use of Surface Texture Symbols:* When required from a functional standpoint, the desired surface characteristics should be specified. Where no surface texture control is specified, the surface produced by normal manufacturing methods is satisfactory provided it is within the limits of size (and form) specified in accordance with ANSI/ASME Y14.5M-1994, Dimensioning and Tolerancing. It is considered good practice to always specify some maximum value, either specifically or by default (for example, in the manner of the note shown in Fig. 2).

*Material Removal Required or Prohibited:* The surface texture symbol is modified when necessary to require or prohibit removal of material. When it is necessary to indicate that a surface must be produced by removal of material by machining, specify the symbol shown in Fig. 7b. When required, the amount of material to be removed is specified as shown in Fig. 7c, in millimeters for metric drawings and in inches for non-metric drawings. Tolerance for material removal may be added to the basic value shown or specified in a general note. When it is necessary to indicate that a surface must be produced without material removal, specify the machining prohibited symbol as shown in Fig. 7d.

*Proportions of Surface Texture Symbols:* The recommended proportions for drawing the surface texture symbol are shown in Fig. 7f. The letter height and line width should be the same as that for dimensions and dimension lines.

## Surface Texture Symbols and Construction

| Symbol  | Meaning  |
|---|--|
| <br>Fig. 7a.                                 | Basic Surface Texture Symbol. Surface may be produced by any method except when the bar or circle (Fig. 7b or 7d) is specified.  |
| <br>Fig. 7b.                                 | Material Removal By Machining Is Required. The horizontal bar indicates that material removal by machining is required to produce the surface and that material must be provided for that purpose.   |
| <br>Fig. 7c.                                 | Material Removal Allowance. The number indicates the amount of stock to be removed by machining in millimeters (or inches). Tolerances may be added to the basic value shown or in general note.   |
| <br>Fig. 7d.                                 | Material Removal Prohibited. The circle in the vee indicates that the surface must be produced by processes such as casting, forging, hot finishing, cold finishing, die casting, powder metallurgy or injection molding without subsequent removal of material. |
| <br>Fig. 7e.                                 | Surface Texture Symbol. To be used when any surface characteristics are specified above the horizontal line or the right of the symbol. Surface may be produced by any method except when the bar or circle (Fig. 7b and 7d) is specified.                       |
|  <p style="text-align: center;">Fig. 7f.</p> |  |

**Applying Surface Texture Symbols.**—The point of the symbol should be on a line representing the surface, an extension line of the surface, or a leader line directed to the surface, or to an extension line. The symbol may be specified following a diameter dimension. Although ANSI/ASME Y14.5M-1994, “Dimensioning and Tolerancing” specifies that normally all textual dimensions and notes should be read from the bottom of the drawing, the surface texture symbol itself with its textual values may be rotated as required. Regardless, the long leg (and extension) must be to the right as the symbol is read. For parts requiring extensive and uniform surface roughness control, a general note may be added to the drawing which applies to each surface texture symbol specified without values as shown in Fig. 8.

When the symbol is used with a dimension, it affects the entire surface defined by the dimension. Areas of transition, such as chamfers and fillets, shall conform with the roughest adjacent finished area unless otherwise indicated.

Surface texture values, unless otherwise specified, apply to the complete surface. Drawings or specifications for plated or coated parts shall indicate whether the surface texture values apply before plating, after plating, or both before and after plating.

Only those values required to specify and verify the required texture characteristics should be included in the symbol. Values should be in metric units for metric drawing and non-metric units for non-metric drawings. Minority units on dual dimensioned drawings are enclosed in brackets.

Fig. 8. Application of Surface Texture Symbols

Roughness and waviness measurements, unless otherwise specified, apply in a direction which gives the maximum reading; generally across the lay.

*Cutoff or Roughness Sampling Length, (l):* Standard values are listed in Table 2. When no value is specified, the value 0.8 mm (0.030 in.) applies.

**Table 2. Standard Roughness Sampling Length (Cutoff) Values**

| mm   | in.   | mm   | in. |
|------|-------|------|-----|
| 0.08 | 0.003 | 2.5  | 0.1 |
| 0.25 | 0.010 | 8.0  | 0.3 |
| 0.80 | 0.030 | 25.0 | 1.0 |

*Roughness Average (Ra):* The preferred series of specified roughness average values is given in Table 3.

**Table 3. Preferred Series Roughness Average Values (R<sub>a</sub>)**

| μm                 | μin            | μm                | μin              | μm                | μin               |
|--------------------|----------------|-------------------|------------------|-------------------|-------------------|

| 0.0020 | 0.00008 | 0.025 | 0.001  | 0.38 | 0.015 |
| 0.0025 | 0.0001  | 0.05  | 0.002  | 0.50 | 0.020 |
| 0.005  | 0.0002  | 0.08  | 0.003  | 0.80 | 0.030 |

*Lay:* Symbols for designating the direction of lay are shown and interpreted in Table 5.

**Example Designations.**—Table 6 illustrates examples of designations of roughness, waviness, and lay by insertion of values in appropriate positions relative to the symbol.

Where surface roughness control of several operations is required within a given area, or on a given surface, surface qualities may be designated, as in Fig. 9a. If a surface must be produced by one particular process or a series of processes, they should be specified as shown in Fig. 9b. Where special requirements are needed on a designated surface, a note should be added at the symbol giving the requirements and the area involved. An example is illustrated in Fig. 9c.

**Surface Texture of Castings.**—Surface characteristics should not be controlled on a drawing or specification unless such control is essential to functional performance or appearance of the product. Imposition of such restrictions when unnecessary may increase production costs and in any event will serve to lessen the emphasis on the control specified for important surfaces. Surface characteristics of castings should never be considered on the same basis as machined surfaces. Castings are characterized by random distribution of non-directional deviations from the nominal surface.

Surfaces of castings rarely need control beyond that provided by the production method necessary to meet dimensional requirements. Comparison specimens are frequently used for evaluating surfaces having specific functional requirements. Surface texture control should not be specified unless required for appearance or function of the surface. Specification of such requirements may increase cost to the user.

Engineers should recognize that different areas of the same castings may have different surface textures. It is recommended that specifications of the surface be limited to defined areas of the casting. Practicality of and methods of determining that a casting's surface texture meets the specification shall be coordinated with the producer. The Society of Automotive Engineers standard J435 "Automotive Steel Castings" describes methods of evaluating steel casting surface texture used in the automotive and related industries.

**Metric Dimensions on Drawings.**—The length units of the metric system that are most generally used in connection with any work relating to mechanical engineering are the meter (39.37 inches) and the millimeter (0.03937 inch). One meter equals 1000 millimeters. On mechanical drawings, all dimensions are generally given in millimeters, no matter how large the dimensions may be. In fact, dimensions of such machines as locomotives and large electrical apparatus are given exclusively in millimeters. This practice is adopted to avoid mistakes due to misplacing decimal points, or misreading dimensions as when other units are used as well. When dimensions are given in millimeters, many of them can be given without resorting to decimal points, as a millimeter is only a little more than  $\frac{1}{32}$  inch. Only dimensions of precision need be given in decimals of a millimeter; such dimensions are generally given in hundredths of a millimeter—for example, 0.02 millimeter,

## SURFACE TEXTURE

Table 5. Lay Symbols

| Lay Symbol | Meaning  | Example Showing Direction of Tool Marks |
|------------|--|---|
| =          | Lay approximately parallel to the line representing the surface to which the symbol is applied.      |   |
| ⊥          | Lay approximately perpendicular to the line representing the surface to which the symbol is applied. |   |
| X          | Lay angular in both directions to line representing the surface to which the symbol is applied.      |   |
| M          | Lay multidirectional   |   |
| C          | Lay approximately circular relative to the center of the surface to which the symbol is applied.     |   |
| R          | Lay approximately radial relative to the center of the surface to which the symbol is applied.       |   |
| P          | Lay particulate, non-directional, or protuberant   |   |

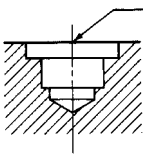

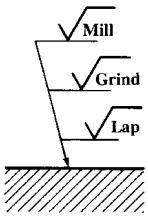

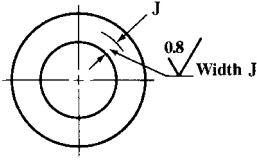

which is equal to 0.0008 inch. As 0.01 millimeter is equal to 0.0004 inch, dimensions are seldom given with greater accuracy than to hundredths of a millimeter.

*Scales of Metric Drawings:* Drawings made to the metric system are not made to scales of  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ , etc., as with drawings made to the English system. If the object cannot be drawn full size, it may be drawn  $\frac{1}{2}$ ,  $\frac{1}{5}$ ,  $\frac{1}{10}$ ,  $\frac{1}{20}$ ,  $\frac{1}{50}$ ,  $\frac{1}{100}$ ,  $\frac{1}{200}$ ,  $\frac{1}{500}$ , or  $\frac{1}{1000}$  size. If the object is too small and has to be drawn larger, it is drawn 2, 5, or 10 times its actual size.

**Table 6. Application of Surface Texture Values to Symbol**

|   |   |
|---|---|
|  <p>Roughness average rating is placed at the left of the long leg. The specification of only one rating shall indicate the maximum value and any lesser value shall be acceptable. Specify in micrometers (microinch).</p>  |  <p>Material removal by machining is required to produce the surface. The basic amount of stock provided for material removal is specified at the left of the short leg of the symbol. Specify in millimeters (inch).</p>  |
|  <p>The specification of maximum and minimum roughness average values indicates permissible range of roughness. Specify in micrometers (microinch).</p>  |  <p>Removal of material is prohibited.</p>   |
|  <p>Maximum waviness height rating is the first rating placed above the horizontal extension. Any lesser rating shall be acceptable. Specify in millimeters (inch).</p> <p>Maximum waviness spacing rating is the second rating placed above the horizontal extension and to the right of the waviness height rating. Any lesser rating shall be acceptable. Specify in millimeters (inch).</p> |  <p>Lay designation is indicated by the lay symbol placed at the right of the long leg.</p>  <p>Roughness sampling length or cutoff rating is placed below the horizontal extension. When no value is shown, 0.80 mm (0.030 inch) applies. Specify in millimeters (inch).</p>  <p>Where required maximum roughness spacing shall be placed at the right of the lay symbol. Any lesser rating shall be acceptable. Specify in millimeters (inch).</p> |

### ISO Surface Finish

**Differences Between ISO and ANSI Surface Finish Symbology.**—ISO surface finish standards are comprised of numerous individual standards that taken as a whole form a set of standards roughly comparable in scope to American National Standard ANSI/ASME Y14.36M.

The primary standard dealing with surface finish, ISO 1302:1992, is concerned with the methods of specifying surface texture symbology and additional indications on engineering drawings. The parameters in ISO surface finish standards relate to surfaces produced by abrading, casting, coating, cutting, etching, plastic deformation, sintering, wear, erosion, and some other methods.

ISO 1302 defines how surface texture and its constituents, roughness, waviness, and lay, are specified on the symbology. Surface defects are specifically excluded from consideration during inspection of surface texture, but definitions of flaws and imperfections are discussed in ISO 8785.

As with American National Standard ASME Y14.36M, ISO 1302 is not concerned with luster, appearance, color, corrosion resistance, wear resistance, hardness, sub-surface microstructure, surface integrity, and many other characteristics that may govern considerations in specific applications. Visually, the ISO surface finish symbol is similar to the ANSI symbol, but the proportions of the symbol in relationship to text height differs from ANSI, as do some of the parameters as described in Fig. 10. Examples of the application of the ISO surface finish symbol are illustrated in Table 10.

The ISO 1302 standard does not define the degrees of surface roughness and waviness or type of lay for specific purposes, nor does it specify the means by which any degree of such irregularities may be obtained or produced. Also, errors of form such as out-of-roundness and out-of-flatness are not addressed in the ISO surface finish standards.

#### Other ISO Standards Related To Surface Finish

|                |   |
|----------------|---|
| ISO 468:1982   | “Surface roughness — parameters. Their values and general rules for specifying requirements.”   |
| ISO 4287:1997  | “Surface texture: Profile method — Terms, definitions and surface texture parameters.”  |
| ISO 4288:1996  | “Surface texture: Profile method — Rules and procedures for the assessment of surface texture.” Includes specifications for precision reference specimens, and roughness comparison specimens, and establishes requirements for stylus-type instruments.” |
| ISO 8785:1998  | “Surface imperfections — Terms, definitions and parameters.”  |
| ISO 10135-1:CD | “Representation of parts produced by shaping processes — Part 1: Molded parts.”   |

**Rules for Comparing Measured Values to Specified Limits.**—*Max rule:* When a maximum requirement is specified for a surface finish parameter on a drawing (e.g.  $Rz1.5_{max}$ ), none of the inspected values may extend beyond the upper limit over the entire surface. MAX must be added to the parametric symbol in the surface finish symbology on the drawing.

*16% rule:* When upper and lower limits are specified, no more than 16% of all measured values of the selected parameter within the evaluation length may exceed the upper limit. No more than 16% of all measured values of the selected parameter within the evaluation length may be less than the lower limit.

Fig. 10. ISO Surface Finish Symbol

**ISO Surface Parameter Symbols**

|   |   |
|---|---|
| $R_p$ = max height profile                        | $R\delta c$ = profile section height difference |
| $R_v$ = max profile valley depth                  | $l_p$ = sampling length – primary profile       |
| $Rz^*$ = max height of the profile                | $l_w$ = sampling length – waviness profile      |
| $R_c$ = mean height of profile                    | $l_r$ = sampling length – roughness profile     |
| $R_t$ = total height of the profile               | $l_n$ = evaluation length                       |
| $R_a$ = arithmetic mean deviation of the profile  | $Z(x)$ = ordinate value                         |
| $R_q$ = root mean square deviation of the profile | $dZ/dX$ = local slope                           |
| $Rsk$ = skewness of the profile                   | $Z_p$ = profile peak height                     |
| $Rku$ = kurtosis of the profile                   | $Z_v$ = profile valley depth                    |
| $RSm$ = mean width of the profile                 | $Z_r$ = profile element height                  |
| $RDq$ = root mean square slope of the profile     | $X_s$ = profile element width                   |
| $Rmr$ = material ration of the profile            | $MI$ = material length of profile               |

**Exceptions to the 16% rule:** Where the measured values of roughness profiles being inspected follow a normal distribution, the 16% rule may be overridden. This is allowed when greater than 16% of the measured values exceed the upper limit, but the total roughness profile conforms with the sum of the arithmetic mean and standard deviation ( $\mu + \sigma$ ). Effectively this means that the greater the value of  $\sigma$ , the further  $\mu$  must be from the upper limit (see Fig. 11).

**Basic rules for determining cut-off wavelength:** When the sampling length is specified on the drawing or in documentation, the cut-off wavelength  $\lambda_c$  is equal to the sample length. When no sampling length is specified, the cut-off wavelength is estimated using Table 8.

Fig. 11.

**Basic rules for measurement of roughness parameters:** For non-periodic roughness the parameter  $Ra$ ,  $Rz$ ,  $RzI_{max}$  or  $RSm$  are first estimated using visual inspection, comparison to specimens, graphic analysis, etc. The sampling length is then selected from Table 8, based on the use of  $Ra$ ,  $Rz$ ,  $RzI_{max}$  or  $RSm$ . Then with instrumentation, a representative sample is taken using the sampling length chosen above.

**Table 8. Sampling Lengths**

| Curves for Non-periodic Profiles<br>such as Ground Surfaces |                                      | Curves for Periodic and<br>Non-periodic Profiles | Sampling length,<br>$l_r$ (mm) | Evaluation length,<br>$l_n$ (mm) |
|---|--------------------------------------|--|--------------------------------|----------------------------------|
| For $Ra$ , $Rq$ , $Rsk$ , $Rku$ , $R\Delta q$               | For $Rz$ , $Rv$ , $Rp$ , $Rc$ , $Rt$ | For $R$ -parameters and $RSm$                    |                                |                                  |
| $Ra$ , $\mu m$  | $Rz$ , $RzI_{max}$ , $\mu m$         | $RSm$ , $\mu m$                                  |                                |                                  |
| $(0.006) < Ra \leq 0.02$                                    | $(0.025) < Rz, RzI_{max} \leq 0.1$   | $0.013 < RSm \leq 0.04$                          | 0.08                           | 0.4                              |
| $0.02 < Ra \leq 0.1$  | $0.1 < Rz, RzI_{max} \leq 0.5$       | $0.04 < RSm \leq 0.13$                           | 0.25                           | 1.25                             |
| $0.1 < Ra \leq 2$   | $0.5 < Rz, RzI_{max} \leq 10$        | $0.13 < RSm \leq 0.4$                            | 0.8                            | 4                                |
| $2 < Ra \leq 10$  | $10 < Rz, RzI_{max} \leq 50$         | $0.4 < RSm \leq 1.3$                             | 2.5                            | 12.5                             |
| $10 < Ra \leq 80$   | $50 < Rz, RzI_{max} \leq 200$        | $1.3 < RSm \leq 4$                               | 8                              | 40                               |

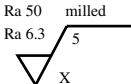

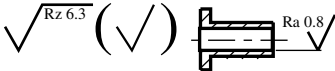

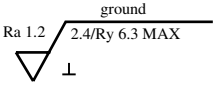

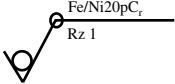

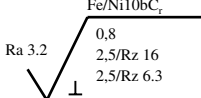

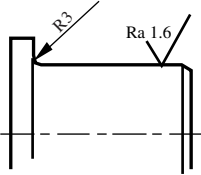

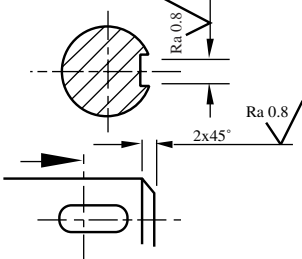

The measured values are then compared to the ranges of values in Table 8 for the particular parameter. If the value is outside the range of values for the estimated sampling length, the measuring instrument is adjusted for the next higher or lower sampling length and the measurement repeated. If the final setting corresponds to Table 8, then both the sampling length setting and  $Ra$ ,  $Rz$ ,  $RzI_{max}$  or  $RSm$  values are correct and a representative measurement of the parameter can be taken.

For periodic roughness, the parameter  $RSm$  is estimated graphically and the recommended cut-off values selected using Table 8. If the value is outside the range of values for the estimated sampling length, the measuring instrument is adjusted for the next higher or lower sampling length and the measurement repeated. If the final setting corresponds to Table 8, then both the sampling length setting and  $RSm$  values are correct and a representative measurement of the parameter can be taken.

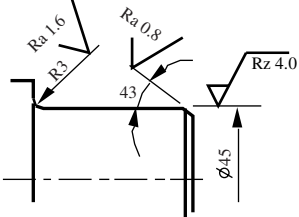

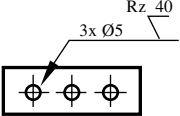

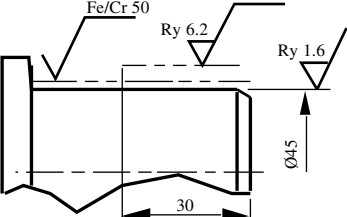

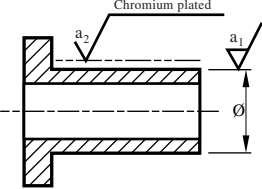

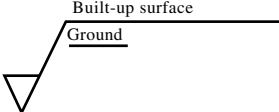

**Table 9. Preferred Roughness Values and Roughness Grades**

| Roughness values, $Ra$ |          | Previous Grade Number<br>from ISO 1302 | Roughness values, $Ra$ |          | Previous Grade Number<br>from ISO 1302 |
|------------------------|----------|--|------------------------|----------|--|
| $\mu m$                | $\mu in$ |  | $\mu m$                | $\mu in$ |  |
| 50                     | 2000     | N12                                    | 0.8                    | 32       | N6                                     |
| 25                     | 1000     | N11                                    | 0.4                    | 16       | N5                                     |

| 1.6                    | 63       | N7                                     | 0.025                  | 1        | N1                                     |

**Table 10. Examples of ISO Applications of Surface Texture Symbology**

| Interpretation   | Example   |
|--|---|
| Surface roughness is produced by milling and between upper limit of $Ra = 50 \mu\text{m}$ and $Ra = 6.3 \mu\text{m}$ ; direction of lay is crossed in oblique directions relative to plane of projection; sampling length is 5 mm.   |    |
| Surface roughness of $Rz = 6.3 \mu\text{m}$ is the default for all surfaces as indicated by the $Rz = 6.3$ specification, plus basic symbol within parentheses. Any deviating specification is called out with local notes such as the $Ra = 0.8 \mu\text{m}$ specification. |    |
| Surface roughness is produced by grinding to $Ra = 1.2 \mu\text{m}$ and limited to $Ry = 6.3 \mu\text{m}$ max; direction of lay is perpendicular relative to the plane of projection; sampling length is 2.4 mm.   |    |
| Surface treatment without any machining; nickel-chrome plated to $Rz = 1 \mu\text{m}$ on all surfaces.   |    |
| Surface is nickel-chrome plated to roughness of $Ra = 3.2 \mu\text{m}$ with a sampling length of 0.8 mm; limited to $Rz = 16 \mu\text{m}$ to $Rz = 6.3 \mu\text{m}$ with a sampling length of 2.5 mm.  |    |
| Surface roughness of $Rz = 6.3 \mu\text{m}$ is the default for all surfaces except the inside diameter which is $Ra = 0.8 \mu\text{m}$ .   |   |
| Surface texture symbology may be combined with dimension leaders and witness (extension) lines.  |  |

**Table 10. (Continued) Examples of ISO Applications of Surface Texture Symbology**

| Interpretation   | Example   |
|--|---|
| <p>Surface texture symbology may be applied to extended extension lines or on extended projection lines.</p>   |    |
| <p>Surface roughness is produced by milling and between upper limit of <math>Ra = 50 \mu\text{m}</math> and <math>Ra = 6.3 \mu\text{m}</math>; direction of lay is crossed in oblique directions relative to plane of projection; sampling length is 5 mm.</p> |    |
| <p>Surface treatment without any machining; nickel-chrome plated to <math>Rz = 1 \mu\text{m}</math> on all surfaces.</p>   |    |
| <p>Surface texture characteristics may be specified both before and after surface treatment.</p>   |   |
| <p>The symbol may be expanded with additional lines for textual information where there is insufficient room on the drawing.</p>   |  |

### Gage Blocks

**Precision Gage Blocks.**—Precision gage blocks are usually purchased in sets comprising a specific number of blocks of different sizes. The nominal gage lengths of individual blocks in a set are determined mathematically so that particular desired lengths can be obtained by combining selected blocks. They are made to several different tolerance grades which categorize them as master blocks, calibration blocks, inspection blocks, and workshop blocks. *Master blocks* are employed as basic reference standards; *calibration blocks* are used for high precision gaging work and calibrating inspection blocks; *inspection blocks* are used as toolroom standards and for checking and setting limit and comparator gages, for example. The *workshop blocks* are working gages used as shop standards for a variety of direct precision measurements and gaging applications, including sine-bar settings.

Federal Specification GGG-G-15C, Gage Blocks (see below), lists typical sets, and gives details of materials, design, and manufacturing requirements, and tolerance grades. When there is in a set no single block of the exact size that is wanted, two or more blocks are combined by “wringing” them together. Wringing is achieved by first placing one block crosswise on the other and applying some pressure. Then a swiveling motion is used to twist the blocks to a parallel position, causing them to adhere firmly to one another.

When combining blocks for a given dimension, the object is to use as few blocks as possible to obtain the dimension. The procedure for selecting blocks is based on successively eliminating the right-hand figure of the desired dimension.

*Example:* Referring to gage block set number 1 in [Table 1](#), determine the blocks required to obtain 3.6742 inches. *Step 1:* Eliminate 0.0002 by selecting a 0.1002 block. Subtract 0.1002 from 3.6743 = 3.5740. *Step 2:* Eliminate 0.004 by selecting a 0.124 block. Subtract 0.124 from 3.5740 = 3.450. *Step 3:* Eliminate 0.450 with a block this size. Subtract 0.450 from 3.450 = 3.000. *Step 4:* Select a 3.000 inch block. The combined blocks are 0.1002 + 0.124 + 0.450 + 3.000 = 3.6742 inches.

**Federal Specification for Gage Blocks, Inch and Metric Sizes.**—This Specification, GGG-G-15C, March 20, 1975, which supersedes GGG-G-15B, November 6, 1970, covers design, manufacturing, and purchasing details for precision gage blocks in inch and metric sizes up to and including 20 inches and 500 millimeters gage lengths. The shapes of blocks are designated Style 1, which is rectangular; Style 2, which is square with a center accessory hole, and Style 3, which defines other shapes as may be specified by the purchaser. Blocks may be made from steel, chromium-plated steel, chromium carbide, or tungsten carbide. There are four tolerance grades, which are designated Grade 0.5 (formerly Grade AAA in the GGG-G-15A issue of the Specification); Grade 1 (formerly Grade AA); Grade 2 (formerly Grade A+); and Grade 3 (a compromise between former Grades A and B). Grade 0.5 blocks are special reference gages used for extremely high precision gaging work, and are not recommended for general use. Grade 1 blocks are laboratory reference standards used for calibrating inspection gage blocks and high precision gaging work. Grade 2 blocks are used as inspection and toolroom standards, and Grade 3 blocks are used as shop standards.

Inch and metric sizes of blocks in specific sets are given in [Tables 1](#) and [2](#), which is not a complete list of available sizes. It should be noted that some gage blocks must be ordered as specials, some may not be available in all materials, and some may not be available from all manufacturers. Gage block set number 4 (88 blocks), listed in the Specification, is not given in [Table 1](#). It is the same as set number 1 (81 blocks) but contains seven additional blocks measuring 0.0625, 0.078125, 0.093750, 0.100025, 0.100050, 0.100075, and 0.109375 inch. In [Table 2](#), gage block set number 3M (112 blocks) is not given. It is similar to set number 2M (88 blocks), and the chief difference is the inclusion of a larger number of blocks in the 0.5 millimeter increment series up to 24.5 mm. Set numbers 5M (88 blocks), 6M (112 blocks), and 7M (17 blocks) also are not listed.

## PRECISION GAGE BLOCKS

**Table 1. Gage Block Sets—Inch Sizes** *Federal Specification GGG-G-15C*

## CUTTING TOOLS

### Terms and Definitions

**Tool Contour.**—Tools for turning, planing, etc., are made in straight, bent, offset, and other forms to place the cutting edges in convenient positions for operating on differently located surfaces. The contour or shape of the cutting edge may also be varied to suit different classes of work. Tool shapes, however, are not only related to the kind of operation, but, in roughing tools particularly, the contour may have a decided effect upon the cutting efficiency of the tool. To illustrate, an increase in the side cutting-edge angle of a roughing tool, or in the nose radius, tends to permit higher cutting speeds because the chip will be thinner for a given feed rate. Such changes, however, may result in chattering or vibrations unless the work and the machine are rigid; hence, the most desirable contour may be a compromise between the ideal form and one that is needed to meet practical requirements.

**Terms and Definitions.**—The terms and definitions relating to single-point tools vary somewhat in different plants, but the following are in general use.

Fig. 1. Terms Applied to Single-point Turning Tools

**Single-point Tool:** This term is applied to tools for turning, planing, boring, etc., which have a cutting edge at one end. This cutting edge may be formed on one end of a solid piece of steel, or the cutting part of the tool may consist of an insert or tip which is held to the body of the tool by brazing, welding, or mechanical means.

**Shank:** The shank is the main body of the tool. If the tool is an inserted cutter type, the shank supports the cutter or bit. (See diagram, Fig. 1.)

**Nose:** A general term sometimes used to designate the cutting end but usually relating more particularly to the rounded tip of the cutting end.

**Face:** The surface against which the chips bear, as they are severed in turning or planing operations, is called the face.

**Flank:** The flank is that end surface adjacent to the cutting edge and below it when the tool is in a horizontal position as for turning.

**Base:** The base is the surface of the tool shank that bears against the supporting tool-holder or block.

**Side Cutting Edge:** The side cutting edge is the cutting edge on the side of the tool. Tools such as shown in Fig. 1 do the bulk of the cutting with this cutting edge and are, therefore, sometimes called side cutting edge tools.

**End Cutting Edge:** The end cutting edge is the cutting edge at the end of the tool.

On side cutting edge tools, the end cutting edge can be used for light plunging and facing cuts. Cutoff tools and similar tools have only one cutting edge located on the end. These

tools and other tools that are intended to cut primarily with the end cutting edge are sometimes called end cutting edge tools.

**Rake:** A metal-cutting tool is said to have rake when the tool face or surface against which the chips bear as they are being severed, is inclined for the purpose of either increasing or diminishing the keenness or bluntness of the edge. The magnitude of the rake is most conveniently measured by two angles called the back rake angle and the side rake angle. The tool shown in Fig. 1 has rake. If the face of the tool did not incline but was parallel to the base, there would be no rake; the rake angles would be zero.

**Positive Rake:** If the inclination of the tool face is such as to make the cutting edge keener or more acute than when the rake angle is zero, the rake angle is defined as positive.

**Negative Rake:** If the inclination of the tool face makes the cutting edge less keen or more blunt than when the rake angle is zero, the rake is defined as negative.

**Back Rake:** The back rake is the inclination of the face toward or away from the end or the end cutting edge of the tool. When the inclination is away from the end cutting edge, as shown in Fig. 1, the back rake is positive. If the inclination is downward toward the end cutting edge the back rake is negative.

**Side Rake:** The side rake is the inclination of the face toward or away from the side cutting edge. When the inclination is away from the side cutting edge, as shown in Fig. 1, the side rake is positive. If the inclination is toward the side cutting edge the side rake is negative.

**Relief:** The flanks below the side cutting edge and the end cutting edge must be relieved to allow these cutting edges to penetrate into the workpiece when taking a cut. If the flanks are not provided with relief, the cutting edges will rub against the workpiece and be unable to penetrate in order to form the chip. Relief is also provided below the nose of the tool to allow it to penetrate into the workpiece. The relief at the nose is usually a blend of the side relief and the end relief.

**End Relief Angle:** The end relief angle is a measure of the relief below the end cutting edge.

**Side Relief Angle:** The side relief angle is a measure of the relief below the side cutting edge.

**Back Rake Angle:** The back rake angle is a measure of the back rake. It is measured in a plane that passes through the side cutting edge and is perpendicular to the base. Thus, the back rake angle can be defined by measuring the inclination of the side cutting edge with respect to a line or plane that is parallel to the base. The back rake angle may be positive, negative, or zero depending upon the magnitude and direction of the back rake.

**Side Rake Angle:** The side rake angle is a measure of the side rake. This angle is always measured in a plane that is perpendicular to the side cutting edge and perpendicular to the base. Thus, the side rake angle is the angle of inclination of the face perpendicular to the side cutting edge with reference to a line or a plane that is parallel to the base.

**End Cutting Edge Angle:** The end cutting edge angle is the angle made by the end cutting edge with respect to a plane perpendicular to the axis of the tool shank. It is provided to allow the end cutting edge to clear the finish machined surface on the workpiece.

**Side Cutting Edge Angle:** The side cutting edge angle is the angle made by the side cutting edge and a plane that is parallel to the side of the shank.

**Nose Radius:** The nose radius is the radius of the nose of the tool. The performance of the tool, in part, is influenced by nose radius so that it must be carefully controlled.

**Lead Angle:** The lead angle, shown in Fig. 2, is not ground on the tool. It is a tool setting angle which has a great influence on the performance of the tool. The lead angle is bounded by the side cutting edge and a plane perpendicular to the workpiece surface when the tool is in position to cut; or, more exactly, the lead angle is the angle between the side cutting edge and a plane perpendicular to the direction of the feed travel.

Fig. 2. Lead Angle on Single-point Turning Tool

**Solid Tool:** A solid tool is a cutting tool made from one piece of tool material.

**Brazed Tool:** A brazed tool is a cutting tool having a blank of cutting-tool material permanently brazed to a steel shank.

**Blank:** A blank is an unground piece of cutting-tool material from which a brazed tool is made.

**Tool Bit:** A tool bit is a relatively small cutting tool that is clamped in a holder in such a way that it can readily be removed and replaced. It is intended primarily to be reground when dull and not indexed.

**Tool-bit Blank:** The tool-bit blank is an unground piece of cutting-tool material from which a tool bit can be made by grinding. It is available in standard sizes and shapes.

**Tool-bit Holder:** Usually made from forged steel, the tool-bit holder is used to hold the tool bit, to act as an extended shank for the tool bit, and to provide a means for clamping in the tool post.

**Straight-shank Tool-bit Holder:** A straight-shank tool-bit holder has a straight shank when viewed from the top. The axis of the tool bit is held parallel to the axis of the shank.

**Offset-shank Tool-bit Holder:** An offset-shank tool-bit holder has the shank bent to the right or left, as seen in Fig. 3. The axis of the tool bit is held at an angle with respect to the axis of the shank.

**Side cutting Tool:** A side cutting tool has its major cutting edge on the side of the cutting part of the tool. The major cutting edge may be parallel or at an angle with respect to the axis of the tool.

**Indexable Inserts:** An indexable insert is a relatively small piece of cutting-tool material that is geometrically shaped to have two or several cutting edges that are used until dull. The insert is then indexed on the holder to apply a sharp cutting edge. When all the cutting edges have been dulled, the insert is discarded. The insert is held in a pocket or against other locating surfaces on an indexable insert holder by means of a mechanical clamping device that can be tightened or loosened easily.

**Indexable Insert Holder:** Made of steel, an indexable insert holder is used to hold indexable inserts. It is equipped with a mechanical clamping device that holds the inserts firmly in a pocket or against other seating surfaces.

**Straight-shank Indexable Insert Holder:** A straight-shank indexable insert tool-holder is essentially straight when viewed from the top, although the cutting edge of the insert may be oriented parallel, or at an angle to, the axis of the holder.

**Offset-shank Indexable Insert Holder:** An offset-shank indexable insert holder has the head end, or the end containing the insert pocket, offset to the right or left, as shown in Fig. 3.

3.

Fig. 3. Top: Right-hand Offset-shank, Indexable Insert Holder  
Bottom: Right-hand Offset-shank Tool-bit Holder

*End cutting Tool:* An end cutting tool has its major cutting edge on the end of the cutting part of the tool. The major cutting edge may be perpendicular or at an angle, with respect to the axis of the tool.

*Curved Cutting-edge Tool:* A curved cutting-edge tool has a continuously variable side cutting edge angle. The cutting edge is usually in the form of a smooth, continuous curve along its entire length, or along a large portion of its length.

*Right-hand Tool:* A right-hand tool has the major, or working, cutting edge on the right-hand side when viewed from the cutting end with the face up. As used in a lathe, such a tool is usually fed into the work from right to left, when viewed from the shank end.

*Left-hand Tool:* A left-hand tool has the major or working cutting edge on the left-hand side when viewed from the cutting end with the face up. As used in a lathe, the tool is usually fed into the work from left to right, when viewed from the shank end.

*Neutral-hand Tool:* A neutral-hand tool is a tool to cut either left to right or right to left; or the cut may be parallel to the axis of the shank as when plunge cutting.

*Chipbreaker:* A groove formed in or on a shoulder on the face of a turning tool back of the cutting edge to break up the chips and prevent the formation of long, continuous chips which would be dangerous to the operator and also bulky and cumbersome to handle. A chipbreaker of the shoulder type may be formed directly on the tool face or it may consist of a separate piece that is held either by brazing or by clamping.

**Relief Angles.**—The end relief angle and the side relief angle on single-point cutting tools are usually, though not invariably, made equal to each other. The relief angle under the nose of the tool is a blend of the side and end relief angles.

The size of the relief angles has a pronounced effect on the performance of the cutting tool. If the relief angles are too large, the cutting edge will be weakened and in danger of breaking when a heavy cutting load is placed on it by a hard and tough material. On finish cuts, rapid wear of the cutting edge may cause problems with size control on the part. Relief angles that are too small will cause the rate of wear on the flank of the tool below the cutting edge to increase, thereby significantly reducing the tool life. In general, when cutting hard and tough materials, the relief angles should be 6 to 8 degrees for high-speed steel tools and 5 to 7 degrees for carbide tools. For medium steels, mild steels, cast iron, and other average work the recommended values of the relief angles are 8 to 12 degrees for high-speed steel tools and 5 to 10 degrees for carbides. Ductile materials having a relatively low modulus of elasticity should be cut using larger relief angles. For example, the relief angles recommended for turning copper, brass, bronze, aluminum, ferritic malleable

iron, and similar metals are 12 to 16 degrees for high-speed steel tools and 8 to 14 degrees for carbides.

Larger relief angles generally tend to produce a better finish on the finish machined surface because less surface of the worn flank of the tool rubs against the workpiece. For this reason, single-point thread-cutting tools should be provided with relief angles that are as large as circumstances will permit. Problems encountered when machining stainless steel may be overcome by increasing the size of the relief angle. The relief angles used should never be smaller than necessary.

**Rake Angles.**—Machinability tests have confirmed that when the rake angle along which the chip slides, called the true rake angle, is made larger in the positive direction, the cutting force and the cutting temperature will decrease. Also, the tool life for a given cutting speed will increase with increases in the true rake angle up to an optimum value, after which it will decrease again. For turning tools which cut primarily with the side cutting edge, the true rake angle corresponds rather closely with the side rake angle except when taking shallow cuts. Increasing the side rake angle in the positive direction lowers the cutting force and the cutting temperature, while at the same time it results in a longer tool life or a higher permissible cutting speed up to an optimum value of the side rake angle. After the optimum value is exceeded, the cutting force and the cutting temperature will continue to drop; however, the tool life and the permissible cutting speed will decrease.

As an approximation, the magnitude of the cutting force will decrease about one per cent per degree increase in the side rake angle. While not exact, this rule of thumb does correspond approximately to test results and can be used to make rough estimates. Of course, the cutting force also increases about one per cent per degree decrease in the side rake angle. The limiting value of the side rake angle for optimum tool life or cutting speed depends upon the work material and the cutting tool material. In general, lower values can be used for hard and tough work materials. Cemented carbides are harder and more brittle than high-speed steel; therefore, the rake angles usually used for cemented carbides are less positive than for high-speed steel.

Negative rake angles cause the face of the tool to slope in the opposite direction from positive rake angles and, as might be expected, they have an opposite effect. For side cutting edge tools, increasing the side rake angle in a negative direction will result in an increase in the cutting force and an increase in the cutting temperature of approximately one per cent per degree change in rake angle. For example, if the side rake angle is changed from 5 degrees positive to 5 degrees negative, the cutting force will be about 10 per cent larger. Usually the tool life will also decrease when negative side rake angles are used, although the tool life will sometimes increase when the negative rake angle is not too large and when a fast cutting speed is used.

Negative side rake angles are usually used in combination with negative back rake angles on single-point cutting tools. The negative rake angles strengthen the cutting edges enabling them to sustain heavier cutting loads and shock loads. They are recommended for turning very hard materials and for heavy interrupted cuts. There is also an economic advantage in favor of using negative rake indexable inserts and tool holders inasmuch as the cutting edges provided on both the top and bottom of the insert can be used.

On turning tools that cut primarily with the side cutting edge, the effect of the back rake angle alone is much less than the effect of the side rake angle although the direction of the change in cutting force, cutting temperature, and tool life is the same. The effect that the back rake angle has can be ignored unless, of course, extremely large changes in this angle are made. A positive back rake angle does improve the performance of the nose of the tool somewhat and is helpful in taking light finishing cuts. A negative back rake angle strengthens the nose of the tool and is helpful when interrupted cuts are taken. The back rake angle has a very significant effect on the performance of end cutting edge tools, such as cut-off tools. For these tools, the effect of the back rake angle is very similar to the effect of the side rake angle on side cutting edge tools.

**Side Cutting Edge and Lead Angles.**—These angles are considered together because the side cutting edge angle is usually designed to provide the desired lead angle when the tool is being used. The side cutting edge angle and the lead angle will be equal when the shank of the cutting tool is positioned perpendicular to the workpiece, or, more correctly, perpendicular to the direction of the feed. When the shank is not perpendicular, the lead angle is determined by the side cutting edge and an imaginary line perpendicular to the feed direction.

The flow of the chips over the face of the tool is approximately perpendicular to the side cutting edge except when shallow cuts are taken. The thickness of the undeformed chip is measured perpendicular to the side cutting edge. As the lead angle is increased, the length of chip in contact with the side cutting edge is increased, and the chip will become longer and thinner. This effect is the same as increasing the depth of cut and decreasing the feed, although the actual depth of cut and feed remain the same and the same amount of metal is removed. The effect of lengthening and thinning the chip by increasing the lead angle is very beneficial as it increases the tool life for a given cutting speed or that speed can be increased. Increasing the cutting speed while the feed and the tool life remain the same leads to faster production.

However, an adverse effect must be considered. Chatter can be caused by a cutting edge that is oriented at a high lead angle when turning and sometimes, when turning long and slender shafts, even a small lead angle can cause chatter. In fact, an unsuitable lead angle of the side cutting edge is one of the principal causes of chatter. When chatter occurs, often simply reducing the lead angle will cure it. Sometimes, very long and slender shafts can be turned successfully with a tool having a zero degree lead angle (and having a small nose radius). Boring bars, being usually somewhat long and slender, are also susceptible to chatter if a large lead angle is used. The lead angle for boring bars should be kept small, and for very long and slender boring bars a zero degree lead angle is recommended. It is impossible to provide a rule that will determine when chatter caused by a lead angle will occur and when it will not. In making a judgment, the first consideration is the length to diameter ratio of the part to be turned, or of the boring bar. Then the method of holding the workpiece must be considered — a part that is firmly held is less apt to chatter. Finally, the overall condition and rigidity of the machine must be considered because they may be the real cause of chatter.

Although chatter can be a problem, the advantages gained from high lead angles are such that the lead angle should be as large as possible at all times.

**End Cutting Edge Angle.**—The size of the end cutting edge angle is important when tool wear by cratering occurs. Frequently, the crater will enlarge until it breaks through the end cutting edge just behind the nose, and tool failure follows shortly. Reducing the size of the end cutting edge angle tends to delay the time of crater breakthrough. When cratering takes place, the recommended end cutting edge angle is 8 to 15 degrees. If there is no cratering, the angle can be made larger. Larger end cutting edge angles may be required to enable profile turning tools to plunge into the work without interference from the end cutting edge.

**Nose Radius.**—The tool nose is a very critical part of the cutting edge since it cuts the finished surface on the workpiece. If the nose is made to a sharp point, the finish machined surface will usually be unacceptable and the life of the tool will be short. Thus, a nose radius is required to obtain an acceptable surface finish and tool life. The surface finish obtained is determined by the feed rate and by the nose radius if other factors such as the work material, the cutting speed, and cutting fluids are not considered. A large nose radius will give a better surface finish and will permit a faster feed rate to be used.

Machinability tests have demonstrated that increasing the nose radius will also improve the tool life or allow a faster cutting speed to be used. For example, high-speed steel tools were used to turn an alloy steel in one series of tests where complete or catastrophic tool failure was used as a criterion for the end of tool life. The cutting speed for a 60-minute tool

life was found to be 125 fpm when the nose radius was  $\frac{1}{16}$  inch and 160 fpm when the nose radius was  $\frac{1}{4}$  inch.

A very large nose radius can often be used but a limit is sometimes imposed because the tendency for chatter to occur is increased as the nose radius is made larger. A nose radius that is too large can cause chatter and when it does, a smaller nose radius must be used on the tool. It is always good practice to make the nose radius as large as is compatible with the operation being performed.

**Chipbreakers.**—Many steel turning tools are equipped with chipbreaking devices to prevent the formation of long continuous chips in connection with the turning of steel at the high speeds made possible by high-speed steel and especially cemented carbide tools. Long steel chips are dangerous to the operator, and cumbersome to handle, and they may twist around the tool and cause damage. Broken chips not only occupy less space, but permit a better flow of coolant to the cutting edge. Several different forms of chipbreakers are illustrated in Fig. 4.

*Angular Shoulder Type:* The angular shoulder type shown at A is one of the commonly used forms. As the enlarged sectional view shows, the chipbreaking shoulder is located back of the cutting edge. The angle  $a$  between the shoulder and cutting edge may vary from 6 to 15 degrees or more, 8 degrees being a fair average. The ideal angle, width  $W$  and depth  $G$ , depend upon the speed and feed, the depth of cut, and the material. As a general rule, width  $W$ , at the end of the tool, varies from  $\frac{3}{32}$  to  $\frac{7}{32}$  inch, and the depth  $G$  may range from  $\frac{1}{64}$  to  $\frac{1}{16}$  inch. The shoulder radius equals depth  $G$ . If the tool has a large nose radius, the corner of the shoulder at the nose end may be beveled off, as illustrated at B, to prevent it from coming into contact with the work. The width  $K$  for type B should equal approximately 1.5 times the nose radius.

*Parallel Shoulder Type:* Diagram C shows a design with a chipbreaking shoulder that is parallel with the cutting edge. With this form, the chips are likely to come off in short curled sections. The parallel form may also be applied to straight tools which do not have a side cutting-edge angle. The tendency with this parallel shoulder form is to force the chips against the work and damage it.

Fig. 4. Different Forms of Chipbreakers for Turning Tools

*Groove Type:* This type (diagram D) has a groove in the face of the tool produced by grinding. Between the groove and the cutting edge, there is a land  $L$ . Under ideal conditions, this width  $L$ , the groove width  $W$ , and the groove depth  $G$ , would be varied to suit the feed, depth of cut and material. For average use,  $L$  is about  $\frac{1}{32}$  inch;  $G$ ,  $\frac{1}{32}$  inch; and  $W$ ,  $\frac{1}{16}$  inch. There are differences of opinion concerning the relative merits of the groove type and

the shoulder type. Both types have proved satisfactory when properly proportioned for a given class of work.

*Chipbreaker for Light Cuts:* Diagram E illustrates a form of chipbreaker that is sometimes used on tools for finishing cuts having a maximum depth of about  $\frac{1}{32}$  inch. This chipbreaker is a shoulder type having an angle of 45 degrees and a maximum width of about  $\frac{1}{16}$  inch. It is important in grinding all chipbreakers to give the chip-bearing surfaces a fine finish, such as would be obtained by honing. This finish greatly increases the life of the tool.

**Planing Tools.**—Many of the principles which govern the shape of turning tools also apply in the grinding of tools for planing. The amount of rake depends upon the hardness of the material, and the direction of the rake should be away from the *working part* of the cutting edge. The angle of clearance should be about 4 or 5 degrees for planer tools, which is less than for lathe tools. This small clearance is allowable because a planer tool is held about square with the platen, whereas a lathe tool, the height and inclination of which can be varied, may not always be clamped in the same position.

*Carbide Tools:* Carbide tools for planing usually have negative rake. Round-nose and square-nose end-cutting tools should have a “negative back rake” (or front rake) of 2 or 3 degrees. Side cutting tools may have a negative back rake of 10 degrees, a negative side rake of 5 degrees, and a side cutting-edge angle of 8 degrees.

### Indexable Inserts

**Introduction.**—A large proportion of the cemented carbide, single-point cutting tools are indexable inserts and indexable insert tool holders. Dimensional specifications for solid sintered carbide indexable inserts are given in American National Standard ANSI B212.12-1991 (R2002). Samples of the many insert shapes are shown in Table 3. Most modern, cemented carbide, face milling cutters are of the indexable insert type. Larger size end milling cutters, side milling or slotting cutters, boring tools, and a wide variety of special tools are made to use indexable inserts. These inserts are primarily made from cemented carbide, although most of the cemented oxide cutting tools are also indexable inserts.

The objective of this type of tooling is to provide an insert with several cutting edges. When an edge is worn, the insert is indexed in the tool holder until all the cutting edges are used up, after which it is discarded. The insert is not intended to be reground. The advantages are that the cutting edges on the tool can be rapidly changed without removing the tool holder from the machine, tool-grinding costs are eliminated, and the cost of the insert is less than the cost of a similar, brazed carbide tool. Of course, the cost of the tool holder must be added to the cost of the insert; however, one tool holder will usually last for a long time before it, too, must be replaced.

Indexable inserts and tool holders are made with a negative rake or with a positive rake. Negative rake inserts have the advantage of having twice as many cutting edges available as comparable positive rake inserts, because the cutting edges on both the top and bottom of negative rake inserts can be used, while only the top cutting edges can be used on positive rake inserts. Positive rake inserts have a distinct advantage when machining long and slender parts, thin-walled parts, or other parts that are subject to bending or chatter when the cutting load is applied to them, because the cutting force is significantly lower as compared to that for negative rake inserts. Indexable inserts can be obtained in the following forms: utility ground, or ground on top and bottom only; precision ground, or ground on all surfaces; prehoned to produce a slight rounding of the cutting edge; and precision molded, which are unground. Positive-negative rake inserts also are available. These inserts are held on a negative-rake tool holder and have a chipbreaker groove that is formed to produce an effective positive-rake angle while cutting. Cutting edges may be available on the top surface only, or on both top and bottom surfaces. The positive-rake chipbreaker surface may be ground or precision molded on the insert.

Many materials, such as gray cast iron, form a discontinuous chip. For these materials an insert that has plain faces without chipbreaker grooves should always be used. Steels and other ductile materials form a continuous chip that must be broken into small segments when machined on lathes and planers having single-point, cemented-carbide and cemented-oxide cutting tools; otherwise, the chips can cause injury to the operator. In this case a chipbreaker must be used. Some inserts are made with chipbreaker grooves molded or ground directly on the insert. When inserts with plain faces are used, a cemented-carbide plate-type chipbreaker is clamped on top of the insert.

**Identification System for Indexable Inserts.**—The size of indexable inserts is determined by the diameter of an inscribed circle (I.C.), except for rectangular and parallelogram inserts where the length and width dimensions are used. To describe an insert in its entirety, a standard ANSI B212.4-2002 identification system is used where each position number designates a feature of the insert. The ANSI Standard includes items now commonly used and facilitates identification of items not in common use. Identification consists of up to ten positions; each position defines a characteristic of the insert as shown below:

|          |          |          |          |          |          |          |                |                |                 |
|----------|----------|----------|----------|----------|----------|----------|----------------|----------------|-----------------|
| 1        | 2        | 3        | 4        | 5        | 6        | 7        | 8 <sup>a</sup> | 9 <sup>a</sup> | 10 <sup>a</sup> |
| <b>T</b> | <b>N</b> | <b>M</b> | <b>G</b> | <b>5</b> | <b>4</b> | <b>3</b> |                |                | <b>A</b>        |

<sup>a</sup> Eighth, Ninth, and Tenth Positions are used only when required.

1) *Shape*: The shape of an insert is designated by a letter: **R** for round; **S**, square; **T**, triangle; **A**, 85° parallelogram; **B**, 82° parallelogram; **C**, 80° diamond; **D**, 55° diamond; **E**, 75° diamond; **H**, hexagon; **K**, 55° parallelogram; **L**, rectangle; **M**, 86° diamond; **O**, octagon; **P**, pentagon; **V**, 35° diamond; and **W**, 80° trigon.

2) *Relief Angle (Clearances)*: The second position is a letter denoting the relief angles: **N** for 0°; **A**, 3°; **B**, 5°; **C**, 7°; **P**, 11°; **D**, 15°; **E**, 20°; **F**, 25°; **G**, 30°; **H**, 0° & 11°; **J**, 0° & 14°; **K**, 0° & 17°; **L**, 0° & 20°; **M**, 11° & 14°; **R**, 11° & 17°; **S**, 11° & 20°. When mounted on a holder, the actual relief angle may be different from that on the insert.

3) *Tolerances*: The third position is a letter and indicates the tolerances which control the indexability of the insert. Tolerances specified do not imply the method of manufacture.

| Symbol   | Tolerance<br>(± from nominal) |                   | Symbol   | Tolerance<br>(± from nominal) |                    |
|----------|-------------------------------|-------------------|----------|-------------------------------|--------------------|
|          | Inscribed<br>Circle, Inch     | Thicknes,<br>Inch |          | Inscribed<br>Circle, Inch     | Thickness,<br>Inch |
| <b>A</b> | 0.001                         | 0.001             | <b>H</b> | 0.0005                        | 0.001              |
| <b>B</b> | 0.001                         | 0.005             | <b>J</b> | 0.002–0.005                   | 0.001              |
| <b>C</b> | 0.001                         | 0.001             | <b>K</b> | 0.002–0.005                   | 0.001              |

<sup>a</sup> Exact tolerance is determined by size of insert. See ANSI B212.12.

4) *Type*: The type of insert is designated by a letter. **A**, with hole; **B**, with hole and countersink; **C**, with hole and two countersinks; **F**, chip grooves both surfaces, no hole; **G**, same as **F** but with hole; **H**, with hole, one countersink, and chip groove on one rake surface; **J**, with hole, two countersinks and chip grooves on two rake surfaces; **M**, with hole and chip groove on one rake surface; **N**, without hole; **Q**, with hole and two countersinks; **R**, without hole but with chip groove on one rake surface; **T**, with hole, one countersink, and chip

\* Second angle is secondary facet angle, which may vary by ± 1°.

groove on one rake face; **U**, with hole, two countersinks, and chip grooves on two rake faces; and **W**, with hole and one countersink. *Note:* a dash may be used after position 4 to separate the shape-describing portion from the following dimensional description of the insert and is not to be considered a position in the standard description.

5) *Size:* The size of the insert is designated by a one- or a two-digit number. For regular polygons and diamonds, it is the number of eighths of an inch in the nominal size of the inscribed circle, and will be a one- or two-digit number when the number of eighths is a whole number. It will be a two-digit number, including one decimal place, when it is not a whole number. Rectangular and parallelogram inserts require two digits: the first digit indicates the number of eighths of an inch width and the second digit, the number of quarters of an inch length.

6) *Thickness:* The thickness is designated by a one- or two-digit number, which indicates the number of sixteenths of an inch in the thickness of the insert. It is a one-digit number when the number of sixteenths is a whole number; it is a two-digit number carried to one decimal place when the number of sixteenths of an inch is not a whole number.

7) *Cutting Point Configuration:* The cutting point, or nose radius, is designated by a number representing  $\frac{1}{64}$ ths of an inch; a flat at the cutting point or nose, is designated by a letter: **0** for sharp corner; **1**,  $\frac{1}{64}$  inch radius; **2**,  $\frac{1}{32}$  inch radius; **3**,  $\frac{3}{64}$  inch radius; **4**,  $\frac{1}{16}$  inch radius; **5**,  $\frac{5}{64}$  inch radius; **6**,  $\frac{3}{32}$  inch radius; **7**,  $\frac{7}{64}$  inch radius; **8**,  $\frac{1}{8}$  inch radius; **A**, square insert with 45° chamfer; **D**, square insert with 30° chamfer; **E**, square insert with 15° chamfer; **F**, square insert with 3° chamfer; **K**, square insert with 30° double chamfer; **L**, square insert with 15° double chamfer; **M**, square insert with 3° double chamfer; **N**, truncated triangle insert; and **P**, flattened corner triangle insert.

8) *Special Cutting Point Definition:* The eighth position, if it follows a letter in the 7th position, is a number indicating the number of  $\frac{1}{64}$ ths of an inch measured parallel to the edge of the facet.

9) *Hand:* **R**, right; **L**, left; to be used when required in ninth position.

10) *Other Conditions:* The tenth position defines special conditions (such as edge treatment, surface finish) as follows: **A**, honed, 0.0005 inch to less than 0.003 inch; **B**, honed, 0.003 inch to less than 0.005 inch; **C**, honed, 0.005 inch to less than 0.007 inch; **J**, polished, 4 microinch arithmetic average (AA) on rake surfaces only; **T**, chamfered, manufacturer's standard negative land, rake face only.

**Indexable Insert Tool Holders.**—Indexable insert tool holders are made from a good grade of steel which is heat treated to a hardness of 44 to 48 Rc for most normal applications. Accurate pockets that serve to locate the insert in position and to provide surfaces against which the insert can be clamped are machined in the ends of tool holders. A cemented carbide seat usually is provided, and is held in the bottom of the pocket by a screw or by the clamping pin, if one is used. The seat is necessary to provide a flat bearing surface upon which the insert can rest and, in so doing, it adds materially to the ability of the insert to withstand the cutting load. The seating surface of the holder may provide a positive-, negative-, or a neutral-rake orientation to the insert when it is in position on the holder. Holders, therefore, are classified as positive, negative, or neutral rake.

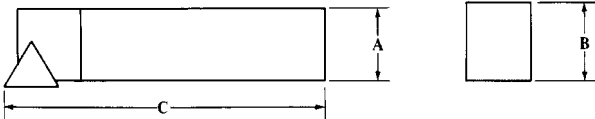

Four basic methods are used to clamp the insert on the holder: 1) Clamping, usually top clamping; 2) Pin-lock clamping; 3) Multiple clamping using a clamp, usually a top clamp, and a pin lock; and 4) Clamping the insert with a machine screw.

All top clamps are actuated by a screw that forces the clamp directly against the insert. When required, a cemented-carbide, plate-type chipbreaker is placed between the clamp and the insert. Pin-lock clamps require an insert having a hole: the pin acts against the walls of the hole to clamp the insert firmly against the seating surfaces of the holder. Multiple or combination clamping, simultaneously using both a pin-lock and a top clamp, is recommended when taking heavier or interrupted cuts. Holders are available on which all the above-mentioned methods of clamping may be used. Other holders are made with only a

top clamp or a pin lock. Screw-on type holders use a machine screw to hold the insert in the pocket. Most standard indexable insert holders are either straight-shank or offset-shank, although special holders are made having a wide variety of configurations.

The common shank sizes of indexable insert tool holders are shown in Table 1. Not all styles are available in every shank size. Positive- and negative-rake tools are also not available in every style or shank size. Some manufacturers provide additional shank sizes for certain tool holder styles. For more complete details the manufacturers' catalogs must be consulted.

**Table 1. Standard Shank Sizes for Indexable Insert Holders**

| Basic Shank Size  | Shank Dimensions for Indexable Insert Holders |       |       |       |                |        |
|---|---|-------|-------|-------|----------------|--------|
|   | A   |       | B     |       | C <sup>a</sup> |        |
|   | In.   | mm    | In.   | mm    | In.            | mm     |
| $\frac{1}{2} \times \frac{1}{2} \times 4\frac{1}{2}$    | 0.500   | 12.70 | 0.500 | 12.70 | 4.500          | 114.30 |
| $\frac{3}{8} \times \frac{3}{8} \times 4\frac{1}{2}$    | 0.625   | 15.87 | 0.625 | 15.87 | 4.500          | 114.30 |
| $\frac{3}{8} \times 1\frac{1}{4} \times 6$              | 0.625   | 15.87 | 1.250 | 31.75 | 6.000          | 152.40 |
| $\frac{3}{4} \times \frac{3}{4} \times 4\frac{1}{2}$    | 0.750   | 19.05 | 0.750 | 19.05 | 4.500          | 114.30 |
| $\frac{3}{4} \times 1 \times 6$                         | 0.750   | 19.05 | 1.000 | 25.40 | 6.000          | 152.40 |
| $\frac{3}{4} \times 1\frac{1}{4} \times 6$              | 0.750   | 19.05 | 1.250 | 31.75 | 6.000          | 152.40 |
| $1 \times 1 \times 6$                                   | 1.000   | 25.40 | 1.000 | 25.40 | 6.000          | 152.40 |
| $1 \times 1\frac{1}{4} \times 6$                        | 1.000   | 25.40 | 1.250 | 31.75 | 6.000          | 152.40 |
| $1 \times 1\frac{1}{2} \times 6$                        | 1.000   | 25.40 | 1.500 | 38.10 | 6.000          | 152.40 |
| $1\frac{1}{2} \times 1\frac{1}{4} \times 7$             | 1.250   | 31.75 | 1.250 | 31.75 | 7.000          | 177.80 |
| $1\frac{1}{4} \times 1\frac{1}{2} \times 8$             | 1.250   | 31.75 | 1.500 | 38.10 | 8.000          | 203.20 |
| $1\frac{3}{8} \times 2\frac{1}{16} \times 6\frac{3}{8}$ | 1.375   | 34.92 | 2.062 | 52.37 | 6.380          | 162.05 |

<sup>a</sup>Holder length; may vary by manufacturer. Actual shank length depends on holder style.

**Identification System for Indexable Insert Holders.**—The following identification system conforms to the American National Standard, ANSI B212.5-2002, Metric Holders for Indexable Inserts.

Each position in the system designates a feature of the holder in the following sequence:

1 2 3 4 5 — 6 — 7 — 8<sup>a</sup> — 9 — 10<sup>a</sup>  
**C T N A R — 85 — 25 — D — 16 — Q**

1) *Method of Holding Horizontally Mounted Insert:* The method of holding or clamping is designated by a letter: **C**, top clamping, insert without hole; **M**, top and hole clamping, insert with hole; **P**, hole clamping, insert with hole; **S**, screw clamping through hole, insert with hole; **W**, wedge clamping.

2) *Insert Shape:* The insert shape is identified by a letter: **H**, hexagonal; **O**, octagonal; **P**, pentagonal; **S**, square; **T**, triangular; **C**, rhombic, 80° included angle; **D**, rhombic, 55° included angle; **E**, rhombic, 75° included angle; **M**, rhombic, 86° included angle; **V**, rhombic, 35° included angle; **W**, hexagonal, 80° included angle; **L**, rectangular; **A**, parallelogram, 85° included angle; **B**, parallelogram, 82° included angle; **K**, parallelogram, 55° included angle; **R**, round. The included angle is always the smaller angle.

3) *Holder Style*: The holder style designates the shank style and the side cutting edge angle, or end cutting edge angle, or the purpose for which the holder is used. It is designated by a letter: **A**, for straight shank with  $0^\circ$  side cutting edge angle; **B**, straight shank with  $15^\circ$  side cutting edge angle; **C**, straight-shank end cutting tool with  $0^\circ$  end cutting edge angle; **D**, straight shank with  $45^\circ$  side cutting edge angle; **E**, straight shank with  $30^\circ$  side cutting edge angle; **F**, offset shank with  $0^\circ$  end cutting edge angle; **G**, offset shank with  $0^\circ$  side cutting edge angle; **J**, offset shank with negative  $3^\circ$  side cutting edge angle; **K**, offset shank with  $15^\circ$  end cutting edge angle; **L**, offset shank with negative  $5^\circ$  side cutting edge angle and  $5^\circ$  end cutting edge angle; **M**, straight shank with  $40^\circ$  side cutting edge angle; **N**, straight shank with  $27^\circ$  side cutting edge angle; **R**, offset shank with  $15^\circ$  side cutting edge angle; **S**, offset shank with  $45^\circ$  side cutting edge angle; **T**, offset shank with  $30^\circ$  side cutting edge angle; **U**, offset shank with negative  $3^\circ$  end cutting edge angle; **V**, straight shank with  $17\frac{1}{2}^\circ$  side cutting edge angle; **W**, offset shank with  $30^\circ$  end cutting edge angle; **Y**, offset shank with  $5^\circ$  end cutting edge angle.

4) *Normal Clearances*: The normal clearances of inserts are identified by letters: **A**,  $3^\circ$ ; **B**,  $5^\circ$ ; **C**,  $7^\circ$ ; **D**,  $15^\circ$ ; **E**,  $20^\circ$ ; **F**,  $25^\circ$ ; **G**,  $30^\circ$ ; **N**,  $0^\circ$ ; **P**,  $11^\circ$ .

5) *Hand of tool*: The hand of the tool is designated by a letter: **R** for right-hand; **L**, left-hand; and **N**, neutral, or either hand.

6) *Tool Height for Rectangular Shank Cross Sections*: The tool height for tool holders with a rectangular shank cross section and the height of cutting edge equal to shank height is given as a two-digit number representing this value in millimeters. For example, a height of 32 mm would be encoded as 32; 8 mm would be encoded as 08, where the one-digit value is preceded by a zero.

7) *Tool Width for Rectangular Shank Cross Sections*: The tool width for tool holders with a rectangular shank cross section is given as a two-digit number representing this value in millimeters. For example, a width of 25 mm would be encoded as 25; 8 mm would be encoded as 08, where the one-digit value is preceded by a zero.

8) *Tool Length*: The tool length is designated by a letter: **A**, 32 mm; **B**, 40 mm; **C**, 50 mm; **D**, 60 mm; **E**, 70 mm; **F**, 80 mm; **G**, 90 mm; **H**, 100 mm; **J**, 110 mm; **K**, 125 mm; **L**, 140 mm; **M**, 150 mm; **N**, 160 mm; **P**, 170 mm; **Q**, 180 mm; **R**, 200 mm; **S**, 250 mm; **T**, 300 mm; **U**, 350 mm; **V**, 400 mm; **W**, 450 mm; **X**, special length to be specified; **Y**, 500 mm.

9) *Indexable Insert Size*: The size of indexable inserts is encoded as follows: For insert shapes **C**, **D**, **E**, **H**, **M**, **O**, **P**, **R**, **S**, **T**, **V**, the side length (the diameter for **R** inserts) in millimeters is used as a two-digit number, with decimals being disregarded. For example, the symbol for a side length of 16.5 mm is 16. For insert shapes **A**, **B**, **K**, **L**, the length of the main cutting edge or of the longer cutting edge in millimeters is encoded as a two-digit number, disregarding decimals. If the symbol obtained has only one digit, then it should be preceded by a zero. For example, the symbol for a main cutting edge of 19.5 mm is 19; for an edge of 9.5 mm, the symbol is 09.

10) *Special Tolerances*: Special tolerances are indicated by a letter: **Q**, back and end qualified tool; **F**, front and end qualified tool; **B**, back, front, and end qualified tool. A qualified tool is one that has tolerances of  $\pm 0.08$  mm for dimensions *F*, *G*, and *C*. (See Table 2.)

**Table 2. Letter Symbols for Qualification of Tool Holders**  
Position 10 ANSI B212.5-2002

| Qualification of Tool Holder | Letter Symbol               |                              |                                     |
|------------------------------|-----------------------------|------------------------------|-------------------------------------|
|                              | Q                           | F                            | B                                   |
|                              |                             |                              |                                     |
|                              | Back and end qualified tool | Front and end qualified tool | Back, front, and end qualified tool |

**Selecting Indexable Insert Holders.**—A guide for selecting indexable insert holders is provided by [Table 3b](#). Some operations such as deep grooving, cut-off, and threading are not given in this table. However, tool holders designed specifically for these operations are available. The boring operations listed in [Table 3b](#) refer primarily to larger holes, into which the holders will fit. Smaller holes are bored using boring bars. An examination of this table shows that several tool-holder styles can be used and frequently are used for each operation. Selection of the best holder for a given job depends largely on the job and there are certain basic facts that should be considered in making the selection.

*Rake Angle:* A negative-rake insert has twice as many cutting edges available as a comparable positive-rake insert. Sometimes the tool life obtained when using the second face may be less than that obtained on the first face because the tool wear on the cutting edges of the first face may reduce the insert strength. Nevertheless, the advantage of negative-rake inserts and holders is such that they should be considered first in making any choice. Positive-rake holders should be used where lower cutting forces are required, as when machining slender or small-diameter parts, when chatter may occur, and for machining some materials, such as aluminum, copper, and certain grades of stainless steel, when positive-negative rake inserts can sometimes be used to advantage. These inserts are held on negative-rake holders that have their rake surfaces ground or molded to form a positive-rake angle.

*Insert Shape:* The configuration of the workpiece, the operation to be performed, and the lead angle required often determine the insert shape. When these factors need not be considered, the insert shape should be selected on the basis of insert strength and the maximum number of cutting edges available. Thus, a round insert is the strongest and has a maximum number of available cutting edges. It can be used with heavier feeds while producing a good surface finish. Round inserts are limited by their tendency to cause chatter, which may preclude their use. The square insert is the next most effective shape, providing good corner strength and more cutting edges than all other inserts except the round insert. The only limitation of this insert shape is that it must be used with a lead angle. Therefore, the square insert cannot be used for turning square shoulders or for back-facing. Triangle inserts are the most versatile and can be used to perform more operations than any other insert shape. The 80-degree diamond insert is designed primarily for heavy turning and facing operations, using the 100-degree corners, and for turning and back-facing square shoulders using the 80-degree corners. The 55- and 35-degree diamond inserts are intended primarily for tracing.

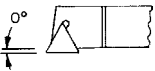

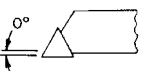

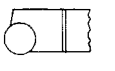

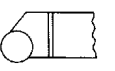

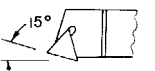

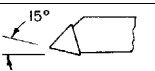

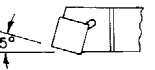

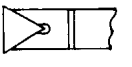

*Lead Angle:* Tool holders should be selected to provide the largest possible lead angle, although limitations are sometimes imposed by the nature of the job. For example, when turning and back-facing a shoulder, a negative lead angle must be used. Slender or small-diameter parts may deflect, causing difficulties in holding size, or chatter when the lead angle is too large.

*End Cutting Edge Angle:* When tracing or contour turning, the plunge angle is determined by the end cutting edge angle. A 2-deg minimum clearance angle should be provided between the workpiece surface and the end cutting edge of the insert. [Table 3a](#) provides the maximum plunge angle for holders commonly used to plunge when tracing where insert shape identifiers are *S* = square, *T* = triangle, *D* = 55-deg diamond, *V* = 35-deg diamond. When severe cratering cannot be avoided, an insert having a small, end cutting edge angle is desirable to delay the crater breakthrough behind the nose. For very heavy cuts a small, end cutting edge angle will strengthen the corner of the tool. Tool holders for numerical control machines are discussed in the NC section, beginning page [1309](#).

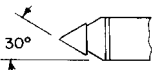

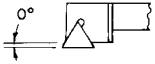

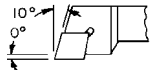

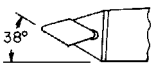

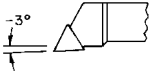

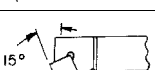

**Table 3a. Maximum Plunge Angle for Tracing or Contour Turning**

| Tool Holder Style | Insert Shape | Maximum Plunge Angle | Tool Holder Style | Insert Shape | Maximum Plunge Angle |
|-------------------|--------------|----------------------|-------------------|--------------|----------------------|
| E                 | T            | 58°                  | J                 | D            | 30°                  |
| D and S           | S            | 43°                  | J                 | V            | 50°                  |
| H                 | D            | 71°                  | N                 | T            | 55°                  |
| J                 | T            | 25°                  | N                 | D            | 58°–60°              |

**Sintered Carbide Blanks and Cutting Tools**

**Sintered Carbide Blanks.**—As shown in [Table 4](#), American National Standard ANSI B212.1-2002 provides standard sizes and designations for eight styles of sintered carbide blanks. These blanks are the unground solid carbide from which either solid or tipped cutting tools are made. Tipped cutting tools are made by brazing a blank onto a shank to produce the cutting tool; these tools differ from carbide *insert* cutting tools which consist of a carbide insert held mechanically in a tool holder. A typical single-point carbide-tipped cutting tool is shown in [Fig. 1](#) on page 766.

**Single-Point, Sintered-Carbide-Tipped Tools.**—American National Standard ANSI B212.1-2002 covers eight different styles of single-point, carbide-tipped general purpose tools. These styles are designated by the letters A to G inclusive. Styles A, B, F, G, and E with offset point are either right- or left-hand cutting as indicated by the letters R or L. Dimensions of tips and shanks are given in [Tables 5 to 12](#). For dimensions and tolerances not shown, and for the identification system, dimensions, and tolerances of sintered carbide boring tools, see the Standard.

A number follows the letters of the tool style and hand designation and for square shank tools, represents the number of sixteenths of an inch of width, *W*, and height, *H*. With rectangular shanks, the first digit of the number indicates the number of eighths of an inch in the shank width, *W*, and the second digit the number of quarters of an inch in the shank

<sup>a</sup> All dimensions are in inches.<sup>b</sup> See Fig. 1 on page 766 for a description of styles.

height, *H*. One exception is the 1 1/2 × 2-inch size which has been arbitrarily assigned the number 90.

A typical single-point carbide tipped cutting tool is shown in Fig. 2. The side rake, side relief, and the clearance angles are normal to the side-cutting edge, rather than the shank, to facilitate its being ground on a tilting-table grinder. The end-relief and clearance angles are

## CARBIDE TIPS AND TOOLS

Fig. 1. Eight styles of sintered carbide blanks (see Table 4.)

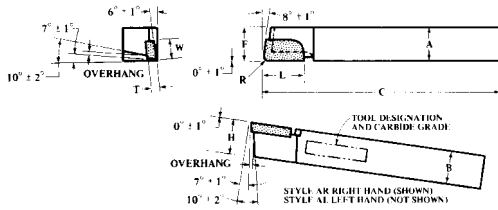

Fig. 2. A typical single-point carbide tipped cutting tool.

normal to the end-cutting edge. The back-rake angle is parallel to the side-cutting edge. The tip of the brazed carbide blank overhangs the shank of the tool by either  $\frac{1}{32}$  or  $\frac{1}{16}$  inch, depending on the size of the tool. For tools in Tables 5, 6, 7, 8, 11 and , the maximum overhang is  $\frac{1}{32}$  inch for shank sizes 4, 5, 6, 7, 8, 10, 12 and 44; for other shank sizes in these tables, the maximum overhang is  $\frac{1}{16}$  inch. In Tables 9 and 10 all tools have maximum overhang of  $\frac{1}{32}$  inch.

**Single-point Tool Nose Radii:** The tool nose radii recommended in the American National Standard are as follows: For square-shank tools up to and including  $\frac{3}{8}$ -inch square tools,  $\frac{1}{64}$  inch; for those over  $\frac{3}{8}$ -inch square through  $1\frac{1}{4}$ -inches square,  $\frac{1}{32}$  inch; and for those above  $1\frac{1}{4}$ -inches square,  $\frac{1}{16}$  inch. For rectangular-shank tools with shank section of  $\frac{1}{2} \times 1$  inch through  $1 \times 1\frac{1}{2}$  inches, the nose radii are  $\frac{1}{32}$  inch, and for  $1 \times 2$  and  $1\frac{1}{2} \times 2$  inch shanks, the nose radius is  $\frac{1}{16}$  inch.

**Single-point Tool Angle Tolerances:** The tool angles shown on the diagrams in the Tables 5 through 12 are general recommendations. Tolerances applicable to these angles are  $\pm 1$  degree on all angles except end and side clearance angles; for these the tolerance is  $\pm 2$  degrees.

**Table 5. American National Standard Style A Carbide Tipped Tools**  
ANSI B212.1-2002

The diagrams illustrate the geometry of Style A carbide tipped tools. The top-left diagram shows a square shank tool with a cutting edge angle of  $7^\circ \pm 1^\circ$ , a side clearance angle of  $10^\circ \pm 2^\circ$ , and a nose radius of  $6'' - 1''$ . The top-right diagram shows a rectangular shank tool with a cutting edge angle of  $7^\circ \pm 1^\circ$ , a side clearance angle of  $10^\circ \pm 2^\circ$ , and a nose radius of  $8'' + 1''$ . The bottom diagram shows a rectangular shank tool with a cutting edge angle of  $7^\circ \pm 1^\circ$ , a side clearance angle of  $10^\circ \pm 2^\circ$ , and a nose radius of  $7'' + 1''$ . Dimensions include shank width (W), shank height (H), shank length (C), tip thickness (T), tip width (B), and tip length (L). The tool designation and carbide grade are indicated on the tool.

<sup>a</sup> Where a pair of tip numbers is shown, the upper number applies to BR tools, the lower to BL tools. All dimensions are in inches.

**Brazing Carbide Tips to Steel Shanks.**—Sintered carbide tips or blanks are attached to steel shanks by brazing. Shanks usually are made of low-alloy steels having carbon contents ranging from 0.40 to 0.60 per cent. *Shank Preparation:* The carbide tip usually is inserted into a milled recess or seat. When a recess is used, the bottom should be flat to provide a firm even support for the tip. The corner radius of the seat should be somewhat smaller than the radius on the tip to avoid contact and insure support along each side of the recess. *Cleaning:* All surfaces to be brazed must be absolutely clean. Surfaces of the tip may be cleaned by grinding lightly or by sand-blasting. *Brazing Materials and Equipment:* The brazing metal may be copper, naval brass such as Tobin bronze, or silver solder. A flux such as borax is used to protect the clean surfaces and prevent oxidation. Heating may be done in a furnace or by oxy-acetylene torch or an oxy-hydrogen torch. Copper brazing usually is done in a furnace, although an oxy-hydrogen torch with excess hydrogen is sometimes used. *Brazing Procedure:* One method using a torch is to place a thin sheet material, such as copper foil, around and beneath the carbide tip, the top of which is covered with flux. The flame is applied to the under side of the tool shank, and, when the materials melt, the tip is pressed firmly into its seat with tongs or with the end of a rod. Brazing material in the form of wire or rod may be used to coat or tin the surfaces of the recess after the flux melts and runs freely. The tip is then inserted, flux is applied to the top, and heating continued until the coatings melt and run freely. The tip, after coating with flux, is placed in the recess and the shank end is heated. Then a small piece of silver solder, having a melting point of 1325 degrees F., is placed on top of the tip. When this solder melts, it runs over the nickel-coated surfaces while the tip is held firmly into its seat. The brazed tool should be cooled slowly to avoid cracking due to unequal contraction between the steel and carbide.

All dimensions are in inches. Where a pair of tip numbers is shown, the upper number applies to FR tools, the lower number to FL tools.

**Carbide Tools.**—Cemented or sintered carbides are used in the machine building and various other industries, chiefly for cutting tools but also for certain other tools or parts subject to considerable abrasion or wear. Carbide cutting tools, when properly selected to obtain the right combination of strength and hardness, are very effective in machining all classes of iron and steel, non-ferrous alloys, non-metallic materials, hard rubber, synthetic resins, slate, marble, and other materials which would quickly dull steel tools either because of hardness or abrasive action. Carbide cutting tools are not only durable, but capable of exceptionally high cutting speeds. See *CEMENTED CARBIDES* starting on page 773 for more on these materials.

*Tungsten carbide* is used extensively in cutting cast iron, nonferrous metals which form short chips in cutting; plastics and various other non-metallic materials. A grade having a hardness of 87.5 Rockwell A might be used where a strong grade is required, as for roughing cuts, whereas for light high-speed finishing or other cuts, a hardness of about 92 might be preferable. When tungsten carbide is applied to steel, craters or chip cavities are formed

All dimensions are in inches. Where a pair of tip numbers is shown, the upper number applies to GR tools, the lower number to GL tools.

back of the cutting edge; hence other carbides have been developed which offer greater resistance to abrasion.

*Tungsten-titanium carbide* (often called "titanium carbide") is adapted to cutting either heat-treated or unheattreated steels, cast steel, or any tough material which might form chip cavities. It is also applicable to bronzes, monel metal, aluminum alloys, etc.

*Tungsten-tantalum carbide* or "tantalum carbide" cutting tools are also applicable to steels, bronzes or other tough materials. A hardness of 86.8 Rockwell A is recommended by one manufacturer for roughing steel, whereas a grade for finishing might have a hardness ranging from 88.8 to 91.5 Rockwell A.

## CEMENTED CARBIDES

### Cemented Carbides and Other Hard Materials

**Carbides and Carbonitrides.**—Though high-speed steel retains its importance for such applications as drilling and broaching, most metal cutting is carried out with carbide tools. For materials that are very difficult to machine, carbide is now being replaced by carbonitrides, ceramics, and superhard materials. Cemented (or sintered) carbides and carbonitrides, known collectively in most parts of the world as hard metals, are a range of very hard, refractory, wear-resistant alloys made by powder metallurgy techniques. The minute carbide or nitride particles are “cemented” by a binder metal that is liquid at the sintering temperature. Compositions and properties of individual hardmetals can be as different as those of brass and high-speed steel.

All hardmetals are *cermets*, combining *ceramic* particles with a *metallic* binder. It is unfortunate that (owing to a mistranslation) the term *cermet* has come to mean either all hardmetals with a titanium carbide (TiC) base or simply cemented titanium carbonitrides. Although no single element other than carbon is present in all hard-metals, it is no accident that the generic term is “tungsten carbide.” The earliest successful grades were based on carbon, as are the majority of those made today, as listed in [Table 1](#).

The outstanding machining capabilities of high-speed steel are due to the presence of very hard carbide particles, notably tungsten carbide, in the iron-rich matrix. Modern methods of making cutting tools from pure tungsten carbide were based on this knowledge. Early pieces of cemented carbide were much too brittle for industrial use, but it was soon found that mixing tungsten carbide powder with up to 10 per cent of metals such as iron, nickel, or cobalt, allowed pressed compacts to be sintered at about 1500°C to give a product with low porosity, very high hardness, and considerable strength. This combination of properties made the materials ideally suitable for use as tools for cutting metal.

Cemented carbides for cutting tools were introduced commercially in 1927, and although the key discoveries were made in Germany, many of the later developments have taken place in the United States, Austria, Sweden, and other countries. Recent years have seen two “revolutions” in carbide cutting tools, one led by the United States and the other by Europe. These were the change from brazed to clamped carbide inserts and the rapid development of coating technology.

When indexable tips were first introduced, it was found that so little carbide was worn away before they were discarded that a minor industry began to develop, regrinding the so-called “throwaway” tips and selling them for reuse in adapted toolholders. Hardmetal consumption, which had grown dramatically when indexable inserts were introduced, leveled off and began to decline. This situation was changed by the advent and rapid acceptance of carbide, nitride, and oxide coatings. Application of an even harder, more wear-resistant surface to a tougher, more shock-resistant substrate allowed production of new generations of longer-lasting inserts. Regrinding destroyed the enhanced properties of the coatings, so was abandoned for coated tooling.

Brazed tools have the advantage that they can be reground over and over again, until almost no carbide is left, but the tools must always be reset after grinding to maintain machining accuracy. However, all brazed tools suffer to some extent from the stresses left by the brazing process, which in unskilled hands or with poor design can shatter the carbide even before it has been used to cut metal. In present conditions it is cheaper to use indexable inserts, which are tool tips of precise size, clamped in similarly precise holders, needing no time-consuming and costly resetting but usable only until each cutting edge or corner has lost its initial sharpness (see [Introduction](#) and related topics starting on page [756](#) and *Indexable Insert Holders for NC* on page [1309](#)). The absence of brazing stresses and the “one-use” concept also means that harder, longer-lasting grades can be used.

**Table 1. Typical Properties of Tungsten-Carbide-Based Cutting-Tool Hardmetals**

| ISO Application Code | Composition (%) |     |     |    | Density (g/cm <sup>3</sup> ) | Hardness (Vickers) | Transverse Rupture Strength (N/mm <sup>2</sup> ) |
|----------------------|-----------------|-----|-----|----|------------------------------|--------------------|--|

A complementary development was the introduction of ever-more complex chip-breakers, derived from computer-aided design and pressed and sintered to precise shapes and dimensions. Another advance was the application of hot isostatic pressing (HIP), which has moved hardmetals into applications that were formerly uneconomic. This method allows virtually all residual porosity to be squeezed out of the carbide by means of inert gas at high pressure, applied at about the sintering temperature. Toughness, rupture strength, and shock resistance can be doubled or tripled by this method, and the reject rates of very large sintered components are reduced to a fraction of their previous levels.

Further research has produced a substantial number of excellent cutting-tool materials based on titanium carbonitride. Generally called "cermets," as noted previously, carbonitride-based cutting inserts offer excellent performance and considerable prospects for the future.

*Compositions and Structures:* Properties of hardmetals are profoundly influenced by microstructure. The microstructure in turn depends on many factors including basic chemical composition of the carbide and matrix phases; size, shape, and distribution of carbide particles; relative proportions of carbide and matrix phases; degree of intersolubility of carbides; excess or deficiency of carbon; variations in composition and structure caused by diffusion or segregation; production methods generally, but especially milling, carburizing, and sintering methods, and the types of raw materials; post sintering treatments such as hot isostatic pressing; and coatings or diffusion layers applied after initial sintering.

*Tungsten Carbide/Cobalt (WC/Co):* The first commercially available cemented carbides consisted of fine angular particles of tungsten carbide bonded with metallic cobalt. Intended initially for wire-drawing dies, this composition type is still considered to have the greatest resistance to simple abrasive wear and therefore to have many applications in machining.

For maximum hardness to be obtained from closeness of packing, the tungsten carbide grains should be as small as possible, preferably below 1  $\mu\text{m}$  (swaging 0.00004 in.) and considerably less for special purposes. Hardness and abrasion resistance increase as the cobalt content is lowered, provided that a minimum of cobalt is present (2 per cent can be

enough, although 3 per cent is the realistic minimum) to ensure complete sintering. In general, as carbide grain size or cobalt content or both are increased—frequently in unison—tougher and less hard grades are obtained. No porosity should be visible, even under the highest optical magnification.

WC/Co compositions used for cutting tools range from about 2 to 13 per cent cobalt, and from less than 0.5 to more than 5  $\mu\text{m}$  (0.00002–0.0002 in.) in grain size. For stamping tools, swaying dies, and other wear applications for parts subjected to moderate or severe shock, cobalt content can be as much as 30 per cent, and grain size a maximum of about 10  $\mu\text{m}$  (0.0004 in.). In recent years, “micrograin” carbides, combining submicron (less than 0.00004 in.) carbide grains with relatively high cobalt content have found increasing use for machining at low speeds and high feed rates. An early use was in high-speed wood-working cutters such as are used for planing.

For optimum properties, porosity should be at a minimum, carbide grain size as regular as possible, and carbon content of the tungsten carbide phase close to the theoretical (stoichiometric) value. Many tungsten carbide/cobalt compositions are modified by small but important additions—from 0.5 to perhaps 3 per cent of tantalum, niobium, chromium, vanadium, titanium, hafnium, or other carbides. The basic purpose of these additions is generally inhibition of grain growth, so that a consistently fine structure is maintained.

*Tungsten–Titanium Carbide/Cobalt (WC/TiC/Co):* These grades are used for tools to cut steels and other ferrous alloys, the purpose of the TiC content being to resist the high-temperature diffusive attack that causes chemical breakdown and cratering. Tungsten carbide diffuses readily into the chip surface, but titanium carbide is extremely resistant to such diffusion. A solid solution or “mixed crystal” of WC in TiC retains the anticratering property to a great extent.

Unfortunately, titanium carbide and TiC-based solid solutions are considerably more brittle and less abrasion resistant than tungsten carbide. TiC content, therefore, is kept as low as possible, only sufficient TiC being provided to avoid severe cratering wear. Even 2 or 3 per cent of titanium carbide has a noticeable effect, and as the relative content is substantially increased, the cratering tendency becomes more severe.

In the limiting formulation the carbide is tungsten-free and based entirely on TiC, but generally TiC content extends to no more than about 18 per cent. Above this figure the carbide becomes excessively brittle and is very difficult to braze, although this drawback is not a problem with throwaway inserts.

WC/TiC/Co grades generally have two distinct carbide phases, angular crystals of almost pure WC and rounded TiC/WC mixed crystals. Among progressive manufacturers, although WC/TiC/Co hardmetals are very widely used, in certain important respects they are obsolescent, having been superseded by the WC/TiC/Ta(Nb)C/Co series in the many applications where higher strength combined with crater resistance is an advantage. TiC, TiN, and other coatings on tough substrates have also diminished the attractions of high-TiC grades for high-speed machining of steels and ferrous alloys.

*Tungsten-Titanium-Tantalum (-Niobium) Carbide/Cobalt:* Except for coated carbides, tungsten-titanium-tantalum (-niobium) grades could be the most popular class of hardmetals. Used mainly for cutting steel, they combine and improve upon most of the best features of the longer-established WC/TiC/Co compositions. These carbides compete directly with carbonitrides and silicon nitride ceramics, and the best cemented carbides of this class can undertake very heavy cuts at high speeds on all types of steels, including austenitic stainless varieties. These tools also operate well on ductile cast irons and nickel-base superalloys, where great heat and high pressures are generated at the cutting edge. However, they do not have the resistance to abrasive wear possessed by micrograin straight tungsten carbide grades nor the good resistance to cratering of coated grades and titanium carbide-based cermets.

*Titanium Carbide/Molybdenum/Nickel (TiC/Mo/Ni):* The extreme indentation hardness and crater resistance of titanium carbide, allied to the cheapness and availability of its main raw material (titanium dioxide,  $TiO_2$ ), provide a strong inducement to use grades based on this carbide alone. Although developed early in the history of hardmetals, these carbides were difficult to braze satisfactorily and consequently were little used until the advent of clamped, throwaway inserts. Moreover, the carbides were notoriously brittle and could take only fine cuts in minimal-shock conditions.

Titanium-carbide-based grades again came into prominence about 1960, when nickel-molybdenum began to be used as a binder instead of nickel. The new grades were able to perform a wider range of tasks including interrupted cutting and cutting under shock conditions.

The very high indentation hardness values recorded for titanium carbide grades are not accompanied by correspondingly greater resistance to abrasive wear, the apparently less hard tungsten carbide being considerably superior in this property. Moreover, carbonitrides, advanced tantalum-containing multicarbides, and coated variants generally provide better all-round cutting performances.

*Titanium-Base Carbonitrides:* Development of titanium-carbonitride-based cutting-tool materials predates the use of coatings of this type on more conventional hardmetals by many years. Appreciable, though uncontrolled, amounts of carbonitride were often present, if only by accident, when cracked ammonia was used as a less expensive substitute for hydrogen in some stages of the production process in the 1950's and perhaps for two decades earlier.

Much of the recent, more scientific development of this class of materials has taken place in the United States, particularly by Teledyne Firth Sterling with its  $SD_3$  grade and in Japan by several companies. Many of the compositions currently in use are extremely complex, and their structures—even with apparently similar compositions—can vary enormously. For instance, Mitsubishi characterizes its Himet NX series of cermets as  $TiC/WC/Ta(Nb)C/Mo_2C/TiN/Ni/Co/Al$ , with a structure comprising both large and medium-size carbide particles (mainly TiC according to the quoted density) in a superalloy-type matrix containing an aluminum-bearing intermetallic compound.

*Steel- and Alloy-Bonded Titanium Carbide:* The class of material exemplified by Ferro-Tic, as it is known, consists primarily of titanium carbide bonded with heat-treatable steel, but some grades also contain tungsten carbide or are bonded with nickel- or copper-base alloys. These cemented carbides are characterized by high binder contents (typically 50–60 per cent by volume) and lower hardnesses, compared with the more usual hardmetals, and by the great variation in properties obtained by heat treatment.

In the annealed condition, steel-bonded carbides have a relatively soft matrix and can be machined with little difficulty, especially by CBN (superhard cubic boron nitride) tools. After heat treatment, the degree of hardness and wear resistance achieved is considerably greater than that of normal tool steels, although understandably much less than that of traditional sintered carbides. Microstructures are extremely varied, being composed of 40–50 per cent TiC by volume and a matrix appropriate to the alloy composition and the stage of heat treatment. Applications include stamping, blanking and drawing dies, machine components, and similar items where the ability to machine before hardening reduces production costs substantially.

*Coating:* As a final stage in carbide manufacture, coatings of various kinds are applied mainly to cutting tools, where for cutting steel in particular it is advantageous to give the flank and clearance surfaces characteristics that are quite different from those of the body of the insert. Coatings of titanium carbide, nitride, or carbonitride; of aluminum oxide; and of other refractory compounds are applied to a variety of hardmetal substrates by chemical or physical vapor deposition (CVD or PVD) or by newer plasma methods.

The most recent types of coatings include hafnium, tantalum, and zirconium carbides and nitrides; alumina/titanium oxide; and multiple carbide/carbonitride/nitride/oxide, oxynitride or oxycarbonitride combinations. Greatly improved properties have been claimed for variants with as many as 13 distinct CVD coatings. A markedly sharper cutting edge compared with other CVD-coated hardmetals is claimed, permitting finer cuts and the successful machining of soft but abrasive alloys.

The keenest edges on coated carbides are achieved by the techniques of physical vapor deposition. In this process, ions are deposited directionally from the electrodes, rather than evenly on all surfaces, so the sharpness of cutting edges is maintained and may even be enhanced. PVD coatings currently available include titanium nitride and carbonitride, their distinctive gold color having become familiar throughout the world on high-speed steel tooling. The high temperatures required for normal CVD tends to soften heat-treated high-speed steel. PVD-coated hardmetals have been produced commercially for several years, especially for precision milling inserts.

Recent developments in extremely hard coatings, generally involving exotic techniques, include boron carbide, cubic boron nitride, and pure diamond. Almost the ultimate in wear resistance, the commercial applications of thin plasma-generated diamond surfaces at present are mainly in manufacture of semiconductors, where other special properties are important.

For cutting tools the substrate is of equal importance to the coating in many respects, its critical properties including fracture toughness (resistance to crack propagation), elastic modulus, resistance to heat and abrasion, and expansion coefficient. Some manufacturers are now producing inserts with graded composition, so that structures and properties are optimized at both surface and interior, and coatings are less likely to crack or break away.

*Specifications:* Compared with other standardized materials, the world of sintered hardmetals is peculiar. For instance, an engineer who seeks a carbide grade for the finish-machining of a steel component may be told to use *ISO Standard Grade P10* or *Industry Code C7*. If the composition and nominal properties of the designated tool material are then requested, the surprising answer is that, in basic composition alone, the tungsten carbide content of P10 (or of the now superseded C7) can vary from zero to about 75, titanium carbide from 8 to 80, cobalt 0 to 10, and nickel 0 to 15 per cent. There are other possible constituents, also, in this so-called standard alloy, and many basic properties can vary as much as the composition. All that these dissimilar materials have in common, and all that the so-called standards mean, is that their suppliers—and sometimes their suppliers alone—consider them suitable for one particular and ill-defined machining application (which for P10 or C7 is the finish machining of steel).

This peculiar situation arose because the production of cemented carbides in occupied Europe during World War II was controlled by the German Hartmetallzentrale, and no factory other than Krupp was permitted to produce more than one grade. By the end of the war, all German-controlled producers were equipped to make the G, S, H, and F series to German standards. In the postwar years, this series of carbides formed the basis of unofficial European standardization. With the advent of the newer multicarbides, the previous identities of grades were gradually lost. The applications relating to the old grades were retained, however, as a new German DIN standard, eventually being adopted, in somewhat modified form, by the International Standards Organization (ISO) and by ANSI in the United States.

The American cemented carbides industry developed under diverse ownership and solid competition. The major companies actively and independently developed new varieties of hardmetals, and there was little or no standardization, although there were many attempts to compile equivalent charts as a substitute for true standardization. Around 1942, the Buick division of GMC produced a simple classification code that arranged nearly 100 grades derived from 10 manufacturers under only 14 symbols (TC-1 to TC-14). In spite of serious deficiencies, this system remained in use for many years as an American industry

standard; that is, Buick TC-1 was equivalent to industry code C1. Buick itself went much further, using the tremendous influence, research facilities, and purchasing potential of its parent company to standardize the products of each carbide manufacturer by properties that could be tested, rather than by the indeterminate recommended applications. Many large-scale carbide users have developed similar systems in attempts to exert some degree of in-house standardization and quality control. Small and medium-sized users, however, still suffer from so-called industry standards, which only provide a starting point for grade selection.

ISO standard 513, summarized in [Table 2](#), divides all machining grades into three color-coded groups: straight tungsten carbide grades (letter K, color red) for cutting gray cast iron, nonferrous metals, and nonmetallics; highly alloyed grades (letter P, color blue) for machining steel; and less alloyed grades (letter M, color yellow, generally with less TiC than the corresponding P series), which are multipurpose and may be used on steels, nickel-base superalloys, ductile cast irons, and so on. Each grade within a group is also given a number to represent its position in a range from maximum hardness to maximum toughness (shock resistance). Typical applications are described for grades at more or less regular numerical intervals. Although coated grades scarcely existed when the ISO standard was prepared, it is easy to classify coated as uncoated carbides—or carbonitrides, ceramics, and superhard materials—according to this system.

In this situation, it is easy to see how one plant will prefer one manufacturer's carbide and a second plant will prefer that of another. Each has found the carbide most nearly ideal for the particular conditions involved. In these circumstances it pays each manufacturer to make grades that differ in hardness, toughness, and crater resistance, so that they can provide a product that is near the optimum for a specific customer's application.

Although not classified as a hard metal, new particle or powder metallurgical methods of manufacture, coupled with new coating technology have led in recent years to something of an upsurge in the use of high speed steel. Lower cost is a big factor, and the development of such coatings as titanium nitride, cubic boron nitride, and pure diamond, has enabled some high speed steel tools to rival tools made from tungsten and other carbides in their ability to maintain cutting accuracy and prolong tool life. Multiple layers may be used to produce optimum properties in the coating, with adhesive strength where there is contact with the substrate, combined with hardness at the cutting surface to resist abrasion. Total thickness of such coating, even with multiple layers, is seldom more than 15 microns (0.000060 in.).

*Importance of Correct Grades:* A great diversity of hardmetal types is required to cope with all possible combinations of metals and alloys, machining operations, and working conditions. Tough, shock-resistant grades are needed for slow speeds and interrupted cutting, harder grades for high-speed finishing, heat-resisting alloyed grades for machining superalloys, and crater-resistant compositions, including most of the many coated varieties, for machining steels and ductile iron.

**Ceramics.**—Moving up the hardness scale, ceramics provide increasing competition for cemented carbides, both in performance and in cost-effectiveness, though not yet in reliability. Hardmetals themselves consist of ceramics—nonmetallic refractory compounds, usually carbides or carbonitrides—with a metallic binder of much lower melting point. In such systems, densification generally takes place by liquid-phase sintering. Pure ceramics have no metallic binder, but may contain lower-melting-point compounds or ceramic mixtures that permit liquid-phase sintering to take place. Where this condition is not possible, hot pressing or hot isostatic pressing can often be used to make a strong, relatively pore-free component or cutting insert. This section is restricted to those ceramics that compete directly with hardmetals, mainly in the cutting-tool category as shown in [Table 3](#).

Ceramics are hard, completely nonmetallic substances that resist heat and abrasive wear. Increasingly used as clamped indexable tool inserts, ceramics differ significantly from tool

**Table 2. ISO Classifications of Hardmetals (Cemented Carbides and Carbonitrides) by Application**

| Main Types of Chip Removal |  | Groups of Applications |   |  | Direction of Decrease in Characteristic |            |
|----------------------------|--|------------------------|---|--|---|------------|
| Symbol and Color           | Broad Categories of Materials to be Machined                                   | Designation (Grade)    | Specific Material to be Machined  | Use and Working Conditions   | of cut                                  | of carbide |
| P<br>Blue                  | Ferrous with long chips  | P01                    | Steel, steel castings   | Finish turning and boring; high cutting speeds, small chip sections, accurate dimensions, fine finish, vibration-free operations   | ↑<br>speed<br>↑<br>wear                 |            |
|                            |  | P10                    | Steel, steel casting  | Turning, copying, threading, milling; high cutting speeds; small or medium chip sections   |   |            |
|                            |  | P20                    | Steel, steel castings, ductile cast iron with long chips  | Turning, copying, milling; medium cutting speeds and chip sections, planing with small chip sections   |   |            |
|                            |  | P30                    | Steel, steel castings, ductile cast iron with long chips  | Turning, milling, planing; medium or large chip sections, unfavorable machining conditions   |   |            |
|                            |  | P40                    | Steel, steel castings with sand inclusions and cavities   | Turning, planing, slotting; low cutting speeds, large chip sections, with possible large cutting angles, unfavorable cutting conditions, and work on automatic machines                                  |   |            |
|                            |  | P50                    | Steel, steel castings of medium or low tensile strength, with sand inclusions and cavities  | Operations demanding very tough carbides; turning, planing, slotting; low cutting speeds, large chip sections, with possible large cutting angles, unfavorable conditions and work on automatic machines |   |            |
| M<br>Yellow                | Ferrous metals with long or short chips, and non-ferrous metals                | M10                    | Steel, steel castings, manganese steel, gray cast iron, alloy cast iron   | Turning; medium or high cutting speeds, small or medium chip sections  |   |            |
|                            |  | M20                    | Steel, steel castings, austenitic or manganese steel, gray cast iron  | Turning, milling; medium cutting speeds and chip sections  |   |            |
|                            |  | M30                    | Steel, steel castings, austenitic steel, gray cast iron, high-temperature-resistant alloys  | Turning, milling, planing; medium cutting speeds, medium or large chip sections  |   |            |
|                            |  | M40                    | Mild, free-cutting steel, low-tensile steel, non-ferrous metals and light alloys  | Turning, parting off; particularly on automatic machines   |   |            |
| K<br>Red                   | Ferrous metals with short chips, non-ferrous metals and non-metallic materials | K01                    | Very hard gray cast iron, chilled castings over 85 Shore, high-silicon aluminum alloys, hardened steel, highly abrasive plastics, hard cardboard, ceramics                                | Turning, finish turning, boring, milling, scraping   |   |            |
|                            |  | K10                    | Gray cast iron over 220 Brinell, malleable cast iron with short chips, hardened steel, silicon-aluminum and copper alloys, plastics, glass, hard rubber, hard cardboard, porcelain, stone | Turning, milling, drilling, boring, broaching, scraping  |   |            |
|                            |  | K20                    | Gray cast iron up to 220 Brinell, nonferrous metals, copper, brass, aluminum  | Turning, milling, planing, boring, broaching, demanding very tough carbide   |   |            |
|                            |  | K30                    | Low-hardness gray cast iron, low-tensile steel, compressed wood   | Turning, milling, planing, slotting, unfavorable conditions, and possibility of large cutting angles   |   |            |
|                            |  | K40                    | Softwood or hard wood, nonferrous metals  | Turning, milling, planing, slotting, unfavorable conditions, and possibility of large cutting angles   |   |            |
|                            |  |                        |   |  | ↓<br>feed<br>↓<br>toughness             |            |

steels, which are completely metallic. Ceramics also differ from cermets such as cemented carbides and carbonitrides, which comprise minute ceramic particles held together by metallic binders.

**Table 3. Typical Properties of Cutting Tool Ceramics**

| Group   | Alumina  | Alumina/TiC                               | Silicon Nitride  | PCD  | PCBN |
|---|--|---|--|------|------|
| Typical composition types                                 | Al <sub>2</sub> O <sub>3</sub> or Al <sub>2</sub> O <sub>3</sub> /ZrO <sub>2</sub> | 70/30 Al <sub>2</sub> O <sub>3</sub> /TiC | Si <sub>3</sub> N <sub>4</sub> /Y <sub>2</sub> O <sub>3</sub> plus |      |      |

Alumina-based ceramics were introduced as cutting inserts during World War II, and were for many years considered too brittle for regular machine-shop use. Improved machine tools and finer-grain, tougher compositions incorporating zirconia or silicon carbide “whiskers” now permit their use in a wide range of applications. Silicon nitride, often combined with alumina (aluminum oxide), yttria (yttrium oxide), and other oxides and nitrides, is used for much of the high-speed machining of superalloys, and newer grades have been formulated specifically for cast iron—potentially a far larger market.

In addition to improvements in toolholders, great advances have been made in machine tools, many of which now feature the higher powers and speeds required for the efficient use of ceramic tooling. Brittleness at the cutting edge is no longer a disadvantage, with the improvements made to the ceramics themselves, mainly in toughness, but also in other critical properties.

Although very large numbers of useful ceramic materials are now available, only a few combinations have been found to combine such properties as minimum porosity, hardness, wear resistance, chemical stability, and resistance to shock to the extent necessary for cutting-tool inserts. Most ceramics used for machining are still based on high-purity, fine-grained alumina (aluminum oxide), but embody property-enhancing additions of other ceramics such as zirconia (zirconium oxide), titania (titanium oxide), titanium carbide, tungsten carbide, and titanium nitride. For commercial purposes, those more commonly used are often termed “white” (alumina with or without zirconia) or “black” (roughly 70/30 alumina/titanium carbide). More recent developments are the distinctively green alumina ceramics strengthened with silicon carbide whiskers and the brown-tinged silicon nitride types.

Ceramics benefit from hot isostatic pressing, used to remove the last vestiges of porosity and raise substantially the material's shock resistance, even more than carbide-based hard-metals. Significant improvements are derived by even small parts such as tool inserts, although, in principle, they should not need such treatment if raw materials and manufacturing methods are properly controlled.

*Oxide Ceramics:* Alumina cutting tips have extreme hardness—more than HV 2000 or HRA 94—and give excellent service in their limited but important range of uses such as the machining of chilled iron rolls and brake drums. A substantial family of alumina-based materials has been developed, and fine-grained alumina-based composites now have suf-

ficient strength for milling cast iron at speeds up to 2500 ft/min (800 m/min). Resistance to cratering when machining steel is exceptional.

**Oxide/Carbide Ceramics:** A second important class of alumina-based cutting ceramics combines aluminum oxide or alumina-zirconia with a refractory carbide or carbides, nearly always 30 per cent TiC. The compound is black and normally is hot pressed or hot isostatically pressed (HIPed). As shown in Table 3, the physical and mechanical properties of this material are generally similar to those of the pure alumina ceramics, but strength and shock resistance are generally higher, being comparable with those of higher-toughness simple alumina-zirconia grades. Current commercial grades are even more complex, combining alumina, zirconia, and titanium carbide with the further addition of titanium nitride.

**Silicon Nitride Base:** One of the most effective ceramic cutting-tool materials developed in the UK is Syalon (from SiAlON or silicon-aluminum-oxynitride) though it incorporates a substantial amount of yttria for efficient liquid-phase sintering). The material combines high strength with hot hardness, shock resistance, and other vital properties. Syalon cutting inserts are made by Kennametal and Sandvik and sold as Kyon 2000 and CC680, respectively. The brown Kyon 200 is suitable for machining high-nickel alloys and cast iron, but a later development, Kyon 3000 has good potential for machining cast iron.

Resistance to thermal stress and thermal shock of Kyon 2000 are comparable to those of sintered carbides. Toughness is substantially less than that of carbides, but roughly twice that of oxide-based cutting-tool materials at temperatures up to 850°C. Syon 200 can cut at high edge temperatures and is harder than carbide and some other ceramics at over 700°C, although softer than most at room temperature.

**Whisker-Reinforced Ceramics:** To improve toughness, Greenleaf Corp. has reinforced alumina ceramics with silicon carbide single-crystal “whiskers” that impart a distinctive green color to the material, marketed as WG300. Typically as thin as human hairs, the immensely strong whiskers improve tool life under arduous conditions. Whisker-reinforced ceramics and perhaps hardmetals are likely to become increasingly important as cutting and wear-resistant materials. Their only drawback seems to be the carcinogenic nature of the included fibers, which requires stringent precautions during manufacture.

**Superhard Materials.**—Polycrystalline synthetic diamond (PCD) and cubic boron nitride (PCBN), in the two columns at the right in Table 3, are almost the only cutting-insert materials in the “superhard” category. Both PCD and PCBN are usually made with the highest practicable concentration of the hard constituent, although ceramic or metallic binders can be almost equally important in providing overall strength and optimizing other properties. Variations in grain size are another critical factor in determining cutting characteristics and edge stability. Some manufacturers treat CBN in similar fashion to tungsten carbide, varying the composition and amount of binder within exceptionally wide limits to influence the physical and mechanical properties of the sintered compact.

In comparing these materials, users should note that some inserts comprise solid polycrystalline diamond or CBN and are double-sized to provide twice the number of cutting edges. Others consist of a layer, from 0.020 to 0.040 in. (0.5 to 1 mm) thick, on a tough carbide backing. A third type is produced with a solid superhard material almost surrounded by sintered carbide. A fourth type, used mainly for cutting inserts, comprises solid hard metal with a tiny superhard insert at one or more (usually only one) cutting corners or edges. Superhard cutting inserts are expensive—up to 30 times the cost of equivalent shapes or sizes in ceramic or cemented carbide—but their outstanding properties, exceptional performance and extremely long life can make them by far the most cost-effective for certain applications.

**Diamond:** Diamond is the hardest material found or made. As harder, more abrasive ceramics and other materials came into widespread use, diamond began to be used for grinding-wheel grits. Cemented carbide tools virtually demanded diamond grinding wheels for fine edge finishing. Solid single-crystal diamond tools were and are used to a

small extent for special purposes, such as microtomes, for machining of hard materials, and for exceptionally fine finishes. These diamonds are made from comparatively large, high-quality gem-type diamonds, have isotropic properties, and are very expensive. By comparison, diamond abrasive grits cost only a few dollars a carat.

Synthetic diamonds are produced from graphite using high temperatures and extremely high pressures. The fine diamond particles produced are sintered together in the presence of a metal "catalyst" to produce high-efficiency anisotropic cutting tool inserts. These tools comprise either a solid diamond compact or a layer of sintered diamond on a carbide backing, and are made under conditions similar to, though less severe than, those used in diamond synthesis. Both natural and synthetic diamond can be sintered in this way, although the latter method is the most frequently used.

Polycrystalline diamond (PCD) compacts are immensely hard and can be used to machine many substances, from highly abrasive hardwoods and glass fiber to nonferrous metals, hardmetals, and tough ceramics. Important classes of tools that are also available with cubic boron nitride inserts include brazed-tip drills, single-point turning tools, and face-milling cutters.

*Boron Nitride:* Polycrystalline diamond has one big limitation: it cannot be used to machine steel or any other ferrous material without rapid chemical breakdown. Boron nitride does not have this limitation. Normally soft and slippery like graphite, the soft hexagonal crystals (HBN) become cubic boron nitride (CBN) when subjected to ultrahigh pressures and temperatures, with a structure similar to and hardness second only to diamond. As a solid insert of polycrystalline cubic boron nitride (PCBN), the compound machines even the hardest steel with relative immunity from chemical breakdown or cratering.

Backed by sintered carbide, inserts of PCBN can readily be brazed, increasing the usefulness of the material and the range of tooling in which it can be used. With great hardness and abrasion resistance, coupled with extreme chemical stability when in contact with ferrous alloys at high temperatures, PCBN has the ability to machine both steels and cast irons at high speeds for long operating cycles. Only its currently high cost in relation to hardmetals prevents its wider use in mass-production machining.

Similar in general properties to PCBN, the recently developed "Wurbon" consists of a mixture of ultrafine (0.02  $\mu\text{m}$  grain size) hexagonal and cubic boron nitride with a "wurtzite" structure, and is produced from soft hexagonal boron nitride in a microsecond by an explosive shock-wave.

*Basic Machining Data:* Most mass-production metalcutting operations are carried out with carbide-tipped tools but their correct application is not simple. Even apparently similar batches of the same material vary greatly in their machining characteristics and may require different tool settings to attain optimum performance. Depth of cut, feed, surface speed, cutting rate, desired surface finish, and target tool life often need to be modified to suit the requirements of a particular component.

For the same downtime, the life of an insert between indexings can be less than that of an equivalent brazed tool between regrinds, so a much higher rate of metal removal is possible with the indexable or throwaway insert. It is commonplace for the claims for a new coating to include increases in surface-speed rates of 200–300 per cent, and for a new insert design to offer similar improvements. Many operations are run at metal removal rates that are far from optimum for tool life because the rates used maximize productivity and cost-effectiveness.

Thus any recommendations for cutting speeds and feeds must be oversimplified or extremely complex, and must be hedged with many provisos, dependent on the technical and economic conditions in the manufacturing plant concerned. A preliminary grade selection should be made from the ISO-based tables and manufacturers' literature consulted for recommendations on the chosen grades and tool designs. If tool life is much

greater than that desired under the suggested conditions, speeds, feeds, or depths of cut may be increased. If tools fail by edge breakage, a tougher (more shock-resistant) grade should be selected, with a numerically higher ISO code.

Alternatively, increasing the surface speed and decreasing the feed may be tried. If tools fail prematurely from what appears to be abrasive wear, a harder grade with numerically lower ISO designation should be tried. If cratering is severe, use a grade with higher titanium carbide content; that is, switch from an ISO K to M or M to P grade, use a P grade with lower numerical value, change to a coated grade, or use a coated grade with a (claimed) more-resistant surface layer.

*Built-Up Edge and Cratering:* The big problem in cutting steel with carbide tools is associated with the built-up edge and the familiar phenomenon called cratering. Research has shown that the built-up edge is continuous with the chip itself during normal cutting. Additions of titanium, tantalum, and niobium to the basic carbide mixture have a remarkable effect on the nature and degree of cratering, which is related to adhesion between the tool and the chip.

**Hardmetal Tooling for Wood and Nonmetallics.**—Carbide-tipped circular saws are now conventional for cutting wood, wood products such as chipboard, and plastics, and tipped bandsaws of large size are also gaining in popularity. Tipped handsaws and mechanical equivalents are seldom needed for wood, but they are extremely useful for cutting abrasive building boards, glass-reinforced plastics, and similar material. Like the hardmetal tips used on most other woodworking tools, saw tips generally make use of straight (unalloyed) tungsten carbide/cobalt grades. However, where excessive heat is generated as with the cutting of high-silica hardwoods and particularly abrasive chipboards, the very hard but tough tungsten-titanium-tantalum-niobium carbide solid-solution grades, normally reserved for steel finishing, may be preferred. Saw tips are usually brazed and reground a number of times during service, so coated grades appear to have little immediate potential in this field.

*Cutting Blades and Plane Irons:* These tools comprise long, thin, comparatively wide slabs of carbide on a minimal-thickness steel backing. Compositions are straight tungsten carbide, preferably micrograin (to maintain a keen cutting edge with an included angle of 30° or less), but with relatively high amounts of cobalt, 11–13 per cent, for toughness. Considerable expertise is necessary to braze and grind these cutters without inducing or failing to relieve the excessive stresses that cause distortion or cracking.

*Other Woodworking Cutters:* Routers and other cutters are generally similar to those used on metals and include many indexable-insert designs. The main difference with wood is that rotational and surface speeds can be the maximum available on the machine. High-speed routing of aluminum and magnesium alloys was developed largely from machines and techniques originally designed for work on wood.

*Cutting Other Materials:* The machining of plastics, fiber-reinforced plastics, graphite, asbestos, and other hard and abrasive constructional materials mainly requires abrasion resistance. Cutting pressures and power requirements are generally low. With thermoplastics and some other materials, particular attention must be given to cooling because of softening or degradation of the work material that might be caused by the heat generated in cutting. An important application of cemented carbides is the drilling and routing of printed circuit boards. Solid tungsten carbide drills of extremely small sizes are used for this work.

## FORMING TOOLS

When curved surfaces or those of stepped, angular or irregular shape are required in connection with turning operations, especially on turret lathes and "automatics," forming tools are used. These tools are so made that the contour of the cutting edge corresponds to the shape required and usually they may be ground repeatedly without changing the shape of the cutting edge. There are two general classes of forming tools—the straight type and the circular type. The circular forming tool is generally used on small narrow forms, whereas the straight type is more suitable for wide forming operations. Some straight forming tools are clamped in a horizontal position upon the cut-off slide, whereas the others are held in a vertical position in a special holder. A common form of holder for these vertical tools is one having a dovetail slot in which the forming tool is clamped; hence they are often called "dovetail forming tools." In many cases, two forming tools are used, especially when a very smooth surface is required, one being employed for roughing and the other for finishing.

There was an American standard for forming tool blanks which covered both straight or dovetailed, and circular forms. The formed part of the finished blanks must be shaped to suit whatever job the tool is to be used for. This former standard includes the important dimensions of holders for both straight and circular forms.

**Dimensions of Steps on Straight or Dovetail Forming Tools.**—The diagrams at the top of the accompanying Table 1 illustrate a straight or "dovetail" forming tool. The upper or cutting face lies in the same plane as the center of the work and there is no rake. (Many forming tools have rake to increase the cutting efficiency, and this type will be referred to later.) In making a forming tool, the various steps measured perpendicular to the front face (as at  $d$ ) must be proportioned so as to obtain the required radial dimensions on the work. For example, if  $D$  equals the difference between two radial dimensions on the work, then:

$$\text{Step } d = D \times \text{cosine front clearance angle}$$

**Angles on Straight Forming Tools.**—In making forming tools to the required shape or contour, any angular surfaces (like the steps referred to in the previous paragraph) are affected by the clearance angle. For example, assume that angle  $A$  on the work (see diagram at top of accompanying table) is 20 degrees. The angle on the tool in plane  $x-x$ , in that case, will be slightly less than 20 degrees. In making the tool, this modified or reduced angle is required because of the convenience in machining and measuring the angle square to the front face of the tool or in the plane  $x-x$ .

If the angle on the work is measured from a line parallel to the axis (as at  $A$  in diagram), then the reduced angle on the tool as measured square to the front face (or in plane  $x-x$ ) is found as follows:

$$\tan \text{ reduced angle on tool} = \tan A \times \cos \text{ front clearance angle}$$

If angle  $A$  on the work is larger than, say, 45 degrees, it may be given on the drawing as indicated at  $B$ . In this case, the angle is measured from a plane perpendicular to the axis of the work. When the angle is so specified, the angle on the tool in plane  $x-x$  may be found as follows:

$$\tan \text{ reduced angle on tool} = \frac{\tan B}{\cos \text{ clearance angle}}$$

**Table Giving Step Dimensions and Angles on Straight or Dovetailed Forming Tools.**—The accompanying table gives the required dimensions and angles within its range, direct or without calculation.

**Table 1. Dimensions of Steps and Angles on Straight Forming Tools**

| Radial Depth of Step <i>D</i> | Depth <i>d</i> of step on tool |                     |                     | Radial Depth of Step <i>D</i> | Depth <i>d</i> of step on tool |                     |                     |
|-------------------------------|--------------------------------|---------------------|---------------------|-------------------------------|--------------------------------|---------------------|---------------------|
|                               | When <i>C</i> = 10°            | When <i>C</i> = 15° | When <i>C</i> = 20° |                               | When <i>C</i> = 10°            | When <i>C</i> = 15° | When <i>C</i> = 20° |

Upper section of table gives depth *d* of step on forming tool for a given dimension *D* that equals the actual depth of the step on the work, measured radially and along the cutting face of the tool (see diagram at left). First, locate depth *D* required on work; then find depth *d* on tool under tool clearance angle *C*. Depth *d* is measured perpendicular to front face of tool.

| Angle <i>A</i> in Plane of Tool Cutting Face | Angle on tool in plane <i>x-x</i> |        |                     |     |                     |        |         |
|--|-----------------------------------|--------|---------------------|-----|---------------------|--------|---------|
|  | When <i>C</i> = 10°               |        | When <i>C</i> = 15° |     | When <i>C</i> = 20° |        |         |

Lower section of table gives angles as measured in plane *x-x* perpendicular to front face of forming tool (see diagram on right). Find in first column the angle *A* required on work; then find reduced angle in plane *x-x* under given clearance angle *C*.

**To Find Dimensions of Steps:** The upper section of **Table 1** is used in determining the dimensions of steps. The radial depth of the step or the actual cutting depth *D* (see left-hand diagram) is given in the first column of the table. The columns that follow give the corresponding depths *d* for a front clearance angle of 10, 15, or 20 degrees. To illustrate the use of the table, suppose a tool is required for turning the part shown in **Fig. 1**, which has diameters of 0.75, 1.25, and 1.75 inches, respectively. The difference between the largest and the smallest radius is 0.5 inch, which is the depth of one step. Assume that the clearance angle is 15 degrees. First, locate 0.5 in the column headed "Radial Depth of Step *D*"; then find depth *d* in the column headed "when *C* = 15°." As will be seen, this depth is 0.48296

inch. Practically the same procedure is followed in determining the depth of the second step on the tool. The difference in the radii in this case equals 0.25. This value is not given directly in the table, so first find the depth equivalent to 0.200 and add to it the depth equivalent to 0.050. Thus, we have  $0.19318 + 0.04829 = 0.24147$ . In using Table 1, it is assumed that the top face of the tool is set at the height of the work axis.

*To Find Angle:* The lower section of Table 1 applies to angles when they are measured relative to the axis of the work. The application of the table will again be illustrated by using the part shown in Fig. 1. The angle used here is 40 degrees (which is also the angle in the plane of the cutting face of the tool). If the clearance angle is 15 degrees, the angle measured in plane  $x-x$  square to the face of the tool is shown by the table to be  $39^{\circ} 1'$  - a reduction of practically 1 degree.

Fig. 1.

Fig. 2.

If a straight forming tool has rake, the depth  $x$  of each step (see Fig. 2), measured perpendicular to the front or clearance face, is affected not only by the clearance angle, but by the rake angle  $F$  and the radii  $R$  and  $r$  of the steps on the work. First, it is necessary to find three angles, designated  $A$ ,  $B$ , and  $C$ , that are not shown on the drawing.

$$\text{Angle } A = 180^{\circ} - \text{rake angle } F$$

$$\sin B = \frac{r \sin A}{R}$$

$$\text{Angle } C = 180^{\circ} - (A + B)$$

$$y = \frac{R \sin C}{\sin A}$$

$$\text{Angle } D \text{ of tool} = 90^{\circ} - (E + F)$$

$$\text{Depth } x = y \sin D$$

If the work has two or more shoulders, the depth  $x$  for other steps on the tool may be determined for each radius  $r$ . If the work has curved or angular forms, it is more practical to use a tool without rake because its profile, in the plane of the cutting face, duplicates that of the work.

*Example:* Assume that radius  $R$  equals 0.625 inch and radius  $r$  equals 0.375 inch, so that the step on the work has a radial depth of 0.25 inch. The tool has a rake angle  $F$  of 10 degrees and a clearance angle  $E$  of 15 degrees. Then angle  $A = 180 - 10 = 170$  degrees.

$$\sin B = \frac{0.375 \times 0.17365}{0.625} = 0.10419 \quad \text{Angle } B = 5^\circ 59' \text{ nearly.}$$

$$\text{Angle } C = 180 - (170^\circ + 5^\circ 59') = 4^\circ 1'$$

$$\text{Dimension } y = \frac{0.625 \times 0.07005}{0.17365} = 0.25212$$

$$\text{Angle } D = 90^\circ - (15 + 10) = 65 \text{ degrees}$$

$$\text{Depth } x \text{ of step} = 0.25212 \times 0.90631 = 0.2285 \text{ inch}$$

**Circular Forming Tools.**—To provide sufficient peripheral clearance on circular forming tools, the cutting face is offset with relation to the center of the tool a distance  $C$ , as shown in Fig. 3. Whenever a circular tool has two or more diameters, the difference in the radii of the steps on the tool will not correspond exactly to the difference in the steps on the work. The form produced with the tool also changes, although the change is very slight, unless the amount of offset  $C$  is considerable. Assume that a circular tool is required to produce the piece  $A$  having two diameters as shown.

Fig. 3.

If the difference  $D_1$  between the large and small radii of the tool were made equal to dimension  $D$  required on the work,  $D$  would be a certain amount oversize, depending upon the offset  $C$  of the cutting edge. The following formulas can be used to determine the radii of circular forming tools for turning parts to different diameters:

Let  $R$  = largest radius of tool in inches;  $D$  = difference in radii of steps on work;  $C$  = amount cutting edge is offset from center of tool;  $r$  = required radius in inches; then

$$r = \sqrt{\left(\sqrt{R^2 - C^2} - D\right)^2 + C^2} \quad (1)$$

If the small radius  $r$  is given and the large radius  $R$  is required, then

$$R = \sqrt{\left(\sqrt{r^2 - C^2} + D\right)^2 + C^2} \quad (2)$$

To illustrate, if  $D$  (Fig. 3) is to be  $\frac{1}{8}$  inch, the large radius  $R$  is  $1\frac{1}{8}$  inches, and  $C$  is  $\frac{5}{32}$  inch, what radius  $r$  would be required to compensate for the offset  $C$  of the cutting edge? Inserting these values in Formula (1):

$$r = \sqrt{\sqrt{\left(1\frac{1}{8}\right)^2 - \left(\frac{5}{32}\right)^2} - \left(\frac{1}{8}\right)^2 + \left(\frac{5}{32}\right)^2} = 1.0014 \text{ inches}$$

The value of  $r$  is thus found to be 1.0014 inches; hence, the diameter =  $2 \times 1.0014 = 2.0028$  inches instead of 2 inches, as it would have been if the cutting edge had been exactly on the center line. Formulas for circular tools used on different makes of screw machines can be simplified when the values  $R$  and  $C$  are constant for each size of machine. The accompanying Table 2, *Formulas for Circular Forming Tools*, gives the standard values of  $R$  and  $C$  for circular tools used on different automatics. The formulas for determining the

<sup>a</sup>For notation, see Fig. 3

radius  $r$  (see column at right-hand side of table) contain a constant that represents the value of the expression  $\sqrt{R^2 - C^2}$  in Formula (1).

Table 3, *Constant for Determining Diameters of Circular Forming Tools* has been compiled to facilitate proportioning tools of this type and gives constants for computing the various diameters of forming tools, when the cutting face of the tool is  $\frac{1}{8}$ ,  $\frac{3}{16}$ ,  $\frac{1}{4}$ , or  $\frac{5}{16}$  inch below the horizontal center line. As there is no standard distance for the location of the cutting face, the table has been prepared to correspond with distances commonly used. As an example, suppose the tool is required for a part having three diameters of 1.75, 0.75, and 1.25 inches, respectively, as shown in Fig. 1, and that the largest diameter of the tool is 3 inches and the cutting face is  $\frac{1}{4}$  inch below the horizontal center line. The first step would

be to determine approximately the respective diameters of the forming tool and then correct the diameters by the use of the table. To produce the three diameters shown in Fig. 1, with a 3-inch forming tool, the tool diameters would be approximately 2, 3, and 2.5 inches, respectively. The first dimension (2 inches) is 1 inch less in diameter than that of the tool, and the necessary correction should be given in the column "Correction for Difference in Diameter"; but as the table is only extended to half-inch differences, it will be necessary to obtain this particular correction in two steps. On the line for 3-inch diameter and under corrections for  $\frac{1}{2}$  inch, we find 0.0085; then in line with  $2\frac{1}{2}$  and under the same heading, we find 0.0129, hence the total correction would be  $0.0085 + 0.0129 = 0.0214$  inch. This correction is added to the approximate diameter, making the exact diameter of the first step  $2 + 0.0214 = 2.0214$  inches. The next step would be computed in the same way, by noting on the 3-inch line the correction for  $\frac{1}{2}$  inch and adding it to the approximate diameter of the second step, giving an exact diameter of  $2.5 + 0.0085 + 2.5085$  inches. Therefore, to produce the part shown in Fig. 1, the tool should have three steps of 3, 2.0214, and 2.5085 inches, respectively, provided the cutting face is  $\frac{1}{4}$  inch below the center. All diameters are computed in this way, from the largest diameter of the tool.

Tables 4a, 4b, and 4c, *Corrected Diameters of Circular Forming Tools*, are especially applicable to tools used on Brown & Sharpe automatic screw machines. Directions for using these tables are given on page 789.

**Circular Tools Having Top Rake.**—Circular forming tools without top rake are satisfactory for brass, but tools for steel or other tough metals cut better when there is a rake angle of 10 or 12 degrees. For such tools, the small radius  $r$  (see Fig. 3) for an outside radius  $R$  may be found by the formula

$$r = \sqrt{P^2 + R^2 - 2PR \cos \theta}$$

To find the value of  $P$ , proceed as follows:  $\sin \phi =$  small radius on work  $\times$   $\sin$  rake angle  $\div$  large radius on work. Angle  $\beta =$  rake angle  $- \phi$ .  $P =$  large radius on work  $\times$   $\sin \beta \div$   $\sin$  rake angle. Angle  $\theta =$  rake angle  $+ \delta$ .  $\sin \delta =$  vertical height  $C$  from center of tool to center of work  $\div R$ . It is assumed that the tool point is to be set at the same height as the work center.

**Using Tables for "Corrected Diameters of Circular Forming Tools."**—Tables 4a, 4b, and 4c are especially applicable to Brown & Sharpe automatic screw machines. The maximum diameter  $D$  of forming tools for these machines should be as follows: For No. 00 machine,  $1\frac{3}{4}$  inches; for No. 0 machine,  $2\frac{1}{4}$  inches; for No. 2 machine, 3 inches. To find the other diameters of the tool for any piece to be formed, proceed as follows: Subtract the smallest diameter of the work from the diameter of the work that is to be formed by the required tool diameter; divide the remainder by 2; locate the quotient obtained in the column headed "Length  $c$  on Tool," and opposite the figure thus located and in the column headed by the number of the machine used, read off directly the diameter to which the tool is to be made. The quotient obtained, which is located in the column headed "Length  $c$  on Tool," is the length  $c$ , as shown in Fig. 4.

*Example:* A piece of work is to be formed on a No. 0 machine to two diameters, one being  $\frac{1}{4}$  inch and one 0.550 inch; find the diameters of the tool. The maximum tool diameter is  $2\frac{1}{4}$  inches, or the diameter that will cut the  $\frac{1}{4}$ -inch diameter of the work. To find the other diameter, proceed according to the rule given:  $0.550 - \frac{1}{4} = 0.300$ ;  $0.300 \div 2 = 0.150$ . In Table 4b, opposite 0.150, we find that the required tool diameter is 1.9534 inches. These tables are for tools without rakes.

Table 3. Constant for Determining Diameters of Circular Forming Tools

| Dia. of Tool   | Radius of Tool | Cutting Face $\frac{1}{8}$ Inch Below Center |                    |                    | Cutting Face $\frac{3}{16}$ Inch Below Center |                    |                    | Cutting Face $\frac{1}{4}$ Inch Below Center |                    |                    | Cutting Face $\frac{5}{16}$ Inch Below Center |                    |                    |
|----------------|----------------|--|--------------------|--------------------|---|--------------------|--------------------|--|--------------------|--------------------|---|--------------------|--------------------|

Dimensions of Forming Tools for B. &amp; S. Automatic Screw Machines

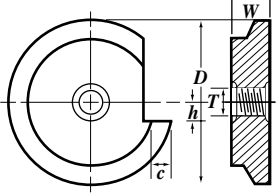

|  | No. of<br>Machine | Max.<br>Dia., <i>D</i> | <i>h</i>          | <i>T</i>          | <i>W</i>      |
|---|-------------------|------------------------|-------------------|-------------------|---------------|
|   | 00                | 1 $\frac{3}{4}$        | $\frac{1}{8}$     | $\frac{3}{8}$ -16 | $\frac{1}{4}$ |
| 0   | 2 $\frac{1}{4}$   | $\frac{5}{32}$         | $\frac{1}{2}$ -14 | $\frac{5}{16}$    |               |
| 2   | 3                 | $\frac{1}{4}$          | $\frac{5}{8}$ -12 | $\frac{3}{8}$     |               |
| 6   | 4                 | $\frac{5}{16}$         | $\frac{3}{4}$ -12 | $\frac{3}{8}$     |               |

Fig. 4.

**Arrangement of Circular Tools.**—When applying circular tools to automatic screw machines, their arrangement has an important bearing on the results obtained. The various ways of arranging the circular tools, with relation to the rotation of the spindle, are shown at A, B, C, and D in Fig. 5. These diagrams represent the view obtained when looking toward the chuck. The arrangement shown at A gives good results on long forming operations on brass and steel because the pressure of the cut on the front tool is downward; the support is more rigid than when the forming tool is turned upside down on the front slide, as shown at B; here the stock, turning up toward the tool, has a tendency to lift the cross-slide, causing chattering; therefore, the arrangement shown at A is recommended when a high-quality finish is desired. The arrangement at B works satisfactorily for short steel pieces that do not require a high finish; it allows the chips to drop clear of the work, and is especially advantageous when making screws, when the forming and cut-off tools operate after the die, as no time is lost in reversing the spindle. The arrangement at C is recommended for heavy cutting on large work, when both tools are used for forming the piece; a

rigid support is then necessary for both tools and a good supply of oil is also required. The arrangement at D is objectionable and should be avoided; it is used only when a left-hand thread is cut on the piece and when the cut-off tool is used on the front slide, leaving the heavy cutting to be performed from the rear slide. In all "cross-forming" work, it is essential that the spindle bearings be kept in good condition, and that the collet or chuck has a parallel contact upon the bar that is being formed.

Fig. 5.

**Feeds and Speeds for Forming Tools.**—Approximate feeds and speeds for forming tools are given in the table beginning on page 1132. The feeds and speeds are average values, and if the job at hand has any features out of the ordinary, the figures given should be altered accordingly.

#### Dimensions for Circular Cut-Off Tools

|  | Dia. of Stock   | Soft Brass, Copper    |       | Norway Iron, Machine Steel |       | Drill Rod, Tool Steel |       |
|--|-----------------|-----------------------|-------|----------------------------|-------|-----------------------|-------|

|  | 1               | 0.124                 | 0.053 | 0.156                      | 0.042 | 0.175                 | 0.037 |

The length of the blade equals radius of stock  $R + x + r + \frac{1}{32}$  inch (for notation, see illustration above);  $r = \frac{1}{16}$  inch for  $\frac{3}{8}$  to  $\frac{3}{4}$ -inch stock, and  $\frac{3}{32}$  inch for  $\frac{3}{4}$ - to 1-inch stock.

## MILLING CUTTERS

## Selection of Milling Cutters

The most suitable type of milling cutter for a particular milling operation depends on such factors as the kind of cut to be made, the material to be cut, the number of parts to be machined, and the type of milling machine available. Solid cutters of small size will usually cost less, initially, than inserted blade types; for long-run production, inserted-blade cutters will probably have a lower overall cost. Depending on either the material to be cut or the amount of production involved, the use of carbide-tipped cutters in preference to high-speed steel or other cutting tool materials may be justified.

Rake angles depend on both the cutter material and the work material. Carbide and cast alloy cutting tool materials generally have smaller rake angles than high-speed steel tool materials because of their lower edge strength and greater abrasion resistance. Soft work materials permit higher radial rake angles than hard materials; thin cutters permit zero or practically zero axial rake angles; and wide cutters operate smoother with high axial rake angles. See *Rake Angles for Milling Cutters* on page 826.

Cutting edge relief or clearance angles are usually from 3 to 6 degrees for hard or tough materials, 4 to 7 degrees for average materials, and 6 to 12 degrees for easily machined materials. See *Clearance Angles for Milling Cutter Teeth* on page 825.

The number of teeth in the milling cutter is also a factor that should be given consideration, as explained in the next paragraph.

**Number of Teeth in Milling Cutters.**—In determining the number of teeth a milling cutter should have for optimum performance, there is no universal rule.

There are, however, two factors that should be considered in making a choice: 1) The number of teeth should never be so great as to reduce the chip space between the teeth to a point where a free flow of chips is prevented; and 2) The chip space should be smooth and without sharp corners that would cause clogging of the chips in the space.

For milling ductile materials that produce a continuous and curled chip, a cutter with large chip spaces is preferable. Such coarse tooth cutters permit an easier flow of the chips through the chip space than would be obtained with fine tooth cutters, and help to eliminate cutter "chatter." For cutting operations in thin materials, fine tooth cutters reduce cutter and workpiece vibration and the tendency for the cutter teeth to "straddle" the workpiece and dig in. For slitting copper and other soft nonferrous materials, teeth that are either chamfered or alternately flat and V-shaped are best.

As a general rule, to give satisfactory performance the number of teeth in milling cutters should be such that *no more than two teeth at a time are engaged in the cut*. Based on this rule, the following formulas are recommended:

For face milling cutters,

$$T = \frac{6.3D}{W} \quad (1)$$

For peripheral milling cutters,

$$T = \frac{12.6D \cos A}{D + 4d} \quad (2)$$

where  $T$  = number of teeth in cutter;  $D$  = cutter diameter in inches;  $W$  = width of cut in inches;  $d$  = depth of cut in inches; and  $A$  = helix angle of cutter.

To find the number of teeth that a cutter should have when other than two teeth in the cut at the same time is desired, **Formulas (1) and (2)** should be divided by 2 and the result multiplied by the number of teeth desired in the cut.

*Example:* Determine the required number of teeth in a face mill where  $D = 6$  inches and  $W = 4$  inches. Using [Formula \(1\)](#),

$$T = \frac{6.3 \times 6}{4} = 10 \text{ teeth, approximately}$$

*Example:* Determine the required number of teeth in a plain milling cutter where  $D = 4$  inches and  $d = \frac{1}{4}$  inch. Using [Formula \(2\)](#),

$$T = \frac{12.6 \times 4 \times \cos 0^\circ}{4 + (4 \times \frac{1}{4})} = 10 \text{ teeth, approximately}$$

In *high speed milling* with sintered carbide, high-speed steel, and cast non-ferrous cutting tool materials, a formula that permits full use of the power available at the cutter but prevents overloading of the motor driving the milling machine is:

$$T = \frac{K \times H}{F \times N \times d \times W} \quad (3)$$

where  $T$  = number of cutter teeth;  $H$  = horsepower available at the cutter;  $F$  = feed per tooth in inches;  $N$  = revolutions per minute of cutter;  $d$  = depth of cut in inches;  $W$  = width of cut in inches; and  $K$  = a constant which may be taken as 0.65 for average steel, 1.5 for cast iron, and 2.5 for aluminum. These values are conservative and take into account dulling of the cutter in service.

*Example:* Determine the required number of teeth in a sintered carbide tipped face mill for high speed milling of 200 Brinell hardness alloy steel if  $H = 10$  horsepower;  $F = 0.008$  inch;  $N = 272$  rpm;  $d = 0.125$  inch;  $W = 6$  inches; and  $K$  for alloy steel is 0.65. Using [Formula \(3\)](#),

$$T = \frac{0.65 \times 10}{0.008 \times 272 \times 0.125 \times 6} = 4 \text{ teeth, approximately}$$

**American National Standard Milling Cutters.**—According to American National Standard ANSI/ASME B94.19-1997 milling cutters may be classified in two general ways, which are given as follows:

*By Type of Relief on Cutting Edges:* Milling cutters may be described on the basis of one of two methods of providing relief for the cutting edges. *Profile sharpened* cutters are those on which relief is obtained and which are resharpened by grinding a narrow land back of the cutting edges. Profile sharpened cutters may produce flat, curved, or irregular surfaces. *Form relieved* cutters are those which are so relieved that by grinding only the faces of the teeth the original form is maintained throughout the life of the cutters. Form relieved cutters may produce flat, curved or irregular surfaces.

*By Method of Mounting:* Milling cutters may be described by one of two methods used to mount the cutter. *Arbor type* cutters are those which have a hole for mounting on an arbor and usually have a keyway to receive a driving key. These are sometimes called *Shell type*. *Shank type* cutters are those which have a straight or tapered shank to fit the machine tool spindle or adapter.

**Explanation of the "Hand" of Milling Cutters.**—In the ANSI Standard the terms "right hand" and "left hand" are used to describe hand of rotation, hand of cutter and hand of flute helix.

*Hand of Rotation or Hand of Cut:* is described as either "right hand" if the cutter revolves counterclockwise as it cuts when viewed from a position in front of a horizontal milling machine and facing the spindle or "left hand" if the cutter revolves clockwise as it cuts when viewed from the same position.

| High-helix Cutters <sup>d</sup> |       |       |  |               |         |        |
| 3                               | 3.015 | 2.985 | 4 and 6                                    | 1¼            | 1.2510  | 1.2500 |
| 4                               | 4.015 | 3.985 | 8  | 1½            | 1.5010  | 1.5000 |

<sup>a</sup> *Tolerances on Face Widths:* Up to 1 inch, inclusive,  $\pm 0.001$  inch; over 1 to 2 inches, inclusive,  $+0.010, -0.000$  inch; over 2 inches,  $+0.020, -0.000$  inch.

<sup>b</sup> Light-duty plain milling cutters with face widths under ¾ inch have straight teeth. Cutters with ¾-inch face and wider have helix angles of not less than 15 degrees nor greater than 25 degrees.

<sup>c</sup> Heavy-duty plain milling cutters have a helix angle of not less than 25 degrees nor greater than 45 degrees.

<sup>d</sup> High-helix plain milling cutters have a helix angle of not less than 45 degrees nor greater than 52 degrees.

All dimensions are in inches. All cutters are high-speed steel. Plain milling cutters are of cylindrical shape, having teeth on the peripheral surface only.

**Hand of Cutter:** Some types of cutters require special consideration when referring to their hand. These are principally cutters with unsymmetrical forms, face type cutters, or cutters with threaded holes. *Symmetrical* cutters may be reversed on the arbor in the same axial position and rotated in the cutting direction without altering the contour produced on the work-piece, and may be considered as either right or left hand. *Unsymmetrical* cutters reverse the contour produced on the work-piece when reversed on the arbor in the same axial position and rotated in the cutting direction. A *single-angle* cutter is considered to be a right-hand cutter if it revolves counterclockwise, or a left-hand cutter if it revolves clockwise, when cutting as viewed from the side of the larger diameter. The *hand of rotation* of a single angle milling cutter need not necessarily be the same as its *hand of cutter*. A *single corner rounding* cutter is considered to be a right-hand cutter if it revolves counterclockwise, or a left-hand cutter if it revolves clockwise, when cutting as viewed from the side of the smaller diameter.

| 6   | 6.015 | 5.985 | $\frac{3}{4}$   | $1\frac{1}{4}$ | 1.2510  | 1.2500 |

<sup>a</sup> *Tolerances on Face Widths:* For side cutters, +0.002, -0.001 inch; for staggered-tooth side cutters up to  $\frac{3}{4}$  inch face width, inclusive, +0.000 -0.0005 inch, and over  $\frac{3}{4}$  to 1 inch, inclusive, +0.000 -0.0010 inch; and for half side cutters, +0.015, -0.000 inch.

<sup>b</sup> Side milling cutters have straight peripheral teeth and side teeth on both sides.

<sup>c</sup> Staggered-tooth side milling cutters have peripheral teeth of alternate right- and left-hand helix and alternate side teeth.

<sup>d</sup> Half side milling cutters have side teeth on one side only. The peripheral teeth are helical of the same hand as the cut. Made either with right-hand or left-hand cut.

All dimensions are in inches. All cutters are high-speed steel. Side milling cutters are of cylindrical shape, having teeth on the periphery and on one or both sides.

**Hand of Flute Helix:** Milling cutters may have *straight flutes* which means that their cutting edges are in planes parallel to the cutter axis. Milling cutters with flute helix in one direction only are described as having a right-hand helix if the flutes twist away from the observer in a clockwise direction when viewed from either end of the cutter or as having a left-hand helix if the flutes twist away from the observer in a counterclockwise direction when viewed from either end of the cutter. *Staggered tooth cutters* are milling cutters with every other flute of opposite (right and left hand) helix.

An illustration describing the various milling cutter elements of both a profile cutter and a form-relieved cutter is given on page 801.

<sup>a</sup>Tolerances on face widths are plus or minus 0.001 inch.

<sup>b</sup>Plain metal slitting saws are relatively thin plain milling cutters having peripheral teeth only. They are furnished with or without hub and their sides are concaved to the arbor hole or hub.

<sup>c</sup>Metal slitting saws with side teeth are relatively thin side milling cutters having both peripheral and side teeth.

<sup>d</sup>Metal slitting saws with staggered peripheral and side teeth are relatively thin staggered tooth milling cutters having peripheral teeth of alternate right- and left-hand helix and alternate side teeth.

All dimensions are in inches. All saws are high-speed steel. Metal slitting saws are similar to plain or side milling cutters but are relatively thin.

<sup>a</sup> Face width tolerances are plus or minus 0.015 inch.

<sup>b</sup> Single-angle milling cutters have peripheral teeth, one cutting edge of which lies in a conical surface and the other in the plane perpendicular to the cutter axis. There are two types: one has a plain keyway hole and has an included tooth angle of either 45 or 60 degrees plus or minus 10 minutes; the other has a threaded hole and has an included tooth angle of 60 degrees plus or minus 10 minutes. Cutters with a right-hand threaded hole have a right-hand hand of rotation and a right-hand hand of cutter. Cutters with a left-hand threaded hole have a left-hand hand of rotation and a left-hand hand of cutter. Cutters with plain keyway holes are standard as either right-hand or left-hand cutters.

<sup>c</sup> These cutters have threaded holes, the sizes of which are given under "Hole Diameter."

<sup>d</sup> Double-angle milling cutters have symmetrical peripheral teeth both sides of which lie in conical surfaces. They are designated by the included angle, which may be 45, 60 or 90 degrees. Tolerances are plus or minus 10 minutes for the half angle on each side of the center.

All dimensions are in inches. All cutters are high-speed steel.

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard.

The helix angle is not less than 10 degrees for multiple-flute cutters with plain straight shanks; the helix angle is optional with the manufacturer for two-flute cutters with Weldon shanks.

Tolerances: On  $W$ ,  $\pm\frac{1}{32}$  inch; on  $L$ ,  $\pm\frac{1}{16}$  inch.

**ANSI Regular-, Long-, and Extra Long-Length, Multiple-Flute Medium Helix Single-End End Mills with Weldon Shanks ANSI/ASME B94.19-1997**

As Indicated By The Dimensions Given Below, Shank Diameter S May Be Larger, Smaller, Or The Same As The Cutter Diameter D

| Cutter Dia., D    | Regular Mills |       |         |                | Long Mills |       |        |                | Extra Long Mills |       |        |                |

<sup>a</sup>N = Number of flutes.

<sup>b</sup>In this size of regular mill a left-hand cutter with left-hand helix is also standard.

All dimensions are in inches. All cutters are high-speed steel. Helix angle is greater than 19 degrees but not more than 39 degrees. Right-hand cutters with right-hand helix are standard.

Tolerances: On D, +0.003 inch; on S, -0.0001 to -0.0005 inch; on W, ±1/32 inch; on L, ±1/16 inch.

<sup>a</sup>B is the length below the shank.

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

**Tolerances:** On C and D, - 0.0015 inch for stub and regular length; + 0.003 inch for long length (if the shank is the same diameter as the cutting portion, however, then the tolerance on the cutting diameter is - 0.0025 inch.); on W, + 1/32, - 1/64 inch; and on L, ± 1/16 inch.

**American National Standard Multiple Flute, Helical Series End Mills with Brown & Sharpe Taper Shanks**

| Dia., D | W     | L       | Taper No. | Dia., D | W     | L     | Taper No. |
|---------|-------|---------|-----------|---------|-------|-------|-----------|
| 1/2     | 15/16 | 4 15/16 | 7         | 1 1/4   | 2     | 7 1/4 | 9         |

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

**Tolerances:** On C and D, -0.0015 inch for stub-length mills, + 0.003 inch for regular-length mills; on S, -0.0001 to -0.0005 inch; on W, ± 1/32 inch; and on L, ± 1/16 inch.

The following single-end end mills are available in premium high speed steel: ball end, two flute, with D ranging from 1/8 to 1 1/2 inches; ball end, multiple flute, with D ranging from 1/8 to 1 inch; and plain end, two flute, with D ranging from 1/8 to 1 1/2 inches.

**American National Standard Long-Length Single-End and Stub-, and Regular Length, Double-End, Plain- and Ball-End, Medium Helix, Two-Flute End Mills with Weldon Shanks ANSI/ASME B94.19-1997**

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

Tolerances: On D, +0.003 inch; on S, -0.0001 to -0.0005 inch; on W, ±1/32 inch; and on L, ±1/16 inch.

The following center-cutting, single-end end mills are available in premium high speed steel: regular length, multiple flute, with D ranging from 1/8 to 1 1/2 inches; long length, multiple flute, with D ranging from 3/8 to 1 1/4 inches; and extra long-length, multiple flute, with D ranging from 3/8 to 1 1/4 inches.

<sup>a</sup> In this size of regular mill a left-hand cutter with a left-hand helix is also standard.

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

**Tolerances:** On *D*, +0.003 inch (if the shank is the same diameter as the cutting portion, however, then the tolerance on the cutting diameter is -0.0025 inch); on *S*, -0.0001 to -0.0005 inch; on *W*, ±1/32 inch; and on *L*, ±1/16 inch.

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

Tolerances: On C and D, + 0.005 inch for 2, 3, 4 and 6 flutes; on W, ± 1/16 inch; and on L, ± 1/16 inch.

| 3/4   | 2 1/32  | 0.675          | 0.455               | 2     | 3 1/4   | 1.900          | 0.700               |
| 7/8   | 2 1/32  | 0.810          | 0.455               | 2 1/2 | 3 1/2   | 2.400          | 0.700               |

<sup>a</sup>X is distance from bottom of flat to opposite side of shank.

<sup>b</sup>Minimum.

All dimensions are in inches.

Centerline of flat is at half-length of shank except for 1 1/2-, 2- and 2 1/2-inch shanks where it is 1 3/16, 1 27/32 and 1 15/16 from shank end, respectively.

Tolerance on shank diameter, - 0.0001 to - 0.0005 inch.

<sup>a</sup> Tolerances on cutter diameter are  $+\frac{1}{16}$ ,  $-\frac{1}{16}$  inch for all sizes.

<sup>b</sup> Tolerance does not apply to convex cutters.

<sup>c</sup> Size of cutter is designated by specifying diameter  $C$  of circular form.

<sup>d</sup> Size of cutter is designated by specifying radius  $R$  of circular form.

All dimensions in inches. All cutters are high-speed steel and are form relieved.

Right-hand corner rounding cutters are standard, but left-hand cutter for  $\frac{1}{4}$ -inch size is also standard.

For key and keyway dimensions for these cutters, see page 819.

All dimensions are in inches.

All gear milling cutters are high-speed steel and are form relieved.

For keyway dimensions see page 819.

*Tolerances:* On outside diameter, + 1/16, -1/16 inch; on hole diameter, through 1-inch hole diameter, +0.00075 inch, over 1-inch and through 2-inch hole diameter, +0.0010 inch.

For cutter number relative to numbers of gear teeth, see page 2052. Roughing cutters are made with No. 1 cutter form only.

All dimensions are in inches.

All cutters are high-speed steel and are form relieved.

For keyway dimensions see page 819. For cutter selection see page 2091.

**Tolerances:** On outside diameter, + $\frac{1}{16}$ , - $\frac{1}{16}$  inch; on hole diameter, through 1-inch hole diameter, +0.00075 inch, for 1¼-inch hole diameter, +0.0010 inch.

To select the cutter number for bevel gears with the axis at any angle, double the back cone radius and multiply the result by the diametral pitch. This procedure gives the number of equivalent spur gear teeth and is the basis for selecting the cutter number from the table on page 2054.

All dimensions are in inches.

All cutters are high-speed steel and are form relieved.

For keyway dimensions see page 819.

*Tolerances:* Outside diameter,  $+\frac{1}{16}$ ,  $-\frac{1}{16}$  inch; hole diameter, through 1-inch diameter,  $+0.00075$  inch, above 1-inch diameter and through 2-inch diameter,  $+0.0010$  inch.

For tooth form, see ANSI sprocket tooth form table on page 2458.

All dimensions are given in inches. All cutters are high-speed steel.

Shank type cutters are standard with right-hand cut and straight teeth. All sizes have 1/2-inch diameter straight shank.

Arbor type cutters have staggered teeth.

For Woodruff key and key-slot dimensions, see pages 2369 through 2371.

Tolerances: Face with W for shank type cutters: 1/16 - to 5/32-inch face, +0.0000, -0.0005; 3/16 to 7/32, -0.0002, -0.0007; 1/4, -0.0003, -0.0008; 5/16, -0.0004, -0.0009; 3/8, -0.0005, -0.0010 inch. Face width W for arbor type cutters; 3/16 inch face, -0.0002, -0.0007; 1/4, -0.0003, -0.0008; 5/16, -0.0004, -0.0009; 3/8 and over, -0.0005, -0.0010 inch. Hole size H: +0.00075, -0.0000 inch. Diameter D for shank type cutters: 1/4 - through 3/4-inch diameter, +0.010, +0.015, 7/8 through 1 1/8, +0.012, +0.017; 1 1/4

through  $1\frac{1}{2}$ ,  $+0.015$ ,  $+0.020$  inch. These tolerances include an allowance for sharpening. For arbor type cutters diameter  $D$  is furnished  $\frac{1}{32}$  inch larger than listed and a tolerance of  $\pm 0.002$  inch applies to the oversize diameter.

**Setting Angles for Milling Straight Teeth of Uniform Land Width in End Mills, Angular Cutters, and Taper Reamers.**—The accompanying tables give setting angles for the dividing head when straight teeth, having a land of uniform width throughout their length, are to be milled using single-angle fluting cutters. These setting angles depend upon three factors: the number of teeth to be cut; the angle of the blank in which the teeth are to be cut; and the angle of the fluting cutter. Setting angles for various combinations of these three factors are given in the tables. For example, assume that 12 teeth are to be cut on the end of an end mill using a 60-degree cutter. By following the horizontal line from 12 teeth, read in the column under 60 degrees that the dividing head should be set to an angle of 70 degrees and 32 minutes.

The following formulas, which were used to compile these tables, may be used to calculate the setting-angles for combinations of number of teeth, blank angle, and cutter angle not covered by the tables. In these formulas,  $A$  = setting-angle for dividing head,  $B$  = angle of blank in which teeth are to be cut,  $C$  = angle of fluting cutter,  $N$  = number of teeth to be cut, and  $D$  and  $E$  are angles not shown on the accompanying diagram and which are used only to simplify calculations.

$$\tan D = \cos(360^\circ/N) \times \cot B \quad (1)$$

$$\sin E = \tan(360^\circ/N) \times \cot C \times \sin D \quad (2)$$

$$\text{Setting-angle } A = D - E \quad (3)$$

*Example:* Suppose 9 teeth are to be cut in a 35-degree blank using a 55-degree single-angle fluting cutter. Then,  $N = 9$ ,  $B = 35^\circ$ , and  $C = 55^\circ$ .

$$\tan D = \cos(360^\circ/9) \times \cot 35^\circ = 0.76604 \times 1.4281 = 1.0940; \text{ and } D = 47^\circ 34'$$

$$\sin E = \tan(360^\circ/9) \times \cot 55^\circ \times \sin 47^\circ 34' = 0.83910 \times 0.70021 \times 0.73806 \\ = 0.43365; \text{ and } E = 25^\circ 42'$$

$$\text{Setting angle } A = 47^\circ 34' - 25^\circ 42' = 21^\circ 52'$$

For end mills and side mills the angle of the blank  $B$  is 0 degrees and the following simplified formula may be used to find the setting angle  $A$

$$\cos A = \tan(360^\circ/N) \times \cot C \quad (4)$$

*Example:* If in the previous example the blank angle was 0 degrees,

$$\cos A = \tan(360^\circ/9) \times \cot 55^\circ = 0.83910 \times 0.70021 = 0.58755, \\ \text{and setting-angle } A = 54^\circ 1'$$

## MILLING CUTTERS

## Angles of Elevation for Milling Straight Teeth in 0-, 5-, 10-, 15-, 20-, 25-, 30-, and 35-degree Blanks Using Single-Angle Fluting Cutters

| No. of Teeth | Angle of Fluting Cutter |         |         |       |         |           |         |         |       |         |         |

**Spline-Shaft Milling Cutter.**—The most efficient method of forming splines on shafts is by hobbing, but special milling cutters may also be used. Since the cutter forms the space between adjacent splines, it must be made to suit the number of splines and the root diameter of the shaft. The cutter angle *B* equals 360 degrees divided by the number of splines. The following formulas are for determining the chordal width *C* at the root of the splines or the chordal width across the concave edge of the cutter. In these formulas, *A* = angle between center line of spline and a radial line passing through the intersection of the root circle and one side of the spline; *W* = width of spline; *d* = root diameter of splined shaft; *C* = chordal width at root circle between adjacent splines; *N* = number of splines.

$$\sin A = \frac{W}{d} \quad C = d \times \sin\left(\frac{180}{N} - A\right)$$

Splines of involute form are often used in preference to the straight-sided type. Dimensions of the American Standard involute splines and hobs are given in the section on splines.

**Cutter Grinding**

**Wheels for Sharpening Milling Cutters.**—Milling cutters may be sharpened either by using the periphery of a disk wheel or the face of a cup wheel. The latter grinds the lands of the teeth flat, whereas the periphery of a disk wheel leaves the teeth slightly concave back of the cutting edges. The concavity produced by disk wheels reduces the effective clearance angle on the teeth, the effect being more pronounced for wheels of small diameter than for wheels of large diameter. For this reason, large diameter wheels are preferred when sharpening milling cutters with disk type wheels. Irrespective of what type of wheel is used to sharpen a milling cutter, any burrs resulting from grinding should be carefully

removed by a hand stoning operation. Stoning also helps to reduce the roughness of grinding marks and improves the quality of the finish produced on the surface being machined. Unless done very carefully, hand stoning may dull the cutting edge. Stoning may be avoided and a sharper cutting edge produced if the wheel rotates toward the cutting edge, which requires that the operator maintain contact between the tool and the rest while the wheel rotation is trying to move the tool away from the rest. Though slightly more difficult, this method will eliminate the burr.

### Specifications of Grinding Wheels for Sharpening Milling Cutters

| Cutter Material                                     | Operation             | Grinding Wheel      |                   |              |                        |

<sup>a</sup> Not indicated in diamond wheel markings.

<sup>b</sup> For hardnesses above Rockwell C 56.

**Wheel Speeds and Feeds for Sharpening Milling Cutters.**—Relatively low cutting speeds should be used when sharpening milling cutters to avoid tempering and heat checking. Dry grinding is recommended in all cases except when diamond wheels are employed. The surface speed of grinding wheels should be in the range of 4500 to 6500 feet per minute for grinding milling cutters of high-speed steel or cast non-ferrous tool material. For sintered carbide cutters, 5000 to 5500 feet per minute should be used.

The maximum stock removed per pass of the grinding wheel should not exceed about 0.0004 inch for sintered carbide cutters; 0.003 inch for large high-speed steel and cast non-ferrous tool material cutters; and 0.0015 inch for narrow saws and slotting cutters of high-speed steel or cast non-ferrous tool material. The stock removed per pass of the wheel may be increased for backing-off operations such as the grinding of secondary clearance behind the teeth since there is usually a sufficient body of metal to carry off the heat.

**Clearance Angles for Milling Cutter Teeth.**—The clearance angle provided on the cutting edges of milling cutters has an important bearing on cutter performance, cutting efficiency, and cutter life between sharpenings. It is desirable in all cases to use a clearance angle as small as possible so as to leave more metal back of the cutting edges for better heat dissipation and to provide maximum support. Excessive clearance angles not only weaken the cutting edges, but also increase the likelihood of “chatter” which will result in poor finish on the machined surface and reduce the life of the cutter. According to The Cincinnati Milling Machine Co., milling cutters used for general purpose work and having diameters from  $\frac{1}{8}$  to 3 inches should have clearance angles from 13 to 5 degrees, respectively, decreasing proportionately as the diameter increases. General purpose cutters over 3

inches in diameter should be provided with a clearance angle of 4 to 5 degrees. The land width is usually  $\frac{1}{64}$ ,  $\frac{1}{32}$ , and  $\frac{1}{16}$  inch, respectively, for small, medium, and large cutters.

The primary clearance or relief angle for best results varies according to the material being milled about as follows: low carbon, high carbon, and alloy steels, 3 to 5 degrees; cast iron and medium and hard bronze, 4 to 7 degrees; brass, soft bronze, aluminum, magnesium, plastics, etc., 10 to 12 degrees. When milling cutters are resharpened, it is customary to grind a secondary clearance angle of 3 to 5 degrees behind the primary clearance angle to reduce the land width to its original value and thus avoid interference with the surface to be milled. A general formula for plain milling cutters, face mills, and form relieved cutters which gives the clearance angle  $C$ , in degrees, necessitated by the feed per revolution  $F$ , in inches, the width of land  $L$ , in inches, the depth of cut  $d$ , in inches, the cutter diameter  $D$ , in inches, and the Brinell hardness number  $B$  of the work being cut is:

$$C = \frac{45860}{DB} \left( 1.5L + \frac{F}{\pi D} \sqrt{d(D-d)} \right)$$

**Rake Angles for Milling Cutters.**—In peripheral milling cutters, the rake angle is generally defined as the angle in degrees that the tooth face deviates from a radial line to the cutting edge. In face milling cutters, the teeth are inclined with respect to both the radial and axial lines. These angles are called *radial* and *axial* rake, respectively. The radial and axial rake angles may be positive, zero, or negative.

Positive rake angles should be used whenever possible for all types of high-speed steel milling cutters. For sintered carbide tipped cutters, zero and negative rake angles are frequently employed to provide more material back of the cutting edge to resist shock loads.

**Rake Angles for High-speed Steel Cutters:** Positive rake angles of 10 to 15 degrees are satisfactory for milling steels of various compositions with plain milling cutters. For softer materials such as magnesium and aluminum alloys, the rake angle may be 25 degrees or more. Metal slitting saws for cutting alloy steel usually have rake angles from 5 to 10 degrees, whereas zero and sometimes negative rake angles are used for saws to cut copper and other soft non-ferrous metals to reduce the tendency to "hog in." Form relieved cutters usually have rake angles of 0, 5, or 10 degrees. Commercial face milling cutters usually have 10 degrees positive radial and axial rake angles for general use in milling cast iron, forged and alloy steel, brass, and bronze; for milling castings and forgings of magnesium and free-cutting aluminum and their alloys, the rake angles may be increased to 25 degrees positive or more, depending on the operating conditions; a smaller rake angle is used for abrasive or difficult to machine aluminum alloys.

**Cast Non-ferrous Tool Material Milling Cutters:** Positive rake angles are generally provided on milling cutters using cast non-ferrous tool materials although negative rake angles may be used advantageously for some operations such as those where shock loads are encountered or where it is necessary to eliminate vibration when milling thin sections.

**Sintered Carbide Milling Cutters:** Peripheral milling cutters such as slab mills, slotting cutters, saws, etc., tipped with sintered carbide, generally have negative radial rake angles of 5 degrees for soft low carbon steel and 10 degrees or more for alloy steels. Positive axial rake angles of 5 and 10 degrees, respectively, may be provided, and for slotting saws and cutters, 0 degree axial rake may be used. On soft materials such as free-cutting aluminum alloys, positive rake angles of 10 to 20 degrees are used. For milling abrasive or difficult to machine aluminum alloys, small positive or even negative rake angles are used.

**Eccentric Type Radial Relief.**—When the radial relief angles on peripheral teeth of milling cutters are ground with a disc type grinding wheel in the conventional manner the ground surfaces on the lands are slightly concave, conforming approximately to the radius of the wheel. A flat land is produced when the radial relief angle is ground with a cup wheel. Another entirely different method of grinding the radial angle is by the eccentric method, which produces a slightly convex surface on the land. If the radial relief angle at

the cutting edge is equal for all of the three types of land mentioned, it will be found that the land with the eccentric relief will drop away from the cutting edge a somewhat greater distance for a given distance around the land than will the others. This is evident from a study of Table 1 entitled, *Indicator Drops for Checking the Radial Relief Angle on Peripheral Teeth*. This feature is an advantage of the eccentric type relief which also produces an excellent finish.

**Table 1. Indicator Drops for Checking the Radial Relief Angle on Peripheral Teeth**

| Cutter Diameter, Inch | Rec. Range of Radial Relief Angles, Degrees | Checking Distance, Inch | Indicator Drops, Inches     |       |                      |       | Rec. Max. Primary Land Width, Inch |
|-----------------------|---|-------------------------|-----------------------------|-------|----------------------|-------|------------------------------------|
|                       |   |                         | For Flat and Concave Relief |       | For Eccentric Relief |       |                                    |
|                       |   |                         | Min.                        | Max.  | Min.                 | Max.  |                                    |

The setup for grinding an eccentric relief is shown in Fig. 1. In this setup the point of contact between the cutter and the tooth rest must be in the same plane as the centers, or axes, of the grinding wheel and the cutter. A wide face is used on the grinding wheel, which is trued and dressed at an angle with respect to the axis of the cutter. An alternate method is to tilt the wheel at this angle. Then as the cutter is traversed and rotated past the grinding wheel while in contact with the tooth rest, an eccentric relief will be generated by the angular face of the wheel. This type of relief can only be ground on the peripheral teeth on milling cutters having helical flutes because the combination of the angular wheel face and the twisting motion of the cutter is required to generate the eccentric relief. Therefore, an eccentric relief cannot be ground on the peripheral teeth of straight fluted cutters.

Table 2 is a table of wheel angles for grinding an eccentric relief for different combinations of relief angles and helix angles. When angles are required that cannot be found in this table, the wheel angle,  $W$ , can be calculated by using the following formula, in which  $R$  is the radial relief angle and  $H$  is the helix angle of the flutes on the cutter.

$$\tan W = \tan R \times \tan H$$

**Table 2. Grinding Wheel Angles for Grinding Eccentric Type Radial Relief Angle**

| Radial Relief Angle, $R$ , Degrees | Helix Angle of Cutter Flutes, $H$ , Degrees |       |       |        |        |        |        |        |
|------------------------------------|---|-------|-------|--------|--------|--------|--------|--------|

**Indicator Drop Method of Checking Relief and Rake Angles.**—The most convenient and inexpensive method of checking the relief and rake angles on milling cutters is by the indicator drop method. Three tables, [Tables 1, 3 and 4](#), of indicator drops are provided in this section, for checking radial relief angles on the peripheral teeth, relief angles on side and end teeth, and rake angles on the tooth faces.

Fig. 1. Setup for Grinding Eccentric Type Radial Relief Angle

**Table 3. Indicator Drops for Checking Relief Angles on Side Teeth and End Teeth**

| Checking Distance, Inch | Given Relief Angle   |        |        |        |       |       |       |       |       |
|-------------------------|----------------------|--------|--------|--------|-------|-------|-------|-------|-------|
|                         | 1°                   | 2°     | 3°     | 4°     | 5°    | 6°    | 7°    | 8°    | 9°    |
|                         | Indicator Drop, inch |        |        |        |       |       |       |       |       |
| .005                    | .00009               | .00017 | .00026 | .00035 | .0004 | .0005 | .0006 | .0007 | .0008 |
| .010                    | .00017               | .00035 | .00052 | .0007  | .0009 | .0011 | .0012 | .0014 | .0016 |
| .015                    | .00026               | .0005  | .00079 | .0010  | .0013 | .0016 | .0018 | .0021 | .0024 |
| .031                    | .00054               | .0011  | .0016  | .0022  | .0027 | .0033 | .0038 | .0044 | .0049 |
| .047                    | .00082               | .0016  | .0025  | .0033  | .0041 | .0049 | .0058 | .0066 | .0074 |
| .062                    | .00108               | .0022  | .0032  | .0043  | .0054 | .0065 | .0076 | .0087 | .0098 |

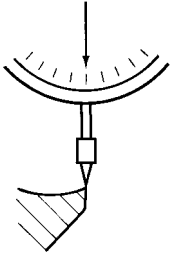

Fig. 2. Setup for Checking the Radial Relief Angle by Indicator Drop Method

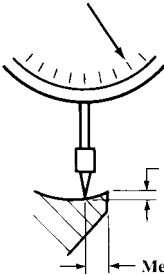

The setup for checking the radial relief angle is illustrated in [Fig. 2](#). Two dial test indicators are required, one of which should have a sharp pointed contact point. This indicator is positioned so that the axis of its spindle is vertical, passing through the axis of the cutter. The cutter may be held by its shank in the spindle of a tool and cutter grinder workhead, or

between centers while mounted on a mandrel. The cutter is rotated to the position where the vertical indicator contacts a cutting edge. The second indicator is positioned with its spindle axis horizontal and with the contact point touching the tool face just below the cutting edge. With both indicators adjusted to read zero, the cutter is rotated a distance equal to the checking distance, as determined by the reading on the second indicator. Then the indicator drop is read on the vertical indicator and checked against the values in the tables. The indicator drops for radial relief angles ground by a disc type grinding wheel and those ground with a cup wheel are so nearly equal that the values are listed together; values for the eccentric type relief are listed separately, since they are larger. A similar procedure is used to check the relief angles on the side and end teeth of milling cutters; however, only one indicator is used. Also, instead of rotating the cutter, the indicator or the cutter must be moved a distance equal to the checking distance in a straight line.

**Table 4. Indicator Drops for Checking Rake Angles on Milling Cutter Face**

Set indicator to read zero on horizontal plane passing through cutter axis.  
Zero cutting edge against indicator.

Move cutter or indicator measuring distance.

| Rate Angle, Deg. | Measuring Distance, inch |       |       |       | Rate Angle, Deg. | Measuring Distance, inch |       |       |       |

**Relieving Attachments.**—A relieving attachment is a device applied to lathes (especially those used in tool-rooms) for imparting a reciprocating motion to the tool-slide and tool, in order to provide relief or clearance for the cutting edges of milling cutters, taps, hobs, etc. For example, in making a milling cutter of the formed type, such as is used for cutting gears, it is essential to provide clearance for the teeth and so form them that they may be ground repeatedly without changing the contour or shape of the cutting edge. This may be accomplished by using a relieving attachment. The tool for “backing off” or giving clearance to the teeth corresponds to the shape required, and it is given a certain amount of reciprocating movement, so that it forms a surface back of each cutting edge, which is of uniform cross-section on a radial plane but eccentric to the axis of the cutter sufficiently to provide the necessary clearance for the cutting edges.

## Various Set-ups Used in Grinding the Clearance Angle on Milling Cutter Teeth

## Distance to Set Center of Wheel Above the Cutter Center (Disk Wheel)

| Dia. of Wheel, Inches | Desired Clearance Angle, Degrees                            |      |      |      |      |      |      |      |      |      |      |       |

<sup>a</sup> Calculated from the formula: Offset = Cutter Diameter  $\times \frac{1}{2} \times$  Sine of Clearance Angle.

**Distance to Set Tooth Rest Below Center Line of Wheel and Cutter.**—When the clearance angle is ground with a disk type wheel by keeping the center line of the wheel in line with the center line of the cutter, the tooth rest should be lowered by an amount given by the following formula:

$$\text{Offset} = \frac{\text{Wheel Diam.} \times \text{Cutter Dia.} \times \text{Sine of One-half the Clearance Angle}}{\text{Wheel Dia.} + \text{Cutter Dia.}}$$

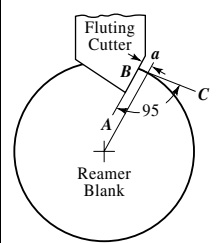

**Distance to Set Tooth Rest Below Cutter Center When Cup Wheel is Used.**—When the clearance is ground with a cup wheel, the tooth rest is set below the center of the cutter the same amount as given in the table for *Distance to Set Center of Wheel Below the Cutter Center (Disk Wheel)*.

## REAMERS

**Hand Reamers.**—Hand reamers are made with both straight and helical flutes. Helical flutes provide a shearing cut and are especially useful in reaming holes having keyways or grooves, as these are bridged over by the helical flutes, thus preventing binding or chattering. Hand reamers are made in both solid and expansion forms. The American standard dimensions for solid forms are given in the accompanying table. The expansion type is useful whenever, in connection with repair or other work, it is necessary to enlarge a reamed hole by a few thousandths of an inch. The expansion form is split through the fluted section and a slight amount of expansion is obtained by screwing in a tapering plug. The diameter increase may vary from 0.005 to 0.008 inch for reamers up to about 1 inch diameter and from 0.010 to 0.012 inch for diameters between 1 and 2 inches. Hand reamers are tapered slightly on the end to facilitate starting them properly. The actual diameter of the shanks of commercial reamers may be from 0.002 to 0.005 inch under the reamer size. That part of the shank that is squared should be turned smaller in diameter than the shank itself, so that, when applying a wrench, no burr may be raised that may mar the reamed hole if the reamer is passed clear through it.

When fluting reamers, the cutter is so set with relation to the center of the reamer blank that the tooth gets a slight negative rake; that is, the cutter should be set *ahead* of the center, as shown in the illustration accompanying the table giving the amount to set the cutter ahead of the radial line. The amount is so selected that a tangent to the circumference of the reamer at the cutting point makes an angle of approximately 95 degrees with the front face of the cutting edge.

Amount to Set Cutter Ahead of Radial Line to Obtain Negative Front Rake

| Fluting Cutter | Size of Reamer  | $a$ , Inches  | Size of Reamer | $a$ , Inches  | Size of Reamer | $a$ , Inches |
|----------------|---|---------------|----------------|---------------|----------------|--------------|
|                |  | $\frac{1}{4}$ | 0.011          | $\frac{7}{8}$ | 0.038          | 2            |
|                | $\frac{3}{8}$   | 0.016         | 1              | 0.044         | $2\frac{1}{4}$ | 0.098        |
|                | $\frac{1}{2}$   | 0.022         | $1\frac{1}{4}$ | 0.055         | $2\frac{1}{2}$ | 0.109        |
|                | $\frac{5}{8}$   | 0.027         | $1\frac{1}{2}$ | 0.066         | $2\frac{3}{4}$ | 0.120        |
|                | $\frac{3}{4}$   | 0.033         | $1\frac{3}{4}$ | 0.076         | 3              | 0.131        |

When fluting reamers, it is necessary to “break up the flutes”; that is, to space the cutting edges unevenly around the reamer. The difference in spacing should be very slight and need not exceed two degrees one way or the other. The manner in which the breaking up of the flutes is usually done is to move the index head to which the reamer is fixed a certain amount more or less than it would be moved if the spacing were regular. A table is given showing the amount of this additional movement of the index crank for reamers with different numbers of flutes. When a reamer is provided with helical flutes, the angle of spiral should be such that the cutting edges make an angle of about 10 or at most 15 degrees with the axis of the reamer.

The relief of the cutting edges should be comparatively slight. An eccentric relief, that is, one where the land back of the cutting edge is convex, rather than flat, is used by one or two manufacturers, and is preferable for finishing reamers, as the reamer will hold its size longer. When hand reamers are used merely for removing stock, or simply for enlarging holes, the flat relief is better, because the reamer has a keener cutting edge. The width of the land of the cutting edges should be about  $\frac{1}{32}$  inch for a  $\frac{1}{4}$ -inch,  $\frac{1}{16}$  inch for a 1-inch, and  $\frac{3}{32}$  inch for a 3-inch reamer.

## Irregular Spacing of Teeth in Reamers

| Number of flutes in reamer | 4  | 6      | 8      | 10     | 12     | 14     | 16     |
|----------------------------|--|--------|--------|--------|--------|--------|--------|
| Index circle to use        | 39   | 39     | 39     | 39     | 39     | 49     | 20     |
| Before cutting             | Move Spindle the Number of Holes below More or Less than for Regular Spacing |        |        |        |        |        |        |
| 2d flute                   | 8 less   | 4 less | 3 less | 2 less | 4 less | 3 less | 2 less |

**Threaded-end Hand Reamers.**—Hand reamers are sometimes provided with a thread at the extreme point in order to give them a uniform feed when reaming. The diameter on the top of this thread at the point of the reamer is slightly smaller than the reamer itself, and the thread tapers upward until it reaches a dimension of from 0.003 to 0.008 inch, according to size, below the size of the reamer; at this point, the thread stops and a short neck about  $\frac{1}{16}$  inch wide separates the threaded portion from the actual reamer, which is provided with a short taper from  $\frac{3}{16}$  to  $\frac{7}{16}$  inch long up to where the standard diameter is reached. The length of the threaded portion and the number of threads per inch for reamers of this kind are given in the accompanying table. The thread employed is a sharp V-thread.

## Dimensions for Threaded-End Hand Reamers

| Sizes of Reamers                | Length of Threaded Part | No. of Threads per Inch | Dia. of Thread at Point of Reamer | Sizes of Reamers                 | Length of Threaded Part | No. of Threads per Inch | Dia. of Thread at Point of Reamer |
|---------------------------------|-------------------------|-------------------------|-----------------------------------|----------------------------------|-------------------------|-------------------------|-----------------------------------|
|                                 |                         |                         | Full diameter                     |                                  |                         |                         | Full diameter                     |
| $\frac{1}{8}$ – $\frac{5}{16}$  | $\frac{3}{8}$           | 32                      | –0.006                            | $1\frac{1}{32}$ – $1\frac{1}{2}$ | $\frac{9}{16}$          | 18                      | –0.010                            |
| $\frac{11}{32}$ – $\frac{1}{2}$ | $\frac{7}{16}$          | 28                      | –0.006                            | $1\frac{7}{32}$ –2               | $\frac{9}{16}$          | 18                      | –0.012                            |
| $\frac{17}{32}$ – $\frac{3}{4}$ | $\frac{1}{2}$           | 24                      | –0.008                            | $2\frac{1}{32}$ – $2\frac{1}{2}$ | $\frac{9}{16}$          | 18                      | –0.015                            |
| $\frac{23}{32}$ –1              | $\frac{9}{16}$          | 18                      | –0.008                            | $2\frac{17}{32}$ –3              | $\frac{9}{16}$          | 18                      | –0.020                            |

**Fluted Chucking Reamers.**—Reamers of this type are used in turret lathes, screw machines, etc., for enlarging holes and finishing them smooth and to the required size. The best results are obtained with a floating type of holder that permits a reamer to align itself with the hole being reamed. These reamers are intended for removing a small amount of metal, 0.005 to 0.010 inch being common allowances. Fluted chucking reamers are provided either with a straight shank or a standard taper shank. (See table for standard dimensions.)

## Fluting Cutters for Reamers

<sup>a</sup> Sharp corner, no radius

**Rose Chucking Reamers.**—The rose type of reamer is used for enlarging cored or other holes. The cutting edges at the end are ground to a 45-degree bevel. This type of reamer will remove considerable metal in one cut. The cylindrical part of the reamer has no cutting edges, but merely grooves cut for the full length of the reamer body, providing a way for the chips to escape and a channel for lubricant to reach the cutting edges. There is no relief on the cylindrical surface of the body part, but it is slightly back-tapered so that the diameter at the point with the beveled cutting edges is slightly larger than the diameter farther back. The back-taper should not exceed 0.001 inch per inch. This form of reamer usually produces holes slightly larger than its size and it is, therefore, always made from 0.005 to 0.010 inch smaller than its nominal size, so that it may be followed by a fluted reamer for finishing. The grooves on the cylindrical portion are cut by a convex cutter having a width equal to from one-fifth to one-fourth the diameter of the rose reamer itself. The depth of the groove should be from one-eighth to one-sixth the diameter of the reamer. The teeth at the end of the reamer are milled with a 75-degree angular cutter; the width of the land of the cutting edge should be about one-fifth the distance from tooth to tooth. If an angular cutter is preferred to a convex cutter for milling the grooves on the cylindrical portion, because of the higher cutting speed possible when milling, an 80-degree angular cutter slightly rounded at the point may be used.

**Cutters for Fluting Rose Chucking Reamers.**—The cutters used for fluting rose chucking reamers on the end are 80-degree angular cutters for  $\frac{1}{4}$ - and  $\frac{5}{16}$ -inch diameter reamers; 75-degree angular cutters for  $\frac{3}{8}$ - and  $\frac{7}{16}$ -inch reamers; and 70-degree angular cutters for all larger sizes. The grooves on the cylindrical portion are milled with convex cutters of approximately the following sizes for given diameters of reamers:  $\frac{5}{32}$ -inch convex cutter

## Dimensions of Formed Reamer Fluting Cutters

The making and maintenance of cutters of the formed type involves greater expense than the use of angular cutters of which dimensions are given on the previous page; but the form of flute produced by the formed type of cutter is preferred by many reamer users. The claims made for the formed type of flute are that the chips can be more readily removed from the reamer, and that the reamer has greater strength and is less likely to crack or spring out of shape in hardening.

for  $\frac{1}{2}$ -inch reamers;  $\frac{5}{16}$ -inch cutter for 1-inch reamers;  $\frac{3}{8}$ -inch cutter for  $1\frac{1}{2}$ -inch reamers;  $\frac{13}{32}$ -inch cutters for 2-inch reamers; and  $\frac{15}{32}$ -inch cutters for  $2\frac{1}{2}$ -inch reamers. The smaller sizes of reamers, from  $\frac{1}{4}$  to  $\frac{3}{8}$  inch in diameter, are often milled with regular double-angle reamer fluting cutters having a radius of  $\frac{1}{64}$  inch for  $\frac{1}{4}$ -inch reamer, and  $\frac{1}{32}$  inch for  $\frac{5}{16}$ - and  $\frac{3}{8}$ -inch sizes.

**Reamer Terms and Definitions.**—*Reamer:* A rotary cutting tool with one or more cutting elements used for enlarging to size and contour a previously formed hole. Its principal support during the cutting action is obtained from the workpiece. (See Fig. 1.)

*Actual Size:* The actual measured diameter of a reamer, usually slightly larger than the nominal size to allow for wear.

*Angle Of Taper:* The included angle of taper on a taper tool or taper shank.

*Arbor Hole:* The central mounting hole in a shell reamer.

*Axis:* the imaginary straight line which forms the longitudinal centerline of a reamer, usually established by rotating the reamer between centers.

*Back Taper:* A slight decrease in diameter, from front to back, in the flute length of reamers.

*Bevel:* An unrelieved angular surface of revolution (not to be confused with chamfer).

*Body:* The fluted full diameter portion of a reamer, inclusive of the chamfer, starting taper, and bevel.

*Chamfer:* The angular cutting portion at the entering end of a reamer (see also *Secondary Chamfer*).

**Chamfer Angle:** The angle between the axis and the cutting edge of the chamfer measured in an axial plane at the cutting edge.

**Chamfer Length:** The length of the chamfer measured parallel to the axis at the cutting edge.

**Chamfer Relief Angle:** See under *Relief*.

**Chamfer Relief:** See under *Relief*.

**Chip Breakers:** Notches or grooves in the cutting edges of some taper reamers designed to break the continuity of the chips.

**Circular Land:** See preferred term *Margin*.

## Illustration of Terms Applying to Reamers

Hand Reamer

Machine Reamer

Straight Flutes

Hand Reamer, Pilot and Guide

Chucking Reamer, Straight and Taper Shank

**Clearance:** The space created by the relief behind the cutting edge or margin of a reamer.

**Core:** The central portion of a reamer below the flutes which joins the lands.

**Core Diameter:** The diameter at a given point along the axis of the largest circle which does not project into the flutes.

**Cutter Sweep:** The section removed by the milling cutter or grinding wheel in entering or leaving a flute.

**Cutting Edge:** The leading edge of the relieved land in the direction of rotation for cutting.

**Cutting Face:** The leading side of the relieved land in the direction of rotation for cutting on which the chip impinges.

**External Center:** The pointed end of a reamer. The included angle varies with manufacturing practice.

**Flutes:** Longitudinal channels formed in the body of the reamer to provide cutting edges, permit passage of chips, and allow cutting fluid to reach the cutting edges.

**Angular Flute:** A flute which forms a cutting face lying in a plane intersecting the reamer axis at an angle. It is unlike a helical flute in that it forms a cutting face which lies in a single plane.

**Helical Flute:** Sometimes called spiral flute, a flute which is formed in a helical path around the axis of a reamer.

**Spiral flute:** 1) On a taper reamer, a flute of constant lead; or, 2) in reference to a straight reamer, see preferred term helical flute.

**Straight Flute:** A flute which forms a cutting edge lying in an axial plane.

**Flute Length:** The length of the flutes not including the cutter sweep.

*Guide:* A cylindrical portion following the flutes of a reamer to maintain alignment.

*Heel:* The trailing edge of the land in the direction of rotation for cutting.

*Helix Angle:* The angle which a helical cutting edge at a given point makes with an axial plane through the same point.

*Hook:* A concave condition of a cutting face. The rake of a hooked cutting face must be determined at a given point.

*Internal Center:* A 60 degree countersink with clearance at the bottom, in one or both ends of a tool, which establishes the tool axis.

*Irregular Spacing:* A deliberate variation from uniform spacing of the reamer cutting edges.

*Land:* The section of the reamer between adjacent flutes.

*Land Width:* The distance between the leading edge of the land and the heel measured at a right angle to the leading edge.

*Lead of Flute:* The axial advance of a helical or spiral cutting edge in one turn around the reamer axis.

*Length:* The dimension of any reamer element measured parallel to the reamer axis.

*Limits:* The maximum and minimum values designated for a specific element.

*Margin:* The unrelieved part of the periphery of the land adjacent to the cutting edge.

*Margin Width:* The distance between the cutting edge and the primary relief measured at a right angle to the cutting edge.

*Neck:* The section of reduced diameter connecting shank to body, or connecting other portions of the reamer.

*Nominal Size:* The designated basic size of a reamer overall length—the extreme length of the complete reamer from end to end, but not including external centers or expansion screws.

*Periphery:* The outside circumference of a reamer.

*Pilot:* A cylindrical portion preceding the entering end of the reamer body to maintain alignment.

*Rake:* The angular relationship between the cutting face, or a tangent to the cutting face at a given point and a given reference plane or line.

*Axial Rake:* Applies to angular (not helical or spiral) cutting faces. It is the angle between a plane containing the cutting face, or tangent to the cutting face at a given point, and the reamer axis.

*Helical Rake:* Applies only to helical and spiral cutting faces (not angular). It is the angle between a plane, tangent to the cutting face at a given point on the cutting edge, and the reamer axis.

*Negative Rake:* Describes a cutting face in rotation whose cutting edge lags the surface of the cutting face.

*Positive Rake:* Describes a cutting face in rotation whose cutting edge leads the surface of the cutting face.

*Radial Rake Angle:* The angle in a transverse plane between a straight cutting face and a radial line passing through the cutting edge.

*Relief:* The result of the removal of tool material behind or adjacent to the cutting edge to provide clearance and prevent rubbing (heel drag).

*Axial Relief:* The relief measured in the axial direction between a plane perpendicular to the axis and the relieved surface. It can be measured by the amount of indicator drop at a given radius in a given amount of angular rotation.

*Cam Relief:* The relief from the cutting edge to the heel of the land produced by a cam action.

*Chamfer Relief Angle:* The axial relief angle at the outer corner of the chamfer. It is measured by projection into a plane tangent to the periphery at the outer corner of the chamfer.

*Chamfer Relief:* The axial relief on the chamfer of the reamer.

*Eccentric Relief:* A convex relieved surface behind the cutting edge.

*Flat Relief:* A relieved surface behind the cutting edge which is essentially flat.

*Radial Relief:* Relief in a radial direction measured in the plane of rotation. It can be measured by the amount of indicator drop at a given radius in a given amount of angular rotation.

*Primary Relief:* The relief immediately behind the cutting edge or margin. Properly called relief.

*Secondary Relief:* An additional relief behind the primary relief.

*Relief Angle:* The angle, measured in a transverse plane, between the relieved surface and a plane tangent to the periphery at the cutting edge.

*Secondary Chamfer:* A slight relieved chamfer adjacent to and following the initial chamfer on a reamer.

*Shank:* The portion of the reamer by which it is held and driven.

*Squared Shank:* A cylindrical shank having a driving square on the back end.

*Starting Radius:* A relieved radius at the entering end of a reamer in place of a chamfer.

*Starting Taper:* A slight relieved taper on the front end of a reamer.

*Straight Shank:* A cylindrical shank.

*Tang:* The flattened end of a taper shank which fits a slot in the socket.

*Taper per Foot:* The difference in diameter between two points 12 in. apart measured along the axis.

*Taper Shank:* A shank made to fit a specific (conical) taper socket.

**Direction of Rotation and Helix.**—The terms “right hand” and “left hand” are used to describe both direction of rotation and direction of flute helix or reamers.

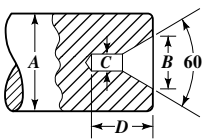

*Hand of Rotation (or Hand of Cut): Right-hand Rotation (or Right-hand Cut):* When viewed from the cutting end, the reamer must revolve counterclockwise to cut

*Left-hand Rotation (or Left-hand Cut):* When viewed from the cutting end, the reamer must revolve clockwise to cut

*Hand of Flute Helix: Right-hand Helix:* When the flutes twist away from the observer in a clockwise direction when viewed from either end of the reamer.

*Left-hand helix:* When the flutes twist away from the observer in a counterclockwise direction when viewed from either end of the reamer. The standard reamers on the tables that follow are all right-hand rotation.

All dimensions are given in inches. Material is high-speed steel. Reamers and countersinks have 3 or 4 flutes. Center reamers are standard with 60, 82, 90, or 100 degrees included angle. Machine countersinks are standard with either 60 or 82 degrees included angle.

**Tolerances:** On overall length A, the tolerance is  $\pm\frac{1}{8}$  inch for center reamers in a size range of from  $\frac{1}{4}$  to  $\frac{3}{8}$  inch, incl., and machine countersinks in a size range of from  $\frac{1}{2}$  to  $\frac{5}{8}$  inch, incl.;  $\pm\frac{3}{16}$  inch for center reamers,  $\frac{1}{2}$  to  $\frac{3}{4}$  inch, incl.; and machine countersinks,  $\frac{3}{4}$  to 1 inch, incl. On shank diameter D, the tolerance is  $-0.0005$  to  $-0.002$  inch. On shank length S, the tolerance is  $\pm\frac{1}{16}$  inch.

**Reamer Difficulties.**—Certain frequently occurring problems in reaming require remedial measures. These difficulties include the production of oversize holes, bellmouth holes, and holes with a poor finish. The following is taken from suggestions for correction of these difficulties by the National Twist Drill and Tool Co. and Winter Brothers Co.\*

**Oversize Holes:** The cutting of a hole oversize from the start of the reaming operations usually indicates a mechanical defect in the setup or reamer. Thus, the wrong reamer for the workpiece material may have been used or there may be inadequate workpiece support, inadequate or worn guide bushings, or misalignment of the spindles, bushings, or workpiece or runout of the spindle or reamer holder. The reamer itself may be defective due to chamfer runout or runout of the cutting end due to a bent or nonconcentric shank.

When reamers gradually start to cut oversize, it is due to pickup or galling, principally on the reamer margins. This condition is partly due to the workpiece material. Mild steels, certain cast irons, and some aluminum alloys are particularly troublesome in this respect.

Corrective measures include reducing the reamer margin widths to about 0.005 to 0.010 inch, use of hard case surface treatments on high-speed-steel reamers, either alone or in combination with black oxide treatments, and the use of a high-grade finish on the reamer faces, margins, and chamfer relief surfaces.

**Bellmouth Holes:** The cutting of a hole that becomes oversize at the entry end with the oversize decreasing gradually along its length always reflects misalignment of the cutting portion of the reamer with respect to the hole. The obvious solution is to provide improved guiding of the reamer by the use of accurate bushings and pilot surfaces. If this solution is not feasible, and the reamer is cutting in a vertical position, a flexible element may be employed to hold the reamer in such a way that it has both radial and axial float, with the hope that the reamer will follow the original hole and prevent the bellmouth condition.

In horizontal setups where the reamer is held fixed and the workpiece rotated, any misalignment exerts a sideways force on the reamer as it is fed to depth, resulting in the forma-

\*"Some Aspects of Reamer Design and Operation," *Metal Cuttings*, April 1963.

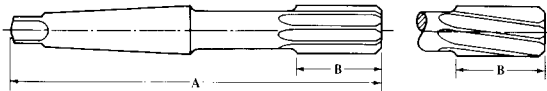

tion of a tapered hole. This type of bellmouthing can frequently be reduced by shortening the bearing length of the cutting portion of the reamer. One way to do this is to reduce the reamer diameter by 0.010 to 0.030 inch, depending on size and length, behind a short full-diameter section,  $\frac{1}{8}$  to  $\frac{1}{2}$  inch long according to length and size, following the chamfer. The second method is to grind a high back taper, 0.008 to 0.015 inch per inch, behind the short full-diameter section. Either of these modifications reduces the length of the reamer tooth that can cause the bellmouth condition.

**Poor Finish:** The most obvious step toward producing a good finish is to reduce the reamer feed per revolution. Feeds as low as 0.0002 to 0.0005 inch per tooth have been used successfully. However, reamer life will be better if the maximum feasible feed is used.

The minimum practical amount of reaming stock allowance will often improve finish by reducing the volume of chips and the resulting heat generated on the cutting portion of the chamfer. Too little reamer stock, however, can be troublesome in that the reamer teeth may not cut freely but will deflect or push the work material out of the way. When this happens, excessive heat, poor finish, and rapid reamer wear can occur.

Because of their superior abrasion resistance, carbide reamers are often used when fine finishes are required. When properly conditioned, carbide reamers can produce a large number of good-quality holes. Careful honing of the carbide reamer edges is very important.

<sup>a</sup> American National Standard self-holding tapers (see Table 7a on page 933.)

All dimensions are given in inches. Material is high-speed steel.

Helical flute reamers with right-hand helical flutes are standard.

**Tolerances:** On reamer diameter,  $\frac{1}{4}$ -inch size, +.0001 to +.0004 inch; over  $\frac{1}{4}$ - to 1-inch size, +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On length overall A and flute length B,  $\frac{1}{4}$ - to 1-inch size, incl.,  $\pm\frac{1}{16}$  inch;  $\frac{1}{16}$ - to  $1\frac{1}{2}$ -inch size, incl.,  $\frac{3}{32}$  inch.

**Expansion Chucking Reamers—Straight and Taper Shanks**

<sup>a</sup> Straight shank only.<sup>b</sup> Taper shank only.

All dimensions in inches. Material is high-speed steel. The number of flutes is as follows:  $\frac{3}{8}$ - to  $1\frac{5}{32}$ -inch sizes, 4 to 6;  $\frac{1}{2}$ - to  $3\frac{1}{32}$ -inch sizes, 6 to 8; 1- to  $1\frac{1}{16}$ -inch sizes, 8 to 10;  $1\frac{3}{4}$ - to  $1\frac{15}{16}$ -inch sizes, 8 to 12; 2- to  $2\frac{1}{4}$ -inch sizes, 10 to 12;  $2\frac{3}{8}$ - and  $2\frac{1}{2}$ -inch sizes, 10 to 14. The expansion feature of these reamers provides a means of adjustment that is important in reaming holes to close tolerances. When worn undersize, they may be expanded and reground to the original size.

**Tolerances:** On reamer diameter,  $\frac{3}{8}$ - to 1-inch sizes, incl., +0.0001 to +0.0005 inch; over 1-inch size, +0.0002 to +0.0006 inch. On length A and flute length B,  $\frac{3}{8}$ - to 1-inch sizes, incl.,  $\pm\frac{1}{16}$  inch;  $1\frac{1}{32}$ - to 2-inch sizes, incl.,  $\pm\frac{3}{32}$  inch; over 2-inch sizes,  $\pm\frac{1}{8}$  inch.

Taper is Morse taper: No. 1 for sizes  $\frac{3}{8}$  to  $1\frac{19}{32}$  inch, incl.; No. 2 for sizes  $\frac{5}{8}$  to  $2\frac{29}{32}$  inch, incl.; No. 3 for sizes  $1\frac{1}{16}$  to  $1\frac{1}{32}$  inch, incl.; No. 4 for sizes  $1\frac{1}{4}$  to  $1\frac{5}{8}$  inch, incl.; and No. 5 for sizes  $1\frac{3}{4}$  to  $2\frac{1}{2}$  inch, incl. For amount of taper, see [Table 1b](#) on page 928.

## Hand Reamers—Straight and Helical Flutes ANSI B94.2-1983 (R1988)

All dimensions in inches. Material is high-speed steel. The nominal shank diameter  $D$  is the same as the reamer diameter. Helical-flute hand reamers with left-hand helical flutes are standard. Reamers are tapered slightly on the end to facilitate proper starting.

**Tolerances:** On diameter of reamer, up to 1/4-inch size, incl., +.0001 to +.0004 inch; over 1/4- to 1-inch size, incl., +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On length overall  $A$  and flute length  $B$ , 1/8- to 1-inch size, incl.,  $\pm 1/16$  inch; 1 1/8- to 1 1/2-inch size, incl.,  $\pm 3/32$  inch. On length of square  $C$ , 1/8- to 1 inch size, incl.,  $\pm 1/32$  inch; 1 1/8- to 1 1/2-inch size, incl.,  $\pm 1/16$  inch. On shank diameter  $D$ , 1/8- to 1-inch size, incl.,  $-0.001$  to  $-0.005$  inch; 1 1/8- to 1 1/2-inch size, incl.,  $-0.0015$  to  $-0.006$  inch. On size of square, 1/8- to 1/2-inch size, incl.,  $-0.004$  inch; 7/32- to 1-inch size, incl.,  $-0.006$  inch; 1 1/8- to 1 1/2-inch size, incl.,  $-0.008$  inch.

All dimensions are given in inches. Material is carbon steel. Reamers with helical flutes that are left hand are standard. Expansion hand reamers are primarily designed for work where it is necessary to enlarge reamed holes by a few thousandths. The pilots and guides on these reamers are ground under-size for clearance. The maximum expansion on these reamers is as follows: .006 inch for the 1/4 to 7/16-inch sizes, .010 inch for the 1/2 to 7/8-inch sizes and .012 inch for the 1- to 1 1/4-inch sizes.

**Tolerances:** On length overall A and flute length B,  $\pm 1/16$  inch for 1/4- to 1-inch sizes,  $\pm 3/32$  inch for 1 1/8- to 1 1/4-inch sizes; on length of square C,  $\pm 1/32$  inch for 1/4- to 1-inch sizes,  $\pm 1/16$  inch for 1 1/8- to 1 1/4-inch sizes; on shank diameter D,  $-0.001$  to  $-0.005$  inch for 1/4- to 1-inch sizes,  $-0.0015$  to  $-0.006$  inch for 1 1/8- to 1 1/4-inch sizes; on size of square,  $-0.004$  inch for 1/4- to 1/2-inch sizes,  $-0.006$  inch for 9/16- to 1-inch sizes, and  $-0.008$  inch for 1 1/8- to 1 1/4-inch sizes.

<sup>a</sup> American National Standard self-holding tapers (Table 7a on page 933.)

All dimensions in inches. Material is high-speed steel.

**Tolerances:** On reamer diameter, 1/4-inch size, +.0001 to +.0004 inch; over 1/4- to 1-inch size, incl., +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On overall length A and length of flute B, 1/4- to 1-inch size, incl., ±1/16 inch; and 1 1/16- to 1 1/2-inch size, incl., ±3/32 inch.

## American National Standard Driving Slots and Lugs for Shell Reamers or Shell Reamer Arbors ANSI B94.2-1983 (R1988)

| Arbor Size No. | Fitting Reamer Sizes | Driving Slot |         | Lug on Arbor |         | Reamer Hole Dia. at Large End |

<sup>a</sup> Reamer with straight flutes is standard only.

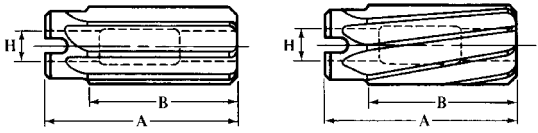

<sup>b</sup> Reamer with helical flutes is standard only.

All dimensions are given in inches. Material is high-speed steel. Chucking reamers are end cutting on the chamfer and the relief for the outside diameter is ground in back of the margin for the full length of land. Lands of rose chucking reamers are not relieved on the periphery but have a relatively large amount of back taper.

**Tolerances:** On reamer diameter, up to  $\frac{1}{4}$ -inch size, incl., +.0001 to +.0004 inch; over  $\frac{1}{4}$ - to 1-inch size, incl., +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On length overall *A* and flute length *B*, up to 1-inch size, incl.,  $\pm\frac{1}{16}$  inch;  $1\frac{1}{16}$ - to  $1\frac{1}{2}$ -inch size, incl.,  $\pm\frac{3}{32}$  inch.

Helical flutes are right- or left-hand helix, right-hand cut, except sizes  $1\frac{1}{16}$  through  $1\frac{1}{2}$  inches, which are right-hand helix only.

<sup>a</sup> Helical flutes only.

All dimensions are given in inches. Material is high-speed steel. Helical flute shell reamers with left-hand helical flutes are standard. Shell reamers are designed as a sizing or finishing reamer and are held on an arbor provided with driving lugs. The holes in these reamers are ground with a taper of  $\frac{1}{8}$  inch per foot.

**Tolerances:** On diameter of reamer,  $\frac{3}{4}$ - to 1-inch size, incl., +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On length overall *A* and flute length *B*,  $\frac{3}{4}$ - to 1-inch size, incl.,  $\pm\frac{1}{16}$  inch;  $1\frac{1}{16}$ - to 2-inch size, incl.,  $\pm\frac{3}{32}$  inch;  $2\frac{1}{16}$ - to  $2\frac{1}{2}$ -inch size, incl.,  $\pm\frac{1}{8}$  inch.

All dimensions in inches. Material is high-speed steel.

These reamers are standard with right-hand cut and left-hand helical flutes within the size ranges shown.

**Tolerances:** On diameter of reamer, for sizes 00 to 7, incl., plus .0001 to plus .0004 inch and for sizes 8 to 23, incl., plus .0001 to plus .0005 inch. On overall length A, plus or minus ⅞ inch. On length of flute B, plus or minus ⅞ inch. On diameter of shank D, minus .0005 to minus .002 inch.

<sup>a</sup>Morse. For amount of taper see [Table 1b](#) on page 928.

All dimensions are given in inches. Material is high-speed steel. The chamfer on the cutting end of the reamer is optional. Squared shank reamers are standard with straight flutes. Tapered shank reamers are standard with straight or spiral flutes. Spiral flute reamers are standard with left-hand spiral flutes.

**Tolerances:** On overall length *A* and flute length *B*, in taper numbers 0 to 3, incl.,  $\pm\frac{1}{16}$  inch, in taper numbers 4 and 5,  $\pm\frac{3}{32}$  inch. On length of square *C*, in taper numbers 0 to 3, incl.,  $\pm\frac{1}{32}$  inch; in taper numbers 4 and 5,  $\pm\frac{1}{16}$  inch. On shank diameter *D*,  $-.0005$  to  $-.002$  inch. On size of square, in taper numbers 0 and 1,  $-.004$  inch; in taper numbers 2 and 3,  $-.006$  inch; in taper numbers 4 and 5,  $-.008$  inch.

**Center Reamers.**—A “center reamer” is a reamer the teeth of which meet in a point. By their use small conical holes may be reamed in the ends of parts to be machined as on lathe centers. When large holes—usually cored—must be center-reamed, a large reamer is ordinarily used in which the teeth do not meet in a point, the reamer forming the frustum of a cone. Center reamers for such work are called “bull” or “pipe” center reamers.

**Bull Center Reamer:** A conical reamer used for reaming the ends of large holes—usually cored—so that they will fit on a lathe center. The cutting part of the reamer is generally in the shape of a frustum of a cone. It is also known as a pipe center reamer.

<sup>a</sup> For taper per foot, see Table 10 on page 936.

These reamers are no longer ANSI Standard.

All dimensions are given in inches. Material is high-speed steel. The chamfer on the cutting end of the reamer is optional. All reamers are finishing reamers. Spiral flute reamers are standard with left-hand spiral flutes. (Tapered reamers, especially those with left-hand spirals, should not have circular lands because cutting must take place on the outer diameter of the tool.) B & S taper reamers are designed for use in reaming out Brown & Sharpe standard taper sockets.

**Tolerances:** On length overall A and flute length B, taper nos. 1 to 7, incl., ±1/16 inch; taper nos. 8 to 10, incl., ±3/32 inch. On length of square C, taper nos. 1 to 9, incl., ±1/32 inch; taper no. 10, ±1/16 inch. On shank diameter D, - .0005 to - .002 inch. On size of square, taper nos. 1 to 3, incl., - .004 inch; taper nos. 4 to 9, incl., - .006 inch; taper no. 10, - .008 inch.

All dimensions in inches. Material is high-speed steel. These reamers are designed for use in die-making, have a taper of ¾ degree included angle or 0.013 inch per inch, and have 2 or 3 flutes. Reamers are standard with left-hand spiral flutes.

Tip of reamer may have conical end.

Tolerances: On length overall A and flute length B, ±1/16 inch.

<sup>a</sup> Not applicable to high-spiral flute reamers.

<sup>b</sup> Not applicable to straight and left-hand spiral fluted, squared shank reamers.

All dimensions in inches. Reamers have a taper of ¼ inch per foot and are made of high-speed steel. Straight flute reamers of carbon steel are also standard. The number of flutes is as follows; 3 or 4, for 7/0 to 4/0 sizes; 4 to 6, for 3/0 to 0 sizes; 5 or 6, for 1 to 5 sizes; 6 to 8, for 6 to 9 sizes; 7 or 8, for the 10 size in the case of straight- and spiral-flute reamers; and 2 or 3, for 8/0 to 8 sizes; 2 to 4, for the 9 and 10 sizes in the case of high-spiral flute reamers.

Tolerances: On length overall A and flute length B, ±1/16 inch. On length of square C, ±1/32 inch. On shank diameter D, -.001 to -.005 inch for straight- and spiral-flute reamers and -.0005 to -.002 inch for high-spiral flute reamers. On size of square, -.004 inch for 7/0 to 7 sizes and -.006 inch for 8 to 10 sizes.

## TWIST DRILLS AND COUNTERBORES

Twist drills are rotary end-cutting tools having one or more cutting lips and one or more straight or helical flutes for the passage of chips and cutting fluids. Twist drills are made with straight or tapered shanks, but most have straight shanks. All but the smaller sizes are ground with "back taper," reducing the diameter from the point toward the shank, to prevent binding in the hole when the drill is worn.

*Straight Shank Drills:* Straight shank drills have cylindrical shanks which may be of the same or of a different diameter than the body diameter of the drill and may be made with or without driving flats, tang, or grooves.

*Taper Shank Drills:* Taper shank drills are preferable to the straight shank type for drilling medium and large size holes. The taper on the shank conforms to one of the tapers in the American Standard (Morse) Series.

**American National Standard.**—American National Standard B94.11M-1993 covers nomenclature, definitions, sizes and tolerances for High Speed Steel Straight and Taper Shank Drills and Combined Drills and Countersinks, Plain and Bell types. It covers both inch and metric sizes. Dimensional tables from the Standard will be found on the following pages.

**Definitions of Twist Drill Terms.**—The following definitions are included in the Standard.

*Axis:* The imaginary straight line which forms the longitudinal center of the drill.

*Back Taper:* A slight decrease in diameter from point to back in the body of the drill.

*Body:* The portion of the drill extending from the shank or neck to the outer corners of the cutting lips.

*Body Diameter Clearance:* That portion of the land that has been cut away so it will not rub against the wall of the hole.

*Chisel Edge:* The edge at the ends of the web that connects the cutting lips.

*Chisel Edge Angle:* The angle included between the chisel edge and the cutting lip as viewed from the end of the drill.

*Clearance Diameter:* The diameter over the cutaway portion of the drill lands.

*Drill Diameter:* The diameter over the margins of the drill measured at the point.

*Flutes:* Helical or straight grooves cut or formed in the body of the drill to provide cutting lips, to permit removal of chips, and to allow cutting fluid to reach the cutting lips.

*Helix Angle:* The angle made by the leading edge of the land with a plane containing the axis of the drill.

*Land:* The peripheral portion of the drill body between adjacent flutes.

*Land Width:* The distance between the leading edge and the heel of the land measured at a right angle to the leading edge.

*Lips—Two Flute Drill:* The cutting edges extending from the chisel edge to the periphery.

*Lips—Three or Four Flute Drill (Core Drill):* The cutting edges extending from the bottom of the chamfer to the periphery.

*Lip Relief:* The axial relief on the drill point.

*Lip Relief Angle:* The axial relief angle at the outer corner of the lip. It is measured by projection into a plane tangent to the periphery at the outer corner of the lip. (Lip relief angle is usually measured across the margin of the twist drill.)

*Margin:* The cylindrical portion of the land which is not cut away to provide clearance.

*Neck:* The section of reduced diameter between the body and the shank of a drill.

*Overall Length:* The length from the extreme end of the shank to the outer corners of the cutting lips. It does not include the conical shank end often used on straight shank drills, nor does it include the conical cutting point used on both straight and taper shank drills. (For core drills with an external center on the cutting end it is the same as for two-flute

drills. For core drills with an internal center on the cutting end, the overall length is to the extreme ends of the tool.)

**Point:** The cutting end of a drill made up of the ends of the lands, the web, and the lips. In form, it resembles a cone, but departs from a true cone to furnish clearance behind the cutting lips.

**Point Angle:** The angle included between the lips projected upon a plane parallel to the drill axis and parallel to the cutting lips.

**Shank:** The part of the drill by which it is held and driven.

**Tang:** The flattened end of a taper shank, intended to fit into a driving slot in the socket.

**Tang Drive:** Two opposite parallel driving flats on the end of a straight shank.

**Web:** The central portion of the body that joins the end of the lands. The end of the web forms the chisel edge on a two-flute drill.

**Web Thickness:** The thickness of the web at the point unless another specific location is indicated.

**Web Thinning:** The operation of reducing the web thickness at the point to reduce drill-thrust.

ANSI Standard Twist Drill Nomenclature

**Types of Drills.**—Drills may be classified based on the type of shank, number of flutes or hand of cut.

**Straight Shank Drills:** Those having cylindrical shanks which may be the same or different diameter than the body of the drill. The shank may be with or without driving flats, tang, grooves, or threads.

**Taper Shank Drills:** Those having conical shanks suitable for direct fitting into tapered holes in machine spindles, driving sleeves, or sockets. Tapered shanks generally have a driving tang.

**Two-Flute Drills:** The conventional type of drill used for originating holes.

**Three-Flute Drills (Core Drills):** Drill commonly used for enlarging and finishing drilled, cast or punched holes. They will not produce original holes.

**Four-Flute Drills (Core Drills):** Used interchangeably with three-flute drills. They are of similar construction except for the number of flutes.

**Right-Hand Cut:** When viewed from the cutting point, the counterclockwise rotation of a drill in order to cut.

**Left-Hand Cut:** When viewed from the cutting point, the clockwise rotation of a drill in order to cut.

**Teat Drill:** The cutting edges of a teat drill are at right angles to the axis, and in the center there is a small teat of pyramid shape which leads the drill and holds it in position. This form is used for squaring the bottoms of holes made by ordinary twist drills or for drilling the entire hole, especially if it is not very deep and a square bottom is required. For instance, when drilling holes to form clearance spaces at the end of a keyseat, preparatory to cutting it out by planing or chipping, the teat drill is commonly used.

TWIST DRILLS

**Table 1. ANSI Straight Shank Twist Drills — Jobbers Length through 17.5 mm, Taper Length through 12.7 mm, and Screw Machine Length through 25.4 mm Diameter ANSI/ASME B94.11M-1993**

| Drill Diameter, $D^{\circ}$ |      |             |       | Jobbers Length |     |         |    | Taper Length |     |         |     | Screw Machine Length |     |         |    |

<sup>a</sup>Fractional inch, number, letter, and metric sizes.

## TWIST DRILLS

Nominal Shank Size is Same as Nominal Drill Size

**Table 2. ANSI Straight Shank Twist Drills — Taper Length — Over ½ in. (12.7 mm) Dia., Fractional and Metric Sizes ANSI/ASME B94.11M-1993**

| Diameter of Drill |       |             |            | Flute Length |     | Overall Length |     | Length of Body |     | Minimum Length of Shk. |    | Maximum Length of Neck |    |
|-------------------|-------|-------------|------------|--------------|-----|----------------|-----|----------------|-----|------------------------|----|------------------------|----|
| D                 |       | Decimal     | Millimeter | F            |     | L              |     | B              |     | S                      |    | N                      |    |
| Frac.             | mm    | Inch Equiv. | Equiv.     | Inch         | mm  | Inch           | mm  | Inch           | mm  | Inch                   | mm | Inch                   | mm |
| 33/64             | 12.80 | 0.5039      | 12.800     | 4 3/4        | 121 | 8              | 203 | 4 7/8          | 124 | 2 3/8                  | 66 | 1/2                    | 13 |

<sup>a</sup> Taper rate in accordance with ANSI/ASME B5.10-1994 (R2002), Machine Tapers.

<sup>b</sup> Size 0 is not an American National Standard but is included here to meet special needs.

All dimensions are in inches.

TWIST DRILLS

**Table 9. ANSI Three- and Four-Flute Straight Shank Core Drills — Fractional Sizes Only ANSI/ASME B94.11M-1993**

Nominal Shank Size is same as Nominal Drill Size

| Drill Diameter, <i>D</i> |              |        | Three-Flute Drills |     |                |     | Four-Flute Drills |     |                |     |
|--------------------------|--------------|--------|--------------------|-----|----------------|-----|-------------------|-----|----------------|-----|

**British Standard Combined Drills and Countersinks (Center Drills).**—BS 328: Part 2: 1972 (1990) provides dimensions of combined drills and countersinks for center holes. Three types of drill and countersink combinations are shown in this standard but are not given here. These three types will produce center holes without protecting chamfers, with protecting chamfers, and with protecting chamfers of radius form.

**Drill Drivers—Split-Sleeve, Collet Type.**—American National Standard ANSI B94.35-1972 (R1995) covers split-sleeve, collet-type drivers for driving straight shank drills, reamers, and similar tools, without tangs from 0.0390-inch through 0.1220-inch diameter, and with tangs from 0.1250-inch through 0.7500-inch diameter, including metric sizes.

For sizes 0.0390 through 0.0595 inch, the standard taper number is 1 and the optional taper number is 0. For sizes 0.0610 through 0.1875 inch, the standard taper number is 1, first optional taper number is 0, and second optional taper number is 2. For sizes 0.1890 through 0.2520 inch, the standard taper number is 1, first optional taper number is 2, and second optional taper number is 0. For sizes 0.2570 through 0.3750 inch, the standard taper number is 1 and the optional taper number is 2. For sizes 0.3860 through 0.5625 inch, the standard taper number is 2 and the optional taper number is 3. For sizes 0.5781 through 0.7500 inch, the standard taper number is 3 and the optional taper number is 4.

The depth  $B$  that the drill enters the driver is 0.44 inch for sizes 0.0390 through 0.0781 inch; 0.50 inch for sizes 0.0785 through 0.0938 inch; 0.56 inch for sizes 0.0960 through 0.1094 inch; 0.62 inch for sizes 0.1100 through 0.1220 inch; 0.75 inch for sizes 0.1250 through 0.1875 inch; 0.88 inch for sizes 0.1890 through 0.2500 inch; 1.00 inch for sizes 0.2520 through 0.3125 inch; 1.12 inches for sizes 0.3160 through 0.3750 inch; 1.25 inches for sizes 0.3860 through 0.4688 inch; 1.31 inches for sizes 0.4844 through 0.5625 inch; 1.47 inches for sizes 0.5781 through 0.6562 inch; and 1.62 inches for sizes 0.6719 through 0.7500 inch.

**British Standard Metric Twist Drills.**—BS 328: Part 1:1959 (incorporating amendments issued March 1960 and March 1964) covers twist drills made to inch and metric dimensions that are intended for general engineering purposes. ISO recommendations are taken into account. The accompanying tables give the standard metric sizes of Morse taper shank twist drills and core drills, parallel shank jobbing and long series drills, and stub drills.

All drills are right-hand cutting unless otherwise specified, and normal, slow, or quick helix angles may be provided. A “back-taper” is ground on the diameter from point to shank to provide longitudinal clearance. Core drills may have three or four flutes, and are intended for opening up cast holes or enlarging machined holes, for example. The parallel shank jobber, and long series drills, and stub drills are made without driving tenons.

Morse taper shank drills with oversize dimensions are also listed, and [Table 11](#) shows metric drill sizes superseding gage and letter size drills, which are now obsolete in Britain. To meet special requirements, the Standard lists nonstandard sizes for the various types of drills.

The limits of tolerance on cutting diameters, as measured across the lands at the outer corners of a drill, shall be  $h8$ , in accordance with BS 1916, Limits and Fits for Engineering (Part I, Limits and Tolerances), and [Table 14](#) shows the values common to the different types of drills mentioned before.

The drills shall be permanently and legibly marked whenever possible, preferably by rolling, showing the size, and the manufacturer's name or trademark. If they are made from high-speed steel, they shall be marked with the letters H.S. where practicable.

*Drill Elements:* The following definitions of drill elements are given.

*Axis:* The longitudinal center line.

*Body:* That portion of the drill extending from the extreme cutting end to the commencement of the shank.

*Shank:* That portion of the drill by which it is held and driven.

*Flutes:* The grooves in the body of the drill that provide lips and permit the removal of chips and allow cutting fluid to reach the lips.

*Web (Core):* The central portion of the drill situated between the roots of the flutes and extending from the point end toward the shank; the point end of the web or core forms the chisel edge.

*Lands:* The cylindrical-ground surfaces on the leading edges of the drill flutes. The width of the land is measured at right angles to the flute helix.

*Body Clearance:* The portion of the body surface that is reduced in diameter to provide diametral clearance.

*Heel:* The edge formed by the intersection of the flute surface and the body clearance.

*Point:* The sharpened end of the drill, consisting of all that part of the drill that is shaped to produce lips, faces, flanks, and chisel edge.

*Face:* That portion of the flute surface adjacent to the lip on which the chip impinges as it is cut from the work.

*Flank:* The surface on a drill point that extends behind the lip to the following flute.

*Lip (Cutting Edge):* The edge formed by the intersection of the flank and face.

*Relative Lip Height:* The relative position of the lips measured at the outer corners in a direction parallel to the drill axis.

*Outer Corner:* The corner formed by the intersection of the lip and the leading edge of the land.

*Chisel Edge:* The edge formed by the intersection of the flanks.

*Chisel Edge Corner:* The corner formed by the intersection of a lip and the chisel edge.

**Table 11. British Standard Drills — Metric Sizes Superseding Gauge and Letter Sizes BS 328: Part 1:1959, Appendix B**

| Obsolete Drill Size | Recommended Metric Size (mm) | Obsolete Drill Size | Recommended Metric Size (mm) | Obsolete Drill Size | Recommended Metric Size (mm) | Obsolete Drill Size | Recommended Metric Size (mm) | Obsolete Drill Size | Recommended Metric Size (mm) |
|---------------------|------------------------------|---------------------|------------------------------|---------------------|------------------------------|---------------------|------------------------------|---------------------|------------------------------|
| 80                  | 0.35                         | 58                  | 1.05                         | 36                  | 2.70                         | 14                  | 4.60                         | I                   | 6.90                         |

Gauge and letter size drills are now obsolete in the United Kingdom and should not be used in the production of new designs. The table is given to assist users in changing over to the recommended standard sizes.

**Table 12. British Standard Morse Taper Shank Twist Drills and Core Drills — Standard Metric Sizes BS 328: Part 1:1959**

| Diameter | Flute Length | Overall Length | Diameter | Flute Length | Overall Length | Diameter | Flute Length | Overall Length |
|----------|--------------|----------------|----------|--------------|----------------|----------|--------------|----------------|
| 3.00     | 33           | 114            | 16.75    |              |                | 30.25    |              |                |
| 3.20     | 36           | 117            | 17.00    | 125          | 223            | 30.50    |              |                |

| 71.00    |              |                | 86.00    |              |                |          |              |                |
| 72.00    |              |                | 87.00    |              |                |          |              |                |
| 73.00    | 255          | 442            | 88.00    | 270          | 524            |          | 280          | 534            |
| 74.00    |              |                | 89.00    |              |                |          |              |                |
| 75.00    |              |                | 90.00    |              |                |          |              |                |

All dimensions are in millimeters. Tolerances on diameters are given in the table below.

Table 13, shows twist drills that may be supplied with the shank and length oversize, but they should be regarded as nonpreferred.

The Morse taper shanks of these twist and core drills are as follows: 3.00 to 14.00 mm diameter, M.T. No. 1; 14.25 to 23.00 mm diameter, M.T. No. 2; 23.25 to 31.50 mm diameter, M.T. No. 3; 31.75 to 50.50 mm diameter, M.T. No. 4; 51.00 to 76.00 mm diameter, M.T. No. 5; 77.00 to 100.00 mm diameter, M.T. No. 6.

**Table 13. British Standard Morse Taper Shank Twist Drills — Metric Oversize Shank and Length Series BS 328: Part 1:1959**

| Dia. Range     | Overall Length | M. T. No. | Dia. Range     | Overall Length | M. T. No. | Dia. Range     | Overall Length | M. T. No. |
|----------------|----------------|-----------|----------------|----------------|-----------|----------------|----------------|-----------|
| 12.00 to 13.20 | 199            | 2         | 22.50 to 23.00 | 276            | 3         | 45.50 to 47.50 | 402            | 5         |
| 13.50 to 14.00 | 206            | 2         | 26.75 to 28.00 | 319            | 4         | 48.00 to 50.00 | 407            | 5         |
| 18.25 to 19.00 | 256            | 3         | 29.00 to 30.00 | 324            | 4         | 50.50          | 412            | 5         |
| 19.25 to 20.00 | 251            | 3         | 30.25 to 31.50 | 329            | 4         | 64.00 to 67.00 | 499            | 6         |
| 20.25 to 21.00 | 266            | 3         | 40.50 to 42.50 | 392            | 5         | 68.00 to 71.00 | 504            | 6         |
| 21.25 to 22.25 | 271            | 3         | 43.00 to 45.00 | 397            | 5         | 72.00 to 75.00 | 509            | 6         |

Diameters and lengths are given in millimeters. For the individual sizes within the diameter ranges given, see Table 12.

This series of drills should be regarded as non-preferred.

**Table 14. British Standard Limits of Tolerance on Diameter for Twist Drills and Core Drills — Metric Series BS 328: Part 1:1959**

| Drill Size<br>(Diameter measured across lands at outer corners) | Tolerance (h8)            |
|---|---------------------------|
| 0 to 1 inclusive  | Plus 0.000 to Minus 0.014 |
| Over 1 to 3 inclusive   | Plus 0.000 to Minus 0.014 |
| Over 3 to 6 inclusive   | Plus 0.000 to Minus 0.018 |
| Over 6 to 10 inclusive  | Plus 0.000 to Minus 0.022 |
| Over 10 to 18 inclusive   | Plus 0.000 to Minus 0.027 |
| Over 18 to 30 inclusive   | Plus 0.000 to Minus 0.033 |
| Over 30 to 50 inclusive   | Plus 0.000 to Minus 0.039 |
| Over 50 to 80 inclusive   | Plus 0.000 to Minus 0.046 |
| Over 80 to 120 inclusive  | Plus 0.000 to Minus 0.054 |

All dimensions are given in millimeters.

| 4.80     | 26           | 62             | 9.20     |              |                | 13.80    | 54           | 107            | 25.00    |              |                |

All dimensions are given in millimeters. Tolerances on diameters are given in Table 14.

**Steels for Twist Drills.**—Twist drill steels need good toughness, abrasion resistance, and ability to resist softening due to heat generated by cutting. The amount of heat generated indicates the type of steel that should be used.

*Carbon Tool Steel* may be used where little heat is generated during drilling.

*High-Speed Steel* is preferred because of its combination of red hardness and wear resistance, which permit higher operating speeds and increased productivity. Optimum properties can be obtained by selection of alloy analysis and heat treatment.

*Cobalt High-Speed Steel* alloys have higher red hardness than standard high-speed steels, permitting drilling of materials such as heat-resistant alloys and materials with hardness greater than Rockwell 38 C. These high-speed drills can withstand cutting speeds beyond the range of conventional high-speed-steel drills and have superior resistance to abrasion but are not equal to tungsten-carbide tipped tools.

**Accuracy of Drilled Holes.**—Normally the diameter of drilled holes is not given a tolerance; the size of the hole is expected to be as close to the drill size as can be obtained.

The accuracy of holes drilled with a two-fluted twist drill is influenced by many factors, which include: the accuracy of the drill point; the size of the drill; length and shape of the chisel edge; whether or not a bushing is used to guide the drill; the work material; length of the drill; runout of the spindle and the chuck; rigidity of the machine tool, workpiece, and the setup; and also the cutting fluid used, if any.

The diameter of the drilled holes will be oversize in most materials. The table *Oversize Diameters in Drilling* on page 885 provides the results of tests reported by The United States Cutting Tool Institute in which the diameters of over 2800 holes drilled in steel and cast iron were measured. The values in this table indicate what might be expected under average shop conditions; however, when the drill point is accurately ground and the other machining conditions are correct, the resulting hole size is more likely to be between the mean and average minimum values given in this table. If the drill is ground and used incorrectly, holes that are even larger than the average maximum values can result.

## Oversize Diameters in Drilling

| Drill Dia.,<br>Inch | Amount Oversize, Inch |        |              | Drill Dia.,<br>Inch | Amount Oversize, Inch |       |              |
|---------------------|-----------------------|--------|--------------|---------------------|-----------------------|-------|--------------|
|                     | Average Max.          | Mean   | Average Min. |                     | Average Max.          | Mean  | Average Min. |
| $\frac{1}{16}$      | 0.002                 | 0.0015 | 0.001        | $\frac{1}{2}$       | 0.008                 | 0.005 | 0.003        |
| $\frac{1}{8}$       | 0.0045                | 0.003  | 0.001        | $\frac{3}{4}$       | 0.008                 | 0.005 | 0.003        |
| $\frac{1}{4}$       | 0.0065                | 0.004  | 0.0025       | 1                   | 0.009                 | 0.007 | 0.004        |

Some conditions will cause the drilled hole to be undersize. For example, holes drilled in light metals and in other materials having a high coefficient of thermal expansion such as plastics, may contract to a size that is smaller than the diameter of the drill as the material surrounding the hole is cooled after having been heated by the drilling. The elastic action of the material surrounding the hole may also cause the drilled hole to be undersize when drilling high strength materials with a drill that is dull at its outer corner.

The accuracy of the drill point has a great effect on the accuracy of the drilled hole. An inaccurately ground twist drill will produce holes that are excessively over-size. The drill point must be symmetrical; i.e., the point angles must be equal, as well as the lip lengths and the axial height of the lips. Any alterations to the lips or to the chisel edge, such as thinning the web, must be done carefully to preserve the symmetry of the drill point. Adequate relief should be provided behind the chisel edge to prevent heel drag. On conventionally ground drill points this relief can be estimated by the chisel edge angle.

When drilling a hole, as the drill point starts to enter the workpiece, the drill will be unstable and will tend to wander. Then as the body of the drill enters the hole the drill will tend to stabilize. The result of this action is a tendency to drill a bellmouth shape in the hole at the entrance and perhaps beyond. Factors contributing to bellmouthing are: an unsymmetrically ground drill point; a large chisel edge length; inadequate relief behind the chisel edge; runout of the spindle and the chuck; using a slender drill that will bend easily; and lack of rigidity of the machine tool, workpiece, or the setup. Correcting these conditions as required will reduce the tendency for bellmouthing to occur and improve the accuracy of the hole diameter and its straightness. Starting the hole with a short stiff drill, such as a center drill, will quickly stabilize the drill that follows and reduce or eliminate bellmouthing; this procedure should always be used when drilling in a lathe, where the work is rotating. Bellmouthing can also be eliminated almost entirely and the accuracy of the hole improved by using a close fitting drill jig bushing placed close to the workpiece. Although specific recommendations cannot be made, many cutting fluids will help to increase the accuracy of the diameters of drilled holes. Double margin twist drills, available in the smaller sizes, will drill a more accurate hole than conventional twist drills having only a single margin at the leading edge of the land. The second land, located on the trailing edge of each land, provides greater stability in the drill bushing and in the hole. These drills are especially useful in drilling intersecting off-center holes. Single and double margin step drills, also available in the smaller sizes, will produce very accurate drilled holes, which are usually less than 0.002 inch larger than the drill size.

**Counterboring.**—Counterboring (called spot-facing if the depth is shallow) is the enlargement of a previously formed hole. Counterbores for screw holes are generally made in sets. Each set contains three counterbores: one with the body of the size of the screw head and the pilot the size of the hole to admit the body of the screw; one with the body the size of the head of the screw and the pilot the size of the tap drill; and the third with the body the size of the body of the screw and the pilot the size of the tap drill. Counterbores are usually provided with helical flutes to provide positive effective rake on the cutting edges. The four flutes are so positioned that the end teeth cut ahead of center to provide a shearing action and eliminate chatter in the cut. Three designs are most common: solid, two-piece, and three-piece. Solid designs have the body, cutter, and pilot all in one piece. Two-piece designs have an integral shank and counterbore cutter, with an interchangeable pilot, and provide true concentricity of the cutter diameter with the shank, but allowing use of various

pilot diameters. Three-piece counterbores have separate holder, counterbore cutter, and pilot, so that a holder will take any size of counterbore cutter. Each counterbore cutter, in turn, can be fitted with any suitable size diameter of pilot. Counterbores for brass are fluted straight.

### Counterbores with Interchangeable Cutters and Guides

| No. of Holder | No. of Morse Taper Shank | Range of Cutter Diameters, A      | Range of Pilot Diameters, B      | Total Length, C | Length of Cutter Body, D | Length of Pilot, E | Dia. of Shank, F |
|---------------|--------------------------|-----------------------------------|----------------------------------|-----------------|--------------------------|--------------------|------------------|
| 1             | 1 or 2                   | $\frac{3}{4}$ - $1\frac{1}{16}$   | $\frac{1}{2}$ - $\frac{3}{4}$    | $7\frac{1}{4}$  | 1                        | $\frac{5}{8}$      | $\frac{3}{4}$    |
| 2             | 2 or 3                   | $1\frac{1}{16}$ - $1\frac{9}{16}$ | $1\frac{1}{16}$ - $1\frac{1}{8}$ | $9\frac{1}{2}$  | $1\frac{3}{8}$           | $\frac{7}{8}$      | $1\frac{1}{8}$   |
| 3             | 3 or 4                   | $1\frac{5}{8}$ - $2\frac{1}{16}$  | $\frac{7}{8}$ - $1\frac{5}{8}$   | $12\frac{1}{2}$ | $1\frac{3}{4}$           | $1\frac{1}{8}$     | $1\frac{5}{8}$   |
| 4             | 4 or 5                   | $2\frac{1}{8}$ - $3\frac{1}{2}$   | $1$ - $2\frac{1}{8}$             | 15              | $2\frac{1}{4}$           | $1\frac{3}{8}$     | $2\frac{1}{8}$   |

### Solid Counterbores with Integral Pilot

| Counterbore Diameters | Pilot Diameters |                 |                 | Straight Shank Diameter | Overall Length |                |
|-----------------------|-----------------|-----------------|-----------------|-------------------------|----------------|----------------|
|                       | Nominal         | $+\frac{1}{64}$ | $+\frac{1}{32}$ |                         | Short          | Long           |
| $\frac{13}{32}$       | $\frac{1}{4}$   | $\frac{17}{64}$ | $\frac{9}{32}$  | $\frac{3}{8}$           | $3\frac{1}{2}$ | $5\frac{1}{2}$ |
| $\frac{1}{2}$         | $\frac{5}{16}$  | $\frac{21}{64}$ | $\frac{11}{32}$ | $\frac{3}{8}$           | $3\frac{1}{2}$ | $5\frac{1}{2}$ |
| $\frac{19}{32}$       | $\frac{3}{8}$   | $\frac{25}{64}$ | $\frac{13}{32}$ | $\frac{1}{2}$           | 4              | 6              |
| $1\frac{1}{16}$       | $\frac{7}{16}$  | $\frac{29}{64}$ | $\frac{15}{32}$ | $\frac{1}{2}$           | 4              | 6              |

All dimensions are in inches.

Small counterbores are often made with three flutes, but should then have the size plainly stamped on them before fluting, as they cannot afterwards be conveniently measured. The flutes should be deep enough to come below the surface of the pilot. The counterbore should be relieved on the end of the body only, and not on the cylindrical surface. To facilitate the relieving process, a small neck is turned between the guide and the body for clearance. The amount of clearance on the cutting edges is, for general work, from 4 to 5 degrees. The accompanying table gives dimensions for straight shank counterbores.

**Three Piece Counterbores.**—Data shown for the first two styles of counterbores are for straight shank designs. These tools are also available with taper shanks in most sizes. Sizes of taper shanks for cutter diameters of  $\frac{1}{4}$  to  $\frac{9}{16}$  in. are No. 1, for  $\frac{19}{32}$  to  $\frac{7}{8}$  in., No. 2; for  $\frac{15}{16}$  to  $1\frac{3}{8}$  in., No. 3; for  $1\frac{1}{2}$  to 2 in., No. 4; and for  $2\frac{1}{2}$  to  $2\frac{1}{2}$  in., No. 5.

**Counterbore Sizes for Hex-head Bolts and Nuts.**—Table 2, page 1531, shows the maximum socket wrench dimensions for standard  $\frac{1}{4}$ -,  $\frac{1}{2}$ - and  $\frac{3}{4}$ -inch drive socket sets. For a given socket size (nominal size equals the maximum width across the flats of nut or bolt head), the dimension *K* given in the table is the minimum counterbore diameter required to provide socket wrench clearance for access to the bolt or nut.

**Sintered Carbide Boring Tools.**—Industrial experience has shown that the shapes of tools used for boring operations need to be different from those of single-point tools ordinarily used for general applications such as lathe work. Accordingly, Section 5 of American National Standard ANSI B212.1-2002 gives standard sizes, styles and designations for four basic types of sintered carbide boring tools, namely: solid carbide square; carbide-tipped square; solid carbide round; and carbide-tipped round boring tools. In addition to these ready-to-use standard boring tools, solid carbide round and square unsharpened boring tool bits are provided.

*Style Designations for Carbide Boring Tools:* Table 1 shows designations used to specify the styles of American Standard sintered carbide boring tools. The first letter denotes solid (S) or tipped (T). The second letter denotes square (S) or round (R). The side cutting edge angle is denoted by a third letter (A through H) to complete the style designation. Solid square and round bits with the mounting surfaces ground but the cutting edges unsharpened (Table 3) are designated using the same system except that the third letter indicating the side cutting edge angle is omitted.

**Table 1. American National Standard Sintered Carbide Boring Tools — Style Designations ANSI B212.1-2002**

| Side Cutting Edge Angle <i>E</i> |             | Boring Tool Styles |                    |                  |                   |
|----------------------------------|-------------|--------------------|--------------------|------------------|-------------------|
| Degrees                          | Designation | Solid Square (SS)  | Tipped Square (TS) | Solid Round (SR) | Tipped Round (TR) |
| 0                                | A           |                    | TSA                |                  |                   |
| 10                               | B           |                    | TSB                |                  |                   |
| 30                               | C           | SSC                | TSC                | SRC              | TRC               |
| 40                               | D           |                    | TSD                |                  |                   |
| 45                               | E           | SSE                | TSE                | SRE              | TRE               |
| 55                               | F           |                    | TSF                |                  |                   |
| 90 (0° Rake)                     | G           |                    |                    |                  | TRG               |
| 90 (10° Rake)                    | H           |                    |                    |                  | TRH               |

*Size Designation of Carbide Boring Tools:* Specific sizes of boring tools are identified by the addition of numbers after the style designation. The first number denotes the diameter or square size in number of  $\frac{1}{32}$ nds for types SS and SR and in number of  $\frac{1}{16}$ ths for types TS and TR. The second number denotes length in number of 1/8ths for types SS and SR. For styles TRG and TRH, a letter "U" after the number denotes a semi-finished tool (cutting edges unsharpened). Complete designations for the various standard sizes of carbide boring tools are given in Tables 2 through 7. In the diagrams in the tables, angles shown without tolerance are  $\pm 1^\circ$ .

*Examples of Tool Designation:* The designation TSC-8 indicates: a carbide-tipped tool (T); square cross-section (S); 30-degree side cutting edge angle (C); and  $\frac{8}{16}$  or  $\frac{1}{2}$  inch square size (8).

The designation SRE-66 indicates: a solid carbide tool (S); round cross-section (R); 45 degree side cutting edge angle (E);  $\frac{6}{32}$  or  $\frac{3}{16}$  inch diameter (6); and  $\frac{6}{8}$  or  $\frac{3}{4}$  inch long (6).

The designation SS-610 indicates: a solid carbide tool (S); square cross-section (S);  $\frac{6}{32}$  or  $\frac{3}{16}$  inch square size (6);  $\frac{10}{8}$  or  $1\frac{1}{4}$  inches long (10).

It should be noted in this last example that the absence of a third letter (from A to H) indicates that the tool has its mounting surfaces ground but that the cutting edges are unsharpened.

**Table 2. ANSI Carbide-Tipped Round General-Purpose Square-End Boring Tools Style TRG with 0° Rake and Style TRH with 10° Rake ANSI B212.1-2002**

| Tool Designation |                            | Shank Dimensions, Inches |          |                  |               |                  | Rake Angle Deg. | Tip No. | Tip Dimensions, Inches |      |     |

**Boring Machines, Origin.**—The first boring machine was built by John Wilkinson, in 1775. Smeaton had built one in 1769 which had a large rotary head, with inserted cutters, carried on the end of a light, overhanging shaft. The cylinder to be bored was fed forward against the cutter on a rude carriage, running on a track laid in the floor. The cutter head followed the inaccuracies of the bore, doing little more than to smooth out local roughness of the surface. Watt's first steam cylinders were bored on this machine and he complained that one, 18 inches in diameter, was  $\frac{3}{8}$  inch out of true. Wilkinson thought of the expedient, which had escaped both Smeaton and Watt, of extending the boring-bar completely through the cylinder and giving it an out-board bearing, at the same time making it much larger and stiffer. With this machine cylinders 57 inches in diameter were bored which were within  $\frac{1}{16}$  inch of true. Its importance can hardly be overestimated as it insured the commercial success of Watt's steam engine which, up to that time, had not passed the experimental stage.

## TAPS AND THREADING DIES

## Taps

General dimensions and tap markings given in the ASME B94.9 Standard for straight fluted taps, spiral pointed taps, spiral pointed only taps, spiral fluted taps, fast spiral fluted taps, thread forming taps, pulley taps, nut taps, and pipe taps are shown in the tables on the pages that follow. This Standard also gives the thread limits for taps with cut threads and ground threads. The thread limits for cut thread and ground thread taps for screw threads are given in [Tables 1](#) through [5](#) and [Tables 4a](#) and [4b](#); thread limits for cut thread and ground thread taps for pipe threads are given in [Tables 6a](#) through [7c](#). Taps recommended for various classes of Unified screw threads are given in [Tables 8a](#) through [11](#) in numbered sizes and [Table 9](#) for nuts in fractional sizes.

**Types of Taps.**—Taps included in ASME B94.9 are categorized either by the style of fluting or by the specific application for which the taps are designed. The following types 1 through 6 are generally short in length, and were originally called “Hand Taps” but this design is generally used in machine applications. The remaining types have special lengths, which are detailed in the tables.

The thread size specifications for these types may be fractional or machine screw inch sizes, or metric sizes. The thread form may be ground or cut (unground) as further defined in each table. Additionally, the cutting chamfer on the thread may be Bottoming (B), Plug (P), or Taper (T).

(1) *Straight Flute Taps:* These taps have straight flutes of a number specified as either standard or optional, and are for general purpose applications.

(2) *Spiral Pointed Taps:* These taps have straight flutes and the cutting face of the first few threads is ground at an angle to force the chips ahead and prevent clogging in the flutes.

(3) *Spiral Pointed Only Taps:* These taps are made with the spiral point feature only without longitudinal flutes. These taps are especially suitable for tapping thin materials.

(4) *Spiral Fluted Taps:* These taps have right-hand helical flutes with a helix angle of 25 to 35 deg. These features are designed to help draw chips from the hole or to bridge a keyway.

(5) *Fast Spiral Fluted Taps:* These taps are similar to spiral fluted taps, except the helix angle is from 45 to 60 deg.

(6) *Thread Forming Taps:* These taps are fluteless except as optionally designed with one or more lubricating grooves. The thread form on the tap is lobed, so that there are a finite number of points contacting the work thread form. The tap does not cut, but forms the thread by extrusion.

(7) *Pulley Taps:* These taps have shanks that are extended in length by a standard amount for use where added reach is required. The shank is the same nominal diameter as the thread.

(8) *Nut Taps:* These taps are designed for tapping nuts on a low-production basis. Approximately one-half to three-quarters of the threaded portion has a chamfered section, which distributes the cutting over many teeth and facilitates entering the hole to be tapped. The length overall, the length of the thread, and the length of the shank are appreciably longer than on a regular straight fluted tap. Nut taps have been removed from ASME B94.9 but are retained for reference.

(9) *Pipe Taps:* These taps are used to produce standard straight or tapered pipe threads.

**Definitions of Tap Terms.**—The definitions that follow are taken from ASME B94.9 but include only the more important terms. Some tap terms are the same as screw thread terms; therefore, see *Definitions of Screw Threads* starting on page [1727](#).

*Back Taper:* A gradual decrease in the diameter of the thread form on a tap from the chamfered end of the land toward the back, which creates a slight radial relief in the threads.

**Base of Thread:** Coincides with the cylindrical or conical surface from which the thread projects.

**Chamfer:** Tapering of the threads at the front end of each land or chaser of a tap by cutting away and relieving the crest of the first few teeth to distribute the cutting action over several teeth.

**Chamfer Angle:** Angle formed between the chamfer and the axis of the tap measured in an axial plane at the cutting edge.

**Chamfer Relief Angle:** Complement of the angle formed between a tangent to the relieved surface at the cutting edge and a radial line to the same point on the cutting edge.

**Core Diameter:** Diameter of a circle which is tangent to the bottom of the flutes at a given point on the axis.

**First Full Thread:** First full thread on the cutting edge back of the chamfer. It is at this point that rake, hook, and thread elements are measured.

**Crest Clearance:** Radial distance between the root of the internal thread and the crest of the external thread of the coaxially assembled design forms of mating threads.

**Class of Thread:** Designation of the class that determines the specification of the size, allowance, and tolerance to which a given threaded product is to be manufactured. It is not applicable to the tools used for threading.

Tap Terms

*Flank Angle:* Angle between the individual flank and the perpendicular to the axis of the thread, measured in an axial plane. A flank angle of a symmetrical thread is commonly termed the "half angle of thread."

*Flank—Leading:* 1) Flank of a thread facing toward the chamfered end of a threading tool; and 2) The leading flank of a thread is the one which, when the thread is about to be assembled with a mating thread, faces the mating thread.

*Flank—Trailing:* The trailing flank of a thread is the one opposite the leading flank.

*Flutes:* Longitudinal channels formed in a tap to create cutting edges on the thread profile and to provide chip spaces and cutting fluid passages. On a parallel or straight thread tap they may be straight, angular or helical; on a taper thread tap they may be straight, angular or spiral.

*Flute-Angular:* A flute lying in a plane intersecting the tool axis at an angle.

*Flute-Helical:* A flute with uniform axial lead and constant helix in a helical path around the axis of a cylindrical tap.

*Flute-Spiral:* A flute with uniform axial lead in a spiral path around the axis of a conical tap.

*Flute Lead Angle:* Angle at which a helical or spiral cutting edge at a given point makes with an axial plane through the same point.

*Flute-Straight:* A flute which forms a cutting edge lying in an axial plane.

*Front Taper:* A gradual increase in the diameter of the thread form on a tap from the leading end of the tool toward the back.

*Heel:* Edge of the land opposite the cutting edge.

*Hook Angle:* Inclination of a concave cutting face, usually specified either as Chordal Hook or Tangential Hook.

*Hook-Chordal Angle:* Angle between the chord passing through the root and crest of a thread form at the cutting face, and a radial line through the crest at the cutting edge.

*Hook-Tangential Angle:* Angle between a line tangent to a hook cutting face at the cutting edge and a radial line to the same point.

*Interrupted Thread Tap:* A tap having an odd number of lands with alternate teeth in the thread helix removed. In some designs alternate teeth are removed only for a portion of the thread length.

*Land:* One of the threaded sections between the flutes of a tap.

*Lead:* Distance a screw thread advances axially in one complete turn.

*Lead Error:* Deviation from prescribed limits.

*Lead Deviation:* Deviation from the basic nominal lead.

*Progressive Lead Deviation:* (1) On a straight thread the deviation from a true helix where the thread helix advances uniformly. (2) On a taper thread the deviation from a true spiral where the thread spiral advances uniformly.

*Length of Thread:* The length of the thread of the tap includes the chamfered threads and the full threads but does not include an external center. It is indicated by the letter "B" in the illustrations at the heads of the tables.

*Limits:* The limits of size are the applicable maximum and minimum sizes.

*Major Diameter:* On a straight thread the major diameter is that of the major cylinder. On a taper thread the major diameter at a given position on the thread axis is that of the major cone at that position.

*Minor Diameter:* On a straight thread the minor diameter is that of the minor cylinder. On a taper thread the minor diameter at a given position on the thread axis is that of the minor cone at that position.

*Pitch Diameter (Simple Effective Diameter):* On a straight thread, the pitch diameter is the diameter of the imaginary coaxial cylinder, the surface of which would pass through the thread profiles at such points as to make the width of the groove equal to one-half the basic pitch. On a perfect thread this coincidence occurs at the point where the widths of the thread and groove are equal. On a taper thread, the pitch diameter at a given position on the thread axis is the diameter of the pitch cone at that position.

*Point Diameter:* Diameter at the cutting edge of the leading end of the chamfered section.

*Rake:* Angular relationship of the straight cutting face of a tooth with respect to a radial line through the crest of the tooth at the cutting edge. Positive rake means that the crest of the cutting face is angularly ahead of the balance of the cutting face of the tooth. Negative rake means that the crest of the cutting face is angularly behind the balance of the cutting face of the tooth. Zero rake means that the cutting face is directly on a radial line.

*Relief:* Removal of metal behind the cutting edge to provide clearance between the part being threaded and the threaded land.

*Relief-Center:* Clearance produced on a portion of the tap land by reducing the diameter of the entire thread form between cutting edge and heel.

*Relief-Chamfer:* Gradual decrease in land height from cutting edge to heel on the chamfered portion of the land on a tap to provide radial clearance for the cutting edge.

*Relief-Con-eccentric Thread:* Radial relief in the thread form starting back of a concentric margin.

*Relief-Double Eccentric Thread:* Combination of a slight radial relief in the thread form starting at the cutting edge and continuing for a portion of the land width, and a greater radial relief for the balance of the land.

*Relief-Eccentric Thread:* Radial relief in the thread form starting at the cutting edge and continuing to the heel.

*Relief-Flatted Land:* Clearance produced on a portion of the tap land by truncating the thread between cutting edge and heel.

*Relief-Grooved Land:* Clearance produced on a tap land by forming a longitudinal groove in the center of the land.

*Relief-Radial:* Clearance produced by removal of metal from behind the cutting edge. Taps should have the chamfer relieved and should have back taper, but may or may not have relief in the angle and on the major diameter of the threads. When the thread angle is relieved, starting at the cutting edge and continuing to the heel, the tap is said to have "eccentric" relief. If the thread angle is relieved back of a concentric margin (usually one-third of land width), the tap is said to have "con-eccentric" relief.

*Size-Actual:* Measured size of an element on an individual part.

*Size-Basic:* That size from which the limits of size are derived by the application of allowances and tolerances.

*Size-Functional:* The functional diameter of an external or internal thread is the pitch diameter of the enveloping thread of perfect pitch, lead and flank angles, having full depth of engagement but clear at crests and roots, and of a specified length of engagement. It may be derived by adding to the pitch diameter in an external thread, or subtracting from the pitch diameter in an internal thread, the cumulative effects of deviations from specified profile, including variations in lead and flank angle over a specified length of engagement. The effects of taper, out-of-roundness, and surface defects may be positive or negative on either external or internal threads.

*Size-Nominal:* Designation used for the purpose of general identification.

*Spiral Flute:* See *Flutes*.

*Spiral Point:* Angular fluting in the cutting face of the land at the chamfered end. It is formed at an angle with respect to the tap axis of opposite hand to that of rotation. Its length is usually greater than the chamfer length and its angle with respect to the tap axis is usually made great enough to direct the chips ahead of the tap. The tap may or may not have longitudinal flutes.

*Thread Lead Angle:* On a straight thread, the lead angle is the angle made by the helix of the thread at the pitch line with a plane perpendicular to the axis. On a taper thread, the lead angle at a given axial position is the angle made by the conical spiral of the thread, with the plane perpendicular to the axis, at the pitch line.

## TAPS AND THREADING DIES

**Table 1. ANSI Standard Fraction-Size Taps — Cut Thread Limits**  
ASME B94.9-1999

| Tap Size | Threads per Inch |        |        | Major Diameter |        |        | Pitch Diameter |        |        |

Basic pitch diameter is the same as minimum pitch diameter of internal thread, Class 6H as shown in table starting on page 1798.

Pitch diameter limits are designated in the Standard as D3 for 1.6 to 3 mm diameter sizes, incl.; D4 for 3.5 to 5 mm sizes, incl.; D5 for 6 and 8 mm sizes; D6 for 10 and 12 mm sizes; D7 for 14 to 20 mm sizes, incl.; D8 for 24 mm size; and D9 for 30 and 36 mm sizes.

Angle tolerances are plus or minus 30 minutes in half angle for pitches ranging from 0.35 through 2.5 mm, incl. and plus or minus 25 minutes in half angle for pitches ranging from 3 to 4 mm, incl.

A maximum deviation of plus or minus 0.0005 inch within any two threads not farther apart than one inch is permitted.

**Table 4b. ANSI Standard Metric Tap Ground Thread Limits in Millimeters — M Profile ASME B94.9-1999**

| Nominal Diam, mm | Pitch, mm | Major Diameter (mm) |        |        | Pitch Diameter (mm) |        |        |
|------------------|-----------|---------------------|--------|--------|---------------------|--------|--------|
|                  |           | Basic               | Min    | Max    | Basic               | Min    | Max    |
| 1.6              | 0.35      | 1.600               | 1.628  | 1.653  | 1.373               | 1.397  | 1.412  |

All dimensions are given in inches.

*Lead Tolerance:* Plus or minus 0.003 inch per inch of thread. *Angle Tolerance:* Plus or minus 45 min. in half angle and 65 min. in full angle for 20 to 28 threads per inch; plus or minus 60 min. in half angle and 90 min. in full angle for 30 or more threads per inch.

<sup>a</sup>Distance that small end of tap projects through L1 taper ring gage (see ANSI B1.20.3).

<sup>b</sup>No longer included in ASME B94.9-1999 shown for reference only.

<sup>c</sup>Taper per foot, inches.

All dimensions are given in inches.

*Lead Tolerance:* Plus or minus 0.003 inch per inch of cut thread and plus or minus 0.0005 inch per inch of ground thread.

*Angle Tolerance:* Plus or minus 40 min. in half angle and 60 min. in full angle for 8 cut threads per inch; plus or minus 45 min. in half angle and 60 min. in full angle for 11 1/2 to 27 cut threads per inch; plus or minus 25 min. in half angle for 8 ground threads per inch; and plus and minus 30 min. in half angle for 11 1/2 to 27 ground threads per inch.

<sup>a</sup> Minimum minor diameter flats are not specified. May be sharp as practicable.

All dimensions are given in inches.

Note: Cut Thread taps made to Column I are marked NPT but are not recommended for ANPT applications. Ground Thread taps made to Column I are marked NPT and may be used for NPT and ANPT applications. Ground Thread taps made to Column II are marked NPTF and used for Dryseal application.

The following are approximate formulas, in which *M* = measured pitch diameter in inches:

Major dia., min. =  $M + A$

Major dia., max. =  $M + B$

Minor dia., max. =  $M - C$

All dimensions are given in inches.

*Lead Tolerance:* Plus or minus 0.003 inch per inch of thread.

*Angle Tolerance:* All pitches, plus or minus 45 min. in half angle and 68 min. in full angle. Taps made to these specifications are to be marked NPS and used for NPSC thread form.

The maximum Pitch Diameter of tap is based upon an allowance deducted from the maximum product pitch diameter of NPSC or NPSM, whichever is smaller.

The minimum Pitch Diameter of tap is derived by subtracting the ground thread pitch diameter tolerance for actual equivalent size.

<sup>a</sup>In the formulas, *M* equals the actual measured pitch diameter.

All dimensions are given in inches.

*Lead tolerance:* Plus or minus 0.0005 inch within any two threads not farther apart than one inch.

*Angle Tolerance:* All pitches, plus or minus 30 min. in half angle. Taps made to these specifications are to be marked NPS and used for NPSC and NPSM.

**Table 8a. ANSI Standard Ground Thread Straight Fluted Taps  
Machine Screw Sizes ASME B94.9-1999**

<sup>a</sup> Chamfer designations are: T = taper, P = plug, and B = bottoming.

<sup>b</sup> Optional number of flutes.

All dimensions are given in inches.

These taps are standard as high-speed steel taps with ground threads, with standard and optional number of flutes and pitch diameter limits and chamfers as given in the table.

These are style 1 taps and have external centers on thread and shank ends (may be removed on thread end of bottoming taps).

For standard thread limits see Table 3. For eccentricity tolerances see Table 22.

Tolerances: Numbers 0 to 12 size range — A, ± 1/32; B, ± 3/64; C, ± 1/32; D, -0.0015; E, -0.004.

All dimensions are given in inches.

Styles 1 and 2 cut thread taps have optional style centers on thread and shank ends.

For standard thread limits see Table 5. For eccentricity tolerances see Table 22.

| Square Length, C                  | 1/4 to 1/2     | ±1/32     |                   |                |           |

All dimensions are given in inches. These ground thread high-speed steel taps are standard in H3 limit only. All taps have an internal center in thread end. For standard limits see Table 2.

Chamfer J is made 1/2 to 3/4 the thread length of B.

All dimensions are in inches. Chamfer designations are: P = plug and B = bottoming. Cut thread taps are standard with plug chamfer only. Style 1 ground thread taps have external centers on thread and shank ends (may be removed on thread end of bottoming taps). Style 1 cut thread taps have optional style centers on thread and shank ends. Standard thread limits for ground threads are given in Table 3 and for cut threads in Table 5. For eccentricity tolerances see Table 22.

<sup>a</sup> Bottom chamfer applies only to regular and fast spiral-fluted machine screw taps.

<sup>b</sup> Applies only to fast spiral-fluted machine screw taps.

<sup>c</sup> Does not apply to fast spiral-fluted machine screw taps.

<sup>d</sup> Does not apply to regular spiral-fluted machine screw taps.

| Square Length, C                  | 3 to 12    | $\pm 1/32$ |                   |            |           |

All dimensions are given in inches. These standard taps are made of high-speed steel with ground threads. For standard thread limits see [Table 3](#). For eccentricity tolerances see [Table 22](#).

**Spiral Pointed Only Taps:** These taps are standard with plug chamfer only. They are provided with a spiral point only; the balance of the threaded section is left unfluted. These Style 1 taps have external centers on thread and shank ends.

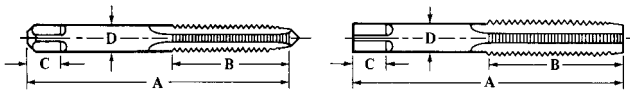

**Regular Spiral Fluted Taps:** These taps have right-hand spiral flutes with a helix angle of from 25 to 35 degrees.

**Fast Spiral Fluted Taps:** These taps have right-hand spiral flutes with a helix angle of from 45 to 60 degrees.

Both regular and fast spiral-fluted Style 1 taps have external centers on thread and shank ends (may be removed on thread end of bottoming taps).

Chamfer designations: P = plug and B = bottoming.

<sup>a</sup> This size has 11 or 16 threads per inch NS-UNS.  
<sup>b</sup> These sizes are also available with plug chamfer in H6 pitch diameter limits.  
<sup>c</sup> This size has 14 threads per inch NS-UNS.  
<sup>d</sup> In these sizes NF-UNF thread taps have six flutes.

| Tolerances for General Dimensions |                     |           |                      |                      |           |

|                                   | 1 1/8 to 1 1/2 incl | ±1/16     |                      |                      |           |

All dimensions are given in inches.  
 These taps are standard in high-speed steel.  
 Chamfer designations are: T = taper, P = plug, and B = bottoming.  
 Style 2 taps, 3/8 inch and smaller, have external center on thread end (may be removed on bottoming taps) and external partial cone center on shank end with length of come approximately one-quarter of diameter of shank.  
 Style 3 taps, larger than 3/8 inch, have internal center in thread and shank ends.  
 For standard thread limits see Table 2. For eccentricity tolerances see Table 22.

All dimensions are given in inches.

These taps are standard in carbon steel and high-speed steel.

Except where indicated, these taps are standard with taper, plug, or bottoming chamfer.

Cut thread taps, sizes 3/8 inch and smaller have optional style center on thread and shank ends; sizes larger than 3/8 inch have internal centers in thread and shank ends.

For standard thread limits see Table 1. For eccentricity tolerances see Table 22.

**Table 13. ANSI Standard Straight Fluted (Optional Number of Flutes) and Spiral Pointed Taps—Fractional Sizes ASME B94.9-1999**

| Thread Length, B                  | 1/4 to 1/2     | ±1/16         | ±1/16      | Size of Square, E | 1/4 to 1/2     | -0.0040<br>-0.0060 | -0.004<br>... |
| Square Length, C                  | 1/4 to 3/4     | ±1/32         |            |                   | 3/8 to 3/4     |                    |               |

All dimensions are given in inches. P = plug and B = bottoming. Ground thread taps — Style 2, 3/8 inch and smaller, have external center on thread end (may be removed on bottoming taps) and external partial cone center on shank end, with length of cone approximately 1/4 of shank diameter. Ground thread taps—Style 3, larger than 3/8 inch, have internal center in thread and shank ends. Cut thread-taps, 3/8 inch and smaller have optional style center on thread and shank ends; sizes larger than 3/8 inch have internal centers in thread and shank ends. For standard thread limits see Tables 1 and 2.

| Thread Length, B                  | 1/4 to 1/2     | ±1/16     | Size of Square, E | 1/4 to 1/2     | -0.004    |
| Square Length, C                  | 1/4 to 1/2     | ±1/32     |                   |                |           |

All dimensions are given in inches. These standard taps are made of high-speed steel with ground threads. For standard thread limits see Table 2.

**Spiral Pointed Only Taps:** These taps are standard with plug chamfer only in H3 limit. They are provided with spiral point only. The balance of the threaded section is left unfluted.

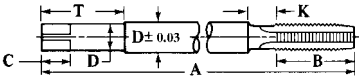

**Spiral Fluted Taps:** These taps are standard with plug or bottoming chamfer in H3 limit and have right-hand spiral flutes with a helix angle of from 25 to 35 degrees.

**Fast Spiral Fluted Taps:** These taps are standard with plug or bottoming chamfer in H3 limit and have right-hand spiral flutes with a helix angle of from 45 to 60 degrees.

Style 2 taps, 3/8 inch and smaller, have external center on thread end (may be removed on bottoming taps) and external partial cone center on shank end with cone length approximately 1/4 shank diameter.

Style 3 taps larger than 3/8 inch have internal center in thread and shank ends.

For standard thread limits see Table 2. For eccentricity tolerances see Table 22.

| 3/4         | 10                      | 4                | 10, 12            | 2.00                | 0.75                | 0.7590           | 2.25  | 0.569                          | 0.75                           |

<sup>a</sup> T is minimum length of shank which is held to eccentricity tolerances.

<sup>b</sup> Size of square is equal to 0.75D to the nearest 0.001 inch.

<sup>c</sup> K neck optional with manufacturer.

Tolerances for General Dimensions

| Element           | Diameter Range | Tolerance | Element           | Diameter Range | Tolerance |
|-------------------|----------------|-----------|-------------------|----------------|-----------|
| Overall Length, A | 1/4 to 3/4     | ±0.06     | Shank Diameter, D | 1/4 to 3/4     | -0.0050   |
| Thread Length, B  | 1/4 to 3/4     | ±0.06     | Size of Square, E | 1/4 to 1/2     | -0.004    |
| Square Length, C  | 1/4 to 3/4     | ±0.03     |                   | 5/8 to 3/4     | -0.006    |

All dimensions are given in inches. These ground thread high-speed steel taps are standard with plug chamfer in H3 limit only. All taps have an internal center in thread end. For standard thread limits see Table 2. For eccentricity tolerances see Table 22.

**Table 16. ANSI Standard Ground Thread Spark Plug Taps Metric Sizes ASME B94.9-1999**

| Tap Diameter, mm | Pitch, mm | Number of Flutes | Overall Length, In. A           | Thread Length, In. B            | Square Length, In. C | Shank Dia., In. D | Square Size, In. E |
|------------------|-----------|------------------|---------------------------------|---------------------------------|----------------------|-------------------|--------------------|
| 14               | 1.25      | 4                | 3 <sup>19</sup> / <sub>32</sub> | 1 <sup>21</sup> / <sub>32</sub> | 1/2                  | 0.429             | 0.322              |
| 18               | 1.50      | 4                | 4 <sup>1</sup> / <sub>32</sub>  | 1 <sup>13</sup> / <sub>16</sub> | 5/8                  | 0.542             | 0.406              |

These are high-speed steel Style 3 taps and have internal center in thread and shank ends. They are standard with plug chamfer only, right-hand threads with 60-degree form of thread.

Tolerances: Overall length, ± 1/32 inch; thread length, ± 1/32 inch; square length, ± 1/32 inch; shank diameter, 14 mm, -0.0015 inch, 18 mm, -0.0020 inch; and size of square, -0.0040 inch.

TAPS AND THREADING DIES
