*Selye et al. D32,610/63*: In rats, calciphylaxis produced by bilateral nephrectomy + ferric dextrin can be prevented by parathyroidectomy. Hence, it may be concluded that autologous parathyroid hormones in amounts secreted by the glands can act as calciphylactic sensitizers.

**Stressors ←**

*Genitis et al. 68,723/35*: In young thyroparathyroidectomized rats, exposure to heat 24 hrs following the operation greatly increased the mortality rate, whereas cold surrounding temperature diminished it. The number of tetanic convulsions was greatest at an intermediate temperature. [From the brief abstract it is difficult to differentiate between the role of parathyroid and of thyroid deficiency (H.S.).]

*Sanfilippo 56,085/35*: In rabbits, parathyroid extract increases resistance to cold.

*Rixon et al. C61,789/58*: In rats, parathyroid extract prolongs survival after X-irradiation.

*Czarnecki & Kiersz D15,579/61*: In dogs, shock produced by trypan blue or peptone injection is more powerfully inhibited by thyro-parathyroidectomy than by thyroidectomy.

### ← CALCITONIN

**Parathyroid Hormone** ←. Calcitonin inhibits the production of soft tissue calcification by parathyroid extract in the rat. Thyroxine has a similar effect, and combined treatment with the two hormones leads to a summation of their actions.

**Drugs** ←. In rats, the organ lesions produced by intoxication with holmium or indium chlorides, unlike the nephrocalcinosis produced by mercury, are completely prevented by calcitonin. The calcergy, induced by lead acetate i.v. + topical administration of polymyxin, is inhibited by calcitonin in the rat simultaneously with the hypercalcemia resulting from lead acetate administration.

The myocardial lesion, produced in rats as a consequence of the obstructive nephropathy caused by sulfa compounds is also inhibited by calcitonin.

The bone lesions characteristic of vitamin-A overdosage in the rat are prevented by calcitonin, although those elicited by various other techniques are not influenced by this hormone.

**Renal Lesions** ←. Calcitonin inhibits the metastatic calcification and the osteitis fibrosa induced by bilateral nephrectomy in the rat.

**Parathyroid Hormone** ← cf. also *Selye G60,083/70*, p. 413.

*Tuchweber et al. G46,759/68; Gabbiani et al. G46,731/68; G46,730/68*: Pretreatment with thyroxine or calcitonin inhibits the soft tissue calcification and osteitis fibrosa induced by parathyroid extract overdosage. In the event of concurrent administration, the effect of the two protective hormones is summated. Thyroxine retains its effect upon calcium metabolism in thyro-parathyroidectomized or adrenalectomized but not in nephrectomized rats. The stress of restraint likewise prevents parathyroid overdosage, but the associated biochemical changes are different from those caused by thyroxine.

#### Drugs ←

**Digitoxin** ←. *Selye PROT. 33541, 34074*: In rats, PCN is highly efficacious in preventing digitoxin poisoning, even after parathyroidectomy, thyro-parathyroidectomy, or concurrent treatment with propylthiouracil (PTU). No protection was obtained by thyroidectomy, parathyroidectomy or treatment with PTU,

thyroxine, parathyroid extract or calcitonin. Apparently, the goitrogenic effect of PCN plays no indispensable role in its catatoxic action.

**Holmium, Indium** ←. *Gabbiani & Tuchweber G70,453/70*: In rats, the organ lesions produced by toxic doses of holmium and indium chlorides—unlike the nephrocalcinosis elicited by HgCl<sub>2</sub>—are completely prevented by calcitonin.

**Lead** ←. *Gabbiani et al. G46,731/68*: In rats, calcitonin (but not thyroxine) inhibits the local calcergy induced by intravenous injection of lead acetate followed by topical administration of polymyxin and the hypercalcemia produced by a single injection of lead acetate.

**Mercury** ←. *Gabbiani & Tuchweber G70,453/70*: In rats, the organ lesions produced by toxic doses of holmium and indium chlorides—unlike the nephrocalcinosis elicited by HgCl<sub>2</sub>—are completely prevented by calcitonin.

**Sulfa Drugs** ←. *Fujita et al. H2,733/68*: In rats, calcitonin inhibits the myocardial lesions that occur as a consequence of the obstructive nephropathy after the administration of N-sulfacetylthiazole (SAT).

*Okano et al. H25,894/70*: In rats, the calcification and necrosis of the aortic media induced by the "obstructive nephropathy" developing after injection of sodium sulfathiazole (SAT) can be prevented by parathyroidectomy, and to a lesser extent by calcitonin.

**Vitamin A** ←. *Clark et al. H5,009/68*: In rats, the bone lesions produced by vitamin-A overdosage were prevented by calcitonin, but those induced by various other techniques were not influenced, or actually aggravated.

### **Renal Lesions** ←

*Lefort et al. G46,725/67; Côté et al. G46,741/68*: In rats, calcitonin inhibits the metastatic calcification and bone lesions induced by bilateral nephrectomy. In nephrectomized animals, thyroxine does not modify the changes induced by endogenous hyperparathyroidism consequent to bilateral nephrectomy. "Presumably, to be effective against soft-tissue calcification and bone resorption induced by parathyroid extract overdosage, thyroxine requires the presence of the kidney."

## ← PANCREATIC HORMONES

The pancreatic hormones affect resistance to various agents, mainly through their influence upon carbohydrate metabolism. It is interesting, however, that while the effect of insulin and surgically or drug-induced diabetes have been studied in connection with many toxicants, virtually no attention has been given to the possible corresponding effects of glucagon.

### **Steroids** ←

**Progesterone** anesthesia is aggravated by insulin and prevented by epinephrine, presumably by virtue of the blood sugar changes produced by these hormones.

### **Nonsteroidal Hormones and Hormone-Like Substances** ←

**Thyroid** feeding greatly increases mortality in rats on a diet containing desiccated pancreas. However, there is no proof that here pancreatic hormones play a role.

The toxicity of **histamine**, **5-HT**, and of the **anaphylactoidogenic** agents that liberate these amines from mastocytes, is greatly influenced by pancreatic hormones. The anaphylactoid edema produced by dextran or egg-white in the rat is inhibited by alloxan diabetes and aggravated by insulin. The response to Cpd. 48/80 is less consistently influenced by these agents. In mice, sensitized with pertussis vaccine, alloxan also inhibits the response to 5-HT, histamine or anaphylaxis.

**Steroids** ← cf. also *Selye G60,083/70*, pp. 414—419.

*Winter & Selye A35,658/41; Winter A36,333/41*: Epinephrine increases, whereas insulin decreases, the resistance of the rat to the anesthetic action of progesterone.

**Hydroxydione** ← Carbutamide, Mouse: *Rümke G69,768/63\**

### **Nonsteroidal Hormones and Hormone-Like Substances** ←

**Thyroid Hormones** ←. *Ershoff B24,883/48*: In immature female rats fed purified rations containing both pancreas and desiccated thy-

roid, mortality was high. Similar diets containing only pancreas or desiccated thyroid induced no comparable mortality.

**Histamine and 5-HT** ←. *Goth et al. C43,836/57*: In rats, alloxan diabetes inhibits the anaphylactoid edema produced by dextran or egg white; insulin aggravates it. Cpd. 48/80 is not influenced by these agents. "These results suggest a hitherto unrecognized role of insulin in certain types of inflammation and histamine release."

*Adamkiewicz & Adamkiewicz C73,760/59*: In rats, alloxan diabetes prevents the ana-

phylactoid reaction caused by dextran; insulin restores this reactivity.

*Ganley & Robinson C66,305/59*: In mice, sensitized with *B. pertussis* vaccine, alloxan inhibits the response to 5-HT and somewhat less to histamine and anaphylaxis.

*Sanyal et al. C79,555/59*: In rats, anaphylactoid edema produced by egg white is aggravated by insulin pretreatment.

*Ganley D31,168/62*: In mice, alloxan diabetes inhibits the sensitizing properties of

*Bordetella pertussis* vaccine as measured by challenge with histamine, 5-HT or anaphylaxis. This effect is reversed by insulin.

**Insulin** ←. *Hasselblatt & Bastian C59,171/58*: In mice, sensitivity to insulin convulsions is increased by thyroxine and even more markedly by tolbutamide.

Tolbutamide ← Tolbutamide, Dog: Charbon G76,685/61\*; Remmer et al. D19,894/64\*

### Drugs ←

Among the drug actions subject to regulation by pancreatic hormones, one of the most interesting is the previously mentioned response to **anaphylactoidogens**. Various antigen-antibody reactions are influenced in a similar way and since overdosage with sugars, cortisol or epinephrine also inhibit the anaphylactoid edema, it is assumed that the latter agents, like insulin and alloxan, act through their effect upon the blood sugar. Since these interrelations have been discussed at length in a previous monograph (*Selye G19,425/65*) they need not be discussed here in detail.

**Barbiturate** anesthesia can be markedly influenced by insulin but in a somewhat unpredictable manner. In mice, hexobarbital sleeping time is allegedly prolonged both by epinephrine and by insulin, whereas in rabbits, pentobarbital sleeping time is shortened by the same two hormones. In guinea pigs, hexobarbital sleeping time is also reduced by insulin and it has been postulated that here a direct effect upon both the CNS and upon hepatic detoxication may be involved. In mice, thiopental anesthesia is prolonged by alloxan diabetes, perhaps as a consequence of a deranged metabolic degradation of the barbiturate, but insulin fails to correct this effect.

Pancreatic hormones also appear to affect the toxicity of **digitalis** alkaloids. In dogs, pancreatectomy offers moderate protection against lethal doses of k-strophanthin; in rats, insulin enhances the cardiac action of this compound but not of its aglycon, strophanthidin.

The beriberi produced in pigeons by **vitamin-B<sub>1</sub>** deficiency is aggravated by insulin, but only under certain circumstances. In rats, moderate alloxan diabetes does not significantly affect thiamine deficiency.

In rats pretreated with **vitamin D**, alloxan produces selective calcification of the Langerhans islets as a consequence of calciphylaxis.

### Acetone ←

*Hirschfelder & Maxwell 26,930/24*: In rabbits, insulin fails to antagonize the toxic effects of ethanol or acetone.

### Acetonitrile ←

*Paal 22,603/30*: Review of the literature and extensive personal studies on the acetonitrile test in mice and its use for the determina-

tion of thyroid hormone in human blood. Thyroidectomy does not increase the resistance of the mice to acetonitrile but diminishes the protective effect of thyroxine. Concurrent treatment with insulin also inhibits the prevention of acetonitrile toxicity by thyroxine.

Aminopyrine ← Alloxan + Insulin: Dixon et al. *E35,705/63*; Kato et al. *F57,817/65*

**Anaphylactoidogens** ← cf. also *Selye G46,715/68, pp. 104, 108, 177, 179, 184, 197.*

*Adamkiewicz & Langlois C31,853/57:* In rats, insulin sensitizes to the production of anaphylactoid edema by the systemic or intrapedal injection of small doses of dextran. The sensitization manifests itself even despite cortisone treatment.

*Adamkiewicz D61,626/63:* Review showing that "hyperglycemias resulting from overdosage with sugars, cortisol, adrenaline, or from diabetes inhibit the anaphylactoid reactions; anaphylaxis, and the tuberculin reaction, but potentiate infections. Hypoglycemias resulting from fasting, insulin and adrenalectomy potentiate the anaphylactoid reactions, anaphylaxis, and the tuberculin reaction; but inhibit infections. The hypothesis is proposed that hyperglycemia inhibits certain antigen-antibody combinations; this results in an inhibition of hypersensitivity, but an aggravation of infection."

*Sacra & Adamkiewicz F49,352/65:* In rats, the toxicity of Cpd. 48/80 is increased by insulin and diminished by glucose.

Aniline ← Alloxan + Insulin: Dixon et al. *E35,705/63*

Aniline ← Alloxan + Orchidectomy + Methyltestosterone: Kato et al. *F57,817/65*

Anticoagulants ← Tolbutamide, Rb, Man: Chaplin et al. *D99,463/58\**

Anticoagulants ← Glucagon, Man: Koch-Weser *G73,494/70\**

### **Barbiturates** ←

*Reinhard B283/45:* In mice, the hexobarbital sleeping time is prolonged by epinephrine or insulin.

*Westfall B31,306/46:* In rabbits, pentobarbital sleeping time is shortened by epinephrine and insulin despite their opposite effect upon blood sugar. [This contradicts Reinhard B283/45 (H.S.).]

*Holck B42,745/48:* In mice, neither epinephrine nor insulin altered significantly the fatal dose of hexobarbital given 20 min later.

*Dixon et al. D9,331/61:* In alloxan diabetic rats, the ability of the hepatic microsomal fractions to inactivate hexobarbital, chlorpromazine or codeine in vitro is diminished and the sleeping time following hexobarbital injection in vivo prolonged. These effects can be reversed by insulin and roughly parallel the glycogen content of the liver. "Factors leading to severe depletion of hepatic glycogen will

probably affect the rate at which drugs are metabolized by the microsomes."

*Shrotri et al. D27,239/62:* In guinea pigs, hexobarbital sleeping time is reduced by insulin. "A direct effect on the CNS as well as a role in the detoxification in liver are postulated."

*Dixon et al. E35,705/63:* In alloxan-diabetic rats, "a depressed metabolism of hexobarbital and aminopyrine in vitro, an increased in vitro hydroxylation of aniline, and a prolonged in vivo effect of hexobarbital were evident. The O-dealkylation of codeine was unaffected by the chronic diabetic state. Insulin treatment returned the rate of metabolism of hexobarbital to normal levels but had no effect on aminopyrine metabolism. Metabolism of aniline was decreased below the normal rate after insulin treatment. Phenobarbital treatment of diabetic animals resulted in a stimulation of most of the drug-metabolizing enzyme systems studied. However, the hydroxylation of aniline by livers from diabetic rats treated with phenobarbital was decreased." A relationship between hepatic glycogen and drug-metabolizing enzyme activity is suspected.

*Kato & Gillette F57,817/65:* The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Vincent & Motin G51,414/67:* Description of a patient who recovered from severe combined intoxication with barbiturates and insulin.

*Quevauviller & Podevin G57,209/68:* In mice, alloxan diabetes prolongs thiopental anesthesia by interfering with the metabolic degradation of the barbiturate. Insulin fails to correct this effect.

*Weiner et al. H24,942/70:* In rats, glucagon, alloxan and starvation all increased hexobarbital sleeping time. This effect was markedly antagonized by insulin. Perhaps, cyclic AMP may be involved since theophylline greatly increases the action of glucagon. This synergism

also occurred in isolated, perfused rat livers and, hence, "inhibition of hexobarbital metabolism by cyclic AMP would appear to be mediated in the liver."

Amobarbital ← Insulin + Glucose, Rb: Maloney et al. 61,235/31\*

Hexobarbital ← Insulin, Mouse: Reinhard B283/45\*; Holck B42,745/48\*, D28,543/49\*

Hexobarbital ← Alloxan + Insulin: Dixon et al. D9,331/61\*; Fouts G77,514/62; Dixon et al. E35,705/63

Hexobarbital ← Tolbutamide: Remmer G66,542/62\*; Rümke et al. G74,669/60\*; Kato et al. E47,494/64; Remmer et al. D19,394/64\*, G66,868/65\*; Remmer F90,864/67\*

#### Bilirubin ←

Müller-Oerlinghausen & Schinke G79,199/70: In rats, the maximal transport capacity of the liver (Tm) for bilirubin is reduced in diabetes caused by alloxan or anti-insulin serum. "It is suggested that the reduced synthesis of UDP-glucuronic acid which has been found in former experiments in vitro is responsible for the impaired bilirubin excretion." The excretion of indocyanine green is likewise inhibited in experimental diabetes.

Bilirubin ← Tolbutamide, Dog: Singh et al. D6,799/61\*

#### Caffeine ←

Labbé & Théodoresco I7,831/24: In dogs and rabbits, resistance to caffeine is somewhat increased by insulin but the results are not impressive.

#### Carbon Tetrachloride ←

Furukawa F71,711/65: In rats, hepatic steatosis produced by CCl<sub>4</sub> is inhibited by adrenalectomy and, to some extent, also by hypophysectomy. Corticoids restore the effect of CCl<sub>4</sub> after adrenalectomy; epinephrine does not, but it increases the effect of corticoids. STH does not counteract the effect of hypophysectomy. Alloxan diabetes inhibits CCl<sub>4</sub>-induced hepatic lipidosis.

#### Carcinogens ←

Dunning et al. A48,770/48: In rats, "the diabetic condition induced by alloxan shortened the life span of the affected individuals, thereby reducing both the percentage of rats

surviving long enough to develop benzpyrene sarcomas and the average latent period of those which did, but did not prevent or delay the malignant process in the rats surviving to the average time of occurrence for these neoplasms."

Salzberg & Griffin B68,802/52: In rats, hepatic carcinogenesis following treatment with 3'-Me-DAB is inhibited by alloxan diabetes.

Klärner & Klärner C45,812/58: In BAF<sub>1</sub> mice, the growth of urethan-induced pulmonary tumors is significantly inhibited by alloxan diabetes and exposure to heat, but only slightly affected by thyroxine and insulin.

Tinozzi & Pannella D54,092/61: In rats, alloxan diabetes largely prevents the induction of tumors by 20-methylcholanthrene.

Lacassagne & Hurst G78,530/69: In rats, tolbutamide (a hypoglycemic sulfonamide) accelerates, whereas diazoxide (a hyperglycemic sulfonamide) retards hepatoma formation after treatment with AAF. When the two compounds are given together, they nullify each other's actions.

Heuson G78,138/70: In rats, DMBA-induced mammary tumors appear to be influenced by insulin, both in vivo and in vitro. DNA synthesis in organ cultures of these carcinomas is stimulated by insulin. Large doses have a strong, probably direct stimulating effect on DMBA-induced neoplasms in vivo, whereas regression is noted in alloxan-diabetic rats.

Carisoprodol ← Tolbutamide: Kato et al. E47,494/64

#### Chlorpromazine ←

Wisniewski & Danysz G40,054/66: In rats, insulin administered simultaneously with chlorpromazine increases the potency and the brain concentration of the latter. "It can be supposed that insulin increases the velocity of the penetration of chlorpromazine across cell membranes in both directions. Hypoglycemia does not show any influence on this effect of insulin and it may be concluded that insulin acts directly on cell membranes."

Wisniewsky & Buczko G51,489/67: In rats, the depressive effect of chlorpromazine is decreased by alloxan and restored to normal by concurrent treatment with insulin.

Chlorpromazine ← Alloxan + Insulin: Dixon et al. D9,331/61\*

Cholesterol ← cf. also Selye B40,000/50, p. 551; G60,083/70, pp. 414-419, 430.

**Cholesterol** ←

*McGill et al. B32,954/49*: In rabbits, cholesterol atherosclerosis is inhibited by alloxan diabetes contrary to the author's expectations.

*Hamprecht G69,560/69*: Review (7 pp., 153 refs.) on the mechanisms regulating cholesterol synthesis. A special section deals with the effect of thyroid hormones, steroids, epinephrine, norepinephrine and glucagon.

*Wellmann et al. H9,536/69*: In cholesterol-fed rabbits, alloxan aggravates the characteristic renal lesions.

**Chromium** ←

*Zondek 36,326/14*: In rabbits, the hypertension produced by uranium and mercury nephritis, unlike that of chromium nephritis, is counteracted by i.v. injection of a beef pancreas extract.

**Cobalt** ←

*Avezzu C46,134/57*: In rabbits, cobalt destroys the alpha cells, alloxan the beta cells, of the Langerhans islets, and hence, there exists a mutual antagonism between these two substances as regards the consequent metabolic effects also.

Codeine ← Alloxan + Insulin:  
*Dixon et al. D9,331/61, E35,705/63*

**Digitalis** ←

*Freund A26,153/32*: Studies on the effect of thyroidectomy or pretreatment with thyroxine or insulin upon the in vitro metabolic changes induced by digitalis compounds in the cat's heart.

*Travis et al. C18,863/56*: In dogs, pancreatectomy offers a slight but significant degree of protection against lethal doses of k-strophanthin. "This would appear to be related to the absence of insulin since hyperglycemia per se, does not afford any protection. Thus these results are in harmony with the concept that insulin facilitates the transport of glycosides having d-glucose as a terminal sugar in somewhat the same manner as it facilitates the transport of the simple sugar."

*Adamkiewicz C97,993/61*: In rats, insulin enhances the cardiac action of k-strophanthin but not of the aglycon strophanthidin.

*Cohn et al. H26,723/70*: In dogs, glucagon abolishes ouabain-induced arrhythmias. The mechanism of this anti-arrhythmic action could not be clarified but glucagon causes an im-

mediate rise, followed by a fall in serum potassium and this may have been involved.

**Dyes** ←

*Müller-Oerlinghausen & Schinke G79,199/70*: In rats, the maximal transport capacity of the liver (Tm) for bilirubin is reduced in diabetes caused by alloxan or anti-insulin serum. "It is suggested that the reduced synthesis of UDP-glucuronic acid which has been found in former experiments in vitro is responsible for the impaired bilirubin excretion." The excretion of indocyanine green is likewise inhibited in experimental diabetes.

Dye (BSP) ← Tolbutamide, Rb:  
*Hasselblatt et al. G77,523/62\**

Dye (BSP) ← Tolbutamide + Ethionine, Mouse: *Fujimoto et al. G30,289/65\**

**Ethanol** ←

*Hirschfelder & Maxwell 26,930/24*: In rabbits, insulin fails to antagonize the toxic effects of ethanol or acetone.

*Hiestand et al. B78,576/53*: In mice, alloxan diabetes and epinephrine increase, whereas insulin decreases, sensitivity to lethal doses of ethanol.

*Hirvonen et al. G59,966/68*: In rats, moderate chronic ethanol intoxication causes hypertrophy of the adrenal glomerulosa. This effect is inhibited by insulin. On the other hand, the ethanol-induced activation of the fasciculata is actually enhanced by insulin.

Ethanol ← Alloxan, Mouse: *Hiestand et al. B78,576/53\**

Ethanol ← Insulin + Glucose, Dog:  
*Greenberg A48,342/42\**; *Sammalisto G76,362/62\**

**Hexadimethrine** ←

*Kovács & Szijj F96,892/68*: In rats, insulin increases sensitivity to hexadimethrine-induced pituitary necrosis; alloxan fails to affect it.

**Lathyrogens** ←

*Franchimont et al. D13,136/61*: In rats, osteolathyrisism produced by AAN is aggravated by 5-HT, whereas glucagon does not modify it significantly.

*van Cauwenberge & Lefebvre G58,189/64*: In rats, osteolathyrisism produced by AAN is not influenced by glucagon.

Meprobamate ← Tolbutamide: *Kato et al. E47,494/64*

**Mercury** ←

*Zondek 36,326/14*: In rabbits, the hypertension produced by uranium and mercury nephritis, unlike that of chromium nephritis, is counteracted by i.v. injection of a beef pancreas extract.

Methampyrone ← Tolbutamide: Remmer *F 90,864/67*

Methylaminoantipyrine ← Tolbutamide: Remmer *G 6,542/62*

Monomethylaminoantipyrine ← Tolbutamide: Remmer et al. *D 19,894/64*

**Morphine** ←

*Wiśniewski E 32,005/63*: In rabbits, insulin increases the analgesic action of morphine and dolantin.

**Pentylentetrazol** ←

*Waltregny & Mesdjan F 78,025/66*: In cats, insulin hypoglycemia raises sensitivity to pentylentetrazol convulsions.

**Peptone** ←

*Barral et al. 8,860/32*: In guinea pigs, anaphylactic and peptone shocks are aggravated by insulin and diminished by glucose.

**Pesticides** ←

*DuBois et al. B 3,089/47*: In rats, both insulin and hypophysectomy antagonize the hyperglycemic effect of ANTU but do not prolong survival.

Dieldrin ← Tolbutamide: Matsu-mura et al. *G 74,472/68*

Picrotoxin ← Insulin: Holck *D 28,543/49\**

**Salicylates** ←

*Wiśniewski & Zarebski F 85,977/67; F 96,973/68*: In mice, insulin greatly increases the analgesic effect of Na-salicylate and its concentration in the brain, heart and skeletal muscle. Alloxan has an opposite effect.

Strychnine ← Tolbutamide: Kato et al. *E 47,494/64*

**Thiouracil** ←

*Pyatnitskaya C 43,809/56*: In rats, the fatty degeneration of the liver produced by thiouracil is prevented by conjoint administration of insulin and glucose.

**Thioacetamide** ←

*Georgii et al. C 69,388/59*: In rats, the hepatic lesions produced by chronic treatment with thioacetamide are at first inhibited and later aggravated by concurrent administration of an antidiabetic sulfanil urea preparation (*D 860, artosin, tolbutamide*).

**Toluene Diisocyanate** ←

*Thompson & Scheel G 55,229/68*: In rats, the toxicity of toluene diisocyanate is diminished by alloxan and increased by insulin or pertussis vaccine. Yet, other evidence suggests that the pulmonary changes produced by this drug are not due to an allergic reaction but to direct chemical damage.

**Uranium** ←

*Zondek 36,326/14*: In rabbits, the hypertension produced by uranium and mercury nephritis, unlike that of chromium nephritis, is counteracted by i.v. injection of a beef pancreas extract.

**Vitamin-B Complex** ← *cf. also Selye C 92,918/61, p. 231.*

*Chahovitch 26,462/25*: In pigeons, insulin aggravates the already manifest symptoms of incipient thiamine deficiency.

*Chahovitch 26,685/25*: In pigeons, insulin pretreatment retards the development of beriberi on a thiamine-deficient diet.

*Baglioni & Console 45,284/34*: In pigeons on a thiamine-deficient diet, the development of beriberi is delayed by daily treatment with insulin, but only under certain experimental circumstances. The extensive literature on the effect of insulin upon beriberi is reviewed.

*Janes & Brady 98,541/47; B 23,359/48*: In rats, alloxan diabetes does not significantly alter the thiamine-deficiency syndrome.

**Vitamin D** ←

*Kodousová et al. D 69,797/63*: In rats pretreated with vitamin D, alloxan causes calcification of the Langerhans islets as a manifestation of calciphylaxis.

**Zinc** ←

*Kamikubo D 7,362/59*: In rats, alloxan decreased the comparatively high zinc content of Yoshida's ascites tumor.

**Varia** ←

*Störtebecker* 76,398/39: Review of the early literature (1924—1937) on the effect of the pancreas upon resistance to various drugs.

*Selye* G70,480/71: In rats, tolbutamide protects against intoxication with dioxathion,

parathion, hexobarbital, progesterone (anesthesia), indomethacin but not against digitoxin, nicotine, zoxazolamine, DHT or the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

**Microorganisms, Vaccines and Parasites** ←

It is a well-known fact that both pancreatic and alloxan diabetes increase sensitivity to a great variety of bacteria, including *Mycobacterium tuberculosis*, pneumococcus, staphylococcus, streptococcus, perfringens and many others.

Alloxan diabetes also aggravates the course of infestation with various parasites, especially, fungus infections.

In mice, insulin decreases resistance to endotoxins allegedly because the hypoglycemic state interferes with defense against the stressor effect of these lipopolysaccharides.

**Bacteria and Vaccines** ←

**Bordetella Pertussis** ←. *Ganley & Robinson* C66,305/59: In mice, sensitized with *B. pertussis* vaccine, alloxan inhibits the response to 5-HT and somewhat less to histamine and anaphylaxis.

*Ganley* D31,168/62: In mice, alloxan diabetes inhibits the sensitizing properties of *B. pertussis* vaccine as measured by challenge with histamine, 5-HT or anaphylaxis. This effect is reversed by insulin.

**Clostridium Welchii** ←. *Wishart & Pritchett* 12,285/20: In dogs, partial pancreatectomy, conducive to severe glycosuria, fails to diminish resistance to infection with *Cl. welchii*.

**Escherichia Coli** ←. *Krizek & Davis* F14,734/64: In rats given alloxan and maintained with insulin, the proliferation of *E. coli* injected s.c. was not greatly altered.

**Mycobacterium Tuberculosis** ←. *Schäfer* B99,955/54: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas and gonads.

*Renovanz* C78,772/59: In guinea pigs, the course of experimental tuberculosis was not markedly influenced by ACTH, tolbutamide derivatives or antithyroid treatment with perchlorates.

*Schäfer & Greuel* D54,900/62: In guinea pigs, the oral antidiabetic, tolbutamide has a deleterious effect upon the development of experimental tuberculosis.

*Dobrev* G23,362/64: In rabbits, alloxan diabetes aggravates the course of experimental tuberculosis and diminishes the allergic response to tuberculin.

**Pneumococcus** ←. *Drachman et al.* F81,617/66: In rats, alloxan diabetes increases susceptibility to experimental Type 25 pneumococcal pneumonia presumably through a depression in phagocytosis.

**Staphylococcus, Streptococcus** ← cf. also *Selye* G60,083/70, p. 418. *Lauber* 9,102/32: Observations on the effect of insulin upon streptococcal and staphylococcal infections in mice.

*Schultz & Rose* B31,347/39: "Guinea pigs treated with maximum tolerated doses of protamine insulin and subjected to chronic, hemolytic streptococcus, focal infection develop nonpurulent carditis. This susceptibility to cardiac damage during infection is probably associated with the altered metabolic activity incident to insulin treatment."

*Bóbr* G30,418/65: In mice, alloxan diabetes raises susceptibility to *Staphylococcus pyogenes*.

**Welchia Perfringens** ←. *Adamkiewicz et al.* F99,983/67: Mice rendered diabetic by alloxan are sensitive to doses of washed *Welchia perfringens* which are innocuous for normal controls.

**Mucormycosis** ←. *Elder & Baker* C12,831/56: In rabbits, alloxan diabetes aggravates the course of pulmonary mucormycosis following intratracheal inoculation of *Rhizopus* spores.

**Trypanosoma Equiperdum** ←. *Ewing et al. B50,244/50*: In mice infected with *T. equiperdum*, severe hypoglycemia develops and both alloxan and glucose exert an immediate analeptic effect.

**Varia** ←. *Sheldon & Bauer D46,962/62*: Review on the role of predisposing factors, particularly alloxan diabetes and ACTH-treatment, upon various fungus infections.

**Bacterial Toxins** ← cf. also *Selye E5,986/66, p. 82*.

*Pieroni & Levine G68,105/69*: In mice, insulin increases mortality produced by endotoxin. "This result is consistent with the thesis that there is a reciprocal relationship between the glycemc state of a host and its susceptibility to a wide variety of stressor agents."

### Immune Reactions ←

We have already mentioned that insulin increases, whereas alloxan diabetes decreases, the anaphylactoid reaction as well as various antigen-antibody responses in different species. Similar effects have been noted in connection with the response to histamine and 5-HT in normal or pertussis sensitized animals. Let us add here that in guinea pigs, anaphylactic and peptone shock are aggravated by insulin and diminished by glucose. Alloxan also desensitizes the guinea pig to tuberculin and this effect is inhibited by insulin.

*Barral et al. 8,860/32; 8,858/32*: In guinea pigs, anaphylactic and peptone shocks are aggravated by insulin and diminished by glucose.

*Cornforth & Long B77,176/53*: In guinea pigs sensitized to tuberculin, single s.c. injections of ATP prevent desensitization by alloxan, cortisone and dihydroascorbic acid. Single s.c. injections of insulin do not in themselves influence sensitivity but prevent desensitization by alloxan and cortisone. Single s.c. injections of STH depress tuberculin sensitivity and synergize the action of cortisone or alloxan.

*Long & Shewell G71,833/54*: In guinea pigs, allergic hypersensitivity to BCG is increased by thyroxine or insulin. Partial pancreatectomy

has no effect on sensitivity by itself but prevents the action of thyroxine, although not that of insulin.

*Long & Shewell G71,832/55*: In guinea pigs, thyroxine increases immunity as judged by the local response to diphtheria toxin injected intradermally and of circulating antitoxin after immunization with diphtheria toxoid. Partial pancreatectomy prevents this effect of thyroxine.

*Ganley & Robinson C66,305/59; Ganley D31,168/62*: In mice, alloxan diabetes inhibits the sensitizing properties of Bordetella pertussis vaccine as measured by challenge with histamine, 5-HT or anaphylaxis. This effect is reversed by insulin.

### Stressors ←

There is no conclusive evidence to suggest that resistance to ionizing rays can be significantly affected by pancreatic preparations. However, in rats, both insulin and carbutamide diminish resistance to hypoxia.

In cats, dogs and chickens, insulin delays the appearance of the shivering reflex upon exposure to cold, whereas glucose reinstalls it. Combined treatment with cold and insulin elicits a state simulating hibernation. Both insulin and alloxan diminish resistance to cold in various species; however, in guinea pigs, insulin allegedly increases resistance to heat stroke.

Combined treatment with insulin + glucose increases the resistance of the rat to trauma in the Noble-Collip drum.

**Ionizing Rays ←**

*Cavallot & Einaudi C 30,084/56*: In guinea pigs, resistance to whole body X-irradiation is increased by treatment with an insulin-free pancreatic extract.

*Gardeyeva C 97,407/60*: In rats, resistance to total body X-irradiation is increased by glucose but additional administration of insulin is of no further advantage.

**Hypoxia and Hyperoxygenation ←**

*Campbell A 14,903/37*: In rats exposed to six atmospheres of oxygen in a pressure chamber, subsequent decompression is better tolerated at low than at high external temperatures. At 24°C, the following substances, administered s.c., enhance oxygen poisoning: thyroxine, dinitrophenol, ac-tetrahydro- $\beta$ -naphthylamine, epinephrine, pituitary extract (posterior lobe), insulin, and eserine + atropine. These doses in themselves are harmless.

*Fister C 97,077/59*: In the rat, both insulin and carbutamide lower resistance to hypoxia.

*Kawashima & Ueda F 68,970/66*: In rats, insulin sensitizes to hypoxia. This effect is inhibited by urethan.

**Cold ←**

*Cassidy et al. 24,604/25*: In cats and dogs, insulin hyperglycemia abolishes the shivering reflex elicited by exposure to cold. Glucose

causes its reappearance. Combined treatment with cold and insulin elicits a state simulating hibernation in cats and dogs.

*Cassidy et al. 26,459/26*: In chickens, insulin delays the appearance of shivering upon exposure to cold until the blood sugar rises.

*Tullio 22,671/30*: In rabbits, exposure to cold decreases the blood sugar, and insulin hypoglycemia decreases resistance to cold.

*Poe & Davis D 27,155/62*: In rats, alloxan diabetes diminishes resistance to cold.

*Poe et al. E 21,412/63*: In rats, alloxan diabetes diminishes resistance to cold but some adaptation to low temperature is possible even during the diabetic stage.

**Heat ←**

*Grazia & Sardo 27,853/34*: In guinea pigs, insulin increases resistance to heat stroke.

**Trauma ←**

*Triner et al. D 65,801/63*: In rats, treatment with insulin + glucose increases resistance to trauma in the Noble-Collip drum.

**Varia ←**

*Ouzelat C 36,618/57*: In rats, insulin aggravates the production of gastric ulcers by pylorus ligation.

**Hepatic Changes ←**

In rats, alloxan and various antidiabetics can produce severe, often necrotizing, hepatic lesions.

*Scharf et al. F 69,957/66*: In rats, chronic treatment with methylthiouracil or paroxypropion produces essentially similar hepatic lesions. T2 reduces liver glycogen and the size of the hepatocytes. Single large doses of alloxan cause severe necrotizing lesions followed by cell proliferation. Concurrent treatment with methylthiouracil inhibits the allo-

xan-induced hepatic lesions and diminishes mortality.

*Klatskin G 65,221/69*: Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis with special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

**Hepatic Enzymes ←**

For the literature concerning the effect of pancreatic hormones upon the basic levels of hepatic TPO, TKT, GOT, GPT, SDH, TDH cf. Abstracts.

**TPO, TKT** ←

*Schor & Frieden C57,994/58:* In the rat, insulin can induce TPO activity, and its effect is only partly inhibited by adrenalectomy. In the intact rat, the effect of insulin and tryptophan, or insulin and cortisone, are additive. Possibly, "hormonal induction may be a form of substrate induction in that certain hormones might affect the availability of typtophan for the enzyme-forming system."

*Finch et al. G71,208/69:* In senescent mice, the induction of hepatic TKT by exposure to cold is delayed in comparison with young mice. Corticosterone and insulin are equally effective in this respect in mice of both age groups.

**SDH, TDH** ←

*Freedland & Avery G67,766/64:* In the rat, the TDH and SDH activity of liver homogenates was increased by high-protein diets, alloxan diabetes, or cortisol. Factors affecting the activity of TDH caused a proportional change in SDH suggesting that both of these activities may be due to a single protein. The SDH activity was decreased by adrenalectomy or hypophysectomy. Adrenalectomy had no effect upon the response of this enzyme to protein feeding, whereas, after hypophysectomy, this response was diminished.

*Ishikawa et al. F41,763/65:* In alloxan-diabetic rats, the SDH and TDH levels of the hepatic microsomes are greatly enhanced. SDH was readily induced by cortisol in the diabetic, but not in the normal rat. The effects of actinomycin S, STH, and starvation upon SDH have also been studied in intact, hypophysectomized, adrenalectomized and thyroidectomized rats. It is concluded that "serine dehydratase activity in the liver plays an important role in the production of pyruvate as a starting material for gluconeogenesis."

**GPT, GOT** ←

*Rosen et al. C50,741/58:* In rats treated with cortisol, cortisone or prednisone for 1 week, there was an increase in hepatic GPT but not in GDT. DOC had no such effect. Hypophysectomy or adrenalectomy did not prevent this action of cortisone. STH, testosterone or insulin failed to alter GPT activity nor did they influence its stimulation by cortisol.

*Rosen et al. C71,414/59:* Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol,

prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nongluocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol, they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT-inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Rosen et al. G66,496/59:* In the rat, cortisol, cortisone and prednisone cause a 6–13 fold increase in hepatic GPT activity. This effect was directly related to the protein content of the ration. In alloxan diabetic rats, the rise in this enzyme activity was equivalent to that obtained by cortisol or high-protein diets and could be inhibited by insulin. Adrenalectomy diminished but did not abolish the rise in GPT activity obtained by feeding high-protein diets. Thus, the initiation of enzyme synthesis by dietary protein is not mediated exclusively through the adrenals.

**Other Enzymes** ←

*Schweppe & Jungmann H15,266/69:* The ability of rat liver microsomes to **synthesize cholesterol palmitate**, oleate and linoleate in vitro is increased by the addition of thyroxine or glucagon to the incubation medium. Testosterone increases cholesterol palmitate and oleate formation. 17 $\beta$ -Estradiol stimulates mainly oleate synthesis.

*Harada et al. H15,156/69:* The **acetyl-CoA-synthetase** activity of the rat liver increases 2–3-fold during alloxan diabetes, fasting, or high-fat diet feeding.

*Kato & Takahashi H11,853/69:* "The magnitude of increase in the activities of microsomal drug-metabolizing enzymes and NADPH-linked electron transport system in the alloxan diabetic rats was greater than in normal rats, in contrast, the magnitude of increase in the thyroxine-treated rats was smaller than in normal rats."

*Müller-Oerlinghausen et al. G64,175/69:* Hepatic tissue of mice which had been injected with tolbutamide, synthesizes an increased

amount of glucuronide when incubated *in vitro* with o-aminophenol. Insulin given at a dose causing a similar degree of hypoglycemia is much less effective in enhancing glucuronide synthesis. Adrenalectomy diminishes the formation of o-aminophenol glucuronide, despite hypoglycemia. However, adrenalectomized mice given cortisone again respond with increased glucuronide synthesis following tolbutamide.

*Shou et al. H15,277/69:* In the rat, the hepatic **methionine adenosyl transferase** activity was not much influenced by glucagon, but during alloxan diabetes it increased considerably. Combined treatment with alloxan and triamcinolone resulted in an additive effect. The response to alloxan could be prevented and even reversed by insulin or adrenalectomy. In normal rats, insulin caused no consistent increase.

### ← EPINEPHRINE AND NOREPINEPHRINE

Even before Walter Cannon put forth his classic concept of the "emergency reaction," it had been realized that the adrenal medulla plays an important part in defense, especially through its effect upon the cardiovascular system. In a sense, the secretion of vasopressor catecholamines into the blood stream complements the protective and adaptive effects of the sympathetic nervous system. On the other hand, we know very little about the possible direct effects of these hormones upon detoxication mechanisms apart from the fact that they may influence these by altering the liver glycogen and blood sugar concentrations.

### Steroids ←

In the rat, epinephrine increases, whereas insulin decreases the anesthetic effect of progesterone. Also in rats, epinephrine and norepinephrine produce eclampsia-like manifestations following pretreatment with DOC + NaCl.

### Nonsteroidal Hormones and Hormone-Like Substances ←

In mice, pretreatment with epinephrine increases resistance to this catecholamine in a rather specific manner.

The diabetogenic action of **alloxan** is diminished by epinephrine in the rabbit.

In dogs, many of the changes produced by **thyroid preparations** are abolished by sympathetic blockade and increased by epinephrine and norepinephrine.

The toxicity of **histamine** is as markedly increased by complete sympathetic blockade as it is by total adrenalectomy in the rat. Epinephrine counteracts the increased susceptibility to histamine, but not to several other stressor agents. It appears that the adrenergic system is the first line of defense against certain stressors (e.g., histamine, endotoxin), whereas resistance to others (e.g., formalin, tourniquet shock) is more dependent upon glucocorticoids.

**Steroids** ← *cf. also Selye G60,083/70, pp. 331, 358, 360.*

*Winter & Selye A35,658/41; Winter A36,333/41:* Epinephrine increases, whereas insulin decreases, the resistance of the rat to the anesthetic action of progesterone.

*Pellanda C7,961/55:* In rats pretreated with DOC and NaCl, epinephrine or norepinephrine produces an eclampsia-like syndrome.

**Cortisol** ← Epinephrine: Kumagai et al. *C57,345/58*

**Steroids** ← Norepinephrine, Cattle: Cooper et al. *D20,337/62*

**17 $\alpha$ -Hydroxyprogesterone** ← Epinephrine, Cattle: Cooper et al. *D20,338/62*

**Nonsteroidal Hormones and Hormone-Like Substances** ← *cf. also Selye C92,918/61, pp. 112, 121; G60,083/70, pp. 358—362.*

*Brewster Jr. et al. C11,771/56:* In dogs, the physiologic changes produced by **thyroid** extract are abolished following sympathetic blockade. The inotropic, chronotropic and calorogenic effects of epinephrine and norepinephrine are increased by thyroid feeding. "It is concluded that there is a dynamic interrelationship between the thyroid hormones and those of the adrenal medulla and sympathetic nerve endings."

*Carrasco-Formiguera & Escobar B19,877/48:* In rabbits, epinephrine i.m. inhibits the diabetogenic action of **alloxan**.

*Gasic B17,561/47:* In mice, pretreatment with **epinephrine** increased resistance to this catecholamine but not to formalin. Apparently, at least under these conditions, cross-resistance does not occur.

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bitylium-like agents (preventing nerve impulse from releasing catecholamines)

or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and **histamine** after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

### Drugs ←

The **anaphylactoid** edema produced in rats by egg-white can be prevented by epinephrine or norepinephrine, but not by isoproterenol. The gastric hemorrhages elicited by polymyxin (another anaphylactoidogen) are even more effectively prevented by epinephrine than by various antihistamines.

In guinea pigs, epinephrine injected on awakening from **barbiturate** anesthesia produced a return of sleep. This effect could be duplicated by glucose, lactate or glutamate in intact animals but after adrenalectomy only epinephrine was effective. In mice, epinephrine also prolongs the hypnotic effect of various barbiturates, although allegedly thiopental and barbital anesthesia is mildly reduced by it, under certain circumstances, perhaps because epinephrine (unlike norepinephrine) enhances the penetration of barbital into the brain. In any event barbital and epinephrine (but not norepinephrine) may cause very peculiar neurologic manifestations — associated with ataxia, incoordination and loss of righting reflex — at doses at which barbital alone has no such effect.

In rabbits, pentobarbital sleeping time is shortened by epinephrine, but if administered just after awakening from thiopental anesthesia, epinephrine reinduces sleep; yet, epinephrine (unlike norepinephrine) causes rapid awakening if given to rabbits during thiopental anesthesia.

**Carbon tetrachloride** given simultaneously with epinephrine to the dog often leads to fatal ventricular fibrillation. In rats, epinephrine or norepinephrine fails to potentiate the hepatotoxic effect of  $\text{CCl}_4$  and, in isolated perfused rat livers, the hemodynamic effects of norepinephrine are increased by  $\text{CCl}_4$ . On the other hand, in mice the hepatotoxicity of  $\text{CCl}_4$  has been claimed to be considerably increased by concurrent administration of either epinephrine or norepinephrine.

In dogs, epinephrine injected during **chloroform** anesthesia readily produces collapse and death. Pretreatment with epinephrine has no such effect, indeed it may protect the dog against subsequent combined treatment with chloroform and epinephrine. The chloroform-epinephrine collapse can be prevented in dogs by lithium carmine or induced hypothermia.

The muscular paralysis produced by **curare** derivatives can be inhibited by epinephrine in several species.

Various observations suggest that at least under certain circumstances norepinephrine may increase the effect of **digitalis** derivatives.

The toxicity of **ganglioplegics** (e.g., hexamethonium) is counteracted by epinephrine in the guinea pig. On the other hand, tetraethylammonium may considerably sensitize the dog to the pressor effect of epinephrine and other vasopressor agents. In rabbits, combined treatment with epinephrine and tetraethylammonium may also result in dangerous intoxication.

There is some evidence that in rats and dogs, epinephrine offers some protection against **mescaline** intoxication.

The head and neck edema induced by **paraphenylenediamine** is moderately inhibited by epinephrine.

In mice, **pentylene-tetrazol** convulsions can be inhibited by combined administration of norepinephrine and 5-HT into certain regions of the brain. In one-day old chicks in which the blood-brain barrier is still incompletely formed, epinephrine (as well as 5-HT or histamine) prevent pentylene-tetrazol convulsions and produce sleep.

**Picrotoxin** convulsions are also inhibited by intracerebral administration of epinephrine or 5-HT in mice.

In various species, **reserpine** intoxication is counteracted by epinephrine.

In rabbits, concurrent treatment with **sparteine** and epinephrine causes cardiac and hepatic lesions which are not obtained at comparable dose levels by either agent alone.

Epinephrine offers considerable protection against **strychnine** convulsions in frogs, guinea pigs and mice.

In cholesterol-fed rabbits, the anti-atheromatous action of **Tween 80** is inhibited by norepinephrine.

It has been claimed that, in **vitamin-D** deficient rats, the healing of rickets can be initiated by epinephrine, but these observations require confirmation. On the other hand, the production of cardiovascular calcification by DHT is enhanced by norepinephrine in the rat. The progeria-like syndrome produced by chronic treatment with small doses of DHT in rats is not influenced by epinephrine. However, a single large dose of this catecholamine often causes calcifying mural ball valve thrombi in the left atrium of rats pretreated with large doses of DHT (or parathyroid extract).

#### **Acetonitrile** ←

*Paal 22,603/30:* In mice, acetonitrile resistance is not consistently influenced by posterior pituitary extract (hypophysin), a

folliculoid preparation (progynon), or epinephrine.

*Dessau 34,845/35:* In rats, adrenalectomy decreases resistance to acetonitrile. Resistance

can be slightly restored by adrenocortical transplants, but not by the adrenocortical extract tested or by epinephrine.

#### **Allyl Alcohol** ←

*Strubel et al. G80,282/70*: In rats, norepinephrine did not augment the hepatotoxicity of  $\text{CCl}_4$  or allyl alcohol at doses of 0.25 mg/kg or less. However, at the dose of 1 mg/kg, at which norepinephrine itself causes liver damage, it potentiates the hepatotoxicity of these agents. Earlier claims that  $\text{CCl}_4$  causes liver damage only through the massive liberation of endogenous catecholamines could not be confirmed.

Aminopyrine ← Norepinephrine + Phenoxybenzamine: Dixon et al. *G11,757/64*

#### **Amitriptyline** ←

*Nymark & Rasmussen G42,054/66*: In rabbits, norepinephrine offered no considerable protection against the ECG changes produced by amitriptyline.

**Anaphylactoidogens** ← cf. also *Selye B40,000/50*, p. 758; *G46,715/68*, pp. 177, 178, 181, 187.

*Clark & MacKay B36,925/49*: In rats, the anaphylactoid edema produced by egg white i.p. is prevented by epinephrine or norepinephrine s.c.; isoproterenol is ineffective.

*Moreno & Brodie D20,261/62*: In rats, the gastric hemorrhages that occur 2 hrs after polymyxin s.c. are more effectively prevented by epinephrine than by various antihistamines (cypheptadine, chlorpheniramine, pyrilamine). At very high doses, chlorpromazine and dibenzylamine were also effective but anticholinergic drugs and antacids were not. Presumably, lesions were due to gastric vascular changes without involvement of the secretory mechanism.

*Adamkiewicz D61,626/63*: Review showing that "hyperglycemias resulting from overdosage with sugars, cortisol, adrenaline, or from diabetes inhibit the anaphylactoid reactions; anaphylaxis, and the tuberculin reaction; but potentiate infections. Hypoglycemias resulting from fasting, insulin and adrenalectomy, potentiate the anaphylactoid reactions, anaphylaxis, and the tuberculin reaction; but inhibit infections. The hypothesis is proposed that hyperglycemia inhibits certain antigen-antibody combinations; this results in an inhibition of hypersensitivity, but an aggravation of infection."

Aniline ← Norepinephrine + Phenoxybenzamine: Dixon et al. *G11,757/64*

**Antibiotics** ← cf. *Selye G60,083/70*, pp. 358, 361.

#### **Anticoagulants** ←

*Jaques G70,979/68*: Review (30 pp., 13 refs.) on the "hemorrhagic stress syndrome" that is produced in various mammals treated with indirect anticoagulants (e.g., phenindione, dicoumarol) and then exposed to stress or treated with DOC, ACTH, or STH. Conversely, cortisone, epinephrine, ephedrine and adrenochrome inhibit this syndrome.

#### **Arsenic** ←

*Hanzlink & Karsner 10,286/20*: In guinea pigs, epinephrine can prevent true anaphylactic shock but not the anaphylactoid shock produced by peptone, dextrin or agar. The arsenamine-induced disturbances (which have been regarded by some as anaphylactoid) are diminished by epinephrine, presumably as a consequence of its circulatory action.

#### **Barbiturates** ←

##### Dog

*Werle & Lentzen A28,007/38*: In dogs and rabbits, various vasoactive substances (epinephrine, histamine, vasopressin, kallikrein) tend to prolong the anesthetic effect of pro-narcon and hexobarbital.

*Rolf & Campbell H18,467/69*: In dogs, anesthesia by various thiobarbiturates sensitizes for the production of cardiac arrhythmias by epinephrine.

Hexobarbital ← Epinephrine, Dog: Dallemagne *A47,748/41\**

##### GUINEA PIG

*Lamson et al. B89,712/52*: In guinea pigs, epinephrine injected i.p. on awakening from barbiturate anesthesia produced a return to sleep. A similar effect was caused by glucose, lactate, or glutamate. However, in adrenalectomized animals, only epinephrine was effective.

Hexobarbital ← Epinephrine, Gp: Lamson et al. *C14,547/51\**

##### MOUSE

*Reinhard B283/45*: In mice, the hexobarbital sleeping time is prolonged by epinephrine or insulin.

*Holck B42,745/48*: In mice, neither epinephrine nor insulin altered significantly the fatal dose of hexobarbital given 20 min later.

*Fastier D95,950/56*: In mice, 5-HT considerably potentiates the hypnotic effect of cyclobarbitol and chloral hydrate. However, this property is not very specific, since bufotamine, tryptamine, histamine, and epinephrine likewise prolong cyclobarbitol hypnosis. Literature on numerous other drugs which prolong barbiturate anesthesia is cited. "It therefore seems possible that the ability of 5-HT to prolong hypnosis may be due to a relatively unspecific, vascular effect."

*Pradhan et al. C13,632/56*: In 3 strains of mice, urethan sleeping time was greatly increased by epinephrine and norepinephrine. Phenobarbital sleeping time was only mildly increased by epinephrine.

*Komiya et al. C21,326/56*: In mice, thiopental anesthesia is reduced in severity, but not in duration, by epinephrine. Barbitol anesthesia was slightly reduced by norepinephrine but not by epinephrine. Unpublished experiments suggest that ACTH and glucocorticoids shorten the duration of barbitol anesthesia in mice.

*Holtz et al. C76,300/58*: In mice just awakening from hexobarbital anesthesia, sleep is reinduced by norepinephrine but not by epinephrine.

*Kato C78,047/59*: In mice, the prolongation of pentobarbital or hexobarbital sleeping time by 5-HT (administered in the form of its precursor 5-HTP which penetrates the brain barrier more readily) is inhibited by DOPA; the latter presumably acts as a precursor of norepinephrine.

*Mazel & Bush D4,194/61*: In mice, the penetration of barbitol into the brain and the resulting anesthesia are enhanced by epinephrine but not by norepinephrine.

*Fouts D43,347/62*: Repeated injections of epinephrine i.p. increase the hexobarbital- and chlorpromazine-destroying effect of hepatic microsomal fractions in the rat.

*Ellinwood & Prange E39,187/64*: In mice, high doses of epinephrine prolonged sleeping time in themselves and potentiated the effect of thyroid feeding. The prolongation of pentobarbital sleeping time by epinephrine may be due to depletion of hepatic glycogen which interferes with hepatic microsomal-drug metabolism.

*Kato & Gillette F57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by

adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Vizet F77,760/67*: In mice, combined treatment with barbital and epinephrine causes "spectacular neurologic modifications," with ataxia, muscular incoordination and loss of righting reflex, at dose levels at which barbital alone has no such effect. Norepinephrine does not markedly influence barbital intoxication. There is a parallel increase in the cerebral concentration of the barbiturate when epinephrine is added to barbital, but an augmentation of the blood-brain barrier permeability does not completely account for the increase in toxicity.

*Mazel & Bush G65,299/69*: In mice, epinephrine increases the anesthetic effect and brain concentration of barbital. "The epinephrine effect, however, cannot be attributed to increased brain barbital levels alone, because at 10 min the controls showed no signs of depression with the same brain barbital levels as the 'anesthetized' epinephrine-treated animals."

Hexobarbital ← Epinephrine,  
Mouse: Reinhard B283/45\*; Holck B42,745/48\*; Holtz et al. C76,300/58\*; Mathies et al. D84,334/61\*

Pentobarbital ← Epinephrine +  
Thyroid extract, Mouse: Ellinwood et al. E39,187/64\*

#### RABBIT

*Westfall B31,306/46*: In rabbits, pentobarbital sleeping time is shortened by epinephrine and insulin despite their opposite effect upon blood sugar.

*Fenu C17,650/54*: In rabbits just awakening from thiopental anesthesia, epinephrine i.v. reinduces sleep. A smaller dose of epinephrine injected intracysternally, though equivalent as regards its stressor effects, does not reinduce sleep under these conditions. Since other stressors likewise failed to share this effect of epinephrine, the latter cannot be merely due to an activation of the pituitary-adrenocortical axis.

*Cahn et al. G71,537/56:* In rabbits, the prolongation of barbiturate (Kemithal, Meubarbital) anesthesia by 5-HT is further prolonged by phentolamine, neostigmine and several other drugs, whereas epinephrine and pantheline have an opposite effect.

*Savoldi et al. C92,984/60:* In rabbits, epinephrine, unlike norepinephrine, causes rapid awakening from thiopental anesthesia.

#### RAT

*Milošević C39,053/56:* In rats, epinephrine i.p. administered almost simultaneously with thialbarbital i.v. prolongs anesthesia. The effect of several other anesthetics (chloral hydrate, paraldehyde, tribromoethanol, chlorobutanol, chloralose and ethanol) is likewise significantly prolonged by epinephrine pretreatment. Norepinephrine, cobefrine, synephrine, suprifren and ephedrine also prolong thialbarbital anesthesia, whereas amphetamine and methamphetamine exert an inverse effect. The somewhat contradictory earlier literature on the effect of catecholamines upon anesthesia is briefly reviewed.

*Slocombe C14,144/56:* In rats under thiopental anesthesia, epinephrine, norepinephrine, adrenochrome, and 5-HT cause a flattening of the electrical activity both at cortical and at subcortical sites.

#### MAN

*von Reis C76,244/59:* In patients with barbiturate intoxication, norepinephrine i.v. is beneficial presumably because it prevents anuria by inhibiting the hypotension.

Hexobarbital ← Epinephrine: Fouts *D43,347/62, G76,304/63*

Hexobarbital ← Norepinephrine + Phenoxybenzamine: Dixon et al. *G11,757/64*

#### **Benzol** ←

*Dautrebande 8,083/32:* In dogs, benzol inhalation during epinephrine treatment tends to produce fatal collapse.

#### **Caffeine** ←

*Johnson & Siebert C91,021/28; C91,037/28:* In rabbits, the cardiac lesions produced by caffeine are greatly aggravated by concurrent treatment with epinephrine.

#### **Carbon Tetrachloride** ←

*Hermann et al. 10,215/31; Hermann & Vial 32,885/35:* In dogs, fatal ventricular

fibrillation is elicited by epinephrine not only when the hormone is given in combination with chloroform but also when administered with CCl<sub>4</sub> or CH<sub>2</sub>Cl<sub>2</sub>.

*Furukawa F71,711/65:* In rats, hepatic steatosis produced by CCl<sub>4</sub> is inhibited by adrenalectomy and, to some extent, also by hypophysectomy. Corticoids restore the effect of CCl<sub>4</sub> after adrenalectomy; epinephrine does not but it increases the effect of corticoids. STH does not counteract the effect of hypophysectomy. Alloxan diabetes inhibits CCl<sub>4</sub>-induced hepatic lipidosis.

*Larson & Plaa F29,496/65:* In rats, infusion of large amounts of epinephrine or norepinephrine did not potentiate the hepatotoxic effect of CCl<sub>4</sub> nor did it induce CCl<sub>4</sub>-like hepatic lesions after transection of the spinal cord. These and other observations suggest that protection of the liver against CCl<sub>4</sub>-induced lesions by cervical cordotomy is not due to blockade of adrenergic mechanisms but to reduced hepatic metabolism consequent to hypothermia.

*Rice et al. G55,767/67:* In isolated perfused rat livers, the hemodynamic effects of norepinephrine are increased by CCl<sub>4</sub>.

*Schwetz & Plaa G67,000/69:* In mice, the hepatotoxicity of CCl<sub>4</sub> i.p. is greatly increased by simultaneous treatment with epinephrine or norepinephrine s.c. "Epinephrine and norepinephrine may play a secondary potentiating role in CCl<sub>4</sub>-induced hepatotoxicity."

*Strubelt et al. G80,282/70:* In rats, norepinephrine did not augment the hepatotoxicity of CCl<sub>4</sub> or allyl alcohol at doses of 0.25 mg/kg or less. However, at the dose of 1 mg/kg, at which norepinephrine itself causes liver damage, it potentiates the hepatotoxicity of these agents. Earlier claims that CCl<sub>4</sub> causes liver damage only through the massive liberation of endogenous catecholamines could not be confirmed.

#### **Chloral Hydrate** ←

*Fastier et al. C37,038/57:* In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone and DOC did not prolong chloral hydrate sleeping time at the doses tested.

**Chloroform** ←

*Davis & Whipple 58,731/19*: In dogs, pretreatment with epinephrine protects against the production of hepatic necrosis produced by chloroform anesthesia. This resistance requires several days of pretreatment and cannot be obtained by a single epinephrine injection just before chloroform administration.

*Bardier & Stillmunkès 25,803/26*: The collapse produced by epinephrine + chloroform is inhibited by scorpion and vipera venom [species is not stated but presumably dog (H.S.).] In dogs, epinephrine injected during chloroform anesthesia readily produces collapse and death. Injected before chloroform, epinephrine is harmless at similar dose levels. Indeed, pretreatment with epinephrine can protect the dog against subsequent combined administration of chloroform plus epinephrine.

*Hermann et al. 10,215/31; Hermann & Vial 32,885/35*: In dogs, fatal ventricular fibrillation is elicited by epinephrine not only when the hormone is given in combination with chloroform but also when administered with  $\text{CCl}_4$  or  $\text{CH}_2\text{Cl}_2$ .

*Tournade & Raymond-Hamet 7,436/32*: In dogs, norepinephrine i.v. produces fatal collapse during chloroform anesthesia.

*Velluda & Russu 38,782/36*: In dogs, chloroform-epinephrine collapse can be prevented by lithium carmine.

*Szilágyi et al. D21,498/61*: In dogs, the epinephrine-chloroform syncope is inhibited by hypothermia.

**Chlorpromazine** ← **Epinephrine**:  
*Fouts D43,347/62, G76,304/63*

**Cholesterol** ← cf. also *Selye G60,083/70*, pp. 358, 359.

*Trentini et al. G71,152/68*: In rabbits, the cholesterol-atherosclerosis-inhibiting effect of Tween 80 is diminished both by 5-HT and by norepinephrine.

*Hamprecht G69,560/69*: Review (7 pp., 153 refs.) on the mechanisms regulating cholesterol synthesis. A special section deals with the effect of thyroid hormones, steroids, epinephrine, norepinephrine and glucagon.

**Cocaine** ←

*Avant & Weatherby C81,325/60*: Review on the inhibition of the systemic toxicity of various local anesthetics by admixture of epinephrine which delays their absorption. Personal observations on mice showed that among five cocaine derivatives, only one

(tetracaine) exhibited considerably decreased systemic toxicity upon addition of epinephrine to the s.c. injected anesthetic.

**Curare** ←

*Bremer & Titeca 23,673/28*: In decerebrate cats, the abolition of rigidity by curare is counteracted by epinephrine i.v.

*Maddock et al. B18,670/48*: In dogs, intra-arterial injection of epinephrine blocks the effect of i.v.-administered curare upon the musculature. This blockade is abolished by Dibenamine.

*Constantin & Bouyard H15,750/69*: In rabbits, the muscular paralysis produced by alcuronium is inhibited by epinephrine presumably through an  $\alpha$ -adrenergic mechanism.

**Cyclohexylamine** ← cf. *Selye G60,083/70*, pp. 358, 363.

**Digitalis** ←

*Ghedini & Ollino A21,128/14*: Brief mention of observations on rabbits showing that epinephrine i.v. "favorably influences" the hemodynamic actions of digitalin, whereas pancreatic powder influences them "unfavorably."

*Lage & Spratt F86,237/67*: In mice, norepinephrine does not influence the toxicity of digitoxigenin. However, the protection by reserpine against digitoxigenin poisoning is inhibited by large doses of norepinephrine which "would suggest that the depletion of catecholamines by reserpine may be responsible for the protection."

*Morrow G47,272/67*: In dogs under pentobarbital anesthesia, ouabain tolerance was diminished by large doses of norepinephrine. "The studies suggest that a therapeutic level of digitalis may become toxic during the administration of large doses of norepinephrine."

**Ergotamine** ←

*Tinel & Ungar I4,897/33*: In guinea pigs, epileptoid convulsions are produced by epinephrine given conjointly with ergotamine, peptone or yohimbine.

**Ethanol** ←

*Hiestand et al. B78,576/53*: In mice, alloxan diabetes and epinephrine increase, whereas insulin decreases, sensitivity to lethal doses of ethanol.

Ethanol ← Epinephrine, Mouse:  
Hiestand et al. B78,576/53\*

#### Formalin ←

*Gasic B17,561/47*: In mice, pretreatment with epinephrine increased resistance to this catecholamine but not to formalin. Apparently, at least under these conditions, cross-resistance does not occur.

#### Ganglioplegics ←

*Page & Taylor B24,841/47*: In earlier publications, epinephrine "has been recommended as the antidote of choice after excessive doses of tetraethyl ammonium chloride." In the present experiments on dogs, it is shown that under certain circumstances, especially during pentobarbital anesthesia, TEA may considerably sensitize to the pressor effect of epinephrine, renin and angiotensin.

*Byrne C46,341/56*: In rabbits, the effect of various drugs upon pulmonary embolisms produced by graphite particles has been investigated. "The combination of epinephrine and tetraethyl-ammonium was dangerous, since epinephrine is a ganglion blocking agent and enhances the effect of tetraethyl-ammonium."

*Orione C37,851/56*: Guinea pigs are protected by epinephrine against the hypothermia and mortality of hexamethonium intoxication.

#### Halothane ←

*Nikki & Rosenberg G71,574/69*: In mice, shivering and hypothermia are prevented by norepinephrine and 5-HT but not by dopamine. "The results suggest that brain catecholamines participate in the control of shivering and return of normothermia after halothane anesthesia in mice."

#### Hexamethonium ← cf. Ganglioplegics

*Lathyrogens* ← cf. also *Selye G60,083/70*, pp. 358, 361.

*Kohn & Rivera-Velez F73,678/65*: In rats pressed lathyrin by APN fumarate, the vaso-pressor effect of norepinephrine is diminished.

*Lead Acetate* ← cf. *Selye C19,425/65*, p. 137.

#### Meperidine ←

*Radouco-Thomas et al. E60,201/57*: In guinea pigs, the analgesic effect of meperidine is diminished by reserpine and counteracted by concurrent administration of norepinephrine.

#### Meprobamate ←

*Belaval & Widen C76,528/58*: In a few patients, some of the effects of meprobamate intoxication were antagonized by norepinephrine.

#### Mescaline ←

*Speck C31,193/57*: In rats, epinephrine inhibits the bradycardia and hypoglycemia but not the mortality induced by mescaline.

*Schopp et al. E92,442/61*: In the dog, epinephrine (like KCl and neostigmine) can oppose the paralyzing action of mescaline.

#### Methanol ←

*Severin & Bashkurov G49,801/67*: In patients with acute methanol poisoning, combined treatment with norepinephrine, cortisone and various other agents facilitated recovery. [In view of the complex treatment given, it is impossible to ascertain the relative value of each component of the therapeutic regimen (H.S.).]

#### Methoxyflurane ←

*Catton G71,124/69*: In rabbits given epinephrine i.v., methoxyflurane anesthesia depends largely upon CO<sub>2</sub> and O<sub>2</sub> tensions.

#### Methyltropolone ←

*Murnaghan & Mazurkiewicz D68,260/63*: In mice, the toxicity of 4-methyltropolone is greatly increased by epinephrine. "The results suggest that the in vivo effects of methyltropolone are not only due to inhibition of O-methyltransferase but are also due to a blockade at both alpha and beta receptor sites. Blockade of alpha receptors by methyltropolone suggests that attachment of the ring hydroxyls of the adrenergic amine is a prerequisite for excitation at this receptor."

#### Morphine ←

*Miller et al. G73,877/55*: Review of earlier literature suggesting that morphine analgesia is mediated through the release of epinephrine from the adrenal medulla. It had been claimed that adrenalectomy decreases the pain reaction threshold to morphine and that morphine itself has an analgesic effect. However, in the authors' experiments on rats these observations could not be confirmed and TEA failed to reverse the effect of morphine on pain. In mice,

near lethal doses of epinephrine or norepinephrine were required to raise the pain threshold.

*Heller et al. H2,707/68:* In mice, epinephrine, norepinephrine, and isoproterenol possess a certain analgesic effect of their own and enhance analgesia produced by morphine.

*Heller et al. H13,896/68:* In mice and rats, the analgesic effect of morphine is increased by epinephrine or norepinephrine i.v.

#### Nicotine ←

*Hueper 91,722/43:* In rats, the cardiovascular lesions produced by chronic nicotine intoxication are aggravated both by epinephrine and by DOC.

**Papain** ← *cf. also Selye C50,810/58, p. 106; C92,918/61, p. 110; G60,083/70, pp. 358, 361.*

*Zacco & Pratesi B37,559/47:* In guinea pigs, papain shock can be prevented by pre-treatment with epinephrine.

#### Paraoxon ←

*de Candole C25,237/56:* In rabbits, resistance to the anticholinesterase paraoxon is increased, under certain conditions, by norepinephrine.

#### Paraphenylenediamine ←

*Meissner E52,567/19:* The head and neck edema produced by paraphenylenediamine in the rabbit is not prevented by epinephrine, posterior pituitary extract or thyroid extract.

*Tainter 25,429/26; 23,737/28:* In rabbits, the head and neck edema produced by paraphenylenediamine is inhibited by epinephrine and related catecholamines.

*Cohen et al. 92,880/33:* In rabbits, paraphenylenediamine-induced head and neck edema is delayed but not completely abolished by epinephrine.

#### Pentylentetrazol ←

*Schmidt & Matthies D34,219/62:* In mice, 5-HT or norepinephrine injected into certain regions of the brain is without effect upon pentylentetrazol injections in itself, but counteracts the inhibitory effect of intracerebrally-injected reserpine.

*Schmidt E32,188/63:* In mice, pentylentetrazol convulsions are inhibited by combined administration of 5-HT and norepinephrine into certain regions of the brain.

*Kobrin & Seifter F74,422/66:* In one day old chicks, in which the blood-brain barrier is

still incompletely formed, various  $\omega$ -amino acids as well as 5-HT, histamine and epinephrine, produce sleep and prevent pentylentetrazol convulsions.

*Jones & Roberts G60,654/68:* In mice, the convulsive effect of pentylentetrazol is inhibited by norepinephrine administered intracerebroventricularly.

*Schlesinger et al. G69,565/69:* In mice, intracranial injections of 5-HT or norepinephrine protect against pentylentetrazol convulsions.

#### Peptone ←

*Hanzlink & Karsner 10,286/20:* In guinea pigs, epinephrine can prevent true anaphylactic shock but not the anaphylactoid shock produced by peptone, dextrin or agar. The arspenamine-induced disturbances (which have been regarded by some as anaphylactoid) are diminished by epinephrine, presumably as a consequence of its circulatory action.

*Tinel & Ungar 14,897/33:* In guinea pigs, epileptoid convulsions are produced by epinephrine given conjointly with ergotamine, peptone or yohimbine.

#### Pesticides ←

*Cueto Jr. G72,544/70:* In dogs, o,p'-DDD produces a selective glucocorticoid deficiency due to its damaging effect upon the fascicula and reticularis of the adrenal. Epinephrine and norepinephrine produce hypotensive failure in DDD-treated dogs presumably as the consequence of their stressor action. Prednisolone largely restores the resistance of the DDD-treated animals.

#### Phenylethylamine ←

*Fischer et al. G48,517/67:* In mice pre-treated with iproniazid (as a MAO-inhibitor), phenylethylamine produces amphetamine-like motor effects which are inhibited by epinephrine.

#### Picrotoxin ←

*Saito et al. E27,616/63:* In mice, picrotoxin convulsions are inhibited by the intracerebral administration of epinephrine or 5-HT.

**Picrotoxin** ← **Epinephrine:** Holck D28,543/49\*

**Plasmocid** ← *cf. Selye C50,810/58, p. 110; C92,918/61, p. 83; C92,918/61, pp. 96, 110; G60,083/70, pp. 358, 361.*

**Potassium** ←

*Lum H22,940/70*: In anesthetized dogs, epinephrine i.v. protected against the lethal effects of potassium i.v.

**Procaine** ←

*Cole & Hulpieu B32,910/49; B57,578/50*: In dogs the toxicity of procaine is not consistently counteracted by epinephrine.

**Reserpine** ←

*Schmidt & Matthies D34,219/62*: In mice, 5-HT or norepinephrine injected into certain regions of the brain is without effect upon pentylenetetrazol injections in itself, but counteracts the inhibitory effect of intracerebrally injected reserpine.

*Agostini & Giagheddu G14,490/63*: Reserpine catalepsy in guinea pigs is inhibited by various folliculoid, testoid and corticoid hormones as well as by epinephrine.

*Simionovici et al. F43,099/65*: In mice, epinephrine and norepinephrine, as well as histamine, offer partial protection against reserpine intoxication (sedation blepharoptosis, hypothermia). 5-HT has no such effect.

**Sparteine** ←

*Christian D1,675/11; Christian et al. C81,653/11*: In rabbits given concurrent treatment with sparteine and epinephrine, cardiac and hepatic lesions develop which are not seen if either of these agents is given alone.

**Strychnine** ←

*Falta & Jvcovic A1,273/09*: In frogs and guinea pigs, epinephrine protects against strychnine-induced convulsions, even if the two compounds are injected in different points of the body.

*Januschke 50,228/10*: In frogs, epinephrine i.v. does not protect against strychnine intoxication. Protection following treatment with mixtures of the two compounds by routes other than i.v. is ascribed to a delay in strychnine absorption.

*Bálint & Molnár 34,586/11*: In guinea pigs, the fatal effect of strychnine intoxication is inhibited by epinephrine or thyroid extract i.p.

*Marañón & Aznar 46,926/15*: In frogs, the fatal convulsions produced by strychnine can be prevented if, prior to injection, the drug is

mixed with extracts of the posterior pituitary, the thyroid, various other tissues, and particularly epinephrine. [The possibility of delayed absorption owing to local vasoconstriction has not been considered (H.S.).]

*Amici C5,836/54*: In mice, mortality from acute strychnine intoxication can be diminished by epinephrine and norepinephrine as well as by some of their derivatives.

**Tetraethylammonium (TEA)** ← cf. **Ganglioplegics****Tremorine** ←

*Falutz F85,463/67*: In cats, tremorine-induced tremor is uninfluenced by norepinephrine and epinephrine but inhibited by L-dopa.

**Tween 80** ←

*Scilabra & Pugliese G68,796/68; Trentini et al. G71,152/68*: In cholesterol-fed rabbits, norepinephrine inhibits the anti-atheromatous action of Tween 80.

**Urethan** ←

*Pradhan et al. C13,632/56*: In 3 strains of mice, urethan sleeping time was greatly increased by epinephrine and norepinephrine. Phenobarbital sleeping time was only mildly increased by epinephrine.

**Vitamin D, DHT** ← cf. also *Selye C92,918/61, pp. 133, 188; G19,425/65, p. 137; G60,083/70, pp. 353, 361.*

*de Bosányi 367/25*: In rats kept on a vitamin-D deficient diet, the healing of rickets can be initiated by epinephrine.

**Yohimbine** ←

*Tinel & Ungar 14,897/33*: In guinea pigs, epileptoid convulsions are produced by epinephrine given conjointly with ergotamine, peptone or yohimbine.

**Varia** ←

*Schou E92,436/61*: Review (23 pp., 147 refs.) on factors influencing the absorption of drugs from subcutaneous connective tissue. Special sections deal with the effect of epinephrine, folliculoids and glucocorticoids which can alter the actions of various drugs by modifying their absorption rate.

**Microorganisms, Vaccines and Venoms ←**

Comparatively few investigators dealt with the effect of catecholamines upon bacterial infections. In guinea pigs, infection with *Clostridium welchii* is enhanced by the addition of epinephrine to the inoculum and, in rats, acute hypertension produced by epinephrine (or angiotensin) facilitates the production of pyelonephritis by *E. coli*. Topical resistance to inoculation with various pathogenic microbes is diminished by the injection of epinephrine into the site of inoculation.

Injection of epinephrine conjointly with various viruses enhances their infectivity in mice. In rabbits, herpes simplex infection followed by norepinephrine treatment may cause plaques of demyelination in the central nervous system.

At the beginning of this century, it has been claimed that epinephrine can inactivate bacterial toxins, e.g., diphtheria or tetanus toxin in guinea pigs, mice and rabbits, both in vivo and in vitro. It has subsequently been shown, however, that neutralization only occurs if epinephrine and the toxin, are mixed before injection, presumably because the vasopressor hormone delays absorption. In rabbits, combined administration of typhoid toxin and norepinephrine produces cardiac necroses. Data on the effectiveness of catecholamines in preventing endotoxin shock in various species are rather conflicting. Under certain circumstances, combined treatment with endotoxin and epinephrine produces a generalized Shwartzman-Sanarelli phenomenon in the rabbit.

In rats, complete blockade of the sympathetic function greatly diminishes resistance to endotoxins and this effect can be counteracted by epinephrine.

In guinea pigs, intoxication with cobra venom applied to skin erosions can be inhibited by the delay of absorption that results from topical treatment with epinephrine.

**Bacteria ←**

*Lauber 9,102/32*: Observations on the effect of vasopressin, epinephrine, thyroid extract and insulin upon streptococcal and staphylococcal infections in mice.

*Evans et al. B65,652/48*: In guinea pigs and rabbits, epinephrine diminishes local resistance to a large series of pathogenic microbes.

*Bishop & Marshall C95,333/60*: In guinea pigs, infection with *Clostridium welchii* is greatly enhanced by addition of epinephrine in oil or water to the inoculum.

*Jones & Shapiro D55,793/63*: In rats, an acute episode of hypertension produced by epinephrine or angiotensin i.v. facilitates the production of pyelonephritis following infection with *E. coli*.

**Viruses ←**

*Sellers H10,893/69*: In mice, epinephrine or 5-HT injected simultaneously with various viruses i.v. enhances their infectivity and their penetration into the brain.

*Connor H23,400/70*: In rabbits, infection with herpes simplex followed by treatment with norepinephrine may cause plaques of demyelination in the subcortical white matter and brain-stem. Possibly, in man, disseminated sclerosis is "multifactorial in origin" resulting from an apparently innocuous infection with herpes simplex in childhood followed later by challenge through physical or mental stress resulting in norepinephrine liberation. [A largely speculative "Letter to the Editor" (H.S.).]

**Bacterial Toxins ←** cf. also *Selye E5,986/66*, pp. 14, 72; *G60,083/70*, p. 362.

*Marie 37,085/13*: In guinea pigs, the lethal effect of diphtheria or tetanus toxin s.c. is diminished by previous incubation with epinephrine.

*Marie 32,348/18; 37,087/19*: In mice and rabbits, tetanus toxin is largely inactivated by epinephrine in vivo or in vitro.

*Tawara 12,478/21*: In mice, the lethal effect of tetanus toxin is not significantly influenced by epinephrine unless the two

compounds are mixed before injection. This neutralizing effect may be due to the acidity of the epinephrine solution employed, since various acids are equally effective.

*Mezzano & Peluffo D9,328/60:* In rabbits, combined administration of typhoid toxin and norepinephrine produces cardiac necrosis not observed following treatment with either of these agents alone.

*Altura et al. F43,209/65:* In rats, norepinephrine and angiotensin fail to prolong survival after traumatic shock, temporary ligation of the superior mesenteric artery or endotoxin shock. However, vasopressin (PLV-2) was significantly effective in traumatic and intestinal ischemia shock but not in endotoxemia.

*Patel & Rao G36,076/65:* In mice, epinephrine offers virtually no protection against tetanus toxin.

*Vick F48,509/65:* In the dog, cortisol and/or isoproterenol cause temporary improvement in endotoxin shock but no increase in survival time.

*Bruce & Brunson F79,682/67:* In dogs, mortality from endotoxin shock is diminished after pretreatment with norepinephrine. Survival is further improved by concurrent administration of the tranquilizer propiomazine.

*Kutner et al. G46,379/67:* In dogs, norepinephrine considerably decreases thoracic-duct lymph-flow both under normal conditions and during endotoxin shock.

*Zeller et al. F92,117/67:* In rats, simultaneous treatment with endotoxin and large amounts of 5% glucose solution i.v. produces a generalized "Shwartzman reaction" which can be blocked by phenoxybenzamine but is not modified by norepinephrine.

*Brown et al. H456/68:* In dogs, survival from endotoxin shock was improved by combined treatment with norepinephrine and adrenergic blockade.

*Hruza & Stetson Jr. H455/68:* Pretreatment with depot epinephrine or norepinephrine increased resistance to trauma in the Noble-Collip drum and to endotoxin.

*Anas et al. G64,139/69:* In dogs, norepinephrine, isoproterenol and phenoxybenzamine increase oxygen consumption during endotoxin shock. In this respect, norepinephrine is most active, but its effect is transient.

*Boler et al. G65,722/69:* "Treatment of endotoxin-shocked dogs with propiomazine and levarterenol promoted their survival and prevented or reduced the severity of most of

the previously described ultrastructural alterations of the liver."

*Barksdale et al. H21,684/70:* In rabbits prepared and challenged for the generalized Shwartzman reaction by two i.v. injections of endotoxin spaced at an interval of 24 hrs, "epinephrine treatment was shown to increase the mortality when the normal optimum dose of endotoxin was used, ie, 100  $\mu$ g per injection, but did not increase the incidence of the generalized Shwartzman reaction. When sublethal doses of endotoxin were used, ie, 25  $\mu$ g or 10  $\mu$ g, epinephrine treatment profoundly increased the mortality and incidence of the generalized reaction."

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

#### Venoms ←

*Bardier & Stillmunkès 13,522/23:* In dogs and rabbits, scorpion venom exerts cardiovascular actions similar to those of epinephrine but does not produce collapse during chloroform anesthesia. The pharmacologic interactions between the venom and epinephrine are briefly discussed.

*Douglas 21,321/24*: In guinea pigs, intoxication with cobra venom applied to skin erosions can be inhibited by the delay of absorption that results from topical treatment with epinephrine.

*Stahnke F 57,253/65*: In rats treated with various scorpion and snake venoms, resistance was decreased by pretreatment with heat, cold or epinephrine. In all three cases, the change in resistance is ascribed to stress as such.

### **Immune Reactions ←**

In guinea pigs and dogs, anaphylactic shock can be inhibited by epinephrine and norepinephrine. In rats, allegedly large amounts of epinephrine depress antibody formation against sheep serum. In rabbits, massive doses of epinephrine + norepinephrine decrease the incidence of chicken anti-rabbit-kidney nephritis.

*Hanzlik & Karsner 10,286/20*: In guinea pigs, epinephrine can prevent true anaphylactic shock but not the anaphylactoid shock produced by peptone, dextrin or agar. The arsphenamine-induced disturbances (which have been regarded by some as anaphylactoid) are diminished by epinephrine, presumably as a consequence of its circulatory action.

*Marmorston-Gottesman & Perla 23,446/28*: In rats, large amounts of epinephrine, injected repeatedly before and after injection of an

antigen (sheep serum), depress antibody formation.

*Cirstea & Suhaciu G2,471/63*: In dogs, anaphylactic shock is diminished by epinephrine and norepinephrine.

*Hinton et al. G21,390/64*: In rabbits, large doses of epinephrine + norepinephrine decrease the incidence of chicken anti-rabbit-kidney nephritis. Fluorescent antibody studies "suggest the final antigen-antibody reaction may be of lesser magnitude in the treated animals."

### **Ionizing Rays ←**

In mice, cutaneous purpura produced by heavy X-irradiation is allegedly inhibited by adrenochrome. Resistance to total body X-irradiation is increased by numerous amines including norepinephrine, epinephrine, histamine and 5-HT, allegedly because these compounds reduce the oxygen tension in tissues. Even topical treatment with norepinephrine is said to protect the hair follicles against radiation injury.

In rats, mortality after total body X-irradiation is likewise diminished by epinephrine; similar observations with epinephrine and its derivatives have been made in guinea pigs, hamsters and chicks.

*Hervé & Lecomte B46,855/49*: In mice, the cutaneous purpura produced by heavy X-irradiation is inhibited by adrenochrome semicarbazone.

*Gray et al. B68,316/52*: In rats, pretreatment with either epinephrine or vasopressin diminishes mortality after total body X-irradiation.

*Gray et al. B69,100/52*: In rats, pretreatment with Pitressin or epinephrine increases survival following exposure to lethal X-irradiation.

*Bacq D77,006/54*: In mice, resistance to whole body X-irradiation is increased by numerous amines, particularly cysteamine

( $\beta$ -mercaptoethylamine), norepinephrine, 5-HT and histamine.

*Stearner et al. B92,163/54*: In chicks, both epinephrine and decreased oxygen tension protect against mortality from X-irradiation. Presumably both agents act by decreasing oxygen supply to tissues during an early phase of the events initiated by ionizing rays.

*Rigat C10,747/55*: Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

*van der Meer & van Bekkum G71,673/59:* In mice, the radioprotective effect of histamine, epinephrine and other biologic amines is related to their pharmacologic activity and can be blocked by their pharmacologic antagonists. "It is concluded that histamine, epinephrine and a number of other biological amines protect against irradiation by reducing the oxygen tension in the spleen and possibly in other blood forming organs."

*Semenov D7,087/60:* In mice, 5-HT offers better protection against radiation sickness than epinephrine although the latter is also

effective, especially when given in combination with acetylcholine.

*Gabler G40,828/66:* In guinea pigs and rats, mortality from whole body X-irradiation is diminished by epinephrine and metaproterenol.

*Letov H19,253/68:* In mice, topical treatment with norepinephrine protects the hair follicles against radiation-induced injury.

*Prewitt & Musacchia H16,155/69:* In hamsters exposed to <sup>60</sup>Co radiation, survival was improved by pretreatment with norepinephrine > epinephrine and > isoproterenol. It is dubious whether these agents act simply through tissue hypoxia.

### Cold ←

In rats, in which gastrointestinal ulcers were produced as part of an alarm reaction elicited by cold or other stressors, epinephrine p.o. produces lung edema, presumably because the hormone is well absorbed from the wound surfaces of the stress ulcers. Also in rats, epinephrine "appears to improve survival during exposure to cold, and adaptation to low temperatures increases the calorogenic effect of norepinephrine." However, depending upon circumstances, the catecholamines may also have an adverse effect upon survival during exposure to cold. In cold adapted guinea pigs, nonshivering thermogenesis is induced by cold or norepinephrine. It is suggested that nonshivering thermogenesis is essentially a catecholamine-mediated mechanism.

In dogs, norepinephrine infusions during cooling reduce the incidence of ventricular fibrillation, whereas epinephrine has an opposite effect.

In minipigs, nonshivering thermogenesis plays a major role in adaptation to cold only during neonatal life, if at all. Epinephrine and norepinephrine fail to stimulate nonshivering thermogenesis in minipigs, whereas they do have this effect in cold adapted rats.

In the ground squirrel, norepinephrine produces nonshivering thermogenesis after curarization.

*De Gaetani 33,111/35:* In dogs, the cardiovascular changes produced by epinephrine are greatly altered by exposure to cold.

*Selye A8,052/38:* Rats and guinea pigs normally tolerate very large doses of epinephrine or histamine p.o. but these substances cause toxic manifestations (lung edema, emphysema) if administered following the production of an alarm reaction by cold, forced muscular exercise or other stressors. Presumably the gastrointestinal lesions characteristic of the alarm reaction facilitate the absorption of substances which normally do not traverse the intestinal epithelium in active form.

*DesMarais & Dugal B51,093/50; B64,359/51:* In rats exposed to cold, epinephrine

"appears to improve survival." [Brief abstract without details (H.S.).]

*Hannon & Larson D4,112/61:* In rats, the effect of norepinephrine upon calorigenesis and the mobilization of nonesterified fatty acids is considerably modified by cold.

*Evonuk & Hannon E21,027/63:* In rats, adaptation to cold increases the calorogenic effect of norepinephrine.

*Schönbaum et al. E21,028/63:* In rats, norepinephrine (like epinephrine) has an adverse effect upon survival during exposure to cold. This effect is less pronounced following adaptation to cold. Adrenal-demedullated animals (whether receiving guanethidine or not) showed evidence of acclimation to cold. "These observations suggest that increased

amounts of adrenaline and noradrenaline in tissues or circulation are not essential for acclimation."

*Leblanc & Pouliot F4,622/64*: In rats, norepinephrine facilitates adaptation to cold.

*Pohl & Hart F62,568/66*: In the ground squirrel (*Citellus tridecemlineatus*), exposure to cold or injection of norepinephrine produced nonshivering thermogenesis after curarization.

*Zeisberger & Brück F89,184/67*; *Zeisberger et al. F89,185/67*: In cold-adapted guinea pigs, nonshivering thermogenesis is induced by exposure to cold or by injection of norepinephrine. Several observations suggest "that the nonshivering thermogenesis in the guinea pig

is essentially due to a catecholamine-mediated mechanism."

*Angelakos & Daniels G64,739/69*: In dogs, infusion of norepinephrine during cooling reduced the incidence of ventricular fibrillation, whereas epinephrine had an opposite effect.

*Brück et al. H13,180/69*: In minipigs, as in most species other than the rat, nonshivering thermogenesis plays a major role in adaptation to cold only during neonatal life if at all. Epinephrine and norepinephrine, which stimulate considerable nonshivering thermogenesis in cold-adapted adult rats, failed to do so in minipigs.

### Other Stressors ←

In rats, various adrenergic blocking agents inhibit, whereas epinephrine increases mortality during traumatic shock in the Noble-Collip drum. However, some investigators failed to observe any effect of epinephrine or norepinephrine upon this type of shock; indeed, occasionally they noted an increase in resistance when the catecholamines were administered in the form of depots.

In rabbits, survival following trauma in the Noble-Collip drum has been said to be moderately improved by epinephrine and other vasopressor amines. On the other hand, rabbits, made tolerant to normally lethal doses of epinephrine, showed an increased susceptibility to "rotational shock," whereas drum-tolerant animals were less susceptible to the lethal effect of epinephrine.

Death from hypoxia in rats kept in closed vessels is accelerated by epinephrine. Mortality from hyperoxygenation (exposure to 6 atmospheres of oxygen) is increased in rats by pretreatment with epinephrine, whereas survival from hemorrhagic shock is improved by long-lasting infusions of norepinephrine.

Small doses of epinephrine or norepinephrine prolong the duration of electrically-induced seizures in the rat.

In rats, irreversible hypovolemic shock, produced by complete occlusion of the portal vein, is effectively combated by continuous infusions of norepinephrine, whereas epinephrine has an inverse effect.

In rats, with complete blockade of the sympathetic nervous system, epinephrine considerably increases resistance to certain stressors (endotoxin, histamine) but not to others (formalin, tourniquet shock). Apparently, the adrenergic system is of special importance only in combating certain types of stress.

### Trauma ←

*Levy et al. C10,848/54*: In rats, various adrenergic-blocking agents increase resistance to traumatic shock (Noble-Collip drum), whereas epinephrine has an opposite effect.

*Noble C10,541/55*: In rats, mortality from trauma in the Noble-Collip drum is strikingly increased by pretreatment with epinephrine

but not diminished by various adrenergic-blocking agents.

*Brunson et al. C78,005/59*: In rabbits, survival following trauma in the Noble-Collip drum is moderately improved by epinephrine and other vasopressor amines.

*Walden & Brunson G5,968/63*: Studies on rabbits gradually adapted to trauma in the Noble-Collip drum led to the conclusion that

"animals tolerant to normally lethal doses of epinephrine showed an increased susceptibility to rotational shock, but drum tolerant animals were less susceptible to lethal doses of epinephrine."

*Altura et al. F 36,124/65; F 43,209/65:* In rats, survival following temporary ligation of the superior mesenteric artery was improved by PLV-2 but not by epinephrine or angiotensin. The associated changes in the microcirculation of the meso-appendix are described.

*Cronin & Tan F 29,408/65:* In dogs, the inotropic effect of norepinephrine is increased during cardiogenic shock elicited by closed-chest coronary embolization.

*Hruza & Stetson Jr. H 455/68:* In rats, pretreatment with depot epinephrine or norepinephrine increased resistance to trauma in the Noble-Collip drum and to endotoxin.

*Calof & Smith H 10,412/69:* In rats, mortality from traumatic shock (Noble-Collip drum) is not modified by epinephrine or norepinephrine but considerably reduced by various  $\beta$ -adrenergic agents.

*Hruza & Zweifel G 77,195/70:* Rats adapted to trauma in a Noble-Collip drum show an increased catecholamine content in their fat tissue and an increased resistance to epinephrine. Conversely, rats rendered resistant to epinephrine or norepinephrine become more resistant to trauma in the Noble-Collip drum. [This may be one of the mechanisms involved in the induction of cross resistance (H.S.).]

#### **Hypoxia and Hyperoxygenation ←**

*Campbell A 14,903/37:* In rats exposed to six atmospheres of oxygen in a pressure chamber, subsequent decompression is better tolerated at low than at high external temperatures. "Using an external temperature of 24°C and white rats of about 80 g, the following substances, administered subcutaneously, are found to enhance oxygen poisoning: thyroxin (0.4 mg), dinitrophenol (1.5 mg), ac-tetrahydro- $\beta$ -naphthylamine (0.5 c.c., 1 p.c.), adrenaline (0.02 mg), pituitary extract (posterior lobe, above 3.5 units), insulin (0.025 u.) and eserine (0.045 mg administered with atropine 0.075 mg). These doses in themselves are harmless."

*Keminger G 42,501/66:* In rats, death from lack of oxygen in closed vessels is accelerated by T3 and retarded after thyroidectomy or cortisone treatment. Epinephrine further accelerates mortality in hyperthyroid animals.

#### **Hemorrhage ←**

*Lansing et al. C 30,227/57:* In rats, survival from hemorrhagic shock is improved by long-lasting infusions of norepinephrine.

#### **Electric Stimuli ←**

*Minz & Domino B 81,852/53:* In rats, small doses of epinephrine or norepinephrine prolong the duration of electrically-induced seizures. Since glucose, ACTH and cortisone failed to prolong seizure duration, it is unlikely that epinephrine acts by release of these substances. Histamine depressed the cortical response to electroshock.

*Varia ← cf. also Selye B 40,000/50, p. 64; B 58,650/51, p. 53; G 60,083/70, pp. 358, 361.*

*Mejia et al. G 60,637/68:* In rats with irreversible hypovolemic shock produced by complete occlusion of the portal vein, neither cortisol pretreatment nor adrenalectomy influenced the survival time, whereas selective extirpation of the adrenal medulla or continuous infusion of norepinephrine increased it. Similar infusion of epinephrine decreased survival time.

*Krawczak & Brodie H 25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

**Hepatic Enzymes ←**

For the effect of adrenergic agents upon hepatic enzyme induction *cf.* the Abstract Section as well as the individual toxicants, whose metabolism is affected (*cf.* "Drugs").

*Dixon et al. G11,757/64:* In the rat, both norepinephrine and adrenergic blocking agents inhibit the hepatic drug-metabolizing enzyme activity as judged by tests in vitro.

*Terayama & Takata F69,475/66:* Epinephrine markedly reduces the N-demethylating activity of rat liver.

← **SPECIAL SURGICAL PROCEDURES**← **Thymectomy**

**Hormones and Hormone-Like Substances ←.** During the early part of this century, a great deal of work has been done on the influence of thymus extract upon the toxicity of **thyroid** preparations. In tadpoles, thyroid extract inhibits growth, and concurrent administration of thymus extract neutralizes this effect. In mice, the toxic manifestations of thyroid feeding are allegedly inhibited also by feeding thymus tissue.

In pigeons, the loss of weight elicited by thyroid extract or thyroid feeding is inhibited by dietary administration of thymus tissue. This effect could not be duplicated by equivalent amounts of nucleic acid preparations, but the specificity of an antithyroid thymus principle remains in doubt.

In rats, the hypercalcemia and osteitis fibrosa produced by **parathyroid extract** overdosage are said to be inhibited by concurrent treatment with a thymus extract and thymectomy is claimed to raise **histamine** resistance, but all these findings require confirmation.

*Cameron & Carmichael 27,015/25:* In young rats, feeding of desiccated **thyroid** frequently produces tetany, perhaps as a consequence of the decreased blood supply to the entire thyroparathyroid apparatus. This tetany cannot be influenced by simultaneous feeding of thymus.

*Kříženecký & Podhradský 4,186/26:* In frog tadpoles, feeding of thyroid extract inhibits growth; concurrent administration of thymus extract neutralizes this effect.

*Sklower 25,299/27:* In mice, the toxic manifestations of thyroid feeding can be inhibited by concurrent thymus feeding. Earlier literature on antagonistic interactions between thyroid and thymus is reviewed.

*Kříženecký 4,176/28; 23,688/28; 277/30:* In pigeons, the loss of weight produced by desiccated thyroid is greatly diminished by concurrent administration of a thymus extract. Equivalent amounts of nucleic acid preparations do not have this effect. "The thymus appears to be a regulator of the thyroid gland."

*Scholtz 4,272/32:* In rats, the hypercalcemia and osteofibrosis produced by excess **parathyroid extract** are inhibited by concurrent treatment with thymus extract.

*Weltman & Sackler D14,302/61:* In adult rats, thymectomy raises resistance to **histamine** and to swimming in cold water. The effect is ascribed to a raised resistance to nonspecific stress. [The results are not statistically significant (H.S.).]

**Drugs ←.** The thymus involution of the alarm reaction is one of the most sensitive indicators of exposure to the stress of any toxicant, yet, we have very little evidence to show that the thymus could influence resistance to drugs. Except for the well-known immunologic disturbances produced by neonatal thymectomy, neither

removal of the organ nor treatment with extracts of its tissue succeeded in altering general resistance in a significant and reproducible manner.

It has been stated that the hepatic changes caused in rats by such **carcinogens** as dimethylaminoazobenzol are diminished by treatment with thymus extract, and that in newborn mice, the induction of pulmonary tumors by DMBA is facilitated by the injection of neonatal thymus tissue. Furthermore, in neonatal mice, the otherwise permanent immunosuppression induced by DMBA can be reversed by syngenic thymus, bone marrow, or spleen cell transplants.

Probably, one of the first observations on the effects of neonatal thymectomy was that removal of the thymus during the first days of life increases the sensitivity of the rabbit to **morphine, heroin, and codeine**. However, the change in resistance was not very pronounced and was presumably due to the general debilitation of neonatally thymectomized animals.

At about the same time, it had been claimed that thymus extract decreases the sensitivity to **thallium** intoxication in mice, but this observation has never been confirmed.

Resistance to **vitamin A** or **vitamin D** is not significantly affected in rats thymectomized at 2-3 weeks of age. The claim that thymectomy partially protects the adult rabbit against overdosage with irradiated ergosterol remained unconfirmed. In vitamin-D deficient rats, the development of rickets could not be significantly altered by lipid soluble thymus extracts.

*Anaphylactoidogens* ← cf. *Selye G46,715/68*, pp. 180, 184, 200.

#### **Carcinogens** ←

*Fumarola & Giordano D33,779/62*: In rats, the production of tumors by benzpyrene is allegedly somewhat inhibited after thymectomy and accelerated by treatment with thymus extract.

*Potop et al. E39,894/62*: In rats, the hepatic changes produced by dimethylaminoazobenzol are diminished by treatment with a thymus extract.

*Simpson et al. F2,965/64*: In rats, neonatal thymectomy did not significantly influence the induction of tumors by DMBA.

*Balmer & Dersjant G37,980/66*: In mice, neonatal thymectomy does not significantly influence the induction of cutaneous tumors by intradermal 3-MC administration. Surprisingly, tumor incidence in mice with depressed homograft reactivity was, if anything, lower than in the immunologically competent animals.

*Grant et al. F66,117/66*: In mice, the induction of cutaneous papillomas and carcinomas by 3,4-benzopyrene is accelerated by neonatal thymectomy. "It may be that some tumours initiated by benzopyrene do not differ sufficiently from the host to evoke a homograft

reaction against them even when the immunological competence is unimpaired. It may be that factors such as the growth-rate of the tumour allow it to progress in spite of a reaction against it, or it may be that under some conditions an animal may become specifically tolerant to a tumour which it bears."

*Allison & Taylor F83,300/67*: From experiments on mice treated with DMBA and various viruses, "it is concluded that neonatal thymectomy does not consistently increase the incidence of chemically induced tumors but does increase the incidence of tumors after exposure to polyoma and SV40 viruses and adenovirus type 12."

*Flaks F95,414/67*: In mice, the induction of pulmonary tumors by DMBA, soon after birth, is intensified by injections of neonatal thymus tissue.

*Smiecinski & Górski H20,765/68*: In 2-3 week old female mice, topical tumorigenesis by intravaginal application of 20-methylcholanthrene is "slightly retarded" by thymectomy. This effect has been tentatively ascribed to the removal of "promine," an allegedly tumor growth-stimulating substance of thymic origin. [The results do not lend themselves to statistical evaluation (H.S.).]

*Ball & Dawson G67,723/69*: In neonatal mice "the permanent immunosuppression

induced by DMBA could be reversed by the injection of normal syngeneic bone marrow and spleen cells but not with thymic implants."

*Kobayashi H 27,113/69; H 27,114/69:* In mice, thymectomy inhibits the production of cutaneous papillomas by DMBA, whereas transfusion of thymus cells has an opposite effect.

*Schneiberg & Gorski G 68,745/69:* In mice, thymectomy followed by whole-body X-irradiation increases the incidence of skin cancers after serial spraying with methylcholanthrene. In itself, neither thymectomy nor X-irradiation was effective in this respect.

**Cholesterol** ← *cf. Selye G 60,083/70, p. 442.*

#### **Chloroform** ←

*Bomskov et al. A 56,954/42:* In rats and guinea pigs, sensitivity to chloroform can be diminished by a thymus extract.

#### **Curare** ←

*Blaw et al. F 65,571/66:* In mice, neonatal thymectomy increases the sensitivity of the myoneural junction to blockade by tubocurarine.

#### **Morphine** ←

*Arima 60,156/35:* In rabbits thymectomized during the first few days of life, sensitivity to morphine, heroin, and codeine is slightly diminished. Treatment with thymus extract has an opposite effect.

**Sulfa Drugs** ← *cf. Selye G 60,083/70, p. 442.*

#### **Thallium Acetate** ←

*Buschke et al. 43,284/33; 4,823/33:* In mice, thyroxine increases, whereas thymus extract decreases sensitivity to intoxication with thallium acetate.

#### **Vitamin A** ←

*Vogt et al. B 36,750/48:* In rats thymectomized at 2–3 weeks of age, resistance to vitamin-A or vitamin-D deficiency was not significantly affected.

#### **Vitamin C** ←

*Lopez-Lomba 17,165/23:* In guinea pigs, thymectomy prolonged survival on a vitamin-C deficient diet. [The difference was not impressive (H.S.).]

#### **Vitamin D** ←

*Coppo 3642/32:* In rabbits, thymectomy does not characteristically influence the syndrome of overdosage with irradiated ergosterol.

*Messini & Coppo 31,827/35:* In rabbits, thymectomy partially protects against intoxication with irradiated ergosterol.

*Vogt et al. B 36,750/48:* In rats thymectomized at 2–3 weeks of age, resistance to vitamin-A or vitamin-D deficiency was not significantly affected.

*Nassi G 1,107/62; G 1,108/62:* In vitamin-D deficient rats, treatment with a lipid soluble thymus extract did not significantly affect the development of rickets.

**Microorganisms, Parasites and Their Products** ←. Despite several claims to the contrary, there does not seem to be any convincing evidence that thymectomy or thymus extracts have any specific effect upon **bacterial infections**.

Mice thymectomized at birth become extremely resistant to the **virus of lymphocytic choriomeningitis**, but this infection may aggravate the course of the wasting syndrome produced by neonatal thymectomy. The susceptibility of neonatally thymectomized mice against this virus is restored by implants of Millipore diffusion chambers containing newborn thymic tissue. It is assumed that the neurologic symptoms in mice and man result from an antigen-antibody reaction in the brain which can be prevented by neonatal thymectomy.

In newborn mice infected with **polyoma virus**, neonatal thymectomy delays mortality of certain strains only. Inoculation of polyoma virus into neonatally thymectomized weanling hamsters resulted in tumor formation, whereas sham operated litter mates developed no neoplasms. Apparently, "neonatal thymectomy may render some resistant animals susceptible to the effects of an oncogenic virus."

In inbred BALB/c mice, inoculated with **Rauscher virus**, thymectomy did not influence the erythroblastic reaction, but thymectomy did alter the response to a variety of other viruses in various species.

In neonatally thymectomized mice, susceptibility to infection with **C. albicans** is increased.

In chickens from embryos inoculated in ovo with testosterone, after about one week of incubation, the bursa of Fabricius spleen and thymus are permanently atrophic and the antibody formation against repeated infection with **Eimeria tenella** fails to develop antibodies. Surgical thymectomy 90 min after hatching was rarely complete and did not constantly block immunization against **Eimeria tenella**.

Neonatally thymectomized rats infected with **P. berghei** are highly subject to parasitemia, whereas neonatally thymectomized hamsters are comparatively resistant and develop the disease slowly. It is postulated that the thymectomized hamsters failed to develop an antibody that normally causes microembolization of the cerebral capillaries with agglutinated parasites.

In neonatally thymectomized mice, susceptibility to the toxic effects of **E. coli** or **S. typhosa endotoxins** is increased.

#### **Bacteria and Vaccines** ←

*Cody & Code G4,417/63*: In rats sensitized with **Bordetella pertussis** vaccine, the anaphylaxis produced by challenge with horse serum is inhibited by concurrent thymectomy and splenectomy but not by thymectomy alone.

*Schäfer B99,955/54*: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas, and gonads.

*Kratter & Martelli B60,263/49*: In adult rabbits, thymectomy increases susceptibility to staphylococcus infection.

*Schmüßis et al. G55,003/67*: In mice, neonatal thymectomy protects against lymphocytic choriomeningitis produced by Junin virus. Presumably, the "neurological symptoms in mice and human patients result from an antigen-antibody reaction in the brain and that this reaction between the virus and its antibody is prevented by thymectomy."

**Polyoma** ←. *Kodama & Moore D56,877/63*: In newborn mice infected with polyoma virus, thymectomy (performed two weeks later) delayed mortality in the AKR but not in the C3H strain. The incidence and latency of parotid tumors were not affected by thymectomy in either strain.

*Lang G55,002/68*: "Inoculation of polyoma virus into weanling hamsters, thymectomized as neonates, has resulted in the production of tumors. In contrast, the sham operated litter mates developed no demonstrable neoplasms over a 12—18 month period of observation. Thus, it has been confirmed in these studies that neonatal thymectomy may render some resistant animals susceptible to the effects of an oncogenic virus."

**Rauscher** ←. *Dunn & Green G40,311/66*: In inbred BALB/c mice inoculated with Rauscher virus "thymectomy had no apparent effect on the erythroblastic reaction, while splenectomy intensified the process in the liver and erythroblastic foci appeared in the lymph nodes. Granulocytopoiesis was also stimulated in some mice."

#### **Viruses** ←

**Lymphocytic Choriomeningitis** ←. *Levey et al. E30,471/63*: In mice, neonatal thymectomy protects against the virus of lymphocytic choriomeningitis, but susceptibility is restored by implants of Millipore diffusion chambers containing newborn thymic tissue. "A humoral mechanism of action of the tissue in the chamber is proposed."

*Rowe et al. E29,673/63*; *East et al. E38,279/64*; *Földes et al. G29,263/65*: Mice thymectomized at birth become resistant to lymphocytic choriomeningitis virus infection.

*Szeri et al. G56,565/66*: In mice, infection with lymphocytic choriomeningitis virus accelerates and aggravates the course of the wasting syndrome produced by neonatal thymectomy.

**Varia** ←. *Dunn E29,253/63*: "When BALB/c mice given the **Moloney virus** were thymectomized, splenectomized or subjected to both procedures, the incidence of lymphocytic leukemia was reduced." *Li et al. E33,523/63*: Various types of calf thymus extracts exhibit antiviral and antibacterial activity **in vitro**.

*Crispens & Rey F87,332/67*: In mice, neonatal thymectomy increases sensitivity to **lactate dehydrogenase virus**.

*van Hoosier Jr. et al. F78,860/67*: In hamsters, thymectomy facilitates tumor formation by weakly oncogenic **adenoviruses**.

*Jahkola et al. G47,813/67*: In mice, the infection by **cytomegalic inclusion virus** is aggravated by thymectomy.

*Yohn et al. G57,790/68*: In hamsters given **adenovirus-12**, strain Huie, s.c. at birth, thymectomy at one week of age increased tumor incidence in both sexes, although it remained higher in females as is usually the case. Cortisone treatment, begun at one week of age, increased tumor incidence but, again, this remained higher in females. Antibody responses to adenovirus-12 T-antigen were depressed in thymectomized and cortisone-treated animals.

#### **Fungi and Yeasts, Parasites** ←

**Candida Albicans** ←. *Salvin et al. G30,533/65; F35,876/65*: In mice thymectomy diminishes resistance to infection with *C. albicans* as well as to the endotoxins of *E. coli* and *S. typhosa* but not to *C. albicans* endotoxin.

**Eimeria** ←. *Pierce & Long G36,006/65*: Chickens from embryos inoculated in ovo with testosterone hatched between the 6th and 9th day of incubation without a detectable bursa of Fabricius; their spleen and thymus weights were also significantly reduced. These fowls failed to develop antibodies as a result of repeat-

ed infection with *Eimeria tenella*. Surgical thymectomy 90 min after hatching was rarely complete and did not consistently lead to a failure of immunization against *E. tenella*.

*Rose & Long G74,020/70*: Review of the literature with personal observations on the effect of thymectomy and removal of the bursa of Fabricius upon *Eimeria* infections in the chicken.

**Plasmodium Berghei** ←. *Steckschulte H15,256/69*: "Neonatally thymectomized rats infected with *P. berghei* develop higher percentage parasitemias and have a higher percentage mortality than sham-operated animals."

*Brown et al. H1,304/68*: In rats, neonatal thymectomy decreases resistance to infection with *P. berghei*. [Although throughout the paper the authors speak of rats, in their conclusion they refer to mice (H.S.).]

*Wright H1,836/68*: In hamsters, neonatal thymectomy delays death from infection with *P. berghei*. "It is postulated that the non-thymectomized animals develop an agglutinin, in response to the malarial infection, that causes microembolisation of the cerebral capillaries with agglutinated parasitised RBC, and that neonatal thymectomy inhibits or delays the production of this agglutinin."

**Trypanosoma Lewisi** ←. *Perla & Marmorston-Gottesman 810/30*: In young rats, thymectomy diminishes, whereas orchidectomy increases the severity of *T. lewisi* infection.

#### **Bacterial Toxins** ←

*Salvin et al. G30,533/65; F35,876/65*: In mice, thymectomy diminishes resistance to infection with *C. albicans* as well as to the endotoxins of *E. coli* and *S. typhosa*, but not to *C. albicans* endotoxin.

**Immune Reactions** ←. The extensive literature on neonatal thymectomy upon immune reactions is beyond the scope of this monograph and should be consulted in the reviews cited in the Abstract Section which are specifically devoted to this topic. Let us point out merely that in rats sensitized with *Bordetella pertussis* vaccine, anaphylaxis to horse serum is inhibited by concurrent thymectomy and splenectomy, but not by thymectomy alone. In adult rats which had been neonatally thymectomized, the production of nephrotoxic serum nephritis remains possible.

*Kemény et al. B66,729/51*: In guinea pigs, both ovariectomy and orchidectomy diminish anaphylactic shock, whereas thymectomy has no effect upon it.

*Miller E37,260/63*: Review on the role of the thymus in immunity.

*Cody & Code G4,417/63*: In rats sensitized with *B. pertussis* vaccine, the anaphylaxis

produced by challenge with horse serum is inhibited by concurrent thymectomy and splenectomy, but not by thymectomy alone.

*Fisher & Fisher F690/64*: In adult rats which had been neonatally thymectomized, the production of nephrotoxic serum nephritis

remains possible. This "indicates that progression of the disease is not necessarily dependent upon those immunologic functions related to thymic function, at least during the time interval studied."

**Hepatic Lesions** ←. In partially hepatectomized adult rats, thymectomy inhibits mitotic proliferation of the hepatocytes, but does not significantly affect the associated enzymic changes.

*Forabosco & Narducci G70,746/69*; *Forabosco & Toni G70,747/69*; *Forabosco & Guli G70,748/69*; *Forabosco et al. G70,749/69*: In

adult rats, thymectomy inhibits mitotic proliferation in hepatocytes after partial hepatectomy. Earlier literature is reviewed.

**Ionizing Rays** ←. In mice, thymectomy increases the incidence of epithelial tumor formation after X-irradiation. Thymus transplants do not significantly influence the incidence of leukemia.

In neonatally thymectomized mice, both thymus implants and cystamine tend to correct the comparatively low X-ray resistance. The intercapillary glomerulosclerosis produced by neonatal X-irradiation is potentiated by neonatal thymectomy, but reduced by splenectomy in mice. In adult, unlike in neonatal mice, thymectomy does not reduce resistance to total body X-irradiation. X-ray resistance is restored in neonatally thymectomized mice by the i.p. implantation of thymus-bearing diffusion chambers.

*O'Gara & Ards D12,341/61*: In mice, thymectomy appears to increase the incidence of epithelial tumors following X-irradiation. In thymectomized mice bearing intrasplenic thymus transplants, the incidence of leukemia was not significantly altered in comparison to thymectomized controls.

*Mévisse & Lagneau G14,713/64*: In mice thymectomized at 40 days of age, cystamine retains its protective action, and implantation of a thymus lobe likewise increases resistance.

*Goedbloed & Vos G33,427/65*: In mice, neonatal thymectomy had little if any effect on the incidence of secondary disease in radiation chimeras.

*Mévisse et al. F45,017/65*: Mice thymectomized during the first days of life show a very low resistance to total body X-irradiation, but this can be improved by thymus transplants.

*Guttman G45,255/67*: In mice, the intercapillary glomerulosclerosis produced by neonatal X-irradiation is potentiated by neonatal thymectomy but reduced by splenectomy.

*Schneiberg et al. G56,009/67*; *G58,580/67*: In three-week old mice, thymectomy reduces natural resistance to whole body X-irradiation, but this is not the case in rats thymectomized at a later age.

*Schneiberg et al. G69,791/68*: In mice, sensitization to X-irradiation produced by thymectomy is restored by i.p. implantation of thymus-bearing diffusion chambers, presumably owing to the production of a humoral lymphopoietic factor by the thymus implant.

*Schneiberg et al. G58,579/68*: In mice, thymectomy does not significantly affect the blood protein changes produced by acute X-irradiation, although it does increase mortality.

**Varia** ←. In germ-free mice, the lethality of parabiotic intoxication is aggravated by neonatal thymectomy, presumably because here the thymus-dependent immune reactions are actually beneficial. Adaptive enzyme formation does not appear to be significantly affected by neonatal thymectomy in the rat.

**Cold ←**

*Weltman & Sackler D14,302/61*: In adult rats, thymectomy raises resistance to histamine and to swimming in cold water. The effect is ascribed to a raised resistance to nonspecific stress. [The results are not statistically significant (H.S.).]

**Tumors ←**

*Potop et al. F38,309/65*: In the mouse and rat as well as in chick embryos, the growth of various experimental tumors is stimulated by a lipoprotein extract of the thymus.

**Parabiosis ←**

*Anderson et al. H11,186/69*: In germ-free mice, the lethality of parabiotic intoxication

is aggravated by neonatal thymectomy. "It is concluded that with respect to parabiotic union of germ-free mice, the primary consequence of neonatal thymectomy is a dampening of the characteristic anemia-polycythemia which is not associated with an enhanced survival, and that thymic dependent immune reactions may actually promote survival."

**Hepatic Enzymes ←**

*Bonetti et al. G48,030/67*: Induction of hepatic TPO-activity by tryptophan i.p. is not prevented by postnatal thymectomy in the rat. These observations do not confirm the view that adaptive enzyme formation depends upon a mechanism similar to that of immunologic defense.

**← Splenectomy**

Splenectomy does not appear to have any conspicuous effects upon detoxicating mechanisms.

It has been claimed that immunosuppression induced by neonatal administration of **DMBA** in mice could be reversed by syngenic spleen, bone marrow, or thymus cell implants. In rats sensitized with *B. pertussis* vaccine, the anaphylaxis produced by challenge with horse serum is inhibited by concurrent splenectomy and thymectomy, but not by thymectomy alone. In certain inbred strains of mice inoculated with **Rauseher virus**, splenectomy intensified the erythroblastic reaction in the liver, whereas thymectomy had no such effect. In rats, splenectomy does not significantly alter the regeneration of the liver after **partial hepatectomy**, although some investigators claimed that splenectomy accelerates it. This acceleration does not occur if the spleen is reimplanted into either the portal or the systemic circulation. However, all these claims have been challenged by some investigators.

The intercapillary glomerular sclerosis produced by neonatal **X-irradiation** in mice is said to be reduced by splenectomy.

**Drugs ←**

*Ball & Dawson G67,723/69*: In neonatal mice "the permanent immunosuppression induced by **DMBA** could be reversed by the injection of normal syngenic bone marrow and spleen cells but not with thymic implants."

*Brodeur & Marchand H37,030/71*: In rats, splenectomy significantly decreases cytochrome P-450 during the first few days after the operation but not at seven days. **Parathion**, **p-nitroanisole** and **zoxazolamine** metabolism is also decreased, whereas that of **hexobarbital** is unchanged during the first four days after

splenectomy. Apparently, splenectomy inhibits certain hepatic microsomal enzymes, perhaps by influencing the blood supply of the liver.

**Microorganisms and Vaccines ←**

*Cody & Code G4,417/63*: In rats sensitized with *B. pertussis* vaccine, the anaphylaxis produced by challenge with horse serum is inhibited by concurrent thymectomy and splenectomy, but not by thymectomy alone.

*Dunn E29,253/63*: "When **BALB/c** mice given the **Moloney virus** were thymectomized, splenectomized or subjected to both procedu-

res, the incidence of lymphocytic leukemia was reduced."

*Dunn & Green G40,311/66:* In inbred BALB/c mice inoculated with **Rauscher virus** "thymectomy had no apparent effect on the erythroblastic reaction, while splenectomy intensified the process in the liver and erythroblastic foci appeared in the lymph nodes. Granulocytopenia was also stimulated in some mice."

#### ← *Hepatectomy Partial* ←

*Pontremoli & Arrigo D63,528/50:* In rats partially hepatectomized and splenectomized simultaneously, hepatic regeneration is just as rapid, and sometimes even accelerated, in the absence of the spleen.

*Trasino B56,794/50:* In rats, splenectomy does not significantly alter the regeneration of the liver remnant after partial hepatectomy.

*Zaltzman D92,764/56:* Splenectomy enhances regeneration of the liver after partial hepatectomy in the rat.

*Pérez-Tamayo & Romero D38,897/58:* In rats, splenectomy stimulates hepatic regeneration after partial hepatectomy. This acceleration does not occur if the spleen is reimplanted either into the portal circulation or s.c. Apparently, a humoral factor is involved.

*Molimard & Benozio G75,048/70:* In rats, splenectomy does not influence hepatic regeneration after partial hepatectomy, but the latter operation causes an increase in splenic weight.

#### ← *Ionizing Rays* ←

*Guttman G45,255/67:* In mice, the intercapillary glomerulosclerosis produced by neonatal X-irradiation is potentiated by neonatal thymectomy but reduced by splenectomy.

### ← *Other Surgical Interventions*

← **Pinealectomy.** In rats, pinealectomy inhibits the induction of hepatic cancers by some but not by all carcinogens.

← **Sympathectomy.** The extensive literature on the effect of sympathectomy with or without adrenal demedullation has been discussed in many earlier review articles to which the reader must be referred. Suffice it here to summarize certain recent investigations which show that in rats, complete blockade of the sympathetic function by demedullation combined with reserpine-like, bretylium-like or ganglioplegic agents, increases mortality from **histamine** or **endotoxin** as much as does complete adrenalectomy. Pretreatment with epinephrine alone counteracts this diminished resistance. On the other hand, the lethal effect of other stressors such as **formalin** or **tourniquet shock** is greatly increased by adrenalectomy, but not by a sympathetic blockade. In this event cortisone is especially effective in restoring resistance. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

#### ← *Pinealectomy*

*Jelínek & Křeček H2,778/68:* In young, unlike in adult rats, pinealectomy inhibits the adrenal regeneration hypertension that results from an excessive mineralocorticoid production by the regenerating adrenal cortex.

*Lacassagne et al. G74,931/69:* In rats, removal of the pineal inhibits the induction of hepatic cancers by 4-dimethylaminoazobenzene, but does not influence the carcinogenic effect of 2-acetylaminofluorene and diethylnitrosamine.

*Aubert & Bohuon G77,483/70:* In hamsters, certain carcinogens (DMBA, urethan) induce

melanomas, preceded by depigmentation. Epiphysectomy does not alter this result.

#### ← *Sympathectomy*

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epine-

phrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or

tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

### ← HISTAMINE

**Drugs** ←. Histamine does not considerably influence drug-resistance in general, but it does tend to increase the anesthetic effect of **barbiturates**, **chloral hydrate** and several other hypnotics.

In rats given **lead acetate** i.v., subcutaneous injection of histamine causes topical calcergy, and if the dose of histamine is large, this may be associated with widespread calcification in the autonomic nervous system ("neurocalcergy").

**Varia** ←. Sensitivity to histamine is greatly increased in mice by pretreatment with *B. pertussis* vaccine, but resistance to botulinum toxin and nereis toxin is not affected.

Several investigators reported that histamine offers protection against total body **X-irradiation** in mice. It has also been claimed that histamine aggravates the pulmonary lesions produced by **hyperoxygenation** and depresses the cortical response to **electroshock**. On the other hand, an alarm reaction produced by exposure to **cold** increases the toxicity of orally administered histamine in rats, presumably because the amine is readily absorbed from the exulcerated gastrointestinal mucosa.

#### **Drugs** ←

**Acetonitrile** ←. *Wuth A 48,026/21*: In mice, tyramine and diiodotyramine—like thyroid extract—offer protection against acetonitrile, histamine does not.

**Barbiturates** ←. *Werle & Lentzen A 28,007/38*: In dogs and rabbits, various vasoactive substances (epinephrine, histamine, vasopressin, kallikrein) tend to prolong the anesthetic effect of pronarcon and hexobarbital.

*Fastier D 95,950/56*: In mice, 5-HT considerably potentiates the hypnotic effect of cyclobarbitol and chloral hydrate. However, this property is not very specific, since bufotanine, tryptamine, histamine, and epinephrine likewise prolong cyclobarbitol hypnosis. Literature on numerous other drugs which prolong barbiturate anesthesia is cited. "It therefore seems possible that the ability of 5-HT to prolong hypnosis may be due to a relatively unpecific, vascular effect."

**Hexobarbital** ← **Histamine**, **Mouse**: *Ambrus et al. C 16,607/52\**; *Bousquet et al. F 35,073/65\**

#### **Chloral Hydrate** ←. *Fastier et al. C 37,038/57*:

In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine, and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone, and DOC did not prolong chloral hydrate sleeping time at the doses tested.

**Lead** ←. *Selye et al. G 11,123/64*: "In rats simultaneously given an intravenous injection of lead acetate and a subcutaneous injection of histamine, extensive calcium deposition occurs in various parts of the autonomic nervous system. This neurotropic form of mastocalcergy can be inhibited by pretreatment with various mast-cell dischargers (compound 48/80, polymyxin, chlorpromazine), mast-cell components (histamine, 5-HT) or drugs known to inhibit the pharmacologic actions of such mast-cell components (cyproheptadine, neo-antergan). This prophylactic effect appears to be largely specific to compounds related to mast-cell

activity since it was not shared by various other drugs and stressors tested."

**Pentylentetrazol** ←. *Kobrin & Seifter F74,422/66*: In one day old chicks, in which the blood-brain barrier is still incompletely formed, various  $\omega$ -amino acids as well as 5-HT, histamine, and epinephrine, produce sleep and prevent pentylentetrazol convulsions.

**Reserpine** ←. *Simionovič et al. F43,099/65*: In mice, epinephrine and norepinephrine, as well as histamine, offer partial protection against reserpine intoxication (sedation blepharoptosis, hypothermia). 5-HT has no such effect.

#### Varia ←

**Microorganisms, Vaccines, and Bacterial Toxins** ←. *Kind E67,787/58*: Review (9 pp., 80 refs.) on increased sensitivity to 5-HT, histamine, and anaphylaxis induced in mice by *B. pertussis* vaccine.

*Fishel et al. E8,474/64*: Review (8 pp., 26 refs.) on the mechanism of sensitization by *B. pertussis* vaccine to histamine and 5-HT. The published data "indicate that the basis of this hypersensitivity is a blockade of a part of adrenergic division of the sympathetic nervous system. Preliminary experiments are also described, which suggest that a similar mechanism may also be operative in the local Schwartzman reaction."

*Simpson H5,300/68*: In mice, 5-HT increases, whereas pargyline decreases resistance to both botulinum toxin and nereis toxin. Histamine has no effect on either intoxication.

**Ionizing Rays** ←. *Bacq D77,006/54*: In mice, resistance to whole body X-irradiation is increased by numerous amines, particularly cysteamine ( $\beta$ -mercaptoethylamine), norepinephrine, 5-HT, and histamine.

*van der Meer & van Bekkum G71,673/59*: In mice, the radioprotective effect of histamine, epinephrine, and other biologic amines is related to their pharmacologic activity and can be blocked by their pharmacologic antagonists. "It is concluded that histamine, epinephrine

and a number of other biological amines protect against irradiation by reducing the oxygen tension in the spleen and possibly in other blood forming organs."

*Langendorff et al. G34,793/65*: In mice, incorporation of  $^{59}\text{Fe}$  in the erythrocytes can be used as a test for the radioprotective effect of 5-HT, histamine, and other chemicals.

*Langendorff et al. G38,385/65*: In mice, an open skin wound considerably increases mortality following total body X-irradiation. After this combined treatment, 5-HT has no protective effect, whereas histamine diminishes mortality.

*Langendorff & Messerschmidt G45,424/66*: In mice, the effect of 5-HT and histamine upon whole body irradiation combined with standard skin wounds is examined.

*Koch G51,862/67*: Theoretical considerations on the protective effect of 5-HT and histamine against X-irradiation.

**Hyperoxygenation** ←. *Grognot & Senelar C41,294/57*: In rats and guinea pigs, the pulmonary inflammation induced by inhalation of pure oxygen at barometric pressure is aggravated by ACTH or histamine.

**Electric Stimuli** ←. *Minz & Domino B81,852/53*: In rats, small doses of epinephrine or norepinephrine prolong the duration of electrically-induced seizures. Since glucose, ACTH, and cortisone failed to prolong seizure duration, it is unlikely that epinephrine should act by release of these substances. Histamine depressed the cortical response to electroshock.

**Cold** ←. *Selye A8,052/38*: Rats and guinea pigs normally tolerate very large doses of epinephrine or histamine p.o., but these substances cause toxic manifestations (lung edema, emphysema) if administered following the production of an alarm reaction by cold, forced muscular exercise, or other stressors. Presumably the gastrointestinal lesions characteristic of the alarm reaction facilitate the absorption of substances which normally do not traverse the intestinal epithelium in active form.

#### ← 5-HT

**Nonsteroidal Hormones and Hormone-Like Substances** ←. Comparatively little is known about the protective effect of 5-HT against overdosage with hormones and related compounds. The duration of hydroxydione anesthesia is prolonged by 5-HT in rats and mice. The toxicity of epinephrine is allegedly unaffected by 5-HT in the mouse, but it is diminished in the rabbit.

**Drugs** ←. 5-HT greatly potentiates the action of various barbiturates in the mouse, rabbit, and rat.

5-HT is also said to augment the antitumor actions of various chemical **carcinogens** diminishing at the same time their damaging effect upon the hemopoietic system.

The toxicity of **carbon tetrachloride** upon rat liver is decreased by 5-HT.

5-HT also prolongs **chloral hydrate**, **ethanol**, **ether**, **halothane** and **chloroform anesthesia** and tends to protect rabbits and dogs against **curare**.

The toxic effects of **harmine** in chickens are inhibited by 5-HT, whereas the bone lesions caused by **lathyrogens** in rats are aggravated.

In mice, the depression of spontaneous activity produced by **LSD** is converted into stimulation by 5-HT, but the prolonging effect of this amine upon hexobarbital narcosis is augmented by **LSD**.

5-HT potentiates the effects of **mephenesin** and **meprobamate** in the mouse. In rabbits, it increases the analgesic effect of **morphine**.

In rats, 5-HT increases the effects of **nitrogen mustard** but diminishes the myotoxic action of **paraphenylenediamine**.

**Pentylentetrazol** convulsions are inhibited by combined treatment with 5-HT and norepinephrine in the mouse. 5-HT also antagonizes pentylentetrazol in newly hatched chicks in which the blood-brain barrier is still incomplete; here the amine has an anesthetic effect. In mice, intracranial injection of 5-HT protects against pentylentetrazol convulsions. In strains susceptible to audiogenic and pentylentetrazol-induced seizures, 5-HTP presumably protects because it raises the 5-HT concentration in the brain.

**Picrotoxin** convulsions are also inhibited by intracerebral administration of 5-HT in mice. On the other hand, the inhibition of pentylentetrazol convulsions by intracerebrally injected **reserpine** is counteracted by 5-HT injected into certain regions of the brain.

In dogs, 5-HT inhibits the epilepsy provoked by direct application of **strychnine** or of an electric current to the brain.

In **DHT**-sensitized rats, calcification of the submaxillary glands can be obtained by 5-HT given s.c.

**Microorganisms and Their Products** ←. 5-HT (like histamine) is especially toxic to mice sensitized with *Bordetella pertussis* vaccine. If injected simultaneously with various viruses i.v., 5-HT tends to enhance their infectivity and their penetration into the brain.

In mice, resistance to **botulinum toxin** is increased by 5-HT given 30-60 min earlier. 5-HT also increases resistance to various endotoxins in the mouse. This effect, which is greater in females than in males, is potentiated by cortisol and aggravated by thyroxine.

**Ionizing Rays** ←. In mice, resistance to total body X-irradiation is increased by numerous amines including 5-HT, histamine, norepinephrine, and cystamine. 5-HTP offers similar protection, and the beneficial effect of 5-HT can be enhanced by concurrent administration of other radioprotective substances such as MAO-inhibitors and sulfhydryl-containing compounds. The radioprotective effect of 5-HT has also been confirmed in rats.

**Various Stressors** ←. 5-HT also increases the resistance of mice against **hyperoxygenation**. In rats it is said to decrease resistance to cold. In dogs it inhibits the epilepsy produced by direct electric stimulation of the brain, and in rats it elevates

the EST. The characteristic response of rats treated with **methionine sulfoximine** is reduced by 5-HT. Finally, in susceptible strains of mice, **audiogenic seizures** are prevented by 5-HTP, presumably because of the resulting increase in brain 5-HT.

**Steroids** ← cf. also *Selye G60,083/70, p.429.*

*Bianchi & de Maio C54,169/58:* In rats, anesthesia produced by hydroxydione i.p. is aggravated by 5-HT, reserpine or hexamethonium.

*Vacek D10,919/61:* In mice, 5-HT prolongs the duration of hydroxydione anesthesia, whereas LSD shortens it.

Estradiol ← 5-HT: *Inscoc et al. F70,325/66*

#### **Nonsteroidal Hormones and Hormone-Like Substances** ←

*Milošević C41,594/57:* In mice, reserpine potentiates the toxicity of epinephrine, but this effect should not be ascribed to depletion of 5-HT, since the latter given i.v. does not significantly modify the lethal effect of epinephrine.

*Sanyal G55,044/68:* In rabbits, 5-HT prevents production of pulmonary edema by epinephrine.

5-HT(N-acetyl) ← 5-HT: *Inscoc et al. F70,325/66*

#### **Drugs** ←

N-Acetyl-p-aminophenol ← 5-HT: *Inscoc et al. F70,325/66*

N-Acetyltyramine ← 5-HT: *Inscoc et al. F70,325/66*

**Anaphylactoid Edema** ← cf. *Selye G46,715/68, p. 201.*

**Barbiturates** ←.

#### **MAN**

*Poloni D95,333/55; D99,472/55:* Studies on the effect of 5-HT upon barbiturate or LSD intoxication in man (especially in schizophrenics) and in leeches.

#### **MOUSE**

*Shore et al. C18,383/55:* In mice, 5-HT markedly potentiates the hypnotic action of hexobarbital. In addition, 5-HT i.v. given to mice which have just recovered from hexobarbital hypnosis, immediately causes them to fall asleep again. Thus, it acts like chlorpromazine or reserpine by increasing the sensitivity of the brain to barbiturates, rather

than like SKF 525-A which inhibits drug detoxication.

*Fastier D95,950/56:* In mice, 5-HT considerably potentiates the hypnotic effect of cyclobarbital and chloral hydrate. However, this property is not very specific, since bufotamine, tryptamine, histamine, and epinephrine likewise prolong cyclobarbital hypnosis. Literature on numerous other drugs which prolong barbiturate anesthesia is cited. "It therefore seems possible that the ability of 5-HT to prolong hypnosis may be due to a relatively unspecific, vascular effect."

*Zanowiak & Rodman C85,018/59:* In mice, 5-HT potentiates the effects of various barbiturates, mephenesin, and meprobamate. This potentiation is counteracted by LSD.

*Kato C78,047/59:* In mice, the prolongation of pentobarbital or hexobarbital sleeping time by 5-HT (administered in the form of its precursor 5-HTP which penetrates the brain barrier more readily) is inhibited by DOPA; the latter presumably acts as a precursor of norepinephrine.

*Rümke G76,693/62:* In the mouse, hexobarbital anesthesia is prolonged by an immediately preceding i.p. or s.c. injection of 5-HT.

Hexobarbital ← 5-HT, Mouse: *Shore et al. C18,383/55\**; *Sturtevant D87,568/56\**; *Brown C31,328/57\**; *Holtz et al. C76,300/58\**; *Matthies et al. D84,334/61\**; *Rümke G76,693/62\**, *G69,768/63\**

#### **RABBIT**

*Antona C11,379/55:* In rabbits, large doses of 5-HT increase the duration and depth of thiopental anesthesia.

*Cahn et al. G71,537/56:* In rabbits, the prolongation of barbiturate (Kemithal, Meubarbital) anesthesia by 5-HT is further prolonged by phentolamine, neostigmine, and several other drugs, whereas epinephrine, and pantheline have an opposite effect.

*Mantegazzini C33,637/56:* In rabbits, the potentiation of pentobarbital anesthesia by 5-HT does not depend upon the hypotensive action of large doses of the latter.

*Cahn et al. C64,625/58:* In rabbits, thiopental anesthesia is prolonged by pretreatment with 5-HT i.v. This is associated with charac-

teristic changes in the carbohydrate metabolism of the brain.

*Lauria & Sharma F67,259/66*: In mice, pentobarbital sleeping time is prolonged by 5-HT and several other indole derivatives.

*Kadzielawa & Widy-Tyszkiewicz H13,469/69*: In mice, p-chlorophenylalanine decreases the duration of hexobarbital sleeping time. This effect is counteracted by 5-HTP, presumably as a consequence of increased 5-HT formation.

#### RAT

*Correll et al. E57,669/52*: In rats, anesthesia with various barbiturates or ether diminishes resistance to the lethal effect of 5-HT.

*Pierre & Cahn C24,570/55*: In rats, 5-HT prolongs thiopental anesthesia, but has no definite effect upon pentobarbital, urethan, or ether narcosis. In rabbits, 5-HT prolongs pentobarbital anesthesia, but has no definite effect upon thiopental and urethan narcosis.

*Cahn et al. C19,722/56*: In rats thiopental anesthesia is prolonged by 5-HT and this effect can be inhibited by a variety of 5-HT antagonists; further prolongation of sleep is obtained in decreasing order by chlorpromazine, Hydergine, acetylcholine, neostigmine, and phentolamine.

*Slocombe C14,144/56*: In rats under thiopental anesthesia, epinephrine, norepinephrine, adrenochrome, and 5-HT cause a flattening of the electrical activity both at cortical and at subcortical sites.

*Gaddum C25,117/56*: Brief review on the synergism between barbiturates and 5-HT.

*Garattini & Valzelli G71,229/56*: In rats, the prolongation of pentobarbital anesthesia by 5-HT is influenced by numerous drugs.

*Salmoiraghi et al. C21,596/56*: 5-HT prolongs the hypnotic action of hexobarbital both in mice and in rats.

*Fornaroli C47,728/57*: In rats, 5-HT prolongs anesthesia produced by various barbiturates or ether. Earlier literature is reviewed.

*Bose et al. D58,773/63*: In rats, hexobarbital sleeping time is prolonged by 5-HT. This prolongation is inhibited by Cannabis resin.

Phenobarbital ← 5-HT(N-acetyl):  
*Inscoc et al. F70,325/66*

Bemegride ← 5-HT, Mouse: Rümke  
*G76,692/62\**

**Carcinolytic Agent** ←. *Man'ko F74,715/66; F82,459/66*: In mice and rats, 5-HT increases the carcinolytic action of dopan, chlorambucil and cyclophosphamide upon certain transplantable tumors, and simultaneously decreases

their damaging effect upon the hemopoietic system.

**Carbon Tetrachloride** ←. *Fiore-Donati et al. C62,200/58; C78,953/59*: In rats, 5-HT offers partial protection against the hepatic lesions produced by CCl<sub>4</sub>.

*Erspamer E5,915/66*: A monograph on 5-HT and related indolealkylamines, with a special section on their protective effect against radiation injury, hepatic cirrhosis produced by CCl<sub>4</sub> or allyl alcohol, and cardiovascular calcifications produced by DHT.

**Cholesterol** ←. *Trentini et al. G71,152/68*: In rabbits, the cholesterol-atherosclerosis-inhibiting effect of Tween 80 is diminished both by 5-HT and by norepinephrine.

**Chloral Hydrate** ←. *Fastier D95,950/56*: In mice, 5-HT considerably potentiates the hypnotic effect of cyclobarbitol and chloral hydrate. However, this property is not very specific, since bufotenine, tryptamine, histamine and epinephrine likewise prolong cyclobarbitol hypnosis. Literature on numerous other drugs which prolong barbiturate anesthesia is cited. "It therefore seems possible that the ability of 5-HT to prolong hypnosis may be due to a relatively unspecific, vascular effect."

*Fastier et al. C37,038/57*: In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine, and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone, and DOC did not prolong chloral hydrate sleeping time at the doses tested.

**Chloroform** ←. *Wulfsohn & Politzer D22,421/61*: In mice, 5-HT greatly prolongs chloroform anesthesia but has little or no effect upon ether or halothane narcosis.

**Curare** ←. *Sala & Perris C78,420/58*: In rabbits treated with D-tubocurarine, 5-HT causes a rapid but transient restoration of neuromuscular transmission.

*Schopp & Rife E24,636/63*: In dogs, 5-HT exerts a mild anticurare action upon the indirectly stimulated peroneal-tibialis-anticus nerve-muscle preparation.

**Ethanol** ←. *Rosenfeld G72,151/60*: In mice, ethanol anesthesia is prolonged by 5-HT, tryptamine, and dopamine. "Analytical data provided experimental proof that the potentiating effect of the aromatic amines was not attributable either to an increase in the brain alcohol content or to an interference with the over-all rate of alcohol destruction in the body."

Ethanol ← 5-HT + Iproniazid, Mouse: Besendorf et al. C31,623/56\*

**Ether** ←. *Fornaroli C47,728/57*: In rats, 5-HT prolongs anesthesia produced by various barbiturates or ether. Earlier literature is reviewed.

*Wulfsohn & Politzer D22,421/61*: In mice, 5-HT greatly prolongs chloroform anesthesia, but has little or no effect upon ether or halothane narcosis.

**Halothane** ←. *Wulfsohn & Politzer D22,421/61*: In mice, 5-HT greatly prolongs chloroform anesthesia, but has little or no effect upon ether or halothane narcosis.

*Nikki & Rosenberg G71,574/69*: In mice, shivering and hypothermia are prevented by norepinephrine and 5-HT, but not by dopamine. "The results suggest that brain catecholamines participate in the control of shivering and return of normothermia after halothane anaesthesia in mice."

**Harmine** ←. *Bowman & Osuide F98,712/68*: In chickens, the toxic effects of tremorine and harmine are inhibited by 5-HT and numerous other drugs.

**Lathyrogens** ←. *Franchimont et al. D13,136/61*: In rats, osteolathyrism produced by AAN is aggravated by 5-HT, whereas glucagon does not modify it significantly.

**Lead** ←. *Selye et al. G11,123/64*: "In rats simultaneously given an intravenous injection of lead acetate and a subcutaneous injection of histamine, extensive calcium deposition occurs in various parts of the autonomic nervous system. This neurotropic form of mastocalcergy can be inhibited by pretreatment with various mast-cell dischargers (compound 48/80, polymyxin, chlorpromazine), mast-cell components (histamine, 5-HT) or drugs known to inhibit the pharmacologic actions of such mast-cell components (cycloheptadine, neo-antergan). This prophylactic effect appears to be largely specific to compounds related to mast-cell activity since it was not shared by various other drugs and stressors tested."

**LSD** ←. *Poloni D95,333/55; D99,472/55*: Studies on the effect of 5-HT upon barbiturate or LSD intoxication in man (especially in schizophrenics) and in leeches.

*Brown C31,328/57*: In mice, the depression of spontaneous activity induced by LSD is converted into stimulation by 5-HT.

*Salmoiraghi & Page C38,518/57*: In mice, LSD and various other hallucinogens (bufotenine, mescaline, ibogaine) augment the pro-

longing effect of 5-HT upon hexobarbital narcosis.

**Mephesisin, Meprobamate** ←. *Zanowiak & Rodman C85,018/59*: In mice, 5-HT potentiates the effects of various barbiturates, mephesisin, and meprobamate. This potentiation is counteracted by LSD.

**Mercury** ←. *Erspamer B84,587/53*: In rats given large doses of HgCl<sub>2</sub> survival is prolonged and mortality decreased by repeated s.c. injections of 5-HT, perhaps because the latter diminishes renal blood flow.

**Methionine Sulfoximine** ←. *Wada et al. G48,380/67*: Rats treated with methionine sulfoximine show a characteristic response to audiogenic stimuli, which is reduced by 5-HT and increased by DOPA.

**Morphine** ←. *Nicák F47,918/65*: In rats and mice, the analgesic effect of small doses of morphine is potentiated by 5-HT.

*Saarnivaara H2,855/68; G71,565/69*: In rabbits, 5-HT increases morphine analgesia.

**Nitrogen Mustard** ←. *Uroic et al. E37,637/64*: In rats, 5-HT increases the toxicity of mustine hydrochloride (nitrogen mustard), a typical radiomimetic poison.

*Ballerini & Bosi G31,956/65*: In rats, 5-HT increases the lethality of intoxication with uracil mustard. Antiserotonins have an opposite effect.

**Paraphenylenediamine** ←. *Jasmin & Bois C73,640/59; C83,058/60*: In rats, the myotoxic action of paraphenylenediamine can be partially prevented by 5-HT, but also by KCl, methylene blue, and vitamin C. The mechanism of protection is not understood.

**Pentylenetetrazol** ←. *Bonnycastle et al. C37,036/57*: In rats, anticonvulsants increase the 5-HT concentration of the brain, but administration of 5-HT, iproniazid, or 5-hydroxytryptophan, in doses which elevate the brain levels of 5-HT, did not protect against the convulsant or lethal action of pentylenetetrazol.

*Schmidt & Matthies D34,219/62*: In mice, 5-HT or norepinephrine injected into certain regions of the brain is without effect upon pentylenetetrazol injection in itself, but counteracts the inhibitory effect of intracerebrally injected reserpine.

*Schmidt E32,188/63*: In mice, pentylenetetrazol convulsions are inhibited by combined administration of 5-HT and norepinephrine into certain regions of the brain.

*Seifter et al. G71,087/63*: In chicks, pentylenetetrazol convulsions can be inhibited by 5-HT and some of its analogues.

*Kobrin & Seifter F74,422/66:* In one day old chicks, in which the blood-brain barrier is still incompletely formed, various  $\omega$ -amino acids as well as 5-HT, histamine, and epinephrine, produce sleep and prevent pentylene-tetrazol convulsions.

*Schlesinger et al. G61,802/68:* In susceptible mice, audiogenic and pentylene-tetrazol-induced seizures are prevented by 5-HTP, presumably because of the resulting increase in brain 5-HT concentration.

*Schlesinger et al. G69,565/69:* In mice, intracranial injections of 5-HT or norepinephrine protect against pentylene-tetrazol convulsions.

Pentylene-tetrazol ← 5-HTP + Genetics, Mouse: Schlesinger et al. G61,802/68\*

**Picrotoxin** ←. *Saito et al. E27,616/63:* In mice, picrotoxin convulsions are inhibited by the intracerebral administration of epinephrine or 5-HT.

**Plasmocid** ← *cf. Selye G60,083/70, p. 429.*

**Reserpine** ←. *Schmidt & Matthies D34,219/62:* In mice, 5-HT or norepinephrine injected into certain regions of the brain is without effect upon pentylene-tetrazol injection in itself, but counteracts the inhibitory effect of intracerebrally injected reserpine.

*Simionovici et al. F43,099/65:* In mice, epinephrine and norepinephrine, as well as histamine, offer partial protection against reserpine intoxication (sedation blepharoptosis, hypothermia). 5-HT has no such effect.

**Strychnine** ←. *Scarinci G66,316/55:* In dogs, 5-HT inhibits the epilepsy produced by direct application of strychnine to, or direct electric stimulation of the brain.

**Tremorine** ←. *Bowman & Osuide F98,712/68:* In chickens, the toxic effects of tremorine and harmine are inhibited by 5-HT and numerous other drugs.

**Tween 80** ←. *Trentini et al. G71,152/68:* In rabbits, the cholesterol-atherosclerosis-inhibiting effect of Tween 80 is diminished both by 5-HT and by norepinephrine.

Tyramine ← 5-HT: *Inscoe et al. F70,325/66*

**Urethan** ←. *Pierre & Cahn C24,570/55:* In rats, 5-HT prolongs thiopental anesthesia, but has no definite effect upon pentobarbital, urethan, or ether narcosis. In rabbits, 5-HT prolongs pentobarbital anesthesia but has no definite effect upon thiopental and urethan narcosis.

**Vitamin D, DHT** ← *cf. also Selye G60,083/70, p. 429. Selye & Gentile D6,950/61:* In rats pretreated with DHT p.o., selective calcification of the submaxillary glands can be obtained by 5-HT s.c. as a manifestation of calciphylaxis.

*Erspamer E5,915/66:* A monograph on 5-HT and related indolealkylamines, with a special section on their protective effect against radiation injury, hepatic cirrhosis produced by CCl<sub>4</sub> or allyl alcohol, and cardiovascular calcifications produced by DHT.

### Microorganisms ←

*Fishel et al. E8,474/64:* Review (8 pp., 26 refs.) on the mechanism of sensitization by B. pertussis vaccine to histamine and 5-HT. The published data "indicate that the basis of this hypersensitivity is a blockade of a part of adrenergic division of the sympathetic nervous system. Preliminary experiments are also described, which suggest that a similar mechanism may also be operative in the local Shwartzman reaction."

*Sellers H10,893/69:* In mice, epinephrine or 5-HT injected simultaneously with various viruses i.v. enhances their infectivity and their penetration into the brain.

**Bacterial Toxins** ← *cf. also Selye E5,986/66, p. 85.*

*Boroff C75,371/59:* In mice, both the toxicity and ultraviolet fluorescence of Cl. botulinum toxin are inhibited by 5-HT and tryptophan, as well as by substances releasing 5-HT into the circulation (e.g. reserpine, chlorpromazine).

*Gordon & Lipton C94,649/60:* 5-HT reduces endotoxin mortality in mice. This effect is greater in females than in males and is potentiated by cortisol. Thyroxine aggravates the toxicity of endotoxin.

*Boroff & Fleck F87,254/67:* In mice, 5-HT increases resistance to botulinum toxin given 30–60 min later.

*Simpson G60,451/68; H5,300/68:* In mice, botulinum poisoning is prevented by 5-HT. Although both 5-HT and the toxin act upon mechanisms of cholinergic synaptic transmission, work with isolated nerve-muscle preparations showed that the synaptic junction is not the site of 5-HT and toxin interaction, suggesting "that it is the circulatory system rather than the nervous system at which the two drugs interact."

**Ionizing Rays ←****MOUSE**

*Bacq D77,006/54:* In mice, resistance to whole body X-irradiation is increased by numerous amines, particularly cysteamine ( $\beta$ -mercaptoethylamine), norepinephrine, 5-HT, and histamine.

*Langendorff & Koch C36,881/57:* In mice, both tryptamine and 5-HT offered protection against X-irradiation, whereas amphetamine and d,l-ephedrine were ineffective.

*Melching et al. C76,527/58:* In mice, 5-HT i.p. increases resistance against whole body X-irradiation, but only under certain conditions of dosage and timing.

*Langendorff et al. C69,396/59:* In mice, 5-HT exerts a prophylactic effect against total body X-irradiation.

*Semenov D7,087/60:* In mice, 5-HT offers better protection against radiation sickness than epinephrine, although the latter is also effective, especially when given in combination with acetylcholine.

*Doull & Tricou D4,271/61:* In mice, pretreatment with 5-HT increases resistance to whole body X-irradiation.

*Feinstein & Seaholm E29,638/63:* In mice, both 5-HT and the 5-HT antagonist KB-95 exhibit some radioprotective activity. Conjoint administration of both compounds is somewhat less effective than treatment with either drug alone.

*Maisin et al. E36,751/63:* In mice, the protection against X-irradiation offered by 2- $\beta$ -aminoethylisothiourea (AET) is only slightly improved by concurrent administration of 5-HT.

*Vittorio et al. D56,243/63:* Review of the literature and personal observations in mice on the radio protective effect of 5-HT.

*Abe & Langendorff G23,763/64:* In mice, 5-HT protects the testes against damage caused by X-irradiation. The histologic manifestations of the damage and protection have been studied under varying circumstances.

*Langendorff et al. G34,793/65:* In mice incorporation of  $^{59}\text{Fe}$  in the erythrocytes can be used as a test for the radioprotective effect of 5-HT, histamine, and other chemicals.

*Langendorff et al. G38,385/65:* In mice, an open skin wound considerably increases mortality following total body X-irradiation. After this combined treatment, 5-HT has no protective effect, whereas histamine diminishes mortality.

*Kobayashi et al. G73,566/66:* In mice, under suitable experimental conditions, 5-HTP offers as good, or even better, protection against whole body X-irradiation as does 5-HT.

*Langendorff & Langendorff G38,396/66:* In mice, the protective effect of 5-HT against X-irradiation largely depends upon the age of the animals.

*Langendorff & Messerschmidt G45,424/66:* In mice, the effect of 5-HT and histamine upon whole body irradiation combined with standard skin wounds is examined.

*Maisin & Mattelin F78,796/67:* In mice, the radioprotective effect of 5-HT can be enhanced by conjoint administration of other radioprotectors.

*Cier et al. F85,815/67:* In mice, the protection against total body X-irradiation given by 5-HT is considerably increased by concurrent treatment with thiosulfate. Various other radioprotective compounds offer likewise better protection and are less toxic if administered conjointly than if given singly.

*Graul & R  ther G66,718/67:* In mice and rabbits, 5-HT, cysteamine, and AET ( $\beta$ -aminoethylisothiuronium) have proved to be particularly effective as radioprotective substances against  $^{60}\text{CO-}\gamma$  and X-irradiation.

*Hasegawa & Landahl G48,428/67:* In mice, the radioprotective effect of 5-HT depends upon the oxygen content of the air.

*Maisin & Mattelin H719/67:* In mice, the radioprotective effect of 5-HT is enhanced by concurrent treatment with one or more sulfhydryl compounds.

*Westphal & Hagen G45,683/67:* In mice, the chromosome aberrations in the thymus induced by X-irradiation are reduced by 5-HT and cysteamine.

*Barnes & Lowman G63,518/68:* In mice, the radioprotective effect of 5-HT can be augmented by simultaneous administration of phenelzine, a MAO-inhibitor.

*Maisin et al. G59,894/68:* In mice, the radioprotective effect of 5-HT can be increased by simultaneous treatment with other radioprotectors.

*Streffer et al. G55,078/68:* In mice, the protective effect of 5-HT against X-irradiation was compared under different experimental conditions.

*Barnes & Lowman G64,917/69:* In mice, 5-HT gave better protection against total body X-irradiation than did 5-HTP. Earlier claims to the contrary are not confirmed.

*L  onard et al. G71,644/69:* In mice, the radio-protective effect of various chemicals

given conjointly is increased by the addition of 5-HT to the mixture.

#### RAT

*Gray et al. B92,332/52*: In rats, 5-HT greatly increases survival following total body X-irradiation. The production of methemoglobinemia by para-aminopropiophenone has a similar effect; hence, the protection is ascribed to temporary tissue anoxia.

*van den Brenk & Elliott C76,268/58*: In rats, the protective effect of 5-HT against whole body X-irradiation is compared with that of tryptamine and other agents.

*van den Brenk & Moore C71,353/59*: In rats, the protective effect of 5-HT upon total body X-irradiation is reversed by breathing oxygen under high pressure.

*Ladner et al. G31,673/65*: In rats, 5-HT protects against whole body X-irradiation especially when combined with tryptophan.

*Frölen G43,045/66*: In rats "the genetic radio-protective effects of cysteamine, AET, cystamine, glutathion and serotonin have been studied. Only cysteamine showed a clear mutation-reducing effect on spermatids and spermatozoa."

*Rixon & Baird G55,192/68*: In rats, studies on the radioprotective effect of 5-HT suggest that intense vasoconstriction and hypoxia-induced reduction in cellular respiration may have a beneficial effect.

#### VARIA

*Maisin & Doherty C91,781/60*: A review on chemical protection against X-irradiation, with special emphasis upon the protective effect of 5-HT alone or given in combination with MEA [bis(2-aminoethyl)disulfide (cystamine)] or AET (2-aminoethylisothiourea).

*Erspamer E5,915/66*: A monograph on 5-HT and related indolealkylamines with a special section on their protective effect against radiation injury, hepatic cirrhosis produced by CCl<sub>4</sub> or allyl alcohol, and cardiovascular calcifications produced by DHT.

*Koch G51,862/67*: Theoretical considerations on the protective effect of 5-HT and histamine against X-irradiation.

#### Various Stressors ←

**Hyperoxygenation** ←. *Laborit et al. C48,371/57; C52,731/58; C77,964/59*: In mice, 5-HT protects against the convulsions produced by exposure to oxygen under high pressure.

**Cold** ←. *Zilberstein C80,282/60*: In rats, 5-HT, vasopressin, and reserpine lower resistance to cold, allegedly because they interfere with pituitary hormone secretion and cause a state of "temporary functional adrenalectomy."

**Electric Stimuli** ←. *Scarinci G66,316/55*: In dogs, 5-HT inhibits the epilepsy produced by direct application of strychnine to, or direct electrical stimulation of the brain.

*de Salva et al. C51,842/58*: In rats, the EST was lowered by hypophysectomy and adrenalectomy, but only insignificantly by thyroidectomy. 5-HT elevated the EST.

**Sound** ←. *Wada et al. G48,380/67*: Rats treated with methionine sulfoximine show a characteristic response to audiogenic stimuli, which is reduced by 5-HT and increased by DOPA.

*Schlesinger et al. G61,802/68*: In susceptible mice, audiogenic and pentylenetetrazol-induced seizures are prevented by 5-HTP, presumably because of the resulting increase in brain 5-HT concentration.

#### ← VARIOUS OTHER HORMONE-LIKE SUBSTANCES

**Prostaglandin E<sub>1</sub>** partially protects mice against strychnine-induced convulsions.

**Erythropoietin** increases the resistance of mice against X-irradiation.

In dogs and rabbits, **kallikrein** (like other vasoactive substances) prolongs the anesthetic effect of barbiturates.

"**Toxohormone**" (a Walker tumor extract) allegedly causes pronounced changes in the microsomal steroidases of the rat liver.

**Drugs (Var)** ← cf. *Selye B87,000/52, pp. 59—66, 210—216, 250, 256, 264, 269, 277, 278; B90,100/53, pp. 86—93, 267—277, 321, 322, 335, 336; C1,001/54, pp. 294—301, 451—460, 465—468, 478, 490, 491; C9,000/56, pp. 233—241, 348—352, 449—460, 470—476, 485, 486;*

**Bacterial Toxins** ← cf. *Selye E5,986/66, pp. 71, 85, 86.*

**Stress** ← cf. *Selye B58,650/51, p. 50; B87,000/52; B90,100/53; C1,001/54; C9,000/56.*

*Varia* ←

*Werle & Lentzen A 28,007/38*: In dogs and rabbits, various vasoactive substances (epinephrine, histamine, vasopressin, **kallikrein**) tend to prolong the anesthetic effect of pronarcon and hexobarbital.

*Čapek D 54,290/62*: In mice, **bradykinin** decreases the seizure threshold to strychnine, pentylenetetrazol, and electroshock. Substance P has the opposite effect.

*Jones & Shapiro D 55,793/63*: In rats, an acute episode of hypertension produced by epinephrine or **angiotensin** i.v. facilitates the production of pyelonephritis following infection with *E. coli*.

*Altura et al. F 36,124/65*: In rats, survival following temporary ligation of the superior mesenteric artery was improved by PLV-2, but not by epinephrine or **angiotensin**. The associated changes in the microcirculation of the mesoappendix are described.

*Altura et al. F 43,209/65*: In rats, norepinephrine and **angiotensin** fail to prolong survival after traumatic shock, temporary ligation of the superior mesenteric artery, or endotoxin shock. However, vasopressin (PLV-2) was significantly effective in traumatic and intestinal ischemia shock, but not in endotoxemia.

*Naidu & Reddi F 80,336/67*: In mice, resistance to X-irradiation is increased by **erythropoietin** preparations.

*Duru & Türker H 10,307/69*: In mice, **prostaglandin E<sub>1</sub>** partially protects against strychnine-induced convulsions.

*Takahashi & Kato H 15,250/69*: Studies on changes in hepatic microsomal steroidases induced in rats by treatment with "**toxohormone**" (a Walker tumor extract).

*Vittorio et al. H 7,759/69*: In mice, polycythemia induced by transfusion, increases resistance to X-irradiation. A similar result can be obtained by stimulation of stem cell activity by **erythropoietin**.

← *TISSUE EXTRACTS*

← **Hepatic Extracts**. In view of the important role played by the liver in detoxicating mechanisms, many investigations have been performed to determine whether drug resistance could be conferred by pretreatment with hepatic extracts. In rats, a certain hepatic preparation ("**Yakriton**") has been claimed to offer protection against a variety of toxicants. Hepatic extracts have also been said to protect the rat against methanol and its metabolites, pyruvate and acetaldehyde. Finally, rats have been protected against thyroxine intoxication by feeding hepatic extracts containing an "antitoxic factor."

← **Other Tissue Extracts**. In order to test the specificity of the acetonitrile test, mice have been pretreated with a great variety of tissue extracts; it has been found that these offer also some protection against acetonitrile, KCN and propionitrile, although they are much less efficacious than thyroid preparations. Resistance to pentobarbital anesthesia is decreased in male rats by a variety of tissue extracts (anterior pituitary, thymus, pancreas, liver, kidneys, spleen, testis, brain). On the other hand "among eight damaging agents given in doses sufficient to elicit an alarm reaction, only colchicine and atropine prolong the duration of anesthesia because of their high degree of toxicity." It remains questionable, however, whether the increase in barbiturate sleeping time produced by tissue extracts is solely due to their stressor action.

Vitamin-D<sub>3</sub> intoxication is largely inhibited by placenta extracts in the rat.

In frogs, fatal strychnine convulsions can be prevented if the drug is mixed with various tissue extracts prior to injection, but this may well be due to delayed absorption as a consequence of local inflammatory phenomena.

← *Hepatic Extracts*

*Ravdin et al. B25,566/39*: In rats, xanthine, allantoin, caffeine, sodium ricinoleate and suspensions of colloidal carbon injected s.c. protect the liver against injury from chloroform, presumably as a consequence of the resulting inflammatory reaction which is associated with the absorption of protein split-products. This would also explain the protective effect of various hepatic extracts (including Yakriton) and of high protein diets.

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram), are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

*Ershoff D5,818/61*: Review of the literature, and personal observations on the protection of rats against toxic doses of thyroxine by feeding hepatic extracts containing the "antitoxic factor of liver."

*Grandpierre & Robert H22,252/69*: In rats, i.p. administration of a lyophilized liver extract detoxifies estradiol as judged by a diminished sex hormone activity in prepubertal animals.

← *Other Tissue Extracts*

*Marañón & Aznar 46,926/15*: In frogs, the fatal convulsions produced by strychnine can be prevented if, prior to injection, the drug is mixed with extracts of the posterior pituitary, the thyroid, various other tissues, and particularly epinephrine. [The possibility of delayed absorption owing to local vasoconstriction has not been considered (H.S.).]

*Gellhorn 16,839/23*: In mice, resistance against acetonitrile can be increased not only by thyroid extract, but to a lesser extent, also by extracts of various other tissues. These preparations likewise augment resistance to KCN and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

*Masson 94,205/47*: Various tissue extracts (anterior pituitary, thymus, pancreas, liver, kidney, spleen, testis, brain) as well as casein s.c. decrease resistance to pentobarbital anesthesia in male rats. On the other hand, "among eight damaging agents given in doses sufficient to elicit an alarm reaction, only colchicine and atropine prolonged the duration of anesthesia, because of their high degree of toxicity." Yet, the prolongation of barbiturate anesthesia by pituitary extracts must be ascribed to a nonspecific stressor effect.

*Wietek & Taupitz C40,028/57*: In rats, the syndrome of vitamin-D<sub>3</sub> intoxication is largely inhibited by placenta extract i.m.

## VII. EFFECT OF NONHORMONAL FACTORS UPON RESISTANCE

### ← DRUGS

There exists a very extensive literature on the effect of various drugs upon resistance to toxicants. In fact, as regards the induction of defensive hepatic microsomal enzymes, much more has been published in this connection about drugs than about hormones (particularly steroids) as inducers. However, this book deals primarily with the role of hormones in resistance, hence the defensive action of drugs will be considered only in as far as it sheds some light upon our principal subject.

We shall deal here mainly with such classic hepatic microsomal-enzyme inducers as the barbiturates, pesticides and carcinogens whose actions are closely related to those of steroids. However, we shall also consider the protective effects of other drugs against certain substrates (e.g., anesthetics and hypnotics, digitalis alkaloids, indomethacin, steroids) that are highly subject to detoxication through hormones and often help to illustrate the actions of the latter. On the other hand, specific pharmacologic antagonisms (e.g., between histamine and antihistamines, 5-HT and antiserotonins, vasopressor and vasodilator substances) will not be considered. The so-called phenomena of nonspecific cross-resistance, that are related to stress, will be mentioned only in passing.

In the Abstract Section, the resistance-modifying drugs will be considered in alphabetic order, always together with all the toxicants that they affect. Here, we shall comment only on a few particularly interesting data, and on observations which can be clarified by correlating them with facts not mentioned by the authors of the original articles cited.

As with hormones, we may distinguish syntoxic and catatoxic drugs. The syntoxic effect is due to the suppression of excessive tissue reactions to an irritant, without destroying the latter; the catatoxic effect is the consequence of the destruction of the aggressor, e.g., through the induction of hepatic microsomal drug-metabolizing enzymes.

Weight for weight **amiloride** is even more active than spironolactone in protecting the rat against various forms of infarctoid cardiopathies produced by gluco-mineralocorticoids plus Na-salts and other conditioning factors. However, this effect is apparently quite unrelated to steroid-metabolizing enzyme induction, it depends upon the potassium-sparing action of amiloride. Accordingly, this drug is ineffective in protecting the rat against hexobarbital, progesterone, parathion or dioxathion, all of which are readily detoxified by spironolactone and other steroidal or nonsteroidal hepatic microsomal-enzyme inducers.

Perhaps the most carefully studied class of nonhormonal drug-metabolizing enzyme inducers are the **barbiturates**. Several investigators found that phenobarbital counteracts the uterotrophic effect of estradiol in immature intact or ovariectomized rats.

It also enhances the estradiol-metabolizing activity of isolated hepatic microsomal fractions in rats treated in vivo with phenobarbital. This action of the barbiturate remains obvious after adrenalectomy or hypophysectomy. The uterine weight-increasing effect of synthetic luteoids, such as norethindrone and norethynodrel, is likewise inhibited by phenobarbital, as is that of synthetic folliculoids. When isotope-marked folliculoids are used, e.g., tritiated diethylstilbestrol, this inhibition is paralleled by decreased radioactivity in the uterus and increased diethylstilbestrol degradation by hepatic microsomes.

In mice, the uterotrophic effect of estrone, estradiol and stilbestrol is also reduced by phenobarbital pretreatment. Endogenous folliculoid production is presumably likewise inhibited by this drug, since phenobarbital interferes with the maintenance of normal uterine weight in intact mice.

There is some evidence that in immature or gonadectomized male rats, phenobarbital diminishes the effect of testosterone upon the accessory sex organs.

Finally, in rats the half-life of i.v.-injected cortisol is decreased by pretreatment with phenobarbital; in man, this barbiturate accelerates the plasma clearance of cortisol.

Experiments with radioactive thyroxine indicate that phenobarbital increases the turnover of thyroid hormone and stimulates the function of the thyroid after enhancing the hepatocellular binding of thyroxine. Furthermore, the hepatic microsomes of phenobarbital-pretreated rats exhibit an increased ability to de-iodinate thyroxine and T3 in vitro.

There is good experimental evidence that phenobarbital and other barbiturates also enhance the metabolism of certain anticoagulants (bishydroxycoumarin, coumarin, warfarin) in various species, including man. They even promote the enzymic biotransformation of many barbiturates, bilirubin, carbon disulfide, cholesterol (at the same time inhibiting the atheromatosis produced by cholesterol feeding), diphenylhydantoin, antipyrine, ethanol, various pesticides, phenylbutazone, picrotoxin, quinine, strychnine, etc. The elimination of ascorbic acid is enhanced by phenobarbital in the rat. On the other hand, unlike various catatoxic steroids, phenobarbital does not appear to protect against cyclophosphamide, digitoxin, D-tubocurarine, tribromoethanol, mephenesin etc. (*cf. also* Tables 137, 138).

The effect of barbiturates upon hepatic enzymes has already been mentioned, especially in connection with the increase in various steroidases; for additional data, the reader is referred to the Abstract Section.

The extensive literature on the effect of **carbon tetrachloride** on hepatic microsomal-enzyme induction is discussed, with that of other hepatotoxic blockers, in the section on "General Pharmacology."

Next to the barbiturates, probably the most intensively studied class of microsomal-enzyme inducers is that of the **carcinogens**. The relationship, if any, between carcinogenic and enzyme-inducing potency is not clear but empirical observations show that many carcinogens enhance the activity of thiophosphate-oxidizing enzymes, steroidases and several other enzyme systems, including those that accelerate the biotransformation of other carcinogens. Thus, it has been possible in some instances to protect animals against the tumorigenic action of a strong carcinogen by pretreating it with a weaker one. The spectrum of enzyme induction exhibited by carcinogens does not correspond to that of the barbiturates or of steroids.

It is of special interest that some factors naturally occurring in cedar chips can induce various hepatic enzymes and diminish hexobarbital sleeping time. This is of practical importance in that mice and rats kept on soft wood bedding may develop a great resistance to certain toxicants.

**Desipramine** (an antidepressant) reduces the activity of modaline by inhibiting its biotransformation into a more active compound in the hepatic microsomes of the rat. Furthermore, desipramine potentiates the uterotrophic action of estrone in immature rats by delaying its degradation in the hepatic microsomes.

**Diphenylhydantoin** (an anticonvulsant and anti-epileptic drug) alters corticoid metabolism in man, but this effect will be discussed under "Clinical Implications."

In our most recent experiments on rats, we found that diphenylhydantoin offers excellent protection against digitoxin dioxathion, parathion, nicotine, hexobarbital, progesterone, zoxazolamine and indomethacin, but only at the very high dose of 100 mg, twice daily, per 100 g body weight. At lower dose levels, the protective effect decreases rapidly (*cf.* Table 137).

Curiously, in dogs or guinea pigs just awakening from barbiturate anesthesia, i.v. injection of glucose produces a return of sleep, perhaps because it increases barbiturate penetration into the brain.

In view of the important role played by thyroid hormones in the regulation of drug-metabolizing enzyme induction, it is of interest that in rabbits inhibition of thyroid function by iodine accelerates the recovery of the spinal cord following anoxia induced by temporary compression of the abdominal aorta. Destruction of the thyroid with radio-iodine has essentially the same effect as surgical thyroidectomy.

**Iproniazid** is discussed with the other MAO-inhibitors, under inhibitors of microsomal enzyme induction in the section on "General Pharmacology" (p. 68).

In rats, the adrenal necrosis produced by DMBA or 7-OH-MBA is prevented by **metyrapone** and related inhibitors of corticoid synthesis. This drug delays the blood clearance of exogenous cortisol presumably because it "inhibits the liver enzyme system(s) responsible for inactivation of adrenal steroids." Addition of metyrapone to liver microsomes of mice does not interfere with electron transport; hence, the point of attack of the inhibitor on the hydroxylation of substrate appears to be on cytochrome P-450.

The well-known adrenal-stimulating effect of metyrapone and of related compounds is ascribed to a compensatory ACTH secretion, resulting from a diminished feed-back because of the inhibition of steroid  $11\beta$ -hydroxylase activity in the adrenals. However, the compound also acts on hepatic enzyme induction since it prolongs hexobarbital sleeping time and inhibits the oxidative metabolism of hexobarbital, aminopyrine and acetanilide by hepatic microsomes *in vitro*.

In rats, metyrapone inhibits the catatonic effect of spironolactone against digitoxin and indomethacin poisoning; it also prolongs the anesthetic action of progesterone, DOC and hydroxydione.

**Pesticides** were among the first compounds shown to possess hepatic microsomal drug-metabolizing enzyme-inducing capacity. They stimulate the SER of the hepatocytes, diminish hexobarbital sleeping time, inhibit the effect of various carcinogens and interfere with the metabolism of steroids (including corticoids, folliculoids and testoids). This latter action has caused some concern with regard to the probable

effect of pesticides, as pollutants of the atmosphere, upon fertility, particularly among birds.

The stimulation by pesticides of the metabolism of bilirubin and of excess corticoids in Cushing's syndrome, cardiovascular diseases, etc. will be discussed at length in the section on "Clinical Implications."

Several **phenothiazines** appear to have microsomal enzyme-blocking actions similar to those of SKF 525-A. Thus they prolong hexobarbital anesthesia, potentiate the effect of various spasmolytic compounds, and inhibit DMBA-induced adrenal necrosis in the rat.

**Phenylbutazone** as a typical anti-inflammatory (and hence syntoxic) drug, deserves special attention as regards its effect upon hepatic microsomal enzyme induction. *In vitro*, when added to pig liver homogenates, it inhibits the enzymic inactivation of cortisone. However, treatment of immature rats with phenylbutazone increases several-fold the hepatic microsomal enzymes that hydroxylate testosterone and 4-androstene-3,17-dione.

In man, phenylbutazone increases the urinary excretion of  $6\beta$ -hydroxycortisol. In rabbits, cholesterol atherosclerosis is diminished by phenylbutazone and oxyphenylbutazone, although to a lesser extent than by glucocorticoids.

Phenylbutazone also increases its own metabolism. That is allegedly why rats treated for short periods develop gastric ulcers which disappear upon more prolonged treatment.

Unlike salicylic acid, phenylbutazone does not significantly affect the plasma concentration or biliary and fecal excretion of  $^{14}\text{C}$ -indomethacin.

**RES-blocking agents** allegedly abolish the sex difference in the picrotoxin sensitivity of rats, a species in which males are normally more resistant to this drug than females.

On theoretic grounds, it has been postulated that the anti-endotoxic activity of corticoids "in some way involves the reticuloendothelial system." However, up to now this possibility has remained purely speculative.

On the other hand, several RES-stimulants prolong pentobarbital sleeping time in the mouse. Furthermore, in this species, endotoxin, zymosan, glucan and saccharated iron oxide (all RES-blocking agents) lower TPO and increase TKT *in vivo* but not *in vitro*. "These results suggest a cause and effect relationship between inducibility of key liver enzymes and survival against stress."

In rats, pretreated with India ink *i.v.*, phenobarbital elimination is delayed.

**Salicylic acid** decreases the plasma concentration of  $^{14}\text{C}$ -indomethacin and increases its urinary and biliary excretion in the rat. Probenecid raises the plasma concentration of indomethacin. These interrelations are tentatively ascribed to the similarity in the chemical structure of the three compounds.

In rabbits, salicylic acid causes dilatation of the endoplasmic reticulum and its spaces become filled with electron-dense material.

**Sucrose feeding**, like starvation, interferes with the detoxication of zoxazolamine, barbiturates, strychnine, carisoprodol and OMPA in the rat, presumably through the depression of the synthesis of hepatic microsomal enzymes.

The detoxifying action of **sulfur** compounds has been known since time immemorial. Thiosulfates and various other sulfur compounds inhibit methemoglobin for-

mation following treatment with aniline or sodium nitrite; they also counteract intoxication with iodine, arsenic, cyanides, thallium and many other toxicants.

It has been claimed that thiosulfate protects against anaphylactic shock and other immune reactions, but these observations require confirmation. On the other hand, it appears definitely established that various sulfur compounds — especially those containing SH- and SS-groups — offer protection against total body X-irradiation. In this respect, cysteamine and cysteine are particularly efficacious.

High doses of **vitamin C** offer some protection against mercurial intoxication and large doses of **vitamin E** combat the progeria-like syndrome produced by DHT in the rat.

← *Actidione cf. Cycloheximide*

*Actinomycin cf. Blockers under Pharmacology* (p. 73).

← *Adrenochrome*

*Hervé B61,654/51*: In mice, adrenoxyol (adrenochrome) is as active p.o. as i.p. in preventing the purpura induced by X-irradiation, but it does not prolong survival.

← *Allyl Alcohol*

*Varga & Fischer G76,189/69*: In rats, hepatic damage produced by bromobenzene, CCl<sub>4</sub>, allyl alcohol and thioacetamide is associated with prolonged hexobarbital sleeping time owing to interference with the hepatic microsomal metabolism of the barbiturate. However, the degree of hepatic injury does not run strictly parallel with the prolongation of the hexobarbital sleeping time; hence, the latter cannot serve as an accurate hepatic function test.

← *Amiloride*

*Selye PROT. 31639,31649*: In rats (100 g ♀), pretreatment with triamterene (1 mg in 1 ml water p.o. x2/day) or amiloride (300 µg in 1 ml water p.o. x2/day) fails to protect against hexobarbital, progesterone, parathion or dioxathion.

← *Amphenone*

*Gaunt et al. G63,202/68*: A review on the metabolic effects of metyrapone- and amphenone-derivatives.

← *Antibiotics cf. also Clinical Implications*

*Common et al. B59,914/50*: In pullets given chlortetracycline, the changes in blood calcium

and serum riboflavin following folliculoid treatment are enhanced. "It seems possible from this experiment that the addition of antibiotics to a reasonably adequate diet may modify its nutritional effects in such a way that the responsiveness of the pullet to parental oestrogen is enhanced."

*Geller et al. B98,147/54*: Cortisone offers definite protection in mice given otherwise lethal doses of *Escherichia intermedium* endotoxin. In order to be effective, cortisone must be injected simultaneously with, or before, the endotoxin. Complicating transient bacteremia, presumably of intestinal origin, can be suppressed by antibiotics. Interference by antibiotics with cortisone protection was demonstrable only when the antibiotics were given after cortisone.

← *Anticoagulants cf. also Clinical Implications*

*Aggeler & O'Reilly G68,730/69*: In man, pretreatment with heptabarbital diminished the reduction in prothrombin level, the amount of bishydroxycoumarin in plasma and half-life of bishydroxycoumarin more markedly after p.o. than after i.v. administration of the anticoagulant. Unchanged bishydroxycoumarin was found in the stool only after p.o. administration. Presumably, part of the response to heptabarbital was caused by increased hepatic enzymic destruction of bishydroxycoumarin although, in the event of p.o. administration, decreased absorption from the gastrointestinal tract also played a role.

← *Antihistamines*

*Holten & Larsen G74,395/56*: In mice, hexobarbital anesthesia is considerably prolonged by benactyzine (a compound used for the treatment of psychoneuroses). The effect

resembles that of SKF 525-A and when given together, the two compounds synergize each other. Extensive review of the literature and of numerous personal observations concerning the barbiturate potentiating effect of various antihistamines and spasmolytic compounds.

*McCull et al. H24,915/70:* In rats, dimenhydrinate (an antihistamine) increases the abortifacient effect of various folliculoids when given conjointly with the latter on the second day of gestation. In itself, dimenhydrinate has no such effect.

*Salvador et al. G74,397/70:* In cholesterol-fed rabbits, phenobarbital inhibits the increase in serum cholesterol and phospholipids as well as the development of aortic atheroma. At the same time, "the protein concentration of liver microsomes increased significantly in cholesterol-fed rabbits given phenobarbital, and phenobarbital stimulated the activity of liver microsomal enzymes that hydroxylate testosterone in the 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -positions." Chlorcyclizine was ineffective in this respect.

*Salvador et al. G75,529/70:* In mice, chlorcyclizine (an antihistamine) and phenobarbital reduced serum cholesterol, triglycerides and phospholipids more markedly than phenobarbital. In rats, chlorcyclizine had little or no effect on the serum concentration of cholesterol and phospholipids but the serum triglycerides were markedly reduced. These changes were not clearly related to any increase in hepatic fat content.

#### ← Atropine

*Selye A 35,659/41:* "Pretreatment with atropine prevents, while vagotomy actually intensifies the anesthetic action of progesterone."

*Selye A 36,210/41:* "Short pretreatment with atropine increases and chronic pretreatment with this drug decreases resistance to the anesthetic action of progesterone."

#### ← Barbiturates

**Corticoids** ←. *Burstein & Klaiber F31,533/65:* Phenobarbital increases the urinary 6 $\beta$ -hydroxycortisol excretion in otherwise untreated, as well as in cortisol-treated, patients possibly through enzyme induction.

*Conney et al. G29,083/65:* Treatment of guinea pigs with diphenylhydantoin or phenobarbital increases the 6 $\beta$ -hydroxylase-activity of the liver as shown by incubation of hepatic homogenates with <sup>14</sup>C-cortisol.

*Birchall et al. F76,581/66:* In Cebus albifrons monkeys, phenobarbital pretreatment increases the urinary elimination of 6 $\beta$ -hydroxycortisol.

*Hagino et al. F69,360/66:* Pentobarbital can inhibit the estradiol-induced precocious ovulation in the rat, presumably as a consequence of hepatic microsomal enzyme induction.

*Burstein & Bhavnani F77,040/67:* In guinea pigs, pretreatment with phenobarbital stimulated the hepatic microsomal metabolism of cortisol, 2 $\alpha$ - and 6 $\beta$ -hydrocortisol but not to the same extent. In rats, phenobarbital pretreatment enhanced hepatic microsomal 6 $\beta$ -hydroxylation of cortisol without causing a significant change in the overall metabolism of substrate or product. 2 $\alpha$ -Hydroxylation of cortisol was not observed with rat liver microsomes.

*Burstein F95,565/68:* Pretreatment with phenobarbital increased hepatic microsomal 2 $\alpha$ -hydroxylation of cortisol in two strains of guinea pigs, distinguished by high and low production of hydroxylated cortisol derivatives. Under the same conditions, phenobarbital caused no significant change in the hepatic 6 $\beta$ -hydroxylation activity of either strain.

*Marc & Morselli G71,617/69:* In rats, the half-life of i.v.-injected cortisol is greatly decreased by pretreatment with phenobarbital. Preliminary data suggest that in man the disappearance rate of exogenous cortisol is also enhanced by phenobarbital.

*Morselli et al. G76,129/70:* In man, phenobarbital accelerates the plasma clearance of cortisol injected i.v.

**Fluorocortisol Acetate** ← *cf. also Tables 12-14*

**DOC** ← *cf. also Table 15*

**Triamcinolone** ← *cf. also Table 18*

**Testoids** ←. *Garren et al. G66,660/61:* Pretreatment of rats with phenobarbital increases the metabolism of androsterone to a more polar compound by hepatic microsomes.

*Conney & Klutch D65,813/63:* "Treatment of rats with phenobarbital or chlorcyclizine stimulates several fold the activity of triphosphopyridine nucleotide-dependent enzyme systems in liver microsomes that hydroxylate testosterone and  $\Delta^4$ -androstene-3,17-dione."

*King et al. H16,446/68:* In orchidectomized rats, phenobarbital pretreatment diminishes the effect of testosterone upon the seminal vesicles and prostate presumably as a consequence of increased hepatic microsomal

enzyme production. These findings may "offer a therapeutic modality for gynecologic syndromes that are associated with overproduction of androgens."

*Heinrichs & Colás H11,717/68*: Studies on the hepatic microsomal hydroxylations of 3 $\beta$ -hydroxyandrost-5-en-17-one (DHA) by microsomes of rats treated in vivo with phenobarbital. The effect upon such hydroxylations of aminopyrine, and SU-9055 additions to the incubation medium are also described.

*Levin et al. G64,184/69*: "Treatment of immature male rats with phenobarbital or chlordane for several days prior to an injection of testosterone or testosterone propionate inhibits the growth-promoting effect of these androgens on the seminal vesicles. It is suggested that phenobarbital and chlordane decrease the action of the androgens by enhancing their metabolism."

*Orrenius et al. E8,231/69*: In rats, pretreatment with phenobarbital increases the in vitro hydroxylation of testosterone by hepatic microsomal enzymes in the 2 $\beta$ -, 6 $\beta$ -, 7 $\alpha$ -, and 16 $\alpha$  positions.

*Conney et al. E8,232/69*: The microsomal enzymes required for the 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -hydroxylation of testosterone are selectively influenced, as shown by the speed of their development with age or after treatment with phenobarbital or 3-methylcholanthrene. Addition of Chlorthion in vitro to hepatic microsomes markedly inhibits the 16 $\alpha$ -hydroxylation of testosterone, has a lesser effect on 16 $\beta$ -hydroxylation and no effect on 7 $\alpha$ -hydroxylation.

*Fahim et al. G77,345/70*: In rats, phenobarbital accelerates steroid metabolism as reflected by significant reductions in the weight and RNA content of male accessory sex organs.

**Folliculoids** ←. *Levin & Conney F64,557/66*: In immature, intact or adrenalectomized rats, the uterine weight increase produced by small doses of estradiol i.p. is markedly inhibited by pretreatment of animals with phenobarbital. At the same time, the estradiol-metabolizing activity of hepatic microsomal enzymes is augmented. In order to demonstrate the inhibition of uterine growth, very small doses of estradiol must be used (less than 0.5  $\mu$ g) and phenobarbital must be administered for several days prior to the test.

*Levin et al. F75,365/67*: Phenobarbital increases the 17 $\beta$ -estradiol-metabolizing activity of hepatic microsomal enzymes in immature female rats. The in vitro activity is

paralleled by in vivo blockade of the estradiol-induced uterine weight increase. The phenobarbital-induced resistance to the uterine weight-increasing effect of estradiol is not prevented by adrenalectomy or hypophysectomy, indicating that the barbiturate does not act through the pituitary-adrenal axis.

*Conney G69,760/67*: "Pretreatment of immature female rats with phenobarbital for several days inhibits the uterotrophic effect of tritiated estradiol and decreases the concentration of the labeled steroid in the uterus."

*Singhal et al. G67,770/67*: Phenobarbital pretreatment inhibits the uterotrophic effect of estradiol as well as the induction of phosphofructokinase in the uterus of the ovariectomized rat. The most marked results were obtained with threshold doses of estradiol.

*Levin et al. F94,711/68*: The uterotrophic action of estrone and estradiol is inhibited in phenobarbital-pretreated rats. Furthermore, "the metabolism of estradiol by liver microsomes in vitro is enhanced when the microsomes are harvested from animals pretreated with several unrelated microsomal enzyme inducers such as phenobarbital, chlordane, orphenadrine, chlorcyclizine, norchlorcyclizine and phenylbutazone. Pretreatment of rats with these chemicals also inhibits the action of estradiol on the uterus and decreases the concentration of estradiol in this organ."

*Levin et al. H894/68*: Pretreatment of immature female rats with phenobarbital inhibits the uterotrophic action of synthetic folliculoids such as ethynylestradiol, ethynylestradiol-3-methyl ether (mestranol), and diethylstilbestrol. The inhibitory effect of phenobarbital upon the action of diethylstilbestrol-<sup>3</sup>H is paralleled by decreased radioactivity in the uterus, and increased diethylstilbestrol-metabolizing activity in hepatic microsomes. The uterine weight-increasing effect of synthetic luteoids such as norethindrone and norethynodrel is likewise inhibited by phenobarbital pretreatment.

*Fahim et al. G67,772/68*: Phenobarbital reduces the uterotrophic action of both exogenous estradiol and endogenous folliculoids. This effect is somewhat lessened by ovariectomy. The authors consider the possibility that the barbiturate may induce steroidases not only in the hepatic microsomes, but also in the ovary. Enzyme determinations in the liver were not performed, but phenobarbital significantly increased hepatic weight and total nitrogen content.

Welch *et al.* F96,172/68: Pretreatment with phenobarbital accelerates the disappearance from the whole carcass of the rat of tritium-labeled estrone more markedly than that of tritium-labeled estradiol.

Fahim *et al.* G65,075/69: In mice, the uterotrophic action of estrone, estradiol, and stilbestrol was significantly reduced following phenobarbital pretreatment. This effect, which was accompanied by an increase in hepatic weight, is ascribed to hepatic microsomal enzyme induction. Endogenous folliculoid production is presumably likewise inhibited by phenobarbital, since the drug interferes with the maintenance of normal uterine weight in intact mice. It is suggested "that the biologic activity observed for estrogens is dependent upon the level of activity of hepatic microsomal enzymes." [The possibility that prolonged phenobarbital pretreatment may have caused uterine atrophy through the well-known stress-induced inhibition of gonadotropin secretion has not been controlled by the use of stressors which do not share the enzyme-inducing action of phenobarbital (H.S.).]

Estradiol ← *cf. also Table 16*

Various Steroids ←. Kuntzman *et al.* F27,893/64: The rat liver contains a steroid hydroxylase system which metabolizes testosterone and estradiol to more polar compounds (incubation of microsomal fraction). The steroid hydroxylase and hexobarbital oxydase systems are similar as regards the following points:

1. Localized in liver microsomes and require TPNH and oxygen for activity.
2. Present in mammalian liver but absent in fish liver.
3. Higher activity in male Sprague-Dawley rats than in male CF1 mice.
4. Higher activity in adult male rats than in adult female rats.
5. Little or no sex difference in enzyme activity in mice.
6. Activity is higher in adult male rats than in immature rats.
7. Inhibition by the *in vitro* addition of SKF 525-A.
8. Activity is increased after treatment of rats with phenobarbital or chlordane.
9. Activity not increased after treatment of rats with 3-methylcholanthrene."

Conney & Schneidman F35,870/65: Pretreatment of male rats with phenobarbital stimulates the hepatic microsomal metabolism

of progesterone, testosterone,  $\Delta^4$ -androstene-3,17-dione, androsterone and DOC.

Conney *et al.* G65,135/65: In the rat, phenobarbital stimulates the hepatic microsomal metabolism of testosterone,  $\Delta^4$ -androstene-3,17-dione, androsterone and estradiol, but not of corticosterone, cortisone or cortisol. Similar effects were obtained with chlorcyclizine and phenylbutazone. Administration of "the carcinogenic hydrocarbon 3-methylcholanthrene to rats caused a several-fold increase in the oxidative metabolism of certain drugs such as zoxazolamine and acetophenetidin but had little or no effect on the oxidation of hexobarbital or the hydroxylation of testosterone and  $\Delta^4$ -androstene-3,17-dione." In female rats, chlordane stimulates the metabolism of estradiol to more polar metabolites. Similar observations have also been made in the mouse and dog.

Remmer & Merker G66,868/65: The hepatic  $\Delta_4$ - $\Delta_3$ -ketoreductase activity is much higher in female than in male rats, but cannot be further increased by phenobarbital, although the barbiturate does induce two similar TPHN-dependent microsomal reductases involved in the metabolism of p-aminoazobenzol and of chloramphenicol.

Kuntzman *et al.* G57,741/68: The nonhypnotic barbiturate n-phenylbarbital (phetharbital) increases the formation of polar metabolites from estradiol, testosterone and DOC added *in vitro* to the hepatic microsomal fraction. The effect is essentially the same as that of phenobarbital. Hepatic microsomes of n-phenylbarbital-treated guinea pigs exhibit an increased capacity to introduce a  $6\beta$ -hydroxyl into cortisol added *in vitro*. In man, chronic treatment with phetharbital greatly increases urinary excretion of  $6\beta$ -hydroxycortisol but not that of 17-OHCS, suggesting that an increased adrenal output of cortisol is not responsible for the observed rise in  $6\beta$ -hydroxycortisol elimination. In the guinea pig, this nonhypnotic barbiturate increases the  $6\beta$ -hydroxycortisol-forming ability of the hepatic microsomes.

Ying & Meyer H13,672/69: In immature rats, the induction of ovulation by a single injection of PMS is inhibited by phenobarbital. This block was prevented by progesterone and other ovarian steroids administered 3.5 hrs after phenobarbital. The effect of the barbiturate may have been due to the induction of hepatic microsomal steroidases.

Progesterone ← *cf. also Table 17*

Pancuronium ← *cf. also Table 19*

**Nonsteroidal Hormones and Hormone-Like Substances** ←. *Brown & Wells F57,759/65*: In mice, pretreatment with barbital diminishes the ovulatory response to gonadotrophic hormone preparations. It is uncertain however whether this is due to accelerated biotransformation of the pituitary factors.

*Oppenheimer et al. F99,583/68*: In rats, phenobarbital increases thyroxine turnover and thyroidal function after stimulation of hepatocellular binding of thyroxine as judged by studies with radioactive thyroxine.

*Schwartz et al. H9,326/69*: In rats treated with phenobarbital, the hepatic microsomes exhibit an increased ability to de-iodinate L-thyroxine and L-T3 in vitro.

*Schwartz et al. H26,012/70*: In rats, the inhibition of somatic growth induced by thyroxine was enhanced by phenobarbital. At the same time, oxygen consumption was reduced and mitochondrial  $\alpha$ -glycerophosphate dehydrogenase (GPD) activity in the liver, kidney and heart was lowered.

**3,3,5-Triido-L-thyronine** ← *cf. also Table 20*

**Propylthiouracil** ← *cf. also Tables 21, 22*

**Epinephrine** ← *cf. also Table 23*

**Acetanilide** ← *cf. Table 24*

**Acrylamide** ← *cf. Table 25*

**Acrylonitrile** ← *cf. Table 26*

**Aminopyrine** ← *cf. Table 27*

**Anticoagulants** ← *cf. also Tables 28, 29.*

*Dayton et al. D42,366/61*: In the guinea pig, dog and man pretreatment with barbiturates antagonizes the hypoprothrombinemic effect of coumarin anticoagulants. At the same time the plasma level of the coumarin is depressed.

*Cucinell et al. G66,286/65*: In the rat, dog and man, phenobarbital accelerates the metabolism of bishydroxycoumarin, diphenylhydantoin and antipyrine.

*Goss & Dickhaus F53,987/65*: Phenobarbital increases the daily maintenance dose of bishydroxycoumarin in man.

*Corn H33,065/66*: In man, phenobarbital or glutethimide treatment decreases the life span of warfarin.

*Robinson & MacDonald F69,377/66*: Phenobarbital antagonizes the anticoagulant effect of warfarin in man.

**Barbiturates** ← *cf. also Tables 30—34*

*Buchel & Levy G74,850/70*: In mice, pretreatment with phenobarbital decreases pentobarbital sleeping time; this phenomenon is detectable within 24 hrs and reaches a maximum 48 hrs after phenobarbital administration. The resistance is no longer detectable in males after 96, in females after 120 hrs.

*Klinger H25,517/70*: In rats, hexobarbital sleeping time is shortened following pretreatment with barbital.

**Bile Pigments** ← *cf. also Clinical Implications. Catz & Yaffe G71,888/62*: In mice, pretreatment with sodium barbital i.p. increased the hepatic bilirubin-conjugating activity.

*Schmid et al. G68,199/66*: Study on enhanced formation of rapidly-labeled bilirubin by phenobarbital through the stimulation of hepatic microsomal cytochromes. In the rat, the amount of bilirubin formed from non-hemoglobin sources in the liver may equal that produced on sequestration of senescent erythrocytes.

*Lüders H34,593/70*: In Gunn rats, biliary bilirubin excretion is normally minimal, presumably because of a deficiency in bilirubin glucuronyltransferase activity. Phenobarbital decreases the serum bilirubin level owing to the formation of water soluble metabolites as shown by <sup>14</sup>C-bilirubin determinations.

**Bromobenzene** ←. *Brodie et al. G80,473/71*: In rats, pretreatment with phenobarbital greatly facilitates the production of hepatic necrosis by bromobenzene and other chemically inert halogenated hydrocarbons. Radioautographic and other studies suggest that "a number of aromatic halogenated hydrocarbons are converted by microsomes in vitro to active intermediates which form covalent complexes with glutathione (GSH)."

**Cadmium** ← *cf. Table 35*

**Caramiphen** ← *cf. Table 36*

**Carbon Disulfide** ←. *Bond et al. H18,559/69*: In rats, pretreatment with phenobarbital does not change the LD<sub>50</sub> of CS<sub>2</sub> p.o. but results in the production of central lobular hepatic necrosis. After pretreatment with SKF 525-A these hepatic lesions no longer occur in rats pretreated with phenobarbital and then given CS<sub>2</sub>. SKF 525-A may inhibit the production of toxic CS<sub>2</sub> metabolites by hepatic microsomal enzymes.

**Carbon Tetrachloride** ←. *Stenger et al. G78,940/70*: In rats, pretreatment with phenobarbital in doses which cause proliferation of the SER and a decrease in hexobarbital sleeping time greatly diminished resistance to the fatal effects of CCl<sub>4</sub>. Phenobarbital pretreatment delayed the onset of CCl<sub>4</sub>-induced hepatic necrosis, but greatly aggravated its eventual severity. "This altered hepatotoxic response might be related either to the increase of smooth-surfaced membranes or to the augmentation of drug-metabolizing enzyme systems in

the livers of the phenobarbital-pretreated animals."

**Carisoprodol** ← *cf. Table 37*

**Chlordiazepoxide** ← *cf. Table 38*

**Cholesterol** ← *Jones & Armstrong F 51,262/65*: In the hamster, the hepatic SER undergoes hypertrophy following treatment with phenobarbital and, at the same time, cholesterol biosynthesis is increased.

*Wada et al. G 67,771/67*: In rats pretreated with phenobarbital, cholesterol synthesis from either acetate or mevalonate by hepatic microsomes is increased in vitro.

*Wada et al. H 15,247/69*: In rats, cholesterol synthesis from various precursors is inhibited by CO and accelerated by phenobarbital as shown by incubation with hepatic microsomes in vitro. Cholesterol synthesis requires NADPH, molecular oxygen, and cytochrome P-450.

*Salvador et al. G 74,397/70*: In cholesterol-fed rabbits, phenobarbital inhibits the increase in serum cholesterol and phospholipids as well as the development of aortic atheroma. At the same time, "the protein concentration of liver microsomes increased significantly in cholesterol-fed rabbits given phenobarbital, and phenobarbital stimulated the activity of liver microsomal enzymes that hydroxylate testosterone in the 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -positions." Chlorcyclizine was ineffective in this respect.

*Salvador et al. G 75,529/70*: In mice, chlorcyclizine (an antihistamine) and phenobarbital reduced serum cholesterol, triglycerides and phospholipids more markedly than phenobarbital. In rats, chlorcyclizine had little or no effect on the serum concentration of cholesterol and phospholipids but the serum triglycerides were markedly reduced. These changes were not clearly related to any increase in hepatic fat content.

**Cinchophen** ← *cf. Table 39*

**Cocaine** ← *cf. Table 40*

**Colechicine** ← *cf. Table 41*

**DL-Coniine** ← *cf. Table 42*

**Croton Oil** ← *cf. Table 43*

**Cycloheximide** ← *cf. Tables 44, 45*

**Cyclophosphamide** ← *cf. also Table 46.*

*Cohen & Jao H 27,933/70*: In rats, pretreatment with phenobarbital increases the cyclophosphamide-activating enzyme system in the liver as demonstrated in vitro and, at the same time, augments mortality following treatment with cyclophosphamide in vivo. A number of observations confirmed "the thesis that the activation of cyclophosphamide by liver is mediated through the mixed function oxidase system

involved in the metabolism of drugs, steroids and carcinogens."

*Selye G 70,466/70*: In rats, cyclophosphamide intoxication can be prevented by PCN, CS-1 and spironolactone. Progesterone, ethyl-estrenol and norbolethone were slightly active; oxandrolone, DOC, hydroxydione and phenobarbital were inactive, whereas prednisolone, triamcinolone, estradiol and thyroxine actually decreased resistance to this drug.

**Digitalis** ← *cf. Clinical Implications*

**Diisopropyl Fluorophosphate** ← *cf. Table 52*

**Diphenylhydantoin** ← *cf. also Table 53.*

*Cucinell et al. G 66,286/65*: In the rat, dog and man, phenobarbital accelerates the metabolism of bishydroxycoumarin, diphenylhydantoin and antipyrine.

**Dyes** ← *Klaassen & Plaa F 99,395/68*: In rats, pretreatment with phenobarbital accelerated the plasma clearance of BSP. There was no change in hepatic storage but significant increases of in vitro metabolism, biliary transport maximum and bile flow were observed. With a dibrominated analog of BSP and with indocyanine green, which are apparently not biotransformed before excretion; enhanced plasma clearance was also elicited by phenobarbital. It is assumed "that the enhanced biliary excretion of these dyes is an important factor after phenobarbital treatment and that the role of increased biotransformation is not as important for the enhanced plasma disappearance of these dyes as might be expected from the effect of phenobarbital on the biologic half-life of other substances."

*Reyes et al G 71,233/69*: In rats, phenobarbital "enhanced hepatic uptake of an organic anion, bromsulphalein, in vivo and simultaneously increased the amount of Y, a hepatic cytoplasmic organic anion-binding protein. This study supports the postulate that Y is a major determinant in the selective hepatic uptake of certain organic anions from plasma." Induction of Y may enhance hepatic uptake and metabolism of various substrates following treatment with phenobarbital and other inducers.

**Dipicrylamine** ← *cf. Table 54*

**Emetine** ← *cf. Table 55*

**Ethanol** ← *Koff et al. G 76,179/70*: In rats, pretreatment with phenobarbital reduces the hepatic steatosis produced by a single dose of ethanol. The inhibition is associated with a striking elevation of blood ethanol and no increase in blood lactate. In phenobarbital pretreated animals, the enhanced incorporation of fatty acids into triglyceride by micro-

somal preparations, after in vivo ethanol treatment, also failed to occur. Furthermore, liver slices and supernatant fractions of phenobarbital-pretreated rats exhibit a diminished capacity to oxidize ethanol. "It is suggested that the inhibitory effect of phenobarbital pretreatment on the ethanol-induced fatty liver is due to inhibition of the alcohol dehydrogenase-mediated oxidation of ethanol."

**Ethylene Glycol** ← *cf. Table 56*

**Ethylmorphine** ← *cf. Table 57*

**Flufenamic Acid** ← *cf. Table 58*

**Fluphenazine** ← *cf. Table 59*

**Ganglioplegics** ← *cf. Tables 61, 62*

**Glutethimide** ← *cf. Table 63*

**Glycerol** ← *cf. Table 64*

**Hydroquinone** ← *cf. Table 65*

**Imipramine** ← *cf. Table 66*

**Indomethacin** ← *cf. Table 67*

**Lidocaine** ← *Heinonen et al. G80,898/70:*

In epileptic patients, phenobarbital decreases the plasma lidocaine level only very slightly.

**LSD** ← *cf. Table 74*

**Mechlorethamine** ← *cf. Table 75*

**Mephesisin** ← *cf. Table 76*

**Meproamate** ← *cf. Table 77*

**Mercury** ← *cf. Tables 78—80*

**Methadone** ← *cf. Table 82*

**n-Methylaniline** ← *cf. Table 83*

**Methyprylon** ← *cf. Table 84*

**α-Naphthylisothiocyanate** ← *cf. Table 85*

**Nicotine** ← *cf. also Table 86. Stålhandske G80,388/70:* In mice, phenobarbital increases the metabolism of <sup>14</sup>C-labelled nicotine and accelerates its disappearance from blood and tissues. Tolerance to the fatal effect of nicotine overdosage is also increased by nicotine.

**Nikethamide** ← *cf. Table 87*

**p-Nitroanisole** ← *cf. Table 88*

**Pentylentetrazol** ← *cf. Table 89*

**Perchlorate** ← *cf. Table 90*

**Pesticides** ← *cf. also Tables 91—99. DuBois & Kinoshita G66,349/68:* In mice and rats, pretreatment with phenobarbital either decreased or failed to affect the toxicity of 15 anticholinesterase organic phosphates. The only exception was OMPA whose toxicity was actually increased after phenobarbital pretreatment, but only in rats.

*Carlson & DuBois H24,653/70:* Male rats are much more susceptible to the insecticide 6-methyl-2,3-quinoxalinedithiol cyclic carbamate (Morestan) than females. "The toxicity to rats could not be altered by castration, administration of testosterone to females and estradiol to males. Pretreatment with phenobarbital decreased the toxicity to adult males

and increased the toxicity to adult females." Chronic Morestan feeding caused hepatic enlargement and inhibition of microsomal enzymes.

**Phenylbutazone** ← *Zbinden G66,033/66:* Following pretreatment with phenylbutazone or phenobarbital p.o., rats become resistant to the production of peritoneal adhesions by phenylbutazone i.p. "Since the peritoneal reaction appears to be related to a direct injury of the peritoneal cells which occurred before the drug had been absorbed into the blood stream and before it had a chance to be metabolized by the liver, it is most unlikely that the differences in local toxicity could be due to a faster removal of phenylbutazone from the general circulation."

**Phenylramidol** ← *cf. Table 100*

**Physostigmine** ← *cf. Table 101*

**Picrotoxin** ← *cf. also Table 102. Cole A30,204/43:* In rats, pentobarbital and phenobarbital antagonizes strychnine or picrotoxin convulsions even if the convulsives are given long after the narcotic effect of the barbiturates has disappeared. Indeed, phenobarbital was more effective against death from strychnine when given 22 hrs than when given 20 min before strychnine. Phenobarbital was equally effective against death from picrotoxin whether given 20 min or 22 hrs before picrotoxin. It is considered unlikely that active amounts of the barbiturates would persist in the body for such a long time but their decomposition products may still possess anticonvulsant activity. [Enzyme induction is not considered (H.S.)]

**Piperidine** ← *cf. Table 103*

**Pralidoxime** ← *cf. Table 104*

**Propionitrile** ← *cf. Table 105*

**Quinine** ← *Saggers et al. G73,683/70:* In rat liver microsomes, quinine is metabolized by enzymes requiring NADPH; this metabolism is increased by phenobarbital.

**SKF 525-A** ← *cf. Table 106*

**Strychnine** ← *cf. also Table 107. Cole A30,204/43:* In rats, pentobarbital and phenobarbital antagonizes strychnine or picrotoxin convulsions even if the convulsives are given long after the narcotic effect of the barbiturates has disappeared. Indeed, phenobarbital was more effective against death from strychnine when given 22 hrs than when given 20 min before strychnine. Phenobarbital was equally effective against death from picrotoxin whether given 20 min or 22 hrs before picrotoxin. It is considered unlikely that active amounts of the barbiturates would persist in the body

for such a long time but their decomposition products may still possess anticonvulsant activity. [Enzyme induction is not considered (H.S.).]

*Kato D46,405/61*: Following pretreatment with phenaglycodol or thiopental resistance to strychnine is increased, whereas resistance to OMPA is considerably diminished in the rat.

*Chiesara et al. G75,314/70*: In rats, a single injection of phenobarbital suffices to stimulate the SER and to increase the hexobarbital and strychnine-metabolizing enzyme activity of the hepatic microsomes. The effect of partial hepatectomy, performed either immediately before or at various times after the administration of the inducer drug, was investigated in relation to these phenomena.

**Theobromine** ← *cf. Table 108*

**Theophylline** ← *cf. Table 109*

**Thimerosal** ← *cf. Table 110*

**Tribromoethanol** ← *cf. Table 111*

**Trichloroethanol** ← *cf. Table 112*

**Tri-o-cresyl Phosphate** ← *cf. Table 113*

**D-Tubocurarine** ← *cf. Table 114*

**Tyramine** ← *cf. Table 115*

**L-Tyrosine** ← *cf. Table 116*

**Vitamin C** ← *Klinger et al. F62,929/65*: The normal excretion of ascorbic acid and the increase in its elimination induced by barbital are higher in male than in female rats. Orchidectomy reduced both normal excretion and its enhancement by barbital, whereas ovariectomy increased them. Thus, the sex-specific differences decreased but did not disappear completely. One week's treatment of males with stilbestrol or females with testosterone diminished ascorbic acid excretion. In mice, no sex-specific differences of this kind were observed. [The authors probably used hexobarbital although sometimes they speak of barbital (H.S.).]

**Vitamin D, DHT** ← *cf. also Table 117. Dent et al. H30,946/70; Richens & Rowe H30,947/70*: In four epileptic patients, osteomalacia developed during long-term treatment with diphenylhydantoin and barbiturates. Vitamin D exerted a curative effect. "It is suggested that drug-mediated enzyme induction may be the mechanism responsible by causing a greatly increased inactivation of vitamin D in these patients."

*Hahn et al. H34,347/71*: In patients on phenobarbital, osteomalacia is allegedly common, perhaps because of accelerated biotransformation of vitamin D. The hepatic microsomes of phenobarbital pretreated rats readily convert tritiated vitamin D<sub>3</sub> to metabolites

other than 25-hydroxy-cholecalciferol, the biologically active metabolite. Presumably, "the increased incidence of osteomalacia in individuals on anticonvulsant therapy can be attributed to accelerated in vivo inactivation of vitamin D by liver microsomes."

**W-1372** ← *cf. Table 118*

**Zoxazolamine** ← *cf. Table 119*

**Various Drugs** ← *Selye G70,480/70*: In rats, phenobarbital and phetharbital inhibit intoxication with dioxathion, parathion, nicotine, hexobarbital, progesterone (anesthesia), zoxazolamine (paralysis), indomethacin (intestinal ulcers) and acute DHT-induced calcinosis. Phenobarbital does, while phetharbital does not, inhibit the toxicity of digitoxin. On the other hand, both barbiturates fail to affect the production of infarctoid cardiac necroses by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

**E. coli endotoxin No. 08** ← *cf. Table 123*

**Pregnancy** ← *Fahim et al. G77,383/70*: In pregnant rats, phenobarbital given throughout gestation "results in a significant increase in embryonic death and a 28 per cent incidence of fetal subcutaneous hemorrhage. Placentas of treated animals weighed less than controls and exhibited a significant increase in demethylation activity."

**Hepatic Enzymes** ← *Cucinell et al. G66,286/65*: In the rat, dog and man, phenobarbital accelerates the metabolism of bishydroxycoumarin, diphenylhydantoin and antipyrine.

*Zbinden G66,033/66*: Following pretreatment with phenylbutazone or phenobarbital p.o., rats become resistant to the production of peritoneal adhesions by phenylbutazone i.p. "Since the peritoneal reaction appears to be related to a direct injury of the peritoneal cells which occurred before the drug had been absorbed into the blood stream and before it had a chance to be metabolized by the liver, it is most unlikely that the differences in local toxicity could be due to a faster removal of phenylbutazone from the general circulation."

← **Benactyzine** *cf. Phenothiazines*

← **Benzydamine**

*Burberi et al. G80,224/70*: Benzydamine, although a potent anti-inflammatory agent, does not produce gastric ulcers in the rat but prevents the production of gastric ulcers such as occur 18 hrs after s.c. administration of indomethacin. [No mention of intestinal ulcers (H.S.).]

← **Bradykinin cf. Hormone-Like Substances**← **Bromobenzene**

*Varga & Fischer G76,189/69*: In rats, hepatic damage produced by bromobenzene,  $\text{CCl}_4$ , allyl alcohol and thioacetamide is associated with prolonged hexobarbital sleeping time owing to interference with the hepatic microsomal metabolism of the barbiturate. However, the degree of hepatic injury does not run strictly parallel with the prolongation of the hexobarbital sleeping time; hence, the latter cannot serve as an accurate hepatic function test.

← **Carbon Tetrachloride cf. Blockers under General Pharmacology** (p. 79).

← **Carcinogens**

*Richardson et al. B70,382/52*: Review of the literature and personal observations on the inhibition of tumor formation by one carcinogen through concurrent treatment with another.

*Murphy & DuBois D28,546/58*: The activity of the microsomal enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). Yet, in vivo, adult males are more resistant to EPN than females perhaps because the accelerated formation of toxic oxidation products is overcompensated by a more efficient detoxication of the latter. The low enzyme activity of female livers is enhanced by pretreatment with testosterone in vivo, whereas the high activity of male livers is diminished by previous castration, partial hepatectomy or treatment with progesterone or diethylstilbestrol. SKF 525-A inhibits, whereas pretreatment with carcinogens or a protein-deficient diet enhances, the activity of the thiophosphate-oxidizing enzyme.

*Conney & Burns G66,473/63*: Review (25 pp., 73 refs.) on the induced synthesis of oxidative enzymes in hepatic microsomes by polycyclic hydrocarbons and drugs.

*Conney & Schneidman F24,913/64*: "Treatment of immature rats and dogs with phenylbutazone increased several-fold the activity of enzymes in liver microsomes that hydroxylate testosterone and  $\Delta^4$ -androstene-3,17-dione. Treatment of rats with phenylbutazone or phenobarbital stimulated a minor pathway of corticosteroid metabolism to polar metabo-

lites chromatographically similar to hydroxylated substrate. Administration of the carcinogenic hydrocarbon 3-methylcholanthrene to rats did not stimulate polar metabolite formation but markedly inhibited the microsomal metabolism of corticosteroids to metabolites chromatographically less polar than the substrate."

*Conney et al. E8,232/69*: The microsomal enzymes required for the 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -hydroxylation of testosterone are selectively influenced, as shown by the speed of their development with age or after treatment with phenobarbital or 3-methylcholanthrene. Addition of Chlorthion in vitro to hepatic microsomes markedly inhibits the 16 $\alpha$ -hydroxylation of testosterone, has a lesser effect on 16 $\beta$ -hydroxylation and no effect on 7 $\alpha$ -hydroxylation.

*Chivers et al. H25,819/70*: In mice, the peak of mitotic index induced by partial hepatectomy occurs after 48 hrs. DMBA given 34–38 hrs after partial hepatectomy inhibits mitosis, whereas given after 48 hrs it increases the mitotic index.

*Dewhurst & Kitchen G73,848/70*: In mice, zoxazolamine paralysis is greatly shortened soon after a single dose of the carcinogen, whereas upon prolonged treatment, an inverse response is obtained. It is speculated that "an active metabolite formed in relatively small amounts may gradually accumulate or the stimulation of microsomal enzymes by the first dose might lead to enhanced conversion of a subsequent dose into an active metabolite."

*Soyka et al. H33,315/70*: Partial hepatectomy sensitized only slightly to the anesthetic effect of 5 $\beta$ -pregnane-3 $\alpha$ -ol-20-one, whereas it greatly prolonged sleeping time following treatment with progesterone and many other steroids. Neither inhibition of hepatic mixed function oxydase activity by SKF 525-A nor its stimulation by 3-MC affected the duration of pregnanolone narcosis and even phenobarbital reduced its length only slightly. These findings, and distribution studies, "suggest that termination of hypnosis is due mainly to redistribution with hepatic metabolism playing a relatively minor role." [Species not mentioned; probably rat (H.S.)]

← **Cedar Chips**

*Vesell F88,031/67*: In mice and rats kept on softwood bedding of either red cedar, white pine, or ponderosa pine, three drug-metabolizing hepatic enzymes (morphine N-demethylase, aniline hydroxylase, and hexobarbital

oxidase) were induced. Hexobarbital sleeping time was reduced. Apparently, the drug-metabolizing enzyme mechanism of an animal can be significantly altered by changes in its natural habitat.

*Hart & Adamson G69,481/69*: In mice, "SKF 525-A and Lilly 18947 reduced the lethality of cyclophosphamide over a 28 day observation period, while pretreatment with phenobarbital did not change the 28 day lethality. Neither SKF 525-A nor phenobarbital had an effect on the antitumor efficacy of cyclophosphamide. Mice housed on cedar chip bedding were less susceptible to the lethal effects of cyclophosphamide, but tumor-bearing mice on this bedding showed greater antitumor response to the drug than those on hardwood bedding."

← *Chloramphenicol cf. Inhibitors under General Pharmacology* (p. 67).

← *Chlorcyclizine cf. Antihistamines*

← *Chlordane cf. Pesticides*

← *Chlorpromazine*

*Parant D82,116/62*: In mice, resistance to endotoxin is greatly decreased a few hours after adrenalectomy or hypophysectomy. Cortisone protects normal, adrenalectomized, and hypophysectomized animals against high doses of endotoxin, whereas chlorpromazine is effective only in the presence of both the adrenals and the pituitary. ACTH also protects the hypophysectomized mouse but only if slow absorption is assured.

*Wurtman et al. F99,396/68*: In rats, pretreatment with chlorpromazine or other phenothiazines increases the level of i.v. administered  $^3\text{H}$ -melatonin in brain and blood. Chlorpromazine has no effect on the level of  $^3\text{H}$ -melatonin when the latter is injected into the lateral cerebral ventricle. Since chlorpromazine inhibits the in vitro metabolism of  $^3\text{H}$ -melatonin by liver slices, the drug presumably alters the tissue levels of the indole by slowing its metabolism.

← *Cholesterol*

*Farson et al. A49,680/47*: In dogs and rabbits, cholesterol i.v. or i.p. intensifies thiopental anesthesia. The anesthesia induced by ether inhalation was not affected but that caused by ether s.c. was prolonged. "It is reasonable to assume that any compound

which elicits a depression of the central nervous system would exert an additive effect or potentiation of the action of a general anesthetic. The mechanism of action of cholesterol in these studies may be explained on such a basis."

← *Cinchophen*

*Aitio & Hänninen G66,417/67*: Both in intact and in adrenalectomized rats, cinchophen increased the hepatic TKT activity, but had no effect upon that of alanine and aspartate aminotransferase.

← *Cobaltous Chloride*

*Tephly & Hibbeln G81,868/71*: In rats,  $\text{CoCl}_2$  inhibits the synthesis of P-450 and the N-dealkylation of ethylmorphine by hepatic microsomes. The induction by phenobarbital of P-450 and ethylmorphine N-demethylation are likewise prevented by  $\text{CoCl}_2$ , but cobalt does not influence NADPH-cytochrome c reductase either under normal conditions or after stimulation by phenobarbital.

← *Cycloheximide cf. also Blockers under Pharmacology* (p. 77).

*Verbin et al. G70,533/69*: In rats, single i.p. injections of cycloheximide during, following or prior to DNA synthesis induced by partial hepatectomy completely abolished the first wave of mitosis seen in regenerating liver. Presumably, "this interference with cell division can be attributed to a block in the S phase as indicated by a 98 per cent inhibition of incorporation of thymidine- $\text{C}^{14}$  into DNA, and to a block in G-2 as evidenced by a 95 per cent inhibition of incorporation of leucine- $\text{C}^{14}$  into protein."

*Alonso G81,092/70*: In rats, hepatic carcinogenesis induced by diethylnitrosamine is not prevented by cycloheximide. The associated electron microscopic changes in the liver are described.

← *Desipramine*

*Jori & Pugliatti G70,112/67*: In rats, in vivo and in vitro experiments suggest that desipramine reduces the activity of modaline by inhibiting its biotransformation into an active compound in the hepatic microsomes. The in vivo tests were gaged by the "tryptamine symptomatology" (hunching of the back, backward locomotion, Straub tail, salivation and clonic convulsions of the anterior paws) induced by modaline.

*Levin et al. H 26,593/70*: In rats,  $\text{CCl}_4$  given to immature females 24 hrs before sacrifice inhibited the activity of hepatic microsomal enzymes that hydroxylate estradiol-17 $\beta$  and estrone. This inhibition was reflected in vivo by an altered metabolism of estradiol-17 $\beta$  and estrone, by a potentiation of the uterotrophic action of folliculoids and by an increased concentration of these steroids in the uterus. By contrast, tetrachloroethylene did not influence the action of estrone. SKF 525-A and desipramine, which are also inhibitors of drug metabolism, likewise potentiate the uterotrophic action of estrone in immature rats.

#### ← *Digitalis*

*Pines et al. C 87,661/59*: Intracardiac or i.v. injections of prednisolone produce premature ventricular beats and ventricular bigeminy (ECG) in the dog. These changes can be prevented or suppressed by digitalis, chlorothiazide or chloroquine.

*Selye G 70,480/71*: In rats, pretreatment with digitoxin offered no protection against intoxication with digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone (anesthesia), zoxazolamine, indomethacin, acute DHT-induced calcinosis or the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

#### ← *Dimenhydrinate cf. Antihistamines*

##### ← *Dimethyl Sulfoxide (DMSO)*

*Highman et al. H 19,382/69*: In rats exposed to X-irradiation or hypoxia, i.v. injections of *Streptococcus mitis* produce severe bacterial endocarditis. "The radioprotective compound, DMSO, did not affect the lesions in nonirradiated animals but reduced the incidence and severity of lesions in irradiated rats."

#### ← *Diphenylhydantoin cf. also Clinical Implications and Table 136*

*Tyler et al. G 79,955/69*: In epileptic patients on diphenylhydantoin, a negative metyrapone test for pituitary insufficiency may result from increased glucuronic acid conjugation of metyrapone by the liver.

*Dent et al. H 30,946/70; Richens & Rowe H 30,947/70*: In four epileptic patients, osteomalacia developed during long-term treatment with diphenylhydantoin and barbiturates. Vitamin D exerted a curative effect. "It is suggested that drug-mediated enzyme induc-

tion may be the mechanism responsible by causing a greatly increased inactivation of vitamin D in these patients."

#### ← *Disulfiram*

*Scholler G 75,794/70*: In rats, disulfiram inhibits whereas phenobarbital aggravates, the toxic effects of chloroform anesthesia, as manifested by hepatic necroses and plasma enzyme GOT and GPT determinations.

#### ← *Ethanol*

*Waltman et al. H 19,551/69*: In women, i.v. injection of ethanol just before delivery, reduces serum bilirubin levels in their infants on the 3—5th day of life. "The findings suggest a simple, safe, and expedient agent which may be used to prevent raised levels of bilirubin in the newborn—levels which may affect mental and motor development in the first year of the infant's life."

#### ← *Ethionine cf. Blockers under General Pharmacology (p. 78).*

#### ← *Ferric Dextran*

*Selye et al. E 24,117/64*: The progeria-like syndrome produced by DHT, vitamin-D<sub>2</sub> or vitamin-D<sub>3</sub> can be prevented by ferric dextran, methyltestosterone or vitamin E in the rat.

#### ← *Glucose*

*Lamson et al. C 14,547/51*: In dogs, awakening from anesthesia induced by various barbiturates, glucose i.v. (as well as certain intermediates of the tricarboxylic-acid cycle) reinitiates sleep and increases barbiturate penetration into the brain. The effect is presumably due to interference with the brain barrier.

*Lamson et al. B 89,712/52*: In guinea pigs, epinephrine when injected i.p. on awakening from barbiturate anesthesia, produced a return to sleep. A similar effect was produced by glucose, lactate or glutamate. However, in adrenalectomized animals, only epinephrine was effective.

#### ← *Glutethimide cf. Clinical Implications*

##### ← *Hydrazine*

*Kato et al. H 15,638/69*: The inhibitory action of various hydrazine derivatives on the oxidation of pentobarbital and carisoprodol,

and the N-demethylation of aminopyrine, closely parallel their lipid solubility.

#### ← *Indomethacin*

*Jeremy & Towson G77,324/70*: In patients with rheumatoid arthritis,  $^{14}\text{C}$ -2-indomethacin plasma clearance is accelerated, and urinary excretion decreased, by acetylsalicylic acid. "The study showed interference between aspirin and indomethacin, the mechanism possibly being due to decreased gastro-intestinal absorption. This could account for clinical reports that the combination of the two drugs was no better than aspirin alone."

*Selye G70,480/71*: In rats, pretreatment with indomethacin offered no significant protection against indomethacin itself, digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone (anesthesia), zoxazolamine, DHT or the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

#### *Iodine*

*Voss & Walther E53,093/60; Walther & Voss G71,664/60*: In rabbits, inhibition of thyroid function by iodine accelerates the recovery time of the spinal cord following anoxia induced by temporary compression of the abdominal aorta.

#### ← *Iproniazid cf. Inhibitors under General Pharmacology* (p. 68).

#### ← *Isoproterenol*

*Zwadyk & Harrison H19,753/70*: Soterenol is considerably more potent than the structurally related isoproterenol in reducing endotoxin lethality in chick embryos and mice.

#### ← *Lactone*

*Cosmides et al. G45,832/56*: "Tetrahydrofurfuryl alcohol and butyrolactone protected chicken embryos from digitoxin toxicity. They also prolonged the time for A-V blockade to appear when perfused simultaneously with digitoxin in the frog heart. Tetrahydrofurfuryl alcohol abolished cardiac arrhythmias in the dog and permitted the failing heart to return to relative regularity. The results appear to support the theory that the unsaturated lactone of digitoxin is essential for cardiotonic activity and that a chemically related structure may compete for the same receptor to antagonize its action on the myocardium."

#### ← *Methoxyflurane*

*Berman & Bochantin G75,502/70*: In rats, subanesthetic concentrations of methoxyflurane decreased hexobarbital sleeping time, increased aminopyrine demethylase activity in the hepatic microsomal fraction and raised resistance to otherwise fatal doses of methoxyflurane.

#### ← *Methylenedioxyphenyl Compounds*

*Fujii et al. G77,242/70*: In mice, 61 methylenedioxyphenyl compounds (including synthetic insecticide synergists, natural products, and related open-ring analogs) showed approximately parallel potency as regards hepatic microsomal-enzyme inhibition manifested by prolongation of hexobarbital narcosis and zoxazolamine paralysis.

#### ← *Metyrapone*

*Currie et al. D48,292/62*: In rats, the production of adrenal necrosis by DMBA is prevented by metyrapone, but not significantly influenced by ACTH.

*Jull F74,180/66*: In rats, the induction of mammary carcinomas by DMBA is inhibited by progesterone, DOC and metyrapone.

*Gaunt et al. G63,202/68*: Metyrapone has been compared to other inhibitors of adrenal steroidogenesis, mostly acting at different sites. Some of these comparisons are shown on p. 583.

*Jellinck et al. F96,053/68*: In rats, the DMBA-induced adrenocortical necrosis is prevented both by metyrapone (which inhibits  $11\beta$ -hydroxylation and the synthesis of corticosterone) and by Su-9055 (which inhibits  $17\alpha$ -hydroxylation of steroids). Since the rat adrenal normally does not synthesize  $17\alpha$ -hydroxylated corticoids it is suggested that "competition for specific receptor sites in the adrenals occurs between the metabolites of DMBA, Metopirone and Su-9055 rather than the original compounds."

*Wheatley F98,919/68*: In rats, adrenal cortical necrosis produced by DMBA or 7-OH-MBA is prevented by metyrapone and related inhibitors of corticoid synthesis (Su 9055, Su 10603) but not by Ay 9944 or aminogluthimide (Elipten). No correlation was found between the influence of these drugs on corticoidogenesis and their ability to protect against adrenal necrosis. Pretreatment with ethionine abolished the protective action of metyrapone, Su 9055 and Su 10603. It is concluded that these drugs protect by virtue of

α-Ethyltryptamine

Tranlycypromine

their hepatic drug-metabolizing enzyme inducing ability, not by direct effect upon corticoidogenesis. Brief reference is made to the observation "that pretreatment of rats with Su 4885 (Metyrapone), while initially potentiating the action of Nembutal, subsequently led to a considerably enhanced rate of detoxification and a shorter duration of narcosis."

*Kahl G69,105/69:* Addition of metyrapone to liver microsomes of mice does not interfere with electron transport. The point of attack of the inhibitor on the hydroxylation of substrate appears to be on cytochrome P-450.

*Leibman G66,210/69:* Metyrapone [SU-4885, 2-methyl-1,2-bis(3-pyridyl)-1-propanone] is a potent inhibitor of adrenal steroid 11β-hydroxylase which also blocks hydroxylation of steroids at other points during their biogenesis in the adrenal gland. The 11β-hydroxylase system of the adrenal cortex is dependent

upon NADPH oxygen and cytochrome P-450 thus resembling hepatic microsomal enzymes. It is of interest therefore that metyrapone prolongs hexobarbital sleeping time in rats and inhibits the oxidative metabolism of hexobarbital, aminopyrine and acetanilide by hepatic microsomes *in vitro*.

*Netter et al. G71,785/69:* In mouse liver microsomes, the inhibition by metyrapone of p-nitroanisole and N-monomethyl-p-nitroaniline was shown to be competitive. The degree of inhibition was correlated to the amount of metyrapone bound to cytochrome P-450. On the other hand, metyrapone does not seem to displace naphthalene from its binding to P-450. Possibly, simultaneous binding of substrate and inhibitor may occur at different binding sites of the same enzyme.

*Szeberényi & Garattini G66,140/69:* In rats, pretreatment with metyrapone delays the disappearance from the blood of i.v.-injected

cortisol presumably because the compound "inhibits the liver enzyme system(s) responsible for inactivation of adrenal steroids." This effect must be taken into consideration in evaluating the metyrapone test for pituitary function.

*Selye & Méc's G60,095/70*: In rats, metyrapone inhibits the catatonic effect of spironolactone against digitoxin and indomethacin poisoning.

*Magalhães & Magalhães G76,648/70*: In rats, metyrapone causes hypertrophy of the hepatic SER and almost complete glycogen depletion. The relative volume of the SER (calculated by stereological methods) is also increased. These changes may be related to the increase by metyrapone of non-11 $\beta$ -hydroxylated corticoids.

*Dardacchi et al. G79,006/71*: In rats, metyrapone stimulates the proliferation of SER, even after adrenalectomy.

*Selye PROT. 26163*: In rats, metyrapone (at dose levels which produce no obvious signs of toxicity) prolongs the anesthetic effect of progesterone, DOC and hydroxydione.

Table 125. Effect of metyrapone upon progesterone, DOC and hydroxydione anesthesia

Treatment <sup>a</sup>	Anesthesia <sup>b</sup> (Positive/Total) Con. Mety- rapone		Mortality <sup>b</sup> (Dead/Total) Con. Mety- rapone	
	Con.	Mety- rapone	Con.	Mety- rapone
None	—	0/10	—	0/10
Progesterone	0/10	6/10 **	0/10	1/10
DOC	0/10	6/10 **	0/10	1/10
Hydroxydione	0/10	6/9 ***	0/10	0/9

<sup>a</sup> Progesterone, DOC acetate and hydroxydione sodium hemisuccinate 5 mg in 1 ml oil, i.p. were administered once to each of the two groups respectively designated. The controls received no other treatment, whereas the experimental animals were given metyrapone 8 mg in 0.1 ml oil, i.p., once, 30 min before the steroid anesthetic.

<sup>b</sup> The severity of anesthesia was read after 3 hrs for progesterone and DOC, after 1 hr for the more rapidly acting hydroxydione. Mortality was listed 24 hrs after metyrapone administration "Exact Probability Test."

For further details on technique of tabulation cf. p. VIII.

DOC  $\leftarrow$  Metyrapone: Netter et al. G53,255/67; Colby et al. G75,695/70

17 $\alpha$ -Hydroxyprogesterone  $\leftarrow$  Metyrapone: Netter et al. G53,255/67

Acetanilide, Aminopyrine  $\leftarrow$  Metyrapone + Phenobarbital, Mouse: Netter et al. G53,255/67

Carcinogens  $\leftarrow$  Metyrapone: Currie et al. D48,292/62\*; Dao et al. D67,132/63\*; Helfenstein et al. G76,331/63\*; Dao et al. F21,633/64; Wheatley F98,919/68\*

N-Monomethyl-p-nitroaniline, p-Nitroanisole  $\leftarrow$  Metyrapone + Phenobarbital: Netter et al. G53,255/67

#### $\leftarrow$ Nicotine

*Beckett & Triggs G70,154/67*: In man, nicotine excretion in the urine following intravenous injection of nicotine, inhalation of nicotine vapor or smoking is greater among nonsmokers than among smokers. The difference is ascribed to the induction of drug-metabolizing enzymes by nicotine. Following discontinuation of smoking, the accelerated nicotine metabolism persists for many months.

*Welch et al. G65,788/69*: No detectable benzpyrene hydroxylase or aminoazo dye N-demethylase activity was observed in the placentas of women who did not smoke but these enzymes were found in the placentas of smokers. In rats, treatment with 3,4-benzpyrene, 1,2-benzanthracene, 1,2,5,6-dibenzanthracene, chrysene, 3,4-benzofluorene, anthracene, pyrene, fluoranthene, perylene, or phenanthrene during pregnancy increased benzpyrene hydroxylase activity in the placenta.

*Stålhandske & Slanina G73,544/70*: In mice, repeated i.p. injections of nicotine impaired nicotine metabolism in vitro, whereas nicotine p.o. slightly increased its own metabolism. "However, the increase was not significant and the stimulating effects of nicotine on hepatic metabolism under the experimental conditions used, must be considered to be limited."

*Selye G70,480/71*: In rats, pretreatment with nicotine offered some protection against intoxication with digitoxin and indomethacin but not against any of the other toxicants tested.

#### $\leftarrow$ Nikethamide

*Brazda & Baucum D48,613/61*: In rats, five days' pretreatment with nikethamide decreases pentobarbital sleeping time and increases the pentobarbital-destroying potency of hepatic microsomes in vitro.

← **Nitrogen Mustard**

*Brin & McKee C31,261/56:* In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase glutamic-aspartic and glutamic-alanine transaminase activities in the liver. Adrenalectomy decreases the activity of these enzymes. The glutamic-alanine enzyme is more sensitive to stress than the glutamic-aspartic enzyme.

← **Pentylentetrazol**

*Dille & Seeberg 84,277/41:* In cats, the acute toxicity of pentylentetrazol is not influenced by bilateral nephrectomy, whereas liver damage induced by yellow phosphorus greatly increases sensitivity to pentylentetrazol.

*Selye A36,443/42:* In rats, the anesthesia produced by progesterone or DOC can be interrupted by pentylentetrazol. Conversely, these anesthetic steroids protect the rat against otherwise fatal doses of pentylentetrazol.

*Kerman A43,330/47:* In the rat, DOC anesthesia is sometimes preceded by a state of catalepsy which can be interrupted by pentylentetrazol.

← **Pesticides cf. also Clinical Implications**

*Nichols & Hinnigar C48,736/57:* In dogs, DDD tends to produce abortion and increases the toxicity of barbiturates.

*Welch & Conney F36,508/65:* Observations on the hydroxylation of testosterone by microsomes of the rat liver showed that different types of hydroxylation are selectively inhibited by various organophosphate insecticides. Treatment of immature male rats with phenobarbital revealed a selective increase in the various hydroxylase activities. "These results suggest that the 16 $\alpha$ -hydroxylation of testosterone is catalysed by a different enzyme system than that required for the 6 $\beta$ - and 7 $\alpha$ -hydroxylation of testosterone."

*Conney et al. G65,135/65:* In the rat, phenobarbital stimulates the hepatic microsomal metabolism of testosterone,  $\Delta^4$ -androstene-3,17-dione, androsterone and estradiol, but not of corticosterone, cortisone or cortisol. Similar effects were obtained with chlorcyclizine and phenylbutazone. Administration of "the carcinogenic hydrocarbon 3-methylcholanthrene to rats caused a several-fold increase in the oxidative metabolism of certain drugs such as zoxazolamine and acetophenetidin but had little or no effect on the oxidation of hexo-

barbital or the hydroxylation of testosterone and  $\Delta^4$ -androstene-3,17-dione." In female rats, chlordane stimulates the metabolism of estradiol to more polar metabolites. Similar observations have also been made in the mouse and dog.

*Azarnoff et al. G42,999/66:* In the rat, pretreatment with DDD markedly shortens anesthesia produced by various steroids and barbiturates. Simultaneously, there is proliferation of the SER and a rise in the level of hepatic hexobarbital-metabolizing enzyme. In dogs, DDD decreases hexobarbital sleeping time, but prolongs pentobarbital anesthesia. Cortisone prevents the prolongation of pentobarbital sleep.

*Conney et al. F73,731/66:* In rats, pretreatment with phenobarbital, chlorcyclizine, phenylbutazone, chlordane or DDT stimulates in vitro hydroxylation of various anesthetic steroids and decreases their anesthetic effect in vivo. "The ability of liver microsomal-enzyme stimulators to decrease the central depressant effects of progesterone raises the possibility that liver microsomal-enzyme stimulators may also alter physiologic actions of endogenous steroids in the body."

*Kupfer & Peets G40,053/66:* In the rat, o,p'-DDD stimulates the cortisol- and hexobarbital-metabolizing ability of the hepatic microsomal fraction.

*Peakall F90,310/67:* In pigeons pretreated with DDT or dieldrin, incubation of the hepatic microsomal fraction with progesterone and testosterone revealed increased rates of steroid metabolism.

*Welch et al. F76,642/67:* "The in vitro addition of organic phosphorothionate insecticides, such as parathion, malathion and chlorthion, or halogenated hydrocarbon insecticides, such as chlordane and DDT, inhibited the liver microsomal hydroxylation of testosterone. Treatment of rats with chlorthion for 10 days inhibited the liver microsomal hydroxylation of testosterone, estradiol-17 $\beta$ , progesterone and deoxycorticosterone, whereas chronic treatment of rats with chlordane or DDT stimulated the hydroxylation of these steroids." Chlorthion had a more marked inhibitory effect upon the 16 $\alpha$ -hydroxylation than on the 6 $\beta$ - or 7 $\alpha$ -hydroxylation. Chlordane or DDT-pretreatment stimulated 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -hydroxylation of testosterone, but particularly the latter reaction. Apparently, the microsomal enzyme system responsible for 16 $\alpha$ -hydroxylation of testosterone differs from

the systems regulating 6 $\beta$ - and 7 $\alpha$ -hydroxylation.

*Conney et al. G43,018/67*: Review of the literature and personal observations on the induction of steroid hydroxylases in hepatic microsomes by various pesticides. "In contrast to the stimulatory effect of halogenated hydrocarbon insecticides on hepatic steroid hydroxylases, treatment of rats with organophosphate insecticides, such as chlorthion, inhibits the liver microsomal metabolism of several steroid hormones. Chlorthion has a greater inhibitory effect on the 16 $\alpha$ -hydroxylation of testosterone than on the 6 $\beta$ - or 7 $\alpha$ -hydroxylation of this steroid, suggesting that separate enzyme systems are required for the various hydroxylation reactions."

*Good & Ware G76,670/69*: In mice, feeding of the insecticides endrin or dieldrin did not significantly affect fertility, fecundity or the number of young produced per day.

*Lacassagne et al. G74,932/69*: In rats, production of hepatic cancers by DAB is powerfully inhibited by  $\Delta^5$ -pregnenolone, DOC or DDD. Various other steroids give less clear-cut results.

*Levin et al. G64,184/69*: "Treatment of immature male rats with phenobarbital or chlordane for several days prior to an injection of testosterone or testosterone propionate inhibits the growth-promoting effect of these androgens on the seminal vesicles. It is suggested that phenobarbital and chlordane decrease the action of the androgens by enhancing their metabolism."

*Fahim et al. G81,358/70*: In rats, "DDT administered to cycling females or estrogen-maintained castrated animals causes decreased uterine weight and alkaline phosphatase."

*Greim G76,366/70*: In patients with constitutional hyperbilirubinemia (Gilbert- or Meulengracht syndrome) as well as in Cushing's disease, the stimulation of hepatic microsomal-enzyme induction by DDT or DDD is followed by remissions. Because of its corticolytic effect in the dog, it is assumed that DDD acts by blocking corticoid production, but in vitro experiments with rat liver microsomes, show that DDD and DDT increase the metabolism of corticoids and hence their therapeutic effect is ascribed to this action.

*Kimbrough et al. G81,969/71*: In rats, DDT and dieldrin reduce hexobarbital sleeping time, increase liver weight and cause proliferation of the SER with the formation of a typical mitochondria which often contain numerous longitudinally arranged parallel cristae.

#### ← *Phenaglycodol*

*Kato D46,405/61*: In the rat, following pretreatment with phenaglycodol or thiopental, resistance to strychnine is increased, whereas resistance to OMPA is considerably diminished.

#### ← *Phentolamine*

*Selye G70,480/71*: In rats, pretreatment with phentolamine protected against intoxication with digitoxin and dioxathion but not against any of the other nonadrenergic drugs tested.

#### ← *Phenothiazines*

*Holten & Larsen G74,395/56*: In mice, hexobarbital anesthesia is considerably prolonged by benactyzine (a compound used for the treatment of psychoneuroses). The effect resembles that of SKF 525-A and when given together, the two compounds synergize each other. Extensive review of the literature and numerous personal observations concerning the barbiturate-potentiating effect of various antihistamines and spasmolytic compounds.

*Wattenberg & Leong F38,140/65*: In rats, the production of adrenal necrosis by DMBA is inhibited by phenothiazine and several of its derivatives which increase benzyrene hydroxylase activity.

#### ← *Phenylbutazone*

*Kersten & Staudinger G67,796/56*: Addition of phenylbutazone to pig liver homogenates inhibits the enzymic inactivation of cortisone in vitro.

*Conney & Schneidman F24,913/64*: "Treatment of immature rats and dogs with phenylbutazone increased several-fold the activity of enzymes in liver microsomes that hydroxylate testosterone and  $\Delta^4$ -androstene-3,17-dione. Treatment of rats with phenylbutazone or phenobarbital stimulated a minor pathway of corticosteroid metabolism to polar metabolites chromatographically similar to hydroxylated substrate. Administration of the carcinogenic hydrocarbon 3-methylcholanthrene to rats did not stimulate polar metabolite formation but markedly inhibited the microsomal metabolism of corticosteroids to metabolites chromatographically less polar than the substrate."

*Kuntzman et al. G67,761/66*: In man, phenylbutazone increases the urinary excretion of 6 $\beta$ -hydroxycortisol, and simultaneously decreases the nonpolar 17-OHCS. These findings are in agreement with earlier in vitro observa-

tions showing that the hydroxylation of cortisol to 6 $\beta$ -hydroxycortisol by guinea pig liver microsomes is increased following pretreatment with phenylbutazone in vivo.

*Welch et al. G47,232/67*: "When rats received 75 mg/kg of phenylbutazone twice a day for 1 day, a high incidence of gastric ulcers was observed 24 hours later. However, when rats received the same dose daily for 14 days, the metabolism of the drug was markedly stimulated and no ulcers were observed."

*Bailey et al. H450/68*: In rabbits, cholesterol atherosclerosis is inhibited by cortisone, prednisone, triamcinolone, methylprednisolone, dexamethasone and 9 $\alpha$ -fluorocortisol, although hyperlipemia is aggravated. Phenylbutazone and oxyphenylbutazone also diminished cholesterol atherosclerosis, although to a lesser extent and without augmenting hyperlipemia.

*Klinger et al. H28,896/70*: In rats, phenylbutazone reduces hexobarbital sleeping time and increases the fresh weight of the liver as well as the ability of the hepatic 9000 g supernatant to enhance aminophenazone-N-demethylation. An increase in the ascorbic acid concentration of the liver was noted only in young animals, but the urinary excretion of ascorbic acid was as pronounced as after barbituric treatment. Phenylbutazone administration to the pregnant mother failed to elicit an induction effect in the fetuses as judged by hepatic ascorbic acid determinations and by ultrastructural studies of the fetal livers. Proliferation of the SER was obtained by phenylbutazone in 10-day-old or older rats, often in association with an increase in the number of lysosomes and mitochondrial changes, as well as by evidence of intrahepatic cholestasis.

*Yesair et al. G75,388/70*: In rats, salicylic acid i.v. decreases the plasma concentration of indomethacin. Simultaneously, the urinary excretion of <sup>14</sup>C-indomethacin is decreased, whereas biliary and fecal excretions are increased. Phenylbutazone, chlorogenic acid and acetic acid had no effect on plasma radioactivity. Probenecid increased plasma concentration of indomethacin. "The specificity of salicylic acid in decreasing concentrations of indomethacin in plasma of rats and of probenecid in increasing indomethacin concentrations in plasma of both rat and man may arise from the similarity in structure of the benzoyl group of the three compounds."

*Selye G70,480/71*: In rats, phenylbutazone pretreatment protects against intoxication with dioxathion, parathion, nicotine, hexobarbital, progesterone and indomethacin but not against

poisoning with digitoxin, zoxazolamine, DHT or the infarctoid cardiopathy produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

#### ← Probenecid

*Yesair et al. G75,388/70*: In rats, probenecid increased the plasma concentration of indomethacin.

← *Puromycin cf. Inhibitors under General Pharmacology* (p. 75).

#### ← Pyridinolcarbamate

*Shimamoto G70,917/69*: In cholesterol-fed rabbits, pyridinolcarbamate induced the regression of the atheromatous lesions and their replacement by regenerating smooth muscle fibers.

#### ← RES-Blockers

*Holck D28,543/49*: Adult male rats are more resistant than females to toxic doses of picrotoxin. Such a sex difference is absent in one-month-old rats. Castration lowers picrotoxin resistance in rats of either sex. Testosterone raises picrotoxin resistance in normal and especially in spayed females, but not in males. Blockade of the RES abolished the sex difference but corticosterone failed to influence it.

*Kass D35,079/60*: "The antiendotoxic activity of corticosteroids seems to be sufficiently different from the anti-inflammatory activity to offer the possibility that these two activities may be structurally separable. The anti-inflammatory action of corticosteroids is apparently related largely to an effect on vascular permeability, whereas the antiendotoxic activity in some way involves the reticuloendothelial system."

*DiCarlo et al. F74,536/65*: Several RES stimulants prolong pentobarbital sleeping time in the mouse. There is no evidence of this effect being due to induction of pentobarbital-metabolizing enzymes. "An alternative hypothesis is that the stimulants induce the biological inactivation of corticosterone, which may regulate barbiturate hydroxylase as well as tryptophan pyrrolase and certain transaminases of liver microsomes."

*Wooles & Borzelleca F93,374/66*: Repeated administration of zymosan i.v. prolongs hexobarbital, pentobarbital and barbital sleeping time in the mouse. This effect is ascribed to stimulation of the RES.

*Agarwal & Berry G66,480/67*: "Four hours after zymosan administration, cortisone was

able to induce mouse liver tryptophan pyrrolase production almost at a normal rate and, under these conditions, protected mice against a concurrent injection of endotoxin. Administration of zymosan, at either 2 or 4 hours after cortisone administration, resulted in little change in tryptophan pyrrolase activity while endotoxin, when similarly administered, caused a rapid decline in liver tryptophan pyrrolase activity. . . . Glucan and zymosan, like endotoxin, increased tyrosine- $\alpha$ -ketoglutarate transaminase activity in intact but not in adrenalectomized mice. Zymosan and thorotrast, unlike endotoxin, neither lowered liver carbohydrate levels nor influenced cortisone induced neosynthesis of liver glycogen. These results suggest a cause and effect relationship between inducibility of key liver enzymes and survival against stress."

*Berry et al. E7,069/67*: In mice, endotoxin, zymosan, glucan, and saccharated iron oxide (all RES-blocking agents) lower hepatic TPO and increase TKT *in vivo*, but not *in vitro*. Endotoxin also prevents the induction of TPO by cortisone, especially when the latter is given 2–4 hrs after endotoxin. The transaminase responds normally. Zymosan and glucan do not prevent the induction of TPO by cortisone. "Perhaps one might relate these effects to the dose of colloid used in relation to its toxicity, but even large doses of saccharated iron oxide capable of killing mice fail to prevent the induction of tryptophan pyrrolase by cortisone."

*Timar et al. F 82,696/67*: In rats pretreated with India ink *i.v.*, phenobarbital elimination is delayed.

#### ← Reserpine

*Radouco-Thomas et al. E 60,201/57*: In guinea pigs, the analgesic effect of meperidine is diminished by reserpine and counteracted by concurrent administration of norepinephrine.

*Westermann et al. C 83,072/60*: In the rat, large doses of reserpine produce an alarm reaction with an increase in the hepatic tryptophan peroxidase activity associated with lowered brain serotonin and norepinephrine. Hypophysectomy prevents these responses.

#### ← Salicylic Acid

*Jeremy & Towson G77,324/70*: In patients with rheumatoid arthritis,  $^{14}\text{C}$ -2-indomethacin plasma clearance is accelerated, and urinary excretion decreased, by acetylsalicylic acid. "The study showed interference between aspi-

rin and indomethacin, the mechanism possibly being due to decreased gastro-intestinal absorption. This could account for clinical reports that the combination of the two drugs was no better than aspirin alone."

*Kaczak et al. G75,716/70*: In rabbits chronically treated with acetylsalicylic acid, the liver shows considerable dilatation of the endoplasmic reticulum whose spaces are filled with electron dense material. At the same time, various enzyme activities of the liver are changed and the glycogen content of the hepatocytes is diminished.

*Yesair et al. G75,388/70*: In rats, salicylic acid *i.v.* decreases the plasma concentration of indomethacin. Simultaneously, the urinary excretion of  $^{14}\text{C}$ -indomethacin is decreased, whereas biliary and fecal excretions are increased. Phenylbutazone, chlorogenic acid and acetic acid had no effect on plasma radioactivity. Probenecid increased plasma concentration of indomethacin. "The specificity of salicylic acid in decreasing concentrations of indomethacin in plasma of rats and of probenecid in increasing indomethacin concentrations in plasma of both rat and man may arise from the similarity in structure of the benzoyl group of the three compounds."

*Selye G70,480/71*: In rats, acetylsalicylic acid or sodium salicylate protected against progesterone anesthesia and indomethacin-induced intestinal ulcers. Acetylsalicylic acid, unlike sodium salicylate, also offered some protection against zoxazolamine paralysis and sodium salicylate against parathion intoxication but neither of these salicylates protected against poisoning with digitoxin, dioxathion, nicotine, hexobarbital or DHT, nor did they prevent the infarctoid necroses produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

#### ← Soterenol

*Zwadyk & Harrison H 19,753/70*: Soterenol is considerably more potent than the structurally-related isoproterenol in reducing endotoxin lethality in chick embryos and mice.

#### ← Sucrose

*Kato & Takanaka F 88,660/67*: Observations on the *in vivo* and *in vitro* detoxification of zoxazolamine, hexobarbital, pentobarbital, strychnine, carisoprodol, and OMPA show that sucrose feeding or starvation for 48 hrs before the tests markedly decreases the hepatic microsomal detoxication of those substrates,

which are less toxic for male than for female rats. It is assumed that sucrose depresses the synthesis of hepatic microsomal enzymes.

### ← Sulfur

*Sakurai E67,662/25*: In cats, unlike in rabbits, thiosulfate inhibits methemoglobin formation following treatment with aniline or sodium nitrite.

*Myers & Ferguson A48,023/28*: In rabbits, intoxication with tincture of iodine s.c. is counteracted by sodium thiosulfate i.v. or p.o.

*Young & Taylor A48,227/30; A48,535/31*: In rabbits, sodium thiosulfate does not appreciably decrease the toxicity of mercury compounds.

*Kabelik 9,032/32*: In guinea pigs, sodium or magnesium thiosulfate i.p. offers considerable protection against otherwise lethal anaphylactic shock. This "anti-anaphylaxis" persists several days. Even better results are obtained with the serum of horses which have received sodium thiosulfate i.v. 4 hrs before bleeding. The serum of untreated horses is ineffective. The protective action of "thiosulfate serum" cannot be due to the presence of thiosulfate, since activity persists after no more thiosulfate can be detected by chemical means in the serum. The protective factor can be extracted from the serum by ethanol.

*Schreiber A48,020/33*: Review on the detoxifying action of sulfur compounds (particularly SH- and SS-groups) upon various drugs.

*Vandestratt A48,036/33*: Contrary to earlier claims, sodium thiosulfate does not protect the guinea pig against tuberculin.

*Chambon & Bouvet A48,279/33*: In dogs returned to an atmosphere of pure air after CO-intoxication, treatment with sodium thiosulfate does not improve detoxication as had been previously suggested.

*Hochwald 36,114/36*: In guinea pigs, anaphylactic shock is diminished by pretreatment with cysteine or sodium thiosulfate.

*Wendt A48,250/38*: Review (19 pp., 264 refs.) on the use of sodium thiosulfate in the treatment of various intoxications and diseases with special reference to the detoxication of arsenic and cyanides.

*Vauthey & Vauthey A48,670/47*: In guinea pigs, acute intoxication with mercuric cyanide (excitation, paralysis, death) is partially combated by 20 days' pretreatment with 100 mg of ascorbic acid per day s.c. A similar moderate protection is obtained by sodium thiosulfate

and, to a much lesser extent, by glucose. [The very preliminary experiments suggest that none of the protective actions was very evident (H.S.).]

*Patt et al. B54,521/49*: In rats, resistance to total body X-irradiation is increased by pretreatment, 5 min before exposure, with cysteine (but not with cystine) i.v. Injection of cysteine immediately after exposure is ineffective.

*Patt et al. B54,522/50*: In rats and mice, cysteine-pretreatment increases resistance to whole body X-irradiation. Cysteine, methionine, sodium sulfide, and ascorbic acid are ineffective under similar conditions. When administered after X-irradiation, cysteine also fails to protect.

*Bacq et al. E91,032/51*: In mice, cysteamine i.p. protects against total body X-irradiation.

*Stavinoha et al. C94,628/59*: Review and personal observations on protection by various sulfur compounds against thallium intoxication.

*Cahn & Herold G72,124/60*: Review (9 pp., 58 refs.) on the importance of sulfhydryl groups in the detoxication of various agents.

*Passow et al. G38,172/61*: Review (39 pp., 130 refs.) on the general pharmacology of heavy metals with special reference to their detoxication by sulfur compounds.

*Langendorff F42,481/65*: Review on radioprotective agents with special reference to sulfur containing compounds.

*Lumper & Zahn G72,128/65*: Review (38 pp., 187 refs.) on the biochemistry of disulfide exchange reactions with special reference to their detoxicating value.

*Cier et al. F85,815/67*: In mice, the protection against total body X-irradiation given by 5-HT is considerably increased by concurrent treatment with thiosulfate. Various other radioprotective compounds likewise offer better protection, and are less toxic if administered conjointly than if given singly.

*Varga & Fischer G76,189/69*: In rats, hepatic damage produced by bromobenzene, CCl<sub>4</sub>, allyl alcohol and thioacetamide is associated with prolonged hexobarbital sleeping time owing to interference with the hepatic microsomal metabolism of the barbiturate. However, the degree of hepatic injury does not run strictly parallel with the prolongation of the hexobarbital sleeping time; hence, the latter cannot serve as an accurate hepatic function test.

← **Tetrachloroethylene**

*Levin et al. H 26,593/70:* In rats,  $\text{CCl}_4$  given to immature females 24 hrs before sacrifice inhibited the activity of hepatic microsomal enzymes that hydroxylate estradiol-17 $\beta$  and estrone. This inhibition was reflected in vivo by an altered metabolism of estradiol-17 $\beta$  and estrone, by a potentiation of the uterotrophic action of folliculoids and by an increased concentration of these steroids in the uterus. By contrast, tetrachloroethylene did not influence the action of estrone. SKF 525-A and desipramine, which are also inhibitors of drug metabolism, likewise potentiate the uterotrophic action of estrone in immature rats.

← **Thiadiazoles cf. Sulfa Drugs**← **Threonine**

*Sidransky et al. G 65,724/69:* In rats, forced a threonine-devoid diet for 3—7 days, hepatic protein synthesis is enhanced as shown by various techniques. This increase is further augmented by cortisone, and causes a shift in hepatic polyribosomes toward heavier aggregates.

← **Tolbutamide cf. Pancreatic Hormones**← **Tryptamine**

*Langendorff & Koch C 36,881/57:* In mice, both tryptamine and 5-HT offered protection against X-irradiation, whereas benzedrine and d,l-ephedrine were ineffective.

← **Triamterene**

*Selye PROT. 31649:* In rats (100 g ♀), pretreatment with triamterene (1 mg in 1 ml water p.o. x2/day) or amiloride (300  $\mu\text{g}$  in 1 ml water p.o. x2/day) fails to protect against hexobarbital, progesterone, parathion or dioxathion.

← **Vitamin A**

*Ehrlich & Hunt G 55,237/68:* In rats, vitamin A has no effect upon wound healing but it overcomes the inhibitory effect of cortisone.

*Selye G 70,480/71:* In rats, pretreatment with vitamin A offered no significant protection against digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone, zoxazolamine, indomethacin, DHT or the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

← **Vitamin-B<sub>12</sub>**

*Bengmark & Olsson E 34,736/63:* Review and personal observations on the effect of vitamin-B<sub>12</sub> upon hepatic regeneration following partial hepatectomy in the rat.

← **Vitamin C**

*Vauthey & Vauthey A 48,670/47:* In guinea pigs, acute intoxication with mercuric cyanide (excitation, paralysis, death) is partially combated by 20 days pretreatment with 100 mg of ascorbic acid per day s.c. A similar moderate protection is obtained by sodium thiosulfate and, to a much lesser extent, by glucose. [The very preliminary experiments suggest that none of the protective actions was very evident (H.S.).]

*Selye G 70,480/71:* In rats, pretreatment with large doses of vitamin C offered no significant protection against digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone (anesthesia), indomethacin, acute DHT intoxication or the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil. Ascorbic acid actually aggravated zoxazolamine intoxication.

← **Vitamin D**

*Selye G 70,480/71:* In rats, pretreatment with vitamin D<sub>2</sub> offered no significant protection against intoxication with digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone (anesthesia), zoxazolamine, indomethacin, acute DHT poisoning or the infarctoid cardiac necroses produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil.

← **Vitamin E**

*Tuchweber et al. D 65,261/63:* Both methyltestosterone and vitamin E prevent the production of a progeria-like syndrome by DHT in the rat.

*Selye et al. E 24,117/64:* The progeria-like syndrome produced by DHT, vitamin-D<sub>2</sub> or vitamin-D<sub>3</sub> can be prevented by ferric dextran, methyltestosterone or vitamin E in the rat.

*Cawthorne et al. H 26,441/70:* In rats, the acute toxicity of  $\text{CCl}_4$  p.o. is greater in males than in females. Vitamin E and various antioxidants exert a protective effect. It is suggested that the protection may be partly dependent upon the induction of hepatic microsomal enzymes.

*Selye G70,480/71*: In rats, pretreatment with vitamin E offered some protection against dioxathion intoxication, hexobarbital and progesterone anesthesia, and acute DHT intoxication, but not against any of the other toxicants tested.

← *W-1372*

*Selye G70,480/71*: In rats, W-1372 protects against intoxication with dioxathion, parathion, hexobarbital, progesterone (anesthesia), zoxazolamine and indomethacin but not against digitoxin, nicotine, acute DHT intoxication or the infarctoid cardiopathy produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

← *Xanthine*

*Ravdin et al. B25,566/39*: In rats, xanthine, allantoin, caffeine, sodium ricinoleate and suspensions of colloidal carbon injected s.c. protect the liver against injury from chloroform, presumably as a consequence of the resulting inflammatory reaction which is associated with the absorption of protein split products. This would also explain the protective effect of various hepatic extracts (including Yakriton) and of high-protein diets.

← *Varia*

*Fastier et al. C37,038/57*: In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone and DOC did not prolong chloral hydrate sleeping time at the doses tested.

*Kato & Vassanelli D40,237/62*: "Rats pretreated with phenobarbital, phenaglycodol, glutethimide, nikethamide, chlorpromazine, triflupromazine, meprobamate, carisoprodol, pentobarbital, thiopental, primidone, chloretone, diphenylhydantoin and urethane showed an accelerated metabolism of meprobamate and, at the same time, a diminished duration of sleeping time and paralysis due to meprobamate." SKF 525-A accelerated meprobamate metabolism and counteracted the action of the enzyme inducers. In hypophysectomized or adrenalectomized rats, phenobarbital still increased meprobamate metabolism in vitro.

*Conney & Schneidman F35,870/65*: Treatment of young male rats with phenobarbital stimulated the liver microsomal metabolism of

progesterone, testosterone,  $\Delta^4$ -androstene-3,17-dione, androsterone, and DOC to polar metabolites identified in most cases as hydroxylated derivatives of the substrates. These in vitro effects were associated with a decreased hypnotic action of high doses of these steroids. Similar effects in vitro and in vivo were obtained with **chlorcyclizine**, **phenylbutazone** or **chlordane**.

*Kuntzman et al. F55,537/65*: In the rats, anesthesia produced by progesterone, DOC, androsterone, or  $\Delta^4$ -androstene-3,17-dione is inhibited by phenobarbital. Progesterone anesthesia is also inhibited by **chlorcyclizine**, **phenylbutazone**, **chlordane** and **DDT**-pretreatment. These effects are tentatively ascribed to a stimulation of hepatic drug-metabolizing enzyme synthesis.

*Burns et al. G66,103/67*: Review (8 pp., 22 refs.) on "Drug Effects on Enzymes" with special reference to chronic toxicity tests.

*Groppetti & Costa H31,959/69*: In adult male rats, the disappearance of amphetamine is faster than in adult females. Estradiol retards the rate of amphetamine disappearance in adult males. Such potent hepatic microsomal enzyme inducers as **phenobarbital**, **3-MC**, or **diphenylhydantoin** do not change the tissue levels of amphetamine.

*Pérez E8,836/69*: A review (270 pp., numerous refs.) on the role of the liver in drug detoxication and the hepatotoxic activity of certain drugs (Spanish).

*Jori et al. G81,674/70*: In the rat, there is linear correlation between sleeping time and brain pentobarbital concentration. This correlation was abolished or modified by various drugs, suggesting that **SKF 525-A**, **DDT** and low doses of **chlorpromazine** act only by modifying barbiturate metabolism, whereas **amphetamine**, high doses of **chlorpromazine** and **diazepam** affect pentobarbital sleeping time without altering its metabolism.

*Shafer & Adicoff G80,179/70*: In dogs, **tetrahydrofurfuryl alcohol** (THFA), despite its resemblance to the lactone moiety of **digoxin** offers no protection against the latter compound in vivo. The authors emphasize that despite these "negative results, the development of a specific nontoxic pharmacological antagonist to digitalis would be of major clinical importance." [These investigators appear to be unaware of the inhibition of digitalis toxicity by spironolactone (H.S.).]

*Calhoun et al. H34,806/71*: In immature rats, the uterotrophic effect of **mestranol** or **norethynodrel** was affected by numerous drugs.

"Pretreatment with phenobarbital or SKF 525A was found to decrease and increase, respectively, the uterine wet weight in controls as well as in mestranol-treated groups. Of the other drugs tested, only tolbutamide increased uterine wet weights in both control and mestranol-treated groups. In addition, the response to mestranol was increased following

pretreatment with p-aminosalicylic acid, chlorpromazine, and imipramine and decreased following diphenylhydantoin, phenylbutazone, or scopolamine pretreatment. The response to norethynodrel was decreased after pretreatment with phenobarbital or diphenylhydantoin and increased following SKF 525A pretreatment."

#### ← DIET

Dietary factors undoubtedly exert an important influence upon defensive reactions in general and upon the induction of microsomal enzymes in particular. For example, the protein intake is a critical factor involved in maintaining the folliculoid-inactivating system of the liver.

A good deal of work has been done on the influence of dietary factors on the detoxication of **barbiturates**. In mice, starvation prolongs hexobarbital sleeping time and diminishes the ability of isolated hepatic microsomes to metabolize this drug. Following repeated periods of fasting (as after other types of stress), hexobarbital hypnosis is also prolonged in male rats. Allegedly, hexobarbital detoxication by hepatic microsomes of rats is optimal if the diet contains about 3% of the calories in the form of corn oil (or equivalent amounts of linoleate). Both higher and lower essential fatty acid concentrations are detrimental.

The toxicity of **carcinogens** and **chloroform** is also considerably influenced by the diet.

In rats, 24 hrs fasting after a single injection of **indomethacin** can prevent intestinal ulcer formation, whereas earlier or later fasting had no such effect. The intestinal ulcers could also be prevented by ligation of the common bile duct; consequently it is possible that fasting acts through its influence upon bile secretion.

**Pesticide** detoxication is likewise modified by nutritional factors. In rats kept on a protein-deficient diet, the activity of the thiophosphate-oxidizing system is enhanced. The detoxication of heptachlor (as that of hexobarbital) proceeds most favorably if the diet contains about 3% of the calories in the form of corn oil or of equivalent amounts of linoleate.

Much attention has been given also to the action of nutritional factors upon the detoxication of **other drugs** and on the activity of various **hepatic enzyme systems** as well as on liver regeneration after **partial hepatectomy** but for corresponding data the reader is referred to the Abstract Section.

#### **Steroids** ←

*György E 86,573/45*: Review of the literature and personal observations on the influence of the diet upon the hepatic detoxication of estrone in the rat.

*Vanderlinde & Westerfeld B 51,537/50*: "The estrogen draining through the liver from mesenterically implanted pellets of estrone in castrate rats was inactivated when the rats were maintained on: 1) chow ad libitum, 2) normal or 50% restricted intake of a 21% purified

casein diet. The liver estrogen inactivating system was not maintained by: 1) an 8% purified casein diet ad libitum, or 2) 50% of the usual intake of chow. The results are consistent with the concept that protein intake is the critical dietary factor involved in maintaining the estrogen inactivating system in the liver."

#### **Drugs** ←

**Barbiturates** ←. *Dixon et al. G 65,886/60*: In mice, starvation prolongs sleeping time after

hexobarbital i.p. and simultaneously diminishes the ability of isolated hepatic microsomes to metabolize the drug.

*Kalyanpur et al. F99,270/68*: Review of the literature and personal observations on the effect of dietary factors upon barbital sleeping time in rats.

*Hüssler et al. H23,853/69*: Male rats are more resistant than females to the anesthetic effect of hexobarbital. In rats raised under extreme conditions of stress (cold or repeated periods of fasting) hexobarbital sleeping time is prolonged.

*Caster et al. G73,426/70*: In rats, hexobarbital and heptachlor detoxication by hepatic microsomes *in vitro*, is optimal if the diet contains about 3% of the calories in the form of corn oil (or equivalent amounts of linoleate). Both higher and lower levels of fatty acids are detrimental for the detoxication of these substrates and this was confirmed by determinations of hexobarbital sleeping time *in vivo*. The results are interpreted as indicating that an optimum amount of essential fatty acid is required for the most efficient functioning of the hepatic microsomal drug-metabolizing system.

*Weiner et al. H24,942/70*: In rats, glucagon, alloxan and starvation all increased hexobarbital sleeping time. This effect was markedly antagonized by insulin. Perhaps, cyclic AMP may be involved since theophylline greatly increases the action of glucagon. This synergism also occurred in isolated, perfused rat livers and, hence, "inhibition of hexobarbital metabolism by cyclic AMP would appear to be mediated in the liver."

**Carbon Tetrachloride** ←. *Nayak et al. G80,728/70*: In rats, a protein-free diet or starvation caused deterioration of the ER and diminution of drug-metabolizing enzymes, but failed to make the hepatocytes less susceptible to the effects of CCl<sub>4</sub>.

**Carcinogens** ←. *Brown et al. G57,030/54*: "The activity of an enzyme system in mouse and rat liver which N-demethylates 3-methyl-4-monomethylaminoazobenzene has been found to depend on the nature of the diet. The lowest activity occurred when a grain or purified diet was fed. The activity of mouse liver approximately doubled when any of several commercial chows was fed; the activity of rat liver increased about 30 per cent. The factor was also contained in a number of aged or otherwise treated animal products, such as an old cholesterol preparation, liver extracts, and peptones. A variety of pure sterols were inac-

tive, but could be made active by peroxidation."

**Chloroform** ←. *Ravdin et al. B25,566/39*: In rats, xanthine, allantoin, caffeine, sodium ricinoleate and suspensions of colloidal carbon injected s.c. protect the liver against injury from chloroform, presumably as a consequence of the resulting inflammatory reaction which is associated with the absorption of protein-split products. This would also explain the protective effect of various hepatic extracts (including Yakriton) and of high-protein diets.

**Digitoxin** ←. *Selye PROT. 24423*: In rats (100 g ♀) fasting 24 hrs before or after administering 2 mg of digitoxin p.o. failed to prevent the development of convulsions and actually seemed to aggravate the resulting mortality.

**Indomethacin** ←. *Brodie et al. G67,797/69*: In rats given a single injection of indomethacin s.c., starvation during the following 24 hrs completely prevented intestinal ulcer formation, whereas starvation for 24 hrs on the second, third, or second + third day had no such effect. Intestinal ulcers could also be prevented by ligation of the common bile duct. When segments of small intestine were isolated by Thiry-Vella loops, ulceration was prevented in the loops but not in the adjacent anastomosed intestine.

*Selye PROT. 24733,25025,24423*: In rats (100 g ♀) complete fasting during a 24 hrs period before or after the injection of 3 mg of indomethacin s.c., or even 24 hrs before and continuing until 24 hrs after this injection, failed to prevent the development of perforating intestinal ulcers.

**Pesticides** ←. *Murphy & DuBois D28,546/58*: The activity of the microsomal enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). SKF 525-A inhibits, whereas pretreatment with carcinogens or a protein-deficient diet enhances, the activity of the thiophosphate-oxidizing enzyme.

*Caster et al. C73,426/70*: In rats, hexobarbital and heptachlor detoxication by hepatic microsomes *in vitro*, is optimal if the diet contains about 3% of the calories in the form of corn oil (or equivalent amounts of linoleate). Both higher and lower levels of fatty acids are detrimental for the detoxication of these substrates and this was confirmed by determinations of hexobarbital sleeping time in

vivo. The results are interpreted as indicating that an optimum amount of essential fatty acid is required for the most efficient functioning of the hepatic microsomal drug-metabolizing system.

**Varia** ←. *Conney & Burns G67,166/62*: Review on the effect of starvation on drug metabolism with special reference to microsomal enzymes.

*Kato & Gillette F5,638/64*: In female rats, 3 days starvation "increases the activity of TPNH-dependent enzymes that catalyze the metabolism of TPNH, aniline, aminopyrine, p-nitrobenzoate, neotetrazolium, and neoprontosil, but does not alter the activity of TPNH-cytochrome c reductase. In contrast, starvation of male rats decreases the activity of aminopyrine demethylase, although it increases the activity of aniline hydroxylase and does not alter the activity of nitroreductase, TPNH-cytochrome c reductase or TPNH oxidase." Sucrose fed to rats of either sex for 3 days lowers the activity of all these enzymes, but does not interfere with their induction by phenobarbital.

*Kato & Gillette F57,816/65*: The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females but the sex difference varies with the substrate. There is a more than 3-fold sex difference with aminopyrine and hexobarbital but virtually none with hydroxylation of aniline and zoxazolamine. In male rats, starvation impairs sex-dependent enzymes which metabolize aminopyrine and hexobarbital but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital and enhances that of aminopyrine by microsomes of castrated rats but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Kato G66,471/67*: "The metabolism of hexobarbital, aminopyrine and aniline by liver microsomes were increased in rats fasted for 72 hrs and they were drastically decreased by refeeding on a standard diet as well as on sucrose. ... The relationship between the activities of drug metabolisms and NADPH dehydrogenase and content of P-450 was discussed."

*Kato & Takanaka F88,660/67*: Observations on the in vivo and in vitro detoxication of zoxazolamine, hexobarbital, pentobarbital,

strychnine, carisoprodol, and OMPA showed that starvation for 48 hrs before the tests markedly decreases the hepatic microsomal detoxication of those substrates, which are less toxic for male than for female rats. Sucrose feeding had an effect similar to that of starvation and it is assumed that sucrose depresses the synthesis of hepatic microsomal enzymes.

*Kato et al. H11,854/69*: "The administration of thyroxine or starvation resulted in marked decrease in the hydroxylation of pentobarbital and hexobarbital and N-demethylation of aminopyrine in male rats, whereas the hydroxylation of aniline and zoxazolamine and N-demethylation of N-methylaniline were significantly increased."

#### **Partial Hepatectomy** ← *cf. also Effect of Partial Hepatectomy Upon Nutritional Disorders*

*Brues et al. A45,962/36*: In rats submitted to partial hepatectomy, "the number of cells in the residual fragment shows no significant increase in the first 24 hours" although the mass of the liver remnant increases about 50%. After the first day, cell number and liver mass increase approximately at the same rate. The effect of various dietary constituents upon hepatic regeneration is described.

#### **Hepatic Enzymes** ←

*Brin & McKee C31,261/56*: In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase glutamic-aspartic and glutamic-alanine transaminase activities in the liver. Adrenalectomy decreases the activity of these enzymes. The glutamic-alanine enzyme is more sensitive to stress than the glutamic-aspartic enzyme.

*Freedland et al. G66,662/62*: The phenylalanine hydroxylase activity of rat liver increases with age from embryonic life to 50–60 days and then declines to stabilize at a lower level in females than in males after maturity. Fasting and diets deficient in phenylalanine cause a rapid decrease in this enzymic activity.

*Gillette G67,333/67*: Brief review on the effect of dietary factors upon hepatic microsomal-enzyme induction.

*Freedland et al. H2,949/68*: Review (5 pp., 33 refs.) on the relationship of nutritional and hormonal influences in hepatic enzyme activity.

*Harada et al. H15,156/69:* The acyl-CoA synthetase activity of the rat liver increases 2–3-fold during alloxan diabetes, fasting, or high-fat diet feeding.

*Lane & Mavrides H12,953/69:* Cortisol caused a greater increase of hepatic tyrosine aminotransferase in hypophysectomized than in adrenalectomized rats. In general, elevation of enzyme activity after cortisol was inversely proportional to the initial enzyme level, and

the latter was in turn higher on protein-rich than on protein-poor diets.

*Yuwiler et al. H9,994/69:* Comparative observations on fasted and cortisol-injected rats led to the conclusion that “the natural stress of fasting is accompanied by alterations in some corticoid-inducible enzymes, but that these changes are not analogous to those obtained following glucocorticoid administration.”

#### ← MICROORGANISMS, VACCINES AND PARASITES

**Pneumococcal** infection raises the hepatic TPO in intact but not in adrenalectomized mice. In rats infected with malaria (*P. berghei*), the hepatic microsomal metabolism of ethylmorphine, aniline, p-nitroanisole and hexobarbital progressively decrease and correspondingly hexobarbital sleeping time is prolonged. However, the malarial infection does not prevent the induction of microsomal enzymes by phenobarbital.

**Endotoxin** shock is associated in rabbits with a release of hepatic lysosomal acid hydrolases. This effect is prevented by glucocorticoids but not by DOC. It is assumed that the glucocorticoids may protect against endotoxin shock by decreasing the liberation of potentially harmful lysosomal enzymes.

In mice, hepatic TPO is lowered by *S. typhimurium* endotoxin, which also prevents the induction of the enzyme by concurrent injection of cortisone. In the intact unlike in the adrenalectomized mouse, the endotoxin induces TKT almost as well as does cortisone.

#### ← Bacteria

*Rapoport et al. G53,334/68:* Pneumococcal infection raised the hepatic TPO-activity in intact, but not in adrenalectomized, mice. Cortisol increased TPO-activity both in control and in pneumococcus-infected mice, but only if administered early after inoculation. Later during the course of infection, some inhibitory factor develops which counteracts the induction of TPO by cortisol.

*Einheber et al. G75,665/70:* In mice infected with *P. berghei*, hexobarbital sleeping time is prolonged. “This may be due to a disturbance in function of hepatocellular smooth endoplasmic reticulum and its associated drug-metabolizing enzymes because phenobarbital treatment, which ordinarily stimulates an increase of the latter, corrects the ‘defect’ in hexobarbital sleeping time.”

*McCarthy et al. G75,511/70:* In rats infected with malaria (*P. berghei*) “the hepatic microsomal metabolism of ethylmorphine, aniline, p-nitroanisole and hexobarbital showed progressive decreases in rates over the 8-day period. The decreases in metabolism were accompanied by progressive increases in hexo-

barbital sleeping time.” The malarial infectoin did not prevent the induction of microsomal enzymes by phenobarbital.

#### ← Bacterial Toxins

*Weissmann & Thomas D35,555/62:* In rabbits, endotoxin shock is associated with the release of hepatic lysosomal acid hydrolases ( $\beta$ -glucuronidase, cathepsin). This effect is prevented by glucocorticoids, but not by DOC. “Thus, glucocorticoids, in a variety of experimental situations, appear to decrease the liberation of potentially harmful enzymes from lysosomes, and may in fact function physiologically to stabilize the boundaries of these subcellular particles.”

*Berry et al. G67,237/66:* *S. typhimurium* endotoxin lowers liver TPO in mice and prevents the induction of the enzyme by concurrent injection of cortisone. It lowers, but does not prevent, substrate induction. Actinomycin D has a similar effect on TPO. In the intact mouse, the endotoxin induces TKT almost as well as does cortisone, but not in the adrenalectomized animal. Actinomycin D, on the other hand, has an effect on this transaminase similar to that on TPO.

## ← IMMUNE REACTIONS

Comparatively little work has been done on the influence of immune reactions upon resistance to nonimmunologic pathogens. In rats with adjuvant arthritis, the hepatic microsomal N-demethylase and NADPH<sub>2</sub>-oxidase enzyme activity, as well as the levels of P-450, are reduced. This implies a diminished capacity for the oxidative metabolism of steroids and drugs.

*Morton & Chatfield G73,681/70:* In rats with adjuvant arthritis, "the liver microsomal N-demethylase and NADPH<sub>2</sub>-oxidase enzyme activity and levels of cytochrome P-450 are greatly reduced. This implies a diminished capacity for the oxidative metabolism of

steroids and foreign compounds in adjuvant arthritic rats which should influence the toxicity and half-life of any administered compound. The ability of the liver to form  $\beta$ -glucuronide conjugates is also reduced."

## ← HEPATIC LESIONS

**Steroids** ←

The role of the liver in the detoxication of steroids is now well established. The first observations along these lines gave somewhat variable results but in ovariectomized rats, hepatic damage induced by CCl<sub>4</sub> appeared to increase sensitivity to threshold amounts of estrone.

More conclusive results were obtained in rats by the demonstration that partial hepatectomy greatly increases their sensitivity to the anesthetic effect of DOC, whereas nephrectomy is virtually ineffective in this respect. It was subsequently demonstrated that such partial hepatectomy also increases the anesthetic effect of many other steroids, including progesterone, pregnanedione, pregnanediol, testosterone, estradiol and even the nonsteroidal folliculoid, stilbestrol. Since this operation does not increase sensitivity to many other anesthetics (e.g., ether, MgCl<sub>2</sub>), it was concluded "that the liver is the site at which all the above mentioned (steroid and stilbene) compounds are normally detoxified."

In immature rabbits, estradiol and progesterone given s.c., are much more effective in causing uterine changes than if administered p.o., presumably because an important portion of the injected steroids is inactivated during its passage through the liver.

In ovariectomized rats, the uterotrophic effect of estradiol is reduced 12 hrs after partial hepatectomy; it increases only later, as hepatic regeneration progresses. Hence, contrary to virtually every other report, it was concluded that the presence of hepatic tissue is essential for the folliculoid effect and that the liver actually activates estradiol. This view has not received confirmation by subsequent investigators.

In orchidectomized rats poisoned with CCl<sub>4</sub>, implantation of testosterone into the spleen fails to increase prostatic weight, presumably because even the severely-damaged liver can detoxicate this steroid.

In rats, an <sup>14</sup>C-marked androstene derivative was eliminated mainly in the feces and to a much lesser extent in the urine. In rats bearing bile-duct fistulas, the major fraction of the isotopic carbon is excreted in the bile, but after choledochus ligation the <sup>14</sup>C is almost quantitatively recovered from the urine. In rats with bile-duct ligation, testosterone prolongs survival and inhibits the body weight loss, but its

effect upon the prostate is diminished. Curiously, estradiol has been claimed to exert inverse effects in all these respects.

In rats, progesterone given i.v. was extensively metabolized within one hour, even after total evisceration (including liver, kidneys and adrenals). Among the recovered metabolic products of progesterone, there were no polar metabolites, similar to the conjugates of glucuronic or sulfuric acid. Some steroids such as desoxycortisone (Cpd. S) produce convulsions instead of the usual anesthesia, when given in large amounts to rats; allegedly partial hepatectomy does not sensitize to this convulsive effect of desoxycortisone. These observations have not yet been confirmed, but it is difficult to interpret them on the basis of the generally accepted view that hepatic insufficiency augments the effects of steroids by diminishing their degradation. Of course it is conceivable that lack of hepatic tissue also interferes with metabolic processes necessary for muscular contraction and thereby compensates for the delay in steroid degradation with respect to the convulsive effect.

In hepatectomized cats, the elimination of endogenous cortisol and corticosterone is greatly delayed, and in totally eviscerated animals it is completely abolished. Perhaps part of the extrahepatic steroid elimination occurs in the intestine.

In rats, spironolactone shortens the half-life of its main metabolite (the dethioacetylated 4,6-dienone) and partial hepatectomy delays the blood clearance of this metabolite. Apparently, spironolactone accelerates its own hepatic metabolism.

In rats, the activity of the hepatic enzymes metabolizing progesterone is decreased within 16 hrs following partial hepatectomy and reaches a minimum on the 4–5th post-operative day.

*Pincus & Martin A 34,939/40:* Following liver damage induced by  $\text{CCl}_4$ , threshold doses of estrone become more efficacious in producing vaginal estrus in ovariectomized rats. Although the results are inconstant and not very pronounced, they suggest "that liver damage by  $\text{CCl}_4$  results in a decreased inactivation of administered estrone."

*Selye A 35,003/41:* First description of the anesthetic effect of steroids. Among those tested in rats, DOC and progesterone were most potent, several testoids and folliculoids showed mild hypnotic activity (often complicated by convulsions), whereas cholesterol, stigmasterol and  $\Delta^4$ -cholestenone were inactive. Partial hepatectomy greatly increased sensitivity to anesthesia induced by DOC, whereas bilateral nephrectomy caused only a slight prolongation of the sleeping time, which may have been due to nonspecific stress.

*Selye A 35,150/41:* Partial hepatectomy sensitizes the rat to the production of anesthesia by DOC, progesterone, testosterone, estradiol, and stilbestrol. "Since this operation does not increase sensitivity to other anesthetics such as ether and magnesium chloride, but is

known to sensitize animals to the action of anesthetics which are detoxified in the liver (e.g., tribromethanol), it appears most probable that the liver is the site at which all the above mentioned compounds are normally detoxified."

*Leblond 82,066/42:* Even 20 mg of pregnanediol i.p. produced only little or no anesthesia in intact young female rats, whereas in partially hepatectomized animals it elicited profound narcosis. "It is concluded, therefore, that pregnanediol is at least partly detoxified by the liver and is probably not the last link of the various compounds that may result from progesterone degradation in the rat."

*Leblond A 55,928/42:* In partially hepatectomized rats, pregnanediol and pregnanedione produce a much more pronounced anesthetic effect than in intact controls. The "detoxification of these substances by the liver is not essentially dependent upon the path of absorption; it is not due to storage in the liver or to excretion in the bile, but is the result of an inactivation by the liver cells."

*Selye A 36,447/42:* The partially hepatectomized immature female rat is particularly

sensitive to the anesthetic effect of various steroids and represents a suitable test object for the detection of this activity.

*György E 86,573/45*: Review of the literature and personal observations on the influence of the diet upon the hepatic detoxication of estrone in the rat.

*Masson & Hoffman B 513/45*: In immature rabbits pretreated with estradiol, progesterone s.c. is much more effective in causing progestational changes in the uterus than if administered p.o. In the partially hepatectomized rabbit, even comparatively small doses of progesterone are active in this respect, "indicating that the liver plays an important role in the inactivation of progesterone in the rabbit." Earlier data on the role of the liver in the inactivation of progesterone are reviewed.

*Roberts & Szego A 49,254/47*: In ovariectomized rats, the uterotrophic effect of estradiol was markedly reduced 12 hrs after partial hepatectomy and thereafter increased to or even above the normal level in proportion to the ensuing liver regeneration. Contrary to earlier reports, it is concluded that the liver is essential for the folliculoid effect, and that hepatic tissue activates rather than inactivates estradiol.

*Grayhack & Scott B 58,923/51*: In orchidectomized rats poisoned with  $\text{CCl}_4$ , implantation of testosterone propionate into the spleen fails to increase prostatic weight, whereas under identical conditions, testosterone propionate implanted s.c. does stimulate the prostate. Apparently, even the severely damaged liver can detoxicate testoids.

*Szego & Roberts B 73,573/53*: In rats, partial hepatectomy diminishes the "estrogenic effect" of estradiol as judged by increased uterine water imbibition. Since various stressors exert a similar effect, this imbibition might have been due to stress but neither hypophysectomy nor adrenalectomy prevent it. "It seems evident that a major portion of this inhibition must be referable to the removal of functional hepatic tissue, which appears to be necessary for estrogenic activity."

*Hyde et al. D 99,140/54*: In rats,  $17\alpha$ -methyl- $\text{C}^{14}$ - $\Delta^5$ -androstene- $3\beta,17\beta$ -diol administered by gavage was mostly eliminated in the feces and, to a lesser extent, in the urine. "Rats with two types of bile fistula excreted the major fraction of administered isotopic carbon in the bile. Almost quantitative recovery of the administered  $\text{C}^{14}$  was obtained in the urine of rats after ligation of the bile ducts."

*Giuliani C 15,153/55*: In rats with bile duct ligation, testosterone prolongs survival and inhibits body weight loss, but its effect upon the prostate is diminished. Estradiol exerts inverse effects in all these respects.

*Berliner & Wiest C 22,807/56*: Progesterone given i.v. is extensively metabolized in one hour by totally eviscerated rats, even if the kidneys and adrenals are also removed. After one hour, 7 compounds could be isolated from the tissues of these animals, although there were no polar metabolites similar to the conjugates with glucuronic or sulfuric acid, and the 7 isolated compounds retained their  $\Delta^4,3$ -ketone configuration.

*Heuser C 54,451/58*: Desoxycortisone (Cpd. S)—like dehydroisoandrosterone—given in large amounts i.p. or p.o. produces no anesthesia but intense convulsions in the rat. Allegedly, "neither adrenalectomy nor partial hepatectomy sensitized the rat to the convulsive actions of Cpd. S."

*Yates et al. C 56,413/58*: In rats, passive venous congestion of the liver, induced surgically, impairs the enzymic reduction of ring A of DOC, cortisol, cortisone, and aldosterone.

*Witzel C 68,395/59*: Review (29 pp., 113 refs.) on steroid anesthesia including chapters on adaptation to steroids, the effect of partial hepatectomy, and the influence of steroid anesthetics upon various types of convulsions.

*Bojesen & Egense G 75,996/60*: In adrenalectomized cats, the elimination of endogenous corticoids (cortisol and corticosterone) is greatly delayed by hepatectomy and totally abolished by evisceration. "A few experiments suggested that the intestine is responsible for the main part of the extrahepatic elimination. In experiments with the perfused isolated hindquarter preparation it was impossible to demonstrate any elimination of corticosteroids in spite of electrical stimulation or the administration of large amounts of insulin."

*Kulcsár-Gergely & Kulcsár C 99,083/60*: In ovariectomized rats, estrone aggravates the hepatic damage produced by  $\text{CCl}_4$ . The activity of endogenous folliculoids (estrus) is increased by hepatic damage, which again shows that these hormones are inactivated by the liver. Presumably, this process of inactivation diminishes the resistance of hepatic tissue to damage.

*Balabanski & Dachev F 68,584/66*: Hepatic cirrhosis produced in rats by  $\text{CCl}_4$  greatly increases the folliculoid effect of an "estrogenic preparation vitestrol." This effect is ascribed to interference with hepatic detoxication.

*Crane et al. H25,068/70:* In rats, the activity of the hepatic enzymes metabolizing progesterone is decreased within 16 hrs following partial hepatectomy, and becomes minimal on the 4—5th postoperative day. "The fraction of the radioactivity present in the several metabolites from incubations of progesterone with liver tissue 7 days following hepatectomy suggests that the ring A reductases appear earlier than the 20 $\alpha$ -steroid reductase."

*Hellman et al. H21,323/70:* In patients with extrahepatic bile duct obstruction owing to compression by carcinoma tissue, the metabolism of <sup>3</sup>H-estradiol is characteristically altered. "The similarity of these changes to those reported in cirrhosis suggests a major role for cholestasis in the causation of the altered estrogen metabolism of cirrhosis."

*Solymsos et al. G70,464/70:* In rats, spironolactone shortens the half-life of its main metabolite, the dethioacetylated 4,6-dienone (metabolite A), which is interconvertible with the 17-hydroxy carboxylic acid derivative (metabolite B). This alteration is only slightly accentuated if the steroid is given chronically, and it wears off within eight days after spironolactone treatment is interrupted. After a test dose of spironolactone or of its metabolites A and B, partial hepatectomy delays the blood clearance of metabolite A. Cycloheximide and SKF 525-A also suppress the blood clearance of metabolite A under these conditions. Presumably "spironolactone influences its own biotransformation and the steroid is also a substrate of the hepatic drug-metabolizing enzymes which are induced by spironolactone itself."

*Soyka et al. H33,315/70:* Partial hepatectomy sensitized only slightly to the anesthetic effect of 5 $\beta$ -pregnane-3 $\alpha$ -ol-20-one, whereas it

greatly prolonged sleeping time following treatment with progesterone and many other steroids. Neither inhibition of hepatic mixed function oxidase activity by SKF 525-A nor its stimulation by 3-MC affected the duration of pregnanolone narcosis and even phenobarbital reduced its length only slightly. These findings, and distribution studies, "suggest that termination of hypnosis is due mainly to redistribution with hepatic metabolism playing a relatively minor role." [Species not mentioned; probably rat (H.S.).]

*Selye PROT. 42214:* In rats, choledochus ligation offered considerable protection against the toxicity of indomethacin and dioxathion, slightly prolonged hexobarbital sleeping time, and failed to affect digitoxin poisoning. Partial hepatectomy had little, if any, effect upon indomethacin, dioxathion and digitoxin poisoning under the prevailing experimental conditions, but considerably prolonged hexobarbital sleeping time. Partial nephrectomy (removal of 80% of the kidney tissue) likewise prolonged hexobarbital sleeping time without significantly influencing indomethacin, dioxathion and digitoxin overdosage. The protective effect of spironolactone against indomethacin, dioxathion and digitoxin remained manifest after most of these surgical interventions. But the protection against indomethacin offered by choledochus ligation could not be further improved by spironolactone, nor was the considerable prolongation by hepatectomy of hexobarbital sleeping time markedly reduced by spironolactone. It must be kept in mind, however, that in these experiments only a single dose of spironolactone was given 5 min after the surgical interventions and 24 hrs before a single dose of the toxicants. These observations can be summarized as shown in Table 126, p. 600.

### **Nonsteroidal Hormones and Hormone-Like Substances ←**

There is some evidence that catecholamines are detoxified in the liver. In the rat, the amount of radioactive norepinephrine accumulating in hepatic tissue is sufficiently large to decrease the total amount of circulating hormone considerably.

In rats, partial hepatectomy facilitates the production of gastric ulcers by insulin. Here probably, excessive hypoglycemia with the resulting strong stress response is the cause of the enhanced effect; other observations suggest, however, that hepatic tissue is involved in the degradation of insulin.

After partial hepatectomy or bile duct ligation, rats become unusually sensitive to the tachycardia and the increase in metabolism produced by excessive amounts of thyroxine. It is assumed that the liver both metabolizes the hormone and eliminates it in the bile, but hepatic inactivation does not appear to play an important role when circulating thyroxine is within physiologic limits.

Table 126. *Influence of various hepatic and renal interventions upon resistance to certain toxicants and upon the catatoxic effect of spironolactone<sup>a</sup>*

<sup>a</sup> All surgical interventions were performed under light ether anesthesia 24 hrs before treatment with the toxicants. The latter were given as follows: indomethacin 5 mg in 0.2 ml water, s.c.; dioxathion 4 mg in 1 ml corn oil, p.o.; hexobarbital 7.5 mg in 1 ml water, i.p.; digitoxin 2 mg in 1 ml water, p.o. Spironolactone (10 mg in 1 ml water, p.o.) was administered once 5 min after surgery. For statistical purposes, the results obtained after choledochus ligature, partial hepatectomy and partial nephrectomy (Series 2—4) were compared with the corresponding readings in intact animals (Series 1) given the same toxicant (without spironolactone). The results obtained with a toxicant alone (A), or following pretreatment with spironolactone (B), were compared with each other, separately in the intact animals and in those subjected to each of the three types of surgical interventions. That is Series 2,3 and 4 were compared with 1, and Series A with B for the corresponding readings obtained with each toxicant. The readings and mortality were listed as follows: indomethacin — intestinal ulcers on day of death, mortality on 6th day; dioxathion — dyskinesia and mortality on 3rd day; hexobarbital — sleeping time immediately after injection of the anesthetic; digitoxin — convulsions and mortality on 4th day. For further details on the technique of tabulation *cf.* p. VIII.

Partial hepatectomy does not appear to have a striking effect upon the toxicity of 5-HT in the rat, and treatment with 5-HTP brings about an increase in the 5-HT content of the brain which is essentially the same in intact and in completely hepatectomized dogs. Yet, both the 5-HT and the 5-hydroxyindole acetic acid (5-HIAA) content of the brain increases in dogs after complete hepatectomy. Thus, the role of the liver in 5-HT metabolism is still not clear.

Hepatic detoxication does not appear to play an important role in the metabolism of **parathyroid hormone**, at least partial hepatectomy fails to affect the soft tissue calcification elicited in rats by **parathyroid extract**.

The pressor effect of **vasopressin** injected into a peripheral vein is greater than if the same amount is injected into the spleen. Hence, it was concluded that vasopressin is detoxified during its passage through the liver.

#### **Catecholamines** ←

*Caskey 20,936/27*: In dogs, ligation of the hepatic artery and portal vein inhibits the rise in muscle temperature normally produced by epinephrine.

*Guerra & Siccardi D69,656/62*: Studies on the catecholamine content of the hepatic residue following partial hepatectomy in the rat confirm earlier literature showing that epinephrine and norepinephrine are detoxified in the liver.

*Eckhardt F 36,030/65*: It has been suggested that the liver is implicated in limiting pressor responses to norepinephrine i.v. In the rat, the amount of radioactive norepinephrine accumulating in the liver is sufficiently large to decrease considerably the total amount of circulating norepinephrine. Methylphenidate slows the rate of norepinephrine disappearance in intact but much less in partially hepatectomized rats.

#### **Insulin** ←

*Selye et al. 58,020/36*: Removal of the median and left lateral lobes of the rat liver produces gastric ulcers only occasionally but these are severe if the animals are treated with small doses of insulin, or if the hepatectomy is combined with adrenalectomy or hypophysectomy. Similarly severe gastric ulcers are produced when the median, left lateral, and right lateral lobes (about 85% of the hepatic tissue) are removed. In all these instances, hypoglycemia is regarded as the cause of gastric erosion.

*Elgee & Williams C430/54*: Review of earlier data, and personal observations on the degradation of insulin by hepatic tissue in vivo and in vitro.

#### **Thyroid Hormones** ←

*Kellaway et al. B14,515/45*: In rats, the activity of thyroxine s.c. was estimated by an increase in pulse rate after partial hepatectomy, thyroidectomy, or bile duct ligation. "It was found (1) that thyroxine activity is greatly

intensified in the absence of the liver; (2) that the liver does not play a significant role when the amount of circulating thyroxine is within physiologic limits; (3) that the liver deals with excess hormone by some process of inactivation and not by simple excretion."

*Grad & Leblond B23,328/48; B49,686/50*: In rats, the increase in oxygen consumption and heart rate induced by thyroxine is raised by partial hepatectomy, bile duct ligation, and especially by the conjoint effect of both interventions. "These results are taken to indicate that the liver excretes and inactivates excess amounts of thyroid hormone."

#### **5-HT** ←

*Garattini et al. D4,913/61*: In rats, partial hepatectomy has no effect upon the toxicity of 5-HT.

*Tyce et al. D23,092/62*: Treatment with 5-HTP brought about an increase in the 5-HT content of the brain, which was essentially the same in intact and in completely hepatectomized dogs.

*Tyce et al. G47,432/67*: The 5-HT and 5-hydroxyindole acetic acid (5-HIAA) content of the brain increases in dogs and rats after complete hepatectomy. The literature on the role of the liver in 5-HT metabolism is reviewed.

#### **Varia** ←

*Selye A36,715/42*: In rats, partial hepatectomy, complete thyroidectomy or bilateral nephrectomy does not prevent the osteitis fibrosa and soft-tissue calcification produced by large doses of **parathyroid extract**. Apparently, the parathyroid hormone does not exert its action through either the thyroid or the kidney, as had previously been postulated by some investigators. Furthermore, hepatic detoxication does not play an important role in the metabolism of parathyroid hormone.

*Møller-Christensen B56,243/51*: In rabbits and cats, a greater increase in blood pressure is obtained by **vasopressin** injected into a peripheral vein than if the same amount is injected into the spleen. It is hence concluded that vasopressin is detoxified by the liver.

**Drugs and Individual Dietary Constituents** ←

In dogs, complete hepatectomy resulted in an increased urinary excretion of 18 amino acids but, to a lesser extent, glucose infusion produced a similar result. Indeed, glycine excretion was more markedly stimulated by glucose than by complete hepatectomy.

The role of hepatic lesions upon barbiturate detoxication has been extensively investigated. In dogs, liver damage produced by prolonged chloroform anesthesia enhances the anesthetic effect of pentobarbital, suggesting inadequate detoxication. Hepatectomy with evisceration prolongs the narcotic effect of hexobarbital in dogs, but after administration of threshold doses recovery is possible. This suggests that extrahepatic tissues also participate in barbiturate clearance. On the other hand, in dogs with an Eck fistula and ligation of both the portal vein and the hepatic artery, thiopental anesthesia was prolonged to such an extent that here extrahepatic detoxication was considered to play a very minor role. This view received further confirmation from the observation that heart-lung-liver preparations of dogs clear thiopental from the blood much more rapidly than heart-lung or heart-lung-kidney preparations.

In mice,  $\text{CCl}_4$ -induced liver damage prolongs thiopental sleeping time.

In rats bearing an Eck fistula, thiopental anesthesia is prolonged, and this barbiturate is degraded in vitro by rat liver slices and mince. Rats with liver cirrhosis produced by  $\text{CCl}_4$  are particularly sensitive to pentobarbital anesthesia. An increase in pentobarbital sleeping time also occurs after partial hepatectomy in the rat, but the effect of thiopental is allegedly not influenced by this operation. A systematic study of 25 barbiturates revealed that in the rat, some are mainly detoxified in the liver (e.g., phenobarbital), others in the kidney (e.g., barbital), still others are about equally detoxified in the liver and kidney (e.g., cyclobarbital) and finally certain barbiturates (e.g., thiopental) appear to be detoxified in other tissues but not to any great extent in liver or kidney.

In rabbits, pentobarbital anesthesia is also prolonged following induction of liver damage by  $\text{CCl}_4$  or elementary yellow phosphorus.

**Carbon tetrachloride** does not markedly interfere with the regeneration of the liver following partial hepatectomy in rats.

Certain **carcinogens** accelerate hepatic regeneration after partial hepatectomy in the rat. The induction of adrenal necrosis by DMBA is greatly increased by dietary production of fatty livers but not by  $\text{CCl}_4$ .

Hepatic lipidosis induced by a **choline**-deficient diet in the rat is not significantly altered by partial hepatectomy, although regeneration of the liver remnant is moderately delayed.

**Digitalis** compounds are also largely detoxified in the liver. Thus, in rats, hepatectomy or poisoning with elementary phosphorus or  $\text{CCl}_4$  increases the lethal effect of acute g-strophanthin overdosage. No more than 10% of a given dose of digitoxin is excreted in the bile of the rat, rabbit, and dog and virtually none is excreted in that of man. Partial hepatectomy greatly increases the digitoxin concentration in the blood and tissues of rats, but has little effect upon it in rabbits and dogs.

Partial hepatectomy reduces digitoxin clearance in the rat approximately in proportion to its aggravating effect upon digitoxin convulsions.

In dogs with an Eck fistula and ligature of the hepatic artery, the clearance of certain dyes, such as BSP, is diminished. After partial hepatectomy, the plasma clearance of BSP, rose bengal, and colloidal radio-gold is immediately decreased, but the excretory and phagocytic capacity of the liver returns to normal within about two months. In rats, a liver bypass — established by ligature of the hepatic artery and deviation of the portal blood into the femoral vein — interferes with BSP clearance much more than does partial hepatectomy or  $\text{CCl}_4$  intoxication.

In rats, partial hepatectomy increases sensitivity to indomethacin, but even after this operation spironalactone has a good protective effect, presumably because its detoxication is also impeded by hepatic insufficiency. The induction of intestinal ulcers by indomethacin can also be prevented by ligature of the common bile duct and, depending upon circumstances (e. g., timing, dosage), the protective effect of diminished biliary secretion or the sensitizing effect of partial hepatectomy may prevail.

The effect of **lathyrogens** (e.g., AAN) upon the skeleton of the rat is greatly enhanced by partial hepatectomy.

The nephrocalcinosis and acute mortality induced by mercury intoxication in the rat are inhibited by choledochus ligature.

It had been claimed that **pentylenetetrazol** given p.o. is highly active in guinea pigs, rats and rabbits, although it must pass through the liver before reaching its target organs, and that after bilateral renal hilus ligature, rats become extremely sensitive to the convulsive effect of this drug. Furthermore, perfusion of pentylenetetrazol through the liver of the frog or cat did not alter its activity. It was concluded that the principal detoxicating organ for pentylenetetrazol is the kidney, not the liver.

However, later observations were diametrically opposed to these findings. It was noted that in cats, the acute toxicity of pentylenetetrazol is not influenced by bilateral nephrectomy, but it is greatly increased following liver damage by yellow phosphorus. In rabbits, the disappearance rate of pentylenetetrazol from the blood and tissues was not influenced by bilateral nephrectomy, but greatly delayed after  $\text{CCl}_4$  poisoning. Still more recent observations suggest that neither partial hepatectomy nor complete nephrectomy increases the resistance of the rat to the convulsive or fatal action of pentylenetetrazol. Hence, it was concluded that neither the liver nor the kidney plays an important role in the detoxication of this drug, although it is readily detoxified by catatoxic steroids.

The **pesticide**, OMPA, is well tolerated by completely hepatectomized rats in doses which kill sham operated controls. Apparently, in the liver this compound normally undergoes biotransformation into a more toxic metabolite. Yet, the comparative resistance of male rats to anticholinesterase phosphorothioates is diminished by partial hepatectomy.

The resistance of the rat to dioxathion is greatly increased by choledochus ligature.

The toxicity of **strychnine** is greatly increased by partial hepatectomy and other interventions which damage the liver. At the same time, the blood clearance of strychnine is delayed. Incubation of strychnine with liver pulp results in the destruction of strychnine as shown by observations made as early as 1931.

{In rabbits in which the liver was “destroyed” by ethylene chlorohydrin, no prolongation of **tribromoethanol** anesthesia was noted. This finding was taken to

mean that the liver plays no important part in the detoxication of this compound. However, in mice and rats, partial hepatectomy greatly prolongs tribromoethanol sleeping time.

The detoxication of **vitamin D** and **DHT** is also dependent upon hepatic factors. Following ligation of the common bile duct, the production of soft tissue calcinosis by DHT is inhibited in the rat. This may be due to insufficient intestinal DHT absorption in the absence of bile, or to an interruption of the enterohepatic circulation. On the other hand, the production of topical calciphylaxis (by vitamin-D<sub>2</sub> p.o. and Fe-Cl<sub>3</sub> s.c.), as well as the associated generalized calcinosis are aggravated by partial hepatectomy in the rat. This aggravation was ascribed to a decrease in the hepatic storage of iron or of vitamin D, but the possible role of deficient hepatic vitamin-D degradation should also be considered. The calcifying arteriosclerosis and atheromatosis produced in rabbits by combined treatment with cholesterol and vitamin-D<sub>2</sub> is aggravated by hepatotoxic amounts of CCl<sub>4</sub>. On the other hand, "hepatectomy" (technique not further characterized) prevents the conversion of vitamin-D<sub>3</sub> to 25-hydroxycholecalciferol. Furthermore perfused liver can hydroxylate vitamin-D<sub>3</sub> through an enzyme which has been identified in liver homogenates. In rats, isolation of the liver from the circulation, almost completely abolishes the conversion of vitamin-D<sub>3</sub> into its biologically active metabolite, 25-hydroxycholecalciferol. It was concluded that the liver is the major if not the only physiologic site of vitamin-D<sub>3</sub> activation. It is noteworthy however that the technique used for the exclusion of the liver from the circulation includes bile duct ligation which — as we have said before — suffices in itself to protect against such vitamin-D derivatives as DHT.

#### **Allylformiate** ←

*Rabes & Tuczek H30,729/68:* In rats, the hepatic necroses produced by allylformiate elicit regenerative phenomena mainly near the periphery of the lobules, whereas after partial hepatectomy the maximum of cell proliferation shifts towards the intermedial and central portions of the liver lobules.

#### **Amino Acid** ←

*Freeman & Svec B64,175/51:* In dogs, the plasma concentration of 18 free amino acids was followed after complete hepatectomy. "a) An increase occurred in the concentration of glycine, histidine, glutamic acid and lysine. b) A decrease occurred in the plasma concentration of methionine, tryptophane, leucine, arginine, and valine. c) There were variable or inconclusive results on the other amino acids studied." Glucose infusion increased the urinary excretion of all 18 amino acids, but a considerable further increase was obtained by complete hepatectomy except for glycine as illustrated on p. 605.

#### **ANIT (α-Naphthylisothiocyanate)** ←

*Bar-Maor & Ungar D41,800/61:* ANIT stimulates mitotic proliferation in the liver of the rat, and this effect is further enhanced by partial hepatectomy.

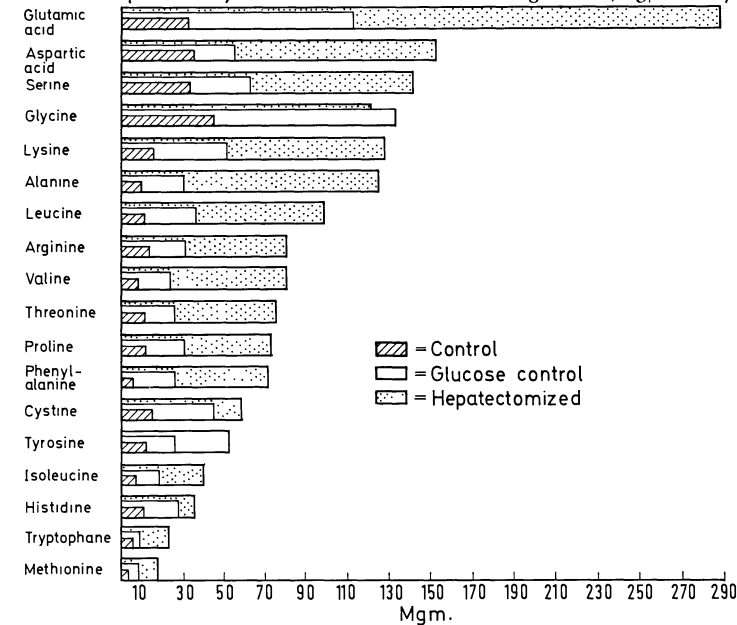

#### **Barbiturates** ←

Dog

*Pratt et al. G72,105/32:* In dogs with an Eck fistula and ligation of the hepatic artery, bromsulphalein's clearance is inhibited, suggesting "that the bromsulphalein injected into the blood is eliminated, specifically, by the liver." Following hepatic damage caused by protracted chloroform anesthesia, the narcotic effect of pentobarbital is greatly prolonged, indicating that the barbiturate is inadequately detoxified when the liver is damaged.

*Martin et al. A48,575/40:* In dogs, hepatectomy with evisceration greatly prolongs the narcotic effect of hexobarbital, but the fact that after administration of threshold doses recovery is possible suggests that extrahepatic tissues also participate in the detoxication of this barbiturate.

Effect of hepatectomy on total amino acids of dog urine (mg/12 hrs.)

Average urinary excretion of amino acids in normal dogs, glucose-infused dogs prior to hepatectomy, and hepatectomized dogs infused with glucose (Freeman & Svec B64,175/51).

*Kelly & Shideman A 49,706/49:* In dogs with Eck fistula, thiopental anesthesia is greatly prolonged. In heart-lung-liver preparations, the plasma levels of thiopental decline much more rapidly than in heart-lung or heart-lung-kidney preparations. The liver is primarily responsible for the detoxication of this barbiturate.

*Meyers & Peoples G 70,570/54:* In dogs, thiopental anesthesia is greatly prolonged following establishment of an Eck fistula with ligation of the portal vein and hepatic artery. "It is believed that tissues other than the liver are quantitatively unimportant in the rapid detoxification of thiopental in the dog."

MOUSE

*Shideman et al. E 60,046/47:* In mice, CCl<sub>4</sub>-induced liver damage prolongs the effect of thiopental. The same is true after subtotal hepatectomy (85—90%) in rats. Diminished blood flow through the liver (Eck fistula) likewise increases the duration of thiopental anesthesia in rats. Thiopental is degraded in vitro by rat liver slices and mince.

RAT

*Cameron & Saram G 72,101/39:* Rats with liver cirrhosis produced by CCl<sub>4</sub> are particularly sensitive to pentobarbital anesthesia.

*Scheifley & Higgins A 48,663/40:* In rats, anesthesia produced by ethyl-o-ethylphenyl-urea or pentobarbital was markedly prolonged by partial hepatectomy. The effect of thiopental was not influenced by this operation.

*Masson & Beland A 72,286/44; B 344/45:* The site of barbiturate detoxication was investigated by comparative studies in bilaterally nephrectomized or partially hepatectomized rats as judged by the prolongation of sleeping time. "From the data obtained with twenty-five compounds, barbiturates can be classified into four groups. Group I: Those mainly detoxified in the kidney (e.g. barbital). Group II: Those mainly detoxified in the liver (e.g., ipral, amytal, nembutal, ortal, phenobarbital, alurate, nostal, seconal, allyl-pental, evipal, thioethamyl, sec. hexyl-ethyl, 1-methyl-allyl-isobutyl, 1-methyl-propylcrotyl and n-allyl-1-methyl-butyl-ethyl barbiturates. Group III: Those approximately equally detoxified in the liver and kidney (e.g., neonal, delvinal, phanodorn, dial). Group IV: Those possibly detoxified in other tissues of the body, but not to any great extent in liver or kidney (pentothal, 1-methyl-allyl-propyl and 1-methyl-allyl-allyl thiobarbiturates)."

*Scheifley A 48,124/46:* In rats, the anesthetic effect of pentobarbital, unlike that of thio-

pental, was greatly prolonged by partial hepatectomy. "These data suggest that the liver is instrumental in protecting against the action of pentobarbital sodium but does not play a significant part in the detoxication of pentothal sodium" (thiopental). Uninephrectomy had no effect upon the production of anesthesia by either of these barbiturates.

*Masson B1,217/46*: In male rats, pretreatment for 6 days with crude pituitary powder s.c. "slightly prolonged the duration of anesthesia with phanodorn, thioethamyl, neonal, delvinal, nostal and amyral, and greatly prolonged (2 to 5 times) with pentothal, secenal, allyl pental, nembutal, evipal, pernoston and sigmodal." There was no difference between the pretreated and control rats as regards the anesthetic effect of phenobarbital, probarbital, barbital, aprobarbital, allobarbital and trichloroacetaldehyde. "The action of pituitary preparations is not specific but can also be obtained with preparations from various organs and with foreign proteins." Hepatic damage is considered to be a likely cause of the prolongation of anesthesia under these conditions.

*Walker & Parry B46,639/49*: In rats, partial hepatectomy increases the anesthetic effect of chloral hydrate, tribromoethanol, phenobarbital, and thiopental. Tests at various time intervals after the operation lead to the conclusion that "there is no apparent correlation between the regeneration of the liver by weight and its power to detoxicate these drugs."

*Butler et al. G76,364/52*: In rats, "partial hepatectomy has such a large effect on the rate of disappearance of mephobarbital and on the rate of production of phenobarbital from mephobarbital as to suggest that the liver is the principal, if not the only, site of the demethylation of mephobarbital."

*Sandberg G71,886/53*: Studies on partially hepatectomized or completely nephrectomized rats suggest that "for 5,5-diallyl-barbituric acid and its 1-(N,N-diethylcarbonylmethyl) derivative the kidneys participate as much as the liver in the detoxication. 1-benzyl-5, 5-diallyl-barbituric acid is destroyed mainly in the liver. 1-carbomethoxymethyl-5,5-diallyl-barbiturates are probably hydrolyzed to the corresponding carbonic acid, 1-carboxymethyl-5,5-diallyl-barbituric acid."

*Robillard et al. G67,325/54*: Adult males are more resistant than females to pentobarbital anesthesia. Castration decreases the resistance in males. Testosterone raises pentobarbital resistance to the normal male level in both

male and female castrates, whereas estradiol and progesterone prolong anesthesia in castrates of both sexes. [The hormones were administered as pellets 15 days before the test, but the amounts are not stated (H.S.).] Partial hepatectomy prolongs pentobarbital anesthesia and accentuates the differences induced by the various interventions just mentioned, without causing qualitative changes in the outcome.

*Fouts et al. G68,041/61*: Partially hepatectomized rats are deficient in the ability to oxidize the side-chain of hexobarbital or the ring-sulfur of chlorpromazine, and to reduce the nitro-group of p-nitrobenzoic acid. Full recovery of these activities occurs only after complete regeneration of the hepatic mass (about ten days after operation). O-dealkylation of codeine is impeded only during the first few days when the regeneration is most active. Sham-hepatectomy (with exteriorization of the liver) has a similar, though much less, pronounced effect.

*Dingell & Heimberg G72,112/68*: In rats, pretreatment with  $\text{CCl}_4$  prolongs hexobarbital sleeping time and interferes with the metabolism of the barbiturate by hepatic microsomes in vivo and in vitro.

*Selye PROT. 42214*: In rats, choledochus ligation offered considerable protection against the toxicity of indomethacin and dioxathion, slightly prolonged hexobarbital sleeping time, and failed to affect digitoxin poisoning. Partial hepatectomy had little, if any, effect upon indomethacin, dioxathion and digitoxin poisoning under the prevailing experimental conditions, but considerably prolonged hexobarbital sleeping time. Partial nephrectomy (removal of 80% of the kidney tissue) likewise prolonged hexobarbital sleeping time without significantly influencing indomethacin, dioxathion and digitoxin overdosage. The protective effect of spironolactone against indomethacin, dioxathion and digitoxin remained manifest after most of these surgical interventions. But the protection against indomethacin offered by choledochus ligation could not be further improved by spironolactone, nor was the considerable prolongation by hepatectomy of hexobarbital sleeping time markedly reduced by spironolactone. It must be kept in mind, however, that in these experiments only a single dose of spironolactone was given 5 min after the surgical interventions and 24 hrs before a single dose of the toxicants, cf. Table 126, p. 600.

#### RABBIT

*Pratt G71,897/33*: In rabbits, pentobarbital anesthesia is prolonged following the induction

of liver damage by  $\text{CCl}_4$  or elementary phosphorus.

*McLuen & Fouts E99,285/61*: In rabbits, obstructive jaundice affects the hepatic microsomal metabolism of hexobarbital in rough proportion to the degree of histologically observable cell damage.

#### VARIA

*Richards & Appel A48,718/41*: Review (13 pp., 44 refs.) on "The Barbiturates and the Liver." Special attention is given to observations on the effect of hypolipotropic diets,  $\text{CCl}_4$  and partial hepatectomy upon barbiturate detoxication.

*Richards & Taylor H19,235/56*: Review on barbiturates with a special section on the role of the liver in their detoxication. (Effect of hepatectomy, hepatotoxic drugs, liver disease).

#### Bilirubin ←

*Weinbren & Billing G76,309/56*: In rats, 24 hrs after partial hepatectomy, the bilirubin excretory capacity does not increase as rapidly as the relative weight of the regenerating liver, but thereafter the excretory capacity tends to increase with the weight rise.

#### n-Butylamine ←

*Merli & Gandini F32,684/64*: n-Butylamine produces a mixture of neuro and osteolathyrisms in the rat. Hepatectomy, performed 7 days before initiation of the n-butylamine treatment, actually delayed the onset of the lathyric manifestations, perhaps as a consequence of overcompensating hepatic regenerative phenomena. [These findings are contrasted with our observation of an increase in the severity of APN-induced lathyrisms by partial hepatectomy, without commenting upon the fact that, in our experiments, the operation was performed concurrently with the initiation of APN-treatment, that is, before significant hepatic regeneration could have occurred (H.S.).]

#### Carbon Tetrachloride ←

*Costa & Smorlesi E34,570/51*: In rats, hepatic cirrhosis induced by  $\text{CCl}_4$  is favorably influenced by partial hepatectomy.

*Kaufmann E60,536/53*: In rats, liver regeneration following partial hepatectomy occurs normally after hepatic damage induced by  $\text{CCl}_4$ . Earlier claims that, under these

conditions, partial hepatectomy actually causes remission in the  $\text{CCl}_4$ -induced sclerosis could not be fully confirmed.

*Novelli & Mor D36,206/62*: In rats, the regeneration of mitochondria in hepatocytes after partial hepatectomy is disturbed by treatment with small doses of  $\text{CCl}_4$ .

*McLean et al. H18,569/69*: In rats, simultaneous treatment with phenobarbital accelerates and aggravates the production of hepatic cirrhosis by  $\text{CCl}_4$ . This aggravation may depend upon an activation of  $\text{CCl}_4$  toxicity by the induction of hepatic microsomal enzymes but the hepatic growth stimulating effect of phenobarbital could also be involved.

#### Carcinogens ←

*Gershbein G71,667/58*: In rats, liver regeneration following partial hepatectomy was greatly accelerated by treatment with various carcinogens.

*Brody G71,680/60*: In rats, the immediate and prolonged effect of p-dimethylaminoazobenzene (DAB) on the regeneration of the liver after partial hepatectomy has been studied.

*von der Decken & Hultin G68,039/60*: Observations on the induction of microsomal enzymes by 3-methylcholanthrene in the liver of the rat as affected by partial hepatectomy.

*Tanaka & Dao G34,593/65*: In rats, the induction of adrenal necrosis by DMBA is greatly increased by the dietary production of fatty livers but not by  $\text{CCl}_4$ .

*Hughes C74,311/70*: In rats subjected to a first or a second partial hepatectomy, the mitotic responses are essentially similar in magnitude and time with a mitotic peak 28 hrs postoperatively. In rats fed 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB) or 2-methyl-4-dimethylaminoazobenzene (2-MeDAB), partial hepatectomy elicits a similar mitotic response if the pretreatment is of short duration. However, following more prolonged feeding with the above agents, the mitotic peak may be delayed up to 60 hrs postoperatively. This delayed mitotic responsiveness may play a part in pre-neoplasia.

#### Chloral Hydrate ←

*Walker & Parry B46,639/49*: In rats, partial hepatectomy increases the anesthetic effect of chloral hydrate, tribromoethanol, phenobarbital and thiopental. Tests at various time intervals after the operation lead to the conclusion that "there is no apparent correla-

tion between the regeneration of the liver by weight and its power to detoxicate these drugs."

#### **Chloramphenicol** ←

*Firkin & Linnane H 31,607/70*: In rats, the toxicity of chloramphenicol is greatly augmented by partial hepatectomy.

#### **Cholesterol** ←

*Olivecrona & Fax G 74,083/70*: In rats, the disappearance from the circulation of fatty acid labeled chylomicra is retarded by partial hepatectomy. When chylomicra labeled in vitro with cholesteryl palmitate were injected, about 80% of the radioactivity was in the liver within an hour in both intact and partially hepatectomized rats.

#### **Choline** ←

*Saint Omer & Mincione D 53,460/60*: In rats, partial hepatectomy does not significantly change hepatic lipidosis on a choline deficient diet but regeneration of the liver remnant is inhibited during the first 72 hrs after the operation.

#### **Cyclophosphamide** ←

*Brock & Hohorst G 71,533/62*: Cyclophosphamide has no cytotoxic effect upon Yoshida sarcoma cells in vitro, but is rapidly transformed into an active compound in mice, rats and dogs in vivo. The active form is demonstrable in the blood and urine by bioassay if added to tumor cells in vitro. In completely hepatectomized rats, only a little fraction of cyclophosphamide is thus activated. However, activation can be demonstrated in vitro by incubation with liver slices. Pretreatment of rats with SKF 525-A inhibits in vivo activation which presumably takes place in hepatic microsomes.

#### **Digitalis** ←

*Farah & Smuskowicz A 49,134/49*: In rats, total hepatectomy with evisceration or poisoning with elementary phosphorus or  $\text{CCl}_4$  increases the lethal effect of acute g-strophanthin-overdosage. "This reduction is due to the reduced excretion of g-strophanthin by the liver and to an increase in the sensitivity of the rat heart to g-strophanthin."

*St. George et al. G 71,843/52*: No more than 10% of a given dose of digitoxin is excreted in the bile of the rat, rabbit and dog, whereas none could be detected in the bile of two humans. Partial hepatectomy greatly increases the digitoxin concentration in the blood and tissues of rats, but has comparatively little effect upon digitoxin clearance in rabbits, and virtually none in dogs.

*Gibson & Becker E 65,709/67*: In mice, "hypoexcretory states" were produced by penile ligation, bile duct ligation or drugs (phenylisothiocyanate,  $\alpha$ -naphthylisothiocyanate) which reduce bile flow. "Intraperitoneal administration of ouabain to mice with no or diminished bile flow resulted in enhanced mortality rates. Digoxin and digitoxin effected enhanced lethality in anuric mice. Lanatoside-C was not more toxic to hypoexcretory mice. The use of hypoexcretory mice in toxicologic evaluations of pharmacologic agents is suggested."

*Greenberger et al. H 13,503/69*: In rats and guinea pigs, the absorption of six tritium-labeled cardiac glycosides was studied, using isolated intestinal loops in vivo and everted duodenal and jejunal gut sacs in vitro. The nonpolar glycosides (digitoxin, digoxin and proscillaridin) were more readily absorbed than the polar glycosides (ouabain, dihydroouabain and convallatoxin). Bile duct ligation did not affect the absorption of digitoxin from isolated intestinal loops in rats. Furthermore, "the transport of digitoxin was not inhibited by another cardiac glycoside, digoxin, suggesting that there are no specific transport sites that allow for competition between glycosides. These observations indicate that digitoxin is absorbed by a passive (nonsaturable) transport process."

*Solymoss et al. G 70,463/70; G 70,461/70*: In rats, pretreatment with spironolactone, norbolethone, or ethylestrenol accelerated the plasma clearance of digitoxin, in proportion to the in vivo protective effect of these catatonic steroids. Partial hepatectomy reduces digitoxin clearance. The effect of spironolactone is suppressed by SKF 525-A and cycloheximide.

*Solymoss G 70,484/70*: In rats, the plasma clearance of digitoxin is accelerated by spironolactone, norbolethone, and ethylestrenol in doses that protect against the toxicity of the alkaloid in vivo. On the other hand, partial hepatectomy reduces digitoxin plasma clearance and increases the severity of the convulsions. The protective action of the steroids is suppressed by SKF 525-A and cycloheximide.

*Selye PROT. 42214*: In rats, choledochus ligature offered considerable protection against the toxicity of indomethacin and dioxathion, slightly prolonged hexobarbital sleeping time, and failed to affect digitoxin poisoning. Partial hepatectomy had little, if any, effect upon indomethacin, dioxathion and digitoxin poisoning under the prevailing experimental conditions, but considerably prolonged hexobarbital sleeping time. Partial nephrectomy (removal of 80% of the kidney tissue) likewise prolonged hexobarbital sleeping time without significantly influencing indomethacin, dioxathion and digitoxin overdosage. The protective effect of spironolactone against indomethacin, dioxathion and digitoxin remained manifest after most of these surgical interventions. But the protection against indomethacin offered by choledochus ligature could not be further improved by spironolactone, nor was the considerable prolongation by hepatectomy of hexobarbital sleeping time markedly reduced by spironolactone. It must be kept in mind, however, that in these experiments only a single dose of spironolactone was given 5 min after the surgical interventions and 24 hrs before a single dose of the toxicants, *cf.* Table 126, p. 600.

#### Dyes ←

*Pratt et al. G72,105/32*: In dogs with an Eck fistula and ligature of the hepatic artery, bromsulphalein clearance is inhibited, suggesting "that the bromsulphalein injected into the blood is eliminated, specifically, by the liver."

*Cherrick et al. E98,251/60*: Indocyanine green is rapidly and completely bound to plasma protein and excreted in the bile in unconjugated form. It is not cleared by extrahepatic mechanisms in detectable amounts. Its plasma clearance is similar to that of BSP in controls and patients with liver lesions.

*Eckhardt & Armstrong F79,670/67*: In rats, a liver bypass can be established by ligature of the hepatic artery combined with a deviation of the portal vein into the femoral vein through a cannula. Under these conditions, bromsulphalein (BSP) disappears much more slowly from the plasma than after partial hepatectomy or intoxication with  $\text{CCl}_4$ .

*Aronsen et al. H22,143/69*: In dogs, immediately after partial hepatectomy, the plasma clearance of bromsulphalein  $^{131}\text{I}$ , rose bengal, and colloidal radio-gold is decreased. The excretory and phagocytic capacity of the liver returned to normal within 6—8 weeks.

#### Ethyl-o-Ethylphenylurea ←

*Scheifley & Higgins A48,663/40*: In rats, anesthesia produced by ethyl-o-ethylphenylurea or pentobarbital was markedly prolonged by partial hepatectomy. The effect of thiopental was not influenced by this operation.

#### Hexadimethrine ←

*Selye et al. D25,745/63*: Partial hepatectomy does not significantly influence the nephrocalcinosis produced by hexadimethrine in the rat.

#### Indomethacin ←

*Selye G60,058/69*: In the rat, partial hepatectomy increases sensitivity to toxic doses of indomethacin. Comparatively small doses of spironolactone readily inhibit this form of indomethacin intoxication even in the presence of surgically induced hepatic insufficiency. "These results are compatible with the assumption that both indomethacin and spironolactone are subject to hepatic detoxification, and hence, their respective pathogenic and prophylactic actions are enhanced after extensive resection of liver tissue."

*Brodie et al. G67,797/71*: In rats given a single injection of indomethacin s.c., starvation during the following 24 hrs completely prevented intestinal ulcer formation, whereas starvation for 24 hrs on the second, third or second + third day had no such effect. Intestinal ulcers could also be prevented by ligature of the common bile duct. When segments of small intestine were isolated by Thiry-Vella loops, ulceration was prevented in the loops but not in the adjacent anastomosed intestine.

*Selye PROT. 42214*: In rats, choledochus ligature offered considerable protection against the toxicity of indomethacin and dioxathion, slightly prolonged hexobarbital sleeping time, and failed to affect digitoxin poisoning. Partial hepatectomy had little, if any, effect upon indomethacin, dioxathion and digitoxin poisoning under the prevailing experimental conditions, but considerably prolonged hexobarbital sleeping time. Partial nephrectomy (removal of 80% of the kidney tissue) likewise prolonged hexobarbital sleeping time without significantly influencing indomethacin, dioxathion and digitoxin overdosage. The protective effect of spironolactone against indomethacin, dioxathion and digitoxin remained manifest after most of these surgical interventions. But the protection against indomethacin offered by choledochus ligature could not be further improved by spiro-

nalactone, nor was the considerable prolongation by hepatectomy of hexobarbital sleeping time markedly reduced by spironolactone. It must be kept in mind, however, that in these experiments only a single dose of spironolactone was given 5 min after the surgical interventions and 24 hrs before a single dose of the toxicants, *cf.* Table 126, p. 600.

#### **Lathyrogens** ←

*Selye C25,013/57; C31,369/57:* In rats, extensive partial hepatectomy greatly increases the effect of AAN upon the bones.

*Glickman et al. E24,104/63:* In rats, the dental changes produced by AAN are aggravated following partial hepatectomy and thyroidectomy, whereas they are reduced by ACTH or almost completely abolished by thyroxine.

#### **Lead** ←

*Selye et al. D25,657/63:* Topical calcergy produced by local trauma after i.v. injection of lead acetate in the rat is uninfluenced by partial hepatectomy, but inhibited by hypophysectomy or bilateral nephrectomy. Splenectomy itself does not influence this response, but when combined with partial hepatectomy, the animals die within a few hours after the lead-acetate injection, before calcification could develop.

#### **Lidocaine** ←

*Aldrete et al. G78,399/70:* In dogs, the disappearance of i.v. injected lidocaine from the blood was retarded by hepatectomy. Similar observations were made in hepatectomized patients with liver transplants in the stage of rejection.

#### **Mercury** ←

*Selye PROT. 30550:* In rats in which the bile duct had been ligated prior to the injection of  $\text{HgCl}_2$  i.v., the usual nephrocalcinosis and mortality failed to occur. The mechanism of this protective effect is not clear but it may be related to the interruption of the enterohepatic circulation, *cf.* Fig. 23.

#### **Nicotine** ←

*Biebl et al. 44,898/32:* Hepatectomy sensitizes the dog to the pressor effect of nicotine. Perfusal of nicotine through a canine heart-lung preparation inactivates the compound rapidly. In frogs, both complete and partial

hepatectomy diminish the maximum tolerable amount of nicotine. It is concluded that nicotine is destroyed by the liver.

#### **Octamethyl Pyrophosphamide (OMPA)** ← *cf. Pesticides*

##### **Pentylene-tetrazol** ←

*Voss A47,860/26:* In guinea pigs, rats and rabbits, pentylene-tetrazol p.o. is highly active, although it must pass through the liver before reaching its target organs. On the other hand, following bilateral ligation of the renal hilus rats become extremely sensitive to the production of convulsions by pentylene-tetrazol. It is concluded that the principal detoxicating organ for pentylene-tetrazol is the kidney, whereas the liver plays no important role in this respect.

*Ridder A47,894/27:* Perfusion of pentylene-tetrazol through the liver of the frog or cat does not alter its activity. "The surviving liver of cold- or warm-blooded animals is hence unable to destroy Cardiazol."

*Dille & Seeberg 84,277/41:* In cats, the acute toxicity of pentylene-tetrazol is not influenced by bilateral nephrectomy, whereas liver damage induced by yellow phosphorus greatly increases sensitivity to pentylene-tetrazol.

*Tatum & Kozelka 81,376/41:* In rabbits, the disappearance rate of pentylene-tetrazol from blood, liver and muscle was not influenced by bilateral nephrectomy, but it was greatly delayed by  $\text{CCl}_4$  poisoning which caused a 50% decrease in the functional capacity of the liver as judged by the bromsulphalein test. It is concluded that, contrary to earlier reports, the liver plays an important part in the detoxication of pentylene-tetrazol whereas the kidney does not.

*Fournier & Selye 81,980/42:* In the rat, partial hepatectomy does not alter sensitivity to pentylene-tetrazol. Apparently, hepatic detoxication does not significantly alter resistance to this compound.

*Fournier 84,151/43:* Partial hepatectomy or complete nephrectomy does not increase the resistance of the rat to the convulsive or fatal effect of pentylene-tetrazol. It is concluded that neither the liver nor the kidney plays an important role in the detoxication of this drug.

##### **Peptone** ←

*deNicola 43,101/30:* Review of the literature, and personal observations on the prevention of peptone shock (with the characteristic leuko-

**Fig. 23. Prevention of mercury poisoning by choledochus ligation.** A + C: Kidney of rat given  $\text{HgCl}_2$  shows heavy cortical calcification. B + D: Similarly-treated rat in which the choledochus had been ligated. Here, calcification is prevented (von Kóssa: A and B, X 9; C and D, X 32)

penia, hypotension and incoagulability of the blood) in dogs. Evidently, these changes are not the direct effects of peptone, but of some substance liberated by the liver.

#### **Pesticides** ←

*Cheng G71,450/51*: Completely hepatectomized rats survived the injection of a dose of OMPA which killed sham-operated controls.

*Murphy & DuBois D28,546/58*: The activity of the microsomal enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion, or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). Yet, in vivo, adult males are more resistant to EPN than females, perhaps because the accelerated formation of toxic oxidation products is overcompensated by a more efficient detoxication of the latter. The low enzyme activity of female liver is enhanced by pretreatment with testosterone in vivo, whereas the high activity of male liver is diminished by previous castration, partial hepatectomy, or treatment with progesterone or diethylstilbestrol. SKF 525-A inhibits, whereas pretreatment with carcinogens or a protein-deficient diet enhances the activity of the thiophosphate-oxidizing enzyme.

*DuBois & Puchala D43,878/61*: Male rats are much more resistant than females to various anticholinesterase phosphorothioates. Male mice and guinea pigs are not particularly resistant to DMP. Partial hepatectomy and/or castration abolishes the comparative resistance of the male rat, whereas testosterone restores resistance in hepatectomized or orchidectomized rats. It is concluded "that androgens govern the development of this system."

*Selye PROT. 42214*: In rats, choledochus ligature offered considerable protection against the toxicity of dioxathion. Partial hepatectomy or partial nephrectomy (removal of 80% of the kidney tissue) had little, if any, effect upon experimental conditions. The protective effect of spironolactone against dioxathion remained manifest after these surgical interventions, *cf.* Table 126, p. 600.

#### **Phalloidin** ←

*Tuchweber et al. (in preparation)*: In rats, mortality and peliosis-like hemorrhagic necrosis of the liver induced by phalloidin i.p. are prevented by partial hepatectomy performed 1 to 5 days prior to this treatment.

#### **Phosphorothioates** ← *cf.* **Pesticides**

#### **Phlogogens** ←

*Novelli & Zinnari H8,990/68*: In rats, collagen formation in carrageenin granulomas is inhibited by partial hepatectomy.

#### **RES-Blockers** ←

*Aronsen et al. H22,143/69*: In dogs, immediately after partial hepatectomy, the plasma clearance of bromsulphalein <sup>131</sup>I, rose bengal, and colloidal radio-gold is decreased. The excretory and phagocytic capacity of the liver returned to normal within 6—8 weeks.

*Gans et al. G71,042/69*: Thrombin rapidly disappears from the blood of intact, but not of completely hepatectomized heparinized dogs. Thrombin clearance appears to depend mainly upon phagocytosis by the Kupffer cells.

#### **Silica** ←

*Novelli et al. H24,185/69*: In rats, collagen formation in pulmonary silicotic granulomas is inhibited by partial hepatectomy during liver regeneration, perhaps as a consequence of diminished collagen synthesis.

#### **Strychnine** ←

*Priestley et al. 9,158/31*: The following six methods have been tested for the study of hepatic detoxication using strychnine as a substrate.

1. Comparison of dogs with Eck fistula and normal dogs.
2. Comparison of the effectiveness of strychnine injected into the peripheral vascular system, and injection into the portal vein.
3. The ability of incubated pulp of liver to destroy strychnine.
4. Estimation of strychnine introduced into the circulation of a heart-lung-liver perfusion, compared with that introduced into a heart-lung-limb preparation.
5. Susceptibility of normal and dehepatized dogs to strychnine.
6. Rate of disappearance of strychnine from the blood stream of normal and dehepatized dogs.

Among these six methods "the study of the dehepatized dog and the perfused liver appears to have yielded the most conclusive and accurate data. The exclusive use of any single method is not recommended. However, by the combined use of the analytic and the synthetic methods (organism without a liver and

surviving liver without the organism), respectively, definite evidence concerning the liver as a detoxicating organ can be obtained." The canine liver possesses a highly specialized ability to immediately arrest and subsequently destroy strychnine.

#### **Tetrahydronaphthylamine ←**

*Borchardt 23,683/28:* In cats, neither thyro-parathyroidectomy nor adrenalectomy prevents the production of fever by tetrahydronaphthylamine, whereas denervation of the liver inhibits it almost completely.

#### **Tribromoethanol ←**

*Eichholtz A27,018/27:* In rabbits, "destruction of the liver" by ethylene chlorohydrin does not significantly affect the length of tribromoethanol anesthesia. After bilateral nephrectomy, sleeping time is somewhat prolonged but still variable. On the other hand, bilateral adrenalectomy prolongs the sleeping time very considerably.

*Waelch & Selye 3,972/31:* First description of a technique for the removal of about 70% of the liver in mice which lends itself for the detection of drugs that are detoxified in the liver. Thus, in such partial hepatectomized mice, tribromoethanol (Avertin) causes much more prolonged anesthesia than in intact controls, whereas magnesium anesthesia is not significantly affected by this hepatic insufficiency; presumably because tribromoethanol is, whereas  $MgCl_2$  is not detoxified by the liver.

*Walker & Parry B46,639/49:* In rats, partial hepatectomy increases the anesthetic effect of chloral hydrate, tribromoethanol, phenobarbital, and thiopental. Tests at various time intervals after the operation lead to the conclusion that "there is no apparent correlation between the regeneration of the liver by weight and its power to detoxicate these drugs."

#### **Urethan ←**

*Chernozemski & Warwick H33,929/70:* In female mice, hepatic tumors are much more rarely induced by urethan than in males. Partial hepatectomy greatly increases the hepatocarcinogenic effect of urethan.

#### **Vitamin D, DHT ←**

*Selye C27,736/57:* In rats pretreated with DHT, the pressure building up in the renal pelvis after ureter ligation causes calcification of the renal papilla; after choledochus ligation, hepatic calcification is not observed, although small necrotic islets are formed in the liver parenchyme. "Apparently, necrotic tissue does not necessarily calcify even in the DHT over-

dosed animal." [The effect of bile duct ligation upon DHT-induced extrahepatic calcinosis is not described (H.S.).]

*Rosenfeld et al. G55,854/67; G67,785/67:* Partially hepatectomized rats given vitamin- $D_2$  (Calciferol) p.o. and  $FeCl_3$  s.c. developed calciphylaxis at the iron injection site, as well as generalized calcinosis, of greater intensity than intact animals given the same combined treatment, or than hepatectomized rats given Calciferol without iron. The aggravating effect of partial hepatectomy is ascribed to a decrease in the storage of iron which, consequently, floods the organism and challenges for calciphylaxis. [The possible role of hepatic vitamin-D detoxication has not been considered (H.S.).]

*Rosenfeldová et al. G55,855/67:* In rats given vitamin- $D_2$  (Calciferol) at the dose of 7.5 mg in 0.5 ml oil [route of administration not stated (H.S.)], 48 hrs after partial hepatectomy, mortality was significantly greater than in sham-operated rats given the same amount of vitamin- $D_2$ . Additional treatment with  $FeCl_3$  s.c., in order to produce calciphylaxis, caused a further increase of the mortality rate, particularly after partial hepatectomy. It is concluded that "the liver by storing calciferol, protects the organism against its toxic effects."

*Hass et al. H19,697/69:* Under standard conditions, rabbits develop particularly severe calcifying arteriosclerosis and atheromatosis when given combined treatment with cholesterol + vitamin- $D_2$  p.o. The vascular damage is further aggravated by the production of hepatic damage with  $CCl_4$ .

*DeLuca H17,327/69:* Brief mention of unpublished experiments indicating that "hepatectomy" prevents the conversion of vitamin- $D_3$  to 25-hydroxycholecalciferol. In addition, perfused liver can hydroxylate vitamin- $D_3$ . The enzyme for the 25 hydroxylation has been identified in liver homogenates.

*Ponchon et al. H18,243/69:* In rats, isolation of the liver from the circulation (portocaval shunt + hepatic artery ligation and bile duct ligation) "eliminates almost completely their ability to convert [1,2]- $H_3$  vitamin  $D_3$  into its biologically active metabolite, 25-hydroxycholecalciferol, as well as certain other metabolites. It is concluded that the liver is the major if not the only physiologic site of hydroxylation of vitamin  $D_3$  (cholecalciferol) into 25-hydroxycholecalciferol."

#### **W-1372 ←**

*Selye & Lefebvre G79,005/71:* "Partial hepatectomy increases the intoxication (hepa-

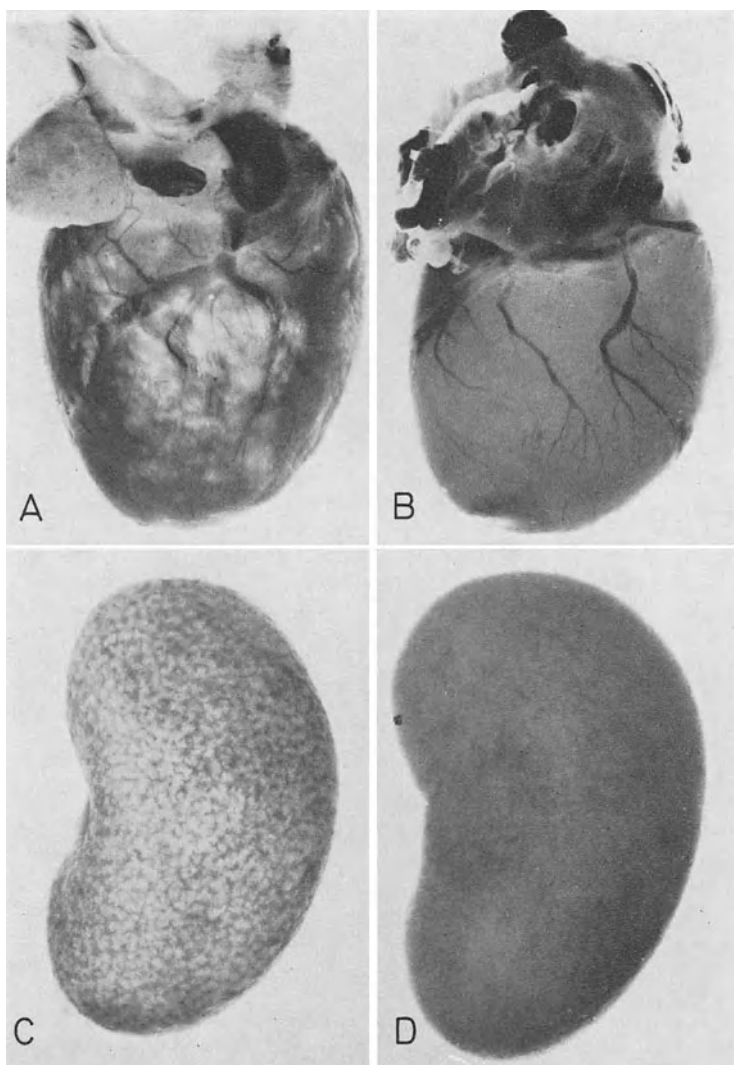

Fig. 24. **Protection against DHT intoxication by choledochus ligation.** A + C: Heavily calcified heart and kidney of rat treated with  $\text{HgCl}_2$ . B + D: Corresponding organs of similarly-treated rat in which the choledochus had been ligated

tic steatosis and necrosis) produced by W-1372. Catatoxic steroids (PCN, spironolactone) inhibit, whereas glucocorticoids (prednisolone acetate, triamcinolone) aggravate, these effects."

**Varia ←**

*Selye G70,480/71:* In rats, complete occlusion of the choledochus diminished resistance

to hexobarbital, progesterone and zoxazolamine but offered considerable protection against intoxication with indomethacin and the acute tissue calcinosis elicited by DHT. The infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil was also prevented but in view of the high mortality this latter finding is difficult to interpret.

Fig. 25. Prevention of DHT intoxication by choledochus ligature. A: Femur of rat given toxic doses of DHT. Intense fibrosis, bone absorption and partial necrosis of bone marrow. B: Similarly-treated rat in which the choledochus was ligated before DHT administration. Essentially normal bone structure

### Complex Diets ←

In rats, the hepatic necrosis produced by a diet containing yeast as the sole source of protein is greatly accelerated by partial hepatectomy.

In mice, starvation inhibits hepatic regeneration after partial hepatectomy.

*Aterman D15,536/61*: In male weanling rats, the hepatic necrosis induced by feeding a diet containing yeast as the sole source of protein is greatly accelerated by partial hepatectomy or treatment with STH.

*Vilchez et al. H15,524/68*: In mice, a first mitotic wave occurs in the liver 40—48 hrs after partial hepatectomy. Mitotic counts and DNA content indicate that starvation produces a significant decrease in the number of cells

undergoing mitosis, and a parallel reduction in DNA.

*Oliverona & Fex G74,083/70*: In rats, the disappearance from the circulation of fatty acid labeled chylomicra is retarded by partial hepatectomy. When chylomicra labeled in vitro with cholesteryl palmitate were injected, about 80% of the radioactivity was in the liver within an hour, in both intact and partially hepatectomized rats.

### Hepatic Changes ←

A considerable amount of work has been done upon hepatic regeneration and other changes in the liver remnant after partial hepatectomy. It is not within the scope of this volume to discuss the pertinent literature in detail. Suffice it to say that during the first 24 hrs after operation, hepatic steatosis occurs and its intensity

is increased by hemorrhage, withdrawal of drinking water, intravenous injection of NaCl, and other stressor agents. The fat content tends to return to normal within 3 to 4 days. Mitotic proliferation in the liver remnant does not begin immediately after partial hepatectomy but only after a latency period of several hours and it tends to reach a maximum after 48 hrs. In the regenerating rat liver there is a marked proliferation of the endoplasmic reticulum. The capacity of the liver to regenerate is maintained in rats even after 12 successive partial hepatectomies performed within one year. In rats subjected to a first or a second partial hepatectomy, the mitotic responses are essentially similar in magnitude and time, with a mitotic peak at about 28 hrs postoperatively.

In rats, choledochus ligature inhibits the growth of liver cells in autotransplanted hepatic segments, but hepatic regeneration after partial hepatectomy is not diminished by simultaneous choledochus ligature. The claim that in rats, liver regeneration after partial hepatectomy is accelerated by hepatic extracts requires confirmation.

*Mann et al. 712/31:* In dogs with an Eck fistula, partial hepatectomy failed to stimulate regeneration in the remnant. Such regenerative phenomena were also inhibited by  $\text{CCl}_4$ , or by ligation of the common bile duct.

*Cameron A 48,168/35:* In rats, choledochus ligature inhibits the growth of liver cells in autotransplanted small hepatic segments, but leaves the bile ducts unaffected.

*Selye et al. 32,783/35:* Following partial hepatectomy, fatty degeneration of the liver developed within the first 24 hrs after the operation. The reaction was increased by hemorrhage, withdrawal of drinking water, or intravenous injection of NaCl.

*Collip et al. 36,231/35:* Following partial hepatectomy, the remnant undergoes fatty metamorphosis within the first 2 days in the rat, rabbit and dog. Experiments on rats show that the fat content returns to normal within 3 to 4 days, and that neither hypophysectomy nor adrenalectomy can completely abolish this response.

*Brues et al. A 45,962/36:* In rats submitted to partial hepatectomy, "the number of cells in the residual fragment shows no significant increase in the first 24 hours," although the mass of the liver remnant increases about 50%. After the first day, cell number and liver mass increase approximately at the same rate. The effect of various dietary constituents upon hepatic regeneration is described.

*Brues & Marble A 47,729/37:* Following partial hepatectomy, rats evince a latent period of one day during which the rapidly growing organ shows no increase in cell number. Mitosis then begins and reaches a rate of 2.13% but rapidly diminishes again.

*Ludewig 74,865/39:* In rats, the fatty acid, phospholipid, and cholesterol concentrations in the liver at first increased and then decreased after partial hepatectomy.

*Christensen & Jacobsen A 49,204/49:* In rats, the mitotic rate in the liver remnant reaches a maximum 48 hrs after partial hepatectomy. If two rats are united by parabiosis, one being partially hepatectomized, some increase in mitotic proliferation occurs also in the nonhepatectomized partner, suggesting the formation of cell division stimulating substances.

*Harkness E 80,279/52:* Studies on the biochemical changes in the liver remnant after partial hepatectomy in the rat.

*Weinbren B 90,949/53:* In rats, hepatic regeneration is not diminished when bile duct ligature is performed simultaneously or 18—21 days before partial hepatectomy.

*Jaffe G 77,570/54:* Studies on the diurnal mitotic periodicity of regenerating rat liver.

*Harkness E 57,419/57:* Extensive review on the structural biochemical and functional changes induced by partial hepatectomy in the rat.

*Ingle & Baker C 40,980/57:* "The capacity of liver to regenerate was maintained in rats which were subjected to partial hepatectomy 12 times within a period of one year. At the end of the experiment, only minor cytological changes were observed in the regenerated liver and there was no neoplasia."

*Pérez-Tamayo & Romero D 38,897/58:* Review of various factors which influence regeneration of liver tissue after partial hepatectomy in the rat.

*Weinbren D 95,941/59:* Review (11 pp., 110 refs.) and personal observations on factors

influencing hepatic regeneration after partial hepatectomy in the rat, with special sections on the effects of hypophysectomy and thyroid hormones.

*Kahlson G52,949/60*: The rate of histamine formation in the regenerating liver of the rat is particularly rapid during the first week after partial hepatectomy. When radioactive histidine is injected at this time, decarboxylation is particularly rapid.

*Rogers et al. E93,548/61*: In rats, liver regeneration following partial hepatectomy was studied in parabiotic pairs and triplets. The results "do not support the conclusion that the blood in parabiotic rats carries stimulating or inhibitory 'humoral factors' directly governing hepatic regeneration."

*Dagradi & de Candia D56,609/62*: Comparative studies on hepatic regeneration in the dog, mouse, rat and man after partial hepatectomy.

*Dagradi & Galanti D62,332/62*: In rats, a technique for the successive removal of several hepatic lobes has been employed to study the regenerative phenomena in the remnant.

*MacDonald et al. D41,743/62*: In newts (*Triturus viridescens*), hepatic regeneration was studied by means of autoradiographs to quantitate DNA synthesis.

*Marsili & de Simone G1,552/62*: In rats, liver regeneration following partial hepatectomy leads to marked proliferation of the endoplasmic reticulum.

*Oehlert et al. D36,669/62*: In rats, DNA synthesis after partial hepatectomy is studied with autoradiographic techniques.

*Bucher G68,621/63*: Review (55 pp., about 400 refs.) on factors influencing the regeneration of mammalian liver.

*Scheffler & Westphal D56,080/63*: In rats, hepatic regeneration after partial hepatectomy can be accelerated by feeding a mixture of adenosine, xanthine, hypoxanthine, and orotic acid.

*Leduc G79,104/64*: Review (26 pp., about 130 refs.) on "Regeneration of the Liver" after various types of surgical or chemical injuries. Special attention is given to regeneration after superficial wounds, lobectomies and bile-duct obstruction.

*Trotter G71,660/64*: Electron-microscopic studies on liver regeneration following partial hepatectomy in the mouse.

*Rizzo and Webb H21,587/68*: In rats, during liver regeneration after partial hepatectomy, the correspondence between the rate of transport of newly-synthesized ribosome to

the cytoplasm and the size of the nonfunctional monomer pool, suggests that the two parameters are directly, or indirectly coupled.

*Stöcker G76,916/68*: Autoradiographic and isotopic studies on cellular proliferation in the liver of the rat following an injection of  $^3\text{H}$ -thymidine and partial hepatectomy with special reference to intracellular RNA and protein synthesis.

*Ronzoni et al. H18,986/68*: In rats, the hydroxyproline content of the liver furnishes a better quantitative index of sclerosis than histologic studies. The technique is recommended for the evaluation of sclerosis and its regression after various types of liver damage, e.g., partial hepatectomy or  $\text{CCl}_4$  poisoning.

*Rosene Jr. G71,661/68*: In mice, partial hepatectomy greatly elevates mitotic proliferation in the liver, which reaches a peak on the third day after the operation and returns to near normal by the fifth day. Injections of Ehrlich ascites tumor homogenates moderately accelerated the rate of hepatic mitosis. Partial hepatectomy accelerated tumor cell proliferation.

*Bader G70,347/69*: Detailed description of the ultrastructural changes induced by partial hepatectomy in the rat.

*Bengmark et al. G71,689/69*: In rats, ligation of the hepatic artery does not markedly alter regeneration of the liver after partial hepatectomy.

*Bengmark G74,917/69*: Review (25 pp., about 375 refs.) on the chemical and structural changes in the regenerating hepatic tissue based mainly upon the effects of partial hepatectomy in the rat.

*Günther et al. H18,480/69*: Correlative study of weight increase and mitotic index in the liver of partially hepatectomized rats.

*Bucher and Swaffield H21,579/69*: In rats, the rate of RNA synthesis during early stages of regeneration after partial hepatectomy has been evaluated with a radioactive precursor technique.

*Zelioli-Lanzini H19,493/69*: In rats, small doses of X-rays as well as hepatic extracts improve liver regeneration following partial hepatectomy.

*Ove et al. H23,725/69*: In rats, following partial hepatectomy, liver polymerase had a preference for native DNA primer, whereas the deoxyribonuclease in the same preparation acted preferentially on denatured DNA.

*Parks H28,647/69*: In mice, electron-microscopic studies showed the source and direction of movement of lipid granules appearing in the

hepatic perisinusoidal space following partial hepatectomy.

*Simmons & Boyle H 22,141/69*: In partially hepatectomized rats, heterologous serum albumin or saline i.p. is followed by the same increase in the mitotic rate of the hepatocytes. The results do not support the hypothesis that lowered extra-cellular albumin plays an important role in controlling hepatic regeneration.

*Johnson H 18,571/69*: In mice "after partial hepatectomy the regenerating liver shows a mitotic response characterized by a lag phase during the first postoperative day, a rather sudden burst of mitotic activity at 24—48 hr, and a decline to normal levels within a week. This unexplained pattern of hyperplasia, characteristic of compensatory growth in other tissues as well as in liver, can be accounted for by the 'critical mass' hypothesis, which proposes that cell division is triggered when the growing cell reaches a certain critical mass or size."

*Sugihara H 18,030/69; Kimura G 75,331/69*: Detailed description of the ultrastructural changes in the hepatic remnant after partial hepatectomy in the rat.

*Ungváry et al. G 72,366/69*: In rats, hepatic regeneration was carefully investigated with special reference to changes in the vascular structure. Attention is called to the work of Cruveilhier (A 73,454/1829—35) who "was the

first to describe hepatic regeneration in 1833. He found that removal of 75% of the liver was followed by complete regeneration of the organ in eight weeks in dogs and in three weeks in rats." [A careful search of Cruveilhier's works failed to confirm that he ever made this statement (H.S.).]

*Hughes C 74,311/70*: In rats subjected to a first or a second partial hepatectomy, the mitotic responses are essentially similar in magnitude and time, with a mitotic peak 28 hrs postoperatively.

*Orlova & Rodionov G 73,079/70*: In rats, following partial hepatectomy "the amount of histones in the nuclei of regenerating liver cells and the incorporation of <sup>3</sup>H-leucine in them started to increase and reached the maximum earlier than the respective onset and peak of the DNA content and uptake of <sup>14</sup>C-thymidine."

*Lancker H 28,381/70*: Summary of literature, and personal observations on DNA synthesis in regenerating rat liver.

*Rabes & Tuzek H 33,839/70*: In rats, quantitative autoradiographic studies revealed a great heterogeneity of liver cell proliferation after partial hepatectomy.

*Tavassoli & Crosby G 73,038/70*: In rats, liver fragments implanted into ectopic sites do not survive even if the regenerative stimulus is activated by partial hepatectomy.

### *Varia* ←

In eviscerated rats, survival is shortened by simultaneous **nephrectomy** and vice versa.

Partial hepatectomy diminishes resistance to **cold** in guinea pigs and spontaneous **muscular activity** is reduced by this operation in rats. However, these effects are probably due to the stress of the operation rather than to any specific hepatic deficiency.

In rats, the growth of some transplantable **tumors** is increased, whereas that of others is not influenced by partial hepatectomy. Intraportal injection of Walker tumor suspensions, immediately followed by partial hepatectomy, increases the incidence of hepatic metastases in the rat. Several observers claimed that under certain circumstances, partial hepatectomy can accelerate the growth of transplantable tumors in rats and mice, or that the tumor transplants enhance hepatic regeneration after partial hepatectomy. These effects were ascribed to the production of some humoral growth factors, by the regenerating liver or the proliferating neoplasm but such substances have not yet been identified with certainty.

Comparatively little work has been done about the importance of the liver for resistance to **bacterial toxins** and to damaging **immune reactions**. In adrenalectomized

mice, *E. coli* endotoxin injected i.v. or into the spleen is about equally toxic. "Thus, the liver does not appear to play an immediate role in the detoxication of this antigen."

Surgical interference with the hepatic circulation impedes the formation of various antibodies in the guinea pig, but a detailed discussion of hepatic influences upon immune reactions would be beyond the scope of this monograph.

In pregnant rats, partial hepatectomy often causes fetal absorption but liver regeneration is essentially normal.

### Renal Lesions ←

*Ingle et al. B42,752/47*: In eviscerated rats, survival is shortened by simultaneous nephrectomy and vice versa.

### Cold ←

*Calcagno & Quercio G46,022/65*: Partial hepatectomy as well as various other surgical operations diminish the resistance of the guinea pig to cold, presumably as an expression of an increased sensitivity to stress in general.

### Muscular Contraction ←

*Dugal & Ross 84,992/43*: In rats, spontaneous running activity stops after partial hepatectomy as well as after a sham-operation. However, motor activity becomes normal within 72 hrs after a sham-operation, and within only seven days following partial hepatectomy.

*Smith & Dugal F65,692/66*: In rats, partial hepatectomy does not influence spontaneous running activity more than does a sham-operation.

### Tumors ←

*Paschkis et al. C8,982/55*: In rats, the growth of Walker tumors and of transplantable hepatomas—unlike that of Jensen sarcomas and Murphy lymphosarcomas—was increased after partial hepatectomy. Perhaps "the regenerating liver may release a humoral agent causing increased growth of some tumors." Hepatic regeneration was enhanced by the presence of a growing tumor regardless of whether the latter was influenced or not by partial hepatectomy.

*Fisher & Fisher G72,106/59*: In rats, intra-portal injection of Walker tumor suspensions immediately followed by partial hepatectomy increases the incidence of hepatic metastases. No such increase was observed if partial hepatectomy was performed 48 hrs prior to or after partial hepatectomy.

*Llanos & Saffe G71,663/61*: In C3H/mza mice, the development of spontaneous hepatomas is accelerated by partial hepatectomy.

*Peyster et al. G71,671/61*: In rats, partial hepatectomy enhances the growth of s.c. injected Walker tumor cells. When two rats are joined in parabiosis and one is partially hepatectomized, tumor growth is accelerated in both partners. Presumably "a humoral growth accelerator induced by liver regeneration is a major factor influencing distant tumor takes and growth."

*Trotter E90,324/61*: In mice, partial hepatectomy increases mitotic proliferation in some s.c.-transplanted hepatomas, but not in others.

*Gershbein E71,030/63*: In rats, s.c. transplantation of Walker or Flexner-Jobling tumors did not significantly alter the extent of hepatic regeneration. However, under certain circumstances, partial hepatectomy accelerated tumor growth.

*Gershbein F71,304/66*: Studies on the effect of various agents upon liver regeneration and Walker tumor growth in partially hepatectomized rats.

*Rosene Jr. G71,661/68*: In mice, partial hepatectomy greatly elevates mitotic proliferation in the liver, which reaches a peak on the third day after the operation, and returns to nearly normal by the fifth day. Injections of Ehrlich ascites tumor homogenates moderately accelerated the rate of hepatic mitosis. Partial hepatectomy increased tumor cell proliferation.

### Bacterial Toxins ←

*Chedid et al. B99,547/54*: In mice rendered particularly sensitive by adrenalectomy, *E. coli* endotoxin injected i.v. or into the spleen is equally toxic. Similar results have been obtained in intact rats. "Thus the liver does not appear to play an immediate role in the detoxication of this antigen." In partially hepatectomized rats "which become more sensitive to any toxic substance" cortisone continues to exert its protective effect against endotoxin.

The same is true of the splenectomy or thymectomy.

*Kocsár et al. G69,983/69:* In rats, incubation of tritium-labeled endotoxin with bile or Na-deoxycholate reduces its absorption when subsequently injected i.p. In rats rendered bile-deficient by cannulation of the choledochus, unlike in normal rats, endotoxin is absorbed after administration p.o. "Our experimental findings suggest that bile acids play an important role in the defense mechanism of the macroorganism against bacterial endotoxins."

*Wardle & Wright H32,903/70:* In rats, a single dose of endotoxin i.v., given after choledochus ligation, causes death from intravascular coagulation (generalized Sanarelli Schwartzman phenomenon) owing to delayed clearance of endotoxin from the circulation. [Earlier pertinent data of Bertók and Kocsár are not discussed (H.S.).]

#### **Immune Reactions ←**

*Müller A47,855/11:* In guinea pigs, the formation of various antibodies is inhibited by thyroidectomy as well as by surgical interference with hepatic circulation. Treatment with thyroid extract has an opposite effect. The latter is not due to shock, since removal of all abdominal organs except the liver is ineffective. Furthermore, the blood loses its "alexia power" when perfused through an isolated liver preparation.

#### **Pregnancy ←**

*Paschkis et al. C14,122/56:* In pregnant rats partial hepatectomy causes absorption of

many fetuses, but liver regeneration is not affected by pregnancy.

#### **Varia ←**

*Selye & Dosne A30,702/40:* "Experiments on partially hepatectomized rats indicate that the decrease in the blood volume, blood chlorides and blood sugar caused by ablation of 85 per cent of the liver tissue in fasted rats is inhibited by administration of an adrenal cortical extract, rich in the life-preserving principle. . . . The decrease in blood sugar produced by complete hepatectomy is not significantly influenced even by large doses of cortin. This finding makes it probable that the cortical hormone does not inhibit the utilization of circulating sugar."

*Heim & Kerrigan G68,369/63:* The serum concentration of slow  $\alpha_2$ -globulin increases in rats after partial hepatectomy or  $\text{CCl}_4$  intoxication.

*Menguy & Masters F61,098/65:* The increase in serum glycoproteins, and the changes in serum glycoprotein fractions produced by parathyroid extract in intact rats are abolished by partial hepatectomy, whereas the hypercalcemia and nephrocalcinosis are not influenced by it.

*Heim & Ellenson F77,887/67:* A slow  $\alpha_2$ -globulin appears among the serum proteins of the rat after partial hepatectomy or treatment with Salmonella endotoxin, s.c. as well as postpartum or after implantation of Walker tumors. Adrenalectomy prevents the appearance of the  $\alpha_2$ -globulin in all these situations, unless substitution therapy with corticosterone is administered.

#### **Hepatic Enzymes ←**

The induction by hepatic lesions of enzyme changes specifically related to certain toxicants is discussed with the latter under "Drugs." For other hepatic enzyme alterations consult the Abstract Section.

#### **TPO, TKT ←**

*Cabibbe et al. G52,346/67:* Hepatic TPO-activity is increased by partial hepatectomy in the rat, allegedly as a mere consequence of the resulting "surgical stress."

*Seidman et al. F88,452/67:* The induction of TPO has been studied in the liver remnant of partially hepatectomized rats following treatment with cortisol, and after adrenalectomy. "It seems possible, therefore that the lessened

response to hydrocortisone in hepatic cells preparing to divide is related to repression of transcriptional rather than translational mechanisms and that the duplicating genome itself may be unable to participate simultaneously in other functions."

*Terawaki et al. G50,735/67:* Studies on the phenylalanine hydroxylase activity of normal and regenerating rat liver after tyrosine and tryptophan injection.

*Benes & Zicha G67,159/69:* Exposure to

1400 R does not inhibit the tryptophan oxygenase activity of rat liver. In fact, substrate induction of tryptophan oxygenase is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated, and then inhibited by X-irradiation. X-irradiation before partial hepatectomy inhibits the increase in tryptophan oxygenase normally observed 12 hrs after the operation. Similar results are obtained by actinomycin D applied one hour after partial hepatectomy. "The diminished synthesis of tryptophan oxygenase in irradiated regenerating rat liver tissue, as well as the decrease of hormonal induction after the irradiation can be explained by the inhibition of the specific messenger RNA's synthesis."

*Kulcsár et al. G72,002/69:* In rats, the substrate-induced synthesis of TPO was inhibited by hepatic injury ( $\text{CCl}_4$ ) as well as by thyroxine. Thyroidectomy was without effect, and actually inhibited the influence of  $\text{CCl}_4$ .

#### OKT ←

*Räihä & Kekomäki G68,114/68:* In the rat, the OKT activity of the liver is very low in the fetus, exhibiting a small transient elevation around term; it then drops, and eventually reaches the high adult activity level during the third postnatal week. Triamcinolone given postnatally causes a pronounced elevation of OKT, but has no such effect in fetal or adult rats. Puromycin prevents the rise in OKT after triamcinolone administration. In adult rats fed a protein- or arginine-free diet, OKT activity decreases and fails to rise under the influence of triamcinolone. Partial hepatectomy or STH depresses OKT activity in the livers of adult rats.

#### GOT, GPT ←

*Cohen & Hekhuits 93,220/41:* GOT activity was subnormal in six types of mouse tumors, regenerating rat liver, and fetal kitten (compared with adult cat) tissues. Apparently, an inverse relationship exists between transaminase activity and protein synthesis.

*Bengmark & Olsson E34,627/63:* Studies on the GPT content of the hepatic remnant after partial hepatectomy in the rat.

#### DNA-Polymerase ←

*Feigelson et al. G68,042/62:* In partially hepatectomized rats, cortisone causes a transient stimulation and subsequent depression

in the incorporation of precursors into the DNA of the regenerating liver.

*Hayasaki & Tsukada G73,554/70:* In rats, partial hepatectomy increases the serum DNA inhibitor concentration. This inhibitor may control the activity of DNA and is therefore of considerable importance.

#### Glucuronidase ←

*Yano & Nobunaga E21,714/63:* Studies on the serum transaminase and  $\beta$ -glucuronidase activity following partial hepatectomy in the guinea pig and rat.

#### Phosphatase ←

*Brachet & Jeener B23,118/46:* In rats, partial hepatectomy increases alkaline phosphatase activity in the nuclei but decreases it in the cytoplasm of hepatocytes. It is assumed that alkaline phosphatase in chromatin facilitates the renewal of phosphorus in thymonucleic acid.

*Oppenheimer & Flock B4,738/47:* Alkaline phosphatase activity is elevated in the plasma and liver after partial hepatectomy in the rat. Since the initial elevation is greater in the liver, it is assumed that plasma alkaline phosphatase originates in hepatocytes.

#### Thrombin ←

*Gans et al. G71,042/69:* Thrombin rapidly disappears from the blood of intact, but not of completely hepatectomized heparinized dogs. Thrombin clearance appears to depend mainly upon phagocytosis by the Kupffer cells.

#### Other Enzymes ←

*von der Decken & Hultin G37,124/60:* Studies on the enzymic composition of rat liver microsomes during hepatic regeneration after partial hepatectomy.

*Myers et al. D48,663/61:* Studies on the deoxycytidylate deaminase content of regenerating liver tissue after partial hepatectomy in the rat.

*Bucher G68,621/63 (p. 255):* Review on hepatic regeneration, with a special section on enzyme changes, in the liver remnant.

*Terayama & Takata F69,475/66:* The N-demethylating activity of rat liver is considerably reduced during regeneration after partial hepatectomy but, for a much shorter period, also after sham-operations.

*Gram et al. G62,231/68:* In rats, "the regenerating liver, like the fetal or newborn liver and certain rodent hepatomas, although exhibiting low levels of microsomal enzymes, has the capacity to respond to the enzyme inducers, phenobarbital and 3-MC."

*Bengmark G74,917/69:* Review on hepatic regeneration with a special chapter on enzymic changes in the liver remnant.

*Barker et al. H13,059/69:* In the rat, CCl<sub>4</sub>-induced liver injury decreases the P-450 level in hepatic microsomes and diminishes both steps in the oxidative N-demethylation of dimethylalanine (N-oxide accumulation and formaldehyde release). Cytochrome b<sub>5</sub> was rapidly restored to control levels. Partial hepatectomy decreased the cytochromes and formaldehyde production but increased N-oxide accumulation. These results are unaffected by adrenalectomy.

*Henderson & Kersten G77,181/70:* In partially hepatectomized rats, "the *p*-hydroxylating and N-demethylating activities decreased during the period of rapid cellular proliferation and subsequently rose to about 100 and 80 per cent respectively of their initial values within 7 days postoperatively. The UDPglucuronyltransferase activity, measured

in ultrasonicated homogenates, however was not reduced during the regeneration process. Pretreatment of the rats with phenobarbital resulted in a considerable increase of the drug-oxidizing enzymes even during the period of rapid growth."

*Hutterer et al. G75,925/70:* In rats, 4 days after bile duct ligation, the activity of aminopyrine demethylase was greatly decreased, while the content of cytochrome P-450 and the activities of aniline hydroxylase, NADPH-cytochrome c reductase, and cytochrome P-450 reductase were only slightly decreased in the hepatic microsomes. Binding of type II substrate to cytochrome P-450 was unimpaired, and its modifier effect on P-450 reductase was intact. The binding of type I substrate was greatly decreased, and its stimulating effect on P-450 reductase was abolished. Presumably cholestasis alters the type I binding sites of the hepatic SER, which is responsible for the hypoactivity of the biotransformation system.

*Kattiala G79,608/70:* In male rats in which 50% of the liver was removed, "hexobarbital, chlorpromazine and pethidine were metabolized significantly less well by the microsomal enzymes of the regenerating livers than by those of the controls (sham-operated)."

#### ← RENAL LESIONS

Next to the liver, the kidney appears to be the most important organ of detoxication. Thus, in various species, **pentylene-tetrazol** is highly active when given p.o. although it has to traverse the portal circulation, whereas after bilateral ligation of the renal hilus, rats become extremely sensitive to the convulsive effect of this drug. It had been concluded from these observations that the principal detoxicating organ for pentylene-tetrazol is the kidney. However, subsequent investigations showed that the disappearance rate of pentylene-tetrazol from the blood and tissues of rabbits is not significantly influenced by bilateral nephrectomy; conversely, it is greatly delayed by CCl<sub>4</sub>-poisoning, presumably owing to the resulting hepatic damage. Essentially similar observations have been made in comparing nephrectomy with other types of chemically or surgically-induced hepatic damage. In the case of very acutely acting drugs, detoxication or excretion may not be rapid enough to induce a detectable change; hence it is not surprising that certain investigators found no effect of either partial hepatectomy or complete nephrectomy upon pentylene-tetrazol poisoning.

The effect of the kidney upon **barbiturate** intoxication has also been extensively examined, but here the relative importance of the liver and the kidney appears to differ depending on the type of compound examined. Allegedly, some barbiturates are detoxified mainly in the kidney, others in the liver, yet, others in both organs or in extrahepatic and extrarenal tissues. It is important to retain, however, that

for the detoxication of certain barbituric acid derivatives, the kidney can be even more important than the liver.

The renal damage produced in rats and rabbits by systemic intoxication with **mercury** is prevented by previous ureter ligation. This may be related to the disappearance of alkaline phosphatase from the proximal convoluted tubules and a diminished accumulation of Hg in the nonexcreting organ. Following temporary ligation of one ureter, the production of nephrocalcinosis and sclerosis is prevented on this side, whereas the contralateral kidney undergoes severe damage resulting in atrophy and loss of function. If after several weeks, the protected kidney is removed, the contralateral organ undergoes rigid and pronounced hypertrophy so that, at least in many instances, it can maintain life by itself.

It has been stated that in rabbits, **tribromoethanol** anesthesia is not markedly affected if the liver is "destroyed" by ethylene chlorhydrin but prolonged after bilateral nephrectomy.

The osteitis fibrosa and soft tissue calcification produced by large doses of **parathyroid extract** are not prevented by bilateral nephrectomy in the rat. From this it was concluded that, contrary to earlier views, parathyroid hormone does not exert its action exclusively through its effect upon the renal elimination of electrolytes.

Finally, it might be mentioned in this connection that the mitotic index in the **regenerating rat liver** rises after one hour of renal ischemia but not after bilateral nephrectomy.

*Voss A 47,860/26:* In guinea pigs, rats and rabbits, **pentylenetetrazol** p.o. is highly active although it must pass through the liver before reaching its target organs. On the other hand, following bilateral ligation of the renal hilus, rats become extremely sensitive to the production of convulsions by pentylenetetrazol. It is concluded that the principal detoxicating organ for pentylenetetrazol is the kidney, whereas the liver plays no important role in this respect.

*Eichholtz A 27,018/27:* In rabbits, "destruction of the liver" by ethylene chlorhydrin does not significantly affect the length of **tribromoethanol** anesthesia. After bilateral nephrectomy, sleeping time is somewhat prolonged but still variable. On the other hand, bilateral adrenalectomy prolongs the sleeping time very considerably.

*Holck et al. A 8,011/37:* In rats, bilateral nephrectomy does not alter the sex difference in **hexobarbital** sleeping time.

*Dille & Seeberg 84,277/41:* In cats, the acute toxicity of **pentylenetetrazol** is not influenced by bilateral nephrectomy, whereas liver damage induced by yellow phosphorus greatly increases sensitivity to pentylenetetrazol.

*Tatum & Kozelka 81,376/41:* In rabbits the disappearance rate of **pentylenetetrazol** from blood, liver and muscle was not influenced by

bilateral nephrectomy but greatly delayed by CCl<sub>4</sub> poisoning causing a 50% decrease in the functional capacity of the liver as judged by the bromsulphalein test. It is concluded that, contrary to earlier reports, the liver plays an important part in the detoxication of pentylenetetrazol, whereas the kidney does not.

*Selye A 36,715/42:* In rats, partial hepatectomy, complete thyroidectomy or bilateral nephrectomy do not prevent the osteitis fibrosa and soft-tissue calcification produced by large doses of **parathyroid extract**. Presumably, parathyroid hormone does not exert its action either through the thyroid or through the kidney, as had previously been postulated by some investigators. Furthermore, hepatic detoxication does not play an important role in the metabolism of parathyroid hormone.

*Fournier 84,151/43:* Neither partial hepatectomy nor complete nephrectomy decreases the resistance of the rat to the convulsive or fatal effect of **pentylenetetrazol**. It is concluded that neither the liver nor the kidney plays an important role in the detoxication of this drug.

*Wilmer A 48,603/43:* In rabbits, unilateral permanent ureter ligation protects the corresponding kidney against **HgCl<sub>2</sub>** and many other nephrotoxic substances, whereas the contralateral kidney shows severe damage. The

protection offered by hydronephrosis is associated with a disappearance of alkaline phosphatase from the convoluted tubules which may reflect lack of elimination and concentration of the nephrotoxic substances in the renal tissue.

*Masson & Beland B344/45*: Review of the literature on the effect of partial hepatectomy and other forms of liver damage upon **barbiturate** anesthesia. Personal observations on a series of 29 barbiturates tested on partially hepatectomized or completely nephrectomized rats led to the conclusion that the compounds can be classified into four groups: "Group I, those detoxified mainly in the kidney; Group II, those detoxified mainly in the liver; Group III, those detoxified approximately equally in both liver and kidney; Group IV, those possibly detoxified in other tissues of the body, but not to any great extent in the liver and the kidney."

*Scheibley A48,124/46*: In rats, the anesthetic effect of **pentobarbital** unlike that of thiopental, was greatly prolonged by partial hepatectomy. "These data suggest that the liver is

instrumental in protecting against the action of pentobarbital sodium but does not play a significant part in the detoxication of pentothal sodium" (thiopental). Uninephrectomy had no effect upon the production of anesthesia by either of these barbiturates.

*Sandberg G71,886/53*: Studies on **barbiturate** intoxication in partially hepatectomized or completely nephrectomized rats suggest that, "for 5,5-diallyl-barbituric acid and its 1-(N,N-diethylcarbonylmethyl) derivative the kidneys participate as much as the liver in the detoxication. 1-benzyl-5,5-diallyl-barbituric acid is destroyed mainly in the liver. 1-carbethoxymethyl-5,5-dialkyl-barbiturates are probably hydrolyzed to the corresponding carbonic acid, 1-carboxymethyl-5,5-dialkyl-barbituric acid."

*Richards & Taylor H19,235/56*: Review on **barbiturates** with a special section on the role of the kidney in their detoxication. (Nephrectomy, nephrotoxic drugs, patients with liver disease).

*Gibson & Becker E65,709/67*: In mice, "hypoexcretory states" were produced by pe-

Table 127. Protection of the kidney against mercury by temporary ureter ligation

Group	Treatment <sup>a</sup>	Renal weight (mg)		Nephrocalcinosis (Positive/Total)		Mortality (Dead/Total)
		Left	Right	Left	Right	
1	None		648	0/15	0/15	0/15
2	HgCl <sub>2</sub>	—	—	18/18 a	18/18 f	18/18 b
3	Nephrectomy (right)	945 ± 17 d	557 ± 14 d' d:d'***	0/15	—	0/15
4	HgCl <sub>2</sub> + ureter ligation (left)	1183 ± 76 c	277 ± 44 c' c:c'*** e	0/6 a' a:a'***	6/6 f' f:f' NS	0/6 b' b:b'***
5	HgCl <sub>2</sub> + ureter ligation (left) + nephrectomy (left)	799	977 ± 43 e' e:e'***	0/17	11/16 f'' f:f''*	6/17 b'' b:b''***

<sup>a</sup> In groups 4 and 5, the left ureter was ligated on the 1st day. In groups 2, 4 and 5, HgCl<sub>2</sub> (400 µg in 1 ml water) was given i. v. on 2nd day in groups 4 and 5, the ureter ligation was removed 4 hrs. after this injection. In group 3 the right, and in group 5 the left kidney was removed and examined for calcinosis (by loupe inspection and by staining with the von Kóssa technique) on 34th day. All rats of group 2 died by the 3rd day. In the other groups, mortality was registered on the 54th day the experiment was terminated and the presence of nephrocalcinosis appraised in all survivors. The surgically removed kidneys in groups 3 and 5 were weighed immediately after nephrectomy on the 34th day, the others upon termination of the experiment 20 days later. The statistical significance of the apparent differences between the readings in groups indicated by the same letter (a—f) was determined by the "Exact Probability Test" for nephrocalcinosis and mortality, by Student's t-test for renal weight.

Fig. 26. **Protection of the kidney against  $HgCl_2$  by ureter ligation.** All rats whose kidneys are shown here have received the same dose of  $HgCl_2$  i. v. A: Left kidney almost completely protected against nephrocalcinosis by temporary ureter ligation. B: Unprotected right kidney which underwent considerable atrophy, cyst formation and extensive calcinosis. C: Right kidney of a similarly treated rat whose protected left kidney has been removed 20 days earlier. Compensatory hypertrophy is virtually complete and nephrocalcinosis minimal. D, E and F: Higher magnifications of areas from the renal cortex of the animals shown above (A, B and C, X 6,6; D, E and F, X 80)

nile ligation, bile duct ligation or drugs (phenylisothiocyanate,  $\alpha$ -naphthylisothiocyanate) which reduce bile flow. "Intraperitoneal administration of ouabain to mice with no or diminished bile flow resulted in enhanced mortality rates. **Digoxin** and **digitoxin** affected enhanced lethality in anuric mice. Lanatoside-C was not more toxic to hypoxcretory mice. The use of hypoxcretory mice in toxicologic evaluations of pharmacologic agents is suggested."

*Hyde H 15,523/69*: In rats, the mitotic index in **regenerating liver** rises after one hour of renal ischemia but not after bilateral nephrectomy.

*Selye & Szabo PROT. 35492*: In rats, comparatively small doses of  $\text{HgCl}_2$  regularly produce fatal bilateral nephrocalcinosis (*cf.* Table 127, p. 624 in which values to be compared are identified by the same letter). Nephrocalcinosis (a : a') and mortality (b : b') are completely prevented if one of the ureters (here left) is temporarily obstructed by a ligature, from 24 hrs before to 4 hrs after the injection of the  $\text{HgCl}_2$  *cf.* Fig. 26.

In order to occlude the ureter, its middle section was placed into a cranio-caudal slit of the psoas muscle and constricted by a thick silk ligature placed around the ureter-containing segment. Correspondingly, the unprotected kidney becomes sclerotic and atrophic, whereas the contralateral organ undergoes compensatory hypertrophy (c : c') such as is also seen in otherwise untreated unilaterally nephrectomized rats (d : d'). In the present experiment, this physiologic compensatory hypertrophy (d : d') was less evident than that noted in the kidney protected by temporary ligature following calcinotic destruction of the contralateral kidney (c : c'), because in the latter group, the protected kidney was weighed on the 54th day after destruction of the right kidney by mercury, whereas normal compensatory hypertrophy of the left kidney was determined 20 days after ablation of the right kidney.

Survival in group 4 was possible only because the kidney protected by ureter ligation

suffices to maintain life as did the normal kidney after right nephrectomy in group 3. In group 5, removal of the protected left kidney on the 34th day resulted in hypertrophy of the nephrocalcinotic and atrophic right kidney (e : e') which also lost most of its pathological calcium deposits (f : f' and f''). This regenerative impulse also has a life-maintaining effect in that the previously atrophic calcinotic right kidney suffices by itself to maintain the life of more than half of the rats which had received the dose of mercury ordinarily sufficient to produce nephrocalcinosis resulting in a 100% mortality (*cf.* b' with b'). Apparently, under such conditions, the increased demand occasioned by contralateral nephrectomy promotes the functional and structural rehabilitation of a kidney severely damaged by a normally fatal mercurial intoxication.

*Selye PROT. 42214*: In rats, choledochus ligation offered considerable protection against the toxicity of **indomethacin** and **dioxathion**, slightly prolonged **hexobarbital** sleeping time, and failed to affect **digitoxin** poisoning. Partial hepatectomy had little, if any, effect upon indomethacin, dioxathion and digitoxin poisoning under the prevailing experimental conditions, but considerably prolonged hexobarbital sleeping time. Partial nephrectomy (removal of 80% of the kidney tissue) likewise prolonged hexobarbital sleeping time without significantly influencing indomethacin, dioxathion and digitoxin overdosage. The protective effect of spironolactone against indomethacin, dioxathion and digitoxin remained manifest after most of these surgical interventions. But the protection against indomethacin offered by choledochus ligation could not be further improved by spironolactone, nor was the considerable prolongation by hepatectomy of hexobarbital sleeping time markedly reduced by spironolactone. It must be kept in mind, however, that in these experiments only a single dose of spironolactone was given 5 min after the surgical interventions and 24 hrs before a single dose of the toxicants' *cf.* Table 126, p 600.

#### ← SEX

Resistance to many agents is sex-dependent. In some species, the female, in others, the male is more resistant to a given toxicant.

Thus, female rats are generally much more sensitive than males to the production of anesthesia by steroids and by most barbiturates; indeed even *in vitro*, their hepatic microsomes are less active in metabolizing these anesthetics than those of males. On the other hand, the catatoxic action of spironolactone against indo-

methacin, digitoxin and pentobarbital is evident both in male and in female rats. However, allegedly, hexobarbital sleeping time is greatly shortened by spironolactone in female but not in male rats.

Epinephrine arteriosclerosis is more readily produced in female than in male rabbits, and male rats are more resistant than females to the toxic actions of thyroxine.

The tumorigenic effect of certain carcinogens is also sex-dependent, but in this respect, it is difficult to generalize since some of these compounds are more effective in females, others in males.

In certain strains of mice, males are unusually sensitive to the production of renal tubular necrosis by chloroform vapor, and treatment with testoids renders females as susceptible as males.

Many additional examples of such sex differences in sensitivity will be discussed in the following pages and we shall see that in most instances, castration tends to abolish and treatment with the appropriate sex hormones to reestablish them. Since, furthermore, these differences usually appear only after puberty, it may be assumed that in many cases, they depend upon the continued presence within the body of the corresponding sex hormones. Yet, in a few instances, sex-dependent resistance phenomena have been observed even after gonadectomy.

### *Steroids* ←

The first publication on the anesthetic effect of steroids emphasized already that male rats are less sensitive than females. This observation has repeatedly been confirmed with a great variety of anesthetic steroids, including progesterone, DOC, and many others that do not exhibit obvious hormonal actions.

There is also a sex difference in the metabolism of <sup>14</sup>C-marked androstane derivatives during perfusion through the isolated rat liver. The protection by spironolactone against indomethacin, digitoxin, and pentobarbital is obvious in both sexes, but quantitative studies concerning the comparative efficacy of catatoxic steroids in males and females have not been performed.

In the mouse, females are more resistant than males to toxic doses of estradiol and stilbestrol. Female C3H mice regularly develop myocardial calcification after prolonged cortisol treatment, whereas males are comparatively resistant.

Although some investigators claimed that female mice are more sensitive than males to hydroxydione anesthesia, this has not been confirmed, so that in this respect the mouse appears to differ essentially from the rat.

In mature female dogs, the production of hypertension and vascular changes by DOC is more difficult than in males.

*Steroids* ← cf. also Selye G60,083/70, pp. 475, 477.

#### RAT

*Selye A 35,003/41*: First description of the anesthetic effect of steroids. Male rats are less sensitive than females of equal size.

*Selye A 35,150/41*: Female rats are more sensitive to anesthesia produced by various

steroids than are males, and young animals of either sex are more sensitive than adults.

*Winter & Selye A 35,658/41; Winter A 36,333/41*: Female rats are more sensitive than males to the anesthetic action of progesterone but this sex difference is obvious only after maturity. "The normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the males since

castration increases sensitivity in males but is without effect in female rats. Conversely the resistance of castrate males and females may be raised by methyl testosterone administration."

*Selye & Pentz A 59,789/43*: Female rats are much more sensitive than males to the production of hyalinosis and hypertension by DOC + uninephrectomy + NaCl.

*Emmens A 46,574/46*: In immature rats of both sexes, pentobarbital has an approximately equal anesthetic effect, whereas DOC and progesterone are twice as potent in females as in males.

*Allardyce et al. B 29,416/48*: Following a single i.m. injection of DOC, male rats exhibit a greater rise in blood pressure than do females.

*Fonts et al. B 54,459/50*: Female rats are about ten times more sensitive to progesterone and DOC anesthesia than are males.

*Forchielli et al. D 75,874/58*: The rate of  $\Delta^4$  reduction of 11-desoxycortisol was 3—4 fold greater in female than in male rat liver homogenates and in microsomal fractions containing the  $\Delta^4$ -5 $\alpha$ -hydrogenase. Female rat liver contains only one  $\Delta^4$ -hydrogenase (5 $\alpha$ -microsomal), whereas the male liver contains the soluble  $\Delta^4$ -5 $\beta$ -hydrogenase as well. Ovariectomy caused no marked change in enzyme titer, but hypophysectomy decreased it sharply. Curiously, ACTH, STH and pregnant mare serum partially restored the enzyme level in the hypophysectomized rat. In young animals, increase in the titer of hepatic  $\Delta^4$ -5 $\alpha$ -hydrogenase occurs prior to puberty. This fact (like the negative results after ovariectomy) suggests an independence of enzyme regulation from ovarian hormones.

*Yates et al. C 61,952/58*: "Homogenates of livers from adult female rats reduce Ring A of  $\Delta^4$ -3-keto-steroids at rates 3 to 10 times greater than those from males. This large sex difference has been observed for all substrates so far tested: aldosterone, desoxycorticosterone, hydrocortisone, cortisone, corticosterone, testosterone and progesterone. . . . Castration increases and testosterone decreases  $\Delta^4$ -steroid hydrogenase activity in males. In females, neither castration nor estrogen administration had appreciable effect."

*Leybold & Staudinger C 77,908/59*: Description of sex differences in the ability of the hepatic microsomes of the rat to metabolize various steroid hormones.

*Rummel et al. C 80,035/59*: Male rats are more resistant than females to the anesthetic effect of DOC.

*Colás D 20,925/62*: The livers of male rats contain more dehydroepiandrosterone 16 $\alpha$ -hydroxylase than that of males. Castration reduces the enzyme activity but not quite to the low level of the female.

*Kuntzman et al. F 27,893/64*: The steroid hydroxylase of the microsomal fraction of rat liver is more active in males than in females.

*Schrievers & Wassmuth G 23,742/64*: "The  $\Delta^4$ -5 $\alpha$ -hydrogenase activity in liver microsomes of female rats is 8.5 times that of males; but liver slices from females reduce cortisone at only twice the rate of slices from males." Comparative kinetic analysis showed that, in the female, the rate of diffusion, whereas, in the male, the low enzyme activity, is the limiting factor.

*Kuntzmann & Jacobson F 35,869/65*: "Incubation of progesterone-4-C<sup>14</sup> with liver microsomes from adult male rats resulted in oxidation of the steroid to a more polar fraction made up of 6 $\beta$ - and 16 $\beta$ -hydroxyprogesterone and an unidentified U.V. absorbing product. In contrast, female rats metabolized progesterone primarily by reduction of the A ring followed by subsequent metabolism to polar compounds. Unlike the female rat, female rabbits and guinea pigs metabolized progesterone by hydroxylation. With microsomes from immature male rats, both hydroxylation and reduction occurred. Chronic administration of phenobarbital, chlorocycline or chlordane to female rats caused an increased formation of polar metabolites but had little effect on the disappearance of progesterone, since the main pathway in the female rat is A-ring reduction. In contrast, chronic phenobarbital administration to female rabbits increased markedly the metabolism of progesterone to hydroxylated derivatives when measured either by formation of polar metabolites or by progesterone disappearance."

*Conney et al. G 65,135/65*: In the male rat, the oxidative metabolism of hexobarbital, testosterone and estradiol by hepatic microsomes is more pronounced than in the female. The mouse shows no comparable sex difference.

*Remmer & Merker G 66,868/65*: The hepatic  $\Delta^4$ -3-ketoreductase activity is much higher in female than in male rats, but cannot be further increased by phenobarbital, although the barbiturate does induce two similar TPHN-dependent microsomal reductases involved in

the metabolism of p-amino-azobenzol and of chloramphenicol.

*Denej & de Moor H15,811/69:* The sexual differentiation of steroid-metabolizing enzymes appears in the rat liver from the 30th day of life on. From experiments on neonatally-gonadectomized or intact rats treated with folliculoid or testoid compounds, "it is concluded that, as far as the differentiation of cortisol metabolizing enzymes is concerned, estradiol is able to counteract the organizing action of testosterone at birth as well as the expression of these neonatal testosterone effects after the 30th day of life."

*Grossman et al. H18,545/69:* In male rats, adrenalectomy decreases the protein content and the number of zymogen granules in the pancreas. "The female rat does not demonstrate these changes following adrenalectomy. However, if the ovaries are removed in addition to the adrenal glands, alterations similar to those observed in the adrenalectomized rat with triamcinolone acetonide reverts the pancreas to normal. In contrast to the male, the female rat apparently had dual control of the pancreas through estrogenic as well as adrenal cortical hormones."

*Schrievers et al. H21,007/70:* Demonstration of sex differences in the metabolism of <sup>14</sup>C-marked androstane derivatives during perfusion through the isolated rat liver.

*Kato et al. H34,571/71:* Male rats are more resistant to the anesthetic effect of progesterone than females. Correspondingly the formation of hydroxylated metabolites of this steroid is greater with hepatic microsomes from males, whereas the formation of  $\Delta^4$ -reduced metabolites is greater with female microsomes. In mice, there was no such difference either in the anesthetic action or in the in vitro metabolism of progesterone. In rats, the blood and tissue level of polar metabolites of tritiated progesterone was higher in males, whereas that of nonpolar metabolites was higher in females. "These results suggest that the stronger anesthetic action of progesterone in female rats is associated with higher tissue levels of progesterone and  $\Delta^4$ -reduced metabolites, possessing the anesthetic action."

*Selye PROT. 29733:* In rats weighing 100–200 g, the catatonic action of spironolactone against indomethacin, digitoxin and pentobarbital is evident in both sexes.

*Selye PROT. 42911:* In male rats, the protective effect of PCN, spironolactone, ethylestrenol, betamethasone, phenobarbital and phenylbutazone against intoxication with digi-

toxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf.* Table 128, p. 630). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf.* Table 136), but PCN and spironolactone were effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (Table 136).

Testosterone ← Sex, Rat: Kuntzman et al. *F27,893/64*; Conney et al. *G65,135/65*

#### MOUSE

*Selye & Stevenson 77,177/40:* In Strong's C3H strain mice, females are more resistant than males to toxic doses of estradiol or stilbestrol. This sex difference is even more pronounced in the case of combined administration of folliculoids and progesterone, which increases the toxicity of folliculoids. The gonads of both sexes show considerable atrophy under the influence of folliculoids but this is inhibited by progesterone.

*Koller C19,288/56:* Mice of both sexes are approximately equally sensitive to hydroxydione anesthesia. Gonadectomy increases sensitivity to this form of narcosis especially in females but to a lesser extent also in males.

*Loströh C54,348/58:* Female mice of the C3H strain regularly develop myocardial calcification following prolonged cortisol treatment, whereas males are comparatively resistant. Ovariectomy offers no protection but testosterone renders females more resistant. In hypophysectomized mice neither cortisol nor ACTH produces myocardial calcification.

*Atkinson et al. D33,188/62:* Female mice are more sensitive than males to hydroxydione anesthesia but allegedly there is no such sex difference to the anesthesia produced by 3 $\alpha$ -hydroxy-5 $\beta$ -pregnane-11,20-dione 3-phosphate disodium.

*Rümke G68,532/66:* The anesthetic effect of hydroxydione is greater in female than in male mice.

*Jelinek H1,518/68:* There was no difference in the duration of hydroxydione anesthesia in male and female intact or gonadectomized mice. Pretreatment with methyltestosterone p.o. prolonged hydroxydione anesthesia in males but not in females or castrate males.

Neither thiopental nor pentobarbital anesthesia was influenced by methyltestosterone. Pretreatment with methandrostenolone or 17 $\alpha$ -methyl-androst-2-ene-17 $\beta$ -ol failed to influence hydroxydione anesthesia in mice.

Cortisone  $\leftarrow$  Sex + Adrenalectomy, Mouse: Wragg et al. B74,080/52\*; Kato et al. H31,735/70

Resistance to histamine shows no distinct sex specificity in normal rats, but thyroparathyroidectomy allegedly increases histamine tolerance in females only. After sensitization with pertussis vaccine, female mice become more sensitive to histamine than males. In rats, in which acetic acid was administered by aerosol, subsequent inhalation of vaporized histamine produces an asthmatic attack among females only.

**Catecholamines** ← cf. also Selye G60,083/70, p. 478.

Astarabadi & Essex B75,437/52: Female rats are more resistant to epinephrine i.v. than males. Gonadectomy was without effect on the resistance of males but caused females to become as susceptible as males.

Plotka et al. C51,239/57: In rabbits, the production of aortic lesions by epinephrine i.v. is partly inhibited by adrenosterone; yet, normally males are more sensitive than females to epinephrine arteriosclerosis.

ACTH ← cf. Selye G60,083/70, pp. 476, 479.

**Pancreatic Hormones** ←

Dotti 34,994/36: Female rabbits are more sensitive to insulin than males.

Beach et al. B61,498/51: The diabetogenic effect of alloxan is greater in female than in male rats.

Fogliá & Penhos B79,957/52: In male rats, extensive partial pancreatectomy causes severe diabetes more frequently than in females. Postnatal orchidectomy abolishes this difference.

**Thyroid Hormones ←**

*Garvin et al. D21,160/62:* Male rats are more sensitive than females to the production of hyperthyroidism by thyroxine.

*Fonzo et al. G77,635/70:* In rats, the hepatic storage of  $^{125}\text{I}$ -thyroxine is greater and its subsequent deiodation smaller among females than among males. "It may be concluded that the female liver has a greater affinity for thyroxine and that a stronger binding of the hormone with the proteins of hepatocytes accounts for the decreased deiodation among females."

**Parathyroid Hormone ←**

*Rowinski & Manunta B64,144/51:* Mortality after parathyroidectomy is equal in male and in spayed female rats, whereas intact females are more resistant.

Histamine ← Sex: Sackler et al. B78,749/53\*

**Histamine ←**

*Sackler et al. B78,749/53:* In rats, thyro-parathyroidectomy increases histamine tolerance, but only in females. Intact rats show no sex difference in histamine tolerance. Gonadectomy raises histamine tolerance in both sexes.

*Chedid C1,930/54:* After sensitization with pertussis vaccine, female mice become more sensitive to histamine than males.

*Gross C30,649/55:* In rats, administration of histamine by aerosol or of egg-white i.p. elicits an asthmatic attack if the lung was previously irritated by inhalation of acetic acid given by a spray. This response is obtained in females, castrate males or males treated with folliculoids but not in normal males. Testosterone and progesterone abolish this effect in females and castrate males.

**Drugs ←**

The toxicity of innumerable drugs is sex-dependent to some extent. Here, we shall deal mainly with those toxicants which are of particular interest in connection with the problem of hormonal regulation of resistance. A more complete enumeration of pertinent observations will be found in the Abstract Section.

It is difficult to make any generalizations concerning the sex difference in the sensitivity to barbiturates since this differs depending upon the particular compound and animal species used. In the mouse, susceptibility to hexobarbital anesthesia does not appear to be sex-dependent, but females are more sensitive to amobarbital and pentobarbital than males. There are strains of mice, however, in which hexobarbital produces longer lasting anesthesia in males than in females and the 9000 g liver supernatant of the latter hydroxylates hexobarbital faster than that of males. The resistance to pentobarbital anesthesia induced by pretreatment with phenobarbital lasts longer in female than in male mice.

Most of the investigations concerning the sex dependence of barbiturate anesthesia have been performed in rats. It has been noted as early as 1932, that in this species, males are more resistant to amobarbital anesthesia than females. Similar observations have subsequently been made with numerous other barbiturates. This sex difference appears only after puberty and is abolished by castration. On the other hand, testosterone treatment raises the barbiturate resistance both in females and in castrate males to approximately the normal male level. Upon repeated pentobarbital injections, rats of both sexes become comparatively tolerant to this barbiturate, but when treatment is interrupted, susceptibility rises more rapidly in females and male castrates than in intact males.

Sexual activity as such does not significantly influence ectylurea sleeping time in rats of either sex; however, females are comparatively resistant during and shortly after pregnancy.

Unlike most other barbiturates, thiopental is about equally effective in male and in female rats.

Liver slices of male rats detoxify hexobarbital *in vitro* more actively than similar preparations of female rats, but no such sex difference could be demonstrated for thiopental. Certain microsomal enzyme-inhibitors, such as Sch 5712, prolong hexobarbital sleeping time about 12-fold in female and only 3-fold in male rats *in vivo*. Yet, this difference is absent when Sch 5712 is added to unfortified liver homogenate from rats of either sex.

The D-enantiomer of hexobarbital has a much greater anesthetic effect in female than in male rats, whereas no such sex difference in sleeping time is observed for the L-enantiomer. This is unexpected, since the metabolism of both enantiomers is more rapid in males.

In general, it may be said that the sex differences in sensitivity to barbiturate anesthesia appear only after puberty, being virtually abolished by gonadectomy in both sexes, and that they can be raised to the male level by the administration of testoids to females or gonadectomized males. The sex differences are attributed to an increased microsomal enzyme activity in the livers of males, since even *in vitro* liver slices or microsomal fractions of males are more potent in detoxifying most barbiturates than those of females. Yet, not all barbiturates are subject to such sex differences of their detoxication in rats, and no clear-cut and constant sex dependence of hexobarbital anesthesia could be demonstrated in mice, guinea pigs, rabbits and dogs.

Under identical dietary conditions, male rats are more susceptible than females to the hepatotoxic and nephrotoxic actions of  $\text{CCl}_4$ . However, some investigators obtained opposite results, presumably because this sex difference appears to be highly dependent upon incidental circumstances, such as dosage, duration of exposure and the strain of rat used.

A definite sex difference has also been noted with regard to the tumorigenic effects of various carcinogens. In certain strains of mice, o-aminoazotoluene produces hepatomas much more frequently in females than in males. Furthermore, intact females are more susceptible than spayed females; castrate males approach intact females in the degree of their susceptibility. The incidence of pulmonary tumors produced by this carcinogen is not dependent upon any of the factors just mentioned.

AAF induces hepatomas only in male mice. Male rats develop hepatomas on various azo-dyes more readily than females: they are also more sensitive than females to aflatoxin and to various other carcinogens.

On the other hand, diacetamidofluorene allegedly produces more hepatic tumors in female than in male mice.

The fact that carcinogens which elicit mammary tumors easily in females fail to do so in males is too well-known to deserve detailed discussion.

The adrenal necrosis produced by DMBA in the rat does not appear to be sex dependent.

A sex difference in susceptibility to carcinolytic agents has also been described. In the mouse, rat and man, females are more sensitive than males to the toxic effects of numerous antineoplastic compounds. Thus cycloheximide is more toxic to female than to male rats or mice, but no such sex difference is noted in dogs. On the other hand, in rats, females are more resistant than males to vinblastine, and

cyclophosphamide produces less extensive and less lasting bladder lesions in female than in male rats.

In adult male mice of various strains, exposure to **chloroform** vapor produced necrosis of the renal tubules, whereas females showed no such change. Testoids rendered females susceptible, whereas folliculoids decreased the sensitivity of males.

Female rats are much more resistant than males to the production of cardiovascular lesions by **choline** deficiency. Mature intact or ovariectomized females — but not intact males — develop fatty infiltration of the liver when fed a choline-containing but methionine-deficient diet, for three days. Castrate males are as susceptible as females, and testosterone raises resistance both in females and in castrate males.

Sensitivity to certain **digitalis** compounds is also sex-dependent, at least in some species. Female mice are more resistant to ouabain than males, but resistance to strophanthin-k is the same in both cases. Adult female rats are also more resistant to ouabain than males, but the sex difference does not become evident before 2-4 months of age. The lethal dose of ouabain for the isolated heart of female rats is considerably higher than that for the heart of male rats. Male and castrate female dogs are more sensitive than intact females to intoxication with digoxin.

The tail necrosis produced in rats by large doses of **ergotamine** does not appear to be conspicuously sex-dependent. However, males are allegedly more sensitive than females to the production of neurofibromas and renal calcification by chronic ergot intoxication.

Male rats are more resistant than females to the production of fatty livers by **ethionine**. Orchidectomy abolishes this resistance, and testosterone protects both females and castrate males.

**Ethylene glycol** intoxication elicits oxalate and calcium precipitation in the kidneys more readily in male than in female rats.

**Lathrogens** produce aortic aneurysms more readily in young males than in females. On the other hand, in male rats — unlike in females or orchidectomized males — the osteolathyrism produced by AAN is inhibited by rich casein diets.

Data on the sex-dependence of **nicotine** intoxication are so contradictory that they cannot be profitably discussed.

Periportal fatty degeneration of the liver is produced by chronic **orotic acid** feeding more readily in female than in male rats. Orchidectomy abolishes this resistance unless testosterone treatment is administered.

There is also a definite sex difference in the response of animals to various **pesticides**. Data concerning DDT sensitivity are somewhat contradictory, but male rats are more resistant than females to various cholinergic phosphorothioates, and particularly to parathion. On the other hand, the toxicity of OMPA is about the same in rats of either sex. In an extensive series in which 98 pesticides and two metabolites of DDT were tested in the rat, most compounds proved to be more toxic to females; yet, nine pesticides were more toxic to males. Morestan, which belongs to the exceptional pesticides that are more toxic to males, appears to be equally damaging after orchidectomy or estradiol treatment of males, and after testosterone treatment of females.

Female rats are more sensitive than males to intoxication with **strychnine**. This difference is abolished by SKF525-A.

Excessive tyrosine feeding causes more pronounced manifestations of tyrosinosis (conjunctivitis, alopecia, pancreatic lesions, inflammation of the paws) in male than in female rats.

Male rats are much more resistant than females to intoxication with vitamin D or DHT. Earlier claims that female mice are more resistant than males to irradiated ergosterol intoxication require confirmation.

Acetophenetidin ← Sex, Man, Rat:  
Kuntzman et al. H30,992/66

Aniline ← Sex: Quinn et al. E89,993/58\*; Kato G74,104/66; Kato et al. F76,403/66, G68,411/66; Schenkman et al. G67,777/67

#### Acetylcholine ←

Bonino C30,089/56: Female guinea pigs are more sensitive to lethal acetylcholine intoxication than males. Earlier literature is reviewed.

#### Aminopterin ←

Goldin et al. D76,907/50: There is no sex difference in the toxicity of aminopterin in immature mice, but among adults, males are more resistant than females. Estradiol increases aminopterin tolerance in immature and mature males, whereas testosterone does not influence it.

Aminopterin ← Sex + Steroids,  
Mouse: Goldin et al. D76,907/50\*

#### Aminopyrine ←

Soyka G66,626/69: In rat liver, the aminopyrine demethylase activity of the microsomal fraction increased considerably during the first 30 days after birth. Evidence of an inhibitor was not found during this newborn period. After puberty, the activity in male rats was about twice as high as in females. Testosterone produced only an insignificant rise in females.

Aminopyrine ← Sex: Herken et al. G74,662/58; Siegert et al. G71,866/64\*; Kato et al. F57,817/65, F76,403/66, G68,411/66, G80,897/68; Kato G74,104/66; Kinoshita et al. G71,863/66; Schenkman et al. G67,777/67

#### Amphetamine ←

Groppetti & Costa H31,959/69: In adult male rats, the disappearance of amphetamine is faster than in adult females. Estradiol retards the rate of amphetamine disappearance in adult males. Such potent hepatic microsomal enzyme inducers as phenobarbital, 3-MC, or diphenylhydantoin do not change the tissue levels of amphetamine.

Anaphylactoidogens ← cf. Selye G46,715/68, p. 209.

#### Antibiotics ←

Hurst D33,743/58: Female mice are much more susceptible than males to the therapeutic action of streptomycin on streptococcal infection.

Anticoagulants ← Sex: Feuer et al. G76,853/67

Antipyrine ← Sex, Dog, Gp, Man,  
Mouse, Rat, Rb: Quinn et al. E89,993/58\*

#### Arsenic ←

Durham et al. A49,445/29: Female mice weighing over 18 g are more sensitive to novarsenobenzene (Neosalvarsan) than males, whereas mice weighing less than 15 g show no such sex difference.

Agduhr A51,257/37: In mice and rats of both sexes, sexual intercourse increases resistance against As<sub>2</sub>O<sub>3</sub> and vitamin D.

Agduhr E70,688/41: Repeated mating increases the resistance of both male and female mice to arsenic. Pregnancy further augments this protective effect in females.

Skanse A72,698/41: Review on the effect of sex, sexual intercourse and gonadectomy upon the storage of arsenic in the tissues of mice.

#### Barbiturates ←

##### MOUSE

Kennedy A43,060/34: The susceptibility of mice and rats to hexobarbital anesthesia does not appear to be sex dependent. These findings are contrasted with those obtained with amobarbital to which females are more sensitive.

Buchel & Liblau E89,233/63: In Swiss mice, there is no sex difference in hexobarbital sleeping time or in the disappearance rate of this drug from the brain.

Westfall et al. F2,504/64: Pentobarbital anesthesia is more prolonged in male than in female mice. Sleeping time in males is shortened by stilbestrol and, in females, prolonged by testosterone. Apparently, the mechanism

for barbiturate detoxication is different in mice and rats.

*Rümke G71,098/68*: In mice of the CPB-N strain, hexobarbital anesthesia lasts longer in males than in females, but only after puberty. Following gonadectomy of mature animals, the sex difference persists for about 2 weeks but then disappears.

*Rümke & Noordhoek H21,659/69*: Among mice of many strains, hexobarbital produces longer anesthesia in males than in females. This difference is evident only after sexual maturation. If 10 week old males are castrated, the difference persists for at least 2 weeks, but it disappears after a month. Ovariectomy has no effect upon sleeping time; testosterone increases it in females but not in males.

*Noordhoek & Rümke H21,660/69*: In mice, the 9000 g liver supernatant of females hydroxylates hexobarbital faster than that of males. After orchidectomy, the in vitro metabolism of hexobarbital becomes equal to that of females but ovariectomy has no effect upon it. Testosterone decreases the rate of in vitro hexobarbital hydroxylation in females but not in males. Female livers contain more cytochrome P-450 and testosterone lowers its concentration in female but not in male livers.

*Buchel & Levy G74,850/70*: In mice, pretreatment with phenobarbital decreases pentobarbital sleeping time; this phenomenon is detectable within 24 hrs and reaches a maximum 48 hrs after phenobarbital administration. The resistance is no longer detectable in males after 96, in females after 120 hrs.

*Gerald & Feller G74,396/70*: In mice, spiro-nolactone and its  $\Delta^8$ -dethioacetylated metabolite reduce hexobarbital sleeping time and cause nearly identical increases in liver weight, microsomal protein content, NADPH-cytochrome c reductase, cytochrome P-450 content and the N-demethylation of ethylmorphine. Preliminary observations suggest that these actions of spiro-nolactone and of its metabolite are evident in both sexes.

Amobarbital, Butallylonal, Hexobarbital ← Sex, Mouse: Holck et al. A8,011/37\*

Barbital, Hexobarbital, Pentobarbital ← Sex, Mouse: Blackham et al. G69,913/69\*

Hexobarbital ← Sex + Testosterone, Mouse: Holck et al. A55,755/42\*

Hexobarbital ← Sex + Genetics, Mouse: Fujii et al. H28,618/68\*

Pentobarbital ← Sex + Testosterone, Mouse: Westfall et al. F2,504/64\*

Secobarbital ← Sex + Disulfiram, Mouse: Gruber et al. D41,363/54

#### RAT

*Nicholas & Barron 62,223/32*: Male rats are more resistant than females to amobarbital anesthesia.

*Barron A42,858/33*: Male rats are more resistant than females to amobarbital anesthesia. Castration increases the sensitivity of the male but not quite to the female level. Castration before puberty does not diminish resistance. Ancillary experiments suggest that the effect of castration is due to changes in water metabolism.

*Holck & Kanan 31,302/35*: Female rats are more sensitive than males to various barbiturate anesthetics. No such sex difference could be detected in the dog, cat, rabbit, guinea pig, mouse, turtle or frog.

*Holck et al. 68,297/37*: Female rats are much more sensitive to anesthesia by various barbiturates than are males. Orchidectomy diminished barbiturate sensitivity, but not quite to the low level of normal females. Barbital anesthesia was not influenced by sex. Testosterone increased barbiturate resistance in normal or ovariectomized females, but not quite to the level of normal males.

*Holck et al. A8,011/37*: "Using duration of hypnosis and incidence of mortality as criteria, no sex-difference was found in the white or hybrid rat to barbiturates with two short side-chains, or one such with an iso-aliphatic or a phenyl group (barbital, ipral, alurate, diallyl barbiturate, nostal, dichlor allyl barbiturate, phenobarbital). No sex-difference was found to chloral hydrate. A slight to moderately higher male resistance was seen with barbiturates having one short and one longer straight aliphatic chain (neonal, ortal; also to ethyl 2-methyl-amyl barbiturate). Much higher male resistance was present with barbiturates having one short and one long, forked chain (not of the iso type) or a cyclohexenyl group (amytal, pentobarbital, seconal, pernoston and its chlorine homologue, rectidon (sigmodal), phanodorn and evipal), or those with a methylated nitrogen (eunarcon, evipal). These are the short acting ones, but nostal is also short acting and the rat exhibits no sex-difference to it. No sex-difference was found to evipal in certain other species of animals (dog, cat, rabbit, guinea pig, mouse, frog). In mice sex-difference was also absent to amytal, but was present in case of pernoston to a slight extent."

*Moir E54,544/37*: Very young female rats are more resistant to pentobarbital than males, whereas the reverse was true in mature rats. Both males and females developed tolerance to pentobarbital upon repeated injections, but when treatment was interrupted and then resumed, susceptibility was greatly increased in females and castrate males but not in intact males. "Inasmuch as the castrated males still remained more resistant than females, the superior resistance of the males was held to be due at least in part to some factor or factors other than the male gonads."

*Carmichael D68,076/38*: The LD 50 of pentobarbital increases with age but "there does not seem to be a definite sex difference in reaction to the median lethal dose of nembutal of either young or old rats." In earlier observations in which males were found to be more resistant to barbiturates, the anesthetic action and not the lethal effect was determined.

*Holck & Fink A35,663/40*: Sexual activity or the absence of it failed to influence ectylurea (Nostal, isopropyl bromallyl barbituric acid) anesthesia in male or female rats. However, resistance to this barbiturate was markedly raised during pregnancy and in females which recently had been pregnant although, even in these, it was not brought up to the male level.

*Kinsey A39,742/40*: Female rats sleep about twice as long as males when given either single or repeated injections of pentobarbital. Testosterone increases pentobarbital resistance in females. Ovariectomy diminishes the sleeping time.

*Holck & Mathieson 80,435/41*: Male rats are more resistant than females to the lethal effect of pentobarbital. Castration reduced the tendency to develop tolerance following repeated pentobarbital injections in males but increased it in females. Testosterone pretreatment increased resistance in castrate males and intact females, but not in intact males.

*Horinaga A36,414/41*: Male rats are more resistant to barbiturate anesthesia than females. Orchidectomy and treatment with folliculoids increase sensitivity, whereas ovariectomy does not affect it.

*Holck et al. 84,766/43*: Adult male rats are more resistant than females to sodium vinbarbital and calcium 5-ethyl 5-(2-butyl) N-methyl barbituric acid.

*Holck & Mathieson B644/44*: In rats, the development of tolerance to pentobarbital was determined by injecting increasing doses every 90 min day and night for periods up to 5 days. 1—2 Month-old rats practically all developed

tolerance as did adult males in contrast to females. Castration lowered the ability of adult males to develop tolerance, but did do so in 2 month-old males. Ovariectomy of 2 month-old females increased their ability to detoxify pentobarbital, once tolerance had developed.

*Masson B275/45*: Male rats are more resistant to pentobarbital anesthesia than females. However, upon treatment with LAP (lyophilized anterior pituitary) s.c., resistance decreased considerably in both sexes and eventually reached the same low level in males and females. LAP produced a similar increase in sensitivity to amobarbital, hexobarbital, cyclobarbital and vinbarbital, but did not influence barbital or phenobarbital anesthesia.

*Emmens A46,574/46*: In immature rats of both sexes, pentobarbital has an approximately equal anesthetic effect, whereas DOC and progesterone are twice as potent in females as in males.

*Homburger et al. E61,371/47*: Female rats are more sensitive than males to pentobarbital but not to thiopental anesthesia. Age and strain differences in barbiturate resistance have also been noted in the rat.

*Crevier et al. B54,151/50*: Pentobarbital anesthesia lasts longer in female than in male rats as judged by the linguo-maxillary reflex. Castration abolishes the high resistance of the male, but testosterone restores it again to the normal level. In ovariectomized rats, estradiol has virtually no effect but testosterone raises resistance to the male level. These in vivo effects run parallel to the in vitro pentobarbital detoxifying power of the liver.

*Jarcho et al. B59,706/50*: Adult male rats require larger amounts of pentobarbital than do females for the prolonged maintenance of deep surgical anesthesia.

*Maloney et al. E48,771/52*: The pentobarbital sleeping time is greatly increased after adrenalectomy in rats of both sexes, males being more resistant than females. Vitamin C lengthened the sleeping time in both intact and adrenalectomized animals. Cortisone shortened the sleeping time of adrenalectomized, but lengthened that of intact animals. DOC diminished sleeping time more markedly in females than in males. [This brief abstract gives, as the authors themselves are careful to point out, "somewhat of a confused picture" (H.S.).]

*Grewe D35,140/53*: Male rats are more resistant than females to barbiturate (eunarcon, hexobarbital) anesthesia. After gonadectomy both sexes exhibit the longer sleeping

time characteristic of females. Twenty-eight days following orchidectomy, the sleeping time is reduced to the level seen in intact males. Testosterone shortens the sleeping time of females.

*Buchel D59,654/53*: Extensive investigations on the influence of sex upon the sensitivity of the rat to numerous barbiturates, chloral hydrate and ethyl urethan.

*Buchel D73,669/54*: Review on the literature and personal observations on the increased sleeping time of female as compared to male rats after treatment with certain barbiturates particularly hexobarbital. The increased sleeping time is associated with a prolonged persistence of the concentration of the drug in the blood. Gonadectomy prolongs the sleeping time of males but does not influence that of females. In immature rats no such sex difference is observed.

*Quinn et al. G67,327/54*: The biologic half-life of hexobarbital was found to be 15 min for mice, 60 min for rabbits, 140 min for rats, and 260 min for dogs and man. There was an inverse relationship between the rate of biotransformation of hexobarbital to keto-hexobarbital and the duration of its hypnotic effect. Male rats are more resistant to hexobarbital anesthesia than females but in the latter, resistance as well as the enzyme activity of the microsomes was increased by testosterone.

*Robillard et al. G67,325/54*: Adult males are more resistant than females to pentobarbital anesthesia. Castration decreases the resistance in males. Testosterone raises pentobarbital resistance to the normal male level in both male and female castrates, whereas estradiol and progesterone prolong anesthesia in castrates of both sexes. [The hormones were administered as pellets 15 days before the test, but the amounts are not stated (H.S.).] Partial hepatectomy prolongs pentobarbital anesthesia and accentuates the differences induced by the various interventions just mentioned, without causing qualitative changes in the outcome. Liver homogenates of adult male rats destroy pentobarbital in vitro (spectrophotometric determination) more rapidly than those of castrate males. Pretreatment of the castrates in vivo with testosterone increases the detoxication process, whereas estradiol pretreatment has an opposite effect.

*de Boer & Mukomela C5,245/55*: In rats, ACTH and cortisone shorten thiopental and pentobarbital sleeping times, especially in

females whose sleeping time is normally longer than that of males.

*Streicher & Garbus G76,681/55*: Hexobarbital sleeping time is much longer in females than in male rats. This sex difference is evident also if the hexobarbital effect is augmented by concurrent treatment with SKF 525-A or chlorpromazine.

*Brodie C12,157/56*: The hexobarbital sleeping time of female rats is about four times that of males; correspondingly, the plasma levels of hexobarbital drop much more rapidly in males, whose hepatic microsomes also inactivate the drug more actively in vitro than those of females. Male rats, pretreated with estradiol, sleep as long as females and their hepatic microsomes lose much of their activity to metabolize hexobarbital. Females, pretreated with testosterone, assume the characteristics of males in all these respects. No sex differences were seen in mice, guinea pigs, rabbits, and dogs, and their ability to handle hexobarbital is not influenced by estradiol or testosterone.

*Edgren C45,010/57*: Female rats are more sensitive than males to the anesthetic effect of hexobarbital. Gonadectomy prolongs hexobarbital sleeping time in males and shortens it in females. Estrone prolongs hexobarbital sleeping time in ovariectomized females, whereas testosterone is ineffective. In orchidectomized rats, testosterone shortens hexobarbital sleeping time, whereas estrone is ineffective.

*Remmer G79,941/57*: In female rats, cortisone and prednisolone are much more efficacious than testosterone in shortening hexobarbital anesthesia and increasing microsomal hexobarbital metabolism. Adrenalectomy diminishes the capacity of hepatic microsomes of male rats to metabolize hexobarbital unless the animals are pretreated with cortisone or prednisolone.

*Remmer D86,916/58*: The anesthetic effect of hexobarbital is greater in female than in male rats and liver slices of males detoxify the compound more actively in vitro. No such sex difference could be demonstrated for thiopental.

*Quinn et al. E89,993/58*: In rats, hexobarbital sleeping time is considerably longer in females than in males; it can be reduced in females by testosterone and in males by estradiol. The plasma levels of hexobarbital run parallel with the sleeping time and the hepatic microsomal-enzyme activity inversely. The

guinea pig and mouse show no such sex differences in hexobarbital metabolism.

*Remmer C73,857/58*: The oxidation of hexobarbital and the demethylation of methylaminoantipyrine by liver slices *in vitro* are inhibited by adrenalectomy performed 10–12 days before the experiment, unless the animals are given prednisolone substitution therapy. Addition of prednisolone to the incubation medium has no effect. The drug-metabolizing activity is contained in the microsomal fraction and, in this respect, the microsomes of males are more active than those of females.

*Kramer & Arrigoni-Martelli G74,673/59*: The hexobarbital metabolism by hepatic microsomal-enzyme systems is inhibited, whereas hexobarbital sleeping time is prolonged by certain malonic and succinic acid derivatives, such as Sch 5712. The latter compound prolongs hexobarbital sleeping time about 12-fold in female and only 3-fold in male rats, yet it inhibits hexobarbital metabolism *in vitro* about equally when tested with the unfortified liver homogenate from rats of either sex. Furthermore, Sch 5712 is singularly ineffective in prolonging hexobarbital sleeping time in rats pretreated with phenobarbital.

*King & Becker E38,612/60*: Male rats are more resistant than females to anesthesia produced by pentobarbital.

*Buchel & Liblau E87,108/62*: In rats, the prolonged hexobarbital sleeping time of females, compared to males, is associated with a delayed disappearance of the drug from the blood and brain; yet, at the time of awakening, the blood and brain concentration of hexobarbital is the same in both sexes.

*King & Becker G78,964/63*: In rats, pregnancy prolongs pentobarbital sleeping time, and males are even less susceptible than non-pregnant females.

*Backus & Cohn D92,313/66*: The hexobarbital sleeping time of female mice is shorter than that of males, and varies also according to strain. In general, the length of the sleeping time is inversely proportional to the hexobarbital-metabolizing potency of liver homogenates.

*Nair & Zeitlin G65,099/67*: The hexobarbital-metabolizing activity of the rat liver is extremely low after birth and rises gradually up to the age of 80 days to levels much higher in males than in females. Prenatal X-irradiation suppresses this normal development of enzyme activities in the male so that it only reaches the normal female level. Irradiation

at 21 days (total body or head alone) also suppresses the developmental increase of enzyme activity, but to a lesser extent. Adults are still more resistant.

*Schenkman et al. G67,777/67*: Sex differences in the drug-oxidizing ability of liver microsomes appear to be related to substrate affinity for mixed function oxidases, and not to a difference in the content of cytochrome P-450. "These results, as well as spectral studies of substrate interaction with microsomal cytochrome, showed that microsomes isolated from livers of male rats had over twice the magnitude of substrate (hexobarbital and aminopyrine) binding than did microsomes isolated from the livers of female rats."

*Bardin et al. H12,120/69*: In pseudohermaphrodite rats [not otherwise characterized (H.S.)], unlike in castrates, testosterone fails to increase hexobarbital metabolism and other hepatic microsomal-enzyme activities. The weight of the preputial glands is not increased by testosterone in pseudohermaphrodite rats and the rate of dihydrotestosterone formation from testosterone is diminished in these preputial glands *in vitro*. It is concluded that the pseudohermaphrodite rat has an end-organ insensitivity to testosterone.

*Ganesan H12,504/69*: Male rats are more resistant than females to pentobarbital anesthesia. Orchidectomy or treatment with estradiol decreases the pentobarbital resistance of male rats.

*Furner et al. H17,931/69*: In rats of both sexes, L-hexobarbital has a longer latency, a longer half-life and achieves higher blood concentrations after equivalent doses of the two enantiomers. The L-enantiomer has a much greater anesthetic effect for females than for males, whereas no such sex difference in sleeping time was observed for the L-enantiomer. This is unexpected since the metabolism of both enantiomers is more rapid in males. Pretreatment with phenobarbital always accelerated the metabolism of both enantiomers. D-hexobarbital is about twice as susceptible to inhibition by SKF 525-A as the L-enantiomer.

*Hüssler et al. H23,853/69*: Male rats are more resistant than females to the anesthetic effect of hexobarbital. In rats raised under extreme conditions of stress (cold or repeated periods of fasting) hexobarbital sleeping time is prolonged.

*Stripp et al. H22,743/70*: In rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of

the *in vitro* metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone-treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Gillette H 34,126/71*: In male rats, spironolactone caused a relatively small increase in ethylmorphine N-demethylation and decreased the oxidation of hexobarbital and 3,4-benzpyrene. However, like in females, spironolactone did not affect the type I spectral changes induced in males by ethylmorphine and hexobarbital but caused a small decrease in cytochrome P-450 content and increased NADPH-cytochrome c reductase. Moreover, in males, spironolactone increased the substrate-dependent cytochrome P-450 reduction but not its endogenous reduction. The sex difference in the effect of spironolactone upon hepatic microsomal drug metabolism is illustrated by the tabulation of data concerning ethylmorphine and hexobarbital biotransformation.

*Stripp et al. G79,538/71*: In rats, the induction of hepatic microsomal enzymes by spironolactone "differed from the phenobarbital or methylcholanthrene induction in that it did not increase cytochrome P-450 content or microsomal protein. Furthermore the induction seemed to be sex dependent."

*Selye PROT. 42911*: In male rats, the protective effect of PCN, spironolactone, ethyltestrenol, betamethasone, phenobarbital and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf.* Table 128). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf.* Table 136), but PCN and spironolactone were

effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (Table 136).

#### VARIA

*Holck & Kanân A 43,097/34*: No definite sex difference could be established in the amobarbital sensitivity of dogs and rabbits, but, on the whole, females appeared to be more resistant.

*Donatelli B 38,172/47*: Extensive investigations on the sex difference in barbiturate sensitivity of guinea pigs, mice, rabbits and man.

Butynamine ← Sex + Phenobarbital: Kato et al. F76,403/66

#### Cadmium ←

Ishizaki et al. F94,533/66: Female rats are more sensitive than males to the production of bone decalcification by cadmium on a calcium-deficient diet.

Tanabe G72,457/68: Female rats are more sensitive to cadmium intoxication than males.

#### Caffeine ←

Peters & Boyd F77,819/67: Male rats are more sensitive to caffeine intoxication than females.

#### Carbon Monoxide ←

Smith et al. 45,163/35: Male rats are more sensitive to the lethal action of illuminating gas than females. This difference is eliminated by gonadectomy. Thyroid feeding or dinitrophenol injections decrease survival time.

#### Carbon Tetrachloride ←

György et al. E86,574/46: Under identical dietary conditions, male rats are more susceptible than females to the hepatotoxic and nephrotoxic effects of  $\text{CCl}_4$ .

Bengmark & Olsson D48,932/62: Female rats are more susceptible to the hepatotoxic action of  $\text{CCl}_4$  than males. Testosterone raised the resistance of females to this form of liver damage.

Glover & Reuber F77,043/67: In inbred buffalo strain rats, chronic thyroiditis is produced by  $\text{CCl}_4$  more commonly among females than among males. There was no clear-cut relationship between the occurrence of thyroiditis and hepatic sclerosis.

Chaturvedi G69,350/69: Female rats are less susceptible than males to the hepatotoxic effect of  $\text{CCl}_4$  and other hepatotoxic agents.

Cauthorne et al. H26,441/70: In rats, the acute toxicity of  $\text{CCl}_4$  p.o. is greater in males than in females. Vitamin E and various antioxidants exert a protective effect. It is suggested that the protection may be partly dependent upon the induction of hepatic microsomal enzymes.

#### Carcinogens ←

Andervont et al. A94,080/42; Andervont & Dunn A96,182/47: Among strain C mice, o-aminoazotoluene produced hepatomas more frequently in females than in males. Furthermore, "intact females were more susceptible than castrate females; castrate males approached intact females in their degree of susceptibility; castrate females and castrate males bearing testosterone propionate-cholesterol pellets approached intact males in their degree of susceptibility." The incidence of pulmonary tumors produced by this carcinogen, was not dependent upon any of the factors just mentioned.

Kirby B30,101/47: Female rats are less susceptible than males to the production of hepatomas and hepatic cirrhosis by AAF. Rats simultaneously treated with pellets of estradiol or testosterone and AAF showed no carcinoma formation in the target organs of the sex hormones.

*Stasney et al. B26,653/47*: In rats, 2-acetaminofluorene feeding produces mammary carcinoma only in females, and its development is not significantly accelerated by estradiol or gonadotrophin. "Malignant lesions of the liver occurred in 54.8 per cent of females and 92.3 per cent of males receiving the carcinogen alone. Administration of estradiol and PMS gonadotrophin to females and of testosterone and chorionic gonadotrophin to males intensified the cystic and neoplastic hepatic lesions induced by 2-acetaminofluorene."

*Shay et al. H26,763/49*: In intact female rats, 3-MC p.o. produces a high incidence of mammary adenocarcinomas, whereas this is exceptional in intact or castrate males as well as in spayed females.

*Bielschowski & Hall G71,797/51*: In intact female rats joined in parabiosis with gonadectomized litter-mates, AAF induced a 50% incidence of malignant tumors, mostly of the granulosa. The gonadectomized partners were free of neoplastic lesions.

*Leathem G74,736/51*: In male mice, 2-acetylaminofluorene induced hepatomas only on certain semi-synthetic diets and only in males. In rats receiving this carcinogen in fox chow diet, hepatomas likewise developed exclusively in males [hepatic cyst formation was observed in one female only (H.S.).]

*Rumsfeld et al. G73,677/51*: Male rats fed 3'-methyl-4-dimethylaminoazobenzene or 4'-fluoro-4-dimethylaminoazobenzene develop hepatomas more readily than females. "The ability of liver slices or homogenates to destroy DAB, 3'-Me-DAB, or 4'-F-DAB in vitro did not vary with sex unless a carcinogen had been fed for a long period of time."

*Shay et al. H31,719/52*: In rats, chronic administration of 3-MC p.o. produces glandular tumors of the breast (predominantly in females and estradiol-treated males), spindle-cell and collagenous tumors of the breast and mesenteric sarcomas (predominantly in males and testosterone-treated females), and fibroadenomas of the breast (predominantly in ovariectomized and orchidectomized animals "in which the sex hormone effects were experimentally counterbalanced").

*Dao & Sunderland D79,860/59; Dao et al. E57,368/60*: In rats, the induction of mammary carcinomas by 3-methylcholanthrene is enhanced during pregnancy, pseudopregnancy, and progesterone treatment. Regression of neoplasms occurs after parturition. Males are virtually resistant. In fully formed tumors,

regression could be induced by hypophysectomy or ovariectomy.

*Dao & Greiner D91,850/61*: In male rats, unlike in females or castrate males, 3-MC rarely produces mammary tumors. Ovarian transplants placed into castrate males induce predisposition for mammary carcinogenesis under these conditions.

*Leathem & Oddis D2,742/61*: Female rats are less responsive than males to the induction of hepatomas by AAF. Thyroid feeding increases the incidence of hepatomas in females treated with AAF. It has the same effect in mice of both sexes given DMBA.

*Sidransky et al. C99,347/61*: In rats fed N-2-fluorenylacetylamide hepatic tumors developed in all males but only in 5 of 14 females. "Although castrated males had liver changes similar to those seen in females, these males receiving testosterone had the same changes as were found in the intact males. Intact females receiving testosterone developed earlier and more extensive changes regularly found only in the livers of males." Testosterone may accelerate hepatic tumorigenesis by this carcinogen.

*Dao D36,011/62*: In male, unlike in female rats, 3-MCA fails to induce mammary cancer irrespective of the dose given. In gonadectomized males or females, ovarian grafts enable the production of mammary cancers by 3-MCA.

*Morii G34,628/65*: Male rats are less susceptible to DMBA-induced adrenal necrosis than females.

*Colafranceschi & Tosi G59,115/67*: The adrenal necrosis produced by DMBA in the rat is of equal severity in males and females and cannot be influenced by ovariectomy, orchidectomy, testosterone or estradiol.

*Weisburger et al. F78,862/67*: Male rats are more prone to liver cancer induction by N-hydroxy-N-2-fluorenylacetylamide (N-OH-FAA) than females. In newborn males treated with estradiol and placed on a diet containing N-OH-FAA, the incidence of hepatic carcinomas was decreased, whereas testosterone did not change it. In females, estradiol had a "mixed effect," and testosterone enhanced hepatoma induction.

*Bates H13,409/68*: Male Swiss mice are more sensitive than females to the induction of cutaneous carcinomas by DMBA + croton oil. This is especially true of females in which the initiator was applied during diestrus. Gonadectomy before application of DMBA increased tumor incidence in females but decreased it in males.

*Glover et al. H12,898/68:* In Buffalo strain rats, single s.c. injections of 3-methylcholanthrene produce thyroiditis more often among females than among males.

*Reuber & Glover H5,582/68:* In female Buffalo strain rats, a single s.c. injection of 3-methylcholanthrene produces thyroiditis more constantly than in males.

*Newberne & Williams G69,601/69:* In rats, hepatic carcinogenesis produced by aflatoxin is inhibited by diethylstilbestrol. Male rats are less resistant to aflatoxin than females.

*Svoboda et al. G64,564/69:* Hepatocytes of male rats given CPIB (ethyl- $\alpha$ -p-chlorophenoxyisobutyrate) show a pronounced increase in microbodies and in catalase activity while those of intact females do not. In castrate males given estradiol and CPIB, the increase in catalase activity and microbody proliferation is abolished, whereas in ovariectomized rats given testosterone and CPIB, there is an increase in microbodies and catalase activity.

*Dehnen et al. G74,165/70:* In rats, the ability of hepatic microsomal enzymes to metabolize benzo(a)pyrene is not influenced by sex. The highest breakdown values were found at about 20 days of age in both sexes. After 50 days, hydroxylase activity decreased slowly but inducibility remained constant throughout life.

*Kozuka H27,469/70:* "Repeated injection of reserpine and simultaneous administration of 2,7-diacetamidofluorene in SMA/Ms strain mice prevented the development of liver tumors but failed to induce gastric cancer. Female mice developed more hepatic tumors than males both in the carcinogen groups and in the reserpine-treated group. Castration increased the formation of hepatic cancer in male mice but not in females. In castrated female mice, estradiol benzoate had little effect and testosterone propionate reduced liver tumor incidence somewhat."

*Levine H31,806/70:* In rats, 3,4-benzpyrene is rapidly excreted through the bile in the form of its metabolic products. Pretreatment with microsomal drug-metabolizing enzyme inducers (e.g., phenobarbital, methylcholanthrene, 3,4-benzpyrene) greatly enhances the rate of biliary excretion of this compound. Both the rate of metabolism and of biliary excretion are enhanced to a similar extent throughout the induction period. Male rats both metabolize 3,4-benzpyrene and excrete its metabolites in the bile at rates approximately 2.5 times that of females. The induction by methylcholanthrene of both the metabo-

lism and the biliary excretion of 3,4-benzpyrene can be partially blocked by ethionine. It has been concluded that conversion to its metabolites is the rate-limiting step in the biliary excretion of 3,4-benzpyrene.

*Stripp et al. H22,743/70:* In rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Stromberg & Reuber G75,306/70:* Males are more sensitive than females to the production of hepatic carcinomas by N-4-(4'-fluorodiphenyl)acetamide.

*Young et al. G77,809/70:* In rats given single oral doses of DMBA during diestrous, the mean number of tumors per animal was significantly greater than when the carcinogen was given during other stages of the estrous cycle.

*Gillette H34,126/71:* In male rats, spironolactone caused a relatively small increase in ethylmorphine N-demethylation and decreased the oxidation of hexobarbital and 3,4-benzpyrene. However (like in females), spironolactone did not affect the type I spectral changes induced in males by ethylmorphine and hexobarbital but caused a small decrease in cytochrome P-450 content and increased NADPH-cytochrome c reductase. Moreover, in males, spironolactone increased the substrate-dependent cytochrome P-450 reduction but not its endogenous reduction. The sex difference in the effect of spironolactone upon hepatic microsomal drug metabolism is illustrated by the tabulation of data concerning ethylmorphine and hexobarbital biotransformation.

#### **Carcinolytic Agents $\leftarrow$**

*Bennette D77,417/52*: Male mice are much more sensitive than females to the toxic and tumor growth-inhibiting effects of methotrexate.

*Pallotta et al. D26,380/62*: "Acetoxycycloheximide, an antibiotic with anti-tumor activity, was much more toxic to female rats than to males. It was also more toxic to female mice than to males, but no such difference occurred in dogs." Two closely related cycloheximide derivatives showed no such sex difference.

*Rall G72,239/64*: In the mouse, rat and man, females are more sensitive than males to the toxic effects of various antineoplastic agents such as methotrexate, cyclophosphamide, nitrogen mustard and 6-mercaptopurine. Rats also show a similar sex difference in their sensitivity to acetoxycycloheximide, but no such difference is noted in mice with regard to this compound.

*Cutts H22,100/68*: In rats, diethylstilbestrol protects against lethal doses of vinblastine. Among otherwise untreated rats, females are more resistant to vinblastine than males.

*Koss & Lavin G75,309/70*: In rats, the production of bladder lesions by cyclophosphamide is sex dependent. "In the female, the initial epithelial necrosis was less extensive, epithelial regeneration was more rapid, and subsequent hyperplasia and atypia were less pronounced and of shorter duration. One week after injection, the histology of the bladder epithelium was close to normal in the female, whereas in the male the epithelium was still markedly hyperplastic and atypical."

Methotrexate  $\leftarrow$  Sex, Mouse: *Bennette D77,417/52\**

#### **Carisoprodol $\leftarrow$**

*Kato et al. G66,023/61*: Adult (but not immature) male rats are less sensitive to

carisoprodol-induced muscular paralysis than females. Castration or treatment with SKF 525-A abolishes the increased resistance of the adult male rat. Incubation of liver slices with carisoprodol shows that the resistance of the male is due to accelerated substrate inactivation. No sex difference is noted in adult mice or guinea pigs.

Carisoprodol  $\leftarrow$  Sex + SKF 525-A + Age: *Kato et al. G66,023/61\**

Carisoprodol  $\leftarrow$  Sex + Testosterone: *Kato et al. G64,325/62\**

Carisoprodol  $\leftarrow$  Sex + Starvation: *Kato et al. F88,660/67\**

#### **Cerium $\leftarrow$**

*Snyder et al. C99,417/59*: In rats, i.v. injection of cerium produced extremely high levels of liver fat in females but not in males. After castration males reacted as strongly as females. Testosterone reduced fatty infiltration in both intact and ovariectomized females. Hypophysectomy prevented fatty liver formation in both sexes, whereas adrenalectomy did so only in males.

#### **Chloral Hydrate $\leftarrow$**

*Buchel D59,654/53*: Extensive investigations on the influence of sex upon the sensitivity of the rat to numerous barbiturates, chloral hydrate and ethyl urethan.

*Buchel D73,669/54*: Male rats are only questionably more resistant than females to chloral hydrate anesthesia.

Chloral Hydrate  $\leftarrow$  Sex: *Holck et al. A8,011/37\**

Chloramphenicol  $\leftarrow$  Sex: *Remmer et al. G66,868/65*

Chlorcyclizine  $\leftarrow$  Sex: *Kuntzman et al. F45,464/65\**

#### **Chloroform $\leftarrow$**

*Eschenbrenner 93,202/45*: Chloroform induces renal necrosis in male but not in female strain A mice.

*Eschenbrenner & Miller 94,309/45*: Following administration of large amounts of chloroform p.o., "there was extensive necrosis of portions of the proximal and distal convoluted tubules in normal male and in testosterone-treated castrated male mice and no necrosis in female and in castrated male mice."

*Deringer et al. G64,723/53*: Chloroform inhalation produced renal damage in male but not in female C3H mice.

*Shubik & Ritchie D67,964/53*: Small doses of chloroform produce fatal tubular necrosis in the kidneys of male but not of female DBA mice.

*Hewitt C41,385/56*: Exposure to chloroform vapor produces renal tubular necrosis in male, but not in female mice.

*Culliford & Hewitt C28,738/57*: In adult male mice of two strains, exposure to chloroform vapor produced necrosis of the renal tubules, whereas females showed no such change. Testoids rendered females fully susceptible, whereas folliculoids decreased the sensitivity of the males. Orchidectomy abolished susceptibility in one strain of mice but only diminished it in another, although the residual sensitivity could be annulled by adrenalectomy. In gonadectomized mice, methyltestosterone, testosterone propionate, dehydroepiandrosterone, progesterone and very large doses of cortisone induced susceptibility.

**Cholesterol** ← *cf. Selye G60,083/70, pp. 474, 476.*

Cholesterol ← Sex: Kritchevsky et al. *G16,024/63*

### **Choline** ←

*Wilgram & Hartcroft C14,392/55*: Female rats are much more resistant than males to the production of cardiovascular lesions by choline deficiency. However, simultaneous administration of "androgens" [kind not specified (H.S.)] and STH sensitizes the female to the induction of these lesions by hypolipotropic rations.

*Nakamura et al. C41,067/57*: Among rats about 30 days of age, males are more sensitive than females to the production of renal lesions by choline-deficient diets.

*Sidransky & Farber C55,020/58*: "Force-feeding of purified choline-containing diets devoid of methionine for 3 to 6 days induces fatty liver in adult female rats, but not in adult male rats. Excess lipid accumulates in the periportal region of liver lobule." Force-feeding of threonine-devoid diet also induces periportal fatty infiltration but without sex difference. Since choline does not protect against hepatic steatosis induced by methionine deficiency, the latter amino acid must play some role in the regulation of fatty liver formation other than the contribution of methyl groups for the synthesis of choline.

*Sidransky et al. G48,110/67*: In rats, mature intact or ovariectomized females, but not intact males, develop fatty infiltration of the liver when first fed a choline containing methionine-deficient diet for three days. Castrated males are as susceptible as females and testosterone raises the resistance in females as well as in castrated males. Presumably, testosterone is responsible for the natural resistance of male rats to this type of hepatic steatosis. Earlier literature on sex differences in susceptibility to fatty liver formation is reviewed.

*Reuber H29,035/69*: In male Buffalo strain rats, the liver cirrhosis produced by a choline-deficient diet is more severe than in females.

*Griffith A33,347/70*: Among young rats, females are more resistant than males to the production of hepatic steatosis and hemorrhagic renal lesions by choline deficiency.

*Wilson et al. G79,508/70*: In mice on hypolipotropic diets, the development of atrial thrombosis was independent of sex and not markedly influenced by gonadectomy. The same was true of castrated males given testosterone. Only gonadectomized females on estrone showed an unusually low incidence of thromboses.

### **Cocaine** ←

*Downs & Eddy 58,426/32*: Female rats are more resistant than males to the lethal action of cocaine i.p.

*Guerrero et al. F70,995/65*: Resistance to cocaine is significantly lower in male than in female rats, but no such sex difference is observed in castrates. Testosterone diminished the cocaine-resistance of castrates in either sex, whereas estradiol did not influence it. At the time of death, the plasma cocaine concentration was the same in both sexes, and hence it was concluded that testosterone interferes with the enzymic inactivation of cocaine.

*Paeile et al. G75,994/65*: Male rats are significantly more resistant than females to lidocaine and dibucaine, whereas females are more resistant than males to cocaine.

Cyanide ← Sex, Mouse: Störtebecker *76,398/39\**

Cyclural ← Sex: Graham et al. *G77,527/51\**

### **Dibucaine** ←

*Paeile et al. G75,994/65*: Male rats are significantly more resistant than females to lidocaine and dibucaine, whereas females are more resistant than males to cocaine.

**Digitalis** ←

*Holck & Kimura 84,604/44*: Female mice are more resistant to ouabain than males. Resistance to strophanthin-K is the same in both sexes. Ovariectomy, orchidectomy and treatment with "estrogenic hormones" produced inconsistent changes in ouabain resistance.

*Holck & Kimura D99,625/51*: One month old rats of both sexes are equally sensitive to ouabain. Adult female rats are more resistant to ouabain than males but the difference does not become evident before 2—4 months of age. Rats rapidly become resistant to ouabain, and upon repeated injections, the sex difference tends to disappear. Castration does not alter the sex difference in ouabain resistance significantly in either sex. "However, in case of pentobarbitalized rats the usual higher female resistance was plainly seen and spaying definitely decreased the number of injections required to cause death."

*Wollenberger & Karsh D95,331/51*: The lethal dose of ouabain for the isolated heart of female rats is considerably higher than that for the heart of male rats.

*Grinnell & Smith C31,428/57*: On the basis of studies in dogs treated with estrone, estradiol or diethylstilbestrol, it is concluded that folliculoids protect the rat against the induction of cardiac arrhythmia by digoxin. "Male dogs and castrate female dogs have been found to be highly sensitive to toxic manifestations of a cardiac glycoside on cardiac rhythm, in comparison with normal females in anestrus, or castrate females treated with estrogenic substance. A high degree of resistance to toxicity of digoxin was exhibited by the 3 normal females in natural estrus which were available."

*Selye PROT. 42911*: In male rats, the protective effect of PCN, spironolactone, ethyl-estrenol, betamethasone, phenobarbital, and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf.* Table 128). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf.* Table 136), but PCN and spironolactone were effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be com-

pared with similar experiments on females (Table 136).

N,N-Dimethylaniline ← Sex: Kato et al. *F76,403/66*; Ziegler et al. *G79,382/66*; Machinist et al. *H15,503/68*

N,N-Dimethylnaphthylamine ← Sex + Methylcholanthrene: Kato et al. *F76,403/66*

N-Nitrosodimethylamine ← Sex + 3-MC + Age: Venkatesan et al. *H31,273/70*

**Dinitrophenol** ←

*Chamberlin & Hall 66,611/36*: Male cats are more resistant than females to the fatal action of dinitrophenol.

Diphenhydramine ← Sex + Phenobarbital: Kato et al. *F76,403/66*

**Dye** ←

*Reuber G64,737/69*: In Buffalo strain rats, chronic treatment with trypan blue s.c. causes thyroiditis more often among females than among males.

*Reuber G77,295/70*: Among rats chronically treated with trypan blue, females develop chronic thyroiditis more often than males.

**Ergot** ← *cf. also Selye G60,083/70, pp. 476, 479.*

*McGrath A29,208/35*: In rats of both sexes, tail necrosis is produced by large amounts of ergotamine. Estrone prevents this change in females but not in males.

*Loewe & Lenke A43,451/38*: In the rat, the tail-necrosis produced by ergotamine s.c. is essentially the same in both sexes. Contrary to earlier claims, it cannot be prevented by folliculoid hormones and/or orchidectomy.

*Suzman et al. A44,452/38*: Repeated administration of estrone completely protects female rats against the tail-necrosis produced by ergotamine; males are only partially protected. Orchidectomy has no effect in itself, but enhances the protective effect of estrone in the male. Otherwise untreated rats showed no marked sex difference in their sensitivity to ergotamine.

*Fitzhugh et al. A46,537/44*: In rats, chronic intoxication with ergot leads to the formation of neurofibromas and renal calcification. Males are more sensitive than females.

*Messina G18,016/64*: In rats, ergotamine produces vascular lesions conducive to tail necrosis more readily in females than in males. Hypophysectomy prevents these toxic manifestations in both sexes, whereas treatment

with chorionic gonadotrophin does not affect them.

*Contreras et al. F81,599/67*: In intact male rats, unlike in females or castrate males, ergonovine induced an analgesic effect (electrical stimulation of the genital papilla) unless the latter were treated with testosterone.

#### **Ether ←**

*Störtebecker A1,993/37*: Rabbits pretreated with "folliculin" tolerate normally anesthesia-producing doses of butallylonal (Pernocton). Subsequent experiments were conducted to determine the blood ether level during ether anesthesia at the time the corneal reflex is lost in intact and gonadectomized rabbits and mice. Similar observations were made during pregnancy and in relation to the estrous cycle. [Several conclusions were drawn suggesting an influence of sex hormones upon anesthesia but the number of animals per group was small and hence statistical evaluation impossible (H.S.).]

#### **Ethionine ←**

*Farber et al. B47,283/50; D24,923/51*: Male rats are more resistant than females to the production of fatty livers by ethionine. Orchidectomy abolished this resistance, whereas ovariectomy did not influence the lesions. Testosterone protected both females and castrate males.

*Jensen et al. D83,567/51*: DL- or L-ethionine i.p. causes hepatic steatosis in fasted female but not in fasted male rats.

Ethionine ← Sex + CFT 1201: *Herken et al. G74,662/58\**; *Maibauer et al. G74,663/58\**

#### **Ethyl Alcohol ←**

*Aberhalden & Wertheimer A49,424/27*: Female mice are more resistant than males to chronic ethanol poisoning.

*Mallow C47,222/53*: Ethanol p.o. produces more severe fatty infiltration of the liver in female than in male rats. Ovariectomy or administration of estradiol to males did not influence fatty infiltration but testosterone reduced hepatic steatosis in females, whereas castration increased it in males.

#### **Ethyl-O-Ethylphenylurea ←**

*Hjort et al. A32,832/40*: Male rats are more resistant than females to the anesthetic effect of unsymmetrical ethyl-O-ethylphenylurea.

#### **Ethylene Glycol ←**

*Tanret et al. G68,367/61*: Female rats are much more resistant than males to the production of renal oxalate deposits by ethylene glycol.

*Tanret et al. D44,140/62*: Prolonged oral administration of ethylene glycol produces calcium oxalate precipitation in the kidney of male, but not of female, rats. Estradiol abolishes the susceptibility of intact or castrated males, but orchidectomy does not. Intact, unlike ovariectomized, females cannot be made susceptible by treatment with testosterone.

*Richardson D88,284/65*: In rats, dietary supplements of glycolic acid or ethylene glycol produce oxaluria and kidney oxalate deposition in males but not in females.

#### **Ethyl Ether ←**

*Störtebecker 76,398/39*: Review of the literature (up to 1935) on the effect of sex and sex hormones upon ether anesthesia.

#### **Ethylmorphine ←**

*Gerald & Feller G74,396/70*: In mice, spiranolactone and its  $\Delta^6$ -dethioacetylated metabolite reduce hexobarbital sleeping time and cause nearly identical increases in liver weight, microsomal protein content, NADPH-cytochrome c reductase, cytochrome P-450 content and the N-demethylation of ethylmorphine. Preliminary observations suggest that these actions of spiranolactone and its metabolite are evident in both sexes.

*Stripp et al. G79,538/71*: In rats, the induction of hepatic microsomal enzymes by spiranolactone "differed from the phenobarbital or methylcholanthrene induction in that it did not increase cytochrome P-450 content or microsomal protein. Furthermore the induction seemed to be sex dependent. Thus ethylmorphine N-demethylation, hexobarbital oxidation and 3,4-benzpyrene hydroxylation were increased 2-4 fold in female rats, but of these activities only ethylmorphine N-demethylase was increased in male rats."

Ethylmorphine ← Sex: *Castro et al. G77,558/67*; *Davies et al. H22,054/68*; *Gigon et al. G76,365/68*; *Sasame et al. G72,114/68*; *Davies et al. G76,865/69*; *Gigon et al. G66,216/69*; *Sladek et al. G66,220/69*

**Ethyl Urethan** ←

*Buchel D59,654/53*: Extensive investigations on the influence of sex upon the sensitivity of the rat to numerous barbiturates, chloral hydrate and ethyl urethan.

**Fluoride** ←

*Ramseyer et al. C29,608/57*: Following chronic administration of NaF p.o., female rats store more fluoride in their bones than males.

**Glycolic Acid** ←

*Richardson D88,284/65*: In rats, dietary supplements of glycolic acid or ethylene glycol produce oxaluria and kidney oxalate deposition in males but not in females.

*Griseofulvin* ← Sex: *Busfield et al. D10,983/60, G74,680/64\**; *Epstein et al. H30,997/67\**

**Heliotrine** ← *cf. Plant Extracts***Hexachlorobenzene** ←

*Viale et al. G74,147/70*: Female rats are more sensitive than males to the production of porphyria by hexachlorobenzene.

**Hexaethyl Tetraphosphate** ←

*Hagan & Woodard A48,819/47*: The insecticide hexaethyl tetraphosphate is more toxic to female than to male rats.

**Hexamethonium** ←

*Bonino C30,099/56*: Female guinea pigs are more sensitive than males to hexamethonium intoxication.

**Indomethacin** ←

*Selye PROT. 42911*: In male rats, the protective effect of PCN, spironolactone, ethylstrenol, betamethasone, phenobarbital, and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf. Table 128*). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf. Table 136*), but PCN and spironolactone were

effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (*Table 136*).

*Isoniazid* ← Sex + Age, Man: *Murray G77,553/62\**

*Isoproterenol* ← *cf. Selye G60,083/70, pp. 475, 478.*

**Lasiocarpine** ← *cf. Plant Extracts*

*Lathyrogens* ← *cf. also Selye G60,083/70, pp. 475, 478.*

*Wajda et al. C33,241/57*: Among weanling rats fed *Lathyrus odoratus* seeds, males developed aortic aneurysms more frequently than females. "Androgens" [kind not stated (H.S.)] considerably increased the incidence and severity of aortic medionecrosis on this diet.

*McCallum C61,614/58*: In mice, *Lathyrus odoratus* feeding, initiated at the age of two weeks or later, causes aortic damage predominantly among males.

*Aschkenasy C91,685/60; C90,362/60*: In male rats, the osteolathyrism produced by AAN is inhibited by a diet containing 18–30% casein. This protective effect is not seen in females or in orchidectomized males.

**Lidocaine** ←

*Paeile et al. G75,994/65*: Male rats are significantly more resistant than females to lidocaine and dibucaine, whereas females are more resistant than males to cocaine.

**Lithium** ←

*Schmidt & Bernauer D65,293/63*: Female rats are more resistant than males to chronic lithium citrate intoxication.

**Magnesium** ←

*Störtebecker A1,993/37*: In rabbits and mice, the depth of MgSO<sub>4</sub> anesthesia is influenced by sex hormones as judged by observations in different phases of the estrous cycle as well as after injection of folliculin or androsterone. [In view of the wide individual variations and the small number of animals, the significance of the data is in doubt (H.S.).]

MgSO<sub>4</sub> ← Sex, Mouse: *Störtebecker 76,398/39\**

**MAO-Inhibitors** ←

*Wurtman & Axelrod E36,478/63*: Hepatic MAO activity is greater in male than in female

rats. This difference can be reversed by estradiol in male and by testosterone in female gonadectomized rats.

#### **Mepacrine ←**

*Hurst D33,743/58*: Female mice are much more sensitive than males to the curative action of mepacrine following infection with equine encephalomyelitis.

Meperidine ← Sex: *Axelrod D28,544/56*; *Remmer et al. G67,790/58*; *Timmler E48,422/60*; *Remmer G66,542/62*; *Clouet et al. F14,837/64\**; *Siegert et al. G71,866/64\**; *Kato et al. F76,403/66*

#### **Mercury ←**

*Donatelli B38,554/47*: Women are much more sensitive to  $\text{HgCl}_2$  intoxication than men. Testosterone pretreatment gives appreciable protection against  $\text{HgCl}_2$  poisoning in mice and guinea pigs.

*Heimburg & Schmidt C69,587/59*: Female rats are more resistant than males to chronic intoxication with  $\text{HgCl}_2$ . Ovariectomy abolishes this difference. Neither estradiol nor progesterone caused any significant change in resistance to mercurial intoxication.

*Spode G72,979/60*: In mice, the renal storage of  $^{203}\text{Hg}$  acetate given s.c. or i.p. reaches higher values in males than in females.

*Haber & Jennings G10,684/64*: Female rats are more resistant than males to the production of renal tubular necroses by  $\text{HgCl}_2$ .

*Tessman G65,320/68*: In mice and rats, there was no sex difference in the speed of regeneration of the renal epithelium following  $\text{HgCl}_2$ -intoxication.

#### **Methionine ← cf. Choline**

#### **Methotrexate ← cf. Carcinolytic Agents**

Methylaminoantipyrine ← Sex: *Remmer C73,857/58*, *G66,542/62*

N-Methylaniline ← Sex + Phenobarbital: *Kato et al. F76,403/66*

#### **Monocrotaline ←**

*Ratnoff & Mirick B48,154/49*: Monocrotaline i.p. produces necrosis of the liver and of the renal tubules, as well as pulmonary edema in rats. Males are somewhat more susceptible than females, especially if kept on protein-deficient diets. Testosterone increases monocrotaline susceptibility in both sexes, but neither castration nor estradiol influences survival time.

*Goldenthal et al. G18,384/64*: "The oral and intravenous  $\text{LD}_{50}$ 's were determined for monocrotaline. The  $\text{LD}_{50}$  was essentially the same for males and females and for oral and intravenous administration for a 90-day observation period. There was a marked sex difference with respect to the median survival time, females living significantly longer than males. Castration of either male or female rats had no significant effect on the median survival time. Pretreatment of males with estradiol cyclopentyl propionate caused the median survival time to correspond to that of females. Pretreatment of females with testosterone propionate caused the median survival time to approximate that of male animals. Pretreatment of female rats with methandrostenolone (Dianabol), an anabolic agent, caused the median survival time to correspond to that of males."

Monocrotaline ← Sex + Testosterone + Diet: *Ratnoff et al. B48,154/49\**

#### **Morphine ←**

*MacKay & MacKay 56,167/36*: Female rats are more resistant to morphine than males, a difference ascribed to their larger adrenals.

*Yeh & Woods H17,933/69*: Twenty-four hours after s.c. injection of  $^{14}\text{C}$ -DHM the recovery (as expired  $^{14}\text{CO}_2$ ) in nontolerant female and male rats was 0.5 and 3.7%, respectively.

*Stripp et al. H22,743/70*: In rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

Morphine ← Sex + Testosterone: Axelrod *D28,544/56*

Morphine ← Sex: Timmler *E48,422/60\**; Kato et al. *G68,411/66*

Morphine ← Sex + Phenobarbital: Kato et al. *F76,403/66*

Neoprontosil ← Sex + Phenobarbital: Kato et al. *F76,403/66*

#### Nickel Sulfide ←

*Jasmin et al. D68,263/63*: In rats a single i.m. injection of nickel sulfide produces metastatic rhabdomyosarcomas whose incidence is increased by methylandrostenolone but is uninfluenced by sex, ovariectomy or orchidectomy.

Nicotine ← *cf. also Selye G60,083/70, pp. 476, 478.*

*Kosdoba A39,432/29—30*: Male rabbits are much more resistant than females to the production of cardiovascular lesions by chronic nicotine intoxication.

*Lee 32,854/35*: No pronounced sex difference to nicotine intoxication could be observed in the mouse or rabbit.

*Holck et al. A8,011/37*: Male rats are more resistant to fatal nicotine intoxication than females.

*Yun & Lee 34,178/35*: Female mice and rabbits are more resistant to nicotine than males. Ovariectomy diminishes nicotine resistance, whereas orchidectomy does not change it. Treatment with "luteohormone" increases nicotine resistance, whereas "follicular hormone" has no effect.

*Hueper 91,722/43*: Female rats are much more sensitive than males to chronic nicotine intoxication.

*Selye PROT. 42911*: In male rats, the protective effect of PCN, spironolactone, ethyl-estrenol, betamethasone, phenobarbital, and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf. Table 128*). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf. Table 136*), but PCN and spironolactone were effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (*Table 136*).

Nortriptyline ← Sex, Man: Hammer et al. *G79,581/67\**

#### Octamethyl Pyrophosphamide ← *cf. Pesticides*

##### Orotic Acid ←

*Sidransky D64,556/63*: The periportal fatty degeneration of the liver produced by chronic orotic acid feeding is more pronounced in female than in male rats. Orchidectomized males developed more severe fatty changes than intact males, or castrate males treated with testosterone. Ovariectomized females developed marked fatty liver changes similar to those of intact females, but this response was diminished by testosterone or estradiol.

*Sidransky et al. G4,364/63*: The production of fatty livers by orotic acid supplements to the diet is more pronounced in female than in male rats. Orchidectomized males develop more severe fatty livers than intact controls unless they are treated with testosterone propionate.

##### Pesticides ←

*Fitzhugh & Nelson A47,885/47*: Among rats given DDT in the diet, females showed a greater mortality than males. The difference was attributed to an increased DDT intake by the females.

*Deichmann et al. D98,307/50*: In rats, the acute toxicity of DDT in oil p.o. appears to be essentially the same in both sexes.

*DuBois et al. D92,992/50*: In rats, there is no sex or age difference in the toxicity of OMPA.

*Aldridge & Barnes G41,307/52*: Several organophosphorus insecticides are more toxic for female than for male rats. However, the reverse is true of octamethyl pyrophosphamide and bis-dimethylaminofluorophosphine oxide.

*Frawley et al. G69,644/52*: Comparative toxicologic studies on organic phosphate-anticholinesterase compounds in guinea pigs, mice

and rats, with a rapid procedure for the measurement of brain, plasma and erythrocyte cholinesterase. "The oral LD<sub>50</sub>'s for these compounds for male and female rats are DFP, 13.5 and 7.7 mgm/kgm; Parathion 30 and 3 mgm/kgm; TEPP 2 and 1.2 mgm/kgm; EPN 91 and 14.5 mgm/kgm; OMPA 13.5 and 35.5 mgm/kgm; and E-838 42 and 19 mgm/kgm. The administration of oral LD<sub>75</sub> doses of these compounds caused brain cholinesterase inhibition varying with each compound: DFP > Parathion > E-838 > EPN > TEPP > OMPA."

*Durham et al. C14,264/56:* Diethylstilbestrol increased DDT and DDE storage in the fat of male rats, whereas testosterone decreased the storage of these compounds in the female.

*Durham et al. C27,425/56:* In rats, DDT increased the liver weight/body weight ratio. Diethylstilbestrol increased the storage of DDT and of its metabolite DDE in the fat of male rats, whereas testosterone propionate decreased these values in females. "An endocrine mechanism may account for the sex differences in this regard."

*Ortega et al. E40,218/56:* When repeatedly exposed to moderate levels of DDT, male rats show much more frequent and extensive histologic changes in the liver than females.

*Swann et al. C73,379/58:* Male rats are more resistant than females to parathion poisoning. Testosterone increases the resistance of females, whereas estrone diminishes that of the males. Curiously, testosterone decreases the resistance of intact males although it increases that of castrated males. After orchidectomy, estrone slightly decreases resistance over that of untreated male castrates.

*Murphy & DuBois D28,546/58:* The activity of the microsomal-enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). Yet, in vivo, adult males are more resistant to EPN than females, perhaps because the accelerated formation of toxic oxidation products is overcompensated by a more efficient detoxication of the latter. The low enzyme activity of female livers is enhanced by pretreatment with testosterone in vivo, whereas the high activity of male livers is diminished by previous castration, partial hepatectomy or treatment with progesterone or diethylstilbestrol. SKF 525-A inhibits, whereas pretreatment

with carcinogens or a protein-deficient diet enhances the activity of the thiophosphate-oxidizing enzyme.

*DuBois & Puchala D43,878/61:* Male rats are much more resistant than females to various cholinergic phosphorothioates. Male mice and guinea pigs are not particularly resistant to DMP. Partial hepatectomy and/or castration abolishes the comparative resistance of the male rat, whereas testosterone restores resistance in hepatectomized or orchidectomized rats. It is concluded "that androgens govern the development of this system."

*DuBois & Kinoshita G66,247/65:* Female rats are much more sensitive than males to several phosphorothioates.

*Gaines G67,102/69:* LD<sub>50</sub> values have been determined for 98 pesticides, and 2 metabolites of DDT in the rat. Most compounds were more toxic to females than to males, but 9 of 85 compounds were more toxic in males. In chickens, several of the pesticides produced paralysis.

*Carlson & DuBois H24,653/70:* Male rats are much more susceptible to the insecticide 6-methyl-2,3-quinoxalinedithiol cyclic carbonate (Morestan) than females. "The toxicity to rats could not be altered by castration, administration of testosterone to females and estradiol to males. Pretreatment with phenobarbital decreased the toxicity to adult males and increased the toxicity to adult females." Chronic Morestan feeding caused hepatic enlargement and inhibition of microsomal enzymes.

*Gershbein H31,893/70:* In intact male rats, unlike in females, DDT caused liver enlargement. This and other insecticides also enhance liver regeneration after partial hepatectomy in males but not in females.

*Gish & Chura G80,046/70:* In Japanese quails, sensitivity to DDT is increased by starvation and during the breeding season. Males are more sensitive than females.

*Kinoshita & DuBois G78,681/70:* Male rats are more susceptible than females to the induction of hepatic microsomal enzymes by substituted urea herbicides (diuron, Herban).

*Klevay G80,049/70:* Radiolabelled dieldrin added to perfusates of rat liver appears in the bile of male donors much more rapidly than in that of females. "These findings are consonant with both the lesser toxicity of dieldrin for male rats and the greater storage of dieldrin in adipose tissue by female rats reported by other investigators."

*Hayes Jr. E53,090/71:* Female rats store more DDT in their fat than males when fed this insecticide at the same dose level.

*Selye PROT. 42911:* In male rats, the protective effect of PCN, spironolactone, ethylstrenol, betamethasone, phenobarbital, and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf.* Table 128). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf.* Table 136), but PCN and spironolactone were effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (Table 136).

#### **Plant Extract ←**

*Campbell C38,327/57:* In cockerels, the hepatic damage produced by the pyrrolizidine alkaloids of ragwort (*Senecio jacobaea* L.) disappears very slowly if at all, whereas hens recover. In both sexes, but particularly in cockerels, stilbestrol accelerates hepatic regeneration.

*Bull et al. C49,278/58:* Personal observations on rats and review of the entire literature on the pronounced sex differences in resistance against heliotrine, lasiocarpine and other plant alkaloids of *Senecio* species.

Propyl Gallate ← Sex: Johnson et al. E51,900/61\*

#### **Potassium ←**

*Robertson B70,810/52:* Female rats are more tolerant than males to i.p. injection of KCl. No such sex difference was observed in mice.

#### **Procaine ←**

*Muñoz et al. G68,223/61:* Male rats are more resistant than females to the convulsant action of procaine i.p. Gonadectomy decreased resistance in males but not in females. Testosterone did not significantly alter resistance in either sex.

*Paeile et al. F52,633/64:* Adult male rats are more resistant to procaine than adult females. Chronic CCl<sub>4</sub> poisoning, pretreatment with SKF 525-A and orchidectomy diminish the resistance of the males approximately to the female level. The plasma procainesterase activity is approximately the same in both sexes and not affected by orchidectomy or CCl<sub>4</sub> intoxication.

*Brodeur et al. F99,981/67*: The procainesterase activity of the liver is higher in adult male rats than in adult females or immature rats of either sex. Ovariectomy and chronic treatment with testosterone or norethandrolone increase hepatic procainesterase activity in adult females. Conversely, orchidectomy and chronic treatment with estradiol or progesterone decrease this enzyme activity in the livers of adult males. However, immature rats are more resistant to procaine in vivo than could be expected from the reduced ability of their livers to hydrolyze procaine in vitro. "Factors other than drug metabolism appear to govern the ultimate toxicity of procaine in immature rats."

#### **Pyribenzamine ←**

*Mayer et al. B3,674/46*: Male rats are much more resistant to pyribenzamine than females. Castration of females rendered them almost as resistant as males but treatment of ovariectomized rats with "estrogen" did not give consistent results in a small series of preliminary experiments.

#### **RES-Blocking Agents ←**

*Bernick et al. C39,526/56*: The Kupffer cells of male rabbits take up more i.v. injected Thorotrast, Evans blue and colloidal carbon than those of females.

*Hartveit & Andersen G67,345/69*: I.v.-injected carbon particles are cleared more rapidly from the blood by female than by male mice. The difference is ascribed to the phagocytosis stimulating effect of folliculoids.

#### **Safrole ←**

*Homburger et al. E94,913/62*: In male rats, safrole (4-allyl-1,2-methylene dioxybenzene), a flavoring agent, is less active in causing hepatic fibrosis and ceroid deposition than in females.

#### **Salicylates ←**

*Hanzlik A49,483/13*: "For females the toxic dose of salicylates is approximately 80% of that for males. Individuals show idiosyncrasy towards toxic doses of the synthetic salicylate, but no connection was found between these idiosyncrasies and the factors of age, sex, race, and diseased condition. The idiosyncrasy generally varies in the same patient, and is not influenced by previous salicylate medication."

Scilliroside ← Sex: Rothlin et al. G75,565/52\*

#### **Selenium ←**

*Fitzhugh et al. A45,940/44*: Female rats are more sensitive than males to the toxic actions of selenium p.o., especially to the production of hepatic cirrhosis.

*Sodium Chloride ← cf. Selye G60,083/70, p. 477.*

#### **Squill ←**

*Winton A42,964/27*: "Female rats succumb to doses of red squills, only one-half as great as those needed to kill males."

*Crabtree et al. A19,999/39*: Male rats are twice as resistant as females to the fatal action of powdered red squill (*Urginea maritima*). Castration has no effect in females but abolishes the increased squill resistance of the male.

Red Squill ← Sex: Winton A42,964/27\*; Crabtree et al. A19,999/39\*

#### **Strychnine ←**

*Poe et al. A45,388/36*: Female rats are more susceptible to strychnine than males and, in both sexes, toxicity decreases with age.

*Ward & Crabtree A29,199/42*: Female rats are more sensitive than males to strychnine i.p. or p.o.

*Poe & Suchy D75,977/51*: Female rats are more sensitive than males to strychnine poisoning.

*Kato & Chiesara G68,581/60*: Male rats are more resistant than females to the toxic action of strychnine. This difference is abolished by SKF 525-A.

*Kato et al. D38,983/62*: Male rats are more resistant than females to strychnine intoxication especially if the drug is given s.c. whereby its activity is delayed. The greater strychnine-metabolizing potency of microsomes from male rats than from females has also been demonstrated in vitro. SKF 525-A increases strychnine toxicity and renders both sexes equally sensitive. Castration diminishes the high strychnine resistance of the male rat but has no effect in females. Pretreatment with testosterone or 4-chlortestosterone augments the strychnine-metabolizing ability of liver slices or isolated hepatic microsomes from both male and female castrates, whereas estradiol has no effect.

Strychnine ← Sex: Poe et al. A45,388/36\*; Ward et al. A29,199/42\*; Kato et al. D38,983/62\*, G64,325/62\*, F88,660/67\*

#### Sulfa Drugs ←

*Krems et al. A46,116/41*: Female rats are more susceptible than males to sulfanilamide i.p.

*Sacra & McColl C73,654/59*: Female rats are less resistant than males to chronic intoxication with hypoglycemic thiazidazoles but no such sex difference was observed in acute tests. Testosterone increased, whereas stilbestrol decreased, the resistance of female rats to these drugs.

Sulfanilamide ← Sex: Krems et al. A46,116/41\*

#### Tannic Acid ←

*Korpássy et al. B74,333/52*: Male rats are more sensitive than females to the acute lethal effects of tannic acid.

Tannic Acid ← Sex: Korpássy et al. B74,333/52\*

#### Tyrosine ←

*Schweizer B3,047/47*: Addition of excessive amounts of l-tyrosine to the diet produces alkaptonuria, keratitis, conjunctivitis, alopecia, and inflammation of the paws in young rats. Among older animals, males are more sensitive than females. The severity of the syndrome is aggravated by thyroxine and inhibited by thiouracil.

#### Urethan ←

*Vesselinovitch & Mihailovich F91,584/67*: In male mice, urethan induced a higher incidence of hepatomas than in females. Gonadectomy decreased the incidence in males and increased it in females, thus practically eliminating the sex difference.

*Chernozemski & Warwick H33,929/70*: In female mice, hepatic tumors are much more rarely induced by urethan than in males. Partial hepatectomy greatly increases the hepatocarcinogenic effect of urethan.

Urethan ← Sex + Hepatectomy, partial, Mouse: Lane et al. H28,306/70\*

#### Vitamin-B Complex ←

*Taylor & Carmichael A49,002/49*: Male mice are much more resistant than females to fatal overdosage with folic acid.

#### Vitamin C ←

*Klinger et al. F62,929/65*: The normal excretion of ascorbic acid and the increase in its elimination induced by barbital are higher in male than in female rats. Orchidectomy reduced both normal excretion and its enhancement by barbital, whereas ovariectomy increased them. Thus, the sex specific differences decreased but did not disappear completely. One week's treatment of males with stilbestrol or females with testosterone diminished ascorbic acid excretion. In mice, no sex specific differences of this kind were observed. [The authors probably used hexobarbital although sometimes they speak of barbital (H.S.).]

Vitamin D, DHT ← cf. also *Selye D15,540/62*, p. 291; *G60,083/70*, pp. 476, 479.

*Agduhr 52,908/34; 70,849/35*: Female mice are more resistant than males to overdosage with irradiated ergosterol. Repeated mating increases ergosterol resistance in both sexes.

*Agduhr A51,257/37*: In mice and rats of both sexes, sexual intercourse increases resistance against  $As_2O_3$  and vitamin D.

*Strebel et al. F25,229/64*: Male rats are much more resistant than females to the production by DHT of the progeria-like syndrome (with soft-tissue calcification and osteosclerosis).

*Frumara et al. H34,170/68*: Male rats are more resistant than females to the production of the progeria-like syndrome by DHT.

*Chury & Kasparek H29,730/69*: Female rats are more sensitive than males to the production of a progeria-like syndrome by chronic treatment with DHT. Castration increases the sensitivity of the males.

*Chury & Nevrtal H33,801/70*: Rats, orchidectomized immediately after birth, are more sensitive to the production of the "progeria-like syndrome" by DHT than are females or males castrated after puberty. The ECG alterations in all these groups run roughly parallel with the morphologic changes.

Vitamin D<sub>2</sub> ← Sex + Age, Mouse: *Agduhr A51,257/37\**

#### Vitamin K ←

*Mellette D7,939/61*: Female rats are more resistant to dietary vitamin-K deficiency than males. Castration increases the susceptibility of the female rat and decreases that of the male. In males, estradiol decreases, whereas testosterone increases, mortality on such diets.

**Zoxazolamine** ←

*Selye PROT. 42911*: In male rats, the protective effect of PCN, spironolactone, ethylstrenol, betamethasone, phenobarbital, and phenylbutazone against intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine has been systematically examined (*cf.* Table 128). Hexobarbital sleeping time was not shortened by PCN, spironolactone or betamethasone. For betamethasone, this is not remarkable since this compound failed to affect hexobarbital sleeping time in females also (*cf.* Table 136), but PCN and spironolactone were effective in this respect in females. In order to evaluate these data, the effect of each conditioner against each toxicant should be compared with similar experiments on females (Table 136).

Zoxazolamine ← Sex: Kato et al. *F 57,817/65, F 76,403/66, F 88,660/67\**

**Varia** ←

*Holck et al. A 8,011/37*: Female rats are more sensitive than males to various **barbiturates** and **nicotine**. Orchidectomy abolishes this increased resistance to barbiturates. Pretreatment with an androgenic urinary extract shortens the anesthesia produced by hexobarbital in intact or spayed females. Androsterone is ineffective.

*Agduhr 75,856/39*: Review of the effect of sex and sexual intercourse upon the resistance of various species to diverse toxic substances.

*Agduhr A 39,060/41*: Review of the author's investigations on the effect of sex and mating upon drug resistance in animals.

*Hurst D 33,743/58*: Review (25 pp. 87 refs.) on sex differences in the toxicity of various drugs.

*Booth & Gillette D 34,656/62*: Review of sex differences in drug resistance.

*Kato et al. G 64,325/62*: Adult male rats are more resistant than females to **pentobarbital** anesthesia, **carisoprodol** paralysis and **strychnine** convulsions. Conversely, the lethal effect of **OMPA** is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids which enhance the decomposition of these substrates, the first three of which are inactivated, the last activated in the process. The differences were also demonstrated *in vitro* using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

*Conney & Burns G 67,166/62*: Review on sex differences in drug metabolism.

*Meier E 690/63*: Monograph on "Experimental Pharmacogenetics" (213 pp., about 400 refs.) with special sections on the influence of sex and genetic factors, including species variations, upon drug sensitivity.

*Kato & Gillette F 5,638/64*: In female rats, 3 days' starvation "increases the activity of TPNH-dependent enzymes that catalyze the metabolism of TPNH, **aniline**, **aminopyrine**, **p-nitrobenzoate**, **neotetrazolium**, and **neoprontosil**, but does not alter the activity of TPNH-cytochrome c reductase. In contrast, starvation of male rats decreases the activity of aminopyrine demethylase, although it increases the activity of aniline hydroxylase and does not alter the activity of nitroreductase, TPNH-cytochrome c reductase or TPNH oxidase." Sucrose fed to rats of either sex for 3 days lowers the activity of all these enzymes, but does not interfere with their induction by phenobarbital.

*Kato & Gillette F 57,816/65*: The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females but the sex difference varies with the substrate. There is a more than 3-fold sex difference with **aminopyrine** and **hexobarbital** but virtually none with hydroxylation of **aniline** and **zoxazolamine**. In male rats, starvation impairs sex-dependent enzymes which metabolize aminopyrine and hexobarbital but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital and enhances that of aminopyrine by microsomes of castrated rats, but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Gillette G 67,333/67*: Brief review on the effect of sex on hepatic microsomal-enzyme induction.

*Kato et al. H 11,854/69*: "There was marked sex difference in the hydroxylation of **pentobarbital** and **hexobarbital**, in contrast only slight or negligible sex difference was observed in the hydroxylation of **aniline** and **zoxazolamine**. Similarly, there are marked sex differences in the N-demethylation of **aminopyrine**, while only slight sex difference was observed in the N-demethylation of **N-methylaniline**. The administration of methylcholanthrene

to female and male rats resulted in marked increase in the hydroxylation of aniline and zoxazolamine and N-demethylation of N-methylaniline, whereas the hydroxylation of

pentobarbital and hexobarbital and N-demethylation of aminopyrine were not significantly altered in female rats and they were markedly decreased in male rats."

### **Microorganisms and Their Products, Venoms ←**

Allegedly, female rats and mice are more resistant than males to various types of infections with plasmodia and bacteria. Variable observations have been reported with regard to viruses. In the mouse, but not in the guinea pig, males are more susceptible than females to infection with equine encephalomyelitis. Female hamsters are more sensitive than males to inoculation with adenovirus-12, and also show a greater incidence of tumors. Among mice infected with Coxsackie virus B<sub>1</sub>, a much higher percentage of males than of females developed hepatic necrosis.

Sex difference to various bacterial toxins was not found to be very pronounced.

Female guinea pigs are more sensitive than males to Cape cobra venom, but this difference does not appear to be subject to modification by testosterone, estradiol, or progesterone.

#### **Bacteria, Plasmodia ←**

*Bennison & Coatney B17,600/47*: Following inoculation with *P. gallinaceum*, the parasite counts are much higher in females than in males. This difference in parasite count was not significantly influenced by testosterone or estradiol.

*Greenberg et al. G70,739/53*: Female mice of various strains survive longer than males after infection with *Plasmodium berghei*.

*Weisskopf et al. D35,320/61*: Review of the protective action of folliculoids against viruses and bacteria, with personal observations on the increase in the resistance of mice that can be induced by Premarin against virulent streptococcal infection. Females are more resistant than males, and castration increases resistance in males. The effect of folliculoids is tentatively ascribed to an increase in the acid mucopolysaccharide content of the ground substance which decreases the subcutaneous spread of germs.

#### **Viruses ←**

*Hurst et al. C94,088/60*: In the mouse, but not in the guinea pig, males are more susceptible than females to infection with equine encephalomyelitis.

*McFarlane & Embil H18,880/68*: Female hamsters (*Mesocricetus auratus*) are much more sensitive (90%) than males (15%) to the inoculation of adenovirus-12. After gonadectomies, 42% of the female and 38% of the male hamsters developed tumors. The somewhat contradictory earlier literature on this sex difference is reviewed.

*Yohn et al. G57,790/68*: In hamsters given adenovirus-12, strain Huie, s.c. at birth, thymectomy at one week of age increased tumor incidence in both sexes, although it remained higher in females as is usually the case. Cortisone treatment, begun at one week of age, increased tumor incidence but, again, this remained higher in females. Antibody responses to adenovirus-12 T-antigen were depressed in thymectomized and cortisone-treated animals.

*Yohn & Funk G68,339/69*: Adenovirus-12 produced a higher incidence of tumors in female than in male Syrian hamsters. Ovariectomy lowered tumor incidence, whereas estradiol increased it but only in males.

*Minkowitz & Berkovich H23,844/70*: Among mice infected with Coxsackie virus B<sub>1</sub>, 73% of the males and only 9% of the females showed extensive hepatic necrosis.

#### **Bacterial Toxins ←**

*Lamanna et al. G60,750/55*: The resistance of mice to type A botulinus toxin shows no sex difference, but females are more resistant than males to type B and type C toxin even if the animals have the same body weight.

*Gordon & Lipton C94,649/60*: 5-HT reduces endotoxin mortality in mice. This effect is greater in females than in males and is potentiated by cortisol. Thyroxine aggravates the toxicity of endotoxin.

#### **Venoms ←**

*Dossena B47,510/49*: Female guinea pigs appear to be more sensitive than males to

Cape cobra venom but pretreatment with testosterone, estradiol or progesterone failed to affect their resistance.

#### **Immune Reactions ←**

*Lippman et al. B68,238/52:* Female rats are much more sensitive than males to the production of nephrotoxic nephritis by anti-rat kidney gamma globulin.

#### **Varia ←**

According to some investigators, the hepatic steatosis produced by fasting, plus partial hepatectomy, is more pronounced in female than in male rats. Other authors maintain the opposite.

Hypertension caused by unilateral renal artery constriction is more readily produced in male than in female rats.

Several investigators claimed that female mice and rats are more resistant to total body X-irradiation than males. However, this difference is not particularly pronounced and may not be obvious under extreme experimental conditions. Male rats (unlike females), fed X-irradiated beef, die of internal hemorrhages, the severity of which is aggravated by testosterone.

Female rats and mice are more resistant to anoxia than males.

In rats, resistance to burns or exposure to cold is not clearly related to sex.

Rats in proestrus and estrus show a subnormal EST.

Male rats are allegedly less resistant than females to trauma in the Noble-Collip drum.

Gastric ulcer formation under the stressor effect of forced muscular exercise is more common in female than in male rats.

Tumor formation following inoculation with adenovirus-12 is more common in female than in male hamsters.

Certain investigators also reported sex-dependent differences in hepatic enzyme activities; these will be described in greater detail in the Abstract Section.

#### **Hepatic Lesions ←**

*MacKay & Carne A14,767/38:* In rats, the hepatic steatosis normally occurring during 24 hrs of fasting after partial hepatectomy is more pronounced in females than in males and can be largely prevented by adrenalectomy.

*Berman A46,758/46:* Contrary to earlier claims less hepatic fat deposition has been found following partial hepatectomy in female than in male rats.

*Chambon et al. F80,788/66:* In the rat, hepatic regeneration following partial hepatectomy is more rapid in females than in males. However, castration stimulates hepatic regeneration in both sexes.

*Gershbein H31,893/70:* In intact male rats, unlike in females, DDT caused liver enlargement. This and other insecticides also enhance liver regeneration after partial hepatectomy in males but not in females.

#### **Renal Lesions ←**

*Bein et al. C57,714/58:* In male rats with hypertension produced by unilateral renal

artery constriction, vascular lesions are more common than in females. Gonadectomy does not significantly alter these changes in males but aggravates them in females. Parathyroidectomy has no significant effect upon them.

#### **Ionizing Rays ←**

*Dobrovol'skaia-Zavad'skaia et al. 86,799/41:* Female rats are much more resistant than males to total body X-irradiation.

*Abrams B58,956/51:* "In general, sex appears to exert no significant influence on the capacity of mice to withstand whole body irradiation."

*Ingbar & Freinkel B68,221/52:* Post-pubertal male mice are more sensitive to total body X-irradiation than females.

*Langendorff & Koch B98,043/54:* Male mice are more sensitive than females to X-irradiation but after gonadectomy females are more sensitive than males. Testosterone increases the radioresistance of the female far

beyond the norm. Estradiol causes no further increase in the radioresistance of the castrated male.

*Betz C13,907/55*: There is no obvious sex difference in X-ray resistance among mice. Pretreatment with testosterone offers definite protection especially to females, but here again, treatment after exposure is without effect. Curiously, estradiol pretreatment also offers protection, whereas given after exposure it actually decreases resistance.

*Rugh & Clugston C11,209/55*: Male CF<sub>1</sub> mice are more X-ray sensitive than females regardless of the phase of the estrous cycle in the latter. Females are most resistant during estrus.

*Kohn & Kallman C25,371/56*: Female mice are only very slightly more resistant to total body X-irradiation than males.

*Rugh & Wolff C19,209/56*: Female mice are more resistant to total body X-irradiation than are males. Orchidectomy raises resistance, and this is further increased by treatment with estradiol. In intact males, estradiol raises X-ray resistance to the same level as in castrates.

*Langendorff et al. C36,885/57*: Male mice are much more sensitive to X-irradiation than females. Orchidectomy increases resistance.

*Hamilton et al. D64,060/63*: Male mice survived  $\gamma$ -irradiation somewhat longer than females. Orchidectomy has no effect upon the survival time, but ovariectomy slightly prolongs it.

*Malhotra & Reber E36,906/63*: Male, unlike female, rats fed X-irradiated beef die of internal hemorrhage with severity and lethality which can be aggravated by testosterone. The literature on the effect of sex, castration and stilbestrol upon the lethality of irradiated beef feeding is discussed.

*Flemming & Langendorff G38,381/65*; *Langendorff & Langendorff G42,801/66*: Females are more resistant than males to total body X-irradiation, and resistance can be increased in both sexes by natural and synthetic folliculoids.

### Hypoxia ←

*Britton & Kline 93,980/45*: Adult female rats are much more resistant to anoxia than males perhaps because their adrenals are larger. Adrenocortical extract raises resistance to anoxia, whereas DOC does not.

*Kline & Britton 85,856/45*: At 16°C female rats withstand anoxia longer than males. At higher temperatures the difference is less

pronounced. "Estrous conditions and estrogens, castration, etc., do not appear related to the different responses."

*Emmens & Parkes B4,928/47*: Male mice are considerably more sensitive than females to anoxia (closed vessel technique). Various thyroid preparations increase sensitivity to anoxia.

### Temperature Variations ←

*Denison & Zarrow B77,713/52*: Female rats are more resistant than males to chronic exposure to cold.

*Einheber et al. B68,195/52*: Male rats are more resistant to burn shock than females.

*Munan & Einheber B74,511/52*: Female rats are more resistant than males when exposed to the combined stressor effect of scalding and starvation.

*Munan & Einheber B82,207/53*: In rats, mortality from burn shock is not influenced by sex.

### Electric Stimuli ←

*Woolley et al. D4,062/61*: "Rats in proestrus and estrus showed a greater excitability, as evidenced by a significantly lower EST (—6%), than rats in postestrus and diestrus."

**Stressors** ← cf. also *Selye B40,000/50*, p. 81.

*Hruza & Poupa C44,659/57*; *Hruza C74, 576/59*; *D5,993/61*: Male rats are less resistant than females to trauma in the Noble-Collip drum.

*Aschkenasy-Lelu G9,425/64*: Review of the various damaging agents against which females are more resistant than males, and of the resistance-increasing effect of folliculoids.

*Kato & Gillette F57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Robert et al. G74,748/70*: In rats, the gastric ulcers produced by forced muscular exercise were more common in females than in males and could be totally prevented by fasting.

**Diet ←**

*Silberberg & Silberberg B48,364/50*: "Under the influence of a high fat diet, female C57 mice showed less acceleration of epiphyseal development and articular aging than males."

**Tumors ←**

*McFarlane & Embil H18,880/68*: Female hamsters (*Mesocricetus auratus*) are much more sensitive (90%) than males (15%) to the inoculation of adenovirus-12. After gonadectomies, 42% of the female and 38% of the male hamsters developed tumors. The somewhat contradictory earlier literature on this sex difference is reviewed.

**Hepatic Enzymes ←**

**TKT ←**. *Lin et al. C96,929/59*: TKT activity is higher in the liver of male than of female rats. This enzyme activity is diminished by castration in males, and increased by testosterone in females. Cortisol increases this transaminase activity in males much more than in females, both in the presence and in the absence of the adrenals.

**Glucuronidase ←**. *Inscoc & Axelrod D1,700/60*: The ability of microsomes from liver of male rats to form o-aminophenol glucuronide in vitro is four times as great as in females. Estradiol diminishes this enzyme activity in males, whereas testosterone increases it in females.

*Künzel & Müller-Oerlinghausen G64,178/69*: In vitro glucuronide synthesis is much higher in male than female rat liver tissue because of a larger UDP-glucuronic acid supply in the male liver. Orchidectomy decreases glucuronide synthesis and this decrease can be counteracted by testosterone administration in a dose-dependent manner. However, very large doses of testosterone (more than 100 µg per day) decrease

glucuronide formation. Cyproterone (an anti-testoid) does not inhibit the increase in glucuronide synthesis induced by testosterone.

**Other Enzymes ←**. *Knox et al. E83,471/56*: Review (90 pp., 752 refs.) on "Enzymatic and Metabolic Adaptations in Animals" with special reference to hormonal, sex-dependent and diet-induced adaptive enzymic changes, but without special reference to hepatic microsomes.

*Freedland et al. G66,662/62*: The phenylalanine hydroxylase activity of rat liver increases with age from embryonic life to 50—60 days and then declines to stabilize at a lower level in females than in males after maturity. Fasting and diets deficient in phenylalanine cause a rapid decrease in this enzymic activity.

*Pan et al. H3,934/68*: The methionine adenosyltransferase activity of hepatic homogenates is higher in female than in male rats. "Ovariectomy decreased the enzyme level, whereas the administration of 17β-estradiol or diethylstilbestrol, but not progesterone, reversed the effect of ovariectomy. Estradiol also raised the enzyme level in intact male rats to that of the female. Adrenalectomy had no effect on the response of the enzyme to estradiol. Castration of the male resulted in an increase in the activity of methionine adenosyltransferase, and the administration of androgenic-anabolic hormones brought the elevated activity down to the normal level of intact males or even lower. Adrenalectomy did not abolish the effect of castration. 17α-Ethyl-19-nortestosterone and 1-methyl-Δ<sup>1</sup>-androstenedione were more effective in this respect than testosterone, 17α-methyl-Δ<sup>5</sup>-androstene-3β,17β-diol and 5α-androstan-17β-ol-3-one. The effect of the steroids in decreasing methionine adenosyltransferase activity seems to be associated with their anabolic rather than their androgenic action."

**← PREGNANCY**

Pregnancy greatly changes the resistance of mammals to many agents. This altered tolerance may carry over into the postpartum period or it may terminate sharply at the time of delivery.

The altered tolerance during gestation can be primarily due to activities of the embryo, the placenta, the ovaries or other organs. In some cases, the underlying mechanism has been, at least partially, clarified. For example, some types of resistance persist in pregnant animals whose embryos have been removed as long as the placentas remain intact. In other cases, when resistance to a toxicant continues during

lactation, there is good reason to suspect that excretion of the poisons through the milk or the characteristic hormone-secretion pattern necessary for the maintenance of milk secretion are responsible.

In most cases, the reasons for altered tolerance are not known, but they will be discussed in the following pages because of their possible dependence upon protective hormone secretion and drug-metabolizing enzyme induction.

### **Steroids ←**

Pregnant rats are unusually resistant to various actions of glucocorticoids, such as glycogen deposition in the liver, adrenocortical atrophy, catabolism, and decreased resistance to infection. This tolerance persists, as long as the placenta remains intact, even if the fetuses are removed.

Pregnant rats are also very resistant to the production of various cardiopathies in which corticoids act as conditioning factors, for example, against the infarctoid necroses elicited by methylchlorocortisol + NaH<sub>2</sub>PO<sub>4</sub>.

#### **Glucocorticoids ←**

*Chedid et al. C621/54*: Pregnancy interferes with various actions of cortisone in the rat, e.g., decreased resistance to infection by *S. enteritidis*, glycogen deposition in the liver and adrenocortical atrophy.

*Beaton & Curry C42,333/57*: Pregnant rats are unusually resistant to intoxication with cortisone even after removal of the fetuses, as long as the placentas remain intact.

*Curry & Beaton C56,647/58*: Although pregnant rats are particularly resistant towards the toxic effects of cortisone, their sensitivity to glucagon is not diminished.

Cortisone ← Pregnancy: Hagen et al. *G77,512/60*

**Gluc-Mineralocorticoids ←** cf. also *Selye C50,810/58, p. 140; G60,083/70, pp. 480, 483, 484.*

*Selye C44,470/58*: In rats, the infarctoid cardiac necrosis and the nephrocalcinosis produced by Me-Cl-COL + NaH<sub>2</sub>PO<sub>4</sub> are largely inhibited by pregnancy.

**Mineralocorticoids ←** cf. *Selye G60,083/70, pp. 480, 482.*

Progesterone ← Pregnancy, Rb: Chat-terton et al. *H31,456/70\**

### **Nonsteroidal Hormones and Hormone-Like Substances ←**

Pregnant rats are unusually resistant to overdosage with thyroxine and parathyroid hormone; however, their sensitivity to glucagon is not diminished. On the other hand, the production of intracapillary glomerular thrombi and hepatic necroses by 5-HT is facilitated by pregnancy in rats.

#### **Thyroid Hormones ←**

*Bodansky & Duff 63,084/36*: Pregnant rats are extraordinarily resistant to the catabolic effect of heavy overdosage with thyroxine.

**Parathyroid Hormone ←** cf. also *Selye G60,083/70, pp. 479, 482.*

*Lehr & Krukowski D81,044/61; D22,446/61*: In rats, late pregnancy (third week) offers considerable protection against the nephrocalcinosis, myocardial injury, hypercalcemia, and hyperphosphatemia normally produced by heavy parathyroid extract overdosage.

This protective effect does not extend to the immediate postpartum period.

*Lehr & Krukowski E21,312/63*: Pregnancy protects against soft-tissue calcification produced by parathyroid extract, even in adrenalectomized rats.

#### **Pancreatic Hormones ←**

*Curry & Beaton C56,647/58*: Although pregnant rats are particularly resistant towards the toxic effects of cortisone, their sensitivity to glucagon is not diminished.

**Catecholamines** ← *cf. Selye C92,918/61, p. 114; G60,083/70, pp. 480, 483, 484.*

**Vasopressin** ← *cf. Selye G60,083/70, p. 484.*

**5-HT** ← *cf. also Selye E5,986/66, pp. 44, 47; G60,083/70, pp. 480, 483.*

*Waugh & Pearl C83,389/60:* In rats, intracapillary glomerular thrombi and hepatic necroses are produced by 5-HT only during pregnancy.

### Drugs ←

The barbiturate resistance of the rat increases during pregnancy, and allegedly remains high during lactation. A shortening of barbiturate anesthesia has also been reported during gestation in guinea pigs. However the relevant literature is somewhat contradictory. For example, certain investigators found that though sleeping times are shorter, mortality and respiratory depression are significantly greater in pentobarbital-treated virgin rats than in pregnant rats. Indeed, pregnancy may increase sleeping time, although it diminishes mortality after pentobarbital treatment.

The resistance of the rat to the production of bone lesions by lathyrogens is likewise increased during gestation; this has been ascribed mainly to a rise in glucocorticoid secretion.

During pregnancy, the detoxication of meperidine, pethidine, and promazine is impeded as judged by the fact that increased amounts of these drugs are eliminated in the urine.

There is a considerable rise in resistance to overdosage with vitamin-D derivatives and DHT during pregnancy in the rat, but apparently not in the cow.

**o-Aminophenol** ← Pregnancy + **o-Aminobenzoic acid**: Schmid et al. *G76, 338/59; Feuer et al. H14,579/69\**

**Anaphylactoidogens** ← *cf. Selye G46,715/68, p. 209.*

**Aniline** ← Pregnancy: Guarino et al. *H15,843/69*

during pregnancy is ascribed to an excess of folliculoids.

**4-Methylcoumarin** ← Pregnancy + **Phenobarbital**: Feuer et al. *H14,579/69*

### Arsenic ←

*Agduhr E70,688/41:* Repeated mating increases the resistance of mice to arsenic. Pregnancy further augments this protective effect in females.

*Agduhr G37,252/41:* In the mouse, sexual intercourse as well as some sex hormone preparations increase the storage of arsenic in the ground substance of various organs, especially the skin, whereas repeated pregnancies have an opposite effect and at the same time augment resistance against intoxication with  $As_2O_3$ .

### Barbiturates ←

*Holck & Fink A35,663/40:* Sexual activity or the absence of it failed to influence ectylurea (Nostal) (isopropyl bromallyl barbituric acid) anesthesia in rats. However, resistance to this barbiturate was markedly raised in females which were or recently had been pregnant although, even in these, it was not brought up to the male level.

### Anticoagulants ←

*Feuer & Liscio H14,579/69:* Review of the literature and personal observations on the unusually low drug-metabolizing enzyme activity of the liver in newborn rats. In pregnant rats, the pentobarbital sleeping time is prolonged, and there is a reduction in the activities of 4-methylcoumarin-3-hydroxylase and uridine diphosphoglucuronic acid: o-aminophenol transglucuronylase in the liver. The low activities of these and other enzymes can be raised to or even above those of nonpregnant animals by giving inducers in vivo, such as 4-methylcoumarin, 3-methylcholanthrene, or phenobarbital. Among newborn rats, those weaned early had a shorter pentobarbital sleeping time than nonweaned controls. The reversible reduction of enzyme activity

*Holck & Mathieson B644/44*: In the rat, pregnancy increases the ability to develop tolerance against pentobarbital injected every 90 min over several days and nights. This increase in tolerance persisted during lactation, but disappeared 8 weeks after parturition.

*Giotti & Donatelli B39,580/48*: In guinea pigs, barbiturate (Enallypropymal) anesthesia is considerably shortened during the later part of pregnancy but returns to its normal length after parturition.

*King & Becker E38,612/60*: Although sleeping times are shorter, mortality and the degree of respiratory depression are significantly greater in pentobarbital-treated virgin rats than in pregnant rats.

*King & Becker D5,106/61*: Pregnancy increases sleeping time, but diminishes the mortality following pentobarbital treatment.

*King & Becker G78,964/63*: In rats, pregnancy prolongs pentobarbital sleeping time, and males are even less susceptible than nonpregnant females.

*King G78,963/64*: Review of earlier reports and personal observations showing that, in the rat, pentobarbital anesthesia is prolonged, but lessened in depth during pregnancy. Correspondingly, pentobarbital disappears more rapidly from the blood and tissues of nonpregnant than of pregnant rats.

*Neale & Parke G67,965/69*: In rats, during pregnancy, the hepatic microsomal enzymes responsible for the hydroxylation of diphenyl, reduction of p-nitrobenzoic acid, microsomal protein, and cytochrome P-450, are all increased when expressed as a function of total liver weight. However, when calculated per g liver weight, the 4-hydroxylation of diphenyl and cytochrome P-450 content are both significantly decreased. Since, during pregnancy, the animal increases in body weight, these findings may explain why the hexobarbital sleeping time is increased in full-term pregnant rats.

Barbital(sodium) ← Pregnancy: Franke et al. H31,874/66\*

Pentobarbital, Propallylonal ← Pregnancy: Holck et al. A35,663/40\*; Holck et al. B644/44\*; Feuer et al. H14,579/69\*

#### BCP ←

*Tanabe F92,176/67*: BCP (5-n-butyl-1-cyclohexyl-2,4,6-trioxoperhydropyrimidine) is more toxic for female than for male rats, and pregnant females are more sensitive than nonpregnant controls.

#### Bile Pigments ←

*Soffer 7,166/33*: The excretion of injected bilirubin is almost invariably delayed in pregnant women, suggesting impairment of the hepatic function.

*Shibata et al. G80,058/66*: In rats, hepatic glucuronyl transferase activity is greatly increased during the last third of gestation, whereas enzymic activity is virtually absent in the fetal liver. These divergent changes "raise doubt as to whether low enzymic activity in the fetus and increased activity after birth are the consequence, respectively, of high hormone levels in pregnancy, and falling hormone concentrations in the postpartum period. The maximal rate of bilirubin excretion into bile, the bilirubin  $T_m$ , remained unchanged in pregnancy despite the potential for increased bilirubin conjugation. When coupled with other observations, this suggests that the rate of delivery of conjugated bilirubin into bile is the rate-limiting step involved in the maximal transfer rate of bilirubin from blood to bile, and that the excretory step for bilirubin remains unaffected during pregnancy in the rat."

*Song & Kappas G89,521/70*: Brief review of the literature on the effect of various hormones and of pregnancy upon the activity of hepatic UDP-glucuronyltransferase.

Bilirubin ← Pregnancy: Halac et al. G77,576/69

#### Cadmium ←

*Pařízek F31,959/65*: In rats, pregnancy increases susceptibility to the fatal effect of cadmium intoxication. At autopsy, the kidneys are found to be swollen, hyperemic and hemorrhagic, especially in the medulla, and there is a high incidence of adrenal hemorrhages and thrombi in the pulmonary vessels.

#### Carbon Tetrachloride ←

*Douglas & Clower H20,791/68*: In rats, pregnancy offers some protection against the hepatotoxic effect of  $CCl_4$ .

#### Carcinogens ←

*Dao & Sunderland D79,860/59*; *Dao et al. E57,368/60*: In rats, the induction of mammary carcinomas by 3-MC is enhanced during pregnancy, pseudopregnancy, and progesterone treatment. Regression of neoplasms occurs after parturition. Males are virtually resistant. In fully formed tumors, regression could be induced by hypophysectomy or ovariectomy.

*Bock & Dao D11,892/61*: In rats, 3-MC accumulation in the mammary glands is increased by hypophysectomy or ovariectomy, but diminished during pregnancy. The affinity of mammary tissue for certain carcinogens may be due to its close association with adipose tissue.

*Huggins et al. C99,772/61*: In rats, the production of mammary cancers by DMBA or 3-MC is inhibited by pregnancy, estradiol, progesterone, or combined treatment of estradiol + progesterone.

*Bird et al. H30,425/70*: In rats less than 30 days of age, DMEA or 7-OHM-12-MBA produces no adrenal necrosis unless animals are pretreated with ACTH. However, a single i.v. injection of 7-OHM-12-MBA on the 17th day of gestation causes adrenal necrosis in the embryos as well as in the mothers. Pretreatment with SKF 525-A protected the adrenals both of the embryos and of the mothers.

3-MC ← Pregnancy: *Huggins et al. C99,772/61\**; *Bresnick et al. H215/68\**

Chlorcyclizine ← Pregnancy + SKF 525-A: *Posner et al. H31,661/67\**

3-Methyl-4-monomethylaminoazobenzene ← Pregnancy: *Bresnick et al. H215/68*

**Cholesterol** ← cf. *Selye G60,083/70, pp. 479, 480.*

Promazine ← Pregnancy, Man: *Crawford et al. G78,958/65\**

**Tetraethylammonium (TEA)** ←

*Brust et al. B18,590/48*: Observations on women revealed that "in normal term pregnancy the TEAC blood pressure floor is strikingly low and rises to normal levels after delivery. In toxemia the TEAC floor is higher than normal and consistently falls to normal levels after recovery." The TEA (or TEAC) floor is defined as the lowest point to which the blood pressure descends in the first 5 min following injection.

**Vitamin D, DHT** ← cf. also *Selye C50,810/58*, p. 140; *G60,083/70*, pp. 479, 480

*Selye C25,011/57*: The generalized calcinosis produced by heavy DHT overdosage in the rat is inhibited by pregnancy, cf. Fig. 27.

*Potvliege E98,323/62*: Pregnancy affords considerable protection against vitamin-D intoxication in the rat.

*Greig G68,415/63*: In cows given vitamin-D<sub>3</sub> i.v., intense metastatic calcification occurred in the subendocardium and the subintima of the aorta. "These lesions occurred whether or not the cows were pregnant at the time of injection and whether or not lactation followed."

*Strebel et al. F35,901/65*: Cardiovascular calcification produced by DHT in the rat is inhibited by pregnancy.

**Vitamin E** ← cf. *Selye G60,083/70*, pp. 480, 483

**Diet** ← cf. *Selye E5,986/66*, pp. 43, 45.

**Microorganisms** ←

The progress of brucellosis is inhibited in the cow by pregnancy, but not by injections of progesterone.

Pregnancy increases the susceptibility of mice to poliomyelitis virus and makes the otherwise resistant rat sensitive to the virus of ovine enzootic abortion. Even pseudopregnancy increases resistance of the rabbit to vaccine virus.

On the other hand, resistance of pregnant rats and mice to various types of endotoxins is considerably increased during gestation.

**Varia** ←

The arterial lesions that develop in dogs kept on a high fat diet upon subsequent nephrectomy are prevented by pregnancy.

Regeneration of the liver following partial hepatectomy is accelerated during pregnancy in the rat.

In rats exposed to strong auditory and visual stimuli, pregnancy did not prevent the usual manifestations of stress.

**Microorganisms** ←

**Bacteria** ←. *Payne C 89,814/60*: In cows, the progress of experimental brucellosis is inhibited by pregnancy but not by progesterone.

**Viruses** ←. *Sprunt & McDearman A 33, 321/40*: Treatment with estradiol or estrone, as well as pseudopregnancy, increased the resistance of the rabbit to vaccine virus.

*Knox B 47,631/50*: Pregnancy enhances the susceptibility of mice to inoculation with Col. SK-strain murine poliomyelitis virus p.o. This increased susceptibility does not appear to depend wholly on a greater permeability of the intestinal mucosa, since in a small series, essentially similar results were obtained by i.v. inoculation.

*Payne & Belyavin C 95,892/60*: Pregnancy renders the otherwise resistant rat susceptible to infection with the virus of enzootic abortion of sheep (E.A. virus). This resistance is probably "due to the presence of placental tissue, which allows the virus to establish itself."

**Bacterial Toxins** ← *cf. also Selye E 5,986/66, pp. 43, 44.*

*Jasmin B 80,596/53*: A dose of meningococcus toxin i.v. well tolerated by nonpregnant rats produces eclampsia-like hemorrhagic lesions in the liver of pregnant or cortisone pretreated animals.

*Chedid & Boyer C 10,098/55*: In mice, resistance to *S. enteritidis* endotoxin is greatly diminished and the protective effect of cortisone is also inhibited during pregnancy.

*Tarján et al. G 54,411/67*: Review of the literature, and personal observations on the sensitization to endotoxin shock by pregnancy.

**Varia** ←

**Ionizing Rays** ←. *Mitznegg et al. G 77,075/70*: In rats, pregnancy protects against X-irra-

diation, presumably through the increased production of endogenous folliculoids. Combined treatment with clomiphene blocks the protective effect of pregnancy perhaps because it counteracts the action of folliculoids.

**Renal Lesions** ←. *Holman & Jones B 93, 771/53*: The arterial lesions that develop in dogs kept on a standard high-fat diet upon subsequent nephrectomy, are prevented by pregnancy, cortisone, ACTH, or diethylstilbestrol.

**Hepatic Lesions** ←. *Gershbein G 71,666/58*: Pregnancy greatly accelerates regeneration of rat liver after partial hepatectomy.

*González-Angulo et al. H 30,301/70*: In normal pregnant women, liver biopsies revealed elongation, gigantism and lamellar osmiophilic material in hepatocytes during the last trimester of gestation. In women with hydatidiform mole or choriocarcinoma, mild focal dilatation and vesiculation of both RER and SER were noted.

**Stressors** ←. *Soiva et al. C 97,218/60*: In rats exposed to strong auditory and visual stimuli, "pregnancy could not protect the organism from the consequences of stress."

**Hepatic Enzymes** ←. *Beaton et al. A 49,354/54*: In rats, on about the fifteenth day of gestation, there is a marked increase in protein anabolism accompanied by a decrease in hepatic GPT and in the rate of urea formation in liver slices.

*Beaton et al. C 10,012/55*: STH decreases the GPT and d-amino acid oxidase activity in nonpregnant female rats. These effects are even more pronounced if the animals receive STH + "equine estrogenic substances" + progesterone. This enzyme activity also decreases during pregnancy both in intact and in hypophysectomized rats.

## ← AGE

**Steroids** ←

There appear to be considerable differences in the biotransformation of steroids, which depend upon age or, at least, upon changes (e.g., sexual maturation, senile involution of the gonads) that are, in themselves, age-dependent.

Female rats are more sensitive to steroid anesthesia than males, but this sex difference is obvious only after maturity, and young animals of either sex are more sensitive than adults.

The effect of age upon the metabolites formed from various steroid hormones has been studied in detail. (cf. Abstract Section.)

**Drugs ←**

In general, the metabolizing ability of the liver for a variety of substrates is low in newborn rats.

The **aminopyrine** demethylase activity of the microsomal fraction, though low at birth, rises during the first 30 days, and after puberty, particularly in males.

Much work has been done on the age-dependence of **barbiturate** detoxication. Pentobarbital resistance increases with age up to puberty, particularly in male rats. Among 2-month-old rats, practically all developed tolerance to the injection of pentobarbital (given at 90 min intervals, day and night, for periods up to five days). The same was true of adult males in contrast to females. Orchidectomy decreased the ability to develop tolerance in adults, but not in 2-month-old males. There is good evidence to suggest that the lack of a clear-cut sex difference in the barbiturate-detoxifying ability of immature rats is due to the comparatively low level of cata-toxic testoid secretions.

Among newborn rats, those weaned early exhibit a shorter pentobarbital sleeping time than nonweaned controls.

According to recent observations, the  $LD_{50}$  of hexobarbital rises considerably between the 12th and 130th day of life; however, the blood concentration of the barbiturate at waking time is not age-dependent.

The hexobarbital-metabolizing activity of the rat liver is extremely low during the neonatal period and rises gradually, up to the 80th day of life, to a level which is much higher in males than in females. X-irradiation of pregnant rats results in a deficiency of hexobarbital-metabolizing enzymes in their male offspring. However, such irradiation does not suppress the subsequent induction of this enzyme activity by phenobarbital. Actinomycin D inhibits both ontogenic and phenobarbital-induced increases in enzyme activity. Apparently, the X-ray-induced inhibition of hepatic enzymes is mediated through an effect upon the hormonal regulation of enzyme-induction, whereas the substrate-induced enzyme synthesis is independent of such endocrine controls.

In young and old rats, the anti-**indomethacin** effect of PCN is essentially the same if the dose levels are adjusted to body weight.

In pregnant women and in their neonates, the capacity to metabolize meperidine, pethidine and promazine is low as judged by the increased urinary excretion of these drugs.

Immature rats are especially sensitive to certain **pesticides** (e.g., Malathion), and their livers detoxify such compounds at a slow rate.

Female rats are more sensitive to **strychnine** intoxication than males, but resistance increases with age in both sexes.

**Hepatic Enzymes ←**

The **TPO** and **TKT** activity of rat liver is very low during fetal life but begins to rise a few hours after birth. This increase in TKT activity is prevented by adrenalectomy, and tyrosine cannot substitute for cortisol in restoring it towards normal. Premature delivery by cesarean section is also rapidly followed by increased TKT activity. Under all these conditions, the possibility to induce enzymic activity by cortisol coincides with delivery.

In guinea pigs, TKT activity is also absent during fetal life and increases to adult values within 24 hrs after birth.

In chickens, enzymic activity is relatively constant during the embryonic period, but rises after hatching.

Hepatic TKT activity increases in immature stressed (reciprocating shaker) rats, whereas intact stressed adults show no change. In stressed adrenalectomized adults, TKT activity dropped precipitously, whereas this was not the case in immature adrenalectomized rats.

TPO activity, when present, was increased by stress in old rats, but this increase was abolished by adrenalectomy or hypophysectomy. From these and other observations, it was concluded that "stress-activation of a pituitary mechanism that inhibits or represses activation of tyrosine transaminase may not function during early postnatal life."

Several other enzyme mechanisms (e.g., GOT, phenylalanine hydroxylase, OKT) have been found to be largely age-dependent.

#### *Steroids* ←

*Selye A 35,150/41*: Female rats are more sensitive to anesthesia produced by various steroids than are males, and young animals of either sex are more sensitive than adults.

*Winter & Selye A 35,658/41; Winter A 36, 333/41*: Female rats are more sensitive than males to the anesthetic action of progesterone, but this sex difference is obvious only after maturity. "The normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the males since castration increases sensitivity in males but is without effect in female rats. Conversely the resistance of castrate males and females may be raised by methyl testosterone administration."

*Karnofsky et al. B 69,772/52*: Newborn mice are extremely sensitive to the anesthetic and lethal effect of progesterone, but within 2-3 days resistance develops, and by the 7th day the mouse can tolerate about 100 times as much progesterone as on the day of birth. "The rapid development of resistance to progesterone within a few days after birth suggests that a system or mechanism has appeared which is capable of detoxifying, catabolizing, counterbalancing or accelerating the excretion of progesterone."

*Forchielli et al. D 75,874/58*: The rate of  $\Delta^4$  reduction of 11-desoxycortisol was 3-4-fold greater in female than in male rat liver homogenates and in microsomal fractions containing the  $\Delta^4$ -5 $\alpha$ -hydrogenase. Female rat liver contains only one  $\Delta^4$ -hydrogenase (5 $\alpha$ -microsomal), whereas the male liver contains the soluble  $\Delta^4$ -5 $\beta$ -hydrogenase as well. Ovariecto-

my caused no marked change in enzyme titer, but hypophysectomy decreased it sharply. Curiously, ACTH, STH, and pregnant mare serum partially restored the enzyme level in the hypophysectomized rat. In young animals, an increase in the titer of hepatic  $\Delta^4$ -5 $\alpha$ -hydrogenase occurs prior to puberty. This fact (like the negative results after ovariectomy) suggests an independence of enzyme regulation from ovarian hormones.

*Lehmann & Schütz H 14,215/69*: The microsomal fraction of the liver of the mature human fetus metabolizes 4-<sup>14</sup>C-estrone twice as fast as that of the 12-week-old fetus. The highest rate of metabolism was found in the microsomal fraction of the liver of an adult man. "By paperchromatography, microchemical reactions and crystallization to constant specific activity, the following metabolites were identified: 6 $\alpha$ -, 6 $\beta$ -, 7 $\alpha$ -, 15 $\alpha$ - and 16 $\alpha$ -hydroxyoestrone, 6 $\alpha$ -, 6 $\beta$ - and 7 $\alpha$ -hydroxyoestradiol-17 $\beta$  and oestriol."

*Conney et al. E 8,232/69*: The microsomal enzymes required for the 6 $\beta$ -, 7 $\alpha$ - and 16 $\alpha$ -hydroxylation of testosterone are selectively influenced, as shown by the speed of their development with age or after treatment with phenobarbital or 3-methylcholanthrene. Addition of chlorthion, in vitro, to hepatic microsomes markedly inhibits the 16 $\alpha$ -hydroxylation of testosterone, whereas it has a lesser effect on 16 $\beta$ -hydroxylation and no effect on 7 $\alpha$ -hydroxylation.

**Barbiturates** ←. *Carmichael D68,076/38*: The LD<sub>50</sub> of pentobarbital (Nembutal) increases with age but "there does not seem to be a definite sex difference in reaction to the median lethal dose of Nembutal of either young or old rats." In earlier observations in which males were found to be more resistant to barbiturates, the anesthetic action and not the lethal effect was determined.

*Holck & Mathieson B644/44*: In rats, the development of tolerance to pentobarbital was determined by injecting increasing doses every 90 min, day and night, for periods up to 5 days. Practically all 1–2-month-old rats developed tolerance as did adult males in contrast to females. Castration lowered the ability of adult males to develop tolerance, but did not do so in 2 month-old males. Ovariectomy of 2 month-old females increased their ability to detoxify pentobarbital, once tolerance had developed.

*Homburger et al. E61,371/47*: Female rats are more sensitive than males to pentobarbital but not to thiopental anesthesia. Age and strain differences in barbiturate resistance have also been noted in the rat.

*Buchel D73,669/54*: Review on the literature, and personal observations on the increased sleeping time of female as compared to male rats, after treatment with certain barbiturates, particularly hexobarbital. The increased sleeping time is associated with a prolonged persistence of the concentration of the drug in the blood. Gonadectomy prolongs the sleeping time of males but does not influence that of females. In immature rats no such sex difference is observed.

*Kato E87,340/60*: Chlorpromazine pretreatment reduces barbiturate sleeping time even in adrenalectomized or immature rats.

*Nair & Zeitlin G65,099/67*: The hexobarbital-metabolizing activity of the rat liver is extremely low after birth and rises gradually, up to the 80th day of life, to levels much higher in males than in females. Prenatal X-irradiation suppresses this normal development of enzyme activities in the male so that it only reaches the normal female level. Irradiation at 21 days (total body or head alone) also suppresses the developmental increase of enzyme activity, but to a lesser extent. Adults are still more resistant.

*Nair et al. G67,245/68*: X-irradiation of pregnant rats results in male offspring deficient in hepatic microsomal enzymes which

metabolize hexobarbital. However, irradiation did not suppress the increase of enzyme activity brought about by chemical inducers (phenobarbital). Actinomycin inhibited both the ontogenic and phenobarbital-induced increases in enzyme activity. "The ontogenic increase in enzyme activity is hormone-dependent, while that following phenobarbital administration is independent of hormonal regulation as evidenced by the response in hypophysectomized or sexually immature animals. It is concluded from these results that the inhibitory effect of x-irradiation on the hepatic enzyme system is mediated through an action on the hormonal regulation of enzyme activity."

*Feuer & Liscio H 14,579/69*: Review of the literature and personal observations on the unusually low drug-metabolizing enzyme activity of the liver in newborn rats. Among newborn rats, those weaned early had a shorter pentobarbital sleeping time than nonweaned controls.

*Klinger H 25,517/70*: In male rats, the LD<sub>50</sub> of hexobarbital in mg/kg rises from 160 to 343, between 12–130 days after birth; however, the blood concentration of hexobarbital at waking time is not age-dependent. The sleeping time is directly correlated with the speed of biotransformation by hepatic microsomes in vitro. CCl<sub>4</sub>-prolongs sleeping time. Following acute habituation in CCl<sub>4</sub>-treated rats, the hexobarbital concentration of the plasma at waking time is comparatively high.

#### **Hepatic Lesions** ←

*Bucher G68,621/63*: Review on the influence of age upon hepatic regeneration.

#### **Hepatic Enzymes** ←

**TPO, TKT** ←. *Rivlin & Knox C71,249/59*: The TPO activity of rat liver increases with age and body weight, as well as after STH-injection.

*Sereni et al. C80,562/59*: TKT activity is very low in the livers of fetal rats, but rapidly increases 2 hrs after birth, reaching a maximum (at least twice the usual adult level) at 12 hrs. Adrenalectomy or injection of amphenone at birth delays the development of this enzyme, whereas cortisol reverses the effect of adrenalectomy.

*Kenney D98,193/60*: In the rat, hepatic TKT activity increases sharply after birth. This increase is prevented by adrenalectomy, and tyrosine cannot substitute for cortisol in restoring transaminase development. Methionine is as active as tyrosine in increasing the response to cortisol after adrenalectomy, and this process does not depend upon the specific substrate as such, but apparently upon the presence of certain amino acids. Immunological assays "are clearly incompatible with a mechanism of induction involving de novo synthesis of enzyme protein and suggest that adrenal steroids promote either the activation of an antigenically similar but enzymically inactive precursor protein, or the release of an inhibitor."

*Greengard et al. D63,145/63*: In adrenalectomized rats, "the administration of puromycin inhibited the cortisone-induced elevation of tryptophan pyrrolase and tyrosine- $\alpha$ -keto-

glutarate transaminase activity as well as the substrate-induced elevation of the latter. Actinomycin D abolished the cortisone-mediated rise in the level of both enzymes but did not influence the tryptophan-mediated increase in the level of tryptophan pyrrolase." In newborn rats, the development of hepatic TKT was inhibited by actinomycin, but neither adrenalectomy nor actinomycin interfered with the postnatal development of hepatic TPO. Apparently, accumulation of TPO (unlike that of TKT) is not under adrenal control and can proceed despite inhibited RNA synthesis.

*Litwack & Nemeth G26,050/65*: Hepatic TKT activity increases in the rabbit 2-4-fold at birth. A similar increase is obtained precociously in the event of premature delivery by cesarian section, whereas prolonging gestation delays the rise in enzymic activity. Under all these conditions, the ability of cortisol to cause a further rise in enzymic activity coincides with delivery. In the guinea pig, TKT is absent during fetal life, and increases to adult values within 24 hrs after birth. The enzyme activity in the newborn is stimulated by cortisol, though a single injection is without effect in the fetus or adult. In chickens, enzymic activity is relatively constant during the embryonic period, but rises 2-3-fold after hatching.

*Schapiro et al. F65,746/65-66*: "Infant rats, four and eight days after birth, respond to the stress of 30 minutes on a noisy reciprocating shaker with a large increase in liver aromatic amino acid transaminase activities. Adult rats exposed to the same stress do not exhibit this change. In the adult rat the inducing effects of cortisol on transaminase activities are blocked by this stress. These results suggest the activation of a mechanism(s) in the adult rat which opposes the enzyme inducing effects of cortisol."

*Schapiro et al. F67,227/66*: Hepatic TKT activity increased in immature, stressed (reciprocating shaker) rats, whereas intact stressed adults showed no change. In the stressed adrenalectomized adults, TKT activity markedly decreased, while in adrenalectomized immature rats it showed no change. Hypophysectomy largely abolished inhibition in the adults. TPO activity, when present, was increased by stress in old-age groups, but the increase was abolished by adrenalectomy and hypophysectomy. "The results suggest stress-activation of a pituitary mechanism that inhibits or represses activation of tyrosine transaminase and that may not function during early postnatal life."

*Adelman H 32,850/70*: Brief review on age-dependent enzyme induction with personal observations on ACTH-induced hepatic TKT in the rat.

**Other Enzymes** ←. *Cohen & Hekhuis 93, 220/41*: GOT activity was subnormal in six types of mouse tumors, regenerating rat liver, and fetal kitten (compared with adult cat) tissues. Apparently, an inverse relationship exists between transaminase activity and protein synthesis.

*Knox et al. E 83,471/56*: Review on metabolic and particularly enzymic adaptations, with a special section on the effect of age.

*Conney & Burns G 67,166/62*: Review on drug metabolism in the newborn.

*Freedland et al. G 66,662/62*: The phenylalanine hydroxylase activity of rat liver increases with age, from embryonic life to 50–60 days, and then declines to stabilize after maturity at a lower level in females than in males. Fasting and diets deficient in phenylalanine cause a rapid decrease in this enzymic activity.

*Conney F 88,649/67 (p. 338)*: A review of the literature on enzyme induction in animals of different species, strains and age.

*Goldstein et al. E 165/68 (p. 274)*: Review on the age factor in the induction of microsomal drug-metabolizing enzymes.

*Nair & DuBois G 67,244/68*: Review on hepatic microsomal enzyme induction in pre-natal and early postnatal life.

*Räihä & Kekomäki G 68,114/68*: In the rat, the OKT activity of the liver is very low in the fetus, exhibiting a small transient elevation around term; it then drops, and eventually reaches the high adult activity level during the third postnatal week. Triamcinolone given postnatally causes a pronounced elevation of OKT, but has no such effect in fetal or adult rats. Puromycin prevents the rise in OKT after triamcinolone administration. In adult rats fed a protein- or arginine-free diet, OKT activity decreases and fails to rise under the influence of triamcinolone. Partial hepatectomy or STH depresses OKT activity in the livers of adult rats.

*Vest et al. H 14,687/68*: Brief review on changes in hepatic enzyme production during the perinatal period.

## ← GENETIC AND SPECIES-DEPENDENT FACTORS

(For Data on Man *cf. also* "Clinical Implications")

### **Steroids** ←

There are considerable differences in the influence of hormones upon resistance in various species. The chemical basis of this genetic variation has not yet been adequately studied, but a few facts are known especially as regards the activation of enzymes by sex hormones.

The steroid hydroxylase activity of hepatic microsomes is higher in male than in female rats, but no such sex difference exists in mice. Fish liver does not contain this enzyme. Incubation of radio-marked progesterone with hepatic microsomes of male rats results in the oxidation of the steroid to a more polar fraction containing 6 $\beta$ - and 16 $\beta$ -hydroxyprogesterone, whereas microsomes of female rats metabolize progesterone mainly by reduction of the A ring, and its subsequent transformation into more polar compounds. By contrast, female rabbits and guinea pigs metabolize progesterone by hydroxylation. There is also a species difference in the type of steroid metabolism induced by phenobarbital and chlordane in rats and rabbits of both sexes. In monkeys, phenobarbital increases the urinary elimination of 6 $\beta$ -hydroxycortisol. In two strains of guinea pigs, distinguished by high and low production of hydroxylated cortisol derivatives, phenobarbital increased hepatic microsomal 2 $\alpha$ -hydroxylation of cortisol, but caused no significant change in the 6 $\beta$ -hydroxylation activity in either strain.

There is some controversy in the literature concerning the existence of a sex difference in the susceptibility of the mouse to hydroxydione anesthesia (perhaps

owing to the use of different strains), but in rats, the males are definitely more resistant.

It has been claimed that neither thiopental nor pentobarbital anesthesia can be influenced by catatoxic steroids in the mouse. Our own observations failed to confirm this; we have obtained a significant shortening of pentobarbital sleeping time in female mice by pretreatment with ethylestrenol, CS-1, spironolactone, and norbolethone.

*Kuntzman et al. F27,893/64:* The steroid hydroxylase present in the microsome fraction of rat liver exhibits higher activity in male than in female rats, but no such sex difference is seen in mice. Fish liver does not contain this enzyme.

*Kuntzman & Jacobson F35,869/65:* "Incubation of progesterone-4-C<sup>14</sup> with liver microsomes from adult male rats resulted in oxidation of the steroid to a more polar fraction made up of 6 $\beta$ - and 16 $\beta$ -hydroxyprogesterone and an unidentified U.V. absorbing product. In contrast, female rats metabolized progesterone primarily by reduction of the A ring followed by subsequent metabolism to polar compounds. Unlike the female rat, female rabbits and guinea pigs metabolized progesterone by hydroxylation. With microsomes from immature male rats, both hydroxylation and reduction occurred. Chronic administration of phenobarbital, chlorcycline or chlordane to female rats caused an increased formation of polar metabolites but had little effect on the disappearance of progesterone, since the main pathway in the female rat is A-ring reduction. In contrast, chronic phenobarbital administration to female rabbits increased markedly the metabolism of progesterone to hydroxylated derivatives when measured either by formation of polar metabolites or by progesterone disappearance."

*Birchall et al. F76,581/66:* In Cebus albifrons monkeys, phenobarbital pretreatment increases the urinary elimination of 6 $\beta$ -hydroxycortisol.

*Rümke G68,532/66:* The anesthetic effect of hydroxydione is greater in female than in male mice.

*Burstein & Bhavnani F77,040/67:* In guinea pigs, pretreatment with phenobarbital stimulated the hepatic microsomal metabolism of cortisol, 2 $\alpha$ - and 6 $\beta$ -hydrocortisol, but not to the same extent. In rats, phenobarbital pretreatment enhanced hepatic microsomal 6 $\beta$ -

hydroxylation of cortisol without causing a significant change in the overall metabolism of substrate or product. 2 $\alpha$ -Hydroxylation of cortisol was not observed with rat liver microsomes.

*Burstein F95,565/68:* Pretreatment with phenobarbital increased hepatic microsomal 2 $\alpha$ -hydroxylation of cortisol in two strains of guinea pigs distinguished by high and low production of hydroxylated cortisol derivatives. Under the same conditions, phenobarbital caused no significant change in the hepatic 6 $\beta$ -hydroxylation activity of either strain.

*Jelinek H1,518/68:* There was no difference in the duration of hydroxydione anesthesia in male and female intact or gonadectomized mice. Pretreatment with methyltestosterone p.o. prolonged hydroxydione anesthesia in males but not in females or castrate males. Neither thiopental nor pentobarbital anesthesia was influenced by methyltestosterone. Pretreatment with methandrostenolone or 17 $\alpha$ -methyl-androst-2-ene-17 $\beta$ -ol failed to influence hydroxydione anesthesia in mice.

*Kato et al. H34,571/71:* Male rats are more resistant to the anesthetic effect of progesterone than females. Correspondingly the formation of hydroxylated metabolites of this steroid is greater with hepatic microsomes from males, whereas the formation of  $\Delta^4$ -reduced metabolites is greater with female microsomes. In mice, there was no such difference either in the anesthetic action or in the *in vitro* metabolism of progesterone. In rats, the blood and tissue level of polar metabolites of tritiated progesterone was higher in males, whereas that of nonpolar metabolites was higher in females. "These results suggest that the stronger anesthetic action of progesterone in female rats is associated with higher tissue levels of progesterone and  $\Delta^4$ -reduced metabolites, possessing the anesthetic action."

Epinephrine ← Genet, Rat, Rb: Inscoc et al. F70,325/66

### Drugs ←

Pretreatment with various thyroid preparations greatly increases the acetoneitrile resistance of mice, whereas this is not so in most other species.

Female rats are more sensitive than males to various **barbiturates** but no such sex difference could be observed by most investigators in the dog, cat, rabbit, guinea pig, mouse, turtle or frog. However, strain differences in barbiturate resistance have been noted by some workers in the rat and mouse also. In Swiss mice, there is allegedly no sex difference in hexobarbital sleeping time. Rats can be separated into "long-sleepers" and "short-sleepers" on the basis of their response to hexobarbital. Hepatic "post-mitochondrial supernatant fraction" from long-sleepers possesses correspondingly less drug-metabolizing activity than that from short-sleepers not only with respect to hexobarbital but also as regards several other substrates. Rats that show a particularly long hexobarbital sleeping time are also especially sensitive to zoxazolamine, strychnine and methyprylon. Repeated administration of phenobarbital causes resistance in the rat but not in the guinea pig.

Male rats are more sensitive to **carisoprodol** paralysis than females but no such sex difference exists in mice or guinea pigs.

Small doses of **chloroform** produce fatal tubular necrosis in the kidneys of DBA mice, but no comparable renal lesion is elicited by chloroform in other species.

In mice, **digitoxin** poisoning is inhibited by CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone, and thyroxine. Hence, contrary to earlier claims, mice are sensitive to catatoxic steroid actions, although in some respects their responsiveness differs from that of the rat.

**Indomethacin** intoxication is prevented in mice by ethylestrenol, CS-1, spironolactone, norbolethone, and to a lesser extent perhaps, by prednisolone, and estradiol.

Certain strains of rats which are particularly sensitive to **methyprylon** also have a low resistance to **zoxazolamine**, **strychnine**, and **hexobarbital**.

Male rats are more resistant than females to various anticholinesterase **pesticides**, whereas no such sex difference is noted in mice and guinea pigs. In mice, the lethal effect of dioxathion (Navadel) is strongly inhibited by ethylestrenol, norbolethone, prednisolone, and estradiol, but not significantly influenced by spironolactone, although the latter is effective in this respect in the rat.

**Picrotoxin** poisoning is not significantly influenced in mice by spironolactone, ethylestrenol, triamcinolone, or thyroxine, whereas in rats, this intoxication is readily prevented by pretreatment with various catatoxic steroids.

#### **Acetonitrile** ←

*Hunt 13,889/23:* Pretreatment with thyroid preparations greatly increases the resistance of mice to acetonitrile, whereas the reverse is true in many other species.

#### **Anticoagulants** ←

*Dayton et al. D42,366/61:* In the guinea pig, dog and man, pretreatment with barbiturates antagonizes the hypoprothrombinemic effect of coumarin anticoagulants. At the same time, the plasma level of the coumarin is depressed.

*Goss & Dickhaus F53,987/65:* Phenobarbital increases the daily maintenance dose of bishydroxycoumarin in man.

*Robinson & MacDonald F69,377/66:* Phenobarbital antagonizes the anticoagulant effect of warfarin in man.

#### **Barbiturates** ←

*Holck & Kanan 31,302/35:* Female rats are more sensitive than males to various barbiturate anesthetics. No such sex difference could be detected in the dog, cat, rabbit, guinea pig, mouse, turtle or frog.

*Holck et al. A8,011/37:* In the dog, cat, rabbit, guinea pig, mouse and frog (unlike in the rat), males are no more sensitive to hexobarbital anesthesia than females. In mice, the sex difference was also absent to amobarbital,

but the butallylonal sleeping time was slightly longer in females.

*Homburger et al. E61,371/47:* Female rats are more sensitive than males to pentobarbital but not to thiopental anesthesia. Age and strain differences in barbiturate resistance have also been noted in the rat.

*Quinn et al. G67,327/54:* The biologic half-life of hexobarbital was found to be 15 min for mice, 60 min for rabbits, 140 min for rats, and 260 min for dogs and man. There was an inverse relationship between the rate of biotransformation of hexobarbital to keto-hexobarbital and the duration of its hypnotic effect. Male rats are more resistant to hexobarbital anesthesia than females but in the latter, resistance as well as the enzyme activity of the microsomes were increased by testosterone.

*Jay G71,140/55:* Various strains of mice show considerable differences in their responsiveness to hexobarbital anesthesia.

*Quinn et al. E89,993/58:* Guinea pigs and mice, unlike rats, show no sex difference in the metabolism of hexobarbital. In the rat, the sex difference is also manifest with regard to antipyrine and amidopyrine. The difference is largely dependent upon the effect of sex hormones upon microsomal drug metabolism, although variations in the inherent sensitivity of the central nervous system may also play a part.

*Catz & Yaffe G37,059/61:* Description of striking differences in hexobarbital sensitivity among various strains of mice. Curiously, mortality and sleeping time do not run parallel, perhaps because toxicity is due to a metabolite of the drug.

*Brodie G55,013/62:* Review on species differences in the duration of action and in the metabolism of hexobarbital in the mouse, rat, guinea pig, rabbit, dog and man. Fish, aquatic species of frogs and aquatic salamanders do not oxidize drugs *in vivo*, nor do their liver microsomes carry out the oxidative mechanisms of N- or O-dealkylation, hydroxylation, deamination and sulfoxidation, common to mammals. Presumably, fish can dispose of foreign compounds by diffusion through the gills, whereas aquatic frogs and salamanders eliminate them unchanged through their skins which behave as lipid membranes. Terrestrial arthropods which must conserve water, e.g., crickets (*Acheta domestica*) and grasshoppers (*Romlea microptera*) metabolize hexobarbital, amphetamine, chlorpromazine and amidopyrine very rapidly. Surprisingly, aquatic arthropods such as crayfish and lobsters also metabolize

these substances although at a much slower rate. However, these animals lead a partly terrestrial existence and possess rigid gills which are impermeable to lipid-soluble drugs.

*Buchel & Liblau E89,233/63:* In Swiss mice, there is no sex difference in hexobarbital sleeping time or in the disappearance rate of this drug from the brain.

*Backus & Cohn D92,313/66:* The hexobarbital sleeping time of female mice is shorter than that of males, and varies also according to strain. In general, the length of the sleeping time is inversely proportional to the hexobarbital-metabolizing potency of liver homogenates.

*Gessner et al. F77,776/67:* In mice, "testosterone pretreatment produces a biphasic effect on the duration of action of hexobarbital, prolonging the action initially and shortening the action in 4—8 days after the pretreatment. The early action of testosterone appears to be associated with an effect on the hypnotic property of a drug, since both hexobarbital and barbital sleep times are prolonged while the duration of action of the muscle relaxant chlorzoxasone remains unaffected. The long-term pretreatment with testosterone leads to a shorter duration of action of drugs that are deactivated by detoxification, notably hexobarbital and chlorzoxasone, but has no effect on the duration of hypnosis produced by barbital, a drug which is predominantly eliminated unchanged." Folliculoids (ethinyl-estradiol, diethylstilbestrol) prolong the actions of both drugs.

*Mitoma et al. G69,268/67:* Rats were separated into "long-sleepers" and "short-sleepers" on the basis of their response to hexobarbital. "The drug-metabolizing activities of the hepatic postmitochondrial supernatant fraction from long-sleepers were less than those from short-sleepers with respect to hexobarbital, acetanilide, aminopyrine, and o-nitroanisole, each of which represents a different drug-metabolism pathway. This trend was observed in all 5 strains of rats examined."

*T'imar et al. F82,696/67:* Repeated administration of phenobarbital causes resistance in the rat but not in the guinea pig.

*Selye PROT. 31380:* In the mouse, the duration of pentobarbital anesthesia is shortened by ethylestrenol, CS-1 spironolactone, and norbolethone, but not significantly by oxandrolone, prednisolone, progesterone, triamcinolone, DOC, hydroxydione, estradiol, or thyroxine, *cf.* Table 129.

Table 129. *Conditioning for pentobarbital anesthesia in mice*

Group	Treatment <sup>a</sup>	Anesthesia time (min) <sup>b</sup>	Mortality (dead/total)
1	None	52 ± 7	0/12
2	Ethylestrenol	4 ± 3***	0/14
3	CS-1	15 ± 5***	0/13
4	Spirolactone	19 ± 5**	0/13
5	Norbolethone	1 ± 1***	0/12
6	Oxandrolone	37 ± 9NS	0/13
7	Prednisolone acetate	37 ± 6NS	0/13
8	Progesterone	43 ± 6NS	0/13
9	Triamcinolone	89 ± 15NS	0/13
10	Desoxycorticosterone acetate	68 ± 14NS	0/12
11	Hydroxydione sodium hemisuccinate	97 ± 20NS	1/14
12	Estradiol	32 ± 7NS	0/13
13	Thyroxine	91 ± 17NS	0/13

<sup>a</sup> In 20 g ♀ mice all steroids (Groups 2—12) were administered (at the dose of 10 mg in 0.2 ml water p.o. x2/day, 1st day ff.), and thyroxine as Na salt (at the dose of 200 µg in 0.2 ml water/100 g body weight s.c., once daily, 1st day ff.). In addition, the mice of all groups were given pentobarbital (6 mg in 0.2 ml oil/100 g body weight i.p. once on the 4th day).

<sup>b</sup> Statistics: Student's t-test.

For further details on technique of tabulation cf. p. VIII.

*Feller & Gerald H22,744/70:* In male mice, pretreatment with spironolactone shortened pentobarbital and "testosterone-potentiated" pentobarbital sleeping times. It also increased liver microsomal protein, liver weight, aniline hydroxylation and ethylmorphine N-demethylation.

*Gerald & Feller G74,092/70:* In mice, pretreatment with spironolactone shortens pentobarbital sleeping time as well as "testosterone-potentiated pentobarbital sleeping time." Furthermore, spironolactone enhances the microsomal metabolism of aniline and ethylmorphine, and increases hepatic weight. It is concluded that the in vivo protective effect of spironolactone is due to the induction of hepatic microsomal enzymes.

*Gerald & Feller G78,804/70:* In mice, pretreatment with spironolactone reduces

pentobarbital sleeping time and accelerates the hepatic microsomal metabolism of hexobarbital in vivo and in vitro.

*Mitoma H25,522/70:* Rats that show a long hexobarbital sleeping time are also particularly sensitive to zoxazolamine, strychnine and methypylon.

### Bilirubin ←

*Lüders G81,789/70:* In Gunn rats which have a high serum bilirubin level, Na-dehydrocholate i.v. decreased the serum and increased the brain bilirubin content. This effect was also seen when the initial serum bilirubin level was raised by infusion of bilirubin. The decrease in serum bilirubin induced by Na-dehydrocholate did not coincide with an increased biliary excretion of the pigment. Indeed, Gunn rats with

Table 130. *Conditioning for digitoxin intoxication in mice*

Thyroxine (200 µg)	3/16***	10/16 NS

<sup>a</sup> The mice (20 g ♀) of all groups were given digitoxin (1 mg/100 g body weight in 0.2 ml water, p.o./day, daily from 4th day ff.). In addition, certain groups received thyroxine (200 µg/100 g body weight in 0.2 ml water + NaOH + Tween, s.c./day, on 1st day ff.), triamcinolone (2 mg/100 g body weight) and other steroids (10 mg/100 g body weight in 0.2 ml water, p.o. x2/day, on 1st day ff.).

<sup>b</sup> Convulsions were estimated on 7th day, and mortality listed on 9th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

bile fistulas showed that Na-dehydrocholate interferes with the biliary excretion of diazopositive substances.

#### **Carisoprodol** ←

*Kato et al. G66,023/61:* Adult (but not immature) male rats are more sensitive to carisoprodol-induced muscular paralysis than females. Castration or treatment with SKF 525-A abolishes the increased resistance of the adult male rat. Incubation of liver slices with carisoprodol shows that the resistance of the male is due to accelerated substrate inactivation. No sex difference is noted in adult mice or guinea pigs.

#### **Chloroform** ←

*Shubik & Ritchie D67,964/53:* Small doses of chloroform produce fatal tubular necrosis in the kidneys of male but not of female DBA mice.

#### **Digitalis** ←

*Szabo et al. G79,013/71:* In hamsters, spironolactone and ethylestrenol pretreatment prevents digitoxin convulsions and indomethacin-

induced intestinal ulcers. Curiously, hamsters are resistant to as much as 100 mg of digitoxin p.o. given repeatedly, whereas 1 mg i.v. produces strong convulsions. Apparently, in this species, the absorption of digitoxin from the gastrointestinal tract is deficient. Indomethacin intoxication is also different in rats and hamsters since in the latter, unlike the former, the drug produces predominantly pyloric ulcers which often perforate.

*Selye PROT. 27594, 28284, 29742, 29751:* In mice, digitoxin poisoning is inhibited by CS-1 spironolactone, norbolethone, oxandrolone, prednisolone, progesterone and thyroxine. Ethylestrenol, triamcinolone, DOC, hydroxydione and estradiol are ineffective, *cf.* Table 130, p. 677.

#### **Ethanol** ←

*Jabbari & Leevy G45,526/67:* Various anabolics (norethandrolone, testosterone, oxandrolone) protect the liver of the rat against ethanol-induced fatty degeneration and various functional disturbances. They are also useful in the management of alcoholic patients.

Table 131. *Conditioning for indomethacin intoxication in mice*

Thyroxine 200 µg	2/7 NS	—	—	15/15 *	—	—

<sup>a</sup> The mice (25 g ♀) of all groups received indomethacin s.c. 1 mg/day, from the 4th day to the 7th day, and 2 mg/day on the 8th day ff. Thyroxine 200 µg/day, triamcinolone 2 or 10 mg as indicated, and other catatoxic steroids 10 mg x2/day, subcutaneous, intraperitoneal or oral, as described in the table, on the 1st day ff. Every substance was given per 100 g body weight in 0.2 ml water.

<sup>b</sup> Intestinal ulcers and mortality listed on the 12th day (Statistics Fisher & Yates). For further details on technique of tabulation *cf.* p. VIII.

**Fig. 28. Typical perforating pyloric ulcer produced by indomethacin in the rabbit.**  
 A: Naked eye view from anterior surface. B: Histologic appearance of the ulcer which undermines the still well-preserved portion of the stomach which is covered by an intact mucosa (PAS X 29)

### ***Indomethacin*** ←

*Szabo et al. G79,013/71:* In hamsters, spironolactone and ethylestrenol pretreatment prevents digitoxin convulsions and indomethacin induced intestinal ulcers. Curiously, hamsters are resistant to as much as 100 mg of digitoxin p.o. given repeatedly, whereas 1 mg i.v. produces strong convulsions. Apparently, in this species, the absorption of digitoxin from the gastrointestinal tract is deficient. Indomethacin intoxication is also different in rats and hamsters since in the latter, unlike the former, the drug produces predominantly pyloric ulcers which often perforate.

*Selye PROT. 28397:* In mice, indomethacin intoxication can be prevented by ethylestrenol, CS-1, spironolactone, norbolethone and to a lesser extent, perhaps also by prednisolone, and estradiol administered by various routes. Thyroxine appears to have an opposite effect. Progesterone, triamcinolone, DOC, and hydroxydione had little if any effect, cf. Table 131, p. 678.

### ***Methpyrylon*** ←

*Mitoma H25,522/70:* Rats that show a long hexobarbital sleeping time are also particularly sensitive to zoxazolamine, strychnine, and methpyrylon.

**Morphine** ←

*Adler et al. G79,852/57:* In Sprague-Dawley rats, given <sup>14</sup>C-labeled morphine, the ratio of bound to free morphine is 2–3 times greater in the urine and plasma than in Long-Evans rats. The tissue of adrenalectomized rats of both strains contains higher concentrations of <sup>14</sup>C-labeled morphine than do control rats. Plasma bound morphine levels indicate no impairment of morphine conjugation. Vasopressin increases, whereas ACTH decreases morphine sensitivity. Yet both after ACTH and after vasopressin, tissue concentrations of morphine are either reduced or unaffected in marked contrast to the increased values after adrenalectomy. Apparently, the decreased morphine sensitivity induced by ACTH is not reflected by lower brain morphine concentrations.

Table 132. *Conditioning for dioxathion intoxication in mice*

13	Thyroxine	11/11 NS	11/11 NS

<sup>a</sup> In 20 g ♀ mice all steroids (Groups 2–12) were administered at the dose of 10 mg in 0.1 ml water, p.o., x2/day on the 1st day ff.; thyroxine as Na salt at the dose of 200 µg in 0.2 ml water, s.c., once daily on the 1st day ff. All drugs/100 g body weight. In addition, the mice of all groups received dioxathion 15 mg in 0.2 ml oil/100 g body weight, p.o., once on the 4th day.

<sup>b</sup> Mortality was listed 24 hrs after dioxathion. (Statistics: Fisher & Yates.)

For further details on technique of tabulation cf. p. VIII.

**Pesticides** ←

*DuBois & Puchala D43,878/61:* Male rats are much more resistant than females to various cholinergic phosphorothioates. Male mice and guinea pigs are not particularly resistant to dimethyl phthalate (DMP). Partial hepatectomy and/or castration abolishes the comparative resistance of the male rat, whereas testosterone restores resistance in hepatectomized or orchidectomized rats. It is concluded "that androgens govern the development of this system."

*Selye PROT. 31563, 31612:* In mice, the lethal effect of dioxathion is powerfully inhibited by ethylestrenol, norbolethone, prednisolone, and estradiol, and only moderately by CS-1 and oxandrolone, but it is not influenced by spironolactone, progesterone, triamcinolone, DOC, hydroxydione, or thyroxine, cf. Table 132.

**Picrotoxin** ←

*Selye PROT. 27594:* In mice, pretreatment with spironolactone, ethylestrenol, triamcinolone or thyroxine had little if any effect upon the toxicity of picrotoxin under our experimental conditions, cf. Table 133.

Table 133. *Conditioning for picrotoxin intoxication in mice*

Treatment <sup>a</sup>	Convulsions <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/Total)
None	6/6	3/6
Spirolactone	4/6 NS	2/6 NS
Ethylestrenol	4/6 NS	2/6 NS
Triamcinolone	6/6 NS	5/6 NS
Thyroxine	6/6 NS	4/6 NS

<sup>a</sup> The mice (20 g ♀) of all groups were given picrotoxin 0.6 mg/100 g body weight in 0.4 ml water, s.c., once on the 4th day. Thyroxine 200 µg/100 g body weight in 0.2 ml water + NaOH + Tween, s.c./day, on the 1st day ff.; triamcinolone 2 mg/100 g body weight, spironolactone and ethylestrenol 10 mg/100 g body weight in 0.2 ml water, p.o. x2/day, on the 1st day ff.

<sup>b</sup> The severity of the convulsions was estimated 30 min after picrotoxin injection. Mortality was listed 24 hrs later. (Statistics: Fisher & Yates.)

For further details on technique of tabulation *cf.* p. VIII.

### **Strychnine, Zoxazolamine ←**

*Mitoma H 25,522/70*: Rats that show a long hexobarbital sleeping time, are also particularly sensitive to zoxazolamine, strychnine, and methyprylon.

### **Varia ←**

*Kalow E 695/62*: A monograph on "Pharmacogenetics, Heredity and the Response to Drugs" containing special sections on human hereditary defects with altered drug response and racial differences in drug sensitivity.

*Meier E 690/63*: Monograph on "Experimental Pharmacogenetics" (213 pp., about 400 refs.) with special sections on the influence of sex and genetic factors, including species variations, upon drug sensitivity.

*Brodie et al. F 42,949/65*: Considerations on species variations in drug sensitivity. Unlike

most other drugs, antitumor agents (usually antimetabolites of alkylating compounds) interact with pathways of metabolism common to normal and neoplastic tissues. These drugs exert an antitumor action because, in being metabolized, they become enmeshed in mechanisms essential to the normal economy of the body and are usually toxic for the same reason. Their toxicity in various animal species agrees well with the maximum tolerated doses in man when expressed on the basis of weight to the 0.7 power. Species variations are also of lesser importance as regards tolerance of poorly liposoluble compounds, such as tubocurarine or ganglionic blocking agents. If a drug affects the target organ equally in various species, dependable predictions might be made from experimental animals to man, even with regard to agents that are unequally metabolized, provided that the effects are expressed in terms of plasma or tissue concentrations, rather than dosage per body weight. Thus, despite a 20- to 50-fold variation in the duration of narcosis produced by hexobarbital and other barbiturates in various animal species and man, the plasma concentration of the drugs at waking time is essentially the same in various species.

### **Varia ←**

Guinea pigs, unlike rats and rabbits, are not protected against endotoxin by cortisone. Correspondingly, cortisone increases TPO in rats and rabbits but not in guinea pigs. Actinomycin D and ethionine augment the lethal effect of endotoxin and abolish the protective action of cortisone, presumably because both endogenous and exogenous glucocorticoids exert their prophylactic effect through the induction of hepatic enzymes whose synthesis can be inhibited by actinomycin D and ethionine.

Vertebrates above the evolutionary level of amphibians respond to cortisol with an increased hepatic TKT activity, but lower vertebrates do not respond in this manner. The appearance of TKT in the course of ontogenesis, as well as the possibility of inducing this enzyme by glucocorticoids, is subject to considerable species variation.

It is generally assumed that aquatic animals, especially fish, which can excrete nonpolar toxicants through the gills or skin are less dependent upon the induction of microsomal drug-metabolizing enzymes than are mammals, which must depend mainly upon renal excretion of polar compounds and polar metabolites of lipid soluble toxicants.

### **Bacterial Toxins ←**

*Berry G 68,858/64*: Both actinomycin D and ethionine increase the lethal effect of endotoxin in the mouse and abolish the protection offered by cortisone. Presumably, both endogenous and exogenous glucocorticoids protect

through the induction of hepatic enzymes whose synthesis can be inhibited by actinomycin D and ethionine. Cortisone increases TPO in rats and rabbits, but not in guinea pigs. Correspondingly, guinea pigs cannot be protected against endotoxin by cortisone.

**Hepatic Lesions** ←

*Bucher G68,621/63*: Review on the influence of species and strain differences upon hepatic regeneration.

**Hepatic Enzymes** ←

**TPO, TKT** ←. *Chan & Cohen D18,552/64*: Vertebrates above the evolutionary level of amphibians respond to cortisol with an increased hepatic TKT activity. "Animals showing this response include the rat, guinea pig, chick, pigeon, horned toad (*Phrynosoma cornatum*), and painted turtle (*Chrysemys picta*). In contrast, vertebrates at the amphibian level or below failed to show this response. Animals failing to show this response include the bull frog (*Rana catesbeiana*), grass frog (*Rana pipiens*), marine toad (*Bufo marinus*), tiger salamander (*Ambystoma trigrinum*), mud puppy (*Necturus*), white bass (*Roccus chrysops*), and black crappie (*Promoxis nigromaculatus*)."

*Litwack & Nemeth G26,050/65*: In the rabbit hepatic TKT activity increases 2-4-fold at birth in the rabbit. A similar increase is obtained precociously in the event of premature delivery by cesarian section, whereas prolonging gestation delays the rise in enzymic activity. Under all these conditions, the ability of cortisol to cause a further rise in enzymic activity coincides with delivery. In the guinea pig, TKT is absent during fetal life and increases to adult values within 24 hrs after birth. The enzyme activity in the newborn is stimula-

ted by cortisol, though a single injection is without effect in the fetus or adult. In chickens, enzymic activity is relatively constant during the embryonic period, but rises 2-3-fold after hatching.

**Other Enzymes** ←. *Brodie & Maickel G67,800/62*: Review (25 pp., no refs.) on the authors' work on microsomal drug-metabolizing enzymes in fish, amphibia, reptiles, birds and mammals.

*Dewaide G80,406/70*: Comparative studies on the effect of adaptation to cold or heat upon hepatic drug oxidation in various species. Contrary to earlier claims, drug metabolizing enzymes do play a decisive role in the resistance of fishes to changes in their environment. "The effect of a change of ambient temperature on the liver of the hamster, rat, roach, and trout becomes manifest in an almost equal way for the different species."

← **IONIZING RAYS****Drugs** ←

In the rat, X-irradiation of the head increases the anesthetic effect of such barbiturates as thiopental, barbital and pentobarbital. However, the induction by phenobarbital of resistance to pentobarbital is not inhibited. X-irradiation of entire 23-day-old male rats, or of the head only, inhibited the rapid increase in hexobarbital-metabolizing microsomal oxidases following hexobarbital pretreatment in the same manner as did hypophysectomy. Normally, the hexobarbital metabolizing activity of rat liver is extremely low after birth, but rises rapidly up to the age of 80 days, to levels much higher in males than in females. Prenatal X-irradiation suppresses this normal development of enzyme activities in the male so that it reaches only the normal female level. The effect of the irradiation decreases as the animals mature. In adult rats, selective irradiation of the head does not inhibit microsomal enzyme induction by phenobarbital but does, nevertheless, increase the anesthetic effect, presumably by raising the permeability of the blood-brain barrier.

In summary, it may be said that whereas the ontogenic increase in enzyme activity is hormone dependent, the phenobarbital-induced induction is not, since it is evident even in hypophysectomized or sexually immature animals. Presumably, the inhibitory effect of X-irradiation is due to interference with the hormonal regulation of enzyme activity.

In weanling male rats, total body X-irradiation or irradiation of the head only inhibits the development of microsomal enzymes which metabolize the pesticide Guthion.

#### **Barbiturates** ←

*Nair et al. F53,576/65:* In the rat, X-irradiation of the head considerably enhanced the anesthetic effect of thiopental, barbital, and pentobarbital. The induction by phenobarbital of resistance to subsequent pentobarbital anesthesia was not inhibited by cephalic X-irradiation.

*Nair G67,247/67:* In adult male rats, selective irradiation of the head did not inhibit hepatic microsomal enzyme induction by phenobarbital. In such experiments, the increased anesthetic effect of the barbiturate is ascribed to enhanced permeability of the blood-brain barrier.

*Nair & Bau G67,246/67:* Exposure of rats to X-irradiation in utero or during early post-natal life suppresses the hexobarbital-metabolizing enzyme system in the liver. Hypophysectomy or irradiation of the head (but not of the body with the head shielded) has a similar effect in adult rats.

*Nair & Zeitlin G65,099/67:* The hexobarbital-metabolizing activity of the rat liver is extremely low after birth and rises gradually up to the age of 80 days to levels much higher in males than in females. Prenatal X-irradiation suppresses this normal development of enzyme activities in the male so that it only reaches the normal female level. Irradiation at 21 days (total body or head alone) also suppresses the developmental increase of enzyme activity, but to a lesser extent. Adults were still more resistant.

*Yam & DuBois G58,163/67:* In 23-day-old male rats, X-irradiation of the whole animal, or the head only, inhibited the rapid increase in hexobarbital-metabolizing hepatic microsomal oxidase normally obtained by hexobarbital treatment. Hypophysectomy produced the same result.

*Nair et al. G67,245/68:* X-irradiation of pregnant rats results in male offspring deficient in the hepatic microsomal enzymes which metabolize hexobarbital. However, irradiation did not suppress the increase of enzyme activity brought about by chemical inducers (pheno-

barbital). Actinomycin inhibited both the ontogenic and phenobarbital-induced increases in enzyme activity. "The ontogenic increase in enzyme activity is hormone-dependent, while that following phenobarbital administration is independent of hormonal regulation as evidenced by the response in hypophysectomized or sexually immature animals. It is concluded from these results that the inhibitory effect of x-irradiation on the hepatic enzyme system is mediated through an action on the hormonal regulation of enzyme activity."

*Nair et al. G67,304/68:* Comparative studies suggest that the induction of drug-metabolizing enzymes by phenobarbital in the rat can be inhibited by both X-irradiation and actinomycin, but through different mechanisms.

#### **Carcinogens** ←

*Terayama & Takata F69,475/66:* "Whole body irradiation of rats with Co<sup>60</sup>γ rays did not affect either the aminoazo dye N-demethylating activity or the hydroxylating activity of rat-liver. It also had no significant effect on the induction of the enzymatic activities by methylcholanthrene. The ionizing irradiation, however, appeared to increase the reduction of enzymatic activity following partial hepatectomy."

#### **Pesticides** ←

*Hietbrink & DuBois F65,296/66:* In weanling male rats, total body X-irradiation inhibits the development of the hepatic microsomal enzyme fraction that catalyzes the oxydative desulfuration of Guthion. Shielding of the liver and testes does not prevent this inhibition, whereas irradiation of the head area (while the remainder of the body is shielded) produces a degree of inhibition similar to that obtained by total body irradiation. "The same dose of irradiation did not inhibit the enzyme development in hypophysectomized weanling rats. Thus, the pituitary is necessary for the radiation effect, but involvement of the pituitary is not the result of a radiation-induced deficiency of pituitary hormones."

**Varia** ←

Studies on the effect of X-irradiation upon **microbial infection**, **endotoxin poisoning** and **hepatic regeneration** are not particularly instructive in connection with the hormonal regulation of resistance.

Among the **enzymic** changes induced by total body X-irradiation in the rat, a dose-dependent increase in TPO activity is noteworthy in that it occurs within a few hours, but only in the presence of the adrenals. The substrate induction of TPO is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated but later inhibited by X-irradiation.

**Microorganisms and Their Toxins** ←

*Cremer & Watson C37,986/57*: Deposition of endotoxin of *S. typhosa* was followed in normal and stressed rabbits by the fluorescein tagging technique. "Pretreatment with cortisone and x-irradiation did not affect initial phagocytosis of toxin but inhibited degradation and elimination of toxin by the RES."

*Vick F79,609/67*: X-irradiation prolongs the survival of dogs following subsequent endotoxin treatment.

*Highman et al. H19,382/69*: In rats exposed to X-irradiation or hypoxia, i.v. injection of *Streptococcus mitis* produces severe bacterial endocarditis. "The radioprotective compound, dimethyl sulfoxide (DMSO), did not affect the lesions in nonirradiated animals but reduced the incidence and severity of lesions in irradiated rats."

**Hepatic Lesions** ←

*Fabrikant H8,091/68*: In mice, X-irradiation interferes with hepatic regeneration after partial hepatectomy. A radiation free interval prior to partial hepatectomy improves the regenerative capacity of the liver.

*Zelioli-Lanzini H19,493/69*: In rats, small doses of X-rays as well as hepatic extracts improve liver regeneration following partial hepatectomy.

**Hepatic Enzymes** ←

**TPO, TKT** ←. *Thomson & Mikuta B90,975/54*: "Total-body x-irradiation produces within a few hours a dose-dependent increase in the tryptophan peroxidase-oxydase system of rat liver. The increase does not occur in adrenalectomized rats, and hence cannot be construed as a direct effect of X-irradiation." After hypophysectomy, enzyme induction became progressively less pronounced as adrenal

atrophy developed. ACTH restored the ability of the hypophysectomized rat to respond with enzyme induction.

*Benes & Zicha G67,159/69*: Exposure to 1400 R does not inhibit the TPO activity of rat liver. In fact, substrate induction of TPO is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated and then, inhibited by X-irradiation. X-irradiation before partial hepatectomy inhibits the increase in TPO normally observed 12 hrs after the operation. Similar results are obtained by actinomycin D applied 1 hr after partial hepatectomy. "The diminished synthesis of tryptophan oxygenase in irradiated regenerating rat liver tissue, as well as the decrease of hormonal induction after the irradiation can be explained by the inhibition of the specific messenger RNA's synthesis."

**Other Enzymes** ←. *Brin & McKee C31,261/56*: In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase glutamic-aspartic and glutamic-alanine transaminase activities in the liver. Adrenalectomy decreases the activity of these enzymes. The glutamic-alanine enzyme is more sensitive to stress than the glutamic-aspartic enzyme.

*Gresham & Pover G58,354/68*: In the rat, alkaline RNase levels increase in the mucosa of the small intestine after total body or selective head X-irradiation, as well as after treatment with such radiomimetic drugs as chlorambucil or busulfan but not after treatment with ACTH, cortisol or various stressors. Still, a relationship to the G.A.S. is suspected because blockade of the normal neuroendocrine responses to stress by combined treatment with morphine + pentobarbital blocked the intestinal RNase response to X-irradiation. The latter was also lacking in newborn rats in which hypothalamic control of anterior pituitary function has not yet developed.

## ← ULTRAVIOLET RAYS

In mice, daylight or ultraviolet irradiation increases acetonitrile resistance even after thyroidectomy; hence, this effect of the rays is not necessarily mediated through the thyroid.

*Paal 18,183/33*: In mice, exposure to light greatly influences sensitivity to acetonitrile. Even after thyroidectomy, daylight as well as ultraviolet irradiation increase the MLD of acetonitrile. Hence, resistance to this drug is

not always influenced through variations in thyroid activity.

*Ellinger 78,163/38*: In mice, ultraviolet irradiation increases resistance against acetonitrile, presumably through activation of the thyroid.

## ← HYPOXIA

In mice, reduced oxygen tension does not necessarily diminish and may even increase resistance to X-rays.

**Barbiturates** ←

*DeFeo et al. H 32,863/70*: "Mice under acute hypobaric conditions exhibited lower levels of pentobarbital in the body at the time of awakening than did control mice at room atmosphere. The fact that the hypoxic animals remain asleep at otherwise inadequate concentration of drug suggests enhanced sensitivity to barbiturates." The pentobarbital concentration of the body declined at a subnormal rate in mice exposed to hypobaric hypoxia. In isolated mice (1 per cage), the duration of hexobarbital, pentobarbital, barbital or chloral hydrate sleeping time was markedly reduced in comparison with controls kept in a more normal social environment (10 per cage). The magnitude of the reduction of sleeping time was greatest with hexobarbital, and least with barbital. Furthermore, "in vitro studies showed that the hepatic microsomal fractions isolated from socially deprived mice metabolized hexobarbital at a rate higher than the hepatic fractions isolated from control mice." In male mice, in which aggressive behavior develops following prolonged deprivation of social interaction (isolation), hexobarbital sleeping time was also reduced. In females which did not develop fighting behavior, the reduction in hexobarbital sleeping time was likewise evident which "would suggest that development of aggressive behavior during isolation has a different biological basis and is not related to the alteration in pharmacological activity."

*Medina & Merritt G 81,699/70*: In mice, the in vivo effect and hepatic metabolism of various barbiturates, zoxazolamine and other drugs are significantly altered by a reduced barometric

pressure, but the action of this stressor largely depends on the length of exposure.

**Bacteria** ← *cf. also Selye G 60,083/70, pp. 455, 456.*

*Highman et al. H 19,382/69*: In rats exposed to X-irradiation or hypoxia, i.v. injection of *Streptococcus mitis* produces severe bacterial endocarditis. "The radioprotective compound, dimethyl sulfoxide (DMSO), did not affect the lesions in nonirradiated animals but reduced the incidence and severity of lesions in irradiated rats."

**Ionizing Rays** ←

*Smith et al. B 48,252/48*: In mice, reduced oxygen tension did not adversely influence survival following X-irradiation.

*Limperos B 50,944/50*: In X-irradiated mice, "low oxygen atmosphere exerts a protective effect possibly because it decreases the concentration of OH and HO<sub>2</sub> radicals and of H<sub>2</sub>O<sub>2</sub>."

**Hepatic Enzymes** ←

*Kato & Gillette F 57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic

microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Agarwal & Berry G66,480/67*: Brief mention of unpublished experiments showing that mice

“exposed to hypoxic stress clearly establish that enzyme induction occurs in the absence of exogenous hormone, and hence from stress alone, and that this induction is also subject to inhibition by endotoxin.”

### ← TEMPERATURE VARIATIONS

Variations in atmospheric temperature may greatly influence **barbiturate** toxicity. Rats kept in the cold for several weeks show an increased hexobarbital sleeping time which does not correspond to an increased hexobarbital metabolism of the liver in vitro.

Lynestrenol reduced, whereas mestranol prolonged the duration of pentobarbital and hexobarbital anesthesia in mice. The effect of the luteoid was inhibited, whereas that of the folliculoid was increased when pentobarbital was prevented from inducing hypothermia.

During the acute phase of  $\text{CCl}_4$  intoxication, the induction of TKT and TPO activity in the livers of rats is diminished by the stress of exposure to cold and the associated decrease in corticosterone production. However, after chronic hepatic injury is induced by repeated doses of  $\text{CCl}_4$ , TKT and TPO induction by cold or exogenous corticosterone may be virtually normal.

In mice, exposure to the stress of cold decreases resistance to endotoxin, possibly because of an initial “depletion of corticoid reserves.” Cortisone protects even against the combined effect of endotoxin + cold. After one week of acclimatization to low temperatures, endotoxin resistance is increased, perhaps owing to the induction of excess TPO. In senescent mice, the induction of TKT by cold is delayed.

### Drugs ←

**Barbiturates** ←. *Richards 79,646/41*: The toxicity of thiopental to frogs is higher at 10 than at 20° C, but this does not hold true of paraldehyde.

*Blackham & Spencer G69,913/69*: Mestranol (a folliculoid) prolonged, while lynestrenol (a luteoid) reduced the duration of pentobarbital and hexobarbital sleep in mice. Barbiturates were not affected. The effects of lynestrenol were abolished by SKF 525-A, while those of mestranol were markedly potentiated. Lynestrenol increased, whereas mestranol and SKF 525-A reduced the rate of clearance of barbiturate from the plasma. The effect of lynestrenol disappeared and that of mestranol was increased when pentobarbital was prevented from inducing hypothermia.

*Hässler et al. H23,853/69*: Male rats are more resistant than females to the anesthetic effect of hexobarbital. In rats raised under extreme conditions of stress (cold or repeated periods of fasting) hexobarbital sleeping time is prolonged.

*Kalser & Kunig G65,211/69*: “Rats exposed to 5° for at least 3 days and for as long as 7 weeks sleep longer than their age-matched 25° controls when given hexobarbital. This increase in sleep time does not correspond with a diminished metabolism in vitro, since the rate of metabolism by the liver of the cold-exposed rats remains essentially constant for the entire 7 weeks.”

**Carbon Tetrachloride** ←. *Murphy & Malley G68,408/69*: Studies on hepatic TKT, alkaline phosphatase (AP), and tryptophan pyrrolase (TP) in relation to stress and  $\text{CCl}_4$ -intoxication in the rat. “Liver TKT elevation, but not AP elevation, was prevented by adrenalectomy prior to  $\text{CCl}_4$ . Experiments on rats subjected to simultaneous acute cold stress and  $\text{CCl}_4$  indicated that, during the acute phase of  $\text{CCl}_4$  hepatotoxicity, their livers had reduced capacity for induction of TKT and TP by endogenous corticosterone. However, chronically injured livers of rats given repeated doses of  $\text{CCl}_4$  were fully responsive to the TKT- and TP-inducing effects of exogenous corticosterone or acute cold stress.”

**Chloral Hydrate** ←. *Fastier et al. C37,038/57*: In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine, and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone and DOC did not prolong chloral hydrate sleeping time at the doses tested.

**Cholesterol** ←. *cf. Selye G60,083/70, p. 453.*

**Dinitrophenol** ←. *Haydu & Wolfson C77, 942/59*: In mice, the toxicity of DPN is increased by exposure to either cold or heat; the effect of temperature extremes is further aggravated by cortisone.

**Magnesium** ←. *cf. Selye G60,083/70, pp. 453, 455.*

**Tyrosine** ←. *Fuller G75,131/70*: In rats, exposure to cold, as well as treatment with cortisol or glucagon after adrenalectomy, induced TKT activity in the liver but not in the brain. Apparently, the TKT "of brain differed from the enzyme in liver since it did not exhibit diurnal variations of activity and was not affected by hormones, drugs, or stress."

**Varia** ←. *Keplinger et al. G70,208/59*: In rats, the acute i.p. toxicity of 58 drugs was compared at 8°, 26°, and 36° C. "Except for strychnine, chlorpromazine, and promazine, all compounds were most toxic at 36° C. Strychnine was equally toxic at 8° and 36° C, while promazine and chlorpromazine were most toxic at 8° C."

*Furner & Stitzel G54,558/68*: The hepatic microsomal metabolism of ethylmorphine, aniline, and hexobarbital is diminished in vitro by previous adrenalectomy in the rat. Phenobarbital pretreatment of adrenalectomized rats raised the metabolism of all three substrates above the level characteristic of otherwise untreated, adrenalectomized controls. Exposure of adrenalectomized rats to cold stress, or treatment with cortisol, increased the metabolism of aniline and ethylmorphine, but further depressed that of hexobarbital. In intact rats, cold stress diminished hexobarbital metabolism in vitro. Apparently, both stress and phenobarbital can bring about changes in hepatic drug metabolism independent of the presence of the adrenals, and the two agents act through different mechanisms, since phenobarbital invariably stimulates, whereas stress either increases or decreases microsomal enzyme activity, depending upon the drug pathway examined.

### **Bacterial Toxins** ←

*Previte & Berry E89,101/63*: In mice, exposure to the stress of cold decreases resistance to endotoxin, perhaps because of an initial "depletion of corticoid reserves." Cortisone protects even against the combined effect of endotoxin + cold.

*Berry F69,416/66*: When exposed to extremes of temperature, the resistance of mice to the lethal effect of endotoxin is greatly reduced. "It is believed that endotoxin sensitizes mice to heat and cold rather than these temperatures sensitizing to endotoxin. After 1 week of acclimatization at 5°C of 37°C, the LD<sub>50</sub> of endotoxin increased, respectively, to 790 µg and 260 µg. Inducibility of the liver enzyme tryptophan pyrrolase, believed to play a role in an animal's response to endotoxin, was evaluated at each environmental temperature. Only at the extremes was it suppressed."

### **Venoms** ←

*Stahnke F57,253/65*: In rats treated with various scorpion and snake venoms, resistance was decreased by pretreatment with heat, cold or epinephrine. In all three cases, the change in resistance is ascribed to stress as such.

*Cittadini et al. G76,028/70*: In X-irradiated mice, the formation of hemopoietic islets in the spleen is inhibited by dexamethasone, ACTH or the stress of exposure to cold.

**Immune Reactions** ← *cf. Selye G60,083/70, pp. 453, 455, 456.*

### **Hepatic Enzymes** ←

*Metzenberg et al. D86,024/61*: Thyroxine induces carbamyl phosphate synthetase in hepatic microsomes of the liver in tadpoles.

*Davis D92,322/63*: The decarboxylation of o-tyrosine and 5-hydroxytryptophan by livers of adrenalectomized rats, given water, was significantly lower than in controls. No significant effects on decarboxylation of these substrates were observed in adrenalectomized animals given NaCl, or in intact animals treated with DOC or exposed to cold. On the other hand, cortisone increased the inherent hepatic decarboxylating activity for both substrates, in normal as well as in pyridoxine-deficient rats.

*Finch et al. G71,208/69*: In senescent mice, the induction of hepatic TKT by exposure to cold is delayed in comparison with young mice. Corticosterone and insulin are equally effective in this respect in mice of both age groups.

*Klain & Hannon H13,174/69:* In rats, exposure to cold induces an increase in the hepatic glucose-6-phosphatase, fructose-1,6-diphosphatase, phosphoenolpyruvate carboxykinase and glutamic-pyruvic transaminase, presumably as a consequence of increased corticoid and thyroid hormone production.

*Dewaide G80,406/70:* Comparative studies on the effect of adaptation to cold or heat upon

hepatic drug oxidation in various species. Contrary to earlier claims, drug metabolizing enzymes do play a decisive role in the resistance of fishes to changes in their environment. "The effect of a change of ambient temperature on the liver of the hamster, rat, roach, and trout becomes manifest in an almost equal way for the different species."

### ← STRESSORS

The effect of stress on the action of various pathogens is of special importance in connection with our topic, since stress can influence resistance through its effect upon the secretion of hormones as well as through nonhormonal mechanisms. It can also both diminish susceptibility to disease through "cross-resistance" and increase it by the activation of various "conditioning" mechanisms.

### *Steroids* ←

The effect of stressors upon the biogenesis, metabolism and especially the hydroxylation of steroids by hepatic microsomes has been the subject of extensive studies. In connection with our topic, it is of special interest that the infarctoid cardiopathies produced by various corticoids + sodium salts are very regularly aggravated by diverse stressors, including even the noise made by a loud bell.

Rats pretreated with various stressors are particularly sensitive to progesterone anesthesia.

*Selye A36,210/41:* Rats pretreated with various stressors become particularly sensitive to progesterone anesthesia.

*Mäkinen et al. E20,847/63:* Conjoint treatment with cortisone + NaCl produces myocardial necroses in orchidectomized but not in normal male rats. Testosterone restores the resistance of the male castrates to normal, whereas concomitant exposure to the stress of a loud bell aggravates the cardiopathy.

*Kuntzman et al. G66,245/66:* Review (11 pp., 19 refs.) on factors influencing steroid hydroxylases in hepatic microsomes.

**Corticoids** ← cf. *Selye C50,810/58, pp. 88, 114—122, 143; C92,918/61, pp. 58, 75, 254; G60,083/70, pp. 446, 449, 452, 457, 459, 462.*

Corticosterone ← Stress (Cold): Maikkel et al. G41,515/66\*

Cortisol ← Stress (Tourniquet shock): Firschein et al. C30,553/57\*

### *Nonsteroidal Hormones and Hormone-Like Substances* ←

In rabbits, epinephrine arteriosclerosis can be prevented by concurrent exposure to electroshock. There is very little evidence to suggest that sublethal amounts of **catecholamines** can be detoxicated by catatoxic steroids that increase hepatic drug metabolism; acute epinephrine or norepinephrine poisoning is actually aggravated by the syntoxic glucocorticoids.

In rabbits, the organ changes produced by heavy **thiouracil** intoxication can be prevented by electroshock.

In rats, the stress of restraint tends to prevent **parathyroid hormone** overdosage.

In mice sensitized with pertussis vaccine, the increased sensitivity to **histamine** and **5-HT** is inhibited by various stressors. In rats, the renal necroses elicited by acute 5-HT intoxication are also inhibited by forced restraint. This protection occurs even after adrenalectomy and is not shared by cortisol, hence here the action of stress is presumably not mediated through glucocorticoid secretion.

**Epinephrine** ← cf. also Selye B40,000/50, p. 55; B58,650/51, pp. 322, 373; G60,083/70, pp. 446, 450, 457.

*Del'ini* B52,659/50: In rabbits, epinephrine arteriosclerosis can be prevented by concurrent exposure to electroshock.

Epinephrine ← Stress (Cold): Inscocoe et al. F70,325/66

**Hypophyseal Hormones** ← cf. Selye B40, 000/50, p. 616.

**STH** ← cf. also Selye G60,083/70, p. 457.

*Wakabayashi et al.* H27,784/70: In rats, exposure to stressors [kind not stated (H.S.)] or administration of dexamethasone suppresses plasma STH (radio-immunoassay) both in the presence and in the absence of the adrenals. Adrenalectomy increases plasma STH. [These findings support the view that during stress—perhaps owing to increased ACTH and/or glucocorticoid secretion, the “shift in pituitary hormone production” results in a diminished STH secretion (H.S.).]

**Thyroid Hormones** ← cf. also Selye C50, 810/53, p. 88; C92,918/61, p. 121.

*Baraldi* B52,651/50: In rabbits, the organ changes produced by heavy methylthiouracil intoxication can be prevented by electroshock.

**Parathyroid Hormone** ← cf. also Selye G60,083/70, pp. 446, 451.

*Tuchweber et al.* G46,759/68: Pretreatment with thyroxine or calcitonin inhibits the soft tissue calcification and osteitis fibrosa induced by parathyroid extract overdosage. In the event of concurrent administration, the effect of the two protective hormones is summated. Thyroxine retains its effect upon calcium metabolism in thyroparathyroidectomized or adrenalectomized but not in nephrectomized rats. The stress of restraint likewise prevents parathyroid overdosage, but the associated biochemical changes are different from those caused by thyroxine.

**Histamine, 5-HT** ← cf. also Selye B40, 000/50, p. 55.

*Munoz* E8,473/64: In mice sensitized with *B. pertussis*, the development of increased sensitivity to histamine or 5-HT is inhibited by various stressors.

*Selye et al.* E24,146/64: The renal necroses normally produced by acute intoxication with 5-HT, can be inhibited by forced restraint both in intact and in adrenalectomized rats. Cortisol has no such inhibitory effect; hence, the action of stress is not mediated through glucocorticoid secretion.

5-HT ← Stress (Cold): Inscocoe et al. F70,325/66

### Drugs ←

The effect of numerous drugs can be either increased or decreased by pretreatment or concurrent treatment with stressors. Such interactions are important in the pathogenesis of the so-called “pluricausal diseases,” in which stress plays a decisive but not an exclusive role.

In particular, stress can greatly alter the toxicity of **agar** (thrombohemorrhagic syndromes), **amphetamine**, **anaphylactoidogens** and **antibiotics**. In combination with several indirect **anticoagulants**, stress can elicit the “hemorrhagic syndrome of Jaques.”

The anesthetic effect of various **barbiturates** is prolonged in rats pretreated with various toxic organ extracts, casein or colchicine, presumably as a consequence of their stressor effect. A similar prolongation of barbiturate sleeping time has been noted following treatment with toxic drugs, electroshock, etc.

On the other hand, the sedative effect of hexobarbital and pentobarbital (unlike that of barbital) was diminished by tourniquet stress in intact but not in hypophysectomized or adrenalectomized rats. In intact rats, ACTH or cortisone decreases hexobarbital sleeping time, whereas SKF 525-A blocks the protective action of stress; hence, protection by stressors has been ascribed to the liberation of glucocorticoids. The blood levels of hexobarbital, pentobarbital and meprobamate (but not of phenobarbital) were diminished by tourniquet stress in intact but not in hypophysectomized or adrenalectomized rats. However, many of these experiments gave inconsistent results, presumably because stress has a dual action in general, inhibiting barbiturate anesthesia through the liberation of glucocorticoids but aggravating it perhaps through some extra-adrenal mechanism.

For the effect of stressors upon the toxicity of other drugs, consult the Abstract Section. However, in evaluating all these data, we must keep in mind that timing is particularly important here, since pretreatment or concurrent treatment with stressors may affect potential pathogens in opposite ways.

N-Acetyl-p-aminophenol ← Stress (Cold): Inscow et al. *F70,325/66*

N-Acetyltyramine ← Stress (Cold): Inscow et al. *F70,325/66*

*Agar* ← cf. *Selye E5,986/66, p. 150.*

#### **Aminopyrine** ←

*Nakanishi et al. G79,299/70:* "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

#### **Amphetamine** ←

*Clark et al. F92,621/67:* Crowding increases the toxicity of amphetamine in the mouse. "The administration of either dexamethasone, ethanol, glucose, 2-deoxy-d-glucose or diphenylhydantoin reduced the excitement, hyperactivity and mortality in aggregated mice given d-amphetamine. The reduction in mortality was proportional to the decrease in excitement and hyperactivity."

Amphetamine ← Stress, Mouse: Harding et al. *E26,072/63\**

#### **Aniline** ←

*Stitzel & Furner G48,920/67:* In rats, stress (cold) increases the rate of p-hydroxylation of aniline and N-dealkylation of ethylmorphine

simultaneously with an increase in adrenal ascorbic acid content. The stress-induced stimulation of microsomal metabolism and adrenal ascorbic acid levels are additive with those produced by phenobarbital. "It is tentatively concluded that stress and phenobarbital appear to act through different mechanisms in inducing increases in enzyme activity, although each treatment may have a common final step, namely an increased net synthesis of enzyme protein."

*Nakanishi et al. G79,299/70:* "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

*Antibiotics* ← cf. *Selye G60,083/70, pp. 460, 464, 465.*

#### **Anticoagulants** ←

*Jaques G70,979/68:* Review (30 pp., 13 refs.) on the "hemorrhagic stress syndrome" that is produced in various mammals treated with indirect anticoagulants (e.g., phenindione, dicoumarol) and then exposed to stress or treated with DOC, ACTH, or STH. Conversely, cortisone, epinephrine, ephedrine and adrenochrome inhibit this syndrome.

#### **Barbiturates** ←

*Masson B1,217/46:* In male rats, pretreatment for 6 days with crude pituitary powder

s.c. "slightly prolonged the duration of anesthesia with phanodorn, thioethamyl, neonal, delvinal, nostal and amyral, and greatly prolonged (2 to 5 times) with pentothal, seconal, allyl pental, nembital, evipal, pernoston and sigmodal." There was no difference between the pretreated and control rats as regards the anesthetic effect of phenobarbital, probarbital, barbital, aprobarbital, allobarbital and chloral. "The action of pituitary preparations is not specific but can also be obtained with preparations from various organs and with foreign proteins." Hepatic damage is considered to be a likely cause of the prolongation of anesthesia under these conditions.

*Masson 94,205/47*: Various tissue extracts (anterior pituitary, thymus, pancreas, liver, kidney, spleen, testis, brain) as well as casein s.c. decrease resistance to pentobarbital anesthesia in male rats. On the other hand, "among eight damaging agents given in doses sufficient to elicit an alarm reaction, only colchicine and atropine prolonged the duration of anesthesia, because of their high degree of toxicity." Yet, the prolongation of barbiturate anesthesia by pituitary extracts must be ascribed to a nonspecific stressor effect.

*Cook et al. D23,923/54*: A review of the literature shows that barbiturate anesthesia can be prolonged by alcohol, cholesterol, antihistaminics, histamine, certain nitrates, thiamine, ascorbic acid, cystine, disulfiram, glycerin and many other agents.

*Kato E87,340/60*: Mention of unpublished experiments which show "that, in rats pretreated with electroshock, the sleeping-time induced by barbiturates (48—72 h later) is much longer than in normal animals."

*Rupe et al. E26,910/63*: The sedative effect of hexobarbital and pentobarbital, but not of barbital, was diminished by tourniquet stress, in the intact but not in the hypophysectomized or adrenalectomized rat. In intact rats, ACTH or cortisone decreases hexobarbital sleeping time, the same as stress does, whereas SKF 525-A completely blocks the protective action of the latter. Presumably "the stress effect on the duration of drug action is mediated through increased drug metabolism."

*Driever & Bousquet G31,872/65; Driever et al. F73,812/66*: In rats with tourniquet stress, the blood levels of hexobarbital, pentobarbital and meprobamate, but not of phenobarbital, were diminished after injection of these drugs. These effects are prevented by hypophysectomy or adrenalectomy. Pentobarbital blood levels are lowered in adrenalectomized rats by

corticosterone, but not by ACTH, whereas in hypophysectomized rats, both these hormones are active. "The ability of stress situations to stimulate drug metabolism and its dependence upon an intact pituitary-adrenal axis is suggestive of a regulatory function of the endocrine system in mediating a rapid induction of liver microsomal enzymes responsible for drug metabolism." [An addendum states that the experiments could not be repeated in the summer (H.S.).]

*Wooles & Borzelleca F93,374/66*: Repeated administration of zymosan i.v. prolongs hexobarbital, pentobarbital, and barbital sleeping time in the mouse. This effect is ascribed to stimulation of the RES.

*Dairman & Balazs G78,636/70*: Individually caged rats tend to become aggressive; they show enlarged adrenals and thyroids, but atrophic spleens and thymus glands as compared with community-caged controls. This has been referred to as "isolation stress." Individually caged rats also exhibit diminished barbiturate sleeping times, possibly as a consequence of microsomal enzyme induction.

*DeFeo et al. H 32,863/70*: "Mice under acute hypobaric conditions exhibited lower levels of pentobarbital in the body at the time of awakening than did control mice at room atmosphere. The fact that the hypoxic animals remain asleep at otherwise inadequate concentration of drug suggests enhanced sensitivity to barbiturates." The pentobarbital concentration of the body declined at a subnormal rate in mice exposed to hypobaric hypoxia. In isolated mice (1 per cage), the duration of hexobarbital, pentobarbital, barbital or chloral hydrate sleeping time was markedly reduced in comparison with controls kept in a more normal social environment (10 per cage). The magnitude of the reduction of sleeping time was greatest with hexobarbital, and least with barbital. Furthermore, "in vitro studies showed that the hepatic microsomal fractions isolated from socially deprived mice metabolized hexobarbital at a rate higher than the hepatic fractions isolated from control mice." In male mice, in which aggressive behavior develops following prolonged deprivation of social interaction (isolation), hexobarbital sleeping time was also reduced. In females which did not develop fighting behavior, the reduction in hexobarbital sleeping time was likewise evident which "would suggest that development of aggressive behavior during isolation has a different biological basis and is not related to the alteration in pharmacological activity."

*Nakanishi et al. G79,299/70*: "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

*Sethy et al. G77,511/70*: In rats, pentobarbital sleeping time is reduced immediately after stress (centrifugation), but returns to normal eight hours later. In adrenalectomized animals, this effect of stress is abolished.

*Weiner et al. H24,942/70*: In rats, glucagon, alloxan and starvation all increased hexobarbital sleeping time. This effect was markedly antagonized by insulin. Perhaps, cyclic AMP may be involved since theophylline greatly increases the action of glucagon. This synergism also occurred in isolated, perfused rat livers and, hence, "inhibition of hexobarbital metabolism by cyclic AMP would appear to be mediated in the liver."

**Barbiturates** ← Stress: Rupe et al. E26,910/63\*; Bosquet et al. F35,073/65\*; Driever et al. G31,872/65\*, F73,812/66\*

#### **Brombenzene** ←

*Schultz B18,183/46*: In rabbits, the detoxication of brombenzene as mercapturic acid is enhanced by the presence of a sterile abscess. Presumably, "a specific metabolic reaction can utilize the tissue breakdown products resulting from the formation of a sterile abscess."

#### **Bromides** ←

*Prioreschi C68,485/59*: In the rat, exposure to stress intensifies NaBr anesthesia.

**Calcium** ← cf. *Selye G60,083/70*, pp. 446, 452, 453.

#### **Carbon Tetrachloride** ←

*Calvert & Brody C82,653/60*: "A hypothesis is proposed which states that the characteristic hepatic changes seen after the administration of carbon tetrachloride are the result of stimulation of central sympathetic areas which produce a massive discharge of the peripheral sympathetic nervous system." This hypothesis is based mainly upon the observation that in rats, adrenergic blocking agents, reserpine, adrenalectomy, and section of the spinal cord

are all effective in preventing the changes characteristic of CCl<sub>4</sub> intoxication. [The possibility that the protection might be due to stress or the associated hypothermia has not been considered. (H.S.).]

#### **Carcinogens** ←

*Wheatley et al. F68,548/66*: Partial hepatectomy protects the adrenals of the rat against the hemorrhagic necrosis produced by DMBA. On the other hand, "operative stress," as in sham-hepatectomy or nephrectomy, actually increases the susceptibility of the adrenals to DMBA. Other factors influencing DMBA-induced adrenal necrosis are reviewed.

*Somogyi G70,416/70*: In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, SC-1, and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocorticolytic effect of 7-OHM-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovács G70,482/70*: In rats, the stress of restraint or of forced muscular exercise significantly increases the adrenocorticolytic effect of DMBA. Spironolactone can abolish this stress-induced aggravation. The mammary carcinogenicity of DMBA is not influenced by stress.

**Carrageenin** ← cf. *Selye E5,986/66*, p. 150.

#### **Chloral Hydrate** ←

*DeFeo et al. H32,863/70*: "Mice under acute hypobaric conditions exhibited lower levels of pentobarbital in the body at the time of awakening than did control mice at room atmosphere. The fact that the hypoxic animals remain asleep at otherwise inadequate concentration of drug suggests enhanced sensitivity to barbiturates." The pentobarbital concentration of the body declined at a subnormal rate in mice exposed to hypobaric hypoxia. In isolated mice (1 per cage), the duration of hexobarbital,

Fig. 29. Aggravation by stress of DMBA-induced adrenocortical necrosis. Adrenals of rat given threshold amounts of DMBA. A: Without exposure to stress, this amount of the carcinogen causes no obvious adrenal change. B: Following exposure to stress of restraint increases sensitivity to the carcinogen and results in severe adrenocortical necrosis and hemorrhage. [Courtesy of Somogyi & Kovacs.]

pentobarbital, barbital or chloral hydrate sleeping time was markedly reduced in comparison with controls kept in a more normal social environment (10 per cage). The reduction of sleeping time was greatest with hexobarbital, and least with barbital. Furthermore, "in vitro studies showed that the hepatic microsomal fractions isolated from socially deprived mice metabolized hexobarbital at a rate higher than the hepatic fractions isolated from control mice." In male mice, in which aggressive behavior develops following prolonged deprivation of social interaction (isolation), hexobarbital sleeping time was also reduced. In females which did not develop fighting behavior, the reduction in hexobarbital sleeping time was likewise evident which "would suggest that development of aggressive behavior during isolation has a different biological basis and is not related to the alteration in pharmacological activity."

#### **Ethanol** ←

*Fazekas & Rengei G58,271/68:* In rats, not pretreated with ethanol, the alcohol-dehydrogenase (ADH) activity of the liver, heart, and kidneys is diminished by adrenalectomy. Upon s.c. administration of ethanol, the ADH-activity of the liver increases both in intact and in adrenalectomized rats. The authors speculate that ADH-activity may result not only in the microsomes but also in other cellular fraction, and that part of the enzyme induction may be due to the stressor effect of ethanol.

**Formaldehyde** ← cf. *Selye B40,000/50, p. 387; B58,650/51, p. 248.*

#### **Ganglioplegics** ←

*Selye G70,448/70:* In rats, intoxication with TEA, hexamethonium and pentolinium could be prevented by all of the seven glucocorticoids tested. On the other hand, glucocorticoids offered no protection against trimethaphan, mecamlamine, trimethidinium or pempidine. Typical catatoxic steroids (ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone) as well as progesterone, DOC, and hydroxydione failed to offer significant protection against hexamethonium or TEA. Various stressors (bone fractures, fasting, spinal cord transection and formalin) gave excellent protection against TEA, whereas others (restraint, cold) did not. "Since even large doses of ACTH are ineffective in this respect the anti-TEA effect of stressors cannot be ascribed merely to increased corticoid secretion."

**Indomethacin** ←

*Selye PROT. 22977,22161*: In rats (100 g ♀) various severe stressors (restraint, spinal cord transection, intestinal traumas, bone fractures, formalin injections) did not significantly modify the development of perforating intestinal ulcers.

**Parasites** ←

*Noble G81,736/71:* In hamsters, various stressors as well as glucocorticoids aggravate infection with *Leishmania braziliensis*.

**Varia** ←

Innumerable publications deal with the effect of stressors upon **microbial infections** and the stressor effect of the infections themselves.

Rats, in which tolerance to **bacterial endotoxins** is induced by repeated daily injections, become highly resistant also to traumatic and hemorrhagic shock, but rats adapted to traumatic shock do not develop any significant degree of endotoxin tolerance. In general, exposure to stress increases mortality from endotoxin shock in various species of animals.

In rats, resistance to the **venoms** of scorpions and snakes is decreased by pretreatment with various stressors (heat, cold, epinephrine.)

It has been claimed that in mice, moderate sensitivity to various stressors is associated with the highest **X-ray** tolerance, whereas individuals especially sensitive or insensitive to stress have a low X-ray tolerance. In rats, repeated exhaustive muscular exercise after X-irradiation increases the ensuing mortality.

For the extensive literature on the effect of stressors upon the response to subsequent exposure to the same or other **stressors** (that is "nonspecific cross-resistance"), the reader must be referred to our earlier monographs quoted in the Abstract Section.

Among the first studies on the mechanism through which stress-induced hormone secretion could affect resistance are those dealing with **defensive enzyme** induction. Tryptophan induces hepatic **TPO** both in intact and in adrenalectomized rats, but various stressors which are equally effective in intact animals are ineffective in the absence of the adrenals. These findings called attention to the fact that in addition to substrate-induced hepatic enzyme activity, there is a second corticoid-mediated response which produces essentially the same results and is presumably responsible for much of the stress-induced nonspecific resistance. In agreement with this interpretation, hypophysectomy also prevents stress-induced TPO induction in rat liver. In intact rats, an i.p. injection of diatomaceous earth acts as a strong stressor and increases hepatic **TKT** activity. This effect is abolished by adrenalectomy, whereas cortisol is a good inducer of TKT both in intact and in adrenalectomized rats. In the latter, the effect of small doses of cortisol is potentiated by a simultaneous administration of either tyrosine or diatomaceous earth. Presumably, the glucocorticoid not only induces TKT but also acts as a conditioning agent for TKT activation both by its substrate and by nonspecific stress. The induction of TPO is regulated essentially in the same manner.

There is some evidence that at least certain stressors (reciprocating shaker) can stimulate corticoid secretion without any change in hepatic TKT or TPO activity. This was ascribed to the activation of mechanisms which specifically inhibit the induction of enzymes by glucocorticoids. However, the possibility must also be considered that certain types of stressors do not produce a sufficient quantity of

glucocorticoids for effective enzyme induction. Extensive investigations have shown that cortisol enhances enzyme synthesis following an increased rate of synthesis of ribosomal transfer and "DNA-like" RNA. A repressor can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis prolongs corticoid-induced increases in enzyme synthesis.

Addition of cortisol to the blood perfused through a normal rat liver *in vitro* induces TPO, whereas this is not the case with livers of rats bearing large Walker tumors. The inhibition of induction is ascribed to a "toxohormone" which arises in the tumor tissue. This finding again suggests that stress may be associated not only with enzyme-inducing but also with induction-inhibiting mechanisms.

During the first days of life, rats exposed to the stress of a noisy reciprocating shaker respond with a large increase in TPO and TKT, whereas adult rats do not exhibit this change. Presumably, an induction-opposing mechanism is more developed in the adult than in the infant rat. In stressed adrenalectomized adults, TKT activity decreased markedly, whereas this was not the case in adrenalectomized immature rats. Hypophysectomy essentially abolished the inhibition in adults.

There is some evidence that STH may play a role in the repression of TKT induction by stressors. In any event, STH inhibits the synthesis of hepatic TKT in intact, hypophysectomized or adrenalectomized rats. Stress (reciprocating shaker) had no effect on hepatic TKT of intact rats, but increased TPO activity, although both these enzymes are corticoid inducible. Similarly stressed adrenalectomized rats exhibited a decreased TKT activity with no change in TPO. This inhibition was abolished by hypophysectomy. STH inhibited induction of TKT by cortisol, but had no effect upon cortisol-induced TPO activity.

The claim that the stress of forced muscular work, immobilization or cold can increase hepatic TPO activity even in adrenalectomized (though not in hypophysectomized) rats, requires confirmation.

Extensive studies on rats and rabbits exposed to various types of stress suggest that **lysosomal hydrolases** are released from the liver and intestine under the influence of various stressors and that this process may play a decisive role in the development of irreversible shock. The increase in lysosomal stability produced by glucocorticoids may constitute an important defensive response.

For the effect of stress upon **GOT, GPT, DNA- and RNA-polymerase** and other enzyme activities influenced by stress *cf.* the Abstract Section.

Zweifach & Thomas D91,826/57:* "Rats in which tolerance to bacterial endotoxin is induced, by repeated doses given daily, become highly resistant to the lethal effects of both drum trauma and hemorrhagic shock. However, rats in which the adaptation to traumatic shock is produced by repeated exposure to drum trauma, do not develop a significant degree of tolerance to lethal doses of endotoxin."

*Renaud C77,620/63*: Review of the literature showing that exposure to stress greatly increases mortality in rats, rabbits and guinea pigs given *E. coli* endotoxin.

**Venoms** ←. *Stahnke F57,253/65*: In rats treated with various scorpion and snake venoms, resistance was decreased by pretreatment with heat, cold or epinephrine. In all three cases, the change in resistance is ascribed to stress as such.

**Immune Reactions** ← *cf. Selye B40,000/50, p. 752*.

**Ionizing Rays** ← *cf. also Selye B87,000/52, p. 58; B90,100/53, p. 83; C1,001/54, p. 293*.

*Kimeldorf et al. B49,240/50*: In rats, repeated exhaustive muscular exercise (swimming) after X-irradiation increases the resulting mortality.

*Vácha & Pospíšil H17,170/69*: In mice, moderate sensitivity to various stressors is associated with the highest X-ray tolerance. Individuals exhibiting a specially mild or severe stress reaction are comparatively intolerant to X-irradiation.

#### **Hypoxia and Hyperoxygenation** ←

*Campbell A14,903/37*: In rats exposed to six atmospheres of oxygen in a pressure chamber, subsequent decompression is better tolerated at low than at high external temperatures. "Using an external temperature of 24° C and white rats of about 80 g, the following substances, administered subcutaneously, are found to enhance oxygen poisoning: thyroxin (0.4 mg), dinitrophenol (1.5 mg), ac-tetrahydro-β-naphthylamine (0.5 c.c., 1 p.c.), adrenaline (0.02 mg), pituitary extract (posterior lobe, above 3.5 units), insulin (0.025 u.) and eserine (0.045 mg administered with atropine 0.075 mg). These doses in themselves are harmless."

*Berry et al. H2,124/68*: Studies on the influence of hypoxia, glucocorticoids and endotoxin on hepatic enzyme induction and survival in mice. "Endotoxin inhibited the induction of tryptophan oxygenase, prevented the increase in liver glycogen, induced the transaminase, and increased the lethality of simulated altitude. Cortisone increased survival at all altitudes except the highest. These observations emphasize the importance of these metabolic adjustments for the survival of animals subjected to hypoxic stress."

#### **Hepatic Lesions** ← *cf. also "Hepatic Lesions" as Agents*

*Bucher et al. G72,546/69*: Review of the humoral factors responsible for hepatic re-

generation following partial hepatectomy. Hepatic DNA synthesis is stimulated in intact rats by parabiosis or cross-circulation with partially hepatectomized partners. Furthermore, tiny liver grafts implanted outside the portal area proliferate in response to partial ablation of the parent organ. Various stressors inhibit hepatic regeneration in partially hepatectomized rats, but this effect is not reproduced by ATCH or cortisol. On the other hand, adrenalectomy increases hepatic regeneration.

*Moolten et al. H30,606/70*: In rats, the rise in hepatic DNA synthesis after partial hepatectomy is accelerated by surgical interventions or STH. Cortisone, cortisol and ACTH were ineffective. Neither stress nor STH stimulated DNA synthesis significantly in nonhepatectomized rats.

#### **Hepatic Enzymes** ←

**TPO, TKT** ←. *Knox B71,418/51*: Tryptophan induces hepatic TPO both in intact and in adrenalectomized animals. Various other compounds (including epinephrine and histamine) which, to a lesser extent, have the same effect in intact animals, fail to act after adrenalectomy. "The first mechanism has been identified as that of enzyme adaptation, previously known only in micro-organism, and the second has been identified as the stress reaction, acting through the adrenal glands."

*Wood et al. C27,721/56*: In mice, bearing sarcoma implants, the hepatic TPO activity was first diminished, but rose above normal as the neoplasms grew. "Changes analogous to this biphasic depression and elevation of the enzyme level in tumor-bearing animals could be produced in control mice by growth hormone and by adrenal-stimulating stress, respectively."

*Lin & Knox C73,824/58*: In rats, the hepatic TKT activity increased after treatment with cortisone, cortisol, or corticosterone, and L-tyrosine. This effect was observed also following adrenalectomy. On the other hand, a comparable effect of other amino acids was probably due to stress. "That a nonspecific stress-producing agent could actually increase the level of tyrosine-α-ketoglutarate transaminase was further supported by the results obtained with a compound which is unrelated to tyrosine metabolism. Injections of propylene glycol in doses of 0.5 ml per 100 gm of body weight caused the level of this enzyme to increase to an average of 1390 units in three

intact rats." Adrenalectomized rats did not support this dose of propylene glycol.

*Knox G67,799/58*: Review of the literature and personal observations lead to the conclusion that hepatic microsomal TPO activity plays an important role in metabolic adaptation to stress. Stressors act through the pituitary and adrenal axis upon hepatic TPO, whereas tryptophan, STH and cortisol may act upon the liver directly.

*Maickel & Brodie C83,071/60*: TPO in rat liver is increased by ACTH, cortisone, or cortisol, as well as by various stressor agents and barbiturates. Hypophysectomy prevents the effect of stressors and of barbiturates, suggesting that the latter act through the pituitary-adrenal system.

*Kenney & Flora D12,237/61*: Tryptophan and i.p. injections of diatomaceous earth (Celite) were as effective as tyrosine in inducing increases in hepatic TKT in intact, but not in adrenalectomized rats. Cortisol was an effective inducer at low doses in both intact and adrenalectomized animals. In the latter, the effect of a small dose of cortisol was potentiated by simultaneous administration of tyrosine, methionine or diatomaceous earth. "It is concluded that induction of tyrosine transaminase is entirely mediated by adrenal hormone." In not adrenalectomized rats, diatomaceous earth i.p. is believed to act as a stressor through adrenocortical stimulation.

*Knox G51,969/62*: Review on the effect of stress upon hepatic TPO production. In adrenalectomized animals, only tryptophan of a series of analogues induces this enzyme, whereas, in intact rats, various stressors, ACTH, cortisone, cortisol and corticosterone (but not DOC) do so. "The recognition of the adrenal hormone-induced adaptation of the tryptophan pyrrolase has provided the unified explanation for a large number of different stressful stimuli which increase the enzyme level."

*Geller et al. G22,722/64*: In rats, hepatic TPO and TKT activities are increased 3.5 hrs after i.p. injection of cortisol, but no such activation was seen after stress (animals placed in a mechanical shaker) which causes an increase in adrenal and plasma glucocorticoids, as well as a depletion of adrenal ascorbic acid. Possibly, the amount of glucocorticoid secreted was not equivalent to that injected.

*Schapiro et al. G21,848/64*: In the rat, cortisol greatly increases hepatic TPO, TKT and tryptophan transaminase activity, whereas stress (reciprocating shaker) stimulates corti-

cid secretion without any change in hepatic transaminase or pyrrolase activity. Apparently, stress activates not only the adrenal cortex, but also the mechanisms which block the induction of these enzymes by corticoids, because shaker stress inhibited the elevation of hepatic transaminase that occurred following cortisol, although it did not block the elevation of tryptophan pyrrolase in the rat.

*Kenney & Albritton G64,557/65*: Review of the literature suggesting that transaminase induction in response to stressors can be due to corticoid secretion during the stress reaction. Cortisol enhances enzyme synthesis following an increased rate of synthesis of ribosomal transfer and "DNA-like" RNAs. The present experiments confirm the view that repressor(s) can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis can prolong the corticoid-induced increase in enzyme synthesis under suitable conditions. "Administration of stressing agents (tyrosine, Celite) to adrenalectomized rats initiates a highly selective repression of the synthesis of hepatic tyrosine- $\alpha$ -ketoglutarate transaminase. The enzyme level falls with a  $t^{1/2}$  of about 2.5 hr. Immunochemical measurement of the rate of enzyme synthesis indicates that it is reduced essentially to zero in stressed, adrenalectomized rats, whereas labeling of total liver soluble proteins is unaffected. Actinomycin does not itself influence the enzyme level, but it blocks the stress-initiated repression of enzyme synthesis, indicating that repression acts at the translational level, whereas initiation of repression involves transcriptional processes." In hypophysectomized rats stressors are ineffective and preliminary data suggest that STH is responsible for transaminase repression.

*Nomura et al. G33,405/65*: Various forms of stress (forced exercise, immobilization, cold), as well as the administration of chlorpromazine, increased the TPO activity of the liver in both intact and adrenalectomized, but not in hypophysectomized, rats.

*Shiba et al. G31,114/65*: The addition of cortisol to the blood perfused through a normal rat liver in vitro induced hepatic TPO, whereas this was not the case with livers of rats bearing large Walker tumors. The inhibitory effect upon enzyme induction is ascribed to "toxohormone" (an extract of Walker tumors), since addition of a toxohormone preparation to the perfusion fluid also prevented enzyme induction by cortisol.

*Schapiro et al. F65,746/65-66*: "Infant rats, four and eight days after birth, respond to

the stress of 30 minutes on a noisy reciprocating shaker with a large increase in liver aromatic amino acid transaminase activities. Adult rats exposed to the same stress do not exhibit this change. In the adult rat the inducing effects of cortisol on transaminase activities are blocked by this stress. These results suggest the activation of a mechanism(s) in the adult rat which opposes the enzyme inducing effects of cortisol."

*Schapiro et al. F67,227/66:* Hepatic TKT-activity increased in immature, stressed (reciprocating shaker) rats, but not in intact stressed adults. In the stressed adrenalectomized adults, TKT activity markedly decreased, while adrenalectomized immature rats showed no change. Hypophysectomy largely abolished inhibition in the adults. TPO activity, when present, was increased by stress in old-age groups, but the increase was abolished by adrenalectomy and hypophysectomy. "The results suggest stress-activation of a pituitary mechanism that inhibits or represses activation of tyrosine transaminase and that may not function during early postnatal life."

*Agarwal & Berry G66,479/66:* In the mouse, stress produced by i.p. injection of celite or bentonite causes no significant change in hepatic TPO activity at the time when sensitization to endotoxin is already developed. The inducibility of TPO is delayed by injections of cortisone at a time when the hormone protects against endotoxin. Still, the results are considered to be "in agreement with the concept that maintenance of liver (TPO) is necessary for continued survival of endotoxin poisoned mice. The absence of change in this enzyme seen in celite- and bentonite-injected mice sensitized to endotoxin is an apparent exception." Presumably, "suppression of TP-activity is not the only way in which mice may be sensitized to endotoxin."

*Kenney G50,810/67:* In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The rate of enzyme synthesis is reduced nearly to 0 (immunochemical-isotopic analyses), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actinomycin. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized) animals. Trans-

aminase levels were unchanged in a single experiment, where the stressing agent was administered to the hypophysectomized partner.

*Schapiro H2,360/68:* Stress (30 min rough agitation in a noisy laboratory shaker) had no effect upon the corticoid sensitive enzyme TKT in the liver of the intact rat, but it increased TPO activity, which is likewise corticoid inducible. Adrenalectomized rats similarly stressed exhibited a decreased TKT activity with no change in TPO. This inhibitory effect was abolished by hypophysectomy. STH inhibited induction of TKT by cortisol but had no effect upon cortisol-induced TPO activity. The opposing actions of STH and glucocorticoids may be involved in adaptive reactions to stress.

*Finch et al. G71,207/69:* In mice, various stressors (cold, shaking) cause a rapid and transient increase in hepatic TKT activity during fasting. Recent feeding or adrenalectomy inhibits TKT induction by cold.

*Geller et al. H8,414/69:* The stress of laparotomy increases hepatic TKT activity in intact, but not in the adrenalectomized rat, which actually responds in an inverse manner. Hypophysectomy eliminates some, but not all of this laparotomy-induced repression. Under these conditions, the TPO- and the TKT-responses are somewhat different.

*Schapiro et al. H12,411/69:* Brief abstract stating (without giving experimental details) that "the severe stress of laparotomy in the intact adult rat induces a large corticoid-dependent increase in transaminase activity. STH administered simultaneously, or one hour before laparotomy will completely inhibit this enzyme increase. During the early postnatal period, however, STH will not block transaminase induction caused by cortisol or laparotomy."

**Lysosomal Hydrolases** ←. *Janoff et al. D35,553/62:* Studies on the hepatic lysosomal enzymes of rats and rabbits after traumatic or endotoxin shock, adrenalectomy, or treatment with cortisone suggested that "a) disruption of lysosomes and release of their contained enzymes in free, active form may occur in liver and intestine of shocked animals. b) The activation of lysosomal hydrolases within cells and their release into the circulation may play an important role in exacerbating tissue injury and accelerating the development of irreversibility during shock. c) The increased stability of lysosomes of tolerant and of cortisone-treated animals may constitute an impor-

tant component of the resistance of these animals to shock."

**GOT, GPT** ←. *Brin & McKee C31,261/56*: In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase GOT and GPT activities in the liver. Adrenalectomy decreases the activity of these enzymes. The glutamic-alanine enzyme is more sensitive to stress than the glutamic-aspartic enzyme.

*Hänninen & Hartiala F76,119/67*: In the rat, the stress of restraint causes within 12 hrs a linear increase in hepatic GOT to 4 times the initial level. This effect was partially inhibited by actinomycin D and totally by adrenalectomy.

**DNA-, RNA-Polymerase** ←. *Gresham & Pover G58,354/68*: In the rat, alkaline RNase levels increase in the mucosa of the small intestine after total body or selective head X-irradiation, as well as after treatment with such radiomimetic drugs as chlorambucil or busulfan but not after treatment with ACTH, cortisol or various stressors. Still, a relationship to the G.A.S. is suspected because blockade of the normal neuroendocrine responses to stress by combined treatment with morphine + pentobarbital blocked the intestinal RNase response to X-irradiation, and the latter was also lacking in newborn rats in which hypothalamic control of anterior pituitary function has not yet developed.

*Šimek et al. H13,837/68*: Comparative studies on DNA synthesis, fatty acid content, and weight regeneration in the liver remnant of partially hepatectomized rats after treatment with cortisol, ACTH and various stressor agents.

**Trypsin** ← *cf. Selye C92,918/61, p. 106.*

**Other Enzymes** ←. *Remmer C73,857/58*: Drug-metabolizing enzyme formation in hepatic microsomes of adrenalectomized rats is inhibited unless the rats receive glucocorticoid treatment. The decreased general resistance of adrenalectomized animals may depend upon an interference with defensive enzyme formation.

*Terayama & Takata F69,475/66*: The N-demethylating activity of rat liver is considerably reduced during regeneration after partial hepatectomy but, for a much shorter period, also after sham-operations.

*Morton & Chatfield G73,681/70*: In rats with adjuvant arthritis, "the liver microsomal N-demethylase and NADPH<sub>2</sub>-oxidase enzyme activity and levels of cytochrome P-450 are greatly reduced. This implies a reduced capacity for the oxidative metabolism of steroids and foreign compounds in adjuvant arthritic rats which should influence the toxicity and half-life of any administered compound. The ability of the liver to form  $\beta$ -glucuronide conjugates is also reduced."

#### ← VARIA

Here, we shall briefly discuss the effect upon resistance and particularly upon hepatic detoxication, of a few additional agents which are only indirectly, related to hormonal mechanisms, if at all.

#### ← **Parabiosis**

The factors regulating the intense mitotic proliferation induced by **partial hepatectomy** in the regenerating liver remnant have aroused the interest of many investigators. If two rats are joined in parabiosis, one being partially hepatectomized, mitotic proliferation is stimulated to some extent even in the intact partner. It was concluded that some blood-borne humoral factor is involved in this type of growth stimulation. Although this claim has been contradicted, negative data have been ascribed to the inadequate establishment of a cross-circulation, especially since even tiny liver grafts implanted outside of the portal area proliferate in response to partial ablation of the parent organ.

In another experiment, a hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed, hepatic TKT induction was repressed in both partners. Since repression can also be obtained by STH, this hormone was held responsible for the stress-induced repression.

### ← *Diurnal Variations*

In rats, the incorporation of radioactive acetate into **cholesterol** reaches a maximum at about midnight, and a minimum at about noon.

Hepatic **hexobarbital oxidase** induction is likewise subject to a light-dependent circadian rhythm. **TKT** activity in rat liver undergoes also considerable diurnal change.

### ← *Nervous Lesions*

In rats, the anesthetic effect of progesterone is prevented by pretreatment with atropine, and intensified by vagotomy, but it remains to be seen whether these actions are specific.

### ← *Tumors*

In young rats transplants of a pituitary mammotrophic tumor did not prevent the induction by phenobarbital of hepatic microsomal **hexobarbital-** and **aminopyrine-metabolizing enzymes**. However, the normal development of these enzyme systems was inhibited, presumably by the STH, ACTH, LTH or other hormones secreted by the hypophysial neoplasms.

Tumor transplants and tumor extracts have also been shown to affect microsomal **steroidases** in the rat liver.

In mice, small subcutaneous sarcoma implants depress the hepatic **TPO** activity, whereas large tumors have an opposite effect. In intact (unlike in adrenalectomized, ascites-tumor-bearing) mice, hepatic **TKT** activity is elevated.

The growth of Walker tumors and transplantable hepatomas, unlike that of Jensen sarcomas and Murphy lymphosarcomas, is increased by **partial hepatectomy** in the rat. It has been postulated that the regenerating liver may release humoral agents which stimulate the growth of some neoplasms. Conversely, both in rats and in mice, hepatic regeneration was enhanced by the presence of growing tumor tissue irrespective of whether the latter was affected by partial hepatectomy.

### ← *Parabiosis*

*Christensen & Jacobsen A 49,204/49; Bucher et al. D 42,066/51:* In rats, the mitotic rate in the liver remnant reaches a maximum 48 hrs after partial hepatectomy. If two rats are united by parabiosis, one being partially hepatectomized, some increase in mitotic proliferation occurs also in the nonhepatectomized partner, suggesting the formation of cell division stimulating substances.

*Bielschowsky & Hall G 71,797/51:* In intact female rats joined in parabiosis with gonadectomized litter-mates, AAF induced a 50% incidence of malignant tumors, mostly of the granulosa. The gonadectomized partners were free of neoplastic lesions.

*Bucher G 68,621/63 (p. 281):* Review of the conflicting data on the stimulation of hepatic regeneration in the intact partner of a pair

of parabiotic rats in which the other partner is partially hepatectomized. Apparent contradictions may be due to differences in the efficiency of the cross-circulation.

*Kenney G 50,810/67:* In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The rate of enzyme synthesis is reduced nearly to 0 (immunochemical-isotopic analysis), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actinomycin. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized)

animals. TKT levels were unchanged in a single experiment where the stressing agent was administered to the hypophysectomized partner.

*Bucher et al. G72,546/69:* Review of the humoral factors responsible for hepatic regeneration following partial hepatectomy. Hepatic DNA synthesis is stimulated in intact rats by parabiosis or cross-circulation with partially hepatectomized partners. Furthermore, tiny liver grafts implanted outside the portal area, proliferate in response to partial ablation of the parent organ. Various stressors inhibit hepatic regeneration in partially hepatectomized rats, but this effect is not reproduced by ACTH or cortisol. On the other hand, adrenalectomy increases hepatic regeneration.

#### ← Diurnal Variations

**Barbiturates** ←. *Roberts et al. H31,840/70:* In rats, the degradation of marked barbiturates by hepatic microsomal enzymes in vitro reached a maximum at 8.00 A.M. and a minimum at 8.00 P.M. The diurnal rhythm in vivo was much less pronounced. "A variation in the sensitivity of the central nervous system to barbiturate has also been observed, rats being least sensitive at a time when they were normally highly active." The literature on diurnal variations in drug metabolism is briefly reviewed.

**Cholesterol** ←. *Hamprecht G69,560/69:* In rats, the incorporation of radioactive acetate into cholesterol is subject to pronounced diurnal variations with a minimum at about noon, and a maximum at midnight.

**Hepatic Enzymes** ←. *Nair et al. G67,250/69:* Hepatic hexobarbital oxidase induction is inhibited by head X-irradiation, hypophysectomy or bilateral electrolytic lesions in the posterior hypothalamus. The in vitro data were verified by measurements of the hexobarbital sleeping time. "It is suggested that the microsomal enzyme system metabolizing hexobarbital is normally under the regulatory control of hypothalamo-hypophyseal hormonal activity. The light dependent circadian rhythm for this enzyme, recently reported by us, is also consistent with this interpretation."

*Civen et al. H12,169/69:* TKT activity in rat liver undergoes a 4-fold diurnal change, which is independent of steroid secretion, although the enzyme is inducible by glucocorticoids.

#### ← Nervous Lesions

*Selye A35,659/41:* "In rats, pretreatment with atropin prevents, while vagotomy actually intensifies the anesthetic action of progesterone."

#### ← Tumors (in Animals) cf. also Carcinogens under Drugs

*Wilson G63,125/68:* In young rats, transplants of a pituitary mammatrophic tumor "did not prevent an increase in the liver microsomal metabolism of hexobarbital or the formation of formaldehyde from aminopyrine which followed phenobarbital pretreatment. High levels of somatotropin, corticotropin, and prolactin in blood, or possibly some other unknown factors produced by this tumor, appeared to prevent the normal development of the liver enzyme system which metabolized hexobarbital, aminopyrine, and p-nitrobenzoic acid in the rat."

*Wood Jr. & Knox D81,779/54:* In mice bearing small subcutaneous sarcoma implants, the hepatic TPO activity was depressed, whereas animals with large tumor transplants showed a marked increase in the activity of this enzyme.

*Paschkis et al. C8,982/55:* In rats, the growth of Walker tumors and of transplantable hepatomas, unlike that of Jensen sarcomas and Murphy lymphosarcomas, was increased after partial hepatectomy. Perhaps "the regenerating liver may release a humoral agent causing increased growth of some tumors." Hepatic regeneration was enhanced by the presence of a growing tumor regardless of whether the latter was influenced by partial hepatectomy or not.

*Gershbein E71,030/63:* In rats, s.c. transplantation of Walker or Flexner-Jobling tumors did not significantly alter the extent of hepatic regeneration. However, under certain circumstances, partial hepatectomy accelerated tumor growth.

*Kato G54,276/67:* In intact, unlike in adrenalectomized, ascites-tumor-bearing mice, the hepatic TKT activity is elevated.

*Rosene Jr. G71,661/68:* In mice, partial hepatectomy greatly elevates mitotic proliferation in the liver, which reaches a peak on the third day after the operation and returns to near normal by the fifth day. Injections of Ehrlich ascites tumor homogenates moderately accelerated the rate of hepatic mitosis. Partial hepatectomy accelerated tumor cell proliferation.

*Saint-Omer et al. G71,148/68:* In mice bearing ascites tumors, mitotic proliferation and regeneration of the liver after partial hepatectomy is delayed.

*Konishi H14,720/69:* Changes in  $\Delta^4$ -steroid hydrogenase activity in rat liver after tumor implantation.

*Takahashi & Kato H15,250/69:* Studies on changes in hepatic microsomal steroidases induced in rats by treatment with toxohormone (a Walker tumor extract).

*Theologides & Zaki H19,577/69:* In C3H mice bearing transplanted mammary carcinomas s.c., increased mitotic activity in the liver remnant after partial hepatectomy began earlier than in controls.

*Wilson H34,926/71:* In rats, implants of mammotropic tumor (which secretes STH, ACTH and LTH) decreased the hepatic metabolism of hexobarbital and aminopyrine. Similar but much less pronounced changes were observed in rats bearing very large Walker tumors.

## VIII. CLINICAL IMPLICATIONS

To evaluate the clinical applicability of the hormonal regulation of resistance, a few introductory words may be in order.

We need say little here about the major applications of **syntoxic** hormones, particularly glucocorticoids (e.g., in inflammatory diseases or as immunosuppressants), since these have been extensively discussed in our earlier monographs on stress, and are by now generally known. Suffice it to call attention to the possible future clinical applicability of a few new syntoxic hormones which, in animals, have proven their value as antagonists of systemic intoxications with various drugs (e.g., ganglionic blocking agents, lathyrogens, endotoxins, certain barbiturates). These effects are manifest even in the presence of normally functioning adrenals. They suggest that glucocorticoids do not merely act against the excessive stress-sensitivity of hypocorticoïd organisms or as anti-inflammatory compounds, but possess certain rather specific protective effects against some toxicants. It remains to be seen to what extent these prophylactic actions are due to so-called "physiologic antagonisms" between certain effects of glucocorticoids and toxicants which happen to be opposed (e.g., the glyconeogenic effect which prevents insulin hypoglycemia; the potassium loss which counteracts potassium intoxication.)

Here we shall try to survey primarily the possible clinical uses of **catatoxic** hormones under the following headings:

1. Hepatic microsomal drug metabolism in man
  - Contraceptives
  - Other steroids
  - Barbiturates
  - Diphenylhydantoin
  - Other drugs (glutethimide, griseofulvin, salicylates, etc.)
2. Diseases
  - Hyperbilirubinemia
  - Adrenal tumors and Cushing's syndrome
  - Other diseases (cardiac diseases, hepatic lesions, osteoporosis, galactosemia, v. Gierke's disease, endotoxin shock)
3. Pregnancy (abortifacient action of microsomal enzyme inducers)

### *1. HEPATIC MICROSOMAL DRUG METABOLISM IN MAN*

There is ample evidence that many of the drugs which have been shown to induce drug-metabolizing enzymes in animals exert the same effect in man. Of these inducers, contraceptives, barbiturates, diphenylhydantoin, glutethimide, meprobamate, phenylbutazone and griseofulvin have received the greatest attention. Among the substrates whose metabolism is accelerated by these inducers are various steroids,

anticonvulsants, anticoagulants, bilirubin, meprobamate, aminopyrine, salicylamide and many others. Chlorinated insecticides are particularly effective enzyme inducers in man, but their use is limited by their toxicity. Smoking during pregnancy may induce benzpyrene hydroxylase in the placenta.

The widespread use of **contraceptives** poses an especially important problem, in that some of them may induce microsomal enzymes which interfere with the action of various drugs, and in turn, other microsomal enzyme inducers may inactivate the contraceptives. In addition, these pills may interfere with hepatic function in general (as reflected by demonstrable increases in GOT, GPT, bilirubin or prolonged BSP retention) and thereby enhance the action of drugs. Liver biopsies have repeatedly revealed signs of hepatocellular damage, proliferation of the SER, and intrahepatic cholestasis. The commonly used oral contraceptives contain folliculoids and luteoids in combination; hence, it is often difficult to verify which of the two components is responsible for an observed change. Some authors claimed that hepatotoxicity is primarily referable to the folliculoid component, whereas stimulation of drug metabolism is predominantly due to the luteoid element, but this view has been challenged.

Following administration of meperidine, pethidine or promazine, women on oral contraceptives, like pregnant women, excreted a larger than normal amount of these drugs unchanged in the urine. Similar effects were observed in neonates as well as in males given stilbestrol or progesterone. Apparently, pregnancy diminishes the capacity to metabolize meperidine, pethidine and promazine, a change also seen in neonates and subjects taking oral contraceptives.

The plasma tyrosine level is sometimes significantly decreased in women taking contraceptives, presumably because the folliculoid component stimulates the production of glucocorticoids which elevate the TPO activity. This view is supported by observations in rats, in which estradiol increases hepatic TPO, TKT and GPT.

In man, **barbiturates** (e.g., phenobarbital) increase tolerance to digitoxin by enhancing its conversion and urinary excretion as digoxin. Because of its almost negligible hypnotic effect, phetharbital has been used by some clinicians and was shown to increase urinary excretion of  $6\beta$ -hydroxycortisol in man. Phenobarbital also accelerates the plasma clearance of i.v. injected cortisol. Heptabarbital and several other barbiturates increase the hepatic destruction of bishydroxycoumarin as well as of related anticoagulants. This fact is of considerable practical importance, since in patients receiving both types of drugs simultaneously, the dosage of the anticoagulant must be raised in order to obtain the usual action. Furthermore, when barbiturate administration is suddenly stopped, the effect of the anticoagulant may rise sufficiently to cause severe hemorrhagic complications.

A farmer from an area of heavy pesticide usage was given phenobarbital and diphenylhydantoin for the treatment of epilepsy. His blood levels of DDT, DDE, dieldrin and heptachlor were far below those of other farmers living in the same area.

In man, **diphenylhydantoin** increases 6-hydroxycortisol excretion and simultaneously decreases the elimination of conjugated tetrahydro derivatives. As previously stated, diphenylhydantoin diminishes the blood level of various pesticides in man.

Following prolonged treatment with diphenylhydantoin, usually in combination with barbiturates, osteomalacia-like changes have been observed to develop in

epileptic patients. These skeletal lesions respond well to vitamin-D compounds, and have been attributed to the acceleration of vitamin-D metabolism by enhanced microsomal enzyme activity.

In cases of **glutethimide** abuse, the gradual development of tolerance is apparently due to a transient acceleration of its own metabolic inactivation.

The anticoagulant activity of warfarin is sometimes markedly depressed in patients treated with **griseofulvin**. This has been ascribed to an accelerated metabolic degradation of the anticoagulant.

In patients with rheumatoid arthritis, the plasma clearance of radiomarked indomethacin is accelerated, and its urinary excretion diminished by **acetylsalicylic acid**. However, this effect has been ascribed to diminished gastrointestinal absorption rather than to accelerated metabolic degradation of indomethacin.

In patients given **phenylbutazone**, the urinary excretion of  $6\beta$ -hydroxycortisol is increased, whereas the elimination of 17-OHCS is decreased. It will be recalled that  $6\beta$ -hydroxycortisol formation from cortisol is enhanced by hepatic microsomes of guinea pigs *in vitro*, following pretreatment of the animals with phenylbutazone *in vivo*.

### Reviews

*Williams G77,567/63*: Review (21 pp., 84 refs.) on drug detoxication mechanisms in man.

*Burns & Conney G71,448/64*: Review (25 pp., 57 refs.) on the therapeutic implications of drug-metabolism in man.

*Conney F88,649/67 (p. 348)*: Review of the literature on enzyme induction in man.

*Mannering G71,818/68 (pp. 74, 90)*: Review on species differences in susceptibility to

the induction of hepatic microsomal drug-metabolizing enzymes. Special attention is given to the induction of drug-metabolizing enzymes in man.

*Mannering G75,979/69*: Review (4 pp., 32 refs.) briefly summarizing the salient facts about stimulation and inhibition of drug metabolism. Observations of drug-induced stimulation of drug metabolism in man are tabulated as follows:

Inducing agent	Substrate	Reference
Phenobarbital	Diphenylhydantoin	Cucinell et al., 1965
	Digitoxin	Jelliffee and Blankenhorn, 1966
	Griseofulvin	Busfield et al., 1963
	Coumadin	Robinson and MacDonald, 1966
	Bishydroxycoumarin	Cucinell et al., 1965; Corn and Rockett, 1965; Goss and Dickhaus, 1965
	Salicylamide	Crigler and Gold, 1966
Barbital	Bilirubin	Yaffe et al., 1966; Crigler and Gold, 1966
	Dipyron	Remmer, 1962
Heptobarbital	Acenocoumarin	Catalano and Cullen, 1966
	Biscoumacetate	Catalano and Cullen, 1966
	Bishydroxycoumarin	Catalano and Cullen, 1966
Diphenylhydantoin	Cortisol	Werk et al., 1964
Glutethimide	Glutethimide	Schmid et al., 1964
Meprobamate	Meprobamate	Douglas et al., 1963
Phenylbutazone	Aminopyrine	Chen et al., 1962
Griseofulvin	Coumadin	Catalano and Cullen, 1966

*Mannering G74,881/71*: Review of the literature concerning drugs known to influence metabolism of other drugs in man. The following drugs have been shown to induce increased rates of metabolism of coumarins in man: barbiturates, chloral hydrate, griseofulvin and meprobamate. Phenobarbital stimulates the metabolism of diphenylhydantoin, griseofulvin, digitoxin, and the glucuronidation of salicylamide in man. Phenylbutazone increases the metabolism of aminopyrine, whereas meprobamate and glutethimide enhance their own rates of metabolism in man. Chlorinated insecticides are particularly effective in this respect. For example, DDT shortens the plasma half-lives of antipyrine in man.

### Clinical Implications

*Prescott H19,333/69*: Review (5 pp., 89 refs.) on pharmacokinetic drug interactions with special reference to clinical problems.

*Tuohy G66,351/69*: Brief review (3 pp., 26 refs.) on microsomal drug-metabolizing enzyme induction as it affects clinical medicine.

### ← Contraceptives

*Eisalo et al. F18,828/64*: In postmenopausal women treated during 28 days with contraceptive pills containing various folliculoids and luteoids, hepatic impairment was regularly demonstrable by increased serum GOT and GPT levels associated with BSP retention. The luteoid component in itself was inactive, but the folliculoid showed essentially the same hepatotoxic activity as the whole drug.

*Palva & Mustala F21,067/64*: In women taking contraceptive pills, hepatotoxic damage is clearly demonstrable by increased BSP retention associated with a rise in serum bilirubin and GOT.

*Borglin F40,990/65*: Among 36 patients treated with oral contraceptives "in only a few instances did the values obtained deviate from normal—namely, an increase of the transaminase activity and a slight increase of the BSP retention. The serum alkaline phosphatase values, the serum bilirubin level, and the thymol turbidity tests were invariably normal. In those cases where abnormal laboratory values were noted, the S.G.P.T. proved the most sensitive value."

*Cullberg et al. F34,942/65*: "A case of jaundice which appeared during treatment with the oral contraceptive Lyndiol is reported. It is probable that the jaundice was

caused by the drug. Laboratory data of the case include elevated levels of bilirubin, alkaline phosphatases, and transaminases. Biopsy of the liver showed intrahepatic cholestasis and hepatocellular damage." The relevant literature is reviewed.

*Swyer & Little F42,188/65*: Review of the literature, and personal observations on the rarity of hepatic damage among women who have used various oral contraceptives for long periods.

*Crawford & Rudofsky G42,454/66*: In women taking various oral contraceptives, as well as in pregnant women and in neonates, the urinary excretion of meperidine and promazine is increased, suggesting interference with the detoxication of these drugs.

*Rudofsky & Crawford E58,989/66*: Following administration of meperidine or promazine "pregnant women, women on oral contraceptives and neonates excreted significantly more unchanged meperidine than normeperidine, whereas the reverse held for the male 'controls' and other female groups. Pregnant women, women on oral contraceptives and neonates excreted more unchanged and minimally degraded promazine than nonpregnant women. Stilbestrol and progesterone each changed the pattern of excretion by male subjects toward that associated with pregnancy." Apparently, pregnancy diminishes the capacity to metabolize meperidine and promazine, a change reflected in neonates and subjects taking oral contraceptives.

*Conti & Neglia H30,753/68*: In 18 women kept on contraceptive pills (norethinodrel + mestranol) up to six months, no derangement in hepatic function tests (GOT, GPT, serum-proteins, cholesterol, bilirubin) was noted. Yet, the authors recommend caution in the use of such contraceptives in women with hepatic disease.

*Larsson-Cohn G74,875/69*: In women continuously taking norethindrone (NET) or chlormadinone acetate (CMA), no significant changes were observed in serum alanine aminotransferase activity or BSP clearance. Apparently "low doses of NET and CMA have a lower tendency to influence liver function than combined oral contraceptive agents."

*Mowat & Arias G74,246/69*: "Oral contraceptive agents cause a predictable and reversible fall in hepatic excretory function in all subjects appropriately tested." At the same time, there is induction of hepatic drug-metabolizing enzymes which may alter the responsiveness of women to various drugs,

and conversely, others have shown that the uterotrophic effect of oral contraceptives is reduced by phenobarbital, at least in rats. "We can only speculate as to what this may mean for the insomniac on phenobarbitone who relies on the pill for contraception."

*Perez et al. H14,794/69:* In women on oral contraceptives (chlormadinone + mestranol or noretisterone + ethinylestradiol) for 1–6 months, liver biopsies showed proliferation of the SER, whereas after 12–30 months, there were also often striking changes in the shape and size of the mitochondria, with the development of paracrystalline inclusions. Liver function tests were unaltered.

*Eisalo H29,326/70:* In women on various types of contraceptive pills containing luteoids and folliculoids, the most common anomalies of hepatic functions are elevation of SGOT and SGPT with increased BSP-retention.

*Kreek & Sleisenger G77,590/70:* "Classification of patients developing abnormal liver function tests or clinical jaundice while receiving oral contraceptive agents is proposed. The results of a recent study concerning the effects on liver function of low dose estrogen-progestin replacement therapy in menopausal and post-menopausal females are discussed."

*Luhby et al. H32,376/70:* In women taking ethinylestradiol-containing contraceptives, there develops a derangement in tryptophan metabolism associated with "functional" vitamin-B<sub>6</sub> deficiency.

*Martinez-Manautou et al. H30,302/70:* In women treated for several years with oral contraceptives containing a luteoid (chlormadinone acetate) with or without folliculoids "a moderate dilatation and vesiculation of the rough and smooth surfaced endoplasmic reticulum both in the women treated with microdoses of progestogens, and in those treated with a combination of progestogens and oestrogens. A more marked vesiculation of this organelle was present in those women under sequential medication. Elongation of mitochondria with crystalloid inclusions in their matrices was found in 5 to 10% of the whole population of mitochondria per cell examined in the chlormadinone treated women."

*Rose & Braidman H25,726/70:* In rats, estradiol increases hepatic TPO, TKT and GPT. The depression which develops in some women using contraceptive pills may be due to an increased metabolism of tryptophan to nicotinic acid ribonucleotide, and to a raised aminotransferase activity which may divert

pyridoxal phosphate away from other metabolic functions, including 5-HT synthesis.

*Rose & Cramp G75,215/70:* In women using folliculoid-luteoid contraceptives, the plasma tyrosine level is significantly decreased. Two women treated with ethinylestradiol alone showed a similar decrease of plasma tyrosine. "It is suggested that increased levels of glucocorticoids, due to the action of oestrogen, induce elevated levels of tyrosine aminotransferase, and that as a consequence there is an enhanced rate of degradation of the amino acid in the liver."

#### ← Other Steroids

*Kory et al. G75,742/59:* In patients given norethandrolone to induce weight gain, abnormal BSP retention is frequently noted but other evidence of hepatic damage is exceptional.

*Marquardt et al. D82,860/61:* In man, 6 anabolic testoids increased BSP retention, creatine and creatinine excretion in the following order of decreasing potency: norethandrolone, SC-7294, methandrostenolone, fluoxymesterone, methyltestosterone and SC-6507.

*Kleiner et al. F47,209/65:* In women on oral contraceptives (norethynodrel and mestranol), BSP-excretion through the bile was impaired. The effect is ascribed to the luteoid component since estradiol does not cause BSP-retention.

*Aspinall H32,269/70:* In rats, spironolactone can inhibit the ulcerogenic effect of indomethacin without blocking its antiphlogistic property (adjuvant arthritis test). This dissociation may be due to 1. a direct protective action of spironolactone upon the intestinal tract, 2. the formation of indomethacin metabolites which retain antiphlogistic but loose ulcerogenic properties or 3. a mere diminution of indomethacin activity to a level sufficient to inhibit inflammation without causing intestinal ulceration.

*Linèt G79,963/70:* Detailed review of the literature and personal observations on the effect of anabolic testoids upon glucocorticoid overdosage in animals and man. Special attention is given to the effect of anabolic testoids upon glucocorticoid-induced loss of body weight and other metabolic changes, adrenal atrophy, osteoporosis, wound healing, inflammation and gastric ulcer formation. Antigluccorticoids devoid of anabolic properties are also surveyed. In clinical medicine, various forms of hyperglucocorticoidism are not, or only moderately,

improved by treatment with anabolic testoids. [Excellent source of pertinent references (H. S.).]

*Nelson & Lanza G80,151/70*: In nine patients with massive hepatic necrosis due to viral hepatitis, prednisone proved to be a valuable adjunct to treatment.

*Shafer & Adicoff G80,179/70*: In dogs, tetrahydrofurfuryl alcohol (THFA), despite its resemblance to the lactone moiety of digoxin, offers no protection against the latter compound in vivo. The authors emphasize that despite these "negative results, the development of a specific nontoxic pharmacological antagonist to digitalis would be of major clinical importance." [These investigators appear to be unaware of the inhibition of digitalis toxicity by spironolactone (H.S.).]

*Tolckmitt G77,793/70*: In man, prednisolone increases the turnover of tryptophan with a shortening of its biologic half-life. Methandrostrenolone exerts an inverse effect.

#### ←*Barbiturates*

*Burstein & Klaiber F31,533/65*: In man, phenobarbital increases urinary excretion of 6-hydroxycortisol. This effect is tentatively ascribed to "enhancement of cortisol 6 $\beta$ -hydroxylase activity by enzyme induction."

*Jelliffe & Blankenhorn E65,188/66*: In man, pretreatment with phenobarbital increases tolerance to digitoxin by enhancing its conversion to, and urinary excretion as, digoxin. "These findings show that phenobarbital stimulates the metabolic conversion of digitoxin to digoxin, possibly by its marked effect upon smooth endoplasmic reticulum (ER) of mammalian hepatic cells."

*Kuntzman et al. G57,741/68*: In man, chronic treatment with phetharbital greatly increases urinary excretion of 6 $\beta$ -hydroxycortisol, but not that of 17-OHCS, suggesting that an enhanced adrenal output of cortisol is not responsible for the observed rise in 6 $\beta$ -hydroxycortisol elimination. In the guinea pig, this nonhypnotic barbiturate increases the 6 $\beta$ -hydroxycortisol-forming ability of the hepatic microsomes.

*Aggeler & O'Reilly G68,730/69*: In man, pretreatment with heptabarbital diminished the reduction in prothrombin level, the amount of bishydroxycoumarin in plasma, and the half-life of bishydroxycoumarin more markedly after p.o. than after i.v. administration of the anticoagulant. Unchanged bishydroxycoumarin was found in the stool only after p.o. adminis-

tration. Presumably, part of the response to heptabarbital was caused by increased hepatic enzymic destruction of bishydroxycoumarin although, in the event of p.o. administration, decreased absorption from the gastrointestinal tract also played a role.

*Davies et al. G77,532/69*: In patients exposed to DDT, treatment with diphenylhydantoin or (to a lesser extent) with phenobarbital resulted in a decrease in the plasma level of DDE, the principle metabolite of DDT.

*Glogner & Ermert H27,073/70*: In man, the de-ethylation of phenacetin cannot be accelerated by methylphenobarbital, a good hepatic microsomal enzyme inducer. It is assumed that, under ordinary conditions, in man, the transformation of phenacetin into its metabolite N-acetyl-p-aminophenol (NAPAP) is optimal, and hence not subject to acceleration. [The possibility has not been considered that certain inducers are substrate specific, and that methylphenobarbital may not be a potent inducer of phenacetin-metabolizing enzymes (H.S.).]

*Morselli et al. G76,129/70*: In man, phenobarbital accelerates the plasma clearance of cortisol injected i.v.

*Riegelman et al. H27,268/70*: In healthy men, phenobarbital failed to influence the metabolism of griseofulvin. However, the absorption of the orally administered antibiotic was considerably diminished. The barbiturate may increase the secretion of bile which in turn would stimulate peristalsis. There is some evidence of increased bile secretion and enhanced biliary elimination of dyes following barbiturate treatment in animals.

*Schoor H28,965/70*: A farmer from an area of heavy pesticide usage, was given phenobarbital and diphenylhydantoin for the treatment of epilepsy. His blood levels of DDT, DDE, dieldrin and heptachlor were far below those of other farmers living in the same area. It is assumed that either the drugs activated, microsomal enzymes which destroy the pesticides or "that the pesticides are bound by serumproteins, and are consequently relatively inert. The action of the drugs on the pesticides depends on the competition of both for the same binding sites on the proteins."

*Sotaniemi et al. G78,917/70*: In epileptic patients treated simultaneously with phenobarbital and diphenylhydantoin, the serum levels of both drugs were significantly lower than in those given one of these drugs only. Presumably, the two drugs accelerate each other's metabolism.

← **DDD cf. "Cushing's Disease"**← **Diphenylhydantoin**

*Werk et al. F20,780/64*: In man, diphenylhydantoin increases the 6-hydroxycortisol excretion and decreases the elimination of conjugated tetrahydro derivatives. These effects were accentuated by ACTH.

*Werk et al. G67,762/66*: In man, "diphenylhydantoin alters cortisol catabolism by increasing 6-hydroxylation and decreasing A-ring reduction; it may also inhibit ACTH release." In two women with nontumorous Cushing's syndrome, diphenylhydantoin diminished the urinary output of 17-OHCS and increased that of 6-OH cortisol.

*Choi et al. H12,299/69*: Brief abstract on the enhancement of tissue uptake and turnover of cortisol by diphenylhydantoin in man.

*Davies et al. G77,532/69*: In patients exposed to DDT, treatment with diphenylhydantoin or (to a lesser extent) with phenobarbital resulted in a decrease in the plasma level of DDE, the principle metabolite of DDT.

*Tyler et al. G79,955/69*: In epileptic patients on diphenylhydantoin, a negative metyrapone test for pituitary insufficiency may result from increased glucuronic acid conjugation of metyrapone by the liver.

*Schoor H28,965/70*: A farmer, from an area of heavy pesticide usage was given phenobarbital and diphenylhydantoin for the treatment of epilepsy. His blood levels of DDT, DDE, dieldrin and heptachlor were far below those of other farmers living in the same area. It is assumed that either the drugs activated the microsomal enzymes which destroy the pesticides or "that the pesticides are bound by serumproteins, and are consequently relatively inert. The action of the drugs on the pesticides depends on the competition of both for the same binding sites on the proteins."

*Sotaniemi et al. G78,917/70*: In epileptic patients treated simultaneously with phenobarbital and diphenylhydantoin, the serum levels of both drugs were significantly lower than in those given one of these drugs only. Presumably, the two drugs accelerate each other's metabolism.

*Westmoreland & Bass G80,590/71*: Pregnant rats are unusually sensitive to the toxic effects of diphenylhydantoin, and show a more prolonged and intense rise in the blood level of the drug than do nonpregnant controls. The drug is readily transported across the placenta and may damage the fetus. Presumably, "inhibi-

tion of hydroxylation in maternal liver by high concentrations of female sex hormones is a probable mechanism for the accumulation of toxic concentrations of the drug in the tissues of the pregnant rat and fetus."

← **Glutethimide**

*Schmid et al. G34,008/64*: "In two cases of glutethimide abuse, it was demonstrated that tolerance to glutethimide is due to marked acceleration of its metabolic inactivation. After a 20-day withdrawal cure, the metabolism of glutethimide was found to have reverted to normal."

*Corn H33,065/66*: In man, phenobarbital or glutethimide treatment decreases the life span of warfarin.

← **Griseofulvin**

*Cullen & Catalano G68,707/67*: In three out of four patients, the anticoagulant activity of warfarin was significantly depressed by concurrent treatment with griseofulvin, but it returned to the initial level after discontinuation of the latter drug. Possibly, griseofulvin induces enzymes which metabolize warfarin.

← **Salicylates**

*Jeremy & Towson G77,324/70*: In patients with rheumatoid arthritis, <sup>14</sup>C-2-indomethacin plasma clearance is accelerated and urinary excretion decreased by acetylsalicylic acid. "The study showed interference between aspirin and indomethacin, the mechanism possibly being due to decreased gastro-intestinal absorption. This could account for clinical reports that the combination of the two drugs was no better than aspirin alone."

← **Phenylbutazone**

*Kuntzman et al. G67,761/66*: In men given cortisol, the urinary excretion of 6 $\beta$ -hydroxycortisol is increased by phenylbutazone. At the same time, the urinary excretion of a non-polar 17-hydroxycorticosteroid is diminished. Similar changes in the pattern of endogenous urinary corticoids were observed in man treated with phenylbutazone without exogenous cortisol administration.

*Poland et al. G78,061/70*: In men who work in DDT factories, the serum DDT level was

20–30 times that in a control population. The serum half-life of phenylbutazone was 19% lower and the urinary excretion of  $6\beta$ -cortisol 57% higher in the DDT factory workers.

#### ← *Thyroxine*

*Owens et al. D21,725/62:* In man, D-thyroxine potentiates the anticoagulant action of warfarin.

*Solomon & Schrogie H1,868/68:* In women, thyroxine greatly potentiates the anticoagulant effect of warfarin. Analysis of the data (according to the method of Lineweaver and Burk) suggests that an increased affinity of the drug for its receptor site is responsible for the potentiation of its effect. The literature on the increase in the response to various indirect anticoagulants by thyroxine in man is briefly reviewed.

## 2. DISEASES

### *Hyperbilirubinemia* ←

The various types of hyperbilirubinemia may be considered here conjointly, especially since some of them are closely related to each other, and since in many instances the clinical descriptions do not permit exact classification. According to an extensive study on 23,000 infants observed during the first eight months of life, there seems to exist a positive relationship between increasing neonatal hyperbilirubinemia and the incidence of low motor and/or mental scores. It appears therefore, that the development of the central nervous system may be inhibited by jaundice even in the absence of severe kernicterus; hence, prophylactic and therapeutic measures designed to diminish neonatal hyperbilirubinemia may have far-reaching effects upon the intellectual development of mankind, and deserve most serious consideration.

In newborn infants, **barbiturates** (e.g., phenobarbital) may induce a glucuronide conjugating enzyme system and considerably lower the serum bilirubin concentration in congenital, unconjugated hyperbilirubinemia, kernicterus and various other types of jaundice. The effect is not due entirely to bilirubin conjugation, but in part also to the proven effect of barbiturates upon biliary excretion. There is also some evidence that barbiturates induce an acceptor protein “Y”, which takes up bilirubin as well as BSP and may play a crucial part in hepatic detoxication. The most important contraindication to this form of treatment is that at effective dose levels, phenobarbital causes drowsiness. In adult epileptic patients, the total bilirubin level is considerably reduced by phenobarbital. In Chinese babies, among whom neonatal jaundice is very common (as a consequence of ABO incompatibility, glucose-6-phosphatase dehydrogenase deficiency, cephalhematoma and other causes), phenobarbital likewise proved to be effective.

In 10 out of 13 patients with Gilbert's syndrome, phenobarbital induced a rapid fall in plasma bilirubin. A beneficial result was also noted in a patient with hepatitis followed by chronic unconjugated hyperbilirubinemia. In the Crigler-Najjar-syndrome, favorable effects have been obtained with phenobarbital only if the glucuronyltransferase activity was not completely absent to start with.

Unlike phenobarbital, **DDT** causes no drowsiness when administered for the treatment of neonatal hyperbilirubinemia, yet it appears to be equally effective. In patients with constitutional hyperbilirubinemia (Gilbert or Meulengracht syndrome), induction of hepatic microsomal enzymes by DDT or BDT is followed by remissions. DDT appears to have the same efficacy in “physiological” as in familial unconjugated hyperbilirubinemia with nonhemolytic jaundice.

Certain studies suggest that human milk contains steroids which may cause unconjugated hyperbilirubinemia. Early observations implied that the responsible factor may be pregnane-3 $\alpha$ ,20 $\alpha$ -diol, since this steroid allegedly does induce hyperbilirubinemia when fed to normal full term infants, in amounts corresponding to those isolated from human milk. However, subsequent investigations failed to confirm this claim. In fact, neither pregnane-3 $\alpha$ ,20 $\beta$ -diol nor pregnane-3 $\alpha$ ,20 $\alpha$ -diol inhibited bilirubin conjugation by human liver slices or by solubilized human liver microsomes. On the other hand, estradiol was effective in this respect. In newborn infants, progesterone increased folliculoid excretion and serum bilirubin concentrations. Hence, sex steroids in mother's milk may influence the course of neonatal jaundice.

The common association of congenital myxedema with prolonged icterus neonatorum suggested a relationship between the thyroid and jaundice of the newborn. In support of this assumption, T<sub>3</sub> decreased peak bilirubin levels in both mature and premature infants but significantly only in the latter.

### *Adrenal Tumors and Cushing's Syndrome ←*

Since hepatic microsomal enzyme inducers have been shown to accelerate the metabolic degradation of steroids, including corticoids, it was natural to test their possible efficacy in the treatment of hypercorticism.

In patients with Cushing's disease, a barbiturate (N-phenylbarbital, or phenetharbital) caused a moderate decrease in the metabolic clearance and production rates of testosterone, associated with an appreciable decrease in urinary excretion of androsterone, etiocholanolone, and 11-oxyketosteroids. However, the clinical usefulness of this form of therapy remains to be demonstrated.

DDD was tested as a possible treatment for hypercorticism because, in dogs, it causes adrenocortical necrosis and involution. However, its effects, like those of DDT, may be due in part to the powerful microsomal enzyme-inducing properties of these pesticides. Allegedly, o,p'-DDD can cause regression of metastatic adrenal cancer in man, at the same time inhibiting its hormone secretion. The compound is said to suppress even the normal hormonal secretion of the human adrenal cortex. On the other hand, patients given large amounts of exogenous cortisol, like those with Cushing's disease, respond to o,p'-DDD with a prompt decrease of urinary 17-OHCS excretion and plasma 17-OHCS levels. From these and other metabolic studies it was concluded that o,p'-DDD altered the extra-adrenal metabolism of cortisol so as to decrease the proportion of cortisol excreted as tetrahydrocortisol and tetrahydrocortisone, whereas 6 $\beta$ -hydroxycortisol elimination was increased. In the rat, 6 $\beta$ -hydroxycortisol is a potent inhibitor of the induction of hepatic TPO by cortisol. Hence the induction by o,p'-DDD of 6 $\beta$ -hydroxycortisol, the direct adrenal damaging effect of the pesticide, as well as the induction of steroid inactivating hepatic microsomal enzymes may all participate in the production of clinical improvement.

The cortisol-binding capacity of the plasma does not seem to be significantly affected by o,p'-DDD in patients with Cushing's disease.

**Other Diseases ←**

It was reasonable to suspect that the use of microsomal enzyme inducers might be of value in the prophylaxis and treatment of various additional diseases in whose pathogenesis, endogenous or exogenous toxicants play an important role. This was to be expected especially in maladies related to an excess of steroid hormones, cholesterol and other known substrates of microsomal enzymes. This therapeutic approach was primarily based upon animal experiments.

For example, the use of spironolactone in **mineralocorticoid hypertension** was introduced because of the potent antiminerlocorticoid effect of this steroid, but later investigations have shown that it also possesses catatoxic activities against many other substrates, and hence, part of its beneficial action may be due to the accelerated detoxication of endogenous steroids and other compounds.

In cholesterol-fed rabbits, phenobarbital diminishes **atherosclerosis** and hypercholesterolemia. It remains to be seen whether this effect of folliculoids and thyroid hormones in experimental atherosclerosis, as well as in certain clinical cardiovascular diseases, is related to a catatoxic activity.

Anabolic agents have been claimed to be beneficial in the treatment of certain **hepatic lesions**, such as virus hepatitis, in man. On the other hand, several steroids in common clinical use—especially testoids and the folliculoids contained in contraceptive pills—can cause hepatic lesions of possible practical significance. Only extensive clinical tests will be able to reveal whether the typical catatoxic steroids, such as PCN or CS-1 can be used therapeutically in liver diseases, which damage the hepatic parenchyme and thereby interfere with detoxication processes. However, animal experiments suggest that after partial hepatectomy such steroids do improve resistance to many drugs in that they compensate for the loss of liver tissue by increased drug-metabolizing enzyme induction in the remnant. Furthermore, mitotic regeneration of healthy hepatic tissue is enhanced by catatoxic steroids after partial hepatectomy.

Since **prostatic hypertrophy** and certain types of **hormone-dependent cancers** (prostatic, mammary) are beneficially influenced by gonadectomy, it is conceivable that the induction of steroidases by hormonally inactive catatoxic steroids may be beneficial here also. The same considerations apply to various endogenous intoxications by **hormone-producing neoplasms**, **porphyria**, etc. Indeed, there may even exist specific diseases of the endoplasmic reticulum with defects in microsomal enzyme production, but meanwhile we have no evidence for this.

It is unlikely that the beneficial effect of anabolics in **osteoporosis**, or of progesterone in congenital **galactosemia**, are related to hepatic enzyme induction, but this possibility should be more seriously considered in relation to the favorable effects exerted by glucocorticoids in *v. Gierke's glycogen storage disease* and in **endotoxin shock**.

**Hyperbilirubinemia ← cf. also Bilirubin under Drugs**

*Boggs et al. G71,887/67:* Data on 23,000 infants who have been observed from birth to eight months of age "appear to indicate

a positive relationship between increasing neonatal hyperbilirubinemia and the incidence of low motor and/or mental scores attained at 8 months."

*Koivisto et al. G78,915/70:* The serum bilirubin level of neonates whose mothers had

been given estradiol for induction of labor was considerably higher than normal.

← **Barbiturates.** *Yaffe et al. G67,125/66:* In a female infant with congenital unconjugated hyperbilirubinemia, phenobarbital lowered the serum bilirubin concentration. "This constitutes the first indication of the apparent induction of a glucuronide-conjugating enzyme system by phenobarbital in man and therefore may also represent the first therapeutic application of enzyme induction."

*Crigler Jr & Gold G68,552/66; G68,705/67:* Phenobarbital lowers the serum bilirubin concentration in infants with congenital nonhemolytic jaundice and marked kernicterus.

*Thompson & Williams G71,813/67; Kreek & Sleichner G71,811/68; Maurer et al. G71,810/68; Trolle G71,807/68; G71,809/68:* In various forms of icterus, serum bilirubin can be depressed by treatment with phenobarbital.

*McMullin G77,713/68:* Neonates with comparatively high serum bilirubin levels showed a decrease in bilirubinemia following treatment with phenobarbital.

*Trolle G77,159/68:* In low-birth-weight infants treated with phenobarbital during the first 3 days of life, the first week mortality rate was 34/1000, whereas in controls it was 101/1000. This improvement may have been due to suppression of hyperbilirubinemia, but this point was not checked in the present investigation.

*Anonymous H19,246/69:* Editorial on the beneficial effects of immediate postnatal barbiturate treatment upon neonatal hyperbilirubinemia, and its secondary consequences. The beneficial effect of phenobarbital may not be due entirely to increasing bilirubin conjugation, but in part also to its proven enhancing effect upon biliary excretion. There is also some evidence that barbiturates induce an acceptor protein "Y" which takes up bilirubin as well as BSP and may play an important role in hepatic detoxication. The necessary dose of phenobarbital may cause drowsiness, but DDT is equally effective, both in "physiological" and in congenital unconjugated hyperbilirubinemia, at well tolerated dose levels.

*Arias et al. G72,103/69:* In patients with chronic nonhemolytic unconjugated hyperbilirubinemia and glucuronyl transferase deficiency, phenobarbital exerted a dramatic therapeutic effect.

*Crigler Jr. G72,545/69:* Historical remarks on the use of phenobarbital in infants with nonhemolytic hyperbilirubinemia.

*Crigler & Gold H7,119/69:* In a male infant with congenital nonhemolytic, unconjugated hyperbilirubinemia and severe kernicterus, phenobarbital decreased serum bilirubin, whereas T3, STH and testosterone had little or no effect. During phenobarbital treatment, liver specimens obtained by biopsy showed proliferation of the SER and an increased in vitro capacity to conjugate p-nitrophenol.

*Cunningham et al. G77,715/69:* In healthy full-term neonates, phenobarbital given daily from the time icterus neonatorum first appeared about 24 hrs after birth, serum bilirubin levels did not differ significantly from those of untreated controls. "Once unconjugated hyperbilirubinaemia exists in the neonate, it is unresponsive to phenobarbitone." Apparently, treatment has to start prior to or immediately after birth.

*Ertel & Newton Jr. G68,390/69:* "These studies suggest that phenobarbital is the agent of choice for therapy of congenital hyperbilirubinemia. The medical indications for therapy are the prevention of kernicterus and the psychological advantage of rendering these children anicteric."

*Powell et al. H17,195/69:* It was noted previously that pre-eclamptic toxemia is associated with a reduction in the incidence and severity of nonhemolytic jaundice in the neonate. Reexamination of these data have now shown "that for nontoxaemic mothers receiving any barbiturate at any time there was a slight but statistically insignificant reduction (11.3%) in incidence of jaundice in their infants. Toxaemic mothers not receiving barbiturate had a similar insignificant reduction (10.4%). When both P.E.T. and barbiturate were present together, however, the reduction was 30.7% and this was statistically significant ( $P < 0.01$ )."

*Ramboer et al. H12,643/69:* Controlled trials of phenobarbital therapy in neonatal jaundice.

*Thompson et al. G71,801/69:* In a boy with familial unconjugated, nonhemolytic jaundice who had previously shown a good response to phenobarbital, DDT (dicophane) also rapidly reduced the plasma bilirubin.

*Thompson et al. G71,802/69:* In epileptic patients, the plasma-total-bilirubin level is considerably reduced by phenobarbital, presumably "by the persistent induction of glucuronyl transferase or by increased excretion of bilirubin from the hepatic cell."

*Walker et al. G77,714/69:* Earlier studies suggested that neonatal jaundice is compara-

tively rare in the infants of mothers who were treated with barbiturate for preeclampsia. In reexamining the question, "no significant difference between the infants of mothers receiving or not receiving barbiturate could be demonstrated. It is confirmed that hyperbilirubinaemia is less common in infants or women with pre-eclamptic toxemia. The apparent effect of toxemia could not be explained as a feature secondary to the administration of barbiturate in these patients."

*Yeung & Field G73,821/69*: In Chinese babies, among whom neonatal jaundice is very common, phenobarbital therapy reduced bilirubin levels when these were high as a consequence of ABO incompatibility, glucose-6-phosphate dehydrogenase deficiency, cephal-hematoma and other causes. The relevant literature is discussed in detail.

*Behrman & Fisher G75,312/70*: Review (4 pp., 16 refs.) on the use of phenobarbital for neonatal jaundice in man.

*Black & Sherlock H26,290/70*: In 13 patients with Gilbert's syndrome, phenobarbital induced a rapid fall in plasma bilirubin, and in 3 of the 10 symptomatic patients the symptoms improved. The reduction in plasma bilirubin was associated with, and thought to be the results of, an increased hepatic bilirubin UDP-glucuronyl transferase activity.

*Christoforov et al. G77,086/70*: The heterozygous Gunn rat has a lower capacity for bilirubin excretion than the Wistar rat. However, this defect can be corrected by phenobarbital.

*Jouppila & Suonio G78,916/70*: In neonates of toxemic mothers who were treated with phenobarbital during the last two weeks of pregnancy, the serum bilirubin content dropped below the control level.

*Kobayashi et al. H28,794/70*: In a 30-year-old male with Gilbert's syndrome, phenobarbital restored the serum bilirubin level to normal, and at the same time caused pronounced proliferation of the SER. Less pronounced but qualitatively similar changes were observed in a patient with Dubin-Johnson's syndrome.

*Levin et al. G73,664/70*: From a study on 24 babies given phenobarbital for three days after the first appearance of jaundice, "it is concluded that phenobarbitone has no place in the management of established neonatal jaundice."

*Lüders H24,062/70*: Review (8 pp., 117 refs.) on the use of barbiturates, particularly phenobarbital, in the treatment of neonatal hyperbilirubinemias. In the Crigler-Najjar-syn-

drome, beneficial effects can be expected only if the glucuronyltransferase is not completely absent to start with. Among the major dangers of prolonged barbiturate treatment, the following are mentioned (mainly on the basis of animal experiments): depression of the central nervous system, increased perinatal mortality (in animals pretreated during gestation), derangement of steroid hormone and cholesterol metabolism, inhibition of thyroid hormone production, intrahepatic cholestasis, barbiturate withdrawal or hypersensitivity symptoms, and hepatic enlargement.

*Maurer H29,765/70*: Review (8 pp., 9 refs.) on the reduction in serum bilirubin of neonates after barbituric treatment of the mother. Essentially similar results are obtained by exposure of premature infants to artificial light. Possibly, "photodecomposition is a normal alternate route of excretion of bilirubin and is increased or activated in newborn infants by the use of light." Hence possibly combined barbiturate and phototherapy may prove especially efficacious.

*McMullin et al. H31,772/70*: In infants affected by Rhesus hemolytic disease, phenobarbital, given from the first few hours of life, is of considerable value.

*Oya et al. H28,966/70*: In a patient with hepatitis, followed by chronic unconjugated hyperbilirubinemia, phenobarbital corrected the jaundice and caused a considerable drop in plasma bilirubin.

*Specchia H27,907/70*: In an adult patient with nonhemolytic indirect hyperbilirubinemia, treatment with phenobarbital was followed by a marked decrease in blood bilirubin and icterus.

*Stern et al. G76,135/70*: In full-term newborns, phenobarbital, given during the first four days of life, significantly lowered the serum concentration of indirect bilirubin. In vivo glucuronidation of salicylamide was similarly increased "suggesting that the effect of phenobarbital in reducing serum bilirubin levels is mediated, at least in part, by enhanced glucuronide formation."

*Thaler et al. H23,990/70*: In patients suffering from various forms of jaundice, microsomal enzyme induction was studied in biopsy material, simultaneously with a quantitative analysis of the biliary excretion of i.v.-administered <sup>131</sup>I-Rose-Bengal, a cholephil whose excretion does not require biotransformation. The results indicate that phenobarbital (PB) "induces an enzyme essential to drug and steroid metabolism in human liver. PB also

stimulates hepatic excretion of inert dyes and endogenous cholephils, e.g., Rose Bengal and conjugated bilirubin, respectively. Enzyme induction and excretory stimulation can occur independently. These effects are greatest in patients with relatively well preserved hepatic functions, suggesting diagnostic and therapeutic applications of PB in several cholestatic conditions.”

*Theile & Reich G73,421/70:* In premature infants, 5 mg of phenobarbital/kg i.m., daily, decreased the serum bilirubin level; the effect was more pronounced with higher dosages; however these caused marked sedation.

*Vest et al. H32,456/70:* Description of beneficial results in phenobarbital treated babies with neonatal hyperbilirubinemia.

*Windorfer H28,824/70:* Review and personal observations on the treatment of neonatal icterus with phenobarbital.

*Felsher et al. H34,479/71:* In patients with hepatic cirrhosis and elevated unconjugated serum bilirubin values, phenobarbital inhibited the previously demonstrated acute rise in serum bilirubin during fasting.

*Felsher et al. H34,480/71:* In patients with acute icteric viral hepatitis, the hepatic glucuronyl transferase activity is enhanced by phenobarbital.

*Hunter et al. H36,993/71:* In epileptic patients, the urinary excretion of D-glucaric (a metabolite of glucuronic acid) is considerably increased during phenobarbital treatment. Similar observations have been made in patients with Gilbert's syndrome after administration of various drugs known to induce hepatic enzymes. Because of its simplicity and sensitivity, the D-glucaric acid excretion test is recommended for the clinical assessment of drug-metabolizing enzyme induction. It is noteworthy, however, that except in primates and guinea pigs, glucuronolactone is converted to ascorbic acid and, in the rat, inducers of drug metabolizing enzymes increase the excretion of ascorbic acid rather than of D-glucaric acid.

← **DDD, DDT.** *Anonymous H19,246/69:* Editorial on the beneficial effects of immediate postnatal barbitol treatment upon neonatal hyperbilirubinemia and its secondary consequences. The necessary dose of phenobarbital may cause drowsiness, but DDT is equally effective, both in “physiological” and in congenital, unconjugated hyperbilirubinemia, at well-tolerated dose levels.

*Thompson et al. G71,801/69:* In a boy with familial unconjugated, nonhemolytic jaundice who had previously shown a good

response to phenobarbital, DDT (dicophane) also rapidly reduced the plasma bilirubin.

*Greim G76,366/70:* In patients with constitutional hyperbilirubinemia (Gilbert- or Meulengracht syndrome) as well as in Cushing's disease, the stimulation of hepatic microsomal enzyme induction by DDT or DDD is followed by remissions. Because of its corticolytic effect in the dog, it had been assumed that DDD acts by blocking corticoid production, but in vitro experiments with rat liver microsomes show that DDD and DDT increase the metabolism of corticoids, and hence, their therapeutic effect is ascribed to this action.

← **Steroids.** *Arias et al. G76,756/63:* In neonates, unconjugated hyperbilirubinemia is often associated with breast feeding. The milk contains a factor that inhibits glucuronide formation in vitro by rat, guinea pig and rabbit liver microsomes.

*Arias & Gartner F21,711/64:* “Unconjugated hyperbilirubinaemia can be produced in very young, full-term infants by feeding pregnane-3( $\alpha$ ), 20( $\beta$ )-diol in amounts equivalent to that isolated from inhibitory human milk.”

*Ramos et al. G38,868/66:* Newborn infants fed pregnane-3 $\alpha$ , 20 $\alpha$ -diol or pregnane-3 $\alpha$ , 20 $\beta$ -diol from the fifth to the tenth day of life showed no anomaly in serum bilirubin levels or in the rate of the physiologic decline of the bilirubin values. “In the doses used these two pregnanediol isomers are not responsible for the conjugation inhibition effect seen in the breast milk of infants with ‘physiologic’ jaundice.”

*Kreek et al. F92,343/67:* Review of the literature and personal observations suggesting that idiopathic cholestatic jaundice during pregnancy may result from increased folliculoid production and is aggravated by challenge with ethinylestradiol.

*Kreek et al. G51,605/67:* In one patient, cholestatic jaundice recurred during each of eight pregnancies, and during periods of menorrhagia. Liver biopsies revealed intrahepatic cholestasis during pregnancy with a return to normal after delivery. An identical picture with jaundice and abnormal liver function was obtained upon treatment of the patient with ethinylestradiol.

*Crigler & Gold H7,119/69:* In a male infant with congenital nonhemolytic, unconjugated hyperbilirubinemia and severe kernicterus, phenobarbital decreased serum bilirubin, whereas T3, STH and testosterone had little or no effect. During phenobarbital treatment, liver specimens obtained by biopsy

showed proliferation of the SER and an increased in vitro capacity to conjugate p-nitrophenol.

*Adlard & Lathe G74,759/70*: In newborn infants, jaundice develops more frequently on breast feeding than on cow's milk, and earlier investigators assumed that 3 $\alpha$ , 20 $\beta$ -pregnanediol present in human milk may competitively inhibit glucuronyl transferase, thereby interfering with bilirubin clearance. The present observations suggest that "neither 3 $\alpha$ , 20 $\beta$ -pregnanediol nor 3 $\alpha$ , 20 $\alpha$ -pregnanediol inhibited conjugation by human liver slices or by solubilized human liver microsomes. 3 $\alpha$ , 20 $\beta$ -pregnanediol is unlikely to be the inhibitor causing breast milk jaundice." However, estriol inhibited conjugation by human liver slices.

*Rosta et al. G77,094/70*: In 4 cases of neonatal jaundice, an increased pregnanediol content was observed in the mother's milk, but on the whole, "clinical trials failed to support the role of steroid inhibition in our cases of protracted neonatal jaundice."

*Sas & Herczeg G77,093/70*: In newborn infants, progesterone increases folliculoid excretion and serum bilirubin concentrations. Sex steroids in mother's milk may influence the course of neonatal jaundice.

← **Thyroid Hormones.** *Akerrén G76,866/54*: Compilation of 10 cases of congenital myxedema with prolonged icterus neonatorum. A relationship between the thyroid and jaundice of the newborn is suspected.

*Less & Ruthven C74,543/59*: "In a trial of L-triiodothyronine by mouth in the treatment of neonatal hyperbilirubinaemia, mean peak bilirubin levels were decreased in both mature and premature-treated infants compared with controls, but this difference was statistically significant in the premature group only. . . . Triiodothyronine may act by stimulating the maturation of glucuronyl transferase and other enzyme systems which are responsible for conjugating bilirubin."

*MacGillivray et al. G48,968/67*: In a newborn with congenital myxedema and hyperbilirubinemia, T<sub>3</sub> treatment caused a prompt fall in bilirubin and improvement of hypothyroidism. Accidental withdrawal of treatment was followed by an early recurrence of both jaundice and myxedema. Earlier reports of an association between intense neonatal jaundice and congenital myxedema are reviewed.

← **Pregnancy.** *Kreek et al. F92,343/67*: Review of the literature and personal observations

suggesting that idiopathic cholestatic jaundice during pregnancy may result from increased folliculoid production and is aggravated by challenge with ethinylestradiol.

*Kreek et al. G51,605/67*: In one patient, cholestatic jaundice recurred during each of eight pregnancies, and during periods of menorrhagia. Liver biopsies revealed intrahepatic cholestasis during pregnancy with a return to normal after delivery. An identical picture with jaundice and abnormal liver function was obtained upon treatment of the patient with ethinylestradiol.

← **Light.** *Giunta & Rath H35,532/69; Lucey H35,539/69*: In the newborn and especially in premature babies, exposure to light diminishes the risk of hyperbilirubinemia.

#### **Adrenal Tumors and Cushing's Syndrome ←**

← **Aminoglutethimide.** *Bochner et al. H31,656/69*: In a patient with metastatic adrenocortical carcinoma and Cushing's syndrome, DDD caused gradual diminution in the size of metastases and some fall in 17-hydroxycorticoid excretion. Aminoglutethimide caused clinical evidence of hypocorticism despite an increase in the size of the metastases.

← **Barbiturates.** *Southren et al. H8,265/69*: In patients with Cushing's disease, N-phenylbarbital (phenetharbital) caused "a moderate decrease in the metabolic clearance and plasma production rates of testosterone. In addition, there occurred an appreciable decrease in the urinary excretions of androsterone, etiocholanolone and the 11-oxyketosteroids, associated with an increased excretion of polar metabolites of testosterone."

← **DDD.** *Sheehan et al. B77,668/53*: In a woman with Cushing's syndrome, no beneficial results could be obtained by DDD, suggesting that the human adrenal may be resistant to this compound.

*Bergental et al. G74,073/59*: "Preliminary observations with the use of o,p'-DDD have shown it capable of producing regression of metastatic adrenal cancer in man and inhibition of its hormonal secretion. At the present time this appears to be reversible. o,p'-DDD has likewise suppressed the function of the normal human adrenal."

*Bergental et al. C94,436/60*: o,p'-DDD causes regression of adrenocortical carcinoma metastases in some, but not in all, patients.

*Wallace et al. E89,875/61*: In two cases of Cushing's syndrome due to adrenocortical

hyperplasia, clinical improvement and diminished excretion of 17-hydroxycorticosteroids and 17-ketosteroids were obtained by o,p'-DDD.

*Geyer D27,915/62:* In a patient with Cushing's syndrome o,p'-DDD caused remission of the disease manifestations.

*Geyer & Schüller D38,170/62:* Both in normal man and in patients suffering from various forms of adrenocortical hyperactivity, o,p'-DDD was found to be beneficial.

*Bar-Hay et al. G1,283/64:* A 10-year-old girl with nontumorous Cushing's syndrome showed dramatic improvement following treatment with o,p'-DDD.

*Bledsoe et al. E20,690/64:* In patients with Cushing's disease or given large amounts of exogenous cortisol, treatment with o,p'-DDD resulted in "a prompt 50—80% decrease in urinary 17-OHCS, regardless of whether the patient's source of cortisol was endogenous or exogenous. Plasma 17-OHCS levels and cortisol secretion rates, however, did not fall. Evaluation of the pattern of cortisol metabolites excreted in the urine of these patients revealed that o,p'-DDD altered the extra-adrenal metabolism of cortisol so as to decrease the proportion of cortisol excreted as tetrahydrocortisol and tetrahydrocortisone and to increase the proportion excreted as 6 $\beta$ -hydroxycortisol."

*Pichler G43,794/66:* In a young girl with adrenal hyperplasia and Cushing's syndrome "complete remission" was obtained after 7 months of DDD treatment. Pigmentation and decreased steroid excretion were noted at this time. However, 9 months after discontinuation of treatment, urinary steroid secretion increased again. The effect is ascribed to a blockade of corticoid production by the adrenals.

*Southren et al. F63,163/66:* In two patients with Cushing's syndrome, a remission with a reduction of urinary and plasma 17-OH-CS levels has been obtained by treatment with o,p'-DDD.

*Southren et al. F73,262/66:* o,p'-DDD accelerates the metabolism of infused cortisol-7-<sup>3</sup>H in a patient with Cushing's disease, as well as in an adrenalectomized castrated subject.

*Southren et al. F66,647/66:* Clinical improvement has been observed in Cushing's syndrome after treatment with o,p'-DDD. This effect might have been due to a direct interference by o,p'-DDD with the biologic action of cortisol or by giving rise to cortisol metabolites which inhibit cortisol competitively at the effector site. In the rat, o,p'-DDD had no effect upon

the induction of TPO in the liver, whereas 6 $\beta$ -hydroxycortisol was found to be a potent inhibitor of cortisol action in this test system. Since o,p'-DDD induces 6 $\beta$ -hydroxycortisol, the protective effect may have been due to the latter.

*Bochner et al. H31,656/69:* In a patient with metastatic adrenocortical carcinoma and Cushing's syndrome, DDD caused gradual diminution in the size of metastases and some fall in 17-hydroxycorticoid excretion. Aminogluthimide caused clinical evidence of hypocorticism despite an increase in the size of the metastases.

*Temple Jr. et al. H17,091/69:* In patients with Cushing's disease, o,p'-DDD diminished cortisol secretion. Since adrenal responsiveness to ACTH infusion was reduced and the adrenals showed electron-microscopic changes in the mitochondria of the fasciculata, the effect was ascribed to the adrenolytic action of the drug.

*Burger et al. H28,702/70:* In patients with Cushing's disease, the cortisol-binding capacity (CBC) of the plasma was not significantly altered by o,p'-DDD.

*Greim G76,366/70:* In patients with constitutional hyperbilirubinemia (Gilbert- or Meulengracht syndrome) as well as in Cushing's disease, the stimulation of hepatic microsomal enzyme induction by DDT or DDD is followed by remissions. Because of its corticolytic effect in the dog, it had been assumed that DDD acts by blocking corticoid production, but in vitro experiments with rat liver microsomes show that DDD and DDT increase the metabolism of corticoids, and hence, their therapeutic effect is ascribed to this action.

*Hellman et al. H28,347/70:* In a patient with Cushing's syndrome, treatment with o,p'-DDD "converted the cortisol secretory pattern from a well-defined series of peaks and valleys to an almost level pattern fluctuating about the lowest plasma concentration measured in the untreated state." The changes in plasma cortisol pattern are ascribed to direct adrenal damage.

#### Other Diseases ←

**Cardiac Diseases** ← *cf. also Selye G60,083/70. Salvador et al. G68,113/67:* Pretreatment with phenobarbital diminished hypercholesterolemia and atherosclerosis in cholesterol-fed rabbits. The cholesterol content of the aorta was likewise diminished.

*Orrenius et al. E8,231/69*: Review of the literature, and personal observations on the increase in the synthesis of cholesterol from  $^{14}\text{C}$ -acetate obtained by phenobarbital pre-treatment in rats and hamsters.

*Tourniaire et al. G66,481/69*: "Spironolactone is now the drug of choice in severe heart failure complicated by increased myocardial sensitivity. It enables one to stop other drugs such as digitalis and salt diuretics which are liable to increase the arrhythmia and lead to fibrillation. . . . This action on myocardial excitability in heart failure may probably be explained by the antagonism between spironolactone and aldosterone in the kidney and its effects on potassium metabolism."

**Hepatic Lesions** ←. *Krüschemper & Noell G48,300/66*: Methyltrienolone (17 $\alpha$ -methyl-4, 9, 11-estratriene-17 $\beta$ -ol-3-one), though a strong anabolic agent, is definitely hepatotoxic as judged by various function tests in man.

*Caviles H30,761/68*: In patients receiving massive doses of stanozolol for the treatment of aplastic anemia, indications of significant hepatic disturbances were not observed.

*Adlercreutz H21,321/70*: Review (34 pp., about 240 refs.) on folliculoid metabolism in liver disease.

*Jannuzzi et al. H27,335/70*: In patients with viral hepatitis, various anabolics, including

stanozolol and 4-chlorotestosterone, exert a beneficial effect.

**Osteomalacia** ←. *Dent et al. H30,946/70*; *Richens & Rowe H30,947/70*: In four epileptic patients, osteomalacia developed during long-term treatment with diphenylhydantoin and barbiturates. Vitamin D exerted a curative effect. "It is suggested that drug-mediated enzyme induction may be the mechanism responsible by causing a greatly increased inactivation of vitamin D in these patients."

**Osteoporosis** ←. *Heather G67,332/63*: SKF-6612 is recommended for the treatment of osteoporosis in man, owing to its anabolic effect.

**Galactosemia** ←. *Pesch et al. C79,957/60*: "Administration of progesterone to three prepubertal patients with congenital galactosemia resulted in a significant increase in ability to oxidize a tracer dose of galactose-1- $\text{C}^{14}$  to  $\text{C}^{14}\text{O}_2$ ."

**v. Gierke's Disease** ←. *Moses et al. G40,253/66*: In a patient with glycogen storage disease, triamcinolone caused a 4-fold increase in hepatic glucose-6-phosphatase activity.

**Endotoxin Shock** ←. *Weil et al. G68,706/62*: In man, combined treatment with glucocorticoids (cortisol, prednisone, dexamethasone) and vasoactive agents (especially metaraminol) is particularly efficacious in preventing endotoxin shock.

### 3. PREGNANCY (ABORTIFACIENT ACTION OF HEPATIC MICROSOMAL ENZYME INDUCERS)

It has been noted some time ago that in dogs, DDD tends to produce abortion, and in rats, phenobarbital increases embryonic death causing subcutaneous hemorrhages in the fetuses. The placentas of the rats so treated were small and showed an increased demethylation activity. Our own hitherto unpublished observations suggest that various catatoxic steroids such as ethylestrenol, spironolactone and CS-1 interrupt pregnancy in the rat and, if administered after delivery, interfere with lactation. It is tempting to assume that these effects result from the induction by catatoxic steroids of microsomal enzymes that metabolize the hormones necessary for the maintenance of gestation and milk production; yet, in our experience, highly catatoxic amounts of PCN and phenobarbital failed to interrupt pregnancy in the rat.

*Dille 45,154/34*: In cats, guinea pigs and rabbits, a single anesthetic dose of barbital or amital does not interrupt pregnancy, but "in no case where barbiturates were administered over a major part of pregnancy was a successful delivery obtained."

*Courrier 86,924/45*: Monograph (396 pp., about 1250 refs.) on the endocrinology of gestation, with a special section (70 pp.) on hor-

monal interventions which interrupt pregnancy. An excellent survey of the literature up to 1945.

*Nichols & Hennigar C48,736/57*: In dogs, DDD tends to produce abortion.

*Pincus E689/65*: Monograph (360 pp., 1459 refs.) on the control of fertility. Special attention is given to the abortifacient action of drugs and hormones.

*Badarau et al. G69,247/68:* In rats, various adrenal and ovarian steroids can produce necrosis of the trophoblast during the early stages of gestation. In certain steroid combinations, a mutual antagonism has been noted. [The cursory descriptions in this brief abstract do not permit evaluation of the data (H.S.).]

*Einer-Jensen G75,787/68:* Review of the literature on the abortifacient action of natural and artificial folliculoids. Personal observations show that in the dog, mouse, rat and rabbit, early pregnancy can be interrupted with comparatively small doses of "F6066" [Bis(p-acetoxyphenyl)-cyclohexylidene-methane] and "F6103" [Bis-(p-acetoxyphenyl)-2-methylcyclohexylidene-methane.]

*Jacob & Morris G73,856/69:* In rabbits, norethindrone, testosterone, dehydrotestosterone and certain so-called "nonsteroidal anti-folliculoids" inhibited implantation when given during the first three days after copulation. With the exception of chlormadinone, all these compounds showed some degree of folliculoid (uterotrophic) activity which parallels the anti-fertility potency. Progesterone and chlormadinone failed to inhibit implantation under similar conditions.

*Morrison & Kilpatrick G69,282/69:* Observation of a personal case and report of several others from the literature, showing that in women taking glucocorticoids during pregnancy, estriol excretion is diminished. "The effect could be the result of direct depression of the placental enzymic systems."

*Szontagh & Kovacs G73,899/69:* Brief post-coital treatment with dienestrol prevents pregnancy in women.

*Adams & Wagner G80,309/70:* In cattle, dexamethasone i.m. readily induces parturition during late pregnancy. In ewes, it is much less effective. The plasma corticoid level spontaneously rises just prepartum in cattle and ewes. "This abrupt elevation in maternal plasma corticoids may result from increased synthesis by the fetal adrenals and provide the signal for termination of the pregnancy." Early literature on the effect of corticoids, ACTH and hypophysectomy upon pregnancy is reviewed.

*Bačić et al. G75,837/70:* In women, the administration of large doses of ethinylestradiol during early pregnancy failed to cause abortion or bleeding. It is concluded that, unlike in several other species, folliculoids are not reliable abortifacients in man.

*Bačić et al. H28,711/70:* In women, the artificial folliculoid F-6103 (Bis-(p-acetoxyphenyl)-2-methyl-cyclohexylidene-methane)

has no abortifacient effect, although earlier studies showed that it does interrupt early pregnancy in rats and mice.

*Fahim et al. G77,383/70:* In pregnant rats, phenobarbital given throughout gestation "results in a significant increase in embryonic death and a 28 per cent incidence of fetal subcutaneous hemorrhage. Placentas of treated animals weighed less than controls and exhibited a significant increase in demethylation activity."

*Jean H33,486/70:* In mice and rats, estradiol dipropionate injected on the 14th day of gestation failed to interrupt gestation but moderately diminished the subsequent growth of the offspring.

*Jean & Jean H33,485/70:* In rats and mice, estradiol injected during the second third of gestation interferes with parturition and causes considerable fetal and perinatal mortality. The earlier literature on postcoital contraception by folliculoids and testoids is reviewed.

*O'Leary et al. G80,260/70:* In women living in areas where DDT and DDE are extensively used for pest control, spontaneous abortions are not correlated with the blood pesticide levels. There is no reason to believe that the pesticides have a significant abortifacient action.

*Nocke et al. H29,580/70:* Brief abstract indicating that in pregnant women, spironolactone decreases the urinary elimination of folliculoids, 17-hydroxycorticoids and 17-oxosteroids. It is concluded that spironolactone "may have an influence on the biogenesis and/or metabolism of steroid hormones."

*Meyers G77,432/70:* In rats, stimulation of the sterile uterine horn of the 1-4th day of pregnancy does not lead to the usual decidual formation whether the animals are intact or ovariectomized and maintained on progesterone + estrorene. However, the decidual response (DR) produced by trauma with a needle or intra-uterine instillation of oil was not equally influenced by the antifolliculoids I.C.I. 46474, CN-55945-27, U-11100A, and U-11555A. "The oil-induced, but not the trauma-induced DR, in intact pregnant rats was completely inhibited by all the anti-estrogenic compounds when they were given on Day 4, while administration of the same drugs on Day 1 prevented both the oil-induced and the trauma-induced DR. Implantation was uniformly prevented by these compounds after administration on either Day 1 or Day 4. It was concluded that, in the rat, oil installa-

tion is preferable to the use of trauma for deciduoma induction, since it more closely resembles the conditions under which implantation takes place."

*Sananès & Psychoyos G78,230/70*: In rats, deciduoma formation is inhibited by actino-

mycin D presumably by interfering with RNA formation.

*Bloch et al. H 34,907/71*: In mice, unlike in rats, TMACN administered during gestation often causes fetal absorption but no gross malformations in the reproductive tract.

### SUMMARY

In the preceding pages we have surveyed evidence suggesting that catatoxic steroids may be of use in patients suffering from the most varied forms of endogenous or exogenous intoxications with bilirubin, steroids, digitalis compounds, pesticides, carcinogens, etc. In addition, knowledge of the catatoxic mechanism is indispensable in evaluating the possible effect that enzyme-inducing hormones or drugs (e.g., contraceptive pills, antimineralocorticoids, barbiturates, anticonvulsants) may exert upon the efficacy of simultaneously administered pharmaceuticals and vice versa, since many inducers are also substrates for inducible microsomal enzymes.

Furthermore, attention is called to the fact that catatoxic steroids are comparatively ineffective in attacking near physiologic levels of hormones and other normal body constituents. Yet they may interfere with pregnancy and lactation, through the enhanced metabolic degradation of the excess steroids necessary for the maintenance of these states, or through other mechanisms.

Finally, catatoxic steroids may be useful when only topical drug or hormone actions are required. Here these steroids would selectively prevent undesirable systemic side effects through the induction of hepatic microsomal enzymes which could degrade only the blood-borne fraction of the topical medications.

## IX. MORPHOLOGY ←

### *HEPATIC TISSUE* ←

*Cf. also* Hepatic Lesions ← Steroids p. 354

#### ← *Steroids*

In general it may be said that glucocorticoids decrease, whereas catatoxic steroids increase, the weight of the liver in various species. However, these effects largely depend upon a variety of conditioning factors such as the dosage of the hormones, as well as the age, diet and species of the animals under investigation. Here we shall deal only with those changes which have been shown or at least suspected to be related to adaptive enzyme formation.

← **Corticoids.** In the fowl, DOC causes hypertrophy and hyperplasia of the liver. This is all the more remarkable since after adrenalectomy, DOC is singularly ineffective in promoting hepatic regeneration induced by partial hepatectomy. Conversely, heavy overdosage with cortisone causes involution and sometimes even focal necrosis of hepatic tissue in the rat and mouse. Unilateral nephrectomy which sensitizes the rat to many of the toxic actions of DOC, very markedly increases its ability to enlarge the liver.

On the other hand, in the rabbit, cortisone causes pronounced increase in liver weight with glycogen deposition and cellular hypertrophy, whereas DOC is ineffective in this respect. Small doses of cortisone may even cause hepatic enlargement in rats when liver weight is expressed as a percentage of body weight. However, at high dose levels the general catabolic action of the hormone predominates.

Flumedroxone and its unsaturated analogue cause hepatic enlargement and SER proliferation in mice and rats. Furthermore in mice, the mean mitochondrial volume increased 4-fold after cortisone treatment, possibly as a result of mitochondrial fusion.

← **Adrenalectomy.** In adrenalectomized mice, cortisone increases protein synthesis in the liver with the formation of heavy polysomes during the first hour. After 3 hrs cortisone represses protein synthesis under otherwise comparable conditions.

In adrenalectomized rats, the number of hepatic mitochondria and lysosomes increases and vesicular forms of endoplasmic reticulum arise around the Golgi complexes. All these changes are prevented by cortisol.

← **Folliculoids.** In C3H mice, chronic treatment with estradiol or diethylstilbestrol increases hepatic weight. A similar increase is obtained in pullets by estradiol. In the mouse, stilbestrol derivatives induce mitochondrial swelling and dilatation of the RER with considerable changes in the activity of various enzymes but no obvious proliferation of SER.

Heavy overdosage with natural and artificial folliculoids may cause enlargement of the liver hepatitis, hepatic necroses, and even death with severe icterus in certain

strains of mice. In immature pullets, thyroxine antagonizes the hepatic changes produced by estradiol.

The hepatotoxic effects of folliculoids in man have been discussed in the section on "Clinical Implications," especially in connection with oral contraceptives.

← **Luteoids.** In hamsters, progesterone increases hepatic weight and causes proliferation of the SER accompanied by chemically demonstrable augmentation of microsomal phospholipid content. The changes are similar to those produced by barbiturates. In rats, lynestrenol causes increased vacuole formation in the Golgi apparatus without any alterations in the endoplasmic reticulum.

← **Testoids.** In mice, large doses of testosterone failed to produce significant changes in hepatic weight, although in rats it does elicit moderate hepatic hypertrophy. The capacity to excrete conjugated bilirubin is impaired in rats by norethandrolone and even more strikingly by icterogenin. Simultaneously, ultrastructural changes appear in the hepatocytes and bile canaliculi.

Methyltrienolone, a strong anabolic agent, is definitely hepatotoxic as judged by various function tests in man. In partially hepatectomized rats, the fat and phosphatase accumulation in the liver remnant is enhanced by prednisolone but not significantly affected by 4-chlorotestosterone.

Norbolethone produces pronounced proliferation of the SER in the hepatocytes of the rat presumably reflecting increased microsomal-enzyme induction.

← **Antitestoids.** In rats, cyproterone stimulates the proliferation of the SER in hepatocytes presumably again as a manifestation of microsomal enzyme induction.

← **Catatoxic Steroids in General.** Both in intact and in partially hepatectomized rats, spironolactone increases hepatic weight and the mitotic activity of hepatocytes. Several of the most active catatoxic steroids (spironolactone, norbolethone, CS-1, ethylestrenol) stimulate the SER of the hepatocytes in the rat. Progesterone and testosterone are much less effective. However, alterations in the endoplasmic reticulum are also produced by noncatatoxic steroids (estradiol) and nonsteroidal folliculoids (stilbestrol). "Thus it can be concluded that there is no close correlation between the catatoxic potency and the proliferation of the SER although all the catatoxic compounds tested lead to a marked transformation of the endoplasmic reticulum in the hepatocytes."

PCN, one of the most active catatoxic steroids, induces intense proliferation of the SER in the hepatocytes of the rat. This is accompanied by swelling of the mitochondria and a moderate increase in the lipid content of hepatocytes as well as by some hypertrophy of the microvilli in the bile canaliculi.

← **Other Steroids.** We have already mentioned the great capacity of icterogenin to reduce the elimination of conjugated bilirubin, without producing any obvious light microscopic changes in the liver. Electron microscopic lesions are noted however in hepatocytes and bile canaliculi.

For an extensive study concerning the effect of various steroids, thyroxine and phenobarbital upon body and organ weights in rats, *cf.* Table 140, p. 860.

#### ← **Nonsteroidal Hormones and Hormone-Like Substances**

← **Anterior Pituitary Hormones.** It had long been noted that in rats, treatment with crude anterior lobe extract causes a disproportionate increase in hepatic weight. From this it has been concluded that certain anterior pituitary extracts selectively

stimulate hepatic growth and that the hepatotrophic effect is not merely due to their STH content. The anterior pituitary extracts not only increase hepatic size but produce extreme polymorphism of hepatocyte nuclei and an outburst of mitotic divisions some of which are abnormal and conducive to the formation of large polymorphonuclear giant cells. In addition, crude lyophilized anterior pituitary may cause infiltration of the hepatic stroma with hemopoietic cells and megakaryocytes. It remains to be seen however whether these latter effects are due to a specific hormone or to impurities in the crude hypophyseal extracts. Curiously in intact (unlike in hypophysectomized) rats, purified STH also causes disproportionate hepatic enlargement possibly by stimulating the secretion of a hypophyseal hepatotrophic principle.

ACTH causes hepatic steatosis in rats especially if they are maintained on high-carbohydrate diets or force-fed. Particularly pronounced hepatotrophic effects have been obtained in rats upon combined treatment with ACTH + STH. The production of fatty livers by purified ACTH is prevented by adrenalectomy in the rat.

← **Thyroid Hormones.** High doses of thyroxine may cause functional and occasionally even structural hepatic damage in various species and even in man (Selye 94,572/49).

In rats, thyroid feeding increases hepatic weight and produces diffuse basophilia with palisade-like basophilic rods in the cytoplasm of the hepatocytes, but similar changes have been described previously using a variety of stressor agents (epinephrine, bleeding). Thiourea also stimulates mitotic proliferation in the rat liver. The ESR shows no important changes in rats overdosed with thyroxine or in thyrotoxic patients.

← **Pancreatic Hormones.** In mice, insulin causes some increase in the mean mitochondrial volume of hepatocytes.

#### ← *Drugs*

In the rat, hepatic microsomal-enzyme induction by **barbiturates** (e.g. phenobarbital) is regularly associated with a pronounced proliferation of the hepatic SER, apparently at the expense of the RER. Essentially similar changes are produced by barbiturates in the rabbit and hamster. These morphologic abnormalities are usually first seen around the central parts of the lobule gradually spreading to the periphery. Concurrent treatment with SKF 525-A further aggravates these changes but in itself SKF 525-A produces no detectable anomalies in the hepatocytes. In rats, a single injection of phenobarbital suffices to stimulate the SER. Enzyme histochemical studies on rats treated with phenobarbital suggested that NADPH tetrazolium red is directly involved in the hydroxylation chain, whereas G6PD and ICD are more indirectly affected.

$\text{CCl}_4$  greatly increases the proliferation of the SER in hepatocytes but apparently it stimulates only the synthesis of abnormal microsomal membranes, since protein synthesis is greatly impaired, whereas incorporation of  $^{35}\text{P}$  into the membrane phospholipids is enhanced.

**Chlorazasil**, a diuretic drug, depresses mitotic division in the regenerating liver of the mouse after partial hepatectomy.

In rats, **clofibrate** first causes deformation of hepatic mitochondria and depletion of succinic oxidase and after 12 hrs proliferation of the SER.

Sublethal doses of **digitoxin** cause proliferation of the hepatic SER in the rat with enzyme changes which have been interpreted as suitable for the enhancement of glycoside metabolism. However, our *in vivo* experiments showed no increase in digitoxin resistance following pretreatment with the same compound.

In rats treated with **metyrapone**, the SER of the hepatocytes becomes hypertrophic concurrently with a loss of glycogen. This effect is not obtained *in vitro* when liver slices are incubated with metyrapone.

Various **pesticides**, which act as microsomal enzyme inducers, stimulate the proliferation of the SER in the hepatocytes of the rat. DDT is particularly effective in this respect and in addition produces inclusion bodies with myelin-like capsules.

In the hepatocytes of the rat, dieldrin (a chlorinated hydrocarbon pesticide) produces characteristic lesions which develop in three stages: 1. Increase in liver weight and microsomal protein, with SER proliferation, associated with increased activity of aniline hydroxylase and p-nitroreductase as well as a rise in the concentration of P-450 hemoprotein. 2. A "steady state" in which the elevated levels are maintained and tolerance to otherwise fatal doses of dieldrin develops. 3. A "stage of decompensation" elevation of liver weight, microsomal proteins, and P-450 persists, and the SER is abundant but drug-handling enzyme ability is diminished. The authors speak of a hypoactive hypertrophic SER which reflects a stage of exhaustion. [It is interesting to speculate upon the similarity between these three stages and those of the G.A.S. (H.S.).]

In rats, large parenteral doses of **salicylates** increase a number of peroxisomes in multivesicular bodies around the Golgi zone of the hepatocytes but the endoplasmic reticulum remains normal.

In addition to those mentioned above, a large variety of **other drugs** are capable of stimulating the SER of hepatocytes. However, not all of these are effective enzyme inducers.

#### ← **Steroids**

← **Corticoids.** *Selye A 56,607/43*: In chickens, chronic treatment with DOC or methyltestosterone produces hepatic enlargement.

*Selye and Pentz A 59,789/43*: In the rat, many of the toxic manifestations of DOC overdosage are considerably increased by uninephrectomy + NaCl administration. Under these conditions, DOC also produces an unusually pronounced hepatic enlargement.

*Antopol B 47,052/50*: In mice, heavy cortisone overdosage produces considerable atrophy of the liver associated with other manifestations of the alarm reaction.

*Selye B 40,000/50*: Early observations on the induction of hepatic hypertrophy by DOC in the fowl and rat. Cortisone causes involution and sometimes focal necrosis in the rat liver. Unilateral nephrectomy which sensitizes the rat to many toxic actions of DOC, markedly increases its ability to enlarge the liver.

*Timiras & Koch B 53,947/51; B 54,551/52*:

In the rabbit, cortisone causes a pronounced increase in liver weight with glycogen deposition and cellular hypertrophy; DOC has no such effect.

*Clark Jr. & Pesch C 18,864/56*: In female rats kept on an adequate diet, cortisone increases hepatic weight and protein content, although it arrests somatic growth. On a protein-deficient diet, cortisone increases the relative weight of the liver and maintains its protein content.

*Korenchevsky C 18,714/56*: In male rats, testosterone and to a lesser extent cortisone increased hepatic weight.

*Klatskin G 65,221/63*: Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis with special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

*Koike et al. H 15,766/68*: In adrenalectomized mice, cortisone increases protein synthesis

in the liver with the formation of heavy polyosomes within about 30—60 min. However, after 3 hrs, cortisone represses protein synthesis in the mouse liver, and the repressive factor is present in the polysomal fraction and the S-105 fluid. The early and late effects of cortisone are similar in intact mice. The “cytoplasmic repression” factor of the S-105 fluid is larger than that of the polysomal fraction.

*Birchmeier G69,512/69:* In mice, hepatic ultrastructure studies were performed after temporary treatment with cortisone or insulin. “The mean mitochondrial volume increased up to fourfold in the cortisone-treated series and to a much lesser extent in the insulin-treated series. The increase in mean mitochondrial volume was balanced by a decrease in the number of mitochondria per cell such that the total cell mitochondrial volume remained relatively constant. It is suggested that the changes in mitochondrial volume and number were a result of mitochondrial fusion. These changes were temporary. Ten days after the hormone treatment the cells were only slightly different from the control cells.”

*Hines G68,829/69:* Flumedroxone and its unsaturated analogue cause liver enlargement and proliferation of the SER in hepatocytes of mice and rats. This change may be related to the induction by these steroids of certain esterases as previously reported.

*Garg et al. G79,011/71:* In rats, betamethasone and dexamethasone cause mild dilatation and irregularities of the RER in hepatocytes. There is a marked increase in the amount of glycogen granules, and the mitochondria show slight swelling and partial loss of cristae.

← **Adrenalectomy.** *Koike et al. H15,766/68:* In adrenalectomized mice, cortisone increases protein synthesis in the liver (with the formation of heavy polyosomes) within about 30—60 min. However, after 3 hrs, cortisone represses protein synthesis in the mouse liver, and the repressive factor is present in the polysomal fraction and the S-105 fluid. The early and late effects of cortisone are similar in intact mice. The “cytoplasmic repression” factor of the S-105 fluid is larger than that of the polysomal fraction.

*Shigei H27,112/69:* In rats, adrenalectomy, changed the ultrastructure of hepatocytes by reducing the glycogen areas, increasing the number of mitochondria and lysosomes, and inducing vesicular forms of endoplasmic reticulum around the Golgi complexes. All these changes are prevented by cortisol. In partially

hepatectomized rats, adrenalectomy and cortisol also exert antagonistic effects upon hepatocyte ultrastructure.

*Dardacchi et al. G79,006/71:* In rats, metyrapone stimulates the proliferation of SER, even after adrenalectomy.

← **Folliculoids.** *Selye A18,206/39:* In certain strains of mice, heavy overdosage with estradiol or diethylstilbestrol produces considerable increase in the weight of the liver often associated with hepatitis, hepatic necrosis, severe icterus and even death. Estrone and estradiol are somewhat less toxic than diethylstilbestrol.

*Selye & Stevenson 77,177/40:* In Strong's C3H strain mice, the liver shows a transitory increase in weight under the influence of chronic treatment with estradiol or diethylstilbestrol.

*Common et al. B23,003/48:* In immature pullets, estradiol increases the weight, as well as the fat and protein content of the liver. Concurrent treatment with testosterone does not modify these changes but thyroxine i.v. antagonizes them.

*Kotra & Kappas F79,911/67:* Review (7 pp., 40 refs.) on the hepatotoxic action of various steroids (particularly folliculoids) especially in man.

*Kemmer & Müller F89,190/67:* In the mouse, “oestrastilben D” induces mitochondrial swelling and a dilatation of the RER associated with a considerable change in activity of various enzymes, but no obvious proliferation of the SER.

*Klatskin G65,221/69:* Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis with special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

← **Luteoids.** *Emans & Jones H20,754/68:* In hamsters, progesterone increases liver weight and the proliferation of the SER accompanied by chemically demonstrable augmentation of microsomal phospholipid content. The changes are similar to those produced by phenobarbital. Presumably “stimulation by steroids may be responsible in part for the maintenance of microsomal hydroxylases and smooth reticulum in the normal hepatic cell.”

*Klatskin G65,221/69:* Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis with special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

*Bartók et al. G74,513/70:* In rats, six day treatment with lynestrenol caused no light

**Fig. 33. Effect of norbolethone upon the SER in the hepatocytes.** A: Normal hepatocyte of a rat. Nucleus (N), mitochondrion (M), rough endoplasmic reticulum (RER), smooth endoplasmic reticulum (SER).  $\times 16,400$ . B: Hepatocyte after 5 days of norbolethone treatment. Marked proliferation of the SER with comparative scarcity of RER. One vesicle of the SER is continuous with a microbody (arrow).  $\times 16,800$ . [Gardell *et al.* G 60,062/70. Courtesy of J. Micr.]

**Fig. 34. Effect of spironolactone upon the SER of hepatocytes.** A: Untreated rat. Portion of hepatocyte showing the normal nucleus (N), RER and mitochondria (M).  $\times 13,400$ . B: Spiro-nolactone-treated rat. Portions of two hepatocytes. The SER is increased, the mitochondria are essentially normal. Parts of the Golgi complex (G) are visible, as well as lysosomes (L), biliary canaliculi (BC) and the cell border (CB).  $\times 10,600$ . C: Portions of two other hepatocytes in a spironolactone-treated rat. There is again proliferation of the SER. Note also mitochondrion and cell border.  $\times 19,500$ . [Kovaacs *et al.* G60,045/70. Courtesy of Z. ges. exp. Med.]

**Fig. 35. Ultrastructural changes induced by PCN in the hepatocytes.** A: Untreated control rat. Portions of two hepatocytes showing characteristic features of rough endoplasmic reticulum (RER), mitochondria (M), biliary canaliculus (BC) and of the cell border (CB) between the two hepatocytes.  $\times 12,000$ . B: PCN-treated rat. Accumulation of smooth endoplasmic reticulum (SER) in a portion of the hepatocyte in small lipid granules (L).  $\times 11,000$ . [Garg *et al.* G70,474/70. Courtesy of J. Pharm. Pharmacol.]

**Fig. 36. Protection by spironolactone against cardiopathy produced by digitoxin +  $\text{Na}_2\text{HPO}_4$  + oil.**  
 A: Apex of myocardium in the rat after 72 hrs of cardiotoxic treatment. There is an advanced stage of necrosis, the myofibrils (MY) are almost completely destroyed and the glycogen granules have virtually disappeared. The mitochondria (M) show vacuoles with destruction of their internal structure. Occasional lipid (L) granules are visible.  $\times 20,000$ . B: Region from the cardiac apex of a rat which in addition to the cardiotoxic treatment has received spironolactone. The ultrastructure is virtually normal. Z-band (Z), sarcoplasmic reticulum (SR).  $\times 14,000$ . [Gardell *et al.* G 60,065/70. Courtesy of Path. Biol.]

microscopically visible hepatic changes but the electron microscope revealed increased vacuole formation in the Golgi apparatus without any alterations of the endoplasmic reticulum.

← **Testoids.** *Selye A18,308/39*: In mice, large doses of testosterone sufficient to cause ovarian and adrenal atrophy as well as renal hypertrophy did not significantly alter the weight of the liver.

*Common et al. B23,003/48*: In immature pullets, estradiol increases the weight, as well as the fat and protein content of the liver. Concurrent treatment with testosterone does not modify these changes but thyroxine i.v. antagonizes them.

*Korenchevsky C18,714/56*: In male rats, testosterone and, to a lesser extent, cortisone increased hepatic weight.

*Goldfischer et al. D20,605/62*: In rats treated with norethandrolone, and even more strikingly in those given icterogenin, the capacity to excrete conjugated bilirubin is impaired although light microscopically no obvious hepatic change is noted. There are, however, histochemical and electron microscopic lesions in hepatocytes and bile canaliculi.

*Krüskenper & Noell G48,300/66*: Methyltrienolone (17 $\alpha$ -methyl-4,9,11-estratriene-17 $\beta$ -ol-3-one), though a strong anabolic agent, is definitely hepatotoxic as judged by various function tests in man.

*Petzold & Ziegler F92,832/67*: The fat and phosphatase accumulation in the liver remnant of partially hepatectomized rats is enhanced by prednisone. 4-Chlorotestosterone does not significantly affect the tissue phosphatase but delays the removal of fats from the liver.

*Klatskin G65,221/69*: Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

*Gardell et al. G60,062/70*: In the rat, norbolethone an active catatoxic steroid produces pronounced proliferation of the SER in hepatocytes, presumably a morphologic reflection of increased microsomal enzyme production.

*Mikuni et al. H28,797/70*: In rats, norethandrolone decreased iodipamide (Biligradin) excretion into the bile. In electron micrographs, the pinocytic vesicles and lysosomes of Kupffer cells and hepatocytes contained a homogenous material interpreted to be deposits of the injected X-ray contrast medium.

← **Antitestoids.** *Kovács et al. G70,476/71*: In rats, cyproterone acetate p.o. causes marked

proliferation of the SER in hepatocytes, perhaps reflecting microsomal-enzyme induction.

← **Catatoxic Steroids.** *Horvath et al. G70,405/70*: Both in intact and in partially hepatectomized rats, spironolactone increases the weight of the liver and the mitotic activity of hepatocytes.

*Horvath et al. G70,408/70*: In rats "treatment with the most active catatoxic steroids (spironolactone, norbolethone, SC-11927, ethylestrenol) invariably induced marked proliferation of the SER. Progesterone and testosterone had a less pronounced effect. However, alterations of the endoplasmic reticulum can also be produced by some non-catatoxic steroids (estradiol) or non-steroidal compounds (stilbestrol). Thus it can be concluded that there is no close correlation between the catatoxic potency and the proliferation of the SER although all the catatoxic compounds tested lead to a marked transformation of the endoplasmic reticulum in the hepatocytes."

*Kovács et al. G60,045/70*: In the rat, spironolactone given in amounts suitable to produce a catatoxic effect causes marked proliferation of smooth-surfaced endoplasmic reticulum in hepatocytes. This change presumably reflects and induction of drug-metabolizing microsomal enzymes and may explain why spironolactone protects against the injurious effects of different compounds.

*Garg et al. G70,474/70*: In rats, PCN causes proliferation of the SER in the hepatocytes, with some swelling of the mitochondria and a moderate increase in the lipid content of hepatocytes, as well as some hypertrophy of the microvilli in the bile canaliculi.

*Garg et al. G60,031/71*: In rats, PCN p.o. induced proliferation of the SER in hepatocytes. At the high dosage used, it also caused disorganization of the RER, a slight increase in ribosomal granules and lipid droplets with mitochondrial injury and myelin figure formation.

*Garg et al. G79,002/71*: In rats, PCN p.o. induces proliferation of SER even after hypophysectomy.

*Garg et al. G70,495/71*: In rats, phenobarbital, 3-MC, spironolactone, cyproterone and PCN cause proliferation of the SER in hepatocytes without producing marked changes in other cell organelles. In comparing electron microscopic with biochemical and toxicity studies "it seems that there is no obligatory parallelism between SER proliferation and catatoxic potency. However, it is clear that all

catatoxic substances tested so far, lead to SER accumulation."

*Garg et al. G79,008/71:* In rats, hypophysectomy causes a decrease of SER and glycogen granules as well as disorganization of the RER. PCN induces SER proliferation in the hepatocytes even after hypophysectomy.

*Garg et al. G79,030/71:* In rats, neither spironolactone nor PCN prevents the dilatation, disorganization and breakdown of the RER induced by dactinomycin.

*Horvath et al. G70,490/71:* In rats, the SER of the hepatocytes proliferates under the influence of CS-1. Ethylestrenol, oxandrolone, and hydroxydione are less effective; progesterone, testosterone, estradiol, stilbestrol, prednisolone, triamcinolone, and DOC are virtually inactive in this respect.

*Khandekar et al. G79,014/71:* In rats, cycloheximide elicited nucleolar alterations in hepatocytes with disruption, dilatation, degranulation and ballooning of the RER. Accumulation of SER also occurred when spironolactone or PCN was administered one hour before cycloheximide. It is concluded "that the steroids enhance the metabolic degradation of cycloheximide and thus SER proliferation is not inhibited; that this morphologic change does not always denote enzyme induction and the two can therefore be dissociated; or that SER accumulation is a nonspecific response to cellular injury."

*Khandekar et al. G79,026/71:* In rats, the hepatic SER proliferation induced by spironolactone or PCN is not prevented by concurrent administration of cycloheximide. Either the catatoxic steroids enhance the metabolic degradation of cycloheximide (thereby blocking its effect upon the SER) or this morphologic change does not necessarily indicate active enzyme induction.

*Solymoss et al. G79,015/71:* In rats, PCN (unlike the naturally-occurring pregnenolone) enhances the plasma clearance of pentobarbital and the production of <sup>14</sup>C-pentobarbital metabolites. It also increases liver weight, microsomal protein concentration, NADPH-cytochrome c-reductase activity and cytochrome P-450 content. It is concluded "that microsomal enzyme-induction accounts for the remarkable resistance-increasing effect of this steroid against many toxicants."

*Szabo et al. G79,024/71:* In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent

the induction of SER proliferation in the hepatocytes.

*Tuchweber et al. G79,020/71:* In rats, PCN causes liver hypertrophy with SER proliferation, even if administered during pregnancy.

*Tuchweber et al. G79,031/71:* In pregnant rats, PCN produces the usual characteristic SER accumulation associated with the formation of intramitochondrial lamellae whose significance is not clear.

← **Other Steroids.** *Goldfischer et al. D20,605/62:* In rats treated with norethandrolone, and even more strikingly in those given icterogenin, the capacity to excrete conjugated bilirubin is impaired although light microscopically no obvious hepatic change is noted. There are, however, histochemical and electron microscopic lesions in hepatocytes and bile canaliculi.

*Kotra & Kappas F79,911/67:* Review (7 pp., 40 refs.) on the hepatotoxic action of various steroids (particularly folliculoids) especially in man.

*Song & Kappas G68,413/68:* Review (48 pp., numerous refs.) on the influence of folliculoids, luteoids and pregnancy upon the structure and chemical composition of the liver.

*Song et al. G70,575/69:* Review (34 pp., 390 refs.) on the effect of various steroid hormones and pregnancy upon hepatic function in animals and man.

#### ← **Nonsteroidal Hormones and Hormone-Like Substances**

← **Anterior Pituitary Hormones.** *Selye A75, 044/44:* In rats, crude lyophilized anterior pituitary extracts cause not only hepatic enlargement, but also infiltration of the liver with hemopoietic cells and megakaryocytes. However, this response may not be entirely specific since various impure protein extracts (especially if they are infected) can cause ectopic hemopoiesis in rodents.

*Selye and Nielsen 84,644/44:* In rats, crude anterior pituitary extracts cause disproportionate hepatic weight increase, hence the effect cannot be merely considered to be one aspect of the general growth-promoting effect of pituitary STH.

*Baker et al. B26,490/48:* In rats maintained on a high-carbohydrate diet, ACTH produced a specially pronounced hepatic steatosis.

*Li and Evans B29,320/48:* In intact (unlike in hypophysectomized) rats, purified STH causes disproportionate hepatic enlargement, possibly by stimulating the secretion of a hypophyseal "hepatotropic principle."

*Payne B32,809/49*: In rats (especially if they are maintained on high carbohydrate diets or force-fed) ACTH causes fatty degeneration of the liver. This effect can be prevented by adrenalectomy. Particularly pronounced hepatotropic effects are obtained in rats upon combined treatment with ACTH + STH.

*Selye 94,572/49*: In rats, treatment with crude anterior pituitary extracts causes a disproportionate increase in hepatic weight. Particularly pronounced hepatotropic effects have been obtained in rats upon combined treatment with ACTH + STH.

*Garg et al. G79,008/71*: In rats, hypophysectomy causes a decrease of SER and glycogen granules as well as disorganization of the RER. PCN induces SER proliferation in hepatocytes even after hypophysectomy.

← **Thyroid Hormones.** *Common et al. B23,003/48*: In immature pullets, estradiol increases the weight, as well as the fat and protein content of the liver. Concurrent treatment with testosterone does not modify these changes but thyroxine i.v. antagonizes them.

*Selye 94,572/49*: High doses of thyroxine may cause functional or even structural hepatic damage in various species including man.

*Stenram B69,173/52*: In rats, thyroid feeding increases hepatic weight and produces diffuse basophilia and palisade-like basophilic rods in the cytoplasm of the hepatocytes. Similar structures had been described previously, by others, after epinephrine treatment or acute bleeding.

*Fautrez et al. C23,124/55*: In rats, thiourea stimulates mitotic proliferation in hepatocytes.

*Scharf et al. F69,957/66*: In rats, chronic treatment with methylthiouracil of paroxypion (POP) produces essentially similar hepatic lesions. T2 reduces liver glycogen and the size of the hepatocytes. Single large doses of alloxan cause severe necrotizing lesions followed by cell proliferation. Concurrent treatment with methylthiouracil inhibits the alloxan-induced hepatic lesions and diminishes mortality.

*Funahashi F98,400/67*: In rats overdosed with thyroxine, as well as in thyrotoxic patients, the hepatic SER shows no important changes.

*Klatskin G65,221/69*: Review (103 pp., 809 refs.) on toxic and drug-induced hepatitis with special sections on the hepatotoxic effect of testoids, corticoids, thioureas, luteoids, folliculoids and oral antidiabetics.

*Stenram G70,339/69*: The literature on the effects of thyroid hormone upon the ultra-

structure of hepatocytes is reviewed. Personal observations on the rat, show disappearance of cytoplasmic glycogen. "Mitochondria, endoplasmic reticulum, and free ribosomes and polysomes are evenly distributed all over the cytoplasm. There seems to be an increase in the ratio of free to membrane-bound ribosomes and polysomes in the thyroid-fed rats."

← **Pancreatic Hormones.** *Birchmeier G69,512/69*: In mice, hepatic ultrastructure studies were performed after temporary treatment with cortisone or insulin. "The mean mitochondrial volume increased up to fourfold in the cortisone-treated series and to a much lesser extent in the insulin-treated series. The increase in mean mitochondrial volume was balanced by a decrease in the number of mitochondria per cell such that the total cell mitochondrial volume remained relatively constant. It is suggested that the changes in mitochondrial volume and number were a result of mitochondrial fusion. These changes were temporary. Ten days after the hormone treatment the cells were only slightly different from the control cells."

#### ← **Drugs**

← **Barbiturates.** *Remmer & Merker D61,064/63*: In the rat, hepatic microsomal-enzyme induction by phenobarbital is associated with a proliferation of the hepatic SER.

*Remmer & Merker E36,389/63*: In the rabbit, "repeated administration of phenobarbital and several other drugs results in a quantitative increase of the smooth endoplasmic reticulum of the liver cell. The marked increase in drug-metabolizing enzymes is found to occur in this enlarged smooth membrane fraction of the endoplasmic reticulum."

*Jones & Armstrong F51,262/65*: In the hamster, the hepatic SER undergoes hypertrophy following treatment with phenobarbital and, at the same time, cholesterol biosynthesis is increased.

*Orrenius et al. G66,249/65*: Ultrastructural studies on the hepatic endoplasmic reticulum in relation to phenobarbital-induced synthesis of microsomal drug-metabolizing enzyme systems in the rat.

*Burger & Herdson G66,499/66*: In the rat, phenobarbital causes liver enlargement and ultrastructural changes characterized by "proliferation of smooth endoplasmic reticulum with concomitant shortening and dispersion of rough endoplasmic cisternae, mitochondrial abnormalities, and the development of myelin figures. The morphologic abnormal-

lities at first affect only central cells, but progressively involve cells further out in the lobule so that after medication for 10 days most of the lobule is involved. Nevertheless, a peripheral zone of normal-looking cells is always present." Concurrent treatment with SKF 525-A further aggravates these changes, but SKF 525-A itself causes no detectable abnormalities in the liver.

*Koudstaal & Hardonk G69,482/69*: In male rats given phenobarbital i.p., "enzymohistochemically an increase in activity was noted for NADPH tetr. red., G6PD, ICD, and Naftol AS-D-esterase; a decrease was seen in G6Pase and glycogen, but no difference was found in NADH tetr. red. From these results it has been suggested that NADPH tetr. red. is directly involved in the hydroxylation chain, while G6PH and ICD are more indirectly involved."

*Chiesara et al. G75,314/70*: In rats, a single injection of phenobarbital suffices to stimulate the SER and to increase the hexobarbital and strychnine-metabolizing enzyme activity of the hepatic microsomes. The effect of partial hepatectomy, performed either immediately before or at various times after the administration of the inducer drug, was investigated in relation to these phenomena.

*Franken & Hagelskamp H28,823/70*: Review (4 pp., 58 refs.) on hepatic lesions produced by barbiturates.

*Brodie et al. G80,473/71*: In rats, pretreatment with phenobarbital greatly facilitates the production of hepatic necrosis by bromobenzene and other chemically inert halogenated hydrocarbons. Radioautographic and other studies suggest that "a number of aromatic halogenated hydrocarbons are converted by microsomes in vitro to active intermediates which form covalent complexes with glutathione (GSH)."

← **Carbon Tetrachloride.** *Meldolesi et al. G69,793/68*: In rats,  $\text{CCl}_4$  greatly increases the proliferation of the SER in hepatocytes and the incorporation of  $^{32}\text{P}$  in structural membrane phospholipids. Concurrently, protein synthesis is greatly impaired. Presumably,  $\text{CCl}_4$  stimulates the rate of synthesis only of abnormal microsomal membranes.

*Smuckler G80,996/68*: Brief report on the structural and functional alterations of the endoplasmic reticulum in the hepatocytes of rats intoxicated with  $\text{CCl}_4$ . "The morphological alterations that have been observed include a dilation and vesiculation of the cisternae of the endoplasmic reticulum, a loss of ordered array of free ribosomes in the cytoplasm and on the

endoplasmic reticulum, a dispersal of ribosomes from the membrane surface, and the formation of dense smooth-membrane aggregates." The associated changes in protein synthesis, microsomal electron transport, etc., are briefly noted.

← **Chlorazanyl.** *Hyde & Davis F82,461/66*: Both cortisol and the diuretic drug chlorazanyl depress mitotic division in the regenerating liver of the mouse, following partial hepatectomy.

← **Clofibrate.** *Kaneko et al. H19,398/69*: In rats, clofibrate at first causes deformation of hepatic mitochondria and depletion of succinic oxidase but these changes disappear within 24 hrs. At 12 hrs after administration of the drug, the SER proliferates, reaching maximal development on the 4th day conjointly with an increase in drug-metabolizing enzyme activity. After 24 hrs there begins an increased formation of microbodies without nucleoides.

← **Dieldrin cf. Pesticides**

← **Digitalis.** *Arcasoy & Smuckler C63,705/69*: In the rat, a single sublethal dose of digitoxin causes proliferation of the hepatic SER and, concomitantly, an increase in aromatic ring hydroxylation and microsomal cytochrome P-450. Presumably, "digitoxin may induce in the liver enzyme systems capable of glycoside metabolism."

← **Ethanol.** *Leevy & Paumgartner G72,234/68*: In three volunteers who developed alcoholic hepatitis on an ethanol + low-protein regimen, jaundice appeared only in advanced stages of liver necrosis and inflammation. In earlier stages, there was proliferation of SER which was further increased by norethandrolone and yet, this anabolic reduced serum bilirubin.

*Mincis H30,210/70*: In patients, hepatic biopsies taken after ingestion of large amounts of ethanol show various ultrastructural lesions including the proliferation of SER lamellae which take on a vesicular form.

← **Metyrapone.** *Magalhães & Magalhães G76,648/70*: In rats treated with metyrapone, the SER of the hepatocytes becomes hypertrophic currently with glycogen depletion. Hepatic slices incubated with metyrapone show no ultrastructural changes. The effect of metyrapone is ascribed to increased production of  $11\beta$ -hydroxylated corticoids.

*Dardachti et al. G79,006/71*: In rats, metyrapone stimulates the proliferation of SER, even after adrenalectomy.

← **Pesticides.** *Ortega G76,671/66*: Detailed description of the electron microscopic changes

in the livers of rats treated with DDT. There was marked proliferation of the SER, inclusion bodies appeared to represent specialization of this system with myelin-like capsules. These changes were compatible with protein synthesis, glycogen storage and normal weight gain. Necrosis, cirrhosis or bile-duct proliferation were not observed.

*Ortega H 15,674/69:* In rats pretreated with DDT for four months, partial hepatectomy was followed by an essentially normal liver regeneration, yet it developed much more rapidly than after DDT or partial hepatectomy alone.

*Hutterer et al. G 66,323/69:* In rats given daily injection of dieldrin (a chlorinated hydrocarbon pesticide) i.p. hepatic changes developed in three stages. "The first stage, that of induction, is characterized by an increase in liver weight, microsomal protein, smooth endoplasmic reticulum, the activity of aniline hydroxylase and p-nitroreductase, and the concentration of P-450 hemoprotein. During the second stage, a 'steady state,' the elevated levels are maintained and tolerance to otherwise fatal doses of dieldrin prevails. In the third stage, that of decompensation, elevation of liver weight, microsomal proteins, and P-450 hemoproteins persists, and the smooth endoplasmic reticulum appears as abundant as in the previous stages, but the activity of the drug-handling enzymes decreases. The smooth endoplasmic reticulum, however, in this last stage consisted of packed tubules. This hypotrophic, hypertrophic, smooth endoplasmic reticulum is accompanied by biochemical and morphologic alterations of mitochondria." 3'-Methyl-4-dimethylaminoazobenzene (butter yellow) produces an essentially similar but accelerated three-stage response.

*Kimbrough et al. G 81,969/71:* In rats, DDT and dieldrin reduce hexobarbital sleeping time, increase liver weight and cause proliferation of the SER with the formation of a typical mitochondria which often contain numerous longitudinally arranged parallel cristae.

← **Phenylbutazone.** *Klinger et al. H 28,896/70:* In rats, phenylbutazone reduces hexobarbital sleeping time and increases the fresh weight of the liver as well as the ability of the hepatic 9000 g supernatant to enhance aminophenazone-N-demethylation. An increase in the ascorbic acid concentration of the liver was noted only in young animals but urinary excretion of ascorbic acid was as pronounced as after barbital treatment. Phenylbutazone administration to the pregnant mother failed

to elicit an induction effect in the fetuses as judged by hepatic ascorbic acid determinations and by ultrastructural studies of the fetal livers. Proliferation of the SER was obtained by phenylbutazone in 10-day-old or older rats, often in association with an increase in the number of lysosomes and mitochondrial changes as well as by evidence of intrahepatic cholestasis.

← **Salicylates.** *Bullock et al. G 73,358/70:* In rats, given large parenteral doses of N-salicylate, there was an electronmicroscopically detectable "early increase in the number of peroxisomes, and multivesicular bodies were in evidence around the Golgi zone. The endoplasmic reticulum and attached ribosomes exhibited a normal appearance." The corresponding changes in plasma and hepatic enzyme activity are described.

← **W-1372.** *Khandekar et al. G 79,016/71:* In rats, W-1372 in oil p.o. causes hepatic steatosis with liposome accumulation, dilatation disorganization, ballooning and degranulation of the RER.

*Kovacs et al. G 79,003/71:* In rats, W-1372 causes electron microscopic changes in the liver characterized by "accumulation of lipid droplets and liposomes, progressive dilatation, disorganization and degranulation of the RER, injury to mitochondria and distension of the sacs of the Golgi apparatus." [This is of interest in view of earlier findings showing that depending upon dosage, W-1372 can produce hepatic necrosis and death or induce resistance to many of the drugs amenable to detoxication by catatoxic steroids (H.S.).]

*Selye & Lefebvre G 79,005/71:* In rats, W-1372 causes hepatic enlargement and fatty degeneration, often with necrosis, if the compound is administered in vegetable oil. W-1372 is much less toxic when given in propylene glycol, mineral oil or DMSO, and virtually nontoxic in water.

#### ← **Hepatic Lesions**

*Rigatuso et al. G 80,722/70:* In rats, partial hepatectomy enhances microbody formation in the liver remnant. "It is suggested that the formation of new microbodies from pre-existing microbodies may be an important general method of microbody proliferation."

*Rohr et al. H 30,433/70:* In rats, an ultrastructural morphometric study of liver cells has been performed during the early regenerative phase after partial hepatectomy.

*Stenram et al. H30,015/70*: In rats fed low- or high-protein diets, liver ultrastructure and RNA-labelling was studied after partial hepatectomy. "The results suggest that the protein-deprived rats have a good ability to regenerate liver cell structures after partial hepatectomy, that their enlarged liver cell nucleoli have a high synthesis of RNA, and that the processing and delivering of nucleolar RNA to the cytoplasm proceeds in a normal way."

#### ← *Bile Duct Ligation*

*Hutterer et al. G75,925/70*: In rats, 4 days after bile duct ligation the activity of aminopyrine demethylase was greatly decreased, while the content of cytochrome P-450 and the activities of aniline hydroxylase, NADPH-cytochrome c reductase, and cytochrome P-450 reductase were only slightly decreased in the hepatic microsomes. Binding of type II substrate to cytochrome P-450 was unimpaired and its modifier effect on P-450 reductase was intact. The binding of type I substrate was greatly decreased, and its stimulating effect on P-450 reductase was abolished. Presumably cholestasis alters the type I binding sites of the hepatic SER, which is responsible for the hypoactivity of the biotransformation system.

#### ← *Sex*

*Koudstaal and Hardonk G78,115/70*: Enzyme histochemical studies suggest that "the difference in hydroxylating capacity between male and female rats may be caused by the fact that the number of cells with hydroxylating activity in the liver lobule, as judged by the NADPH-nitro-BT reductase and Naphthol-AS-D esterase activity, is higher in male than in female rats."

#### ← *Tumors*

*Theologides & Zaki H19,577/69*: In C3H mice bearing transplanted mammary carcinomas s.c., increased mitotic activity in the liver remnant after partial hepatectomy began earlier than in controls.

*Kovacs et al. G46,737/71*: In rats bearing Walker tumor transplants, the RER is dilated, disorganized and degranulated, whereas the SER proliferates.

#### ← *Varia*

*Fouts D43,347/62*: A review of evidence suggesting that the SER of the liver is responsible for the induction of drug-metabolizing enzymes.

*Remmer G67,786/64*: Review (20 pp., 55 refs.) on the relationship between hepatic microsomal-enzyme induction and the development of the SER.

*Fouts & Rogers F29,497/65*: In the rat, "phenobarbital and chlordan stimulate a variety of microsomal drug metabolisms and also appear to cause a marked proliferation of smooth-surfaced endoplasmic reticulum (SER) in the hepatic cell. Benzpyrene and methylcholanthrene stimulate only a few microsomal drug metabolizing enzymes and do not appear to cause any pronounced increase in hepatic cell SER."

*Conney F88,649/67 (p. 334)*: Review of the literature on the participation of the SER in the induction of drug-metabolizing hepatic enzymes.

*Meldolesi G66,053/67*: A review of the literature shows that the following drugs are capable of producing hypertrophy of the SER: ethionine, dimethyl-, and diethylnitrosamine, 2-aminofluorene, flurenyldiacetamide, thioacetamide, p-dimethylaminoazobenzene, 3,4-benzopyrene, p-dimethylcholanthrene,  $\alpha$ -naphthylisothiocyanate, SKF 525-A, carbon tetrachloride, chlordan, DDT, ethanol, phosphorus, phenobarbital, Bax 422 Z (a thiohydantoin derivative), cysteine, 2-methyldiazobenzene, nikethamide, tolbutamide. In some cases, this hypertrophy is associated with an increased, in others with a decreased microsomal enzyme activity. Possibly, "SER hypertrophy may be produced by one and the same mechanism and all substances capable of producing SER hypertrophy may act as inducers of microsomal enzymes, thus stimulating hepatic cell to produce both endoplasmic reticulum membranes and enzymes. However, some of these substances, or their metabolites, are inhibitors of protein synthesis. In this case synthesis of new enzyme molecules is impossible and the response of the hepatic cell to the pharmacological stimulus is limited to the formation of the SER membranes."

*EXTRAHEPATIC TISSUES* ←*Endocrine Glands* ←

Partial hepatectomy protects the rat against the production of **adrenal** necrosis by DMBA. A similar inhibition is obtained by CCl<sub>4</sub> pretreatment.

In patients treated with spironolactone, concentric lamellar formations ("spironolactone bodies") develop in the adrenal cortical cells. Electronmicroscopically, these phospholipid-containing structures correspond to concentric whorls of SER which may reflect a compensatory increase in mineralocorticoid secretion.

In rats, phenobarbital and PCN produce **thyroid** hypertrophy and hyperplasia which are inhibited by hypophysectomy or thyroxine. These changes may correspond to an increased TTH secretion evoked by interference with the biosynthesis of thyroid hormones or an increase in their metabolic degradation.

*Other Tissues* ←

In rats treated with DDT or some of its analogues, a folliculoid effect upon the **uterus** occurs even after ovariectomy. The effect is inhibited by CCl<sub>4</sub> and may depend upon the conversion of DDT into folliculoids.

Spironolactone pretreatment inhibits the ultrastructural changes characteristic of the **myocardial necroses** produced in rats by digitoxin + Na<sub>2</sub>HPO<sub>4</sub> + oil.

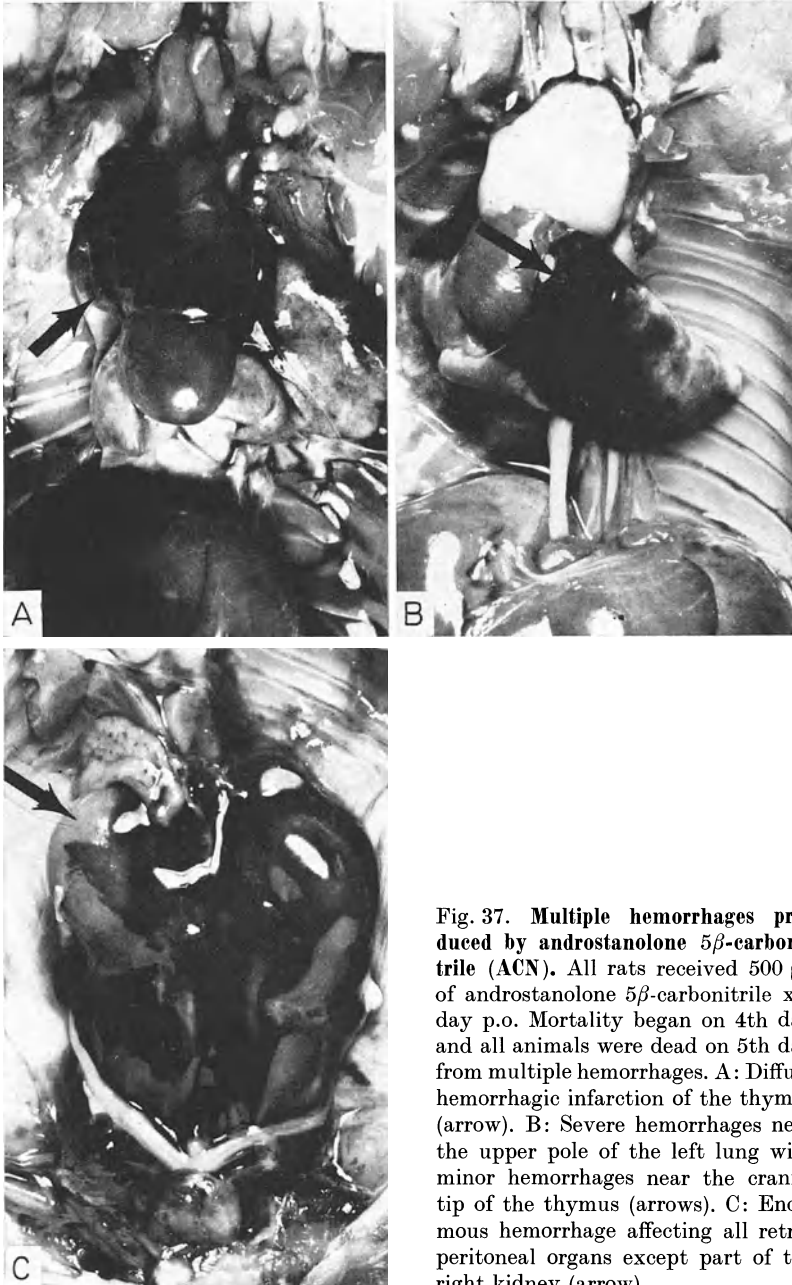

An entirely unexpected side effect of one of the steroids tested for catatoxic activity was its anticoagulant property, which resulted in **multiple hemorrhages** affecting primarily the facial connective tissue and the thymus of the rat. Such changes had been seen exceptionally in our earliest work with PCN, and even then only with huge doses (25 mg twice daily p.o.). Little attention was attached to this side effect since as much as 30–50 μg of PCN possesses sufficient catatoxic potency to protect the rat against otherwise fatal doses of indomethacin or digitoxin. However, recently we noted that very small doses of androstanolone-5β-carbonitrile (ACN) occasionally produce a similar hemorrhagic syndrome within a few days, although the compound appears to be totally devoid of catatoxic activity. These findings suggest that the anticoagulant effect of steroids can be separated from their catatoxic potency; indeed, it may represent another independent pharmacologic action, since ACN is not known to possess any of the classical hormonal properties either. Yet, further work will be required to prove this point with certainty, since death from multiple hemorrhages interferes with the bioassay of ACN at high dose levels. In any event the production of hemorrhages is so inconstant that it may depend on variable amounts of some contaminant.

*Endocrine Glands* ←

*Wheatley et al. F68,548/66:* Partial hepatectomy protects the adrenals of the rat against the hemorrhagic necrosis produced by DMBA. On the other hand, "operative stress," as in sham-hepatectomy or nephrectomy, actually increases the susceptibility of the adrenals to DMBA. Other factors influencing DMBA-induced adrenal necrosis are reviewed.

*Colafranceschi & Tosi G61,860/67:* The induction of adrenal necrosis by DMAB is inhibited in the rat by pretreatment with CCl<sub>4</sub> or partial hepatectomy. The results confirm the view that DMBA becomes toxic only after it is metabolized in the liver.

*Japundzic G74,862/69:* In rats, phenobarbital produces thyroid enlargement with hypertrophy and hyperplasia of the follicular cells. This effect is inhibited by hypophysecto-

**Fig. 37. Multiple hemorrhages produced by androstanolone  $5\beta$ -carbonitrile (ACN).** All rats received  $500\ \mu\text{g}$  of androstanolone  $5\beta$ -carbonitrile x2/day p.o. Mortality began on 4th day and all animals were dead on 5th day from multiple hemorrhages. A: Diffuse hemorrhagic infarction of the thymus (arrow). B: Severe hemorrhages near the upper pole of the left lung with minor hemorrhages near the cranial tip of the thymus (arrows). C: Enormous hemorrhage affecting all retroperitoneal organs except part of the right kidney (arrow)

my or thyroxine and may therefore be ascribed to increased TSH secretion. Earlier data on the effect of thiopental and other barbiturates upon the thyroid are reviewed. Possibly barbiturates interfere with the biosynthesis of thyroid hormones, increase their metabolic degradation or their storage in the liver.

*Davis & Medline G76,611/70*: Description of concentric lamellar formations, the so-called "spironolactone bodies," in the adrenal cortical cells of patients treated with spironolactone. Earlier literature is described. "These phospholipid-containing bodies, as disclosed by electron microscopy, are concentric whorls of smooth membranes arranged in a pattern similar to that in many organs under experimental conditions . . . the authors believe that these structures represent a compensatory attempt on the part of the cell to produce increased mineralocorticoid."

*Selye G70,480/71*: In rats, unusually large doses of PCN produce thyroid hyperplasia and hypertrophy.

#### **Other Tissues ←**

*Welch et al. G65,737/69*: In rats, DDT and some of its analogs exhibit a folliculoid effect

upon the uterus, even after castration. Since this action is inhibited by  $\text{CCl}_4$ , it may depend on the conversion of DDT analogs into folliculoids.

*Gardell et al. G60,065/70*: In rats, spironolactone pretreatment inhibits the ultrastructural changes characteristic of the myocardial necroses induced by digitoxin +  $\text{Na}_2\text{HPO}_4$  + corn oil.

*Selye PROT. 35304*: In rats 500  $\mu\text{g}$  of androstanolone-5 $\beta$ -carbonitrile (ACN) x2/day p.o. occasionally causes multiple, eventually fatal, hemorrhages affecting most frequently the thymus and the retroperitoneal organs, but sometimes also the lung, the facial connective tissue and other sites. The blood remains incoagulable even many hours after being shed. Subsequent experiments have shown that almost the same effect is produced at a dose level of 100  $\mu\text{g}$  x2/day or even less. When given at enormous dose levels (e.g., 25 mg x2/day p.o.), PCN can produce similar manifestations, but ACN is the only steroid known to possess a high degree of anticoagulant potency. It remains to be seen whether any of the naturally occurring steroids can exert similar effects under appropriate conditions.

## X. THEORIES

In this last section, we shall survey the theories concerning the role of hormones in the maintenance of resistance in general, as well as current concepts concerning certain links in the mechanism of individual, hormonally controlled resistance phenomena. This chapter is based upon what we have learned from the entire literature on the subject as listed in all the other sections of this monograph. Hence, the abstracts supporting our discussion will often be found elsewhere in this book; only those of the most pertinent original publications are reproduced here. In agreement with the general principles that have guided us throughout this treatise, major emphasis will be placed upon the newly discovered catatoxic actions of steroids, particularly on their effect upon general resistance through the induction of hepatic enzymes. However, for comparative purposes, some resistance effects of syntoxic hormones and a few extrahepatic defense mechanisms will also be considered.

The main theoretic problems shall be classified as follows:

1. Hepatic participation in general;
2. The role of hepatic enzymes;
3. SER and microsomes;
4. RNA and DNA;
5. Lysosomes;
6. Reticulo-endothelial system (RES);
7. Hepatic glycogen;
8. Vitamin C;
9. Defense against "natural" vs. "foreign" compounds;
10. Stressors;
11. Homeostasis and the nonspecificity of steroid-induced resistance.

### *1. HEPATIC PARTICIPATION IN GENERAL*

*cf. also Abstract Sections under "History," "General Pharmacology,"  
"← Hepatic Lesions"*

It has been demonstrated beyond any possible doubt that most of the known protective effects of steroids against exogenous or endogenous toxicants depend upon the stimulation of defensive responses in hepatic tissue. Perhaps, most important among these defensive reactions is the induction of the so-called drug-metabolizing microsomal enzymes. However, undoubtedly other phenomena are also involved in many cases: activation of enzymes which regulate intermediate metabolism in general provides building blocks for structural or enzymic proteins; stimulation of the Kupffer cells or increased storage in hepatocytes can offer temporary protection against acute flooding of the blood with poisons until they are gradually excreted or inactivated through other mechanisms.

Yet, the liver is rarely the only organ involved in detoxication. Usually, toxicants are first subjected to biotransformation — for example in the SER — into compounds especially suitable for elimination through the urine or bile. In this respect, the transformation of a nonpolar toxicant into a more polar metabolite offers the advantage of making it unsuitable for reabsorption by the renal tubules after its filtration through the glomerulus; normally the ready reabsorption of lipid soluble compounds prevents their elimination. However, even the hormonal control of biliary excretion depends not only upon a cholagogue effect; it is also modified by biotransformations which render compounds more or less suitable for excretion into the bile.

Evidence showing the relative importance of these hepatic activities has been obtained by many techniques, e.g.: the increase in sensitivity to toxicants induced by partial or complete hepatectomy and hepatotoxic agents, or the decrease in the *in vivo* activities of many agents when they are forced to traverse the liver before getting into the general circulation. The latter can be accomplished in many ways, for example by administration per os or through the portal vein, injection of drugs and hormones (or implantation of hormone-producing glands) into the spleen or other parts of the portal area.

Additional evidence of hepatic detoxication has been obtained by the demonstration that certain toxicants are inactivated by incubation with liver slices, liver homogenates and various liver fractions (e.g., those rich in microsomes). Biliary excretion has been followed by the chemical determination of toxicants or their metabolites in bile obtained through a fistula. The importance of the enterohepatic circulation could frequently be demonstrated by the observation that the effects of a drug are diminished or abolished following ligation of the choledochus. As has been shown by the literature cited in the sections referred to, virtually all these forms of hepatic participation in detoxication mechanisms are influenced by one or the other hormonal principle.

In connection with the action of catatoxic steroids, the most important mechanisms involved in hepatic detoxication are the induction of enzymes in the membrane systems of the endoplasmic reticulum which become smooth (SER) and break up into small vesicles, the microsomes.

*Zondek 30,531/34:* Estrone injected into a mouse rapidly disappears and can no longer be extracted from its tissues. On theoretic grounds, it is assumed that hepatic enzymes are responsible for this inactivation.

*Weiner et al. H24,942/70:* In rats, glucagon, alloxan and starvation all increased hexobarbi-

tal sleeping time. This effect was markedly antagonized by insulin. Perhaps, cyclic AMP may be involved since theophylline greatly increases the action of glucagon. This synergism also occurred in isolated, perfused rat livers and, hence, "inhibition of hexobarbital metabolism by cyclic AMP would appear to be mediated in the liver."

## 2. THE ROLE OF HEPATIC ENZYMES

It has been demonstrated in various ways that synthesis of new enzyme protein, rather than mere enzyme activation, is involved in the increased biotransformation of various substrates by hormonal and nonhormonal catatoxic substances. For example in the rat, the induction of hepatic TKT by cortisol is associated with an equivalent

increase in enzyme antigen. Tryptophan also induces significant increases in hepatic TKT activity. Isotope incorporation studies, combined with the analysis of the time course of changing enzyme levels, indicate that cortisol accelerates the rate of enzyme synthesis, whereas tryptophan acts predominantly by decreasing the rate of enzyme degradation. Certain additional studies suggest, however, that some enzyme activation may also play a role in connection with the augmentation of TPO and TKT.

The defensive role of TPO induction has by no means been demonstrated. It is true that in mice, endotoxin lowers TPO, whereas glucocorticoids which increase endotoxin resistance augment TPO activity. However,  $\alpha$ -methyltryptophan maintains TPO activity without increasing survival and 5-hydroxytryptophan lowers TPO activity without sensitizing to endotoxin.

The so-called nonspecific drug-metabolizing hepatic enzymes are presumably subject to similar regulatory mechanisms. It is difficult to understand why these systems are so largely nonspecific. It has been assumed that either a multitude of specific oxidases or an oxidase of remarkable nonspecificity is at work. There are arguments in favor of both these possibilities. It must not be forgotten however that the degree of the nonspecificity of protection (and hence presumably of enzyme induction) is subject to great variations. Probably none of the microsomal enzyme inducers is completely specific, but some act only against few, others against many toxicants, and the particular combination of substrates inactivated by any one inducer is quite unpredictable. It is also impossible to determine from *in vitro* data alone whether inhibitors of cytochrome P-450 enzymes will significantly block the metabolism of drugs *in vivo*. In view of the innumerable factors which can influence the synthesis, degradation, activation and inactivation of the microsomal enzymes (as well as of the inducers, the toxicants and their metabolites) in the living organism, our approach to these problems must meanwhile depend almost entirely on empiricism.

Work on catatoxic steroids has brought out with particular clarity one additional complication, namely that the enzyme inducers may or may not enhance their own metabolic degradation. Thus, spironolactone enhances not only the inactivation of digitoxin and indomethacin but also its own metabolism as judged by blood clearance rates. However, the capacity of the catatoxic steroids to inactivate themselves is limited, and hence, they continue to detoxify drugs in chronic experiments for many weeks or months as long as the toxicant is administered in combination with an appropriate inducer. As soon as administration of the latter ceases, the toxicant again exhibits its usual effects indicating that whatever the mechanism of enzymic defense, its persistence depends upon continued stimulation by the inducer.

### **TPO, TKT**

*Kenney E 89,716/62:* In the rat, the induction of hepatic TKT by cortisol is associated with an equivalent increase in enzyme antigen. A cross-reactive precursor could not be detected in any of the subcellular liver fractions. Induction in the presence of  $^{14}\text{C}$ -labeled amino acids results in extensive labeling of transaminase, with or without induction.

*Rosen & Milholland E 32,652/63:* Tryptophan induced significant increases in hepatic TKT activity in intact and in adrenalectomized (NaCl-maintained) rats. Tyrosine, histidine and methionine slightly depressed the hepatic TKT activity of the adrenalectomized rats. Analogues of tryptophan (including D-tryptophan, acetyl-L-tryptophan, indole, DL-5-hydroxytryptophan and 5-HT *i.p.*) increase both TKT and TPO activity by 50—300% in the livers

of intact or adrenalectomized rats. 5-HT and DL-5-hydroxytryptophan were most active. After hypophysectomy, the response of each of these enzymes to tryptophan gradually diminished. After 6 months, tryptophan, 5-hydroxytryptophan and 5-HT failed to cause significant increases in the hepatic activity of these enzymes, but cortisol remained highly effective, causing increases in both enzyme activities comparable to those seen in intact or adrenalectomized rats. "Experiments with two known inhibitors of protein synthesis, DL-ethionine and puromycin, indicate that a major fraction or the induced activity of tryptophan pyrrolase seen in adrenalectomized or hypophysectomized rats treated by injection with tryptophan is due to activation rather than synthesis of new enzyme protein. The responses of tryptophan pyrrolase and tyrosine transaminase in liver following cortisol administration appear to be mainly the result of the synthesis of each of these enzymes."

*Schimke et al. G24,293/65:* In adrenalectomized rats, both cortisol and tryptophan increase hepatic TPO, but a particularly pronounced rise is obtained by combined treatment with both these agents. An analysis of the time course of changing enzyme levels, and the results of isotope incorporation studies indicate that cortisol increases the rate of enzyme synthesis, whereas tryptophan decreases the rate of enzyme degradation.

*Moon & Berry G57,245/68:* "Using substrate induction as a tool, we attempted to determine the role of tryptophan pyrrolase in the response to endotoxin in mice. Previous results have shown that the administration of the LD<sub>50</sub> of endotoxin lowers tryptophan pyrrolase activity.  $\alpha$ -Methyltryptophan was found to maintain tryptophan pyrrolase activity above control levels in endotoxin-poisoned mice without increasing survival. 5-Hydroxytryptophan, by contrast, lowered tryptophan pyrrolase activity but did not sensitize mice to endotoxin. These results suggest that tryptophan pyrrolase per se does not play a unique role in survival of mice poisoned with endotoxin."

### **Microsomal Enzymes**

*Karlson & Sekeris F73,338/66:* Review of the literature and personal observations on the biochemical mechanisms of hormone actions. It is postulated "that hormones may act as gene activators ... Gene activation would lead to production of messenger-RNA and induced enzyme synthesis."

*Conney F88,649/67 (p. 330):* Review on the role of enzyme synthesis and degradation in the induction of drug-metabolizing activity.

*Mannering G71,818/68 (pp. 57, 84):* The comparative nonspecificity of detoxication by microsomal enzymes suggests "that a multitude of oxidases of remarkable substrate specificity exists or, at the other extreme, that an oxidase of remarkable nonspecificity exists." The arguments for and against each of these possibilities are carefully reviewed.

*Mannering G71,818/68 (p. 79):* Review of the data suggesting that inducers actually increase the synthesis of new hepatic microsomal drug-metabolizing enzyme proteins.

*Selye et al. G60,020/69:* The antianesthetic and antidigitoxin activities of spironolactone and norbolethone may depend upon competitive inhibition or induction of hepatic microsomal enzymes.

*Various authors G68,203/69:* Review (27 pp., 42 refs.) on "Application of metabolic data to the evaluation of drugs. A report prepared by the Committee on Problems of Drug Safety of the Drug Research Board, National Academy of Sciences—National Research Council." A large section of this report is devoted to the inactivation of drugs by microsomal enzymes. It is emphasized that "it is difficult to predict from in vitro data alone whether inhibitors of the cytochrome P-450 enzymes will significantly block the metabolism of drugs in laboratory animals and in patients." Furthermore, "phenobarbital administration leads to an increase in virtually all known enzymatic pathways by causing an increase in both NADPH cytochrome C reductase and cytochrome P-450. Although phenobarbital is known to act by increasing the synthesis of enzyme protein, it may also act by slowing the turnover of the various components of the endoplasmic reticulum."

*Solymoss & Selye G70,409/70:* Rats given daily treatment with normally fatal amounts of indomethacin or digitoxin can survive for an apparently indefinite period if they are concurrently treated with spironolactone or oxandrolone. Upon interruption of catatoxic steroid administration, death ensues within a few days. "Spironolactone enhances not only the degradation of digitoxin and indomethacin but also its own metabolism as judged by their disappearance rate from the blood. However, the capacity of the steroids to inactivate themselves is limited and, hence, they continue to detoxify both drugs, even in chronic experiments."

### 3. SER and MICROSOMES

*cf. also* Electron Microscopic Data under "Morphology"

It appears to be well established that the induction of microsomal enzymes takes place within the endoplasmic reticulum. The electron microscopic expression of such enzyme induction is the gradual transformation of the rough into the smooth ER whose membrane systems eventually are broken up into vesicles which may become very large and give the cytoplasm a spongy appearance. It is assumed that the substrates enter these vesicles and are therein destroyed by the induced enzymes. For several of the enzyme activities, both the microsomes and soluble cell constituents are necessary as shown by the fact that pure microsomes isolated by ultracentrifugation are active only if supernatant cytosol is added.

There is some doubt about the relative participation in detoxication of the highly substrate specific amino acid deaminating (TPO, TKT) enzymes and the relatively nonspecific microsomal enzymes. Glucocorticoids, which are good inducers of TPO and TKT, shorten barbiturate and meperidine sleeping time and combat endotoxin shock. However, these latter effects may be unrelated to the activation of TPO and TKT; they have been tentatively ascribed to the induction of microsomal enzymes by glucocorticoids.

Several review articles list the many drugs and hormones capable of transforming the RER into an SER, simultaneously activating microsomal enzymes. Among these there are even typical hepatotoxic substances such as  $\text{CCl}_4$  which increase the SER in hepatocytes and enhance the incorporation of  $^{32}\text{P}$  in structural membrane phospholipids. Yet, concurrently, protein synthesis is impaired presumably because  $\text{CCl}_4$  stimulates the rate of synthesis only in abnormal microsomal membranes.

Recent studies suggest that cortisol, which is a substrate for microsomal enzymes, is bound rapidly in the SER of hepatocytes, poorly in the RER, and virtually not at all in ribosomes.

Microsomal mixed function oxidases and cytochrome P-450 are relatively more concentrated in the SER than in the RER. Curiously, benzpyrene does not affect the SER or microsomal protein although it stimulates the biotransformation of many substrates. Apparently, this carcinogen acts through a mechanism different from that of the barbiturates and of most other drug-metabolizing enzyme inducers.

Certain herbicides inhibit the induction by phenobarbital of cytochrome P-450 and of drug hydroxylase activity, yet, they do not prevent the proliferation of the SER. Presumably, induced increases in cytochrome P-450 and proliferation of the SER are controlled by separate mechanisms.

Review of the entire pertinent literature suggests that most, if not all, typical catatoxic steroids do induce proliferation of the SER but not all steroids that produce this latter effect are also potent inducers of resistance *in vivo*. It is possible that following excessive or abnormal stimulation of the SER, its enzyme-producing activity declines without there being any morphologically detectable manifestations of its functional exhaustion.

*Bucher & McGarrah* 667,470/56: For the biosynthesis of cholesterol from acetate *in vitro*, both microsomes and soluble cell constituents of the rat liver are required. *In vivo*, over 90% of newly formed cholesterol,

obtained shortly after the injection of labeled acetate, is in the microsomal fraction.

*Remmer* D86,728/58: In the rat, cortisol and prednisolone shorten the meperidine and hexobarbital sleeping time as well as the

detoxication of these sedatives by liver slices. This effect is tentatively ascribed to an activation of hepatic microsomal enzymes, since the known effect of glucocorticoids upon the deamination of amino acids depends upon highly substrate-specific enzymes.

*Fouts G79,654/61*: When SER and RER particles of rabbit liver are separated by ultracentrifugation in various sucrose gradients, the NADPH oxidase and drug-metabolizing enzyme activity can be shown to be higher in the SER than in the RER.

*Remmer & Merker E36,389/63*: In the rabbit, "repeated administration of phenobarbital and several other drugs results in a quantitative increase of the smooth endoplasmic reticulum of the liver cell. The marked increase in drug-metabolizing enzymes is found to occur in this enlarged smooth membrane fraction of the endoplasmic reticulum."

*Fouts & Rogers F29,497/65*: Benzpyrene and methylcholanthrene which stimulate only few microsomal drug-metabolizing enzymes do not cause any pronounced increase in the SER of hepatocytes.

*Conney F88,649/67 (p. 336)*: Review on the effect of drugs on electron transport systems in liver microsomes.

*Meldolesi G66,053/67*: A review of the literature shows that the following drugs are capable of producing hypertrophy of the SER: ethionine, dimethyl-, and diethylnitrosamine, 2-aminoflourene, flurenlyl diacetamide, thioacetamide, p-dimethylaminoazobenzene, 3-4-benzopyrene, p-dimethylcholanthrene,  $\alpha$ -naphthylisothiocyanate, SKF 525-A, carbon tetrachloride, chlordane, DDT, ethanol, phosphorus, phenobarbital, Bax 422 Z (a thiohydantoin derivative), cysteine, 2-methyldiazobenzene, nikethamide, tolbutamide. In some cases, this hypertrophy is associated with an increased, in others with a decreased, microsomal enzyme activity. Possibly, "SER hypertrophy may be produced by one and the same mechanism and all substances capable of producing SER hypertrophy may act as inducers of microsomal enzymes, thus stimulating hepatic cell to produce both endoplasmic reticulum membranes and enzymes. However, some of these substances, or their metabolites, are inhibitors of protein synthesis. In this case synthesis of new enzyme molecules is impossible and the response of the hepatic cell to the pharmacological stimulus is limited to the formation of the SER membranes."

*Meldolesi et al. G69,793/68*: In rats,  $\text{CCl}_4$  greatly increases the proliferation of the SER

in hepatocytes and the incorporation of  $^{32}\text{P}$  in structural membrane phospholipids. Concurrently, protein synthesis is greatly impaired. Presumably  $\text{CCl}_4$  stimulates the rate of synthesis only of abnormal microsomal membranes.

*Mannering G71,818/68 (pp. 52, 78)*: Review on the participation of the SER in drug metabolism.

*Hutterer et al. G66,323/69*: In rats, treated with dieldrin, serial ultrastructural studies of the liver showed a three-stage response. "The first stage, that of induction, is characterized by an increase in liver weight, microsomal protein, smooth endoplasmic reticulum, the activity of aniline hydroxylase and p-nitroreductase, and the concentration of P-450 hemoprotein. During the second stage, a 'steady state,' the elevated levels are maintained and tolerance to otherwise fatal doses of dieldrin prevails. In the third stage, that of decompensation, elevation of liver weight, microsomal proteins, and P-450 hemoprotein persists, and the smooth endoplasmic reticulum appears as abundant as in the previous stages, but the activity of the drug-handling enzymes decreases. The smooth endoplasmic reticulum, however, in this last stage consisted of packed tubules. This hypoactive, hypertrophic, smooth endoplasmic reticulum is accompanied by biochemical and morphologic alterations of mitochondria." 3-Methyl-4-dimethylaminoazobenzene caused a rapid decompensation without significant steady state. Literature concerning other observations on hypoactive hypertrophic SER is summarized.

*Mayewski & Litwack G70,720/69*: In adrenalectomized rats, radioactive cortisol is bound rapidly to the SER of hepatocytes, poorly to the RER and virtually not at all to the ribosomes.

*Williams & Rabin G77,164/69*: In rats, the effect of aflatoxin  $\text{B}_1$  and steroid hormones on polysome binding to microsomal membranes has been measured by the activity of an enzyme-catalyzing disulfide interchange. Corticosterone and, to a much lesser extent cortisol, antagonizes the effect of aflatoxin, presumably by competition at a site on microsomal membranes responsible for polysome binding. The authors postulate the "simple hypothesis that a steroid hormone, related to corticosterone, can occupy specific sites on the membrane and that, when these sites are occupied, polysome binding can occur. The difference between 'rough' and 'smooth' endoplasmic reticulum would then be that the specific sites of the former are

occupied by hormone, whereas those of the latter are not."

*Fouts G76,868/70:* Review of the literature showing that in rats and rabbits, microsomal mixed-function oxidases and cytochrome P-450 are relatively more concentrated in the SER than in the RER. It is noteworthy, furthermore, that benzpyrene treatment does not affect hepatic weight, microsomal protein or the appearance of the SER in the rat liver, indicating that this carcinogen acts through a mechanism different from that of barbiturates and of most other microsomal drug-metabolizing enzyme inducers.

*Raisfeld et al. G75,045/70:* In rats, the herbicide 3-amino-1,2,4,-triazole inhibits the induction by phenobarbital of cytochrome P-450 and drug hydroxylase activity, but does not prevent the proliferation of the SER in hepatocytes. Presumably "induced increases of cytochrome P-450 and of the membranes of endoplasmic reticulum may be controlled by separate mechanisms."

*Stenger G74,578/70:* Review (21 pp., 177 refs.) with special reference to the alterations in RER and SER produced by various agents and the relationship of these changes to glyco-gen and drug metabolism.

*Stenger et al. G78,940/70:* In rats, pretreatment with phenobarbital in doses which cause proliferation of the SER and a decrease in hexobarbital sleeping time greatly diminished resistance to the fatal effects of  $\text{CCl}_4$ . Phenobarbital pretreatment delayed the onset of

$\text{CCl}_4$ -induced hepatic necrosis, but greatly aggravated its eventual severity. "This altered hepatotoxic response might be related either to the increase of smooth-surfaced membranes or to the augmentation of drug-metabolizing enzyme systems in the livers of the phenobarbital-pretreated animals."

*Garg et al. G79,002/71:* In rats, PCN p.o. induces proliferation of SER even after hypophysectomy.

*Garg et al. G70,495/71:* In rats, phenobarbital, 3-MC, spironolactone, cyproterone, and PCN cause proliferation of the SER in hepatocytes without producing marked changes in other cell organelles. In comparing electron-microscopic with biochemical and toxicity studies "it seems that there is no obligatory parallelism between SER proliferation and catatoxic potency. However, it is clear that all catatoxic substances tested so far, lead to SER accumulation."

*Khandekar et al. G79,026/71:* In rats, the hepatic SER proliferation induced by spironolactone or PCN is not prevented by concurrent administration of cycloheximide. Either the catatoxic steroids enhance the metabolic degradation of cycloheximide (thereby blocking its effect upon the SER) or this morphologic change does not necessarily indicate active enzyme induction.

*Kovacs et al. G46,737/71:* In rats bearing Walker tumor transplants, the RER is dilated, disorganized and degranulated, whereas the SER proliferates.

#### 4. RNA and DNA

The many and often conflicting concepts concerning the manner in which RNA and DNA participate in the induction of microsomal enzymes will be described in the following Abstract Section. However, it would by far exceed the scope of this monograph and the competence of its author to attempt a critical integration of all pertinent data.

*Feigelson et al. D25,364/62:* The induction of hepatic TPO by tryptophan or cortisone in the rat is used as a model for the study of interrelations between hormonal- and substrate-dependent enzyme induction processes. Following i.p. administration of either inducer, there is a rise in liver TPO activity, reaching a maximum after 4—5 hrs, the peak being higher for tryptophan than for cortisone. Judged by  $^{14}\text{C}$ -glycine and  $^{32}\text{P}$ -orthophosphate incorporation experiments, both tryptophan- and cortisone-induced stimulation of protein

metabolism follow the same time course, but their effects on RNA metabolism do not coincide. Tryptophan causes no increase in RNA turnover, while the enzyme level is rising. When enzyme activity has returned to normal, precursor incorporation into RNA is stimulated. Cortisone, on the other hand, markedly stimulates RNA turnover with a peak at 4 hrs corresponding to peak enzyme levels. The pattern of incorporation of the purine precursor, glycine-2- $^{14}\text{C}$ , into the RNA of various hepatic subcellular fractions showed

that cortisone increases precursor incorporation into the proteins of all liver cell constituents, but much less than into RNA. On the basis of these and many other experiments concerning the mechanism of enzyme induction, a hypothesis is proposed according to which the difference between enzyme and hormone induction might be explained. "This hypothesis rests on the assumption that the increase in enzyme activity, in excess of that due to hematin activation, is due to the presence of increased levels of enzyme protein derived from an increased rate either of enzyme protein synthesis or of release. It is herein proposed that apotryptophan pyrrolase is synthesized at a specific vacant enzyme-forming site. Furthermore, it is postulated that apoenzyme molecules (E) on the enzyme-forming site or template are in dynamic equilibrium with the apoenzyme molecules of the cytoplasm. Holoenzyme molecules (EH), however, are incapable of binding at this site. It follows that saturation of apotryptophan pyrrolase with hematin, promoted by tryptophan, would render many enzyme-forming sites vacant, thus shifting the equilibrium toward further enzyme protein synthesis. With the fall in intracellular tryptophan concentration, EH combination would be retarded, apotryptophan pyrrolase would accumulate, occupying the enzyme-forming site, and inhibit its own synthesis; a gradual return to basal enzyme levels would then take place. In this manner, a tryptophan-regulated saturation of the enzyme with hematin cofactor would control the synthetic rate and the level of this enzyme in liver. Cortisone clearly influences the level of tryptophan pyrrolase by a different mechanism. As indicated by the arrow, it is proposed that cortisone may stimulate enzyme protein synthesis by interfering with the equilibrium between the template-bound and soluble apotryptophan pyrrolase in such a way as to prevent the accumulated apotryptophan pyrrolase from binding to the template and inhibiting its own synthesis. This interference might be envisaged as a cortisone-induced alteration of the structure of the apotryptophan pyrrolase, or as a change in the ribosome itself."

*Feigelson & Feigelson D59,123/63:* In rat liver tissue, "cortisone rapidly elevates incorporation of glycine-2-C<sup>14</sup> into acid-soluble adenine nucleotides as well as into RNA. Intraperitoneal administration of a variety of L- and D-amino acids, NH<sub>4</sub><sup>+</sup>, and glutamine into adrenalectomized rats imitated cortisone by stimulating glycine-2-C<sup>14</sup> incorporation into acid-soluble and RNA purines. Although liver adenosine triphosphate levels rise after cortisone administration, such alterations in ATP per se do not influence the rate of precursor incorporation into RNA or protein. On the basis of these findings, it is proposed that increased amino acid deamination, implicit in the gluconeogenic action of the glucocorticoids, results in the liberation of  $\alpha$ -amino nitrogen moieties that mediate the cortisone-induced increases in hepatic purine biosynthetic rates."

*Knox D66,995/63:* The "push-pull theory" of enzyme induction is formulated on the basis of experiments concerning the production of TPO and TKT by cortisol or by the respective substrates in intact and adrenalectomized rats. As illustrated by the diagram on p. 751, the substrate-type induction "pulls protein synthesis through the existing templates and, by depleting the species of marked enzyme, slows the rate of enzyme degradation. The hormone-type induction acts by causing the production of more of the limited, essential species of RNA that is necessary for making the tryptophan pyrrolase. Thus hormonal induction pushes additional enzyme synthesis through the provision of additional RNA templates."

*Lindergren G66,494/63:* Discussion of the receptor-hypothesis of induction of gene-controlled adaptive enzymes.

*Garren et al. G28,021/64:* In adrenalectomized rats, a single i.p. injection of cortisol produces an increase in hepatic TPO and TKT activity. Actinomycin D did not inhibit synthesis of these enzymes, but blocked their induction when injected early after cortisol administration. Actinomycin D and fluorouracil stimulated TPO and TKT synthesis when injected 5 hrs or later after cortisol. "It is proposed that repression of the synthesis of these enzymes occurs at the level of messenger RNA translation."

*Knox G65,171/64:* Observations on adrenalectomized rats lead to the distinction between two types of TPO induction, one called the "hormone type" because glucocorticoids act this way. Thus, in adrenalectomized rats,

Model of the two known mechanisms of enzymic adaptation in animal tissues: substrate-type induction, which accumulates more total enzyme by combining with the free enzyme in effective equilibrium with its precursors, and hormone-type induction, which provides more of the limiting RNA species for the specific enzyme synthesis.

cortisol increased the amount of some limiting RNA moiety, thereby augmenting enzyme synthesis. This action is prevented by actinomycin through the inhibition of RNA synthesis as well as by puromycin, which inhibits protein synthesis. The second form or "substrate type" of induction is obtained by tryptophan which increases the amount of TPO without stimulating RNA synthesis. This increase is not prevented by actinomycin although it is, of course, blocked by puromycin, which inhibits protein synthesis. These and other observations led to the formulation of the "push-pull" theory of enzyme induction which is illustrated on p. 752.

*Gelboin F 62,759/65:* Review of the literature on the role played by RNA in the induction of hepatic microsomal enzymes.

*Greenman et al. G 35,063/65; Wicks et al. G 35,046/65:* Studies on the stimulation of hepatic  $^{32}P$ -RNA synthesis in adrenalectomized rats treated with cortisol.

*Singer & Mason G 66,500/65:* Na-benzoate increased hepatic TKT activity both in intact and in NaCl-maintained adrenalectomized rats. Among 31 cyclic compounds tested for this inducing ability after adrenalectomy, only cortisol, its hemisuccinate and diethylstilbestrol disulfate were more effective than benzoate. Curiously, enzyme induction by cortisol was actually enhanced after adrenalectomy. "Strong inhibition of the increase by injected puromycin and actinomycin D, compounds which inhibit protein and RNA synthesis respectively, suggests that the benzoate-mediated effect occurred by a mechanism involving increases in protein and RNA synthesis. In this respect, the effect of benzoate resembles that of the glucocorticoids."

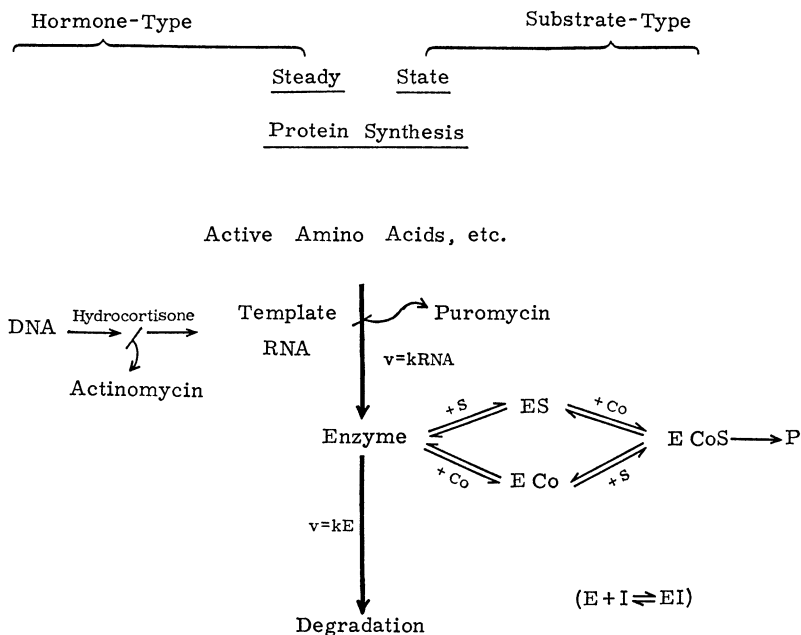

*Tomkins et al. G 35,353/65:* Following a single injection of cortisol into adrenalectomized rats, the hepatic TPO and TKT levels rise. "Although actinomycin D blocks the initial steroid-induced increase, later administration of the antibiotic (or of 5-fluorouracil) causes an increase in the levels of these enzymes. A mechanism is proposed to account for the late response to inhibitors of RNA synthesis in which a 'cytoplasmic repressor' can inhibit the translation of the messenger RNA's corresponding to tryptophan pyrrolase and tyrosine transaminase. Cytoplasmic repression is postulated to depend on continued RNA and protein synthesis, and the 'repressor' is thought to have a rapid rate of turnover."

*Griffin & Cox F 86,851/66:* "The induction of alkaline phosphatase by prednisolone in HeLa cell cultures appears to occur at the level of protein synthesis (translation) as a result of a steroid-induced change in the conformational state of the enzyme during its synthesis."

*Tomkins et al. G 49,588/66:* Glucocorticoids stimulate TKT induction in rat hepatoma cells in vitro. Inhibitor and immunochemical experiments indicate that the corticoids do not activate a precursor but increase the number of enzyme protein molecules. Apparently, the hormones exert some control at the level of translation of the transaminase messenger by antagonizing a repressor of messenger function. "It cannot yet be determined whether the presumed increase in messenger concentration occurs as a secondary response to the stimulation of translation, or whether there is a direct effect of the hormone on gene transcription."

*Conney F 88,649/67 (pp. 330, 333, 334):* Review on the role of enzyme synthesis and

The "push-pull" model of enzyme inductions in animal tissues. In the steady state of enzyme synthesis and degradation, accumulations of total enzyme are "pushed" by temporarily increased synthesis of nascent enzyme (E) through the extra RNA templates produced by hydrocortisone (hormone-type induction), or "pulled" by the temporary specific combination of substrates, coenzymes, and inhibitors with the nascent enzyme (substrate-type induction). Sites of action are indicated for actinomycin, which distinguishes between the two mechanisms, and of puromycin.

degradation in the induction of drug-metabolizing activity.

*Drews & Brawer* *G52,150/67*: Studies on changes in RNA-synthesis in the rat liver during regeneration and after cortisol administration. The relationship between enzyme induction and RNA-synthesis is discussed.

*Gelboin* *G53,802/67*: Review (81 pp., about 90 refs.) on enzyme induction in connection with carcinogenesis and gene action.

*Gelehrter & Tomkins* *G51,315/67*: Dexamethasone induced a 3-15-fold increase in TKT activity in hepatoma cells of the rat (in tissue culture) but no increase in total RNA nor its synthesis as measured by the rate of incorporation of labeled precursors. Various experiments also failed to demonstrate gross stimulation of RNA synthesis associated with enzyme induction by steroid hormones in vivo, "suggesting that these changes are not an essential part of the mechanism of enzyme induction by glucocorticoids."

*Grossman & Mavrides* *G46,206/67*: Studies on the kinetics of cortisol-induced hepatic TKT

activity in adrenalectomized rats. "Puromycin inhibited enzyme synthesis when it was given during the initial phase of induction. However, it unexpectedly caused a rapid reappearance of enzyme activity following its administration during the inactivation phase. This potentiated response is consistent with other observations which lead to the idea that a repressor is formed about 4 hours after hormone administration and that inhibition of repressor synthesis allows, at least temporarily, continued synthesis of enzyme." The inactivator appears to depend upon pituitary function, since adrenalectomized and hypophysectomized rats showed little or no inactivation phase following cortisol treatment.

*Peterkofsky & Tomkins* *G52,839/67*: TKT can be induced by dexamethasone in tissue cultures from Morris hepatoma 7288C. Cytosine arabinose completely inhibits DNA synthesis in these cells, but does not affect RNA synthesis or enzyme induction. Conversely, mitomycin C and actinomycin D preferentially inhibit RNA synthesis and completely block

induction. Kinetic experiments in which actinomycin D was added at increasing intervals after dexamethasone suggest that messenger RNA accumulates during the early phase of induction. From these and other observations, it is concluded "that messenger RNA for both tyrosine aminotransferase and general cell protein are relatively stable. After inhibition of protein synthesis by cycloheximide, tyrosine aminotransferase activity decreased exponentially with a half-life of seven hours, and this rate was not affected by either steroid or actinomycin."

*Benes & Zicha G67,159/69:* Exposure to 1400 R does not inhibit the TPO activity of rat liver. In fact, substrate induction of TPO is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated and then, inhibited by X-irradiation. X-irradiation before partial hepatectomy inhibits the increase in tryptophan oxygenase normally observed 12 hrs after the operation. Similar results are obtained by actinomycin D applied one hour after partial hepatectomy. "The diminished synthesis of tryptophan oxygenase in irradiated regenerating rat liver tissue, as well as the decrease of hormonal induction after the irradiation can be explained by the inhibition of the specific messenger RNA's synthesis."

*Lindgren E8,182/69:* Review of the receptor hypothesis of gene action.

*Tomkins et al. H19,499/69:* Review of the evidence in favor of the following theory of enzyme induction by steroids.

Theory of enzyme induction in mammalian cells. The configuration shown on the left is assumed to exist during the inducible phases of the cell cycle, while that on the right, during the noninducible phases. The  $G^S$  refers to the structural gene for the inducible enzyme, while  $G^R$  refers to the regulatory gene. During the inducible periods,  $G^S$  is transcribed and the resulting messenger, M, can be translated to form the enzyme. The  $G^R$  is likewise transcribed and its messenger translated to produce the protein R. The R combines reversibly with M to produce the inactive complex MR which leads to M degradation. The R itself is labile, as shown by the thin arrow leading away from R. The inducer is indicated to inactivate R by an unknown mechanism. During the noninducible phases of the cycle, neither  $G^S$  nor  $G^R$  is transcribed, but M can be translated. Although for the case of tyrosine aminotransferase the degradation of the enzyme might also be depicted, we have not done so because its concentration is not regulated by changing the rate of its inactivation under constant cultural conditions.

## 5. LYSOSOMES

According to certain investigators an excess of vitamin A or ultraviolet irradiation may liberate lysosomal proteases; this effect is counteracted by glucocorticoids, such as cortisol, allegedly through the stabilization of lysosomal membranes. A similar mechanism has been invoked to explain the protective action of glucocorticoids against endotoxins which are also thought to cause damage by the release of lysosomal enzymes. The interactions between glucocorticoids and other toxicants may likewise act by preventing a kind of autointoxication with lysosomal proteases. This concept appears to have been confirmed using many model systems, yet, it is not uniformly agreed to play a decisive role in glucocorticoid-induced resistance phenomena in vivo. In particular, serum levels of  $\beta$ -glucuronidase (presumed to reflect lysosomal enzyme release) do not correlate with survival in rats given cortisol during tourniquet shock. In fact, even in vitro studies suggest that neither glucocorticoids nor nonsteroidal anti-inflammatory drugs stabilize lysosomes with respect to the release of enzymes, when the lysosomes are thermally labilized.

*Weissmann D10,768/61:* In larvae of *Xenopus laevis*, bone absorption and other manifestations of vitamin-A overdosage were accelerated by cortisol. "This was held to be due to liberation of vitamin A from hepatic stores by the steroid, and is in contrast to the retardation of hypervitaminosis A by hydrocortisone in vitro." Presumably an excess of vitamin A causes release of cathepsins from intracellular lysosomes.

*Weissmann & Dingle D14,268/61:* The hepatic lysosomal proteases of the rat are released by ultraviolet irradiation in vitro and this effect is greatly diminished by pretreatment of the animals with cortisol in vivo.

*Weissmann & Fell D46,242/62:* The damage caused to fetal rat skin explants by ultraviolet irradiation can be inhibited by the addition of cortisol to the culture medium. This protection "might be due, at least in part, to a reduced proteolytic activity in the damaged tissue through a stabilising action of the hormone on the lysosomes."

*Weissmann & Thomas D23,630/62:* Following endotoxin treatment in vivo, the hepatic lysosomes of the rabbit release their enzymes readily upon ultraviolet irradiation. This increased lability is in turn prevented by pretreatment of the animals with cortisone for three days before endotoxin administration. Apparently, "one action of endotoxin is to release acid hydrolases from particulate form within cells, and that glucocorticoids serve to stabilize such particles against injury by several agents."

*Weissmann & Thomas D65,709/63:* Various in vivo and in vitro experiments "are compatible with the hypothesis that excess vitamin A releases acid hydrolases from liver and cartilage lysosomes in vivo and in vitro, and that cortisone antagonizes this action." This interaction may explain earlier observations on the protective effect of glucocorticoids against intoxication with vitamin-A.

*Janoff G68,991/64:* A review of the literature and personal observations. It is concluded that "(1) disruption of lysosomes and release of their contained enzymes in free, active form occurs in the liver of shocked animals; (2) the activation of lysosomal hydrolases within cells and their release into the circulation may play an important role in exacerbating tissue injury and accelerating the development of irreversibility at the cellular level during shock; (3) rendering animals tolerant or pretreating them with cortisone selectively stabilizes lysosomes and this effect may constitute an

important component of the resistance of such animals to shock; (4) the exacerbating effect of reticuloendothelial-blocking colloids on the lethality of shock procedures may be due, in part, to a direct action of these agents on lysosomes."

*Janoff & Kaley E8,484/64:* Review of the literature supporting the concept that endotoxins act by disruption of lysosomes with release of their contained enzymes and that cortisone protects against the resulting shock by stabilizing lysosomal membranes.

*Weissmann & Thomas E4,216/64:* Review (30 pp., 81 refs.) on the stabilizing action of glucocorticoids upon lysosome membranes.

*Weissmann & Thomas E8,482/64:* Review of the literature showing that cortisone, unlike DOC, stabilizes hepatic microsomal membranes against the permeability-increasing effect of endotoxin.

*Replogle et al. G40,447/66:* In patients with cardiopulmonary bypass, dexamethasone pretreatment appeared to improve the clinical condition and diminished the serum beta-glucuronidase and LDH levels. It is assumed that postoperative complications following cardiopulmonary bypass may be related in part to damage of lysosome membranes and that "massive doses of dexamethasone may stabilize the lysosome membrane during periods of circulatory stress."

*Serkes et al. F92,105/67:* Cortisol administered to tourniquet-traumatized rats in infusion fluid lowered serum  $\beta$ -glucuronidase but did not prolong survival time. "Serum levels of beta-glucuronidase presumed to reflect lysosomal enzyme release, did not correlate with survival."

*Janoski et al. E7,896/68 (p. 280):* Review suggesting that many of the actions of glucocorticoids—particularly their inhibition of ultraviolet ray injury, vitamin-A overdosage and endotoxin shock—are due to the stabilization of lysosomal membranes which prevents the escape of toxic lysosomal enzymes.

*Lefer & Martin H7,806/69:* In cats, "pharmacologic doses of cortisol or dexamethasone given intravenously prior to induction of hemorrhagic shock prolonged survival significantly after reinfusion of all shed blood. High doses of aldosterone were ineffective in prolonging survival, as was cortisol when administered at the time of reinfusion. . . . Glucocorticoids may prevent the disruption of lysosomes and/or prevent proteases from being released into the blood."

*Brown & Schwartz H14,096/69:* In vitro studies on the hepatic lysosomes of the rat suggest that "neither steroidal nor non-steroidal anti-inflammatory drugs, in general, stabilized lysosomes with respect to release of enzymes when the lysosomes were labilized thermally. . . . That anti-inflammatory drugs exert their prime pharmacologic action at the level of the lysosome is thus very doubtful."

*Curreri et al. H11,525/69:* In rabbits with cholesterol atherosclerosis various hydrolytic enzymes present in lysosomes ( $\beta$ -glucuronidase, acid phosphatase, cathepsin and aryl sulfatase) showed a marked increase in activity. Cortisone inhibited this atherosclerosis and the increased enzyme activity despite very high levels of serum cholesterol.

*Weissmann G79,855/69:* Review (20 pp., 105 refs.) on "The Effects of Steroids and Drugs on Lysosomes." Special attention is given to the effect of lysosome stabilization by glucocorticoids which may be responsible for the prevention by these steroids of endotoxin shock, etiocholanolone fever, hypervitaminosis E and other conditions.

*Lewis et al. G80,342/70:* In general, glucocorticoids stabilize rabbit liver lysosomes in vitro, although at very high concentrations they have an inverse effect. Etiocholanolone, a pyrogenic steroid, has a lytic action on lysosomes, even at comparatively low concentrations.

*Polliack et al. H32,366/70:* In hamsters, tumor formation by topical application of DMBA to the cheek pouch is partially sup-

pressed by concurrent application of cortisone, perhaps owing to depression of DNA synthesis and of mitotic activity by the hormone. "Cortisone stabilizes biological membranes; its action on cell multiplication may be related to decreased membrane permeability with consequent inhibition of release of lysosomal enzymes which play a part in early stages of cell division. Decreased membrane permeability may also have resulted in less effective penetration of carcinogen into cells. Results are in accordance with those of previous studies, which demonstrated promotion of tumor formation by labilizers of biological membranes such as vitamin A and estrogen."

*Symons et al. G80,345/70:* Rabbit hepatic lysosomes take up  $^3\text{H}$ -labeled cortisol and cortisone from the surrounding medium in vitro. It may be that the lytic effect exerted by high doses of glucocorticoids upon lysosomes is due to structural changes produced in the membrane.

*Glenn & Lefer H34,576/71:* In cats subjected to hemorrhagic shock, methylprednisolone increased survival time in proportion to a diminution of plasma levels of a myocardial depressant factor (MDF) and of the lysosomal enzymes,  $\beta$ -glucuronidase and plasma cathepsin-like activity (PCLA). Presumably, "methylprednisolone exerts a protective effect in hemorrhagic shock by preventing the release of lysosomal enzymes which may be responsible for the formation of MDF, a peptide implicated in the reduction of myocardial contractility during postologic shock."

## 6. RETICULO-ENDOTHELIAL SYSTEM (RES)

It is generally agreed that the RES helps to prevent sudden flooding of the circulation with blood-borne particulate substances. It is more questionable whether some particles engulfed by the RES cells are topically digested; certainly most of them are gradually released (through shedding and decomposition of the phagocytes) for subsequent degradation in other tissues and/or eventual excretion. It has been suggested that RES cells also participate in the enzymic degradation of soluble toxicants. In isolated RES cells, acetylation of foreign compounds has allegedly been demonstrated. Furthermore, such RES active agents as Thorotrast or endotoxin lower the hepatic TPO (but not TKT) activity and prevent cortisol from inducing these enzymes in the isolated perfused liver. It has been assumed that the RES cells can produce some "inhibitory substances."

The interpretation of pertinent data is somewhat complicated by the fact that the same particulate substances can both inhibit and stimulate RES cells depending upon dosage and other factors. Still, it is of considerable interest that there exists some relationship between the functional status of the RES and drug detoxication.

Thus, in mice, various compounds which decrease the blood clearance of colloidal carbon, prolong hexobarbital anesthesia; however, the same is true of zymosan, endotoxin and stilbestrol, which enhance RES activity. On the other hand, typical catatoxic drugs (e.g., phenobarbital) and inhibitors of drug-metabolizing enzymes (e.g., SKF525-A) do not appreciably alter RES activity.

These and many other observations suggest that the RES may participate in drug metabolism but its role remains to be elucidated and it certainly does not appear to be as important as that of the hepatic parenchyme.

*Govier F57,820/65:* In rabbits, acetylation of sulfanilamide and p-aminobenzoic acid (one of the major routes of metabolism of acrylamines) has been examined utilizing isolated intact hepatic and RES cells of various other tissues. "The acetylation of these compounds, usually attributed to the liver, was found to occur in cells of the reticulo-endothelial system. No acetylation could be demonstrated in the hepatic parenchymal cells. Lung and spleen, organs known to contain a high percentage of reticuloendothelial cells, were also found to acetylate these compounds."

*Agarwal et al. G65,716/69:* In the rat, both *S. typhimurium* endotoxin and Thorotrast lowered hepatic TPO activity, and prevented cortisol from inducing this enzyme in the isolated, perfused liver. Under these conditions, the TKT activity of the liver remained unaffected. Partial purification of hepatic TPO induced by endotoxin or Thorotrast indicated the presence of some inhibitory substance. "Since histological studies revealed that thorotrast is localized in Kupffer cells, it is suggested that the reticuloendothelial system contributes to the control of enzyme induction in rat liver."

*Benveniste et al. G80,804/70:* In axenic mice, the phagocytic function of the RES is regularly depressed by prednisolone. Holoxenic mice are more resistant to this effect. Various observations suggest "that depression of the immune response by cortisone, obtained under septic conditions, is more probably related to a lymphoid atrophy than to a depression of the RES."

*Greisman & Woodward G80,339/70:* In rabbits, extensive studies (RES blockade, liver perfusion, etc.) "fully support the concept that tolerance to the pyrogenic activity of bacterial endotoxin is based upon increased uptake of the toxin by hepatic Kupffer cells which have become refractory to further release of endogenous pyrogen."

*Munson et al. H22,843/70:* "Drugs which alter the phagocytic activity of the RES have been shown to prolong barbiturate anesthesia. In this study, these observations were extended to include agents which decrease RES activity. Methyl palmitate, thorium dioxide and pyran copolymer (PCP) markedly decreased the intravascular clearance of colloidal carbon and prolonged hexobarbital anesthesia. Zymosan, endotoxin, diethylstilbestrol and PCP enhance RES activity and also prolong hexobarbital narcosis. Conversely, chlorcyclizine, SKF 525 A and phenobarbital, which markedly alter drug metabolism, did not alter RES activity. PCP and zymosan prolonged the half life of hexobarbital in brain, liver and serum. Hexobarbital metabolism was markedly depressed in 9000x g liver supernatant fractions from PCP and zymosan-treated mice. Further studies demonstrated that the inhibition of barbiturate metabolism was non-competitive. PCP and SKF 525 A were additive in microsomal inhibitory ability whereas chlorcyclizine, given in a protocol which stimulates microsomal enzyme activity, reverses the inhibitory effect of zymosan. The toxicity of cyclophosphamide, which requires hepatic microsomal enzyme activity for cytotoxicity, was markedly enhanced by PCP suggesting the enzymes necessary for the activation of cyclophosphamide are stimulated by PCP."

*Song & Kappas G80,521/70:* Review (21 pp., 215 refs.) on the "Influence of Hormones on Hepatic Function" with special sections on their effect upon phagocytosis, drug metabolism and biliary excretion. Folliculoids stimulate whereas glucocorticoids inhibit the RES, whereby they may influence drug resistance.

*Wooles & Munson G78,975/71:* Review of the literature and personal observations on mice suggest that there is a relationship between the functional activity of the RES and the duration of hexobarbital anesthesia. It is suggested that the RES plays an important role in drug detoxication.

### 7. HEPATIC GLYCOGEN

Glucocorticoids which protect mice against bacterial endotoxins also increase hepatic glycogen stores, whereas the noxious endotoxins deplete the liver of its glycogen content. In alloxan diabetic rats, hexobarbital and aminopyrine metabolism is depressed in vitro. These and several studies on the effect of insulin upon such enzyme activities raised the suspicion of some relationship between hepatic glycogen and drug-metabolizing enzyme activity.

This view appeared to receive further support from the observation that SKF 525-A and other inhibitors of enzyme activities share the property of reducing liver glycogen. However, it must be kept in mind that virtually all stressors, if sufficiently severe, reduce liver glycogen and hence a causal relationship between this change and responsiveness to enzyme inducers is difficult to prove. Besides, PAS, which increases hepatic glycogen, also prolongs hexobarbital sleeping time and it has been assumed that, here, the glycogen infiltration of the liver is responsible for the enzyme inhibitory effect.

*Berry et al. C73,198/59:* Mice of different strains were protected by cortisone against the lethal effect of various bacterial endotoxins. The effect may be related in some way to the hepatic glycogen stores which are depleted by endotoxin and increased by cortisone.

*Dixon et al. E35,705/63:* In alloxan-diabetic rats, "a depressed metabolism of hexobarbital and aminopyrine in vitro, an increased in vitro hydroxylation of aniline, and a prolonged in vivo effect of hexobarbital were evident. The O-dealkylation of codeine was unaffected by the chronic diabetic state. Insulin treatment returned the rate of metabolism of hexobarbital to normal levels but had no effect on aminopyrine metabolism. Metabolism of aniline was decreased below the normal rate after insulin treatment. Phenobarbital treatment of diabetic animals resulted in a stimulation of most of the drug metabolizing enzyme systems studied. However, the hydroxylation of aniline by livers from diabetic rats treated with phenobarbital was decreased." A relationship between hepatic glycogen and drug-metabolizing enzyme activity is suspected.

*Rogers et al. E31,897/63:* In rats, PAS feeding induces glycogen infiltration of the liver and prolongation of hexobarbital sleeping time. This is apparently due to its diminished ability to excrete the barbiturate. The in vitro metabolism of hexobarbital and aminopyrine, by the microsomes of rats pretreated with PAS, is diminished. Acute administration of PAS had no effect on hexobarbital sleeping time, nor did addition of PAS in vitro inhibit drug-metabolizing enzymes. There may exist some relationship between hepatic glycogen deposition and changes in the SER. This might account for the inhibitory effect of PAS which is definitely different from that of chloramphenicol and SKF 525-A.

*Rogers & Fouts F27,894/64:* In studies with SKF 525-A and other inhibitors, a relationship has been noted between reduced glycogen content of hepatocytes and low enzymic activities.

*Stenger G74,578/70:* Review (21 pp., 177 refs.) with special reference to the alterations in RER and SER produced by various agents and the relationship of these changes to glycogen and drug metabolism.

### 8. VITAMIN C

Induction of hepatic microsomal drug-metabolizing enzymes is usually associated with increased ascorbic acid synthesis and a rise in the urinary elimination of vitamin C. However, a loss of urinary ascorbic acid is characteristic of stressors, and incidentally, shared not only by microsomal enzyme inducers but also by SKF 525-A and other inhibitors of induction.

*Longenecker et al. A47,520/40:* In rats, various barbiturates, paraldehyde, chlorobutanol, aminopyrine, antipyrine, phenols, salicylates, sulfanilamide, sulfapyridine, and several other compounds increased ascorbic acid excretion. Earlier work had shown that vitamin C helps in the detoxication of such compounds as elementary phosphorus, phenol, phenylquinolinecarboxylic acid, benzene, lead and arsenicals. "No evidence was obtained to indicate that the urinary ascorbic acid was conjugated with any of the toxic substances fed, but its endogenous production appeared to be related to the animal's detoxication processes."

*Kato et al. D27,768/62:* In rats, urinary vitamin-C excretion was enhanced by pretreatment with inhibitors of microsomal drug metabolism such as SKF 525-A, Lilly 18947, Lilly 32391 and MG 3062. Apparently in this respect the inducers and inhibitors of microsomal enzymes exert similar effects. [The possibility that the increase in ascorbic acid excretion may have been due to the stressor effect of the drugs should also be considered (H.S.).]

*Stitzel & Furner G48,920/67:* In rats, stress (cold) increases the rate of p-hydroxylation of aniline and N-dealkylation of ethylmorphine simultaneously with an increase in adrenal ascorbic acid content. The stress-induced stimulation of microsomal metabolism and adrenal ascorbic acid levels are additive with those produced by phenobarbital. "It is tentatively concluded that stress and phenobarbital appear to act through different mechanisms in inducing increases in enzyme activity, although each treatment may have a common final step, namely an increased net synthesis of enzyme protein."

*Mannering G71,818/68 (pp. 61, 97):* Review of data showing that induction of hepatic microsomal drug-metabolizing enzymes is usually associated with increased ascorbic acid synthesis.

*Klinger et al. H28,896/70:* In rats, phenylbutazone reduces hexobarbital sleeping time and increases the fresh weight of the liver as well as the ability of the hepatic 9000 g supernatant to enhance aminophenazone-N-demethylation. An increase in the ascorbic acid concentration of the liver was noted only in young animals, but urinary excretion of ascorbic acid was as pronounced as after barbital treatment. Phenylbutazone administration to the pregnant mother failed to elicit an induction effect in the fetuses as judged by hepatic ascorbic acid determinations and by ultrastructural studies of the fetal livers. Proliferation of the SER was obtained by phenylbutazone in 10-day-old or older rats, often in association with an increase in the number of lysosomes and mitochondrial changes as well as by evidence of intrahepatic cholestasis.

*Hunter et al. H36,993/71:* In epileptic patients, the urinary excretion of D-glucaric (a metabolite of glucuronic acid) is considerably increased during phenobarbital treatment. Similar observations have been made in patients with Gilbert's syndrome after administration of various drugs known to induce hepatic enzymes. Because of its simplicity and sensitivity, the D-glucaric acid excretion test is recommended for the clinical assessment of drug-metabolizing enzyme induction. It is noteworthy, however, that except in primates and guinea pigs, glucuronolactone is converted to ascorbic acid and, in the rat, inducers of drug metabolizing enzymes increase the excretion of ascorbic acid rather than of D-glucaric acid.

## 9. DEFENSE AGAINST "NATURAL" VS. "FOREIGN" COMPOUNDS

It had been thought initially that the microsomal enzyme systems in the liver may be there just to detoxicate foreign compounds. It seemed tempting to "speculate that these systems are not essential to the normal economy of the body, but operate primarily against the toxic influences of foreign compounds that gain access to the body from the alimentary tract." It has been assumed, furthermore, that perhaps the SER membranes are ordinarily permeable only to nonpolar compounds, which would present "a plausible picture of the way the body protects its essential substrates from wasteful metabolism due to the non-specific microsomal enzyme." Indeed, the view that the microsomal enzyme system exists merely to attack foreign material has led to the suggestion that the substrates of microsomal mixed-function

oxygenases should be designated as "xenobiotics" (from the Greek "xenos" and "bios" for "stranger to life"). However, in many cases it is difficult to draw a sharp line of demarcation between "natural" and "foreign" compounds. In mice and rats kept on soft wood bedding of either cedar, white pine, or ponderosa pine, several drug-metabolizing hepatic enzymes were induced and hexobarbital sleeping-time was reduced. Apparently, the microsomal enzyme mechanism of an animal can be significantly altered by changes in its natural habitat.

Finally, numerous recent observations, especially with catatoxic steroids, but also with many nonsteroidal enzyme inducers, have amply demonstrated that these can stimulate the microsomal enzyme systems to metabolize such natural compounds as tyrosine, hormones, cholesterol, bilirubin, and many others. For reasons explained in the Introduction, we prefer to think of the catatoxic compounds as especially suited for the detoxication of abnormally high blood concentrations of substrates, be they "natural" or "foreign"; their metabolizing activities are much less evident at near physiologic concentrations of the substrates. In this sense, the catatoxic substances are primarily guardians of homeostasis (*cf. also* p. 763.).

*Brodie et al. G66,772/55:* Although SKF 525-A inhibits various hepatic microsomal-enzyme activities in the rabbit's liver it is relatively nontoxic and, hence, "one can speculate that these systems are not essential to the normal economy of the body, but operate primarily against the toxic influences of foreign compounds that gain access to the body from the alimentary tract."

*Brodie C12,157/56:* "The microsomal enzyme systems in liver may be there just to 'detoxicate' foreign compounds. . . . We have found no normal substrate which is metabolized by the drug enzyme systems in microsomes. . . . If we think of the microsomes as particles with a membrane which will, ordinarily, pass non-polar compounds but not polar compounds, we have a plausible picture of the way the body protects its essential substrates from wasteful metabolism due to the non-specific microsomal enzymes."

*Williams G73,007/62:* In connection with the theory that drug detoxication depends upon a special class of microsomal enzymes, it is noteworthy that several toxic compounds foreign to the body, can be metabolized by "normal enzymes" which perform a physiologic role in ordinary metabolism. This is well illustrated by the following table:

*Franklin G32,826/65:* When incubated under appropriate conditions with hepatic microsomes of male rats, "morphine, atropine, aminopyrine, lysergic acid, streptomycin, eserine, caffeine, N-methyl urethan, and 6-amino-N-methyl nicotinamide were N-demethylated at various rates. Those compounds

Table 134. Some foreign compounds metabolized by "normal enzymes"

Foreign compound	"Normal" enzyme acting on foreign compound
p-Nitrobenzyl alcohol (and some other foreign alcohols)	alcohol dehydrogenase
p-Nitrobenzaldehyde (and other foreign aldehydes)	aldehyde dehydrogenase
Benzylamine	monoamine oxidase
Procaine	non-specific plasma cholinesterase
Succinylcholine	
8-Azaguanine	guanase, purine nucleotide phosphorylase
Azuridine	nucleosidase
2:6-Diaminopurine	
6-Mercaptopurine	
6-Thioxanthine	xanthine oxidase
4-Aminopyrazolo-pyrimidine	

not demethylated were N-methyl nicotinamide, N-methyl glycine, betaine, N-methyl guanidine, creatine, and methylamine. None of the compounds tested which occur naturally in mammalian tissues were demethylated, whereas those from exogenous sources were demethylated." Of the tested foreign compounds, only ephedrine was not demethylated.

*Mason et al. F51,528/65:* The authors recommend the term "xenobiotics" (from the Greek "xenos" and "bios" for "stranger to life") for compounds which "are foreign to the metabolic network of the organism." It is clearly recognized that the mixed-function oxidases responsible for the degradation of many xenobiotic compounds are also participating in the metabolism of steroids, lipids and other normal components of the body and food.

*Vesell F88,031/67:* In mice and rats kept on softwood bedding of either red cedar, white pine, or ponderosa pine, three drug-metabolizing hepatic enzymes (morphine N-demethylase, aniline hydroxylase, and hexobarbital oxidase) were induced. Hexobarbital sleeping time was reduced. Apparently, the drug-metabolizing enzyme mechanism of an animal can be significantly altered by changes in its natural habitat.

*Gillette et al. E8,216/69:* The term "xenobiotics" is used (in the preface of a symposium

on "Microsomes and Drug Oxidations") to denote the substrates which "are metabolized by mixed-function oxidases localized in the endoplasmic reticulum of the liver."

*Calhoun et al. H34,806/71:* In immature rats, the uterotrophic effect of mestranol or norethynodrel was affected by numerous drugs. "Pretreatment with phenobarbital or SKF 525A was found to decrease and increase, respectively, the uterine wet weight in controls as well as in mestranol-treated groups. Of the other drugs tested, only tolbutamide increased uterine wet weights in both control and mestranol-treated groups. In addition, the response to mestranol was increased following pretreatment with p-aminosalicylic acid, chlorpromazine, and imipramine and decreased following diphenylhydantoin, phenylbutazone, or scopolamine pretreatment. The response to norethynodrel was decreased after pretreatment with phenobarbital or diphenylhydantoin and increased following SKF 525A pretreatment."

## 10. STRESSORS

The very first indication of an improvement of nonspecific resistance by steroids was based on the observation that adrenalectomized animals are extraordinarily sensitive to virtually every kind of damage and that their resistance can be restored by treatment with glucocorticoids. It was difficult to imagine an antidote that could impart such a wide spectrum of protection unless the glucocorticoids would act by antagonizing a common endogenous endproduct of exposure to any type of stressor or would induce a similarly nonspecific protective enzyme mechanism. In fact, conceivably both types of defense against stressors may be of importance: glucocorticoids might help to increase resistance to some such common metabolites as histamine, or to some byproduct of energy liberation, which would be produced under the influence of the most diverse stressors. In addition, a stress-induced increase in some endogenous substances (e.g., catatoxic steroids) might evoke nonspecific multipurpose oxygenases which could inactivate a great variety of toxicants.

In support of the view that many stimuli may induce enzyme systems which act through common pathways, it has been emphasized that an increase in TPO—produced by histidine, epinephrine or histamine and other compounds—occurs as a consequence of stress with the resulting increase in glucocorticoid secretion. Even X-irradiation, starvation or terminal tumor growth can enhance TPO activity through this mechanism. Accordingly, adrenalectomy prevents this form of stress-induced enzyme synthesis, whereas the glucocorticoid or substrate-induced TPO synthesis proceeds unimpeded.

These and other observations led to the conclusion that hepatic TPO activity plays an important role in metabolic adaptation to stress. The stressors are thought to act upon hepatic TPO induction through the pituitary-adrenal axis, whereas STH and cortisol may act directly. There is some evidence that STH actually inhibits

certain hepatic enzyme induction mechanisms and it is conceivable that stress exerts a corresponding action either directly or through the intermediary of the pituitary. If so, exposure to stress would have a dual effect in that the inhibitory actions just mentioned could be compensated, or even overcompensated, by enhanced glucocorticoid production.

The fact that adrenalectomized rats are extraordinarily sensitive to endotoxin and that cortisone antagonizes this effect both in the absence and in the presence of the adrenals appeared to support the concept of a close relationship between stress and enzymic defense. Curiously, the adrenals of mice given endotoxin failed to respond sufficiently to exogenous ACTH. It must be kept in mind however, that enormous doses of glucocorticoids are required to antagonize the fatal effect of endotoxin and it is unlikely that the glands could produce equivalent amounts under the influence of either exogenous or endogenous ACTH.

Hypoxia produces enzymic changes reminiscent of those elicited by endotoxin, and cortisone increases survival at high altitudes. These and other observations led to the conclusion that hypoxia also acts upon enzyme induction as a stressor and is correspondingly subject to the protective effect of cortisone.

Perhaps the most interesting recent observations in this connection are those showing that complete blockade of sympathetic function achieved by various means increases mortality from endotoxin or histamine as markedly as does adrenalectomy. This decrease in resistance is counteracted by treatment with epinephrine alone, whereas cortisone offers only partial protection. Presumably sympathetic stimulation is "the first line of defense against vasomotor disturbances elicited by endotoxin and histamine." On the other hand, the lethal effect of formalin or tourniquet shock, which is also greatly increased by adrenalectomy, is not increased by sympathetic blockade. Furthermore, cortisone counteracts the toxicity of these latter stressors in adrenalectomized rats suggesting that "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin."

*Knox et al. E 83,471/56:* Review of the literature suggesting that many stimuli which induce specific enzyme systems may act through common pathways. This is especially true of adaptive reactions to stress. "Thus increases in the tryptophan peroxidase produced by the administration of histidine, of epinephrine, of histamine, and of certain other compounds were found to occur by the common mechanism of adrenal cortical stimulation. Other stressing conditions such as X-irradiation, starvation, and terminal tumor growth have also been recognized to increase this enzyme by the same mechanism. These effects can all be eliminated by adrenalectomy, and thus can be distinguished as a group from the increase in tryptophan peroxidase induced by substrate administration. Further investigation along these lines of changes in other specific proteins which occur with X-irradiation, starvation, stress, or other agents causing adrenal cortical

stimulation (e.g. colchicine) may be expected to identify still more adrenal hormone-induced adaptations."

*Knox G 67,799/58:* Review of the literature and personal observations lead to the conclusion that hepatic microsomal TPO activity plays an important role in metabolic adaptations to stress. Stressors act through the pituitary-adrenal axis upon hepatic TPO whereas tryptophan, STH and cortisol may act upon the liver directly.

*Berry et al. C 73,199/59:* The observation that adrenalectomized rats are extraordinarily sensitive to endotoxin strengthens the stress concept and would "place injections of endotoxin in the category of 'stressful situation'. Completely contradictory to this notion is the total loss in the ability of the adrenals of mice given endotoxin to respond to exogenous ACTH . . . These results might be explained by a destruction or inactivation of ACTH in vivo.

One is still at a loss, however, to understand why adrenalectomized animals should be more susceptible to endotoxin poisoning unless it is assumed that adrenal hormones other than glucocorticoids act beneficially against endotoxin." [Here, the antagonism between glucocorticoids and endotoxin was tested mainly by changes in glyconeogenesis (liver and muscle glycogen, total carbohydrate of carcass, urinary nitrogen). Hence, the alternative hypothesis should also be considered that these effects of endotoxin could be antagonized by the large dose of cortisone (5 mg p.o.), whereas the glucocorticoids secreted under the influence of ACTH did not, suffice to block these biochemical consequences of endotoxin poisoning (H.S.)]

*Insoe & Axelrod D1,700/60:* In rats, exposure to stress (cold) depressed the ability of the liver to produce o-aminophenol glucuronide. However, this was due only to a diminution of microsomal protein per gram liver. The ability of microsomes to hydroxylate acetanilide was stimulated by exposure to cold, whereas N-demethylation of meperidine and methadon was depressed. Apparently, the effect of stress upon drug-detoxication depends upon the substrate used.

*Rupe et al. E26,910/63:* In rats, stress produced by placing a tourniquet on one hind leg decreases the pharmacologic response to hexobarbital, meprobamate and pentobarbital. This effect is prevented by hypophysectomy or adrenalectomy, but simulated by ACTH or corticosterone. No such effect on stress was noted with barbital, a compound not metabolized by hepatic microsomal enzymes. Furthermore, the protective effect of stress is counteracted by SKF 525-A. Apparently, the "pituitary-adrenal activity exerts a regulating influence on drug responses."

*Bousquet et al. F35,073/65:* In rats, stressed by application of a tourniquet to one hind leg, the duration of response to hexobarbital, pentobarbital, meprobamate and zoxazolamine is significantly reduced, but only in the presence of both the pituitary and the adrenal glands. Pretreatment with ACTH or corticosterone simulates the effects of stress in shortening hexobarbital anesthesia. "It is suggested that the pituitary-adrenal axis serves a regulatory function with respect to duration of drug responses which may be mediated by an alteration of drug metabolism."

*Juchau et al. E50,728/65:* In rats, benzpyrene hydroxylase activity can be induced even in the perfused liver in which systemic

stress and the actions of the pituitary-adrenal axis cannot intervene.

*Stitzel & Furner G48,920/67:* In rats, stress (cold) increases the rate of p-hydroxylation of aniline and N-dealkylation of ethylmorphine simultaneously with an increase in adrenal ascorbic acid content. The stress-induced stimulation of microsomal metabolism and adrenal ascorbic acid levels are additive with those produced by phenobarbital. "It is tentatively concluded that stress and phenobarbital appear to act through different mechanisms in inducing increases in enzyme activity, although each treatment may have a common final step, namely an increased net synthesis of enzyme protein."

*Berry et al. H2,124/68:* Studies on the influence of hypoxia, glucocorticoids and endotoxin on hepatic enzyme induction and survival in mice. "Endotoxin inhibited the induction of tryptophan oxygenase, prevented the increase in liver glycogen, induced the transaminase, and increased the lethality of simulated altitude. Cortisone increased survival at all altitudes except the highest. These observations emphasize the importance of these metabolic adjustments for the survival of animals subjected to hypoxic stress."

*Furner & Stitzel G54,558/68:* In rats, adrenalectomy reduces the rate of metabolism of ethylmorphine, aniline and hexobarbital. Cortisol or stress (cold) stimulates ethylmorphine and aniline metabolism, even in adrenalectomized animals, whereas phenobarbital enhances the metabolism of all three compounds. Apparently, "both stress and phenobarbital can bring about changes in drug metabolism independent of the presence of an intact adrenal."

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance

elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone coun-

teracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

### 11. HOMEOSTASIS AND THE NONSPECIFICITY OF STEROID-INDUCED RESISTANCE

Two of the most intriguing problems in connection with the hormonal regulation of resistance are that:

1. The actions of the adaptive hormones are primarily homeostatic; they readily correct severe deviations from the norm but have little or no effect upon near normal blood and tissue concentrations of most chemical compounds.

2. The defensive actions of protective hormones are largely nonspecific; they raise the resistance of the body against the damaging actions of many toxicants upon the most diverse organs.

We have already touched upon the first problem in the previous sections in connection with the old debate about whether catatoxic compounds act only against "foreign compounds" and came to the conclusion that this is not the case, at least not in the original formulation of this concept. These compounds do act against numerous natural constituents of the body, but mainly if the latter are present in abnormally large amounts. This postulate is, of course, most readily fulfilled with "foreign compounds" (e.g., barbiturates) which are "present in abnormally large amounts" whatever their blood concentration.

One must also consider the possibility that the magnitude of a detoxifying reaction may depend primarily on the amount of substrate present. If an enzyme system is more than sufficient to cope with near physiologic amounts of substrates, induction of further enzymic activity can be beneficial only when abnormally high demands are imposed by considerable increase in substrate concentration. In other words, under near-physiologic circumstances, the available enzyme concentration is not the rate-limiting factor in detoxication.

We also saw that the glucocorticoids are most effective in raising resistance to stress towards normal, but not above a near-physiologic level. This was probably one of the first pertinent observations. It seemed odd that small doses of the earliest impure cortical extracts should be so eminently effective in restoring the subnormal resistance of adrenalectomized rats to a stressor such as cold, whereas even large amounts of the same preparations (or of the subsequently discovered highly potent synthetic glucocorticoids) failed to make intact rats more than normally resistant to cold. Yet, selectively homeostatic actions of drugs are not unprecedented: antipyretics are highly active in decreasing fever but cause no hypothermia; antiphlogistics combat inflammatory edema but do not diminish the hydration of normal tissues.

It remains to be seen why this type of homeostatic arrangement is effective against so many potential pathogens. We have no definite information about this point but, for example in the case of glucocorticoids, it is conceivable that their effect upon capillary permeability, or membrane permeability in general, endows them with

the properties of "tissue tranquilizers" in that, by diminishing fluid transport and metabolic turnover, they paralyze topical reactivity in general. This would explain why they are "syntoxic" and facilitate tolerance of potential irritants even without attacking the latter. This hypothesis is also compatible with the observation that the defensive effect of syntoxic compounds is so largely nonspecific, since innumerable agents cause damage not by directly destroying or attacking tissues, but by evoking excessive reactions through their irritating effect.

But how could we explain the almost equally great nonspecificity of the protective effect of catatoxic steroids which act against different toxicants and through a different mechanism? These hormones (or at least the great majority of those among them that have been adequately studied) act by destroying pathogens, not by rendering tissues insensitive to them. Furthermore, catatoxic steroids are most effective in raising resistance far above normal whereas syntoxic steroids are especially efficacious in restoring the subnormal stress-resistance of the hypocorticoid organism to the normal level. In other words, here again, the actions of catatoxic compounds are virtually the opposite of those elicited by syntoxic steroids.

In both these instances it is difficult to imagine through what chemical mechanisms the same steroid could offer nonspecific resistance against so many kinds of damaging agents, especially since this nonspecificity, though considerable, is not absolute. Both syntoxic and catatoxic steroids protect against numerous potential pathogens, quite unrelated in their chemical structure or toxicologic activities; yet both types of hormones offer considerable protection against some, but little or none against other forms of damage. In the case of the catatoxic steroids it is highly unlikely that Nature would have foreseen a specific enzyme for the destruction of each of the many substrates which they detoxify, including even newly synthesized toxicants to which no defense mechanism could have been developed during evolution of the species or the individual. On the other hand, if the body would manufacture a single enzyme (or a small set of enzymes) with an enormous range of detoxifying power, how could this protection nevertheless be specific to some extent in that certain catatoxic compounds are more selectively effective or ineffective against individual toxicants.

In reviewing all our data concerning the effect of hormones upon resistance, and particularly the Synoptic Tables 138 and 139 it appears that, at least in theory, we should distinguish between the following actions:

**I. Nonspecific detoxication.** The power of many steroids to protect against a large number of apparently unrelated toxicants.

**II. Nonspecific toxication.** The property of decreasing resistance to many toxicants.

**III. Specific detoxication.** The ability of increasing resistance selectively to one, or only a few, of the toxicants tested.

**IV. Specific toxication.** The selective diminution of resistance to one or few toxicants.

It is remarkable that most catatoxic steroids exhibit the "Type I" action in that they increase nonspecific resistance to many agents. Only very few, if any, catatoxic steroids show a "Type II" effect, although to some extent this may be true of estradiol and of the only nonsteroidal hormone in our series, thyroxine. These do impair

resistance to numerous toxicants; yet, their effect is by no means as pronounced or general as that of actinomycin, puromycin, ethionine or SKF 525-A, which interfere with various steps in enzyme-protein synthesis or function. Finally, among the intoxications included in our series, only few are specifically prevented or aggravated by steroids, thyroxine or phenobarbital.

We cannot explain the great predominance of "Type I" activity among the cata-toxic steroids nor do we understand through what mechanism a single compound could provide resistance against so many toxicants. However, as a tentative working hypothesis, it is tempting to assume the existence of some nonspecific "common prerequisites" which might participate, and even be rate-limiting, in numerous chemical reactions that influence resistance. This could be achieved by general regulators of enzyme synthesis and degradation, as well as by factors influencing the availability of common co-enzymes or of substrates which provide the energy necessary for the most diverse chemical reactions. Similarly, very different types of defensive responses could be modified by factors affecting membrane permeability (e.g., fat solubility), or the binding of toxicants to blood proteins.

To take the most common "Type I" effect as an example, it may be postulated that some common prerequisites of defense reactions are used up in the fight against stress or for the development of resistance to substrates of catatoxic steroids. If so, the need for such adjuvant substances would be a nonspecific prerequisite for the activation of many specific defense reactions. The syntoxic and catatoxic steroids may produce such common adjuvants and thereby exert a highly nonspecific protective effect. Understandably, supplements of the common prerequisites (provided through appropriate steroid treatment) would have little effect under near-physiologic circumstances when they are in ample supply to start with. Conversely, at times of excessive demands, an appropriate increase in the availability of the common adjuvants may be the decisive rate-limiting factor in the development of resistance to many agents.

In summary, we might assume as a tentative working hypothesis that the protective steroids (both syntoxic and catatoxic) activate a limited number of comparatively nonspecific enzyme systems which can attack diverse substrates by facilitating prototypes of biotransformation reactions (e.g., oxidation, reduction, conjugation) and by providing "common adjuvants" (cofactors, energy yielding substances) which enhance many types of enzymic responses.

On the other hand, certain protective steroids are selectively effective against certain toxicants or, conversely (despite a very general protective effect), selectively fail to induce resistance against certain drugs. This fact might be ascribed to specific characteristics of either the substrates or the protective steroids which happen to block the degradation of individual toxicants or interfere with their effect by fortuitous pharmacologic synergisms or antagonisms. Such interactions could occur either at the site of enzyme induction or even in the peripheral target organs. Furthermore, a certain type of enzymic reaction (e.g., S-demethylation, aliphatic oxidation or aromatic hydroxylation) may abolish the damaging effects of many toxicants and yet have no effect or actually aggravate those of others, depending upon the pharmacologic properties of the resulting metabolites. It is not unexpected therefore that the enzyme induced by very "broad spectrum" catatoxic steroids may selectively be without avail in offering protection against a given substrate and conversely that

the substrate easily detoxified by numerous steroids may be resistant to one of them.

The following schematic drawing may help to remember what we consider to be the principal facts concerning the observations just mentioned. At least in theory, we assume the existence of four basic types of hormonal influences upon resistance.

Here, the horizontal bar represents a series of ten intoxications (the consecutively numbered squares). The numbers themselves indicate the amenability of these intoxications to various types of hormonal regulations. In this theoretical series, every toxicant (1–10) is shown as amenable to the nonspecific detoxication of “Type I”. The narrow shaded lower part of this series would correspond to nonspecific toxication of the “Type II” variety, but it is questionable whether any hormone actually possesses sufficiently nonspecific toxifying actions to fulfill the requirements for this hypothetical category. Among those tested, several (thyroxine, folliculoids) tend to enhance the toxicity of many agents, but no hormone or hormone derivative possesses as broad a spectrum of toxicant actions as the detoxicant effects of “Type I” steroids or the resistance aggravating actions of such antagonist drugs, as SKF 525-A, puromycin or actinomycin.

“Type III,” specific detoxication, is indicated by the squares 2A and 7A, whereas “Type IV,” specific toxication, is represented by 9B. The same intoxication is not necessarily amenable to modification by specific (Type III & IV) and nonspecific (Type I & II) conditioning agents; in fact these positive and negative conditioning effects (detoxication and toxication) obviously cannot occur at the same time as might be implied by the drawing, which only attempts to illustrate all possibilities. Spironolactone definitely possesses considerable “Type I” activity, but its protective effect upon mercury intoxication is specific (Type III). On the other hand, triamcino- lone and other glucocorticoids may exert specific protective actions (Type III) against various ganglionic blocking agents, lathyrogens or inflammation without possessing nonspecific catatoxic properties of “Type I.”

It remains to be shown whether this attempt at a classification will prove to be of heuristic value, but it is clear that any attempt to explain the relative non-specificity of catatoxic steroids must be compatible with the fact that none of them has an identical protective spectrum; the type and degree of protection they offer against different toxicants is as individualistic as the fingerprints or the genetic code of a man.

*Solymoss et al. G79,023/71:* In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norbolethone and oxandrolone (anabolics), also enhance plasma clearance of BSP, probably through the same mechanism. In contrast to these effects of pretreatment, administration of spiro-

nolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, these observations clearly show that the catatoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may also be mediated through extramicrosomal enzyme mechanisms or even through enhanced biliary excretion (H.S.).]

## XI. SYNOPSIS OF PHARMACO-CHEMICAL AND PHARMACO-PHARMACOLOGIC INTERRELATIONS

In analyzing the mechanisms through which hormones can influence resistance, we must consider first the various forms of drug interactions in general and second the structural prerequisites for the protective actions of hormones. It is obvious that drugs and hormones may interact by influencing each other's absorption, excretion, distribution within the organism, metabolism, as well as by direct chemical or pharmacologic interactions that occur between drugs *in vivo*. However, these mechanisms are the subject of general pharmacology and hence they will only receive cursory attention here.

The principal objective of this section is to correlate the many experiments which we performed to obtain material for a glimpse into the structural (chemical) or pharmacologic prerequisites for the ability of steroids to protect the body against toxicants.

### *VARIOUS FORMS OF DRUG INTERACTIONS*

In discussing the various forms of interactions between drugs (including hormones), several mechanisms must be considered, for example:

1. The gastrointestinal **absorption** of one drug can be affected by another which alters the pH of the alimentary tract, the permeability of its epithelium or peristalsis.
2. Drugs may affect the renal, biliary, or intestinal **excretion** of other drugs.
3. One drug may alter the **distribution** of another drug within the organism, e.g.:
  - a) by altering the permeability of the hemato-encephalic barrier;
  - b) by competing for shared protein-binding sites in the plasma, thus augmenting the biologic activity of the displaced drug;
  - c) by competing for receptor sites in tissues, thus diminishing the activity of the displaced drug.
4. Drugs may affect the synthesis, degradation or activity of microsomal and extramicrosomal **drug-metabolizing enzymes**.
5. Direct **chemical interactions between drugs** (e.g., chelation) may lead to their inactivation *in vivo*. Addition of a pharmacologically inert radical to a potent drug may also alter the susceptibility of the latter to microsomal enzyme activity (e.g., morphine and barbital are resistant, whereas ethylmorphine and phenobarbital are highly susceptible to degradation by microsomal enzymes). Such an "opsonization" by addition of a radical may increase the liposolubility of a drug and hence, its capacity to penetrate through membranes. This type of synthesis has not been definitely proven to occur *in vivo*, but it may play a role in drug interactions.
6. Direct **pharmacologic interactions between drugs** (e.g., between a vasoconstrictor and a vasodilator, or between two vasodilators) may lead to an increase or a decrease in their activity.

**Drug Interactions in General**

*Fouts G77,566/64*: Review (5 pp., 18 refs.) on the effect of drugs upon drug metabolism.

*McIver G78,391/65*: Review (4 pp., 43 refs.) on drug incompatibilities.

*Remmer G78,385/65*: Review (24 pp., 156 refs.) on the mechanism of drug interactions.

*Gillette G78,390/67*: Review (19 pp., 96 refs.) on theoretical aspects of drug interaction.

*McIver G77,708/67*: Review (6 pp., 41 refs.) on drug incompatibilities.

*Block & Lamy G81,054/68*: Review (6 pp., 82 refs.) on therapeutic incompatibilities of importance to pharmacists.

*Hartshorn G78,178/68*: Greatly simplified but excellent revue (8 pp., about 35 refs.) enumerating various ways in which drugs can interact and illustrating each type with a few examples.

*Hartshorn G81,056/68*: Review (4 pp., 17 refs.) with practical hints on drug interactions useful to the pharmacist.

*Hartshorn G81,057/68*: Review (7 pp., 3 refs.) consisting mainly of tables concerning drug interactions.

*Hussar G81,059/68*: Review (11 pp., 82 refs.) on drug incompatibilities.

*Pelissier & Burgee, Jr. G79,655/68*: A brief guide to drug incompatibilities irrespective of the underlying mechanism.

*Block & Lamy G81,052/69*: Review (5 pp., 27 refs.) on drug interactions with tabular summaries on changes in metabolism, binding to plasma and urinary pH changes produced by one substance which may alter the activity of another compound.

*Dunphy G77,712/69*: Review (11 pp., about 30 refs.) on drug interactions with an outline of an extremely simplified index listing a few examples of these.

*Hartshorn G81,055/69*: Review (7 pp., 33 refs.) on interactions among anti-infective agents.

*Hussar G81,053/69*: Practical hints concerning drug interactions of interest to the pharmacist.

*Visconti G77,709/69*: Review (10 pp., no refs.) on how drug interaction information may be used preventively.

*Ariëns G79,943/70*: Review (48 pp., about 160 refs.) on drug interactions with special reference to antagonisms, metabolic inactivation and metabolic activation. [Excellent summary, but the poor English is difficult to follow (H.S.).]

*Neumann G80,018/70; G80,550/70*: Review (5 pp., no refs.) on drug interactions in the style of a postgraduate lecture.

*Mannering G74,881/71*: Review of the literature on drug interactions in general leads to the conclusion that "a drug may alter the action of another drug in several ways: a) by producing one or more effects similar or opposite to those of the drug in question, b) by direct chemical or physical interaction of drugs, c) by displacement of drugs bound to plasma or other proteins, d) by altered renal clearance of drugs, e) through conditioning by previous drug effects, f) by interaction of drugs with receptor sites, and g) by inhibition or stimulation of the metabolic site. Examples of all of these interactions are given . . ."

**Lipid Solubility**

*Brodie G55,013/62*: "Metabolism of the microsomal enzymes seems to be governed by lipid solubility, for only substances that are highly lipid soluble are metabolized by microsomes."

*Mannering G71,818/68 (p. 74)*: A survey of the literature shows that compounds with low lipid solubility are poor inducers of drug-metabolizing microsomal enzymes, whereas potent inducers are, in general, highly soluble in organic solvents. [Yet all steroids are lipid soluble but are not good inducers (H.S.).]

**Carriers**

*Baird & Reid G51,827/67*: Pancuronium bromide produces neuromuscular blockade in man.

*Lewis et al. F95,691/67*: In various test procedures, steroidal monoquaternary ammonium salts exhibited non-depolarizing neuromuscular blocking activity.

*Bonta & Goorissen G75,052/68; Buckett G75, 531/68*: Pharmacologic studies on the neuromuscular-blocking effect of pancuronium.

*Buckett et al. G56,175/68*: "Pancuronium possesses up to ten times the potency of tubocurarine according to the species used for testing, while possessing similar duration of action."

*Reyes et al. G71,233/69*: In rats phenobarbital "enhanced hepatic uptake of an organic anion, bromsulphalein, in vivo and simultaneously increased the amount of Y, a hepatic cytoplasmic organic anion-binding protein. This study supports the postulate that Y is a major determinant in the selective hepatic uptake of certain organic anions from

plasma." Induction of Y may enhance hepatic uptake and metabolism of various substrates following treatment with phenobarbital and other inducers.

*Wall et al. G69,969/69:* A series of steroid esters of p-[N,N-bis(2-chloroethyl)amino] phenylacetic acid (BCAPAA), steroidal sulfides of p-(N,N-bis-2-chloroethylamino)thiophenol, and a variety of steroidal ethylenimine derivatives were synthesized and tested for antitumor activity. "Activity was found only in those instances in which the steroid and potential oncolytic agent were connected by ester or heterocyclic ether linkages. The steroidal BCAPAA esters were of particular interest showing excellent inhibition of a DMBA-induced and transplantable mammary adenocarcinoma, and marked increase in survival when tested on a variety of rat leukemias. . . . The steroidal BCAPAA esters were judged to be less toxic than some of the well-known nitrogen mustards in general use."

*Chaouki et al. G77,223/70:* In 50 patients, pancuronium bromide was found to be an active non-depolarizing neuromuscular blocking agent, about 5 times as active as curare and 25 times more potent than gallamine triethiodide. Its advantages are rapid onset of action, no release of histamine and little disturbance in blood pressure, because of a weak ganglioplegic action.

*Dick et al. G77,777/70:* Favorable clinical experiences with pancuronium as a muscle relaxant in anesthetized patients.

*Feldman & Tyrrell G76,666/70:* Dacuronium bromide (2 $\beta$ , 16 $\beta$ -dipiperidino-5 $\alpha$ -androstane-17 $\beta$ -diol-3 $\alpha$ -acetate dimethobromide) is closely related to pancuronium bromide but the acetoxy group at C<sub>17</sub> is replaced by a hydroxyl group. It has proven its usefulness as a non-depolarizing muscle relaxant in man. Its effect is fully reversible by edrophonium or neostigmine.

### PREREQUISITES FOR THE PROTECTIVE ACTIONS OF HORMONES

Looking back upon research on hormones and resistance, as outlined in this monograph, it may be instructive to reexamine the justification of the path followed and to summarize the main points.

It is not without hesitation that we embarked upon this project some 35 years ago; we realized, to start with, that this would be a life-long undertaking with virtually no background data for logical planning. On the basis of what we had learned in 1936 about the role of the adrenal cortex in defense against stress, no other course seemed to be open to us but that of a purely empirical, large-scale screening of many steroids (more or less closely related to the corticoids) for possible protective effects against many toxicants.

However, the possibility of finding highly potent and comparatively nontoxic protective steroids appeared to hold considerable promise of practical applicability and the screening did not have to rely on chance alone. To some extent, we could be guided by the pharmacologic and chemical characteristics of compounds previously shown to have protective potency against certain substrates. We used the same guide lines for the identification of toxicants amenable to prophylaxis by steroids. It is on the basis of this kind of empirical research that we are now beginning to see outlines of a classification which permits us to predict, with some degree of probability, what compounds are likely to possess protective effects against what types of toxicants.

Because of the large number of experiments required to explore the many possible combinations of such interactions, we had to rely on simple *in vivo* observations in which directly visible (functional or structural) changes and mortality rates were our principal indices of activity. Yet, in the early days we were encouraged by the knowledge that similar screening efforts did prove to be eminently successful in many other fields. The classification of bacteria on the basis of their ability to grow on

certain media or to take up the Gram stain, the screening of antibiotics on plates inoculated with various bacteria, the blind testing of 606 chemotherapeutic agents that finally led Ehrlich to the discovery of "Salvarsan," are but a few examples to illustrate this point.

In our own work we could demonstrate the nonspecificity of the pituitary-adrenal response only by countless *in vivo* tests with many stressors; only the screening of numerous calciphylactic sensitizers and challengers permitted us eventually to induce localized tissue calcification in a predictable and highly specific manner.

Naturally, as soon as any new protective phenomenon was discovered, *in vitro* studies in depth became necessary to clarify the underlying mechanisms; for example, after we noted the prevention by spironolactone of digitoxin and mercurial intoxication, or the extraordinary degree and spectrum of protective effects that can be induced in steroids by the introduction of a nitrile group. Much of this work is still to be done, but before we could even think about elucidating the manner in which a protective phenomenon works, we had to know first that the phenomenon exists.

So much for self-justification.

To begin with, we had to develop an economic procedure which permitted large scale experimentation with a minimum waste of steroids, many of which are difficult to synthesize. Then we had to design a technique for the correlative evaluation of the many individual observations made.

Our assay procedure consisted of the following three steps:

1. Establishment of possible protective potency against two standard toxicants: digitoxin and indomethacin.

2. Determination of the "protective spectrum" of the steroids found to be active in step 1.

3. Identification of damaging agents amenable to prophylaxis by steroids which have revealed interesting activities in step 2.

Before describing these steps in detail, we shall have to say a few words about the evaluation of the data obtained. The results of the first screening have been tabulated in the conventional way (Table 135) by listing the mean severity of the actual changes as previously described for comparable studies on the effect of 304 steroids upon indomethacin and digitoxin poisoning (*Selye G70,421/70*).

In addition, we constructed **Synoptic Tables** (Tables 136, 137, 138) in which these and many additional results are summarized on the basis of the degree of the significance ratings (*cf.* "Statistical Evaluation," p. IX) according to a system developed by Mrs. I. Mécs of this Institute. The figures indicate the means of the statistical significance grades of the changes (functional or structural) used as indicators, plus that of the mortality rates divided by 2. Thus, in an experiment in which the protection against intestinal ulcers had a significance rating of "0" (no protection), and the signifi-

cance of the protection against mortality was 3 "\*\*\*" (perfect protection), the figure given in the tables would be 1.5. Only in the case of compounds which normally cause no mortality (e.g., anesthetics, muscle relaxants) do the grades correspond to structural or functional lesions alone.

The Synoptic Tables (136, 137, 138) also list the "**Mean Overall Protective Index**" computed according to a procedure closely related to the "Simplified Activity Grading" system previously described (*Selye G70,421/70*). This index represents the algebraic sum of all the individual activity gradings for a certain protective substance divided by the number of toxicants against which it was tested.

In addition, we computed the "**Total Overall Protective Index**" which represents the arithmetic sum of all the individual activity gradings (disregarding negative grades).

Furthermore, we computed the "**Protective Spectrum Index**" which is the percentage of

those toxicants tested against which significant protection is obtained (irrespective of the degree of significance). Thus, if a steroid offers significant protection against 6 out of 10 toxicants examined, its "Protective Spectrum Index" is 60%.

In the Synoptic Tables, these Indexes have also been computed for the amenability to protection of the various toxicants (three bottom horizontal lines). In other words, here the figures indicate the mean degree or the percentile frequency of protection offered by the entire series of conditioners against any one toxicant.

Finally, to further facilitate the overview of this complex field we constructed a "Diagram Table" (Table 139) which graphically summarizes the highlights of Table 138, except that the results are registered only for one dose level of the toxicants and are expressed in a scale in

which intermediates between the four grades are not recognized (for details *cf.* footnote on Table 139). Furthermore, in Table 138, the toxicants are listed in alphabetical order for easy identification, whereas in Table 139, they are enumerated according to decreasing "Total Overall-Protective Index" values.

Since the large number of experiments to be reported here was performed over a considerable period of time, in each case, a group of unpretreated controls received the same toxicant, simultaneously with the rats that had been pretreated with potentially protective substances. The statistical significance of the resulting changes in the pretreated animals was always calculated in comparison with the corresponding group of unpretreated controls handled under identical circumstances, at the same time and by the same technician.

Using these procedures for the evaluation of our data, we examined the steroids available for this work according to the above mentioned three-step procedure.

### ***First Step: Protection Against Digitoxin and Indomethacin***

The first systematic investigations designed to identify protective steroids consisted of a series of bioassays in which 304 natural and synthetic steroidal compounds were tested for their ability to protect the rat against digitoxin and indomethacin, under the experimental conditions outlined in the preceding section. Since these results have been the subject of an extensive review (*Selye G70,421/70*), we shall limit ourselves here to a brief description of the principal conclusions derived from them.

Protective activity was widespread among the steroids of this first series; it was demonstrable among gonanes, estranes, androstanes, androstenes, 5 $\beta$ - and 5 $\alpha$ -pregnanes as well as among pregnenes, with one or more double bonds, and with or without halogen substitution in the ring system. On the other hand, cholanes, cholestanes and genins were uniformly inactive, with the sole exception of methylnordeoxycholanate (3 $\alpha$ ,12 $\alpha$ -dihydroxy-24-nor-5 $\beta$ -cholan-23-oic acid methyl ester).

Because of this widespread distribution of anti-indomethacin and antidigitoxin activity throughout various classes of steroids, it was difficult to formulate any clear-cut rules about pharmaco-chemical correlations in this field. It does appear, however, that although catatoxic activity is not strictly dependent upon any single structural prerequisite, in general the 17 $\alpha$ -propionic acid- $\gamma$ -lactone side-chain is advantageous for both antidigitoxin and anti-indomethacin activity. It is perhaps also not purely coincidental that a very large number of active catatoxic steroids is found among the 1,4-androstadienes as well as among halogenated androstene and pregnene derivatives. It is likewise noteworthy that several of the most active catatoxic steroids are 19-nor compounds, hence the angular methyl group at C<sub>10</sub> is not only dispensable but often advantageous. The most striking observation in this series of tests was that among all 304 steroids tested the most active against both substrates proved to be a cyano-compound, namely PCN.

This first systematic screening series also revealed that the catatoxic activity is not strictly dependent upon any other known pharmacologic property, although most of the highly potent antidigitoxin and anti-indomethacin steroids also exhibit anti-mineralocorticoid or anabolic properties.

Because of the comparatively small number of animals that could be used for the bioassay of the many, not readily available, steroids, only the lowest and the highest activity grades were given serious consideration. However, even on this rigid basis of appraisal, we found that at a 10 mg dose level, among 304 steroids tested, there were:

Active only against indomethacin: 42  
 Active only against digitoxin: 32  
 Active against both substrates: 24  
 the remainder being inactive or of doubtful activity.

At the 0.5 mg dose level, we found:

Active only against indomethacin: 1  
 (Cpd. 277 and betamethasone acetate)  
 Active only against digitoxin: 1  
 (CS-1)  
 Active against both substrates: 1  
 (PCN)

These compounds correspond to the following structures:

CS-1

9 $\alpha$ -Fluoro-11 $\beta$ -,17-dihydroxy-3-oxo-4-androstene-17 $\alpha$ -propionic acid potassium salt (SC-11927)

PCN

3 $\beta$ -Hydroxy-2-oxo-5-pregnene-16 $\alpha$ -carbonitrile (SC-4674)

Betamethasone acetate

9 $\alpha$ -Fluoro-16 $\beta$ -methyl-11 $\beta$ ,17,21-trihydroxy-1,4-pregnadiene-3,20-dione 21-acetate

"Cpd. 277"

21-Hydroxy-3-oxo-1,4,9(11)-pregnatrieno-[17 $\alpha$ ,16 $\alpha$ -d]-2'-methyl-oxazoline acetate

It is especially noteworthy that several of the active catatoxic steroids are naturally occurring hormones, hormone precursors or hormone metabolites such as: progesterone, 17 $\alpha$ -hydroxyprogesterone, 5-pregnenolone, dehydroisoandrosterone.

Encouraged by these first observations, we then proceeded to repeat some of the key observations at lower dose levels. We also performed similar tests on many additional steroids, especially carbonitriles and other compounds related to the most active members in the preliminary series. This work (Selye G 70,480/71) was done under experimental conditions exactly corresponding to those of the first screening tests, and the results are summarized in Table 135.

However, before describing these most recent experiments, we must say a few words about the SSS steroid terminology. Up to now, in discussing the literature, we used essentially the same terms as did the authors quoted. This was far from satisfactory, but unfortunately unavoidable, because we could not have taken the responsibility of translating into any accepted steroid nomenclature the often ambiguous mixtures of trivial and systematic designations that are sometimes employed even by the most reputable pharmacologists and clinicians. However, in the following description of our own experiments with fully characterized compounds, these will be identified not only by their structure formulas and the official designations accepted by the International Union for Pure and Applied Chemistry (IUPAC Commission G82,068/69), but also by the much more easily understandable and simpler SSS terms. The SSS (Symbolic Shorthand System of steroid terminology) (Selye et al. G79,034/71) can be briefly summarized as follows:

#### **Basic Principles**

The main advantages of the SSS nomenclature are: **shortness** of code terms, **logical consistency**, and **simplicity**. The principles which guided its design are:

**Rigid observance of left-to-right precedence order** in the coining of symbols. The parent hydrocarbon comes first, then its substituents in a strictly determined sequence. Each substituent is named by a symbol followed by a positional number according to the principle of: "first what, then where" (e.g., 17 $\beta$ -Hydroxyandrostane-3-one = Aol<sub>17 $\beta$</sub> on<sub>3</sub>).

We deviate from this rule only in the case of "secondary parent hydrocarbons" in which the main parent hydrocarbons (e.g., estrane, androstane) are provided with side-chains attached by C—C linkages (e.g., methyl-androstane or cyanopregnane). In such cases, substituents of the side-chains are mentioned immediately after the latter. E.g., an androstane with a hydroxylated (ol) methyl group (I) attached at 16 $\beta$  is written AIol<sub>16 $\beta$</sub>  and the whole expression is underlined (or boldface) to distinguish it from substituents on the main parent hydrocarbon itself which follow according to the order of precedence described below. For example, if the methyl-androstane just mentioned also contains a ketone group at 3 and a fluorine in the 9 $\alpha$ -position, we write AIol<sub>16 $\beta$</sub> on<sub>3</sub>F<sub>9 $\alpha$</sub> .

**No signs to indicate two or more identical characteristics** (e.g., diene, triol, dione). The

sign  $\Delta$  and the suffix "-ene" are also omitted since appropriate position numbers make them superfluous. After the symbol of the parent hydrocarbon (e.g., A = Androstane) superscript numerals suffice to designate the degree of unsaturation, while subscripts qualify the position and number of functional groups (e.g.: A<sup>4,6</sup>ol<sub>11 $\beta$ ,17 $\alpha$</sub> on<sub>3</sub> = 11 $\beta$ ,17 $\alpha$ -Dihydroxy-4,6-androstadien-3-one).

**No silent "e"** (e.g., in "one"). This is always omitted, not only when the next syllable begins with a vowel. The final "e" does not change either the meaning or the pronunciation of the syllable and, in many languages, it is not used in any case. Besides, SSS (like IUPAC) is not meant for oral communication.

Since esters are always formed with alcohols, the **esterified OH groups are not separately indicated**. E.g., instead of 5 $\alpha$ -Androstane-3 $\beta$ ,17 $\alpha$ -diol 3-acetate 17-propionic acid ester, we merely write A5 $\alpha$ \*II''<sub>3 $\beta$</sub> \*III''<sub>17 $\alpha$</sub>  (\* = ester; '' = acid), since the 3 $\beta$ -acetate or 17 $\alpha$ -propionate can only be formed with the corresponding alcohols (*cf. also* p. 775 and 776). Furthermore, we employ short symbols instead of writing out the full names of the esterified acids and, instead of the usual ".", we separate ester functions from the parent hydrocarbon by an asterisk which uses no more space than the dash and yet further characterizes the following symbols as an ester.

**No prefixes.** It is superfluous to burden a codifier with a complex dictionary of rules according to which he must write a given symbol as a prefix or suffix. In SSS, the parent hydrocarbon is the first part of any designation; all other symbols are added as suffixes.

**No synonyms.** Every structural feature receives one name or symbol. This procedure is greatly facilitated by the omission of prefixes which complicate other systems. For example in IUPAC:

Carboxylic acids are named "Carboxy-" as prefix, and "-oic", "-ic" or "carboxylic acid" as suffix.

Alcohols are "Hydroxy-" as prefix and "-ol" as suffix.

Aldehydes are "Oxo-" as prefix and "-al" as suffix.

Most confusingly, ketones are also "Oxo-" as prefix, but "-one" as suffix.

**Typesetting and punctuation are used to specify chemical characteristics without lengthening names.** Instead of separating all parts of a term by dashes (-), SSS uses no separating sign or (where there may be ambiguity) the shorter comma (.). The latter is replaced by an asterisk (\*) to indicate ester function. Commas also separate the position numerals of identical functions (e.g.,  $01_{3\beta,9\beta,17\alpha}$ ). No punctuation is used to separate the constituents of a single functional group. E.g., \*III''<sub>3β</sub>, fully characterizes the location on C<sub>3</sub> and the steric position of an alcohol group esterified with propionic acid; the three ingredients (3, β, III'') need not be separated by dashes or any other sign which would only tend to break up what is actually one unit of expression.

**The simplest symbolic code terms are used for the most common expressions.** Thus, the main parent hydrocarbons have symbols consisting only of the first letter of their full name (e.g., **G** = Gonane, **E** = Estrane, **A** = Androstane) although, in some instances, one or two additional letters are added to avoid ambiguity (e.g., **CH** = Cholane, **CHT** = Cholestane, etc.). For emphasis, the symbols of the main and secondary parent hydrocarbons — including signs of intrinsic modifications such as: isomerism, unsaturation, nor, homo, abeo — are underlined and always capitalized (in printing, italicized or set in boldface).

Whenever possible, simple, self-explanatory **mnemonic abbreviations** are used for all substituent radicals, e.g., for normal alkyls roman numerals, indicating the number of carbon atoms contained:

I = Methyl II = Ethyl III = Propyl  
IV = Butyl V = Pentyl.

Longer and more complex radicals are represented by letter symbols, usually contractions of the IUPAC names (*cf.* below).

When **alkyls appear as side chains** (secondary parent hydrocarbons), they follow the name of the parent hydrocarbon (on the same line) and, like the latter, are boldface (e.g., **AI** = methylandrostane).

Whenever the chemical formula characterizing a substituent is shorter than a meaningful corresponding word or abbreviation could be, we use the former (e.g., =CH<sub>2</sub>, =NH, —CN, K, F respectively for methylene, imino, carbonitrile, potassium or fluorine). In order to avoid three-line symbols, the positional numbers of such formulas as =CH<sub>2</sub> are appended to a bracketed symbol e.g. (CH<sub>2</sub>)<sub>16β</sub>.

#### *The Main Parent Hydrocarbons (in order of precedence)*

Gonane	= <b>G</b>	Ergostane	= <b>ER</b>
Estrane	= <b>E</b>	Stigmastan	= <b>ST</b>
Androstane	= <b>A</b>	Cardanolide	= <b>CAR</b>
Pregnane	= <b>P</b>	Bufanolide	= <b>BUF</b>
Cholane	= <b>CH</b>	Spirostane	= <b>SP</b>
Cholestane	= <b>CHT</b>	Other nuclei	

All ring modifications, other than those recognized above as parent hydrocarbons, are listed as derivatives at the end of each main category in this order:

Heterocyclic steroids, *cf.* p. 777

Nor-ring steroids = **n** (e.g., **AnA** = A-nor-androstane, **PnB** = B-nor-pregnane).

Homo = **ho** (e.g., **PhoD** = D-homo-pregnane)

Abeo = **ab**

Cyclo = **cy**

Retro = **ret**

Seco = **sec**

#### *Derivatives (in order of precedence)*

With each parent hydrocarbon, its immediate derivatives are classified in the following order:

**Isomerism:** Isomerism at C<sub>5</sub> is indicated by **5α** or **5β** following the symbol of the parent hydrocarbon (e.g., **A5α** = 5α-androstane). Isomers are listed next to each other, α before β. For ring-isomers, *cf.* below.

**Unsaturation:** —C—C— (an), e.g., **A** (for Androstane),

—C=C— (en), e.g., A<sup>4</sup> (for Androst-4-ene), A<sup>4,6</sup> (for Androsta-4,6-diene).

The number of unsaturations is not indicated as it is evident from the positional number(s) in the superscript. Thus, A<sup>4,6</sup> suffices to indicate that we are dealing with a diene. [Not Δ<sup>1,2</sup>, etc.]. Cyclosteroids are also identified by superscripts, e.g., A<sup>3(5)</sup>. The superscript numbers of triple bonds (-yn) are repeated (e.g., P<sup>20-20</sup>).

**Alcohols:** —OH (ol), e.g., Aol<sub>17α</sub> (for Androstan-17α-ol),

Aol<sub>3β,17α</sub> (for Androstane-3β,17α-diol). [Not hydroxy, dihydroxy, etc.]

**Esters:** —CO[OHH]OC— (\*), e.g., P\*Bz''<sub>3α</sub>\*II''<sub>17β</sub> (for 3α,17β-Dihydroxypregnane 3-benzoate 17-acetate).

Esters are identified by an asterisk preceding the symbol of the acid, with which the steroid hydroxy group is esterified; they are listed immediately following the corresponding free alcohols. Since ester formation is possible only with alcohol groups, it is redundant to identify the position of each (the alcohol and acid) separately (*cf. also* below). [Not oxy (e.g., acetoxy) or "acid ester" (e.g., acetic acid ester)]. Esters of steroid acids are distinguished by placing the symbol for acid (") immediately after that of the steroid, before the asterisk (e.g., P''\*IIol<sub>21</sub> for 21-pregnanoic acid esterified with ethanol).

**Ketones:** C=O (-on), e.g., E<sup>1,3,5(10)</sup>ol<sub>3on</sub><sub>17β</sub> (for 3-Hydroxy-1,3,5(10)-estratrien-17-one or estrone). [Not oxo, keto, one (with terminal "e") and the redundant indication of the number of ketone groups by dione, trione, etc.]

**Carboxylic acids:** —COOH ("), e.g., P''<sub>21</sub> (for Pregnan-21-oic acid). Here the carboxyl group itself is considered to be part of the steroid skeleton, not an oxidized methyl side-chain on 21-norpregnane. However, a carboxyl which is not part of a recognized main parent hydrocarbon, but is attached to it by a C—C linkage, is written as an oxidized methyl side-chain (e.g., AI''<sub>16α</sub> for androstane 16α-carboxylic acid). Carboxylic acids not attached to the steroid skeleton by C—C linkages, e.g., those of esters, are similarly identified (by "), e.g., I'' = formic, III'' = propionic, V'' = pentanoic. Bz'' = benzoic acid (*cf. p. 778*) for alkane symbols). [Not carboxylic acid or -oic acid.]

Steroid acid esterified (e.g., P''\*IIIol<sub>16α</sub>).

Steroid alcohol esterified (e.g., P\*III''<sub>16α</sub>).

**Ethers:** —CO[HHC]C— (θ), e.g., θI, θII, θPIII (for methyl, ethyl or propyl ethers). [Not methoxy or methyl ether.]

**Lactones:**  $\begin{array}{c} \text{O} \\ || \\ \text{C}-\text{O} \end{array}$  (-lac, -ylac), e.g., A<sup>4</sup>III''<sub>γ</sub>lac<sub>17αol</sub><sub>11β,17on</sub><sub>3F</sub><sub>9α</sub> (for 9α-Fluoro-11β,17-dihydroxy-3-oxo-4-androstene-17α-propionic acid γ-lactone).

**Aldehydes:** —CHO (-al), e.g., P<sup>4</sup>ol<sub>11β,21on</sub><sub>3,20al</sub><sub>18</sub> (for 11β,21-Dihydroxy-3,20-dioxo-4-pregnen-18-al or aldosterone). As with the carboxylic acids, here the carbon bearing the aldehyde function is considered part of the parent hydrocarbon and is not derived from a methyl side chain. Otherwise, we would have the grotesque situation of deriving aldosterone from an 18nor, but 18 methylated pregnane.

**Hemiacetals, acetals, hemiketals and ketals:** The symbols used for hydroxy and other groups (e.g., ol, θI) will be applied.

**Hemiacetals:**  $\begin{array}{c} \text{H} \\ | \\ \text{R}-\text{C}-\text{OH} \\ | \\ \text{OR}^1 \end{array}$  (1/2acetal) reaction product of an aldehyde with one alcohol group.

**Acetals:**  $\begin{array}{c} \text{H} \\ | \\ \text{R}-\text{C}-\text{OR}^1 \\ | \\ \text{OR}^2 \end{array}$  (acetal, not abbreviated) reaction product of an aldehyde with two alcohol groups.

**Hemiketals:**  $\begin{array}{c} \text{R}^1 \\ | \\ \text{R}-\text{C}-\text{OH} \\ | \\ \text{OR}^2 \end{array}$  (1/2ketal) combination of a ketone with one alcohol group.

**Ketals:**  $\begin{array}{c} \text{R}^1 \\ | \\ \text{R}-\text{C}-\text{OR}^2 \\ | \\ \text{OR}^3 \end{array}$  (ketal, not abbreviated) combination of a ketone with two alcohol groups.

**Epoxy:**  $\begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{C} \quad \text{C} \end{array}$  (regarded as ethers). An oxygen attached to two vicinal carbons, e.g., A<sub>θ</sub><sub>1α-2</sub> (for 1,2α-epoxy-androstane).

**Halo compounds:** Br, Cl, F, i (-bromo, -chloro, -fluoro, -iodo), e.g., P<sup>4</sup>Cl<sub>9α</sub> (for 9α-Chloro-4-pregnene). Instead of "I" for iodine write "i" (e.g., P<sup>4</sup>i<sub>9α</sub>) to avoid confusion with methyl, whose symbol is roman one.

**Nitrogen containing steroids:** NH<sub>2</sub> (for amino), NH (for imino), CN (for carbonitrile or

cyano). These symbols are used as such in SSS terms. However, symbols with subscript numbers (NH<sub>2</sub>) are bracketed.

e.g., ANH<sub>17</sub> (for 17-imino-androstane),

P<sup>5</sup>CN<sub>16α</sub>Ol<sub>3β</sub>On<sub>20</sub> (for 3β-Hydroxy-20-oxo-5-pregnene-16α-carbonitrile or PCN). All other N-containing steroids, including the alkaloids, belong to this group. The aza-steroids are listed last, in the heterocyclic category (*cf.* below).

**Sulfosteroids:** All thio compounds, e.g.,

—SH (-thiol),  $\begin{array}{c} \text{S} \\ \diagup \quad \diagdown \\ \text{C} \end{array}$  epithio, (θS), thioether.

**Heterocyclic steroids:** These are listed separately for each element replacing carbon in the ring structure. They are indicated by the chemical symbol of the substituent in brackets, followed by a subscript number identifying the position of the replaced ring carbon after the symbol of the parent hydrocarbon (e.g., A(O<sub>2</sub>) for 2-Oxa-androstane, P(N<sub>3</sub>) for 3-Aza-pregnane).

**Ring modifications:** (*cf.* p. 775).

**Other non alkyl-substituted compounds:**

Here, we list all those non alkyl-substituted compounds for which no category has been foreseen above.

### Secondary Parent Hydrocarbons

All radicals attached to the parent hydrocarbon by a **carbon-to-carbon linkage** are considered to form "secondary parent hydrocarbons." They are written by attaching the symbol for the substituent following that of the parent hydrocarbon, both being underlined (e.g., A $\underline{5\alpha}$ I $\underline{17\alpha}$  = 17α-methyl-5α-androstane).

All alkyl derivatives, except those listed themselves as main parent hydrocarbons (e.g., 17β-ethyl-androstane = pregnane), are regarded as alkyl derivatives of the latter. This includes even 17α-ethyl-androstane whose essential difference from pregnane is further emphasized by attaching the side chain to the structure formula of androstane, not only by an alpha (...) bond, but horizontally.

The alkyl side-chains are enumerated:

1. according to the increasing numbers of the carbon atoms to which they are attached on the skeleton of the main parent hydrocarbon and
2. according to increasing numbers of the carbon atoms they contain (methyl, ethyl, propyl, butyl, etc.). Saturated radicals are mentioned first, and those with double bonds in the order of increasing unsaturation. Triple bonds (superscript position numbers boldface e.g.: P<sup>20</sup>) are mentioned after all

multiple double bonds. Branched and ring-substituents are listed in the order of increasing complexity. (For corresponding symbols, *cf.* p. 778.)

Among the aliphatic 17-alkyl-androstanes, only pregnanes, cholanes, cholestanes, ergostane and stigmastan are regarded as special parent hydrocarbons because of their common occurrence.

### Order of Precedence in General

The order of precedence for the above mentioned substituents is rigidly observed except in the first (underlined or boldface) portion of the SSS terms of secondary parent hydrocarbons. As previously stated, here all substituents attached to a side-chain are listed immediately after the positional number of the latter, to avoid subsequent repetition of the locant, e.g., A<sup>5</sup>I'<sub>16β</sub>III<sub>17α/on/</sub>lOl<sub>3β</sub>.

When two or more identical substituents appear in the same molecule, all these must be enumerated before considering compounds possessing additional substituents mentioned later in the above list (e.g., all -enes before -dienes, before -trienes, etc.; all -ols before -diols, before -triols, etc.). Only after this do we proceed to compounds having an additional type of substituent (e.g., only after all mono- and polyols do we proceed to -ones).

All unsaturations (double, triple and cyclizing bonds) and substitution products are listed according to the **ascending order of the affected carbons** (e.g., in pregnanes 1–21). Ring modifications, such as contractions (nor), expansions (homo), openings (sec), etc. are listed in the **order of the ring lettering** (A–D).

### Computerization

Subscript and superscript notations are unsuitable for computerization but SSS names can be written in a single line without loss of precision. E.g., normally we write dehydroepiandrosterone thus: A<sup>5</sup>Ol<sub>17β</sub>On<sub>3</sub> and the corresponding 5α saturated compound thus: A $\underline{5\alpha}$ Ol<sub>17β</sub>On<sub>3</sub>. For computer use, these two steroids can be written respectively A5 ol 17β on 3 and A5α ol 17β on 3.

The superscript position of a number following the symbol for the parent hydrocarbon (e.g., A<sup>5</sup>) merely facilitates its immediate recognition as a double bond. Similarly the subscript position of numbers helps to identify them as locants. But actually, this style is not indispensable if the constituent symbols are properly separated. The rule of "first what,

then where" makes it obvious that the "5" belongs to the "A", the "17 $\beta$ " to the "ol", and the "3" to the "on". The number 5 could only indicate a double bond; it would have to be followed by  $\alpha$ ,  $\beta$ , or  $\xi$  if it were to denote the steric position of the 5-hydrogen. Even the omission of underlining (or boldface printing) of the parent hydrocarbon would not introduce any ambiguity. Greek letters such as  $\alpha$ ,  $\beta$ , or  $\xi$ , can be written out as alpha, beta or xi, and the roman numerals can be composed by capitals on computers, just as on typewriters that do not have corresponding signs. The use of capital and small letters is likewise not necessary, but it helps rapid reading and is recommended for those who have the appropriate modern computer equipment.

### Chemical Symbols

, = sign of separation. To be used at discretion of codifier, wherever two adjacent symbols might be read as one (e.g., on<sub>4,6</sub>).

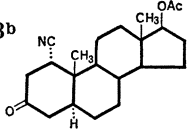

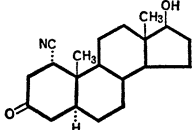

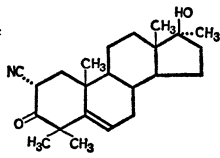

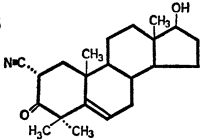

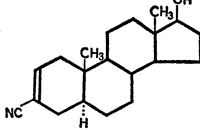

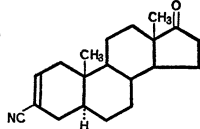

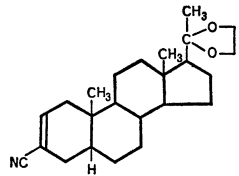

\* = ester (precedes symbol of acid. E.g.: \*III = propyl ester).  
 $\theta$  = ether (precedes symbol of alkyl. E.g.:  $\theta$ I = methoxy or methyl ether).  
**A** = androstan (for symbols of other parent hydrocarbons, *cf.* p. 775). Only parent hydrocarbons and all alkyls attached to them by carbon-to-carbon linkages are bold face (E.g.: **A**III<sub>17 $\beta$</sub> **I**<sub>2 $\alpha$</sub> **ol**<sub>4 $\beta$</sub> **on**<sub>11</sub> = 17 $\beta$ -propyl-2 $\alpha$ -methyl androstane with 4 $\beta$ -alcohol and 11-keto groups.)  
 /, // = successive levels (subdivisions) in a code, obviating the need for more than one subscript line (e.g., 2-methylbutane = IV<sub>I/2</sub>). The successive levels of more complex branchings coded according to the general formula: R<sub>R'</sub>/<sub>2</sub>//R''/<sub>3</sub> (e.g., 2(3-methylbutyl)-heptane = VII<sub>IV/2</sub>//I/<sub>3</sub>.)  
 ( ) = brackets are used to enclose symbols with subscript numbers which might be confused with locants, e.g., (NH<sub>2</sub>), (CH<sub>2</sub>).

Substituents	Methyl Formic	Ethyl Acetic	Propyl Propionic	Butyl	
Alkanes, normal	I	II	III	IV	
Alkanes, branched	—	—	III <sub>I/2</sub> (2-methyl-propane)	IV <sub>I/2,3</sub> (2,3-dimethyl-butane)	
Alcohols	I ol	II ol	III ol	IV ol	} Symbols of side chains bound to ring by carbon-to-carbon linkages, follow roman numerals.
Acids	I''	II''	III''	IV''	
Aldehydes	Ial	IIal	IIIal	IVal	
Esters	*I	*II	*III	*IV	} Symbols of groups bound to ring by oxygen, precede roman numerals.
Ethers	$\theta$ I	$\theta$ II	$\theta$ III	$\theta$ IV	

The 92 carbonitriles of Table 135 have been arranged according to the increasing number of the skeletal carbon atoms to which the —CN groups or —CN-bearing side-chains are attached. A few additional steroids, other than nitriles (Cpds. 93—99) are listed in arbitrary order.

The most potent catatoxic steroids against both substrates of this test were those bearing a 2 $\alpha$ - or 16 $\alpha$ -carbonitrile group. Among these, several showed potency against one or both substrates at individual dose levels as low as 100  $\mu$ g or even 30  $\mu$ g. In general, protection against indomethacin was more readily obtained than against digitoxin.

Table 135. *First step: Screening of steroids against digitoxin and indomethacin intoxication*

Cpd. 54, the only 16 $\beta$ -carbonitrile of our series, as well as Cpd. 53 in which the steric position of the 16-carbonitrile is unknown, were inactive in protecting against either substrate, even at the dose level of 500  $\mu$ g. Cpds. 69–71 in which the —CN group is attached to a 16 $\alpha$ -side-chain (rather than to the C<sub>16</sub> carbon of the steroid skeleton itself) showed no protective activity, even at the dose of 10 mg. On the other hand, it is hardly coincidental that among 28 16 $\alpha$ -carbonitriles tested (Cpds. 27–54) all but three (Cpds. 47, 51, 52) were active, and most of them even at very low dose levels. This suggests that the attachment of a —CN group in the 16 $\alpha$ -position directly to the steroid skeleton is very favorable for this type of protective effect; the configuration of the rest of the steroid molecule, though capable of influencing the degree of activity, is of much lesser importance.

It is known from our previous work that a carbonitrile group in position 2 $\alpha$  (e.g., Cpd. 3, TMACN) is also compatible with high catatoxic activity against a variety of substrates; additional evidence justifying this conclusion is given in Tables 135, 136.

Carbonitrile groups in position 3, may or may not convey some potency (Cpds. 5–9), but steroids with carbonitriles attached to C<sub>1</sub> (Cpds. 1, 2), C<sub>5</sub> (Cpds. 10–20) or C<sub>6</sub> (Cpds. 21–26) were uniformly inactive at all dose levels tested.

Carbonitrile substitution at C<sub>17</sub>, C<sub>20</sub>, C<sub>21</sub> or in side-chains resulted in no remarkable catatoxic potency at the dose levels tested, with the exception of Cpds. 83 and 86 which were moderately effective in this respect at the dose level of 500  $\mu$ g.

Among the steroids of Table 135 other than carbonitriles (Cpds. 93–99), special interest is attached to Cpd. 96 (an aza-steroid), Cpd. 95 (mestranol), a strong folliculoid used in anticonceptual pills, and Cpd. 93 (a 16 $\beta$ -carboxylic acid) all of which showed some catatoxic activity at comparatively high dose levels. This degree of activity is of little practical significance, but it is interesting that a heterocyclic aza-compound, a 16 $\beta$ -carboxylic acid and a folliculoid can possess some catatoxic potency.

Finally, it is noteworthy that (except for the moderate potency of Cpd. 93) all 16-carboxylic acids (Cpds. 66, 67 and 69 in Table 135A) are devoid of catatoxic potency against both substrates. A priori, the possibility could not have been excluded that nitriles are metabolized *in vivo* into the corresponding carboxylic acids and that the latter would be responsible for catatoxic activity, but this does not appear to be the case.

Additional inactive steroids are listed in Table 135A *cf.*, p. 794.

### ***First Step: Synopsis of all 500 Steroids Tested for Their Ability to Prevent Digitoxin and Indomethacin Intoxication***

The preceding tables summarize our hitherto unpublished data on the protection by steroids, and particularly by carbonitriles, against digitoxin and indomethacin intoxication. However, in order to obtain a proper overview of this field, the following list summarizes the results obtained with *all 500 steroids tested up to now*, *cf.* Table 135B, p. 807. It will be kept in mind that all these experiments were performed under essentially identical conditions as outlined on p. VIII and in earlier publications (Selye G 70,421/70, G 70,480/71). Since no other laboratory has published comparable data on the detoxication of digitoxin and indomethacin by steroids, the list is assumed to be a reasonably complete inventory of all steroids tested for this effect and

Table 135 A. *First step (Ctd.): Other inactive steroids.* (Tested at 0.5 mg dose level unless otherwise stated)

1 IM 522 <sup>a</sup>		17β-Hydroxy-4-estren-3-one 17-trichloroacetate <i>19-Nortestosterone trichloroacetate</i> (Bio. Research Lab.) (B.R.L.)

eminently suitable for pharmaco-chemical correlation studies. It must be kept in mind, however, that these assessments of activity are subjective and hence only very high or essentially negative ratings deserve serious consideration as indexes of strong and negligible activity respectively. This is all the more true since, in many instances, the total number of rats had to be limited to five per group because the majority of the steroids tested were available only in small amounts. On the other hand, all compounds which are highly potent in increasing resistance to one or both of these toxicants were retested at lower dose levels.

Table 135B. *First step (ctd.): Synopsis of all 500 steroids tested for their ability to prevent digitoxin and indomethacin intoxication*

<sup>a</sup> As in the previously reported data the figures indicate the means of the statistical difference grades of protection ranging from "0" (no protection) to "3" (perfect protection). For further data concerning the techniques *cf.* p. VIII.

<sup>b</sup> Based on the formula  $\frac{D+I}{2} \times \frac{1}{\text{mg}}$ , where D = reading for digitoxin, I = indomethacin, mg = the dose tested.

It is noteworthy that, among the 500 steroids listed in Table 135B, only 20 exhibited an activity index of 10 or more. It is hardly coincidental that all compounds of this select group are 16 $\alpha$ -carbonitriles, except for TMACN (Cpd. 149) which is a 2 $\alpha$ -carbonitrile, the 16 $\alpha$ -17-methyl-oxazolyl (Cpd. 329), CS-1 (Cpd. 191), and dexamethasone acetate (Cpd. 360). It may be significant that within this small group of exceptions we find: one steroid (Cpd. 149) which also carries a carbonitrile substituent on the ring, although in the 2 $\alpha$ -position, two 9 $\alpha$ -fluoro-compounds (CS-1 and dexamethasone), one steroid (Cpd. 329) substituted at 16 $\alpha$ , although not by a carbonitrile. It will be interesting to see whether other 16 $\alpha$ -substituted or halogenated steroids possess considerable catatoxic activity and whether the latter can be further increased by the introduction of several apparently advantageous substituents into the same molecule.

The "Activity Index" is based on the formula  $\frac{D+I}{2} \times \frac{1}{\text{mg}}$  where D = reading for digitoxin, I = indomethacin, and mg = the dose tested. Thus, the index reflects overall activity against both substrates at any one dose level. The highest Activity Index reading for each steroid is emphasized by boldface numerals, but direct inter-comparisons are possible only at corresponding dose levels. Naturally, a compound tested only at the high level of 10 mg per dose could not reveal its full potency in this method of expression, but if it had little or no activity, lower doses were not tested.

On the other hand, steroids available only in very small amounts could be assayed only at dose levels too low for comparison with many other compounds.

For simplicity's sake the compounds are designated and sequentially enumerated according to the rules of the "SSS Nomenclature of Steroids" (*cf.* p. 774).

### ***Second Step: Determination of "Protective Spectrum"***

Having selected the most promising protective substances by first screening them for activity against digitoxin and indomethacin, we proceeded to appraise the "Protective Spectrums" of the most potent ones among them. These compounds were now tested against a heterogenous set of 10 pathogens, widely differing in their chemical structure and in the organ changes that they elicit.

The statistical significance of the results was computed (as outlined on p. 771) for the inhibition or aggravation of the changes produced by each of the 10 model toxicants. After this, the "Overall Protective Indexes" ("OPI") and the "Protective Spectrum Index" ("PSI") were calculated, as rough indications of the mean degree and the specificity of protection, that is of the quantitative and qualitative prophylactic potencies respectively. These data are summarized in Tables 136, p. 836 and 137.

For the 10 toxicants enumerated in the caption of Table 136 the techniques of administration and the manner in which protection is expressed have been described in an earlier paper (Selye G 70,420/71), as well as in the sections devoted to the effect of various steroids upon each toxicant in this monograph. Suffice it to recall that the highest possible degree of protection corresponds to grade "3", the "OPI" expresses the mean grade of protection, whereas the "PSI" gives the percentage of the toxicants tested against which significant protection is obtained (irrespective of the degree of significance). These two indexes — given in the last two vertical columns of Table 136 — do not run strictly parallel but the various compounds tested for protective potency are listed roughly in decreasing order of their OPIs. Whenever the material at our disposal permitted it, compounds active at a certain dose were retested at a lower dose level. Of course, the two indexes were not calculated for dose levels at which, because of toxicity or lack of material, not all protective compounds could be tested (marked with a dash); hence the OPI and PSI are listed only for the highest, but still well tolerated, dose of each protective compound. The last two horizontal lines in Table 136 list the indexes for the amenability of the toxicants to detoxication by the conditioning agents as explained on p. 772.

Perusal of Table 136 indicates that almost all steroids were active in offering protection, at least against some of the damaging agents; but this is so merely because most of the steroids tested here were included in this study precisely because they had shown some potency in preliminary tests.

It is noteworthy that among all steroids tested PCN (Cpd. 1), again exhibited the highest catatoxic activity as judged by both indexes. It was even more active than any of the other 16 $\alpha$ -carbonitriles tested against all 10 substrates. CS-1, spironolactone, Cpd. 4, 5, cyproterone acetate, ethylestrenol, norbolethone, TMACN and Cpd. 10 were almost equally efficacious at the highest dose (10 mg), but at the 500  $\mu$ g dose level, activity fell roughly in the order in which the compounds are mentioned here. Indomethacin and digitoxin are most readily detoxified by these steroids — in the case of PCN even at the dose level of 300  $\mu$ g/kg. However, the general indexes of

activity are not very meaningful at the low dose levels at which efficacy against other toxicants has not been examined; hence they are listed only for the optimal protective dose. It will be noted that usually this is 10 mg (the highest dose tested) but in the case of such compounds as the strong glucocorticoids or estradiol, inherent toxicity of heavy overdosage counteracts the protective effect against drugs by causing severe mortality. In these instances, lower dose levels were selected for the computation of the OPI and PSI (last two vertical columns at right).

On the other hand, Cpd. 34 and the steroids listed after it in Table 136 exhibit only negligible if any activity, with the exception of occasional strong inhibitory effects (grade 2 or 3) against individual toxicants (e.g., pregnanedione against parathion, hexobarbital and indomethacin; progesterone against indomethacin;  $11\alpha$ -hydroxyprogesterone against indomethacin, hydroxydione against digitoxin, DOC against nicotine). This singular specificity of protection among compounds having a very low, if any, protective effect against other substrates may well depend upon specific so-called "physiologic antagonisms" (e.g., the anesthetic effect of hydroxydione or the mineralocorticoid action of DOC), but further experiments will be necessary to prove this.

A glance at the OPI and PSI of the toxicants (last two horizontal lines at the bottom of Table 136) shows that digitoxin, dioxathion, hexobarbital, progesterone, indomethacin and DHT were most readily detoxified by the largest number of conditioning agents, whereas parathion, nicotine, zoxazolamine and especially the infarctoid cardiopathy produced by fluorocortisol +  $\text{Na}_2\text{HPO}_4$  + corn oil were most resistant.

Among the nonsteroidal agents of Table 137 rather specific antagonisms were quite common. For example, ACTH increased resistance to the neuromuscular blocking action of zoxazolamine, although it had little if any effect against other agents.

Vitamin E offered some protection against DHT; whereas acetylsalicylic acid protected against progesterone anesthesia, zoxazolamine paralysis and indomethacin ulcers, but these compounds offered no noteworthy protection against other toxicants.

Bile duct ligation offered complete protection against DHT-induced calcinosis, the F-COL +  $\text{Na}_2\text{HPO}_4$  + oil cardiopathy and indomethacin ulcers, but the mortality was not completely prevented and hence, the grade of protection — which reflects the mean inhibition of lesions plus mortality — is comparatively moderate. It is very likely that occlusion of the choledochus acts by preventing bile secretion, thereby interfering with lipid absorption and the enterohepatic circulation of drugs.

Digitoxin, indomethacin, vitamin A and vitamin D — all of which are readily detoxified under the influence of catatoxic steroids — do not act as inducers of protective enzymes against any of the substrates tested. Obviously, there is no relationship between amenability to detoxication by steroid-induced enzymes and the power to induce such enzymes.

As with the steroidal protective agents, indomethacin intoxication appears to be particularly easy to prevent, but digitoxin poisoning (which is likewise combated by virtually all catatoxic steroids) is singularly resistant to protection by nonsteroidal agents, with the exception of nicotine and phentolamine.

Among the nonsteroidal agents, the highest general protective indexes are exhibited by phetharbital, diphenylhydantion, phenobarbital and phenylbutazone, but at high dose levels, tolbutamide and compound W-1372 are also quite efficacious.

The infarctoid cardiopathy produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil, which is inhibited by several steroids (particularly spironolactone and spiroxasone, among those listed in Table 136), was consistently resistant to prophylaxis by any of the nonsteroidal drugs in Table 137. Of course, potassium salts (e.g., KCl) or potassium-sparing agents (e.g., amiloride, triamterene) offer excellent protection against this cardiopathy, as shown by our previous investigations, and since spironolactone and spiroxasone likewise retain potassium, it is probable that here they also act primarily through this mechanism.

The relative amenability of the other toxicants to protection by nonsteroidal conditioning agents can be most readily appraised on the basis of the indexes listed in the last two horizontal lines of Table 137, p. 848. It will be seen that indomethacin and dioxathion have the highest PSI, but in general, the overall protective effect of these nonsteroidal agents falls far short of that of the steroids listed in Table 136. Indeed, whatever overall protective values can be ascribed to the set of nonsteroidal agents are mainly due to the comparatively high efficacy of phenobarbital, phetharbital, diphenylhydantoin, phenylbutazone, and to a lesser extent, of tolbutamide and W-1372; the other agents in this list are either inactive or offer protection only against very few toxicants.

### ***Third Step: Identification of Damaging Agents Amenable to Prophylaxis***

As previously stated, this third step of the screening procedure was designed primarily to identify the types of compounds that can be detoxified by steroids. However, for comparative purposes, we have also tested thyroxine and phenobarbital under identical conditions, as examples of nonsteroidal agents previously shown to influence resistance against many toxicants. The steroids included in this battery of tests were purposely selected to comprise proven syntoxic or catatoxic substances, as well as compounds which had never been shown to protect against any toxic agent.

The prophylactic steroids were administered, as outlined on p. VIII, in 1 ml water by a stomach tube, twice daily, from the first day until termination of the experiment, unless otherwise stated in the footnotes. Thyroxine was administered at the dose of 0.2 mg in 0.2 ml water s.c., once daily, and phenobarbital at the dose of 6 mg in 1 ml water p.o., twice daily, as described in Table 137. The treatment with the toxicants and the assessment of the lesions they produce was again expressed as outlined on p. 834. The results are summarized in Table 138, p. 850.

In this series of experiments, the "OPI" and "PSI" refer to the amenability of the individual damaging agents to the protective effect of the compounds listed in the caption of Table 138. In other words, in the two last vertical columns of Tables 135, 136, 137, these indexes were computed to express the protective action of many agents against a standard set of toxicants, whereas in Table 138 (as in the two last horizontal lines of Tables 136, 137) they are meant to reflect the amenability of diverse toxicants to inactivation by a standard set of potential prophylactic agents.

In Table 137, the damaging agents are listed merely in alphabetic order but a glance at the OPI column reveals that the toxicants most amenable to prophylaxis by diverse agents are: cocaine, cyclobarbital, cycloheximide, digitoxin, EPN, ethion, ethylmorphine, glutethimide, hexobarbital, indomethacin, methyprylon, nicotine,

phenylamidol, picrotoxin, and piperidine. The PSI of these toxicants runs roughly parallel to their OPI, that is to say the agents whose toxicity is most significantly impeded by various prophylactics are, in general, also detoxified by the largest number of potentially prophylactic substances.

Several substrates in Table 138 are very amenable to detoxication but only by few compounds; hence, despite their great activity in one or two respects, they have extremely low general protective indexes. For example, mercuric chloride is almost completely detoxified by spironolactone, yet its overall amenability to protection is very low, because its detoxication depends upon a steroid-borne thioacetyl group. In this series of conditioners, such a substituent occurs only in this particular steroid. Similarly, the intoxications amenable to protection by glucocorticoids only (lathyrogens, ganglioplegics, croton oil, *E. coli*, pralidoxime, strychnine, ethylene glycol), give comparatively low overall protective indexes, because only two of the prophylactic substances tested possess strong glucocorticoid potency.

Reading the columns in Table 138 vertically, we confirmed that the best **protection against the largest number of toxicants** is offered by the typical catatoxic steroids: PCN, ethylestrenol, CS-1, spironolactone, norbolethone, and oxandrolone.

Furthermore, some systemic toxicants (e.g., cyclobarbitol, methyprylon, SKF 525-A, d-tubocurarine) are combated both by catatoxic steroids and by the two glucocorticoids included in this series. Several other drugs (e.g., barbital, cinchophen, cocaine, ethion, meprobamate, picrotoxin, thiopental, tribromoethanol, trichloroethanol) are well detoxified by prednisolone but not by triamcinolone, although the latter is the more potent glucocorticoid. Presumably, prednisolone possesses both catatoxic and syntoxic properties. Yet, here again we must remember that such *in vivo* tests can only determine whether a compound is or is not amenable to detoxication by steroids that have syntoxic or catatoxic actions with respect to other substrates. Further investigations will be required to identify the underlying mechanism.

DOC, hydroxydione, estradiol and thyroxine are comparatively **ineffective** both as regards the intensity and the spectrum of protection. In fact, in many cases, pretreatment with thyroxine results in toxication rather than detoxication. In the computation of the OPI and PSI, the results of toxication are not deducted from those of detoxication, but merely considered as "O"; hence the aggravating effect of thyroxine emerges only from the MPI.

In general, intoxications that can be inhibited by catatoxic steroids are also amenable to **prophylaxis by phenobarbital**. Yet, here again, there are exceptions: chlordiazepoxide, cyclophosphamide, digitoxin, digitoxin +  $\text{Na}_2\text{HPO}_4$  + corn oil, haloperidol, mephenesin, triamcinolone, tribromoethanol, and tubocurarine, though readily detoxified by most catatoxic steroids, are virtually resistant to phenobarbital. In several other instances, phenobarbital is effective, but much less so than the most potent catatoxic steroids. The converse is rarely if ever the case; among the intoxications tested, only strychnine and piperidine poisoning responded much better to phenobarbital than to catatoxic steroids, but perhaps here, the hypnotic effect of the drug played a special role.

It must be emphasized that we cannot draw far-reaching conclusions as to the **specificity of catatoxic and syntoxic steroid actions** from this experimental series, since in some groups, the number of experimental animals may have been too small to compensate for individual variations in susceptibility. Furthermore, the conditioners

were administered in fixed amounts; dose effect curves would be required in each case to make more meaningful comparisons. Still even these data suffice to show that there are qualitative differences in the prophylactic actions of the various conditioning agents.

In surveying Table 138, it is striking how few conditioning agents induced a considerable decrease in resistance ( $- 2.5$  or more) to the toxicants tested. This is all the more noteworthy since overdosage with two drugs (the toxicant and the conditioning agent) might be expected to be more difficult to resist than treatment with the toxicant alone. Most of the apparent decreases in resistance were seen after conditioning with prednisolone and triamcinolone, but of course here the toxic effect of heavy glucocorticoid overdosage (loss of body weight with a predisposition for spontaneous infections) was probably the decisive factor. In addition, when given in combination with DOC-Ac +  $\text{NaH}_2\text{PO}_4$ , the glucocorticoids notoriously sensitize to myocardial necrosis. Furthermore, when triamcinolone was used as a toxicant, it was obvious a priori that additional treatment with the same or another glucocorticoid would aggravate the overdosage syndrome. It is perhaps more remarkable that intoxication with hydroquinone was greatly accentuated by triamcinolone.

Among the other steroids, let us point out that PCN appears to sensitize to the toxic effects of propionitrile, whereas estradiol considerably aggravates poisoning with OMPA and triamcinolone. Thyroxine markedly diminishes resistance to epinephrine and propionitrile, but to a lesser extent, it also accentuates the toxicity of several other agents and rarely offers protection.

### **Synoptic "Diagram Table"**

The "Diagram Table" (Table 139) graphically summarizes the highlights of Table 138 except that:

1. The results are registered only for inhibitions (not for aggravations) of intoxications.
2. Intermediates between the four basic grades (0, 1, 2 and 3) are disregarded in that:

□	= 0.5 or less
●	= 1
▲	= 1.5 to 2
■	= 2.5 to 3

The absence of any sign indicates that the corresponding experiment has not been done.

3. Here, the toxicants are listed according to decreasing "Total OPI" values.

When thus arranged, it becomes particularly obvious that among the hormonal conditioning agents, PCN is effective against the largest number of toxicants and its protective potency roughly parallels that of phenobarbital at the dose levels employed here. However — as mentioned in discussing Table 138 — the parallelism in the protective value of these two compounds is not absolute. Tables 138 and 139 clearly show furthermore that (in addition to PCN) ethylestrenol, CS-1, spironolactone and oxandrolone have high protective potencies, prednisolone and progesterone are much less active, whereas triamcinolone, DOC, hydroxydione, estradiol and thyroxine protect only against very few toxicants.

<sup>a</sup> In this Table the compounds are enumerated in the same order as in Table 138. However, in the latter, grades of 0.5 or less were also considered whereas here they were taken as 0 (□). Furthermore, no distinction is made here between 1.5 and 2 or 2.5 and 3. This explains the minor discrepancies between the grading judged by the pictorial symbols and the sequence in which the compounds are listed.

<sup>a</sup> 25 ♀ 100 g rats per group. All treatments were given at the standard dose levels (*cf.* p. VIII) from the 1st to the 8th day. Final body weights were registered on the 9th day at which time the organs were fixed in formalin saturated with picric acid. All organ weights are listed as a percentage of the final body weight. (Student's t-test comparing all weights with the corresponding values of the untreated controls.)

For further details on technique of tabulation, *cf.* p. VIII.

This conclusion is further supported by the fact that cortisone, which has a ketone group in the 11-position, had no effect under these conditions."

*Wattenberg et al. G71,805/68:* In rats, the relationship between chemical structure and benzpyrene hydroxylase activity was studied on a large series of 2-phenylbenzothiazoles. "Introduction of an appropriate halogen into the 4'-phenyl position approximately doubles inducing activity compared to unsubstituted 2-phenylbenzothiazole. Other substitutions and modifications of the molecule result in either lesser increases in inducing activity or, in some instances, reduction or total loss of inducing activity. Most compounds show similar inducing effects on both lung and liver."

*Selye G70,421/70:* 304 Steroid were tested for their ability to protect rats against usually fatal intoxication with indomethacin or digitoxin. Using a "Simplified Activity Grading" system, 65 among these compounds were found to be active against indomethacin, 54 against digitoxin, and 23 against both substrates at a 10 mg dose level. But only 4 of these steroids were still capable of inhibiting one or both of these substrates at the 0.5 mg

dose level. The only steroid still active against both substrates at the dose of 0.2 mg was pregnenolone carbonitrile "PCN" (3β-hydroxy-20-oxo-5-pregnene-16α-carbonitrile).

*Selye G70,480/71:* A review (28 pp., 111 refs.) on "Hormones and Resistance." The historic developments and present status of our concept of syntoxic and catatoxic steroids is summarized and the standard techniques for the *in vivo* bioassay of protective hormones are described at length.

*Solymoss et al. G60,084/71:* In rats, ethylestrenol, norbolethone, progesterone, triamcinolone, prednisolone and hydroxydione exhibited no antiminerolocorticoid properties (Kagawa's test). Thus, the catatoxic effect of steroids appears to be unrelated to antiminerolocorticoid potency.

*Selye PROT. 43477:* In otherwise untreated 100 g ♀ rats, the influence of the most commonly used conditioners upon the final body and organ weights (the latter expressed as a percentage of the body weight) has been determined for comparison with the experiments in which such conditioning agents were given conjointly with toxicants. After eight days of treatment, the final *body weight* was diminished

by prednisolone, triamcinolone and estradiol. To a lesser extent, hydroxydione also caused a decrease in body weight gain, but this may have been due to the prolonged daily anesthetic effect of this steroid. The rats treated with anabolics, particularly ethylestrenol and norbolethone, showed a body weight increase but this was not pronounced during this short time experiment. Although oxandrolone likewise proved to be anabolic in earlier experiments (in that it combated the catabolism produced by DHT or glucocorticoids) it did not cause an absolute increase in body weight. When organ weights were expressed as percentages of the final body weight, significant *hepatic* enlargement was obtained by PCN, CS-1, spironolactone, norbolethone, prednisolone, triamcinolone, estradiol and phenobarbital. This is of interest since triamcinolone and estradiol are virtually devoid of catatoxic potency. Among all steroids, PCN caused the greatest hepatic enlargement, exceeding even that elicited by phenobarbital. The percental increase in *renal* weight was especially conspicuous following treatment with prednisolone, triamcinolone, estradiol and thyroxine, although the glucocorticoids and estradiol markedly diminished the absolute final body weight of these same animals. Phenobarbital and PCN caused no renal enlargement. The *preputial glands* are only imperfect indicators of testoid activity. Our earlier experiments showed that ordinary pregnenolone ( $3\beta$ -hydroxy-5-pregnen-20-one)

possesses a pronounced preputial gland stimulating effect, although it is virtually devoid of typical testoid actions upon the capon's comb or the castrate rat's seminal vesicles. The insignificant increase in preputial gland weight, observed under our experimental conditions following treatment with PCN, suggests that the attachment of the carbonitrile group to this molecule decreases rather than increases its preputial gland stimulating action. In any event, the compound is much less "virilizing" under these conditions than is progesterone. The preputial glands were most markedly enlarged following treatment with ethylestrenol, norbolethone and oxandrolone, but to a lesser extent also by CS-1, progesterone and phenobarbital, perhaps owing to the endogenous production of testoid metabolites. As expected, *uterine* enlargement was greatest after treatment with estradiol, but some increase in uterine weight was noted also under the influence of oxandrolone, whereas thyroxine had an inverse effect. None of the conditioners tested caused *ovarian* enlargement, but PCN, ethylestrenol, norbolethone, progesterone and thyroxine induced significant ovarian atrophy. The *thymus* weight was most markedly diminished by prednisolone, triamcinolone and estradiol, but to a lesser extent also by ethylestrenol, norbolethone and oxandrolone. Curiously, phenobarbital appears to have caused a barely significant and PCN a nonsignificant increase in thymus weight. Phenobarbital, prednisolone,

PCN, CS-1, norbolethone and estradiol also increased the weight of the *thyroid* approximately in decreasing order as enumerated. The most pronounced *adrenal* hypertrophy was elicited by estradiol, but minor degrees were also obtained by PCN and phenobarbital. Possibly, detoxication of endogenous corticoids might have led to a compensatory hypertrophy of this magnitude. On the other hand, CS-1, ethylestrenol, spironolactone, norbolethone, oxandrolone, prednisolone, triamcinolone, progesterone and DOC caused a diminution of the percental adrenal weight, *cf.* Table 140, p. 860.

*Selye PROT. 22393:* There appears to be no obligatory relationship between glucocorticoid and catatoxic activity. Thus, large doses of prednisolone offer excellent protection against the ulcerogenic effect of indomethacin, whereas triamcinolone, a much more potent glucocorticoid, is devoid of this protective effect over a broad dose range *cf.* Table 141.

*Solymoss PROT. 42234:* As judged by the Kagawa test, PCN is practically devoid of antiminerlocorticoid activity. In male adrenalectomized adult rats, 6  $\mu$ g of DOC s.c. produced

a pronounced decrease in the urinary Na/K excretion, which could not be counteracted by 1 mg of PCN.

Table 141. *Glucocorticoid potency not responsible for inactivation of indomethacin by prednisolone*

Treatment (mg) <sup>a</sup>	Intestinal ulcers (%) <sup>b</sup>	Mortality (Dead/Total) <sup>b</sup>
None	100	5/5
Triamcinolone 0.1	100	5/5
Triamcinolone 0.5	100	5/5
Triamcinolone 10	100	5/5
Prednisolone 0.1	100	5/5
Prednisolone 0.5	100	4/5
Prednisolone 10	0	0/5

<sup>a</sup> In addition to the treatments listed in this column, the rats (100 g ♀) of all groups received indomethacin 1 mg in 0.2 ml water/day, s.c., on 4th day ff. Triamcinolone and prednisolone were given at the doses indicated in 1 ml water  $\times$  2/day, p.o., 1st day ff.

<sup>b</sup> Intestinal ulcers (% positive) and mortality on 10th day.

## SUMMARY AND OUTLOOK

This treatise attempts to outline the history and present status of research on the regulation of resistance by hormones. It would obviously be impossible to give a meaningful résumé of this vast field here, but it may be helpful to summarize the highlights of the research with which our group has had personal experience, namely: the effect of natural and artificial steroids upon comparatively nonspecific resistance phenomena.

The protective agents are classified, according to their mechanism of action, into two main groups: 1. "syntoxic" compounds which improve tissue tolerance by permitting a symbiotic type of coexistence with the pathogen (e.g., by suppressing inflammatory reactions); 2. "catatoxic" substances which actually destroy the aggressor (e.g., through the induction of hepatic microsomal enzymes).

The syntoxic effects are virtually limited to glucocorticoids, and since these have received sufficient attention in the past, this monograph deals primarily with recent studies on catatoxic steroids.

We have tested more than 500 steroids, under comparable conditions, for their possible protective effect against numerous toxicants. The results of these studies are tabulated and their evaluation revealed the following principal facts:

1. The catatoxic effect can manifest itself independently of all classic hormonal actions, although it is frequently associated with anabolic, antiminerlocorticoid or glucocorticoid properties.

2. Some of the most potent catatoxic steroids are carbonitriles; these also have an unusually broad "spectrum of activity", in that they protect against many toxicants.

3. The  $16\alpha$ -position of the  $-\text{CN}$  group appears to be particularly advantageous for catatoxic activity. Its introduction into a virtually ineffective steroid, e.g., 5-pregnenolone, endows the latter with sufficient catatoxic potency to protect a rat, at dose levels as low as  $300 \mu\text{g}/\text{kg}$ , against fatal digitoxin or indomethacin intoxication.

4. Steroids may serve as especially favorable carriers of pharmacologically active groups, for example of thioacetyl (for the detoxication of mercury), quaternary ammonium bases (for the induction of a neuromuscular block), oncolytic agents, etc.

5. Certain catatoxic steroids possess abortifacient properties and interfere with lactation.

6. It is not yet proven that effective amounts of catatoxic steroids are normally secreted in response to a need (as glucocorticoids are during stress). However, they certainly represent basic "soil-factors" determining normal resistance; for example testosterone in amounts secreted by the testis raises the resistance of male rats far above that of females or gonadectomized animals of either sex. Furthermore, corticosterone — the natural life-maintaining steroid of the rat — possesses catatoxic activity against several substrates and is undoubtedly secreted in response to a need during stress.

7. Certain substrates, which are not subject to inactivation by steroidal or non-steroidal catatoxic compounds, can be "opsonized" (that is made amenable to this type of detoxication) by the addition of a radical. Thus, morphine is resistant, whereas ethylmorphine is highly sensitive, to inactivation by various compounds (catatoxic steroids, phenobarbital). This may well be due to a decrease in the polarity of the compound which may facilitate its penetration through membranes to the sites where enzymic detoxication can occur. It is interesting to speculate about the multitude of toxicants that might be made amenable to steroid-induced degradation if we learned how to stimulate their fat solubilization in vivo.

8. Many observations suggest that both syntoxic and catatoxic steroids may have important clinical applications in a variety of diseases caused by exogenous or endogenous toxicants. This is particularly true of maladies due to pathogens amenable to biotransformation by hepatic microsomal enzymes. In principle, here, enzyme induction would have to precede contact with the pathogen, and, hence, catatoxic steroids would be expected to have only prophylactic potency. Yet, if the pathogens act over a prolonged period (e.g., chronic indomethacin or digitoxin intoxication), curative effects have been obtained even when treatment was begun only after clinical manifestations of intoxication had become evident. Finally, if catatoxic steroids are important, "soil-factors" determining normal resistance, we should search for the possible existence of diseases caused by inadequate production of these compounds, or of disturbances in the responsiveness of the enzyme-inducing mechanisms which they regulate. Such maladies might be expected to result not only in deficient detoxication of exogenous pathogens but also in deficient or excessive degradation of endogenous chemical constituents of the body, such as hormones and metabolites.

As we have said in the Introduction to this monograph, animals are endowed with a complex hormonal defense system comparable in its scope to those based upon nervous, or immunologic reactions. Through conscious planning of defense, conditioned reflexes, or autonomic "emergency reactions," the body can adapt standard responses of its nervous system to defense against a multitude of specific injuries. Appropriate

immunologic reactions can adjust the basic phenomenon of antibody formation to cope with a great variety of potential pathogens which possess antigenic properties.

The main purpose of this monograph was to show that there exists a third general adaptive system in which a group of hormones and hormone derivatives (particularly steroids) offer resistance to agents not easily combated through the first-mentioned two defensive mechanisms; here, syntoxic hormones help to tolerate a pathogen, whereas catatoxic substances destroy it.

The 35 years of research — from the first description of the defensive role of corticoids in combating stress, to the latest observations on the extraordinary catatoxic potency of steroid carbonitriles — represent only a rough outline of the introductory phase in the elucidation of the hormonal defense system. The many references cited in the preceding pages clearly show that even in this first sketch, our own observations provided only a small percentage of the established facts. We have raised more questions than we have answered; but perhaps, by providing an inventory of pertinent facts, this monograph will help others to clarify this new field, which appears to have implications in virtually all phases of homeostasis under physiologic and pathologic conditions.

# INDEX

To facilitate the use of this index, boldface numerals refer to my own comments (single column, large type in text), the others to abstracts (double column, small print in text).

Greek letters, numbers and prefixes (p-, o-, m-) in chemical compounds are neglected in determining the alphabetic position of entries.

When a "target" A (drug or hormone) is influenced by an "agent" B (drug, hormone, surgical interventions or external environment), this is indicated by an arrow pointing from B to A, thus: A ← B, and the reverse entry B → A.

If two agents (B and C) act conjointly upon the same target, this is indexed thus: A ← B + C; B → A ← C; C → A ← B; that is each agent and the target appear once in the first position. The same rule applies when there are three or more agents.

The following group names are used: Anaphylactoidogenic agents, Antibiotics, Anticoagulants, Barbiturates, Carcinogens, Carcinolytics, Digitalis, Lathyrogens, Steroids in general, Corticoids, Folliculoids, Luteoids, Testoids. Pesticides and Vitamins are listed individually. However, entries for drugs or hormones belonging to any of these groups, should also be consulted individually.

Since most experiments have been performed on rats, this is not specifically mentioned; other species are identified at the end of the entry thus: A ← B/Mouse.

Salts of electrolytes are listed under the presumably most important ion; for example, instead of indium chloride (InCl<sub>3</sub>), we write "indium", instead of sodium phosphates (NaH<sub>2</sub>PO<sub>4</sub>, Na<sub>2</sub>HPO<sub>4</sub>), "phosphates".

AAN; *cf.* also Lathyrogens
