## PREFATORY REMARKS ON THE STYLE OF THIS BOOK

In four previous monographs, *The Mast Cells* (Butterworth, Washington, 1965), *Thrombohemorrhagic Phenomena* (Thomas, Springfield, 1966), *Anaphylactoid Edema* (Green, St. Louis, 1968) and *Experimental Cardiovascular Diseases* (Springer-Verlag, Berlin-Heidelberg-New York, 1970), I have tested the practicality of what might be called the "analytico-synthetic style." In essence, it attempts to facilitate fact-finding by strictly separating: 1. the *analysis* of previous publications in search of facts, which must be objective, and 2. the author's evaluation and *synthesis* which, being guided by his personal experience, is largely subjective.

The lessons learned in compiling these earlier monographs are incorporated in the present volume and, since no major changes have been made, the rationale of the analytico-synthetic style may be described here in essentially the same terms.

Conventionally, the preparation of a monograph progresses in two stages:

1. The author surveys the literature and makes brief abstracts of each publication pertinent to his subject.

2. In writing the successive chapters of his book, the author transforms these abstracts into a current narrative.

In theory, this seems to be a perfectly logical procedure, and undoubtedly it can be successfully applied in some cases. However, the second phase of the work usually meets with virtually insurmountable difficulties. Whenever numerous data are accumulated by many investigators who used different techniques, the interpretations may be consonant, contradictory or unrelated, so that a unified, concise report of all relevant facts and views is hardly possible without confusing distortions or oversimplifications.

Take a sentence such as "Allegedly, it is possible to produce thrombohemorrhagic phenomena by a single intravenous injection of substance X in the rabbit (Smith and Johnson, 1943; Jones, 1944; Jackson, 1952) but not in the mouse (Simpson, 1961; Walker, 1964), however, these claims have been challenged by several investigators (McKay, 1963; Dow, 1963; Fisher, 1964), who have obtained positive results in both these species." Did all these investigators use exactly the same technique? Did all of them use the same criteria for a "positive result?" Were the animals used of the same age and weight? Were the animals invariably killed after the same length of time following the injection, so as to give them an equal chance to develop the lesions? Only in the rarest instances would the answers to all these questions be affirmative. In other words, the sentence designed to combine the three reports has made them quite meaningless.

But why stoop to the customary practice of verbal acrobatics to give the un-unifiable the appearance of unity? To make sense, the incongruous monster sentences painfully synthesized by the author must later be mentally broken down into their constituent parts by the reader. What the author has coded, the reader must decode. Statements must be very diplomatically worded to fit several papers because different

authors bracketed after one remark have rarely, if ever, said exactly the same thing. Hence, such texts are difficult to read and, in the final analysis, they accomplish little more than to act as indices to the literature, which still has to be procured and read in the original before it can serve as a reliable guide to further work. The essential weakness of this conventional style is that the author must formulate his remarks very vaguely whenever he wants to cite several related, but of course never identical, papers in support of a statement. This procedure is necessary for unification, but the result is uninformative or misleading, usually both.

I have learned these facts by bitter experience while writing sixteen earlier medical texts in the conventional style. Could the usual drawbacks of monographs be avoided by a totally different approach? In compiling a scientific treatise, it was undoubtedly necessary first to peruse all pertinent publications and to prepare concise abstracts of them. (Incidentally, I never minded this part of the work, which was instructive and pleasant; it gave me a broad panoramic view of the observations and reflections of others, the very basis for any correlative scientific study.) But then came the deadly and uninformative task of modifying and paraphrasing portions of my summaries so that they could be squeezed into more or less cohesive, current prose. Why bother? All that was accomplished in this second stage was to conform with the style sanctified by common usage, but in the process the practical value of my abstract collection was largely lost. I must admit that even after the book appeared in print, I usually still preferred to look up my original *résumés*. After all, the book contained only portions of these, and even they were not expressed as clearly as in the abstracts mainly for three reasons:

1. Whenever several references are cited to document a statement, certain details have to be eliminated or put vaguely to make the text fit all the publications quoted in support of it.
2. Transitional sentences are needed to connect one idea with another and these are only confusing ballast which does no real work.
3. Many circumlocutions are necessary to distinguish tactfully between data which are fully, partly, or not at all, acceptable.

In other words, the first part of the work, the reading and abstracting, is pleasant, instructive and comparatively easy, while the second part, the paraphrasing into current narrative, is tedious and largely spoils the earlier accomplishments.

Of course, a collection of abstracts is not a monograph; it does not possess any overall structure or continuity and, even with the aid of an extensive index, it cannot act as a handy guide to a new field. Such a compendium is also necessarily uncritical and devoid of originality. It gives none of the interpretations and personal findings of the reviewer.

How could we devise a style which would combine concise, objective reporting with original interpretations without creating any confusion between the two? How could we simplify the writing of scientific monographs sufficiently so that even a large field may be covered by a single author who could give it unity instead of resorting to the current practice of writing "monographs" which, in reality, are only a series of independent reviews by many authors who deal with more or less related topics? This is what I have tried to accomplish here and it may be worthwhile to describe the technique in detail for those interested in the compilation of extensive monographs. We proceeded as follows:

**1. Collection of Literature.** A list comprising most of the literature on hormones and resistance was compiled from abstract journals, the *Index Medicus* and the bibliographies given by previous authors who wrote on this subject. The corresponding original articles were then obtained in the form of reprints or as photo-reproductions. These came mostly from the journals in our two local university libraries (Université de Montréal and McGill University) and from the National Medical Library in Washington, D. C. More than 15,000 articles thus became available for study in original form and, of these about 5,000 were finally selected as being sufficiently relevant to warrant inclusion in the bibliography of this volume. There (pp. 865—1051) they are listed in alphabetic order, with the accession number they carry in our library. These same numbers, followed by a stroke and the year of publication, are also used in the text for identification (e.g., Remmer G66,542/62).

**2. Abstracting.** Every abstract was dictated on magnetic tape with the original source material before me. I had to quote at second hand only a few quite unavailable Doctors' Theses, remarks made at congresses which published no proceedings, and "personal communications" cited by others. To avoid constant spelling out and to facilitate the task of transcription, key words, names, numbers, and complex technical terms were underlined in the original texts for the guidance of our typists.

In preparing the abstracts, we tried to incorporate all the essentials, including the species on which an observation was made, the route of administration of drugs, the techniques of determination, etc., wherever these facts may have significantly influenced the findings. However, equal care was taken to eliminate all irrelevant data in order to make the abstracts concise and readable.

Whenever an author summarized a salient point concisely or expressed a particularly unexpected view, his own wording was quoted. Each abstract was preceded by a brief title [using the Symbolic Shorthand System (SSS) for Physiology and Medicine (*Selye & Ember E24,113/64*)] identifying its subject matter. Articles which contained data pertaining to several chapters of this monograph were separately abstracted for each section. However, the same summary could often be used for this purpose, changing only the title. For example, let us take an article concerned with the prevention by spironolactone of the adrenal

necrosis produced by dimethylbenzanthracene and the inhibition of this protection by ethionine. Here I first dictated my abstract with the title:

**"DMBA ← SNL"**

meaning (in SSS) toxic manifestations produced by dimethylbenzanthracene (DMBA) as influenced by (←) spironolactone (SNL). Then I merely added: repeat the same abstract also with the title:

**"Pharmacology/Blockers/Ethionine"**

Thus, the same abstract was made available for the corresponding sections on: 1. the detoxication of carcinogens by steroids (spironolactone) and 2. the general pharmacology of blockers (ethionine) that interfere with steroid-induced hepatic microsomal enzyme activity.

When typed out, this abstract with its two titles looked like this:

2 Titles	{	DMBA ← SNL Pharm/Blockers/Ethionine
Abstract	{	<i>Kovacs &amp; Somogyi G60,060/69:</i> In rats, the adrenal necrosis produced by DMBA is prevented by pretreatment with spironolactone and this protection is in turn blocked by ethionine.

Once carefully proof-read, a Xerox copy was prepared, in addition to the original, in order to avoid possible errors that may slip in by retyping the abstract. When — as in this case — the same abstract was supposed to be used in several connections, a corresponding number of Xerox copies was prepared and on each of these, a different title was marked with a hook to indicate the section of the manuscript where it should go. In this manner, with a minimum of effort, the article can be called to the attention of those interested in any of the topics on which it contains information.

Finally, the pages containing these abstracts were cut up into slips and taped into proper position — according to the "rail paper technique" (*Selye E24,140/64 p. 350*) — on a master copy provided with index tabs.

Throughout this phase of the work, my main concern was to reflect the authors' statements objectively whether I agreed with them or not. Only in a few instances (e.g., when the statements were contradictory or the technique faulty) was it necessary to point out possible sources of confusion, but this was done after the reference in separate, initialed comments.

The resulting classified abstract collection corresponds to the double column, small print in this volume.

**3. Critique and Personal Observations.** We now had a classified collection of concise abstracts which served as a convenient guide to the literature on hormones and resistance. However, precisely because of its strict objectivity and the absence of any connecting sentences between the abstracts, this text completely lacked both originality and continuity. It was useful for the experienced specialist who only wants to look up the literature on a certain point, but it gave no guidance to the beginner and contributed no unpublished new thoughts or observations.

The published data of our group were handled in the usual manner, by preparing objective abstracts of them for the small print sections. However, my own interpretation of the literature and our hitherto unpublished observations were reported in an entirely different, current narrative form; this text is clearly separated from the rest by being printed in a single column of large type. Here, there are no references, it being tacitly understood that the conclusions are my own, based on a critical interpretation of the literature and my personal experience. In addition, numerous photographs and tables were prepared to make the report informative.

Thus, we end up having a book within a book: the *small-print* sections represent concise and impersonal abstracts of published and unpublished data, formulated in telegraphic style, to be looked up but not to be read through from cover to cover; the *large-print* text, on the other hand, is a critical evaluation of the literature and an illustrated description of unpublished observations. The reader who only wishes to get an overall view of the present status of knowledge on hormones and resistance can do so without getting lost in detail and confusing contradictory statements by reading only the large-type sections. The investigator who wants to verify a special point quickly will find it without having to wade through much text by merely consulting the classified abstracts in the corresponding section.

This "analytico-synthetic style" would not lend itself to the writing of textbooks for students, nor would it be suitable for monographs on entirely new subjects on which there is virtually no earlier literature; however, I think it could be profitably employed in the compilation of any review, monograph or

handbook which is to combine an extensive literature survey with personal observations and critical interpretations.

**4. Tables and Previously Unpublished Data.** In view of the very large number of facts that have come to light of late concerning the possibility of influencing the toxicity of the most diverse agents by catatoxic compounds, it was not possible to publish all of our pertinent observations in the form of original articles. Hence, the results of these studies will be presented in this monograph in the form of standardized tables or brief summaries inserted in the text under each of the toxicants examined.

Otherwise unpublished observations are referred to by their protocol numbers (e.g.: "Selye PROT. 27645"). Thus, if interested readers wish to obtain further information, they can get it by writing us. In the case of previously published data, reference is made to the original papers, although often additional data are included in our tables.

The term "*Standard Conditioners*" always refers to PCN, CS-1, ethylestrenol, spironolactone, norbolethone, oxandrolone, prednisolone-Ac, progesterone, triamcinolone, DOC Ac, hydroxydione, estradiol, thyroxine and phenobarbital administered under the standard conditions as described here. Unless otherwise stated in the tables themselves, all steroids to be assayed for possible protective effects have been given in 1 ml water by stomach tube (p. o.) twice daily, as pretreatment and treatment, usually from the first day (4th day before toxicant) until the termination of the experiment. Steroids poorly soluble in water were given in the form of microcrystal suspensions, prepared with the addition of a trace of Tween 80. Thyroxine was administered at the dose of 200  $\mu$ g in 0.2 ml water (traces of Tween 80 and NaOH added to facilitate solubilization) once daily s.c. Only when steroids were not given p. o., or not at the 10 mg dose level, is this indicated in the tables. Phenobarbital sodium (a typical nonsteroidal catatoxic drug) was administered at the 6 mg dose level in 1 ml water p. o. twice daily on the same days as the steroids.

In addition to these tables concerning individual toxicants, Tables 135—137 present the "Protective Spectra" of some steroidal and nonsteroidal agents respectively, in a synoptic manner and according to a procedure which is outlined on pp. 770 ff.

Unless otherwise specified, all experiments were performed on female 90—110 g Holtzman

or ARS/Sprague-Dawley strain rats kept on Purina Fox Chow and tap water ad lib.

With each toxicant we registered the characteristic functional (motor disturbances) or structural (intestinal ulcers, cardiac necrosis, calcinosis) changes in terms of an *arbitrary scale* in which 0 = no change, 1 = just detectable, 2 = moderate, 3 = maximal change, as previously described (Selye G70,421/70, G60,083/70).

However, for *statistical evaluation* we recognized only two grades: minor and sometimes dubious degrees of lesions (between "0" and "1" in our scale) were rated as negative, all others as positive. In the exceptional groups comprising less than 10 rats, these data as well as the mortality rates were then arranged in a  $2 \times 2$  contingency table, and their statistical significance was determined by the "Exact Probability Test" of Fisher and Yates (Finney D31,291/48 and Siegel G67,296/56). In all the other groups, comprising 10 rats or more, we used the same procedure of grading, but the statistical evaluation was performed by the Chi-square test using the  $2 \times 2$  table. The severity of all functional disturbances was listed at the time, when the difference between the pretreated and not pretreated animals was most evident.

Only in the case of anesthesia or paralysis did we assess the results by the time (in minutes) necessary to regain the righting reflex. Here, the significance of the apparent differences between the sleeping or paralysis time of the controls and the experimental animals was computed by Student's t-test. When one of the two results was "0", we calculated the statistical significance on the basis of confidence limits.

In all tables: \*\*\* =  $P < 0.005$ , \*\* =  $P < 0.01$ , \* =  $P < 0.05$ , NS = Not Significant. Only in the evaluation of the Synoptic Tables 135–137 did we follow another procedure as outlined on pp. 770. Plain asterisks (\*) indicate inhibition, underlined asterisks (\*) aggravation of toxicity.

The results of *completely negative experiments* are not tabulated but merely mentioned under the corresponding toxicants, indicating the technique of administering the latter and adding the sentence "the 'Standard Conditions' (p. VIII) showed no noteworthy change in activity."

**Enzymologic References.** The principal purpose of this book was to discuss the effect of hormones upon resistance, irrespective of the underlying mechanisms involved. However,

since hormones usually regulate resistance to toxicants through the induction of drug-metabolizing enzymes, we also wished to provide at least a key to the most pertinent references concerning purely enzymologic studies in this field. Dr. Jürgen Werringloer of our Biochemistry Department and Mr. Antonio Rodriguez, our Chief-Documentalist, are preparing an extensive reference list of defensive enzyme induction which will be published at a later date. However, they have kindly supplied me with those sections of their index that are particularly pertinent to the subject of this monograph. Thus the readers will have easy access to references on enzymic studies, concerning the action of an inducer upon the biotransformation of a toxicant, immediately after our discussion of the associated morphologic or functional changes.

These references to observations on the induction of potentially defensive enzymes are listed without comments, indicating only the substrate, the agent used to influence its metabolism and the reference. For details, the reader will invariably have to consult the original publications listed in the bibliography.

Among the agents influencing drug metabolism, hormones have received the greatest attention, but stress, sex, age and various interventions considered to be of potential endocrinologic interest have also been included. On the other hand, excluded from the enzymologic references are: 1. Substrates (e.g., amino acids, fatty acids) that are primarily involved in general metabolism and participate only very indirectly, if at all, in detoxication processes and resistance. 2. Purely endocrinologic or physiologic interactions between hormones and/or drugs, as well as pharmacologic test methods. 3. Spontaneous diseases of man, be they targets or agents. 4. The metabolism of endogenous hormones or metabolites, with the exception of bilirubin, which is of special interest in the treatment of hyperbilirubinemias by enzyme inducers.

In the mechanics of indexing, we observed the following rules:

1. Since most pertinent experiments were performed on the rat, this species is not specifically mentioned. Otherwise, the name of the experimental animal is given but, for the sake of brevity, in the case of the commonly employed rabbit (Rb), guinea pig (Gp), and monkey (Mky), in abridged form.

"In vitro" experiments are defined as those in which the entire metabolic study was carried out with tissue slices, homogenates or

fractions, independently of whether the induction took place in the living animal or in the test tube. The accession numbers of these experiments are italicized (e.g. *G74,673/59*). All other types of observations (e.g., disappearance rates of substrates from body fluids and tissues, rates of drug elimination in urine or bile) are considered "in vivo" and especially marked by an asterisk following the accession number which is printed in ordinary roman numerals (e.g. *G74,673/59\**). When both types of observations were combined, the accession number is italicized and followed by an asterisk (e.g. *G74,673/59\**).

If a Target "T" (drug or substrate) is influenced by an Agent "A" (drug), this is indicated, thus: T ← A.

The enzymologic references dealing with a given substrate are listed in a distinctive small

type (immediately after the abstracts concerning the same substrate), thus:

Hexobarbital ← Luteoids: Juchau et al. *G40,275/66*; Blackham et al. *G69,913/69\**; Rümke et al. *H14,039/69\**

Ethylmorphine ← Ovariectomy: Davies et al. *H22,054/68*

3-Methylcholanthrene ← Estradiol, Mouse: Kirschbaum et al. *H27,666/53\**

Carisoprodol ← Ovariectomy + 4-Chlor-testosterone, Testosterone: Kato et al. *G66,023/61\**

If the same substrate is simultaneously affected by two or more inducers and/or antagonists, these are listed in arbitrary order, but the first position is assigned preferably to agents of endocrine importance.

\*

In our era, in which interest and material support for research has reached unprecedented proportions, one of the greatest handicaps to the further development of science is the growing difficulty of keeping track of the ever expanding mass of literature. Hence, a generally acceptable, simplified style of reporting could be of immeasurable value. Of course, many laboratory men will say that they lack the time, money, library facilities, or the knowledge of foreign languages necessary for a thorough personal search of the original literature in an extensive field. Yet, any competent scientist must master his own subject. The breadth of his investigations may be very limited by lack of documentation, but in his restricted field he will eventually gather valuable, expert knowledge which should be made available to others as well. It is hoped that the extreme simplicity of reporting in the style recommended here will encourage the writing of surveys by authors who would not have ventured to do so in the more time-consuming conventional form. Should this be the case, correlative investigations would certainly receive a welcome stimulus at a time when mass production threatens to discourage the integration of knowledge. H.S.

## ACKNOWLEDGEMENTS

I would like to take this opportunity first of all to express my heartfelt gratitude to all my past and present associates who have assisted me in many of the experiments that form the subject matter of this treatise. I am thinking here particularly of Drs. Béla Solymoss and Kálmán Kovács, to whom we owe respectively the first data on the biochemical, and on the ultrastructural changes associated with the protective effect of typical catatoxic steroids. However, since virtually all other members of our teaching staff, as well as most visiting scientists and postgraduate students have given their attention primarily to the hormonal regulation of resistance, it would be impossible to mention them all by name. Suffice it to express my special thanks to those "Claude Bernard Visiting Professors" whose presence in our Institute during this year has been a special stimulus to the planning of the original experiments reported in this book, namely to: J. Axelrod, J. Berry, B. Brodie, A. H. Conney, J. R. Fouts, H. V. Gelboin, R. J. Gillette, F. T. Kenney, W. E. Knox, G. J. Manering, G. L. Plaa and H. Remmer.

My thanks are due furthermore to Dr. J. Werringloer and Mr. A. Rodriguez, of our Biochemistry and Documentation department respectively, for having supplied me with the "Enzymologic References."

I am especially indebted to Mrs. I. Mécs, our Chief-Technician. She managed to coordinate the activities of some sixteen technicians so that they efficiently performed the more routine aspects of the laboratory work on an average of about 1200—1500 rats per week, during these last years. In addition Mrs. Mécs was responsible for many original ideas in the design of these experiments and co-authored several publications with my colleagues and myself.

For the editorial work I am most indebted to Mrs. L. Traeger (and her group: K. Bennett, M. Brault, D. Duguay, C. Micusan, M. Mondal, F. Pece and J. Ramu), who, through her dedicated efforts, coordinated all the work involved and brought about the successful completion of this book. I am also thankful to Mr. A. Rodriguez and Mrs. M. Timm for compiling the subject index.

Mr. J. Krzyzanowski (with Mrs. R. Santaca and Mr. I. Lemieux), ingeniously collected even the most inaccessible publications, a crucial task in the preparation of a book of this kind which depends so largely upon the completeness of its bibliography. I also wish to thank Mr. K. Nielsen for preparing the histologic slides and photographic illustrations, as well as to Springer-Verlag for the meticulous attention given to all details of manufacture and design.

Except for about twenty quite inaccessible but important publications, no work was discussed on the basis of second-hand information obtained from references made to it by others. Hence, all works unavailable to us in the original form had to be photographically reproduced, a colossal undertaking for which I am most indebted to Mr. Marcel Bilodeau (our beloved "Uncle Bill") who prepared 104,524 pages of Xerox copies for this purpose.

This publication and the original experimental work done at our Institute was subsidized in part by USPHS, National Library of Medicine (Grant 5 RO 1 LM 00522-03), the Ministère de la Santé, Québec, the Medical Research Council of Canada (Block Term Grant MT-1829), the Quebec Heart Foundation, Montreal, the Succession J. A. DeSève, Montreal and was also undertaken as a special project of the Council for Tobacco Research, U.S.A. and the Canadian Tobacco Industry.

## GLOSSARY

This glossary furnishes succinct descriptions of some of the technical terms and abbreviations most commonly used. For additional data of this kind (especially synonyms, code numbers and pharmacologic actions of chemical compounds) consult the corresponding sections of the text, through the subject index at the end of the volume.

**AAF.** See N-2-fluorenylacetamide.

**AAN.** Acetoaminonitrile, a lathyrogenic compound.

**ACTH.** Adrenocorticotrophic hormone of the pituitary.

**Actinomycin.** Unless otherwise specified, this term is used for actinomycin D, recently given the official designation dactinomycin. An antineoplastic agent, especially for Wilms' tumor, which blocks the effect of several microsomal enzyme inducers presumably at the level of the DNA-dependent RNA polymerase reaction (transcription).

**Adaptive hormones.** Hormones which increase resistance and facilitate adaptive processes.

**ADH (antidiuretic hormone).** Vasopressin; a hormone of the posterior pituitary, which influences reabsorption of water by the renal tubule.

**ADH (enzyme).** Alcohol dehydrogenase (Ec 1.1.1.1). Substrates: ethanol and other alcohols, also: aldehyde dehydrogenase (EC 1.2.1.3). Substrates: aldehydes.

**ADP (adenosine diphosphate).** A nucleotide which participates in high-energy phosphate transfer.

**AF.** See aminofluorene.

**Aminofluorene.** AF, a carcinogenic hydrocarbon.

**AMP (adenosine monophosphate).** A nucleotide which participates in high-energy phosphate transfer.

**Antagonists (of enzymes).** Substances which inhibit enzyme actions through hitherto unspecified mechanisms.

**Antifolliculoid.** Blocking the effect of folliculoids (e.g., MER-25). Term first intro-

duced for certain androstanes by Selye (A60,638/44).

**Antimineralocorticoid.** Blocking the effect of mineralocorticoids, e.g., spironolactone.

**Antitestoid.** Blocking the effect of testoids (e.g., cyproterone).

**ANTU.** 1-(1-Naphthyl)-2-thiourea.

**APN.** Aminopropionitrile, a lathyrogenic compound.

**ATP (adenosine triphosphate).** A nucleotide which is an important source of high-energy phosphate.

**ATPase (adenosine triphosphatase).** An enzyme which catalyzes the dephosphorylation of ATP.

**Blockers (of enzymes).** Substances which impede the synthesis of enzymes by interfering with the production of RNA or proteins (e.g., actinomycin, puromycin, ethionine).

**BMR.** Basal metabolic rate.

**BSP (Bromsulphalein®, sulfobromophthalein).** A dye used in tests of liver function.

**Catatoxic actions.** Increased metabolic degradation and/or excretion of potentially toxic substances. Usually, catatoxic substances result in detoxication, but if the metabolites formed are more poisonous than the parent compounds, the reverse may be true.

**CNS.** Central nervous system.

**Co A.SH (free [uncombined] coenzyme A).** A pantothenic acid-containing nucleotide which functions in the metabolism of fatty acids, ketone bodies, acetate, and amino acids.

O

||

**Co A.S.C.CH<sub>3</sub> (acetyl-Co A, "active acetate").** The form in which acetate is "activated" by

combination with coenzyme A for participation in various reactions.

**Co I (coenzyme I).** Now called NAD (q. v.).

**Co II (coenzyme II).** Now called NADP (q. v.).

**Co III (coenzyme III).** A nicotinamide-containing nucleotide which functions in the oxidation of cysteine.

**Competitors.** Substances which act by competitively inhibiting the actions of enzymes upon their substrates.

**Conditioning Actions.** Actions which prepare the organism for a special type of response. In this volume, the term is mainly used for the induction of changes in resistance through catatoxic or syntoxic compounds, irrespective of the underlying mechanisms and of whether the change in reactivity is advantageous or disadvantageous.

**CS-1.** 9 $\alpha$ -Fluoro-11 $\beta$ ,17-dihydroxy-3-oxo-4-androstene-17 $\alpha$ -propionic acid potassium salt, the first catatoxic steroid to be identified as such. Manufacturer's code number is SC-11927.

**CTP (cytidine triphosphate).** A source of high-energy phosphate in phospholipid synthesis.

**Cytochrome "P-450".** A heme protein capable of binding CO to yield a pigment with a characteristic absorption peak at 450 m $\mu$ . The "active oxygen" produced in the reaction of reduced P-450 cytochrome with molecular oxygen is thought to be a hydroxylating intermediate, possibly a peroxide.

**DAB.** See p-diethylaminoazobenzene.

**Dactinomycin.** New official name for actinomycin D.

**p,p'-DDD.** 1,1-Dichloro-2,2-bis(p-chlorophenyl)ethane, insecticide related to DDT.

**DDT.** 1,1-Trichloro-2,2-bis(p-chlorophenyl)ethane, pesticide.

**DHT.** Dihydrotachysterol, a vitamin-D derivative which at high doses causes tissue calcification.

**Dicoumarol.** Bishydroxycoumarin.

**p-Diethylaminoazobenzene.** DAB, Butter Yellow, a carcinogenic hydrocarbon.

**Dioxathion.** The new generic name for the pesticide previously known as navadel or Delnav.

**DMBA.** 7,12-Dimethylbenz(a)anthracene, a carcinogenic hydrocarbon.

**DMP.** Dimethyl phthalate.

**DMSO.** Dimethyl sulfoxide.

**DNA (deoxyribonucleic acid).** The characteristic nucleic acid of the nucleus.

**DOC.** Desoxycorticosterone.

**DOPA.** Dioxypheylalanine or dihydroxyphenylalanine.

**DPN.** See NAD.

**ECG.** Electrocardiogram.

**EEG.** Electroencephalogram.

**EFA (essential fatty acids).** Polyunsaturated fatty acids, essential for nutrition.

**EPB.** N-Ethyl-3-piperidyl benzilate, an antagonist of drug-metabolizing enzyme induction.

**EPDA.** N-Ethyl-3-piperidyl diphenylacetate, an antagonist of drug-metabolizing enzyme induction.

**EPN.** Phenylphosphonothioic acid O-ethyl O-p-nitrophenyl ester, pesticide.

**ESCN.** Electrolyte-Steroid-Cardiopathy with Necrosis.

**ESR.** Electron spin resonance.

**EST.** Electroshock threshold.

**FAD (flavin adenine dinucleotide).** A riboflavin-containing nucleotide which participates as a coenzyme in oxidation-reduction reactions.

**F-COL.** 9 $\alpha$ -Fluorocortisol, a gluco-mineralocorticoid.

**ff.** This sign indicates continuation of treatment, e.g., "First day, ff." means treatment was started on the first day and continued until termination of the experiment.

**FFA.** Unesterified free fatty acid (also called NEFA, UFA).

**Fisher-Yates test.** Statistical procedure as described by Finney D31,291/48 and Siegel G67,296/56.

**N-2-Fluorenylacetylamine.** 2-Acetylaminofluorene or AAF, a carcinogenic hydrocarbon.

**FMN (flavin mononucleotide).** A riboflavin-containing cofactor in cellular oxidation-reduction systems.

**Folliculoid.** Follicle-hormone-like, estrogenic, gynecogenic or estromimetic, e.g., estradiol.

**FSH (follicle-stimulating hormone).** A gonadotrophic hormone of the anterior pituitary.

**Glucocorticoid.** Possessing the effects of the carbohydrate active hormones of the adrenal cortex, e.g., cortisol, triamcinolone.

**G-6-P-ase.** Glucose-6-phosphatase (EC 3.1.3.9). Substrate: D-glucose-6-phosphate.

**GOT.** Glutamic-oxalacetic transaminase; aspartate aminotransferase (EC 2.6.1.1). Substrate: L-aspartate.

**$\alpha$ GPDH.**  $\alpha$ -Glycerolphosphate dehydrogenase; glycerol-3-phosphate dehydrogenase (EC 1.1.1.8). Substrate: L-glycerol-3-phosphate).

**GPT.** Glutamic-pyruvic transaminase; alanine aminotransferase (EC 2.6.1.2). Substrate: L-alanine.

**Hepatectomy (partial).** The term, if applied to the rat and not otherwise qualified, refers to the usual procedure which removes about 65–70% of the liver tissue (Waelsch and Selye 3972/31).

**HMP shunt (hexose monophosphate shunt).** An alternate pathway of carbohydrate metabolism.

**IDP (inosine diphosphate).** A hypoxanthine-containing nucleotide which participates in high-energy phosphate transfer.

**IDPN.**  $\beta,\beta'$ -Iminodipropionitrile, a compound producing neurolethyrism.

**Induction.** Selective stimulation of enzyme synthesis.

**Inhibitors (of enzymes).** Substances which antagonize the enzymes themselves (e.g., SKF 525-A), in contradistinction to blockers of enzyme synthesis and to substances which act by competition for substrates.

**ITP (inosine triphosphate).** A deamination product of ATP, functioning similarly to ATP, as a source of high-energy phosphate.

**IU.** International unit(s).

**Lathrogens.** Compound producing either osteo- or neurolethyrism, e.g., aminopropionitrile, or "APN", iminodipropionitrile, or "IDPN".

**LDH (lactic acid dehydrogenase).** (EC 1.1.1.27). An enzyme whose activity may be measured in serum for diagnosis of certain acute diseases, e.g., acute myocardial infarction.

**LH (luteinizing hormone).** A gonadotrophic hormone of the anterior pituitary.

**LTH (luteotrophic hormone).** A hormone of the anterior pituitary possibly identical with the lactogenic hormone.

**Luteoid.** Corpus luteum hormone-like, progestational, gestagenic, progestagenic, e.g., progesterone.

**MAD.** Methylandrostenediol, 17 $\alpha$ -methyl-5-androstene-3 $\beta$ ,17-diol, an anabolic testoid.

**MAO.** Monoamine oxidase.

**MAT.** Methionine adenosyltransferase (EC 2.5.1.6). Substrate: L-methionine.

**3-MC.** See 3-methylcholanthrene.

**3-Methylcholanthrene.** 3-MC, same as 20-methylcholanthrene. A carcinogenic hydrocarbon.

**Mineralocorticoid.** Possessing the effects of the salt metabolism regulating hormones of the adrenal cortex, e.g., aldosterone, DOC.

**MPDC.** N-Methyl-3-piperidyl diphenyl-carbamate, an antagonist of drug-metabolizing enzyme induction.

**MSH (melanocyte-stimulating hormone).** A hormone of the pituitary which increases deposition of melanin by the melanocytes.

**NAD (nicotinamide adenine dinucleotide).** Formerly termed DPN (diphosphopyridine nucleotide). A nicotinamide-containing nucleotide which functions in electron and hydrogen transfer in oxidation-reduction reactions. Coenzyme I.

**NADH.** Reduced form of NAD.

**NADP (nicotinamide adenine dinucleotide phosphate).** Formerly termed TPN (triphosphopyridine nucleotide). A nucleotide with functions and structure similar to those of NAD. Coenzyme II.

**NADPH.** Reduced form of NADP.

**Navadel.** A pesticide now known as dioxathion.

**NEFA (nonesterified fatty acids).** The major form of circulating lipid used for energy (= UFA).

**NPN.** Nonprotein nitrogen.

**OKT.** Ornithine-ketoacid aminotransferase (EC 2.6.1.13). Substrate: L-ornithine.

**OMPA.** Octamethyl pyrophosphoramidate. An anticholinergic insecticide.

**PABA (para-aminobenzoic acid).** A factor among the B vitamins.

**PCN.** 3 $\beta$ -Hydroxy-20-oxo-5-pregnene-16 $\alpha$ -carbonitrile, SC-4674. A synthetic steroid carbonitrile with strong catatoxic activity.

**Repression.** Selective inhibition of enzyme synthesis.

**RER.** Rough endoplasmic reticulum.

**RES.** Reticulo-endothelial system.

**Reversal.** The phenomenon of the inverse response to a catatoxic agent which causes the latter to aggravate the same lesion which it normally prevents (e.g., aggravation of digitoxin convulsions by spironolactone, when the latter is administered a few hours after digitoxin).

**RNA (ribonucleic acid).** The characteristic nucleic acid of cytoplasm involved in protein synthesis.

**mRNA.** Messenger RNA.

**SER.** Smooth endoplasmic reticulum.

**sRNA.** Soluble RNA (same as tRNA [transfer RNA]).

**SC-11927.** The manufacturer's code number for CS-1.

**SDH.** L-Serine dehydratase (EC 4.2.1.13). Substrate: L-serine.

**SGOT (serum glutamic oxaloacetic transaminase).** An enzyme often measured in serum for diagnosis of acute myocardial infarction or liver diseases.

**SGPT (serum glutamic pyruvic transaminase).** An enzyme which may be measured in serum for diagnosis of certain types of liver disease.

**Spermatogenic.** Having the ability to stimulate the spermatogenic epithelium and mainly to protect it against atrophy caused by deficiency in gonadotrophic hypophyseal hormones, e.g., pregnenolone, androstenediol.

**STH.** Somatotrophic hormone of the pituitary (growth hormone).

**Syntoxic actions.** Stimulation of biologic responses which permit coexistence with potential pathogens by altering the irritability of the host's tissues without attacking the pathogen.

**T3.** Triiodothyronine.

**T4.** Tetraiodothyronine, thyroxine.

**TDH.** Threonine dehydratase (EC 4.2.1.16).  
Substrate: L-threonine.

**TEA.** Tetraethylammonium, a ganglionic blocking agent usually given as the bromide or chloride.

**Testoid.** Male-hormone-like, androgenic, andromimetic, e.g., testosterone.

**TKT.** Tyrosine- $\alpha$ -ketoglutarate transaminase; tyrosine aminotransferase (EC 2.6.1.5).  
Substrate: L-tyrosine.

**TMACN.** 17 $\beta$ -Hydroxy-4,4,17-trimethyl-3-oxoandrost-5-ene-2 $\alpha$ -carbonitrile, trimethyl-androstenolone carbonitrile, also designated as 2 $\alpha$ -cyano-4,4,17 $\alpha$ -trimethylandrost-5-ene, 17 $\beta$ -ol, 3-one. A highly potent catatoxic steroid carbonitrile which causes a syndrome of adrenocortical hyperplasia with sexual anomalies in the newborn, when given to pregnant rats. The effect is presumably due to persistent inhibition of fetal 3 $\beta$ -hydroxysteroid dehydrogenase and  $\Delta^5$ -4-isomerase. The compound is often referred to as "cyanoketosteroid."

**TPN.** See NADP.

**TPO.** Tryptophan oxygenase (EC 1.13.1.12).  
Substrate: L-tryptophan.

**TPP (thiamine pyrophosphate).** The thiamine-containing coenzyme which is cofactor in decarboxylation.

**Transcription.** Readout of genetic information to form an RNA template.

**Translation.** Readout of the RNA-coded information in the process of enzyme synthesis.

**TSH (thyroid-stimulating hormone).** A hormone of the anterior pituitary which influences the activity of the thyroid.

**TTH (thyrotrophic hormone).** Same as TSH.

**UDPG (uridine diphosphoglucose).** An intermediary in glycogen synthesis.

**UDPGal.** Uridine diphosphogalactose.

**UDPGluc.** Uridine diphosphoglucuronic acid.

**UFA.** Unesterified free fatty acids (= NEFA).

**UTP.** Uridine triphosphate.

**Xenobiochemistry.** Term recommended for the "biochemistry of foreign organic compounds" in the preface of the monograph "Detoxication Mechanisms" (Williams E906/59).

**Xenobiotics.** The authors recommend the term "xenobiotics" (from the Greek "xenos" and "bios" for "stranger to life") for compounds which "are foreign to the metabolic network of the organism." It is clearly recognized that the mixed function oxidases responsible for the degradation of many xenobiotic compounds are also participating in the metabolism of steroids, lipids and other normal components of the body and food (Mason et al. F51,528/65). Substrates for NADPH oxygen and cytochrome P-450 dependent microsomal enzymes (Leibman G 66,210/69). Also defined as substrates which "are metabolized by mixed function oxidases localized in the endoplasmic reticulum of the liver" (Gillette et al. E8,216/69).

## REVIEWS

This book attempts to abstract and discuss the literature directly concerned with the effect of hormones and hormone derivatives upon resistance. The theoretic interpretation of the underlying mechanisms, in particular the mobilization of enzymic mechanisms for defense, are still quite incompletely understood and will consequently receive much less meticulous attention. However, the true understanding of hormone-dependent resistance phenomena can only come through further exploration and clarification of the basic chemical mechanisms which in many cases are similar to, if not identical with, those underlying hepatic microsomal drug-metabolizing enzyme inductions by nonhormonal agents.

In the following pages special emphasis is laid therefore upon review articles covering those fields which are less completely discussed in the body of this monograph. Foremost among these are generalities about enzyme induction especially by hormones and hormone-like substances, particularly by catatoxic steroids, as well as the concept of adaptive enzymes in general. Additional review articles specifically dealing with certain aspects of the role of hormones in resistance will be found in the corresponding sections of the text.

### *Enzyme Induction in General*

*Dorfmann B76,571/52*: Review (40 pp., about 70 refs.) on "Steroids and Tissue Oxidation," with special reference to the activation of enzyme systems but not particularly those involved in detoxication.

*Knox et al. E83,471/56*: Review (90 pp., 752 refs.) on "Enzymatic and Metabolic Adaptations in Animals" with special reference to hormonal, sex-dependent and diet-induced adaptive enzymic changes, but without special reference to hepatic microsomes.

*Brodie et al. E92,717/58*: Review (27 pp., 148 refs.) on the enzymic metabolism of drugs with special reference to the kind of enzyme systems that can be induced.

*Knox G67,799/58*: Review (17 pp., 35 refs.) on "Adaptive Enzymes in the Regulation of Animal Metabolism" mainly concerned with factors inducing hepatic TPO activity.

*Williams E906/59*: Monograph (796 pp., numerous refs.) on "Detoxication Mechanisms—The Metabolism and Detoxication of Drugs, Toxic Substances and Other Organic Compounds."

*Axelrod G66,350/62*: Review on the demethylation and methylation of drugs and physiologically active compounds by hepatic microsomes.

*Brodie G55,013/62*: Review (22 pp., 26 refs.) on drug metabolism with special reference to subcellular mechanisms in hepatic microsomes.

*Bousquet H11,613/62*: Review (12 pp., 135 refs.) on the pharmacology and biochemistry of drug metabolism with special reference to microsomal enzymes.

*Conney & Burns G67,166/62*: Review on factors influencing drug metabolism with special emphasis upon microsomal enzyme induction.

*Gillette E52,874/62*: Review (16 pp., 51 refs.) on "Oxidation and Reduction by Microsomal Enzymes."

*Remmer G67,788/62*: Review (21 pp., 22 refs.) on drugs which induce drug-metabolizing enzymes in the liver. "Administration of these drugs results in (1) accelerated metabolism of steroids such as testosterone and  $\Delta^4$ -androstene-3,17-dione by liver microsomes, (2) accelerated metabolism of TPNH by liver microsomes, and (3) accelerated in vivo

metabolism of D-glucose and D-galactose to D-glucuronic acid, L-gulonic acid and L-ascorbic acid."

*Remmer G66,542/62*: Review (21 pp., 34 refs.) on drug tolerance with special reference to barbiturates.

*Gillette G51,908/63*: Review (62 pp., numerous refs.) on "Metabolism of Drugs and Other Foreign Compounds by Enzymatic Mechanisms."

*Gillette G66,248/63*: Review (8 pp., 14 refs.) on the induction of hepatic microsomal enzymes by various drugs and hormones.

*Rosen & Nichol E3,837/63*: Review (38 pp., about 170 refs.) on the effect of corticoids and adrenalectomy upon enzyme activity mainly in the liver, but also in other tissues, in vivo and in vitro.

*Burns G41,546/64*: Editorial on the implications of enzyme induction for drug therapy.

*Burns & Conney G71,448/64*: Review (25 pp., 57 refs.) on the therapeutic implications of drug metabolism in man.

*Shuster F38,575/64*: Review (25 pp., 173 refs.) on the "Metabolism of Drugs and Toxic Substances."

*Burns & Conney F56,503/65*: Brief review on the role of enzyme induction in the metabolism of drugs.

*Conney G41,879/65*: Review (20 pp., 104 refs.) on the role of enzyme induction in drug toxicity.

*Gillette G66,246/65*: Review on factors influencing the toxicity of drugs, with a brief section on hepatic microsomal enzymes.

*Gillette E7,538/66*: Review (42 pp., about 200 refs.) on the biochemistry of drug oxidation and reduction by enzymes in hepatic endoplasmic reticulum.

*Jayle & Pasqualini G67,284/66*: Review (36 pp., 267 refs.) on glucuronic acid conjugation of steroids and thyroxine. Literature is cited to show that glucuroconjugation of thyroid hormones occurs also in eviscerated rats and hepatectomized dogs, whereas steroid glucuronides are not formed in hepatectomized and eviscerated mice. This suggests that glucuroconjugation of thyroid hormones, unlike that of steroids, can occur in extrahepatic tissue.

*Chiancone F85,259/67*: Review of the mechanisms regulating hepatic TPO activity.

*Conney F88,649/67*: Review (49 pp., 379 refs.) on the "Pharmacological Implications of Microsomal Enzyme Induction."

*Gillette G67,333/67*: Review (25 pp., about 150 refs.) on drug detoxication by hepatic microsomal enzymes.

*King & Burgard G46,498/67*: Review (6 pp., 40 refs.) on the induction of drug-metabolizing enzymes.

*Goldstein et al. E165/68 (p. 274)*: Review on the age factor in the induction of microsomal drug-metabolizing enzymes.

*Mannering G71,818/68*: Review (68 pp., 325 refs.) on the "Significance of Stimulation and Inhibition of Drug Metabolism in Pharmacological Testing." Most of the inducing agents and substrates tested are tabulated with references to the corresponding literature. Special emphasis is laid upon the existence of several mechanisms of induction (phenobarbital type, polycyclic hydrocarbon type), the chemistry of microsomal drug metabolism, tests for enzyme induction, and clinical applications.

*Mannering G75,980/68*: Review (26 pp., 89 refs.) on stimulation and inhibition of drug metabolism.

*Brodie G72,492/69*: Review (4 pp., no refs.) on "Some Prospects in Toxicology" with special reference to drug-metabolizing enzymes.

*Conney H8,988/69*: Review (7 pp., 28 refs.) on drug metabolism with special reference to its application in therapeutics.

*Filner et al. H15,309/69*: Review of the literature on enzyme induction in plants. An extensive Table lists the plants examined with the enzymes, cofactors, or inhibitors involved.

*Gillette et al. E8,216/69*: Proceedings of a symposium (547 pp., numerous refs.) on "Microsomes and Drug Oxidations" held with the participation of 52 internationally known specialists, in Bethesda, Maryland, February 1968.

*Hayashi H13,776/69*: Review (23 pp., 201 refs.) on enzymic hydroxylation with a special section on microsomal monooxygenases.

*Kuntzman G64,989/69*: Review (35 pp., 109 refs.) on "Drugs and Enzyme Induction."

*Staudinger et al. H20,267/69*: Review (7 pp., 40 refs.) on oxidative drug metabolism with special reference to the underlying mechanism.

*Various authors G68,203/69*: Review (27 pp., 42 refs.) on "Application of Metabolic Data to the Evaluation of Drugs. A Report Prepared by the Committee on Problems of Drug Safety of the Drug Research Board, National Academy of Sciences—National

Research Council." A large section of this report is devoted to the inactivation of drugs by microsomal enzymes. It is emphasized that "it is difficult to predict from in vitro data alone whether inhibitors of the cytochrome P-450 enzymes will significantly block the metabolism of drugs in laboratory animals and in patients." Furthermore, "phenobarbital administration leads to an increase in virtually all known enzymatic pathways by causing an increase in both NADPH cytochrome C reductase and cytochrome P-450. Although phenobarbital is known to act by increasing the synthesis of enzyme protein, it may also act by slowing the turnover of the various components of the endoplasmic reticulum."

*Aldrete & Weber G75,396/70*: Review (17 pp., 96 refs.) on the role of the liver in the detoxication of anesthetics and muscle relaxants.

*Conney G70,316/70*: Review on environmental factors influencing drug metabolism with special reference to hepatic microsomal enzyme induction.

*Conney & Kuntzman G70,540/70*: Review on the metabolism of normal body constituents by drug-metabolizing enzymes in hepatic microsomes; special chapters deal with the metabolism of steroid hormones, cholesterol, fatty acids, thyroxine, bilirubin, indoles, sympathomimetic amines, heme, methylated purines, kynurenine and anthranilic acid.

*Fouts G76,868/70*: Review on the effects of various insecticides, both as inducers and as substrates for hepatic microsomal enzymes.

*Fouts G79,537/70*: Review (6 pp., 19 refs.) on the influence of various factors, especially environmental contaminants, upon hepatic microsomal drug-metabolizing enzymes.

*Greim H32,018/70*: Brief review (4 pp., 18 refs.) on microsomal enzymes and their possible clinical implications (German).

*Schimke & Doyle G75,997/70*: Review (44 pp., 307 refs.) on the "Control of Enzyme Levels in Animal Tissues," with a special section on the regulation of enzyme levels by hormones.

*Schreiber G73,539/70*: Review (22 pp., 77 refs.) on "The Metabolic Alteration of Drugs." Special chapters deal with epinephrine, norepinephrine, mescaline, diethylpropion, pronethalol, phenothiazine, diazepam and chlordiazepoxide.

*Schmidt & Schmidt G73,170/70*: Review (62 pp., 272 refs.) on "Enzyme Activities in Human Liver."

*Mannering G74,558/71*: Review on microsomal enzyme systems which catalyze drug metabolism.

### **Enzyme Induction by Hormones**

*Schou E92,436/61*: Review (23 pp., 147 refs.) on factors influencing the absorption of drugs from the subcutaneous connective tissue. Special sections deal with the effect of epinephrine, folliculoids and glucocorticoids which can alter the action of various drugs by modifying their absorption rate.

*Ghione & Turolla G18,525/64*: Review on the effect of anabolics upon inflammatory responses, with special reference to the granuloma pouch technique, anaphylactoid edema and cotton pellet granulomas.

*Conney F88,649/67 (p. 342)*: Review on the hormonal regulation of drug metabolism.

*Freedland et al. H2,949/68*: Review (5 pp., 33 refs.) on the relationship of nutritional and hormonal influences in hepatic enzyme activity.

*Selye G70,465/70*: Brief review on "Stress, Hormones and Cardiovascular Disease."

### **Enzymes and Adaptation**

*Cedrangolo B46,622/49*: Review on "Adaptation as an Enzymological Problem."

*Selye B40,000/50 (pp. 246-254)*: Review on the changes in the enzyme activity of various tissues and the blood during the G.A.S., with special reference to the "adaptive enzymes" or "protective enzymes" which undoubtedly play an important role in adaptation to stress.

*Fregly G72,594/69*: Review (6 pp., 11 refs.) on cross-adaptation, with special reference to the induction of drug-metabolizing enzymes.

*Hale G72,522/69*: Review (11 pp., 86 refs.) on cross-adaptation in general.

### **Catatoxic Steroids**

*Selye A36,744/42; A37,822/42; 94,572/47*: Reviews on the pharmacology of steroid hormones and their derivatives, with special reference to correlations between chemical structure and pharmacologic actions.

*Conney & Kuntzman G70,540/70*: Review on the metabolism of steroid hormones as influenced by the induction of hepatic drug-metabolizing enzymes.

*Selye G60,083/70*: Monograph (2 vol., 1155 pp., about 5500 refs.) on "Experimental Cardiovascular Diseases," with a section on

catatoxic steroids capable of affecting lesions in the heart and vessels.

*Selye G60,087/70*: Review on the history of adaptive steroids with special reference to catatoxic steroids.

*Selye G60,070/70*: First detailed presentation of the concept of catatoxic steroids, with a review of the literature from 1931 to 1969.

*Selye G60,100/70*: Review (French) on catatoxic steroids.

*Selye G70,427/70*: Editorial on steroids and nonspecific resistance, with special reference to catatoxic steroids.

*Selye G70,421/70*: 304 Steroids were tested for their ability to protect rats against usually fatal intoxication with indomethacin or digitoxin. Using a "Simplified Activity Grading" system, 65 among these compounds were found to be active against indomethacin, 54 against digitoxin, and 23 against both substrates at a 10 mg dose level. But only 4 of these steroids were still capable of inhibiting one or both of these substrates at the 0.5 mg dose level. The only steroid still active against both substrates at the dose of 0.2 mg was PCN (3 $\beta$ -hydroxy-20-oxo-5-pregnene-16 $\alpha$ -carbonitrile).

*Song & Kappas G80,521/70*: Review (21 pp., 215 refs.) on "The Influence of Hormones on Hepatic Function" with special sections on their effect upon phagocytosis, drug metabolism and biliary excretion. Folliculoids stimulate, whereas glucocorticoids inhibit, the RES whereby they may influence drug resistance.

*Khandekar G70,492/71*: Brief letter to the editor outlining the salient facts about catatoxic steroids.

*Selye G70,491/71*: Review (Italian) on the history and pharmacology of catatoxic steroids (70 refs.).

*Selye G79,017/71*: Brief review (German) of the history and present status of the concept of catatoxic steroids.

*Selye G79,021/71*: Brief review on steroids and resistance with special reference to catatoxic steroids (Russian).

*Selye & Tuchweber G70,494/71*: Review on the concept of catatoxic steroids and its possible clinical implications (Spanish).

*Solymoss G79,009/71*: Review (Hungarian) on microsomal drug-metabolizing enzymes, with special reference to their induction by catatoxic steroids.

*Szabo G70,498/71*: Brief review of catatoxic steroids (Serbo-croatian).

# I. INTRODUCTION, TERMINOLOGY AND CLASSIFICATION, METHODS

## A. INTRODUCTION

The purpose of this book is to examine how hormones can influence the resistance of the body to changes in its environment.

We became interested in this matter when we began to realize the decisive role played by hormones in the "General Adaptation Syndrome" (G.A.S.), the stereotyped response to stress as such, which develops whenever exposure to any kind of stimulus requires acute or chronic adaptive readjustment.

In the earlier stages of the G.A.S., the instantly acting epinephrine and norepinephrine, later the corticoids, appear to be more important for defense. Among the latter, the glucocorticoids play a particularly crucial part in the regulation of nonspecific resistance. They are secreted under the influence of ACTH, whose discharge from the pituitary is in turn regulated by a hypothalamic releasing factor. These observations showed that a whole chain of endocrine messengers is concerned with the maintenance of resistance to environmental changes.

It is not yet clear to what extent hormones, other than those of the hypothalamus-pituitary-adrenal axis, influence adaptability to stress in general, but numerous accidental observations have suggested that resistance to many pathogens can also be greatly enhanced or diminished by an excess or deficiency of thyroid, gonadal and pancreatic hormones. These may be secreted in response to a need, or they may modify reactivity merely through their continuous presence in the body, irrespective of requirements.

Originally, the principal functions of hormones were seen in the regulation of sex, growth, differentiation and metabolism in general. Analysis of the mechanism of the G.A.S. called attention to the fact that at least the pituitary and adrenal hormones participate in a natural adaptive mechanism. Occasional observations on changes in resistance to certain agents, caused by other hormones, were usually brushed off as mere curiosities or incidental "pharmacologic actions" having no fundamental biologic importance.

The time has come to question this view. Resistance to many drugs is influenced by the removal of endocrine glands or the administration of physiologic amounts of their hormones which could hardly be said to act as "drugs." In order to facilitate work on the role of endocrine factors in resistance, this book was designed to accomplish a dual task: 1. To describe numerous (partly unpublished) personal observations on the effect of various hormones upon adaptation to exogenous stimuli; 2. to review and correlate the relevant observations scattered throughout the literature, many of which are hard to find, since they are often recorded incidentally in publications on other topics.

At this stage, it is still not easy to detect much lawfulness in the hormonal control of nonspecific resistance, apart from the G.A.S.; yet it is now, when pertinent systematic studies are just beginning, that an inventory of the established facts is most urgently needed.

Meanwhile, it is even difficult to see how this kind of research should be planned. In the past, relevant facts were obtained mainly by chance, but we are not likely to succeed in unravelling the complex hormonal regulatory system of resistance by mere empiricism.

Of course, the great question is: Through what mechanisms do hormones affect resistance? We have learned that some of them, the predominantly "syntoxic hormones," merely adjust the body's response, so that it tolerates pathogens without attacking them; others, the predominantly "catatoxic hormones," actually destroy the aggressor, mostly through the induction of drug-metabolizing enzymes. That much has been found more or less by chance.

Because of their antistress effect, the glucocorticoids proved to be highly efficient in normalizing the otherwise low resistance of adrenalectomized animals to virtually all types of damage. However, our hopes of raising stress resistance above normal did not materialize. Neither treatment with corticoids, nor with any other hormones succeeded in increasing nonspecific resistance much above the level assured by a normally functioning endocrine system. Yet, the experiments which established this disappointing fact, quite unexpectedly showed that certain hormones or hormone derivatives possess also an extraordinary protective effect, at least against certain types of intoxications. Thus, we saw that thyroxine protects against such diverse lesions as the nephrocalcinosis produced by dietary excess of  $\text{NaH}_2\text{PO}_4$ , the skeletal changes elicited by lathyrogenic amines and intoxication with elementary yellow phosphorus. Later, we found that ethylestrenol prevents digitoxin poisoning and shortens the anesthetic effect of various barbiturates and steroid hormone derivatives. It also became evident that the antimineralocorticoid compound CS-1 protects against acute intoxication by dihydrotachysterol and the infarctoid cardiac necroses produced by various combinations of corticoids, electrolytes, lipids and stress. Conversely, thyroxine proved to increase sensitivity to various insecticides, anticoagulants and indomethacin. These, and many other observations cited in this volume, clearly showed that resistance to many agents is decisively influenced by the endocrine system, but we still had no way of predicting which hormones would raise or decrease the effect of a given drug.

It was at this point that we decided to initiate systematic investigations on the possible resistance-modifying effect of a carefully selected series of hormones and hormone derivatives, with vastly different endocrine properties. These compounds were tested against numerous drugs chosen more or less at random; yet, the toxicity of most of them was decisively influenced by one or the other compound in our series. Random fact gathering is not a very elegant way of scientific investigation; yet, in the beginning, all we could do was to test many hormones for their possible protective effect against many agents. At this stage, our work was not guided by any logically conceived theory concerning the underlying mechanisms; it rested merely on the hope that the adaptive hormones could be properly classified on the basis of their defensive actions as manifested by simple observations *in vivo*.

If so, the individual members of each class thus identified could then be subjected to a more profound pharmacokinetic analysis.

In other words, we had to determine first which hormone protects against which drug, before we could explore how it did this. We had to know first that a hormone has adaptive value before we could ask whether this is due to a syntoxic or a catatoxic mechanism. Such observations, as the fact that an indomethacin-induced intestinal ulcer can be prevented by ethylestrenol, or that cortisol aggravates certain infections, reveal nothing about how these hormones work; but only findings of this type can tell us where further research would be rewarding.

Of course, scientists can rarely identify by direct observation the things that they are looking for; most of the time they have to be guided by indirect indices. The chemist often first detects a compound, or even a particular functional group in its molecule, by inference from a color reaction, a revealing X-ray diffraction pattern or the formation of a characteristic precipitate. The physician must first suspect the presence of a microbe through certain clinical signs and symptoms before he can verify his diagnosis by looking for a particular organism. It is perhaps not too daring to hope that in our first efforts to clarify the role of hormones in resistance, simple, directly visible indicators might also serve us best.

These thoughts have guided the experimental investigations and the selection of the literature discussed in this book. Therefore, major emphasis will be placed on such immediately detectable manifestations of activity as morphologic and functional changes or mortality rates, these being most suitable for the large-scale experimentation on many compounds, which is required to obtain material for meaningful generalizations. Unfortunately, it will not be possible to present an equally complete picture of the much more fundamental biochemical changes that are responsible for the observed phenomena. Besides, in most cases, these have not yet been elucidated; but where such information is available, key references will be given, especially to the most important data on enzyme induction.

It would have been redundant to burden the Abstract Section and the bibliography of this volume by the repetition of literature surveys on related phenomena already published in other monographs. These earlier data helped us considerably in the evaluation of the topics presented here and will be incorporated in the discussions, but without specific reference to individual papers. In particular, it would have served no useful purpose to dilute our account with the voluminous literature on the antistress, antiphlogistic, immunosuppressive, ulcerogenic and other well-known actions of corticoids, or the specific interactions between various sex hormones. The same is true of the bibliographies on the restoration of resistance by corticoids in adrenal insufficiency and the hormonal control of various "pluricausal lesions." For details on all of these subjects, the reader is referred to the corresponding sections of the monographs listed below:

## B. TERMINOLOGY AND CLASSIFICATION

### *PRINCIPLES GUIDING THE CLASSIFICATION OF HORMONE ACTIONS IN GENERAL*

Before attempting to present a system for the classification of the adaptive hormones let us say a few words about the justification for the distinction of such pharmacologic categories in general. We shall use the steroids as our example, not only because many of them have adaptive value, but also because in this field of endocrinology, systematization has been most necessary and most feasible. Organic chemistry has furnished the pharmacologist with several thousands of steroids for bioassay, and the complexity of the interrelations between chemical structure and pharmacologic potency, as well as between the various pharmacologic actions of the same compound, appeared to defy all attempts to define circumscribable groups of biologic actions. Yet, without the recognition of classes which can be distinguished from each other on the basis of such criteria, science could not progress.

In biology, classifications invariably lack precision, because all vital processes are more or less interdependent, and the transitions between the different manifestations of life are gradual. A dog is obviously an animal, an apple tree a plant, but no matter how we define these two classes, there will always remain some primitive organisms which fit both equally well. A horse is a living being, a rock an inanimate object, but although in certain viruses the distinction is virtually impossible, biology could not get along without the concept of "life."

The same difficulties exist in every type of pharmacologic classification. The study of drug actions would be impossible without such concepts as anesthetics, diuretics, hepatotoxic substances, or antiphlogistics; yet, no drug exhibits a single action selectively. We would be hard put to define a "poison," but the science of toxicology could not exist without this concept.

No one would quarrel with these truisms but, in practice, we tend to forget them and make desperate efforts to find non-overlapping classifications. This is impossible. The typical members of any group are easy to place, but there always remain intermediates which fit two or more classes. Yet, science could not exist without systematization, that is the creation of classes, imperfect as they may be. The point is not to avoid such imperfections, which would be a futile effort, but to define them as clearly as possible. The singular biologic polyvalence of the steroid molecule makes the classification of its manifold actions particularly difficult, but some degree of precision is attainable.

The basic principle according to which the pharmacologic activities of steroids are classified, is that certain actions are independent of each other, while others are merely subordinate manifestations of such independent actions, and hence, dependent upon them. It must be clearly understood that **independent steroid-**

**hormone actions** are characterized by the fact that each of them can be exhibited independently of any of the others; that is to say, there is no direct parallelism between the degree to which a compound exhibits its various independent actions. In this sense, we recognize the independent nature of the following pharmacologic properties:

1. **Folliculoid** (follicle-hormone-like, estrogenic, gynecogenic or estromimetic); e.g., estradiol.

2. **Testoid** (male-hormone-like, virilizing, androgenic, andromimetic); e.g., testosterone.

3. **Luteoid** (corpus luteum-hormone-like, progestational, gestogenic, gestagenic, progestagenic); e.g., progesterone.

4. **Glucocorticoid** (possessing the effects of the carbohydrate-active hormones of the adrenal cortex); e.g., cortisol, triamcinolone.

5. **Mineralocorticoid** (possessing the effects of the salt metabolism-regulating hormones of the adrenal cortex); e.g., aldosterone, DOC.

6. **Spermatogenic** (having the ability to stimulate the spermatogenic epithelium and mainly to protect it against atrophy caused by deficiency in gonadotrophic hypophyseal hormones); e.g., pregnenolone, androstenediol.

7. **Anabolic** (stimulating protein anabolism). This effect is usually combined with testoid activity, but does not necessarily run parallel with it. The **renotrophic** action (enlargement of kidney size due to tubular hypertrophy) of certain steroids parallels their anabolic actions more closely and may be dependent upon the latter; e.g., ethylestrenol, norbolethone.

8. **Antimineralocorticoid** (blocking the effect of mineralocorticoids); e.g., spironolactone.

9. **Anesthetic** (production of general anesthesia); e.g., pregnanedione, hydroxydione.

10. **Catatoxic** (ability to enhance the metabolic inactivation and/or excretion of toxic substances); e.g., spironolactone, ethylestrenol. (As far as can be judged from presently available evidence, **syntoxic** activity is inseparably linked with corticoid actions and hence cannot be regarded as an independent hormone effect.)

Probably this list could be considerably prolonged if we had enough evidence to prove the independent nature of several additional steroid-hormone effects which, on the basis of available data, may well be independent; e.g., the antifolliculoid, antitestoid, antigonadotrophic and nephrocalcinotic actions. The distinction is often difficult; for example, some steroids produce excitation and convulsions instead of anesthesia, but it would be hazardous to regard the two effects as truly independent, since even the sleep induced by typical steroid anesthetics is often preceded by a state of excitation.

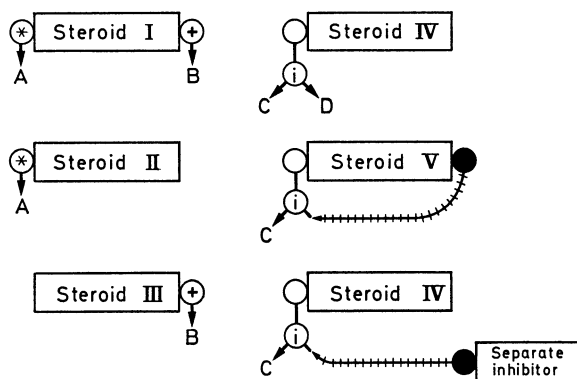

While some steroid-hormone actions are *completely independent* (e.g., the anesthetic effect), many are *preferentially associated* with certain other effects (e.g., the thymolytic action). The latter is characteristic of glucocorticoids, folliculoids and testoids, but not of mineralocorticoids, anesthetics or luteoids. Similarly, the cata-toxic effect may be associated with antimineralocorticoid, anabolic, or even glucocorticoid properties but, as far as we know, never with folliculoid or mineralocorticoid actions.

A **dependent steroid-hormone action** is merely an individual manifestation of one of the independent action groups just enumerated (e.g., the vaginal, uterine and behavioral estrus changes characteristic of folliculoids, or the stimulation of the different male accessory sex organs by testoids). Even here, the interdependence of the various manifestations subordinate to the same independent effect is not absolute; certain sex hormones may stimulate different sex organs preferentially, though never quite selectively.

It is of fundamental importance to know that certain steroid actions can, whereas others cannot, be obtained selectively; however, the distinction between totally independent effects and those preferentially associated with certain other actions is not sharp. Some steroid-hormone actions appear to be quite incompatible (e.g., corticoid and folliculoid), whereas others show a more or less pronounced tendency to be combined (e.g., anabolic and catatoxic).

We still know virtually nothing about the **molecular properties responsible for the various steroid-hormone actions**. However, if we are to analyze these, we must first attempt to formulate concepts which — no matter how speculative they may be — could give us some idea of the physico-chemical properties that might account for the observed, virtually innumerable, combinations of the biologic effects that can be elicited by the steroid molecule. We know that concurrent treatment with two steroids may lead simultaneously to synergisms between some, and antagonisms between others of their pharmacologic actions; hence, we must first consider the possibility of intramolecular pharmacologic interactions between different properties of the same molecule.

Certain effects, thought to be subordinate to an independent action with which they are usually associated, may be inhibited either by additional repressor properties of the evocative steroid itself or by concurrent treatment with a second agent. However, if they can be selectively blocked by any means, they are not obligatory consequences of the main independent effect, and must act through a distinct mechanism. These are the actions which we regard as independent, but preferentially associated with certain other pharmacologic activities. Their interrelations may be schematically illustrated as follows:

"Steroid I" possesses two groupings "\*" and "+," responsible respectively for actions "A" and "B." Without further evidence, the possible independence of these actions cannot be ascertained. However, if a "Steroid II" exhibits only action "A"

and "Steroid III" only action "B," the separability of the two properties is established.

"Steroid IV" also exhibits two properties, "C" and "D," but these are due to the same molecular characteristic (white circle), and hence are interdependent. For example, they may merely represent different effects of an intermediate "i." However, this basic interdependence may be overcome by a selective blockade of action "D." In "Steroid V," the molecule itself possesses an appropriate D-repressive grouping (black circle), but a selective C-type of effect can also be obtained with Steroid IV if a separate D-inhibitor substance is concurrently applied.

Intramolecular antagonisms make it difficult to distinguish with certainty, dependent from independent hormone actions. But this distinction would be only theoretic in any case, because the end result is the same, whether a compound has only one effect or two potentially interdependent actions, one of which is suppressed. It is immaterial whether an effect is selective because it is caused by a single molecular property, or because other potentialities are masked by additional features of the same molecule.

The study of pharmaco-chemical interrelations within a steroid molecule is not concerned with the feasibility of blocking one of two interdependent actions by other compounds. However, it is very important to explore this possibility, when only one of two interdependent actions is desirable. In addition, such studies on intermolecular antagonisms show us which actions are incompatible and may therefore be expected to be also suppressed by intramolecular antagonisms.

For example, the observation that steroids with strong folliculoid activity are usually devoid of catatoxic actions has led to experiments showing that the effects of typical catatoxic steroids can be blocked by concurrent treatment with folliculoids. This finding strongly suggests that chemical characteristics, adequate for the induction of catatoxic effects, might likewise be blocked through intramolecular antagonisms in compounds possessing also strong folliculoid actions.

It is not our purpose to discuss every theoretically possible intramolecular antagonism, but one additional common source of confusion should be mentioned. As previously stated, it is generally agreed that the thymolytic activity is a subordinate effect of glucocorticoids, invariably associated with their other actions; yet, it is also an obligatory subordinate effect of folliculoids. It may be tempting to assume therefore that this effect is dependent upon either glucocorticoid or folliculoid activity. Still, in folliculoids it occurs independently of glucocorticoid, and in glucocorticoids independently of folliculoid activity; hence, it is not necessarily dependent upon either one of these.

As shown here, in addition to their thymolytic effect, glucocorticoids act (among other things) on carbohydrate metabolism and they maintain life after adrenalectomy, whereas folliculoids cause vaginal estrus and block the life-maintaining action

of glucocorticoids. The thymolytic effect is not wholly independent, it is associated with either glucocorticoid or folliculoid activity, but it is not necessarily dependent upon either one of these. If this type of antagonistic interaction could also occur within a single molecule, it would explain why among the numerous steroids proven to possess life maintenance activity in adrenalectomized animals, none exhibits appreciable folliculoid actions; if it did, its life-maintaining corticoid effect would be blocked. For the same reason, no active folliculoid has ever been found to prolong the life of adrenalectomized animals. On the other hand, the thymolytic effect of folliculoids would not be blocked (and might even be expected to be increased) by the concurrent possession of a latent glucocorticoid potency.

The many gradations that exist between totally independent and completely interdependent actions may create the impression that an attempt to distinguish the two is fruitless; yet, we could hardly explore this field if we did not have such concepts as "corticoid," "testoid," "folliculoid," or "catatoxic" activity. Such distinctions are indispensable. They imply that: 1. in practice, the activities of each of these classes are largely independent of each other; 2. the many effects characteristic of each member of any one class are largely interdependent.

In fact, without the formulation of this fundamental distinction between independent and subordinate actions, a planned systematic study of steroid pharmacology would hardly have been possible. The usual attempt of simply ascribing certain pharmacologic actions to the presence of one or the other functional group has been singularly unsuccessful. Specific chemical characteristics of a molecule can be effective only if other features do not block them through opposing pharmacologic effects or by altering absorption, membrane permeability, metabolic degradation, etc.

These considerations will also have to guide our attempts to correlate the adaptive manifestations of hormones.

### *THE ADAPTIVE HORMONES*

It is useful to distinguish adaptive hormone actions from those responsible for growth, reproduction and general metabolism. The adaptive hormones help to adjust the organism to life under unusual conditions, although they do have nonadaptive functions as well. Here we shall use the adaptive steroids (both natural and synthetic) as a basis for the discussion of terminology and classification, because these have been most extensively studied; yet the nonsteroidal hormones (e.g., catecholamines, thyroxine) likewise play an important role in adaptation. The adaptive steroids (like other hormones and even drugs that regulate resistance) appear to fall naturally into two main groups which control essentially different adaptive processes:

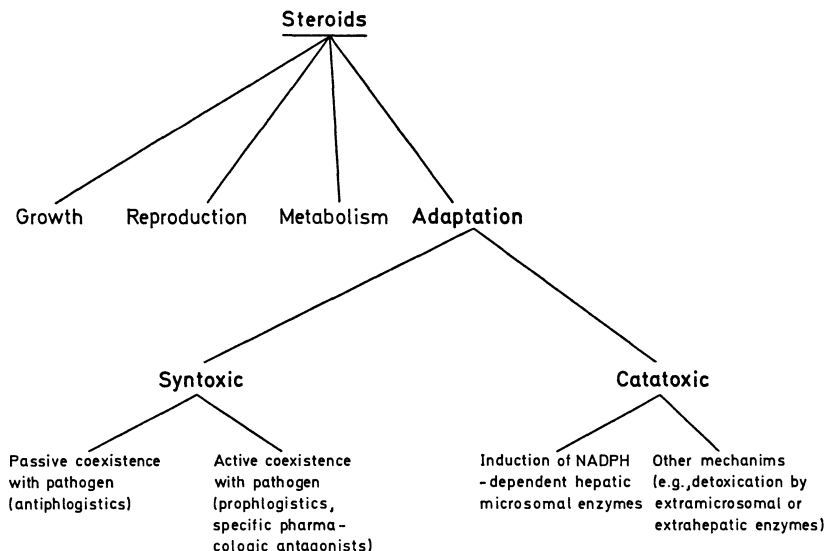

1. **The syntoxic steroids** (e.g., cortisol, triamcinolone, aldosterone, desoxycorticosterone) initiate changes which permit adjustment to topical or systemic injury without directly attacking the aggressor. They create conditions for coexistence with toxic agents, either through passive indolence to them (e.g., antiphlogistics), or by actively stimulating the formation of a granulomatous barricade, which tends to isolate the irritant from the surrounding tissue (e.g., prophlogistics). Through similar mechanisms, the syntoxic steroids also promote repair (e.g., cicatrization).

The systemic action of the syntoxic steroids is mainly of the "life-maintaining corticoid" type; it is highly efficient in restoring the nonspecific resistance of adrenal-deficient organisms to normal, but then, it reaches a plateau above which tolerance is not easily raised. Only in a few instances (e.g., damage due to endotoxins, inflammatory irritants, immune reactions, lathyrogenic compounds) can syntoxic steroids increase tolerance far above normal because here, the "disease" is primarily due to active morbid reactions of the tissues, not to passive, direct tissue damage by the exogenous aggressor. Thus, endotoxin shock is thought to be caused mainly by the liberation of enzymes normally sequestered in lysosomes, whereas inflammation, various pathogenic immune reactions (allergies, anaphylaxis, homograft rejection) and osteolathyrism represent excessive responses of the body to different types of irritation. In all these cases, homeostasis is achieved by adjusting the body's reaction to the damaging agent, not by destroying the latter.

2. **The catatoxic steroids** (e.g., ethylestrenol, spironolactone, certain cyanosteroids) act primarily by stimulating aggressive reactions which destroy toxic substances (e.g., by accelerating their metabolic degradation). They do not merely restore a deficient resistance to normal (as the glucocorticoids do after adrenalectomy), but are capable of raising it far above the norm. Sometimes this reaction defeats its purpose, because the products of metabolic degradation are more toxic than the original drug which was to be inactivated. Yet, the response is still catatoxic since it attacks the aggressor. For similar reasons we speak of allergy and anaphylaxis as "immune reactions," although they actually produce damage.

There are many overlaps between syntoxic and catatoxic steroid actions, for example, the stimulation of inflammation may lead to topical degradation of the irritant by enzyme activation in the inflammatory focus; or under certain circumstances, the primarily syntoxic glucocorticoids may enhance the hepatic detoxication of barbiturates. Yet, the distinction between the two categories is justified because, usually, individual hormones act predominantly by eliciting one or the other reaction form. Furthermore, available evidence suggests that the two types of defense are mediated through essentially distinct mechanisms. For example, as stated above, homeostatic reactions to endotoxins or inflammatory irritants appear to depend upon the stabilization of membranes which isolate toxic enzymes preformed within the cell. Thereby they protect against damage resulting from a kind of autointoxication by natural substances liberated under the influence of an aggressor. Conversely, many catatoxic hormones have been shown to induce NADPH-dependent hepatic microsomal enzymes which destroy endogenous or exogenous toxic substances. Yet, without further evidence, it would be hazardous to equate this mechanism with the catatoxic action. It is already evident that not all catatoxic steroids inactivate the same set of substrates and it will be necessary in each case to determine whether the detoxication occurs: 1. in the liver, 2. in the microsomal fraction, 3. as a consequence of NADPH-dependent enzymes, and 4. by enzymes that have been induced "de novo" and not merely activated. Hence, it is more prudent, meanwhile, to recognize the possibility of other catatoxic mechanisms, and to ascribe detoxication reactions to the induction of NADPH-dependent hepatic microsomal enzymes only whenever this has been definitely proven.

The following diagram will help to illustrate the classification used in this review:

In addition to the typical syntoxic and catatoxic effects, a few hormonal defense mechanisms should also be mentioned which appear to represent special types, although they might as well be regarded as particular variants of the above mentioned actions (*cf. also pp. 768ff.*).

One of these is the **increased elimination** of poisonous substances (e.g., through the kidney, bile, intestine or skin) which for lack of pertinent information can not be discussed here at length. Although some hormones undoubtedly do influence drug excretion, the endocrine regulation of this detoxicating mechanism has not yet been shown to play a particularly important role in defense.

Similarly, we shall mention only in passing that the **distribution** of toxic substances at a distance from the site of application (e.g., in the RES, adipose tissue, bones), as well as the regulation of their passage through the hemato-encephalic barrier, may also affect their toxicity. Obviously, the formation of a temporary depot in tissues will prevent toxicants from flooding the blood; thereby time is gained for their metabolic degradation. Variations in the permeability of the hematoencephalic barrier will especially affect the toxicity of compounds influencing the central nervous system.

Finally, changes in the **absorption rate** (e.g., from the intestine, skin, or connective tissue) may likewise play a decisive role in determining the amount of a toxicant which can reach its receptor site within a critical period.

Hormones can thus influence toxicity by their actions upon the excretion, distribution and absorption of potential pathogens, but in all these cases, the end result is a change in the tolerance for toxic compounds, not in their destruction. Hence, all these hormone actions may be regarded as essentially syntoxic. In some instances, the products of an altered drug metabolism are more readily excreted, but here the primary process is catatoxic, a chemical alteration of the toxicant, not merely a change in the excretion rate of the unaltered poison.

Finally, we should mention **specific drug antagonisms**, such as interactions between hormones and pathogens which happen to have opposite specific effects (e.g., the influence of mineralocorticoids upon potassium tolerance, or the effect of epinephrine upon hypotensive agents). These so-called "physiologic antagonisms" need not receive special attention here.

Any one adaptive hormone can be conveniently classified according to its predominant activity, although it may act through several of the above mentioned mechanisms. Yet, because of this overlap, it is more correct to speak of syntoxic or catabolic "actions" rather than of "hormones." However, in common parlance, it would be awkward always to make such a distinction; we refer to syntoxic or catabolic hormones as we speak of vasopressors, anabolic or folliculoid compounds, although individual members of each group may exhibit several additional effects. Defensive responses that are mainly due to catabolic (e.g., glucocorticoids, thyroxine, folliculoids) or anabolic (e.g., STH, anabolic steroids) stimuli may be considered to be syntoxic when they act mainly by permitting life despite the continued presence of a pathogen. However, when antiminerlocorticoids are used merely to protect against the effects of mineralocorticoids, the resistance is evidently due to specific antagonisms.

The fact that many hormones have multiple adaptive effects has encouraged attempts to classify them according to their "activity spectrums."

Thus, among the hepatic microsomal enzyme inducers, the "phenobarbital type" stimulates many pathways of metabolism by liver microsomes, including oxidation, reduction, glucuronide formation and de-esterification. In contrast, the polycyclic "aromatic hydrocarbon type" exemplified by 3-methylcholanthrene, stimulates a much more limited group of reactions. The hormonal enzyme inducers are more difficult to fit into groups because of the great variety of their actions. Yet, as we shall see in later sections of this book, some such categories are beginning to emerge as regards the type of drug against which protection can be provided. For example, the antiminerlocorticoid (CS-1) and the anabolic steroids (e.g., ethylestrenol, norbolethone) generally protect against indomethacin, digitoxin and barbiturates; the glucocorticoids (e.g., cortisol, triamcinolone) protect against lathyrogens and the hexamethonium type of ganglioplegic drugs; the thioacetyl-containing steroids (e.g., spironolactone, emdabol, spiroxasone) protect against mercuric chloride. Of course, here again there is a considerable overlap between the classes and we shall have to learn much more about the underlying chemical mechanisms before arriving at a truly satisfactory classification.

Independently of these attempts to classify the inducers or "conditioning agents," it is customary to **differentiate two types of substrates on the basis of the types of difference spectra** they give by binding to hepatic microsomal P-450. We shall discuss this matter at greater length in the section on "Toxicants," suffice it to say here that hexobarbital is a characteristic "Type I" compound, whereas aniline is "Type II" in this sense. However, the distinctive spectrographic characteristics of drugs combining with microsomal cytochrome P-450 do not change from one type to the other under the influence of enzyme-inducers and there is no clear-cut connection between the various classes of inducers mentioned above and their ability to metabolize Type I or Type II substrates preferentially.

### **Classification of Steroid Hormone Actions in General**

*Selye A 37,822/42*: Review (53 pp., 227 refs.) on "The Pharmacology of Steroid Hormones and Their Derivatives." First distinction between dependent and independent steroid hormone actions, with a detailed discussion of the principles which permit the classification of these properties.

*Selye A 57,606/43*: A treatise (4 volumes) which represents a "Classified Index of the Steroid Hormones and Related Compounds" as far as these were known in 1943. A special section on the "Pharmacological Nomenclature and System of Classification" distinguishes between independent subordinate, and potentially subordinate steroid hormone actions.

*Selye 94,572/47*: A "Textbook of Endocrinology" (914 pp.) with a special extensive section (39 pp.) on the chemistry and pharmacologic classification of steroid hormones and their derivatives.

### **Syntoxic vs. Catatoxic Actions**

*Selye B 76,060/53*: In rats, cortisol inhibits inflammation in granuloma pouches produced by croton oil. However, the croton oil removed after 14 days of sojourn in the pouch still retains the ability to produce inflammatory changes when injected into other rats. Apparently, the glucocorticoid acts by depressing the inflammatory potential of the tissues, not by destroying the irritant.

*Kass D 35,079/60*: "In only two situations have adrenocortical hormones been shown to be protective to the host: the replacement of hormone in hypoadrenalism, and the protective action against the lethal toxicity of bacterial lipopolysaccharides . . . The antiendotoxic activity of corticosteroids seems to be sufficiently different from the anti-inflammatory activity to offer the possibility that these two activities may be structurally separable. The anti-inflammatory action of corticosteroids is apparently related largely to an effect on vascular permeability, whereas the antiendotoxic activity in some way involves the reticuloendothelial system."

*Selye G 60,070/70*: For the classification of a catatoxic steroid effect as due to "induction of NADPH-dependent hepatic microsomal enzymes," it is essential to ascertain that the action depends upon: 1. the liver; 2. enzymes

in the liver; 3. microsomal enzymes; 4. NADP-dependent microsomal hepatic enzymes. In each case, it has to be shown that the activity is not significantly dependent upon non-enzymic mechanisms or extra-hepatic enzymic mechanisms.

### **Activity Spectrums of Enzyme Inducers**

*Gillette G 66,248/63*: A review of the literature on the induction of hepatic microsomal drug-metabolizing enzymes is summarized as follows: "These studies provide evidence that the administration of foreign compounds enhances the activity of the drug metabolizing enzymes through at least three different mechanisms: one evoked by anabolic steroids, another by polycyclic hydrocarbons, and a third by phenobarbital. It seems likely that further studies will reveal still other mechanisms through which foreign compounds alter the activity of liver microsomal enzymes that metabolize foreign compounds." It is emphasized furthermore that according to available evidence "the barbiturates and the steroids act through different mechanisms. For example, the levator ani muscle in castrated rats is enlarged by the administration of 19-nortestosterone and other anabolic steroids but not by the injection of phenobarbital or 3,4-benzpyrene; ascorbic acid synthesis is enhanced by pretreating rats with barbital and 3-methylcholanthrene but not with the anabolic steroids; finally, phenobarbital produces its stimulatory effects within 1-4 days after administration whereas methyltestosterone elicits its effects only after prolonged administration."

*Conney F 88,649/67*: A review of the literature on enzyme induction leads to the conclusion that "inducers are of at least two types, exemplified by phenobarbital and 3-methylcholanthrene. Many compounds are like phenobarbital in stimulating varied pathways of metabolism by liver microsomes, including oxidation and reduction reactions, glucuronide formation, and de-esterification. In contrast, polycyclic aromatic hydrocarbons, typified by 3-methylcholanthrene and 3,4-benzpyrene, stimulate a more limited group of reactions."

*Mannering G 71,818/68 (p. 82)*: The inducible hepatic microsomal enzymes may be classified into two distinct categories, the "phenobarbital type" and the "polycyclic hydrocarbon type."

*Gillette H34,126/71*: The inducers of drug metabolism are classified into: 1. "Phenobarbital-like" agents which increase NADPH-cytochrome c reductase and cytochrome P-450 thus augmenting the amount of cytochrome P-450-substrate complex and its rate of reduction; 2. polycyclic hydrocarbons (e.g. methylcholanthrene) which form a variant of cytochrome P-450 that differs from the usual form in its affinity to various drugs. This kind of inducer does not increase either NADPH-cytochrome c reductase or the rate of cytochrome P-450 reduction; 3. spironolactone and other catatoxic steroids which increase NADPH-cytochrome c reductase activity and the rate of cytochrome P-450 substrate reduction, but have little if any effect upon the amount of cytochrome P-450. The relationship between the electron flux and hepatic microsomal drug metabolism largely depends upon the substrate.

*Solymoss et al. G79,023/71*: In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norbolethone and oxandrolone (anabolics), also enhance plasma clearance of BSP, probably through the same mechanism. In contrast to these effects of pretreatment, administration of spironolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, these observations clearly show that the catatoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may also be mediated through

extramicrosomal enzyme mechanisms or even through enhanced biliary excretion (H.S).]

### **Specific Antagonisms**

*Weil & Allen D7,883/61*: A review on the protection offered by various glucocorticoids against endotoxin shock in the mouse, rat and dog. The rate of removal and organ distribution of radioactive *E. coli* endotoxin is unaltered by cortisone; the steroids are assumed to protect the tissues "by their physical presence." This view is allegedly supported by the suppression of increased serum transaminase by cortisol. In any event, the corticoids do not protect in a "nonspecific manner" against insults, since prednisolone phosphate i.p. protects against the lethal effects of endotoxin but not against that of mecamlamine, chlorpromazine, metaraminol or dibenzyline (as judged by experiments on intact mice). The protective effect of glucocorticoids administered i.p. at 15 min and again at 4 hrs after *E. coli* endotoxin i.p. decreases in the following order: cortisol sodium succinate, prednisolone phosphate, methyl prednisolone sodium succinate, and dexamethasone phosphate.

### **Competitive Inhibition**

*Kagawa et al. D88,974/59*: In the rat, spironolactone blocks the hypertensive action of aldosterone by competitive inhibition.

*Kagawa E4,593/64*: A review of the literature revealed several observations suggesting that spironolactone possesses certain extrarenal effects, for example, on Na- and K-transport across the membrane of human erythrocytes, or the toad bladder in vitro, as well as the Na- and water-influx across the ciliary epithelium of the rabbit's eye.

*Kagawa et al. D88,974/59; Liddle D14,432/61; Mudge E4,490/65*: According to current opinion, the pharmacologic actions of spironolactone are due to competitive inhibition of the action of mineralocorticoids upon urinary electrolyte excretion.

## **C. METHODS**

Research on hormones and resistance actually has no specific methodology of its own. Hence, it will suffice here to give a few key references to the literature on the chemical and surgical techniques most commonly employed in this type of study. The special methods for the screening and characterization of new hormonal agents that increase resistance, and of the toxicants whose actions are particularly amenable

to this type of conditioning, is only now beginning to take concrete shape. Indeed it was only while compiling material for this treatise that we began to develop methods specifically designed for the bioassay of the many, ever more active, steroids exhibiting protective actions of possible clinical significance. For this type of study we need simple, rapid and highly sensitive bioassay techniques enabling us to test many compounds, even if available only in minute amounts.

In addition, it has become essential to perfect procedures for the statistical evaluation and presentation of large numbers of data in the form of "Diagram Tables" which permit the rapid overview and correlation of the numerous facts that have come to light recently in this general field.

Most of the relevant procedures were elaborated while trying to obtain material for the documentation of this monograph and will be presented in Chapter XI. There, we shall deal with the very practical problem of the most economic "Three-Step Procedure" for the identification of new protective hormones.

### *Chemical Methodology*

It would be beyond the scope of this treatise to discuss the chemical methods employed for the study of changes in resistance induced by hormones. Most of the pertinent investigations were concerned with the neosynthesis or activation of enzyme systems which helped in the detoxication of various substrates and the pertinent literature has been quoted in the reviews listed on p. 1-3.

### *Surgical Methodology*

Since the liver is the principal organ of detoxication, most of the surgical techniques employed in the study of catatoxic steroids were concerned with the elimination of certain, or all, hepatic functions.

The most commonly used techniques are briefly listed below and more extensively discussed in the following Abstract Section.

**Partial hepatectomy** was employed since the 19th century for the study of hepatic regeneration, but not until 1931 was this operation perfected as a means of estimating hepatic participation in drug detoxication. In mice and rats the median and left lateral lobes have a narrow pedicle; hence they can be removed without difficulty by a single ligature, thus depriving the animal of about 70% of its hepatic tissue. This operation greatly reduces resistance to drugs which are predominantly inactivated in the liver but the intervention causes little or no shock and does not significantly interfere with resistance to agents which are not subject to hepatic inactivation.

**Subtotal hepatectomy** can be employed to remove 85% or more of the hepatic tissue, but since this operation causes considerable nonspecific damage it is less suitable for hepatic detoxication studies in general. Through repeated partial hepatectomies, performed at sufficient intervals to permit considerable regeneration, it can be shown that the regenerative power of the liver is truly enormous.

**Complete hepatectomy** is of course the only procedure that totally deprives an animal of hepatic tissue, but it causes severe shock and can be employed only for very acute detoxication studies.

There are various techniques for the production of **bile fistulas** and **bile duct ligatures** which permit the collection of bile for the determination of materials excreted in it or the interruption of the enterohepatic circulation of compounds. Choledochus ligature has also been found useful in examining the role played by the bile in the absorption of ingested materials from the gut.

**Ligature of hepatic vessels**, which may be complete or limited to a mere constriction of the lumen, has been employed to study the effect of selective interference with the arterial or venous circulation of the liver.

Among other hepatic interventions recommended for detoxication studies let us merely mention here the techniques for **perfusion of the liver** (in situ or after its isolation in vitro), the **Eck fistula**, and **hepatic denervation**.

Of the **renal interventions** employed in detoxication studies the most common are complete or partial nephrectomy, ureter ligation or ligation of the penis to prevent the urinary elimination of toxicants. The effect of partial nephrectomy upon resistance may be due to interference with the urinary elimination of toxicants, their chemical inactivation by renal tissues or interactions between the toxicants and the renin-angiotensin system. We have first used this intervention in the study of renal participation in corticoid-hypertension, having observed that uninephrectomy greatly enhances the susceptibility of the rat to the production of hypertensive cardiovascular disease by DOC. If, in addition to one kidney, two-thirds of the other are likewise removed, the remaining fragment, which represents approximately 20% of the kidney tissue, suffices for life-maintenance in the rat, but greatly enhances sensitivity for a variety of drugs whose detoxication depends upon renal tissue. This "80%" nephrectomy is now currently used for detoxication studies in our Institute.

### **Chemical Methodology**

*Goldstein et al. E165/68 (p. 210):* Review on the methodology of studies concerning the elucidation of the manner in which various inducers alter the metabolism of drugs.

### **Surgical Methodology in General**

*Priestley et al. 9,158/31:* The following six methods have been tested for the study of hepatic detoxication using strychnine as a substrate.

1. Comparison of dogs with Eck fistula and normal dogs.

2. Comparison of the effectiveness of strychnine injected into the peripheral vascular system, and injection into the portal vein.

3. The ability of incubated pulp of liver to destroy strychnine.

4. Estimation of strychnine introduced into the circulation of a heart-lung-liver perfusion, compared with that introduced into a heart-lung-limb preparation.

5. Susceptibility of normal and dehepatized dogs to strychnine.

6. Rate of disappearance of strychnine from the blood stream of normal and dehepatized dogs.

Among these six methods "the study of the dehepatized dog and the perfused liver appears to have yielded the most conclusive and accurate data. The exclusive use of any single method is not recommended. However, by the combined use of the analytic and the synthetic methods (organism without a liver and surviving liver without the organism), respectively, definite evidence concerning the liver as a detoxicating organ can be obtained." The canine liver possesses a highly specialized ability to immediately arrest and subsequently destroy strychnine.

**Partial Hepatectomy.** *Ponfick A 24,568/1889:* Extensive description (41 pp.) of the technique and consequences of partial hepatectomy in the rabbit. As much as 2/3 of the hepatic parenchyme can be removed without causing serious functional disturbances. Complete hepatectomy is incompatible with life. If performed in several stages, enormous amounts of liver tissue can be removed. Earlier, mostly unsuccessful attempts at complete removal

of the liver in frogs and birds are reviewed. [No effort was made as yet to examine hepatic regeneration following partial hepatectomy (H.S.).]

von Meister A25,263/1894: Monograph (116 pp., 54 refs.) on the history of research on the regenerative power of the liver after various forms of mutilations. Personal observations on rabbits revealed the histologic details of regeneration in the hepatic parenchyme and bile duct as they develop at various intervals of time after extensive partial hepatectomy. Following two months, regeneration is virtually complete. Similar regenerative phenomena occurred in partially hepatectomized rats and dogs, although the latter do not tolerate extensive removal of hepatic tissue as well as rodents do. In rats, the operation consisted in removing 1 to 3 "hepatic lobes" (not otherwise identified).

Waelsh & Selye 3,972/31: First description of a technique for the removal of about 70% of the liver in mice, which lends itself for the detection of drugs that are detoxified in the liver. Thus, in such partial hepatectomized mice, tribromoethanol (Avertin) causes much more prolonged anesthesia than in intact controls, whereas magnesium anesthesia is not significantly affected by this hepatic insufficiency; presumably because tribromoethanol is, while  $MgCl_2$  is not, detoxified by the liver.

Higgins & Anderson 597/31: Description of a technique for the removal of the median and left lateral lobes of the rat's liver which correspond to 70% of the hepatic tissue. Regeneration begins almost immediately and is virtually complete after 2 weeks. The mortality rate was 25%. [No attempt was made to determine the functional consequences of this intervention (H.S.).]

Marchal & Benichoux D37,572/62: Historic review of partial hepatectomy as a means for the study of hepatic regeneration in animals. The first operations of this type were performed by von Podwysozki (1886), Ponfick (1887—1895), Hess (1890) and Meister (1894).

Leduc G79,104/64: Review (26 pp., about 130 refs.) on "Regeneration of the Liver" after various types of surgical or chemical injuries. Special attention is given to regeneration after superficial wounds, lobectomies and bile duct obstruction.

Horák et al. G71,097/68: In rats, partial hepatectomy diminishes the blood volume only to an extent corresponding approximately to the amount of blood removed with the resected liver segment.

Bruckner et al. H34,704/69: "Abrasive ablation" is a new experimental method designated to induce localized hepatic regeneration in guinea pigs, rabbits, dogs and Rhesus monkeys.

Figueroa & Yáñez H18,495/69: A two stage intervention for partial hepatectomy in the dog and rat is recommended in which, first portal branches are ligated to induce atrophy of the lobes that are subsequently to be removed. [No controls demonstrating the usefulness of preliminary portal vein occlusion. The authors appear to be unaware of earlier relevant literature (H.S.).]

Porto & Donato H34,703/69: Description of the technique of partial hepatectomy and of the resulting hepatic regeneration in guinea pigs.

Tavassoli & Crosby G73,038/70: In rats, liver fragments implanted into ectopic sites do not survive even if a regenerative stimulus is activated by partial hepatectomy.

**Subtotal Hepatectomy.** Selye & Dosne A30,702/40: Description of a technique for the removal of 85% of the rat liver by ablation of the median, left lateral, and right lateral lobes. The operation produces severe hypoglycemia and hypochloremia. Complete hepatectomy (with evisceration) induces an even more rapid fall in blood sugar unaccompanied by hypochloremia, during the short period of survival after this operation.

Ingle & Baker C40,980/57: "The capacity of liver to regenerate was maintained in rats which were subjected to partial hepatectomy 12 times within a period of one year. At the end of the experiment, only minor cytological changes were observed in the regenerated liver and there was no neoplasia."

Dagradi & Galanti D62,332/62: In rats, a technique for the successive removal of several hepatic lobes has been employed to study the regenerative phenomena in the remnant.

Honjo & Kozaka E51,472/65: Description of a technique for extensive hepatectomy in the rabbit. Following ligation of the portal branches to the lobes which are to be resected, these undergo atrophy, whereas the remaining parenchyma hypertrophies. Under these conditions, resection of the atrophic lobes is well tolerated in a second operation.

**Complete Hepatectomy.** Biedl & Winterberg 47,485/01: Extensive studies on the role of the liver in the synthesis of uric acid from ammonia in the dog, using various methods for the elimination of the liver (e.g., destruction of the parenchyma by injection of acids into the

choledochus, Eck fistula). A 19th-century literature on complete extirpation of the liver in the goose, and in vitro perfusion of the liver with ammonia determinations in the afferent and efferent blood, etc. is reviewed.

*Selye A 8,052/33*: Description of a technique for the total evisceration of the rat. Since this operation causes thymus atrophy and adrenocortical hyperplasia, the liver and other visceral organs cannot be indispensable for the production of an alarm reaction.

*Ingle et al. B2,737/47*: In completely hepatectomized and eviscerated rats (with kidneys and adrenals intact) receiving continuous i.v. infusions of glucose + insulin, the adrenocortical extract caused a rise in blood sugar.

*Ingle & Nezamis B28,601/48*: In rats, survival time after complete evisceration is more effectively prolonged by insulin + glucose than by glucose alone.

*Ingle B39,012/49*: Description of a technique of total hepatectomy with evisceration in the rat.

*Ingle & Nezamis B37,742/49*: In rats given insulin + glucose, survival is particularly prolonged after evisceration if aseptic operative conditions are observed.

*Cheng G71,450/51*: Description of a two-stage technique for total hepatectomy in the rat.

*Ingle & Nezamis B65,286/51*: In rats, survival after evisceration is most effectively prolonged by combined treatment with glucose, insulin and various antibiotics.

**Bile Fistulas, Bile Duct Ligatures.** *Ferguson et al. G71,528/49*: In rats, hepatic regeneration following partial hepatectomy is not significantly impaired by bile duct ligation.

*Hyde & Williams C40,540/57*: The enterohepatic circulation of radio-cortisol can be readily studied in rats with hepatic duct fistulae.

*Weber et al. G71,819/60*: In rats, the histologic features of hepatic regeneration following partial hepatectomy performed simultaneously with, or several days after, bile duct ligation are described in detail.

*Leduc G79,104/64*: Review (26 pp., about 130 refs.) on "Regeneration of the Liver" after various types of surgical or chemical injuries. Special attention is given to regeneration after superficial wounds, lobectomies and bile duct obstruction.

*Plaa & Becker G76,082/65*: Description of a technique for bile duct cannulation in the mouse. The results regarding bile flow corre-

late well with those obtained by the indirect technique which is based on fluorescein excretion into the bile duct, as revealed by direct inspection under ultraviolet light.

*Gibson & Becker E65,709/67*: In mice, the role played by drug excretion in determining the toxicity of digitalis alkaloids was tested following the production of cholestasis by bile duct ligation or cholestatic aryl isothiocyanates such as phenylisothiocyanate (PIT) and  $\alpha$ -naphthylisothiocyanate (ANIT). The part played by anuria was examined after ligation of the penis. Subsequent to ouabain i.p., mortality was enhanced by diminution or stoppage of bile flow. Digoxin and digitoxin enhanced lethality in anuric mice. "Lanatoside-C was not more toxic to hypoexcretory mice. The use of hypoexcretory mice in toxicologic evaluations of pharmacologic agents is suggested."

*Chenderovitch G80,059/68*: Technique for stop-flow analysis of bile secretion in anesthetized rabbits after catheterization of the common bile duct, the accessory lateral ducts, and the cystic duct being ligated.

*Plaa G73,820/70*: Review on biliary and other routes of excretion of drugs with special attention to cannulation techniques, hepatic slice techniques, isolated liver perfusion procedures and available information on biliary, salivary, mammary, and sweat gland, as well as on other routes of drug excretion.

**Ligation of Hepatic Vessels.** *Rous & Larimore D88,911/20*: In rabbits, ligation of portal vein branches of the liver produced atrophy in the corresponding lobes. "The conditional character of the atrophy is proven by its failure to occur to any similar degree in the absence of a compensating parenchyma, as when the portal stream is diverted from the whole liver by way of an Eck fistula."

*Cameron A48,168/35*: In rats, choledochus ligation inhibits the growth of liver cells in autotransplanted small hepatic segments, but leaves the bile ducts unaffected.

*Raffucci & Wangenstein G33,029/51*: Dogs tolerate continuous occlusion of the hepatic artery and portal vein for no longer than 20 min, without showing evidence of hepatic necrosis. Necrosis is less likely to occur following treatment with aureomycin, and after intermittent anoxia.

*Raffucci B33,148/53*: Dogs tolerate repeated temporary occlusion of the hepatic artery and portal vein much better than continuous occlusion. ACTH in combination with antibiotics greatly enhances tolerance for discon-

tinued occlusion of the afferent hepatic vessels.

*Hines & Roncoroni G72,976/56:* In dogs, total temporary interruption of the afferent hepatic blood flow for one hour is almost invariably fatal; even an interruption for 15 min killed 2 out of 6 dogs.

*Andrews D94,471/57:* Review on the changes in hepatic morphology and blood flow, induced by obstruction of the hepatic artery, and the hepatic vein or portal vein, in various animal species.

*Hines & Roncoroni C40,870/57:* In dogs, the hepatic damage produced by ligation of all the afferent vessels of the liver during one hour is diminished by ACTH, and survival is improved.

*Steiner & Martinez D40,903/61:* In rats, ligation of the portal vein branches to two-thirds of the liver is followed by great atrophy of the affected lobes, and compensatory hypertrophy of the others. Concurrent ligation of the hepatic artery and lobar portal veins causes massive infarction of the lobes totally deprived of blood circulation. Lobar necrosis also occurs if lobar portal vein ligation is combined with lobar bile duct ligation. Occlusion of the main hepatic artery or its lobar branches is relatively harmless, although associated with histologic degenerative changes and duct hyperplasia.

*Carroll G71,190/63; G71,191/63:* Technique for the temporary ligation of the "hilar pedicle" (portal branch, hepatic artery branch, bile duct) to certain lobes of the liver in rabbits. Ischemia lasting up to 3 hrs produces degenerative and necrotic changes detectable in animals killed three days later. Permanent morphologic changes or functional disturbances have not been examined.

*Eckhardt & Armstrong F79,670/67:* In rats, a liver bypass can be established by ligation of the hepatic artery combined with a deviation of the portal vein into the femoral vein through a cannula. Under these conditions, bromsulphalein (BSP) disappears much more slowly from the plasma than after partial hepatectomy or intoxication with  $\text{CCl}_4$ .

*Bengmark et al. G71,689/69:* In rats, various chemical changes occurring in the liver after partial hepatectomy are modified by concurrent ligation of the hepatic artery.

*Yanagimoto G71,560/69:* Chemical and histochemical studies on the glycogen content of the liver following ligation of the blood vessels supplying individual lobes.

*Yanagimoto et al. G71,328/69:* In rats, ligation of the blood vessels supplying indi-

vidual lobes of the liver is used as a technique for the study of morphologic and biochemical changes induced by interference with hepatic circulation.

*Mizumoto et al. H28,787/70:* Studies on the effect of hepatic artery inflow upon regeneration, hypertrophy and portal pressure of the liver after 50% hepatectomy in the dog.

**Hepatic Denervation.** *Makino H19,101/68:* In dogs, hepatic periarterial neurectomy increases hepatic arterial flow without decreasing blood flow through the portal vein. Regeneration of the liver following partial hepatectomy is not significantly affected by hepatic periarterial neurectomy.

**Perfusion of the Liver.** *Israel et al. A16,424/37:* Estrone "is not inactivated by dog blood in vitro or by the circulation in a heart-lung perfusion system. It is rapidly inactivated by circulation in a heart-lung-liver perfusion system."

*Evans et al. G65,279/63:* Description of a technique for the study of detoxication in isolated rat liver preparations, by determining the concentration of a drug (here ethanol, pentobarbital, morphine or lead) in the perfusate (donor rat blood), bile, and hepatic tissue at different intervals. The technique is used to examine detoxication in the livers of rats which were treated in vivo with hepatotoxic substances (here  $\text{CCl}_4$  or allyl alcohol).

*Poser & Jahns F90,235/67:* Description of a technique for functional hepatectomy in rats in which the portal vein blood is transferred to the jugular vein by a polyethylene tube and the liver thereby excluded from the circulation. After this operation the rats are unable to maintain a normal blood-sugar level and fail to eliminate pentobarbital or detoxicate ammonia.

**Liver Slices.** *Heller A32,137/40:* In vitro studies on tissue slices and tissue mince of rats and rabbits indicate that "estradiol is inactivated by liver and kidney and not by the other tissues studied. This inactivation of estradiol is, in all probability, not due to conjugation or conversion to a less active form, but due to enzymatic destruction of an oxidative nature. This is indicated by the relative inactivity of the treated estradiol, the inability of hydrolysis procedures to increase activity and the effect of tissue poisons upon inhibiting the estradiol-destroying enzyme system. Estrone is increased 20 times in potency by incubation with minced uterine tissue. Spleen, lung, heart and kidney tissues also caused estrone to be converted to a more

active substance. The suggestion is made that this conversion is accomplished by enzymatic reduction of estrone to estradiol."

*Crevier et al. B54,151/50*: Pentobarbital anesthesia is shorter in male than in female rats as judged by the linguo-maxillary reflex. Castration abolishes the high resistance of the male, but testosterone restores it to the normal level. In ovariectomized rats, estradiol has virtually no effect but testosterone raises resistance to the male level. These in vivo effects run parallel to the in vitro pentobarbital detoxifying power of the liver.

**Renal Interventions.** *Gibson & Becker E65,709/67*: In mice, the role played by drug excretion in determining the toxicity of digitalis alkaloids was tested following the production of cholestasis by bile duct ligation or cholestatic aryl isothiocyanates such as

phenylisothiocyanate (PIT) and  $\alpha$ -naphthylisothiocyanate (ANIT). The part played by anuria was examined after ligation of the penis. Subsequent to ouabain i.p., mortality was enhanced by diminution or stoppage of bile flow. Digoxin and digitoxin enhanced lethality in anuric mice. "Lanatoside-C was not more toxic to hypoexcretory mice. The use of hypoexcretory mice in toxicologic evaluations of pharmacologic agents is suggested."

*Selye G60,083/70*: Description of a technique for the "80%" partial nephrectomy in rats. Following ablation of the right kidney, the upper and lower poles of the left kidney are tied off and removed by constricting ligatures. This leaves a wedge-shaped central segment, corresponding to 20% of the organ and oriented with the tip of the wedge next to the renal pelvis.

## II. HISTORY

The idea that the body possesses inherent mechanisms for the restoration of health after exposure to pathogens is very old; it was clearly recognized by Hippocrates (460—377 B.C.) as the remarkable “*vis medicatrix naturae*.” However, this concept gained much in precision when Claude Bernard (E 719/1879) pointed out that the internal medium of living organisms is not merely a vehicle for carrying nourishment to cells far removed from contact with the outside world, but that “it is the fixity of the ‘*milieu intérieur*’ which is the condition of free and independent life.” The English physiologist J. S. Haldane (E715/22) said of this phrase that “no more pregnant sentence was ever framed by a physiologist.” Certainly, few if any statements about life have been more frequently quoted, but one wonders whether its great impact was not largely due to what has been intuitively read into it. Naturally, the fixity of any system is what makes it independent of changes in its surroundings — indeed the independence, the resistance of any system is what we call its fixity — but many inanimate objects are more independent of their atmosphere than living beings. The salient feature of life, the secret of its resistance, is adaptability to change, not rigid fixity.

A much greater merit by Bernard was to call attention to the importance of the mechanisms safeguarding the immutability of the “*milieu intérieur*.” Thereby he stimulated innumerable investigators throughout the world to follow him in his classic investigations on the adaptive changes responsible for the “steady state.”

In Germany, Pflüger (A4,877/1877) pointed to the relationship between active adaptation (the “*vis medicatrix naturae*”) and the “steady state” by his famous dictum: “The cause of every need of a living being is also the cause of the satisfaction of that need.”

A similar thought was expressed by the Belgian physiologist Léon Fredericq (A5,288/1885) when he said: “The living being is an agency of such sort that each disturbing influence induces by itself the calling forth of compensatory activity to neutralize or repair the disturbance.”

In France, Charles Richet (E1,101/00) wrote as a commentary about the steady state that: “By an apparent contradiction it (living matter) maintains its stability only if it is excitable and capable of modifying itself according to external stimuli and adjusting its response to the stimulation. In a sense it is stable because it is modifiable — the slight instability is the necessary condition for the true stability of the organism.

The great American physiologist, Walter B. Cannon (B14,905/39) has spent some 20 years of his life studying various mechanisms that help the organism to maintain its steady state which he first called “homeostasis.” Cannon’s most important contribution was to show that there exist numerous highly specific homeostatic mechanisms for protection against hunger, thirst, hemorrhage, or against agents which tend to disturb the normal body temperature, the blood pH

or the plasma level of sugar, protein, fat, or calcium. He placed special emphasis upon the stimulation of the sympathetic nervous system, and the resulting catecholamine discharge, which occur during acute emergencies such as pain or rage.

He taught us that this autonomic response induces metabolic and cardiovascular changes that prepare the body for fight or flight. Cannon's classic studies revealed many valuable facts about the mechanism through which the steady state of the "milieu intérieur" can be maintained in the face of agents that tend to alter one or the other of its constituents selectively. It soon became evident also that, in addition to the nervous system, hormones play an important part in such specific adaptive responses, e.g.: adrenal medullary catecholamines and pancreatic hormones in the maintenance of carbohydrate metabolism, parathyroid hormone in calcium homeostasis, thyroid hormones in temperature regulation.

Stimulated by all these earlier findings, we became interested in the possible nonspecific adaptive function of hormones against what we called "biologic stress," that is, the nonspecific response of the organism to any demand made upon it. In 1936, we observed "a syndrome produced by diverse noxious agents" (Selye 36,031/36), which was essentially the same irrespective of the evocative agent, and later became known as the "stress syndrome." It was characterized, among other things, by manifestations of adrenocortical hypertrophy and increased production of those steroids for which I recommended the terms "glucocorticoids" or "antiphlogistic corticoids" because of their characteristic effects on sugar metabolism and on inflammation. As outlined in the section on Terminology and Classification, the principal antistress and antiphlogistic actions of these adrenocortical hormones depend upon their syntoxic effects; they help to tolerate pathogens, not to destroy them.

As time went by, it became evident that many of the manifestations of "nonspecific resistance" (or "cross-resistance") induced by stress, especially those which offer protection against inflammatory lesions, are due to the activation of the hypothalamus-pituitary-adrenocortical axis. However, by 1961, we had seen that "certain types of cross-resistance are demonstrable even in adrenalectomized animals, and in some cases, increased thyroid-hormone activity appears to be the cause of the induced tolerance. The bulk of evidence now available suggests that all forms of cross-resistance cannot be attributed to any single biochemical mechanism. This is true even of those very nonspecific types that are induced by stress itself. We must remember that, although the response to stress is essentially stereotyped and largely independent of the evocative agent, it represents a mosaic of numerous local and systemic, humoral and nervous reactions, some of which may protect against one pathogen, others against another" (Selye C95,972/61).

Thus, it became clear that there exist adaptive mechanisms that are nonspecific both as regards their causation and their effects: they can be activated by, and protect against, many agents. Some of these nonspecific adaptive phenomena are undoubtedly regulated through the hypothalamus-pituitary-adrenocortical axis; these largely depend upon the resulting suppression of inflammatory lesions by an excessive production of glucocorticoids. However, we had to conclude that there must exist additional mechanisms which raise nonspecific resistance through other means, since they are manifest even following removal of the adrenals. Little was known at that time about the nature of these additional resistance phenomena, except

that: 1. Unlike glucocorticoid-dependent reactions, they are not directed particularly against stress or inflammatory changes, 2. their protective effect, although not specifically aimed against any one agent, is not as general as that of glucocorticoids, 3. they often raise resistance far above normal and do not merely restore the low stress resistance of hypocorticotid individuals towards the norm.

The effects of stress and of the hormones produced during stress have been extensively discussed in several earlier monographs (Selye B71,000/42; B58,650/51; B87,000/52; B90,100/53; C1,001/54; C9,000/55—56). Here we shall place major emphasis upon those adaptive hormones which act either by accelerating the metabolic degradation of pathogens, or through unknown mechanisms, as long as they increase resistance, nonspecifically, to many agents and do not merely rectify one particular homeostatic derangement.

For many among these adaptive hormones, it has not yet been clearly shown that they can be secreted in response to a need; but they undoubtedly represent decisive factors in disease susceptibility, since their concentration in the "milieu intérieur" can determine whether a stimulus will or will not be pathogenic.

Apparently, animals are endowed with a complex **hormonal defense system** comparable in its scope to those based upon nervous or immunologic reaction. When faced with situations that require adaptation, the organism can respond essentially in three distinct ways:

1. The nervous system: through conscious planning of defense, the development of appropriate conditioned reflexes (Pavlov) and autonomic "emergency reactions" (Cannon).

2. Immunologic reactions: immunity (Pasteur), including even such derailed, actually pathogenic, defensive responses as anaphylaxis (Richet) or allergy (v. Pirquet).

3. The adaptive hormonal system: through the syntoxic hormones which permit tolerance of the pathogen and through the catatoxic substances that eliminate the aggressor.

These were the main facts and speculations which guided our research on the hormonal regulation of resistance. However, in addition to this concise introductory sketch which was essential to emphasize the outlines of our approach, a historic survey of our field should mention some independently-made findings which, undoubtedly, have also influenced our thinking and are likely to stimulate further research in this domain.

The **thyroid gland** was probably the first endocrine organ whose role in detoxication could be shown by objective animal experiments. At the beginning of this century, Hunt (60,064/05) demonstrated that mice given thyroid powder in their food become unusually resistant to acetonitrile; this increased drug tolerance has even been used as a basis for the bioassay of thyroid preparations.

The role of the **adrenals** as organs of detoxication has been suspected for a long time, but at first only on the basis of very indirect evidence. There was much discussion about whether poisonous substances brought to the glands by the blood are destroyed locally, or whether the adrenals increase resistance by remote action through their hormones. Either interpretation appeared to be equally compatible with the striking diminution of drug resistance seen in adrenalectomized animals and in patients with Addison's disease (Lewis 12,272/21; 61,803/23). This question

was subsequently settled when numerous investigators showed that after adrenalectomy, resistance to various drugs can be restored by adrenal extracts. In this respect, adrenocortical preparations proved to be much more efficient than medullary catecholamines. Still later, the extraction, followed by the synthesis, of pure corticoids made it possible to establish certain relationships between the resistance-increasing effect of these compounds and their chemical structure.

By 1940 it became evident that whereas cortical extracts are highly efficient in elevating the low stress resistance of adrenalectomized animals, they rarely raise it above the normal level in the presence or in the absence of the adrenals. Indeed, even as late as 1960, it had been claimed that "in only two situations have adrenocortical hormones been shown to be protective to the host: the replacement of hormone in hypoadrenalism, and the protective action against the lethal toxicity of bacterial lipopolysaccharides" (Kass D35,079/60). Yet, as early as 1940, it had been noted that the great sensitivity to surgical shock and other stressors, that is induced by partial hepatectomy even in not adrenalectomized rats, could be combated by cortical extracts; hence, at least in this condition, endogenous corticoids were not optimally efficacious (Selye et al. A32,768/40). These findings called attention to the existence of close relationships between the liver and the resistance-increasing effect of corticoids. The subsequent observation that desoxycorticosterone could not, whereas corticosterone could, replace the adrenocortical extracts, first demonstrated the importance of an 11-oxygen for antistress activity.

The claim that specific **defensive enzymes** ("Abwehrfermente") are produced against various compounds and tissues, including endocrine organs following their parenteral administration, could not be substantiated by the techniques available to Abderhalden (67,622/33) who first enunciated this concept. On the other hand, there can be no doubt that protein extracts of heterologous endocrine glands can gradually induce resistance through the development of **antihormones** (Collip et al., A32,156/40; Thomson et al., A35,782/41).

However, it seemed unlikely that the **body could become insensitive to its own hormones**, since this type of resistance would be expected to interfere with the physiologic activity of endocrine glands. Still, the observation that partial hepatectomy sensitizes to the anesthetic effect of natural steroid hormones suggested that the liver does possess a mechanism for the inactivation of these compounds. The question arose whether this defensive activity could be stimulated by very large amounts of those substrates which the inactivating mechanism is designed to metabolize.

Experiments performed in rats to check this possibility revealed that, following repeated massive overdosage with progesterone, desoxycorticosterone or testosterone, the anesthetic effect of these hormones gradually diminishes. In fact, this type of resistance is not substrate specific, since pretreatment with any one of these natural steroids also induced resistance to the others (Selye A35,410/41).

Apparently, at near-physiologic dose levels, the natural steroids do not markedly activate this defense mechanism (a phenomenon which would interfere with their normal function); yet, they may accelerate their own degradation more intensely when given in abnormally high and potentially pathogenic amounts. It is difficult to explain this dose dependence of the inactivating mechanism, and available data do not justify far-reaching speculations. However, it may be pertinent that at near-

physiologic concentrations, the steroid hormones circulate mainly as protein complexes, which are perhaps unable to reach the inactivating receptors; conversely, after sudden flooding of the body with very large amounts of them, a certain portion of the injected steroid may enter the inactivating sites (e.g., the SER) before being thus protected from it by coupling to large carrier molecules (Selye G60,070/70).

Still, even at physiologic concentrations, gonadal steroid hormones do appear to affect drug sensitivity to some extent, as shown by sex differences in the susceptibility to various intoxications. It remained to be seen, however, whether this physiologic difference in sensitivity, and the induction of resistance by excessive amounts of exogenous steroids depend upon the same mechanism.

Several earlier observers noted sex differences in drug sensitivity, which are apparently due to steroid hormones produced by the gonads, and not to genetically determined resistance factors inherent in the somatic cells. Thus, it was found that adult male rats are less sensitive to barbiturates than females. This difference disappears after gonadectomy, but the resistance characteristic of intact males can be induced by treatment with testosterone and related compounds, in females and in gonadectomized rats of either sex (Holck et al. A8,011/37; Holck & Mathieson B644/44; Buchel G67,326/54; Robillard et al. G67,325/54). Furthermore, female rats proved to be more sensitive than males to progesterone anesthesia, but this sex difference became obvious only after maturity. We concluded that the "normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the male, since castration increases sensitivity in males but is without effect in female rats. Conversely, the resistance of castrate males and females may be raised by methyltestosterone administration" (Winter & Selye A35,658/41; Winter A36,333/41).

A similar sex difference in susceptibility has also been noted with regard to cardiovascular calcification elicited in rats by overdosage with DHT. This form of calcinosis was aggravated by orchidectomy; hence, we concluded that "some testicular factor exerts a protective effect against this type of intoxication" (Selye C27,682/57).

These findings were the first to suggest that, like the steroids of the adrenal cortex, those of the gonads can increase resistance, although not necessarily against the same agents and through the same mechanism.

The liver, as the "central laboratory of the body," has long been suspected of playing an important part in the inactivation of exogenous and endogenous toxic substances. However, large-scale systematic studies, designed to identify the compounds subject to hepatic detoxication, were virtually impossible because of the lack of appropriate techniques. Comparisons between the drug resistance of intact and **hepatectomized** animals were difficult to interpret, since complete removal of the liver causes severe shock rapidly terminating in death, especially when toxic substances are given, irrespective of whether or not these are amenable to hepatic detoxication. Animals in which partial hepatic insufficiency was created (e.g., by ligation of the bile duct, hepatotoxic drugs, or the establishment of an Eck fistula) likewise yielded variable results, often complicated by damage to extrahepatic tissues. Finally, the search for presumed drug metabolites in hepatic vein blood, *in vivo*, did not lend itself to the screening of many drugs, whereas similar studies on liver perfusates, *in vitro*, often failed to reflect *in vivo* conditions.

In order to test hepatic participation in the detoxication of numerous compounds, a screening test became necessary. It was to answer this need that we devised a simple surgical technique for the ablation of the left lateral and median lobes of the liver in mice (Waelsch & Selye 3,972/31). This operation removes about 70 percent of the hepatic tissue and markedly reduces resistance only with respect to drugs detoxified by the liver. For such tests it is best to use the animals about 24 hrs after the intervention, when they have recovered from the surgical insult, but hepatic regeneration is still negligible. With this technique we showed, for example, that the partially hepatectomized mouse is extremely sensitive to the anesthetic effect of tribromoethanol (Avertin), which is detoxified by the liver, but not to that of an equally anesthetic dose of  $MgCl_2$ , which is not subject to hepatic detoxication. Almost at the same time, Higgins and Anderson (597/31) recommended an essentially similar operation for the stimulation of hepatic regeneration in the rat; yet, like many earlier investigators, they did not attempt to use partial hepatectomy for detoxication studies.

About ten years later, the site of steroid hormone detoxication became a major subject of controversy, difficult to solve with the chemical methods then available. However, in the meantime, we had observed that sudden overdosage with steroid hormones and their derivatives produces profound anesthesia in the rat (Selye A35,003/41). This indication of activity was clear-cut, common to virtually all steroid hormones, not particularly damaging, and immediately evident; thus, it was applicable to acute experiments on partially hepatectomized rats before regeneration could become important. Hence, we injected threshold doses of DOC, progesterone, testosterone, and estradiol into intact and partially hepatectomized rats. The latter proved to be unusually sensitive to all these steroids, whereas their resistance to several other anesthetics remained uninfluenced. Even overdosage with the non-steroidal folliculoid, stilbestrol (which normally causes only a very mild hypnotic effect), produced prolonged narcosis after partial hepatectomy. These observations lead us to conclude that "it appears most probable that the liver is the site at which all the above-mentioned compounds are normally detoxified" (Selye A35,150/41).

Subsequent investigations have amply confirmed the importance of the liver as the organ principally responsible for the detoxication of steroid hormones, and the value of partial hepatectomy as a simple screening test for compounds whose actions largely depend upon the speed of their hepatic detoxication. Furthermore, we have recently seen (in agreement with our expectations) that following partial resection of the liver, drugs, against which catatoxic steroids can offer protection through hepatic microsomal enzyme induction, become particularly toxic. However, the steroidal enzyme inducers themselves are also subject to hepatic detoxication, and consequently their catatoxic activity likewise increases when their metabolic degradation is impeded by partial hepatectomy. Thus, in the rat, this operation facilitates both the production of perforating intestinal ulcers by indomethacin (a substrate for hepatic detoxication) and the prevention of these lesions by small doses of a catatoxic steroid such as spironolactone (Selye G60,058/69).

In evaluating the results of partial hepatectomy upon drug toxicity it must be kept in mind, however, that the liver may also participate in the defense against toxic substances, through mechanisms unrelated to the induction of microsomal enzymes (e.g., synthesis of energy yielding metabolites or hormone- and drug-binding

proteins, elimination of pathogens through the bile or their storage in the RES). Hence, in any one case, aggravation of drug toxicity by partial hepatectomy merely suggests, but does not prove, that resistance may be increased by catatoxic steroids.

Some of the earliest work on the hepatic detoxication of steroids was performed *in vitro* by incubation with **liver slices or fractions**. Soon after it had been observed that partial hepatectomy increases sensitivity to the anesthetic action of steroid hormones, Zondek et al. (A74,477/43) showed that both estrone and stilbestrol can be inactivated by rat liver pulp *in vitro*, and that "in rats treated with large amounts of stilbestrol, the capacity of the liver to inactivate stilbestrol is increased."

Subsequently, a group of investigators at our school undertook an extensive study of the relationship between sex differences in barbiturate resistance and the inactivation of barbiturates by liver tissue. They noted that pentobarbital anesthesia lasts much longer in female than in male rats, and that the high resistance of the male is abolished by castration but restored to normal by testosterone. In ovariectomized rats, estradiol was virtually ineffective, but testosterone raised resistance to the male level. All these *in vivo* effects were found to run parallel with the pentobarbital detoxifying power of hepatic tissues *in vitro* (Crevier et al. B54,151/50). Liver homogenates of intact adult male rats destroyed pentobarbital *in vitro* more rapidly than those of castrate males. Furthermore, pretreatment of the castrates with testosterone enhanced the detoxication process, whereas estradiol pretreatment had an opposite effect (Robillard et al. G67,325/54).

The most recent development in the field of hormonal regulation of resistance is the recognition that **hepatic microsomal enzyme induction** may play a decisive role here. The fact that many drugs and certain hormones can induce hepatic enzymes has been well established by the fundamental biochemical observations of J. Axelrod, W. F. Bousquet, B. B. Brodie, A. H. Conney, K. P. DuBois, R. W. Estabrook, J. R. Fouts, H. V. Gelboin, R. J. Gillette, R. Kato, F. T. Kenney, W. E. Knox, R. Kuntzman, G. J. Mannering, E. C. and J. A. Miller, H. Remmer and many others. For example, it was found that the liver of the mouse and rat possesses an enzyme system which N-demethylates 3-methyl-4-monomethylaminoazobenzene. The activity of this system depends upon the diet, being highest on aged or otherwise treated animal products, such as an old cholesterol preparation, liver extracts, and peptones. A variety of pure sterols were inactive but could be activated by peroxidation (Brown et al. G57,030/54).

There followed a large number of publications suggesting that the induction of this type of resistance depends upon corticoid (Lin & Knox C73,824/58; Remmer D86,728/58; Rosen et al. C47,568/58; Sulman et al. C79,823/59; Maickel & Brodie C83,071/60; Tomkins et al. G49,588/66), folliculoid (Grinnel & Smith C31,428/57), testoid or anabolic (Axelrod D28,544/56; Brodie C12,157/56; Booth & Gillette D34,656/62; Kato et al. G64,325/62; Novick et al. F63,768/66; Conney F88,649/67; Kalyanpur et al. G66,147/69) activity.

It was not until quite recently that the independence of this enzyme-inducing capacity from all known steroid hormone actions could be demonstrated (Selye G60,039/69). It was found that in the rat, pretreatment with a variety of catatoxic steroids, such as spironolactone, norbolethone, and ethylestrenol, increases the oxidation of pentobarbital by hepatic microsomes and enhances its disappearance from the blood proportionally to their ability to shorten the depth of

anesthesia in vivo (Solymoss et al. G60,053/70). Norbolethone and ethylestrenol possess strong anabolic properties but little or no antiminerlocorticoid effect, whereas spironolactone is a strong antiminerlocorticoid devoid of anabolic actions. Since none of these steroids exhibits glucocorticoid, mineralocorticoid, or folliculoid effects, the catatoxic enzyme-inducing property appears to be independent of the former.

Another early approach to the problem of hepatic hormone metabolism was based on the demonstration that the **portal route of administration** is unfavorable for the obtention of various physiologic effects by steroids. For example, the implantation of functional ovaries or of pellets of folliculoid and testoid compounds into the spleen or mesenteries of gonadectomized rats produces much less stimulation of the accessory sex organs than if the same hormone sources are introduced subcutaneously or elsewhere into the systemic circulation. These findings, and the fact that many steroids are more active when given parenterally than enterally, strongly suggested that sex steroids are presumably inactivated by hepatocytes when brought directly to the liver through the portal vein. Of course, such observations do not distinguish between hepatic degradation, storage or biliary excretion of hormones, and in any event, are not concerned with the hormonal stimulation of resistance but merely with the site of hormone inactivation.

Essentially the same is true of what is perhaps the first clear-cut demonstration of hepatic inactivation of a steroid, in which a **liver perfusion** technique was used (Israel et al. A16,424/37).

Many investigators believe that the induction of hepatic microsomal enzymes by various drugs and steroids is associated with a marked proliferation of the **smooth endoplasmic reticulum (SER) in hepatocytes** (Conney F88,649/67; Claude E8,217/69; Remmer & Merker E36,389/63, D61,064/63; Burger & Herdson G66,499/66; Fouts & Rogers F29,497/65). This effect is also independent of the known steroid hormone actions and can be demonstrated in rats after treatment with such typical catatoxic steroids as spironolactone (Kovacs et al. G60,045/70) or norbolethone (Gardell et al. G60,062/70). However, more recent investigations show that the relationship between catatoxic activity and the proliferation of the SER is much less constant than had been originally thought (Horvath et al. G70,408/70).

Our attempts to distinguish between **syntoxic and catatoxic** actions go back to the earliest studies on the role of corticoids in inflammatory responses, such as the acute anaphylactoid reaction (Selye 38,798/37) and the myocarditis, nephritis, periarteritis and arthritis that are elicited under certain conditions by mineralocorticoids (Selye et al. A72,284/44). The fact that the antiphlogistics, or glucocorticoids, are truly syntoxic was first demonstrated in rats, using the granuloma pouch technique. Cortisol inhibits inflammation produced by croton oil in this test. However, if this irritant is removed after 14 days of sojourn in the pouch of a cortisol treated animal, and injected into the paw of an untreated control, it still produces an intense inflammatory response in the latter. It was concluded that glucocorticoids act by depressing the inflammatory potential of tissues, not by destroying the irritant. By contrast, typical catatoxic steroids such as PCN, ethylestrenol, norbolethone or spironolactone, do not significantly modify the direct response of tissues to potential pathogens, but attack the latter, usually through enzymic degradation. Numerous

observations have subsequently shown that the catatoxic effect of steroids is independent of all their previously known effects.

**Clinical implications** of treatment with glucocorticoids have been reviewed in the first monograph on stress (Selye A40,000/50) and it would be far beyond the scope of this volume to discuss the extensive literature on their manifold uses in inflammatory diseases, allergies as immunosuppressants, adjuncts in cancer therapy, etc. The initial enthusiasm for systemic glucocorticoid therapy, especially in chronic rheumatic diseases, has been greatly dampened by their undesirable side-effects, but nevertheless these hormones have come to represent a very important group of therapeutic agents.

As this book goes to press, we are just beginning to explore the possible clinical applications of catatoxic steroids. There is no doubt that hepatic microsomal enzyme induction can be useful in the treatment of certain spontaneous diseases of man. This had first been shown in 1966. In an infant with congenital unconjugated hyperbilirubinemia, a considerable lowering of serum bilirubin was produced by phenobarbital (Yaffe et al. G67,125/66), presumably as a result of the induction of a glucuronide-conjugating enzyme system. Subsequently, the value of barbiturate treatment in similar cases has been well established by many investigators. Since we now know that man possesses the same mechanisms for enzyme induction by catatoxic drugs as do experimental animals, we infer that he would presumably also respond to catatoxic steroids in a similar manner. If so, we may hope to obtain favorable results by pretreatment with catatoxic steroids in patients suffering from the most varied forms of endogenous or exogenous intoxications with steroids, digitalis compounds, pesticides and carcinogens.

It is more debatable whether this type of steroid would also be effective in treating an already established acute morbid condition, since the induction of defensive enzymes often takes several days. In mice and rats however, under certain circumstances, enzyme induction has been demonstrated within hours, and the speed of its development appears to depend upon genetic predisposition, the type of inducer used, the route of its administration, etc. To what extent such factors would limit the practical applicability of catatoxic steroids as therapeutic agents remains to be seen. In any event, beneficial results may be expected in patients suffering from chronic diseases in which even the gradual activation of defensive mechanisms over several days would be useful.

It has long been known that glucocorticoids, folliculoids and thyroxine can protect the rabbit against cholesterol atheromatosis (Lit. in Selye G60,083/70). Recently, it has been shown that pretreatment with phenobarbital diminishes hypercholesterolemia and atheromatosis in cholesterol-fed rabbits (Salvador et al. G68,113/67), although this barbiturate also augments the synthesis of cholesterol from  $^{14}\text{C}$ -acetate in rats and hamsters (Orrenius E8,231/69). Furthermore, several catatoxic steroids are highly potent in protecting the rat against various types of cardiovascular disease (Selye G60,083/70). Yet, only clinical trials will be able to show whether any of these agents exerts comparable effects in the spontaneous cardiovascular diseases of man.

### ***Evolution of the Concept: Hormones and Resistance***

*Pflüger A4,877/1877*: Essay entitled "The Teleological Mechanics of Living Nature."

*Bernard E719/1879*: Monograph entitled "Leçons sur les Phénomènes de la Vie Communs aux Animaux et aux Végétaux." (vol. 1, 404 pp.; vol. 2, 564 pp., published respectively in 1878 and 1879) based largely on lectures given at the Museum of Paris during 1859 and 1860. It is in these lectures that Bernard first developed his concept of the fixity of the "milieu intérieur."

*Fredericq A5,288/1885*: Essay on the influence of the external medium upon the composition of blood in aquatic animals.

*Richet E1,101/00*: A dictionary of physiology with general considerations upon mechanisms of adaptation.

*Haldane E715/22*: Monograph (427 pp.) on respiration with many interesting speculative passages on the nature of homeostasis.

*Selye 36,031/36*: A letter to the editor of NATURE, entitled "A Syndrome Produced by Diverse Nocuous Agents," in which the nonspecific response of the body to biologic stress was first described.

*Selye 38,798/37*: "A reaction is described under the name of 'alarm reaction' which represents a non-specific response of the organism to damage as such. Its main symptoms are: adrenal enlargement, involution of the lymphatic organs, degeneration and death of cells in various tissues, ulcer formation in the digestive tract, and edema formation. These symptoms are the same whatever the specific nature of the damaging agent may be. Drugs, surgical injuries, spinal shock, excessive muscular exercise, all elicit this same reaction." It is in this paper also that the anaphylactoid reaction was first described on the basis of experiments on rats given egg-white i.p. "The significance of this peculiar reaction to egg-white is not clear, but it seems evident that in this case an alarm reaction, elicited by another drug, exerted a protective influence." On the other hand, adrenalectomy aggravated the course of the anaphylactoid inflammation. These facts suggested that this inflammatory response is adrenal dependent and amenable to prevention by corticoids in amounts that can be secreted during stress.

*Cannon B14,905/39*: A monograph entitled "The Wisdom of the Body" (333 pp.) in which the author summarizes his work on "homeostasis" and on the many mechanisms involved

in the maintenance of a steady state despite exposure to hunger, thirst, hemorrhage or to factors which specifically tend to alter certain blood constituents.

*Störtebecker 76,398/39*: Review of the early literature (from 1896 to the discovery of the alarm reaction in 1936) on the effect of adrenalectomy and crude adrenal extracts upon resistance to drugs.

*Selye B40,000/50*: Monograph (822 pp., about 6,000 refs.) summarizing the literature on the General Adaptation Syndrome (G.A.S.), the Local Adaptation Syndrome (L.A.S.) as well as the pathogenic and protective actions of stress.

*Selye B58,650/51*: "First Annual Report on Stress" (644 pp., about 4,000 refs.).

*Selye B71,000/52*: Monograph (225 pp.) on "The Story of the Adaptation Syndrome."

*Selye & Horava B37,000/52*: "Second Annual Report on Stress" (526 pp., about 5,300 refs.).

*Selye & Horava B90,100/53*: "Third Annual Report on Stress" (637 pp., about 5,700 refs.).

*Selye & Heuser C1,001/54*: "Fourth Annual Report on Stress" (749 pp., about 4,300 refs.).

*Selye & Heuser C9,000/56*: "Fifth Annual Report on Stress" (815 pp., about 6,200 refs.).

*Selye C95,972/61*: Review (32 pp., 85 refs.) on "Nonspecific Resistance," with special reference to the local and general adaptation syndrome, as well as to resistance phenomena that are not mediated through the hypothalamus-pituitary-adrenocortical axis.

### ***Thyroid***

*Hunt 60,064/05*: In mice, thyroid feeding greatly increases resistance to acetonitrile, but not to various other cyanides, such as hydrocyanic acid or sodium ferricyanide.

*Blum 38,401/00; 38,405/06*: Studies on the effect of thyroidectomy upon the resistance of dogs, rabbits and sheep to various diets led to the conclusion that the thyroid is not an organ of internal secretion, but acts by accumulating and destroying toxic substances, especially those derived from meat diets.

*Scarborough 34,971/36*: In rats, feeding of thyroid extract diminishes the anesthetic effect of pentobarbital.

### ***Adrenals***

*Lewis 12,272/21; 61,803/23*: Adrenalectomized rats are unusually sensitive to intoxication with cobra venom, curare, veratrine,

morphine, digitoxin and diphtheria toxin. On the other hand, adrenalectomy does not appreciably alter the susceptibility of the rat to strychnine or picrotoxin. The protective effect of the adrenals is thought to be due either to topical detoxication of the drugs within the gland, or to "general metabolic changes" induced by adrenal principles. The earlier literature on the increased sensitivity of adrenalectomized animals to various toxic substances is reviewed.

*Scott 16,870/23*: Review of the early literature on the relationship between the adrenals and resistance to drugs. Personal observations confirm the high morphine sensitivity of adrenalectomized rats.

*Scott 17,400/24*: Adrenalectomized rats are unusually susceptible to killed streptococci and staphylococci.

*Rogoff & DeNecker 63,527/25*: The increase in morphine sensitivity observed by Lewis (12,272/21) after bilateral adrenalectomy in the rat is ascribed to the nonspecific damage of the operation. Most deaths occur during the first ten days after adrenalectomy, but the animals that recover are not particularly sensitive to morphine, "there is indeed, no evidence that any significant change in tolerance occurs." [In the light of our subsequent work, it is highly probable that many of the rats used by these investigators had accessory adrenals, or that the adrenalectomy was incomplete, so that upon compensatory hypertrophy of the cortical remnants, resistance returned towards normal (H.S.).]

*Selye et al. A 32,768/40*: Review of the earlier literature on the ability of epinephrine and "cortin" to raise resistance against various stressors. Attention is called to the fact that whereas cortin is very effective in this respect in adrenalectomized animals, it rarely raises resistance above normal in the presence of the adrenals. The slight effect that cortical extracts do possess during severe shock is presumably due to the fact that "a condition of 'relative adrenal insufficiency' exists in organisms exposed to nonspecific damage." Following extensive partial hepatectomy in rats, "suitable cortin therapy prevents the hypochloremia, and the decrease in blood volume and in blood sugar which are usually elicited by this intervention." In rats damaged by repeated s.c. injections of formaldehyde, cortical extract prevented the hypoglycemia and hypochloremia of severe shock, whereas DOC was virtually ineffective; in fact, it aggravated the s.c. edema caused by formaldehyde.

Chronic pretreatment with cortical hormones causes adrenal atrophy which counteracts their beneficial effect in protecting against stress. "These experiments should be interpreted as a warning against prolonged pretreatment with this substance in preparation for a surgical intervention." The best protective effect was obtained in rats with surgical shock produced by crushing of the intestines, if given repeated injections of cortical extract s.c. during the subsequent 24 hrs. An "Addendum" reports on similar experiments performed with corticosterone prepared for this purpose by E. C. Kendall. This compound, which differs from DOC only in that it possesses an  $11\beta$ -hydroxyl group, proved to be especially effective in protecting the rat against traumatic shock caused by crushing of the intestines. [This was the first observation showing that 11-oxygenation of corticoids is required to endow them with antistress activity (H.S.).]

*Kass D 35,079/60*: "In only two situations have adrenocortical hormones been shown to be protective to the host: the replacement of hormone in hypoadrenalism, and the protective action against the lethal toxicity of bacterial lipopolysaccharides . . ."

#### *Adaptation to Hormones*

*Abderhalden 67,622/33*: Defensive enzymes (Abwehrfermente) are produced by the parenteral administration not only of complex proteins but also of polypeptides, cane sugar or galactose. The induced enzyme activity, as manifested in the blood or urine, is highly specific for the substrate used to induce it. Even specific products of internal (particularly endocrine) organs or cancer tissue may generate such defensive enzymes whose demonstration is often of diagnostic value.

*Collip et al. A 32,156/40*: Review (34 pp., about 200 refs.) on "The Antihormones."

*Selye A 35,410/41*: In rats, pretreatment with anesthetic doses of certain steroid hormones induces resistance not only to the same but also to other anesthetic steroids.

*Thomson et al. A 35,782/41*: Review (13 pp., 78 refs.) on "The Antihormones."

#### *Sex Differences*

*Holck & Kanan 31,302/35*: Female rats are more sensitive than males to various barbiturate anesthetics. No such sex difference could be detected in the dog, cat, rabbit, guinea pig, mouse, turtle or frog.

*Falk A 337/36*: In mice, the anesthetic effect of certain barbiturates is inhibited by crude testicular extracts. [It is unlikely that these preparations antagonized barbiturates by virtue of their negligible testoid content (H.S.).]

*Holck et al. A 8,011/37*: Female rats are more sensitive than males to various barbiturates and nicotine. Orchidectomy abolishes this increased resistance to barbiturates. Pretreatment with a testoid urinary extract shortens the anesthesia produced by hexobarbital in intact or spayed females. Androsterone is ineffective.

*Winter & Selye A 35,658/41; Winter A 36,333/41*: Female rats are more sensitive than males to the anesthetic action of progesterone but this sex difference is obvious only after maturity. "The normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the males since castration increases sensitivity in males but is without effect in female rats. Conversely, the resistance of castrate males and females may be raised by methyltestosterone administration."

*Holck & Mathieson B 644/44*: In rats, the development of tolerance to pentobarbital was determined by injecting increasing doses every 90 min, day and night, for periods up to 5 days. Practically all 1-2 month-old rats developed tolerance, as did adult males in contrast to females. Castration lowered the ability of adult males to develop tolerance, but did not do so in 2 month-old males. Ovariectomy of 2 month-old females increased their ability to detoxify pentobarbital, once tolerance had developed.

*Buchel G 67,326/54*: Testosterone decreases hexobarbital sleeping time in adult intact or ovariectomized female rats. Estradiol has an inverse effect in normal or castrate males. Indirect evidence suggests that the changes in hexobarbital sleeping time are associated with its reduced or prolonged presence in the body.

*Selye C 27,682/57*: In rats, the production of cardiovascular calcification by DHT is facilitated, and the loss of weight increased, by orchidectomy. Presumably, "some testicular factor exerts a protective effect against this type of intoxication."

### **Hepatectomy, Hepatotoxins**

*Gluck A 5,289/1883*: Rabbits tolerate extirpation of 1/3, but not of 2/3 of the liver.

*Ponjick A 24,568/1889*: Extensive description (41 pp.) of the technique and consequences of partial hepatectomy in the rabbit. As much as 2/3 of the hepatic parenchyme can be removed without causing serious functional disturbances. Complete hepatectomy is incompatible with life. If performed in several stages, enormous amounts of liver tissue can be removed. Earlier, mostly unsuccessful, attempts at complete removal of the liver in frogs and birds are reviewed. No effort was made as yet to examine hepatic regeneration following partial hepatectomy (H.S.).]

*Podwyszozki E 77,767/1885; Hess E 74,646/1890*: Description of the early literature on the regenerative phenomena in the liver, following trauma in experimental animals, and man.

*von Meister A 25,263/1894*: Monograph (116 pp., 54 refs.) on the history of research on the regenerative power of the liver after various forms of mutilations. Personal observations on rabbits revealed the histologic details of hepatic regeneration in the parenchyme and bile duct at various intervals of time, after extensive partial hepatectomy. Two months later regeneration is virtually complete. Similar regenerative phenomena occurred in partially hepatectomized rats and dogs, although the latter do not tolerate extensive removal of hepatic tissue as well as rodents do. In rats, the operation consisted in removing 1 to 3 "hepatic lobes" (not otherwise identified).

*Biedl & Winterberg 47,485/01*: Extensive studies on the role of the liver in the synthesis of uric acid from ammonia in the dog, using various methods for the elimination of the liver (e.g., destruction of the parenchyme by injection of acids into the choledochus, Eck fistula). A 19th-century literature on complete extirpation of the liver in the goose, and in vitro perfusion of the liver with ammonia determinations in the afferent and efferent blood, etc. is reviewed.

*Higgins & Anderson 597/31*: Description of a technique for the removal of the median and left lateral lobes of the rat's liver which correspond to 70% of the hepatic tissue. Regeneration begins almost immediately and is virtually complete after 2 weeks. The mortality rate was 25%. [No attempt was made to determine the functional consequences of this intervention (H.S.).]

*Walsch & Selye 3,972/31*: First description of a technique for the removal of about 70% of the liver in mice, which lends itself for the

detection of drugs that are detoxified in the liver. Thus, in such partial hepatectomized mice, tribromoethanol (Avertin) causes much more prolonged anesthesia than in intact controls, whereas magnesium anesthesia is not significantly affected by this hepatic insufficiency; presumably because tribromoethanol is, whereas  $MgCl_2$  is not detoxified by the liver.

*Pincus & Martin A 34,939/40*: Following liver damage induced by  $CCl_4$ , threshold doses of estrone become more efficacious in producing vaginal estrus in ovariectomized rats. Although the results were inconstant and not very pronounced, they suggest "that liver damage by  $CCl_4$  results in a decreased inactivation of administered estrone."

*Selye A 35,150/41; A 35,003/41; A 36,447/42*: In rats, partial hepatectomy increases sensitivity to the anesthetic effect of various steroids, presumably because most if not all steroid hormones and their derivatives are largely detoxified in the liver. Consequently, the prolongation of anesthesia in the rat by partial hepatectomy is a suitable test object for the assays of potential steroid anesthetics of which only small amounts are available.

*Selye G 60,058/69*: In the rat, partial hepatectomy facilitates the production of perforating intestinal ulcers by indomethacin. Comparatively small doses of spironolactone readily inhibit this form of indomethacin intoxication even in the presence of surgically induced hepatic insufficiency. "These results are compatible with the assumption that both indomethacin and spironolactone are subject to hepatic detoxication, and hence, their respective pathogenic and prophylactic actions are enhanced after extensive resection of liver tissue."

#### Liver Slices or Fractions

*Heller A 32,137/40*: In vitro studies on tissue slices and tissue mince of rats and rabbits indicate that "estradiol is inactivated by liver and kidney, and not by the other tissues studied. This inactivation of estradiol is, in all probability, not due to conjugation or conversion to a less active form, but due to enzymatic destruction of an oxidative nature. This is indicated by the relative inactivity of the treated estradiol, the inability of hydrolysis procedures to increase activity and the effect of tissue poisons upon inhibiting the estradiol-destroying enzyme system. Estrone is increased

20 times in potency by incubation with minced uterine tissue. Spleen, lung, heart and kidney tissues also caused estrone to be converted to a more active substance. The suggestion is made that this conversion is accomplished by enzymatic reduction of estrone to estradiol."

*Zondek et al. A 74,477/43*: Stilbestrol is inactivated by rat liver pulp in vitro, though less rapidly than estrone. "In rats treated with large amounts of stilbestrol, the capacity of the liver to inactivate stilbestrol is increased."

*Crevier & d'Iorio B 54,151/50*: Pentobarbital anesthesia lasts longer in female than in male rats as judged by the linguo-maxillary reflex. Castration abolishes the high resistance of the male, but testosterone restores it to the normal level. In ovariectomized rats, estradiol has virtually no effect, but testosterone raises resistance to the male level. These in vivo effects run parallel to the in vitro pentobarbital detoxifying power of liver slices.

*Robillard et al. B 51,110/50*: Male rats are more resistant than females to the narcotic effect of pentobarbital. Gonadectomized rats of both sexes exhibit high pentobarbital resistance after treatment with testosterone, presumably as a consequence of accelerated hepatic detoxication of the barbiturates, since incubation of pentobarbital with liver slices of normal males or testosterone-treated castrates exhibit accelerated pentobarbital detoxication in vitro.

*Robillard et al. G 67,325/54*: Live homogenates of adult male rats destroy pentobarbital in vitro (spectrophotocolorimetric determination) more rapidly than those of castrate males. In vivo, pretreatment of the castrates, with testosterone, increases the detoxication process, whereas estradiol pretreatment has an opposite effect.

#### Hepatic Microsomal Enzyme Induction

*Brown et al. G 57,030/54*: "The activity of an enzyme system in mouse and rat liver which N-demethylates 3-methyl-4-monomethylaminoazobenzene has been found to depend on the nature of the diet. The lowest activity occurred when a grain or purified diet was fed. The activity of mouse liver approximately doubled when any of several commercial chows was fed; the activity of rat liver increased about 30 per cent. The factor was also contained in a number of aged or otherwise treated animal products, such as an old cholesterol preparation, liver extracts, and peptones.

A variety of pure sterols were inactive, but could be made active by peroxidation."

*Axelrod E40,270/55*: "An enzyme system in rabbit liver microsomes catalyzes the deamination of amphetamine to yield phenylacetone and ammonia. The enzyme system requires reduced triphosphopyridine nucleotide and oxygen. The TPN-dependent dehydrogenases in the soluble supernatant fraction of the liver serve to maintain a reservoir of reduced triphosphopyridine nucleotide."

*Brodie et al. G66,772/55*: Both the microsomes and soluble fractions of rabbit liver are required for drug metabolism. The activity of the microsomal enzyme systems that demethylate monomethyl-4-aminoantipyrine necessitate both NADPH and oxygen which are provided here by the soluble fraction. It is unusual for enzyme systems to require both reduced NADPH and oxygen but the common step in the various microsomal reactions could involve the production of hydrogen peroxide by the oxidation of NADPH. The generated peroxide might then be utilized to catalyze the transformation of various foreign compounds. "It is likely that the number of these enzymes is relatively small and that they are unusually nonspecific . . . one can speculate that these systems are not essential to the normal economy of the body, but operate primarily against the toxic influences of foreign compounds that gain access to the body from the alimentary tract."

*Axelrod D28,544/56*: First description of enzyme systems which N-demethylate morphine and its congeners to the corresponding norderivatives and formaldehyde. "The enzyme systems are located in the liver microsomes of a number of mammalian species and they require reduced triphosphopyridine nucleotide, oxygen, and other cofactors. . . . There are marked sex differences in the enzymatic demethylation of narcotic drugs in the rat. Administration of estradiol to male rats results in a decrease in enzyme activity, while treatment of female rats with testosterone enhances enzyme activity."

*Brodie C12,157/56*: The hexobarbital sleeping time of female rats is about four times that of males; correspondingly, the plasma levels of hexobarbital drop much more rapidly in males, whose hepatic microsomes also inactivate the drug more markedly in vitro than those of females. Male rats, pretreated with estradiol, sleep as long as females and their hepatic microsomes lose much of their ability to metabolize hexobarbital. Females, pretreat-

ed with testosterone, assume the characteristics of males in all these respects. No sex differences were seen in mice, guinea pigs, rabbits and dogs, and their ability to handle hexobarbital is not influenced by estradiol or testosterone.

*Conney et al. D87,867/56*: In rats, 3-methylcholanthrene i.p. considerably increased the ability of fortified liver homogenates to N-demethylate 3-methyl-4-monomethylaminoazobenzene (demethylase activity) and to reduce the azo linkage of 4-demethylaminoazobenzene (reductase activity) within 24 hrs. Significant demethylase activity was obtained even after 6 hrs. A number of other polycyclic hydrocarbons caused similar increases in demethylase activity but there was no relationship between carcinogenicity and enzyme induction. None of these compounds was active in vitro and their effect could be inhibited in vivo by ethionine. This inhibition was in turn prevented by methionine.

*Lin & Knox C73,824/58*: In rats, the hepatic TKT activity increased following treatment with cortisone, cortisol or corticosterone and L-tyrosine. This effect was observed also after adrenalectomy. On the other hand, a comparable effect of other aminoacids was probably due to stress. "That a nonspecific stress-producing agent could actually increase the level of tyrosine- $\alpha$ -ketoglutarate transaminase was further supported by the results obtained with a compound which is unrelated to tyrosine metabolism. Injections of propylene glycol in doses of 0.5 ml per 100 gm of body weight caused the level of this enzyme to increase to an average of 1390 units in three intact rats." Adrenalectomized rats did not support this dose of propylene glycol.

*Remmer D86,728/58*: In rats, 3 days pretreatment with cortisone or prednisolone diminishes the anesthetic effect of hexobarbital and increases the degradation of the anesthetic by liver slices. Adrenalectomy inhibits the degradation of hexobarbital by liver slices of male rats, an effect which can be counteracted by pretreatment with cortisone. Mention of unpublished experiments indicating that cortisone and prednisolone accelerate the detoxication of meperidine in the rat, exclusively through demethylation and not through hydrolysis.

*Rosen et al. C47,568/58*: Cortisol, cortisone and prednisone increase the GPT activity of the rat liver. GOT activity is not similarly influenced. "These facts, added to the observation that a substantial rise in hepatic GPT

occurs in rats treated with hydrocortisone, in contrast to treatment with deoxycorticosterone, strongly suggests that the control of hepatic levels of GPT by glucocorticosteroids is importantly related to the mechanism whereby these compounds exert their gluconeogenic activity."

*Sulman et al. C 79,823/59*: In rats injected for 4 months with prednisone or prednisolone, an increase in the hepatic content of the enzymes which decompose these steroids could be demonstrated in vitro. Various histologic stains failed to reveal any associated light-microscopic change in the hepatocytes. Addition of SKF 525-A to the homogenate of activated livers blocked their enzymic activity.

*Maackel & Brodie C 83,071/60*: TPO in rat liver is increased by ACTH, cortisone, or cortisol, as well as by various stressors and barbiturates. Hypophysectomy prevents the effect of stressors and barbiturates, suggesting that the latter act through the pituitary-adrenal system.

*Kato et al. G 64,325/62*: Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect of OMPA is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids that enhance the decomposition of these substrates, the first three of which being inactivated whereas the last activated in the process. The differences were also demonstrated in vitro, using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration, and restored by several anabolic testoids.

*Booth & Gillette D 34,656/62*: Testosterone propionate, 19-nortestosterone, 4-androstene-3, 17-dione and 4-chloro-19-nortestosterone acetate (SKF 6611) were tested for their ability to induce hepatic microsomal enzymes in female rats. "All of the steroids produced 2- to 3-fold increases in the activity of the enzyme systems that metabolize hexobarbital, demethylate monomethyl-4-aminoantipyrine and hydroxylate naphthalene, but only 19-nortestosterone, testosterone propionate and methyltestosterone increased the activity of microsomal TPNH oxidase. . . . The increase in microsomal enzyme activity is more closely related to the anabolic activity than to the androgenic activity of the steroid."

*Novick Jr. et al. F 63,768/66*: "Subcutaneous administration of several 19-nortestosterone derivatives produced an increased

hepatic microsomal metabolism of hexobarbital and decreased zoxazolamine prostration time in mice. Testosterone and methyltestosterone produced an increased hexobarbital sleep time and testosterone decreased the rate of hepatic microsomal metabolism of hexobarbital. Although the ability of norethandrolone and SK&F 6612 (4-chloro-17 $\alpha$ -methyl-19-nortestosterone) to shorten hexobarbital sleep time occurs within 6 to 12 hr. after a single dose in mice, this effect of testosterone derivatives in rats occurs only after prolonged treatment."

*Tomkins et al. G 49,588/66*: Glucocorticoids stimulate TKT induction in rat hepatoma cells, in vitro. Inhibitor and immunochemical experiments indicate that the corticoids do not activate a precursor but increase the number of enzyme protein molecules. Apparently, the hormones exert some control at the level of translation of the transaminase messenger by antagonizing a repressor of messenger function. "It cannot yet be determined whether the presumed increase in messenger concentration occurs as a secondary response to the stimulation of translation, or whether there is a direct effect of the hormone on gene transcription."

*Conney F 88,649/67*: A review of the literature on more than 200 drugs leads to the conclusion that "there is no apparent relationship between either their actions or structure and their ability to induce enzymes. It is of interest that most of the inducers are soluble in lipid at a physiological pH."

*Mannering G 71,818/68 (p. 53)*: Review of the early history of studies on hepatic microsomal drug metabolism.

*Kalyanpur et al. G 66,147/69*: In mice, various anabolic steroids (methandienone, 4-chlorotestosterone acetate, nandrolone, phenpropionate) given i.p. 90 min before pentylene-tetrazol, inhibit convulsions. The protective effect is compared to that produced by various anesthetic steroids. [A relationship to enzyme induction is not suggested, nor is it probable in view of the shortness of the necessary pretreatment (H.S.).]

*Solymoss et al. G 60,054/69*: "In the rat, pretreatment with spironolactone, norbolethone or ethylestrenol increased the oxidation of pentobarbital by liver microsomes, enhanced its disappearance from blood and proportionally decreased the depth of anesthesia."

### Portal Route of Administration

*Golden & Sevringhaus A 37,803/38:* In ovariectomized rats, ovarian homotransplants placed into the mesenteries failed to maintain the sexual cycle, whereas retransplantation of the gonads into the axillary region reinitiated estrus. Apparently, folliculoids are detoxified during their passage through the liver.

*Biskind & Mark A 31,656/39:* "Pellets of testosterone propionate and estrone do not exert their specific effect on the appropriate castrate rats when implanted in the spleen. The specific effect returns when the spleens containing the pellets are transplanted and the splenic artery and vein are ligated." Possibly, both testosterone and estrone are inactivated during their passage through the liver.

*Biskind A 31,848/40:* Both testosterone and methyltestosterone, when implanted in pellet-form into the spleen of the castrate rat, failed to stimulate the accessory sex organs. When the pellet-containing spleen is transplanted subcutaneously, with the splenic vessels ligated, the testoid effect returns. "The differences in the specific effects of these two substances when administered orally may be due to different routes of absorption from the intestinal tract (e.g., via the lymphatics), rather than different sites of inactivation."

*Burrill & Greene A 32,956/40:* In immature orchidectomized rats, autotransplants of testicular tissue stimulated the growth of the accessory sex organs when placed subcutaneously but not when inserted into the portal circulation. Presumably, testoids are detoxicated during their passage through the liver.

*Eversole et al. 78,679/40:* In adrenalectomized rats "autoplastic cortical grafts placed on the kidney, ovary or mesentery are of approximately equal functional capacity." Hence it is concluded that "unlike ovarian transplants, the function of cortical tissue is not impaired by having a site (intestinal mesentery) with hepatic portal drainage."

*Biskind A 35,907/41:* Female rats become anestrus upon s.c. implantation of a testosterone pellet. The estrus cycle remains normal if the pellet is implanted into the spleen but if subsequently this spleen is transplanted subcutaneously and its vessels ligated, the estrus cycle is resumed. Presumably intrasplenically-located testosterone is detoxified during its passage through the liver.

*Biskind A 36,315/41:* Pellets of estradiol benzoate implanted into the spleens of adult ovariectomized rats produce only a short

period of estrus. However, if these spleens are transposed (pedicle transplant) s.c., their estrogenic action reappears. Apparently, estradiol is inactivated in the liver, as had previously been shown for estrone.

*Biskind A 36,481/41:* Estrone pellets implanted into the spleen do not cause such marked testicular atrophy in adult rats, as do similar pellets placed s.c. If the pellet-bearing spleens are transplanted s.c., and their hilum ligated (to prevent drainage of splenic blood into the portal circulation), then severe testicular atrophy develops, suggesting that estrone is inactivated during its passage through the liver.

*Biskind & Biskind A 38,221/42:* The anestrus condition of ovariectomized rats with splenic implants of estrone pellets gives way to constant estrus under the influence of vitamin-B complex deficiency. Administration of brewers yeast restores anestrus. Presumably the hepatic detoxication of folliculoids depends upon vitamin-B factors.

*Burrill & Greene A 38,214/42:* In rats, pellets of testosterone or methyltestosterone implanted s.c. stimulated the growth of the accessory sex organs after orchidectomy. Upon implantation into the spleen, methyltestosterone was, but testosterone was not active. Presumably, the latter is more subject to hepatic detoxication.

*Eversole & Gaunt A 56,551/43:* In rats, DOC pellets placed into the portal circulation are less effective in maintaining life after adrenalectomy than those implanted elsewhere. Apparently, DOC is partly inactivated during its passage through the liver.

*Green B 28,239/48:* In rats kept on a high NaCl intake the disturbances in fluid exchange, cardiac and renal hypertrophy, hypertension and mortality induced by DOC implantation s.c. are all diminished or absent if the same type of DOC pellet is implanted into the spleen. It is concluded that DOC is detoxified in the liver.

*Shipley et al. B 50,163/50:* In ovariectomized rats maintained on a hypolipotropic diet supplemented with methionine, estrone pellets protected against the development of hepatic steatosis if implanted s.c. but not if placed in the spleen.

*Moller-Christensen B 56,243/51:* In rabbits and cats, a greater increase in blood pressure is obtained by vasopressin injected into a peripheral vein than if the same amount is injected into the spleen. It is concluded that vasopressin is detoxified by the liver.

### **Liver Perfusion**

*Israel et al. A 16,424/37:* Estrone "is not inactivated by dog blood in vitro or by the circulation in a heart-lung perfusion system. It is rapidly inactivated by circulation in a heart-lung-liver perfusion system."

### **Smooth Endoplasmic Reticulum (SER)**

*Fouts G 79,654/61:* When SER and RER particles of rabbit liver are separated by ultracentrifugation in various sucrose gradients, the NADPH oxidase and drug-metabolizing enzyme activity can be shown to be higher in the SER than in the RER.

*Remmer & Merker D 61,064/63:* In the rat, hepatic microsomal enzyme induction by phenobarbital is associated with a proliferation of the hepatic SER.

*Fouts & Rogers F 29,497/65:* In the rat, "phenobarbital and chlordane stimulate a variety of microsomal drug metabolisms and also appear to cause a marked proliferation of smooth-surfaced endoplasmic reticulum (SER) in the hepatic cell. Benzpyrene and methylcholanthrene stimulate only a few microsomal drug metabolizing enzymes and do not appear to cause any pronounced increase in hepatic cell SER."

*Burger & Herdson G 66,499/66:* In the rat, phenobarbital causes liver enlargement and ultrastructural changes characterized by "proliferation of smooth endoplasmic reticulum with concomitant shortening and dispersion of rough endoplasmic cisternae, mitochondrial abnormalities, and the development of myelin figures. The morphologic abnormalities at first affect only central cells, but progressively involve cells further out in the lobule so that after medication for 10 days most of the lobule is involved. Nevertheless, a peripheral zone of normal-looking cells is always present." Concurrent treatment with SKF 525-A further aggravates these changes, but SKF 525-A itself causes no detectable abnormalities in the liver.

*Claude E 8,217/69:* Review on "Microsomes, Endoplasmic Reticulum and Interactions of Cytoplasmic Membranes."

*Gardell et al. G 60,062/70:* In the rat, norbolethone—an active catatotoxic steroid—produces pronounced proliferation of the SER in hepatocytes, presumably a morphologic reflection of increased microsomal enzyme production.

*Horvath et al. G 70,408/70:* In rats "treatment with the most active catatotoxic steroids

(spironolactone, norbolethone, SC-11927, ethylestrenol) invariably induced marked proliferation of the SER. Progesterone and testosterone had a less pronounced effect. However, alterations of the endoplasmic reticulum can also be produced by some non-catatotoxic steroids (estradiol) or non-steroidal compounds (stilbestrol). Thus it can be concluded that there is no close correlation between the catatotoxic potency and the proliferation of the SER although all the catatotoxic compounds tested lead to a marked transformation of the endoplasmic reticulum in the hepatocytes."

*Kovács et al. G 60,045/70:* In the rat, spironolactone given in amounts suitable to produce a catatotoxic effect causes marked proliferation of the SER in hepatocytes. This change presumably reflects an induction of drug-metabolizing microsomal enzymes, and may explain why spironolactone protects against the injurious effects of different compounds.

### **Syntoxic vs. Catatoxic Actions**

*Selye et al. A 72,284/44:* Demonstration of a relationship between the adrenal cortex and inflammatory lesions. In rats, DOC can produce carditis, periarteritis and sometimes arthritis under appropriate experimental conditions.

*Selye B 76,060/53:* In rats, cortisol inhibits inflammation in granuloma pouches produced by croton oil. However, the croton oil removed after 14 days of sojourn in the pouch still retains the ability to produce inflammatory changes when injected into other rats. Apparently, the glucocorticoid acts by depressing the inflammatory potential of the tissues, not by destroying the irritant.

*Selye G 60,039/69:* First description of the concept of "catatoxic steroids." The term refers to steroid hormones and their derivatives which increase resistance to various toxic agents above normal. Corticoids, which merely restore normal resistance in adrenal insufficiency, are not included in this concept, nor is the antiplogistic effect that is not directed against toxic agents but suppresses a particular somatic response to them, namely inflammation which may be harmful or beneficial depending upon circumstances. Many, if not all, catatoxic steroid hormone actions depend upon increased detoxication of noxious compounds, through the induction of adaptive

microsomal enzymes in the liver, not upon suppression of specific morbid reactions to them.

*Selye G60,070/70*: First detailed review (21 pp., 65 refs.) on "Adaptive Steroids" with special emphasis upon their classification and the history of research on their role as regulators of nonspecific resistance.

*Selye G60,087/70*: Brief review on the history of adaptive hormones with special reference to catatoxic steroids.

*Solymoss et al. G79,023/71*: In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norethone and oxandrolone (anabolics), also enhance plasma clearance of BSP, probably through the same mechanism. In contrast to these effects of pretreatment, administration of spironolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, these observations clearly show that the catatoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may also be mediated through extra-microsomal enzyme mechanisms or even through enhanced biliary excretion (H.S.).]

*Solymoss PROT. 42234*: As judged by the Kagawa test, PCN is practically devoid of antimineralocorticoid activity. In male adrenalectomized adult rats, 6 µg of DOC s.c. produced a pronounced decrease in the urinary Na/K excretion, which could not be counteracted by 1 mg of PCN.

### Clinical Implications

*Yaffe et al. G67,125/66*: In a female infant with congenital unconjugated hyperbilirubinemia, phenobarbital lowered the serum bilirubin concentration. "This constitutes the first indication of the apparent induction of a glucuronide-conjugating enzyme system by phenobarbital in man and therefore may also represent the first therapeutic application of enzyme induction."

*Salvador et al. G68,113/67*: Pretreatment

with phenobarbital diminished hypercholesterolemia and atherosclerosis in cholesterol-fed rabbits. The cholesterol content of the aorta was likewise diminished.

*Crigler & Gold H7,119/69*: In a male infant with congenital, nonhemolytic, unconjugated hyperbilirubinemia and severe kernicterus, phenobarbital decreased serum bilirubin, whereas L-triiodothyronine, STH, and testosterone had little or no effect. During phenobarbital treatment, liver specimens obtained by biopsy showed proliferation of the SER and increased in vitro capacity to conjugate p-nitrophenol.

*Mowat & Arias G74,246/69*: "Oral contraceptive agents cause a predictable and reversible fall in hepatic excretory function in all subjects appropriately tested." At the same time, there is induction of hepatic drug-metabolizing enzymes which may alter the responsiveness of women to various drugs, and conversely, others have shown that the uterotrophic effect of oral contraceptives is reduced by phenobarbital at least in rats. "We can only speculate as to what this may mean for the insomniac on phenobarbitone who relies on the pill for contraception."

*Orrenius et al. E8,231/69*: Review of the literature and personal observations on the increase in the synthesis of cholesterol from <sup>14</sup>C-acetate obtained by phenobarbital pretreatment in rats and hamsters.

*Powell et al. H17,195/69*: It had previously been noted that pre-eclamptic toxemia (P.E.T.) is associated with a reduction in the incidence and severity of nonhemolytic jaundice in the neonate. Reexamination of these data now showed "that for nontoxaemic mothers receiving any barbiturate at any time there was a slight but statistically insignificant reduction (11.3%) in incidence of jaundice in their infants. Toxaemic mothers not receiving barbiturate had a similar insignificant reduction (10.4%). When both P.E.T. and barbiturate were present together, however, the reduction was 30.7% and this was statistically significant (P < 0.01)."

*Temple Jr. et al. H17,091/69*: In patients with Cushing's disease, o,p'DDD diminished cortisol secretion. Since adrenal responsiveness to ACTH infusion was reduced and the adrenals showed electron-microscopic changes in the mitochondria of the fasciculata, the effect was ascribed to the adrenolytic action of the drug.

*Selye G60,083/70*: Experimental Cardiovascular Diseases. Berlin—Heidelberg—New York: Springer Verlag, 1970.

### III. CHEMISTRY

It is not within the scope of this monograph to discuss the chemical basis of drug metabolism in detail. This subject has been adequately covered by others in several excellent reviews (listed at the end of this chapter). Here we shall merely present a very succinct outline, followed by abstracts of key papers on enzymic reactions likely to participate in the metabolism of substrates that are influenced by adaptive hormones.

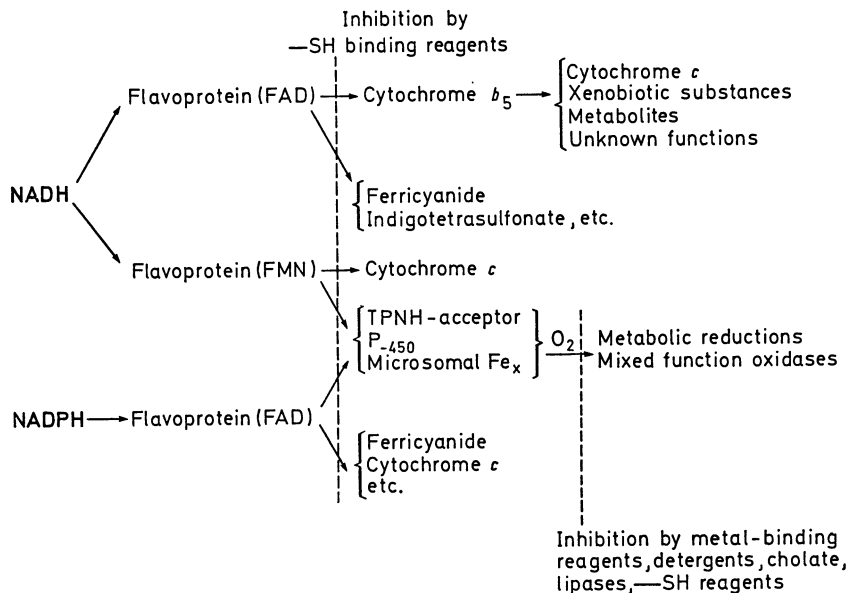

Most drugs undergo some metabolic transformation in the body. The same is true of hormones and of other physiologic constituents of the organism. The majority of these chemical changes takes place in the liver as a result of enzymic activity, but many metabolic transformations occur in extrahepatic tissues, and not all are the direct consequences of enzymic degradation or synthesis. Since we are concerned primarily with all aspects of the humoral regulation of tolerance to toxic agents, we must remember that hormones can increase resistance through entirely different mechanisms, e.g., by enhancing the excretion of toxicants through the urine, bile, etc., or by stimulating their uptake into the RES. Indeed, the entire group of syntoxic hormones acts by influencing the body's response to aggressors, without necessarily having any direct effect upon the latter. Furthermore, we shall see that some steroids act merely as particularly efficient carriers of active groups (e.g., of the thioacetyl radical) which bind and inactivate toxic materials (e.g., mercury).

Here we shall speak mainly about the most common biochemical mechanisms for the inactivation of toxic substrates which, in general, are characterized by the **production of metabolites more polar than the parent compounds**. This transformation is a useful preparation for renal and biliary excretion because substances with a high lipid/water partition coefficient pass readily across membranes; hence they are easily reabsorbed from the tubular urine, a process which interferes with their elimination. In addition, the specific secretory mechanisms for anions and cations in the proximal renal tubules and in the hepatic parenchyme act upon highly polar substances. For example, the oxidation of a methyl group to carboxyl can prepare a compound for renal or biliary excretion, thereby reducing its biologic half-life from many hours to a few minutes. The same effect is achieved by conjugation of a relatively nonpolar drug with sulfate. However, decreased lipid solubility is useful in this connection only if combined with increased water solubility.

The reactions undergone by drugs in the body are: oxidation, reduction, hydrolysis and synthesis (conjugation). The most important oxidative reactions include aliphatic oxidation, aromatic hydroxylation, N-dealkylation, O-dealkylation, S-demethylation, deamination, sulfoxide formation, desulfuration, N-oxidation and N-hydroxylation.

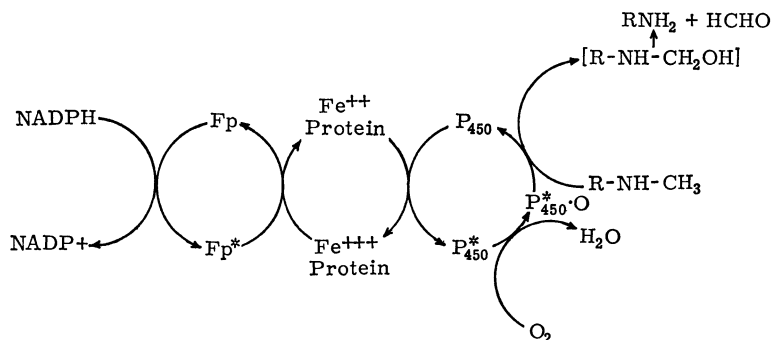

## OXIDATIONS MEDIATED BY HEPATIC MICROSOMAL ENZYMES

The microsomal organization of redox components by which reducing equivalents are brought into reaction is of interest, since mixed-function oxidations require reducing equivalents. Such redox components occur in the endoplasmic reticulum of various tissues. The components identified in hepatic microsomes are summarized as follows (Mason et al. F51,528/65):

Here, NADH reduces cytochrome  $b_5$  through the FAD-containing flavoprotein, NADH-cytochrome  $b_5$  reductase; the reduced cytochrome  $b_5$  transfers reducing equivalents to acceptors with  $E_0'$  above about 0 volts at pH 7; the reductase itself transfers reducing equivalents to dyestuffs but not to cytochrome  $c$ . NADH may likewise reduce cytochrome  $c$  through an FMN-containing microsomal flavoprotein, NADH cytochrome  $c$  reductase, but no cytochrome  $c$  occurs in carefully prepared microsomes. NADH also reduces a CO-binding cytochrome pigment P-450 (so called from the position of absorption of the CO complex). This P-450 appears to be the functional site of several microsomal mixed-function oxidases. NADH reduces also a hemoprotein-like component of hepatic microsomes, which is detectable by electron-spin resonance spectroscopy. Its reduced form, known as "microsomal  $Fe_x$ ," is extremely autoxidizable. A much more active enzyme toward P-450 and microsomal  $Fe_x$  reduction is NADPH-cytochrome  $c$  reductase, an FAD-containing flavoprotein which reduces a NADPH-acceptor with a b-type cytochrome spectrum probably related to P-450 and microsomal  $Fe_x$ . NADPH-cytochrome  $c$  reductase also catalyzes the reduction of dyestuffs and other nonspecific acceptors. In addition to these redox-active components, the hepatic microsomes contain non-heme iron, copper, manganese, and coenzyme X, whose functions are unknown.

A graphic representation of the interactions between these microsomal components is given in the graph below in which the FAD-containing liver protein is indicated as "Fp" and its reduced form as "Fp\*" (Mannering G75,980/68):

The relative nonspecificity of microsomal drug-metabolizing systems has been ascribed to the function of a single oxidase system involving cytochrome P-450, or at least a limited number of oxidase systems involving one or more cytochromes. Even if drugs are structurally unrelated, they would compete with each other for metabolism, assuming that the latter depends upon a single enzyme system or a single rate-limiting component common to the systems involved in the metabolic degradation of the defense substrates. In fact, it could be shown that many substrates acted as competitive inhibitors mutually inhibiting one another.

The important initial **hydroxylation reactions** are written as follows [Goldstein et al. 165/68 (p. 231)]:

Oxidative Deamination

Sulfoxide Formation

N-Oxidation

N-Hydroxylation

In the oxidative desulfuration reactions, the oxygen atom replaces sulfur which later appears as sulfate.

Table 1 (p. 46) represents a compilation from the literature of enzyme activities that could be traced to the hepatic microsomal fractions of mammals, mainly of the rat.

### *OXIDATIONS NOT MEDIATED BY HEPATIC MICROSOMES*

These include aromatization of cyclohexane derivatives (mitochondrial enzymes)

**Alcohol and aldehyde oxidation** (cytosol enzymes)

**Purine oxidation**

**Monoamine oxidase (MAO) and diamine oxidase (DAO).** MAO is a particularly important mitochondrial enzyme (found in liver, kidney, intestine and nervous tissue) because its substrates include physiologic substances such as: phenylethylamine, tyramine, dopamine, norepinephrine, epinephrine, tryptamine and 5-HT. DAO also converts amines to aldehydes in the presence of oxygen; its substrate specificity overlaps with that of MAO.

**Dehalogenation** (e.g., of halogenated insecticides).

### *REDUCTIVE DETOXYFYING REACTIONS*

**Azo and nitro reduction,** first thought to occur in the cytosol, but later shown to depend upon a class of light microsomes that sediment very slowly. In contrast to the oxidizing microsomal enzymes, these reductases are found also in extra-hepatic tissues.

**Alcohol dehydrogenase** can function as a reductase, e.g. when it catalyzes the conversion of chloral hydrate to trichloroethanol.

Table 1. *Enzymic activities of liver microsomal fractions.* (Simplified after an extensive compilation by Reid (G71,333/67) where references to the original articles may be found)

Enzyme or enzyme system	% in microsomal fraction <sup>a</sup>	Enzyme or enzyme system	% in microsomal fraction <sup>a</sup>
<i>Oxidoreductases</i>		<i>Hydrolases</i>	
L-Amino-acid oxidase (1.4.3.2)		Alkaline phosphatase (3.1.3.1)	42%
Aryl-4-hydroxylase (1.14.1.1)	~100%	Amylase (3.2.1.1)	52%
Ascorbate-forming system (1.1.1.19)		Arginase (3.5.3.1)	41%
Azo-dye reductase (1.6.6.7)		Arylsulphatase C (3.1.6.1)	62%
Catalase (1.11.1.6)	14%	ATPase (ATP pyrophosphohydrolyase; Mg <sup>2+</sup> ions in assay) (3.6.1.4)	low
Cystine reductase (1.6.4.1)		<i>N</i> -Deacylase ("esterase") (3.5.1. )	
Desmosterol reductase (1.3.1. )	35%	{ Acetylcholinesterase {46%

		Prothrombin-forming system	

*DRUG METABOLISM BY HYDROLYSIS*

This is essentially restricted to esterases and amidases found in plasma, liver and other tissues, usually in the cytosol fraction. A pertinent example is the hydrolysis of procaine by plasma choline esterase to p-aminobenzoic acid and diethylaminoethanol.

*CONJUGATION REACTIONS*

**Synthesis of glucuronides**, e.g., of steroid alcohols, thyroxine, bilirubin and various substances foreign to the body, can be achieved by hepatic enzymes. Those catalyzing the synthesis of uridine diphosphate-glucuronic acid (UDPGA) serve as a glucuronic acid donor to the various receptors in the cytosol. Transferases in hepatic microsomes and other tissues mediate this latter process.

**Synthesis of ribosides and riboside phosphates** shows that carbohydrates other than glucuronic acid can participate in synthetic drug metabolism. Ribonucleosides and ribonucleotides are formed with purine and pyrimidine analogues by a soluble enzyme system of the hepatic cytosol. This type of reaction participates in the metabolism of histamine and of various carcinolytic agents, e.g., in the conversion of 6-mercaptopurine to a ribonucleotide.

**Acylation reactions** are mediated by enzymes of the hepatic cytosol fraction. Here, coenzyme-A through its free-SH group reacts with an activated form of carboxylic acid to form acyl-CoA. The acyl group is then transferred to an appropriate acceptor, e.g., an aromatic amine.

**Mercapturic acid formation** occurs in preparation for the urinary excretion of aromatic hydrocarbons, halogenated aromatic hydrocarbons and halogenated nitrobenzenes. A "glutathio kinase," found in the hepatic cytosol, is thought to activate glutathione; the conjugation then proceeds in the microsomal fraction in the presence of NADPH and oxygen. The glutathione conjugate is subsequently hydrolyzed to an arylcysteine intermediate, the cysteine amino group of which is acetylated to mercapturic acid.

**Sulfuric acid esters or "ethereal sulfates"** are formed by the reaction of aromatic or aliphatic —OH groups and certain —NH<sub>2</sub> groups with an activated form of sulfate. Hepatic cytosol enzymes mediate the sulfate activation and the transfer of sulfate to the acceptor.

**N-, O-, and S-methylation** can be achieved with S-adenosylmethionine as a methyl donor. Catechol O-methyltransferase (found in hepatic cytosol but also in many other tissues) catalyzes the transfer of —CH<sub>3</sub> to a phenolic —OH, e.g., in epinephrine,

## Footnote to Table 1

---

<sup>a</sup> %-values are given only where there were reasonably quantitative results, and the recovery of homogenate activity in the fractions was satisfactory. Where low %-values have been included, the homogenate may have contained at least two enzymes one of which was truly associated with the microsomal fraction. On the other hand, some fairly high values in the literature have been excluded because, for example, the enzyme is really lysosomal.

norepinephrine, dihydroxyphenylethylamine and dihydroxybenzoic acid. This enzyme may be responsible for the physiologic inactivation of norepinephrine.

N-methylation is involved in the methylation of histamine, phenylethanolamine and the conversion of norepinephrine to epinephrine. The reaction occurs in the cytosol of the adrenal medulla and other tissues. This is not strictly speaking a detoxication reaction but nicotine, nicotinamide, quinoline, etc. can also be methylated through a similar pathway.

S-methylation appears to be limited to lipid-soluble substrates which have access to microsomal enzymes. Various exogenous —SH compounds are methylated in this manner, but physiologic substrates (homocysteine, cysteine, glutathione) are not.

**Transsulfuration and cyanide metabolism** are also important for detoxication. In cyanide poisoning, CN becomes bound to the Fe in cytochromes destroying their electron transport capacity. The immediate removal of CN is achieved by promoting its binding to methemoglobin. This process is followed by the conversion of cyanide to the nontoxic thiocyanate by furnishing thiosulfate or mercaptopyruvate as substrates. Normally cyanide is metabolized in the body by sulfur transferase ("rhodanese"), a mitochondrial enzyme found in liver, kidney and other tissues.

#### **Enzymes and Resistance in General**

*Rubin et al. G58,057/64:* Discussion of factors which may explain the relative nonspecificity of microsomal enzymes by affecting pathways common to many detoxicating reactions.

*Reid G71,333/67:* A chapter on "Membrane Systems" (86 pp., numerous refs.) with a tabular compilation of the literature on microsomal enzyme systems.

*Goldstein et al. E165/68 (p. 218):* Review on the effect of various inducers upon the pathways of drug metabolism.

*Gillette H 34,126/71:* The principal oxidative reactions catalyzed by hepatic microsomal mixed function oxygenases are tabulated as follows:

Reaction	Substrate	Product
Deamination	amphetamine	phenylacetone
O-dealkylation	phenacetin	p-hydroxyacetanilide
Aliphatic hydroxylation	pentobarbital	3-hydroxypentobarbital
Aromatic hydroxylation	aniline	p-hydroxyaniline
Epoxidation	aldrin	aldrin epoxide
N-dealkylation	aminopyrine	4-aminoantipyrine
Alkylol formation	schradan	hydroxymethyl schradan
N-oxide formation	dimethylaniline	dimethylaniline N-oxide
N-oxidation	aniline	phenylhydroxylamine
S-demethylation	6-methylmercaptopyrine	mercaptopyrine
S-oxidation	chlorpromazine	chlorpromazine sulfoxide
Phosphothionate oxidation	parathion	paraoxon
Desulfuration	thiobarbital	barbital
Dehalogenation	halothane	trifluoroacetic acid
Dealkylations of metallo alkanes	tetraethyl tin	triethyl tin

The mechanism of drug oxidations is graphically illustrated as follows:

### Steroidases in General

*Tomkins C 32,526/57*: Characterization of the hepatic enzymes responsible for the *in vitro* reduction of  $\Delta^4$ -3-ketosteroids.

*McGuire & Tomkins E 91,579/59*: In the rat, thyroxine causes a pronounced increase in the microsomal  $5\alpha$ -reductase activity of the liver, but the rate of reduction of some steroid substrates is increased more than that of others. Furthermore, when microsomes are "aged" at 0–5°C for several weeks, the decline in activity varies with different steroid substrates. "Further evidence for the substrate specificity of the  $5\alpha$ -hydrogenases was the observation that 4-androstene-3,17-dione strongly inhibited the reduction of cortisone, while the converse was not true." These and other observations suggest that each series of  $\Delta^4$ -3-ketosteroid hydrogenases,  $5\alpha$  and  $5\beta$ , contains multiple enzymes capable of discerning small variations in the steroid molecule.

*Kuntzman et al. E 55,528/65*: "The  $K_m$  values for the hydroxylation of progesterone, testosterone, and estradiol are about 10 times lower than the  $K_m$  values for several drug oxidations, thereby suggesting that the steroid hormones are better than drugs as substrates for the TPNH-dependent oxidative enzymes." These  $K_m$  values are in the same range as those reported for the reduction of the A ring of  $\Delta^4$ -3-ketosteroids by enzymes of liver microsomes. These findings "suggest that these enzymes can also play a physiological role in the metabolism of steroids in the body."

*Conney et al. F 79,331/67*: Hepatic microsomes of adult rats metabolize testosterone, estradiol, progesterone and DOC to polar hydroxylated metabolites in the presence of an NADPH-generating system. CO inhibits the hepatic metabolism of all four steroids.

*Koerner G 65,718/69*:  $11\beta$ -Hydroxysteroid dehydrogenase activity of rat liver micro-

somes has been assayed by a quantitative spectrophotometric method. "Several  $11\beta$ -hydroxysteroids are substrates of the enzyme but there is no activity towards  $11\beta$ -hydroxysterone or  $11\beta$ -hydroxysteroids with a C-21 sulfate, phosphate, acetate or hemisuccinate group."

### Corticoidases

*Forchielli & Dorfman G 66,498/56*: "With 11-deoxycortisol as a substrate, it has been demonstrated that rat liver contains both the  $\Delta^4$ - $5\alpha$ -hydrogenase and  $\Delta^4$ - $5\beta$ -hydrogenase systems, which yield, after incubation, the  $5\alpha$  (androstane and allopregnane) and  $5\beta$  (etiocholane and pregnane) stereoisomers." The  $5\alpha$  system is associated with the particulate fraction, whereas the  $5\beta$  system is in the supernatant fluid produced by centrifugation at 78,000 X g.

*McGuire Jr. & Tomkins D 5,722/60*: In the microsomal fraction of rat liver, there appear to be at least 5  $\Delta^4$ -3-ketosteroid reductases ( $5\alpha$ ). When rats are treated with thyroxine, the reductase activity for cortisone, cortisol, DOC, 4-androstene-3,17-dione and 11-desoxycortisol (Cpd. S) increases, but the increment is different for each of these substrates.

*Starnes G 68,434/69*: Rat liver slices incubated *in vitro* in the presence of  $^3\text{H}$ -dexamethasone. The steroid was metabolized to glucuronides and sulfates.

### Testoidases

*Conney et al. G 67,773/68*: The metabolism of testosterone to  $6\beta$ -,  $7\alpha$ -, and  $16\alpha$ -hydroxy-testosterone by rat liver microsomes, is differently inhibited by CO *in vitro*. Apparently, "one or more CO-binding cytochromes function in the hydroxylation of testosterone by rat liver microsomes."

### Folliculoidases

*Graubard & Pincus 80,931/41*: In the Barcroft-Warburg respirometer, estriol, estradiol and estrone are oxidized by mushroom laccase and form precipitates whose nature has not been established. No oxidation of any of these substrates was observed with potato tyrosinase.

*Mueller & Rumney C30,708/57*: Formation of 6 $\beta$ -hydroxy and 6-keto derivatives of estradiol-16-<sup>14</sup>C by the hepatic microsomes of the mouse.

*Lehmann & Schütz H14,215/69*: The microsomal fraction of the liver of the mature human fetus metabolizes 4-<sup>14</sup>C-estrone twice as fast as that of the 12-week-old fetus. The highest rate of metabolism was found in the microsomal fraction of the liver of an adult man. "By paperchromatography, microchemical reactions and crystallization to constant specific activity, the following metabolites were identified: 6 $\alpha$ -, 6 $\beta$ -, 7 $\alpha$ -, 15 $\alpha$ - and 16 $\alpha$ -hydroxyestrone, 6 $\alpha$ -, 6 $\beta$ - and 7 $\alpha$ -hydroxyoestradiol-17 $\beta$  and oestriol."

### Cholesterolase

*Bucher & McGarrahan G67,470/56*: For the biosynthesis of cholesterol from acetate in vitro, both microsomes and soluble cell constituents of the rat liver are required. In vivo, over 90% of newly formed cholesterol, obtained shortly after the injection of labeled acetate, is in the microsomal fraction.

*Olson et al. G61,438/57*: The metabolism of labeled lanosterol in rat liver homogenates yields cholesterol and CO<sub>2</sub> as the principal products. The demethylation of lanosterol requires both the particulate and the soluble fraction of liver homogenates, but the latter can be partially replaced by NADH.

*Tchen & Bloch G66,130/57*: Hog-liver homogenate can convert squalene only to lanosterol and not to cholesterol. Rat-liver homogenate converts squalene to either lanosterol or cholesterol according to the method of preparation of the homogenates. Separated mitochondria and microsomes were both active if supplemented with supernatant fluid.

### Thyroxinase

*Stanbury et al. C90,693/60*: Description of the microsomal enzyme system which deiodinates thyroxine in the presence of Fe<sup>++</sup> and oxygen.

*Wynn et al. G67,767/62*: The microsomes are the most active thyroxine-degrading subcellular fraction of rat liver. The optimal reaction conditions for this degradation are described.

### Cytochrome P-450, NADPH Cytochrome c Reductase, Cytochrome b<sub>5</sub>

*Omura et al. F51,529/65*: Studies on the participation of cytochrome P-450 in "mixed function oxidase" reactions.

*Lu & Coon G71,879/68*: Studies on the role of hemoprotein P-450 in fatty acid  $\omega$ -hydroxylation in the soluble enzyme system from liver microsomes.

*Hildebrandt et al. G69,992/69*: From experiments on the interaction of metyrapone with hepatic microsomal cytochrome P-450 in rats treated with phenobarbital, "it is concluded that metyrapone changes the equilibrium between two functionally different forms of cytochrome P-450 which exists in microsomes. The decrease of one form of cytochrome P-450 appears as an 'inhibition' of aminopyrine or hexobarbital metabolism; the concomitant increase of the other form of cytochrome P-450 results in a 'stimulation' of other types of hydroxylation reactions, for example, the ring hydroxylation of acetanilide."

*Lu et al. G67,623/69*: Resolution of the cytochrome P-450-containing  $\omega$ -hydroxylation system of liver microsomes into three components.

*Netter et al. G71,785/69*: In mouse liver microsomes, the inhibition by metyrapone of p-nitroanisole and N-monomethyl-p-nitroaniline were shown to be competitive. The degree of inhibition was correlated to the amount of metyrapone bound to cytochrome P-450. On the other hand, metyrapone does not seem to displace naphthalene from its binding to P-450. Possibly, simultaneous binding of substrate and inhibitor may occur at different binding sites of the same enzyme.

*Wada et al. H19,993/69*: Studies on rat liver microsomes using radioactive cholesterol led to the assumption "that the microsomal electron transport system, involving cytochrome P-450, functions in 7 $\alpha$ -hydroxylation of cholesterol. The existence of a specific cytochrome P-450 for 7 $\alpha$ -hydroxylation, i.e., multiplicity of cytochrome P-450, is suggested."

*Bidleman & Mannering G80,042/70*: In rats, treatment with 3-MC causes the formation of P<sub>1</sub>-450, a variant of cytochrome P-450. It has been claimed that P<sub>1</sub>-450 is formed when

3-MC, or one of its metabolites combines irreversibly with the type I binding site of pre-existing P-450. However, the authors present evidence that P<sub>1</sub>-450 is synthesized independently of P-450 and probably does not contain 3-MC or any of its metabolites.

*Kato & Onada G75,544/70*: In rats, pretreated in vivo with various testoids, the affinity of P-450 for binding with numerous substrates is increased. Folliculoids counteract this effect.

*Kato et al. H27,934/70*: "The administration of morphine significantly decreased the content of cytochrome P-450 in male rats, but not in female rats. Progesterone and testosterone hydroxylation is markedly decreased in morphine-treated male rats, but not in the females. . . . The magnitude of spectral change induced by progesterone or testosterone per unit of P-450 content was decreased in morphine-treated male rats, but not in the females. Since the binding capacity of P-450 with progesterone or testosterone is dependent on the action of androgen, an impairment of the action of androgen by morphine is assumed to be a responsible factor."

*Mangum et al. G81,296/70*: A soluble cytochrome has been partially purified from pig kidney. Its absorption spectra in both the oxidized and reduced state resemble microsomal cytochrome b<sub>5</sub>.

*Mannering G78,897/70*: Review on the properties of P-450 as affected by environmental factors, particularly the administration of polycyclic hydrocarbons.

*Mannering G78,898/70*: Review on the role of substrate binding to P-450 hemoproteins in drug metabolism.

*Perry G74,358/70*: Cytochrome P-450 was demonstrated in microsomal preparations from several strains of houseflies. The highest yield was obtained from the abdomen. Housefly eggs contain no measurable amounts of cytochrome P-450, which appears in traces in the larvae, but declines to almost nil in the pupal stage. A few hours after the adult emerges, cytochrome P-450 rises rapidly.

*Stripp et al. H22,743/70*: In rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome

P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Yu & Gunsalus G81,295/70*: Cytochrome P-450<sub>cam</sub> was discovered and purified in homogeneous crystalline form from camphor grown *Pseudomonas putida* strain PpG786.

*Chaplin & Mannering G75,976/71*: Review of the literature and personal observations suggesting that the physical and biochemical properties of cytochrome P-450 depend largely upon its association with microsomal phospholipids. "Drugs have been classified into two groups depending upon whether they form a type I or a type II difference spectrum when they combine with cytochrome P-450." The studies suggest that the type I and type II binding sites differ and that the type I site is associated with membrane phospholipids (*cf.* also p. 103.)

*Estabrook et al. G81,261/71*: Description of a new spectral intermediate associated with cytochrome P-450.

*Estabrook et al. H34,125/71*: Studies on the influence of hepatic microsomal mixed function oxidation reactions on cellular metabolic control. The requirements of this system for NADPH and NADH could markedly affect the cytosol concentration and subsequent oxidized: reduced ratio of these pyridine nucleotides. The involvement of cytochrome b<sub>5</sub> in the oxidative reaction, the necessity of enzymes for the transfer of reducing equivalents from the reduced pyridine nucleotides to both cytochromes b<sub>5</sub> and P-450 and mercurial inhibition studies which demonstrate the autonomy of the units that catalyze the microsomal NADPH supported mixed-function oxidations help our understanding of the organization of this enzyme system. The authors speculate on possible models that might represent the spatial organization of these enzyme systems within the endoplasmic reticulum.

*Gillette H34,126/71*: The inducers of drug metabolism are classified into: 1. "Phenobarbital-like" agents which increase NADPH-

cytochrome c reductase and cytochrome P-450 thus augmenting the amount of cytochrome P-450-substrate complex and its rate of reduction; 2. polycyclic hydrocarbons (e.g. methylcholanthrene) which form a variant of cytochrome P-450 that differs from the usual form in its affinity to various drugs. This kind of inducer does not increase either NADPH-cytochrome c reductase or the rate of cytochrome P-450 reduction; 3. spironolactone and other catatoxic steroids which increase NADPH-cytochrome c reductase activity and the rate of cytochrome P-450 substrate reduction, but have little if any effect upon the amount of cytochrome P-450. The relationship between the electron flux and hepatic microsomal drug metabolism largely depends upon the substrate.

*Ishimura et al. G81,262/71:* Description of a new spectral species of P-450 interpreted to be an oxygenated form.

*Leber et al. H35,676/71:* In male rats, pretreatment with spironolactone stimulated the specific activity of isolated hepatic microsomes for aminopyrine demethylation and 4-methylumbelliferone glucuronidation. Microsomal cytochrome P-450 content increased about 66%. Under comparable conditions, ethacrynic acid increased the specific activity of the microsomes for the demethylation of aminopyrine and the P-450 content, but glucuronidation of 4-methylumbelliferone was not significantly altered. Another nonsteroidal diuretic, furosemid, did not influence any of these parameters.

*Mannering H34,127/71:* Additional evidence supporting the concept that polycyclic hydrocarbons cause the appearance of an abnormal "cytochrome P<sub>1</sub>-450" in the hepatic microsomes of the rat. This may be an aberrant hemoprotein which does not result from the combination of polycyclic hydrocarbons with cytochrome P-450 but represents a specific molecular entity.

*Solymoss et al. G79,015/71:* In rats, PCN (unlike the naturally-occurring pregnenolone) enhances the plasma clearance of pentobarbital and the production of <sup>14</sup>C-pentobarbital metabolites. It also increases liver weight, microsomal protein concentration, NADPH-cytochrome c reductase activity and cytochrome P-450 content. It is concluded "that microsomal enzyme-induction accounts for the remarkable resistance-increasing effect of this steroid against many toxicants."

*Stripp et al. G79,538/71:* In rats, the induction of hepatic microsomal enzymes by spiro-

nolactone "differed from the phenobarbital or methylcholanthrene induction in that it did not increase cytochrome P-450 content or microsomal protein. Furthermore the induction seemed to be sex dependent."

*Zsigmond & Solymoss G79,025/71:* In rats, PCN increases hepatic microsomal protein and cytochrome P-450 content. In vitro incubation of labelled progesterone with these microsomes shows enhanced progesterone biotransformation. The production of several hydroxylated progesterone metabolites (including 6 $\beta$ - and 16 $\alpha$ -hydroxyprogesterone) is accelerated by PCN.

### Other Enzymes

*Stoffel G66,819/61:* Description of the biosynthesis of polyenoic fatty acids by dehydrogenating enzyme systems of hepatic microsomes.

*Axelrod D64,159/63:* An enzyme that forms epinephrine from p- and m-sympathol, and dopamine from p- and m-tyramine, is demonstrated in the microsomes of rabbit liver. It requires NADPH<sub>2</sub> and is nonspecific in that it can form catechols from the following, normally occurring, or foreign phenols: p- and m-octopamine, p-hydroxyephedrine, phenol, stilbestrol, N-acetyl-p-aminophenol, estradiol and N-acetyl serotonin.

*Berlin & Schimke G37,616/65:* In adrenalectomized rats, 4 days of pretreatment with cortisone increased the activity of hepatic TPO, TKT, glutamic-alanine transaminase and arginase. Differences in the turnover rate or enzymes thus induced may simulate differential selective-inducing effects upon one or the other enzyme.

*Yamamoto et al. G67,939/67:* Description of some properties of 2,3-oxidosqualene sterol cyclase in hepatic microsomes of the pig.

*Roach et al. G68,807/69:* Review of the literature and personal observations on the oxidation of ethanol by rat liver in vitro. "It is concluded that ethanol oxidation by the microsomal fraction is mediated through H<sub>2</sub>O<sub>2</sub> dependent systems one of which is catalase."

*Valeriate et al. G67,621/69:* Purification and properties of rat liver TKT induced by triamcinolone.

*Ward & Pollak G69,320/69:* The structural proteins of rat liver microsomal membranes are made up of a heterogenous group of proteins which can be characterized by their phospholipid-binding capacity. "It is suggested that reticulosomes consist largely of enzymic proteins of the endoplasmic reticulum."

## IV. GENERAL PHARMACOLOGY

### *SYNTOXIC COMPOUNDS*

The term syntoxic compounds comprises all drugs and hormones which increase resistance merely by influencing the reactions of the body, not by destroying or eliminating the pathogens. Thus, for example, the inhibition of inflammation or of immune reactions by antiphlogistic or immunosuppressive hormones and drugs, as well as the maintenance of the blood pressure by vasoactive substances, would be considered as syntoxic reactions as long as these effects are not dependent upon the chemical inactivation of the pathogens.

This entire field has been covered in our earlier publications (Selye B40,000/50, B58,650/51, C19,000/56, G19,425/65, E5,986/66; Selye et al. B87,000/52, B90,100/53, C1,001/54, C9,000/56) and it has also been summarized in the Introduction and History sections of the present volume, hence, we shall not consider it again here.

### *CATATOXIC COMPOUNDS (AGONISTS)*

What little we know about the so-called "structure-function" or pharmacological correlations among catatoxic compounds will be summarized in the "Synopsis" (p. 768 ff.). Suffice it here to reemphasize that systematic studies on the structural prerequisites of catatoxic actions have been performed only in connection with steroids. In this respect the main generalizations arrived at were that nitrile and spirolactone groups as well as the 19-nor-steroid configuration are in general advantageous for catatoxic activity, although their effect is largely dependent upon other structural characteristics of the molecule.

With regard to pharmaco-pharmacologic interrelations we have seen that the catatoxic potency is independent of any other known hormonal property, but among steroids those exhibiting anabolic or antimineralocorticoid properties are always endowed with some catatoxic potency, whereas folliculoids appear to be singularly ineffective in this respect.

Literature on some of the salient characteristics of various syntoxic and catatoxic compounds is presented in the following Abstract Section (with special reference to glucocorticoids, testoids, anabolics, antimineralocorticoids, antifolliculoids, antitestoids, myoneural blocking agents and interactions between inducers).

#### *Syntoxic Compounds*

**Corticoids.** *Janoski et al. E7,896/68:* Review (112 pp., about 700 refs.) "On the pharmacologic actions of 21-carbon hormonal steroids

('glucocorticoids') of the adrenal cortex in mammals." A large section is devoted to the effect of glucocorticoids upon reactions mediated through lysosomal enzymes.

*Williams E8,139/68, (p. 371):* For compara-

tive purposes, it is important to determine the relative anti-inflammatory and Na-retaining activity of the most commonly used glucocorticoids and gluco-mineralocorticoids. Such comparisons have only limited value because they depend upon the test conditions; still, the following approximate tabulation is of value:

Table 2. *Relative anti-inflammatory and Na-retaining activities of some antiphlogistic corticoids*

Compound	Relative potency compared to cortisol	Relative Na-retaining activity
Cortisol	1	++
Cortisone acetate	0.8	++
Prednisolone	4	+
Prednisone	3.5	+
Triamcinolone	5	0
6-Methylprednisolone	5	0
Haldranolone	10	0
Betamethasone	25	0
Dexamethasone	30	0
9 $\alpha$ -Fluorohydrocortisone <sup>a</sup>	15	++++

<sup>a</sup> Used chiefly topically or as a Na-retainer.

### Catatoxic Compounds (Agonists)

**Testoids, Anabolics.** *Overbeek E 8,318/66:* A review (78 pp., about 220 refs.) on anabolic steroids.

*Krüs Kemper E 933/68:* Monograph (236 pp., 1367 refs.) on the pharmacology of anabolic steroids. Special attention is given to the relationship between virilizing and anabolic effects, the various tests for anabolic and anticatabolic actions, as well as clinical applications, but the catabolic and enzyme-inducing effects are only briefly mentioned.

**Antiglucocorticoids.** *Linét G 79,963/70:* Detailed review of the literature and personal observations on the effect of anabolic testoids upon glucocorticoid overdosage in animals and man. Special attention is given to the effect of anabolic testoids upon glucocorticoid-induced loss of body weight and other metabolic changes, adrenal atrophy, osteoporosis, wound healing, inflammation and gastric ulcer formation. Antiglucocorticoids devoid of anabolic properties are also surveyed. In clinical medi-

cine, various forms of hyperglucocorticoidism are not, or only moderately, improved by treatment with anabolic testoids. [Excellent source of pertinent references (H.S.).]

**Antimineralocorticoids.** *Kagawa E 4,593/64:* Review (63 pp., about 400 refs.) on "Anti-Aldosterones."

*Kagawa E 4,772/64:* Review (11 pp., about 50 refs.) on the "Action of Anti-Aldosterone Compounds in the Laboratory."

**Antifolliculoids.** *Selye A 60,638/44:* In rodents, the production of anterior pituitary hormones by estradiol is inhibited by a variety of steroids, most of which are androstene derivatives and are designated as "antifolliculoids."

*Emmens et al. D 25,360/62:* Description of the antifolliculoid effects of dimethylstilbestrol (DMS).

*Duncan et al. D 58,473/63:* In rats, U-10520 A and U-11100 A, derivatives of 1,2-diphenyl-3,4-dihydronaphthalene, possess antifolliculoid activity as judged by the inhibition of estradiol effects after ovariectomy. Both compounds also interrupt pregnancy when administered during the first four days of gestation.

*Pincus E 689/65:* Monograph (360 pp., 1459 refs.) with sections on the literature concerning antifolliculoids and antiluteoids.

*Gaunt et al. G 63,202/68:* A review on the metabolic effects of nonsteroidal antifolliculoids related to diethylstilbestrol and chlorotrianisene, drawn to emphasize structural similarities, *cf.* drawing p. 55.

**Antiluteoids.** *Pincus E 689/65:* Monograph (360 pp., 1459 refs.) with sections on the literature concerning antifolliculoids and antiluteoids.

**Antitestoids.** *Gaunt et al. G 63,202/68:* A review on the metabolic effects of anti-testoids. Antagonists related to testosterone and progesterone, *cf.* drawing p. 56.

*König G 66,684/69:* Brief review of the literature on "antiandrogens" with special reference to cyproterone. [No mention is made of its possible effect upon enzyme induction (H.S.).]

*Bottiglioni et al. G 76,203/69:* Cyproterone does not interfere with testosterone formation from radioactive pregnenolone in vitro. Its antitestoid effect is exclusively peripheral.

*Prasad et al. G 78,450/70:* In rats, continuous release of microquantities of cyproterone from Silastic capsules causes infertility with loss of sperm motility at dose levels which have no evident antitestoid effect.

Chlorotrianiisene

ORF-3858

CN-55,945-27

U-11,555A

## Antifolliculoids

**Myoneural Blockers.** *Baird H27,487/70:* Clinical "experience with pancuronium suggests that it is a useful non-depolarizing myoneural blocker with few side-effects. The absence of cardiovascular side-effects makes the drug particularly valuable in poor-risk patients and in intensive care units."

*Chaouki et al. G77,223/70:* In 50 patients,

pancuronium bromide was found to be an active non-depolarizing neuromuscular blocking agent about 5 times as active as curare and 25 times more potent than gallamine triethiodide. Its advantages are rapid onset of action, no release of histamine and little disturbance in blood pressure, because of a weak ganglioplegic action.

### Antitestoids

#### *Interactions between Inducers*

The enzyme induction pattern of various inducers such as phenobarbital and the carcinogens is different. Summation of effects may be obtained by giving these two types of inducers conjointly.

Interactions between the protective effects of various steroids have not yet been systematically explored but these are now under intensive study at our Institute. It will be interesting to note the effects of combined treatment with syntoxic and catatoxic steroids or with two catatoxic steroids having different protective spectra. Unfortunately, systematic studies of this type are extremely costly and time consuming because of the large number of combinations to be explored. Yet, even

combinations between protective hormones and catatoxic drugs should be examined since the interactions between them are not only of considerable theoretic but also possibly of practical interest.

*Conney F 88,649/67:* Review of data in the literature showing that the enzyme induction patterns of phenobarbital and carcinogens are different. "When rats were given doses of the inducers that were maximal for their characteristic enzyme inductions, the liver microsomes were more active in metabolizing drugs when both 3,4-benzpyrene and phenobarbital had been given than when either had been given separately." Similar studies suggest that anabolic steroids and phenobarbital induce drug-metabolizing activity through different mechanisms.

*Badarau et al. G 69,247/68:* In rats, various adrenal and ovarian steroids can produce necrosis of the trophoblast during the early

stages of gestation. In certain steroid combinations, a mutual antagonism has been noted. [The cursory descriptions in this brief abstract do not permit evaluation of the data (H.S.).]

*Fouts G 76,868/70:* Experiment on concurrent treatment with several inducers showed that enzyme induction by maximally effective doses of chlordane+phenobarbital was no greater than the effect of chlordane or phenobarbital given alone. However, combinations of chlordane with benzpyrene or 3-methylcholanthrene resulted in additive effects. Methyltestosterone+chlordane gave the same effect as chlordane alone. The interpretation of these results has not been attempted.

### ANTICATATOXIC COMPOUNDS (ANTAGONISTS)

Anticatatoxic effects can be elicited in various ways. The underlying mechanisms have not yet been clarified for each anticatatoxic substance but there appears no doubt that we should distinguish between:

A. **Inhibitors** which antagonize the enzymes themselves (e.g., SKF 525-A).

B. **Blockers** which impede the synthesis of enzymes by interfering with the production of RNA or of the hormones whose synthesis it directs (e.g., actinomycin, puromycin, ethionine).

C. **Competitors** which act by competitively inhibiting the action of enzymes upon their substrates. Such competitive inhibition may occur between two substrates or even between a substrate and an inducer since many inducers are actually also substrates themselves.

Several anticatatoxic substances may act through a combination of the above mentioned effects.

### *Inhibitors of Enzymes*

**Classification.** On theoretical grounds, Netter (E52,768/62) enumerated the following possible mechanisms for enzyme inhibition:

1. The inhibitor combines directly with the enzyme at the active center (competitive inhibition) or at some other point (noncompetitive inhibition). Many antimetabolites act by competitive inhibition of enzymes participating in the metabolism of physiologic substrates. An example of competitive inhibition in drug metabolism is the effect of esters or amides on procaine hydrolysis.

2. The inhibitor decreases a coenzyme concentration by interfering with its biosynthesis or accelerating its catabolism. The latter mechanism is exemplified by the inhibition of methylation (e.g., choline biosynthesis), by nicotinamide, which forms methylnicotinamide, thereby depleting active methyl groups from the coenzyme.

3. The inhibitor alters membrane permeability. This mechanism has not yet been proven to play an important role.

*Conney & Burns G67,166/62:* Review on the inhibition of microsomal enzyme actions by SKF 525-A, CFT 1201, Lilly 18947, iproniazid, Sch 5712, MPDC, JB-516, and EPDA.

*Netter E52,768/62:* Review (15 pp., 55 refs.) on "Drugs as Inhibitors of Drug Metabolism" with special reference to SKF 525-A and related compounds.

*King & Burgard G46,498/67:* Review on various types of antagonists of drug-metabolizing enzymes.

*Mannering G71,818/68:* Review on microsomal enzyme induction with a special chapter on inhibitors of the drug-metabolizing system.

*Mannering G75,980/68:* Review (26 pp., 89 refs.) on stimulation and inhibition of drug metabolism.

*Mannering G74,572/71:* Review on the inhibition of drug metabolism "as it is more narrowly defined to mean the interference of the metabolism of one agent by another agent at the enzymic site."

### SKF 525-A ( $\beta$ -diethylaminoethyl diphenylpropylacetate).

SKF 525-A is considered to be a selective inhibitor of microsomal drug-oxidizing systems. It has no sedative action of its own, but when administered prior to agents subject to detoxication by microsomal enzymes it strikingly prolongs their pharmacologic action. For example, rats given hexobarbital plus SKF 525-A slept 35 times longer than rats given the barbiturate alone. Both treatment with SKF 525-A in vivo and addition of the drug to liver slices also reduce subsequent enzymic detoxication in vitro. This shows that the compound acts directly upon microsomal enzyme systems, not merely upon their synthesis in vivo.

Kinetic analysis revealed a noncompetitive type of inhibition, for example, of O-demethylation of p-nitroanisole in vivo and in vitro; conversely the inhibition of plasma procaine esterase is allegedly competitive. SKF 525-A inhibits many oxidative reactions in vivo and in vitro (e.g., side chain oxidation and O-dealkylation, N-dealkylation, deamination, aromatic hydroxylation and sulfoxide formation) presumably by interfering with some step common to all of these reactions. However, NADPH oxidase activity of hepatic microsomes is unaffected by SKF 525-A, although drug metabolism is inhibited in the same preparation. The broad spectrum of reactions inhibited by SKF 525-A includes azo- and nitro-reduction (dependent upon NADPH, but not oxygen) glucuronide formation (a microsomal

transfer reaction independent of NADPH); however, not all microsomal reactions are equally sensitive to inhibition by this compound.

Unlike iproniazid and many other microsomal enzyme inhibitors, SKF 525-A is strongly bound to hepatic microsomes and cannot be removed by dialysis or washing.

The fact that SKF 525-A does not act by increasing the drug sensitivity of tissues but merely by delaying their metabolic degradation, is particularly well demonstrated by observations on its influence upon barbiturate anesthesia. In otherwise untreated and SKF 525-A-pretreated rats given hexobarbital, the plasma level of the barbiturate is the same at the moment of awakening although SKF 525-A greatly prolongs the sleeping time. Furthermore, if rats are given SKF 525-A immediately after awakening from hexobarbital anesthesia they do not fall asleep again as they would if SKF 525-A had increased the barbiturate sensitivity of their central nervous system.

Among the hydrolytic products of SKF 525-A, diphenylpropylacetic acid is a potent inhibitor of drug-metabolizing enzymes, whereas diethylaminoethanol is not. It has been claimed so often that microsomal enzymes influence only "xenobiotics," that is, foreign substances, yet SKF 525-A also inhibits the metabolism of various naturally-occurring substrates (e.g., the tricarboxylic acid cycle intermediates: succinate, fumarate and maleate) in rat liver mitochondrial preparations. On the other hand, it has been said that since SKF 525-A is relatively nontoxic the enzyme systems it inactivates "are not essential to the normal economy of the body but operate primarily against toxic influences of foreign compounds." However, in rat liver homogenates the conversion of mevalonate-2-<sup>14</sup>C to cholesterol and other nonsaponifiable lipids is inhibited by SKF 525-A and plasma cholesterol levels are lowered. Furthermore, SKF 525-A also inhibits the steroid hydroxylases in the hepatic microsomes of the rat, thus blocking the hydroxylation of testosterone and estradiol as well as the degradation of cortisol.

Mestranol (a folliculoid) prolonged while lynestrenol (a luteoid) reduced, pentobarbital sleeping time in mice. The effect of lynestrenol was abolished; that of mestranol potentiated by SKF 525-A. Lynestrenol increases, whereas both mestranol and SKF 525-A reduce, barbiturate clearance from the plasma. Presumably folliculoids share certain enzyme inhibitory reactions of SKF 525-A. Lynestrenol reduces, whereas mestranol or SKF 525-A increases, the anticonvulsive effect of various drugs. This may also be due to altered microsomal drug metabolism but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentration the latter mechanism may likewise be involved.

Using a variety of *in vivo* or *in vitro* test procedures, it has been shown that SKF 525-A inhibits the biotransformation and/or the catatoxic action of innumerable agents, e.g.:

Alanine-1-<sup>14</sup>C  
Aminopyrine  
p-Aminosalicylic acid  
Amobarbital  
Amphetamine  
Azo dyes

Barbital  
Barbiturates (Various)  
Bishydroxycoumarin  
Butethal  
Carisoprodol  
Catatoxic steroids (Various)

CCl <sub>4</sub>	N-Methylanaline
Chloral hydrate	3-Methyl-4-monomethylaminoazobenzene
Chlordiazepoxide	Methylparafynol
Chloretone	Monobutyl-4-aminoantipyrine
Chlorpromazine	Monoethyl-4-aminoantipyrine
Cholesterol	Monomethyl-4-aminoantipyrine
Codeine	Morphine
Cortisol	Narcotics (Various)
CS <sub>2</sub>	Naturally-occurring substrates (Various)
Cyclophosphamide	Nikethamide
Dethioacetylated 4-6-dienone	o-Nitroanisole
Diazepam	Norbolethone
Digitoxin	7-OHM-12-MBA
Diphenylhydantoin	Pentobarbital
DMBA	Pethidine
Ephedrine	Phenaglycodol
Estradiol	Phenobarbital
Estrone	Prednisolone
p-Ethoxyacetanilide	Prednisone
Ethylestrenol	Primidone
Glutethimide	Procaine
Hexethal	Progesterone
Hexobarbital	Secobarbital
d-Hexobarbital	Spirocholactone
Hydroxydione	Strychnine
Indocyanine green	Succinylcholine
Indomethacin	Sulfacetamide
Lynestrenol	TEA
Meperidine	Testosterone
Mephesisin	Thioethamyl
Meprobamate	Thiopental
Mestranol	Thiophosphates
Methadone	Triflupromazine
Methorphan	Urethane

*LaDu et al. G74,654/53:* The inhibitory action of SKF 525-A is noncompetitive on the microsomal enzyme system that catalyzes N-demethylation of **monomethyl-4-aminoantipyrine**.

*Axelrod et al. D79,919/54:* In rats, SKF 525-A prolongs the action and inhibits the rate of biotransformation of **hexobarbital** and **pentobarbital**. The inhibitor also retards the demethylation of **meperidine**, **aminopyrine** and **ephedrine**.

*Cook et al. D23,923/54:* First demonstration of the fact, that the inhibitory effect of SKF 525-A on drug-metabolizing enzymes accounts for the long duration of drug action as exemplified by **hexobarbital** sleeping time. SKF 525-A markedly prolongs the hypnotic action of hexobarbital in mice and rats without significantly altering its toxicity. The length of hexobarbital sleeping time thus achieved cannot be duplicated with any dose

of the hypnotic agent alone. In this respect, SKF 525-A is equally effective i.p. and p.o., the latter route being less toxic. SKF 525-A is almost immediately effective and the duration of its action is approximately 15 hrs.

*Cook et al. D94,204/54:* The analgesic action of **methadone**, **meperidine**, **morphine**, **codeine** and **methorphan** was enhanced by SKF 525-A in the rat, but the LD<sub>50</sub>'s of **morphine** and **meperidine** were not significantly altered.

*Cook et al. E34,395/54:* Experiments on rats and mice indicate that SKF 525-A potentiates the hypnotic effects of **hexobarbital**, **secobarbital**, **pentobarbital**, **amobarbital**, **butethal**, **hexethal**, **phenobarbital** and **chloral hydrate**, but does not significantly influence that of **barbital**, **thioethamyl**, **thiopental** or **methylparafynol**.

*Cooper et al. H25,117/54:* SKF 525-A also inhibits the metabolism of various **naturally-**

occurring substrates (e.g., the tricarboxylic acid cycle intermediates: succinate, fumarate, and maleate) in rat liver mitochondrial preparations. Among the hydrolytic products of SKF 525-A, diphenylpropylacetic acid is a potent inhibitor of drug-metabolizing enzymes, whereas diethylaminoethanol is not.

*Brodie et al. G66,772/55:* Although SKF 525-A inhibits various hepatic microsomal enzyme activities in the rabbit's liver it is relatively nontoxic and, hence, "one can speculate that these systems are not essential to the normal economy of the body, but operate primarily against the toxic influences of foreign compounds that gain access to the body from the alimentary tract."

*Fouts & Brodie D83,597/55:* SKF 525-A and the closely-related compound Lilly 18947 prolong the hypnotic action of hexobarbital in mice by inhibiting its metabolism by hepatic microsomes.

*Axelrod G74,652/56:* SKF 525-A inhibits the O-dealkylation of codeine but not that of p-ethoxyacetanilide. Presumably, more than one O-dealkylating enzyme exists in the liver.

*Brodie C12,157/56:* Review on the early work on SKF 525-A showing that it prolongs the effect of hexobarbital, pethidine, codeine, morphine, mephesisin, amphetamine and other compounds. The metabolic pathways through which these drugs are normally inactivated, and their blockade by SKF 525-A are described in detail.

*Richards & Taylor H19,235/56:* Review on the pharmacology of barbiturates with a special section on the sleep-enhancing effect of SKF 525-A and related compounds.

*Murphy & DuBois D28,546/58:* The activity of the microsomal enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). Yet, in vivo, adult males are more resistant to EPN than females, perhaps because the accelerated formation of toxic oxidation products is overcompensated by a more efficient detoxication of the latter. The low enzyme activity of female livers is enhanced by pretreatment with testosterone in vivo, whereas the high activity of male livers is diminished by previous castration, partial hepatectomy or treatment with progesterone or diethylstilbestrol. SKF 525-A inhibits, whereas pretreatment with carcinogens or a

protein-deficient diet enhances, the activity of the thiophosphate-oxidizing enzyme.

*Takemori & Mantering H24,294/58:* SKF 525-A inhibits the N-demethylation of several narcotics but does not inhibit the demethylation of the azo dye, 3-methyl-4-monomethyl-aminoazobenzene. Such observations suggest that inhibitors of drug-metabolizing enzymes can be used as tools to determine if more than one enzyme system can catalyze the same reaction.

*Gaudette & Brodie E90,437/59:* SKF 525-A inhibits the N-dealkylation of aminopyrine and monomethyl-4-aminoantipyrene but not that of monoethyl-4-aminoantipyrene, monobutyl-4-aminoantipyrene, or N-methylaniline. Presumably, more than one enzyme system can N-dealkylate drugs.

*Netter G74,665/59:* The inhibitory action of SKF 525-A on plasma procaine esterase is competitive.

*Sulman et al. C79,823/59:* In rats injected for 4 months with prednisone or prednisolone, an increase in the hepatic content of the enzymes which decompose these steroids could be demonstrated in vitro. Various histologic stains failed to reveal any associated light-microscopic change in the hepatocytes. Addition of SKF 525-A to the homogenate of activated livers blocked their enzymic activity.

*Dick et al. G74,672/60:* In dogs, chronic administration of SKF 525-A lowers plasma cholesterol.

*Holmes & Bentz G74,656/60:* In rat liver homogenates, the conversion of mevalonate-2-<sup>14</sup>C to cholesterol and other nonsaponifiable lipids is inhibited by SKF 525-A. It remains to be shown whether this effect could explain the lowering of plasma cholesterol levels obtained in dogs by SKF 525-A.

*Kato & Chiesarà G68,581/60:* Male rats are more resistant than females to the toxic action of strychnine. This difference is abolished by SKF 525-A.

*Netter G74,666/60:* The inhibitory action of SKF 525-A on O-demethylation of o-nitroanisole is noncompetitive.

*Neubert & Timmler G74,668/60:* SKF 525-A and CFT 1201 inhibit incorporation of alanine-1-<sup>14</sup>C into hepatic microsomal protein.

*Kato et al. G66,023/61:* Adult (unlike immature) male rats are less sensitive to carisoprodol-induced muscular paralysis than females. Castration or treatment with SKF 525-A abolishes the increased resistance of the adult male rat. Incubation of liver slices with carisoprodol shows that the resistance of

the male is due to accelerated substrate inactivation. No sex difference is noted in adult mice or guinea pigs.

*Bella et al. G77,568/62:* In various species, SKF 525-A enhances the neuromuscular-blocking action of **succinylcholine**, and similar compounds. The inhibition appears to occur at the neuromuscular junction.

*Brock & Hohorst G71,533/62:* **Cyclophosphamide** has no cytotoxic effect upon Yoshida sarcoma cells in vitro but it is rapidly transformed into an active compound in mice, rats and dogs in vivo. The active form is demonstrable in the blood and urine by bioassay if added to tumor cells in vitro. In completely hepatectomized rats, only a little fraction of cyclophosphamide is thus activated. However, activation can be demonstrated in vitro by incubation with liver slices. Pretreatment of rats with SKF 525-A inhibits in vivo activation which presumably takes place in hepatic microsomes.

*Kato et al. D38,983/62:* Male rats are more resistant than females to **strychnine** intoxication especially if the drug is given s.c. whereby its activity is delayed. The greater strychnine metabolizing potency of microsomes from male rats than from females has also been demonstrated in vitro. SKF 525-A increases strychnine toxicity and renders both sexes equally sensitive.

*Kato & Vassanelli D40,237/62:* "Rats pretreated with **phenobarbital**, **phenaglycodol**, **glutethimide**, **nikethamide**, **chlorpromazine**, **triflupromazine**, **meprobamate**, **carisoprodol**, **pentobarbital**, **thiopental**, **primidone**, **chlorethone**, **diphenylhydantoin** and **urethane** showed an accelerated metabolism of meprobamate and, at the same time, a diminished duration of sleeping time and paralysis due to meprobamate." SKF 525-A counteracted these actions of the enzyme inducers.

*Rümke G69,768/63:* In mice, SKF 525-A, phenobarbital, chlorpromazine, hexobarbital and iproniazid given one hour before **hydroxydione** i.v. increases sleeping time. When the interval is two days, single doses of SKF 525-A, phenobarbital or chlorpromazine decrease hydroxydione anesthesia. Phenytoin, acetylcarbromal, morphine, chloramphenicol, 5-HT, phenobarbital and hydroxydione given one hour before hexobarbital increase the duration of anesthesia whereas dioxone and chlorothiazide decrease it. It is concluded that central effects as well as changes in microsomal enzyme activity may be involved.

*Kuntzman et al. F27,893/64:* SKF 525-A inhibits the **steroid hydroxylase** present in the microsomal fraction of rat liver.

*Paeile et al. F52,633/64:* Adult male rats are more resistant to **procaine** than adult females. Chronic CCl<sub>4</sub> poisoning, pretreatment with SKF 525-A and orchidectomy diminish the resistance of the males approximately to the female level. The plasma procainesterase activity is approximately the same in both sexes and not affected by orchidectomy or CCl<sub>4</sub> intoxication.

*Rogers & Fouts F27,894/64:* In vitro experiments in rats have shown that SKF 525-A is strongly **bound to hepatic microsomes** and cannot be removed by dialysis or washing, whereas the reverse is true of iproniazid and other microsomal enzyme inhibitors.

*Conney et al. G65,135/65:* In the rat, SKF 525-A markedly inhibits **hexobarbital** metabolism and the hydroxylation of **testosterone** and **estradiol**.

*Kupfer & Peets F85,854/67:* **Cortisol** s.c. increases hepatic TKT activity in adrenalectomized male rats and this effect is further augmented by SKF 525-A which in itself has no effect. In intact rats SKF 525-A raises hepatic TKT activity in itself but this effect is not further augmented by cortisol. Possibly the potentiation of cortisol induction of TKT by SKF 525-A is due to an inhibition of the degradation of cortisol.

*Mannering G71,818/68 (p. 105):* Review listing the **large number of substrates** whose in vivo or in vitro transformation by hepatic microsomal enzymes is inhibited by SKF 525-A. However, this drug does not inhibit the biotransformation of all substrates known to be metabolized by microsomal systems. "These differences in the action of SKF 525-A on the biotransformation of different drugs strengthen the view that more than one drug-metabolizing enzyme system exists in hepatic microsomes or that the rate-limiting component may not be the same in all species or under all conditions."

*Blackham & Spencer G69,913/69:* **Mestranol** (a folliculoid) prolonged while **lynestrenol** (a luteoid) reduced the duration of pentobarbital and hexobarbital sleeping time in mice. Barbitol was not affected. The effects of **lynestrenol** were abolished by SKF 525-A while those of **mestranol** were markedly potentiated. **Lynestrenol** increased, whereas **mestranol** and SKF 525-A reduced, the rate of clearance of barbiturate from the plasma.

*Bond et al. H 18,559/69:* In rats, pretreatment with phenobarbital does not change the LD<sub>50</sub> of CS<sub>2</sub> p.o. but results in the production of central lobular hepatic necrosis. After pretreatment with SKF 525-A these hepatic lesions no longer occur in rats pretreated with phenobarbital and then given CS<sub>2</sub>. SKF 525-A may inhibit the production of toxic CS<sub>2</sub> metabolites by hepatic microsomal enzymes.

*Furner et al. H 17,931/69:* In rats, **d-hexobarbital** is about twice as susceptible to inhibition by SKF 525-A as dl- or l-hexobarbital.

*Hart & Adamson G 69,481/69:* In mice "SKF 525-A and Lilly 18947 reduced the lethality of **cyclophosphamide** over a 28 day observation period while pretreatment with phenobarbital did not change the 28 day lethality. Neither SKF 525-A nor phenobarbital had an effect on the antitumor efficacy of cyclophosphamide. Mice housed on cedar chip bedding were less susceptible to the lethal effects of cyclophosphamide, but tumor bearing mice on this bedding showed greater antitumor response to the drug than those on hardwood bedding."

*Bird et al. H 30,425/70:* In rats less than 30 days of age, **DMBA** or **7-OHM-12-MBA** produces no adrenal necrosis unless animals are pretreated with ACTH. However, a single i.v. injection of 7-OHM-12-MBA on the 17th day of gestation causes adrenal necrosis in the embryos as well as in the mothers. Pretreatment with SKF 525-A protected the adrenals both of the embryos and of the mothers.

*Blackham & Spencer G 73,813/70:* In mice, lynestrenol reduced, whereas mestranol or SKF 525-A increased the anticonvulsive effect (tested with electroshock) of **diphenylhydantoin**, **phenobarbital**, **chlordiazepoxide** and **diazepam** administered i.p. after five days of pretreatment. This may be due to altered microsomal drug metabolism but since mestranol and lynestrenol have opposite effects upon the brain 5-HT concentrations, the latter mechanism must also be considered.

*Levine G 75,350/70:* In rats, SKF 525-A has previously been found to depress the biliary excretion of **indocyanine green** (ICG), a dye which is not metabolized prior to excretion. With this exception, SKF 525-A depresses only the biliary excretion of compounds that are metabolized. However, it is now shown that the biliary excretion of ICG and the bile flow itself are not influenced by SKF 525-A

provided normal body temperature is maintained.

*McLean and Marchand G 78,253/70:* In rats, SKF 525-A decreases the plasma concentration of orally-administered **barbital**, **p-aminosalicylic acid**, **sulfacetamide** and **CCl<sub>4</sub>**, presumably because of a nonspecific effect on the gastrointestinal absorption of polar and nonpolar compounds. Various other mechanisms of SKF 525-A action are discussed, which must be kept in mind in interpreting the possible effect of SKF 525-A through the inhibition of hepatic microsomal drug metabolism.

*Levin et al. H 26,593/70:* In rats, CCl<sub>4</sub> given to immature females 24 hrs before sacrifice inhibited the activity of hepatic microsomal enzymes that hydroxylate estradiol-17 $\beta$  and estrone. This inhibition was reflected in vivo by an altered metabolism of estradiol-17 $\beta$  and estrone, by a potentiation of the uterotrophic action of folliculoids and by an increased concentration of these steroids in the uterus. By contrast, tetrachloroethylene did not influence the action of estrone. SKF 525-A and desipramine, which are also inhibitors of drug metabolism, likewise potentiate the uterotrophic action of **estrone** in immature rats.

*Solymoss et al. G 60,099/70:* In rats, pentobarbital anesthesia is inhibited by spironolactone, ethylestrenol, norbolethone and, to a lesser extent, even by progesterone. These **catatoxic steroids** also accelerate the disappearance rate of barbiturate from the blood; their effects are counteracted by SKF 525-A. Irrespective of the steroid pretreatment, the rats awake roughly at the same blood pentobarbital level.

*Solymoss et al. G 70,423/70:* In rats, pretreatment with spironolactone, norbolethone or ethylestrenol enhances the disappearance of bishydroxycoumarin from blood and restores the prothrombin time. Triamcinolone and progesterone fail to do so. SKF 525-A increases the blood concentration and the anticoagulant effect of **bishydroxycoumarin** and counteracts the beneficial effect of **ethylestrenol**.

*Solymoss et al. G 70,445/70:* In rats, the acute hematologic changes observed six days after a single oral dose of DMBA are suppressed by spironolactone but the alterations normally observed 12 days after DMBA still occur. The hematologic damage produced by a smaller dose of **DMBA** i.v. is prevented both by spironolactone and by SKF 525-A. Apparently "the hemopoietic alterations, elicited by DMBA, are dose-dependent and influenced also

by the biotransformation of this polycyclic hydrocarbon, since both acceleration (by spironolactone) and blockade (by SKF 525-A) of this latter process can suppress the development of hematologic alterations."

*Solymoss et al. G70,461/70*: In rats, spironolactone, norbolethone and ethylestrenol pretreatment accelerate the disappearance-rate of digitoxin from serum in proportion to the inhibition of the convulsions. Partial hepatectomy reduces digitoxin elimination. The action of **spironolactone** is blocked by SKF 525-A.

*Solymoss et al. G70,463/70*: In rats, pretreatment with spironolactone, norbolethone or ethylestrenol accelerated the plasma clearance of digitoxin, in proportion to the in vivo protective effect of these catatoxic steroids. Partial hepatectomy reduces digitoxin clearance. The effect of **spironolactone** is suppressed by SKF 525-A and cycloheximide.

*Solymoss et al. G70,464/70*: In rats, spironolactone shortens the half-life of its main metabolite, the **dethioacetylated 4,6-dienone** (metabolite A), which is interconvertible with the 17-hydroxy carboxylic acid derivative (metabolite B). This alteration is only slightly accentuated if the steroid is given chronically and it wears off within eight days after spironolactone treatment is interrupted. After a test dose of spironolactone or of its metabolites A and B, partial hepatectomy delays the blood clearance of metabolite A. Cycloheximide and SKF 525-A also suppress the blood clearance of metabolite A under these conditions. Presumably "spironolactone influences its own biotransformation and the steroid is also a substrate of the hepatic drug-metabolizing enzymes which are induced by spironolactone itself."

*Solymoss G70,484/70*: In rats, the plasma clearance of digitoxin is accelerated by spironolactone, norbolethone and ethylestrenol in doses that protect against the toxicity of the

alkaloid in vivo. On the other hand, partial hepatectomy reduces digitoxin plasma clearance, and increases the severity of the convulsions. The protective action of the **catatoxic steroids** is suppressed by SKF 525-A and cycloheximide.

*Soyka et al. H33,315/70*: Partial hepatectomy sensitized only slightly to the anesthetic effect of **5 $\beta$ -pregnane-3 $\alpha$ -ol-20-one**, whereas it greatly prolonged sleeping time following treatment with progesterone and many other steroids. Neither inhibition of hepatic mixed function oxidase activity by SKF 525-A nor its stimulation by 3-MC affected the duration of pregnanolone narcosis and even phenobarbital reduced its length only slightly. These findings, and distribution studies, "suggest that termination of hypnosis is due mainly to redistribution with hepatic metabolism playing a relatively minor role." [Species not mentioned; probably rat (H.S.).]

*Solymoss et al. G60,093/71*: In rats, spironolactone, norbolethone and progesterone, unlike hydroxydione, accelerate the clearance from the blood of s.c.-injected indomethacin. SKF 525-A significantly suppresses the activity of these **catatoxic steroids** which probably act through increased metabolic degradation of indomethacin.

*Solymoss & Varga G70,500/71*: In rats, spironolactone, norbolethone and ethylestrenol diminish the anticoagulant action and accelerate the plasma clearance of bishydroxycoumarin. Progesterone and triamcinolone are devoid of this effect. SKF 525-A counteracts the influence of **ethylestrenol** upon **bishydroxycoumarin** metabolism. The hepatic microsomes of rats treated with spironolactone or ethylestrenol in vivo accelerate bishydroxycoumarin degradation by NADPH-dependent enzymes in vitro.

### CFT 1201 (phenyldiallylacetic acid ester of diethylaminoethanol), CFT 1215, CFT 1042.

Much less work has been done with the phenylacetic acid derivatives which, like SKF 525-A, act as hepatic microsomal enzyme inhibitors. The most active member of this group is CFT 1201. It prolongs the action of hexobarbital, propallylonal, eunarcon and butallylonal, without affecting the hypnotic action of barbital, a compound notoriously not metabolized within the body. CFT 1201 uncouples oxidative phosphorylation when  $\alpha$ -ketoglutarate or  $\beta$ -oxybutyrate are used as

substrates, but it also inhibits the incorporation of alanine-1-<sup>14</sup>C into hepatic microsomal protein.

*Neubert & Herken G74,660/55:* Several phenylacetic acid derivatives prolong the action of hexobarbital. The most active of these compounds is the phenyldiallylacetic acid ester of diethylaminoethanol (CFT 1201), which also prolongs the action of propallylonal, eunarcon, and butallylonal. However, CFT 1201 does not affect the hypnotic action of barbital, which notoriously is not metabolized in the rat.

*Maibauer et al. G74,663/58:* In rats, CFT 1201 causes hepatic steatosis.

*Neubert & Hoffmeister G74,667/60:* CFT 1201 uncouples oxidative phosphorylation when  $\alpha$ -ketoglutarate or  $\beta$ -oxybutyrate are used as substrates.

*Neubert & Timmler G74,668/60:* SKF 525-A and CFT 1201 inhibit incorporation of alanine-1-<sup>14</sup>C into hepatic microsomal protein.

### Lilly 18947 (2,4-dichloro-6-phenylphenoxyethyl diethylamine).

This compound is chemically closely related to SKF 525-A and resembles the latter also in its pharmacologic actions. In acute experiments on mice it prolongs hexobarbital sleeping time by inhibiting barbiturate metabolism in hepatic microsomes. When given over a 28 day observation period Lilly 18947 reduces the lethality of cyclophosphamide perhaps because its inhibitory effect upon drug metabolism is reversed following chronic administration.

*Fouts & Brodie D83,597/55:* SKF 525-A and the closely-related compound Lilly 18947 prolong the hypnotic action of hexobarbital in mice by inhibiting its metabolism by hepatic microsomes.

*Fouts & Brodie D95,674/56:* 2,4-Dichloro-6-phenylphenoxyethyl diethylamine (Lilly 18947) and iproniazid (2-isopropyl-1-isonicotinyl hydrazine, Marsilid) prolong hexobarbital sleeping time by inhibiting its metabolism in hepatic microsomes.

*Hart & Adamson G69,481/69:* In mice

“SKF 525-A and Lilly 18947 reduced the lethality of cyclophosphamide over a 28 day observation period while pretreatment with phenobarbital did not change the 28 day lethality. Neither SKF 525-A nor phenobarbital had an effect on the antitumor efficacy of cyclophosphamide. Mice housed on cedar chip bedding were less susceptible to the lethal effects of cyclophosphamide, but tumor bearing mice on this bedding showed greater antitumor response to the drug than those on hardwood bedding.”

MPDC (N-methyl-3-piperidyl diphenylcarbamate), EPDA (N-ethyl-3-piperidyl diphenylacetate), EPB (N-ethyl-3-piperidyl benzylate) and JB 516 ( $\beta$ -phenylisopropylhydrazine).

MPDC

All these piperidyl compounds prolong barbiturate sleeping time by inhibiting microsomal drug metabolism. MPDC given 1–12 hrs before hexobarbital prolongs sleeping time and inhibits the metabolism of the barbiturate, although the reverse is true if MPDC is given 24–48 hrs before hexobarbital. In all these respects the compound resembles the numerous other inhibitors which exhibit similar biphasic responses.

*Fujimoto et al. D78,955/60; Serrone & Fujimoto D83,863/60:*  $\beta$ -Phenylisopropylhydrazine (JB 516), N-ethyl-3-piperidyl benzylate (EPB), N-ethyl-3-piperidyl diphenylacetate (EPDA), and N-methyl-3-piperidyl diphenylcarbamate (MPDC) prolong barbiturate sleeping time by inhibiting microsomal drug metabolism.

*Serrone & Fujimoto D48,610/61:* MPDC given 1–12 hrs before hexobarbital prolongs sleeping time and the metabolism of the barbiturate. However, if MPDC is given

24–48 hrs before hexobarbital, the metabolism of the drug is stimulated and sleeping time is shortened. Data are presented to show that the accelerated metabolism of hexobarbital results from induced synthesis of microsomal enzyme systems that metabolize barbiturates. A similar biphasic response on hexobarbital sleeping time was observed with SKF 525-A, JB 516, iproniazid, orphenadrine, chlorpromazine, and hydroxyzine by several investigators (Holtz et al. D98,342/57; Arrigoni-Martelli & Kramer G74,659/59; Rümke & Bout G74,669/60).

### Sch 5712, Sch 5705 (malonic and succinic acid derivatives).

Hexobarbital metabolism is inhibited and sleeping time prolonged by certain malonic and succinic acid derivatives such as Sch 5712 or Sch 5705. Sch 5712 prolongs hexobarbital sleeping time about 12-fold in female and only 3-fold in male rats, yet it inhibits hexobarbital metabolism in vitro about equally in unfortified liver homogenates of both sexes.

*Kramer & Arrigoni-Martelli G74,673/59:* The hexobarbital metabolism by hepatic microsomal enzyme systems is inhibited, whereas hexobarbital sleeping time is prolonged, by certain malonic and succinic acid derivatives, such as Sch 5712. The latter compound prolongs hexobarbital sleeping time about 12-fold in female and only 3-fold in male rats, yet it inhibits hexobarbital metabolism in vitro about equally when tested with the unfortified liver homogenate

from rats of either sex. Furthermore, Sch 5712 is singularly ineffective in prolonging hexobarbital sleeping time in rats pretreated with phenobarbital.

*Arrigoni-Martelli et al. G74,653/60:* Several malonic and succinic acid derivatives potentiate the action of hexobarbital, chlorpheniramine (Chlortrimeton), and amphetamine.

Hexobarbital ← Sch 5705, Sch 5712  
+ Sex: Kramer et al. G74,673/59\*

### Chloramphenicol.

This antibiotic does not induce sedation by itself and fails to potentiate subhypnotic doses of hexobarbital but inhibits the metabolism of the latter if given to mice and rats a short time before the barbiturate. In vitro, a number of other enzymic reactions are also inhibited by chloramphenicol which acts essentially like SKF 525-A and other related compounds.

*Dixon & Fouts E53,752/62:* In mice and rats, chloramphenicol inhibits hexobarbital metabolism. When chloramphenicol is given 45 min before hexobarbital, the sleeping time in mice is greatly prolonged and the total body levels of the barbiturates are increased. This antibiotic does not induce sedation by itself and fails to potentiate a subhypnotic dose of hexobarbital. In vitro, a number of enzymic reactions are inhibited by chloramphenicol and the pathways blocked are essentially the same as those inhibited by SKF 525-A and related compounds.

*Firkin & Linnane H31,607/70:* In rats, partial hepatectomy greatly increases sensitivity to the lethal effect of heavy chloramphenicol overdose. Lower doses of "chloramphenicol appeared to specifically inhibit the synthesis of the mitochondrial cytochromes a, a<sub>3</sub>, b and c<sub>1</sub> in the actively growing liver tissue. In some of the liver cells there was extensive cytoplasmic vacuolation resulting from dilation of the endoplasmic reticulum, and the mitochondria were swollen and appeared to contain fewer cristae.

It is suggested that chloramphenicol has at least three effects in the cells of higher organisms—a specific inhibitory effect on the synthesis of some mitochondrial cytochromes which is presumably a reflection of its action on the mitochondrial protein synthesizing system, an effect on cellular ultrastructure, and a direct inhibitory effect on cellular respiration only at relatively high concentrations of the drug."

*Solymoss et al. G70,412/70:* "In rats, 24 hours after a single dose of spironolactone or ethylestrenol, the disappearance of pentobarbital from blood is enhanced to a rate in proportion to the decreasing depth of anesthesia. This action is completely suppressed by ribonucleic acid- or protein-synthesis inhibitors such as actinomycin D, puromycin aminonucleoside and cycloheximide, and only partially by 6-mercaptopurine or chloramphenicol... Induction of drug-metabolizing enzymes is involved in the resistance-increasing effect of spironolactone or ethylestrenol against various compounds."

constipation, dry mouth, delusions and hallucinations. They have little, if any, potentiating action upon the cardiovascular effects of natural catecholamines, presumably because O-methylation and tissue uptake, rather than oxidative deamination, are responsible for terminating their peripheral actions.

However, the MAO-inhibitors greatly potentiate the cardiovascular effects of simple phenylethylamines like tyramine. Thus, patients receiving tranlycypromine conjointly with phenylethylamine derivatives may experience exaggerated hypertensive effects conducive to apoplexy. Even foods may become dangerous following MAO-inhibitor treatment. Some cheeses (Camembert, Brie, Stilton, New York Cheddar) are rich in tyramine, which is ordinarily harmless because it is rapidly oxidized by MAO, however, after treatment with tranlycypromine, the tyramine in these cheeses may elicit the dangerous hypertensive crises just mentioned.

Curiously, iproniazid also potentiates the lathyrogenic action of APN in turkey poult, but this may be a nonspecific stress effect.

Both desipramine and imipramine exert an "SKF 525-A-like" inhibitory effect upon hepatic microsomes *in vitro* and they prolong hexobarbital sleeping time; however there appears to be no close correlation between the MAO-inhibitor activity of these compounds on their ability to interfere with hexobarbital metabolism.

*Fouts & Brodie D 83,597/55*: 2,4-Dichloro-6-phenylphenoxyethyl diethylamine HBr (Lilly 18947) and iproniazid (2-isopropyl-1-isonicotinyl hydrazine, Marsilid) prolong hexobarbital sleeping time by inhibiting its metabolism in hepatic microsomes.

*Fouts & Brodie D 95,674/56*: Iproniazid, though practically devoid of sedative action, prolongs the hypnotic activity of hexobarbital in mice by interfering with its metabolism through hepatic microsomal enzymes. In this respect, iproniazid acts like SKF 525-A and Lilly 18947.

*Arrigoni-Martelli & Kramer G 74,659/59*: In mice, hexobarbital and thiopental meta-

bolism is impeded by the MAO-inhibitors, iproniazid and  $\beta$ -phenylisopropyl hydrazine (JB 516).

*Fujimoto et al. D 78,955/60*; *Serrone & Fujimoto D 83,863/60*:  $\beta$ -Phenylisopropylhydrazine (JB 516), N-ethyl-3-piperidyl benzilate (EPB), N-ethyl-3-piperidyl diphenylacetate (EPDA), and N-methyl-3-piperidyl diphenylcarbamate (MPDC) prolong barbiturate sleeping time by inhibiting microsomal drug metabolism.

*Laroche & Brodie H 21,467/60*: There appears to be no correlation between the MAO-inhibitor activity of chemical compounds and their ability to interfere with hexobarbital metabolism.

*Strong G73,964/62*: Iproniazid can potentiate the lathyrogenic action of APN in turkey poults.

*Rogers & Fouts F27,894/64*: In vitro experiments in rats have shown that SKF 525-A is strongly bound to hepatic microsomes and cannot be removed by dialysis or washing, whereas the reverse is true of iproniazid and other microsomal enzyme inhibitors.

*Blackwell E65,708/63*: MAO-inhibitors such as tranlycypromine can produce severe pa-

roxysmal hypertension and intracranial bleeding in patients following ingestion of certain cheeses.

*Jori & Pugliatti G70,112/67*: Desipramine and imipramine exert an SKF 525-A-like inhibitory effect upon the hepatic microsomes.

*Bowman et al. E714/68 (p. 520)*: Iproniazid is an inhibitor of MAO and of other extramicrosomal enzymes. Like SKF 525-A which also inhibits a number of other enzymes, it has been termed a "multi-potent" enzyme inhibitor.

**p-Aminosalicylic Acid (PAS)**. PAS feeding induces glycogen infiltration of the rat liver; it also prolongs hexobarbital sleeping time, presumably by decreasing barbiturate excretion. There may exist some relationship between hepatic glycogen deposition and the changes in the SER. This could account for the inhibitory effect of PAS which is distinctly different from the enzyme inhibition caused by chloramphenicol or SKF 525-A. The latter compounds inhibit both aminopyrine and codeine metabolism, whereas PAS inhibits only the former.

*Rogers et al. E31,897/63*: In rats, PAS feeding induces glycogen infiltration of the liver and prolongation of hexobarbital sleeping time, apparently due to diminished ability to excrete the barbiturate. The in vitro metabolism of hexobarbital and aminopyrine, by the microsomes of rats pretreated with PAS, is diminished. Acute administration of PAS had no effect on hexobarbital sleeping time, nor did addition of PAS in vitro inhibit drug-metabolizing enzymes. There may exist some relationship between hepatic glycogen deposition and changes in the SER. This might account for the inhibitory effect of PAS,

which is definitely different from that of chloramphenicol and SKF 525-A.

*Rogers & Fouts F27,894/64*: In the utilization of PAS, there is an increase in hepatic glycogen content associated with a decreased hexobarbital-metabolizing activity of the hepatic microsomes. PAS inhibits aminopyrine metabolism but not codeine metabolism. Conversely, both aminopyrine and codeine metabolism are inhibited by chloramphenicol and SKF 525-A. Presumably PAS, after prolonged administration, induces a more selective inhibition than other antagonists.

### **Competition between Substrates**

Various substrates of hepatic enzymes potentiate the toxicity of other simultaneously-applied substrates of the same enzymes. This phenomenon can be illustrated by many examples:

Triorthotolyl phosphate potentiates the toxicity of malathione by inhibiting the metabolism of the latter. EPN has the same effect by inhibiting the esterases responsible for malathione detoxication. In man, oxyphenbutazone prolongs the elevation of plasma levels of bishydroxycoumarin with a potentiation of its anti-coagulant action. In rats, ethylmorphine and codeine retard the metabolism of hexobarbital in vivo as measured by its plasma clearance. In isolated hepatic microsomal preparations of the rat the N-demethylation of ethylmorphine is competitively inhibited by hexobarbital, chlorpromazine, zoxazolamine, phenylbutazone and

acetanilide; in fact ethylmorphine and chlorpromazine are mutually inhibitory, each retarding the metabolism of the other. All these drugs are known to be oxidized by microsomal enzymes. On the other hand, barbital and acetazolamide, drugs which are not metabolized, fail to act as inhibitors in this system.

Jaundice develops more often in newborn infants fed on breast than on cow's milk. This has been ascribed to the presence in human milk of  $3\alpha$ ,  $20\beta$ -pregnanediol which competitively might inhibit glucuronyl transferase and thereby interfere with bilirubin clearance. However, more recent observations suggest that neither  $3\alpha$ ,  $20\beta$ -pregnanediol nor  $3\alpha$ ,  $20\alpha$ -pregnanediol inhibit conjugation by human hepatic microsomes, whereas estradiol does have such an action.

Many additional examples could be cited to illustrate the mutual competitive inhibition between substrates for microsomal drug-metabolizing enzymes; yet, not all drugs known to be metabolized by microsomes inhibit drug metabolism in vivo even if they do so in vitro. Of course drugs metabolized by separate pathways cannot interfere with each other's metabolism unless they share rate-limiting cofactors or other endogenous intermediates in their metabolic pathways. Finally, a very potent drug is not likely to interfere with a much less potent drug in vivo simply because their concentrations at the metabolic site are likely to be very different, although this factor could be offset if the  $K_m$  of the more potent drug is far below that of the less potent competitor. Since most of this information is seldom available the simplest and most reliable way to determine if one drug prolongs the metabolism of another is the in vivo experiment.

*Cook et al. G74,655/57; Murphy & DuBois G74,670/57:* EPN (ethyl p-nitrophenyl thionobenzenephosphonate) aggravates the toxicity of malathion [S-(1,2-dicarbethoxyethyl)-0,0-dimethyl phosphorodithioate] by inhibiting the esterases responsible for its detoxication.

*Murphy et al. G74,671/59:* Triorthotolyl phosphate potentiates the toxicity of malathion by inhibiting its metabolism.

*Newman & Gross G75,237/63:* Observations on infants showed that prolonged increases in indirect reacting bilirubin may be due to interference with the normal conjugating mechanism by the presence in human milk of a factor (possibly pregnanediol) which is not present in cow's milk. Changing the infants from breast feeding to cow's milk formulas enhanced the disappearance of the hyperbilirubinemia.

*Rubin et al. G58,057/64:* Numerous drugs competitively inhibit the metabolism of other drugs when employed as substrates for the microsomal enzyme system. Thus, using hepatic microsomes of the rat, it could be shown that "the N-demethylation of ethylmorphine was competitively inhibited by hexobarbital, chlorpromazine, zoxazolamine,

phenylbutazone, and acetanilide; and ethylmorphine, and chlorpromazine were mutually inhibitory, each retarding the metabolism of the other. All these drugs are known to be oxidized by microsomal enzymes. Barbital and acetazoleamide, drugs which are not metabolized, failed to act as inhibitors."

*Rubin et al. G58,747/64:* Various chemically-unrelated drugs may compete for microsomal enzymes of the liver in vitro and in vivo. Observations on rats show that "ethylmorphine and codeine were shown to retard the metabolism of hexobarbital in vivo, as measured by the rate of hexobarbital disappearance from the blood of rats, whereas morphine, norcodeine, dextromethorphan, levomethorphan, meprobamate, and acetanilide were without effect."

*Fox F3,079/64; Weiner et al. F35,871/65:* In man, oxyphenbutazone (Tandearil) considerably prolongs the elevation of plasma levels of bishydroxycoumarin with a potentiation of its anticoagulant action.

*Mannering G71,818/68 (p. 103):* Review of the literature showing that concurrent pretreatment with two substrates of microsomal drug-metabolizing systems sometimes mutually and competitively antagonize each

other. However, interestingly, not all drugs which are known to be metabolized by microsomes, inhibit drug metabolism *in vivo*. "The biotransformation studied *in vitro* may not represent the major metabolic route *in vivo*, and drugs metabolized by separate routes cannot interfere with each others' metabolism as alternative substrates, unless rate-limiting cofactors or other endogenous intermediates are shared by both metabolic pathways. Potency of the drugs in question is also of great importance in this regard. Very potent drugs are not likely to interfere with much less potent drugs simply because their concentrations at the metabolic site are likely to be very different, although this factor could be offset if the  $K_m$  of the more potent drug is much less than that of the drug of lesser potency. Most of this information is seldom available, and the quickest and most reliable way to determine if one drug will prolong the metabolism of another is to do the *in vivo* experiment."

*Adlard & Lathe G74,759/70*: In newborn

infants, jaundice develops more frequently on breast feeding than on cow's milk and earlier investigators assumed that  $3\alpha$ ,  $20\beta$ -pregnanediol present in human milk may competitively inhibit glucuronyl transferase and thereby interfere with bilirubin clearance. The present observations suggest that "Neither  $3\alpha$ ,  $20\beta$ -pregnanediol nor  $3\alpha$ ,  $20\alpha$ -pregnanediol inhibited conjugation by human liver slices or by solubilized human liver microsomes.  $3\alpha$ ,  $20\beta$ -pregnanediol is unlikely to be the inhibitor causing breast milk jaundice." However, estriol inhibited conjugation by human liver slices.

*Solymoss & Varga, G70,500/71*: In rats, pretreatment with various catatoxic steroids accelerates the degradation of bishydroxycoumarin by NADPH-dependent hepatic enzymes. However, if the bishydroxycoumarin is administered immediately after treatment with catatoxic steroids (norbolethone, ethylestrenol, progesterone or triamcinolone), an inverse effect is observed, presumably because of competitive inhibition.

### **Blockers of Enzyme Induction**

**Classification.** The blockers of microsomal enzyme induction may be roughly classified according to the sites of their actions as follows:

1. **Blockade of DNA-directed synthesis of nuclear messenger RNA (required for protein synthesis) by binding to DNA.** (E.g., actinomycin D is thus bound to DNA.)

2. **Blockade of transfer of soluble RNA-bound amino acids into microsomal protein.** (E.g., puromycin, an antibiotic, blocks the transfer of RNA-bound amino acids to the new protein chain.)

3. **Blockade of protein synthesis by decreasing the ATP content of the liver.** (E.g., ethionine, an antimetabolite of methionine, combines with ATP to form S-adenosyl-methionine. This reaction blocks transmethylation which requires S-adenosyl-methionine for the production of amino acids needed in protein synthesis.)

The first type of blockade interferes with transcription of information, the second and third with translation.

The ethionine-induced inhibition of hepatic protein synthesis can be prevented *in vivo* by either methionine or ATP. All these facts suggest that S-adenyl-methionine may be important for the synthesis of microsomal enzymes in the liver. When puromycin, ethionine or actinomycin D is administered several hours after 3-MC these blocking agents prevent further increase in the level of aminoazo dye N-demethylase, so that enzyme activity is maintained at a partially-elevated level. The results of actinomycin D suggest that the carcinogen may increase the formation of short-lived messenger RNA required for the further synthesis of aminoazo dye N-demethylase. (For literature see Conney F88,649/67.)

*Conney F 88,649/67 (p. 329):* Review of interference with enzyme induction by inhibitors of protein synthesis. inhibition of drug metabolism "as it is more narrowly defined to mean the interference of the metabolism of one agent by another agent at the enzymic site."

*Mannering G74,572/71:* Review on the

**Actinomycin.** Actinomycin presumably blocks hepatic microsomal-enzyme induction at the level of the DNA-dependent RNA polymerase reaction (transcription); it thus differs essentially from the effect of puromycin which blocks the induction at the ribosomal level (translation).

It is thought that the regulatory effect of cortisone on carbohydrate metabolism may be brought about by its action on certain enzyme proteins. In starved rats, hepatic glycogen deposition by cortisone is inhibited both by actinomycin and by puromycin. The former may act by interfering with the cortisone-induced hepatic TKT, whereas the latter inhibits enzyme induction in general. Glucocorticoids are known to protect against endotoxins, whereas actinomycin and other inhibitors of enzyme protein synthesis (such as 2-thiouracil and 8-azaguanine and ethionine) increase endotoxin lethality.

In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. This inhibition is blocked when RNA synthesis is impeded by actinomycin.

The increase in hepatic serine dehydrogenase, induced in rats by protein-deficient diets and starvation, can be prevented by actinomycin as well as by puromycin.

The induction of drug-metabolizing enzymes by phenobarbital is blocked in the rat both by actinomycin and by X-irradiation but through different mechanisms. X-irradiation of pregnant rats resulted in male offspring deficient in hepatic microsomal enzymes which metabolize hexobarbital. However irradiation did not suppress the induction of this enzyme by phenobarbital. Actinomycin inhibited both the ontogenetic and the phenobarbital-induced increases in enzyme activity.

In the perfused rat liver preparation, cortisol, insulin and glucagon induce TKT activity. Cortisol acts as long as it is present in the perfusion fluid, whereas enzyme synthesis by pancreatic hormones ceases after 2 or 3 hrs regardless of their continued presence. It is assumed that cortisol is a "primary inducer," whereas the pancreatic hormones presumably act indirectly as a consequence of their initial hepatic effect and are therefore "secondary inducers." Both types of induction are blocked by actinomycin D.

Actinomycin prevents the degradation of various substrates and inhibits enzyme induction by numerous agents, such as:

Cortisol	Protein-deficient diets
Cortisone	Spironolactone
Endotoxin	Starvation
Ethylestrenol	Stress
Glucagon	Tyrosine
Insulin	X-irradiation
Phenobarbital	

*Greengard et al. E20,258/63:* In starved rats, hepatic glycogen deposition following cortisone treatment is inhibited by puromycin and actinomycin. The former interferes with enzyme induction in general, the latter with cortisone-induced rise in hepatic enzyme, including tyrosine transaminase. "The regulatory effect of cortisone on carbohydrate

metabolism may be brought about by its action on the cellular concentration of certain enzyme proteins."

*Berry G68,858/64:* Both actinomycin D and ethionine increase the lethal effect of endotoxin in the mouse and abolish the protection offered by cortisone. Presumably, both endogenous and exogenous glucocorticoids protect through the induction of hepatic enzymes whose synthesis can be inhibited by actinomycin D and ethionine. Cortisone increases TPO in rats and rabbits, but not in guinea pigs. Correspondingly, guinea pigs cannot be protected against endotoxin by cortisone.

*Berry & Smythe D19,640/64:* In mice, *Salmonella typhimurium* endotoxin lowers hepatic tryptophan pyrrolase, whereas cortisone raises it; when the two are administered simultaneously, a normal enzyme level is maintained and mortality greatly diminished. If cortisone injection is delayed for a few hours it fails to induce tryptophan pyrrolase or protect against the lethal effect of endotoxin. Inhibitors of enzyme protein synthesis (actinomycin D, ethionine, 2-thiouracil and 8-azaguanine) potentiate the lethal effect of endotoxin and abolish cortisone protection.

*Kenney & Albritton G64,557/65:* Review of the literature suggesting that transaminase induction in response to stressors can be due to corticoid secretion during the stress reaction. Cortisol increases enzyme synthesis following an increased rate of synthesis of ribosomal, transfer and "DNA-like" RNA's. The present experiments confirm the view that repressor(s) can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis can prolong the corticoid-induced increase in enzyme synthesis under suitable conditions. "Administration of stressing agents (tyrosine, Celite) to adrenalectomized rats initiates a highly selective repression of the synthesis of hepatic TKT. The enzyme level falls with a  $t_{1/2}$  of about 2.5 hrs. Immunochemical measurement of the rate of enzyme synthesis indicates that it is reduced essentially to zero in stressed, adrenalectomized rats, whereas labeling of total liver soluble proteins is unaffected. Actinomycin does not itself influence the enzyme level, but it blocks the stress-initiated repression of enzyme synthesis, indicating that repression acts at the translational level, whereas initiation of repression involves transcriptional processes." In hypophysectomized rats, stressors are ineffective and preliminary data

suggest that STH is responsible for transaminase repression.

*Singer & Mason G66,500/65:* Na-benzoate increased hepatic TKT activity both in intact and in NaCl-maintained adrenalectomized rats. Among 31 cyclic compounds tested for this inducing ability after adrenalectomy, only cortisol, its hemisuccinate and diethylstilbestrol disulfate were more effective than benzoate. Curiously, enzyme induction by cortisol was actually enhanced after adrenalectomy. "Strong inhibition of the increase by injected puromycin and actinomycin D, compounds which inhibit protein and RNA synthesis respectively, suggests that the benzoate-mediated effect occurred by a mechanism involving increases in protein and RNA synthesis. In this respect, the effect of benzoate resembles that of the glucocorticoids."

*Berry et al. G67,237/66:* *S. typhimurium* endotoxin lowers liver TPO in mice and prevents the induction of the enzyme by concurrent injection of cortisone. It lowers, but does not prevent, substrate induction. Actinomycin D has a similar effect on TPO. In the intact mouse, the endotoxin induces TKT almost as well as cortisone, but not in the adrenalectomized animal. Actinomycin D, on the other hand, has an effect on this transaminase similar to that on TPO.

*Kenney G50,810/67:* In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The rate of enzyme synthesis is reduced nearly to 0 (immunochemical-isotopic analyses), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actinomycin. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized) animals. TKT levels were unchanged in a single experiment where the stressing agent was administered to the hypophysectomized partner.

*Schmidinger & Kröger F92,031/67:* The increase in hepatic serine dehydratase induced by protein-deficient diets and starvation in intact rats is prevented by actinomycin, puromycin or glucose, but aggravated after adrenalectomy. Cortisone administered during the starvation period increases serine dehydratase activity, perhaps owing to utilization

of inhibitors of this enzyme during gluconeogenesis.

*Hager & Kenney G58,950/68:* Cortisol, insulin, and glucagon, induced TKT in the isolated, perfused rat liver. The hormonal induction of all these enzymes was sensitive to actinomycin D, but STH (which represses TKT induction in vivo) apparently acts indirectly since it loses this effect in vitro. Cortisol acts as long as it is present in the perfusion fluid, whereas enzyme synthesis by the pancreatic hormones ceases after two or three hours, regardless of the continued presence of the protein hormones. It is assumed that cortisol is a "primary inducer," whereas the pancreatic hormones probably act indirectly as a consequence of their initial hepatic effect and are therefore "secondary inducers." Both the primary and the secondary induction mechanisms are blocked by actinomycin D.

*Nair et al. G67,304/68:* Comparative studies suggest that the induction of drug-metabolizing enzymes by phenobarbital in the rat can be inhibited by both X-irradiation and actinomycin, but through different mechanisms.

*Nair et al. G67,245/68:* X-irradiation of pregnant rats results in male offspring deficient in the hepatic microsomal enzymes which metabolize hexobarbital. However, irradiation did not suppress the increase of enzyme activity brought about by chemical inducers (phenobarbital). Actinomycin inhibited both the ontogenic and phenobarbital-induced increases in enzyme activity. "The ontogenic increase in enzyme activity is hormone-dependent, while that following phenobarbital administration is independent of hormonal regulation as evidenced by the response in hypophysectomized or sexually immature animals. It is concluded from these results that the inhibitory effect of x-irradiation on the hepatic enzyme system is mediated through an action on the hormonal regulation of enzyme activity."

*Benes & Zicha G67,159/69:* Exposure to 1400 R does not inhibit the TKT activity of

rat liver. In fact, substrate induction of TKT is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated and then, inhibited by X-irradiation. X-irradiation before partial hepatectomy inhibits the increase in TKT normally observed 12 hrs after the operation. Similar results are obtained by actinomycin D applied one hour after partial hepatectomy. "The diminished synthesis of tryptophan oxygenase in irradiated regenerating rat liver tissue, as well as the decrease of hormonal induction after the irradiation can be explained by the inhibition of the specific messenger RNA's synthesis."

*Becker & Brenowitz G75,528/70:* Studies on the concentration of actinomycin D in rat hepatocyte nuclei as related to inhibition of RNA synthesis. The normal hepatocyte possesses mechanisms for rapidly eliminating administered actinomycin D.

*Dowling & Feldman H31,139/70:* In mice, the lethality of typhoid endotoxin is increased 550-20,000-fold by actinomycin D.

*Pieroni et al. H31,137/70:* In mice, actinomycin D enhances endotoxin lethality up to 100,000-fold. The lethality of tetanus and diphtheria exotoxins is not similarly augmented.

*Sananès & Psychoyos G78,230/70:* In rats, deciduoma formation is inhibited by actinomycin D presumably by interfering with RNA formation.

*Solymoss et al. G70,412/70:* "In rats, 24 hours after a single dose of spironolactone or ethylestrenol, the disappearance of pentobarbital from blood is enhanced to a rate in proportion to the decreasing depth of anesthesia. This action is completely suppressed by ribonucleic acid- or protein-synthesis inhibitors such as actinomycin D, puromycin aminonucleoside and cycloheximide, and only partially by 6-mercaptopurine or chloramphenicol. . . Induction of drug-metabolizing enzymes is involved in the resistance-increasing effect of spironolactone or ethylestrenol against various compounds."

**Puromycin.** As previously stated, puromycin blocks protein synthesis at the ribosome (translation) level; in this manner it interferes with the induction of various hepatic enzymes, for example, the induction by cortisol of TKT and TPO in the perfused rat liver.

The induction by dexamethasone of TKT in tissue cultures of cells is blocked by puromycin (but also by cycloheximide, chloramphenicol, progesterone, actinomycin D

and mitomycin C). Paradoxically, after induction by the glucocorticoid has taken place, actinomycin D produces a further increase of this enzyme activity. The cortisol-induced hepatic TKT activity in adrenalectomized rats is inhibited by puromycin given during the initial phase of induction. However, if given during the inactivation phase, the antibiotic unexpectedly causes a rapid reappearance of enzyme activity. Perhaps a repressor is formed after a few hours of hormone action, and inhibition of repressor synthesis allows continued production of enzyme. The inactivator appears to depend upon pituitary function since adrenalectomized and hypophysectomized rats show little or no inactivation following cortisol treatment.

Ornithine-ketoaminotransferase (OKT) is very low in the fetal rat liver, and reaches the high adult level only during the third postnatal week. Triamcinolone given at this time elevates OKT although it has no effect in fetal or adult rats. Puromycin prevents the rise in OKT caused by triamcinolone.

*Goldstein et al. D70,931/62:* Cortisol produced an increase in both TKT and TPO activities in the isolated, perfused rat liver. This effect was prevented by puromycin. Cortisol "may exert some of its physiological effects directly on liver cells by altering the level of enzyme activities."

*Alexander & Hunt E20,128/63:* **Partial hepatectomy** did not significantly affect proteinuria or liver regeneration following puromycin aminonucleoside intoxication in the rat.

*Thompson et al. F81,633/66:* "Tyrosine  $\alpha$ -ketoglutarate transaminase can be induced by steroid hormones in a newly established line of tissue culture cells, derived from primary culture of the ascites form of an experimental rat hepatoma." Dexamethasone, triamcinolone and cortisol were highly active, DOC and aldosterone much less potent, whereas stilbestrol, estradiol, testosterone and progesterone were virtually inactive. The induction by dexamethasone was blocked by puromycin, cycloheximide, chloramphenicol, progesterone, actinomycin D and mitomycin C. Paradoxically, after induction by the steroid had taken place, actinomycin D produced a further increase in enzyme activity.

*Grossman & Mavrides G46,206/67:* Studies on the kinetics of cortisol-induced hepatic TKT activity in adrenalectomized rats. "Puromycin inhibited enzyme synthesis when it was given during the initial phase of induction. However, it unexpectedly caused a rapid reappearance of enzyme activity following its administration during the inactivation phase. This potentiated response is consistent with other observations which lead to the idea

that a repressor is formed about 4 hours after hormone administration and that inhibition of repressor synthesis allows, at least temporarily, continued synthesis of enzyme." The inactivator appears to depend upon pituitary function, since adrenalectomized and hypophysectomized rats showed little or no inactivation phase following cortisol treatment.

*Räihä & Kekomäki G68,114/68:* In the rat, the OKT activity of the liver is very low in the fetus, exhibits a small transient elevation around term, then drops, and eventually reaches the high adult activity level during the third postnatal week. Triamcinolone given postnatally causes a pronounced elevation of OKT, but has no such effect in fetal or adult rats. Puromycin prevents the rise in OKT after triamcinolone administration. In adult rats fed a protein- or arginine-free diet, OKT activity decreases and fails to rise under the influence of triamcinolone. Partial hepatectomy or STH depresses OKT-activity in the livers of adult rats.

*Solymoss et al. G70,412/70:* "In rats, 24 hours after a single dose of spironolactone or ethylestrenol, the disappearance of pentobarbital from blood is enhanced to a rate in proportion to the decreasing depth of anesthesia. This action is completely suppressed by ribonucleic acid- or protein-synthesis inhibitors such as actinomycin D, puromycin aminonucleoside and cycloheximide, and only partially by 6-mercaptopurine or chloramphenicol. . . Induction of drug-metabolizing enzymes is involved in the resistance-increasing effect of spironolactone or ethylestrenol against various compounds."

**Cycloheximide.** Cycloheximide allegedly inhibits protein synthesis in mammalian systems without inhibiting RNA synthesis. In the rat it does not prevent the uterine response to estradiol although it blocks the increase in various enzyme activities of the uterus that are associated with this response. Cycloheximide also inhibits the induction of hepatic TPO assayed 4 hrs after administration of the substrate or cortisol; however, it does not abolish the induction of TKT by cortisol, in fact, it increases TKT activity even in the absence of cortisol treatment.

The anesthetic effect of progesterone in the rat is augmented by cycloheximide pretreatment.

*Fiala & Fiala F65,983/66:* In the rat, cycloheximide i.p. inhibits the induction of hepatic TPO assayed 4 hrs after administration of the substrate, or of cortisol. By contrast, it did not abolish the induction of TKT by cortisol and, in fact, it increased the level of TKT even in the absence of cortisol treatment. A similar, though smaller, effect occurred in hypophysectomized or adrenalectomized rats, suggesting a direct induction of TKT by cycloheximide. Puromycin inhibited the induction of TKT. Apparently, an inhibitor of protein synthesis such as actidione may also act as an inducer for the synthesis of TKT, thus simulating the action of cortisol. "This 'pseudohormonal' action of actidione may explain the toxicity of actidione in certain mammalian species and also the fact that hydrocortisone may act as an antidote in actidione poisoning. It does not explain why a similar effect of 'pseudohormonal' induction is not observed in the case of TPO, but only the inhibition of enzyme induction."

*Hilf et al. F88,514/67:* Cycloheximide has been reported to inhibit protein synthesis in mammalian systems without inhibiting RNA synthesis. In the rat, it did not prevent the uterotrophic response to estradiol but blocked the increase in various enzyme activities of the uterus normally associated with this response.

*Solymoss et al. G70,412/70:* "In rats, 24 hours after a single dose of spironolactone or ethylestrenol, the disappearance of pentobarbital from blood is enhanced to a rate in proportion to the decreasing depth of anesthesia. This action is completely suppressed by ribonucleic acid- or protein-synthesis inhibitors such as actinomycin D, puromycin aminonucleoside and cycloheximide, and only partially by 6-mercaptopurine or chloramphenicol. . . Induction of drug-metabolizing enzymes is involved in the resistance-increasing

effect of spironolactone or ethylestrenol against various compounds."

*Solymoss et al. G70,463/70:* In rats, pretreatment with spironolactone, norbolethone, or ethylestrenol accelerated the plasma clearance of digitoxin, in proportion to the *in vivo* protective effect of these catatoxic steroids. Partial hepatectomy reduces digitoxin clearance. The effect of spironolactone is suppressed by SKF 525-A and cycloheximide.

*Solymoss et al. G70,464/70:* In rats, spironolactone shortens the half-life of its main metabolite, the dethioacetylated 4,6-dienone (metabolite A), which is interconvertible with the 17-hydroxy carboxylic acid derivative (metabolite B). This alteration is only slightly accentuated if the steroid is given chronically, and it wears off within eight days after spironolactone treatment is interrupted. After a test dose of spironolactone or of its metabolites A and B, partial hepatectomy delays the blood clearance of metabolite A. Cycloheximide and SKF 525-A also suppress the blood clearance of metabolite A under these conditions. Presumably "spironolactone influences its own biotransformation and the steroid is also a substrate of the hepatic drug-metabolizing enzymes which are induced by spironolactone itself."

*Solymoss G70,484/70:* In rats, the plasma clearance of digitoxin is accelerated by spironolactone, norbolethone and ethylestrenol in doses that protect against the toxicity of the alkaloid *in vivo*. On the other hand, partial hepatectomy reduces digitoxin plasma clearance and increases the severity of the convulsions. The protective action of the steroids is suppressed by SKF 525-A and cycloheximide.

*Khandekar et al. G79,014/71:* In rats, cycloheximide elicited nucleolar alterations in hepatocytes with disruption, dilatation, degranulation and ballooning of the RER. Accumulation

of SER also occurred when spironolactone or PCN was administered one hour before cycloheximide. It is concluded "that the steroids enhance the metabolic degradation of cycloheximide and thus SER proliferation is not inhibited; that this morphologic change does not always denote enzyme induction and the two can therefore be dissociated; or that SER accumulation is a nonspecific response to cellular injury."

*Khandekar et al. G79,026/71:* In rats, the hepatic SER proliferation induced by spiro-

nolactone or PCN is not prevented by concurrent administration of cycloheximide. Either the catatoxic steroids enhance the metabolic degradation of cycloheximide (thereby blocking its effect upon the SER) or this morphologic change does not necessarily indicate active enzyme induction.

*Selye PROT. 27251:* In rats, cycloheximide (25 or 50  $\mu$ g—4th day ff.) aggravates and prolongs progesterone (5 mg in oil i.p.) anesthesia.

**Hepatotoxic Substances.** Ethionine (like  $\text{CCl}_4$ , chloroform and phosphorus) causes fatty liver formation which cannot be prevented by choline. The hepatic damage is associated with inhibition of protein synthesis in the liver. Presumably the action of ethionine is due to a decline in mRNA and protein synthesis caused by reduction in the available ATP. This occurs when ethionine replaces methionine in S-adenosyl methionine and traps available adenine, thus preventing the synthesis of ATP. In agreement with this concept, the effect of ethionine can be reversed by administration of either ATP or adenine.

In rats, the hepatic lesions produced by  $\text{CCl}_4$  enhance the effect of various anti-convulsants.

Also in rats,  $\text{CCl}_4$  prolongs hexobarbital sleeping time; but after acute habituation, the plasma hexobarbital at waking time is comparatively high, and hence, peripheral resistance within the nervous tissue itself may also play a role here.

A variety of hepatotoxic agents (incl. ethionine,  $\text{CCl}_4$ , yellow phosphorus,  $^{32}\text{P}$ ) markedly inhibits hexobarbital oxidation and aminopyrine dealkylation by isolated hepatic microsomes. However, in vitro, ethionine fails to inhibit hexobarbital metabolism.

### *Ethionine*

*Conney et al. D87,867/56:* In rats, 3-methylcholanthrene i.p. considerably increased the ability of fortified liver homogenates to N-demethylate 3-methyl-4-monomethylaminoazobenzene (demethylase activity) and to reduce the azo-linkage of 4-demethylaminoazobenzene (reductase activity) within 24 hrs. However, significant demethylase activity was obtained even after 6 hrs. A number of other polycyclic hydrocarbons caused similar increases in demethylase activity but there was no relationship between carcinogenicity and enzyme induction. None of these compounds was active in vitro and their effect could be inhibited in vivo by ethionine. This inhibition was in turn prevented by methionine.

*Takabatake & Ariyoshi D48,245/62:* "19-Nortestosterone derivatives" (not other-

wise characterized) shortened the duration of cyclobarbital anesthesia in rats. Ethionine had an inverse effect.

*Berry G68,858/64:* Both actinomycin D and ethionine increase the lethal effect of endotoxin in the mouse and abolish the protection offered by cortisone. Presumably, both endogenous and exogenous glucocorticoids protect through the induction of hepatic enzymes whose synthesis can be inhibited by actinomycin D and ethionine. Cortisone increases TPO in rats and rabbits, but not in guinea pigs. Correspondingly, guinea pigs cannot be protected against endotoxin by cortisone.

*Wheatley F98,919/68:* In rats, adrenocortical necrosis produced by DMBA or 7-OH-MBA is prevented by metyrapone and related inhibitors of corticoid synthesis (Su 9055 and Su 10603) but not by Ay 9944 or aminoglut-

ethimide (Elipten). No correlation was found between the influence of these drugs on corticoidogenesis and their ability to protect against adrenal necrosis. Pretreatment with ethionine abolished the protective action of **metyrapone**, Su 9055 and Su 10603. It is concluded that these drugs protect by virtue of their hepatic drug-metabolizing enzyme inducing ability, not by direct effect upon corticoidogenesis.

*Kovacs & Somogyi G60,060/69:* In rats, the adrenal necrosis produced by DMBA is prevented by pretreatment with **spironolactone** and this protection is in turn blocked by ethionine.

*Domschke et al. G74,897/70:* In rats, ethionine fails to prevent the induction of TPO by the pesticide **soman**. "Since ethionine is known as an effective inhibitor of the protein synthesis in the liver the negative results are probably due to a stimulating effect of soman on the de-novo-synthesis of liver enzymes."

*Ariyoshi & Takabatake G75,246/70:* In rats, with ethionine-induced fatty livers, the inductive effect of **ethanol** and **phenobarbital** was almost completely blocked, whereas aniline hydroxylase activity was increased.

*Gardell et al. G60,076/70:* In rats, protection against digitoxin intoxication by **spironolactone** is blocked by dl-ethionine and the blockade is in turn antagonized by dl-methionine.

*Levine H 31,806/70:* In rats, 3,4-benzpyrene is rapidly excreted through the bile in the form of its metabolic products. Pretreatment with microsomal drug-metabolizing enzyme inducers (e.g., phenobarbital, methylcholanthrene, 3,4-benzpyrene) greatly enhances the rate of biliary excretion of this compound. Both the rate of metabolism and of biliary excretion are enhanced to a similar extent throughout the induction period. Male rats both metabolize 3,4-benzpyrene and excrete its metabolites in the bile at rates approximately 2.5 times that of females. The induction by **methylcholanthrene** of both the metabolism and the biliary excretion of 3,4-benzpyrene can be partially blocked by ethionine. It has been concluded that conversion to its metabolites is the rate-limiting step in the biliary excretion of 3,4-benzpyrene.

### Carbon Tetrachloride

*Shideman et al. E60,046/47:* In mice, CCl<sub>4</sub>-induced liver damage prolongs the effect of **thiopental**. The same is true after subtotal

hepatectomy (85—90%) in rats. Diminished blood flow through the liver (Eck fistula) likewise increases the duration of thiopental anesthesia in rats. Thiopental is degraded in vitro by rat liver slices and mince.

*Swinyard et al. G74,657/52:* In rats, hepatic lesions produced by CCl<sub>4</sub> enhance the anti-convulsant effect of **diphenylhydantoin**, **mesantoin**, and **thiantoin**.

*Neubert G74,661/57; Herken et al. G74,662/58; Neubert & Maibauer G74,664/59; Neubert et al. G74,668/60:* In rats, various hepatotoxic agents (ethionine, CCl<sub>4</sub>, yellow phosphorus, <sup>32</sup>P) markedly inhibit **hexobarbital** oxidation and **aminopyrine** dealkylation by isolated hepatic microsomes. However, the inhibition of hexobarbital metabolism by ethionine given in vivo is not seen in vitro.

*Paeile et al. F52,633/64:* Adult male rats are more resistant to **procaine** than adult females. Chronic CCl<sub>4</sub> poisoning, pretreatment with SKF 525-A and orchidectomy diminish the resistance of the males approximately to the female level. The plasma procainesterase activity is approximately the same in both sexes and not affected by orchidectomy or CCl<sub>4</sub> intoxication.

*Ronzoni et al. H18,986/68:* In rats, the **hydroxyproline** content of the liver furnishes a better quantitative index of sclerosis than histologic studies. The technique is recommended for the evaluation of sclerosis and its regression after various types of liver damage, e.g., partial hepatectomy or CCl<sub>4</sub> poisoning.

*Querci et al. G70,597/69:* In rats pretreated with CCl<sub>4</sub>, parallel blood determinations were performed of **parathion**, its toxic metabolite **paraoxon**, and the product of hydrolysis of the latter, **paranitrophenol**. They suggest that the increase in toxicity following hepatic damage is primarily due to a defect in the synthesis of hepatic pseudocholinesterase.

*Varga & Fischer G76,189/69:* In rats, hepatic damage produced by bromobenzene, CCl<sub>4</sub>, allyl alcohol and thioacetamide is associated with prolonged **hexobarbital** sleeping time owing to interference with the hepatic microsomal metabolism of the barbiturate. However, the degree of hepatic injury does not run strictly parallel with the prolongation of the hexobarbital sleeping time; hence, the latter cannot serve as an accurate hepatic function test.

*Klinger H 25,517/70:* In male rats, the LD<sub>50</sub> of **hexobarbital** in mg/kg, rises from 160 to 343 between the ages of 12—130 days; however, the blood concentration of hexobar-

bital at waking time is not age-dependent. The sleeping time is directly correlated with the speed of biotransformation by hepatic microsomes *in vitro*.  $\text{CCl}_4$  prolongs sleeping time. Following acute habituation in  $\text{CCl}_4$  treated rats, the hexobarbital concentration of the plasma at waking time is comparatively high.

*Lal et al. G77,285/70*: In rats, hexobarbital anesthesia is prolonged by inhalation of  $\text{CCl}_4$ . The hepatic microsomal fraction of the livers of rats exposed to  $\text{CCl}_4$  exhibited a diminished hexobarbital-metabolizing activity, and the livers of rats so treated were enlarged.

*Levin et al. H26,593/70*: In rats,  $\text{CCl}_4$  given to immature females 24 hrs before sacrifice inhibited the activity of hepatic microsomal enzymes that hydroxylate estradiol-17 $\beta$  and estrone. This inhibition was reflected *in vivo* by an altered metabolism of estradiol-17 $\beta$  and estrone, by a potentiation of the uterotrophic action of folliculoids and by an in-

creased concentration of these steroids in the uterus. By contrast, tetrachloroethylene did not influence the action of estrone. SKF 525-A and desipramine, which are also inhibitors of drug metabolism, likewise potentiate the uterotrophic action of estrone in immature rats.

*Priestly & Plaa G80,048/70*: In rats, "impaired BSP excretion, bile flow rate, relative hepatic storage, and plasma BSP retention were observed as early as 3 hrs after  $\text{CCl}_4$  administration. However, impaired BSP conjugation was not unequivocally demonstrated until 12 hrs after  $\text{CCl}_4$ . In experiments where BSP was administered by slow i.v. infusion (2.5 mg/min/kg), increases in the ratio of biliary unconjugated BSP to conjugated BSP were suggestive of impaired conjugation during the early stages of intoxication, although such changes were not marked when BSP was rapidly injected (60 mg/kg, i.v.)." Presumably, impaired biliary excretion is the main cause of BSP retention after  $\text{CCl}_4$ .

**Steroids.** In man, methandrostenolone increases plasma oxyphenbutazone levels, presumably by interfering with the metabolism of the drug. A variety of steroids inhibits NADH-oxidase and succinate oxidase activities in heart muscle sarcosomal fragments.

In mice, lynestrenol reduces whereas mestranol, like SKF 525-A, increases the anticonvulsive effect of diphenylhydantoin, barbiturates and other drugs, possibly through altered microsomal drug metabolism.

Experiments now under way at our Institute suggest that various steroids (e.g., estradiol) can also act as antagonists of catatonic steroid actions (*cf.* Table 50). However, these studies are still incomplete and will be published in detail later.

*Weiner et al. F35,871/65*: Earlier studies had shown that methandrostenolone inhibits glucuronyl transferase and oxyphenbutazone is excreted largely as the glucuronide. Accordingly, it was found in man that methandrostenolone increases plasma oxyphenbutazone levels, presumably by interfering with its metabolism.

*Stoppani et al. H19,278/68*: "A series of  $\text{C}_{21}$ ,  $\text{C}_{19}$ , and  $\text{C}_{18}$ -steroids (including hormonal steroids and derivatives) have been tested as inhibitors of NADH-oxidase and succinate oxidase activities of heart-muscle sarcosomal fragments (Keilin-Hartree preparation). NADH oxidation is much more sensitive to steroids than succinate oxidation, in accordance with electron transfer inhibition in the vicinity of the NADH-flavoprotein site." The structural

characteristics of the active compounds "are consistent with the interaction of steroids with the phospholipid components of the electron transfer chain at the NADH-flavoprotein site. Many of the structural requirements for inhibition of electron transfer resemble those for androgenicity."

*Blackham & Spencer G73,813/70*: In mice, lynestrenol reduced, whereas mestranol or SKF 525-A increased, the anticonvulsive effect (tested with electroshock) of diphenylhydantoin, phenobarbital, chlordiazepoxide and diazepam administered i.p. after five days of pretreatment. This may be due to altered microsomal drug metabolism but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentrations, the latter mechanism must also be considered.

**Various Other Antagonists.** Among other antagonists of hepatic enzymes, suffice it merely to mention **Thorotrast** (perhaps owing to blockade of the R<sub>ES</sub>) and **metyrapone** (perhaps because of its effect upon P-450) which will be discussed under **Drugs** on p. 582. The latter initially potentiates the action of pentobarbital but subsequently enhances the rate of its detoxication and shortens its narcotic effect in rats. The adrenal cortical necrosis induced by DMBA or 7-OH-MBA is prevented by metyrapone and related compounds. However, no close correlation exists between the influence of these drugs on corticoidogenesis and their ability to protect against adrenal necrosis; they apparently act by inducing hepatic drug-metabolizing enzymes, not by direct effect upon the adrenals.

In mice, **starvation** depresses hepatic microsomal drug metabolism as measured both in vivo and in vitro, perhaps owing to an actual loss of enzyme protein from the microsomes. Oxidative pathways are much more affected than reductive pathways; in fact the latter may actually be activated with regard to certain substrates.

Several observations suggest that RNA synthesis is inhibited by **nickel carbonyl**. **Benactyzine** or infection with **P. berghei** prolong hexobarbital sleeping time. Numerous **methylenedioxyphenyl** compounds, **6-mercaptopurine** and **3-amino-1,2,4-triazole** exert similar effects although in many instances the mechanisms of their actions are still unknown.

*Holten & Larsen G74,395/56:* In mice, hexobarbital anesthesia is considerably prolonged by **benactyzine** (a compound used for the treatment of psychoneuroses). The effect resembles that of SKF 525-A and when given together, the two compounds synergize each other. Extensive review of the literature and of numerous personal observations concerning the barbiturate potentiating effect of various antihistamines and spasmolytic compounds.

*Dixon et al. G65,886/60:* In mice, even the **nutritional status** is an important factor in determining microsomal enzyme induction. "Starvation depresses hepatic microsomal drug metabolism both as measured in vitro and in vivo. This depression is believed to be caused by an actual loss of enzyme protein in the microsomes. Oxidative pathways are affected more than reductive pathways and indeed starvation may result in an activation of reduction of nitro and azo groups." This is shown in Table 3 modified by Goldstein et al. (E165/68) from the original, more complete version of Dixon et al. (G65,886/60).

Mice were starved for 36 hrs then given hexobarbital (80 mg/kg) intraperitoneally. Normal animals usually slept less than 10 min but sleeping time varied greatly in starved mice. Twelve hours later (48 hrs starvation) the mice were sacrificed and the liver microsomes were tested for their drug-metabolizing ability. Figures represent drug metabolized in a fixed incubation time.

Table 3. *Effects of starvation on drug metabolism by mouse liver microsomes*

Substrate	Drug metabolized ( $\mu$ moles/g liver)		
	Sleeping time min		
	5—15	20—40	
	Normal	Starved	> 80
Hexobarbital (aliphatic oxidation)	4.46	2.79	0.77
Chlorpromazine (sulfur oxidation)	2.80	1.98	1.19
Aminopyrine (N-dealkylation)	1.48	1.11	0.46
Acetanilid (aromatic hydroxylation)	2.03	2.22	0.93
p-Nitrobenzoic acid (nitro reduction)	8.22	17.03	8.43
Neoprontosil (azo reduction)	15.55	17.65	12.59

*Agarwal et al. G65,716/69:* In the rat, both *S. typhimurium* endotoxin and Thorotrast lowered hepatic TPO activity, and prevented cortisol from inducing this enzyme in the isolated, perfused liver. Under these conditions, the TKT activity of the liver remained

unaffected. Partial purification of hepatic TPO induced by endotoxin or Thorotrast indicated the presence of some inhibitory substance. "Since histological studies revealed that thorotrast is localized in Kupffer cells, it is suggested that the **reticuloendothelial** system contributes to the control of enzyme induction in rat liver."

*Biezunski G78,643/70*: In rats pretreated with **warfarin**, protein synthesis in hepatic microsomes is inhibited *in vitro*. Vitamin K injected after warfarin almost completely restores the low level of the prothrombin complex in plasma and microsomes, but the general inhibition of protein synthesis by liver microsomes is much less markedly relieved.

*Einheber et al. G75,665/70*: In mice infected with **P. berghei**, hexobarbital sleeping time is prolonged. "This may be due to a disturbance in function of hepatocellular smooth endoplasmic reticulum and its associated drug-metabolizing enzymes because phenobarbital treatment, which ordinarily stimulates an increase of the latter, corrects the 'defect' in hexobarbital sleeping time."

*Fujii et al. G77,242/70*: In mice, 61 **methylenedioxyphenyl compounds** (including synthetic insecticide synergists, natural products, and related open-ring analogues) showed approximately parallel potency as regards hepatic microsomal enzyme inhibition manifested by prolongation of hexobarbital narcosis and zoxazolamine paralysis.

*Raisfeld et al. G75,045/70*: In rats, the herbicide **3-amino-1,2,4-triazole** inhibits the induction by phenobarbital of cytochrome P-450 and drug hydroxylase activity, but does not prevent the proliferation of the SER in

hepatocytes. Presumably "induced increases of cytochrome P-450 and of the membranes of endoplasmic reticulum may be controlled by separate mechanisms."

*Sunderman Jr. G73,628/70*: In rats, <sup>14</sup>C-leucine incorporation into hepatic microsomal proteins is inhibited by **nickel carbonyl**. Previous studies on the inhibition of hepatic RNA synthesis by nickel carbonyl are reviewed.

*Sunderman & Leibman H28,301/70*: "Exposure of rats to **nickel carbonyl**, Ni(CO)<sub>4</sub>, in LD<sub>50</sub> dosage inhibited the basal (noninduced) levels of hepatic aminopyrine demethylase activity. The maximum inhibition of hepatic aminopyrine demethylase occurred on the 2nd day after an injection of Ni(CO)<sub>4</sub>, and aminopyrine demethylase activity returned to normal levels by the 4th day after Ni(CO)<sub>4</sub>. Administration of Ni(CO)<sub>4</sub> also inhibited hepatic aminopyrine demethylase activity in rats that had received daily injections of phenobarbital beginning 5 days before the Ni(CO)<sub>4</sub>."

*Solymoss et al. G70,412/70*: "In rats, 24 hours after a single dose of spironolactone or ethylestrenol, the disappearance of pentobarbital from blood is enhanced to a rate in proportion to the decreasing depth of anesthesia. This action is completely suppressed by ribonucleic acid- or protein-synthesis inhibitors such as actinomycin D, puromycin aminonucleoside and cycloheximide, and only partially by **6-mercaptopurine** or chloramphenicol. . . Induction of drug-metabolizing enzymes is involved in the resistance-increasing effect of spironolactone or ethylestrenol against various compounds."

## TIMING

### *Length of Pretreatment Necessary for Conditioning*

The length of pretreatment necessary for the obtention of resistance by either syntoxic or catatoxic hormones is subject to great variations depending upon dosage, route of administration, the kind of toxicant used, species differences, etc. Some of the protective effects of glucocorticoids are almost immediate if water soluble hormone preparations are given *i.v.* (e.g., against endotoxin shock or certain ganglioplegics); others are much more time-consuming (e.g., the suppression of chronic inflammation). In the case of catatoxic effects, which depend upon defensive enzyme induction, the protection offered always requires some time for enzyme synthesis. With most of the currently employed catatoxic steroids, about 24—48 hrs

of pretreatment are needed to achieve good protection under ordinary conditions of testing against commonly employed toxicants, but often less than 24 hrs suffice and yet it may take several days to reach peak resistance (*cf.* Table 6, p. 88).

Extensive experiments in rats have shown however that the length of pretreatment necessary to obtain a just detectable protective effect depends also largely upon the speed with which the toxicant elicits detectable pharmacologic effects. Thus, even single doses of various catatoxic steroids offer definite protection against many agents whose effects become manifest only after a prolonged latency period. For example, virtually simultaneous treatment with catatoxic steroids and digitoxin *s.c.* can prevent the convulsions and death which the cardiac glycoside would normally produce one or more days later. Here, presumably, the latency period of the drug action allows sufficient time for the induction of defensive enzymes. On the other hand, many hours, or days, of pretreatment with catatoxic steroids are necessary to offer protection against instantly acting anesthetics or convulsive agents.

In the rat and dog, the blood clearance of barbiturates is maximally accelerated within 48–72 hrs and cannot be further enhanced by more prolonged treatment with these drugs. In man, induction is much less rapid and its estimation somewhat complicated by the development of cumulative effects and of local adaptive reactions within the central nervous system. According to some investigators, in mice, effective enzyme induction can occur in less than one hour.

There is some evidence that certain inducers may elicit a three-phasic change in resistance, reminiscent of that characteristic of the general adaptation syndrome. Thus, in rats given daily injections of the pesticide dieldrin, the increase in hepatic weight, microsomal protein, P-450 hemoprotein and SER development persist, yet it is possible to distinguish: 1. The stage of induction when dieldrin tolerance is still low, 2. the steady state with tolerance to otherwise fatal doses of dieldrin and 3. the state of decompensation when drug-handling ability is sharply decreased. Butter yellow produces an essentially similar three stage response.

#### *Duration of Effect after Withdrawal of Conditioner*

In rats, continued treatment with oxandrolone or spironolactone offers protection against daily administration of normally fatal amounts of indomethacin or digitoxin for indefinite periods. However, upon interruption of the catatoxic steroid administration death ensues within a few days. Furthermore, the plasma concentration of the substrates which remains low during catatoxic steroid treatment rises after withdrawal of the medication.

In mice, pentobarbital resistance is evident 24 hrs after pretreatment with phenobarbital, reaches a maximum within 48 hrs and disappears after about 4–5 days.

#### *Reversal of Actions Due to Timing*

**Reversal of Inducer Actions.** In speaking about the duration of inducer effects we already mentioned the three-phasic response in which a period of incomplete induction is followed by a resistant steady state and eventually by exhaustion.

Certain observations suggest however that during the initial period inducers may even have an inverse effect.

For example, 2–4 hrs after administration of hexobarbital the enzyme oxidizing this substrate is reduced in rat liver and activation commences only after 12 hrs, reaching a maximum after 48 hrs.

Pentobarbital anesthesia is shortened and the blood clearance of the barbiturate accelerated within 24 hrs after a single dose of spironolactone or ethylestrenol.

In mice, testosterone exerts a biphasic effect upon hexobarbital hypnosis: prolongation of sleeping time during the initial period of hormone administration is followed by protection. However, here, the initial potentiation is apparently due to a direct effect upon the CNS and unrelated to enzyme induction since it is seen also with barbital which is not metabolized. Yet, many excellent inducing agents have been shown to inhibit drug metabolism during the initial 6 hrs.

**Reversal of Antagonist Actions.** It has been shown of actinomycin, as of many other antagonists, that following an initial period during which they inhibit induction their effect may be reversed. This has been seen with regard to TPO and TKT induction by glucocorticoids. It was tentatively ascribed to a delayed response to inhibitors of RNA synthesis in which a "cytoplasmic repressor" can inhibit the translation of the mRNA's corresponding to TPO and TKT. Cytoplasmic depression might depend upon continued RNA and protein synthesis, the repressor having a rapid turnover rate.

MPDC given 1–12 hrs before hexobarbital prolongs sleeping time and inhibits barbiturate metabolism, whereas MPDC administered 24–48 hrs before the barbiturate has an inverse effect.

**Metirapone** initially potentiates and later inhibits the hypnotic action of pentobarbital in rats, presumably because it gradually enhances hepatic detoxication.

It has been shown for several other antagonists (SKF 525-A, CFT 1201) that, after an initial period of inhibition, microsomal enzyme activity recovers and then increases above normal. Thus, actually many inducers and antagonists exert essentially similar effects in which an initial phase of suppression is followed by stimulation of microsomal drug-metabolizing enzyme activity, but with the inducers the induction, and with the inhibitors the suppression, is by far more pronounced.

**Reversal of Substrate Actions.** For the sake of completeness we should mention the reversal of substrate actions although in practice this is a phenomenon identical with the very common self-induction of catatonic activity by many substrates, such as barbiturates, pesticides, steroids, etc. This type of protection may be more or less limited to the inducer itself or be effective also against other substrates, as we shall see later in discussing the specificity of induction.

In classifying and coordinating the data on the induction of defensive enzymes, it was useful—perhaps even indispensable—to distinguish between inducers, substrates and blockers. Yet, a detached appraisal of the facts does not support the concept that these three classes of compounds are essentially different. Depending upon timing and other experimental conditions, all three types of drugs can either protect or sensitize. It seems that these three groups of compounds have in common a singular effect upon the defensive enzyme-producing mechanism but the direction of the response depends upon modifying factors. It is hardly a coincidence that:

1. Many excellent inducers are also readily detoxified by pretreatment with the same or other inducers. 2. Many substrates can induce or (by competition with other substrates) block enzyme activity. 3. Many blockers can readily be blocked in turn by pretreatment with inducers or, after chronic treatment, can even act as inducers themselves. 4. Most of the substances which are inactive in one of these three respects (e.g. are not inducers, substrates or blockers of the catatoxic mechanism), are also inert with respect to the other two types of effects.

#### **Length of Pretreatment Necessary for Conditioning**

*Remmer G66,542/62:* In the rat and dog, the blood clearance of barbiturates is maximally accelerated within 2—3 days of pretreatment and cannot be further enhanced by prolonged administration of these drugs. In man, oxidation of barbiturates is much less rapid and drug accumulation may develop. Here, tolerance may result from adaptation of the CNS in addition to accelerated oxidative breakdown.

*Hutterer et al. G66,323/69:* In rats, given daily injections of dieldrin (a chlorinated hydrocarbon pesticide), i.p. hepatic changes developed in three stages. "The first stage, that of induction, is characterized by an increase in liver weight, microsomal protein, smooth endoplasmic reticulum, the activity of aniline hydroxylase and p-nitroreductase, and the concentration of P-450 hemoprotein. During the second stage, a 'steady state,' the elevated levels are maintained and tolerance to otherwise fatal doses of dieldrin prevails. In the third stage, that of decompensation, elevation of liver weight, microsomal proteins, and P-450 hemoprotein persists, and the smooth endoplasmic reticulum appears as abundant as in the previous stages, but the activity of the drug-handling enzymes decreases. The smooth endoplasmic reticulum, however, in this last stage consisted of packed tubules. This hypoactive, hypertrophic, smooth endoplasmic reticulum is accompanied by biochemical and morphologic alterations of mitochondria." 3'-Methyl-4-dimethylaminoazobenzene (butter yellow) produces an essentially similar but accelerated three-stage response.

*Kalyanpur et al. G66,147/69:* In mice, various anabolic steroids (methandienone, 4-chlorotestosterone acetate, nandrolone, phenpropionate) given i.p. 90 min before pentylene-tetrazol, inhibit convulsions. The protective effect is compared to that produced by various anesthetic steroids. [A relationship to enzyme

induction is not suggested, nor is it probable in view of the shortness of the necessary pretreatment (H.S.).]

*Solymoss et al. G70,412/70:* In rats, 24 hrs after a single injection of spironolactone or ethylestrenol, the blood clearance of pentobarbital is already greatly enhanced and its anesthetic effect shortened.

*Selye PROT. 17663:* In rats, spironolactone, given simultaneously with digitoxin, has little protective effect; pretreatment for 24 hrs. is moderately effective, whereas spironolactone, given over a period of 48—96 hrs prior to digitoxin, completely abolishes the lethal action of the latter.

Table 4. *Influence of the duration of spironolactone pretreatment upon its antidigitoxin effect*

Spironolactone (Beginning hrs before digitoxin) <sup>a</sup>	Convulsions (Scale: 0—3) <sup>b</sup>	Mortality (Dead/Total) <sup>b</sup>
Controls	3.0	10/10
0	1.4 ± 0.44 **	10/10
24	0 ***	3/10
48	0 ***	0/10
72	0 ***	0/10
96	0 ***	0/10

<sup>a</sup> Digitoxin (1 mg in 1 ml water, p.o., 1st day, and 2 mg 2nd day) in all groups including controls. Spironolactone (10 mg in 1 ml water, p.o. x2/day) beginning at time indicated, on or before initiation of digitoxin treatment.

<sup>b</sup> Convulsions on 3rd day and mortality 7th day after digitoxin administration. Statistics Student's t-test. For further details on technique of tabulation cf. p. VIII.

#### **Duration of Effect after Withdrawal of Conditioner**

*Orrenius et al. E8,231/69:* In rats, 5 days of treatment with phenobarbital greatly in-

creased aminopyrene demethylation by hepatic microsomes, but upon discontinuation of the treatment, this enzyme activity reverted to the starting level within about 3 days.

*Sladek & Mannering G66,219/69*: In rats, 3 days of treatment with phenobarbital, 3-MC, thioacetamide or 3-methyl-4-methylaminoazobenzene (3-MMAB) induced different relative changes in the cytochrome P-450 and the N-demethylase activities of hepatic microsomes. Furthermore, the effect of phenobarbital treatment lasted only about 5 days after discontinuation of this treatment, whereas most of the other agents exerted more persistent effects.

*Buchel & Levy G74,850/70*: In mice, pretreatment with phenobarbital decreases pentobarbital sleeping time; this phenomenon is detectable within 24 hrs and reaches a maximum 48 hrs after phenobarbital administration. The resistance is no longer detectable in males after 96, in females after 120 hrs.

*Solymoss & Selye G70,409/70; Solymoss et al. G70,441/70*: Rats given daily treatment with normally fatal amounts of indomethacin or digitoxin can survive for an apparently indefinite period if they are concurrently treated with spironolactone or oxandrolone. Upon interruption of catatonic steroid administration death ensues within a few days. "Spironolactone enhances not only the degradation of digitoxin and indomethacin but also its own metabolism as judged by their disappearance rate from the blood. However, the capacity of the steroids to inactivate themselves is limited and, hence, they continue to detoxify both drugs, even in chronic experiments."

*Selye PROT. 18125*: In rats pretreated with spironolactone for 6 days, the anti-digitoxin effect remains obvious for about 5 days after discontinuation of treatment, but its efficacy in inhibiting convulsions rapidly diminishes during this time, *cf.* Table 5.

Table 5. Duration of antidigitoxin effect after spironolactone withdrawal

Pretreatment <sup>a</sup>	Digitoxin (hrs after spironolactone) <sup>b</sup>	Convulsions (Scale: 0—3) <sup>c</sup>	Mortality (Dead/Total) <sup>d</sup>
None	3	2.5	10/10
Spironolactone	3	0	0/10
None	48	2.1	5/10
Spironolactone	48	1.3	2/10
None	96	2.4	4/10
Spironolactone	96	3.0	4/10

<sup>a</sup> Spironolactone (10 mg in 1 ml water p.o. x2/day) during 6 days before digitoxin.

<sup>b</sup> Digitoxin (2 mg in 1 ml water/100 g body weight, p.o., once on day indicated) after discontinuation of spironolactone treatment.

<sup>c</sup> 48 hrs after digitoxin treatment.

<sup>d</sup> Mortality on 5th day after digitoxin treatment.

*Selye PROT. 39927*: Rats were given a single treatment with various toxicants, before or after a single dose of certain conditioners. In the event of suitable timing (adjustment of interval between application of the two agents) a single dose of PCN, CS-1 or phenobarbital suffices to inhibit intoxication with digitoxin, indomethacin, dioxathion, parathion, nicotine, progesterone, hexobarbital and zoxazolamine. Taking treatment with the toxicants as "0 hr," it appears that pretreatment with these conditioners at

—24 hrs offers manifest protection in most cases. In some instances, the resistance thus induced lasts several days, e.g., PCN or phenobarbital administered on the —4th day still protects against anesthesia produced by progesterone at 0 hr. On the other hand, some of the conditioners, administered after acutely acting toxicants, may aggravate the effect of the latter. Thus, CS-1 given 30 min after progesterone actually prolongs the resulting anesthesia. The same is true of phenobarbital administered 30 min before or after progesterone.

rone or hexobarbital. The effect of conditioners given 6 hrs after these anesthetics could not be tested since by that time the rats were awake. It will be recalled that such inverse effects had previously been noted when spironolactone was given to rats pretreated with digitoxin. In the case of the more chronically acting toxicants, treatment with the conditioners at -30 or +30 min, can offer definite protection. This was the case especially for digitoxin and indomethacin, but in some instances also for dioxathion. CS-1 diminished indomethacin mortality even when administered 6 hrs after the latter. In all these instances, it may be assumed that the time interval between administration of the toxicant and the manifestation of its damaging actions is sufficiently long to permit drug metabolizing enzyme induction. Apparently, it is not so much the time interval between the administration of the conditioners and the toxicants that counts, but the time interval between conditioning and the appearance of obvious toxic manifestations, *cf.* Table 6, p. 88.

*Selye PROT. 41919:* Rats were given temporary pretreatment with various conditioners, followed by a resting period before challenge with a single dose of a toxicant. In general a 24 hrs interval between cessation of conditioning and challenge offered the best protection. With rapidly acting toxicants (such as progesterone, hexobarbital, zoxazolamine, dioxathion and parathion) good protection was usually obtained even after a rest period of 72 or 120 hrs (*cf.* Table 7, p. 90). Among the toxicants tested in this series, only nicotine and DHT proved to be virtually resistant to this type of conditioning.

### Reversal of Actions Due to Timing

**Reversal of Inducer Actions.** *Remmer G66,542/62:* Brief mention of unpublished experiments showing that 2-4 hrs after administration of hexobarbital, the enzyme oxidizing this substrate is reduced. Activation commences after 12 hrs reaching a maximum after 48 hrs. "Obviously stimulation followed a short phase of inhibition."

*Gessner et al. F77,776/67:* In mice, "testosterone pretreatment produces a biphasic effect on the duration of action of hexobarbital, prolonging the action initially and shortening the action in 4-8 days after the pretreatment. The early action of testosterone appears to be associated with an effect on the

hypnotic property of a drug, since both hexobarbital and barbital sleep times are prolonged, while the duration of action of the muscle relaxant chlorzoxasone remains unaffected. The long-term pretreatment with testosterone leads to a shorter duration of action of drugs that are deactivated by detoxification, notably hexobarbital and chlorzoxasone, but has no effect on the duration of hypnosis produced by barbital, a drug which is predominantly eliminated unchanged." Folliculoids (ethinyl estradiol, diethylstilbestrol) prolong the actions of both drugs.

*Mannerling G71,818/68 (p. 74):* Review of the literature showing that "many good inducing agents actually inhibit drug metabolism during the first 6 hr after administration."

*Wheatley F98,919/68:* Brief reference is made to the observation "that pretreatment of rats with Su 4885 (Metyrapone), while initially potentiating the action of Nembutal, subsequently led to a considerably enhanced rate of detoxification and a shorter duration of narcosis."

*Caster et al. G73,426/70:* In rats, hexobarbital and heptachlor detoxication by hepatic microsomes, *in vitro*, is optimal if the diet contains about 3% of the calories in the form of corn oil (or equivalent amounts of linoleate). Both higher and lower levels of fatty acids are detrimental for the detoxication of these substrates and this was confirmed by determinations of hexobarbital sleeping time *in vivo*. The results are interpreted as indicating that an optimum amount of essential fatty acid is required for the most efficient functioning of the hepatic microsomal drug-metabolizing system.

*Dewhurst & Kitchen G73,848/70:* In mice, zoxazolamine paralysis is greatly shortened soon after a single dose of the carcinogen, whereas upon prolonged treatment, an inverse response is obtained. It is speculated that "an active metabolite formed in relatively small amounts may gradually accumulate or the stimulation of microsomal enzymes by the first dose might lead to enhanced conversion of a subsequent dose into an active metabolite."

*Solymoss et al. G70,423/70:* In rats, pretreatment with catatoxic steroids (e.g., norbolethone, ethylestrenol) enhances the disappearance of bishydroxycoumarin from the blood and counteracts its effect on prothrombin time whereas administration of such steroids

Table 6. *Duration of effect after a single dose of a conditioner*

the animals pretreated with conditioners (asterisks or NS) and the corresponding unpretreated controls have been computed, as in all tables throughout this volume, according to the "Exact Probability Test" for nonparametric values and according to Student's *t*-test for sleeping and paralysis times.

For the group in which the conditioners were administered after the toxicants (when the latter had already produced some mortality) the statistics are computed only on the basis of animals that survived until treatment with the conditioners.

For further details on technique of tabulation *cf.* p. VIII.

<sup>a</sup> 100 g female rats received phenobarbital at the dose of 6 mg, PCN, CS-1, spironolactone and prednisolone acetate at the dose of 10 mg, always in 1 ml water p.o., twice daily during 3½ days, and the toxicants (per 100 g body weight) once, 24 (a), 72 (b) or 120 (c) hrs after the last injection of the conditioners. The signs of intoxication (intestinal ulcers, cardiac calcification, etc.) are registered at the times given in the corresponding column headings. The sleeping and paralysis time is given in min after administration of progesterone, hexobarbital or zoazolamine. For each reading the statistical significance of the apparent differences between the animals pretreated with conditioners and the corresponding unpretreated controls have been computed, as in all Tables throughout this volume, according to the "Exact Probability Test" for nonparametric values and according to "Student's t-test" for sleeping and paralysis times.

For further details on technique of tabulation cf. p. VIII.

2 hrs after bishydroxycoumarin has an inverse effect.

*Szeberényi & Fekete H29,579/70*: Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone, meprobamate, estrone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

*Solymoss & Varga, G70,500/71*: In rats, pretreatment with various cataotoxic steroids accelerates the degradation of bishydroxycoumarin by NADPH-dependent hepatic enzymes. However, if the bishydroxycoumarin is administered immediately after treatment with cataotoxic steroids (norbolethone, ethylestrenol, progesterone or triamcinolone), an inverse effect is observed, presumably because of competitive inhibition.

*Solymoss et al. G79,007/71*: In rats, various cataotoxic steroids (spironolactone, PCN) increase liver weight, glutathione S-aryltransferase activity, bile flow, and BSP clearance from the blood with an accelerated urinary excretion of conjugated BSP metabolites. Ethylestrenol similarly affects liver weight, but not the other parameters. The antimineralocorticoids, spiroxasone, SC-9376 and CS-1, unlike the anabolic steroids norbolethone and oxandrolone, also enhance plasma clearance of BSP. Contrary to the effects of pretreatment, the administration of spironolactone, ethylestrenol or estradiol immediately before BSP results in retention of the dye, probably through competitive inhibition of biliary excretion.

*Solymoss et al. G79,023/71*: In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norbolethone and oxandrolone (anabolics), also enhance plasma clearance of BSP, probably through the same mechanism. In contrast to these effects of pretreatment, administration of spironolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A

does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, these observations clearly show that the cataotoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may also be mediated through extramicrosomal enzyme mechanisms or even through enhanced biliary excretion (H.S.).]

### Reversal of Antagonistic Actions.

#### ACTINOMYCIN

*Serrone & Fujimoto D48,610/61*: MPDC given 1—12 hrs before hexobarbital prolongs sleeping time and delays the metabolism of the barbiturate. However, if MPDC is given 24—48 hrs before hexobarbital, the metabolism of the drug is stimulated and sleeping time is shortened. Data are presented to show that the accelerated metabolism of hexobarbital results from induced synthesis of microsomal enzyme systems that metabolize barbiturates. A similar biphasic response on hexobarbital sleeping time was observed with SKF 525-A, JB 516, iproniazid, orphenadrine, chlorpromazine, and hydroxyzine by several investigators (Holtz et al. D98,342/57; Arrigoni-Martelli & Kramer G74,659/59; Rümke & Bout G74,669/60).

*Garren et al. G28,021/64*: In adrenalectomized rats, a single i.p. injection of cortisol produces an increase in hepatic TPO and TKT activity. Actinomycin D did not inhibit synthesis of these enzymes, but blocked their induction when injected early after cortisol administration. Actinomycin D and fluorouracil stimulated TPO and TKT synthesis when injected 5 hrs or later after cortisol. "It is proposed that repression of the synthesis of these enzymes occurs at the level of messenger RNA translation."

*Tomkins et al. G35,353/65*: Following a single injection of cortisol into adrenalectomized rats, the hepatic TPO and TKT levels rise. "Although actinomycin D blocks the initial steroid-induced increase, later administration of the antibiotic (or of 5-fluorouracil) causes an increase in the levels of these enzymes. A mechanism is proposed to account for the late response to inhibitors of RNA synthesis in which a 'cytoplasmic repressor' can inhibit the translation of the messenger RNA's corresponding to tryptophan pyrrolase and tyrosine transaminase. Cyto-

plasmic repression is postulated to depend on continued RNA and protein synthesis, and the 'repressor' is thought to have a rapid rate of turnover."

*Thompson et al. F81,633/66*: "Tyrosine  $\alpha$ -ketoglutarate transaminase can be induced by steroid hormones in a newly-established line of tissue culture cells, derived from primary culture of the ascites form of an experimental rat hepatoma." Dexamethasone, triamcinolone and cortisol were highly active, DOC and aldosterone much less potent, whereas stilbestrol, estradiol, testosterone and progesterone were virtually inactive. The induction by dexamethasone was blocked by puromycin, cycloheximide, chloramphenicol, progesterone, actinomycin D and mitomycin C. Paradoxically, after induction by the steroid had taken place, actinomycin D produced a further increase in enzyme activity.

*Grossman & Mavrides G46,206/67*: Studies on the kinetics of cortisol-induced hepatic TKT activity in adrenalectomized rats. "Puromycin inhibited enzyme synthesis when it was given during the initial phase of induction. However, it unexpectedly caused a rapid reappearance of enzyme activity following its administration during the inactivation phase. This potentiated response is consistent with other observations which lead to the idea that a repressor is formed about 4 hrs after hormone administration and that inhibition of repressor synthesis allows, at least temporarily, continued synthesis of enzyme." The inactivator appears to depend upon pituitary function, since adrenalectomized and hypophysectomized rats showed little or no inactivation phase following cortisol treatment.

#### SKF 525-A AND OTHER ANTAGONISTS

*Conney & Burns G67,166/62*: Review of the literature on the biphasic effect of SKF 525-A and various related compounds which inhibit microsomal enzymes when given just before the substrate, but actually induce drug-metabolizing enzymes following a more prolonged pretreatment.

*Rümke G69,768/63*: In mice SKF 525-A, phenobarbital, chlorpromazine, hexobarbital and iproniazid given one hour before hydroxydione i.v. increase sleeping time. When the interval is two days, a single dose of SKF 525-A, phenobarbital or chlorpromazine decreases hydroxydione anesthesia. Phenytoin, acetylcarbromal, morphine, chloramphenicol, 5-HT, phenobarbital and hydroxydione given one hour before hexobarbital increase the duration of anesthesia, whereas dioxone and chlorothiazide decrease it. It is concluded that central effects as well as changes in microsomal enzyme activity may be involved.

*Serrone & Fujimoto D80,098/62; Kato et al. E47,494/64*: Considerable changes in the effect of SKF 525-A upon microsomal enzyme activity are seen, depending upon the length of administration. SKF 525-A causes intense enzyme inhibition resulting in prolonged hexobarbital sleeping time when given acutely. However, if administered for prolonged periods, the metabolism of barbiturates is actually enhanced and their effectiveness diminished. This reversal of activity has been noted for several microsomal enzyme inhibitors.

*Bowman et al. E714/68 (p. 520)*: After repeated administration of some of the inhibitors, the activity of the microsomal enzymes recovers and then increases. This has been shown for iproniazid, tolbutamide, carbutamide, CFT 1201 and SKF 525-A.

*Buchel & Levy G74,851/70*: In rats, SKF 525-A may either prolong or shorten pentobarbital sleeping time depending upon dosage and timing.

**Reversal of Substrate Actions.** *Remmer E61,211/59*: In rabbits and dogs, single i.v. injections of various barbiturates caused adaptation with accelerated degradation (judged by enhanced blood clearance).

*Schmid et al. G34,008/64*: "In two cases of glutethimide abuse, it was demonstrated that tolerance to glutethimide is due to marked acceleration of its metabolic inactivation. After a 20-day withdrawal cure, the metabolism of glutethimide was found to have reverted to normal."

### DOSE AND ROUTE OF ADMINISTRATION

Few comparative studies have been done on the relative potency of inducers as influenced by the dosage and route of administration of the inducers themselves and of the substrates. It is clear, however, that both inducers and substrates can be active when administered enterally or parenterally, as long as they are properly

absorbed. However, there are considerable species differences in the gastrointestinal absorption rate of common toxicants, which may give the erroneous impression of innate resistance. Thus, in the hamster, even enormous doses of digitoxin given p.o. cause no signs of poisoning, whereas intravenous injection of this toxicant readily elicits fatal convulsions which can be prevented by catatoxic steroids.

In an extensive study on 304 steroids tested in the rat for catatoxic activity against indomethacin s.c. and digitoxin p.o., it was found that when administered at the dose of 10 mg p.o. twice daily, 42 compounds were active against indomethacin only, 32 merely against digitoxin and 24 against both substrates. At the dose of 0.5 mg, two were active against indomethacin alone, one against digitoxin only and one against both substrates. The most active steroid of this series, PCN was subsequently shown to be active against both substrates even at the 30  $\mu$ g dose level; it also proved to have the broadest spectrum of protective activity against other toxicants. Hence, PCN may be regarded as the most potent catatoxic compound among all hormonal and nonhormonal substances tested up-to-date.

A comparative study on the relative potency of spironolactone and norbolethone against unusually high doses of toxicants showed that spironolactone protects against as much as 2 mg of digitoxin per day p.o., whereas the same dose of norbolethone protects even against 5 mg of digitoxin under identical conditions. Without pretreatment with catatoxic steroids, as little as 0.5 mg of digitoxin per day is fatal to rats in such tests. More recent unpublished observations show that 100 g female rats given 25 mg of PCN, twice daily p.o., can tolerate as much as 30 mg twice daily p.o.(!) for many days without detectable manifestations of damage.

Table 8. *Limits of digitoxin inactivation by spironolactone and norbolethone*

Pretreatment <sup>a</sup>	Digitoxin (mg) <sup>b</sup>	Convulsions (Scale: 0—3) <sup>c</sup>	Mortality (Dead/Total) <sup>d</sup>

<sup>a</sup> Spironolactone and norbolethone (10 mg in 1 ml water x2/day, p.o., 1st day ff.).

<sup>b</sup> Digitoxin dose indicated/100 g body weight (in 1 ml water/day, p.o., 6th day ff.).

<sup>c, d</sup> Convulsions and mortality on 12th day.

*Masson & Hoffman B513/45*: In immature rabbits pretreated with estradiol, progesterone s.c. is much more effective in causing progestational changes in the uterus than if administered p.o. In the partially hepatectomized rabbit, even comparatively small doses of progesterone are active in this respect, "indicating that the liver plays an important role in the inactivation of progesterone in the rabbit." Earlier data on the role of the liver in the inactivation of progesterone are reviewed.

*Selye G70,421/70*: A systematic study on the comparative antidigitoxin anti-indomethacin activities of 304 steroids tested at different dose levels.

*Szabo et al. G79,013/71*: In hamsters, spironolactone and ethylestrenol pretreatment prevents digitoxin convulsions and indomethacin-induced intestinal ulcers. Curiously, hamsters are resistant to as much as 100 mg of digitoxin, given repeatedly p.o., whereas 1 mg i.v. produces strong convulsions. Apparently, in this species, the absorption of digitoxin from the gastrointestinal tract is deficient. Indomethacin intoxication is also different in rats and hamsters since in the latter,

unlike the former, the drug produces predominantly pyloric ulcers which often perforate.

*Selye PROT. 20023:* In rats, spironolactone (10 mg x2/day p.o.) protects against as much as 2 mg of digitoxin/day p.o., whereas the same dose of norbolethone protects even against 5 mg of digitoxin, *cf.* Table 8, p. 94.

*Selye PROT. 28397:* In mice, indomethacin intoxication can be prevented by ethylestrenol, CS-1, spironolactone, norbolethone and, to a lesser extent perhaps, also by prednisolone and estradiol administered by various routes. Thyroxine appears to have an opposite effect. Progesterone, triamcinolone, DOC and hydroxydione had little if any effect.

*Selye PROT. 42710:* In female rats, with an initial body weight of about 100 g, phenobarbital, PCN, ethylestrenol, CS-1, spironolactone, norbolethone and estradiol were administered p.o., i.p., and s.c. at very low dose levels under comparable conditions. Although in a few instances minor differences in the protective effect against progesterone and hexobarbital anesthesia or zoxazolamine paralysis could be ascribed to the route of administration, the latter did not appear to be of paramount importance. In general, conditio-

ners given at the dose administered by one route were also effective when introduced through another portal. Interestingly, the very low dose (0.1 mg) of phenobarbital employed in this experiment appeared to have actually prolonged the effect of zoxazolamine. In order to permit meaningful comparisons, each toxicant had to be tested at the same dose, irrespective of the route of administration and of the toxicant against which it was employed. Since various conditioners are not equally active against progesterone, hexobarbital and zoxazolamine, doses effective against one of these compounds were not necessarily active against the other two, irrespective of the route of administration. Hence, the interpretation of these findings is limited, but they definitely show that no considerable enhancement of the conditioning effect can be expected from changing the portal of its administration. This is particularly interesting in connection with the fact that administration p.o. leads the compound primarily to the liver (the major site of its conditioning effect) and, yet, in general i.p. and/or s.c. administration proved to be about equally efficacious, as shown in Table 9, p. 96.

### *SPECIFICITY OF CONDITIONING*

One of the most astonishing characteristics of the adaptive hormones is the extraordinary spectrum of the toxicants against which they can offer protection. Some of these steroids are highly selective, but others increase resistance to a very large number of chemical or physical agents. Indeed, the spectrum of activity may depend upon circumstances: the syntoxic glucocorticoids protect the adrenalectomized animal against virtually any agent that can produce stress, but there are only a few pathogens to which they can raise tolerance above the normal level. Conversely, the catatoxic steroids, if they possess any protective power at all against a toxicant, can usually augment resistance to it far above the norm.

We shall discuss the activity spectrum of individual adaptive hormones in Chapter XI, but a few characteristic examples should be cited here. Thus, among the catatoxic steroids adequately studied up-to-date, the 16 $\alpha$ -carbonitriles exhibit the broadest activity spectrum, in that they offer some protection against almost every substrate subject to detoxication by steroid-induced enzymes. On the other hand, progesterone and prednisolone protect only against a few toxicants. Many catatoxic steroids protect against digitoxin but not against indomethacin or vice versa.

In rats, spironolactone or oxandrolone administered for as long as 60 days continue to protect against daily administration of normally fatal doses of digitoxin or indomethacin. During this period, the plasma concentrations of digitoxin and indomethacin are diminished although they rise again following discontinuation of catatoxic steroid administration. As judged by the blood level of its metabolite

Table 9. *Effect of route of administration upon catactoxic actions of various conditioners*

The indicated dose of all conditioners was given (per rat) in 1 ml water twice daily, from the first day to the end of the experiment. The toxicants were administered once on the 4th day (per 100 g body weight), as follows: Progesterone (10 mg in 1 ml corn oil, i.p.), hexobarbital (7.5 mg in 1 ml water, i.p.), and zoxazolamine (10 mg in 1 ml water, i.p.).

Statistics: Student's t-test.

SC-9376, spironolactone also enhances its own biotransformation, but not sufficiently to interfere with the continued manifestation of protective activity against the substrates tested. Here, we are faced with a peculiar type of specificity of induction, in that a compound (spironolactone or oxandrolone) can induce an extraordinary amount of enzymic activity against structurally-unrelated toxicants (digitoxin or indomethacin), whereas it develops no noteworthy resistance against itself. In other words, these steroids are much more efficient in eliciting cross-resistance than straight resistance. This is unusual, since in most instances, adaptation to one agent is more easily obtained by pretreatment with the same than with an unrelated agent. The phenomenon is of practical importance since it would be impossible to offer continued protection against toxicants by treatment with catactoxic steroids if they were very efficient in enhancing their own enzymic degradation.

As previously mentioned, substrates readily metabolized by catatoxic steroids, often exhibit inducer and/or blocker activities themselves. Yet, there are many exceptions: digitoxin, nicotine, DHT and indomethacin are all excellent substrates for catatoxic steroids, yet they induce no demonstrable resistance against themselves or against other substrates; indeed, upon chronic treatment at the dose levels tested, their effects were cumulative.

*Solymoss et al. G70,441/70:* In rats, spironolactone or oxandrolone given for as long as two months, continues to exhibit a protective effect against fatal doses of digitoxin or indomethacin. Upon withdrawal of the catatoxic steroids, continued administration of digitoxin or indomethacin is rapidly fatal. The plasma concentration of digitoxin and indo-

methacin is diminished during the catatoxic steroid administration.

*Solymoss et al. G70,464/70:* As judged by the blood level of its metabolite, SC-9376, spironolactone also enhances its own biotransformation, yet its catatoxic effect remains evident during long periods of administration.

### BILIARY EXCRETION

Many of the inducible hepatic microsomal enzymes act upon substrates in such a manner as to facilitate their excretion through the bile or urine. The effect of hormones upon the biliary excretion of toxicants has not received very much attention so far; there can be no doubt that it deserves to be considered more than it has in the past. Several of the toxicants amenable to the influence of certain steroids (e.g., HgCl<sub>2</sub>, indomethacin, DHT) are well tolerated after bile duct ligation, suggesting that their activity depends largely upon the prolongation of their effect by enterohepatic recirculation, poor absorption in the absence of bile, or other factors associated with bile secretion.

Up to now, major emphasis has been placed upon the identification of biliary elimination of bile pigments, bile acids and steroids (as well as their metabolites), using isotope marked substrates.

*Kellaway et al. B14,515/45:* In rats, the activity of thyroxine s.c. was estimated by an increase in pulse rate after partial hepatectomy, thyroidectomy or bile duct ligation. "It was found (1) that thyroxine activity is greatly intensified in the absence of the liver; (2) that the liver does not play a significant role when the amount of circulating thyroxine is within physiologic limits; (3) that the liver deals with excess hormone by some process of inactivation and not by simple excretion."

*Grad & Leblond B49,686/50:* In rats, the increase in oxygen consumption and heart rate induced by thyroxine is increased by partial hepatectomy, or bile duct ligation, and especially by the conjoint effect of both interventions. "These results are taken to indicate that the liver excretes and inactivates excess amounts of thyroid hormone."

*Hyde et al. D99,140/54:* In rats, 17 $\alpha$ -methyl-C<sup>14</sup>- $\Delta^5$ -androstene-3 $\beta$ , 17 $\beta$ -diol administered by gavage was mostly eliminated in the feces and, to a lesser extent, in the urine. "Rats with two types of bile fistula excreted the major fraction of administered isotopic carbon in the bile. Almost quantitative recovery of the administered C<sup>14</sup> was obtained in the urine of rats after ligation of the bile ducts."

*Cherrik et al. E98,251/60:* Indocyanine green is rapidly and completely bound to plasma protein and excreted in the bile in unconjugated form. It is not cleared by extrahepatic mechanisms in detectable amounts. Its plasma clearance is similar to that of BSP in controls and patients with liver lesions.

*Preisig et al. F70,515/66:* In acromegalic patients, biliary BSP excretion is increased. [It is not known which, if any, of the hormones

secreted by the hyperactive pituitary are responsible for this effect (H.S.)]

*Heikel G81,287/67*: In rabbits with an external biliary fistula, norethandrolone and 17 $\alpha$ -ethyl-4-estrone-3 $\beta$ ,17 $\beta$ -diol-3-propionate cause a progressive decline of bile flow and total bilirubin. Methyltestosterone is less effective.

*Kreek et al. F83,145/67*: In rats, ethinyl-estradiol considerably diminishes bile flow and delays biliary excretion of BSP and of tritium-labeled estradiol.

*Klaassen & Plaa F99,395/68*: In rats, pretreatment with phenobarbital accelerated the plasma clearance of BSP. There was no change in hepatic storage but significant increases of *in vitro* metabolism, biliary transport maximum and bile flow were observed. With a dibrominated analogue of BSP and with indocyanine green, which are apparently not biotransformed before excretion, enhanced plasma clearance was also elicited by phenobarbital. It is assumed "that the enhanced biliary excretion of these dyes is an important factor after phenobarbital treatment and that the role of increased biotransformation is not as important for the enhanced plasma disappearance of these dyes as might be expected from the effect of phenobarbital on the biologic half-life of other substances."

*Stowe & Plaa G73,241/68*: Review (19 pp., 226 refs.) on the extrarenal excretion (bile, gastrointestinal tract, sweat, milk, tears, lung and reproductive tract) of drugs and hormones.

*Roberts & Plaa G69,070/69*: In mice and rats, the hyperbilirubinemia induced by  $\alpha$ -naphthylisothiocyanate (ANIT) is enhanced by various drugs and steroids, presumably because of an increased rate of bilirubin production and not as a consequence of decreased biliary bilirubin excretion. "Studies of the rate of endogenous bile bilirubin excretion and the incorporation of  $\delta$ -aminolevulinic acid-<sup>14</sup>C (ALA-<sup>14</sup>C) into bilirubin in rats revealed that phenobarbital and chlorpromazine significantly increased the rate of bile bilirubin production ( $\mu$ g/100 g/hr.) and that phenobarbital, chlorpromazine, and norethandrolone significantly increased the percent incorporation of ALA-<sup>14</sup>C into bilirubin. Acetohexamide and Enovid both produced an increased, but irregular, response in bile bilirubin excretion and ALA-<sup>14</sup>C incorporation."

*Bickel & Minder G77,613/70*: In rats, imipramine is to a large extent excreted in the bile, as judged by observations with bile fistulas or perfused livers. Besides large amounts

of glucuronides, the bile also contains unchanged imipramine or desmethylimipramine following their introduction into the blood stream. In addition, the influence of SKF 525-A and phenobarbital have been studied. A review of the literature suggests that "foreign compounds, in order to be excreted in the bile, must have a molecular weight of more than about 300 and have a certain degree of polarity. Anions of conjugates are particularly suitable for concentrative transfer into bile. In contrast, unchanged lipophilic drugs are assumed not to be excreted by this route, or to occur in bile in concentrations not exceeding the plasma levels."

*Bickel & Minder G77,614/70*: Studies on rats with biliary fistulas show that "uptake of imipramine and desmethylimipramine, but not of hydrophilic metabolites, into the bile salt-phospholipid-micelles of bile could be demonstrated by equilibrium dialysis and ultracentrifuge sedimentation using rat bile or micellar model systems. Biliary proteins and small molecules which do not form micelles do not participate in uptake." These observations throw some light on earlier apparently conflicting claims by showing that both polar and nonpolar metabolites can be excreted through the bile although through different mechanisms.

*Heikel & Lathe G73,162/70*: In rats, various folliculoids and luteoids reduce bile flow. The bilirubin maximum secretion rate (T<sub>m</sub>) is but slightly affected. Following *i.v.* infusion of bilirubin folliculoids (unlike luteoids) raise the serum conjugated bilirubin level.

*Karim & Taylor G74,179/70*: In rabbits, the biliary and urinary excretion of metabolites of [4-<sup>14</sup>C] estradiol are described.

*Klaassen G75,506/70*: In rats, the effects of phenobarbital, chlordane, phenylbutazone, nikethamide, and chlorcyclizine upon bile flow and microsomal enzyme induction have been compared. "There generally appears to be a good correlation in the ability of these agents to increase biliary flow in rats and their ability to increase the plasma disappearance and biliary excretion of BSP and DBSP."

*Kreek & Sleichenger G77,590/70*: In rats, folliculoids are to a large extent excreted through biliary fistulas and under normal conditions they undergo a very large enterohepatic circulation in animals as well as in man.

*Laatikainen G78,706/70*: A review (22 pp., 118 refs.) and personal observations on the excretion of steroid hormones in human bile.

*Levine et al. G73,357/70:* In rats, phenobarbital stimulates biliary excretion of diphenyl, stilbestrol and phenolphthalein, all of which are metabolized prior to excretion. This treatment does not affect biliary elimination of stilbestrol glucuronide, phenolphthalein glucuronide, succinylsulphathiazole, and indocyanine green, all of which are excreted unchanged. These and other observations "suggest that although the endoplasmic reticulum is involved in the metabolism of foreign compounds it does not appear to play a role in their transfer from liver to bile."

*Levine H 31,806/70:* In rats, 3,4-benzpyrene is rapidly excreted through the bile in the form of its metabolic products. Pretreatment with microsomal drug-metabolizing enzyme inducers (e.g., phenobarbital, methylcholanthrene, 3,4-benzpyrene) greatly enhances the rate of biliary excretion of this compound. Both the rate of metabolism and of biliary excretion are enhanced to a similar extent throughout the induction period. Male rats both metabolize 3,4-benzpyrene and excrete its metabolites in the bile at rates approximately 2.5 times that of females. The induction by methylcholanthrene of both the metabolism and the biliary excretion of 3,4-benzpyrene can be partially blocked by ethionine. It has been concluded that conversion to its metabolites is the rate-limiting step in the biliary excretion of 3,4-benzpyrene.

*Song & Kappas G80,521/70:* Review (21 pp., 215 refs.) on the "Influence of Hormones on Hepatic Function," with special sections on the effect of endocrine factors upon bile formation. Some of the principal relevant data are summarized in Table 10.

*Taylor G74,178/70:* In rabbits, the biliary and urinary excretion of metabolites of [4-<sup>14</sup>C] cortisone are described.

*Despopoulos H 35,471/71:* In isolated perfused rat liver preparations, the volume of bile was reduced by progesterone, methyltestosterone, norethynodrel and ethisterone but not by estradiol, mestranol and norethandrolone. The effect of steroids upon biliary secretion is reviewed.

*Solymoss et al. G79,007/71:* In rats, various catatoxic steroids (spironolactone, PCN) increase liver weight, glutathione S-aryltransferase activity, bile flow, and BSP clearance from the blood with an accelerated urinary excretion of conjugated BSP metabolites. Ethylestrenol similarly affects liver weight, but not the other parameters. The anti-

Table 10. *Effect of hormones on hepatic bile flow*

Hormones	Species Studied	Effect
Cholecystokinin-pancreozymin	Dog	Increase
Epinephrine	Dog	Increase, followed by decrease
Ethinylestradiol	Rat	Decrease
Gastrin	Dog	Increase
Insulin	Dog	Increase
Norepinephrine	Dog	Decrease
Norethandrolone	Rabbit	Decrease
Secretin	Dog	Increase

mineralocorticoids, spiroxasone, SC-9376 and CS-1, unlike the anabolic steroids norbolethone and oxandrolone, also enhance plasma clearance of BSP. Contrary to the effects of pretreatment, the administration of spironolactone, ethylestrenol or estradiol immediately before BSP results in retention of the dye, probably through competitive inhibition of biliary excretion.

*Solymoss et al. G79,023/71:* In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione, S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norbolethone and oxandrolone (anabolics) also enhance plasma clearance of BSP, probably through the same mechanism. By contrast to these effects of pretreatment, administration of spironolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, these observations clearly show that the catatoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may be mediated also through extramicrosomal enzyme mechanisms or even through enhanced biliary excretion (H.S.)]

### EXTRAHEPATIC CONDITIONING

The liver is undoubtedly the principal site of drug metabolism, but virtually all cells are endowed with some adaptive ability to toxicants.

Probably, the first observation on the extrahepatic detoxication of a steroid was the finding that estradiol is inactivated by slices or mince of renal tissue of rats and rabbits. It was realized, as early as 1940, that this inactivation is, in all probability, not due to conjugation or conversion to a less active form, but to oxidative enzymic degradation.

Pretreatment with cortisol increases the GPT activity not only in the liver, but also in the thymus, pancreas, and kidney of the rat. In the thymus, this increase may reach 16 times the normal level.

1,2-Benzanthracene increases benzpyrene hydroxylase activity throughout the entire gastrointestinal tract of various species.

Glucuronic acid conjugation of thyroid hormones occurs even after hepatectomy in the dog or after evisceration in rats, whereas steroid glucuronides are not formed following hepatectomy or evisceration.

Phenobarbital increases both hepatic and (to a lesser extent) renal weight. At the same time, the cytochrome  $b_5$  and P-450 concentrations and the drug metabolism are raised 2–3 fold by phenobarbital in the kidneys of rabbits.

Phenobarbital also enhances incorporation of acetate into cholesterol by both the liver and the small intestine *in vitro*.

Smoking during pregnancy causes an increase in the benzpyrene hydroxylase activity of the human placenta. A similar enzyme activation can be obtained in the placenta of the rat by pretreatment with various polycyclic hydrocarbons.

In man, pretreatment with heptabarbital diminishes the plasma bishydroxycoumarin level more markedly if the anticoagulant is given *p.o.* than *i.v.* Presumably, part of the protective effect of heptabarbital is caused by increased hepatic destruction of bishydroxycoumarin, but diminished gastrointestinal absorption also plays a role.

Isotope-marked progesterone placed in the small intestine of dogs, was found in the effluent venous plasma, at first mainly as unchanged progesterone, but later in the form of various metabolites which must have been formed locally.

In connection with extrahepatic drug detoxication, it should be remembered that a sizable percentage of various drugs and hormones is excreted through the kidney, bile, gastrointestinal tract, sweat, milk, tears, lung and reproductive tract. Stimulation of these excretory mechanisms also plays an important part in resistance to toxicants. These phenomena are considered here although often toxicants are excreted only after biotransformation in the liver.

For further details on extrahepatic drug inactivation, *cf.* the reviews cited in the following Abstract Section.

#### **Kidney**

*Masson & Beland A72,286/44; B344/45:* Review of the literature on the effect of partial hepatectomy and other forms of liver damage upon barbiturate anesthesia. Personal obser-

vations on a series of 29 barbiturates tested on partially hepatectomized or completely nephrectomized rats led to the conclusion that the compounds can be classified into four groups: "Group I, those detoxified mainly in the kidney; Group II, those detoxified mainly

in the liver; Group III, those detoxified approximately equally in both liver and kidney; Group IV, those possibly detoxified in other tissues of the body, but not to any great extent in the liver and the kidney."

*Friedman et al. A49,249/49:* In rats, urinary excretion of digitoxin is negligible.

*Smith D27,805/62:* Studies on the effect of hyaluronidase and cortisol on the inactivation of vasopressin by rat kidney slices.

*Weiner G74,032/67:* Review (18 pp., 146 refs.) on the mechanism of renal excretion of drugs.

*Uhleke & Greim G70,906/68:* In rats and rabbits, phenobarbital increases the weight of the liver and, to a much smaller extent, that of the kidney. "Pretreatment with Phenobarbital, 3,4-Benzpyrene or Chlorophenothane neither significantly increased the cytochromes of rat kidney microsomes, nor the oxidative drug metabolism. However, in the kidneys of rabbits the cytochrome  $b_5$  and  $P_{450}$  concentrations and drug metabolism were 2-3 fold higher after Phenobarbital. The correlation between  $P_{450}$  content and drug oxidase activity in the kidney microsomes of untreated and Phenobarbital treated rabbits was low. Suspension of rabbit kidney microsomes revealed the same spectral changes after addition of Hexobarbital or Aniline as those reported for liver microsomes."

*Karim & Taylor G74,179/70:* In rabbits, the biliary and urinary excretions of metabolites of [4- $^{14}C$ ] estradiol are described.

*Maruyama et al. G74,893/70:* Review of the literature indicating that the main site of parathyroid hormone inactivation in the rat is the kidney. The present authors succeeded in isolating a microsomal endopeptidase from the rat kidney which preferentially hydrolyzes parathyroid hormone.

*Taylor G74,178/70:* The biliary and urinary excretions of metabolites of [4- $^{14}C$ ] cortisone in rabbits are described.

### Gastrointestinal Tract

*Berliner & Wiest C22,807/56:* Progesterone, given i.v., is extensively metabolized in 1 hour by totally eviscerated rats, even if the kidneys and adrenals are also removed. After 1 hour, 7 compounds could be isolated from the tissues of these animals, although there were no polar metabolites similar to the conjugates with glucuronic or sulfuric acid, and the 7 isolated compounds retained their  $\Delta^4$ -3-ketone configuration.

*Bojesen & Egense G75,996/60:* In adrenalectomized cats, the elimination of endogenous corticoids (cortisol and corticosterone) is greatly delayed by hepatectomy and totally abolished by evisceration. "A few experiments suggested that the intestine is responsible for the main part of the extrahepatic elimination. In experiments with the perfused isolated hindquarter preparation it was impossible to demonstrate any elimination of corticosteroids in spite of electrical stimulation or the administration of large amounts of insulin."

*Wattenberg et al. D40,287/62:* Benzpyrene hydroxylase activity can be demonstrated in the small intestine of various species. Following 1,2-benzanthracene p.o., this enzyme activity is increased throughout the entire gastrointestinal tract but varies in magnitude from one region to another.

*Aggler & O'Reilly G68,730/69:* In man, pretreatment with heptabarbital diminished the reduction in the prothrombin level, the amount of bishydroxycoumarin in plasma, and the half-life of bishydroxycoumarin more markedly after p.o. than after i.v. administration of the anticoagulant. Unchanged bishydroxycoumarin was found in the stool only after p.o. administration. Presumably, part of the response to heptabarbital was caused by increased hepatic enzymic destruction of bishydroxycoumarin although, in the event of p.o. administration, decreased absorption from the gastrointestinal tract also played a role.

*Middleton & Isselbacher H17,133/69:* In rats, phenobarbital increases incorporation of acetate into cholesterol not only by the liver but also by the small intestine *in vitro*.

*Nienstedt & Hartiala G69,886/69:* "Progesterone-4- $^{14}C$  placed in the small intestine of anaesthetized, heparinized dogs was found in the effluent venous plasma, first mainly as unchanged progesterone, then increasingly in the form of different metabolites. These include 5 $\alpha$ -pregnanedione, 20 $\beta$ -hydroxypregn-4-en-3-one, 3 $\beta$ -hydroxy-5 $\alpha$ -pregnan-20-one, 3 $\alpha$ -hydroxy-5 $\alpha$ -pregnan-20-one, at least one pregnanediol epimer and a large group of polar metabolites."

*Lien et al. H25,091/70:* In dogs and Rhesus monkeys, serum corticoid concentrations were measured by the corticosteroid binding-globulin (CBG) technique which measures cortisol, corticosterone and 11-desoxycortisol in plasma as judged by differences in the corticoid concentration in portal and aortic

blood. A noteworthy portion of corticoids is removed through clearance by the gut, especially during conditions of stress.

### RES

*Reichard et al. C32,593/56:* Review of the literature, and personal observations on the role of the RES in the hormonal regulation of resistance to bacterial infection and nonspecific stress.

*Agarwal et al. C65,716/69:* In the rat, both *S. typhimurium* endotoxin and Thorotrast lowered hepatic TPO activity, and prevented cortisol from inducing this enzyme in the isolated, perfused liver. Under these conditions, the TKT activity of the liver remained unaffected. Partial purification of hepatic TPO induced by endotoxin or Thorotrast indicated the presence of some inhibitory substance. "Since histological studies revealed that thorotrast is localized in Kupffer cells, it is suggested that the reticuloendothelial system contributes to the control of enzyme induction in rat liver."

*Munson et al. H22,843/70:* "Drugs which alter the phagocytic activity of the RES have been shown to prolong barbiturate anesthesia. In this study, these observations were extended to include agents which decrease RES activity. Methyl palmitate, thorium dioxide and pyran copolymer (PCP) markedly decreased the intravascular clearance of colloidal carbon and prolonged hexobarbital anesthesia. Zymosan, endotoxin, diethylstilbesterol and PCP enhance RES activity and also prolong hexobarbital narcosis. Conversely, chlorcyclizine, SKF 525-A and phenobarbital, which markedly alter drug metabolism, did not alter RES activity. PCP and zymosan prolonged the half life of hexobarbital in brain, liver and serum. Hexobarbital metabolism was markedly depressed in 9000x g liver supernatant fractions from PCP and zymosan-treated mice. Further studies demonstrated that the inhibition of barbiturate metabolism was non-competitive. PCP and SKF 525-A were additive in microsomal inhibitory ability whereas chlorcyclizine, given in a protocol which stimulates microsomal enzyme activity, reverses the inhibitory effect of zymosan. The toxicity of cyclophosphamide, which requires hepatic microsomal enzyme activity for cytotoxicity, was markedly enhanced by PCP suggesting the enzymes necessary for the activation of cyclophosphamide are stimulated by PCP."

### Placenta

*Welch et al. G65,788/69:* No detectable benzpyrene hydroxylase or aminoazo dye N-demethylase activity was observed in the placentas of women who did not smoke but these enzymes were found in the placentas of smokers. In rats, treatment with 3,4-benzpyrene, 1,2-benzanthracene, 1,2,5,6-dibenzanthracene, chrysene, 3,4-benzofluorene, anthracene, pyrene, fluoranthene, perylene, or phenanthrene during pregnancy increased benzpyrene hydroxylase activity in the placenta.

### Brain

*Angel & Burkett G39,712/66:* Review of the literature (6 pp., 21 refs.) on the role of stress and corticoids in influencing resistance to various drugs through alterations in the blood-brain barrier.

*Fuller G75,131/70:* In rats, exposure to cold, as well as treatment with cortisol or glucagon after adrenalectomy induced TKT activity in the liver but not in the brain. Apparently, the TKT "of brain differed from the enzyme in liver since it did not exhibit diurnal variations of activity and was not affected by hormones, drugs, or stress."

### Varia

*Heller A32,137/40:* In vitro studies on tissue slices and tissue mince of rats and rabbits indicate that "estradiol is inactivated by liver and kidney and not by the other tissues studied. This inactivation of estradiol is, in all probability, not due to conjugation or conversion to a less active form, but due to enzymic destruction of an oxidative nature. This is indicated by the relative inactivity of the treated estradiol, the inability of hydrolysis procedures to increase activity and the effect of tissue poisons upon inhibiting the estradiol-destroying enzyme system. Estrone is increased 20 times in potency by incubation with minced uterine tissue. Spleen, lung, heart and kidney tissues also caused estrone to be converted to a more active substance. The suggestion is made that this conversion is accomplished by enzymatic reduction of estrone to estradiol."

*Chedid et al. B99,547/54:* In mice rendered particularly sensitive by adrenalectomy, *E. coli* endotoxin injected i.v. or into the spleen is equally toxic. Similar results have been ob-

tained in intact rats. "Thus the liver does not appear to play an immediate role in the detoxification of this antigen." In partially hepatectomized rats "which become more sensitive to any toxic substance" cortisone continues to exert its protective effect against endotoxin. The same is true of the **splenectomy** or **thymectomy**.

*Rosen et al. C71,414/59*: Pretreatment with cortisol increased the GPT activity not only in the liver but also in the **thymus, pancreas** and **kidney** of the rat. In the thymus the increase was 16-fold on the basis of protein content.

*Šulcová & Stárka E37,298/63*: Demonstration of extrahepatic 7 $\alpha$ -hydroxylation of dehydroepiandrosterone by in vitro studies using different rat organs (**lung, kidney, spleen, muscle, blood**).

*Govier F57,820/65*: In rabbits, acetylation of sulfanilamide and p-aminobenzoic acid (one of the major routes of metabolism of acrylamines) has been examined utilizing isolated intact hepatic and **RES cells** of various other tissues. "The acetylation of these compounds, usually attributed to the liver, was found to occur in cells of the reticuloendothelial system. No acetylation could be demonstrated in the hepatic parenchymal cells. Lung and spleen, organs known to contain a high percentage of reticuloendothelial cells, were also found to acetylate these compounds."

*Jayle & Pasqualini G67,284/66*: Review (36 pp., 267 refs.) on glucuronic acid conjugation of steroids and thyroxine. Literature is cited to show that glucuroconjugation of thyroid hormones occurs also in **eviscerated** rats and hepatectomized dogs, whereas steroid glucuronides are not formed in hepatectomized and eviscerated mice. This suggests that glucuroconjugation of thyroid hormones, unlike that of steroids, can occur in extrahepatic tissues.

*Conney F88,649/67 (p. 340)*: Review of the literature on enzyme induction in **nonhepatic tissues**.

*Goldstein et al. E165/68 (p. 232)*: Review on **extrahepatic** drug metabolism as influenced by various inducers.

*Mannering G71,818/68 (p. 77)*: Review on the induction of drug-metabolizing enzymes in the **lung, gastrointestinal tract** and **kidney**.

*Stowe & Plaa G73,241/68*: Review (19 pp., 226 refs.) on the extrarenal excretion (**bile, gastrointestinal tract, sweat, milk, tears, lung and reproductive tract**) of drugs and hormones.

*Wattenberg et al. G71,805/68*: In rats, the increase in benzpyrene hydroxylase activity induced by various 2-phenylbenzothiazoles usually shows a similar trend in **liver** and **lung**.

*Uehleke G70,915/69*: Review on **extrahepatic** microsomal drug metabolism.

*Conney G70,316/70*: Review on environmental factors influencing drug metabolism with a special section on **extrahepatic** microsomal-enzyme induction.

*Schoor H28,965/70*: A farmer from an area of heavy pesticide usage was given phenobarbital and diphenylhydantoin for the treatment of epilepsy. His blood levels of DDT, DDE, dieldrin and heptachlor were far below those of other farmers living in the same area. It is assumed that either the drugs activated microsomal enzymes which destroy the pesticides or "that the pesticides are bound by **serumproteins**, and are consequently relatively inert. The action of the drugs on the pesticides depends on the competition of both for the same binding sites on the proteins."

*McArthur et al. G81,040/71*: Studies on the binding of indomethacin, salicylate and phenobarbital to human whole **blood, plasma**, and **erythrocytes** (equilibrium dialysis), showed that "the red cells bound appreciable proportions of salicylate and phenobarbitone but not indomethacin. It is concluded that prediction of the extent of the drug binding to the circulating blood should be made from the results obtained with whole blood, red cells and plasma."

## TOXICANTS (CHARACTERISTICS OF TYPICAL SUBSTRATES)

At present, the most popular basis for the classification of substrates amenable to biotransformation by hepatic microsomal enzyme systems is their preferential binding to hepatic hemoprotein P-450 as determined by difference spectra. It is generally agreed that, on this basis, the response of the substrates remains of the same

type whether they are exposed to naturally-occurring microsomal enzyme constituents or to those artificially induced by different compounds. Furthermore (with one or two possible exceptions), the **Type I** or **Type II** behavior of a substrate (*cf.* p. 15) is unchanged upon incubation with hepatic microsomes of different species. It is suggested that the Type I and Type II binding sites differ and that the Type I site is associated with membrane phospholipids (Chaplin & Mannering G75,976/71).

The following is a partial list of substrates that have been categorized in this manner (largely based on Mannering G74,558/71):

<b>TYPE I</b>	<b>TYPE II</b>
Aminopyrine	Acetanilide
(Dimethylaminoantipyrine)	Acetone
Amobarbital	Alcohols (methyl-, ethyl-, 2-propyl-, isobutyl-, isoamyl-)
3,4-Benzpyrene	1-Butanol
Chlorpromazine	Amines (n-propyl-, n-butyl-, n-pentyl-, n-heptyl-, n-acetyl-, n-decyl-, benzyl-, cyclohexyl-)
Coumarin	p-Aminophenol
Cyclohexane	Amphetamine
DDT	Aniline
Dihydrosafrole	Corticosterone
N,N-Dimethylaniline	Cortisol
$\beta$ -Estradiol	Cyanide
Ethylbenzene	Desdimethylimipramine
Ethylmorphine	Dioxane
Hexobarbital	DPEA
Imipramine	Ethyl isocyanide
Lilly 327—169—22B	Imidazole
Lilly 390—378—23B*	Lilly 390—378—23B*
Methylphenidate	N-Methylaniline
Morphine	3-Methyl-4-Methylaminoazobenzene
Naphthalene	Metirapone
Phenacetin	Monomethylaminopyrine
Phenobarbital*	Nicotinamide
Pregnenolne	Nicotine
Progesterone	Phenobarbital*
SKF 525-A	Phenylhydrazine
SKF 8742-A*	Pyridine
Testosterone	Rotenone
	SKF 8742-A*
	SKF 26754-A

\* Can be Type I or II depending upon circumstances (e.g., species).

It will be noted that among the steroids in this list, some (estradiol, pregnenolone, progesterone, testosterone) are classified as Type I substrates, whereas others (corticosterone, cortisol) belong to Type II. Much more work will be necessary to classify, according to these criteria, all steroids that have been found to be either inducers of, or substrates for, microsomal enzymes. Meanwhile, it is even debatable whether there is any close relationship between the differential spectrographic behavior of substrates and their effects *in vivo*.

Within the frame of this monograph it would be impossible to describe in detail the characteristics of all the substrates whose metabolism and toxicity are

influenced by catatoxic compounds. Most of the pertinent data will be found in the sections on individual inducers affecting these toxicants since it is according to the inducers that our material is arranged. Here, we should like to give only brief outlines and key references on the characteristics of the substrates themselves.

**Steroid hormones** are especially important both as substrates and as inducers of catatoxic activity; hence, they deserve special attention in connection with our subject. The major pathways of biosynthesis of adrenal steroids and some of the enzymes and coenzymes involved may be summarized as shown on p. 106.

Here the major secretory products are underlined. In the zona fasciculata and zona reticularis, no aldosterone is formed. In the zona glomerulosa, aldosterone is produced but no 17-hydroxylated compounds or sex hormones are formed. The enzymes and cofactors for the reactions progressing down each column are shown on the left and from the first to the second column at the top of the chart. When a particular enzyme is deficient, hormone production is blocked at the points indicated by the shaded bars.

Among the most interesting steroid substrates is **cholesterol**, because of its important role in atherosclerosis. Experimental findings suggest that by accelerating its metabolic degradation through catatoxic compounds, cholesterol atherosclerosis can be prevented in animals and perhaps even in man.

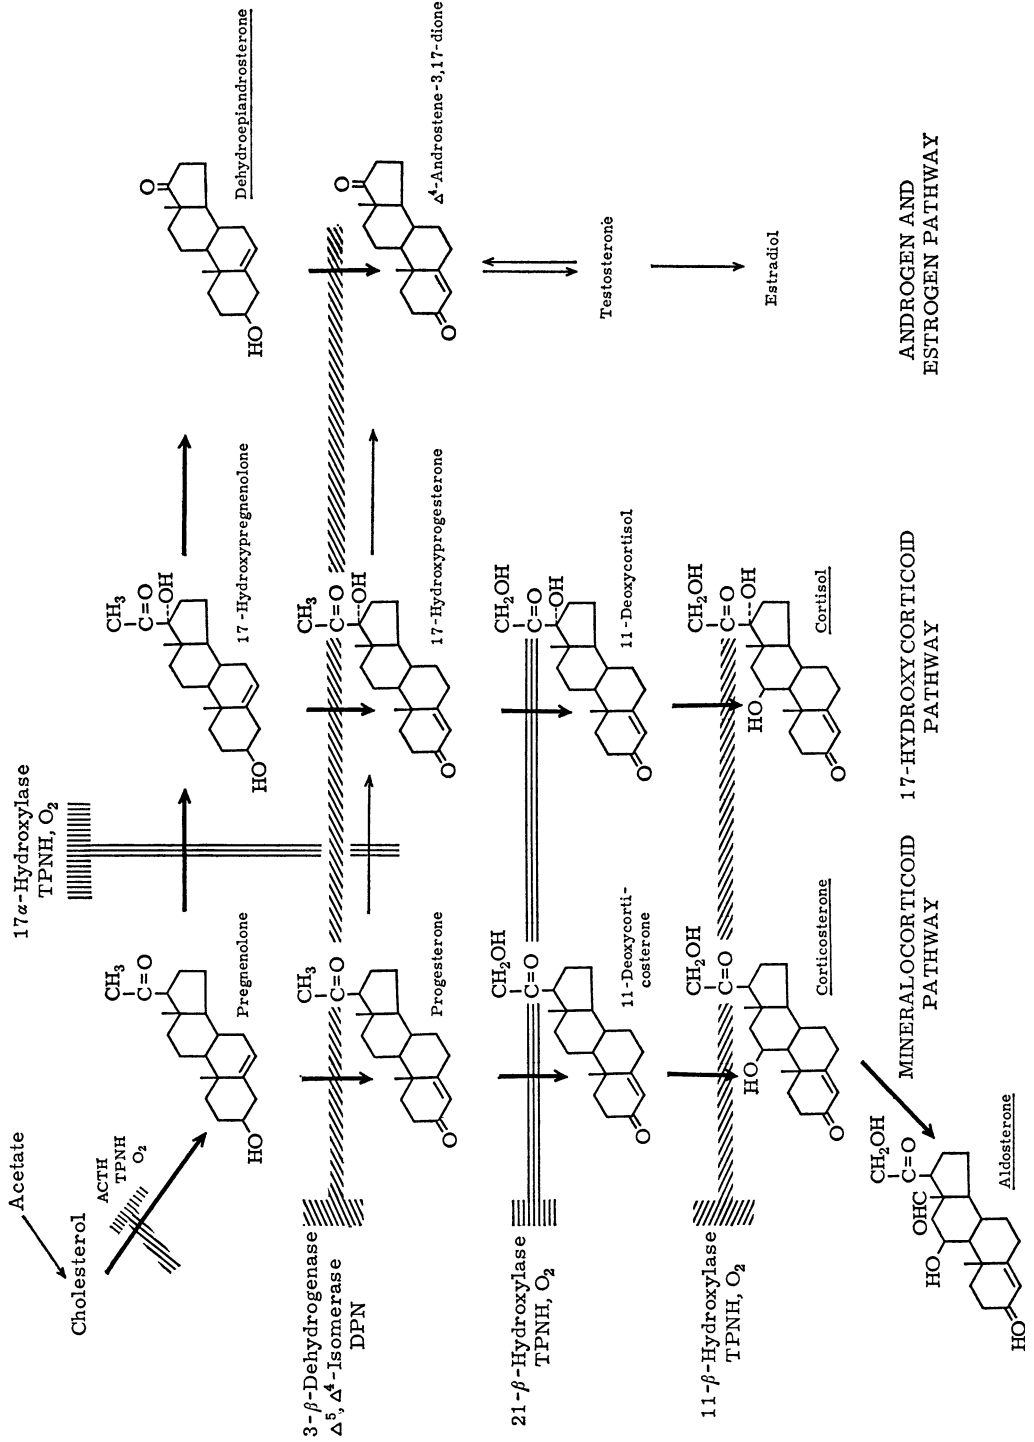

The **digitalis compounds** (closely related to steroid hormones and cholesterol) are among the most commonly-used substrates in work on catatoxic steroids. The following Abstract Section lists several excellent reviews on the pharmacology of digitalis compounds and data concerning the mechanism of digitoxin hydroxylation in the rat. Chronic administration of digitoxin significantly inhibits both the synthesis and the stress-induced release of ACTH, thereby causing some degree of adrenal atrophy. Digitoxin has even been claimed to inhibit stress-induced adrenal hypertrophy suggesting close relationships between this cardiac glycoside and corticoids.

The **barbiturates** represent another large group of drugs commonly employed in experimental work on the action of catatoxic compounds, because — like digitoxin, pesticides or indomethacin — they are readily attacked by induced hepatic microsomal enzymes. For these reasons the various factors influencing the distribution, metabolism and action of barbiturates have been carefully explored but all these data cannot be reviewed here.

An interesting fact from the point of view of barbiturate detoxication is that both in animals and in man just awakening from barbiturate hypnosis, it is possible to reinduce sleep by cortisone or i.v. injection of glucose. The mechanism of this singular phenomenon is not understood, but it obviously cannot be due to interference with induction or enhanced degradation of drug-metabolizing enzymes, since the plasma-barbiturate concentration has already fallen below the anesthetic level when sleep is reinduced. It is conceivable, however, that glucocorticoids and glucose discharge barbiturates from tissue stores into the blood, increase the barbiturate sensitivity of the brain, or augment the permeability of the blood-brain barrier.

Despite great individual variations in the duration of pentobarbital narcosis or zoxazolamine paralysis among rats, the brain concentration of these drugs closely parallels their pharmacologic activity. Apparently, individual variations in barbitu-

Composite outline of major pathways in adrenocortical hormone biosynthesis (after Weliky, Mulrow & others, from Ganong G74,400/69).

rate (and zoxazolamine) sensitivity among rats are not due to great differences in the drug-sensitivity of the nervous system but to differences in drug absorption and metabolism.

The salient characteristics of the barbiturates most commonly employed in North America are illustrated as follows (Sharpless E 8,852/70):

Table 11. *Barbiturates most commonly used in North America*

Barbiturate	Trade name	R <sub>1</sub>	R <sub>2</sub>	R <sub>3</sub>	X
Allobarbital	Dial	allyl	allyl	H	O
Amobarbital	Amytal	ethyl	isopentyl	H	O
Aprobarbital	Alurate	allyl	isopropyl	H	O
Barbital	Veronal	ethyl	ethyl	H	O
Butobarbital	Butisol	ethyl	<i>sec</i> -butyl	H	O
Butalbital	Sandoptal	allyl	isobutyl	H	O
Butallylonal	Pernoston	<i>sec</i> -butyl	2-bromoallyl	H	O
Butethal	Neonal	ethyl	butyl	H	O
Cyclobarbital	Phanodorn	ethyl	cyclohexen-1-yl	H	O
Cyclopentyl allylbarbituric acid	Cyclopal	allyl	2-cyclopenten-1-yl	H	O
Heptabarbital	Medomin	ethyl	1-cyclohepten-1-yl	H	O
Hexethal	Ortal	ethyl	<i>n</i> -hexyl	H	O
Hexobarbital	Evipal	methyl	1-cyclohexen-1-yl	CH <sub>3</sub>	O
Mephobarbital	Mebaral	ethyl	phenyl	CH <sub>3</sub>	O
Metharbital	Gemonil	ethyl	ethyl	CH <sub>3</sub>	O
Methitural	Neraval	2-methylthioethyl	1-methylbutyl	H	S
Methohexital	Brevital	allyl	1-methyl-2-pentynyl	CH <sub>3</sub>	O
Pentobarbital	Nembutal	ethyl	1-methylbutyl	H	O
Phenobarbital	Luminal	ethyl	phenyl	H	O
Probarbital	Ipral	ethyl	isopropyl	H	O
Secobarbital	Seconal	allyl	1-methylbutyl	H	O
Talbutal	Lotusate	allyl	<i>sec</i> -butyl	H	O
Thiamylal	Surital	allyl	1-methylbutyl	H	S
Thiopental	Pentothal	ethyl	1-methylbutyl	H	S
Vinbarbital	Delvinal	ethyl	1-methyl-1-butenyl	H	O

The pharmaco-chemical correlations in the barbiturate series have been the subject of very numerous and careful studies. In general, structural changes resulting in increased lipid solubility shorten the duration of action (presumably owing to more rapid metabolic degradation) and often accelerate and increase hypnotic potency. Such changes result for example from an increase in the length of one or both alkyl side-chains at C<sub>5</sub> (R<sub>1</sub>, R<sub>2</sub>, up to 6 or 7 carbon atoms). On the other hand, hypnotic activity is abolished by the introduction into the alkyl side-chains of func-

tional or polar groups, such as keto, ether, hydroxylamino or carboxyl groups. Methylation of one of the nitrogens increases lipid solubility and also decreases the duration of action. A very reactive alkyl group or phenyl group at C<sub>5</sub> endows the barbiturate with selective anticonvulsant effects. On the other hand, slight changes in structure may convert barbituric acid derivatives into convulsants (e.g., prolongation of the side-chain at C<sub>5</sub>). Alkyl substitution of both nitrogens also tends to yield convulsant compounds. Replacement of the carbonyl oxygen at C<sub>2</sub> (X) yields thio-barbiturates which are also fat soluble, rapid in onset of activity and short in duration of action.

Because of their great economic importance, the organic phosphate-anticholinesterase pesticides have been the subject of extensive comparative toxicologic studies in many species. Many of these compounds are also readily detoxified by catatoxic drugs and hormones, and most of them are more toxic to female than to male rats, but in a few cases the reverse is true. For example, OMPA is in itself virtually devoid of toxicity but both mammalian liver and plant tissue can transform it into an active anticholinesterase. Accordingly the toxicity of OMPA—unlike that of most toxicants subject to biotransformation by hepatic enzymes—is actually diminished by partial hepatectomy. Yet, as we shall see later, contrary to expectations, highly potent catatoxic steroids do not increase OMPA toxicity, perhaps because they not only transform the compound into a toxic anticholinesterase but also enhance the further degradation of the latter into nontoxic end products. For a few key references on the metabolic inactivation and toxicology of mercury, CCl<sub>4</sub>, nicotine, indomethacin, etc., the reader is referred to the Abstract Section.

### **Steroids**

*Danielsson & Tchen G72,327/68:* Review (51 pp., 242 refs.) on the biosynthesis and metabolism of cholesterol, phytosterol, insect sterols, bile salts and bile pigments, including the factors (diet, hormones) influencing these. Steroid hormone metabolism is not discussed.

*Samuels & Eik-Nes G73,454/68:* Review (52 pp., 223 refs.) on the biosynthesis, transport, distribution and metabolism of steroid hormones. Several instructive tables summarize the steroid hormones naturally produced by the various endocrine glands or demonstrated to occur in the blood stream.

### **Digitalis**

*Cox & Wright G66,614/59:* In rats, paper chromatographic and colorimetric studies revealed that “in bile lanatosides A and C were excreted unchanged. Digitoxin, digoxin and digoxigenin were present partly unaltered and partly as metabolites which still retained the unsaturated lactone ring. Digitoxigenin was excreted entirely as metabolites.”

*Repke D27,189/59:* Studies on the mechanism of digitoxin hydroxylation in the rat.

*Vernikos-Danellis & Marks D21,210/62:* Review of the literature on the interrelations between digitoxin and the hormones of the pituitary-adrenal axis. “The experiments described here demonstrate that chronic administration of digitoxin significantly inhibits both synthesis and stress-induced release of pituitary ACTH.” In rats, small doses of digitoxin produce adrenal atrophy although large doses (which act as stressors) have an opposite effect. Earlier publications had shown that digitalis glycosides increase the performance of animals subjected to stress, prevent the adrenal hypertrophy caused by stress, and prolong the life of adrenalectomized rats, mice and cats.

*Dutta & Marks G73,208/66:* In rats and guinea pigs the distribution studies of isotope marked ouabain and digoxin show that particularly high concentrations are found in the liver, kidney, adrenal and pituitary.

*Gibson & Becker E65,709/67:* In mice, the role played by drug excretion in determining the toxicity of digitalis alkaloids was tested

following the production of cholestasis by bile duct ligation or cholestatic aryl isothiocyanates such as phenylisothiocyanate (PIT) and  $\alpha$ -naphthylisothiocyanate (ANIT). The part played by anuria was examined after ligation of the penis. After ouabain i.p., mortality was enhanced by diminution or stoppage of bile flow. Digoxin and digitoxin enhanced lethality in anuric mice. Lanatoside-C was not more toxic to hypoexcretory mice. "The use of hypoexcretory mice in toxicologic evaluations of pharmacologic agents is suggested."

*Burckhardt & LaDue H15,071/68*: Review of the literature on the production of gynecomastia in man and of vaginal cornification in postclimacteric women treated with digitalis. Personal observations show a diminution of urinary FSH in postclimacteric women treated with digitalis. This is ascribed to depression of FSH formation through a folliculoid effect of digitalis.

*Wilson G71,238/69*: Review (8 pp., 55 refs.) on the metabolism of digitalis compounds.

*Morgan & Binnion G76,782/70*: In dogs, the distribution of  $^3\text{H}$ -digoxin has been determined under normal and hypokalemic conditions. Reasons for the reduced myocardial uptake of the glycoside during hypokalemia are discussed.

### Barbiturates

*Richards & Taylor H19,235/56*: Review (44 pp., 233 refs.) on various factors influencing the distribution, metabolism and action of barbiturates.

*Dhunè & Nordqvist D98,693/57*: In 11 of 13 patients who recovered from barbiturate poisoning, sleep was reinduced by cortisone treatment or i.v. injection of glucose.

*Kato et al. H15,635/69*: Although there are great individual variations in the duration of pentobarbital narcosis and zoxazolamine paralysis among rats, the brain concentration of the drugs parallels their pharmacologic activity quite closely. Apparently, variations in drug activity from rat to rat are not due to individual variations in the sensitivity of the nervous system, but to differences in drug absorption and metabolism.

*Sharpless E8,852/70*: A textbook article (21 pp., about 85 refs.) on the pharmacology of barbiturates with special reference to pharmacological correlations and mechanisms of action.

### Pesticides

*DuBois et al. D92,992/50*: Extensive investigations on the toxicology of OMPA in various species, with an analysis of its mechanism of action. Both mammalian liver and plant tissue can transform OMPA into an active anticholinesterase.

*Aldridge & Barnes G41,307/52*: Systematic studies on the toxicology of several organophosphorus insecticides in mammals.

*Frawley et al. G69,644/52*: Comparative toxicologic studies on organic phosphate-anticholinesterase compounds in guinea pigs, mice and rats, with a rapid procedure for the measurement of brain, plasma and erythrocyte cholinesterase. "The oral  $\text{LD}_{50}$ 's for these compounds for male and female rats are DFP, 13.5 and 7.7 mgm./kgm.; Parathion 30 and 3 mgm./kgm.; TEPP 2 and 1.2 mgm./kgm.; EPN 91 and 14.5 mgm./kgm.; OMPA 13.5 and 35.5 mgm./kgm.; and E-838 42 and 19 mgm./kgm. The administration of oral  $\text{LD}_{75}$  doses of these compounds caused brain cholinesterase inhibition varying with each compound: DFP > Parathion > E-838 > EPN > TEPP > OMPA."

*Davison A49,341/55*: In rats, neither OMPA nor parathion possesses any significant toxic effect until they are transformed by hepatic microsomal enzymes into more active cholinesterase inhibitors. These pesticides furnish clear-cut examples of the fact that the transformation or drugs by microsomal enzymes does not necessarily diminish but may actually increase the toxicity of substrates.

*Gaines G67,102/69*:  $\text{LD}_{50}$  values have been determined for 98 pesticides, and 2 metabolites of DDT in the rat. Most compounds were more toxic to females than to males, but 9 of 85 compounds were more toxic in males. In chickens several of the pesticides produced paralysis.

*Datta G75,362/70*: In rats, the detoxication pathways of p,p'DDT to p,p'DDE were examined after DDE pretreatment. Apparently, "two different pathways exist and may be operated simultaneously in intact animals. The predominance of one or the other may depend on physiologic response or the amount of toxicant used."

*Domschke et al. G74,897/70*: In rats, ethionine fails to prevent the induction of TPO by the pesticide soman. "Since ethionine is known as an effective inhibitor of the protein synthesis in the liver the negative results are prob-

ably due to a stimulating effect of soman on the de-novo-synthesis of liver enzymes."

*Fouts G76,368/70*: Review on the effects of various insecticides, both as inducers and as substrates for hepatic microsomal enzymes.

*Hayes et al. G80,268/71*: "The average dosage of p,p'-DDT administered in this study was 555 times the average intake of all DDT-related compounds by 19-year-old men in the general population and 1,250 times their intake of p,p'-DDT. Since no definite clinical or laboratory evidence of injury by DDT was found in this study, these factors indicate a high degree of safety of DDT for the general population."

### Mercury

*Spode G72,979/60*: In mice injected with  $^{203}\text{Hg}$  acetate, by far the highest Hg concentration was detected in the kidneys about 24 hrs after s.c. and about 3 hrs after i.p. injection. Correspondingly the blood concentration of Hg reaches its maximum about 1 hour after i.p. and only 3 hrs after s.c. administration. The liver stores about 1/10 as much as the kidney but still much more than other organs. Various "decorporation-stimulating substances" were tested but none of them diminished Hg storage in the liver or spleen. In the kidneys, Ca-EDTA and, to a lesser extent, citrate and Graham salt reduced storage but only Na-citrate and Ca-EDTA enhanced mercury elimination. Other reputed "decorporating substances" such as hexamethylene, diaminetetraacetic acid, gallic acid, gallic acid propylester, tannic acid, tripolyphosphate and amobarbital proved to be essentially ineffective in these respects.

*Swensson & Ulfarson F89,451/67*: Review of the literature and extensive personal investigations on the effect of various antidotes upon mercury poisoning in the rat.

### Carbon Tetrachloride

*Recknagel F85,043/67*: Review (63 pp., 351 refs.) on the hepatotoxic effects of  $\text{CCl}_4$ .

*Fowler G70,865/69*: In rabbits,  $\text{CCl}_4$  p.o. is distributed in the fat, liver, kidney, and

muscles. Some of its metabolites have been identified.

*Nayak et al. G80,728/70*: In rats, a protein-free diet or starvation caused deterioration of the ER and diminution of drug-metabolizing enzymes, but failed to make the hepatocytes less susceptible to the effects of  $\text{CCl}_4$ .

### Nicotine

*Harke et al. G73,847/70*: Comparative studies on the oxidative degradation of nicotine in the rat and hamster.

### Griseofulvin

*Osment G72,369/69*: Review on the pharmacology of griseofulvin. It can act both as a hepatic microsomal-enzyme inducer and as a substrate for such enzymes.

### Indomethacin

*Hucker et al. G67,791/66*: First systematic studies on the metabolism of indomethacin in various species. Most of a single dose is eliminated from the body in 24 hrs. The drug is largely excreted through the bile but then reabsorbed and eliminated through the urine in most species, except the dog in which reabsorption of biliary material is not followed by urinary excretion. The dog excretes indomethacin through the bile as a glucuronide. The drug is highly bound to plasma protein but does not accumulate in the intestinal wall of either guinea pigs or rats.

*Yesair et al. G75,388/70*: In rats, salicylic acid i.v. decreases the plasma concentration of indomethacin. Simultaneously, the urinary excretion of  $^{14}\text{C}$ -indomethacin is decreased, whereas biliary and fecal excretions are increased. Phenylbutazone, chlorogenic acid and acetic acid had no effect on plasma radioactivity. Probenecid increased plasma concentration of indomethacin. "The specificity of salicylic acid in decreasing concentrations of indomethacin in plasma of rats and of probenecid in increasing indomethacin concentrations in plasma of both rat and man may arise from the similarity in structure of the benzoyl group of the three compounds."

## V. EFFECT OF STEROIDS UPON RESISTANCE

### *STEROIDS* ←

In a book on "Hormones and Resistance" it would hardly be appropriate to discuss all the antagonistic interactions between steroids. As explained in the Introduction, the reader is referred to our earlier monographs for such topics as the mutual inhibition of gluco- and mineralocorticoids as regards the regulation of inflammation or the interplay between folliculoids and luteoids in the regulation of the menstrual cycle. Here we shall deal primarily with the effects of one steroid upon systemic intoxications with other steroidal compounds. In retrospect it is interesting to speculate however about the possibility that some of the apparently specific antifolliculoid, antitestoid or antimineralocorticoid actions of steroids may be nonspecific consequences of defensive enzyme activation.

### ← *Glucocorticoids*

It has long been known that, at least in rats, glucocorticoids antagonize certain actions of mineralocorticoids, particularly the hypernatremia, the hyalinosis (after uninephrectomy + NaCl), the elevation of the EST and insulin hypersensitivity. In addition, cortisol and cortisone prolong the anesthetic effect of hydroxydione. Data concerning the effect of glucocorticoids on DOC anesthesia are somewhat contradictory.

The antipyretic effect of glucocorticoids against fever produced by etiocholanolone has been ascribed to a stabilization of lysosomal membrane.

The well-known antagonism between gluco- and mineralocorticoids, as regards various forms of inflammation and the balance between catabolism and anabolism, are clearly demonstrable only after adrenalectomy; presumably in the presence of the suprarenals, endogenous corticoids tend to mask any disproportion between an exogenous excess of either type.

In this connection, brief mention should be made of the "law of intersecting dose-effect curves" which plays a role in many apparently paradox interactions between steroid hormones, but is applicable also to countless other interrelationships between drugs. In brief, it says that if two mutually antagonistic agents are administered concurrently in fixed proportions, the action of one or the other constituent may predominate at different dose levels. An agent whose effect increases rapidly with rising doses but soon reaches a plateau will preponderate at low dose levels, whereas an agent whose activity rises slowly but persistently to reach much higher final values will predominate at high dose levels. This type of interaction can explain, for example, why the actions of glucocorticoids are largely counteracted by endogenous mineralocorticoids at near physiologic low levels but not in the event

of heavy overdosage. The same law also explains why a given mixture of two antagonistic hormones may exert opposite effects at low and at high dose levels as indicated below:

**Illustration of the "law of intersecting dose effect curves."** It will be seen that certain glucocorticoid effects can be antagonized by mineralocorticoids only at near physiologic low dose levels. The antiphlogistic, thymolytic, splenolytic and catabolic actions of glucocorticoids are largely compensated by endogenous mineralocorticoids in the intact animal or by near physiologic amounts of mineralocorticoids after adrenalectomy. However, by raising the glucocorticoid level far above normal, a corresponding rise in mineralocorticoid dosage no longer suffices because the action curves cross each other slightly above the level of normal corticoid production

← **Glucocorticoids** cf. also Selye B40,000/50, pp. 515, 536, 584, 585; B58,650/51, p. 324; G60,083/70, pp. 347, 348.

Friedman & Friedman B48,306/50: In intact male rats on a normal NaCl intake, the hypertension and cardiac hypertrophy produced by s.c. implantation of DOC pellets was inhibited by an adrenocortical extract but not by progesterone, testosterone, pregnenolone, estradiol or acetoxypregnenolone.

Woodbury et al. B47,201/50: In rats, ACTH and adrenocortical extract antagonize the following actions of DOC: 1. hypernatremia; 2. electroshock threshold elevation; 3. insulin hypersensitivity; 4. hyalinosis (after sensitization by uninephrectomy plus NaCl).

Heuser C54,451/58: In rats, cortisol succinate, given s.c. shortly before progesterone, hydroxydione, pentobarbital or ether, prolongs anesthesia produced by any of these compounds. When given i.v., cortisol does not exhibit this effect. In itself, cortisol is not an anesthetic. " $\Delta^1$ -Cortisol has a similar action to cortisol. Still, in marked contrast to its effect on other anesthetics, it does not influence DOC-anesthesia." Desoxycortisone elicits long-lasting convulsions which can be counteracted by various anesthetic steroids.

Rummel et al. C80,035/59: In rats, chronic or acute pretreatment with cortisone increases the sensitivity to subnarcoctic doses of DOC.

Sulman et al. C79,823/59: In rats injected for 4 months with prednisone or prednisolone, an increase in the hepatic content of the enzymes which decompose these steroids could be demonstrated in vitro. Various histologic stains failed to reveal any associated light-microscopic change in the hepatocytes. Addition of SKF 525-A to the homogenate of activated livers blocked their enzymic activity.

Janoski et al. E7,896/68 (p. 287): Review of data suggesting that the antipyretic effect of glucocorticoids against fever produced by etiocholanolone and related steroids is due to the stabilization of lysosomal membranes.

Morrison & Kilpatrick G69,282/69: Observation of a personal case and report of several others from the literature, showing that in women taking glucocorticoids during pregnancy, estriol excretion is diminished. "The effect could be the result of direct depression of the placental enzymic systems."

Kostowski & Nowacka H26,526/70: In mice, cortisol and methylprednisolone decrease hexobarbital sleeping time, whereas DOC prolongs it. Hydroxydione anesthesia is

not changed by cortisol but prolonged by methylprednisolone as well as by high doses of DOC.

*Selye G60,064/70*: In the rat, the ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + corn oil cannot be prevented by prednisolone or triamcinolone.

### ← Mineralocorticoids and Gluco-Mineralocorticoids

In rats heavily overdosed with glucocorticoids, normally saprophytic organisms tend to proliferate and often cause multiple abscesses resulting in death. This "saprophytosis" is more effectively combated by STH in intact than in adrenalectomized animals perhaps because the adrenals produce some antiglucocorticoid compound. However, DOC alone or in combination with other steroids, fails to duplicate the anti-infectious action of STH in cortisone-treated rats.

Aldosterone inhibits the anti-inflammatory effect of cortisol in various tests on adrenalectomized rats. This type of antagonism is also negligible in the presence of the adrenals, perhaps because the resting mineralocorticoid secretion is already near optimal in antagonizing the antiphlogistic actions of glucocorticoids.

DOC and progesterone increase each other's anesthetic effect but this appears to represent a simple summation of their narcotic potency.

The 2-cyano-steroid, TMACN, administered to pregnant rats, causes nipple formation in male and inhibition of nipple development in female fetuses, presumably owing to its characteristic effect upon steroid synthesis in the maternal adrenal. Corticosterone prevents the effect of TMACN upon female fetuses, probably because it inhibits ACTH secretion and thereby diminishes overproduction of 3β-hydroxy-androstanes. Pure mineralocorticoids have not been tested in this connection, but in view of their lesser inhibitory action on ACTH production they might be expected to be also less effective in counteracting TMACN.

← **Mineralocorticoids and Glucomineralocorticoids** *cf.* also *Selye C92,918/61, p. 280.*

*Ducommun & Ducommun B70,251/53*: In rats, saprophytosis produced by heavy overdosage with cortisone is inhibited by concurrent administration of STH. This "anti-infectious effect of STH" is much less evident after adrenalectomy. DOC, testosterone, estradiol alone or in combination failed to duplicate the anti-infectious action of STH cortisone-treated rats.

*Negrete C23,001/55*: In male rats, pretreatment with nonanesthetic doses of progesterone increases sensitivity to DOC-anesthesia.

*Selye B98,268/55*: In adrenalectomized rats the diminution of body weight, inflammation in the granuloma pouch, as well as the atrophy of the thymus and spleen, produced by cortisol, are all inhibited by aldosterone.

*Selye & Bois C14,534/56*: In adrenalectomized rats bearing granuloma pouches, 2-methyl-9α-fluorocortisol (Me-F-COL) antago-

nizes the antiphlogistic, catabolic, thymolytic and splenolytic actions of cortisol. This effect is ascribed to the strong mineralocorticoid effects of Me-F-COL, which counteract glucocorticoid actions. However, since Me-F-COL itself possesses some glucocorticoid potency, its cortisol antagonizing action is evident only at very low dose levels (about 75  $\mu\text{g}/\text{kg}$ ) at which mineralocorticoid effects predominate in agreement with the "law of intersecting dose-effect curves."

*Neumann & Goldman H25,234/70:* In pregnant rats, treatment with TMACN (2-cyano-4,4,17 $\alpha$ -trimethylandro-5-en-17 $\beta$ -ol 3-one) causes nipple formation in male fetuses and inhibits the normal development of nipples in female fetuses, presumably owing to characteristic derangements in the enzymic mechanisms responsible for steroid production in the adrenals. Testosterone prevents these effects of TMACN in male fetuses, suggesting

that its feminizing property upon the nipples (like that of fetal orchidectomy) is merely due to deficient testosterone production. Corticosterone prevents the actions of TMACN upon female fetuses, probably because it inhibits fetal ACTH-mediated adrenal enlargement and the consequent overproduction of 3 $\beta$ -hydroxyandrostanes.

*Kostowski & Nowacka H26,526/70:* In mice, cortisol and methylprednisolone decrease hexobarbital sleeping time, whereas DOC prolongs it. Hydroxydione anesthesia is not changed by cortisol but prolonged by methylprednisolone as well as by high doses of DOC.

TMACN  $\leftarrow$  Corticosterone: Neumann et al. H25,234/70\*

### $\leftarrow$ *Testoids and Anabolic Steroids*

**Glucocorticoids  $\leftarrow$ .** It has long been known that anabolic testoids antagonize many, but not all, of the actions of glucocorticoids. For example, according to most investigators, the inhibition of growth, the reduction in the widths of the epiphyseal cartilage, the impairment of wound healing, the production of gastric ulcers (especially during fasting), are all blocked by concurrent treatment with certain anabolics, at least under optimal experimental conditions; conversely, the thymus atrophy and saprophytosis in rats, as well as the characteristic cortisone myopathy of the rabbit, are not significantly prevented by anabolics.

A variety of anabolic testoids proved to be highly potent in preventing progesterone and pentobarbital anesthesia in rats; however, since spironolactone exhibits the same anti-anesthetic effect, the latter cannot be attributed to anabolic potency.

**Mineralocorticoids and Gluco-Mineralocorticoids  $\leftarrow$ .** The nephrosclerosis, proteinuria and hypercholesterolemia produced by DOC in the rat can be prevented by methyltestosterone even after sensitization by uninephrectomy. However, this inhibition appears to depend upon circumstances yet to be identified, since it is by no means constant.

Pretreatment with ethylestrenol inhibits DOC anesthesia in the rat and this protective effect can be blocked, in turn, by thyroxine.

The ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + corn oil in the rat is prevented by ethylestrenol, norbolethone and some other catatoxic steroids but not by oxandrolone.

**Luteoids  $\leftarrow$ .** Female and castrate male rats are more sensitive to the anesthetic effect of progesterone than are intact males but methyltestosterone pretreatment raises the resistance of females and castrates to the male level.

**Folliculoids** ←. In mice, estradiol produces pubic bone resorption and hypercalcification of other bones. This effect is inhibited by testosterone.

The actions of folliculoids upon various target organs are not equally affected by testoids. Among a series of virilizing steroids examined, androstenediol was most potent in preventing the body-weight loss caused by estradiol in adult male rats, whereas the estradiol-induced pituitary and adrenal enlargement was most markedly inhibited by testosterone and methyltestosterone. The thymus involution caused by folliculoids is further enhanced by testoids since both these types of steroids possess a thymolytic effect. The ability of steroids to protect the testis against estradiol-induced atrophy is independent of their virilizing effect; thus ethynyltestosterone is a strong testoid but not gonad protecting, whereas the reverse is true of pregnenolone. Curiously, estradiol increases the renotropic effect of testosterone in the rat although it decreases body weight in general. These organ specific interactions show that not all catatoxic effects can be ascribed to complete destruction of a steroid substrate by hepatic microsomal enzymes. However, partial destruction may lead to selective abolition of those effects which are obtained by comparatively small residual amounts of the hormone.

The production of adrenal and pituitary tumors by stilbestrol can also be prevented by certain androstane derivatives.

**Other Steroids** ←. The anesthetic effect of progesterone, DOC, testosterone or even stilbestrol can be diminished by pretreatment with testosterone in rats.

Methyltestosterone failed to influence hydroxydione anesthesia in mice, whereas norbolethone protects the rat against anesthesia produced by progesterone, DOC, pregnanedione, testosterone and several other steroids.

The 2 $\alpha$ -cyano-steroid, TMACN, given to the mother during pregnancy, causes nipple formation in male, and suppression of nipple development in female rat fetuses. These alterations are ascribed to deficient adrenal steroid biosynthesis. They can be prevented by testosterone in male fetuses, suggesting that the feminizing effect of TMACN upon the nipples is merely due to deficient testoid production.

**Glucocorticoids** ← cf. also *Selye* *G60,083/70*, pp. 374, 377.

*Gaunt et al. B71,987/52*: DOC and testosterone propionate counteracted the growth inhibition produced in immature adrenalectomized rats by cortisone acetate. MAD had no consistent effect on growth. Both MAD and testosterone propionate caused thymus atrophy and this effect was further increased by conjoint administration of cortisone. In intact rats, MAD prevented the cortisone-induced adrenal atrophy. [It is not clear from this brief abstract whether the other interactions were also tested in intact animals (H.S.).]

*Ducommun & Ducommun B70,251/53*: In rats, saprophytosis produced by heavy overdosage with cortisone is inhibited by concurrent administration of STH. This "anti-infectious effect of STH" is much less evident

after adrenalectomy. DOC, testosterone, estradiol alone or in combination failed to duplicate the anti-infectious action of STH in cortisone-treated rats.

*Studer B89,161/53*: In the rat, cortisone reduces the width of the epiphyseal cartilage, and concurrent treatment with testosterone partially antagonizes this effect.

*Winter et al. B79,381/53*: In rats, testosterone and MAD prevent the adrenal atrophy produced by cortisone without counteracting the antiphlogistic effect of the latter.

*Enghardt-Gölkel C42,792/55*: In man, the protein catabolic effect of cortisone is antagonized by MAD.

*Róna et al. C39,946/56*: In rabbits, the vascular lesions characteristic of "steroid diabetes" induced by cortisone + alloxan are inhibited by MAD although the latter induces considerable hyperlipemia.

*Baldratti et al. C45,101/57*: In rats, 4-chloro-19-nortestosterone acetate (like testosterone propionate and MAD) prevents the cortisone-induced adrenal atrophy. However, none of the steroids tested prevents the body weight loss and catabolism induced by cortisone.

*Dontenwill & Mancini C35,119/57*: In rabbits, the catabolic effect of cortisone upon bones is antagonized by testosterone.

*Kar et al. G79,565/57*: In rats, 19-nortestosterone prevents the adrenal changes normally produced by cortisone overdosage.

*Kowalewski C48,527/58*: In 6 day old cockerels, the inhibition by cortisone of body weight gain and radiosulfur incorporation into long bones are counteracted by norethandrolone.

*Kowalewski C61,936/58*: In young cockerels, norethynodrel, and to a lesser extent methyltestosterone and testosterone, counteract the inhibition of bodyweight gain induced by cortisone. The inhibition by cortisone of <sup>35</sup>S uptake in bones is also counteracted by norethynodrel but not by the other testoids examined.

*Loströh C54,348/58*: Female mice of the C3H strain regularly develop myocardial calcification following prolonged cortisol treatment, whereas males are comparatively resistant. Ovariectomy offers no protection but testosterone renders females more resistant. In hypophysectomized mice, neither cortisol nor ACTH produces myocardial calcification.

*Reifenstein Jr. C47,377/58*: Review of the literature suggests that "androgens and estrogens, are anabolic and thus stimulate the growth of protein and osseous tissues." The clinical value of anabolic steroids in counteracting the catabolism caused by endogenous and exogenous glucocorticoids is discussed.

*Rinne & Näätänen C50,335/58*: In rats, norandrosthenolone phenylpropionate greatly diminishes the adrenal atrophy produced by cortisone, but has little if any effect upon its catabolic and somatic growth diminishing action.

*Selye & Mishra C38,201/58*: In the rat, methyltestosterone prevents the loss of body weight produced by overdosage with DHT, vitamin-D<sub>2</sub>, partial fasting, AAN and estradiol. The catabolism elicited by IDPN (imidodipropionitrile) or cortisol is not influenced.

*Ducommun et al. C62,099/59*: In rats, testosterone failed to counteract the growth inhibiting effect of prednisolone.

*Kowalewski & Gort C63,274/59*: Cortisone impairs the healing of humerus fractures in

the rat and concurrent treatment with norethandrolone antagonizes this effect.

*Kowalewski C68,938/59*: Pretreatment with norethandrolone protects the rat against the induction of gastric ulcers by subsequent fasting plus cortisone. Testosterone enanthate does not share this effect.

*Llaurado et al. G79,936/59*: In rats, norethandrolone prevents the adrenal lesions normally produced by cortisone. However, the thymolytic effect of the latter was increased.

*Jasmin et al. C89,132/60*: Both in intact and in adrenalectomized rats, norethandrolone diminishes the body weight loss caused by cortisol without inhibiting the antiphlogistic effect of the latter.

*Arlander D5,055/61*: In mice, various testoids (17 $\alpha$ -ethyl-19-nortestosterone, testosterone and MAD) failed to prevent the cortisone-induced loss of body weight.

*Bernick et al. D5,063/61*: In rats, testosterone inhibited the osteosclerosis, but failed to influence the narrowing of the epiphyseal plates and the body weight loss induced by cortisone.

*Laron & Boss D10,620/61*: Nandrolone phenpropionate failed to inhibit the loss of body weight and the skeletal changes produced by cortisone in the rat.

*Steinetz & Leatham D14,366/61*: In rats, the adrenal changes produced by cortisone are counteracted by concurrent treatment with MAD.

*Suchowsky & Junkmann D2,674/61*: 1-Methyl- $\Delta^1$ -androsten-17 $\beta$ -ol-3-one-17 $\beta$ -acetate is about as equally effective as testosterone propionate in preventing the cortisol-induced gastric ulcers in fasting rats.

*Weller D13,995/61; D22,262/62*: In man, methenolone antagonizes the catabolic effect of prednisolone and desiccated thyroid.

*Arcuri et al. D65,779/62*: Methyltestosterone protects the gastric mucosa of the rat against the damage produced by prednisolone.

*Bavetta et al. D29,035/62*: In the rat, "anabolic hormones such as methyltestosterone and growth hormone did not counteract the over-all catabolic effects of methyl prednisolone on nitrogen metabolism nor on body weight retardation."

*Bavetta et al. D29,064/62*: In the rat, "growth hormone, methyl testosterone or stilbestrol, when given alone or in combination were not able to counteract the inhibitory effects of 6-methyl prednisolone on body weight gain and collagen synthesis at the site

of subcutaneously implanted polyvinyl sponges."

*Herrmann D34,026/62*: In guinea pigs, following interruption of corticoid administration, the adrenocortical hypofunction and atrophy as well as the irresponsiveness to the production of adrenocortical necrosis by diphtheria toxin reappear much more rapidly if the animals are simultaneously treated with testosterone.

*Herrmann & Winkler D20,550/62*: In guinea pigs, methandrostenolone accelerates the restitution of the adrenal cortex after interruption of cortisone therapy as judged by the more rapid reappearance of sensitivity to diphtheria toxin and histologic criteria.

*Ippolito et al. D57,498/62*: The gastric ulcers produced by prednisolone in guinea pigs can be prevented by concurrent treatment with oxymesterone.

*Jöchle & Langecker D22,258/62*: In the rat and mouse, methenolone-enanthane counteracts the weight loss produced by cortisone or a reduction of food intake.

*Kowalewski G41,978/62*: "In the femora of cortisone-treated cockerels there was increased size of chondrocytic lacunae, thinning and irregularity of primary trabeculae, and focal absence of osteoblasts. These changes coincided with a decrease in acid mucopolysaccharides and a decrease in alkaline phosphatase. The alkaline phosphatase decrease was directly related to a decrease in the numbers of osteoblasts. Somewhat similar changes were seen in humeri of rats, except that changes in alkaline phosphatase activity were not so evident." Methandrostenolone protected the bones of birds and rats against these cortisone-induced changes.

*Kühn et al. D64,992/62*: In the rat, testosterone does not prevent the loss of body weight induced by heavy overdosage with cortisone or prednisolone.

*Walser D33,753/62*: In patients, the catabolic effect of prednisone or triamcinolone is inhibited by ethylestrenol or nandrolone decanoate.

*Galletti & Bruni G16,710/63*: In the rat, the catabolic effect of prednisone can be counteracted by simultaneous treatment with quindienone, an anabolic and weakly testoid compound described as the 17-cyclopentyl ether of  $\Delta^1$ -dehydrotestosterone.

*Lund E38,261/63*: In man, osteoporosis following prolonged treatment with cortisone was not prevented by conjoint administration of nandrolone phenpropionate.

*Rodin & Kowalewski D60,272/63*: Methandrostenolone protects the bones of cockerels and rats from the deleterious effects of cortisone overdosage.

*Bordberg & Lückner F24,271/64*: In the rat, methenolone inhibits the osteoporosis and the loss of bone mineral produced by large doses of cortisone.

*Harding & Potts F55,311/65*: In rats, glucocorticoids characteristically increased hepatic TPO-activity and this effect is suppressed by various anabolics such as stanozolol, norethandrolone and methandrostenolone in decreasing order of activity. In intact rats, methyltestosterone produced no suppression (even when given in very high doses) presumably because it increased corticosterone secretion; suppression was obtained with all anabolics in adrenalectomized rats. "These data support the concept that anabolic agents are useful in offsetting the catabolic effects observed clinically following chronic administration of glucocorticoids."

*Murakami & Kowalewski G41,228/66*: Stanozolol counteracts the inhibition of bone fracture healing induced by cortisone in guinea pigs.

*Valderrama & Munuera E6,008/66*: In rabbits, overdosage with cortisone inhibits osteoblast action and causes massive bone absorption with fatty marrow formation. Endochondral ossification ceases. All these changes are greatly diminished by stanozolol.

*Kaeser & Wüthrich F80,357/67*: The myopathy produced in rabbits by overdosage with cortisone is not influenced by treatment with Ro 4-8932 the highly anabolic, chlorinated retrosteroid.

*Linet & Mikulašková F86,027/67*: The gastric erosions produced by cortisol in the rat are not significantly influenced by such anabolic steroids as 19-nortestosterone phenylpropionate, methandrostenolone and dimethylandrostanolone.

*Preziosi et al. F78,520/67*: The cachectic wasting syndrome produced by a single dose of betamethasone given to rats on the first day of life is not influenced by nandrolone decanoate or phenylpropionate, unless betamethasone is administered in the form of its phosphate and, even then, the protection is not very marked.

*Zicha & Heck F78,128/67*: In guinea pigs, asthma produced by 5-HT, histamine or acetylcholine is inhibited by various glucocorticoids. This inhibition is in turn blocked

by certain, but not all, anabolic steroids tested.

*Ehrlich & Hunt G68,785/69*: In rats, the delay in wound healing caused by cortisone is counteracted by testosterone, nandrolone phenpropionate or 19-nortestosterone-17 $\beta$ -adamantoate (Bolmantalate) although these anabolic steroids were unable to counteract the body weight loss caused by the glucocorticoid.

*Linè G79,963/70*: Detailed review of the literature and personal observations on the effect of anabolic testoids upon glucocorticoid overdosage in animals and man. Special attention is given to the effect of anabolic testoids upon glucocorticoid-induced loss of body weight and other metabolic changes, adrenal atrophy, osteoporosis, wound healing, inflammation and gastric ulcer formation. Antigluco-corticoids devoid of anabolic properties are also surveyed. In clinical medicine, various forms of hyperglucocorticoidism are not, or only moderately, improved by treatment with anabolic testoids. [Excellent source of pertinent references (H.S.).]

#### **Luteoids** $\leftarrow$

*Winter & Selye A35,658/41; Winter A36,333/41*: Female rats are more sensitive than males to the anesthetic action of progesterone but this sex difference is obvious only after maturity. "The normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the males since castration increases sensitivity in males but is without effect in female rats. Conversely the resistance of castrate males and females may be raised by methyltestosterone administration."

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, desoxycorticosterone, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Selye G60,044/70*: Among various steroids tested for their ability to inhibit progesterone and pentobarbital anesthesia, all anabolic testoids were highly potent. However, since spironolactone exhibited the same anti-anesthetic effect, the latter could not be attributed to anabolic potency. "This inhibi-

tion of anesthesia is assumed to represent a special instance of the catatonic effect which appears to be a property of certain steroids, independent of their classic hormonal actions."

**Progesterone** ← Testoids *cf. also Table 17*

#### **Folliculoids** ←

*Gardner & Pfeiffer 72,281/38*: In mice, the skeletal changes (pubic bone resorption and hypercalcification of other bones) produced by estradiol are inhibited by concurrent treatment with testosterone.

*Albert A37,132/42*: In immature rats given estradiol alone or in combination with testosterone until puberty was attained, the pituitary and adrenal enlargement as well as the testis atrophy produced by estradiol were prevented by the testoid whereas the thymus atrophy was intensified.

*Albert & Selye A37,637/42*: Among many steroids examined androstenediol was most potent in preventing the bodyweight loss caused by estradiol in adult male rats. The pituitary and adrenal hypertrophy characteristic of estradiol overdosage was most markedly inhibited by testosterone and methyltestosterone. The thymus involution caused by estradiol was aggravated by most of the hormonally active steroids tested. "The ability of steroids to protect the testis against the atrophy caused by estradiol is entirely independent of their 'male hormone' or testoid activity. Ethinyl testosterone, though a potent testoid, is not gonad-protecting while the reverse is true of pregnenolone." The decrease in kidney weight caused by estradiol was effectively prevented only by highly active testoids such as testosterone and methyltestosterone. [These organ specific interactions emphasize the danger of attributing the protective effects of catatonic steroids to increased destruction by the induction of hepatic microsomal enzymes. Both specific interactions at the target organ and the induction of qualitatively different steroid metabolites must also be considered (H.S.).]

*Selye A60,638/44*: In rodents, the production of anterior pituitary hormones by estradiol is inhibited by a variety of steroids, most of which are androstene derivatives and are designated as "antifolliculoid."

*Constantinides & Gordon B41,764/50*: Among three synthetic steroids tested for their ability to prevent the tumorigenic

effect of stilbestrol on the pituitary and adrenal glands "17 ( $\beta$ )-ethyl-androstane-3-one-17( $\alpha$ )-ol proved a potent stilbestrol inhibitor of only moderate androgenic potency, while 17( $\beta$ )-ethyl- $\Delta^5$ -androstane-3( $\beta$ ), 17( $\alpha$ )-diol and 17( $\beta$ )-ethyl-androstane-3( $\beta$ ), 17( $\alpha$ )-diol showed no such activities."

*Selye & Mishra C38,201/58*: In the rat methyltestosterone prevents the loss of body weight produced by overdosage with DHT, vitamin-D<sub>2</sub>, partial fasting, AAN and estradiol. The catabolism elicited by IDPN or cortisol is not influenced.

*Granitsas & Leatham D25,514/60*: In the rat, estradiol in doses causing a decrease in body and kidney weight nevertheless increases the renotropic effect of testosterone although it fails to block body nitrogen loss.

*Verne & Roth E48,050/63*: Out of 13 mice treated with estradiol, 6 developed cancers, whereas among 102 mice treated with estradiol + norandrostenediol phenylpropionate, only 9 developed cancers. [Neither the sites nor the types of tumors are identified (H.S.).]

*Roth F29,450/64*: In mice, the carcinogenic action of estradiol is inhibited by norandrostenediol phenylpropionate.

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Dmowski et al. G80,777/71*: In various species, Danazol (2,3 isoxazol derivative of 17 $\alpha$ -ethinyl testosterone) was found to inhibit the effect of endogenous, but not of exogenous gonadotrophins. In addition, it had a mild testoid and progestational effect, but was devoid of antitestoid, antifolliculoid or antiluteoid properties.

**Estradiol** ← Testoids *cf. also Table 16*

Estradiol, Estrone, Stilbestrol ← 19-Nortestosterone, Testosterone: Jellineck et al. *F37,592/65*

Estradiol ← Norethandrolone + Biliary obstruction, Man: Zumoff et al. *H25,277/70\**

#### **Other Steroids** ←

*Selye A35,410/41*: Following repeated injections of progesterone, DOC, testosterone

or stilbestrol to rats, the anesthetic effect of these hormones gradually diminishes. Pretreatment with one of these anesthetic compounds also induces resistance to others, whereas pretreatment with cholesterol (which is not anesthetic) induces no such resistance.

*Jelinek H1,518/68*: There was no difference in the duration of hydroxydione anesthesia in male and female intact or gonadectomized mice. Pretreatment with methyltestosterone p.o. prolonged hydroxydione anesthesia in males but not in females or castrate males. Neither thiopental nor pentobarbital anesthesia was influenced by methyltestosterone. Pretreatment with methandrostenolone or 17 $\alpha$ -methyl-androst-2-ene-17 $\beta$ -ol failed to influence hydroxydione anesthesia in mice.

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Neumann & Goldman H25,234/70*: In pregnant rats, treatment with TMACN (2 $\alpha$ -cyano-4,4,17 $\alpha$ -trimethylandrost-5-en-17 $\beta$ -ol-3-one) causes nipple formation in male fetuses and inhibits the normal development of nipples in female fetuses, presumably owing to characteristic derangements in the enzymic

mechanisms responsible for steroid production in the adrenals. Testosterone prevents these effects of TMAN in male fetuses, suggesting that its feminizing effect upon the nipples (like that of fetal orchidectomy) is merely due to deficient testosterone production. Corticosterone prevents the effect of TMACN upon female fetuses, probably because it inhibits fetal ACTH-mediated adrenal enlargement and the consequent overproduction of 3 $\beta$ -hydroxyandrostanes.

*Selye et al. G60,020/69*: Pretreatment with norbolethone protects the rat against anesthesia produced by progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol and methyprylon. It does not significantly alter the sedative effects of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, KBr or MgCl<sub>2</sub>.

TMACN ← Testosterone: Neumann et al. *H25,234/70\**

#### ← **Luteoids**

In C3H strain mice, females are more resistant than males to the toxic action of folliculoids. This sex difference becomes even more evident in the case of combined treatment with folliculoids and progesterone since the latter increases the toxicity of estradiol and stilbestrol in this strain. The gonads of both sexes show considerable atrophy under the influence of folliculoids but this is inhibited by progesterone.

The anesthetic effect of various steroids is diminished in rats by pretreatment with progesterone (as well as by other anesthetic steroids). Cholesterol induces no such resistance.

The hypertensive disease produced in rats by DOC is not influenced by progesterone.

Concurrent treatment with subthreshold doses of progesterone and DOC exhibit an additive effect upon the development of anesthesia in rats.

In weanling rats, medroxyprogesterone (a luteoid) does not affect the growth-promoting action of testosterone upon the seminal vesicles but inhibits the

stimulation of the ventral prostate. It would be difficult to ascribe this effect to an altered metabolic degradation of the testoid, although in patients medroxyprogesterone allegedly accelerates the clearance of testosterone.

In the rat, the ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + corn oil is not prevented by progesterone.

← **Luteoids** *cf. also Selye G60,083/70, pp. 370, 371.*

*Selye & Stevenson 77,177/40:* In Strong's C3H strain mice, females are more resistant than males to toxic doses of estradiol or stilbestrol. This sex difference is even more pronounced in the case of combined administration of folliculoids and progesterone, which increases the toxicity of folliculoids. The gonads of both sexes show considerable atrophy under the influence of folliculoids but this is inhibited by progesterone.

*Selye A35,410/41:* Following repeated injections of progesterone, DOC, testosterone or stilbestrol to rats, the anesthetic effect of these hormones gradually diminishes. Pretreatment with one of these anesthetic compounds also induces resistance to others, whereas pretreatment with cholesterol (which is not anesthetic) induces no such resistance.

*Friedman & Friedman B48,306/50:* In intact male rats on a normal NaCl intake, the hypertension and cardiac hypertrophy produced by s.c. implantation of DOC pellets was inhibited by an adrenocortical extract but not by progesterone, testosterone, pregnenolone, estradiol or acetoxy-pregnenolone.

*Negrete C23,001/55:* In male rats, pretreatment with doses of progesterone, which in

themselves are nonanesthetic, increases sensitivity to DOC-anesthesia.

*Gordon et al. H24,106/70:* In rats, medroxyprogesterone had no effect upon zoxazolamine "sleeping time." In weanling rats, medroxyprogesterone did not affect the growth promoting action of testosterone upon the seminal vesicles but it inhibited the stimulation of the ventral prostate. In several patients the steroid accelerated the metabolic clearance of testosterone.

*Selye G60,064/70:* In the rat, the ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + corn oil cannot be prevented by progesterone.

### ← **Antimineralocorticoids**

← **Spirolactone.** The ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub>, with or without oil supplements, can be prevented by spironolactone in the rat. The mineralocorticoid hypertension produced by DOC + NaCl in uninephrectomized rats is not prevented by spironolactone, but the associated hyalinosis is inhibited. Clinical experience shows, furthermore, that spironolactone is beneficial not only in primary aldosteronism but also in many other common types of hypertension.

In immature castrate rats, the stimulation of the ventral prostate and seminal vesicles by testosterone is inhibited by spironolactone. The gynecomastia and the libido-inhibiting effect of spironolactone in man, may be due to its antitestoid activity.

The anesthetic effect of various steroids (as that of barbiturates) is strongly inhibited by pretreatment with spironolactone, even following adrenalectomy.

← **Spiroxasone.** Spiroxasone (like spironolactone) inhibits the stimulation of the ventral prostates and seminal vesicles by testosterone in immature castrate rats. It also protects the rat against progesterone anesthesia.

← **Aldadiene (SC-9376).** Aladadiene and aldadiene-kalium (SC-14266) protect the rat against progesterone anesthesia.

← **CS-1.** CS-1 protects the rat against progesterone anesthesia and against the ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> in combination with restraint, or with an excess of corn oil.

← **Phanurane.** In rats, the hypertensive syndrome produced by DOC + uninephrectomy + NaCl can be inhibited by phanurane allegedly because of the antiminerlocorticoid activity of this steroid.

← **Antiminerlocorticoids** cf. also *Selye C92,918/61*, pp. 18, 74; *G60,083/70*, pp. 492, 493.

← **Spironolactone** cf. also *Selye C92,918/61*, p. 74; *G60,083/70*, pp. 385, 491, 492, 494. *Ducommun et al. C91,529/60*: In rats sensitized by uninephrectomy + NaCl, spironolactone inhibits the hyalinosis but not the hypertension caused by DOC.

*Selye C82,516/60*: In the rat, spironolactone "offers considerable protection against induction of acute, infarct-like, often fatal myocardial necroses normally produced by fluorocortisol plus some Na-salts and stress, alone or in combination."

*Hollander & Wilkins C37,370/62*; *Johnston & Griebel F94,590/67*; *Bracharz et al. D37,973/62*: Spironolactone is beneficial not only in primary aldosteronism but also in many of the common types of clinical hypertension.

*Selye G60,003/69*: Spironolactone protects the rat against the anesthetic effect of progesterone, DOC and hydroxydione. It also prevents acute digitoxin poisoning even after bilateral nephrectomy.

*Selye et al. G60,016/69*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, KBr or MgCl<sub>2</sub>.

*Steelman et al. G69,340/69*: In immature castrate rats, the stimulation of the ventral prostates and seminal vesicles by testosterone enathate s.c. is inhibited both by spiroxasone and by spironolactone given p.o. or s.c. In dogs,

spironolactone decreased the output of acid phosphatase in the prostatic fluid. Possibly the gynecomastia and the libido-inhibiting effect of spironolactone in man may be due to its antitestoid activity.

*Gardell et al. G60,065/70*: In rats, spironolactone pretreatment inhibits the ultrastructural changes characteristic of the myocardial necroses induced by digitoxin + Na<sub>2</sub>HPO<sub>4</sub> + oil.

*Nocke et al. H29,580/70*: Brief abstract indicating that in pregnant women, spironolactone decreases the urinary elimination of folliculoids, 17-hydroxycorticoids and 17-oxosteroids. It is concluded that spironolactone "may have an influence on the biogenesis and/or metabolism of steroid hormones."

*Selye G60,044/70*: Among various steroids tested for their ability to inhibit progesterone and pentobarbital anesthesia, all anabolic androgens were highly potent. However, since spironolactone exhibited the same anti-anesthetic effect, the latter could not be attributed to anabolic potency. "This inhibition of anesthesia is assumed to represent a special instance of the catatoxic effect which appears to be a property of certain steroids, independent of their classic hormonal actions."

*Selye et al. G60,050/70*: Spironolactone protects the rat against digitoxin intoxication as well as against the anesthetic effect of progesterone and pentobarbital.

*Selye G60,064/70*: In the rat, the ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + corn oil can be prevented by CS-1 and spironolactone.

*Solymoss et al. G70,464/70*: In rats, spironolactone shortens the half-life of its main metabolite, the dethioacetylated 4-6-dienone (metabolite A), which is interconvertible with the 17-hydroxy carboxylic acid derivative (metabolite B). This alteration is only

**Fig. 1. Protection by spironolactone against infarctoid cardiac necroses and nephrocalcinosis.** Both rats were treated with fluorocortisol +  $\text{Na}_2\text{HPO}_4$ , which resulted in extensive cardiac infarction and cortico-medullary nephrocalcinosis (white areas) in the otherwise untreated (A, C), but not in the spironolactone-treated (B, D), animal. [Selye C82,516/60. Courtesy of Proc. Soc. exp. Biol. Med.]

slightly accentuated if the steroid is given chronically and it wears off within eight days after spironolactone treatment is interrupted. After a test dose of spironolactone or of its metabolites A and B, partial hepatectomy delays the blood clearance of metabolite A. Cycloheximide and SKF 525-A also suppress the blood clearance of metabolite A under these conditions. Presumably "spironolactone influences its own biotransformation and the steroid is also a substrate of the hepatic drug-metabolizing enzymes which are induced by spironolactone itself."

*Selye PROT. 27691:* In rats, (100 g♀) progesterone (6 mg in 1 ml oil i.p.) or pentobarbital (3 mg in 0.5 ml oil i.p.) anesthesia is prolonged by adrenalectomy with maintenance on NaCl, but blocked, both in intact and adrenalectomized animals, by spironolactone (10 mg in 1 ml water p.o. x2/day) pretreatment for 4 days.

← **Spiroxasone.** *Steelman et al. G69,340/69:* In immature castrate rats, the stimulation of the ventral prostates and seminal vesicles by testosterone enanthate s.c. is inhibited both by spiroxasone and by spironolactone given p.o. or s.c. In dogs, spironolactone decreased the output of acid phosphatase in the prostatic fluid. Possibly, the gynecomastia and the libido-inhibiting effect of spironolactone in man may be due to its antitestoid activity.

*Selye et al. G60,050/70:* Spiroxazone protects the rat against digitoxin intoxication and progesterone anesthesia, but not against the anesthetic effect of pentobarbital.

← **Aldadiene (SC-9376).** *Selye et al. G60,050/70:* Aldadiene (SC-9376) and aldadiene-kalium (SC-14266) protect the rat against digitoxin intoxication as well as against the anesthetic effect of progesterone and pentobarbital.

← **CS-1.** *Selye G60,064/70:* The ESCN produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + restraint in the rat is much more difficult to inhibit with catatoxic steroids than that elicited by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + oil. However, even the former cardiopathy can be greatly diminished in intensity by CS-1 and spironolactone.

*Selye et al. G60,050/70:* CS-1 protects the rat against digitoxin intoxication as well as

against the anesthetic effect of progesterone and pentobarbital.

← **Phanurane.** *Sturtevant C54,613/58:* In rats, the hypertensive syndrome produced by DOC after sensitization with uninephrectomy + NaCl can be inhibited by phanurane, presumably because of the antiminerocorticoid activity of the latter.

### ← **Folliculoids**

Pretreatment with stilbestrol increases the resistance of the rat against various steroid anesthetics.

It has been claimed that mineralocorticoid hypertension produced in rats by DOC is inhibited by stilbestrol but not by estradiol. However, here, incidental experimental conditions (e.g., uninephrectomy + NaCl or the dosage and timing of the folliculoids) may have a decisive effect.

The saprophytosis produced by cortisone overdosage in the rat is not prevented by estradiol.

In rats, orchidectomy decreases testosterone and progesterone hydroxylation as well as the associated hepatic microsomal changes. All these effects are restored by in vivo treatment of the castrate with testoids and the effect of the latter is in turn blocked by folliculoids. Curiously, the folliculoids fail to block the effect of testoids upon the seminal vesicles and levator ani muscles of orchidectomized rats.

The proposed sites at which thyroid hormones and folliculoids are presumed to influence testoid and folliculoid metabolism are summarized on p. 125.

← **Folliculoids** cf. also *Selye B40,000/50, p. 531; B58,650/51, pp. 326, 359; G60,083/70, p. 368.*

*Selye A35,410/41:* Following repeated injections of progesterone, DOC, testosterone, or stilbestrol to rats, the anesthetic effect of these hormones gradually diminishes. Pretreatment with one of these anesthetic compounds also induces resistance to others, whereas pretreatment with cholesterol (which is not anesthetic) induces no such resistance.

*Zondek et al. A74,477/43:* Stilbestrol is inactivated by rat liver pulp in vitro, though less rapidly than estrone. "In rats treated with large amounts of stilbestrol, the capacity of the liver to inactivate stilbestrol is increased."

*Friedman & Friedman B48,306/50:* In intact male rats, on a normal NaCl intake, the hypertension and cardiac hypertrophy produced through s.c. implantation of DOC pellets was inhibited by an adrenocortical extract but not by progesterone, testosterone,

pregnenolone, estradiol, or acetoxyprogesterone.

*Selye B53,941/51:* In rats conditioned by uninephrectomy + NaCl, the production by DOC of nephrosclerosis, periarteritis nodosa and polyuria is prevented by conjoint administration of stilbestrol.

*Ducommun & Ducommun B70,251/53:* In rats, saprophytosis produced by heavy overdosage with cortisone is inhibited by concurrent administration of STH. This "anti-infectious effect of STH" is much less evident after adrenalectomy. DOC, testosterone, estradiol alone or in combination, failed to duplicate the anti-infectious action of STH in cortisone-treated rats.

*Reifenstein Jr. C47,377/58:* Review of the literature suggests that "androgens and estrogens are anabolic and thus stimulate the growth of protein and osseous tissues." The clinical value of anabolic steroids in counteracting the catabolism caused by endogenous and exogenous glucocorticoids is discussed.

**Proposed sites of influence of thyroid hormones (T) and estrogens (E) on metabolism of androgens and estrogens:** + = stimulation, - = either inhibition or stimulation when factor lacking (Gaunt et al. G 63,202/68)

*Bavetta et al. D29,064/62*: In the rat, "growth hormone, methyl testosterone or stilbestrol, when given alone or in combination were not able to counteract the inhibitory effects of 6-methyl prednisolone on body weight gain and collagen synthesis at the site of subcutaneously implanted polyvinyl sponges."

*Herrmann & Winkler D27,922/62*: In guinea pigs, the adrenocortical atrophy and hypofunction produced by chronic cortisone treatment is prevented by simultaneous administration of estradiol. The responsiveness of the adrenal cortex to the induction of hemorrhagic necrosis by diphtheria toxin returns much more rapidly after interruption of cortisone treatment if estradiol is simultaneously administered.

*Kreek et al. F83,145/67*: In rats, ethinyl-estradiol considerably diminishes bile flow and delays biliary excretion of BSP and of tritium-labeled estradiol.

*Denej & de Moor H15,811/69*: The sexual differentiation of steroid-metabolizing enzymes appears in the rat liver from the 30th day of life onwards. From experiments on neonatally gonadectomized or intact rats treated with folliculoid or testoid compounds, "it is concluded that, as far as the differentiation of cortisol metabolizing enzymes is concerned, estradiol is able to counteract the organizing action of testosterone at birth as well as the expression of these neonatal testosterone effects after the 30th day of life."

*Kato et al. H25,499/69*: In rats, orchidectomy decreased testosterone and progesterone hydroxylation, as well as the spectral change caused by these steroids in liver microsomes reflecting a less pronounced decrease in microsomal P-450 content and NADPH-neotetrazolium reductase activity. All these changes

were restored to normal by in vivo treatment of the castrates with testosterone or methyl-testosterone, whereas simultaneous administration of estradiol or diethylstilbestrol blocked these actions of the testoids. Curiously, the folliculoids failed to block the effects of the testoids upon seminal vesicles and levator ani muscle, as well as on hepatic microsomal proteins in these same orchidectomized rats. Earlier literature on the antagonism between folliculoid and testoid actions upon hepatic drug-metabolizing enzymes is reviewed.

*Schulz et al. H19,404/69*: Clomiphene (an ovulation promoting folliculoid analogue of stilbestrol) decreases the hepatic microsomal NAD-specific  $17\beta$ -ol-steroid dehydrogenase in immature female guinea pigs.

### ← **Antitestoids**

Cyproterone is the prototype of the antitestoid compounds. It antagonizes the effect of testosterone upon the accessory organs of various species even after orchidectomy; hence its effect is assumed to be peripheral and not mediated through the gonads. The compound also interferes with the production of sexual anomalies by testosterone in embryonic animals of both sexes and it blocks even such not manifestly sex-linked effects of testosterone as the erythropoietic action in the mouse.

Cyproterone is also one of the most potent catatoxic steroids having a broad spectrum of activity against almost all substrates that can be detoxified by any

hormone. It powerfully counteracts progesterone anesthesia, yet the shortening effect of testosterone upon hexobarbital anesthesia in ovariectomized rats is not counteracted by cyproterone. Perhaps this failure of effectiveness is again due to the fact that catatoxic steroids are proportionately much less active against near physiologic than against massive amounts of substrates; the small amounts of testosterone needed to raise hexobarbital resistance are more difficult to block than a decisive proportion of the large doses of progesterone required to produce anesthesia. Besides cyproterone itself also shortens hexobarbital sleeping time.

*Neumann et al. F78,500/67:* Review of the testosterone antagonizing effect of cyproterone in the mouse, rat and rabbit. Special attention is given to the blockade of testoid-induced lesions in the accessory sex organs of embryonic and adult males and females.

*Medlinsky et al. G67,839/69:* In mice, the erythropoietic effect of testosterone is anta-

gonized by cyproterone at the same dose level which also blocks other testoid actions.

*Wenzel et al. H14,785/69:* Change of the sex-specific hydrogen transfer from estradiol- $17\beta$  to androstenedione in rat liver after feminization by the antitestoid substance, cyproterone.

### ← *Adrenalectomy*

In discussing the effects of steroids upon resistance, it is indispensable to consider also the effect of creating a deficiency in the steroid producing glands, especially the adrenals and the gonads (*cf.* next section). As stated in the introduction to this volume, the extensive literature on the effect of adrenalectomy upon resistance has been discussed in our previous monographs to which the reader is referred. Here, we shall limit ourselves to a few observations on the influence of adrenalectomy upon certain effects of hormones and drugs in the regulation of steroid metabolism.

In our earlier work we emphasized the "buffering action of the adrenals" as regards the actions of glucocorticoids and mineralocorticoids upon various targets. The production by glucocorticoids of thymolysis and catabolism as well as the inhibition of growth and inflammation are all readily counteracted by mineralocorticoids (e.g., DOC, aldosterone) in adrenalectomized rats; in intact animals all these effects are produced only by larger doses of glucocorticoids, but then, they are also less-readily counteracted by mineralocorticoids. It was assumed that these glucocorticoid effects are almost optimally blocked by physiological doses of mineralocorticoids (such as are normally produced by the adrenals), but that no considerable further inactivation is obtained by adding exogenous mineralocorticoids. Thus, by increasing the dose of the glucocorticoids, their above-mentioned effects rapidly rise to reach a very high intensity, whereas by correspondingly raising the dosage of mineralocorticoids, the antagonistic (inhibitory) effect of the latter soon reaches a plateau above which further interference with glucocorticoid overdosage becomes insignificant. This is illustrated by the graph on p. 112.

The growth inhibition produced by cortisone in immature adrenalectomized rats can be inhibited both by DOC and by testosterone; MAD exerts no consistent effect.

Progesterone anesthesia is prolonged by adrenalectomy in rats maintained on NaCl alone, but blocked both in intact and in adrenalectomized animals by

spironolactone. Desoxycortisone (Cpd. S), like dehydroisoandrosterone, produces no anesthesia but intense convulsions in the rat. These are allegedly not influenced by adrenalectomy or even by partial hepatectomy.

The uterine weight increase produced by estradiol is markedly inhibited by phenobarbital both in intact and in adrenalectomized rats. Simultaneously the estradiol-metabolizing activity of the hepatic microsomal enzymes is augmented. The adrenal does not seem to play a role in this estradiol-metabolizing effect of the barbiturate but the latter is demonstrable only at very low dose levels. This again illustrates the fact which we have emphasized in connection with so many catatoxic steroid actions upon natural compounds, namely that they are much more efficient in antagonizing the toxic effects of heavy overdosage than in counteracting the physiologic actions of small amounts. It is comparatively easy to prevent steroid anesthesia with catatoxic steroids or drugs, but much more difficult to block the normal actions of steroids upon their natural targets. Presumably, the catatoxic mechanism readily destroys a great excess of a substrate but is much less efficient in degrading the last remnants of it, which are still sufficient to produce physiologic actions.

*Gaunt et al. B71,987/52:* DOC (1 mg/day) and testosterone propionate (0.25 mg/day) counteracted the growth inhibition produced in immature adrenalectomized rats by cortisone acetate (1 mg/day). MAD (2 mg/day) had no consistent effect on growth. Both MAD and testosterone propionate caused thymus atrophy, and this effect was further increased by conjoint administration of cortisone. In intact rats, MAD prevented the cortisone-induced adrenal atrophy. [It is not clear from this brief abstract whether the other interactions were also tested in intact animals (H.S.).]

*Selye B98,268/55:* In adrenalectomized rats, the diminution of body weight, inflammation in the granuloma pouch as well as the atrophy of the thymus and spleen produced by cortisol are all inhibited by aldosterone.

*Selye & Bois C14,534/56:* In adrenalectomized rats bearing granuloma pouches, 2-methyl-9(a) fluorocortisol (Me-F-COL) antagonizes the antiphlogistic, catabolic, thymolytic and splenolytic actions of cortisol. This effect is ascribed to the strong mineralocorticoid effects of Me-F-COL, which counteract glucocorticoid actions. However, since Me-F-COL itself possesses some glucocorticoid potency, its cortisol antagonizing action is evident only at very low dose levels (about 75  $\mu\text{g}/\text{kg}$ ) at which mineralocorticoid effects predominate in agreement with the "law of intersecting dose-effect curves."

*Heuser C54,451/58:* Desoxycortisone (Cpd. S)—like dehydroisoandrosterone—given in large amounts i.p. or p.o. produces no

anesthesia but intense convulsions in the rat. Allegedly, "neither adrenalectomy nor partial hepatectomy sensitized the rat to the convulsive actions of Cpd. S."

*Jasmin et al. C89,132/60:* Both in intact and in adrenalectomized rats, norethandrolone diminishes the body weight loss caused by cortisol without inhibiting the antiphlogistic effect of the latter.

*Levin & Conney F64,557/66:* In immature intact or adrenalectomized rats, the uterine weight increase produced by small doses of estradiol i.p. is markedly inhibited by pretreatment with phenobarbital. At the same time, the estradiol-metabolizing activity of hepatic microsomal enzymes is augmented. In order to demonstrate the inhibition of uterine growth, very small doses (less than 0.5  $\mu\text{g}$ ) of estradiol must be used and phenobarbital must be administered for several days prior to the test.

*Levin et al. F75,365/67:* Phenobarbital increases the  $17\beta$ -estradiol-metabolizing activity of hepatic microsomal enzymes in immature female rats. The *in vitro* activity is paralleled by *in vivo* blockade of the estradiol-induced uterine weight increase. The phenobarbital-induced resistance to the uterine weight-increasing effect of estradiol is not prevented by adrenalectomy or hypophysectomy, indicating that the barbiturate does not act through the pituitary-adrenal axis.

*Orrenius et al. E8,231/69:* In rats, adrenalectomy has no immediate effect upon the phenobarbital induction of steroid hydroxy-

lases in the hepatic microsomes. However, simultaneously adrenalectomized and castrate rats, subsequently maintained in this state for a period of time, showed a strikingly decreased hydroxylating activity of the hepatic microsomes measured with either aminopyrine or testosterone as substrate. The cytochrome P-450 content of the microsomes decreased in a parallel fashion, whereas the cytochrome  $b_5$  remained unchanged. When these steroid-deficient animals were treated with prednisolone or testosterone, the cytochrome P-450 content and the aminopyrine—as well as testosterone—hydroxylating activities of the liver microsomes returned to normal. In the steroid-deficient rats, repeated injections of phenobarbital caused only a minimal increase in the cytochrome P-450 content, the NADPH-cytochrome reductase, and aminopyrine-hydroxylation activities of hepatic microsomes. In intact controls, combined treatment with phenobarbital and prednisolone or testosterone resulted in an increase of these levels as compared to those obtained by phenobarbital alone. Apparently,

“steroid hormones are involved both in the maintenance of normal hydroxylating activity in the rat liver endoplasmic reticulum and in the increase of this activity caused by drugs.”

*Southren & Gordon G77,117/70*: Review and personal observations on the application of radioisotopes to the in vivo study of the kinetics of steroid metabolism in man, with special reference to the effect of sex differences, adrenalectomy, orchidectomy and various diseases upon the plasma clearance of testosterone.

*Selye PROT. 27691*: In rats, (100 g♀) progesterone (6 mg in 1 ml oil i.p.) or pentobarbital (3 mg in 0.5 ml oil i.p.) anesthesia is prolonged by adrenalectomy with maintenance on NaCl, but blocked, both in intact and adrenalectomized animals, by spiro-nolactone (10 mg in 1 ml water p.o. x2/day) pretreatment for 4 days.

Cortisone ← Adrenalectomy + Genetics: Wragg et al. B74,080/52\*; Hagen et al. G77,512/60

Estradiol ← Adrenalectomy + Phenobarbital: Levin et al. F75,365/67\*

### ← Gonadectomy

Female rats are more sensitive than males to the anesthetic action of progesterone; since this sex difference is obvious only after maturity, it has been ascribed to gonadal hormones. Castration increases the sensitivity of males but not of females. Conversely, the resistance of female and castrate males can be raised to the normal male level by methyltestosterone.

On the other hand, mice of both sexes are approximately equally sensitive to the hydroxydione anesthesia. Yet, gonadectomy increases sensitivity to this form of narcosis, especially in females, but to some extent also in males. Methyltestosterone prolongs hydroxydione anesthesia in male mice but not in females or castrate males. Neither thiopental nor pentobarbital anesthesia is influenced by methyltestosterone in mice.

In C3H strain mice, myocardial calcification develops following prolonged cortisol treatment. Females are much more sensitive to this effect than males. Ovariectomy offers no protection but testosterone renders females more resistant.

Conjoint treatment with cortisone + NaCl produces myocardial necroses in orchidectomized but not in normal male rats nor in orchidectomized testosterone-treated males.

In ovariectomized rats, phenobarbital inhibits the uterotrophic effect of estradiol, as well as the induction of phosphofructokinase in the uterus, but the results are obvious only at threshold doses of estradiol treatment. In orchidectomized rats, phenobarbital diminishes the effect of testosterone upon the seminal vesicles and prostate, thereby furnishing further proof that physiologic hormonal substrates can be inactivated by hepatic microsomal enzyme-inducing drugs.

In rats, orchidectomy decreases testosterone and progesterone hydroxylation as well as the associated changes in the hepatic microsomes. All these derangements are counteracted by in vivo treatment of the castrates with various testoids; the action of the latter is in turn blocked by concurrent treatment with folliculoids.

*Winter & Selye A 35,658/41; Winter A 36,333/41:* Female rats are more sensitive than males to the anesthetic action of progesterone, but this sex difference is obvious only after maturity. "The normal endocrine activity of the testis is largely, if not entirely, responsible for this comparative resistance of the males, since castration increases sensitivity in males but is without effect in female rats. Conversely, the resistance of castrate males and females may be raised by methyl testosterone administration."

*Koller C 19,288/56:* Mice of both sexes are approximately equally sensitive to hydroxydione anesthesia. Gonadectomy increases sensitivity to this form of narcosis especially in females and to a lesser extent, in males also.

*Forchielli et al. D 75,874/58:* The rate of  $\Delta^4$ -reduction of 11-desoxycortisol was 3—4 fold greater in female than in male rat liver homogenates and in microsomal fractions containing the  $\Delta^4$ -5 $\alpha$ -hydrogenase. Female rat liver contains only one  $\Delta^4$ -hydrogenase (5 $\alpha$ -microsomal), whereas the male liver contains the soluble  $\Delta^4$ -5 $\beta$ -hydrogenase as well. Ovariectomy caused no marked change in enzyme titer, but hypophysectomy decreased it sharply. Curiously, ACTH, STH and pregnant mare serum partially restored the enzyme level in the hypophysectomized rat. In young animals, increase in the titer of hepatic  $\Delta^4$ -5 $\alpha$ -hydrogenase occurs prior to puberty. This fact—like the negative results after ovariectomy—suggests an enzyme regulation independent of ovarian hormones.

*Loströh C 54,348/58:* Female mice of the C3H strain regularly develop myocardial calcification following prolonged cortisol treatment, whereas males are comparatively resistant. Ovariectomy offers no protection but testosterone renders females more resistant. In hypophysectomized mice, neither cortisol nor ACTH produces myocardial calcification.

*Yates et al. C 61,952/58:* "Homogenates of livers from adult female rats reduce Ring A of  $\Delta^4$ -3-keto-steroids at rates 3 to 10 times greater than those from males. This large sex difference has been observed for all substrates so far tested: aldosterone, desoxycorticosterone, hydrocortisone, cortisone, corticosterone, tes-

tosterone, and progesterone. ... Castration increases and testosterone decreases  $\Delta^4$ -steroid hydrogenase activity in males. In females, neither castration nor estrogen administration had appreciable effect."

*Colás D 20,925/62:* The livers of male rats contain more dehydroepiandrosterone 16 $\alpha$ -hydroxylase than that of males. Castration reduces the enzyme activity but not quite to the low level of the female.

*Mäkinen et al. E 20,847/63:* Conjoint treatment with cortisone + NaCl produces myocardial necroses in orchidectomized, but not in normal male rats. Testosterone restores the resistance of the male castrates to normal, whereas concomitant exposure to the stress of a loud bell aggravates the cardiopathy.

*Singhal et al. G 67,770/67:* Phenobarbital pretreatment inhibits the uterotrophic effect of estradiol as well as the induction of phosphofructokinase in the uterus of the ovariectomized rat. The most marked results were obtained with threshold doses of estradiol.

*Denef & de Moor H 3,569/68:* In female rats, spayed and given testosterone immediately after birth, there developed a characteristic male pattern of hepatic microsomal steroidases. In male rats, castrated at birth, a single injection of testosterone given at the same time prevented the differentiation of the feminine type of steroid metabolism found after neonatal castration. In adults, testosterone had a similar effect, but unlike in neonates, its action was only temporary.

*Fahim et al. G 67,772/68:* Phenobarbital reduces the uterotrophic action of both exogenous estradiol and endogenous folliculoids. This effect is somewhat lessened by ovariectomy. The authors consider the possibility that the barbiturate may induce steroidases not only in the hepatic microsomes, but also in the ovary. Enzyme determinations in the liver were not performed, but phenobarbital significantly increased hepatic weight and total nitrogen content.

*Jelinek H 1,518/68:* There was no difference in the duration of hydroxydione anesthesia in male and female intact or gonadectomized mice. Pretreatment with methyltestosterone p.o. prolonged hydroxydione anesthesia

in males, but not in females or castrate males. Neither thiopental, nor pentobarbital anesthesia was influenced by methyltestosterone. Pretreatment with Dianabol or 17 $\alpha$ -methyl-androst-2-ene-17 $\beta$ -ol failed to influence hydroxydione anesthesia in mice.

*King et al. H 16,446/68:* In orchidectomized rats, phenobarbital pretreatment diminishes the effect of testosterone upon the seminal vesicles and prostate, presumably as a consequence of increased hepatic microsomal enzyme production. These findings may "offer a therapeutic modality for gynecologic syndromes that are associated with overproduction of androgens."

*Denef & de Moor H 15,811/69:* The sexual differentiation of steroid-metabolizing enzymes appears in the rat liver from the 30th day of life onwards. From experiments on neonatally gonadectomized or intact rats treated with folliculoid or testoid compounds, "it is concluded that, as far as the differentiation of cortisol metabolizing enzymes is concerned, estradiol is able to counteract the organizing action of testosterone at birth as well as the expression of these neonatal testosterone effects after the 30th day of life."

*Kato et al. H 25,499/69:* In rats, orchidectomy decreased testosterone and progesterone hydroxylation, as well as the spectral change caused by these steroids in liver microsomes, reflecting a less pronounced decrease in microsomal P-450 content and NADPH-neotetrazolium reductase activity. All these changes were restored to normal by in vivo treatment

of the castrates with testosterone or methyltestosterone, whereas simultaneous administration of estradiol or diethylstilbestrol blocked these actions of the testoids. Curiously, the folliculoids failed to block the effects of the testoids upon the seminal vesicle and levator ani muscle as well as on hepatic microsomal proteins in these same orchidectomized rats. Earlier literature on the antagonism between folliculoid and testoid actions upon hepatic drug-metabolizing enzymes is reviewed.

*Southren & Gordon G 77,117/70:* Review and personal observations on the application of radioisotopes to the in vivo study of the kinetics of testoid metabolism in man, with special reference to sex differences, adrenalectomy, orchidectomy, and various diseases upon the plasma clearance of testosterone.

### ← *Various Steroids*

← **TMACN.** TMACN administered to rats between the 15th and 20th day of gestation produces a syndrome of congenital adrenocortical hyperplasia, hypospadias, clitoral hypertrophy due to inactivation of 3 $\beta$ -hydroxysteroid-dehydrogenase and  $\Delta^5$ - $\Delta^4$ -3-ketosteroid isomerase. Furthermore, TMACN suppresses nipple formation in females and induces it in males. 17 $\beta$ -hydroxy-4,4,17 $\alpha$ -trimethylandrost-5-ene-(2,3d)-isoxazole produces similar effects.

In the male offspring which develop severe hypospadias, the anogenital distance is greatly reduced almost to that of females. Small amounts of testosterone prevent the production of hypospadias without affecting the adrenal hyperplasia or the inhibition of 3 $\beta$ -hydroxysteroid-dehydrogenase and  $\Delta^5$ - $\Delta^4$ -3-ketosteroid isomerase. TMACN interferes with the biogenesis of various corticoids also as judged by analyses on adrenal vein blood as well as in adrenal homogenates. The "cyano-ketone" appears to inhibit the conversion of pregnenolone to progesterone and thereby reduce corticosterone secretion which would result in an increased ACTH production and adrenal hypertrophy. Even a single injection of TMACN on the 16th or 19th day of

gestation, produces a permanent effect in  $3\beta$ -hydroxysteroid-dehydrogenase activity in the maternal adrenal.

TMACN is an analogue of androstenolone (the substrate of  $3\beta$ -hydroxysteroid-dehydrogenase) but has little or no testoid or folliculoid activity itself. The compound also produces luteal and Leydig cell hyperplasia. Its persistent effect is presumably due to the fact that unlike most enzyme inhibitors, it is very tightly and irreversibly bound to  $3\beta$ -hydroxysteroid-dehydrogenase at its active site.

In guinea pigs, TMACN increases the mitochondrial and microsomal fractions of the adrenal cortex.

← **Varia.** DOC-induced mineralocorticoid hypertension is not significantly influenced in rats by pregnenolone or acetoxypregnenolone.

SC-8109 and SC-5233 do not protect the rat against the anesthetic effect of progesterone.

← **Various Steroids** cf. also *Selye C92,918/61, p. 70; G60,083/70, p. 385.*

← **TMACN.** *Goldman et al. F64,070/66:* In rats, TMACN administered between the 15th and 20th day of gestation produces a syndrome of congenital adrenocortical hyperplasia, hypospadias and clitoral hypertrophy due to inactivation of  $3\beta$ -hydroxysteroid dehydrogenase.

*McCarthy et al. F74,065/66:* In rats, TMACN interferes with the biogenesis of various corticoids in vivo (adrenal vein blood) and in vitro (adrenal homogenates). "The cyano-ketone appears to inhibit the conversion of pregnenolone to progesterone by the rat adrenal gland. This inhibition would account for the reduction in corticosterone secretion and adrenal hypertrophy that follows administration of the cyano-ketone to rats."

*Bongiovanni et al. E7,039/67:* Review on the inhibition of  $3\beta$ -hydroxysteroid dehydrogenase by TMACN in vivo and in vitro. This analogue of androstenolone (the substrate of the enzyme) has little or no testoid or folliculoid activity, but produces adrenocortical hyperplasia by blocking the biosynthesis of glucocorticoids. It also produces luteal and Leydig cell hyperplasia; "unlike most enzyme inhibitors, this analogue is very tightly and irreversibly bound to  $3\beta$ -hydroxysteroid dehydrogenase at, or very near, its active site." When TMACN is given to pregnant rats, their offspring "have severe adrenal cortical hyperplasia, deficient histochemical activity of the  $3\beta$ -hydroxysteroid dehydrogenase in the adrenals and testes, increased activity of G-6-PD in adrenals, testes, and liver, and no change in the activities of the 3 $\alpha$  or 17 $\beta$ -hydroxysteroid dehydrogenases in these

tissues. The experimental gonadal males have severe hypospadias, and their anogenital distance is reduced from that of normal to almost that of the normal females in proportion to dose. The gonadal females have marked clitoral hypertrophy but no change in anogenital distance from the normal." Small amounts of testosterone prevent the production of hypospadias without affecting the adrenal hyperplasia or the inhibition of  $3\beta$ -hydroxysteroid dehydrogenase by TMACN.

*Goldman F85,342/67:* In rats, a single injection of TMACN on the 16th or 19th day of gestation produces a permanent defect in  $3\beta$ -hydroxysteroid dehydrogenase in the maternal adrenal and corresponding permanent changes in the pituitary, adrenals, and sex organs of the offspring.

*Goldman H15,818/69:* In rats, the maternal and fetal changes induced by two inhibitors of  $3\beta$ -hydroxysteroid dehydrogenase and  $\Delta^5$ - $4$ -3-ketosteroid isomerase [TMACN and 17 $\beta$ -hydroxy-4,4,17 $\alpha$ -trimethylandro-5-ene-(2,3d)-isoxazole] are described and their mechanism of action discussed.

*Goldman & Neumann H18,122/69:* In rats given TMACN during pregnancy, functional and structural changes occur in the adrenals and sex organs as a consequence of  $3\beta$ -hydroxysteroid dehydrogenase and  $\Delta^5$ - $4$ -3-ketosteroid isomerase inhibition.

*Castells & Bransome Jr. H21,283/70:* In guinea pigs treated with TMACN in vivo, the protein content of the mitochondrial and microsomal fractions was increased. "Exposure to a high level of ACTH for 4 hr or 4 days seemed to exert less net effect on mitochondrial protein than on microsomal protein synthesis: an observation consistent with an intrinsic

difference in the regulation of the synthesis of adrenocortical mitochondrial and microsomal proteins."

Steroids ← TMACN: McCarthy et al. *F74,065/66*; Goldman *F78,224/67*

← **Varia.** Friedman & Friedman *B48,306/50*: In intact male rats, on a normal NaCl intake, the hypertension and cardiac hypertrophy produced by s.c. implantation of DOC pellets could be inhibited by an adrenocortical extract, but not by progesterone, testosterone, pregnenolone, estradiol, or acetoxypregnenolone.

Gaunt et al. *B82,200/53*: In rats, MAD was the most active in preventing cortisone-induced adrenal atrophy among a large series of steroids. To some extent, this was true even after hypophysectomy.

Heuser *C33,938/57*: Doctor's thesis (193 pp., 272 refs.) on steroid anesthesia with sections on: **adaption to steroid anesthesia** by pretreatment with the same or other steroids, the effect of adrenalectomy and corticoids upon steroid anesthesia and the interaction between anesthetic and convulsive steroids.

Witzel *C68,395/59*: Review (29pp., 113 refs.) on steroid anesthesia, including chapters on adaptation to steroids, the effect of partial hepatectomy, the influence of steroid anesthetics upon various types of convulsions.

McGuire Jr. et al. *D82,559/60*: The hepatic microsomal steroid 5 $\alpha$ -reductases have a high substrate specificity and an absolute requirement for TPNH. Addition of various other steroids can competitively inhibit the reduction of the substrate by the rat liver microsomal enzymes in vitro.

Linè et al. *F58,620/65*: In rats, **1,2 $\alpha$ -epoxyandrostan-3,17-dione**, though devoid of anabolic, testoid or folliculoid properties, inhibits the increase in liver glycogen caused by cortisol, but does not prevent the inhibition of inflammation and the atrophy of the adrenal cortex characteristic of glucocorticoid overdosage.

Selye et al. *G60,050/70*: **SC-8109** and **SC-5233** fail to protect the rat against the anesthetic effect of progesterone or pentobarbital.

Selye *G60,064/70*: In rats, PCN, CS-1 and spironolactone offer considerable protection against the infarctoid cardiopathy produced by F-COL + Na<sub>2</sub>HPO<sub>4</sub> + restraint. The possible protection offered by other conditioners requires further investigation, cf. Table 12.

Despoupoulos *H35,471/71*: In a system containing isolated mitochondrial fractions from rat liver homogenates, the synthesis of

taurocholate from cholate was inhibited by **testosterone, cortisone, estradiol, stilbestrol, norethandrolone** and progesterone but not by mestranol. Synthesis of cholate from cholesterol was not inhibited by any of these steroids. "These experiments demonstrate an effect of steroids on a specific step in the sequence of bile salt synthesis; namely, conjugation of cholate with taurine to form taurocholate."

Selye *G70,480/71*: In rats, the infarctoid cardiopathy produced by combined treatment with F-COL + NaClO<sub>4</sub> + corn oil is most effectively combated by CS-1 and spironolactone. Phenobarbital diminished the incidence of cardiac necroses but did not significantly decrease mortality. The two glucocorticoids of our series greatly accelerated and aggravated mortality; this made it im-

possible to assess their effect upon the development of cardiac necroses. Since F-COL possesses both gluco- and mineralocorticoid potencies it is not unexpected that additional treatment with glucocorticoids, would increase its toxicity. It is noteworthy however, that among the many catatoxic compounds tested, only few offer protection against this cardiopathy in whose pathogenesis corticoids (excellent substrates for catatoxic steroids) play an indispensable role. The most active protective steroids (CS-1, spironolactone) are also distinguished by a marked potassium retaining effect which undoubtedly helps to prevent a cardiopathy primarily characterized by potassium losses, *cf.* Table 13.

For further details on technique of tabulation cf. p. VIII.

*Selye G70,480/71*: In rats, the body weight loss produced by chronic triamcinolone overdosage is significantly counteracted by PCN, CS-1, spiro lactone and norbolethone. Curiously, ethylestrenol has no such action, although this anabolic testoid is highly effective in increasing body weight under other conditions and in counteracting the catabolism produced by chronic DHT intoxication. As expected, concurrent treatment with triamcinolone and other glucocorticoids such as prednisolone aggravate the catabolic effect

of the former as does estradiol which likewise possesses an inherent catabolic effect. Phenobarbital, although a potent microsomal drug-metabolism inducer, fails to counteract the catabolic action of triamcinolone, cf. Table 18, p. 136.

Table 16. *Conditioning for nephrocalcinosis produced by estradiol + NaH<sub>2</sub>PO<sub>4</sub>*

Treatment <sup>a</sup>	Nephrocalcinosis <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

## NONSTEROIDAL HORMONES AND HORMONE-LIKE SUBSTANCES ←

## ACTH ←

In guinea pigs, combined treatment with ACTH and estradiol allegedly produces extensive myocardial necroses, similar to the infarctoid cardiopathy elicited by steroids in combination with stress and certain sodium salts. However, these findings have not yet been confirmed.

**ACTH ← estradiol** cf. also *Selye G60,083/70, p. 331.*

*Lupulescou E21,838/63:* In guinea pigs, combined treatment with norepinephrine + estradiol or ACTH + estradiol produces extensive myocardial necrosis. "This infar-

ctoid cardiopathy appears without any addition of phosphates or other sodium salts which is evidence of the fact that large doses of oestrogens prepare or sensitize the myocardium as regards the cardiotoxic action of noradrenalin or the corticotropic hormone."

## STH ←

The interactions between STH and corticoids have been the subject of numerous studies. The hyalinosis syndrome produced by DOC in uninephrectomized NaCl-treated rats is aggravated by STH; indeed STH alone can produce malignant hypertension following conditioning by uninephrectomy + NaCl. These effects of STH are inhibited by cortisone as well as by adrenalectomy. Conversely, the cortisone-induced involutions of the adrenal cortex and thymus are inhibited by STH.

It is possible that STH exerts its toxic effect upon the kidney and the cardiovascular system (hyalinosis) only through (or at least in the presence of) a responsive adrenal cortex. Adrenal atrophy produced by cortisone or adrenalectomy prevents these toxic actions of STH. On the other hand, the prothyllogistic and anabolic actions of STH are increased by DOC or aldosterone even after adrenalectomy.

**STH ← glucocorticoids** cf. also *Selye B58,650/51, pp. 317, 357; C9,000/56, p. 58; G60,083/70, pp. 348, 357.*

**STH ← mineralocorticoids** cf. also *Selye B58,650/51, pp. 316, 357; C9,000/56, p. 59.*

**STH ← testoids** cf. also *Selye G60,083/70, pp. 374, 378.*

*Selye B53,940/51:* In uninephrectomized NaCl-treated rats, the hyalinosis syndrome produced by DOC is aggravated by STH; indeed, STH alone can produce malignant hypertensive disease. These effects of STH are inhibited by cortisone. Apparently STH increases mineralocorticoid production by the adrenals (unless these are rendered atrophic by cortisone) and/or sensitizes the peripheral tissue to mineralocorticoids.

*Selye B53,934/51:* In rats conditioned by uninephrectomy + NaCl, both STH and DOC produce generalized hyalinosis and hypertension. The same as adrenalectomy or hypophysectomy, large doses of cortisone (which cause adrenocortical atrophy) prevent the cardiovascular and renal damage. "Apparently, STH exerts its toxic effects upon the kidney and the cardiovascular system only through (or at least in the presence of) a responsive adrenal cortex."

*Selye B75,329/52:* In rats the involution of the adrenal cortex and of the thymus as well as the antiphlogistic effect of cortisone are counteracted by simultaneous STH treatment. "Curiously, even those organs which normally undergo an absolute or relative increase in size as a result of either

cortisone or STH treatment, e.g. the heart, kidney, liver, are maintained in an essentially normal weight range if both hormones are given conjointly."

*Selye & Bois C1,718/55*: In intact and in adrenalectomized rats, a synergism between mineralocorticoids (DOC, aldosterone) and STH was evident in their effects upon many target organs.

*Wakabayashi et al. H27,784/70*: In rats,

exposure to stressors [kind not stated (H.S.)], or administration of dexamethasone suppresses plasma STH (radioimmunoassay) both in the presence and in the absence of the adrenals. Adrenalectomy increases plasma STH. [These findings support the view that during stress—perhaps owing to increased ACTH and/or glucocorticoid secretion, the "shift in pituitary hormone production" results in a diminished STH secretion (H.S.).]

### **Other Anterior Lobe Extracts ←**

The preputial gland stimulating effect of crude anterior pituitary extract is enhanced by concurrent administration of pregnenolone, although in itself, the latter produces only very slight preputial gland stimulation.

*Selye & Clarke 55,978/43*: In the rat,  $\Delta^5$ -pregnenolone greatly augments the preputial gland stimulating effect of crude anterior pituitary extracts. In itself,  $\Delta^5$ -pregnenolone causes only very slight preputial gland stimulation and even this effect is abolished by hypophysectomy and hence is apparently dependent upon the simultaneous activity of hypophyseal hormones.

*Rondell H32,853/70*: In vitro experiments on the ovarian follicles of the pig suggest that LH, cyclic AMP or progesterone augment the distensibility of follicular strips, thereby preparing for rupture. TMACN blocks the effects of LH or cyclic AMP on both steroid release

and distensibility. This blockade can be counteracted by progesterone. Presumably, "LH stimulates steroid secretion from the follicular tissue which in turn causes the activation of the ovulatory enzyme."

*Dmowski et al. G80,777/71*: In various species, Danazol (2,3 isoxazol derivative of 17 $\alpha$ -ethinyl testosterone) was found to inhibit the effect of endogenous, but not of exogenous gonadotrophins. In addition, it had a mild testoid and progestational effect, but was devoid of antitestoid, antifolliculoid or antiluteoid properties.

Gonadotrophins ← Estradiol-17 $\beta$ , Progesterone: Brown et al. F57,759/65\*

### **Posterior Pituitary Hormones ←**

The production of renal cortical necrosis by vasopressin is facilitated in rats by pretreatment with estradiol or estrone. Though 5-HT produces similar renal lesions, their development is not modified by folliculoids. In ovariectomized weanling rats, pretreated with progesterone and estradiol, even oxytocin preparations produce renal cortical necrosis, although, by themselves, the latter have no such effect.

The metacorticoid hypertension produced by temporary overdosage with DOC + NaCl predisposes for the pressor effect of vasopressin and other vasopressor substances.

**Posterior Pituitary Hormones ← cf. also**  
*Selye G60,083/70, pp. 364, 369.*

*Byrom A9,905/38*: In rats, the production of renal cortical necrosis by vasopressin is facilitated by pretreatment with estradiol or estrone.

*Sturtevant C9,089/55; C21,591/56*: In rats with metacorticoid hypertension (produced by temporary overdosage with DOC + NaCl), the pressor effect of epinephrine, norepinephrine, vasopressin and renin was increased, but the effect of histamine, 5-HT, yohimbine and

TEA on the blood pressure was not consistently altered.

*Szarvas & Kovács E34,633/63*: In the rat, estrone aggravates the renal necroses produced by posterior pituitary extracts, but not those elicited by 5-HT.

*Moore G11,771/64*: In intact or ovariectomized weanling rats pretreated for ten days with progesterone and estradiol, renal cortical necrosis develops under the influence of oxytocin, whereas in itself, the latter is ineffective.

### **Thyroid Hormones ←**

In rats, testoid extracts of urine have been claimed to counteract the adipose tissue atrophy and other manifestations of overdosage with desiccated thyroid. In baby rats, the retardation of tooth eruption and opening of the eyelids induced by thiouracil are inhibited by DOC, but the stunting of body growth and the thyroid changes themselves are not influenced by this steroid. Testosterone fails to affect the body and organ weight changes induced by thioureas in the rat. However, the thiourea-induced glycogen storage and pathologic changes in the liver are allegedly counteracted by testosterone, whereas the glycogenolytic action of thyroid is prevented by cortisone. The pulmonary edema induced in rats by thiourea (or other agents such as  $\text{NH}_4\text{Cl}$ , epinephrine, chloropicrin) are prevented by the administration, 5 min earlier, of a single dose of prednisolone i.v. On the other hand, prednisolone aggravates the myopathy produced by thyroid overdosage in the rat.

Extensive recent studies performed in our Institute show that, in general, catabolic steroids are not particularly efficient in preventing the body weight loss produced by large doses of T3. The comparatively mild protective effect exerted in this respect by ethylestrenol and norbolethone may well be ascribed to the anabolic effect of these steroids. On the other hand, the glucocorticoids, prednisolone and triamcinolone, as well as estradiol, greatly aggravate the toxicity of T3. The prostration and mortality induced by high doses of propylthiouracil are counteracted by PCN, CS-1 and several other potent catabolic steroids, but the thyroid enlargement induced by small amounts of this goitrogen is further enhanced by PCN, which possesses a mild goitrogenic effect itself.

In guinea pigs, the weight loss produced by thyroxine can be counteracted by cardiac glycosides or DOC.

In dogs, estradiol stimulates the proliferation of spongy bone, an effect which is inhibited by thyroidectomy and enhanced by thyroxine.

Methenolone (a testoid) antagonizes the catabolic effect of desiccated thyroid or of prednisolone in man.

**Thyroid Hormones ← corticoids** cf. also *Selye G60,033/70*, pp. 347, 355.

*Korenchevsky et al. 16,451/33*: In the rat, a testoid extract prepared from urine failed to influence the decrease in fat deposition and other manifestations of overdosage with desiccated thyroid.

*Kinsell et al. A37,369/42*: Experiments on guinea pigs and mice suggested that "therapeutic dosage of cardiac steroid-glycosides prevents a weight loss in thyroxin-treated

animals similar to that obtained with adrenal cortical hormone and desoxycorticosterone acetate. Larger dosage of these cardiac glycosides either fails to modify such weight loss or actually increases it."

*Oettel & Franck A72,420/42*: In rats, DOC allegedly offers some protection against the hepatic changes produced by thyroxine or allylformiate.

*Parmer B17,568/47*: In baby rats, the retardation of tooth eruption and of the

opening of the eyelids induced by thiouracil is counteracted by DOC. However, the stunting of body growth and the thyroid changes produced by thiouracil are not influenced by DOC.

*Benoit & Clavert B27,669/48:* In ducks, estradiol stimulates the proliferation of spongy bone consisting of fine trabeculae. Thyroidectomy retards this bone proliferation, whereas conjoint treatment with thyroxine and estradiol leads to the abundant development of thick trabeculae.

*Leathem B38,768/48:* In rats the effect of thiourea and thiouracil upon body and organ weights is not significantly influenced by testosterone.

*Kar et al. C17,531/55:* In rats, thiourea causes glycogen storage and severe pathologic changes in the liver. Testosterone counteracts these lesions.

*Kusama C58,473/57:* In rats, the glycogenolytic action of thyroid feeding is counteracted by cortisone.

Table 20. *Conditioning for T3 (3,3,5-Triiodo-L-thyronine)*

<sup>b</sup> The thyroid weight in completely untreated control rats (receiving no propylthiouracil) was 9.5 ± 0.5.

<sup>c</sup> Mortality was listed on 13th day ("Exact Probability Test"), simultaneously with thyroid weight and final body weight (Student's *t*-test). For further details on technique of tabulation *cf.* p. VIII.

### Parathyroid Hormones ←

In rats, pretreatment with DOC allegedly inhibits the nephrocalcinosis produced by parathyroid extract.

Cortisone antagonizes the effect of parathyroid extract upon the teeth and bones of the rat, simultaneously inhibiting hypercalcemia and nephrocalcinosis. Cortisone also prevents the accumulation of strontium and calcium in the kidney, as well as their urinary elimination following parathyroid extract injection. The elevation of serum total glycoproteins induced by parathyroid extract as well as the associated nephrocalcinosis can be prevented by cortisone, although the latter does not prevent the nonspecific elevation of serum glycoproteins induced by turpentine. Even the production of osteitis fibrosa and of an increase in gastric mucus production are inhibited by glucocorticoids in the rat.

Small doses of **estradiol** increase the cortical nephrocalcinosis in parathyroid extract treated rats. In hens, folliculoids increase blood calcium, but do not augment the hypercalcemic action of parathyroid extract. Both hormone preparations cause osteosclerosis in chickens, but the lesions are qualitatively distinct.

**Parathyroid Hormones ← corticoids** cf. also *Selye G60,083/70, pp. 347, 354.*

*Baker et al. C24,277/54:* In rats, pre-treatment with DOC greatly diminishes the nephrocalcinosis normally produced by parathyroid hormone.

*Bacon et al. C26,675/56:* In rats, parathyroid extract increases the urinary excretion of radioactive calcium and strontium, as well as the deposition of these elements in the kidney. Cortisone prevents the accumulation of strontium and calcium in the kidney, but does not influence their urinary excretion under these conditions.

*Laron et al. C47,872/58:* In rats, cortisone antagonizes the effect of parathyroid extract upon the teeth and bones; it also inhibits hypercalcemia and nephrocalcinosis.

*Bradford et al. D76,315/60:* In rats, cortisone prevents the elevation of serum total glycoproteins induced by parathyroid extract as well as the associated nephrocalcinosis.

Cortisone does not prevent the nonspecific elevation of serum glycoproteins resulting from turpentine injections.

*Urist et al. C95,236/60:* In hens, parathyroid extract and "equine estrogenic substances" had an additive effect on blood calcium and bone structure. Both hormone preparations caused osteosclerosis although of a different type and, whereas parathyroid extract increased ultrafilterable calcium, the folliculoid preparation augmented the nonultrafilterable fraction of the serum calcium.

*Grob et al. E20,745/63:* Small doses of estradiol increase cortical nephrocalcinosis in the parathyroid extract treated rat.

*Stoerk et al. G5,410/63:* In rats, the production of osteitis fibrosa by parathyroid extract is inhibited through cortisol.

*Menguy & Masters F17,447/64:* In rats, parathyroid extract greatly increases the production of gastric mucus and this effect can be partially blocked by cortisone.

**Pancreatic Hormones ←**

In rats, adrenocortical extracts (with predominantly **glucocorticoid** activity) proved to inhibit both insulin hypoglycemia and epinephrine hyperglycemia. It was concluded that "cortin exerts a stabilizing effect upon the blood sugar." In mice, ACTH and glucocorticoids increase insulin resistance, as judged by toxicity tests. The renal changes produced by alloxan are aggravated by cortisone in guinea pigs but not in rats. The mortality induced by phenformin (an oral antidiabetic) is diminished by cortisol in rats but not in dogs.

DOC allegedly antagonizes the toxic actions of insulin, and in combination with the latter can produce extreme obesity in rats. It also protects against alloxan diabetes.

Fluoxymesterone renders the rat hypersensitive to insulin shock, perhaps because this **testoid** induces adrenocortical atrophy. Durabolin (another anabolic testoid) decreases alloxan ketosis in the rat, whereas diethylstilbestrol tends to aggravate it, at least on certain diets.

In rabbits, alloxan diabetes is not significantly affected by DOC, testosterone or **progesterone**, whereas **stilbestrol** rapidly decreases alloxan hyperglycemia in both sexes. The toxicity of tolbutamide is increased by stilbestrol in the rat.

*Selye & Dosne A 30,701/39*: In rats, under certain conditions, an adrenocortical extract may inhibit both insulin hypoglycemia and epinephrine hyperglycemia. "It appears that cortin exerts a stabilizing effect on the blood sugar."

*Jensen & Grattan 77,887/40*: In mice, ACTH, glucocorticoids and cortical extracts increase insulin resistance, whereas other pituitary hormones and thyroxine have no such effect.

*Levens & Swann 80,483/41*: In rats, DOC antagonizes the toxic actions of insulin, and in combination with the latter, produces extreme obesity.

*Ingle et al. B 3,163/47*: In rats, diethylstilbestrol tends to aggravate alloxan diabetes but its effect depends upon the diet.

*Carrasco & Vargas B 50,792/49*: In rabbits, alloxan diabetes is not significantly affected by DOC, testosterone or progesterone. Stilbestrol rapidly decreases alloxan hyperglycemia in both sexes.

*Grunert & Phillips B 48,993/49*: In rats, DOC protects against alloxan diabetes.

*Avezzu et al. C 12,653/54*: In guinea pigs, the renal changes produced by alloxan are aggravated by cortisone.

*Penhos & Blaquier C 59,755/58*: The mortality induced by phenformin (an oral antidia-

betic) is diminished by cortisol and epinephrine in rats but not in dogs.

*Greenberg D 21,811/62*: In the rat, the renal changes produced by alloxan are not significantly affected by cortisone.

*McCull & Sacra D 34,973/62*: "Pretreatment of female Sprague-Dawley rats with diethylstilbestrol for 15 days significantly increased the acute toxic effect of tolbutamide, isobuzote, terbuzole, and insulin. Testosterone pretreatment resulted in a significant decrease in toxicity of tolbutamide, isobuzole, and terbuzole but not of insulin."

*Grella E 21,538/63*: Pretreatment with fluoxymesterone renders the rat hypersensitive to insulin shock, allegedly because this steroid produces adrenocortical atrophy.

*Rudas & Weissel E 34,762/63*: Nandrolone decreases alloxan ketosis in the rat.

*Pokrajac et al. G 49,275/67*: Review of the literature and personal observations on the increased insulin resistance of cortisol-treated rats.

*Isacson & Nilsson G 80,478/70*: In healthy men, combined treatment with phenformin and ethylestrenol raised the fibrinolytic activity of the blood and the platelet adhesiveness. Thus, "the combined treatment produced changes tending to counteract the development of thrombosis."

### *Epinephrine, Norepinephrine ←*

As previously stated, under certain conditions, glucocorticoid adrenal extracts may inhibit both insulin hypoglycemia and epinephrine hyperglycemia in rats. That is why we concluded that "cortin exerts a stabilizing effect upon the blood sugar."

Prednisone pretreatment facilitates the production of pulmonary edema by small doses of epinephrine in rabbits. On the other hand, in the rat, pulmonary edema induced by epinephrine (or thiourea, chloropicrin or  $\text{NH}_4\text{Cl}$ ) is prevented by the administration of a single dose of prednisolone 5 min earlier. In dogs, prednisolone failed to protect against shock induced by epinephrine or norepinephrine.

Both in rats and in dogs, the pressor action of epinephrine and norepinephrine (as well as that of renin and angiotensin) is considerably enhanced by previous uninephrectomy and treatment with DOC + NaCl.

Pretreatment with stilbestrol diminishes the severity of pulmonary edema following epinephrine treatment in guinea pigs. On the other hand, combined treatment with norepinephrine and estradiol produces extensive myocardial necrosis in guinea pigs, similar to the ESCN produced in rats.

In rabbits, the production of calcifying aortic lesions by epinephrine is partially inhibited by adrenosterone, a steroid compound, although normally males are more sensitive than females to this type of arteriosclerosis.

**Epinephrine, Norepinephrine** ← **corticoids** cf. also Selye B58,650/51, p. 322; C92,918/61, pp. 107, 109, 111; G60,083/70, pp. 347, 352.

**Epinephrine, Norepinephrine** ← **folliculoids** cf. also Selye G60,083/70, pp. 364, 368.

**Epinephrine, Norepinephrine** ← **luteoids** cf. also Selye G60,083/70, p. 370.

**Epinephrine, Norepinephrine** ← **testoids** cf. also Selye G60,083/70, p. 379.

Selye & Dosne A30,701/39: In rats, under certain conditions, the adrenocortical extract may inhibit both insulin hypoglycemia and epinephrine hyperglycemia. "It appears that cortin exerts a stabilizing effect on the blood sugar."

Masson et al. B47,635/50: In dogs pre-treated with DOC + uninephrectomy + NaCl, the hypotensive effect of TEA was not significantly altered. Similarly, both in rats and in dogs, the pressor action of epinephrine, norepinephrine, renin and angiotensin was not consistently altered by previous uninephrectomy and treatment with DOC + NaCl.

Franco C27,538/54: In guinea pigs, pre-treatment with testosterone does not modify the development of pulmonary edema following the administration of epinephrine.

Giuseppe C27,530/54: In guinea pigs, pre-treatment with stilbestrol diminishes the severity of pulmonary edema following treatment with epinephrine.

Sturtevant C9,089/55; C21,591/56: In rats with metacorticoid hypertension (produced by temporary overdosage with DOC + NaCl), the pressor effect of epinephrine, norepinephrine, vasopressin and renin was increased, but the effect of histamine, 5-HT, yohimbine and TEA on the blood pressure was not consistently altered.

Barbe C46,902/57: In rabbits, prednisone pretreatment facilitates the production of fatal pulmonary edema by small doses of epinephrine.

Moss & Dury C44,068/57: In rabbits, the development of cholesterol atherosclerosis is inhibited by cortisone, and the regression of already established lesions accelerated. The epinephrine-induced aortic medial necrosis is not prevented by cortisone, but the fibroblast reaction in the lesions is inhibited.

Plotka et al. C51,239/57: In rabbits, the production of aortic lesions by epinephrine i.v. is partly inhibited by adrenosterone; yet, normally males are more sensitive than females to epinephrine arteriosclerosis.

Henschler & Reich C71,216/59: In rats, the pulmonary edema induced by ammonium

chloride, epinephrine, thiourea or chloropicrin is prevented by the administration about 5 min earlier of a single large dose of prednisolone i.v.

Lupulescou E21,838/63: In guinea pigs, combined treatment with norepinephrine + estradiol or ACTH + estradiol produces extensive myocardial necrosis. "This infarctoid cardiopathy appears without any addition of phosphates or other sodium salts which is evidence of the fact that large doses of oestrogens prepare or sensitize the myocardium as regards the cardiotoxic action of noradrenalin or the corticotropic hormone."

Szabó et al. G44,867/66: In dogs, prednisolone failed to protect against shock induced by epinephrine or norepinephrine.

Motsay et al. H32,852/70: In dogs, massive doses of glucocorticoids (e.g., methylprednisolone) can offer protection against circulatory shock produced by overdosage with epinephrine or endotoxin. The prophylactic effect is ascribed primarily to a protection of the microcirculation.

Selye PROT. 32804: In rats, none of the conditioning agents of our series offered any significant protection against acute intoxication.

Table 23. *Conditioning for epinephrine*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

Progesterone	5/10 NS	2/10 NS
Estradiol	8/10 *	4/10 *
DOC-Ac	6/9 NS	0/9 NS
Hydroxydione	8/10 *	2/10 NS
Thyroxine	9/9 ***	8/9 ***
Phenobarbital	8/10 *	3/10 NS

<sup>a</sup> The rats of all groups were given epinephrine bitartrate (1.5 mg/100 g body weight in 0.2 ml water, s.c., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 5 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

tion with epinephrine. The glucocorticoids and thyroxine actually decreased resistance to this catecholamine. The apparent increase in

epinephrine sensitivity induced by estradiol hydroxydione and phenobarbital was barely significant, *cf.* Table 23, p. 144.

### *Histamine* ←

Earlier observations suggested that in mice and rats, adrenocortical extract or DOC, in combination with NaCl, can raise histamine resistance above normal. This has subsequently been confirmed with cortisol and DOC as regards the hypotensive effect of histamine in rats. Yet, in new-born rats, fatal intoxication with histamine was not significantly influenced by cortisol, cortisone, corticosterone or ACTH.

In rats given histamine by aerosol, or egg-white i.p., an asthmatic attack ensues if the lung was previously irritated by inhalation of acetic acid. This response is obtained in females, castrate males, and in intact males treated with folliculoids, but not in normal males. Testosterone and progesterone abolish this effect in females and castrate males, thus indicating a sex hormone dependence of histamine resistance.

In rats, complete blockade of the sympathetic system by adrenal demedullation, combined with reserpine or bretylium-like agents or with ganglioplegics, causes a considerable increase in histamine sensitivity, comparable in degree to that induced by complete adrenalectomy. Epinephrine alone counteracts the lethality of histamine after such sympathetic blockade, but cortisone offers only partial protection. Presumably, sympathetic stimulation is "the first line of defense" against the vasomotor disturbances produced by histamine and, in this respect, is more important than cortisone, although the latter offers greater protection against other stressors.

In mice, sensitized by histamine plus pertussis vaccine, cortisol and cortisone increased, whereas DOC decreased resistance to shock produced by this combined treatment.

In guinea pigs, ACTH and cortisone failed to protect against histamine shock or anaphylaxis.

*Perla et al. A 31,863/40:* In mice and rats, pretreatment with NaCl in combination with DOC or adrenocortical extract increased resistance to histamine. Favorable results have also been obtained by DOC plus NaCl in a few patients suffering from surgical shock.

*Malkiel G 71,451/51:* In guinea pigs, ACTH and cortisone are without effect on the end results of histamine shock, or of passive or active anaphylaxis.

*Malkiel & Hargis D 27,396/52:* Cortisone s.c. protects the rat against histamine intoxication even after sensitization by pertussis vaccine.

*Kind B 81,943/53:* In H. pertussis-inoculated mice, cortisone inhibits the lethal effect of both histamine and H. pertussis vaccine. Cortisone also protects uninoculated mice against lethal intoxication with this vaccine.

*Sackler et al. B 78,749/53:* In rats, thyro-parathyroidectomy increases histamine tolerance, but only in females. Intact rats show no sex difference in histamine tolerance. Gonadectomy raises histamine tolerance in both sexes.

*Chédid C 622/54:* Pertussis vaccine sensitizes the intact mouse both to histamine and to typhoid endotoxin. Under these conditions, both phenergan and cortisone protect the animals against fatal doses of histamine but not against endotoxin. In adrenalectomized mice, cortisone does protect against endotoxin.

*Gross C 30,649/55:* In rats, administration of histamine by aerosol, or of egg-white i.p. elicits an asthmatic attack if the lung was previously irritated by inhalation of acetic acid given by a spray. This response is obtained in females, castrate males or males treat-

ed with folliculoids, but not in normal males. Testosterone and progesterone abolish this effect in females and castrate males.

*Lecomte D12,212/61:* Both cortisol and DOC increase the resistance of the rat to the hypotensive effect of histamine i.v.

*Higginbotham D21,395/62:* In mice, resistance to 5-HT, endotoxin and anaphylactic shock is markedly decreased by adrenalectomy. Cortisol readily restored resistance to 5-HT, but was less effective with regard to endotoxin and anaphylactic shock. Resistance to histamine and histamine releasers is less markedly diminished by adrenalectomy in the mouse, and large doses of cortisol are required to induce a measurable increase in resistance to histamine.

*Lecomte & Sodoysz D20,641/62:* The hypotension and shock produced by endogenous histamine liberation following treatment with compound L-1935 in the rat is not significantly influenced by cortisol or DOC.

*Pekárek & Vrána D52,098/62:* In rats sensitized to histamine by pertussis vaccine, DOC decreases resistance to the combined treatment.

*Munoz E8,473/64:* Cortisone and cortisol protect the pertussis-sensitized mouse against histamine, cold and anaphylaxis even after adrenalectomy.

*Schapiro F31,856/65:* In newborn rats, fatal intoxication with histamine was not significantly influenced by ACTH, cortisol, cortisone or corticosterone.

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy, but in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

Histamine ← Ovariectomy: Sackler et al. B78,749/53\*

### 5-HT ←

In rats, metacorticoid hypertension does not influence the effect of 5-HT upon blood pressure.

The gastric ulcers produced by large doses of 5-HT in the rat are prevented by cortisol and aggravated by DOC.

The production of renal infarcts by 5-HT is partially prevented by hypophysectomy, DOC, or testosterone, uninfluenced by ACTH, and aggravated by cortisone. On the other hand, such renal necroses are also inhibited by the stress of restraint, both in intact and in adrenalectomized rats. Estradiol aggravates the 5-HT induced renal necroses, whereas estrone allegedly has no such sensitizing effect.

The 5-HT content of the brain decreases after cortisol treatment, presumably through the induction of hepatic TPO.

*Sturtevant C9,089/55; C21,591/56:* In rats with metacorticoid hypertension (produced by temporary overdose with DOC + NaCl) the pressor effect of epinephrine, norepine-

phrine, vasopressin and renin was increased, but the effect of histamine, 5-HT, yohimbine and TEA on the blood pressure was not consistently altered.

*Selye & Bois C23,958/57*: The gastric ulcers produced by large doses of 5-HT in the rat can be prevented by cortisol, and aggravated by DOC.

*Jasmin & Bois C92,099/60*: Hypophysectomy partially protects the rat against the production of renal infarcts by 5-HT. ACTH does not affect this change; cortisol aggravates it, whereas DOC and testosterone offer partial protection against it. Estradiol pretreatment sensitizes the rat for the production of ischemic renal infarcts by 5-HT.

*Higginbotham D21,395/62*: In mice, resistance to 5-HT, endotoxin, and anaphylactic shock is markedly decreased by adrenalectomy. Cortisol readily restored resistance to 5-HT, but was less effective with regard to endotoxin and anaphylactic shock. Resistance to histamine and histamine releasers is less

markedly diminished by adrenalectomy in the mouse, and large doses of cortisol are required to induce a measurable increase in resistance to histamine.

*Szarvas & Kovács E34,633/63*: In the rat, estrone aggravates the renal necroses produced by posterior pituitary extracts, but not those elicited by 5-HT.

*Selye et al. E24,146/64*: The renal necroses normally produced in rats by acute intoxication with 5-HT can be inhibited by forced restraint both in intact and in adrenalectomized rats. Cortisol has no such inhibitory effect.

*Green & Curzon H5,891/68*: In the rat, the 5-HT content of the brain decreases after treatment with cortisol, presumably through the induction of TPO in the liver.

5-HT(N-acetyl) ← Prednisolone:  
*Inscoe et al. F70,325/66*

### Various Tissue Extracts ←

A few publications deal with the effect of steroids upon the toxicity of crude tissue extracts. For example, estradiol increases, whereas progesterone and adrenocortical extract decrease the toxicity of menstrual discharge injected s.c. into rats.

In mice, adrenocortical extract diminishes the toxicity of the peritoneal exudate elicited by intestinal strangulation.

Submandibular gland grafts obtained from testosterone-treated donors are said to be highly toxic to mice, although testosterone is not toxic in the presence of submandibular glands. Apparently, the latter do not release the induced toxic factor.

In rabbits, aldosterone and cortisone increased, whereas spironolactone inhibited the angiotensin-induced glycosuria.

*Smith & Smith A32,972/40*: In rats, the toxicity of menstrual discharge s.c. is increased by estradiol and diminished by progesterone or adrenocortical extract pretreatment. Gonadectomy offers moderate protection in both sexes. DOC is ineffective.

*Laufman & Freed 88,861/43*: In mice, adrenocortical extract diminishes the toxicity of the peritoneal transudate of dogs with intestinal strangulation.

*Hori et al. G72,331/69*: In rabbits, aldosterone and cortisone increased the angiotensin-induced glycosuria, whereas spironolactone inhibited it.

*Lin & Hoshino H9,995/69*: "Submandibular grafts obtained from both immature male and adult female donors which received pretreatment with testosterone enanthate exerted a lethal effect on the hosts. Large dosages of testosterone enanthate, which obviously increased the lethal factor level in the submandibular gland, did not kill normal intact adult mice; nor did it increase the mortality of bilaterally submandibular-sialoadenectomized immature mice beyond that of controls without testosterone treatment, when they were not transplanted."

*DRUGS* ←

The effect of steroids upon numerous intoxications has been the subject of many investigations which could hardly be condensed more than has been done in the Abstract Section. Here, we shall comment only on a few particularly interesting data and on observations which can be clarified by correlating them with facts not mentioned in the original articles.

*Anaphylactoidogens* ←

The production of anaphylactoid edema by various mast cell dischargers, histamine, or 5-HT, is facilitated by mineralocorticoids and inhibited by glucocorticoids, as are other forms of acute inflammatory reactions.

The gastric ulcers and the anaphylactoid edema produced by such mast cell dischargers as 48/80 or polymyxin are likewise prevented by various glucocorticoids and by stressors, although both these steroids and stress, are capable of producing gastric ulcers in themselves. Curiously, DOC likewise prevents polymyxin-induced gastric erosions.

When, following pretreatment with polymyxin, the gastric mucosa is depleted of histamine, the ulcerogenic property of prednisolone overdose is unimpaired; hence, histamine liberation cannot be responsible for glucocorticoid-induced gastric ulceration.

Curiously, the cardiovascular and renal calcification produced by chronic treatment with polymyxin is increased by triamcinolone, DOC, or by combined treatment with both these steroids. Fluorocortisol, which possesses both gluco- and mineralocorticoid properties, also shares this effect.

*Anticoagulants* ←

The "hemorrhagic stress syndrome" can be produced by indirect anticoagulants (phenindione, dicoumarol, warfarin) subsequent pretreatment with various stressors, ACTH, STH or DOC. Conversely, cortisone, epinephrine, ephedrine and adreno-chrome inhibit this syndrome.

In man, some testoids (methandrostenolone, norethandrolone) increase the anticoagulant response after pretreatment with warfarin, phenindione, or bishydroxycoumarin. It has been assumed that certain steroids can increase the affinity of receptor sites for anticoagulants.

On the other hand, in rats, the fatal hemorrhagic diathesis produced by phenindione is inhibited by pretreatment with numerous catatoxic steroids such as PCN, ethylestrenol, CS-1, spironolactone, norbolethone and oxandrolone. Progesterone, hydroxydione, DOC, and estradiol have a much less pronounced effect. Prednisolone, triamcinolone, and thyroxine are inactive.

It has been shown at least for spironolactone, norbolethone, and ethylestrenol that these catatoxic steroids actually enhance the disappearance of bishydroxycoumarin

from the blood, and restore the prothrombin time. Triamcinolone and progesterone fail to do so.

SKF 525-A increases the blood concentration and the anticoagulant effect of bishydroxycoumarin, counteracting the beneficial effect of ethylestrenol.

### ***Barbiturates*** ←

Barbiturates are probably the most extensively used nonsteroidal catatoxic substances. Interest in them has been heightened by the fact that they also act as excellent substrates for both steroidal and nonsteroidal enzyme inducers. Furthermore, it is easy to determine changes in barbiturate activity in vivo, by measuring either the "sleeping time" (the interval between the loss and the reappearance of the righting reflex) or the depth of the anesthesia induced by threshold doses (expressed in an arbitrary scale, ranging from wobbly gait to surgical narcosis). Both types of measurement have their advantages and disadvantages. The sleeping time reflects the duration of anesthesia, but does not distinguish between mere abolition of the righting reflex and almost lethal narcosis, if the duration of action is the same. Conversely, measurement of the depth of anesthesia does not reflect its duration. Most of the published experimental work is based on measurements of sleeping time.

← **Glucocorticoids.** Soon after the introduction of cortisone into clinical medicine, it was noted that it often helped to combat abstinence symptoms following discontinuation of barbiturates or morphine in man.

The anesthetic effect of various barbiturates is shortened by cortisone, cortisol and other glucocorticoids, both in rats and in mice. Although, barbital is not metabolized in the body, its anesthetic effect in mice is likewise diminished by glucocorticoids. It has been claimed, however, that pretreatment with cortisol, two hours before pentobarbital intoxication increases the lethal effect of the latter in mice. The protection of mice against barbital anesthesia is ascribed to a glucocorticoid-induced decrease in the barbital concentration of the brain. In rabbits, barbital anesthesia and the barbital content of the blood are not significantly influenced by cortisone, although urinary barbital elimination is increased.

In patients recovering from barbiturate poisoning, sleep is often re-induced by cortisone or i.v. injection of glucose.

Pretreatment of rats with cortisone or prednisolone for three days diminishes the anesthetic effect of hexobarbital and increases its degradation by liver slices.

When given simultaneously, cortisol prolongs pentobarbital sleeping time, but if the hormone is given one day before the barbiturate, the anesthetic effect of the latter is shortened.

Pretreatment with cortisone also prolongs phenobarbital anesthesia in guinea pigs and hexobarbital anesthesia in mice, although it shortens thiopental anesthesia in rabbits.

In rats, ACTH and cortisone decrease hexobarbital sleeping time, as does exposure to stress, whereas SKF 525-A blocks the protective effect of stress. In dogs, DDT decreases hexobarbital sleeping time but prolongs pentobarbital anesthesia. The latter effect is prevented by cortisone.

Brain hyperexcitability induced in rats by cortisone is diminished by phenobarbital as judged by EST measurements.

On the basis of these findings, it would be difficult to formulate any meaningful generalizations concerning the action of glucocorticoids upon barbiturate anesthesia. The latter depends upon species, timing, and the type of barbiturate used, but in general, a shortening of the hypnotic effect may be expected as long as the glucocorticoid is administered before the barbiturate.

← **Glucocorticoids, Mineralocorticoids.** Comparatively few investigations deal with the effect of glucocorticoids or mineralocorticoids upon barbiturate anesthesia. Since several of these steroids are strong anesthetics themselves, combined treatment with barbiturates usually results in a summation of their effects. In our own experience, pretreatment with DOC did not significantly influence the duration of pentobarbital anesthesia in rats, unless the steroid was given just before the barbiturate so as to permit the summation of their actions.

← **Antimineralocorticoids.** In rats, pentobarbital sleeping time is shortened by pretreatment with aldosterone, aldosterone-kalium, spironolactone, CS-1 and several other antimineralocorticoids tested. These observations agree with the concept that antimineralocorticoids are in general powerful catatoxic steroids.

← **Testoids.** All strong anabolic testoids appear to shorten barbiturate anesthesia in general. However, barbital is not metabolized by hepatic microsomal enzymes and is consequently resistant to detoxication by microsomal enzyme-inducing steroids.

There appears to be a species difference in the effect of testoids upon barbiturate anesthesia, since in rats, testosterone shortens, whereas in mice it allegedly prolongs pentobarbital anesthesia. In any event, even physiologic doses of testoids appear to confer relative resistance to male rats, since castration increases their barbiturate sensitivity, and subsequent testosterone treatment restores it to normal.

← **Luteoids.** Many luteoids are strong anesthetics themselves; hence, their narcotic effect is added to that of the barbiturates if the two types of compounds are given in rapid succession. Pretreatment with luteoids may induce some degree of resistance against barbiturates, but the effect is not very pronounced.

Medroxyprogesterone given alone or in combination with ethynylestradiol and other folliculoids, over a period of 30 days, decreases the level of brain pentobarbital without affecting pentobarbital narcosis. Combined treatment with lynestrenol (a luteoid) and mestranol (a folliculoid) reduces the duration of pentobarbital and hexobarbital sleep in mice. Barbital is not affected. The effects of lynestrenol are abolished by SKF 525-A, whereas those of mestranol are potentiated.

← **Folliculoids.** Estradiol does not markedly influence hexobarbital sleeping time in female rats, but increases it in males. The enhanced hexobarbital resistance of male as compared to female rats is abolished by estradiol. There are marked species variations, and not all folliculoids act upon all barbiturates in the same manner; yet it may be said that in general, both the natural and the artificial folliculoids increase sensitivity to barbiturate hypnosis.

← **Adrenalectomy.** Adrenalectomy tends to increase barbiturate sleeping time in itself, but does not significantly interfere with the effects of various steroids upon barbiturate hypnosis.

In guinea pigs, epinephrine injected i.p. on awakening from barbiturate anesthesia re-induces sleep, and this effect is not prevented by adrenalectomy. Glucose lactate

and glutamate exert similar effects in intact but not in adrenalectomized guinea pigs.

The lengthening of barbiturate sleeping time in adrenalectomized rats can be abolished by cortisone, but not by DOC. Pretreatment of adrenalectomized mice with cortisone or cortisol reduces the high rate of barbital uptake by the brain to normal, whereas DOC has no such effect.

Adrenalectomy inhibits the degradation of hexobarbital by liver slices of male rats; this effect can be counteracted by pretreatment with cortisone.

Chlorpromazine pretreatment reduces barbiturate sleeping time even in adrenalectomized rats.

In adrenalectomized rats maintained on NaCl, pretreatment with spironolactone still induces resistance to pentobarbital and hexobarbital, but not to phenobarbital. This is so even if the anesthetics are given in doses normally causing approximately equal anesthesia.

← **Gonadectomy.** It has been known since 1933, that male rats are less sensitive to barbiturate anesthesia than females, and that castration increases sensitivity of the male but not of the female. Testosterone raises the pentobarbital resistance of intact or ovariectomized females and castrate males, but has little effect upon the barbiturate sensitivity of intact males. Upon injections of pentobarbital, repeated every 90 min, adult male rats rapidly developed resistance, whereas females did not. Castration lowered the ability of adult males to develop tolerance. In females, ovariectomy may actually increase the ability to detoxify pentobarbital once tolerance has developed.

Barbital anesthesia does not appear to be considerably affected by orchidectomy in rats, presumably because unlike other barbiturates, barbital is not metabolized in the body.

Thyroidectomy, which in itself prolongs pentobarbital anesthesia, increases even further the barbiturate sensitivity of simultaneously orchidectomized rats.

The increased hexobarbital sleeping time of females and castrate males, as compared to intact males, is associated with a delay in barbiturate metabolism as reflected by the prolonged persistence of the drug in the blood, and by the decreased rate of detoxication *in vitro*, by liver slices or microsomal fractions.

The hexobarbital sleeping time, which is prolonged by orchidectomy in the rat, is shortened by testosterone, whereas cyproterone (an antitestoid) fails to inhibit the anti-anesthetic effect of testosterone; indeed, it actually shares this property.

The effect of gonadectomy and sex hormone treatment depends largely upon the species under investigation. Thus, in guinea pigs, orchidectomy and ovariectomy prolong pentobarbital sleeping time while testosterone diminishes it, in agreement with the results obtained in the rat.

On the other hand, in the mouse, hexobarbital anesthesia lasts longer in males than in females and orchidectomy decreases sleeping time, whereas ovariectomy does not affect it. Testosterone prolongs hexobarbital sleeping time in orchidectomized, intact male as well as in ovariectomized mice, and in the same species, this effect is blocked by cyproterone. *In vitro* experiments with the 9000g liver supernatant of female mice reveals a greater hexobarbital hydroxylating activity than a similar hepatic preparation made from male mice. After orchidectomy, the *in vitro* metabolism of hexobarbital becomes equal to that of female mice.

← **Varia.** In rats, pretreatment with hydroxydione does not significantly influence pentobarbital sleeping time. In mice, phenobarbital given one hour before hydroxydione increases sleeping time, but when the interval is two days, single doses of phenobarbital decrease hydroxydione anesthesia.

In rats, pentobarbital sleeping time is significantly decreased by DOC, 4-chlorotestosterone, aldosterone, and stilbestrol, when given 30 min before the barbiturate. Progesterone has an inverse effect, perhaps because of its own acute anesthetic action. On the other hand, chronic pretreatment with progesterone, stilbestrol or aldosterone decreased pentobarbital sleeping time without causing any significant change in the brain pentobarbital concentration.

Typical catatoxic steroids, such as ethylestrenol, spironolactone, and norbolethone diminish the depth of hexobarbital anesthesia in rats, and increase the aliphatic hydroxylation of this barbiturate by hepatic microsomes, thereby enhancing its elimination from the blood. The effect of these catatoxic steroids upon pentobarbital anesthesia is essentially the same. On the other hand, progesterone, SC-8109, and SC-5233 failed to affect pentobarbital sleeping time in the rat.

In mice, an aza-steroid (17 $\alpha$ -methyl-17 $\beta$ -hydroxy-4-aza-estran-3-one) shortened the duration of hexobarbital anesthesia. Also in the mouse, pentobarbital anesthesia is shortened by ethylestrenol, CS-1, spironolactone, and norbolethone, but not by oxandrolone, prednisolone, progesterone, triamcinolone, DOC, hydroxydione, estradiol, or thyroxine.

### ***Bilirubin*** ←

In mice,  $\alpha$ -naphthylisothiocyanate-induced hyperbilirubinemia and cholestasis are aggravated by norethandrolone and norethynodrel, but not by mestranol. This response is largely dependent upon the ambient temperature.

### ***Carbon Tetrachloride*** ←

The literature on the effect of various steroids upon CCl<sub>4</sub> poisoning is extensive but very contradictory. Most investigators agree, however, that under suitable conditions of timing and dosage, various glucocorticoids and testoids can protect the rat and several other species against the hepatotoxic action of CCl<sub>4</sub>, whereas DOC and various folliculoids appear to have an inverse effect.

Ovariectomy protects the liver against CCl<sub>4</sub> intoxication, perhaps because it removes the source of endogenous folliculoids whose hepatic degradation might compete with the defense against CCl<sub>4</sub>. Particularly good protection is obtained if ovariectomy is combined with thyroidectomy. Even adrenalectomy and hypophysectomy inhibit the CCl<sub>4</sub>-induced hepatic steatosis in the rat; here substitution therapy with corticoids allegedly restores normal responsiveness. Enovid (mestranol + norethynodrel) aggravates the liver damage caused by CCl<sub>4</sub> in rats.

The apparent contradictions in the findings of various investigators may well be due in part to differences in the actions of steroids, depending upon the criteria used (hepatic steatosis, necroses, regeneration, sclerosis), as well as the dosage and timing of the steroids and of CCl<sub>4</sub>.

***Carcinogens*** ←

In rats given 2-acetaminofluorine (AAF), the development of hepatic neoplasms is accelerated by estradiol, testosterone, and gonadotrophic preparations. On the other hand, testosterone delays the induction of subcutaneous tumors by 20-methylcholanthrene. Painting of the skin with this carcinogen produces papillomas earlier in male or female castrate mice than in intact controls.

In rats, the induction of mammary cancers by DMBA is allegedly inhibited by progesterone, DOC or metyrapone. The adrenal necrosis produced by DMBA in the rat has been claimed to be independent of sex, ovariectomy, orchidectomy, testosterone or estradiol. However, more recent investigations suggest that the adrenolytic effect of DMBA is greatly enhanced by estradiol pretreatment. Spironolactone definitely inhibits the adrenolytic action of DMBA and probably also diminishes its carcinogenic effect. The question arises whether spironolactone protects against this action of DMBA by preventing its activation through hydroxylation; however, spironolactone protects the adrenals also against 7-OHM-MBA, the activated DMBA metabolite. The hematologic damage produced by DMBA can be suppressed both by spironolactone, which presumably accelerates the biotransformation of this polycyclic hydrocarbon, and by SKF 525-A, which inhibits it.

Ovariectomy greatly decreases the incidence of mammary tumors produced by DMBA in the rat, and results in the induction of renal tumors which are not seen in similarly treated intact controls. The rate of induction by DMBA of cervico-vaginal sarcomas is reduced by ovariectomy in the rat, and this reduction is counteracted by various folliculoids. Progesterone slightly retards the induction of these sarcomas and testosterone lengthens the induction period.

In rats, neonatal estradiol treatment enhances hepatoma formation following treatment with N-hydroxy-N-2-fluorenylacetamide.

In rats, hepatic carcinogenesis produced by aflatoxin is inhibited by diethylstilbestrol; females are more resistant to this carcinogen than are males.

***Chlordiazepoxide*** ←

In rats, PCN, CS-1, ethylestrenol and, to a lesser extent, spironolactone and norbolethone decrease the sleeping time after administration of chlordiazepoxide (Diazepam).

***Chloroform*** ←

Extensive renal tubular necrosis occurs following exposure to chloroform in intact male or testosterone-treated orchidectomized mice, but not in females or in otherwise untreated orchidectomized males. As little as 10 µg of testosterone propionate suffices to reinduce chloroform sensitivity in castrate male mice with such regularity that the technique has been recommended for the bioassay of testoids.

### ***Cholesterol*** ←

The potential enhancement of cholesterol degradation by catatoxic steroids is of great clinical significance in connection with the possible prophylaxis or treatment of atherosclerosis. For a detailed discussion of the literature concerning the morphologic changes characteristic of cholesterol atherosclerosis and of their modification by steroids, the reader is referred to the corresponding sections of our earlier monographs on metabolic cardiovascular diseases. Among the steroids examined in this connection, the corticoids and folliculoids have received the greatest attention.

In rabbits, cholesterol atheromatosis is diminished by cortisone, cortisol and other **glucocorticoids**. The associated hyperlipemia and hypercholesterolemia may likewise be depressed under these conditions, but this is not always the case; indeed, an inhibition of atherosclerosis by glucocorticoids may occur even if the serum lipids and cholesterol actually rise during treatment. The regression of the established cholesterol atherosclerosis itself can also be accelerated by glucocorticoids. It is characteristic of the cholesterol atherosclerosis in rabbits that various lysosomal enzymes ( $\beta$ -glucuronidase, acid phosphatase, cathepsin and aryl sulfatase) show an increased activity; this change is likewise inhibited during the prevention of cholesterol atherosclerosis by cortisone.

**Folliculoids** counteract coronary atherosclerosis in cholesterol-fed chicks without affecting blood cholesterol or hypercholesterolemia. This effect is demonstrable even if the feminizing actions of the folliculoids are blocked by concurrent administration of testosterone.

**DOC** or **progesterone** do not prevent cholesterol atherosclerosis in rabbits; in fact DOC may actually aggravate it.

### ***Choline*** ←

The syndrome of choline-deficiency is most readily obtained in young rapidly growing male rats. It is characterized by hepatic steatosis, cardiovascular lesions and renal hemorrhages often associated with nephrocalcinosis. The severity of the changes is aggravated by methionine deficiency or an excess of ethionine. Glucocorticoids and folliculoids protect the rat against the manifestations of choline deficiency, whereas testoids aggravate these changes. Orchidectomy abolishes the normally greater resistance of males as compared with females.

### ***Cinchophen*** ←

Cinchophen (Atophane) notoriously produces peptic ulcers in the dog. This effect can be prevented by estradiol and stilbestrol, both in intact and in gonadectomized dogs of either sex. Cortisone fails to affect the cinchophen-induced gastric ulcers in dogs, whereas prednisolone actually aggravates them. On the other hand, it has been claimed that aldosterone and DOC partially inhibit the production of gastric and duodenal ulcers as well as of liver damage in the cinchophen-treated dog.

***Colchicine*** ←

Colchicine is of special interest because of its uricosuric action and its ability to inhibit mitotic division in various cells. In rats, colchicine poisoning can be prevented by various catatoxic steroids (e.g., spironolactone, CS-1, ethylestrenol, PCN and less constantly by oxandrolone). Progesterone, norbolethone, prednisolone, triamcinolone, DOC, hydroxydione, estradiol and thyroxine are virtually ineffective in this respect.

***Cycloheximide*** ←

Since cycloheximide is a potent blocking agent for hepatic protein and particularly enzyme synthesis, it is of interest that in rats, its toxicity is powerfully inhibited by PCN, ethylestrenol, CS-1 and spironolactone. Norbolethone, oxandrolone, progesterone, hydroxydione, and prednisolone offer less perfect protection. Triamcinolone, DOC, estradiol and thyroxine have no protective effect.

The loss of liver glycogen and adrenal ascorbic acid as well as the stress-induced adrenal hypertrophy and allegedly even the thymic atrophy that develop in cycloheximide intoxicated rats can all be prevented by concurrent administration of cortisol.

***Cyclophosphamide*** ←

Cyclophosphamide is a latent alkylating agent which is almost inactive in vitro, but is activated by the liver in vivo, and then exhibits carcinolytic actions as well as a strong toxic effect upon the hemopoietic system. In rats, cyclophosphamide intoxication can be prevented by PCN, CS-1 and spironolactone. Progesterone, ethylestrenol and norbolethone are distinctly less active, whereas oxandrolone, DOC, hydroxydione and phenobarbital are inactive. Resistance to this drug is actually decreased by prednisolone, triamcinolone, estradiol and thyroxine.

***Digitalis*** ←

Since digitalis alkaloids are steroids themselves, a great deal of work has been done to elucidate their possible metabolic interactions with steroid hormones.

It appears that female mice are more resistant to ouabain than males, whereas resistance to strophanthin-K is the same in both sexes. Ovariectomy, orchidectomy and treatment with folliculoids do not change ouabain resistance in mice consistently.

In frogs, lethal strophanthin intoxication is allegedly delayed by simultaneous treatment with DOC, but this may be merely due to a delay in absorption.

In cats, cortisone has been claimed to potentiate the convulsive effects of digitalis.

In guinea pigs, chronic digitoxin intoxication is moderately counteracted by cortisone, whereas acute digitoxin poisoning is not affected.

In dogs, various folliculoids protect against the production of arrhythmia by digoxin. It has been claimed furthermore that male and castrate female dogs are

highly sensitive to the toxic manifestations of various cardiac glycosides, in comparison with intact females or with folliculoid-treated spayed females.

In rats, ouabain and digitoxin resistance is greatly diminished by adrenalectomy, but this is hardly surprising, since in the absence of the adrenals, the toxicity of most drugs is increased. In adrenalectomized rats, strophanthin-K increases Na and K excretion, and this effect is prevented by DOC. In isolated strips of rat aorta, corticosterone inhibits the contraction caused by ouabain.  $\beta$ -Methasone aggravates the neuromotor disturbances produced in the rat by strophanthin-G. Adult female rats are more resistant to ouabain than males, but no such sex difference is noted in one-month-old animals. Gonadectomy does not alter the sex difference to ouabain in rats of either sex.

All these results, obtained in different species with various digitalis derivatives and under dissimilar experimental conditions, were difficult to evaluate and correlate. However, in 1969, it was found that spironolactone protects the rat against infarctoid necroses produced by digitoxin +  $\text{Na}_2\text{HPO}_4$  + corn oil; simultaneously, the convulsions characteristic of digitalis intoxication are likewise prevented. This finding stimulated many investigations on the effect of various catatoxic steroids upon digitalis intoxication.

Preliminary studies showed that both norbolethone and spironolactone protect the rat against severe intoxication with digitoxin, gitalin, proscillaridin, digoxin and digitalin. The corresponding effects of strophanthin-K, ouabain and digitoxigenin were not prevented.

In an extensive study, comprising 304 steroids, it was found that, at the dose of 100 mg/kg, 32 of them gave definite protection against digitoxin but not against indomethacin, 42 protected against indomethacin but not against digitoxin, whereas 24 were active against both substrates. The most active compound, which gave protection against both substrates even at the dose of 100  $\mu\text{g}/\text{kg}$ , was PCN (pregnenolone carbonitrile, that is 3 $\beta$ -hydroxy-20-oxo-5-pregnene-16 $\alpha$ -carbonitrile). Further analysis of this study revealed that the catatoxic activity against digitoxin or indomethacin is not strictly dependent upon any other known pharmacologic effect, although most of the highly potent catatoxic compounds also exhibit anti-mineralocorticoid or anabolic properties. Among the most powerful antidigitoxin compounds, in addition to PCN, are: ethylestrenol, CS-1, spironolactone and oxandrolone.

Upon long continued conjoint daily administration of spironolactone or oxandrolone plus lethal doses of digitoxin, the resistance against this cardiac glycoside can be maintained in rats for virtually indefinite periods (certainly more than two months).

On the other hand, the antidigitoxin effect of spironolactone can be blocked in turn by high doses of estradiol, and perhaps to some extent also by progesterone, whereas DOC, cortisol, methylandrostenediol, methyltestosterone, pregnanedione, pregnenolone and testosterone do not interfere with this type of prevention. The protection against digitoxin by spironolactone can also be blocked by concurrent treatment with metyrapone.

The plasma concentration of digitoxin is diminished during the administration of catatoxic steroids, but rises again if digitoxin administration is continued after withdrawal of the prophylactic steroids.

In mice, digitoxin poisoning is inhibited by CS-1, spironolactone, norbolethone, oxandrolone, progesterone and even by thyroxine. Ethylestrenol, triamcinolone, DOC, hydroxydione and estradiol are ineffective. It appears, therefore, that there exist some species differences in the effect of hormones and hormone derivatives upon digitalis intoxication.

### **Dyes ←**

The effect of steroids upon dye clearance was studied mainly as a means of detecting interference with hepatic function.

In rats, the biliary excretion of  $^{131}\text{I}$  marked rose bengal was inhibited by several anabolic steroids, although upon chronic treatment, adaptation usually developed in this respect. Estradiol markedly delayed plasma clearance of BSP both in its free and conjugated forms. A large series of steroids was compared and this effect was found to be common to estrone, estriol and various other C18 steroids, including those used in contraceptives. Cortisone transiently increased the bile flow and reduced BSP excretion through the bile of the rat. Norethandrolone, norethynodrel, and norlutin reduced bile flow and BSP excretion (without affecting the concentrating mechanism for the dye). Testosterone, methyltestosterone, estradiol, progesterone, and stilbestrol irreversibly reduced the rate of bile formation and transiently diminished the excretion of BSP. Among typical catatoxic steroids, PCN, CS-1, spironolactone and spiroxasone enhanced plasma clearance of BSP, presumably by stimulating glutathione, S-aryltransferase activity and bile flow through mechanisms which are not limited to microsomal enzymes.

In dogs, large doses of methyltestosterone and norethandrolone did not affect BSP clearance even after 50 days of treatment.

In rabbits, methyltestosterone and norethandrolone caused dose related increases in BSP retention. Oxandrolone was less active, and testosterone completely inactive in this respect.

In man, 17-ethyl-19-nortestosterone increased biliary BSP retention and plasma bilirubin concentration. In patients with no evidence of liver disease, norethandrolone caused a reversible reduction in the hepatic transport maximum for BSP. The relative hepatic storage of BSP was unimpaired, and the dye was retained in the plasma primarily as a conjugate. According to other investigators, however, norethandrolone interferes with the hepatic uptake and the biliary excretion of BSP. Estriol and estradiol rapidly reduce the hepatic excretory capacity for BSP in man, presumably because the excretion of both free and conjugated dye is impaired. These folliculoids may even provoke hepatic porphyria in patients.

### **Ergot ←**

In rats, various ergot preparations elicit a characteristic gangrene of the tail, owing to their vasotoxic effect. Although the literature is somewhat contradictory, most investigators agree that this response is inhibited by estradiol, estrone and other folliculoids. The effect of castration and of testoids is rather irregular. In intact

male rats, unlike in females or castrate males, ergonovine induces analgesia and this is allegedly counteracted by testosterone.

### *Ethanol* ←

Despite the great practical interest attached to the problem of ethanol intoxication, little is known about its responsiveness to treatment with steroids.

In rats, ovariectomy allegedly interferes with adaptation to chronic ethanol administration. The toxic ethanol metabolites are pyruvate and acetaldehyde, which accumulate in the body under the influence of disulfiram. This response is inhibited by cortisone and ACTH but also by hepatic extracts. Conversely, DOC, thyroxine and testosterone appear to aggravate ethanol intoxication. Chronic treatment with ethanol p.o. allegedly produces more severe fatty infiltration in the liver of female than of male rats. Ovariectomy or estradiol fails to influence this response. Testosterone reduces hepatic steatosis in females, whereas castration increases it in males. Various anabolics (norethandrolone, testosterone, oxandrolone) allegedly protect the rat's liver against ethanol-induced fatty degeneration and may even be useful in alcoholic patients.

In rabbits and mice, gonadectomy allegedly diminishes alcohol tolerance, whereas estrone raises it. Alcohol metabolism does not appear to be influenced, but presumably its effect upon the nervous system is diminished by folliculoids, since in rabbits treated with such hormones, intoxication occurs only at very high blood alcohol levels. Fatal doses of ethanol p.o. produce adrenal necrosis in rabbits, but neither this lesion nor mortality is prevented by dexamethasone.

In mice, ethanol anesthesia is prolonged by cortisone, but not by either prednisolone or DOC pretreatment. Estrone allegedly increases alcohol tolerance in the mouse, whereas gonadectomy diminishes it in both sexes.

### *Ethionine* ←

Since it blocks protein and drug-metabolizing enzyme synthesis, ethionine is of special interest in connection with the study of catatoxic compounds. Yet, comparatively little is known about the influence of steroids, other than glucocorticoids and anabolics, upon the toxicity of ethionine.

In the rat, the hepatic damage caused by ethionine is inhibited by cortisone and cortisol especially during the acute stage of intoxication; consequently, survival is usually prolonged, although the associated pancreatic lesions characteristic of ethionine intoxication appear to be rather resistant to glucocorticoid treatment.

Male rats are much more resistant than females to the production of fatty livers by ethionine. Orchidectomy abolishes the resistance of the male, whereas testosterone protects females and castrate males. MAD fails to influence this form of hepatic steatosis in rats of either sex. 17-Ethyl-19-nortestosterone, in doses which do not stimulate the growth of the seminal vesicles, blocks the production of fatty livers by ethionine in orchidectomized males, whereas testosterone exerts this effect only at definitely virilizing dose levels. DOC, estradiol, and progesterone

are ineffective. In mice, *17 $\alpha$ -methyl-5 $\alpha$ -androstan-17 $\beta$ -ol* prevents hepatic steatosis produced by ethionine.

### ***Ganglioplegics*** ←

In rats, intoxication with TEA, hexamethonium and pentolinium can be prevented by all the glucocorticoids tested. On the other hand, these same steroids offer no protection against trimethaphan, mecamlamine, trimethidinium or pempidine. All the other steroids tested remained without effect against hexamethonium or TEA.

Several, though not all stressors gave excellent protection against TEA, but since even large doses of ACTH were ineffective in this respect, the anti-TEA effect of stressors cannot be ascribed merely to an increased glucocorticoid secretion.

In guinea pigs, ovariectomy allegedly increases resistance to lethal doses of hexamethonium, but it remains to be seen whether this effect is specific.

### ***Indomethacin*** ←

The production of multiple ulcers in the small intestine, with the ensuing fatal peritonitis, has become a standard test of indomethacin toxicity in the rat. These lesions are readily prevented by all of the highly potent catatoxic steroids, particularly by PCN (even at individual dose levels of 0.3 mg/kg), ethylestrenol, norbolethone, CS-1, spironolactone, oxandrolone, etc. Progesterone and prednisolone are less active, while certain glucocorticoids, e.g., triamcinolone, are totally inactive.

In an extensive study on 304 steroids, conducted under rigorously comparable conditions in female rats, it was found that 42 were effective in preventing indomethacin intoxication.

In the rat, partial hepatectomy facilitates the production of perforating intestinal ulcers by indomethacin but comparatively small doses of spironolactone readily inhibit the toxicity of this compound even after surgically induced hepatic insufficiency.

In adrenalectomized rats maintained on NaCl alone, the lethal effect of indomethacin is increased, and intestinal ulcers develop at least as frequently as in intact controls. The anti-indomethacin effect of threshold doses of spironolactone can be further increased by cortisol alone or in combination with DOC. This point is of theoretic importance; it shows that although a catatoxic steroid, such as spironolactone, is not endowed with corticoid activity, and although cortisol does not possess any significant catatoxic effect against indomethacin, combined treatment with both types of hormones enhances their protective effect.

In rats, the protection against indomethacin by spironolactone can be blocked in turn by concurrent treatment with metyrapone.

The blood clearance of s.c. injected indomethacin is accelerated in rats by spironolactone, norbolethone and progesterone, but not by hydroxydione. SKF 525-A significantly suppresses this activity of the catatoxic steroids. Hence, it was concluded that they probably act through an increased metabolic degradation of indomethacin.

Prolonged treatment with such catatoxic steroids as spironolactone or oxandrolone can protect rats for a virtually unlimited period (certainly more than two months) against the continued daily administration of fatal doses of indomethacin. Upon withdrawal of the catatoxic steroids, fatal intestinal ulcers develop rapidly. The plasma concentration of indomethacin is diminished during the administration of catatoxic steroids, but rises rapidly upon withdrawal of this treatment in the presence of continued indomethacin injection.

In mice, indomethacin intoxication can also be prevented by numerous catatoxic steroids (e.g., ethylestrenol, CS-1, spironolactone, norbolethone), whereas thyroxine appears to have an opposite effect.

### *Isoproterenol* ←

Both in intact and in adrenalectomized rats, mineralocorticoids (DOC, fluorocortisol) increase the mortality and aggravate the cardiac lesions normally produced by isoproterenol. On the other hand, glucocorticoids (cortisone, triamcinolone) have been said not to exert any evident effect of this kind. Since we have previously found that both DOC and triamcinolone aggravate the severity of the cardiac lesions induced by norepinephrine, it was concluded that there might be "an essential difference in the lesions produced by noradrenaline compared to those of isoproterenol." Moderate amounts of ACTH allegedly also fail to affect the production of cardiac necroses by isoproterenol, but it remains to be seen whether very large doses of glucocorticoids or ACTH might not be effective in this respect.

Various antimineralocorticoids (SC-5233, CS-1, spironolactone and SC-8109) have been claimed to inhibit isoproterenol-induced myocardial necrosis in rats. However, in view of recent findings, the possibility must be considered that all these compounds might act, at least in part, by virtue of their catatoxic and not only of their antimineralocorticoid potency.

### *Lathyrogens* ←

We distinguish two types of lathyrogenic substances: 1. Osteolathyrogens (e.g., *Lathyrus odoratus* seeds, aminopropionitrile or "APN," aminoacetonitrile or "AAN," methyleneaminoacetonitrile or "MAAN") induce severe degenerative changes in bones, especially at tendon insertion sites and in the junction cartilages; 2. neurolathyrogens (e.g.,  $\beta,\beta'$ -iminodipropionitrile or "IDPN") which elicit a syndrome characterized mainly by extreme excitation, circling movements and ocular lesions. Under certain circumstances, osteolathyrisms is associated with dissecting aneurysms of the aorta; some authors refer to this form of the disease as angio-lathyrisms.

Most of the work on the effect of steroids upon lathyrisms has been performed in rats fed *Lathyrus* seeds or pure lathyrogenic amines. Under these conditions, the course of osteolathyrisms is not significantly affected by testosterone, whereas folliculoids and glucocorticoids exert a definite protective effect. DOC—especially when combined with uninephrectomy + NaCl—increases the incidence of dissecting

aneurysms without considerably affecting the skeletal changes. Thus, the vascular and osseous manifestations of lathyrisms can be dissociated.

STH aggravates osteolathyrisms in rats even after adrenalectomy, indicating that the effect of the hormone is not mediated through the liberation or activation of corticoids.

It has been claimed that after adrenalectomy, cortisone no longer inhibits lathyrisms produced by AAN in the rat; indeed, in the absence of the adrenals, the glucocorticoids facilitate the production of hernias, which are common complications of the disease. The osteolathyrisms produced by APN in rats is associated with an increase in the GPT and GOT activities in the serum. Prednisolone prevents these changes concurrently with the bone lesions.

### ***LSD*** ←

In the rabbit, the EEG (lysergide) changes produced by LSD are allegedly prevented by hydroxydione, methylandrostanolone, androstanolone and 19-nortestosterone. In rats, the behavioural changes induced by LSD can be suppressed by DOC, corticosterone, 17-dehydrocortisone, 11-dehydrocortisol, dehydroisoandrosterone, testosterone, androsterone, pregnenolone, etiocholanolone and progesterone. Several other naturally-occurring steroids proved to be ineffective. The time required by a rat to climb a rope for food reward is prolonged by LSD and this response is also prevented by a number of steroids widely differing in their pharmacologic activities and chemical structure.

### ***Magnesium*** ←

It has been claimed that in rabbits and mice, the depth of  $MgSO_4$  anesthesia is increased by gonadectomy in either sex, but can be restored to about normal by both folliculoid and testoid hormones. However, this claim requires confirmation.

Certain manifestations of an Mg-deficiency syndrome are also inhibited by cortisol, estradiol, hypophysectomy or thyroparathyroidectomy; hence, the specificity of this type of prophylaxis is very dubious.

### ***Mephenesin*** ←

Mephenesin (a muscle relaxant) proved to be a substrate for many catatonic drugs, especially: PCN, ethylestrenol, CS-1, spironolactone and norbolethone.

### ***Meprobamate*** ←

Various catatonic drugs accelerate the metabolism of meprobamate, and this effect is not prevented by adrenalectomy. Meprobamate intoxication is also inhibited in rats by PCN, ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone and prednisolone. No protection is obtained by progesterone, triamcinolone, hydroxydione, DOC, or estradiol.

**Mercury** ←

A large number of investigations is concerned with the effect of various steroids upon mercury intoxication. Special interest in this field stems from an observation made in 1940, that the renal and hepatic lesions produced by  $\text{HgCl}_2$  in the mouse are prevented by many **testoids** (e.g., testosterone, methyltestosterone, androstenediol, dehydroisoandrosterone and androstenedione). This observation has been repeatedly confirmed with various testoids in different species intoxicated with diverse inorganic salts of mercury, but apparently the protective effect is most readily obtained in the mouse and much more variable in the rat. Such protection against renal damage by  $\text{HgCl}_2$  has also been noted in dogs, guinea pigs, parrots and man. In rabbits, both sublimate and Masugi nephritis are allegedly prevented by testosterone and even more actively by estradiol. It has been claimed furthermore that the protective effect of testosterone against mercurial renal damage can be further improved by additional administration of cortisone or ACTH.

It is clear, however, that none of the testoids offers absolute protection against large doses of mercury and the great variability of the findings reported suggests that incidental circumstances (e.g., sex, age, strain, dosage, timing) are likely to alter the results considerably. A distinction should be made furthermore between prophylactic and curative actions. In mice and rats, the regeneration of the kidney following  $\text{HgCl}_2$ -induced damage is stimulated by 2-bromo-1-androstene-3,17-dione but not by methyltestosterone or 1,17-dimethylandrosterane-17-ol-3-one.

There is some evidence suggesting that, in the rat, other steroid hormones, especially the **glucocorticoids**, may also offer slight protection against intoxication with inorganic mercury, but in this respect, the results reported are even more variable.

The only steroids which offer constant, significant, and always very pronounced protection against  $\text{HgCl}_2$  in the rat are those containing a thioacetyl group, especially **spironolactone**, **spiroxasone** and **emdabol**. Na-thioacetate given alone, or mixed with various steroids, also exerts some protective effect, but only at dose levels which cause considerable acute mortality often in association with bilateral adrenocortical necrosis. Apparently, the steroid molecule acts as a suitable carrier for the thioacetyl group and enhances its protective action against mercury.

**Methyprylon** ←

In rats, anesthesia produced by heavy overdosage with methyprylon can be prevented not only by pretreatment with PCN, ethylestrenol, CS-1, spironolactone, norbolethone, or oxandrolone, all of which are typical catatoxic steroids, but also by prednisolone and triamcinolone, presumably as a consequence of their glucocorticoid effect. DOC, progesterone and hydroxydione, which are devoid of both catatoxic and glucocorticoid activities, offer little or no protection against methyprylon.

**Monocrotaline** ←

Female rats are more resistant than males to fatal intoxication with monocrotaline. Gonadectomy has no significant effect upon survival in either sex; however,

when given as a pretreatment, estradiol increases, whereas testosterone decreases monocrotaline resistance.

### ***Morphine, Ethylmorphine* ←**

It has been claimed that various steroids can influence morphine resistance in different species, but the results are so contradictory that no valid generalization can be made. In our experience, none of the steroids tested — not even the most potent catatoxic steroids — exert a striking effect upon morphine intoxication in the rat.

On the other hand, ethylmorphine (which is much more fat soluble than morphine) is readily detoxified not only by all catatoxic steroids tested, but also by prednisolone, progesterone, estradiol and, to some extent, even by DOC.

### ***Nicotine* ←**

Earlier investigators asserted that in mice and rabbits, the males, whereas in rats, the females are more sensitive to nicotine. It has also been stated that the cardiovascular lesions produced by chronic nicotine intoxication in rats are aggravated by DOC. These data require confirmation.

More recent studies have shown that in rats, nicotine intoxication can be prevented by PCN, ethylestrenol, norbolethone, CS-1, spironolactone, and oxandrolone, whereas DOC, hydroxydione, prednisolone, progesterone, and triamcinolone offer little or no prophylaxis.

### ***Papain* ←**

In the rabbit, papain i.v. causes softening and degenerative changes in the otic and epiphyseal cartilages. At the same time, the basophilic substance in the cartilage matrix is depleted. The return of these papain-induced cartilage changes to normal can be delayed by cortisone, cortisol and prednisolone.

### ***Pentylentetrazol* ←**

Pentylentetrazol (pentamethylenetetrazol, metrazole, Cardiazole) convulsions have been used by many investigators as an indicator of catatoxic steroid effects, ever since 1942, when it was observed that various steroid anesthetics (DOC, progesterone) can protect the rat against pentylentetrazol. Conversely, this drug can interrupt an already established steroid anesthesia.

In rats, the pentylentetrazol convulsions and ECG changes are inhibited by ACTH and cortisone according to some investigators; others state that single, nonanesthetic doses of cortisol enhance the production of pentylentetrazol convulsions in the rat, whereas aldosterone has no such effect. The interpretation of these findings is rendered even more difficult because yet other investigators maintain that, although cortisone and prednisolone aggravate pentylentetrazol convulsions in

rats, prednisone and hexamethasone are less active, while cortisol, triamcinolone and DOC are virtually inactive in this respect.

According to our own investigations in rats, both the motor disturbances and the mortality caused by pentylenetetrazol intoxication were markedly inhibited by PCN, norbolethone and progesterone, whereas the other standard conditioners, including glucocorticoids and DOC, were ineffective.

Various aminosteroids also prevent pentylenetetrazol convulsions, allegedly owing to interneuronal blockade and not to general anesthesia.

In guinea pigs, pretreatment with large doses of DOC allegedly fails to influence pentylenetetrazol convulsions, whereas cortisone, ACTH and vasopressin aggravate them.

In mice, different investigators obtained contradictory results regarding the effect of steroids upon pentylenetetrazol convulsions. It has been claimed that cortisone and DOC do not influence them, and that the latter decreases the pentylenetetrazol (as well as the electroshock) seizure threshold owing to the induction of hypernatremia. Both DOC and progesterone anesthesia protect the mouse against the convulsive and lethal effects of pentylenetetrazol (or other convulsive agents), whereas estrone has an opposite effect.

$3\beta$ -(Aminoalkyl) esters of pregnenolone and various other steroids also inhibit pentylenetetrazol and electroshock seizures in mice. Methyltestosterone is said not to influence pentylenetetrazol convulsions in this species, whereas other anabolic steroids (methandienone, 4-chlorotestosterone, nandrolone, given i.p. 90 min before pentylenetetrazol) inhibit them.

It would be difficult to evaluate many of the contradictory data just mentioned, because they were obtained under vastly different circumstances in diverse species, but it is safe to assume that certain catatonic or anesthetic steroids reliably antagonize pentylenetetrazol convulsions under suitable experimental conditions.

### ***Perchlorates*** ←

Overdosage with perchlorates exerts a singular effect upon the voluntary musculature. For example, in the rat,  $\text{NaClO}_4$  p.o. causes spastic muscular contractions and a pronounced predisposition to the development of extensor cramps in the hind paws after a tap on the sacrum ("flick test"). These spasms are inhibited by cortisol or triamcinolone, but aggravated by DOC and methylchlorocortisol (Me-Cl-COL). Methyltestosterone, estradiol and progesterone do not significantly affect this response in the rat. Triamcinolone also protects the dog against the syndrome of heavy  $\text{NaClO}_4$  overdosage.

### ***Pesticides*** ←

The possible detoxication of pesticides (insecticides, herbicides) by steroids has been extensively studied ever since it was found, in 1956, that DDT increased hepatic weight in the rat and that diethylstilbestrol enhanced the storage of DDT (and of its metabolite DDE) in the fat of male rats, whereas testosterone decreased these

values in females. Thus, it was concluded that "an endocrine mechanism may account for the sex differences in this regard." Yet DDT is particularly resistant to detoxication by steroids.

It was subsequently observed that male rats are more resistant than females to **parathion** poisoning, and that testosterone raises the resistance of females and of castrate males, whereas estrone diminishes that of intact males. Using the anticholinesterase action of **DMP** as an indicator, it was found that in female rats, administration of various hepatic microsomal enzyme-inducing drugs, as well as estradiol, cortisone, and a number of other steroids, causes resistance. Immature rats are more sensitive to **malathion** than adults and their livers detoxify this insecticide at a slower rate. Orchidectomy decreases, whereas testosterone increases malathion detoxication. It was concluded that testoids play an important part in the maintenance of the malathion-hydroxylating enzyme system.

On the other hand, male rats are more susceptible than females to the insecticide, **Morestan**. This sex difference could not be altered by castration, the administration of testosterone to females or of estradiol to males. Phenobarbital decreased the toxicity of **Morestan** in males and increased it in females.

More recent investigations showed that most catatoxic steroids (e.g., **PCN**, ethylestrenol, **CS-1**, spironolactone and norbolethone) counteract the lethal effects of **ethion**, **dioxathion**, **EPN**, **Guthion** and **parathion**. To a lesser extent, this is also true of oxandrolone, prednisolone and progesterone. However, triamcinolone, **DOC**, hydroxydione, estradiol, and thyroxine offer no consistent protection against these pesticides. Indeed, in many instances, thyroxine counteracts the protective effect of catatoxic steroids.

In view of the high efficacy of spironolactone, a potassium-retaining agent, it is noteworthy that such nonsteroidal potassium-sparing drugs as triamterene and amiloride do not protect against **parathion** or **dioxathion**.

In mice, the lethal effect of **dioxathion** is strongly inhibited by ethylestrenol, norbolethone, prednisolone, and estradiol, moderately by **CS-1**, and oxandrolone but not influenced by spironolactone, progesterone, triamcinolone, **DOC**, hydroxydione, and thyroxine. Evidently, here again, as in the case of most other substrates, genetic predisposition can greatly alter the catatoxic effect of steroids.

Since it was at first thought that the protective effect of steroids against various pesticides is linked to their testoid actions, it is of special interest that cyproterone, (an antitestoid steroid) also protects the rat against otherwise fatal doses of **parathion**.

The insecticide, **OMPA**, is assumed to become toxic only after transformation by hepatic microsomal enzymes into a potent anticholinesterase. Accordingly, it behaves somewhat differently from most other pesticides with regard to the effect of steroids upon its toxicity. Thus, cyproterone, one of the most potent catatoxic steroids known, which detoxifies many other pesticides, does not protect the rat against **OMPA**. In this respect, ethylestrenol, **CS-1**, spironolactone and norbolethone are also ineffective. Yet, these catatoxic steroids do not increase the toxicity of **OMPA**, which is noteworthy because hepatic microsomal enzyme-inducing barbiturates do transform it into its more toxic metabolite. On the other hand, estradiol, estrone, and stilbestrol which have no typical catatoxic actions, considerably increase **OMPA** toxicity in the ovariectomized rat. Although, the protective effect of the catatoxic

steroids against most substrates is independent of their pharmacologic action, the sensitization to OMPA does appear to depend upon folliculoid activity as such, since it is induced both by steroidal and by nonsteroidal folliculoids. Prednisolone, triamcinolone, progesterone, DOC, hydroxydione and thyroxine fail to influence OMPA toxicity.

### ***Phosphates*** ←

In uninephrectomized rats given large doses of  $\text{NaH}_2\text{PO}_4$  p.o., there develops a selective cortico-medullary nephrocalcinosis even after adrenalectomy. This effect is aggravated by DOC and prevented by cortisol. The action of DOC can be counterbalanced by cortisol under these conditions.

Estradiol facilitates the production of cortico-medullary nephrocalcinosis by  $\text{NaH}_2\text{PO}_4$ , whereas ovariectomy largely inhibits it. Folliculoids (estradiol, stilbestrol) facilitate the production of this type of nephrocalcinosis even in ovariectomized rats. The effect of estradiol is not significantly affected by progesterone, but is aggravated by methyltestosterone under these conditions. Parathyroidectomy or thyroidectomy prevents this nephrocalcinosis even after combined treatment with DOC, or estradiol +  $\text{Na}_2\text{HPO}_4$ .

### ***Potassium*** ←

Since corticoids have a pronounced influence upon potassium metabolism, their protective action against potassium intoxication has been carefully investigated. As early as 1937, it has been shown that adrenocortical extract can protect mice and guinea pigs against otherwise fatal amounts of KCl i.p. DOC proved to be even more effective in this respect.

On the other hand, pretreatment of rats with glucocorticoids diminishes their resistance to KCl i.p., perhaps as a consequence of the resultant adrenocortical atrophy. Concurrent administration of DOC, aldosterone, adrenocortical extract, corticosterone, or ACTH counteracts this unfavorable effect of cortisol upon K tolerance in the rat. Besides, addition of KCl to the drinking water prolongs the survival of rats given large doses of cortisone.

The protective action of DOC upon acute potassium intoxication has been confirmed in rabbits and mice.

### ***Phosphorus*** ←

The hepatotoxic effect of elementary yellow phosphorus is allegedly diminished both by cortisone and by testosterone in the rat.

### ***Physostigmine*** ←

In rats, intoxication with physostigmine is lessened by ethylestrenol, CS-1, PCN, spironolactone, and prednisolone, but aggravated by estradiol and thyroxine. Norbo-

lethone, oxandrolone, progesterone, triamcinolone, DOC, and hydroxydione do not significantly alter physostigmine poisoning. The protective action of ethylestrenol is counteracted by concurrent administration of thyroxine.

### ***Picrotoxin*** ←

In rats, the convulsive effect of picrotoxin can be prevented by anesthetic doses of DOC. Adult males are more resistant than females. Gonadectomy lowers picrotoxin resistance in both sexes, whereas testosterone raises it in normal, and especially in spayed females, but not in males.

Among the catatoxic steroids, PCN, ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, and progesterone inhibit picrotoxin poisoning in the rat, whereas triamcinolone, DOC, estradiol, hydroxydione, corticosterone, cholesterol, and  $\beta$ -sitosterol have no such protective action.

In mice, pretreatment with spironolactone, ethylestrenol, triamcinolone, or thyroxine had little, if any, effect upon picrotoxin poisoning.

### ***Piperidine*** ←

In rats, given piperidine at doses which caused very little mortality, the motor disturbances were inhibited by CS-1, ethylestrenol, norbolethone, oxandrolone, triamcinolone and hydroxydione. Curiously, PCN, one of the most active catatoxic steroids, failed to prevent piperidine intoxication.

### ***Pralidoxime*** ←

Pralidoxime is an inhibitor of anticholinesterases and hence, represents a useful antidote against certain pesticides which interfere with cholinergic mechanisms. In rats, pralidoxime intoxication is prevented by prednisolone or triamcinolone and, to a lesser extent, by ethylestrenol and estradiol. CS-1, PCN, spironolactone, norbolethone, oxandrolone, progesterone, DOC, hydroxydione, and thyroxine do not significantly influence pralidoxime poisoning.

### ***Puromycin Aminonucleoside (PAN)*** ←

The nephrosis and osteitis fibrosa produced by PAN in the rat are inhibited by glucocorticoids (cortisol, triamcinolone, dexamethasone, 6-methylprednisolone) according to several investigators. However, others claimed that these steroids have no effect or actually aggravate the renal changes. Presumably, many experimental conditions (e.g., dosage, timing, the age and strain of the rats used) may modify the prophylactic effect of glucocorticoids. DOC aggravates PAN nephrosis in the rat.

***Reserpine*** ←

In rats, adrenalectomy greatly decreases resistance to reserpine, whereas hypophysectomy does not change it. Hence, it has been assumed that the great reserpine sensitivity of the adrenalectomized animal is related to an absolute lack in certain adrenal steroids, rather than to the inability of the pituitary-adrenal system to respond to the stress caused by this drug.

Dexamethasone protects the gastric mucosa of the rat against the production of ulcers by reserpine.

In guinea pigs, the reserpine catalepsy is inhibited by various folliculoids, testoids, and corticoids.

***Reticulo-Endothelial System (RES)-Blocking Agents*** ←

In rats and mice, the blood clearance of carbon particles and their phagocytosis by RES cells is enhanced by various folliculoids, but not by testoids.

Cortisol does not significantly alter the accumulation of intratracheally administered quartz dust in rats, but delays its transfer to the regional lymph nodes.

In rats pretreated with ACTH, fluorocortisol, or stress (restraint), a single i.v. injection of thorium dextrin produces thrombohemorrhagic lesions in the adrenals, liver, and kidneys, which resemble the Shwartzman-Sanarelli phenomenon.

The localization of i.v. injected carbon particles in the paws of rats with dextran-induced anaphylactoid edema, can be topically prevented by intrapedal injection of cortisol, which interferes with local angiotaxis. In rats with arthritis produced by intrapedal injection of formalin mixed with India ink, the migration of the carbon particles into the regional lymph nodes is accelerated by concurrent treatment with ACTH. This is presumably a consequence of an increased glucocorticoid secretion and the resulting inhibition of inflammatory barrier formation around the carbon particles.

***SKF 525-A*** ←

In rats, severe intoxication with SKF 525-A was significantly diminished by PCN, CS-1, spironolactone, oxandrolone, prednisolone, triamcinolone and progesterone.

***Sodium*** ←

The potentiating effect of Na-salts upon mineralocorticoid hypertension has been extensively discussed in our previous monographs and need not be reconsidered here. Suffice it to state that in rats, dogs, and various other species including man, the toxic action of mineralocorticoid overdosage is aggravated by an excess of sodium. Indeed, it appears that the picture of mineralocorticoid intoxication is actually a sodium poisoning whose severity is enhanced by mineralocorticoids.

In frogs, high concentrations of NaCl decrease the Na-uptake and increase the electric resistance in the skin, as does destruction of the interrenal bodies. These effects are reversed by aldosterone but unaffected by spironolactone. Aldosterone and

spironolactone also fail to influence either the urine or the plasma Na in frogs; hence, it has been assumed that aldosterone is perhaps not an indispensable participant in salt regulation in this species.

### ***Strychnine*** ←

One of the earliest — though negative — observations concerning the influence of hormones upon resistance to drugs was the finding, in 1911, that in dogs and rabbits, orchidectomy and thyroidectomy do not consistently influence resistance to strychnine poisoning. On the other hand, DOC anesthesia protects the mouse against the convulsive and local effects of strychnine.

Also in mice, several water soluble esters of cortisol and prednisolone decreased strychnine sensitivity, but testosterone offered the best protection. Some piperidino-androstane derivatives actually increased strychnine sensitivity or produced convulsions by themselves.

Male rats are more resistant than females to strychnine intoxication, and the hepatic microsomes of male rats also exhibit a greater strychnine-metabolizing potency *in vitro*. SKF 525-A increases the toxicity of strychnine, presumably by interfering with its microsomal metabolism. Gonadectomy diminishes the high strychnine resistance of male rats, but has no effect upon females. 4-Chlorotestosterone augments the strychnine-metabolizing ability of isolated hepatic microsomes or liver slices.

Comparative studies on the effect of various steroids upon the strychnine sensitivity of the rat revealed that in this respect, the glucocorticoids (prednisolone and triamcinolone) and estradiol are most efficient. Ethylestrenol, spironolactone and PCN are much less potent, whereas CS-1, norbolethone, oxandrolone, progesterone, DOC, and hydroxydione are totally devoid of strychnine antagonizing capacity.

### ***Thimerosal*** ←

In rats, thimerosal intoxication is inhibited by all catatoxic steroids, prednisolone and estradiol.

### ***Thioacetamide*** ←

Several investigators noted that glucocorticoids (prednisolone, prednisone, cortisone) do not significantly inhibit the hepatocellular damage produced by thioacetamide in rats; however, they may slightly suppress cirrhosis even if the hepatic parenchymal lesions are increased. On the other hand, various testoids, especially 4-chlorotestosterone, appeared to offer some protection against these thioacetamide-induced hepatic lesions.

### ***Tribromoethanol*** ←

Bilateral adrenalectomy prolongs tribromoethanol sleeping time both in rabbits and in rats. DOC, and adrenocortical extract tend to compensate for this manifestation of adrenal insufficiency.

In the mouse, estradiol allegedly increases resistance to "partially decomposed solutions" of tribromoethanol. In rats, tribromoethanol sleeping time is significantly shortened by typical catatoxic steroids. A similar effect is obtained by prednisolone, but not by triamcinolone.

### ***Trichloroethanol*** ←

Trichloroethanol is more easily detoxified by catatoxic steroids than tribromoethanol. In rats, trichloroethanol sleeping time is significantly diminished by PCN, CS-1, ethylestrenol, spironolactone and prednisolone.

### ***Tubocurarine*** ←

The motor disturbances produced in rats by D-tubocurarine were virtually abolished by all typical catatoxic steroids (except oxandrolone), as well as by prednisolone, triamcinolone and progesterone.

### ***Tyrosine*** ←

Excessive dietary intake of tyrosine causes characteristic lesions in the paws and eyes of rats, especially on a low protein diet. Cortisol or stress (infusorial earth i.p.) prevents the manifestations of tyrosine intoxication, presumably as a consequence of hepatic TPO induction. However, PCN fails to augment hepatic TPO activity, yet it also offers excellent protection against tyrosine intoxication in the rat. Since thyroid hormones aggravate tyrosine intoxication, it is conceivable that PCN acts partly by interfering with thyroid hormone secretion (as do thioureas), or that it augments the metabolic degradation of thyroid hormones, thus exerting an indirect effect upon tyrosine intoxication.

### ***Vitamin A*** ←

The vitamins, as many other normal food constituents such as electrolytes, cholesterol, etc., could have been discussed in the section on dietary factors; we deal with them here, since many of the most pertinent data are concerned with the effect of hormones upon intoxication with excessive amounts of vitamins.

In the rat, vitamin-A overdosage produces widespread bone absorption, resulting in severe skeletal lesions. It was claimed at first that in weanlings, adrenalectomy aggravates these changes, whereas cortisone has no effect upon them, but subsequent studies have shown that various glucocorticoids increase the skeletal defects of hypervitaminosis A even in the very young animal. Indeed, vitamin-A overdosage during pregnancy produces malformations of the brain and calvarium in the newborn rat, and the intensity of these lesions is aggravated by cortisone. During postnatal life, vitamin A also elicits severe bone absorption in rats; this effect is likewise increased by cortisol, whose action is in turn inhibited by STH.

However, as we shall see, the effect of glucocorticoids upon hypervitaminosis A is variable and often even reversed depending upon experimental conditions (e.g., dosage, the form in which the vitamin is administered).

In rats, vitamin A itself has no effect upon wound healing, but it overcomes the inhibitory action of cortisone.

The atrophy of the accessory sex organs induced by vitamin-A deficiency in the rat has been ascribed to interference with the synthesis of testoids, not to a target-organ insensitivity. Estradiol increases, whereas methyltestosterone counteracts the bone absorption and catabolism produced by hypervitaminosis A in the rat.

Progesterone increases body weight and re-establishes a normal estrous cycle in vitamin-A deficient rats.

More recent experiments have shown that the skeletal lesions characteristic of vitamin-A overdosage in rats are inhibited not only by glucocorticoids, but also by typical catatoxic steroids such as spironolactone, norbolethone and ethylestrenol. Simultaneously, the hepatic and serum vitamin-A concentrations are decreased.

In rabbits, large doses of vitamin A produce collapse of the ears and loss of basophilic and metachromatic staining of their cartilage. These changes, which resemble those elicited by papain, can be prevented by cortisone. The lesions produced by cortisone in the epiphyseal plates of rabbits are not significantly influenced by vitamin A.

It has been postulated that cortisone protects the otic cartilage of rabbits from dissolution by excess vitamin A through the stabilizing action of glucocorticoids upon lysosomes, whose proteases are responsible for the degradation of chondromucoprotein.

Also in rabbits, acute overdosage with vitamin-A palmitate, or vitamin-A acid produces loss of hair and collapse of the ear cartilage with depletion of the cartilage matrix. Similar changes occur in the articular and epiphyseal cartilages. All these lesions are prevented by cortisone, whose protective effect is demonstrable even topically upon intra-articular injection in hypervitaminotic rabbits. These inhibitory actions of glucocorticoids upon vitamin-A overdosage (like those against ultraviolet ray injury or endotoxin shock) were again ascribed to lysosomal stabilization.

Additional *in vitro* studies confirmed that the dissolution of murine bone explants by vitamin A can be prevented by cortisol. Furthermore, fragments of murine esophagus cultured *in vitro* show inhibition of keratinization, and differentiation under the influence of vitamin A, but in this respect cortisol exerts similar actions, and if the two agents are given conjointly, they synergize each other.

In the larvae of *Xenopus laevis*, bone absorption, and other manifestations of vitamin-A overdosage are enhanced by cortisol. This was ascribed to the liberation of vitamin A from hepatic stores, and is in contrast to the retardation of hypervitaminosis A by cortisol, *in vitro*. Presumably, an excess of vitamin A causes release of cathepsins from intracellular lysosomes. It is also noteworthy that the osseous lesions produced by vitamin-A alcohol overdosage in *Xenopus laevis* larvae are aggravated, whereas those caused by vitamin-A acid are prevented by cortisol. Probably, the vitamin-A acid is not stored in the liver to any important degree, whereas the alcohol is stored in the liver as an ester and can be released by

cortisol. In **tissue cultures** of chick and mouse bone cartilage implants rapidly disintegrate under the influence of excess vitamin A, and this response is prevented by cortisol; thus, the glucocorticoid has opposite actions *in vivo* and *in vitro*.

### *Vitamin B ←*

In **chickens**, the responsiveness of the genital tract to folliculoids depends upon the availability of folic acid, and is suppressed by folic acid antagonists. Male mice are more sensitive than females to intoxication with the folic acid antagonist, aminopterin. Orchidectomy raises aminopterin tolerance, but estradiol fails to affect it in males and testosterone does not influence it in females.

In **pigeons**, thiamine deficiency has been claimed to be favorably influenced by DOC.

In **rats**, triamcinolone, dexamethasone, corticosterone, and DOC protect against the syndrome of nicotinamide deficiency. Allegedly, the corticoids raise the otherwise low NAD and NADH levels of the liver in nicotinamide deficient rats, augmenting at the same time the NADP and NADPH concentration, perhaps through an increase in tryptophan availability.

### *Vitamin C ←*

Early observations suggested that adrenocortical extracts can protect **guinea pigs** against scurvy, but this might have been due merely to the high vitamin-C content of the adrenal cortex. Yet, subsequent research showed that cortisone and ACTH exert a similar protective effect.

The bone lesions characteristic of scurvy in guinea pigs are diminished by conjugated equine estrogens (Premarin), but not by estriol.

The normal excretion of ascorbic acid, and the increase in its elimination induced by barbital, are higher in male than in female **rats**. Orchidectomy reduces both the normal excretion and its enhancement by barbital, whereas ovariectomy has an opposite effect. Treatment of males with stilbestrol, or females with testosterone, diminishes ascorbic acid excretion. No such sex difference was noted in **mice**.

### *Vitamin D, DHT ←*

Most of the work on the effect of steroids upon intoxication with vitamin-D derivatives, including DHT was performed in **rats**. These respond to acute poisoning by vitamin-D compounds with a syndrome of generalized calcinosis, affecting primarily the cardiovascular system, the kidney, the gastrointestinal tract, and the lungs. Death usually ensues within a few days. On the other hand, chronic intoxication with comparatively smaller doses, especially of DHT, leads to a "progeria-like syndrome." Here soft-tissue calcification is also pronounced, but affects predominantly the arteries, and it is associated with a very severe cachexia, involution of the thymicolymphatic and sex organs, the musculature and the adipose

tissue. There are also dental and skeletal anomalies characterized by the development of a poorly calcified but excessive bone matrix, kyphosis and loss of skin elasticity. Although there are minor differences between the toxic manifestations of overdosage with vitamin-D<sub>2</sub>, vitamin-D<sub>3</sub> and DHT, we shall discuss them conjointly because all three compounds are chemically and pharmacologically closely related. However, the acute and the chronic form of hypervitaminosis D respond quite differently to certain steroids, especially to those that exhibit powerful catatoxic effects against other substrates.

← **Glucocorticoids.** In mice, severe vitamin-D intoxication could not be prevented by cortisone.

In vitamin-D deficient chicks, cortisone and cortisol inhibit the maturation of cartilage matrix, whereas norethandrolone promotes it.

In rats on a vitamin-D deficient diet, cortisone decreases the inorganic serum phosphorus, but it either does not affect calcemia, or raises it slightly.

The arterial lesions produced by severe vitamin-D intoxication in rats, are aggravated by DOC, and ameliorated by cortisone. However, this protective effect is variable and appears to depend upon several unidentified experimental circumstances (perhaps including dietary factors), because several investigators claim that cortisol and cortisone do not influence, or actually aggravate, hypervitaminosis D. Similarly contradictory findings have been published concerning the alleged antirachitic action of glucocorticoids.

In rats, cortisol (unlike folliculoids) fails to cause a shift of the vitamin-D-induced nephrocalcinosis from the cortex to the cortico-medullary junction of the kidney.

After calciphylactic sensitization with DHT, neonatal rats respond with severe thymus calcification to a challenging dose of triamcinolone. Here, apparently, the acute glucocorticoid-induced thymus involution attracts calcium salts in the presence of DHT-induced sensitization.

In patients, cortisone has repeatedly been claimed to improve the manifestations of vitamin-D overdosage.

← **Mineralocorticoids.** The literature on the effect of DOC upon DHT intoxication in the rat is likewise quite contradictory, but in any event, mineralocorticoids do not appear to have any consistent and striking effects in this respect.

← **Adrenalectomy.** Both in intact and in adrenalectomized or hypophysectomized rats, vitamin-D overdosage produces a predominantly cortical nephrocalcinosis. Additional treatment with dienestrol (a folliculoid) shifts the calcium deposition predominantly to the cortico-medullary junction, irrespective of the presence or absence of the hypophysis and adrenals.

← **Folliculoids.** Early investigators suggested, on the basis of X-ray studies of the bones of rats kept on a vitamin-D deficient diet, that testosterone is "rachitogenic," whereas estradiol is "antirachitic." Yet, gonadectomy did not appear to influence experimental rickets in rats of either sex.

The renal calcification produced by vitamin-D<sub>2</sub> overdosage in the rat is not significantly influenced by estrone, although it does appear to have a tendency to shift from the cortical to the cortico-medullary junction in the rat. This effect is not evident in the mouse, rabbit and dog. Other investigators claimed that in rats overdosed with vitamin D or DHT, calcification occurs predominantly in the interstitial tissue of the renal cortex, whereas after simultaneous treatment with

folliculoids, mineralization occurs intracanalicularly in the cortico-medullary junction.

In the Wistar-Imamichi strain of rats, the "progeria-like syndrome" produced by chronic DHT administration is unaccompanied by aorta calcinosis. This strain also reacts with osteoporosis, instead of the osteosclerosis (consisting of decalcified matrix) that is seen in most other strains. Conjugated estrogens offer virtually complete protection against these changes in the Wistar-Imamichi rat.

← **Testoids.** Whereas the effects of corticoids and folliculoids upon hypervitaminosis D are rather variable and dependent upon many incidental conditioning factors, anabolic testoids undoubtedly exert an extraordinary degree of protection. The first observation which called attention to this effect was the finding that male rats are much more resistant than females to DHT intoxication, but orchidectomy abolishes this sex difference. Hence, it was concluded that "some testicular factor exerts a protective effect against this type of intoxication."

It has been shown subsequently that various anabolic testoids protect not only against acute, but also against the chronic "progeria-like" form of intoxication with DHT or vitamin-D<sub>2</sub>. These anabolics offer partial protection even against the loss of weight induced by AAN, estradiol, and food restriction; hence, at least part of their protective action may be ascribed to their anabolic or anticatabolic potency.

The original articles will have to be consulted for a comparative appraisal of the relative anti-DHT and anti-vitamin-D activities of various anabolic steroids; it is clear however, that in general, their protective action in this respect parallels their anabolic potency much more closely than their virilizing properties.

The anaphylactoid shock organs of the rat can also be prevented by anabolic steroids (e.g., methyltestosterone).

It is especially noteworthy that the progeria-like syndrome produced with DHT, vitamin-D<sub>2</sub> or vitamin-D<sub>3</sub> can be prevented not only by methyltestosterone but also by ferric dextran and vitamin E, although presumably through different mechanisms.

The cystic transformation of the parathyroids, normally elicited in rats by combined treatment with DHT and calcium acetate, is likewise prevented by methyltestosterone.

Among the 36 steroids examined for their ability to protect the rat against the progeria-like syndrome induced by DHT, the strongest anabolic steroids (e.g., norbolethone, SC-7294 and fluoxymesterone) proved to be most efficacious.

Incidentally, ethynyltestosterone (like folliculoids) tends to shift the nephrocalcinosis induced by vitamin D from the renal cortex to the cortico-medullary junction.

In **rabbits**, the production of gallstones and cholecystitis by DHT is inhibited by methyltestosterone; at the same time, the serum concentration of DHT falls, allegedly as a consequence of diminished intestinal absorption.

In **chicks** on a vitamin-D deficient diet, norethandrolone promotes the maturation of cartilage matrix, whereas glucocorticoids inhibit it.

← **Other Steroids.** Among other steroids, two antimineralocorticoids, spironolactone and CS-1, proved to be highly efficacious in antagonizing the acute lethal effect of the intoxication with large doses of DHT or DHT + Na<sub>2</sub>HPO<sub>4</sub>, in the rat.

More recently, it was found that this is common to numerous other catatoxic steroids (e.g., ethylestrenol, PCN), so that it cannot depend upon the anabolic, anti-mineralocorticoid, corticoid, or any other known pharmacologic action of steroids; it must be regarded as an independent property. However, although all these catatoxic steroids are highly potent in preventing acute vitamin-D or DHT intoxication, only those with strong anabolic properties (e.g., ethylestrenol, oxandrolone, norbolethone, methyltestosterone) are very efficacious against the progeria-like syndrome. Several other catatoxic compounds (e.g., PCN, CS-1, spironolactone) prevent acute DHT intoxication but they either have no effect upon the progeria-like syndrome, or actually aggravate its course.

### **W-1372 ←**

In rats, the blood lipid decreasing factor W-1372 causes severe hepatic lipidosis, sometimes with necrosis and high mortality if administered in oil solution. These toxic manifestations are prevented by PCN, CS-1, spironolactone and, to a lesser extent, by ethylestrenol, norbolethone, oxandrolone, progesterone and estradiol.

### **Zoxazolamine ←**

Zoxazolamine, a muscle relaxant, is an excellent substrate for various non-steroidal catatoxic drugs. Its action is also shortened by 19-nortestosterone derivatives, but not by medroxyprogesterone (a luteoid), although the latter compound does appear to counteract testosterone.

Our own observations in rats show that the muscular paralysis produced by zoxazolamine is greatly shortened by PCN, CS-1, ethylestrenol and, to a lesser extent, by spironolactone. Other steroids tested are ineffective.

### **Acetaldehyde ←**

*Lecoq et al. B66,406/51:* In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde, (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

### **2-Acetaminofluorene ← cf. Carcinogens**

#### **Acetonitrile ←**

*Gellhorn 16,839/23:* In mice, resistance against acetonitrile can be increased not only by thyroid extract, but to a lesser extent, also by extracts of various other tissues. These preparations also augment resistance to KCN

and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

*Eufinger & Wiesbader 4,663/30:* In mice, pretreatment with gonadotrophic urinary extracts or folliculoid preparations increases acetonitrile resistance and hence, this phenomenon is not characteristic for the thyroid hormone.

*Paal 22,603/30:* In mice, acetonitrile resistance is not consistently influenced by the posterior pituitary extract (hypophysin), a folliculoid preparation (progynon), or by epinephrine.

*Dessau 34,845/35:* In rats, adrenalectomy decreases resistance to acetonitrile. This resistance can be slightly improved by adrenocortical transplants, but not by the adrenocortical extract tested, or by epinephrine.

N-Acetyl-p-aminophenol ← Prednisolone: *Inscoc et al. F70,325/66*

N-Acetyltyramine ← Prednisolone: *Inscoc et al. F70,325/66*

**Acetanilide** ←

*Selye PROT. 42918:* In rats, acute acetanilide intoxication is markedly inhibited by PCN, CS-1, ethylestrenol, spironolactone, norbolethone, prednisolone, thyroxine and phenobarbital. Estradiol tends to aggravate the toxicity of acetanilide, *cf.* Table 24. [Dr. S. Szabo noticed at the autopsy of these animals that some of them had developed perforating duodenal ulcers (H.S.).]

Table 24. *Conditioning for acetanilide*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	15/15	2/15
PCN	2/10 ***	0/10 NS
CS-1	5/10 ***	0/10 NS
Ethylestrenol	3/10 ***	0/10 NS
Spironolactone	3/10 ***	0/10 NS
Norbolethone	5/10 ***	0/10 NS
Oxandrolone	7/10 NS	2/10 NS
Prednisolone-Ac	1/10 ***	0/10 NS
Triamcinolone	9/10 NS	4/10 NS
Progesterone	10/10 NS	3/10 NS
Estradiol	10/10 NS	7/10 **
DOC-Ac	8/10 NS	4/10 NS
Hydroxydione	9/10 NS	3/10 NS
Thyroxine	4/10 ***	4/10 NS
Phenobarbital	3/10 ***	0/10 NS

<sup>a</sup> The rats of all groups were given acetanilide (50 mg/100 g body weight in 0.15 ml DMSO, s.c., once daily from 4th day to the end of the experiment).

<sup>b</sup> Dyskinesia was estimated on 6th day 8 hrs after injection and mortality listed on 7th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

**Acrylamide** ←

*Selye PROT. 41419:* In rats, acrylamide intoxication is efficiently combated by PCN and phenobarbital. The protective effect of CS-1 and spironolactone is less evident. The other standard conditioners are ineffective, *cf.* Table 25.

**Acrylonitrile** ←

*Szabo & Selye G70,493/71:* In rats, the adrenal necrosis and mortality produced by acrylonitrile were readily prevented by phenobarbital, but not or only doubtfully influenced by the other conditioners of our series, *cf.* Table 26, p. 177.

Table 25. *Conditioning for acrylamide*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

#### *Allylformiate* ←

*Oettel & Franck A72,420/42*: In rats, DOC allegedly offers some protection against the hepatic changes produced by thyroxine or allylformiate.

#### *Aminoacetonitrile* ← cf. *Lathyrogens*

#### *Aminogluthethimide* ←

*Goldman H31,449/70*: In rats, "testosterone prevents the testicular and male genital changes produced by aminogluthethimide. On the other hand, corticosterone markedly reduces the adrenal and female genital changes produced by this drug."

#### *6-Aminonicotinamide* ←

*Mikes & Todorovic C86,716/59*: In guinea pigs, the hepatic lesions produced by 6-aminonicotinamide are inhibited by prednisolone.

#### *o-Aminophenol* ←

*Inscoc & Axelrod D1,700/60*: The ability of microsomes from the liver of male rats to form o-aminophenol glucuronide in vitro is four times as great as in females. Estradiol diminishes this enzyme activity in males, whereas testosterone increases it in females.

*Müller-Oerlinghausen et al. G64,175/69*: Hepatic tissue of mice injected with tolbutamide synthesizes an increased amount of glucuronide when incubated in vitro with o-aminophenol. Insulin, given at a dose causing a similar degree of hypoglycemia, is much less effective in enhancing glucuronide synthesis. Adrenalectomy diminishes the formation of o-aminophenol glucuronide, despite hypoglycemia. However, the adrenalectomized mice given cortisone again, respond with increased glucuronide synthesis after tolbutamide.

*Selye G70,480/71*: In rats, o-aminophenol hydrochloride (50 mg/100 g body weight in 2 ml water) was administered s.c. once, on the 4th day of conditioning. Dyskinesia was listed 1 hr, mortality 24 hrs after this injection. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication, only thyroxine exhibited an aggravating effect. PCN was not tested.

*o-Aminophenol* ← Pregnane-3 $\alpha$ ,20 $\alpha$ -diol, Pregnane-3 $\alpha$ ,20 $\beta$ -diol, Gp: Arias et al. *F24,502/64*

*o-Aminophenol* ← Steroids, Mouse: Jones *G19,777/64*

#### *Aminopterin* ←

*Goldin et al. D76,907/50*: There is no sex difference in the toxicity of aminopterin in immature mice, but among adults, males are more resistant than females. Estradiol increases aminopterin tolerance in immature and mature males, whereas testosterone does not influence it.

*Penhos G8,997/62*: In the rat, the loss of weight, diarrhea and other characteristic changes of aminopterin intoxication are more markedly aggravated by dexamethasone than by triamcinolone. Aminopterin counteracts the increase in liver weight produced by the glucocorticoids.

*Aminopterin* ← Adrenalectomy: Higgins et al. B40,212/49\*; Dougherty et al. G77,517/50\*; Goldin et al. D76,907/50\*

*Aminopterin* ← Orchidectomy, Mouse: Goldin et al. D76,907/50\*

Aminopterin ← Estradiol, Testosterone: Goldin et al. D76,907/50\*

### *Aminopyrine* ←

*Borglin & Mansson B62,206/51*: Gonadectomy does not change aminopyrine resistance in male mice but decreases it in females. This decrease is counteracted by estradiol.

*Kato & Gillette F57,816/65*: The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females, but the sex difference varies with the substrate. There is more than a 3-fold sex difference with aminopyrine and hexobarbital, but virtually none with hydroxylation of aniline and zoxazolamine. In male rats, starvation impairs the sex-dependent enzymes which metabolize aminopyrine and hexobarbital, but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as of the aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital; it enhances that of aminopyrine by microsomes of castrated rats, but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Kato & Gillette F57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, the hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly diminished by the agents which do have an inhibitory effect in males.

*Radzialowski & Bousquet H2,264/68*: The circadian variation in aminopyrine, p-nitroanisole and hexobarbital-metabolizing microsomal enzymes of the rat and mouse liver is abolished by adrenalectomy, but the rhythm of dimethylaminoazobenzene metabolism remains unaffected.

*Ichii & Yago H15,158/69*: Studies on bilaterally adrenalectomized and/or orchidectomized rats, given cortisol or testosterone, led to the conclusion that corticoids and testoids regulate different fractions of the aminopyrine N-de-

methylase activity of the hepatic microsomes, which is mainly maintained by these hormones in intact male rats. On the other hand, phenobarbital-inducible aminopyrine N-demethylase activity is quite independent of adrenal and testicular control.

*Orrenius et al. E8,231/69*: In rats, adrenalectomy has no immediate effect upon the induction of steroid hydroxylases in the hepatic microsomes by phenobarbital. However, simultaneously adrenalectomized and castrate rats, subsequently maintained in this state for a period of time, showed a strikingly decreased hydroxylating activity of the hepatic microsomes, measured with either aminopyrine or testosterone as substrate. The cytochrome P-450 content of the microsomes decreased in a parallel fashion, whereas the cytochrome  $b_5$  remained unchanged. When these steroid-deficient animals were treated with prednisolone or testosterone, the cytochrome P-450 content and the aminopyrine- and testosterone-hydroxylating activities of the liver microsomes returned to normal. In the steroid-deficient rats, repeated injections of phenobarbital caused only a minimal increase in the cytochrome P-450 content as well as in the NADPH-cytochrome reductase and aminopyrine-hydroxylation activities of the hepatic microsomes. Combined treatment with phenobarbital and prednisolone or testosterone resulted in an increase of these levels to those obtained by phenobarbital alone, in intact controls. Apparently, "steroid hormones are involved both in the maintenance of normal hydroxylating activity in the rat liver endoplasmic reticulum and in the increase of this activity caused by drugs."

*Soyka G66,626/69*: In rat liver, the aminopyrine demethylase activity of the microsomal fraction increased considerably during the first 30 days after birth. Evidence of an inhibitor was not found during this newborn period. After puberty, the activity in male rats was about twice as high as in females. Testosterone produced only an insignificant rise in females.

*Nakanishi et al. G79,299/70*: "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

*Solymoss et al. G60,075/70*: In rats pretreated with spironolactone, norbolethone or ethylestrenol, hexobarbital anesthesia was diminished, and its aliphatic hydroxylation by hepatic microsomes enhanced. Pretreatment with the same steroids also accelerated the N-dealkylation of aminopyrine by hepatic microsomes. Progesterone was inactive against hexobarbital, but slightly increased the production of 4-aminoantipyrine by hepatic microsomes.

*Selye PROT. 36785*: In rats, aminopyrine intoxication was readily prevented by all classic catatotoxic steroids, except oxandrolone whose beneficial effect was just below the level of statistical significance. Prednisolone, triamcinolone and phenobarbital also offered protection, cf. Table 27.

Table 27. *Conditioning for aminopyrine*

<sup>a</sup> The rats of all groups were given aminopyrine (30 mg/100 g body weight in 1 ml water, s.c., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 2 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

Aminopyrine ← Adrenalectomy + Pesticides (Chlordane): Hart et al. *G27,102/65*; Orrenius *G74,389/65*

Aminopyrine ← Corticoids + Phenobarbital, Mouse, Rat: Wada et al. *H15,468/68*; Lu et al. *G68,802/69*

Aminopyrine ← Estradiol: Mitoma et al. *G72,113/68*

Aminopyrine ← Gonadectomy: Kato et al. *F57,817/65*, *F76,403/66*; Schenkman et al. *G67,777/67*

Aminopyrine ← Methyltestosterone: Kato et al. *F57,817/65*, *F76,403/66*; Mullen et al. *G37,764/66*

Aminopyrine ← Norethynodrel: Juchau et al. *G40,275/66*

#### Ammonium Chloride ←

*Henschler & Reich C71,216/59*: In rats, the pulmonary edema induced by ammonium chloride, epinephrine, thiourea, or chloropicrin is prevented by the administration (about 5 min earlier) of a single large dose of prednisolone i.v.

#### AMP (cyclic) ←

*Rondell H32,853/70*: In vitro experiments on the ovarian follicles of the pig suggest that LH, cyclic AMP or progesterone augment the distensibility of follicular strips, thereby preparing for rupture. TMACN blocks the effects of LH or cyclic AMP on both steroid release and distensibility. This blockade can be counteracted by progesterone. Presumably, "LH stimulates steroid secretion from the follicular tissue which in turn causes the activation of the ovulatory enzyme."

#### Amphetamine ←

*D'Arcy & Spurling D8,818/61*: The fact that mice living in crowded conditions are more susceptible to amphetamine than those housed in single cages is ascribed to an increased glucocorticoid secretion under the stress of crowding. Accordingly, cortisol pretreatment increased the amphetamine sensitivity of mice.

*Clark et al. F92,621/67*: Crowding increases the toxicity of amphetamine in the mouse. "The administration of either dexamethasone, ethanol, glucose, 2,deoxy-d-glucose or diphenylhydantoin reduced the excitement, hyperactivity and mortality, in aggregated mice given d-amphetamine. The reduction in mortality was proportional to the decrease in excitement and hyperactivity."

*Groppetti & Costa H31,959/69*: In adult male rats, the disappearance of amphetamine is faster than in adult females. Estradiol retards the rate of amphetamine disappear-

ance in adult males. Such potent hepatic microsomal enzyme inducers as phenobarbital, 3-MC, or diphenylhydantoin do not change the tissue levels of amphetamine.

*Selye G70,480/71:* In rats, DL-amphetamine (12 mg/100 g body weight in 0.2 ml water) was administered s.c. once on the 4th day of conditioning. Dyskinesia was listed 4 hrs, mortality 24 hrs, after this injection. Under these circumstances, the "Standard Conditions" (p. VIII) caused no noteworthy change in the resulting intoxication, only triamcinolone and thyroxine exhibited an aggravating effect.

#### **Amyl Nitrite** ←

*Fischer 50,723/20:* In rabbits, adrenalectomy prevents the induction of convulsions by amyl nitrite.

*Specht 13,475/23:* In guinea pigs, neither thyroidectomy nor orchidectomy influences the course of the convulsions produced by amyl nitrite inhalation or the electric irritation of the peripheral nerves.

#### **Amyloid** ← cf. also **Casein**

*Lurie et al. B31,933/49:* Estradiol suppresses the development of amyloidosis in tuberculous rabbits.

**Anaphylactoidogens** ← **corticoids** cf. also *Selye C1,001/54, p. 96; C92,918/61, p. 220; G46,715/68, pp. 109, 117, 178, 184, 189, 194.*

**Anaphylactoidogens** ← **folliculoids** cf. also *Selye G46,715/68, pp. 178, 194.*

*Chen & Wickel B74,534/52:* In adrenalectomized rats, the anaphylactoid edema produced by egg-white i.p. was prevented by cortisone, dehydrocorticosterone, 17-hydroxycorticosterone and 6,7-dehydrocorticosterone, whereas a large number of other steroids were inactive.

*Selye et al. C70,942/59:* Topical injection of cortisol acetate microcrystals into a hind paw of a rat selectively protects the surrounding region against the angiotactic sequestration of i.v. injected carbon (India ink) particles during a dextran-induced anaphylactoid edema.

*Selye et al. C78,128/60:* The gastric ulcers, as well as the associated anaphylactoid edema produced by 48/80 in the rat are prevented by cortisol or exposure to various stressors. This is all the more noteworthy because the stressors themselves are capable of producing gastric erosions.

*Selye et al. C83,616/61:* In rats, the cardiovascular and renal calcification produced by

chronic treatment with polymyxin is increased by triamcinolone or DOC, and particularly by combined treatment with both these steroids or by F-COL which possesses both gluco- and mineralocorticoid properties.

*Robert & Nezamis D23,289/62; D23,064/62:* The acute gastric ulcers produced by polymyxin in the rat can be prevented by glucocorticoids (cortisol, prednisolone), but also by DOC. On the other hand, when following pretreatment with polymyxin the gastric mucosa is depleted of histamine, the ulcerogenic property of prednisolone overdosage is unimpaired. Hence, histamine liberation cannot be held responsible for the production of gastric ulcers by glucocorticoids.

#### **Anesthetics (Various)** ← cf. also **Individual Anesthetics**

**Anesthetics (Various)** ← **catatoxic steroids** cf. also *Selye G60,083/70, p. 385.*

*Selye et al. G60,020/69:* Norbolethone protects the rat against the anesthetic action of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital, and methyprylon; it does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, KBr or MgCl<sub>2</sub>. In all these cases, the effects of norbolethone simulate those of spironolactone.

#### **Aniline** ←

*Kato & Gillette F57,816/65:* The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females, but the sex difference varies with the substrate. There is more than a 3-fold sex difference with aminopyrine and hexobarbital, but virtually none with hydroxylation of aniline and zoxazolamine. In male rats, starvation impairs the sex-dependent enzymes which metabolize aminopyrine and hexobarbital, but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as of the aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital; it enhances that of aminopyrine by microsomes of castrated rats, but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Kato & Gillette F57,817/65:* The metabolism of aminopyrine and hexobarbital by he-

patic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, the hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Furner & Stitzel G54,558/68*: The hepatic microsomal metabolism of ethylmorphine, aniline and hexobarbital is diminished in vitro by previous adrenalectomy in the rat. Phenobarbital pretreatment of adrenalectomized rats raised the metabolism of all three substrates above the level characteristic of untreated, adrenalectomized controls. Exposure of adrenalectomized rats to cold stress, or treatment with cortisol, increased the metabolism of aniline and ethylmorphine, but depressed that of hexobarbital. In intact rats, cold stress diminished hexobarbital metabolism in vitro. Apparently, both the stress and the phenobarbital can bring about changes in the hepatic drug metabolism, independent of the presence of the adrenals; the two agents act through different mechanisms, since phenobarbital invariably stimulates, whereas stress either increases or decreases the microsomal enzyme activity, depending upon the drug pathway examined.

*Nakanishi et al. G79,299/70*: "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

*Selye et al. G70,424/70*: In rats, aniline produces pronounced lipid hyperplasia of the adrenal cortex similar to that elicited by amphenone. This change is prevented by glucocorticoids and is presumably caused by an increased ACTH production as a consequence of diminished  $11\beta$ -hydroxylated corticoid secretion.

Aniline ← Prednisolone, Cortisol + Phenobarbital, Mouse, Rat: Wada et al. *H15,468/68*

Aniline ← Methyltestosterone: Kato et al. *F57,817/65, F76,403/66*

Aniline ← Gonadectomy: Kato et al. *F57,817/65, F76,403/66*; Schenkman et al. *G67,777/67*

Aniline ← Norethynodrel: Juchau et al. *G40,275/66*

#### **Antibiotics ← cf. also Individual Antibiotics**

**Antibiotics** ← **corticoids** cf. also *Selye G60,083/70, pp. 348, 357.*

*Giberti et al. B90,116/53*: In guinea pigs, the organ lesions—particularly the hemorrhagic adrenalitis produced by chlortetracycline (Aureomycin)—are diminished by cortisone, but the mortality is not influenced.

*Tuchmann-Duplessis & Mercier-Parot H23,371/70*: In rats, actinomycin given before implantation causes only abortion; after implantation, it elicits both abortion and severe malformations. These effects are not prevented by progesterone or estradiol alone or in combination.

*Selye PROT. 38752*: In rats, griseofulvin (7.5 mg/100 g body weight in 0.1 ml DMSO) was administered i.v. once on the 4th day. Dyskinesia was estimated 30 min, mortality 24 hrs after this injection. Under these circumstances, the "Standard Conditioners" caused no noteworthy change in the resulting intoxication, although in an earlier experiment some alterations in the course of this intoxication were noted (Table 138).

#### **Anticoagulants ←**

*van Cauwenberge & Jaques C58,521/58*: A dose of dicoumarol, well tolerated by untreated rabbits, causes death with widespread hemorrhage when given together with ACTH. The hemorrhagic tendency induced by dicoumarol was not accentuated by STH, cortisone, or DOC.

*Paluszka & Hamilton C72,116/59*: In rats, the leukocytosis produced by heparin is inhibited by cortisol.

*van Cauwenberge & Jaques C72,748/59*: The "hemorrhagic stress" syndrome produced by dicoumarol treatment in rats simultaneously exposed to various stressors can be reproduced by the administration of ACTH, STH or DOC, instead of stressors. Dicoumarol + cortisol or cortisone did not reproduce this syndrome.

*Oliver et al. D54,029/63:* In man, the requirements for anticoagulants (warfarin, phenindione) are reduced during simultaneous treatment with androsterone (Atromid). It is suggested that perhaps the ethyl-*a*-*p*-chlorophenoxyisobutyrate (C.P.I.B.) contained in this particular androsterone preparation may be involved.

*Pyörälä & Kekki E31,756/63:* In man, methandrostenolone increases sensitivity to certain anticoagulants (warfarin, phenindione). "The use of methandrostenolone should be avoided in patients receiving anticoagulants, because it may precipitate hemorrhagic complications."

*Schrogie & Solomon G43,019/66:* In man, both D-thyroxine and norethandrolone increase the anticoagulant response to bishydroxycoumarin at doses which do not change the rate of its metabolism. "Since clinically effective doses of these three drugs do not decrease the concentration of vitamin-K-dependent clotting factors, or affect the absorption, distribution, or metabolism of bishydroxycoumarin in man, it seems likely that they potentiate the pharmacologic effect of bishydroxycoumarin by increasing the affinity of the receptor site for the anticoagulant."

*Jaques G70,979/68:* Review (30 pp., 13 refs.) on the "hemorrhagic stress syndrome" that is produced in various mammals treated with indirect anticoagulants (e.g., phenindione, bishydroxycoumarin) and then exposed to stress or treated with DOC, ACTH, or STH. Conversely, cortisone, epinephrine, ephedrin, and adrenochrome inhibit this syndrome.

*Selye G70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs, and inhibits the protective effect of ethylestrenol.

*Selye G60,094/70:* In rats, the fatal hemorrhagic diathesis produced by phenindione is inhibited by ethylestrenol, CS-1, spironolactone, norbolethone and oxandrolone. Progesterone, hydroxydione, DOC, and estradiol have a much less pronounced effect. Prednisolone, triamcinolone, and thyroxine are inactive.

*Solymoss et al. G70,423/70:* In rats, pretreatment with spironolactone, norbolethone, or ethylestrenol enhances the disappearance

of bishydroxycoumarin from blood, and restores the prothrombin time. Triamcinolone and progesterone fail to do so. SKF 525-A increases the blood concentration and the anticoagulant effect of bishydroxycoumarin and counteracts the beneficial effect of ethylestrenol. Furthermore, pretreatment with spironolactone or ethylestrenol (but not with progesterone) enhances the NADPH-dependent enzymic decay of bishydroxycoumarin in liver microsomal + supernatant fraction.

*Szeberényi & Fekete H29,579/70:* Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone, meprobamate, estrone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

*Selye G70,480/71:* In rats, fatal intoxication with bishydroxycoumarin was beneficially influenced by pretreatment with various catatotoxic steroids or estradiol, *cf.* Table 28.

Hydroxydione	12/15 NS	9/15 **
Thyroxine	14/15 NS	14/15 NS
Phenobarbital	2/10 ***	1/10 ***

<sup>a</sup> The rats of all groups were given phenindione (10 mg/100 g body weight in 0.2 ml DMSO, s.c., daily from 4th day ff.).

<sup>b</sup> Intestinal hemorrhage was estimated on day of death and mortality listed on 8th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

*Selye G70,480/71*: In rats, warfarin (10 mg/100 g body weight in 1 ml water) was administered p.o. twice, from the 4th day of conditioning to the end of experiment. Mean survival was listed, and mortality registered on the 9th day. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication.

*Solymoss & Varga G70,500/71*: In rats, spironolactone, norbolethone and ethylestrenol diminish the anticoagulant action and accelerate the plasma clearance of bishydroxycoumarin. Progesterone and triamcinolone are devoid of this effect. SKF 525-A counteracts the influence of ethylestrenol upon bishydroxycoumarin metabolism. The hepatic microsomes of rats treated with spiro-

lactone or ethylestrenol in vivo accelerate bishydroxycoumarin degradation by NADPH-dependent enzymes in vitro.

Coumarin, 4-Methylcoumarin ← 1-7 Methyltestosterone: Feuer *H24,218/70*

### Antipyrine ←

*Remmer C73,857/58*: The oxidation of hexobarbital and the demethylation of methylaminoantipyrine by liver slices in vitro are inhibited by adrenalectomy performed 10–12 days before the experiment, unless the animals are given prednisolone substitution therapy. Addition of prednisolone to the incubation medium has no effect. The drug-metabolizing activity is contained in the microsome fraction and, in this respect, the microsomes of males are more active than those of females.

*Booth & Gillette D34,656/62*: Testosterone propionate, 19-nortestosterone, 4-androstene-3, 17-dione and 4-chloro-19-nortestosterone acetate (SKF 6611) were tested for their ability to induce hepatic microsomal enzymes in female rats. "All of the steroids produced 2- to 3-fold increases in the activity of the enzyme systems that metabolize hexobarbital, demethylate monomethyl-4-aminoantipyrine and hydroxylate naphthalene, but only 19-nortestosterone, testosterone propionate and methyltestosterone increased the activity of microsomal TPNH oxidase. . . . The increase in microsomal enzyme activity is more closely related to the anabolic activity than to the androgenic activity of the steroid."

### ANTU ← cf. 1-(1-Naphthyl)-2-thiourea under Thioureas

*Arsenic* ← cf. also *Selye C50,810/58*, p. 102.

*Agduhr G37,252/41*: In the mouse, sexual intercourse as well as some sex hormone preparations increase the storage of arsenic in the ground substance of various organs, especially the skin, whereas repeated pregnancies have an opposite effect, and at the same time augment resistance against intoxication with As<sub>2</sub>O<sub>3</sub>.

*Skanse A72,698/41*: Review on the effect of sex, sexual intercourse and gonadectomy upon the storage of arsenic in the tissues of mice.

*Beck B58,869/50*: In mice, adrenocortical extract protects against lethal doses of arsenious acid.

*Beck & Voloshin B58,271/50*: In mice, resistance to arsenite and other arsenicals is

increased by cortisone, adrenocortical extracts and ACTH.

*Beck B64,609/51*: "Prior administration of beef adrenal extract increased the resistance of mice, particularly male mice, to semi-lethal doses of arsenite, oxophenarsine and clorarsen. Male mice were protected against arsenite by cortisone and ACTH, but not by desoxy-corticosterone."

**Aspartate** ← *cf. GOT under Influence of Steroids upon Enzymes*

**Atophane** ← *cf. Cinchophen*

**Bacterial Toxins** ← *cf. Microorganisms, Vaccines and Parasites*

**Barbiturates** ←

← **Glucocorticoids.**

**RAT**

*Einhäuser A19,433/39*: Survival of rats after heavy intoxication with barbital can be improved by pretreatment with adrenocortical extract especially in combination with vitamin C. Synthetic corticosterone has no such protective effect.

*Fingl et al. D38,091/52*: In rats, chronic administration of phenobarbital or diphenylhydantoin diminishes the brain hyperexcitability induced by cortisone as judged by EST measurements.

*Robillard & Pellerin B75,692/52*: In rats, the anesthetic effect of pentobarbital is prolonged by adrenalectomy. This effect is inhibited by cortisone and enhanced by DOC. Cortisone also shortens sleeping time in intact or gonadectomized male rats.

*Robillard et al. G67,325/54*: Cortisone diminishes pentobarbital anesthesia in adult male rats. It also restores to normal the prolonged anesthetic effect of pentobarbital observed after adrenalectomy (with maintenance on 1% NaCl), orchidectomy, or simultaneous adrenalectomy + orchidectomy. Furthermore, cortisone decreases the length of pentobarbital anesthesia in ovariectomized rats, but this effect is blocked by estradiol treatment.

*de Boer & Mukomela C5,245/55*: In rats, ACTH and cortisone shorten thiopental and pentobarbital sleeping times, especially in females whose sleeping time is normally longer than that of males.

*Remmer G79,941/57*: In female rats, cortisone and prednisolone are much more efficacious than testosterone in shortening hexo-

barbital anesthesia and increasing microsomal hexobarbital metabolism. Adrenalectomy diminishes the capacity of hepatic microsomes of male rats to metabolize hexobarbital unless the animals are pretreated with cortisone or prednisolone.

*Heuser C54,451/58*: In the rat, large doses of cortisol, its succinate or acetate, prolong pentobarbital sleeping time when given simultaneously with the latter, but shorten it if the steroids are administered one day before the barbiturate.

*Remmer C73,857/58*: The oxidation of hexobarbital and the demethylation of methylaminoantipyrine by liver slices, in vitro, are inhibited by adrenalectomy performed 10–12 days before the experiment, unless the rats are given prednisolone substitution therapy. Addition of prednisolone to the incubation medium has no effect. The drug-metabolizing activity is contained in the microsomes fraction and, in this respect, the microsomes of males are more active than those of females.

*Remmer D86,728/58*: In rats, 3 days pretreatment with cortisone or prednisolone diminishes the anesthetic effect of hexobarbital, and increases the degradation of the anesthetic by liver slices. Adrenalectomy inhibits the degradation of hexobarbital by liver slices of male rats, an effect which can be counteracted by pretreatment with cortisone.

*Rupe et al. E26,910/63*: The sedative effect of hexobarbital and pentobarbital, yet not of barbital, was diminished by tourniquet stress, in the intact but not in the hypophysectomized or adrenalectomized rat. In intact rats, ACTH or cortisone decreases hexobarbital sleeping time as does stress, whereas SKF 525-A completely blocks the protective action of stress. Presumably "the stress effect on the duration of drug action is mediated through increased drug metabolism."

*Azarnoff et al. G42,999/66*: In the rat, pretreatment with DDD markedly shortens anesthesia produced by various steroids and barbiturates. Simultaneously, there is proliferation of the SER and a rise in the level of hepatic hexobarbital-metabolizing enzymes. In dogs, DDD decreases hexobarbital sleeping time, but prolongs pentobarbital anesthesia. Cortisone prevents the prolongation of pentobarbital sleep.

**MOUSE**

*Winter & Flataker B73,509/52*: Cortisone or ACTH, unlike DOC, shortens the sleeping

time of barbiturate anesthesia. The markedly prolonged sleeping time of mice receiving both barbiturates and diphenhydramine is also decreased by cortisone, but the effect of the steroid can be fully accounted for by its antagonism to the barbiturate.

*Gorby et al. B84,489/53:* Pretreatment with cortisol or DOC had little effect upon pentobarbital anesthesia in the mouse although cortisone offered slight protection and DOC had a feeble enhancing effect. Both corticoids increased the toxicity of phenobarbital.

*Komiya C7,045/55:* In mice, barbital anesthesia was decreased by cortisone, cortisol and ACTH, but not changed by DOC or "substance S." The barbital concentration of the brain approximately paralleled the depth of anesthesia.

*Komiya C8,533/55:* In mice, barbital sleeping time is decreased by cortisone, cortisol, and ACTH, but not affected by compound S (desoxocortisone) or DOC.

*Satoskar & Trivedi C8,678/55:* In mice, mortality after pentobarbital intoxication is increased by pretreatment with cortisol 2 hrs prior to the barbiturate.

*Komiya & Shibata C16,708/56:* In mice, the induction time of barbital anesthesia was not changed by cortisone, cortisol, substance S, or DOC. The duration of anesthesia was shortened, its depth diminished, and the barbital concentration of the brain decreased by cortisone, cortisol, or ACTH, but none of these parameters was affected by substance S or DOC. Apparently, the active hormones protect against anesthesia by decreasing the barbital concentration of the brain.

*Komiya et al. C21,326/56:* In mice, thiopental anesthesia was reduced in severity, but not in duration, by epinephrine. Barbital anesthesia was slightly reduced by norepinephrine, yet not by epinephrine. Unpublished experiments suggest that ACTH and glucocorticoids shorten the duration of barbital anesthesia in mice.

*Kostowski & Nowacka H26,526/70:* In mice, cortisol and methylprednisolone decrease hexobarbital sleeping time, whereas DOC prolongs it. Hydroxydione anesthesia is not changed by cortisol, but prolonged by methylprednisolone as well as by high doses of DOC.

#### RABBIT

*Komiya et al. D26,331/56:* In rabbits, barbital sodium anesthesia was not significantly influenced by cortisone.

*Shibata et al. C49,533/57:* In rabbits, barbital anesthesia is only moderately shortened by cortisone. The barbital concentration of the blood is not significantly influenced, whereas barbital elimination in the urine is markedly increased by cortisone.

#### MAN

*Fraser et al. B57,226/51:* In man, abstinence symptoms following discontinuation of various barbiturates or morphine are favorably influenced by cortisone.

*Dhuner & Nordqvist D98,693/57:* In 11 out of 13 patients who recovered from barbiturate poisoning, sleep was reinduced by cortisone treatment or i.v. injection of glucose.

#### VARIA

*Frommel et al. E37,967/62:* Pretreatment with cortisone prolongs phenobarbital anesthesia in the guinea pig and hexobarbital anesthesia in the mouse. It shortens thiopental anesthesia in rabbits.

**Barbiturates** ← Corticoids *cf. also Tables 30—34*

Hexobarbital ← Glucocorticoids + Sex: Remmer D86,728/58\*

Hexobarbital ← Cortisol + Phenobarbital: Lu et al. G68,802/69

Hexobarbital ← Prednisolone: Remmer C73,857/58

Pentobarbital ← Corticoids: Robillard et al. G67,325/54\*; Driever et al. G31,872/65\*

← **Gluc-Mineralocorticoids, Mineralocorticoids.** *Driever & Bousquet G31,872/65; Driever et al. F73,812/66:* In rats with tourniquet stress, the blood levels of hexobarbital, pentobarbital and meprobamate, but not of phenobarbital, were diminished after injection of the above drugs. These effects are prevented by hypophysectomy or adrenalectomy. Pentobarbital blood levels are lowered in adrenalectomized rats by corticosterone, but not by ACTH, whereas in hypophysectomized rats, both these hormones are active. "The ability of stress situations to stimulate drug metabolism and its dependence upon an intact pituitary-adrenal axis is suggestive of a regulatory function of the endocrine system in mediating a rapid induction of liver microsomal enzymes responsible for drug metabolism."

*Bousquet et al. F35,073/65:* In rats with stress produced by applying a tourniquet around one hind limb, for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate

and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection. [The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet, but this is not specifically stated. Allegedly, a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

*Kostowski & Nowacka H 26,526/70*: In mice, cortisol and methylprednisolone decrease hexobarbital sleeping time, whereas DOC prolongs it. Hydroxydione anesthesia is not changed by cortisol but prolonged by methylprednisolone, as well as by high doses of DOC.

Hexobarbital ← Corticosterone: Bousquet et al. F35,073/65\*

Pentobarbital ← Corticosterone + Hypophysectomy + Stress: Driever et al. G31,872/65\*

Thiopental ← DOC + Adrenalectomy: Eichholtz et al. B45,516/49\*

← Antimineralocorticoids. *Selye et al. G60,016/69*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide, or MgCl<sub>2</sub>.

*Selye G60,044/69*: Among various steroids tested for their ability to inhibit progesterone and pentobarbital anesthesia, all anabolic androgens were highly potent. However, since spironolactone exhibited the same anti-anesthetic effect, the latter could not be attributed to anabolic potency. "This inhibition of anesthesia is assumed to represent a special instance of the catatonic effect which appears to be a property of certain steroids, independent of their classic hormonal actions."

*Feller & Gerald H 22,744/70*: In male mice, pretreatment with spironolactone shortened pentobarbital and "testosterone-potentiated" pentobarbital sleeping times. It also increased liver microsomal protein, liver weight, aniline hydroxylation and ethylmorphine N-demethylation.

*Gerald & Feller G74,396/70*: In mice, spironolactone and its Δ<sup>6</sup> de-thioacetylated

metabolite reduce hexobarbital sleeping time and cause nearly identical increases in liver weight, microsomal protein content, NADPH-cytochrome c reductase, cytochrome P-450 content, and the N-demethylation of ethylmorphine. Preliminary observations suggest that these actions of spironolactone and its metabolite are evident in both sexes.

*Gerald & Feller G74,092/70*: In mice, pretreatment with spironolactone shortens pentobarbital sleeping time as well as "testosterone-potentiated pentobarbital sleeping time." Furthermore, spironolactone enhances the microsomal metabolism of aniline and ethylmorphine, and increases hepatic weight. It is concluded that the in vivo protective effect of spironolactone is due to the induction of hepatic microsomal enzymes.

*Gerald & Feller G78,804/70*: In mice, pretreatment with spironolactone reduces pentobarbital sleeping time and accelerates the hepatic microsomal metabolism of hexobarbital in vivo and in vitro.

*Selye et al. G60,050/70*: Aldadiene (SC-9376), aldadiene-kalium (SC-14266), spironolactone and CS-1 protect the rat against digitoxin intoxication as well as against the anesthetic effect of progesterone and pentobarbital. Spiroxasone, SC-8109 and SC-5233 fail to protect the rat both against digitoxin intoxication and the anesthetic effect of progesterone or pentobarbital.

*Stripp et al. H 22,743/70*: In rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Szeberényi & Fekete H29,579/70*: Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone, meprobamate, estrone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

*Gillette H34,126/71*: In male rats, spironolactone caused a relatively small increase in ethylmorphine N-demethylation and decreased the oxidation of hexobarbital and 3,4-benzpyrene. However (like in females), spironolactone did not affect the type I spectral changes induced in males by ethylmorphine and hexobarbital but caused a small decrease in cytochrome P-450 content and increased NADPH-cytochrome c reductase. Moreover, in males, spironolactone increased the substrate-dependent cytochrome P-450 reduction but not its endogenous reduction. The sex difference in the effect of spironolactone upon hepatic microsomal drug metabolism is illustrated by the tabulation of data concerning ethylmorphine and hexobarbital biotransformation.

*Stripp et al. G79,538/71*: In rats, the induction of hepatic microsomal enzymes by spironolactone "differed from the phenobarbital or methylcholanthrene induction in that it did not increase cytochrome P-450 content or microsomal protein. Furthermore the induction seemed to be sex dependent."

#### ← Testoids.

##### RAT

*Holck et al. 68,297/37*: Female rats are much more sensitive than males to anesthesia by various barbiturates. Orchidectomy diminishes barbiturate sensitivity, but not quite to the low level of normal females. Barbital anesthesia is not influenced by sex. Testosterone increases barbiturate resistance in normal or ovariectomized females, but not quite to the level of normal males.

*Holck et al. A8,011/37*: In rats, prolonged treatment with testoid extracts from human urine (unlike androsterone) shortens hexobarbital sleeping time in intact or ovariectomized females, but not quite to the male level.

*Kinsey A39,742/40*: Female rats sleep about twice as long as males when given either single or repeated injections of pentobarbital. Testosterone increases pentobarbital resistance in females. Ovariectomy diminishes the sleeping time.

*Holck & Mathieson 80,435/41*: Male rats were more resistant than females to the lethal effect of pentobarbital. Castration reduced the tendency to develop tolerance following repeated pentobarbital injections in males, but increased it in females. Testosterone pretreatment enhanced resistance in castrate males and intact females, but not in intact males.

*Robillard et al. B51,110/50*: Male rats are more resistant than females to the narcotic effect of pentobarbital. Gonadectomized rats of both sexes exhibit high pentobarbital resistance after treatment with testosterone, presumably as a consequence of accelerated hepatic detoxication of the barbiturates, since incubation of pentobarbital with liver slices of normal males or testosterone-treated castrates exhibit accelerated pentobarbital detoxication *in vitro*.

*Buchel G67,326/54*: Testosterone decreases hexobarbital sleeping time in adult, intact or ovariectomized female rats. Estradiol has an inverse effect in normal or castrate males. Indirect evidence suggests that the changes in hexobarbital sleeping time are associated with its reduced or prolonged presence in the body.

*Robillard et al. G67,325/54*: In rats adrenalectomized 5 days prior to phenobarbital treatment and maintained on 1% NaCl, anesthesia was prolonged. This effect could not be influenced by DOC, but was abolished by cortisone. Simultaneous orchidectomy does not further prolong pentobarbital anesthesia in adrenalectomized rats, but even in animals thus deprived of all steroids, cortisone greatly diminishes anesthesia, while testosterone has no influence upon it. Apparently, testosterone requires the presence of glucocorticoids, in order to be effective, whereas cortisone does not require the presence of testoids.

*Edgren C45,010/57*: Female rats are more sensitive than males to the anesthetic effect of hexobarbital. Gonadectomy prolongs hexobarbital sleeping time in males and shortens it in females. Estrone prolongs hexobarbital sleeping time in ovariectomized females, whereas testosterone is ineffective. In orchidectomized rats testosterone shortens hexobarbital sleeping time, while estrone is ineffective.

*Remmer G79,941/57*: In female rats, cortisone and prednisolone are much more efficacious than testosterone in shortening hexobarbital anesthesia and increasing microsomal hexobarbital metabolism. Adrenalectomy diminishes the capacity of hepatic

microsomes of male rats to metabolize hexobarbital unless the animals are pretreated with cortisone or prednisolone.

*Takabatake G76,713/57*: Male rats are more resistant than females or castrates of either sex, to the anesthetic effect of ethylhexobarbital. Testosterone raises the resistance of males and gonadectomized animals of either sex to the male level. In vitro studies on liver slices indicate that the sex difference is due to the effect of testosterone upon the barbiturate-metabolizing ability of the liver, not upon brain sensitivity.

*Quinn et al. E89,993/58*: In intact rats, estradiol prolonged the hexobarbital sleeping time and the elevation of the plasma level of this barbiturate, whereas the hepatic microsomal enzyme activity required to metabolize hexobarbital was considerably diminished. In all these respects, testosterone exerted an opposite effect in females.

*Booth & Gillette D34,656/62*: Testosterone propionate, 19-nortestosterone, 4-androstene-3, 17-dione and 4-chloro-19-nortestosterone acetate (SKF 6611) were tested for their ability to induce hepatic microsomal enzymes in female rats. "All of the steroids produced 2- to 3-fold increases in the activity of the enzyme systems that metabolize hexobarbital, demethylate monomethyl-4-aminoantipyrine and hydroxylate naphthalene, but only 19-nortestosterone, testosterone propionate and methyltestosterone increased the activity of microsomal TPNH oxidase. . . . The increase in microsomal enzyme activity is more closely related to the anabolic activity than to the androgenic activity of the steroid."

*Kato et al. G64,325/62*: Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect of OMPA is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids which enhance the decomposition of these substrates, the first three being inactivated, and the last activated in the process. The differences were also demonstrated in vitro, using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

*Takabatake & Ariyoshi D48,245/62*: The ability of rat liver slices to metabolize cyclo-barbital in vitro is uninfluenced by the addition of testosterone or estradiol.

*Rubin et al. F73,811/66*: Both testosterone and the antitestoid substance 17 $\alpha$ -methyl-B-nortestosterone (SK&F 7690) increase the hepatic microsomal hexobarbital oxidase activity in intact female rats. However, if the two compounds are administered conjointly, the effect is less pronounced than that obtained by testosterone alone. Apparently "a 'weak' enzyme inducer (SK&F 7690) may compete with a 'strong' inducer (testosterone) for occupation of a common receptor site for enzyme induction."

*Chang & Lei F78,943/67*: In female rats, 17 $\alpha$ -methyl-5 $\alpha$ -androstane-17 $\beta$ -ol shortens pentobarbital but not diethylbarbital sleeping time. Since the former barbiturate is — whereas the latter is not — metabolized by hepatic microsomes, the steroid is thought to act through the latter.

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, desoxycorticosterone, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital, and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide, or magnesium chloride.

*Solymoss et al. G60,054/69*: "In the rat, pretreatment with spironolactone, norbolethone or ethylestrenol increased the oxidation of pentobarbital by liver microsomes, enhanced its disappearance from blood and proportionally decreased the depth of anesthesia."

*Solymoss et al. G60,075/70*: In rats pretreated with spironolactone, norbolethone, or ethylestrenol, hexobarbital anesthesia was diminished and its aliphatic hydroxylation by hepatic microsomes enhanced. Pretreatment with the same steroids also accelerated N-dealkylation of aminopyrine by hepatic microsomes. Progesterone was inactive against hexobarbital, but slightly increased the production of 4-aminoantipyrine by hepatic microsomes.

*Selye PROT. 33876*: In rats, hexobarbital anesthesia is prolonged by orchidectomy and shortened by methyltestosterone both in intact and in orchidectomized animals. Progesterone significantly reduces the hexobarbital sleeping time in intact rats, but causes only a nonsignificant decrease in castrates. Estradiol prolongs hexobarbital anesthesia in intact and orchidectomized rats as compared with the corresponding controls.

## MOUSE

*Falk A337/36*: In mice, the anesthetic effect of certain barbiturates is inhibited by crude testicular extracts. [It is unlikely that these preparations antagonized barbiturates by virtue of their negligible testoid content (H.S.).]

*Westfall et al. F2,504/64*: Pentobarbital anesthesia is more prolonged in male than in female mice. Sleeping time in males is shortened by stilbestrol and, in females, prolonged by testosterone. Apparently, the mechanism for barbiturate detoxication is different in mice and rats.

*Novick Jr. et al. F63,768/66*: "Subcutaneous administration of several 19-nortestosterone derivatives produced an increased hepatic microsomal metabolism of hexobarbital and decreased zoxazolamine prostration time in mice. Testosterone and methyltestosterone produced an increased hexobarbital sleep time and testosterone decreased the rate of hepatic microsomal metabolism of hexobarbital. Although the ability of norethandrolone and SK&F 6612 (4-chloro-17 $\alpha$ -methyl-19-nortestosterone) to shorten hexobarbital sleep time occurs within 6 to 12 hr. after a single dose in mice, this effect of testosterone derivatives in rats occurs only after prolonged treatment."

*Roberts & Plaa G39,694/66*: In mice, hexobarbital sleeping time is shortened, and the in vivo metabolism of the barbiturate increased by pretreatment with norethandrolone.

## GUINEA PIG

*Brena & d'Agostino C11,921/54*: In guinea pigs, orchidectomy prolongs thiopental sleeping time; testosterone diminishes it, both in castrate and in intact males.

## VARIA

*Quinn et al. G67,327/54*: The biologic half-life of hexobarbital was found to be 15 min for mice, 60 min for rabbits, 140 min for rats, and 260 min for dogs and man. There was an inverse relationship between the rate of biotransformation of hexobarbital to keto-hexobarbital and the duration of its hypnotic effect. Male rats are more resistant to hexobarbital anesthesia than females, but in the latter, resistance, as well as the enzyme activity of the microsomes, was increased by testosterone.

*Selye G60,044/69*: Among various steroids tested for their ability to inhibit progesterone

and pentobarbital anesthesia, all anabolic androgens were highly potent. However, since spironolactone exhibited the same anti-anesthetic effect, the latter could not be attributed to anabolic potency. "This inhibition of anesthesia is assumed to represent a special instance of the catatoxic effect which appears to be a property of certain steroids, independent of their classic hormonal actions."

← **Luteoids**. *Pellerin et al. B98,672/54*: Testosterone reduces the duration of pentobarbital anesthesia in castrate male or female rats, and concomitantly increases the degradation of pentobarbital by the liver. Estradiol prolongs the duration of anesthesia and proportionally lowers the rate of pentobarbital destruction by the liver. Progesterone diminishes the pentobarbital resistance of the ovariectomized rats and synergizes estradiol. Testosterone almost entirely neutralizes the action of estradiol but is less active against progesterone.

*Blackham & Spencer G69,913/69*: Mestranol (a folliculoid) prolonged, while lynestrenol (a luteoid) reduced the duration of pentobarbital and hexobarbital sleep in mice. Barbital was not affected. The action of lynestrenol was counteracted by SKF 525-A, while that of mestranol was markedly potentiated. Lynestrenol increased, whereas mestranol and SKF 525-A reduced the rate of clearance of barbiturates from the plasma.

*Jori et al. H17,070/69*: In rats, "two hours after norethynodrel (50 mg/kg, oral) the sleeping time produced by pentobarbital was prolonged due to an increase in the level of brain pentobarbital. Medroxyprogesterone

(10 mg/kg) either alone or combined with ethynylestradiol (0.018 mg/kg) and norethynodrel (10 mg/kg) combined with mestranol (0.018 mg/kg) given orally for 30 days decreased the level of brain pentobarbital without affecting pentobarbital narcosis. Medroxyprogesterone alone or combined with ethynylestradiol in the same experimental conditions increased the metabolism of p-nitroanisol, aminopyrine and aniline in vitro (liver 9000 X g supernatant)."

*Rümke & Noordhoek G76,850/69:* In mice, phenobarbital and phenytoin exert an anti-convulsant effect against electroshock and bemegride shock, if administered 24 hrs previously. Lynestrenol given 2 days before the anticonvulsants diminishes the effect of the latter, although it does not affect the actions of the convulsive agents given alone.

*Rümke & Noordhoek H14,039/69:* Lynestrenol (a luteoid) decreases the hexobarbital sleeping time, and diminishes the anti-convulsant effect of phenobarbital and diphenylhydantoin, by accelerating their metabolisms through the hepatic microsomal enzymes.

*Blackham & Spencer G73,813/70:* In mice, lynestrenol reduced, whereas mestranol or SKF 525-A increased the anticonvulsive effect (tested with electroshock) of diphenylhydantoin, phenobarbital, chlorthalidoxepoxide and diazepam administered i.p. after five days of pretreatment. This may be due to altered microsomal drug metabolism, but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentrations, the latter mechanism must also be considered.

*Solymoss et al. G60,075/70:* In rats pretreated with spironolactone, norbolethone, or ethylestrenol, hexobarbital anesthesia was diminished, and its aliphatic hydroxylation by hepatic microsomes enhanced. Pretreatment with the same steroids also accelerated N-dealkylation of aminopyrine by hepatic microsomes. Progesterone was inactive against hexobarbital, but slightly increased the production of 4-aminoantipyrine by hepatic microsomes.

*Selye PROT. 33876:* In rats, hexobarbital anesthesia is prolonged by orchidectomy and shortened by methyltestosterone both in intact and in orchidectomized animals. Progesterone significantly reduces the hexobarbital sleeping time in intact rats, but causes only a nonsignificant decrease in castrates. Estradiol prolongs hexobarbital anesthesia in

intact and orchidectomized rats as compared with the corresponding controls.

Phenobarbital ← Lynestrenol, Mouse: Blackham et al. *G73,813/70\**

← **Folliculoids.** *Störtebecker A1,993/37:* Rabbits pretreated with "folliculin" tolerate normally anesthesia-producing doses of butallylonal (Pernocton). Subsequent experiments were conducted to determine the blood ether level during ether anesthesia, at the time the corneal reflex is lost in intact and gonadectomized rabbits and mice. Similar observations were made during pregnancy, and in relation to the estrous cycle. [Several conclusions were drawn suggesting an influence of sex hormones upon anesthesia, but the number of animals per group was small and hence a statistical evaluation was impossible (H.S.).]

*Horinaga A36,414/41:* Male rats are more resistant to barbiturate anesthesia than females. Orchidectomy and treatment with folliculoids increase sensitivity, whereas ovariectomy does not affect it.

*Holck et al. A55,755/42:* Estradiol did not markedly influence the reaction of female rats to hexobarbital, but it increased sleeping time in males. Testosterone shortened barbiturate anesthesia in female rats, but not in male rats or female mice.

*Donatelli B38,172/47:* Systematic studies on the effect of folliculoids and testoids upon barbiturate anesthesia in the guinea pig, mouse and rabbit.

*Robillard et al. G67,325/54:* Cortisone diminishes pentobarbital anesthesia in adult male rats. It also restores to normal the prolonged anesthetic effect of pentobarbital observed after adrenalectomy (with maintenance on 1% NaCl), orchidectomy, or simultaneous adrenalectomy + orchidectomy. Furthermore, cortisone decreases the length of pentobarbital anesthesia in ovariectomized rats, but this effect is blocked by estradiol treatment.

*Brodie C12,157/56:* The hexobarbital sleeping time of female rats is about four times that of males; correspondingly, the plasma levels of hexobarbital drop faster in males,

whose hepatic microsomes in vitro also inactivate the drug more actively than those of females. Male rats, pretreated with estradiol, sleep as long as females, and their hepatic microsomes lose much of their activity to metabolize hexobarbitone. Females, pretreated with testosterone, assume the characteristics of males in all these respects. No sex differences were seen in mice, guinea pigs, rabbits and dogs, and their ability to handle hexobarbital is not influenced by estradiol or testosterone.

*Quinn et al. E89,993/58*: In intact rats, estradiol prolonged the hexobarbital sleeping time and the elevation of the plasma level of this barbiturate, whereas the hepatic microsomal enzyme activity required to metabolize hexobarbital was considerably diminished. In all these respects, testosterone exerted an opposite effect in females.

*Westfall et al. F2,504/64*: Pentobarbital anesthesia is more prolonged in male than in female mice. Sleeping time in males is shortened by stilbestrol and, in females, prolonged by testosterone. Apparently, the mechanism for barbiturate detoxication is different in mice versus rats.

*Gessner et al. F77,776/67*: In mice, "testosterone pretreatment produces a biphasic effect on the duration of action of hexobarbital, prolonging the action initially and shortening the action in 4—8 days after the pretreatment. The early action of testosterone appears to be associated with an effect on the hypnotic property of a drug, since both hexobarbital and barbital sleep times are prolonged while the duration of action of the muscle relaxant chlorzoxasone remains unaffected. The long-term pretreatment with testosterone leads to a shorter duration of action of drugs that are deactivated by detoxification, notably hexobarbital and chlorzoxasone, but has no effect on the duration of hypnosis produced by barbital, a drug which is predominantly eliminated unchanged." Folliculoids (ethinylestradiol, diethylstilbestrol) prolong the action of both drugs.

*Ganesan H12,504/69*: Male rats are more resistant than females to pentobarbital anesthesia. Orchidectomy or treatment with estradiol decreases the pentobarbital resistance of male rats.

*Selye PROT. 33876*: In rats, hexobarbital anesthesia is prolonged by orchidectomy and shortened by methyltestosterone both in intact and in orchidectomized animals. Progesterone significantly reduces the hexobar-

bital sleeping time in intact rats, but causes only a nonsignificant decrease in castrates. Estradiol prolongs hexobarbital anesthesia in intact and orchidectomized rats as compared with the corresponding controls.

#### ← Adrenalectomy.

##### RAT

*Sindram 52,504/35*: In rats, pretreatment with adrenocortical extract ("Cortin") increases resistance to urethan anesthesia. Adrenalectomy has an inverse effect but Cortin shortens urethan anesthesia even in the absence of the adrenals. Tribromoethanol sleeping time is likewise shortened by adrenocortical extract in intact rats.

*Eichholtz et al. B45,516/49*: Adrenalectomy greatly prolongs the tribromoethanol and thiopental sleeping time in rats. In both instances, the sleeping time could be shortened again, if adrenalectomized rats were treated with desoxycorticosterone or adrenocortical extract.

*Maloney et al. E48,771/52*: The pentobarbital sleeping time is greatly increased after adrenalectomy in rats of both sexes, males being more resistant than females. Vitamin C lengthened the sleeping time in both intact and adrenalectomized animals. Cortisone shortened the sleeping time of adrenalectomized, but lengthened that of intact animals. DOC diminished sleeping time more markedly in females than in males. [This brief abstract gives, as the authors themselves are careful to point out, "somewhat of a confused picture" (H.S.).]

*Tureman et al. B80,379/52*: In rats, adrenalectomy increases susceptibility to the

depressant action of pentobarbital. "Cortisone decreases somewhat this susceptibility. The concentration of pentobarbital in the tissues seems to have no significant relationship to the sleeping time."

*Robillard et al. G67,325/54:* In rats adrenalectomized 5 days prior to phenobarbital treatment, and maintained on 1% NaCl, anesthesia was prolonged. This effect could not be influenced by DOC, but it was abolished by cortisone. Simultaneous orchidectomy did not further prolong pentobarbital anesthesia in adrenalectomized rats, but even in animals thus deprived of all steroids, cortisone greatly diminished anesthesia, whereas testosterone had no effect upon it. Apparently, testosterone requires the presence of glucocorticoids in order to be effective, whereas cortisone does not require the presence of testoids.

*Remmer G79,941/57:* In female rats, cortisone and prednisolone are much more efficacious than testosterone in shortening hexobarbital anesthesia and increasing microsomal hexobarbital metabolism. Adrenalectomy diminishes the capacity of hepatic microsomes of male rats to metabolize hexobarbital unless the animals are pretreated with cortisone or prednisolone.

*Remmer D86,728/58:* In rats, 3 days pretreatment with cortisone or prednisolone diminishes the anesthetic effect of hexobarbital and increases the degradation of the anesthetic by liver slices. Adrenalectomy inhibits the degradation of hexobarbital by liver slices of male rats, an effect which can be counteracted by pretreatment with cortisone.

*Remmer E52,112/59:* In rats, the oxidation of hexobarbital and the demethylation of methylaminoantipyrine by hepatic microsomes is accelerated after pretreatment with phenobarbital even in the absence of the adrenals.

*Kato E87,340/60:* Chlorpromazine pretreatment reduces barbiturate sleeping time even in adrenalectomized or immature rats.

*Markova D49,769/60:* In adult, but not in one month old rats, adrenalectomy greatly prolongs hexobarbital anesthesia. In intact animals, ACTH has an inverse effect.

*Conney et al. D52,543/61:* Pretreatment of male rats with chlorcyclizine shortened the duration of action and increased the hepatic microsomal metabolism of hexobarbital, pentobarbital and zoxazolamine. These effects were not prevented by hypophysectomy or adrenalectomy combined with castration.

*Rupe et al. E26,910/63:* In rats, stress produced by placing a tourniquet on one hind leg decreases the pharmacologic response to hexobarbital, meprobamate and pentobarbital. This effect is prevented by hypophysectomy or adrenalectomy, but simulated by ACTH or corticosterone. No such effect on stress was noted with barbital, a compound not metabolized by hepatic microsomal enzymes. Furthermore, the protective effect of stress is counteracted by SKF 525-A. Apparently, the "pituitary-adrenal activity exerts a regulating influence on drug responses."

*Nichol & Rosen F4,729/64:* In the rat, adrenalectomy prolongs hexobarbital sleeping time. Pretreatment of adrenalectomized rats with cortisol or DOC shortens the sleeping time.

*Bousquet et al. F35,073/65:* In rats, stressed by application of a tourniquet to one hind leg, the duration of response to hexobarbital, pentobarbital, meprobamate and zoxazolamine is significantly reduced, but only in the presence of both the pituitary and the adrenal glands. Pretreatment with ACTH or corticosterone simulates the effects of stress in shortening hexobarbital anesthesia. "It is suggested that the pituitary-adrenal axis serves a regulatory function with respect to duration of drug responses which may be mediated by an alteration of drug metabolism."

*Radzialowski & Bousquet G53,591/67:* In rats of both sexes, the diurnal variation in the aminopyrine-, p-nitroanisole- and hexobarbital-metabolizing activity of hepatic microsomes is abolished by adrenalectomy.

*Furner & Stitzel G54,558/68:* The hepatic microsomal metabolism of ethylmorphine, aniline and hexobarbital is diminished in vitro by previous adrenalectomy in the rat. Phenobarbital pretreatment of adrenalectomized rats raises the metabolism of all three substrates above the level characteristic of untreated, adrenalectomized controls. Exposure of adrenalectomized rats to cold stress, or treatment with cortisol increases the metabolism of aniline and ethylmorphine, but further depresses that of hexobarbital. In intact rats, cold stress diminishes hexobarbital metabolism in vitro. Apparently, both stress and phenobarbital can bring about changes in hepatic drug metabolism, independent of the presence of the adrenals; the two agents act through different mechanisms, since phenobarbital invariably stimulates, whereas stress either increases or de-

creases microsomal enzyme activity depending upon the drug pathway examined.

*Nakanishi et al. G79,299/70*: "Cold exposure or immobilization of intact or adrenalectomized rats significantly impaired side-chain oxidation of hexobarbital and N-demethylation of aminopyrine in vitro. In contrast, p-hydroxylation of aniline in vitro was not affected under stress conditions." The pertinent literature is somewhat contradictory but, possibly, the effect of stress on drug-metabolizing enzyme induction may vary with the substrate employed.

*Sethy et al. G77,511/70*: In rats, pentobarbital sleeping time is reduced immediately after stress (centrifugation), but returns to normal eight hours later. In adrenalectomized animals, this effect of stress is abolished.

*Selye PROT. 28922, 28985, 28996*: In adrenalectomized rats maintained on NaCl, 4 days pretreatment with spironolactone (10 mg in 1 ml water p.o. x2/day) offers definite resistance to pentobarbital (3 mg in 0.5 ml oil i.p.) and hexobarbital (7.5 mg in 1 ml water i.p.), but not to phenobarbital (10 mg in 1 ml water i.p.), although all these anesthetics give approximately equal degrees of anesthesia in rats not pretreated with spironolactone. Smaller doses of spironolactone were less effective, or ineffective even against pentobarbital and hexobarbital under these conditions.

#### MOUSE

*Richards 79,646/41*: "The increase in toxicity of pentothal sodium for mice after temperature is raised from 22—30 or 35 degrees is relatively small. However, if metabolic regulation is disturbed by adrenalectomy, an increased susceptibility is observed which becomes particularly marked at higher temperatures."

*Shibata & Komiya B88,660/53*: In the mouse, thiopental anesthesia is prolonged by adrenalectomy, but resistance is restored by cortisone or cortisol. DOC has no effect.

*Komiya & Shibata C13,129/56*: In the mouse, adrenalectomy intensifies barbital anesthesia. Cortisone and cortisol restore anesthesia time to normal; whereas DOC has little effect upon it, although it offers some protection against anesthetic death. Pretreatment of adrenalectomized mice with cortisone or cortisol reduces the high rate of barbital uptake by the brain to normal. DOC has no effect upon cerebral barbital uptake or discharge. Apparently, "the abnormal anesthetic

course is elicited by abnormal concentration of barbiturate in the brain, both of which are restored to the normal by glucocorticoid administration."

#### GUINEA PIG

*Lamson et al. B89,712/52*: In guinea pigs, epinephrine, when injected i.p. on awakening from barbiturate anesthesia, produced a return to sleep. A similar effect was produced by glucose, lactate, or glutamate. However, in adrenalectomized animals, only epinephrine was effective.

##### RAT

*Barron A42,858/33*: Male rats are more resistant than females to amobarbital anesthesia. Castration increases the sensitivity of the male, but not quite to the female level. Castration before puberty does not diminish resistance. Ancillary experiments suggest that the effect of castration is due to changes in water metabolism.

*Holck et al. A8,014/37*: In rats, orchidectomy prolongs the sleeping time of those barbiturates to which males are normally more resistant. Orchidectomy does not lengthen the hexobarbital sleeping time in rabbits. In female rats, neither ovariectomy nor the estrus cycle influences hexobarbital sleeping time.

*Moir E54,544/37*: Very young female rats were more resistant to pentobarbital than males, whereas the reverse was true in mature rats. Both males and females developed tolerance to pentobarbital upon repeated injections, but when treatment was interrupted and then resumed, susceptibility was greatly increased in females and castrate males, but not in intact males. "Inasmuch as the castrated males still remained more resistant than females, the superior resistance of the males was held to be due at least in part to some factor or factors other than the male gonads."

*Cameron A 34,503/39*: In rats, ovariectomy greatly increases sensitivity to the anesthetic and lethal effect of pentobarbital.

*Holck & Mathieson B 644/44*: In rats, the development of tolerance to pentobarbital was determined by injecting increasing doses every 90 min day and night for periods up to 5 days. Practically all 1—2 month-old rats developed tolerance, as did adult males in contrast to females. Castration lowered the ability of adult males to develop tolerance, but did not do so in 2 month-old males. Ovariectomy of 2 month-old females increased their ability to detoxify pentobarbital, once tolerance had developed.

*Cameron et al. B 45,221/48*: In rats, orchidectomy diminishes tolerance for quick acting barbiturates such as pentobarbital sodium, but not for the slow acting barbital sodium. Testosterone improves the tolerance of gonadectomized males.

*de Boer A 48,817/48*: Pentobarbital hypnosis was prolonged in ovariectomized rats for a period of 3—16 weeks, but was reduced 12 months after spaying. Castration of males prolonged sleeping time. Thiamine decreased pentobarbital sleeping time in ovariectomized rats towards the normal level.

*Crevier et al. B 54,151/50*: Pentobarbital anesthesia lasts longer in female than in male rats as judged by the linguo-maxillary reflex. Castration abolishes the high resistance of the male, but testosterone restores it to the normal level. In ovariectomized rats, estradiol has virtually no effect, but testosterone raises resistance to the male level. These in vivo effects run parallel to the in vitro pentobarbital detoxifying power of the liver.

*Robillard et al. B 66,661/51*: In rats, thyroidectomy prolongs pentobarbital anesthesia and delays hepatic detoxication of the drug, whereas thyroxine pretreatment diminishes the duration and depth of this anesthesia without enhancing the hepatic detoxication of pentobarbital as determined by incubation of the drug with liver slices. After simultaneous thyroidectomy and orchidectomy, pentobarbital detoxication is more markedly delayed than after simple thyroidectomy or orchidectomy, and the anesthetic effect is correspondingly further intensified than after ablation of the thyroid or testes alone.

*Grewe D 35,140/53*: Male rats are more resistant than females to barbiturate (eunarccon, hexobarbital) anesthesia. After gonadectomy, both sexes exhibit the longer sleeping time characteristic of females. Twenty-eight

days after orchidectomy, the sleeping time is reduced to the level seen in intact males. Testosterone prolongs the sleeping time of females.

*Buchel D 73,669/54*: Review on the literature, and personal observations on the increased sleeping time of female as compared to male rats, after treatment with certain barbiturates, particularly hexobarbital. The increased sleeping time is associated with a prolonged persistence of the concentration of the drug in the blood. Gonadectomy prolongs the sleeping time of males but does not influence that of females. In immature rats no such sex difference is observed.

*Buchel G 67,326/54*: Testosterone decreases hexobarbital sleeping time in adult, intact or ovariectomized female rats. Estradiol has an inverse effect in normal or castrate males. Indirect evidence suggests that the changes in hexobarbital sleeping time are associated with its reduced or prolonged presence in the body.

*Robillard et al. G 67,325/54*: Adult males are more resistant than females to pentobarbital anesthesia. Castration decreases the resistance in males. Testosterone raises pentobarbital resistance to the normal male level in both male and female castrates, whereas estradiol and progesterone prolong anesthesia in castrates of both sexes. [The hormones were administered as pellets, 15 days before the test, but the amounts are not stated (H.S.).] Partial hepatectomy prolongs pentobarbital anesthesia and accentuates the differences induced by the various interventions just mentioned, without causing qualitative changes in the outcome. Liver homogenates of adult male rats destroy pentobarbital in vitro (spectrophotometric determination) more rapidly than those of castrate males. Pretreatment of the castrates in vivo with testosterone increases the detoxication process, whereas estradiol pretreatment has an opposite effect.

*Takabatake G 76,713/57*: Male rats are more resistant than females or castrates of either sex, to the anesthetic effect of ethylhexabital. Testosterone raises the resistance of females and gonadectomized animals of either sex to the male level. In vitro studies on liver slices indicate that the sex difference is due to the effect of testosterone upon the barbiturate-metabolizing ability of the liver, not upon brain sensitivity.

*Kato et al. G 64,325/62*: Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect

of OMPA is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids that enhance the decomposition of these substrates, the first three of which being inactivated, and the last activated in the process. The differences were also demonstrated *in vitro*, using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

*Kato & Gillette F57,816/65*: The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females, but the sex difference varies with the substrate. There is more than a 3-fold sex difference with aminopyrine and hexobarbital, but virtually none with hydroxylation of aniline and zoxazolamine. In male rats, starvation impairs sex-dependent enzymes which metabolize aminopyrine and hexobarbital, but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as of aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital; it enhances that of aminopyrine by microsomes of castrated rats, but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Kato & Gillette F57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Hempel G57,828/68*: Cyproterone acetate shortens hexobarbital anesthesia in the rat, probably through enhanced hepatic microsomal enzyme activity. This effect is evident both in intact and in gonadectomized rats. Orchidectomy prolongs hexobarbital sleeping time, and subsequent testosterone treatment shortens it. It is emphasized that, under the conditions of this experiment, cyproterone failed to inhibit the anti-anesthetic effect of

testosterone and, unexpectedly, shared this very action of the testoid substance.

*Selye PROT. 33876*: In rats, hexobarbital anesthesia is prolonged by orchidectomy, and shortened by methyltestosterone (both in intact and orchidectomized animals). Progesterone significantly reduces the hexobarbital sleeping time in intact rats, but causes only a nonsignificant decrease in castrates. Estradiol prolongs hexobarbital anesthesia in intact and orchidectomized rats as compared with the corresponding controls, *cf.* Table 30.

Table 30. *Effect of orchidectomy upon hexobarbital anesthesia in intact and orchidectomized rats with or without steroid pretreatment*

Pretreatment <sup>a</sup>	Sleeping time (min) b	
	Intact	Castrate
None	35 ± 3	48 ± 5 *
PCN	32 ± 4 NS	38 ± 4 NS
Estradiol	50 ± 5 *	70 ± 6 *
Progesterone	18 ± 4 **	35 ± 6 NS
Methyltestosterone	13 ± 3 ***	23 ± 5 **

<sup>a</sup> The rats (140 g♂) of all groups received hexobarbital 10 mg/100 g body weight in 1 ml water, *i.p.* once, on the 12th day. The groups so designated were castrated on the 1st day. Estradiol 1 mg, and other steroids 10 mg/100 g body weight were given in 1 ml water, *p.o.* x2/day, on the 9th day *ff.* On the 12th day, the steroids were administered 1 hr before hexobarbital.

<sup>b</sup> The significance of the apparent differences in sleeping time is calculated for the untreated rats between the intact and the castrates, and for all other groups between unpretreated and the steroid pretreated animals of corresponding gonadal status (intact or castrate). (Student's *t*-test.)

For further details on technique of tabulation *cf.* p. VIII.

#### MOUSE

*Hempel F84,763/67*: Hexobarbital anesthesia lasts longer in mature male than in female mice. Orchidectomy decreases sleeping time, whereas ovariectomy does not affect it. Testosterone prolongs the hexobarbital sleeping time in orchidectomized males, as well as ovariectomized or normal female mice. This effect is blocked by the antitestoid, cyproterone. By itself, cyproterone shortens the sleeping time in mice under all circumstances.

In rats, hexobarbital sleeping time is shorter among males than among females, and prolonged by orchidectomy, whereas ovariectomy does not affect it. Testosterone shortens hexobarbital sleeping time in females and in castrate rats of both sexes. This effect is not inhibited by cyproterone which in itself shortens sleeping time in the rat also.

*Rümke G71,098/68*: In mice of the CPB-N strain, hexobarbital anesthesia lasts longer in males than in females, but only after puberty. Following gonadectomy of mature animals, the sex difference persists for about 2 weeks, but then disappears.

*Noordhoek & Rümke H21,660/69*: In mice, the 9000 g liver supernatant of females hydroxylates hexobarbital faster than that of males. After orchidectomy, the in vitro metabolism of hexobarbital becomes equal to that of females, but ovariectomy has no effect upon it. Testosterone decreases the rate of in vitro hexobarbital hydroxylation in females, but not in males. Female livers contain more cytochrome P-450 and testosterone lowers its concentration in female but not in male livers.

*Rümke & Noordhoek H21,659/69*: Among mice of many strains, hexobarbital produces longer anesthesia in males than in females. This difference is evident only after sexual maturation. If 10 week old males are castrated, the difference persists for at least 2 weeks, but it disappears after a month. Ovariectomy has no effect upon sleeping time, whereas testosterone increases it in females but not in males.

#### GUINEA PIG

*Störtebecker 76,398/39*: In mature female guinea pigs, ovariectomy diminishes barbiturate (butallylonal, Pernocton) anesthesia.

*Brena & d'Agostino C11,921/54*: In guinea pigs, orchidectomy prolongs thiopental sleeping time; testosterone diminishes it, both in castrate and in intact males.

Amobarbital Sodium ← Orchidectomy + Age: *Barron A42,858/33\**

Butallylonal ← Gonadectomy: *Holck et al. A55,846/36\**; *Störtebecker 76,398/39\**

Hexobarbital ← Gonadectomy: *Buchel G67,326/54\**; *Kramer et al. G75,673/59\**; *Kato et al. F57,817/67*; *Schenkman et al. G67,777/67*

Pentobarbital ← Gonadectomy: *Moir E54,544/37\**; *Cameron A34,503/39\**; *Holck et al. A55,755/42\**, *B644/44\**; *Gaylord*

*et al. B11,425/44\**; *BoerA48,817/48\**; *Cameron et al. B45,221/48\**; *Crevier et al. B54,151/50\**; *Robillard et al. G67,325/54\**

← *Varia. Kato E60,785/59*: In rats, pretreatment with various substances such as phenaglycodol, thiopental, phenobarbital, glutethimide, meprobamate, etc. diminishes pentobarbital sleeping time, whereas hydroxydione does not exert a significant effect upon it.

*Rümke G69,768/63*: In mice SKF 525-A, phenobarbital, chlorpromazine, hexobarbital and iproniazid given one hour before hydroxydione i.v. increases sleeping time. When the interval is two days, single doses of SKF 525-A, phenobarbital or chlorpromazine decrease hydroxydione anesthesia. Phenytoin, acetylcarbromal, morphine, chloramphenicol, 5-HT, phenobarbital and hydroxydione, given one hour before hexobarbital, increase the duration of anesthesia, whereas dioxone and chlorothiazide decrease it.

*Overbeek & Bonta E4,775/64*: Several azaestrans (in which C<sub>4</sub> is replaced by nitrogen) shorten the duration of anesthesia when given to mice 24 hrs before hexobarbital. They have an opposite effect when given 1 hour before the anesthetic. One of the compounds of this series, 17 $\alpha$ -methyl-17 $\beta$ -hydroxy-4-azaestrans-3-one, was also shown to diminish the hexobarbital concentration in the brain and carcass of mice, in comparison with unpretreated controls. These steroids are presumed to "exert their antidepressant effect by augmenting the elimination of the anesthetics both from the brain and from the whole carcass, as shown for hexobarbital. So far we do not know by what mechanism of action this is achieved." [No technical details are given and since several of the structure formulas are misprinted, the text is difficult to evaluate (H.S.).]

*Bonta & Overbeek E5,494/65*: In mice, 17 $\alpha$ -methyl-17 $\beta$ -hydroxy-4-azaestrans-3-one shortens the duration of hexobarbital anesthesia.

*Hempel G57,828/68*: In orchidectomized rats, the hexobarbital sleeping time is prolonged. Testosterone shortens it, but this effect of the male hormone is not inhibited by cyproterone. Indeed, the latter, in itself, actually shares the anti-anesthetic effect of testosterone.

*Kalyanpur et al. F99,270/68*: DOC, 4-chlorotestosterone, aldosterone and stilbestrol significantly decreased pentobarbital sleeping time in rats when given as a single injection,

30 min before the anesthetic. **Progesterone** has an inverse effect. Chronic pretreatment with progesterone, stilbestrol or aldosterone markedly decreased pentobarbital sleeping time without causing any significant change in brain pentobarbital levels.

*Tephly & Mannering G53,874/68:* **Estradiol, testosterone, androsterone, progesterone** and **cortisol** inhibit competitively the oxidation of ethylmorphine and hexobarbital, when added in vitro to hepatic microsomes of rats. The inhibitor constant for each steroid was the same, whether ethylmorphine or hexobarbital served as substrates. "Results are consistent with the concept that certain drugs and steroids are alternative substrates for a common microsomal mixed function oxidase system." The steroids were less potent inhibitors of chlorpromazine oxidation and the inhibition was not competitive in this case.

*Solyoss et al. G60,054/69:* "In the rat, pretreatment with **spironolactone, norbolethone** or **ethylestrenol** increased the oxidation of pentobarbital by liver microsomes, enhanced its disappearance from blood and proportionally decreased the depth of anesthesia."

*Selye et al. G60,050/70:* SC-8109 and SC-5233 fail to protect the rat against digitoxin intoxication and the anesthetic effect of progesterone or pentobarbital.

*Solyoss et al. G60,099/70:* In rats, pentobarbital anesthesia is inhibited by **spironolactone, ethylestrenol, norbolethone** and, to a lesser extent, even by **progesterone**. These catatoxic steroids also accelerate the disappearance rate of barbiturate from the blood; their effects are counteracted by SKF 525-A. Irrespective of the steroid pretreatment, the rats awake roughly at the same blood pentobarbital level.

*Selye G70,480/71:* In rats, **thiopental** sleeping time is significantly shortened by PCN, CS-1, ethylestrenol, spironolactone, oxandrolone and prednisolone. However, even cholesterol appears to provide a barely significant protection, cf. Table 31.

*Selye G70,480/71:* In rats, **hexobarbital** sleeping time is significantly shortened by all classic catatoxic steroids, prednisolone and phenobarbital. Triamcinolone and estradiol offer barely significant protection, cf. Table 32.

For further details on technique of tabulation cf. p. VIII.

*Selye G70,480/71:* In rats, barbital anesthesia was not significantly shortened by any of the classic catatoxic steroids and, in fact, may have been slightly prolonged by CS-1 and norbolethone. Estradiol and DOC prolonged barbital anesthesia and the same was true of hydroxydione and phenobarbital, but since the latter have strong hypnotic effects themselves, the apparent potentiation of barbital anesthesia may have been merely due to a summation of effects, cf. Table 34.

*Solymoss et al. G79,015/71:* In rats, PCN (unlike the naturally-occurring pregnenolone) enhances the plasma clearance of pentobarbital and the production of <sup>14</sup>C-pentobarbital metabolites. It also increases liver weight, microsomal protein concentration, NADPH-cytochrome c-reductase activity and cytochrome P-450 content. It is concluded "that microsomal enzyme-induction accounts for the remarkable resistance-increasing effect of this steroid against many toxicants."

*Szabo et al. G79,024/71:* In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

*Selye PROT. 31367,31380:* In the mouse, the duration of pentobarbital anesthesia is shortened by ethylestrenol, CS-1, spironolactone and norbolethone, but not significantly by oxandrolone, prednisolone, progesterone, triamcinolone, DOC, hydroxydione, estradiol, or thyroxine.

For further details on technique of tabulation cf. p. VIII.

Hexobarbitol ← Hydroxydione,  
Mouse: Rümke G69,768/63\*

Pentobarbitol ← Hydroxydione:  
Kato E60,785/59\*

Bemegride ← Lynestrenol: Rümke  
et al. G76,850/69\*, H14,039/69\*

#### Benzene ←

*Hirokawa G71,106/55:* Female rabbits are more sensitive to chronic benzene poisoning than males. Gonadectomized estradiol-treated males respond like females.

Benzphetamine ← Cortisol + Phenobarbitol: Lu et al. G68,802/69

**Benzpyrene ← cf. Carcinogens****Beryllium ←**

*Kline et al. B65,488/51:* In patients with beryllium granulomatosis, ACTH and cortisone were found to be beneficial.

**Bilirubin ← cf. also  $\alpha$ -Naphthylisothiocyanate (ANIT)**

*Hargreaves & Lathe G81,289/63:* In vitro, addition of norethandrolone to the incubation medium of rat liver slices increased the bilirubin accumulation in the hepatic tissue.

*Roberts & Plaa G39,694/66:* In mice,  $\alpha$ -naphthylisothiocyanate-induced hyperbilirubinemia and cholestasis are aggravated by norethandrolone and norethynodrel but not by mestranol.

*Shibata et al. G80,058/66:* In rats, hepatic glucuronyl transferase activity is greatly increased during the last third of gestation, whereas enzymic activity is virtually absent in the fetal liver. These divergent changes "raise doubt as to whether low enzymic activity in the fetus and increased activity after birth are the consequence, respectively, of high hormone levels in pregnancy, and falling hormone concentrations in the postpartum period. The maximal rate of bilirubin excretion into bile, the bilirubin  $T_m$ , remained unchanged in pregnancy despite the potential for increased bilirubin conjugation. When coupled with other observations, this suggests that the rate of delivery of conjugated bilirubin into bile is the rate-limiting step involved in the maximal transfer rate of bilirubin from blood to bile, and that the excretory step for bilirubin remains unaffected during pregnancy in the rat."

*Roberts et al. H8,328/68:* In rats, biliary excretion of bilirubin (administered by constant infusion) was not significantly affected by norethandrolone, but depressed by methyltestosterone. Special emphasis is laid upon the influence of temperature: an apparent decrease in the maximum biliary excretion of bilirubin was produced by norethandrolone, only in rats allowed to become hypothermic, whereas the reverse was true in normothermic rats.

*Heikel & Lathe G73,162/70:* In rats, various folliculoids and luteoids reduce bile flow. The bilirubin maximum secretion rate ( $T_m$ ) is but slightly affected. Following i.v. infusion of bilirubin, folliculoids (unlike luteoids) raise the serum conjugated bilirubin level.

*Patrignani H32,792/70:* In rats, pretreatment with testosterone increases bilirubin excretion and augments the incorporation of  $^{14}C$   $\Delta$ -amino levulinic acid ( $\Delta$ -ALA) into bilirubin. The effect is tentatively ascribed to stimulation of hepatic microsomal cytochrome activity.

*Sas & Herczeg H27,522/70:* In male newborn babies, androstenedione and dehydroepiandrosterone increase the serum bilirubin-concentration or, at least, delay its post-partal decline, presumably by inhibiting glucuronic acid conjugation of the bile pigment "possibly due to a competitive displacement between the steroids and bilirubin." Similar effects had previously been obtained with progesterone,  $3\alpha$ ,  $20\alpha$ - and  $3\alpha$ ,  $20\beta$ -pregnandiol and folliculoids. The steroids in human milk may thus influence detoxicating mechanisms.

*Sas & Herczeg H27,523/70:* In breast fed babies,  $3\alpha$ ,  $20\beta$ - and  $3\alpha$ ,  $20\alpha$ -pregnandiol p.o. increase pregnandiol and folliculoid excretion as well as the serum level of bilirubin.

Bilirubin ← Steroids: *Lathe et al. C55,335/58; Sherlock G79,591/59\**; *Holton et al. E35,112/63; Arias et al. F21,711/64\**; *Bevan et al. G35,435/65; Catz et al. H14,471/68; Mowat et al. G74,246/69\**

**Bishydroxycoumarin ← cf. Anticoagulants****Bromide ←**

*Bondurant & Campbell A36,066/41:* In man, adrenocortical extract in combination with NaCl is beneficial in the treatment of bromide intoxication.

*Wohl & Robertson 93,481/44:* In man, combined therapy with DOC plus NaCl is effective in combating chronic bromide intoxication.

*Prioreschi C68,485/59:* In the rat, anesthesia produced by NaBr is increased in intensity by exposure to stress or treatment with triamcinolone or Me-Cl-COL. DOC or estradiol do not modify it considerably.

*Selye et al. G60,020/69; G60,016/69:* In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or  $MgCl_2$ .

**Bromobenzene** ←

*Selye G70,480/71*: Rats received bromobenzene (50 mg daily from the 4th to the 6th day of conditioning, 75 mg once on the 7th day of conditioning and twice on the 8th day of conditioning /100 g body weight, in 1 ml corn oil p.o.). Hepatic steatosis was estimated on the day of death, prostration and mortality on the 9th day. Under these circumstances the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication. PCN and phenobarbital were not tested.

**Brompheniramine** ← *cf.* **Parabromdylamine**

Butynamine ← Ovariectomy +  
Methyltestosterone: Kato et al. *F76,403/66*

**Cadmium** ←

*Das & Kar D14,801/61*: In rats treated with cadmium, the testicular atrophy and, particularly, fibroblast proliferation in the testis can be moderately influenced by corticoids during the period of regeneration, but the results are not very striking.

*Gunn et al. F46,162/65*: In mice, the testicular hemorrhage, thrombosis and necrosis produced by CdCl<sub>2</sub> are not influenced by pretreatment with testosterone, whereas estradiol, in doses resulting in tubular atrophy, protects against the cadmium-induced testicular damage. Curiously, stilbestrol, at doses which fail to cause tubular regression, protects the testis against the production of vascular injury by cadmium.

*Maekawa & Hosoyama G79,815/65*: In rats, the testicular damage produced by cadmium is somewhat antagonized by testoids.

*Maekawa & Tsunenari H1,627/67*; *Maekawa et al. G79,814/67*: In rats, contrary to earlier claims, the testicular injury produced by cadmium is not prevented by folliculoids (estradiol, estrone, estriol).

*Pařízek et al. H7,672/68*: In adult rats in which persistent estrus had been induced by a single s.c. injection of testosterone or 19-nortestosterone on the fifth day of life, cadmium s.c. elicited particularly severe ovarian changes. Pretreatment with pregnant mare serum gonadotrophin protected the ovaries of such animals.

*Johnson et al. H23,801/70*: In rats, orchidectomy or surgically induced cryptorchidism increase the drop in body temperature produced by cadmium intoxication.

*Selye G70,480/71*: In rats, the characteristic hemorrhagic lesions produced in the gasserian ganglia by cadmium chloride intoxication are significantly prevented by PCN, prednisolone, triamcinolone and estradiol. The apparent protective action of thyroxine is open to doubt because most of the animals treated with this hormone died prematurely, *cf.* Table 35.

Table 35. *Conditioning for cadmium*

Treatment <sup>a</sup>	Hemorrhage in gasserian ganglia <sup>b</sup> (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)
None	14/18	15/20
PCN	1/13 ***	8/15 NS
CS-1	4/6 NS	6/10 NS
Ethylestrenol	5/9 NS	2/10 **
Spirolactone	7/10 NS	2/10 **
Norbolethone	7/9 NS	3/10 *
Oxandrolone	7/9 NS	6/10 NS

DOC-Ac	6/10 NS	4/10 NS
Hydroxydione	7/10 NS	5/10 NS
Thyroxine	10/10 *	10/10 *
Phenobarbital	2/10 NS	0/10 *

<sup>a</sup> The rats of all groups were given caramiphen hydrochloride (10 mg on 4th day and 15 mg on 5th day, /100 g body weight in 1 ml water i.p.).

<sup>b</sup> Dyskinesia was estimated on 5th day, 1 hr after injection, and mortality listed on 6th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

#### Carbon Monoxide ←

*Smith et al. 45,163/35*: Male rats are more sensitive to the lethal action of illuminating gas than females. This difference is eliminated by gonadectomy. Thyroid feeding or dinitrophenol injections decrease survival time.

#### Carbon Tetrachloride ←

##### RAT

*Masson 96,335/47*: The hepatotoxic action of CCl<sub>4</sub> is aggravated by DOC and testosterone, but partially prevented by anterior pituitary extracts in the rat.

*Aterman B52,265/50*: In rats, the hepatic sclerosis produced by CCl<sub>4</sub> is inhibited by concurrent treatment with cortisone.

*Cavallero et al. B54,229/51*: In the rat, "cortisone definitely modifies the evolution of carbon tetrachloride cirrhosis. Fatty degeneration is not affected, but fibrosis, reticulosis, and parenchymal regeneration are greatly inhibited."

*Cavallero et al. B69,181/52*: Cortisone partially inhibits hepatic fibrosis in rats treated with CCl<sub>4</sub>.

*Aterman & Ahmad B76,967/53*: "Cortisone increases the susceptibility of the rat's liver to chronic damage by carbon tetrachloride."

*Aterman B92,038/54*: In rats, cortisone significantly decreases hepatic fibrosis produced by CCl<sub>4</sub>, as judged by histologic studies and collagen determinations.

*Diengott & Ungar E84,645/54*: "In albino rats exposed to vapors of CCl<sub>4</sub> the administration of cortisone enhanced the cirrhotic process in the liver considerably. In comparison with the controls, the liver of cortisone-treated animals showed marked epithelial and mesenchymal alterations. The former was manifested by the presence of multinucleated giant cells, foci of necrosis, and fatty changes; the latter, by the development of dense bundles of tortuous and clumped reticulum fibers."

*Vorhaus & Vorhaus B97,869/54*: Cortisone pretreatment offers partial protection against the hepatic damage produced by CCl<sub>4</sub> in the rat.

*Arrigo & Trasino C21,687/55*: In rats, crude alkaline anterior pituitary extracts (rich in STH) do, whereas acid extracts (rich in ACTH and STH) do not protect the liver and pancreas against damage by CCl<sub>4</sub>. Cortisone protects the liver but not the pancreas.

*Allegri et al. C31,532/57*: In rats, the hepatic fibrosis induced by prolonged inhalation of CCl<sub>4</sub> is aggravated by concurrent testosterone treatment.

*Guérios et al. C58,363/57*: In rats, the hepatotoxic action of CCl<sub>4</sub> is aggravated by cortisone.

*Mehrotra et al. C54,806/57*: The ascites associated with CCl<sub>4</sub>-induced hepatic cirrhosis is aggravated in rats by DOC.

*Girolami C55,043/58*: Testosterone propionate protects the rat against fatty degeneration and cirrhosis of the liver produced either by CCl<sub>4</sub> or by a choline deficient diet.

*Asagoe D13,524/59*: Hepatic cirrhosis produced in rats by CCl<sub>4</sub>-inhalation can be prevented by cortisone, but recovery from well-established cirrhosis is not significantly enhanced by this hormone.

*Grassi et al. E58,693/59*: In the rat, testosterone, 4-chlorotestosterone and prednisolone alone or in combination protect the kidney against CCl<sub>4</sub> intoxication.

*Massei et al. D2,594/59*: Testosterone has a beneficial effect upon the hepatic lesions produced by CCl<sub>4</sub> in the rat.

*Asagoe D13,523/60*: In rats, the hepatic cirrhosis induced by CCl<sub>4</sub> was slightly increased by testosterone after castration, but not in the presence of the testes.

*Kulcsár & Kulcsár-Gergely C94,710/60*: Ovariectomy partly protects the rat against

the hepatotoxic and fatal effects of  $\text{CCl}_4$ . The degradation of endogenous folliculoids may weaken the resistance of the liver, and thereby predispose it for damage by this drug.

*Kulcsár-Gergely & Kulcsár C99,083/60*: In ovariectomized rats, estrone aggravates the hepatic damage produced by  $\text{CCl}_4$ . The activity of endogenous folliculoids (estrus) is increased by hepatic damage, which again shows that these hormones are inactivated by the liver. Presumably, this process of inactivation diminishes the resistance of hepatic tissue to damage.

*Tada E96,131/60*: Brief abstract on the effect of "androgen," "estrogen" and cortisone upon the lipid, glycogen, and collagen content of the rat liver following intoxication with  $\text{CCl}_4$ . [No experimental details (H.S.).]

*Bengmark & Olsson D48,932/62*: Female rats are more susceptible to the hepatotoxic action of  $\text{CCl}_4$  than males. Testosterone raised the resistance of females to this form of liver damage.

*Bengmark & Olsson D14,663/63*: "The authors have been able to demonstrate a beneficial effect of testosterone propionate in female rats subjected to carbon tetrachloride intoxication and a definite lipotropic effect of the hormone in partially hepatectomized male rats."

*Discher et al. D64,428/63*: The stroma proliferation in rat livers damaged by  $\text{CCl}_4$  can be inhibited by cortisone or prednisolone only in the event of s.c., not of p.o., administration. Additional treatment with testosterone did not significantly influence this effect.

*Bengmark & Olsson G13,853/64*: Orchidectomy increases the susceptibility of the rat to the hepatotoxic action of  $\text{CCl}_4$ . Testosterone raises the resistance of castrate, but not of intact rats.

*Czeizel et al. F23,802/64*: Heavy overdosage with various folliculoids aggravates the hepatic damage produced in rats by  $\text{CCl}_4$  whereas "physiologic amounts" accelerate healing.

*Kulcsár-Gergely et al. F32,037/64*: In rats, simultaneous thyroidectomy and ovariectomy offer some protection against the induction of hepatic cirrhosis by  $\text{CCl}_4$ .

*Kulcsár-Gergely & Kulcsár G1,372/64*: In rats intoxicated with  $\text{CCl}_4$ , survival is increased by ovariectomy and thyroidectomy.

*Tessmann F8,084/64*: The hepatic necrosis produced in rats by  $\text{CCl}_4$  was aggravated by prednisone and repair delayed.

*Furukawa F71,711/65*: In rats, the hepatic steatosis produced by  $\text{CCl}_4$  is inhibited by

adrenalectomy and, to some extent, also by hypophysectomy. Corticoids restore the effect of  $\text{CCl}_4$  after adrenalectomy; epinephrine, though not restoring it, increases the effect of corticoids. STH does not counteract the effect of hypophysectomy. Alloxan diabetes inhibits  $\text{CCl}_4$ -induced hepatic lipidosis.

*Kulcsár & Kulcsár-Gergely F74,930/66*: In rats, ovariectomy, thyroidectomy or removal of both glands, offers partial protection against  $\text{CCl}_4$  intoxication.

*Tessmann & Ziegler F64,393/66*: Prednisolone aggravated the hepatic lesions and yet prolonged survival in rats intoxicated with  $\text{CCl}_4$ .

*Rimniceanu et al. F98,503/67*: In the rat, cortisone given simultaneously with  $\text{CCl}_4$  aggravates the hepatic parenchymal lesions produced by the latter, whereas if the hormone is administered after  $\text{CCl}_4$  it hastens hepatic regeneration.

*Rimniceanu et al. G66,073/68*: In rats, the hepatic lesions produced by  $\text{CCl}_4$  are intensified by cortisone, even in the presence of vitamin- $\text{B}_{12}$ , but cortisone treatment after interruption of  $\text{CCl}_4$  hastens hepatic regeneration.

*Becker H17,711/69*: In rats, the hepatic cirrhosis produced by thioacetamide or  $\text{CCl}_4$  is not inhibited by cortisone, and damage of the parenchymal cells is actually increased.

*Joshi & Rao G72,489/69*: In rats, Enovid (mestranol + norethynodrel) aggravates the liver damage caused by  $\text{CCl}_4$ .

*Murphy & Malley G68,408/69*: Studies on hepatic TKT, alkaline phosphatase (AP), and TPO in relation to stress and  $\text{CCl}_4$ -intoxication in the rat. "Liver TKT elevation, but not AP elevation, was prevented by adrenalectomy prior to  $\text{CCl}_4$ . Experiments on rats subjected to simultaneous acute cold stress and  $\text{CCl}_4$  indicated that, during the acute phase of  $\text{CCl}_4$  hepatotoxicity, their livers had reduced capacity for induction of TKT and TP by endogenous corticosterone. However, chronically injured livers of rats given repeated doses of  $\text{CCl}_4$  were fully responsive to the TKT- and TP-inducing effects of exogenous corticosterone or acute cold stress."

*Tarnowski et al. G75,524/70*: In adrenalectomized rats maintained on cortisol, even lethal amounts of  $\text{CCl}_4$  did not depress protein biosynthesis and the ATP/ADP ratio below a relatively high minimal level. " $\text{CCl}_4$  poisoned liver should not be used as a model for studies on regulation of liver metabolism."

*Tuchweber and Kovacs G70,489/71*: In rats, pretreatment with progesterone, triamcinolone,

or phenobarbital increases the mortality, liver damage, and triglyceride accumulation induced by  $\text{CCl}_4$ . Spironolactone, CS-1, ethylstrenol, norbolethone, oxandrolone, estradiol, and DOC do not share this effect.

#### RABBIT

*Regniers et al. C7,634/55*: In rabbits, cortisone can either increase or decrease the hepatotoxic effect of  $\text{CCl}_4$  depending upon the time elapsing between the treatment with the two agents.

*Germer & Regoeczi C64,975/58*: In rabbits pretreated with plasmapheresis, the hepatotoxic effect of  $\text{CCl}_4$  could be diminished by testosterone.

*Petzold & Meincke D39,959/62*: 6-Methylprednisolone hemisuccinate sodium failed to prevent the proliferation of connective tissue in the liver of rabbits damaged by  $\text{CCl}_4$ , except in the case of chronic intoxication.

*Ferruccio F62,336/64*: Testosterone inhibits the hepatic steatosis produced by  $\text{CCl}_4$  in the rabbit.

*Petzold F61,425/65*: In rabbits, hepatic cirrhosis produced by  $\text{CCl}_4$  is largely inhibited by 4-chlorotestosterone.

#### GUINEA PIG

*Aragona B53,747/49*: In guinea pigs, testosterone accelerates hepatic regeneration following  $\text{CCl}_4$  treatment.

*Aragona B53,056/50*: In guinea pigs, estradiol and hexestrol given after the induction of hepatic damage by  $\text{CCl}_4$ , produce anemia with myeloid metaplasia in various organs.

#### MOUSE

*Chang & Lei F78,943/67*: 17 $\alpha$ -Methyl-5 $\alpha$ -androstan-17 $\beta$ -ol prevents the production of fatty hepatic degeneration by ethionine or  $\text{CCl}_4$  in mice.

#### VARIA

*Patrick C12,967/55*: In rats and mice, cortisone or ACTH inhibited the mesenchymal reaction, and delayed repair following production of hepatic damage by tannic acid or  $\text{CCl}_4$ .

*Stolk D2,285/61*: In Iguana iguana, ovariectomy protects against the hepatic lesions produced by  $\text{CCl}_4$ .

*Berdjis F79,528/67*: The hepatotoxic effect of  $\text{CCl}_4$ , phosphorus and ethionine could be diminished by cortisone, and survival prolonged.

$\text{CCl}_4$  ← Cortisone: Aterman B52,265/50\*

**Carcinogens** ← cf. also *Selye G60,083/70*, p. 357.

← **Corticoids**. *Ratsimamanga & Buu-Hoi B33,923/47*: Various carcinogenic polycyclic hydrocarbons diminish the resistance of the rat to fatigue (swim test). This effect is ascribed to impairment of adrenocortical function since it can be corrected by treatment with adrenocortical extract.

*Robertson et al. B88,672/53*: In rats, hypophysectomy prevents the production of hepatic cirrhosis and hepatomas by 3'-Me-DAB. The susceptibility to tumorigenesis is restored by ACTH, but not by CON, DOC or testosterone. These hormones likewise failed to prevent carcinogenesis in intact rats.

*Symeonidis et al. B93,003/54*: In rats, the production of hepatomas by DAB is prevented by adrenalectomy and by DOC in doses causing adrenocortical atrophy.

*Reid B93,930/54*: Review (18 pp., 181 refs.) on the effect of STH and corticoids upon carcinogen-induced and transplantable neoplasms.

*Hoch-Ligeti C14,407/55*: In rats, "cortisone under certain experimental conditions seemed to accelerate the occurrence and increase the number of tumors induced by p-dimethylaminoazobenzene or 2-acetylaminofluorene." On the other hand, cortisone had no consistent effect upon transplanted hepatomas.

*Schnitzer C32,871/56*: In mice, the production of skin tumors by topical application of DMBA is allegedly somewhat increased by cortisone s.c.

*Glenn et al. C64,744/59*: In the rat, various carcinogens potentiate the testoid and anabolic (levator ani) effects of 17-methyltestosterone as well as the glycogenic and antiphlogistic properties of cortisol. Noncarcinogenic hydrocarbons do not exhibit this effect. "Both in vivo and in vitro studies indicate that the ability of carcinogenic hydrocarbons to potentiate biological effects of steroids is due to a direct effect of carcinogenic agent at the cellular level and not to a decreased rate of steroid metabolism by the liver."

*Chany & Boy D2,278/60*: In rats, cortisone accelerates the production of hepatic cancers by DAB.

*Perry D10,864/61*: In rats, the induction of hepatic cancers by AAF is prevented by adrenalectomy but not modified by DOC either in intact or in adrenalectomized animals.

*Goodall G77,088/62*: In rats, the production of hepatomas by AF is prevented by hypophysectomy or thyroidectomy. Cortisone re-

stores the ability of the thyroidectomized but not of the hypophysectomized rats to develop hepatomas after AF treatment. Cortisone strongly accelerates the appearance of hepatomas in intact rats.

*Siegler & Duran-Reynals D54,814/62*: "Methylcholanthrene applied over the site of dermal vaccinia infection in the skin of cortisone-treated mice results in a tumor effect which is more rapid and severe than that seen after the application of methylcholanthrene alone."

*Duran-Reynals E29,252/63*: "Mice rendered susceptible to vaccinia dermal infection by cortisone injections and untreated mice received MC skin paintings at the site of virus infection. Under certain conditions, the MC applied before virus inoculation inhibited the virus-induced skin ulcers; applied after it enhanced them."

*Lacassagne & Hurst G12,688/63*: In rats, hepatic cancer formation under the influence of DAB is retarded by DOC and accelerated by cortisol.

*Serental et al. D61,608/63*: In rats, mammary tumors induced by DMBA regressed after adrenalectomy+ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy+ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Trainin D61,599/63*: In mice, given a single feeding of DMBA as an initiating stimulus and twice-weekly paintings of 5% croton oil to the skin as a promoting stimulus, carcinogenesis was not significantly altered by cortisol or adrenalectomy during the initiating phase. Conversely, the promoting phase of cutaneous carcinogenesis was strikingly inhibited by cortisol and enhanced by adrenalectomy. The data are discussed in the light of the "two-stage mechanism of carcinogenesis."

*Mancini et al. D18,183/64*: In CF-1 albino mice, minimal doses of cortisone slightly decreased the incidence of 3-MC induced tumors.

*Young et al. F20,579/64*: In rats treated with DMBA, neither the adrenocortical necrosis nor the tumor incidence was significantly influenced by cortisone.

*Ketkar & Sirsat G32,601/65*: In mice, the induction of tumors by 3-MC is not markedly affected by DOC but the pattern of tumor growth and the mast cell response in the

connective tissue are altered by the mineralocorticoid.

*Jull et al. G41,663/66*: It had previously been noted that in certain strains of mice treated with DMBA, granulosa cell tumors of the ovary develop even if the gonad is transplanted into unpretreated recipients. Both DOC and 17 $\alpha$ -hydroxyprogesterone completely inhibit the appearance of granulosa cell tumors when the steroids are injected concurrently with DMBA into the donor mice. Possibly, this protection is due to competitive inhibition.

*Jull F74,180/66*: In rats, the induction of mammary carcinomas by DMBA is inhibited by progesterone, DOC and metyrapone.

*Lacassagne et al. G39,677/66*: In rats given DAB, hepatic carcinogenesis is inhibited by DOC; various corticoids having the 17 $\alpha$ -hydroxyl group exert an opposite effect.

*Qureshi & Zaman F68,389/66*: In mice, the induction of subcutaneous sarcomas by 3-MC is inhibited by prednisolone.

*Shklar F74,973/66*: In hamsters, the induction of carcinomas by painting the buccal pouch with DMBA was enhanced by cortisone s.c., i.p. or i.m.

*Ronzoni et al. H18,409/68*: In rats, prostatic carcinogenesis induced by the introduction of 20-methylcholanthrene crystals into the prostate is inhibited by ACTH, T3 and, to a lesser extent, by progesterone and 19-nortestosterone phenylpropionate. Estradiol and cortisone facilitate carcinogenesis, whereas testosterone, orchidectomy and methylthiouracil failed to influence it.

*Sugiura G64,932/68*: In mice, the regression of DMBA-induced papillomas is increased by testosterone and, if anything, decreased by estradiol. Cortisone apparently also increases the number of regressions.

*Cole & Foley H35,251/69*: In mice, the induction of pulmonary carcinomas by urethan can be enhanced by cortisone especially in combination with X-irradiation.

*Shisa G72,582/69*: In mice of the Swiss, C57BL and A/Jax strains, DMBA injected s.c. on the third day of life induced lymphomas whose incidence could be increased or decreased by cortisone, depending upon the strain and the time of treatment. Earlier literature on the effect of cortisone upon virus or X-ray induced leukemias is reviewed.

*Siegel & Shklar H35,238/69*: In hamsters, topical application of DMBA (in DMSO) to the cheek pouch induces a chemical carcino-

genesis which can be inhibited by triamcinolone.

*Metzler H27,243/70*: In rats, 3-MC causes a drop in blood pressure, but the hypertension produced by DOC + uninephrectomy is not blocked by the carcinogen. On the other hand, the induction of neoplasms is inhibited by DOC.

*Polliack et al. H32,366/70*: In hamsters, tumor formation by topical application of DMBA to the cheek pouch is partially suppressed by concurrent application of cortisone, perhaps owing to depression of DNA synthesis and of mitotic activity by the hormone. "Cortisone stabilizes biological membranes; its action on cell multiplication may be related to decreased membrane permeability with consequent inhibition of release of lysosomal enzymes which play a part in early stages of cell division. Decreased membrane permeability may also have resulted in less effective penetration of carcinogen into cells. Results are in accordance with those of previous studies, which demonstrated promotion of tumor formation by labilizers of biological membranes such as vitamin A and estrogen."

*Schauer et al. G81,318/70*: In rats, the enzyme histochemically demonstrable pre-cancerous lesions produced in the liver by N-nitrosodiethylamine are inhibited by glucocorticoids and enhanced by estradiol. Males are somewhat more resistant than females, but under the experimental conditions used, testosterone is ineffective.

*Somogyi G70,416/70*: In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, CS-1, and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocorticolytic effect of 7-OHM-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovacs G60,074/70*: In rats, the adrenal necrosis produced by DMBA is inhi-

bited by spironolactone and ethylestrenol; it is aggravated by estradiol, MAD, cortisol and testosterone but not significantly influenced by progesterone, norbolethone, triamcinolone or DOC.

3-Methyl-4-monomethylaminoazobenzene ← Cortisone, Mouse: Reif et al. *D97,006/54*

7,12-Dimethylbenzanthracene ← Cortisol: Harris *F98,166/68\**

Benzo(a)pyrene ← Cortisol + Age Hamster: Nebert et al. *H23,692/68*

← Folliculoids. *Cantarow et al. B18,774/46*: In rats, given AAF p.o., the development of cystic and neoplastic hepatic lesions was accelerated and intensified by GTH (pregnant mare serum), estradiol and testosterone, but inhibited by thiouracil. "This phenomenon may be related to the role of the liver in the intermediary metabolism and excretion of the sex steroid." No tumors occurred in the hyperplastic target organs of the sex hormones in contrast to the high incidence of tumors in the thyroids of rats given thiouracil simultaneously with the carcinogens.

*Kirby B30,101/47*: Female rats are less susceptible than males to the production of hepatomas and hepatic cirrhosis by AAF. Rats simultaneously treated with pellets of estradiol or testosterone and AAF showed no carcinoma formation in the target organs of the sex hormones.

*Stasney et al. B26,653/47*: In rats, AAF feeding produces mammary carcinoma only in females, and its development is not significantly accelerated by estradiol or gonadotrophin. "Malignant lesions of the liver occurred in 54.8 per cent of females and 92.3 per cent of males receiving the carcinogen alone. Administration of estradiol and PMS gonadotrophin to females and of testosterone and chorionic gonadotrophin to males intensified the cystic and neoplastic hepatic lesions induced by 2-acetaminofluorene."

*Shay et al. H31,719/52*: In rats, chronic administration of 3-MC p.o. produces glandular tumors of the breast (predominantly in females and estradiol-treated males), spindle-cell and collagenous tumors of the breast and mesenteric sarcomas (predominantly in males and testosterone-treated females), and fibroadenomas of the breast (predominantly in ovariectomized and orchidectomized animals "in which the sex hormone effects were experimentally counterbalanced").

*Geyer et al. H 31,923/53:* In rats, the induction of mammary tumors by DMBA is greatly enhanced by estradiol and stilbestrol.

*Miyaji et al. D 24,881/53:* In rats, the production of hepatic, mammary and sebaceous gland tumors by AAF was not significantly influenced by adrenalectomy. On the other hand, after gonadectomy, testosterone increased, whereas estrone, estradiol and progesterone decreased carcinogenesis. [A brief abstract which is difficult to evaluate (H.S.).]

*Shelton G 76,339/54:* In mice, 2-amino-5-azotoluene added to a semi-synthetic diet produced a high incidence of hepatomas only in the case of concurrent treatment with stilbestrol.

*Huggins et al. C 99,772/61:* In rats, the production of mammary cancers by DMBA or 3-MC is inhibited by pregnancy, estradiol, progesterone or combined treatment of estradiol + progesterone.

*Seguy et al. D 5,238/61:* In rats, high doses of folliculoids enhanced the carcinogenic action of benzpyrene. Hypophysectomy or ovariectomy did not significantly influence this type of carcinogenesis, but the number of animals used was very small.

*Shay et al. D 2,760/61:* In rats, the induction of mammary cancers by methylcholanthrene is inhibited by folliculoids.

*Pannella & Gasparini D 64,636/63:* In female rats, the carcinogenic action of 20-methylcholanthrene is accelerated by folliculoids, partially inhibited by testosterone and completely blocked by ovariectomy. When tumors do arise, however, their histologic character is not influenced by any of these treatments.

*Sterental et al. D 61,608/63:* In rats, mammary tumors induced by DMBA regressed after adrenalectomy+ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy+ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Sirsat & Ketkar F 65,926/66:* In mice, the induction of cutaneous carcinomas by topical treatment with 3-MC is stimulated by pre-treatment and inhibited by subsequent treatment with DOC.

*Weisburger et al. F 72,720/66:* In the rat, neonatal estradiol treatment enhances hepatoma formation following administration of the carcinogen N-hydroxy-N-2-fluorenylac-  
etamide.

*Colafranceschi & Tosi G 59,115/67:* The adrenal necrosis produced by DMBA in the rat is of equal severity in males and females and cannot be influenced by ovariectomy, orchidectomy, testosterone or estradiol.

*Weisburger et al. F 78,862/67:* Male rats are more prone to liver cancer induction by N-hydroxy-N-2-fluorenylac-  
etamide (N-OH-FAA) than females. In newborn males treated with estradiol, and placed on a diet containing N-OH-FAA, the incidence of hepatic carcinomas was decreased, whereas testosterone did not change it. In females, estradiol had a "mixed effect," and testosterone enhanced hepatoma induction.

*Poel H 23,662/68:* Review of the literature with personal observations on the co-carcinogenic effect of folliculoids and luteoids. Neither of these groups of steroids are truly carcinogenic in themselves, but they enhance mammary cancer development under the influence of viral and chemical carcinogens. [The possible mechanism of these interactions is not discussed (H.S.).]

*Sugiura G 64,932/68:* In mice, the regression of DMBA-induced papillomas is increased by testosterone and, if anything, decreased by estradiol. Cortisone apparently also increased the number of regressions.

*Weisburger & Yamamoto F 97,904/68:* Rats of both sexes were injected neonatally with a single dose of testosterone or estradiol. After weaning they were placed on a diet containing N-hydroxy-N-2-fluorenylac-  
etamide (N-OH-FAA) for 16 weeks. Autopsies were performed after an additional 10 weeks on controlled diets. In males, the hepatic tumor incidence was not affected by testosterone but reduced by estradiol. In females, testosterone enhanced carcinogenicity while estradiol had a dual effect, augmenting carcinogenesis in a few rats but reducing it in most.

*Newberne & Williams G 69,601/69:* In rats, hepatic carcinogenesis produced by aflatoxin is inhibited by diethylstilbestrol. Male rats are less resistant to aflatoxin than females.

*Polliack et al. G 72,389/69:* In orchidectomized hamsters, stilbestrol increases topical carcinogenesis if one cheek pouch is repeatedly treated with DMBA. Among hamsters not treated with folliculoids, orchidectomy did not change the incidence of carcinogenesis under these conditions.

*Griswold Jr. & Green H 26,709/70:* Review of the literature and personal observations on the effect of ovariectomy, testoids and folliculoids alone and in combination upon the

hormone sensitivity of DMBA-induced mammary tumors in the rat.

*Horvath et al. G70,443/70*: In rats, estradiol pretreatment markedly increases the susceptibility of the adrenals to the corticolytic effect of DMBA. The associated histochemical changes are described.

*Schauer et al. G81,318/70*: In rats, the enzyme histochemically demonstrable precancerous lesions produced in the liver by N-nitrosodiethylamine are inhibited by glucocorticoids and enhanced by estradiol. Males are somewhat more resistant than females but, under the experimental conditions used, testosterone is ineffective.

*Somogyi G70,416/70*: In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, CS-1, and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocorticytic effect of 7-OHM-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovacs G60,074/70*: In rats, the adrenal necrosis produced by DMBA is inhibited by spironolactone and ethylestrenol; it is aggravated by estradiol, MAD, cortisol and testosterone but not significantly influenced by progesterone, norbolethone, triamcinolone or DOC.

3-MC ← Progesterone: Huggins et al. C99,772/61\*

← Testoids. *Maisin et al. A30,500/39*: Unlike folliculoids, testosterone propionate does not augment the incidence of mammary cancers in benzpyrene-treated mice.

*Cantarow et al. B18,774/46*: In rats, given AAF p.o., the development of cystic and neoplastic hepatic lesions was accelerated and

intensified by GTH (pregnant mare serum), estradiol and testosterone, but inhibited by thiouracil. "This phenomenon may be related to the role of the liver in the intermediary metabolism and excretion of the sex steroid." No tumors occurred in the hyperplastic target organs of the sex hormones in contrast to the high incidence of tumors in the thyroids of rats given thiouracil simultaneously with the carcinogens.

*Kirby B30,101/47*: Female rats are less susceptible than males to the production of hepatomas and hepatic cirrhosis by AAF. Rats simultaneously treated with pellets of estradiol or testosterone and AAF showed no carcinoma formation in the target organs of the sex hormones.

*Stasney et al. B26,653/47*: In rats, 2-acetaminofluorene feeding produces mammary carcinoma only in females, and its development is not significantly accelerated by estradiol or gonadotrophin. "Malignant lesions of the liver occurred in 54.8 per cent of females and 92.3 per cent of males receiving the carcinogen alone. Administration of estradiol and PMS gonadotrophin to females and of testosterone and chorionic gonadotrophin to males intensified the cystic and neoplastic hepatic lesions induced by 2-acetaminofluorene."

*Flaks B35,572/48*: Testosterone delays the induction of subcutaneous tumors by 20-methylcholanthrene.

*Shay et al. H31,719/52*: In rats, chronic administration of 3-MC p.o. produces glandular tumors of the breast (predominantly in females and estradiol-treated males), spindle-cell and collagenous tumors of the breast and mesenteric sarcomas (predominantly in males and testosterone-treated females), and fibroadenomas of the breast (predominantly in ovariectomized and orchidectomized animals "in which the sex hormone effects were experimentally counterbalanced").

*Miyaji et al. D24,881/53*: In rats, the production of hepatic, mammary and sebaceous gland tumors by AAF was not significantly influenced by adrenalectomy. On the other hand, after gonadectomy, testosterone increased, whereas estrone, estradiol and progesterone decreased, carcinogenesis. [A brief abstract which is difficult to evaluate (H.S.).]

*Robertson et al. B88,672/53*: In rats, hypophysectomy prevents the production of hepatic cirrhosis and hepatomas by 3'-Me-DAB. The susceptibility to tumorigenesis is restored

by ACTH, but not by cortisone, DOC or testosterone. These hormones likewise failed to prevent carcinogenesis in intact rats.

*Huggins et al. C62,178/59*: In rats, mammary carcinomas induced by 3-methylcholanthrene involute following ovariectomy or hypophysectomy and, hence, they may be regarded as "hormone-dependent." Similar regression of tumors is frequently achieved by dihydrotestosterone. Only a few mammary cancers continue to grow after ovariectomy and these are considered to be "hormone-independent."

*Thompson et al. C92,646/60*: In mice with transplanted myelomas, 3-methylcholanthrene retarded or even completely suppressed the growth of the neoplastic tissue. Concurrent treatment with dihydrotestosterone increased the body weight of the host but did not exert an additive-suppressing effect upon the myeloma's growth.

*Dao & Greiner D91,850/61*: In male rats, unlike in females or castrate males, 3-MC rarely produces mammary tumors. Ovarian transplants placed into castrate males induce predisposition for mammary carcinogenesis under these conditions.

*Pannella & Gasparrini D64,636/63*: In female rats, the carcinogenic action of 20-methylcholanthrene is accelerated by folliculoids, partially inhibited by testosterone and completely blocked by ovariectomy. When tumors do arise, however, their histologic character is not influenced by any of these treatments.

*Sidransky et al. C99,347/61*: In rats, fed AAF, hepatic tumors developed in all males but only in 5 out of 14 females. "Although castrated males had liver changes similar to those seen in females, these males receiving testosterone had the same changes as were found in the intact males. Intact females receiving testosterone developed earlier and more extensive changes regularly found only in the livers of males." Testosterone may accelerate hepatic tumorigenesis by this carcinogen.

*Kovacs G34,582/65*: In rats given a single injection of testosterone at 1-2 days of age, the subsequent production of mammary cancers by DMBA is inhibited. However, this form of testosterone treatment does not prevent the production of leukemia by DMBA.

*Reuber F36,234/65*: Concurrent treatment with testosterone and thyroid powder sensitizes the rat for the production of hepatic cirrhosis and hepatomas by AAF.

*Mody G49,656/67:* The yield of ovarian tumors induced by DMBA "was significantly greater in C<sub>3</sub>H (Jax) mammetomised mice when treated with testosterone. It is suggested that testosterone has a promoting action for chemically induced ovarian tumours in mice."

*Stern & Mickey F89,080/67:* In 50-day old female rats with "androgen sterility" (induced by a single injection of testosterone at five days of age) DMBA elicits less mammary tumors than in unpretreated controls.

*Weisburger et al. F78,862/67:* Male rats are more prone to liver cancer induction by N-hydroxy-N-2-fluorenylacetamide (N-OH-FAA) than females. In newborn males treated with estradiol, and placed on a diet containing N-OH-FAA, the incidence of hepatic carcinomas was decreased, whereas testosterone did not change it. In females, estradiol had a "mixed effect," and testosterone enhanced hepatoma induction.

*Glucksmann & Cherry H19,200/68:* In rats, ovariectomy reduces the rate of induction by DMBA of cervico-vaginal sarcomas. This inhibition is counteracted by various folliculoids. In intact rats, progesterone slightly retards the induction of these sarcomas and in castrates it fails to raise the rate of carcinogenesis. Testosterone lengthens the induction period of sarcomas in intact rats and increases the rate of sarcoma formation in castrates.

*Sugiura G64,932/68:* in mice, the regression of DMBA-induced papillomas is increased by testosterone and, if anything, decreased by estradiol. Cortisone apparently also increased the number of regressions.

*Weisburger & Yamamoto F97,904/68:* Rats of both sexes were injected neonatally with a single dose of testosterone or estradiol. After weaning they were placed on a diet containing N-hydroxy-N-2-fluorenylacetamide (N-OH-FAA) for 16 weeks. Autopsies were performed after an additional 10 weeks on controlled diet. In males, the hepatic tumor incidence was not affected by testosterone but reduced by estradiol. In females, testosterone enhanced carcinogenicity while estradiol had a dual effect augmenting carcinogenesis in a few rats but reducing it in most.

*Dmitriev H28,154/69:* In mice, the production of preneoplastic mammary changes by benzpyrene is diminished by testosterone.

*Griswold Jr. & Green H26,709/70:* Review of the literature and personal observations on the effect of ovariectomy, testoids and folliculoids, alone and in combination, upon the

hormonal sensitivity of DMBA-induced mammary tumors in the rat.

*Mückter et al. H23,589/70:* In rats, survival time after induction of mammary tumors by DMBA is increased by treatment with a combination of drostanolone propionate (2 $\alpha$ -methyl dihydrotestosterone propionate) and a cyclic imide [1-(morpholinomethyl)-4-phthalimido-piperidindione-2,6]. The catabolic effect of the carcinolytic cyclic imide is particularly well antagonized by the anabolic testoid but there is no decrease in the number of tumor centers that develop.

*Polliack et al. H31,578/70:* In intact male hamsters, the induction of carcinomas by topical application of DMBA to the cheek pouch was reduced by testosterone. In castrate males, this effect was less striking. Castration itself had no effect on tumorigenesis.

*Schauer et al. G81,318/70:* In rats, the enzyme histochemically demonstrable precancerous lesions produced in the liver by N-nitrosodiethylamine are inhibited by glucocorticoids and enhanced by estradiol. Males are somewhat more resistant than females but, under the experimental conditions used, testosterone is ineffective.

*Somogyi G70,416/70:* In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, CS-1, and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocorticolytic effect of 7-OHM-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovacs G60,074/70:* In rats, the adrenal necrosis produced by DMBA is inhibited by spironolactone and ethylestrenol; it is aggravated by estradiol, MAD, cortisol and testosterone but not significantly influenced by progesterone, norbolethone, triamcinolone or DOC.

9,10-Dimethyl-1,2-benzanthracene

N-2-Fluorenylacetylamide ← Testosterone: Kirby B30,101/47\*; Miyaji et al. D24,881/53\*

← **Gonadectomy.** *Maisin et al.* 25,708/26: In male mice, the production of skin cancers by topical application of tar is not inhibited and appears to be aggravated by castration.

*Andervont & Dunn A 96,182/47:* Among strain C mice, o-aminoozotoluene produced hepatomas more frequently in females than in males. Furthermore, "intact females were more susceptible than castrate females; castrate males approached intact females in their degree of susceptibility; castrate females and castrate males bearing testosterone propionate-cholesterol pellets approached intact males in their degree of susceptibility." The incidence of pulmonary tumors, after treatment with this carcinogen, was not dependent upon any of the factors just mentioned.

*Shay et al. H 26,763/49:* In intact female rats, 3-MC p.o. produces a high incidence of mammary adenocarcinomas, whereas this is exceptional in intact or castrate males as well as in spayed females.

*Bielschowsky & Hall G 71,797/51:* In intact female rats joined in parabiosis with gonadectomized litter-mates, AAF induced a 50% incidence of malignant tumors, mostly of the granulosa. The gonadectomized partners were free of neoplastic lesions.

*Shay et al. H 31,719/52:* In rats, chronic administration of 3-MC p.o. produces glandular tumors of the breast (predominantly in females and estradiol-treated males) spindle-cell and collagenous tumors of the breast and mesenteric sarcomas (predominantly in males and testosterone-treated females), and fibroadenomas of the breast (predominantly in ovariectomized and orchidectomized animals "in which the sex hormone effects were experimentally counterbalanced").

*Miyaji et al. D 24,881/53:* In rats, the production of hepatic, mammary and sebaceous gland tumors by AAF was not significantly influenced by adrenalectomy. On the other hand, after gonadectomy, testosterone increased, whereas estrone, estradiol and progesterone decreased carcinogenesis. [A brief abstract which is difficult to evaluate (H.S.).]

*Dao & Sunderland D 79,860/59; Dao et al. E 57,368/60:* In rats, the induction of mammary carcinomas by 3-methylcholanthrene is enhanced during pregnancy, pseudopregnancy,

and progesterone treatment. Regression of neoplasms occurs after parturition. Males are virtually resistant. In fully formed tumors, regression could be induced by hypophysectomy or ovariectomy.

*Huggins et al. C 62,178/59:* In rats, mammary carcinomas induced by 3-MC involute following ovariectomy or hypophysectomy and, hence, they may be regarded as "hormone-dependent." Similar regression of tumors is frequently achieved by dihydrotestosterone. Only a few mammary cancers continue to grow after ovariectomy and these are considered to be "hormone-independent."

*Marchant C 69,830/59:* In mice, painting of the skin with methylcholanthrene produced papillomas earlier in male or female castrates than in intact controls.

*Kim & Furth H 31,205/60:* In rats, the induction of mammary cancers by 3-MC is considerably inhibited by ovariectomy or hypophysectomy. Grafts of functional mammatropic pituitary tumors counteract the inhibitory effect of hypophysectomy in that they not only stimulate the growth of involuting preexisting cancers, but also cause the appearance of new mammary tumors.

*Bock & Dao D 11,892/61:* In rats, 3-MC accumulation in the mammary glands is increased by hypophysectomy or ovariectomy, but diminished during pregnancy. The affinity of mammary tissue for certain carcinogens may be due to its close association with adipose tissue.

*Dao & Greiner D 91,850/61:* In male rats, unlike in females or castrate males, 3-MC rarely produces mammary tumors. Ovarian transplants placed into castrate males induce predisposition for mammary carcinogenesis under these conditions.

*Seguy et al. D 5,238/61:* In rats, high doses of folliculoids enhanced the carcinogenic action of benzpyrene. Hypophysectomy or ovariectomy did not significantly influence this type of carcinogenesis, but the number of animals used was very small.

*Dao D 36,011/62:* In rats, ovariectomy performed before the administration of 3-MC or DMBA inhibited mammary carcinogenesis, but if the ovaries were removed 7 days after feeding the carcinogenic hydrocarbons, no significant reduction of mammary cancer resulted.

*Huggins & Fukunishi E 35,442/63:* In rats, mammary tumors induced by DMBA or by X-irradiation regress following ovariectomy.

“Tumors of this sort are, by definition, hormone-dependent.”

*Pannella & Gasparrini D64,636/63:* In female rats, the carcinogenic action of 20-methylcholanthrene is accelerated by folliculoids, partially inhibited by testosterone and completely blocked by ovariectomy. When tumors do arise, however, their histologic character is not influenced by any of these treatments.

*Sterental et al. D61,608/63:* In rats, mammary tumors induced by DMBA regressed after adrenalectomy+ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy+ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Dao G37,357/64:* Review of the literature on the effect of various hormones upon the induction of mammary cancers by carcinogens in the rat. The induction of these cancers requires the presence of ovarian hormones. Ovariectomy prevents this type of carcinogenesis unless ovarian transplants or estradiol are administered.

*Reuber F4,431/64:* In rats, the production of hepatomas by N-2-fluorenyldiacetamide was prevented by orchidectomy or thyroidectomy. However, the carcinogenic effect was restored in thyroidectomized animals by thyroid feeding.

*Huggins & Grand F74,177/66:* In rats, neither hypophysectomy nor orchidectomy causes regression of DMBA-induced mammary cancers.

*Ito et al. G42,670/66:* In mice, the development of urethan-induced thymic lymphomas was enhanced by orchidectomy but not significantly affected by ovariectomy. In the early latent period, adrenalectomy accelerated the development of thymic lymphomas, especially in females.

*Biancifiore et al. F98,833/67:* Both in intact and in ovariectomized mice, estrone increased the incidence of mammary carcinomas produced by DBA or 3-MC; only minimal effects were obtained with benzopyrene or DMBA.

*Bates H13,409/68:* Male Swiss mice are more sensitive than females to the induction of cutaneous carcinomas by DMBA+croton oil. This is especially true of females in which the initiator was applied during diestrus. Gonadectomy before application of DMBA

increased tumor incidence in females but decreased it in males.

*Heimann et al. F95,958/68:* In rats, the production of mammary carcinomas by DMBA is almost totally inhibited by ovariectomy. However, a high percentage of the spayed rats presents tumors of the ear duct, neurofibrosarcomas of the ear lobe and various cutaneous neoplasms. The appearance of these extramammary tumors may be due in part to the prolongation of the life span by the inhibition of mammary carcinogenesis.

*Svoboda et al. G64,564/69:* Hepatocytes of male rats given CPIB (ethyl- $\alpha$ -p-chlorophenoxyisobutyrate) show a pronounced increase in microbodies and in catalase activity while those of intact females do not. In castrate males given estradiol and CPIB the increase in catalase activity and microbody proliferation is abolished, whereas in ovariectomized rats given testosterone and CPIB there is an increase in microbodies and catalase activity.

*Glucksmann & Cherry G77,810/70:* In rats, ovariectomy offers partial protection against the induction of cervico-vaginal neoplasms after repeated topical applications of DMBA.

*Griswold Jr. & Green H26,709/70:* Review of the literature and personal observations on the effect of ovariectomy, testoids and folliculoids, alone and in combination, upon the hormone sensitivity of DMBA-induced mammary tumors in the rat.

*Jasmin & Riopelle H23,587/70:* In rats, ovariectomy greatly increased the incidence of mammary tumors produced by DMBA p.o. and also induced renal tumors which were not seen in similarly-treated intact controls.

*Kozuka H27,469/70:* “Repeated injection of reserpine and simultaneous administration of 2,7-diacetamidofluorene in SMA/Ms strain mice prevented the development of liver tumors but failed to induce gastric cancer. Female mice developed more hepatic tumors than males both in the carcinogen groups and in the reserpine-treated group. Castration increased the formation of hepatic cancer in male mice but not in females. In castrated female mice, estradiol benzoate had little effect and testosterone propionate reduced liver tumor incidence somewhat.”

*Polliack et al. H31,578/70:* In intact male hamsters, the induction of carcinomas by topical application of DMBA to the cheek pouch was reduced by testosterone. In castrate males, this effect was less striking. Castration itself had no effect on tumorigenesis.

*Simpson-Herren & Griswold, Jr. H26,708/70:* In rats, with DMBA-induced mammary carcinomas, the thymidine index was followed during different stages of cell development. "Administration of estradiol and progesterone to ovariectomized animals with regressed or static tumors results in an approximately 10-fold increase in thymidine index."

*Somogyi & Kovacs G60,074/70:* In rats, ovariectomy followed by grafting of ovarian tissue into the spleen, and consequent direct inflow of folliculoids into the liver, does not enhance DMBA-induced adrenal necrosis.

*Zackheim H26,549/70:* In mice, painted with methylcholanthrene, the incidence and extent of skin neoplasms was decreased by orchidectomy.

← **Adrenalectomy.** *Miyaji et al. D24,881/53:* In rats, the production of hepatic, mammary and sebaceous gland tumors by AAF was not significantly influenced by adrenalectomy. On the other hand, after gonadectomy, testosterone increased, whereas estrone, estradiol and progesterone decreased, carcinogenesis. [A brief abstract which is difficult to evaluate (H.S.).]

*Symeonidis et al. B93,003/54:* In rats, the production of hepatomas by DAB is prevented by adrenalectomy and by DOC in doses causing adrenocortical atrophy.

*Conney et al. D87,867/56:* Injection of 3-MC i.p. greatly increases the ability of rat liver homogenates to N-demethylate 3-methyl-4-monomethylaminoazobenzene and to reduce the azo linkage of 4-dimethylaminoazobenzene. Neither of these activities was altered after adrenalectomy, but both systems were slightly depressed after hypophysectomy.

*Eversole C45,823/57:* In rats, 3'MeDAB-induced hepatic carcinogenesis is not inhibited by DOC (in contradiction of earlier findings), whereas similarly DOC-treated adrenalectomized rats developed no hepatomas. The presence of even small remnants of adrenocortical tissue permitted the azo dye to exert its carcinogenic effect. "Total adrenalectomy is apparently the key factor in inhibiting azo dye carcinogenesis."

*Bielschowsky D10,255/61:* In rats, hypophysectomy, thyroidectomy and adrenal-

ectomy inhibit the development of hepatomas by treatment with 2-acetylaminofluorene (AAF) or 2-aminofluorene (AF).

*Perry D10,864/61:* In rats, the induction of hepatic cancers by AAF is prevented by adrenalectomy but not modified by DOC either in intact or in adrenalectomized animals.

*Benton D22,526/62:* In male mice, dibenzpyrene-induced tumors involute and most of them disappear after adrenalectomy.

*Sterental et al. D61,608/63:* In rats, mammary tumors induced by DMBA regressed after adrenalectomy+ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy+ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Trainin D61,599/63:* In mice, given a single feeding of DMBA as an initiating stimulus and twice-weekly paintings of 5% croton oil to the skin as a promoting stimulus, carcinogenesis was not significantly altered by cortisol or adrenalectomy during the initiating phase. Conversely, the promoting phase of cutaneous carcinogenesis was strikingly inhibited by cortisol and enhanced by adrenalectomy. The data are discussed in the light of the "two-stage mechanism of carcinogenesis."

*Shimazu G31,110/65:* 20-Methylcholanthrene increases hepatic dimethylaminoazobenzene-demethylase in the rat, even after adrenalectomy, ovariectomy, or hypophysectomy. Hypothalamic lesions decrease the basal level of the enzyme and its response to methylcholanthrene. On the other hand, glutamine synthetase (a microsomal enzyme not induced by methylcholanthrene) is unaffected by hypothalamic lesions.

*Ito et al. G42,670/66:* In mice, the development of urethan-induced thymic lymphomas was enhanced by orchidectomy but not significantly affected by ovariectomy. In the early latent period, adrenalectomy accelerated the development of thymic lymphomas, especially in females.

*Radzialowski & Bousquet H2,264/68:* The circadian variation in aminopyrine, p-nitroanisole and hexobarbital-metabolizing microsomal enzymes of the rat and mouse liver is abolished by adrenalectomy, but the rhythm of 4-dimethylaminoazobenzene metabolism remains unaffected.

*Symeonidis H27,336/70:* In C3Hf mice, which are spontaneously predisposed to hepatic tumor formation, the induction of liver

**Fig. 2. Prevention by spironolactone of DMBA-induced adrenal necrosis.** Both rats received the same dose of DMBA. A: Otherwise-untreated control shows hemorrhagic necrosis of the adrenal with periaidrenal edema. B: Adrenal is normal in the rat which received pretreatment with spironolactone. ← **Other Steroids** cf. also Selye G60,083/70, p. 385. Kovacs G70,404/69: In rats, electron-microscopic changes produced by DMBA are ascribed to primary damage in the capillary endothelium. The protective effect of spironolactone is ascribed to the induction of drug metabolizing microsomal enzymes.

Kovacs & Somogyi G60,025/69: In the rat, the adrenal necrosis produced by DMBA is inhibited by pretreatment with spironolactone.

Kovacs & Somogyi G60,060/69: In rats, the adrenal necrosis produced by DMBA is prevented by pretreatment with spironolactone and this protection is in turn blocked by ethionine.

Lacassagne et al. G74,932/69: In rats, production of hepatic cancers by DAB is powerfully inhibited by  $\Delta^5$ -pregnenolone, DOC or DDD. Various other steroids give less clearcut results.

Somogyi G70,406/69: In rats, the adrenal necrosis produced by DMBA or 7-hydroxy-

methyl-12-methylbenzanthracene is inhibited by pretreatment with spironolactone.

Wall et al. G69,969/69: A series of steroid esters of p-[N,N-bis(2-chloroethyl)amino]phenylacetic acid (BCAPAA), steroidal sulfides of p-(N,N-bis-2-chloroethylamino)thiophenol, and a variety of steroidal ethylenimine derivatives were synthesized and tested for antitumor activity. "Activity was found only in those instances in which the steroid and potential oncolytic agent were connected by ester or heterocyclic ether linkages. The steroidal BCAPAA esters were of particular interest showing excellent inhibition of a DMBA-induced and transplantable mammary adenocarcinoma, and marked increase in survival when tested on a variety of rat leukemias ... The steroidal BCAPAA esters were judged to be less toxic than some of the well-known nitrogen mustards in general use."

Kovacs & Somogyi G60,089/70: In rats, pretreatment with spironolactone delays the development and decreases the incidence of mammary tumors induced by a single injection of DMBA.

Solymoss et al. G70,445/70: In rats, the acute hematologic changes observed six days after a single oral dose of DMBA are suppressed by spironolactone but the alterations normally observed 12 days after DMBA still occur. The hematologic damage produced by a smaller dose of DMBA i.v. is prevented both by spironolactone and by SKF 525-A. Apparently "the hemopoietic alterations, elicited by DMBA, are dose-dependent and

**Fig. 3. Prevention of DMBA-induced adrenal necrosis by spironolactone.** A: Massive necrosis of the zona fasciculata and reticularis of the adrenal cortex 3 days after oral administration of DMBA. B: This lesion is completely inhibited by pretreatment with spironolactone. Hematoxylin phloxine,  $\times 120$ . [Somogyi and Kovacs G60,074/70. Courtesy of Rev. canad. Biol.]

influenced also by the biotransformation of this polycyclic hydrocarbon, since both acceleration (by spironolactone) and blockade (by SKF 525-A) of this latter process can suppress the development of hematologic alterations.”

*Somogyi G70,416/70:* In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, CS-1, and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocorticolytic effect of 7-OHM-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation

of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovacs G60,061/70:* It had been shown previously that the adrenocortical necrosis produced in rats by DMBA, unlike that elicited by its metabolite 7-hydroxymethyl-12-methylbenz(a)anthracene (7-OHM-MBA), is inhibited by partial hepatectomy. Perhaps DMBA is active only after having been metabolized in the liver to 7-OHM-MBA whose effect is independent of hepatic function. The question arose whether spironolactone protects against the adrenolytic effect of DMBA by preventing its hydroxylation; however, spironolactone protects the adrenals against 7-OHM-MBA also.

*Somogyi & Kovacs G60,074/70:* In rats, the adrenal necrosis produced by DMBA is inhibited by spironolactone and ethylestrenol; it is aggravated by estradiol, MAD, cortisol and testosterone but not significantly influenced by progesterone, norbolethone, triamcinolone or DOC.

*Stripp et al. H22,743/70:* In rats, spironolactone pretreatment shortened hexobarbital

sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Solymoss et al. G70,488/71:* In rats, spironolactone and ethylestrenol, like phenobarbital, enhance the NADPH-dependent hydroxylation of benzo(a)pyrene in hepatic microsomal + supernatant fraction.

*Somogyi & Kovacs G70,482/71:* In rats, the stress of restraint or of forced muscular exercise significantly increases the adrenocorticolytic effect of DMBA. Spironolactone can abolish this stress-induced aggravation. The mammary carcinogenicity of DMBA is not influenced by stress.

DMBA ← Steroids: Dao F19,168/64\*

#### **Carcinolytic Agents ← cf. also Individual Carcinolytic Agents**

*Andreani et al. C14,628/55:* In rats, the different organ changes produced by TEM are unequally influenced by combined treatment with ACTH + cortisone.

*Cutts H22,100/68:* In rats, diethylstilbestrol protects against lethal doses of vinblastine. Among otherwise untreated rats, females are more resistant to vinblastine than males.

*LePage & Kaneko H22,380/69:* Review and personal observations on mice showing that the toxicity of certain carcinostatic agents can be reduced by concurrent treatment with glucocorticoids without the loss of therapeutic efficacy.

*Grushina et al. H31,216/70:* Both in intact and in adrenalectomized rats, DOC stimulated the growth of sarcoma 45 and counteracted

the carcinolytic and general toxic effects of thiophosphamide.

*Mercier-Parot & Tuchmann-Duplessis G73,572/70:* In rats and mice, administration of the carcinolytic agent Natulan [chlorhydrate of 1-methyl 2p-(isopropylcarbomoyl) benzylhydrazine or RO 4-6467] causes fetal absorption and malformations. Even large doses of progesterone offer no protection against these effects.

*Gillette H34,126/71:* In male rats, spironolactone caused a relatively small increase in ethylmorphine N-demethylation and decreased the oxidation of hexobarbital and 3,4-benzpyrene. However (like in females), spironolactone did not affect the type I spectral changes induced in males by ethylmorphine and hexobarbital but caused a small decrease in cytochrome P-450 content and increased NADPH-cytochrome c reductase. Moreover, in males, spironolactone increased the substrate dependent cytochrome P-450 reduction but not its endogenous reduction. The sex difference in the effect of spironolactone upon hepatic microsomal drug metabolism is illustrated by the tabulation of data concerning ethylmorphine and hexobarbital biotransformation.

#### **Carisoprodol ←**

*Kato et al. G66,023/61:* Adult (unlike immature) male rats are less sensitive to carisoprodol-induced muscular paralysis than females. Castration or treatment with SKF 525-A abolishes the increased resistance of the adult male rat. Incubation of liver slices with carisoprodol shows that the resistance of the male is due to accelerated substrate inactivation. No sex difference is noted in adult mice or guinea pigs.

*Kato et al. G64,325/62:* Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect of OMPA is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids which enhance the decomposition of these substrates, the first three of which are inactivated, the last activated in the process. The differences were also demonstrated in vitro using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

*Selye G70,480/71:* In rats, carisoprodol sleeping time was moderately shortened by

the classic catatoxic steroids except norbolethone and oxandrolone. Prednisolone was also slightly efficacious, whereas triamcinolone was not. Progesterone and thyroxine moderately aggravated carisoprodol sleeping time, cf. Table 37.

Table 37. *Conditioning for carisoprodol*

Treatment <sup>a</sup>	Sleeping time <sup>b</sup> (min)	Mortality <sup>b</sup> (Dead/ Total)

Thyroxine	77 ± 12 *	4/5 NS
Phenobarbital	36 ± 5 NS	3/9 NS

<sup>a</sup> The rats of all groups were given carisoprodol (10 mg/100 g body weight in 0.1 ml DMSO, i.v., on 4th day).

<sup>b</sup> Mortality was listed on 5th day ("Exact Probability Test").

Sleeping time: Student's t-test.

For further details on technique of tabulation cf. p. VIII.

Carisoprodol ← Estradiol, Testosterone: Kato et al. *G66,023/61\**, *G64,325/63\**

#### Casein ← cf. also Amyloid

*Latvalahti B88,191/53; Peräsalo & Latvalahti C9,661/54*: In mice, the amyloidosis produced by repeated s.c. injections of casein is aggravated by ACTH and cortisone but not by DOC or testosterone, although orchidectomy facilitated its development.

*Kozlowski & Hrabowska H14,243/69*: Nandrolone, an anabolic steroid, enhances the development of amyloidosis in mice given casein s.c.

#### Cerium ←

*Snyder et al. C99,417/59*: In rats, i.v. injection of cerium produced extremely high levels of liver fat in females but not in males.

After castration males reacted as strongly as females. Testosterone reduced fatty infiltration in both intact and ovariectomized females. Hypophysectomy prevented fatty liver formation in both sexes, whereas adrenalectomy did so only in males.

*Selye PROT. 43437*: In rats (100 g ♀), the production of hepatic steatosis and mortality by  $CeCl_3$  (5 mg in 1 ml water, i.v.) are considerably inhibited by PCN, ethylestrenol and, to a somewhat lesser extent, by spironolactone (all 10 mg in 1 ml water × 2/day, p.o., beginning on the fourth day before  $CeCl_3$  administration). Under similar conditions, triamcinolone (10 mg × 2/day) and thyroxine (200 µg of Na-salts, s.c., once daily) actually aggravate  $CeCl_3$  intoxication. It is particularly noteworthy that, here, as in the case of cadmium and mercury intoxication, the catatoxic steroids offer protection against inorganic salts which could hardly be detoxified by the usual microsomal drug metabolizing mechanisms.

#### Chloral Hydrate ←

*Fastier et al. C37,038/57*: In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone and DOC did not prolong chloral hydrate sleeping time at the doses tested.

*Selye et al. G60,016/69; G60,020/69*: In the rat, pretreatment with norbolethone or spironolactone does not protect against the anesthetic effect of chloral hydrate.

#### Chlordecone ←

*McFarland & Lacy G68,855/69*: Japanese quail fed the insecticide, chlordecone (Kepone) developed a characteristic tremor, hepatic enlargement with fatty degeneration and a strong "estrogenic" effect on the oviduct which was not prevented by ovariectomy. The oviduct enlargement was considerably diminished, however, after hypophysectomy.

#### Chlordiazepoxide ←

*Blackham & Spencer G73,813/70*: In mice, lynestrenol reduced, whereas mestranol or SKF increased, the anticonvulsive effect (tested with electroshock) of diphenylhydantoin.

toin, phenobarbital, and chlordiazepoxide, administered i.p. after five days of pretreatment. This may be due to altered microsomal-drug metabolism but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentrations, the latter mechanism must also be considered.

*Selye PROT. 39493:* In rats, PCN, CS-1, ethylestrenol and to a lesser extent spironolactone and norbolethone shorten chlordiazepoxide sleeping time. The other standard conditioners were without significant effect but triamcinolone even in combination with chlordiazepoxide causes considerable mortality at doses at which the latter alone is well tolerated, cf. Table 38.

Chlordiazepoxide ← Mestranol, Lynestrenol: Blackham et al. G73,813/70\*

**Chloroform ←**

*Eschenbrenner & Miller 94,309/45:* Following administration of large amounts of chloroform p.o., "there was extensive necrosis of portions of the proximal and distal convoluted tubules in normal male and in testosterone-treated castrated male mice and no necrosis in female and in castrated male mice."

*Culliford & Hewitt C28,738/57:* In adult male mice of two strains, exposure to chloroform vapor produced necrosis of the renal tubules, whereas females showed no such change. Testoids rendered females fully susceptible, whereas folliculoids decreased the sensitivity of the males. Orchidectomy abolished susceptibility in one strain of mice but only diminished it in another, although the residual sensitivity could be annulled by adrenalectomy. In gonadectomized mice, methyltestosterone, testosterone propionate, dehydroepiandrosterone, progesterone and very large doses of cortisone induced susceptibility.

*Hewitt C28,739/57:* The high susceptibility of male mice to the induction of renal tubular necrosis by chloroform vapor is inhibited by castration and restored with as little as 10 µg of testosterone propionate. "These findings appear to provide the basis of a sensitive method for the detection and assay of androgens."

**Chloropicrin ←**

*Henschler & Reich C71,216/59:* In rats, the pulmonary edema induced by ammonium chloride, epinephrine, thiourea or chloropicrin is prevented by the administration of a single large dose of prednisolone i.v. about 5 min earlier.

Table 38. *Conditioning for chlordiazepoxide*

Treatment <sup>a</sup>	Sleeping time <sup>b</sup> (min)	Mortality <sup>b</sup> (Dead/Total)
None	308 ± 34	0/20
PCN	13 ± 6 ***	0/30 NS
CS-1	91 ± 22 ***	0/15 NS
Ethylestrenol	124 ± 27 ***	0/20 NS
Spironolactone	196 ± 27 *	0/20 NS
Norbolethone	169 ± 38 *	0/15 NS
Oxandrolone	228 ± 36 NS	0/15 NS
Prednisolone-Ac	247 ± 41 NS	1/15 NS
Triamcinolone	393 ± 39 NS	10/20 ***
Progesterone	313 ± 42 NS	2/15 NS
Estradiol	334 ± 35 NS	0/15 NS
DOC-Ac	290 ± 33 NS	0/15 NS
Hydroxydione	291 ± 50 NS	0/15 NS
Thyroxine	376 ± 43 NS	1/20 NS
Phenobarbital	218 ± 36 NS	0/19 NS

<sup>a</sup> The rats of all groups were given chlordiazepoxide, 15 mg/100 g body weight in 1 ml oil i.p. once on the 4th day.

<sup>b</sup> Mortality was listed on the fifth day ("Exact Probability Test").

Sleeping time: Student's t-test.

For further details on technique of tabulation cf. p. VIII.

**Chlorpromazine ←**

*Weil G68,214/61:* In rats, prednisolone i.p. "which protects against the lethal effects of endotoxin, is not effective in protecting against lethal amounts of ganglionic blocking agents (mecamylamine, chlorpromazine), adrenergic blocking drugs (dibenzylamine), or sympathomimetic amines (metaraminol). To the contrary, treatment with corticosteroid is associated with a significant increase in fatality in animals injected with mecamylamine and chlorpromazine (p = <0.01)." These findings are interpreted as evidence against the assumption that glucocorticoids protect in a nonspecific manner against injuries that produce hypotension.

*Fletcher et al. F44,604/65:* In the rat, "chlorpromazine hypothermia is potentiated by estradiol treatment. The potentiation may be brought about by a decreased metabolism of the drug but is not reflected in the protein content of liver or liver microsomes."

*Chatterjee G48,145/66:* In rats, small doses of cortisone prevent the ovarian inhibition

produced by chlorpromazine. "This may be explained as prevention of a competitive inhibitory phenomenon on pituitary gonadotrophin secretion produced by an excessive production of adenohipophyseal corticotrophin in chlorpromazine-treated animals."

*Selye et al. G60,016/69; G60,020/69:* In the rat, pretreatment with norbolethone or spironolactone does not protect against the anesthetic effect of chlorpromazine.

Chlorpromazine ← Norethynodrel, Progesterone: Juchau et al. *G40,275/66*

#### **Chlortetracycline ←**

*Sparano F71,594/65:* The hepatic steatosis-produced by chlortetracycline is more pronounced in orchidectomized and ovariectomized, testosterone-treated rats, than in otherwise untreated castrate females. Estradiol protects the liver of castrated males against this form of steatosis. "The results indicate that estradiol exerts a protective effect against chlortetracycline-induced lipid accumulation in the liver."

#### **Chlorzoxazone ←**

*Gessner et al. F77,776/67:* In mice, "testosterone pretreatment produces a biphasic effect on the duration of action of hexobarbital, prolonging the action initially and shortening the action in 4–8 days after the pretreatment. The early action of testosterone appears to be associated with an effect on the hypnotic property of a drug, since both hexobarbital and barbital sleep times are prolonged while the duration of action of the muscle relaxant chlorzoxazone remains unaffected. The long-term pretreatment with testosterone leads to a shorter duration of action of drugs that are deactivated by detoxification, notably hexobarbital and chlorzoxazone, but has no effect on the duration of hypnosis produced by barbital, a drug which is predominantly eliminated unchanged." Folliculoids (ethinylestradiol, diethylstilbestrol) prolong the actions of both drugs.

*Szeberényi & Fekete H29,579/70:* Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone meprobamate, estrone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

Chlorzoxazone ← Diethylstilbestrol, Testosterone: Gessner et al. *F77,776/67\**

**Cholesterol** ← cf. also *Selye G60,083/70, pp. 346, 348, 363, 364, 370, 371, 372, 374.*

*Gualandi et al. C7,736/51:* In rats, orchidectomy does not make it possible to produce atheromatosis by cholesterol feeding as earlier investigators have claimed.

*Oppenheim & Bruger B74,288/52:* In rabbits, cholesterol atheromatosis is diminished by cortisone and to a lesser extent by ACTH.

*Adlersberg et al. B82,951/53:* In rabbits on a high-cholesterol diet, cortisone and cortisol produce extreme elevations of plasma lipids.

*Stamler et al. B91,353/53:* In cholesterol-fed chicks, coronary atherosclerosis is prevented by estradiol even if the feminizing effects are eliminated by concurrent administration of testosterone. The protective effect of the folliculoid is not due to its effect upon blood cholesterol since hypercholesterolemia remains uninfluenced by it, but estradiol elevates the plasma phospholipid levels. In itself, neither testosterone nor chorionic gonadotrophin affect coronary atherosclerosis under these conditions.

*Gordon et al. B95,119/54:* In rabbits, cortisone inhibits the development of cholesterol atherosclerosis in the aorta as well as the accompanying hypercholesterolemia.

*Stumpf & Wilens B95,325/54:* In rabbits, cholesterol-induced atherosclerosis and hyperlipemia are inhibited by cortisone.

*Oester et al. C8,951/55:* In rabbits, the calcifying arteriosclerosis produced by combined treatment with thyroxine and epinephrine is not influenced by progesterone but cholesterol atherosclerosis is greatly diminished.

*Wang et al. E83,672/55:* In rabbits, cholesterol atherosclerosis is inhibited by cortisone despite an aggravation of the hypercholesterolemia. This effect of the glucocorticoid can be prevented by hyaluronidase.

*Dury C25,675/56:* In rabbits with established cholesterol atherosclerosis, cortisone accelerates the regression of the lesions.

*Moss & Dury C44,068/57:* In rabbits, the development of cholesterol atherosclerosis is inhibited by cortisone and the regression of already established lesions accelerated. The epinephrine-induced aortic medial necrosis is not prevented by cortisone but the fibroblast reaction in the lesions is inhibited.

*Constantinides et al. D21,813/62:* In rabbits, the regression of cholesterol atherosclerosis following return to normal diet is accelerated both by estriol and by prednisolone.

*Ferruccio F62,336/64*: Testosterone in combination with vitamin E diminishes the induction of fat deposition in the liver in cholesterol-fed rabbits.

*Rossi et al. F18,184/64*: In rabbits, cholesterol atherosclerosis is aggravated by DOC.

*Harman F59,112/65*: In rabbits, cortisone, prednisone and dexamethasone inhibit cholesterol atherosclerosis, although they elevate the serum cholesterol levels. Their protective action is ascribed to their antiphlogistic activity.

*Alper et al. H5,589/68*: In rabbits, cholesterol atheromatosis is prevented by methylprednisolone (Medrol) despite persisting hyperlipemia. The corticoid diminished the aortic concentration of acid mucopolysaccharides (AMPS) of low sulfate content. "Since all animals fed cholesterol developed some degree of pulmonary atherosclerosis, it is postulated that the antiatherogenic action of the hormone on the aorta is more closely related to alterations in the AMPS pattern than to changes in the pattern of circulating lipids."

*Bailey et al. H450/68*: In rabbits, cholesterol atherosclerosis is inhibited by cortisone, prednisone, triamcinolone, methylprednisolone, dexamethasone and 9 $\alpha$ -fluorocortisol, although hyperlipemia is aggravated. Phenylbutazone and oxyphenylbutazone also diminished cholesterol atherosclerosis, although to a lesser extent and without augmenting hyperlipemia.

*Porrazzi et al. H34,157/68*: In rabbits, DOC aggravates the severity of cholesterol atheromatosis, possibly through depolymerization of the ground substance.

*Curreri et al. H11,525/69*: In rabbits with cholesterol atherosclerosis various hydrolytic enzymes present in lysosomes ( $\beta$ -glucuronidase, acid phosphatase, cathepsin and aryl sulfatase) showed a marked increase in activity. Cortisone inhibited this atherosclerosis and the increased enzyme activity despite very high levels of serum cholesterol.

*Hamprecht G69,560/69*: Review (7 pp., 153 refs.) on the mechanisms regulating cholesterol synthesis. A special section deals with the effect of thyroid hormones, steroids, epinephrine, norepinephrine and glucagon.

*Schweppe & Jungmann H15,266/69*: The ability of rat liver microsomes to synthesize cholesterol palmitate, oleate and linoleate in vitro is increased by the addition of thyroxine or glucagon to the incubation medium. Testosterone increases cholesterol

palmitate and oleate formation. 17 $\beta$ -Estradiol stimulates mainly oleate synthesis.

*Schweppe & Jungmann H15,978/69*: Observations on the metabolism of marked cholesterol added together with various hormones to hepatic microsomes of the rat led to the conclusion that "1) cholesterol palmitate and oleate were synthesized most rapidly; 2) at high concentrations, testosterone decreased the formation of all esters but at lower dose levels, testosterone increased the synthesis of cholesterol oleate and palmitate; 3) estradiol caused a two-fold increase in cholesterol oleate formation; 4) ACTH decreased the synthesis rate of cholesterol palmitate and oleate; 5) insulin had a significant inhibitory effect on cholesterol linoleate; 6) epinephrine had little significant effect at the dose level used; and 7) L-thyroxine increased the synthesis of all cholesterol esters."

*Saini & Patrick G74,405/70*: Using isolated rat liver preparations it was found that estrone stimulates the conversion of radio-active cholesterol to bile acids.

Cholesterol ← Steroids: Kritchevsky et al. *G16,024/63*

#### **Choline Deficiency** ← cf. also **Ethionine**

← **Corticoids**. *György et al. D77,819/49*: In rats kept on a hypolipotropic diet supplemented with methionine, estrone, estradiol and ethinylestradiol p.o. inhibited hepatic steatosis. Of these folliculoids, ethinylestradiol was the most effective and produced a lipotropic effect even in the absence of methionine. Progesterone, DOC and testosterone were not lipotropic under identical conditions.

*Sellers et al. B52,716/50*: Cortisone partially protects the rat against the renal lesions produced by hypolipotropic diets.

*Katine et al. B80,347/52*: In weanling male rats, the production of fatty livers by choline deficiency is prevented by cortisone.

*Hurd et al. B83,869/53*: In rats kept on a choline-deficient diet, the development of fatty liver is inhibited by cortisone and adrenocortical extract.

← **Testoids**. *Emerson et al. B59,636/51*: Testosterone aggravates the renal and hepatic lesions induced in rats by dietary choline deficiency. Estradiol protects against hepatic cirrhosis in male rats, and against fatty liver formation in both sexes.

*Wilgram & Hartroft C14,392/55*: Female rats are much more resistant than males to the production of cardiovascular lesions by choline

deficiency. However, simultaneous administration of "androgens" (kind not specified) and STH sensitizes the female to the induction of these lesions by hypolipotropic rations.

*Wilgram et al. C15,960/56*: Both STH and testosterone aggravate the renal and cardiovascular lesions characteristic of choline deficiency in the rat.

*Girolami C55,043/58*: Testosterone propionate protects the rat against fatty degeneration and cirrhosis of the liver produced either by  $\text{CCl}_4$  or by a choline deficient diet.

*Bengmark et al. F67,484/66*: In rats with liver cirrhosis induced by choline deficiency "histological examination, determinations of liver nitrogen, nucleic acid and hydroxyproline concentration, liver transaminase activity, liver capacity to synthesize tauro- and glycocholic acid in vitro as well as determinations of the serum protein fractions did not reveal any definitely beneficial effects which could be ascribed to the testosterone treatment."

*Wilson et al. G79,508/70*: In mice, on hypolipotropic diets, the development of atrial thrombosis was independent of sex and not markedly influenced by gonadectomy. The same was true of castrated males given testosterone. Only gonadectomized females on estrone showed an unusually low incidence of thromboses.

← **Folliculoids** cf. also *Selye G60,083/70*, p. 369; *György et al. A47,909/47*: In rats kept on a hypolipotropic diet, estrone p.o. inhibits hepatic steatosis and greatly increases the lipotropic effect of methionine.

*Ferret E50,456/50*: Ovariectomized rats were kept either on a hypolipotropic choline-deficient diet which causes hepatic steatosis or on a complex ration (deficient in sulfur and vitamin E, yeast being the only source of protein) which causes hepatic necrosis. If such animals received estradiol implants into the spleen, vaginal estrus occurred, whereas in animals kept on a normal diet such implants failed to cause estrus because of the inactivation of folliculoids by the liver. Additional supplements of choline to the first or cystine to the second hepatotoxic diet restores the power to inactivate the folliculoid.

*Shipley et al. B50,163/50*: In ovariectomized rats maintained on a hypolipotropic diet supplemented with methionine, estrone pellets protected against the development of hepatic steatosis if implanted s.c. but not if placed in the spleen.

*Emerson et al. B59,636/51*: Testosterone aggravates the renal and hepatic lesions

induced in rats by dietary choline deficiency. Estradiol protects against hepatic cirrhosis in male rats, and against fatty liver formation in both sexes.

*Kotin et al. C16,597/56*: Brief note on the inhibiting effect of folliculoids upon the development of hepatic cirrhosis and hepatocellular carcinoma in rats kept on a choline-deficient diet.

*Wilson et al. G79,508/70*: In mice, on hypolipotropic diets, the development of atrial thrombosis was independent of sex and not markedly influenced by gonadectomy. The same was true of castrated males given testosterone. Only gonadectomized females on estrone showed an unusually low incidence of thromboses.

← **Gonadectomy**. *Plagge et al. C50,216/58*: In ovariectomized weanling rats, estradiol (but not estrone) pellets implanted into the spleen inhibited the fatty metamorphosis resulting from high-fat, low-choline diets.

*Sidransky et al. G48,110/67*: In rats, mature, intact or ovariectomized females, unlike intact males, develop fatty infiltration of the liver when first fed a choline containing methionine-deficient diet for three days. Castrated males are as susceptible as females and testosterone raises the resistance in females as well as in castrated males. Presumably, testosterone is responsible for the natural resistance of male rats to this type of hepatic steatosis. Earlier literature on sex differences in susceptibility to fatty liver formation is reviewed.

*Wilson et al. G79,508/70*: In mice, on hypolipotropic diets, the development of atrial thrombosis was independent of sex and not markedly influenced by gonadectomy. The same was true of castrated males given testosterone. Only gonadectomized females on estrone showed an unusually low incidence of thromboses.

#### **Cinchophen** ←

*Nasio 97,932/46*: Estriol and stilbestrol offer partial protection against cinchophen-induced peptic ulcers in the dog.

*Nasio B34,100/46*: In intact and gonadectomized dogs of both sexes the production of gastric ulcers by cinchophen is inhibited by stilbestrol.

*Nasio B77,063/46*: Monograph (151 pp., numerous refs.) on various factors influencing the development of cinchophen-induced peptic ulcers in the dog. Special emphasis is laid

upon personal observations showing that various folliculoids inhibit these lesions.

*Rodriguez-Olleris & Galindo C17,868/56, C38,499/57*: Neither ACTH nor cortisone modified the production of gastric ulcers by cinchophen in the dog.

*Selye G70,480/71*: In rats, cinchophen intoxication appears to have been inhibited by all classic catatoxic steroids and phenobarbital, although the diminution of toxic manifestations by CS-1 and oxandrolone was not statistically significant, *cf.* Table 39.

Table 39. *Conditioning for cinchophen*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	9/13	1/13
PCN	0/10 ***	0/10 NS
CS-1	3/10 NS	0/10 NS
Ethylestrenol	1/10 **	0/10 NS

Hydroxydione	10/10 NS	0/10 NS
Thyroxine	9/10 NS	2/10 NS
Phenobarbital	0/10 ***	0/10 NS

<sup>a</sup> The rats of all groups were given cinchophen (35 mg/100 g body weight in 0.2 ml DMSO, s.c., on 4th day).

<sup>b</sup> The characteristic dyskinesia was measured ("Flick-Test") 4 hrs after injection and mortality listed on 5th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Groza et al. H6,695/68*: In the dog, gastric ulcer formation and liver damage induced by cinchophen is partially inhibited by aldosterone.

*Hámori et al. G65,054/68*: In the dog, prednisolone greatly aggravates the production of gastric ulcers by cinchophen. [Since prednisolone has some ulcerogenic effects even when given by itself, the synergism with cinchophen probably occurs within the gastric mucosa. In any event, an action through the hepatic microsomal enzyme system has not been considered (H.S.).]

*Hamori et al. G72,363/69*: In dogs, the production of gastric duodenal ulcers by cinchophen is inhibited by DOC and aggravated by cortisone.

### Cocaine ←

*Aird B683/44*: DOC i.p. protected mice against cocaine-induced convulsions, but had no effect upon the electroshock seizure threshold of cats.

*Guerrero et al. F70,995/65*: Resistance to cocaine is significantly lower in male than in female rats, but no such sex difference is observed in castrates. Testosterone diminished the cocaine-resistance of castrates in either sex, whereas estradiol did not influence it. At the time of death, the plasma cocaine concentration was the same in both sexes, and hence it was concluded that testosterone interferes with the enzymic inactivation of cocaine.

*Selye G70,471/71*: In rats, cocaine intoxication was inhibited by all classic catatoxic steroids, prednisolone, estradiol and phenobarbital, *cf.* Table 40.

Table 40. *Conditioning for cocaine*

<sup>b</sup> Dyskinesia was estimated 2 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Copper** ← cf. also *Selye G60,083/70*, p. 369.

*Gregoriadis & Sourkes G72,808/70*: Review and personal observations on the effect of adrenalectomy, DOC, COL and corticosterone upon copper metabolism.

**Croton Oil** ←

*Selye G70,480/71*: In rats, the inflammatory response, as judged by exudate formation in granuloma pouches, was markedly inhibited

only by the two glucocorticoids among our conditioning agents, but PCN also appeared to cause a barely significant inhibition, cf. Table 43.

Table 43. *Conditioning for croton oil*

Treatment <sup>a</sup>	Accumulated Exudate (ml) <sup>b</sup>
None	4.6 ± 1.2
PCN	1.1 ± 0.5 *
CS-1	7.5 ± 1.5 NS

Norbolethone	7.4 ± 1.7 NS
Oxandrolone	6.9 ± 1.4 NS
Prednisolone-Ac	0.3 ± 0.1 **
Triamcinolone (2 mg)	0.2 ± 0.1 **
Progesterone	3.0 ± 0.5 NS
Estradiol (1 mg)	3.0 ± 0.5 NS
Estradiol (1 mg s.c.)	3.7 ± 0.5 NS
DOC-Ac	6.3 ± 1.9 NS
Hydroxydione	8.1 ± 1.1 NS
Cholesterol	5.0 ± 1.9 NS
Thyroxine	6.2 ± 0.8 NS
Phenobarbital	4.1 ± 1.0 NS

<sup>a</sup> The rats of all groups were given croton oil [1 ml/100 g body weight of a 1% solution in corn oil injected into the lumen of a 25 ml air pouch under the shaved dorsal skin (granuloma pouch technique) on 4th day].

<sup>b</sup> The accumulated exudate was measured on 11th day (Student's t-test).

For further details on technique of tabulation cf. p. VIII.

#### Curare ←

*Störtebecker 69,765/37*: In the mouse, the resistance to curare, KCN or ethanol is particularly high during estrus and decreased by ovariectomy. Castrates treated with estrone show increased tolerance to these drugs.

*Störtebecker 76,398/39*: Ovariectomized mice are unusually sensitive to curare, but their resistance is restored by estrone.

Curare ← Ovariectomy, Mouse: *Störtebecker 76,398/39\**

#### Cyanides ←

*Gellhorn 16,839/23*: In mice, resistance against acetonitrile can be increased not only by thyroid extract but, to a lesser extent, by

extracts of various other tissues, which augment resistance to KCN. Thyroidectomy and orchidectomy have an opposite effect.

*Störtebecker 69,765/37*: In the mouse, the resistance to curare, KCN or ethanol is particularly high during estrus and decreased by ovariectomy. Castrates treated with estrone show increased tolerance to these drugs.

*Störtebecker 76,398/39*: Ovariectomized mice are unusually sensitive to KCN intoxication, but their resistance is restored by estrone.

*Verne et al. B99,912/54*: In rats, the toxicity of KCN is diminished following pretreatment by cortisone.

KCN ← Ovariectomy, Mouse: *Störtebecker 76,398/39\**

#### Cycloheximide ←

*Greig & Gibbons C94,626/59*: Both cortisol and adrenal cortical extract protect the rat against fatal intoxication with cycloheximide. DOC is ineffective.

*Fiala & Fiala F70,819/65*: Cycloheximide produces rapid loss of liver glycogen and adrenal ascorbic acid, with an increase in adrenal weight and glucocorticoid secretion (as manifested by thymic atrophy). "All these changes" [including thymus atrophy? (H.S.)] can be prevented by the concurrent administration of cortisol. It is concluded "that increased adrenal function protects against actidione poisoning in rats."

*Selye G70,403/70; G70,480/71*: In rats, chronic cycloheximide intoxication can be prevented or at least diminished by all classic catatoxic steroids, as well as by progesterone and phenobarbital. Glucocorticoids and folliculoids exhibit no protective action and the apparent protection offered by hydroxydione and, to a lesser extent, even by DOC and cholesterol requires further study, cf. Table 44.

*Selye G70,480/71*: In rats, acute cycloheximide intoxication was prevented by all classic catatoxic steroids, as well as by prednisolone, progesterone and phenobarbital, cf. Table 45.

#### Cyclophosphamide ←

*Deppe & Lutzmann G14,653/64*: In the rat, Dianabol ( $\Delta^1$ -17 $\alpha$ -methyltestosterone) counteracts the toxicity of cyclophosphamide (a cytostatic agent) as well as the inhibitory effect of the latter upon antibody formation.

Table 44. *Conditioning for cycloheximide (low dosage)*

Treatment <sup>a</sup>	Mortality <sup>b</sup> (Dead/Total)

<sup>a</sup> The rats of all groups were given cycloheximide (100  $\mu$ g/100 g body weight in 0.2 ml physiologic NaCl solution, s.c., twice daily from 4th to 6th day).

<sup>b</sup> Mortality was listed on 8th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Fleischer & Riedel G20,778/64:* The toxic effect of cyclophosphamide upon hematopoietic organs and the adrenals of the rabbit is aggravated by pretreatment with prednisolone.

*Lutzmann & Schmidt F57,784/65:* In rats,  $\Delta^1$ -17 $\alpha$ -methyltestosterone failed to prevent the antimetabolic effect of cyclophosphamide or mitomycin upon Jensen sarcomas.

*Hayakawa et al. G64,146/69:* Cyclophosphamide is a latent alkylating agent which is almost inactive in vitro but is activated by the liver of the rat in vivo. Addition of prednisolone to liver slices inhibits cyclophosphamide activation. A similar inhibition of cyclophosphamide activation by prednisolone can be obtained in vivo as judged by the blood level of its metabolites. It is assumed that prednisolone hydroxylation and cyclophosphamide activation compete for the NADPH<sub>2</sub>-dependent drug-metabolizing enzyme system.

<sup>b</sup> Dyskinesia was estimated 24 hrs after injection and mortality listed on 5th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Selye G70,466/70:* In rats, cyclophosphamide intoxication (including the characteristic changes in the hemopoietic tissue and the body weight loss) was inhibited by all catabolic steroids, except oxandrolone. Progesterone diminished mortality without affecting the weight loss, whereas the glucocorticoids, estradiol and thyroxine, aggravated the weight loss, but failed to influence mortality, *cf.* Table 46.

### Cyclopropane ←

*Chase & Saidman H35,774/71:* In rats, pretreatment with spironolactone shortens the anesthetic effect of DOC but does not alter the minimum alveolar concentration of cyclopropane required to prevent movement in response to a painful stimulus. "It is suggested that central nervous system responsiveness is unaltered by spironolactone and that the reduction in potency of systemically administered sedatives in rats following spironolactone pretreatment may be a reflection of induction of drug metabolizing enzymes."

Fig. 4 (A + B). **Protection by catatoxic steroids against cyclophosphamide.** All animals received the same cyclophosphamide treatment. A: Ethylestrenol fails to prevent the characteristic swelling, hemorrhage and necrosis of the lips. B: PCN offers complete protection.

<sup>a</sup> The rats of all groups were given cyclophosphamide (10 mg/100 g body weight in 0.4 ml water, s.c., daily from 4th day ff.).

<sup>b</sup> Student's t-test.

<sup>c</sup> Mortality listed on 15th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

#### DDD ←

*Brown et al. C37,523/57:* The adrenal damage produced by DDD in the dog is not prevented by cortisone.

*Cueto Jr. G72,544/70:* In dogs, o,p'DDD produces a selective glucocorticoid deficiency

due to its damaging effect upon the fasciculata and reticularis of the adrenal. Epinephrine and norepinephrine produce hypotensive failure in DDD-treated dogs presumably as the consequence of their stressor action. Prednisolone largely restores the resistance of the DDD-treated animals.

#### Dexamphetamine ←

*Blackham & Spencer G76,301/69:* In female mice, pretreatment with lynestrenol (a luteoid) reduced the hyperthermia induced by dexamphetamine, whereas mestranol (a folliculoid) increased it. Fencamfamine (also a CNS-stimulant) failed to induce hyperthermia in control or lynestrenol pretreated mice but did raise the temperature after mestranol pretreatment. The potentiating effect of mestranol could be mimicked by pretreatment with nialamide (a MAO-inhibitor) but not by SKF 525-A. Increased locomotor activity induced by dexamphetamine and fencamfamine was enhanced by mestranol and reduced by lynestrenol. Dopamine, norepinephrine and 5-HT levels in the brain were reduced by lynestrenol and 5-HT was increased by mestranol. "If the actions of dexamphetamine (and fencamfamine) are due predominantly to the release of endogenous amines, then an increase (with lynestrenol) or a decrease (with mestranol) of tissue MAO activity should change the potency of these two stimulant drugs."

Dextroamphetamine ← Mestranol, Lynestrenol + Crowding, Mouse: Blackham et al. G76,301/69\*

Fig. 4 (C—F). C: Ethylestrenol fails to prevent the development of necrotizing myocarditis (light areas near the base of the heart) and fibrinous pericarditis characteristic of cyclophosphamide intoxication. The virtually complete atrophy of the thymus reflects the intense stress reaction which was associated with pronounced adrenocortical enlargement. The thymic lymph nodes (as those in other parts of the body) are hemorrhagic. D: Complete prevention of cardiac lesions by PCN. The thymus is normally developed. E: Numerous microbial colonies in myocardium and in the fibrinous pericardial covering. Complete absence of leukocytes, presumably secondary to cyclophosphamide-induced destruction of hemopoietic tissues. Multiple myocardial necroses.

F: PCN prevents all these lesions. PAS  $\times 60$ .

Fig. 4 (G + H). G: In rat given cyclophosphamide alone, the bone marrow consists virtually only of gelatinous connective tissue. H: CS-1 offers virtually complete protection to the bone marrow. PAS×60

Fig. 4 (I + J). I: Cyclophosphamide causes enlargement of the glomerulosa (between arrows) which is heavily laden with PAS positive granules. J: PCN prevents this change. PAS×170. [Selye G70,466/70. Courtesy of Virchows Arch. Abt. A pathol. Anat.]

**DHT** ← *cf. Vitamin D***Diazepam** ← *cf. Chlordiazepoxide***Diethylnitrosamine** ←

*Boquoi & Kreuzer F 82,383/65:* In the rat, the hepatic cirrhosis produced by diethylnitrosamine was not significantly influenced by progesterone. Estradiol aggravated the liver lesions and accelerated mortality before hepatomas could develop.

**Digitalis** ← *cf. also Selye G 60,083/70, pp. 369, 381, 385, 491, 492, 494.*

**RAT**

*Kupperman & de Graff B 47,267/50:* In rats, the ECG disturbances caused by ouabain or digitoxin i.v. are aggravated by adrenalectomy, and diminished by DOC.

*Holck & Kimura D 99,625/51:* One month old rats of both sexes are equally sensitive to ouabain. Adult female rats are more resistant to ouabain than males but the difference does not become evident before 2–4 months of age. Rats rapidly become resistant to ouabain, and upon repeated injections, the sex difference tends to disappear. Castration does not alter the sex difference in ouabain resistance significantly in either sex. "However, in case of pentobarbitalized rats the usual higher female resistance was plainly seen and spaying definitely decreased the number of injections required to cause death."

*Schatzmann C 73,682/59:* "Corticosterone was shown to have an inhibitory effect on the contraction caused by a cardiac glycoside (g-Strophanthin = Ouabain) in isolated strips of rat aorta. It could be demonstrated that over a tenfold concentration range of Ouabain, the kinetics of this antagonism are in accord with the assumption of a competitive inhibition."

*Sulser et al. D 96,543/59:* In adrenalectomized rats, K-strophanthin increases Na and K excretion and this effect is prevented by DOC. In intact rats, K-strophanthin causes Na retention; yet, K excretion is augmented as it is after adrenalectomy.

*Bouyard & Klein D 69,070/63:* Betamethasone aggravates the neuromotor disturbances produced in the rat by strophanthin-G.

*Savoie et al. G 60,080/69:* In rats, the infarctoid cardiopathy produced by digitoxin + Na<sub>2</sub>HPO<sub>4</sub> + corn oil is prevented by spironolactone. This protection is ascribed in part to

the potassium-sparing and in part to the catatoxic action of the steroid.

*Selye et al. G 46,800/69; Savoie et al. G 60,028/69:* Spironolactone protects the rat against the myocardial necroses produced by digitoxin + Na<sub>2</sub>HPO<sub>4</sub> + corn oil. The associated neuromuscular disturbances are also prevented. Neither amiloride nor KCl prevent the convulsions; hence, presumably, spironolactone does not act through K-retention.

*Selye G 60,003/69:* In rats, spironolactone prevents acute digitoxin poisoning even after bilateral nephrectomy.

*Selye et al. G 60,042/69:* In the rat, both spironolactone and norbolethone inhibit the toxic effects of digitoxin, gitalin, proscillaridin, digoxin and digitalin. The corresponding effects of strophanthin K, ouabain and digitoxigenin were not prevented.

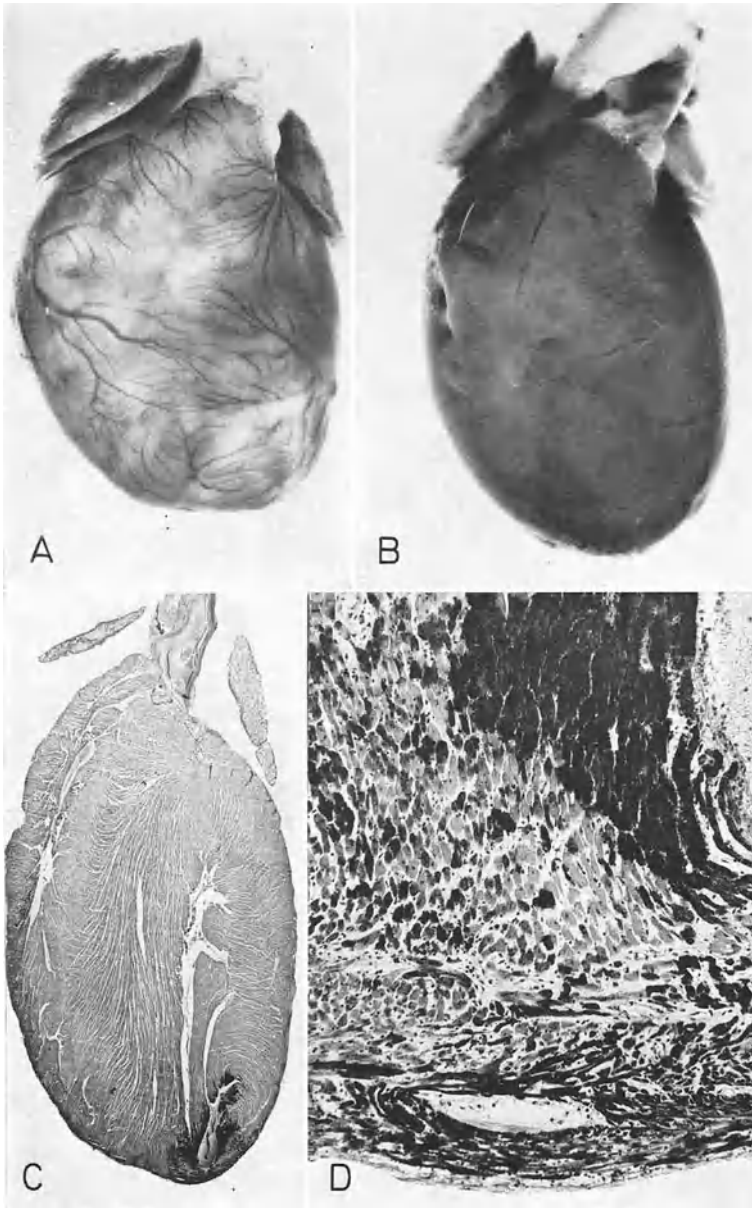

*Selye et al. G 60,050/70:* Spironolactone, spiroxasone, SC-5233, SC-8109, CS-1, aldadiene and aldadiene-kalium (SC-14266), like norbolethone, protect the rat against convulsions induced by digitoxin.

*Selye G 70,421/70; G 70,480/71:* In rats, fatal digitoxin convulsions are readily prevented by all classic catatoxic steroids and, to a lesser extent, also by prednisolone, progesterone and hydroxydione. All other standard conditioning agents of our series, including phenobarbital, proved to be completely ineffective in combating digitoxin poisoning *cf.* Table 47, p. 230.

*Selye G 60,064/70:* In rats, the mortality associated with the cardiac necroses produced by digitoxin + Na<sub>2</sub>HPO<sub>4</sub> + corn oil was excellently prevented by all classic catatoxic steroids as well as by progesterone and, to a much lesser extent, by phenobarbital. The prevention of the macroscopically visible cardiac necroses themselves followed a similar pattern but was much less constant *cf.* Table 48, p. 230.

*Selye G 70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Solymoss et al. G 70,441/70:* In rats, spironolactone or oxandrolone given for as long as two months, continues to exhibit a protective effect against fatal doses of digitoxin or indomethacin. Upon withdrawal of the catatoxic steroids, continued administration of digitoxin

**Fig. 5. Prevention by CS-1 of the cardiopathy produced by digitoxin +  $\text{Na}_2\text{HPO}_4$  + corn oil.** All rats received the same treatment with digitoxin +  $\text{Na}_2\text{HPO}_4$  + corn oil p.o. A: Macroscopic appearance of the extensive myocardial necroses (light areas) in a control rat. B: Similarly-treated rat in which the cardiac lesions were completely prevented by CS-1. C: Cross-section through the ventricles of the heart showing the mildest degree of the digitoxin cardiopathy, in this case limited to the apical region (von Kóssa  $\times 6.5$ ). D: Severe digitalis lesions in the apex of another myocardium under higher magnification (von Kóssa  $\times 170$ ). [Selye G60,064/70. Courtesy of J. molec. cell. Cardiol.]

<sup>a</sup> The rats of all groups were given digitoxin [0.4 mg in 2 ml water mixed with Na<sub>2</sub>HPO<sub>4</sub> (1 mM per rat)] and corn oil (1 ml, p.o., twice daily from 4th day ff.).

<sup>b</sup> Cardiac necrosis was estimated on day of death in animals that lived at least 6 days and mortality listed on 9th day ("Exact Probability Test").

For further details on technique of tabulation *cf. p. VIII.*

Partial hepatectomy reduces digitoxin clearance. The effect of spironolactone is suppressed by SKF 525-A and cycloheximide.

*Solymoss G70,484/70:* In rats, the plasma clearance of digitoxin is accelerated by spiro-lactone, norbolethone, and ethylestrenol in doses that protect against the toxicity of the alkaloid *in vivo*. On the other hand, partial hepatectomy reduces digitoxin plasma clearance and increases the severity of the convulsions. The protective action of the steroids is suppressed by SKF 525-A and cycloheximide.

*Selye G70,480/71:* In the rat, comparative studies with 59 steroid nitriles indicate that the highest antidigitoxin and anti-indomethacin is exhibited by 16 $\alpha$ -carbonitrile. All 11 steroids of this series which possessed a 16 $\alpha$ -carbonitrile group were endowed with this type of protective activity. Most active among them were: PCN, its acetate, 20,20(ethylenedioxy)-

3 $\beta$ -hydroxypregn-5-ene-16 $\alpha$ -carbonitrile (U-19553), 3 $\beta$ -hydroxy-7,20-dioxopregn-5-ene-16 $\alpha$ -carbonitrile acetate (SC-6703), 3 $\beta$ -hydroxy-7,20-dioxopregn-5-ene-16 $\alpha$ -carbonitrile (SC-6813), 3,3-(ethylenedioxy)-11,20-dioxopregn-5-ene-16 $\alpha$ -carbonitrile (U-35006), 3,3,20,20-Bis-(ethylenedioxy)-11-oxopregn-5-ene-16 $\alpha$ -carbonitrile (U-35910), 3 $\beta$ -Hydroxy-20-oxopregn-5-ene-16 $\alpha$ -carbonitrile acetate (U-34889), 3 $\beta$ -hydroxy-20,20-ethylendioxy-5-ene-16 $\alpha$ -carbonitrile acetate. Certain 2 $\alpha$ -carbonitriles (and 2-ene-3 $\alpha$ -carbonitriles) were also effective but to a lesser degree. Steroids with carbonitriles in other positions of the nucleus or side chains were not effective. In this series only a few steroids devoid of -CN groups showed any significant antidigitoxin and anti-indomethacin effect. Among these one was a 16 $\beta$ -carboxylic acid, the other a 4-aza steroid. Mestranol protected against indomethacin but not against digitoxin. Among the carbonitriles, in general the same tendency was noted at low doses where anti-indomethacin effect exceeded the antidigitoxin action.

*Szabo et al. G79,024/71*: In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

*Selye PROT. 17663*: In rats, spironolactone given simultaneously with digitoxin has little, if any, protective effect. Pretreatment for 24 hrs is moderately effective, whereas after 48—96 hrs of spironolactone treatment, digitoxin toxicity is completely abolished.

*Selye PROT. 18125*: In rats pretreated with 10 mg of spironolactone, the antidigitoxin effect remains obvious for about 5 days after discontinuation of treatment, but its efficacy in inhibiting convulsions rapidly diminishes during this time.

*Selye PROT. 20023*: In rats, spironolactone (10 mg x2/day p.o.) protects against as much as 2 mg of digitoxin/day p.o., whereas the same dose of norbolethone protects even against 5 mg of digitoxin.

*Selye PROT. 20049*: In rats, the inhibition of digitoxin poisoning by spironolactone can be blocked by high doses of estradiol and apparently to some extent also by progesterone, whereas DOC, cortisol, methylandrostenediol, methyltestosterone, pregnanedione, pregnenolone and testosterone do not interfere with this type of protection, *cf.* Table 49.

*Selye PROT. 34038,34405*: In rats of different age groups, the antidigitoxin effect of PCN is essentially the same if administered at dose levels adjusted to body weight, *cf.* Table 50.

Table 49. *Effect of various steroids upon the antidigitoxin effect of spironolactone*

300	10/10	0/10 ***	10/10	0/10 ***

<sup>a</sup> The rats of all groups were given digitoxin 2 mg in 1 ml water, p.o. 4th and 5th day. The groups so designated received PCN 0.2 mg in 1 ml water, p.o. x2/day, from the 1st day up to 4th day and once on the 5th day. Doses per 100 g body weight.

<sup>b</sup> The severity of the convulsions was estimated on the 7th day and mortality was listed on the 9th day. (Statistics: Fisher & Yates.)

For further details on technique of tabulation cf. p. VIII.

*Selye PROT. 25766:* In rats, the blockade by spironolactone of indomethacin or digitoxin poisoning is abolished if metyrapone is administered simultaneously with the conditioner, cf. Table 51.

*Selye PROT. 42269:* In rats chronically poisoned with digitoxin (0.5–1.0 mg, p.o./day) or indomethacin (0.75 mg, s.c./day), the administration of PCN (1 mg x2/day, p.o., beginning on the 3rd or 4th day of treatment with the

toxicants), when clinical signs of poisoning were already evident, caused these to disappear and permitted survival, whereas the controls receiving no PCN invariably died. These experiments show that, although presumably the protective effect of PCN against digitoxin and indomethacin depends upon the induction of drug-metabolizing enzymes, the steroid can act not only prophylactically but also curatively, if the intoxication is sufficiently slow to permit effective enzyme induction in time.

#### Dog

*Grinnell & Smith C31,428/57:* On the basis of studies in dogs treated with estrone, estradiol or diethylstilbestrol, it is concluded that folliculoids protect against the induction of cardiac arrhythmia by digoxin. "Male dogs and castrate female dogs have been found to be highly sensitive to toxic manifestations of a cardiac glycoside on cardiac rhythm, in comparison with normal females in anestrus, or castrate females treated with estrogenic substance. A high degree of resistance to toxicity of digoxin was exhibited by the 3 normal females in natural estrus which were available."

*Grinnell et al. D10,545/61:* In ovariectomized dogs, various folliculoids increase resistance to the production of ECG changes by digoxin.

*Shafer & Adicoff G80,179/70:* In dogs, tetrahydrofurfuryl alcohol (THFA), despite its resemblance to the lactone moiety of digoxin, offers no protection against the latter com-

Table 51. Effect of metyrapone upon the blockade of indomethacin and digitoxin toxicity by spironolactone

Group	Treatment <sup>a</sup>	Digitoxin		Indomethacin	
		Convulsions <sup>b</sup> (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)	Intestinal ulcers <sup>b</sup> (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)

2	Spironolactone	0/15 ***	0/15 ***	0/15 ***	0/15 ***
3	Metyrapone	14/15 NS	14/15 NS	13/15 NS	7/15 *
4	Metyrapone + Spironolactone	11/15 ***	10/15 ***	10/10 ***	2/10 NS

<sup>a</sup> The rats of all groups received indomethacin 1 mg in 0.2 ml water, s.c., or digitoxin 1 mg in 1 ml water p.o., once daily from the 4th day; spironolactone 2 mg in 1 ml water p.o., twice daily from the 1st day; metyrapone 6 mg in 0.1 ml oil, i.p., the 4th and 5th days and 12 mg daily from the 6th day 30 min. before indomethacin or digitoxin administration.

<sup>b</sup> The severity of convulsions was estimated on 7th day; intestinal ulcers were appraised on day of death (but only in animals which survived at least 6 days), and mortality was listed on 9th day. (Statistics Fisher & Yates; groups 2 and 3 compared with group 1, group 4 compared with group 2).

Fig. 6. Prevention of digitoxin convulsions by spironolactone. All four rats were given 2 mg of digitoxin p.o., but only D was pretreated with spironolactone and thereby protected against digitoxin convulsions

pound in vivo. The authors emphasize that despite these “negative results, the development of a specific nontoxic pharmacological antagonist to digitalis would be of major clinical importance.” [These investigators appear to be unaware of the inhibition of digitalis toxicity by spironolactone (H.S.).]

#### FROG

*Von Metzler & Hergott B63,494/51:* In frogs, induction of lethal cardiac arrest by strophanthin is delayed by simultaneous treatment with DOC. This may reflect a true antagonism or merely a delay in absorption.

*Wilbrandt & Weiss C88,230/60:* Review of the literature on the antagonisms between cardiac glycosides and corticoids. Personal investigations showed that the electric potential lowering effect of K-strophanthin in frog’s skin can be inhibited by aldosterone and DOC, but only if the corticoids are administered in vivo.

#### GUINEA PIG

*Lindner & Stoklaska C35,550/56:* In guinea pigs, chronic intoxication with digitoxin is moderately counteracted by chronic treatment with cortisone but pretreatment with

cortisone offers no protection against subsequent acute digitoxin poisoning. Chronic pretreatment with sublethal doses of digitoxin diminishes resistance to subsequent i.v. injection of a higher dose, presumably owing to the cumulative effect of the alkaloid.

*Godfraind & Godfraind-De Becker D45,080/61:* The contractions of the guinea pig ilium produced in vitro by various digitalis alkaloids is competitively inhibited by DOC.

#### MOUSE

*Holck & Kimura 84,604/44:* Female mice are more resistant to ouabain than males but resistance to strophanthin K is the same in both sexes. Ovariectomy, orchidectomy and treatment with “estrogenic hormones” produced inconsistent changes in ouabain resistance.

*Selye PROT. 27594, 28284, 29742, 29751:* In mice, digitoxin poisoning is inhibited by CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone and thyroxine. Ethylestrenol, triamcinolone, DOC, hydroxydione and estradiol are ineffective.

#### CAT

*Pozo & Negrete B68,183/52:* On skeletal muscles of the cat, cortisone “produced a

very marked potentiation of the effects of digitalis."

#### HAMSTER

*Szabo et al. G79,013/71:* In hamsters, spironolactone and ethylestrenol pretreatment prevents digitoxin convulsions and indomethacin-induced intestinal ulcers.

#### VARIA

*Selye et al. G60,023/69:* Among numerous steroids tested, all anabolic testoids inhibited digitoxin toxicity. However, spironolactone was likewise highly effective in this respect although it is devoid of both anabolic and testoid potency. Apparently, anabolic potency endows steroids with antidigitoxin properties but is not indispensable for them. (Literature on catatonic actions of spironolactone and anabolic steroids).

#### **Diisopropyl Fluorophosphate (DFP) ←**

*Fontan et al. F55,419/65:* Pretreatment with spironolactone protects the mouse against lethal DFP intoxication. When spironolactone is given simultaneously with or after DFP, a protection is still demonstrable but less evident.

*Fontan et al. F98,752/68:* Spironolactone, phanurane, aldosterone and dexamethasone, despite their different pharmacologic actions protect the mouse against DFP-intoxication, a fact which is ascribed to their common possession of the cyclopentanophenanthrene nucleus. Triamterene, whose renal action resembles that of the antiminerlocorticoids does not protect against DFP. [No other steroids have been tested to verify whether the protective effect is common to all compounds possessing the cyclopentanophenanthrene nucleus (H.S.).]

*Selye G70,480/71:* In rats, most catatonic steroids offered some protection against "DFP" intoxication, but their prophylactic effect was not as striking as against other anticholinesterases, perhaps because in this experiment, the intoxication of the controls was not sufficiently severe to reveal a major protective effect, *cf.* Table 52.

#### **Dimercaprol ←**

*Selye G70,480/71:* In rats, dimercaprol "BAL" (0.2 ml/100 g body weight of a 5% solution in corn oil) was administered s.c. once on the 4th day of conditioning. Dyskinesia was listed 4 hrs, mortality 24 hrs, after injection. Under these circumstances none of the

"Standard Conditioners" (p. VIII) or cholesterol caused any noteworthy change in the resulting intoxication. Hydroxydione and phenobarbital were not tested.

Table 52. *Conditioning for "DFP"*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

Thyroxine	3/10 NS	3/10 NS
Phenobarbital	4/10 NS	0/10 NS

<sup>a</sup> The rats of all groups were given diisopropyl fluorophosphate, "DFP" (250 µg/100 g body weight in 0.2 ml corn oil s.c. once on 4th day).

<sup>b</sup> Dyskinesia was estimated on 5th day and mortality listed on 6th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

#### **Dinitrophenol ←**

*Selye PROT. 27780:* In rats, dinitrophenol (3.2 mg/100 g body weight in 0.2 ml DMSO) was administered s.c. once on 4th day of conditioning. Dyskinesia was listed 1 hr, mortality 24 hrs, after this injection. Under these circumstances none of the "Standard Conditioners" (p. VIII) or cholesterol caused any noteworthy change in the resulting intoxication, only thyroxine exhibited an aggravating effect. Hydroxydione and phenobarbital were not tested.

#### **Dioxathion ← *cf.* Pesticides**

#### **Diphenylhydantoin ←**

*Fingl et al. D38,091/52:* In rats, chronic administration of phenobarbital or diphenylhydantoin diminishes the brain hyperexcitability induced by cortisone as judged by electroshock-seizure threshold measurements.

Rümke & Noordhoek H14,039/69: Lyne-strenol (a luteoid) decreases the hexobarbital sleeping time and diminishes the anticonvulsant effect of phenobarbital and diphenylhydantoin by acceleration of their metabolisms through the hepatic microsomal enzymes.

Blackham & Spencer G73,813/70: In mice, lynestrenol reduced, whereas mestranol or SKF 525-A increased the anticonvulsive effect (tested with electroshock) of diphenylhydantoin, phenobarbital, chlordiazepoxide and diazepam administered i.p. after five days of pretreatment. This may be due to altered microsomal drug metabolism but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentrations, the latter mechanism must also be considered.

Selye PROT. 37772: In rats, moderate intoxication with diphenylhydantoin was prevented by CS-1 and spironolactone, whereas prednisolone and triamcinolone considerably aggravated its intensity. The effect of the other standard conditioners was less clear-cut, cf. Table 53.

Table 53. *Conditioning for diphenylhydantoin*

<sup>a</sup> The rats of all groups were given dipicrylamine (10 mg on 4th day, 15 mg on 5th day, /100 g body weight in 0.2 ml DMSO, s.c.).

<sup>b</sup> Dyskinesia was estimated on 5th day 2 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Disulfiram ← cf. also Pharmacology (Inhibitors)**

Lecoq B79,754/51: In rabbits, injection of disulfiram + ethanol or of Na-pyruvate produces essentially the same syndrome of intoxication, since pyruvic acid is the principal

metabolite of ethanol after pretreatment with disulfiram. In either case, ACTH and cortisone offer little, if any, protective effect.

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

#### **DMP ← cf. Phosphorothioates**

##### **Doxepin ←**

*Selye PROT. 40821*: In rats, doxepin hydrochloride (20 mg/100 g body weight in 1 ml water) was administered p.o. twice daily from the 4th day of conditioning to the 9th day. Dyskinesia was estimated on the 8th day one hour after the last injection, mortality listed on the 9th day. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication.

#### **Dyes ← cf. also RES-Blocking Agents, Bilirubin, Clinical Implications (for BSP)**

##### **MAN**

*Heaney & Whedon C56,394/58*: In man, methyltestosterone and norethandrolone p.o. markedly delay BSP clearance, whereas comparable amounts of testosterone are ineffective in this respect.

*Carbone et al. C77,294/59*: In patients with impaired hepatic function caused by methyltestosterone, large amounts of conjugated BSP accumulate in the serum.

*Arias D63,323/63*: In man, 17-ethyl-19-nortestosterone increases biliary BSP retention and plasma bilirubin concentration. Both in Wistar rats and in Gunn rats (the latter have chronic nonhemolytic unconjugated hyperbilirubinemia due to a hereditary defect), norethandrolone, methyltestosterone and icterogenin (an icterogenic steroid) interfered with the excretion of bilirubin and BSP through the bile. This was accompanied by certain electron microscopic changes in cytomembranes and lysosomes, without cell necrosis or any obvious change in various enzymic

activities of hepatocytes. No effect was noted in rats treated with cortisone or testosterone.

*Scherb et al. D58,943/63*: In man, with no evidence of liver disease, norethandrolone caused a reversible reduction in the hepatic transport maximum for BSP. "The relative hepatic storage of BSP was unimpaired and BSP was retained in the plasma primarily as a conjugate. Light microscopic examination of two liver biopsies was normal except for BSP within parenchymal cells and fragmented ATPase-staining reaction of bile canaliculi. Electron microscopic examination revealed variable dilatation of bile canaliculi and normal intracellular organelles." The clinical literature on the effect of anabolics upon hepatic function is reviewed.

*Mueller & Kappas F22,282/64*: In man, estradiol and estriol rapidly and consistently reduced the hepatic excretory capacity for BSP.

*Mueller & Kappas G81,288/64*: Review and personal observations on the impairment of hepatic BSP excretion following treatment with natural folliculoids and during pregnancy in women.

*Schoenfield & Foulk F16,158/64*: In man, norethandrolone p.o. interferes with hepatic uptake and biliary excretion of BSP.

*DeLorimier et al. G31,525/65*: In man, BSP retention, without clinical or laboratory evidence of impaired hepatic function, developed after treatment with methyltestosterone, normethandrone, norethindrone, fluoxymesterone and methandriol. No significant retention occurred with 17 $\alpha$ -vinyltestosterone, oxandrolone, unesterified testosterone, 17 $\alpha$ -ethynyl-19-norandrostenediol or allylestrenol. The structural prerequisites for BSP retention are discussed. The factors responsible for jaundice (which is rarely reported in patients receiving most of these compounds) could not be identified.

*Kleiner et al. F47,209/65*: In women on oral contraceptives (norethynodrel and mestranol), BSP-excretion through the bile was impaired. The effect is ascribed to the luteoid component since estradiol does not cause BSP-retention.

*Kotra & Kappas G37,574/66*: In man, estradiol delays the clearance of BSP from the plasma, presumably because the excretion of both free and conjugated dye is impaired.

*Larsson-Cohn G46,952/67*: In 16 out of 22 women taking various contraceptives containing folliculoids and luteoids, BSP clearance was delayed.

*Kappas F 94,299/68*: In man, estradiol and estriol impair BSP excretion through the liver and may provoke hepatic porphyria.

1.11

#### RAT

*Clodi & Schnack D41,569/62*: In rats, the biliary excretion (fistula technique) of BSP is inhibited by numerous anabolic steroids. Earlier clinical and experimental data are discussed.

*Kolb et al. D22,260/62*: In rats, the biliary excretion of <sup>131</sup>I marked rose bengal is inhibited by daily p.o. administration of various 17-alkylated anabolic steroids although after several weeks, adaptation develops in this respect. Among eight such anabolics tested, only methenolone acetate failed to impair dye excretion. [The possibility that decreased dye excretion may not reflect hepatic damage but increased dye metabolism has not been considered (H.S.).]

*Gallagher & Kappas F35,850/65*: In rats, estradiol markedly delays plasma clearance of BSP, both in its free and conjugated form. "The structural specificity of this steroid action was examined in a variety of C18, C19, C21 and C24 compounds; the effect extends to estrone, estriol and other C18 steroids, including those used for contraceptive purposes."

*Gallagher et al. F86,156/67*: In rats, 42 steroids (mostly folliculoids) were compared for their ability to interfere with BSP clearance.

*Kreek et al. F83,145/67*: In rats, ethinyl-estradiol considerably diminishes bile flow and delays biliary excretion of BSP and of tritium-labeled estradiol.

*Song et al. G70,575/69*: Comparative studies on the effect of 43 steroids upon BSP clearance in the rat, as an indicator of their hepatotoxic effect.

*Despopoulos H24,651/70*: In rats, "1) Cortisone transiently increased bile flow and reduced concentration and rate of excretion of sulfobromophthalein in the bile. 2) Norethandrolone, norethynodrel and Nurlutin reduced rates of bile formation and of sulfobromophthalein excretion without affecting the concentrating mechanism for sulfobromophthalein.

3) Testosterone and methyltestosterone, estradiol, progesterone and stilbestrol irreversibly reduced the rate of bile formation and transiently reduced excretion and concentration of sulfobromophthalein."

*Solymoss et al. G79,007/71*: In rats, various catatoxic steroids (spironolactone, PCN) increase liver weight, glutathione S-aryltransferase activity, bile flow, and BSP clearance from the blood with an accelerated urinary excretion of conjugated BSP metabolites. Ethylestrenol similarly affects liver weight, but not the other parameters. The antimineralocorticoids, spiroxasone, SC-9376 and CS-1, unlike the anabolic steroids norbolethone and oxandrolone, also enhance plasma clearance of BSP. Contrary to the effects of pretreatment, the administration of spironolactone, ethylestrenol or estradiol immediately before BSP results in retention of the dye, probably through competitive inhibition of biliary excretion.

*Solymoss et al. G79,023/71*: In rats, pretreatment with PCN or spironolactone increases liver weight, glutathione S-aryltransferase activity and bile flow. At the same time, the plasma clearance and biliary excretion of BSP and its conjugated metabolites are enhanced. Ethylestrenol likewise increases liver weight but does not alter the other parameters mentioned above. Spiroxasone, SC-9376 and CS-1 (antimineralocorticoids), unlike norbolethone and oxandrolone (anabolics), also enhance plasma clearance of BSP, probably through the same mechanism. In contrast to these effects of pretreatment, administration of spironolactone, ethylestrenol or estradiol immediately before BSP delays plasma clearance of the dye, probably through competitive inhibition of biliary excretion. SKF 525-A does not suppress the enhanced BSP clearance induced either by spironolactone or by phenobarbital. [Although the authors did not evaluate their data from this point of view, their observations clearly show that the catatoxic activity of steroids is not merely the result of hepatic microsomal drug metabolizing enzyme induction. It may also be mediated through extramicrosomal enzyme mechanisms or even through enhanced biliary excretion (H.S.).]

#### RABBIT

*Carmichael E28,041/63*: In rabbits, methyltestosterone and norethandrolone significantly delay BSP clearance.

*Lennon F69,077/65*: In rabbits, methyltestosterone and norethandrolone caused dose related increases in BSP retention. Oxandrolone

was less active and testosterone inactive in this respect.

*Lennon F 63,769/66*: In rabbits, various 17 $\alpha$ -alkylated anabolics delayed BSP clearance, whereas non-17 $\alpha$ -alkylated testoid-anabolics failed to do so. "BSP retention in rabbits was shown to be a simple laboratory test for estimating the effects of anabolic steroids on hepatic excretory function."

BSP  $\leftarrow$  Testoids, Steroids (anabolic), Rb: Carmichael et al. E28,041/63\*; Lennon F69,077/65\*, F63,769/66\*

#### CHICKEN

*Despopoulos H 35,471/71*: In chickens, the renal tubular excretion of BSP and of N-methylnicotinamide is inhibited by bile salts.

#### DOG

*Gass & Umberger C 94,624/59*: In dogs, large doses of methyltestosterone or norethandrolone given for periods of up to 50 days did not affect BSP clearance.

#### VARIA

*Szeberényi & Fekete H 29,579/70*: Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone, mepro-

bamate, estrone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

**Emetine** ← *cf. also Selye G60,083/70, p.379.*

*Gregorio & Armellini G64,277/64:* In rabbits, the production of cardiac lesions by emetine is inhibited by chorionic gonadotrophin and testosterone but not by estradiol.

*Selye G70,480/71:* In rats, emetine intoxication is largely prevented by pretreatment with PCN and CS-1. Spironolactone has a barely significant protective effect. Indeed, several other standard conditioners appear to increase the mortality, *cf.* Table 55.

### **Endoxan** ← *cf. Cyclophosphamide*

#### **Ephedrine** ←

*Selye G70,480/71:* In rats, ephedrine sulfate (50 mg/100 g body weight in 0.2 ml water) was administered s.c. twice on the 4th day of conditioning. Dyskinesia was listed 4 hrs after the first injection and mortality registered 3 days later. Under these circumstances, none of the "Standard Conditioners" (p. VIII) caused any noteworthy change in the resulting intoxication.

#### **Ergot** ←

*McGrath A29,208/35:* In rats of both sexes, tail necrosis is produced by large amounts of ergotamine. Estrone prevents this change in females but not in males.

*Loewe & Lenke A43,451/38:* In the rat, the tail necrosis produced by ergotamine s.c. is essentially the same in both sexes. Contrary to earlier claims, it cannot be prevented by folliculoid hormones and/or orchidectomy.

*Ratschow & Klostermann A19,494/38:* In rats, the tail necrosis produced by ergotamine is much more readily inhibited by estradiol in females than in males. Ovariectomy aggravates the tail necrosis and diminishes the protective effect of estradiol. Castrate males are less sensitive to ergotamine than intact males. Testosterone propionate protects intact males, but not females.

*Suzman et al. A44,452/38:* Repeated administration of estrone completely protects female rats against the tail necrosis produced by ergotamine; males are only partially protected. Orchidectomy has no effect in itself, but enhances the protective effect of estrone in the male. Otherwise untreated rats showed no marked sex difference in their sensitivity to ergotamine.

*Thomas A33,372/40:* Neither a folliculoid preparation (theelin) nor testosterone s.c. (given daily for five days prior to treatment with ergotamine s.c.) prevented the characteristic ergot gangrene of the tail.

*McGrath & Herrmann B500/44:* In rats, the characteristic gangrene of the tail produced by ergotamine tartrate is prevented by estrone.

*Contreras et al. F81,599/67:* In intact male rats, unlike in females or castrate males, ergonovine induced an analgesic effect (electrical stimulation of the genital papilla) unless the latter were treated with testosterone.

#### **Ethanol** ←

##### RAT

*Klotz A96,052/37:* In rats, ovariectomy interferes with adaptation to ethanol.

*Lecoq et al. B66,406/51:* In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

*Mallov C47,222/58:* Ethanol p.o. produces more severe fatty infiltration of the liver in female than in male rats. Ovariectomy or administration of estradiol to males did not influence fatty infiltration but testosterone reduced hepatic steatosis in females, whereas castration increased it in males.

*Fazekas et al. D22,442/61:* Review on the enzymic detoxication of ethanol. The authors' observations show that the ADH activity of hepatic homogenates diminishes after adrenalectomy in the rat, and can be increased by adrenocortical extract both in intact and adrenalectomized rats.

*Fazekas D55,397/62:* Both in intact and in adrenalectomized rats, addition of aldosterone and, to a lesser extent, of corticosterone, cortisone, and cortisol to hepatic homogenates greatly augmented their ADH activity in vitro. DOC was very much less active. Adrenalectomy diminishes the hepatic ADH activity.

*Fazekas G9,347/63; F71,641/64:* In the rat, adrenalectomy delays the decrease in blood ethanol level following s.c. injection of ethanol, whereas corticoids have an inverse effect, both in adrenalectomized and in intact rats. The action is ascribed to a stimulation of hepatic ADH activity by corticoids as judged by observations with the methylene blue

decolorizing technique [spectrophotometric determinations were not performed (H.S.).]

*Jabbari & Leevy G45,526/67*: Various anabolics (norethandrolone, testosterone, oxandrolone) protect the liver of the rat against ethanol-induced fatty degeneration and various functional disturbances. They were also found to be useful in the management of alcoholic patients.

*Fazekas & Rengei G58,271/68*: Among rats, not pretreated with ethanol, the ADH activity of the liver, heart, and kidneys is diminished by adrenalectomy. Upon s.c. administration of ethanol, the ADH-activity of the liver increases both in intact and in adrenalectomized rats. The authors speculate that ADH-activity may result not only in the microsomes but also in other cellular fraction, and that part of the enzyme induction may be due to the stressor effect of ethanol.

*Selye et al. G60,016/69*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or  $MgCl_2$ .

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of ethanol, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Selye PROT. 37234*: In rats, ethyl alcohol (2 ml/100 g body weight of a 50% aqueous solution) was administered p.o. from the 4th day to the 6th day of conditioning. Dyskinesia was listed on the 6th day 3hrs after injection and mortality registered on the 8th day. Under these circumstances none of the "Standard Conditioners" (p. VIII) caused any noteworthy change in the resulting intoxication, only prednisolone exhibited an aggravating effect.

#### MOUSE

*Goodsell D3,916/61*: In mice, ethanol anesthesia is prolonged by cortisone pretreatment but not influenced by prednisolone or DOC.

*Störtebecker 69,765/37*: In the mouse, the resistance to curare, KCN or ethanol is particularly high during estrus and decreased by ovariectomy. Castrates treated with estrone show increased tolerance to these drugs.

Ethanol ← Ovariectomy, Mouse: *Störtebecker 76,398/39\**

#### RABBIT

*Störtebecker 76,398/39*: In both male and female mice and rabbits, gonadectomy diminishes alcohol tolerance, whereas estrone treatment raises it.

*Goldberg & Störtebecker B31,834/43*: In rabbits, estrone increases alcohol tolerance so that intoxication occurs only at very high blood alcohol levels. Alcohol metabolism is not influenced but presumably its effect upon the nervous system is diminished by folliculoids. The experiments were performed after ovariectomy to avoid complications by varying endogenous folliculoid production.

*Barta & Beregi F24,783/64*: Fatal doses of ethanol p.o. produce adrenal necrosis in the rabbit and neither this lesion nor mortality can be prevented by pretreatment with dexamethasone.

#### MAN

*Levy & Paumgartner G72,234/68*: In three volunteers who developed alcoholic hepatitis on an ethanol-low-protein regimen, jaundice appeared only in advanced stages of liver necrosis and inflammation. In earlier stages, there was proliferation of SER which was further increased by norethandrolone and yet, this anabolic reduced serum bilirubin. It is especially emphasized that "anabolic steroids may facilitate reduction of serum bilirubin despite capacity of these drugs to decrease hepatic excretory capacity."

#### Ether ←

*Störtebecker A1,993/37*: Rabbits pretreated with "folliculin" tolerate normally anesthesia-producing doses of butallylonal (Pernocton). Subsequent experiments were conducted to determine the blood ether level during ether anesthesia at the time the corneal reflex is lost in intact and gonadectomized rabbits and mice. Similar observations were made during pregnancy and in relation to the estrous cycle. [Several conclusions were drawn suggesting an influence of sex hormones upon anesthesia but the number of animals per group was small and hence statistical evaluation impossible (H.S.).]

*Störtebecker 76,398/39*: Castration decreases the ether resistance of both male and female rabbits and mice. In castrated rabbits, both estrone and androsterone increase ether tolerance.

### Ethionine ←

← **Glucocorticoids.** *Popper et al. C 33,264/57*: In rats, the hepatic damage caused by ethionine is inhibited by cortisone.

*Stein et al. C 59,992/58*: "Cortisone inhibits accumulation of interstitial cells between liver cell plates, otherwise produced by oral administration of ethionine to rats." The associated degeneration of hepatic cells characteristic of the ethionine intoxication is not influenced by cortisone.

*Daugharty et al. C 74,925/59*: In rats, the pancreatic lesions induced by ethionine i.p. were not influenced by cortisone i.p.

*Hutterer et al. D 902/61*: Cortisone offers moderate protection against ethionine induced liver damage in the rat.

*Rubin & Hutterer D 4,173/61*: In rats with subacute ethionine intoxication, hepatic fibrosis is inhibited by cortisone and fat accumulation is increased; however, during the chronic phase the steroid has no marked effect.

*Hutterer et al. E 54,152/62*: As judged by cytochemical autoradiographic and histologic studies, cortisone and cortisol are effective in certain phases of the hepatic lesions produced by ethionine in the rat.

*Berdjis F 79,528/67*: The hepatotoxic effect of  $\text{CCl}_4$ , phosphorus and ethionine could be diminished by cortisone and survival prolonged.

← **Gonadal Steroids.** *Farber et al. B 47,283/50; D 24,923/51*: The production of fatty livers in rats treated with ethionine is possible only in females or orchidectomized males. Testosterone renders females and orchidectomized males resistant.

*Farber & Segaloff D 95,996/55*: In ovariectomized rats, various testoids and STH protected the liver against fatty infiltration produced by ethionine i.p., whereas cortisone and ACTH aggravated it. Estradiol, DOC and TSH had no effect.

*Tedeschi & Gualandi C 33,614/56*: In rats of both sexes, MAD failed to influence the ethionine-induced hepatic steatosis.

*Ranney & Drill C 41,986/57*: In adult orchidectomized male rats, the fatty infiltration of the liver caused by ethionine i.p.

is blocked by 17-ethyl-19-nortestosterone in doses which do not stimulate the growth of the seminal vesicles, whereas testosterone propionate exerts this effect only in definitely testoid amounts. Progesterone is ineffective. Apparently, the protective effect of anabolics against this type of fatty liver formation does not depend either upon testoid or luteoid activity.

*Grunt et al. C 84,696/60*: In rats, both neonatal and postpubertal orchidectomy facilitates the production of hepatic steatosis by ethionine.

*Chang & Lei F 78,943/65*: 17 $\alpha$ -Methyl-5 $\alpha$ -androstan-17 $\beta$ -ol prevents the production of fatty hepatic degeneration by ethionine or  $\text{CCl}_4$  in mice.

### Ethylene Chlorohydrin ←

*Selye G 70,480/71*: In rats, "ethylene chlorohydrin," that is 2-chloroethanol (0.2 ml/100 g body weight of a 4% aqueous solution) was administered p.o. once on the 4th day and (0.3 ml) on the 5th day of conditioning. Dyskinesia was listed on the 5th day 1 hr, and mortality 24 hrs, after this injection. Under these circumstances none of the "Standard Conditioners" (p. VIII) or cholesterol caused any noteworthy change in the resulting intoxication. Hydroxydione and phenobarbital were not tested.

### Ethylene Glycol ←

*Tanret et al. D 44,140/62*: Prolonged oral administration of ethylene glycol produces calcium oxalate precipitation in the kidney of male, but not of female, rats. Estradiol abolishes the susceptibility of intact or castrated males, but orchidectomy does not. Intact, unlike ovariectomized, females cannot be made susceptible by treatment with testosterone.

*Szablowska & Selye G 70,475/71*: In the rat, pretreatment with thyroxine or triamcinolone inhibits the mortality rate and renal lesions induced by ethylene glycol intoxication; estradiol exerts an opposite effect.

*Selye G 70,480/71*: In rats, ethylene glycol intoxication is markedly prevented by prednisolone, triamcinolone and thyroxine, whereas all other conditioning agents of our series, including phenobarbital, are ineffective in this respect. In fact, estradiol (given at various doses and through various routes) greatly aggravates mortality, whereas the other agents have no pronounced effect upon it. These findings confirm and extend earlier observa-

**Fig. 7. Effect of various steroids upon ethylene glycol intoxication.** All rats received the same amount of ethylene glycol. A: Under polarized light, numerous calcium oxalate crystals are visible in the tubules of an animal sensitized to ethylene glycol by estradiol ( $\times 32$ ). B: Under higher magnification these crystals are still more clearly visible ( $\times 200$ ). C: Complete prevention of renal lesions by triamcinolone pretreatment ( $\times 32$ ). All sections stained with hematoxylin-phloxine and viewed under partially polarized light. [Szabłowska & Selye G70,475/71. Courtesy of Arch. Environm. Med.]

tions in which it was found that the production of renal oxalate crystal deposits, as well as the fatal effects of ethylene glycol intoxication can be prevented by triamcinolone and thyroxine, whereas spironolactone and estradiol have an opposite effect (*Szablowska & Selye G70,499/70*), cf. Table 56.

Table 56. *Conditioning for ethylene glycol*

<sup>a</sup> The rats of all groups were given ethylene glycol (0.8 ml/100 g body weight of a 100% solution, p.o., daily from the 4th day ff.).

<sup>b</sup> Dyskinesia was estimated on the 5th day 5 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

Ethyl Ether ← Gonadectomy, Rb: Störtebecker 76,398/39\*

#### *Ethylmorphine* ← cf. also *Morphine*

*Tephly & Mannering G67,764/64*: The N-demethylation of ethylmorphine by hepatic microsomes is competitively inhibited by estradiol, testosterone, androsterone, diethylstilbestrol and cortisol in vitro. "These findings are consistent with the view that steroids are normally-occurring substrates for oxidative drug-metabolizing enzymes in hepatic microsomes."

*Tephly & Mannering G53,874/68*: Estradiol, testosterone, androsterone, progesterone

and cortisol inhibit competitively the oxidation of ethylmorphine and hexobarbital when added in vitro to hepatic microsomes of rats. The inhibitor constant for each steroid was the same, whether ethylmorphine or hexobarbital served as substrates. "Results are consistent with the concept that certain drugs and steroids are alternative substrates for a common microsomal mixed function oxidase system." The steroids were less potent inhibitors of chlorpromazine oxidation and the inhibition was not competitive in this case.

*Furner & Stitzel G54,558/68*: The hepatic microsomal metabolism of ethylmorphine, aniline and hexobarbital is diminished in vitro by previous adrenalectomy in the rat. Phenobarbital pretreatment of adrenalectomized rats raised the metabolism of all three substrates above the level characteristic of otherwise untreated, adrenalectomized controls. Exposure of adrenalectomized rats to cold stress, or treatment with cortisol, increased the metabolism of aniline and ethylmorphine, but further depressed that of hexobarbital. In intact rats, cold stress diminished hexobarbital metabolism in vitro. Apparently, both stress and phenobarbital can bring about changes in hepatic drug metabolism independent of the presence of the adrenals, and the two agents act through different mechanisms, since phenobarbital invariably stimulates, whereas stress either increases or decreases, microsomal-enzyme activity depending upon the drug pathway examined.

*Castro et al. G77,615/70*: Studies on the effect of adrenalectomy upon the N-demethylation of ethylmorphine (EM) "suggest that the well known decrease in drug-metabolizing activity seen in liver microsomes of adrenalectomized animals is not related to changes in cytochrome P-450 content or to a decrease in the ability of cytochrome P-450 to bind drug substrates. However, there appears to be a relationship between the reductase activities and the adrenal function, because the changes in activities in NADPH cytochrome c reductase and cytochrome P-450 reductase in liver microsomes from adrenalectomized and cortisone-treated adrenalectomized rats paralleled the changes in EM demethylase activity."

*Gerald & Feller G74,396/70*: In mice, spironolactone and its  $\Delta^6$  de-thioacetylated metabolite reduce hexobarbital sleeping time and cause nearly identical increases in liver weight, microsomal protein content, NADPH-cytochrome c reductase, cytochrome P-450 content and the N-demethylation of ethyl-

morphine. Preliminary observations suggest that these actions of spironolactone and its metabolite are evident in both sexes.

*Selye G70,480/71*: In rats, the motor disturbances and the mortality produced by ethylmorphine intoxication are well prevented by all catatoxic steroids as well as by prednisolone, progesterone, estradiol, DOC and phenobarbital. The protection by prednisolone appears to be independent of glucocorticoid activity since triamcinolone (a stronger glucocorticoid) offers no protection, *cf.* Table 57.

Table 57. *Conditioning for ethylmorphine*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	14/15	11/15
PCN	0/10 ***	0/10 ***

<sup>a</sup> The rats of all groups were given ethylmorphine HCl (20 mg/100 g body weight in 0.2 ml water, once on 4th day s.c.).

<sup>b</sup> Dyskinesia was estimated 3 hrs after injection and mortality registered 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Stripp et al. G79,538/71*: In rats, the induction of hepatic microsomal enzymes by spironolactone "differed from the phenobarbital or methylcholanthrene induction in that it did not increase cytochrome P-450 content or microsomal protein. Furthermore the induction seemed to be sex dependent."

Ethylmorphine ← Gonadectomy:  
Davies et al. *H22,054/68*

Ethylmorphine ← Cortisol + Pheno-  
barbital: Lu et al. *G68,802/69*

### **Fencamfamine** ←

*Blackham & Spencer G76,301/69*: In female mice, pretreatment with lynestrenol (a luteoid) reduced the hyperthermia induced by dexamphetamine, whereas mestranol (a folliculoid) increased it. Fencamfamine (also a CNS-stimulant) failed to induce hyperthermia in control or lynestrenol-pretreated mice but did raise the temperature after mestranol pretreatment. The potentiating effect of mestranol could be mimicked by pretreatment with nialamide (a MAO-inhibitor) but not by SKF 525-A. Increased locomotor activity induced by dexamphetamine and fencamfamine was enhanced by mestranol and reduced by lynestrenol. Dopamine, norepinephrine and 5-HT levels in the brain were reduced by lynestrenol and 5-HT was increased by mestranol. "If the actions of dexamphetamine (and fencamfamin) are due predominantly to the release of endogenous amines, then an increase (with lynestrenol) or a decrease (with mestranol) of tissue MAO activity should change the potency of these two stimulant drugs."

Fencamfamine ← Mestranol, Lynestrenol + Crowding: Blackham et al. *G76,301/69\**

### **Flufenamic Acid** ←

*Selye PROT. 38279*: In rats, PCN, CS-1, ethylestrenol, spironolactone and phenobarbital offered highly significant protection against the production of intestinal ulcers by flufenamic acid. At the same time, the lethal effect of the drug was also diminished, but not always significantly, presumably because under the conditions of this experiment the mortality was not particularly high even among the unpretreated controls. Glucocorticoids and thyroxine greatly increased mortality, *cf.* Table 58, p. 245.

### **N-2-Fluorenyldiacetamide** ← *cf.* **Carcinogens**

### **Fluoride** ←

*Gedalia et al. F17,787/64*: In rats, increased fluoride intake inhibits the osteosclerotic effect of estradiol.

*Furstman et al. G31,603/65*: Histologic studies on the interaction of cortisol and fluoride in the induction of changes in the mandibular joint of the rat.

Table 58. *Conditioning for flufenamic acid*

Treatment <sup>a</sup>	Intestinal ulcers <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

Thyroxine	9/12 NS	13/15 *
Phenobarbital	3/10 ***	0/10 *

<sup>a</sup> The rats of all groups were given flufenamic acid, 10 mg/100 g body weight in 0.2 ml water s.c. twice daily from 4th day.

<sup>b</sup> Intestinal ulcers were appraised on day of death and mortality was listed on the 9th day ("Exact Probability Test").

<sup>c</sup> Only one of the animals in this group survived long enough to permit meaningful appraisal of intestinal ulcers.

For further details on technique of tabulations cf. p. VIII.

**5-Fluorouracil** ←

*Ambre H24,704/70*: In rats, pretreatment with a single dose of prednisolone protected against the lethality of 5-fluorouracil.

**Fluphenazine** ←

*Selye PROT. 39639*: In rats, PCN, CS-1 and to a lesser extent ethylestrenol, prednisolone and possibly DOC protect against otherwise fatal fluphenazine intoxication. The other standard conditioners of our series are inactive, cf. Table 59.

**Flurothyl** ←

*Davis & Mei Quey Su H31,927/69*: In rats, the convulsive effect of flurothyl is diminished by adrenalectomy.

**Formaldehyde** cf. *Selye B40,000/50*, pp. 392, 393, 534, 589, 751; *B58,650/51*, pp. 244, 248.

**Ganglioplegics** ←

*Masson et al. B47,635/50*: In dogs pretreated with DOC + uninephrectomy + NaCl, the hypotensive effect of TEA was not significantly altered. Similarly, both in rats and in dogs, the pressor action of epinephrine, nor-epinephrine, renin and angiotensin was not consistently altered by previous uninephrectomy and treatment with DOC + NaCl.

*Brust et al. B57,917/51*: In man, "administration of ACTH or cortisone significantly alters the blood pressure and 'TEAC floor.' The responses are independent of sodium retention and indicate that the vascular effects of these drugs are mediated by a humoral mechanism which is potentiated by autonomic blockade." Observations on both normotensive and hypertensive patients showed that "the usual depressor effects of TEAC were ultimately converted to a pressor rise, suggesting that autonomic blockade potentiates the vascular effects of ACTH and cortisone." DOC exhibited no such action.

<sup>a</sup> Dyskinesia was estimated 30 min after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Bonino C13,016/55*: In guinea pigs, ovariectomy increases resistance to lethal doses of hexamethonium.

*Sturtevant C9,089/55; C21,591/56*: In rats with metacorticoid hypertension (produced by temporary overdosage with DOC + NaCl), the pressor effect of epinephrine, norepinephrine, vasopressin and renin was increased but the effect of histamine, 5-HT, yohimbine and TEA on the blood pressure was not consistently altered.

*Weil G68,214/61*: In rats, prednisolone i.p. "which protects against the lethal effects of endotoxin, is not effective in protecting against lethal amounts of ganglionic blocking agents (mecamylamine, chlorpromazine), adrenergic blocking drugs (dibenzylamine), or sympathomimetic amines (metaraminol). To the contrary, treatment with corticosteroid is associated with a significant increase in fatality in animals injected with mecamylamine and chlorpromazine ( $p = <0.01$ ).” These findings are interpreted as evidence against the assumption that glucocorticoids protect in a nonspecific manner against injuries that produce hypotension.

*Selye G70,448/70*: In rats, various glucocorticoids and stressors offer protection against certain ganglioplegics, whereas highly active typical catatoxic steroids are ineffective in this respect as shown by Table 60. A: Pretreatment for 4 days with various typically catatoxic steroids fails to protect against hexamethonium or TEA. B: Pretreatment with a single dose of various glucocorticoids p.o., 4 hrs before the ganglioplegics, uniformly offers good protection against TEA, hexamethonium and pentolinium. C: Pretreatment for 4 days with various stressors (bone fractures, fasting, spinal cord transection, formalin, restraint) protects the rat against TEA intoxication as does cortisol or the endogenous glucocorticoids secreted under the influence of ACTH. On the other hand, unexpectedly, similar exposure to the stress of cold or hemorrhage offers no significant protection.

*Gwee & Lim G81,043/71*: In mice, cortisol sodium succinate given one hour before hemicholinium-3 (HC-3) or its p-terphenyl analogue (TPHC-3), offered very slight protection against the fatal effects of these ganglioplegics.

*Selye G70,480/71*: In rats, hexamethonium intoxication was completely prevented by pretreatment with prednisolone or triamcinolone, but unaffected by all other standard conditioning agents of our series, cf. Table 61.

Table 61. *Conditioning for hexamethonium*

<sup>a</sup> The rats of all groups were given hexamethonium chloride (8 mg/100 g body weight in 0.2 ml water, s.c., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 30 min after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

*Selye G70,480/71*: In rats, prednisolone offered partial, triamcinolone complete protection against TEA intoxication. Estradiol, phenobarbital and perhaps to a lesser extent even progesterone and thyroxine diminished the mortality without preventing the characteristic motor disturbances, cf. Table 62, p. 248.

#### **D-Glucose-6-phosphate ← cf. G-6-P-ase under Influence of Steroids upon Enzymes**

##### **Glutamic Acid ←**

*Brim & McKee C31,261/56*: In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase glutamic-aspartic and glutamic-alanine transaminase activities in the liver. Adrenalectomy decreases the activity of these enzymes. The glutamic-alanine enzyme is more sensitive to stress than the glutamic-aspartic enzyme.

##### **Glutethimide ←**

*Selye PROT. 39300*: In rats, glutethimide sleeping time is considerably shortened by

to hexadimethrine with strong nephrocalcinosis. Under similar conditions in intact rats, the corticoids did not significantly change the syndrome of hexadimethrine intoxication, except that the anaphylactoid reaction to this compound is inhibited by triamcinolone.

**Hexamethonium** ← cf. *Ganglioplegics*

**Hg** ← cf. *Mercury*

**Homatropine Hydrobromide** ←

*Selye G70,480/71*: In rats, homatropine hydrobromide (80 mg on the 4th day and 100 mg on the 5th day of conditioning, in 1 ml water) was administered p.o. /100 g body weight. Dyskinesia was listed on the 5th day 1 hr, and mortality 48 hrs after this injection. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication, only PCN exhibited an inhibitory effect. Phenobarbital was not tested.

**Hydroquinone** ←

*Selye G70,480/71*: In rats, the motor disturbances produced by hydroquinone intoxication were completely prevented by PCN, CS-1, ethylestrenol and phenobarbital, whereas prednisolone and triamcinolone increased their severity, cf. Table 65.

Table 65. *Conditioning for hydroquinone*

<sup>a</sup> The rats of all groups were given hydroquinone (15 mg/100 g body weight in 0.2 ml water, s.c., on 4th day).

<sup>b</sup> Dyskinesia was estimated 15 min after injection ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Imipramine** ←

*McClure & Cleghorn G76,696/68*: In depressive psychotics, dexamethasone enhances the therapeutic effect of imipramine.

*Selye PROT. 41834*: In rats, imipramine intoxication is markedly inhibited by PCN, CS-1, ethylestrenol, spironolactone and phenobarbital. Estradiol exhibits a just barely significant protective effect, cf. Table 66, p. 250.

**Indium Trichloride** ←

*Selye G70,480/71*: In rats, indium trichloride (800 µg/100 g body weight in 1 ml water) was administered i.v. once on the 4th day of conditioning. Hepatic lipidosis was estimated

on day of death, and mortality registered on the 9th day. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication. Phenobarbital was not tested.

<sup>b</sup> Dyskinesia was estimated on 4th day 3 hrs after injection and mortality listed on 5th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Indomethacin** ← cf. also *Selye G60,083/70*, p. 385.

*Selye G60,046/69*: Both spironolactone and norbolethone protect the rat against the production of multiple intestinal ulcers and peritonitis by indomethacin.

*Selye G60,058/69*: In the rat, partial hepatectomy facilitates the production of perforating intestinal ulcers by indomethacin. Comparatively small doses of spironolactone readily inhibit this form of indomethacin intoxication even in the presence of surgically-induced hepatic insufficiency. "These results are compatible with the assumption that both indomethacin and spironolactone are subject to hepatic detoxication, and hence, their respective pathogenic and prophylactic actions are enhanced after extensive resection of liver tissue."

*Aspinall H32,269/70*: In rats, spironolactone can inhibit the ulcerogenic effect of indo-

methacin without blocking its antiphlogistic property (adjuvant arthritis test). This dissociation may be due to: 1. a direct protective action of spironolactone upon the intestinal tract, 2. the formation of indomethacin metabolites which retain antiphlogistic but loose ulcerogenic properties or 3. a mere diminution of indomethacin activity to a level sufficient to inhibit inflammation without causing intestinal ulceration.

*Selye G66,066/70*: In the rat, the production of perforating jejunal ulcers and peritonitis by indomethacin can be prevented by ethylestrenol, CS-1, spironolactone, norbolethone and oxandrolone. Progesterone and prednisolone are less active, triamcinolone and hydroxydione inactive.

*Selye G70,421/70; G70,480/71*: In rats, formation of perforating intestinal ulcers and the consequent mortality produced by indomethacin intoxication are prevented by all classic catatoxic steroids, as well as by prednisolone, progesterone and phenobarbital, cf. Table 67.

Table 67. *Conditioning for indomethacin*

<sup>a</sup> The rats of all groups were given indomethacin (1 mg in 0.2 ml water, s.c., once daily, from 4th day ff.).

<sup>b</sup> Intestinal ulcers were appraised on day of death, but only in animals which survived at least 6 days and mortality was listed on 10th day ("Exact Probability Test").

For additional pertinent data cf. also Table 135.

For further details on technique of tabulation cf. p. VIII.

**Fig. 8. Prevention of indomethacin-induced intestinal ulcers by spironolactone.** All animals received the same dose of indomethacin. A: Intestinal tract of otherwise-untreated control rat. The jejunal segment (between 2 arrows) forms a packet of intestinal loops connected by fibrin threads to each other as well as to the pancreas (top arrow) and stomach. B: Normal intestinal tract of rat pretreated with indomethacin. Stomach, spleen and pancreas (upper right corner) as well as all intestinal loops are free of adhesions. C: Gross view of intestinal ulcer which runs along the entire length of the mesenteric attachment. The resulting lesions are responsible for the folding of this jejunal segment (viewed here from the mucosal side) in the control rat. D: In animal pretreated with spironolactone, the jejunal mucosa is of normal appearance. E: Section through the jejunum of control rat shows large ulcer along mesenteric attachment (right side), which is close to perforation at several points. F: In animal pretreated with spironolactone, the jejunal mucosa is normal. [Selye G60,046/69. Courtesy Can. J. Physiol. Pharmacol.]

*Selye G70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Solymoss et al. G60,093/70:* In rats, spironolactone, norbolethone and progesterone,

unlike hydroxydione, accelerate the clearance from the blood of s.c.-injected indomethacin. SKF 525-A significantly suppresses the activity of these steroids which probably act through increased metabolic degradation of indomethacin.

*Solymoss et al. G70,441/70:* In rats, spironolactone or oxandrolone given for as long as two months, continues to exhibit a protective effect against fatal doses of digitoxin or indomethacin. Upon withdrawal of the cata-

toxic steroids, continued administration of digitoxin or indomethacin is rapidly fatal. The plasma concentration of digitoxin and indomethacin is diminished during the catatoxic steroid administration.

*Selye G70,480/71*: In rats, the indomethacin-induced intestinal ulcers and mortality are inhibited by PCN, CS-1, cyproterone, ethylestrenol, spironolactone, norbolethone, TMACN, oxandrolone, 6 $\alpha$ -methylprednisolone, fluoxymesterone, spiroxasone, 16 $\beta$ -methyl-16,17-epoxy-3 $\beta$ ,11 $\alpha$ -dihydroxy-5 $\alpha$ -pregnan-20-one, prednisolone, dexamethasone, betamethasone, emdabol, 17 $\alpha$ -acetoxyprogesterone, corticosterone, dehydroisoandrosterone, pregnanedione, progesterone, DOC and 11 $\alpha$ -hydroxyprogesterone. The syndrome of indomethacin intoxication is not significantly inhibited by MAD, testosterone, triamcinolone, hydroxydione-fluorocortisol, cortisol, cortisone and estradiol.

*Szabo et al. G79,013/71*: In hamsters, spironolactone and ethylestrenol pretreatment prevents digitoxin convulsions and indomethacin-induced intestinal ulcers.

*Szabo et al. G79,024/71*: In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

*Selye PROT. 25007, 32215*: In rats, the protection against indomethacin and digitoxin intoxication by pretreatment with spironolactone can be blocked by concurrent pretreatment with metyrapone.

*Selye PROT. 28397*: In mice, indomethacin intoxication can be prevented by ethylestrenol, CS-1, spironolactone, norbolethone and to a lesser extent perhaps also by prednisolone and estradiol administered by various routes. Thyroxine appears to have an opposite effect. Progesterone, triamcinolone, DOC and hydroxydione had little if any effect.

*Selye PROT. 22030*: In adrenalectomized rats maintained in good condition by cortisol, DOC or cortisol + DOC with the substitution of 1% NaCl as drinking fluid, spironolactone offers excellent protection against the mortality and somewhat inhibits the ulcerogenic effects of indomethacin. Large doses of spironolactone (10 mg) are effective in this respect even in adrenalectomized rats maintained on 1% NaCl alone, *cf.* Table 68.

*Selye PROT. 29958*: In adrenalectomized rats maintained on 1% NaCl alone, the lethal effect of indomethacin is increased and intestinal ulcers develop just as frequently as in intact controls. Small doses of spironolactone (0.3 mg) protect the rats only partially against the mortality and ulcerogenesis induced by indomethacin, whereas concurrent administration of cortisol, DOC or cortisol + DOC appears to improve the protective effect of spironolactone, *cf.* Table 69.

*Selye PROT. 32221, 32230, 32255*: In adrenalectomized rats maintained on DOC, cortisol or DOC + cortisol, threshold doses of spironolactone still offer protection against mortality. In the absence of corticoid maintenance

Table 68. *Effect of adrenalectomy and corticoid substitution therapy upon the protection by spironolactone against indomethacin*

Group	Treatment <sup>a</sup>	Intestinal ulcers <sup>b</sup> frequency (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)
1	None	4/18	18/18
2	Spironolactone	0/11	2/11
3	Spironolactone + Cortisol	0/15	0/15
4	Spironolactone + DOC	0/14	3/15
5	Spironolactone + DOC + Cortisol	0/16	0/16

<sup>a</sup> All rats were adrenalectomized on 1st day and given 1% NaCl as drinking fluid. They all received indomethacin 1 mg in 0.2 ml water, s.c./day, 4th day ff. The groups so designated were given spironolactone 10 mg in 1 ml water, p.o., x2/day, cortisol acetate 0.5 mg and DOC acetate 1 mg in 0.2 ml water, s.c./day, 1st day ff.

<sup>b</sup> Intestinal ulcers on day of death; mortality up to 9th day when experiment was terminated.

therapy, however these doses of spironolactone failed to diminish the lethal effect of indomethacin significantly. The ulcerogenic effect is difficult to interpret in these series because of the high mortality and the post-mortal decomposition. In any event it is clear that cortisol + DOC increase resistance to the lethal effect of indomethacin but have little or no influence upon the ulcerogenic action, *cf.* Tables 70, 71.

*Selye PROT. 34038, 34405:* In rats of different age groups, the anti-indomethacin effect of PCN is essentially the same if

administered at dose levels adjusted to body weight, *cf.* Table 72, p. 254.

*Selye PROT. 42269:* In rats chronically poisoned with digitoxin (0.5–1.0 mg, p.o./day) or indomethacin (0.75 mg, s.c./day), the administration of PCN (1 mg x2/day, p.o., beginning on the 3rd or 4th day of treatment with the toxicants), when clinical signs of poisoning were already evident, caused these to disappear and permitted survival, whereas the controls receiving no PCN invariably died. These experiments show that, although presumably the protective effect of PCN against

digitoxin and indomethacin depends upon the induction of drug-metabolizing enzymes, the steroid can act not only prophylactically but also curatively, if the intoxication is sufficiently slow to permit effective enzyme induction in time.

In interpreting all these data on indomethacin, it must be kept in mind that although this compound (like digitoxin) acted as a standard in our studies on the detoxication of substrates by catatoxic steroids, the mechanism of its accelerated bio-degradation has not yet been established.

#### Iodoacetate ←

*Laszt & Verzar 34,843/35:* The cessation of growth induced by chronic iodoacetate feeding in the rat is counteracted by an andrenocortical extract, "eucorton," s.c. A similar inhibition was obtained by feeding yeast or flavine phosphate.

*Clark & Barnes A 33,441/40:* Adrenocortical extract offers no protection against iodoacetate intoxication in the rat.

#### Isoniazid ←

*Ferraris C 27,552/54; C 30,097/56:* In rats, ovariectomy increases resistance to lethal doses of isoniazid.

*Mrozikiewicz & Strzyzewski G 68,152/66; H 7,524/67:* In the mouse, isoniazid-induced convulsions are facilitated, not only by glucocorticoids (cortisol, prednisolone) and ACTH, but also by DOC.

Isoniazid ← Prednisone, Man: Levi et al. F 99,523/68\*

**Isoproterenol** ← *cf. also Selye C92,918/61, p. 117; G60,083/70, p. 493.*

*Chappel et al. C76,910/59:* In rats, the production of myocardial necrosis by isoproterenol is facilitated by pretreatment with mineralocorticoids (DOC, F-COL) but not influenced by glucocorticoids (cortisone, triamcinolone).

*Moudgil G65,314/69:* In rats, various antiminerocorticoids inhibited the production of cardiac necroses by isoproterenol in the following order: SC 5233 > SC 9420 (spironolactone) > CS-1 and SC 8109. The reported relative effectiveness of these compounds as aldosterone antagonists is CS-1 > SC 9420, SC 8109 > SC 5233.

RAT

*Ponseti D49,845/54:* In rats fed *Lathyrus odoratus* seeds, testosterone does not significantly affect the development of osteo- and angiolathyrus lesions.

*Bean & Ponseti C29,403/55:* In rats chronically fed a sweet pea diet, dissecting aneurysms of the aorta were commonly found in combination with scoliosis and other lathyrus skeletal lesions. Attention is called to the occasional occurrence of dissecting aneurysms in connection with scoliosis and other bone lesions in man (e.g., in Marfan's syndrome and related collagen diseases). Since, in rats, lathyrism was accompanied by testicular atrophy, it was attempted to prevent the lathyrus aneurysms by testosterone, but the results were negative.

*Dasler C15,943/56:* Cortisone added to the diet allegedly offered no protection against osteolathyrism in rats given APN p.o.

*Hamre & Yaeger D76,147/56:* In rats fed sweet peas, the development of osteolathyrism is inhibited by cortisone.

*Selye & Bois C18,280/56:* In rats, the osteolathyrism produced by *Lathyrus odoratus* seeds is aggravated by STH and inhibited by cortisol. Combined treatment with DOC + uninephrectomy + NaCl resulted in dissecting aneurysms of the aorta. Very small doses of thyroxine or estradiol were without effect upon this form of lathyrism.

*Dasler C36,068/57:* Brief mention of unpublished observations indicating that in rats, osteolathyrism produced by APN is not inhibited by cortisone or thyroxine, but aggravated by STH.

*Diaz et al. C50,497/57:* Thyroxine inhibits the osteolathyrism produced in rats by methyleneaminoacetonitrile (MAAN). Estrogens allegedly have a similar, though somewhat less pronounced, effect. [The authors actually tested only estrone in combination with progesterone (H.S.).]

*Meyer & Vos C41,429/57:* In rats kept on a *Lathyrus odoratus* meal, estradiol raised the resistance of males but decreased that of females. Cortisone moderately diminished the severity of scoliosis and of the exostoses whereas testosterone was without effect.

*Selye & Bois C22,712/57:* In rats, osteolathyrism (produced by AAN) is inhibited by cortisol and augmented by STH. The combination of STH and AAN enhances the development of polyarthritus in the small joints of the extremities. DOC facilitates the production of aortic aneurysms by AAN.

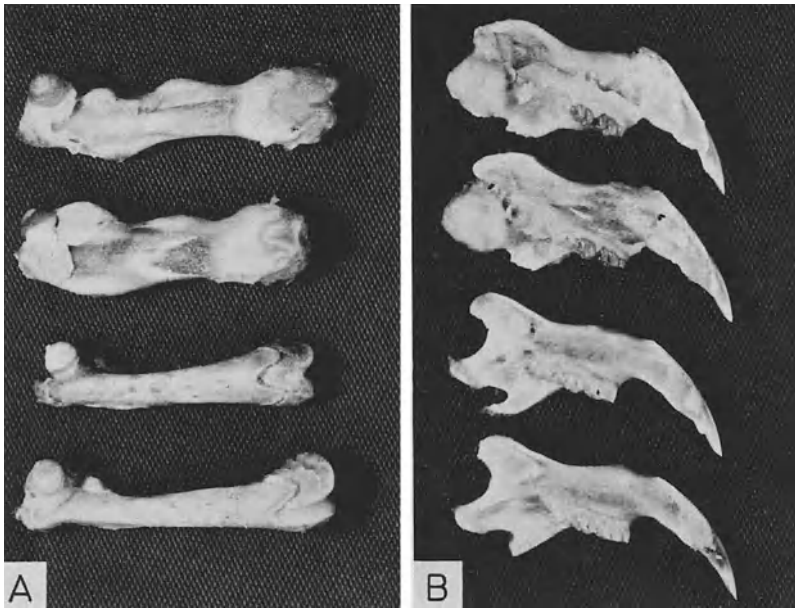

*Selye & Bois C23,298/57:* In rats, the osteolathyrism produced by AAN is suppressed by cortisol and uninfluenced by DOC, although the associated aortic aneurysm formation is aggravated by the mineralocorticoid. Combined treatment with DOC + COL so modifies the action of AAN that aortic aneurysms are produced in the virtual absence of bone lesions. "It is noteworthy that the individual morbid changes, characteristic of the malady, can be totally dissociated from each other by merely changing the mineralo- or glucocorticoid level of the milieu in which an experimental disease develops."

*Selye C31,369/57:* In the rat, the osteolathyrism produced by AAN is aggravated by STH, LTH and partial hepatectomy but it is inhibited by ACTH, cortisol or estradiol.

*Selye C31,790/57:* In rats, osteolathyrism produced by AAN is inhibited by thyroxine, cortisol and estradiol but aggravated by STH even after adrenalectomy.

*Diaz et al. D99,329/58:* In rats, the osteolathyrism produced by methyleneaminoacetonitrile (MAAN) is mildly inhibited by progesterone and estrone, completely prevented by thyroxine and aggravated by thyroidectomy.

*Selye C28,810/58:* In rats, osteolathyrism was produced by high doses of AAN. This treatment was discontinued when administration of various hormones began. Under these

**Fig. 9. Effect of various hormones upon osteolathyrism.** All rats were treated with the same amount of aminoacetonitrile (AAN). Top to bottom: Otherwise untreated controls, animals treated with ethylestrenol, prednisolone and thyroxine, respectively. Note strong lathyric changes: A: femurs, B: mandibles (especially at tendon insertion sites) in the control and ethylestrenol-treated rat, whereas the bones of the animals receiving prednisolone or thyroxine are essentially normal

conditions, the healing of established osteolathyrism was accelerated by thyroxine and to a lesser extent by cortisol and estradiol. STH delayed healing, whereas methyltestosterone and DOC did not influence it significantly.

*Wajda et al. C48,618/58:* Lathyrism was produced in immature rats by feeding *Lathyrus odoratus* seeds, "whereas testosterone shortened the life span and increased the incidence of aortic rupture in female rats, estradiol increased survival time of both sexes and had no influence on aortic rupture."

*Kowalewski et al. C63,273/59:* In rats, osteolathyrism produced by a sweet pea diet inhibits the uptake of  $^{35}\text{S}$  into fractured bones. Norethandrolone diminishes this inhibition.

*Ponseti C68,050/59:* In rats, the lathyric bone lesions produced by AAN were strongly suppressed by triiodothyronine and thyroxine, whereas those elicited by APN were much less evidently inhibited by these hormones. "Corticosterone and cortisone suppressed only slightly the lesions produced by aminoacetonitrile in rats."

*Pyörälä et al. C67,833/59:* Dissecting aneurysms of the aorta developed in 40% of immature rats fed *Lathyrus odoratus*. The media was remarkably thickened and the ground substance showed increased metachromasia and PAS reaction. This response was suppressed by cortisone and thyroxine but not by ACTH, TSH or DOC at the doses employed.

*Aschkenasy C91,685/60:* In male rats, the osteolathyrism produced by AAN is inhibited by a diet containing 18–30% casein. This protective effect is not seen in females or in orchidectomized males.

*Kowalewski & Emery C86,516/60:* In rats with osteolathyrism produced by APN, norethandrolone promotes the healing of bone fractures as judged by  $^{35}\text{S}$  uptake into the mucopolysaccharides of the callus.

*Gabay et al. D98,867/61:* In rats, the osteolathyrism produced by methyleneaminoacetonitrile (MAAN) is associated with a considerable increase in bone hexosamine. This change is more effectively inhibited by thyroxine than by cortisone. Both hormones

are virtually ineffective in protecting against osteolathyrism produced by the feeding of *Lathyrus odoratus* seeds.

*Selye & Cantin C88,878/61*: In rats, the osteolathyrism produced by AAN is inhibited by thyroxine and cortisol but aggravated by STH. The cardiac infarcts elicited in rats by ligation of the descending branch of the left coronary artery are often transformed into rupturing cardiac aneurysms under the influence of AAN. The incidence of these cardiac ruptures is augmented by cortisol and DOC, but not significantly influenced by thyroxine and STH. Evidently, there is no direct relationship between the skeletal and the cardiac lesions under these circumstances.

*Wiancko & Kowalewski D270/61*: In APN-treated rats, the healing of a humerus fracture (tensile strength of callus) is significantly decreased. This decrease was less pronounced in animals pretreated with cortisone, whereas fluoxymesterone (predominantly testoid) and methandrostenolone (predominantly anabolic) actually increase the tensile strength of the lathyric callus above the control (nonlathyric) level.

*Aschkenasy D30,892/62*: In rats, lathyrism produced by AAN is aggravated by adrenalectomy and, in the absence of the adrenals, the usual antilathyric effect of cortisone is no longer demonstrable; in fact the glucocorticoid facilitates the production of hernias. STH aggravates the osteolathyrism but not the induction of hemorrhages by AAN.

*Holzmann et al. F56,165/65*: In rats rendered osteolathyric by APN, severe histologic changes occur also in the skeletal musculature accompanied by corresponding variations in the serum level of muscle-specific enzymes, particularly creatinekinase and myokinase (adenylatekinase). These lesions can be partially suppressed by prednisone.

*Holzmann et al. G33,879/65*: In rats, treatment with APN increases the serum transaminase activity. This effect is inhibited by prednisone but other blood enzyme changes are less markedly affected.

*Trnavský et al. F49,077/65*: In rats kept on a diet of *Lathyrus odoratus*, cortisol inhibited the increase in the hydroxyproline content of the skin.

*Korting et al. F63,363/66*: In rats made lathyric by APN, the GPT and the GOT activities of the serum are increased. Prednisone prevents this change.

*Trnavská & Trnavský G54,556/68*: In rats, the collagen changes induced by feeding *Lathyrus odoratus* seeds are more effectively inhibited by salicylates, phenylbutazone and chloroquine than by cortisol.

*Henneman H12,251/69*: Estradiol protects the rat against the skeletal and cutaneous changes produced by APN. "The data suggest estrogens induce the synthesis of a collagen which is resistant to lathrogenic agents; this same collagen might be more resistant to the vicissitudes of age and hormonal imbalance."

*Selye G70,480/71*: In rats, the osteolathyrism produced by aminoacetonitrile is readily prevented by prednisolone, triamcinolone and thyroxine, but not, or only doubtfully, affected by the other conditioners of our series. Large doses of glucocorticoids cause mortality in aminoacetonitrile treated animals, but much smaller doses suffice to prevent skeletal lesions, cf. Fig. 9, p. 256 and Table 73.

Table 73. Conditioning for aminoacetonitrile

<sup>a</sup> The rats all of groups were given aminoacetonitrile, "AAN" (20 mg/100 g body weight in 1 ml water, p.o., twice daily from 4th day ff.).

<sup>b</sup> Osteolathyrism was assessed and mortality listed on 16th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

## VARIA

*Cameron et al. D38,527/62:* In chicks, the osteolathyrisism produced by semicarbazide and acetone semicarbazone is only doubtfully inhibited by cortisone, prednisolone or DOC.

*Simmons et al. G28,592/65:* Detailed description of the bone lesions produced by AAN in the mouse and of their inhibition by estradiol.

**Lead ←**

*Benkö 95,966/42:* In rabbits, the porphyria induced by lead intoxication could be prevented by nicotinamide given in combination with adrenocortical extracts, whereas neither of these agents exhibited prophylactic potency when given by itself.

*Chiodi & Sammartino B52,225/50:* In rats, the nephrotoxic effect of chronic lead feeding is inhibited by testosterone.

**Lithium ←**

*Radomski et al. B63,492/50:* In dogs, neither DOC nor adrenocortical extract affects the manifestations of lithium intoxication.

**LSD ←**

*Pierre C55,459/57:* In the rabbit, the EEG changes produced by LSD are prevented by hydroxydione.

*Pierre et al. C46,326/57:* Both methylandrostanolone and hydroxydione protect against chronic LSD intoxication. [Species not stated (H.S.).]

*Pierre C52,727/58:* In rabbits, the EEG changes characteristic of LSD intoxication are completely prevented by hydroxydione and androstanolone. 19-Nortestosterone and methylandrostanolone are somewhat less effective.

*Bergen & Pincus C82,720/60:* In rats, the behavioral changes induced by LSD can be suppressed by DOC, corticosterone, 17-dehydrocortisone, 11-dehydrocortisol, dehydroisoandrosterone, testosterone, androsterone,  $\Delta^5$ -pregnenolone, etiocholanolone and progesterone. Other naturally occurring steroids tested were ineffective.

*Bergen et al. C97,551/60:* Earlier unpublished experiments had shown that the effect of LSD on smooth muscle contraction can be inhibited by various steroids added to the bathing medium *in vitro*. The authors reexamined this antagonism *in vivo*. The time required by a rat to climb a rope for a food reward is prolonged by LSD but this behavior

change is counteracted by pretreatment during 3 days with *i.p.* injections of 1 mg quantities of dehydroisoandrosterone,  $\Delta^4$ -androstenedione, cortisol, progesterone, testosterone, pregnenolone, DOC, dehydrocorticosterone, androsterone, etiocholanolone, corticosterone and 11-desoxycortisol approximately in decreasing order of activity. Of all steroids tested only estradiol was inactive in this respect.

*Krus et al. G78,688/61:* In normal man, "the magnitude of changes found to occur under LSD-25 in behavior representing sensorimotor, perceptual and conceptual levels of organization, was reduced when LSD ingestion was preceded by progesterone ingestion."

*Bergen et al. E5,492/65:* In the rat, progesterone, dehydroepiandrosterone and DOC, reduce the severity of LSD-induced "confusion." In rabbits, both LSD and progesterone alter the characteristics of optically evoked cortical potentials. "From the foregoing experimental results and the additional information that progesterone inhibits LSD metabolism in an *in vitro* system, it may be postulated that both drugs act on common cellular sites. It is suggested that progesterone may block the action of LSD by interfering with the LSD-receptor relationship of the cell."

Table 74. Conditioning for LSD

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup>
None	11/15
PCN	0/14 ***
CS-1	0/10 ***
Ethylestrenol	2/15 ***
Spiroinolactone	6/15 NS
Norbolethone	1/10 ***
Oxandrolone	5/10 NS
Prednisolone-Ac	0/10 ***
Triamcinolone	0/15 ***
Progesterone	3/10 *
Estradiol	0/10 ***
DOC-Ac	4/8 NS
Hydroxydione	4/10 NS
Thyroxine	11/15 NS
Phenobarbital	3/10 *

<sup>a</sup> The rats of all groups were given D-lys-ergic acid diethylamid 100  $\mu$ g/100 g body weight in 1 ml water *i.v.* once on the 4th day.

<sup>b</sup> Dyskinesia was estimated 30 min after injection ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

*Selye PROT. 40258*: In rats, the dyskinesia elicited by severe, but usually not fatal, LSD intoxication was well prevented by PCN, CS-1, ethylestrenol, norbolethone, prednisolone, triamcinolone and estradiol but only just significantly by progesterone and phenobarbital. The other standard conditioning agents remained without effect, *cf.* Table 74, p. 258.

**Magnesium** ← *cf. also Selye C92,918/61, pp. 87, 257; G60,083/70, pp. 348, 357, 358.*

*Störtebecker A1,993/37*: In rabbits and mice, the depth of  $MgSO_4$  anesthesia is influenced by sex hormones, as judged by observations in different phases of the estrous cycle as well as after injection of folliculin or androsterone. [In view of the wide individual variations and the small number of animals, the significance of the data is in doubt (H.S.).]

*Störtebecker 76,398/39*: In gonadectomized male and female mice, the anesthetic effect of  $MgSO_4$  is increased, but it can be restored to about normal by both estrogenic and androgenic hormones.

*Farnell H15,528/68*: In mice, cortisone inhibits the convulsions but aggravates the organ changes induced by Mg-deficiency.

*Jasmin E7,631/68*: In rats, certain manifestations of the Mg-deficiency syndrome are inhibited by cortisol, hypophysectomy or thyroparathyroidectomy.

*Whitfield & Tidball H549/68*: Rats ovariectomized and maintained on an Mg-deficient diet were either otherwise untreated or given 1  $\mu g$  of estradiol per day. "The results indicate that estrogen given to an ovariectomized rat will significantly retard the rate and extent of development of dietary magnesium deficiency."

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Selye et al. G60,016/70*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly

alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or  $MgCl_2$ .

$MgSO_4$  ← Gonadectomy + Testoids, Folliculoids, Mouse: Störtebecker 76,398/39\*

#### MAO-Inhibitors ←

*Blackham & Spencer G76,301/69*: In female mice, pretreatment with lynestrenol (a luteoid) reduced the hyperthermia induced by dexamphetamine, whereas mestranol (a folliculoid) increased it. Fencamfamine (also a CNS-stimulant) failed to induce hyperthermia in control or lynestrenol-pretreated mice but did raise the temperature after mestranol pretreatment. The potentiating effect of mestranol could be mimicked by pretreatment with nialamide (a MAO-inhibitor) but not by SKF 525-A. Increased locomotor activity induced by dexamphetamine and fencamfamine was enhanced by mestranol and reduced by lynestrenol. Dopamine, norepinephrine and 5-HT levels in the brain were reduced by lynestrenol and 5-HT was increased by mestranol. "If the actions of dexamphetamine (and fencamfamin) are due predominantly to the release of endogenous amines, then an increase (with lynestrenol) or a decrease (with mestranol) of tissue MAO activity should change the potency of these two stimulant drugs."

#### Mecamylamine ← *cf. Ganglioplegics*

#### Mechlorethamine ←

*Selye G70,480/71*: In rats, mechlorethamine intoxication was not prevented by any of the standard conditioning agents of our series. Indeed, prednisolone, triamcinolone, hydroxydione, thyroxine and, to a lesser extent, possibly also oxandrolone aggravated the toxicity of this compound, *cf.* Table 75, p. 260.

Mechlorethamine ← Cortisone: Hutchinson et al. B84,257/55\*

#### Meperidine ←

*Axelrod D28,544/56*: Hepatic microsomal-enzyme systems are described which can N-demethylate several narcotic drugs, including morphine and its congeners, methadone and meperidine. "There are marked sex differences

Table 75. *Conditioning for mechlorethamine*

Treatment <sup>a</sup>	Mortality <sup>b</sup> (Dead/Total)
None	4/15
PCN	0/10 NS
CS-1	4/10 NS
Ethylestrenol	5/15 NS
Spirolactone	4/15 NS
Norbolethone	5/10 NS
Oxandrolone	8/10 *
Prednisolone-Ac	10/10 ***
Triamcinolone	14/15 ***
Progesterone	4/10 NS

DOC-Ac	5/10 NS
Hydroxydione	9/10 ***
Thyroxine	15/15 ***
Phenobarbital	3/10 NS

<sup>a</sup> The rats of all groups were given mechlorethamine hydrochloride (100 µg per rat in 0.2 ml water, s.c., daily from 4th to 6th day).

<sup>b</sup> Mortality listed on 8th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

in the enzymatic demethylation of narcotic drugs in the rat. Administration of estradiol to male rats results in a decrease in enzyme activity while treatment of female rats with testosterone enhances enzyme activity."

*Remmer D86,728/58*: Mention of unpublished experiments indicating that cortisone and prednisolone accelerate the detoxication of meperidine in the rat exclusively through demethylation, not through hydrolysis.

*Crawford & Rudofsky G42,454/66*: In women taking various oral contraceptives, as well as in pregnant women and in neonates, the urinary excretion of pethidine and promazine is increased, suggesting interference with the detoxication of these drugs.

*Rudofsky & Crawford E58,989/66*: Following administration of meperidine or promazine "pregnant women, women on oral contraceptives and neonates excreted significantly more unchanged meperidine than normeperidine, whereas the reverse held for the male 'controls' and other female groups. Pregnant women, women on oral contraceptives and neonates excreted more unchanged

and degraded promazine than non-pregnant women. Stilbestrol and progesterone each changed the pattern of excretion by male subjects toward that associated with pregnancy." Apparently, pregnancy diminishes the capacity to metabolize meperidine and promazine, a change reflected in neonates and subjects taking oral contraceptives.

Meperidine ← Chloromethyltestosterone, 19-Nortestosterone + Chlorpromazine: Clouet et al. *F14,837/64*

**Mephenesin** ← cf. also *Selye G60,083/70*, p. 385.

*Selye G60,086/70*: In rats, mephenesin paralysis was very effectively prevented by all classic catatoxic steroids, except oxandrolone. Prednisolone and DOC offered barely significant protection, cf. Table 76.

Table 76. *Conditioning for mephenesin*

Treatment <sup>a</sup>	Paralysis <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	9/10	3/10
PCN	2/10 ***	0/10 NS
CS-1	0/15 ***	0/15 NS
Ethylestrenol	0/10 ***	0/10 NS
Spirolactone	0/10 ***	0/10 NS
Norbolethone	0/10 ***	0/10 NS
Oxandrolone	8/15 NS	1/15 NS
Prednisolone-Ac	7/15 *	0/15 NS
Triamcinolone (2mg)	15/15 NS	6/15 NS
Progesterone	8/15 NS	4/15 NS
Estradiol	8/10 NS	0/10 NS
DOC-Ac	7/15 *	2/15 NS
Hydroxydione	8/15 NS	2/15 NS
Thyroxine	9/10 NS	1/10 NS
Phenobarbital	5/10 NS	0/10 NS

<sup>a</sup> The rats of all groups were given mephenesin (30 mg on 4th day and 60 mg on 5th day, /100 g body weight in 0.2 ml propylene glycol s.c.).

<sup>b</sup> Paralysis was estimated on 5th day 2½ hrs after injection and mortality listed on 5th day p.m. ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

### **Meprobamate** ←

*Kato & Vassanelli D40,237/62*: "Rats pretreated with phenobarbital, phenaglycodol, glutethimide, nikethamide, chlorpromazine triflupromazine, meprobamate, carisoprodol,

pentobarbital, thiopental, primidone, chloretone, dyphenylhydantoin and urethan showed an accelerated metabolism of meprobamate and, at the same time, a diminished duration of sleeping time and paralysis due to meprobamate." SKF 525-A counteracted these actions of the enzyme inducers. In hypophysectomized or adrenalectomized rats, phenobarbital still increased meprobamate metabolism *in vitro*.

*Bousquet et al. F 35,073/65*: In rats with stress produced by applying a tourniquet around one hind limb for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection. [The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet but this is not specifically stated. Allegedly a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

*Selye G70,402/70*: In rats, meprobamate intoxication is inhibited by ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone and prednisolone. No protection is obtained by progesterone, triamcinolone, DOC, hydroxydione or estradiol.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Szeberényi & Fekete H29,579/70*: Brief abstract stating that after four days of pretreatment (species not mentioned), spironolactone decreased the action and accelerated the metabolism of hexobarbital, chlorzoxazone, meprobamate, esterone, testosterone, acenocoumarol and BSP, whereas after short treatment it had an inverse effect. It is concluded that spironolactone is a microsomal enzyme inducer.

*Selye G70,480/71*: In rats, the motor disturbances produced by meprobamate intoxication are readily prevented by all classic catatonic steroids, as well as by prednisolone and phenobarbital, *cf.* Table 77.

Meprobamate ← Adrenalectomy: Kato *et al. D40,237/62*

Table 77. *Conditioning for meprobamate*

<sup>a</sup> The rats of all groups were given meprobamate (50 mg/100 g body weight in 0.2 ml DMSO, *s.c.*, once on 4th day).

<sup>b</sup> Dyskinesia was estimated 3 hrs after injection and mortality registered 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

#### MER-25 ←

*Abdul-Karim et al. G55,510/68*: The offspring of rabbits treated with MER-25 [1-(p-2-diethylamino-ethoxyphenyl)-1-phenyl-2-methoxyphenylethanol] during gestation exhibit defects in endochondral ossification which can be prevented by concomitant administration of estradiol.

#### Mercury ←

← **Testoids** *cf. also Selye B40,000/50, p. 631. Selye A31,128/40; A31,126/40*: The renal and hepatic lesions produced by HgCl<sub>2</sub> in the mouse are prevented by testosterone, methyltestosterone, androstenediol, dehydroisoandrosterone and androstenedione.

*Longley A37,552/42*: "Treatment with testosterone propionate apparently increases the survival rate of rats poisoned with small doses of mercuric chloride, but is without effect when larger doses of poison are used."

*Feyel 99,416/43*: In mice, testosterone pretreatment does not protect either against HgCl<sub>2</sub> or uranium nitrate intoxication.

Fig. 10. Prevention of mersalyl-induced nephrocalcinosis by ethylestrenol. Kidneys of two rats, both of which were given 3 mg/100 g of mersalyl i.v. A: Control rat. B: Ethylestrenol given at the dose of 10 mg  $\times$  2/day — 4th day ff. completely prevents nephrocalcinosis (von Kóssa  $\times$  30)

*de Oliveira et al. B43,032/47:* In dogs, fatal renal damage produced by  $\text{HgCl}_2$  can be prevented by pretreatment with testosterone.

*Donatelli B38,554/47:* Women are much more sensitive to  $\text{HgCl}_2$  intoxication than men. Testosterone pretreatment gives appreciable protection against  $\text{HgCl}_2$  poisoning in mice and guinea pigs.

*Vargas B44,689/48:* In parrots, testosterone pretreatment protects the kidney against damage induced by  $\text{HgCl}_2$ .

*Cournot & Halpern B54,669/50:* In mice, testosterone failed to protect the kidney against  $\text{HgCl}_2$ .

*Levy et al. B47,634/50:* Testosterone offered no protection against the renal damage caused by  $\text{HgCl}_2$  in the rat.

*Sarre B99,950/54:* In rabbits, both the Masugi nephritis and sublimate nephrosis are inhibited by testosterone and even more actively by estradiol.

*Kádas & Zsámbéky C26,265/56:* The renal damage produced by  $\text{HgCl}_2$  in the rat is most effectively prevented by testosterone but, to a lesser extent, also by cortisone, particularly when the latter is given in combination with ACTH.

*Dérot & Tutin C67,130/57:* In patients with mercury intoxication, treatment with testosterone is beneficial.

*Kádas & Zsámbéky C49,522/57:* In rats poisoned with  $\text{HgCl}_2$ , both testosterone and combined treatment with ACTH + cortisone inhibit renal damage and improve survival.

*Jelínek et al. E32,261/63:* In mice, 2-bromoandrostene-3,17-dione, which is neither testoid nor anabolic, hastens the regeneration of the renal epithelium damaged by  $\text{HgCl}_2$ . Methyltestosterone actually aggravates the changes, whereas methandrostenolone and nandrolone phenpropionate had no effect.

*Jelínek et al. F20,543/64:* In mice and rats, regeneration following  $\text{HgCl}_2$ -induced renal damage is stimulated by 2-bromo-1-androstene-3,17-dione but not by methyltestosterone or 1,17-dimethylandrostan-17-ol-3-one.

*Klinkmann & Hübel F19,820/64:* Testosterone allegedly protected the kidneys of a patient from severe sublimate-overdosage.

*Wüstenberg et al. G38,225/65:* In female rats given sublethal doses of  $\text{HgCl}_2$ , the protective effect of testosterone upon the resulting renal damage was doubtful although the rise in blood NPN was significantly inhi-

Fig. 11. **Protection by spironolactone against mercury.** Both rats received the same dose of  $\text{HgCl}_2$  i.v. A + C: Heavy calcification of the renal cortex in the otherwise-untreated control rat. B + D: Complete prevention of calcification by prior treatment with spironolactone. Top: External surface. [Selye G70,426/70. Courtesy of Science]

Fig. 12 (A–D). **Prevention of  $\text{HgCl}_2$ -induced nephrocalcinosis by spironolactone.** All animals received the same  $\text{HgCl}_2$ -treatment. A: Left kidney of otherwise-untreated control in its natural position with part of the right kidney just visible across the mesentery of the rectum. The tubular localization of the calcification in the cortex is clearly visible. B: Pretreatment with spironolactone prevents this change. C: Cross section through the kidney shown above. Note strictly cortical localization of calcification. D: Cross section through the kidney shown above. No calcification is visible

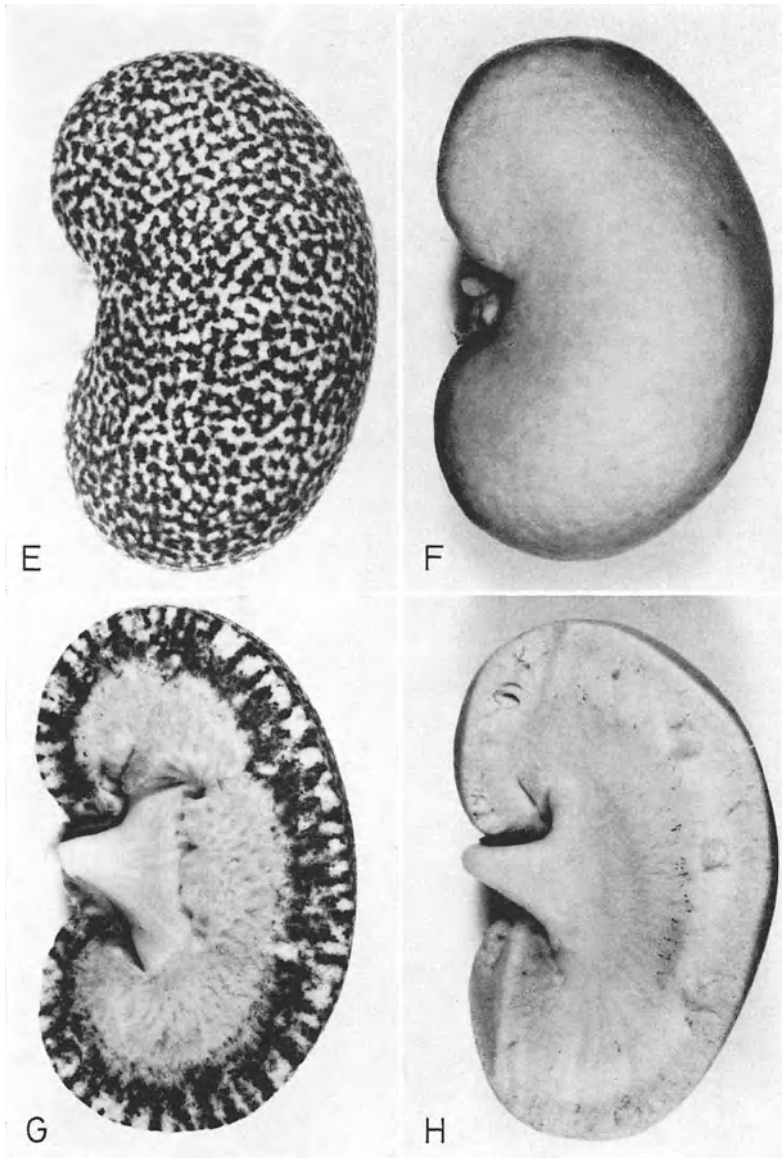

Fig. 12 (E—H). E: Macroscopic aspect of the control kidney after staining with von Kóssa technique. The calcified tubules (now black) are especially clearly visible. F: Similarly-prepared kidney of the rat pretreated with spironolactone. G, H: Cross sections through the kidneys shown above

Fig. 12 (I—L). I: Histologic appearance of the control kidney showing cortical calcification. J: Prevention of calcification by spironolactone. K, L: Higher magnification of the kidneys shown above. All sections stained with von Kóssa technique: top  $\times 9$ , bottom  $\times 27$ . [Selye *et al.* G70,440/70. Courtesy of Urol. and Nephrol.]

bited. In males, no definite protective action could be shown.

*Tessmann G65,320/68*: In the mouse and rat, regeneration of the renal epithelium following HgCl<sub>2</sub>-intoxication was not significantly enhanced by testosterone.

**Mercury** ← Testoids *cf. also Tables 78—80*  
← **Other Steroids** *cf. also Selye G60,083/70, p. 353. Clark & Barnes A33,441/40*: Pretreatment with DOC failed to protect intact rats against HgCl<sub>2</sub>.

*Kádas & Zsámbéky C26,265/56*: The renal damage produced by HgCl<sub>2</sub> in the rat is most effectively prevented by testosterone but, to a lesser extent, also by cortisone, particularly when the latter is given in combination with ACTH.

*Selye & Bois C14,441/57*: The calcification and foreign-body granuloma formation in the kidneys of rats poisoned with HgCl<sub>2</sub> is prevented by cortisol but not by DOC. The necrotizing ulcers in the cecum of the rat which develop under the influence of HgCl<sub>2</sub> were actually aggravated by cortisol but not influenced by DOC.

*Heimburg & Schmidt C69,587/59*: Female rats are more resistant than males to chronic intoxication with HgCl<sub>2</sub>. Ovarietomy abolishes this difference. Neither estradiol nor progesterone caused any significant change in resistance to mercurial intoxication.

*Miller et al. G77,153/69*: In chicks, cortisol and several other glucocorticoids increase mercury retention in the kidney and, at least in certain strains, also in the liver. [The experiments were terminated after four days and no mention is made of mortality (H.S.).]

*Selye G70,426/70*: In the rat, spironolactone is highly efficacious in preventing renal tubular necrosis and calcification as well as the mortality induced by HgCl<sub>2</sub>. Possibly this protective effect is due to the sulfur in the thioacetyl substituent of the steroid, *cf. Fig. 11, p. 263*.

*Szabó & Selye G70,478/70*: In rats, hypophysectomy greatly diminishes the nephrocalcinosis produced by HgCl<sub>2</sub>. This effect of HgCl<sub>2</sub> is completely abolished in hypophysectomized rats treated with triamcinolone.

*Garg et al. G60,078/71*: In rats, given HgCl<sub>2</sub>, spironolactone decreases the mercury content of the kidney, blood, urine, liver, spleen and lung by about 40—50%. This decrease is accompanied by an increased fecal elimination of Hg. However, the protection by spironolactone against nephrocalcinosis cannot be due exclusively to a diminished mercury

content since the kidneys of animals receiving spironolactone contain more mercury than those of rats showing renal calcification after treatment with lower doses of HgCl<sub>2</sub> given alone.

*Selye G70,480/71*: In rats, fatal intoxication with HgCl<sub>2</sub> was readily prevented by spironolactone. Among the other standard conditioning agents, only ethylestrenol, prednisolone, progesterone and estradiol offered moderate protection, *cf. Fig. 12, p. 264—266 and Table 78*.

Table 78. *Conditioning for mercuric chloride*

Treatment <sup>a</sup>	Nephrocalcinosis <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

<sup>b</sup> Dyskinesia was estimated on 6th day 6 hrs after injection and mortality listed on 8th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

or cholesterol caused any noteworthy change in the resulting intoxication, only thyroxine exhibited an aggravating effect.

#### *Methypylon* ←

*Selye et al. G60,020/69:* In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methypylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

*Selye et al. G60,016/70:* In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methypylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine,

reserpine, phenoxybenzamine, chloral hydrate, KBr or MgCl<sub>2</sub>.

*Selye G60,097/70; G70,480/71:* Methypylon (a hypnotic piperidine derivative) is unusual in its behavior in that its effect is diminished by all standard conditioning agents except DOC and thyroxine. The inhibition by estradiol is not very marked and hydroxydione pretreatment gives a barely significant shortening of the sleeping time but the potent classical conditioners and particularly PCN are extremely effective, cf. Table 84.

#### *Metrazol* ← cf. *Pentylene-tetrazol*

#### *Metyrapone* ←

*Szeberényi et al. G64,752/69:* In rats given metyrapone i.p., the disappearance of the drug from the plasma is accelerated by pretreatment with cortisol and numerous other drugs that induce hepatic-microsomal enzymes.

#### *Mitomycin* ←

*Lutzmann & Schmidt F57,784/65:* In rats, Δ<sup>1</sup>-17α-methyltestosterone failed to prevent the antimetabolic effect of cyclophosphamide or mitomycin upon Jensen sarcomas.

Table 84. *Conditioning for methypylon*

Treatment <sup>a</sup>	Sleeping time <sup>b</sup> (min)
None	485 ± 10
PCN	2 ± 1 ***
CS-1	35 ± 6 ***
Ethylestrenol	28 ± 5 ***
Spirolactone	158 ± 17 ***
Norbolethone	90 ± 10 ***
Oxandrolone	149 ± 17 ***
Prednisolone-Ac	11 ± 4 ***
Triamcinolone	234 ± 27 ***

Thyroxine	416 ± 32 NS
Phenobarbital	50 ± 14 ***

<sup>a</sup> The rats of all groups were given methypylon (20 mg/100 g body weight in 0.2 ml water, s.c., once on 4th day).

<sup>b</sup> Student's t-test.

For further details on technique of tabulation cf. p. VIII.

**Monocrotaline** ←

*Ratnoff & Mirick B48,154/49*: Monocrotaline i.p. produces necrosis of the liver and of the renal tubules, as well as pulmonary edema in rats. Males are somewhat more susceptible than females, especially if kept on protein-deficient diets. Testosterone increases monocrotaline susceptibility in both sexes, but neither castration nor estradiol influences survival time.

*Goldenthal et al. G18,384/64*: "The oral and intravenous LD<sub>50</sub>'s were determined for monocrotaline. The LD<sub>50</sub> was essentially the same for males and females and for oral and intravenous administration for a 90-day observation period. There was a marked sex difference with respect to the median survival time, females living significantly longer than males. Castration of either male or female rats had no significant effect on the median survival time. Pretreatment of males with estradiol cyclopentyl propionate caused the median survival time to correspond to that of females. Pretreatment of females with testosterone propionate caused the median survival time to approximate that of male animals. Pretreatment of female rats with methandrostenolone (Dianabol), an anabolic agent, caused the median survival time to correspond to that of males."

Monocrotaline ← Orchidectomy + Estradiol + Diet: *Ratnoff et al. B48,154/49\**

Monomethyl-4-aminoantipyrine ← Testoids: *Booth et al. D34,656/62*

**Morphine** ← cf. also **Ethylmorphine**

*Benetato et al. 33,773/35*: In rats, neither adrenocortical extract nor an adrenotropic anterior pituitary preparation altered resistance to morphine or to typhoid-paratyphoid vaccine.

*Michalek et al. B91,619/51*: In dogs, cortisone "modifies" the addiction syndrome induced by chronic morphine treatment. [Brief abstract without details (H.S.).]

*Winter & Flataker B62,935/51*: In rats, cortisone inhibits the toxic effects of methadone and the hyperactivity caused by morphine. Cortisone also increases the excitatory effect of morphine in cats. On the other hand, cortisone synergizes the analgesic antagonist N-allylnormorphine. After spinal cord section, cortisone and ACTH reduce the effect of morphine on the spinal reflex (tail-flick response), whereas DOC enhances it.

*Paroli G14,277/54*: In rats of either sex, stilbestrol, hexestrol, and estradiol pretreatment reduce morphine tolerance. Orchidectomy does not influence it.

*Miller et al. G73,877/55*: Review of earlier literature suggesting that morphine analgesia is mediated through the release of epinephrine from the adrenal medulla. It had been claimed that adrenalectomy decreases the pain reaction threshold to morphine and that morphine itself has an analgesic effect. However, in the authors' experiments on rats these observations could not be confirmed and TEA failed to reverse the effect of morphine on pain. In mice, near lethal doses of epinephrine or norepinephrine were required to raise the pain threshold.

*Axelrod D28,544/56*: Hepatic microsomal-enzyme systems are described which can N-demethylate several narcotic drugs, including morphine and its congeners, methadone and meperidine. "There are marked sex differences in the enzymatic demethylation of narcotic drugs in the rat. Administration of estradiol to male rats results in a decrease in enzyme activity while treatment of female rats with testosterone enhances enzyme activity."

*Adler et al. G79,852/57*: In Sprague-Dawley rats, given <sup>14</sup>C-labeled morphine, the ratio of bound to free morphine is 2–3 times greater in the urine and plasma than in Long-Evans rats. The tissues of adrenalectomized rats of both strains contain higher concentrations of <sup>14</sup>C-labeled morphine than do control rats. Plasma bound morphine levels indicate no impairment of morphine conjugation. Vasopressin increases, whereas ACTH decreases morphine sensitivity. Yet both after ACTH and after vasopressin, tissue concentrations of morphine are either reduced or unaffected in marked contrast to the increased values after adrenalectomy. Apparently, the decreased morphine sensitivity induced by ACTH is not reflected by lower brain morphine concentrations.

*Paroli & de Arcangelis C63,937/57*: In rats, progesterone enhanced the anesthetic effect of morphine; pregnanediol and pregnanediol had little effect upon it, whereas pregnenolone shortened its duration.

*Paroli C62,998/57*: In rats, estradiol, stilbestrol and hexestrol increase sensitivity to the lethal effects of morphine overdosage. Androsterone and orchidectomy are without effect upon it.

*Paroli C63,938/57; C63,939/57*: Estradiol, stilbestrol and hexestrol decrease the morphine resistance of the rat.

*Cochin & Axelrod G67,795/59*: Chronic treatment with morphine and morphine-nalorphine mixtures caused profound diminution of the analgesic response to a test dose of morphine. This was associated with a severe reduction in the ability of the liver enzymes to N-dealkylate morphine and nalorphine. Testosterone failed to affect the development of morphine tolerance or to modify enzymic activity.

*Sobel et al. C90,836/60*: Morphine increases the mortality of guinea pigs exposed to reduced oxygen tension. Prior treatment with cortisone or ACTH protects against this combined treatment.

*Markova D47,081/62*: Pretreatment with ACTH or cortisone increases the morphine resistance of newborn rats, although not quite to the adult level. DOC does not share this effect.

*Paroli G12,543/63*: In the rat, cortisol and ACTH inhibit the analgesic effect of morphine, whereas dexamethasone and prednisolone (though more active glucocorticoids) do not.

*Franklin G32,826/65*: The demethylation of morphine by rat hepatic microsomes was greatly diminished by pretreatment with cortisone, although, simultaneously, the G-6-P-ase activity of the liver increased. Pretreatment with morphine exhibited essentially similar effects upon these two enzymes.

*Lecannelier & Quevedo H8,759/67*: In rabbits, the analgesic effect of morphine is reduced by ACTH or cortisone.

*Dobrescu et al. H26,899/70*: In rats, the establishment of tolerance to morphine is delayed by prednisolone and accelerated by testosterone.

*Selye et al. G60,016/70*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or MgCl<sub>2</sub>.

*Stripp et al. H22,743/70*: In female rats, spironolactone pretreatment shortened hexobarbital sleeping time. "Moreover, treatment of female rats with spironolactone doubled the rate of the in vitro metabolism of hexobarbital and benzpyrene by liver microsomes and quadrupled that of ethylmorphine. The inducing effects of spironolactone were very

different from those of phenobarbital and 3-methylcholanthrene. The amount of cytochrome P-450 was either unaltered or decreased, but the NADPH cytochrome c reductase activity was increased 2-fold. Although the endogenous rate of cytochrome P-450 reduction by NADPH was not altered, the stimulatory effects of ethylmorphine or hexobarbital on the rate of cytochrome P-450 reduction were significantly greater with microsomes from spironolactone-treated animals. By contrast, treatment of male rats with spironolactone caused no change in hexobarbital sleeping time and no change or a slight decrease in hexobarbital and benzpyrene metabolism by liver microsomes."

*Selye PROT. 36205*: In rats, morphine sulfate (20 mg/100 g body weight in 0.2 ml water) was administered s.c. once on the 4th day of conditioning. Dyskinesia was listed 2 hrs, mortality 24 hrs, after this injection. Under these circumstances none of the "Standard Conditioners" (p. VIII) caused any noteworthy change in the resulting intoxication.

Morphine ← Adrenalectomy: Rogoff et al. G63,527/25\*; Zauder G75,347/52

Morphine ← Testosterone: Cochin et al. G67,795/59\*

Morphine ← Estradiol: Axelrod D28,544/56

Morphine ← Cyclopentyltestosterone: March et al. G77,519/54\*

#### Mustard Gas ←

*Kuchárik & Telbisz 96,165/45*: Certain adrenocortical extracts offer protection against mustard gas in the mouse.

Mustard Powder ← cf. *Selye B58,650/51*, p. 248.

#### Na ← cf. Sodium

Nalorphine ← Testosterone: Cochin et al. G67,795/59

#### Naphthalene ←

*Booth & Gillette D34,656/62*: Testosterone propionate, 19-nortestosterone, 4-androstene-3, 17-dione and 4-chloro-19-nortestosterone acetate (SKF 6611) were tested for their ability to induce hepatic microsomal enzymes in female rats. "All of the steroids produced 2- to 3-fold increases in the activity of the enzyme systems that metabolize hexobarbital, demethylate monomethyl-4-aminoantipyrine

and hydroxylate naphthalene, but only 19-nortestosterone, testosterone propionate and methyltestosterone increased the activity of microsomal TPNH oxidase. . . . The increase in microsomal enzyme activity is more closely related to the anabolic activity than to the androgenic activity of the steroid."

2-Naphthylamine ← 3β-Methoxyandrost-5-ene-17-one, Gp, Rat: Roy D5,284/61

**α-Naphthylisothiocyanate** ← *cf. also Bilirubin*

*Roberts & Plaa G39,694/66:* In mice, α-naphthylisothiocyanate-induced hyperbilirubinemia and cholestasis are aggravated by norethandrolone and norethynodrel but not by mestranol.

*Roberts & Plaa G69,070/69:* In mice and rats, the hyperbilirubinemia induced by α-naphthylisothiocyanate (ANIT) is enhanced by various drugs and steroids presumably because of an increased rate of bilirubin production and not as a consequence of decreased biliary bilirubin excretion. "Studies of the rate of endogenous bile bilirubin excretion and the incorporation of δ-aminolevulinic acid-<sup>14</sup>C (ALA-<sup>14</sup>C) into bilirubin in rats revealed that phenobarbital and chlorpromazine significantly increased the rate of bile bilirubin production (μg/100g/hr) and that phenobarbital, chlorpromazine, and norethandrolone significantly increased the percent incorporation of ALA-<sup>14</sup>C into bilirubin. Acetohexamide and Enovid both produced an increased, but irregular, response in bile bilirubin excretion and ALA-<sup>14</sup>C incorporation."

*Selye PROT. 42722:* In rats, acute ANIT intoxication is markedly inhibited by pretreatment with PCN, CS-1, ethylestrenol and phenobarbital and barely significantly by norbolethone, *cf.* Table 85.

Thyroxine	10/10 NS	10/10 NS
Phenobarbital	1/10 ***	2/10 ***

<sup>a</sup> The rats of all groups were given α-naphthylisothiocyanate (40 mg/100 g body weight in 1 ml oil, p.o., on 4th day).

<sup>b</sup> Dyskinesia was estimated on 8th day and mortality listed on 9th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

**Nickel Sulfide** ←

*Jasmin et al. D68,263/63:* In rats, a single i.m. injection of nickel sulfide produces metastatic rhabdomyosarcomas whose incidence is increased by methylandrostenolone but is uninfluenced by sex, ovariectomy or orchidectomy.

**Nicotinamide** ← *cf. Vitamin B*

**Nicotine** ← *cf. also Selye G60,083/70, p.385.*

*Yun & Lee 34,178/35:* Female mice and rabbits are more resistant to nicotine than males. Ovariectomy diminishes nicotine resistance, whereas orchidectomy does not change it. Treatment with "luteohormone" increases nicotine resistance, whereas "follicular hormone" has no effect.

*Holck et al. A8,011/37:* Female rats are more sensitive than males to various barbiturates and nicotine. Orchidectomy abolishes this increased resistance to barbiturates. Pretreatment with a testoid urinary extract shortens the anesthesia produced by hexo-

barbital in intact or spayed females. Androst-  
terone is ineffective.

*Hueper 91,722/43*: In rats, the cardio-  
vascular lesions produced by chronic nicotine  
intoxication are aggravated both by epine-  
phrine and by DOC.

*Selye G60,069/70*: In rats, both the motor  
disturbances and the mortality produced by  
heavy nicotine intoxication were readily  
prevented by the standard catatoxic steroids  
and by phenobarbital. Curiously, even DOC  
appeared to offer some degree of pro-  
tection, *cf.* Table 86.

*Selye G70,428/70*: In rats, ethylestrenol  
powerfully inhibits the toxicity of digitoxin,  
nicotine, indomethacin, phenindione, diox-  
athion, EPN, physostigmine, hexobarbital,  
cyclopental, thiopental, DOC (anesthesia),  
meprobamate and picrotoxin. Thyroxine  
increases the toxicity of many among these  
drugs and inhibits the protective effect of  
ethylestrenol.

Table 86. *Conditioning for nicotine*

<sup>a</sup> The rats of all groups were given nicotine  
(1 ml/100 g body weight of a 1% aqueous  
solution, p.o., daily from 4th day ff.).

<sup>b</sup> Dyskinesia was estimated on 6th day  
30 min after injection and mortality listed on  
9th day ("Exact Probability Test").

For additional pertinent data *cf. also*  
Table 135.

For further details on technique of tabu-  
lation *cf.* p. VIII.

*Selye G70,480/71*: In the rat, nicotine  
intoxication is inhibited by PCN, CS-1,  
cyproterone, ethylestrenol, spironolactone, nor-  
bolethone, oxandrolone, fluoxymesterone, pro-  
gesterone and DOC. It is not significantly  
altered by TMACN, 6 $\alpha$ -methylprednisolone,  
spiroxasone, 16 $\beta$ -methyl-16,17-epoxy-3 $\beta$ ,11 $\alpha$ -  
dihydroxy-5 $\alpha$ -pregnan-20-one, prednisolone,  
dexamethasone, betamethasone, MAD, emda-  
bol, 17 $\alpha$ -acetoxyprogesterone, testosterone,  
corticosterone, dehydroisoandrosterone, pre-  
gnanedione, triamcinolone, 11 $\alpha$ -hydroxypro-  
gesterone, hydroxydione, fluorocortisol, cor-  
tisol, cortisone or estradiol.

#### Nicotinic Acid ←

*Jelinek & Zikmund B52,661/49*: In male  
rabbits, nicotinic acid i.v. causes less pro-  
nounced dilatation of the ear vessels than in  
females. Castration doubles this effect of nico-  
tinic acid in males but does not change it in  
females. Testosterone propionate reduces this  
action of nicotine in orchidectomized males.

Table 87. *Conditioning for nikethamide*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	13/15	3/15
PCN	3/10 **	2/10 NS
CS-1	2/10 ***	2/10 NS
Ethylestrenol	2/10 ***	1/10 NS

Phenobarbital	0/10 ***	0/10 NS

<sup>a</sup> The rats of all groups were given niketh-  
amide (35 mg/100 g body weight in 0.2 ml wa-  
ter, s.c., on 4th day).

<sup>b</sup> Dyskinesia was estimated on 4th day,  
4 hrs after injection, and mortality listed on  
5th day ("Exact Probability Test").

For further details on technique of tabu-  
lation *cf.* p. VIII.

**Nikethamide** ←

*Selye PROT. 42379:* In rats, nikethamide (the diethylamide of nicotinic acid) is effectively detoxified by PCN, CS-1, ethylestrenol, norbolethone, progesterone, estradiol, DOC, phenobarbital and apparently even by hydroxydione. Spironolactone exhibits a just significant protective effect, whereas triamcinolone and, to a lesser extent, thyroxine aggravate nikethamide mortality. The amenability of nikethamide to detoxication by steroids is somewhat unusual in that progesterone, estradiol, DOC and hydroxydione, which are endowed with little or no protective effect against most toxicants, appear to be equally, or even more, potent than spironolactone in offering protection against this drug, *cf.* Table 87, p. 274.

**p-Nitroanisole** ←

*Radzialowski & Bousquet G53,591/67:* In rats of both sexes, the diurnal variation in the aminopyrine-, p-nitroanisole- and hexobarbital-metabolizing activity of hepatic microsomes is abolished by adrenalectomy.

*Selye PROT. 40471:* In rats, severe intoxication with p-nitroanisole is readily prevented by PCN and triamcinolone but the other standard conditioning agents were found to have little, if any, effect, *cf.* Table 88.

o-Nitroanisole ← Estradiol: Mitoma et al. G72,113/68

p-Nitrobenzoic Acid ← Progesterone: Juchau et al. G40,275/66

p-Nitrobenzoic Acid ← Ovariec-tomy: Kato et al. F76,403/66

p-Nitrobenzoic Acid ← Adrenal-ectomy + Pesticides (Chlordane): Hart et al. G27,102/65

**Nitrogen Mustard** ←

*Hutchinson et al. B84,257/53:* In rats, cortisone failed to protect against the lethal effect of nitrogen mustard.

*Field et al. F33,399/65; F78,812/67:* In mice, the leukopenia and mortality induced by nitrogen mustard (HN<sub>2</sub>) or 5-fluorouracil (FU) are diminished by pretreatment with testosterone. "Pretreatment with androgens may be a useful device for reducing the toxic and lethal effects of some anti-cancer drugs but the effects have not been as substantial as previously reported with anti-serotonins and anti-histamines."

Table 88. *Conditioning for p-nitroanisole*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	9/15	7/15
PCN (1 mg)	0/5 *	0/5 NS
PCN	1/10 ***	1/10 *
CS-1	2/10 NS	2/10 NS
Ethylestrenol	1/10 *	1/10 NS
Spironolactone	3/10 NS	3/10 NS
Norbolethone	1/10 *	1/10 NS
Oxandrolone	2/10 NS	2/10 NS

Thyroxine	3/10 NS	1/10 NS
Phenobarbital	6/10 NS	1/10 NS

<sup>a</sup> The rats of all groups were given p-nitroanisole, 15 mg/100 g body weight in 0.1 ml DMSO i.v. once on the 4th day.

<sup>b</sup> Dyskinesia was estimated 30 min after injection and mortality listed on the 5th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

**Nitrose Gas** ← *cf.* **Ozone**

**Nitrous Oxide** ←

*Rummel C79,429/59:* In guinea pigs and rats thyroxine increases whereas thyroidec-tomy decreases the threshold for N<sub>2</sub>O anesthesia. Dinitrophenol is ineffective. DOC lowers, whereas cortisone raises, this anesthesia threshold.

*Rummel et al. C80,035/59:* In rats, pre-treatment with cortisone increases, DOC decreases, whereas progesterone, testosterone and hydroxydione do not alter the N<sub>2</sub>O anesthesia threshold.

**Nortriptyline** ←

*Bahr et al. H21,089/70:* In dogs given nortriptyline and, 6—10 hrs later, various doses of cortisol, the rate of plasma clearance of the drug was delayed. Similarly, in rats, both cortisone and testosterone markedly decreased the rate of nortriptyline disappearance from isolated perfused liver preparations.

These changes may be due to a competition for the hepatic microsomal enzymes which metabolize both nortriptyline and the steroids.

**Octamethyl Pyrophosphoramidate** ← *cf.*  
**Pesticides**

**Ornithine** *cf.* **OKT under Influence of Steroids upon Enzymes**

**Orotic Acid** ←

*Sidransky D64,556/63; Sidransky et al. G4,364/63:* The periportal fatty degeneration of the liver produced by chronic orotic acid feeding is more pronounced in female than in male rats. Orchidectomized males developed more severe fatty changes than intact males, or castrate males treated with testosterone. Ovariectomized females developed marked fatty liver changes similar to those of intact females, but this response was diminished by testosterone or estradiol.

**Ozone** ←

*Matzen C39,985/57:* Neither cortisol nor prednisolone protects the mouse against the production of pulmonary edema by ozone.

*Henschler & Jacob C56,126/58:* In rats, the pulmonary edema induced by ozone ("Nitrose gas") is inhibited by prednisolone.

*Fairchild G71,531/63:* Review (6 pp., 26 refs.) on the effect of thyroidectomy, thioureas, thyroid hormones, glucocorticoids and hypophysectomy upon the resistance of various species to inhaled irritants especially ozone.

**Papain** ← *cf. also Selye C50,810/58, p. 105; C92,918/61, p. 102; G60,083/70, pp. 348, 357.*

*Thomas C20,800/56:* "Cortisone prevents the return of papain-collapsed ears to their normal shape and rigidity. Possibly this reflects a capacity of cortisone to impede the synthesis of deposition of sulfated mucopolysaccharides in tissues."

*McCluskey & Thomas C71,485/59:* In rabbits "the restoration of the normal rigidity of cartilage and the reaccumulation of basophilic substance in cartilage matrix following its *in vivo* depletion by papain were largely prevented by cortisone, hydrocortisone or prednisolone. Recovery of cartilage could be prevented locally in joint surfaces by the intra-articular injection of cortisone, hydrocortisone or prednisolone." Studies with <sup>35</sup>S sulfate suggest that the glucocorticoids inhibit

the synthesis of chondroitin sulfate in cartilage as a result of a topical action.

*Potter D23,805/61:* Review of the influence of glucocorticoids upon the cartilage lesions produced by papain.

*Lack D54,382/62:* The softening of the ear cartilages produced by papain *i.v.* in rabbits can be prevented by pretreatment with cortisone *i.m.*

*Hulth & Westerborn D56,601/63:* In rabbits, the lesions produced by cortisone in the growth cartilages are not significantly influenced by vitamin A, but recovery from the papain-induced cartilaginous damage is delayed by cortisone.

*Thomas E37,875/64:* Review on the effects of papain, vitamin A and cortisone on cartilage matrix *in vivo*.

*Weismann & Thomas E4,216/64:* Review of the literature showing that the reconstitution of cartilages in rabbits treated with papain can be prevented by subsequent administration of glucocorticoids for as long as these are administered. In the event of topical application of cortisone to certain cartilages damaged by papain, the delay in reconstitution of cartilage matrix is limited to the treated area.

*Lieberman H34,495/71:* In hamsters, the emphysema produced by a papain aerosol is inhibited by progesterone and to a lesser extent, by stilbestrol.

**Parabromdylamine** ←

*Selye G70,480/71:* In rats, brompheniramine maleate (30 mg/100 g body weight in 0.5 ml DMSO) was administered *p.o.* twice daily from the 4th to the last day of the experiment. Dyskinesia was estimated on the 5th day 3 hrs after injection, mortality 24 hrs later. Under these circumstances none of the "Standard Conditioners" (p. VIII) caused any noteworthy change in the resulting intoxication. PCN and phenobarbital were not tested.

**Pb** ← *cf.* **Lead**

**Pentylene-tetrazol** ←

*Selye A36,443/42:* In rats, the anesthesia produced by progesterone or DOC can be interrupted by pentylene-tetrazol. Conversely, these anesthetic steroids protect the rat against otherwise fatal doses of pentylene-tetrazol.

*Cicardo B964/45:* In guinea pigs, pretreatment with large doses of DOC does not modify sensitivity to pentylene-tetrazol convulsions.

*Torda & Wolff B57,149/51:* In rats, the convulsions and EEG changes produced by pentylenetetrazol are inhibited by ACTH or cortisone.

*Leonard et al. B86,814/53:* In mice, pretreatment with cortisone or DOC does not affect pentylenetetrazol-induced convulsions.

*Swinyard et al. C17,213/55:* In mice, DOC decreases pentylenetetrazol seizure threshold, whereas it increases EST. The effect upon pentylenetetrazol sensitivity is ascribed to DOC-induced hypernatremia.

*Boeri C78,610/58:* In guinea pigs, cortisone, ACTH and vasopressin aggravate pentylenetetrazol convulsions.

*Vacek C63,230/58:* DOC anesthesia protects the mouse against the convulsive and lethal effects of strychnine, pentylenetetrazol and caffeine.

*Rosadini & Bernardini D58,047/62:* In the mouse, pentylenetetrazol convulsions are inhibited by progesterone (given in anesthetic doses) and facilitated by large amounts of estrone sulfate.

*Seller & Spector D36,979/62:* Pretreatment with single nonanesthetic doses of cortisol enhances the production of pentylenetetrazol convulsions in the rat. Aldosterone has no such effect.

*Dashputra et al. F19,871/64:* Cortisone and prednisolone aggravated pentylenetetrazol convulsions in rats. Prednisone and dexamethasone were much less active, cortisol, triamcinolone, and DOC virtually inactive in this respect.

*Hewett et al. D19,834/64:* In mice, various amino-steroids possess "loss-of-righting-reflex activity" and prevent tremorine-induced tremor as well as pentylenetetrazol convulsions. Their effect is ascribed to interneuronal blockade and not to general anesthesia.

*Craig F69,385/66:* In mice, progesterone, DOC, a series of 3 $\beta$ -(aminoalkyl) esters of pregnenolone and various other steroids proved to inhibit pentylenetetrazol convulsions and electroshock seizures.

*Craig & Deason F99,058/68:* The anti-convulsant activity (metrazole test) "of a series of 4-pregnene and 5 $\beta$ -pregnane steroids has been studied after oral administration to mice. With a few exceptions it was noted that in general the addition of functional groups to the steroid nucleus resulted in compounds with diminished anticonvulsant activity."

*Jelinek H1,518/68:* Pretreatment with methyltestosterone does not influence pentylenetetrazol convulsions in the mouse.

*Kalyanpur et al. G66,147/69:* In mice, various anabolic steroids (methandienone, 4-chlorotestosterone acetate, nandrolone phenpropionate) given i.p. 90 min before pentylenetetrazol, inhibit convulsions. The protective effect is compared to that produced by various anesthetic steroids. [A relationship to enzyme induction is not suggested nor is it probable in view of the shortness of the necessary pretreatment (H.S.).]

*Selye G70,480/71:* In rats, both the motor disturbances and the mortality caused by severe pentylenetetrazol intoxication were markedly inhibited by PCN, norbolethone and progesterone. Phenobarbital appeared to have a less pronounced effect whereas the other standard conditioners were essentially ineffective, *cf.* Table 89.

For further details on technique of tabulation cf. p. VIII.

were grossly hemorrhagic, "it may be reasonable to assume that a damaged gland is unable to meet its requirements for secretory activity as effectively as does an undamaged gland" and that the extract acted as a substitution therapy.

*Perchlorates* ← cf. also *Selye C92,918/61*, p. 277.

*Bajusz & Selye C64,511/59; C57,180/59; Selye C61,814/59*: The spastic muscular contractions (with positive "Flick-test") produced by NaClO<sub>4</sub> in the rat can be inhibited by cortisol or triamcinolone, and aggravated by DOC or methylchlorocortisol (Me-Cl-COL). Thyroparathyroidectomy or parathyroidectomy likewise exert a sensitizing effect. Triamcinolone also protects the dog against the syndrome produced by heavy overdosage with NaClO<sub>4</sub>. Methyltestosterone, estradiol and progesterone did not significantly affect the response of the rat to NaClO<sub>4</sub>.

*Selye G70,480/71*: In rats, intoxication with NaClO<sub>4</sub> (manifested by the "Flick-test")

was most effectively prevented by thyroxine. Prednisolone and triamcinolone also diminished the motor disturbances but greatly increased mortality under the conditions of our test, cf. Table 90.

*Permanganate* ← cf. also *Selye D15,540/62*, p. 302.

*Selye et al. D8,010/62*: Topical calciphylaxis produced by KMnO<sub>4</sub> s.c. in the rat is not prevented by systemic treatment with large doses of triamcinolone.

#### *Pesticides* ←

*Durham et al. C27,425/56; C14,264/56*: In rats, DDT raised the liver weight/body weight ratio. Diethylstilbestrol increased the storage of DDT and of its metabolite DDE in the fat of male rats, whereas testosterone propionate decreased these values in females. "An endocrine mechanism may account for the sex differences in this regard."

*Murphy & Du Bois D28,546/58*: The activity of the microsomal-enzyme system which oxidizes thiophosphates to potent anticholinesterase agents is considerably higher in male than in female rats (incubation of liver homogenates with Guthion or ethyl p-nitrophenyl thionobenzenephosphonate or "EPN"). Yet, in vivo, adult males are more resistant to EPN than females perhaps because the accelerated formation of toxic oxidation products is overcompensated by a more efficient detoxication of the latter. The low enzyme activity of female livers is enhanced by pretreatment with testosterone in vivo, whereas the high activity of male livers is diminished by previous castration, partial hepatectomy or treatment with progesterone or diethylstilbestrol. SKF 525-A inhibits, whereas pretreatment with carcinogens or a protein-deficient diet enhances the activity of the thiophosphate-oxidizing enzyme.

*Swann et al. C73,379/58*: Male rats are more resistant than females to parathion poisoning. Testosterone increases the resistance of females, whereas estrone diminishes that of the males. Curiously, testosterone decreases the resistance of intact males although it increases that of castrated males. After orchidectomy estrone slightly decreases resistance over that of untreated male castrates.

*Kato et al. G64,325/62*: Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect of OMPA is greater in the male. The sex

difference is ascribed to the increased production of anabolic testoids which enhance the decomposition of these substrates, the first three of which are inactivated, the last activated in the process. The differences were also demonstrated *in vitro* using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

*Brodeur & DuBois F 40,590/65*: Immature rats are more sensitive to malathion than adults and their livers detoxify the insecticide at a slower rate. Orchidectomy decreases, whereas testosterone increases, malathion detoxication. All of this suggests that testoids play an important role in the maintenance of the malathion-hydroxylating enzyme system.

*Dubois & Kinoshita G 66,247/65*: Utilizing the anticholinesterase action of 0,0-diethyl 0-(4-methylthio-m-tolyl) phosphorothioate (DMP) as an indicator, it was found that in female rats, "administration of phenobarbital, nikethamide, 3,4-benzpyrene, testosterone, estradiol, cortisone and a number of other steroids induce resistance to the anticholinesterase action of DMP."

*Brodeur & DuBois F 85,072/67*: Immature rats are highly susceptible to the organophosphate insecticide malathion. *In vitro*, their livers show low malathionase activity. Prolonged pretreatment with testosterone significantly increases the enzymic activity of the livers of castrated young male and adult female rats. Conversely, castration interferes with the maintenance of normal levels of malathionase in adult males and inhibits its development in weanlings. Estradiol decreases malathionase activity in adult males.

*Brooks & Harrison G 65,297/69*: Studies on the kinetics of the inhibition by norethynodrel of epinephrine metabolism by pig liver microsomes *in vitro*.

*Carlson & DuBois H 24,653/70*: Male rats are much more susceptible to the insecticide 6-methyl-2,3-quinoxalinedithiol cyclic carbonate (Morestan) than females. "The toxicity to rats could not be altered by castration, administration of testosterone to females and estradiol to males. Pretreatment with phenobarbital decreased the toxicity to adult males and increased the toxicity to adult females." Chronic Morestan feeding caused hepatic enlargement and inhibition of microsomal enzymes.

*Selye G 70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin,

nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Selye et al. G 70,457/70*: In rats, ethylestrenol, CS-1, spironolactone and norbolethone fail to alter sensitivity to OMPA although these typical catatotoxic steroids have previously been shown to induce hepatic microsomal enzymes and to detoxify numerous other pesticides. This is of interest because catatotoxic barbiturates greatly increase the toxicity of OMPA, presumably by transforming it into a more toxic metabolite. On the other hand, estradiol, estrone and stilbestrol, which have no typical catatotoxic actions, considerably increase OMPA toxicity in ovariectomized rats. "The protective effect of catatotoxic steroids is presumably due to their structural characteristics and is independent of other pharmacologic actions. Conversely, sensitization to OMPA depends more upon the estrogenic action of compounds than upon their chemical structure, since stilbestrol, a nonsteroidal estrogen, is also highly effective in this respect." Prednisolone, triamcinolone, progesterone, DOC, hydroxydione and thyroxine fail to influence OMPA toxicity.

*Selye G 70,435/70*: In rats, ethylestrenol, CS-1, spironolactone, and norbolethone counteract the lethal effects of ethion, dioxathion, EPN, Guthion and parathion. To a lesser extent, this is also true of oxandrolone, prednisolone and progesterone. Triamcinolone, DOC, hydroxydione, estradiol, and thyroxine offer no consistent protection against these pesticides. DDT is much more resistant against detoxication by even the most powerful catatotoxic steroids.

*Szabo & Selye G 70,497/70*: In rats, various catatotoxic steroids, and particularly PCN, offer protection against intoxication with parathion and dioxathion. This protective effect is not prevented by hypophysectomy.

*Selye G 70,480/71*: In rats, DDT [1,1,1-Trichloro-2,2-bis (p-chlorophenyl) ethane] (25 mg/100 g body weight in 1 ml corn oil) was administered *p.o.* once on the 4th day of conditioning. Dyskinesia was measured 24 hrs, mortality 48 hrs, after this injection. Under these circumstances the "Standard Conditioners" (p. VIII) caused no noteworthy change

in the resulting intoxication, only phenobarbital exhibited an inhibiting effect.

*Selye G70,480/71:* In rats, parathion intoxication is prevented by PCN, CS-1, cyproterone, ethylestrenol, spironolactone, norbolethone, TMACN, 16 $\beta$ -methyl-16,17-epoxy-3 $\beta$ ,11 $\alpha$ -dihydroxy-5 $\alpha$ -pregnan-20-one, spiroxasone, dehydroisoandrosterone and pregnanedione. It is not significantly ameliorated by oxandrolone, 6 $\alpha$ -methylprednisolone, fluoxymesterone, prednisolone, dexamethasone, MAD, cortisol, emdabol, 17 $\alpha$ -acetoxyprogesterone, testosterone, corticosterone, cortisone, progesterone, triamcinolone, 11 $\alpha$ -hydroxyprogesterone, hydroxydione, DOC and fluorocortisol. Its toxicity is actually aggravated by betamethasone and estradiol. Dioxathion intoxication is prevented by PCN, CS-1, cyproterone, ethylestrenol, spironolactone, norbolethone, TMACN, oxandrolone, 6 $\alpha$ -methylprednisolone, fluoxymesterone, spiroxasone, 16 $\beta$ -methyl-16,17-epoxy-3 $\beta$ ,11 $\alpha$ -dihydroxy-5 $\alpha$ -pregnan-20-one, prednisolone, dexamethasone, betamethasone, hydroxydione, MAD, emdabol, 17 $\alpha$ -acetoxyprogesterone, testosterone, pregnanedione, desoxycorticosterone and estradiol. It is not significantly prevented by corticosterone, cortisone, dehydroisoandrosterone, progesterone, cortisol, 11 $\alpha$ -hydroxyprogesterone or fluorocortisol but aggravated by triamcinolone.

*Selye PROT. 31563,31612:* In mice, the lethal effect of dioxathion is powerfully inhibited by ethylestrenol, norbolethone, prednisolone and estradiol, moderately by CS-1 and oxandrolone, but not influenced by spironolactone, progesterone, triamcinolone, DOC, hydroxydione and thyroxine.

*Selye G70,480/71:* In rats, the lethal effect of heavy dioxathion intoxication could be completely prevented only by the standard catatoxic steroids and by phenobarbital. However, prednisolone, estradiol, DOC, and to a much lesser extent perhaps, progesterone likewise offered some protection against mortality. Triamcinolone and thyroxine diminished resistance to dioxathion. It is especially noteworthy that here as in many other experiments the conditioning effect of the two glucocorticoids in our series differs essentially in that prednisolone protects, whereas triamcinolone aggravates the toxicity of this pesticide, *cf.* Table 91.

*Selye G70,480/71:* In rats, heavy intoxication with ethion is readily prevented by all standard conditioners, prednisolone, progesterone and phenobarbital. Estradiol given p.o.

#### Phenylalanine ←

*Reiss et al. F 81,632/66:* In rabbits given large amounts of phenylalanine the blood and tissue concentration of this compound could be reduced by pretreatment with norbolethone decanoate or STH.

Phenylbutazone ← Prednisone, Man: Levi et al. F99,523/68\*

Phenytoin ← Lynestrenol, Mouse: Rümke et al. H 14,039/69\*

#### Phenyramidol ←

*Selye PROT. 42329:* In rats, phenyramidol sleeping time is significantly shortened by PCN, CS-1, ethylestrenol, spiroinolactone, norbolethone, oxandrolone, prednisolone and phenobarbital but, somewhat unexpectedly, estradiol also shares this effect, cf. Table 100.

Table 100. Conditioning for phenyramidol

Treatment <sup>a</sup>	Sleeping Time <sup>b</sup> (min)
None	100 ± 8
PCN	17 ± 8 ***
CS-1	15 ± 8 ***

<sup>a</sup> The rats of all groups were given phenyramidol (50 mg/100 g body weight in 0.2 ml water, s.c., on 4th day).

<sup>b</sup> Sleeping time (Student's t-test).

For further details on technique of tabulation cf. p. VIII.

#### Phlorhizin ←

*Winter & Belanger A 36,751/41:* In the rat, pretreatment with testosterone inhibits phlorhizin glycosuria and the associated renal lesions.

#### Phosgene ←

*English F 399/64:* Description of a single patient who recovered from phosgene poisoning after treatment with cortisol.

**Phosphate** ← cf. also *Selye B 40,000/50, p. 613; C 92,918/61, p. 205.*

*Selye & Bois C 12,616/56:* The nephrocalcinosis which develops in rats treated with DOC + NaH<sub>2</sub>PO<sub>4</sub> is inhibited by cortisol.

*Selye & Bois C 13,168/56:* Selective corticomedullary nephrocalcinosis can be obtained in uninephrectomized rats by NaH<sub>2</sub>PO<sub>4</sub> p.o. even after adrenalectomy. This effect is aggravated by DOC and virtually absent if the animals are maintained exclusively with cortisol. The action of DOC is counteracted by concurrent treatment with cortisol. "It appears that the corticoids exert an important regulating influence upon the ability of the kidney to handle an excess of phosphate."

*Selye C 38,401/57:* In the rat, estradiol facilitates the production of cortico-medullary

nephrocalcinosis by  $\text{NaH}_2\text{PO}_4$ . A similar effect is produced by DOC. "Since oestradiol is completely devoid of mineralocorticoid, and deoxycorticosterone of folliculoid actions, the enhancement of nephrocalcinosis appears to be an 'independent steroid hormone action'."

*Selye C38,768/58*: The cortico-medullary nephrocalcinosis produced in rats by an excessive intake of  $\text{NaH}_2\text{PO}_4$  is largely inhibited by ovariectomy and enhanced even in the ovariectomized animal by comparatively small doses of estradiol or stilbestrol. The nephrocalcinotic effect of estradiol is not significantly influenced under these conditions by large doses of progesterone but greatly aggravated by methyltestosterone, although luteoids and testoids counteract many of the other actions of folliculoids.

*Selye C39,319/58*: In rats, nephrocalcinosis produced by excess  $\text{NaH}_2\text{PO}_4$  p.o. is aggravated by estradiol, but even the severe calcification induced by this combined treatment is prevented by hypophysectomy.

*Cantin D36,815/62*: In the rat, the nephrocalcinosis produced by  $\text{Na}_2\text{HPO}_4$  is aggravated by DOC or estradiol. Parathyroidectomy prevents this change, even following combined hormone and phosphate treatment.

*Cornelius D58,739/63*: In sheep, large amounts of urinary calculi were regularly produced by a high phosphate diet after orchidectomy. [The author gives no evidence that the orchidectomy was essential (H.S.).]

*Cantin F5,681/64*: The nephrocalcinosis produced in rats by combined treatment with  $\text{NaH}_2\text{PO}_4$  + either estradiol or DOC is prevented by parathyroidectomy or thyroparathyroidectomy, and in either case additional treatment with thyroxine prevents nephrocalcinosis.

### Phosphorus ←

*Berdjis F79,528/67*: The hepatotoxic effect of  $\text{CCl}_4$ , phosphorus and ethionine could be diminished by cortisone and survival prolonged.

*Allegri & Ferrari B53,060/49*: In rats, testosterone offers moderate protection against the hepatic damage produced by phosphorus poisoning.

*Selye G70,480/71*: In rats, elementary yellow phosphorus (150  $\mu\text{g}/100$  g body weight in 0.4 ml corn oil) was administered p.o. once daily, from the 4th day of conditioning to the end of the experiment. Osteosclerosis and hepatic steatosis were listed on the day of death, and the mean survival was computed.

Under these circumstances, none of the "Standard Conditioners" (p. VIII) or cholesterol caused any noteworthy change in the resulting intoxication. Hydroxydione, PCN and phenobarbital were not tested.

### Physostigmine ←

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Selye G70,435/70*: In rats, intoxication with physostigmine was diminished by ethylestrenol, CS-1, spironolactone, and prednisolone, but aggravated by estradiol and thyroxine. Norbolethone, oxandrolone, progesterone, triamcinolone, DOC, and hydroxydione had no significant effect.

*Selye G70,480/71*: In rats, the toxicity of physostigmine (unlike that of the anticholines-

Table 101. Conditioning for physostigmine

Estradiol (1 mg s.c.)	10/10 NS	5/10 NS
DOC-Ac	11/15 *	4/15 ***
Hydroxydione	11/15 *	6/15 *
Thyroxine	10/10 NS	10/10 NS
Phenobarbital	0/10 ***	0/10 ***
$\beta$ -Sitosterol	14/15 NS	11/15 NS

<sup>a</sup> The rats of all groups were given picrotoxin (350  $\mu$ g/100 g body weight in 0.2 ml water, s.c., on 4th day).

<sup>b</sup> Dyskinesia was estimated 30 min after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

terase pesticides) is only moderately diminished by PCN, CS-1, ethylestrenol, spironolactone and prednisolone. Estradiol and thyroxine diminish physostigmine resistance, whereas phenobarbital does not affect it significantly, cf. Table 101, p. 285.

**Picrotoxin** ← cf. also *Selye G60,083/70*, p. 385.

*Clarke A 36,747/41*: Rats can be protected against otherwise fatal doses of picrotoxin by the administration of anesthetic doses of DOC.

*Holck D28,543/49*: Adult male rats are more resistant than females to toxic doses of picrotoxin. Such a sex difference is absent in one-month-old rats. Castration lowers picrotoxin resistance in rats of either sex. Testosterone raises picrotoxin resistance in normal and especially in spayed females, but not in males. Blockade of the RES abolished the sex difference but corticosterone failed to influence it.

*Selye G60,070/70*: In rats, picrotoxin poisoning can be prevented by ethylestrenol,

CS-1, spironolactone, norbolethone, oxandrolone, prednisolone and progesterone. Triamcinolone, DOC, hydroxydione, cholesterol and  $\beta$ -sitosterol have no such protective effect.

*Selye G60,087/70*: In rats, fatal intoxication with picrotoxin is readily combated by the classic catatoxic steroids, prednisolone, progesterone and phenobarbital. To a lesser extent DOC, and hydroxydione may also be effective.  $\beta$ -Sitosterol (a pharmacologically inert steroid included in this series as an additional control) is quite ineffective in protecting against picrotoxin, cf. Table 102.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

*Selye PROT. 27594*: In mice, pretreatment with spironolactone, ethylestrenol, triamcinolone or thyroxine had little, if any, effect upon the toxicity of picrotoxin under our experimental conditions.

Picrotoxin ← Corticosterone: *Holck D28,543/49\**

Picrotoxin ← Ovariectomy + Testosterone: *Holck D28,543/49\**

### **Piperidine** ←

*Selye G70,480/71*: In rats, moderate intoxication with piperidine did not cause sufficient mortality among the controls to identify the possible protective effect of our standard conditioning agents but in any event, none of them increased susceptibility to this toxicant. On the other hand, the motor disturbances were most significantly inhibited by CS-1, ethylestrenol, norbolethone, oxandrolone, triamcinolone, progesterone, hydroxydione and phenobarbital. Even DOC and thyroxine appeared to have offered some protection. This rather nonspecific protective effect of so many among our conditioners is reminiscent of their effect upon intoxication with methyprylon (a piperidine derivative). One noteworthy difference is that methyprylon intoxication is completely prevented by PCN whereas piperidine is singularly resistant to prophylaxis by this highly potent catatoxic steroid, cf. Table 103.

Table 103. *Conditioning for piperidine*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	12/15	2/15
PCN	10/10 NS	0/10 NS

Hydroxydione	0/10 ***	0/10 NS
Thyroxine	5/15 *	2/15 NS
Phenobarbital	0/10 ***	0/10 NS

<sup>a</sup> The rats of all groups were given piperidine (50 mg/100 g body weight in 1 ml water, p.o., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 5 hrs after injection and mortality listed on the 5th day ("Exact Probability Test"). This experiment was subsequently repeated several times and the results were too variable for reliable evaluation. Depending upon uncontrollable factors, the same conditioners, which provided good protection in certain instances, were ineffective when the experiments were repeated.

For further details on technique of tabulation cf. p. VIII.

#### **Pipradol ←**

*Selye G70,480/71*: In rats, pipradol hydrochloride (30 mg/100 g body weight in 1 ml corn oil) was administered p.o. once on the 4th day of conditioning. Dyskinesia was listed 3 hrs, mortality 24 hrs after this injection. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication, only PCN exhibited an inhibitory effect. Phenobarbital was not tested.

#### **Plant Extracts ←**

*Campbell C38,327/57*: In cockerels, the hepatic damage produced by the pyrrolizidine alkaloids of ragwort (*Senecio jacoboea* L.) disappears very slowly if at all, whereas hens recover. In both sexes, but particularly in

cockerels, stilbestrol accelerates hepatic regeneration.

**Plasmocid** ← cf. *Selye C50,810/58*, p. 110; *C92,918/61*, p. 95.

**Polyvinyl Alcohol** ← cf. *Selye G60,083/70*, p. 358.

#### **Potassium ←**

*Zwemer & Truszkowski A2,330/37*: Adrenocortical extract protects intact mice and guinea pigs against otherwise fatal amounts of KCl i.p.

*Lowenstein et al. A74,481/43*: In rats, pretreatment with DOC increased, whereas thyroid feeding decreased resistance to KCl i.p.

*Mullins et al. 83,885/43*: In rabbits, both adrenocortical extract and DOC can protect against acute potassium intoxication, but only under certain experimental conditions.

*Thatcher & Radike B4,515/47*: In rats, resistance to KCl intoxication was increased by DOC or adrenocortical extract.

*Robertson B32,963/49*: In mice and rats, DOC increases resistance to multiple injections of KCl, both in the absence and in the presence of the adrenals. Potassium tolerance may be used as a test for adrenocortical function.

*Collins C7,486/55*: In rats, the resistance to KCl i.p. is diminished by pretreatment with glucocorticoids perhaps as a consequence of adrenal atrophy.

*Collins C12,721/56*: In rats, prolonged pretreatment with cortisol decreases tolerance to the i.p. injection of KCl. This "is probably due to hypofunction of the adrenal-pituitary axis rather than to steroid-induced alterations of electrolyte balance."

*Collins C17,662/56*: Survival after KCl i.p. (referred to as "potassium stress") is diminished after the induction of adrenocortical atrophy by cortisol. Concurrent administration of DOC, aldosterone, adrenocortical extract, corticosterone or ACTH counteracts this effect of cortisol upon K-tolerance.

*Wallon & Browaeys C78,322/59*: Addition of KCl to the drinking water prolongs the survival of rats given large doses of cortisone.

*Spremolla & Grassi G68,941/63*: Renal lesions produced in rats by a K-deficient diet can be corrected by 4-chlorotestosterone.

*Grassi & Spremolla F28,126/64*: 4-Chlorotestosterone prevents the drop in K, glycogen, and nitrogen as well as the morphologic changes produced in the liver of rats kept on a K-deficient diet.

**Pralidoxime** ←

*Selye G70,435/70*: In rats, pralidoxime intoxication was counteracted by prednisolone and, to a lesser extent, by ethylestrenol and estradiol, CS-1, spironolactone, norbolethone, oxandrolone, progesterone, triamcinolone, DOC, hydroxydione, and thyroxine had no significant effect.

*Selye G70,480/71*: In rats, intoxication with pralidoxime (an anticholinesterase inhibitor and cholinesterase reactivator) was readily prevented by triamcinolone and prednisolone, the two glucocorticoids of our series, whereas the other conditioning agents had little if any effect upon this toxicant, *cf.* Table 104.

Table 104. *Conditioning for pralidoxime*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	11/13	7/13
PCN	10/10 NS	7/10 NS
CS-1	7/9 NS	5/9 NS
Ethylestrenol	3/8 *	0/8 *
Spironolactone	8/10 NS	6/10 NS
Norbolethone	6/10 NS	2/10 NS
Oxandrolone	6/10 NS	3/10 NS
Prednisolone-Ac	0/10 ***	0/10 **
Triamcinolone	0/10 ***	1/10 *
Progesterone	8/10 NS	4/10 NS
Estradiol	3/9 *	0/9 *
DOC-Ac	8/10 NS	1/10 *
Hydroxydione	8/10 NS	6/10 NS
Cholesterol	4/9 NS	2/9 NS
Thyroxine	4/9 NS	1/9 NS
Phenobarbital	3/10 *	4/10 NS

<sup>a</sup> The rats of all groups were given pralidoxime Cl (16 mg/100 g body weight in 0.2 ml water, *s.c.*, on 4th and 5th day).

<sup>b</sup> Dyskinesia was estimated on 4th day 30 min after injection and mortality listed on 6th day ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

**Primaquine** ←

*el-Denshary et al. G77,356/69*: In rabbits, the hepatic damage produced by primaquine is most effectively prevented by choline but, to a lesser extent, also by dexamethasone.

**Procaine** ←

*Munoz et al. G68,223/61*: Male rats are more resistant than females to the convulsant action of procaine *i.p.* Gonadectomy decreased resistance in males but not in females. Testosterone did not significantly alter resistance in either sex.

*Paeile et al. F52,633/64*: Adult male rats are more resistant to procaine than adult females. Chronic CCl<sub>4</sub> poisoning, pretreatment with SKF 525-A and orchidectomy diminish the resistance of the males approximately to the female level. The plasma procainesterase activity is approximately the same in both sexes and not affected by orchidectomy or CCl<sub>4</sub> intoxication.

*Brodeur et al. F99,981/67*: The procainesterase activity of the liver is higher in adult male rats than in adult females or immature rats of either sex. Ovariectomy and chronic treatment with testosterone or norethandrolone increase hepatic procainesterase activity in adult females. Conversely, orchidectomy and chronic treatment with estradiol or progesterone decrease this enzyme activity in the livers of adult males. However, immature rats are more resistant to procaine *in vivo* than could be expected from the reduced ability of their livers to hydrolyze procaine *in vitro*. "Factors other than drug metabolism appear to govern the ultimate toxicity of procaine in immature rats."

**Promazine** ←

*Rudofsky & Crawford E58,989/66*: Following administration of meperidine or promazine "pregnant women, women on oral contraceptives and neonates excreted significantly more unchanged meperidine than normeperidine, whereas the reverse held for the male 'controls' and other female groups. Pregnant women, women on oral contraceptives and neonates excreted more unchanged and minimally degraded promazine than non-pregnant women. Stilbestrol and progesterone each changed the pattern of excretion by male subjects toward that associated with pregnancy." Apparently, pregnancy diminishes the capacity to metabolize meperidine and promazine, a change reflected in neonates and subjects taking oral contraceptives.

*Crawford & Rudofsky G42,454/66*: In women taking various oral contraceptives, as well as in pregnant women and in neonates, the

urinary excretion of pethidine and promazine is increased, suggesting interference with the detoxication of these drugs.

**Propionitrile ←**

*Gellhorn 16,839/23:* In mice, resistance against acetonitrile can be increased not only by thyroid extract but, to a lesser extent, also by extracts of various other tissues. These preparations also augment resistance to KCN and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

*Selye G70,480/71:* In rats, propionitrile poisoning was aggravated by PCN, prednisolone, triamcinolone and thyroxine but not strikingly affected by the other conditioners involved in this series, although estradiol and hydroxydione may have offered barely significant protection, cf. Table 105.

Table 105. *Conditioning for propionitrile*

<sup>a</sup> The rats of all groups were given propionitrile (15 mg by 100 g body weight in 0.2 ml water, s.c., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 4 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Puromycin Aminonucleotide (PAN) ←**

*Selye C38,594/57:* The nephrosis and osteitis fibrosa produced by PAN in the rat

is inhibited by cortisol and aggravated by DOC.

*Fiegelson et al. D96,580/57:* In the rat, PAN-nephrosis is adversely influenced by cortisol, whereas anti-kidney-serum nephritis is largely inhibited by it.

*Wilson et al. C45,755/57:* In rats, PAN nephrosis is not prevented by cortisone or ACTH.

*Gupta & Giroud C73,800/59:* In rats, the production of nephrosis by PAN is inhibited by spironolactone. Apparently "in aminonucleoside nephrosis the increased rate of secretion of aldosterone is one of the main factors operating in fluid retention."

*Borowsky et al. D2,508/61:* The course of an already-established PAN nephrosis was not altered by treatment with 0.4 mg/day of prednisolone after cessation of PAN-treatment. From this, it was concluded that "steroids do not modify this lesion."

*Fisher & Gruhn D12,898/61:* The histologic and electron microscopic alterations produced by PAN (6-dimethyl-aminopurine-3-amino-d-ribose) in the rat are not affected by cortisone, adrenalectomy or hypophysectomy.

*Herken et al. G15,041/63:* In rats, both the functional and the ultrastructural kidney lesions produced by PAN are counteracted by triamcinolone, dexamethasone and 6-methyl-prednisolone.

*Lannigan D69,709/63:* Chronic treatment with low doses of hydrocortisol (3 mg/kg in the drinking water) moderately diminished the severity of PAN-nephrosis in rats.

**Pyribenzamine ←**

*Mayer et al. B3,674/46:* Male rats are much more resistant to pyribenzamine than females. Castration of females rendered them almost as resistant as males but treatment of ovariectomized rats with "estrogen" did not give consistent results in a small series of preliminary experiments.

**Pyrilamine ←**

*Selye G70,480/71:* In rats, pyrilamine maleate (8 mg/100 g body weight in 0.2 ml water) was administered s.c. once on the 4th day of conditioning. Dyskinesia was listed 30 min, mortality 24 hrs after this injection. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication. PCN and phenobarbital were not tested.

**Pyruvate** ←

*Lecoq B79,754/51*: In rabbits, injection of disulfiram + ethanol or of Na-pyruvate produces essentially the same syndrome of intoxication, since pyruvic acid is the principal metabolite of ethanol after pretreatment with disulfiram. In either case, ACTH and cortisone offer little, if any, protective effect.

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

Red Squill ← Gonadectomy + Testosterone: Crabtree et al. A19,999/39\*

**Reserpine** ←

*Efron D59,758/62*: In rats, adrenalectomy greatly decreases resistance to reserpine, whereas hypophysectomy leaves it almost unchanged. It is assumed therefore, "that the increased toxicity of reserpine in adrenalectomized rats is related to the absolute lack of certain adrenal steroids, which in some way may condition the nervous system to the effects of the drugs, rather than to the inability of the pituitary-adrenal system to respond to so-called 'nonspecific stress' caused by the drug."

*Agostini & Giagheddu G14,490/63*: Reserpine catalepsy in guinea pigs is inhibited by various folliculoid, testoid and corticoid hormones as well as by epinephrine.

*Räsänen & Taskinen G51,026/67*: Dexamethasone protects the gastric mucosa of the rat against the production of ulcers by reserpine. The effect is ascribed to the degranulation of the gastric mast cells induced by the glucocorticoid.

*Selye et al. G60,016/69*: In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or MgCl<sub>2</sub>.

*Selye et al. G60,020/69*: In the rat, pretreatment with norbolethone protects against the anesthetic effect of progesterone, DOC pregnanedione, dehydroepiandrosterone, tes-

tosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

**RES-Blocking Agents** ←

*Selye B39,702/49*: In rats in which an arthritis was produced by intrapedal injection of formalin and India ink, phagocytosis and transport of the carbon particles to the regional lymph nodes are accelerated by ACTH. This is ascribed to glucocorticoid formation and the resulting diminution of the inflammatory barrier at the formalin injection site.

*Heller et al. C40,073/57*: In rats, the phagocytosis of India ink i.v. by the RES is stimulated by various folliculoids but not by testoids.

*Selye et al. C70,942/59*: Topical injection of cortisol acetate microcrystals into a hind paw of a rat selectively protects the surrounding region against the angiotactic sequestration of i.v. injected carbon (India ink) particles during a dextran-induced anaphylactoid edema.

*Nicol et al. C92,079/60*: In male mice, various diethylstilbestrol derivatives increase the blood clearance of i.v.-injected carbon owing to stimulation of the RES. There is corresponding enlargement of the spleen and liver.

*Kelly et al. D32,495/62*: "In livers of mice whose reticulo-endothelial system was stimulated by estradiol, it was established that the cells preparing for division and those which had recently divided were actively phagocytic."

*Gabbiani et al. G19,450/65*: In rats pretreated with ACTH, F-COL or restraint, a single i.v. injection of thorium dextrin (an RES-blocking agent) produces thrombohemorrhagic lesions with necrosis in the adrenals, liver and kidneys. The changes are reminiscent of the Shwartzman-Sanarelli phenomenon.

*Göthe H20,084/70*: In rats, cortisol p.o. does not significantly alter the accumulation of intratracheally-administered quartz dust, although it delays its transfer from the lung to the regional lymph nodes.

*Göthe H20,085/70*: In rats, ACTH accelerates, whereas prednisolone retards, the transport of intratracheally-administered quartz dust from the lung to the regional lymphatics.

**Salicylates** ←

*Montuori G60,881/54*: In mice, cortisone s.c. raises resistance to sodium salicylate given 6 hrs later i.p.

*Barnett & Teague C56,641/58*: In rats, stilbestrol antagonizes the hepatic glycogenolytic action of sodium salicylate.

*Abbott & Harrison F36,510/65*: In rats, cancellous bone formation is stimulated by various salicylates. This effect is blocked by parathyroid extract and vitamin D but not influenced by cortisone.

*Klingenberg & Müller F54,504/65*: In rheumatic patients, prednisone given conjointly with salicylates increases the glomerular filtration and decreases the plasma concentration of the latter. "The ability of corticosteroids to increase glomerular filtration rate and diminish tubular reabsorption of water might partially explain their ability to increase the clearance of salicylate."

**Selenium** ←

*Romeo et al. F91,552/67; H7,930/68*: In the rat, the hepatic cirrhosis produced by chronic intoxication with Na<sub>2</sub>SeO<sub>3</sub> is inhibited by 19-norandrostenedione and 4-chlorotestosterone.

**Serine** ← *cf. SDH under Influence of Steroids upon Enzymes*

**SKF 525-A** ←

*Selye G70,480/71*: In rats, acute and severe intoxication with SKF 525-A was significantly diminished by pretreatment with PCN, CS-1, spironolactone, oxandrolone, prednisolone, triamcinolone and progesterone. The other conditioners of our series were not or only very slightly effective, *cf.* Table 106.

**Silicon** ← *cf. RES*

**Sodium** ← *cf. also Selye C50,810/58, p. 107.*

*Baisset et al. C84,788/58*: In rats and dogs, the effects of NaCl-overdosage are ameliorated by posterior pituitary extracts and aggravated by NaCl.

*Scheer et al. D3,935/61*: Exposure of frogs to high concentrations of NaCl decreases Na-uptake and increases electrical resistance in the skin, as does destruction of the interrenal bodies. These effects are reversed in both cases by aldosterone but treatment of frogs, in tap water or saline, with spironolactone has no effect on the skin. Aldosterone

and spironolactone have no significant effect on either the urine or the plasma Na. "We conclude that the inter-renals of frogs are involved in control of the regulatory functions of the skin but not of the kidneys. The absence of effect of aldactone may mean that this agent is not an aldosterone antagonist in frogs, or that aldosterone is not an indispensable participant in salt regulation in these animals."

Table 106. *Conditioning for SKF 525-A*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)

DOC-Ac	14/19 NS	1/19 NS
Hydroxydione	10/19 *	2/19 NS
Cholesterol	5/10 *	0/10 NS
Thyroxine	16/20 NS	9/20 *
Phenobarbital	5/10 *	1/10 NS

<sup>a</sup> The rats of all groups were given SKF 525-A, β-diethylaminoethyl diphenylpropyl-acetate (15 mg/100 g body weight in 1 ml water, i.p., once on 4th day).

<sup>b</sup> Dyskinesia was estimated 2 hrs after injection and mortality listed 24 hrs later ("Exact Probability Test").

For further details on technique of tabulation *cf.* p. VIII.

**Squill** ←

*Crabtree et al. A19,999/39*: Male rats are twice as resistant as females to the fatal action of powdered red squill (*Urginea maritima*). Castration has no effect in females but abolishes the increased squill resistance of the male.

**Strychnine** ←

*Parhon & Urechia A23,732/11; 62,361/13*: In dogs and rabbits, orchidectomy and thyroidectomy do not influence resistance to strychnine consistently, but thyroid feeding appears to aggravate the characteristic convulsions.

Vacek C63,230/58: DOC anesthesia protects the mouse against the convulsive and lethal effects of strychnine, pentylenetetrazol and caffeine.

Kato et al. D38,983/62: Male rats are more resistant than females to strychnine intoxication especially if the drug is given s.c. whereby its activity is delayed. The greater strychnine-metabolizing potency of hepatic microsomes from male rats than from females has also been demonstrated in vitro. SKF 525-A increases strychnine toxicity and renders both sexes equally sensitive. Castration diminishes the high strychnine resistance of the male rat but has no effect in females. Pretreatment with testosterone or 4-chlorotestosterone augments the strychnine-metabolizing ability of liver slices or isolated hepatic microsomes from both male and female castrates, whereas estradiol has no effect.

Kato et al. G64,325/62: Adult male rats are more resistant than females to pentobarbital anesthesia, carisoprodol paralysis and strychnine convulsions. Conversely, the lethal effect of OMPA is greater in the male. The sex difference is ascribed to the increased production of anabolic testoids which enhance the decomposition of these substrates, the first three of which are inactivated, the last activated in the process. The differences were also demonstrated in vitro using liver slices or microsomal fractions. The high microsomal activity of the male could be abolished by castration and restored by several anabolic testoids.

Bonta & Overbeek E5,494/65: In mice, several water-soluble esters of cortisol and prednisolone decreased sensitivity to the induction of convulsions by strychnine, but testosterone 17-glycinate offered the best protection. 16 $\beta$ -N-piperidino-3 $\beta$ -hydroxy-androst-5-en-17-one and 16 $\beta$ -N-piperidino-17 $\beta$ -hydroxy-5 $\alpha$ -androst-3-one actually increased strychnine sensitivity and the latter produced convulsions by itself.

Selye G70,480/71: In rats, acute fatal strychnine intoxication is readily and completely prevented by prednisolone, triamcinolone, estradiol and phenobarbital. Here, the classic catatonic steroids have little if any prophylactic effect, cf. Table 107.

Strychnine  $\leftarrow$  Gonadectomy + Folliculoids, Testoids: Kato et al. D38,983/62\*

Strychnine  $\leftarrow$  Adrenalectomy: Kato et al. G74,030/62

Table 107. Conditioning for strychnine

<sup>a</sup> The rats of all groups were given strychnine hydrochloride, 150  $\mu$ g/100 g body weight in 0.2 ml water, s.c., once on 4th day.

<sup>b</sup> Dyskinesia was estimated 15 min after injection and mortality listed on same day p.m. ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

#### Sulfa Drugs $\leftarrow$

Sacra & McColl C73,654/59: Female rats are less resistant than males to chronic intoxication with hypoglycemic thiazidiazoles but no such sex difference was observed in acute tests. Testosterone increased, whereas stilbestrol decreased, the resistance of female rats to these drugs.

Sulfonamide  $\leftarrow$  cf. Selye C92,918/61, p. 219.

#### Tannic Acid $\leftarrow$

Patrick C12,967/55: In rats and mice, cortisone or ACTH inhibited the mesenchymal reaction and delayed repair following production of hepatic damage by tannic acid or CCl<sub>4</sub>.

Korpássy et al. B74,333/52: In rats given toxic doses of tannic acid, DOC has no protective effect.

Tannic acid  $\leftarrow$  DOC: Korpássy et al. B74,333/52\*

**TEM ← cf. Carcinolytic Agents**

**Tetracaine ←**

Zykov H21,879/69: In mice, ACTH, cortisol and DOC failed to influence tetracaine intoxication.

**Tetraethylammonium ← cf. Ganglioplegics**

**Tetrahydronaphthylamine ←**

Borchardt 23,683/28: In cats, neither thyroparathyroidectomy nor adrenalectomy prevents the production of fever by tetrahydronaphthylamine, whereas denervation of the liver inhibits it almost completely.

**Thalidomide ←**

Leone & Rinaldi G44,123/65: In pigeons, the medullary bone formation produced by estradiol is inhibited by Thalidomide.

**Thallium ←**

Stavinoha et al. C94,628/59: In mice, testosterone (0.6 mg/kg) i.m. failed to protect against the lethal effect of thallium sulfate intoxication.

Selye G70,480/71: In rats, thallium chloride (16 mg/100 g body weight in 0.5 ml corn oil) was administered s.c. once on the 4th day of conditioning. Nephrocalcinosis was estimated on day of death, and mortality listed on the 7th day. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication, only estradiol exhibited an inhibitory effect. Phenobarbital was not tested.

**Theobromine ←**

Selye PROT. 40890: In rats, severe intoxication with theobromine is well prevented by PCN, CS-1 and phenobarbital, less conspicuously by progesterone, whereas the other standard conditioning agents are ineffective, cf. Table 108.

**Theophylline ←**

Selye PROT. 42044: In rats, theophylline intoxication is considerably inhibited by pretreatment with PCN, CS-1, ethylestrenol, norbolethone, oxandrolone, prednisolone, progesterone and phenobarbital. Spirolactone, DOC and hydroxydione offer barely significant protection, cf. Table 109.

<sup>b</sup> Dyskinesia was estimated on 5th day 3 hrs after injection and mortality listed on 7th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

**Thioacetamide ←**

*Eger et al. E58,108/59*: In rats, prednisolone does not prevent hepatic cirrhosis induced by allyl alcohol or thioacetamide.

*Arnold et al. E27,627/63*: Chemical investigations suggest that collagen formation in rats with hepatic cirrhosis induced by thioacetamide is inhibited by cortisone.

*Prellwitz & Bässler E36,762/63*: Detailed biochemical studies on the effect of  $\Delta^1$ -cortisone and nandrolone phenpropionate upon the hepatic cirrhosis produced by thioacetamide in the rat.

*Röttger et al. D64,427/63*: In the rat, the hepatic cirrhosis produced by chronic treat-

ment with thioacetamide is not influenced by prednisolone or testosterone, although mortality from acute intoxication with thioacetamide is diminished by prednisolone.

*Becker H22,471/68*: In rats, the hepatic cirrhosis produced by chronic treatment with thioacetamide cannot be prevented by simultaneous cortisone administration.

*Becker H17,711/69*: In rats, the hepatic cirrhosis produced by thioacetamide or  $\text{CCl}_4$  is not inhibited by cortisone and damage to the parenchymal cells is actually increased.

*Petzold et al. H20,651/69*: In rats, the hepatic cirrhosis produced by thioacetamide can be prevented by concurrent treatment with Turinabol (the latter is described as 4-chloro-1-dehydro-methyl-testosterone, although in the Merck Index it is listed as 4-chlorotestosterone). Turinabol administered after the induction of thioacetamide damage enhances the regeneration of the liver.

**Thiophosphamide ← cf. Carcinolytic Agents****Thiourea ←**

*Glock B23,056/45*: In rats given normally fatal doses of thiourea, treatment with adrenocortical extract plus NaCl offers greater protection than NaCl alone. Thyroxine is a still more effective prophylactic even when given without NaCl.

*DuBois et al. B3,103/46*: In dogs, adrenal cortical extract offers moderate protection against ANTU poisoning.

**Threonine ← cf. TDH under Influence of Steroids upon Enzymes****Tolbutamide ← cf. Pancreatic Hormones****Tremorine ←**

*Hewett et al. D19,834/64*: Various aminosteroids possess "loss-of-righting-reflex activity" and prevent tremorine-induced tremor as well as pentylenetetrazol convulsions. Their effect is ascribed to interneuronal blockade and not to general anesthesia.

*Selye G70,480/71*: In rats, tremorine dihydrochloride (5 mg/100 g body weight in 1 ml water) was administered p.o. once on the 4th day of conditioning. Dyskinesia was listed 5 hrs, mortality 24 hrs after this injection. Under these circumstances, the "Standard Conditioners" (p. VIII) caused no noteworthy change in the resulting intoxication. PCN was not tested.

**Tribromoethanol** ←

*Eichholtz A27,018/27*: In rabbits, "destruction of the liver" by ethylene chlorhydrin does not significantly affect the length of tribromoethanol anesthesia. After bilateral nephrectomy, sleeping time is somewhat prolonged but still variable. On the other hand, bilateral adrenalectomy prolongs the sleeping time very considerably.

*Eichholtz et al. B45,516/49*: Adrenalectomy greatly prolongs the tribromoethanol and thiopental sleeping time in rats. In both instances the sleeping time could be shortened again if adrenalectomized rats were treated with DOC or adrenocortical extract.

*Nicol et al. F58,460/65*: In the mouse, resistance to partially decomposed solutions of tribromoethanol is increased by estradiol.

*Selye PROT. 41492*: In rats,  $\beta$ -tribromoethanol sleeping time is considerably shortened by pretreatment with PCN, CS-1, ethylestrenol, spironolactone, norbolethone and prednisolone. Progesterone and DOC tend to prolong tribromoethanol anesthesia, perhaps because these steroids possess an anesthetic effect of their own, *cf.* Table 111.

Tribromoethanol ← Adrenalectomy + DOC: *Eichholtz et al. B45,516/49\**

**Trichloroethanol** ←

*Selye G70,480/71*: In rats,  $\beta$ -trichloroethanol is subject to detoxication by essentially the same conditioners as  $\beta$ -tribromoethanol. Its hypnotic effect is strongly counteracted by all catatoxic steroids (except oxandrolone) as well as by prednisolone and phenobarbital. Thyroxine exerts a barely significant inhibitory action whereas estradiol actually prolongs  $\beta$ -trichloroethanol anesthesia, *cf.* Table 112.

**Trichloroethylene** ←

*de Dominicis B3,412/42*: Combined treatment with adrenocortical extracts + vitamin C raises the resistance of guinea pigs to trichloroethylene.

**Triorthocresyl Phosphate** ←

*Glees D7,966/61; D14,872/61*: Triorthocresyl phosphate (TOCP) is an anticholinesterase compound which induces widespread neurologic symptoms with demyelination of the central nervous system in the chick. These changes can be prevented by pretreatment with cortisone.

Table 111. *Conditioning for  $\beta$ -tribromoethanol*

### **Tyrosine ← *cf. also* TKT under Enzymes Influenced by Steroids**

*Alam et al. G53,636/67:* In rats fed low-protein diets, excessive tyrosine intake depresses growth and causes characteristic lesions in the paws and eyes. Injections of cortisol or stress caused by infusorial earth i.p. prevented the manifestations of tyrosine intoxication, presumably as a consequence of hepatic microsomal TPO induction. The effect of infusorial earth i.p. is ascribed to the resulting stress-induced increases in corticoid secretion.

*Fuller G75,131/70:* In rats, exposure to cold, as well as treatment with cortisol or glucagon after adrenalectomy induced TKT activity in the liver but not in the brain. Apparently, the TKT "of brain differed from the enzyme in liver since it did not exhibit diurnal variations of activity and was not affected by hormones, drugs, or stress."

*Rose & Cramp G75,215/70:* In women using folliculoid-luteoid contraceptives, the plasma tyrosine level is significantly decreased. Two women treated with ethinylestradiol

alone showed a similar decrease of plasma tyrosine. "It is suggested that increased levels of glucocorticoids, due to the action of oestrogen, induce elevated levels of tyrosine aminotransferase, and that as a consequence there is an enhanced rate of degradation of the amino acid in the liver."

*Selye G70,468/70:* In rats, dietary tyrosine intoxication results in inflammation of the eyes, pancreas, paws and snout. These changes can be prevented not only by glucocorticoids (triamcinolone, prednisolone) but also by catatoxic steroids devoid of glucocorticoid potency, such as PCN, ethylestrenol, CS-1 and, to a lesser extent, by spironolactone and norbolethone. Estradiol is likewise effective in protecting against tyrosine intoxication although it is devoid of both glucocorticoid and catatoxic potencies. Progesterone, oxandrolone, DOC, hydroxydione and cholesterol are ineffective. Thyroxine actually aggravates tyrosine intoxication, *cf.* Fig. 13, p.298

*Selye G70,480/71:* Rats given a great dietary excess of L-tyrosine have developed a syndrome characterized by dermatitis on the paws and around the eyes, panophthalmia, pancreatic lesions, loss of body weight and high mortality. These signs of tyrosinosis were suppressed, or at least diminished, by phenobarbital, PCN and to a lesser extent by various other catatoxic steroids. Prednisolone, triamcinolone, and thyroxine decreased the resistance to tyrosinosis. The mean food intake was actually increased by the steroids that offered protection, hence the beneficial effect of the latter could not have been the result of a diminished L-tyrosine intake consequent upon decreased food consumption, *cf.* Table 116, p. 299.

Tyrosine ← Prednisone + Methemalbumin: Marver et al. *G76,839/68*

Uranium ← *cf. also* *Selye G60,083/70, p. 353.*

*Feyel 99,416/43:* In mice, testosterone pretreatment does not protect either against HgCl<sub>2</sub> or uranium nitrate intoxication.

### **Urethan ←**

*Sindram 52,504/35:* In rats, pretreatment with adrenocortical extract ("Cortin") increases resistance to urethan anesthesia. Adrenalectomy has an inverse effect but Cortin shortened urethan anesthesia even in the absence of the adrenals. Tribromoethanol sleeping time is likewise shortened by adrenocortical extract in intact rats.

**Fig. 13. Protection by PCN against tyrosinosis.** Both rats received the same tyrosine treatment. A: Inflammatory lesions affecting the eyes, snout, and paws of the otherwise-untreated control. B: No such changes are observed in the rat pretreated with PCN. C: In the pancreas of the rat shown above, there are extensive necroses of parenchymal cells and edema in the stroma, characteristic of tyrosine intoxication. D: The pancreas of the PCN-pretreated rat shows no obvious anomaly. [Selye G 70,468/70. Courtesy of J. Nutr.]

<sup>a</sup> The rats of all groups were given a diet containing 10% L-tyrosine (from 2nd day until end of the experiment).

<sup>b</sup> Eye lesions were estimated from 8th day to time of death and mortality registered on 15th day ("Exact Probability Test").

<sup>c</sup> Student's t-test.

<sup>d</sup> Premature mortality.

For further details on technique of tabulation *cf.* p. VIII.

*Ito et al. G42,670/66:* In mice, the development of urethan-induced thymic lymphomas was enhanced by orchidectomy but not significantly affected by ovariectomy. In the early latent period, adrenalectomy accelerated the development of thymic lymphomas, especially in females.

*Vesselinovitsh & Mikhailovich F91,584/67:* In male mice, urethan induced a higher incidence of hepatomas than in females. Gonadectomy decreased the incidence in males and increased it in females, thus practically eliminating the sex difference.

*Selye et al. G60,016/69:* In rats, spironolactone protects against anesthesia produced by progesterone, DOC, hydroxydione, pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, methyprylon, pentobarbital and ethanol. It does not significantly alter the corresponding actions of morphine, codeine, urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, KBr or MgCl<sub>2</sub>.

*Selye et al. G60,020/69:* In the rat, pre-treatment with norbolethone protects against

the anesthetic effect of progesterone, DOC pregnanedione, dehydroepiandrosterone, testosterone, diethylstilbestrol, pentobarbital and methyprylon. It does not significantly alter the corresponding actions of urethan, diazepam, chlorpromazine, reserpine, phenoxybenzamine, chloral hydrate, potassium bromide or magnesium chloride.

#### Vitamin A ←

*Mayer & Truant B43,456/49:* Both in intact and in castrate male rats kept on a vitamin-A deficient diet, testosterone exerts its normal stimulating effect upon the seminal vesicles. The atrophy of the accessory sex organs induced by vitamin-A deficiency is presumably due to interference with the synthesis or release of testoids, not to a target organ insensitivity.

*Wolbach et al. C14,796/55:* The skeletal lesions produced by vitamin-A overdose in weanling rats are aggravated by adrenalectomy but not influenced by cortisone.

*Millen & Woollam C38,328/57*: In rats, vitamin-A overdosage during pregnancy produces gross malformations of the brain and calvarium in the young. This teratogenic effect is considerably aggravated by cortisone.

*Selye C37,276/57*: Estradiol increases, whereas methyltestosterone counteracts the bone absorption and catabolism produced by hypervitaminosis A in the rat.

*Selye C36,386/58*: Cortisol aggravates the bone absorption produced by vitamin-A overdosage in the rat. In this respect the effect of cortisol is opposite to that of STH.

*Grangaud & Conquy C71,751/58; G71,675/58*: In rats kept on a vitamin-A deficient diet, progesterone induces an increase in body weight and reestablishes a normal estrus cycle.

*Grangaud et al. C97,508/59; C88,406/60; C89,715/60*: Progesterone s.c. protects the male rat against the manifestations of vitamin-A deficiency.

*Fell & Thomas D10,358/61*: In tissue culture, chick and mouse bone and cartilage implants rapidly disintegrate in the presence of excess vitamin A and this response was prevented by cortisol. Earlier observations had shown that, in vivo, cortisol sensitizes the rat for the production of skeletal lesions by vitamin A. "It is suggested that this discrepancy between the results obtained in vitro and in vivo is probably due to systemic factors that operate in the body but are eliminated in organ cultures."

*Nicol & Grangaud D20,176/61*: In rats, thiouracil ameliorates the manifestations of vitamin-A deficiency. Progesterone has a similar effect.

*Weissmann D10,768/61*: In larvae of *Xenopus laevis*, bone absorption and other manifestations of vitamin-A overdosage were accelerated by cortisol. "This was held to be due to liberation of vitamin A from hepatic stores by the steroid, and is in contrast to the retardation of hypervitaminosis A by hydrocortisone in vitro." Presumably an excess of vitamin A causes release of cathepsins from lysosomes.

*Thomas et al. D23,234/62*: In rabbits, large doses of vitamin A produce cartilage changes resulting in the collapse of the ears, and loss of basophilic and metachromatic staining of their cartilage. Pretreatment with cortisone prevents these changes.

*Hulth & Westerborn D56,601/63*: In rabbits, the lesions produced by cortisone in the growth cartilages are not significantly influenced by vitamin A but recovery from the

papain-induced cartilaginous damage is delayed by cortisone.

*Thomas et al. D57,729/63*: In rabbits, acute overdosage with vitamin-A palmitate or vitamin-A acid produced loss of hair and collapse of the ear cartilage. Histologically, depletion of cartilage matrix was seen also in the articular and epiphyseal cartilages. All these changes were largely prevented by simultaneous administration of cortisone, and a local protective effect was demonstrated by intra-articular injection of cortisol in hypervitaminotic rabbits. The protective effect of cortisol may be due to lysosome stabilization. Earlier observations which showed a synergism between cortisone and vitamin A after chronic steroid treatment may have been due to excessive increases in the blood levels of vitamin A occasioned by glucocorticoids.

*Weissmann et al. D64,001/63*: Earlier experiments have shown that cortisone protects the cartilage of rabbits from dissolution by an excess of vitamin A. This was ascribed to the stabilizing action of cortisone upon lysosomes whose proteases may be responsible for the degradation of chondromucoprotein. Unexpectedly, the osseous and other types of lesions produced by vitamin-A alcohol overdosage in *Xenopus laevis* larvae is aggravated by cortisol, whereas similar hypervitaminosis induced by vitamin-A acid is prevented by this glucocorticoid. The difference is ascribed to the fact that vitamin-A acid is not stored in the liver to any degree, whereas the alcohol is stored as the ester and can then be released from the hepatic store by cortisol. The inhibitory effect of cortisol is attributed to lysosomal stabilization.

*Fell F48,679/64*: The degenerative changes developing in cartilaginous limb-bone rudiments of mice, when excess vitamin A is added in tissue culture, can be diminished by cortisol in vitro, perhaps owing to antagonistic effects upon lysosomal membranes.

*Thomas E37,875/64*: Review on the effects of papain, vitamin A and cortisone on cartilage matrix in vivo.

*Goldhaber E5,596/65*: Description of the optimum conditions for the inhibition of vitamin-A-induced bone resorption by cortisol on explants of murine bones.

*Soriano G44,574/67*: Fragments of murine esophagus cultured in vitro show inhibition of keratinization and differentiation into multistratified epithelium under the influence of vitamin A. Cortisol has the same effect and

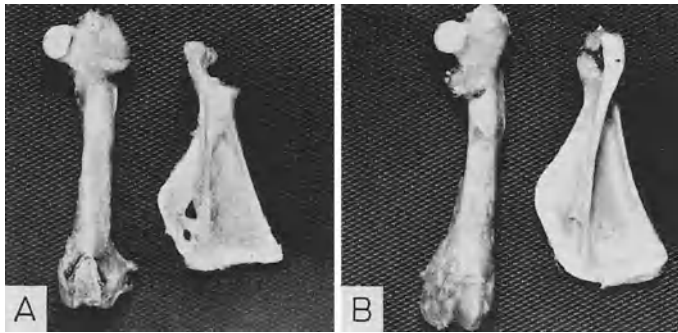

Fig. 14. **Protection by spironolactone against hypervitaminosis-A.** Both rats received the same excessive amount of vitamin A. A: In the control rat, the bones are very thin, the femur is narrow and the scapula even shows perforations. B: Spironolactone prevents these changes. [Tuchweber *et al.* G70,477/70. Courtesy of Int. Ztschr. Vitaminforsch.]

when given conjointly the two compounds synergize each other.

*Ehrlich & Hunt G55,237/68:* In rats, vitamin A has no effect upon wound healing but it overcomes the inhibitory effect of cortisone.

*Janoski et al. E7,896/68 (p. 281):* Review suggesting that many of the actions of glucocorticoids, particularly their inhibition of ultraviolet ray injury, vitamin-A overdosage and endotoxin shock are due to the stabilization of lysosomal membranes which prevents the escape of toxic lysosomal enzymes.

*Tuchweber & Garg G70,434/70:* In rats, the bone lesions characteristic of vitamin-A overdosage are inhibited by spironolactone, norbolethone and ethylestrenol; the hepatic and serum vitamin-A concentrations are simultaneously decreased.

*Tuchweber et al. G70,477/70:* In rats, pretreatment with spironolactone, norbolethone, ethylestrenol and oxandrolone inhibits the bone absorption and catabolism induced by hypervitaminosis A. On the other hand, estradiol, prednisolone and triamcinolone actually aggravate vitamin-A intoxication. Progesterone, DOC and thyroxine do not significantly alter this intoxication. In spironolactone and norbolethone pretreated animals, the serum clearance of vitamin A is accelerated; triamcinolone has an opposite effect, especially in chronic experiments. The hepatic vitamin-A concentration is significantly decreased by spironolactone or norbolethone, *cf.* Fig. 14.

#### **Vitamin B ← *cf.* also Aminopterin**

*Hertz B18,379/48:* In chickens, the responsiveness of the genital tract to folliculoids depends upon the availability of folic acid and can be suppressed by folic acid antagonists.

*Weintraub et al. B49,800/50:* Male mice are more sensitive than females to intoxication with the folic acid antagonist aminopterin. The low tolerance of the males was abolished by castration, but not influenced by estradiol. Testosterone failed to affect the tolerance of the female.

*Meites et al. C39,753/57:* Review on the effect of cortisone upon various components of the vitamin-B complex with personal observations on the guinea pig and rat.

*Paroli C63,940/57:* In pigeons, vitamin-B<sub>1</sub> deficiency is beneficially influenced by DOC.

*Greengard et al. F74,421/66:* Prevention by various corticoids of nicotinamide-deficiency disorders and of 6-aminonicotinamide toxicity in rats and dogs.

*Greengard et al. G63,690/68:* In rats, triamcinolone, dexamethasone, corticosterone and DOC protect against the syndrome of nicotinamide deficiency. "Moreover, in animals in which liver NAD and NADH had been depleted by feeding the deficient diet, the levels of these coenzymes could be restored to normal, or above normal, by steroid administration. Administration of steroids also increased the amount of NADP and NADPH. Evidence is presented that the ability of the steroids to increase the levels of the pyridine nucleotides

is mediated by increasing the availability of tryptophan."

*Lukby et al. H 32,376/70:* In women taking ethinylestradiol-containing contraceptives, there develops a derangement in tryptophan metabolism associated with "functional" vitamin-B<sub>6</sub> deficiency.

#### Vitamin C ←

*Lockwood & Hartman 15,573/33:* An adrenocortical extract protects guinea pigs against scurvy when given i.p., but is ineffective p.o.

*Svirbely 33,140/35:* In scorbutic guinea pigs, adrenocortical extract does not prolong survival.

*Hyman et al. B 53,374/50:* "Cortisone and ACTH prolong life and reduce the hemorrhagic manifestations of scurvy in guinea pigs." [In an addendum the authors state that the large doses of ACTH and cortisone used may produce severe toxic effects which overshadow their beneficial actions (H.S.).]

*Hyman et al. B 57,989/51:* In guinea pigs on a vitamin-C deficient diet, ACTH and cortisone ameliorate the manifestations of scurvy.

*Pirani et al. B 57,272/51:* In guinea pigs kept on a vitamin-C deficient diet, cortisone abolishes some but not all the manifestations of scurvy.

*Herrick et al. B 69,259/52:* In vitamin-C deficient guinea pigs, cortisone diminished the manifestations of scurvy and prolonged survival.

*McGraw C 68,484/59; C 80,136/59:* Doctor's thesis describing numerous experiments on the effect of adrenalectomy, cortisone, thyroxine, thyroidectomy, thioureas and STH upon scorbutic guinea pigs, with special emphasis upon changes in capillary resistance and cold tolerance.

*Rona D 26,276/62; Rona & Chappel D 48, 101/63; Hajdu et al. G 32,889/65:* Conjugated equine estrogens (Premarin) protect the guinea pig against the production of bone lesions by vitamin-C deficiency. Estriol sodium succinate offered no such protection.

*Klinger et al. F 62,929/65:* The normal excretion of ascorbic acid and the increase in its elimination induced by barbital are higher in male than in female rats. Orchidectomy reduced both normal excretion and its enhancement by barbital, whereas ovariectomy increased them. Thus, the sex specific differences decreased but did not disappear completely. One week's treatment of males with stilbestrol or females with testosterone dimin-

ished ascorbic acid excretion. In mice, no sex specific differences of this kind were observed. [The authors probably used hexobarbital although sometimes they speak of barbital (H.S.).]

**Vitamin D, DHT ← Glucocorticoids** cf. also *Selye C 50,810/58, p. 92; C 92,918/61, p. 174; D 15,540/62, pp. 278, 281; G 60,083/70, pp. 347, 354, 385, 494.*

*Polemann & Froitzheim B 87,589/53:* In mice, severe vitamin-D<sub>2</sub> intoxication could not be prevented by cortisone.

*Gillman & Gilbert C 31,076/56:* The arterial lesions produced by heavy vitamin-D overdose in the rat are aggravated by thyroxine or DOC, whereas cortisone and thyroidectomy offered considerable protection.

*Hanssler C 18,293/56:* In rats on a vitamin-D deficient rachitogenic diet, cortisone decreases inorganic serum phosphorus but does not affect the calcemia or raises it slightly.

*Kodicek C 32,412/56:* Although in patients cortisone tends to antagonize vitamin-D overdose "cortisone treatment did not ameliorate the weight loss, clinical appearance, histological lesions or the increased urinary phosphate excretion of the hypervitaminotic rats."

*Laron et al. C 12,833/56:* In rats first kept on a vitamin-D deficient diet, cortisone increases serum calcium and depresses alkaline phosphatase but retards the process of dental calcification during subsequent healing of the rickets induced by vitamin-D supplements.

*Winberg & Zetterström C 12,829/56:* In a child with severe vitamin-D intoxication, cortisone brought about rapid recovery.

*Harrison et al. C 45,829/57:* In rats kept on a vitamin-D and phosphorus deficient diet, cortisol p.o. reduced the serum citrate and prevented vitamin-D from increasing serum and bone citrate levels. On the other hand, the antirachitic effect of vitamin D (as measured by the rise in serum phosphorus and histologic evidence of rachitic cartilage and osteoid calcification) was not suppressed by cortisol. "The antirachitic action of Vit. D and its effect upon citrate metabolism can, therefore, be separated. The tibias of Vit. D deficient cortisol fed rats show evidences of increased calcification in comparison with rachitic controls which might in part be due to inhibition of bone resorption as well as retardation of cartilage growth by cortisol."

*Selye & Bois C 16,506/57:* In rats given daily s.c. injections of ergocalciferol, which in themselves caused no pathologic calcification, calcium deposition was produced in the

gastric mucosa by concurrent treatment with cortisol, whereas DOC had so such effect.

*Selye C27,735/57*: The cardiovascular calcification and nephrocalcinosis produced by DHT in rats are aggravated by estradiol, cortisol, DOC, ACTH and thyroxine. Conversely, methyltestosterone and STH exert a protective effect.

*Wilson et al. C33,679/57*: In rats, the nephrocalcinosis produced by overdosage with vitamin-D<sub>2</sub> could not be prevented by concurrent treatment with large doses of cortisone p.o.

*Cruickshank & Kodicek C53,881/58*: Cortisone did not prevent intoxication with vitamin-D<sub>2</sub> in rats.

*Laron et al. C50,634/58*: In rats kept on a vitamin-D deficient diet until rickets developed and then given dietary supplements of vitamin D, concurrent treatment with cortisone did not prevent healing, as shown by newly formed trabeculae and osteoblast proliferation although the extent of these changes was reduced. Qualitatively, the changes produced by cortisone and vitamin D are essentially different. "The findings suggest that the two steroids, vitamin D and cortisone, have different sites of action."

*Thoenes & Schröter C56,987/58*: In rats kept on a vitamin-D deficient diet, cortisone tends to inhibit the development of rickets, whereas ACTH does not. DOC actually aggravates vitamin-D deficiency.

*Thomas & Morgan C55,688/58*: In rats, chronic treatment with vitamin-D<sub>2</sub> or cortisone causes sclerosis of the metaphyses in long bones owing to proliferation of trabeculae. Combined administration of vitamin-D<sub>2</sub> and cortisone did not lessen the hypercalcemia induced by vitamin D and further intensified osteosclerosis. "These results suggest that in rats cortisone and vitamin D act independently rather than competitively on bone."

*Skanse et al. C69,514/59*: In a woman with vitamin-D intoxication, symptoms of psychosis and EEG manifestations developed, which disappeared together with the associated hypercalcemia under treatment with cortisone.

*Bélanger & Migicovsky C95,269/60*: In vitamin-D deficient chicks, norethandrolone promotes the maturation of cartilage matrix, whereas cortisone and cortisol inhibit it.

*Vanha-Perttula & Näätänen C90,637/60*: In rats, the calcifying mediasclerosis produced by overdosage with vitamin-D<sub>3</sub> is aggravated by cortisone.

*Bekemeier & Leiser D76,994/61*: Cortisol (unlike folliculoids) fails to cause a shift of the vitamin-D-induced nephrocalcinosis from the cortex to the cortico-medullary junction in the rat.

*Kleinbaum E23,570/62*: Several earlier reports and personal observations suggest that, in children heavily overdosed with vitamin-D<sub>2</sub>, prednisone diminishes the blood calcium and in the event of interruption of vitamin-D<sub>2</sub> therapy may even lead to severe tetanic attacks.

*Stroder et al. D36,990/62*: Both in infants and in rats, the skeletal changes produced by vitamin-D deficiency are inhibited by cortisone, prednisone and prednisolone.

*Schottek & Bekemeier E39,551/63*: The renal calcification produced by an excess of vitamin-D<sub>2</sub> in the rat was not significantly influenced by DOC, cortisol, estrone, testosterone or methyltestosterone.

*Strebel et al. F34,734/65*: After calciphylactic sensitization with DHT, neonatal rats respond with severe thymus calcification to a challenging dose of triamcinolone.

*Calandi et al. F75,662/66*: Review of data suggesting that glucocorticoids counteract vitamin-D intoxication in animals and man.

← **Mineralocorticoids** *cf. also Selye C50,810/58, p. 92. Selye et al. G60,055/70*: In the rat, the calcinosis produced by a single high dose of DHT p.o. can be markedly inhibited by various testoids and antimineralecorticoids, but DOC has no protective effect.

← **Adrenalectomy.** *Bekemeier & Leiser D65,289/63*: Vitamin-D<sub>2</sub> overdosage produces predominantly cortical nephrocalcinosis in intact, adrenalectomized, or hypophysectomized rats. Additional treatment with dienes-trol (an artificial folliculoid) shifts calcium deposition predominantly to the cortico-medullary junction, irrespective of the presence or absence of the hypophysis or adrenals.

← **Gonadectomy.** *Selye C27,682/57*: In rats, the production of cardiovascular calcification by DHT is facilitated and the loss of weight increased by orchidectomy. Presumably, "some testicular factor exerts a protective effect against this type of intoxication." *cf. Fig. 15, p. 304.*

*Chury & Kasperek H29,730/69*: Female rats are more sensitive than males to the production of a progeria-like syndrome by chronic treatment with DHT. Castration increases the sensitivity of the males.

*Chury & Nevrtal H33,801/70*: Rats, orchidectomized immediately after birth, are more sensitive to the production of the "progeria-

Fig. 15. **Enhancement of DHT intoxication by orchidectomy.** Both rats received the same threshold amount of DHT. In the intact male, the aorta is normal (left), whereas in the orchidectomized animal, intense calcifying arteriosclerosis has developed. [Selye C27,682/57. Courtesy of Lab. Invest.]

like syndrome" by DHT than are females or males castrated after puberty. The ECG alterations in all these groups run roughly parallel with the morphologic changes.

← **Folliculoids** cf. also Selye D15,540/62, p. 281; G60,083/70, pp. 364, 369, 370. Korenchevsky 14,032/23: In rats kept on a vitamin-D deficient diet, the development of rickets is not influenced by gonadectomy in either sex.

Saviano 60,155/35: Estradiol has a beneficial effect upon the vitamin-D deficiency rickets of the rat.

Norman & Mittler B18,001/48: On the basis of chemical and X-ray studies of the bones in rats kept on diets with varying vitamin-D content, the authors conclude that testosterone is "rachitogenic," whereas estradiol is "antirachitic."

Schottek & Bekemeier E39,551/63: The renal calcification produced by an excess of vitamin-D<sub>2</sub> in the rat was not significantly influenced by DOC, cortisol, estrone, testosterone or methyltestosterone.

Bekemeier F 80,690/67: In rats, vitamin-D<sub>2</sub> overdosage causes predominantly cortical nephrocalcinosis which shifts to the cortico-medullary junction upon treatment with estrone. This effect is not evident in the mouse, rabbit and dog.

Chang & McGinnis F83,363/67: Male quail remain in good physical condition with vitamin-D deficient diets for at least a year, whereas females die. "Injections of testosterone and estradiol into vitamin-D deficient hens did not influence egg production, but significantly improved bone ash of tibia, sternum, and femur. Alleviation of debility caused by vitamin-D deficiency was observed in laying hens when testosterone was injected."

Pohle & Bekemeier F91,972/67: In rats overdosed with vitamin D or DHT, calcification occurs especially in the interstitial tissue of the renal cortex, whereas after simultaneous treatment with dienestrol, calcium deposition occurs intracranially at the cortico-medullary junction.

Orimo et al. H 20,265/70: In female Wistar-Imamichi rats, a progeria-like syndrome can be produced by chronic DHT administration, but in this strain, the emaciation, muscular weakness, kyphosis, cutaneous wrinkle formation, and nephrocalcinosis were unaccompanied by calcification of the aorta. The latter was atrophic but showed no trace of metastatic calcinosis. Also characteristic of this strain is that it reacts with osteoporosis instead of the usual osteosclerosis of DHT progeria. Treatment with "conjugated estrogens" (Premarin)

Fig. 16 (A—D). Effect of various steroids upon DHT intoxication. All rats were treated with the same toxic dose of DHT. A: Distal femoral growth-cartilage of otherwise-untreated controls. Atrophy of the distal layers of the cartilage plate and osteoclastic bone absorption ( $\times 80$ ). B: Methyltestosterone protects the bone against these changes ( $\times 80$ ). C: Periosteum of a rat simultaneously-treated with ACTH. The dark tissue near the left edge of the field is the femoral shaft. In the periosteum, numerous "basophilic bone globules" are visible, but there is no transformation of the periosteum into bone ( $\times 320$ ). D: Treatment with DHT + STH. Here only very few "basophilic bone granules" are visible, but the periosteal connective tissue is in the process of osseous metaplasia ( $\times 320$ ). Thus, ACTH aggravates, whereas STH slightly protects, against DHT intoxication

Fig. 16 (E—G). E: At the dosage used, DHT causes only mild calcification in the aorta. F: Methyltestosterone prevents this effect of DHT. G: Estradiol aggravates this effect of DHT (von Kóssa  $\times 95$ )

Fig. 16 (H, I). H: DHT + methyltestosterone results in the formation of only a few calcified cylinders in the cortico-medullary junction of the kidney. I: DHT + estradiol results in massive calcification of this region. The intensity of the calcification in rats treated with DHT alone was intermediate between that seen in Figs. H and I (von Kóssa  $\times 80$ ). [Selye C27,735/57. Courtesy of Acta endocr.]

offered virtually complete protection against all these changes.

*Selye G70,467/70*: In rats, the catabolism and calcinosis induced by chronic DHT intoxication is counteracted by: norbolethone > ethylestrenol > CS-1 > PCN. Spiroolactone, though previously shown to antagonize acute DHT intoxication does not protect against chronic poisoning with this same compound, in fact it totally abolishes the high anti-DHT potency of norbolethone and ethylestrenol.

← **Testoids** cf. also *Selye D15,540/62*, p. 281; *G19,425/65*, p. 142; *G60,083/70*, pp. 374, 376, 385. *Selye C27,735/57*: The cardiovascular calcification and nephrocalcinosis produced by DHT in rats are aggravated by estradiol, cortisol, ACTH and thyroxine. Conversely, methyltestosterone and STH exert a protective effect, cf. Fig. 16, p. 305, 306.

*Selye & Mishra C38,201/58*: In the rat, methyltestosterone prevents the loss of body weight produced by overdosage with DHT, vitamin-D<sub>2</sub>, partial fasting, AAN and estradiol. The catabolism elicited by IDPN ∴ cortisol is not influenced.

*Selye & Renaud C40,518/58*: In the rat, norethandrolone is highly efficacious in inhibiting the cardiovascular calcinosis and catabolism produced by DHT. In these respects, it is approximately as effective as methyltestosterone.

*Bélanger & Migicovsky C95,269/60*: In vitamin-D deficient chicks, norethandrolone promotes the maturation of cartilage matrix, whereas cortisone and cortisol inhibit it.

*Suchowsky & Junkmann D2,674/61*: 1-Methyl- $\Delta^1$ -androst-17 $\beta$ -ol-3-one-17 $\beta$ -acetate is more potent than testosterone propionate in preventing the DHT-induced catabolism and soft-tissue calcification in the rat.

*Bekemeier et al. E97,156/62*: In the rat, overdosage with vitamin-D<sub>2</sub> produces predominantly cortical nephrocalcinosis, whereas simultaneous treatment with testosterone shifts the calcium deposits to the cortico-medullary junction.

*Gabbiani D32,379/62*: In the rat, calciophylaxis produced by DHT + egg-white or Thorotrast is inhibited by pretreatment with methyltestosterone.

*Bertolotti & Giordano D57,171/62*: 19-Norandrost-17-one phenylpropionate inhibits the soft-tissue calcification produced by vitamin-D overdosage in rats. [The type of vitamin-D preparation used is not indicated (H.S.).]

*Mosbach & Bevans D65,362/63*: In rabbits, the production of gallstones and cholecystitis by DHT is inhibited by methyltestosterone and, to a lesser extent, by testosterone. At the same time, the serum concentration of DHT falls under the influence of methyltestosterone, presumably owing to diminished intestinal absorption of the latter.

*Selye et al. D28,648/63; D30,544/63*: The progeria-like syndrome produced in the rat by chronic intoxication with DHT can be prevented by methyltestosterone.

*Tuchweber et al. D65,261/63*: Both methyltestosterone and vitamin E prevent the production of a progeria-like syndrome by DHT in the rat.

*Selye et al. E24,117/64*: The progeria-like syndrome produced by DHT, vitamin-D<sub>2</sub> or vitamin-D<sub>3</sub> can be prevented by ferric dextran, methyltestosterone or vitamin E in the rat.

*Selye et al. G11,109/64*: Methyltestosterone prevents not only the soft-tissue calcification and catabolism but also the cystic transformation of the parathyroids normally elicited by combined treatment with DHT + calcium acetate in the rat.

*Baldratti E5,460/65*: In rats, the catabolism and tissue calcification produced by DHT overdosage are prevented by 4-hydroxy-17 $\alpha$ -methyltestosterone.

*Bekemeier F53,774/65*: In rats, folliculoids are much more active than testoids in shifting nephrocalcinosis from the cortex to the cortico-medullary junction after vitamin-D<sub>2</sub> intoxication.

*Bekemeier G31,719/65*: Ethynyltestosterone shifts calcium deposition from the renal cortex to the cortico-medullary junction in vitamin-D<sub>2</sub> treated rats, whereas progesterone has no such effect.

*Friedrich et al. F39,223/65*: Nandrolone phenpropionate does not significantly influence vitamin-D deficiency rickets in the rat, but it increases the antirachitic effect of sub-threshold doses of vitamin-D<sub>3</sub>.

*Selye et al. G19,426/65*: Among 36 steroids examined for their ability to protect the rat against the catabolism and soft-tissue calcification induced by DHT, the strongest anabolic steroids (e.g., norbolethone, SC-7294 and fluoxymesterone) proved to be most efficacious.

*Selye et al. G60,055/70*: In the rat, the calcinosis produced by a single high dose of DHT p.o. can be inhibited by pretreatment

Fig. 17. **Protection by CS-1 against DHT.** Both rats received the same treatment with DHT +  $\text{Na}_2\text{HPO}_4$ . A, C: Heavy calcification of the heart and kidney in the control rat. B, D: Normal heart and kidney in the animal pretreated with CS-1 (manufacturer's code number SC-11927). [Selye *et al.* C93,872/60. Courtesy of Lancet]

with CS-1, norbolethone, oxandrolone, ethyl-estrenol, methylandrostenediol (MAD), methyltestosterone, prednisone and spironolactone approximately in decreasing order of activity. A trace of inhibition was apparently also obtained with progesterone, prednisolone and triamcinolone, but with these compounds the mortality was so high that the low degree of calcification may have been caused by the premature death of the animals. DOC had no protective effect.

← **Other Steroids** *cf. also Selye C92,918/61, p. 179; G60,083/70, pp. 331, 333, 372, 373, 385. Selye et al. C93,872/60:* The myocarditis with calcification of the cardiac muscle and coronary arteries as well as the nephrocalcinosis produced in rats by combined treatment with DHT +  $\text{Na}_2\text{HPO}_4$  are prevented by CS-1 *s.c.* It is assumed that CS-1 may act by blocking the effect of endogenous mineralocorticoids necessary for the production of lesions by DHT. However, the possibility is also considered that CS-1 may block the actions of DHT-type steroids directly as it is assumed to inhibit the actions of mineralocorticoids, *cf.* Fig. 17.

*Selye C92,918/61:* Both spironolactone and CS-1 protect the rat against DHT-intoxication. Not all actions of these antagonists are due to their mineralocorticoids, blocking effect.

*Selye G60,055/70:* In rats, the cardiovascular calcinosis and mortality induced by acute overdosage with DHT is inhibited by all catatoxic steroids as well as by both glucocorticoids of our standard series of conditioners and by phenobarbital, *cf.* Table 117.

*Selye G70,480/71:* In rats, the fatal calcinosis induced by acute DHT intoxication is inhibited by PCN, CS-1, cyproterone, ethyl-estrenol, spironolactone, norbolethone, TMACN, oxandrolone, 6 $\alpha$ -methylprednisolone, fluoxymesterone, spiroxasone, prednisolone, dexamethasone, betamethasone, MAD, emdabol, 17 $\alpha$ -acetoxyprogesterone, testosterone, corticosterone, progesterone, 16 $\beta$ -methyl-16, 17-epoxy-3 $\beta$ ,11 $\alpha$ -dihydroxy-5 $\alpha$ -pregnan-20-one, cortisone, cortisol, and triamcinolone. It is not significantly affected by dehydroisoandrosterone, pregnanedione, 11 $\alpha$ -hydroxyprogesterone, hydroxydione, DOC, fluorocortisol or estradiol.

Table 117. *Conditioning for DHT*

Treatment <sup>a</sup>	Cardio-vascular calcinosis <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	20/30	16/20
PCN	0/15 ***	6/15 *

Ethylestrenol	1/9 ***	1/10 ***
Spirolactone	4/10 ***	3/10 *
Norbolethone	0/10 ***	0/10 ***
Oxandrolone	0/10 ***	0/10 ***
Prednisolone-Ac	0/10 ***	5/10 NS
Triamcinolone	2/8 ***	9/10 NS
Triamcinolone (2mg)	10/18 ***	14/20 NS
Progesterone	3/8 ***	4/9 NS
Estradiol	7/9 NS	5/10 NS
DOC-Ac	7/10 *	6/10 NS
Hydroxydione	8/10 NS	5/10 NS
Thyroxine	8/10 NS	6/10 NS
Phenobarbital	0/10 ***	0/10 ***

<sup>a</sup> The rats of all groups were given dihydrotachysterol "DHT" (3 mg per rat in 0.5 ml corn oil, p.o., once on 4th day).

<sup>b</sup> Cardiovascular calcinosis was estimated on day of death (but only in animals that survived at least 7 days). Mortality was listed on 9th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

### Vitamin E ←

*Aterman C35,275/57*: The fatal hepatic necrosis which develops in weanling rats fed a diet deficient in sulfur-containing amino acids and vitamin E is inhibited by ACTH and cortisone, but aggravated by thyroid powder feeding. In the case of simultaneous treatment with thyroid and cortisone, the two types of hormones antagonize each other.

### Vitamin K ←

*Mellette D7,939/61*: Female rats are more resistant to dietary vitamin-K deficiency than males. Castration increases the susceptibility of the female rat and decreases that of the male. In males, estradiol decreases, whereas testosterone increases, mortality on such diets.

*Selye G70,480/71*: In rats, W-1372 is well tolerated when administered p.o. in water or mineral oil whereas, in corn oil solution, it causes severe hepatic lipidosis, sometimes with necrosis and high mortality. These toxic manifestations are very well prevented by PCN, CS-1, spironolactone and to a lesser extent by ethylestrenol, norbolethone, oxandrolone, progesterone, estradiol and phenobarbital cf. Table 118.

Table 118. *Conditioning for W-1372*

Treatment <sup>a</sup>	Hepatic lipidosis <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
W-1372 in water	0/10	0/10
W-1372 in mineral oil	3/10	2/10
None	10/10	10/10
PCN	0/10 ***	0/10 ***
CS-1	1/10 ***	0/10 ***
Ethylestrenol	8/10 NS	2/10 ***
Spirolactone	3/10 ***	1/10 ***
Norbolethone	7/10 NS	0/10 ***
Oxandrolone	9/10 NS	4/10 **
Prednisolone-Ac	10/10 NS	10/10 NS
Triamcinolone	9/10 NS	10/10 NS
Progesterone	8/10 NS	0/10 ***
Estradiol	3/9 ***	5/10 *
DOC-Ac	9/10 NS	4/10 **
Hydroxydione	9/10 NS	5/10 *
Thyroxine	8/10 NS	9/10 NS
Phenobarbital	5/9 *	2/10 ***

<sup>a</sup> The rats of all groups were given W-1372 [(N-γ-phenylpropyl-N-benzyloxy acetamide), 40 mg/100 g body weight in 1 ml corn oil (except for the first two groups), p.o., twice daily, on 4th and 5th day].

<sup>b</sup> Hepatic lipidosis was estimated on day of death and mortality listed on the 7th day ("Exact Probability Test").

No statistics for the two first groups, but in water and mineral oil W-1372 was manifestly less toxic than in oil (compare with 3rd group).

For further details on technique of tabulation cf. p. VIII.

Fig. 18. Left hepatic lobe after treatment with W-1372 (40 mg). A: Untreated control. B: W-1372 in water. Liver hypertrophy. C: W-1372 in mineral oil. Liver hypertrophy. D: W-1372 in vegetable oil. Lipid infiltration and hypertrophy of the liver. E: W-1372 in vegetable oil + progesterone treatment. Hypertrophy, lipid infiltration and necrotic foci. F: W-1372 in vegetable oil + PCN treatment. Liver is hypertrophic but lipid infiltration and necrosis are prevented. [Selye & Lefebvre G79,005/71. Courtesy of Arch. Anat. path.]

*Selye & Lefebvre G79,005/71*: "Partial hepatectomy increases the intoxication produced by W-1372. Catatoxic steroids (PCN, spironolactone) inhibit, whereas glucocorticoids (prednisolone acetate, triamcinolone) aggravate, these effects." *cf.* Figs. 18 and 19.

**Warfarin ← *cf.* Anticoagulants**

**Water ←**

*Gaunt A63,323/43*: Large doses of adrenocortical extract or DOC protect the rat against otherwise fatal water intoxication.

**Fig. 19. Rat liver after treatment with W-1372 (40 mg) in vegetable oil.** A: W-1372 alone. Diffuse lipid infiltration. Hepatocytes contain multiple lipid droplets. B: W-1372 + phenobarbital treatment. Inflammatory infiltration in a necrotic focus. C: W-1372 + PCN treatment. Hepatocytes are hypertrophied and show few lipid droplets (PAS×90). [Selye & Lefebvre G 79,005/71. Courtesy of Arch. Anat. path.]

**Yohimbine** ←

*Sturtevant C9,089/55; Sturtevant C21,591/56*: In rats with metacorticoid hypertension (produced by temporary overdosage with DOC + NaCl), the pressor effect of epinephrine, norepinephrine, vasopressin and renin was increased but the effect of histamine, 5-HT, yohimbine and TEA on the blood pressure was not consistently altered.

**Zoxazolamine** ←

*Conney et al. D52,543/61*: Pretreatment of male rats with chlorcyclizine shortens the duration of action and increases the hepatic microsomal metabolism of hexobarbital, pentobarbital and zoxazolamine. These effects were not prevented by hypophysectomy or adrenalectomy combined with castration.

*Bousquet et al. F35,073/65*: In rats with stress produced by applying a tourniquet around one hind limb for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection. [The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet, but this is not specifically stated. Allegedly a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

*Kato & Gillette F57,816/65*: The ability of rat liver microsomal enzymes to inactivate various substrates is greater in males than in females, but the sex difference varies with the substrate. There is a more than 3-fold sex difference with aminopyrine and hexobarbital but virtually none with hydroxylation of aniline and zoxazolamine. In male rats, starvation impairs sex-dependent enzymes which metabolize aminopyrine and hexobarbital but enhances those that hydroxylate aniline. On the other hand, in female rats, starvation increases the specific activity of the aminopyrine and hexobarbital-metabolizing enzymes as well as aniline hydroxylase. Starvation does not alter the metabolism of hexobarbital and enhances that of aminopyrine by microsomes of castrated rats but impairs the metabolism of these compounds by microsomes of methyltestosterone-treated castrates.

*Kato & Gillette F57,817/65*: The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Novick Jr. et al. F63,768/66*: In mice, the zoxazolamine prostration time is shortened by pretreatment with several 19-nortestosterone derivatives.

*Buu-Hoi & Hien G66,135/69*: Studies on the induction of zoxazolamine-hydroxylase activity in the liver of the rat by treatment with various polycyclic aromatic hydrocarbons with the purpose of determining pharmacological interrelations. It is incidentally mentioned that estradiol induces this enzyme and thereby shortens zoxazolamine paralysis in the rat.

*Gordon et al. H24,106/70*: In rats, medroxyprogesterone had no effect upon zoxazolamine "sleeping time." In weanling rats, medroxyprogesterone did not affect the growth-promoting action of testosterone upon the seminal vesicles but it inhibited the stimulation of the ventral prostate. In several patients the steroid accelerated the metabolic clearance of testosterone.

*Selye G70,480/71*: In rats, zoxazolamine paralysis is inhibited by PCN, CS-1, cyproterone, ethylestrenol, spironolactone, TMACN, 6 $\alpha$ -methylprednisolone, fluoxymesterone, 16 $\beta$ -methyl-16,17-epoxy-3 $\beta$ ,11 $\alpha$ -dihydroxy-5 $\alpha$ -pregnan-20-one, MAD, cortisone, cortisol and testosterone. It is not significantly affected by norbolethone, oxandrolone, spiroxasone, prednisolone, dexamethasone, betamethasone, emdabol, 17 $\alpha$ -acetoxyprogesterone, corticosterone, dehydroisoandrosterone, pregnanedione, progesterone, triamcinolone, 11 $\alpha$ -hydroxyprogesterone, hydroxydione, DOC, F-COL and estradiol.

*Selye G70,480/71*: In rats, the duration of the muscular paralysis produced by zoxazolamine was greatly shortened by PCN, CS-1, ethylestrenol, and to a lesser extent by spironolactone, and phenobarbital. The other standard conditioners were ineffective, cf. Table 119.

Table 119. *Conditioning for zoxazolamine*

Treatment <sup>a</sup>	Paralysis time <sup>b</sup> min
None	225 ± 50
PCN	38 ± 7 **
CS-1	63 ± 16 **
Ethylestrenol	57 ± 20 **
Spironolactone	105 ± 23 *
Norbolethone	151 ± 34 NS
Oxandrolone	155 ± 42 NS
Prednisolone-Ac	106 ± 40 NS
Triamcinolone	201 ± 30 NS
Progesterone	144 ± 23 NS
Estradiol	342 ± 32 NS
DOC-Ac	209 ± 34 NS
Hydroxydione	247 ± 35 NS
Thyroxine	268 ± 27 NS
Phenobarbital	103 ± 25 *

<sup>a</sup> The rats of all groups were given zoxazolamine (10 mg/100 g body weight in 1 ml water, i.p., once on 4th day).

<sup>b</sup> Student's t-test.

For additional pertinent data *cf. also* Table 135.

For further details on technique of tabulation *cf. p. VIII.*

*Szabo et al. G79,024/71:* In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

Zoxazolamine ← Adrenalectomy:  
Kato et al. *F57,817/65*

Zoxazolamine ← Norethynodrel:  
Juchau et al. *G40,275/66*

Zoxazolamine ← Ovariectomy +  
Methyltestosterone + Phenobarbital:  
Kato et al. *F76,403/66*

Zoxazolamine ← Testoids: Novick  
et al. *F63,768/66\**

#### DIET ←

(Chemically well-characterized factors, e.g., cholesterol, electrolytes, vitamins, choline, are listed conjointly with drugs.)

Among the complex diets to be discussed here, those containing large amounts of yeast are especially noteworthy because, in rats, they can produce fatal hepatic necroses. This toxic effect of the yeast is prevented by glucocorticoids and ACTH but not by progesterone, folliculoids, testoids or DOC. Aldosterone allegedly prolongs survival, but this effect cannot be ascribed to its mineralocorticoid potency since DOC is inactive in this respect. There is also some contradiction in the literature concerning the effect of folliculoids; in ovariectomized rats, the yeast-induced hepatic necroses are said to be inhibited by estradiol but aggravated by estriol.

In orchidectomized rats kept on **protein-deficient** diets, testoids still promote the growth of the levator ani muscle, although the animals lose much body weight; hence it was concluded that the hormone-induced growth of this muscle is not an appropriate index for the general "myotrophic" activity of testoid anabolics.

The hepatic necroses seen on certain high-fat low-protein diets are prevented by 4-chlorotestosterone.

In ovariectomized rats kept on low protein rations, folliculoid pellets implanted into the mesenteric circulation maintain estrus, whereas this is not the case on normal diets. Apparently, the folliculoid-inactivating system of the liver depends upon an adequate protein intake.

The weight loss and eventual death of **fasting** rats are somewhat delayed by testosterone but the effect upon the final carcass weight is minimal. On the other hand, the weight of the testicles is maintained and that of the accessory sex organs

actually increased by testoids despite starvation. The renotropic effect of testoids, though comparatively mild, continues to be demonstrable during fasting.

Among other complex dietary deficiencies the "stiffness syndrome" deserves special mention. It develops in guinea pigs kept on a skim milk powder diet and is said to be prevented by dietary supplements of a hitherto unidentified steroid compound isolated from cane juice.

Several investigators examined the effect of steroids upon voluntary food consumption but these studies are not strictly relevant to our subject. A few pertinent key references will be found in the Abstract Section.

#### Yeast ←

*Schwartz B57,985/51*: The fatal hepatic necrosis produced in rats by feeding a diet containing 30% yeast can be inhibited by cortisone.

*Aterman C61,786/58*: The hepatic necrosis produced in rats by feeding a diet containing yeast as the only source of protein is inhibited by cortisone, cortisol or ACTH, but not influenced by progesterone, "estrogen," testosterone or DOC. Aldosterone prolongs survival time providing 50 µg or more is administered daily. Although the author did not report any observations on the effect of aldosterone upon carbohydrate metabolism, he arrived at the conclusion that "these results, therefore, suggest that in the system examined here aldosterone has some 'glucocorticoid' activity and differs significantly from deoxycortone acetate which in doses of 0.5 and 2.5 mgm. daily has been completely ineffective."

*Brenner et al. D24,411/62*: In ovariectomized rats, the hepatic necrosis produced by a yeast diet is inhibited by estradiol but aggravated by estriol.

#### Protein Deficiency ←

*Shipley & György B20,418/44*: "Liver damage produced in rats by diets low in protein and high in fat was consistently reflected in the living animal by impairment in ability to inactivate estrone."

*Vanderlinde & Westerfeld B51,537/50*: "The estrogen draining through the liver from mesenterically implanted pellets of estrone in castrate rats was inactivated when the rats were maintained on: 1) chow ad libitum, 2) normal or 50% restricted intake of a 21% purified casein diet. The liver estrogen inactivating system was not maintained by: 1) an 8% purified casein diet ad libitum, or 2) 50% of the usual intake of chow. The results are

consistent with the concept that protein intake is the critical dietary factor involved in maintaining the estrogen inactivating system in the liver."

*Nimni & Geiger C31,438/57*: Testosterone and norethandrolone promote the growth of the levator ani muscle in normal and castrated male rats on protein-free diets. Under these circumstances the animals lose weight despite steroid treatment. "It is, therefore, concluded that the hormone-induced growth of this muscle is not an appropriate index for the general 'myotropic,' i.e. anabolic effects of steroid compounds."

*Cicchini et al. C57,934/58*: In rats kept on the high-fat low-protein diet of Handler, 4-chlorotestosterone inhibits the development of hepatic steatosis.

#### Fasting ←

*Uselli et al. B34,756/49*: The daily weight loss and eventual death of fasting rats are somewhat delayed by testosterone but the effect upon total carcass weight is minimal. Conversely, the weight of the testicles is perfectly maintained and that of the seminal vesicles actually increased by the hormone despite complete food deprivation.

*Quimby B62,481/51*: In rats recovering from prolonged inanition, large doses of testosterone actually delayed subsequent weight gain.

*Homburger & Pettengill C8,310/55*: In rats of different strains given testosterone on normal or restricted diets, "renotropism, virilization, and adrenal depressor effect occurred to almost the same degree under all experimental conditions, whether or not the animals were growing at an increased rate. Conversely, the growth stimulation of testosterone propionate in the mice on a normal diet depended on the source of the animals and did

not occur either on a restricted intake nor on a high-protein diet."

*Tillotson & Kochakian C14,153/56*: In orchidectomized guinea pigs, testosterone was unable to prevent the loss of body and organ weight induced by fasting.

*Kowalewski C68,938/59*: Cortisone prolongs the survival of rats during fasting; testosterone enanthate and norethandrolone do not share this effect.

*Jöchle & Langecker D22,258/62*: In the rat and mouse, methenolone-enanthate counteracts the weight loss produced by cortisone or a reduction of food intake.

*Rubino & Giacalone E36,677/63*: In starving rats, 17 $\alpha$ -methyl-17 $\beta$ -hydroxy-androsta-1,4-dien-3-one does not influence weight loss during starvation.

*Selye G70,480/71*: In rats, the mean survival after total fasting (with drinking water ad lib.) beginning on 4th day of conditioning was listed and the body weight measured on the 6th day. Under these circumstances none of the "Standard Conditioners" (p.VIII) or cholesterol caused any noteworthy change in the resulting intoxication. PCN, CS-1, thyroxine and phenobarbital were not tested.

**Various Other Complex Dietary Deficiencies** ← *cf. also Selye C50,810/58, p. 109; G60,083/70, p. 364.*

*Ross et al. B37,268/49*: In guinea pigs kept on a deficient regime of **skim milk powder**, the

"stiffness syndrome" can be prevented by a steroid compound (probable formula C<sub>28</sub>H<sub>46</sub>O) isolated from cane juice, but not further characterized.

*Larizza & Ventura B38,397/49*: In rats, the hepatic steatosis produced by high fat diets can be partially inhibited by moderate doses of diethylstilbestrol, whereas large doses actually aggravate it.

*Kalter C8,008/55*: In pregnant mice, cortisone increased **food consumption** but decreased body weight.

*Dewar G9,079/64*: From experiments on free-fed mice bearing progesterone tablet implants "it is concluded that progesterone fundamentally affects body weight by promoting water and nitrogen retention and, at the same time, increasing energy expenditure. The increase in **food intake** usually observed is, at least in part, a secondary response to the demands created by the latter two effects and fat deposition occurs also if this response is overadjusted."

*Leung et al. G60,800/68*: Observations on the **food intake** and growth of rats on amino acid imbalanced diets as influenced by cortisol.

*Borgman & Haselden H29,947/70*: In rabbits kept on a **gallstone producing ration**, ACTH, thyroid hormones or cortisone did not inhibit the production of biliary calculi, but several of these hormones inhibited usually associated hepatic steatosis.

## MICROORGANISMS AND PARASITES ←

Ever since the discovery of the nonspecific adaptive properties of glucocorticoids, numerous investigators examined the effect of these and other steroids upon the course of infections. Much of the pertinent literature has been described in our earlier monographs (*Selye B40,000/50, p. 67; C92,918/61, p. 241; G60,083/70, pp. 347—354*), but in view of the great importance of this topic in relation to the hormonal regulation of resistance in general, we shall have to reconsider and update these data here.

In general, the antiphlogistic effect of glucocorticoids diminishes resistance to infection, primarily because it interferes with the formation of an effective granulomatous barricade between the invader and the host, but in part also because of the immunosuppressive properties of glucocorticoids. Usually these effects are unfavorable for the host; but the glucocorticoids may also exert beneficial actions by suppressing excessive inflammatory responses to comparatively mild pathogens or their toxins. None of these actions are catatoxic, since they are not directed against the invader but merely alter the tissue reactivity of the host. The suppression of inflammatory reactions is a typical syntoxic effect in that it inhibits the development of a morbid lesion—here inflammation—without destroying the pathogen; thereby it facilitates the coexistence of host and invader.

On the other hand, certain steroids, especially testoid anabolics, have been shown to stimulate defensive reactions against some microorganisms through mechanisms which are not yet fully understood. In the final analysis, this effect may be catatoxic if it depends upon the stimulation of systematic or local immunologic and inflammatory response which facilitate the destruction of the invader.

In the following pages we shall discuss the actions of steroids upon both living and dead microorganisms and parasites in this order:

1. Bacteria and Vaccines
2. Viruses
3. Fungi and Yeasts
4. Parasites
  - A. Protozoa
  - B. Worms

In the immediately following pages we shall summarize only some of the most salient facts; additional detail will be found in the Abstract Section. The effects of hormones upon bacterial toxins will be discussed separately in the next section.

### ***Bacteria and Vaccines*** ←

In rats, cortisone has been found to increase the pathogenicity of inherently virulent *actinomyces*, without affecting normally avirulent strains.

The resistance of mice against *B. anthracis* does not appear to be significantly affected by testosterone, progesterone or folliculoids.

The development of Tyzzer's disease, induced in mice by inoculation with *B. piliformis* or with liver tissue from severely infected animals, is enhanced by cortisone, cortisol, and prednisolone but not by DOC or testosterone.

It is well-known that mice can be sensitized to histamine, 5-HT and anaphylaxis by pretreatment with *B. pertussis* vaccine. This hypersensitivity has been tentatively ascribed to a blockade of part of the adrenergic sympathetic nervous system. Even after adrenalectomy, cortisone and cortisol protect the pertussis-sensitized mouse against histamine, cold and anaphylaxis. This protection is dose-dependent and has been recommended as a basis for the bioassay of antiphlogistic and anti-endotoxic activity.

After injection of *B. pertussis*, intact mice become even more sensitive to cold than otherwise untreated adrenalectomized animals. Cortisone and cortisol protect the pertussis-treated mice from cold but not to the same extent as they protect adrenalectomized ones.

In mice, guinea pigs and rabbits, cortisone greatly aggravates the course of infection with various types of *Brucella* organisms. In cows, the progress of experimental brucellosis is allegedly inhibited by pregnancy but not by progesterone.

Neither cortisone nor DOC appears to affect the response of the mouse to tetanus toxin or to infection with tetanus spores.

In guinea pigs infected with *Cl. welchii*, survival can allegedly be prolonged by adrenocortical extract.

The resistance of mice to various types of unidentified *Corynebacteria* is diminished by cortisone and to a lesser extent by corticosterone. Furthermore, guinea pigs could not be protected by cortisone against inoculation with *diphtheriae* and cortisol activates a latent *kutscheri* infection in mice.

In rabbits, cortisone is said to inhibit the local reaction to inoculation with *pneumococci* at the same time accelerating the spread of the infection and death. DOC has no such effect.

The resistance of mice to various types of pneumococci can be raised by estrone. According to some investigators diethylstilbestrol has the same effect but others claim that this artificial folliculoid (like progesterone) is ineffective.

Cortisol increases the susceptibility of chickens to *E. rhusiopathiae*.

Various glucocorticoids reduce resistance to *E. coli* infection in different species.

In the rat, hematogenous pyelonephritis produced by i.v. inoculation of *E. coli* is allegedly facilitated by diethylstilbestrol.

Neither cortisone nor ACTH exerts any favorable effect upon *Leptospira* infection; no mention is made of possible detrimental effects.

In mice intracorneally inoculated with *M. lepraemurium*, cortisone inhibits both the topical and the systemic inflammatory lesions, although the liver and spleen are filled with bacilli.

In mice and rats infected with *M. paratuberculosis (johni)*, cortisone inhibits the inflammatory lesions; yet the natural resistance of the mouse to this type of infection is diminished by pretreatment with cortisone.

Especially extensive investigations have been performed on the effect of steroids upon infection with *M. tuberculosis*. The natural resistance of rats to this infection is overcome by cortisone pretreatment, and this induced susceptibility is in turn abolished by concurrent administration of STH or norethandrolone.

In mice, cortisone greatly aggravates the course of experimental tuberculosis and overcomes the beneficial effect of vaccination. It does not impair the chemotherapeutic effect of isoniazid but reduces that of streptomycin. In this species, STH allegedly does not prevent the detrimental influence of cortisone upon tuberculosis. There is some reason to think that the decrease in tuberculosis resistance induced by glucocorticoids is not merely the consequence of an antiphlogistic action since indomethacin (which is also antiphlogistic) fails to diminish the resistance of the mouse to tuberculosis.

In guinea pigs, glucocorticoids, folliculoids and allegedly even testosterone diminish resistance to virulent strains of tuberculosis. However, cortisone does not aggravate the lesions produced by low-virulence strains (e.g., BCG). The proliferation of tubercle bacilli in macrophages isolated from cortisone-treated and control guinea pigs is virtually identical. From this it has been concluded that the increased susceptibility of cortisone-treated animals is not caused by an altered rate of intracellular multiplication of bacilli but by an enhanced susceptibility of the host cells to toxic bacterial products.

In rabbits, cortisone facilitates and estradiol retards the progress of tuberculosis. Ovariectomy and progesterone do not influence it.

In mice, infection with *Nocardia asteroides* is enhanced by cortisone, but this effect can be blocked by concurrent administration of 4-chlorotestosterone.

Cortisone allegedly protects the rabbit against the toxic effects of **typhoid** vaccine; in patients with typhoid fever, cortisol may have a beneficial effect upon the toxemia. However, these actions appear to be directed against the bacterial products, not the bacteria themselves, since in rabbits, infection by small numbers of typhoid bacilli is facilitated by cortisone.

Curiously, although cortisone aggravates the course of many infections in different species it gives definite protection against otherwise lethal infection with *S. typhi* in mice. It was concluded that here again, the corticoid does not attack the germs but induces resistance to their toxins.

In patients with typhoid the bactericidal effect of the blood is increased by pre-treatment with certain testoid anabolics.

Resistance to *S. typhimurium* is decreased by cortisone in mice; progesterone and DOC fail to affect it.

Some of the first observations on the effect of glucocorticoids upon infections were made in connection with the so-called "**saprophytosis**" syndrome. The latter occurs in rats, mice and other species following heavy overdosage with glucocorticoids, as a consequence of the proliferation of normally saprophytic organisms (usually *Corynebacteria*) which in many of the earlier experiments have not been further identified. STH offers indubitable protection against this form of endogenous infection.

Data on the effect of cortisone upon **staphylococcal** infection are contradictory. Most investigators found that this and other glucocorticoids diminish resistance to various strains of staphylococci; yet, some data in the literature suggested that, under certain conditions, cortisone can protect both the rabbit and the mouse against staphylococcal infection.

Various folliculoids aggravate staphylococcal infection in mice but this effect is not directly proportional to their folliculoid potency. Progesterone is ineffective in this respect.

**Streptococcal** infections are likewise aggravated by glucocorticoids in rats, mice and rabbits. On the other hand, if rabbits are immunized with streptococci, prior to cortisone treatment and infection, little or no bacteremia occurs "indicating that enhancement of infection by cortisone is probably not caused by interference with the immune mechanism." Furthermore, chlortetracycline and oxytetracycline are ineffective against streptococcus infection in nonimmunized mice if these are treated with large doses of cortisone. Immunized mice similarly treated with cortisone are protected by these antibiotics. Only one team of investigators claimed that cortisone or ACTH actually increases survival following streptococcal infection in rats and further enhances the protective effect of penicillin.

"Conjugated equine estrogens" (Premarin) allegedly protect mice against streptococcal infection, perhaps owing to an increase in the acid mucopolysaccharide content of the ground substance which diminishes the spread of germs.

The spread of **Treponema pallidum** is enhanced by cortisone in the rabbit and if syphilomas are already developed they become soft and spongy. The production of Wassermann reagin is inhibited. After interruption of cortisone treatment there is a "rebound phenomenon" in that the lesions become unusually large.

**Actinomycetes** ←

*Piantoni C38,895/55*: In rats, cortisone increases the pathogenicity of inherently virulent actinomycetes, but does not affect the activity of normally avirulent strains.

**Bacillus Anthracis** ←

*Weinstein B15,029/39*: In mice, various anterior pituitary preparations protect against infection with *B. anthracis*. Parathyroid extract was also very effective, whereas thyroxine and testosterone offered little protection and progesterone, insulin, "estrin" and posterior lobe extract were virtually ineffective.

**Bacillus Piliformis (Tyzzer's disease)** ←

*Fujiwara et al. E34,642/63*: Tyzzer's disease with hepatic necroses can be produced in various species by inoculation with liver tissue of severely infected animals, with or without cortisone treatment, although the glucocorticoid facilitates infection.

*Takagaki et al. D69,101/63*: In the mouse, the production of Tyzzer's disease by infection with *B. piliformis* or hepatic emulsion of spontaneously-affected mice (in which the bacilli parasitize the hepatic cells), is possible only after pretreatment with cortisone or cortisol.

*Fujiwara et al. F17,247/64*: In mice, Tyzzer's disease produced by inoculation of *B. piliformis* is enhanced by cortisone, cortisol and prednisolone, but not affected by DOC or testosterone.

**Bordetella Pertussis** ← *cf. also Histamine + Vaccine*

*Kind B81,943/53*: In *B. pertussis* inoculated mice, cortisone inhibits the lethal effect of both histamine and *B. pertussis* vaccine. Cortisone also protects uninoculated mice against lethal intoxication with this vaccine.

*Munoz & Schuchardt C28,986/57*: After an injection of *B. pertussis* cells, intact mice become even more sensitive to "cold stress" than are otherwise untreated adrenalectomized mice. Cortisone and cortisol protect pertussis-treated and, to a lesser degree, adrenalectomized mice from cold. Cortisol also increases the cold resistance of normal mice. "It is suggested that while pertussis possibly affects adrenal function, it must in addition affect other

functions in the mouse which are also concerned with the protection against stress."

*Munoz E8,473/64*: Cortisone and cortisol protect the pertussis-sensitized mouse against histamine, cold and anaphylaxis even after adrenalectomy.

*Parfentjev F10,707/64*: Review on the use of mice hypersensitized by pertussis vaccine in testing corticoids for antiphlogistic and anti-endotoxic activity.

**Brucella** ←

*Abernathy B57,911/51*: In mice, guinea pigs and rabbits infected with *Brucella abortus*, *Br. mellitensis* or *Br. suis*, cortisone increased the dissemination of the lesions and the death rate. The agglutinin response was not affected.

*Abernathy & Spink B75,468/52*: In mice, cortisone greatly aggravates the course of acute infection with *Br. suis*. Observations on the effect of cortisone upon other forms of brucellosis in various species are also reviewed.

*Payne C89,814/60*: In cows, the progress of experimental brucellosis is inhibited by pregnancy but not by progesterone.

**Clostridium Tetani** ←

*Greene et al. B94,257/53*: In mice, cortisone or DOC did not significantly affect the response to tetanus toxin or tetanus spore infection.

**Clostridium Welchii** ←

*Kepl et al. A56,633/43*: In guinea pigs infected with *Cl. welchii*, treatment with adrenocortical extract prolonged survival.

***Corynebacteria*** ← *cf. also Selye C92,918/61, p. 233.*

*Mason et al. C14,288/56*: Corticosterone is approximately half as active as cortisone in suppressing the resistance of mice to *Corynebacterium pseudotuberculosis murium*. The relative pro-infectious potency of the two steroids roughly parallels their glucocorticoid activity.

*Speirs C34,744/56*: In BBF<sub>1</sub> mice, cortisone s.c. produces pseudotuberculosis owing to proliferation of *C. pseudotuberculosis murium*. Oxytetracycline p.o. reduces the incidence of these lesions.

*di Nola et al. C33,308/57*: In guinea pigs, cortisone pretreatment failed to protect against inoculation of live diphtheria organisms or diphtheria toxin.

*Caren & Rosenberg G41,288/66*: "When mice harboring latent *C. kutscheri* are administered hydrocortisone, which depresses mouse serum C' levels, pseudotuberculosis is activated with equal frequency in mice of both C' types."

#### ***Diplococcus Pneumoniae* ←**

*Magara 35,283/36*: Brief description (without experimental details) stating that both "male and female hormone extracts" increase resistance of the mouse to pneumococcal infection.

*von Haam & Rosenfeld A44,924/42*: In mice, estrone i.p. increases resistance to experimental pneumococcus infection. Stilbestrol and progesterone are ineffective. Testosterone protects both males and females to a moderate degree.

*Tobian & Strauss B28,613/48*: In mice surviving from pneumococcal infection owing to penicillin treatment, no further improvement was obtained by adrenocortical extract.

*Glaser et al. B57,933/51*: In mice and rats with streptococcal and pneumococcal infections, cortisone depresses cellular exudation and increases mortality.

*Kass et al. B69,981/51*: In mice, the final mortality rate after infection with influenza virus or pneumococci is not significantly altered by ACTH or cortisone, although the course of the disease may be modified.

*Robinson B57,249/51*: The local lesions, bacteremia and mortality following intradermal injection of virulent Type I pneumococci were aggravated by cortisone pretreatment and larger than ordinary doses of penicillin were required to control the infection.

*Germuth et al. D77,106/52*: In rabbits, cortisone increases susceptibility to pneumococcal infection as manifested by greater mortality, increased bacterial growth in the locally infected sites and enhanced bacteremia. The decreased resistance is ascribed to interference with the migration of phagocytic cells to the infected sites. On the other hand, cortisone increases the resistance of the rabbit to hemolytic *Staphylococcus aureus*.

*Kass et al. B95,353/54*: In mice, resistance to pneumococcal and influenza virus infections is depressed by pretreatment with cortisone or cortisol, but not by ACTH. STH failed to overcome the effect of cortisone and did not increase resistance to infection when given alone.

*Ertuganova C97,404/60*: In rabbits, cortisone inhibits the local response to inoculation

with pneumococci but accelerates the spread of infection and death. DOC does not influence this infection.

*Nicol et al. F70,028/66*: The survival time of intact or ovariectomized mice infected with *Pneumococcus* Type 1 is increased by pretreatment with diethylstilbestrol.

#### ***Erysipelothrix Rhusiopathiae* ←**

*Malik D34,701/62*: "Hydrocortisone increased the susceptibility of chicken to *E. rhusiopathiae*, shortened the course of infection, increased the percentage of deaths and resulted in septicaemia even with poorly virulent strains."

#### ***Escherichia Coli* ←**

*Moll D38,927/56*: Review of the literature on reduction of resistance by glucocorticoids against bacterial infections. Personal observations on mice showing that cortisone predisposes to the production of fatal septicemia by *E. coli*.

*Andriole & Cohn G807/63*: In the rat, hematogenous pyelonephritis produced by *E. coli* infection i.v. is facilitated by diethylstilbestrol.

#### ***Gonococci* ← cf. *Neisseria Gonorrhoeae***

##### ***Klebsiella Pneumoniae* ←**

*da Rocha Lagoa B49,008/47*: In rabbits, an otherwise fatal infection with *Klebsiella pneumoniae* can be combated by adrenocortical extracts and at the same time the otherwise considerable hyperkalemia is prevented.

##### ***Leptospira* ←**

*Derom & van Hoydonck C17,095/55*: "ACTH and cortisone have not been found to have any favorable effects on the infection of guinea pigs with *Leptospira ictero-haemorrhagiae*, strain 'Afsnee'."

##### ***Mycobacterium Leprae* ←**

*Naguib & Robson C23,199/56*: In mice, intracorneally inoculated with *M. lepraemurium*, cortisone decreased the development of both corneal and systemic lesions; nevertheless, the liver and spleen usually contained large numbers of lepra cells filled with bacilli. Cortisone did not appreciably modify the beneficial action of isoniazid.

***Mycobacterium Paratuberculosis***  
(*johneii*) ←

*Ford G67,455/57*: Mice are normally resistant to infection by *M. johnei* but they become sensitive following pretreatment with cortisone.

*Chandler D5,239/61*: In mice infected with *M. johnei*, cortisone reduced the hepatic and splenic infection but had no definite effect upon the intestinal lesions.

*Chandler D5,240/61*: In the rat, cortisone did not enhance infection with *M. johnei* and may have actually reduced it.

***Mycobacterium Tuberculosis*** ←

RAT

*Michael Jr. et al. B53,378/50*: Rats infected with virulent *M. tuberculosis* (H37Rv) do not die of tuberculosis unless they are pretreated with cortisone.

*Cummings & Hudgins B66,423/51*: Cortisone increases susceptibility to tuberculosis in the rat and rabbit although it diminishes the allergic manifestations of the disease.

*Lemondé et al. B70,248/52; B69,349/52*: The rat, which is naturally resistant to human tuberculosis, can be made sensitive to this infection by pretreatment with cortisone. This sensitivity is in turn abolished by concurrent treatment with STH. Mice which are naturally sensitive to tuberculosis can also be protected by STH.

*Lemondé et al. C95,984/60*: Norethandrolone inhibits the development of tuberculous lesions in the rat and counteracts the opposite effect of cortisol.

MOUSE

*D'Arcy-Hart & Rees B50,249/50*: Cortisone greatly aggravates the course of tuberculosis in mice following inoculation of human-type tubercle bacilli.

*Solotorovsky et al. B56,305/51*: "Cortisone overcame the beneficial effect of vaccination in mice infected with a highly virulent strain of *M. tuberculosis*, human type, but did not significantly enhance the lethality in non-vaccinated mice."

*Ilavsky & Foley C7,577/54*: In mice infected with massive doses of tubercle bacilli, "the chemotherapeutic effect of isoniazid was not impaired by concomitant treatment with large doses of cortisone. The effectiveness of streptomycin was reduced, and the weak effect of PAS was not significantly altered."

*Youmans & Youmans B95,169/54*: In mice, cortisone markedly reduced the survival time after infection with human tubercle bacilli and this effect could not be prevented by STH. Given alone, ACTH, STH and TTH likewise failed to influence the course of the infection.

*Batten & McCune C53,554/57*: ACTH, cortisol and cortisone greatly reduce the resistance of mice to infection with human *M. tuberculosis*.

*Wagner & Lammers C83,426/58*: The course of experimental tuberculosis is aggravated by cortisone and prednisolone in the mouse. The glucocorticoids also largely counteract the beneficial effect of streptomycin.

*Robinson et al. G53,271/68*: Unlike cortisol, indomethacin does not reduce the resistance of mice to virulent human strain of *M. tuberculosis*. A striking difference between the two drugs was also noted in respect to the high incidence of activated latent infection by cortisol, but not by indomethacin. "It would appear that indomethacin, like other nonsteroid, anti-inflammatory agents, has no influence on resistance to infection in spite of its anti-inflammatory action."

RABBIT

*Lurie et al. B31,931/49; B31,932/49*: In highly inbred, sexually mature rabbits, estradiol retarded the progress of tuberculosis following i.c. inoculation. In immature rabbits, estradiol was less effective. LH accelerated the progress of the disease, whereas ovariectomy or progesterone remained without effect.

*Lurie et al. B31,933/49*: In rabbits, estradiol retards the progress of experimental tuberculosis at the portal of entry in the skin and diminishes its dissemination to internal organs, presumably by reducing the permeability of connective tissue. Chorionic gonadotropin has an inverse effect.

*Lurie et al. B55,625/51*: In rabbits infected with *M. tuberculosis*, the number of bacilli in the pulmonary lesions as well as the number of tubercles are increased by cortisone; yet, dissemination to the tracheobronchial lymph nodes appears to be inhibited by the hormone.

*Lurie et al. B68,457/52*: In rabbits genetically resistant to tuberculosis, cortisone facilitated the infection.

*Lepri & Fornaro D91,865/54*: In rabbits rendered allergic to tuberculosis, the ocular manifestations of topical challenge by tubercle

bacilli were variably influenced by ACTH and cortisone.

*Bodaiji & Mori C35,586/57*: In rabbits, cortisone facilitates the development of pulmonary lesions after inoculation with tubercle bacillus, H37Rv.

#### GUINEA PIG

*Aycock & Foley B773/45*: In guinea pigs, pretreatment with estradiol, diethylstilbestrol or testosterone diminishes resistance against tuberculosis.

*Spain & Molomat B80,256/50; B60,878/50*: Cortisone greatly aggravates the course of tuberculosis in guinea pigs and renders them very refractory to streptomycin treatment.

*Spain B69,019/51*: Cortisone diminishes the resistance of guinea pigs to tuberculosis.

*Swedberg B59,988/51*: Thyroxine diminishes the resistance of guinea pigs to tuberculosis. "Estrogen" has the same effect, whereas testosterone does not significantly change the course of the infection.

*Okada et al. C18,328/55*: In guinea pigs inoculated with B.C.G. or Vole bacillus, cortisone did not aggravate the lesions or increase the bacterial count.

*Greuel & Schäfer E54,589/56*: In guinea pigs treated with ACTH, DOC or cortisone, the progress of tuberculosis was proportional to the size of the adrenals, and least severe in animals given cortisol.

*Kracht & Meissner C21,867/56*: Cortisone aggravates tuberculosis in guinea pigs but infection with low virulence strains (e.g., B.C.G.) are not activated.

*Tao et al. C82,168/59*: Bovine type RM strain mycobacteria grew much more vigorously in the organs of rabbits and guinea pigs after treatment with cortisone; but no such enhancement of virulence was observed in hamsters and rats.

*Vakilzadeh & Vandiviere E32,626/63*: In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T3, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

*Hsu G70,576/69*: The proliferation of tubercle bacilli in macrophages isolated from cortisone-treated and nontreated guinea pigs is virtually identical. Cytologic studies revealed that intracellular infection is toxic to the host cells derived from cortisone-treated animals. This toxicity is combated by serum from B.C.G.-vaccinated animals although the

serum does not alter the rate of intracellular bacterial multiplication. "Hence, the increased susceptibility of cortisone-treated animals to tuberculous infection is not likely to be caused by an altered rate of intracellular multiplication of tubercle bacilli but the enhanced susceptibility of the host cells to toxic injury imposed by the intracellular multiplication of the pathogen."

#### VARIA

*Lemonde C310/54*: Doctor's thesis (186 pp., 564 refs.) on humoral factors influencing infections with special reference to the effect of STH and cortisone upon experimental tuberculosis.

*Schäfer B99,955/54*: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas and gonads.

*Lurie C14,768/55*: Review (30 pp., 128 refs.) on the effect of hormones in experimental tuberculosis. Special emphasis is placed upon the retardation of tuberculosis by folliculoids and its aggravation by cortisone.

#### *Mycoplasma* ←

*Muftic & Redmann G58,918/68*: In vitro tests on the effect of about 200 steroids upon cultures of *Mycoplasma gallisepticum*. No definite pharmaco-chemical correlations could be established.

#### *Neisseria Gonorrhoeae* ←

*Rupp & Knackstedt C42,998/57*: Cortisone increases the susceptibility of mice to both living and heat-killed gonococci.

#### *Nocardia Asteroides* ←

*Ghione D87,868/57*: 4-Chlorotestosterone enhances anaphylactic shock in guinea pigs, prolongs survival in systemic nocardiosis of mice and improves healing in cutaneous nocardiosis of rabbits.

*Ghione C51,954/58*: 4-Chlorotestosterone prolongs the survival time of mice infected with *Nocardia asteroides* or *Staphylococcus aureus*. Thus it counteracts the pro-infectious effect of cortisone.

#### *Pasteurella Pestis* ←

*Girard C22,665/56*: Infection with a comparatively avirulent strain of *P. pestis* is facilitated by cortisone pretreatment in the mouse.

***Pasteurella Tularensis* ←**

*Pinchot et al. B39,038/49:* In rats infected with *P. tularensis*, survival time was not influenced by potent adrenocortical extract.

***Pneumococci* ← *cf. Diplococcus Pneumoniae******Psittacosis* — *Ornithosis* ←**

*Moritsch C15,606/56:* Observations on the treatment of psittacosis by cortisone + antibiotics in the mouse.

*Stewart C59,979/58:* Administration of cortisone with psittacosis virus to embryonated hens' eggs prolonged the survival of the embryos.

***Rickettsia* ←**

*Jackson & Smadel E52,720/51:* Intact mice pretreated with cortisone or ACTH, "were given lethal amounts of the toxins of *R. tsutsugamushi*, *R. prowazeki*, or *S. typhosa*. Such animals were as susceptible to the toxins as normal controls. Neither hormone had any therapeutic effect in mice infected with *R. tsutsugamushi*. Furthermore, treated and untreated mice in a terminal phase of infection with *R. tsutsugamushi* were equally susceptible to the toxin of this rickettsia when injected intravenously. In the current experiments the adrenal cortex of normal or infected animals apparently contributed as effectively as possible in the host's response to rickettsial or bacterial toxins and further stimulation was without advantage."

***Salmonella Enteritidis* ←**

*Chedid et al. B91,161/52:* Infection with *S. enteritidis* p.o. causes an intestinal infection in intact rats but is rarely fatal. After adrenalectomy mortality is greatly increased although blood cultures are usually negative. "Death is not due to invasion by the organism but to an increase in the sensitivity to its toxic product after ablation of the adrenals."

*Chedid et al. B99,547/54:* In rats, pretreatment with cortisone diminishes survival following oral inoculation with *S. enteritidis*.

***Salmonella Typhi* ←**

*Benetato et al. 33,773/35:* In rats, neither adrenocortical extract nor an adrenotropic anterior pituitary preparation altered resistance to morphine or to typhoid-paratyphoid vaccine.

*Chedid et al. B91,160/51:* Although cortisone aggravates the course of various infections, it gives definite protection against otherwise lethal infections with *S. typhi* in mice.

*Chedid et al. B91,161/52:* Intact mice can be protected against otherwise fatal infections with *S. typhi* by a single dose of cortisone given one hour before infection. The corticoid does not appear to attack the germs but induces resistance to their toxin.

*Germuth et al. D77,106/52:* Rabbits are protected against the toxic effects of typhoid vaccine by cortisone pretreatment.

*Mody et al. C45,962/56:* Two patients with toxemia of typhoid fever resistant to chloramphenicol responded well to cortisol i.v.

*Heyman & Jandl C94,285/60:* In rabbits, infection by small numbers of typhoid bacilli is facilitated by cortisone.

*Loschiavo G28,338/65:* In patients with typhoid, the bactericidal property of the blood is increased by treatment with 19-nortestosterone-17-cyclopentylpropionate.

***Salmonella Typhimurium* ←**

*Bowen et al. C31,414/57:* In mice, cortisone decreased resistance to *S. typhimurium*. Progesterone and DOC were without effect.

*Bowen et al. C31,415/57:* Cortisone reduces the survival time following infection with *S. typhimurium* especially in mice kept at a warm environmental temperature.

*Bowen et al. C31,416/57:* Cortisone given one day before infection with *S. typhimurium* reduces survival in various strains of mice selected for a wide range in their natural resistance to this germ.

**"*Saprophytosis*" ←**

*Selye B40,000/50:* Large doses of cortisone predispose the rat to the development of septicemia with abscess formation especially in the lungs (but also in other organs) as a consequence of diminished resistance against normally saprophytic organisms.

*Selye B57,451/51:* In rats, "saprophytosis" due to proliferation of normally nonpathogenic microorganisms, such as develops after heavy overdosage with cortisone or ACTH, can be completely prevented by concurrent administration of STH.

*Ducommun & Ducommun B70,251/53:* In rats, saprophytosis produced by heavy overdosage with cortisone is inhibited by concurrent administration of STH. This

"anti-infectious effect of STH" is much less evident after adrenalectomy. DOC, testosterone, and estradiol alone or in combination failed to duplicate the anti-infectious action of STH in cortisone-treated rats.

*von Wasielewski & Knick G68,292/58*: In mice, cortisone decreases resistance to inoculation with various pathogenic, but not to saprophytic, organisms.

**Staphylococcus** ← *cf. also Selye G60,083/70, p. 378.*

*Kligman et al. G64,164/51*: In guinea pigs, infection with *Trichophyton mentagrophytes*, vaccinia virus and *S. aureus* is adversely influenced by cortisone.

*Germuth et al. D77,106/52*: In rabbits cortisone increases susceptibility to pneumococcal infection as manifested by greater mortality, increased bacterial growth in the locally infected sites and enhanced bacteremia. The decreased resistance is ascribed to interference with the migration of phagocytic cells to the infected sites. On the other hand cortisone increases the resistance of the rabbit to hemolytic *S. aureus*.

*Debry C30,870/56*: Doctor's thesis (176 pp. 578 refs.) on the influence of hormones upon infection. Personal observations on guinea pigs and rats indicate that ACTH, STH and DOC do not significantly affect the course of acute staphylococcus infection, whereas cortisone aggravates it.

*Herbeuval et al. C55,674/58*: Testosterone does not significantly influence staphylococcus septicemia in the rabbit. Earlier literature on the effect of testoids upon infection is reviewed.

*Herbeuval et al. C55,676/58*: In rabbits, DOC does not influence the development of septicemia following infection with *S. aureus*, whereas cortisone aggravates its course.

*Smith et al. F68,892/66*: Testosterone, cortisone, as well as various organ extracts, partially protect the mouse against staphylococcal infection.

*Toivanen G49,847/67; G59,609/66*: Staphylococcal infection in mice is enhanced by estradiol benzoate given once or several times immediately before infection. "The enhancement of the infection was also demonstrated by the use of estrone, estriol, 17 $\alpha$ -estradiol, 17 $\beta$ -estradiol, estradiol sulphate, estradiol phosphate, ethynylestradiol, diethylstilbestrol, methallenestril and chlorotriani-sene. The effect was not directly correlated to the estrogenic potency of the drug. Progesterone was found to be inert."

*Toivanen G49,848/67*: In mice, estradiol pretreatment enhanced infection with staphylococci, but the degree of this activity depended upon the time interval between infection and the initiation of hormone treatment as well as upon the magnitude of the microbial inoculum.

### **Streptococcus** ←

*Glaser et al. B58,299/50*: In mice, neither ACTH nor cortisone exerted a beneficial effect upon streptococcal or pneumococcal infections; indeed they may have aggravated them.

*Glaser et al. B57,933/51*: In mice and rats with streptococcal and pneumococcal infections, cortisone depresses cellular exudation and increases mortality.

*Glaser et al. B65,298/51*: "Cortisone shortens the survival time of mice with cervical adenitis due to group A streptococci. Rats with streptococcal pneumonia were similarly affected by cortisone therapy."

*Thomas et al. B57,977/51*: "When the rabbits are immunized with streptococci prior to cortisone treatment and infection, bacteremia occurs briefly or not at all and the animals survive, indicating that enhancement of infection by cortisone is probably not caused by interference with the immune mechanism."

*Mogabgab & Thomas B72,457/52*: In rabbits, pretreatment with ACTH or cortisone greatly aggravated streptococcal septicemia. DOC had no such effect.

*Foley C13,263/55*: "Chlortetracycline and oxytetracycline are ineffective against streptococcus infections in nonimmunized mice which are treated with large doses of cortisone. Immunized mice similarly treated with cortisone are effectively protected by these antibiotics."

*Fazio et al. C34,111/56*: In rats, cortisone or ACTH increases survival following streptococcal infection and further enhances the protective effect of penicillin.

*Foley et al. C31,073/57*: Prednisone, prednisolone, cortisone and cortisol aggravate streptococcus infections in mice and interfere with the efficacy of chlortetracycline.

*Kuck C69,754/59*: Comparative studies on the increase in tetracycline requirements for the control of streptococcal infections caused by triamcinolone, prednisolone and cortisol, in mice.

*Weisskopf et al. D35,320/61*: Review of the protective action of folliculoids against viruses

and bacteria, with personal observations on the increase in the resistance of mice that can be induced by Premarin against virulent streptococcal infection. Females are more resistant than males, and castration increases resistance in males. The effect of folliculoids is tentatively ascribed to an increase in the acid mucopolysaccharide content of the ground substance which decreases the subcutaneous spread of germs.

#### *Treponema Pallidum* ←

*Turner & Hollander B55,488/50*: In rabbits, syphilomas induced by intradermal or intratesticular injection of *Treponema pallidum* become soft and spongy under the influence of cortisone, and the production of Wassermann reagin is inhibited. Upon withdrawal of cortisone, there is a rebound phenomenon in which the lesions become unusually large.

*Gastinel et al. D8,309/60*: In rabbits, infected with syphilis by various routes, cortisone accelerates the generalization of the lesions.

*Wicher & Jakubovski G26,810/64*: In guinea pigs, cortisone prolongs the incubation period, shortens the duration and alters the character of the changes elicited by i.c. inoculation with *T. pallidum*. Serologic tests and the infectivity of the organisms are not affected.

#### *Varia* ←

*Kass & Finland B59,076/51*: Review on the effect of ACTH and corticoids upon various types of infections in animals and man.

*Kay et al. B60,579/51*: In dogs, cortisone offered no protection against the lethal effect of an experimental appendical peritonitis.

*Chedid et al. B91,161/52*: Review (21 pp., 75 refs.) on the relationship between the adrenals and infection.

*Kass & Finland C80,582/53*: Review (27 pp., 313 refs.) on the role of corticoids in infection and immunity.

*Cavallero C829/54*: Review on the effect of STH, ACTH and cortisone upon various infections, especially in the rat.

*Maral & Cosar C14,760/55*: Review of the literature and personal observations on the effect of cortisone upon various types of infection in the mouse, rabbit and rat.

*Kass & Finland E56,566/57*: Review (18 pp., 181 refs.) on the effect of corticoids upon various infections.

*Kass & Finland D87,314/58*: Review (35 pp., 151 refs.) on "Corticosteroids and infections."

*Spink C91,027/60*: Review on the pathogenesis of shock due to infection and its treatment by glucocorticoid.

*Ghione & Turolla G18,525/64*: Review of investigations on mice, guinea pigs and rats showing that the infection facilitating effect of glucocorticoids (cortisone, prednisone) is counteracted by anabolic steroids such as 4-hydroxymethyltestosterone or 4-chlorotestosterone.

*Nicol et al. F25,320/64*: Review of the literature and personal observations suggest that folliculoids increase resistance against various infections, but the sex-stimulating and anti-infectious effects of diverse natural or synthetic folliculoids do not run parallel.

#### *Viruses* ←

The tumorigenic effect of adenovirus-12 is greater in female than in male hamsters. Ovariectomy diminishes this effect. Estradiol increases it in males but not in females.

The susceptibility of mice to the lethal effect of various arboviruses is increased by cortisone but uninfluenced by DOC, testosterone, progesterone or estradiol.

Pretreatment with cortisone aggravates the course of Coxsackie infection in guinea pigs and mice. In mice, gonadectomy diminishes mortality from Coxsackie infection but only during the first 10 days after operation. Testosterone does not alter this beneficial effect.

In mice, cortisone increases mortality following inoculation with Japanese encephalomyelitis virus. Allegedly concurrent treatment with splenic extract blocks this action. DOC has no adverse effect.

In dogs, cortisone, ACTH, estradiol, stilbestrol and thyroxine all stimulate the growth of equine encephalomyelitis virus, whereas testosterone and progesterone do not. The hormones which aggravate the infection also counteract the prophylactic effect of mepacrine and abolish the normally greater resistance of females as compared to males.

In rats, cortisone offers partial protection against the paralysis induced by encephalomyocarditis virus.

Susceptibility to virus hepatitis is greatly increased by glucocorticoids in the mouse. The associated severe lymphoid necrosis is prevented although the hepatic lesions are aggravated. Infected animals pretreated with cortisol may show up to a 1000-fold increase in the hepatic virus concentration as compared with similarly infected but untreated animals. Suppression of immune phenomena and of RES activity may be responsible for this sensitization. STH counteracts the glucocorticoid-induced increase in virus susceptibility. In weanling mice and in rats, which are normally resistant to virus hepatitis, susceptibility can be induced by cortisone.

Pretreatment with estradiol allegedly facilitates the production of murine virus hepatitis.

In man, 4-chlorotestosterone and several other anabolic testoids allegedly protect the liver against the damaging effect of viral hepatitis.

In mice, resistance to various strains of influenza virus and Newcastle-disease viruses is reduced by cortisone given 24 hrs before challenge. However, under certain conditions various glucocorticoids can also increase the survival of mice infected with influenza virus and diminish the severity of the pulmonary changes.

In chick embryos, infected with influenza B., pretreatment with cortisone prolongs survival although virus proliferation is enhanced.

Various testoid anabolics have also been said to exert a protective effect against the damaging action of influenza virus upon embryonated chicken eggs; yet, in mice, testosterone allegedly accelerates the proliferation of influenza virus, presumably because of its protein anabolic effect.

Cortisone accelerates the course of poliomyelitis infection in mice and hamsters; DOC, progesterone and stilbestrol are ineffective. Yet, earlier investigators claimed that estradiol can protect various species against poliomyelitis, but only in the event of intranasal and not following i.p. or intracerebral inoculation.

In monkeys, cortisone did not increase susceptibility to poliomyelitis under the conditions in which the tests were performed.

Cortisone allegedly increases susceptibility of mice to rabies virus perhaps because of its immunosuppressive effect. Prednisolone has been claimed to protect against the paralytic complications of antirabies vaccines.

Cortisone definitely enhances vaccinia infection in rabbits; estradiol, estrone and pseudopregnancy have an opposite effect in this species. In guinea pigs, cortisone also exerts an adverse influence upon vaccinia infection. In mice, it depresses interferon formation but fails to inhibit the protection offered by N-ethylisatin- $\beta$ -thiosemicarbazone.

Aldosterone is said to inhibit the reproduction of vaccinia virus in vitro.

Rabbits are allegedly protected against variola by aldosterone.

In sheep, ACTH and dexamethasone aggravate the lesions produced by the smallpox virus; STH has an opposite effect, presumably because its prothogistic action helps to delimit the lesions.

**Adenoviruses ←**

*Yohn et al. G57,790/68:* In hamsters given adenovirus-12, strain Huie, s.c. at birth, thymectomy at one week of age increased tumor incidence in both sexes, although it remained higher in females as is usually the case. Cortisone treatment, begun at one week of age, increased tumor incidence but, again, this remained higher in females. Antibody responses to adenovirus-12 T-antigen were depressed in thymectomized and cortisone-treated animals.

*Yohn & Funk G68,339/69:* Adenovirus-12 produced a higher incidence of tumors in female than in male Syrian hamsters. Ovariectomy lowered tumor incidence, whereas estradiol increased it but only in males.

**Arboviruses ←**

*Southam & Babcock B63,662/51:* "Large doses of cortisone greatly increased the susceptibility of mice to lethal infection by West Nile, Ilheus, and Bunyamwera viruses. ACTH in massive dosage produced the same effect with West Nile virus. Desoxycorticosterone, testosterone, progesterone, and estradiol in massive doses had no significant effect on these virus infections in mice."

**Columbia-SK Virus ←**

*Siegel et al. D13,002/61:* "Cortisone increased the mortality and nullified the protection afforded by trypan red in mice inoculated intraperitoneally with Columbia-SK virus."

**Coxsackie ←**

*Kilbourne & Horsfall Jr. B65,487/51:* Adult mice normally resistant to Coxsackie virus can be lethally infected following pretreatment with cortisone.

*Graham et al. B68,455/52:* Cortisone increases the susceptibility of the mouse to Coxsackie virus infection.

*Angela & di Nola C12,561/54:* In guinea pigs, pretreatment with cortisone aggravates the course of the subsequent Coxsackie infection.

*Berkovich & Ressel F46,105/65:* In mice, mortality after Coxsackie B1 virus infection was diminished by gonadectomy in both sexes but only during the first ten days after operation. Testosterone did not significantly influence this beneficial effect.

**Encephalomyelitis ←**

*Vollmer & Hurlbut B66,973/51:* In mice, moderate doses of cortical extract or cortisone had no effect on Japanese B encephalitis virus infection, although in doses that inhibit growth, cortisone did increase the mortality rate. Testosterone had no adverse effect.

*Kudo et al. C11,417/54:* In mice, cortisone increases mortality following inoculation with Japanese encephalomyelitis virus, whereas DOC has no adverse effect.

*Nakagawa & Kanda C9,941/55; C8,165/55:* Cortisone increases the susceptibility of mice to infection with encephalomyelitis virus but concurrent administration of a splenic extract blocks this action of the glucocorticoid.

*Hurst et al. C94,089/60:* Cortisone, ACTH, estradiol, stilbestrol and thyroxine all stimulate the growth of the virus of equine encephalomyelitis in the dog, whereas testosterone and progesterone do not. The hormones which aggravate the infection also counteract the prophylactic effect of mepacrine and abolish the normally greater resistance of the females.

*Olivier & Cheever G15,789/63:* Cortisone diminishes the susceptibility of rats to the development of paralysis following inoculation of encephalomyocarditis virus.

**Hepatitis ←**

*Melcher Jr. et al. B69,381/52:* Rats normally resistant to viral hepatitis become susceptible after pretreatment with cortisone.

*Starr & Pollard C60,012/58:* Cortisone induced susceptibility of comparatively resistant weanling Swiss mice to infection with the Gledhill strain of mouse hepatitis virus.

*Pecori et al. C89,121/59:* In mice, virus hepatitis is aggravated by prednisolone and beneficially influenced by STH.

*Pecori et al. C89,118/59:* Prednisone, triamcinolone and dexamethasone increase sensitivity of the mouse to infection with the MHV-3 hepatitis virus. This pro-infectious effect is largely counteracted by STH.

*Manso et al. C68,152/59:* In mice infected with hepatitis virus, the levels of GOT, GPT, lactic dehydrogenase, and glutathione reductase increased under the influence of cortisol, whereas in intact mice the hormone did not influence these enzyme activities. It is assumed that cortisol "may exert an adverse effect on the natural course of the experimentally-induced infection."

*Jones & Cohen D55,380/63:* Pretreatment with estradiol valerate facilitates the production of murine virus hepatitis.

*Terragna et al. G25,811/64:* In man, 4-chlorotestosterone ameliorates the course of viral hepatitis.

*Terragna et al. G36,590/65:* In patients with viral hepatitis, various anabolic testoids protect the liver (needle biopsy) against damage.

*Hirano & Ruebner G38,763/66:* In mice, the severe lymphoid necrosis produced by murine hepatitis virus (MHV<sub>3</sub>) was prevented by cortisone whereas the liver lesions were aggravated. Essentially the same results were obtained with puromycin although it failed to aggravate the hepatic lesions. Presumably suppression of protein synthesis was the common underlying mechanism. "It is concluded that multiplication of the virus alone did not produce the lymphoid necrosis but that protein synthesis induced by the infection, presumably an immune reaction, was primarily responsible for this lesion."

*Ruebner et al. G48,873/67:* In the mouse, cortisone not only increases the number and size of necrotic foci produced by MHV<sub>3</sub>-virus but also alters the light-microscopic and ultrastructural appearance of the hepatocytes.

*Datta & Isselbacher G68,822/69:* Cortisol and methylprednisolone greatly increase the susceptibility of the mouse to virus hepatitis. "Infected animals pretreated with hydrocortisone showed from 50-fold to a more than 1,000-fold increase of virus in the liver compared with untreated infected animals."

*Lavelle & Starr H18,566/69:* In mice, cortisone increases susceptibility to virus hepatitis and depresses RES activity.

*Nelson & Lanza G80,151/70:* In nine patients with massive hepatic necrosis due to viral hepatitis, prednisone proved to be a valuable adjunct to treatment.

### **Influenza ←**

*Kalter et al. B49,656/50:* In mice, the proliferation of influenza virus is accelerated by STH and testosterone, presumably because of an enhanced protein synthesis in general.

*Kass et al. B69,981/51:* In mice, the final mortality rate after infection with influenza virus or pneumococci is not significantly altered by ACTH or cortisone, although the course of the disease may be modified.

*Kilbourne B69,376/52:* Pretreatment with cortisone prolongs the survival of chick

embryos infected with influenza B although virus proliferation is enhanced.

*Khoobvarian & Walker C30,210/57:* In mice, resistance to i.v. inoculation of PR8 influenza A, Lee influenza B, and Newcastle disease viruses was reduced by cortisone given at least 24 hrs before challenge.

*Lagba D58,191/62:* Cortisol and prednisolone, unlike dexamethasone and cortisone, increase the survival of mice infected with influenza PR8 virus.

*Mims G68,101/62:* Glucocorticoids did not protect mice from the lethal action of ectromelia virus but increased survival and delayed death after inoculation with influenza virus.

*Terragna G36,765/63:* In tests on embryonated chicken eggs and in mice infected with influenza virus A-PR8, treatment with anabolic hormones (dehydroisoandrosterone, 4-chlorotestosterone) exerts a certain protective effect, but the results are variable.

*Sobis G29,127/64:* In mice, the pulmonary changes induced by influenza virus are diminished by cortisol.

### **Measles ←**

*Coraggio et al. D58,058/62:* In rabbits immunized with measles virus, 19-norandrosthenolone raises antibody formation.

### **Mumps ←**

*Kilbourne & Horsfall Jr. B55,005/51:* In chicken eggs, the concentration in the allantoic fluid of Lee, PR8 or mumps virus is increased by cortisone.

### **Pneumonia ←**

*Smith et al. B64,635/51:* In mice, susceptibility to pneumonia virus (PVM) is not influenced by ACTH but is enhanced by cortisone.

### **Poliomyelitis ←**

*Levaditi & Haber 33,069/35:* In *Macacus cynomolgus* monkeys, resistance to poliomyelitis virus, acquired by prior infection, is not influenced by thyroidectomy, orchidectomy or thyroxine administration.

*Foley & Aycock B764/45:* Review of the literature and personal observations on the protective effect of estradiol against poliomyelitis infection in various species. In general, the folliculoids are effective against intranasal infection, but not against i.p. or intracerebral inoculation.

*Shwartzman B54,248/50:* "ACTH and cortisone in combination or cortisone alone

produce a marked acceleration of poliomyelitis infection (strain MEF1) in mice and an extraordinary enhancement of susceptibility to this infection in hamsters giving rise to a violent and uniformly fatal disease. ACTH alone fails to produce this effect possibly due to elaboration of an unknown factor capable of reversing the enhancing effect of cortisone."

*Shwartzman B66,955/51*: ACTH and cortisone accelerate poliomyelitis (strain MEF) in mice and hamsters. DOC, progesterone and diethylstilbestrol are ineffective.

*Findlay & Howard B81,142/52*: In mice and hamsters, cortisone and ACTH increase susceptibility to poliomyelitis and other virus infections.

*Shwartzman B69,778/52*: Cortisone, unlike ACTH, greatly increases the susceptibility of Syrian hamsters to i.p. inoculation with strain MEF1 poliomyelitis virus.

*Shwartzman & Fisher B69,580/52*: In Syrian hamsters, cortisone enhances infection with MEF1 and Lansing strains of poliomyelitis virus. ACTH, DOC, progesterone and stilbestrol are without effect. Earlier literature on the influence of various hormones upon poliomyelitis is reviewed.

*Shwartzman & Aronson B84,833/53*: In the hamster, pretreatment with cortisone facilitates infection with poliomyelitis.

*Hoosier et al. D12,216/61*: "In several comparative experiments with and without cortisone, no enhancing effect of this compound on the susceptibility of monkeys to infection with poliovirus was found."

#### **Rabies ←**

*Yaoi et al. C34,360/56*: Cortisone increases the susceptibility of mice to rabies virus.

*Finger E26,273/62*: Prednisolone protects the rabbit against the paralytic complications elicited by antirabies vaccines, presumably because it depresses allergic reactions to the contaminating foreign brain tissue.

#### **Vaccinia ←**

*Sprunt & McDearman A33,321/40*: Treatment with estradiol or estrone, as well as pseu-

dopregnancy, increased the resistance of the rabbit to vaccinia virus.

*Kligman et al. G64,164/51*: In guinea pigs, infection with *Trichophyton mentagrophytes*, vaccinia virus and *Staphylococcus aureus* is adversely influenced by cortisone.

*Bugbee et al. C84,115/60*: "Cortisone has a definite enhancing effect on vaccinia infection in rabbits."

*Coraggio et al. D12,550/61*: Aldosterone inhibits the reproduction of vaccinia virus in vitro.

*Lieberman et al. F67,288/66*: In mice, cortisone did not inhibit the protection offered by N-ethylisatin- $\beta$ -thiosemicarbazone against neurovaccinia virus. However, it did depress interferon formation.

#### **Variola ←**

*Cilli et al. D12,192/61*: In sheep, STH, owing to its prophlogistic effect, delimits the lesions produced by variola virus. ACTH and dexamethasone exert an opposite effect.

*Pecori et al. D12,549/61*: Aldosterone protects the rabbit against inoculation with smallpox virus.

#### **Varia ←**

*Altucci et al. D65,818/62*: Review and personal observations on the effect of various glucocorticoids upon viral infections in vivo and in vitro.

*Smart & Kilbourne G33,810/66*: In chick embryos infected with various viruses, cortisol diminishes interferon formation but its effect upon survival depends upon experimental circumstances.

*Poel H23,662/68*: Review of the literature with personal observations on the co-carcinogenic effect of folliculoids and luteoids. Neither of these groups of steroids are truly carcinogenic in themselves but they enhance mammary cancer development under the influence of viral and chemical carcinogens. [The possible mechanism of these interactions is not discussed (H.S.).]

#### **Fungi and Yeasts ←**

Resistance to *Candida albicans* infection is decreased by cortisone in the mouse and rabbit. Testosterone allegedly enhances, whereas STH counteracts, this deleterious effect of cortisone in mice.

Cortisone also aggravates infection with *Trichophyton mentagrophytes*, *Histoplasma capsulatum* and various other fungi in several species of animals.

**Bronchopulmonary Aspergillosis** ←

*Sandhu et al. G75,603/70:* In mice, bronchopulmonary aspergillosis produced by inhalation of various species of these fungi was greatly enhanced by cortisone.

**Candida Albicans (monilia)** ←

*Roth et al. C32,916/56:* Pretreatment with cortisone or X-rays, singly or in combination, reduces the inherent resistance of mice to infection with *Candida albicans*.

*Scherr C39,263/57:* In mice infected with *Candida albicans*, the development of moniliasis may either be increased or decreased by cortisone depending upon various factors, particularly sex, pregnancy, or the severity of the infection. Testosterone enhanced and STH counteracted the deleterious effect of cortisone. Gonadotrophin (pregnant mare's serum) was without effect.

*Henry & Fahlberg C81,623/60:* Repeated i.p. injections of cortisol (unlike a single dose) aggravate monilial infection in mice.

*Louria et al. C91,764/60:* "Monilial infections in mice were enhanced to a far greater degree by cortisone than were infections due to *Histoplasma capsulatum* or *Cryptococcus neoformans*."

*de Mitri et al. D64,042/63:* In rabbits intrabronchially inoculated with *Candida albicans*, cortisone treatment causes: "1. a quicker onset of necrosis; 2. a larger extension

of tissue alterations with a tendency to haematic diffusion (which could never be established in animals not treated with cortisone); 3. late occurrence of a reduced defense reaction of the mesenchyma."

*Nishikawa G73,894/69:* In germ-free mice, cortisone decreases host resistance so that oral inoculation with *Candida albicans* results in stomach ulcers in which the organisms proliferate.

**Histoplasma Capsulatum** ←

*Vogel et al. C10,597/55:* In guinea pigs, cortisone failed to cause significant aggravation of the infection following inoculation with *Histoplasma capsulatum*.

*Grunberg & Titsworth D67,985/63:* Cortisone i.m. enhances the susceptibility of mice to infection with *Histoplasma capsulatum*.

**Trichophyton Mentagrophytes** ←

*Kligman et al. G64,164/51:* In guinea pigs, infection with *Trichophyton mentagrophytes*, vaccinia virus and *Staphylococcus aureus* is adversely influenced by cortisone.

**Varia** ←

*Piantoni C38,892/55:* An extensive review of the literature and personal observations on rabbits and rats lead to the conclusion that cortisone does not cause normally apathogenic fungi to become virulent, but greatly enhances the virulence of normally pathogenic fungi.

**Parasites** ←

**Protozoa** ←. As judged by observations on different animal species many protozoan infections are adversely influenced by glucocorticoids. Among these are infections with various strains of *Ameba*, *Besnoitia*, *Eimeria mivati* and *meleagriditis*, various forms of *Plasmodia*, *Trypanosomes* and *Toxoplasma*.

Steroids devoid of glucocorticoid activity have only rarely been noted to exert any pronounced influence on protozoan infections. Yet, it has been claimed that orchidectomy increases the severity of *Trypanosoma lewisi* infection in rats, although not to the same extent as adrenalectomy.

**Worms** ←. Glucocorticoids also diminish resistance against infestation with various worms such as *Ancylostoma caninum*, *Fasciola hepatica*, *Hymenolepis nana*, *Schistosoma mansoni* (*Bilharzia*), *Trichinella spiralis* and *Trichuris muris*. On the other hand, allegedly, under certain conditions progesterone may beneficially affect bilharziosis in the mouse, although among 30 steroids tested all folliculoids and testoids were ineffective in this respect.

**Protozoa ←**

**Ameba ←.** *Teodorovic et al. D52,087/63:* In the guinea pig, amebiasis is aggravated by cortisone or cortisol.

**Besnoitia ←.** *Frenkel C13,371/56:* The adrenal necrosis produced by *Besnoitia jellisoni* (an obligate intracellular protozoan organism) is inhibited by cortisol, corticosterone, 11-dehydrocorticosterone and possibly by DOC. This is associated with a depression of general immunity. The organisms do not proliferate around sites of corticosterone, DOC, testosterone or epinephrine injections. "It is postulated that certain glucocorticoids can so modify immunity mechanisms locally, that general immunity becomes ineffective."

*Frenkel C52,043/58:* Hamsters inoculated s.c. with the intracellular protozoan *Besnoitia jellisoni* recovered owing to sulfadiazine treatment. However, latent infection persisted and relapses could be precipitated by a subsequent treatment with cortisone, cortisol, prednisone or prednisolone. The relapse phenomenon is recommended for the assay of the immuno-depressing activity of corticoids.

*Frenkel C84,036/60:* Chronic latent *Besnoitia* infection in Golden hamsters is greatly enhanced by glucocorticoids (22 modified luteoids and corticoids have been tested). The procedure is suitable for the routine assay of pro-infectious activity.

**Eimeria ←.** *McLoughlin G73,149/69:* In chickens, dexamethasone permits *Eimeria meleagridis* to complete its development, whereas this is not the case in untreated chickens or in either dexamethasone treated or untreated turkeys.

*Rose G73,104/70; Long & Rose G72,642/70:* In partially immunized chickens, betamethasone increases oocyst production and extends the patent period of *Eimeria mivati* infection. In fully susceptible chickens, betamethasone had a similar but less pronounced effect, presumably because the major action of the steroid is to reduce acquired immunity to this form of coccidiosis.

**Plasmodia (malaria) ←.** *Bennison & Coatsney B17,600/48:* Following inoculation with *P. gallinaceum*, the parasite counts are much higher in females than in males. This difference in parasite count was not significantly influenced by testosterone or estradiol.

*Overman et al. B49,805/49:* An adrenocortical extract prolongs survival of monkeys infected with *P. knowlesi*.

*Redmond B67,882/52:* Cortisone increases susceptibility to malaria in pigeons infected with *P. relictum*.

*Jackson C11,604/55:* Cortisone delays the course of *Plasmodium berghei* malaria in rats but increases mortality.

*Cox G64,797/68:* In mice, betamethasone suppresses the acquisition of immunity to infection with *Plasmodium vinckei* but has no effect once immunity is established.

**Trypanosoma Cruzi ←.** *Pizzi & Chemke C34,555/55:* In rats, cortisone aggravates the course of infection with *Trypanosoma cruzi*. The mechanism of this resistance and its histopathologic characteristics are extensively discussed.

*Rubio C34,556/55:* In mice, cortisone aggravates the course of *Trypanosoma cruzi* infection.

*Sommer C9,937/55:* The cortisone-induced increase in the susceptibility of mice to *Trypanosoma cruzi* infection is not abolished by STH.

*Rubio C41,052/56:* In mice, cortisone treatment during the first days after *Trypanosoma cruzi* inoculation did not significantly affect the course of the infection.

**Trypanosoma Equiperdum ←.** *Scott et al. 15,446/33:* The resistance of intact guinea pigs to diphtheria toxin or that of rats to *Trypanosoma equiperdum* or mice to infection with *Pneumococcus Type I* was not influenced by pretreatment with large amounts of a life-maintaining adrenocortical extract ("cortin"). It does not appear to be possible to raise resistance above normal in intact animals but there is considerable evidence to show that various types of intoxication and infection cause structural damage to the adrenal and interfere with its function.

*Cantrell C64,723/59:* Cortisone does not significantly influence infection with *Trypanosoma equiperdum* in the rat.

**Trypanosoma Lewisii ←.** *Perla & Marmorston-Gottesman 810/30:* In young rats, thymectomy diminishes, whereas orchidectomy increases, the severity of *T. lewisii* infection.

*Perla & Marmorston-Gottesman 10,865/31:* Intact rats infected with *T. lewisii* rarely succumb, whereas in adrenalectomized animals the infection is usually fatal, although the bacterial growth is not modified. The authors attributed this mortality to the toxicity of the flagellate.

*Herbert & Becker G63,454/61:* In rats, cortisone does not cause inhibition of the production of Taliaferro's antibody, albastin, or

of its maintenance after infection with *T. lewisi*. Cortisone does not appear to exert a deleterious effect on antibody production or maintenance and, if anything, it diminishes the duration of the infection.

*Sherman & Ruble G49,628/67*: In rats, pretreatment with cortisone diminishes resistance to *T. lewisi*, presumably as a consequence of impaired host immune responses.

*Patton & Clark G73,195/68*: In rats infected with *T. lewisi*, dexamethasone resulted in the development of exceedingly large populations of trypanosomes which were fatal to their hosts. This effect of dexamethasone is ascribed to the inhibition of the production of ablastin and trypanocidal antibodies.

**Toxoplasma** ←. *Frenkel C34,875/57*: Combined treatment with cortisone and X-rays diminished the resistance of Golden hamsters with the RH strain of toxoplasma and significantly depressed acquired immunity.

*Giroud et al. D68,563/62*: Various strains of toxoplasma, harmless for untreated rats, become virulent following treatment of the animals with glucocorticoids.

### Worms ←

**Ancylostoma Caninum** ←. *Sen et al. F76,261/65*: Pretreatment with cortisone increased the susceptibility of mice to infection with *Ancylostoma caninum* perhaps by suppression of immunity. The effect of glucocorticoids upon infestation with other worms is reviewed.

**Bilharzia** ← *cf. Schistosomiasis*.

**Fasciola Hepatica** ←. *Sinclair G65,622/68*: In sheep infected with *Fasciola hepatica*, the growth of the flukes and the development of extensive hepatic hemorrhages with severe clinical signs was aggravated by dexamethasone but the usual splenomegaly and hepatic fibrosis were prevented by this glucocorticoid.

**Hymenolepis Nana** ←. *Pinto D23,719/60*: *Hymenolepis nana* type "M" is a natural parasite of the mouse; the rat is resistant to it, unless it is pretreated with cortisone.

**Schistosomiasis** ←. *Nagata et al. D26,285/56*: Cortisone increases the susceptibility of the mouse to infection with *S. japonicum*.

*Coker C42,296/57*: Cortisone does not significantly alter the susceptibility to infestation with *S. mansoni* in the mouse, as judged by the number of worms recovered from the portal circulation.

*Lagrange D57,434/62*: Combined treatment with ultrasound + progesterone +

estradiol protects the mouse against bilharziosis following infection with *S. mansoni*. None of these agents alone nor testosterone + ultrasound were effective.

*Lagrange D69,093/63*: In mice, a protective effect against *S. mansoni* has been obtained by progesterone, dexamethasone and its 16 $\beta$ -isomer (celestone), as well as by the hormonally inactive 21-acetoxy-nor-12-prednisone (Win 1303). Among 30 steroids tested, all folliculoids and testoids were negative, pregnan-derivatives appeared to show anti-bilharziosis activity irrespective of their steroid hormone actions. The mechanism of this protection is not known, but bilharziosis in the mouse leads to a transformation of the liver "into a veritable sponge loaded with eggs surrounded by tubercles. The circulation of the liver and intestine is greatly disturbed at the same time by the accumulation of the eggs in the mesenteric venules and the resulting phlebitis." Mortality is ordinarily 100% within 1–15 months. Even in mice killed after 6–10 months in apparently good health, adult worms are eliminated but are atrophic and sterile. It is assumed that the protective steroids act upon the parasites themselves.

**Trichinella Spiralis** ←. *Coker C48,693/56*: In mice immunized against *Trichinella spiralis*, cortisone abolishes established immunity as judged by adult worm counts in the small intestine and suppression of the characteristic cellular response following a challenging infection of immune controls.

*Ritterson C78,122/59*: Chinese hamsters which possess an innate resistance to *Trichinella spiralis* can be infected with this organism following pretreatment with cortisone.

*Howard et al. D22,789/62*: In rats, "the anti-inflammatory effect of cortisone appears to inhibit the cellular reaction seen in trichinous myocarditis and this may impair the destruction and removal of the migrating larvae."

*Pawlowski G65,301/68*: In the rat, the development of trichinella infestation is not influenced by DOC, but enhanced by norandrostrenolone (Durabolin). [The brief abstract gives no experimental details (H.S.).]

**Trichuris Muris** ←. *Campbell & Collette D61,500/62*: Cortisone enhances infection with the whipworm *Trichuris muris* in the mouse. Perhaps "the normal refractoriness of albino mice to this infection may be the result of inflammation of the gut evoked by parasitic invasion or associated immunologic phenomena."

*BACTERIAL TOXINS* ←← *Corticoids*

In chick embryos, hemorrhages and mortality occur after inoculation of various endotoxins into the chorio-allantoic membrane. These effects are inhibited by cortisone, cortisol, fluorocortisol and aldosterone; DOC, prednisolone and cholesterol are inactive in this respect. Thus, there does not appear to be any close relationship between this protective action and the classic, glucocorticoid and mineralocorticoid, effects of steroids.

Cats can be protected against fatal endotoxin shock by aldosterone given i.v. 30 min after endotoxin, but no such protection is observed if the aldosterone is administered 30 min before or simultaneously with the endotoxin.  $3\beta,16\alpha$ -Dihydroxy-allopregnan-20-one competitively antagonizes this protective action. Although cortisol and prednisolone also afford some protection against endotoxin shock, aldosterone is about 100 times more active than these glucocorticoids. When aldosterone is incubated with *E. coli* endotoxin, it allegedly diminishes the toxicity of the latter as judged by in vivo tests on cats. It has been suggested "that aldosterone combines with, or otherwise alters the chemical structure of the endotoxin."

In dogs, cortisone failed to modify the circulatory failure produced by meningococcus toxin. As regards *E. coli* endotoxin shock, the results reported are contradictory. Most investigators stated that glucocorticoids, particularly cortisol and prednisolone, do improve survival and counteract circulatory shock to some extent but the best results are obtained if glucocorticoids are given in combination with some vasoactive drugs such as metaraminol, hydralazine or isoproterenol. In 6–9 day old beagles, cortisol sodium succinate given i.v. one hour before a lethal dose of *E. coli* endotoxin increased the survival rate, whereas it offered no protection if given immediately after endotoxin.

According to one team of investigators, aldosterone does not prevent endotoxin shock in the dog as it does in the cat; however, since the assay technique was not the same, this difference cannot be ascribed entirely to an essentially distinct reaction form of the two species.

Early investigations on the effect of adrenocortical extracts upon diphtheria intoxication in guinea pigs have yielded contradictory results. More recently it was found that neither ACTH nor cortisone improves the resistance of the guinea pig to diphtheria toxin (or of mice to Shiga and meningococcus toxin). However, the subnormal diphtheria-toxin resistance of the hypophysectomized guinea pigs is restored to normal by cortisone.

Allegedly the bronchoconstriction induced by *S. typhosa* endotoxin in guinea pigs can be prevented by prednisolone, but this observation requires confirmation.

In monkeys both cortisol and aldosterone (the latter especially when given in combination with angiotensin) offer some protection against the vascular collapse of endotoxin shock.

The literature on the effect of corticoids upon endotoxin shock in mice is extremely voluminous and contradictory. Apparently the results depend not only upon the type of corticoid given but also upon numerous other technical details (e.g., dose, timing, route of administration of the toxin and corticoid, age and strain of the

mice). Hence, it is virtually impossible to arrive at meaningful generalizations beyond the conclusion that under most experimental conditions, glucocorticoids offer definite protection against various endotoxins.

Curiously, pertussis vaccine abolishes the ability of cortisone to protect mice against endotoxin.

In most respects the endotoxins of various bacteria exhibit essentially similar toxic effects; yet, considerable differences appear to exist between various preparations as regards the ability of corticoids to inhibit their toxicity. It is noteworthy that mice protected by cortisone against an initial lethal challenge with *Brucella* endotoxin, still develop resistance to subsequent challenge by a second injection of the same endotoxin. Apparently, the manifestations of shock are not necessary for the acquisition of resistance.

Pregnancy diminishes resistance of mice to *S. enteritidis* endotoxin; at the same time the protective effect of cortisone is also inhibited. 5-HT is said to protect against endotoxin and to augment the prophylactic effect of cortisol at otherwise ineffective dose levels.

There appears to be some relationship between the induction of resistance and the hepatic glycogen stores; the latter are depleted by endotoxin and increased by cortisone.

The toxicity of staphylococcal  $\alpha$ -toxin was prevented by pretreatment with either cortisol or alloxan, whereas tolbutamide increased sensitivity to  $\alpha$ -toxin. Again the protective action of cortisol was ascribed to its gluconeogenic effect which antagonizes the hypoglycemia induced by the  $\alpha$ -toxin.

The amyloidosis produced by chronic treatment with endotoxins is also prevented by cortisone. The hepatic glycogen-depleting effect of endotoxin is inhibited by cortisone. Aminoglutethimide (an inhibitor of corticoid biosynthesis) increases susceptibility to endotoxin as well as the associated hepatic glycogen depletion but cortisone combats even the glycogen-depleting effect of this combined treatment. Similarly, methylprednisolone increases resistance to endotoxin even if the toxicity of the latter is enhanced by concurrent treatment with certain antitumor antibiotics.

The increased endotoxin susceptibility induced by zymosan is abolished by cortisone, perhaps as a result of an antagonistic interaction at the level of the RES. On the other hand, cortisone fails to alter the clearance of radioactive endotoxin from the blood or tissues.

Reserpine inhibits the protection against endotoxin that is induced in intact mice by cortisone. (The same is true in adrenalectomized but not in hypophysectomized rats. Apparently reserpine interferes with the cortisone effect only in the presence of the pituitary.)

Stress (cold) decreases the resistance of the mouse to endotoxin (perhaps owing to a "depletion of corticoid reserves") but cortisone protects even against the combined effect of stress + endotoxin.

Aldosterone exhibited no protective value against the lethal effect of *Clostridium welchii*  $\alpha$ -toxin in the mouse, perhaps because corticoids are effective only against endotoxins, not against exotoxins.

Aldosterone admixture to tetanus toxin *in vitro* protects the mouse against the shock.

In rabbits, the febrile response to diphtheria endotoxin is diminished by 48 hrs pretreatment with repeated large doses of cortisone or ACTH; pretreatment during 24 hrs with smaller doses of these hormones exerts an opposite effect. This dependence upon dosage and timing may explain the discrepancies in earlier reports on the effect of glucocorticoids upon endotoxin reactions.

Cortisone also prevents the early reaction of prostration and death produced by endotoxin i.v. but in some rabbits pretreated for three days with this hormone, a generalized Shwartzman response-like renal cortical necrosis occurred within 24 hrs after endotoxin administration. When a single injection of cortisone was given 6 hrs before the endotoxin, prostration and death were prevented without subsequent development of renal cortical necrosis.

In the rabbit, endotoxin shock is associated with a release of hepatic lysosomal acid hydrolases. This effect is likewise prevented by glucocorticoids but not by DOC, presumably because only the former stabilize lysosomal membranes.

The topical response to intradermal or intraconjunctival injection of endotoxin is also inhibited by cortisone in rabbits, but this may well be merely a manifestation of the antiphlogistic effect.

Observations on rats gave contradictory results; whereas some authors state that this species can be protected against endotoxin shock by glucocorticoids, others reported negative results, apparently owing to differences in timing and dosage. However, there appears to be little doubt that, under optimal experimental conditions, glucocorticoids can protect the rat against endotoxin shock. DOC is devoid of this effect.

A dose of meningococcus toxin, well tolerated by normal nonpregnant rats, produces eclampsia-like hemorrhagic lesions in the liver of pregnant or cortisone pretreated animals. On the other hand, in rats kept on hyperlipemic diets, the induction of hepatic vein thromboses by *S. typhosa* endotoxin is inhibited by cortisol and prednisolone.

The ability of glucocorticoids to protect against various types of endotoxin may differ but there is no definite proof of this. The great variability of the results appears to depend not upon the kind of endotoxin used but upon other hitherto unidentified factors. We found considerable variation in the prophylactic effect of glucocorticoids even in experiments in which all controllable factors (steroid, endotoxin, timing, strain, age and sex of rats) were identical. In our laboratory, the most reliable results were obtained in rats heavily overdosed by cortisol, cortisone, triamcinolone, dexamethasone, betamethasone, prednisolone or cortisol 21-sodium succinate 1–4 days before the i.v. injection of a near lethal dose of *E. coli* endotoxin.

In man, endotoxin shock appears to be particularly well prevented by combined treatment with glucocorticoids and vasoactive agents, especially metaraminol.

In summary, it may be said that under suitable experimental conditions glucocorticoids undoubtedly offer considerable protection against shock produced by diverse endotoxins in various species. Since the clearance of radioactive *E. coli* endotoxin is not significantly altered by cortisone, it was concluded that the corticoids act "by their physical presence," presumably through a syntoxic effect upon the host's tissues. The protection is not merely a "nonspecific anti-stress effect" as no similar protection is offered under identical conditions against many other stressors.

There appears to be no clear-cut relationship between the glucocorticoid and anti-endotoxic activity of steroids. For example, prednisone and prednisolone are considerably more potent antiphlogistics than cortisol, yet they exhibit essentially the same anti-endotoxic effect as the latter. However, to some extent, the two pharmacologic actions tend to run parallel. The singularly strong anti-endotoxic effect of aldosterone is exhibited only in certain species and appears to depend mainly on the immediate effect of this hormone upon the circulation.

### ← *Adrenalectomy*

It has been known, even before the description of the stress syndrome, that adrenalectomized rats are particularly sensitive to bacterial endotoxins. Subsequently, the important role played by the adrenal in this connection has been confirmed in various species both by the decrease in endotoxin resistance induced by adrenalectomy and by the efficacy of corticoid substitution therapy.

In adrenalectomized mice, the lethal effect of *Brucella* endotoxin could be inhibited by cortisone, cortisol, fluorocortisol, and aldosterone, in decreasing order of activity. Indeed, the protective effect of corticoids against the lethal action of endotoxin in adrenalectomized rats has been recommended as the basis for the bioassay of these hormones, although it was recognized that the anti-endotoxin and antiphlogistic effects do not run strictly parallel.

In mice, endotoxin resistance is greatly decreased a few hours after adrenalectomy or hypophysectomy; however, while cortisone protects normal, adrenalectomized or hypophysectomized animals against high doses of endotoxin, chlorpromazine is effective only in the presence of both the adrenals and the pituitary.

It is particularly important to note that following total sympathetic blockade (adrenal demedullation combined with blockade or depletion of catecholamines), mortality from both histamine and endotoxin is as markedly increased in rats as by complete adrenalectomy. Pretreatment with epinephrine alone suffices to counteract the lethality of endotoxin and histamine after sympathetic blockade. Cortisone alone only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection. Presumably, sympathetic stimulation is the first line of defense against the vasomotor disturbance induced by endotoxin or histamine. By contrast, the lethal effects of other stressors (formalin, tourniquet shock) though likewise increased by adrenalectomy cannot be aggravated by mere sympathetic blockade. On the other hand, cortisone alone counteracts the toxicity of these latter stressors after adrenalectomy. Apparently, "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

### ← *Luteoids*

The resistance of the mouse to *S. enteritidis* endotoxin is allegedly diminished by progesterone, whereas in the cat, progesterone given conjointly with, or 30 min after, endotoxin stabilizes the blood pressure and prolongs survival. These observations require confirmation.

← **Testoids**

Comparatively few studies have been carried out concerning the effect of testoids upon endotoxin resistance and even these yielded contradictory results. It appears, however, that 4-chlorotestosterone may increase the resistance of the guinea pig to diphtheria endotoxin under certain experimental conditions.

← **Folliculoids**

Even before pure folliculoids were available, it had been reported by several investigators that follicular fluid of cow's ovaries or crude folliculoid extracts can protect the mouse against tetanus toxin or the guinea pig against diphtheria toxin.

In rats, considerable protection against the lethal effect of endotoxin was allegedly obtained by conjugated estrogens given 30—60 min before endotoxin.

This protection, which lasts only a few hours, has been ascribed to the liberation of corticoids by the adrenal cortex under the influence of folliculoids. However, this interpretation must take into account that under identical conditions, the folliculoids are even more active than cortisol. Furthermore, if folliculoids are administered 24 hrs before the endotoxin they actually reduce resistance to the latter and predispose to the production of hepatic necroses.

← **Other Steroids**

That there is no close parallelism between glucocorticoid and anti-endotoxic activity among steroids is well illustrated by the observation that 19-oxoprogesterone and aldosterone are highly effective in preventing endotoxin shock in the cat, although they have no glucocorticoid potency. In fact, 19-oxoprogesterone is also devoid of anti-inflammatory and salt-retaining properties.

**Bacterial Toxins** ← cf. also Selye B40,000/50, p. 68; E5,986/66, pp. 14, 75, 81, 82; G60,083/70, pp. 347, 354.

← **Corticoids.**

## CHICKEN

Smith & Thomas C5,334/55: In chick embryos, the hemorrhages and death caused by inoculation of endotoxins into the chorio-allantoic membrane, were inhibited by cortisone or cortisol administered simultaneously in the same manner.

Smith & Thomas C97,047/56: In chick embryos, the lethal effect of various endotoxins is prevented by cortisone, cortisol and F-COL but not by DOC, prednisone or cholesterol.

Dooley & Holtman C84,689/59: In chicks, the hypoglycemia and fever produced by

Salmonella pullorum endotoxin are inhibited by cortisone. However, both endotoxin and cortisone produce similar patterns of non-protein nitrogen excretion.

Wyler et al. D5,696/60: In the chick embryo, dexamethasone is 1000 times more active than cortisone in preventing fatal endotoxin poisoning. Aldosterone is about as active as cortisone, whereas prednisolone is somewhat more so. DOC is inactive. "Since aldosterone, like the anti-inflammatory steroids, influences the carbohydrate metabolism, this property is discussed as an underlying common denominator for the observed effect."

## CAT

Bein & Jaques D41,862/60: Cats can be protected against fatal endotoxin shock by

aldosterone i.v. However, 3 $\beta$ ,16 $\alpha$ -dihydroxy-allopregnan-20-one exerts a competitively antagonistic effect on this protective action of aldosterone. To a lesser extent, cortisol and prednisolone also afford protection, whereas corticosterone and DOC are inactive. Aldosterone was 100 times more active than cortisol or prednisolone, but in contrast to the latter, it also offered protection in advanced stages of endotoxin poisoning. In guinea pigs, all the corticoids tested offered protection. Furthermore, pretreatment with aldosterone "protects mice against the lethal action of *E. coli* or *S. typhimurium* toxin as well as against that of hemorrhagic snake venoms (*Vipera aspis*, *Crotalus adamanteus*), but not against the neurotoxic venom of *Naja tripudians*. Prednisolone, which is effective to roughly the same degree in the mouse as in the rat, has to be administered in doses some 10–30 times larger, whereas hydrocortisone and cortexone [DOC] display no protective action, even in high dosage."

*Bondoc et al. D69,984/62*: In cats, aldosterone given 30 min after endotoxin prolonged survival, and frequently even prevented death. No such protection was observed when aldosterone was given 30 min before, or simultaneously with, endotoxin.

*Hayasaka & Howard G10,112/63*: In the cat, aldosterone administered 30 min after an otherwise fatal dose of *E. coli* endotoxin increased survival. On the other hand, when aldosterone was incubated with diphtheria toxin it did not prevent the development of a positive Schick test when the mixture was injected into non-immunized guinea pigs. Furthermore, aldosterone given to immunized guinea pigs did not prevent the antigen-antibody reaction upon subsequent injection of diphtheria toxin.

*Hayasaka & Howard D31,136/63*: "d-Aldosterone, when incubated for 30 minutes at 37° C. with the lipopolysaccharide derived from *E. coli*, appears to reduce the resulting toxicity of the endotoxin as measured by the survival rate in cats. The possibility that aldosterone combines with, or otherwise alters, the chemical structure of the endotoxin is suggested."

*Hayasaka et al. E31,522/63*: Aldosterone and, to a lesser extent, cortisol given 30 min after endotoxin, protect the cat against lethal shock. Earlier literature on the prevention of endotoxin shock by various corticoids is reviewed.

## Dog

*Ebert et al. E56,239/55*: In dogs, cortisone failed to modify the effect of meningococcus toxin on the circulation. Apparently "adrenal insufficiency was not playing an important role in the production of circulatory failure following the administration of meningococcus toxin."

*Lillehei & McLean D59,725/58; D84,873/59*: In dogs, cortisol treatment increased survival from endotoxin shock.

*Melby et al. C65,221/59*: In dogs, *E. coli* endotoxin i.v. raises SGOT presumably as a consequence of cellular injury and this effect can be prevented by cortisol.

*Vick C84,708/60*: In dogs, survival from shock due to *E. coli* endotoxin is prolonged by cortisol, especially if given in combination with metaraminol.

*Weil & Miller D97,273/60; Weil C91,305/60*: In dogs, both metaraminol and prednisolone increased survival after treatment with *E. coli* endotoxin. The best results were obtained by combined treatment with prednisolone and metaraminol.

*Longerbeam & Lillehei D3,868/61*: In dogs, pretreatment with cortisone did not appreciably alter the disturbances in intestinal hemodynamics caused by endotoxin shock. However dibenzylamine did ameliorate them, and catecholamines aggravated them. Apparently "the protective action of cortisone is not mediated through a hemodynamic mechanism."

*Spink & Vick C98,717/61*: In the dog, endotoxin shock could not be prevented by cortisol unless metaraminol was simultaneously administered.

*Vick & Spink D43,929/61*: Canine endotoxin shock is effectively combated by cortisol + a pressor drug. Addition of hydralazine to this combination further augments its beneficial effect.

*Smith et al. D18,862/64*: Large doses of cortisol improved blood pressure, cardiac output and survival in canine endotoxin shock.

*Vick F48,509/65*: In the dog, cortisol and/or isoproterenol cause temporary improvement in endotoxin shock but no increase in survival time.

*Vick et al. F58,531/65*: In dogs, survival from endotoxin shock was not significantly altered by cortisol.

*Hinshaw et al. F65,403/66*: Observations on perfused organ preparations of dogs "suggest that prednisolone exerts significant vascular effects on both hepatic and forelimb vascular beds in endotoxin shock."

*Thomas & Brockman F 82,789/66*: In dogs, survival in lethal endotoxin shock was prolonged by pretreatment with methylprednisolone or cortisol but post treatment with the same glucocorticoids hastened death. Aldosterone was without effect. "These studies do not support the use of steroids in endotoxin shock."

*Lillehei et al. G 45,335/67*: Cortisol given 30—60 min after endotoxin greatly reduces mortality from shock in the dog.

*Loggie et al. F 99,839/68*: In 6—9 day old beagles, cortisol sodium succinate i.v. one hour before i.v. injection of lethal doses of *E. coli* endotoxin increased the survival rate, whereas given immediately after endotoxin, the glucocorticoid offered no protection.

*Motsay et al. H 32,852/70*: In dogs, massive doses of glucocorticoids (e.g., methylprednisolone) can offer protection against circulatory shock produced by overdosage with epinephrine or endotoxin. The prophylactic effect is ascribed primarily to a protection of the microcirculation.

#### GUINEA PIG

*Scott et al. I 5,446/33*: The resistance of intact guinea pigs to diphtheria toxin or that of rats to *Trypanosoma equiperdum* or mice to infection with *Pneumococcus* Type I was not influenced by pretreatment with large amounts of a life-maintaining adrenocortical extract ("cortin"). It does not appear to be possible to raise resistance above normal in intact animals but there is considerable evidence to show that various types of intoxication and infection cause structural damage to the adrenal and interfere with its function.

*Zwemer & Jungeblut 53,287/35*: Pretreatment with an adrenocortical extract containing the "life maintaining principle" protects guinea pigs against the cutaneous necrosis elicited by i.c. injection of diphtheria toxin. The lethal effect of s.c. injected diphtheria toxin in guinea pigs is diminished upon incubation with the adrenocortical extract in vitro at room temperature.

*Berger 95,075/37*: Contrary to earlier claims, it has not been possible to combat diphtheria intoxication in guinea pigs by adrenocortical extracts in combination with vitamin C.

*Schmidt 94,670/37*: In guinea pigs, infection with diphtheria bacilli or intoxication with diphtheria toxin can be combated by adrenocortical extracts in combination with vitamin C.

*de Marchi A 30,837/38*: In guinea pigs, adrenocortical extract offers partial protection against diphtheria toxin.

*Murray & Brankham B 65,414/51*: Neither ACTH nor cortisone improved the resistance of guinea pigs to diphtheria toxin or of mice to Shiga and meningococcus toxin.

*Tonutti B 69,136/52*: Although cortisone normalizes the low diphtheria toxin resistance of hypophysectomized guinea pigs, it does not raise the resistance of intact guinea pigs above normal.

*Brainerd & Scaparone B 87,957/53*: In guinea pigs, cortisone failed to influence the lethal effect of diphtheria toxin or to prevent its neutralization by diphtheria antitoxin in vivo.

*Boquet et al. E 52,759/56*: In guinea pigs, cortisone may either increase or decrease resistance to typhoid endotoxin, depending upon dosage.

*Nola et al. C 33,308/57*: In guinea pigs, cortisone pretreatment failed to protect against inoculation of live diphtheria organisms or diphtheria toxin.

*Farrar & Magnani F 6,647/64*: Homogenates of normal guinea pig liver rapidly detoxify endotoxins in vitro, whereas homogenates of livers damaged by  $\text{CCl}_4$  do not. Adrenalectomized animals are notoriously sensitive to endotoxin, but pretreatment of guinea pigs with testosterone or cortisone does not influence their resistance to toxic doses of endotoxin and hence the detoxifying ability of the liver does not appear to be under steroid control.

*Batlivala & Deshpande G 43,844/66*: In guinea pigs, cortisone can protect the myocardium, liver, kidney and suprarenals against damage induced by diphtheria toxin.

*Kovács & Görög H 2,570/68*: *Salmonella typhosa* endotoxin i.v. induces a bronchoconstriction in guinea pigs; this can be prevented both by antihistamine and by prednisolone.

#### MONKEY

*Spink et al. D 61,007/63*: In Mangabey monkeys, *E. coli* endotoxin produces hypotension, oliguria, hyperkalemia and death. These effects are counteracted by aldosterone, especially in combination with angiotensin.

*Vick et al. E 20,146/63*: In the dog and monkey, cortisol helped to maintain the arterial blood pressure during endotoxin shock.

## MOUSE

*Singer B 316/40*: Mice are protected against *Clostridium welchii* toxin i.p. by pretreatment with DOC s.c.

*Beck & Voloshin B 58,271/50*: In mice, tolerance for *Serratia marcescens* tumor-necrotizing polysaccharide is increased by cortisone.

*Jackson & Smadel B 77,408/51*: In intact mice, neither ACTH nor cortisone pretreatment raised resistance to the toxins of *R. tsutsugamushi*, *R. prowazeki* or *S. typhosa*.

*Jackson & Smadel E 52,720/51*: Intact mice pretreated with cortisone or ACTH "were given lethal amounts of the toxins of *R. tsutsugamushi*, *R. prowazeki*, or *S. typhosa*. Such animals were as susceptible to the toxins as normal controls. Neither hormone had any therapeutic effect in mice infected with *R. tsutsugamushi*. Furthermore, treated and untreated mice in a terminal phase of infection with *R. tsutsugamushi* were equally susceptible to the toxin of this rickettsia when injected intravenously. In the current experiments the adrenal cortex of normal or infected animals apparently contributed as effectively as possible in the host's response to rickettsial or bacterial toxins and further stimulation was without advantage."

*Chédid et al. B 91,161/52*: DOC does not alter the resistance of the intact or adrenalectomized mouse to *S. enteritidis* endotoxin but progesterone diminishes it considerably.

*Boyer & Chédid C 624/53*: Cortisone protects the mouse against lipopolysaccharide antigens or infections with germs possessing such antigens, such as *S. typhi*, *Neisseria meningitidis*. Cortisone does not protect against the infection with *E. coli*, *Shigella dysenteriae*, although they also possess lipopolysaccharide antigens, nor against *Staphylococcus aureus*, *Streptococcus pyogenes*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*, which do not possess such antigens. Cortisone is also ineffective against the exotoxins of diphtheria, tetanus or dysentery organisms.

*Greene et al. B 94,257/53*: In mice, cortisone or DOC did not significantly affect the response to tetanus toxin or tetanus spore infection.

*Maral C 17,604/53*: Cortisone is highly effective in combating endotoxin poisoning in the mouse but comparatively less potent against tetanus toxin. It has no effect upon diphtheria intoxication in the guinea pig or *Cl. histolyticum*-toxin poisoning in mice. The

effect of cortisone is compared with that of chlorpromazine in all these tests.

*Parker et al. D 77,476/53*: In mice and guinea pigs, cortisone failed to alter the effect of diphtheria tetanus and botulinum toxins.

*Chédid C 1,930/54*: Pertussis vaccine abolishes the ability of cortisone to protect the mouse against endotoxin. The protective effect of chlorpromazine is also abolished.

*Chédid C 622/54*: Pertussis vaccine sensitizes the intact mouse both to histamine and to typhoid endotoxin. Under these conditions, both promethazine and cortisone protect the animals against fatal doses of histamine but not against endotoxin. In adrenalectomized mice, cortisone does protect against endotoxin.

*Geller et al. B 98,147/54*: Cortisone offers definite protection in mice given otherwise lethal doses of *Escherichia intermedium* endotoxin. In order to be effective, cortisone must be injected simultaneously with or before the endotoxin. Complicating transient bacteremia, presumably of intestinal origin, can be suppressed by antibiotics. Interference by antibiotics with cortisone protection was demonstrable only when the antibiotics were given after cortisone.

*Spink & Anderson B 95,168/54*: Cortisone protects mice against the lethal effect of *Brucella* endotoxin.

*Gallut C 14,519/55*: Mice can be protected against fatal intoxication with cholera *Vibrio* endotoxin by cortisone or ACTH but the degree of protection depends upon dosage and timing.

*Barbazza C 13,021/55*: Pretreatment with cortisol protects the mouse against fatal intoxication with typhoid endotoxin. [In the Italian text, the animals are described as "topi" which may mean rat or mouse; they are said to have weighed 20 g which would suggest mice, but in the foreign language summaries, they are consistently referred to as rats, which makes interpretation difficult (H.S.).]

*Biozzi et al. E 22,483/55*: In mice multiple i.v. injections of killed *S. typhi* or of its endotoxin greatly stimulate the phagocytic activity of the RES. Cortisone inhibits this effect, "in this way it impairs the defences of the animal against invading bacteria."

*Chédid & Boyer C 10,098/55*: In mice, resistance to *S. enteritidis* endotoxin is greatly diminished during pregnancy and the protective effect of cortisone is also inhibited.

*Moll D 38,913/56*: "The resistance of weaned mice to the effects of *Escherichia coli*

and *Salmonella typhimurium* endotoxins was increased during the administration of cortisone and markedly decreased subsequent to its abrupt withdrawal."

*Abernathy & Spink G68,366/57*: "Mice protected against an initial lethal challenge with brucella endotoxin by treatment with cortisone acetate, 9-alpha-fluorohydrocortisone acetate, or chlorpromazine develop resistance to subsequent challenge to endotoxin."

*Gordon & Lipton C33,200/57*: Certain strains of mice can be protected against endotoxin shock by 5-HT. While cortisol has no effect in itself, it increases the prophylactic action of 5-HT.

*Tauber & Garson C51,966/58*: "Cortisone significantly protected mice from the lethality of *Neisseria gonorrhoeae* endotoxin."

*Benaceraff et al. C67,852/59*: Zymosan renders mice highly susceptible to lethal effects of endotoxin at a time when the RES is greatly stimulated but this sensitization is abolished by cortisone.

*Berry et al. C73,198/59*: Mice of different strains were protected by cortisone against the lethal effect of various bacterial endotoxins. The effect may be related in some way to the hepatic glycogen stores which are depleted by endotoxin and increased by cortisone.

*Ribble et al. C92,576/59*: "Doses of cortisone that prevented death did not materially influence the rate of removal or organ distribution of lethal amounts of radioactive *E. coli* endotoxin in normal mice." Cortisone did not alter the resistance of mice made tolerant to *E. coli* endotoxin or their ability to clear radioactive endotoxin from the blood and tissue.

*Gordon & Lipton C94,649/60*: 5-HT reduces endotoxin mortality in mice. This effect is greater in females than in males and is potentiated by cortisol. Thyroxine aggravates the toxicity of endotoxin.

*Chedid & Parant D6,761/61*: The protection of intact mice against endotoxin shock by cortisone is inhibited by reserpine. The same is true in adrenalectomized rats, whereas after hypophysectomy cortisone is even more effective in offering protection against endotoxin but reserpine no longer blocks this effect. Apparently the drug interferes with the cortisone effect only in the presence of the pituitary.

*Liashenko D51,368/60; D50,402/61*: A single dose of cortisone can protect mice from intoxication with dysenteric endotoxin. The

hormone also offers resistance against infections with *Bacterium dysenteriae* Flexneri and *Staphylococcus aureus* and increases the therapeutic efficacy of levomycetin.

*Berry & Smythe E28,203/63*: Review of the literature and personal observations on the protection of intact mice by cortisone against fatal endotoxin poisoning. Cortisone increases hepatic TPO activity and both nicotinamide and DPN (compounds involved in TPO induction), hence the protective effect of cortisone may be mediated through these compounds.

*Previte & Berry E89,101/63*: In mice, exposure to the stress of cold decreases resistance to endotoxin perhaps because of an initial "depletion of corticoid reserves." Cortisone protects even against the combined effect of endotoxin + cold.

*Turner & Berry E36,911/63*: In mice, various bacterial endotoxins prolong gastric emptying time while cortisone reduces this inhibition.

*Berry F24,603/64*: The glyconeogenetic effect of a single cortisone injection is about the same in mice whether they are kept in the cold or at room temperature. However, endotoxin causes a much more pronounced fall in hepatic glycogen in the cold and this effect cannot be readily prevented by cortisone. In cold-exposed mice, cortisone also fails to induce an increase in hepatic TPO.

*Berry G68,858/64*: In mice, injection of endotoxin causes a drop in TPO as well as in oxidized pyridine nucleotides in the liver, presumably DPN and TPN. (This is not unexpected since TPO catalyzes a key reaction in the conversion of tryptophan into nicotinamide, a portion of the pyridine nucleotide molecule.) Possibly, the decline in DPN and/or TPN "is one of the significant metabolic lesions avoided or corrected by the administration of corticoid to the endotoxin-poisoned animals. This suggestion is supported by the finding that either nicotinamide or DPN, when given at the same time as endotoxin, protects against lethality to about the same extent as cortisone."

*Berry & Smythe D19,640/64*: In mice, *S. typhimurium* endotoxin lowers hepatic TPO, whereas cortisone raises it; when the two are administered simultaneously a normal enzyme level is maintained and mortality greatly diminished. If cortisone injection is delayed for a few hours it fails to induce TPO or protect against the lethal effect of endotoxin. Inhibitors of enzyme protein synthesis (acti-

nomycin D, ethionine, 2-thiouracil and 8-azaguanine) potentiate the lethal effect of endotoxin and abolish cortisone protection.

*Chedid et al. E 3,476/64:* In mice, moderate doses of cortisone increase resistance to endotoxin without accelerating its blood clearance and detoxication. Heavy prolonged cortisone overdosage increases susceptibility to endotoxin.

*Kostrubiak & Howard G 57,804/64:* In mice, aldosterone exhibited no protective value against the lethal effect of *Clostridium welchii* alpha-toxin. Apparently corticoids are effective only against endotoxins, not against exotoxins.

*Kostrubiak & Howard F 43,646/65:* Aldosterone, admixture to tetanus toxin, protects the mouse against shock.

*Bóbr & Ptak G 47,053/66:* Four-day pretreatment with cortisol i.p. increases the resistance of intact male or female mice to fatal doses of staphylococcal  $\alpha$ -toxin i.v. Since alloxan had a similar effect, whereas tolbutamide increased sensitivity to  $\alpha$ -toxin, the protective action of cortisol is ascribed to its gluconeogenic effect. "It should also be noted that  $\alpha$ -toxin in rabbits produces disturbances in carbohydrate metabolism, leading to hypoglycaemia. Present findings of hypoglycaemia following the  $\alpha$ -toxin inoculation in mice confirm these earlier observations."

*Berry et al. H 2,124/68:* Studies on the influence of hypoxia, glucocorticoids and endotoxin on hepatic enzyme induction and survival in mice. "Endotoxin inhibited the induction of tryptophan oxygenase, prevented the increase in liver glycogen, induced the transaminase, and increased the lethality of simulated altitude. Cortisone increased survival at all altitudes except the highest. These observations emphasize the importance of these metabolic adjustments for the survival of animals subjected to hypoxic stress."

*Laufer et al. H 13,434/68:* The amyloidosis produced in mice by tubercle bacilli in Freund's adjuvant, or by mixtures of endotoxins can be prevented by pretreatment with cortisone, but once the amyloid is deposited cortisone had no effect.

*Agarwal & Berry G 65,866/69:* In mice, cortisone induced liver TPO and increased liver pyridine nucleotide levels after pretreatment with zymozan or glucan. It also protected such animals against the lethal effects of endotoxin. The observations are "consistent with the view that a cause and effect relationship may exist between hormone induction of

selected hepatic enzymes and survival against stress."

*Jeffries H 19,361/69:* In mice the liver glycogen-depleting effect of endotoxin is inhibited by cortisone. Aminoglutethimide (an inhibitor of corticosteroid synthesis) increases the susceptibility to endotoxin and the associated liver glycogen depletion but cortisone is able to combat even the glycogen depleting effect of this combination treatment to some extent.

*Rose & Bradley H 19,375/69:* In mice, endotoxin resistance is greatly decreased by concurrent treatment with the antitumor antibiotics, sparsomycin or pactamycin. Even this enhanced toxicity is inhibited by methylprednisolone.

*Rose & Bradley G 79,576/70:* In mice, endotoxin resistance is greatly decreased by simultaneous treatment with sparsomycin. Aldosterone fails to protect against the toxicity of the combined treatment.

#### RABBIT

*Katabuchi 44,803/29:* In rabbits injected with typhoid toxin, the production of an antiserum is enhanced by adrenocortical extract but to a lesser degree also by extracts of various other organs.

*Duffy Jr. & Morgan B 65,399/51:* In rabbits, the febrile response to *Shigella dysenteriae* endotoxin is diminished following pretreatment during 48 hrs with repeated large doses of ACTH or cortisone. Pretreatment during 24 hrs with smaller doses of these hormones exerts an opposite effect. "This appears to account for the discrepancies in the results previously reported."

*Thomas et al. B 57,977/51:* The topical response to an intradermal or intraconjunctival injection of endotoxin is inhibited by cortisone in rabbits. On the other hand, endotoxin i.v. causes bilateral cortical necroses in rabbits and hamsters pretreated with cortisone.

*Bennett Jr. & Beeson B 95,351/53:* In rabbits, the febrile response to a single injection of various endotoxins may be decreased, increased or unchanged by treatment with ACTH or cortisone. Acquired resistance to pyrogen fever is abolished by Thorotrast but not by cortisone although both these agents prevent the Shwartzman reaction.

*Thomas B 92,009/54:* In mature rabbits, the early lethal effects of endotoxin can be prevented by cortisone pretreatment, although renal necrosis does occur.

*Thomas & Smith E23,202/54:* In rabbits, cortisone prevented the early reaction of prostration and death produced by endotoxin i.v. but in some of the rabbits pretreated for three days bilateral renal cortical necrosis occurred within 24 hrs after endotoxin. When a single injection of cortisone was given 6 hrs before endotoxin, protection against prostration and death was demonstrable without subsequent development of renal cortical necrosis. The early lethal reaction caused by small amounts of endotoxin following colloidal iron saccharate i.v. was prevented by cortisone.

*Janoff et al. D35,553/62:* Studies on the hepatic lysosomal enzymes of rats and rabbits after traumatic or endotoxin shock, adrenalectomy, or treatment with cortisone suggested that "a) disruption of lysosomes and release of their contained enzymes in free, active form may occur in liver and intestine of shocked animals. b) The activation of lysosomal hydrolases within cells and their release into the circulation may play an important role in exacerbating tissue injury and accelerating the development of irreversibility during shock. c) The increased stability of lysosomes of tolerant and of cortisone-treated animals may constitute an important component of the resistance of these animals to shock."

*Weissmann & Thomas D23,630/62:* Following endotoxin treatment in vivo, the hepatic lysosomes of the rabbit release their enzymes readily upon ultraviolet irradiation. This increased lability is in turn prevented by pretreatment of the animals with cortisone for three days before endotoxin administration. Apparently "one action of endotoxin is to release acid hydrolases from particulate form within cells, and that glucocorticoids serve to stabilize such particles against injury by several agents."

*Weissmann & Thomas D35,555/62:* In rabbits, endotoxin shock is associated with the release of hepatic lysosomal acid hydrolases ( $\beta$ -glucuronidase, cathepsin). This effect is prevented by glucocorticoids, but not by DOC. "Thus, glucocorticoids, in a variety of experimental situations, appear to decrease the liberation of potentially harmful enzymes from lysosomes, and may in fact function physiologically to stabilize the boundaries of these subcellular particles."

*Gonzalez et al. F88,028/67:* In rabbits, neither corticosterone nor cortisol offered any significant protection against shock produced by *E. coli* endotoxin.

*Dieckhoff et al. H1,991/68:* Prednisolone diminished endotoxin shock and prolonged survival following production of a generalized Shwartzman-Sanarelli phenomenon in the rabbit, without significantly altering the characteristic vascular lesions.

*Fine et al. G53,608/68:* General review on the beneficial effect of treatment with various glucocorticoids upon hemorrhagic, endotoxin and traumatic shock in rabbits.

#### RAT

*Ingle B42,751/47:* Neither adrenocortical extract nor DOC protects the rat against diphtheria toxin.

*Jasmin B80,596/53:* A dose of meningococcus toxin i.v. well tolerated by nonpregnant rats produces eclampsia-like hemorrhagic lesions in the liver of pregnant or cortisone pretreated animals.

*Ganley et al. C7,489/55:* Rats cannot be protected against the lethal effect of *Cl. perfringens* toxin by ACTH, adrenocortical extract, cortisol, cortisone or DOC.

*Levitin et al. C26,683/56:* Cortisol, corticosterone, and cortisone, as well as ACTH protect the rat against endotoxin, whereas DOC does not.

*Weil et al. F4,907/64; Weil & Allen F14,091/64:* Experiments on the protection by various glucocorticoids against endotoxin shock in the mouse and rat. "The demonstration of significantly higher survival rates with prednisolone, and especially with dexamethasone in pharmacological doses indicates that a drug action rather than hormonal replacement accounts for therapeutic effectiveness."

*Renaud et al. F74,449/66:* In rats, kept on a hyperlipemic diet, ACTH, cortisol or prednisolone protected against the production of shock and hepatic vein thromboses by *S. typhosa* lipopolysaccharide. DOC increased mortality and did not protect these thromboses.

*Nolan & Ali G55,490/68; Nolan et al. H5,204/68:* In rats, pretreatment with cortisol, corticosterone, ACTH, Thorotrast (to block the RES) or endotoxin 24 hrs before endotoxin challenge did not increase the mortality rate.

*Renaud & Latour F99,806/68:* In rats kept on a hyperlipemic diet, the production of phlebothromboses by *S. typhosa* lipopolysaccharide is inhibited by triamcinolone.

*Selye PROT. 32990:* In rats, pretreatment for 4 days, or even for only one day, with large doses of cortisol, cortisone, triamcinolone, dexamethasone, betamethasone, prednisolone,

Table 120. *Protection by glucocorticoids against endotoxin poisoning*

Treatment <sup>a</sup>	Prostration <sup>c</sup> (Positive/Total) Pretreatment		Mortality <sup>c</sup> (Dead/Total) Pretreatment	
	1 day ff.	3 days ff.	1 day ff.	3 days ff.
None	5/5	2/10	5/5	9/10

Cortisone-Ac 10 mg	0/5 ***	0/10 NS	2/5 NS	2/10 ***
Triamcinolone 10 mg	0/5 ***	0/10 NS	0/5 ***	1/10 ***
Dexamethasone-Ac 2 mg	0/5 ***	0/10 NS	1/5 *	0/10 ***
Betamethasone-Ac 2 mg	0/5 ***	0/10 NS	0/5 ***	0/10 ***
Prednisolone-Ac 10 mg	0/5 ***	0/10 NS	0/5 ***	0/10 ***
Prednisone-Ac 10 mg	0/5 ***	0/10 NS	1/5 *	1/10 ***
Solu-Cortef 10 mg <sup>b</sup>	—	0/10 NS	—	0/10 ***

<sup>a</sup> The rats (100 g ♀) of all groups received *E. coli* 026:B6 1.5 mg per 100 g body weight, in 1 ml water, i.v. once, 4th day. The glucocorticoids were given at the doses indicated in 1 ml water, p.o. x2/day, 1st day or 3rd day ff. and on the 4th day 1 hr before *E. coli* injection, except Solu-Cortef (cortisol-21-Na-succinate).

<sup>b</sup> Solu-Cortef was given in 1 ml water, i.v. once, 30 min before *E. coli* endotoxin administration.

<sup>c</sup> The severity of the prostration was estimated for the 1 day pretreated groups: 3 hrs after endotoxin injection and for the 3 days pretreated groups: 2 hrs later. Mortality was listed 24 hrs later (Fisher & Yates test).

For further details on technique of tabulation *cf.* p. VIII.

prednisone or Solu-Cortef offered considerable protection against the lethal effects of *E. coli* endotoxin i.v. *cf.* Table 120

*Selye PROT. 41632*: In rats, the inhibition of *E. coli* toxicity by cortisol is abolished following pretreatment with dactinomycin or cycloheximide at dose levels at which these antagonists are not demonstrably toxic by themselves. On the other hand, metyrapone, puromycin aminonucleoside (PAN) and ethionin do not block cortisol protection; indeed, metyrapone may slightly enhance it *cf.* Table 121.

#### SHEEP

*Halmagyi et al. D68,121/63*: In sheep, the cardiovascular manifestations of endotoxin shock could not be prevented by 0.2 mg/kg of d-aldosterone i.v. 30 min before the injection of *E. coli* endotoxin.

#### MAN

*Abernathy & Spink C48,635/58*: In man, cortisol or ACTH suppressed or ameliorated reactions to *Brucella* endotoxin.

*Weil et al. G68,706/62*: In man, endotoxin shock is very effectively prevented by combined treatment with glucocorticoids (cortisol, prednisone, dexamethasone) and vasoactive agents (especially metaraminol).

*Cherry G74,846/70*: Review of the use of glucocorticoids in the treatment of endotoxin shock in man.

#### VARIA

*Chedid & Boyer C17,612/55*: Review of the literature and personal observations on the effect of cortisone upon resistance to bacterial toxins in comparison with similar effects of chlorpromazine.

*Weil & Spink D96,274/57*: Review on the prevention of endotoxin shock by glucocorticoids in various species.

*Kass D35,079/60*: "In only two situations have adrenocortical hormones been shown to be protective to the host: the replacement of hormone in hypoadrenalism, and the protective action against the lethal toxicity of bacterial lipopolysaccharides." There appears to be no clear-cut relationship between the glucocorticoid and anti-endotoxic activity of steroids, as judged by Table 122.

*Weil G68,214/61*: Review of the literature on the prevention of endotoxin shock by glucocorticoids in the dog, mouse and rat. Personal observations on mice demonstrated the efficacy of cortisol, prednisolone, dexamethasone and methylprednisolone in increasing survival after *E. coli* endotoxin i.p.

Table 121. *Effect of dactinomycin, metyrapone, puromycin aminonucleoside and cycloheximide upon the prevention of endotoxin shock by cortisol*

Group	Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)
1	E. coli	20/21	20/21
2	Cortisol ac. + E. coli	9/20 ***	7/20 ***
3	Dactinomycin	0/10	0/10
4	Dactinomycin + E. coli	10/10	10/10
5	Cortisol ac. + Dactinomycin + E. coli	10/10 ***	10/10 ***
6	Metyrapone	0/10	0/10
7	Metyrapone + E. coli	10/10	10/10
8	Cortisol ac. + Metyrapone + E. coli	0/10 *	0/10 *
9	PAN	0/10	0/10
10	PAN + E. coli	9/10	9/10
11	Cortisol ac. + PAN + E. coli	3/10 NS	3/10 NS
12	Cycloheximide	0/10	0/10
13	Cycloheximide + E. coli	10/10	10/10
14	Cortisol ac. + Cycloheximide + E. coli	10/10 ***	10/10 ***
15	Ethionin	0/10	0/10
16	Ethionin + E. coli	10/10	10/10
17	Cortisol ac. + Ethionin + E. coli	2/10 NS	2/10 NS

<sup>a</sup> The rats received E. coli 0.26: B6 (1.5 mg in 1 ml water, i.v.) at 0 hr after cortisol acetate (2 mg in 1 ml water, p.o.) was administered at -1 hr. In addition, at -30 min, certain groups received dactinomycin (70 µg in 0.2 ml water, i.v.), metyrapone (12 mg in 0.1 ml corn oil, i.p.) puromycin aminonucleoside "PAN" (10 mg in 0.2 ml water, i.p.), cycloheximide (25 µg in 0.2 ml NaCl, s.c.), or ethionin (50 mg in 2 ml 0.9% NaCl, i.p.).

<sup>b</sup> Dyskinesia was estimated 24 hrs after injection of E. coli, and mortality listed 24 hrs later. For statistical purposes, group 2 was compared with group 1, and groups 5, 8, 11, 14, and 17 with group 2 ("Exact Probability Test"). For further details on technique of tabulation cf. p. VIII.

*Weil & Allen D7,883/61*: A review on the protection offered by various glucocorticoids against endotoxin shock in the mouse, rat and dog. The rate of removal and organ distribution of radioactive E. coli endotoxin is unaltered by cortisone, and the steroids are assumed to protect the tissues "by their physical

presence." This view is allegedly supported by the suppression of increased serum transaminase by hydrocortisone. In any event, the corticoids do not protect in a "nonspecific manner" against injuries, since prednisolone phosphate i.p. protects against the lethal effect of endotoxin but not against that of mecamlamine, chlorpromazine, metaraminol or dibenzylamine as judged by experiments on intact mice. The protective effect of glucocorticoids administered i.p. at 15 min and again at 4 hrs after E. coli endotoxin i.p. decreases in the following order: cortisol sodium succinate, prednisolone phosphate, methylprednisolone sodium succinate, and dexamethasone phosphate.

Table 122. *Relative anti-inflammatory (glucocorticoid) and anti-endotoxic effects of steroids*

Steroid	Anti-inflam- matory	Anti-endo- toxic
Cortisol	1.0	1.0
Corticosterone	0.5	0.7
Prednisone	3.5	0.7
Prednisolone	4.0	1.3
6- $\alpha$ -Methylprednisone	5.0	30.0
11-Deoxycorticosterone	<0.1	0.1
11- $\alpha$ -OH-progesterone	<0.1	0.03

*Spink D39,028/62*: Review on the protective effect of glucocorticoids in endotoxin shock. "Although endotoxin shock does not appear to be associated with adrenal insufficiency except on rare occasions, this does not preclude the possibility that under severe

stress physiologic amounts of adrenal hormone are inadequate, and pharmacologic doses of exogenous adrenal steroid are desirable." Protection has also been obtained with aldosterone.

*Lillehei et al. E31,273/63:* Review on the beneficial action of cortisol in canine endotoxin shock.

*Fukui E8,467/64:* Review of the literature on the increased endotoxin resistance induced by cortisone with a discussion of possible underlying mechanisms.

*Janoff & Kaley E8,484/64:* Review of the literature supporting the concept that endotoxins act by disruption of lysosomes with release of their contained enzymes and that cortisone protects against the resulting shock by stabilizing lysosomal membranes.

*Sambhi et al. G68,985/64:* Review on the action of glucocorticoids and aldosterone in traumatic and endotoxin shock in animals and men.

*Weissmann & Thomas E8,482/64:* Review of the literature showing that cortisone, unlike DOC, stabilizes hepatic lysosomal membranes against the permeability-increasing effect of endotoxin.

*Janoski et al. E7,896/68 (p. 282):* Review suggesting that many of the actions of glucocorticoids particularly the inhibition of ultraviolet ray injury, vitamin-A overdosage and endotoxin shock are due to the stabilization of lysosomal membranes which prevents the escape of toxic lysosomal enzymes.

← **Adrenalectomy.** *Belding & Wyman 3,915/26:* Adrenalectomized rats are particularly sensitive to diphtheria toxin.

*Halberg et al. G68,353/56:* Adrenalectomized mice are protected against the hypothermic and lethal effects of *Brucella* endotoxin by cortisone, cortisol, fluorocortisol and aldosterone in decreasing order of activity.

*Brooke et al. D11,627/61:* In adrenalectomized rats protection against the lethal effects of endotoxin can serve as the basis of an assay of corticoids. However, this effect does not parallel antiphlogistic activity.

*Yokoi et al. D8,839/61:* In rabbits, a biphasic fever pattern is elicited by Sh. flexneri type 6 pyrogen. The biphasic nature of the response was maintained after thyroidectomy but largely abolished by adrenal demedullation.

*Higginbotham D21,395/62:* In mice, resistance to 5-HT, endotoxin and anaphylactic shock is markedly decreased by adrenalectomy. Cortisol readily restored resistance to

5-HT but was less effective with regard to endotoxin and anaphylactic shock. Resistance to histamine and histamine releasers is less markedly diminished by adrenalectomy in the mouse, and large doses of cortisol are required to induce a measurable increase in resistance to histamine.

*Parant D82,116/62:* In mice, resistance to endotoxin is greatly decreased a few hours after adrenalectomy or hypophysectomy. Cortisone protects normal, adrenalectomized, and hypophysectomized animals against high doses of endotoxin, whereas chlorpromazine is effective only in the presence of both the adrenals and the pituitary. ACTH also protects the hypophysectomized mouse, but only if slow absorption is assured.

*Krawczak & Brodie H25,296/70:* In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines) or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offers complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly increased by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be increased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

← **Luteoids.** *Chedid et al. B91,161/52:* DOC does not alter the resistance of the intact or adrenalectomized mouse to *S. enteritidis* endotoxin but progesterone diminishes it considerably.

*Silk F95,477/67:* In the cat, progesterone given with—or 30 min after—endotoxin stabilizes the blood pressure and markedly prolongs survival.

← **Testoids.** *Dutz et al. C31,646/56*: In rats, gonadectomy did not significantly change the course of Masugi nephritis, whereas a folliculoid preparation (Östrasid) and testosterone ameliorated it. STH considerably aggravated the glomerular lesions and the hypertension.

*Herrmann D34,026/62*: In guinea pigs, following interruption of corticoid administration, the adrenocortical hypofunction and atrophy as well as the irresponsiveness to the production of adrenocortical necrosis by diphtheria toxin reappear much more rapidly if the animals are simultaneously treated with testosterone.

*Herrmann & Winkler D20,550/62*: In guinea pigs, methandrostenolone accelerates the restitution of the adrenal cortex after interruption of cortisone therapy as judged by the more rapid reappearance of sensitivity to diphtheria toxin and histologic criteria.

*Farrar & Magnani F6,647/64*: Homogenates of normal guinea pig liver rapidly detoxify endotoxins in vitro, whereas homogenates of livers damaged by  $\text{CCl}_4$  do not. Adrenalectomized animals are notoriously sensitive to endotoxin but pretreatment of guinea pigs with testosterone or cortisone does not influence their resistance to toxic doses of endotoxin and hence the detoxifying ability of the liver does not appear to be under steroid control.

*Terragna et al. E66,111/66*: In guinea pigs, pretreatment with 4-chlorotestosterone increases resistance to diphtheria toxin.

*Terragna et al. F86,979/66*: In the mouse, 4-chlorotestosterone administered simultaneously or soon after *E. coli* endotoxin protects against the lethal action of the latter but the anabolic steroid fails to protect if administered before the endotoxin. [The statistical significance of these data has not been analyzed (H.S.).]

*Evangelista et al. H16,824/69*: Neither ACTH nor stanozolol gave any significant protection against endotoxin shock in dogs.

← **Folliculoids.** *Imamura 14,567/29*: In mice, resistance to tetanus toxin is increased by the injection of follicular fluid from cows' ovaries.

*Crainiceanu & Copelman 67,918/35*: A folliculoid extract "folliculine" prolongs the survival of guinea pigs which have received fatal doses of diphtheria toxin. [Brief abstract containing no details (H.S.).]

*Herrmann & Winkler D27,922/62*: In guinea pigs, the adrenocortical atrophy and hypofunction produced by chronic cortisone treatment is prevented by simultaneous administration of

estradiol. The responsiveness of the adrenal cortex to the induction of hemorrhagic necrosis by diphtheria toxin returns much more rapidly after interruption of cortisone treatment if estradiol is simultaneously administered.

*Nolan F75,232/67*: In rats, a significant protection against the fatal effect of endotoxin was obtained by giving "equine estrogens" 30–60 min before the endotoxin. Protection is short-lived and does not occur when endotoxin is given 2–8 hrs after folliculoid treatment. Since earlier workers had shown that cortisol offers a similar protection, it is possible that the effect of the folliculoids is mediated through the adrenal cortex.

*Nolan & Ali F79,610/67*: In rats, "conjugated estrogens administered from 0 to 2 hours before endotoxin afforded greater protection on a weight basis than hydrocortisone succinate. No protection was noted when estrogen pretreatment was 3 to 8 hours prior to challenge. In contrast, however, if conjugated estrogens or estriol was given 24 hours prior to the endotoxin, the L.D. 50 in female rats was reduced ten-fold, from 2.0 mg to 0.25 mg."

*Nolan et al. H5,204/68*: In intact rats, conjugated "equine estrogens" antagonize the lethal effects of *E. coli* endotoxin. In this respect, the folliculoid preparation is even more active than cortisol succinate. A parallel type of blockade to the vasoconstrictive effect of endotoxin was also noted both for the folliculoid and the corticoid preparations in the isolated rat liver.

*Nolan & Ali G55,490/68*: Various folliculoids administered up to one hour before an injection of *E. coli* endotoxin reduce the lethal effect of the latter, but when estrogens are administered 18–48 hrs before the endotoxin, the mortality rate is increased. Pretreatment with cortisol, corticosterone, ACTH, Thorotrast (to block the RES) or endotoxin 24 hrs before endotoxin challenge did not increase the mortality rate. Endotoxin doses that normally cause no hepatic damage elicited liver necrosis in rats pretreated with folliculoids.

← **Other Steroids.** *Bein D37,982/62*: Whereas earlier work suggested that protection by steroids against endotoxin shock depends upon glucocorticoid activity, it has now been demonstrated in acute experiments on anesthetized cats that the sharp drop in blood pressure produced by endotoxin, and the lack of pressor response to epinephrine are prevented by aldosterone i.v. given just before the endotoxin. It is incidentally mentioned

that 19-oxoprogesterone with the following formula:

is active in this respect, although it has neither anti-inflammatory nor salt-retaining properties. It is concluded that the anti-endotoxin effect is independent of corticoid activities. [The experimental conditions of the 19-oxoprogesterone tests (experimental animal, dose, route of administration) are not given (H.S.).]

*Kocsár et al. G69,983/69:* In rats, incubation of tritium-labeled endotoxin with bile or Na-deoxycholate reduces its absorption when subsequently injected i.p. In rats rendered bile-deficient by cannulation of the choledochus, unlike in normal rats, endotoxin is absorbed after administration p.o. "Our experimental findings suggest that bile acids play an important role in the defense mechanism of the macroorganism against bacterial endotoxins."

*Selye G70,480/71:* In rats, the prostration and mortality produced by i.v. injection of *E. coli* endotoxin could be prevented by prednisolone, triamcinolone and cortisone. Conversely, PCN, CS-1, norbolethone, and thyroxine tended to aggravate endotoxin shock and mortality. The other members of our standard series of conditioners were ineffective, as was aldosterone even at the high dose of 1 mg p.o., twice daily, cf. Table 123.

Table 123. *Conditioning for E. coli endotoxin No. 08*

Treatment <sup>a</sup>	Dyskinesia <sup>b</sup> (Positive/ Total)	Mortality <sup>b</sup> (Dead/ Total)
None	7/12	8/13
PCN	10/10 *	10/10 *
CS-1	10/10 *	4/10 NS
Ethylestrenol	3/8 NS	4/8 NS
Spiro lactone	9/10 NS	4/10 NS
Norbolethone	9/10 NS	10/10 *
Oxandrolone	7/10 NS	3/10 NS
Prednisolone-Ac	0/9 **	1/9 *
Triamcinolone (2 mg)	0/10 ***	0/10 ***
Progesterone	8/10 NS	4/10 NS
Estradiol (1 mg)	8/10 NS	9/10 NS
DOC-Ac	6/9 NS	3/9 NS
Hydroxydione	9/10 NS	6/10 NS
Cortisone-Ac	0/10 ***	4/10 NS

Thyroxine	10/10 *	10/10 *
Phenobarbital	8/10 NS	5/10 NS
Aldosterone (1 mg)	5/5 NS	3/5 NS

<sup>a</sup> The rats of all groups were given *E. coli* endotoxin No. 08 (800 µg/100 g body weight in 0.8 ml water, i.v., once on 4th day).

<sup>b</sup> Dyskinesia was measured 3 hrs after injection of the endotoxin and mortality listed on 7th day ("Exact Probability Test").

For further details on technique of tabulation cf. p. VIII.

## VENOMS AND PLANT POISONS ←

Cortisone, cortisol and other glucocorticoids have been shown to protect various mammals, including man, against venoms of snakes, spiders and wasps.

The claim that the resistance of rats against a poisonous extract of *Amanita phalloides* can be raised by adrenocortical extract requires confirmation. However, estradiol offers striking protection against the peliosis-like hepatic necrosis induced by pure phalloidin in the rat.

### Snakes ←

*Dossena B47,510/49:* Female guinea pigs appear to be more sensitive than males to Cape cobra venom but pretreatment with testosterone, estradiol or progesterone failed to affect their resistance.

*Maral C17,604/53:* In mice, cortisone exerts a favorable influence upon intoxication with viper venom.

*Schöttler C10,890/54:* In mice and guinea pigs injected with the venom of *Bothrops jararaca* or *Crotalus terrificus* s.c., ACTH, cortisone and cortisol failed to offer protection.

*Deichmann et al. C33,188/57:* Cortisol largely protects the dog against the lethal, but not against the local, effect of *Crotalus adamanteus* venom i.m.

*Deichmann et al. C73,854/58:* In dogs, cortisol i.v. protects against the lethal but not against the local effects of rattlesnake (*Crotalus adamanteus*) venom i.m.

*Bein & Jaques D41,862/60:* Pretreatment with aldosterone "protects mice against the lethal action of *E. coli* or *S. typhimurium* toxin as well as against that of hemorrhagic snake venoms (*Vipera aspis*, *Crotalus adamanteus*), but not against the neurotoxic venom of *Naja tripudians*. Prednisolone, which is effective to roughly the same degree in the mouse as in the rat, has to be administered in doses some 10—30 times larger, whereas hydrocortisone and cortexone display no protective action, even in high dosage."

*Russell & Emery D2,497/61:* Review of the literature on the protective effect of ACTH and glucocorticoids against snake venom with personal observations on the lethality of *Ancistrodon contortrix* venom in mice.

*Arora et al. D27,786/62:* Cortisol given within an hour after s.c. injection of *Echis carinatus* venom protects the rat against fatal intoxication. It also greatly augments the therapeutic efficacy of the specific antivenom.

*Bonta et al. F28,544/65:* Estriol-16,17-disodium succinate inhibits the local hemorrhages induced by snake venom in canine heart-lung preparations.

*Halmagyi et al. G31,584/65:* In sheep, *Crotalus* venom shock was moderately counteracted by concurrent treatment with cortisol, aldosterone or  $\beta$ -methasone.

*Ogawa F54,550/65:* In adrenalectomized, as in intact rats, the toxicity of Habu snake venom is reduced by dexamethasone and F-COL, whereas DOC shortens the survival period.

*Haas G38,758/66:* Extensive review on the use of corticoids and ACTH in the treatment of snake bites in man and in animals.

*Bonta et al. G69,044/69:* Topical treatment with estriol prevents the hemorrhagic action of cobra venom placed directly upon the dog's lung. The comparable effect of *Agkistrodon piscivorus* venom is not prevented. The former venom does, whereas the latter does not, contain the "heparin precipitable factor."

*Clark & Higginbotham G77,169/70:* In mice, the lethal effect of moccasin venom i.v. is aggravated by adrenalectomy or vaccination; cortisol offers protection in both intact and adrenalectomized or vaccinated animals.

### Spiders ←

*Mohammed et al. C7,579/54:* Rats can be protected against fatal doses of scorpion toxin by pretreatment with cortisone or ACTH.

*Bettini & Cantore C21,801/55:* Comparative studies on the protective effect of ACTH, cortisone and chlorpromazine against lethal poisoning with the venom of the spider *Latrodectus tredecimguttatus*.

### Wasp ←

*Jaques H13,146/69:* Cortisol protects the guinea pig against lethal wasp-venom shock.

### Mushrooms ←

*Cheymol & Pfeiffer B54,350/49:* The resistance of intact rats to intoxication with a highly poisonous extract of *Amanita phalloides* rises considerably following treatment with adrenocortical extract or NaCl, whereas DOC has little, if any, prophylactic potency.

*Tuchweber et al. (in preparation):* In rats, mortality and peliosis-like hemorrhagic necrosis of the liver induced by phalloidin i.p. are prevented by pretreatment with estradiol, PCN, ethylestrenol, spironolactone, triamcinolone, betamethasone, cortisol, progesterone and phenobarbital were ineffective in this respect.

## IMMUNE REACTIONS ←

### ← Corticoids

The immunosuppressive effect of corticoids is so well known that it need not be discussed here in detail. Besides, this topic has been dealt with at length in our earlier monographs. Here, we shall limit ourselves to a few points of special theoretic interest.

In guinea pigs, allegedly neither cortisone nor ACTH can suppress passive or active anaphylaxis, or a positive Schick test. Yet, apparently, under suitable conditions, both cortisone and ACTH diminish tuberculin sensitivity. Curiously, two weeks after interruption of cortisone or ACTH administration, the hormone-treated animals become even more sensitive than the controls.

There appears to exist a singular interaction between corticoids and thyroid hormones. Thyroxine increases hypersensitivity to tuberculin in guinea pigs but, here again, 14 days after stopping the treatment the effect is reversed and the pretreated animals surpass the unpretreated controls in the degree of their tuberculin resistance. Since propylthiouracil diminishes the immunosuppressive effect of cortisone, it was postulated that thyroxine is necessary for the desensitizing action of these hormones. This assumption is not contradicted by the fact that thyroxine increases tuberculin hypersensitivity because it fails to block desensitization by ACTH or cortisone.

Much has been written about a "cabbage factor" (possibly an SH-compound) which on ingestion inhibits the desensitization to tuberculin produced by the metabolism of ascorbic acid in the tissues of allergic guinea pigs. The desensitizing action of cortisone or ACTH in cabbage-fed animals has therefore been thought to be indirect, depending upon the reversal of the cabbage effect by the hormone. Apparently, ATP prevents the desensitizing effect of cortisone upon tuberculin, whereas STH depresses tuberculin sensitivity and synergizes the action of cortisone.

Certain hypothalamic lesions can suppress anaphylactic reactivity in guinea pigs. This inhibitory effect can be partially blocked in turn by chronic treatment with thyroid hormones, adrenalectomy or adrenal inactivation by metyrapone. It has been concluded that the sharp, inhibiting effect of hypothalamic lesions may be partly due to hypothyroidism and partly to hypercorticoidism.

In hyperimmunized rabbits, the development of nephritis is inhibited by cortisone. Some investigators claimed that various luteoids can prolong skin homograft survival in rabbits. Curiously, combined treatment with cortisone and luteoids actually interferes with the beneficial effect of the latter.

In mice, pretreatment with cortisone suppresses the amyloidosis normally produced by repeated injections of killed tubercle bacilli. Also, in the mouse (unlike in the rat), triamcinolone reduces anaphylactic mortality, but various glucocorticoids act differently in this respect: betamethasone and dexamethasone are effective in the rat but not in the mouse; dexamethasone is active, whereas cortisol is inactive, in both species.

In rats hemolysin formation following i.p. injection of sheep erythrocytes is inhibited by pretreatment with cortisone, but only if the hormone is administered before the antigen. Hemolysin formation is also inhibited in rats by dexamethasone, but not by prednisolone or norandrostenolone.

Rats whose thymus is partly destroyed by calciphylaxis (DHT + triamcinolone), allegedly accept skin homografts, although the thymic medulla is usually well preserved. This finding requires confirmation.

Certain experiments on dogs suggest that aldosterone may prolong the life of renal homografts, but here also confirmatory evidence would be welcome.

← *Adrenalectomy*

For the extensive literature on the effect of adrenalectomy the reader must again be referred to our earlier monographs. Suffice it to point out here, merely for its historic interest, an observation made over 40 years ago which shows that hemolysin formation is inhibited in rats by adrenalectomy.

← *Folliculoids and Luteoids*

It has been claimed that medroxyprogesterone increases survival of renal allografts in dogs and of skin allografts in rabbits by immunosuppression. Melengestrol, another primarily progestational steroid with less pronounced glucocorticoid activity, is more effective than cortisol in suppressing allergic encephalomyelitis in rats. These observations have led to the supposition that both luteoid and glucocorticoid activity is somehow related to immunosuppression.

← *Testoids*

Several investigators presented evidence to show a regulating effect of testoids upon immune phenomena.

In rats, gonadectomy did not significantly change the course of Masugi nephritis but testosterone inhibited its development. In rats, immunized by sheep erythrocytes, various anabolic steroids enhance antibody formation. These compounds also stimulate antibody formation in infants vaccinated against diphtheria.

← *Gonadectomy*

In guinea pigs, allegedly gonadectomy diminishes anaphylactic shock in both sexes, whereas in rats this is not the case. Gonadectomy also fails to influence the development of allergic nephritis in the rat.

**Immune Reactions** ← *cf. also Selye B40, 000/50, p. 69; G60,083/70, pp. 347, 355.*

← **Corticoids.** *Wolfram & Zwemer 30,809/35:* In sensitized guinea pigs, anaphylactic shock caused by reinjection of crystalline ovalbumin is inhibited by "cortin."

*Dworetzky et al. B52,246/50:* In guinea pigs, anaphylactic shock was not significantly influenced by cortisone or ACTH.

*Long & Miles D41,973/50:* In guinea pigs, moderate thyrotoxicosis produced by two weeks' treatment with thyroxine increases hypersensitivity to tuberculin whereas moderate doses of propylthiouracil do not affect it. ACTH and cortisone diminish tuberculin sensitivity. Fourteen days after stopping thyroxine injections, the animals became actually less hypersensitive than the controls. A simi-

lar reversal of effect was noted two weeks after interruption of cortisone or ACTH treatment in that the animals became more hypersensitive than the controls.

*Long et al. B60,189/51:* In B.C.G.-infected guinea pigs, hypersensitivity to tuberculin is considerably diminished by cortisone or ACTH. This diminution is abolished by pretreatment with propylthiouracil, which alone has no effect upon hypersensitivity. Pretreatment with thyroxine increases tuberculin hypersensitivity but does not block desensitization by ACTH or cortisone. Apparently, thyroxine is necessary for the desensitizing action of ACTH and cortisone.

*Long et al. D85,907/51:* In guinea pigs, single injections of cortisone or ACTH diminish allergic hypersensitivity on a cabbage diet, but

not on a basal diet deficient in the "cabbage factor." The authors conclude "that there is in cabbage a factor which on ingestion leads to the inhibition of the desensitisation produced by the metabolism of ascorbic acid in the tissues of the allergic guinea pig; and that the desensitising action of cortisone or of ACTH in cabbage-fed animals is indirect, depending on the reversal of the cabbage effect by the hormones. The cabbage factor may possibly be an SH-compound."

*Long et al. B63,843/51:* In guinea pigs, dihydroascorbic acid—unlike ascorbic acid—inhibits the tuberculin reaction after infection with B.C.G. vaccine. The desensitizing effect of dihydroascorbic acid is not inhibited by thiouracil. Alloxan, like ACTH or cortisone, does not modify desensitization by ascorbic acid on diets deprived of the "cabbage factor;" it desensitizes guinea pigs on a cabbage diet and this desensitization is inhibited by propylthiouracil.

*Malkiel G71,451/51:* In guinea pigs, ACTH and cortisone are without effect on the end results of histamine shock, or of passive or active anaphylaxis.

*Teikum et al. B62,687/51:* In hyperimmunized rabbits, the development of nephritis is inhibited by cortisone.

*Cornforth & Long B77,176/53:* In guinea pigs sensitized to tuberculin, single s.c. injections of ATP prevent desensitization by alloxan, cortisone and dihydroascorbic acid. Single s.c. injections of insulin do not in themselves influence sensitivity but prevent desensitization by alloxan and cortisone. Single s.c. injections of STH depress tuberculin sensitivity and synergize the action of cortisone or alloxan.

*Rosenbaum & Obrinsky B85,352/53:* In guinea pigs, cortisone did not affect the development of a positive Schick reaction nor did it prevent death and adrenal hemorrhage after treatment with diphtheria toxin.

*Lepri & Fornaro D91,865/54:* In rabbits, rendered allergic to tuberculosis, the ocular manifestations of topical challenge by tubercle bacilli were variably influenced by ACTH and cortisone.

*Berglund C16,832/56:* In rats, hemolysin formation following i.p. injection of sheep erythrocytes is inhibited by pretreatment with cortisone. No significant effect is obtained by cortisone administration after antigen injection.

*Tolentino et al. D16,593/61:* In rats, hemolysin formation against sheep erythrocytes is decreased by dexamethasone but uninfluenced by prednisolone, norandrostenolone. Under similar conditions, testosterone and dihydroisoandrosterone increase hemolysin formation.

*Todd et al. G10,342/63:* Experiments on dogs "suggest that in certain circumstances aldosterone is capable of prolonging the life of renal homografts in dogs."

*Vakilzadeh & Vandiviere E32,626/63:* In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T3, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

*Webster & Gentile E30,434/63:* Rats "chemically thymectomized" by calciphylaxis of the thymus owing to combined treatment with triamcinolone and DHT accept skin homografts, although the thymic medulla is usually well preserved.

*Hulka & Mohr G44,272/67:* Although earlier observations showed that various luteoids can prolong skin-homograft survival in the rabbit, combined treatment with cortisone + medroxyprogesterone, progesterone, norethynodrel or norethindrone, actually interfered with the homograft survival-prolonging effect obtained by cortisone alone.

*Laddu & Sanyal G60,298/68:* Triamcinolone reduced mortality from anaphylaxis in the mouse but not in the rat. Betamethasone and depersolon were effective in the rat but not in the mouse. Dexamethasone was effective in both species and cortisol ineffective in either species.

*Laufer et al. H13,434/68:* Pretreatment with cortisone suppressed amyloidosis in mice injected with killed *Mycobacterium tuberculosis*.

*Patton & Clark G73,195/68:* In rats infected with *Trypanosoma lewisi*, dexamethasone resulted in the development of exceedingly large populations of trypanosomes which were fatal to their hosts. This effect of dexamethasone is ascribed to the inhibition of the production of ablastin and trypanocidal antibodies.

*Filipp & Mess G71,129/69:* In guinea pigs, suppression of anaphylactic reactivity by anterior hypothalamic lesions can be partially blocked by chronic treatment with

thyroid hormones as well as by adrenalectomy or adrenal inactivation by metyrapone (Metopirone). "Combined treatment of guinea pigs bearing hypothalamic lesions with Metopirone and thyroxine completely eliminated the blocking effect of the tubercular lesion on anaphylactic reactions." Apparently the shock-inhibiting effect of hypothalamic lesions is partly due to hypothyroidism and partly to hypercorticism.

*Nyfors G76,097/70*: In grass pollen-allergic patients, the skin wheal reaction was not significantly influenced by a large dose of prednisone, whereas the tuberculin test (Mantoux) was considerably diminished.

← **Adrenalectomy.** *Perla & Marmorston-Gottesman 16,042/29*: In rats, epinephrine raises the capacity for hemolysin formation after adrenalectomy.

*Higginbotham D21,395/62*: In mice, resistance to 5-HT, endotoxin and anaphylactic shock is markedly decreased by adrenalectomy. Cortisol readily restored resistance to 5-HT, but was less effective with regard to endotoxin and anaphylactic shock. Resistance to histamine and histamine releasers is less markedly diminished by adrenalectomy in the mouse, and large doses of cortisol are required to induce a measurable increase in resistance to histamine.

← **Folliculoids and Luteoids.** *Dutz et al. C31,646/56*: In rats, gonadectomy did not significantly change the course of Masugi nephritis, whereas a folliculoid preparation (Östrasid) and testosterone ameliorated it.

*Turcotte et al. G56,529/68*: Medroxyprogesterone acetate (a potent synthetic luteoid) increases survival of renal allografts in dogs and of skin allografts in rabbits by immunosuppression. Earlier literature on immunosuppression by luteoids is reviewed.

*Greig et al. H24,654/70*: In rats, melen-gestrol acetate (MGA; 6 $\alpha$ -methyl-6-dehydro-16-methylene-17-acetoxypregesterone)—a primarily progestational steroid with less pronounced glucocorticoid activity than that of cortisol—is more effective than the latter in suppressing allergic encephalomyelitis. Melen-gestrol is even effective in reversing the established disease.

← **Testoids.** *Sarre B99,950/54*: In rabbits, both the Masugi nephritis and sublimite nephrosis are inhibited by testosterone and even more actively by estradiol.

*Dutz et al. C31,646/56*: In rats, gonadectomy did not significantly change the course of

Masugi nephritis, whereas a folliculoid preparation (Östrasid) and testosterone ameliorated it. STH considerably aggravated the glomerular lesions and the hypertension.

*Ghione D87,868/57*: 4-Chlorotestosterone enhances anaphylactic shock in guinea pigs, prolongs survival in systemic nocardiosis of mice and improves healing in cutaneous nocardiosis of rabbits.

*Heboyan & Messeri G69,057/62*: In rats vaccinated with *S. typhi* and maintained on the high-fat low-protein diet of Handler, the anabolic steroid 4-hydroxy-19 nortestosterone-17 cyclopentyl propionate increases the formation of agglutinins,  $\gamma$ -globulins, and complement.

*Jannuzzi & Bassi G68,895/62*: In infants vaccinated against diphtheria, serum antitoxin levels were raised by 4-chlorotestosterone and methandrostenolone.

*Toletino D34,052/62*: In rats, immunized by sheep erythrocytes, various anabolic testoids enhance antibody formation. Such steroids also raise the titer of antitoxin in infants vaccinated against diphtheria.

*Terragna & Jannuzzi G2,778/63*: In rats, hemolysin formation following i.p. injection of sheep erythrocytes is greatly increased by various anabolic steroids such as 4-chloro-19-nortestosterone, norandrostenolone, phenylpropionate, methandrostenolone, 4-chlorotestosterone and dehydroisoandrosterone.

*Ghione & Turolla G18,525/64*: Review of the effect of various anabolics upon immune reactions.

*Toletino et al. G70,136/64*: In rats, methandrostenolone, administered several days before or after immunization by sheep erythrocytes, failed to affect antibody formation, whereas concurrent treatment stimulated it.

*Lupulescu et al. F77,999/66*: In rabbits, the formation of antibodies against *Brucella S<sub>6</sub>* is stimulated by thyroxine and 4-chlorotestosterone but decreased by thiourea. The effect of 4-chlorotestosterone is evident even after destruction of the thyroid and hence is not mediated through the latter gland.

← **Gonadectomy.** *Kemény et al. B66,729/51*: In guinea pigs, both ovariectomy and orchidectomy diminish anaphylactic shock, whereas thymectomy has no effect upon it.

*Dutz et al. C31,646/56*: In rats, gonadectomy did not significantly change the course of Masugi nephritis, whereas a folliculoid preparation (Östrasid) and testosterone ameliorated it.

### HEPATIC LESIONS ←

(*cf. also* Section on "Drugs" for lesions produced by hepatotoxic compounds and "Histology" for the effect of steroids on the normal liver).

← **Corticoids.** Probably the first definite proof of some interaction between the liver and the adrenal, in the maintenance or resistance to various damaging agents, was given by the observation that although adrenocortical extracts (rich in glucocorticoid potency) have little influence upon the resistance of intact animals to stress, they do exhibit a marked anti-shock effect in rats subjected to very extensive partial hepatectomy. In these they prevent the characteristic hypovolemia, hypochloremia, and hypoglycemia that normally develop after removal of almost the entire hepatic tissue.

The regeneration of the liver as well as the accumulation of protein and free fatty acids in hepatic tissue are enhanced by moderate doses of adrenocortical extract or ACTH. On the other hand, heavy overdosage with glucocorticoids may interfere with hepatic regeneration as part of the general catabolic effect exerted by these hormones. Allegedly, supplements of vitamin-B<sub>12</sub> counteract the inhibitory action of heavy cortisone overdosage upon hepatic regeneration in partially hepatectomized rats.

After complete hepatectomy "cortin" does not prevent hypoglycemia, presumably because glucocorticoids act upon the blood sugar largely through the liver. However, after total hepatectomy or total evisceration (with intact kidneys and adrenals), rats can maintain a high blood sugar if they receive adrenocortical extract in combination with glucose and insulin. These observations show that glucocorticoids are also capable of affecting the blood sugar through extrahepatic mechanisms. On the other hand, in rats with irreversible hypovolemic shock produced by complete occlusion of the portal vein, neither cortisol nor adrenalectomy influenced the survival time significantly.

There is good reason to believe that glucocorticoids increase bile secretion; this may be of considerable importance in some of the protective effects of steroids against agents eliminated through the bile. Following complete occlusion of the choledochus, cortisol enhances the accumulation of bile in the duct stump; it also favors the formation of perforating choledochus ulcers and hepatic necroses, both in intact and in adrenalectomized rats. All these effects are counteracted by concurrent administration of STH. In dogs, with choledochus ligature, cortisone raises the level of total serum bilirubin, suggesting increased bile pigment synthesis.

← **Adrenalectomy.** In partially hepatectomized rats, adrenalectomy inhibits hepatic regeneration, and decreases the deposition of fat and protein in the liver remnant. Glucocorticoid adrenal extracts, unlike DOC, restore these responses to normal. Yet, some degree of hepatic regeneration is possible even in the absence of the adrenals.

← **Folliculoids.** In partially hepatectomized rats, stilbestrol or hexestrol does not markedly affect the mitotic proliferation of the hepatocytes. In rats with choledochus ligature, estradiol is said to shorten survival.

← **Testoids.** In the rat, testosterone prolongs survival and inhibits the body-weight loss normally observed after choledochus ligature. This steroid also inhibits hepatic steatosis during the first days following partial hepatectomy in rats, but it has no significant effect upon hepatic GPT concentration.

← **Corticoids**

*Selye et al. A 32,768/40:* Review of the earlier literature on the ability of epinephrine and "cortin" to raise resistance against various stressors. Attention is called to the fact that whereas cortin is very effective in this respect in adrenalectomized animals, it rarely increases resistance above normal in the presence of the adrenals. The slight effect that cortical extracts do possess during severe shock is presumably due to the fact that "a condition of 'relative adrenal insufficiency' exists in organisms exposed to nonspecific damage." Following extensive partial hepatectomy in rats, "suitable cortin therapy prevents the hypochloreaemia, and the decrease in blood volume and in blood sugar which are usually elicited by this intervention." In rats damaged by repeated s.c. injections of formaldehyde, cortical extract prevented the hypoglycemia and hypochloreaemia of severe shock, whereas DOC was virtually ineffective, and in fact it aggravated the s.c. edema caused by formaldehyde. Chronic pretreatment with cortical hormones causes adrenal atrophy which counteracts their beneficial effect in protecting against stress. "These experiments should be interpreted as a warning against prolonged pretreatment with this substance in preparation for a surgical intervention." The best protective effect was obtained in rats with surgical shock produced by crushing of the intestines, if given repeated injections of cortical extract s.c. during the subsequent 24 hrs. An "Addendum" reports on similar experiments performed with corticosterone prepared for this purpose by E. C. Kendall. This compound, which differs from DOC only in that it possesses an 11 $\beta$ -hydroxyl group, proved to be especially effective in protecting the rat against traumatic shock caused by crushing of the intestines. [This was the first observation showing that 11-oxygenation of corticoids is required to endow them with anti-stress activity (H.S.).]

*Selye & Dosne A 30,702/40:* In the rat, "the decrease in blood sugar produced by complete hepatectomy is not significantly influenced even by large doses of cortin. This finding makes it probable that the cortical hormone does not inhibit the utilization of circulating sugar. It seems more likely that it prevents the hypoglycemic action of insulin or the decrease in blood sugar following the removal of a large part of the hepatic glycogen stores by stimulating gluconeogenesis in the liver."

*Berman et al. 97,700/47:* DOC stimulates liver regeneration in partially hepatectomized rats as judged by the weight and protein content of the liver remnant.

*Ingle et al. B 2,737/47:* In completely hepatectomized and eviscerated rats (with intact kidneys and adrenals) receiving continuous i.v. infusions of glucose + insulin, adrenocortical extract caused a rise in blood sugar.

*Roberts B 97,023/53:* In rats, the enhanced repair on the liver after treatment with ACTH or adrenocortical extract is characterized mainly by an increased protein deposition in the liver remnant. The usual decline of serum proteins occurring after partial hepatectomy was completely prevented by this treatment.

*Einhorn et al. E 55,369/54:* In rats, "the restoration of the weight of the liver after partial hepatectomy was not markedly affected by cortisone, the multiplication of cells was reduced to a significant degree after the first 2 days of regeneration. Liver restoration in terms of nucleic acids was similarly inhibited by cortisone."

*Selye B 90,556/54:* In rats with jaundice caused by bile duct ligation, minute doses of cortisone exert a strong antiphlogistic action (granuloma-pouch and topical irritation arthritis techniques), presumably because jaundice conditions for the anti-inflammatory effect of glucocorticoids.

*Selye & Bois B 97,074/54:* Following occlusion of the choledochus, cortisol enhances accumulation of bile in the duct stump and favors the development of perforating choledochus ulcers and hepatic necroses both in intact and in the adrenalectomized rats. All these manifestations of cortisol overdosage are inhibited by STH, cf. Fig. 20, p. 356.

*Chandler et al. C 39,998/57:* In dogs with bile duct ligation, cortisone raised the level of total serum bilirubin, indicating increased synthesis of bile pigments. At the same time, proliferation of bile ducts was inhibited.

*Maros et al. D 12,784/61:* In rats, inhibition of hepatic regeneration after partial hepatectomy by cortisone can be blocked by concurrent administration of vitamin-B<sub>12</sub> supplements.

*Miti & Memeo D 27,223/62:* Aldosterone increases hepatic regeneration after partial hepatectomy in the rat. Earlier literature on this subject, including observations on hepatic regeneration after simultaneous partial hepatectomy and adrenalectomy, is reviewed.

**Fig. 20. Effect of corticoids upon bile secretion and the choledochus.** In all animals, the choledochus was ligated. A: Treatment with large doses of cortisol. Macroscopic aspect of the liver (seen from its caudal aspect). To visualize the duodenum, a wooden stick is introduced into its lumen. The bile-duct, though greatly dilated, is collapsed because of a perforation near the duodenum. There are also several other very thin, ulcerated parts where perforation is imminent. B: Treatment with small doses of cortisol. Here, the bile-duct is greatly dilated and a few thin points are distinguishable, but perforation did not occur. C: Treatment with DOC. Bile-duct is only slightly dilated and of dense structure. D: Histologic section through the bile-duct shown above. Note the interruption of the dark epithelial lining and the large ulcer, filled with necrotic tissue (lower right quadrant). Many of the bile-duct branches within the adjacent hepatic tissue were proliferating and greatly dilated. E: Histologic section through the bile-duct shown above. Here, the wall of the choledochus is thin and the surrounding connective tissue very edematous, but actual ulceration has not occurred. The adjacent liver tissue contains several patches of focal necrosis. F: Histologic section through the bile-duct shown above. Note the dense connective tissue underneath the epithelium of the choledochus and the absence of ulcers. Though not shown here, this effect of cortisol is counteracted by concurrent administration of STH. [Selye and Bois B97,074/54. Courtesy of Gastroenterologia (Basel)]

*Souda D62,846/62*: In the rat, cortisone pretreatment inhibits mitotic proliferation in the regenerating liver after partial hepatectomy.

*Bucher G68,621/63*: Review on the influence of adrenalectomy and corticoids upon hepatic regeneration.

*Zimel & Măcrineanu F35,084/64*: In rats, hepatic regeneration following partial hepatectomy is moderately influenced by cytostatic derivatives of hexestrol and cortisol.

*Hyde & Davis F82,461/66*: Both cortisol and the diuretic drug chlorazanyl depress mitotic division in the regenerating liver of the mouse, after partial hepatectomy.

*Petzold & Ziegler F92,832/67*: The fat and phosphatase accumulation in the liver remnant of partially hepatectomized rats is enhanced by prednisone. 4-Chlorotestosterone does not significantly affect the tissue phosphatase, but delays the removal of fats from the liver.

*Deplano H23,483/68; Deplano & Fornara H23,484/68*: In rats, the effect of cortisone upon hepatic regeneration following partial hepatectomy is examined with special reference to DNA and RNA synthesis and alkaline phosphatase activity.

*Mejia et al. G60,637/68*: In rats with irreversible hypovolemic shock produced by complete occlusion of the portal vein, neither cortisol pretreatment nor adrenalectomy influenced the survival time, whereas selective extirpation of the adrenal medulla, or continuous infusion of norepinephrine increased it. Similar infusion of epinephrine decreased survival time.

*Šimek et al. G71,089/68*: In intact, and even more markedly in adrenalectomized rats, the accumulation of free fatty acids in the liver is enhanced by cortisol during the early period after partial hepatectomy. ACTH has the same effect, but only in the presence of the adrenals.

*Šimek et al. H13,837/68*: Comparative studies on DNA synthesis, fatty acid content, and the weight of the regenerating liver in partially hepatectomized rats after treatment with cortisol, ACTH, and various stressor agents.

*Bucher et al. G72,546/69*: Review of the humoral factors responsible for hepatic regeneration following partial hepatectomy. Hepatic DNA synthesis is stimulated in intact rats by parabiosis or cross-circulation with partially hepatectomized partners. Further-

more, tiny liver grafts implanted outside of the portal area proliferate in response to partial ablation of the parent organ. Various stressors inhibit hepatic regeneration in partially hepatectomized rats, but this effect is not reproduced by ACTH or cortisol. On the other hand, adrenalectomy increases hepatic regeneration.

*Raab & Webb H20,502/69*: In rats, the biosynthesis of DNA is maximally inhibited by cortisol 17–19 hrs after partial hepatectomy.

*Shigei H27,112/69*: In rats, adrenalectomy changed the ultrastructure of hepatocytes by reducing the glycogen areas, increasing the number of mitochondria and lysosomes, and inducing vesicular forms of endoplasmic reticulum around the Golgi complexes. All these changes are prevented by cortisol. In partial hepatectomized rats, adrenalectomy and cortisol also exert antagonistic effects upon hepatocyte ultrastructure.

*Wimberly et al. G65,769/69*: In dogs and cats, methylprednisolone alone or in combination with antibiotics failed to increase survival following temporary occlusion of the portal vein and hepatic artery.

#### ← Adrenalectomy

*MacKay & Carne A14,767/38*: In rats, the hepatic steatosis normally occurring during 24 hrs of fasting after partial hepatectomy is more pronounced in females than in males, and can be largely prevented by adrenalectomy.

*Berman et al. 97,700/47*: Adrenalectomy decreases the deposition of fat and protein as well as the increase in cell size and number normally seen in the liver remnant of rats 24 hrs after partial hepatectomy. A glucocorticoid adrenal extract unlike DOC restores these responses to normal.

*Canzanelli et al. B37,729/49*: In rats, hypophysectomy delays liver regeneration after partial hepatectomy but "neither adrenalectomy nor the administration of adrenal-cortex extract has any effect on the amount of liver regeneration."

*Drabkin B53,844/50*: In partially hepatectomized and adrenalectomized rats, active hepatic regeneration occurred despite depletion of cytochrome c.

*Friedgood et al. B52,238/50*: In rats, after partial hepatectomy, regeneration and protein accumulation in the liver are inhibited by adrenalectomy, but restored to a certain degree by adrenocortical extract. 11-Dehydrocorticosterone and 17-hydroxy, 11-dehydrocorti-

costerone share this effect, yet DOC is even more active.

*Uyldert G76,358/50*: In rats, the inhibition of hepatic regeneration following partial hepatectomy (about 1/3 of the liver removed) is inhibited by adrenalectomy and restored both by adrenocortical extract and by DOC.

*Bucher G68,621/63*: Review on the influence of adrenalectomy and corticoids upon hepatic regeneration.

*Camargo et al. F72,052/66*: After partial hepatectomy, lipid infiltration of the rat liver depends upon the proportion of hepatic tissue removed, and not upon surgical stress, post-operative fasting, simultaneous adrenalectomy, or hypophysectomy. The lipid infiltration reaches a maximum 6—12 hrs after the operation, and then declines.

*Šimek et al. H22,183/68*: In rats, the initial increase in liver triglyceride content induced by partial hepatectomy is decreased after adrenalectomy. However, within 24 hrs after the operation, this difference disappears. The effect of adrenalectomy upon the liver triglyceride changes induced by partial hepatectomy can be annulled by epinephrine or cortisone. ACTH augments the immediate rise in liver triglyceride but only in the presence of the adrenals.

*Shigei H27,112/69*: In rats, adrenalectomy changed the ultrastructure of hepatocytes by reducing the glucogen areas, increasing the number of mitochondria and lysosomes, and inducing vesicular forms of endoplasmic reticulum around the Golgi complexes. All these changes are prevented by cortisol. In hepatectomized rats, adrenalectomy and cortisol also exert antagonistic effects upon hepatic ultrastructure.

#### ← Folliculoids

*Cristensen & Jacobsen A49,204/49*: In rats subjected to partial hepatectomy, neither hypophysectomy nor thyroidectomy impairs the rate of regeneration. No significant change in mitotic rate was observed after pretreatment with stilbestrol or STH.

*Giuliani C15,153/55*: In rats with bile duct ligation, testosterone prolongs survival and inhibits body weight loss, but its action upon the prostate is diminished. Estradiol exerts inverse effects in all these respects.

*Zimel & Măcineanu F35,084/64*: In rats, hepatic regeneration following partial hepatectomy is moderately influenced by cyostatic derivatives of hexestrol and cortisol.

*Kappas G43,772/67*: Review (4 p., 42 refs.) on the hepatotoxic effect of folliculoids in animals and man.

*Martinez-Manautou et al. H30,302/70*: Women were treated for several years with oral contraceptives containing a luteoid (chlormadinone acetate) with or without folliculoids. There was "a moderate dilatation and vesiculation of the rough and smooth surfaced endoplasmic reticulum both in the women treated with microdoses of progestogens, and in those treated with a combination of progestogens and oestrogens. A more marked vesiculation of this organelle was present in those women under sequential medication. Elongation of mitochondria with crystalloid inclusions in their matrices was found in 5 to 10% of the whole population of mitochondria per cell examined in the chlormadinone treated women."

#### ← Testoids

*Giuliani C15,153/55*: In rats with bile duct ligation, testosterone prolongs survival and inhibits body weight loss, but its action upon the prostate is diminished. Estradiol exerts inverse effects in all these respects.

*Bengmark & Olsson D6,135/64*: In rats, testosterone inhibits fatty infiltration of the liver during the first days after partial hepatectomy but has no significant effect upon liver weight or hepatic glutamic pyruvic transaminase concentration.

*Petzold & Ziegler F92,832/67*: The fat and phosphatase accumulation in the liver remnant of partially hepatectomized rats is enhanced by prednisone. 4-Chlorotestosterone does not significantly affect the tissue phosphatase, but delays the removal of fats from the liver.

*Porto & Donato H34,703/69*: In guinea pigs, hepatic regeneration after partial hepatectomy is enhanced by testosterone.

#### ← Other Steroids

*Selye G70,480/71*: In rats, the bile duct was ligated on the 4th day of conditioning. Final eviscerated body weight was measured, and mortality listed on the 10th day. Under these circumstances none of the "Standard Conditioners" (p. VIII) or cortisone caused any noteworthy change in the resulting intoxication. CS-1, PCN and phenobarbital were not tested.

*RENAL LESIONS* ←

(*cf. also* Renal Damage Induced by Mercury and Other Toxicants *under* "Drugs")

← **Corticoids.** In mice and rats, pretreatment with DOC prolongs survival and delays the rise in blood NPN following complete nephrectomy. This effect is particularly obvious in rats maintained on high carbohydrate diets. It is possible that depletion of the potassium stores by the mineralocorticoid participates in this protective effect.

In dogs maintained on a standard high-fat diet, arterial lesions develop upon subsequent total nephrectomy. These are prevented by cortisone as well as by ACTH and pregnancy. Cortisol also prolongs survival of dogs after bilateral ligation of the ureters and in rats, the renal damage produced by obstruction of the ureters is diminished by cortisone.

On the other hand, the calcification of the kidney induced in rats by complete ligation of the renal blood vessels is increased by cortisone, whereas the cardiovascular calcification elicited by bilateral nephrectomy, especially in old rats, is not significantly influenced by glucocorticoids (e.g., prednisolone, triamcinolone) or DOC.

← **Testoids.** The most extensive studies on the effect of steroids upon the consequences of renal damage have been performed with testoids. The first pertinent observation was the demonstration that testosterone pretreatment prolongs the survival of mice after bilateral nephrectomy, and protects the kidney against atrophy following the production of hydronephrosis by unilateral ligation of the ureter. MAD also exerts a potent renotropic effect upon the hydronephrotic mouse kidney.

Furthermore, testosterone alone or in combination with DOC delays the development of azotemia in rats, especially if they are kept on a high carbohydrate diet. However, data on the ability of testoids to maintain life after complete nephrectomy are contradictory, presumably because the diet, species, age and other factors may modify the response. It has been claimed that both MAD and nandrolone prolong the survival time of bilaterally nephrectomized rats. Similar results have been obtained with several other anabolic testoids, in various species including man, but these data have not remained unchallenged.

← **Folliculoids and Luteoids.** The arterial lesions that develop following complete nephrectomy in dogs kept on a standard high-fat diet are prevented not only by corticoids but also by diethylstilbestrol.

The cardiovascular calcification elicited by bilateral nephrectomy in aged rats is not significantly affected either by estradiol or by progesterone.

← **Gonadectomy.** Male rats are more sensitive than females to the production of hypertension by unilateral renal artery constriction. Gonadectomy does not significantly alter this change in males, although it appears to aggravate it in females.

← **Other Steroids.** Spironolactone has been claimed to protect the rat against mortality and some of the cardiovascular and renal changes normally produced by an "endocrine kidney" or by a renal encapsulation. On the other hand, the cardiovascular calcification elicited by bilateral nephrectomy in aged rats is not influenced by ethylestrenol, CS-1, spironolactone, norbolethone or oxandrolone.

← **Corticoids**

*Selye A 34,190/40*: "Experiments in mice and rats indicate that pretreatment with desoxycorticosterone acetate prolongs the survival time of animals in which acute uraemia is produced by bilateral nephrectomy."

*Selye & Nielsen A 35,723/41; Dosne A 35,924/41*: In the rat, pretreatment with DOC "not only prolongs the survival time and delays clinical signs of uremia, but actually inhibits the rise in the non-protein nitrogen content of the blood after complete nephrectomy."

*Masson et al. B 40,204/49*: DOC and testosterone, alone or in combination, delayed the development of azotemia only in rats fed a high carbohydrate diet.

*Holman & Jones B 93,771/53*: The arterial lesions that occur in dogs kept on a standard high fat diet upon subsequent nephrectomy are prevented by pregnancy, cortisone, ACTH, or diethylstilbestrol.

*Guze & Beeson C 43,020/57*: In rats with ureteral ligation, damage to the renal tissue is inhibited by cortisone.

*Berman C 74,922/59*: Survival in uremia, produced by bilateral ureteral ligation in dogs, is prolonged by cortisol, but not by testosterone.

*Dési et al. C 69,045/59*: In rats, survival after bilateral nephrectomy is prolonged by STH and DOC, alone or in combination, but the effect of STH is diminished by concurrent administration of MAD.

*Laron & Laufer D 20,687/62*: In rats, cortisone increases calcium deposition in the kidney following ligation of its vessels, but prevents ectopic bone formation.

*Gardell et al. G 70,430/70*: In rats, the cardiovascular calcification produced by bilateral nephrectomy is not significantly influenced by ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone, triamcinolone, DOC, estradiol, or thyroxine.

← **Testoids**

*Selye A 30,863/40*: Testosterone pretreatment prolongs the survival of mice after bilateral nephrectomy. Cholesterol does not share this effect.

*Selye & Friedman A 35,722/41*: "Experiments on the mouse indicate that the renal atrophy, which usually develops subsequent to the hydronephrosis caused by unilateral

ligature of the ureter, may be inhibited and delayed by testosterone administration."

*Masson et al. B 40,204/49*: DOC and testosterone, alone or in combination, delayed the development of azotemia only in rats fed a high carbohydrate diet.

*Homburger et al. B 47,878/50*: MAD exerts "a potent renotropic effect upon the experimental hydronephrotic mouse kidney."

*Berman C 74,922/59*: Survival in uremia produced by bilateral ureteral ligation in dogs, is prolonged by cortisol, but not by testosterone.

*Dési et al. C 69,045/59*: In rats, survival after bilateral nephrectomy is prolonged by STH and DOC, alone or in combination, but the effect of STH is diminished by concurrent administration of MAD.

*Szold et al. C 64,498/59; C 79,889/59*: Nandrolone prolongs the survival time of bilaterally nephrectomized rats.

*Dési et al. D 11,138/61*: 19-Norandrostenolone-decanoate (Durabolin) significantly prolongs the survival time in nephrectomized rats.

*Gerber & Cottier D 12,775/61*: "The 3 tested testosterone derivatives with anabolic properties (19-Nortestosteronphenylpropionate, 17-Ethyl-19-nortestosterone, 1-Dehydro-17-methyltestosterone) did not lower the daily increment of urea concentration in the blood of rats following bilateral nephrectomy, even when the hormones were given prophylactically." [The hormones were tested at a dose of 3 mg/kg body weight (H.S.).]

*Köhnlein & Rehn D 44,607/62*: The kidney damage produced by temporary renal artery obstruction in the rat is effectively combated by testosterone, but not by norandrostenolone phenylpropionate (Durabolin). From this, it is concluded that the nephrotrophic effect depends upon testoid and not upon anabolic activity.

*Börner et al. E 85,972/66*: Review and personal observations on the effect of testoids upon various clinical and experimental uremic conditions.

*Schimmelpfennig et al. F 74,978/66*: In castrate rats, 4-chlorotestosterone did not significantly improve the renal insufficiency caused by 30 min ligation of the left renal artery.

*Tessmann H 5,695/67*: Pretreatment with testosterone exerted no protective effect against the tubular damage elicited by temporary obstruction of the renal vessels in the mouse and rat.

← **Folliculoids and Luteoids**

*Holman & Jones B93,771/53*: The arterial lesions that develop in dogs kept on a standard high fat diet, upon subsequent nephrectomy are prevented by pregnancy, cortisone, ACTH, or diethylstilbestrol.

*Gardell et al. G70,430/70*: In rats, the cardiovascular calcification produced by bilateral nephrectomy is not significantly influenced by ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone, triamcinolone, DOC, estradiol, or thyroxine.

← **Gonadectomy**

*Bein et al. C57,714/58*: In male rats, with hypertension produced by unilateral renal artery constriction, vascular lesions are more common than in females. Gonadectomy does not significantly alter these changes in males, but aggravates them in females. Parathyroidectomy has no significant effect upon them.

← **Other Steroids**

*Fregly D15,796/61*: In the rat, the anti-mineralocorticoid spironolactone SC-8109 diminished the hypertension produced by renal encapsulation.

*Nadasdi D9,288/61*: "Spironolactone significantly protects against the mortality and some of the cardiovascular-renal changes normally produced by the presence of an ischemic (or 'endocrine') kidney in rats."

*Gardell et al. G70,430/70*: In rats, the cardiovascular calcification produced by bilateral nephrectomy is not significantly influenced by ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone, triamcinolone, DOC, estradiol, or thyroxine.

*Selye G70,480/71*: In rats nephrectomized on the 8th day of conditioning, none of the "Standard Conditioners" (p. VIII) or cholesterol caused any noteworthy change in mean survival. CS-1, PCN and phenobarbital were not tested.

**OTHER SURGICAL PROCEDURES** ←

(cf. also "Stress")

After **parathyroidectomy**, the mortality is approximately the same in male and spayed female rats, whereas intact females are said to be more resistant. In orchidectomized rats, estradiol allegedly prolongs survival after thyroparathyroidectomy, the comparatively high resistance of intact females is ascribed to folliculoids.

Extensive **partial pancreatectomy** causes diabetes more readily in male than in female rats. Postnatal orchidectomy abolishes this sex difference.

*Rowinski & Manunta B64,144/51*: Mortality after parathyroidectomy is equal in male and in spayed female rats, whereas intact females are more resistant.

*Foglia & Penhos B79,957/52*: In male rats, extensive partial pancreatectomy causes severe diabetes more frequently than in females.

Postnatal orchidectomy abolishes this difference.

*Manunta B73,160/52*: In orchidectomized rats, estradiol prolongs survival after thyroparathyroidectomy. A comparatively high resistance of intact females to parathyroidectomy is attributed to folliculoid hormones.

**IONIZING RAYS** ←

← **Corticoids**. It has been claimed that in the mouse, pretreatment with DOC offers some protection against total body X-irradiation, but subsequent studies have shown that the resistance so induced, if at all significant, is very moderate. Glucocorticoids have likewise little, if any, prophylactic action against ionizing rays.

On the other hand, cortisone may enhance the protective effect of heterologous bone marrow transplants by suppressing immune reactions against the grafted cells.

Severe X-irradiation greatly increases the sensitivity of the mouse to bacterial endotoxins and this effect is counteracted by shielding the adrenals or treatment with cortisone.

In the **rat**, the recovery of hemopoietic tissue after total body X-irradiation is impaired by cortisone. Furthermore, the protection against such irradiation that may be obtained by reduction of oxygen tension is counteracted by cortisone. The renal lesion induced by topical X-irradiation of the kidneys is aggravated, whereas the pulmonary fibrosis produced by X-irradiation of the lungs is diminished by cortisone.

In **rabbits**, cortisone allegedly increases topical X-ray resistance of the skin. Betamethasone partially inhibits X-ray damage to the nervous system in rabbits.

In **guinea pigs**, cortisone is said to offer some protection against total body X-irradiation.

It has also been claimed that in **man**, radiation sickness can be prevented by DOC or by glucocorticoids, and in a few patients, prednisolone appeared to have a beneficial effect upon radiation pneumonitis. The topical X-ray resistance of the skin is allegedly also increased by cortisone.

← **Testoids**. Several investigators claimed that testosterone and other testoids offer some protection to the **mouse** against total body X-irradiation, but others found this type of treatment ineffective or even harmful. These differences may be due to variations in dosage and timing. Pretreatment with testosterone is allegedly much more efficacious in this respect than treatment after exposure.

Similarly variable protective effects have been observed in the **rat**, **rabbit**, and several **other species**. Various testoid anabolics are not equally potent in this respect, but none appears to have been conspicuously efficacious in counteracting the radiation syndrome.

← **Luteoids**. Virtually all the published data are in agreement stating that progesterone and other luteoids do not offer protection against X-irradiation in any animal species.

← **Adrenalectomy**. In the mouse, the polydipsia, polyuria, and hepatic steatosis seen during the first days after total body X-irradiation tend to be inhibited by adrenalectomy, but these apparent improvements are actually due to the lack of defensive adrenocortical responses. Survival after X-irradiation is undoubtedly shortened by adrenalectomy.

← **Folliculoids**. Many publications deal with the effect of various folliculoids upon X-ray resistance in the **mouse**, but the results are very contradictory. It appears that, in general, pretreatment with folliculoids increases X-ray resistance, whereas treatment after irradiation has an inverse effect; however, the outcome of such experiments depends upon too many hitherto unidentified factors to permit precise evaluation. Among these modifying influences, the type of folliculoid used, the dosage, timing, intensity of irradiation, genetic predisposition and many others may be important.

Similarly contradictory results have been obtained in the **rat** and various **other species**.

← **Gonadectomy**. Several investigators agree that male mice are less resistant than females to total body X-irradiation, although after gonadectomy, the females are even more sensitive than the males. Male, unlike female rats, fed X-irradiated beef, die of internal hemorrhages, the severity of which is aggravated by testosterone.

← **Corticoids**

## MOUSE

*Ellinger 93,367/46:* Pretreatment with DOC lessened fatty degeneration of the liver normally induced in mice by X-irradiation but only slightly decreased mortality, and failed to protect the bone marrow and spleen.

*Ellinger 93,953/47:* DOC reduces mortality in mice exposed to X-rays.

*Ellinger B24,015/48:* DOC offers some protection against total body X-irradiation in mice. Pregnenolone is ineffective in this respect.

*Ellinger B57,402/48:* In mice, DOC increases resistance to X-irradiation.

*Graham & Graham A49,307/49:* In mice, testosterone, estradiol, stilbestrol, and DOC did not significantly alter resistance to X-radiation whereas horse serum i.p. offers considerable protection.

*Straube et al. B39,082/49:* Neither DOC nor adrenocortical extract altered the X-ray resistance of intact or adrenalectomized mice.

*Graham & Graham B58,164/50:* Review of the literature, and personal observations on the effect of folliculoids, luteoids, testoids, adrenocortical extract, and DOC upon the resistance of the mouse to total body X-irradiation.

*Graham et al. B48,335/50:* Survival time is increased in mice given adrenocortical extract immediately after total body X-irradiation, whereas DOC, 11-dehydrocorticosterone (Kendall's Compound A), stilbestrol, and testosterone are inactive in this respect.

*Smith et al. B47,642/50:* In mice, neither ACTH nor cortisone increased survival following X-irradiation.

*Mirand et al. B76,197/52:* In mice exposed to X-irradiation of the head, both cortisone and DOC diminish mortality.

*Ellinger B95,888/54:* Review (8 pp., 54 refs.) on the effect of hormones upon X-ray sensitivity. In mice, DOC increases, whereas cortisone diminishes tolerance to ionizing rays.

*Kaplan et al. B98,601/54:* Review (40 pp., 107 refs.) on the role of folliculoids, corticoids, luteoids, and testoids in the development of radiation-induced lymphoid tumors of mice.

*Betz C13,907/55:* Pretreatment with DOC enhances the resistance of the mouse to X-irradiation, but treatment after exposure is ineffective. Cortisone does not protect, even if administered before X-irradiation. There is no obvious sex difference in X-ray resistance

among mice. Pretreatment with testosterone offers definite protection, especially to females, but here again, its administration after exposure is without effect. Curiously, estradiol pretreatment also offers protection, whereas given after exposure, it actually decreases resistance.

*Cole et al. C14,411/55:* "The administration of cortisone may enhance the protective effect of rat bone marrow in X-irradiated mice."

*Brenk C57,624/58:* Cortisone failed to influence acute radiation lethality in mice, but delayed the appearance of diarrhea.

*Skalka C71,368/59:* In mice, the hepatic steatosis induced by X-irradiation is prevented by adrenalectomy, but restored by cortisone. DOC is ineffective in this respect.

*Smith et al. E21,486/63:* Exposure to severe X-irradiation greatly increases the sensitivity of mice to *S. typhosa* endotoxin, especially on the third day after irradiation. Shielding the adrenals, or treatment with cortisone counteracted the effect of X-irradiation. Shielding the abdominal cavity, but not the adrenals, was even more effective. Possibly, the protection of the intestines plays a decisive role here. "It might be conjectured that absorption of bacterial endotoxins from the intestinal lumen influences the time of the so-called intestinal death following high doses of radiation."

*Cittadini et al. G76,028/70:* In X-irradiated mice, the formation of hemopoietic islets in the spleen is inhibited by dexamethasone, ACTH, or the stress of exposure to cold.

*Mistry et al. H33,481/70:* In certain strains of mice, cortisol inhibits the induction of leukemia by X-rays.

## RAT

*Thiersch et al. B76,313/52:* In rats, the recovery of hemopoietic tissues following total body X-irradiation is impaired by cortisone.

*Stender & Hornykiewytsch C37,079/55:* In rats, the lethal effect of total body X-irradiation is diminished by a reduction in the oxygen tension of the surrounding air. This protective action is counteracted by cortisone, adrenalectomy, and thyroxine.

*Berdjís & Brown C45,470/57:* In rats, the pulmonary fibrosis produced by local X-irradiation is diminished by cortisone.

*Haley et al. C51,851/58:* In rats, adrenocortical extract did not improve the decreased muscular efficiency induced by whole body X-irradiation.

*Berdjis C 83,954/60*: In rats, the renal lesions produced by X-irradiation of both kidneys are aggravated by cortisone. "While the control kidneys showed no alterations, the cortisone-treated animals developed glomerulosclerosis with intercapillary thickening, capillary thrombosis, hyaline masses, and cystic formations. These lesions were more marked in the irradiated groups."

*Bargon et al. G 78,255/70*: In rats, the renal damage, particularly the sclerosis produced by topical X-irradiation, is diminished by prednisolone.

#### RABBIT

*Lehmann et al. C 46,970/56*: Both in the rabbit and in man, systemic treatment with cortisone increases the topical X-ray resistance of the skin.

*Giordano & Invernizzi H 5,873/68*: In rabbits, X-ray damage to the nervous system can be partially inhibited by betamethasone.

#### GUINEA PIG

*Cervini & Longo C 9,357/55*: Cortisone appears to have offered some protection against total body X-irradiation in guinea pigs.

#### MAN

*Ellinger et al. B 44,439/49*: In patients, radiation sickness can be prevented by DOC.

*Painter & Brues B 39,627/49*: Discussion on the use of corticoids in combating the radiation syndrome.

*Douglas C 78,775/59*: In a few patients with radiation pneumonitis, prednisolone had a beneficial effect.

#### ← Testoids

#### MOUSE

*Graham & Graham A 49,307/49*: In mice, testosterone, estradiol, stilbestrol, and DOC did not significantly alter resistance to X-irradiation, whereas horse serum i.p. offers considerable protection.

*Patt et al. B 32,806/49*: In mice, estradiol benzoate greatly enhances resistance to total body X-irradiation. Progesterone and testosterone are ineffectual. The protective action of folliculoids may be mediated through the adrenals.

*Patt et al. B 43,570/49*: In mice, estradiol, unlike testosterone or progesterone, offers significant protection against total body X-irradiation.

*Ellinger B 49,654/50*: Mortality following total body X-irradiation was greatly increased

in mice by daily treatment with testosterone begun after exposure.

*Graham et al. B 48,335/50*: Survival time is increased in mice given adrenocortical extract immediately after total body X-irradiation, whereas DOC, 11-dehydrocorticosterone (Kendall's Compound A), stilbestrol, and testosterone are inactive in this respect.

*Langendorff & Koch B 98,043/54*: Male mice are more sensitive than females to X-irradiation but after gonadectomy, females are more sensitive than males. Castration increases radiosensitivity in females and decreases it in males. Estradiol causes no further increase in the radioresistance of the castrate male. Unexpectedly, after administration of testosterone, the radioresistance of females increases far beyond the norm.

*Betz C 13,907/55*: Pretreatment with DOC enhances the resistance of the mouse to X-irradiation, but treatment after exposure is ineffective. Cortisone does not protect, even if administered before X-irradiation. There is no obvious sex difference in X-ray resistance among mice. Pretreatment with testosterone offers definite protection especially to females, but here again, its administration after exposure is without effect. Curiously, estradiol pretreatment also offers protection, whereas given after exposure it actually decreases resistance.

*Loewit G 23,765/64*: In mice, pretreatment with decadurabolin (19-nortestosterone-decanoate) offers considerable protection against total body X-irradiation.

*Ogandzhanyan et al. F 7,045/64*: In the mouse, survival after total body X-irradiation is diminished by pretreatment with stilbestrol, and uninfluenced by testosterone.

#### RAT

*Darcis & Brisbois C 50,953/57*: In the rat, the sensitivity of the small intestine to topical X-irradiation (unlike that of the vagina) is not influenced by thyroxine or testosterone.

*Oliva & Valli C 50,803/58*: In rats exposed to severe total body X-irradiation, the survival time was only slightly prolonged by pretreatment with estrone, stilbestrol, or testosterone. Progesterone was ineffective.

*Hotterbeex & Darcis C 75,318/59*: In rats, the topical damage produced in the rectum or vagina by local X-irradiation is aggravated following testosterone pretreatment.

*Ghys & Loiseau C 83,564/60*: Testosterone protects female rats against total body X-irradiation, rapid neutron rays, or radio-

active phosphorus. In males, this effect is actually reversed.

*Malhotra & Reber C 83,177/60*: A high percentage of rats fed X-irradiated meat developed a hemorrhagic syndrome with prolonged prothrombin time. Testosterone increases, whereas stilbestrol decreases the severity of the syndrome in both intact and gonadectomized males.

*Szold C 80,607/60*: 19-Norandrostenedione offers moderate protection against X-irradiation in the rat.

*Ghys D 70,483/62*: In hypophysectomized rats, sensitivity to cobalt irradiation is greatly increased by testosterone and estradiol.

*Caprino & Gallina G 10,521/63*: In the rat, norandrostenedione phenylpropionate enhances anabolism and recovery after total body X-irradiation.

*Ghys D 54,640/63*: Review of the literature on the effect of ovariectomy, orchidectomy, estradiol, and testosterone upon resistance of the rat to total body X-irradiation.

*Malhotra & Reber E 36,906/63*: Male, unlike female rats, fed X-irradiated beef, die of internal hemorrhage, the severity and lethality of which can be aggravated by testosterone. The literature on the effect of sex, castration, and stilbestrol upon the lethality of irradiated beef feeding is discussed.

*Danyasz & Panek F 61,858/65*: Methyl-androstenedione protects young rats against total body X-irradiation.

*Danyasz et al. G 38,389/65*: "A radioprotective effect in rats, resulting in an increase in the LD<sub>50</sub> was found after a continuous application of methandrostenedione (1 mg/kg)."

*Danyasz & Panek G 57,847/68*: Methandrostenedione (Dianabol) protects the rat against X-irradiation.

*Vodicka & Dostál G 69,171/68*: Nandrolone reduces the polyuria in female X-irradiated rats during the first day, but has no effect on the negative nitrogen balance or the loss of body weight.

*Picha G 70,118/69*: In rats and mice, methenolone reduces body weight loss and increases survival following X-irradiation. These anabolics also abet the radio-protective effect in man.

#### RABBIT

*Mairese & Darcis D 27,579/62*: Testosterone increases, whereas ovariectomy decreases the resistance of the buccal mucosa to X-irradiation in rabbits.

*Horváth & Horváth G 55,076/68*: The delay in the effect of X-irradiation upon the healing of bone fractures in rabbits is counteracted by nandrolone phenpropionate.

#### ← Luteoids

*Straube et al. B 33,113/48*: In mice, pre-treatment with estradiol benzoate increases resistance to total body X-irradiation, whereas treatment on the day of irradiation has an opposite effect. Progesterone is ineffectual.

*Patt et al. B 32,806/49*: In mice, estradiol benzoate greatly enhances resistance to total body X-irradiation. Progesterone and testosterone are ineffectual. The protective action of folliculoids may be mediated through the adrenals.

*Patt et al. B 43,570/49*: In mice, estradiol, unlike testosterone or progesterone, offers significant protection against total body X-irradiation.

*Graham & Graham B 58,164/50*: Review of the literature, and personal observations on the effect of folliculoids, luteoids, testoids, adrenocortical extract, and DOC upon the resistance of the mouse to total body X-irradiation.

*Kaplan et al. B 98,601/54*: Review (40 pp., 107 refs.) on the role of folliculoids, corticoids, luteoids, and testoids in the development of radiation-induced lymphoid tumors of mice.

*Rigat C 10,747/55*: Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, D<sub>2</sub>C, testosterone, estradiol, progesterone, and thyroxine.

*Oliva & Valli C 50,803/58*: In rats exposed to severe total body X-irradiation, the survival time was only slightly prolonged by pre-treatment with estrone, stilbestrol, or testosterone. Progesterone was ineffective.

*Rooks E 4,589/64*: Review (10 pp., 46 refs.) on protection by hormones against X-irradiation in mammals. In general, folliculoids (particularly estradiol), and DOC exhibit a good radio-protective effect whereas glucocorticoids, testoids and luteoids, do not.

#### ← Adrenalectomy

*Smith & Tyree C 12,045/56*: In rats, the polydipsia and polyuria seen during the first days after X-irradiation tend to be inhibited by adrenalectomy or hypophysectomy.

*Skalka C71,368/59*: In mice, the hepatic steatosis induced by X-irradiation is prevented by adrenalectomy, but restored by cortisone. DOC is ineffective in this respect.

*Etoh & Egami G11,664/63*: In goldfish, resistance to X-irradiation is greatly diminished both by adrenalectomy and by hypophysectomy.

#### ← Folliculoids

##### MOUSE

*Treadwell et al. A56,593/43*: In mice, pretreatment with estradiol diminished mortality following total body X-irradiation, whereas administration of the hormone after irradiation had a contrary result.

*Straube et al. B33,113/48*: In mice, pretreatment with estradiol benzoate increases resistance to total body X-irradiation, whereas treatment on the day of irradiation has an opposite effect. Progesterone is ineffectual.

*Graham & Graham A49,307/49*: In mice, testosterone, estradiol, stilbestrol, and DOC did not significantly alter resistance to X-irradiation, whereas horse serum i.p. offers considerable protection.

*Patt et al. B32,806/49*: In mice, estradiol benzoate greatly enhances resistance to total body X-irradiation. Progesterone and testosterone are ineffectual. The protective action of folliculoids may be mediated through the adrenals.

*Patt et al. B43,570/49*: In mice, estradiol, unlike testosterone or progesterone, offers significant protection against total body X-irradiation.

*Graham et al. B48,335/50*: Survival time is increased in mice given adrenocortical extract immediately after total body X-irradiation, whereas DOC, 11-dehydrocorticosterone (Kendall's Compound A), stilbestrol, and testosterone are inactive in this respect.

*Langendorff & Koch B98,043/54*: Male mice are more sensitive than females to X-irradiation but after gonadectomy, females are more sensitive than males. Castration increases radiosensitivity in females and decreases it in males. Estradiol causes no further increase in the radioresistance of the castrate male. Unexpectedly, after administration of testosterone, the radioresistance of females increases far beyond the norm.

*Betz C13,907/55*: Pretreatment with DOC enhances the resistance of the mouse to X-irradiation, but treatment after exposure is ineffective. Cortisone does not protect, even if administered before X-irradiation. There is

no obvious sex difference in X-ray resistance among mice. Pretreatment with testosterone offers definite protection especially to females, but here again, its administration after exposure is without effect. Curiously, estradiol pretreatment also offers protection, whereas given after exposure it actually decreases resistance.

*Rugh & Wolf C19,209/56*: Female mice are more resistant to total body X-irradiation than are males. Orchidectomy augments resistance, and this is further increased by treatment with estradiol. In intact males, estradiol raises X-ray resistance to the same level as in castrates.

*Nuzhdin et al. D5,866/60*: In mice, diethylstilbestrol offered practically no protection against the induction of gonadal atrophy by X-irradiation.

*Kohn et al. D9,831/61*: In the mouse, even minute doses of estradiol valerianate increase the mortality caused by total body X-irradiation.

*Kohn et al. D42,858/62*: Pretreatment with estradiol-17 $\beta$ -n-valerianate increases the mortality of mice exposed to X-irradiation.

*Ogandzhanyan et al. F7,045/64*: In the mouse, survival after total body X-irradiation is diminished by pretreatment with stilbestrol and uninfluenced by testosterone.

*Rugh et al. F21,653/64*: In ICR and CF1 mice, post-irradiation orchidectomy increased survival time, and estradiol caused a further prolongation of it; yet, the effects depended upon the time lapse between treatment and irradiation.

*Flemming & Langendorff G38,381/65; Langendorff & Langendorff G42,801/66*: In female mice, resistance to total body X-irradiation is greater than in males, and it can be increased in both sexes by natural and synthetic folliculoids.

*Thompson et al. G44,654/67*: In mice, estradiol or estriol administered two weeks after sublethal X-irradiation induced excessive mortality.

*Jenkins et al. H27,688/69*: In mice, treatment with estradiol during repopulation of the spleen after X-irradiation reduced the number of myelocytic colonies and increased the numbers of erythropoietic and undifferentiated colonies.

*Thompson et al. G70,145/69*: In mice, comparative studies were performed on the protection against total body X-irradiation offered by pretreatment with various folli-

culoids (esters of estradiol, estriol and estrone) in relation to their effect upon hemopoietic tissues. Earlier literature indicates a decreased X-ray resistance due to folliculoids given after X-irradiation, and an enhanced resistance induced by pretreatment with them.

#### RAT

*Oliva & Valli C50,803/58*: In rats exposed to severe total body X-irradiation the survival time was only slightly prolonged by pretreatment with estrone, stilbestrol, or testosterone. Progesterone was ineffective.

*Malhotra & Reber C83,177/60*: A high percentage of rats fed X-irradiated meat developed a hemorrhagic syndrome with prolonged prothrombin time. Testosterone increases, whereas stilbestrol decreases the severity of the syndrome, both in intact and in gonadectomized males.

*Ghys D70,483/62*: In hypophysectomized rats, sensitivity to cobalt irradiation is greatly increased by testosterone and estradiol.

*Shellabarger et al. D39,218/62*: In female rats, the production of mammary cancers by X-irradiation is inhibited by diethylstilbestrol in doses which in themselves are not carcinogenic. T3 did not influence carcinogenesis under these circumstances.

*Malhotra & Reber E36,906/63*: Male, unlike female rats, fed X-irradiated beef, die of internal hemorrhage, the severity and lethality of which can be aggravated by testosterone. The literature on the effect of sex, castration, and stilbestrol upon the lethality of irradiated beef feeding is discussed.

*Akoev et al. F73,202/66*: Both stilbestrol and thyroid extract offered some protection against  $^{60}\text{Co}$   $\gamma$ -radiation in rats.

*Mitznegg et al. G77,075/70*: In rats, pregnancy protects against X-irradiation, presumably through the increased production of endogenous folliculoids. Combined treatment with clomiphene blocks the protective effect of pregnancy perhaps because it counteracts the action of folliculoids.

*Segaloff & Maxfield H36,188/71*: In rats, combined treatment with X-irradiation and diethylstilbestrol causes a higher incidence of mammary carcinoma than either of these agents alone.

#### ← Gonadectomy

*Langendorff & Koch B98,043/54*: Male mice are more sensitive than females to X-irradiation but after gonadectomy, females are more sensitive than males. Castration

increases radiosensitivity in females and decreases it in males. Estradiol causes no further increase in the radioresistance of the castrate male. Unexpectedly, after administration of testosterone, the radioresistance of females increases far beyond the norm.

*Rugh & Wolf C19,209/56*: Female mice are more resistant to total body X-irradiation than are males. Orchidectomy augments resistance, and this is further increased by treatment with estradiol. In intact males, estradiol raises X-ray resistance to the same level as in castrates.

*Langendorff et al. C36,885/57*: Male mice are much more sensitive to X-irradiation than females. Orchidectomy increases resistance.

*Kepp & Hofmann C65,530/59*: In rats, resistance to whole body X-irradiation is increased by ovariectomy.

*Cronkite et al. C81,609/60*: In female rats, total body X-irradiation caused a high percentage of mammary carcinomas. Shielding the ovaries, or transplanting nonexposed ovaries into ovariectomized irradiated rats, did not significantly reduce the incidence of mammary neoplasms.

*Mairesse & Darcis D27,579/62*: Testosterone increases, whereas ovariectomy decreases the resistance of the buccal mucosa to X-irradiation in rabbits.

*Ghys D54,640/63*: Review of the literature on the effect of ovariectomy, orchidectomy, estradiol, and testosterone upon resistance of the rat to total body X-irradiation.

*Hamilton et al. D64,060/63*: Male mice survived  $\gamma$ -irradiation somewhat longer than females. Orchidectomy has no effect upon the survival time, but ovariectomy slightly prolongs it.

*Huggins & Fukunishi E35,442/63*: In rats, mammary tumors induced by DMBA or by X-irradiation regress following ovariectomy. "Tumors of this sort are, by definition, hormone-dependent."

*Malhotra & Reber E36,906/63*: Male, unlike female rats, fed X-irradiated beef, die of internal hemorrhage, the severity and lethality of which can be aggravated by testosterone. The literature on the effect of sex, castration, and stilbestrol upon the lethality of irradiated beef feeding is discussed.

*Rugh et al. F21,653/64*: In ICR and CF1 mice, post-irradiation orchidectomy increased survival time and estradiol caused a further prolongation of it but the effects depended upon the time lapse between treatment and irradiation.

← **Other Steroids**

*Ellinger B24,015/48*: DOC offers some protection against total body irradiation in mice. Pregnenolone is ineffective in this respect.

*Ghys D30,012/62*: Review of the literature, and personal observations on the effect of various steroid hormones on the survival of rats exposed to total body X-irradiation.

## REVIEWS

*Graham & Graham B58,164/50*: Review of the literature, and personal observations on the effect of folliculoids, luteoids, testoids, adrenocortical extract, and DOC upon the resistance of the mouse to total body X-irradiation.

*Kaplan et al. B98,601/54*: Review (40 pp., 107 refs.) on the role of folliculoids, corticoids, luteoids and testoids in the development of the radiation-induced lymphoid tumors of mice.

*Rigat C10,747/55*: Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation, with special reference to ACTH, STH, vasopressin, epine-

phrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

*Ghys & Loisel C33,564/60*: Review on the radio-protective effect of DOC.

*Ghys D54,640/63*: Review of the literature on the effect of ovariectomy, orchidectomy, estradiol, and testosterone upon resistance of the rat to total body X-irradiation.

*Kandror E27,416/63*: Review of the literature on the effect of corticoids and ACTH upon total body X-irradiation, especially in connection with the physiopathology of stress.

*Davydova F23,736/64*: Review and personal observations on the effect of folliculoids and testoids upon radiation injury.

*Rooks E4,589/64*: Review (10 pp., 46 refs.) on protection by hormones against X-irradiation in mammals. In general, folliculoids (particularly estradiol), and DOC exhibit a good radio-protective effect, whereas glucocorticoids, testoids, and luteoids, do not.

*Danyisz & Kocmierska-Grodzka F84,845/67*: Review of the literature on the radio-protective action of folliculoids and testoids with personal observations on a prophylactic effect of methandrostenolone (Dianabol).

## ULTRAVIOLET RAYS ←

The hepatic lysosomal proteases of the rat are released by ultraviolet irradiation *in vitro*, and this effect is diminished by glucocorticoid pretreatment of the animals *in vivo*.

Endotoxin treatment *in vivo* facilitates the subsequent release of hepatic lysosomal enzymes by ultraviolet irradiation in rabbits, and here again, cortisone exerts a stabilizing effect.

The damage caused to fetal rat skin explants by ultraviolet irradiation can be inhibited by the addition of cortisol to the culture medium. This protection has also been ascribed to the stabilization of lysosomes by the glucocorticoid.

*Graham A61,343/43*: In dogs, the hypotension produced by carbon arc irradiation (about 6% ultraviolet, 30% luminous and 64% infrared rays) could be prevented by DOC or adrenocortical extract, both in the presence and in the absence of the adrenals.

*Weissmann & Dingle D14,268/61*: The hepatic lysosomal proteases of the rat are released by ultraviolet irradiation *in vitro*, and this effect is greatly diminished by pretreatment of the animals with cortisol *in vivo*.

*Weissmann & Fell D46,242/62*: The damage caused to fetal rat skin explants by ultraviolet irradiation can be inhibited by the addition

of cortisol to the culture medium. This protection "might be due, at least in part, to a reduced proteolytic activity in the damaged tissue through a stabilising action of the hormone on the lysosomes."

*Weissmann & Thomas D23,630/62*: Following endotoxin treatment *in vivo*, the hepatic lysosomes of the rabbit release their enzymes readily upon ultraviolet irradiation. This increased lability is in turn prevented by a three day pretreatment of the animals with cortisone before endotoxin administration. Apparently "one action of endotoxin is to release acid hydrolases from particulate form

within cells, and that glucocorticoids serve to stabilize such particles against injury by several agents."

*Janoski et al. E7,896/68 (p. 280)*: Review suggesting that many of the actions of gluco-

corticoids, particularly their inhibition of ultraviolet ray injury, vitamin-A overdosage, and endotoxin shock are due to the stabilization of lysosomal membranes which prevents the escape of toxic lysosomal enzymes.

### HEMORRHAGE ←

In the dog, early experiments with adrenocortical extracts revealed no significant protection against hemorrhagic shock, but infusion of cortisol (especially in the form of its water soluble sodium hemisuccinate) 30 min after bloodletting prevented the hypotension. If aldosterone is added to the shed blood before reinfusing it, resistance to the production of hemorrhagic shock is likewise greatly increased.

In the cat, large doses of cortisone and dexamethasone given i.v. prior to the induction of hemorrhagic shock also prolonged survival after reinfusion of all shed blood. Aldosterone was apparently ineffective here.

In rats with hemorrhagic shock induced by maintaining the arterial blood pressure at 35 mm Hg for 4 hrs, large amounts of dexamethasone, cortisol, aldosterone and methylprednisolone prolonged survival, allegedly in decreasing order of activity, but since each hormone was given in different amounts, it is difficult to make comparisons between them.

Even in rats submitted to "irreversible" hemorrhagic shock followed 4 hrs later by reinfusion of the shed blood, survival time is prolonged if glucocorticoids are added to the blood transfusate.

Under special circumstances, resistance to hemorrhagic shock could also be improved by glucocorticoids in the rabbit and monkey.

#### Dog

*Fine et al. A56,268/42*: In intact dogs, adrenocortical extract is moderately effective, and DOC completely ineffective, in combating hemorrhagic shock.

*Huizenga et al. A54,816/43; A59,447/43*: Adrenocortical extract fails to protect intact dogs against death from hemorrhagic shock.

*Connolly et al. D57,333/58; Connolly C78,861/59*: In dogs, cortisol given i.v. within 30 min after induction of hemorrhagic shock is highly effective in preventing the drop of blood pressure.

*Kuhn et al. C67,681/59*: Exposure to cold increases the resistance of the dog to hemorrhagic shock, and this resistance is not affected by concurrent treatment with cortisone.

*Hakstian et al. D10,396/61*: Review of the literature, and personal observations on the control of hemorrhagic shock in dogs, by cortisol alone or in association with pressor amines.

*Zapata-Ortiz & de la Mata D37,373/62*: In dogs, mortality from hemorrhagic shock is

greatly reduced when aldosterone is added to the reinfused blood. "Natural secretion of aldosterone probably plays an important role in the evolution of shock."

*Lillehei et al. E37,842/64*: Review, and personal observations on the beneficial effect of cortisol in hemorrhagic and endotoxin shock, mainly based on experiments in the dog.

#### CAT

*Lefer & Martin H7,806/69*: In cats, "pharmacologic doses of cortisol or dexamethasone given intravenously prior to induction of hemorrhagic shock prolonged survival significantly after reinfusion of all shed blood. High doses of aldosterone were ineffective in prolonging survival, as was cortisol when administered at the time of reinfusion. . . . Glucocorticoids may prevent the disruption of lysosomes and/or prevent proteases from being released into the blood."

*Glenn & Lefer H34,576/71*: In cats subjected to hemorrhagic shock methylprednisolone increased survival time in proportion to a diminution of plasma levels of a myocardial

depressant factor (MDF) and of the lysosomal enzymes,  $\beta$ -glucuronidase and plasma cathepsin-like activity (PCLA). Presumably, "methylprednisolone exerts a protective effect in hemorrhagic shock by preventing the release of lysosomal enzymes which may be responsible for the formation of MDF, a peptide implicated in the reduction of myocardial contractility during postligemic shock."

#### RAT

*Weil & Whigham F13,600/64*: Various corticoids differ in their potency to combat hemorrhagic shock in the rat. "Significantly better results were obtained with dexamethasone than with hydrocortisone in terms of early alertness and survival at the end of seven days ( $p < 0.01$ ). Ten of 20 animals treated with methylprednisolone survived ( $p < 0.001$ ). The largest of the three doses of d-aldosterone gave the best results with survival of six of ten rats ( $p < 0.03$ )."

*Weil et al. F48,510/65; F61,024/65*: In rats hemorrhagic shock was produced by maintaining the blood pressure at 30 mm Hg for 4 hrs followed by reinfusion of the withdrawn blood. Dexamethasone (8 mg/kg) given at the completion of the bleeding period kept all animals alive, whereas all untreated controls died. Cortisol and methylprednisolone were less effective, but even aldosterone offered some protection, though only over a narrow dose range.

*Bouyard & Klein G41,843/66*: In rats submitted to "irreversible" hemorrhagic shock, followed 4 hrs later by reinfusion of the removed blood, the addition of various

glucocorticoids (methylprednisolone, triamcinolone, dexamethasone or betamethasone) to the blood transfusate increases the survival rate.

*Weil & Whigham F52,838/65; Whigham F75,787/67*: In rats with intact adrenals, hemorrhagic shock was produced by maintaining the arterial pressure at 35 mm Hg for 4 hrs. When large amounts of corticoids were administered after blood reinfusion, survival was prolonged by dexamethasone, cortisol, d-aldosterone, and methylprednisolone in decreasing order of activity. [However, since each hormone was given in different amounts, comparisons are difficult. Aldosterone was effective only within a narrow dose range of around 0.4 mg/kg, both lower and higher doses being ineffective (H.S.).]

#### RABBIT

*Telivuo & Louhimo G39,506/66*: In rabbits, mortality from hemorrhagic shock was only moderately diminished by concurrent treatment with cortisol i.v.

*Palmerio & Fine G66,810/69*: Rabbits "that recover from an otherwise lethal degree of hemorrhagic shock with the help of special therapy (dexamethasone plus antibiotic) tolerate a subsequent exposure to the same degree of hemorrhagic shock without the need for such therapy."

#### MONKEY

*Schumer G64,570/69*: In Rhesus monkeys, survival from hemorrhagic shock is prolonged by dexamethasone i.v.

### HYPOXIA AND HYPEROXYGENATION ←

← **Corticoids.** In the rat, several early investigators succeeded in prolonging survival under anoxic conditions by treatment with adrenocortical extract. Death from lack of oxygen in closed vessels is accelerated by T3 and retarded by cortisone. Furthermore, the decreased altitude tolerance of thyroxine treated rats is counteracted by cortisol.

In guinea pigs, small doses of cortisone increase, whereas large doses decrease resistance to oxygen deficiency. The enhanced susceptibility to hypoxia induced by morphine is counteracted by pretreatment with ACTH or cortisone.

Early investigators claimed that in the mouse, adrenocortical extracts, unlike pure glucocorticoids or DOC, increase resistance to hypoxia, but more recent observations suggest that cortisone also improves survival at all but the very highest simulated altitudes tested.

In man, cortisone likewise raises resistance to various manifestations of anoxemia.

← **Adrenalectomy.** In rats, adrenalectomy greatly increases sensitivity to anoxia, and cortisol restores it towards normal. On the other hand, it has been claimed that adrenalectomy can give definite protection against the central nervous system manifestations and the lung edema characteristic of oxygen poisoning. Adrenocortical extract and cortisol — unlike cortisone and DOC — allegedly augment the susceptibility of adrenalectomized animals to hyperoxygenation.

← **Folliculoids, Testoids, Gonadectomy.** Estradiol and stilbestrol are ineffective in altering the resistance of the rat to anoxia. Females are allegedly more resistant than males, but this difference is ascribed to the larger size of the female adrenal, and not to any specific activity of the ovaries; indeed, ovariectomy is said to increase resistance to anoxia in the rat.

In hens, tolerance to acute hypoxia is allegedly enhanced by testosterone, and decreased by stilbestrol.

← **Corticoids** cf. also *Selye B40,000/50*, p. 67.

#### RAT

*Dorrance et al. A38,460/42:* Neither a potent adrenocortical extract nor DOC altered the work performance of intact rats under anoxic conditions.

*Johnson et al. 96,626/43:* The altitude tolerance is increased by adrenocortical extract in adrenalectomized, but not in intact rats.

*Britton & Kline 93,980/45:* Adult female rats are much more resistant to anoxia than males, perhaps because their adrenals are larger. Adrenocortical extract raises resistance to anoxia, whereas DOC does not.

*Thorn et al. B335/45:* Adrenocortical extract increased the survival of normal rats exposed to reduced barometric pressure.

*Keminger G42,501/66:* In rats, death from lack of oxygen in closed vessels is accelerated by T3, and retarded after thyroidectomy or cortisone treatment. Epinephrine further accelerates mortality in hyperthyroid animals.

*Debias F69,410/66:* The decreased altitude tolerance of thyroxine-treated rats is counteracted by cortisol.

#### GUINEA PIG

*Arnould et al. C12,257/55:* The resistance of guinea pigs to reduced oxygen pressure is raised by pretreatment with cortisone i.p.

*Volterrani C64,384/57:* In guinea pigs, tolerance to hypoxia is decreased by cortisone, but increased by ACTH pretreatment.

*Volterrani C64,385/57:* In guinea pigs, small doses of cortisone enhanced whereas large doses diminished, resistance to reduced oxygen tension.

*Sobel et al. C90,836/60:* Morphine increases the mortality of guinea pigs exposed to reduced oxygen tension. Prior administration of cortisone or ACTH protects against this combined treatment.

#### MOUSE

*Kottke et al. B25,989/48:* Resistance to hypoxia is increased in mice by adrenocortical extract, but not by DOC. The effect of the extract is not ascribed to glucocorticoids, since other investigators found cortisone to be inactive.

*Berry et al. H2,124/68:* Studies on the influence of hypoxia, glucocorticoids, and endotoxin on hepatic enzyme induction and survival in mice. "Endotoxin inhibited the induction of tryptophan oxygenase, prevented the increase in liver glycogen, induced the transaminase, and increased the lethality of simulated altitude. Cortisone increased survival at all altitudes except the highest. These observations emphasize the importance of these metabolic adjustments for the survival of animals subjected to hypoxic stress."

#### MAN

*Frawley et al. B57,930/51:* In man both cortisone and ACTH improve high altitude tolerance.

*Tabusse et al. C10,563/54:* Cortisone increases resistance to various manifestations of anoxemia (inhalation of 7.5% nitrogen in air) as seen in human volunteers, but simultaneously aggravates the characteristic EEG changes.

#### ← **Adrenalectomy**

*Taylor C47,861/58:* In rats "adrenalectomy gave very definite protection against the

central nervous system manifestations of oxygen poisoning, and gave some protection against lung damage." Adrenocortical extract and cortisol enhanced the susceptibility of adrenalectomized animals to oxygen poisoning, whereas cortisone, DOC, and thyroid powder had no such effect.

*DeBias & Wang-Yen D22,848/62*: In rats, adrenalectomy greatly increases sensitivity to hypobaric oxygenation, but cortisol treatment restores it towards normal.

#### ← *Folliculoids, Testoids, Gonadectomy*

*Britton & Kline 93,980/45*: Adult female rats are much more resistant to anoxia than males, perhaps because their adrenals are larger. Adrenocortical extract raises resistance to

anoxia, whereas DOC does not. Ovariectomy increases resistance to anoxia.

*Goldsmith et al. B333/45*: Thiouracil and thiourea enhance the resistance of rats to lowered barometric pressure. Estradiol and stilbestrol are ineffective in themselves and fail to influence the action of the antithyroid compounds.

*Kline & Britton 85,856/45*: At 16° C, female rats withstand anoxia longer than males. At higher temperatures, the difference is less pronounced. "Estrous conditions and estrogens, castration, etc., do not appear related to the different responses."

*Burton et al. G67,617/69*: In hens, tolerance to acute hypoxia of high altitude is increased by testosterone, and decreased by diethylstilbestrol.

### TEMPERATURE VARIATIONS ←

A very large number of publications deals with the effects of steroids upon resistance to heat or cold environments, or to local burning and freezing. These findings will be discussed together.

#### ← *Corticoids*

**Heat** ←. The earliest observations suggested that, in rabbits, treatment with adrenocortical extract increases resistance to high surrounding temperatures.

In mice, neither adrenocortical extract nor DOC offered significant protection against fatal burns, and in fact, cortisone enhanced mortality after scalding.

In the rat, it is likewise impossible to obtain any significant protection against burn shock by pretreatment with adrenocortical extracts or DOC, although some investigators asserted that, if applied before the burn, DOC is effective in this respect. The action of cortisone and cortisol upon the rat's ability to withstand "heat stress" has not been clearly established, some investigators claiming to have obtained positive, others negative results.

In dogs, adrenocortical extract offered no protection against burn shock.

In a small group of men, acclimatization to heat was not significantly improved by DOC.

**Cold** ←. In intact rats, neither DOC nor adrenocortical extract raised resistance to burn shock significantly. Cold tolerance was likewise not considerably altered by adrenocortical extract, cortisone or DOC, but the improvement of survival obtained by thyroxine was further ameliorated by conjoint treatment with cortisone or corticosterone.

Some increase in cold tolerance has also been obtained in rats by intermittent or prolonged pretreatment with cortisone, prednisone or prednisolone.

In the mouse, injection of *H. pertussis* enhanced sensitivity to "cold stress" even more than does adrenalectomy. Cortisone and cortisol protect the pertussis-treated mouse against cold, and to some extent, cortisol also raises the cold resistance of normal mice.

← *Folliculoids, Testoids, Gonadectomy*

Contrary to earlier claims, neither ovariectomy nor orchidectomy changes the heat resistance of the rabbit significantly.

In rats, orchidectomy has been said to raise resistance to cold, yet, testosterone does not alter it in either intact or castrate males. In intact or spayed rats, restrained in a cold environment, the development of gastric ulcers is allegedly reduced by ovariectomy, but not influenced by estradiol.

← *Adrenalectomy*

Adrenalectomy greatly diminishes the resistance of various species against cold or heat, whereas treatment with adrenocortical extract, glucocorticoids and, to a lesser extent, mineralocorticoids, restore temperature resistance towards normal.

← *Other Steroids*

The acquisition of adaptation to heat is allegedly inhibited by spironolactone pretreatment in the rat, but once resistance is established, the compound does not counteract it. It has been concluded that hyperaldosteronism is necessary only for the acquisition, not for the maintenance of heat resistance.

← *Corticoids*

**Heat** ←. *Maddaloni A18,244/38*: Treatment with adrenocortical extract increases the resistance of the rabbit to a high surrounding temperature.

*Rosenthal B26,228/43*: Neither adrenocortical extract nor DOC protected mice against fatal burns.

*Bergman et al. B2,009/45*: In the mouse and rat, neither adrenocortical extracts nor DOC offered protection against shock caused by a standardized skin burn.

*Ingle & Kuisenga 96,155/45*: In intact rats, neither DOC nor adrenocortical extract raised the resistance to burn shock.

*Cope et al. B52,084/49*: In dogs, adrenocortical extracts offered no protection against burn shock.

*Robinson et al. B56,828/50*: In four men, acclimatization to heat was not significantly improved by DOC.

*You & Sellers B46,218/50*: The resistance of intact rats to severe burns was increased by DOC, but not by adrenocortical extract.

*Neal et al. B80,371/52*: The survival time of severely burned rats is not influenced by cortisone or ACTH, whereas DOC administered before the burn offers considerable protection.

*Kar & De C72,791/55*: Cortisone and cortisol failed to affect the ability of rats to with-

stand "heat stress" upon exposure to extremely warm surrounding temperatures.

*Schöttler C8,455/55*: Neither ACTH nor cortisone protects the mouse against the fatal effects of severe scalding; in fact, cortisone increases mortality.

*Agarkov et al. D40,496/62*: In intact rats, cortisone raises resistance to heat, whereas ACTH does not.

**Cold** ←. *Adolph B35,581/48*: Adrenocortical extract failed to increase the resistance of rats to cold exposure.

*Sellers et al. B65,310/51*: The survival of clipped rats exposed to cold is considerably prolonged by combined treatment with thyroxine + cortisone. Each of these agents alone has much less protective value, and DOC is inactive.

*Kirsteins C41,958/56*: Short-term administration of cortisone or ACTH to rats did not significantly influence cold tolerance, whereas long-term intermittent cortisone administration prior to cold exposure definitely raised tolerance in this respect.

*Dufour & Dugal C26,092/57*: In rats, resistance to cold is diminished by STH or DOC given in combination with vitamin C.

*Munoz & Schuchardt C28,986/57*: After an injection of *H. pertussis* cells, intact mice become even more sensitive to "cold stress" than untreated adrenalectomized mice. Corti-

sone and cortisol protect pertussis-treated mice against cold, but to a lesser degree than the adrenalectomized mice. Cortisol also increases the cold resistance of normal mice. "It is suggested that while pertussis possibly affects adrenal function, it must in addition affect other functions in the mouse which are also concerned with the protection against stress."

*Garrido C77,562/59*: In intact rats, prednisone and ACTH enhanced resistance to cold.

*Garrido D8,112/60*: In rats, resistance to cold is increased by thyroxine and T<sub>3</sub>, and decreased by thyroidectomy or destruction of the thyroid with radio-iodine. Prednisolone exerted only a moderate protective effect.

*Araki G11,847/63*: Pretreatment with ACTH or cortisol raises the resistance of intact mice to cold exposure. Nicotinamide has a similar effect which is ascribed to the stimulation of the pituitary-adrenal system.

*Bauman & Turner F81,331/67*: Pretreatment of rats with thyroxine enhanced their resistance to cold. Additional administration of corticosterone greatly increases this effect although, in itself, corticosterone possesses only a slight protective action.

#### ← Folliculoids, Testoids, Gonadectomy

*Barella B3,397/40*: In rabbits, resistance to heat stroke is diminished by orchidectomy.

*Gigante & Scopinaro B67,617/46*: In man, testosterone improves the circulation of skin areas affected by frostbite.

*Berde & Takács B31,943/48*: In rabbits, ovariectomy does not change heat resistance (in contradiction to earlier claims by others).

*Berde & Takács B38,366/48*: In rabbits, orchidectomy does not alter heat tolerance.

*Dugal & Saucier C53,333/58*: In rats, orchidectomy raises resistance to cold.

*Dugal & Saucier C77,621/58*: Testosterone does not alter the resistance of intact or castrate male rats to cold.

*Luther et al. G70,681/69*: In rats restrained in a cold environment, the development of gastric ulcers is reduced by ovariectomy. Estradiol has no effect upon the induction of these ulcers in either intact or ovariectomized rats.

#### ← Adrenalectomy

*Selye & Schenker A15,353/38*: Adrenalectomized rats are particularly sensitive to exposure to cold but their resistance is greatly (and dose-dependently) increased by pretreatment with adrenocortical extract. This fact is used as the basis of a sensitive test for corticoid activity.

*Tyslowitz & Astwood 80,678/41*: In hypophysectomized rats, the decreased resistance to cold is largely corrected by ACTH and adrenocortical extract. In adrenalectomized rats, adrenocortical extract is also effective in this respect, whereas ACTH is not.

*Dufour et al. C12,151/55*: In adrenalectomized rats, both STH and DOC improve survival following exposure to cold.

#### ← Other Steroids

*Henane & Laurent F71,731/66*: The acquisition of adaptation to heat (swimming in hot baths) is inhibited by spironolactone pretreatment in the rat; but once adaptation is established, the anti-aldosterone does not counteract it. It is concluded that hyperaldosteronism is necessary only for the induction, not for the maintenance of heat adaptation.

### ELECTRIC STIMULI ←

← **Corticoids**. In rats, DOC (like progesterone and several testoids) increases the EST, whereas glucocorticoids (e.g., cortisone, cortisol) have an opposite effect.

In mice, progesterone, DOC, and a series of related steroids inhibit electroshock seizures (as well as pentylenetetrazol convulsions).

In cats, DOC allegedly protects against cocaine convulsions, but has no effect upon the EST. On the other hand, cortisone increases the amplitude and maintenance of muscular responses to the electrical stimulation of the corresponding nerves in the cat. From experiments in which different types of macropotentials are recorded on single nerve cell discharges of the decerebrate cats, it was concluded that prednisolone increases the excitability of each nerve cell, but the effect is potentiated by multiple neuronal connections mediated through the reticular activating system.

← **Adrenalectomy.** In rats, the EST is lowered by adrenalectomy.

← **Folliculoids, Luteoids, Testoids, Gonadectomy.** The earliest observations suggested that in guinea pigs, orchidectomy does not influence the convulsions produced by electric irritation of peripheral nerves.

In rats, progesterone (like DOC and testosterone) increases the EST, whereas gonadectomy decreases it in both sexes.

In mice, progesterone (like DOC and various derivatives of pregnenolone) inhibits electroshock seizures. Lynestrenol reduces the anticonvulsive effect (tested by the EST) of various drugs.

#### ← **Corticoids**

*Spiegel 83,892/43:* In rats DOC, progesterone and testosterone i.p. increase the EST.

*Aird B683/44:* DOC i.p. protected mice against cocaine induced convulsions but had no effect upon the EST of cats.

*Spiegel & Wycis 93,925/45:* Among 29 steroids tested, DOC, progesterone, testosterone, acetoxypregnenolone, androstenedione, and dehydroandrosterone increased the EST significantly in the rat.

*Davenport B36,663/49:* Adrenalectomized rats maintained on plain water show a decreased EST, which can be restored by NaCl or DOC, but not by KCl or MgCl<sub>2</sub>. From plasma electrolyte determinations "it is concluded that the electroshock seizure threshold of the adrenalectomized rat is directly correlated with the plasma sodium level."

*Woodbury & Davenport B37,243/49:* In rats, DOC (like NaCl or CaCl<sub>2</sub> solutions) elevates the EST.

*Woodbury et al. B46,344/50:* In rats, DOC elevates the EST and its effect is counteracted by ACTH or adrenocortical extracts, possibly because of some antagonism between glucocorticoids and mineralocorticoids.

*Fingl et al. D38,091/52:* In rats, chronic administration of phenobarbital or diphenylhydantoin diminishes the brain hyperexcitability induced by cortisone, as judged by EST measurements.

*Pozo & Negrete B68,183/52:* In cats, cortisone increases the amplitude and maintenance of muscular responses to electrical stimulation of the corresponding nerves.

*Minz & Domino B81,852/53:* In rats, small doses of epinephrine or norepinephrine prolong the duration of electrically-induced seizures. Since glucose, ACTH, and cortisone failed to prolong seizure duration, it is unlikely that epinephrine acts by release of these substances. Histamine depresses the cortical response to electroshock.

*Woodbury B98,594/54:* Review (42 pp., 90 refs.) on the "Effect of Hormones on Brain Excitability and Electrolytes." In the rat, the EST is increased by DOC and decreased by cortisone and cortisol. ACTH and 11-dehydrocorticosterone, given chronically, antagonize partially the effect of cortisone.

*Woodbury et al. C34,538/57:* Review (33 pp., 25 refs.) on the effect of corticoids upon the EST in the rat. Cortisone and cortisol decrease it (increased excitability), whereas DOC and, to a lesser extent, aldosterone increase it. Corticosterone and other corticoids have less pronounced effects.

*Vallecalle et al. C93,280/60:* The EST is decreased by gonadectomy both in male and in female rats. "Folliculin" lowers the EST, whereas testosterone raises it in both sexes. The increased CNS excitability induced by ovariectomy is corrected by cortisol, but not by "folliculin."

*Schulte & ten Bruggencate D32,457/62:* From experiments in which different types of macropotentials are recorded on single nerve cell discharges of decerebrate cats "it is concluded that Prednisolone increases the excitability of each single nerve cell but the effect is potentiated by multiple neuronal connections from nerve centers, in our experiments for example, from the reticular activating system."

*Craig F69,385/66:* In mice, progesterone, DOC, a series of 3 $\beta$ -(aminoalkyl) esters of pregnenolone, and various other steroids proved to inhibit pentylenetetrazol convulsions and electroshock seizures.

#### ← **Adrenalectomy**

*Davenport B36,663/49:* Adrenalectomized rats maintained on plain water show a decreased EST, which can be restored by NaCl or DOC, but not by KCl or MgCl<sub>2</sub>. From plasma electrolyte determinations "it is concluded that the electroshock seizure threshold of the

adrenalectomized rat is directly correlated with the plasma sodium level."

*de Salva et al. C51,842/58*: In rats, the EST was lowered by hypophysectomy and adrenalectomy, but only insignificantly by thyroidectomy. 5-HT elevated the EST.

*de Salva D66,176/63*: In rats, the EST is reduced in descending order of magnitude by adrenalectomy, hypophysectomy, and thyroidectomy. The effect of these endocrine deficiencies upon various depressant drugs is also described.

#### ← *Folliculoids, Luteoids, Testoids, Gonadectomy*

*Specht 13,475/23*: In guinea pigs, neither thyroidectomy nor orchidectomy influences the course of the convulsions produced by amyl nitrate inhalation or the electric irritation of peripheral nerves.

*Spiegel 83,892/43*: In rats DOC, progesterone, and testosterone i.p. increase the EST.

*Spiegel & Wycis 93,925/45*: Among 29 steroids tested, DOC, progesterone, testosterone, acetoxyprogrenolone, androstenedione, and dehydroandrosterone increased the EST significantly in the rat.

*Vallecalle et al. C93,280/60*: The EST is decreased by gonadectomy both in male and in female rats. "Folliculin" lowers the EST, whereas testosterone raises it in both sexes.

The increased CNS excitability induced by ovariectomy is corrected by cortisol, but not by "folliculin."

*Craig F69,385/66*: In mice, progesterone, DOC, a series of  $3\beta$ -(aminoalkyl) esters of pregnenolone and various other steroids proved to inhibit pentylenetetrazol convulsions and electroshock seizures.

*Blackham & Spencer G73,813/70*: In mice, lynestrenol reduced, whereas mestranol or SKF 525-A increased the anticonvulsive effect (tested with electroshock) of diphenylhydantoin, phenobarbital, chlordiazepoxide, and diazepam administered i.p. after five days of pretreatment. This may be due to an altered microsomal drug metabolism, but since mestranol and lynestrenol have opposite effects upon brain 5-HT concentrations, the latter mechanism must also be considered.

#### ← *Other Steroids*

*Spiegel & Wycis 93,925/45*: Among 29 steroids tested, DOC, progesterone, testosterone, acetoxyprogrenolone, androstenedione, and dehydroandrosterone increased the EST significantly in the rat.

*Craig F69,385/66*: In mice, progesterone, DOC, a series of  $3\beta$ -(aminoalkyl) esters of pregnenolone, and various other steroids proved to inhibit pentylenetetrazol convulsions and electroshock seizures.

### SYSTEMIC TRAUMA ←

← **Corticoids.** In the rat, adrenocortical extract (Cortin) raises resistance to various forms of systemic trauma (intestinal crushing, formaldehyde injections, extensive partial hepatectomies), but its effect is not as pronounced in the presence as in the absence of the adrenals. The increased nonspecific stress resistance characteristic of the countershock phase in the G.A.S. is largely ascribed to an enhanced corticoid production. DOC is ineffective in this respect, whereas corticosterone (which differs from DOC only in the presence of an  $11\beta$ -hydroxyl group) is highly effective. Apparently, 11-oxygenation of corticoids, with the associated induction of glucocorticoid potency, is an essential prerequisite for antistress activity.

Pretreatment with DOC inhibits adrenocortical enlargement during the alarm reaction produced by various stressors. This mineralocorticoid-induced "compensatory adrenal atrophy" diminishes resistance and particularly interferes with the hyperglycemic response to cold, formalin, atropine, surgical trauma or forced muscular exercise. It is concluded that "overdosage with one of the compounds produced by an endocrine cell can interfere with the production by the same cell of other hormonal compounds (in this case corticoids, such as corticosterone, active in carbohydrate metabolism)." On the other hand, pretreatment of rats with adrenocortical

extract can increase their performance during forced muscular exercise, without previous training. Here, the adrenal hypertrophy is also prevented, but since a glucocorticoid preparation is administered, the protective effect against stress is nevertheless obvious.

However, adrenocortical extract, cortisone, corticosterone, and DOC proved to be singularly ineffective in protecting the rat against tourniquet shock. Resistance to the trauma of the Noble-Collip drum is considerably increased by adrenocortical extract or DOC in adrenalectomized, but only slightly in intact rats. In fact, some investigators claimed that in the presence of the adrenals, large doses of cortisone or prednisone actually diminish resistance to the trauma of the Noble-Collip drum. The catabolic effect of bone fractures is further aggravated by betamethasone.

Under suitable conditions of dosage, the gastric ulcers produced in rats by forced muscular exercise can be prevented by pretreatment with prednisolone, but not by DOC. This is remarkable because heavy overdosage with glucocorticoids is in itself conducive to gastric ulcer formation.

In dogs, both adrenocortical extract and DOC offer only a moderate protection if any against shock produced by tourniquet or muscle trauma. On the other hand, ischemic shock elicited by temporary occlusion of the thoracic aorta appears to be favorably influenced by cortisol, methylprednisolone and methylfluorocortisol (Me-F-COL).

In the cat, both ACTH and cortisone have been claimed to prolong survival following traumatic shock.

In the goat, cortisone had no influence upon survival after trauma, nor did it counteract the sensitizing effect of thyroxine.

In the rabbit, combined treatment with adrenocortical extract and DOC (unlike DOC alone) allegedly reduces mortality from the shock of intestinal manipulation.

The extensive literature on the effect of corticoids on traumatic shock in man has been discussed in our previous monographs. Let us add here only that recent observations in patients with cardiopulmonary bypass suggest that dexamethasone pretreatment improved the clinical condition as well as diminished serum  $\beta$ -glucuronidase and LDH levels. It was assumed that the postoperative complications of cardiopulmonary bypass may be related in part to disruption of lysosomal membranes which can be stabilized by the glucocorticoid during "circulatory stress."

← **Adrenalectomy.** The fact that adrenalectomy diminishes stress resistance in all species and that corticoid therapy restores it towards normal is well known and has been covered extensively in our earlier monographs. However, the interactions between adrenal catecholamines and corticoids in the restoration of systemic stress resistance have been considerably clarified by recent experiments from Brodie's laboratory. Here, complete blockade of sympathetic function, with maintenance of the adrenal cortex, has been compared with complete adrenalectomy, with or without substitution therapy by catecholamines or corticoids. From these observations, it was concluded that sympathetic stimulation is the first line of defense against the vasomotor disturbance elicited by endotoxin or histamine, whereas the lethal effect of formalin or tourniquet shock, which is also increased by adrenalectomy, is not increased by mere sympathetic blockade. Cortisone alone suffices to counteract the toxicity of these stressors in adrenalectomized rats. Apparently, "formalin and

tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

The gastric ulcers produced by forced muscular exercise are not considerably modified by adrenalectomy in the rat, although they can be prevented by prednisolone.

← **Testoids.** Much work has been done in an effort to combat the catabolism of nonspecific stress by anabolic steroids. It is true that postoperative recovery of body weight may be accelerated by such steroids; for example, in cholecystectomized women, methandrostenolone enhanced the weight increase. Yet, animal experiments suggest that the anticatabolic effect of anabolics is not wholly nonspecific. Methyltestosterone is very efficient in preventing the severe catabolism produced by overdosage with DHT or vitamin-D<sub>2</sub>, but it is much less efficacious in protecting against body-weight loss due to undernutrition, estradiol or the osteolathyrisism induced by AAN. The catabolism elicited by cortisol or by the neurolathyric compound IDPN was not influenced by this testoid.

In guinea pigs, the alkaline phosphatase changes characteristic of fatigue, after exhausting exercise, are not prevented by 4-chlorotestosterone, but their return to normal is accelerated.

Anabolics also influence local stress reactions. For example, in rats, 17-ethyl-19-nortestosterone promotes, whereas cortisone inhibits, repair in bone fractures (measured by <sup>35</sup>S uptake). The regeneration of crushed murine skeletal muscle is likewise delayed by cortisone and accelerated by methandienone or methandrostenolone. Anabolics are also said to inhibit the myopathy produced in rats by ligation of the aorta and subsequent cooling of the distal part of the body.

← **Folliculoids, Luteoids, Gonadectomy.** Pretreatment with estradiol allegedly decreases the resistance of the mouse against various stressors (formalin, cold) and facilitates the development of changes characteristic of the alarm reaction. In rats, audiogenic seizures are not significantly influenced by ovariectomy. However, testosterone, progesterone, and estradiol appear to increase the seizure incidence in naturally seizure-resistant rats, whereas in seizure-prone animals, they have an opposite effect.

The development of gastric ulcers in rats restrained in a cold environment is claimed to be reduced by ovariectomy, but uninfluenced by estradiol.

← **Other Steroids.** Spironolactone diminishes the performance of rats adapted to swim in warm surroundings, allegedly because of its anti-aldosterone effect.

← **Corticoids** cf. also Selye B40,000/50, pp. 64-72, 108; B58,650/51, p. 54; G60,083/70, p. 358.

#### RAT

Selye et al. A32,768/40: Review of the earlier literature on the ability of epinephrine and "cortin" to raise resistance against various stressors. Attention is called to the fact that whereas cortin is very effective in this respect in adrenalectomized animals, it rarely increases resistance above normal in the presence

of the adrenals. The slight effect that cortical extracts do possess during severe shock is presumably due to the fact that "a condition of 'relative adrenal insufficiency' exists in organisms exposed to nonspecific damage." Following extensive partial hepatectomy in rats, "suitable cortin therapy prevents the hypochloreaemia, and the decrease in blood volume and in blood sugar which are usually elicited by this intervention." In rats damaged by repeated s.c. injections of formaldehyde, cortical extract prevented the hypoglycemia

and hypochloremia of severe shock, whereas DOC was virtually ineffective, in fact it aggravated the s.c. edema caused by formaldehyde. Chronic pretreatment with cortical hormones caused adrenal atrophy which counteracted their beneficial effect in protecting against stress. "These experiments should be interpreted as a warning against prolonged pretreatment with this substance in preparation for a surgical intervention." The best protective effect was obtained in rats with surgical shock produced by crushing of the intestines, if given repeated injections of cortical extract s.c. during the subsequent 24 hrs. An "Addendum" reports on similar experiments performed with corticosterone prepared for this purpose by E. C. Kendall. This compound, which differs from DOC only in that it possesses an  $11\beta$ -hydroxyl group, proved to be especially effective in protecting the rat against traumatic shock caused by crushing of the intestines. [This was the first observation showing that 11-oxygenation of corticoids is required to endow them with antistress activity (H.S.).]

*Selye & Dosne A 33,299/40*: "Experiments in the rat indicate that pure corticosterone administered in aqueous solution is very effective in combating shock caused by surgical trauma and other means. Desoxycorticosterone is ineffective when tested under similar conditions. From this it appears that the hydroxyl group on carbon atom 11 is important for the shock-combating action of cortical steroids."

*Korényi & Hajdu A 56,945/42*: In rats, adrenocortical extract increases performance during forced muscular exercise without previous training. Simultaneously, the associated adrenal hypertrophy is prevented.

*Noble & Collip A 56,107/42*: Adrenocortical extract and DOC greatly raise the resistance of adrenalectomized rats to the trauma of the Noble-Collip drum. In intact rats, "cortin" and DOC as well as ACTH induce only a slight increase in resistance, under similar circumstances. "From a practical viewpoint the effects of adrenal preparations on this type of shock have been disappointing."

*Root & Mann A 57,542/42*: Adrenocortical extract did not significantly prolong survival of rats in tourniquet shock.

*Selye & Dosne A 37,249/42*: Pretreatment with DOC inhibits, but does not completely prevent the adrenocortical enlargement during the alarm reaction. Under these conditions, the mineralocorticoid-induced "compensatory

adrenal atrophy" diminishes the resistance and particularly the hyperglycemic response to cold, formalin, atropine, trauma or forced muscular exercise. It is concluded that "overdosage with one of the compounds produced by an endocrine cell can interfere with the production by the same cell of other hormonal compounds (in this case corticoids, such as corticosterone, active in carbohydrate metabolism). As a result of this interference symptoms of overdosage with hormones produced by a certain endocrine cell type may coexist with signs of deficiency in the hormone production of that same cell."

*Ingle A 59,854/43*: In intact rats, survival from tourniquet shock was not improved by adrenocortical extract, cortisone, corticosterone or DOC.

*McKenna & Zweifach C 27,414/56*: Large doses of cortisone or prednisone, far from increasing, actually diminish the resistance of rats to the trauma of the Noble-Collip drum. This effect is ascribed to a depression of the RES function.

*Schachter et al. C 63,544/59*: In rats, pretreatment with cortisone, thyroxine or both these agents shortened survival after tourniquet shock.

*Kulagin D 236/60*: In rats with a crush syndrome produced by clamping a thigh, survival was enhanced by ACTH, cortisone and cortisol, whereas DOC aggravated the condition by increasing edema in the injured area.

*Vennet & Schneewind D 23,294/62*: In rats, mortality induced by trauma in the Noble-Collip drum was significantly reduced by treatment with cortisol, prednisolone, and 6 $\alpha$ -methylprednisolone given i.p. immediately after removal from the drum.

*Campbell et al. G 9,081/64*: In the rat, the catabolic effect of a bone fracture is further increased by betamethasone.

*da Vanzo F 19,865/64*: Pretreatment with F-COL protects the rat against tourniquet shock.

*Serkes et al. F 92,105/67*: Cortisol administered to tourniquet traumatized rats in infusion fluid, lowered serum  $\beta$ -glucuronidase but did not prolong survival time. "Serum levels of beta-glucuronidase, presumed to reflect lysosomal enzyme release, did not correlate with survival."

*Robert et al. G 74,748/70*: In rats, the gastric ulcers produced by forced muscular exercise can be prevented by pretreatment with prednisolone, but neither adrenalectomy nor

DOC affects their development. The ulcers were more common in females than in males, and could be totally prevented by fasting.

#### Dog

*Shleser & Asher A 56,711/42*: In dogs, both adrenocortical extract and DOC exert a mildly protective effect against shock following ligation of one common internal iliac vein.

*Bourque et al. A 57,912/43*: Tourniquet shock is effectively combated in dogs by combined treatment with adrenocortical extract i.v. + NaCl s.c. Neither agent alone is effective.

*Swingle et al. A 61,337/43*: In nonadrenalectomized dogs, shock produced by tourniquet or trauma is not alleviated either by DOC or by adrenocortical extract.

*Cleghorn B 2,571/47*: In dogs, shock produced by muscle trauma is not alleviated by large amounts of adrenocortical extract unless treatment is initiated at an early stage.

*Pisanty & Toscano C 30,049/56*: In dogs, DOC, 17-hydroxycorticosterone, and ACTH injected before surgery reduced mortality but had no effect upon the onset of shock. Corticosterone was more effective.

*Levin et al. C 82,785/60*: In dogs, ischemic shock produced by temporary occlusion of the thoracic aorta is favorably influenced by cortisol, methylprednisolone and Me-F-COL.

*Satori & Szabo E 21,902/63*: Dexamethasone administered to dogs just before application, and again before the removal of a tourniquet, increases resistance to shock.

#### CAT

*Khrabrova D 33,557/62*: Both ACTH and cortisone prolong survival following traumatic shock in the cat.

#### GOAT

*Oppenheimer et al. C 50,563/58*: In goats, traumatic shock reduces the capacity of the thyroid to concentrate iodine, but recently thyroidectomized animals showed no change in survival times, although pretreatment with thyroxine greatly sensitized them to traumatic shock. Cortisone had no effect upon survival following trauma nor did it counteract the aggravating effect of thyroxine.

#### RABBIT

*Weil et al. 78,692/40*: "Adrenal cortical extract and desoxycorticosterone acetate given together both before and after trauma without other therapy reduce the mortality from

experimental shock after intestinal manipulation in normal (non-adrenalectomized) rabbits." DOC alone is ineffective.

#### MOUSE

*Perla et al. A 31,863/40*: In mice and rats, pretreatment with NaCl in combination with DOC or adrenocortical extract increased resistance to histamine. Favorable results have also been obtained by DOC + NaCl in a few patients suffering from surgical shock.

#### MAN

*Replogle et al. G 40,447/66*: In patients with cardiopulmonary bypass, dexamethasone pretreatment appeared to improve the clinical condition, and diminished the serum  $\beta$ -glucuronidase and LDH levels. It is assumed that postoperative complications following cardiopulmonary bypass may be related in part to damage of lysosome membranes and that "massive doses of dexamethasone may stabilize the lysosome membrane during periods of circulatory stress."

#### VARIA

*Sambhi et al. G 68,985/64*: Review on the action of glucocorticoids and aldosterone in traumatic and endotoxin shock in animals and men.

#### ← Adrenalectomy

*Krawczak & Brodie H 25,296/70*: In rats, complete blockade of sympathetic function can be achieved by demedullation combined with reserpine-like agents (depleting catecholamine stores), bretylium-like agents (preventing nerve impulse from releasing catecholamines), or ganglioplegics. Following such total sympathetic blockade, mortality from histamine or endotoxin is as markedly increased as by adrenalectomy. Pretreatment with epinephrine alone counteracts the increased lethality of endotoxin and histamine after sympathetic blockade. Cortisone pretreatment only partially corrects the sensitization by adrenalectomy, whereas cortisone + epinephrine offer complete protection against these agents. Presumably, sympathetic stimulation is "the first line of defense against the vasomotor disturbance elicited by endotoxin and histamine." The lethal effect of formalin or tourniquet shock is likewise greatly enhanced by adrenalectomy but, in contrast to that of endotoxin and histamine, it cannot be in-

creased by sympathetic blockade. Furthermore, cortisone alone counteracts the toxicity of these stressors in adrenalectomized rats. Apparently "formalin and tourniquet shock is initiated by a mechanism which differs from that elicited by histamine and endotoxin and does not primarily involve the sympathetic system."

*Robert et al. G74,748/70:* In rats, the gastric ulcers produced by forced muscular exercise can be prevented by pretreatment with prednisolone, but neither adrenalectomy nor DOC affects their development. The ulcers were more common in females than in males, and could be totally prevented by fasting.

#### ← Testoids

*Kowalewski C50,864/58:* Experiments on rats with fractures of the humerus show "that cortisone inhibits and 17-ethyl-19-nortestosterone promotes those processes of repair which may be measured by S<sup>35</sup> uptake method, and that 17-ethyl-19-nortestosterone may protect connective tissue against the catabolic effect of cortisone."

*Selye & Mishra C38,201/58:* In the rat, methyltestosterone prevents the loss of body weight produced by overdosage with DHT, vitamin-D<sub>2</sub>, partial fasting, AAN and estradiol. The catabolism elicited by IDPN or cortisol is not influenced.

*Gandini & Gandini-Collodel D58,657/62:* In guinea pigs, the alkaline phosphatase changes characteristic of fatigue that occur following prolonged running in revolving cages are not prevented by pretreatment with 4-chlorotestosterone but the restoration to normal is greatly accelerated.

*Klug G19,783/64:* In cholecystectomized women postoperative weight increase was enhanced by methandrostenolone.

*Werboff et al. F10,255/64:* In rats, audiogenic seizures are not significantly influenced

by ovariectomy. Testosterone, progesterone and estradiol significantly increased seizure incidence in naturally seizure-resistant animals, whereas they had an opposite effect in seizure-sensitive rats.

*Sloper & Pegrum G49,073/67:* The regeneration of crushed murine skeletal muscle is inhibited by cortisone and accelerated by methandienone (17 $\beta$ -hydroxy-17 $\alpha$ -methyl- $\Delta^1$ -testosterone) or methandrostenolone.

*Igic et al. H13,355/69:* Methenol (an anabolic steroid possibly identical with methenolone, but here not characterized) inhibits the myopathy produced in rats by ligation of the aorta and subsequent cooling of the distal half of the animal.

#### ← Folliculoids, Luteoids, Gonadectomy

*Campbell et al. C23,145/56:* Pretreatment with estradiol decreases the resistance of the mouse to various stressors (formalin, cold) and facilitates the development of organ changes characteristic of the alarm reaction.

*Werboff et al. F10,255/64:* In rats, audiogenic seizures are not significantly influenced by ovariectomy. Testosterone, progesterone and estradiol significantly increased seizure incidence in naturally seizure-resistant animals, whereas they had an opposite effect in seizure-sensitive rats.

*Luther et al. G70,681/69:* In rats restrained in a cold environment, the development of gastric ulcers is reduced by ovariectomy. Estradiol has no effect upon the induction of these ulcers either in intact or in ovariectomized rats.

#### ← Other Steroids

*Henane F52,022/65:* Spironolactone diminishes the performance of rats which adapted themselves to swim in warm surroundings. The effect is ascribed to a suppression of adaptively secreted aldosterone.

### LOCAL TRAUMA ←

The voluminous literature on the effect of steroids upon inflammation, wound healing and other forms of local trauma should be consulted in our earlier monographs on stress (*Selye B40,000/50; B58,650/51; B87,000/52; B90,100/53; C1,001/54; C9,000/55-56*).

Even large doses of adrenocortical extract failed to increase the work capacity (swim test) of intact rats, suggesting that in this respect the corticoids are not very efficacious in combating the topical results of fatigue upon muscle cells.

In rats with bone fractures, 17-ethyl-19-nortestosterone promotes repair ( $^{35}\text{S}$  uptake), whereas cortisone exerts an opposite effect. Apparently, the two types of steroids antagonize each other's actions on connective tissue.

The regeneration of crushed murine skeletal muscle is inhibited by cortisone and accelerated by several anabolic steroids, the two types of steroids thus opposing each other in this respect also.

*Ratsimamanga B48,447/50*: Even very large doses of adrenocortical extract failed to increase the work capacity (swim test) of intact rats.

*Kowalewski C50,864/58*: Experiments on rats with fractures of the humerus show "that cortisone inhibits and 17-ethyl-19-nortestosterone promotes those processes of repair which may be measured by  $\text{S}^{35}$  uptake method, and

that 17-ethyl-19-nortestosterone may protect connective tissue against the catabolic effect of cortisone."

*Sloper & Pegrum G49,073/67*: The regeneration of crushed murine skeletal muscle is inhibited by cortisone and accelerated by methandienone (17 $\beta$ -hydroxy-17 $\alpha$ -methyl- $\Delta^1$ -testosterone) or methandrostenolone.

#### VARIA ←

In general, anabolics counteract body-weight loss and tend to prolong survival in animals with transplanted or spontaneous neoplasms, but this is not invariably the case.

The effect of steroids upon the toxicity of carcinogens (including their ability to induce tumors) is discussed in the section on "Drugs."

In mice with hereditary **muscular dystrophy**, survival is prolonged and catabolism lessened by various anabolic steroids.

The role of hepatic drug-metabolizing enzymes in the maintenance of the **sexual cycle** is discussed at length in the sections on "History" and "Theories." Ovarian homotransplants placed into the portal circulation fail to maintain the sexual cycle in spayed rats, whereas retransplantation of the gonads into the systemic circulation reinitiates estrus. This finding furnished one of the first proofs showing the importance of hepatic detoxifying mechanisms for the physiology of steroid hormones.

It was also of considerable importance for the development of modern ideas concerning metabolic effects of steroids, that folliculoids inhibit **somatic growth**, whereas testosterone actually enhances it.

Also to be mentioned in this connection is the production of **adrenocortical hyperplasia with sexual anomalies** by the 2 $\alpha$ -cyano compound, TMACN, as well as the abortifacient and lactation inhibiting effect of various catatoxic steroids (ethylstrenol, spironolactone), which is now under study in our Institute.

#### Tumors ← cf. also Carcinogens

*Beatson A50,749/1896*: Ovariectomy + thyroid extract administration is recommended for the treatment of inoperable mammary carcinomas in women.

*Reid B93,930/54*: Review (18 pp., 181 refs.) on the effect of STH and corticoids upon carcinogen-induced and transplantable neoplasms.

*Glenn et al. G70,204/60*: Review (48 pp., 11 refs.) on the effect of various steroids, ACTH, GTH, ovariectomy, and adrenalectomy upon the development of C3H mammary carcinoma transplants in mice and fibroadenomas in rats.

*Marmo & Miele D27,478/61*: 4-Chlorotestosterone acetate and 19-nortestosterone

phenpropionate prolong the survival of mice with Ehrlich ascites tumors, and of rats with Walker tumors.

*Krahe & Heinen D35,677/62*: In rats, bearing Yoshida-sarcoma transplants, methandrostenolone caused a loss of body weight, whereas in those bearing Walker sarcomas, it exerted an opposite effect.

*Rooks & Dorfman F62,099/66*: 2 $\alpha$ -Methyl-17 $\beta$ -hydroxy-5 $\alpha$ -androstan-3-one increases the survival time of rats bearing mammary fibroadenomas.

*Bonmassar et al. F85,891/67*: Pretreatment with the anabolic steroid dimetazine increases the resistance of the rat to subsequent inoculations of Ehrlich ascites tumor. The prophylactic effect presumably depends upon the activation of immune mechanisms.

#### Muscular Dystrophy ←

*Dowben C79,563/59*: The survival of mice with hereditary muscular dystrophy is prolonged by treatment with 17 $\alpha$ -ethyl-19-nortestosterone and, to a lesser extent, by 17 $\alpha$ -ethyl- $\Delta^4$ -19-norandrostenediol-3 $\alpha$ ,17 $\beta$ -3-propionate, but not by testosterone propionate.

*Dowben & Gordon D4,188/61*: The median survival time (ST<sub>50</sub>) of mice suffering from hereditary muscular dystrophy is about 17 weeks. This can be prolonged to about 40 weeks by anabolic steroids such as 17 $\alpha$ -ethyl-19-nortestosterone, 9 $\alpha$ -fluoro-11 $\beta$ -hydroxy-17 $\alpha$ -methyltestosterone, methylandrostandiol,  $\Delta^1$ -17 $\alpha$ -methyltestosterone or 17 $\alpha$ -methyl-19-nortestosterone. Some prolongation of the life span was also obtained by cortisone, "spiro-lactone" (presumably spironolactone), and SU-4885. Testosterone propionate did not prolong survival. DOC, aldosterone, and estradiol actually shortened it.

*Borgman D62,710/63*: "Treatment of mice with hereditary muscular dystrophy by an anabolic steroid, methylandrostenediol dieneanthoyleacetate, lengthened survival time but did not otherwise alter the disease syndrome."

*Dowben et al. F10,902/64*: The life span of mice with hereditary muscular dystrophy is prolonged by various anabolic-testoid com-

pounds, but shortened by folliculoids, DOC, or aldosterone.

*Dowben E80/65*: Review on the effect of anabolic steroids in experimental and clinical muscular dystrophies.

#### Miscellaneous Effects of Protective Steroids ←

*McEuen et al. 39,157/37*: First communication on the "Effect of Testosterone on Somatic Growth." Unlike folliculoids, testosterone does not inhibit somatic growth in the rat. Indeed, although only small amounts of the compound were available, they appeared to stimulate growth, at least in females.

*Golden & Sevringhaus A37,808/38*: In ovariectomized rats, ovarian homotransplants placed into the mesenteries failed to maintain the sexual cycle, whereas retransplantation of the gonads into the axillary region reinitiated estrus. Apparently, folliculoids are detoxified during their passage through the liver.

*Colfer A47,355/47*: In rats, audiogenic convulsions cause a loss of K and a gain of Na in the brain. DOC protects against audiogenic convulsions, and produces changes in the microincineration pattern of the cerebral cortex opposite to those associated with convulsive influences. A low K diet also protects against audiogenic convulsions.

*Smith C46,496/56*: In brown trout, thyroxine raises, whereas thiourea and thiouracil reduce salinity tolerance. Anterior pituitary extracts and STH likewise raise salinity tolerance, whereas posterior lobe extracts, testosterone, gonadotrophin, TTH, and ACTH have no effect.

*Aschkenasy-Lelu G9,425/64*: Review of the various damaging agents against which females are more resistant than males, and of the resistance-increasing effect of folliculoids.

*Goldman et al. G73,456/66*: In rats given 2 $\alpha$ -cyano-4,4,17 $\alpha$ -trimethylandrostan-5-en,17 $\beta$ -ol, 3-one (TMACN), the fetuses at term exhibit a syndrome of adrenocortical hyperplasia with sexual anomalies, presumably due to persistent inhibition of fetal 3 $\beta$ -hydroxysteroid dehydrogenase.

#### ENZYMES ←

Most of the catatoxic actions of steroids, that have been adequately analyzed, were found to depend upon the stimulation of drug-metabolizing enzyme systems; hence, our selection of the data to be specifically classified under "Enzymes" is necessarily somewhat arbitrary. In the choice of pertinent facts we were guided by

the principle that this section should be as concise as possible, and limited to enzymologic findings which could not be listed under any other heading. Since the purpose of this monograph is to review our knowledge on the hormonal regulation of resistance, all observations having a direct bearing upon susceptibility to morbid changes have been reserved for more detailed consideration in the section dealing with particular pathogens (*cf.* Enzymologic References).

The following pages are intended merely as a classified guide to the literature on the effect of steroids upon the enzymic activities that may play a part in resistance, although they have not been clearly related to defense against any particular pathogen. Enzyme activities totally unrelated to defense (e.g., those concerned specifically with reproduction) have been completely disregarded; however, borderline observations on enzymes which participate in the regulation of general metabolism but may assume a special role in certain intoxications are listed.

For convenient access, the data are classified according to substrates, but they have not been subjected to personal analysis and critical evaluation, since any effort to do so would have exceeded the scope of this monograph — as well as the competence of its author.

The arrangement of the material is as follows:

All enzyme activities specifically directed against a toxic agent are not considered here but under Drugs, together with the corresponding toxicant itself (e.g. “zoxazolaminase” with zoxazolamine).

Only enzyme activities directed against substrates not usually administered as toxicants [e.g., TKT (tyrosine), TPO (tryptophan), SDH (serine), DNA-polymerase] are listed here and arranged according to the pharmacologic action of the inducing steroid (e.g., corticoid, folliculoid, antimineralocorticoid).

Within the large sections “Corticoids” and “Adrenalectomy” a further subdivision is made, the first section being devoted to “TKT and TPO,” the second to “Other Amino Acid Enzymes” (including GOT, TDH, GPT, SDH, OKT, methionine adenosyl transferase, etc.), and the third to “Other Enzymes.” Here the material is classified according to the regulating steroid.

Separate sections deal with “All Enzymes” as influenced by steroids other than the corticoids. Here, the first criterium for classification is the steroid activity, and data on its effect upon all enzyme systems are discussed conjointly, since even so the corresponding subsections are small in comparison with the extensive accumulations of data on corticoids and adrenalectomy.

In accordance with this plan, the data in the following pages will be classified as follows:

---

TKT and TPO ← Corticoids	All Enzymes ← Luteoids
Other Amino Acid Enzymes <sup>a</sup> ← Corticoids	All Enzymes ← Testoids
Other Enzymes <sup>b</sup> ← Corticoids	All Enzymes ← Gonadectomy
TKT and TPO ← Adrenalectomy	All Enzymes ← Antifolliculoids
Other Amino Acid Enzymes ← Adrenalectomy	All Enzymes ← Antitestoids
Other Enzymes ← Adrenalectomy	All Enzymes ← Antimineralocorticoids
All Enzymes ← Folliculoids	All Enzymes ← Various Steroids

---

<sup>a</sup> GOT, GPT, TDH, SDH, OKT.

<sup>b</sup> G-6-P-ase, UDP-ase, urea-cycle enzymes, DNA- and RNA-polymerase, NAD-ase, phosphatases, etc.

← **Corticoids**

## REVIEWS

*Drews H 12,100/69:* Review of the hepatic enzymes that can be induced by cortisol.

*Hahn & Koldovský E 8,164/69:* Brief summary of the effect of corticoids upon hepatic enzymes.

**TKT (Tyrosine) and TPO (Tryptophan) ←.**

## RAT

*Thomson & Mikuta B 90,975/54:* Cortisol increases the hepatic TPO activity of the rat liver.

*Knox & Auerbach E 76,825/55:* The TPO activity of rat liver is lowered by adrenalectomy and increased in both normal and adrenalectomized animals by cortisone. The increase in TPO activity caused by histidine and other pharmacologically active amines is prevented by adrenalectomy, unless the animals receive glucocorticoids. Hormone-induced and substrate-induced enzyme adaptation must be distinguished.

*Civen & Knox E 53,175/57:* In rats, an increase in the hepatic TPO activity can be obtained by treatment with tryptophan, cortisone or cortisol.

*Lin & Knox E 63,521/57:* The hepatic TKT activity of the rat increases after injections of tyrosine or cortisol. A 4-fold increase was observed within 5 hrs. Tyrosine was an effective inducing stimulus only if the adrenal glands were present, or if cortisol was injected after adrenalectomy.

*Lin & Knox C 73,824/58:* In rats, the hepatic TKT activity increased after treatment with cortisone, cortisol or corticosterone and L-tyrosine. This effect was observed also following adrenalectomy. On the other hand, a comparable action of other amino acids was probably due to stress. "That a nonspecific stress-producing agent could actually increase the level of tyrosine- $\alpha$ -ketoglutarate transaminase was further supported by the results obtained with a compound which is unrelated to tyrosine metabolism. Injections of propylene glycol in doses of 0.5 ml. per 100 mg. of body weight caused the level of this enzyme to increase to an average of 1390 units in three intact rats." Adrenalectomized rats did not support this dose of propylene glycol.

*Schor & Frieden C 57,994/58:* In the rat, insulin can induce hepatic TPO activity, and this is only partly inhibited by adrenalectomy. In the intact rat, the effect of insulin

and tryptophan, or insulin and cortisone, are additive. Possibly, "hormonal induction may be a form of substrate induction in that certain hormones might affect the availability of tryptophan for the enzyme-forming system."

*Civen & Knox E 64,178/59:* In the adrenalectomized rat, the cortisol-induced increase in hepatic TPO activity is not associated with a higher level of tryptophan in the liver of normal rats, nor with an increased tryptophan metabolite excretion by pyridoxine-deficient rats. Tryptophan induction of the enzyme is associated with a rise in hepatic tryptophan and the excretion of metabolites by the deficient rats. The inducing effect of tryptophan and cortisol given together was the sum of their separate actions. In vitro TPO is induced by addition of tryptophan, but not of cortisol, to the medium. It is concluded that cortisol is a primary inducer of enzyme and acts differently from, and independently of, the substrate.

*Feigelson et al. G 67,768/59:* Studies on the half-life of cortisone-induced TPO in rat liver.

*Ginoulhiac G 67,780/59:* Studies on the TPO-induction by various corticoids in adrenalectomized rats suggest that "the TPO test is suitable for the biological evaluation of corticoids."

*Horton & Franz C 63,790/59:* In the rat, the cortisone-induced increase in TPO activity is reduced by ethionine and restored again by methionine.

*Lin et al. C 96,929/59:* TKT activity is higher in the livers of male than of female rats. This enzyme activity is diminished by castration in males, and increased by testosterone in females. Cortisol enhances this transaminase activity in males much more than in females, both in the presence and in the absence of the adrenals.

*Maickel & Brodie C 83,071/60:* TPO in rat liver is increased by ACTH, cortisone, or cortisol, as well as by various stressor agents and barbiturates. Hypophysectomy prevents the effect of stressors and barbiturates, suggesting that the latter act through the pituitary-adrenal system.

*Feigelson D 4,122/61:* In the rat, hepatic TPO activity can be induced both by tryptophan and by cortisone.

*Kennedy & Flora D 12,237/61:* Tryptophan and i.p. injections of diatomaceous earth (Celite) were as effective as tyrosine in inducing increases of hepatic TKT activity in intact, but not in adrenalectomized rats. Cortisol was an efficacious inducer at low doses

in both intact and adrenalectomized animals. In the latter, the effect of a small dose of cortisol was potentiated by simultaneous administration of tyrosine, methionine or diatomaceous earth. "It is concluded that induction of tyrosine transaminase is entirely mediated by adrenal hormone." In adrenalectomized rats, diatomaceous earth i.p. is believed to act as a stressor through adrenocortical stimulation.

*Nicolis & Ginoulhiac D27,485/61:* Hepatic TPO induction is so characteristic of glucocorticoid activity in the rat that it may be used as the basis of a bioassay procedure.

*Feigelson et al. D25,364/62:* In the rat, the induction of hepatic TPO by tryptophan or cortisone is used as a model for the study of interrelations between hormonal- and substrate-dependent enzyme induction processes. Following i.p. administration of either inducer, there is a rise in liver TPO activity, reaching a maximum after 4–5 hrs, the peak being higher for tryptophan than for cortisone. Judged by  $^{14}\text{C}$ -glycine and  $^{32}\text{P}$ -orthophosphate incorporation experiments, both the tryptophan and cortisone-induced stimulation of protein metabolism follow the same time course, but their effects on RNA metabolism do not coincide. Tryptophan causes no increase in RNA turnover while the enzyme level is rising. When the enzyme activity has returned to normal, precursor incorporation into RNA is stimulated. Cortisone, on the other hand, markedly stimulates RNA turnover with maximal effects at 4 hrs corresponding to peak enzyme levels. The pattern of incorporation of the purine precursor, glycine-2- $^{14}\text{C}$ , into the RNA of various hepatic subcellular fractions showed that cortisone increases precursor incorporation into the proteins of all liver cell constituents, but much less than into RNA. On the basis of these and many other experiments concerning the mechanism of enzyme induction, a hypothesis is proposed according to which the difference between substrate and hormone induction might be explained.

*Feigelson & Greengard D46,319/62:* In the rat, a single i.p. injection of cortisone causes a 3-fold increase in the amount of TPO enzyme protein (immunologic assay). When assayed in the presence of saturation levels of its hematin cofactor, a proportionate rise in the catalytic activity of the enzyme is also obtained. Adrenalectomized rats react the same way. "Thus, the increase in liver tryptophan pyrrolase activity during hormonal

induction and during the second phase of substrate induction are due to increased tryptophan pyrrolase protein levels."

*Goldstein et al. D70,931/62:* Cortisol enhanced both TKT and TPO activities in the isolated, perfused rat liver. This effect was prevented by puromycin, an inhibitor of protein synthesis. Cortisol "may exert some of its physiological effects directly on liver cells by altering the level of enzyme activities."

*Greengard & Feigelson G67,329/62:* Immunochemical evidence showing that an increased amount of TPO is found in the liver of adrenalectomized rats after treatment with L-tryptophan. A similar increase is obtained by cortisone. [The brief abstract does not state whether cortisone was also tested in adrenalectomized rats (H.S.).]

*Kennedy E89,716/62:* In the rat, the induction of hepatic TKT by cortisol is associated with an equivalent increase in enzyme antigen. A cross-reactive precursor could not be detected in any of the subcellular liver fractions. Induction in the presence of  $^{14}\text{C}$ -labeled amino acids results in extensive labeling of transaminase, with or without induction.

*Knox G51,969/62:* Review on the effect of stress upon hepatic TPO production. In adrenalectomized animals, only tryptophan of a series of analogues induces this enzyme, whereas, in intact rats, various stressors, ACTH, cortisone, cortisol and corticosterone (but not DOC) do so. "The recognition of the adrenal hormone-induced adaptation of the tryptophan pyrrolase has provided the unified explanation for a large number of different stressful stimuli which increase the enzyme level." Tryptophan pyrrolase is absent from the liver of newborn rabbits and in them, this enzyme cannot be induced by cortisol. Tyrosine transaminase induction is regulated in a very similar manner.

*Davis D92,322/63:* The decarboxylation of o-tyrosine and 5-hydroxytryptophan by livers of adrenalectomized rats, given water, was significantly lower than in controls. No significant effects on decarboxylation of these substrates were observed in adrenalectomized animals given NaCl, or in intact animals treated with DOC or exposed to cold. On the other hand, cortisone increased the inherent hepatic decarboxylating activity for both substrates, in normal as well as in pyridoxine-deficient rats.

*Greengard et al. D63,145/63:* In adrenalectomized rats, "the administration of puromycin inhibited the cortisone-induced eleva-

tion of tryptophan pyrrolase and tyrosine- $\alpha$ -ketoglutarate transaminase activity as well as the substrate-induced elevation of the latter. Actinomycin abolished the cortisone-mediated rise in the level of both enzymes but did not influence the tryptophan-mediated increase in the level of tryptophan pyrrolase." In newborn rats, the development of hepatic TKT was inhibited by actinomycin, but neither adrenalectomy nor actinomycin D interfered with the postnatal development of hepatic TPO. Apparently, accumulation of TPO (unlike that of TKT) is not under adrenal control and can proceed despite inhibited RNA synthesis.

*Greengard et al. E20,258/63:* In starved rats, hepatic glycogen deposition following cortisone treatment is inhibited by puromycin and actinomycin D. The former interferes with enzyme induction in general, the latter with cortisone-induced rise in hepatic enzyme, including TKT. "The regulatory effect of cortisone on carbohydrate metabolism may be brought about by its action on the cellular concentration of certain enzyme proteins."

*Knox D66,995/63:* In intact rats, hepatic TPO or TKT can be induced by pretreatment either with the corresponding substrates or with cortisone. However, after adrenalectomy TKT, unlike TPO, can no longer be induced by the substrate. Cortisol induces both enzymes even after adrenalectomy, and the increase is particularly pronounced if the hormone is given conjointly with these substrates.

*Pitot G65,475/63:* In the Morris hepatoma 5123, TPO activity is normally low and cannot be significantly altered by either tryptophan or cortisone, whereas both these substances induce the enzyme in the normal liver tissue. In adrenalectomized rats, TPO induction by tryptophan is lower than in intact animals, though cortisone induction in the host liver is actually increased. A slight enzyme induction appears to be possible even in the hepatoma when cortisone is administered to the adrenalectomized rat. Essentially similar but not quite identical results have been obtained with rats bearing Morris hepatoma 7800 or 7316. TKT, TDH and G-6-P-ase activities were either minimally or not affected by cortisone in various transplantable hepatic tumors.

*Rosen et al. E32,653/63:* "A period of about 48 hours is required to attain maximal activity of alanine- $\alpha$ -ketoglutarate transaminase in liver after subcutaneous treatment of rats with a single injection of cortisol. In contrast, tyrosine- $\alpha$ -ketoglutarate transaminase reaches

a maximal value in liver between 4 and 5 hours after an intraperitoneal dose of cortisol." The same dose of cortisol causes even greater increases of hepatic TKT in adrenalectomized rats, but GPT or TPO induction by cortisol is not influenced by adrenalectomy.

*Geller et al. G22,722/64:* In rats, hepatic TKT tryptophan- $\alpha$ -ketoglutarate transaminase and TPO activities are increased 3.5 hrs after i.p. injection of cortisol, but no such activation was seen after stress (animals placed in a mechanical shaker) causing an increase in adrenal and plasma glucocorticoids as well as a depletion of adrenal ascorbic acid. Possibly, the amount of glucocorticoid secreted was not equivalent to that injected.

*Pitot et al. G37,125/64:* In intact rats bearing Reuber H-35 hepatomas, TKT activity is much greater in the tumor than in the normal hepatic tissue. Cortisone i.p. induces enzyme in the liver, but not in the tumor. In adrenalectomized hosts, however, the enzyme in the tumor is in the range of the host liver, and cortisone induces enzyme in both liver and tumor. If cortisone is added to cultures 24 hrs before the enzyme assay, a significant induction occurs in vitro, reaching a maximum in 6 hrs. Actinomycin D added to the medium delays enzyme induction without inhibiting it completely.

*Schapiro et al. G21,848/64:* In the rat, cortisol greatly increases hepatic TPO, TKT, and tryptophan transaminase activity, whereas stress (reciprocating shaker) stimulates corticoid secretion without any change in hepatic transaminase or pyrrolase activity. Apparently, stress not only activates the adrenal cortex, but also the mechanisms which block the induction of these enzymes by corticoids, because shaker stress inhibited the elevation of hepatic transaminase that occurred following cortisol, although it did not block the elevation of TPO in the rat.

*Shiba et al. G31,114/65:* The addition of cortisol to the blood perfused through a rat liver in vitro induced hepatic TPO, whereas this was not the case with livers of rats bearing large Walker tumors. The inhibitory effect upon enzyme induction is ascribed to "toxohormone" (an extract of Walker tumors), since addition of a toxohormone preparation to the perfusion fluid also prevented enzyme induction by cortisol.

*Peraino et al. G40,083/66:* In rats pretreated with cortisone, the dietary induction of SDH, OKT and TKT was not much affected, but carbohydrate repression was largely

eliminated. Pretreatment with phenobarbital alone had little effect on the induction of SDH and OKT but, given with cortisone, it considerably enhanced the response of these enzymes to induction by casein hydrolysate feeding. Neither cortisone nor phenobarbital acted as inducers when given alone or in combination. They were active only in the presence of a dietary inducer.

*Southren et al. F66,647/66:* Clinical improvement has been observed in Cushing's syndrome after treatment with *o,p'*-DDD. This effect might have been due to a direct interference by *o,p'*-DDD with the biologic action of cortisol, or by its giving rise to cortisol metabolites which inhibit cortisol competitively at the effector site. In the rat, *o,p'*-DDD had no effect upon the induction of TPO in the liver, whereas  $6\beta$ -hydroxycortisol was found to be a potent inhibitor of cortisol action in this test system. Since *o,p'*-DDD induces the production of  $6\beta$ -hydroxycortisol, the protective effect may have been due to the latter.

*Tomkins et al. G49,588/66:* Glucocorticoids stimulate TKT induction in rat hepatoma cells in vitro. Inhibitor and immunochemical experiments indicate that the corticoids do not activate a precursor, but increase the number of enzyme protein molecules. Apparently, the hormones exert some control at the level of translation of the transaminase messenger by antagonizing a repressor of messenger function. "It cannot yet be determined whether the presumed increase in messenger concentration occurs as a secondary response to the stimulation of translation, or whether there is a direct effect of the hormone on gene transcription."

*Gelehrter & Tomkins G51,315/67:* Dexamethasone induced a 3–15-fold increase of TKT activity in a tissue culture of rat hepatoma cells, but no rise in total RNA nor its synthesis as measured by the rate of incorporation of labeled precursors. Various experiments also failed to demonstrate gross stimulation of RNA synthesis associated with enzyme induction by steroid hormones in vivo, "suggesting that these changes are not an essential part of the mechanism of enzyme induction by glucocorticoids."

*Peterkofsky & Tomkins G52,839/67:* TKT can be induced by dexamethasone in tissue cultures from Morris hepatoma 7288C. Cytosine arabinose completely inhibits DNA synthesis in these cells, but does not affect RNA synthesis or enzyme induction. Conversely,

mitomycin C and actinomycin D preferentially inhibit RNA synthesis, and completely block induction. Kinetic experiments in which actinomycin D was added at increasing intervals after dexamethasone suggest that messenger RNA accumulates during the early phase of induction. From these and other observations, it is concluded "that messenger RNA for both tyrosine aminotransferase and general cell protein are relatively stable. After inhibition of protein synthesis by cycloheximide, tyrosine aminotransferase activity decreased exponentially with a half-life of seven hours, and this rate was not affected by either steroid or actinomycin."

*Seidman et al. F88,452/67:* The induction of TPO has been studied in the liver remnant of partially hepatectomized rats after treatment with cortisol, and subsequent adrenalectomy. "It seems possible, therefore that the lessened response to hydrocortisone in hepatic cells preparing to divide is related to repression of transcriptional rather than translational mechanisms and that the duplicating genome itself may be unable to participate simultaneously in other functions."

*Granner et al. H11,721/68:* Dexamethasone stimulates TKT synthesis when added in vitro to tissue cultures derived from a rat hepatoma.

*Hager & Kenney G58,950/68:* Cortisol, insulin and glucagon induced TKT in the isolated, perfused rat liver. The hormonal induction of all these enzymes was sensitive to actinomycin D, but STH (which represses TKT induction in vivo) apparently acts indirectly, since it loses this effect in vitro. Cortisol acts as long as it is present in the perfusion fluid, whereas enzyme synthesis induced by the pancreatic hormones ceases after two or three hours, regardless of the continued presence of the protein hormones. It is assumed that cortisol is a "primary inducer," whereas the pancreatic hormones probably act indirectly, as a consequence of their initial hepatic effect, and are therefore "secondary inducers." Both the primary and the secondary induction mechanisms are blocked by actinomycin D.

*Schapiro H2,360/68:* Stress (30 min rough agitation in a noisy laboratory shaker) had no effect upon the corticoid sensitive enzyme TKT in the liver of the intact rat, but it increased TPO activity, which is likewise corticoid inducible. Adrenalectomized rats, similarly stressed, exhibited a decreased transaminase activity with no change in TPO. This inhibitory effect was abolished by hypo-

physectomy. STH inhibited induction of transaminase by cortisol, but had no effect upon cortisol-induced TPO activity. The opposing actions of STH and glucocorticoids may be involved in adaptive reactions to stress.

*Agarwal et al. G65,716/69:* In the rat, both *S. typhimurium* endotoxin and Thorotrast lowered hepatic TPO activity, and prevented cortisol from inducing this enzyme in the isolated, perfused liver. Under these conditions, the TKT activity of the liver remained unaffected. Partial purification of hepatic TPO induced by endotoxin or Thorotrast indicated the presence of some inhibitory substance. "Since histological studies revealed that thorotrast is localized in Kupffer cells, it is suggested that the reticuloendothelial system contributes to the control of enzyme induction in rat liver."

*Benes & Zicha G67,159/69:* Exposure to 1400 R does not inhibit the TPO activity of rat liver. In fact, substrate induction of TPO is stimulated by X-irradiation applied 24 hrs earlier. Induction by cortisol is initially stimulated, and then inhibited by X-irradiation. X-irradiation before partial hepatectomy inhibits the increase in TPO normally observed 12 hrs after the operation. Similar results are obtained by actinomycin D applied one hour after partial hepatectomy. "The diminished synthesis of tryptophan oxygenase in irradiated regenerating rat liver tissue, as well as the decrease of hormonal induction after the irradiation can be explained by the inhibition of the specific messenger RNA's synthesis."

*Valeriote et al. G67,621/69:* Purification and properties of rat liver TKT induced by triamcinolone.

*Yuwiler et al. H9,994/69:* Comparative observations on fasted and cortisol-injected rats led to the conclusion that "the natural stress of fasting is accompanied by alterations in some corticoid-inducible enzymes, but that these changes are not analogous to those obtained following glucocorticoid administration."

*Levitan & Webb H20,594/70:* In rats, the purine analogue azaguanine does not inhibit the initial induction of hepatic TKT by cortisol. However, the continued induced synthesis of the enzyme elicited by repeated doses of cortisol is inhibited by azaguanine. "This suggests that the induction cycle involves the activation and renewal of a pool of preexisting messenger RNA."

*Nakano et al. G76,247/70:* "In adrenalectomized rats, hepatic TPO which can be increased in amount in intact rats by feeding either tryptophan or methionine, was activated and increased in amount by feeding tryptophan but not methionine. The feeding of tryptophan resulted in a significant increase in the level of arginase and threonine dehydratase. Methionine produced a similar increase in both threonine dehydratase and arginase activities. Administration of cortisone acetate produced a significant increase in the level of all three enzyme activities."

#### MOUSE

*Agarwal & Berry G66,479/66:* In the mouse, stress produced by i.p. injection of infusorial earth or bentonite causes no significant change in hepatic TPO activity at the time when sensitization to endotoxin is already developed. The inducibility of TPO is delayed by injections of cortisone at a time when the hormone protects against endotoxin. Still, the results are considered to be "in agreement with the concept that maintenance of liver TP is necessary for continued survival of endotoxin poisoned mice. The absence of change in this enzyme seen in celite- and bentonite-injected mice sensitized to endotoxin is an apparent exception." Presumably, "suppression of TP-activity is not the only way in which mice may be sensitized to endotoxin."

*Berry et al. G67,237/66:* *S. typhimurium* endotoxin lowers liver TPO in mice and prevents the induction of the enzyme by concurrent injection of cortisone. It lowers, but does not prevent, substrate induction. Actinomycin D has a similar effect on TPO. In the intact but not adrenalectomized mouse, endotoxin induces TKT almost as well as cortisone. Actinomycin D, on the other hand, has an effect on this transaminase similar to that of TPO.

*Agarwal & Berry G66,480/67:* "Four hours after zymosan administration, cortisone was able to induce mouse liver tryptophan pyrrolase production almost at a normal rate and, under these conditions, protected mice against a concurrent injection of endotoxin. Administration of zymosan, at either 2 or 4 hrs after cortisone administration, resulted in little change in tryptophan pyrrolase activity while endotoxin, when similarly administered, caused a rapid decline in liver tryptophan pyrrolase activity. . . . Glucan and zymosan, like endotoxin, increased tyrosine- $\alpha$ -ketoglutarate transaminase activity in intact but not in adrenal-

ectomized mice. Zymosan and thorotrast, unlike endotoxin, neither lowered liver carbohydrate levels nor influenced cortisone induced neosynthesis of liver glycogen. These results suggest a cause and effect relationship between inducibility of key liver enzymes and survival against stress."

*Berry et al. E7,069/67:* In mice, endotoxin, zymosan, glucan and saccharated iron oxide (all RES-blocking agents) lower hepatic TPO and increase TKT *in vivo*, but not *in vitro*. Endotoxin also prevents the induction of TPO by cortisone, especially when the latter is given 2—4 hrs after endotoxin. The transaminase responds normally. Zymosan and glucan do not prevent the induction of TPO by cortisone. "Perhaps one might relate these effects to the dose of colloid used in relation to its toxicity, but even large doses of saccharated iron oxide capable of killing mice fail to prevent the induction of tryptophan pyrrolase by cortisone."

*Rapoport et al. G53,334/68:* Pneumococcal infection raises the hepatic TPO activity in intact, but not in adrenalectomized, mice. Cortisol increased TPO activity both in control and in pneumococcus-infected mice, but only if administered early after inoculation. Later during the course of infection, some inhibitory factor develops which counteracts the induction of TPO by cortisol.

*Agarwal & Berry G65,866/69:* In mice, cortisone induced liver TPO and increased liver pyridine nucleotide levels after pretreatment with zymosan or glucan. It also protected such animals against the lethal effects of endotoxin. The observations are "consistent with the view that a cause and effect relationship may exist between hormone induction of selected hepatic enzymes and survival against stress."

*Finch et al. G71,208/69:* In senescent mice, the induction of hepatic TKT by exposure to cold is delayed in comparison with young mice. Corticosterone and insulin are equally effective in this respect in mice of both age groups.

#### VARIA

*Chan & Cohen D18,552/64:* Vertebrates above the evolutionary level of amphibians respond to cortisol with an increased hepatic TKT activity. "Animals showing this response include the rat, guinea pig, chick, pigeon, horned toad (*Phrynosoma cornutum*), and painted turtle (*Chrysemys picta*). In contrast, vertebrates at the amphibian level or below failed to show this response. Animals failing to

show this response include the bull frog (*Rana catesbeiana*), grass frog (*Rana pipiens*), marine toad (*Bufo marinus*), tiger salamander (*Ambystoma tigrinum*), mud puppy (*Necturus*), white bass (*Roccus chrysops*), and black crappie (*Promoxis nigromaculatus*)."

*Litwack & Nemeth G26,050/65:* In the rabbit, hepatic TKT activity rises 2—4-fold at birth. A similar increase is obtained precociously in the event of premature delivery by cesarian section, whereas prolonging gestation delays the rise in enzymic activity. Under all these conditions, the ability of cortisol to cause a further rise in enzymic activity coincides with delivery. In the guinea pig, TKT is absent during fetal life and increases to adult values within 24 hrs after birth. The enzyme activity in the newborn is stimulated by cortisol, though a single injection is without effect in the fetus or adult. In chickens, enzymic activity is relatively constant during the embryonic period, but rises 2—3-fold after hatching.

**Other Amino Acid Enzymes: GOT (Aspartate), TDH (Threonine), GPT (Alanine), SDH (Serine), Methionine, OKT (Ornithine) ←.**  
*Beaton et al. D83,636/57:* Following STH treatment, there is a significant depression in the GPT activity of rat liver tissue, whereas cortisone has an inverse effect.

*Gavosto et al. C34,243/57:* In partially hepatectomized rats, cortisone does not significantly influence the rate of hepatic regeneration, but it increases the GOT and GPT activities, in both normal and regenerating liver tissue.

*Rosen et al. C47,568/58:* Cortisol increases the GPT activity of the rat liver. Similar results have been obtained with cortisone and prednisone. GOT activity is not similarly influenced. "These facts, added to the observation that a substantial rise in hepatic GPT occurs in rats treated with hydrocortisone, in contrast to treatment with deoxycorticosterone, strongly suggest that the control of hepatic levels of GPT by glucocorticosteroids is importantly related to the mechanism whereby these compounds exert their gluconeogenic activity."

*Rosen et al. C50,741/58:* In rats treated with cortisol, cortisone or prednisone for 1 week, there was an increase in hepatic GPT but not in GOT. DOC had no such effect. Hypophysectomy or adrenalectomy did not prevent this action of cortisone. STH, testosterone or insulin failed to alter GPT activity, nor did they influence its stimulation by cortisol.

*Rosen et al. C71,414/59:* Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol, were inactive. STH, testosterone, and insulin caused no significant change in GPT by themselves, nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity, but when injected simultaneously with cortisol, they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT inducing activity of cortisol whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Rosen et al. G66,496/59:* In the rat, cortisol, cortisone, and prednisone cause a 6–13-fold increase in hepatic GPT activity. This effect was directly related to the protein content of the ration. In alloxan diabetic rats, the rise in this enzyme activity was equivalent to that obtained by cortisol or high-protein diets, and could be inhibited by insulin. Adrenalectomy diminished but did not abolish the rise in GPT activity obtained by feeding high-protein diets. Thus, the initiation of enzyme synthesis by dietary protein is not mediated exclusively through the adrenals.

*Harding et al. D14,355/61:* In the rat, pretreatment with DOC depresses the hepatic GPT activity. A similar depression is obtained by adrenalectomy, but this is not further aggravated by concurrent treatment with DOC. ACTH increases GPT activity in hypophysectomized, but not in adrenalectomized, animals. In hypophysectomized rats, DOC fails to lower GPT nor does it alter the response of this enzyme to ACTH. "The inhibitory effect of DOC on alanine transaminase activity appears to be due to suppression of ACTH release by the pituitary."

*Segal et al. D45,899/62:* In the rat, prednisolone treatment increases the GPT activity and immunologic evidence suggests that this is due to an actual rise of enzyme protein.

*Segal et al. G67,774/62:* Purification and properties of hepatic GPT from normal rats or from those in which this enzyme was induced by cortisone or prednisolone.

*Davis D92,322/63:* The decarboxylation of o-tyrosine and 5-hydroxytryptophan by livers of adrenalectomized rats, given water, was

significantly lower than in controls. No significant effects on decarboxylation of these substrates were observed in adrenalectomized animals given NaCl, or in intact animals treated with DOC, or exposed to cold. On the other hand, cortisone increased the inherent hepatic decarboxylating activity for both substrates, in normal as well as in pyridoxine-deficient rats.

*Pitot G65,475/63:* In the Morris hepatoma 5123, TPO activity is normally low and cannot be significantly altered by either tryptophan or cortisone, whereas both these substances induce the enzyme in the normal liver tissue. In adrenalectomized rats, TPO induction by tryptophan is lower than in intact animals, although cortisone induction in the host liver is actually increased. A slight enzyme induction appears to be possible even in the hepatoma when cortisone is administered to the adrenalectomized rat. Essentially similar but not quite identical results have been obtained with rats bearing Morris hepatoma 7800 or 7316. TKT, TDH and G-6-P-ase activities were either minimally or not affected by cortisone in various transplantable hepatic tumors.

*Segal & Kim G67,769/63:* Studies on the half-life of prednisolone-induced GPT in rat liver.

*Freedland & Avery G67,766/64:* In the rat, the TDH and SDH activity of liver homogenates was increased by high protein diets, alloxan diabetes, or cortisol. Factors affecting the activity of TDH caused a proportional change in SDH, suggesting that both of these activities may be due to a single protein. The SDH activity was decreased by adrenalectomy or hypophysectomy. Adrenalectomy had no effect upon the response of this enzyme to protein feeding, whereas after hypophysectomy, this response was diminished.

*Peraino et al. G40,083/66:* In rats pretreated with cortisone, the dietary induction of SDH, OKT and TKT was not much affected, but carbohydrate repression was largely eliminated. Pretreatment with phenobarbital alone had little effect on the induction of SDH and OKT, but given with cortisone, it considerably enhanced the response of these enzymes to induction by casein hydrolysate feeding. Neither cortisone nor phenobarbital acted as inducers when given alone or in combination. They were active only in the presence of a dietary inducer.

*Moscona & Piddington F90,487/67:* In retinal explants of 12-day chick embryos,

glutamine synthetase activity can be induced by the addition of various corticoids to the culture medium. Cortisol, corticosterone, and aldosterone are particularly active in this respect, whereas pregnenolone, progesterone, DOC, 11-desoxycortisol, 17 $\alpha$ -hydroxyprogesterone, and 11 $\alpha$ -hydroxyprogesterone had little activity. 11 $\beta$ -Hydroxyprogesterone and 11 $\beta$ ,17 $\alpha$ -dihydroxyprogesterone exhibited intermediate degrees of activity. Apparently, "the 11 $\beta$ -position is of primary significance in the activity of these molecules in inducing retinal glutamine synthetase in this system. This conclusion is further supported by the fact that cortisone, which has a ketone group in the 11-position, had no effect under these conditions."

*Schmidinger & Kröger F92,031/67:* The increase in hepatic SDH induced by protein-deficient diets and starvation in intact rats is prevented by actinomycin D, puromycin or glucose, but aggravated after adrenalectomy. Cortisone administered during the starvation period increases SDH activity, perhaps owing to utilization of inhibitors of this enzyme during gluconeogenesis.

*Räihä & Kekomäki G68,114/68:* In the rat, the OKT activity of the liver is very low in the fetus, exhibits a small transient elevation around term, then drops, and eventually reaches the high adult activity level during the third postnatal week. Triamcinolone given postnatally causes a pronounced elevation of OKT, but has no such effect in fetal or adult rats. Puromycin prevents the rise in OKT activity after triamcinolone administration. In adult rats fed a protein- or arginine-free diet, OKT activity decreases and fails to rise under the influence of triamcinolone. Partial hepatectomy or STH depresses OKT-activity in the livers of adult rats.

*Shou et al. H15,277/69:* In the rat, the hepatic methionine adenosyl transferase activity was not much influenced by glucagon, but during alloxan diabetes it increased considerably. Combined treatment with alloxan and triamcinolone resulted in an additive effect. The response to alloxan could be prevented and even reversed by insulin or adrenalectomy. In normal rats, insulin caused no consistent increase.

*Uete H15,157/69:* Triamcinolone impairs the capacity of a special thymus microsome fraction system to incorporate amino acids into proteins in the rat. Detailed studies using labeled amino acids led to the conclusion "that both the soluble fraction and the ribosomes of thymus cells are involved in the inhibition of

protein synthesis in thymus microsomes following the administration of adrenal cortical hormones."

*Yuwiler et al. H9,994/69:* Comparative observations on fasted and cortisol-injected rats led to the conclusion that "the natural stress of fasting is accompanied by alterations in some corticoid-inducible enzymes, but that these changes are not analogous to those obtained following glucocorticoid administration."

**Other Enzymes (G-6-P-ase, UDP-ase, Urea-Cycle Enzymes, DNA- and RNA-polymerase, Phosphatases, etc.)** ←. *Weber et al. C11,010/56:* In the liver of the rat, "cortisone caused a marked increase in the G-6-P-ase activity of the homogenate, nuclear, mitochondrial and microsomal fractions per unit weight, nitrogen and average cell."

*Feigelson et al. G68,042/62:* In partially hepatectomized rats, cortisone causes a transient stimulation and subsequent depression in the incorporation of precursors into the DNA of the regenerating liver.

*Willmer & Foster D28,163/62:* Studies on the effect of various diets upon carbohydrate-metabolizing hepatic enzymes in intact and adrenalectomized rats, and on the effect of substitution therapy with various corticoids after adrenalectomy.

*Feigelson & Feigelson D59,123/63:* In rat liver tissue, "cortisone rapidly elevates incorporation of glycine-2-<sup>14</sup>C into acid-soluble adenine nucleotides as well as into RNA. Intraperitoneal administration of a variety of L- and D-amino acids, NH<sub>4</sub><sup>+</sup>, and glutamine into adrenalectomized rats imitated cortisone by stimulating glycine-2-<sup>14</sup>C incorporation into acid-soluble and RNA purines. Although liver adenosine triphosphate levels rise after cortisone administration, such alterations in ATP per se do not influence the rate of precursor incorporation into RNA or protein. On the basis of these findings, it is proposed that increased amino acid deamination, implicit in the gluconeogenic action of the glucocorticoids, results in the liberation of  $\alpha$ -amino nitrogen moieties that mediate the cortisone-induced increases in hepatic purine biosynthetic rates."

*Schimke D39,880/63:* Studies on the induction of urea-cycle enzymes (carbamyl phosphate synthetase, ornithine transcarbamylase, argininosuccinate synthetase, argininosuccinase, and arginase) in the liver of intact and adrenalectomized animals given cortisone or cortisol.

*Dietrich & Yero G26,959/65:* Cortisol markedly lowered the nicotinamide deamidase activity of the liver in intact, hypophysectomized, and adrenalectomized rats. Under these conditions, cortisol failed to inhibit hepatic synthesis of NAD significantly after nicotinamide challenge. Hexestrol markedly lowered hepatic deamidase activity in intact, thyroidectomized, and adrenalectomized rats. A lowering of the hepatic NAD-levels after nicotinamide challenge occurred upon hexestrol treatment in intact, but not in adrenalectomized, rats. Hypophysectomy markedly stimulated nicotinamide deamidase activity and NAD-biosynthesis after nicotinamide challenge.

*Dietrich G28,103/65:* In the mouse, hepatic nicotinamide deamidase, and the capacity to synthesize NAD are lowered by dienestrol, diethylstilbestrol, estradiol-17 $\beta$ , estrone, estriol, cortisone and cortisol. Pretreatment with large amounts of hexestrol also lowered the capacity of hepatic tissue to synthesize NAD upon nicotinamide challenge.

*Franklin G32,826/65:* The demethylation of morphine by rat hepatic microsomes was greatly diminished by pretreatment with cortisone, although, simultaneously, the G-6-P-ase activity of the liver increased. Pretreatment with morphine exhibited essentially similar effects upon these two enzymes.

*Griffin & Cox F86,851/66:* "The induction of alkaline phosphatase by prednisolone in HeLa cell cultures appears to occur at the level of protein synthesis (translation) as a result of a steroid-induced change in the conformational state of the enzyme during its synthesis."

*Moses et al. G40,253/66:* In a patient with glycogen storage disease, triamcinolone caused a 4-fold increase in hepatic G-6-P-ase.

*Terayama & Takata F69,475/66:* "Administration of cortisone had no significant effect on the N-demethylating activity of normal liver but partially prevented the decrease in enzymatic activity caused by adrenalin or partial hepatectomy."

*Drews & Brawerman G52,150/67:* Studies on changes in RNA-synthesis in the rat liver during regeneration and after cortisol administration. The relationship between enzyme induction and RNA-synthesis is discussed.

*Wulf & Hers G53,099/67:* In N.M.R.I. mice, prednisolone stimulates not only glycogen synthesis, but also the formation of glycogen synthetase in the liver.

*Freedland et al. G55,808/68:* Extensive studies on the effect of adrenalectomy, hypo-

physectomy and cortisol treatment upon a great variety of rat liver enzymes, with observations on the effect of thyroxine upon these enzymes in intact, adrenalectomized or hypophysectomized rats. The extensive data do not lend themselves to succinct presentation in the form of a summary and must be consulted in the original.

*Gresham & Pover G58,354/68:* In the rat, alkaline RNase levels increase in the mucosa of the small intestine after total body or selective head X-irradiation as well as after treatment with such radiomimetic drugs as Chlorambucil or Myleran but not after treatment with ACTH, cortisol or various stressors. Still, a relationship to the G.A.S. is suspected because blockade of the normal neuroendocrine responses to stress by combined treatment with morphine + pentobarbital blocked the intestinal RNA response to X-irradiation, and the latter was also lacking in newborn rats in which hypothalamic control of anterior pituitary function has not yet developed.

#### ← Adrenalectomy

**TKT, TPO** ←. *Knox B71,418/51:* Tryptophan induces hepatic TPO both in intact and in adrenalectomized animals. Various other compounds, including epinephrine and histamine which (to a lesser extent) have the same effect in intact animals, fail to act after adrenalectomy. "The first mechanism has been identified as that of enzyme adaptation, previously known only in microorganism, and the second has been identified as the stress reaction, acting through the adrenal glands."

*Geschwind & Li B93,277/54:* In the rat, the induction of the TPO enzyme system is diminished by hypophysectomy and adrenalectomy, but increased by thyroidectomy.

*Thomson & Mikuta B96,579/54:* In adrenalectomized rats, maintained on 1% NaCl, the activation of the hepatic TPO system is so specific for glucocorticoids (e.g., cortisone, cortisol) and so accurately dose-dependent that it is recommended as a bioassay method. DOC is ineffective.

*Thomson & Mikuta B90,975/54:* "Total-body X-irradiation produces within a few hours a dose-dependent increase in the tryptophan peroxidase-oxidase system of rat liver. The increase does not occur in adrenalectomized rats, and hence cannot be construed as a direct effect of X-irradiation." After hypophysectomy, enzyme induction became progressively less pronounced as adrenal atrophy

developed. ACTH restored the ability of the hypophysectomized rat to respond with enzyme induction.

*Knox & Auerbach E76,825/55*: The TPO activity of rat liver is lowered by adrenalectomy and increased in both normal and adrenalectomized animals by cortisone. The increase in TPO activity caused by histidine and other pharmacologically active amines is prevented by adrenalectomy, unless the animals receive glucocorticoids. Hormone-induced and substrate-induced enzyme adaptation must be distinguished.

*Lin & Knox E63,521/57*: The hepatic TKT activity of the rat increases following injections of tyrosine or cortisol. A 10-fold increase was observed within 5 hrs. Tyrosine was an effective inducing stimulus only if the adrenal glands were present, or if cortisol was injected after adrenalectomy.

*Lin & Knox C73,824/58*: In rats, the hepatic TKT activity increased following treatment with cortisone, cortisol or corticosterone and L-tyrosine. This effect was observed also after adrenalectomy. On the other hand, a comparable effect of other amino acids was probably due to stress. "That a nonspecific stress-producing agent could actually increase the level of tyrosine- $\alpha$ -ketoglutarate transaminase was further supported by the results obtained with a compound which is unrelated to tyrosine metabolism. Injections of propylene glycol in doses of 0.5 ml per 100 gm of body weight caused the level of this enzyme to increase to an average of 1390 units in three intact rats." Adrenalectomized rats did not support this dose of propylene glycol.

*Schor & Frieden C57,994/58*: In the rat, insulin can induce hepatic TPO activity, and its effect is only partly inhibited by adrenalectomy. In the intact rat, the effect of insulin and tryptophan, or insulin and cortisone, are additive. Possibly, "hormonal induction may be a form of substrate induction in that certain hormones might affect the availability of tryptophan for the enzyme-forming system."

*Canal & Maffei-Faccioli G66,306/59*: Reserpine is a more potent inducer of TPO in the liver of adrenalectomized than in that of intact rats. Hence, the effect of reserpine is not due to stress-induced increased corticoid production; it may be due to the liberation not only of 5-HT but also of its precursor tryptophan.

*Civen & Knox E64,178/59*: In the adrenalectomized rat, the cortisol-induced increase in

hepatic TPO activity is not associated with a higher level of tryptophan in the liver of normal rats, nor with an increased tryptophan metabolite excretion by pyridoxine-deficient rats. Tryptophan induction of the enzyme is associated with a rise in hepatic tryptophan and the excretion of metabolites by the deficient rats. The inducing effect of tryptophan and cortisol given together was the sum of their separate actions. In vitro TPO is induced by addition of tryptophan, but not of cortisol, to the medium. It is concluded that cortisol is a primary inducer of enzyme and acts differently from, and independently of, the substrate.

*Ginouliac G67,780/59*: Studies on the TPO-induction by various corticoids in adrenalectomized rats suggest that "the TPO test is suitable for the biological evaluation of corticoids."

*Lin et al. C96,929/59*: TKT activity is higher in the liver of male than of female rats. This enzyme activity is diminished by castration in males, and increased by testosterone in females. Cortisol increases this transaminase activity in males much more than in females, both in the presence and in the absence of the adrenals.

*Sereni et al. C80,562/59*: Activity of TKT is very low in the livers of fetal rats, but rapidly increases beginning 2 hrs after birth, reaching a maximum at 12 hrs. Injection of amphenone or adrenalectomy at birth delays the development of this enzyme, whereas cortisol reverses the effect of adrenalectomy.

*Kenney D98,193/60*: In the rat, hepatic TKT activity increases sharply after birth. This increase is prevented by adrenalectomy; tyrosine cannot substitute for cortisol in restoring transaminase development. Methionine is as active as tyrosine in increasing the response to cortisol after adrenalectomy and this process does not depend upon the specific substrate as such, but apparently upon the presence of certain amino acids. Immunological assays "are clearly incompatible with a mechanism of induction involving de novo synthesis of enzyme protein and suggest that adrenal steroids promote either the activation of an antigenically similar but enzymically inactive precursor protein, or the release of an inhibitor."

*Kenney & Flora D12,237/61*: Tryptophan and i.p. injections of diatomaceous earth (Celite) were as effective as tyrosine in inducing increases in hepatic TKT in intact, but not in adrenalectomized rats. Cortisol was an

effective inducer at low doses in both intact and adrenalectomized animals. In the latter, the effect of a small dose of cortisol was potentiated by simultaneous administration of tyrosine, methionine or diatomaceous earth. "It is concluded that induction of tyrosine transaminase is entirely mediated by adrenal hormone." In adrenalectomized rats, diatomaceous earth i.p. is believed to act as a stressor through adrenocortical stimulation.

*Feigelson & Greengard D46,319/62*: In the rat, a single i.p. injection of cortisone causes a 3-fold increase in the amount of TPO enzyme protein (immunologic assay). When assayed in the presence of saturation levels of its hematin cofactor, a proportionate increase in the catalytic activity of the enzyme is also obtained. Adrenalectomized rats react the same way. "Thus, the increase in liver tryptophan pyrrolase activity during hormonal induction and during the second phase of substrate induction are due to increased tryptophan pyrrolase protein levels."

*Greengard & Feigelson G67,329/62*: Immunochemical evidence showing that an increased amount of TPO is found in the liver of adrenalectomized rats following treatment with L-tryptophan. A similar increase is obtained by cortisone. [The brief abstract does not state whether cortisone was also tested in adrenalectomized rats (H.S.).]

*Kenney E98,787/62*: Labeling of TKT in the livers of cortisol-pretreated and not pretreated adrenalectomized rats was followed after a single injection of L-leucine-<sup>14</sup>C. The results suggest "that the rate of enzyme synthesis is increased on induction, and that alterations in the rate of enzyme degradation play little or no role in the induced increase in enzyme."

*Lee & Balts D16,649/62*: In rats, adrenalectomy diminishes the ability of the liver to form TPO following tryptophan injection. "Under dosage and time conditions in which hydrocortisone and the adrenocortical extract did not act as inducers, it was demonstrated that they permitted the quantitative response to substrate administration to return to normal; desoxycorticosterone was found to be ineffective. The results have been interpreted as an example of the 'permissive' action of the adrenocortical secretory products."

*Rosen & Milholland D23,053/62*: Administration of L-tryptophan, but not of tyrosine, stimulated hepatic TKT activity in adrenalectomized rats. No such induction was obtained by tryptophan in vitro. Adrenalectomized

rats treated with tyrosine, methionine or histidine had slightly subnormal TKT levels. Tryptophan analogues (D-tryptophan, acetyl-L-tryptophan, indole, D,L-5-OH-tryptophan and 5-HT), increase both TKT and TPO activity in the livers of adrenalectomized rats. In hypophysectomized rats, tryptophan, 5-HT or 5-OH-tryptophan caused only a slight rise in the hepatic activity of TPO or TKT.

*Davis D92,322/63*: The decarboxylation of o-tyrosine and 5-hydroxytryptophan by livers of adrenalectomized rats, given water, was significantly lower than in controls. No significant effects on decarboxylation of these substrates were observed in adrenalectomized animals given NaCl, or in intact animals treated with DOC or exposed to cold. On the other hand, cortisone increased the inherent hepatic decarboxylating activity for both substrates, in normal as well as in pyridoxine-deficient rats.

*Greengard & Gordon G15,572/63*: "The tyrosine- $\alpha$ -ketoglutarate transaminase activity of liver extracts, assayed in the presence of excess pyridoxal phosphate, was increased by the parenteral administration of pyridoxine to adrenalectomized rats. A 3-fold rise can occur in 4 hrs. The administration of puromycin, an inhibitor of protein synthesis, prevents the pyridoxine-induced rise in the amount of tyrosine- $\alpha$ -ketoglutarate transaminase. The results suggest that coenzyme levels, in addition to regulating the activity of existing enzyme, may influence, in vivo, the amount of the protein moiety of appropriate enzyme systems."

*Greengard et al. D63,145/63*: In adrenalectomized rats, "the administration of puromycin inhibited the cortisone-induced elevation of tryptophan pyrrolase and tyrosine- $\alpha$ -ketoglutarate transaminase activity as well as the substrate-induced elevation of the latter. Actinomycin D abolished the cortisone-mediated rise in the level of both enzymes but did not influence the tryptophan-mediated increase in the level of tryptophan pyrrolase." In newborn rats, the development of hepatic TKT was inhibited by actinomycin D, but neither adrenalectomy nor actinomycin interfered with the postnatal development of hepatic TPO. Apparently, accumulation of TPO (unlike that of TKT) is not under adrenal control and can proceed despite inhibited RNA synthesis.

*Kenney & Kull G22,373/63*: In adrenalectomized rats treated with cortisol, the synthesis of nuclear RNA precedes increased

cytoplasmic TKT-synthesis after about 30 min. Enzyme induction is therefore ascribed to the stimulation of messenger RNA.

*Knox D66,995/63*: In intact rats, TPO or TKT can be induced by pretreatment either with the corresponding substrates or with cortisol. However, after adrenalectomy, TKT, unlike TPO can no longer be induced by the substrate. Cortisol induces both enzymes even after adrenalectomy, and the increase is particularly pronounced if the hormone is given conjointly with these substrates.

*Pitot G65,475/63*: In the Morris hepatoma 5123, TPO activity is normally low and cannot be significantly altered either by tryptophan or by cortisone, whereas both these substances induce the enzyme in the normal liver tissue. In adrenalectomized rats, TPO induction by tryptophan is lower than in intact animals, although cortisone induction in the host liver is actually increased. A slight enzyme induction appears to be possible even in the hepatoma when cortisone is administered to the adrenalectomized rat. Essentially similar but not quite identical results have been obtained with rats bearing Morris hepatoma 7800 or 7316. TKT, TDH and G-6-P-ase activities were either minimally or not affected by cortisone in various transplantable hepatic tumors.

*Rosen et al. E32,653/63*: "A period of about 48 hours is required to attain maximal activity of alanine- $\alpha$ -ketoglutarate transaminase in liver after subcutaneous treatment of rats with a single injection of cortisol. In contrast, tyrosine- $\alpha$ -ketoglutarate transaminase reaches a maximal value in liver between 4 and 5 hours after an intraperitoneal dose of cortisol." The same dose of cortisol causes even greater increases in hepatic TKT in adrenalectomized rats, but GPT or TPO induction by cortisol is not influenced by adrenalectomy.

*Rosen & Millholland E32,652/63*: Tryptophan induced significant increases in hepatic TKT activity in intact and in adrenalectomized (NaCl-maintained) rats. Tyrosine, histidine, and methionine slightly depressed the hepatic TKT activity of the adrenalectomized rats. Analogues of tryptophan (including D-tryptophan, acetyl-L-tryptophan, indole, DL-5-hydroxytryptophan and 5-HT i.p.) increase both TKT and TPO activity by 50–300% in the livers of intact or adrenalectomized rats. 5-HT and DL-5-hydroxytryptophan were most active. After hypophysectomy, the response of each of these enzymes to tryptophan gradually diminished. After

6 months, tryptophan, 5-hydroxytryptophan and 5-HT failed to cause significant increases in the hepatic activity of these enzymes, but cortisol remained highly effective, causing increases in both enzyme activities comparable to those seen in intact or adrenalectomized rats. "Experiments with two known inhibitors of protein synthesis, DL-ethionine and puromycin, indicate that a major fraction of the induced activity of tryptophan pyrrolase seen in adrenalectomized or hypophysectomized rats treated by injection with tryptophan is due to activation rather than synthesis of new enzyme protein. The responses of tryptophan pyrrolase and tyrosine transaminase in liver following cortisol administration appear to be mainly the result of the synthesis of each of these enzymes."

*Garren et al. G28,021/64*: In adrenalectomized rats, a single i.p. injection of cortisol produces an increase in hepatic TPO and TKT activity. Actinomycin D did not inhibit synthesis of these enzymes, but blocked their induction when injected early after cortisol administration. Actinomycin D and fluorouracil stimulated TPO and TKT synthesis when injected 5 hrs or later after cortisol. "It is proposed that repression of the synthesis of these enzymes occurs at the level of messenger RNA translation."

*Knox G65,171/64*: Observations on adrenalectomized rats lead to the distinction between two types of TPO induction. One is called the "hormone type" because glucocorticoids act this way. Thus, in adrenalectomized rats, cortisol increased the amount of some limiting RNA moiety, thereby augmenting enzyme synthesis. This action is prevented by actinomycin D through the inhibition of RNA synthesis as well as by puromycin, which inhibits protein synthesis. The second form or "substrate type" of induction is obtained by tryptophan which increases the amount of TPO without stimulating RNA synthesis. This increase is not prevented by actinomycin D although it is, of course, blocked by puromycin, which inhibits protein synthesis.

*Pitot et al. G37,125/64*: In intact rats bearing Reuber H-35 hepatomas, TKT activity is much greater in the tumor than in the normal hepatic tissue. Cortisone i.p. induces enzyme in the liver, but not in the tumor. In adrenalectomized hosts, however, the enzyme in the tumor is in the range of the host liver and cortisone induces enzyme in both liver and tumor. If cortisone is added to cultures 24 hrs before the enzyme assay, a significant

induction occurs *in vitro*, reaching a maximum in 6 hrs. Actinomycin D added to the medium delays enzyme induction without inhibiting it completely.

*Schimke et al. G11,062/64*: In adrenalectomized rats, tryptophan *i.p.* alone causes a linear increase in hepatic TPO reaching a level six times that of the controls within 16 hrs. Cortisol *s.c.* causes an exponential increase reaching a maximum of 7–8 times the control levels. Simultaneous treatment with cortisol and tryptophan produces a linear increase in TPO at a rate 7 times that produced by tryptophan alone, resulting in a 40–50-fold increase. Analysis of the enzyme kinetics led to the conclusion that “the greatest increase in TPO, then, result from both an increased rate of enzyme formation and a decreased rate of enzyme degradation.”

*Berlin & Schimke G37,616/65*: In adrenalectomized rats, 4 days of pretreatment with cortisone increased the activity of hepatic TPO, TKT, GPT and arginase. Differences in the turnover rate of enzymes thus induced may simulate differential selective-inducing effects upon one or the other enzyme.

*Kenney & Albritton G64,557/65*: Review of the literature suggesting that transaminase induction in response to stressors can be due to corticoid secretion during the stress reaction. Cortisol increases enzyme synthesis following an increased rate of synthesis of ribosomal transfer and “DNA-like” RNA’s. The present experiments confirm the view that repressor(s) can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis can prolong the corticoid-induced increase in enzyme synthesis under suitable conditions. “Administration of stressing agents (tyrosine, Celite) to adrenalectomized rats initiates a highly selective repression of the synthesis of hepatic TKT. The enzyme level falls with a  $t_{1/2}$  of about 2.5 hr. Immunochemical measurement of the rate of enzyme synthesis indicates that it is reduced essentially to zero in stressed, adrenalectomized rats, whereas labeling of total liver soluble proteins is unaffected. Actinomycin-D does not itself influence the enzyme level, but it blocks the stress-initiated repression of enzyme synthesis, indicating that repression acts at the translational level, whereas initiation of repression involves transcriptional processes.” In hypophysectomized rats, stressors are ineffective and preliminary data suggest that STH is responsible for transaminase repression.

*Nomura et al. G33,405/65*: Various forms of stress (forced exercise, immobilization, cold), as well as the administration of chlorpromazine, increased the TPO activity of the liver both in intact and in adrenalectomized, but not in hypophysectomized, rats.

*Schimke et al. G24,293/65*: In adrenalectomized rats, both cortisol and tryptophan increase hepatic TPO, but a particularly pronounced rise is obtained by combined treatment with both these agents. An analysis of the time course of changing enzyme levels and results of isotope incorporation studies indicate that cortisol increases the rate of enzyme synthesis, whereas tryptophan decreases the rate of enzyme degradation.

*Singer & Mason G66,500/65*: Na-benzoate increased hepatic TKT activity both in intact and in NaCl-maintained adrenalectomized rats. Among 31 cyclic compounds tested for this inducing ability after adrenalectomy, only cortisol, its hemisuccinate and diethylstilbestrol disulfate were more effective than benzoate. Curiously, enzyme induction by cortisol was actually enhanced after adrenalectomy. “Strong inhibition of the increase by injected puromycin and actinomycin D, compounds which inhibit protein and RNA synthesis respectively, suggests that the benzoate-mediated effect occurred by a mechanism involving increases in protein and RNA synthesis. In this respect, the effect of benzoate resembles that of the glucocorticoids.”

*Tomkins et al. G35,353/65*: Following a single injection of cortisol into adrenalectomized rats, the hepatic TPO and TKT levels rise. “Although actinomycin D blocks the initial steroid-induced increase, later administration of the antibiotic (or of 5-fluorouracil) causes an increase in the levels of these enzymes.”

*Berry et al. G67,237/66*: *S. typhimurium* endotoxin lowers liver TPO in mice and prevents the induction of the enzyme by concurrent injection of cortisone. It lowers, but does not prevent, substrate induction. Actinomycin D has a similar effect on TPO. In the intact mouse, the endotoxin induces TKT almost as well as cortisone, but not in the adrenalectomized animal. Actinomycin D, on the other hand, has an effect on this transaminase similar to that on TPO.

*Fiala & Fiala F65,983/66*: In the rat, actidione *i.p.* inhibits the induction of hepatic TPO assayed 4 hrs after administration of the substrate, or of cortisol. By contrast, cycloheximide did not abolish the induction of

TKT by cortisol and, in fact, actidione increased the level of TKT even in the absence of cortisol treatment. A similar, though smaller, effect occurred in hypophysectomized or adrenalectomized rats, suggesting a direct induction of TKT by actidione. Puromycin inhibited the induction of TKT. Apparently, an inhibitor of protein synthesis, such as actidione, may also act as an inducer for the synthesis of TKT, thus simulating the action of cortisol. "This 'pseudohormonal' action of actidione may explain the toxicity of actidione in certain mammalian species and also the fact that hydrocortisone may act as an antidote in actidione poisoning. It does not explain why a similar effect of 'pseudohormonal' induction is not observed in the case of TPO, but only the inhibition of enzyme induction."

*Schapiro et al. F67,227/66:* Hepatic TKT activity increased in immature, stressed (reciprocating shaker) rats, but not in the intact, stressed adults. In the stressed adrenalectomized adults, TKT activity markedly decreased, while adrenalectomized immature rats showed no change. Hypophysectomy largely abolished inhibition in the adults. TPO activity, when present, was increased by stress in old-age groups, but the increase was abolished by adrenalectomy and hypophysectomy. "The results suggest stress-activation of a pituitary mechanism that inhibits or represses activation of tyrosine transaminase and that may not function during early postnatal life."

*Agarwal & Berry G66,480/67:* "Four hours after zyosan administration, cortisone was able to induce mouse liver tryptophan pyrrolase production almost at a normal rate and, under these conditions, protected mice against a concurrent injection of endotoxin. Administration of zyosan, at either 2 or 4 hours after cortisone administration, resulted in little change in tryptophan pyrrolase activity while endotoxin, when similarly administered, caused a rapid decline in liver tryptophan pyrrolase activity. . . . Glucan and zyosan, like endotoxin, increased tyrosine- $\alpha$ -ketoglutarate transaminase activity in intact but not in adrenalectomized mice. Zyosan and thorotrast, unlike endotoxin, neither lowered liver carbohydrate levels nor influenced cortisone induced neosynthesis of liver glycogen. These results suggest a cause and effect relationship between inducibility of key liver enzymes and survival against stress."

*Aitio & Hänninen G66,417/67:* Both in intact and in adrenalectomized rats, cincho-

phen increased the hepatic TKT activity, but had no effect upon that of GPT and GOT.

*Grossmann & Mavrides G46,206/67:* Studies on the kinetics of cortisol-induced hepatic TKT activity in adrenalectomized rats. "Puromycin inhibited enzyme synthesis when it was given during the initial phase of induction. However, it unexpectedly caused a rapid reappearance of enzyme activity following its administration during the inactivation phase. This potentiated response is consistent with other observations which lead to the idea that a repressor is formed about 4 hours after hormone administration and that inhibition of repressor synthesis allows, at least temporarily, continued synthesis of enzyme." The inactivator appears to depend upon pituitary function, since adrenalectomized and hypophysectomized rats showed little or no inactivation phase following cortisol treatment.

*Hänninen & Hartiala F76,119/67:* In the rat, the stress of restraint causes a linear increase in hepatic TKT to 4 times the initial level within 12 hrs. This effect was partially inhibited by actinomycin D and totally by adrenalectomy.

*Kato G54,276/67:* In intact, unlike in adrenalectomized, ascites-tumor-bearing mice, the hepatic TKT activity is elevated.

*Kennedy G50,810/67:* In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The rate of enzyme synthesis is reduced nearly to 0 (immunochemical-isotopic analyses), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actinomycin D. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized) animals. Transaminase levels were unchanged in a single experiment where the stressing agent was administered to the hypophysectomized partner.

*Kupfer & Peets F85,854/67:* Cortisol s.c. increases hepatic TKT activity in adrenalectomized male rats and this effect is further augmented by SKF 525-A which in itself has no effect. In intact rats, SKF 525-A raises hepatic TKT activity in itself but this effect is not further augmented by cortisol. Possibly, the potentiation of cortisol induction of TKT

by SKF 525-A is due to an inhibition of the degradation of cortisol.

*Seidman et al. F 88,452/67*: The induction of TPO has been studied in the liver remnant of partially hepatectomized rats following treatment with cortisol, and after adrenalectomy. "It seems possible, therefore that the lessened response to hydrocortisone in hepatic cells preparing to divide is related to repression of transcriptional rather than translational mechanisms and that the duplicating genome itself may be unable to participate simultaneously in other functions."

*Goswami et al. G 55,570/68*: L-tyrosine fails to induce TKT in the liver of the adrenalectomized rats unless 8-azaguanine is administered simultaneously. Pretreatment with actinomycin D prevents this response. It is assumed that "tyrosine is a potential stimulator restrained by an inhibitor whose activity is diminished by 8-aG."

*Kenney et al. H 4,503/68*: When adrenalectomized rats are subjected to severe stress, or given STH, the hepatic level of TKT falls markedly. No such effect is obtained by addition of STH to the perfusion fluid of an isolated liver and, hence, the "repression response" is considered secondary to an extrahepatic factor.

*Rapoport et al. G 53,334/68*: Pneumococcal infection raised the hepatic TPO activity in intact, but not in adrenalectomized, mice. Cortisol increased TPO activity both in control and in pneumococcus-infected mice, but only if administered early after inoculation. Later during the course of infection, some inhibitory factor develops which counteracts the TPO induction by cortisol.

*Schapiro H 2,360/68*: Stress (30 min rough agitation in a noisy laboratory shaker) had no effect upon the corticoid sensitive enzyme TKT in the liver of the intact rat, but it increased TPO activity, which is likewise corticoid inducible. Adrenalectomized rats, similarly stressed, exhibited a decreased transaminase activity with no change in TPO. This inhibitory effect was abolished by hypophysectomy. STH inhibited induction of transaminase by cortisol, but had no effect upon cortisol-induced TPO activity. The opposing actions of STH and glucocorticoids may be involved in adaptive reactions to stress.

*Finch et al. G 71,207/69*: In mice, various stressors (cold, shaking) cause a rapid and transient increase in hepatic TKT activity during fasting. Recent feeding or adrenalectomy inhibits TKT induction by cold.

*Geller et al. H 8,414/69*: The stress of laparotomy increases hepatic TKT activity in the intact, but not in the adrenalectomized rat, which actually responds in an inverse manner. Hypophysectomy eliminates some, but not all of these laparotomy-induced repressions. Under these conditions, the TPO- and the TKT-responses are somewhat different.

*Govier & Lovenberg G 70,841/69*: In rats, the increase in hepatic TKT produced by phentolamine is almost completely abolished by adrenalectomy or hypophysectomy. If small doses of cortisol are given to adrenalectomized rats, phentolamine again increases enzyme activity. Aminoglutethimide completely eliminates both the increase in plasma corticosterone and the enzyme induction by phentolamine. "It is concluded that at least two factors are operative in the induction of tyrosine aminotransferase by phentolamine— (1) a response to an increased plasma corticosterone concentration, and (2) an additional effect which may be a direct substrate type of induction."

*Kröger et al. G 66,240/69*: In adrenalectomized rats, the induction of hepatic TKT and TPO is possible only if, in addition to the substrate, small amounts of cortisone are administered.

*Lane & Mavrides H 12,953/69*: Cortisol caused a greater increase of hepatic TKT in hypophysectomized than in adrenalectomized rats. In general, elevation of enzyme activity after cortisol was inversely proportional to the initial enzyme level, and the latter was in turn higher on protein-rich than on protein-poor diets.

*Levitan & Webb G 64,051/69*: Six hours after administering cortisol to adrenalectomized rats, the increased hepatic TKT level begins to fall. Upon concurrent treatment with 8-azaguanine, the increase is greater and much more prolonged. It is assumed that 8-azaguanine affects the degradation of TKT but does not significantly inhibit its synthesis.

*Nicolis & Ginoulhiac H 14,045/69*: In adrenalectomized rats, the hepatic TPO activity turns roughly parallel to the glucocorticoid potency of prednisone, prednisolone, 16 $\alpha$ -methylprednisone, 16 $\beta$ -methylprednisone, dexamethasone and betamethasone.

*Nakano et al. G 76,247/70*: "In adrenalectomized rats, hepatic TPO which can be increased in amount in intact rats by feeding either tryptophan or methionine, was activated and increased in amount by feeding tryptophan but not methionine. The feeding of

tryptophan resulted in a significant increase in the level of arginase and threonine dehydratase. Methionine produced a similar increase in both threonine dehydratase and arginase activities. Administration of cortisone acetate produced a significant increase in the level of all three enzyme activities."

**Other Amino Acid Enzymes** ←. *Brin & McKee C 31,261/56*: In the rat, various stressors (total body X-irradiation, nitrogen mustard, starvation) as well as cortisone increase GOT and GPT activities in the liver. Adrenalectomy decreases the activity of these enzymes. GPT is more sensitive to stress than GOT.

*Rosen et al. C 50,741/58*: In rats treated with cortisol, cortisone or prednisone for one week, there was an increase in hepatic GPT but not in GOT activity. DOC had no such effect. Hypophysectomy or adrenalectomy did not prevent this action of cortisone. STH, testosterone or insulin failed to alter GPT activity nor did any of them influence GPT stimulation by cortisol.

*Rosen et al. C 71,414/59*: Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, 6 $\alpha$ -methylprednisolone, prednisone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol, were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity, but when injected simultaneously with cortisol they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Rosen et al. G 66,496/59*: In the rat, cortisol, cortisone and prednisone cause a 6–13 fold increase in hepatic GPT activity. This effect was directly related to the protein content of the ration. In alloxan diabetic rats, the rise in this enzyme activity was equivalent to that obtained by cortisol or high-protein diets and could be inhibited by insulin. Adrenalectomy diminished but did not abolish the rise in GPT activity obtained by feeding high-protein diets. Thus, the initiation of enzyme synthesis by dietary protein is not mediated exclusively through the adrenals.

*Harding et al. D 14,355/61*: In the rat, pretreatment with DOC depresses the hepatic GPT activity. A similar depression is obtained by adrenalectomy, but this is not further aggravated by concurrent treatment with DOC. ACTH increases GPT activity in hypophysectomized, but not in adrenalectomized, animals. In hypophysectomized rats, DOC fails to lower GPT nor does it alter the response of this enzyme to ACTH. "The inhibitory effect of DOC on alanine transaminase activity appears to be due to suppression of ACTH release by the pituitary."

*Freedland F 17,044/64*: In the rat, adrenalectomy considerably decreases the arginase and arginine synthetase activity of liver homogenates, but has no effect on lactic acid dehydrogenase activity. Various dietary measures, which alter the activities of arginine synthetase, arginase, and lactic acid dehydrogenase in intact rats, are also effective after adrenalectomy.

*Freedland & Avery G 67,766/64*: In the rat, the TDH and SDH activity of liver homogenates was increased by high protein diets, alloxan diabetes, or cortisol. Factors affecting the activity of TDH caused a proportional change in SDH suggesting that both of these activities may be due to a single protein. The SDH activity was decreased by adrenalectomy or hypophysectomy. Adrenalectomy had no effect upon the response of this enzyme to protein feeding, whereas, after hypophysectomy, this response was diminished.

*Ishikawa et al. F 41,763/65*: In alloxan-diabetic rats, the SDH and TDH levels of the hepatic microsomes are greatly enhanced. SDH was readily induced by cortisol in the diabetic, but not in the normal, rat. The effects of actinomycin S, STH, and starvation upon SDH have also been studied in intact, hypophysectomized, adrenalectomized and thyroidectomized rats. It is concluded that "serine dehydratase activity in the liver plays an important role in the production of pyruvate as a starting material for gluconeogenesis."

*Schmidinger & Kröger F 92,031/67*: The increase in hepatic SDH induced by protein-deficient diets and starvation in intact rats is prevented by actinomycin D, puromycin or glucose, but aggravated after adrenalectomy. Cortisone administered during the starvation period increases SDH activity, perhaps owing to utilization of inhibitors of this enzyme during gluconeogenesis.

*Jost et al. H 11,724/68*: Studies on the induction and repression of SDH by rat liver

microsomes. "Amino acid induction and glucose repression as well as hormonal induction by both glucagon and hydrocortisone occur in adrenalectomized animals."

*Pan et al. H 3,934/68:* The methionine adenosyltransferase activity of hepatic homogenates is higher in female than in male rats. "Ovariectomy decreased the enzyme level, whereas the administration of  $17\beta$ -estradiol or diethylstilbestrol, but not progesterone, reversed the effect of ovariectomy. Estradiol also raised the enzyme level in intact male rats to that of the female. Adrenalectomy had no effect on the response of the enzyme to estradiol. Castration of the male resulted in an increase in the activity of methionine adenosyltransferase, and the administration of androgenic-anabolic hormones brought the elevated activity down to the normal level of intact males or even lower. Adrenalectomy did not abolish the effect of castration.  $17\alpha$ -Ethyl- $19\alpha$ -nortestosterone and 1-methyl- $\Delta^1$ -androstenedione were more effective in this respect than testosterone,  $17\alpha$ -methyl- $\Delta^5$ -androstene- $3\beta,17\beta$ -diol and  $5\alpha$ -androstane- $17\beta$ -ol- $3$ -one. The effect of the steroids in decreasing methionine adenosyltransferase activity seems to be associated with their anabolic rather than their androgenic action."

*Hoshino & Kröger H 13,867/69:* SDH was induced in the livers of adrenalectomized rats by fasting and concurrent cortisone treatment. The properties of the purified enzyme preparation are described.

*Murphy & Malley G 68,408/69:* Studies on hepatic TKT, alkaline phosphatase (AP), GPT and TPO in relation to stress and  $\text{CCl}_4$ -intoxication in the rat. "Liver TKT elevation, but not AP elevation, was prevented by adrenalectomy prior to  $\text{CCl}_4$ . Experiments on rats subjected to simultaneous acute cold stress and  $\text{CCl}_4$  indicated that, during the acute phase of  $\text{CCl}_4$  hepatotoxicity, their livers had reduced capacity for induction of TKT and TPO by endogenous corticosterone. However, chronically injured livers of rats given repeated doses of  $\text{CCl}_4$  were fully responsive to the TKT- and TPO-inducing effects of exogenous corticosterone or acute cold stress."

*Shou et al. H 15,277/69:* In the rat, the hepatic methionine adenosyltransferase activity was not much influenced by glucagon, but during alloxan diabetes it increased considerably. Combined treatment with alloxan and triamcinolone resulted in an additive effect. The response to alloxan could be prevented and even reversed by insulin or adrenal-

ectomy. In normal rats, insulin caused no consistent increase.

**Other Enzymes** ←. *Pitot G 65,475/63:* In the Morris hepatoma 5123, TPO activity is normally low and cannot be significantly altered either by tryptophan or by cortisone, whereas both these substances induce the enzyme in the normal liver tissue. In adrenalectomized rats, TPO induction by tryptophan is lower than in intact animals although cortisone induction in the host liver is actually increased. A slight enzyme induction appears to be possible even in the hepatoma when cortisone is administered to the adrenalectomized rat. Essentially similar but not quite identical results have been obtained with rats bearing Morris hepatoma 7800 or 7316. TKT, TDH and G-6-P-ase activities were either minimally or not affected by cortisone in various transplantable hepatic tumors.

*Garren et al. G 19,151/64:* Cortisol increased the rate of synthesis of nuclear RNA in the livers of adrenalectomized rats.

*Dietrich & Yero G 26,959/65:* Cortisol markedly lowered the nicotinamide deamidase activity of the liver in intact, hypophysectomized, and adrenalectomized rats. Under these conditions, cortisol failed to inhibit hepatic synthesis of NAD significantly after nicotinamide challenge. Hexestrol markedly lowered hepatic deamidase activity in intact, thyroidectomized, and adrenalectomized rats. A reduction of the hepatic NAD-ase-levels after nicotinamide challenge occurred upon hexestrol treatment in intact, but not in adrenalectomized, rats. Hypophysectomy markedly stimulated nicotinamide deamidase activity and NAD-biosynthesis after nicotinamide challenge.

*Greenman et al. G 35,063/65; Wicks et al. G 35,046/65:* Studies on the stimulation of hepatic  $^{32}\text{P}$ -RNA synthesis in adrenalectomized rats treated with cortisol.

*Freedland et al. G 55,808/68:* Extensive studies on the effect of adrenalectomy, hypophysectomy and cortisol treatment upon a great variety of rat liver enzymes, with observations on the influence of thyroxine upon these enzymes in intact, adrenalectomized or hypophysectomized rats. The extensive data do not lend themselves to succinct presentation in the form of a summary and must be consulted in the original.

*Fazekas & Rengei G 64,534/69:* Comparative studies on the NAD and  $\text{NADH}_2$  content of various tissues in intact and adrenalectomized rats treated with ethanol s.c.

*Jacob et al. G64,812/69:* Rat liver nucleoli were examined for RNA polymerase activity. A single injection of cortisol into adrenalectomized rats resulted in a 3-fold increase in  $Mg^{2+}$ -dependent polymerase while  $Mn^{2+}$ -dependent polymerase activity was not significantly altered.

*Murphy & Malley G68,408/69:* Studies on hepatic TKT, alkaline phosphatase (AP), GPT and TPO in relation to stress and  $CCl_4$ -intoxication in the rat. "Liver TKT elevation, but not AP elevation, was prevented by adrenalectomy prior to  $CCl_4$ . Experiments on rats subjected to simultaneous acute cold stress and  $CCl_4$  indicated that, during the acute phase of  $CCl_4$  hepatotoxicity, their livers had reduced capacity for induction of TKT and TPO by endogenous corticosterone. However, chronically injured livers of rats given repeated doses of  $CCl_4$  were fully responsive to the TKT- and TPO-inducing effects of exogenous corticosterone or acute cold stress."

#### ← Folliculoids

*Rosen et al. C71,414/59:* Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluoro-cortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol, were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT-inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Dietrich & Yero G26,959/65:* Cortisol markedly lowered the nicotinamide deamidase-activity of the liver in intact, hypophysectomized, and adrenalectomized rats. Under these conditions, cortisol failed to inhibit hepatic synthesis of NAD significantly after nicotinamide challenge. Hexestrol markedly lowered hepatic deamidase activity in intact, thyroidectomized, and adrenalectomized rats. A lowering of the hepatic NAD-ase-levels after nicotinamide challenge occurred upon hexestrol treatment in intact, but not in

adrenalectomized, rats. Hypophysectomy markedly stimulated nicotinamide deamidase activity and NAD-biosynthesis after nicotinamide challenge.

*Dietrich G28,103/65:* In the mouse, hepatic nicotinamide deamidase, and the capacity to synthesize NAD are lowered by dienestrol, diethylstilbestrol, estradiol-17 $\beta$ , estrone, estriol, cortisone and cortisol. Pretreatment with large amounts of hexestrol also lowered the capacity of hepatic tissue to synthesize NAD upon nicotinamide challenge.

*Dietrich et al. H19,763/70:* In mice, large amounts of hexestrol induce marked changes in the means whereby nicotinate is converted into nicotinamide within the liver.

*Rose & Braidman H25,726/70:* In rats, estradiol increases hepatic TPO, TKT and GPT activity. The depression which develops in some women using contraceptive pills may be due to increased metabolism of tryptophan to nicotinic acid ribonucleotide; raised aminotransferase activity may divert pyridoxal phosphate away from other metabolic functions including 5-HT synthesis.

#### ← Luteoids

*Rosen et al. C71,414/59:* Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT-inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Simon et al. C84,793/59:* In the rabbit and rat, progesterone, androsterone and testosterone stimulate the oxidation of galactose by surviving liver slices. The same steroids also stimulate the conversion of UDP-galactose into UDP-glucose by rabbit liver slices and extracts.

*Pesch et al. C79,957/60:* Earlier observations have shown that progesterone, androste-

rone and testosterone stimulate the oxidation of galactose by rabbit liver slices, owing to an increase in the enzymic activity of the hepatic microsomes. In vivo observations revealed that progesterone can also inhibit the formation of cataracts in rats maintained on a high galactose diet.

Galactose ← Progesterone + Galactosemia, Man: Pesch et al. C79,957/60\*

Xylose ← Progesterone + Age: Pesch et al. C79,957/60\*

#### ← Testoids

Rosen et al. C50,741/58: In rats treated with cortisol, cortisone or prednisone for one week, there was an increase in hepatic GPT but not in GOT activity. DOC had no such effect. Hypophysectomy or adrenalectomy did not prevent this action of cortisone. STH, testosterone or insulin failed to alter GPT activity nor did they influence its stimulation by cortisol.

Lin et al. C96,929/59: TKT activity is higher in male than in female rat liver. This enzyme activity is diminished by castration in males, and increased by testosterone in females. Cortisol increases this transaminase activity in males much more than in females, both in the presence and in the absence of the adrenals.

Rosen et al. C71,414/59: Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT-inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

Simon et al. C84,793/59: In the rabbit and rat, progesterone, androsterone and testosterone stimulate the oxidation of galactose by surviving liver slices. The same steroids also stimulate the conversion of UDP-galactose into UDP-glucose by rabbit liver slices and extracts.

#### ← Gonadectomy

Lin et al. C96,929/59: TKT activity is higher in the livers of male than of female rats. This enzyme activity is diminished by castration in males, and increased by testosterone in females. Cortisol increases this transaminase activity in males much more than in females, both in the presence and in the absence of the adrenals.

Wurtman & Axelrod E36,478/63: Hepatic MAO activity is greater in male than in female rats. This difference can be reversed by estradiol in male and by testosterone in female gonadectomized rats.

Pan et al. H3,934/68: The methionine adenosyltransferase activity of hepatic homogenates is higher in female than in male rats. "Ovariectomy decreased the enzyme level, whereas the administration of 17 $\beta$ -estradiol or diethylstilbestrol, but not progesterone, reversed the effect of ovariectomy. Estradiol also raised the enzyme level in intact male rats to that of the female. Adrenalectomy had no effect on the response of the enzyme to estradiol. Castration of the male resulted in an increase in the activity of methionine adenosyltransferase, and the administration of androgenic-anabolic hormones brought the elevated activity down to the normal level of intact males or even lower. Adrenalectomy did not abolish the effect of castration. 17 $\alpha$ -Ethyl-19-nortestosterone and 1-methyl- $\Delta^1$ -androstenolone were more effective in this respect than testosterone, 17 $\alpha$ -methyl- $\Delta^5$ -androstene-3 $\beta$ ,17 $\beta$ -diol and 5 $\alpha$ -androstan-17 $\beta$ -ol-3-one. The effect of the steroids in decreasing methionine adenosyltransferase activity seems to be associated with their anabolic rather than their androgenic action."

Künzel & Müller-Oerlinghausen G64,178/69: In vitro glucuronide synthesis is much higher in male than female rat liver tissue because of a larger UDP-glucuronic acid supply in the male liver. Orchidectomy decreases glucuronide synthesis and this decrease can be counteracted by testosterone administration in a dose-dependent manner. However, very large doses of testosterone (more than 100  $\mu$ g per day) decrease glucuronide formation. Cyproterone (an antitestoid) does not inhibit the increase in glucuronide synthesis induced by testosterone.

#### ← Various Steroids

Thompson et al. F81,633/66: "Tyrosine  $\alpha$ -ketoglutarate transaminase can be induced by steroid hormones in a newly established line

of tissue culture cells, derived from primary culture of the ascites form of an experimental rat hepatoma." Dexamethasone, triamcinolone and cortisol were highly active, DOC and aldosterone much less potent, whereas stilbestrol, estradiol, testosterone and progesterone were virtually inactive. The induction by dexamethasone was blocked by puromycin, cycloheximide, chloramphenicol, progesterone, actinomycin D and mitomycin C. Paradoxically, after induction by the steroid had taken place, actinomycin D produced a further increase in enzyme activity.

*Farese H 27,025/70:* In rats, TMACN inhibits cholesterol side-chain cleavage during

incubation of adrenal homogenates or slices in vitro.

*Leber et al. H 35,676/71:* In male rats, pretreatment with spironolactone stimulated the specific activity of isolated hepatic microsomes for aminopyrine demethylation and 4-methylumbelliferone glucuronidation. Microsomal cytochrome P-450 content increased about 66%. Under comparable conditions, ethacrynic acid increased the specific activity of the microsomes for the demethylation of aminopyrine and the P-450 content but, glucuronidation of 4-methylumbelliferone was not significantly altered. Another nonsteroidal diuretic, furosemid, did not influence any of these parameters.

## VI. EFFECT OF OTHER HORMONES UPON RESISTANCE

← ACTH

**Steroids** ←

The influence of ACTH upon various actions of mineralocorticoids (*Selye C92,918/61, p. 18; G60,083/70, pp. 328—332*) and MAD (*Selye G60,083/70, pp. 328, 330*) has been discussed elsewhere. Let us add here that in rats ACTH (like adrenocortical extract) antagonizes many manifestations of overdosage with DOC, such as the: hypernatremia, EST-elevation, and insulin hypersensitivity, as well as the hyalinosis syndrome produced after uninephrectomy + NaCl. Conversely, the hyalinosis elicited by MAD is actually aggravated by ACTH. This singular "DOC-like" effect is presumably due to the inhibition by MAD of  $11\beta$ -hydroxylation in the adrenals; in the presence of this enzymic defect the corticotrophic action of ACTH shifts towards an excess secretion of DOC which has no  $11\beta$ -OH group.

**Nonsteroidal Hormones and Hormone-Like Substances** ←

ACTH shares with the glucocorticoids the property of increasing insulin resistance. This action is not unexpected in view of the antagonistic effect exerted by insulin and glucocorticoids upon the blood sugar.

In guinea pigs exposed to histamine spray, ACTH has little if any protective effect but the gastric ulcers produced in this species by conjoint treatment with histamine and antihistamines can be prevented by the concurrent administration of ACTH. In newborn rats, fatal histamine intoxication is not significantly influenced either by ACTH or by various glucocorticoids.

The production of renal infarcts by 5-HT in the rat, though diminished by hypophysectomy, is not significantly influenced by ACTH.

**Steroids** ←

*Woodbury et al. B47,201/50:* In rats, ACTH and adrenocortical extract antagonize the following actions of DOC: 1) hypernatremia; 2) EST threshold elevation; 3) insulin hypersensitivity; 4) hyalinosis (after sensitization by uninephrectomy plus NaCl).

*Molteni et al. H4,919/68:* In rats, the vascular lesions produced by MAD following uninephrectomy plus NaCl are aggravated by

ACTH, presumably, because MAD interferes with  $\beta$ -hydroxylation in the adrenals, so that under the influence of ACTH an excess of DOC is secreted.

Cortisol ← ACTH: *Kuipers et al. C48,349/58\**; *Kumagai et al. C57,345/58*; *Berliner et al. G75,988/61\**; *Moor et al. G75,989/61\**; *Werk et al. F20,780/64\**

Cortisone ← ACTH + Sex: *Hagen et al. G77,512/60*

**Nonsteroidal Hormones and Hormone-Like Substances ←**

**Insulin** ←. *Jensen & Grattan 77,887/40*: In mice, ACTH, glucocorticoids and cortical extracts increase insulin resistance, whereas other pituitary hormones and thyroxine have no such effect.

**Thyroxine** ← *cf. Selye G60,083/70, pp. 328, 330, 347, 355.*

**Histamine and 5-HT** ←. *Andreani B63,732/50*: In guinea pigs, conjoint treatment with large doses of histamine and antihistamines had previously been shown to result in gastric ulcer formation although the lethal effects of histamine are suppressed. These ulcers can be prevented by ACTH.

*Friedlaender & Friedlaender B55,467/50*: In guinea pigs, intoxication with histamine (aerosol) and anaphylactic shock (horse serum)

were not influenced by pretreatment with ACTH.

*Buttle & Squires B59,985/51*: In guinea pigs exposed to histamine spray, the time required to induce convulsions is prolonged by ACTH i.p. but only during approximately an hour after the injection.

*Malkiel G71,451/51*: In guinea pigs, ACTH and cortisone are without effect on the end results of histamine shock, or of passive or active anaphylaxis.

*Jasmin & Bois C92,099/60*: Hypophysectomy partially protects the rat against the production of renal infarcts by 5-HT. ACTH does not affect this change, cortisol aggravates it, whereas DOC and testosterone offer partial protection.

*Schapiro F 31,856/65*: In newborn rats, fatal intoxication with histamine was not significantly influenced by ACTH, cortisol, cortisone or corticosterone.

**Drugs ←**

The effect of ACTH upon various intoxications has been the subject of many investigations; these could hardly be condensed more than has been done in the Abstract Section to which the reader is therefore referred. Here, we shall comment only on a few particularly interesting data and on certain observations which can be clarified by correlating them with facts not mentioned by the authors of the original articles cited.

**Anaphylactoid edema** is essentially a special type of serous inflammation, usually studied in rats because these are particularly sensitive to this change. The edema is more or less selectively localized to the acral regions (snout, paws, ears) and is ascribed to the sudden liberation of histamine and 5-HT from the mastocytes of the affected parts. It is provoked by so-called "anaphylactoidogenic agents," such as egg-white, dextran, polymyxin and other typical dischargers of histamine and 5-HT. Like most types of inflammation, this response can be prevented by ACTH and glucocorticoids but only if very large amounts are given. It is noteworthy however, that the specific toxicity of anaphylactoidogenic agents may be uninfluenced or actually aggravated by ACTH, even when the hormone suppresses inflammation itself.

Certain **anticoagulants** such as bishydroxycoumarin (Dicoumarol) and polyanethol sulfonate (Liquoid), at doses normally well tolerated by rabbits, cause death with widespread hemorrhages when given conjointly with ACTH. Curiously bishydroxycoumarin administered with glucocorticoids (cortisol, cortisone) does not elicit this syndrome.

In mice, ACTH shortens sleeping time after treatment with various **barbiturates**, including barbital, thiopental and pentobarbital. The induction time of barbital anesthesia was not changed but its depth was diminished in mice by cortisone, cortisol or ACTH. At the same time the barbital concentration of the brain was decreased by these hormones, which presumably protect against anesthesia by inhibiting

the barbital uptake of the brain. Compound "S" or DOC does not share these effects.

In the rat and in man, ACTH also shortens barbiturate sleeping time. Hexobarbital anesthesia is likewise diminished in rats by exposure to stress, presumably as a consequence of endogenous ACTH secretion.

It is highly probable that most of the barbiturates are detoxified by hepatic microsomal enzymes and some of the hormones which shorten barbital sleeping time may do so by inducing such enzymic activities. However, barbital is not significantly degraded within the body and hence, in this case the effect of ACTH is likely to be mediated through a different mechanism, perhaps a topical effect upon the cerebral barbital uptake.

In rats with tourniquet stress, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effects of stress.

In rats, the organ changes produced by certain **carcinogens** are not regularly influenced by ACTH. However, hepatoma formation by N-OH-FAA is enhanced both by ACTH and by STH.

Prostatic carcinogenesis after topical 20-methylcholanthrene crystal implantation is inhibited by ACTH as well as by several thyroid and steroid hormones.

In mice, the amyloidosis produced by repeated parenteral administration of **casein** is aggravated by ACTH or glucocorticoids and it may be combined with waxy degeneration of the cardiac muscle.

The typical **cholesterol** atherosclerosis of the rabbit is diminished by ACTH as well as by several glucocorticoids. It is not clear as yet, however, whether this effect is due to increased cholesterol degradation by hepatic microsomal-enzyme systems or to some other, possibly local, effect of glucocorticoids upon the vessels.

In rats, fatal intoxication with certain **ganglioplegics** (TEA, hexamethonium, pentolinium) has been prevented by all glucocorticoids tested (triamcinolone, cortisol, prednisolone, etc.) but not by typical catatoxic steroids (ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone) or by progesterone, DOC and hydroxydione. Various stressors (bone fractures, fasting, spinal cord transection, formalin) gave excellent protection against TEA, whereas others (restraint, cold) did not. Since even large doses of ACTH failed to protect against TEA the prophylactic effect of stress cannot be ascribed exclusively to increased production of ACTH. The protective effect of glucocorticoids is not directed against ganglioplegics as such since these steroids offer no protection against trimethaphan, mecamlamine, trimethidinium or pempidine.

Although osteolathyrism produced in rats by **lathyrogens** (AAN, PNA, or the feeding of lathyrus seeds) is readily prevented by small doses of glucocorticoids, very large amounts of ACTH are required to obtain even partial protection. The dissecting aneurysms of the aorta characteristic of angiolathyrism are likewise readily suppressed by cortisone but not by ACTH.

The toxicity of **morphine** is diminished by ACTH in various species.

In guinea pigs, ACTH (like cortisone) ameliorates the manifestations of **vitamin-C** deficiency.

In rats, the generalized calcinosis produced by various vitamin-D and DHT preparations is aggravated by ACTH (as it is by glucocorticoids) but the development of rickets on vitamin-D deficient diets is not significantly affected by ACTH. These findings should be checked under varying experimental conditions of dosage and timing, since it is known that all potent catatoxic steroids prevent acute DHT intoxication in the rat, whereas only the anabolics appear to offer protection against chronic overdosage with the same compound. Indeed, catatoxic steroids with little or no anabolic potency (e.g., PCN, spironolactone) tend to aggravate DHT intoxication and to antagonize the beneficial effect of anabolic catatoxic steroids (e.g., ethyl-estrenol) in long lasting experiments.

#### **Acetaldehyde ←**

*Lecoq et al. B66,406/51:* In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appeared to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

#### **Acrylonitrile ←**

*Szabó & Selye G79,010/71:* In rats, pretreatment with ACTH (but not with STH) prevents the production of adrenal apoplexy by acrylonitrile. Hypophysectomy protects against adrenal apoplexy, but not against mortality under similar conditions.

#### **Allylformiate ←**

*Küchmeister et al. B84,244/53:* In rats, ACTH offers some protection against the hepatic damage produced by allylformiate.

Allylformiate ← ACTH: Küchmeister et al. B84,244/53\*

#### **Aminocaproic Acid ←**

*Pataki F75,591/67:* In rabbits, combined treatment with polyanetholsulfonate (Liquoid) + EACA produces thrombohemorrhagic necrosis of the adrenal cortex. Simultaneous ACTH treatment significantly reduces the number of fibrin thrombi and the extent of adrenal necrosis but enhances the cortical hemorrhages.

#### **Aminopterin ←**

*Traina B72,887/51:* In mice, ACTH does not influence the toxic effects of aminopterin.

Aminopterin ← ACTH, Gp., Mouse: Traina B72,887/51\*

Aminopyrine ← ACTH: Kato et al. F57,817/65

**Anaphylactoid Edema ←** cf. also *Selye B40,000/50, p. 756; G46,715/68, pp. 177, 178, 183.*

*Higginbotham & Dougherty C44,529/57:* In mice, ACTH increased the toxicity of polymyxin B; STH and TTH had no effect upon it.

#### **Anticoagulants ←**

*van Cauwenberge & Jaques C58,521/58:* A dose of phenindione or bishydroxycoumarin, well tolerated by otherwise untreated rabbits, causes death with widespread hemorrhages when given together with ACTH. The hemorrhagic tendency induced by bishydroxycoumarin was not accentuated by STH, cortisone or DOC.

*van Cauwenberge & Jaques C72,748/59:* The "hemorrhagic death syndrome" produced by dicoumarol treatment in rats simultaneously exposed to various stressors can be reproduced by the administration of ACTH, STH or DOC, instead of stressors. Dicoumarol + cortisol or cortisone did not reproduce this syndrome.

*Pataki F75,591/67:* In rabbits, combined treatment with polyanetholsulfonate (Liquoid) + EACA produces thrombohemorrhagic necrosis of the adrenal cortex. Simultaneous ACTH treatment significantly reduces the number of fibrin thrombi and the extent of adrenal necrosis but enhances the cortical hemorrhages.

#### **Arsenic ←**

*Beck & Voloshin B58,271/50:* In mice, resistance to arsenite and other arsenicals is increased by cortisone, adrenocortical extracts and ACTH.

*Beck B64,609/51:* "Prior administration of beef adrenal extract increased the resistance of mice, particularly male mice, to semi-lethal

doses of arsenite, oxophenarsine and clorarsen. Male mice were protected against arsenite by cortisone and ACTH, but not by desoxycorticosterone."

### Barbiturates ←

*Hoyrup & Vinten-Johansen B 84,197/52:* In patients with acute phenobarbital or diphenylhydantoin poisoning, the use of ACTH is contraindicated as judged by impressions gained from a small series of observations.

*Winter & Flataker B 73,509/52:* Cortisone or ACTH, unlike DOC, shortens barbiturate anesthesia. The markedly prolonged sleeping time of mice receiving both barbiturates and diphenhydramine is also decreased by cortisone but the effect of the steroid can be fully accounted for by its antagonism to the barbiturate.

*de Boer & Mukomela C 5,245/55:* In rats, ACTH and cortisone shorten thiopental and pentobarbital anesthesia, especially in females whose sleeping time is normally longer than that of males.

*Komiya C 8,533/55:* In mice, barbital sleeping time is decreased by cortisone, cortisol and ACTH but not affected by compound S (11-desoxocortisone) or DOC.

*Komiya et al. C 21,326/56:* In mice, thiopental anesthesia is reduced in depth, but not in duration, by epinephrine. Barbital anesthesia was slightly reduced by norepinephrine but not by epinephrine. Unpublished experiments suggest that ACTH and glucocorticoids shorten the duration of barbital anesthesia in mice.

*Komiya & Shibata C 16,708/56:* In mice, the induction time of barbital anesthesia was not changed by cortisone, cortisol, 11-desoxycortisone or DOC. The duration of anesthesia was shortened, the depth of anesthesia diminished, and the barbital concentration of the brain decreased by cortisone, cortisol or ACTH, but none of these parameters was affected by 11-desoxycortisone or DOC. Apparently, the active hormones protect against anesthesia by decreasing the barbital concentration of the brain.

*Kubota & Bernstein C 52,401/57:* In man, ACTH ameliorates the symptoms of intoxication with various barbiturates.

*Rupe et al. E 26,910/63:* The sedative effect of hexobarbital and pentobarbital but not of barbital was diminished by tourniquet stress, in the intact but not in the hypophysectomized

or adrenalectomized rat. In intact rats, ACTH or cortisone decreases hexobarbital sleeping time as does stress, whereas SKF 525-A completely blocks the protective action of stress. Presumably "the stress effect on the duration of drug action is mediated through increased drug metabolism."

*Bousquet et al. E 39,107/64:* Morphine-pretreated rats sleep longer than controls after hexobarbital or meprobamate, but not after barbital. ACTH-pretreatment overcomes the morphine inhibition of drug metabolism (verified in vitro).

*Bousquet et al. F 35,073/65:* In rats with stress produced by applying a tourniquet around one hind limb for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection. [The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet but this is not specifically stated. Allegedly a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

Hexobarbital ← ACTH + Morphine: Rupe et al. E 26,910/63\*; Bousquet et al. E 39,107/64\*, F 35,073/65\*

Pentobarbital ← ACTH + Morphine + Stress: Driever et al. G 31,872/65\*

### Beryllium ←

*Ferris et al. B 65,475/51:* In patients with beryllium granulomatosis of the lung, ACTH was found to be beneficial.

*Kennedy et al. B 59,278/51:* In patients, ACTH exerted beneficial effects upon beryllium granulomatosis and silicosis, presumably as a consequence of its antiphlogistic effect.

*Kline et al. B 65,488/51:* In patients with beryllium granulomatosis, ACTH and cortisone were found to be beneficial.

*White et al. B 74,079/52:* In mice, ACTH had no appreciable effect on the distribution or retention of radioberyllium or on the survival rate following acute intoxication with beryllium sulfate.

Beryllium ← ACTH, Mouse: White et al. B 74,079/52\*

Bilirubin ← ACTH, Mouse: Catz et al. H 14,471/68

**Carbon Tetrachloride** ←

*Patrick C12,967/55:* In rats and mice, cortisone or ACTH inhibited the mesenchymal reaction and delayed repair following production of hepatic damage by tannic acid or  $\text{CCl}_4$ .

**Carcinogens** ←

*Robertson et al. B88,672/53:* In rats, hypophysectomy prevents the production of hepatic cirrhosis and hepatomas by 3'-Me-DAB. The susceptibility to tumorigenesis is restored by ACTH, but not by CON, DOC or testosterone. These hormones likewise failed to prevent carcinogenesis in intact rats.

*Currie et al. D48,292/62:* In rats, the production of adrenal necrosis by DMBA is prevented by metyrapone, but not significantly influenced by ACTH.

*Morii & Huggins D45,369/62:* Immature rats are refractory to the production of adrenocortical necrosis by DMBA, unless they are pretreated with ACTH. On the other hand, STH induces no DMBA sensitivity in the immature rat. "The status of susceptibility of the adrenal cortex is correlated with its content of corticosterone."

*Morii & Kuwahara G33,213/63:* Mice, guinea pigs, hamsters, rabbits, cats and dogs, unlike rats, are not susceptible to the production of adrenal apoplexy by DMBA, and pretreatment with ACTH did not make the adrenals of these species responsive.

*Hitachi F67,866/65:* In mice, ACTH inhibits the involution of the adrenal cortex produced by MC.

*Huggins & Sugiama F44,582/65:* In rats, DMBA produces no adrenocortical necrosis if the animals are immature or hypophysectomized. ACTH renders the adrenals of immature rats susceptible to this type of injury.

*Morri G34,628/65:* Pretreatment with small amounts of ACTH failed to protect the rat against DMBA-induced adrenocortical apoplexy. However, administration of ACTH to young rats or to hypophysectomized adults, which normally do not respond to the corticolytic effect of DMBA, makes them susceptible.

*Shirasu et al. F76,819/67:* In the rats, hepatoma formation by N-hydroxy-N-2-fluorenylacetamide (N-OH-FAA) is enhanced by ACTH and STH. Studies with  $^{14}\text{C}$ -labeled N-OH-FAA showed "decreased dehydroxylation and deacetylation of N-OH-FAA. The radioactivity bound to liver proteins was

increased, remarkably so in the animals treated with growth hormone."

*Ronzoni et al. H18,409/68:* In rats, prostatic carcinogenesis induced by the implantation of 20-methylcholanthrene crystals into the prostate is inhibited by ACTH, triiodothyronine and, to a lesser extent, by progesterone and 19-nortestosterone phenylpropionate. Estradiol and cortisone facilitate carcinogenesis, whereas testosterone, orchidectomy and methylthiouracil failed to influence it.

*Bird et al. H30,425/70:* In rats less than 30 days of age, DMBA or 7-OHM-12-MBA produces no adrenal necrosis unless animals are pretreated with ACTH. However, a single i.v. injection of 7-OHM-12-MBA on the 17th day of gestation causes adrenal necrosis in the embryos as well as in the mothers. Pretreatment with SKF 525-A protected the adrenals both of the embryos and of the mothers.

7,12-Dimethylbenz(a)anthracene ←  
ACTH + Age: Morii et al. D45,369/62\*

9,10-Dimethyl-1,2-benzanthracene  
← ACTH: Currie et al. D48,292/62\*

**Carcinolytics** ←

*Andreani et al. C14,628/55:* In rats, the different organ changes produced by TEM are unequally influenced by combined treatment with ACTH + cortisone.

**Casein** ← cf. also *Selye C92,918/61, p. 250.*

*Latvalahti B88,191/53:* In mice, the amyloidosis produced by repeated s.c. injections of casein is aggravated by ACTH and cortisone but not by DOC or testosterone; orchidectomy facilitates its development.

*Peräsalo & Latvalahti C9,661/54:* The amyloidosis produced by sodium caseinate s.c. in mice is uninfluenced by DOC and testosterone but aggravated by cortisone, adrenocortical extract and ACTH.

*Fanfani & Dini C48,253/57:* In mice, combined parenteral administration of casein and ACTH causes necrotic lesions and waxy degeneration in the cardiac muscle but not true amyloidosis.

**Cholesterol** ← cf. also *Selye G60,083/70, pp. 328, 329, 346.*

*Oppenheim & Brugger B74,288/52:* In rabbits, cholesterol atheromatosis is diminished by cortisone and to a lesser extent by ACTH.

*Tarantino & Natali B71,460/52:* In rabbits, ACTH inhibits cholesterol atheromatosis and diminishes the associated hypercholesterolemia.

**Cinchophen** ←

*Rodriguez-Olleros & Galindo C17,868/56:* In dogs, induction of gastric ulcers by cinchophen is not significantly affected by ACTH or cortisone.

**Diphenylhydantoin** ←

*Hoyrup & Vinten-Johansen B84,197/52:* In patients with acute phenobarbital or diphenylhydantoin poisoning, the use of ACTH is contraindicated as judged by impressions gained from a small series of observations.

**Disulfiram** ← *cf.* **Ethanol****Ethanol** ←

*Lecoq et al. B66,406/51:* In rats, the toxic effects of ethanol and of its metabolites pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

*Lecoq B79,754/51:* In rabbits, injection of disulfiram + ethanol or of Na-pyruvate produces essentially the same syndrome of intoxication, since pyruvic acid is the principal metabolite of ethanol after pretreatment with disulfiram. In either case, ACTH and cortisone offer little, if any, protective effect.

**Ethionine** ←

*Farber & Segalorr D95,996/55:* In ovariectomized rats, various testoids and STH protected the liver against fatty infiltration produced by ethionine i.p., whereas cortisone and ACTH aggravated it. Estradiol, DOC and TSH had no effect.

**Formaldehyde** ← *cf.* *Selye B40,000/50, pp. 390, 589.*

**Ganglioplegics** ←

*Brust et al. B57,917/51:* In man, "administration of ACTH or cortisone significantly alters the blood pressure and 'TEAC floor'. The responses are independent of sodium retention and indicate that the vascular effects of these drugs are mediated by a humoral mechanism which is potentiated by autonomic blockade." Observations on both normo-

tensive and hypertensive patients showed that "the usual depressor effects of TEAC were ultimately converted to a pressor rise, suggesting that autonomic blockade potentiates the vascular effects of ACTH and cortisone." DOC exhibited no such action.

*Brust et al. B58,739/51:* In man, the "TEAC floor" rises within 24 hrs after ACTH administration and falls again after discontinuation of hormone treatment. The rise in "TEAC floor" precedes the increase in urinary 17-ketosteroid excretion and precedes or parallels eosinopenia. In patients with uncomplicated essential hypertension blood pressure alterations paralleled the "TEAC floor" changes. "The 'TEAC floor' appears to be a sensitive indicator of the adrenocortical activity produced by ACTH."

*Selye G70,448/70:* In rats, intoxication with TEA, hexamethonium and pentolinium could be prevented by all of seven glucocorticoids tested. On the other hand, glucocorticoids offered no protection against trimethaphan, mecamylamine, trimethidinium or pempidine. Typical catatonic steroids (ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone) as well as progesterone, DOC and hydroxydione failed to offer significant protection against hexamethonium or TEA. Various stressors (bone fractures, fasting, spinal cord transection and formalin) gave excellent protection against TEA, whereas others (restraint, cold) did not. "Since even large doses of ACTH are ineffective in this respect the anti-TEA effect of stressors cannot be ascribed merely to increased corticoid secretion."

**Hexadimethrine** ←

*Tuchweber et al. D27,884/63:* In rats, hypophysectomy prevents the nephrocalcinosis, but aggravates the adrenal necrosis, produced by hexadimethrine. ACTH-treatment of the hypophysectomized rat facilitates the production of nephrocalcinosis, but protects the adrenal. Adrenalectomy prevents this form of nephrocalcinosis even in rats maintained on NaCl or DOC. On the other hand, triamcinolone-treated adrenalectomized rats react to hexadimethrine with strong nephrocalcinosis. Under similar conditions in intact rats, the corticoids did not significantly change the syndrome of hexadimethrine intoxication, except that the anaphylactoid reaction to this compound is inhibited by triamcinolone.

**Isoniazid** ←

*Mrozikiewicz & Strzyzewski G68,152/66; H7,524/67:* In the mouse, isoniazid-induced convulsions are facilitated not only by glucocorticoids (cortisol, prednisolone) and ACTH, but also by DOC.

**Isoproterenol** ← *cf. Selye C92,918/61, p. 117.*

**Lathyrus** ← *cf. also Selye G60,083/70, pp. 331, 357.*

*Selye C25,013/57:* The osteolathyrisms produced in rats by aminoacetonitrile (AAN) is slightly aggravated by thyroparathyroidectomy, and suppressed by large doses of thyroxine. "An amount of ACTH that more than doubles the weight of the adrenals and causes pronounced thymus atrophy also inhibits the effect of AAN, but fails to prevent it completely. This is all the more noteworthy because comparatively small doses of cortisol can totally prevent such bone lesions. Extensive partial hepatectomy greatly increases the effect of AAN upon the bones."

*Selye C31,369/57:* In the rat, the osteolathyrisms produced by AAN is aggravated by STH, LTH and partial hepatectomy but it is inhibited by ACTH, cortisol or estradiol.

*Pjörälä et al. G67,833/59:* Dissecting aneurysms of the aorta developed in 40% of immature rats fed *Lathyrus odoratus*. The media was remarkably thickened and the ground substance showed increased metachromasia and PAS reaction. This response was suppressed by cortisone and thyroxine but not by ACTH, TSH or DOC at the doses employed.

*van Cauwenberge et al. C78,726/59:* In rats, osteolathyrisms is inhibited by ACTH and, to a lesser extent, by salicylates and butazolidine.

*Glickman et al. E24,104/63:* In rats, the dental changes produced by AAN are aggravated following partial hepatectomy and thyroidectomy, reduced by ACTH and almost completely abolished by thyroxine.

**Meprobamate** ←

*Bousquet et al. F35,073/65:* In rats with stress produced by applying a tourniquet around one hind limb for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection.

[The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet but this is not specifically stated. Allegedly a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

**Mercury** ←

*Kádas & Zsámbecky C26,265/56; C49,522/57:* The renal damage produced by HgCl<sub>2</sub> in the rat is most effectively prevented by testosterone, but, to a lesser extent, also by cortisone, particularly when the latter is given in combination with ACTH.

**Morphine** ←

*Winter & Flataker B62,935/51:* In rats, cortisone inhibits the effects of methadone and morphine upon the thermal tail-flick response. Cortisone also increases the excitatory effect of morphine in cats. On the other hand, cortisone synergizes the analgesic antagonist N-allylnormorphine. After spinal cord section, cortisone and ACTH reduce the effect of morphine on the spinal reflex activity in rats (thermal tail-flick response), whereas DOC enhances it.

*Adler et al. G79,852/57:* In Sprague-Dawley rats given <sup>14</sup>C-labeled morphine, the ratio of bound to free morphine is 2–3 times greater in the urine and plasma than in Long-Evans rats. The tissues of adrenalectomized rats of both strains contain higher concentrations of <sup>14</sup>C-labeled morphine than do control rats. Plasma bound morphine levels indicate no impairment of morphine conjugation. Vasopressin increases, whereas ACTH decreases morphine sensitivity. Yet both after ACTH and after vasopressin, tissue concentrations of morphine are either reduced or unaffected in marked contrast to the increased values after adrenalectomy. Apparently, the decreased morphine sensitivity induced by ACTH is not reflected by lower brain morphine concentrations.

*Sobel et al. C90,836/60:* Morphine increases the mortality of guinea pigs exposed to reduced oxygen tension. Prior treatment with cortisone or ACTH protects against this combined treatment.

*Markova D47,081/62:* Pretreatment with ACTH or cortisone increases the morphine resistance of newborn rats although not quite to the adult level. DOC does not share this effect.

*Paroli G12,543/63*: In the rat, cortisol and ACTH inhibit the analgesic effect of morphine; dexamethasone and prednisolone (though more active glucocorticoids) do not share this effect.

*Lecannelier & Quevedo H8,759/67*: In rabbits, the analgesic effect of morphine is reduced by ACTH or cortisol.

**Mustard Powder** ← *cf. Selye B40,000/50, p. 390.*

#### **Pentylentetrazol** ←

*Torda & Wolff B57,149/51*: In rats, the convulsions and EEG changes produced by pentylentetrazol are inhibited by ACTH or cortisone.

*Torda & Wolff B69,986/52*: In rats, the convulsion-threshold of pentylentetrazol is raised by ACTH even after hypophysectomy or adrenalectomy. Furthermore, ACTH increases the electric activity of the brain "by a mechanism that is not dependent on the presence of the adrenal cortex."

*Boeri C78,610/58*: In guinea pigs, cortisone, ACTH and vasopressin aggravate pentylentetrazol convulsions.

Pentylentetrazol ← ACTH: *Torda et al. B69,986/52\**

#### **Phenyldione** ← *cf. Anticoagulants*

**Plasmocid** ← *cf. Selye C92,918/61, p. 95.*

#### **Polyanetholsulfonate** ← *cf. Anticoagulants*

##### **Potassium** ←

*Collins C17,662/56*: Survival after KCl i.p. (referred to as "potassium stress") is diminished after the induction of adrenocortical atrophy by cortisol. Concurrent administration of DOC, aldosterone, adrenocortical extract, corticosterone or ACTH counteracts this effect of cortisol upon K tolerance.

#### **Puromycin Aminonucleoside** ←

*Wilson et al. C45,755/57*: In rats, puromycin aminonucleoside nephrosis is not prevented by cortisone or ACTH.

##### **Pyruvate** ←

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are

inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

*Lecoq B79,754/51*: In rabbits, injection of disulfiram + ethanol or of Na-pyruvate produces essentially the same syndrome of intoxication, since pyruvic acid is the principal metabolite of ethanol after pretreatment with disulfiram. In either case, ACTH and cortisone offer little, if any, protective effect.

#### **RES-Blocking Agents** ←

*Selye B39,702/49*: In rats in which an arthritis was produced by intrapedal injection of formalin and India ink, phagocytosis and transport of the carbon particles to the regional lymph nodes are accelerated by ACTH. This is ascribed to glucocorticoid formation and the resulting diminution of the inflammatory barrier at the formalin injection site.

*Kennedy et al. B59,278/51*: In patients, ACTH exerted beneficial effects upon beryllium granulomatosis and silicosis, presumably as a consequence of its antiphlogistic effect.

*Michalová C56,094/58*: In rabbits exposed to quartz dust, ACTH diminished the severity of silicosis, but this effect was not manifest in chronic experiments.

*Gabbiani et al. G19,450/65*: In rats pretreated with ACTH, fluorocortisol or restraint, a single i.v. injection of thorium dextrin (an RES-blocking agent) produces thrombohemorrhagic lesions with necrosis in the adrenals, liver and kidneys. The changes are reminiscent of the Schwartzman-Sanarelli phenomenon.

*Göthe H20,085/70*: In rats, ACTH accelerates, whereas prednisolone retards, the transport of intratracheally administered quartz dust from the lung to the regional lymphatics.

#### **Silica** ← *cf. RES-Blocking Agents*

##### **Tannic Acid** ←

*Patrick C12,967/55*: In rats and mice, cortisone or ACTH inhibited the mesenchymal reaction and delayed repair following production of hepatic damage by tannic acid or CCl<sub>4</sub>.

##### **Tetracaine** ←

*Zykov H21,879/69*: In mice, ACTH, cortisol and DOC failed to influence tetracaine intoxication.

**Tetraethylammonium (TEA) ← cf. Ganglionic-Blocking Agents****Thorium Dextrin ← cf. RES-Blocking Agents****Vitamin C ←**

*Hyman et al. B53,374/50:* "Cortisone and ACTH prolong life and reduce the hemorrhagic manifestations of scurvy in guinea pigs." [In an addendum the authors state that the large doses of ACTH and cortisone used may produce severe toxic effects which overshadow their beneficial actions (H.S.).]

*Hyman et al. B57,989/51:* In guinea pigs on a vitamin-C deficient diet, ACTH and cortisone ameliorate the manifestations of scurvy.

**Vitamin D, DHT ← cf. also Selye G60,083/70, pp. 329, 331.**

*Selye C27,735/57:* The cardiovascular calcification and nephrocalcinosis produced by DHT in rats are aggravated by estradiol, cortisol, ACTH and thyroxine. Conversely, methyltestosterone and STH exert a protective effect.

*Thoenes & Schröter C56,987/58:* In rats kept on a vitamin-D deficient diet, cortisone tends to inhibit the development of rickets, whereas ACTH does not. DOC actually aggravates vitamin-D deficiency.

*Campeanu et al. G21,413/63:* In rats, combined treatment with vitamin-D<sub>2</sub> and ACTH produces intense generalized calcinosis. [No mention of controls receiving vitamin-D<sub>2</sub> alone (H.S.).]

**Zoxazolamine ←**

*Bousquet et al. F35,073/65:* In rats with stress produced by applying a tourniquet around one hind limb for 2.5 hrs, the toxicity of hexobarbital, pentobarbital, meprobamate and zoxazolamine was significantly diminished, whereas that of barbital and phenobarbital remained unaffected. Pretreatment with ACTH or corticosterone simulated the effect of stress. After hypophysectomy or adrenalectomy, stress failed to offer the usual protection. [The barbiturates and zoxazolamine appear to have been administered immediately after release of the tourniquet but this is not specifically stated. Allegedly a single injection of corticosterone (50 µg per animal) sufficed to offer protection (H.S.).]

*Selye G70,480/71:* In rats, ACTH inhibited zoxazolamine paralysis and acute DHT-induced soft-tissue calcification but failed to influence poisoning with digitoxin, dioxathion, parathion, nicotine, hexobarbital, progesterone, indomethacin or the infarctoid cardiopathy produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

**Complex Diets ←**

ACTH and glucocorticoids inhibit the fatal hepatic necroses which develop in young rats fed diets deficient in sulfur-containing amino acids and vitamin E, as well as in rats kept on diets containing yeast as the only source of protein.

*Aterman C35,275/57:* The fatal hepatic necrosis which develops in weanling rats fed a diet deficient in sulfur-containing amino acids and vitamin E is inhibited by ACTH and cortisone, but aggravated by thyroid powder feeding. In the case of simultaneous treatment with thyroid and cortisone, the two types of hormones antagonize each other.

*Aterman C61,786/58:* The hepatic necrosis produced in rats by feeding a diet containing yeast as the only source of protein is inhibited by cortisone, cortisol or ACTH, but not influenced by progesterone, "estrogen," testosterone or DOC. Aldosterone prolongs survival time providing 50 µg or more is administered

daily. Although the author did not report any observations on the effect of aldosterone upon carbohydrate metabolism, he arrived at the conclusion that "these results, therefore, suggest that in the system examined here aldosterone has some 'glucocorticoid' activity and differs significantly from deoxycortone acetate which in doses of 0.5 and 2.5 mgm. daily has been completely ineffective."

*Borgman & Haselden H29,947/70:* In rabbits kept on a gallstone producing ration, ACTH, thyroid hormones, or cortisone did not inhibit the production of biliary calculi, but several of these hormones inhibited the usually associated hepatic steatosis.

***Microorganisms, Parasites and Their Products ←***

**Bacteria and Vaccines ←.** ACTH does not significantly influence the course of infection with *Clostridium tetani* in the mouse or with *Corynebacterium diphtheriae* and leptospirosis in the guinea pig.

Infection with *M. tuberculosis* is aggravated by ACTH in the mouse, guinea pig, rat and rabbit despite a few dissenting claims. In this respect, ACTH imitates the effects of glucocorticoids and, like the latter, it is antagonized by concurrent treatment with STH.

In rats infected with *P. pestis*, ACTH also decreased, whereas STH increased, survival.

**Pneumococcal and Rickettsial infections** are not very manifestly affected by ACTH in the mouse.

“**Saprophytosis**,” due to proliferation of normally nonpathogenic microorganisms (usually *Corynebacteria*), such as occurs after severe glucocorticoid intoxication, is also induced in rats by heavy overdosage with ACTH. It can be prevented by concurrent treatment with STH.

In guinea pigs and rats, ACTH could not be shown to exert a significant influence upon infection with staphylococci, although cortisone decreased resistance to these organisms.

The effect of ACTH on streptococcal infections varies greatly depending upon experimental conditions.

**Viruses ←.** ACTH undoubtedly exerts an antipyretic effect in rabbits inoculated with influenza virus as it does in various other forms of infection. In mice and ferrets, ACTH does not significantly influence resistance to influenza. On the other hand, large doses of ACTH increase the susceptibility of mice to lethal infection with various arboviruses. Infection with poliomyelitis is likewise facilitated by ACTH in mice and hamsters, although with some strains of poliomyelitis no definite increase in susceptibility could be obtained by ACTH. In the dog, the growth of equine encephalomyelitis is enhanced by ACTH. This hormone also facilitates the spread of variola virus in sheep and it can reactivate a latent rabies infection in guinea pigs.

**Parasites ←.** In guinea pigs, ACTH did not significantly influence the course of infestation with *Trichinella spiralis*.

**Bacterial Toxins ←** *cf. also Selye E 5,986/66.* In rabbits, pretreatment during 48 hrs with large doses of ACTH or cortisone diminishes the febrile response to *Shigella* endotoxin, whereas 24 hrs of pretreatment with smaller doses of these hormones exerts an opposite effect.

In the mouse, neither ACTH nor cortisone pretreatment raised resistance against the toxins of *R. tsutsugamushi*, *R. prowazeki* or *S. typhosa*. However, under suitable conditions of dosage and timing, mice can allegedly be protected by ACTH or cortisone against fatal intoxication with cholera-vibrio endotoxin, diphtheria toxin and various other endotoxins. The effects of tetanus, Shiga, and meningococcus toxin are not influenced by ACTH in the mouse.

In guinea pigs, neither ACTH nor cortisol improved resistance to diphtheria toxin, but the production of hemorrhages and adrenal necroses by pertussis toxin was enhanced by ACTH.

Rats allegedly cannot be protected against the lethal effects of perfringens toxin by ACTH or glucocorticoids, but the resistance to many endotoxins is undoubtedly increased by these hormones. The hepatic vein thromboses produced in rats on hyperlipemic diets by *S. typhosa* endotoxin are prevented by ACTH, cortisol or prednisolone.

In dogs, ACTH gave no significant protection against endotoxin shock.

In man, the febrile response to killed typhoid bacilli and the reactions to *Brucella* endotoxin are inhibited by ACTH.

Venoms ←. ACTH has been found to protect various species against fatal doses of the venoms of scorpions, snakes and spiders.

### **Bacteria and Vaccines ←**

**Clostridium Tetani** ←. *Massalski & Kulejewska C52,338/57*: In mice, ACTH does not influence experimental tetanus, nor does it alter the actions of tetanus toxin and anti-toxin.

**Corynebacterium Diphtheriae** ←. *di Nola et al. C43,232/57*: In guinea pigs, ACTH offered no protection against fatal diphtheria infection.

**Leptospira** ←. *Derom & van Hoydonck C17,095/55*: "ACTH and cortisone have not been found to have any favorable effects on the infection of guinea pigs with *Leptospira ictero-haemorrhagiae*, strain 'Afsnee'."

**Bacillus Piliformis (Tyzzer's disease)** ←. *Yamada et al. H24,079/69*: In mice and rats inoculated with *B. piliformis*, pretreatment with ACTH or cortisone greatly enhances susceptibility to Tyzzer's disease.

**Diplococcus Pneumoniae** ←. *Kass et al. B69,981/51*: In mice, the final mortality rate after infection with influenza virus or pneumococci is not significantly altered by ACTH or cortisone, although the course of the disease may be modified.

*Kass et al. B95,353/54*: In mice, resistance to pneumococcal and influenza virus infections is depressed by pretreatment with cortisone or cortisol, but not by ACTH. STH failed to overcome the effect of cortisone and did not increase resistance to infection when given alone.

**Mycobacterium Tuberculosis** ←. *Reinmuth & Smith B60,585/51*: In rabbits sensitized by tuberculosis bacilli and subsequently challenged with Old Tuberculin introduced into the trachea, the resulting pneumonia is decreased in severity by pretreatment with ACTH.

*Swedberg et al. B58,412/51*: In mice, ACTH aggravates the course of experimental tuberculosis.

*Lucherini et al. B89,088/53*: In guinea pigs, STH inhibits the progress of tuberculosis and counteracts the opposite effect of ACTH.

*Cavallero C829/54*: Review on the effect of STH, ACTH and cortisone upon various infections, especially in the rat.

*Lepri & Fornaro D91,865/54*: In rabbits rendered allergic to tuberculosis, the ocular manifestations of topical challenge by tubercle bacilli were variably influenced by ACTH and cortisone.

*Youmans & Youmans B95,169/54*: In mice, cortisone markedly reduced the survival time after infection with human tubercle bacilli and this effect could not be prevented by STH. Given alone, ACTH, STH and TTH likewise failed to influence the course of the infection.

*Donomae et al. C22,935/55*: In rabbits infected with human tuberculosis bacilli and reinoculated with the same germs into the lung, ACTH greatly enhances cavity formation.

*Greuel & Schäfer E54,859/56*: In guinea pigs treated with ACTH, DOC or cortisone, the progress of tuberculosis was proportional to the size of the adrenals, and least severe in animals given cortisol.

*Shmelev & Uvarova C53,553/56*: Contrary to earlier investigators, the authors found that in guinea pigs and rabbits, ACTH actually increases resistance to tuberculosis.

*Wasz-Höckert & Backman C30,700/56*: In guinea pigs, the progress of tuberculosis can greatly be enhanced by ACTH, which is useful for the diagnosis of tuberculosis.

*Wasz-Höckert & Backman C34,801/56*: In guinea pigs, ACTH aggravates the course of tuberculosis. STH in itself is without conspicuous effect, however, "the strongly deterio-

rating effect on tuberculosis produced by ACTH was evidently counteracted by STH when given simultaneously with ACTH."

*Batten & McCune C53,554/57*: ACTH, cortisol and cortisone greatly reduce the resistance of mice to infection with human tuberculosis.

*Fiorentino D8,379/59*: In guinea pigs, ACTH greatly accelerates the progress of tuberculosis. A test for the rapid diagnosis of tuberculosis is based upon this observation.

*Renovanz C78,772/59*: In guinea pigs, the course of experimental tuberculosis was not markedly influenced by ACTH, tolbutamide derivatives or antithyroid treatment with perchlorates.

*Vakilzadeh & Vandiviere E32,626/63*: In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T<sub>3</sub>, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

*Wasz-Höckert & McCune E31,145/63*: In mice infected with tuberculosis, STH caused an increase in body weight but did not inhibit the development of the infection nor did it counteract the unfavorable effect of ACTH.

*Kampioni G33,098/64*: In tuberculous guinea pigs, ACTH inhibits the proliferation of the pleural stroma but not the thickening of the mesothelial cells.

**Pasteurella Pestis** ←. *Hayashida C37,366/57*: In rats infected with *P. pestis*, ACTH decreased, whereas STH increased, survival.

**Rickettsia** ←. *Jackson & Smadel E52,720/51*: Intact mice pretreated with cortisone or ACTH "were given lethal amounts of the toxins of *R. tsutsugamushi*, *R. prowazeki*, or *S. typhosa*. Such animals were as susceptible to the toxins as normal controls. Neither hormone had any therapeutic effect in mice infected with *R. tsutsugamushi*. Furthermore, treated and untreated mice in a terminal phase of infection with *R. tsutsugamushi* were equally susceptible to the toxin of this rickettsia when injected intravenously. In the current experiments the adrenal cortex of normal or infected animals apparently contributed as effectively as possible in the host's response to rickettsial or bacterial toxins and further stimulation was without advantage."

**"Saprophytosis"** ←. *Selye B57,451/51*: In rats, "saprophytosis" due to proliferation of normally nonpathogenic microorganisms, such as develop after heavy overdosage with

cortisone or ACTH, can be completely prevented by concurrent administration of STH.

**Staphylococcus** ←. *Debry C30,870/56*: Doctor's thesis (176 pp., 578 refs.) on the influence of hormones upon infection. Personal observations on guinea pigs and rats indicate that ACTH, STH and DOC do not significantly affect the course of acute staphylococcus infection, whereas cortisone aggravates it.

**Streptococcus** ←. *Glaser et al. B58,299/50*: In mice, neither ACTH nor cortisone exerted a beneficial effect upon streptococcal or pneumococcal infections, indeed they may have aggravated them.

*Mogabgab & Thomas B72,457/52*: In rabbits, pretreatment with ACTH or cortisone greatly aggravated streptococcal septicemia. DOC had no such effect.

*Fazio et al. C34,111/56*: In rats, cortisone or ACTH increases survival following streptococcal infection and further enhances the protective effect of penicillin.

#### Viruses ←

*Kass & Finland B54,130/50*: In man, the febrile response to i.v. injection of killed typhoid bacilli is reduced by ACTH. A similar antipyretic effect against typhoid bacilli and influenza virus is exerted by ACTH in rabbits.

*Loosli et al. B58,316/50*: In mice and ferrets, ACTH did not significantly influence air-borne influenza-A infection.

*Shwartzman B54,248/50*: "ACTH and cortisone in combination or cortisone alone produce a marked acceleration of poliomyelitis infection (strain MEF1) in mice and an extraordinary enhancement of susceptibility to this infection in hamsters giving rise to a violent and uniformly fatal disease. ACTH alone fails to produce this effect possibly due to elaboration of an unknown factor capable of reversing the enhancing effect of cortisone."

*Kass et al. B69,981/51*: In mice, the final mortality rate after infection with influenza virus or pneumococci is not significantly altered by ACTH or cortisone, although the course of the disease may be modified.

*Shwartzman B66,955/51*: ACTH and cortisone accelerate poliomyelitis (strain MEF) in mice and hamsters. DOC, progesterone and diethylstilbestrol are ineffective.

*Smith et al. B64,635/51*: In mice, susceptibility to pneumonia virus (PVM) is not influenced by ACTH but is enhanced by cortisone.

*Southam & Babcock B63,662/51*: "Large doses of cortisone greatly increased the susceptibility of mice to lethal infection by West Nile, Ilheus, and Bunyamwera viruses. ACTH in massive dosage produced the same effect with West Nile virus. Desoxycorticosterone, testosterone, progesterone, and estradiol in massive doses had no significant effect on these virus infections in mice."

*Findlay & Howard B81,142/52*: In mice and hamsters, cortisone and ACTH increase susceptibility to poliomyelitis and other virus infections.

*Shwartzman B69,778/52*: Cortisone, unlike ACTH, greatly increases the susceptibility of Syrian hamsters to i.p. inoculation with strain MEFl poliomyelitis virus.

*Shwartzman & Fisher B69,580/52*: In Syrian hamsters, cortisone enhances infection with MEFl and Lansing strains of poliomyelitis virus. ACTH, DOC, progesterone and stilbestrol are without effect. Earlier literature on the influence of various hormones upon poliomyelitis is reviewed.

*Kass et al. B95,353/54*: In mice, resistance to pneumococcal and influenza virus infections is depressed by pretreatment with cortisone or cortisol, but not by ACTH. STH failed to overcome the effect of cortisone and did not increase resistance to infection when given alone.

*Hurst et al. C94,089/60*: Cortisone, ACTH, estradiol, stilbestrol and thyroxine all stimulate the growth of the virus of equine encephalomyelitis in the dog, whereas testosterone and progesterone do not. The hormones which aggravate the infection also counteract the prophylactic effect of mepacrine and abolish the normally greater resistance of the females.

*Cilli et al. D12,192/61*: In sheep, STH, owing to its prophlogistic effect, delimits the lesions produced by variola virus. ACTH and dexamethasone exert an opposite effect.

*Soave D22,275/62*: In guinea pigs, latent rabies virus infection can be reactivated by ACTH s.c.

#### Parasites ←

*Luongo et al. B69,505/51*: In guinea pigs, ACTH did not significantly influence the course of infestation with *T. spiralis* but appeared to reduce the associated toxic effects.

*Sheldon & Bauer D46,962/62*: Review on the role of predisposing factors, particularly alloxan diabetes and ACTH-treatment, upon various fungus infections.

#### Bacterial Toxins ←

##### RABBIT

*Duffy & Morgan B65,399/51*: In rabbits the febrile response to *Shigella dysenteriae* endotoxin is diminished following pretreatment during 48 hrs with repeated large doses of ACTH or cortisone. Pretreatment during 24 hrs with smaller doses of these hormones exerts an opposite effect. "This appears to account for the discrepancies in the results previously reported."

*Bennett Jr. & Beeson B95,351/53*: In rabbits, the febrile response to a single injection of various endotoxins may be decreased, increased or unchanged by treatment with ACTH or cortisone. Acquired resistance to pyrogen fever is abolished by Thorotrast but not by cortisone although both these agents prevent the Shwartzman reaction.

##### MOUSE

*Jackson & Smadel E52,720/51; B77,408/51*: Intact mice pretreated with cortisone or ACTH "were given lethal amounts of the toxins of *Rickettsiae tsutsugamushi*, *R. prowazeki*, or *S. typhosa*. Such animals were as susceptible to the toxins as normal controls. Neither hormone had any therapeutic effect in mice infected with *R. tsutsugamushi*. Furthermore, treated and untreated mice in a terminal phase of infection with *R. tsutsugamushi* were equally susceptible to the toxin of this rickettsia when injected intravenously. In the current experiments the adrenal cortex of normal or infected animals apparently contributed as effectively as possible in the host's response to rickettsial or bacterial toxins and further stimulation was without advantage."

*Gallut C14,519/55*: Mice can be protected against fatal intoxication with cholera *Vibrio* endotoxin by cortisone or ACTH but the degree of protection depends upon dosage and timing.

*Massalski & Kulejewska C52,338/57*: In mice, ACTH does not influence experimental tetanus, nor does it alter the actions of tetanus toxin and antitoxin.

*Nadel et al. D12,681/61*: In mice, pretreatment with ACTH offers no protection against endotoxin. Hence, the resistance induced by pretreatment with endotoxin itself cannot be due to mobilization of the pituitary-adrenal axis.

*Parant D82,116/62*: In mice, resistance to endotoxin is greatly decreased a few hours after adrenalectomy or hypophysectomy. Cortisone protects normal, adrenalectomized,

and hypophysectomized animals against high doses of endotoxin, whereas chlorpromazine is effective only in the presence of both the adrenals and the pituitary. ACTH also protects the hypophysectomized mouse but only if slow absorption is assured.

*Skuratova D20,887/62*: In mice, resistance against the fatal effect of diphtheria toxin is more markedly increased by STH than by ACTH.

#### GUINEA PIG

*Murray & Branham B65,414/51*: Neither ACTH nor cortisone improved the resistance of guinea pigs to diphtheria toxin or of mice to Shiga and meningococcus toxin.

*Okonogi et al. C34,465/56*: In guinea pigs the production by pertussis toxin of subcutaneous hemorrhages, pulmonary lesions and adrenal necrosis is enhanced by ACTH.

#### RAT

*Ganley et al. C7,489/55*: Rats cannot be protected against the lethal effect of *Cl. perfringens* toxin by ACTH, adrenocortical extract, cortisol, cortisone or DOC.

*Levitin et al. C26,683/56*: Cortisol, corticosterone, and cortisone, as well as ACTH protect the rat against endotoxin, whereas DOC does not.

*Renaud et al. F74,449/66*: In rats kept on a hyperlipemic diet, ACTH, cortisol or prednisolone protected against the production of shock and hepatic vein thromboses by *S. typhosa* lipopolysaccharide. DOC increased

mortality and did not protect against these thromboses.

#### DOG

*Evangelista et al. H16,824/69*: Neither ACTH nor stanozolol gave any significant protection against endotoxin shock in dogs.

#### MAN

*Kass & Finland B54,130/50*: In man, the febrile response to i.v. injection of killed typhoid bacilli is reduced by ACTH. A similar antipyretic effect against typhoid bacilli and influenza virus is exerted by ACTH in rabbits.

*Abernathy & Spink C48,635/58*: In man, cortisol or ACTH suppressed or ameliorated reactions to brucella endotoxin.

#### Venoms ←

*Mohammed et al. C7,579/54*: Rats can be protected against fatal doses of scorpion toxin by pretreatment with cortisone or ACTH.

*Schöttler C10,890/54*: In mice and guinea pigs injected with the venom of *Bothrops jararaca* or *Crotalus terrificus* s.c., ACTH, cortisone and cortisol failed to offer protection.

*Bettini & Cantore C21,801/55*: Comparative studies on the protective effect of ACTH, cortisone and chlorpromazine against lethal poisoning with the venom of the spider *Latrodectus tredecimguttatus*.

*Haas G38,758/66*: Extensive review on the use of corticoids and ACTH in the treatment of snake bites in man and in animals.

#### Immune Reactions ←

The immunosuppressive effects of ACTH have been discussed in our previous monographs to which the reader is referred for a more detailed account.

In guinea pigs, ACTH does not strikingly influence anaphylactic shock under usual conditions, yet it may inhibit it if given during 3 days before the challenging reinjection. However, ACTH does clearly diminish tuberculine hypersensitivity although only on diets containing the "cabbage factor" (presumed to be an SH-compound).

The beneficial effect of vaccination against tuberculosis is not significantly altered by ACTH or cortisone in the guinea pig.

In rabbits sensitized to tuberculosis, ACTH tends to, but does not regularly, inhibit the manifestations of subsequent topical challenge.

In rats, ACTH decreases, whereas STH increases, antibody formation against *Pasteurella pestis*. The hemolytic icterus produced by appropriate agglutinin treatment, and the renal damage caused by nephrotoxic serum, can also be inhibited by ACTH.

**Hepatic and Renal Lesions** ←

Tolerance to temporary hepatic vessel ligation is increased by ACTH in the dog. In rats, ACTH (like corticoids) enhances repair and fat deposition in the liver remnant after partial hepatectomy. Various stressors inhibit hepatic regeneration under similar conditions, presumably because the stimulating effect of ACTH and corticoids is overcompensated by the stress itself.

The arterial lesions that develop after bilateral nephrectomy in dogs kept on a high-fat diet are prevented by ACTH and cortisone, but also by pregnancy or diethylstilbestrol.

**Immune Reactions** ← *cf. Selye G60,083/70, pp. 328, 329, 347.*

## GUINEA PIG

*Leger et al. A48,766/48:* In sensitized guinea pigs, ACTH, given prior to a shock dose of antigen, failed to influence the course of anaphylactic shock.

*Dworetzky et al. B52,246/50:* In guinea pigs, anaphylactic shock was not significantly influenced by cortisone or ACTH.

*Friedlaender & Friedlaender B55,467/50:* In guinea pigs, intoxication with histamine (aerosol) and anaphylactic shock (horse serum) were not influenced by pretreatment with ACTH.

*Long & Miles D41,973/50:* In guinea pigs, moderate thyrotoxicosis produced by two week's treatment with thyroxine increases hypersensitivity to tuberculin, whereas moderate doses of propylthiouracil do not affect it. ACTH and cortisone diminished tuberculin sensitivity. Fourteen days after stopping thyroxine injections, the animals became actually less hypersensitive than the controls. A similar reversal of this effect was noted two weeks after interruption of cortisone or ACTH treatment in that the animals became more hypersensitive than the controls.

*Malkiel G71,451/51:* In guinea pigs, ACTH and cortisone are without effect on the end results of histamine shock, or of passive or active anaphylaxis.

*Long et al. D85,907/51:* In guinea pigs, single injections of cortisone or ACTH diminish allergic hypersensitivity on a cabbage diet, but not on a basal diet deficient in the "cabbage factor." The authors conclude "that there is in cabbage a factor which on ingestion leads to the inhibition of the desensitization produced by the metabolism of ascorbic acid in the tissues of the allergic guinea pig; and that the desensitizing action of cortisone or of ACTH

in cabbage-fed animals is indirect, depending on the reversal of the cabbage effect by the hormones. The cabbage factor may possibly be an SH-compound."

*Long et al. B60,189/51:* In B.C.G.-infected guinea pigs, hypersensitivity to tuberculin is considerably diminished by cortisone or ACTH. This diminution is abolished by pretreatment with propylthiouracil, which alone has no effect upon hypersensitivity. Pretreatment with thyroxine increases tuberculin hypersensitivity but does not block desensitization by ACTH or cortisone. Apparently, thyroxine is necessary for the desensitizing action of ACTH and cortisone.

*Long et al. B63,843/51:* In guinea pigs, dihydro-ascorbic acid—unlike ascorbic acid—inhibits the tuberculin reaction after infection with B.C.G. vaccine. The desensitizing effect of dihydro-ascorbic acid is not inhibited by thiouracil. Alloxan, like ACTH or cortisone, does not modify desensitization by ascorbic acid on diets deprived of the "cabbage factor;" it desensitizes guinea pigs on a cabbage diet and this desensitization is inhibited by propylthiouracil.

*Hoene et al. B68,152/52:* In guinea pigs, ACTH given during three days before the challenging reinjection inhibits anaphylactic shock.

*Vakilzadeh & Vandiviere E32,626/63:* In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T<sub>3</sub>, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

## RABBIT

*Reinmuth & Smith B60,585/51:* In rabbits sensitized by M. tuberculosis and subsequently challenged with Old Tuberculin introduced into the trachea, the resulting pneumonia is

decreased in severity by pretreatment with ACTH.

*Lepri & Fornaro D91,865/54*: In rabbits rendered allergic to tuberculosis, the ocular manifestations of topical challenge by tubercle bacilli were variably influenced by ACTH and cortisone.

#### RAT

*Hayashida & Li C29,987/57*: In rats, ACTH decreases, whereas STH increases, the formation of antibodies against a soluble protein envelope antigen extracted from *P. pestis*.

*Vivan & Brailo D22,638/62*: In rats, the hemolytic icterus produced by appropriate agglutinin treatment can be prevented by concurrent administration of ACTH and glucuronic acid.

*Wakim et al. D39,883/63*: In rats and dogs, the renal damage produced by nephrotoxic serum can be inhibited by ACTH.

### Hepatic and Renal Lesions ←

**Hepatic Lesions** ←. *Arrigo & Pontremoli B54,373/50*: In rats, ACTH greatly accelerates liver regeneration after partial hepatectomy but does not significantly increase hepatic steatosis.

*Raffucci B83,148/53*: Dogs tolerate much better repeated temporary rather than continuous occlusion of the hepatic artery and portal vein. ACTH in combination with antibiotics greatly enhances tolerance for noncontinued-occlusion of the afferent hepatic vessels.

*Roberts B97,023/53*: In rats, the enhanced repair of the liver following treatment with ACTH or adrenocortical extract is characterized mainly by increased protein deposition in the liver remnant. The usual decline of serum proteins occurring after partial hepatectomy was completely prevented by this treatment.

*Hines & Roncoroni C40,870/57*: In dogs, the hepatic damage produced by ligation of

all the afferent vessels of the liver during one hour is diminished by ACTH, and survival is improved.

*Šimek et al. G71,089/68*: In intact and even more markedly in adrenalectomized rats, the hepatic accumulation of free fatty acids is increased by cortisol during the early period after partial hepatectomy. ACTH has the same effect but only in the presence of the adrenals.

*Šimek et al. H13,837/68*: Comparative studies on DNA synthesis, fatty acid content, and weight regeneration in the liver remnant of partially hepatectomized rats after treatment with cortisol, ACTH and various stressor agents.

*Šimek et al. H22,183/68*: In rats, the initial increase in liver triglyceride content induced by partial hepatectomy is decreased after adrenalectomy. However, within 24 hrs after the operation, this difference disappears. The effect of adrenalectomy upon the liver triglyceride changes induced by partial hepatectomy can be annulled by epinephrine or cortisone. ACTH augments the immediate rise in liver triglyceride but only in the presence of the adrenals.

*Bucher et al. G72,546/69*: Review of the humoral factors responsible for hepatic regeneration following partial hepatectomy. Hepatic DNA synthesis is stimulated in intact rats by parabiosis or cross-circulation with partially hepatectomized partners. Furthermore, tiny liver grafts implanted outside the portal area proliferate in response to partial ablation of the parent organ. Various stressors inhibit hepatic regeneration in partially hepatectomized rats, but this effect is not reproduced by ACTH or cortisol. On the other hand, adrenalectomy increases hepatic regeneration.

**Renal Lesions** ←. *Holman & Jones B93,771/53*: The arterial lesions that develop in dogs kept on a standard high-fat diet upon subsequent nephrectomy are prevented by pregnancy, cortisone, ACTH or diethylstilbestrol.

### Varia ←

**Ionizing Rays** ←. Resistance to total body X-irradiation is not significantly influenced by ACTH in the mouse, rat or man, although some investigators claim to have obtained moderate protection by ACTH at least in rats.

**Hypoxia and Hyperoxygenation** ←. In mice and man, resistance to hypoxia is increased by ACTH, whereas in guinea pigs, allegedly tolerance to both hypoxia and hyperoxygenation is diminished by this hormone. It has been claimed, however,

that in guinea pigs, whose resistance to hypoxia is increased by morphine, prior treatment with ACTH or cortisone protects against this combined treatment.

**Temperature Variations** ←. According to some investigators, the survival time of severely burned rats is not influenced by ACTH; others claim that the hormone prolongs survival. Cold tolerance is allegedly increased by prolonged ACTH pretreatment in this species.

In mice, ACTH does not protect against the fatal effects of burns, but allegedly pretreatment with ACTH increases resistance to cold.

**Other Stressors** ←. In rats, ACTH (like STH) and glucocorticoids decrease the EST.

ACTH allegedly aggravates the calcifying arteriosclerosis that tends to develop in rats exposed to the stress of repeated breeding.

An improvement in muscular performance (swimming) could be induced in rats by ACTH, but only at a critical temperature.

The resistance to trauma (Noble-Collip drum, tourniquet shock) is moderately enhanced by ACTH pretreatment in the rat.

In trout, salinity tolerance is not affected by ACTH, although it can be significantly altered by several other hormones.

#### **Ionizing Rays** ←

*Smith et al. B47,642/50:* In mice, neither ACTH nor cortisone increased survival following X-irradiation.

*Rigat C 10,747/55:* Review (46 pp., 67 refs.) of the literature concerning the effect of hormones upon X-irradiation, with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

*Taber C 10,417/55:* In man, ACTH increases resistance to radiation sickness.

*Kedrova & Krekhova G71,665/59:* In rats, ACTH offers some protection against lethal X-irradiation. Although cysteine has a similar effect by itself, it actually blocks the protective effect of ACTH.

*Kandror E27,416/63:* Review of the literature on the effect of corticoids and ACTH upon total body X-irradiation, especially in connection with the physiopathology of stress.

*Orlova et al. G22,562/63:* In rats, long-acting ACTH preparations offer protection against total body X-irradiation.

*Trinci G45,713/66:* In rats, resistance to X-irradiation was not markedly affected by pretreatment with ACTH.

*Cittadini et al. G76,028/70:* In X-irradiated mice, the formation of hemopoietic islets in the spleen is inhibited by dexamethasone, ACTH or the stress of exposure to cold.

#### **Hypoxia and Hyperoxygenation** ←

*Frawley et al. B57,930/51:* In man, both cortisone and ACTH improve high altitude tolerance.

*Parkes B63,024/51:* In mice, resistance to anoxia is increased by posterior lobe extract as well as by ACTH preparations containing posterior lobe principles.

*Grognot & Senelar C41,294/57:* In rats and guinea pigs, the pulmonary inflammation induced by inhalation of pure oxygen at normal barometric pressure is aggravated by ACTH or histamine.

*Volterrani C64,384/57:* In guinea pigs, tolerance to hypoxia is decreased by cortisone but increased by ACTH pretreatment.

*Sobel et al. C90,836/60:* Morphine increases the mortality of guinea pigs exposed to reduced oxygen tension. Prior treatment with cortisone or ACTH protects against this combined treatment.

#### **Temperature Variations** ←

*Neal et al. B80,371/52:* The survival time of severely burned rats is not influenced by cortisone or ACTH, whereas DOC administered before the burn offers considerable protection.

*Schöttler C8,455/55:* Neither ACTH nor cortisone protect the mouse against the fatal

effects of severe scalding; in fact, cortisone increases mortality.

*Kirsteins C 41,958/56*: Short term cortisone or ACTH administration to rats did not significantly influence cold tolerance, whereas long-term intermittent cortisone administration prior to exposure to cold definitely raised tolerance in this respect.

*Koch et al. C 33,922/57*: In rats, ACTH, unlike STH, prolongs survival following severe burns.

*Garrido C 77,562/59*: In intact rats, prednisone and ACTH increased resistance to cold.

*Hale & Mefferd Jr. C 79,669/59*: In rats exposed to cold and various other stressors, pretreatment with "ACTH had a 'restraining' influence on nonspecific metabolic responses."

*Yang & Lissak C 77,913/59*: In rats, the improvement of muscular performance (swimming) induced by ACTH is fully evident only at a critical temperature.

*Knigge C 97,819/60*: Review on the neuroendocrine mechanisms influencing ACTH and TTH secretion, particularly during adaptation to cold.

*Agarkov et al. D 40,496/62*: In intact rats, cortisone raises resistance to heat, whereas ACTH does not.

*Araki G 11,847/63*: Pretreatment with ACTH or cortisol raises the resistance of intact mice to exposure to cold. Nicotinamide has a similar effect which is ascribed to stimulation of the pituitary-adrenal system.

#### Other Stressors ←

**Electric Stimuli** ←. *Minz & Domino B 81,852/53*: In rats, small doses of epinephrine or norepinephrine prolong the duration of electrically-induced seizures. Since glucose, ACTH and cortisone failed to prolong seizure duration, it is unlikely that epinephrine acts by release of these substances. Histamine depressed the cortical response to electroshock.

*Woodbury B 98,594/54*: Review (42 pp., 90 refs.) on the "Effect of Hormones on Brain Excitability and Electrolytes." In the rat, the EST is increased by DOC and decreased by cortisone and cortisol. ACTH and 11-dehydro-

corticosterone, given chronically, partially antagonize the effect of cortisone.

*Rosenblum C 5,974/55*: In rats, "ACTH and cortisone acetate in combination with vasopressin each produced a greater fall in EST than was produced by vasopressin alone. In contrast, STH in combination with vasopressin prevented the fall induced by vasopressin alone and produced its usual elevation in the EST."

**Trauma** ←. *Noble & Collip A 56,107/42*: Adrenocortical extract and DOC greatly increase the resistance of adrenalectomized rats to the trauma of the Noble-Collip drum. In intact rats, "cortin" and DOC as well as ACTH induce only a slight increase in resistance under similar circumstances. "From a practical viewpoint the effects of adrenal preparations on this type of shock have been disappointing."

*Kulagin D 236/61*: In rats with a crush syndrome produced by clamping a thigh, survival was increased by ACTH, cortisone and cortisol, whereas DOC aggravated the condition by increasing edema in the injured area.

*Khrabrova D 33,557/62*: Both ACTH and cortisone prolong survival following traumatic shock in the cat.

**Muscular Work** ←. *Yang & Lissak C 77,913/59*: In rats, the improvement of muscular performance (swimming) induced by ACTH is fully evident only at a critical temperature.

**Osmosis** ←. *Smith C 46,496/56*: In brown trout, thyroxine raises, whereas thiourea and thiouracil reduce, salinity tolerance. Anterior pituitary extracts and STH likewise raise salinity tolerance, whereas posterior lobe extracts, testosterone, gonadotrophin, TTH and ACTH have no effect.

**Tumors** ←. *Glenn et al. G 70,204/60*: Review (48 pp., 11 refs.) on the effect of various steroids, ACTH, GTH, ovariectomy, and adrenalectomy upon the development of C3H mammary carcinoma transplants in mice and fibroadenomas in rats.

**Repeated Breeding** ← *cf. Selye C 50,810/58, p. 82; C 92,918/61, p. 230; G 60, 083/70, pp. 328, 330.*

#### Hepatic Enzymes ←

In the rat, ACTH increases the TPO and TKT activity of the liver even without concurrent treatment with the corresponding substrates. In this respect, ACTH imitates the actions of glucocorticoids and of various stressors which cause ACTH and glucocorticoid secretion.

ACTH also increases hepatic GPT activity even in hypophysectomized but not in adrenalectomized rats. Presumably this effect is likewise mediated through the adrenal cortex.

Observations with the use of marked cholesterol in the rat showed that ACTH decreases the rate of cholesterol palmitate and oleate synthesis.

#### TPO, TKT ←

*Geschwind & Li B95,517/53*: Hypophysectomy does not abolish (and perhaps even increases) the resting TPO activity of the rat liver. However, in hypophysectomized animals, the ability to induce this enzyme by tryptophan injection is gradually diminishing during the first 14 post-operative days. Treatment with ACTH enhances the formation of this adaptive enzyme system (measured by kynurenin formation) even without treatment with tryptophan.

*Knox & Auerbach E76,825/55*: ACTH increases TPO activity of the liver in the rat.

*Maickel & Brodie C83,071/60*: TPO in rat liver is increased by ACTH, cortisone, or cortisol, as well as by various stressor agents and barbiturates. Hypophysectomy prevents the effect of stressors and barbiturates, suggesting that the latter act through the pituitary-adrenal system.

*Knox G51,969/62*: Review on the effect of stress upon hepatic TPO production. In adrenalectomized animals, only tryptophan of a series of analogues induces this enzyme, whereas, in intact rats, various stressors, ACTH, cortisone, cortisol and corticosterone (but not DOC) do so. "The recognition of the adrenal hormone-induced adaptation of the tryptophan pyrrolase has provided the unified explanation for a large number of different stressful stimuli which increase the enzyme level." Tryptophan pyrrolase is absent from the liver of newborn rabbits and in them, this enzyme cannot be induced by cortisol. Tyrosine transaminase induction is regulated in a very similar manner.

#### GPT ←

*Rosen et al. C71,414/59*: Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocorti-

sol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol.

*Harding et al. D14,355/61*: In the rat, pretreatment with DOC depresses the hepatic GPT activity. A similar depression is obtained by adrenalectomy, but this is not further aggravated by concurrent treatment with DOC. ACTH increases GPT activity in hypophysectomized, but not in adrenalectomized, animals. In hypophysectomized rats, DOC fails to lower alanine transaminase, nor does it alter the response of this enzyme to ACTH. "The inhibitory effect of DOC on alanine transaminase activity appears to be due to suppression of ACTH release by the pituitary."

#### Cholesterolase ←

*Schweppe & Jungmann H15,978/69*: Observations on the metabolism of marked cholesterol added together with various hormones to hepatic microsomes of the rat led to the conclusion that "1) cholesterol palmitate and oleate were synthesized most rapidly; 2) at high concentrations, testosterone decreased the formation of all esters but at lower dose levels, testosterone increased the synthesis of cholesterol oleate and palmitate; 3) estradiol caused a two-fold increase in cholesterol oleate formation; 4) ACTH decreased the synthesis rate of cholesterol palmitate and oleate; 5) insulin had a significant inhibitory effect on cholesterol linoleate; 6) epinephrine had little significant effect at the dose level used; and 7) L-thyroxine increased the synthesis of all cholesterol esters."

### ← SOMATOTROPIC HORMONE (STH)

#### Steroids ←

The effects of corticoids can be modified by STH in many respects. In rats sensitized by uninephrectomy + NaCl, STH produces a hyalinosis syndrome with

malignant hypertension, similar to that elicited by mineralocorticoids. The corresponding action of DOC is aggravated by STH. Adrenalectomy or pretreatment with cortisone (in doses sufficient to produce adrenocortical atrophy) inhibits the production of hyalinosis by STH. It is assumed that STH induces malignant hypertension by increasing the production or the effect of mineralocorticoids.

Glucocorticoid overdosage symptoms (catabolism, splenic and thymic atrophy, "saprophytosis") are prevented in rats by simultaneous administration of STH. On the other hand, a synergism between STH and mineralocorticoids (DOC, aldosterone) has been demonstrated (in both intact and adrenalectomized rats) as judged by their effects upon many target organs.

The inhibition of growth by folliculoids (e.g., stilbestrol) can be blocked in rats by concurrent STH administration, but this conjoint treatment results in particularly severe osteosclerosis.

#### **Corticoids ←**

*Selye B53,940/51:* In uninephrectomized NaCl-treated rats, the hyalinosis syndrome produced by DOC is aggravated by STH; indeed, STH alone can engender malignant hypertensive disease. These effects of STH are inhibited by cortisone. Apparently STH increases mineralocorticoid production by the adrenals (unless these are rendered atrophic by cortisone) and/or sensitizes the peripheral tissue to mineralocorticoids.

*Selye B65,065/52:* In rats, large doses of cortisone permit the proliferation of normally saprophytic organisms which cause multiple abscesses and hepatic necroses (the "saprophytosis syndrome"). All these changes can be prevented by simultaneous treatment with STH.

*Horava & Selye B70,249/53:* In rats, heavy overdosage with cortisol produces intense catabolism with atrophy of the adrenals, thymus and spleen, as well as pulmonary "saprophytosis." Concurrent administration of STH inhibits the body weight loss and the saprophytosis, but not adrenal and thymus atrophy. The renal glomerular changes induced by cortisol intoxication are actually aggravated by STH.

*Ducommun & Ducommun B70,251/53:* In rats, saprophytosis produced by heavy overdosage with cortisone is inhibited by concurrent administration of STH. This "anti-infectious effect of STH" is much less evident after adrenalectomy. DOC, testosterone, and estradiol alone or in combination failed to duplicate the anti-infectious action of STH in cortisone-treated rats.

*Selye & Bois C1,718/55:* In intact and in adrenalectomized rats, a synergism between mineralocorticoids (DOC, aldosterone) and STH was evident in their effects upon many target organs.

*Bavetta et al. D29,064/62:* In the rat, "growth hormone, methyl testosterone or stilbestrol, when given alone or in combination were not able to counteract the inhibitory effects of 6-methyl prednisolone on body weight and collagen synthesis at the site of subcutaneously implanted polyvinyl sponges."

#### **Folliculoids ←**

*Selye B70,245/53:* In rats, the inhibition of growth produced by a folliculoid substance, such as stilbestrol, can be inhibited by STH, but this conjoint treatment results in severe osteosclerosis.

#### **Drugs ←**

STH conspicuously influences the toxicity of only a few drugs. For example in rats, it tends to aggravate the production of hepatic sclerosis by  $\text{CCl}_4$  while diminishing parenchymal injury.

In rats, hepatoma formation by certain carcinogens is enhanced both by STH and by ACTH. Studies with  $^{14}\text{C}$ -labeled N-OH-FAA showed decreased dehydroxylation

and deacetylation of the carcinogens as well as increased binding of radioactivity to liver proteins in animals treated with STH.

Female rats are much more resistant than males to the induction of cardiovascular and renal lesions by **choline** deficient diets. However, STH sensitizes the female to the production of these changes by choline deficiency, perhaps because the increased growth rate accelerates the exhaustion of choline stores.

The bone changes produced by various **lathyrogens** are very considerably aggravated by STH. Conversely, hypophysectomy prevents these changes, and substitution with STH in doses just sufficient to maintain normal growth restores the susceptibility of the skeleton to the production of lathyrisms. It was concluded that the normal STH secretion of the hypophysis decisively influences the development of this bone disease. The lathyrisms-enhancing effect of STH is not mediated through the adrenals, since it is evident even after bilateral adrenalectomy.

The cardiac infarcts produced by coronary artery ligation in the rat tend to develop into rupturing cardiac aneurysms under the influence of the lathyrogen, AAN. This effect is not significantly altered by STH. Similarly, STH fails to influence the hemorrhagic tendency induced by lathyrogens such as AAN. Hence, there does not appear to be any close relationship between the effect of STH upon the skeletal and the cardiovascular manifestations of lathyrisms. Furthermore, the hormones presumably act directly upon the responsiveness of individual target organs, and not by altering the metabolism of the lathyrogens.

In the rat, the catabolism produced by **nitrogen mustard** is not prevented, and even tends to be aggravated, by STH alone; yet, excellent protection is obtained by combined treatment with STH and antibiotics.

On the other hand, the growth stimulating effect of STH is greatly diminished in rats given diets deficient in **phenylalanine, tryptophan, or tyrosine**.

In rats kept on a **vitamin-A** deficient diet, STH fails to promote growth, and actually precipitates the manifestations of avitaminosis. On the other hand, the intense catabolism and bone absorption produced in rats by vitamin-A overdosage are prevented by STH.

The cardiovascular calcification engendered by **vitamin-D** derivatives, such as **DHT**, is somewhat diminished, but not prevented by STH, although the associated catabolism is markedly inhibited.

#### **Acrylonitrile** ←

*Szabó & Selye G79,010/71:* In rats, pretreatment with ACTH (but not with STH) prevents the production of adrenal apoplexy by acrylonitrile. Hypophysectomy protects against adrenal apoplexy, but not against mortality under similar conditions.

#### **Aminopyrine Barbiturates** ←

*Wilson H34,926/71:* In rats, implants of mammatropic tumor (which secretes STH, ACTH and LTH) decreased the hepatic metabolism of hexobarbital and aminopyrine. Simi-

lar but much less pronounced changes were observed in rats bearing very large Walker tumors.

#### **Anaphylactoidogenic Agents** ←

*Higginbotham & Dougherty C44,529/57:* In mice, ACTH increased the toxicity of polymyxin B; STH and TTH had no effect upon it.

#### **Anticoagulants** ←

*van Cauwenberge & Jaques C58,521/58:* A dose of bishydroxycoumarin (Dicoumarol) well tolerated by otherwise untreated rabbits,

causes death with widespread hemorrhage when given together with ACTH. The hemorrhagic tendency induced by coumarol was not accentuated by STH, cortisone or DOC.

*van Cauwenberge & Jaques C72,748/59*: The "hemorrhagic death syndrome" produced by Dicoumarol treatment in rats simultaneously exposed to various stressors can be reproduced by the administration of ACTH, STH, or DOC, instead of stressors. Dicoumarol + cortisol or cortisone did not reproduce this syndrome.

#### **Carbon Tetrachloride ←**

*Campanacci Jr. et al. C20,086/56*: In rats, small doses of STH increase the hepatic sclerosis produced by  $\text{CCl}_4$ , whereas at high dose levels, the hormone aggravates parenchymal degeneration, but inhibits sclerosis.

*Post et al. C40,180/57*: In rats, the hepatic injury produced by  $\text{CCl}_4$  is diminished by STH.

*Furukawa F71,711/65*: In rats, hepatic steatosis produced by  $\text{CCl}_4$  is inhibited by adrenalectomy and, to some extent, also by hypophysectomy. The effect of  $\text{CCl}_4$  after adrenalectomy is restored by corticoids, but not by epinephrine which only increases the action of the former. STH does not counteract the effect of hypophysectomy. Alloxan diabetes inhibits  $\text{CCl}_4$ -induced hepatic lipidosis.

#### **Carcinogens ←**

*Reid B93,930/54*: Review (18 pp., 181 refs.) on the effect of STH and corticoids upon carcinogen-induced and transplantable neoplasms.

*Shirasu et al. F76,819/67*: In the rats, hepatoma formation by N-hydroxy-N-2-Fluorenylacetamide (N-OH-FAA) is enhanced by ACTH and STH. Studies with  $^{14}\text{C}$ -labeled N-OH-FAA showed "decreased dehydroxylation and deacetylation of N-OH-FAA. The radioactivity bound to liver proteins was increased, remarkably so in the animals treated with growth hormone."

7,12-Dimethylbenz(a)anthracene ← STH + Age: Morii et al. D45,369/62\*

#### **Choline ←**

*Wilgram & Hartcroft C14,392/55*: Female rats are much more resistant than males to the production of cardiovascular lesions by choline deficiency. However, simultaneous administration of "androgens" (kind not specified) and

STH sensitizes the female to the induction of these lesions by hypolipotropic rations.

*Wilgram et al. C15,960/56*: Both STH and testosterone aggravate the renal and cardiovascular lesions characteristic of choline deficiency in the rat.

*Wilgram C84,322/59*: In rats, STH increases the severity of the cardiovascular lesions produced by choline deficiency.

*Aterman D15,536/61*: In male weanling rats, the hepatic necrosis induced by feeding a diet containing yeast as the sole source of protein is greatly accelerated by partial hepatectomy or treatment with STH.

#### **Chlorpromazine ←**

*Epple et al. F76,569/66*: In toads, the hypothermic action of chlorpromazine and ethanol is diminished by STH.

#### **Ethanol ←**

*Epple et al. F76,569/66*: In toads, the hypothermic action of chlorpromazine and ethanol is diminished by STH.

#### **Ethionine ←**

*Farber & Segaloff D95,996/55*: In ovariectomized rats, various testoids and STH protected the liver against fatty infiltration produced by ethionine i.p., whereas cortisone and ACTH aggravated it. Estradiol, DOC, and TSH had no effect.

**Lathyrogens ←** cf. also *Selye C92,918/61*, p. 137.

*Selye & Bois C18,280/56*: In rats, the osteolathyrisms produced by lathyrus odoratus seeds is aggravated by STH and inhibited by cortisol. Combined treatment with DOC + uninephrectomy + NaCl resulted in dissecting aneurysms of the aorta. Very small doses of thyroxine or estradiol were without effect upon this form of lathyrisms.

*Dasler C36,068/57*: Brief mention of unpublished observations indicating that in rats, osteolathyrisms produced by APN is not inhibited by cortisone or thyroxine, but aggravated by STH.

*Selye C25,910/57*: In rats, the osteolathyrisms produced by moderate doses of AAN is greatly aggravated by STH.

*Selye C31,369/57*: In the rat, the osteolathyrisms produced by AAN is aggravated by STH, LTH, and partial hepatectomy, but it is inhibited by ACTH, cortisol, or estradiol.

*Selye C31,790/57*: In rats, osteolathyrisms produced by AAN is inhibited by thyroxine,

cortisol, and estradiol, but aggravated by STH even after adrenalectomy.

*Selye & Bois C22,712/57*: In rats, osteolathyrism (produced by AAN) is inhibited by cortisol and augmented by STH. The combination of STH and AAN enhances the development of polyarthritis in the small joints of the extremities. DOC facilitates the production of aortic aneurysms by AAN.

*Selye & Bois C23,297/57*: In rats, STH greatly aggravates the osteolathyrism produced by AAN.

*Selye & Ventura C27,684/57*: In rats, hypophysectomy greatly diminished the development of the osteolathyrism normally produced by AAN, but STH aggravated these bone lesions even more in the absence than in the presence of the pituitary. It is concluded that the normal hormonal secretion of the hypophysis exerts a decisive influence on the development of osteolathyrism.

*Selye & Cantin C88,878/61*: In rats, the osteolathyrism produced by AAN is inhibited by thyroxine and cortisol, but aggravated by STH. The cardiac infarcts elicited in rats by ligation of the descending branch of the left coronary artery are often transformed into rupturing cardiac aneurysms under the influence of AAN. The incidence of these cardiac ruptures is augmented by cortisol and DOC, but not significantly influenced by thyroxine and STH. Evidently, there is no direct relationship between the skeletal and the cardiac lesions under these circumstances.

*Aschkenasy D30,892/62*: In rats, lathyrism produced by AAN is aggravated by adrenalectomy and, in the absence of the adrenals, the usual antilathyr effect of cortisone is no longer demonstrable; in fact the glucocorticoid facilitates the production of hernias. STH aggravates the osteolathyrism, but not the induction of hemorrhages by AAN.

#### **Nitrogen Mustard ←**

*Mitchell & Girerd B82,866/53*: In rats, the catabolism and mortality produced by nitrogen mustard is actually aggravated by STH alone, and only slightly inhibited by antibiotics; STH + antibiotics offer excellent protection.

#### **Phenylalanine ←**

*Scott & Dynes C53,564/57*: In rats on a phenylalanine- and tyrosine-deficient diet, STH caused less stimulation of the epiphyseal growth plate than in pair-fed animals.

*Reiss et al. F81,632/66*: In rabbits given large amounts of phenylalanine, the blood and tissue concentration of this compound could be reduced by pretreatment with norbolethone decanoate or STH.

**Plasmocid ←** *cf. Selye C92,918/61, p. 95.*

#### **Tryptophan ←**

*Bavetta et al. C17,656/56*: In rats on a tryptophan-deficient diet, STH failed to increase body weight, but it did stimulate endochondral osteogenesis and dentin formation.

#### **Tyrosine ←**

*Scott & Dynes C53,564/57*: In rats on a phenylalanine- and tyrosine-deficient diet, STH caused less stimulation of the epiphyseal growth plate than in pair-fed animals.

#### **Vitamin A ←**

*Ershoff & Deuel Jr. B14,516/45*: In vitamin-A deficient rats, STH fails to promote growth, and actually shortens survival by the precipitation of acute vitamin-A deficiency symptoms.

*Selye C36,050/57*: In rats, the intense osteoclastic bone absorption produced by vitamin-A overdosage can be prevented by STH. Although the lutetotropic hormone (LTH) shares many of the actions of STH, it cannot substitute for the latter in counteracting vitamin-A intoxication, *cf. Fig. 21.*

*Bavetta C60,277/58*: In rats, STH failed to increase body weight on a vitamin-A deficient diet, but endochondral ossification was enhanced, and dentin formation stimulated. "The suggestion is made that impaired chondrogenic and osteogenic activity in vitamin A-depleted rats is due, at least in part, to an inadequate production or secretion of growth hormone."

*Bottiglioni et al. C70,889/59*: In rats, the atrophy of the skeletal musculature and the decreased metachromasia of the aortic wall produced by vitamin-A deficiency are aggravated by STH.

#### **Vitamin C ←**

*McGraw C68,484/59; C80,136/59*: Doctor's thesis describing numerous experiments on the effect of adrenalectomy, cortisone, thyroxine, thyroidectomy, thiourea, and STH upon scorbutic guinea pigs, with special emphasis upon changes in capillary resistance and cold tolerance.

**Vitamin D, DHT ←** *cf. also Selye G60,083/70, pp. 331, 333.*

**Fig. 21. Prevention of vitamin-A induced skeletal lesions by STH.** A: Mandible of normal (left), vitamin-A treated (middle) and vitamin-A + STH-treated rats. Note that hypervitaminosis A resulted in several perforations within the flat part of the mandible and in absorption of the coronoid and condyloid processes with disappearance of the angle of the jaw. All these changes have been completely prevented by STH. B: Scapula of normal (left), vitamin-A treated (middle) and vitamin A+STH-treated rat. Again, the resorption of bone normally produced by vitamin A has been prevented by STH. C: Femur of a normal (left), a vitamin-A treated (middle) and vitamin A + STH-treated rat. The antagonism between STH and vitamin-A is clearly visible. [Selye C36,050/57. Courtesy of J. Endocrin.]

*Selye C27,735/57*: The cardiovascular calcification and nephrocalcinosis produced by DHT in rats are aggravated by estradiol, cortisol, ACTH, and thyroxine. Conversely, methyltestosterone and STH exert a protective effect.

#### Zinc ←

*Prasad et al. G64,823/69*: In rats kept on a zinc-deficient diet, STH failed to promote growth.

#### Varia ←

*Selye G70,480/71*: In rats, STH offered some protection against progesterone anesthesia but did not alter the syndrome of intoxication with digitoxin, dioxathion parathion, nicotine, hexobarbital, zoxazolamine, indomethacin, acute DHT intoxication or the myocardial necroses produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

*Diet* ← cf. *Selye G60,083/70*, pp. 331, 333.

### Microorganisms, Parasites and Their Products ←

As previously stated, STH counteracts the facilitating effect of glucocorticoids and of ACTH upon the spread of various infections. This has first been demonstrated for the "saprophytosis" that develops in rats as a consequence of the proliferation of normally saprophytic organisms. STH also exerts a beneficial effect upon resistance of mice to pneumococci and typhoid bacilli, and of rats to *P. pestis*. On the other hand, STH does not appear to modify the course of staphylococcus infection in rabbits.

The most extensive studies on the effect of STH have been conducted in connection with experimental tuberculosis. In the rat, there appears to exist a definite antagonism between the resistance-decreasing action of ACTH and glucocorticoids on the one hand and the protection offered by STH on the other. This has been confirmed by some investigators in guinea pigs and mice; indeed, it has been claimed that STH exerts a favorable effect even in human tuberculosis. However, many of the reports are contradictory, probably owing to genetic differences in the strains of the bacteria and hosts, as well as to variations in the potency and immunologic compatibility of the STH preparations employed.

In mice, the proliferation of influenza virus is accelerated by STH, perhaps as a consequence of enhanced protein synthesis in general. The detrimental effect of ACTH and cortisone upon the course of influenza virus infection in mice is not overcome by STH. However, the increase in the sensitivity of the mouse to infection with MHV-3 hepatitis virus, induced by different glucocorticoids, is largely counteracted by STH. In sheep, STH tends to delimit the lesions produced by variola virus, but in mice its effect upon vaccinia virus is not very pronounced.

In mice, STH retards the development of infection with parasites, *Plasmodium berghei*, and in frogs, it inhibits infection with *Trypanosoma inopinatum*.

The moniliasis produced by *Candida albicans* in mice is aggravated by cortisone and this deleterious effect is counteracted by STH.

STH offers no protection against typhoid endotoxin in the mouse, but resistance against diphtheria toxin appears to be increased.

#### Bacteria and Vaccines ←

*Corynebacteria* ← cf. *Selye C92,918/61*, p. 233.

"Endotheliomyelosis" ← cf. *Selye C92,918/61*, p. 241.

"Saprophytosis" ←. *Selye B57,451/51*: In rats, "saprophytosis" due to proliferation of normally nonpathogenic microorganisms, such as develops after heavy overdosage with cortisone or ACTH, can be completely prevented by concurrent administration of STH.

*Selye B65,065/52*: In rats, large doses of cortisone permit the proliferation of normally saprophytic organisms which cause multiple abscesses and hepatic necroses (the "saprophytosis syndrome"). All these changes can be prevented by simultaneous treatment with STH.

**Pneumococcus** ←. *Kass et al. B95,353/54*: In mice, resistance to pneumococcal and influenza virus infections is depressed by pretreatment with cortisone or cortisol, but not by ACTH. STH failed to overcome the effect of cortisone and did not increase resistance to infection when given alone.

*Meier & Neipp C37,215/56*: In mice, the chemotherapeutic action of sulfonamides against resistant Type III pneumococci is increased by various gonadotrophic and STH preparations. However, certain bacterial polysaccharide fractions possess a similar effect, and hence, the latter is presumably not dependent upon the specific actions of the hormone preparations.

**Staphylococcus** ←. *Debry C30,870/56*: Doctor's thesis (176 pp. 578 refs.) on the influence of hormones upon infection. Personal observations on guinea pigs and rats indicate that ACTH, STH, and DOC do not significantly affect the course of acute staphylococcus infection, whereas cortisone aggravates it.

*Herbeuval et al. C55,675/58*: In rabbits, STH does not modify the course of staphylococcus infection.

**Typhoid Bacilli** ←. *Jude et al. C16,220/55*: In mice, STH pretreatment protects against subsequent infection with typhoid bacilli. The protection is ascribed to improved antibody formation and phagocytosis. STH offers no protection against typhoid endotoxin.

**Pasteurella Pestis** ←. *Hayashida C37,366/57*: In rats infected with *P. pestis*, ACTH decreased, whereas STH increased survival.

**Mycobacterium Tuberculosis** ←. *Lemonde et al. B70,248/52*: The rat which is naturally resistant to human *M. tuberculosis* can be made sensitive to this infection by pretreatment with cortisone. This sensitivity is in turn abolished by concurrent treatment with STH. Mice which are naturally sensitive to tuberculosis can also be protected by STH.

*Lucherini et al. B89,088/53*: In guinea pigs, STH inhibits the progress of tuberculosis and counteracts the opposite effect of ACTH.

*Chirico et al. C5,040/54*: In guinea pigs, the late pulmonary manifestations of tuberculosis are enhanced by STH and the fibrotic healing processes are improved. The effects of the

hormone are ascribed to a stimulation of mesenchymal defense reactions.

*Lemonde C310/54*: Doctor's thesis (186 pp., 564 refs.) on humoral factors influencing infections, with special reference to the effect of STH and cortisone upon experimental tuberculosis.

*Youmans & Youmans B95,169/54*: In mice, cortisone markedly reduced the survival time after infection with human tubercle bacilli, and this effect could not be prevented by STH. Given alone, ACTH, STH, and TTH likewise failed to influence the course of the infection.

*Carstensen et al. C12,300/55*: In man, STH (Somacton) has been found useful in the treatment of tuberculosis.

*Guillermard et al. C15,540/55*: In man, STH [source not indicated (H.S.)] allegedly exerts a very favorable effect upon tuberculosis.

*Lemonde et al. C526/55*: In mice, STH is beneficial in combating chronic but not acute tuberculous infection.

*Lemonde C6,400/55*: In mice and rats, STH has a favorable effect upon the course of experimental tuberculosis.

*Brouet et al. G72,418/56*: Review (47 pp., 55 refs.) on the effect of STH upon clinical and experimental tuberculosis. Personal observations on guinea pigs showed that the hormone has a moderate protective effect.

*Chirico C24,381/56*: Review (32 pp., about 100 refs.) on the effects of STH, with special reference to its influence upon inflammation and tuberculosis.

*Wasz-Höckert & Backman C34,801/56*: In guinea pigs, ACTH aggravates the course of tuberculosis. STH in itself is without conspicuous effect, however, "the strongly deteriorating effect on tuberculosis produced by ACTH was evidently counteracted by STH when given simultaneously with ACTH."

*Wasz-Höckert & McCune E31,145/63*: In mice infected with tuberculosis, STH caused an increase in body weight but did not inhibit the development of the infection, nor did it counteract the unfavorable effect of ACTH.

**Varia** ←. *Cavallero C829/54*: Review on the effect of STH, ACTH, and cortisone upon various infections, especially in the rat.

### Viruses ←

*Kalter et al. B49,656/50*: In mice, the proliferation of influenza virus is accelerated

by STH and testosterone, presumably because of an enhanced protein synthesis in general.

*Kass et al. B95,353/54:* In mice, resistance to pneumococcal and influenza virus infections is depressed by pretreatment with cortisone or cortisol, but not by ACTH. STH failed to overcome the effect of cortisone and did not increase resistance to infection when given alone.

*Pecori et al. C89,118/59; C89,121/59:* Prednisone, triamcinolone, and dexamethasone increase the sensitivity of the mouse to infection with the MHV-3 hepatitis virus. This pro-infectious effect is largely counteracted by STH.

*Cilli et al. D12,192/61:* In sheep, STH, owing to its prophlogistic effect, delimits the lesions produced by variola virus. ACTH and dexamethasone exert an opposite effect.

*Altucci et al. D65,819/62:* In mice, STH alters the tissue reaction to infection by vaccinia virus, but has little effect upon mortality.

#### **Parasites ←**

*Galliard & Lapierre E82,642/53:* In mice, STH retards the development of infection with *P. berghei*.

*Galliard et al. G70,892/53:* In frogs, infection with *T. inopinatum* is inhibited by STH, presumably as a consequence of its phlogistic

action which favors the phagocytosis of the parasites.

*Galliard et al. D89,408/54:* In mice, STH greatly retards infection with *Plasmodium berghei*. STH has no effect upon either toxoplasmosis in the mouse or infection with *T. brucei* in the rat or mouse.

#### **Fungi and Yeasts ←**

*Scherr C39,263/57:* In mice infected with *Candida albicans*, the development of moniliasis may be either increased or decreased by cortisone, depending upon various factors, particularly the severity of the infection, sex or pregnancy. Testosterone enhanced, and STH counteracted the deleterious effect of cortisone. Gonadotrophin (pregnant mare serum) was without effect.

#### **Bacterial Toxins ←**

*Jude et al. C16,220/55:* In mice, STH-pretreatment protects against subsequent infection with typhoid bacilli. The protection is ascribed to improved antibody formation and phagocytosis. STH offers no protection against typhoid endotoxin.

*Skuratova D20,887/62:* In mice, resistance against the fatal effect of diphtheria toxin is more markedly increased by STH than by ACTH.

#### **Immune Reactions ←**

In guinea pigs, STH has been claimed to depress tuberculin sensitivity and to synergize the desensitizing effect of cortisone.

In rats, STH aggravates the glomerular lesions characteristic of the Masugi nephritis, and increases the formation of antibodies against *Pasteurella pestis*. It also raises hemolysin formation following i.p. injection of sheep erythrocytes in the rat.

#### **Hepatic and Renal Lesions ←**

In partially hepatectomized rats, STH failed to further increase the high mitotic rate in the liver remnant.

In completely nephrectomized rats, STH slightly prolonged survival. The renal atrophy produced by temporary ligation of one renal pedicle is counteracted, and survival following removal of the contralateral kidney is prolonged by STH.

#### **Various Stressors ←**

In guinea pigs and rats, STH diminishes the catabolism, and to a lesser extent the mortality, induced by total body X-irradiation.

In the rat, STH counteracts the loss of body weight induced by chronic exposure to cold. Under certain circumstances it also prolongs survival in extreme cold, or

after severe burns. It has been claimed that in man, STH likewise counteracts the catabolism produced by burns.

STH is said to increase the EST in the rat and the salinity tolerance in the trout, and to offer "moderate protection" against various stressors in guinea pigs.

### Hepatic Enzymes ←

In rats, STH decreases hepatic arginase and GPT but not GOT activity. The TPO activity of the rat liver increases with age, as well as after STH injection.

In rats, STH inhibits the synthesis of hepatic TKT and represses TKT induction by stressors or cortisol, but it has no effect upon the cortisol-induced TPO activity.

The OKT activity of the rat liver is diminished after treatment with STH, the same as after partial hepatectomy.

In rats treated with STH during the postnatal period, the development of various drug-metabolizing hepatic microsomal enzymes is suppressed.

In mice, STH first decreases and then increases hepatic TPO activity. A similar biphasic reaction is allegedly produced by exposure to stress; this may explain some of the contradictions in the published data.

### Immune Reactions ←

*Cornforth & Long B77,176/53:* In guinea pigs sensitized to tuberculin, single s.c. injections of ATP prevent desensitization by alloxan, cortisone, and dihydro-ascorbic acid. Single s.c. injections of insulin do not in themselves influence sensitivity but prevent desensitization by alloxan and cortisone. Single s.c. injections of STH depress tuberculin sensitivity and synergize the action of cortisone or alloxan.

*Dutz et al. C31,646/56:* In rats, gonadectomy did not significantly change the course of Masugi nephritis, whereas a folliculoid preparation (Östrasid) and testosterone ameliorated it. STH considerably aggravated the glomerular lesions and the hypertension.

*Hayashida & Li C29,987/57:* In rats, ACTH decreases whereas STH increases the formation of antibodies against a soluble protein envelope antigen extracted from *P. pestis*.

*Ghiringhelli C90,609/60:* In rabbits, the production of anti-ovalbumin antibodies is not significantly influenced by STH.

*Terragna & Januzzi F62,290/66:* Review of the literature on the influence of STH on antibody formation. Personal observations in rats show that hemolysin formation following i.p. injection of sheep erythrocytes was increased by STH, but the change was statistically not significant.

### Hepatic Lesions ←

*Cristensen & Jacobsen A49,204/49:* In rats subjected to partial hepatectomy, neither hypophysectomy nor thyroidectomy impairs the rate of regeneration. No significant change in mitotic rate was observed after pretreatment with stilbestrol or STH.

*Selye & Bois B97,074/54:* In adrenalectomized rats with choledochus ligature, cortisol enhances the accumulation of bile within the bile-duct stem and furthers the development of perforating choledochus ulcers. These actions can be prevented by concurrent treatment with STH.

*Moolten et al. H30,606/70:* In rats, the rise in hepatic DNA synthesis after partial hepatectomy is accelerated by surgical interventions or STH. Cortisone, cortisol and ACTH were ineffective. Neither stress nor STH stimulated DNA synthesis significantly in non-hepatectomized rats.

### Renal Lesions ←

*Dési et al. C69,045/59:* In rats, survival after bilateral nephrectomy is prolonged by STH and DOC, alone or in combination, but the effect of STH is diminished by concurrent administration of MAD.

*Köhnlein et al. D38,961/62:* In rats, the renal atrophy produced by temporary ligation

of one renal pedicle is counteracted, and survival following subsequent removal of the healthy kidney is prolonged by STH.

#### Various Stressors ←

**Ionizing Rays** ←. *Lacassagne & Tuchmann-Duplessis E53,832/53*: In X-irradiated guinea pigs and rats, body-weight loss and to some extent even mortality, were diminished by STH.

*Hoene et al. B92,374/54*: In rats, pretreatment with STH inhibits the loss of body weight and the involution of the lymph nodes following X-irradiation, but it exerts no clear-cut effect upon the involution of the spleen and thymus or the deficient antibody formation induced by irradiation.

*Rigat C10,747/55*: Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation, with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

*Barlow & Sellers C21,626/55*: In rats, STH prevents body-weight loss but does not prolong survival following X-irradiation.

*Bloodworth et al. C14,328/56*: In rats, weight loss and mortality following X-irradiation were diminished by STH.

**Temperature Variations** ←. *Dugal & Dufour C8,603/54*: In rats, the loss of body weight produced by chronic exposure to cold is counteracted by STH.

*Dufour & Dugal C15,508/55*: In rats, STH increases resistance to cold.

*Dufour & Dugal C26,092/57*: In rats, resistance to cold is diminished by STH or DOC given in combination with vitamin C.

*Koch et al. C33,922/57*: In rats, ACTH, unlike STH, prolongs survival following severe burns.

*Soroff et al. G52,127/67*: In man, human STH counteracts the catabolism produced by burns.

**Varia** ←. *Rosenblum C5,974/55*: In rats "ACTH and cortisone acetate in combination with vasopressin each produced a greater fall in EST than was produced by vasopressin alone. In contrast, STH in combination with vasopressin prevented the fall induced by vasopressin alone and produced its usual elevation in the EST."

*Smith C46,496/56*: In brown trout, thyroxine raises, whereas thiourea and thiouracil

reduce salinity tolerance. Anterior pituitary extracts and STH likewise raise salinity tolerance, whereas posterior lobe extracts, testosterone, gonadotrophin, TTH, and ACTH have no such effect.

*Amante C62,537/58*: In guinea pigs, STH "moderately protects" against the stress of burns, tourniquet, or evisceration.

*Vanamee et al. H32,254/70*: In rats, the production of stress ulcers of the stomach by restraint is inhibited by pretreatment with STH.

#### Hepatic Enzymes ←

*Beaton et al. B86,367/53*: In adult male rats, a single i.p. injection of STH causes a decrease in the rate of urea formation by liver slices, as well as in the hepatic arginase and GPT but not GOT activity. No such changes were noted in young male rats.

*Wood Jr. & Knox D81,779/54*: In mice, STH decreases hepatic TPO activity.

*Beaton et al. C10,012/55*: STH decreases the hepatic GPT and d-aminoacid oxidase activity in nonpregnant female rats. These effects are even more pronounced if the animals receive STH + "equine estrogenic substances" + progesterone. This enzyme activity also decreases during pregnancy both in intact and in hypophysectomized rats.

*Wood et al. C27,721/56*: In mice bearing SC-sarcoma implants, the hepatic TPO activity was first diminished, but rose above normal as the neoplasms grew. "Changes analogous to this biphasic depression and elevation of the enzyme level in tumor-bearing animals could be produced in control mice by growth hormone and by adrenal-stimulating stress, respectively."

*Beaton et al. D83,636/57*: Following STH treatment, there is a significant depression in the GPT activity of rat liver tissue, whereas cortisone has an inverse effect.

*Zuchlewski & Gaebler D91,862/57*: Hepatic glutamic acid dehydrogenase activity increases after hypophysectomy in the rat, and it is not altered by STH in either hypophysectomized or sham-operated control animals. GPT and GOT activities have also been investigated under similar conditions.

*Rosen et al. C50,741/58; C71,414/59*: Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epi-

cortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone, and insulin caused no significant change in GPT by themselves, nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol, they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Rivlin & Knox C71,249/59*: The TPO activity of rat liver increases with age and body weight, as well as after STH injection.

*Kenney & Albritton G64,557/65*: Review of the literature suggesting that transaminase induction in response to stressors can be due to corticoid secretion during the stress reaction. Cortisol enhances enzyme synthesis after an increased rate of synthesis of ribosomal transfer and "DNA-like" RNA's. The present experiments confirm the view that repressor(s) can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis can prolong the corticoid-induced increase in enzyme synthesis under suitable conditions. "Administration of stressing agents (tyrosine, Celite) to adrenalectomized rats initiates a highly selective repression of the synthesis of hepatic TKT. The enzyme level falls with a  $t_{1/2}$  of about 2.5 hr. Immunochemical measurement of the rate of enzyme synthesis indicates that it is reduced essentially to zero in stressed, adrenalectomized rats, whereas labeling of total liver soluble proteins is unaffected. Actinomycin does not itself influence the enzyme level, but it blocks the stress-initiated repression of enzyme synthesis, indicating that repression acts at the translational level, whereas initiation of repression involves transcriptional processes." In hypophysectomized rats, stressors are ineffective, and preliminary data suggest that STH is responsible for transaminase repression.

*Rinaudo et al. F95,471/67*: Studies on the induction of various hepatic enzymes by STH and LTH in toad tadpoles.

*Kenney G50,810/67*: In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The rate of enzyme synthesis is reduced nearly to zero (immunochemical-isotopic analyses), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actino-

mycin-D. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized) animals. Transaminase levels were unchanged in one single experiment, where the stressing agent was administered to the hypophysectomized partner.

*Räihä & Kekomäki G68,114/68*: In the rat, the OKT activity of the liver is very low in the fetus; it exhibits a small transient elevation around term, then drops, and eventually reaches the high adult activity level during the third postnatal week. Triamcinolone given postnatally causes a pronounced elevation of OKT, but has no such effect in fetal or adult rats. Puromycin prevents the rise in OKT after triamcinolone administration. In adult rats fed a protein- or arginine-free diet, OKT activity decreases and fails to rise under the influence of triamcinolone. Partial hepatectomy or STH depresses OKT-activity in the livers of adult rats.

*Schapiro H2,360/68*: Stress (30 min rough agitation in a noisy laboratory shaker) had no effect upon the corticoid sensitive enzyme TKT in the liver of the intact rat, but it increased TPO activity, which is likewise corticoid inducible. Adrenalectomized rats, similarly stressed, exhibited a decreased transaminase activity with no change in TPO. This inhibitory effect was abolished by hypophysectomy. STH inhibited induction of transaminase by cortisol, but had no effect upon cortisol-induced TPO activity. The opposing actions of STH and glucocorticoids may be involved in adaptive reactions to stress.

*Schapiro et al. H12,411/69*: Brief abstract stating (without giving experimental details) that "the severe stress of laparotomy in the intact adult rat induces a large corticoid-dependent increase in transaminase activity. STH administered simultaneously, or one hour before laparotomy will completely inhibit this enzyme increase. During the early postnatal period, however, STH will not block transaminase induction caused by cortisol or laparotomy."

*Wilson G69,098/69*: In the rat, in vitro studies suggest that STH depresses hexobarbital, aminopyrine and ethylmorphine metabolism. ACTH and LTH have no such effect and

do not influence the corresponding action of STH. [The hormones were administered s.c. 48 hrs before removal of the liver for the metabolic studies (H.S.).]

*Wilson H21,345/70:* In rats, the development of various drug-metabolizing hepatic microsomal enzymes can be suppressed by postnatal treatment with STH.

#### ← OTHER ANTERIOR PITUITARY PREPARATIONS (LTH, GTH, TTH, CRUDE EXTRACTS)

Many of the experiments concerning the protective action of LTH, GTH, TTH and other anterior pituitary extracts, were performed with more or less purified preparations in which several hormones were present; hence, we shall discuss these experiments conjointly. Most of the relevant work is concerned with the effect of anterior pituitary extract upon resistance to drugs, infections, hypoxia, and various forms of nonspecific stress.

#### *Drugs* ←

Resistance of mice to acetonitrile is considerably increased by thyroid preparations, and hence, it is not surprising that the thyrotrophic hormone (TTH) has a similar effect. However, gonadotrophic urinary extracts and folliculoid preparations also increase acetonitrile resistance in the mouse; hence, this phenomenon is not truly characteristic for the thyroid hormones.

Pretreatment of rats with crude lyophilized anterior pituitary preparations makes them particularly sensitive to the anesthetic effect of pentobarbital and progesterone. However, this effect is also nonspecific, since various tissue extracts and proteins, such as egg white, casein, etc., prolong pentobarbital anesthesia.

The hepatotoxic effect of  $\text{CCl}_4$  is partially prevented by crude anterior pituitary extracts in the rat.

Among the carcinogens, AAF is especially active in producing neoplastic lesions in the rat liver. This effect is intensified by pregnant mare serum, gonadotrophin, but also by estradiol and testosterone. The detoxication of N-OH-FAA is inhibited in rats bearing functional pituitary-tumor transplants, which also enhance hepatic carcinogenesis.

In rabbits, cholesterol atheromatosis is aggravated by TTH. According to some investigators, the severity of the lesions roughly parallels the blood cholesterol level, whereas others claim that TTH decreases the hypercholesterolemia. In cockerels, neither chorionic gonadotrophin nor TTH has any clear-cut effect upon cholesterol atherosclerosis.

In rats, the production of cardiac lesions by emetine, as well as of vascular changes by ergotamine, are inhibited by various gonadotrophic preparations.

The action of lathyrogens upon the bones of the rat is aggravated by luteotrophic hormone (LTH) as well as by STH.

On the other hand, the osteoclastic bone absorption produced by vitamin-A overdosage in rats, though prevented by STH, is not influenced by LTH.

#### *Microorganisms and Their Products* ←

Various anterior pituitary preparations are said to protect mice against bacterial infection, (e.g., with *B. anthracis*, *E. coli* and *Ps. pyocyaneus*), but not against several other organisms.

In rabbits, the progress of tuberculosis is accelerated by LH. In mice, the tuberculosis is not significantly affected by TTH, nor is infection with *Candida albicans* demonstrably altered by gonadotrophin.

Various gonadotrophic preparations have been claimed to counteract the lethal effects of diphtheria toxin in guinea pigs.

### *Hypoxia* ←

In rats and guinea pigs, pretreatment with crude anterior pituitary extracts diminishes resistance to decreased oxygen pressure, presumably as a consequence of their TTH content, since thyroidectomy abolishes this effect. Resistance to hypoxia is also decreased in guinea pigs by purified TTH, an observation which is in agreement with the well-known fact that thyroid hormones act in this manner.

### *Hormones* ←

*Masson et al. B48,694/49*: In rats sensitized by uninephrectomy + NaCl, DOC produced more severe hypertension than a crude anterior pituitary powder (APP). Combined treatment with DOC + APP had no additive effect.

*Oester C84,324/59*: The calcifying arteriosclerosis produced by repeated i.v. injections of epinephrine in the rabbit is aggravated by thyroxine and T3 s.c., but not by TTH or dinitrophenol. Thyroidectomy, unlike propylthiouracil, inhibits the epinephrine arteriopathy.

*Blatt et al. H19,832/69*: In frog tadpoles, prolactin antagonizes thyroxine-induced tail regression in the course of metamorphosis, but pancreatic regression and acid phosphatase development in the liver are not inhibited. Thus, prolactin does not antagonize the entire process of metamorphosis some events of which may not be directly induced by thyroxine.

### *Drugs* ←

*Acetonitrile* ←. *Eufinger et al. 22,082/29*: In mice, acetonitrile resistance is increased by pretreatment with human pregnancy serum. It remains to be seen whether this is due to an increased serum level of GTH, TTH or of other metabolites.

*Eufinger & Wiesbader 4,663/30*: In mice, pretreatment with gonadotrophic urinary extracts or folliculoid preparations increases acetonitrile resistance and hence this phenomenon is not characteristic for thyroid hormones.

*Neuweiler 43,582/32*: In mice, it was not possible to increase acetonitrile resistance by a

variety of gonadotrophic hormone preparations, including the serum of pregnant women.

*Sommer 44,648/34*: In mice, acetonitrile resistance is increased by a variety of gonadotrophic preparations, including the serum of pregnant women.

*Fellinger & Hochstädt 63,744/35*: In mice, the protection against acetonitrile offered by thyroxine or TTH is blocked by an extract of blood which contains the "ether soluble anti-thyroid substances."

*Wiesbader 68,823/36*: In mice, acetonitrile resistance is increased not only by thyroid extract but also by TTH and various gonadotrophic preparations.

*Actinomycin* ←. *Tuchmann-Duplessis & Mercier-Parot H28,876/70*: In rats, LTH does not prevent the abortifacient and teratogenic actions of actinomycin.

*Anaphylactoid Edema* ←. *Higginbotham & Dougherty C44,529/57*: In mice, ACTH increased the toxicity of polymyxin B; STH and TTH had no effect upon it.

*Barbiturates* ←. *Selye & Masson A97,571/44*: Pretreatment of rats with lyophilized anterior pituitary (LAP) makes them particularly sensitive to the anesthetic effect of progesterone or pentobarbital.

*Masson B275/45*: Male rats are more resistant to pentobarbital anesthesia than females. However, upon treatment with LAP s.c., resistance decreased considerably in both sexes, and eventually reached the same low level in males and females. LAP produced a similar increase in sensitivity to amobarbital, hexobarbital, cyclobarbitol and inbarbital, but did not influence barbital or phenobarbital anesthesia.

*Masson A95,888/46*: In rats, not only anterior pituitary preparations, but extracts of

various tissues, as well as egg white, casein, and other proteins prolonged pentobarbital anesthesia. Presumably, "the assimilation of foreign proteins interferes with some important mechanism necessary for the detoxification of barbiturates."

*Masson B1,217/46*: In male rats, pretreatment for 6 days with crude pituitary powder s.c. "slightly prolonged the duration of anesthesia with phanodorn, thioethamyl, neonal, delvinal, nostal and amytal, and greatly prolonged (2 to 5 times) with pentothal, seconal, allyl pental, nembutal, evipal, pernoston and sigmodal." There was no difference between the pretreated and control rats as regards the anesthetic effect of phenobarbital, probarbital, barbital, aprobarbital, diallyl barbituric acid and trichloroacetaldehyde. "The action of pituitary preparations is not specific but can also be obtained with preparations from various organs and with foreign proteins." Hepatic damage is considered to be a likely cause of the prolongation of anesthesia under these conditions.

**Cadmium** ←. *Pařízek et al. H7,672/68*: In adult rats in which persistent estrus had been induced by a single s.c. injection of testosterone or 19-nortestosterone on the fifth day of life, cadmium s.c. elicited particularly severe ovarian changes. Pretreatment with pregnant mare serum gonadotrophin protected the ovaries of such animals.

**Carbon Tetrachloride** ←. *Masson 96,335/47*: The hepatotoxic action of  $\text{CCl}_4$  is aggravated by DOC and testosterone but partially prevented by anterior-pituitary extracts in the rat.

*Arrigo & Trasino C21,687/55*: In rats, crude alkaline anterior-pituitary extracts (rich in STH) do, whereas acid extracts (rich in ACTH and STH) do not protect the liver and pancreas against damage by  $\text{CCl}_4$ . Cortisone protects the liver but not the pancreas.

*Julius 29,127/34*: In mice, the production of skin cancers by topical application of tar was not prevented by a gonadotropic extract of pregnancy urine.

**Carcinogens** ←. *Cantarow et al. B18,774/46*: In rats given AAF p.o., the development of cystic and neoplastic hepatic lesions was accelerated and intensified by GTH (pregnant mare serum), estradiol, and testosterone, but inhibited by thiouracil. "This phenomenon may be related on the role of the liver in the intermediary metabolism and excretion of the sex steroid." In the hyperplastic target organs of the sex hormones tumors did not occur, in

contrast to the high incidence of tumors in the thyroids of rats given thiouracil simultaneously with the carcinogens.

*Stasney et al. B26,653/47*: In rats, 2-acetaminofluorene feeding produces mammary carcinoma only in females, and its development is not significantly accelerated by estradiol or gonadotrophin. "Malignant lesions of the liver occurred in 54.8 per cent of females and 92.3 per cent of males receiving the carcinogen alone. Administration of estradiol and PMS gonadotrophin to females and of testosterone and chorionic gonadotrophin to males intensified the cystic and neoplastic hepatic lesions induced by 2-acetaminofluorene."

*Weisburger et al. D18,583/64*: In rats fed a diet containing N-hydroxy-N-2-fluorenylaceta-mide, implantation of Furth's mammotropic tumor MtT/F4, as a source of pituitary hormones, accelerated hepatic carcinogenesis.

*Shirasu et al. F65,704/66*: In rats, the detoxication of N-hydroxy-N-2-fluorenylaceta-mide (N-OH-FAA) is inhibited by the transplantation of functional pituitary tumors which may account for their enhancing effect upon hepatic carcinogenesis.

**Cholesterol** ←. *Bruger & Fitz A15,324/38*: In cholesterol-fed rabbits, atheromatosis of the aorta is aggravated by chronic treatment with TTH. The severity of the lesions roughly parallels the blood cholesterol level.

*Turner & De Lamater A37,602/42*: In cholesterol-fed rabbits, TTH markedly reduces hypercholesterolemia even after thyroidec-tomy. [Vascular changes are not described (H.S.).]

*Stamler et al. B91,353/53*: In cholesterol-fed chicks, coronary atherosclerosis is prevented by estradiol even if the feminizing effects are eliminated by concurrent administration of testosterone. The protective effect of the folliculoid is not due to its effect upon blood cholesterol, since hypercholesterolemia remains uninfluenced by it, but estradiol elevates the plasma phospholipid levels. In itself, neither testosterone nor chorionic gonadotrophin affects coronary atherosclerosis under these conditions.

*Stamler et al. C81,655/58*: TTH—unlike thyroid preparations—failed to influence cholesterol atherosclerosis in cockerels.

**Emetine** ←. *de Gregorio & Armellini G64,277/64*: In rabbits, the production of cardiac lesions by emetine is inhibited by chorionic gonadotrophin and testosterone but not by estradiol.

*Scaffidi & Arrigo G62,941/68*: In rabbits, the cardiac lesions produced by emetine are

inhibited by various gonadotrophic hormone preparations.

**Ergotamine** ←. *Bolis E50,716/56*: In rats, various gonadotrophic preparations diminish the organ lesions produced by toxic doses of ergotamine.

*Messina G18,016/64*: In rats, ergotamine produces vascular lesions conducive to tail necrosis more readily in females than in males. Hypophysectomy prevents these toxic manifestations in both sexes, whereas treatment with chorionic gonadotrophin does not affect them.

**Ethionine** ←. *Farber & Segaloff D95,996/55*: In ovariectomized rats, various testoids and STH protected the liver against fatty infiltration produced by ethionine i.p., whereas cortisone and ACTH aggravated it. Estradiol, DOC, and TTH had no effect.

**Glycine** ←. *Hay 93,491/47*: In rats, the hepatotoxic and nephrotoxic actions of glycine-enriched diets are not significantly modified by crude anterior pituitary extracts.

**Lathyrogens** ←. *Selye C31,369/57*: In the rat, the osteolathyrisms produced by AAN is aggravated by STH, LTH, and partial hepatectomy, but it is inhibited by ACTH, cortisol, or estradiol.

**Morphine** ←. *Benetato et al. 33,773/35*: In rats, neither adrenocortical extract nor an adrenotrophic anterior pituitary preparation altered resistance to morphine or to thyphoid-parathyphoid vaccine.

**p-Nitrobenzoic Acid** ←. *Wilson G63,125/68*: In young rats, transplants of a pituitary mammatropic tumor "did not prevent an increase in the liver microsomal metabolism of hexobarbital or the formation of formaldehyde from aminopyrine which followed phenobarbital pretreatment. High levels of somatotropin, corticotropin, and prolactin in blood, or possibly some other unknown factors produced by this tumor, appeared to prevent the normal development of the liver enzyme system which metabolized hexobarbital, aminopyrine, and p-nitrobenzoic acid in the rat."

**Reserpine** ←. *Wirtheimer D10,158/59*: In rats, the production of gastric ulcers by reserpine is enhanced following pretreatment with various impure gonadotrophic hormone preparations.

**Vitamin A** ←. *Schneider & Widmann 33,725/35*: In guinea pigs, both thyroidectomy and treatment with TTH considerably alter vitamin-A metabolism.

*Mayer & Goddard B55,008/51*: In rats deficient in vitamin A, the atrophy of the accessory sex organs is abolished by chorionic gonadotrophin, suggesting that the defect is not due to an inability of the gonads to secrete testoids but to inadequate pituitary gonadotrophin secretion.

*Selye C36,050/57*: In rats, the intense osteoclastic bone absorption produced by vitamin-A overdosage can be prevented by STH. Although the luteotrophic hormone (LTH) shares many of the actions of STH, it cannot substitute for the latter in counteracting vitamin-A intoxication.

**Vitamin C** ←. *Agnoli 2,633/32*: In guinea pigs, neither crude pituitary extracts nor urinary gonadotrophins ameliorate the course of scurvy on vitamin-C deficient diets.

**Varia** ←. *Störtebecker 76,398/39*: Review of the early literature (1913—1937) on the effect of the pituitary upon drug resistance.

#### **Microorganisms and Their Products** ←

**Bacteria** ←. *Weinstein B15,029/39*: In mice, various anterior pituitary preparations protect against infection with *B. anthracis*. Parathyroid extract was also very effective, whereas thyroxine and testosterone offered little protection while progesterone, insulin, "estrin" and posterior lobe extract were virtually ineffective.

*Weinstein A33,940/40*: In mice, neither parathyroid extract nor a crude anterior pituitary preparation offered protection against infection with *Klebsiella pneumoniae*, but they did improve survival after inoculation of *E. coli* or *Ps. pyocyaneus*.

*Lurie et al. B31,933/49*: In rabbits, estradiol retards the progress of experimental tuberculosis at the portal of entry in the skin and diminishes its dissemination to internal organs, presumably by reducing the permeability of connective tissue. Chorionic gonadotrophin has an inverse effect.

*Lurie et al. B31,931/49; B31,932/49*: In highly inbred, sexually mature rabbits, estradiol retarded the progress of tuberculosis following i.c. inoculation. In immature rabbits, estradiol was less effective. LH accelerated the progress of the disease, whereas ovariectomy or progesterone remained without effect.

*Schäfer B99,955/54*: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to

the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas, and gonads.

*Youmans & Youmans B95,169/54*: In mice, cortisone markedly reduced the survival time after infection with human tubercle bacilli, and this effect could not be prevented by STH. Given alone, ACTH, STH, and TTH likewise failed to influence the course of the infection.

*Meier & Neipp C37,215/56*: In mice, the chemotherapeutic action of sulfonamides against resistant Type III pneumococci is increased by various gonadotrophic and STH preparations. However, certain bacterial polysaccharide fractions possess a similar effect, and hence, the latter is presumably not dependent upon the specific actions of the hormone preparations.

*Scherr C39,263/57*: In mice infected with *Candida albicans*, the development of moniliasis may be either increased or decreased by cortisone, depending upon various factors, particularly the severity of the infection, sex or pregnancy. Testosterone enhanced, and STH counteracted the deleterious effect of cortisone. Gonadotrophin (pregnant mare serum) was without effect.

**Bacterial Toxins** ←. *Ciulla & Razzini B50,987/39*: In guinea pigs, pretreatment with pregnancy urine gonadotrophins diminishes the lethal effect of diphtheria toxin.

*Tonutti B48,892/50*: In guinea pigs, diphtheria toxin produces marked hemorrhagic necrosis of the testes and ovaries only after pretreatment with gonadotrophic hormones.

*Scaffidi & Fidecaro G51,129/65; G43,543/66*: In guinea pigs, the cardiopathy produced by diphtheria toxin can be prevented by chorionic gonadotrophin and cocarboxylase.

### **Hypoxia** ←

*Houssay & Rietti 3,187/32; 3,283/32*: In rats pretreatment with an impure pituitary extract diminishes resistance against hypoxia, but this effect is abolished by thyroidectomy, and is presumably due to TTH. In untreated rats, thyroidectomy actually increases resistance to anoxia.

*Houssay & Rietti 5,793/32*: In guinea pigs, resistance to decreased oxygen pressure is diminished by anterior pituitary extract, presumably through its TTH content since the effect is abolished after thyroidectomy.

*Rotter A63,564/42*: In guinea pigs, altitude tolerance is greatly reduced by pretreatment with TTH.

### **Varia** ←

*Henriques et al. B24,140/48*: In rats sensitized by uninephrectomy, the production of hyalinosis and hypertension by crude anterior pituitary extracts is facilitated if the diet is rich either in protein or in amino-acids.

*Smith C46,496/56*: In brown trout, thyroxine raises, whereas thiourea and thiouracil reduce **salinity tolerance**. Anterior pituitary extracts and STH likewise raise salinity tolerance, whereas posterior lobe extracts, testosterone, gonadotrophin, TTH, and ACTH have no effect.

*Osipovich C58,570/57*: In **uninephrectomized** rats, methylthiourea enhances compensatory hypertrophy of the remaining kidney, presumably as a consequence of increased TTH secretion. The acceleration of compensatory renal hypertrophy by exposure to cold is ascribed to a similar mechanism.

*Glenn et al. G70,204/60*: Review (48 pp., 11 refs.) on the effect of various steroids, ACTH, GTH, ovariectomy and adrenalectomy upon the development of C3H mammary **carcinoma transplants** in mice and fibroadenomas in rats.

*Knigge C97,819/60*: Review on the neuroendocrine mechanisms influencing ACTH and TTH secretion particularly during adaptation to cold.

*Bucher G68,621/63*: Review on the influence of hypophysectomy and hypophysial hormones upon **hepatic regeneration**.

*Fisher & Fisher F74,176/66*: In rats, the incidence of metastases from Walker **tumor transplants** is not significantly altered by thyroidectomy, propylthiouracil, thyroxine or TTH.

*Preisig et al. F70,515/66*: In acromegalic patients, **biliary BSP excretion** is increased. [It is not known which, if any, of the hormones secreted by the hyperactive pituitary are responsible for this effect (H.S.).]

*Rinaudo et al. F95,471/67*: Studies on the induction of various **hepatic enzymes** by STH and LTH in toad tadpoles.

*Sakamoto & Prasad F95,441/67*: In mice and rats,  $\beta$ -MSH offers moderate protection against **X-irradiation** under certain conditions.

## ← POSTERIOR PITUITARY PREPARATIONS

In dogs and guinea pigs, vasopressor pituitary extracts offer partial protection against histamine intoxication. In rats, the production of renal cortical necrosis by vasopressin is greatly facilitated by 5-HT and folliculoids.

It has been claimed that vasopressor posterior pituitary extracts influence the toxicity of various drugs through different mechanisms. They may improve resistance to hypotensive drugs because of their vasopressor effect, or aggravate the toxicity of substances normally eliminated through the kidney, because of their antidiuretic action. However, none of these effects was shown to be sufficiently striking to have deserved extensive investigation, except for the well-known aggravation of water intoxication by vasopressin.

Under certain circumstances, vasopressin has also been claimed to offer protection against various infections, X-irradiation, hemorrhage, anoxia, electroshock and traumatic shock. On the other hand, vasopressin aggravates or fails to influence the damaging effect of various bacterial toxins, hyperoxygenation, and exposure to cold.

**Steroids** ← *cf. Selye C50,810/58, pp. 83, 84; C92,918/61, p. 124; G60,083/70, p. 334.*

**Hormones and Hormone-Like Substances** ←

*Best & Solandt A33,635/40:* In dogs, shock produced by histamine, trauma, or hemorrhage is successfully treated by vasopressor pituitary extracts.

*Kowalewski & Bain C3,897/54:* In guinea pigs, a vasopressor posterior pituitary extract given s.c., 10 min before the injection of histamine, prevented the induction of gastric ulcers, presumably because of an antagonistic interaction at the level of the vascular system.

**Drugs** ←

**Acetonitrile** ←. *Paal 22,603/30:* In mice, acetonitrile resistance is not consistently influenced by posterior pituitary extract (hypophysin), a folliculoid preparation (pro-gynon), or epinephrine.

**Barbiturates** ←. *Werle & Lentzen A28,007/38:* In dogs and rabbits, various vasoactive substances (epinephrine, histamine, vasopressin, kallikrein) tend to prolong the anesthetic effect of pronarcon and hexobarbital.

*Rümke G69,768/63:* In mice, small doses of vasopressin i.v. failed to prolong hexobarbital sleeping time.

**Hexobarbital** ← Vasopressin, Gp, Mouse: Lamson et al. C14,547/51\*; Rümke G69,768/63\*

**Pentobarbital** ← Vasopressin + H<sub>2</sub>O, Mouse: Borzelleca et al. C40,953/57\*

**Bromoethylamine Hydrobromide** ←. *Fuwa & Waugh F96,546/68:* In rats, the renal papillary necrosis produced by bromoethylamine hydrobromide is inhibited by vasopressin, presumably as a consequence of its antidiuretic effect.

**Carcinolytic Agents** ←. *Connors et al. G17,080/64:* In rats, Mannitol Myleran is normally excreted unchanged in the urine within 5 hrs after i.p. administration. Pretreatment with antidiuretic hormone potentiates both its lethal and antitumor action, presumably because it diminishes excretions.

**Chlorpromazine** ←. *Khrabrova D49,985/61:* In cats, electroshock is effectively antagonized by chlorpromazine if the hypotensive action of the latter is prevented by vasopressin.

**Chloral Hydrate** ←. *Fastier et al. C37,038/57:* In mice, chloral hydrate sleeping time is increased by epinephrine, norepinephrine, phenylephrine, methoxamine, 5-HT, histamine, ergotamine, yohimbine and atropine. "It is suggested that some, at least, of the drugs which prolong the effects of hypnotics do so by virtue of a hypothermic action." Vasopressin, cortisone, and DOC did not prolong chloral hydrate sleeping time at the doses tested.

**Cholesterol** ← *cf. also Selye G60,083/70, p. 335. Cooper & Gutstein F61,290/66:* In rabbits, calcific aortic atherosclerosis is produced by combined treatment with cholesterol and vasopressin.

**Digitalis** ←. *Ghedini & Ollino A21,128/14*: Brief mention of observations on rabbits showing that pretreatment with Pituitrin modifies the hemodynamic actions of digitalis "unfavorably" and those of strophantin "favorably." [For lack of details, these findings cannot be evaluated (H.S.).]

*Nash et al. G9,641/64*: In rats, the toxic cardiac effects of ouabain are antagonized by synthetic oxytocin and by reserpine.

**Ethanol** ←. *Baïssset & Montastruc D34,473/62; D37,918/62*: In dogs, the development of a polyuria and polydipsia, following administration of ethanol, as well as the gradual development of a craving for alcohol are prevented by vasopressor posterior lobe extract.

**Morphine** ←. *Gruber et al. 2,199/31*: In dogs, a vasopressor pituitary extract temporarily lowers the increased general tonus of the intestine produced by morphine.

*Adler et al. G79,852/57*: In Sprague-Dawley rats, given <sup>14</sup>C-labeled morphine, the ratio of bound to free morphine is 2–3 times greater in the urine and plasma than in Long-Evans rats. The tissues of adrenalectomized rats of both strains contain higher concentrations of <sup>14</sup>C-labeled morphine than do control rats. Plasma bound morphine levels indicate no impairment of morphine conjugation. Vasopressin increases, whereas ACTH decreases morphine sensitivity. Yet both after ACTH and after vasopressin, tissue concentrations of morphine are either reduced or unaffected in marked contrast to the increased values after adrenalectomy. Apparently, the decreased morphine sensitivity induced by ACTH is not reflected by lower brain morphine concentrations.

**Paraphenylenediamine** ←. *Meissner E52,567/19*: The head and neck edema produced by paraphenylenediamine in the rabbit is not prevented by epinephrine, posterior pituitary extract of thyroid extract.

**Pentylentetrazol** ←. *Boeri C78,610/58*: In guinea pigs, cortisone, ACTH, and vasopressin aggravate pentylentetrazol convulsions.

**Phosgene** ←. *Rothlin B30,696/47*: In rats, phosgene (COCl<sub>2</sub>) intoxication is effectively combated by posterior pituitary extract as well as by ergotamine, presumably as a consequence of their vasoconstrictor effect.

**Potassium** ← *cf. Selye C92,918/61, pp. 83, 124, 188.*

**Sodium Chloride** ←. *Baïssset et al. C55,475/57*: In the rat and dog, posterior pituitary extracts favorably influence the manifesta-

tions of chronic NaCl-overdosage and prolong survival.

*Baïssset et al. C84,788/58*: In rats and dogs, the effects of NaCl-overdosage are ameliorated by posterior pituitary extracts and aggravated by NaCl.

**Suxamethonium** ←. *Keil D27,254/62*: In rabbits, sheep and pigs, oxytocin did not modify resistance to suxamethonium.

**Strychnine** ←. *Marañón & Aznar 46,926/11*: In frogs, the fatal convulsions produced by strychnine can be prevented if, prior to injection, the drug is mixed with extracts of the posterior pituitary, the thyroid, various other tissues, and particularly epinephrine. [The possibility of delayed absorption owing to local vasoconstriction has not been considered (H.S.).]

**Vitamin D** ← *cf. Selye C92,918/61, pp. 124, 188; G60,083/70, pp. 335, 336.*

**Vitamin E** ←. *Houchin & Smith B6,967/44*: Rabbits deprived of vitamin E, show increased sensitivity to posterior pituitary extracts.

**Water** ←. *Liling & Gaunt 89,147/45*: In rats, vasopressin aggravates the manifestations of water intoxication, even if the animals are adapted by previous administration of water loads.

*Waltregny & Mesdjian F85,818/67*: In cats, combined treatment with "posterior lobe extract" s.c. and large amounts of distilled water i.p. produces a condition of epilepsy with a characteristic EEG as a consequence of water intoxication.

**Bacteria** ← *cf. also Selye G60,083/70, p. 335.*

*Lauber 9,102/32*: Observations on the effect of vasopressin, epinephrine, thyroid extract and insulin upon streptococcal and staphylococcal infections in mice.

*Weinstein B15,029/39*: In mice, various anterior pituitary preparations protect against infection with *B. anthracis*. Parathyroid extract was also very effective, whereas thyroxine and testosterone offered little protection, while progesterone, insulin, "estrin" and posterior lobe extract were virtually ineffective.

**Bacterial Toxins** ← *cf. also Selye G60,083/70, p. 335.*

*Bailey A1,154/17*: In rabbits, vasopressin aggravates the vascular lesions produced by diphtheria toxin.

*Altura et al. F43,209/65*: In rats, norepinephrine and angiotensin fail to prolong survival after traumatic shock, temporary ligation of the superior mesenteric artery, or

endotoxin shock. However, vasopressin (PLV-2) was significantly effective in traumatic and intestinal ischemia shock, but not in endotoxemia.

#### ***Ionizing Rays*** ←

*Gray et al. B68,316/52:* In rats, pretreatment with either epinephrine or vasopressin diminishes mortality after total body X-irradiation.

*Gray et al. B69,100/52:* In rats, pretreatment with vasopressin or epinephrine increases survival following exposure to lethal X-irradiation.

*Hervé D78,167/54:* In mice, an oxytocic posterior lobe preparation increases resistance against total body X-irradiation.

*Rigat C10,747/55:* Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation, with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

*Bacq & Beaumariage C87,128/60:* In mice, synthetic oxytocin (Syntocinon) increases resistance to total body X-irradiation.

#### ***Hemorrhage*** ←

*Best & Solandt A33,635/40:* In dogs, shock produced by histamine, trauma, or hemorrhage is successfully treated by vasopressor pituitary extracts.

*Cort et al. F23,086/64:* In dogs, various synthetic extended-chain analogues of vasopressin and oxytocin exert a beneficial effect upon hemorrhagic shock.

*Cort et al. F96,105/68:* In dogs, certain vasopressin analogues offer protection against hemorrhagic shock.

#### ***Hypoxia and Hyperoxygenation*** ←

*Campbell A14,903/37:* In rats exposed to six atmospheres of oxygen in a pressure chamber, subsequent decompression is better tolerated at low than at high external tempera-

tures. "Using an external temperature of 24°C and white rats of about 80 g, the following substances, administered subcutaneously, are found to enhance oxygen poisoning: thyroxine (0.4 mg), dinitrophenol (1.5 mg), ac-tetrahydro- $\beta$ -naphthylamine (0.5 c.c., 1 p.c.), adrenaline (0.02 mg), pituitary extract (posterior lobe, above 3.5 units), insulin (0.025 u.) and eserine (0.045 mg administered with atropine 0.075 mg). These doses in themselves are harmless."

*Parkes B63,024/51:* In mice, resistance to anoxia is increased by posterior lobe extract as well as by ACTH preparations containing posterior lobe principles.

#### ***Electric Stimuli*** ←

*Rosenblum C5,974/55:* In rats, "ACTH and cortisone acetate in combination with vasopressin each produced a greater fall in EST than was produced by vasopressin alone. In contrast, STH in combination with vasopressin prevented the fall induced by vasopressin alone and produced its usual elevation in the EST."

*Khrabrova D49,985/61:* In cats, electroshock is effectively antagonized by chlorpromazine if the hypotensive action of the latter is prevented by vasopressin.

#### ***Varia*** ←

*Best & Solandt A33,635/40:* In dogs, shock produced by histamine, trauma or hemorrhage is successfully treated by vasopressor pituitary extracts.

*Marino et al. D58,761/63:* In guinea pigs, the cardiopathy produced by vasopressin intoxication is aggravated by concurrent exposure to a **psychologic stress** situation (preconditioning followed by conflict situation).

*Zilberstein C80,282/60:* In rats, 5-HT, vasopressin and reserpine lower resistance to cold allegedly because they interfere with pituitary hormone secretion and cause a state of "temporary functional adrenalectomy."

### ← **HYPOPHYSECTOMY AND HYPOTHALAMIC LESIONS**

The effects of adrenalectomy, orchidectomy and ovariectomy are discussed with the steroids, since ablation of these glands acts upon resistance mainly by creating a lack of steroid hormones. On the other hand, hypophysectomy will be discussed here (immediately following the pituitary hormones) together with hypothalamic lesions, since both of these operations act upon resistance primarily through their

effect upon pituitary hormone secretion. Yet, it must be remembered that, secondarily, several hypophyseal principles (e.g., ACTH and the gonadotrophins) do influence susceptibility to damaging agents through their regulating effect upon steroid secretion.

### **Steroids ←**

It has long been noted that the hyalinosis, polyuria and hypertension produced by mineralocorticoids in rats (conditioned by uninephrectomy + NaCl) are prevented, or at least greatly diminished by hypophysectomy. STH, ACTH and TTH all play important roles in the pathogenesis of this syndrome (as do various steroids and thyroid hormones secreted under pituitary control); hence, it is not clear to what extent the prophylactic effect of hypophysectomy is due to the lack of one or the other hypophyseal hormone.

Phenobarbital increases the estradiol-metabolizing activity of hepatic microsomal enzymes in immature female rats. It also diminishes the uterotrophic effect of this folliculoid. Neither hypophysectomy nor adrenalectomy prevents this phenobarbital-induced estradiol resistance, indicating that the barbiturate does not act through the pituitary-adrenal axis.

In C3H mice, the females, unlike the males, regularly develop myocardial calcification following prolonged cortisol treatment; ovariectomy offers no protection but testosterone renders females more resistant. In hypophysectomized mice of this strain, neither cortisol nor ACTH produces myocardial calcification.

### **Nonsteroidal Hormones and Hormone-Like Substances ←**

In rats, the osteosclerosis produced by small doses of parathyroid extract is diminished but not prevented by hypophysectomy. From this it was first concluded that STH is not necessary for all types of tissue growth.

The osteitis fibrosa and soft-tissue calcification produced by acute overdosage with parathyroid extract (like that caused by DHT) in the rat is also inhibited by hypophysectomy, although the characteristic hypercalcemia is not markedly affected. Presumably, the pituitary acts mainly by altering the calcium avidity of the organic matrix.

Hypophysectomy partially protects the rat against the production of renal necroses by 5-HT. In hypophysectomized rats, the elevation of the EST, induced by 5-HT is preceded by hyperexcitability.

### **Steroids ←**

*Ventura & Selye C24,231/57:* In rats, the hyalinosis (nephrosclerosis, myocarditis, polyuria, edema, etc.) produced by chlorocortisol following conditioning by uninephrectomy + NaCl was prevented by hypophysectomy. However, at the same time, the production of pulmonary saprophytosis by chlorocortisol was enhanced. Apparently, in the absence of the hypophysis, the mineralocorticoid activities

are inhibited, whereas the glucocorticoid actions of the same steroid molecule are augmented.

*Forchielli et al. D75,874/58:* The rate of  $\Delta^4$  reduction of 11-desoxycortisol was 3—4-fold greater in female than in male rat liver homogenates and in microsomal fractions containing the  $\Delta^4$ -5 $\alpha$ -hydrogenase. Female rat liver contains only one  $\Delta^4$ -hydrogenase (5 $\alpha$ -microsomal), whereas the male liver contains the soluble  $\Delta^4$ -5 $\beta$ -hydrogenase as well. Ovariectomy caused no marked change in enzyme

titer, but hypophysectomy decreased it sharply. Curiously, ACTH, STH, and pregnant mare serum partially restored the enzyme level in the hypophysectomized rat. In young animals, increase in the titer of hepatic  $\Delta^4$ -5 $\alpha$ -hydrogenase occurs prior to puberty. This fact (like the negative results after ovariectomy) suggests an independence of enzyme regulation from ovarian hormones.

*Loströh C54,348/58*: Female mice of the C3H strain regularly develop myocardial calcification after prolonged cortisol treatment, whereas males are comparatively resistant. Ovariectomy offers no protection, but testosterone renders females more resistant. In hypophysectomized mice, neither cortisol nor ACTH produces myocardial calcification.

*Selye C39,319/58*: In rats, nephrocalcinosis produced by excess  $\text{NaH}_2\text{PO}_4$  p.o. is aggravated by estradiol, but even the severe calcification induced by this combined treatment is prevented by hypophysectomy.

*Levin et al. F75,365/67*: Phenobarbital increases the  $17\beta$ -estradiol-metabolizing activity of hepatic microsomal enzymes in immature female rats. The in vitro activity is paralleled by in vivo blockade of the estradiol-induced uterine weight increase. The phenobarbital-induced resistance to the uterine weight-increasing effect of estradiol is not prevented by adrenalectomy or hypophysectomy, indicating that the barbiturate does not act through the pituitary-adrenal axis.

*Salgado & Mulroy C84,321/59*: In rats, the cardiovascular changes produced by DOC following sensitization by uninephrectomy and NaCl are inhibited by hypophysectomy or thyroidectomy, although not all the lesions are blocked to an equal extent.

*Garg et al. G79,002/71*: In rats, PCN p.o. induces proliferation of SER even after hypophysectomy.

*Szabó et al. G79,024/71*: In rats, PCN increases resistance to indomethacin, hexobarbi-

tal, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

Adrenal Cortical Extract ← Hypophysectomy: Zauder B57,611/51\*

DOC, Progesterone ← Hypophysectomy: Chamorro A57,215/42\*

Estradiol ← Hypophysectomy + Phenobarbital: Levin et al. F75,365/67\*

### **Nonsteroidal Hormones and Hormone-Like Substances ←**

Parathyroid Hormone ←. *Selye et al. 30,634/34*; *Thomson et al. A239/34*: In rats, osteoblast proliferation and new bone formation following treatment with small doses of parathyroid extract and renal regeneration after uninephrectomy are diminished, yet not completely prevented by hypophysectomy. Apparently, STH is not necessary for all types of growth.

*Selye et al. D25,666/62*: In the rat, hypophysectomy greatly diminishes both soft tissue calcification and osteitis fibrosa produced by parathyroid extract or DHT. The hypercalcemia is not diminished by the absence of the hypophysis, and the latter may act by altering the metabolism of calcifiable organic matrix.

ACTH, Epinephrine ← Hypophysectomy: Zauder B57,611/51\*

5-HT ←. *Jasmin & Bois C92,099/60*: Hypophysectomy partially protects the rat against the production of renal infarcts by 5-HT. ACTH does not affect this change, cortisol aggravates it, whereas DOC and testosterone offer partial protection.

*de Salva D27,783/62*: The "EST elevating effect of serotonin and ephedrine in intact rats was preceded by hyperexcitability in hypophysectomized rats."

### **Drugs ←**

Much work has been done on the effect of the hypothalamus-pituitary system on barbiturate resistance.

In rats, thiopental sleeping time is greatly prolonged within two weeks after hypophysectomy. This increased sensitivity is restored towards normal by ACTH, DOC or testosterone. The depressant effect of phenobarbital and of several other muscle relaxants appears to be diminished after hypophysectomy.

The sedative action of hexobarbital and thiopental is diminished by tourniquet stress in intact but not in hypophysectomized or adrenalectomized rats. Various

observations suggest that "the stress effect on the duration of drug action is mediated through increased drug-metabolism." The stimulation of hepatic microsomal hexobarbital and pentobarbital metabolism by the antihistamine, chlorcyclizine, is not prevented in rats by hypophysectomy or by adrenalectomy plus castration; that is, removal of both steroid hormone-producing glands.

X-irradiation of the head considerably enhances the anesthetic effect of thio-pental, barbital and pentobarbital in the rat. The induction by phenobarbital of resistance to pentobarbital is not inhibited by cephalic X-irradiation. Irradiation of the head is just as effective as total body irradiation or hypophysectomy in inhibiting the rapid induction of hexobarbital-metabolizing microsomal oxidases by hexobarbital. Even X-irradiation in utero produces the same result. X-irradiation of pregnant rats results in male offspring deficient in hepatic microsomal hexobarbital-metabolizing enzymes, but still capable of responding to phenobarbital with increased enzyme activity. Apparently, "the ontogenic increase in enzyme activity is hormone-dependent, while that following phenobarbital administration is independent of hormonal regulation as evidenced by the response of hypophysectomized or sexually immature animals." Bilateral electrolytic lesions in the posterior hypothalamus inhibit hepatic hexobarbital oxidase activity in the same manner as does X-irradiation of the head or hypophysectomy.

The hepatic steatosis produced by  $\text{CCl}_4$  in rats is less completely prevented by hypophysectomy than by adrenalectomy.

The induction of hepatic damage, and even of hepatomas, by certain carcinogens is inhibited by hypophysectomy in the rat. As judged by the few published observations, certain carcinogens do, whereas others do not, induce hepatic microsomal drug-metabolizing enzymes after hypophysectomy or hypothalamic lesions in the rat.

In rats, hypophysectomy greatly diminishes the skeletal changes produced by lathyrogens, such as AAN. STH restores the ability of the skeleton to react even after hypophysectomy. It is concluded that the normal hormonal secretion of the hypophysis exerts a decisive influence on the development of osteolathyrism.

In weanling male rats, total body X-irradiation inhibits the development of hepatic microsomal enzymes which catalyze the oxidative desulfuration of the pesticide Guthion. Shielding of the liver or testes does not prevent this inhibition, whereas shielding of the head area does. Irradiation did not inhibit enzyme development in hypophysectomized rats. "Thus, the pituitary is necessary for the radiation effect, but involvement of the pituitary is not the result of a radiation-induced deficiency of pituitary hormones."

The nephrocalcinosis produced in rats by oral administration of large amounts of phosphates (e.g.,  $\text{Na}_2\text{HPO}_4$  or  $\text{NaH}_2\text{PO}_4$ ) or by  $\text{HgCl}_2$  is inhibited by hypophysectomy.

The nephrosis elicited by puromycin aminonucleoside in the rat is not completely prevented by hypophysectomy, but the associated hypercholesterolemia and hyperlipemia are diminished.

Hypophysectomy decreases survival in rats given excessive amounts of vitamin A but does not significantly affect the characteristic skeletal lesions.

Hypophysectomy greatly diminishes the soft-tissue calcification and osteitis fibrosa produced by DHT in rats, but does not significantly affect the associated hypercalcemia. Possibly, the effect of the pituitary is mediated through metabolic changes in the calcifiable matrix. The predominantly cortical nephrocalcinosis pro-

duced by vitamin-D<sub>2</sub> overdosage in the rat is not altered by hypophysectomy. The calciphylaxis elicited by combined treatment with DHT and CrCl<sub>3</sub> is prevented by hypophysectomy in the rat.

Chlorcyclizine shortens the duration of action and increases the hepatic microsomal metabolism of zoxazolamine in male rats. These effects are not prevented by hypophysectomy or adrenalectomy + castration. However, the depressant action of zoxazolamine is diminished after hypophysectomy.

### **Acrylonitrile**

*Szabó & Selye G79,010/71:* In rats, pretreatment with ACTH (but not with STH) prevents the production of adrenal apoplexy by acrylonitrile. Hypophysectomy protects against adrenal apoplexy, but not against mortality under similar conditions.

Aminopyrine ← Hypophysectomy + Pesticides: Hart et al. G27,102/65

### **Atropine ←**

*de Salva D27,783/62:* "Atropine and diphenhydramine had no effect in intact rats but produced lowered EST in hypophysectomized rats."

### **Barbiturates ←**

*Waltz et al. C11,847/55:* In rats, thiopental sleeping time is greatly prolonged within about two weeks after hypophysectomy. This increased sensitivity is restored towards normal by ACTH, DOC, or testosterone.

*de Salva D27,783/62:* "Drugs with skeletal muscle relaxant properties (phenobarbital, meprobamate, phenaglycodol, mephensin, and zoxazolamine) were less effective as depressants after hypophysectomy than they were in intact rats."

*Rupe et al. E26,910/63:* The sedative effect of hexobarbital and thiopental, but not of barbital, was diminished by tourniquet stress, in the intact, but not in the hypophysectomized or adrenalectomized rat. In intact rats, ACTH or cortisone decreases hexobarbital sleeping time, as does stress, whereas SKF 525-A completely blocks the protective action of stress. Presumably "the stress effect on the duration of drug action is mediated through increased drug metabolism."

*Conney et al. D52,543/61:* Pretreatment of male rats with chlorcyclizine shortens the duration of action and increases the hepatic microsomal metabolism of hexobarbital, pento-

barbital and zoxazolamine. These effects were not prevented by hypophysectomy or adrenalectomy combined with castration.

*Bousquet et al. F35,073/65:* In rats, stressed by application of a tourniquet to one hind leg, the duration of response to hexobarbital, pentobarbital, meprobamate and zoxazolamine is significantly reduced, but only in the presence of both the pituitary and the adrenal glands. Pretreatment with ACTH or corticosterone simulates the effects of stress in shortening hexobarbital anesthesia. "It is suggested that the pituitary-adrenal axis serves a regulatory function with respect to duration of drug responses which may be mediated by an alteration of drug metabolism."

*Nair et al. F53,576/65:* In the rat, X-irradiation of the head considerably enhanced the anesthetic effect of thiopental, barbital, and pentobarbital. The induction by phenobarbital of resistance to subsequent pentobarbital anesthesia was not inhibited by cephalic X-irradiation.

*Nair & Bau G67,246/67:* Exposure of rats to X-irradiation in utero or during early postnatal life suppresses the hexobarbital-metabolizing enzyme system in the liver. Hypophysectomy or irradiation of the head (but not of the body with the head shielded) has a similar effect in adult rats.

*Yam & DuBois G58,163/67:* In 23-day-old male rats, X-irradiation of the whole animal or the head only inhibited the rapid increase in hexobarbital-metabolizing hepatic microsomal oxidase normally obtained by hexobarbital treatment. Hypophysectomy produced the same result.

*Nair et al. G67,245/68:* X-irradiation of pregnant rats results in male offspring deficient in the hepatic microsomal enzymes which metabolize hexobarbital. However, irradiation did not suppress the increase of enzyme activity brought about by chemical inducers (phenobarbital). Actinomycin inhibited both the ontogenic and phenobarbital-induced increases in enzyme activity. "The ontogenic

increase in enzyme activity is hormone-dependent, while that following phenobarbital administration is independent of hormonal regulation as evidenced by the response in hypophysectomized or sexually immature animals. It is concluded from these results that the inhibitory effect of x-irradiation on the hepatic enzyme system is mediated through an action on the hormonal regulation of enzyme activity."

*Nair et al. G67,250/69:* Hepatic hexobarbital oxidase activity is inhibited by head X-irradiation, hypophysectomy, or bilateral electrolytic lesions in the posterior hypothalamus. The in vitro data were verified by measurements of the hexobarbital sleeping time. "It is suggested that the microsomal enzyme system metabolizing hexobarbital is normally under the regulatory control of hypothalamo-hypophyseal hormonal activity. The light dependent circadian rhythm for this enzyme, recently reported by us, is also consistent with this interpretation."

*Norton G80,572/71:* Hypophysectomized rats can become dependent upon barbital and show the same withdrawal symptoms as intact animals. In barbital-dependent rats, the liver, thyroid, adrenals and secondary sex organs are enlarged but the gonads regress. The hepatic enlargement is also evident after hypophysectomy.

*Szabó et al. G79,024/71:* In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

Hexobarbital ← Hypophysectomy: Conney et al. *D52,543/61*; Bousquet et al. *F35,073/65\**; Yam et al. *G58,163/67*; Nair et al. *H21,083/70\**

#### Benactyzine ←

*de Salva D27,783/62:* In hypophysectomized rats, the EST elevating effects of reserpine, mescaline, benactyzine and phenyltoloxamine were replaced by an EST lowering action.

Bilirubin ← Hypophysectomy + Barbital, Mouse: Catz et al. *H14,471/68*

#### Cadmium ←

*Pařízek D23,927/60:* In rats, cadmium intoxication elicits the usual testicular lesions

even if administered 3 months after hypophysectomy.

#### Carbon Tetrachloride ←

*Furukawa F71,711/65:* In rats, hepatic steatosis produced by  $\text{CCl}_4$  is inhibited by adrenalectomy and, to some extent, also by hypophysectomy. The effect of  $\text{CCl}_4$  after adrenalectomy is restored by corticoids but not by epinephrine which increases only the action of the former. STH does not counteract the effect of hypophysectomy. Alloxan diabetes inhibits  $\text{CCl}_4$ -induced hepatic lipidosis.

#### Carcinogens ←

*Lacassagne & Nyka 59,016/36:* Rabbits, whose pituitary was destroyed by radium, become singularly resistant to the production of papillomas by painting of the ears with benzopyrene or tar.

*Korteweg & Thomas A33,075/39:* In mice, hypophysectomy delays but does not prevent the growth of transplanted mammary carcinomas or the induction of cutaneous neoplasms caused by painting the skin with 3:4-benzopyrene.

*Moon et al. B74,251/52:* In rats hypophysectomized two weeks before s.c. implantation of methylcholanthrene pellets, the development of sarcomas was almost completely prevented.

*Griffin et al. B77,163/53:* In rats, hypophysectomy inhibits the induction of liver damage and hepatomas by 3-methyl-4-dimethylaminoazobenzene (3'-Me-DAB).

*Richardson et al. C2,406/53:* In rats, hypophysectomy interferes with the production of hepatic cancers by 3'-Me-DAB.

*Robertson et al. B88,672/53:* In rats, hypophysectomy prevents the production of hepatic cirrhosis and hepatomas by 3'-Me-DAB. The susceptibility to tumorigenesis is restored by ACTH, but not by CON, DOC or testosterone. These hormones likewise failed to prevent carcinogenesis in intact rats.

*Richardson et al. B99,907/54:* In hypophysectomized rats, 3'-Me-DAB failed to produce hepatomas. Conjoint treatment with ACTH + STH partially restored the carcinogenic activity. Other pituitary preparations, cortisone, testosterone and DOC were ineffective. Earlier literature on the effect of hypophysectomy on carcinogenesis is reviewed.

*Robertson et al. E61,212/54:* In rats, hypophysectomy inhibits the carcinogenic action of azo dyes. ACTH, STH and, to a lesser

extent, TTH and GTH restored this activity. DOC permitted the development of cirrhosis and bile duct adenomas in carcinogen-treated hypophysectomized females, whereas testosterone and vasopressin were inactive.

*Griffin et al. C 14,406/55:* In rats, the hepatic carcinogenesis normally induced by 3'-Me-DAB is prevented by hypophysectomy, but may be restored by subsequent treatment with either ACTH or STH. The literature on the effect of various hormones upon the induction of neoplasms by carcinogens is reviewed.

*Conney et al. D 87,867/56:* Injection of 3-methylcholanthrene (3-MC) i.p. greatly increases the ability of rat liver homogenates to N-demethylate 3-methyl-4-monomethylaminoazobenzene and to reduce the azo linkage of 4-demethylaminoazobenzene. Neither of these activities was altered after adrenalectomy, but both systems were slightly depressed after hypophysectomy.

*O'Neal & Griffin, C 31,971/57:* In rats, hypophysectomy prevents the induction of hepatomas by 3'-methyl-4-dimethyl-aminoazobenzene. The hepatoma induction by diacetylaminofluorene (DAAF) is also reduced though not abolished by hypophysectomy, but the induction of facial tumors by DAAF is not impeded in the absence of the pituitary. "The development of hepatic neoplasms is apparently regulated by the pituitary gland, while the mechanism of face tumor carcinogenesis by the same compound is independent of this endocrine system."

*Huggins et al. C 62,178/59:* In rats, mammary carcinomas induced by 3-MC involute following ovariectomy or hypophysectomy and, hence, they may be regarded as "hormone-dependent." Similar regression of tumors is frequently achieved by dihydrotestosterone. Only few mammary cancers continue to grow after ovariectomy and these are considered to be "hormone-independent."

*Dao & Sunderland D 79,860/59; Dao et al. E 57,368/60:* In rats, the induction of mammary carcinomas by 3-MC is enhanced during pregnancy, pseudopregnancy, and progesterone treatment. Regression of neoplasms occurs after parturition. Males are virtually resistant. In fully formed tumors, regression could be induced by hypophysectomy or ovariectomy.

*Kim & Furth H 31,205/60:* In rats, the induction of mammary cancers by 3-MC is considerably inhibited by ovariectomy or hypophysectomy. Grafts of functional mammatropic pituitary tumors counteract the inhibitory effect of hypophysectomy in that they not only

stimulate the growth of involuting preexisting cancers, but also cause the appearance of new mammary tumors.

*Bielschowsky D 10,255/61:* In rats, hypophysectomy, thyroidectomy and adrenalectomy inhibit the development of hepatomas by treatment with 2-acetylaminofluorene (AAF) or 2-aminofluorene (AF).

*Bock & Dao D 11,892/61:* In rats, 3-MC accumulation in the mammary glands is increased by hypophysectomy or ovariectomy, but diminished during pregnancy. The affinity of mammary tissue for certain carcinogens may be due to its close association with adipose tissue.

*Seguy et al. D 5,238/61:* In rats, high doses of folliculoids enhanced the carcinogenic action of benzpyrene. Hypophysectomy or ovariectomy did not significantly influence this type of carcinogenesis, but the number of animals used was very small.

*Goodall G 77,088/62:* In rats, the production of hepatomas by AF is prevented by hypophysectomy or thyroidectomy. Cortisone restores the ability of the thyroidectomized but not of the hypophysectomized rats to develop hepatomas after AF treatment. Cortisone strongly accelerates the appearance of hepatomas in intact rats.

*Morii & Huggins D 45,369/62:* In rats, the adrenal necrosis produced by DMBA is prevented by hypophysectomy performed three weeks earlier. ACTH (but not STH) restores the susceptibility of the adrenals in the absence of the pituitary.

*Sterental et al. D 61,608/63:* In rats, mammary tumors induced by DMBA regressed after adrenalectomy + ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy + ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Huggins & Sugiyama F 44,582/65:* In rats, DMBA produces no adrenocortical necrosis if the animals are immature or hypophysectomized. ACTH renders the adrenals of immature rats susceptible to this type of injury.

*Morii G 34,628/65:* Pretreatment with small amounts of ACTH failed to protect the rat against DMBA-induced adrenocortical apoplexy. However, administration of ACTH to young rats or to hypophysectomized adults, which normally do not respond to the corticolytic effect of DMBA, makes them susceptible.

*Shimazu G31,110/65*: 20-Methylcholanthrene increases hepatic dimethylaminoazobenzene-demethylase in the rat, even after adrenalectomy, ovariectomy, or hypophysectomy. Hypothalamic lesions decrease the basal level of the enzyme and its response to methylcholanthrene. On the other hand, glutamine synthetase (a microsomal enzyme not induced by methylcholanthrene) is unaffected by hypothalamic lesions.

*Huggins & Grand F74,177/66*: In rats, neither hypophysectomy nor orchidectomy causes regression of DMBA-induced mammary cancers.

*Raitschew G76,731/70*: In hamsters, homo-transplantation of a pituitary into the kidney increases the number of melanomas produced under standardized conditions by DMBA.

*Somogyi G70,416/70*: In rats, spironolactone inhibits the adrenocortical necrosis, carcinogenicity and hemopoietic-tissue-damaging action of DMBA. Ethylestrenol, CS-1 and norbolethone are also effective against the DMBA-induced adrenal necrosis. Spironolactone likewise protects against the adrenocortical effect of 7-OH-MBA. Thus, the anti-DMBA action of spironolactone does not seem to be based on the blockade of the transformation of the carcinogen into this supposedly more active metabolite. The preventive action of spironolactone is abolished by ethionine, suggesting the involvement of active protein synthesis. The DMBA-induced adrenal lesions are aggravated by estradiol, testosterone, methyltestosterone, cortisol, triamcinolone, and prednisolone, as well as by the stress of muscular work or restraint. The aggravation of adrenal necrosis by estradiol is diminished but not abolished by hypophysectomy.

*Somogyi & Kovacs G60,074/70*: In rats, hypophysectomy does not abolish the aggravation of DMBA-induced adrenal necrosis but diminishes its intensity.

*Oka & Huggins H36,569/71*: In rats, 7,8,12-trimethylbenz(a)-anthracene elicits an erythroblastic leukemia which regresses considerably after hypophysectomy.

Dimethylaminoazobenzene ← Hypophysectomy: Conney et al. *D87,867/56*; Gelboin et al. *D81,074/58\**; Shimazu et al. *G76,684/59\**, *G31,110/65*

7,12-Dimethylbenz(a)anthracene ← Hypophysectomy: Huggins et al. *D13,007/61\**; Morii et al. *D45,369/62\**; Ford et al. *D69,790/63\**

3-MC ← Hypophysectomy: Moon et al. *B74,251/52\**; Dao *G37,357/64\**

### Cerium ←

*Snyder et al. C99,417/59*: In rats, i.v. injection of cerium produced extremely high levels of liver fat in females but not in males. After castration, males reacted as strongly as females. Testosterone reduced fatty infiltration in both intact and ovariectomized females. Hypophysectomy prevented fatty liver formation in both sexes, whereas adrenalectomy did so only in males.

Chlorpromazine ← Hypophysectomy + Chlordane: Hart et al. *G27,102/65*

### Cycloheximide ←

*Fiala & Fiala F33,398/65*: In rats, cycloheximide increases microsome-bound hepatic RNA, but this effect is prevented by hypophysectomy.

### Digitalis ←

*Szabó et al. G79,024/71*: In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

### Diphenhydramine ←

*de Salva D27,783/62*: Diphenhydramine produces lowered EST in hypophysectomized but not in intact rats.

### Diphenylhydantoin ←

*de Salva D66,177/63*: In rats, hypophysectomy decreases the EST raising effect of diphenylhydantoin.

### Ephedrine ←

*de Salva D27,783/62*: The "EST elevating effect of serotonin and ephedrine in intact rats was preceded by hyperexcitability in hypophysectomized rats."

### Ergot ←

*Messina G18,016/64*: In rats, ergotamine produces vascular lesions conducive to tail necrosis more readily in females than in males. Hypophysectomy prevents these toxic manifestations in both sexes, whereas treatment with chorionic gonadotrophin does not affect them.

**Hexadimethrine ←**

*Tuchweber et al. D27,884/63:* In rats, hypophysectomy prevents the nephrocalcinosis, but aggravates the adrenal necrosis produced by hexadimethrine. ACTH-treatment of the hypophysectomized rat facilitates the production of nephrocalcinosis, but protects the adrenal. Adrenalectomy prevents this form of nephrocalcinosis even in rats maintained on NaCl or DOC. On the other hand, triamcinolone-treated adrenalectomized rats react to hexadimethrine with strong nephrocalcinosis. Under similar conditions in intact rats, the corticoids did not significantly change the syndrome of hexadimethrine intoxication, except that the anaphylactoid reaction to this compound was inhibited by triamcinolone.

**Indomethacin ←**

*Szabó et al. G79,024/71:* In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

**Lathyrogens ←**

*Selye & Ventura C27,684/57:* In rats, hypophysectomy greatly diminished the development of osteolathyrism normally produced by AAN but STH aggravates these bone lesions even more in the absence than in the presence of the pituitary. It is concluded that the normal hormonal secretion of the hypophysis exerts a decisive influence on the development of osteolathyrism.

*Selye C31,369/57:* Hypophysectomy greatly delays the development of osteolathyrism in rats treated with AAN but simultaneous administration of STH results in bone lesions even more severe than those of intact AAN-treated controls.

*Bois et al. E29,177/63:* In rats with lathyrism induced by AAN, the increased mitotic rate in the epiphysial cartilages is prevented by hypophysectomy and restored by subsequent STH administration. STH appears to be indispensable for the development of osteolathyrism.

**Magnesium ←**

*Jasmin E7,631/68:* In rats, certain manifestations of the magnesium-deficiency syndrome are inhibited by cortisol, hypophysectomy or thyroparathyroidectomy.

**Meprobamate ←**

*de Salva D27,783/62:* "(1) Drugs with skeletal muscle relaxant properties (phenobarbital, meprobamate, phenaglycodol, mephensin, and zoxazolamine) were less effective as depressants after hypophysectomy than they were in intact rats; (2) threshold elevating effects in intact rats of reserpine, mescaline, benactyzine and phenyltoloxamine were replaced by a EST lowering action."

*Kato & Vassanelli D40,237/62:* "Rats pretreated with phenobarbital, phenaglycodol, glutethimide, nikethamide, chlorpromazine, trifluorpromazine, meprobamate, carisprodol, pentobarbital, thiopental, primidone, chlore-tone, dyphenylhydantoin and urethane showed an accelerated metabolism of meprobamate and, at the same time, a diminished duration of sleeping time and paralysis due to meprobamate." SKF 525-A counteracted these actions of the enzyme inducers. In hypophysectomized or adrenalectomized rats, phenobarbital still increased meprobamate metabolism in vitro.

**Mercury ←**

*Szabó & Selye G70,478/70:* In rats, hypophysectomy greatly diminishes the nephrocalcinosis produced by HgCl<sub>2</sub>. This effect of HgCl<sub>2</sub> is completely abolished in hypophysectomized rats treated with triamcinolone.

**Morphine ←**

*Tanabe & Cafruny C48,625/58:* "The ability of hypophysectomized rats to tolerate large doses of morphine and morphine-withdrawal stresses did not seem to be impaired."

Morphine ← Hypophysectomy: Zauder B57,611/51\*

p-Nitrobenzoic Acid ← Hypophysectomy + Pesticides: Hart et al. G27,102/65

**Ozone ←**

*Fairchild et al. E32,187/63:* In rats, hypophysectomy protects against the production of pulmonary edema by ozone inhalation. This effect is not abolished by ACTH or TTH and may be dependent upon the posterior lobe.

*Fairchild G71,531/63:* Review (6 pp., 26 refs.) on the effect of thyroidectomy, thiourea, thyroid hormones, glucocorticoids and hypophysectomy upon the resistance of various species to inhaled irritants, especially ozone.

**Pesticides** ←

*DuBois et al. B3,089/47:* In rats, both insulin and hypophysectomy antagonize the hyperglycemic effect of ANTU, but do not prolong survival.

*Hietbrink & DuBois F65,296/66:* In weanling male rats, total body X-irradiation inhibits the development of hepatic microsomal-enzyme fraction that catalyzes the oxidative desulfuration of Guthion. Shielding of the liver and testes does not prevent this inhibition, whereas irradiation of the head area—while the remainder of the body is shielded—produces a degree of inhibition similar to that obtained by total body irradiation. “The same dose of irradiation did not inhibit the enzyme development in hypophysectomized weanling rats. Thus, the pituitary is necessary for the radiation effect, but involvement of the pituitary is not the result of a radiation-induced deficiency of pituitary hormones.”

*Szabo & Selye G70,497/70:* In rats, various catatoxic steroids, and particularly PCN, offer protection against intoxication with parathion and dioxathion. This protective effect is not prevented by hypophysectomy.

Guthion ← Hypophysectomy + X-irradiation: *Hietbrink et al. F65,296/66*

**Phenaglycodol, Phenyltoloxamine** ←

*de Salva D27,783/62:* “(1) Drugs with skeletal muscle relaxant properties (phenobarbital, meprobamate, phenaglycodol, mephedrin, and zoxazolamine) were less effective as depressants after hypophysectomy than they were in intact rats; (2) threshold elevating effects in intact rats of reserpine, mescaline, benactyzine and phenyltoloxamine were replaced by an EST lowering action.”

**Phosphates** ←

*Selye et al. C16,047/56:* In rats, hypophysectomy inhibits the development of nephrocalcinosis after the administration of large amounts of  $\text{Na}_2\text{HPO}_4$  p.o. or  $\text{NaH}_2\text{PO}_4$  by the “granuloma-pouch” technique. However, the atrophy of the outer renal cortex, induced by repeated injections of hypertonic phosphate solutions into the granuloma pouch, is not prevented by hypophysectomy.

*Selye C39,319/58:* In rats, nephrocalcinosis produced by excess  $\text{NaH}_2\text{PO}_4$  p.o. is aggravated by estradiol, but even the severe calcification induced by this combined treatment is prevented by hypophysectomy.

**Puromycin Aminonucleoside** ←

*Oliver & Kelsch F25,772/64:* In rats, the development of the nephrotic syndrome produced by puromycin aminonucleoside (PAN) is not prevented by hypophysectomy.

*Hoak et al. F61,136/65:* In rats with nephrosis induced by PAN the usual hypercholesterolemia and hyperlipemia are inhibited by hypophysectomy.

**Reserpine** ←

*de Salva D27,783/62:* In hypophysectomized rats, the EST-elevating effects of reserpine, mescaline, benactyzine and phenyltoloxamine were replaced by an EST-lowering action.

*Efron D59,758/62:* In rats, adrenalectomy greatly decreases resistance to reserpine, whereas hypophysectomy leaves it almost unchanged. It is assumed therefore, “that the increased toxicity of reserpine in adrenalectomized rats is related to the absolute lack of certain adrenal steroids, which in some way may condition the nervous system to the effects of the drugs, rather than to the inability of the pituitary-adrenal system to respond to so-called ‘nonspecific stress’ caused by the drug.”

Strychnine ← Hypophysectomy: *Kato et al. G74,030/62*

**Vitamin A** ←

*Wolbach & Maddock B83,297/52:* In rats, hypophysectomy decreases survival during vitamin-A overdosage, but does not significantly affect the skeletal response characteristic of this type of hypervitaminosis, except that bone repair processes are inhibited.

**Vitamin D, DHT** ←

*Selye et al. D20,710/62:* In rats, hypophysectomy greatly inhibits the development of calciphylaxis following combined treatment with DHT +  $\text{CrCl}_3$ .

*Selye et al. D25,666/62:* In the rat, hypophysectomy greatly diminishes both soft tissue calcification and osteitis fibrosa produced by parathyroid extract or DHT. The hypercalcemia is not diminished by the absence of the hypophysis and the latter may act by altering the metabolism of calcifiable organic matrix.

*Bekemeier & Leiser D65,289/63:* Vitamin- $\text{D}_2$  overdosage produces predominantly cortical nephrocalcinosis in intact, adrenalectomized, or hypophysectomized rats. Additional treatment with dienestrol (an artificial folliculoid)

shifts calcium deposition predominantly to the cortico-medullary junction, irrespective of the presence or absence of the hypophysis or adrenals.

Water ← Hypophysectomy, Dog:  
Bodo et al. 88,791/45\*

#### **Zoxazolamine ←**

Conney et al. D52,543/61: Pretreatment of male rats with chlorcyclizine shortens the duration of action and increases the hepatic microsomal metabolism of hexobarbital, pentobarbital and zoxazolamine. These effects were

not prevented by hypophysectomy or adrenalectomy combined with castration.

de Salva D27,783/62: "(1) Drugs with skeletal muscle relaxant properties (phenobarbital, meprobamate, phenaglycodol, mephensin, and zoxazolamine) were less effective as depressants after hypophysectomy than they were in intact rats."

Szabó et al. G79,024/71: In rats, PCN increases resistance to indomethacin, hexobarbital, progesterone, zoxazolamine and digitoxin, both in the presence and in the absence of the pituitary. Hypophysectomy also fails to prevent the induction of SER proliferation in the hepatocytes.

### **Microorganisms, Bacterial Toxins and Venoms ←**

Hypophysectomy greatly diminishes the resistance of the rat to tuberculosis and this induced susceptibility can be abolished by STH. In guinea pigs, hypophysectomy reduces resistance even to the toxic actions of killed tubercle bacilli, a defect which cannot be corrected by DOC or cortisone. After hypophysectomy, cortisone is even more effective in protecting mice against endotoxin shock than in the presence of the pituitary, but reserpine fails to block endotoxin shock after hypophysectomy. It has been claimed, however, that resistance to endotoxin is actually increased a few hours after hypophysectomy or adrenalectomy in the mouse. The low endotoxin resistance of hypophysectomized rats is not corrected by parabiosis with an intact partner.

The resistance of the rat to cobra venom is reduced by about 2/3 after hypophysectomy.

#### **Tuberculosis ←**

Steinbach et al. B7,316/44: In rats, hypophysectomy greatly diminishes resistance to experimental tuberculosis.

Tonutti & Felzer B75,190/52: In guinea pigs, hypophysectomy greatly reduces resistance to the toxic actions of killed tubercle bacilli. This defect is uninfluenced by DOC, but abolished by cortisone, although the latter accelerates dissemination of living tubercle bacilli.

Gillissen & Busanny-Caspari C6,858/53: In guinea pigs and rabbits, hypophysectomy did not significantly influence the course of tuberculosis [Only three animals of each species were used (H.S.).]

Bisetti & Barbolini D12,624/61: Rats which are normally highly resistant to infection with tuberculosis bacilli, become sensitive after hypophysectomy. This induced

susceptibility can be abolished by STH. To a much lesser extent ACTH also offers some protection.

#### **Bacterial Toxins ←**

Chedid & Parant D6,761/61: The protection of intact mice against endotoxin shock by cortisone is inhibited by reserpine. The same is true in adrenalectomized rats, whereas after hypophysectomy cortisone is even more effective in offering protection against endotoxin, but reserpine no longer blocks this effect. Apparently the drug interferes with the cortisone effect only in the presence of the pituitary.

Parant D82,116/62: In mice, resistance to endotoxin is greatly increased a few hours after adrenalectomy or hypophysectomy. Cortisone protects normal, adrenalectomized, and hypophysectomized animals against high

doses of endotoxin, whereas chlorpromazine is effective only in the presence of both the adrenals and the pituitary. ACTH also protects the hypophysectomized mouse but only if slow absorption is assured.

*Chedid et al. D57,924/63*: The low resistance of hypophysectomized rats to endotoxin

is not corrected by parabiosis with an intact partner.

#### **Venoms ←**

*Ball & Samuels 7,404/32*: In rats, hypophysectomy is estimated to diminish resistance to cobra venom to about 2/3 of the norm.

### **Immune Reactions ←**

In rats, hypophysectomy does not significantly modify antibody production after treatment with various antigens. On the other hand, fatal anaphylactic shock can be produced in hypophysectomized, but not in intact, rats. In guinea pigs, anaphylactic reactivity can be suppressed by anterior hypothalamic lesions, perhaps through their effect upon adrenal and thyroid secretion.

### **Hepatic and Renal Lesions ←**

In rats and mice, hypophysectomy does not abolish the increase in hepatic polyploidy which occurs after **partial hepatectomy**, but it diminishes mitotic regeneration of the liver. This defect is corrected by STH, but further aggravated by cortisone.

Renal regeneration after **partial nephrectomy** is inhibited, but not abolished, by hypophysectomy in the rat. This observation first called attention to the fact that STH is not necessary for all types of growth.

The compensatory hypertrophy of the remaining kidney following uninephrectomy is diminished, but not abolished, by hypophysectomy in the rat and dog. However, if hypophysectomy precedes uninephrectomy by 15 days, the inhibition of regeneration is much less evidently suppressed. Presumably by that time, involution of the kidneys is already so pronounced that even mild compensatory hypertrophy is proportionately more evident. However, if hypophysectomy is performed two weeks after uninephrectomy, it causes severe involution of the remaining kidney.

#### **Immune Reactions ←**

*Molomut 76,648/39*: In rats, hypophysectomy does not significantly modify antibody production after treatment with various antigens. On the other hand, fatal anaphylactic shock could be produced in hypophysectomized but not in intact rats, though both groups of animals presented a similar antibody picture.

*Filipp & Mess G71,129/69*: In guinea pigs, suppression of anaphylactic reactivity by anterior hypothalamic lesions can be partially blocked by chronic treatment with thyroid hormones as well as by adrenalectomy or adrenal inactivation by metyrapone (Metopirone). "Combined treatment of guinea pigs bearing hypothalamic lesions with Metopirone

and thyroxine completely eliminated the blocking effect of the tuberal lesion on anaphylactic reactions." Apparently the shock-inhibiting effect of hypothalamic lesions is partly due to hypothyroidism and partly to hypoadrenalcorticoidism.

#### **Hepatic Lesions ←**

*Canzanelli et al. B37,729/49*: In rats, hypophysectomy delays liver regeneration after partial hepatectomy but "neither adrenalectomy nor the administration of adrenal-cortex extract has any effect on the amount of liver regeneration."

*Christensen & Jacobsen A 49,204/49*: In rats subjected to partial hepatectomy, neither hypophysectomy nor thyroidectomy impairs

the rate of regeneration. No significant change in mitotic rate was observed after pretreatment with stilbestrol or STH.

*Hemingway & Cater C56,780/58*: In rats subjected to hypophysectomy + partial hepatectomy, mitotic regeneration of the liver is inhibited. Cortisone further inhibits mitosis and causes nuclear degeneration. These changes can in turn be blocked by treatment with STH.

*Weinbren D95,941/59*: Review (11 pp., 110 refs.) and personal observations on factors influencing hepatic regeneration after partial hepatectomy in the rat, with special sections on the effects of hypophysectomy and thyroid hormones.

*Bucher G68,621/63*: Review on the influence of hypophysectomy and hypophysial hormones upon hepatic regeneration.

*Svartz G53,670/67*: Studies in rats and mice on the increase in hepatic polyploidy after partial hepatectomy. In the rat, hypophysectomy does not abolish polyploidization.

#### Renal Lesions ←

*Selye et al. 30,634/34*: In rats, osteoblast proliferation and new bone formation following treatment with small doses of parathyroid extract and renal regeneration after uninephrectomy are not prevented by hypophysectomy. Apparently, STH is not necessary for all types of growth.

*Gonzalez 79,025/38; A34,057/38*: In toads, hypophysectomy diminishes compensatory renal hypertrophy following uninephrectomy. This defect can be partially compensated by either anterior- or posterior-pituitary implants.

*McQueen-Williams & Thompson A33,938/40*: In rats, total hypophysectomy prevented the compensatory hypertrophy of the remaining kidney after uninephrectomy. Thyroidectomy did not prevent renal regeneration under identical conditions.

*Winternitz & Waters A34,910/40*: In dogs, hypophysectomy almost completely prevents

compensatory hypertrophy of the remaining kidney after uninephrectomy.

*Braun-Menendez & Houssay B45,945/49*: In rats, the compensatory hypertrophy of the remaining kidney following uninephrectomy is diminished but not abolished by hypophysectomy. The earlier literature on this topic is reviewed.

*Astarabadi & Essex B75,446/52*: In dogs, hypophysectomy diminishes, but does not completely abolish, compensatory hypertrophy of the remaining kidney after uninephrectomy.

*Astarabadi & Essex B86,411/53*: In dogs, the inhibition of compensatory renal hypertrophy following uninephrectomy is largely overcome by treatment with lyophilized anterior pituitary extract. In rats, hypophysectomy is less effective in inhibiting compensatory renal hypertrophy but treatment with pituitary extract fails to restore normal renal growth after hypophysectomy and uninephrectomy.

*Sandri et al. C13,150/55*: In rats, compensatory hypertrophy of the remaining kidney after uninephrectomy is greatly inhibited by hypophysectomy if the two operations are performed simultaneously, but not if hypophysectomy precedes uninephrectomy by 15 days. [Presumably by that time, involution of the kidneys is already so pronounced that even mild compensatory hypertrophy is proportionately more evident (H.S.).]

*Astarabadi D8,815/61*: In rats, hypophysectomy performed two weeks after uninephrectomy caused involution of the remaining kidney. "The results of the experiment suggest the presence of a renotropic principle in the hypophysis which is required for the compensatory renal hypertrophy." [At the time of hypophysectomy, compensatory hypertrophy was virtually complete, hence, the experiment merely confirms that hypophysectomy causes renal involution, a fact previously established on intact rats (H.S.).]

#### Various Stressors ←

In rats, resistance to total body X-irradiation is considerably decreased after hypophysectomy, although the characteristic polyuria and polydipsia of the first few days are diminished. The tendency to develop duodenal lesions under the influence of X-irradiation is not considerably altered by hypophysectomy in the rat, and ACTH does not consistently ameliorate the irradiation syndrome in the absence of the pituitary.

In hypophysectomized rats, sensitivity to cobalt irradiation is increased by testosterone and estradiol.

Goldfish also become unusually sensitive to X-irradiation after hypophysectomy.

Resistance to increased oxygen tension is enhanced by hypophysectomy, presumably because the thyroid function is diminished; administration of desiccated thyroid or thyroxine restores the high oxygen resistance of the hypophysectomized rat to normal.

Resistance to cold is decreased after hypophysectomy in the rat, but restored towards normal by cortical extract, ACTH, or TTH.

The EST is lowered in rats by hypophysectomy as it is by thyroidectomy or adrenalectomy.

The growth of Walker tumor transplants is essentially normal in hypophysectomized rats maintained on cortisol + DOC.

#### **Ionizing Rays ←**

*Tyree et al. B33,116/48; Patt et al. B33,711/48:* In rats, hypophysectomy decreases resistance to total body X-irradiation.

*Smith & Tyree C12,045/56:* In rats, the polydipsia and polyuria seen during the first days after X-irradiation tend to be inhibited by adrenalectomy or hypophysectomy.

*Baker et al. C56,998/58:* In rats, hypophysectomy does not significantly alter the duodenal lesions produced by total body X-irradiation.

*Ghys D70,483/62:* In hypophysectomized rats, sensitivity to cobalt irradiation is greatly increased by testosterone and estradiol.

*Grafov D20,890/62:* In rats, the decreased resistance to total body X-irradiation induced by hypophysectomy is not consistently ameliorated by ACTH.

*Etoh & Egami G11,664/63:* In goldfish, resistance to X-irradiation is greatly diminished both by adrenalectomy and by hypophysectomy.

#### **Hyperoxygenation ←**

*Bean & Johnson B68,165/52:* In rats exposed to oxygen under high pressure, resistance was increased by hypophysectomy.

*Bean & Bauer B76,951/52:* In rats, desiccated thyroid augments the adverse effects of exposure to high oxygen tension. It also abolishes the protective effect of hypophysectomy.

*Smith et al. C95,244/60:* In rats, desiccated thyroid or thyroxine increases the noxious effects of breathing virtually pure oxygen at atmospheric pressure. Conversely, hypophysectomy increases resistance to oxygen presumably through the elimination of TTH.

#### **Temperature Variations ←**

*Baird et al. 14,881/33:* In rats, resistance to cold is greatly diminished after hypophysectomy but restored by cortical extract, TTH or thyroxine.

*Tyslowitz & Astwood 80,678/41:* In hypophysectomized rats, the decreased resistance to cold is largely corrected by ACTH and adrenocortical extract. In adrenalectomized rats, adrenocortical extract is also effective in this respect, whereas ACTH is not.

#### **Electric Stimuli ←**

*de Salva D66,176/63:* In rats, the EST is reduced in descending order of magnitude by adrenalectomy, hypophysectomy and thyroidectomy. The effect of these endocrine deficiencies upon various depressant drugs is also described.

*de Salva et al. C51,842/58:* In rats, the EST was lowered by hypophysectomy and adrenalectomy, but only insignificantly by thyroidectomy. 5-HT elevated the EST.

*de Salva D66,177/63:* In rats, hypophysectomy decreases the EST raising effect of diphenylhydantoin.

*Gispén et al. G77,123/70:* In rats exposed to unescapable electric shock the threshold for flinch, jerk, run and jump was significantly lowered by hypophysectomy. "Treatment with the ACTH analogue ACTH<sub>1-10</sub> did not affect threshold levels in hypophysectomized or intact rats. It is concluded that the stimulating effect of ACTH<sub>1-10</sub> on conditioned-avoidance acquisition in hypophysectomized rats is not caused by an influence on sensory capacities."

**Tumors ←**

*Korteweg & Thomas A33,075/39:* In mice, hypophysectomy delays but does not prevent the growth of transplanted mammary carcinomas or the induction of cutaneous neoplasms caused by painting the skin with 3:4-benzopyrene.

*Ventura et al. C23,299/57:* In rats, the growth of transplanted Walker tumors is essentially normal after hypophysectomy and maintenance therapy with cortisol + DOC. However, the tumor cachexia is greatly increased, whereas the severe involution of the spleen and liver, as well as the development of leukemoid tissue infiltrates in the adrenals and spleen were inhibited.

**Hepatic Enzymes ←**

For the extensive literature concerning the effect of hypophysectomy on the basic levels of hepatic TPO, TKT, GOT, and other enzymes, as well as upon induction of such enzymes by hormones or substrates, *cf.* the Abstract Section.

**TPO, TKT ←**

*Geschwind & Li B95,517/53:* Hypophysectomy does not abolish (and perhaps even increases) the resting TPO activity of the rat liver. However, in hypophysectomized animals, the ability to induce this enzyme by tryptophan injection is gradually diminishing during the first 14 post-operative days. Treatment with ACTH enhances the formation of this adaptive enzyme system (measured by kynurenin formation) even without treatment with tryptophan.

*Geschwind & Li B93,277/54:* In the rat, the induction of the TPO enzyme system is diminished by hypophysectomy and adrenalectomy, but increased by thyroidectomy.

*Thomson & Mikuta B90,975/54:* "Total-body X-irradiation produces within a few hours a dose-dependent increase in the TPO system of rat liver. The increase does not occur in adrenalectomized rats, and hence cannot be construed as a direct effect of X-irradiation." After hypophysectomy, enzyme induction became progressively less pronounced as adrenal atrophy developed. ACTH restored the ability of the hypophysectomized rat to respond with enzyme induction.

*McCann et al. E93,864/59:* In rats, hypothalamic lesions interfering with ACTH secretion, as well as hypophysectomy decrease the induction of hepatic TPO by histidine, but do not block the response completely.

*Maickel & Brodie C83,071/60:* TPO in rat liver is increased by ACTH, cortisone, or cortisol, as well as by various stressor agents and barbiturates. Hypophysectomy prevents the effect of stressors and barbiturates, suggesting

that the latter act through the pituitary-adrenal system.

*Westermann et al. C83,072/60:* In the rat, large doses of reserpine produce an alarm reaction with an increase in the hepatic TPO activity associated with lowered brain serotonin and norepinephrine. Hypophysectomy prevents these responses.

*Rosen & Milholland D23,053/62:* Administration of L-tryptophan, but not of tyrosine, stimulated hepatic TKT activity in adrenalectomized rats. No such induction was obtained by tryptophan in vitro. Adrenalectomized rats treated with tyrosine, methionine or histidine had slightly subnormal TKT levels. Tryptophan analogues (D-tryptophan, acetyl-L-tryptophan, indole, D,L-5-OH-tryptophan and 5-HT), increase both TKT and TPO activity in the livers of adrenalectomized rats. In hypophysectomized rats, tryptophan, 5-HT or 5-OH-tryptophan caused only a slight rise in the hepatic activity of TPO or TKT.

*Rosen & Milholland E32,652/63:* Tryptophan induced significant increases in hepatic TKT activity in intact and in adrenalectomized (NaCl-maintained) rats. Tyrosine, histidine and methionine slightly depressed the hepatic TKT activity of the adrenalectomized rats. Analogues of tryptophan (including D-tryptophan, acetyl-L-tryptophan, indole, DL-5-hydroxytryptophan and 5-HT i.p.) increase both TKT and TPO activity by 50—300% in the livers of intact or adrenalectomized rats. 5-HT and DL-5-hydroxytryptophan were most active. After hypophysectomy, the response of each of these enzymes to tryptophan gradually diminished. After 6 months, tryptophan, 5-hydroxytryptophan

and 5-HT failed to cause significant increases in the hepatic activity of these enzymes, but cortisol remained highly effective, causing increases in both enzyme activities comparable to those seen in intact or adrenalectomized rats. "Experiments with two known inhibitors of protein synthesis, DL-ethionine and puromycin, indicate that a major fraction of the induced activity of tryptophan pyrrolase seen in adrenalectomized or hypophysectomized rats treated by injection with tryptophan is due to activation rather than synthesis of new enzyme protein. The responses of tryptophan pyrrolase and tyrosine transaminase in liver following cortisol administration appear to be mainly the result of the synthesis of each of these enzymes."

*Nomura et al. G33,405/65:* Various forms of stress (forced exercise, immobilization, cold), as well as the administration of chlorpromazine, increased the TPO-activity of the liver both in intact and in adrenalectomized, but not in hypophysectomized, rats.

*Kenney & Albritton G64,557/65:* Review of the literature suggesting that transaminase induction in response to stressors can be interpreted as due to corticoid secretion during the stress reaction. Cortisol increases enzyme synthesis following an increased rate of ribosomal transfer synthesis and "DNA-like" RNA's. The present experiments confirm the view that repressor(s) can inhibit enzyme synthesis at the translational level because inhibition of RNA synthesis can prolong the corticoid-induced increase in enzyme synthesis under suitable conditions. "Administration of stressing agents (tyrosine, Celite) to adrenalectomized rats initiates a highly selective repression of the synthesis of hepatic tyrosine- $\alpha$ -ketoglutarate transaminase. The enzyme level falls with a  $t_{1/2}$  of about 2.5 hr. Immunochemical measurement of the rate of enzyme synthesis indicates that it is reduced essentially to zero in stressed, adrenalectomized rats, whereas labeling of total liver soluble proteins is unaffected. Actinomycin does not itself influence the enzyme level, but it blocks the stress-initiated repression of enzyme synthesis, indicating that repression acts at the translational level, whereas initiation of repression involves transcriptional processes." In hypophysectomized rats, stressors are ineffective and preliminary data suggest that STH is responsible for transaminase repression.

*Fiala & Fiala F65,983/66:* In the rat, cycloheximide (Actidione) i.p. inhibits the synthesis of hepatic TPO assayed 4 hrs after

administration of the substrate, or of cortisol. By contrast, actidione did not abolish the induction of TKT by cortisol and, in fact, actidione increased the level of TKT even in the absence of cortisol treatment. A similar, though smaller, effect occurred in hypophysectomized or adrenalectomized<sup>1</sup> rats, suggesting a direct induction of TKT by actidione. Puromycin inhibited the synthesis of TKT. Apparently, an inhibitor of protein synthesis such as actidione may also act as an inducer for the synthesis of TKT, thus simulating the action of cortisol. "This 'pseudohormonal' action of actidione may explain the toxicity of actidione in certain mammalian species and also the fact that hydrocortisone may act as an antidote in actidione poisoning. It does not explain why a similar effect of 'pseudohormonal' induction is not observed in the case of TPO, but only the inhibition of enzyme induction."

*Schapiro et al. F67,227/66:* Hepatic TKT-activity increased in immature, stressed (reciprocating shaker) rats, whereas intact stressed adults showed no change. In the stressed adrenalectomized adults, TKT activity markedly decreased, while adrenalectomized immature rats showed no change. Hypophysectomy largely abolished inhibition in the adults. TPO-activity, when present, was increased by stress in old-age groups, but the increase was abolished by adrenalectomy and hypophysectomy. "The results suggest stress-activation of a pituitary mechanism that inhibits or represses activation of tyrosine transaminase and that may not function during early postnatal life."

*Grossman & Mavrides G46,206/67:* Studies on the kinetics of cortisol-induced hepatic TKT activity in adrenalectomized rats. "Puromycin inhibited enzyme synthesis when it was given during the initial phase of induction. However, it unexpectedly caused a rapid reappearance of enzyme activity following its administration during the inactivation phase. This potentiated response is consistent with other observations which lead to the idea that a repressor is formed about 4 hours after hormone administration and that inhibition of repressor synthesis allows, at least temporarily, continued synthesis of enzyme." The inactivator appears to depend upon pituitary function, since adrenalectomized and hypophysectomized rats showed little or no inactivation phase following cortisol treatment.

*Kenney G50,810/67:* In intact, hypophysectomized or adrenalectomized rats, STH inhibits the synthesis of hepatic TKT. The

rate of enzyme synthesis is reduced nearly to zero (immunochemical-isotopic analyses), whereas labeling of the bulk of the liver proteins is increased by STH. Repression is blocked when RNA synthesis is inhibited by actinomycin. STH also appears to play a role in the repression of TKT induction by stressors. A hypophysectomized and an intact rat were united by parabiosis. When the pituitary-bearing member was stressed by tyrosine i.p., repression occurred in the livers of both treated and untreated (hypophysectomized) animals. Transaminase levels were unchanged in a single experiment where the stressing agent was administered to the hypophysectomized partner.

*Labrie & Korner G56,018/68:* The basal level of TPO and TKT was unchanged in the liver of the hypophysectomized rat, but injected cortisol produced greater increases in these enzyme activities. STH depressed these enzyme activities only after pretreatment for four days in either hypophysectomized or adrenalectomized rats, but even shorter pretreatment counteracted the enzyme-inducing effect of cortisol. An amino-acid mixture p.o. enhanced cortisol stimulation of both enzyme activities and abolished the STH-inhibition of the cortisol effect.

*Govier & Lovenberg G70,841/69:* In rats, the increase in hepatic TKT produced by phentolamine is almost completely abolished by adrenalectomy or hypophysectomy. If small doses of cortisol are given to adrenalectomized rats, phentolamine again increases enzyme activity. Aminoglutethimide completely eliminates both the increase in plasma corticosterone and enzyme induction by phentolamine. "It is concluded that at least two factors are operative in the induction of TKT by phentolamine—(1) a response to an increased plasma corticosterone concentration, and (2) an additional effect which may be a direct substrate type of induction."

*Lane & Mavrides H12,953/69:* Cortisol caused a greater increase of hepatic TKT in hypophysectomized than in adrenalectomized rats. In general, elevation of enzyme activity after cortisol was inversely proportional to the initial enzyme level, and the latter was in turn higher on protein-rich than on protein-poor diets.

*Geller et al. H8,414/69:* The stress of laparotomy increases hepatic TKT activity in intact, but not in the adrenalectomized rat, which actually responds in an inverse manner. Hypophysectomy eliminates some, but not

all, of this laparotomy-induced repression. Under these conditions, the TPO- and the TKT-responses are somewhat different.

### GPT, GOT ←

*Beaton et al. C10,012/55:* STH decreases the hepatic GPT and d-amino acid oxidase activity in nonpregnant female rats. These effects are even more pronounced if the animals receive STH + "equine estrogenic substances" + progesterone. This enzyme activity also decreases during pregnancy both in intact and in hypophysectomized rats.

*Rosen et al. C50,741/58:* In rats treated with cortisol, cortisone or prednisone for 1 week, there was an increase in hepatic GPT but not in GOT. DOC had no such effect. Hypophysectomy or adrenalectomy did not prevent this action of cortisone. STH, testosterone or insulin failed to alter GPT activity nor did they influence its stimulation by cortisol.

*Rosen et al. C71,414/59:* Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nongluocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol, were inactive. STH, testosterone and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity but when injected simultaneously with cortisol they appeared to interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

*Harding et al. D14,355/61:* In the rat, pretreatment with DOC depresses the hepatic GPT activity. A similar depression is obtained by adrenalectomy, but this is not further aggravated by concurrent treatment with DOC. ACTH increases alanine transaminase activity in hypophysectomized, but not in adrenalectomized, animals. In hypophysectomized rats, DOC fails to lower alanine transaminase, nor does it alter the response of this enzyme to ACTH. "The inhibitory effect of DOC on alanine transaminase activity appears to be due to suppression of ACTH release by the pituitary."

**Other Amino Acid Enzymes ←**

*Zuchlewski & Gaebler D91,862/57:* Hepatic glutamic acid dehydrogenase activity increases after hypophysectomy in the rat, and is not altered by STH either in hypophysectomized or in sham-operated control animals. GPT and GOT activities have also been investigated under similar conditions.

*Freedland & Avery G67,766/64:* In the rat, the TDH and SDH activity of liver homogenates was increased by high protein diets, alloxan diabetes, or cortisol. Factors affecting the activity of TDH caused a proportional change in SDH suggesting that both of these activities may be due to a single protein. The SDH activity was decreased by adrenalectomy or hypophysectomy. Adrenalectomy had no effect upon the response of this enzyme to protein feeding, whereas, after hypophysectomy, this response was diminished.

*Freedland G28,270/65:* Hypophysectomy causes a marked decrease in the hepatic microsomal arginase and arginine synthetase activity in the rat, and both these urea-cycle enzyme levels are increased by cortisol and high-protein diet, even after hypophysectomy.

*Ishikawa et al. F41,763/65:* In alloxan-diabetic rats, the hepatic SDH and TDH activities are greatly increased. SDH was readily induced by cortisol in the diabetic, but not in the normal, rat. The effects of actinomycin S, STH, and starvation upon SDH have also been studied in intact, hypophysectomized, adrenalectomized and thyroidectomized rats. It is concluded that "serine dehydratase activity in the liver plays an important role in the production of pyruvate as a starting material for gluconeogenesis."

*Shimazu G31,110/65:* 20-Methylcholanthrene increases hepatic dimethylaminoazobenzene-demethylase in the rat, even after adrenalectomy, ovariectomy, or hypophysectomy. Hypothalamic lesions decrease the basal

level of the enzyme and its response to methylcholanthrene. On the other hand, glutamine synthetase (a microsomal enzyme not induced by methylcholanthrene) is unaffected by hypothalamic lesions.

**Various Enzymes ←**

*Greengard et al. D12,966/61:* Hypophysectomy enormously increases the rise in hepatic DPN content induced by nicotinamide i.p. in the rat. ACTH or cortisone suppresses this increase. Many of the metabolic actions of the pituitary-adrenal system may depend upon alterations in the hepatic concentration of this coenzyme.

*Abraham et al. G20,214/64:* Hypophysectomy drastically reduces the citrate-cleavage enzyme activity induced in rat liver by dietary measures.

*Dietrich & Yero G26,959/65:* Cortisol markedly lowered the nicotinamide deamidase-activity of the liver in intact, hypophysectomized, and adrenalectomized rats. Under these conditions, cortisol failed to inhibit hepatic synthesis of NAD significantly after nicotinamide challenge. Hexestrol markedly lowered hepatic deamidase activity in intact, thyroidectomized, and adrenalectomized rats. A lowering of the hepatic NAD-levels after nicotinamide challenge occurred upon hexestrol treatment in intact, but not in adrenalectomized, rats. Hypophysectomy markedly stimulated nicotinamide deamidase activity and NAD-biosynthesis after nicotinamide challenge.

*Freedland et al. G55,808/68:* Extensive studies on the effect of adrenalectomy, hypophysectomy and cortisol treatment upon a great variety of rat liver enzymes, with observations on the effect of thyroxine upon these enzymes in intact, adrenalectomized or hypophysectomized rats. The extensive data do not lend themselves to succinct presentation in the form of a summary and must be consulted in the original.

**← THYROID HORMONES**

The role of the thyroid in resistance, and particularly in drug detoxication, is very great but poorly understood. The discovery by Reid Hunt, at the beginning of this century, that thyroid extract increases the acetonitrile resistance of the mouse was probably one of the first clear-cut demonstrations in the field of hormone-induced drug resistance. The "Hunt test" was so sensitive and reliable that it has been widely used for bioassay purposes, although the underlying mechanism remains mysterious even today.

As we shall see from the following pages, thyroid deficiency and hyperthyroidism alter reactivity to innumerable agents, including hormones, drugs, infections, stressors, and particularly exposure to temperature variations. In all these cases, it is of course tempting to hold changes in the BMR responsible for altered resistance, since a general increase or decrease in metabolism affects the activity of most chemical reactions, be they favorable or detrimental to the organism. However, recent work on the catatoxic steroids indicates that thyroid hormones can significantly influence the activity of the hepatic microsomal drug-metabolizing enzymes and through them the degradative inactivation of toxicants or, conversely, their transformation into metabolites even more toxic than the parent compounds.

Despite the voluminous literature described in the following pages, no systematic study has as yet been carried out along these lines. The exploration of the part played by the thyroid hormones in resistance appears to be particularly promising now against the background of what we have learned recently about the corresponding actions of steroids.

### **Steroids ←**

**Corticoids ←.** The nephrosclerosis produced by DOC + uninephrectomy + NaCl in the rat is greatly aggravated by thyroxine. Thyroidectomy has an inverse effect, although not all the lesions are equally affected by it. The glycogenolytic action of thyroid feeding is counteracted by cortisone. Thyroxine increases the toxicity of many drugs (e.g., digitoxin, indomethacin, nicotine, phenindione, various pesticides) against which ethylestrenol offers excellent protection. The protective effect of catatoxic steroids can be counteracted by concurrent treatment with thyroid hormone.

**Testoids ←.** It has been claimed that in orchidectomized mice, thyroxine increases the seminal vesicle enlargement produced by testosterone. In rats, the renotropic action of methyltestosterone is enhanced by thyroxine.

**Folliculoids ←.** The hypercalcemia produced in cockerels by stilbestrol is inhibited by thyroxine, and the oviduct stimulating effect of estradiol in young pullets is increased by thiouracil.

In ducks, estradiol stimulates the proliferation of fine spongy bone trabeculae. Thyroidectomy retards bone proliferation, whereas conjoint treatment with thyroxine and estradiol leads to the abundant formation of thick trabeculae.

In rats, thyroidectomy diminishes, whereas thyroid extract increases the hepatotoxicity of  $\text{CCl}_4$ .

**Corticoids ←** cf. also *Selye B40,000/50*, p. 552; *C92,918/61*, p. 280; *G60,083/70*, pp. 326, 401.

*Selye et al. B229/45:* In rats, the nephrosclerosis produced by DOC after uninephrectomy + NaCl is greatly aggravated by thyroxine.

*Kusama C58,473/57:* In rats, the glucogenolytic action of thyroid feeding is counteracted by cortisone.

*Yates et al. C51,744/58:* Studies on the Ring A reduction of cortisone by slices and homogenates of rat livers after pretreatment

with thyroxine or previous thyroparathyroidectomy showed that the total hepatic activity is less in normal males than in females. "Activity was increased 37% and 45% in hyperthyroid males and females respectively, and was decreased 39% and 47% in hypothyroid animals."

*Salgado & Mulroy C84,321/59:* In rats, the cardiovascular changes produced by DOC following sensitization by uninephrectomy and NaCl are inhibited by hypophysectomy or thyroidectomy, although not all the lesions are blocked to an equal extent.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many among these drugs, and inhibits the protective effect of ethylestrenol.

**DOC** ← *cf. also Table 15*

**Triamcinolone** ← *cf. also Table 18*

**Cortisone** ← **Thyroxine**: McGuire et al. *E90,938/59, E91,579/59*

**Testoids** ← *cf. also Selye B40,000/50, p. 631; G60,083/70, p. 401.*

*Caridroit & Arvy A57,397/42*: In castrate mice, thyroxine increases the seminal vesicle enlargement produced by testosterone.

*Selye et al. B229/45*: In rats, the renotropic action of methyltestosterone is greatly enhanced by thyroxine.

*Masson 96,171/47*: In orchidectomized mice, thyroxine increases the stimulation of the seminal vesicles by testosterone, but the effect is not very marked and may even be reversed depending upon the dose level at which the two hormones are given.

*Bradlow et al. C27,897/56*: In man, studies with radioactive testosterone suggest that T3 markedly influences the metabolism of this testoid, in that conversion into androsterone is increased with a concomitant fall in etiochol-anolone.

**Androst-4-ene-3,17-dione** ← **Thyroxine**: McGuire et al. *E90,938/59, E91,579/59*

**Androst-4-ene-3,17-dione** ← **Triiodothyronine**: McGuire et al. *E90,938/59*

**Folliculoids** ← *cf. also Selye G60,083/70, p. 406.*

*Benoit & Clavert B27,669/48*: In ducks, estradiol stimulates the proliferation of spongy bone consisting of fine trabeculae. Thyroidectomy retards this bone proliferation whereas conjoint treatment with thyroxine and estradiol leads to abundant development of thick trabeculae.

*von Faber C6,925/55*: In cockerels, the hypercalcemia produced by stilbestrol is inhibited by concurrent administration of thyroxine.

*Common et al. D12,509/61*: In immature pullets, the oviduct-stimulating effect of estradiol is greatly increased by the administration of thiouracil p.o.

*Kulcsar-Gergely & Kulcsar G71,532/62*: In rats, thyroidectomy diminishes, whereas thy-

roid extract increases the hepatotoxicity of  $\text{CCl}_4$ . Correspondingly, the sexual cycle is accelerated by thyroidectomy and delayed by thyroid hormone treatment as a result of changes in hepatic folliculoid degradation.

**Estradiol** ← *cf. also Table 16*

**Progesterone** ← *cf. Table 17*

**Steroidases in General (incl. Bile Acids, Cholesterol)** ← *cf. also Cholesterol under Drugs*

*Schmidt 27,511/34*: In guinea pigs, gastric ulcer formation following i.p. injection of Na-glycocholate or Na-taurocholate is diminished following pretreatment with thyroxine p.o., perhaps because hyperthyroidism causes liver damage and thereby interferes with the biliary excretion of the bile acid.

*McGuire Jr. & Tomkins E90,938/59*: In rats, thyroxine increases the rate of reduction of  $\Delta^4$ -3-ketosteroids by TPNH-dependent microsomal enzymes.

*McGuire & Tomkins E91,579/59*: In the rat, thyroxine causes a pronounced increase in the microsomal 5 $\alpha$ -reductase activity of the liver, but the rate of reduction of some steroid substrates is raised more than that of others. Furthermore, when microsomes are "aged" at 0—5°C for several weeks, the decline in activity varies with different steroid substrates. "Further evidence for the substrate specificity of the 5 $\alpha$  hydrogenases was the observation that 4-androstene-3,17-dione strongly inhibited the reduction of cortisone, while the converse was not true." These and other observations suggest that each series of 4-ene-3-ketosteroid hydrogenases, 5 $\alpha$  and 5 $\beta$ , contains multiple enzymes capable of discerning small variations in the steroid molecule.

*McGuire Jr. & Tomkins D5,722/60*: In the microsomal fraction of rat liver, there appear to be at least 5  $\Delta^4$ -3-ketosteroid reductases (5 $\alpha$ ). When rats are treated with thyroxine, the reductase activity for cortisone, cortisol, DOC, 4-androstene-3,17-dione and 11-deoxycortisol (Cpd. S) increases, but the increment is different for each of these substrates.

*Danielsson & Tchen G72,327/68 (p. 159)*: Brief summary of the influence of the thyroid upon cholesterol and bile acid metabolism.

*Lehmann & Brewer E8,112/68*: The in vitro metabolism of  $^{14}\text{C}$ -estrone by the hepatic microsomes of the rat is markedly influenced by in vivo pretreatment with T3 or  $\text{NaClO}_4$ . Hyperthyroidism increases, whereas hypothyroidism and severe thyrotoxicosis diminish estrone metabolism.

*Lehmann & Breuer H15,110/69*: "After incubation of oestrone with the microsomal fractions of liver of euthyroid, hyperthyroid, thyrotoxic as well as hypothyroid rats the following metabolites were identified in the ether soluble fractions: 6 $\alpha$ , 6 $\beta$ - and 7 $\alpha$ -hydroxy-oestrone, 6 $\alpha$ , 6 $\beta$ - and 7 $\alpha$ -hydroxy-17 $\beta$ -oestradiol, 16 $\alpha$ -hydroxyoestrone, oestriol and 17 $\beta$ -oestradiol. The amounts of metabolites formed depended upon the functional state of the thyroid."

*Schweppe & Jungmann H15,266/69*: The ability of rat liver microsomes to synthesize cholesterol palmitate, oleate, and linoleate in vitro is increased by the addition of thyroxine or glucagon to the incubation medium. Testosterone increases cholesterol palmitate and oleate formation. 17 $\beta$ -Estradiol stimulates mainly oleate synthesis.

*Schweppe & Jungmann H15,978/69*: Observations on the metabolism of marked chole-

sterol added together with various hormones to hepatic microsomes of the rat led to the conclusion that "1) cholesterol palmitate and oleate were synthesized most rapidly; 2) at high concentrations, testosterone decreased the formation of all esters but at lower dose levels, testosterone increased the synthesis of cholesterol oleate and palmitate; 3) estradiol caused a two-fold increase in cholesterol oleate formation; 4) ACTH decreased the synthesis rate of cholesterol palmitate and oleate; 5) insulin had a significant inhibitory effect on cholesterol linoleate; 6) epinephrine had little significant effect at the dose level used; and 7) L-thyroxine increased the synthesis of all cholesterol esters."

#### **Pancuronium** ← *cf. Table 19*

Steroids ← Thyroxine: McGuire et al. *E90,938/59, D5,722/60*

### **Nonsteroidal Hormones and Hormone-Like Substances** ←

**Pituitary, Thyroid and Parathyroid Hormones** ←. The renotropic action of crude anterior pituitary extracts is greatly enhanced by thyroxine in the rat.

Several earlier observations suggested that T2, thiourea, and thiouracil interfere with many of the characteristic effects of thyroxine overdosage in rats and mice.

In rats, the activity of thyroxine is greatly augmented after partial hepatectomy. However, it is only when the circulating amount of thyroxine (or T3) is above physiologic limits that the liver plays an important role in its detoxication.

The osteitis fibrosa produced by parathyroid extract in rats is not prevented by thyroidectomy. Apparently, parathyroid hormone does not act through the thyroid as had been claimed by earlier investigators.

On the other hand, pretreatment with thyroxine inhibits the soft tissue calcinosis, osteitis fibrosa, and hypercalcemia produced by parathyroid overdosage in the rat. This inhibition is manifested even after thyroparathyroidectomy, but not after nephrectomy, in contradistinction to calcitonin which inhibits parathyroid extract overdosage even in the absence of the kidneys.

**Pancreatic Hormones** ←. In rabbits and rats, thyroidectomy decreases resistance to insulin. This effect is much less evident in guinea pigs and dogs. Thyroid feeding has an opposite effect. In cats, thyroidectomy decreases resistance to insulin-induced hypoglycemia even if the parathyroids are preserved.

Thyroidectomy decreases, whereas thyroid extract increases sensitivity to the diabetogenic action of alloxan in rats. The hepatic necrosis produced by alloxan intoxication in rats is prevented by thiouracil, and aggravated by thyroid feeding.

More recent experiments suggest that in mice, sensitivity to insulin convulsions is increased by thyroxine, and that in rats, the diabetogenic effect of alloxan is antagonized by thyroid feeding.

**Catecholamines** ←. In most species, thyroidectomy increases, whereas thyroid hormones decrease resistance to epinephrine and, to a lesser extent, to norepinephrine. This is true not only of the acute toxicity of catecholamines but also of such chronic changes as the calcifying arteriosclerosis produced in the rabbit.

**Histamine and 5-HT** ←. In guinea pigs, thyroidectomy protects against otherwise fatal histamine intoxication, whereas thyroxine has an opposite effect. Rats pretreated with thyroxine become extremely sensitive to 5-HT or to anaphylactoidogenic agents which cause histamine and 5-HT liberation from mastocytes.

Thyroxine inhibits the action of 5-HT upon isolated smooth muscles in rats, whereas in the perfused hindquarter, the vasomotor effects of 5-HT are allegedly enhanced by thyroxine.

In man, wheal formation following 5-HT i.c. is reduced in myxedema and increased in thyrotoxicosis.

**Hypophyseal Hormones** ← cf. also *Selye B40,000/50*, pp. 515, 552; *C92,918/61*, p. 40.

*Selye et al. B229/45*: In rats, the renotropic action of anterior pituitary extracts is greatly enhanced by thyroxine.

#### **Thyroid Hormones** ←

*Abelin & Schönenberger 4,290/33*: In rats, diiodothyronine inhibits many of the effects of thyroxine overdose.

*Diétrich & Beutner B20,412/44*: In mice, thiourea and thiouracil interfere with the action of orally administered thyroid powder when the Reid Hunt test is made the basis of observations. In this test, minute amounts of whole thyroid can be detected by their protective effect against otherwise lethal doses of acetonitrile.

*Kellaway et al. B14,515/45*: In rats, the activity of thyroxine s.c. was estimated by an increase in pulse rate after partial hepatectomy, thyroidectomy, or bile duct ligation. "It was found (1) that thyroxine activity is greatly intensified in the absence of the liver; (2) that the liver does not play a significant role when the amount of circulating thyroxine is within physiologic limits; (3) that the liver deals with excess hormone by some process of inactivation and not by simple excretion."

**3,3,5-Triido-L-thyronine** ← cf. also *Table 20*

**Propylthiouracil** ← cf. also *Tables 21, 22*

**Parathyroid Hormone** ← cf. also *Selye G60,083/70*, pp. 401, 413.

*Selye A36,715/42*: In rats, partial hepatectomy, complete thyroidectomy, or bilateral nephrectomy do not prevent the osteitis fibrosa and soft-tissue calcification produced by large doses of parathyroid extract. Apparently, parathyroid hormone does not exert its

action through either the thyroid or the kidney, as had previously been postulated by some investigators. Furthermore, hepatic detoxication does not play an important role in the metabolism of parathyroid hormone.

*Côté et al. G46,713/67*; *Gabbiani et al. G39,934/67*; *G46,730/68*; *G46,731/68*; *Tuchweber et al. G46,759/68*: Pretreatment with thyroxine or calcitonin inhibits the soft tissue calcification and osteitis fibrosa induced by parathyroid extract overdose. In the event of concurrent administration, the effect of the two protective hormones is summated. Thyroxine retains its effect upon calcium metabolism in thyroparathyroidectomized or adrenalectomized but not in nephrectomized rats. The stress of restraint likewise prevents parathyroid overdose, but the associated biochemical changes are different from those caused by thyroxine.

#### **Pancreatic Hormones** ←

*Ducheneau 20,846/24*: In rabbits, thyroidectomy increases sensitivity to the hypoglycemic and lethal effects of insulin.

*Houssay & Busso 20,601/24*: In rabbits and rats, thyroidectomy decreases resistance to the toxic effects of insulin. The phenomenon is less evident in guinea pigs and still less in dogs. Thyroid feeding has an opposite effect.

*Britton & Myers 18,695/28*: In cats, thyroidectomy greatly increases sensitivity to insulin-induced hypoglycemic reactions even if the parathyroids are preserved. However, about 3 weeks after operation, insulin resistance returns to normal and subsequently rises above that level.

*Jensen & Grattan 77,887/40*: In mice, ACTH, glucocorticoids and cortical extracts increase insulin resistance, whereas other

pituitary hormones and thyroxine have no such effect.

*Martinez B15,837/45; Houssay & Sara B727/45:* In rats, desiccated thyroid feeding increases, whereas thyroidectomy decreases sensitivity to alloxan i.v.

*Martinez B2,342/46:* In rats, thiouracil diminishes the diabetic action of alloxan and of subtotal pancreatectomy.

*Ershoff B24,883/48:* In immature female rats fed purified rations containing both pancreas and desiccated thyroid, mortality was high. Similar diets containing only pancreas or desiccated thyroid induced no comparable mortality.

*Houssay B60,812/50; Martinez B61,239/51:* In rats, thyroidectomy or prolonged treatment with thiouracil or cysteine (which increase the free SH groups of tissues) markedly raises resistance to the diabetogenic action of alloxan. These procedures also diminish the incidence of diabetes after subtotal pancreatectomy in the rat, and can even produce permanent cures in a certain percentage of mild diabetic animals.

*Martin B88,524/53:* In rats, both chloroform and alloxan produce hepatic necrosis and their effect is increased when both agents are given in combination. Thiouracil protects against this form of hepatic necrosis, whereas thyroid feeding aggravates it.

*Houssay et al. C15,702/55:* In dogs, destruction of the thyroid by  $^{131}\text{I}$  alleviates alloxan diabetes.

*Hasselblatt & Bastian C59,171/58:* In mice sensitivity to insulin convulsions is increased by thyroxine and even more markedly by tolbutamide.

*Altieri et al. C71,565/58:* In rats, the toxic and diabetogenic effects of alloxan are aggravated by thyroid feeding and inhibited by  $^{131}\text{I}$ .

**Epinephrine and Norepinephrine** ← cf. also *Selye C92,918/61*, pp. 112, 123, 194; *G60,083/70*, pp. 334, 404.

*Busso 26,684/25:* In rats, thyroidectomy does not change the resistance to epinephrine or phenol. Morphine appears to be slightly more toxic to thyroidectomized than to intact rats, but the results were irregular.

*Spinelli 10,086/31:* In guinea pigs, thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine, and atropine but augments sensitivity to pilocarpine and guanidine.

*Peltola B57,468/50:* In mice, the lethal effect of epinephrine is dose-dependently increased by pretreatment with thyroid powder.

This can serve as a basis for the bioassay of thyroid preparations.

*Kroneberg & Hüter B69,838/51:* In mice, pretreatment with thyroxine increases mortality to subsequently administered epinephrine, whereas norepinephrine sensitivity is essentially unchanged.

*Thibault & Lachaze B69,990/51:* In vitro, the effect of epinephrine upon the contraction of the isolated rabbit intestine, spleen and uterus is enhanced by conjoint application of thyroxamine, the "active form of thyroxine."

*Kroneberg B87,448/52:* In mice, the toxicity of epinephrine, unlike that of norepinephrine, is greatly increased following thyroxine pretreatment.

*Brewster Jr. et al. C11,771/56:* In dogs, the physiologic changes produced by thyroid extract are abolished following sympathetic blockade. The inotropic, chronotropic and calorogenic effects of epinephrine and norepinephrine are increased by thyroid feeding. "It is concluded that there is a dynamic interrelationship between the thyroid hormones and those of the adrenal medulla and sympathetic nerve endings."

*Swanson C22,149/56:* In rats, thyroidectomy inhibited while thyroxine potentiated the calorogenic effect of epinephrine.

*Orosio C31,059/56:* In rats, hypothyroidism ( $^{131}\text{I}$ , propylthiouracil, thyroidectomy) decreased, whereas hyperthyroidism (desiccated thyroid) increased vascular reactivity to epinephrine, norepinephrine, and angiotensin.

*Oester C84,324/59:* In rabbits, the arteriosclerosis produced by combined treatment with epinephrine + thyroxine is readily influenced by various conditioning factors.

*Hoch D25,881/62:* Review (68 pp., 611 refs.) on the biochemical actions of thyroid hormones with a special section on their interactions with epinephrine.

*Halpern et al. G67,689/63:* In mice, thyroxine greatly increases the toxicity of various sympathomimetic compounds, such as amphetamine, ephedrine, dopa, and dopamine. The toxicity of tyramine and norepinephrine is less markedly enhanced and that of mepiramine is uninfluenced.

*Proulx et al. G43,289/66:* In rats made hyperthyroid by feeding iodinated casein, "there was a 25% decrease in liver monoamine oxidase and this decrease does not appear to be related to a decrease in body weight. Liver catechol-O-methyl transferase activity was normal in hyperthyroid animals."

*Svedmyr G39,171/66*: In rabbits, thyroxine potentiates the calorogenic and hyperlactacidemic effect of epinephrine, leaving its hyperglycemic effect undiminished. Thyroidectomy decreases the calorogenic and hyperlactacidemic actions of epinephrine. The metabolic effects of norepinephrine are less strikingly affected by the thyroid.

**Epinephrine** ← cf. also Table 23

### **Histamine and 5-HT** ←

*Spinelli 14,294/29*: In guinea pigs, thyroidectomy protects against otherwise fatal histamine intoxication.

*Spinelli 10,086/31*: In guinea pigs, thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine, and atropine, but augments sensibility to pilocarpine and guanidine.

*Gyermek & Pataky B65,706/50*: In guinea pigs, thyroxine does not influence the bronchoconstriction induced by histamine aerosol.

*Sackler et al. B78,749/53*: In rats, thyroparathyroidectomy increases histamine tolerance, but only in females. Intact rats show no sex difference in histamine tolerance. Gonadectomy raises histamine tolerance in both sexes.

*Long C32,348/57*: In guinea pigs, both anaphylactic shock (horse serum) and sensitivity to histamine are greatly increased by pretreatment with thyroxine. Thyroxine also augments the sensitivity of guinea pigs to intradermal tuberculin injection.

*Jasmin & Bois C92,099/60*: Rats pretreated with thyroxine become extremely sensitive to 5-HT, and readily die in a state of shock reminiscent of anaphylaxis.

*Parratt & West D235/60*: In rats, pretreatment with thyroxine greatly increases sensitivity to dextran, egg white, polymyxin B, compound 48/80, histamine, and 5-HT so that in addition to the anaphylactoid edema, there develops edema and hemorrhage in the intestinal tract. The effect is ascribed to inhibition of intestinal histaminase by thyroxine.

*Panisset et al. F71,775/66*: In vitro observations on isolated organs (duodenum, uterus, lung) of rats indicate that thyroxine inhibits the action of 5-HT upon smooth muscle. Conversely, in the perfused hindquarter, the vasomotor effect of 5-HT was enhanced by thyroxine.

*Skinohø & Quaade G72,600/69*: In man, wheal formation following intracutaneous injection of 5-HT is reduced in myxedema and increased in thyrotoxicosis. A control study with histamine revealed normal reactivity in myxedema and increased response in thyrotoxicosis.

### **Angiotensin** ←

*Osorio C31,059/56*: In rats, hypothyroidism (<sup>131</sup>I, propylthiouracil, thyroidectomy) decreased, whereas hyperthyroidism (desiccated thyroid) increased vascular reactivity to epinephrine, norepinephrine, and angiotensin.

### **Drugs** ←

One of the earliest observations on the effect of hormones upon resistance is the great increase in **acetonitrile** tolerance induced by thyroid preparations in the mouse. During the earliest years of the present century this effect was generally used as the basis for the assay of thyroid preparations and even for the determination of thyroid hormone in blood. This so-called "Reid Hunt test" is fairly specific in that other cyanides are not detoxified by thyroid preparations, and other iodine compounds are virtually ineffective in raising acetonitrile resistance. Curiously, in many species such as the rat, thyroid preparations do not protect against acetonitrile and may even decrease resistance to it. Still, even in mice, the specificity of the acetonitrile test is far from absolute, its outcome depending among others, upon the diet, age, and genetic background of the test animals. Hence, the Reid Hunt test is no longer used for bioassay purposes, yet its underlying mechanism continues to be an intriguing problem.

In mice, thyroxine increases the toxicity of **amphetamine** (as it does that of epinephrine and norepinephrine). It has been claimed that this sensitization occurs

especially when the animals are kept under crowded conditions, but the phenomenon is evident even in individually caged mice. T3 shares this effect of thyroxine. Allegedly, the mortality induced by amphetamine is actually inhibited during the first hour after thyroxine treatment. In rats, thyroidectomy does not significantly affect amphetamine tolerance, but methylthiouracil reduces it, and T3 aggravates it.

Sensitivity to **anaphylactoidogenic agents** is increased by thyroxine and decreased by thyroidectomy or methylthiouracil treatment in the rat. These observations agree with the similar effects of thyroid hormones upon 5-HT and histamine toxicity as previously discussed.

Numerous investigators dealt with the effect of thyroid hormones upon **barbiturate** intoxication. One of the first observations along these lines was made in cats in which profound phenobarbital anesthesia allegedly inhibits a rise in BMR produced by thyroxine.

In the mouse, the toxic effects of several barbiturates are aggravated, and sleeping time is prolonged by thyroid preparations. The latter also delay the removal of barbiturates from the plasma and tissues of the mouse, whereas thioureas have an inverse effect. However, thyroidectomy allegedly also increases pentobarbital sleeping time.

In rabbits, phenobarbital resistance is said to rise during the first hours following thyroxine administration, whereas the narcotic effect of chloral hydrate is not affected. In rats, thyroidectomy prolongs, while thyroxine shortens pentobarbital anesthesia. It had been claimed at first that these effects are not accompanied by changes in hepatic barbiturate detoxication in vitro upon incubation with liver slices. However, more recent observations show that the activity of hexobarbital-metabolizing enzymes in hepatic microsomes is diminished by thyroxine, which would account for the prolongation of anesthesia. It is difficult to see why both thyroidectomy and thyroid preparations prolong barbiturate sleeping time. In fact, some investigators claim that propylthiouracil shortens pentobarbital anesthesia.

Resistance to **carbon monoxide** is diminished by thyroid feeding in rats, presumably because the increased BMR augments oxygen requirements.

According to some investigators, the hepatic cirrhosis produced by **carbon tetrachloride** in the rat is aggravated both by thyroxine and by thiouracil. However, the published results are quite contradictory, presumably because of differences in dosage and timing. Extensive recent investigations suggest that thyroidectomy diminishes, whereas thyroid extract increases the hepatotoxicity of  $\text{CCl}_4$ ; particularly good protection against hepatic cirrhosis is obtained in rats simultaneously thyroidectomized and ovariectomized.

The influence of the thyroid upon the actions of **carcinogens** has also been extensively investigated. The production of cystic and neoplastic hepatic lesions by 2-acetaminofluorene in rats is inhibited by thiouracil; concurrent treatment with thyroid powder and testosterone sensitizes for this carcinogen. Prostatic carcinogenesis induced by topical application of 20-methylcholanthrene is said to be inhibited by T3 without being affected by methylthiouracil.

The anesthetic effect of **chloral hydrate** is not conspicuously affected by thyroid preparations in the mouse, rat or rabbit.

The toxicity of **chlordiazepoxide** is increased by a thyroid extract or T3 in the mouse, whereas methylthiouracil appears to have an opposite effect.

The hepatotoxicity of **chloroform** is increased by a thyroid extract and diminished by thiouracil in rats and rabbits.

In rabbits, **cholesterol** atheromatosis and the associated xanthomatous lesions in the liver are inhibited by thyroxine and increased by thyroidectomy or thiouracil treatment. In chicks, various thyroid preparations diminish the hypercholesterolemia, but do not significantly suppress the coronary or aortic atherogenesis. In rats fed a high-fat, high-cholesterol diet, the increase in hepatic and plasma cholesterol is not significantly changed by thyroxine. However, both D- and L-T<sub>3</sub> diminish the changes in plasma lipids while aggravating the hepatic lesions.

The pyrogenic effect of **cocaine** is increased to fatal levels in rabbits pretreated with thyroxine. In rats, thyroxine also aggravates cocaine intoxication.

In view of the excellent protection offered by thyroid preparations against acetonitrile in the mouse, the effects upon other **cyano-compounds** have also been investigated, but sensitivity to these is not strikingly affected by the thyroid.

Since **digitalis** compounds are extensively used in studies on protective steroids, it is of interest that thyroid preparations augment the hemodynamic effects of digitalin in the rabbit, and aggravate the cardiac lesions produced by digitalis alkaloids in cats. Sensitization to digitalis, and particularly to digitoxin, has been observed in various species using different indicators of activity. It is also noteworthy that therapeutic doses of cardiac glycosides allegedly prevent the thyroxine-induced weight loss in the guinea pig. The convulsions and mortality induced by digitoxin overdosage in the rat are not prevented by thyroidectomy or propylthiouracil, nor do these agents inhibit the antidigitoxin activity of PCN. Apparently, the mild goitrogenic effect of the latter is not involved in its protective action against digitoxin.

The toxicity of **ephedrine** (like that of amphetamine, epinephrine and norepinephrine) is increased by thyroxine, not only in "aggregated" mice as claimed previously, but also in separately caged animals.

The toxicity of **imipramine** is increased by thyroxine or T<sub>3</sub>, and decreased by thiourea in the mouse.

The catatonic effect of ethylestrenol against **indomethacin**-induced intestinal ulceration and mortality is inhibited by thyroxine in the rat. Given by itself, thyroxine shortens survival after indomethacin intoxication.

The skeletal changes produced by **lathyrogens** in the rat are most actively prevented by various thyroid preparations and aggravated by thyroidectomy or thiouracil. Neurolathyrisms produced by IDPN and other neurolathyrogens are similarly influenced, but angiolythyrisms are not significantly affected by thyroid hormones. T<sub>3</sub> is about 50 times as potent as thyroxine in preventing osteolathyrisms. Since both L- and D-T<sub>3</sub> suppress osteolathyrisms in the rat, the effect is allegedly independent of the classical thyroid hormone actions.

The nephrocalcinosis characteristic of **magnesium** deficiency is prevented by thyroxine in the rat, but allegedly some manifestations of the Mg-deprivation are also inhibited by thyroparathyroidectomy.

**Meprobamate** intoxication is counteracted by catatonic steroids but aggravated by thyroxine; in the case of concurrent administration of the two types of hormones, they mutually tend to antagonize each other's influence in this respect.

**Morphine** resistance is diminished in mice, rats, and guinea pigs by pretreatment with thyroid extracts. Thyroidectomy does not appear to have a consistent effect

upon morphine intoxication or upon the development of morphine withdrawal symptoms. However, in most of these respects, the published data are contradictory.

The fatal pulmonary edema produced by **ozone** inhalation in mice and rats is prevented by thiourea and aggravated by thyroxine or T<sub>3</sub>. Thyroxine and T<sub>3</sub> increase the sensitivity of the mouse and rat to the induction of convulsions by **pentylenetetrazol**. The influence of thyroidectomy and thiouracil is less clear-cut.

Thyroxine increases the toxicity of several **pesticides** and antagonizes the protective action of catatoxic steroids. However, this effect of the thyroid hormone is rarely very pronounced, and often absent.

The nephrocalcinosis produced in rats by dietary excess of certain **phosphates** is inhibited both by thyroparathyroidectomy and by thyroxine in the rat. However, allegedly, propylthiouracil increases this type of nephrocalcinosis.

**Physostigmine** intoxication is aggravated by thyroxine in the rat.

**Picrotoxin** poisoning is inhibited by thyroidectomy in guinea pigs. In rats, thyroxine aggravates picrotoxin poisoning and counteracts the protective effect of ethylestrenol.

In mice and rats, thyroid preparations increase the toxicity of **reserpine**.

The characteristic syndrome of **tyrosine** intoxication (keratitis, conjunctivitis, alopecia, inflammation of the paws and snout) produced under certain conditions in young rats is inhibited by thiouracil and aggravated by thyroxine.

There undoubtedly exist close interrelations between the thyroid and **vitamin-A** metabolism. Earlier observations suggested that the toxicity of thyroxine is partly inhibited by carotene (the precursor of vitamin A) in the rat. Furthermore, in goats, the milk is normally rich in vitamin A, but virtually free of carotene, whereas the reverse is true after thyroidectomy. In guinea pigs, thyroxine inhibits the hepatic storage of carotene and its transformation into vitamin A. Early investigators claimed that hypervitaminosis A can be prevented by thyroxine in the rat, but subsequent experiments failed to confirm this. The pertinent literature is very confusing. In rats kept on a vitamin-A deficient diet, thiourea blocks the protective effect of carotene, and this blockade can be in turn abolished by thyroid powder. Yet, it was claimed that thiouracil prolongs the survival of the rat on a vitamin-A deficient diet.

In rats, the hepatic storage of vitamin A is increased by thyroxine, but the total vitamin-A storage of the body is unaffected. Both L- and D-T<sub>3</sub> aggravate hypervitaminosis A in the rat. The offspring of rats given excessive amounts of vitamin A during pregnancy often show deformities of the skull and brain, which are aggravated by methylthiouracil treatment of the pregnant mother.

In pigeons kept on **vitamin-B** deficient polished rice, wasting and death were accelerated by thyroid feeding, but this may not have been true beriberi. In vitamin-B complex deficient rats, thyroid feeding aggravates the resulting skeletal lesions. On the other hand, survival on a thiamine deficient diet is prolonged in thyroparathyroidectomized rats, but not significantly altered by desiccated thyroid. Conversely, thiamine antagonizes thyroxine overdosage in the rat.

Vitamin-B<sub>12</sub> requirements are greatly augmented by thyroxine in the rat, and although vitamin-B<sub>12</sub> possesses no lipotropic potency itself, it prevents the hepatic steatosis produced in thyroxine-treated rats by hypolipotropic diets.

In guinea pigs fed **vitamin-C** deficient diets, the development of scurvy is accelerated by thyroid feeding. Thyroidectomy also aggravates the scorbutic lesions but does not accelerate their onset.

The development of bone lesions on **vitamin-D** deficient diets is not very consistently influenced by thyroidectomy or thyroid administration in the rat. However, the calcinosis produced by excess of vitamin D or DHT is aggravated by thyroxine in the rat. Curiously in rabbits, the calcinosis and other manifestations of vitamin-D<sub>2</sub> overdosage are accentuated by methylthiouracil, whereas in the cow, the production of calcinosis by vitamin-D<sub>3</sub> overdosage has been said to be prevented by thyroxine.

In the chick, **vitamin-E** requirements are increased by thyroid preparations and decreased by thiourea. In rats, the muscular dystrophy produced by vitamin-E deficiency is aggravated by thyroid feeding. In rabbits, suppression of thyroid activity by radioiodine exerts a certain prophylactic effect.

**Zoxazolamine** paralysis is aggravated by thyroidectomy and inhibited by thyroxine or T3 in the rat owing to changes in hepatic microsomal zoxazolamine metabolism.

#### *Acetaldehyde* ←

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

#### **2-Acetaminofluorene** ← *cf. Carcinogens (AAF)*

#### *Acetanilide* ← *cf. Table 24*

#### *Acetonitrile* ←

#### GUINEA PIG

*Spinelli 10,086/31*: In guinea pigs thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine, and atropine, but augments sensitivity to pilocarpine and guanidine.

#### MOUSE

*Hunt 60,064/05*: In mice, thyroid feeding greatly increases resistance to acetonitrile but not to various other cyanides, such as hydrocyanic acid or sodium ferricyanide.

*Hunt 49,717/07*: In mice, acetonitrile resistance is increased by injections of the blood of hyperthyroid patients.

*Hunt & Seidell 46,617/10*: In mice, the protective effect of thyroid extract against acetonitrile is due to the hormone itself and

not to iodine. Other iodine preparations do not have a protective action. Unlike mice, rats are actually sensitized to acetonitrile by thyroid pretreatment.

*Hunt 49,718/11*: In mice, the resistance to acetonitrile induced by thyroid extract is subject to considerable variation depending upon the diet.

*Wuth A48,026/21*: In mice, tyramine and diiodotyramine, like thyroid extract, offer protection against acetonitrile whereas histamine does not.

*Miura 13,081/22*: Mice are protected against acetonitrile by thyroxine and desiccated thyroid, but not by KI or T2.

*Hunt 13,889/23*: Pretreatment with thyroid preparations greatly increases the resistance of mice to acetonitrile, whereas the reverse is true in many other species.

*Gellhorn 16,839/23*: In mice, resistance against acetonitrile can be increased not only by thyroid extract, but to a lesser extent also by extracts of various other tissues. These preparations also augment resistance to KCN and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

*von Zwehl 25,477/26*: Female mice pretreated with repeated doses of T2 tolerate 2–3 lethal doses of acetonitrile, whereas in males, a significant protective effect could not be demonstrated.

*Paal 22,603/30*: Review of the literature, and extensive personal studies on acetonitrile test in mice, and its use for the determination of thyroid hormone in human blood. Thyroidectomy does not increase the resistance of

mice to acetonitrile, but diminishes the protective effect of thyroxine. Concurrent treatment with insulin also inhibits the prevention of acetonitrile toxicity by thyroxine.

*Knaab 14,828/33*: Discussion of the earlier literature, and personal observations on factors influencing the effect of thyroxine upon acetonitrile resistance in the mouse.

*Montgomery 18,184/33*: Review of the literature on the acetonitrile test for thyroid preparations in mice. The protective effect of thyroid is confirmed, but individual variations and dietary factors alter responsiveness so much that the technique is unsuited for bioassay purposes.

*Grab 44,536/33*: In mice, about 50  $\mu$ g of thyroxine suffices to protect with certainty against otherwise lethal acetonitrile intoxication.

*Paal 18,183/33*: In mice, exposure to light greatly influences sensitivity to acetonitrile. Even after thyroidectomy, daylight as well as ultraviolet irradiation increase the MLD of acetonitrile. Hence, resistance to this drug is not always influenced through variations in thyroid activity.

*Santo 27,439/34*: Review on the factors influencing the Reid Hunt-reaction in mice.

*Fellinger & Hochstädt 63,744/35*: In mice, the protection against acetonitrile offered by thyroxine or TTH is blocked by an extract of blood that contains the "ether soluble anti-thyroid substances."

*Fleischmann & Kann 67,360/36*: In mice, vitamin A antagonizes the protective effect of thyroxine against acetonitrile intoxication. Vitamin A also antagonizes the effect of thyroxine upon tadpole metamorphosis.

*Dietrich & Beutner B20,412/44*: In mice, thiourea and thiouracil interfere with the action of orally administered thyroid powder when the Reid Hunt test is made the basis of observations. In this test, minute amounts of whole thyroid can be detected by their protective effect against otherwise lethal doses of acetonitrile.

#### VARIA

*Hunt 49,716/07*: Comparative studies on the effect of thyroid extract upon the acetonitrile and morphine resistance of mice, rats, and guinea pigs.

*Hunt & Seidell 50,346/09*: Monograph (115 pp.) on the use of the acetonitrile test for thyroid function. In rats, thyroid feeding actually lowers resistance to acetonitrile.

*Hunt 50,349/10*: Very detailed description of the acetonitrile test for thyroid. Here, special attention is placed upon the modifying influence of the diet, seasonal variations, species, and other conditioning factors.

*Oehme & Paal 62,442/32*: Review (42 pp., about 200 refs.) on the technique and clinical applications of the acetonitrile test for thyroid action, with a survey of the numerous factors that can influence its outcome.

#### Aconitine ←

*Spinelli 10,086/31*: In guinea pigs thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine, and atropine, but augments sensitivity to pilocarpine and guanidine.

*Acrylamide* ← cf. Table 25

*Acrylonitrile* ← cf. Table 26

#### Adenosine Diphosphate ←

*Chandler & Nordöy G22,017/64*: In rats, the pulmonary thrombi produced by ADP i.v. are stabilized by pretreatment with propylthiouracil, perhaps because the inactivation of ADP is delayed.

#### Allyl Alcohol ←

*Srinivasan et al. G78,977/70*: In rats, pretreatment with thyroxine aggravates the hepatic damage produced by allyl alcohol (judged by hepatic histology, serum GPT and BSP).

#### Allylformiate ←

*Spieß-Bertschinger B40,585/44*: In rats, the hepatic lesions produced by allylformiate are aggravated by thyroid feeding, but regenerative phenomena are active. After thyroidectomy, the hepatic lesions are particularly severe and characterized by necrosis without regeneration.

*o-Aminophenol* ← 6-Propylthiouracil, Mouse: Werder et al. *G12,065/64*

*Aminopyrine* ← cf. Table 27

*Aminopyrine* ← Thyroxine: Kato et al. *F57,817/65*

*Aminopyrine* ← Thyroidectomy: Orrenius et al. *G66,249/65*

#### p-Aminosalicylate ←

*Mehrotra & Sarna D14,287/61*: In rats, the hepatic lesions and glycogen infiltration

produced by p-aminosalicylate (PAS) were not prevented by thyroxine. Hence, these changes are not due to hypothyroidism.

### Amphetamine ←

#### MOUSE

*Pfeifer et al. D12,952/60:* In mice, the increased motility induced by amphetamine is inhibited during the first hour after thyroxine treatment. The possible biochemical reasons for this "negative tendency" during the early phase of thyroxine action are described.

*Askew G72,695/62; Halpern et al. G11,305/63:* In mice, thyroxine increases the lethal effect of amphetamine.

*Halpern et al. G63,588/63:* In mice, thyroxine pretreatment diminishes resistance to amphetamine and DL-dopa, especially under conditions of crowding.

*Gayet-Hallion & Bouvet F16,484/64:* In mice kept under crowded conditions, the toxicity of amphetamine is diminished by pretreatment with the blood of thyroidectomized horses.

*Halpern et al. F24,137/64:* In mice, the toxicity of amphetamine and ephedrine is increased by pretreatment with thyroxine not only—as had been previously shown—when several animals are kept together in a jar, but also when they are kept in solitary cages.

*Moore F36,358/65:* In mice, the toxicity of d-amphetamines is greatly augmented by pretreatment with T3. Simultaneously, there develops a dose-dependent reduction in the levels of brain, heart, and spleen norepinephrine, liver glycogen and blood glucose. Similar changes are observed if amphetamine is given to mice crowded ("aggregated") in small cages.

*Moore G36,616/65:* In mice, pretreatment with T3 greatly increases sensitivity to the lethal effect of amphetamine. "Chlorpromazine, phenoxybenzamine, and propranolol pretreatment reduced the lethality of d-amphetamine in hyperthyroid mice while  $\alpha$ -methyl-m-tyrosine,  $\alpha$ -methyl-p-tyrosine, and reserpine pretreatment did not. The toxicity of  $\alpha$ -methyl-m-tyrosine was enhanced in hyperthyroid mice."

*Winter G71,836/65:* In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentylenetetrazol is increased by T3 or thyroid powder, whereas the narcotic effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects. [The experimental conditions are not

described in sufficient detail to evaluate these findings (H.S.).]

*Winter F64,465/66; F98,019/68:* In mice, pretreatment with thyroid extract p.o. increases the toxicity of reserpine, chlordiazepoxide, imipramine, and amphetamine.

#### RAT

*Tormey & Lasagna C80,689/60:* In rats, thyroidectomy does not significantly affect tolerance to amphetamine.

*Mantegazza & Riva F47,703/65:* In rats, methylthiouracil reduces various manifestations of amphetamine intoxication.

*Dolfini & Kobayashi F91,611/67:* In rats, amphetamine causes more pronounced hyperthermia after pretreatment with T3 than following thyroidectomy or thiouracil treatment.

*Mantegazza et al. H7,676/68:* In rats, pretreatment with methylthiouracil reduces the toxicity, hyperthermia, hyperglycemia, and the increase in plasma free fatty acids induced by amphetamine more than the increased spontaneous activity and anorexia. This dissociation of effects might reflect an altered metabolic pattern of amphetamine.

### Amyl Nitrate ←

*Specht 13,475/23:* In guinea pigs, neither thyroidectomy nor orchidectomy influences the course of the convulsions produced by amyl nitrate inhalation or electric irritation of peripheral nerves.

**Anaphylactoid Edema** ← *cf. also Selye G46,715/68, pp. 117, 180, 184, 199.*

*Parratt & West D235/60:* In rats, pretreatment with thyroxine greatly increases sensitivity to dextran, egg-white, polymyxin B, compound 48/80, histamine, and 5-HT so that in addition to the anaphylactoid edema, there develops edema and hemorrhage in the intestinal tract. The effect is ascribed to inhibition of intestinal histaminase by thyroxine.

*Spencer & West D32,617/62:* In rats, the anaphylactoid edema produced by dextran or egg-white is diminished by thyroidectomy or methylthiouracil, and increased by thyroxine or T3.

**Aniline** ← **Thyroxine + Orchidectomy + Methyltestosterone:** *Kato et al. F57,817/65*

**Anticoagulants** ←

*Lowenthal & Fisher C40,044/57*: In rats, the anticoagulant effect of warfarin is increased by thyroxine and diminished by hypothyroidism (methimazole treatment).

*Owens et al. D21,725/62*: In man, dextrothyroxine potentiates the anticoagulant action of warfarin.

*Solomon & Schrogie H1,868/68*: In women, thyroxine greatly potentiates the anticoagulant effect of warfarin. Analysis of the data (according to the method of Lineweaver and Burk) suggests that an increased affinity of the drug for its receptor site is responsible for the potentiation of its effect. The literature on the increase in the response to various indirect anticoagulants by thyroxine in man is briefly reviewed.

*Selye G60,094/70*: In rats, the fatal hemorrhagic diathesis produced by phenindione is inhibited by ethylestrenol, CS-1, spironolactone, norbolethone, and oxandrolone. Progesterone, hydroxydione, DOC, and estradiol have a much less pronounced effect. Prednisolone, triamcinolone, and thyroxine are inactive.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate, and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

**Bishydroxycoumarin** ← *cf. also Table 28*  
**Phenindione** ← *cf. also Table 29*

**Antimony** ←

*Shih-Chi et al. C72,194/58*: In mice, thyroxine decreases, whereas propylthiouracil increases resistance to the fatal effect of intoxication with ammonium antimonyl gluconate i.p. The differences are not explicable on the basis of the distribution or excretion of antimony.

**Arsenic** ←

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to sodium arsenate.

*Bogdanovitch & Varagitch G71,534/54; Bogdanovitch C18,912/56*: In rats, pretreatment with thyroid extract increases, whereas methylthiouracil decreases the toxicity of organic

arsenicals such as oxophenarsine or dichlorophenarsine.

**Atropine** ←

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not change resistance to atropine.

*Spinelli 10,086/31*: In guinea pigs, thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine, and atropine, but augments sensitivity to pilocarpine and guanidine.

**Barbiturates** ←

## CAT

*von Issekutz & von Issekutz Jr. 45,261/35*: In cats, profound phenobarbital anesthesia inhibits the rise in BMR normally produced by thyroxine. It is assumed that thyroxine raises oxygen consumption indirectly through an effect upon the higher nervous centers.

## FROG

*Richards 79,646/41*: In the frog, stimulation of metabolism by thyroxine increases susceptibility to pentobarbital.

## MOUSE

*Prange Jr. & Lipton F56,756/65*: In mice, the toxic effects of the convulsant barbiturate 5-(1,3-dimethylbutyl)-5-ethyl barbituric acid (DMBEB) are aggravated by desiccated thyroid p.o., and diminished by propylthiouracil.

*Winter G71,836/65*: In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentylenetetrazol is increased by T3 or thyroid powder, whereas the narcotic effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects. [The experimental conditions are not described in sufficient detail to evaluate these findings (H.S.).]

*Schrogie & Solomon C43,019/66*: In mice, the metabolism of bishydroxycoumarin was markedly inhibited by both L- and D-thyroxine. The demethylation of meperidine was likewise inhibited by both isomers but particularly by D-thyroxine. L-thyroxine also increased the lethal effect of meperidine overdosage. Pentobarbital sleeping time was prolonged in mice treated with either L- or D-thyroxine, but the latter was more active in this respect.

*Ellinwood F64,417/66*: In mice, dichloroisoproterenol ( $\beta$ -adrenergic blocker) does not influence pentobarbital sleeping time and, far

from inhibiting, actually potentiates the prolongation of anesthesia by thyroid feeding. It is unlikely therefore that thyroid would increase barbiturate hypnosis through the production of epinephrine.

*Klinger F66,416/66:* In mice and rats, large doses of thyroxine prolong hexobarbital sleeping time and diminish the resistance induced by barbital pretreatment. The associated changes in ascorbic acid metabolism are discussed.

*Prange et al. G40,154/66:* In mice, thyroid feeding increases sensitivity to various barbiturates and delays their removal from the brain, liver, and plasma. Propylthiouracil has an inverse effect. In rats, thyroxine slightly and thyroidectomy markedly increase pentobarbital sleeping time.

*Spencer and Waite H30,100/70:* In mice, pretreatment with thyroxine enhances the hypnotic effect of very small doses of thiopental. Earlier experimenters had shown that hyperthyroidism increases sensitivity to larger doses of barbiturates, but in the present case, metabolic studies suggest that an "enhanced rate of redistribution of thiopentone brought about by increased peripheral and cerebral blood flow in hyperthyroid mice" was probably responsible for the diminished anesthetic effect.

Hexobarbital ← Thiouracil, Mouse: Wenzel et al. G76,357/55\*

Hexobarbital ← Triiodothyronine, Mouse: Holtz et al. C76,300/58\*

Pentobarbital, Thiopental ← Thyroid extract, Mouse: Ellinwood et al. E39,187/64\*; Prange et al. G40,154/66\*

#### RABBIT

*Zárday & Weiner 53,715/35:* In rabbits, thyroxine s.c. does not influence the narcotic effect of chloral hydrate given a few hours later. On the other hand, the resistance to phenobarbital rises through the influence of thyroxine under similar conditions.

#### RAT

*Scarborough 34,971/36:* In rats, feeding of thyroid extract diminishes the anesthetic effect of pentobarbital.

*Horinaga A36,414/41:* Thyroidectomy increases barbiturate sensitivity in the rat.

*Robillard et al. B66,661/51:* In rats, thyroidectomy prolongs pentobarbital anesthesia and delays hepatic detoxication of the drug, whereas thyroxine pretreatment diminishes the duration and depth of this anesthesia with-

out enhancing the hepatic detoxication of pentobarbital as determined by incubation of the drug with liver slices. After simultaneous thyroidectomy and orchidectomy, pentobarbital detoxication is more markedly delayed than after simple thyroidectomy or orchidectomy, and the anesthetic effect is correspondingly further intensified than after ablation of the thyroid or testes alone.

*Holck et al. B95,270/54:* In rats, thyroidectomy or propylthiouracil treatment increased the recovery time from isopropyl- $\beta$ -bromallyl barbituric acid, propallylonal (Nostal), thiopental, and hexobarbital. Thyroglobulin or thyroxine caused no consistent shortening of the average recovery time from isopropyl- $\beta$ -bromallyl barbituric acid; propallylonal (Nostal). Either of these effects is also largely influenced by the sex of the animals.

*Robillard et al. G67,325/54:* Thyroidectomy prolongs pentobarbital anesthesia in intact, and even much more in castrate adult male rats. Thyroxine decreases the anesthetic effect of pentobarbital in thyroidectomized rats even below the normal level. Liver homogenates of thyroidectomized rats metabolize pentobarbital in vitro less rapidly than those of normal rats, but pretreatment in vivo with thyroxine does not increase the pentobarbital-metabolizing activity of these homogenates above the control value.

*Lanzetta C68,990/58:* In rats, thyroxine or dinitrophenol given i.p. 30 min before thiopental prolongs the anesthetic effect of the latter, presumably through uncoupling of oxidative phosphorylation.

*Conney & Garren D93,666/61:* In the rat, thyroxine prolongs the duration of hexobarbital anesthesia by decreasing the activity of hexobarbital-metabolizing enzymes in hepatic microsomes.

*Kato & Gillette F57,817/65:* The metabolism of aminopyrine and hexobarbital by hepatic microsomes of male rats is impaired by adrenalectomy, castration, hypoxia, ACTH, formaldehyde, epinephrine, morphine, alloxan, or thyroxine. The metabolism of aniline and zoxazolamine is not appreciably decreased by any of these agents; in fact, the hydroxylation of aniline is enhanced by thyroxine or alloxan. Apparently, the treatments impair mainly the sex-dependent enzymes. Accordingly, the corresponding enzymic functions of the hepatic microsomes of female rats are not significantly impaired by the agents which do have an inhibitory effect in males.

*Kato & Takahashi* *G55,715/68*: Thyroxine decreased the N-demethylation of aminopyrine and hydroxylation of hexobarbital by liver microsomes of male rats. By contrast, thyroxine increased the metabolism of aminopyrine and hexobarbital in females. The hydroxylation of aniline and reduction of p-nitrobenzoic acid were increased in both sexes. The effect of thyroxine and thyroidectomy upon other microsomal enzyme systems has also been examined.

*Harbison & Becker* *H10,917/69*: Thyroidectomy greatly prolonged hexobarbital sleeping time and zoxazolamine paralysis in rats. T3 increased the response to hexobarbital but diminished the effect of zoxazolamine. The mortality rates induced by high doses of hexobarbital, thiopental, amobarbital, pentobarbital, and phenobarbital were all significantly increased in rats pretreated with T3.

*Kato et al.* *H11,854/69*: "The administration of thyroxine or starvation resulted in marked decrease in the hydroxylation of pentobarbital and hexobarbital and N-demethylation of aminopyrine in male rats, whereas the hydroxylation of aniline and zoxazolamine and N-demethylation of N-methylaniline were significantly increased."

*Selye* *G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate, and picrotoxin. Thyroxine increases the toxicity of many among these drugs and inhibits the protective effect of ethylestrenol.

**Barbiturates** ← *cf. also Tables 30—34*

#### VARIA

*Glaubach & Pick* *11,431/30*: In guinea pigs and rabbits, the hypothermia produced by phenobarbital is counteracted by thyroxine pretreatment.

*Zárday & Weiner* *A52,879/34*: Anesthesia with morphine in rats, and with chloral hydrate in rabbits was not significantly influenced by pretreatment with thyroxine s.c., one hour before the anesthetics. On the other hand, phenobarbital anesthesia was prolonged by thyroxine pretreatment in rabbits under identical conditions. Similar observations have been made on patients suffering from thyrotoxicosis, in that they are unusually resistant to barbiturates but not to other anesthetics. This selective antagonism is ascribed to interactions

between thyroxine and barbiturates at some common receptor site in the midbrain.

*Ellinwood Jr. & Prange Jr.* *E39,187/64*: Review of earlier observations on the effect of thyroid and thiourea preparations upon pentobarbital sleeping time in mice and rats. Since thyroid hormones and epinephrine are synergistic in many respects, mice were treated with various combinations of these agents. Pentobarbital anesthesia was prolonged by desiccated thyroid and shortened by propylthiouracil pretreatment. High doses of epinephrine prolonged sleeping time in themselves and potentiated the effect of thyroid feeding. The prolongation of pentobarbital sleeping time by epinephrine may be due to depletion of hepatic glycogen which interferes with hepatic microsomal drug metabolism.

**Barbital** ← **Thyroidectomy**: *Boylan et al.* *D47,605/62\**

**Hexobarbital** ← **Thyroxine**: *Conney et al.* *D93,666/61\**

**Pentobarbital** ← **Thyroidectomy + Thyroxine**: *Robillard et al.* *G67,325/54\**; *Prange et al.* *G40,154/66\**

**Bilirubin** ← **Triiodothyronine + Age, Man**: *Lees et al.* *C74,543/59\**

**Cadmium** ← *cf. Table 35*

#### **Caffeine** ←

*Hunt & Seidell* *50,346/09*: In mice, pretreatment with thyroid extract did not change resistance to caffeine.

*Strubelt et al.* *G78,572/70*: In rats, T3 increases, whereas thyroidectomy decreases, the calorogenic response to theophylline and caffeine, probably because the thyroid hormone activates adenylyl cyclase and/or inhibits phosphodiesterase.

**Caramiphen** ← *cf. Table 36*

#### **Carbon Dioxide** ←

*Barbour & SeEVERS* *84,296/43*: In rats, exposure to cold and an excess of CO<sub>2</sub> produces a state of narcosis against which considerable resistance can be induced by thyroid extract. No such effect was obtained by dinitrophenol.

#### **Carbon Monoxide** ←

*Mack & Smith* *45,162/34*: In rats, both thyroid feeding and dinitrophenol shorten survival during CO poisoning.

*Smith et al.* *45,163/35*: Male rats are more sensitive to the lethal action of illuminating

gas than females. This difference is eliminated by gonadectomy. Thyroid feeding or dinitrophenol injections decrease survival time.

#### **Carbon Tetrachloride** ←

*Lesca & Mosca B48,329/49*: In rats, the hepatic cirrhosis produced by  $\text{CCl}_4$  is aggravated both by thiouracil and by thyroxine. However, survival time is increased in the thyroxine-treated rat.

*Aragona & Barone B92,455/53*: In rats, thyroxine protects the liver against the damaging effect of  $\text{CCl}_4$ .

*Calvert & Brody C82,829/60*: In rats, brief pretreatment with thyroxine increases, whereas previous thyroidectomy diminishes the metabolic changes produced by  $\text{CCl}_4$  intoxication. Adrenal catecholamines are strongly reduced in hyperthyroid and only slightly reduced in hypothyroid animals. "The changes are consistent with a concept of anoxia being the primary event in  $\text{CCl}_4$  hepatotoxicity."

*Calvert & Brody D61,412/61*: Thyroxine pretreatment increases the susceptibility of the rat to the hepatotoxicity of  $\text{CCl}_4$ .

*Kulcsár-Gergely & Kulcsár G71,532/62; E33,917/63*: In rats, thyroidectomy diminishes, whereas thyroid extract increases the hepatotoxicity of  $\text{CCl}_4$ . Correspondingly, the sexual cycle is accelerated by thyroidectomy and delayed by thyroid hormone treatment as a result of changes in hepatic folliculoid degradation.

*Kulcsár-Gergely et al. F32,037/64*: In rats, simultaneous thyroidectomy and ovariectomy offer some protection against the induction of hepatic cirrhosis by  $\text{CCl}_4$ .

*Kulcsár-Gergely & Kulcsár G1,372/64*: In rats intoxicated with  $\text{CCl}_4$ , survival is increased by ovariectomy and thyroidectomy.

*Berencsi et al. G33,802/65*: In rats, the production of hepatic lesions by  $\text{CCl}_4$  is diminished after thyroidectomy or methylthiouracil treatment.

*Berencsi & Krompecher G43,712/66*: In rats, the hepatic damage caused by  $\text{CCl}_4$  is decreased by thyroidectomy or methylthiouracil and increased by thyroxine or T3.

*Kulcsár & Kulcsár-Gergely F74,930/66*: In rats, ovariectomy, thyroidectomy, or removal of both glands, offers partial protection against  $\text{CCl}_4$  intoxication.

*Srinivasan & Balwani G64,503/68*: In rats, pretreatment with thyroxine increased the liver damage produced by subsequent administration of  $\text{CCl}_4$  or thioacetamide.

*Kulcsár et al. H14,649/69*: In rats, thyroidectomy offers some protection against the production of hepatic damage by  $\text{CCl}_4$ ; this may be due to altered mucopolysaccharide formation.

*Kulcsár et al. H24,478/70*: In rats, thyroxine increases, whereas thyroidectomy decreases, the hepatotoxicity of  $\text{CCl}_4$  as judged by BSP elimination.

#### **Carcinogens** ←

*Cantarow et al. B18,774/46*: In rats given 2-acetaminofluorene p.o., the development of cystic and neoplastic hepatic lesions was accelerated and intensified by GTH (pregnant mare serum), estradiol, and testosterone, but inhibited by thiouracil. "This phenomenon may be related to the role of the liver in the intermediary metabolism and excretion of the sex steroid." In the hyperplastic target organs of the sex hormones, tumors did not occur, in contrast to the high incidence of tumors in the thyroids of rats given thiouracil simultaneously with the carcinogens.

*Miller Jr. & Baumann G74,552/51*: Rats made hyperthyroid by feeding iodinated casein + p-dimethylaminoazobenzene (DAB), exhibited a high mortality, and the incidence of tumors in the survivors was very great. Thiouracil and propylthiouracil did not alter tumor incidence remarkably. "Liver slices from hyperthyroid rats destroyed less than one-fourth as much DAB as slices from normal rats."

*Bielschowsky & Hall C194/53*: In rats, the production of hepatomas by AF or AAF is inhibited following thyroidectomy. The protection is manifest only if the thyroid is removed before the administration of the carcinogens and even then it is restricted to the liver. The production by AF or AAF of extrahepatic neoplasms is not prevented.

*Reid B93,930/54*: Review (18 pp., 181 refs.) on the effect of STH and corticoids upon carcinogen-induced and transplantable neoplasms.

*Klärner & Klärner C45,812/58*: In  $\text{BAF}_1$  mice, the growth of urethan-induced pulmonary tumors is significantly inhibited by alloxan diabetes and exposure to heat, but only slightly affected by thyroxine and insulin.

*Bielschowsky D10,255/61*: In rats, hypophysectomy, thyroidectomy and adrenalectomy inhibit the development of hepatomas by treatment with 2-acetylaminofluorene (AAF) or 2-aminofluorene (AF).

*Leathem & Oddis D2,742/61*: Female rats are less responsive than males to the induction of hepatomas by AAF. Thyroid feeding increases the incidence of hepatomas in females treated with AAF. It has the same effect in mice of both sexes given DMBA.

*Sherwin-Weidenreich & Herrmann D67,842/63*: In mice, tumor induction by DMBA is not inhibited, and perhaps even accelerated, by T3.

*Sterental et al. D61,608/63*: In rats, mammary tumors induced by DMBA regressed after adrenalectomy + ovariectomy or hypophysectomy. Folliculoid treatment reactivated tumor growth after adrenalectomy + ovariectomy but not after hypophysectomy. These tumors remained unresponsive to folliculoids after hypophysectomy even if thyroid and cortisone replacement therapy was given.

*Reuber F4,431/64*: In rats, the production of hepatomas by N-2-fluorenyldiacetamide was prevented by orchidectomy or thyroidectomy. However, the carcinogenic effect was restored in thyroidectomized animals by thyroid feeding.

*Weidenreich-Sherwin & Herrmann F16,179/64*: In mice, the production of skin tumors by topical application of 3-MC is considerably enhanced by T3.

*Reuber F36,234/65*: Concurrent treatment with testosterone and thyroid powder sensitizes the rat for the production of hepatic cirrhosis and hepatomas by N-2-fluorenyldiacetamide.

*Goodall F71,302/66*: In rats, the induction of hepatic tumors by 2-aminofluorene is inhibited by thyroidectomy.

*Ronzoni et al. H18,409/68*: In rats, prostatic carcinogenesis induced by the introduction of 20-methylcholanthrene crystals into the prostate is inhibited by ACTH, triiodothyronine and, to a lesser extent, by progesterone and 19-nortestosterone phenylpropionate. Estradiol and cortisone facilitate carcinogenesis, whereas testosterone, orchidectomy, and methylthiouracil failed to influence it.

*Davidson et al. H10,206/69*: In rats made hypothyroid by <sup>131</sup>I, the incidence of mammary cancer induction by DMBA is increased. Hypothyroidism induced by iodine deficiency did not share this effect and radio-iodine may have acted by radiation injury to the breast tissue rather than the associated hypothyroidism.

3-MC ← Thyroidectomy: Boyland et al. D47,605/62\*

**Carisoprodol** ← cf. Table 37

**Carotene** ← cf. Vitamin A

**Choline** ←

*Tabachnick et al. C50,317/58*: In mice, thyroxine increases sensitivity to decamethonium and neostigmine but not to D-tubocurarine or succinylcholine. Rabbits pretreated with thyroxine also become more sensitive to decamethonium. It is tentatively suggested that the motor disturbances associated with hyperthyroidism may be due to "a change in the muscle itself, probably at the motor endplate where these drugs act."

**Chloral Hydrate** ←

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract questionably diminishes resistance to chloral hydrate.

*Zárday & Weiner A52,879/34*: Anesthesia with morphine in rats, and with chloral hydrate in rabbits was not significantly influenced by pretreatment with thyroxine s.c., one hour before the anesthetics. On the other hand, phenobarbital anesthesia was prolonged by thyroxine pretreatment in rabbits under identical conditions. Similar observations have been made on patients suffering from thyrotoxicosis, in that they are unusually resistant to barbiturates but not to other anesthetics. This selective antagonism is ascribed to interactions between thyroxine and barbiturates at some common receptor site in the midbrain.

*Zárday & Weiner: 53,715/35*: In rabbits, thyroxine s.c. does not influence the narcotic effect of chloral hydrate given a few hours later. On the other hand, the resistance to phenobarbital rises through the influence of thyroxine under similar conditions.

**Chloralose** ←

*Cheymol & Quinquard 3,531/32*: In dogs, thyroparathyroidectomy greatly increases sensitivity to chloralose anesthesia.

**Chlordiazepoxide** ← cf. also Table 38

*Winter G71,836/65; F64,465/66; Winter F98,019/68*: In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentyl-enetetrazol is increased by T3 or thyroid powder, whereas the narcotic effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects.

*Ashford & Ross H2,686/68*: In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlor-

promazine, perphenazine, and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

### **Chloroform** ←

*Hari 40,209/21*: Polemic remarks concerning the technique and interpretation of earlier data on the effect of thyroidectomy upon the resistance to cyanides, chloroform, bacterial toxins, and oxygen deficiency.

*McIver A 35,431/40*: In rats, susceptibility to chloroform poisoning is increased by thyroxine.

*Black-Schaffer et al. B 55,142/50*: In rabbits, chloroform s.c. produces midzonal necrosis of the liver following pretreatment with thyroid extract. Normal or starved rabbits respond to chloroform with centrolobular necrosis. Presumably, "the hyperthyroid state selectively affects the hepatic midzone qualitatively or quantitatively so as to amplify its sensitivity to chloroform beyond that of the periportal or central zones."

*Martin B 88,524/53*: In rats, both chloroform and alloxan produce hepatic necrosis and their effect is increased when both agents are given in combination. Thiouracil protects against this form of hepatic necrosis whereas thyroid feeding aggravates it.

### **Chlorpromazine** ←

*Ashford & Ross H 2,686/68*: In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlorpromazine, perphenazine and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

*Skobba & Miya G 64,738/69*: In rats, the hyperthermia produced by thyroxine or dinitrophenol increases the toxicity of chlorpromazine. Cooling the animals by an air current prevents this increase in toxicity.

**Cholesterol** ← *cf. also Selye G 60,083/70, pp. 385, 395.*

*Suzue et al. 38,509/36*: In rabbits, the production of xanthomatous lesions in the liver by a high-fat high-cholesterol diet is increased by thyroidectomy and inhibited by thyroxine.

*Steiner et al. B 28,166/48*: In dogs, thiouracil greatly enhances the production of atheromatosis by cholesterol feeding.

*Stamler et al. C 81,655/58*: In cholesterol-fed chicks, desiccated thyroid, thyroxine, T3 and T2 diminished hypercholesterolemia, but a

definite and consistent suppression of coronary or aortic atherogenesis was not observed.

*Osumi G 34,534/65*: In cholesterol-fed rabbits, combined treatment with T3 and 3,5,3'-triiodo-4-acetyl-thyroformic acid (TBF-43) inhibited fatty degeneration of the liver, adrenal and spleen, but did not noticeably influence the atheromatous changes in the arteries.

*Kessler et al. F 89,469/67*: In rats fed a high-fat high-cholesterol diet, the resulting increase in hepatic and plasma cholesterol and lipid is not changed by either L- or D-thyroxine but D- or L-T3 diminishes the rise of both values in the serum and increases it further in the liver.

*Danielsson & Tchen G 72,327/68 (p. 159)*: Brief summary of the influence of the thyroid upon cholesterol and bile acid metabolism.

*Hamprecht G 69,560/69*: Review (7 pp., 153 refs.) on the mechanisms regulating cholesterol synthesis. A special section deals with the effect of thyroid hormones, steroids, epinephrine, norepinephrine and glucagon.

**Cholesterol** ← **Thyroxine**: Mitropoulos et al. *G 26,978/65*

**Cinchophen** ← *cf. Table 39*

### **Clofibrate** ←

*Azarnoff & Svoboda H 19,856/69*: In rats, the proliferation of hepatic microbodies induced by clofibrate is not abolished by thyroidectomy nor does it occur after various other compounds which displace thyroxine from the plasma. "These observations make less tenable the hypothesis that thyroid hormone displacement is the mechanism of action of clofibrate."

**Cocaine** ← *cf. also Table 40*

*Glaubach & Pick 11,431/30*: In rabbits, pretreatment with thyroxine increases the fever normally produced by tetrahydro- $\beta$ -naphthylamine or cocaine to fatal levels.

*Glaubach & Pick 6,241/31*: Studies in guinea pigs and rabbits on the increase in dibucaine, cocaine and procaine toxicity caused by thyroxine as judged by the resulting temperature variations.

*Selye G 70,471/71*: In rats, cocaine intoxication is inhibited by PCN, ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone and estradiol. Triamcinolone and DOC fail to protect and thyroxine actually aggravates cocaine intoxication.

**Codeine** ←

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract diminishes resistance to codeine.

*Anan 24,228/29*: In mice, thyroxine increases the toxicity of morphine and heroin but not that of other alkaloids such as ethylmorphine codeine, thebaine, papaverine and narcotine.

**Colchicine** ← *cf. also Table 41*

*Vollmer & Buchholz A48,810/30*: In mice, thyroxine as well as various other "oxidizing substances" (glucose, lactate, methylene blue etc.) protect against alcohol intoxication. The same substances decrease resistance to colchicine or hydroquinone. Morphine resistance is not influenced.

*Selye G60,098/70*: In rats, fatal colchicine poisoning can be prevented by spironolactone, CS-1, ethylestrenol and, less constantly, by oxandrolone. Progesterone, norbolethone, prednisolone, triamcinolone, DOC, hydroxydione, estradiol and thyroxine are virtually ineffective in this respect.

**Compound MO-911** ←

*Carrier & Buday D11,237/61*: In rats, feeding with thyroid extracts greatly augments the lethal effect of a hydrazide (iproniazid) or of a nonhydrazide (N-methyl-N-benzyl-2-propylamine hydrochloride; 'MO-911') enzyme inhibitor.

MO-911 ← Thyroid extract: Carrier et al. D11,237/61\*

**DL-Coniine** ← *cf. Table 42***Curare** ←

*Tabachnick et al. C50,317/58*: In mice, thyroxine increases sensitivity to decamethonium and neostigmine but not to D-tubocurarine or succinylcholine. Rabbits pretreated with thyroxine also become more sensitive to decamethonium. It is tentatively suggested that the motor disturbances associated with hyperthyroidism may be due to "a change in the muscle itself, probably at the motor end-plate where these drugs act."

**Croton Oil** ← *cf. Table 43***Cyanide** ←

*Hunt 60,064/05*: In mice, thyroid feeding greatly increases resistance to acetonitrile but not to various other cyanides, such as hydrocyanic acid or sodium ferricyanide.

*Mansfeld & Müller 35,416/11*: In rabbits, thyroidectomy inhibits the protein catabolic effect of exposure to decreased oxygen tension, hydrocyanic acid intoxication or fasting.

*Mansfeld 11,881/20*: In rabbits and dogs, thyroidectomy diminishes the protein catabolism normally observed after intoxication with hydrocyanic acid, hemorrhage, or hypobaric oxygenation.

*Hari 40,209/21*: Polemic remarks concerning the technique and interpretation of earlier data on the effect of thyroidectomy upon the resistance to cyanides, chloroform, bacterial toxins and oxygen deficiency.

*Gellhorn 16,839/23*: In mice, resistance against acetonitrile can be increased not only by thyroid extract but, to a lesser extent, also by extracts of various other tissues. These preparations also augment resistance to potassium cyanide (KCN) and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

*Busso 26,684/25*: In rats, thyroidectomy decreases sensitivity to KCN, whereas the reverse is true in rabbits.

*Tsuru 44,467/33*: In rabbits, pretreatment with thyroid extract did not significantly influence resistance to hydrocyanic acid or thiocyanides.

*Dietrich & Beutner B20,412/44*: In mice, thiourea and thiouracil interfere with the action of orally administered thyroid powder when the Reid Hunt test is made the basis of observations. In this test, minute amounts of whole thyroid can be detected by their protective effect against otherwise lethal doses of acetonitrile.

**Cycloheximide** ← *cf. also Tables 44, 45*

*Selye G70,403/70*: In rats, cycloheximide intoxication is inhibited by ethylestrenol, CS-1 and spironolactone. Norbolethone, oxandrolone, progesterone, hydroxydione, and prednisolone offer less perfect protection. Triamcinolone, DOC, estradiol and thyroxine have no protective effect.

**Cyclophosphamide** ← *cf. also Table 46*

*Selye G70,466/70*: In rats, cyclophosphamide intoxication can be prevented by PCN, CS-1 and spironolactone. Progesterone, ethylestrenol and norbolethone were slightly active; oxandrolone, DOC, hydroxydione and phenobarbital were inactive, whereas prednisolone, triamcinolone, estradiol and thyroxine actually decreased resistance to this drug, *cf. Fig. 22, p. 480.*

Fig. 22. Effect of thyroxine upon cyclophosphamide intoxication. Hemorrhagic, pericardial exudate in rat given cyclophosphamide after pretreatment with thyroxine. Leucocytes are absent because of the cyclophosphamide-induced atrophy of hemopoietic tissue. PAS X

#### **Cystine** ←

*György & Goldblatt G71,898/45*: In rats kept on a hepatotoxic diet containing large amounts of cystine, the development of liver cirrhosis could be prevented by thiouracil p.o.

#### **Decamethonium** ←

*Tabachnick et al. C50,317/58*: In mice, thyroxine increases sensitivity to decamethonium and neostigmine but not to D-tubocurarine or succinylcholine. Rabbits pretreated with thyroxine also become more sensitive to decamethonium. It is tentatively suggested that the motor disturbances associated with hyperthyroidism may be due to "a change in the muscle itself, probably at the motor end-plate where these drugs act."

Desipramine ← Thyroid extract,  
Mouse: Prange et al. F29,162/64\*

#### **$\alpha,\gamma$ -Diaminobutyric Acid** ←

*Vivanco et al. G43,566/66*: In rats  $\alpha,\gamma$ -diaminobutyric acid (DBA) produced a neurologic syndrome in the rat. "The animals became

irritable and screamed when touched. They moved the head from side to side in the manner of a bear and leaped like kangaroos or frogs. Sometimes they got up on the rear legs with simultaneous quivering of the forearms. They showed excessive salivation. In the preagonal state they presented paresis or paralysis of the hind limbs and motor incoordination. The 'swimming test' was always negative and they did not show circling movements or backward gait as in the IDPN intoxication." Pretreatment with thyroxine prevents these changes as it does the clinically different ECC syndrome (excitation, choreiform and circling movements) elicited by  $\beta,\beta'$ -iminodipropionitrile (IDPN). DBA enters the brain substance in unpretreated but not in thyroxine-treated rats. Possibly the toxic compound is destroyed before it can enter the brain.

#### **Dibucaine** ←

*Glaubach & Pick 6,241/31*: Studies in guinea pigs and rabbits on the increase in dibucaine, cocaine and novocaine toxicity caused by thyroxine as judged by the resulting temperature variations.

**Digitalis** ← *cf. also Selye G60,083/70, p. 408.*

*Ghedini & Ollino A21,128/14:* Brief mention of observations on rabbits showing that pretreatment with thyroid extract augments the hemodynamic actions of digitalin in the rabbit.

*Freund A26,153/32:* Studies on the effect of thyroidectomy or pretreatment with thyroxine or insulin upon the in vitro metabolic changes induced by digitalis compounds in the cat's heart.

*Kinsell et al. A37,369/42:* Experiments on guinea pigs and mice suggested that "therapeutic dosage of cardiac steroid-glycosides prevents a weight loss in thyroxin-treated animals similar to that obtained with adrenal cortical hormone and desoxycorticosterone acetate. Larger dosage of these cardiac glycosides either fails to modify such weight loss or actually increased it."

*Dearing et al. C41,482/43:* In cats, thyroxine aggravates the myocardial lesions produced by various digitalis alkaloids.

*Dearing et al. B53,571/50:* In cats, various digitalis preparations produce myocardial fiber necrosis and inflammation. Pretreatment with thyroxine sensitizes the animals to these lesions.

*Rosen & Moran D65,414/63:* In dogs, the positive inotropic response to ouabain was decreased by thyroxine. The arrhythmia-producing and lethal effect of large doses of this glycoside were delayed by thyroidectomy but not remarkably influenced by thyroxine. The literature on the influence of clinical hyper- and hypothyroidism upon digitalis intoxication is reviewed.

*Phansalkar et al. H20,555/69:* In mice, pretreatment with thyroxine greatly increases mortality from subsequent digoxin administration. Reserpine protects against this intoxication. It is suggested that digoxin toxicity is mediated through a catecholamine mechanism.

*Selye G70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

*Selye PROT. 33541,34074:* In rats, PCN is highly efficacious in preventing digitoxin poisoning, even after parathyroidectomy, thyroparathyroidectomy or concurrent treatment with propylthiouracil (PTU). No pro-

tection was obtained by thyroidectomy, parathyroidectomy or treatment with PTU, thyroxine, parathyroid extract or calcitonin. Apparently, the goitrogenic effect of PCN plays no indispensable role in its catatoxic action, *cf. Table 124, p. 482.*

**Digitoxin** ← *cf. also Tables 47—50*

#### **Diisopropylfluorophosphate (DFP)** ←

*Schreiber C3,482/54:* In mice, pretreatment with methylthiouracil increases resistance against diisopropylfluorophosphate (DFP).

"DFP" ← *cf. also Table 52*

#### **Dinitrophenol** ←

*Glaubach & Pick 30,481/34:* In rabbits, the lethal effect of dinitrophenol, and of several of its pyrogenic derivatives, is greatly aggravated by pretreatment with thyroxine.

#### **Dihydroxyphenylalanine** ←

*Samii B68,269/52:* Both in rats and in rabbits, DOPA produced sustained hypertension following pretreatment with thyroxine. Presumably, thyroid hormone enhances the decarboxylation of DOPA to the pressor agent hydroxytyramine.

*Halpern et al. G63,588/63:* In mice, thyroxine pretreatment diminishes resistance to amphetamine and DL-dopa, especially under conditions of crowding.

**Diphenylhydantoin** ← *cf. Table 53*

**Dipicrylamine** ← *cf. Table 54*

#### **Disulfiram** ←

*Lecog et al. B66,406/51:* In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

#### **Dye** ←

*Aterman & Howell C63,343/59:* In rats, the biliary excretion of bromsulphthalein is delayed after destruction of the thyroid by <sup>131</sup>I. This defect is corrected by treatment with thyroid extract.

Table 124. Role of the thyroparathyroid apparatus in the antidigitoxin effect of PCN

Treatment <sup>a</sup>	Convulsions <sup>b</sup> (Positive/Total)	Mortality <sup>b</sup> (Dead/Total)	Mean Survival (Days)
None	14/15	15/15	4
PCN	1/10 ***	0/10 ***	∞
Thyroidectomy	12/12 NS	12/12 NS	3
Thyroidectomy + PCN	1/12 ***	0/12 ***	∞
Parathyroidectomy	9/9 NS	8/9 NS	3½
Parathyroidectomy + PCN	0/10 ***	2/10 ***	4
PTU	10/10 NS	7/10 NS	3½
PTU + PCN	0/10 ***	0/10 ***	∞
Thyroxine	10/10 NS	10/10 NS	2½
Parathyroid extract	10/10 NS	9/10 NS	3½
Calcitonin	10/10 NS	10/10 NS	3

<sup>a</sup> The rats of all groups were given digitoxin 2 mg in 1 ml water, p.o./day on 10th day ff. PTU 3 mg in 0.1 ml DMSO, i.p. x2/day; PCN 0.1 mg in 1 ml water, p.o. x2/day; thyroxine 100 µg in 0.2 ml water NaOH, s.c./day and surgery on the 1st day. Parathormone 20 I.U. in 0.2 ml s.c. x2/day and calcitonin 10 µg in 0.5 ml water, i.p. x3/day on the 9th day.

<sup>b</sup> The severity of the convulsions was estimated on the 13th day and mortality was listed on the 15th (Statistics Fisher & Yates).

For further details on technique of tabulation cf. p. VIII.

*Dolgov & Dolgov G33,058/64:* In rats, the organ distribution of parenterally administered neutral red is considerably modified by pretreatment with thyroid extract. Increased dye deposition was noted in the liver, spleen, and skeletal muscle, whereas in the brain and testes dye-uptake was reduced.

*Kulcsár et al. H24,478/70:* In rats, thyroxine increases, whereas thyroidectomy decreases, the hepatotoxicity of CCl<sub>4</sub> as judged by BSP elimination.

*Emetine* ← cf. Table 55

#### *Ephedrine* ←

*Halpern et al. F24,137/64; F27,643/64:* In mice, the toxicity of amphetamine and ephedrine is increased by pretreatment with thyroxine not only—as had been previously shown—when several animals are kept together in a jar, but also when they are kept in solitary cages.

#### *EPN* ← cf. *Pesticides*

#### *Ergot* ←

*Griffith Jr. & Comroe A33,738/40:* In rats, pretreatment with thyroxine s.c. increases mortality and the incidence of tail necrosis following s.c. injections of ergotamine tartrate.

*Wells & Anderson G74,995/50:* In rats, the production of tail gangrene by ergotamine is not influenced by propylthiouracil but facilitated by thyroxine. "It is assumed that thyroxine acts, not by altering the resistance of the tissues to vascular occlusion, nor by sensitizing the vascular musculature to ergotamine, but by prolonging the action of the alkaloids, possibly by interfering with their elimination or destruction."

#### *Ethanol* ←

*Preusse 26,352/33:* In mice, thyroxine or thyroid powder causes only a moderate increase in resistance to ethanol.

*Vollmer & Buchholz A48,810/30:* In mice, thyroxine as well as various other "oxidizing substances" (glucose, lactate, methylene blue etc.) protect against alcohol intoxication. The same substances decrease resistance to colchicine or hydroquinone. Morphine resistance is not influenced.

*Lecoq et al. B66,406/51:* In rats, the toxic effects of ethanol and its metabolites, pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol

intoxication. [Statistically evaluated data are not presented (H.S.).]

*Aragona & Barone B92,455/53*: In rats, methylthiouracil aggravates the hepatic lesions produced by ethanol intoxication.

*Choisy & Potron H28,010/68*: In rabbits, pretreatment with thyroxine accelerates the oxidation of ethanol and its clearance from the blood.

#### **Ether ←**

*Rutsch 7,744/33*: In guinea pigs, thyroidectomy decreases, whereas thyroxine pretreatment increases, resistance to ether, paraldehyde or tribromoethanol anesthesia. These findings are ascribed to changes in the responsiveness of the brain.

*Ethylene Glycol* ← cf. Table 56

*Ethylmorphine* ← cf. Table 57

*Flufenamic Acid* ← cf. Table 58

#### **Fluoride ←**

*Phillips et al. 34,798/35*: In chicks, combined treatment with thyroid extract and NaF is particularly toxic.

*Bixler et al. E99,118/56*: In rats with hypothyroidism induced by <sup>131</sup>I, the protective effect of fluorine against dental caries is diminished.

*Fluphenazine* ← cf. Table 59

*Ganglioplegics* ← cf. Tables 61, 62

*Glutethimide* ← cf. Table 63

*Glycerol* ← cf. Table 64

#### **Guanidine ←**

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to guanidine.

*Spinelli 10,086/31; 7,409/32*: In guinea pigs, thyroidectomy decreases resistance to the lethal effects of guanidine intoxication. Subsequent administration of thyroid extract restores the resistance to normal.

*Parhon & Werner 34,844/35*: In dogs, guinea pigs and rabbits, thyroparathyroidectomy causes only a moderate increase in sensitivity to methylguanidine.

#### **Halothane ←**

*Nikki G71,573/69*: In mice, shivering and hypothermia during halothane anesthesia is diminished following pretreatment with thyroxine.

#### **Heroin ←**

*Anan 24,228/29*: In mice, thyroxine increases the toxicity of morphine and heroin but not that of other alkaloids such as ethylmorphine, codeine, thebaine, papaverine and narcotine.

#### **Hydroquinone ← cf. also Table 65**

*Vollmer & Buchholz A48,810/30*: In mice, thyroxine as well as various other "oxidizing substances" (glucose, lactate, methylene blue etc.) protect against alcohol intoxication. The same substances decrease resistance to colchicine or hydroquinone. Morphine resistance is not influenced.

#### **N-(p-Hydroxyphenyl) glycine ←**

*Li & Sos H30,786/68*: In rats, N-(p-hydroxyphenyl)glycine fails to exert its usual pressor effect after thyroidectomy.

#### **Imipramine ← cf. also Table 66**

*Prange & Lipton D42,869/62*: In mice, pretreatment with thyroxine greatly increases the initial convulsive actions and the terminal mortality of imipramine intoxication.

*Prange et al. D62,707/63*: In mice pretreatment with propylthiouracil increases resistance to imipramine, whereas hyperthyroidism has an opposite effect.

*Winter G71,836/65*: In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentylenetetrazol is increased by T3 or thyroid powder, whereas the narcotic effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects. [The experimental conditions are not described in sufficient detail to evaluate these findings (H.S.).]

*Winter F64,465/66; F98,019/68*: In mice, pretreatment with thyroid extract p.o. increases the toxicity of reserpine, chlordiazepoxide, imipramine and amphetamine.

*Ashford & Ross H2,686/68*: In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlorpromazine, perphenazine and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

*Prange Jr. et al. G76,612/70*: In man, the antidepressive effect of imipramine is enhanced by TTH as well as by T3. Earlier literature is cited.

*Prange et al. G69,595/69:* In retarded, depressed patients, small doses of T3 enhanced the therapeutic effect of imipramine.

*Prange et al. H31,796/70:* In depressed patients, T3 increases the therapeutic effect of imipramine.

Imipramine ← Thyroid extract,  
Mouse: *Prange et al. D42,869/62\**

**Indomethacin** ← *cf. also Table 67*

*Selye G70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

**Iodides** ← *cf. Selye G60,083/70, p. 407*

#### **Iproniazid** ←

*Carrier & Buday D11,237/61:* In rats, feeding with thyroid extracts greatly augments the lethal effect of a hydrazide (iproniazid) or of a nonhydrazide (N-methyl-N-benzyl-2-propynylamine hydrochloride; 'MO-911') enzyme inhibitor.

*Carrier & Buday E28,887/63:* In rats, the toxic effects of the MAO inhibitors, pargyline and iproniazid are increased by pretreatment with desiccated thyroid.

#### **Isoniazid** ←

*Hunt & Carlton F3,186/64:* In Pekin ducks, combined administration of semicarbazide and isoniazid p.o. produces a neurolathyrism-like syndrome which is not significantly influenced either by thiouracil or by DL-thyroxine.

**Isoproterenol** ← *cf. also Selye C92,918/61, pp. 117, 123; G60,083/70, pp. 405, 406.*

*Chappel et al. C71,409/59:* In rats, thyroxine aggravates, whereas thyroidectomy or propylthiouracil treatment inhibits the development of myocardial lesions following injection of isoproterenol.

**Lathyrogens** ← *cf. also Selye C92,918/61, p. 137; G60,083/70, p. 357.*

#### **DUCK**

*Hunt & Carlton F3,186/64:* In Pekin ducks, combined administration of semicarbazide and isoniazid p.o. produces a neurolathyrism-like syndrome which is not significantly influenced either by thiouracil or by DL-thyroxine.

#### **RAT**

*Selye & Bois C18,280/56:* In rats, the osteolathyrism produced by *Lathyrus odoratus* seeds is aggravated by STH and inhibited by cortisol. Combined treatment with DOC + uninephrectomy + NaCl resulted in dissecting aneurysms of the aorta. Very small doses of thyroxine or estradiol were without effect upon this form of lathyrism.

*Dasler C36,068/57:* Brief mention of unpublished observations indicating that in rats, osteolathyrism produced by APN is not inhibited by cortisone or thyroxine, but aggravated by STH.

*Diaz et al. C50,497/57:* Thyroxine inhibits the osteolathyrism produced in rats by methyleneaminoacetonitrile (MAAN). Estrogens allegedly have a similar, though somewhat less pronounced, effect. [The authors actually tested only estrone in combination with progesterone (H.S.).]

*Ponseti E54,643/57:* In rats, the osteolathyrism changes produced by AAN are more readily inhibited by T3 than by thyroxine.

*Selye C25,013/57:* The osteolathyrism produced in rats by AAN is slightly aggravated by thyroparathyroidectomy, and suppressed by large doses of thyroxine. "An amount of ACTH that more than doubles the weight of the adrenals and causes pronounced thymus atrophy also inhibits the effect of AAN, but fails to prevent it completely. This is all the more noteworthy because comparatively small doses of cortisol can totally prevent such bone lesions. Extensive partial hepatectomy greatly increases the effect of AAN upon the bones."

*Selye C31,790/57:* In rats, osteolathyrism produced by AAN is inhibited by thyroxine, cortisol and estradiol but aggravated by STH even after adrenalectomy.

*Selye C36,049/57:* In rats, the ocular changes produced by IDPN are even more readily prevented by thyroxine than other manifestations of neurolathyrism.

*Strong et al. G61,885/58:* In rats, T3 or iodinated casein offered only slight protection against APN poisoning, "although skeletal changes were somewhat delayed and reduced in severity, possibly because of slower growth."

*Diaz et al. D99,329/58:* In rats, the osteolathyrism produced by MAAN is mildly inhibited by progesterone and estrone, completely prevented by thyroxine and aggravated by thyroidectomy.

*Ponseti & Aleu C61,715/58:* In rats with lathyrism produced by AAN, bone fractures

produce unusually large calluses which do not ossify well. T3 diminishes the size of the callus and improves its ossification.

*Selye C36,069/58*: In rats, the ECC syndrome (excitement, choreiform movements, and circling) normally produced by IDPN is inhibited by thyroxine. Thyroidectomy had no effect, but since the controls were 100% positive, an aggravation could not have been noted.

*Ponseti C68,050/59*: In rats, the lathyrus bone lesions produced by AAN were strongly suppressed by triiodothyronine and thyroxine, whereas those elicited by APN were much less evidently inhibited by these hormones. "Corticosterone and cortisone suppressed only slightly the lesions produced by aminoacetone trile in rats."

*Ponseti C78,321/59*: In rats, T3 is about 50 times as potent as thyroxine in suppressing osteolathyrism after treatment with AAN.

*Pyörälä et al. G67,833/59*: Dissecting aneurysms of the aorta developed in 40% of immature rats fed *Lathyrus odoratus*. The media was remarkably thickened and the ground substance showed increased metachromasia and PAS reaction. This response was suppressed by cortisone and thyroxine but not by ACTH, TTH or DOC at the doses employed.

*Gabay et al. D98,867/61*: In rats, the osteolathyrism produced by MAAN is associated with a considerable increase in bone hexosamine. This change is more effectively inhibited by thyroxine than by cortisone. Both hormones are virtually ineffective in protecting against osteolathyrism produced by the feeding of *Lathyrus odoratus* seeds.

*Khogali D10,840/61*: In rats, the diminished breaking stress and stiffness of the bones, characteristic of lathyrism induced by APN, can be counteracted both by L- and by D-T3. Since both isomers are equally effective in this respect, it is considered unlikely that their antilathyrus property depends upon classic thyroid hormone properties.

*Selye & Cantin C88,878/61*: In rats, the osteolathyrism produced by AAN is inhibited by thyroxine and cortisol but aggravated by STH. The cardiac infarcts elicited in rats by ligation of the descending branch of the left coronary artery are often transformed into rupturing cardiac aneurysms under the influence of AAN. The incidence of these cardiac ruptures is augmented by cortisol and DOC, but not significantly influenced by thyroxine and STH. Evidently there is no direct rela-

tionship between the skeletal and the cardiac lesions under these circumstances.

*Vivanco et al. D10,627/61*: Thyroxine prevents the osteolathyrism produced by MAAN but not that elicited by a *Lathyrus odoratus* diet.

*Vivanco et al. D15,606/61*: In rats, the neurolathyrism produced by IDPN as well as the associated histologic changes in the central nervous system are prevented by thyroxine.

*Aschkenasy D30,881/62*: In rats, lathyrism produced by AAN is inhibited by thyroxine and aggravated by propylthiouracil.

*Glickman et al. E24,104/63*: In rats, the dental changes produced by AAN are aggravated following partial hepatectomy and thyroidectomy, reduced by ACTH and almost completely abolished by thyroxine.

*Lalich & Turner G44,676/67*: In rats fed APN in combination with cottonseed meal, there occurred severe diarrhea, colonic dilatation and herniation in the costo-vertebral angle. These changes were uninfluenced by T3.

*Morcos F30,855/67*: In rats, thyroxine did not prevent the development of the ECC syndrome following injection of IDPN but only delayed its onset.

*Alper & Ruegamer H17,023/69*: In rats which developed lathyrism under the influence of semicarbazide, the antithyroid agent methimazole prevented the accumulation of chondroitin sulfate in the aorta.

AAN ← cf. also Table 73

### Lead ←

*Gabbiani et al. G46,731/68*: In rats, pretreatment with thyroxine or calcitonin inhibits the soft-tissue calcification and osteitis fibrosa induced by parathyroid extract overdosage. When both hormones are given simultaneously their effects are summated. Calcitonin, but not thyroxine, inhibits the local calcergy (induced by intravenous injection of lead acetate followed by topical administration of polymyxin) and the hypercalcemia produced by a single injection of lead acetate.

LSD ← cf. Table 74

### Magnesium ←

*Forbes G30,402/65*: In rats, thyroxine prevents the nephrocalcinosis of magnesium deficiency.

*Jasmin E7,631/68*: In rats, certain manifestations of the magnesium-deficiency syn-

drome are inhibited by cortisol, hypophysectomy or thyroparathyroidectomy.

*Jacob & Forbes G69,934/69*: In rats, nephrocalcinosis produced by magnesium deficiency is inhibited by approximately equal amounts of D- or L-thyroxine, but only if D-thyroxine is administered frequently enough to offset its more rapid metabolism in the tissue.

*Forbes G81,277/71*: In rats, the renal calcification produced by magnesium deficiency is prevented by thyroxine and aggravated by thyroid deficiency or injection of adenine. Such metabolic stimulators as Na-salicylate or 2,4-dinitrophenol are without effect.

**Mechlorethamine** ← cf. Table 75

#### **Meperidine** ←

*Schrogie & Solomon C43,019/66*: In mice, the metabolism of bishydroxycoumarin was markedly inhibited by both L- and D-thyroxine. The demethylation of meperidine was likewise inhibited by both isomers but particularly by D-thyroxine. L-thyroxine also increased the lethal effect of meperidine overdosage. Pentobarbital sleeping time was prolonged in mice treated with either L- or D-thyroxine but the latter was more active in this respect.

**Mephesisin** ← cf. Table 76

**Meprobamate** ← cf. also Table 77

*Selye & Solymoss G70,402/70*: Although in rats meprobamate intoxication is counteracted by catatoxic steroids, thyroxine actually aggravates it.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

**Mercury** ← cf. Tables 78—80

**Methadone** ← cf. also Table 82

*Sung & Way B91,323/53*: Rats treated with thiouracil or methimazole showed tolerance to toxic actions of methadone (absence of general depression and body rigidity). In thyroidectomized animals, the increase in pain-threshold was also diminished. Feeding of thyroid powder exerted opposite effects. Liver slices from thiouracil and thyroid-fed rats metabolized methadone more slowly than those from controls. Tissue levels of methadone were also increased by both these agents. However, total

urinary and fecal excretion of methadone was essentially the same in all groups.

**n-Methylaniline** ← cf. Table 83

#### **Methylphenidate** ←

*Fregly & Black F15,674/64*: In rats, pretreatment with propylthiouracil appeared to decrease the responsiveness to methylphenidate (given in the diet) as judged by the increased activity level induced by exposure to cold. However, "this difference in activity level is probably associated with differences in the food (and drug) intakes of the two groups."

*Selye PROT. 27955*: In rats, pretreated with thyroxine, methylphenidate produced temporary but very severe paralysis of the hind legs when given at dose levels which in nonpretreated controls caused only excitation.

#### **α-Methyl-p-tyrosine** ←

*Moore G36,616/65*: In mice, pretreatment with T3 greatly increases sensitivity to the lethal effect of amphetamine. "Chlorpromazine, phenoxybenzamine, and propranolol pretreatment reduced the lethality of d-amphetamine in hyperthyroid mice while α-methyl-m-tyrosine, α-methyl-p-tyrosine, and reserpine pretreatment did not. The toxicity of α-methyl-m-tyrosine was enhanced in hyperthyroid mice."

**Methyprylon** ← cf. Table 84

#### **Morphine** ←

*Hunt 49,716/07*: Comparative studies on the effect of thyroid extract upon the acetone-trile and morphine resistance of mice, rats and guinea pigs.

*Hunt & Seidell 50,346/09*: In mice, rats and guinea pigs, pretreatment with thyroid extract diminishes resistance to morphine.

*Olds Jr. 34,544/10*: In rats, thyroidectomy does not alter resistance to morphine.

*Busso 26,684/25*: In rats, thyroidectomy does not change the resistance to epinephrine or phenol. Morphine appears to be slightly more toxic to thyroidectomized than to intact rats but the results were irregular.

*Anan 24,228/29*: In mice, thyroxine increases the toxicity of morphine and heroin but not that of other alkaloids such as ethylmorphine, codeine, thebaine, papaverine and narcotine.

*Lund & Benedict A14,206/29*: In rabbits, morphine causes a more pronounced drop in

the BMR in the absence than in the presence of the thyroid. Morphine does not influence the rise in BMR induced by a thyroid extract.

*Glaubach & Pick 11,431/30*: In guinea pigs, pretreatment with thyroxine diminishes resistance against morphine.

*Vollmer & Buchholz A48,810/30*: In mice, thyroxine as well as various other "oxidizing substances" (glucose, lactate, methylene blue etc.) protect against alcohol intoxication. The same substances decrease resistance to colchicine or hydroquinone. Morphine resistance is not influenced.

*Zárday & Weiner A52,879/34*: In rats, morphine, and in rabbits chloral hydrate anesthesia were not significantly influenced by pretreatment with thyroxine s.c., one hour before the anesthetics. On the other hand, phenobarbital anesthesia was prolonged by thyroxine pretreatment in rabbits under identical conditions. Similar observations have been made on patients suffering from thyrotoxicosis in that they are unusually resistant to barbiturates but not to other anesthetics. This selective antagonism is ascribed to interactions between thyroxine and barbiturates at some common receptor site in the midbrain.

*Zárday & Weiner 53,715/35*: In rats, pretreatment with thyroxine s.c. does not influence the narcotic action of morphine given s.c. a few hours later.

*Swann 80,669/41*: In rats, thyroidectomy does not alter the morphine withdrawal symptoms.

*Bhagat F9,444/64*: In mice, pretreatment with thyroxine increased the analgesic action of morphine.

*Cochin & Sokoloff D29,487/60*: "The effect of in vivo administration of L-thyroxin on in vitro N-demethylation of morphine by rat-liver enzyme preparations from normal and morphine-treated rats has been investigated. Thyroxin given 7 days to otherwise untreated control animals has no effect on N-demethylating activity, but after 10—14 days it significantly depresses this activity. Administration of thyroxin for 7 days prior to and during morphine withdrawal reduces further the enzyme activity already markedly depressed after chronic administration of morphine, and prevents almost completely recovery of activity which occurs some 8—10 days after morphine withdrawal."

*Winter G71,836/65*: In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentylenetetrazol is increased by T3 or thyroid powder, whereas the narcotic

effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects. [The experimental conditions are not described in sufficient detail to evaluate these findings (H.S.).]

Morphine ← Thyroxine + Morphine: *Cochin et al. D29,487/60*

*a-Naphthylisothiocyanate* ← cf. *Table 85*

*Navadel* ← cf. *Dioxathion under Pesticides*

#### *Neostigmine* ←

*Tabachnick et al. C50,317/58*: In mice, thyroxine increases sensitivity to decamethonium and neostigmine but not to D-tubocurarine or succinyl choline. Rabbits pretreated with thyroxine also become more sensitive to decamethonium. It is tentatively suggested that the motor disturbances associated with hyperthyroidism may be due to "a change in the muscle itself, probably at the motor end-plate where these drugs act."

*Nicotine* ← cf. also *Table 86*

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to nicotine.

*Spinelli 10,086/31*: In guinea pigs, thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine and atropine but augments sensibility to pilocarpine and guanidine.

*Gogolák et al. G51,384/67*: In hypothyroid (<sup>131</sup>I, methylthiouracil, NaClO<sub>4</sub>) rats, higher doses of nicotine are required to produce hippocampal-seizure discharges with the typical modifications in EEG than in intact animals. The comparable effect of pentylene-tetrazol is not modified by hypothyroidism.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

*Nikethamide* ← cf. *Table 87*

*p-Nitroanisole* ← cf. *Table 88*

#### *Nitrogen Dioxide* ←

*Fairchild & Graham D56,574/63*: In mice and rats, mortality induced by exposure to respiratory irritants such as ozone or nitrogen dioxide is inhibited by thioureas or thyroidectomy but enhanced by thyroxine or T3.

Dinitrophenol, in doses known to elevate the BMR, did not significantly affect mortality under these conditions.

#### Nitrogen Mustard ←

*Connors & Elson G2,440/62*: In rats, thioureas reduce the toxicity of certain radiomimetic alkylating agents. The same is true of other compounds containing thiol groups.

#### Nitrous Oxide ←

*Rummel et al. D89,013/57*: In guinea pigs and rabbits, thyroxine increases the threshold for N<sub>2</sub>O anesthesia, whereas dinitrophenol has no such effect. Contrary to expectations, methylthiouracil also failed to affect the N<sub>2</sub>O anesthesia threshold.

*Rummel C79,429/59*: In guinea pigs and rats, thyroxine increases, whereas thyroidectomy decreases, the threshold for N<sub>2</sub>O anesthesia. Dinitrophenol is ineffective. DOC lowers, whereas cortisone raises, this anesthesia threshold.

*Rummel & Wellensiek D96,909/68*: In rats, the N<sub>2</sub>O anesthesia threshold is diminished by thyroidectomy and restored to normal by thyroxine but not by dinitrophenol.

#### Nortriptyline ←

*Ashford & Ross H2,686/68*: In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlorpromazine, perphenazine and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

#### Novocaine ←

*Glaubach & Pick 6,241/31*: Studies in guinea pigs and rabbits on the increase in dibucaine, cocaine and novocaine toxicity caused by thyroxine as judged by the resulting temperature variations.

#### Octamethyl Pyrophosphoramidate ← cf. Pesticides

#### Oxalate ←

*Kochmann 55,946/34*: In mice, fatal intoxication with Na-oxalate can be prevented by parathyroid extract in a dose-dependent manner suitable for bioassays.

#### Ozone ←

*Fairchild & Stokinger D4,088/61; Fairchild & Graham D56,574/63*: In mice and rats, mortality induced by exposure to respiratory irritants such as ozone or nitrogen dioxide is inhibited by thioureas or thyroidectomy but enhanced by thyroxine or T3. Dinitrophenol, in doses known to elevate the BMR, did not significantly affect mortality under these conditions.

*Fairchild G71,531/63*: Review (6 pp., 26 refs.) on the effect of thyroidectomy, thioureas, thyroid hormones, glucocorticoids and hypophysectomy upon the resistance of various species to inhaled irritants especially ozone.

#### Paraldehyde ←

*Rutsch 7,744/33*: In guinea pigs, thyroidectomy decreases, whereas thyroxine pretreatment increases, resistance to ether, paraldehyde or tribromoethanol anesthesia. These findings are ascribed to changes in the responsiveness of the brain.

#### Paraphenylenediamine ←

*Meissner E52,567/19*: The head and neck edema produced by paraphenylenediamine in the rabbit is not prevented by epinephrine, posterior pituitary extract or thyroid extract.

#### Pargyline ←

*Carrier & Buday E28,887/63*: In rats, the toxic effects of the MAO inhibitors, pargyline and iproniazid are increased by pretreatment with desiccated thyroid.

#### Paroxypropionine ←

*Scharf et al. C91,620/60*: In rats, the degenerative changes produced in the pituitary by p-hydroxypropiophenone (paroxypropionine or POP) are aggravated by methylthiouracil.

#### Pentachlorophenol ←

*Pasley et al. G67,522/68*: In cichlid fish, the toxic effect of pentachlorophenol (a herbicide, molluscicide and lumber preservative) is counteracted by thyroxine.

#### Pentylene-tetrazol ← cf. also Table 89

*Woodbury et al. B68,423/52*: In rats, brain excitability (pentylene-tetrazol, EST) decreases following thyroidectomy or treatment with

propylthiouracil and increases after thyroxine pretreatment. There are however certain differences between thyroidectomy and propylthiouracil as regards the recovery time from electroshock seizures and their relative effect upon extensor and flexor components.

*Pfeifer et al. D12,952/60:* In rats, the convulsive effect of "Pentametazol" [presumably pentylenetetrazol (H.S.)] is diminished one hour after administration of thyroxine, but increased 18 hrs later. A corresponding biphasic response is also noted with regard to the EST. In mice, the increased motility induced by amphetamine is also inhibited during the first hour after thyroxine treatment. The possible biochemical reasons for this "negative tendency" during the early phase of thyroxine action are described.

*Winter G71,836/65:* In mice, the toxicity of amphetamine, imipramine, chlordiazepoxide and pentylenetetrazol is increased by T3 or thyroid powder, whereas the narcotic effect of amobarbital and morphine is decreased. Methylthiouracil has, in general, opposing effects. [The experimental conditions are not described in sufficient detail to evaluate these findings (H.S.).]

*Gogolák et al. G51,384/67:* In hypothyroid ( $^{131}\text{I}$ , methylthiouracil,  $\text{NaClO}_4$ ) rats higher doses of nicotine are required to produce hippocampal-seizure discharges with the typical modifications in EEG than in intact animals. The comparable effect of pentylenetetrazol is not modified by hypothyroidism.

*Pfeifer et al. G65,057/68:* In mice, thyroxine facilitates the production of convulsions by pentylenetetrazol and electroshock. These effects are inhibited by various amphetamine derivatives.

Pentylenetetrazol ← Thiouracil,  
Mouse: Wenzel et al. G76,357/55\*

### Peptone ←

*Houssay & Cisneros 26,936/25:* In dogs sensitized after thyroidectomy, subsequent anaphylactic shock is diminished. Thyroidectomized dogs are also comparatively insensitive to peptone shock.

*Czarnecki & Kiersz D15,579/61:* In dogs, shock produced by trypan blue or peptone injection is more powerfully inhibited by thyroparathyroidectomy than by thyroidectomy.

**Perchlorates** ← cf. also Table 90

*Bajusz & Selye C64,511/59: C57,180/59; Selye C61,814/59:* The spastic muscular con-

tractions (with positive "flick-test") produced by  $\text{NaClO}_4$  in the rat can be inhibited by cortisol or triamcinolone, and aggravated by DOC or Me-Cl-COL. Thyroparathyroidectomy or parathyroidectomy exerts a sensitizing effect. Triamcinolone also protects the dog against the syndrome produced by heavy overdosage with  $\text{NaClO}_4$ . Methyltestosterone, estradiol and progesterone did not significantly affect the response of the rat to  $\text{NaClO}_4$ .

### Perphenazine ←

*Ashford & Ross H2,686/68:* In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlorpromazine, perphenazine and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

**Pesticides** ← cf. also Tables 91—99

*Byerrum B1,322/46:* In rats, iodine given either as Lugol's solution or as KI protects against ANTU poisoning.

*Byerrum & DuBois B3,076/47:* In rats, ANTU poisoning can be prevented by KI p.o. but very little protection is offered to thyroidectomized rats by the administration of iodine. Desiccated thyroid fed for 2 days offered no protection against ANTU.

*Meyer & Karel B18,102/48:* Of 25 compounds tested only KI and 1-thiosorbitol were unequivocally successful in preventing lethal pulmonary edema and pleural effusion in ANTU-treated rats. Organic iodides (diiodotyrosine, cetyl iodide, n-decyl iodide, amyl iodide, and iodoacetic acid) as well as iodine were ineffective.

*Carroll & Noble B32,718/49:* In rats, resistance to ANTU can be produced not only by pretreatment with ANTU itself but also by previous administration of other thioureas. "Neither the anti-thyroid potency nor the acute toxicity of these substances is directly related to their ability to impart resistance." However, resistance to ANTU is also found in rats fed on certain goitrogenic diets, especially those containing seeds of the brassica species.

*Wassermann et al. G74,485/69:* In rats, hepatic changes induced by p,p'-DDT are aggravated following thyroidectomy and the storage of p,p'-DDT, o,p'-DDT and dieldrin is increased.

*Selye G70,428/70:* In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia),

meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

*Selye G70,435/70*: In rats, ethylestrenol, CS-1, spironolactone, and norbolethone counteract the lethal effects of ethion, dioxathion, EPN, Guthion and parathion. To a lesser extent, this is also true of oxandrolone, prednisolone and progesterone. Triamcinolone, desoxycorticosterone, hydroxydione, estradiol, and thyroxine offer no consistent protection against these pesticides. DDT is much more resistant against detoxication by even the most powerful catatoxic steroids.

*Selye et al. G70,457/70*: In rats, ethylestrenol, CS-1, spironolactone and norbolethone fail to alter sensitivity to OMPA, although these typical catatoxic steroids have previously been shown to induce hepatic microsomal enzymes and to detoxify numerous other pesticides. This is of interest because catatoxic barbiturates greatly increase the toxicity of OMPA, presumably by transforming it into a more toxic metabolite. On the other hand, estradiol, estrone and stilbestrol, which have no typical catatoxic actions, considerably increase OMPA toxicity in ovariectomized rats. "The protective effect of catatoxic steroids is presumably due to their structural characteristics and is independent of other pharmacologic actions. Conversely, sensitization to OMPA depends more upon the estrogenic action of compounds than upon their chemical structure, since stilbestrol, a non-steroidal estrogen, is also highly effective in this respect." Prednisolone, triamcinolone, progesterone, DOC, hydroxydione and thyroxine fail to influence OMPA toxicity.

*Selye PROT. 31612*: In mice, the lethal effect of dioxathion is powerfully inhibited by ethylestrenol, norbolethone, prednisolone and estradiol, moderately by CS-1 and oxandrolone, but not influenced by spironolactone, progesterone, triamcinolone, DOC, hydroxydione and thyroxine.

DDT ← Thyroidectomy: Wassermann et al. G74,485/69\*

#### **Phenol ←**

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to phenol.

*Busso 26,684/25*: In rats, thyroidectomy does not change the resistance to epinephrine or phenol. Morphine appears to be slightly more

toxic to thyroidectomized than to intact rats but the results were irregular.

**Phenylramidol** ← cf. Table 100

#### **Phosphates ←**

*Selye C38,627/58*: In rats the nephrocalcinosis produced by a dietary excess of  $\text{NaH}_2\text{PO}_4$  is inhibited both by thyroparathyroidectomy and by excess thyroxine administration.

*Cantin F5,681/64*: The nephrocalcinosis produced in rats by combined treatment with  $\text{NaH}_2\text{PO}_4$  + either estradiol or DOC is prevented by parathyroidectomy or thyroparathyroidectomy, and in either case additional treatment with thyroxine prevents nephrocalcinosis.

*Meyer & Forbes G53,688/67*: In rats kept on a high-phosphate diet, nephrocalcinosis is decreased by thyroxine and increased by prophylthiouracil.

#### **Phosphorus ←**

*Selye & Mishra C40,183/58*: In the rat, mortality and hepatic degeneration produced by elementary yellow phosphorus is inhibited by thyroxine and aggravated by thyroidectomy. The associated osteosclerosis was not affected under the conditions of this experiment.

**Physostigmine** ← cf. also Table 110

*Selye G70,435/70*: In rats, intoxication with physostigmine was diminished by ethylestrenol, CS-1, spironolactone, and prednisolone, but aggravated by estradiol and thyroxine. Norbolethone, oxandrolone, progesterone, triamcinolone, DOC, and hydroxydione had no significant effect.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

**Picrotoxin** ← cf. also Table 102

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to picrotoxin.

*Spinelli 10,086/31*: In guinea pigs, thyroidectomy increases resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine and atropine but augments sensibility to pilocarpine and guanidine.

*Selye G70,428/70*: In rats, ethylestrenol powerfully inhibits the toxicity of digitoxin, nicotine, indomethacin, phenindione, dioxathion, EPN, physostigmine, hexobarbital, cyclopental, thiopental, DOC (anesthesia), meprobamate and picrotoxin. Thyroxine increases the toxicity of many of these drugs and inhibits the protective effect of ethylestrenol.

#### **Pilocarpine** ←

*Spinelli 10,086/31*: In guinea pigs, thyroidectomy increases the resistance to histamine, acetonitrile, picrotoxin, aconitine, epinephrine, nicotine and atropine but augments sensibility to pilocarpine and guanidine.

**Piperidine** ← *cf. Table 103*

**Potassium** ← *cf. also Selye C92,918/61, p. 83.*

*Lowenstein et al. A74,481/43*: In rats, pretreatment with DOC increased, whereas thyroid feeding decreased, resistance to KCl i.p.

**Pralidoxime** ← *cf. also Table 104*

*Selye G70,435/70*: In rats, pralidoxime intoxication was counteracted by prednisolone and, to a lesser extent, by ethylestrenol and estradiol. CS-1, spironolactone, norbolethone, oxandrolone, progesterone, triamcinolone, DOC, hydroxydione, and thyroxine had no significant effect.

**Propionitrile** ← *cf. also Table 105*

*Gellhorn 16,839/23*: In mice, resistance against acetonitrile can be increased not only by thyroid extract but, to a lesser extent, also by extracts of various other tissues. These preparations also augment resistance to potassium cyanide (KCN) and propionitrile, whereas thyroidectomy and orchidectomy have an opposite effect.

#### **Puromycin Aminonucleoside** ←

*Alexander & Hunt D20,284/61*: In rats, pretreatment with T3 aggravates the proteinuria caused by puromycin aminonucleoside.

#### **Pyruvate** ←

*Lecoq et al. B66,406/51*: In rats, the toxic effects of ethanol and its metabolites pyruvate and acetaldehyde (which accumulate in the body under the influence of disulfiram) are inhibited by ACTH, cortisone, and hepatic extracts. Conversely, thyroxine, DOC, and testosterone appear to aggravate ethanol intoxication. [Statistically evaluated data are not presented (H.S.).]

#### **Quinine** ←

*Karásek B52,652/37*: In guinea pigs pretreated with thyroid extract or thyroxine, the isolated right auricles of the heart exhibit an accelerated pulse. In this respect quinine exerts an antagonistic effect.

#### **Reserpine** ←

*Ershoff C60,006/58*: In rats, reserpine and thyroid extracts, given in well-tolerated amounts, caused 100% mortality when administered concurrently.

*Thier & Gravenstein C83,115/60*: In isolated atria of rats, the slowing of the heart beat produced by reserpine is antagonized by thyroxine pretreatment in vivo.

*Winter G71,836/65; F64,465/66;*

*F98,019/68*: In mice, pretreatment with thyroid extract p.o. increases the toxicity of reserpine, chlordiazepoxide, imipramine and amphetamine.

*Ashford & Ross H2,686/68*: In mice, pretreatment with thyroid extract increased the toxicity of imipramine, nortriptyline, chlorpromazine, perphenazine and chlordiazepoxide, whereas the toxicity of meprobamate and reserpine was not enhanced.

#### **Salicylates** ←

*Pfeiffer 16,694/23*: In guinea pigs, thyroidectomy aggravates the drop in body temperature produced by cooling or salicylate injection i.p.

*Vunder & Lapshina D34,912/56*: In rats, mice and chickens, the goitrogenic effect of paraamino-salicylic acid is prevented by concurrent administration of thyroid extract.

#### **Semicarbazide** ←

*Hunt & Carlton F3,186/64*: In Pekin ducks, combined administration of semicarbazide and isoniazid p.o. produce a neuroathyrisism-like syndrome which is not significantly influenced either by thiouracil or by DL-thyroxine.

*SKF 525-A* ← *cf. Table 106*

#### **Sodium Chloride** ←

*Fregly C77,939/59*: In rats, the hypertension induced by substitution of hypertonic NaCl for drinking fluid, as well as the accompanying cardiac and renal hypertrophy, are prevented by propylthiouracil.

**Strychnine** ← *cf. also Table 107*

*Hunt & Seidell 50,346/09*: In mice, pretreatment with thyroid extract does not influence resistance to strychnine.

*Bálint & Molnár 34,586/11*: In guinea pigs, the fatal effect of strychnine intoxication is inhibited by epinephrine or thyroid extract i.p.

*Marañón & Aznar 46,926/11*: In frogs, the fatal convulsions produced by strychnine can be prevented if, prior to injection, the drug is mixed with extracts of the posterior pituitary, the thyroid, various other tissues, and particularly epinephrine. [The possibility of delayed absorption owing to local vasoconstriction has not been considered (H.S.).]

*Parhon & Urechia 62,361/13*: In dogs and rabbits, orchidectomy and thyroidectomy do not influence resistance to strychnine consistently, but thyroid feeding appears to aggravate the characteristic convulsions.

#### **Sulfa Drugs ←**

*Lehr & Martin C13,119/56*: In rats, the production of cardiovascular lesions by "standard renal injury" (due to treatment with sulfa drugs) is prevented by thyroparathyroidectomy but not by thyroidectomy with parathyroid extract treatment. Curiously, "chemical thyroidectomy" [technique not specified (H.S.)] also inhibited, and thyroid hormone excess aggravated these lesions.

*Lehr & Martin C23,011/56*: In rats, the cardiovascular lesions produced by sodium acetylsulfathiazole (as a consequence of renal injury) are prevented by thyroparathyroidectomy, presumably because in the final analysis the changes observed are due to nephrogenic hyperparathyroidism.

Taurochenodeoxycholate ← Thyroxine: Voigt et al. *H25,247/70*

#### **Tetrahydronaphthylamine ←**

*Borchardt 23,683/28*: In cats, neither thyroparathyroidectomy nor adrenalectomy prevents the production of fever by tetrahydronaphthylamine, whereas denervation of the liver inhibits it almost completely.

*Glanbach & Pick 11,431/30*: In rabbits, the fever normally produced by tetrahydro- $\beta$ -naphthylamine or cocaine is increased to fatal levels following pretreatment with thyroxine.

#### **Thallium ←**

*Buschke 4,823/33*; *Buschke et al. 43,284/33*: In mice, thyroxine increases, whereas thymus

extract decreases, sensitivity to thallium intoxication.

*Uspenskaya D34,628/39*: In rabbits, thallium intoxication is aggravated by chronic pretreatment with thyroid extract but not significantly influenced by thyroidectomy.

**Theobromine ← cf. Table 108**

#### **Theophylline ← cf. also Table 109**

*Strubelt et al. G78,572/70*: In rats, T3 increases, whereas thyroidectomy decreases, the calorogenic response to theophylline and caffeine, probably because the thyroid hormone activates adenylcyclase and/or inhibits phosphodiesterase.

**Thimerosal ← cf. Table 110**

#### **Thioacetamide ←**

*Srinivasan & Balwani G64,503/68*: In rats, pretreatment with thyroxine increased the liver damage produced by subsequent administration of CCl<sub>4</sub> or thioacetamide.

#### **Thiourea ←**

*MacKenzie & MacKenzie A49,024/43*: In rats, thyroidectomy offers no protection against the production of pulmonary edema by acute thiourea-overdosage.

*Glock B23,056/45*: In rats given normally fatal doses of thiourea, treatment with adrenocortical extract plus NaCl offers greater protection than NaCl alone. Thyroxine is a still more effective prophylactic even when given without NaCl.

*Wiberg et al. E23,265/63*: The mouse anoxia test performed after thiouracil treatment permits simultaneous assessment of survival and goitre prevention. The antigoitrogenic assay is more sensitive and permits greater precision than the anoxia test in the bioassay of thyroactive materials.

**Tribromoethanol ← cf. also Table 111**

*Pribram A47,677/29*: Both in rabbits and in man, single i.v. injections of thyroxine a few hours prior to administration of tribromoethanol diminish the actions of the latter.

*Rutsch 7,744/33*: In guinea pigs, thyroidectomy decreases, whereas thyroxine pretreatment increases, resistance to ether, paraldehyde or tribromoethanol anesthesia. These findings are ascribed to changes in the responsiveness of the brain.

**Trichlorethanol ← cf. Table 112**

**Tri-o-cresyl phosphate ← cf. Table 113**

**Triton** ←

*Michel & Truchot C 79,107/59*: In thyroidectomized rats, the hypercholesterolemia and, to a lesser extent, perhaps also the cholesterol accumulation in the liver produced by triton WR-1339 are diminished by thyroxine.

**Tryptophan** ←

*Bavetta et al. C 47,327/57*: In rats, various manifestations of tryptophan deficiency are aggravated by thyroid feeding.

**D-Tubocurarine** ← cf. Table 114

**Tyramine** ← cf. Table 115

**Tyrosine** ← cf. also Table 116

*Schweizer B 3,047/47*: Addition of excessive amounts of L-tyrosine to the diet produces alkaptonuria, keratitis, conjunctivitis, alopecia, and inflammation of the paws in young rats. Among older animals, males are more sensitive than females. The severity of the syndrome is aggravated by thyroxine and inhibited by thiouracil.

*Moore G 36,616/65*: In mice, pretreatment with T<sub>3</sub> greatly increases sensitivity to the lethal effect of amphetamine. "Chlorpromazine, phenoxybenzamine, and propranolol pretreatment reduced the lethality of d-amphetamine in hyperthyroid mice while  $\alpha$ -methyl-m-tyrosine,  $\alpha$ -methyl-p-tyrosine, and reserpine pretreatment did not. The toxicity of  $\alpha$ -methyl-m-tyrosine was enhanced in hyperthyroid mice."

*Boctor et al. H 22,509/70*: In rats, tyrosine intoxication was aggravated by thyroxine and alleviated by thiouracil. "Plasma tyrosine concentration and liver tyrosine transaminase activity were high in rats fed a high tyrosine diet; thyroxine administration increased them further, but depressed slightly the activity of liver p-hydroxyphenylpyruvate hydroxylase."

**Uranium** ←

*Rabboni & Milazzo B 18,975/47*: In rabbits, thyroidectomy protects against the production of toxic nephritis by conjoint administration of uranium acetate and epinephrine.

**Vitamin A** ←

*Euler & Klussmann 4,928/32*: In rats, the toxicity of thyroxine is partly inhibited by carotene and the authors suggest that perhaps "thyroxine is bound to carotene and thereby

inactivated." There may exist a physiologic antagonism between vitamin A and thyroxine.

*Fasold & Heidemann 16,518/33*: A goat normally excreted vitamin A but no carotene in its milk. After thyroidectomy, the milk of the same animal contained carotene but no vitamin A. It is assumed that thyroid hormone participates in the synthesis of vitamin A.

*Abelin 57,019/33*: In guinea pigs, thyroxine inhibits the hepatic storage of carotene and its transformation into vitamin A. In vitro studies suggest an actual chemical interaction between carotene and thyroxine.

*Fasold & Peters A 54,337/33*: In rats, hypervitaminosis A can be prevented by thyroxine. The hormone causes a resumption of growth and of carotene deposition in the liver.

*Schneider & Widmann 33,725/35*: In guinea pigs, both thyroidectomy and treatment with TTH considerably alter vitamin-A metabolism.

*Fleischmann & Kann 67,360/36*: In mice, vitamin A antagonizes the protective effect of thyroxine against acetonitrile intoxication. Vitamin A also antagonizes the effect of thyroxine upon tadpole metamorphosis. The enhancement of fatty acid oxidation by carotene in vitro is inhibited by thyroxine.

*Greaves & Schmidt A 48,725/36*: In rats, laparotomy and various toxic agents failed to influence vitamin-A requirements but these are increased by thyroxine or desiccated thyroid and decreased by thyroidectomy.

*Sure & Buchanan A 48,611/37*: In rats kept on specified diets, thiamine antagonizes the toxic actions of thyroxine but, at the same time, tends to increase vitamin-A requirements as manifested by the onset of xerophthalmia.

*Logaras & Drummond A 16,392/38*: Metabolic studies on rats kept on a vitamin-A-deficient diet "do not support the view that thyroxine increases the utilization or decreases storage of vitamin A."

*Wohl & Feldman A 30,107/39*: In patients with hyperthyroidism or hypothyroidism, dark adaptation is frequently deranged suggesting the existence of a disturbance in vitamin-A metabolism.

*Baumann & Moore C 38,599/39*: In rats given an excess of vitamin A, thyroxine promoted catabolism and shortened survival. Earlier literature on an alleged antagonism between thyroxine and vitamin A is reviewed.

*Canadell & Valdecasas B 25,697/47*: In rats kept on a vitamin-A deficient diet the characteristic trophic changes can be prevented by the administration of carotene. Thiourea blocks the protective effect of the provitamin A and the

effect of the antithyroid compound is in turn blocked by thyroid powder or iodine. The action of thiouracil is ascribed to the inhibition of carotenase activity.

*Wiese et al. B39,257/48*: In rats, thiouracil prolongs survival on vitamin-A deficient diets.

*Woollam & Millen C64,432/58*: The offspring of rats given large doses of vitamin A during pregnancy often show deformities of the skull and brain. This teratogenic effect is potentiated by methylthiouracil administration to the pregnant mother.

*Nicol & Grangaud D20,176/61*: In rats, thiouracil ameliorates the manifestations of vitamin-A deficiency. Progesterone has a similar effect.

*Anderson et al. G11,709/64*: In rats kept on diets with varying vitamin-A contents, the hepatic storage of vitamin A was increased by thyroxine as compared to thiouracil-treated controls, but the total vitamin-A storage of the body remained unaffected.

*Khogali F73,238/66*: In rats, hypervitaminosis A is aggravated both by L- and by D-triiodothyronine.

*Sundaresan et al. G50,127/67*: The vitamin-A requirements of rats are greatly increased during exposure to cold; this increase is abolished by thiouracil.

#### Vitamin-B Complex ←

*Cameron & Moore 57,815/21*: In pigeons kept on polished rice, wasting and death were accelerated by thyroid feeding but it is dubious whether this was true also of the specific manifestations of polyneuritis.

*Nishimura & Nitta 1,171/29*: In vitamin B complex deficient rats, thyroid feeding aggravates the severity of the resulting skeletal lesions.

*Templeton & Patras 9,640/33*: In rats, survival on a thiamine-deficient diet is prolonged by thyroparathyroidectomy but not significantly altered by desiccated thyroid.

*Perelmuter & Miletzkaja 78,650/34*: In pigeons on a B-avitaminotic diet, thyroid feeding accelerates the development of polyneuritis.

*Sure & Buchanan A6,259/37*: In rats, the loss of weight produced by thyroxine can be combated by thiamine.

*Sure & Buchanan A48,611/37*: In rats kept on specified diets, thiamine antagonizes the toxic actions of thyroxine but, at the same time, tends to increase vitamin-A require-

ments as manifested by the onset of xerophthalmia.

*Infante et al. C17,520/55*: In rats, vitamin-B<sub>12</sub> possesses no lipotropic potency in itself but does prevent hepatic steatosis on hypolipotropic diets supplemented with thyroxine.

*Gershoff et al. C54,255/58*: In rats, thyroxine greatly increases vitamin-B<sub>12</sub> requirements.

#### Vitamin C ←

*Mouriquand & Michel 12,231/21*: In guinea pigs kept on a normally adequate diet, scurvy-like bone changes developed upon treatment with thyroid extract. Other manifestations of scurvy have not been noted.

*Abderhalden 13,399/23*: In guinea pigs on an ascorbic acid-deficient diet, thyroidectomy aggravates but does not accelerate the development of scorbutic lesions.

*Svirbely 33,140/35*: In guinea pigs fed a vitamin-C deficient diet, the development of scurvy is accelerated by thyroid feeding.

*Ganguli et al. G71,669/56*: Chlorobutanol increases ascorbic acid synthesis and this effect can be suppressed by simultaneous administration of thyroxine, ATP, or malic acid.

*McGraw C68,484/59; C80,136/59*: Doctor's thesis describing numerous experiments on the effect of adrenalectomy, cortisone, thyroxine, thyroidectomy, thioureas and STH upon scorbutic guinea pigs, with special emphasis upon changes in capillary resistance and cold tolerance.

**Vitamin D, DHT** ← *cf. also Selye G60,083/70, p. 400.*

*Kunde & Williams 18,960/27*: In rats thyroidectomized (without removing the parathyroids) 15–29 days after birth, even very large amounts of cod liver oil cannot prevent the development of rickets on a rachitogenic diet.

*Schechet B61,419/51*: In rats, addition of desiccated thyroid or iodinated casein to a rachitogenic diet assures more regular growth and thereby facilitates the bioassay of vitamin-D preparations.

*Gillman & Gilbert C31,076/56*: The arterial lesions produced by heavy vitamin-D overdosage in the rat are aggravated by thyroxine or DOC, whereas cortisone and thyroidectomy offer considerable protection.

*Selye C27,735/57*: The cardiovascular calcification and nephrocalcinosis produced by DHT in rats are aggravated by estradiol,

cortisol, ACTH and thyroxine. Conversely, methyltestosterone and STH exert a protective effect.

*Takens C69,439/59:* In rabbits, the calcinosis and other toxic manifestations of vitamin-D<sub>2</sub> overdosage are accentuated by pretreatment with methylthiouracil.

*Manston G69,733/69:* The metastatic calcification produced by vitamin-D<sub>3</sub> overdosage in the cow can be prevented by thyroxine.

**DHT** ← *cf. also Table 117*

### **Vitamin E** ←

*Wheeler & Perkinson B43,572/49:* In chicks, vitamin-E requirements are increased by pretreatment with thyroprotein and decreased by thiouracil.

*Tentori et al. C7,904/54:* In rats, thyroid feeding accelerates the development of the characteristic skeletal muscle lesions produced by vitamin-E deficiency.

*Fudema et al. D23,102/62:* In rabbits, the muscular dystrophy and death induced by vitamin-E deficiency are delayed following suppression of thyroid activity by <sup>131</sup>I.

### **Vitamins (Pantothenic Acid)** ←

*Haque et al. B19,204/48:* In chicks fed a ration low in folic acid and pantothenic acid, thyroxine caused high mortality but the pantothenic acid-deficiency symptoms were partially counteracted. Review of the literature.

**W-1372** ← *cf. Table 118*

### **Water** ←

*Gaunt 84,566/44:* Rats are protected against water intoxication by thyroxine. This effect is largely abolished by adrenalectomy.

**Zoxazolamine** ← *cf. also Table 119*

*Conney & Garren D78,956/60:* In rats, pretreatment with thyroxine i.p. shortened the

duration of action of zoxazolamine by increasing its metabolism in vivo. However, thyroxine unlike phenobarbital and other drugs did not accelerate zoxazolamine metabolism by increasing the activity of hepatic microsomal enzymes; the shortening of zoxazolamine action by thyroxine was correlated with increased activity of glucose-6-phosphate and 6-phosphogluconate dehydrogenases which are involved in the generation of NADPH.

*Conney & Garren D93,666/61:* In rats, thyroxine shortens the duration of action of zoxazolamine by accelerating its metabolism through hepatic microsomes.

*Harbison & Becker H10,917/69:* Thyroidectomy greatly prolonged hexobarbital sleeping time and zoxazolamine paralysis in rats. T<sub>3</sub> increased the response to hexobarbital but decreased the effect of zoxazolamine. The mortality rates induced by high doses of hexobarbital, thiopental, amobarbital, pentobarbital and phenobarbital were all significantly increased in rats pretreated with T<sub>3</sub>.

**Zoxazolamine** ← Thyroxine: Conney et al. *D93,666/61\**

### **Varia** ←

*Hunt & Seidell 50,346/09:* Systematic studies on the effect of thyroid extract upon the resistance of mice to a great variety of toxic substances.

*Störtebecker 76,398/39:* Review of the early literature on the effect of thyroid hormone upon resistance to various drugs.

*Selye G70,480/71:* In rats, pretreatment with thyroxine diminished resistance to intoxication with dioxathion and parathion. It failed to affect poisoning with digitoxin, nicotine, hexobarbital, progesterone (anesthesia), zoxazolamine, indomethacin, acute DHT induced tissue calcinosis or the infarctoid myocardial necroses produced by fluorocortisol + Na<sub>2</sub>HPO<sub>4</sub> + corn oil.

### **Complex Diets** ←

In rabbits, thyroidectomy moderately decreases the catabolic effect of fasting. Thyroid feeding accelerates catabolism in rats kept on vitamin-free diets.

Nutritional hepatic cirrhosis (such as is seen on various hypolipotropic diets) is prevented by propylthiouracil and other thioureas in proportion to their goitrogenic effect, whereas thyroid feeding has an opposite action.

In hamsters, gallstone formation on a diet containing 24% rice starch is increased by concurrent treatment with thyroxine.

*Blum 38,401/00; 38,405/06*: Studies on the effect of thyroidectomy upon the resistance of dogs, rabbits, and sheep to feeding various diets led to the conclusion that the thyroid is not an organ of internal secretion but acts by accumulating and destroying endogenous toxic substances especially those derived from meat diets.

*Mansfeld & Müller 35,416/11*: In rabbits, thyroidectomy inhibits the protein catabolic effect of exposure to decreased oxygen tension, hydrocyanic acid intoxication or fasting.

*Hari 51,049/19*: Contrary to earlier claims, even thyroidectomized rabbits show intense protein catabolism during fasting.

*Cameron & Moore 57,815/21*: In rats kept on a vitamin-free diet (oatmeal and water), thyroid feeding produced a particularly rapid loss of weight.

*György et al. 67,701/48*: In rats, hepatic cirrhosis produced by a complex hepatotoxic diet is prevented by propylthiouracil and other thioureas in proportion to their goitrogenic effect.

*Sellers & You 668,641/51*: In rats kept on a choline-deficient diet, propylthiouracil retards

the development of hepatic cirrhosis and fatty cyst formation; thyroid feeding has an opposite effect.

*Dryden & Hartman C 66,416/59*: In rats kept on various complex diets during treatment with thyroprotein, no single nutrient could be found which would antagonize the manifestations of hyperthyroidism.

*Bergman & van der Linden G 30,642/65*: In hamsters, gallstone formation on a diet containing 24% rice starch, is increased by concurrent treatment with D-thyroxine. At the same time, the animals develop fatty livers. On a diet containing 72.3% rice starch, the gallstone-forming action of D-thyroxine is blocked although hepatic steatosis still occurs.

*Bergman & van der Linden G 43,913/66; G 39,200/66*: In hamsters kept on certain diets, thyroxine promotes gallstone formation. Cholestyramine prevents this effect.

*Borgman & Haselden H 29,947/70*: In rabbits kept on a gallstone producing ration, ACTH, thyroid hormones or cortisone did not inhibit the production of biliary calculi, but several of these hormones inhibited the usually associated hepatic steatosis.

### **Microorganisms, Parasites and Their Products ←**

**Bacteria and Vaccines ←**. Numerous investigations dealt with the effect of thyroid hormones upon the course of various bacterial infections but special attention was given in this connection to tuberculosis. In guinea pigs, thyroidectomy and thiouracil diminish, whereas thyroxine and T<sub>3</sub> increase, resistance to tuberculosis. Essentially similar observations were made in rabbits and in mice. However, in the latter species, pretreatment with thyroxine or dinitrophenol in doses sufficient to limit the weight gain of noninfected controls, diminished resistance to infection with tuberculosis.

Heavy overdosage with thyroxine also diminishes resistance to various other bacterial infections (e.g., plague bacilli, *S. typhi*, staphylococcus, streptococcus) although it increases resistance to some infections (e.g., chicken cholera); we have no valid explanation for this dual effect although it may be due to incidental conditioning factors (dosage, timing, diet, etc.) as much as to the type of microbe used.

**Viruses ←**. In monkeys, resistance to poliomyelitis virus is allegedly not affected either by thyroidectomy or by thyroxine, but in mice, it is increased by thyroid extract and decreased by thiouracil.

In rats, sensitivity to various strains of encephalitis virus is augmented by thyroxine and the same appears to be the case in mice vaccinated and subsequently infected with influenza.

**Parasites ←**. Thyroid feeding has an adverse effect upon mice infected with *Hymenolepis tapeworms*, whereas thiouracil increases resistance to these parasites.

In chickens, thiouracil did not appear to alter resistance to cecal coccidiosis (*Eimeria tenella*) significantly but mild hyperthyroidism, induced by thyroactive

iodocasein, increased the ability of chicks to overcome infection with *Ascaridia galli* or *Heterakis gallinae*.

Allegedly thyroidectomy or pretreatment with thioureas also slightly decreases resistance to toxoplasma and to *Trichinella spiralis* in the mouse.

**Bacterial Toxins** ←. In guinea pigs and rabbits, thyroidectomy or treatment with thyroid preparations produced only minor and variable changes in resistance to various endotoxins. Allegedly, in mice, the lethal action of endotoxins is enhanced by T3 or thyroxine, whereas in guinea pigs thyroxine diminishes the lethal effect of tetanus toxin.

### **Bacteria and Vaccines** ←

**Bacillus Anthracis** ←. *Weinstein B15,029/39*: In mice, various anterior pituitary preparations protect against infection with *B. anthracis*. Parathyroid extract was also very effective, whereas thyroxine and testosterone offered little protection and progesterone, insulin, "estrin" and posterior lobe extract were virtually ineffective.

**Brucella Melitensis** ←. *Bradley & Spink C76,042/59*: In mice, infected with small numbers of *B. melitensis*, hepatic granulomas occurred without necrosis. Severe necrosis developed after pretreatment with T3 without multiplication of brucellae and with minimum inflammatory lesions. Necrosis was not induced by T3 in mice given brucella endotoxin after T3 treatment.

**Klebsiella Pneumoniae** ←. *Martin & Bullard H15,263/69*: In mice, resistance to infection by *K. pneumoniae* is increased by propylthiouracil and decreased by thyroxine.

**Mycobacterium Tuberculosis** ←.

### **GUINEA PIG**

*Kepinow & Metalnikov 40,285/22*: Thyroidectomized guinea pigs infected with tubercle bacilli do not respond with fever to a subsequent tuberculin injection although their survival rate is not altered.

*Izzo & Cicardo B23,261/47; B67,482/47*: In guinea pigs, thyroidectomy diminishes, whereas thyroxine increases, resistance to infection with tubercle bacilli. The clinical literature on the effect of hyperthyroidism upon tuberculosis is reviewed.

*Swedberg B59,988/51*: Thyroxine diminishes the resistance of guinea pigs to tuberculosis. "Estrogen" has the same effect, whereas testosterone does not significantly change the course of the infection.

*Wasz-Höckert et al. C30,699/56*: In guinea pigs, methylthiouracil aggravated, whereas

thyroid extract ameliorated, the course of experimental tuberculosis.

*Renovanz C78,772/59*: In guinea pigs, the course of experimental tuberculosis was not markedly influenced by ACTH, tolbutamide derivatives or antithyroid treatment with perchlorates.

*Solanki & Junnarkar D21,370/61*: In guinea pigs, pretreatment with thyroxine increases the resistance to tuberculosis by augmenting the phagocytic capacity of mononuclear leukocytes.

*Bloch D61,174/63*: In guinea pigs, resistance to tuberculosis is increased by T3.

*Vakilzadeh & Vandiviere E32,626/63*: In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T3, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

### **RABBIT**

*Lurie & Ninos C14,387/56*: In rabbits pretreatment with T3 inhibits, whereas thiouracil aggravates, the course of experimental tuberculosis.

*Lurie et al. C14,963/56; C52,055/58*: In rabbits, the course of pulmonary tuberculosis is ameliorated by treatment with T3 or thyroxine and aggravated by propylthiouracil or thyroidectomy. Dinitrophenol exerts no conspicuous effect.

*Lurie et al. C64,295/59*: In rabbits, thyroidectomy or propylthiouracil reduced the native resistance to human tubercle bacilli. T3 exerted no consistent effect upon tuberculin sensitivity but greatly inhibited the growth of bacilli and enhanced resistance to infection.

*Lurie et al. C65,610/59*: Various strains of inbred rabbits were infected with tuberculosis bacilli. "Hyperthyroidism induced by L-triiodothyronine or L-thyroxine suppressed to a greater or lesser degree the inception and

progress of the pulmonary tuberculosis produced by the quantitative inhalation of human tubercle bacilli in four races, AD, III, IIIC, CaC, and IIIA, with low or intermediate genetic resistance to the disease. L-Triiodothyronine also exerted a definite suppressive influence on the development of an already existing tuberculosis when the hormone was administered three weeks after the infection."

*Dzyubinskaya C97,348/60*: Pretreatment with methylthiouracil aggravates the course of experimental tuberculosis in rabbits.

#### MOUSE

*Dubos D93,317/55; G71,484/55*: In mice, resistance to tuberculosis is decreased by pretreatment with thyroxine or dimitrophenol p.o. in amounts sufficient to limit the weight gain of noninfected controls. These findings, as well as observations on dietary factors influencing resistance to tuberculosis, led to "the hypothesis that a decrease in resistance to infection can be brought about by metabolic disturbances which cause either a depletion of the glycogen reserves of the body, or a reduction in the glycolytic activity of inflammatory cells, or an increase in the concentration of certain polycarboxylic acids and ketones in the tissues."

*Maśliński C50,519/56*: In mice, the histologic reaction to infection with tuberculosis is somewhat altered by pretreatment with "thyroid hormone" or methylthiouracil, but survival is not significantly changed.

*Maśliński C50,520/56*: In mice, severe overdosage with methylthiouracil or desiccated thyroid aggravates the course of tuberculosis. There is, however, an optimum state of hyperthyroidism in which the intensity of the tuberculous changes is the lowest.

*Chirico et al. C67,012/59*: In mice, small doses of thyroxine diminish mortality and prolong the mean survival time following infection with tubercle bacilli.

*Backman C94,674/60*: In mice, both methylthiouracil and desiccated thyroid aggravate the course of experimental tuberculosis.

#### RAT

*Steinbach 92,528/32*: In rats, parathyroidectomy lowers resistance to infection with bovine but not with human tuberculosis. Thyroparathyroidectomy makes rats susceptible to both human and bovine tubercle bacilli.

#### VARIA

*Schäfer B99,955/54*: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas and gonads.

*Maśliński C48,845/57*: Review (55 pp., 114 refs.) on the relationship between tuberculosis and the thyroid. Personal observations on mice revealed that following infection with tuberculosis mortality was increased by methylthiouracil in comparison with controls receiving thyroid preparations or no hormone treatment.

*Debry et al. D34,828/62*: Review (14 pp., 64 refs.) on the relationship between tuberculosis and thyroid activity.

*Mycoplasma* ←. *Tripi et al. B12,732/49*: In rats, the production of polyarthritis by PPLO organisms was enhanced and the mortality increased following chronic pretreatment with thiouracil. Thyroidectomy (inducing a similar or greater drop in BMR) did not change this form of polyarthritis. Presumably, thiouracil acts "through some peculiar intrinsic action" rather than by merely diminishing thyroid activity.

*Pasteurella* ←. *Marbé 34,321/10*: In guinea pigs, pretreatment with thyroid extract diminishes resistance to infection with plague bacilli and counteracts the protective effect of antiplague serum.

*Parhon & Parhon 36,340/14*: During a chicken cholera epidemic, a small number of thyroid extract-treated chickens survived better than controls.

*Salmonella Typhi* ←. *Marbé 34,320/10; A23,018/10*: In guinea pigs, resistance to infection with typhoid bacilli is diminished by pretreatment with thyroid extract.

*Marbé A23,015/12*: Addition of thyroid extract to cultures of typhimurium bacilli in vitro increases their virulence.

*Shigella* ←. *Melnik 26,134/25*: In rabbits, thyroidectomy offers some protection against infection with Shiga bacilli.

*Staphylococcus* ←. *Lauber 9,102/32*: Observations on the effect of vasopressin, epinephrine, thyroid extract and insulin upon streptococcal and staphylococcal infections in mice.

*Sealy A56,716/42*: In rabbits, desiccated thyroid does not produce liver necrosis in itself but facilitates its production after infection by *S. aureus*. A review of the literature also suggests that uncomplicated hyperthyroidism does not result in liver necrosis

either in experimental animals or in man unless there is a complicating infection.

*Dubos et al. C21,520/55; Dubos G71,484/55:* In mice, thyroxine pretreatment diminishes resistance to infection with *S. aureus*. The resistance-diminishing effect of thyroxine and dinitrophenol against other infections is briefly mentioned.

*Smith & Dubos C12,130/56:* In mice, pretreatment with thyroid extract or dinitrophenol decreases resistance to staphylococcal infection.

*Hedwall & Heeg D14,804/61:* In rats, an experimental staphylococcus pyelonephritis is aggravated by pretreatment with thyroxine.

**Streptococcus** ←. *Lauber 9,102/32:* Observations on the effect of vasopressin, epinephrine, thyroid extract and insulin upon streptococcal and staphylococcal infections in mice.

*Schultz 99,001/38:* In guinea pigs and rabbits, pretreatment with thyroxine increases susceptibility to the development of purulent myocarditis after s.c. inoculation with hemolytic streptococci.

**Varia** ←. *Marbé A4,623/08; A4,624/08; A4,625/08; A4,626/09; A4,627/09; A23,010/09; A23,011/09; A23,012/09; A23,013/09; A23,016/10; 34, 561/10:* Studies on the effect of thyroidectomy and thyroid extract upon opsonin formation and phagocytosis of bacteria in guinea pigs and rabbits.

*Murphy et al. C60,008/58:* In mice, resistance to infection with *C. albicans* or *S. pyrogens* is increased by pretreatment with T3 but this hormone does not significantly alter resistance to transplanted leukemia.

*Nutter et al. C65,285/59:* In mice, T3 decreases survival time after infection with tubercle bacilli or pneumococci.

#### Viruses ←

*Levaditi & Haber 33,069/35:* In *Macacus cynomolgus* monkeys, resistance to poliomyelitis virus, acquired by prior infection, is not influenced by thyroidectomy, orchidectomy or thyroxine administration.

*Holtman B1,287/46:* In mice, resistance to infection with polio virus is increased by thyroid extract and decreased by thiouracil. The comparative polio resistance of mice kept in a cool environment may be secondary to increased thyroid hormone production.

*Hurst et al. C94,089/60:* Cortisone, ACTH, estradiol, stilbestrol and thyroxine all stimulate the growth of the virus of equine encephalomyelitis in the dog whereas testosterone and

progesterone do not. The hormones which aggravate the infection also counteract the prophylactic effect of mepacrine and abolish the normally greater resistance of the females.

*Jandásek C88,870/60:* In suckling rats infected with tick encephalitis survival was greatly shortened by thyroxine. Neither antibody production nor the number of virus carriers was influenced by the hormone.

*Jandásek C92,117/60:* Mice become particularly sensitive to infection by encephalitis virus (strain Hypr) following pretreatment with thyroxine.

*Lungu et al. F84,406/67:* In mice vaccinated against influenza, subsequent infection with the virus causes an increased mortality following treatment with thyroxine or thiouracil.

*Jannuzzi et al. H27,335/70:* In patients with viral hepatitis, various anabolics, including stanozolol and 4-chlorotestosterone, exert a beneficial effect.

#### Parasites ←

*Larsh Jr. A47,571/47:* In old mice, thyroid feeding has an adverse effect on infestation with *Hymenolepis tapeworms*, whereas thiouracil increases resistance to the parasites. In young mice, the infestation was much less dependent upon the thyroid status.

*Wheeler et al. A48,602/48:* In chickens, a preliminary study suggests that thiouracil-induced hypothyroidism does not significantly affect resistance to cecal coccidiosis induced by infection with *Eimeria tenella*.

*Todd G71,890/48:* In chickens infected with *Ascaridia galli* or *Heterakis gallinae*, mild hyperthyroidism induced by feeding thyroactive iodocasein (Protamone) increased the ability of the birds to overcome the worm infestation. Thiouracil had a detrimental effect.

*Todd B40,185/49:* In chickens infected with *Ascaridia galli* or *Heterakis gallinae*, treatment with thyroactive iodocasein or thiouracil caused no significant difference in the development of either worm; however, "specimens of *H. gallinae* attained significantly greater lengths in mildly hypothyroid birds."

*Hirschlerowa C35,235/56:* Thyroidectomy or pretreatment with methylthiouracil decreases resistance to infection with toxoplasma unless the animals are given substitution therapy with thyroid extract.

*Krupa et al. G45,694/67:* In mice, propylthiouracil slightly decreased resistance to infestation with *Trichinella spiralis* larvae but the results were not consistent.

**Bacterial Toxins** ←

*Marbé 35,374/11*: In guinea pigs, thyroid feeding increases sensitivity to diphtheria toxin.

*Hari 40,209/21*: Polemic remarks concerning the technique and interpretation of earlier data on the effect of thyroidectomy upon the resistance to cyanides, chloroform, bacterial toxins and oxygen deficiency.

*Houssay & Sordelli A 48,113/21*: In rabbits, thyroidectomy does not change sensitivity to diphtheria toxin. In guinea pigs, sensitivity to diphtheria toxin, tetanus toxin and to cobra venom is likewise not modified by removal of the thyroid.

*Locatelli 28,678/34*: In dogs, thyroidectomy diminishes the wave of mitosis in hepatocytes normally produced by small doses of diphtheria toxin.

*Sealy & Lyons B 46,719/49*: In rabbits, sterile inflammation produced by staphylococcus toxin s.c. causes hepatic necrosis if the animals are pretreated with thyroid extract.

*Kroneberg & Pötzsch E 54,858/52*: In mice, thyroxine pretreatment increases sensitivity to endotoxin.

*Melby et al. C 86,232/58*: In mice, T3 increases the lethal effect of Br. melitensis endotoxin. In mice infected with Br. melitensis, unique hepatic lesions develop under the influence of T3 pretreatment which are not seen in unpretreated controls.

*Bradley & Spink C 76,042/59*: In mice, infected with small numbers of Brucella

melitensis, hepatic granulomas occurred without necrosis. Severe necrosis developed after pretreatment with T3 without multiplication of brucellae and with minimum inflammatory lesions. Necrosis was not induced by T3 in mice given Brucella endotoxin after T3 treatment.

*Melby & Spink C 72,440/59*: In mice, the lethal action of various endotoxins is enhanced by pretreatment with T3.

*Gordon & Lipton C 94,649/60*: 5-HT reduces endotoxin mortality in mice. This effect is greater in females than in males and is potentiated by cortisol. Thyroxine aggravates the toxicity of endotoxin.

*Yokoi et al. D 8,839/61*: In rabbits, a biphasic fever pattern is elicited by Sh. flexneri type 6 pyrogen. The biphasic nature of the response was maintained after thyroidectomy but largely abolished by adrenal demedullation.

*Schoen & Voss D 11,906/61*: In guinea pigs, the lethal effect of tetanus toxin is inhibited by pretreatment with thyroxine.

**E-coli Endotoxin** ← *cf. also Table 123*

**Venoms** ←

*Houssay & Sordelli A 48,113/21*: In rabbits, thyroidectomy does not change sensitivity to diphtheria toxin. In guinea pigs, sensitivity to diphtheria toxin, tetanus toxin and cobra venom is likewise not modified by removal of the thyroid.

**Immune Reactions** ←

Most of the studies on the effect of thyroid hormones upon immune reactions have been performed on guinea pigs which are notoriously sensitive to anaphylaxis.

The formation of various antibodies has been claimed to be inhibited by thyroidectomy and stimulated by thyroid extract. In sensitized guinea pigs, thyroid extract, administered a few days before a challenging dose of horse serum, protects against fatal anaphylactic shock. However, thyroidectomy prior to sensitization allegedly has the same effect, whereas this is not the case if the thyroid is removed after sensitization. Indeed, it has been claimed that, in guinea pigs, thyroidectomy blocks anaphylaxis unless the animals are treated with thyroid. Suppression of anaphylactic reactivity by anterior hypothalamic lesions can be partially overcome by thyroid hormones in guinea pigs.

Particularly extensive studies have been performed in guinea pigs concerning the role of the thyroid apparatus in the reaction to tuberculin. Moderate thyrotoxicosis produced by two weeks' pretreatment with thyroxine increases tuberculin hyper-

sensitivity. Propylthiouracil does not affect it, but the suppression of hypersensitivity by cortisone or ACTH is allegedly abolished by pretreatment with this goitrogen.

The beneficial effect of vaccination against tuberculosis is also increased in guinea pigs by thyroxine or T<sub>3</sub>.

If dogs are sensitized after thyroidectomy, subsequent anaphylactic shock is mild. Thyroidectomized dogs are also relatively insensitive to peptone shock. In rabbits, Masugi nephritis is considerably aggravated by pretreatment with thioureas.

*Marbé A4,623/08; A4,624/08; A4,625/08; A4,627/09; A4,626/09; A23,010/09; A23,011/09; A23,012/09; A23,013/09; A23,016/10; 34,561/10:* Studies on the effect of thyroidectomy and thyroid extract upon opsonin formation and phagocytosis of bacteria in guinea pigs and rabbits.

*Müller A47,855/11:* In guinea pigs, the formation of various antibodies is inhibited by thyroidectomy as well as by surgical interference with hepatic circulation. Treatment with thyroid extract has an opposite effect. The latter is not due to shock, since removal of all abdominal organs except the liver is ineffective. Furthermore, the blood loses its "alexical power" when perfused through an isolated liver preparation.

*Savini & Savini A24,559/15:* In sensitized guinea pigs, pretreatment with thyroid extracts a few days before administration of a challenging dose of horse serum protects against fatal anaphylactic shock.

*Képinow 13,298/22:* In guinea pigs, thyroidectomy blocks anaphylaxis unless they are treated with thyroid extract.

*Képinow & Lanzenberg 13,258/22:* Preliminary studies on the effect of thyroidectomy upon anaphylaxis and antibody formation in guinea pigs.

*Lanzenberg & Képinow 13,117/22:* In guinea pigs, thyroidectomy prior to sensitization prevents subsequent anaphylactic shock, whereas this is not the case if the thyroid is removed after sensitization.

*Appelmans 14,085/23:* Anaphylactic shock develops normally in thyroidectomized guinea pigs even if both the sensitizing and the challenging dose of antigen are administered after the operation.

*Houssay & Sordelli 13,430/23:* Comparative studies on the influence of thyroidectomy upon anaphylaxis in the guinea pig, rabbit and dog.

*Képinow 13,941/23:* Discussion of the optimal conditions for the prevention of anaphylaxis by thyroidectomy in guinea pigs.

*Parhon & Ballif 13,548/23; 17,302/23:* In guinea pigs, anaphylaxis is diminished after thyroidectomy but not significantly influenced by thymectomy.

*Houssay & Cisneros 26,936/25:* In dogs sensitized after thyroidectomy, subsequent anaphylactic shock is diminished. Thyroidectomized dogs are also comparatively insensitive to peptone shock.

*Fleisher & Wilhelmj 23,337/27:* In guinea pigs, thyroidectomy before sensitization diminishes the severity of subsequent anaphylactic shock. In rabbits, this inhibition is not clear-cut although there does appear to occur some change in the reaction of thyroidectomized rabbits following the second injection of antigens. Immunological studies suggest that thyroidectomy does not prevent the formation of antibodies but merely alters the reaction during shock.

*Spinelli 7,369/32:* In guinea pigs, thyroidectomy increases resistance to anaphylactic shock.

*Long & Miles D41,973/50:* In guinea pigs, moderate thyrotoxicosis produced by two weeks' treatment with thyroxine increases hypersensitivity to tuberculin, whereas moderate doses of propylthiouracil do not affect it. ACTH and cortisone diminish tuberculin sensitivity. Fourteen days after stopping thyroxine injections, the animals became actually less hypersensitive than the controls. A similar reversal of effect was noted two weeks after interruption of cortisone or ACTH treatment in that the animals became more hypersensitive than the controls.

*Strehler & Sollberger B54,646/50:* In rabbits, Masugi nephritis is greatly aggravated by pretreatment with tetramethylthiourea.

*Long et al. B60,189/51:* In B.C.G.-infected guinea pigs, hypersensitivity to tuberculin is considerably diminished by cortisone or ACTH. This diminution is abolished by pretreatment with propylthiouracil, which alone has no effect upon hypersensitivity. Pre-

treatment with thyroxine increases tuberculin hypersensitivity but does not block the sensitization by ACTH or cortisone. Apparently, thyroxine is necessary for the desensitizing action of ACTH and cortisone.

*Long et al. B63,843/51:* In guinea pigs, dihydroascorbic acid—unlike ascorbic acid—inhibits the tuberculin reaction after infection with B.C.G. vaccine. The desensitizing effect of dihydroascorbic acid is not inhibited by thiouracil. Alloxan, like ACTH or cortisone, does not modify desensitization by ascorbic acid on diets deprived of the “cabbage factor;” it desensitizes guinea pigs on a cabbage diet and this desensitization is inhibited by propylthiouracil.

*Long & Shewell G71,833/54:* In guinea pigs, allergic hypersensitivity to B.C.G. is increased by thyroxine or insulin. Partial pancreatectomy has no effect on sensitivity by itself but prevents the action of thyroxine, although not that of insulin.

*Long & Shewell G71,832/55:* In guinea pigs, thyroxine increases immunity as judged by the local response to diphtheria toxin injected intradermally and of circulating antitoxin after immunization with diphtheria toxoid. Partial pancreatectomy prevents this effect of thyroxine.

*Long C32,348/57:* In guinea pigs, both anaphylactic shock (horse serum) and sensitiv-

ity to histamine are greatly increased by pretreatment with thyroxine. Thyroxine also augments the sensitivity of guinea pigs to intradermal tuberculin injection.

*Vakilzadeh & Vandiviere E32,626/63:* In guinea pigs, the beneficial effect of vaccination against tuberculosis was greatly increased by thyroxine and T3, but not by cortisone, cortisol or ACTH. None of the hormones altered natural host resistance in nonimmunized guinea pigs.

*Lupulescu et al. F77,999/66:* In rabbits, the formation of antibodies against brucella S<sub>6</sub> is stimulated by thyroxine and 4-chlorotestosterone but decreased by thiourea. The effect of 4-chlorotestosterone is evident even after destruction of the thyroid and hence is not mediated through the latter gland.

*Filipp & Mess G71,129/69:* In guinea pigs, suppression of anaphylactic reactivity by anterior hypothalamic lesions can be partially blocked by chronic treatment with thyroid hormones as well as by adrenalectomy or adrenal inactivation by metyrapone (Metopirone). “Combined treatment of guinea pigs bearing hypothalamic lesions with Metopirone and thyroxine completely eliminated the blocking effect of the tuberal lesion on anaphylactic reactions.” Apparently the shock-inhibiting effect of hypothalamic lesions is partly due to hypothyroidism and partly to hyperadrenal-corticoidism.

### Special Surgical Interventions ←

**Hepatic Lesions** ←. In rats, desiccated thyroid feeding increases the weight of the liver under normal conditions and the rate of regeneration after partial hepatectomy. Curiously, thiouracil has also been claimed to accelerate liver regeneration under similar conditions but this was denied by several investigators, who found that even thyroidectomy had no significant effect upon the regeneration of hepatic tissue in the rat.

In dogs, the manifestations of shock produced by constriction of the hepatic veins were aggravated by thyroid feeding and constriction of the portal vein caused ascites only after pretreatment with methylthiouracil.

Ascites produced by subdiaphragmatic constriction of the inferior vena cava was inhibited by thyroidectomy and restored by a thyroid extract in one series of experiments. However, other investigators pointed out that subdiaphragmatic constriction of the inferior vena cava causes ascites in itself and that this can be ameliorated by thyroidectomy, though only if the operation is performed after the caval constriction.

**Renal Lesions** ←. In uninephrectomized rats, compensatory hypertrophy of the remaining kidney is diminished, but not prevented, by thyroidectomy. Regeneration is inhibited by thiouracil and enhanced by thyroxine under these conditions.

The pressor effect of renal encapsulation is diminished by methylthiouracil and increased by thyroxine in the rat. However, thyroidectomy performed after the kidneys had been encapsulated for 9-19 weeks has only a slight effect upon the blood pressure.

The metastatic calcification produced by complete nephrectomy in rats is un-  
influenced by thyroxine although it can be prevented by calcitonin. Presumably, the previously described protective effect of thyroxine against exogenous parathyroid hormone depends upon the presence of the kidney.

In dogs and rats, destruction of the thyroid by radio-iodine increases survival after bilateral nephrectomy perhaps merely because general metabolism is greatly diminished.

#### **Hepatic Lesions ←**

*Higgins 9,809/33:* In rats, desiccated thyroid feeding increases the weight of the liver under normal conditions, and the rate of regeneration after partial hepatectomy.

*Hepler & Simonds A15,174/38:* In dogs, the manifestations of shock produced by constriction of the hepatic veins are aggravated following thyroid feeding.

*Fogelman & Ivy B23,357/48:* In rats, thiouracil accelerates liver regeneration after partial hepatectomy.

*Drabkin B17,795/48:* In rats, thyroidectomy moderately diminishes liver regeneration after partial hepatectomy and reduces cytochrome c in skeletal muscle, heart, liver and kidney.

*Spigolon B52,689/49:* In dogs, gradual constriction of the portal vein caused ascites only if the animals were pretreated with methylthiouracil.

*Christensen & Jacobsen A49,204/49:* In rats subjected to partial hepatectomy, neither hypophysectomy nor thyroidectomy impairs the rate of regeneration. No significant change in mitotic rate was observed after pretreatment with stilbestrol or STH.

*Drabkin D18,388/50:* In rats, thyroidectomy or thiouracil treatment does not significantly impair liver regeneration after partial hepatectomy, whereas thyroxine markedly inhibits it.

*Giberti et al. B82,948/53:* In rats, propylthiouracil does not inhibit liver regeneration after partial hepatectomy but prevents hepatic steatosis.

*Weinbren D95,941/59:* Review (11 pp., 110 refs.) and personal observations on factors influencing hepatic regeneration after partial hepatectomy in the rat, with special sections on the effects of hypophysectomy and thyroid hormones.

*Canter et al. C67,855/59; Baronofsky & Canter C85,341/60:* In dogs, the production of ascites by subdiaphragmatic constriction of the inferior vena cava is inhibited by thyroidectomy and restored by subsequent treatment with thyroid extract.

*Poll et al. D4,775/61:* In dogs, ascites produced by supradiaphragmatic constriction of the vena cava inferior is usually ameliorated by thyroidectomy, but only if the operation is performed after caval constriction.

*Girkin & Kampschmidt C99,934/61:* In rats, the hepatic enlargement induced by Walker tumor transplants or by partial hepatectomy is inhibited by thiouracil and largely restored by subsequent thyroxine treatment.

#### **Renal Lesions ←**

*McQueen-Williams & Thompson A33,938/40:* In rats, total hypophysectomy prevented the compensatory hypertrophy of the remaining kidney after uninephrectomy. Thyroidectomy did not prevent renal regeneration under identical conditions.

*Zeckwer 84,592/44:* In rats, thyroidectomy does not significantly alter renal regeneration following unilateral nephrectomy.

*Herlant B30,957/47:* In uninephrectomized rats, regeneration in the remaining kidney is inhibited by thiouracil.

*Herlant B30,956/48:* In uninephrectomized rats, thyroxine greatly increases the number of mitoses in the proximal tubules of the remaining kidney.

*Valori B46,667/48:* In rats, thyroidectomy diminishes but does not abolish compensatory hypertrophy of the remaining kidney after uninephrectomy.

*Kleinsorg & Loeser B41,137/49:* In rats, compensatory hypertrophy of the remaining kidney following uninephrectomy is enhanced by thyroxine and inhibited by methylthiouracil.

*Bächtold B60,463/50:* In rats, the pressor effect of renal encapsulation is diminished by pretreatment with methylthiouracil and increased by thyroxine.

*Marshall & Freeman B68,239/52; B96,575/54:* In dogs and rats, destruction of the thyroid by  $^{131}\text{I}$  increases survival time after bilateral nephrectomy.

*Braun-Menéndez C4,927/54:* In rats, the hypertension produced by figure-of-8 ligature is diminished by thyroidectomy or thiouracil and increased by thyroid powder p.o.

*Osipovich C58,570/57:* In uninephrectomized rats, methylthiouracil enhances compensatory hypertrophy of the remaining kidney, presumably as a consequence of increased TTH secretion. The acceleration of compensatory renal hypertrophy by exposure to cold is ascribed to a similar mechanism.

*Fregly et al. C66,042/59:* In rats, the hypertension produced by bilateral renal encapsulation is prevented by thyroidectomy or propylthiouracil.

*Fregly et al. C80,398/60:* In rats, after renal encapsulation, propylthiouracil reduced the systolic blood pressure even more than did complete thyroidectomy. However, the cardiac hypertrophy of renal hypertension was not prevented by propylthiouracil, suggesting that the diastolic pressure remained unaffected. Thyroidectomy performed after the kidneys had been encapsulated for 9—19 weeks had only a slight effect on blood pressure.

*Fregly & Cook C88,371/60:* In rats, various thioureas inhibit the development of hypertension and cardiac hypertrophy following bilateral renal encapsulation. This effect is counteracted by feeding desiccated thyroid.

*Mandel et al. D6,027/60:* In rats, the compensatory renal hypertrophy and RNA synthesis in the remaining kidney, which normally occur after uninephrectomy, are inhibited by propylthiouracil.

*Eades Jr. et al. F89,204/67:* In rats with renal hypertension (uninephrectomy + figure-

of-8 ligature), propylthiouracil inhibits hypertension and coronary atherosclerosis but not the hypercholesterolemia.

*Lefort et al. G46,725/67:* In rats, metastatic calcification produced by bilateral nephrectomy is largely inhibited by calcitonin but uninfluenced by thyroxine pretreatment. Presumably the previously demonstrated protective effect of thyroxine against exogenous parathyroid hormone depends upon the presence of the kidney.

*Côté et al. G46,741/68:* In rats, calcitonin inhibits the metastatic calcification and bone lesions induced by bilateral nephrectomy. In nephrectomized animals, thyroxine does not modify the changes induced by endogenous hyperparathyroidism consequent to bilateral nephrectomy. "Presumably, to be effective against soft-tissue calcification and bone resorption induced by parathyroid extract overdosage, thyroxine requires the presence of the kidney."

*Eades Jr. et al. H9,590/69:* In rats with renal hypertension produced by uninephrectomy and a meat diet, thiouracil or sulfadiazine diminishes the blood pressure and protects the remaining kidney from damage.

*Gardell et al. G70,430/70:* In rats, the cardiovascular calcification produced by bilateral nephrectomy is not significantly influenced by ethylestrenol, CS-1, spironolactone, norbolethone, oxandrolone, prednisolone, progesterone, triamcinolone, DOC, estradiol or thyroxine.

#### **Blood-Vessel Ligatures ←**

*Dau & Weber G20,433/63:* Contrary to earlier claims, the recovery of the spinal cord (disappearance of motor disturbances) after temporary aorta ligature is not significantly influenced by "blockade of the thyroid" through pretreatment with iodine or  $\text{KClO}_4$  in rabbits.

#### **Ionizing Rays ←**

In the mouse, according to most investigators, resistance to X-irradiation is decreased by thyroid hormones and increased by thioureas. However, some workers claim that neither thioureas nor thyroidectomy influences X-ray resistance significantly in this species. The timing and dosage of the thyroid treatment also appears to be important since in one series of observations, pretreatment with thyroid extract until five days before X-irradiation diminished the resulting mortality induced by X-irradiation.

In rats also, pretreatment with thyroid hormones generally diminishes X-ray resistance, whereas thiouracil offers little if any protection. Indeed, it has been stated that conjoint treatment with thyroxine and thiourea induces the greatest drop in X-ray resistance.

In rabbits, both systemic damage following total body irradiation, and the renal changes induced by topical X-irradiation of the kidney, are aggravated by thyroxine and T3.

The thyroxine-induced differentiation of limb-buds in toad tadpoles is only insignificantly retarded by X-irradiation.

In the goldfish, as in mammals, thyroxine diminishes X-ray resistance.

#### MOUSE

*Blount & Smith B30,000/49*: In mice exposed to total X-irradiation, mortality was greatly increased by feeding desiccated thyroid and insignificantly diminished by thiouracil.

*Haley et al. B49,990/50*: Contrary to earlier claims, no protection against X-irradiation could be obtained in mice given large doses of thiouracil, propylthiouracil or methylthiouracil.

*Limperos & Mosher B49,737/50*: In mice, pretreatment with thiourea increases resistance to X-irradiation.

*Mole et al. D96,011/50*: In mice, thiourea reduces mortality following whole body X-irradiation.

*Haley et al. B58,913/51*: In rats, thyroparathyroidectomy offers no protection against X-irradiation. The small degree of protection noted by previous investigators after thiouracil may have been due to its sulfhydryl group. On the other hand, thyroxine causes a significant increase in mortality rate, though not in total mortality.

*Smith B66,170/51*: In mice, thyroid feeding increases the mitotic index of the epidermis, but does not influence the effect of X-irradiation upon epidermal mitotic proliferation.

*Pospišil & Novák C67,534/58*: Mice pretreated with thyroid extract until 5 days before X-irradiation were more resistant than untreated mice against mortality induced by ionizing rays. These findings are in sharp contrast with those of earlier authors who have found an increased mortality in animals given thyroid both before and during, or even continuing after X-irradiation.

*Léonard & Maisin E26,654/63*: In mice,  $\beta$ -aminoethylisothiourea offers moderate protection against the toxic effects of X-irradiation.

*Maisin et al. E36,751/63*: In mice, the protection against X-irradiation offered by

2- $\beta$ -aminoethylisothiourea (AET) is only slightly improved by concurrent administration of 5-HT.

#### RAT

*Haley et al. B60,616/51*: In rats, pretreatment with thiourea or thyroxine did not significantly alter mortality after X-irradiation. However, an increase in mortality rate was observed in animals which had received both thyroxine and thiourea.

*Smith & Smith B60,347/51; B60,348/51*: In rats, desiccated thyroid or dinitrophenol increased radiation lethality, but thiouracil and propylthiouracil exerted no significant protective effect.

*Haley et al. G71,834/52*: In rats, mortality after X-irradiation is increased both by propylthiouracil and by thyroxine.

*Stender & Hornykiewytch C37,079/55; C37,086/55*: In rats the lethal effect of total body X-irradiation is diminished by a reduction in the oxygen tension of the surrounding air. This protective effect is counteracted by cortisone, adrenalectomy, and thyroxine.

*Darcis & Brisbois C50,953/57*: In the rat, the sensitivity of the small intestine to topical X-irradiation (unlike that of the vagina) is not influenced by thyroxine or testosterone.

*Krahe & Künkel C77,236/58*: In rats, pretreatment with thyroxine decreases resistance to X-irradiation.

*Shellabarger et al. D39,218/62*: In female rats, the production of mammary cancers by X-irradiation is inhibited by diethylstilbestrol in doses which in themselves are not carcinogenic. T3 did not influence carcinogenesis under these circumstances.

*Caprino & Gallina G13,680/63*: Contrary to earlier claims, propylthiouracil does not offer significant protection against total body X-irradiation in rats.

*Greig et al. E60,304/65:* In rats, irradiation of the thyroid inhibits its capacity to undergo hyperplasia under the influence of a goitrogen. Pretreatment with methylthiouracil before irradiation reduces the degree of this inhibition.

*Akoev et al. F73,202/66:* Both stilbestrol and thyroid extract offered some protection against  $^{60}\text{C}$   $\gamma$ -radiation in rats.

*Srebro et al. H32,848/70:* In rats, thyroxine decreases, whereas propylthiouracil increases, resistance to subsequent X-irradiation.

*Slebdodzinski and Srebro H29,972/71:* In rats, thyroxine pretreatment aggravates the syndrome of total body irradiation, whereas propylthiouracil offers considerable protection.

#### RABBIT

*Vittorio et al. C76,156/59:* Rabbits treated with a mixture of thyroxine and T3 became unusually sensitive to the lethal effect of X-irradiation. Neither untreated nor methimazole treated rabbits succumbed after the dose of irradiation used.

*Caldwell et al. D54,096/63:* In rabbits, renal damage produced by topical X-irradiation of the kidney is aggravated by T3.

#### FISH, TOAD

*Allen & Ervell C92,110/59:* In tadpoles of *Bufo boreas halophilus*, thyroxine-induced differentiation of limb-buds is only insignificantly retarded by X-irradiation.

*Srivastava et al. G23,764/64:* In the goldfish (*Carassius auratus* L.), resistance to X-irradiation is diminished by thyroxine the same as in mammals.

#### VARIA

*Rigat C10,747/55:* Review (46 pp., 67 refs.) on the literature concerning the effect of hormones upon X-irradiation, with special reference to ACTH, STH, vasopressin, epinephrine, cortisone, DOC, testosterone, estradiol, progesterone, and thyroxine.

### *Hypoxia* ←

In the rat, thyroid hormones increase whereas thyroidectomy and thioureas decrease sensitivity to hypoxia. This phenomenon became the basis of what was known as "Asher's method" for testing thyroid function. Pretreatment with thyroxine also predisposes the liver and the brain of the rat to the production of degenerative changes by hypoxia.

Similar observations have subsequently been confirmed by numerous investigators in the mouse in which the sensitization by thyroxine is so consistent and evident that it was made the basis of the Emmens and Parkes "closed vessel technique" for the bioassay of thyroid preparations. If mice are placed in closed vessels, the speed of their mortality during the developing anoxia is proportional to the amount of thyroid hormone with which they have been pretreated. T3 is about five times as active as thyroxine in this respect. The sodium salt of L-thyroxine is about seven times more potent than that of D-thyroxine. Among a series of T2 compounds only 3:5-diiodo-L-thyronine was effective, but even this was much less active than T3.

In rabbits and dogs, thyroidectomy diminishes the protein catabolic effect of hypobaric oxygenation and of several other stressors.

In guinea pigs, thyroidectomy is said not to affect resistance to lack of oxygen, whereas T3 has been claimed actually to increase it.

Fish and various other species are made unusually resistant to asphyxia by thioureas.

#### RAT

*Klinger 51,094/18:* Contrary to earlier claims, thyroparathyroidectomized rats do not tolerate hypoxia better than normals; in fact, they become hypersensitive to it.

*Streuli 32,220/18:* In rats, thyroidectomy increases resistance to hypoxia. Splenectomy has an opposite effect, and rats simultaneously thyroidectomized and splenectomized exhibit a normal resistance to hypoxia.

*Duran A 10,045/20*: In rats, thyroid extract increases, whereas thyroidectomy decreases sensitivity to hypobaric oxygenation.

*Cameron & Carmichael 42,188/26*: In young rats, thyroid feeding produces a predisposition for tetany; in animals so treated, diminished oxygen tension rapidly induces tetanic convulsions.

*Rydin 22,940/28*: In rats, thyroxine pretreatment increases sensitivity to hypobaric oxygenation.

*Asher & Wagner 23,903/29*: Both rats and guinea pigs become highly sensitive to anoxia after pretreatment with thyroid extract. This phenomenon is the basis of what the authors describe as "Asher's method for the testing of thyroid function by lack of oxygen."

*Houssay & Rietti 3,187/32*: In rats, pretreatment with an impure pituitary extract diminishes resistance against hypoxia, but this effect is abolished by thyroidectomy and is presumably due to TTH. In untreated rats, thyroidectomy actually increases resistance to anoxia.

*McIver & Winter B 33,399/43*: In rats pretreated with thyroxine, exposure to diminished atmospheric oxygen tension causes hepatic injury.

*Goldsmith et al. B 333/45*: Thiouracil and thiourea increase the resistance of rats to lowered barometric pressure. Estradiol and stilbestrol are ineffective in themselves and fail to influence the action of the antithyroid compounds.

*Gordon et al. B 761/45*: Review of the literature, and personal observations on the raised resistance to lowered barometric pressures induced in rats by thiourea, para-aminobenzoic acid (PABA), and other agents interfering with the thyroid function.

*Blood et al. B 48,970/49*: As judged by observations in rats pretreated with thyroxine or thiouracil "oxygen availability becomes a limiting factor in oxygen consumption only at altitudes approaching 40,000 feet in normal rats, but at much lower altitudes in animals whose metabolism has been stimulated by cold or by thyroxine."

*Bargeton et al. B 50,869/49*: In rats, pretreatment with thiouracil increases resistance against reduced barometric pressure.

*Zarrow et al. B 63,316/51*: In rats exposed to hypobaric oxygenation, thyroxine diminished survival time, whereas in mice it caused an initial increase followed by a decrease. Thiouracil enhanced survival time in rats and, to a much lesser extent, in mice also.

*Flückiger & Verzár B 86,489/52*: In rats, thyroidectomy does not markedly influence the development of hypothermia upon exposure to decreased oxygen pressure.

*DeBias D 41,419/62*: The survival of rats exposed to reduced oxygen tension was not significantly altered by thyroidectomy.

*Riedel F 22,473/64*: In rats and rabbits, chronic thyroxine overdosage produces morphologic changes in the brain, which are aggravated by hypoxia.

*Keminger G 42,501/66*: In rats, death from lack of oxygen in closed vessels is accelerated by T3, and retarded after thyroidectomy or cortisone treatment. Epinephrine further accelerates mortality in hyperthyroid animals.

*Trojanová G 42,905/66*: In newborn rats, the survival of the respiratory centre (gaspings) during anoxia is greatly reduced by thyroparathyroidectomy.

*Smoake & Mulvey Jr. H 23,262/70*: In rats, thyroidectomy and propylthiouracil increase, whereas feeding of desiccated thyroid decreases resistance to hypobaric hypoxia.

#### MOUSE

*Emmens & Parkes B 4,928/47*: Male mice are considerably more sensitive than females to anoxia (closed vessel technique). Various thyroid preparations increase sensitivity to anoxia.

*Smith B 4,939/47*: In mice, thyroxine shortens, whereas thiourea prolongs, survival in closed vessels. L-thyroxine is considerably more active than d-thyroxine. T2 is even less active, whereas thyroxamine, diiodothyronamine, tetrachlorothyronine, tetrabromothyronine, and T2 are inactive.

*Reisfield & Leathem B 46,491/50*: In mice, survival in closed vessels is reduced by thyroid globulin p.o., but unaffected by propylthiouracil.

*Basil et al. B 53,039/50*: The mouse anoxia test has been found useful in assaying the biologic activity of various thyroxine derivatives.

*Smith & Smith B 60,348/51*: In mice, desiccated thyroid or thyroxine pretreatment decreases resistance to progressive hypoxia or forced muscular exercise. Death may have been due to cardiac failure. "Irradiated mice, whether given thyroid or not, lived longer in the closed vessel and were still alive at lower O<sub>2</sub> concentrations than their corresponding controls."

*Gemmill B 85,291/53*: In mice, T3 is only slightly more potent than thyroxine as judged by the anoxia test.

*Anderson B94,669/54*: In mice, T3 is about 5 times as active as thyroxine in increasing sensitivity to anoxia.

*Tabachnick et al. C22,161/56*: "Using the mouse anoxia assay, Na L-thyroxine was found to be seven times more potent than Na D-thyroxine."

*Tomich et al. C83,307/60*: Six iodo-L-thyronines, viz. 3:3':5'-triiodo-, 3:5-diiodo-, 3:3'-diiodo-, 3':5'-diiodo, 3-monoiodo-, and 3'-monoiodo-L-thyronine, have been compared with 3:5:3'-triiodo-L-thyronine, in mice by the anoxia method. The only compound with any significant activity was 3:5-diiodo-L-thyronine but even this was much less active than 3:5:3'-triiodo-L-thyronine.

*Wiberg et al. E23,265/63*: The mouse anoxia test performed after thiouracil treatment permits simultaneous assessment of survival and goitre prevention. The antigoitrogenic assay is more sensitive and permits greater precision than the anoxia test in the bioassay of thyroactive materials.

#### RABBIT

*Mansfeld & Müller 35,416/11*: In rabbits, thyroidectomy inhibits the protein catabolic

effect of exposure to decreased oxygen tension, hydrocyanic acid intoxication, or fasting.

#### GUINEA PIG

*Stämpfli 931/27*: In guinea pigs, thyroidectomy does not significantly alter resistance to lack of oxygen.

*Lamarche & Pluche F68,410/66*: In guinea pigs, resistance to hypobaric oxygenation is increased by T3 but not by triiodothyroacetic acid.

#### FISH

*Tinacci B28,546/47*: Fish (*Mustelus laevis*) pretreated with various thioureas become unusually resistant to asphyxia.

#### VARIA

*Mansfeld 11,881/20*: In rabbits and dogs, thyroidectomy diminishes the protein catabolism normally observed after intoxication with hydrocyanic acid, hemorrhage, or hypobaric oxygenation.

*Hári 40,209/21*: Polemic remarks concerning the technique and interpretation of earlier data on the effect of thyroidectomy upon the resistance to cyanides, chloroform, bacterial toxins, and oxygen deficiency.

### Hyperoxygenation ←

In rats exposed to six atmospheres of oxygen in a pressure chamber, resistance is diminished by thyroxine. Similar diminutions of tolerance for hyperoxygenation have been noted with various other thyroid preparations, whereas thioureas have an opposite effect.

In the cat also, thyroid extract increases, whereas thyroidectomy decreases sensitivity to oxygen poisoning.

*Campbell A14,903/37*: In rats exposed to six atmospheres of oxygen in a pressure chamber, subsequent decompression is better tolerated at low than at high external temperatures. "Using an external temperature of 24°C and white rats of about 80 g., the following substances, administered subcutaneously, are found to enhance oxygen poisoning: thyroxin (0.4 mg), dinitrophenol (1.5 mg), ac-tetrahydro- $\beta$ -naphthylamine (0.5 c.c., 1 p.c.), adrenaline (0.02 mg), pituitary extract (posterior lobe, above 3.5 units), insulin (0.025 u.) and eserine (0.045 mg administered with atropine 0.075 mg). These doses in themselves are harmless."

*Gersh & Wagner B1,140/45*: In cats, thyroid extract increases, whereas thyroidectomy decreases sensitivity to the convulsive effect of oxygen poisoning.

*Grossman & Penrod B36,303/49*: In rats exposed to high oxygen tension, the mortality is increased by pretreatment with desiccated thyroid, and decreased by propylthiouracil.

*Bean & Bauer B76,951/52*: In rats, desiccated thyroid augments the adverse effects of exposure to high-oxygen tension. It also abolishes the protective effect of hypophysectomy.

*Taylor C47,861/58*: In rats "adrenalectomy gave very definite protection against

the central nervous system manifestations of oxygen poisoning, and gave some protection against lung damage." Adrenocortical extract and cortisol increased susceptibility of adrenalectomized animals to oxygen poisoning, whereas cortisone, DOC, and thyroid powder had no such effect.

*Smith et al. C95,244/60:* In rats, desiccated thyroid or thyroxine increases the noxious

effects of breathing virtually pure oxygen at atmospheric pressure. Conversely, hypophysectomy increases resistance to oxygen, presumably through the elimination of TTH.

*Szilagyi et al. G68,248/69:* In rats and rabbits, mortality from hyperbaric oxygenation is increased by pretreatment with thyroid extract, but uninfluenced by thyroidectomy.

### Temperature Variations ←

In rabbits, thyroid hormones increase resistance to cold, and conversely, tolerance to desiccated thyroid is augmented in a cold environment. Thyroparathyroidectomy and thioureas diminish cold resistance. Tolerance to a warm environment is decreased by desiccated thyroid.

In rats, sensitivity to warm surroundings also rises after pretreatment with thyroid preparations, whereas resistance to cold is increased. Thyroidectomy and thioureas diminish cold resistance. In rats fed thyroid, exposure to cold causes marked pentosuria, whereas thiouracil has an opposite effect. The decreased ability of old rats to adapt themselves to cold is also improved by T3. In thyroidectomized rats, resistance to cold is restored towards normal by intraocular thyroid transplants. The vitamin-A requirements of rats are greatly increased during exposure to cold unless they are pretreated with thiouracil.

In mice, thyroid feeding increases sensitivity to heat stroke and predisposes to the production of hepatic lesions during exposure to high temperature.

In hamsters, thyroidectomy diminishes cold resistance much less than in rats. However, radiothyroidectomy renders them sensitive to cold. Hamsters presumably possess ectopic thyroids which are not eliminated by ordinary thyroidectomy.

Thyroidectomized goats are also very resistant to cold, but this has been ascribed to increased epinephrine secretion.

In various strains of fish, heat tolerance is increased by thiourea. Immature salmon can be completely radiothyroidectomized and yet continue to grow, but their heat tolerance is impaired.

#### RABBIT

*Cori 17,210/22:* In rabbits, thyroidectomy diminishes resistance to cold and increases its hyperthermic effect.

*Draize & Tatum 3,901/31:* The resistance of rabbits to survival at a temperature of 33°C is recommended as a basis for the bioassay of desiccated thyroid preparations.

*Draize & Tatum 3,657/32:* In rabbits, the tolerance for desiccated thyroid is increased in a cold and decreased in a warm environment.

*Sanfilippo & Ricca 31,704/35:* In rabbits, pretreatment with thyroxine increases resistance to cold.

*di Macco 34,121/35:* In rabbits, the hyperthermia induced by exposure to heat is aggravated by thyroxine.

*Capitolo A1,730/36:* In rabbits, thyroparathyroidectomy decreases the resistance to heat stroke, and death occurs at a lower body temperature level than in controls.

*Martinengo & Beghelli B3,426/39:* In rabbits, pretreatment with T2 diminishes resistance to heat.

*Lange et al. B23,962/48:* In rabbits, resistance to cold is increased by pretreatment with thyroid extract and diminished following partial suppression of thyroid function by thiouracil.

*Medvedeva F96,027/68*: Biochemical studies on the decreased cold resistance of thiourea-treated rabbits.

#### RAT

*Aberhalden & Wertheimer 19,292/28*: Rats pretreated with thyroxine are unusually sensitive to warm surrounding temperature.

*Genitts et al. 68,723/35*: In young thyro-parathyroidectomized rats, exposure to heat 24 hrs after the operation greatly increased the mortality rate, whereas cold surrounding temperature diminished it. The number of tetanic convulsions was greatest at an intermediate temperature. [From the brief abstract, it is difficult to differentiate between the role of parathyroid and of thyroid deficiency (H.S.).]

*Barbour & SeEVERS 84,296/43*: In rats, exposure to cold and an excess of CO<sub>2</sub> produce a state of narcosis against which considerable resistance can be induced by thyroid extract. No such effect was obtained by dinitrophenol.

*Zarrow & Money B27,880/49*: In rats, pretreatment with thiouracil diminishes the resistance to cold, a phenomenon which is ascribed to the adrenal cortical involution elicited by thiourea.

*Blood et al. B48,970/49*: As judged by observations in rats pretreated with thyroxine or thiouracil "oxygen availability becomes a limiting factor in oxygen consumption only at altitudes approaching 40,000 feet in normal rats, but at much lower altitudes in animals whose metabolism has been stimulated by cold or by thyroxine."

*Roe & Coover B54,246/51*: In rats, thyroid feeding or exposure to cold markedly increases urinary pentose excretion, whereas thiouracil reduces the output of urinary pentose and decreases resistance to cold. Apparently "the thyroid gland has a dominating role in the production of urinary pentose and that adjustment of animals to cold takes place, at least in part, through activity of the thyroid gland."

*Sellers et al. B65,310/51*: The survival of clipped rats exposed to cold is considerably prolonged by combined treatment with thyroxine + cortisone. Each of these agents alone has much less protective value, and DOC is inactive.

*Money C5,393/54*: Female rats lose their ability to resist a cold environment if they are pretreated with thiouracil.

*Weiss C34,561/57*: Studies on tissue metabolism in rats exposed to cold after thyroidectomy by <sup>131</sup>I. "The hypothesis is advanced

the thyroid gland exerts its effects by way of a few selected tissues only, in which it regulates the level of metabolism so as to provide adequate heat production for suitable adaptation to cold of the entire animal."

*Weiss C66,153/59*: The decreased ability of old rats to adapt themselves to cold is greatly improved by T<sub>3</sub>.

*Garrido D8,112/60*: In rats, resistance to cold is increased by thyroxine and T<sub>3</sub>, and decreased by thyroidectomy or destruction of the thyroid with radio-iodine. Prednisolone exerted only a moderate protective effect.

*Fregly D5,800/61*: In rats, propylthiouracil does not reduce spontaneous running activity in itself, but when exposed to cold, rats thus treated do not increase their activity as much as controls.

*Hsieh D20,969/62*: Rats fed propylthiouracil for four weeks before exposure to cold died in about 17 days, while those fed an iodine-deficient diet and propylthiouracil, for the same period before exposure, died in less than one day. Rats maintained for four weeks in the cold and on T<sub>3</sub> died when the dose levels of the thyroid hormone were reduced. "Thus cold adaptation does not reduce the requirement for thyroid hormone."

*Beaton D55,998/63*: Review of the literature, and personal observations on the effect of thyroid feeding or thyroidectomy upon the cold resistance of rats given diets of varying protein content.

*Pavlovic-Hournac & Andjus E33,972/63*: In rats, the decreased resistance to cold induced by thyroidectomy is restored towards normal by intraocular thyroid transplants.

*Weiss G21,456/63*: In rats, resistance to cold can be increased with T<sub>3</sub> acetate as it can with T<sub>3</sub> or thyroxine.

*Hamburgh & Lynn G21,782/64*: In rats raised at 20°C, the delay in skeletal maturation induced by propylthiouracil is more severe than in controls raised at 30°C.

*Hsieh F71,817/66*: Systematic studies on the thyroid hormone (thyroxine, T<sub>3</sub>) requirements of thyroidectomized curarised rats for resistance to cold in the absence of shivering.

*Weihe F69,421/66*: In rats, thyroxine impedes acclimatization to high altitude.

*Bauman & Turner F81,331/67*: Pretreatment of rats with thyroxine raises their resistance to cold. Additional administration of corticosterone greatly increases this effect, although in itself, corticosterone possesses only a slight protective action.

*Sundaresan et al. G50,127/67*: The vitamin-A requirements of rats are greatly increased during exposure to cold, this increase is abolished by thiouracil.

#### MOUSE

*Lübke C12,952/56*: In mice, thyroid feeding increases sensitivity to heat stroke and causes particularly severe hepatic lesions upon exposure to high temperature.

#### GUINEA PIG

*Pfeiffer 16,694/23*: In guinea pigs, thyroidectomy aggravates the drop in body temperature produced by cooling or salicylate injection i.p.

*Amante & Mancini C21,222/56*: In guinea pigs, pretreatment with methylthiouracil prolongs survival following severe burns. The data are discussed primarily in connection with the role of the thyroid in the alarm reaction.

#### HAMSTER

*Chaffee et al. G71,307/63*: In hamsters, thyroidectomy does not diminish cold resistance nearly as much as in the rat.

*Yousef et al. F86,757/67*: Hamsters, unlike rats, are very resistant to cold even after complete surgical thyroidectomy. In order to determine whether this difference is due to the existence of ectopic thyroids, radio-iodine was administered; since this caused an even more severe drop in plasma PBI than thyroidectomy, it was concluded that hamsters may possess accessory thyroid tissue. However, upon exposure to cold, the BMR rose significantly in both groups and yet, the surgically thyroidectomized hamsters survived, whereas most of the radio-thyroidectomized animals succumbed. Apparently, "increased thyroid activity in cold exposure has no significant effect upon survival" in this species.

*Yousef et al. F98,470/68*: Hamsters are resistant to cold even after surgical thyroidectomy, but not after treatment with  $^{131}\text{I}$ . The plasma PBI is lowered by thyroidectomy, but not as much as by  $^{131}\text{I}$ . Presumably the hamsters have ectopic thyroid tissue which permits survival after surgical thyroidectomy.

#### GOAT

*Andersson et al. G45,246/67*: Thyroidectomized goats maintain body temperature during exposure to acute cold ( $-3^{\circ}\text{C}$ ) and also react to cooling of the hypothalamic thermoregulatory "centre" by a rise in body temperature. However, under these conditions, shivering and urinary catecholamine excretion were greatly increased. "It is concluded that to maintain thermal homeostasis in the cold markedly hypothyroid goats have to compensate the lack of thyroid hormone by a conspicuous increase in adrenaline secretion."

#### CAT

*Boatman C68,449/59*: In cats "thyroidectomy prior to cold exposure makes heat conservation responses less efficient than in the normal animal and the intact thyroid plays a role in maintaining body fluids in an efficient equilibrium for rapid adjustment to a cold environment."

#### FISH

*Evropeitzeva A49,151/49*: Larvae of the fish *Coregonus lavaretus ludoga* withstand exposure to  $29^{\circ}\text{C}$  for five min after treatment with thiourea, whereas untreated animals die.

*La Roche & Leblond C434/54*: Immature salmon can be completely "thyroidectomized" by radio-iodine; yet, they continue to grow, although their resistance to a rise in water temperature is greatly impaired.

*Suhrmann D76,901/55*: Immersion into a solution of thiourea increases the upper lethal temperature tolerated by goldfish (*Carassius auratus*).

*Fortune C17,485/55; C21,670/56*: In the minnow (*Phoxinus phoxinus* L.), the thermal death point is raised considerably by treatment with thiourea.

*Cheverie & Lynn D68,411/63*: In the fish (*Tanichthys albonubes*), inactivation of the thyroid by immersion into a thiourea solution slightly reduces tolerance to high temperatures. The literature on opposite results in other species of fish is reviewed.

*Dodd & Dent E21,585/63*: In minnows (*Phoxinus phoxinus* L.), neither thiourea nor thyroxine pretreatment induced any significant change of heat tolerance.

### Electric Stimuli ←

In guinea pigs, the EST is diminished within two days after initiation of thyroid feeding, and augmented after thyroidectomy.

In rats, the EST is only insignificantly lowered by thyroidectomy. It is allegedly also diminished one hour after thyroxine administration but increased 18 hrs later. This biphasic response may explain some of the contradictions in the literature.

In mice, thyroxine facilitates the production of convulsions by electroshock, and in dogs, it increases irritability of the sympathetic nervous system.

*Specht 13,475/23*: In guinea pigs, neither thyroidectomy nor orchidectomy influences the course of the convulsions produced by amyl nitrate inhalation or electric irritation of peripheral nerves.

*Gerlich B49,124/49*: In guinea pigs, the EST is diminished within two days after initiation of thyroid feeding. Thyroidectomy has an opposite effect.

*Woodbury et al. B68,423/52*: In rats, brain excitability (pentylentetrazol, EST) decreases following thyroidectomy or treatment with propylthiouracil and increases after thyroxine pretreatment. There are however certain differences between thyroidectomy and propylthiouracil as regards the recovery time from electroshock seizures and their relative effect upon extensor and flexor components.

*Thiéblot et al. C18,452/56*: In dogs, thyroxine pretreatment increases the electric irritability of the sympathetic nervous system.

*de Salva et al. C51,842/58*: In rats, the EST was lowered by hypophysectomy and

adrenalectomy, but only insignificantly by thyroidectomy. 5-HT elevated the EST.

*Pfeifer et al. D12,952/60*: In rats, the convulsive effect of "Pentametazol" [presumably pentylentetrazol (H.S.)] is diminished one hour after administration of thyroxine, but increased 18 hrs later. A corresponding biphasic response is also noted with regard to the EST. In mice, the increased motility induced by amphetamine is also inhibited during the first hour after thyroxine treatment. The possible biochemical reasons for this "negative tendency" during the early phase of thyroxine action are described.

*de Salva D66,176/63*: In rats, the EST is reduced in descending order of magnitude by adrenalectomy, hypophysectomy, and thyroidectomy. The effect of these endocrine deficiencies upon various depressant drugs is also described.

*Pfeifer et al. G65,057/68*: In mice, thyroxine facilitates the production of convulsions by pentylentetrazol and electroshock. These effects are inhibited by various amphetamine derivatives.

### Various Stressors ←

Dogs fed desiccated thyroid are particularly susceptible to **traumatic shock**, whereas methylthiouracil offers some protection against it. Similar observations have been made in rats. The formation of peritoneal adhesions in response to local injury is diminished by methylthiouracil.

In mice, thyroid preparations diminish resistance to forced **muscular exercise**.

In rabbits and dogs, thyroidectomy diminishes the protein catabolism that follows **hemorrhage**.

Following pretreatment with T3, the **audiogenic seizures** produced in susceptible mice by strong sound are accelerated in onset, but their pattern remains unchanged. T3 does not induce audiogenic seizure-proneness in nonsusceptible strains.

### Trauma ←

*Schachter & Huntington A32,970/40*: Dogs fed desiccated thyroid are particularly susceptible to the production of traumatic shock by manipulation of their intestines.

*D'Aste & Ardaub B56,421/49*: In dogs, methylthiouracil offers some protection against various forms of traumatic shock, but this effect is ascribed to the antihistaminic property of the drug.

*Takács et al. C29,459/54:* In rats, traumatic shock (produced by freezing the hind limbs) is diminished by methylthiouracil, but aggravated by thyroxine, thyroid extract, or dinitrophenol.

*Dobrokhotova C55,431/57:* In rats, survival following hemorrhagic shock with trauma is prolonged by methylthiouracil.

*Kováč et al. C50,699/57:* In rats, survival from shock (produced by freezing a hind leg with liquid air) is shortened by thyroid feeding, thyroxine, dinitrophenol or epinephrine, all of which accelerate the metabolic rate. Conversely, methylthiouracil increases survival time.

*Oppenheimer et al. C50,563/58:* In goats, traumatic shock reduces the capacity of the thyroid to concentrate iodine, but recently thyroidectomized animals showed no change in survival times, although pretreatment with thyroxine greatly sensitized to traumatic shock. Cortisone had no effect upon survival following trauma nor did it counteract the aggravating effect of thyroxine.

*Schachter et al. C63,544/59:* In rats, pretreatment with cortisone, thyroxine, or both these agents shortened survival after tourniquet shock.

*Németh & Vigaš F98,055/68:* In rats, resistance to trauma in the Noble-Collip drum is reduced by pretreatment with thyroxine or dinitrophenol but increased by thyroidectomy.

*Rusakov & Chernov H9,072/69:* In rabbits, the formation of adhesions by removal of the serosa of peritoneal organs is considerably

diminished by pretreatment with methylthiouracil.

#### **Muscular Work ←**

*Smith & Smith B60,348/51:* In mice, desiccated thyroid or thyroxine pretreatment decreases resistance to progressive hypoxia or forced muscular exercise. Death may have been due to cardiac failure. "Irradiated mice, whether given thyroid or not, lived longer in the closed vessel and were still alive at lower O<sub>2</sub> concentrations than their corresponding controls."

*Valtin & Tenney C66,148/59:* In rats, resistance to forced muscular exercise is diminished following pretreatment with T3.

#### **Hemorrhage ←**

*Mansfeld 11,881/20:* In rabbits and dogs, thyroidectomy diminishes the protein catabolism normally observed after intoxication with hydrocyanic acid, hemorrhage, or hypobaric oxygenation.

#### **Sound ←**

*Hamburgh & Vicari C71,704/58; D11,010/60:* In mice susceptible to audiogenic seizures, T3 does not change the seizure pattern nor does it induce seizures in nonsusceptible strains. It merely accelerates the onset of the period during which susceptible animals respond by convulsions to audiogenic stimulation.

### **Tumors ←**

In rats, the production of cystic and neoplastic hepatic lesions by 2-acetaminofluorene is inhibited by thiouracil. The hepatic enlargement induced by Walker tumor transplants is also diminished by this goitrogen and restored by a subsequent thyroxine treatment.

The growth of transplanted fibrosarcomas is increased by thyroid extract or T3, and decreased by propylthiouracil. The lifespan of rats bearing transplantable leukemia is prolonged by thyroidectomy, but in mice this does not seem to be the case.

*Cantarow et al. B18,774/46:* In rats given 2-acetaminofluorene p.o., the development of cystic and neoplastic hepatic lesions was accelerated and intensified by GTH (pregnant mare serum), estradiol, and testosterone, but inhibited by thiouracil. "This phenomenon may be related to the role of the liver in the intermediary metabolism and excretion of the sex

steroid." In the hyperplastic target organs of the sex hormones, tumors did not occur, in contrast to the high incidence of tumors in the thyroids of rats given thiouracil simultaneously with the carcinogens.

*Murphy et al. C60,008/58:* In mice, resistance to infection with *Candida albicans* or *Streptococcus pyogenes* is increased by pre-

treatment with T3, but this hormone does not significantly alter resistance to transplanted leukemia.

*Girkin & Kampschmidt C99,934/61*: In rats, the hepatic enlargement induced by Walker tumor transplants or by partial hepatectomy is inhibited by thiouracil, and largely restored by subsequent thyroxine treatment.

*Claus et al. D29,754/62*: In rats, the growth of transplanted fibrosarcomas was increased by thyroid extracts or T3 and decreased by propylthiouracil or an iodine-deficient diet.

*Morris & Mokal D65,803/63*: In rats bearing transplantable leukemia, survival is prolonged by thyroidectomy.

*Fisher & Fisher F74,176/66*: In rats, the incidence of metastases from Walker tumor

transplants is not significantly altered by thyroidectomy, propylthiouracil, thyroxine or TTH.

#### Varia ←

*Smith C46,496/56*: In brown trout, thyroxine raises, whereas thiourea and thiouracil reduce salinity tolerance. Anterior pituitary extracts and STH likewise raise salinity tolerance, whereas posterior lobe extracts, testosterone, gonadotrophin, TTH, and ACTH have no such effect.

*Czarnecki & Kiersz D15,579/61*: In dogs, shock produced by trypan blue or peptone injection is more powerfully inhibited by thyroparathyroidectomy than by thyroidectomy.

### Hepatic Enzymes ←

TPO activity is allegedly increased by thyroidectomy in the rat, and substrate-induced TPO synthesis is inhibited by thyroxine.

Hepatic GPT activity is moderately increased by thyroxine.  $\alpha$ -GPDH activity is raised by T3 or thyroxine, but diminished by thyroidectomy or radiothyroidectomy.

#### TPO, TKT ←

*Geschwind & Li B93,277/54*: In the rat, the induction of the TPO enzyme system is diminished by hypophysectomy and adrenalectomy, but increased by thyroidectomy.

*Kulcsar et al. G72,002/69*: In rats, the substrate-induced synthesis of TPO was inhibited by hepatic injury ( $\text{CCl}_4$ ) as well as by thyroxine. Thyroidectomy was without effect, and actually inhibited the influence of  $\text{CCl}_4$ .

#### GPT ←

*Rosen et al. C71,414/59*: Marked increases in GPT activity were observed in the livers of rats given cortisol, cortisone, 9 $\alpha$ -fluorocortisol, prednisone, 6 $\alpha$ -methylprednisolone, 9 $\alpha$ -fluoro-21-desoxy-6 $\alpha$ -methylprednisolone or ACTH, whereas two nonglucocorticoid cortisol derivatives, 11-epicortisol and 9 $\alpha$ -methoxycortisol were inactive. STH, testosterone, and insulin caused no significant change in GPT by themselves nor did they modify the action of cortisol. On the other hand, large doses of estradiol and thyroxine caused a moderate increase in GPT activity, but when injected simultaneously with cortisol, they appeared to

interfere with its action as did progesterone. Adrenalectomy slightly diminished or failed to affect the GPT inducing activity of cortisol, whereas hypophysectomy caused a rise in GPT activity and augmented the effect of cortisol.

#### SDH ←

*Ishikawa et al. F41,763/65*: In alloxan-diabetic rats, SDH and TDH levels of the hepatic microsomes are greatly enhanced. SDH was readily induced by cortisol in the diabetic, but not in the normal, rat. The effects of actinomycin S, STH, and starvation upon serine dehydratase have also been studied in intact, hypophysectomized, adrenalectomized, and thyroidectomized rats. It is concluded that "serine dehydratase activity in the liver plays an important role in the production of pyruvate as a starting material for gluconeogenesis."

#### $\alpha$ -GDPH ←

*Rivlin & Wolf H13,055/69*: In rats, the hepatic  $\alpha$ -GPDH activity is greatly increased by T3 or thyroxine, but diminished by thyroidectomy or  $^{131}\text{I}$  treatment. Both the basal

$\alpha$ -GPDH activity and the maximal increment induced by triiodothyronine are dependent upon adequate intake of riboflavin.

#### **Other Enzymes ←**

*Spinks & Burn B72,891/52*: Thyroid feeding diminishes the amine oxydase activity of the liver in rabbits, whereas thyroidectomy increases it both in rabbits and in rats.

*Metzenberg et al. D86,024/61*: Thyroxine induces carbamyl phosphate synthetase in hepatic microsomes of the liver in tadpoles.

*Freedland F46,702/65*: In hepatic homogenates of rats pretreated with thyroxine "there was a marked increase in glucose-6-phosphatase, a decrease in phosphorylase, and relatively smaller changes in other glycolytic enzyme activities after treatment. The enzymes of the

pentose phosphate pathway increased as did malic enzyme activity, although a fourth TPN-linked dehydrogenase, isocitric, decreased. L- $\alpha$ -Glycerolphosphate dehydrogenase decreased in the hyperthyroid animals. All 3 of the tricarboxylic acid cycle enzymes measured increased in activity after thyroxine injection."

*Kato & Takahashi H11,853/69*: "The magnitude of increase in the activities of microsomal drug-metabolizing enzymes and NADPH-linked electron transport system in the alloxan diabetic rats was greater than in normal rats, in contrast, the magnitude of increase in the thyroxine-treated rats was smaller than in normal rats."

*Kato et al. H11,851/69*: Studies on the effects of thyroxine upon hepatic microsomal enzyme induction by various drugs in diverse species.

### ← PARATHYROIDS

Comparatively few investigators have examined the effect of the parathyroids on resistance in general.

**Steroids** ← *cf. Selye C50,810/58, p. 89; C92,918/61, pp. 77, 164, 280; G60,083/70, pp. 410, 412.*

#### **Hormones and Hormone-Like Substances ←**

The effect of the parathyroids on the action of steroids has been discussed elsewhere. (For references *cf.* Abstract Section.) Parathyroidectomized dogs are allegedly much less resistant against histamine than intact controls, and in rabbits, parathyroid extract protects against histamine, insulin, and a number of other toxicants. However, these early experiments require confirmation.

#### **Histamine ←**

*Dragstedt et al. 17,561/23*: "Parathyroidectomized dogs are much less resistant to guanidine, methyl-guanidine, trimethylamine, histamine, and the various intestinal poisons than are normal dogs."

*McDonagh 19,285/28*: In rabbits, parathyroid extract protects against the toxic effects of histamine, insulin, guanidine, coniine and

"somniafaine" [superficial description of observations which do not inspire confidence (H.S.)].

#### **Insulin ←**

*McDonagh 19,285/28*: In rabbits, parathyroid extract protects against the toxic effects of insulin [superficial description of observations which do not inspire confidence (H.S.)].

**Epinephrine** ← *cf. Selye C92,918/61, p. 194; G60,083/70, pp. 410, 413.*

#### **Drugs ←**

The parathyroids play an important role in resistance only against very few drugs. Even the effects of such compounds as copper or beryllium salts which cause definite bone changes are not markedly influenced by parathyroid extract.

It has been claimed that in mice, parathyroid extract can protect against fatal fluoride intoxication, but this has been denied by subsequent investigators.

During the early part of this century, it was assumed that parathyroidectomy causes tetany because it interferes with the detoxication of guanidine, but this could not be confirmed.

On the other hand, the topical calcification produced by indium chloride in the rat is prevented by parathyroidectomy, although the associated hepatic necrosis and icterus remain unaffected. Pretreatment with parathyroid extract (or DHT) prevents the hepatic necrosis, but augments the topical calcery.

Resistance to  $MgSO_4$  i.v. is increased by parathyroid extract in the dog, presumably because of the well-known antagonism between Ca- and Mg-ions. In mice, parathyroid extract inhibits the development of Mg-anesthesia in a dose-dependent manner.

The nephrocalcinosis induced by a dietary excess of phosphate ( $NaH_2PO_4$ ) in the rat is inhibited by thyroparathyroidectomy as well as by excessive thyroxine administration.

The production of cardiovascular lesions by "standard renal injury" following treatment with sulfa drugs is prevented by thyroparathyroidectomy in the rat — as is the osteitis fibrosa produced by uranium intoxication — probably because these toxicants elicit renal damage with secondary hyperparathyroidism. The latter is presumed to be responsible for the disturbances in skeletal metabolism.

The calcinosis elicited by vitamin-D compounds, including DHT, is not prevented by parathyroidectomy; hence it cannot be ascribed to a secondary hypersecretion of parathyroid hormone as had been originally thought.

**Anaphylactoidogens** ← cf. *Selye G46,715/68, pp. 179, 199.*

**Antibiotics** ← cf. *Selye C92,918/61, p. 91; G60,083/70, pp. 410, 413.*

#### **Barbiturates** ←

*McDonagh 19,285/28:* In rabbits, parathyroid extract protects against the toxic effects of histamine, insulin, guanidine, coniine and "sommifaine" [superficial description of observations which do not inspire confidence (H.S.)].

#### **Copper** ←

*Ulmansky & Sela G70,273/69:* In mice, copper administration causes thickening, and fluoride treatment thinning, of the epiphyseal plates. Neither of these responses is influenced by parathyroid extract, which in itself causes some thickening of epiphyseal plates.

#### **Beryllium** ←

*Jones 33,139/35:* In dogs with beryllium rickets, parathyroid extract failed to raise the blood calcium.

#### **Coniine** ←

*McDonagh 19,285/28:* In rabbits, parathyroid extract protects against the toxic effects of histamine, insulin, guanidine, coniine and "sommifaine" [superficial description of observations which do not inspire confidence (H.S.)].

#### **Digitoxin** ←

*Selye PROT. 33541, 34074:* In rats, PCN is highly efficacious in preventing digitoxin poisoning, even after parathyroidectomy, thyroparathyroidectomy, or concurrent treatment with propylthiouracil (PTU). No protection was obtained by thyroidectomy, parathyroidectomy, or treatment with PTU, thyroxine, parathyroid extract or calcitonin. Apparently, the goitrogenic effect of PCN plays no indispensable role in its catatoxic action.

#### **Fluoride** ←

*Kochmann 55,947/34:* In mice, fatal intoxication with NaF or oxalic acid can be prevented by pretreatment with parathyroid

extract. These inhibitions are dose-dependent and may serve for the assay of parathyroid preparations.

*Muñoz 67,126/36*: In rats, parathyroid extract fails to prevent the manifestations of fluorosis.

*Ulmansky & Sela G70,273/69*: In mice, copper administration causes thickening, and fluoride treatment thinning, of the epiphyseal plates. Neither of these responses is influenced by parathyroid extract, which in itself causes some thickening of epiphyseal plates.

#### **Guanidine** ←

*Dragstedt et al. 17,561/23*: "Parathyroidectomized dogs are much less resistant to guanidine, methyl-guanidine, trimethylamine, histamine, and the various intestinal poisons than are normal dogs."

*Süssmann 24,462/27*: In mice, very impure parathyroid extracts protect against guanidine and picrotoxin but not against strychnine.

*McDonagh 19,285/28*: In rabbits, parathyroid extract protects against the toxic effects of histamine, insulin, guanidine, coniine and "somnifaine" [superficial description of observations which do not inspire confidence (H.S.)].

#### **Indium** ←

*Selye et al. D25,667/62*: In rats,  $\text{InCl}_3$  s.c. produces topical calcification and severe hepatic necrosis with icterus. Parathyroidectomy prevents the topical (calcergic) calcification at the injection site, but not the hepatic necrosis. Pretreatment with parathyroid extract (or with DHT) prevents the hepatic necrosis, although it augments the local tissue calcification at the injection site.

#### **Magnesium** ←

*Matthews & Austin 21,067/27*: In dogs, resistance to  $\text{MgSO}_4$  i.v. is increased by parathyroid extract, and decreased by parathyroidectomy, presumably because of the well-known antagonism between Ca- and Mg-ions.

*Simon 31,369/35*: In mice, parathyroid extract inhibits the development of magnesium narcosis in a dose-dependent manner. This phenomenon can be used for the standardization of parathyroid preparations.

**Perchlorate** ← cf. *Selye C92,918/61*, p. 280.

**Permanganate** ← cf. *Selye D15,540/62*, p. 303.

#### **Oxalate** ←

*Kochmann 55,947/34*: In mice, fatal intoxication with NaF or oxalic acid can be prevented by pretreatment with parathyroid extract. These inhibitions are dose-dependent and may serve for the assay of parathyroid preparations.

#### **Peptone** ←

*Czarnecki & Kiersz D15,579/61*: In dogs, shock produced by trypan blue or peptone injection is more powerfully inhibited by thyroparathyroidectomy than by thyroidectomy.

**Phosphate** ← cf. also *Selye G60,083/70*, p. 410.

*Selye C38,627/58*: In rats, the nephrocalcinosis produced by a dietary excess of  $\text{NaH}_2\text{PO}_4$  is inhibited both by thyroparathyroidectomy and by excess thyroxine administration.

#### **Picrotoxin** ←

*Süssmann 24,462/27*: In mice, very impure parathyroid extracts protect against guanidine and picrotoxin, but not against strychnine.

#### **Potassium** ←

*Thatcher & Radike B4,515/47*: In rats, resistance to KCl intoxication was increased by DOC or adrenocortical extract. Parathyroid extract decreased potassium resistance.

#### **Puromycin Aminonucleoside** ←

*Johnston & Follis Jr. D12,799/61*: In rats, the osteitis fibrosa-like changes produced by puromycin aminonucleoside (PAN) are not prevented by parathyroidectomy.

#### **Salicylates** ←

*Abbott & Harrison F36,510/65*: In rats, cancellous bone formation is stimulated by various salicylates. This effect is blocked by parathyroid extract and vitamin D, but not influenced by cortisone.

#### **Strychnine** ←

*Süssmann 24,462/27*: In mice, very impure parathyroid extracts protect against guanidine and picrotoxin, but not against strychnine.

**Sulfa Drugs** ← cf. also *Selye C92,918/61*, p. 194; *G60,083/70*, pp. 413, 414.

*Lehr & Martin C13,119/56*: In rats, the production of cardiovascular lesions by "standard renal injury" (due to treatment with sulfa drugs) is prevented by thyroparathyroidectomy, but not by thyroidectomy with parathyroid extract treatment. Curiously, "chemical thyroidectomy" [technique not specified (H.S.)] also inhibited, and thyroid hormone excess aggravated these lesions.

*Lehr & Martin C23,011/56*: In rats, the cardiovascular lesions produced by sodium acetyl sulfathiazole (as a consequence of renal injury) are prevented by thyroparathyroidectomy, presumably because in the final analysis, the changes observed are due to nephrogenic hyperparathyroidism.

*Lehr C84,326/59*: In rats, the role of parathyroid hormone in the production of cardiovascular lesions by renal damage (N-acetylsulfathiazole, surgery) was subjected to systematic analysis.

*Okano et al. H25,894/70*: In rats, the calcification and necrosis of the aortic media induced by the "obstructive nephropathy" developing after injection of sodium sulfaacetylthiazole (SAT) can be prevented by parathyroidectomy, and to a lesser extent by calcitonin.

### **Bacteria ←**

In guinea pigs, parathyroid extract allegedly delays the course of experimental tuberculosis, whereas in rats removal of the parathyroids has been claimed to lower resistance to this infection. In mice, parathyroid extract offers some protection against infection with *P. anthracis*, *E. coli* or *Ps. pyocyaneus* but not against *Klebsiella pneumoniae*.

### **Bacterial Toxins ←**

In dogs and rabbits, tetanus intoxication is not significantly affected by parathyroid extract, but the spread of this toxin is allegedly delayed by parathyroid preparations in the mouse.

### **Renal Lesions ←**

Hypertension produced by unilateral renal artery constriction in rats is not significantly affected by parathyroidectomy. However, the cardiovascular calcification produced by nephrectomy and by certain renal lesions in the rat can be prevented by parathyroidectomy presumably because here the calcinosis is a secondary result of increased parathyroid hormone secretion.

In rats, calciphylaxis produced by bilateral nephrectomy + ferric dextrin is prevented by parathyroidectomy. From this it was concluded that endogenous parathyroid hormone in amounts secreted by the gland can act as a calciphylactic sensitizer.

### **Uranium ←**

*Eger B35,694/42*: In rats, the osteodystrophia fibrosa produced by uranium intoxication can be prevented by parathyroidectomy, presumably because the renal damage induced by the heavy metal acts on the bones only through the intermediary of the parathyroids.

**Vitamin A ←** cf. *Selye G60,083/70*, pp. 410, 413.

### **Vitamin C ←**

*Kalnins & Ledina B19,372/47*: In guinea pigs, parathyroid extract accelerates the development of scorbutic changes on a vitamin-C deficient diet.

**Vitamin D, DHT ←** cf. *Selye C92,918/61*, p. 176; *D15,540/62*, p. 231; *G60,083/70*, pp. 408, 410.

**Diet ←** cf. also *Selye G60,083/70*, pp. 410, 413.

*Dragstedt & Peacock 17,556/23*: In dogs, parathyroid tetany is highly subject to modification by certain diets. It is concluded that "the parathyroid glands do not furnish a hormone necessary for life, and dogs may be kept alive indefinitely after their removal if treatment directed to the prevention of this toxemia of intestinal origin is carried out."

**Stressors ←**

Several investigators claimed that the parathyroids play an important part in resistance to cold, X-irradiation and other forms of stress, but all these findings require confirmation.

**Bacteria ←**

*Pelouze & Rosenberger 62,508/24*: In guinea pigs, parathyroid extract or calcium feeding delays the course of experimental tuberculosis.

*Steinbach 92,528/32*: In rats, parathyroidectomy lowers resistance to infection with bovine but not with human tuberculosis. Thyroparathyroidectomy makes rats susceptible to both human and bovine tubercle bacilli.

*Weinstein B15,029/39*: In mice, various anterior pituitary preparations protect against infection with *B. anthracis*. Parathyroid extract was also very effective, whereas thyroxine and testosterone offered little protection, and progesterone, insulin, "estrin" and posterior lobe extract were virtually ineffective.

*Weinstein A33,940/40*: In mice, neither parathyroid extract nor a crude anterior pituitary preparation offered protection against infection with *Klebsiella pneumoniae*, but they did improve survival after inoculation of *E. coli* or *Ps. pyocyaneus*.

*Schäfer B99,955/54; G58,597/54*: Monograph (127 pp., numerous refs.) on the role of endocrine factors in tuberculosis. Special sections are devoted to the hormones of the thyroid, parathyroid, thymus, adrenals, pancreas, and gonads.

**Bacterial Toxins ←**

*Lissák 29,256/34*: In dogs and rabbits, tetanus intoxication is not significantly modified by parathyroid extract.

*Weinstein A33,940/40*: In mice, parathyroid extract prevents the spread of tetanus toxin from the site of inoculation and delays death.

*Quattrocchi & Foresti G43,535/66*: Anaphylactic shock in guinea pigs and the Schwartzman-Sanarelli phenomenon in rabbits are inhibited by pretreatment with parathyroid extract. [The statistical significance of the apparent differences has not been appraised (H.S.).]

**Immune Reactions ←**

*Quattrocchi & Foresti G43,535/66*: Anaphylactic shock in guinea pigs and the Schwartzman-Sanarelli phenomenon in rabbits are inhibited by pretreatment with parathyroid extract. [The statistical significance of the apparent differences has not been appraised (H.S.).]

**Renal Lesions ←**

*Quadri 45,920/06*: In rabbits, i.v. injection of a parathyroid extract ("Paratiroidina") prolongs survival following bilateral ureter ligation. This fact is ascribed to an antitoxic action of the parathyroid hormone, although the hormonal activity of the extract has not been ascertained.

*Bein et al. C57,714/58*: In male rats with hypertension produced by unilateral renal artery constriction, vascular lesions are more common than in females. Gonadectomy does not significantly alter these changes in males, but aggravates them in females. Parathyroidectomy has no significant effect upon them.

*Lehr C84,326/59*: In rats, the role of parathyroid hormone in the production of cardiovascular lesions by renal damage (Na-acetylsulfathiazole, surgery) was subjected to systematic analysis.
