## Haemophilus Immunization

### H influenzae type b Vaccination in Children Immunized Beginning at 2 to 6 Months of Age

Vaccine Product	Total Number of Doses	Regimens
PedvaxHIB (PRP-OMP)	3	2 doses two months apart plus booster at 12-15 months, which must be at least two months after previous dose.
HibTITER (HbOC), ActHIB (PRP-T), OmniHIB (PRP-T)	4	3 doses two months apart plus booster at 12-15 months which must be at least two months after previous dose. Any vaccine may be used for the booster.

## Varicella Immunization

### Indications for Varicella Immunization:

- A.** Age 12 to 18 months: One dose of varicella vaccine is recommended for universal immunization for all healthy children who lack a reliable history of varicella.
- B.** Age 19 months to the 13<sup>th</sup> birthday: Vaccination of susceptible children is recommended and may be given any time during childhood but before the 13<sup>th</sup> birthday because of the potential increased severity of natural varicella after this age. Susceptible is defined by either lack of proof of either varicella vaccination or a reliable history of varicella. One dose is recommended.
- C.** Healthy adolescents and young adults: Healthy adolescents past their 13<sup>th</sup> birthday who have not been immunized previously and have no history of varicella infection should be immunized against

varicella by administration of two doses of vaccine 4 to 8 weeks apart.

- D. All susceptible children aged 1 year to 18 years old who are in direct contact with people at high risk for varicella related complications (eg, immunocompromised individuals) and who have not had varicella.

## Influenza Immunization

### Indications for Influenza Vaccination

- A. Targeted high-risk children and adolescents (eg, chronic pulmonary disease including asthma, sickle cell anemia, HIV infection).
- B. Other high-risk children and adolescents (eg, diabetes mellitus, chronic renal disease, chronic metabolic disease).
- C. Close contacts of high risk patients.
- D. Foreign travel if exposure is likely.

**Vaccine Administration.** Administer in the Fall, usually October 1 - November 15, before the start of the influenza season.

Influenza Immunization Administration			
Age	Vaccine Type	Dosage (mL)	Number of Doses
6-35 months	Split virus only	0.25	1-2*
3-8 years	Split virus only	0.5	1-2*
9-12 years	Split virus only	0.5	1
> 12 years	Whole or split virus	0.5	1

\*Two doses administered at least one month apart are recommended for children who are receiving influenza vaccine for the first time.

# Cardiovascular Disorders

## Pediatric Advanced Life Support

### I. Cardiopulmonary assessment

- A. Airway (A) assessment.** The airway should be assessed and cleared.
- B. Breathing (B) assessment** determines the respiratory rate, respiratory effort, breath sounds (air entry), and skin color. A respiratory rate of less than 10 or greater than 60 is a sign of impending respiratory failure.
- C. Circulation (C) assessment** should quantify the heart rate and pulse. In infants, chest compressions should be initiated if the heart rate is less than 80 beats/minute (bpm). In children, chest compressions should be initiated if the heart rate is less than 60 bpm.

### II. Respiratory failure

- A.** An open airway should be established. Bag-valve-mask ventilation should be initiated if the respiratory rate is less than 10. Intubation is performed if prolonged ventilation is required. Matching the endotracheal tube to the size of the nares or fifth finger provides an estimate of tube size.

Intubation			
Age	ETT	Laryngo- scope Blade	NG Tube Size
Premature	2.0-	0	8
	2.5	1	10
Newborn	3.0-	1	10
>2 kg	3.5	1.5	12
Infant	3.5-	2	12-14
12	4.0	2	14-16
months	4.0-	2	16-18
36	4.5	3	18-20
months	4.5-	3	20
6 year	5.0		
10 year	5.0-		
Adolescent	5.5		
Adult	6.0-		
	6.5		
	.0-7.5		
	7.5-		
	8.0		

Uncuffed ET tube in children <8 years.  
Straight laryngoscope blade if <6-10 years; curved blade if older.

- B.** Vascular access should be obtained. Gastric decompression with a nasogastric or orogastric tube is necessary in endotracheally intubated children and in children receiving bag-valve-mask ventilation.

### III. Shock

- A.** If the child is in shock, oxygen administration and monitoring are followed by initiation of vascular access. Crystalloid (normal saline or lactated Ringer's) solutions are used for rapid fluid boluses of 20 mL/kg over less than 20 minutes until the shock is resolved.
- B.** Shock secondary to traumatic blood loss may require blood replacement if perfusion parameters have not normalized after a total of 40 to 60 mL/kg of crystalloid has been administered.
- C.** Children in septic shock and cardiogenic shock should initially receive crystalloid solution (boluses of 20 mL/kg). Epinephrine should be considered if septic or cardiogenic shock persists after intravenous volume has been repleted (repletion requires 40 to 60 mL/kg of crystalloid).

#### IV. Cardiopulmonary failure

- A. Oxygen is delivered at a concentration of 100%.
- B. Intubation and foreign body removal are completed. If signs of shock persist, crystalloid replacement is initiated with boluses of 20 mL/kg over less than 20 minutes. Inotropic agents are added if hypotension persists.

<b>Inotropic Agents Used in Resuscitation of Children</b>		
<b>Agent</b>	<b>Intravenous dosage</b>	<b>Indications</b>
Epinephrine	0.1 to 1.0 $\mu\text{g}/\text{kg}/\text{minute}$ (continuous infusion)	Symptomatic bradycardia, shock (cardiogenic, septic, anaphylactic), hypotension
Dopamine	2 to 5 $\mu\text{g}/\text{kg}/\text{minute}$ (continuous infusion) 10 to 20 $\mu\text{g}/\text{kg}/\text{minute}$ (continuous infusion)	Low dose: improve renal and splanchnic blood flow. High dose: useful in the treatment of hypotension and shock in the presence of adequate intravascular volume
Dobutamine	2 to 20 $\mu\text{g}/\text{kg}/\text{minute}$ (continuous infusion)	Normotensive cardiogenic shock

#### V. Dysrhythmias

##### A. Bradycardia

1. Bradycardia is the most common dysrhythmia in children. Initial management is ventilation and oxygenation. Chest compressions should be initiated if the heart rate is  $<60$  bpm in a child or  $<80$  bpm in an infant.
2. If these measures do not restore the heart rate, epinephrine is administered. Intravenous or intraosseous epinephrine is given in a dose of 0.1 mL/kg of the 1:10,000 concentration (0.01 mg/kg). Endotracheal tube epinephrine is given as a dose of 0.1 mL/kg of the 1:1,000 concentration (0.1 mg/kg) diluted to a final volume of 3-5 mL in normal saline. This dose may be repeated every three to five minutes.
3. Atropine may be tried if multiple doses of epinephrine are unsuccessful. Atropine is given in a dose of 0.2 mL/kg IV/IO/ET of the 1:10,000 concentration (0.02 mg/kg). The minimum dose is 0.1 mg; the maximum single dose is 0.5 mg for a child and 1 mg for an adolescent. Endotracheal tube administration of atropine should be further diluted to a final volume of 3-5 mL in normal saline.
4. Pacing may be attempted if drug therapy has failed.

##### B. Asystole

1. Epinephrine is the drug of choice for asystole. The initial dose of intravenous or intraosseous epinephrine is given as 0.1 mL/kg of the 1:10,000 concentration of epinephrine (0.01 mg/kg). Endotracheal tube administration of epinephrine is given as 0.1 mL/kg of the 1:1,000 concentration of epinephrine (0.1 mg/kg), diluted to a final volume of 3-5 mL in normal saline.
2. Subsequent doses of epinephrine are administered every three to five minutes at 0.1 mL/kg IV/IO/ET of the 1:1,000 concentration (0.1 mg/kg).

##### C. Supraventricular tachycardia

1. Supraventricular tachycardia presents with a

heart rate >220 beats/minute in infants and >180 beats/minute in children.

Supraventricular tachycardia is the most common dysrhythmia in the first year of life.

**2. Stable children with no signs of respiratory compromise or shock and a normal blood pressure**

- a. Initiate 100% oxygen and cardiac monitoring.
- b. Administer adenosine 0.1 mg/kg (max 6 mg) by rapid intravenous push. The dose of adenosine may be doubled to 0.2 mg/kg (max 12 mg) and repeated if supraventricular tachycardia is not converted.
- c. **Verapamil (Calan)** may be used; however, it is contraindicated under one year; in congestive heart failure or myocardial depression; in children receiving beta-adrenergic blockers; and in the presence of a possible bypass tract (ie, Wolff-Parkinson-White syndrome). Dose is 0.1-0.3 mg/kg/dose (max 5 mg) IV; may repeat dose in 30 minutes prn (max 10 mg).

**3. Supraventricular tachycardia in unstable child with signs of shock:** Administer synchronized cardioversion at 0.5 joules/kg. If supraventricular tachycardia persists, cardioversion is repeated at double the dose: 1.0 J/kg.

**D. Ventricular tachycardia with palpable pulse**

1. A palpable pulse with heart rate  $\geq$ 120 bpm with a wide QRS (>0.08 seconds) is present. Initiate cardiac monitoring, administer oxygen and ventilate.
2. If vascular access is available, administer a lidocaine bolus of 1 mg/kg; if successful, begin lidocaine infusion at 20-50  $\mu$ g/kg/minute.
3. If ventricular tachycardia persists, perform synchronized cardioversion using 0.5 J/kg.
4. If ventricular tachycardia persists, repeat synchronized cardioversion using 1.0 J/kg.
5. If ventricular tachycardia persists, administer a lidocaine bolus of 1.0 mg/kg, and begin lidocaine infusion at 20-50  $\mu$ g/kg/min.
6. Repeat synchronized cardioversion as indicated.

**E. Ventricular fibrillation and pulseless ventricular tachycardia**

1. Apply cardiac monitor, administer oxygen, and ventilate.
2. Perform defibrillation using 2 J/kg. Do not delay defibrillation.
3. If ventricular fibrillation persists, perform defibrillation using 4 J/kg.
4. If ventricular fibrillation persists, perform defibrillation using 4 J/kg.
5. If ventricular fibrillation persists, perform intubation, continue CPR, and obtain vascular access. Administer epinephrine, 0.1 mL/kg of 1:10,000 IV or IO (0.01 mg/kg); or 0.1 mL/kg of 1:1000 ET (0.1 mg/kg).
6. If ventricular fibrillation persists, perform defibrillation using 4 J/kg.
7. If ventricular fibrillation persists, administer lidocaine 1 mg/kg IV or IO, or 2 mg/kg ET.
8. If ventricular fibrillation persists, perform defibrillation using 4 J/kg.
9. If ventricular fibrillation persists, continue epinephrine, 0.1 mg/kg IV/IO/ET, 0.1 mL/kg of 1:1,000; administer every 3 to 5 minutes.
10. If ventricular fibrillation persists, alternate defibrillation (4 J/kg) with lidocaine and epinephrine. Consider bretylium 5 mg/kg IV first dose, 10 mg/kg IV second dose.

**F. Pulseless electrical activity** is uncommon in children. It usually occurs secondary to

hypoxemia, hypovolemia, hypothermia, hypoglycemia, hyperkalemia, cardiac tamponade, tension pneumothorax, severe acidosis or drug overdose. Successful resuscitation depends on treatment of the underlying etiology.

1. The initial dose of IV or IO epinephrine is given in a dose of 0.1 mL/kg of the 1:10,000 concentration (0.01 mg/kg). Endotracheal epinephrine is given as a dose of 0.1 mL/kg of the 1:1,000 concentration (0.1 mg/kg) diluted to a final volume of 3-5 mL in normal saline.
2. Subsequent doses are administered every three to five minutes as 0.1 mL/kg of the 1:1,000 concentration IV/IO/ET (0.1 mg/kg).

**VI. Serum glucose concentration** should be determined in all children undergoing resuscitation. Glucose replacement is provided with 25% dextrose in water, 2 to 4 mL/kg (0.5 to 1 g/kg) IV over 20 to 30 minutes for hypoglycemia. In neonates, 10% dextrose in water, 5 to 10 mL/kg (0.5 to 1 g/kg), is used.

### Digoxin:

-Obtain a baseline ECG, serum electrolytes (potassium), and serum creatinine before administration.

Initial digitalization is given over 24 hours in three divided doses: 1/2 total digitalizing dose (TDD) at time 0 hours, 1/4 TDD at 8-12 hours, and 1/4 TDD 8-12 hours later.

Maintenance therapy is then started.

**Total Parenteral Nutrition:**

-Calculate daily protein solution fluid requirement less fluid from lipid and other sources. Calculate total amino acid requirement.

-Protein: Neonates and infants start with 0.5 gm/kg/day and increase to 2-3 gm/kg/day. For children and young adults, start with 1 gm/kg/day, and increase by 1.0 gm/kg/day (max 2-3 gm/kg/day). Calculate percent amino acid to be

infused: amino acid requirement in grams divided by the volume of fluid from the dextrose/protein solution in mL x 100.

- Advance daily dextrose concentration as tolerated, while following blood glucose levels. Usual maximum concentration is D35W.

<b>Total Parenteral Nutrition Requirements</b>

#### **Dextrose Infusion:**

-Dextrose mg/kg/min = [% dextrose x rate (mL/hr) x 0.167] ÷ kg

-Normal Starting Rate: 6-8 mg/kg/min

#### **Lipid Solution:**

-Minimum of 5% of total calories should be from fat emulsion. Max of 40% of calories as fat (10% soln = 1 gm/10 mL = 1.1 kcal/mL; 20% soln = 2 gm/10 mL = 2.0 kcal/mL). 20% Intralipid is preferred in most patients.

-For neonates, begin fat emulsion at 0.5 gm/kg/day and advance to 0.5-1 gm/kg/day.

-For infants, children and young adults, begin at 1 gm/kg/day, advance as tolerated by 0.5-1 gm/kg/day; max 3 gm/kg/day or 40% of calories/day.

-Neonates - infuse over 20-24h; children and infants - infuse over 16-24h, max 0.15 gm/kg/hr.

-Check serum triglyceride 6h after infusion (maintain <200 mg/dL)

#### **Peripheral Parenteral Supplementation:**

-Calculate daily fluid requirement less fluid from lipid and other sources. Then calculate protein requirements: Begin with 1 gm/kg/day. Advance daily protein by 0.5-0.6 gm/kg/day to maximum of 3 gm/kg/day.

-Protein requirement in grams ÷ fluid requirement in

mL x 100 = % amino acids.

- Begin with maximum tolerated dextrose concentration. (Dextrose concentration >12.5% requires a central line.)
- Calculate maximum fat emulsion intake (3 gm/kg/day), and calculate volume of 20% fat required (20 gm/100 mL = 20 %):  
[weight (kg) x gm/kg/day] ÷ 20 x 100 = mL of 20% fat emulsion.  
Start with 0.5-1.0 gm/kg/day lipid, and increase by 0.5-1.0 gm/kg/day until 3 gm/kg/day. Deliver over 18-24 hours.
- Draw blood 4-6h after end of infusion for triglyceride level.

Free H<sub>2</sub>O deficit in hypernatremic dehydration = 4 mL/kg for every mEq that serum Na >145 mEq/L.

### **Phase 1, Acute Fluid Resuscitation (Symptomatic Dehydration):**

- Give NS 20-30 mL/kg IV at maximum rate; repeat fluid boluses of NS 20-30 mL/kg until blood pressure and pulse are normal.

### **Phase 2, Deficit and Maintenance Therapy (Asymptomatic dehydration):**

#### **Hypotonic Dehydration ( $\text{Na}^+ < 125 \text{ mEq/L}$ ):**

- Calculate total maintenance and deficit fluids and sodium deficit for 24h (minus fluids and electrolytes given in phase 1). If isotonic or hyponatremic dehydration, replace 50% over 8h and 50% over next 16h.
- Estimate and replace ongoing losses q6-8h.
- Add potassium to IV solution after first void.
- Usually D5 1/2 NS or D5 1/4 NS saline with 10-40 mEq KCL/liter 60 mL/kg over 2 hours. Then infuse at 6-8 mL/kg/h for 12h.
- See hyponatremia, page 111.

#### **Isotonic Dehydration ( $\text{Na}^+ 130-150 \text{ mEq/L}$ ):**

- Calculate total maintenance and replacement fluids for 24h (minus fluids and electrolytes given in phase 1) and give half over first 8h, then remaining half over next 16 hours.
- Add potassium to IV solution after first void.
- Estimate and replace ongoing losses.
- Usually D5 1/2 NS or D5 1/4 NS with 10-40 mEq KCL/L.

#### **Hypertonic Dehydration ( $\text{Na}^+ > 150 \text{ mEq/L}$ ):**

- Calculate and correct free water deficit and correct slowly. Reduce serum sodium by 10 mEq/L/day; do not reduce sodium by more than 15 mEq/L/24h or by  $>0.5 \text{ mEq/L/hr}$ .
- If volume depleted, give NS 20-40 mL/kg IV until adequate circulation, then give 1/2-1/4 NS in 5% dextrose to replace half of free water deficit over first 24h. Follow serial serum sodium levels and correct deficit over 48-72h.
- Free water deficit:**  $4 \text{ mL/kg} \times (\text{serum Na}^+ - 145)$
- Also see "hypernatremia" page 111.
- Add potassium to IV solution after first void as KCL.
- Usually D5 1/4 NS or D5W with 10-40 mEq/L KCL. Estimate and replace ongoing losses and maintenance.

#### **Replacement of ongoing losses (usual fluids):**

- Nasogastric suction: D5 1/2 NS with 20 mEq KCL/L or 1/2 NS with KCL 20 mEq/L.
- Diarrhea: D5 1/4 NS with 40 mEq KCL/L

#### **Oral Rehydration Therapy (mild-moderate dehydration $<10\%$ ):**

- Oral rehydration electrolyte solution (Rehydralyte, Pedialyte, Ricelyte, Revital Ice) deficit replacement of 60-80 mL/kg PO or via NG tube over 2h. Provide additional fluid requirement over remaining 18-20 hours; add anticipated fluid losses from stools of 10 mL/kg for each diarrheal stool.

<b>Oral Electrolyte Solutions</b>			
<b>Product</b>	<b>Na (mEq/L)</b>	<b>K (mEq/L)</b>	<b>Cl (mEq/L)</b>

 $\text{Volume of soln (L)} = \text{Sodium to be infused (mEq)} \div \text{mEq/L in solution}$
- Correct half of sodium deficit slowly over 24h.
- For acute correction, the serum sodium goal is 125 mEq/L; max rate for acute replacement is 1 mEq/kg/hr. Serum Na should be adjusted in increments of 5 mEq/L to reach 125 mEq/L. The first dose is given over 4 hrs. For further correction for serum sodium to above 125 mEq/L, calculate mEq dose of sodium and administer over 24-48h.

# Newborn Care

## Neonatal Resuscitation

APGAR Score			
Sign	0	1	2
Heart rate per minute	Absent	Slow (<100)	>100
Respirations	Absent	Slow, irregular	Good, crying
Muscle tone	Limp	Some flexion	Active motion
Reflex irritability	No response	Grimace	Cough or sneeze
Color	Blue or pale	Pink body with blue extremities	Completely pink

Assess APGAR score at 1 minute and 5 minutes, then continue assessment at 5 minute intervals until APGAR is greater than 7.

### General Measures:

1. Review history, check equipment, oxygen, masks, laryngoscope, ET tubes, medications.

**Vigorous, Crying Infant:** Provide routine delivery room care for infants with heart rate >100 beats per minute, spontaneous respirations, and good color and tone: provide warmth, clear the airway, and dry the infant.

### Meconium in Amniotic Fluid:

1. Deliver the head and suction meconium from the hypopharynx on delivery of the head. If the newly born infant has absent or depressed respirations, heart rate <100 bpm, or poor muscle tone, perform direct tracheal suctioning to remove meconium from the airway.
2. If no improvement occurs or if the clinical condition deteriorates, bag and mask ventilate with intermittent positive pressure using 100% FiO<sub>2</sub>; stimulate vigorously by drying. Initial breath pressure: 30-40 cm H<sub>2</sub>O for term infants, 20-30 cm H<sub>2</sub>O for preterm infants. Ventilate at 15-20 cm H<sub>2</sub>O at 30-40 breaths per minute. Monitor bilateral breath sounds and expansion.
3. If spontaneous respirations develop and heart rate is normal, gradually reduce ventilation rate until using only continuous positive airway pressure (CPAP) is required. Wean to blow-by oxygen, but continue blow-by oxygen if the baby remains dusky.
4. Consider intubation if the heart rate remains <100 beats per minute and is not rising, or if respirations are poor and weak.

### Resuscitation:

1. Provide assisted ventilation if stimulation does not achieve prompt onset of spontaneous respirations or the heart rate is <100 bpm.
2. Provide chest compressions if the heart rate is absent or remains <60 bpm despite adequate assisted ventilation for 30 seconds. Coordinate chest compressions with ventilations at a ratio of 3:1 and a rate of 120 events per minute to achieve 90 compressions and 30 breaths per minute.
3. Chest compressions should be done by two thumb-encircling hands. The depth of chest compression should be one third of the anterior-

posterior diameter of the chest. Chest compressions should be sufficiently deep to generate a palpable pulse.

4. If condition worsens or if there is no change after 30 seconds, or if mask ventilation is difficult: use laryngoscope to suction oropharynx and trachea and intubate. Apply positive pressure ventilation. Check bilateral breath sounds and chest expansion. Check and adjust ET tube position if necessary. Continue cardiac compressions if heart rate remains depressed. Check CXR for tube placement.

**Hypotension or Bradycardia or Asystole:** Epinephrine 0.1-0.3 mL/kg [0.01-0.03 mg/kg (0.1 mg/mL = 1:10,000)] IV or ET q3-5min. Dilute ET dose to 2-3 mL in NS. If infant fails to respond, consider increasing dose to 0.1 mg/kg (0.1 mL/kg of 1 mg/mL = 1:1000).

**Hypovolemia:** Insert umbilical vein catheter and give O negative blood, plasma, 5% albumin, Ringer's lactate, or normal saline 10 mL/kg IV over 5-10 minutes. Repeat as necessary to correct hypovolemia.

**Severe Birth Asphyxia, Mixed Respiratory/Metabolic Acidosis (not responding to ventilatory support; pH <7.2):** Give sodium Bicarbonate 1 mEq/kg; dilute 1:1 in sterile water IV q5-10min as indicated.

**Narcotic-Related Depression:**

1. Naloxone (Narcan) 0.1 mg/kg = 0.25 mL/kg (0.4 mg/mL concentration) or 0.1 mL/kg (1 mg/mL concentration) ET/IV/IM/SC, may repeat q2-3 min. May cause drug withdrawal and seizures in the infant if the mother is a drug abuser.

## Congenital Syphilis

### Treatment:

- Penicillin G aqueous: 50,000 U/kg/dose IV/IM; 0-7 days of age: q12h; >7 days: q8h. Treat for 10-14 days. If one or more days is missed, restart entire course **OR**
