**phenotype:** Maternal-effect lethal; homozygous females sterile. Some blastoderms irregularly populated, with some areas on surface devoid of nuclei, others display asynchronous nuclear divisions and nuclei of non uniform size. Gastrulation occurs before full complement of nuclei achieved; mitosis continues into gastrulation. Developmental arrest at time of first muscular activity. In *swa<sup>2</sup>* development normal but abnormal larval mouth parts prevent feeding. Mosaic studies with *swa<sup>1</sup>* indicate that the gene functions in germ line (Perrimon and Gans, 1981, Dev. Biol. 100: 365-73). Morphology of developing embryos shows variable temperature-sensitive failure of head-segment development and abdominal segmentation defects. Anterior defects more severe at 29°, and posterior ones cold sensitive, strongly enhanced at 18°. *ftz* expression pattern abnormal; number of stripes varies from three (PS 2, 4, & 6) at 18° to seven at 29°. Unlike wild-type cytoplasm, anterior cytoplasm from embryos of *swa* mothers ineffective in rescuing *bcd* phenotype; also embryos from *swa* females resistant to the *bcd*-phenocopying effects of removing anterior cytoplasm (Fronhöfer and Nüsslein-Volhard).

**alleles:**

<i>swa<sup>4</sup></i>	EMS	Mohler	<i>fs(1)13C82</i>	2, 3	strong allele
<i>swa<sup>5</sup></i>	EMS	Stephenson	<i>fs(1)T573</i>	3	weak allele
<i>swa<sup>6</sup></i>	EMS		<i>fs(1)384</i>	4	

<sup>α</sup> 1 = Gans, Audit, and Masson, 1975, *Genetics* 81: 683-704; 2 = Mohler, 1977, *Genetics* 85: 259-72; 3 = Mohler and Carroll, 1984, *DIS* 60: 236-41; 4 = Stephenson and Mahowald, 1987, *Dev. Biol.* 124: 1-8; 5 = Zalokar, Audit, and Erk, 1975, *Dev. Biol.* 47: 419-32.

**cytology:** Placed in 5E6-7 based on *in situ* hybridization to a normal X chromosome but not to *Df(1)JF5 = Df(1)5E5-6;5E7-8* (Stephenson and Mahowald).

**molecular biology:** Gene cloned and restriction mapped; identity confirmed by rescue of *swa* by transformation. Detects a 2.1 kb transcript on Northern blots whose expression is restricted to the nurse cells. The message is uniformly distributed in the mature oocyte, becoming more concentrated peripherally at blastoderm formation, and disappearing by the time of gastrulation. The anterior localization of *bcd*<sup>+</sup> product disrupted in the oocytes of homozygous *swa* females (Stephenson, Chao, and Fackenthal, 1988, *Genes Dev.* 2: 1655-65).

**swarthy:** see *swy*

**swb:** see *fa*<sup>swb</sup> listed under *N*

**swi:** see *hfw*

**swiss cheese:** see *sws*

**swollen antenna:** see *crm*<sup>swa</sup>

**sws: swiss cheese (J.C. Hall)**

**location:** 1-22.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg.

**phenotype:** Isolated in anatomical screen (*cf.* Heisenberg and Böhl, 1979, *Z. Naturforsch.* 34: 143-47); many Swiss-cheese-like holes seen in brain sections of adults (similar to phenotype observed in dying *drd* flies).

**alleles:** Three alleles, *sws*<sup>1</sup>, *sws*<sup>2</sup>, and *sws*<sup>3</sup>, with isolation numbers *HK151*, *KS43*, and *RH7*, respectively.

**other information:** Phenotype has become less extreme, apparently due to accumulation of modifiers (Heisenberg).

**\*swy: swarthy**

**location:** 1-42.5.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, *DIS* 33: 92.

**phenotype:** Body color slightly dark; darkened scutellum particularly noticeable. Eyes brownish (best detected immediately after eclosion) and occasionally misshapen. *swy/s* is wild type. Viability about 50% wild type. Both sexes fertile. RK2.

**sx: sexcombless**

**location:** 1- (rearrangement).

**origin:** X ray induced.

**discoverer:** Muller, 261.

**references:** Mukherjee, 1965, *Genetics* 51: 285-304 (fig.). Reinhard and Sánchez, 1982, *Wilhelm Roux's Arch. Dev. Biol.* 191: 264-69 (fig.).

**phenotype:** Number of teeth in primary sex comb reduced from the normal 10 to 1. Bristles intermediate between normal bristles and sex-comb teeth also appear in sex-comb area. Bristle pattern of *sx* male basitarsus feminized in other respects. *sx/+* reduces the mean number of

sex-comb teeth in *tra/tra* female from 11.37 to 3.7. Sex-comb development autonomous in mosaic from either chromosome loss or somatic crossing over in *tra/tra* female (Mukherjee and Stern, 1965, *Z. Indukt. Abstamm. Vererbungsl.* 96: 36-48). Reduces number of teeth in secondary sex comb of *en/en* male and in primary sex comb of *ey*<sup>D/+</sup> male. Homozygous females generated from homozygous *mei-332* mothers have normal leg chaetotaxy (Reinhard and Sánchez). Male sterile owing to imperfect development of internal duct system; testes often remain unattached to ducts, and are therefore ellipsoidal, but contain fully developed sperm (Stern, 1941, *J. Exp. Zool.* 87: 113-58). External genitalia also greatly modified. Size, shape, and arrangement of teeth on clasper varies; occasionally more than one penial apparatus (Mukherjee). Structures frequently missing and usually displays bilateral asymmetry; also extra and missing bristles. Homozygous females characteristically lack vulva; thorn bristles on vaginal plate often present as a double row; internal genitalia absent; ovaries small but normal in shape; anal plates reduced or absent (Reinhard and Sánchez). RK2A.

**cytology:** Associated with *In(1)sx = In(1)11D4-6;11E2-6;14B8-9;15E2-4* (Mukherjee, 1963, *DIS* 38: 62).

**sxc: super sex combs (P.W. Ingham)**

**location:** 2-55.3 (0.8 unit to the right of *pr*).

**references:** Ingham, 1984, *Cell* 37: 815-23.

**phenotype:** Homozygous adults exhibit homeotic transformation of antenna to first leg, of second and third legs to first leg, of wing to haltere, and of abdominal segments A1, A4, and A5 to A2, A5, and A6, respectively. Homozygotes derived from homozygous female germ line exhibit transformation of larval thoracic and abdominal segments toward A8.

**phenotype:** *Sxl*<sup>+</sup> is a switch gene that acts throughout development to control all aspects of sexual dimorphism. Its products are required for female and must be absent for male development. Uniquely among sex-determination genes, after responding early in development to the primary sex-determination signal (the X:A ratio), *Sxl* maintains its own activity state as well as that of the downstream genes with which it interacts. It is required in a cell-autonomous fashion for both germ-line and somatic female development. It controls dosage compensation in females by suppressing hyperactivation of X-linked genes. Mutations of *Sxl* fall into two general classes: (1) recessive loss-of-function alleles that are deleterious to homozygous females, but viable and without phenotypic consequences in males, and (2) dominant gain-of-function alleles that behave as constitutive mutations, dominant and deleterious in males but without adverse effect in females, either heterozygous or homozygous. The variety of functions of the *Sxl* gene can be affected differentially by mutations, accounting in part for the complex complementation pattern observed for the large array of diverse mutant alleles. It is important to be aware that phenotypic parameters of mutant alleles and allele combinations can be very sensitive to culture conditions and genetic background. A number of positive regulators of *Sxl* are known, including the genes *da*, *fs(1)A1621*, *sis-a*, and *sis-b*. The female-specific lethal or sterile effects of mutations in these genes are suppressed by gain-of-function *Sxl* alleles. Throughout all but the very earliest period of development, female-specific expression of *Sxl* is known to be achieved by female-specific splicing of mRNA. The translation products from these female-spliced RNAs appear to help maintain the female-specific (productive) RNA processing mode which generates them, thereby establishing a positive feedback loop that maintains the female state throughout development.

**alleles:** The current convention for this gene is that alleles specifically disrupting female development (generally recessive loss of function) are designated *Sxl*<sup>f</sup>, followed by a number, whereas those specifically disrupting male development (generally dominant gain of function) are

designated *Sxl*<sup>M</sup>, followed by a number. In cases where a single lesion might have both characters, the *Sxl*<sup>M</sup> designation would prevail. *P* in the designation indicates that the allele (and sometimes the stock as well) is likely to harbor *P*-element sequences. For new alleles selected as changes in the functioning of pre-existing mutant alleles, the original allele designation is followed by a *d* (for "derivative"), then a number. If and when such derivatives are shown to carry more than one lesion within the gene, the mutant designation will change to reflect the presence and order on the chromosome of the multiple lesions, individual mutations being separated by commas. For the most part, alleles in common use before these conventions were adopted were renamed only if the changes were relatively minor and self evident.

<sup>β</sup> Shown to be a *hobo* element (Bernstein, 1989) rather than 297 as originally reported.

**cytology:** Placed in 6F4-7B3 (Nicklas and Cline, 1983, *Genetics* 103: 617-31) based on its inclusion in *Df(1)Sxl-ra = Df(1)6F4-5;7B1-3* (Lim).

**molecular biology:** The genomic region cloned by transposon tagging from *Sxl<sup>fPb</sup>*; *ca* 50 kb walk restriction mapped and mutant alleles characterized over a 26 kb region between coordinates -13 and +13 (coordinate 0 corresponds to the site of insertion of the *P* element in *Sxl<sup>fPb</sup>*) (Maine *et al.*, 1985; Salz *et al.*, 1989). Northern blot analysis reveals ten different *Sxl* transcripts derived from a 23 kb region, coordinates +1 to -22. All have closely related structures and are transcribed in the same (increasing negative coordinate) direction (Salz *et al.*, 1989). Three transcripts of 4.0, 3.1, and 1.7 kb appear transiently in blastoderm embryos. All others appear in later embryogenesis and persist throughout the remainder of development. Adult females have four *Sxl* transcripts of 4.2, 3.3, 3.3, and 1.9 kb; one 3.3 and the 1.9 kb species are reduced or absent in adults lacking a functional germ line. Adult males produce transcripts of 4.4, 3.6, and 2.0 kb. Two cDNAs, one from adult males and one from adult females derived from the 5' 15 kb of the *Sxl* transcription unit were sequenced (Bell *et al.*, 1988); the correspondence to the mRNAs is not known. The amino acid sequence inferred from the female cDNA predicts a 354 amino-acid protein of 39,000 daltons; the sequence indicates a basic protein which by hydrophathy analysis has characteristics of a soluble protein; it contains duplicated domains of 74 residues each, one at 126-199 and the other at 212-285, which exhibit 35% identity and show sequence similarity to known RNA-binding proteins (Bell *et al.*). Eight exons have been identified so far, with translation initiation likely from exon 2; exon 3 is found only in the three male specific transcripts, which otherwise correspond closely to three female-specific transcripts. Males are the sex in which genetic analysis shows *Sxl* to be nonfunctional. This exon contains two in-frame stop codons that would abort translation early on. Thus for most of development the on/off regulation of *Sxl* involves alternative modes of RNA processing. Considered in light of the genetic evidence for positive autoregulation of *Sxl* independent of the primary sex-determination signals (Cline, 1984, 1989), it would appear that *Sxl* maintains the female developmental state by controlling its own RNA splicing (Bell *et al.*). The predicted amino-acid sequence of *Sxl* products is consistent with this idea. Since *Sxl* is known to be required for sex-specific splicing of more developmentally specialized genes such as *tra* (Nagoshi, McKeown, Burtis, Belote, and Baker, 1988, *Cell* 53: 229-36), it appears that the biochemical activities of *Sxl* that maintain the sexually determined state may be the same as those that direct sexual differentiation through the regulation of genes downstream. Characteristics of the transcription pattern very early in development suggest that a different mode of regulation operates during this period when the gene is first responding to the primary sex-determination signal to set the sexual fate of cells (Salz *et al.*, 1989). Genetic (Salz *et al.*, 1987) and molecular (Salz *et al.*, 1989) stu-

dies suggest that the promoter operating during this early period is different from that which functions throughout the remainder of development, when sex-specific activity is determined by RNA splicing.

### ***Sxl*<sup>f1</sup>**

**phenotype:** Homozygous females invariably die as embryos but hemizygous males are fully viable and fertile. In most wild-type genetic backgrounds, heterozygous females exhibit normal viability and fertility, although occasionally display morphological defects characteristic of early cell death; however, can be dominant semilethal for females in some wild-type genetic backgrounds and under suboptimal growth conditions. In doubly heterozygous combination with otherwise recessive mutations in positive regulators of *Sxl*, this allele can behave as a dominant: heterozygote viability is reduced for daughters of *dal*<sup>+</sup> females, as well as for females that are also heterozygotes for either *sis-a*, *sis-b* or *fs(1)A1621*. In some such doubly heterozygous situations, escaper females may be incompletely masculinized (mosaic intersex). Homozygosity for mutations in the autosomal male-specific lethal loci does not suppress recessive *Sxl*<sup>f1</sup> lethality, but it does partially masculinize *Sxl*<sup>f1</sup>/+ females (generating mosaic intersexes) and suppresses cell-death-related morphological defects. Homozygous moribund embryos show sex-specific alterations in the phenotypic expression of hypomorphic X-linked alleles such as *run*<sup>25</sup>, a reflection of upsets in dosage compensation (female hyperactivation). Depending on the time of induction, *Sxl*<sup>f1</sup>/*Sxl*<sup>f1</sup> clones induced in *Sxl*<sup>f1</sup>/+ females can be phenotypically male and reduced in size. 2X:3A animals homozygous or heterozygous for *Sxl*<sup>f1</sup> are viable but masculinized. In genetic mosaics and chimeras, *Sxl*<sup>f1</sup> homozygous germ cells develop abnormally and fail to generate functional gametes. In some situations, the mutant female tissue displays masculine traits. *Sxl*<sup>f1</sup> rescues males from the otherwise lethal effects of a simultaneous duplication of *sis-a*<sup>+</sup> and *sis-b*<sup>+</sup>.

### ***Sxl*<sup>f2</sup>**

**phenotype:** Homozygous females are either inviable or very poorly viable, depending on genetic background. Escapers are invariably sterile but otherwise display no obvious sexual abnormalities. Complements *Sxl*<sup>f2593</sup>. Homozygotes defective in dosage compensation as indicated by hyperincorporation of uridine by their polytene chromosomes. Allele fails to support oogenesis in germ-line clones induced by mitotic recombination.

### ***Sxl*<sup>f3</sup>**

**phenotype:** A hypomorphic allele selected as an intragenic suppressor of *Sxl*<sup>M1</sup> male lethality; maps 0.0065 cM to the right of *Sxl*<sup>M1</sup>. Only characterized in *cis* combination with *Sxl*<sup>M1</sup>. The double mutant is fully viable in males and poorly viable in homozygous females, with escapers being phenotypically male and sterile. Hemizygous females are lethal. Partially complements *Sxl*<sup>f2593</sup>, generating true intersexes. Partially complements *Sxl*<sup>f7,M1</sup> with escapers phenotypically male and sterile. Fully complements *Sxl*<sup>fhv1</sup>. By itself, double mutant fails to bypass maternal *da*<sup>+</sup> requirement for activation, but can complement *Sxl*<sup>f7,M1</sup> in this regard. Double heterozygote with *fs(1)A1621* is fertile.

### ***Sxl*<sup>f7</sup>**

**phenotype:** A hypomorphic allele selected as an intragenic suppressor of *Sxl*<sup>M1</sup> male lethality; maps 0.0099 cM to the left of *Sxl*<sup>M1</sup>. Only characterized in *cis* combination with *Sxl*<sup>M1</sup>. The double mutant is male viable and semiviable in homozygous females. Escaper females are phenotypically male and sterile. Hemizygous females are inviable. Double heterozygote with *fs(1)A1621* is sterile, like *Sxl*<sup>f1</sup> but unlike *Sxl*<sup>M1,f3</sup>. The double-mutant allele retains some ability to rescue daughters from the otherwise lethal maternal effect of *da*; however, lowering maternal *da*<sup>+</sup> activity appears to decrease *Sxl*<sup>f7,M1</sup> functioning, consistent with other evidence that the parental allele, *Sxl*<sup>M1</sup>, is not fully constitutive. In the absence of a wild-type *Sxl* allele, *Sxl*<sup>f7,M1</sup> daughters that survive the *da* maternal effect are phenotypically male and sterile; in contrast, the addition to this genotype of a wild-type *Sxl* allele in *trans* renders survivors phenotypically female, but still sterile with masculinized gonads. The latter genotype of female is fertile provided mothers carry at least one *da*<sup>+</sup> allele. The ability of *Sxl*<sup>f7,M1</sup> to rescue daughters is greatly enhanced by mutations in the autosomal, male-specific-lethal loci, genes involved in hyperactivation of X-linked genes in males. The basis for this enhancement is related to the ability of these same mutations to enhance the survival of *Sxl*<sup>f7,M1</sup> hemizygous females. Although *Sxl*<sup>f7,M1</sup> was used to demonstrate the ability of *Sxl* gene products to activate *Sxl*<sup>+</sup> alleles in *trans*, it can be inferred that this allele is far below wild type in this activity. *Sxl*<sup>f7,M1</sup> is a dominant suppressor of *sis-a* female-specific lethality, generating sterile females remarkably similar to those described above rescued from the *da* maternal effect. Unlike *Sxl*<sup>M1,f3</sup>, fails to complement *Sxl*<sup>f2593</sup>, yet partially complements *Sxl*<sup>M1,f3</sup> and *Sxl*<sup>fPb</sup>, generating sterile phenotypic males. Allele supports oogenesis in homozygous mutant germ-line clones induced by mitotic recombination. In males, mutant allele suppresses the otherwise lethal effect of a duplication of region 3C2-5A2; addition of *Sxl*<sup>+</sup> to this aneuploid genotype generates mosaic intersexes indicating that the positive autoregulatory activity of *Sxl* products can bypass the X/A signal. Double heterozygote with *fs(1)A1621* is sterile (like *Sxl*<sup>f1</sup> and unlike *Sxl*<sup>M1,f3</sup>).

### ***Sxl*<sup>f9</sup>**

**phenotype:** A lethal hypomorphic allele defective in some very early steps in the sex-determination process, but which has no adverse effect on the growth or sexual development of homozygous mutant diplo-X clones induced by mitotic recombination. Rare escapers at 18° are phenotypically female; nevertheless, it has a dominant masculinizing effect on the phenotype of triploid intersexes (2X:3A) and interacts in a dominant-lethal fashion with mutations in *da* or *sis-a*, both early acting positive regulators of *Sxl*. Fully complements *Sxl*<sup>fPR</sup> class (partial deletions of *Sxl* information that impair later functions of the gene more than earlier). Complements *Sxl*<sup>M1,fPa-ra</sup>.

### ***Sxl*<sup>f2593</sup>**

**phenotype:** A hypomorphic allele that is temperature sensitive for most *Sxl* functions. Perhaps most notable for the fact that homozygote viability can be quite high, with the females developing as true intersexes (their specific

grade of intersexuality depends on temperature). Lethal over a deficiency, a null allele, or  $Sxl^{f7,M1}$  at any temperature; at permissive temperatures, weakly complements  $Sxl^{M1,f3}$  and hypomorphic alleles of the  $Sxl^{fPR}$  class, generating (true) intersexual escapers; complementation better with  $Sxl^{fPb}$ , generating sterile females; fully complements  $Sxl^{f2}$ ,  $Sxl^{f9}$ , and  $Sxl^{fhv1}$ .

***Sxl<sup>fhv1</sup>***

**phenotype:** A subliminal allele, viable and fertile as homozygous females, but with greatly reduced viability in *trans* to nulls. Polytene chromosomes of  $Sxl^{fhv1}/Sxl^{f1}$  larvae that survive to third instar hyperincorporate uridine, revealing female dosage compensation upsets. Mutation of *mle* appears to partially masculinize this heteroallelic combination and may slightly increase viability under some conditions.  $Sxl^{fhv1}$  homozygotes and heterozygotes display an increased requirement for maternal  $da^+$  activity, suggestive of defects in early *Sxl* regulation.

***Sxl<sup>fLS</sup>***

**phenotype:** A lethal hypomorphic allele that is able to initiate female development, but is defective in its ability to maintain the female developmental commitment and/or to elicit female sexual differentiation. It is masculinizing in homozygous mutant somatic clones induced by mitotic recombination, and it causes the tissue in such clones to grow poorly; nevertheless, it has no dominant effect on the sexual phenotype of triploid intersexes, nor does it interact in a dominant fashion with mutations in *da* or *sis-a*, both early acting positive regulators of *Sxl*. Fully complements  $Sxl^{f9}$ , which appears to have a very different set of defects.

***Sxl<sup>f7BO</sup>***

**phenotype:** Female-lethal null allele that appears to be deleted for the entire *Sxl* transcription unit. Males are fully viable, fertile, and display normal male sexual behavior.

***Sxl<sup>fPa</sup>***

**phenotype:** A hybrid-dysgenesis-induced apparent null allele selected as an intragenic suppressor of  $Sxl^{M1}$  male lethality. Only characterized in *cis* combination with  $Sxl^{M1}$ . A *P*-element insertion 5' to the site of the DNA insertion in  $Sxl^{M1}$  but still within the region of *Sxl* transcribed at all stages. Revertible.

***Sxl<sup>fPa-ra</sup>***

**phenotype:** A hybrid-dysgenesis-induced derivative of  $Sxl^{M1,fPa}$  selected for having regained the ability to complement  $Sxl^{f9}$ . This complex allele disrupts both male and female development, with the magnitude of the effects in either sex depending on culture temperature in a reciprocal fashion: high temperature is more permissive for females and less permissive (more feminizing) for males. Intersexual males show little male sexual behavior and stimulate courtship from other males. Dominant male-lethal effects are greatly enhanced by the presence of a duplication of  $Sxl^+$  in *trans*; male escapers with both alleles exhibit an unusual dorsalization of the abdomen, their sternites being variably transformed into tergites.

***Sxl<sup>fPb</sup>***

**phenotype:** A *P*-insertion-induced lethal hypomorphic allele with the unusual distinction of displaying a mosaic intersex phenotype in homozygous mutant diplo-X clones induced by mitotic recombination; hence, appears to be defective in the cellular maintenance of the female sexual commitment. Under dysgenic conditions, can mutate further to less extreme or to more extreme condition. Partially complements  $Sxl^{f7,M1}$ , generating masculinized individuals; partially complements  $Sxl^{f2593}$ , generating sterile females; fully complements  $Sxl^{f9}$ .

***Sxl<sup>M1</sup>***

**phenotype:** Unconditionally lethal to males, even in the presence of a  $Sxl^+$  duplication. Retains normal level of female function as evidenced by full viability and fertility of homozygous and hemizygous mutant females. Recovered by virtue of ability to bypass the normal requirement by females for maternally supplied  $da^+$  product, a positive regulator of  $Sxl^+$ ; however, bypass is incomplete at higher temperatures. Phenotype in both sexes results from expression of  $Sxl^+$  female sex determination and dosage compensation functions largely (though not completely) independently of the normal controls. This is shown by the observation that induction of mutations in *cis* that suppress dominant, male-specific lethality is invariably associated with a corresponding reduction in  $Sxl^+$  female-specific activities and the dominant *da* maternal-effect bypass phenotype.  $Sxl^{M1}$  is lethal to most gynandromorphs by the pharate-adult stage, disrupting the development of their haplo-X tissue in a cell-autonomous fashion; mutant haplo-X tissue in gynandromorphs is often, but not always, feminized. This variable penetrance of the sex transformation suggests a residual level of control by the X/A balance.  $Sxl^{M1}$  feminizes triploid intersexes, killing them as pharate adults, while suppressing *B* and *Hw* alleles in a fashion consistent with expectations for constitutive expression of normal female dosage-compensation functions. Analysis of effects on the dosage compensation of the very early acting segmentation gene, *run*, suggests that constitutive expression of female functions is not observed prior to the time when the later *Sxl* promoter is required and RNA processing control is known to be operating. Since *run* dosage compensation during this period does require functioning of maternal  $da^+$ , zygotic  $Sxl^+$ , and the X/A balance, the ability of  $Sxl^{M1}$  to bypass these controls during later stages of development would seem to indicate that the effect of the mutant lesion it carries is on *Sxl*-RNA splicing, a process that these other  $Sxl^+$  regulators may only affect indirectly. The position of the  $Sxl^{M1}$  mutant lesion in the vicinity of the male-specific exon is suggestive in this connection. Variable expressivity of this mutant allele may underlie two additional observations: (1)  $Sxl^{M1}$  male lethality can be suppressed by *fs(1)A1621*, yet *fs(1)A1621* female sterility can be suppressed by  $Sxl^{M1}$ , and (2) transplants of  $Sxl^{M1}/Y$  and  $Sxl^{M1}/+$  germ cells show that although the allele does not appear to interfere with spermatogenesis in testes, it blocks the otherwise masculinizing effect of testicular somatic tissue on diplo-X (female) germ cells.

sy: see *os*<sup>s</sup>

**\*Sy: Stubby**

**location:** 1- or 2- (rearrangement).

**discoverer:** Ives, 34j31.

**phenotype:** Bristles short and thick, especially humerals and notopleurals. Male sterile. RK2.

**cytology:** Associated with *T(1;2)Sy*; breakpoints unknown, but break in *X* is genetically at the right end.

*Sy*<sup>30</sup> : see *Bl*<sup>30</sup>

*Sy*<sup>31119</sup> : see *Bl*<sup>311</sup>

**Syb: Synaptobrevin**

**location:** 2- {60}.

**origin:** Isolated from a *Drosophila* cDNA library using a bovine cDNA probe.

**references:** Südhoff, Baumert, Perin, and Jahn, 1989, *Neuron* 2: 1475-81.

**phenotype:** Encodes a 20 kd polypeptide that is recognized by antibodies to rat synaptobrevin. Synaptobrevin is an intrinsic membrane protein of small synaptic vesicles from mammalian brain; it is highly homologous to Torpedo VAMP-1. Signal from *Drosophila* heads exceeds that from rat brain suggesting that it is an abundant protein in flies.

**cytology:** Placed in 46E-F by *in situ* hybridization to polytene chromosomes.

**molecular biology:** The isolated cDNA clone contained an 0.8 kb insert whose conceptual amino acid sequence

defines a polypeptide of 152 amino acids with a calculated molecular weight of 16,585. The polypeptide contains a 47-amino-acid N-terminal sequence that is rich in asparagine (26%) and shows little homology to the N-terminal sequences of mammals and Torpedo; the next 63 amino acids are highly conserved and display 75% identity in all three species; this region is followed by a putative transmembrane domain of 20 amino acids which display 60% identity with bovine synaptobrevin; finally the C-terminal domain, which is thought to be intravesicular comprises 22 amino acids in *Drosophila*, but only two in bovine and Torpedo polypeptides. Northern blots of *Drosophila* head RNA reveals mRNAs of 0.85 and 0.9 kb, much shorter than the 2.2 kb observed in mammals.

**\*syn: syndrome**

**location:** 3-14.7.

**origin:**  $\gamma$  ray induced.

**discoverer:** Wallbrunn, 61i21.

**references:** 1964, *DIS* 39: 58.

**phenotype:** Eyes of male translucent brown, of female slightly darker than normal. Wings of male held at right angle to body, of female held out at about 45°. Viability low. Both sexes sterile. RK2.

**Synaptobrevin:** see **Syb**

**syndrome:** see **syn**

**t: tan (J.C. Hall)**

**location:** 1-27.5.

 Heisenberg and Buchner, 1977, *J. Comp. Physiol.* 117: 127-62.  
 Wright, 1987, *Adv. Genet.* 24: 127-222.

**phenotype:** Body color varies from light tan to almost wild-type. Easiest to identify by light tan antennae; male easier than female. Larval mouthparts in mutant alleles, *t*<sup>1</sup>, *t*<sup>2</sup>, and *t*<sup>3</sup> lighter than normal at basal prongs; classifiable with difficulty in larvae (Brehme, 1941, *Proc. Nat. Acad. Sci. USA* 27: 254-61). Neurological defect first observed in *t*<sup>1</sup> by McEwen (1918), who reported that the mutant flies behaved as if they were nonphototactic in his test apparatus (tube with light at one end); Benzer (1967) and Pak *et al.*, (1969), using a similar but more elaborate apparatus and EMS-induced tan alleles, reached the same conclusion. In a Y-maze test for phototaxis, however, tan mutants are sensitive to light (Hadler, 1984, *Biol. Bull.* 126: 264-73). In the electroretinogram (ERG) tracing obtained when one electrode is inserted in the first optic ganglion (lamina) below the ommatidia, the on- and off-transients of tan flies are reduced or missing, but the other ERG components are present, indicating that the mutant is not blind although it appears behaviorally blind in some tests. Mosaic studies (Hotta and Benzer, 1970, *Proc. Nat. Acad. Sci. USA* 67: 1156-63) indicate that the ERG phenotype of tan is cell autonomous. The optomotor responses of mutants to horizontal and vertical movements are abnormal in that light intensity thresholds for responses are raised, the extent depending on the allele (Heisenberg, 1971, *DIS* 46: 68; Heisenberg and Götz, 1975; Heisenberg and Buchner, 1977). No walking optomotor responses are detected, but there can be positive responses in flying optomotor tests if the rotating vertical stripes are relatively wide.

The enzyme tyrosinase, which converts tyrosine to 3,4-dihydroxyphenylalanine (DOPA), is formed in tan adults (Horowitz). Dopamine, an important component of catecholamine metabolism (involved in both melanization of cuticle and synthesis of neurotransmitters), has been found in reduced amounts (about 60% of the wild-type concentration) in *t*<sup>1</sup> and *t*<sup>5</sup> (Konopka, 1972). The dopamine was detected only in late pupae that show some pigmentation and in adult flies. One of the enzymes involved in the formation of dopamine, β-alanyldopamine hydrolase (BAH), shows no activity in *t/t* and *t/Y* mutants and reduced activity in *t/+* heterozygotes as compared to wild-type (Black, Pentz, and Wright). This dosage effect implicates tan as the structural gene for BAH (Wright, 1987).

The mutant tan is defective in courtship behaviors, the

males showing aberrant visually-mediated responses to moving female flies (Cook, 1980, *Biol. Cybernet.* 37: 41-51; Tompkins, Gross, Hall, Gailey, and Siegel, 1982, *Behav. Genet.* 12: 295-307).

**alleles:** No complementation for body color or phototaxis between *t*<sup>1</sup> and *t*<sup>5</sup>, *t*<sup>6</sup>, *t*<sup>8</sup>, *t*<sup>9</sup>, and *t*<sup>10</sup>. Deficiencies listed in rearrangement section.

*T*<sup>1</sup>: see *Tp1*

**T-cp1: T-complex 1**

**location:** 3- {76}.

**origin:** Molecular cloning.

**references:** Ursic and Ganetzky, 1988, *Gene* 88: 267-74.

**phenotype:** Codes for a cDNA from *Drosophila melanogaster* that shares 66% sequence identity with the mouse *Tcp-1* gene encoding *TCP1* (t-complex polypeptide 1).

**cytology:** Placed in 94B1-2 by *in situ* hybridization to salivaries.

**molecular biology:** Gene cloned and sequenced. The predicted protein is made up of 557 amino acids and is 72% identical to the mouse polypeptide. The yeast *Saccharomyces cerevisiae* also carries a genomic fragment that can be detected by the *Drosophila T-cp1* cDNA.

**ta: tapered** (J.C. Hall)

**location:** 2-56.6.

**origin:** Ultraviolet induced.

**discoverer:** Edmondson and Meyer, 49c.

**references:** 1949, DIS 23: 61.

Wood and Butterworth, 1972, DIS 49: 67-68.

**phenotype:** Wings narrow and pointed, somewhat longer than normal. Veins close together. Viability good. Female fertility low; male sterile. Males show abnormal courtship pattern, *i.e.* vague interest in circling and approaching female with no interest in touching. Periodic wing vibrations at 90° and proboscis movements occur, but females not receptive to mutant males. 20% of *ta/ta* males had non-motile spermatozoa. Frequently, accessory glands on one or both sides were atrophied; testes often atrophied or show club-like structures on the apical ends (Wood and Butterworth, 1972). RK2.

*ta*: see *tar*

**Ta: Thickened arista**

**location:** 3- {47}.

**synonym:** *Ta<sup>L</sup>*: *Thickened arista-Lethal* (used by Cavener *et al.*, 1986b, for *Ta<sup>1</sup>*).

**origin:**  $\gamma$  ray induced (*Ta<sup>1</sup>*).

**references:** Kaufman, 1978, Genetics 90: 579-96.

Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33.

Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.

Cavener, Corbett, Cox, and Whetten, 1986a, EMBO J. 5: 2939-48.

Cavener, Otteson, and Kaufman, 1986b, Genetics 114: 111-23.

**phenotype:** Semidominant homeotic mutant that transforms arista segments into tarsal segments. Both *Ta<sup>1</sup>* and *Ta<sup>2</sup>* are homozygous lethal; lethality of *Ta<sup>2</sup>* may be due to its association with a Minute. The heteroallelic combination *Ta<sup>1</sup>/Ta<sup>2</sup>* is viable and shows transformation of the whole arista and the fourth and fifth antennal segments into a segmented tarsus with a claw at the distal end; little or no transformation of the third antennal segment; males show extreme reduction in the number of sex-comb teeth on the first leg, as in *Df(3R)Scr* (Kaufman *et al.*, 1980). *Ta<sup>1</sup>/+* and *Ta<sup>2</sup>/+* flies have a less extreme antennal phenotype without the reduction in the number of sex-comb teeth.

**alleles:** Two mutant alleles have been identified: *Ta<sup>1</sup>*, associated with *T(2;3)Ta*, and *Ta<sup>2</sup>*, which is cytologically normal. These alleles are partially complementing. Both are viable (but mutant) over *Df(3R)Scr* = *Df(3R)84A1-2;84B1-2*; *Ta<sup>2</sup>* is also viable over *Df(3R)Antp17* = *Df(3R)84B1-2;84D11-12*.

**cytology:** Placed in 84C1-2 on the basis of molecular data for the breakpoint of *T(2;3)Ta* = *T(2;3)51E1-2;84C1-2* which lies between the proximal breakpoint of *Df(3R)dsx2M* = *Df(3R)84C1-2;84E1-2* and the distal breakpoint of *Df(3R)Scx2* = *Df(3R)84A4-5;84C1-2*.

**molecular biology:** Distal (84C1-2) breakpoint of *T(2;3)Ta* located at about +34 kb [in the 15 kb overlap of *Df(3R)Scx2* and *Df(3R)dsx2M* (Baker and Wolfner, 1988, Genes Dev. 2: 477-89; 0 point = Hind III site in  $\alpha$ Tub84B; "+" values to the right, "-" values to the left)].

**\*taw: tawny**

**location:** 1-41.1.

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 75-76.

**phenotype:** Head and thorax slightly dark; abdomen pale. Wings usually scooped or tips curved. Female tergites often narrow, serrated, or broken. Viability and fertility good. RK3.

**taxi:** see **tx**

**\*tb: tiny bristle**

**location:** 1-35.8.

**discoverer:** Bridges, 16a4.

**references:** 1919, J. Gen. Physiol. 1: 645-56.

**phenotype:** All bristles short and fine; wings somewhat short. Female fertility low. RK2.

*tb*: see *tbr*

**Tb: Tubby**

**location:** 3-90.6.

**synonym:** *Tu*.

**references:** Auerbach, 1943, DIS 17: 49.

Lindsley, 1973, DIS 50: 21.

Craymer, 1980, DIS 55: 197-200.

**phenotype:** Dominant; larvae, pupae, and adults shorter and thicker than wild-type in both heterozygotes and homozygotes (not separable). Larvae distinguishable on basis of reduced length and tortuous tracheal trunks. Classification reliable in larvae and pupae but not adults. Both sexes viable and fertile.

**alleles:** Two alleles, *Tb*, induced by chemicals, presumably nitrogen mustard (Auerbach, 1943) and *\*Tb<sup>2</sup>*, induced by

$\gamma$  rays (Lindsley, 1973).

**cytology:** Salivary chromosomes normal (Lindsley, 1973).

*tb-53* : see *mc*

**\**tbd*: tiny bristleoid**

**location:** 1-25.

**origin:** Spontaneous.

**discoverer:** Curry, 37g23.

**phenotype:** Bristles short and thin, like a medium Minute. Fly somewhat smaller than wild type. Good viability and fertility. RK2.

**cytology:** Locus between 7C5 and 8C1 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book – Carnegie Inst. Washington 41: 191). Further restricted to 8A1-C1 on the basis of its genetic location to the right of *oc* at 8A1-2 (Hinton and Welshons, 1955, DIS 29: 125-26).

***tbl*: tastblind (J.C. Hall)**

**references:** Isono and Kikuchi, 1974, Jpn. J. Genet. 49: 113-24.

Tanimura, Isono, and Kikuchi, 1978, Jpn. J. Genet. 53: 71-73.

**phenotype:** Electrophysiological response of labellar hair sensory structures to D-glucose, maltose, and sucrose reduced compared to wild type; no response to D-mannose, D-xylose, and lactose. Response to D-fructose normal.

***tbr*: tracheae broken**

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Slatis.

**synonym:** *tb* (preoccupied).

**references:** 1959, Genetics 44: 536.

**phenotype:** Main tracheal trunks of larva have interruptions. Penetrance 17% at 16°, 5% at 25°. Does not seem to affect viability. RK3.

***tbs*: thin bristles**

**location:** 2-81.6.

**origin:** Spontaneous.

**synonym:** *Ho*.

**references:** Mostashfi and Koliantz, 1970, DIS 48: 104.

**phenotype:** Thin and somewhat short bristles.

***tc*: tiny chaetae**

**location:** 1-51.6.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007)

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 76.

**phenotype:** Bristles extremely short and fine. Eclosion delayed. Viability and fertility good. RK1.

**cytology:** Located in 13F since included in *Df(1)sd72b = Df(1)13F1;14B1* but not in *Dp(1;4)*r*<sup>+</sup> = Dp(1;4)13F10;16A1-2* (Lefevre).

***Tcp*: Third chromosome cold-sensitive paralytic (J.C. Hall)**

**location:** 3-66.0.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *TCP*.

**references:** Sønndergaard, 1980, Heredity 92: 335-40.

**phenotype:** *Tcp/+* mutants kept at 25° show an unsteady gait upon mechanical agitation, the more extreme alleles falling over and having difficulty in righting themselves. Surviving heteroallelic combinations have motor problems even when undisturbed. All heterozygotes reversibly paralyzed within 18 sec at 12° (more variable from 12° to 19°). Homozygotes and heteroallelic combinations lethal for the most part; survivors more sensitive to cold than *Tcp/+*. During development, heterozygous embryos, but not larvae, are killed by exposure to temperatures less than 13°. In extracts from mutant adults, assays of a mitochondrial enzyme show shifts in Arrhenius activation energy.

**alleles:** Eleven alleles designated *Tcp*<sup>1</sup> to *Tcp*<sup>11</sup>. Most alleles are recessive lethals. *Tcp*<sup>2</sup> appears to be a hypomorph; *Tcp*<sup>9</sup> survives as a homozygote, but is lethal in many heteroallelic combinations.

***Tcr*: Third chromosome resistant**

**location:** 3-39.6.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Bishop, Sherald, and Wright.

**synonym:** *l(3)Tcr*.

**references:** Wright, 1987, Adv. Genet. 24: 127-222.

**phenotype:** *Tcr/+* heterozygotes resistant to dietary  $\alpha$  methyl dopa. Homozygous lethal. Heteroallelic combination *Tcr*<sup>40</sup>/*Tcr*<sup>45</sup> partially lethal, 48.3% dying as late embryos, these unhatched larvae having underpigmented mouthparts like lethal *Ddc/Ddc* embryos; only 7.5% go through pupation and manage to eclose, but these adults die soon. Both pharate and hatched adults have cuticular abnormalities involving the eyes (rough, often small, with black, necrotic spots), ocelli (often missing), wings (notched), scutellum (reduced), bristles (missing or *M*-like), sex combs (reduced), and abdomen (grayish). *Tcr/+* heterozygotes suppress the lethality of *amd* heteroallelic combinations; *Tcr* heteroallelic combinations are not rescued genetically by *amd/+*, but show increased embryonic mortality as a maternal effect of *amd*.

**alleles:** Two partially complementing alleles described, *Tcr*<sup>40</sup> and *Tcr*<sup>45</sup>.

**\**tdd*: tiddler**

**location:** 1-0.0 (0/871 crossovers with *sc*).

**origin:** Induced by ethyl methanesulfonate (CB. 1528).

**discoverer:** Fahmy, 1956.

**references:** 1958, DIS 32: 76.

**phenotype:** Body small. Viability and fertility good. RK3.

**\**te*: tenerchaetae**

**location:** 1-5.6.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 76.

**phenotype:** Bristles short and fine. Eyes dark and glistening. Wings frequently small, deformed in various ways. Eclosion delayed. Male viability, but not fertility, good. Female infertile. RK3.

**technical knockout:** see *tko*

**ted: trapped**

**location:** 3- [47].

**references:** Cavener, Otteson, and Kaufman, 1986, *Genetics* 114: 111-23.

**phenotype:** Homozygous lethal; homozygotes attempt to eclose but cannot break the operculum seams. Rescue of fully viable and fertile adults can be effected by dissection from the puparium.

**alleles:** Five mutant alleles have been described.

allele	origin	discoverer	synonym
<i>ted</i> <sup>1</sup>	EMS	Grigliatti	<i>l(3)4.15</i>
<i>ted</i> <sup>2</sup>	EMS	Grigliatti	<i>l(3)5.12</i>
<i>ted</i> <sup>3</sup>	EMS	Cavener	<i>l(3)g8</i>
<i>ted</i> <sup>4</sup>	EMS	R. Lewis	<i>l(3)r5</i>
<i>ted</i> <sup>5</sup>	EMS	R. Lewis	<i>l(3)r12</i>

**cytology:** Placed in 84C6-8 since in the region of overlap between the distal breakpoint of *In(3R)Antp*<sup>73b</sup> = *In(3R)84B1-2;84C5-6* and the proximal breakpoint of *Df(3R)dsx-M29 = Df(3R)84C8-D1;84F6-7*.

**other information:** The rescuable mutant phenotype is the same as that observed in *Gla*<sup>n</sup> mutants (Cavener and MacIntyre, 1983, *Proc. Nat. Acad. Sci. USA* 80: 6286-88).

**Tegula:** see under *shv* in *dpp* entry

**Tekele:** see *Fs(2)Sz10*

**telegraph:** see *tg*

**telescope:** see *ts*

**temperature induced paralysis A:** see *tipA*

**Temporal protein 1:** see *Tp1*

**\*ten: tenuis chaetae**

**location:** 1-43.9.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1953.

**references:** 1958, *DIS* 32: 76.

**phenotype:** Bristles short and thin. Body small. Expression more extreme in female. Eclosion slightly delayed. Viability and fertility good. RK3.

**tender little chaetae:** see *tlc*

**tenerchaetae:** see *te*

**tent:** see *tnt*

**tenuis chaetae:** see *ten*

**ter: terraced**

**location:** 2-36.

**origin:** Spontaneous (*ter*<sup>U</sup> appeared as cluster in mutable *sc z w*<sup>zmz</sup> stock).

**discoverer:** Bridges, 29c12.

**references:** Kalisch, 1970, *Mol. Gen. Genet.* 107: 321-35. 1980, *DIS* 55: 206-07.

**phenotype:** Eye abnormality varies from tiny facetless nick in anterior eye rim plus a horizontal seam of irregular facets to a large indentation in the anterior eye margin. Large tuft of bristles often found in facetless eye area. Penetrance in *ter*<sup>U</sup> about 94% at 16-25°. Viability good, but *ter*<sup>U</sup>/*ter*<sup>U</sup> homozygotes show lower hatching rate than *ter*<sup>U</sup>/+ heterozygotes.

**alleles:** Two alleles of similar phenotype described: *\*ter* (Bridges) and *ter*<sup>U</sup>, *terraced of Umeå* (Kalisch).

**Term: Terminus**

**location:** 3- [45].

**synonym:** *Bsg75C; ter; hid(?)*.

**references:** Roark, Mahoney, Graham, and Lengyel, 1985, *Dev. Biol.* 109: 476-88.

Baldarelli, Mahoney, Salas, Gustavson, Boyer, Chang, Roark, and Lengyel, 1988, *Dev. Biol.* 125: 85-95.

**phenotype:** Blastoderm-specific locus whose function may involve binding to the DNA (see **molecular biology** section). In the syncytial blastoderm stage, *Term* RNA is distributed uniformly throughout the embryo. In late cellular blastoderm, it is concentrated at the posterior pole. At gastrulation, the RNA is found in the invagination that gives rise to the posterior midgut and proctodeum, the region that will form the ventral furrow, and the antero-dorsal neurogenic region, but it disappears by the end of the period of germ band extension.

**cytology:** Placed in 75C1-2 on the basis of *in situ* hybridization to the salivary chromosomes at 75C (Roark *et al.*, 1985) and inclusion in *Df(3L)W10 = Df(3L)75A6-10;75C2-4* (Baldarelli *et al.*, 1988).

**molecular biology:** Gene cloned (Roark *et al.*). A 5.8 kb. *EcoRI* fragment subcloned and restriction mapped and the nucleotide sequence of the *Term* coding region determined (Baldarelli *et al.*, 1988). There are two transcription units,  $\alpha$  and  $\sigma$ , which appear to have identical coding regions and to be oriented in opposing directions with 3' ends adjacent. The longest open reading frame begins at the methionine codon at position 155 and extends without interruption to the tyrosine codon at 1436; it is believed to be the ORF that encodes the *Term* protein. The RNA contains 150 nucleotides of untranslated sequences at its 5' end. A potential regulatory region between positions -387 and -431 contains two identical inverted repeats. The protein predicted from the nucleotide sequences has a TFIIIA-like finger which may bind to the DNA (Baldarelli *et al.*, 1988).

**terraced:** see *ter*

**tet: tetraltera**

**location:** 2- [located on 3 by Vilee (1942); location later revised by Goldschmidt (1952, 1953), who considered *tet* to be multifactorial with the main factor on 2 and enhancing factors on X and 3; placed on 2 by E.B. Lewis and García-Bellido].

**origin:** Spontaneous.

**discoverer:** Goldschmidt, 34l.

**references:** 1940, *Material Basis of Evolution*, Yale University Press, p. 325 (fig.).

Vilee, 1942, *Univ. Calif. Publ. Zool.* 49: 125-84.

Goldschmidt, Hannah, and Pitternick, 1951, *Univ. Calif. Publ. Zool.* 55: 67-294.

Goldschmidt, 1952, *J. Exp. Zool.* 119: 405-60.

1953, *J. Exp. Zool.* 123: 79-114.

James and Bryant, 1981, *Dev. Biol.* 85: 39-54.

**phenotype:** Wings reduced; may have tendency to be haltere-like. Duplications of the notum as well as the costa and ventral hinge of the wing accompanied by deficiencies for the rest of the wing; outgrowths from wing formed by duplications of the costa; no evidence for wing to haltere transformation observed by James and

Bryant (1981). Little cell death in third larval instar. Expression variable; overlaps wild type; enhanced by *os*<sup>S</sup> (E.B. Lewis). Penetrance temperature-sensitive (0-1% at 29°, 35% at 15°). RK3.

**alleles:** *tet* (Goldschmidt; Vilee); *tet*<sup>3</sup> (García-Bellido), \**tet*<sup>Bd</sup> (Goldschmidt; Piternick).

**tetanic:** see *tta*

**tetraltera:** see *tet*

**tetrapter:** see *ttr*

**tetrodotoxin-sensitive:** see *ttx*

**Tevel:** see *Fs(3)Sz21*

**\*tf: trefoil**

**location:** 2-55 (between 50 and 60).

**discoverer:** Morgan, 13k.

**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 244 (fig.).

**phenotype:** Scutellum darkened. Base of trident pattern and back of head have extra areas of dark pigmentation. Classification uncertain. RK3.

**tfd: two-faced (J.C. Hall)**

**location:** Complex; major components on 3.

**origin:** Spontaneous.

**references:** Lipschitz and Kankel, 1985, Dev. Biol. 107: 1-12.

**phenotype:** Flies show variable expression of eye-antennal abnormalities on the dorsal head cuticle, ranging from cuticular deformities with missing bristles and ocelli to duplications of the antennae (frequent), eyes, and labial palps (infrequent). The extra antenna is usually a perfect copy of the normal one, but the extra eye is much smaller, with irregular facets. In the late third instar, larvae often have extra tissue in their eye-antennal disks; in adults there is everted but not externalized disc tissue in the head. Nerves from extra antennae were traced with silver staining and Golgi and tannic acid and found to frequently connect to and make normal projections in the brain; no connections between the extra eyes and the brain were found. The infrequent palp duplications were not examined in detail.

**other information:** The *tfd* phenotype originally appeared with low frequency (about 1%) in a *In(3LR)DcxF, ru h D Sb sr e<sup>S</sup>/Gl Ubx e<sup>4</sup>* stock, was separated from the *DcxF* chromosome and selected for until penetrance was almost complete and 20-40% of the flies showed strong *tdf* expression. Both penetrance and expression decreased rapidly when selection was relaxed except when *tdf* enhancer(s) had accumulated in the stock.

**\*tft: tufts**

**location:** 2-102 (between *px* and *bw*).

**origin:**  $\gamma$  ray induced.

**discoverer:** R. M. Valencia, 1959.

**references:** 1959, DIS 33: 99-100.

**phenotype:** Sternopleural bristles form a dense tuft. Fully penetrant at 20°, poorly so at 25°. RK2.

**Tft: Tufted**

**location:** 2-53.6; 1.2 cM to left of *Bl* (Tokunaga, 1967).

**origin:** X ray induced.

**discoverer:** Ritterhouse, 52f25.

**references:** 1952, DIS 56: 68-69.

Arnheim, 1967, Genetics 56: 253-63.

Tokunaga, 1967, DIS 42: 40.

Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85.

Ghysen and Richelle, 1979, Dev. Biol. 70: 438-52.

**phenotype:** Dominant mutation characterized by an increased number of bristles in the postalar, dorsocentral, and scutellar regions; tufts of bristles formed on mesothorax in both homo- and heterozygotes; bristles shorter in homozygotes. Extra bristles located dorsal to halteres at junction of thorax and abdomen. Posterior part of mesonotum appears wider than normal. Homo- and heterozygous females have a greatly reduced scutellum; scutoscutellar suture almost absent; heterozygous males have a nearly normal scutellum (Arnheim, 1967). Small to moderate amounts of fluid tend to remain between the epithelial layers of the wing. Penetrance of extra-bristle character 100%. *Tft* not suppressed by *Df(1)sc19 = Df(1)1A1;1B4-5* but suppressed by *Df(1)260-1 = Df(1)1A1;1B4-6* (García-Bellido, communicated to Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38). Cell autonomous in mosaics (Arnheim, 1967). Viability and fertility low.

**alleles:** Single *Tft* allele and a viable point mutant revertant, *Tft*<sup>rv54</sup> (Wright *et al.*, 1976).

**cytology:** Probably located in 37A3-6 since reverted to *Tft*<sup>+</sup> by *In(2L)47 = In(2L)37A2-B1;38A6-C1* (Wright *et al.*, 1976). Uncovered by *Df(2L)TW3 = Df(2L)36F7-37A1;37B2-8* and *Df(2L)TW50 = Df(2L)36E4-F1;38A6-7*.

**other information:** Extra bristles often very close together; underlying neurons make functional contacts with the CNS (Ghysen and Richelle, 1979). Innervated bristles also found in the metanotum, which has no bristles in wild-type flies (García-Bellido and Deak).

**tg: telegraph**

**location:** 2-0.0.

**discoverer:** Bridges, 16c27.

**references:** Morgan, Bridges and Sturtevant, 1925, Bibliog. Genet. 2: 237.

Stern and Bridges, 1926, Genetics 11: 507 (fig.), 508-10.

Carlson, 1966, Ohio J. Sci. 66: 340-46.

1970, Ohio J. Sci. 70: 365-71.

Thompson, 1973, DIS 50: 59.

**phenotype:** Vein L2 has one or more gaps or thin sections. Postscutellar bristles erect or misdirected. Overlaps wild type. RK3.

**alleles:** Two alleles: *tg* of Bridges and *tg*<sup>C</sup> of Carlson (1966, 1970).

**Tg: see under shv in dpp entry**

**th: thread**

**location:** 3-43.2.

**references:** Ward and Alexander, 1957, Genetics 42: 42-54.

Korge, 1972, DIS 48: 20.

Mglinetz and Ivanov, 1975, Genetika (Moscow) 11: 88-96.

Ashburner, Richards, and Velissariou, 1980, DIS 55: 196.

**phenotype:** Aristae threadlike, without side branches. Mutation affects development of tarsal claws at 29°

(Mglinetz and Ivanov, 1975). Deficiency for *th* homozygous lethal (Ward and Alexander, 1957; Korge, 1972). Mutant males and females less successful in mating than wild-type (Burnet, Connolly, and Dennis, 1971, Anim. Behav. 19: 409-15).

**alleles:** Mutants and rearrangements (other than deficiencies) are described in the following table.

allele	origin	discoverer	ref <sup>α</sup>	cytology
<i>th</i>	spont	Bridges, 22j31	3	
<i>th</i> 3β	γ ray	Velissariou	1	
* <i>th</i> 293γ	X ray	Alexander	3	<i>In(3L)72A2-B1;76A4-B1;79A4-B1</i>
<i>th</i> SS107	X ray		2	
<i>th</i> SS108	X ray	Smith	2	<i>In(3L)63F3-5;72A3-4 + In(3L)68F5;73F</i>

<sup>α</sup> 1 = Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91; 2 = Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95; 3 = Ward and Alexander, 1957, Genetics 42: 42-54.

β Induced together with *Df(3L)st3 = Df(3L)72E5-F1;73A4-5*.

γ Homozygous lethal.

**cytology:** Placed between 72A2 and 72C1-2 (Korge, 1972) since uncovered by *Df(3L)th701 = Df(3L)72A2;72D* and *Df(3L)th70kl = Df(3L)71C3-4;72C1-2*; probably in 72B1 according to Ashburner *et al.*, 1980.

### **Th: Tyrosine-3-hydroxylase (K. White)**

**location:** 3-{21}.

**origin:** Isolated as a cDNA clone using homology to rat tyrosine hydroxylase (TH).

**references:** Neckameyer and Quinn, 1989, Neuron 2: 1167-75.

**cytology:** Placed in 65B by *in situ* hybridization to the salivaries.

**molecular biology:** Gene cloned and nucleotide sequence of the *Drosophila* cDNA and deduced amino acid sequence of the protein obtained (Neckameyer and Quinn, 1989). A 3.2 kb clone isolated from an adult *Drosophila* head library was analyzed. There is a single open reading frame that encodes a 58 kd protein that is almost 50% identical to rat tyrosine hydroxylase. The protein is specifically recognized by an antibody made against bovine TH. The *Drosophila* gene is expressed in head tissue and first instar larvae. Transcripts of 3.2 and 3.65 kd were detected, the latter appearing to be adult-specific.

**other information:** The *Drosophila melanogaster* mutant pale has been genetically mapped to the same region (65B) as the rat TH-homologous *Drosophila* cDNA clones, suggesting that *ple* may be a TH mutation. The ability of *Th* DNA to rescue *ple* mutants, however, has not been tested.

### **\*tha: thin arched**

**location:** 1-27.8.

**origin:** Induced by S-2-chloroethylcysteine (CB. 1592).

**discoverer:** Fahmy, 1957.

**references:** 1959, DIS 33: 93.

**phenotype:** Fly small, has short thin bristles. Wings arched over abdomen or drooping at sides. Viability and fertility low. RK3.

### **\*thb: thin bristle**

**location:** 1-48.0.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1951.

**references:** 1958, DIS 32: 76.

**phenotype:** Bristles thin, short in female. Occasionally, vibrissae abnormal and eyes rough. Vein L5 sometimes faint or missing beyond posterior crossvein. Viability and fertility good in male and reduced in female. RK2.

### **thg: throng**

**location:** 2-{0}.

**references:** Shamanski and Orr-Weaver, 1989.

**Genetics:** Maternal effect mutant.

**cytology:** Located at 21B.

### **thi: thick head**

**location:** 2-72.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1983, DIS 59: 158-60.

1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Homozygous lethal in embryo. Broad head. In combination with *Pc*-like mutants, abdominal transformations occur.

**alleles:** Two alleles, *thi*<sup>1</sup> and *thi*<sup>2</sup> isolated as *HM* and *HN*.

### **thic: thickened arista**

**location:** 1- (to right of *f*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

Homyk, 1977, Genetics 87: 105-28.

**phenotype:** Aristae and sex combs thickened; dark specks in eye. Lethal at 29°.

**thick:** see *tk*

**thick head:** see *thi*

**thick legs:** see *thl*

**thick legs-darker:** see *thl-d*

**thick vein:** see *thv*

**thick vein delta:** see *thvd*

**thick veins:** see *tkv*

**thickened arista:** see *thic*

**Thickened arista:** see *Ta*

**thickened veins:** see *thiv*

**thickoid:** see *tkd*

**thickset:** see *tht*

**thin:** see *tn*

**thin arched:** see *tha*

**thin bristle:** see *thb*

**thin bristles:** see *tbs*

**thin macros:** see *thm*

**Third chromosome cold-sensitive paralytic:** see *Tcp*

**Third chromosome resistant:** see *Tcr*

**thiv: thickened veins**

**location:** 2-71.4.  
**origin:** Nuclear polyhedrosis virus of *Galleria melonella*.  
**references:** Shandala, 1985, Tsitol. Genet. 19: 179-83.  
**phenotype:** Wing veins thickened. Maximum penetrance at 16°, minimum at 28°; TSP for penetrance between second and third larval instars.

**\*thl: thick legs**

**location:** 1-60.7.  
**origin:** Induced by D-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).  
**discoverer:** Fahmy, 1955.  
**references:** 1959, DIS 33: 93.  
**phenotype:** Legs short and swollen, particularly posterior pair; swelling most pronounced in tibial and tarsal regions. Wings small and broad, divergent or slightly upheld. Body color slightly dusky and eye color a bit brownish. Male fertile; viability about 20% wild type. RK3.  
**other information:** One allele each induced by CB. 1506 and CB. 1528.

**\*thl-d:** see *\*dkl*

**\*thm: thin macros**

**location:** 1-48.9.  
**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**references:** Fahmy, 1958, DIS 32: 76.  
**phenotype:** Bristles slightly shorter and thinner than normal. Viability and fertility good. RK2.

**thorny:** see *tny*

**thr: three rows**

**location:** 2-86.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1983, DIS 59: 158-60.  
 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.  
 Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.  
**phenotype:** Larval denticles sparse and arranged in few rows, all pointing posteriorly. Denticles larger than normal. Apparently no mitoses after the first post-blastoderm mitosis, resulting in embryos with fewer and larger cells than normal. TSP 4-9 h. Homozygous lethal in embryo.  
**alleles:**

allele	synonym	comments
<i>thr</i> <sup>1</sup>	<i>thr</i> <sup>IB</sup>	
<i>thr</i> <sup>2</sup>	<i>thr</i> <sup>IL</sup>	
<i>thr</i> <sup>3</sup>	<i>thr</i> <sup>IIV</sup>	temperature-sensitive
<i>thr</i> <sup>4</sup>	<i>thr</i> <sup>BH</sup>	hybrid dysgenic
<i>*thr</i> <sup>5</sup>		
<i>*thr</i> <sup>6</sup>		
<i>*thr</i> <sup>7</sup>		
<i>*thr</i> <sup>8</sup>		

**cytology:** Placed in 55A-F.

**thread:** see *th*

**thread bristle:** see *trb*

**three rows:** see *thr*

**\*tht: thickset**

**location:** 1-42.1.  
**origin:** Induced by DL-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007)  
**discoverer:** Fahmy, 1953.  
**references:** 1959, DIS 33: 93.  
**phenotype:** Fly reduced in size, more in length than breadth, giving a stocky appearance. Eye shape slightly altered, has a few deranged facets. Viability about 10% wild type. Male fertile. RK3.

**thv: thick vein**

**location:** 1-49.7.  
**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**discoverer:** Fahmy, 1956.  
**references:** 1958, DIS 32: 76.  
**phenotype:** Veins thick, especially at junction of L1 and L2. Wings short and broad; marginal hairs irregular. Eyes small and dark. Body color rather pale. Eclosion delayed. Male viable and fertile. Female fertility sub-normal. RK2.

**\*thvd: thick vein delta**

**location:** 1-55.2.  
**origin:** Induced by L-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1955.  
**synonym:** *dtv: delta vein*.  
**references:** 1958, DIS 32: 69-70.  
**phenotype:** Wings slightly short and broad; has extra venation, especially around L2, which usually ends in a delta. Anal plates and genital arch deformed; genital region protruding. Male fertile but viability about 50% normal. RK3.

**\*ti: tarsi irregular**

**location:** 2-55.9.  
**origin:** Spontaneous.  
**discoverer:** Ives, 38k5.  
**references:** 1942, DIS 16: 48.  
**phenotype:** Third and fourth tarsal segments more or less fused and swollen. Eyes slightly rough. Viability sub-normal. RK2.

**tipA: temperature induced paralysis A**

(J.C. Hall)

**location:** 2-44.0.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.**phenotype:** Becomes paralyzed rapidly at 38°C; time required for recovery (after return to 23°) increases quickly with duration of exposure to high temperature.**alleles:** *tipA*<sup>1</sup> and *tipA*<sup>2</sup>, the latter of which apparently leads to more rapid heat-induced paralysis and a longer recovery time.**TipB (J.C. Hall)****location:** 2-109.9.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.**phenotype:** Homozygous lethal; heterozygotes become rapidly paralyzed at 38°C and recover fairly quickly when temperature is lowered.**tipC (J.C. Hall)****location:** 2-35.3.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.**phenotype:** Becomes paralyzed gradually at high temperatures (the higher the temperature, the faster the paralysis); recovery from paralysis, after temperature lowered, is somewhat slow, and time required for this increases with longer heat exposure.**tipD (J.C. Hall)****location:** 2-110.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.**phenotype:** Becomes paralyzed rapidly at 38°C; recovers fairly quickly when temperature is lowered.**other information:** Complemented lethality associated with *TipB*. *tipD/TipB* adults exhibit same heat-induced paralysis kinetics as does *TipB/+*; these mutations probably define separate genes in spite of similar map locations.**tipE (J.C. Hall)****location:** 3-13.5.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.

Ganetzky, 1986, J. Neurogenet. 3: 19-31.

Jackson, Wilson, and Hall, 1986, J. Neurogenet. 3: 1-17.

**phenotype:** Mutant becomes paralyzed rapidly at 38°; recovers within seconds when temperature is lowered. No apparent increase in recovery times with longer exposure to high temperature (Jackson *et al.*, 1986). When in a double mutant combination with *para*<sup>ts1</sup>, *tipE* results in action potential failures in recordings from larval motor neurons at 33°, a temperature at which either *para*<sup>ts1</sup> or *tipE* alone seems to have normal nerve conduction (Ganetzky, 1986). Adult action potential failures in *nap*<sup>ts</sup>; *tipE* double mutants occur at a lower temperature (31°) than in wild type (Ganetzky, 1986); flies of this double-mutant genotype exhibit poorer viability and become paralyzed at lower temperatures than eithermutant alone. The *para*<sup>ts1</sup>; *tipE* double mutants also survive poorly, showing unconditional lethality in combinations with certain *para* alleles; In *para*+/+; *tipE/tipE* mutants, *para* alleles become semi-dominant for heat-induced paralysis (Ganetzky, 1986).Biochemically, *tipE* leads to reduced levels of saxitoxin binding activity (not temperature-dependent) in adult head extracts, but the dissociation constants for such binding is normal (Jackson *et al.*, 1986). The mutant is slightly resistant to veratrine and shows enhanced tetrodotoxin sensitivity (Jackson *et al.*, 1986). Sodium current density in cultured embryonic neurons is about half that recorded using "tight-seal" techniques from wild-type cells (O'Dowd and Aldrich, 1988, J. Neurosci. 8: 3633-43).When rather lengthy heat treatments are given to *sei*<sup>ts</sup>, the fairly long recovery times are partially suppressed by *tipE*. Partial suppression of *Sh*-induced leg shaking is also effected by *tipE* (Jackson *et al.*, 1986).**cytology:** Located in 64A6-64B12 (L.M. Hall and colleagues) since included in *Df(3L)HR277* = *Df(3R)63B12-C1;64B12* but not in *Df(3L)HR298* = *Df(3L)63B6;64A6*.**tipF (J.C. Hall)****location:** 3-15.2.**origin:** Induced by ethyl methanesulfonate.**references:** Kulkarni and Padhye, 1982, Genet. Res. 40: 191-99.**phenotype:** Kinetics of paralysis at a series of elevated temperatures like that associated with *tipC*, though *tipF* requires substantially longer times to recover after temperature lowered.**other information:** Complements *tipE*.**tk: thick****location:** 2-55.3.**discoverer:** Guthrie, 24k.**references:** 1925, Am. Naturalist 59: 479-80.**phenotype:** Legs and especially tarsi thick. Wings somewhat short and broad, has slight *px*-like effect. According to Waddington [1942, Proc. Zool. Soc. London Ser. A., 111: 181-88 (fig.)], these effects result from inadequate contraction of the legs and whole pupa after inflation period. RK2.**cytology:** Placed in region between 42A2 and 42B1 on the basis of its inclusion in inverted segment of *In(2R)Cy* = *In(2R)42A2-3;58A4-B1* as well as in *Df(2R)M41A-vg11* = *Df(2R)40F-41A1;42A19-B1* (Morgan, Schultz, Bridges, and Curry, 1939, Carnegie Inst. Wash. Year Book 38: 273-77).**tkd: thickoid****location:** 2-40 (30 to 50).**discoverer:** Bridges, 33d25.**phenotype:** Fly large and thickset, has thick legs. Wings blunt at tip. Eyes large and slightly rough. Male genitalia sometimes rotated. Fertile; viability about 50% wild type. RK3.**tko: technical knockout (J.C. Hall)****location:** 1-1.0 (.006 to left of *z* according to Judd *et al.*, 1972).**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Shannon, Kaufman, Shen, and Judd, 1972, Genetics

72: 615-38.

Perrimon, Engstrom, and Mahowald, 1989, *Genetics* 121: 333-52.

**phenotype:** Most *tko* alleles are lethal in all genetic combinations. In homo- and hemizygotes of the viable allele *tko*<sup>25t</sup>, however, mechanically shocked adults fall over and are briefly immobilized; after recovery, there is a refractory period during which sensitivity to further such shocks is reduced. *tko*<sup>25t</sup> is considered a semi-lethal by Judd, 1972, who finds that survivors exhibit a fine bristle phenotype. This allele is also a heat-sensitive paralytic (Burg and Wu, 1987). Its aberrant behavior is suppressed by *nap*<sup>ts</sup> when the latter is kept at its permissive temperature (Ganetsky and Wu, 1982). When heterozygous with deficiencies for the locus, most *tko* alleles are lethal.

**alleles:** One viable and nine lethal alleles have been described.

<sup>β</sup> Discovered by Geer.

<sup>γ</sup> Discovered by Alexander (Judd *et al.*, 1972).

**cytology:** Placed in 3A2 (Judd *et al.*, 1972) based on uncoverage of lethality by *Df(1)w-rJ1 = Df(1)3A1-2;3C2-3*, *Df(1)X12 = Df(1)2F5-3A1;3B5-3C1*, and *Df(1)62g18 = Df(1)3A1-2;3A4-5*, and complementation by *Df(1)64c4 = Df(1)3A3-4;3C2-3*.

**molecular biology:** *tko* region cloned, originally by microdissection (Mariani, Pirrotta, and Manet, 1985, *EMBO J.* 4: 2045-52) and identified molecularly by transformation rescue. A 3.1 kb *XhoI/BamHI* fragment covers lethality caused by *tko*<sup>k11</sup> and behavioral defects of *tko*<sup>25t</sup> (Royden *et al.*, 1987). This genomic DNA fragment encodes one detectable transcript of 0.68 kb. Predicted protein shows considerable sequence similarity to ribosomal protein S12 from *Euglena gracilis* chloroplasts and *E. coli* (Royden *et al.*, 1987).

**Tkr: Tyrosine kinase related**

**location:** 2- {107}.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *dTKR* (Haller *et al.*, 1987); *g2* (Côte *et al.*, 1987).

**references:** Côte, Preiss, Haller, Schuh, Kienlin, Seifert, and Jäckle, 1987, *EMBO J.* 6: 2793-2801.

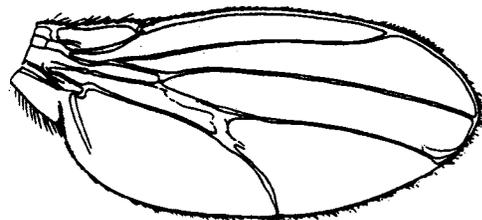

Haller, Côte, Brönnner, and Jäckle, 1987, *Genes Dev.* 1: 862-67.

**phenotype:** No mutant phenotype identified as yet. Transcripts initially expressed in the syncytial blastoderm stage (Haller *et al.*, 1987; Côte *et al.*, 1987), accumulating temporarily at dorsal-lateral positions in the embryo. At the end of blastoderm, the transcripts accumulate unevenly and are restricted to the dorsal region along 20-85% of the egg length. During gastrulation they are found in the dorsal region of the cephalic furrow and cover the neurogenic ectoderm in the procephalic region, disappearing from anterior to posterior during the extended germband stage. Later *Tkr* is expressed anew in the developing nervous system, including the brain, but disappears completely at the end of embryogenesis (Haller *et al.*, 1987).

**cytology:** Located in 60F1 on the basis of *in situ* hybridization. Also, *Tkr* included in *Df(2R)IIX62 = Df(2R)60E9-10;60F1-2* (Côte *et al.*, 1987).

**molecular biology:** To determine the molecular structure of the *Tkr* gene, the cDNA clone, the corresponding genomic DNA, and the genomic DNA upstream of the 5' end of the cDNA were sequenced and the amino acids predicted. There is a single open reading frame of three exons (a 5' exon of 1357 bp, a small exon of 132 bp and a 3' exon of 1895 bp separated by two introns of 2500 and 3800 bp, respectively) which would encode a 753-amino-acid polypeptide. A single major transcript (4 kb long) is indicated by northern blot analysis (Côte *et al.*, 1987).

**other information:** Weak homology has been demonstrated between the putative *Tkr* protein and various serine, threonine, and tyrosine kinases and related oncogenes. The presence of putative ATP-binding and tyrosine autophosphorylation sites in the *tkr* sequence also suggests a tyrosine kinase function (Haller *et al.*, 1987).

**tkv: thick veins**

Edith M. Wallace, unpublished.

**tkv: thick veins**

**location:** 2-16.

**references:** Kotarski, Pickert, and MacIntyre, 1983, *Genetics* 105: 371-86.

Reuter and Szidonya, 1983, *Chromosoma*, 88: 277-85.

 Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.  
 Szidonya and Reuter, 1988a, DIS. 67: 77-79.  
 1988b, Genet. Res. 51: 197-208.

**phenotype:** Two types of mutants have been described, recessive lethals and visibles (viable as adults). Some of the recessive lethals die as embryos, lacking dorsal hypoderm (Nüsslein-Volhard *et al.*, 1984). The wing veins of the viable mutants are thickened and branched in the region of crossveins, near end of L2, and elsewhere. Sometimes there is a blister near the posterior crossvein in female flies; L4 sometimes shortened, especially in females. Expression more extreme at 19° than at higher temperatures and in females than in males. Some heteroallelic combinations are lethal; others are viable with thick veins and thoracic abnormalities (Szidonya and Reuter, 1988b).

**alleles:** Lethal and viable alleles are listed in the following table. Deficiencies for *tkv* are described in the rearrangement section.

alleles	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>tkv</i> <sup>1</sup>	spont	Nichols-Skoog, 33b25			homozygous viable with thick veins
<i>tkv</i> <sup>2</sup>	spont	Bridges, 34e20			homozygous viable with thick veins

Hashimoto, Hudson, and Anderson, 1988, Cell 52: 269-79.

Erdélyi and Szabad, 1989, Genetics 122: 111-27.

**phenotype:** Maternal expression of the Toll gene is required for the normal production and distribution of positional information in the embryo (Anderson *et al.*, 1985); zygotic expression is required to maintain viability in early larvae (Gerttula *et al.*, 1988). Toll mutants and deficiencies occurring in the mother result in lethal abnormalities in the pattern of gastrulation and the differentiation of cuticular structures in the offspring. When null alleles and deficiencies are homozygous in the zygote, delayed development and early lethality result.

Females heterozygous for dominant Toll alleles are sterile, their lethal embryos being partially ventralized regardless of their genotype. Dorsoventral polarity is present; a furrow is formed in the midventral region, but the lateral cephalic fold is shifted to the dorsal side and the normal dorsal folds are missing. The cuticle lacks dorsal hairs, filzkörper, spiracles, head sensory organs, and a head skeleton; there are patches of denticles extending around the entire dorsoventral circumference of the embryo (Anderson *et al.*, 1985a). The ventral nervous system is also expanded (Campos-Ortega, 1983). Embryos produced by females hemizygous for some dominant alleles (*Tl*<sup>1</sup>/*Df*; *Tl*<sup>3</sup>/*Df*) are ventralized, but the embryos of other hemizygotes (*Tl*<sup>2</sup>/*Df*; *Tl*<sup>4</sup>/*Df*) are dorsalized, all cells behaving at gastrulation and in differentiation like wild-type dorsal cells. In embryos derived from *Tll*+ females, virtually the entire ectoderm capable of neurogenesis in response to absence of *Dl* function (Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 317-26).

Whereas females heterozygous for recessive alleles of *Tl* are fertile, homozygous *Tl*-recessive females are viable but sterile, their lethal embryos lacking dorsoventral polarity and forming no ventral furrow at gastrulation. In most recessive alleles (*Tl*<sup>r5</sup>, *Tl*<sup>r6</sup>, *Tl*<sup>r7</sup>), the embryos are partially dorsalized with laterally derived structures (Anderson *et al.*, 1985a); for example, *Tl*<sup>r6</sup> embryos differentiate dorsal hairs, filzkörper, and ventral denticle bands of nearly normal width, but lack mesoderm (Anderson and Nüsslein-Volhard, 1986). In one allele (*Tl*<sup>r4</sup>), however, embryos have no dorsal hairs and show rings of denticles as in *Tl*<sup>D</sup> embryos (Anderson *et al.*, 1985a). Hemizygotes for the Toll-recessives resemble the corresponding homozygotes in phenotype.

A number of Toll alleles were obtained as reversions of the Toll-dominant phenotype (see table). When crossed to wild-type males, females heterozygous for a null-type reversion are fully fertile; however, when crossed to males who are also heterozygous for a Toll null, these females produce *Tl*-homozygotes who are zygotic lethals, dying as early larvae and producing no Toll transcript. Heteroallelic combinations of reversions such as *Tl*<sup>r1</sup>/*Tl*<sup>r2</sup> produce sterile females with lethal dorsalized embryos. Females carrying combinations of certain reversions and Toll-dominant (or Toll-recessive) alleles produce embryos with phenotypes like those of Toll-dominant (or Toll-recessive) hemizygotes. Most of the reversions, when in *trans* to deficiencies, result in females with dorsalized embryos, but a few hemizygous

reversion females ( $Tl^{rv21}$ ,  $Tl^{rv22}$ ,  $Tl^{rv23}$ ) produce ventralized embryos (Hashimoto *et al.*, 1988).

The lethal embryos of  $Df(3R)Tl-X/Df(3R)ro-XB3$  (null) females (Hashimoto *et al.*, 1988), are completely dorsalized, never making ventral furrows, filzkörper, or denticles; their germ bands fail to extend; no Toll transcript is produced in these embryos except when contributed by wild-type fathers (Gerttula *et al.*, 1988). The 97D1-2 breakpoint of the Toll deficiency  $Df(3R)Tl-X$  maps within the 6.0 kb *EcoRI* fragment of a Toll clone (Hashimoto *et al.*, 1988). Injection of wild-type cytoplasm into embryos of Toll-deficient females restores the wild-type dorsoventral pattern, the site of the injection determining the midventral part of the pattern (Anderson *et al.*, 1985b); (also see **molecular biology** section).

**alleles:** Dominant, recessive, and revertant Toll alleles are listed in the following table. Six HD-induced revertants are mentioned but not named (Hashimoto, Hudson, and Anderson, 1988, Cell 52: 269-279). Deficiencies are listed in the rearrangement section.

<sup>α</sup> 1 = Anderson, Bokla, and Nüsslein-Volhard, 1985, Cell 42: 791-98; 2 = Anderson, Jürgens, and Nüsslein-Volhard, 1985, Cell 42: 779-89; 3 = Carroll, Winslow, Trombly, and Scott, 1987, Development 99: 327-32; 4 = Erdélyi and Szabad, 1989, Genetics 122: 111-27; 5 = Gerttula, Jin, and Anderson, 1988, Genetics 119: 123-33; 6 = Hashimoto, Hudson, and Anderson, 1988, Cell 52: 269-79.

- β Pattern normalized by extra copy of wild-type allele. All  $Tl^4/++$  embryos make dorsal hairs and one quarter of these embryos make filzkörper.
- γ Derivative of  $Tl^{rv22}$  that has restored the dominant  $Tl^3$  phenotype; apparently associated with precise excision of the P element (Hashimoto *et al.*, 1988).
- δ Isolated on the basis of a leaky dominant dorsalized phenotype.
- ε Temperature sensitive for the maternal effect, showing stronger dorsalization of the embryonic pattern at 29° than at 18°; also temperature sensitive for viability. TSP for the maternal effect begins slightly before pole cell formation and ends in midsyncytial blastoderm in the offspring of  $Tl^{r7}$  females. TSP for zygotic viability begins late in embryogenesis and extends into the second larval instar in  $Tl^{r5}$  and  $Tl^{r6}$  mutants.
- ζ Discovered by T. Rice, who named it *mel(3)9*. Unique lateralized pattern. Cuticular phenotype of embryos resemble that of Toll-dominant embryos, but denticles finer and less heavily pigmented and body shape often an elongated tube.
- η 97D breakpoint located in the 6.0 kb *EcoRI* fragment of the Toll clone *Tp1* (Hashimoto *et al.*, 1988).
- θ All HD-induced revertants are derivatives of  $Tl^3$ .

**cytology:** Placed in 97D1-2 since uncovered by  $Df(3R)Tl-X = Df(3R)97B;97D1-2$  and  $Df(3R)ro-XB3 = Df(3R)97D1-2;97D9$ .

**molecular biology:** Toll has been cloned using *P* element tagging and the nucleotides have been sequenced (Hashimoto *et al.*, 1988). The Toll clone *Tp1* contains 15 kb of DNA flanking the *P* element insertion. Nucleotide sequencing reveals one long open reading frame, with the initiation codon at nucleotide 575 and the termination codon at 3866; it could encode a protein of 1097 amino acids [thought to be a transmembrane protein made up of a cytoplasmic domain and an extracytoplasmic domain containing multiple copies of a 24-amino-acid leucine-rich sequence in two blocks (Hashimoto *et al.*, 1988)]. This mRNA is transcribed (Hashimoto *et al.*, 1988) and also zygotically (Gerttula *et al.*, 1988); no transcript is found when  $Tl^-$  females are mated to  $Tl^-$  males, but the 5.3 kb mRNA appears in the embryo when either or both parents carry  $Tl^+$ . A 5.3 kb hybrid-selected RNA abundant in young embryos (and also in older embryos and pupae) rescues the  $Tl^-$  mutant phenotype when injected at a posterior ventral site; a wild-type gastrulation pattern and ventral and lateral cuticular structures are produced in these injected  $Tl^-$  embryos. The sequence of cDNAs indicates that *Tl* encodes an integral membrane protein with a cytoplasmic and an extracytoplasmic domain, the latter containing 15 repeats of a 24 amino acid leucine-rich sequence occurring in both human and yeast membrane proteins (Hashimoto *et al.*, 1988) and the former showing striking homology to human interleukin-1 receptor (Gay and Kieth, 1991, Nature 351: 355-56).

**other information:** Females carrying the dominant allele  $Tl^3$ , when combined with the mutants *gd*, *ndl*, *pip*, *snk*, or *ea*, produce embryos that are lateralized like embryos derived from  $Tl^{r8}$  females; these embryos lack dorsal-most and ventralmost pattern elements, and have rings of denticles (Anderson *et al.*, 1985a). Some alleles of *ea* increase the probability that the temperature-sensitive alleles  $Tl^{r5}$ ,  $Tl^{r6}$ , and  $Tl^{r7}$  will survive. An interaction has been reported between the recessive allele  $Tl^{r7}$  and *dpp* (Irish and Gelbart, 1987, Genes and Development 1: 868-79). Double mutants of  $Tl^3$  and *dl* produce embryos that are completely dorsalized and indistinguishable from the embryos of *dl* homozygotes. Females carrying  $Tl^2$  or  $Tl^4$  in combination with *gd*, *ndl*, or *dl* also produce dorsalized embryos.

***tlc: tender little chaetae*****location:** 1- {0.5}.**phenotype:** Short thin bristles.**alleles:** Four alleles induced.

The 2.0 kb *tll* mRNA is maximally expressed in the blastoderm stage embryo. Initial activation of *tll* transcription is in two mirror image symmetrical caps at the poles of the embryo; this expression resolves into a posterior cap and an anterodorsal stripe, consistent with the position on the blastoderm fate map of anlagen which give rise to structures deleted in *tll* embryos. The *tll* gene is also expressed in cells which appear to be neuroblasts of the brain and sensillum precursors of the peripheral nervous system. The conceptual *tll* protein has significant similarity to both the DNA-binding and ligand-binding domains of the members of the steroid receptor superfamily (Pignoni *et al.*, 1990). Transcription of the *tll* gene during early embryogenesis is apparently activated via a phosphorylation cascade containing the membrane-bound, tyrosine kinase receptor-like *tor* gene product and the serine-threonine kinase *phl* gene product. The *tll* gene has a positive effect on gene expression in that it is required for appearance of the seventh stripe of expression of at least two pair-rule genes, *h* and *ftz* (Mahoney and Lengyel, 1987) and for specific domains of expression of *cad*, *hb*, and *fkh* (Mlodzik and Gehring, 1987, *Development* 101: 421-35; Schröder, Tautz, Seifert, and Jäckle, 1988, *EMBO J.* 7: 2881-87; Weigel, Jürgens, Klingler, and Jäckle, 1990, *Science* 248: 495-98). The *tll* gene also has negative effects on gene expression; thus *kni* expression expands posteriorly in *tll* embryos [Pankratz, Hock, Seifert, and Jäckle, 1989, *Nature (London)* 341: 337-40] and *tll* is required for the repression of *Kr* and *ftz* expression that occurs in *tor* gain-of-function embryos [Klingler, Erdélyi, Szabad, and Nüsslein-Volhard, 1988, *Nature (London)* 335: 295-77; Strecker, Halsell, Fisher, and Lipshitz,

1989, Science 243: 1062-66].

**Tm1: Tropomyosin 1 (J.C. Hall)**

**location:** 3- {55}. Closely linked to *Tm2*.

**origin:** Naturally occurring.

**synonym:** *mTm1*; *cTm*(isoform).

**references:** Bautch, Storti, Mischke, and Pardue, 1982, J. Mol. Biol. 162: 231-50.

Basi, Boardman, and Storti, 1984, Mol. Cell. Biol. 4: 2828-36.

Karlik, Mahaffey, Coutu, and Fyrberg, 1984, Cell 37: 469-81.

Basi and Storti, 1986, J. Biol. Chem. 261: 817-27.

Karlik and Fyrberg, 1986, Mol. Cell Biol. 6: 1965-73.

Tansey, Mikus, Dumoulin, and Storti, 1987, EMBO J. 6: 1375-85.

**phenotype:** Structural gene for tropomyosin, a 34,000-dalton protein that acts as a regulator of motility in muscle and nonmuscle cells. At least five tropomyosin isoforms are encoded by *Tm1*, some in embryos (during myogenesis) and myogenic cell culture and others in the myofibrils of adult indirect flight muscles and leg muscles.

**cytology:** Located in 88F4-5 by *in situ* hybridization with cloned DNA (Bautch *et al.*, 1982). *Tm1* proximal to *Tm2*.

**molecular biology:** Gene cloned (Bautch *et al.*, 1982; Karlik *et al.*, 1984). The constant proximal coding region (codons 1-257) and the variable distal coding region (codons 258-284) have been restriction-mapped and sequenced (Basi *et al.*, 1984; Karlik *et al.*, 1984; Karlik and Fyrberg, 1986). Transcripts of 2.0, 2.3 and 2.8 kb accumulate in the cytoplasm of early embryos, while transcripts of 1.3, 1.4, 1.6, 1.7, 1.8, and 1.9 kb accumulate in muscles of later embryos and adults, the 1.7 and 1.9 kb transcripts being restricted to the indirect flight muscle. The proximal coding region at the 5' end occupies about 18 kb and is made up of five exons and four introns (according to Basi *et al.*, 1984) or five to nine exons and up to eight introns (according to Karlik and Fyrberg, 1986). The distal coding region at the 3' end includes four variable exons and three introns, the first exon coding for cytoplasmic tropomyosin, and the second and third for heavy tropomyosins found in the indirect flight muscles (Karlik and Fyrberg, 1986). As a result of the variable splicing at least five developmentally-regulated isoforms are specified.

Tropomyosin in the cytoplasmic (cytoskeletal) form of early embryos and Kc cells (a form originally believed to be encoded by a separate gene) has been found to be an alternatively spliced product of *Tm1* (Hanke, Lepinske and Storti, 1987, J. Biol. Chem. 262: 17370-73; Hanke and Storti, 1988, Mol. Cell Biol. 8: 3591-3602).

**Tm2: Tropomyosin 2 (J.C. Hall)**

**location:** 3- {55} (closely linked to *Tm1*).

**origin:** Naturally occurring and induced by ethyl methanesulfonate.

**synonym:** *mTm1*; *lfm(3)3*.

**references:** Mogami and Hotta, 1981, Mol. Gen. Genet. 183: 407-17.

Bautch, Storti, Mischke, and Pardue, 1982, J. Mol. Biol. 162: 231-50.

Basi, Boardman, and Storti, 1984, Mol. Cell Biol. 4: 2828-36.

Basi and Storti, 1986, J. Biol. Chem. 261: 817-27.

Karlik and Fyrberg, 1986, Mol. Cell Biol. 6: 1965-73.

Fyrberg and Karlik, 1987, Mol. Cell Biol. 7: 2977-80.

Tansey, Mikus, Dumoulin, and Storti, 1987, EMBO J. 6: 1375-85.

**phenotype:** Structural gene for tropomyosin that is active in particular muscle lineages in late embryos and adult flies (Basi *et al.*, 1984). A dominant flightless mutant *lfm(3)3* was induced by Mogami and Hotta (1981); this mutant, which was unable to jump or fly, turned out to be a *Tm2* allele, *Tm2*<sup>3</sup>. Although arranged in sarcomeres, the myofibrils of *Tm2*<sup>3</sup> are structurally weak (Karlik and Fyrberg, 1986). The flightless phenotype can be rescued by *P*-element mediated transformation with two copies of the wild-type allele of *Tm2* (Fyrberg and Karlik, 1987); the ability to jump can be restored with one copy of *Tm2*<sup>+</sup> (Tansey *et al.*, 1987).

**alleles:** One mutant allele *Tm2*<sup>3</sup> [= *lfm(3)3*].

**cytology:** Located in 88F2-3 by *in situ* hybridization with cloned DNA (Bautch *et al.*, 1982). *Tm2* distal to *Tm1*.

**molecular biology:** Gene cloned (Bautch *et al.*, 1982). The constant proximal coding region (codons 1-257) includes two exons and occupies 833 nucleotides that are interrupted by a single 62-nucleotide intron between codons 198 and 199 (Karlik and Fyrberg, 1986). The variable distal coding region (codons 258 to 284) includes two alternate exons with large untranslated regions. The proximal coding region of *Tm2* is 1/20th the size of the corresponding *Tm1* coding region, presumably due to deletion of introns in *Tm2* and duplication of exons in *Tm1* (Karlik and Fyrberg, 1986). The complete nucleotide sequence of *Tm2* has been given by Basi and Storti (1986).

In the flightless mutant *Tm2*<sup>3</sup>, pupae lack the 1.7 and 1.9 kb indirect-flight-muscle transcripts, but accumulate the 1.3 and 1.6 kb transcripts (Karlik and Fyrberg, 1986; Tansey *et al.*, 1987). There is an 8.8 kb insertion of middle-repetitive copia-like DNA in the mutant, interrupting the exon believed to be involved in the synthesis of the indirect flight muscle isoform (Tansey *et al.*, 1987).

**\*tmc: tonomacrochaetae**

**location:** 1-17.5.

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 76.

**phenotype:** Bristles thin. Abdomen underpigmented, especially in female. Eclosion slightly delayed. Viability and fertility good. RK2.

**\*tms: tumorous**

**location:** 1-58.7.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 93.

**phenotype:** Many small, diffuse tumors. Fly slightly small. Both sexes viable and fertile. RK3.

**tn: thin**

**location:** 2-85.6 (between *c* and *px*).

**origin:** Spontaneous.

**synonym:** *l(2)tn*.

**references:** Ball, Ball, and Sparrow, 1985, *Dev. Genet.* (Amsterdam) 6: 77-92.

**phenotype:** Fully penetrant recessive lethal (no homozygous adults recovered). Hatching occurs late and second/third instar moult is delayed. Third instar larvae are long, thin, and rather slow-moving; histological examination shows abnormal muscle structure. Puparium also long and thin. Pupal development of homozygotes incomplete. Since mutants are unable to perform movements necessary for pupation, they die prior to eclosion.

**cytology:** Placed within 55F. Gene lies between the transposing elements *TE55DE* (=TE178) and *TE56B* (=TE124) and is not lethal over *Df(2R)PC4 = Df(2R)55A;55F*.

**\*tne: tiny eggs**

**location:** 3-91.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Anderson.

**phenotype:** Female sterile. Very small eggs.

**alleles:** Four alleles induced.

**cytology:** Located in 97D9-15; it is uncovered by *Df(3R)ro80b = Df(3R)97D1;97D15* but not by *Df(3R)roXB3 = Df(3R)97D1-2;97D9*.

**phenotype:** *Top2* is an essential gene that encodes the large subunit of type II DNA topoisomerase, an enzyme believed to play an important role in the condensation, decondensation, and segregation of chromosomes. The enzyme is a major component of the nuclear matrix of *Drosophila* cells (Berrios *et al.*, 1985) and is distributed along polytene chromosomes paralleling the distribution of the DNA (Heller *et al.*, 1986). It is believed to act by passing a DNA segment through a transient double-stranded break in another segment. Major cleavage sites for type II topoisomerase have been found in nontranscribed spacer segments and in the 5' and 3' ends of *Hsp70* and the histone genes (Udvardy *et al.*, 1985). When prepared from embryos, the purified enzyme is made up of a major polypeptide encoded by *Top2* of 166,000 daltons, with binding sites for both DNA and ATP, and, in addition, smaller polypeptides of 30,000-40,000 and 132,000-145,000 daltons (Sander and Hsieh, 1983; Shelton *et al.*, 1983; Heller *et al.*, 1986). Protein kinase activity is associated with *Drosophila* topoisomerase II (Sander *et al.*, 1984; Ackerman, Glover, and Osheroff, 1985, *Proc. Nat. Acad. Sci. USA* 82: 3164-68).

**cytology:** Located at 37D2-6 (Nolan *et al.*, 1986; Hsieh *et al.*, 1987) or at 36E1-2 (Philip, Heller, and Brutlag) by *in situ* hybridization to the salivary chromosomes. It is a single-copy gene.

**molecular biology:** *Top2* has been cloned and the DNA sequenced (Nolan *et al.*, 1986; Hsieh *et al.*, 1987; Wyckoff *et al.*, 1988). The gene is 5.1 kb in length, as would be expected for a gene encoding topoisomerase II (MW about 170,000) and is divided into five exons of approximately 230, 600, 400, 3100, and 700 nucleotides (Nolan *et al.*, 1986) and four introns of 933, 57, 66, and 81 nucleotides (Wyckoff *et al.*, 1988). The direction of transcription is thought to be from centromere toward

telomere (Hsieh). The predicted protein is 1447 amino acids in length with a molecular weight of 164,424. Drosophila topoisomerase II shows significant sequence identity with the type II topoisomerases of *B. subtilis*, *E. coli*, bacteriophage T4, and two yeasts. The overall sequence identity between Drosophila and yeast is about 46% (Wyckoff and Hsieh, 1988, Nat. Acad. Sci. USA 85: 6272-76). cDNA sequences encoding Drosophila topoisomerase II, when under the transcriptional control of a yeast promoter, were able to complement the lethality of temperature-sensitive or null yeast mutants (provided the Drosophila genes were continually expressed by growth of yeast cells in galactose media) (Wyckoff and Hsieh, 1988).

**phenotype:** Maternal-effect lethal; embryos from homozygous mothers show alterations in the anterior-posterior pattern. Hypoactivity (loss-of-function) mutant embryos lack anteriormost head structures (labrum, dorsal bridges) as well as structures posterior to the seventh abdominal segment. Hyperactivity (gain of function) mutant embryos, on the other hand, show segment defects in the middle of the embryos, but may have enlarged terminal structures (Klingler *et al.*, 1988; Strecker *et al.*, 1989). A large number of revertants have been obtained from dominant or semi-dominant hypermorphic alleles.

During cellularization at the blastoderm stage, hypoactivity mutant embryos show a "pole hole" phenotype. A funnel of yolk-free cytoplasm with a small number of nuclei (between 10 and 20) is formed at the posterior pole, extending from the egg periphery to the inner yolk mass. At gastrulation the cephalic furrow is shifted toward the anterior and the germband extends all the way to the posterior end. Analysis of germline clones indicates that the torso mutant is germline autonomous (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48).

**alleles:** Unless indicated otherwise, alleles are assumed to be recessive. *rv* in superscript = revertant.

α Revertant of *tor<sup>12D</sup>* (Klingler *et al.*, 1988).

β Revertant of *tor<sup>11D</sup>* (Sprenger *et al.*, 1989).

γ Revertant of *tor<sup>12D</sup>* (Sprenger *et al.*, 1989).

**cytology:** Placed in 43C5-E7 by deficiency mapping (Schüpbach and Wieschaus, 1989) and 43E by *in situ* hybridization (Casanova and Struhl, 1989; Sprenger *et al.*, 1989).

**molecular biology:** Gene cloned from DNA isolated by *P*-element transposon tagging from *tor<sup>14</sup>* (= *tor<sup>TC17</sup>*), an allele carrying a *P* insert (Sprenger *et al.*, 1989). Two clones hybridized to *tor<sup>+</sup>* salivary chromosomes at 43E5-11. 35 other *tor* mutants were analyzed and three of them (as well as *tor<sup>14</sup>*) showed restriction map alterations in the cloned region.

Rescue of the *tor<sup>1</sup>* mutant was accomplished by germ-line transformation with *P* elements using a 12 kb *EcoRI* fragment carrying *tor<sup>+</sup>* (Sprenger *et al.*, 1989).

A transcript of 3.6 kb was demonstrated by Northern blot analysis in *tor<sup>+</sup>* mRNA (transcript not shown in *tor<sup>rv66</sup>* mRNA). This transcript was also demonstrated by *in situ* hybridization of *tor<sup>+</sup>* mRNA to tissue sections of wild-type ovaries; a high level of evenly-distributed transcript was found in nurse cells and oocytes as well as in 0-4 hour-old embryos. The transcript level was much reduced in older embryos, but some could be detected throughout development. A high level of transcript expression was found in adult females, but not in males.

The genomic and cDNA's of torso have been sequenced (Sprenger *et al.*, 1989) and the amino acid sequence of the protein predicted. The 3.6 kb transcript includes at least 13 introns, their lengths varying from 54 to 152 kb. The cDNA sequence includes a single open reading frame of 2,936 bp, 2,768 bp of which encode a putative protein of 923 amino acids. Although the amino-terminal half of the torso protein shows no significant identity to any published sequences, the rest of the protein shows significant amino-acid identity to growth-factor receptor tyrosine kinases of other organisms and includes an intermediate hydrophobic region of 22 bp that resembles in structure the transmembrane domain of the receptor protein kinases (Sprenger *et al.*, 1989). The *tor* protein is associated with the surface membrane in early embryos and is distributed everywhere along the cell surface (Casanova and Struhl, 1989), although its activity is localized at both poles. Different levels of active *tor* protein are able to specify distinct parts of the terminal pattern.

**other information:** A single dose of *ill<sup>1</sup>* from a *tor<sup>11D</sup>/tor<sup>11D</sup>* mother can partially rescue the *tor<sup>11D</sup>* mutant effect in the embryo (loss of abdominal segments); complete rescue may occur when the embryo is homozygous for *ill<sup>1</sup>*, receiving the gene from both parents (Strecker *et al.*, 1989). Injection of *tor<sup>+</sup>* cytoplasm from early cleavage embryos can partially rescue *tor* loss-of-function mutants.

*fz* expression is reduced or lost in strong gain-of-

function mutants (Klinger *et al.*, 1988; Strecker *et al.*, 1989).

*phl* mutations have been found to be epistatic over *tor* gain-of-function alleles (Nüsslein-Volhard *et al.*).

### **torp: torpid (J.C. Hall)**

**location:** 1-15.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Singh and Siddiqi, 1981, Mol. Gen. Genet. 181: 400-02.

**phenotype:** Adults reversibly paralyzed at 35° or higher. Time of onset of paralysis increases as temperature is lowered (down to 35°); recovery period on return to room temperature is directly proportional to length of high-temperature paralysis time. Flies seem normal after development at 29° or below; larvae unaffected behaviorally at temperatures up to 39°. After anterior nerve stimulation, responses of flight muscles are blocked in all-or-none fashion at about 35°. Mosaic experiments suggest that heat-induced paralysis of individual legs is due to neural defects, possibly in thoracic ganglia.

*torpid*: see *torp*

*torso*: see *tor*

*torsolike*: see *tsl*

### **tov: tiny ovaries**

**location:** 3- (unmapped).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Nüsslein-Volhard.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.

**phenotype:** Female sterile; no eggs laid; ovaries rudimentary; may be agametic.

**alleles:**

allele	synonym
<i>tov 1</i>	<i>tov 012</i>
<i>tov 2</i>	<i>tov 155</i>
<i>tov 3</i>	<i>tov 267</i>
<i>tov 4</i>	<i>tov 345</i>
<i>tov 5</i>	<i>tov 404</i>

### **·Tp1: Temporal protein 1**

**location:** 2- {54}.

**synonym:** *Tl*.

**references:** Fruscoloni, Al-Atia, and Jacobs-Lorena, 1983, Proc. Nat. Acad. Sci. USA 80: 3359-63.

**phenotype:** Present during oogenesis and later embryogenesis, gene codes for small, acidic protein (TI).

**cytology:** Located in 39C-D by *in situ* hybridization.

**molecular biology:** mRNAs (prepared from egg chambers or embryos) translated in a cell-free system; found to be associated with polysomes in eggs and 18 hr embryos, but not in early embryos. Cloned probe with cDNA complementary to *Tp1* mRNA hybridized to salivaries.

### **Tpi: Triosephosphate isomerase**

**location:** 3-101.3 (between *Acph-1* and *bv*).

**references:** Voelker, Langley, Leigh-Brown, and Ohnishi, 1978, DIS 53: 200.

Voelker, Ohnishi, and Langley, 1979, Biochem. Genet. 17: 769-83.

Voelker, Langley, Leigh-Brown, Ohnishi, Dickson,

Montgomery, and Smith, 1980, Proc. Nat. Acad. Sci. USA 77: 1091-95.

**phenotype:** Structural gene for the glycolytic enzyme triphosphate isomerase [TPI (EC5.3.1.1)] found in muscle. Heterozygote contains the parental isozymes plus a hybrid isozyme.

**alleles:** Two electrophoretic alleles, *Tpi*<sup>4</sup>, the most common and slower allele, and *Tpi*<sup>6</sup>, the fast allele (Voelker *et al.*, 1979).

**cytology:** Located in 99B-E since included in the duplication segregant of *Tp(3;Y)L127 = Tp(3;Y)99B;99E*.

### ***Tpl*: Triplo-lethal**

**location:** 3-47.4 (Roehrdanz and Lucchesi, 1980); to the left of *Ki* [no *ri-Tpl* crossovers among 59 *ri Ki* recombinants (Dorer and Christensen)].

**origin:** Segmental aneuploidy, using the *Y*-autosome translocations *T(Y;3)L132* and *T(Y;3)A109* (Lindsley *et al.*, 1972).

**references:** Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84.

Keppy and Denell, 1979, Genetics 91: 421-41.

Lucchesi and Roehrdanz, 1979, Genetics 91: s71.

Roehrdanz and Lucchesi, 1979, Genetics 91: s105.

1980, Genetics 95: 355-66.

1981, Dev. Genet. (Amsterdam) 2: 147-58.

Kennison and Russell, 1987, Genetics 116: 75-86.

Dorer and Christensen, 1989, Genetics 122: 397-401.

**phenotype:** Unique dosage-sensitive locus at 83D-E; lethal when present in either one (*Tpl/Df*) or three doses (*Tpl/Dp*) in an otherwise diploid individual. These individuals do not survive to the adult stage, but a few larvae with three doses of 83D-E develop to the third instar. The surviving larvae are also hyperploid for the *X* chromosome (as in *3X;2A* metafemales); they can be produced in genotypes duplicated for *7C* and *7D-E* (Roehrdanz and Lucchesi, 1979, 1981). Flies with a deficiency for 83D-E in one *3* and a duplication for the region in the other (two doses in all) are viable (Denell, 1976). Crosses of these *Df/Dp* flies to wild-type (*Tpl*-normal) mates fail to produce viable adults (Keppy and Denell, 1979). When wild-type flies or flies bearing a duplication and a deficiency for 83D-E (*i.e.*, viable *Df/Dp* stocks) are treated with EMS or  $\gamma$ -rays (Keppy and Denell, 1979; Roehrdanz and Lucchesi, 1980), new deficiencies and mutations that are viable over *Tpl* duplications but lethal over *Tpl* deficiencies and *Tpl*-normal chromosomes are produced. No function in measuring the *X/A* ratio has been observed in *Tpl*; it does not interact with the sex-determining genes *Sxl* and *da* (Christiansen and Lucchesi, 1988, DIS 67: 15).

**alleles:** Cytologically normal reversions to the wild-type *Tpl* phenotype at 83D-E were obtained by mutagen-treatment of *Df Tpl/Dp Tpl* flies. Complementation tests confirm the allelism of these mutants; they are viable over *Tpl*-duplicated and *Tpl*-normal chromosomes, but lethal over *Tpl* deficiencies; they are homozygous lethal. *Tpl* deficiencies (viable over *Tpl* duplications; lethal over *Tpl*-deficient and *Tpl*-normal chromosomes) are described in the section on chromosome rearrangements.

*Tpl* reversions are listed in the following table:

revertant	origin	synonym	ref <sup>α</sup>
<i>Tpl</i> <sup>rv1</sup>	EMS	10d77-6	2
<i>Tpl</i> <sup>rv2</sup>	HCHO	18i77	2
<i>Tpl</i> <sup>rv3</sup> β	EMS	<i>tpl</i> <sup>10</sup>	1, 3
<i>Tpl</i> <sup>rv4</sup> β	EMS	<i>tpl</i> <sup>17</sup>	1, 3
<i>Tpl</i> <sup>rv5</sup> β	EMS	<i>tpl</i> <sup>38</sup>	1, 3

<sup>α</sup> 1 = Dorer and Christensen, 1989, Genetics 122: 397-401; 2 = Keppy and Denell, 1979, Genetics 91: 421-41; 3 = Roehrdanz and Lucchesi, 1980, Genetics 95: 355-66.

<sup>β</sup> Causes an increase in recombination between flanking markers of 6.5-10.5 times, while recombination in other adjacent regions is not changed.

**cytology:** Located in 83D5-E1 since included in *Df(3R)Tpl4 = Df(3R)83D4-5;83E1-2* and *Df(3R)Tpl7 = Df(3R)83D4-5;83E1-2* (Keppy and Denell, 1979).

### ***Tpn*: Troponin**

**location:** 2- {67}.

**discoverer:** French and Pardue.

**phenotype:** Structural gene for troponin-C.

**cytology:** Placed in 49D3-50A3 based on the deletion of the cloned sequence in *Df(2R)vg = Df(2R)49D3-4;49F15-50A2-3*.

*tpw*: see *sto*<sup>tpw</sup>

### **\*tr261: triangle 261**

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Spencer.

**references:** 1934, DIS 1: 35.

1935, Am. Naturalist 69: 222-38.

**phenotype:** Small extra crossvein between marginal vein and L2, near their juncture. Variable; overlaps wild type. RK3.

### ***tra*: transformer**

(M. McKeown and J.M. Belote)

**location:** 3-45 (between *st* and *cp*).

**origin:** Spontaneous.

**references:** Sturtevant, 1945, Genetics 30: 297-99.

Brown and King, 1961, Genetics 46: 143-56.

Marsh and Wieschaus, 1978, Nature 272: 249-51.

Butler, Pirrotta, Irminger-Finger, and Nöthinger, 1986, EMBO J. 5: 3607-3613.

McKeown, Belote, and Baker, 1987, Cell 48: 489-499.

McKeown, Belote, and Boggs, 1988, Cell 53: 887-95.

Belote, McKeown, Boggs, Ohkawa, and Sosnowski, 1989, Dev. Genet. 10: 143-54.

**phenotype:** XX flies homozygous for *tra* transformed into sterile males with fully developed sex combs, male-colored abdomen, male abdominal tergites and plates, external and internal male genitalia. Mate readily with females. Testes rudimentary, without sperm, and with ovarian nurse-cell-like cells [Brown and King, 1961]. Testes reduced in size, but of normal color and shape. Transformed female slightly larger than normal male, developmental rate about that of female. *X/X/Y; tra/tra* also sterile. *tra* not required in male since *X/Y, tra/tra* flies are normal males. *X/X/X* and *X/X/Y, tra/tra/tra* like diploid, *i.e.* male in phenotype, but with larger wing cells as expected of triploids. Normal testis Anlagen tran-

splanted into *tra* female becomes attached to duct apparatus and produces sperm. Not needed for female germ cell development since *X/X*, *tra/tra* pole cells transplanted into a wild-type female embryo give rise to progeny of both sexes [Marsh and Wieschaus, 1978]. Cell autonomous in mitotic clones [Baker and Ridge, 1980, Genetics 94: 383-423].

**alleles:**

allele	origin	discoverer	synonym
<i>tra</i> <sup>1</sup> $\alpha$	spont	Sturtevant	<i>tra</i> <sup>AC</sup>
<i>tra</i> <sup>2</sup> $\beta$	spont	Carpenter	<i>tra</i> <sup>Z4</sup>
<i>tra</i> <sup>3</sup> $\gamma$	EMS	Roost	<i>tra</i> <sup>V1</sup>
<i>tra</i> <sup>4</sup> $\beta$	EMS	Hoffmann	<i>tra</i> <sup>V2</sup>
<i>tra</i> <sup>5</sup> $\beta$	EMS	Hoffmann	<i>tra</i> <sup>Z5</sup>
<i>tra</i> <sup>6</sup> $\alpha$	HD	Jacquenoud	

$\alpha$  *tra*<sup>1</sup> and *tra*<sup>6</sup> result from ~1 kb deletions which remove most or all of the *tra* locus.

$\beta$  *tra*<sup>2</sup>, *tra*<sup>4</sup> and *tra*<sup>5</sup> are not detectably rearranged.

$\gamma$  *tra*<sup>3</sup> contains an insertion of ~200 bases.

**cytology:** Placed in salivary chromosome region 73A8-9 as a result of its exclusion from *Df(3L)st-E5* and *Df(3L)st-7P* and its inclusion in *Df(3L)st-E52* and *Df(3L)st-g24* [Belote *et al.*, 1985; Butler *et al.*, 1986; McKeown *et al.*, 1987].

**molecular biology:** *tra* has been cloned [Belote *et al.*, 1985; Butler *et al.*, 1986; McKeown *et al.*, 1987] and shown to lie approximately 85 kb to the right of *st*, at position +85 in the map of McKeown *et al.* or position -1 in the map of Butler *et al.* The immediately adjacent gene on the distal side is *l(3)73Ah* [Boggs, Gregor, Idriss, Belote, and McKeown, 1987, Cell 50: 739-747]. The gene immediately to the proximal side has not been identified mutationally. Nucleotide sequences have been obtained for the genomic region around *tra*, for the non-sex-specific cDNA, and for the female-specific cDNA; the sequence of the putative female-specific *tra* protein has been inferred (Boggs *et al.*, 1987). The *tra* transcription unit is just over 1050 nucleotides long. Transcription is from proximal to distal. There are two size classes of *tra* RNA. One is 0.9 kb and is female-specific and the other is 1.1 kb and is present in both sexes. Both of these overlap the 3' end of *l(3)73Ah* by about 70 bases. These two classes of RNA differ as a result of the use of an alternative splice acceptor for the first intervening sequence. The 0.9 kb RNA has a single long open reading frame and is capable of supplying essentially all *tra*<sup>+</sup> function while the 1.1 kb RNA has no long open reading frame and is dispensable in both males and females [Boggs *et al.*, 1987; McKeown *et al.*, 1988]. Sex-specific splicing, but not transcription, is dependent upon *Sxl*<sup>+</sup>. There is no requirement for *tra*<sup>+</sup>, *tra2*<sup>+</sup> or *dsx*<sup>+</sup> for transcription or sex-specific splicing of *tra* [McKeown *et al.*, 1988; Nagoshi, McKeown, Burtis, Belote, and Baker, 1988, Cell 53: 229-36]. Expression of the 0.9 kb RNA causes XY flies to develop as somatic females. This transformation is independent of *Sxl*<sup>+</sup> and dependent upon *tra2*<sup>+</sup>, *dsx*<sup>+</sup> and *ix*<sup>+</sup> [McKeown *et al.*, 1988]. Molecular studies of *dsx* show that lack of *tra*<sup>+</sup> expression results in *dsx* being expressed in its male mode [Nagoshi *et al.*, 1988], while gain of *tra*<sup>+</sup> expression results in *dsx* being expressed in its female mode [McKeown *et al.*, 1988]. This suggests that, in a formal genetic sense, the regulatory hierarchy controlling sex is

organized in the following order: *X*: A ratio > *Sxl* > *tra* > *tra2* > *dsx*  $\geq$  *ix* > terminal differentiation (Belote *et al.*, 1989).

*tra*<sup>D</sup>: see *dsx*<sup>D</sup>

***tra2*: transformer 2**

**location:** 2-70, between *Bl* and *L* (Watanabe, 1975).

**phenotype:** One role of *tra2*<sup>+</sup> (like *tra*<sup>+</sup>) is to regulate sex determination by directing *dsx*<sup>+</sup> in such a way that female primordia are expressed and male primordia repressed in chromosomal females. In addition, *tra2*<sup>+</sup> serves as a regulator of spermiogenesis and copulation; as a result, functional sperm are produced by chromosomal males and transmitted to the females. Null or amorphic *tra2* mutations, however, transform chromosomal females into flies that are phenotypically male in regard to external cuticular morphology, pigment pattern, internal genital ducts, and mating behavior. Their gonads are much reduced and lack sperm and they are not affected by *mle* (Fujihara *et al.*, 1978). *tra2* mutations in chromosomal males produce normal looking adult males showing normal sexual behavior, but the sperm are amotile (Watanabe, 1975; Belote and Baker, 1981). Some *tra2* mutants are temperature-sensitive; homozygotes become phenotypic males when reared at 29°, but phenotypic females when reared at 16° (Belote and Baker, 1983). When *X/X; tra2<sup>ts2</sup>* homozygotes are shifted to the female-specifying temperature during or before the third instar, no development of the male accessory glands occurs (Chapman and Wolfner, 1988, Dev. Biol. 126: 195-202). In *X/X; tra2<sup>ts2</sup>* homozygotes reared throughout development at the permissive temperature of 16°, yolk polypeptide synthesis occurs as in *X/X; tra2<sup>ts2</sup>/+* controls; in *X/X; tra2<sup>ts2</sup>* homozygotes raised and kept at 29°, however, no synthesis of yolk polypeptides can be detected (Belote *et al.*, 1985). Temperature shift experiments with this temperature-sensitive allele show that *tra2*<sup>+</sup> function must be present in the adult for the initiation and maintenance of yolk polypeptide synthesis. This control over YP on the part of *tra2*<sup>+</sup> was shown to be at the level of transcription (Kraus, Lee, Lis, and Wolfner, 1988, Mol. Cell Biol. 8: 4756-64). *tra2<sup>ts</sup>* homozygous females do not always maintain male courtship behavior at 29°, but transformed females hemizygous for *tra2* [*tra2<sup>ts1</sup>/Df(2R)trix*] court in a reliably male fashion (Belote and Baker, 1987). Temperature-

shift experiments indicate that the TSP for induction of male courtship starts in the last half of the pupal period and ends before the end of pupation.

Biol. 100: 294-307; 8 = Fujihara, Kawabe, and Oishi, 1978, J. Hered. 69: 229-36; 9 = Oishi and Ota, 1982, DIS 58: 121; 10 = Ota, Fukunaga, Kawabe, and Oishi, 1981, Genetics 99: 429-41; 11 = Watanabe, 1975, Jpn. J. Genet. 50: 269-71.
- <sup>β</sup> No yolk-protein precursors in males or females (Ota *et al.*, 1981).
- <sup>γ</sup> *tra2<sup>B</sup>/tra2<sup>B</sup>* identical to *tra2<sup>B</sup>/tra2* or to *tra2<sup>B</sup>/Df(2R)LA* (Baker and Ridge, 1980, Genetics 94: 383-423).
- <sup>δ</sup> Ovaries rudimentary (Fujihara *et al.*, 1978).
- <sup>ε</sup> Mutant can be reverted to wild type or a more extreme mutant. In homozygous females, tergite 6 partially pigmented, vaginal bristles long, sex combs not malelike. *tra2<sup>P</sup>/tra2* females intersexes.
- <sup>ζ</sup> *tra2<sup>Pd1</sup>/tra2* females pseudomales, *tra2<sup>Pd1</sup>/tra2* males normal and fertile.
- <sup>η</sup> *tra2<sup>Pd2</sup>/tra2* females pseudomales.

**cytology:** Located in 51B4-6 since gene deleted by *Df(2R)trix = Df(2R)51A1-2;51B6* but not by *Df(2R)L48 = Df(2R)51A1;51B4* (Goralski *et al.*, 1989).

**molecular biology:** DNA from the 51B region was cloned from wild-type and *tra2<sup>P</sup>* flies by microdissection-microcloning and chromosome walking (Amrein *et al.*, 1988; Goralski *et al.*, 1989; Mattox *et al.*, 1990); mutants, rearrangements, and a P-element insertion were located on the molecular map of the region. Nucleotide sequences of the entire genomic DNA and of ten cDNAs have been obtained and the amino acid sequences of the corresponding proteins predicted (Amrein *et al.*, 1988; Goralski *et al.*, 1989; Mattox *et al.*, 1990). A DNA fragment of 3.9 or 4.5 kb from the *tra2* region was able to rescue (by P-element transformation) homozygous *tra2* flies, both in regard to sex determination and male fertility (Amrein *et al.*, 1988; Goralski *et al.*, 1989). Alternative splicing of *tra2* mRNA creates at least four overlapping transcript structures, each of which encodes one of four different polypeptides. Different combinations of ribonucleoprotein consensus sequences (RNP-CS) and arginine-serine rich regions are included in each polypeptide. The mature mRNAs are described in the following table:

mRNA	location in fly	exons	polypeptide size
type A	soma of males and females	1,2,4-7	264 amino acids
type B	ovary <sup>α</sup>	1-7	226 amino acids
type C <sup>β</sup>	testis	3-7	179 amino acids

mRNA	location in fly	exons	polypeptide size
type D <sup>γ</sup> type E <sup>δ</sup>	testis	3-7	136 amino acids

- <sup>α</sup> Some type B mRNA has been found in somatic tissues (males and females).
- <sup>β</sup> Intron of 232 nucleotides included in the mRNA.
- <sup>γ</sup> Found in low abundance.
- <sup>δ</sup> Not characterized..

*tra2* proteins show similarities to certain known RNA-binding proteins. A *tra2-lacZ* fusion protein has been localized by antibody stains to the nuclei of salivary gland and fat body cells in *Drosophila melanogaster* (Mattox *et al.*, 1990). Molecular studies show that the mutants *tra2<sup>OTF</sup>*, *tra2<sup>P</sup>*, and *tra2<sup>Pd1</sup>*, which are not null alleles, carry insertions of about 1.7 kb and presumably map in the 5' flanking region of the gene; cytological and molecular studies indicate that the mutant *tra2<sup>Pd2</sup>* is associated with an inversion and is accompanied by a deletion (Amrein *et al.*, 1988). The *tra2* product regulates the splicing pattern of the primary transcript of the "downstream" gene *dsx* in females [Baker, 1989, Nature (London) 340: 521-524; Goralski *et al.*, 1990; Mattox *et al.*, 1990]. *tra2* activity in somatic tissues is believed to be regulated by means of a post-translational sex-specific interaction with the protein product of the *tra* gene (Mattox *et al.*, 1990).

**trb: thread bristle**

**location:** 1-36.3.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 93.

**phenotype:** Bristles short and very thin. Hairs small and sparse. Wings more rounded at tips, margins often incised; veins slightly thickened. Trident pattern slightly darker than wild type. Male viable and fertile; female sterile. RK2.

**other information:** One allele induced by CB. 3026.

**trc: tricorner**

**location:** 3-46 (to left of *Pc* at 47.1).

**references:** Ferrus, 1976, Ph.D. Thesis, Univ. Autonoma de Madrid.

Struhl, 1981, Nature 293: 36-41.

Gubb and Garcia-Bellido, 1982, J. Embryol. Exp. Morph. 68: 37-57.

Vinson and Adler, 1987a, DIS 66: 150.

1987b, Nature (London) 329: 549-51.

**phenotype:** Mutant wing and notum have rosettes of three or more short trichomes instead of single long hairs as in wild type. Useful as cell marker. Mutant cell autonomous in mitotic cells in a wild-type background, but not in a Minute background (Vinson and Adler, 1987a).

**trd: tridenticle**

**location:** 2-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1983, DIS 59: 158-60.

**phenotype:** Larval denticles thickset and forked. Some alleles viable.

**\*tre: triangle eye**

**location:** 1-20.2.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 93.

**phenotype:** Eyes triangular with apex pointing forward. Fly large. Wings broad, blunt tipped, and slightly divergent. Male viable and fertile; female sterile. RK3.

**Tre: Trehalose sensitivity (J.C. Hall)**

**location:** 1-13.6 (linked to *cx*).

**origin:** Spontaneous (naturally occurring variants).

**references:** Tanimura, Isono, Takimura, and Shimada, 1982, J. Comp. Physiol. 147: 433-37.

Tanimura, Isono, and Yamamoto, 1988, Genetics 119: 399-406.

**phenotype:** Locus determining differences in sensitivity to the taste of the disaccharide trehalose in behaviorally-based (fluid intake) tests (no differences in sensitivity to glucose, fructose, or sucrose). The *Tre*<sup>+</sup> allele results in high trehalose sensitivity, the *Tre* allele in low trehalose sensitivity. Females with half the normal dose of a given *Tre*<sup>+</sup> allele are half as sensitive to trehalose, but flies (male or female) with twice the normal dose of *Tre*<sup>+</sup> show only a slight increase in sensitivity as compared to normal flies. *Tre* is thought to be a structural gene for the trehalose specific receptor in *D. melanogaster* (Tanimura *et al.*, 1988).

**alleles:** Two alleles, *Tre*<sup>+</sup> and *Tre*, are found in wild-type strains.

**cytology:** Placed by Tanimura *et al.*, 1988, between 5A10 and 5B1-3 by analyzing the sensitivity to trehalose in segmentally aneuploid flies carrying deficiencies or duplications from *T(1;Y)* translocations with breaks in the 5A-C region.

**trefoil: see tf**

**Treh: Trehalase**

**location:** 2-92.9.

**references:** Oliver, Huber, and Williamson, 1978, Biochem. Genet. 16: 927-40.

Oliver and Williamson, 1978, Can. J. Genet. Cytol. 20: 452.

Laurie-Ahlberg, Wilton, Curtsinger, and Emigh, 1982, Genetics 102: 191-206.

**phenotype:** Structural gene for trehalase [TRE (EC 3.2.1.28)], a hydrolase that splits the sugar trehalose into two glucose molecules. Polyacrylamide gel electrophoresis and isoelectric focusing indicates the presence of one molecular form of the enzyme in flight muscles,

hemolymph, and abdomens of adult flies. No mutant alleles obtained.

**cytology:** Placed in 55B-55E on the basis of dosage sensitivity determined by examination of the duplication- and deletion-bearing aneuploids.

**Trehalose sensitivity: see Tre**

**Trf54F: Described as Ntf**

**Trf100D: Described as Ttk**

**trh: trachealess**

**location:** 3;-1.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Kluding, Nüsslein-Volhard, and Wieschaus, 1983, DIS 59: 157-58.

Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**phenotype:** Embryonic lethal. Tracheae are absent and filzkörper not elongated.

**alleles:** Two alleles, *trh*<sup>1</sup> and *trh*<sup>2</sup>, isolated as *trh*<sup>5D</sup> and *trh*<sup>7J</sup>.

**cytology:** Placed in 61E-F since covered by *Y*<sup>P3D</sup> segregant of *T(Y;3)A144* = *T(Y;3)Xhy*<sup>+</sup>;61F and by *Dp(3;Y)G130* = *Dp(3;Y)61E;66F*.

**tri: trident**

**location:** 2-55.

**origin:** Spontaneous.

**synonym:** Probably *tri*<sup>32k</sup>, *tri*<sup>33d27</sup>, and *b-1*<sup>33g18</sup> are the same.

**discoverer:** Plough, 32k.

**references:** Plough and Ives, 1934, DIS 1: 34. 1935, Genetics 20: 42-69.

**phenotype:** Dark trident or streak on thorax. Scutellum and sternopleural plates also dark. Thorax often contains bubbles. Variable; overlaps wild type but also semidominant. RK3.

**triangle 261: see tr261**

**triangle eye: see tre**

**trk: trunk (T. Schüpbach)**

**location:** 2-36.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 302-17.

Nüsslein-Volhard, Frohnhöfer, and Lehmann, 1987, Science 238: 1675-81.

Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal; embryos from homozygous mothers lack anterior-most head structures and structures posterior to the seventh abdominal segment. At gastrulation cephalic furrow is shifted toward anterior and the germband extends all the way to the posterior

end. During cellularization at the blastoderm stage a funnel of yolk free cytoplasm containing a small number of nuclei (between 10 and 30) forms at the posterior pole of the embryos extending from the egg periphery to the inner yolk mass. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, *Dev. Biol.* 113: 443-48).

**phenotype:** Mutation believed to affect an intermediate step in phototransduction, the wild-type gene apparently encoding a protein involved in an intermediate step between photoreception and opening of the light-sensitive ion channels (Minke, 1977, 1982; Minke and Armon, 1980; Montell and Rubin, 1989; Suss *et al.*, 1989). Although the mutants behave normally in dim light, they behave as though blind in bright light and there is an abnormally slow dark recovery (Cosens and Manning, 1969; Cosens, 1971). The light-evoked response of the photoreceptors, as shown in the ERG, decays to baseline during an intense, prolonged stimulus, but not during a dim or brief stimulus (Cosens and Manning, 1969; Minke *et al.*, 1975); each quantum bump, however, seems intrinsically normal in shape and amplitude (Suss *et al.*, 1989); fluoride ions, which lead to excitation and adaptation of wild-type photoreceptors in the dark when superfused onto an eye slice, did neither to mutant cells. A hydrolysis-resistant analogue of GTP, which excites wild-type photoreceptors and results in noisy depolarizations, reduced the mutant's light response.

The visual pigment in R1-6 photoreceptors is normal in young *trp* flies, but its concentration decreases with age (Minke, 1982). The rhabdomeres degenerate with age and there is accumulation of glycogen granules (Cosens and Perry, 1972). Ultimately, photoreceptor cell bodies also degenerate (Isono, unpublished). Raising the mutant flies in complete darkness prevents the degenerative changes from appearing but has no effect on the electrophysiological phenotype (Isono and Pak, unpublished). Initially, the light-evoked migration of pigment granules occurs in a normal manner (*i.e.*, toward the rhabdomeres) in *trp* mutants, but the granules move away after only five seconds of sustained light (Lo and Pak, 1981). The *trp* mutation (unlike *norpA*) does not block degeneration caused by *rdgB* (Chen and Stark, 1983, *J. Insect Physiol.* 29: 133-40); in a *rdgB;trp* genetic background, R1-6 photoreceptors are eliminated and the R7,8 photoreceptors that remain show the *trp* phenotype.

*trp* is expressed in the photoreceptors of the ocelli as well as in those of the compound eyes (Hu *et al.*, 1978; Montell *et al.*, 1985).

*trp* mutants seem to exhibit normal visually-mediated learning under the high light-intensity conditions that largely eliminate photoreceptor potentials (Reichert and Bicker, 1979).

**alleles:** Mutant alleles are listed in the following table:

allele	origin	discoverer	synonym	comments
<i>trp 1</i>	spont	Cosens, Manning	<i>trp</i> <sup>CM</sup>	temperature-sensitive <sup>α</sup>
<i>trp 2</i>	EMS	Pak	<i>trp</i> <sup>P301</sup>

<i>trp 9</i>	EMS	Pak	<i>trp</i> <sup>P343</sup>	
<i>trp 10</i>	EMS	Hardy, Orevi, Merriam	<i>trp</i> <sup>US4699</sup>	

- <sup>α</sup> Rearing at 19° (instead of 25°) slows the rate of the decay-to-baseline of the photoreceptor potential and leads to faster initial dark recovery than occurs under non-permissive conditions. Rearing at 25°, followed by shift of adults to 19°, leads to more nearly normal behavior in bright light within four to six days (Minke, 1983).
- <sup>β</sup> Permissive temperature for normal ERG phenotype <25°; restrictive temperature ≥29°. Temperature-sensitive period limited to last 72 hours of pupal life (Wong *et al.*, 1989).

**cytology:** Located in 99C5-6 by *in situ* hybridization and breakpoint analysis (Montell *et al.*, 1985; Wong *et al.*, 1987, 1989). *trp* is covered by *Dp(3;Y)L127 = Dp(3;Y)99B5-6;99F3-4* and *Dp(3;1)52* [a duplication produced by translocation onto the X chromosome of a piece of the third chromosome (98F14-99A12;100F), followed by deletion of 99A9-10;99C5-6 (Frisardi and MacIntyre, 1984, Mol. Gen. Genet. 197: 403-13)], but is not covered by *Dp(3;1)78 = Dp(3;1)X<sup>P</sup>;99C5-7;100F* (Pye, unpublished) and *Dp(3;1)165P = Dp(3;1)X<sup>P</sup>;99B2-4;99C5-6* (Frisardi and MacIntyre, 1984; Wong *et al.*, 1989).

**molecular biology:** Cloned by isolation of DNA fragments hybridizing preferentially to head rather than body mRNA (Levy *et al.*, 1982; Montell *et al.*, 1985) and by genetic analysis and chromosomal walking (Wong *et al.*, 1987, 1989). cDNA and putative protein of *trp* sequenced (Montell and Rubin, 1989; Wong *et al.*, 1989); total length of the 13 exons is 1645 bp (Wong *et al.*, 1989). In germline transformation experiments (Montell *et al.*, 1985), a 7.1 kb genomic fragment rescued the ERG defects of *trp<sup>1</sup>*. Montell *et al.* (1985) identified a 4.1 kb transcript which appeared during the pupal stage and was localized to the retinula cells of the compound eyes and the ocelli. This transcript encodes a 143 kd integral membrane protein of 1275 amino acids with eight putative transmembrane domains; it is not similar in sequence to any previously analyzed protein (Montell and Rubin, 1989) and is concentrated in the rhabdomeres of the photoreceptor cells. Wong *et al.* (1987, 1989) identified a somewhat larger transcript (4.5 kb) that is believed to be "eye specific" by virtue of its absence from the mutant eyeless. This transcript also encodes an unique protein of 142 kd that seems to be associated with the photoreceptor membrane. Mutants *trp<sup>1</sup>*, *trp<sup>2</sup>*, and especially *trp<sup>9</sup>* (according to Montell and Rubin, 1989) show reduced amounts of the 4.1 kb transcript and completely lack the *trp* protein. The mutant *trp<sup>3</sup>* (according to Wong *et al.*, 1989) also shows a reduction in transcript level, but they find that *trp<sup>1</sup>* and *trp<sup>7</sup>* show close to normal levels; *trp* protein is lacking in head extracts in all three mutants. Transformed *trp* flies show normal protein levels.

**other information:** The same kinds of results from applying fluoride ions or the GPT analogue to the *trp* mutant in *Drosophila* (see "phenotype") were observed in experiments on the *nss* mutant in the blowfly *Lucilia*.

**phenotype:** The presence of *trx<sup>+</sup>* is required throughout embryonic and larval development for the appropriate differentiation in the adult of segments in the head, thorax, and abdomen (Ingham and Whittle, 1980; Ingham, 1981), the primary effect being in the thoracic segments. Mutants show transformations of the first and the third thoracic segments to the second thoracic segment as well as transformations in the abdomen (Mozer and Dawid, 1989). The gene seems to be involved in the positive regulation of the *BXC* and the *ANTC* (Duncan and Lewis, 1982). The viable mutant combinations *trx<sup>1</sup>/trx<sup>1</sup>* and *trx<sup>D</sup>/+* show variable segmental transformations in adults, as do heterozygous deficiencies [*Df(3R)red-P52/+*, for example]. The frequency of homeotic transformations in adults and, to some extent, in larvae of such genotypes varies inversely with the dosage of the *BXC* (Duncan and Lewis, 1982; Sato and Denell, 1987). A similar dosage effect has been proposed for the *ANTC* (Sato and Denell, 1987). When the mutant allele or deficiency is maternal in origin, the frequency of transformations is higher in adults (but not in larvae). The alleles *trx<sup>2</sup>*, *trx<sup>3</sup>*, and *trx<sup>D</sup>* are larval or pupal lethals as homozygotes, trans-heterozygotes, or deficiency heterozygotes, and may show weak homeotic transformations in larvae or in homozygous clones in adults (Capdevila and García-Bellido, 1981; Ingham, 1981, 1983, 1985b).

**alleles:** Alleles that show a recessive or dominant homeotic phenotype and fail to complement each other have been identified. All pairwise combinations of *trx<sup>B14</sup>*, *trx<sup>B16</sup>* - *trx<sup>B18</sup>*, and *trx<sup>E1</sup>* - *trx<sup>E13</sup>* are inviable except for rare survivors of the genotypes *trx<sup>E11</sup>/trx<sup>B16</sup>*, *trx<sup>E11</sup>/trx<sup>B17</sup>*, and *trx<sup>B16</sup>/trx<sup>B17</sup>*. Deficiencies are listed in the rearrangement section under *Df(3R)red*.

<sup>β</sup> Breakpoint in long intron (Moser and Dawid, 1989).

<sup>γ</sup> Slightly reduced pigmentation of fifth abdominal tergite in heterozygotes (Lewis, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 155-72).

<sup>δ</sup> Cited by Capdevila and García-Bellido, 1981.

<sup>ε</sup> Carries transposon *P[rib7/ry<sup>+</sup>]* with one *Drosophila melanogaster* ribosomal transcription unit and *ry<sup>+</sup>* marker at 88B (Karpen, Schaeffer, and Laird, 1988, Genes Dev. 2: 1745-63); fails to complement *trx* (Moser and Dawid, 1989).

**cytology:** Placed in 88A12-B5 since uncovered by *Df(3R)red-P52 = Df(3R)88A12-B1;88B4-5*.

**molecular biology:** The gene was cloned by *P*-element transposon tagging. Five insertion mutants were located within a region of 10 kb; reversion of one of these mutations resulted in excision of the *P*-element insertion (Moser and Dawid, 1989). Two major mRNAs of 12 and 15 kb, transcribed in a distal to proximal direction, are present. The 12-kb mRNA is most abundant in embryos of 0-6 hours, but it also appears in larvae and pupae. The 15 kb mRNA is most abundant in larvae, in pupae eight to nine days after oviposition, and in male and female adults; it also appears in 3- to 6-hr embryos. A 10 kb transcript was seen (but rarely) in 1- to 3-hr embryos and also in adult females; it may be maternally derived. Early embryos show an uniform distribution of transcript, but later (14-15 hours after fertilization) the ventral nerve cord has a higher concentration than other parts (Moser and Dawid, 1989).

**other information:** 22-52% of double heterozygotes involving a null allele of *Ash-1* and the *trx* deficiency, *Df(3R)red-P93*, show partial transformations of halteres to wings and/or partial transformations of third (and sometimes first) legs to second legs, whereas in single heterozygotes no transformations are shown (Shearn, 1989). Heterozygosis for null alleles of *trx* suppresses the extra sex combs phenotype of *+Df(3L)Pc-MK*, and increases penetrance of the maternal-effect homeotic phenotype of *fs(1)h*. *trx* function seems to be necessary for optimal expression of *Scr* (Sato, 1988, Roux's Arch. Dev. Biol. 197: 435-40).

***trx*<sup>1</sup>**

**phenotype:** Flies homozygous for *trx*<sup>1</sup> show a variety of partial homeotic transformations [ventral prothorax and metathorax to mesothorax and second to seventh abdominal segments to first abdominal segment (Ingham and Whittle, 1980)]. Penetrance of the transformation phenotype is stronger in hemizygotes than homozygotes and increases as the temperature is raised from 18° to 25°C. At the higher temperature, the penetrance of the mutant offspring of *trx*<sup>1</sup>/*trx*<sup>1</sup> females is almost 100%, while mutant offspring of *trx*<sup>1</sup>/*+* females show only about 50% penetrance. The temperature-sensitive period occurs prior to hatching. Ingham (1980) noted the following abnormalities in extreme *trx*<sup>1</sup> mutants: (1) Extra bristles between humerus and coxa and on the distal tibia of the first leg; (2) Similar changes on the third leg; (3) Loss or reduction of transverse bristle rows, and, in males, decrease in number of sex comb teeth on the first leg; (4) Replacement of halter disk derivatives by wing blade, notal, and scutellar structures; (5) Rotated genitalia and abnormal tergite pigmentation in male flies. 75% of heterozygotes with *Df(3R)red* or with the lethal allele *trx*<sup>3</sup> are lethal, either as larvae or pupae (Ingham, 1981); the heterozygotes that survive show cuticular transformations of the ventral prothorax and the metathorax, an extra mesonotum developing posterior to the normal one, and anteriorly-directed abdominal transformations (Ingham, 1985a).

***trx*<sup>2</sup>**

**phenotype:** The recessive embryonic lethal *trx*<sup>2</sup> fails to complement *trx*<sup>1</sup>, *trx*<sup>3</sup>, or *trx*<sup>D</sup>, either for the transformation phenotype or for lethality. Trans-heterozygotes

of *trx*<sup>2</sup> with another allele or with a deficiency for the locus show weak expression of the *trx* homeotic phenotype and about 40-50% pupal lethality. Since the lethal mutations are cell viable, *trx*<sup>2</sup>/*trx*<sup>3</sup> clones have been induced by mitotic recombination in *trx*<sup>2</sup>/*trx*<sup>3</sup>; *Dp(3;1)kar*<sup>51</sup>, *trx*<sup>+</sup> flies (Ingham, 1981, 1985b). The clones produced showed transformations of the antenna, eye, head capsule, and proboscis, bristle abnormalities in the legs, vein and bristle abnormalities in the wings, and transformations of halter to wing tissue and of genital to thoracic tissue; mutant clones in abdominal segments one to seven were not found (Ingham, 1985b).

### *trx*<sup>3</sup>

**phenotype:** Like *trx*<sup>2</sup>. About 75% of the *trx*<sup>1</sup>/*trx*<sup>3</sup> trans-heterozygotes are lethals, larval and pupal (Ingham, 1981).

### *trx*<sup>D</sup>

**phenotype:** Adult *trx*<sup>D</sup>/+ flies are viable and characterized by their "bithorax variegated" phenotype (Lewis). These mutants show no prothoracic transformations, but do show patchy transformations of halter into wing and third leg into second leg (as in *bx* and *pbx*) and variable transformations of posterior abdominal segments into more anterior ones (Capdevila and García-Bellido, 1981; Duncan and Lewis, 1982). In homozygotes, deficiency heterozygotes, or trans-heterozygotes over *trx*<sup>1</sup>, *trx*<sup>2</sup>, or *trx*<sup>3</sup>, the *trx*<sup>D</sup> allele is lethal or semilethal in larvae or pupae; in clones it is cell viable. Transformed *trx*<sup>D</sup>/*trx*<sup>D</sup> clones were found in the head region (but not in the thorax or abdomen) by Capdevila and García-Bellido (1981), while transformed *trx*<sup>2</sup>/*trx*<sup>D</sup> clones were found in both head and thorax (but not in the abdomen) by Ingham (1985b).

### *Try: Trypsin*

**locaton:** 2- [60].

**references:** Davis, 1985, Genetics 110: s12.

**phenotype:** Structural gene for enzyme trypsin.

**cytology:** Placed in 47D-47F.

**phenotype:** Abdominal segments somewhat drawn out. Wings drooping and divergent. Overlaps wild type. RK3.

*ts398*: see *l(1)IIA*f

### *tsg: twisted gastrulation*

**location:** 1-36.8.

**origin:** Induced by ethyl methanesulfonate.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307. Zusman and Wieschaus, 1985, Dev. Biol. 111: 359-71. Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52.

**phenotype:** Gene expressed 1.5-3.5 hours after oviposition. Mutants are embryonic lethals and show abnormal gastrulation, with deep dorsal folds resulting in temporary blockage of germband extension. Later, dorsal

folds released, but posterior midgut abnormal in position, dorsal cells very thick, and cephalic folds very deep (Zusman and Wieschaus, 1985). At the end of embryonic development, *tsg* cuticle shows head defects and condensed, retracted posterior spiracles. Ventral nervous system split posteriorly. No particular cell must be wild type for survival in *tsg*//+ mosaics, but wild-type cells on dorsal side are most effective in rescue (Zusman and Wieschaus, 1985).

**alleles:** Four *tsg* alleles have been described.

allele	origin	synonym	ref <sup>α</sup>

### *tt: tilt*

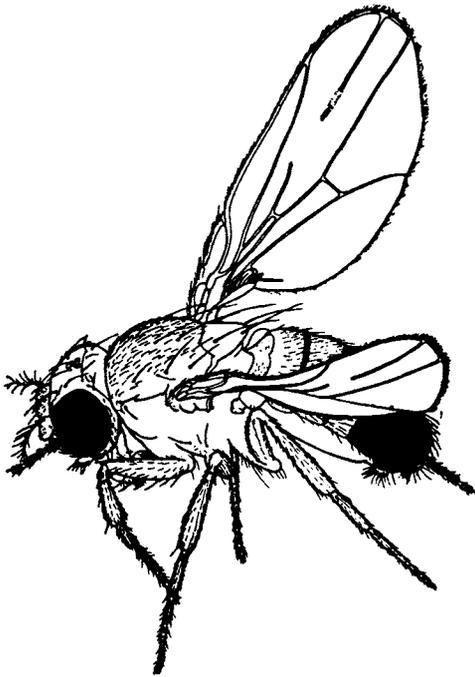

**location:** 3-40.0.

**discoverer:** Bridges, 15h29.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 134 (fig.). Mossige, 1938, Hereditas 24: 115.

**phenotype:** Wings spread, elevated, and warped in a compound curve. Vein L3 shows gap. Eye color may be slightly dilute. Developmentally, L3 originally complete but central section disappears during contraction period (Waddington, 1940, J. Genet. 41: 75-139). Synthetic

lethal in presence of *su(r)* (Strømten, 1974, Hereditas 78: 157-68). RK2.

**tt:** tilt

From Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 135.

**tta:** tetanic

**location:** 1-.

**references:** Ferrús, Llamazares, de la Pompa, and Yuste, 1987, *J. Neurogenet.* 4: 125-26.

**phenotype:** Viable, but shows tetanization under anaesthesia. Unable to learn. *tta* males with two doses of the Shaker gene complex are lethal.

**Ttk:** Tramtrack

**location:** 3-{102}.

**references:** Harrison and Travers, 1990, *EMBO J.* 9: 207-16.

**phenotype:** Gene encodes a zinc-finger protein binding to a number of sites involved in the transcriptional control of *fushi-tarazu* in the Antennapedia complex.

**cytology:** Located in 100D by *in situ* hybridization to the salivary chromosomes.

**molecular biology:** *Ttk* clones from a *Drosophila melanogaster* embryonic cDNA library contain a protein associated with binding site #16 in the *ftz* promoter region. At least three additional *Ttk* binding sites are believed to be present in the *ftz* promoter [Harrison and Travers, 1988, *Nucleic Acids Res.* 16: 11403-16; Topol, Wiederrecht and Parker, 1987, *Genetic Regulation of Development* (Loomis, ed.). Alan R. Liss, New York, pp. 3-12]. Nucleotide and putative amino acid sequences were obtained from the *Ttk* cDNA (Harrison and Travers, 1990). The translated protein has a predicted molecular weight of 69 kd. Two zinc-finger DNA-binding motifs (Cys-Cys His-His class) occur within the 327 amino acids believed to make up the *Ttk* binding domains; the zinc fingers show significant homology to the consensus finger motif and to the fingers of the protein products of

*Kr* and *hb* (Rosenberg, Schroder, Preiss, Kienlin, Côté, Riede, and Jäckle, 1986, *Nature* 319: 336-39; Tautz, Lehmann, Schnurch, Schuh, Seifert, Kienlin, Jones, and Jäckle, 1987, *Nature* 327: 383-89). The *Ttk* protein also contains PEST sequences found in proteins with short half-lives, as well as a serine and alanine-rich region at the C terminus [as in the *hb* and *inv* gene products (Coleman, Poole, Weir, Soeller, and Kornberg, 1987, *Genes Dev.* 1: 19-28]. *Ttk* RNA (probably maternal in origin) can be detected in embryos before stage 3; this RNA has almost disappeared by the start of *ftz* expression in stage 4 and is completely absent by the time the characteristic seven *ftz* stripes develop in the embryo. *Ttk* zygotic expression can be detected in stage 7 in the anterior mid-gut primordia and pole cells and later in the posterior mid-gut primordia. At stage 9, when *ftz* stripes are no longer present, *Ttk* RNA forms a pattern of about 14 stripes in the ectoderm and mesoderm of the extended germ-band. These stripes later fuse, forming a "tram-track" pattern around the germ-band; at stage 13, the *Ttk* RNA is only found in the developing epidermis and gut. Larvae and adults show very weak expression of the zygotic transcript.

**other information:** *Trf100D*: Transcription factor in 100D is a more informative designation.

**\*ttr:** tetrapter

**location:** 3-51.3.

**discoverer:** Tshetverikov, 25b.

**references:** Astaurov, 1929, Wilhelm Roux's Arch. Entwicklungsmech. Org. 115: 424-47.

1930, *Z. Indukt. Abstamm. Vererbungsl.* 55: 183-262.

Timoféeff-Ressovsky, 1934, *Z. Indukt. Abstamm. Vererbungsl.* 67: 248 (fig.).

Villee, 1942, Univ. Calif. (Berkeley) Publ. Zool. 49: 180-81.

**phenotype:** Like *bx*. Halteres tend to become winglike. Most flies wild type but may have, in place of a haltere, an organ one-half the size of a normal wing with veins, bristles, and sense organs. RK3.

**ttx:** tetrodotoxin-sensitive (J.C. Hall)

**location:** 3-45.

**origin:** Spontaneous.

**discoverer:** Kelly, L.M. Hall.

**references:** Gitschier, Strichartz, and Hall, 1980, *Biochim. Biophys. Acta* 595: 291-303.

**phenotype:** Adults and larvae highly sensitive to the sodium channel blocker tetrodotoxin (TTX) by feeding; mutant adults are especially sensitive.

**alleles:** One mutant allele, *ttx*<sup>1</sup>, causing accentuated TTX sensitivity.

**tu:** tumor

General term used to denote genes that lead to formation of single or multiple melanotic masses, either free or attached to internal organs in the abdomen or thorax. In most cases, these tumors (called "pseudotumors" by Barigozzi, 1968) appear in third instar larvae and may persist throughout pupal and adult life. They are formed by aggregation of hemocytes ("plasmatocytes") that have been transformed into flattened disk-like cells ("lamellocytes") which encapsulate other tissues (Rizki, 1957, *J. Morphol.* 100: 437-58; Rizki and Rizki, 1974, *J. Invert. Path.* 24: 37-40). Just before pupation, these masses of

<sup>β</sup> cytology: Located in 10A9 to 10B8 since included in *Df(1)KA7 = Df(1)10A9;10F6-7* but not in *Df(1)N71 = Df(1)10B2-8;10D3-8*.

tumor cells become melanized. Some of the melanotic tumor mutants are larval lethals [for example, eight lethals in the *Ddc* region described by Wright, 1987 (Adv. Genet. 24: 127-222)]; a few of the melanotic lethals are malignant, such as the *mbn* mutants of Gateff (1974, DIS 51: 21; 1977, DIS 52: 4) and the mutant *Tum* (Hanratty and Ryerse, 1981, Dev. Biol. 83: 238-49). In many cases, however, the melanotic tumors are benign and do not affect adult viability. Most of the genes designated *tu* are recessive and act in combination with modifying factors. The encapsulation and subsequent melanization (described for *tu-bw*, *tu-bw<sup>B3</sup>*, *tu-C4*, *tu-K*, *tu-Sz<sup>15</sup>* and *tu-W*) seem to be a reaction to developmental abnormalities in the mutants. General references for the *tu* mutants include:

- CP627.
- Sparrow, 1978, The Genetics and Biology of *Drosophila* (Ashburner and Wright, eds.). Academic Press, London, New York, San Francisco, Vol. 2b, pp. 277-313.

The preceding table describes the mutants and their alleles.

**Tu: Turned-up wing**

- location:** 1-59.
- origin:** X ray induced.
- discoverer:** Muller, 46i19.
- references:** Muller and Valencia, 1947, DIS 21: 70.
- phenotype:** Wings curled; somewhat wrinkled in longitudinal direction. Heterozygous viability good; homozygote also viable. RK1.

**TU36B: see Cyt-b**

**tub: tube**

- location:** 3-47.
- origin:** Induced by ethyl methanesulfonate.
- references:** Anderson and Nüsslein-Volhard, 1984, Nature (London) 311: 223-27.  
Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32.  
Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.
- phenotype:** Maternal effect embryonic lethal. Embryos can be rescued with wild-type cytoplasm and RNA; however, none hatched (Anderson and Nüsslein-Volhard, 1984). Dorsalization observed in the pattern of *ftz* stripes in *tub* embryos (Carroll *et al.*, 1987).
- alleles:** *tub<sup>1</sup>* and *tub<sup>2</sup>* recovered as *tub<sup>118</sup>* and *tub<sup>238</sup>*.

**Tub: Tubulin**

Tubulin proteins are found in a wide variety of species from unicellular organisms to man; their biochemical and molecular structure is highly conserved. The  $\alpha$ - and  $\beta$ -subunits from different organisms can be combined *in vitro* into hybrid microtubule structures and there is a high level of primary amino acid sequence identity in the proteins (Sánchez, Natzle, Cleveland, Kirschner, and McCarthy, 1980, Cell 22: 845-54; Raff, 1984, J. Cell Biol. 99: 1-10).

In *Drosophila melanogaster*, two multigene families, each made up of four members, code for  $\alpha$ - and  $\beta$ -tubulins, each tubulin subunit being a 55,000 dalton polypeptide. Tubulins are the main structural components of microtubules in mitotic and meiotic spindles, cilia, flagella, neural processes, and the cytoskeleton; nontubulin proteins (MAPS or microtubule-associated proteins) are involved along with tubulins in the forma-

tion of specialized microtubules (Theurkauf, Baum, Bo, and Wensink, 1986, Proc. Nat. Acad. Sci. USA 83: 8477-81; Rudolph, Kimble, Hoyle, Subler, and Raff, 1987, Mol. Cell Biol. 7: 2231-42). The tubulin genes in each multigene family are dispersed in the second and/or third chromosomes rather than arranged in clusters.

(1)  $\alpha$ -Tubulin: Codes for the  $\alpha$ -subunit; message of about 2000 bp.

(2)  $\beta$ -Tubulin: Codes for the  $\beta$ -subunit; message of about 1800 bp.

Variants of both  $\alpha$ - and  $\beta$ -subunits have been detected. The following table summarizes current information in regard to these genes in *Drosophila melanogaster*.

locus	synonym	location	cytology	comments
$\alpha$ Tub67C	$\alpha 4t$	3-[29]	67C4-6	maternal
$\alpha$ Tub84B	$\alpha 1t$	3-47.8	84B3-6	ubiquitous
$\alpha$ Tub84D	$\alpha 3t$	3-48	84D4-8	ubiquitous; except in adult male
$\alpha$ Tub85E	$\alpha 2t$	3-49	85E6-10	expressed from 7 hr through adult
$\beta$ Tub56D	$\beta 1t; \beta 4t$	2-[87]	56D	maternal; ubiquitous
$\beta$ Tub60D	$\beta 3t$	2-[107]	60D	embryonic; pupal
$\beta$ Tub85D	$\beta 2t$	3-48.5	85D4-7	testis-specific
$\beta$ Tub97EF	$\beta 4t; \beta 1t$	3-[92]	97E-F	ubiquitous

### $\alpha$ Tub67C ( $\alpha 4t$ )

Theurkauf, Baum, Bo, and Wensink, 1986, Proc. Nat. Acad. Sci. USA 83: 8477-81.

Matthews, Miller, and Kaufman, 1989, Dev. Biol. 132: 45-61.

Rees, Kaufman, and Matthews.

**phenotype:** A structural gene for  $\alpha$ -tubulin. It is transcribed into mRNA that is maternal in origin and is synthesized in the nurse cells; the transcript accumulates in 0- to 3-hr embryos and adult ovaries (Kalfayan and Wensink, 1982; Matthews *et al.*, 1989). The protein is clearly different from the other  $\alpha$ -tubulins of *Drosophila melanogaster* as well as from those of other animal species. A stable pool of  $\alpha 67C$  tubulin is found in ovaries, unfertilized eggs, and embryos, but synthesis of the protein probably only occurs in the ovary (Matthews *et al.*, 1989).

allele	origin	discoverer	comments
$\alpha$ Tub67C <sup>1</sup>	EMS	Matthews	antimorph
$\alpha$ Tub67C <sup>2</sup>	EMS	Rees	hypomorph
$\alpha$ Tub67C <sup>3</sup>	X-ray	Rees	hypomorph
$\alpha$ Tub67C <sup>4</sup>	DEB	Rees	hypomorph

**cytology:** Located in 67C4-6 by *in situ* hybridization (Sánchez *et al.*, 1980; Kalfayan and Wensink, 1981; Mischke and Pardue, 1982, J. Mol. Biol. 156: 449-66; Natzle and McCarthy, 1984); included in *Df(3L)AC1 = Df(3L)67A5;67D9-13* (Carpenter). Single copy present (Kalfayan and Wensink, 1981).

**molecular biology:** Gene cloned (Kalfayan and Wensink,

1981, 1982; Natzle and McCarthy, 1984), nucleotide sequences determined, and transcript maps formulated (Theurkauf *et al.*, 1986).  $\alpha$ Tub67C tubulin differs markedly from the other three  $\alpha$ -tubulins although it is similar in length and shares many sequences with the others; it ends with a carboxyl-terminal phenylalanine residue instead of the tyrosine characteristic of the other tubulins and differs from the  $\alpha$ -tubulin of  $\alpha$ Tub84B at 149 of the 450 residues (Theurkauf *et al.*, 1986). The 3' end of  $\alpha$ Tub67C is complementary to RNA bands on gels of 1.50, 1.70, 1.90, and 1.95 kb (Kalfayan and Wensink, 1982). A transcript of 1.5 kb was detected in early embryos and adult females (Matthews *et al.*, 1989).

Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

Theurkauf, Baum, Bo, and Wensink, 1986, Proc. Nat. Acad. Sci. USA 83: 8477-81.

Matthews and Kaufman, 1987, Dev. Biol. 119: 100-14.

Matthews, Miller, and Kaufman, 1989, Dev. Biol. 132: 45-61.

**phenotype:** A structural gene for  $\alpha$ -tubulin; present in one copy per haploid genome; transcribed into mRNA in the oocyte and the embryo, reaching a maximum concentration 6-9 hr after the egg is laid (Kalfayan and Wensink, 1982). A variety of post-translational modifications of  $\alpha$ Tub84b protein found in all tissues, some of which are tissue-specific (Matthews *et al.*, 1989). The gene appears to be constitutively expressed, its functions being common to most cells; the resulting tubulins are very similar to those of other animal species (Theurkauf *et al.*, 1986). Mutations in  $\alpha$ Tub84B have been induced as lethals over *Df(3R)Scx2*. Alleles  $\alpha$ Tub84B<sup>1</sup> and  $\alpha$ Tub84B<sup>3</sup> produce proteins that are electrophoretic variants of the wild-type tubulin. Based on the extent of lethality and sterility found in interallelic heterozygotes and in heterozygotes over wild type, the severity of  $\alpha$ Tub84B alleles can be ordered as follows:  $\alpha$ Tub84B<sup>6</sup> <  $\alpha$ Tub84B<sup>1</sup> <  $\alpha$ Tub84B<sup>2</sup> <  $\alpha$ Tub84B<sup>4</sup> <  $\alpha$ Tub84B<sup>5</sup> =  $\alpha$ Tub84B<sup>3</sup> (Matthews and Kaufman, 1987). Maternal-effect as well as zygotic lethality is shown by the more severe alleles. In the less severe hypomorphic alleles, heterozygotes die late in pupal life or early in adult life, the adults showing head, thoracic, or abdominal defects, bristle abnormalities, leg tremors, and sterility (Matthews and Kaufman, 1987).

**alleles:** Seven alleles induced by ethyl methanesulfonate.

allele	discoverer	synonym	ref <sup>α</sup>	comments
$\alpha$ Tub84B <sup>1</sup>	Denell	/(3)d10	1, 2	hypomorph

<i>αTub84B</i> <sup>5</sup>	Matthews		2	null
<i>αTub84B</i> <sup>6</sup>	Matthews		2	hypomorph
<i>αTub84B</i> <sup>7</sup>	Kemphues	<i>αTub84B<sup>nc33</sup></i>	3	hypomorph

<sup>α</sup> 1 = Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23;  
 2 = Matthews and Kaufman, 1987, Dev. Biol. 119: 100-14.  
 3 = Hayes, Deuring, Robertson, Prout, and Fuller, 1989, Mol. Cell Biol. 9: 875-84.

**cytology:** Located in 84B3-6 by *in situ* hybridization (Sánchez *et al.*, 1980; Kalfayan and Wensink, 1981; Mischke and Pardue, 1982; Natzle and McCarthy, 1984); cytologically located in 84B since included in *Df(3R)Scx2 = Df(3R)84A4-5;84C1-2* (Matthews and Kaufman, 1987), but not in *Df(3R)Win3 = Df(3R)84A4-5;84B1-2* (Cavener *et al.*, 1986) or *Df(3R)dsx2M = Df(3R)84C1-2;84D14* (B. Baker). The strongest hybridization among the  $\alpha$ -tubulins is observed at the 84B site; cytological data suggest the presence of two copies of *αTub84B* per haploid genome (Mischke and Pardue, 1982, 1983), the cloned DNA fragments hybridizing to salivaries and producing two rows of silver grains at 84B3-6.

**molecular biology:** Gene cloned (Kalfayan and Wensink, 1981, 1982; Mischke and Pardue, 1982; Natzle and McCarthy, 1984), nucleotide sequences determined, and transcript maps formulated (Theurkauf *et al.*, 1986). *αTub84B* and *αTub84D* show 92% nucleotide sequence identity within the protein coding region, the tubulins they encode differing by two substitutions, isoleucine-170 and cysteine II in the 84B tubulin being replaced by valine residues in the 84D tubulin. These *αTub* genes also have blocks of identical sequences outside the coding region (between nucleotides +27 and +147 of *αTub84B* and nucleotides +354 and +503 of *αTub84D*). The tubulin encoded by *αTub85E* differs from the *αTub84B* polypeptide at 21 of the 450 residues, while the tubulin encoded by *αTub67C* differs from the polypeptide of *αTub84B* at 149 residues. The *αTub84B* tubulin, like most of the other  $\alpha$ -tubulins except the *αTub67C* protein, ends with a tyrosine residue (Theurkauf *et al.*, 1986). The 3' end of *αTub84B* is complementary to an RNA band on a gel of approximately 1.8 kb (Kalfayan and Wensink, 1982).

***αTub84D* (*α3t*)**

**synonym:** *ms(3)nc33* (located in 84D).

**phenotype:** A structural gene for  $\alpha$ -tubulin. Coordinately expressed with *αTub84B* at most developmental stages with the exception of the adult stage where no 84D mRNA can be detected in males (Matthews *et al.*, 1989).

**alleles:** *αTub84D<sup>nc33</sup>* [= *ms(3)nc33*] induced by ethyl methanesulfonate, fails to complement certain  $\beta$ *Tub* mutant alleles for male fertility and is male sterile when homozygous (Fuller, 1986).

**cytology:** Located in 84D4-8 by *in situ* hybridization (Sánchez *et al.*, 1980; Kalfayan and Wensink, 1981; Mischke and Pardue, 1982; Natzle and McCarthy, 1984); cytologically located in 84C-D since included in *Df(3R)dsx2D = Df(3R)84C1-3;84D14* (B. Baker), but not in *Df(3R)Scx2 = Df(3R)84A4-5;84C1-2* (Matthews and Kaufman, 1987). Single copy present (Kalfayan and Wensink, 1981).

**molecular biology:** Gene cloned (Kalfayan and Wensink, 1981, 1982; Mischke and Pardue, 1982; Natzle and McCarthy, 1984), nucleotide sequences determined, and transcript maps formulated (Theurkauf *et al.*, 1986). The 3' end of *αTub84D* is complementary to an RNA band on a gel of approximately 1.95 kb (Kalfayan and Wensink, 1982; Matthews *et al.*, 1989). The transcript was found in both ovary and carcass RNA.

***αTub85E* (*α2t*)**

 Matthews, Miller, and Kaufman, 1989, Dev. Biol. 132: 45-61.

**phenotype:** A structural gene for  $\alpha$ -tubulin. Only  $\alpha$ -tubulin not expressed maternally. Transcripts present from 6-8 hr through adult. Protein found in support cells of chordotonal organs, developing muscles, and somatic component of the testis (Matthews, Miller, and Kaufman).

**cytology:** Located in 85E6-10 by *in situ* hybridization (Sánchez *et al.*, 1980; Kalfayan and Wensink, 1981; Mischke and Pardue, 1982; Natzle and McCarthy, 1984). Single copy present (Kalfayan and Wensink, 1981).

**molecular biology:** Gene cloned (Kalfayan and Wensink, 1981, 1982; Mischke and Pardue, 1982; Natzle and McCarthy, 1984), nucleotide sequences determined, and transcript maps formulated (Theurkauf *et al.*, 1986). An *αTub85E*- $\beta$  galactosidase fusion gene was expressed in chordotonal organs (sensory organs in the peripheral nervous system) and in the testes (Bo and Wensink, 1989). Chordotonal expression occurs in males and females from late embryonic to early pupal stages. The 3' end of *αTub85E* is complementary to bands on gels of approxi-

mately 1.65 kb in pupae and adult males and 1.8 kb in larvae according to Kalfayan and Wensink (1982); the 1.8 kb transcript was not found by Natzle and McCarthy (1984) or Matthews *et al.* (1989), who report a single 1.55 kb band.

### $\beta$ Tub56D ( $\beta 1t$ )

Rudolph, Kimble, Hoyle, Subler, and Raff, 1987, *Mol. Cell. Biol.* 7: 2231-42.

Gasch, Hinz, Leiss, and Renkawitz-Pohl, 1988, *Mol. Gen. Genet.* 211: 8-16.

**phenotype:** A structural gene for  $\beta$ -tubulin. Its mRNA is maternally stored in the oocytes and expressed in the nurse cells and in early embryos (Natzle and McCarthy, 1984; Gasch *et al.*, 1988); at this stage, the transcripts are evenly distributed throughout the embryo, but later in development they are concentrated in the primordia of the nervous system and their derivatives (the supraoesophageal ganglion and ventral nerve cord) and in the visceral mesoderm. Since  $\beta$ Tub56D is expressed throughout development and in all adult tissues (Rudolph *et al.*, 1987),  $\beta$ Tub56D tubulin is probably involved in all the microtubular structures necessary for cell division and cell shape (Raff *et al.*, 1982; Bialojan *et al.*, 1984). It is the major  $\beta$ -tubulin of adult flies in all structures except the testis.

**cytology:** Located in 56C (Bialojan *et al.*, 1984) or in 56D (Natzle and McCarthy, 1984) by *in situ* hybridization.

**molecular biology:** Gene cloned (Bialojan *et al.*, 1984; Natzle and McCarthy, 1984); transcript of 1.8 kb present in all developmental stages (Raff, 1984); maximal expression in 6-9 hr embryos (Bialojan *et al.*, 1984). Complete nucleotide sequences and predicted amino acid sequences of the protein-coding regions have been determined (Michiels *et al.*, 1987; Gasch *et al.*, 1988). A single intron of 2.6 kb is found between codons for amino acids 19 and 20. The 5' untranslated region is encoded in the same exon as the first 19 amino acids. There is a typical TATA box promoter element at -27. Transcription starts at an adenosine residue as in most eukaryotic genes, the initiation site being 110 bases upstream of the translation initiation codon (Gasch *et al.*, 1988). The 3' untranslated region of  $\beta$ Tub56D mRNA is not identical to the 3' region of  $\beta$ Tub85D mRNA, but the protein coding regions show 95% identity at the amino acid level; there are 25 differences in amino acid sequence between these two tubulins (Michiels *et al.*, 1987).

### $\beta$ Tub60D ( $\beta 3t$ )

Kimble, Dettman, and Raff, 1990, *Genetics* 126: 991-1105.

**phenotype:** A structural gene for  $\beta$ -tubulin. The mRNA first appears in the mesoderm during mid-embryogenesis at about the time when synthesis of  $\beta$ -tubulin begins and later disappears from the embryo when synthesis of the tubulin ends; the transcript reappears in the mesoderm during the pupal period (Raff *et al.*, 1982; Natzle and McCarthy, 1984; Raff, 1984; Rudolph *et al.*, 1987; Gasch *et al.*, 1988; Kimble *et al.*, 1989). During embryogenesis,  $\beta$ Tub60C is only expressed in developing muscles; in pupae, it is expressed in adult muscles, imaginal discs, wing blades, optic lobes, ovaries and testes, but ceases (except in ovaries and testes) in adults. As compared to the tubulin encoded by  $\beta$ Tub56D, the product of  $\beta$ Tub60C is but a minor component of the total tubulin pool (Rudolph *et al.*, 1987). When synthesis of the  $\beta$ Tub60C tubulin begins in the embryo,  $\alpha$ -tubulin synthesis is increased (Raff *et al.*, 1982).

**alleles:** Five EMS-induced alleles (Kimble *et al.*, 1990).

allele	synonym	comments	$\alpha$	$\beta$
$\alpha$ Tub60D <sup>1</sup>	$\beta 3t^1$	intermediate hypomorph		
$\alpha$ Tub60D <sup>2</sup>	$\beta 3t^2$	strong hypomorph		
$\alpha$ Tub60D <sup>3</sup>	$\beta 3t^3$	strong hypomorph		
$\alpha$ Tub60D <sup>4</sup>	$\beta 3t^4$	weak hypomorph		
$\alpha$ Tub60D <sup>5</sup>	$\beta 3t^5$	intermediate hypomorph		

$\alpha$  Effect on viability:  $\beta 3t^2 > \beta 3t^3 > \beta 3t^4 > \beta t^1 > \beta 3t^5$ .

$\beta$  Effect on fertility:  $\beta 3t^3 > \beta t^2 > \beta 3t^4 > \beta 3t^1 > \beta t^3$ .

**cytology:** Located in 60D; also located in 60A-B (Sánchez *et al.*, 1980), 60B (Bialojan *et al.*, 1984), or 60C (Natzle and McCarthy, 1984) by *in situ* hybridization; placed in 60C6-8 by other molecular methods (see Raff, 1984).

**molecular biology:** Gene cloned (Bialojan *et al.*, 1984; Natzle and McCarthy, 1984); 2.3-2.5 kb transcript found in mid-embryogenesis and during pupation (Bialojan *et al.*, 1984; Raff, 1984). The transcription initiation sites are identical in both of these developmental periods (Gasch *et al.*, 1988). Gene structure, nucleotide sequences, and predicted amino acid sequences of the protein-coding regions have been determined (Rudolph *et al.*, 1987; Gasch *et al.*, 1988). The tubulin encoded by  $\beta$ Tub60C is longer and slightly more basic than that encoded by  $\beta$ Tub56D, and contains 454 amino acids (Rudolph *et al.*, 1987). The first intron occurs between the codons for amino acids 19 and 20 and is about 4.5 kb long; the second intron occurs after the first nucleotide in the codon for amino acid 56 and is only 62 bp long; the third intron occurs between the codons for amino acids 137 and 138 and is about 56 bp long. Six amino acids not found in any other  $\beta$ -tubulin are positioned immediately after the 3' junction of the second intron in a highly variable region. The first and third introns occur in rela-

tively conserved regions of the protein coding sequence (Rudolph *et al.*, 1987). Upstream sequences of  $\beta Tub56D$ ,  $\beta Tub60C$ , and  $\beta Tub85D$  are highly divergent, with the exception of the sequence common to  $\beta Tub60C$  and  $\beta Tub85D$  promoters (Gasch *et al.*, 1988). Upstream of -1.2 kb (relative to the transcription start site) are regulatory elements required for expression of  $\beta Tub60C$  in the somatic muscles, the pharyngeal muscles, and the dorsal vessel (Gasch *et al.*, 1989). The first intron carries an enhancer element necessary for  $\beta Tub60C$  expression in the visceral muscles.

**$\beta Tub85D$  ( $\beta 2t$ )**

**phenotype:** A structural gene for  $\beta$ -tubulin. It is transcribed into mRNA that is testis-specific; the mRNA is translated into a  $\beta$ -tubulin subunit that is involved in the formation of microtubules in the sperm tail axoneme, the cytoplasmic microtubules, and the meiotic spindle (Kempfues *et al.*, 1982; Fuller *et al.*, 1988). Only the microtubules of the mitotic spindle are not affected by a null mutation in  $\beta Tub85D$ . The first mutant discovered,  $\beta Tub85D^D$  (Kempfues *et al.*, 1979, 1980, 1982, 1983), codes in males for an electrophoretic variant of  $\beta_2$ -tubulin that causes disruption of microtubule function in all stages of spermatogenesis (beginning with meiosis) and shows abnormal spindle formation, abnormal chromosome movement, and no cytokinesis. This phenotype is expressed in males in both homo- and heterozygotes; mutants heterozygous over wild type contain both wild-type and mutant  $\beta_2$ -tubulins; mutants over a deficiency for the locus contain only mutant  $\beta_2$ -tubulin. Severity of effect on meiosis is as follows:  $\beta Tub85D^D/\beta Tub85D^D > \beta Tub85D^D/+ > \beta Tub85D^D/+$ , the first two genotypes being sterile and the last weakly fertile. All females are fertile. Chromosome replication and condensation appear normal. Recessive male-sterile mutations have also been induced, two of them in  $\beta Tub85D^D$  chromosomes and the rest in  $\beta Tub85D^+$  chromosomes. Testes of flies homozygous for the recessives  $\beta Tub85D^3$ ,

$\beta Tub85D^4$ ,  $\beta Tub85D^{Drv1}$ , and  $\beta Tub85D^{Drv2}$  synthesize, but later degrade, both  $\alpha$ -tubulin and  $\beta$ -tubulin and show abnormalities in meiotic divisions, nuclear shaping, and formation of the flagellar axoneme (Kempfues *et al.*, 1982, 1983; Fuller, 1986). The most extreme recessive allele,  $\beta Tub85D^n$ , is male sterile but female fertile when homozygous (Fuller *et al.*, 1988); heterozygotes raised at 25° are male fertile, but those raised at 18° are male sterile. Recessive alleles  $\beta Tub85D^6$  -  $\beta Tub85D^{10}$  seem to accumulate normal amounts of  $\beta$ -tubulin but the  $\beta$ -tubulin subunits are defective.  $\beta Tub85D^6$ ,  $\beta Tub85D^7$ , and  $\beta Tub85D^8$  cause different defects in spermatogenesis.  $\beta Tub85D^8$  is unable to form normal closed microtubules (Fuller *et al.*, 1987); in homozygous males it is defective in meiosis, nuclear shaping, and flagellar elongation. This allele is semi-dominant; heterozygous males with one normal and one abnormal tubulin subunit, form some functional sperm. Transheterozygotes between *ms(3)nc* (second site non-complementing) mutations and certain  $\beta Tub85D$  alleles are male sterile even if wild-type copies of both genes are present (Fuller, 1986); a deletion of a *ms(3)nc* mutation in a heterozygote over  $\beta Tub85D^n$ , however, is fertile in males.

**alleles:**

<sup>β</sup> Fertile in transheterozygotes with *hay<sup>nc2</sup>*.  
<sup>γ</sup> Sterile in transheterozygotes with *hay<sup>nc2</sup>*.

**cytology:** Placed in 85D by *in situ* hybridization of cloned DNA (Sánchez *et al.*, 1980; Bialojan *et al.*, 1984; Natzle and McCarthy, 1984); placed in 85D7-11 by deficiency testing since in the 84F1-85E deletion of *In(3R)Msc<sup>L</sup>Anp<sup>BR</sup>* but not in *Df(3R)p46 = Df(3R)84D4-6;85D6* or *Df(3R)by10 = Df(3R)85D8-12;85E7-F1* (Kempfues *et al.*, 1983).

**molecular biology:** Gene cloned (Bialojan *et al.*, 1984; Natzle and McCarthy, 1984); clone contains one complete  $\beta$ -tubulin gene and the 3' end of another tubulin-like sequence; 2.0-2.2 kb transcript specifically expressed in spermatogenesis (Bialojan *et al.*, 1984; Raff, 1984).

Complete nucleotide sequences and predicted amino acid sequences of the protein-coding regions have been determined (Rudolph *et al.*, 1987; Gasch *et al.*, 1988). The proteins encoded by  $\beta$ Tub85D and  $\beta$ Tub60C show 87% overall identity in amino acid sequence; the  $\beta$ Tub85D tubulin contains 446 amino acids while the  $\beta$ Tub60C tubulin contains 454 amino acids. The  $\beta$ Tub85D gene has a single intron of 61 bases and the mRNA contains a 5' untranslated region of 175 bases. The first exon comprises this 5' region, the translation initiation codon ATG, and codons up to amino acid 131; the second exon includes the codons for amino acids from 132 to the stop codon. Transcription starts at an adenosine residue. The sequence for the mutant  $\beta$ Tub85D<sup>8</sup> is identical to that of the wild-type in both intron and protein-coding regions, except that at nucleotide 862 there is a single nucleotide substitution resulting in a change from glu to lys at amino acid residue 288 (Rudolph *et al.*, 1987). *P*-element mediated germline transformation using the  $\beta$ Tub85D-*lacZ* fusion gene resulted in  $\beta$ Tub85D expression in the testis only (Michiels, Gasch, Kaltschmidt, and Renkawitz-Pohl, 1989, EMBO J. 8: 1559-65). 53 bp of upstream sequences are necessary for correct testis expression.

### $\beta$ Tub97EF ( $\beta$ 4t)

**references:** Natzle and McCarthy, 1984, Dev. Biol. 104: 187-98.

Raff, 1984, J. Cell Biol. 99: 1-10.

Gasch, Hinz, Leiss, and Renkawitz-Pohl, 1988, Mol. Gen. Genet. 211: 8-16.

**phenotype:** A structural gene for  $\beta$ -tubulin. It is transcribed into mRNA that occurs ubiquitously throughout development.  $\beta$ Tub97EF is expressed coordinately with  $\beta$ Tub56D, but the  $\beta$ Tub97EF transcripts are much less prevalent. They occur at highest concentration during the first half of embryogenesis and the first and second larval instars (Natzle and McCarthy, 1984). No protein variant has been described (Gasch *et al.*, 1988).

**cytology:** Located in 97E-F by *in situ* hybridization (Natzle and McCarthy, 1984).

**molecular biology:** Gene cloned (Natzle and McCarthy, 1984); 1.8 kb transcript obtained (Raff, 1984).

**tube:** see *tub*

**Tubulin:** see *Tub*

### *tud: tudor* (*T. Schüpbach*)

**location:** 2- {97}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Wieschaus and Nüsslein-Volhard.

**references:** Boswell and Mahowald, 1985, Cell 43: 97-104.

Degelmann, Hardy, Perrimon, and Mahowald, 1986, Dev. Biol. 115: 479-89.

Schüpbach and Wieschaus, 1986, Roux's Arch. Dev. Biol. 195: 302-17.

Nüsslein-Volhard, Frohnhöfer, and Lehmann, 1987, Science 238: 1675-81.

O'Donnell, Boswell, Reynolds, and Mackay, 1989, Genetics 121: 273-80.

Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect mutant; embryos from homozygous mothers exhibit a so-called "grandchildless-knirps"

phenotype: all eggs lack polar granules and no pole cells are formed; most of the embryos show variable deletions of abdominal segments, whereby segment A4 is deleted most frequently; larger deletions may include segments A2 through A7; in extreme cases anterior parts of segment A1 become fused to posterior part of segment A8, but telson elements are always present and relatively normal. Around 30% of all embryos survive and grow into sterile adults. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48).

**synonym:** *ptc*, *patched*.

**phenotype:** The *tuf* gene is involved in patterning within segments in *Drosophila*. The viable first-identified mutant has a small tuft of hairs between eyes and antennae and shows basal twinning of the anterior halves of wings; it overlaps wild type. *tuf*<sup>T(2;3)dp</sup> has an extreme form of this mutant phenotype. Other mutants are embryonic lethals of the segment-polarity type. There is a mirror-image duplication of segment boundaries and adjacent cuticle of all segments with deletion of the remainder of the segment. Defect visible during extended-germ-band stage (6 hr) (Nüsslein-Volhard and Wieschaus, 1980). Normal number of denticle bands; duplicated region of embryo includes some naked cuticle anterior to denticle bands. Pattern of neurons underlying affected epidermal region is altered (Patel, Schafer, Goodman, and Holmgren, 1989, Genes Dev. 3: 890-

904). This mutant has no effect on the spatial expression of the "pair-rule" mutant *ftz* (Carroll and Scott, 1986). *tuf* embryos cultured in vivo produced derivatives of the eye-antennal and thoracic discs, the latter being abnormal in morphology and in *en* expression (Simcox, Roberts, Hersperger, Gribbon, Shearn, and Whittle, 1989, Development 107: 715-22).

**alleles:** One viable allele and numerous lethal alleles reported.

allele	origin	synonym	ref <sup>α</sup>	comments

<sup>α</sup> 1 = Hooper and Scott, 1989, Cell 59: 751-65; 2 = Nakano, Hidalgo, Taylor, Whittle, and Ingham, 1989, Nature (London) 341: 508-13; 3 = Sturtevant, 1948, DIS 22: 56; 4 = Tearle and Nüsslein-Vollard, 1987, DIS 66: 209-26; 5 = Whittle, 1980, DIS 55: 211.

<sup>β</sup> Wings of *tuf*<sup>1</sup>/*tuf*<sup>2</sup> grossly foreshortened and shaped like a ping-pong paddle; these flies also show duplications and triplications of anterior wing structures, lack costal bristles, and have more head abnormalities than *tuf*<sup>1</sup> homozygotes.

**cytology:** *tuf* (= *ptc*) placed in 44D3-4 by *in situ* hybridization to P-element-free polytene chromosomes (Nakano *et al.*, 1989). Located in 44B-E based on uncoverage by the deficiency segregant of *Tp(2;3)eve*<sup>1.18</sup> but not by the deficiency segregant of *Tp(2;3)eve*<sup>2.28</sup> (Nüsslein-Vollard *et al.*, 1984; Tearle and Nüsslein-Vollard, 1987, DIS 66: 209-26); located in 44D1-2 to 44E1-4 since included between the centromere-proximal breaks of *Df(2R)P14TE* (a synthetic deficiency) and *Df(2R)44CE* (Hooper and Scott, 1989).

**molecular biology:** Gene cloned; transcription unit of about 17-30 kb encodes a 5.8 to 7 kb transcript (Hooper and Scott, 1989, Cell 59: 751-65; Nakano *et al.*, 1989). At blastoderm, *tuf* transcribed uniformly except in pole cells and A-D region; later expressed as 14 and then 28 stripes. Expression in larvae occurs in the imaginal disks. Nucleotide sequence of *tuf* and predicted amino acid sequences obtained (Nakano *et al.*, 1989). There is a single open reading frame of 4152 bases (Hooper and Scott, 1989). Predicted protein is large (1286 amino acids) with at least seven putative transmembrane  $\alpha$  helices.

**phenotype:** Maternal effect gene with no phenotypic expression of its own; presence of gene indicated by difference in results obtained from reciprocal crosses between phenotypically tumorous head and inbred wild-type flies, the mutant phenotype only appearing in the offspring when the mother comes from the *tuh* stock (Gardner, 1959). There seems to be an interaction involving maternal effect substances between *tuh1* (or *tuh1*<sup>+</sup>) and *iab9*<sup>tuh3</sup>, an allele of the most distal gene in the *BXC*; the homoeotic effects of homo- or heterozygous *iab9*<sup>tuh3</sup> flies are strongly enhanced by the *tuh1* allele. One type of abnormality in tumorous head mutants involves homoeotic changes, deficiencies, and duplications in the eye, antenna, or rostralhant regions that transform parts of these structures into tergite-like, leg-like, or genital-like growths in the adult (Postlethwait *et al.*, 1972). In the mutant larvae, patches of aldehyde oxidase positive tissue can be demonstrated within the aldehyde oxidase negative eye discs, where, presumably, transformed tissue will occur (Kuhn *et al.*, 1979). Penetrance of these head abnormalities is increased by high temperature during oogenesis and early embryogenesis (Gardner, 1970; Bournias-Vardiabasis and Bownes, 1979) and also by the presence of *E(tuh1)* an enhancer of the mutant phenotype on 3R (Kuhn and Dorgan, 1974, Genetics 77: s37; Kuhn and Packert, 1988a). Modifiers on the first, second, and third chromosomes in certain lines likewise increase the maternal effect of *tuh1* (Gardner, 1970; Woolf and Passage, 1980). The other type of abnormality occurring in tumorous head stocks involves genital disc defects that result in missing or undeveloped testes and associated organs, both in males and in transformed females (Gardner and Woolf, 1949; Woolf, 1966, 1968; Kuhn *et al.*, 1981). Viability of stocks showing head abnormalities is about 70%; lethal-

ity may occur in the egg, larval, or pupal periods (Bournias-Vardiabasis and Bownes, 1978).

**alleles:**

allele	synonym	ref <sup>α</sup>	phenotype with <i>iab9<sup>tuh3</sup> β</i>
<b>tuh1</b>	<i>tuh1<sup>h</sup></i> , <i>tu-1</i>	1, 2	homeotic leg, tergite, or genital tissue in eye-antenna region (penetrance up to 90%)
<b>tuh1<sup>+</sup></b>	<i>tuh1<sup>g</sup></i>	2, 3	defects in male genital disc or complete absence of disc (penetrance up to 60%)

<sup>α</sup> 1 = Gardner and Woolf, 1949, *Genetics* 34: 573-85; 2 = Kuhn and Packert, 1988a, *Dev. Biol.* 125: 8-18; 3 = Kuhn and Packert, 1988b, *Genetics* 118: 103-07; 4 = Kuhn, Züst, and Illmensee, 1979, *Mol. Gen. Genet.* 168: 117-24; 5 = Woolf, 1966, *Genetics* 53: 295-302; 6 = Woolf, 1968, *Genetics* 60: 111-21.

<sup>β</sup> Effect with *tuh1* semidominant; effect with *tuh1<sup>+</sup>* recessive (Kuhn and Packert, 1988a and 1988b).

**cytology:** Located in 20A1-2 since uncovered by *Df(1)JC4* = *Df(1)20A1-2;20E-F* and *Df(1)mal6* = *Df(1)19C3;20A2-3*, but not by *Df(1)Q539* = *Df(1)19E6;19F6-20A1* (Pyati, 1976).

**other information:** A third chromosome EMS-induced mutant *II27*, when homozygous or when heterozygous over *iab9<sup>tuh3</sup>*, produces head abnormalities involving genital and abdominal transformations under the influence of the *tuh1* maternal effect (Bownes, Roberts, Demster, and Bournias-Vardiabasis, 1981, *Mol. Gen. Genet.* 183: 158-62; Kuhn and Packert, 1988a); may be an allele of *iab9<sup>tuh3</sup>*.

*tuh3*: see *iab9<sup>tuh3</sup>*

**Tul: Turneduplike**

**location:** 1-50 (between *g* and *f*).

**origin:** Spontaneous.

**references:** Muller, 1965, *DIS* 40: 35.

**phenotype:** Like *Tu*. Wing tips of heterozygote turned up slightly but definitely not twisted. Male and homozygous female more extreme with wrinkled wings sometimes held somewhat apart; viable and fertile. RK2.

**Tum: Tumorous**

**location:** 1-35.8.

**origin:** Induced by ethyl methanesulfonate.

**references:** Corwin and Hanratty, 1976, *Mol. Gen. Genet.* 144: 345-47.

Hanratty and Ryerse, 1981, *Dev. Biol.* 83: 238-49.

**phenotype:** Dominant tumorous gene that is a temperature-sensitive lethal at 29° in hemizygous males and homozygous females; about two-thirds of the hemizygous males survive at 18° and one-quarter of these have melanotic tumors. Males raised at 26° and heterozygous females raised at 29° survive to adulthood, but show melanotic masses in the abdominal cavity or small black specks in the legs, wings, or thorax. Mutant larvae kept at 29° show enlargement of the lymph glands in the late second- or early third-instar larvae, but no melanotic masses. By mid third-instar, the lymph glands are large and diffuse and the gastric caeca have become encapsulated and melanized. By late third-instar, the larvae have melanotic masses in the body cavity, lack lymph glands, and have reduced, encapsulated and melanized gastric caeca as well as encapsulated and melanized muscles and fat bodies. These mutants do not survive beyond the late third-instar or the early pupal stage. When lymph glands from *Tum* larvae are injected into adult female hosts, transplantable neoplasms are produced. Melanization, at

first associated with the leg joints and later with the head, thorax, and abdomen, takes place; also abdominal bloating. The lymph glands become melanotic and the abdomen is filled with encapsulated masses before the premature death of the injected individuals. Injection of *Tum* tissue other than lymph glands fails to produce these effects. The melanotic neoplasms can be transplanted into a succession of hosts in which they produce the same abnormalities. The neoplastic cells resemble hemocytes; some cell lines are melanotic and others are unpigmented, but in both types, the tissue, when transplanted, grows rapidly in the hosts and kills them.

**other information:** Shown to be allelic to *hop* too late to be included in the *hop* entry (Dearoff).

**tup: tailup**

**location:** 2-54.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, *DIS* 66: 209-69.

**phenotype:** Embryonic lethal. Head broad. Germband shortening apparently ceases early, resulting in the posterior-most three segments remaining on dorsal side of the embryo.

**alleles:** *tup<sup>1</sup>* and *tup<sup>2</sup>*, isolated as *tup<sup>III B</sup>* and *tup<sup>III e</sup>*.

**tur: turnip (J.C. Hall)**

**location:** 1- (proximal to *f*, distal to *car*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Aceves-Piña and Quinn, 1979, *Science* 206: 93-96.

Quinn, Sziber, and Booker, 1979, *Nature* 277: 212-114.

Booker and Quinn, 1981, *Proc. Nat. Acad. Sci. USA* 78: 3940-44.

Duerr and Quinn, 1982, *Proc. Nat. Acad. Sci. USA* 79: 3645-50.

Tully and Quinn, 1985, *J. Comp. Physiol.* 157: 253-77.

Tully, 1987, *Trends Neurosci.* 10: 330-35.

1989, *Adaptation, Learning, and Affect* (Madden, Matthyse, and Barchas, eds.). Raven, New York, pp. 1989.

**phenotype:** Homozygotes or hemizygotes are blocked or impaired in learning, with respect to certain of the conditioning tests used on groups of flies or larvae or on individual adults, e.g. tests involving olfactory "shock-avoidance" learning (Acevas-Piña and Quinn, 1979; Quinn *et al.*, 1979), leg-shock/leg-lift learning (Booker and Quinn, 1981); "courtship conditioning" (Gailey, Jackson, and Siegal, 1982, *Genetics* 102: 771-82; 1984, *Genetics* 106: 613-23), and habituation to sugar stimuli when applied to tarsus (Duerr and Quinn, 1982). When the original shock-odor testing system is modified by redesigning the choice chamber, homozygous and hemizygous mutants show about 60% of the control wild-type values when tested just post-training (Tully and Quinn, 1985; Tully, 1987), but the mutant shows very rapid

short-term and slower long-term memory losses. *tur*+/ heterozygous females show seemingly normal levels of shock-odor conditioned behavior when tested immediately after training, but very rapid memory losses (Quinn *et al.*, 1979). Homozygous *tur* flies are said to have a deficiency in (and possibly absence of) protein kinase C (PKC) (Smith, Choi, Tully, and Quinn, 1986, Soc. Neurosci. Abstr. 12: 399), and *tur* flies are almost totally deficient in phosphorylation of a 76 kd head membrane protein which is a major substrate for PKC (Choi, Smith, Marler, and Quinn, 1989), but the lowered PKC levels and abnormal learning do not map to the same cytogenetic location (see **cytology**).

**cytology:** *Df(1)JA27 = Df(1)18A5;18D1-2*, which uncovers the PKC deficiency and the non-phosphorylation of head membrane protein phenotypes, did not uncover any deficit in classical conditioning in one series of tests (Tully and Quinn, 1985; Tully, 1989). Another series, however, revealed 15% reduction in learning scores for classical conditioning tests and 70% reduction in scores for shock-avoidance tests in *tur/Df(1)JA27* females (Choi *et al.*, submitted). Other proximal X deletions [*Df(1)N19*, *Df(1)mal8*, *Df(1)16-3-22*, and *Df(1)DCB1-35B*] have not uncovered any classical conditioning deficits.

<sup>α</sup> 1 = CP627; 2 = Davis, 1975, Genetics 80: s25; 3 = Davis, 1980, DIS 55: 29-31, 31-33.

**cytology:** Located at 1C5-1D4.

**tw<sup>2</sup>**

**phenotype:** Abdomens of males and females twisted 30°-60° clockwise, as viewed from the posterior; more extreme than *tw*. Male genitalia often twisted counter-clockwise. Viability reduced. Males usually fertile. *tw*<sup>2</sup>/*tw* flies resemble *tw*<sup>2</sup>/*tw*<sup>2</sup>.

**tw<sup>3</sup>**

**phenotype:** Abdomens of males and females twisted up to 90°, as viewed from the posterior. Male genitalia and anal plate often twisted clockwise or counter-clockwise (misalignment up to 180°). Males and females often sterile, although male genitalia appear normal and sperm are motile. 1% nondisjunction for homologues in males (Davis, 1975, 1980).

**\*twg: twisted genitals**

**location:** 1-48.1.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 93-94.

**phenotype:** External genitalia abnormally positioned on extreme tip of abdomen. Tergites often notched at mid-dorsal line. Eyes large, abnormally shaped, and slightly rough. Wings vary from almost normal to small, deformed structures with very abnormal venation. Bristles frequently waved or bent. Male viability and fertility subnormal. RK2.

**twi: twist**

**location:** 2-100.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1983, DIS 59: 158-60.

Simpson, 1983, Genetics 105: 615-32.

Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Thisse, Stoetzel, Gorostiza-Thisse, and Perrin-Schmidt, 1988, EMBO J. 7: 2175-83.

**phenotype:** The wild-type allele of *twi* is involved in the establishment of germ layers. Mutants are embryonic lethals (zygotic), partially dorsalized, and without mesodermal differentiation. A normal blastoderm is formed; at gastrulation, no ventral furrow is visible, but the endoderm invaginates, a cephalic furrow is formed, and the germband elongated. The embryo is twisted or coiled in the egg case, often with posterior side up. There are few mesodermally derived internal tissues. Some embryos fail to make a properly differentiated cuticle, although 40-100% make normal ectodermal derivatives (Simpson, 1983). There is no maternal effect in germline chimeras. *twi*+ heterozygous embryos have delayed ventral furrow formation. The TSP of the *twi* gene is around gastrulation (Thisse *et al.*, 1987).

**cytology:** Placed in 59C3-D2; uncovered by *Df(2R)twi* = *Df(2R)59C3-4;59D1-2*.

**molecular biology:** Region containing *twi* cloned (Thisse, El Messal and Perrin-Schmidt, 1987, Nucleic Acids Research 15: 3439-53) and the nucleotide sequence obtained (Thisse *et al.*, 1988). The sequence is a simple transcription unit, with an unique 5' end and a 120 bp intron near its 3' end. The mature twist mRNA is 1878 bp long excluding the poly(A) tail, and contains one large open reading frame that generates a protein of 490 amino acids that is present at the anterior and posterior poles and in the midventral region at the cellular blastoderm stage. The *twi* protein is localized in the nucleus (Thisse *et al.*, 1988). Translation apparently occurs just after the transcription process.

**other information:** Mutations in *dl*, *pll*, *ea*, or *Tl* abolish the expression of *twi*. At least one dose of *dl*<sup>+</sup> in females is necessary for transcription of *twi* (Thisse *et al.*, 1987). *twi* shows extensive identity to a pair of *myc*-related polypeptides whose dimerized products bind to a sequence in the immunoglobulin kappa chain enhancer; the identical regions have the potential to form two amphipathic helices separated by an intervening loop (Murre, McCaw, and Baltimore, 1989, Cell 56: 777-83).

**cytology:** Placed in 84A1-6 based on its inclusion in *Df(3R)Scr* = *Df(3R)84A1-2;84B1-2* but not in *Dr(3R)Antp17* = *Df(3R)84A6;84D13-14*.

**\*twi: twirled tips**

**location:** 1-37.1.

**origin:** Induced by 1:4-dimethanesulfonylbut-2-yne (CB. 2058).

**discoverer:** Fahmy, 1951.

**references:** 1959, DIS 33: 94.

**phenotype:** Wings completely or partially unexpanded; tips frequently twisted. Male inviable, dies shortly after eclosion, and does not breed. RK3.

**tx: taxi (J.C. Hall)**

**location:** 3-91.

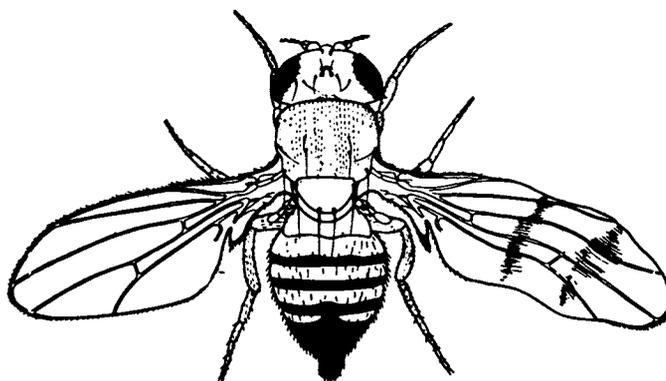

**origin:** Spontaneous.

**phenotype:** Wings held out at about 75° from body axis, often arched or wavy, somewhat narrow and dusky. Unable to fly because of shape and posture of wings. RK2.

**alleles:**

allele	discoverer	ref <sup>α</sup>
<i>tx</i> 1	Collins, 24j30	1, 2

Perrimon and Gans, 1983, Dev. Biol. 100: 365-73.

**phenotype:** Bristles small. Body small. Eclosion delayed. Viability excellent. Female sterile; eggs rarely found and only in a few ovarioles (Perrimon and Gans, 1983). Yolk formation in oocytes inhibited [King and Burnett, 1957, Growth 21: 263-80 (fig.)]. Follicular cells form abnormal derivatives of endoplasmic reticulum and migrate abnormally or form excess of normal endoplasmic reticulum derivative [King and Vanoucek, 1960, Growth 24: 333-38; Falk and King, 1964, Growth 28: 291-324 (fig.)]. *ty* ovaries in *ty*<sup>+</sup> host develop autonomously (King and Bodenstein, 1965, Z. Naturforsch. 20B: 292-97). RK2. The heteroallelic combination *ty/ty*<sup>15</sup> exhibits the visible phenotypes described for *ty* homozygotes (Schalet, 1986, Mutat. Res. 163: 115-44), and, in addition, may show a reduction in thoracic hairs and abnormally-shaped rough eyes; viability severely reduced in some cultures.

**alleles:** A, spontaneous lethal, *l(1)4-103*, was found to be allelic to *ty* (Schalet, 1986).

**cytology:** Located in 12A6-12D3.

**\*tyb2: tiny bristle 2**

**location:** 1-19.5.

**origin:** Spontaneous.

**discoverer:** Neel, 41i9.

**references:** 1942, DIS 16: 52.

**phenotype:** Bristles small and thin. Viability and fertility good. RK1.

**tyl: tinylike**

**location:** 1-36.

**origin:** X ray induced in *In(1)dl-49*.

**discoverer:** Oliver, 28k4.

**references:** 1935, DIS 3: 28.

1942, DIS 16: 53.

**phenotype:** Bristles short, fine, and stubblelike. Eclosion delayed. Both sexes viable and fertile. RK2A.

**alleles:**

**cytology:** Located in 10C3-5 since included in the transposed region of *Tp(1;1)v<sup>N48</sup> = Tp(1;1)9F;10C3-5;20*, but not in *Df(1)GA112 = Df(1)10A11-B1;10C2*.

**tyr1: tyrosine 1 (J.C. Hall)**

**location:** 2-54.5 (Huntly, 1978, Ph.D. Thesis, University of Virginia); inseparable so far from *pr*.

**origin:** Spontaneous.

**discoverer:** H.W. and H.S. Lewis.

**synonym:** *α: alpha; tyrosinase-1*.

**references:** 1960, DIS 34: 51.

H.W. and H.S. Lewis, 1961, Proc. Nat. Acad. Sci. USA 47: 78-86.

H.W. Lewis, 1962, Biol. Bull. 123: 464.

H.W. and H.S. Lewis, 1963, Ann. N.Y. Acad. Sci. 100: 827-39.

Rizki, Rizki, and Bellotti, 1985, Mol. Gen. Genet. 201: 7-13.

Wright, 1987a, Results and Problems in Cell Differentiation (Hennig, ed.), Springer-Verlag, Berlin, Heidelberg, Vol. 14, pp. 95-119.

1987b, Adv. Genet. 24: 127-222.

Pentz, Black, and Wright, 1990, Biochem. Genet. 28: 151-71.

**phenotype:** *tyr1* originally thought to be a structural gene for phenol oxidase (Lewis and Lewis, 1963); the mutant reported to be heat stable relative to wild type, but this differential heat stability in the original mutant strain has not been confirmed (Wright, 1987b). Rizki *et al.* suggest that *tyr1* acts as a regulator of phenol oxidase activity. Mutant homozygotes have about 10% of the phenol oxidase activity of most wild-type strains. 50 h mutant pupae lack activity for the proenzyme PHOX and have detectable but reduced amounts of the diphenol oxidase components A1, A2, and A3 as compared to Samarkand wild-type pupae (Wright, 1987b; Warner, Grell, and Jacobson, 1974, Biochem. Genet. 11: 359-65); result confirmed by Pentz, Black, and Wright, 1987, who also showed that activator preparations from *tyr1* were as efficient as those from wild type (Wright, 1987b). Homozygous *tyr1* adults slightly underpigmented; less so than *qs* which has more phenol oxidase activity. Males (normal or *tyr1*) have three times higher dopamine levels than females (normal or mutant); the mutants (males or females) have 70% normal dopamine levels [Burnell and Daly, 1982, Advances in Genetics, Development, and Evolution of *Drosophila* (Lakovaara, ed.), Plenum Press, New York, pp. 361-70)]. Homozygous viable and fertile. Hemolymph of *tyr1* mutant larvae will turn black but hemolymph from mutant adults will not.

**alleles:** Only one mutant allele identified so far.

**cytology:** Placed in salivary chromosome region 38B3 to 38B6 based on lack of recombinant with *pr* (Pentz *et al.*, 1990); uncovered by *Df(2L)TW150 = Df(2L)37F5-38A1;38B2-C1* which also uncovers *pr* (Huntley, 1978).

**Tyr2: Tyrosine 2 (J.C. Hall)**

**location:** 2-66.3 (between *cn* and *L*; Homyk and Pye, 1989).

**origin:** Spontaneous in *In(2L)Cy* and *In(2R)Cy* or induced by ethyl methanesulfonate.

**discoverer:** H.W. and H.S. Lewis.

**synonym:** *β: beta; Tyrosinase-2*.

**references:** H.W. Lewis, 1962, Biol. Bull. 123: 464.

H.W. and H.S. Lewis, 1963, Ann. N.Y. Acad. Sci. 100: 827-39.

Homyk and Pye, 1989, J. Neurogenet. 5: 37-58.

**phenotype:** *Tyr2/+* heterozygotes show about 50% of the

diphenol oxidase activity of wild-type strains; modifiers involved in this dominant effect. *Tyr2*<sup>P208</sup>, isolated as a recessive light-on/light-off transient-minus mutant by Pak, also affects electroretinograms when in heteroallelic combination with the original *Tyr2* (Homyk and Pye, 1988). *Tyr2* homozygotes also show this ERG defect.

**alleles:** Two alleles, *Tyr2* and *Tyr2*<sup>P208</sup> (the latter not characterized biochemically).

***Tyr3: Tyrosine 3***

**location:** 3- (right arm)

**synonym:** *Tyrosinase-3*.

**references:** H.W. Lewis, 1962, Biol. Bull. 123: 464.

H.W. and H.S. Lewis, 1963, Ann. N.Y. Acad. Sci. 100: 827-39.

**phenotype:** *Tyr3* heterozygotes show 35% of the diphenol oxidase activity of wild-type strains; modifiers involved in this dominant effect.

**UB597**

**location:** 1-55.9.

**origin:** Dysgenic cross of Berlin wild-type (M-cytype) females with Harwich (P-cytype) males (Campos-Ortega).

**references:** Fischbach, Houbé, Boschert, Barleben, and

Gschwander,

1987, J. Neurogenet. 4: 128-29 (abstract).

**phenotype:** Eye mutant. When flies reared in normal light-dark cycle, rhabdomeres are about 40% normal length, not extending down to the basal membrane. Rhabdomeres R7 and R8 are split into two symmetrical halves in nearly all of the ommatidia. The proximal part of the eye is filled with pigment cells. No degeneration of lamina or medulla is observed. When flies are reared in the dark, both rhabdomeres and lamina show the beginnings of disintegration and the pigment cells are swelled.

**UB883**

**location:** 1- (between *y* and *cy*).

**origin:** Dysgenic cross of Berlin wild-type (M-cytype) females with Harwich (P-cytype) males (Campos-Ortega).

**references:** Fischbach, Houbé, Boschert, Barleben, and Gschwander, 1987, J. Neurogenet. 4: 128-29 (abstract).

**phenotype:** Eye mutant. Inner optic chiasma in disorder. Bundles of fibers connecting medulla and lobula plate penetrate neuropil of lobula.

**Ubi: Ubiquitin**

The ubiquitous and highly conserved protein ubiquitin binds to certain proteins within cells, marking them for degradation by various enzymes, and is later released after these proteins have been degraded. The proteins include histone H2A, H2B, and actin. Ubiquitin genes are found in *Drosophila melanogaster* as well as in many eukaryotes from yeast to man. The proteins encoded by these genes may be polypeptides that are later processed into monomeric units or they may be hybrid proteins, each of which is made up of a single unit fused to a nonhomologous tail sequence. Both protein types have been identified in yeast, man, and *Drosophila melanogaster*.

**Ubi-m: Ubiquitin-monomeric**

**location:** 3-.

**synonym:** *UB3-D*.

**references:** Lee, Simon, and Lis, 1988, Mol. Cell Biol. 8: 4727-35.

**phenotype:** Structural gene for ubiquitin (Lee *et al.*, 1988). *Ubi-m* codes for a fusion protein whose single ubiquitin sequence is attached to a tail polypeptide with 65% identity to the yeast ubiquitin tail protein and 82% identity to the human ubiquitin tail protein. Ubiquitin-monomeric is not inducible by heat shock.

**molecular biology:** Gene cloned and nucleotide and deduced amino acids sequences obtained (Lee *et al.*, 1988). The fusion protein is made up of a 76-amino-acid ubiquitin monomer (identical to that of *Ubi-p*) and an 80-amino-acid basic tail polypeptide. *Ubi-m* encodes a 0.9 kb mRNA whose expression is not detectably increased by heat shock.

**Ubi-p: Ubiquitin-polymeric**

**location:** 3- {same map position as an early ecdysone-induced puff; see Ashburner, 1982, Developmental Studies on Giant Chromosomes (Berman, ed.). Springer-Verlag, Berlin, pp. 101-51}.

**synonym:** *polyubiquitin*.

**references:** Lis, Neckameyer, Dubensky, and Costlow,

1981, *Gene* 15: 67-80.

Izquierdo, Arribas, Galcerán, Burke, and Cabrera, 1984, *Biochim. Biophys. Acta* 783: 114-21.

Simon, Sutton, and Lis, 1985, *Chromosoma* 93: 26-30.

Arribas, Sampedro, and Izquierdo, 1986, *Biochim. Biophys. Acta* 868: 119-27.

Lee, Simon, and Lis, 1988, *Mol. Cell Biol.* 8: 4727-35.

**phenotype:** Structural gene for ubiquitin (Arribas *et al.*, 1988); structure and expression described by Lee *et al.* (1988). Threefold increase in level of gene by heat shock. An *Ubi-p-lacZ* fusion gene introduced by germ line transformation has been expressed at high levels at all life stages tested (embryonic, larval, pupal, and adult).

**cytology:** *Ubi-p* has been localized to 63F, previously identified as the early ecdysone and heat-shock puff region (Ashburner, 1972; Lis *et al.*, 1981; Izquierdo *et al.*, 1984; Simon *et al.*, 1985). In the Canton-S strain, the gene contains 18 repeats of a 228-base pair ubiquitin-encoding unit, all arranged in tandem (Lee *et al.*, 1988).

**molecular biology:** Intact *Ubi-p* genes have been cloned. The nucleotide sequences of several monomeric and dimeric repeats have been independently determined (Arribas *et al.*, 1986; Lee *et al.*, 1988). These sequences varied, especially at the third position of the codon. The predicted amino acid sequences of the repeats, however, were identical to those of five of the nine ubiquitin-encoding repeats previously reported. The *Ubi-p* gene encodes a major 4.4 kb mRNA in all tested *in vivo* and *in vitro* *Drosophila melanogaster* cells; the expression of this mRNA is increased by heat shock. The nucleotide sequences of *Ubi-m* and *Ubi-p* are about 83% identical.

**Ubi:** see *RpII215<sup>Ubi</sup>*

**Ubx:** see *BXC*

**uex: unextended**

**location:** 2-55.

**references:** Maeda, 1962, *DIS* 36: 39.

Hilliker, 1976, *Genetics* 83: 765-82.

Maeda, 1984, *Jpn. J. Genet.* 59: 249-57.

**phenotype:** Wings incompletely expanded as in a newly emerged fly, about one-half normal length, and frequently inflated. Tibiae and tarsi of third legs irregularly shortened and gnarled. Posterior scutellars convergent. The rare *uex<sup>2</sup>-uex<sup>7</sup>* hemizygous survivors may also have etched tergites and small bodies.

**alleles:** Original allele found by Maeda, 5813, has not been lost (Maeda, 1984); the six hemizygous late-pupal lethals induced by Hilliker are inferred to be allelic to *uex<sup>1</sup>* on the basis of map position and phenotype.

Krivshenko, 1956, *DIS* 30: 75.

Garen and Kankel, 1983, *Dev. Biol.* 96: 445-66.

**phenotype:** Eyes smaller than normal, surface rough. Hemi- and homozygotes have retinas with slight to moderate disorganization of the ommatidial array, with occasional fused or aberrant ommatidia and missing or condensed rhabdomeres (Garen and Kankel, 1983). There is some variation in the structure of the individual neurons of the optic lobe. Within the retina, *un* behaves in a nonautonomous way as indicated by analysis of genetic mosaics.

**alleles:** The three surviving and three lost alleles are described in the following table:

**unexpanded:** see *unp*

**unexpanded irregular:** see *unr*

**unextended:** see *uex*

**unfolded:** see *uf*

**unp: unexpanded**

**location:** 1-63.1.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 94.

**phenotype:** Wings always unexpanded, frequently droop.

Two symmetrical grooves occur on the pronotum immediately anterior to wing base. Postscutellar bristles often crossed. Eclosion delayed. Male fertile; viability

about 10% normal. Female extremely inviable. RK3.  
**alleles:** One allele each induced by CB. 1356 and X rays.

**unpaired:** see *upd*

**\*unr: unexpanded irregular**

**location:** 1-52.3.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 94.

**phenotype:** Wings usually unexpanded to some degree; if expanded, they are short, broad, and slightly drooping or divergent. Fertility reduced in both sexes. RK3.

*Uo:* see *Uro*

**up: upheld (J.C. Hall)**

**location:** 1-41.0 [between *s* and *g* (Deak *et al.*, 1982)].

**references:** Fahmy, 1958, DIS 32: 77.

Hotta and Benzer, 1972, *Nature (London)* 240: 527-35.

Mogami, Nonomura, and Hotta, 1981, *Jpn. J. Genet.* 56: 51-65.

Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rähmi, Ramp, Reinhardt, and Cotton, 1982, *J. Embryol. Exp. Morphol.* 69: 61-81.

Hall, 1982, *Quart. Rev. Biophys.* 15: 223-479.

Homyk and Emerson, 1988, *Genetics* 119: 105-21.

**phenotype:** Wings held upright and mutants unable to jump or fly when homo- or hemizygous. The indirect flight muscles of the thorax are abnormal, with many mitochondria in the muscle fiber envelopes but with defective myofibrils (Hotta and Benzer, 1972; Deak, 1977); electron microscope and electrophoresis studies indicate that these muscles lack internal structure in the Z-bands and Z-band proteins (Fekete and Szidonya, 1979; Mogami *et al.*, 1981). Although wings are held in normal position, wild-type heterozygotes of certain mutant alleles are unable to jump or fly; their muscles contain half the normal amount of Z-band proteins. Fate maps of the behavioral and morphological foci of *up* and *up*<sup>2</sup> indicate that the gene has its site of action in the presumptive musculature of the ventral mesoderm (Hotta and Benzer, 1972; Deak, 1977). Viability and fertility of *up* is good. RK1.

**alleles:** *up* alleles are listed in the following table. *int*<sup>3</sup> may be an *up* allele since the two genes are close together and do not complement each other, but *int*<sup>3</sup> is not listed in the table because its homozygotes show a different pattern of muscle abnormalities than do *up* homozygotes (Deak *et al.*, 1982; Homyk and Emerson, 1988).

Genet.* 177: 553-65; 9 = Hotta and Benzer, 1972, *Nature (London)* 240: 527-35; 10 = Mogami, Nonomura, and Hotta, 1981, *Jpn. J. Genet.* 56: 51-65; 11 = Vasudev, Krishnamurthy, and Gayathri, 1980, DIS 55: 211.

<sup>β</sup> All mutant flies raised at 29° hold their wings in a vertical position, while 60% of those raised at 18° hold their wings in a ventrolateral position (Deak, 1977); all flies are flightless and have abnormal muscles regardless of temperature. *up*<sup>1</sup> shows more muscle abnormalities than *up*<sup>2</sup>.

<sup>γ</sup> **Synonym:** *wupB*. Flight muscles lack cross-striations (Hotta and Benzer, 1972). "jump" muscle absent or very small. Extracts of indirect flight muscles do not show a 54 kd polypeptide that may be a Z-band component (Deak *et al.*, 1982). Shows electron-dense structures instead of normal Z-bands (Deak *et al.*, 1982).

<sup>δ</sup> **Synonym:** *wupB*<sup>101</sup>. Although allele previously reported as semi-dominant for flightlessness (Homyk *et al.*, 1980), heterozygotes found to be able to hop and fly about as well as wild type (Fekete and Szidonya, 1979; Homyk and Emerson, 1988).

<sup>ε</sup> Semidominant for flightlessness (Homyk and Emerson, 1988).

**cytology:** Located in 12A1-7; between the proximal end of *Df(1)C246 = Df(1)11D-E;12A1-2* and the distal end of *Df(1)HA92 = Df(1)12A6-7;12D3* (Deak *et al.*, 1982), a region thought to be haplolethal since it is not uncovered by known deficiencies (Stewart and Merriam, 1973, DIS 50: 167-70). Although *up*<sup>2/+</sup> females show the dominant flightless phenotype, *up*<sup>2/+/+</sup> females carrying a duplication for 11E-12A can hop and fly as well as wild type (Homyk and Emerson, 1988).

**other information:** Two alleles, *up*<sup>101</sup> and *up*<sup>x</sup>, that show a wild-type flight phenotype as heterozygotes, are flightless when also heterozygous for the wing mutants *hdp* (*hdp-a* and *hdp-b* not distinguished) or *rsd* (Homyk and Emerson, 1988). *up*<sup>2/+;rsd/+</sup> are not only flight-defective, but about 1/3 of them have abnormal wing positions (Deak *et al.*, 1982). *up*<sup>101;Tm2/+;int<sup>3</sup>;Tm2/+</sup>, *up*<sup>x;Tm2/+</sup>, *up*<sup>101;Mhc<sup>5</sup>/+</sup>, and *up*<sup>101;Mhc<sup>16</sup>/+</sup> are lethal. Double heterozygotes involving *up*<sup>101</sup>, *int*<sup>3</sup>, or *up*<sup>x</sup> and *Mhc*<sup>5</sup> cannot fly and have abnormal wing postures. These alleles over *hdp-a*<sup>2</sup> show the same phenotype.

**upd: unpaired**

**location:** 1-58.7.

**origin:** Induced by ethyl methanesulfonate.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 296-307.

**location:** 2- {22}.

**synonym:** *Uo*.

**references:** Friedman and Johnson, 1977, Science 197: 477-79.

Friedman and Barker, 1982, Insect Biochem. 12: 563-70.

Kral, Johnson, Wing, and Friedman, 1982, Dev. Genet. (Amsterdam) 3: 213-15.

**phenotype:** Structural gene for urate oxidase [UO (E.C. 1.7.3.3)], the enzyme involved in the oxidation of uric acid to allantoin. Enzyme confined to the Malpighian tubules and only expressed in third-instar larvae and adults. Rapid decline in urate oxidase activity in late third-instar larvae attributed to the accumulation of 20-hydroxyecdysone for puparium formation; *ecd* larvae, when kept at 29°, fail to accumulate 20-hydroxyecdysone and, unless fed 20-hydroxyecdysone, retain high urate oxidase activity (Kral *et al.*, 1982).

**cytology:** Located in 28C by *in situ* hybridization.

**molecular biology:** Gene cloned (Kral, Johnson, Burnett, and Friedman, 1986, Gene 45: 131-37). Highest concentration of mRNA in third instar larvae; decline in enzyme activity accompanied by disappearance of mRNA. Sequence and expression pattern described by Walbrath, Burnett, and Friedman (1990, Mol. Cell. Biol. 10: 5114-27).

**\*us: undersized**

**location:** 1-52.5.

**origin:** X ray induced.

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 94.

**phenotype:** Body small. Viable and fertile. RK3.

**alleles:** One allele each induced by CB.1506 and CB.1528; two by X rays.

**ush: u-shaped**

**location:** 2-0.1.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(2)19*.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**phenotype:** Embryonic lethal. No shortening of the germ band. Lateral fusion of anterior and posterior hypoderm.

**alleles:** *ush<sup>1</sup>* and *ush<sup>2</sup>*, both strong alleles, recovered as *19* and *Ila*.

**cytology:** Located in 21C since uncovered by *Df(2L)al = Df(2L)21B8-C1;21C8-D1*.

**usp: ultraspiracle (A. E. Oro)**

**location:** 1- {0.5}.

**discoverer:** Lefevre.

**synonym:** *XR2C* (Oro *et al.*, 1990); *Cfl* (Shea *et al.*, 1990).

**references:** Perrimon, Engstrom, and Mahowald, 1984,

Dev. Biol. 105: 404-14.

1985, Genetics 111: 23-41.

Perrimon and Mahowald, 1986, Symp. Soc. Dev. Biol. 44: 221-35.

Henrich, Sliter, Lubahn, MacIntyre, and Gilbert, 1990, Nucleic Acids Res. 18: 4143-48.

Oro, McKeown, and Evans, 1990, Nature 347: 298-301.

Shea, King, Conboy, Mariani, and Kafatos, 1990, Genes Dev. 4: 1128-40.

**phenotype:** Mutants are recessive lethals. *usp/usp* or *usp/γ* progeny of *usp/+* mothers die during the first larval instar or in the molt to the second instar. Those that die during the molt to the second instar sometimes have incompletely molted the first instar set of larval spiracles and thus have two sets of spiracles (Perrimon *et al.*, 1985; Oro, McKeown and Evans, in prep.). *usp/Y* embryos derived from *usp/usp* germ cells die just prior to or just after hatching with an oval scar on the ventral surface of the posterior eighth abdominal or ninth abdominal segment. The spiracles of these animals appear normal as does the rest of the cuticle and the ventral nervous system. Paternally supplied *usp<sup>+</sup>* completely rescues this phenotype and allows survival to adulthood (Perrimon *et al.*, 1985; Oro, McKeown, and Evans, in prep.). Use of a conditional expression system for rescue of the first/second instar lethal phase results in survival into the third instar and early pupal periods, with no animals surviving beyond pupal stage P4 (Oro, McKeown, and Evans, in prep.). *usp/0//usp<sup>+</sup>* gynandromorphs do not survive suggesting that the gene is required in multiple parts of the body and not just in the terminal regions.  $\gamma$ -ray induced *usp/usp* clones survive in the female germline, abdomen, thorax and head, showing that *usp* is not a general cell lethal. Clones in the head are associated with defects in rhabdome and ommatidial morphology (Oro, McKeown, and Evans, in prep.). Expression of a *usp* cDNA at high levels throughout development rescues the *usp<sup>-</sup>* phenotype and has no deleterious effect on *usp<sup>+</sup>*

animals, suggesting that any necessary spatial or temporal regulation of *usp* action occurs by regulation of some other factor such as a ligand.

**alleles:**

<sup>α</sup> 1 = Lefevre; 2 = Oro, McKeown, and Evans, 1990, Nature 347: 298-301; 3 = Perrimon, Engstrom, and Mahowald, 1985, Genetics 111: 23-41.

**cytology:** Placed in 2C1-2D1 since covered by *Dp(1;3)w<sup>vc0</sup>* = *Dp(1;3)2B17-C1;3C5-6* but not by *Dp(1;Y)w<sup>+</sup>303* = *Dp(1;Y)2D1-2;3D3-4* (Perrimon *et al.*, 1970).

**molecular biology:** Cloning and nucleotide and putative amino acid sequencing of the 2C region indicates that the protein product of *usp* (= *XR2C*) is a homologue of the human retinoid X receptor, (Oro *et al.*, 1990). Factors with the same putative DNA-binding domain as *usp* have been cloned and sequenced by Shea *et al.* (1990) and Henrich *et al.* (1990). *usp* produces a single 2.4-kb transcript with higher levels in adults and embryos than in larvae. The colinearity of the cDNA and the genomic DNA indicates that there are no introns. In the mutant *usp<sup>2</sup>*, the coding region has been disrupted by insertion of a 66B-67E fragment from the third chromosome. The structure of the cloned breakpoints of this transposition [*Tp(3;1)usp<sup>4</sup>*] has been determined. The lethal mutants *usp<sup>2</sup>*, *usp<sup>3</sup>*, and *usp<sup>4</sup>* are rescued by germ-line transformation with an 8-kb *EcoR1* fragment carrying the *XR2C* transcription unit, the transformed flies being as viable as wild-type (*usp<sup>+</sup>*) flies (Oro *et al.*, 1990).

**phenotype:** The  $v^+$  gene, expressed in the eyes, fat body, and Malpighian tubules of the wild type (Nissani, 1975, Genet. Res. 26: 63-72), is believed to code for the enzyme tryptophane oxidase (also known as tryptophane pyrrolase)(EC 1.3.11.11), a 150,000 dalton protein that catalyzes the conversion of tryptophane into N-formylkynurenine. The eye color of  $v$  mutants is bright scarlet owing to absence of brown ommochrome; ocelli are colorless. Flies with the mutant combination  $y;w$  have white eyes. The eye color is wild type in genetically  $v$  eyes of gynandromorphs mosaic for wild type and  $v$  tissue (Sturtevant, 1932), indicating the non-autonomous nature of the vermilion gene.  $v$  eye disks develop wild-type pigmentation when transplanted into wild-type larvae (Beadle and Ephrussi, 1936).  $yw$  nuclei from preblastoderm stages implanted into the posterior end of a fertilized  $v;bw$  egg can produce a mosaic fly with brown eyes (Zalokar, 1973, Dev. Biol. 32: 189-93). The diffusible  $v^+$  hormone of Beadle and Ephrussi involved in mosaic and transplantation experiments has been identified as kynurenine (Butenandt, Weidel, and Becker, 1940, Naturwissenschaften 28: 63-64). Activity of the inducible enzyme tryptophane oxidase is absent in  $v$  mutants (Baglioni, 1959, 1960). As a result, nonprotein tryptophane is accumulated in vermilion flies (Green, 1959) rather than converted into N-formylkynurenine and then into formic acid and kynurenine. In mutant larvae tryptophane in the fat body is not converted into kynurenine (Rizki, 1963; Rizki and Rizki, 1968). Certain  $v$  alleles

( $v^l$ ,  $v^2$ , and  $v^k$ ) are suppressed by mutations at the  $su(s)$  locus; these mutants show wild-type eye color, fail to accumulate nonprotein tryptophane, and partially restore tryptophane oxidase activity in spite of the mutation at  $v$  (Schultz and Bridges, 1932; Green, 1952; Baglioni, 1960; Shapard, 1960; Kaufman, 1962; Marzluf, 1965; Tartof, 1969; Jacobson *et al.*, 1982); other  $v$  alleles ( $v^{36f}$ ,  $v^{48a}$ ,  $v^{51a}$ ,  $v^{51b}$ ,  $v^{51c}$ , and  $v^{E1}$ ) show no change in the mutant eye color with these  $su(s)$  alleles and little or no increase in tryptophane oxidase activity (small increase observed in  $su(s) v^{36f}$  flies). Some brown pigment is formed under conditions of partial starvation in suppressed  $v$  mutants (Tatum and Beadle, 1938; Shapard, 1960), but starvation has no effect on unsuppressed  $v$  alleles.

**alleles:** The following table lists wild-type and mutant alleles. The revertants  $v^{+37}$  [Germeraad, 1976, Nature (London) 262: 229-31] and  $v^{36f+}$  (Green) are not described in the table.  $v$  deficiencies are listed as rearrangements.

β Twenty-five alleles; see table in molecular biology.

**cytology:** Left part of the 10A1-2 band between the X breakpoint of  $T(1;Y)BI49 = T(1;Y)10A1-2:YL$  and the proximal break of  $Df(1)v-L4 = Df(1)9F5-6;10A1-2$  (Green, 1954, Proc. Nat. Acad. Sci. USA 40: 92-99; Lefevre, 1969, Genetics 63: 589-60; Zhimulev, Belyaeva, Pokholkova, Kochneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baritcheva, Aizenzon, Kramers, and Eeken, 1982, DIS 58: 210-14). Also located in 10A by *in situ* hybridization (Searles and Voelker, 1986).

**molecular biology:** Gene cloned using the  $v^{H2a}$  allele with a P element insertion (Searles and Voelker, 1986);  $v^+$  allele also cloned. A 1.4 kb transcript is present in  $v^+$  RNA. Mutations that disrupt the wild-type expression of  $v$  are grouped within approximately 2 kb of DNA. Five mutant alleles previously located on the genetic map by fine structure mapping (Schalet, 1971, DIS 46: 135-36; Baillie and Chovnick, 1971, Mol. Gen. Genet. 112: 341-53) have been located on the molecular map of  $v$  (Searles and Voelker, 1986). The suppressible alleles  $v^1$ ,  $v^2$ , and  $v^k$ , inseparable by recombination, appear to be identical insertions of the transposable element 412.  $v^{36f}$ , mapping about 0.7 kb to the right of  $v^1$ , is a *roo* insertion.  $v^{48a}$ , which lies to the left of  $v^{36f}$  on the molecular map, is a 200-bp deletion in the same restriction fragment as  $v^1$ . Base-pair changes were observed in 25 ENU mutants that have been cloned and sequenced (Pastink *et al.*, 1989). The following table summarizes the mRNA and amino acid changes in these mutant alleles:

allele	position	mRNA change	amino acid change
$v^{u101}$	624	GC → AT	gly → ser
$v^{u103}$	365	GC → AT	trp → UGA
$v^{u106}$	58	GC → AT	splice

allele	position	mRNA change	amino acid change
$v^{u107\alpha}$	988	AT → GC	his → arg
	1053	AT → GC	ile → val
$v^{u108}$	1014	GC → AT	arg → cys
$v^{u111}$	1430	GC → AT	asp → asn
$v^{u113}$	372	GC → AT	gln → UAG
$v^{u114}$	838	GC → AT	trp → UAG
$v^{u150}$	1331	GC → AT	ser → asn
$v^{u151}$	1048	AT → CG	ile → ser
$v^{u152}$	468	GC → AT	val → met
$v^{u153\alpha}$	912	AT → TA	lys → UAG
	936	GC → CG	asp → his
$v^{u155\alpha}$	585	GC → AT	asp → asn
$v^{u156}$	224	GC → TA	gln → his
$v^{u158}$	1322	GC → AT	ser → phe
$v^{u159}$	285	GC → AT	his → tyr
$v^{u161}$	207	AT → TA	lys → UAA
$v^{u164}$	1126	GC → AT	ser → leu
$v^{u166}$	1316	AT → GC	leu → pro
$v^{u167}$	1322	GC → AT	ser → phe
$v^{u168}$	796	AT → GC	leu → pro
$v^{u171}$	1017	GC → AT	arg → trp
$v^{u174}$	1117	AT → GC	asp → gly
$v^{u177}$	351	GC → AT	splice
$v^{u185}$	1122	GC → AT	asp → asn

α Two base-pair changes.

**other information:** Hereditary reversion of the eye color of  $v$  mutants to that of wild-type flies by treatment of permeable eggs with DNA (Fox and Yoon, 1970, Proc. Nat. Acad. Sci. USA 67: 1608-15) has been described. Later,  $v^I$  was reverted by microinjection of wild-type DNA (Germeraad, 1976).

**\*Va: Venae abnormeis**

**location:** 2- (not located).

**discoverer:** Timoféeff-Ressovsky.

**references:** 1927, Wilhelm Roux's Arch. Entwicklungsmech. Organ. 109: 70-109 (fig.).

Roelofs, 1937, Genetica 19: 518-36.

**phenotype:** Veins irregularly branched or interrupted. Heterozygote overlaps wild type in 50% of flies. RK3.

**\*vac: vacuolated**

**location:** 1-58.5.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 77.

**phenotype:** Wings blistered; character varies from small vacuole to involvement of entire wing. At least one wing affected in 95% of flies. Viability and fertility good. RK2.

**cytology:** Located in 19E7-8.

**vacuolar pendunculi:** see *vap*

**Vacuolar medulla:** see *Vam*

**vacuolated:** see *vac*

*Vaja:* see *Fs(2)Sz13*

**valois:** see *vls*

**Vam: Vacuolar medulla (J. C. Hall)**

**location:** 1-50.6 (between  $v$  and *f*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Heisenberg and Bohl, 1978, Z. Naturforsch. 34: 143-47.

Coombe, 1984, J. Comp. Physiol. 155: 661-72.

1986, *J. Comp. Physiol.* 159: 655-65.

Coombe and Heisenberg, 1986, *J. Neurogenet.* 3: 135-58.

**phenotype:** Mutants show many vacuoles in the distal part of the medulla. Appearance of vacuoles age-dependent, first appearing in homo- and hemizygotes half an hour after eclosion and occurring in 100% of these mutants after one hour. In older flies, vacuoles are often visible in the lamina and lobula, and occasionally in the central brain. Lamina monopolar neurons L1 and L2 start to degenerate at eclosion and soon afterwards electroretinogram transients disappear. All hemi- or homozygous mutant flies appear nearly blind in tests of movement detection (optomotor response to vertical or horizontal movement and landing response lost). Fixation to a broad stripe has higher light intensity threshold in *Vam* than in wild type (Coombe, 1984). These behavioral defects, but not the anatomical aberrations, have full penetrance (Coombe and Heisenberg, 1986). In heterozygotes, vacuoles make their first appearance in the distal medulla about six days after eclosion and the heterozygous flies show much less lamina degeneration than the homozygotes, the anatomical defects being semi-dominant. Mosaic analysis (Coombe and Heisenberg, 1986) showed the vacuolization to be independent of eye genotype and the degeneration to be sometimes unilateral. Fate mapping leads to a ventral (blastoderm) focus.

**alleles:** Only one mutant allele, isolation number KS74, which is semi-dominant.

**cytology:** Probably located to the right of 13A5 since not uncovered by *Df(1)KA9 = Df(1)12E1;13A5*.

#### **vao: varied outspread**

**location:** 1- {64} (between *lf* and *unc*). Symbol originally used by Fahmy for a mutant (now lost) associated with *In(1)vao* (see CP627); now used for the phenotype shown by *Df(1)A118/Df(1)Q539* females lacking 19E7.

**discoverer:** Fahmy, 1953 (mutant); Schalet and Finnerty, 1970 (deficiency).

**references:** Fahmy, 1959, *DIS* 33: 94.

Schalet and Finnerty, 1970, *DIS* 45: 77.

Schalet, 1972, *DIS* 49: 36-37.

Schalet and Lefevre, 1973, *Chromosoma* 44: 183-202.

Schalet and Lefevre, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 848-902.

Miklos, Healy, Pain, Howells, and Russell, 1984, *Chromosoma* 89: 218-27.

Perrimon, Smouse, and Miklos, 1989, *Genetics* 121: 313-31.

**phenotype:** Wings outspread. Eye color mottled brown. Male sterile. Viability poor.

**alleles:** No point mutations defined yet (Perrimon *et al.*, 1989).

**cytology:** Placed in 19E7 since the heterozygous combination of the overlapping deletions *Df(1)A118 = Df(1)19E4-5;19E7-8* and *Df(1)Q539 = Df(1)19E6;19F6-20A1* reveals the *vao* phenotype (Schalet and Finnerty, 1970; Schalet, 1972; Miklos *et al.*, 1984). Flies with the heterozygous combination of *Df(1)B57 = Df(1)19E1-2;19F1* and *Df(1)Q539* show the *vao* wing and eye abnormalities (plus the *unc* phenotype) at 24° - 25°, but the flies have normal eyes at 17° - 18°

(Schalet, 1972).

#### **vap: vacuolar pedunculi (J. C. Hall)**

**location:** 1-54.2.

**origin:** Induced by ethyl methanesulfonate.

**references:** Heisenberg, 1980, *Development and Neurobiology of Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 373-90.

**phenotype:** Isolated as a neuro-anatomical mutant (Heisenberg and Böhl, 1979, *Z. Naturforsch.* 34: 143-47). Mutant shows vacuolar spaces at a certain depth along the pedunculi of the mushroom bodies as if extrinsic cells are undergoing degeneration. Intrinsic fibers appear continuous. Viability of mutants reduced (Heisenberg).

**alleles:** One allele, isolation number KS67.

**varnished:** see *vr*

#### **vas: vasa (T. Schüpbach)**

**location:** 2- {51}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 302-17.

Nüsslein-Volhard, Frohnhofer, and Lehmann, 1987, *Science* 238: 1675-81.

Hay, Jan, and Jan, 1988, *Cell* 55: 577-87.

Lasko and Ashburner, 1988, *Nature (London)* 335: 611-17.

Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal. Embryos from homozygous mothers exhibit a so-called "grandchildless-knirps" phenotype: all eggs lack polar granules and no pole cells are formed; most of the embryos show large deletions of abdominal segments, whereby anterior parts of segment A1 become fused to posterior parts of segment A8. Telson elements are always present and relatively normal. Eggs have abnormal shape. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, *Dev. Biol.* 113: 443-448). Homozygous *vasa* males cannot be distinguished from wild-type males in viability and fertility.

**alleles:** Seven (*vasa*<sup>1</sup> through *vasa*<sup>7</sup>); isolated as *PD, B5, D1, O11, O14, Q6* and *Q7*.

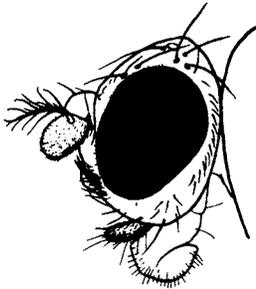

**cytology:** Placed in 35C1-2 on the basis of molecular information (Lasko and Ashburner, 1988); uncovered by *Df(2L)TE35BC-29 = Df(2L)35A3;35C1*, but not by *Df(2L)64j = Df(2L)34D1-2;35B9-C1*, which deletes sequences distal to *vasa*, or by *Df(2L)TE35D-4 [Df(2L)TE116-GW4]*, which deletes sequences proximal to the gene.

**molecular biology:** Gene cloned and the cDNA sequenced (Lasko and Ashburner, 1988; Hay *et al.*, 1988); relatively complex, with seven exons and five small introns between 36 and 70 nucleotides in length and one large intron of 3,700 nucleotides. The major transcript is 2.0 kb long and is found in the female germ line and early

embryos only; it codes for a protein of 650 amino acids. The distribution of this protein is generalized before division, but increases at posterior pole as division proceeds (Ashburner). The predicted amino acid sequence is very similar to that of the murine translation initiation factor eIF-4A and the human nuclear antigen p68 (Lasko and Ashburner, 1988). The amino-terminal region carries five tandem heptad repeats (Hay *et al.*, 1988).

**vb: vibrissae**

**location:** 1-49.3 (Bridges); 1-54.8 (Waddle, Monk, and Williams).  
**discoverer:** Bridges, 25122.  
**phenotype:** Vibrissae form tufts of bristles beneath eyes. Overlaps wild type. RK2.

**vb: vibrissae**

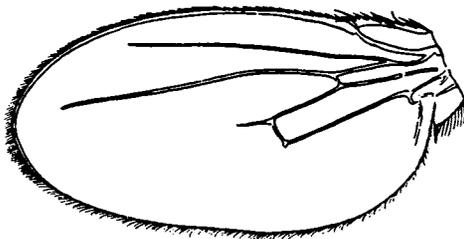

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 212.

**vb<sup>2</sup>**

**origin:** X ray induced.  
**discoverer:** Muller, 261.  
**other information:** Associated with *In(1)sx* (Craymer, 1980, DIS 55: 197-200).

**\*Vc: Vortice**

**location:** Autosomal.  
**origin:** Spontaneous.  
**discoverer:** Smith, 37c20.  
**references:** Novitski, 1937, DIS 8: 10.  
**phenotype:** Enhances *dpldp* to give phenotype like *hy*. Homozygous lethal. RK3.

**ve: veinlet**

From Duncan, 1935, Am. Naturalist 69: 94-96.

**ve: veinlet (E. Bier)**

**location:** 3-0.2; to the right of *ru* (Roberts and Evans-Roberts, 1979, Genetics 93: 663-79; Robertson and Rivera, 1972, DIS 48: 21).

**synonym:** *rho: rhomboid*.

**references:** Duncan, 1935, Am. Nat. 69: 94-96.

 Mayer and Nüsslein-Volhard, 1988, Genes Dev. 2: 1496-1511.  
 Bier, Jan, and Jan, 1990, Genes Dev 4: 190-203.  
 Díaz-Benjumea and García-Bellido, 1990, Wilhelm Roux's Arch. Dev. Biol 198: 336-54.

**phenotype:** Viable alleles exhibit wing venation defects; strong alleles are embryonic lethal. In flies homozygous for viable alleles the L3, L4, and L5 veins do not reach the wing margins (Duncan; Waddington). Developmentally, veins appear complete in prepupa but distal tips are obliterated during the contraction period (Waddington, 1939, 1940). The shortened-vein phenotype is suppressed by *px* (Waddington), *net*, and *su(ve)*, and is enhanced by *vn*, *H*, *Ax*, *ci*, *tg<sup>2</sup>*, and *ri* (Waddington; Díaz-Benjumea and García-Bellido, 1990, Wilhelm Roux's Arch. Dev. Biol 198: 336-54.). Vein-specific modifiers, such as *gp*, (Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 208) or *PL(2)L4a* (Thompson, 1976), interact with the effect of *ve* on L4. The L5 vein seldom extends beyond the posterior crossvein. *ve<sup>2</sup>* is a stronger allele, in which the L2 is also affected (Bertschmann); L2 vein occasionally complete (Thompson, 1976), but other veins do not overlap wild type. Distribution of sense organs (campaniform sensilla and bristles) on L3 is shifted proximally in *ve* (Spivey and Thompson) When a *ve* stock is selected for shortened veins, the F1 produced by mating wild-type males to mutant females show terminal gaps in L5 (Thompson and Thoday, 1976). *ve/ve/+* intersexes are veinlet, whereas *ve/ve/+* triploids are normal, according to Pipkin. Interestingly flies heterozygous for *ve* and strong embryonic lethal alleles display less severe veinlet phenotypes than *ve* homozygotes (Bier *et al.*; Díaz-Benjumea and García-Bellido); furthermore, *ve<sup>1/ve<sup>5</sup></sup>* flies appear wild type (Bier, unpublished). Homozygous *ve<sup>5</sup> embryos exhibit three major types of defects: (1) Dorsoventral defects: Embryos exhibit a deletion of epithelial cells derived from a ventrolateral strip of the blastoderm fate map (i.e., loss of mediolateral cuticular denticles and sensory structures). Other phenotypes resulting from blastoderm patterning defects include failure to complete dorsal closure and development of an abnormal pointed head skeleton (Jürgens *et al.*; Mayer and Nüsslein-Volhard). (2) Midline defects: Mesectodermal cells giving rise to glia and unpaired neurons are abnormal or fail to form. Late developmental consequences include a narrower CNS and pathfinding abnormalities (Mayer and Nüsslein-Volhard). (3) Peripheral-nervous-system defects: Two stretch receptor organs (lateral abdominal chordotonal organs) fail to form in lethal *ve* mutants. The primary chordotonal-organ-precursor cells are likely to be affected since the four progeny sensory-organ cells derived from that precursor cell*

are missing as a group (Bier *et al.*). Other late embryonic defects include loss of longitudinal body-wall muscles, ventrally displaced muscle-attachment sites (Bier *et al.*), and loss of the first row of denticles in abdominal segments (Mayer and Nüsslein-Volhard).

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments

Biol 198: 336-54; 4 = Duncan, 1935, Am. Nat. 69: 94-96; 5 = Mayer and Nüsslein-Volhard, 1988, Genes Dev. 2: 1496-1511; 6 = Waddle and Oster, 1973, DIS 50: 23.

β Transposase induced deletion of *P-lacw* from *ve<sup>4</sup>*.

γ EMS or X rays?

**cytology:** 62A by *in situ* hybridization with a *rho* probe (Bier *et al.*). Also placed in 61B-62D interval on the basis of *ve*'s being covered by *Dp(3;Y)H141 = Dp(3;Y)61B;62D* (Jürgens *et al.*).

**molecular biology:** Genomic clones have been obtained by plasmid rescue of *P-lacw* from *ve<sup>4</sup>* flies (Bier *et al.*). Sequence analysis of cDNA clones corresponding to a 2.5 kb mRNA indicates the mature mRNA is comprised of a 5' noncoding exon and two coding exons. An open reading frame encodes a predicted membrane protein of 355 amino acids. The pattern of *ve* transcription, as monitored by whole mount tissue *in situ* hybridization, correlates well with the spatial requirement for *ve* function: (1) Blastoderm expression includes two longitudinal strips of cells corresponding in location to the domain of the fate map dependent on *ve* function for proper dorso-ventral patterning. Expression in the cells corresponding to head and dorsal cells may also coincide with cells involved in head skeleton formation and dorsal closure. (2) As ventral furrow formation proceeds expression becomes limited to a single row of mesectodermal cells which give rise to the glial and neuronal cells along the ventral midline which are affected in lethal mutant embryos. (3) *ve* is expressed in a single cell per hemisegment at the germband extended stage, which is likely to be the precursor for the chordotonal organs missing in lethal mutants. When the germ band is nearly retracted, *ve* is expressed in rows of cells at the anterior margin of each body segment. This expression may correlate with loss of the first row of denticles in lethal mutants.

**phenotype:** The vestigial locus seems to be mainly involved in the development of the wing margin. The mutants are recessive viable (with or without a visible phenotype), recessive lethal, or dominant (with a visible phenotype over wild type or a *vg* allele); some alleles complement each other; others show pleiotropic effects or homeosis (Bownes and Roberts, 1981). In the classical *vg* mutants, the wings of homozygotes are reduced to vestiges and usually held at right angles to the body, the wing veins still visible. Some mutants have narrow, nicked, or scalloped wings. Halteres may be reduced or absent. Postscutellar bristles are frequently held erect. Viability is somewhat reduced; null mutants are sterile. Temperatures of 29° or greater appreciably increase wing size (Harnly, 1936, *Genetics* 21: 84-103; Stanley, 1935, *J. Exp. Zool.* 69: 459-95). A suppressor of *vg* on the third chromosome, *su(vg)*, results in an almost normal phenotype at 28°, an intermediate *vg* phenotype at 25°, and a strong *vg* phenotype (in wings and especially halteres) under 20° (David, *et al.*, 1970). *vg/+* heterozygotes with certain Minutes show scalloping of the wings (Green and Oliver, 1940; Simpson *et al.*, 1981). *vg/vg/+*

has scalloped wings more often than *vg/+* (Green, 1946). Final size of larva is smaller than in wild type and pupation occurs slightly later. Wing disks of late larva are also somewhat smaller than in wild type (Auerbach, 1936), as are haltere disks (Chen, 1929). Goldschmidt (1935, 1937) claimed that wings are more or less fully formed and subsequently eroded by degeneration during pupation. Waddington (1939, 1940) found no evidence of erosion and concluded that the effect of the gene occurs during the larval period and involves reduction in size of prospective wing area and shift in position of line along which wing area is folded out from the imaginal disk. Fristrom (1968, 1969), however, using both light and electron microscopy, found numerous degenerating cells in the presumptive wing blade region of the *vg* wing disks, as did Bryant and Girton (1980), Bownes and Roberts (1981a, 1981b), James and Bryant (1981), and O'Brochta and Bryant (1983). Duplications of the mesonotum along with deficiencies of wing disk material occur in a small percentage of *vg* mutants (Girton and Bryant, 1980; James and Bryant, 1981).

**vg<sup>1</sup>: vestigial**

From Bridges and Morgan, 1919, *Carnegie Inst. Wash. Publ.* No. 278: 148.

**vg<sup>no</sup>: vestigial-notched**

From Mohr, 1932, *Proc. Intern. Congr. Genet.* 6th Vol. 1: 190-212.

alleles: Mutant *vg* alleles are listed in the following tables. *vg* deficiencies are described in the rearrangement section.

Table I

symbol	name	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>vg</i> <sup>1</sup>	vestigial	spont	Morgan, 101	<i>vg</i> <sup>BG</sup>	2, 5, 7, 8, 38-40, 45-47	wings, halteres reduced; small wing disks
* <i>vg</i> <sup>2</sup>		spont	Ward, 1920		43	wings, halteres absent or reduced to knobs; low viability; females and males (usually) sterile
* <i>vg</i> <sup>11</sup>		X ray	Ruch, 1931		26	wings, halteres smaller than in <i>vg</i> <sup>1</sup> ; some wing nicks in <i>vg</i> <sup>11</sup> /+; fertile
<i>vg</i> <sup>12</sup>		γ ray	Lasko	<i>vg</i> <sup>82h10</sup>	18, 45-46	like <i>vg</i> <sup>1</sup> ; <i>vg</i> <sup>12</sup> /Df inviable
<i>vg</i> <sup>17</sup>		EMS	Lasko	<i>vg</i> <sup>82E28</sup>	18	like <i>vg</i> <sup>1</sup>
<i>vg</i> <sup>18</sup>		γ ray	Lasko	<i>vg</i> <sup>82h11</sup>	18, 45	like <i>vg</i> <sup>1</sup>
<i>vg</i> <sup>21</sup>		HD			45-48	cytotype-dependent allele; homozygote normal; weak <i>vg</i> over <i>vg</i> <sup>1</sup>
* <i>vg</i> <sup>33k</sup>		spont	Ives, 33k30		30, 31	like <i>vg</i> <sup>No1</sup>
<i>vg</i> <sup>34</sup>		EMS	Lasko	<i>vg</i> <sup>82h15</sup>	18	like <i>vg</i> <sup>1</sup>
* <i>vg</i> <sup>37g</sup>		spont	Poulson, 37g		32, 33	weak allele; slight nick in wing; P higher in male
* <i>vg</i> <sup>40b</sup>		spont	Ives, 40b		15	like <i>vg</i> <sup>1</sup> ; <i>vg</i> <sup>1</sup> /+ semidominant for <i>vg</i>
* <i>vg</i> <sup>40c</sup>		spont	Buzzati-Traverso, 40c20		6	like <i>vg</i> <sup>1</sup>
* <i>vg</i> <sup>48a</sup>		spont	King, 48a1		34	15% of homozygotes have wing nicks; halteres and post-scutellars normal;
<i>vg</i> <sup>51h25</sup>		spont	Ives, 51h25		16, 39, 45	<i>vg</i> <sup>1</sup> / <i>vg</i> <sup>51h25</sup> show wing scallops
<i>vg</i> <sup>67d1</sup> - <i>vg</i> <sup>85f3</sup>		like <i>vg</i> <sup>1</sup>	but wings larger			see Table II
<i>vg</i> <sup>72a</sup>		spont			41	like <i>vg</i> <sup>1</sup>
<i>vg</i> <sup>79f</sup>		spont	Ashburner		1	like <i>vg</i> <sup>1</sup>
<i>vg</i> <sup>168</sup>		spont			45	recessive lethal
* <i>vg</i> <sup>a</sup>	vestigial- antlered	spont	Morgan, 12j		25	wings long, but narrow and scalloped; halteres and post-scutellars normal;
* <i>vg</i> <sup>Cli</sup>	vestigial- Clipped	spont	Robertson, Reeves, 1947		3	wings straplike and smaller in females female sterile; no eggs
* <i>vg</i> <sup>dn</sup>	vestigial- double notch	spont	Nolte, 1942		29	two notches on wing; halteres, postscutellars normal; <i>vg</i> <sup>dn</sup> / <i>vg</i> <sup>1</sup> has straplike wings
<i>vg</i> <sup>E7</sup>		(from <i>vg</i> <sup>1</sup> ) EMS			7	normal as homozygote; <i>vg</i> <sup>E7</sup> / <i>vg</i> <sup>1</sup> straplike wings
* <i>vg</i> <sup>h</sup>	vestigial- hemithorax	spont	Ludwig, 1936		19, 20, 37	20% show hemithorax; most mutants like <i>vg</i> <sup>1</sup> , 10-20% like <i>vg</i> <sup>nw</sup>
* <i>vg</i> <sup>hR</sup>	vestigial- hemithorax of Reck	spont	Reck, 1937		35	like <i>vg</i> <sup>h</sup> ; <i>In(2R)49C1-2;50C1-2</i>
<i>vg</i> <sup>ms</sup>	vestigial- more sensitive		Nakashina- Tanaka, 1967		28	small wings at 25°, normal at 27-30°
* <i>vg</i> <sup>n</sup>	vestigial- nick	spont	Bridges, 15h7		25	homozygote normal; <i>vg</i> <sup>n</sup> / <i>vg</i> <sup>1</sup> shows nicks in 85% of females, 45% of males
<i>vg</i> <sup>nG</sup>	vestigial- nick of Green	spont	Green, 40j26		11, 12	homozygote normal (occasional wing nicks); enhanced by Minutes; <i>vg</i> <sup>nG</sup> / <i>vg</i> <sup>1</sup> has scalloped wings
<i>vg</i> <sup>ni</sup>	vestigial- nick of Green	spont	Mohr, 1926		10, 12, 24, 38, 45	homozygote normal; enhanced by Minutes; 1/4 of <i>vg</i> <sup>ni</sup> / <i>vg</i> <sup>1</sup> show wings nicks
<i>vg</i> <sup>ni2</sup>		spont	Mohler, 55b9		23	homozygote normal; nicks or scalloping in heterozygotes over <i>vg</i> <sup>1</sup> , <i>vg</i> <sup>nw</sup> , <i>vg</i> <sup>nwl</sup>
<i>vg</i> <sup>no</sup>	vestigial- notched	spont	Mohr, 1926		24	homozygote notched (45%); <i>vg</i> <sup>no</sup> /+ normal; <i>vg</i> <sup>no</sup> / <i>vg</i> <sup>1</sup> has ragged wings (100%)
* <i>vg</i> <sup>No1</sup>	vestigial- Notch	heat- treatment of parents	Swigert, 31c	<i>vg</i> <sup>31c</sup>	30, 31	homozygote shows vestiges of wings; postscutellars erect; viability 50%; female sterile; terminal nicks in <i>vg</i> <sup>No1</sup> /+ like <i>vg</i> <sup>No1</sup> ; <i>vg</i> <sup>No2</sup> /+ enhanced by Minutes; lethal over <i>vg</i> <sup>nw</sup>
<i>vg</i> <sup>No2</sup>		spont	Plough, 31j	<i>vg</i> <sup>31j</sup>	7, 12, 30, 31, 38, 40, 45	
<i>vg</i> <sup>np</sup>	vestigial- nipped	spont	Wallace, 38a5		7, 10, 38, 39, 42, 45, 46	terminal incisions in wings; overlaps wild type at 25°, not at 19°.
<i>vg</i> <sup>nw</sup>	vestigial- no wing	spont	Morgan, 1924		7, 8, 24, 27, 38, 40, 45, 46	Wing buds show scalloping. tiny knobbed wings and halteres, erect postscutellars; low viability; female usually sterile; occasional wing nicks in <i>vg</i> <sup>np</sup> /+; also shortened L2 vein in <i>vg</i> <sup>np</sup> /+; small wing buds
* <i>vg</i> <sup>nwl</sup>	vestigial-	spont	Mohler, 55b9		23	homozygous lethal; <i>vg</i> <sup>nwl</sup> / <i>vg</i> <sup>nw</sup> like <i>vg</i> <sup>nw</sup> ,

THE GENOME OF *DROSOPHILA MELANOGASTER*

symbol	name	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>vg<sup>P</sup></i>	no wing lethal vestigial-pennant	spont (from <i>vg<sup>I</sup></i> )	Kerr, 30a15		13, 14	sterile; <i>vg<sup>nwI</sup>/+</i> has wing nicks (50%) homozygotes usually normal; <i>vg<sup>P</sup>/vg<sup>I</sup></i> has narrow straplike wings, larger in male (temperature-sensitive)
* <i>vg<sup>PK</sup></i>	vestigial-pennant of Kutschera	spont (from <i>vg<sup>I</sup></i> )	Kutschera, 1955		21, 22	homozygote normal (17°-28°); <i>vg<sup>PK</sup>/vg<sup>I</sup></i> has small wings at 17°, straplike wings at 25°, normal at 30°.
* <i>vg<sup>R1</sup></i>		γ ray	Lasko		18	like <i>vg<sup>I</sup></i>
* <i>vg<sup>S</sup></i>	vestigial-strap	spont (from <i>vg<sup>I</sup></i> )	Morgan, 12d		25	wings narrow, straplike, full length, held at right angles; halteres reduced; postscutellars normal.
* <i>vg<sup>S2</sup></i>		spont	Williams, 56c		44	wings incised, narrow, of variable length.
<i>vg<sup>Uβ</sup></i>	vestigial-Ultra	γ ray	Ives, 55131		17, 39 45, 46	homozygous lethal; dominant; <i>vg<sup>U</sup>/+</i> has much reduced wings and halteres; <i>vg<sup>U</sup>/vg<sup>I</sup></i> has tiny wings, no halteres
<i>vg<sup>Wγ</sup></i>	vestigial-wingless	X ray	Shukla		4, 36 45, 46 49	homozygous lethal; dominant with homeotic effect; <i>vg<sup>W</sup>/+</i> is wingless or has tiny buds, no halteres (or one); female fertile and viable; <i>In(2R)47F15-48A12;49E4-5</i> (Ashburner)
<i>vg<sup>X</sup></i>		γ ray	Erk, Podraza, 1986		9	wings, halteres tiny knobs (sometimes halteres absent); postscutellars erect; defects in legs, abdominal tergites, notum; female sterile; notching or scalloping in heterozygotes.

$\alpha$  Reference for all alleles: Alexandrov and Alexandrova, 1987, DIS 66: 185-87. Other information: Cf = caffeine; AD = actinomycin-D; bristles = postscutellars.

$\beta$  Wings classified according to similarity to known alleles; for halteres and postscutellar bristles, "-" = absence and "+" = presence; under fertility, "-" = sterile, sex unspecified, but probably female.  
 $\gamma$  Other references: Williams and Bell, 1988, EMBO J. 7: 1355-63; Williams, Pappu, and Bell, 1988, Mol. Cell Biol. 8: 1489-97; Williams, Atkin, and Bell, 1990, Mol. Gen. Genet. 221: 8-16.

**cytology:** Placed in 49D2-E1 based on breakpoints common to rearrangements in Table II.

**vestigial molecular map**  
(modified from Williams and Bell, 1988 by D. Conner). Heavy lines represent deficiencies; hatched line represents an inverted segment accompanying *Df(1)vg136*.

**molecular biology:** The vestigial region has been cloned by *P* element transposon tagging (Williams and Bell, 1988). Transcript of 3.8 kb obtained (Williams, Atkin, and Bell, 1990). The proximal breakpoints of *In(2R)vg<sup>U</sup>* and *In(2R)vg<sup>W</sup>* were located at 49D-F by *in situ* hybridization of salivaries. Alleles placed on the molecular map of the *vg* region derived from Oregon-R are listed in the

following table:

alleles	map location (kb) $\alpha$	comments
<i>vg<sup>1</sup></i>	+8	412 insertion (8 kb)
<i>vg<sup>12</sup></i>	+3	insertion (8 kb)
<i>vg<sup>18</sup></i>	+8	412 insertion (8 kb)

$\alpha$  "-" values to left (proximal), "+" values to right (distal); 0 coordinate assigned to insert position of *vg<sup>21</sup>*.  
 $\beta$  Fusion between *mam* and *vg* (second intron) (Williams *et al.*, 1990).  
 $\gamma$  Fusion between *inv* and *vg* (first intron) (Williams *et al.*, 1990).

**Vi:** see *M(1)1B*

**Viability:** see *M(1)1B*

**vibrissae:** see *vb*

**vin:** *vin*

**location:** 3-36.3 (not allelic to *rs<sup>2</sup>*).

**origin:** Spontaneous.

**discoverer:** Periquet, 72c.

**references:** Anxolabehere and Periquet, 1973, DIS 50: 21.

Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25.

Ashburner, Richards, and Velissariou, 1980, DIS 55: 196.

**phenotype:** Eye color reddish brown, paler in young flies.

Eyes become dark brown with age. *v;vin* flies have pale orange eyes. Ocelli, adult testis sheath, and Malpighian tubules colored. Viability and fertility excellent. RK1.

**alleles:** Five alleles described in the following table. Deficiencies for *vin* listed in the rearrangement section.

allele	origin	discoverer	ref $\alpha$	comments
<i>vin<sup>1</sup></i>	spont	Periquet	2	
<i>vin<sup>18</sup></i>	X ray		1	
<i>vin<sup>101</sup></i>	$\gamma$ ray		1	lethal; <i>T(Y;3)87F12-14</i>
<i>vin<sup>123</sup></i>	$\gamma$ ray		1	
<i>vin<sup>M</sup></i>	$\gamma$ ray		1	

$\alpha$  1 = Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25; 2 = Anxolabehere and Periquet, 1973, DIS 50: 21.

**cytology:** Located in 68C8-68D3 (Ashburner *et al.*, 1980); included in *Df(3L)vin6 = Df(3L)68C8-11;69A4-5* and *Df(3L)vin66 = Df(3L)68A3;68D3*.

**vlr:** *virilizer*

**location:** 2-103.3.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Schüpbach.

**references:** Amrein, Gorman, and Nöthinger, 1988, Cell 55: 1025-35;

Hilfiker, Amrein, and Nöthiger, 1988, Crete.

**phenotype:** A new undescribed gene involved in sex determination. Female sterile; may be temperature sensitive.

**alleles:** Six alleles, including *vir*<sup>250</sup>, *vir*<sup>H2</sup>, *vir*<sup>ts</sup>.

**cytology:** Placed in 59D2-8.

**molecular biology:** Region cloned.

**Vitelline membrane:** see *Vm*

**\*vli: veins longitudinally shortened**

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Buchman, 1936.

**references:** 1937, DIS 8: 8.

**phenotype:** Veins L2, L4, and L5 tend to be shortened. Overlaps wild type. Semidominant. RK3.

**vls: valois (T. Schüpbach)**

**location:** 2-53.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 302-17.

Nüsslein-Volhard, Frohnhofer, and Lehmann, 1987, Science 238: 1675-81.

Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal. Embryos from homozygous mothers exhibit a so-called "grandchildless-knirps" phenotype: all eggs lack polar granules and no pole cells are formed; most of the embryos show variable deletions of abdominal segments; whereby segment A4 is deleted most frequently, larger deletions may remove segments A2 through A7; in extreme cases anterior parts of segment A1 become fused to posterior parts of segment A8, but telson elements are always present and relatively normal. In addition, 80-90% of the embryos fail to cellularize normally at the blastoderm stage and die without forming cuticle, or only fragmented pieces of cuticle. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48).

**alleles:** *vls*<sup>1</sup>-*vls*<sup>4</sup> isolated as *RB*, *PE*, *PG*, *HC*.

**cytology:** Placed in 38A6-E9 based on its inclusion in *Df(2L)TW2* = *Df(2L)37D2-E1;38E6-9*, but not *Df(2L)TW50* = *Df(2L)36E4-F1;38A6-7*.

**Vm: Vitelline membrane**

The *Vm* genes make up a multigene family that includes at least four members and is responsible for encoding the major proteins of the first layer of the *Drosophila* eggshell, the vitelline membrane. These proteins are synthesized during the later stages of oogenesis in the follicular epithelium of mature ovaries. The following table describes the four vitelline membrane genes that have been identified and described.

gene	location	synonym	ref <sup>α</sup>	cytology <sup>β</sup>	comments	
					mRNA	protein
<i>Vm26Aa</i> <sup>γ</sup>	2- {20}	<i>Vm23</i>	1, 3-7	26A	700-800 bp	17.5 kd
<i>Vm26Ab</i> <sup>γδ</sup>	2- {20}		3-5	26A	700-800 bp	23 kd

<i>Vm32Ec</i> <sup>ε</sup>	2- {44}		2	32E	430 bp	13kd
<i>Vm34Ca</i>	2- {47}	<i>Vm2</i>	4, 7	34C	650 bp	

<sup>α</sup> 1 = Burke, Waring, Popodi, and Minoo, 1987, Dev. Biol. 124: 441-50; 2 = Gigliotti, Graziani, De Ponti, Rafti, Manzi, Lavorgna, Gargiulo, and Malva, 1989, Dev. Genet. 10: 33-41; 3 = Higgins, Walker, Holden, and White, 1984, Dev. Biol. 105: 155-65; 4 = Mindrinos, Scherer, Garcini, Kwan, Jacobs, and Petri, 1985, EMBO J. 4: 147-53; 5 = Popodi, Minoo, Burke, and Waring, 1988, Dev. Biol. 127: 248-56; 6 = Savant and Waring, 1989, Dev. Biol. 135: 43-52; 7 = Scherer, Harris, and Petri, 1988, Dev. Biol. 130: 768-88.

<sup>β</sup> Determined by *in situ* hybridization to the salivaries (Higgins *et al.*, 1984; Mindrinos *et al.*, 1985; Burke *et al.*, 1987; Gigliotti *et al.*, 1989). *fs(2)QJ42*, a mutant of *Vm26Ab*, was mapped cytologically to 25D-26A by using the chromosome *Df(2L)c17 = Df(2L)25D7-E1;26A7-8* (Savant and Waring, 1989).

<sup>γ</sup> Single long open reading frame; no introns. Transcription occurs from opposite DNA strands in the two genes at 26A (Popodi *et al.*, 1988).

<sup>δ</sup> 10- to 15-fold reduction in transcript level in the mutant *fs(2)QJ42*. This mutant can be rescued by germline transformation with *Vm26Ab*<sup>+</sup> and restored to normal production of vitelline membrane protein and female fertility (Popodi *et al.*, 1988).

<sup>ε</sup> Uninterrupted open reading frame (Gigliotti *et al.*, 1989).

**molecular:** The vitelline membrane genes listed in the table have been cloned and their nucleotide and predicted amino-acid sequences determined (Mindrinos *et al.*, 1985; Burke *et al.*, 1987; Popodi *et al.*, 1988; Scherer *et al.*, 1988; Gigliotti *et al.*, 1989). Clones show cross-hybridization (Mindrinos *et al.*, 1985). High abundance, ovary-specific transcripts have been obtained, but only during vitelline membrane synthesis in adult females in stages 9 and 10 of oogenesis (Higgins *et al.*, 1984; Mindrinos *et al.*, 1985; Gigliotti *et al.*, 1989). A central 114 bp conserved region (the *Vm* domain) occurs in the coding region of three and probably four of these genes (Scherer *et al.*, 1988). At the nucleic acid level, this conserved region shows the following sequence identities: 91% between *Vm26Aa* and *Vm34C*, 79% between *Vm26Ab* and *Vm34C*, and 77% between *Vm26Aa* and *Vm26Ab*. *Vm26Aa* and *Vm34C* show 100% amino acid identity in the VM domain, but *Vm26Ab* and *Vm34C* show only 86% amino acid identity (Scherer *et al.*, 1988). These three *Vm* genes as well as *Vm32E*, which contains at least a portion of the VM domain (Scherer *et al.*, 1988), encode translation products with the high proline and alanine content characteristic of vitelline membrane proteins (Mindrinos *et al.*, 1985; Gigliotti *et al.*, 1989).

**vn: vein**

**location:** 3-16.2.

**origin:** X ray induced.

**discoverer:** Puro, 1960.

**references:** 1982, DIS 58: 205-08.

Díaz-Benjumea, González-Gaitán, and García-Bellido, 1989, Genome 31: 612-19.

**phenotype:** Large section of vein L4 and anterior crossvein missing. Posterior crossvein often incomplete; gap sometimes present in L3. Male sterile, female fertile.

**alleles:** Six (Díaz-Benjumea *et al.*, 1989).

**other information:** Not tested for allelism with *Vn*, a dominant mutant of similar map position and phenotype which has been lost.

**\*Vn: Vein**

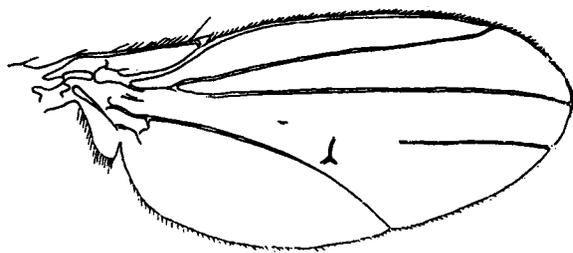

**location:** 3-19.6.

**origin:** Spontaneous.

**discoverer:** Mohr, 28j21.

**references:** 1932, Proc. Intern. Congr. Genet., 6th., Vol. 1: 190-212.

1938, Avh. Nor. Vidensk.-Akad. Oslo, Mat. Naturvi-

vn: vein

Right wing of *vn* (Puro, 1982)

densk. Kl. 4: 1-7.

Mohr and Mossige, 1942, Avh. Nor. Vidensk.-Akad. Oslo, Mat. Naturvidensk. Kl. 7: 1-51.

**phenotype:** Vein L4 not complete. Wings slightly spread. Fly smaller than normal. Homozygous lethal. RK2A.

**cytology:** Associated with *Df(3L)vn = Df(3L)64C12-D1;65D2-E1*.

**vnd: ventral nervous system defective**

**location:** 1-0.0.

From Evang, 1925, Z. Indukt. Abstamm. Vererbungsl. 39: 165-83.

### **vss: variable size and shape**

**location:** 3-.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Nüsslein-Volhard.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal effect female-sterile. Produces eggs of variable size and shape.

**alleles:** *vss*<sup>1</sup> and *vss*<sup>2</sup> isolated as 258 and 2675.

### **\*vst: vestar**

**location:** 2-4.3.

**discoverer:** Glass, 41i15.

**references:** 1944, DIS 18: 40.

**phenotype:** Wings small and straplike, variable. Eyes small, very rough, and somewhat glazed. Female sterile. Viability low. RK3.

### **vt: verticals**

**location:** 1-2.3.

**origin:** Synthetic.

**discoverer:** Gersh.

**references:** 1965, Genetics 51: 477-80.

**phenotype:** Anterior vertical, anterior dorsocentral, and anterior scutellar bristles often missing, verticals being most likely to be affected. RK2.

**cytology:** Placed in 3C5-6 on the basis of the *vt* phenotype of the following genotypes: *Df(1)rst*<sup>2</sup> = *Df(1)3C3-4;3C6-7*; the heterozygote between *Df(1)rst*<sup>2</sup> and the synthetic deficiency for 3C5 and 6 produced by combining the 4<sup>P</sup>*X*<sup>D</sup> element of *T(1;4)w*<sup>258-18</sup> = *T(1;4)3C4-5;101* and the *X*<sup>P4</sup><sup>D</sup> element of *T(1;4)N*<sup>264-12</sup> = *T(1;4)3C6-7;101F*; and the synthetic deficiency for 3C5 and 6 produced by combining the 4<sup>P</sup>*X*<sup>D</sup> element of *T(1;4)w*<sup>258-18</sup> with a recombinant between *In(1LR)l-v139* = *In(1LR)3C6-7* and the right end of a normal *X* chromosome.

**other information:** Not known as a point mutation.

### **vtd: verthandi (J.A. Kennison)**

**location:** 3-46.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1983.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Recessive. Suppresses extra sex combs in *Pc*<sup>4/+</sup> male flies.

**alleles:**

allele	origin
*vtd <sup>1</sup>	EMS
vtd <sup>2</sup>	EMS
vtd <sup>3</sup>	γ ray
vtd <sup>4</sup>	γ ray
vtd <sup>5</sup>	γ ray

### **vtw: vertical wing (J.C. Hall)**

**location:** 1-18 (between *cv* and *sn*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Butler.

**references:** Deak, 1977, J. Embryol. Exp. Morphol. 40: 35-63.

Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rähmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81.

**phenotype:** Flightless, with a penetrance of 85-100%; cannot jump more than 2 cm. Wings held up vertically (penetrance 63-90%). In some flies, large amount of disorganized fibrillar muscle material present in the thorax; in others, most of the fibrillar muscles are absent (Deak *et al.*, 1980). Both dorsal longitudinal muscles (DLMs) and dorsoventral muscles (DVMs) are reduced; in the electron microscope, myofibrillar structure appears disorganized and Z-band structure disturbed (Deak *et al.*, 1982), although the indirect flight muscle fibers that do

form are superficially normal. The abnormal behavioral and muscular phenotypes are thought to be due to a primary defect in embryonic cells that map (in mosaic experiments) to the dorsal region of the blastoderm. Viability of mutant alleles is about 95% (Deak, 1977).

**alleles:** Two recessive alleles, *vtw*<sup>1</sup> (stronger allele) and *vtw*<sup>2</sup> (weaker allele). Penetrance of flightless phenotype 100% for *vtw*<sup>1</sup>, 85% for *vtw*<sup>2</sup>; penetrance of vertical wing phenotype 90% for *vtw*<sup>1</sup>, 63% for *vtw*<sup>2</sup> (Deak, 1977).

***vvl*: ventral veins lacking**

**Location:** 3- (rearranged).

**references:** Díaz-Benjumea, González-Gaitán, and García-Bellido, 1989, Genome 31: 612-19.

**phenotype:** Prevents differentiation of longitudinal veins 2 and 4 which form on the ventral surface of the wing; in *Hw*; *vvl* flies, extra sensillae form in the ventral surface where veins would ordinarily form.

**alleles:** Three.

**phenotype:** The white locus is involved in the production and distribution of ommochrome (brown) and pteridine (red) pigments found in the compound eyes and ocelli of adult flies as well as the pigments in adult testis sheaths and larval Malpighian tubules; the specific function of the protein it encodes is still unknown, but it is believed to be a membrane-associated ATP-binding transport protein for pigment precursors in both the ommochrome and pteridine pathways (Sullivan and Sullivan, 1975; Mount, 1987; Dreesen *et al.*, 1988; Tearle *et al.*, 1989).  $w^1$  was the first mutant found in *Drosophila melanogaster* (Morgan, 1910; Morgan and Bridges, 1916). Mutant alleles do not appreciably affect the viability and fertility of the flies. Extreme white alleles as well as white deficiencies remove both brown and red pigments, the  $w^1$  allele having very little, if any, pteridine (Hadorn and Mitchell, 1951); isoxanthopterin is present in considerable quantity during pupation but is eliminated during the first three days of adult life (Hadorn, 1954, *Experientia* 10: 483-84). Hypomorphic alleles are visibly lighter in combination with  $w^1$  than when present as homozygotes. Intermediate white alleles result in partial loss of ommochromes and pteridines; some alleles also affect the distribution of these pigments in the compound eyes (Lewis, 1956; Green, 1959a, 1959c). Although the mutants are positively phototactic, they show no optomotor responses (Kalmus, 1943, *J. Genet.* 45: 206-13). Wild-type alleles are incompletely dominant over mutant alleles,  $w/w^+$  heterozygotes, though visibly indistinguishable from  $w^+/w^+$ , have less red pigment (Muller, 1935; Ziegler-Günder and Hadorn, 1958; Green, 1959b). Mutant larval

disks transplanted into wild-type host develop autonomously (Beadle and Ephrussi, 1936).

Early genetic studies identified mutations separable by intralocus recombination into at least seven groups spanning 0.03 cm (Lewis, 1952; MacKendrick and Pontecorvo, 1952; Green, 1959a; Judd, 1959). Mutants occupying the centromere-proximal sites apparently play a regulatory role (Judd, 1976). Subsequent molecular analysis has localized the proximal mutations to the 5' end of the transcription unit ( $w^e$ ) and the upstream flanking sequences ( $w^{sp}$ ) (Judd, 1987). Mutations at the distal sites have been mapped to the protein coding exons and the introns between them. The proximally-located regulatory mutants ( $w^e$ , for example) do not show dosage compensation; they suppress the *zeste* gene, and some of them (the  $w^{sp}$  alleles) affect the distribution of the red and brown screening pigments of the eyes. Most of the distally-located structural mutants show dosage compensation,  $w^a/Y$  males having the same eye color as  $w^a/w^a$  females, and do not suppress (but may interact with) *zeste*. Green (1959a) found that  $w^i$  fails to show dosage compensation and does not suppress *zeste*; but  $w^h$  exhi-

bits both *zeste* suppression and dosage compensation. In spite of their heterogeneity, the alleles at the white locus fail to complement each other except for  $w^{sp}$  which partially complements all other  $w$  alleles except in the presence of  $z^a$  [Babu and Bhat, 1980, *Development and Neurobiology of Drosophila*, (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 35-40)]. Some white alleles ( $w^c$  for example) are extremely unstable (Green, 1976);  $w^l$  is slightly unstable, giving rise to  $w^e$  and  $w^h$ , mutants with darker eyes than  $w^l$ . The locus is characterized by asymmetrical recombination involving transposons; the mutants  $w^{r.def}$  and  $w^{r.dup}$  are the result of such exchange (Davis *et al.*, 1987). Some *P*-element white transformations show reproducible patterns of pigmentation which can be altered by the trans-acting gene *zeste* (Rubin *et al.*, 1985).

**alleles:** Mutant and wild-type  $w$  alleles are tabulated below. Deficiencies are described in the rearrangement section. The first table includes alleles believed to be extant, the second alleles known to be lost. See end of text for more detailed description of certain alleles.

- β Heteroalleles with  $w^{sp}$  have brown eyes at eclosion, complementing  $w^{sp}$ ; eyes somewhat darker after 4-5 days.  
 γ Heteroalleles with  $w^{sp}$  have yellow-orange, orange, or orange-brown eyes at eclosion; mottling only on first day.  
 δ Heteroalleles with  $w^{sp}$  usually have orange-brown eyes at eclosion; mottling almost gone after first day; eyes slowly darken.  
 ε Heteroalleles with  $w^{sp}$  have yellow eyes at eclosion, usually with mottling; eyes become orange after 4-5 days, but not brown.

**cytology:** Placed in 3C2 by Schultz and also by Lefevre and Wilkins (1966, *Genetics* 53: 175-987) on the basis of rearrangement breakpoints [ $In(1)w^4 = In(1)3C1-2;20F$ , for example]. An electron microscope study of  $In(1)z^{+64b9} = In(1)3C1-2;12B9-10$  shows a faint band to the right of 3C1 consisting of the leftmost border of 3C2 plus material from 12B9 [Sorsa, Green, and Beerman, 1973, *Nature (London) New Biol.* 245: 34-37]; this band is not seen in most preparations of normal chromosomes. Judd (1976, 1987) suggests that  $w^+$  is located in a very small band between 3C1 and 3C2. Goldberg *et al.* (1982) showed that the 3C1-2 break of  $In(1)z^{+64b9}$  is proximal to the white locus on the molecular map (about 10 kb to the right of the  $w^a$  insertion of *copia*).

**molecular biology:** The  $w^a$  allele was the first gene cloned by "transposon tagging", using previously cloned transposing element *copia* (Bingham *et al.*, 1981). The  $w^a$  clone was extended on both sides by chromosome walking and a segment of 14 kb was found to contain all of the white locus sequences essential to the  $w^+$  eye-color phenotype (Levis *et al.*, 1982). The white locus was also cloned by Goldberg *et al.* (1982), using a large TE containing  $w^a$  and *rst* inserted at 87A7 next to previously cloned sequences (genes encoding *Hsp70*). Pirrotta *et al.* (1983) later cloned white by microdissection of the 3C2 region of the salivary chromosomes.

A physical map of the white locus was prepared after cleaving DNA from various mutants with restriction endonucleases (Levis *et al.*, 1982; Goldberg *et al.*, 1982); transcripts were identified, the major one being a 2.6 kb poly-(A)<sup>+</sup> RNA found in embryos, larvae, pupae, and adults (O'Hare *et al.*, 1983; Pirrotta *et al.*, 1983; Fjose *et al.*, 1984; Pirrotta and Bröckl, 1984). The nucleotide sequence of more than 14 kb of white DNA and the probable structures of the introns and exons were determined (O'Hare *et al.*, 1984). The presence of at least four introns is indicated (Pirrotta and Bröckl, 1984); a 3 kb intron separates the proximal (centromere) sequences from the distal sequences (O'Hare *et al.*, 1984). DNA sequences required for normal expression of  $w^+$  were found to be within a 9.9 kb segment of the gene, with regulatory elements in the 5' flanking region (Levis *et al.*, 1985; Pirrotta *et al.*, 1985); these regions include sequences for Malpighian tubule expression and testis sheath pigment as well as those regulating the pattern of eye pigmentation and zeste interaction.

Insertions associated with  $w$  mutations were found throughout most of the region of the 2.6 kb  $w^+$  transcript as well as 6 kb upstream. Alleles associated with these insertions or with molecular deletions or duplications are listed on the figure and table on the following page.

The mottler of white locus interacts with white alleles that are transposon-insertion mutants, producing a variegated eye color (Birchler *et al.*, 1989). All of the  $w$  sites involved are within the structural part of the gene.

$w^+$  (red-eyed) flies were produced by *P*-element-mediated germ-line transformation, a 12-14 kb segment spanning the  $w^+$  locus (in a *P*-transposon vector) being inserted in various new chromosomal locations (Gehring *et al.*, 1984; Hazelrigg *et al.*, 1984) and with various amounts of upstream sequences (Levis *et al.*, 1984; Pirrotta *et al.*, 1985). These  $w^+$  transformants show the same tissue-specific transcript accumulation as wild-type flies. They also show dosage compensation, but differ markedly in their interactions with *z*. Temperature shocks given at various times in development to white transformants under the control of heat shock regulatory sequences indicate the period of maximum expression of white to be in the first two days of the pupal period (Steller and Pirrotta, 1985).

Extensive amino acid similarity has been found between the putative protein products of the white and brown genes, both involved in the pteridine pathway (Dreesen *et al.*, 1988) and the protein products of the white and scarlet genes, both involved in the ommochrome pathway (Tearle *et al.*, 1989).

While the amount of detectable eye pigment variation among 64 *X* chromosome lines from three collections in North Carolina, Texas, and Fukuoka, Japan, was not large, these lines showed a very large amount of molecular variation in a 45-kb region of the white locus, a total of 109 polymorphisms being found (Miyashita and Langley, 1988).

**other information:** The original *TE35A* [= *TE146(Z)*] which carries two copies of  $w^+rst^+$  in tandem order ( $w^+rst^+w^+rst^+$ ) is prevented by certain rearrangements on the homologous chromosome from interacting with  $z^1$ , but a derivative of *TE35A* which carries two copies of  $w^+rst^+$  in the reversed order ( $rst^+w^+w^+rst^+$ ) is not affected by these rearrangements in regard to its interaction with  $z^1$  (Gubb *et al.*, 1990).

Springer-Verlag, Berlin, Heidelberg, pp. 81-94 and Birchler, Hiebert, and Rabinow, 1989, Genes Dev. 3: 73-84.

- Y Shows *mw* mottling (Birchler *et al.*, 1989).  $w^a$  suppressed by *Doa* (Rabinow and Birchler, 1989, EMBO J. 8: 879-89).
- δ In spite of the variegated pattern of spots in the eye in this mutant, the transcript is like that of  $w^+$  in size, structure, and amount (Levis *et al.*, 1984; Pirrotta and Bröckl, 1984, EMBO J. 3: 563-68).
- ε  $w^+$  mRNA not detected in this allele.  $w^{sp55}$  enhanced by *Doa* (Rabinow and Birchler, 1989).

### $w^a$ : white-apricot

**phenotype:** Placed on the genetic map of white to the right of  $w^{bf}$  and the left of  $w^{ch}$ . The amount of pigment formed by  $w^a$  is a function of gene dose:  $w^a/-$  female <  $w^a/Y$  male =  $w^a/w^a$  female <  $w^a/w^a/w^a$  female <  $w^a/w^a$  male (Muller, 1932). A  $w^a$  optic disk transplanted into a wild-type host shows autonomous eye color development (Beadle and Ephrussi, 1936). Deficiencies and duplications for  $w^a$  can be produced as a result of nonhomologous exchanges within the white region.  $w^a$  gives rise to partial revertants, as  $w^r$  (Muller),  $w^{aM}$  (Mossige), and  $w^{a57i}$  (Green). Eye color is modified in certain mutant combinations.  $w^a;bw$  is slightly lighter than  $w^a$ .  $w^a;st$  is light pinkish yellow (Mainx, 1938) as is  $w^a v$ .  $z w^a$  is lighter than either mutant alone, only slightly darker than  $w^{bf}$  (Green, 1959a).  $w^a rb$  and  $w^a g$  have nearly white eyes;  $w^a w^{ch}$ ,  $w^{bf} w^a$ , and  $w^a$  in combination with *su(f)* all have white eyes. *su(w<sup>a</sup>) w<sup>a</sup>* and *su(w<sup>a</sup>)<sup>G</sup> w<sup>a</sup>* have browner eyes than  $w^a$ . The triple mutant *su(w<sup>a</sup>) w<sup>a</sup> su(f)* has eyes only slightly lighter than  $w^a$  (Levis *et al.*, 1984).  $w^{Bwx} w^a$  is like  $w^a$  (Judd).  $w^a/+$  has lighter eyes than  $+/+$  in *v* homozygotes (Braver, 1953); *Tp(2;3)P* darkens  $w^a$ .

Transpositions of  $w^a$  and the neighboring gene *rst<sup>+</sup>* have been isolated at more than 120 sites in the genome [Ising and Ramel, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 947-54].

**molecular biology:** The  $w^a$  allele of the white locus has been cloned by retrieving previously cloned segments carrying a copy of the transposable element *copia* together with contiguous sequences (Bingham *et al.*, 1981; Gehring and Paro, 1980). Bingham and Judd (1981) have shown that *copia* homology is tightly linked to the site of  $w^a$ , *copia* being located at coordinate 0.0 on the physical map of the white locus (Levis *et al.*, 1982, 1984) and inserted in the small second intron (Pirrotta and Bröckl, 1984). The size of the *copia* insertion is 5 kb. The mutant gene codes for major transcripts of 1.25 and 5.7 kb (Levis *et al.*, 1984). A small amount of the normal 2.6 kb white transcript is also found in  $w^a$  mutants. *su(w<sup>a</sup>)*, which darkens the eyes of  $w^a$  flies, results in a higher level of the 2.6 kb transcript, while *su(f)*, which decreases the amount of pigment, results in a lower level of this transcript. Partial revertants of  $w^a$  have been

sequenced and found to retain one LTR of *copia* (Carbonare and Gehring, 1985; Mount *et al.*, 1988; Zachar *et al.*, 1985).

### $w^{bf}$ : white-buff

**phenotype:** Occupies a recombination site between  $w^{Bwx}$  and  $w^a$  (Judd, 1959). Spontaneous reversions reported by Redfield (1952, DIS 26: 28).  $w^{bf}$ ; *st* has white eyes (Mainx, 1938, Z. Indukt. Abstamm. Vererbungsl. 75: 256-76). Eyes of  $w^{bf} rb$  and  $w^{bf} g$  are lighter than the eyes of  $w^{bf}$ , *rb*, or *g* (Green, 1959a).

**molecular biology:**  $w^{bf}$  is associated with an insertion of the transposable element *roo* (*B104*) at coordinate -1.13 on the molecular map of white within the intron between the third and fourth exons (Levis *et al.*, 1984; Zachar and Bingham, 1982).

### $w^{bl}$ : white-blood

**phenotype:** Located distal to *w* (MacKendrick and Pontecorvo, 1952) and  $w^e$  (Judd, 1958; Green, 1959a). At 19°, eye color as dark as *pn*; at 30°, as light as  $w^{bf}$  or  $w^i$ ; sensitivity greatest 40-48 hr after pupation (Ephrussi and Herold, 1945, Genetics 30: 62-70).

**molecular biology:** The 6 kb transposable element *blood* is inserted in this allele (Bingham and Chapman, 1986, EMBO J. 5: 3343-51).

### $w^{Bwx}$ : white-Brownex

**phenotype:** Located distal to  $w^{bf}$  (Judd, 1957, 1959). Reduces recombination in the *y-spl* interval. Heterozygotes between  $w^{Bwx}$  and other white alleles or deficiencies are indistinguishable in eye color from  $w^{Bwx}/w^{Bwx}$ . The double mutant  $w^{Bwx} w^{col}$  is lighter than either single mutant, but  $w^{Bwx}/w^a$  and  $w^{Bwx}/w^{bf}$  are indistinguishable from  $w^a$  and  $w^{bf}$ , respectively.

**molecular biology:** Restriction map of  $w^{Bwx}$  resembles that of Canton-S wild type except for a deletion of 150 bp (Zachar and Bingham, 1982).

### $w^c$ : white-crimson

**phenotype:** Maps at the same site as  $w^a$ . Derivatives of  $w^c$  may be stable ( $w^+$  for example) or mutable (such as  $w^{dc}$  and  $w^{di}$ ) and include both point mutations and deficiencies (Green, 1967, Genetics 56: 467-82). The mutations take place in both males and females, may occur in clusters, and do not appear to involve recombination. Transpositions of a segment of the *w* gene that includes  $w^c$  to different locations on the third chromosome have been recovered and are mutable (Green, 1969, Genetics 61: 423-28; Green, 1976).

**molecular biology:**  $w^c$  is derived from  $w^i$  which is a tandem duplication of 2.9 kb of the white locus; it contains an *FB* element inserted in the proximal copy of the duplication, near the junction of the duplicated segments (Collins and Rubin, 1982).

### $w^{cf}$ : white-coffee

**phenotype:** Located near  $w^{Bwx}$  and just distal to  $w^a$  (Welshons and Nicoletti, 1963, DIS 38: 80). Females heterozygous for  $w^{cf}$  and  $w$ ,  $w^a$ ,  $w^{co}$ ,  $w^{ch}$ ,  $w^{bl}$ ,  $w^{col}$ , or  $w^{sat}$  have eye color of  $w^{cf}$  homozygous females.  $w^{cf}/+$  flies wild-type.

### $w^{ch}$ : white-cherry

**phenotype:** Occupies site proximal to  $w^a$  and distal to  $w^{sp}$  (Lewis, 1956). Eyes light in double mutant with *rb* or *g*,

white with  $w^a$ . Enhanced by  $P$  and  $e(w^e)$ ; suppressed by  $Su(w^{ch})$ , making eyes brownish (Rasmuson, 1970, *Hereditas* 65: 83-96).

### $w^{co}$ : white-coral

**phenotype:** Located distal to  $w^l$  (MacKendrick and Pontecorvo, 1952). Enhanced by  $e(w^e)$ ; lightens  $rb$  and  $g$  (Green, 1959a).  $w^{co},st$  has yellow eyes (Mainx, 1938).

### $w^{DZL}$ : white-Dominant-zeste-like

**phenotype:**  $w^{DZL}$  is located in or immediately proximal to the rightmost set of previously-defined white mutant sites (Bingham, 1981). While this mutant affects the pigmentation of the eyes, it has no effect on the color of the larval Malpighian tubules or the testis sheath of adult males.  $w^{DZL}$  shows synapsis-dependent dominance over  $w^+$ . It is a highly mutable allele (like  $w^c$ ), giving rise spontaneously to  $w^+$  and  $w^-$  derivatives with a frequency of 0.5-1.5%. Interactions between  $w^{DZL}$  and  $z$  are summarized in the allele table. It was observed that, when carrying the wild-type allele of  $z$ ,  $w^{DZL}/w^-$  females have brown eyes; with  $z^l$ , however, hemizygous  $w^{DZL}$  females have yellow eyes (Bingham, 1980, *Genetics* 95: 341-53).

**molecular biology:** Physical analysis of  $w^{DZL}$  shows that the mutant phenotype results from the insertion (proximal to white) of a complex transposable element made up of sequences normally found at 21D ("unique segment sequences") flanked by sequences of two  $FB$  transposons (Levis, Collins, and Rubin, 1982, *Cell* 30: 551-65; Zachar and Bingham, 1982, *Cell* 30: 529-41; Bingham and Zachar, 1985, *Cell* 40: 819-25). A transcript 1.3 kb larger than the major (2.6 kb)  $w^+$  transcript is found in  $w^{DZL}$  adult heads and head precursor tissues; this is a composite transcript, made up of sequences from the major  $w^+$  transcript and from the  $w^{DZL}$  unique segment (Bingham and Zachar, 1985; Zachar *et al.*, 1985). In  $w^{DZL}$  flies, a reduction in the levels of the  $w^+$  transcript is observed in adult head and head precursor tissues, but not in abdominal tissues. Revertants of  $w^{DZL}$  show loss of most of the unique segments of the insertion with 1.9 and 6.2 kb of the insertion remaining (Levis and Rubin, 1982; Zachar and Bingham, 1982).

### $w^e$ : white-eosin

**phenotype:** Placed proximal to  $w^a$  (Green, 1959a). Amount of pigment formed by  $w^e$  not a function of gene dose:  $w^e$  female =  $w^e$  male <  $w^e/w^e$  male =  $w^e/w^e$  female <  $w^e/w^e/w^e$  female (Muller, 1932). Mutant enhanced by  $P$ ,  $cru$ , and  $whg$  as well as by  $E(w^e)$ . Lightens  $rb$  and  $g$  (Green, 1959a). A  $w^e$  optic disk transplanted into a wild-type host shows autonomous eye color development (Beadle and Ephrussi, 1936).

**molecular biology:**  $w^e$  is derived from  $w^l$  and carries an insertion of the transposable element *pogo* within the  $w^l$  *Doc* insertion (O'Hare).

### $w^i$ : white-ivory

**phenotype:** Placed on the genetic map distal to  $w^l$  (MacKendrick, 1953, *DIS* 27: 100).  $w^i$  is unstable, reverting spontaneously to  $w^+$  with a frequency of  $5 \times 10^{-5}$  in  $w^l/w^i$  females and  $5 \times 10^{-6}$  in  $w^l/Y$  males and  $w^i/Df(1)w$  females (Lewis, 1959, *Genetics* 44: 522; Bowman, 1965, *Genetics* 52: 1069-79). The frequency of germinal reversions and of somatic reversions in larval eye tissue is increased by X rays (Lewis, 1959; Bowman and Green, 1964, *Genetics* 50: 237). No dosage com-

pensation shown by the mutant (Green 1959a). Recombination between flanking  $w$  alleles reduced in  $w^i$ , but restored in its revertants (Bowman, 1965; Bowman and Green, 1966, *Genetica* 37: 7-16).

**molecular biology:** Cloning and analysis of Southern blots of  $w^i$  DNA indicate the presence of a 2.9 kb duplication within the white locus (Karess and Rubin, 1982, *Cell* 30: 63-69). Revertants are produced by excision of one copy of the repeat in derivatives  $w^{i+B}$ ,  $w^{i+C}$ ,  $w^{i+D}$ , and  $w^{i+E}$ .  $w^{i+A}$  and the partial revertant  $w^{ip}$  are insertion mutations that are more complex, their altered phenotype apparently resulting from the insertion of new DNA into  $w^i$  and the loss of some  $w^i$  DNA.

### $w^m$ : white-mottled

**phenotype:** There are many  $w$  alleles that show variegated eye color. The  $w^m$  mutants most commonly used for variegation studies are  $w^{m4}$  and  $w^{m264-58}$ . In these alleles, extra heterochromatin partially suppresses eye mottling (Gowen and Gay, 1933, *Proc. Nat. Acad. Sci. USA* 19: 122-26; Koliantz, Hartmann-Goldstein, and Fuller, 1984, *Heredity* 52: 203-13; Koliantz and Hartmann-Goldstein, 1984, *Heredity* 53: 215-22; Baker and Spofford, 1959, *Univ. Texas Publ.* 5914: 135-54; Spofford, 1959, *Proc. Nat. Acad. Sci. USA* 45: 1003-07). In  $w^{m264-58}$ , variegation less (more wild-type in color) in homozygous females than in heterozygous females. Color variegation found in the testis-sheath as well as the eyes of  $w^{m264-58}$  male flies (Baker, 1968, *Adv. Genet.* 14: 133-169). In some lines, less variegation when paternally inherited; in others, less variegation when maternally inherited or no parental effect. Mottling in  $w^{m4}$  and  $w^{m4h}$  is enhanced by  $E(var)7$  and  $E(var)c^{101}$  (Reuter and Wolff, 1981, *Mol. Gen. Genet.* 182: 516-19); mottling in  $w^{m4}$  and  $w^{m264-58}$  is suppressed by  $Su(var)$  (Spofford, 1962, *Genetics* 47: 986-87) and a number of other suppressor mutations (Reuter and Wolff, 1981).

**molecular biology:** The DNA map location of three white-mottled mutations has been determined (Tartof, Bishop, Jones, Hobbs, and Locke, 1989, *Dev. Genet.* 10: 162-76). The euchromatic breakpoint of  $In(1)w^{m4}$  is at -24.5 kb, and the breakpoints of  $In(1)w^{m51b}$  and  $In(1)w^{mMc}$  are at about -21.3 kb (origin being the site of the *copla* insertion in  $w^a$ ).

### $w^{sp}$ : white-spotted

**phenotype:** Located proximal to  $w^{ch}$  and distal to  $w^{DZL}$ .  $w^{sp}$  affects that deposition of the eye pigments, resulting in a variegated phenotype, but does not affect the pigmentation of the larval Malpighian tubules. Testis pigmentation varies with different alleles,  $w^{sp3}$  males having unpigmented testes, but  $w^{sp1}$  and  $w^{sp2}$  males showing enhanced testis pigmentation (Davison *et al.*, 1985; Pirrotta, Stellar, and Bozzetti, 1985, *EMBO J.* 4: 3501-08; Judd, 1987). Partial complementation occurs between  $w^{sp}$  alleles and certain other  $w$  mutations when they are synapsed; for example,  $w^{sp/w}$ ,  $w^{sp/w^{ch}}$ , and  $w^{sp/w^a}$  females have homogeneous brown eyes (Green, 1959a). The double mutants  $w^a w^{sp}$  and  $w^{ch} w^{sp}$  have white and pale yellow eyes, respectively.  $w^{sp}$ , when heterozygous with a deficiency for all or part of the  $w$  locus, produces a phenotype like that of  $w^{sp}$  homozygotes (Green, 1959c). In the presence of  $z^l$ , two synapsed copies of  $w^{sp}$  in *trans* (or tandemly repeated)

result in yellow-eyed females;  $z^1$  females with one copy of  $w^{sp}$  have wild-type eye color. A specific regulator of the  $w^{sp}$  eye phenotype,  $su(w^{sp})$ , has been isolated as a partial revertant of  $w^{sp1}$  (Chapman and Bingham, 1985); this suppressor restores wild-type eye color to  $w^{sp1}$ ,  $w^{sp2}$ ,  $w^{sp3}$ , and  $w^{sp4}$  flies, but not to the  $w^{sp81d}$  mutant (Davison *et al.*, 1985).

**molecular biology:** The  $w^{sp}$  region has been cloned (Zachar and Bingham, 1982) and sequenced (O'Hare *et al.*, 1984); it is located 1.0-1.9 kb upstream from the 5' end of the start of  $w^+$  transcription (Zachar and Bingham, 1982; O'Hare *et al.*, 1983).  $w^{sp}$  shows sequence homology and behavior analogous to enhancer sequences (Davison *et al.*, 1985). The lesions responsible for  $w^{sp1}$ ,  $w^{sp2}$ , and  $w^{sp4}$  have been analyzed by sequencing cloned portions of these alleles; the breakpoints of  $w^{sp3}$  and  $w^{sp81d}$  have also been established by molecular methods.  $w^{sp1}$  carries *roo*; the other alleles are molecular deletions. Sensitivity to the effect of  $su(w^{sp})$  on eye pigmentation is deleted by  $w^{sp81d}$  but not by  $w^{sp3}$  (Davison *et al.*, 1985).

**$w^{zm}$ : white-zeste mottled**

**phenotype:**  $w^{zm}$  is located to the right of  $w^a$  and to the left of  $w^1$ . It is an unstable white allele, mutating to derivatives, most of which are unstable (Judd, 1963, Proc. Int. Congr. Genet. 11th, Vol. 1: 3-4; 1964, DIS 39: 60). Since all  $z^+$   $w^{zm}$  males (as well as  $z^+$   $w^{zm}/z^+$   $w^{zm}$  females) have wild-type eye color, the mutant  $z$  was used as an indicator of the mutability of  $w^{zm}$  strains. Derivatives of  $w^{zm}$  (Kalisch and Becker, 1970, Mol. Gen. Genet. 107: 321-35) include  $w^{z1}$  (from the  $z w^{zm}$  stock),  $w^{zms}$  (from the  $z w^{zm}$  stock), and  $w^{zmr}$ ,  $w^{zmsz}$  and  $w^{zmsw}$  (from the  $z w^{zms}$  stock). Only  $w^{z1}$  is stable. The mutants were often recovered in clusters.  $w^{zms}$  reverts to  $w^{zm+}$  (eye color between  $z w^{zm}$  and  $z w^+$ ) and the white-eyed  $w^{zmsz}$  and  $w^w$ . Other derivatives ( $w^z$ ,  $w^{zh}$ ,  $w^{zs}$ ) were recovered by Judd (1957; 1969, Genetics 61: s29).

**molecular biology:**  $w^{zm}$  carries an insertion of the transposable element *BEL* near the 5' junction of the first intron at +3.5 (O'Hare *et al.*, 1984). This insertion does not appear to alter the size of the 2.6 kb  $w^+$  transcript in  $w^{zm}$  and  $z w^{zm}$  flies (Levis *et al.*, 1984).

**W: Wrinkled**

**location:** 3-46.0.

**origin:** Recovered among progeny of female exposed to stratosphere.

**discoverer:** Jollos, 1936.

**references:** 1936, Natl. Geograph. Soc. Tech. Papers, Stratosphere Ser. No. 2: 153-57.

Jollos and Waletzky, 1937, DIS 8: 9.

**phenotype:** Homozygote viable. Wings remain small and unexpanded. Black spots on head beside proboscis or ocelli. Heterozygous female like homozygote but less extreme. Male much less extreme; wings often expanded but wrinkled, blistered, and surface finely pebbled and grayish; no overlap with wild type. Suppressed by *D* in male and nearly so in female. From prepupal stage through adult, wing bases abnormally narrow, possibly preventing flow of body fluid in sufficient quantity to expand wings [Waddington, 1940, J. Genet. 41: 75-139 (fig.)]. RK1 as dominant.

**cytology:** Located at 75C5-D3.

**W13:** see *T(1;4)A1*

**\* $wa$ : warty**

**location:** 1-64.4 (based on location of  $wa^2$ ;  $wa$  said to be near *car*).

**origin:** Induced by P<sup>32</sup>.

**discoverer:** Bateman, 1950.

**references:** 1950, DIS 24: 56.

**phenotype:** Eyes rough with scattered enlarged facets.

Occasional notched wing tip. Penetrance low. Viability variable. Male infertile in proportion to degree of expression. Heterozygous female often infertile. RK3.

**$wa^2$**

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 77.

**phenotype:** Eyes irregularly roughened and of varying size and shape; ommatidia deranged. Wing tips rarely notched. RK3.

**alleles:** Allelism inferred from phenotype and genetic location. One allele each induced by CB. 1540, CB. 3025, and X rays.

**waisted:** see *ws*

**wap: wings-apart**

**location:** 1- {66}.

**synonym:** *l(1)20Ab*.

**discoverer:** Lifschytz.

**references:** Schalet, 1972, DIS 49: 36-37, 64-66.

Schalet and Lefevre, 1973, Chromosoma 44: 183-202.

1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 846-902.

Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31.

Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52.

**phenotype:** Semilethal. Most flies die shortly before eclosion. Flies which hatch have wings set slightly apart and a somewhat darker than normal thorax; may have extra crossveins. Mutant males, mutant females, and mutant/deficiency females have the same phenotype, which is more extreme at 29-30°. Viability of heteroallelic compounds usually low (2-9%).

**wb: wing blister**

**location:** 2-49.9 (G. Maroni; 0.2 cM to left of *Adh*).

**synonym:** *l(2)br1* (Woodruff and Ashburner, 1979); A1 group (O'Donnell *et al.*, 1977).

**references:** O'Donnell, Mandel, Krauss, and Sofer, 1977, Genetics 86: 553-66.

Woodruff and Ashburner, 1979, Genetics 92: 133-49.

Ashburner, Faithfull, Littlewood, Richards, Smith, Velisariou, and Woodruff, 1980, DIS 55: 193-95.

**phenotype:** Most of the mutants are characterized by homo- or hemizygous lethality, but a visible phenotype has also been reported. O'Donnell *et al.*, 1977, describe a bent-down-wing phenotype occurring when one of their lethals is crossed to other lethals in the same complementation group and the same phenotype when three of their lethals are crossed to deletions for the locus. Woodruff and Ashburner, 1979, describe the viable and fertile wing blister phenotype (a roughly circular area around the crossveins of the wing, forming a blister which often collapses soon after eclosion, distorting the wing blade). The allele showing this phenotype (*wb*<sup>1</sup>) is viable and fertile in homozygotes and hemizygotes as well as in heteroallelic combinations with lethal alleles.

**alleles:** Viable and lethal (or semilethal) alleles are described in the following table.

**cytology:** Placed in 34F4 since included in *Df(2L)fn1 = Df(2L)34F4-35A1;35D5-7* but not in *Df(2L)A217 = Df(2L)34F5;35B3*.

**wbl: windbeutel**

**location:** 2-86.

**synonym:** *wind*.

**references:** Anderson, 1987, TIG 3: 91-97.

Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal expression of *wbl*, one of the "dorsal group" genes, is required for the production of all lateral and ventral pattern elements. In the absence of the wild-type allele, all embryonic cells differentiate dorsal epidermis.

**alleles:** One allele has been identified (Schüpbach and Wieschaus).

**\*wd: wavoid**

**location:** 2-40.

**origin:** Spontaneous.

**discoverer:** Kellen, 1941.

**references:** Kellen, 1945, Genetics 30: 12.

**phenotype:** Wings waved. Variable penetrance and expressivity, especially in male. Partially suppressed by *y* in both sexes. RK2.

*wdh*: see *sli*

**wdl: wavoidlike**

**location:** 2-39.

**origin:** Induced by ethyl methanesulfonate.

**references:** Sandler, 1977, Genetics 86: 567-82.

**phenotype:** Wavy wings with incomplete L5 vein.

Homozygous viable but female semisterile. Maternal effect results in death of zygotes before egg hatch and is influenced by the X- or Y-chromosome heterochromatin carried by the zygote; effect less severe at 19° than at 25°. Mutation semilethal when heterozygous with a deficiency for the locus.

**cytology:** Located in 32A-32E; included in *Df(2L)J39 = Df(2L)31A-B;32D-E* but not in *Df(2L)J27 = Df(2L)31B-D; 32A*.

**other information:** May be an allele of the lost mutation *wd* reported by Kellen (1945, Genetics 30: 12).

**\*wdn: wings down**

**location:** 3-100.

**discoverer:** Morgan.

**references:** 1929, Carnegie Inst. Washington Publ. No. 399: 187.

**phenotype:** Wings extended and drooping or even directed ventrally, broad with close crossveins. Overlaps wild type. Low viability. RK3.

**\*we: wee**

**location:** 1-3.0.

**origin:** X ray induced.

**discoverer:** Muller, 2615.

**references:** 1935, DIS 3: 30.

Lefevre and Green, 1972, Chromosoma 36: 391-412.

**phenotype:** Fly dwarfed. Eyes rough; bristles fine; wings spread. Fertility very low. RK2.

**\*We: Washed eye**

**location:** 3-43.0.

**origin:** Spontaneous.

**discoverer:** Andres, 42e7.

**references:** 1943, DIS 17: 48.

**phenotype:** Dominant modifier of *w* that produces partial reversion. Produces spot of dilute red pigment varying in size from dot to nearly whole eye. Homozygous lethal. Classification, fertility, and viability of heterozygote excellent. RK2.

**phenotype:** The *wg* gene is involved both in controlling the segmentation pattern of embryos by affecting the pos-

terioormost cells of each parasegment (Baker, 1987) and in controlling the imaginal disk pattern of the meso- and meta-thoracic segments that develop into wing, halter, and notum in pupae and adults (Sharma, 1973; Sharma and Copra, 1976; Morata and Lawrence, 1977). The gene is believed to control segment organization through an intercellular signaling mechanism (Baker, 1987, 1988b; Cabrera, Alonso, Johnston, Phillips, and Lawrence, 1987, Cell 50: 659-63; Ryjsewijk *et al.*, 1987; Martinez-Arias *et al.*, 1988). Mutants may be viable as adults or lethal as embryos or pupae. In embryonic lethal alleles (Babu, 1977; Nüsslein-Volhard and Wieschaus, 1980), each segment shows a mirror-image duplication of the denticle bands at the expense of naked cuticle so that a continuous sheet of denticles (instead of repeated denticle bands) is produced (Cabrera *et al.*, 1987). Dorsal abnormalities are more extreme than ventral ones, the dorsal cuticle being greatly reduced and covered by fine hairs (Baker, 1988a). These embryos lack head structures and filzkörper (Perrimon and Mahowald, 1987, Dev. Biol. 119: 587-600). In the nervous system, a single neuron, RP2, is missing; other neurons in the lineage are normal (Patel, Schafer, Goodman, and Holmgren, 1989, Genes Dev. 3: 890-904). The temperature-sensitive period for *wg*<sup>l-12</sup>, a heat-sensitive allele that is lethal at 25° (Baker, 1988a; Mohler, 1988), lies between gastrulation and the beginning of dorsal closure (11 hours after egg laying at 25°). In pupal lethal and adult viable alleles, the ready-to-emerge pupae and the adults lack one or both wings and/or halteres, and there is a corresponding duplication of the meso- and metanota (Sharma, 1973; Sharma and Copra, 1976; Morata and Lawrence, 1977; Deak, 1978). This adult phenotype shows incomplete penetrance and variable expressivity and is affected by the ability of the wingless gene to function during the larval period (Baker, 1988a). Low temperature fails to rescue heteroallelic combinations of *wg*<sup>1</sup> or *wg*<sup>l-18</sup> with the heat-sensitive allele *wg*<sup>l-12</sup> after the larval stages. Lethal as well as viable *wg* alleles are not cell-autonomous in adult mosaics (Babu and Bhat, 1986; Morata and Lawrence, 1977; Baker, 1988a).

**alleles:** Mutant alleles of *wg* may be viable, showing a visible phenotype involving loss of wings and/or halteres, or they may be homozygous lethal (usually as embryos but sometimes as pupae). Both types of mutants are included in the following table:

Biol. 125: 96-108; 5 = Baker, 1988b, Development 102: 489-97; 6 = Sharma, 1973, DIS 50: 25, 134; 7 = Sharma and Copra, 1976, Dev. Biol. 48: 461-65; 8 = Sharma and Shekaran, 1983, Indian J. Exp. Biol. 21: 143-49; 9 = Tearle and Nüsslein-Volhard, 1987, DIS 86: 209-69.

β At 18°, homozygous *wg*<sup>l-12</sup> embryos develop normally and hatch to produce larvae that have a wild-type cuticular pattern, but these mutants do not survive to become adults. *wg*<sup>l-12</sup>/*wg*<sup>P</sup> mutants, however, do survive at 16.5° to become phenotypically wild-type adults (Baker, 1988a).

**cytology:** *wg* has been located in 28A1-3 by *in situ* hybridization to salivary chromosomes of *In(2L)w<sup>P</sup>* = *In(2L)28A1-3;32E-F* heterozygotes, two sites being labelled in the inversion chromosome (Baker, 1987).

**molecular biology:** DNA from the *wg* gene was cloned by transposon tagging with a *P*-element insertion mutant *wg*<sup>l-18</sup>. Lesions associated with *wg* mutants were located on a molecular map of the region. Alleles involved are listed below:

allele	molecular biology
<i>wg</i> <sup>1</sup>	deletion from +16.8 to +17.1 kb
<i>wg</i> <sup>l-15</sup>	deletion of 0.3 kb
<i>wg</i> <sup>l-16</sup>	break between +10.8 and 15.0 kb
<i>wg</i> <sup>l-17</sup>	deletion of 2 kb at 5' end of gene
<i>In(2L)w<sup>P</sup></i>	28A breakpoint between 16.4 and 17.1 kb

A 3.2 kb transcript was obtained and localized in embryos, where it was first found at the time of cellularization of the blastoderm (Baker, 1987, 1988b). The RNA accumulates as epidermal stripes in the most posterior cells of each parasegment. Transient accumulation of transcript occurs in the mesoderm and the nervous system. *wg* is also expressed in larvae and pupae, but is scarcely detectable in adults. An antisense RNA made from the *wg* transcript produces phenocopies of wingless when injected into wild-type eggs (Cabrera *et al.*, 1987).

The *Drosophila melanogaster* homolog of the mouse mammary oncogene *int-1* has been located in the same cytological region as wingless, cloned and designated *Dint-1* (Ryjsewijk *et al.*, 1987; Urvölgyi *et al.*, 1988); transcripts of 2.9-3.0 kb have been obtained and found to be at approximately the same position on the molecular map and to show the same expression in embryos as *wg*. The identity of *Dint-1* and *wg* was confirmed by positive cross-hybridization of a *Dint-1* cDNA probe to a partial cDNA clone from the 5' half of the *wg* transcript (Ryjsewijk *et al.*, 1987). A partial sequence of *wg* cDNA was obtained (Cabrera *et al.*, 1987) and found to be identical to a region of the complete *Dint-1* sequence (Ryjsewijk *et al.*, 1987). The deduced *Drosophila* protein sequence shows 54% overall identity to the mouse *int-1* sequence (Ryjsewijk *et al.*, 1987; Urvölgyi *et al.*, 1988).

The cysteine-rich protein of *wg* is found in the same region of the embryo as the *wg* mRNA (Van den Heuvel *et al.*, 1989).

**wgo: wings-out**

**location:** 1-16.2.  
**origin:** H<sup>3</sup>TdR-induced.  
**references:** Perez and Kaplan, 1968, DIS 43: 66.  
**phenotype:** Wings divergent, slight thickening of veins, notching effect in 10-15% of flies.  
**other information:** Not an allele of *vs*.

**\*wgv: wing variance**

Rayle, 1969, DIS 44: 98.

Jones, 1971, DIS 47: 90.

**phenotype:** Ocelli colorless. Eye color wild type.

Modifies  $w^e$  to a lighter and less yellow tone. Interacts with  $z$ , producing white-eyed  $z/z;wo/wo$  females and  $z/Y;wo/wo$  males with a slight deviation from wild-type eye color (Rayle, 1969). RK2.

**alleles:**  $wo^1$  (Bridges) and  $wo^{67k}$  (Rayle).

**cytology:** Located in 94A-E by deficiency mapping (Jones, 1971).

**other information:**  $cd$  and  $wo$  map in same genetic interval and heterozygote  $cd/wo$  also shows white eyes; perhaps alleles (Jones, 1971).

$wo$ : see  $cd^{wo}$

**wobA: wobbly A (J.C. Hall)**

**location:** Distal X; no crossing over between  $y$  and  $cv$  (see cytology).

**origin:** Induced by ethyl methanesulfonate.

**references:** Grigliatti, Hall, Rosenbluth, and Suzuki, 1973, Mol. Gen. Genet. 120: 107-15.

Schmidt-Nielsen and Hall, 1977, DIS 52: 71-72.

**phenotype:** Flies cannot coordinate proper sequence of leg movements for normal walking so that legs on one side of the body or the other become entangled with those behind or in front (Grigliatti *et al.*, 1973); legs held out flat when flies are on a horizontal surface. Mutants cannot climb easily or hang upside down; show poor locomotor behavior in counter current experiments involving agitation of flies and their running toward light (Schmidt-Nielsen and Hall, 1977). Males weak and very poorly fertile. Homozygous females inviable. Two genes,  $wobA$  and  $wobB$ , are involved in the extreme phenotype (full uncoordinated walking behavior); both factors were extracted from the original strain. In the absence of  $wobB$ , walking in  $wobA$  flies is only slightly uncoordinated.

**cytology:** Inseparable from a transposition reported as  $Tp(1;2R;3R;1)$  (T. Kaufman cited in Grigliatti *et al.*, 1973).

**wobB: wobbly B (J.C. Hall)**

**location:** 1-near 50 (between  $v$  and  $f$ ).

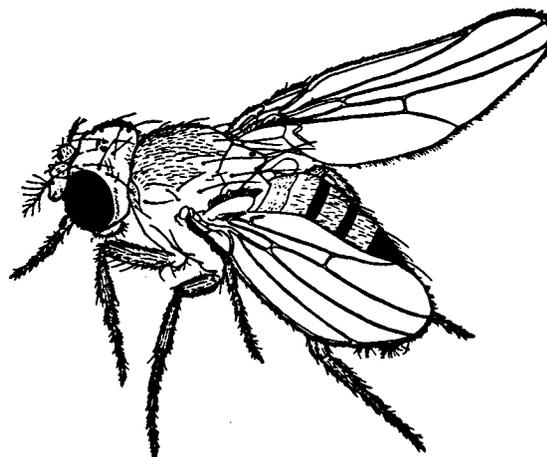

**references:** Grigliatti, Hall, Rosenbluth, and Suzuki, 1973, Mol. Gen. Genet. 120: 107-15.

Schmidt-Nielsen and Hall, 1977, DIS 52: 71-72.

**phenotype:** See  $wobA$  for digenic phenotype. In absence of  $wobA$ , walking is not uncoordinated, but the  $wobB$  flies show weak locomotion and poor climbing.

**wobbly A:** see  $wobA$

**wobbly B:** see  $wobB$

**wp: warped**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 216.

**\*wp: warped**

**location:** 3-47.5.

**discoverer:** Bridges, 19k15.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 215 (fig.).

**phenotype:** Wings small and narrow, dusky, divergent, and warped. RK2.

$wr$ : see  $fw^{wr}$

**\*Wr: Wrinkle**

**location:** 2-76.

**origin:** Spontaneous.

**discoverer:** Goldschmidt, 1933.

**synonym:** *Wrinkled* (preoccupied).

**phenotype:** Wings wrinkled and blistered. Homozygote viable and only slightly more extreme than heterozygote. Development retarded. RK1.

**Wrinkled:** see  $W$

**Wrinkled:** see  $Wr$

**wrl: whirligig (L.L. Green)**

**location:** 3-54.4 (between  $cv-c$  and  $sbd$ ).

**synonym:**  $ms(3)nc4$ .

**references:** Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.

Fuller, 1986, Gametogenesis and the Early Embryo, (G.J. Gall, ed.), Symp. Soc. Dev. Biol., 44th, pp. 19-31.

Green, Wolf, McDonald, and Fuller, 1990, Genetics 126: 961-73.

**phenotype:** Male sterile. Males homozygous for  $wrl$  have defects in post-meiotic spermatid differentiation, including disordered spermatid components, disrupted flagellar axonemes, and axonemes lacking one or both central pair microtubules. Axonemes commonly show defects in the

structure of the outer doublet or accessory microtubules. Onion stage early spermatids normal, indicating normal meiosis. Homozygous viable and female fertile. *wrl* acts as a dominant enhancer of tubulin mutants. Alleles obtained by reverting the failure of *wrl* to complement  $\beta$ *Tub85D*<sup>n</sup> are dominant male sterile, but are suppressed (restored to fertility) when heterozygous with some mutant alleles of  $\alpha$ *Tub84B* or  $\beta$ *Tub85D*. A deficiency for 88C2-E3 generated using *Tp(3;1)kar*<sup>51</sup> and *Tp(3;2)ry*<sup>+</sup> is semi-dominant male sterile, but is restored to fertility when heterozygous with  $\beta$ *Tub85D*<sup>n</sup>. Together these results indicate that *wrl* may be responsible for haploinsufficiency for male fertility located in polytene interval 88C-D. The genetic interactions between mutations in *wrl* and tubulin mutants indicates that the *wrl* gene product could play a role in microtubule function.

**alleles:**

<sup>β</sup> Isolated as revertant of failure of *wrl*<sup>nca</sup> to complement  $\beta$ 2t<sup>n</sup>.

**cytology:** Placed in 88C7-D6 because dominant loss of function alleles covered by *Dp(3;3)E11* = *Dp(3;3)88A5-12;88D6-10* but not by *Dp(3;3)E8* = *Df(3;3)88D4-6;88E4-F2*. Recessive male sterile phenotype of *wrl* not uncovered by *Df(3R)red31* = *Df(3R)87F12-14;88C1-3*. Recessive mutant axonemal phenotype of *wrl* uncovered by the synthetic deficiency generated using *Tp(3;1)kar*<sup>5</sup> = *Tp(3;1)20;87C7-D1;88E2-3* and *Tp(3;2)ry*<sup>+</sup> = *Tp(3;2)2L;87C2-3;88C2-3*.

**ws: waisted**

**location:** 1-1.0.  
**origin:** Induced by L-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1955.  
**references:** 1958, DIS 32: 77.  
**phenotype:** Anterior part of abdomen constricted, giving appearance of long, narrow waist. Wings held abnormally and surface wavy. Most flies die shortly after eclosion, but occasional male is viable and fertile. RK3.  
**alleles:** One allele induced by CB. 1506.

**wl: welt**

**location:** 2-85.3.  
**discoverer:** Bridges, 32119.  
**phenotype:** Eyes small and narrow with horizontal seam or welt. Many bristles, especially postverticals, doubled or even quadrupled in number. Abdomen chunky. Occasional nicks in wing. Expression overlaps wild type at 19° but is excellent at 25° or higher. RK1.  
**alleles:** *wl*<sup>1</sup> (see phenotype) and *wl*<sup>ts</sup>, a temperature-sensitive allele producing cell death in wing and eye discs under restrictive conditions (Vikulova and Mglinetz, 1985, Tsitol. Genet. 19: 60-65).

**cytology:** Placed in 55C based on its inclusion in *Df(2R)Pcl-w5* = *Df(2R)55A-8;55C* but no *Df(2R)PclIIB* = *Df(2R)54F6-55A1;55C1-3* (Deng and Rizki, 1988, Genome 30, suppl. 1: 192).

**\*wtl: weltlike**

**location:** 3-59.5.  
**discoverer:** Bridges, 33c7.  
**phenotype:** Eyes seamed and small. Aristae reduced. Wings rather broad. Female sterile. Expression better at 19°. RK3.

**\*wtw: water wings**

**location:** 1-38.9.  
**origin:** Induced by DL-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).  
**discoverer:** Fahmy, 1954.  
**references:** 1958, DIS 32: 77-78.  
**phenotype:** Wings short and broad, frequently with incomplete crossveins, and often thickened owing to separation of ventral and dorsal surfaces by fluid. Eyes small and slightly rough. Male genitalia twisted; pigmentation of last abdominal segment in female patchy. Penetrance and viability low. Female infertile. RK3.

**\*wtw<sup>clf</sup>: water wings-cleft end**

**origin:** Induced by DL-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).  
**discoverer:** Fahmy, 1953.  
**synonym:** *clf*.  
**references:** 1958, DIS 32: 68.  
**phenotype:** Last male abdominal segment grooved in dorsal midline, has abnormal genitalia. Eyes small; wings short, broad, and slightly divergent. Female fertility low; viability good. Classification difficult. RK3.  
**alleles:** One allele induced by CB. 3007.

*wupA* : see *hdp*

*wupB* : see *up*

*wvn* : see *ddd*

**ww: wider wing**

**location:** 1-32.9.  
**origin:** Induced by L-p -N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1953.  
**references:** 1958, DIS 32: 78.  
**phenotype:** Wings slightly shorter and broader than normal, frequently upheld, and occasionally truncated. Male viability and fertility good; female viability and fertility reduced. RK3.  
**alleles:** One allele induced by CB. 3026.

**\*wx: waxy**

**location:** 2-69.7.  
**origin:** Spontaneous.  
**discoverer:** Ives, 41k15.  
**references:** 1942, DIS 16: 49.  
**phenotype:** Wings heavy textured, more opaque, and smaller than normal. Male completely sterile; female fertile. RK2.

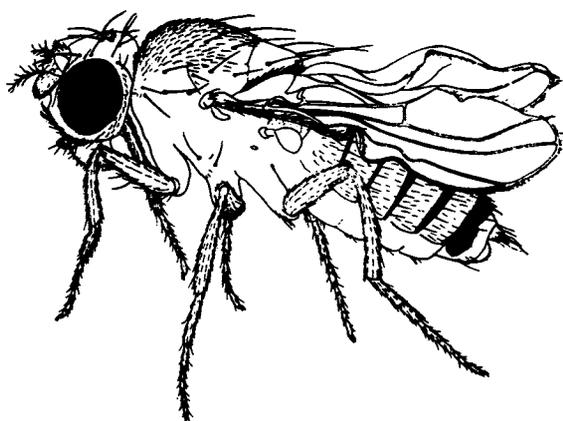

**wx<sup>wxt</sup>: waxy-waxtex**

**origin:** Spontaneous.  
**discoverer:** R. F. Grell, 56k20.  
**synonym:** *wxt*.

**references:** 1957, DIS 31: 81.

**phenotype:** Wings slightly spread and curved down distally, texture heavy and waxy, tips pointed. First posterior wing cell narrow, second posterior cell broad and flared. Fertile in both sexes. RK2.

**other information:** Allelism inferred from similarity in phenotype and genetic location (2-69).

**wy: wavy**

From Nachtsheim, 1928, Z. Indukt. Abstamm. Vererbungsl. 48: 245-58.

**wy: wavy**

**location:** 1-40.7.

**phenotype:** Wings transversely wavy, usually turned up at tip. Abdomen long and narrow. Marginal vein kinked even when other characters overlap wild type. RK2.

**alleles:**

allele	origin	discoverer	ref <sup>α</sup>	comments
<b>wy<sup>1</sup></b>	spont	Nachtsheim, 26g7	3	wavy wings
<b>wy<sup>2β</sup></b>		Ruch	4	more extreme than <b>wy<sup>1</sup></b> , more upward curl to wings

<b>wy<sup>74i</sup></b>	EMS	Craymer	1	extreme <b>wy</b> allele
<b>*wy<sup>274-2</sup></b>	X ray	Demerec, 34a		male lethal; associated with <i>T(1;2;3)</i>
<b>wy<sup>spn</sup></b>	spont	Waddle	5	male resembles <b>wy<sup>1</sup></b> ; female has deeply dishd wing distal to wave

<sup>α</sup> 1 = Craymer, 1980, DIS 55: 197-200; 2 = Haskell, 1941, DIS 14: 39; 3 = Nachtsheim, 1928, Z. Indukt. Abstamm. Vererbungsl. 48: 245-58; 4 = Parker, 1935, DIS 4: 62; 5 = Waddle, 1977, DIS 52: 3.

<sup>β</sup> Synonym: *cx-b*.

**cytology:** Placed in 11E [Lefevre, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 66-31].

**\*wz: wizened**

**location:** 3-47.8.

**discoverer:** Bridges, 1921.

**synonym:** *shrunken-3*.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 241.

**phenotype:** Small fly; not filled out. Body color dark dull; bristles small. Late hatching. Infertile. RK3.

**x1**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, Grossfield, and White, 1969, *Nature* (London) 222: 351-54.

**phenotype:** Nonphototactic mutant showing ERG more or less like wild type, although reduced in amplitude and with somewhat different wave form. Other abnormalities include fused wing veins, undeveloped ocelli, and forked bristles.

**x2, x3, x4, x5, x6**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, Grossfield, and White, 1969, *Nature* (London) 222: 351-54.

**phenotype:** Nonphototactic mutants; external morphology wild type.

*x7*: see *tan*

**x8**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, Grossfield, and Arnold, *Nature* (London) 227: 518-20.

**phenotype:** Nonphototactic mutant with normal ERG. Abnormalities include reduced ocelli, fused wing veins, and forked bristles.

**x10**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, Grossfield, and Arnold, *Nature* (London) 227: 518-20.

**phenotype:** Nonphototactic mutant with normal ERG.

Resembles *sc* in absence of some scutellar, ocellar, and other bristles.

**phenotype:** The yellow locus controls the melanotic pigment pattern of the cuticle of the adult fly and the pigmented mouth parts and denticle belts of the larval cuticle. *y* mutants can be separated into the following phenotypic classes, each group involving a color change from gray-black to yellow-brown (Nash, 1973, Genetics 74: s191): (1) Mutants that show a total loss of pigmentation from the cuticle (*y*-type) and (2) mutants that show a mosaic pigment pattern, some regions of the cuticle being wild type and others yellow in color (*y*<sup>2</sup>-type). In the latter type of mutants, at least 40 different adult cuticular structures can express their color independently (Nash and Yarkin, 1974); phenotypes of these mutants indicate that they may play a regulatory role in the expression of yellow (Chia *et al.*, 1986). Some of these type (2) mutants are not temperature-sensitive; others are heat- or cold-sensitive (Nash *et al.*, 1983). For the most part, the yellow gene is autonomous in mosaics, but there is some nonautonomy over limited distances (Hannah, 1953). The function of the gene product in the pigmentation process is still unknown (Biessmann, 1985; Geyer *et*

*al.*, 1986). Hemizygous males are at a mating disadvantage when paired with wild type females (Bastock, 1956, Evolution 10: 421-39), exhibiting a reduced level of locomotion and abnormal courtship (Wilson, Burnet, Eastwood, and Connolly, 1976, Genet. Res. 28: 75-88; Burnet and Wilson, 1980, Genet. Res. 36: 235-47).

**alleles:** Mutant alleles (but not revertants) are tabulated below. Deficiencies are described in the rearrangement section. Table I includes extant alleles from Russia, Table IIa extant alleles, Table IIb lost alleles.

<sup>β</sup> Synonym: *y*<sup>31e</sup>.

<sup>γ</sup> Synonym: *y*<sup>S</sup> (Muller, 1946; preoccupied); *y*<sup>Si</sup> (Green, 1961; error).

<sup>δ</sup> Synonym: *y*<sup>px-bl</sup>: yellow-plexus blistered.

**cytology:** Located at the tip of the X chromosome at 1B1 on the cytological map (Lefevre, 1976, 1981).

**molecular biology:** The yellow locus has been cloned by chromosome walking (Biessmann, 1985) and a *y* transcript of 1.9-2.1 kb identified (Biessmann, 1985; Campuzano *et al.*, 1985; Chia *et al.*, 1986; Parkhurst and Corces, 1986). The transcript consists of two exons processed in both larval and pupal stages into an mRNA of 1990 bp. The nucleotide sequence of yellow genomic DNA has been determined (Geyer *et al.*, 1986; Geyer and Corces, 1987), and the amino acid sequence of the yellow protein predicted from it. Breakpoints of chromosomal aberrations of type 1 and type 2 mutants have been located on the molecular map. Most of the type 1 mutants show structural lesions in the yellow coding region; a majority of the type 2 lesions, however, have been mapped 5' to the transcription start point (Biessmann, 1985; Biessmann and Green, 1986; Chia *et al.*, 1986; Biessmann and Mason, 1988). The allele *y*<sup>2</sup> is associated with the insertion of the transposable element *gypsy* 700 bp distal to the yellow coding region (Biessmann, 1985; Parkhurst and Corces, 1986); revertants of *y*<sup>2</sup> are obtained by excision of *gypsy*, leaving

behind a long terminal repeat (LTR) (Geyer *et al.*, 1986) or by replacing the central part of *gypsy* with another transposable element, *wallaby*, and leaving behind all of the 3' LTR and half of the 5' LTR (Geyer *et al.*, 1988a). Another allele, *y*<sup>76d28</sup>, results from the insertion of a *P* element into the 5' untranslated part of the yellow gene (Geyer *et al.*, 1988b). A high frequency of reversion occurs among the progeny of *y*<sup>76d28</sup> males carrying the element. Each revertant carries residual *P*-element DNA in the 5' untranslated region. Sequence analysis of several phenotypically wild-type revertants shows imprecise excision of *P*-element sequences within the inverted repeats (20 bp remaining in *y*<sup>+1</sup>, 4 in *y*<sup>+13</sup>, 7 in *y*<sup>1#7+</sup>, and 340 in *y*<sup>+13-11</sup>) (Geyer *et al.*, 1988b). Sequencing of two *y* mutants arising from the revertant *y*<sup>+13-11</sup> indicates that these mutants are produced by insertion of another *P*-element at the exact site of the original one without duplication of *P* DNA or *y* DNA. *P*-element-mediated transformations of mutants with plasmids carrying *y* DNA with various deletions in the 5' region show which sequences are responsible for regulation of *y* transcription in wings, body, and bristles of adults and mouth parts and denticle belts of larvae (Geyer and Corces, 1987). The

same upstream controlling regions have also been identified using terminal chromosome deficiencies (Biessmann and Mason, 1988).

The yellow polypeptide (60,752 daltons) was localized by immuno-histochemical techniques in the epidermis and adult cuticle of three- and four-day old pupae. Its expression precedes visible melanin deposition by 26 hours. Spatial distribution anticipates the later cuticular melanization pattern. Expression in the embryo was detected in the head region, at the ventral setal belts, and in cells scattered near the ventral nerve cord (Walter, Black, Afshar, Kermabon, Wright, and Biessmann, 1991, Dev. Biol.).

*Y<sup>bb</sup>*: see *bb<sup>Y</sup>*

*Y2*: see *fs(1)Ya*

**yea: yeast**

**origin:** Induced by ethyl methanesulfonate.

**references:** Falk and Nash, 1974, Genetics 76: 755-66.

**phenotype:** A group of genes (all sex-linked) whose mutants require the addition of dead yeast to the standard sucrose *Drosophila* medium in order to show either normal viability or normal rate of development under certain temperature conditions. Some mutants are sensitive to cold or to heat even on yeast-supplemented media. These yeast-auxotroph genes are described in the following table:

locus	genetic location	number of alleles	temperature effects <sup>α</sup>	
			with yeast	without yeast
<i>yea1</i> <sup>β</sup>	1-37	1	lethal at 18°; viable at 25° and 29°	lethal or almost lethal at temperatures tested
<i>yea2</i>	1-16	1	viable at 29°	viable at 20°; lethal at 29°
<i>yea3</i>	1-0.8	1	viable at 18° and 25°; lethal at 29°	lethal at 25°
<i>yea4-1</i> <sup>γ</sup>	1-(3-5)	2	develop normally at 29°	develop slowly at 29°
<i>yea5</i> <sup>-2 γ</sup>	1-66	1	viable at 29°	lethal at 29°
<i>yea5</i>	1-66	1	viable at 18° and 25°; lethal at 29°	lethal at 25°
<i>yea6</i>	1-45	1	viable at 29°	viable at 20°; lethal at 29°
<i>yea7</i>	1-53	1	develop normally at 29°	develop slowly at 29°; (delay of four to five days)

<sup>α</sup> Temperatures used in tests given in table.

<sup>β</sup> Females sterile.

<sup>γ</sup> Noncomplementing mutant alleles; *yea4-1* shows a developmental delay of about three to five days when grown without yeast at the high temperature.

**yellow:** see *y*

**yem: yema**

**location:** 3- {99}.

**origin:** Differential screen for genes active during oogenesis whose transcripts disappear at gastrulation.

**references:** Ait-Ahmed, Thomas, Cavallin, and Rosset, 1987, Dev. Biol. 122: 153-62.

**phenotype:** Cluster of maternal effect genes active in oogenesis that have been isolated through their messenger RNAs and located by molecular methods at the distal end of 3R.

**cytology:** Located in 98F3-10 by *in situ* hybridization.

**molecular biology:** Genomic clone obtained that codes for four transcripts of 4.5, 4, 2.8, and 2.6 kb that are synthesized during oogenesis, are abundant throughout the preblastoderm embryo, and disappear during gastrulation.

All of the transcripts show germ line specific expression in the female. The 4 kb transcript seems to be synthesized in the nurse cells and is transferred to the oocyte; it reappears at postembryonic stages (Ait-Ahmed *et al.*, 1987).

**yl: yolkless**

**location:** 1-48.

**origin:** Induced by ethyl methanesulfonate.

**references:** Waring, DiOrio and Hennen, 1983, Dev. Biol. 100: 452-63.

Mohler and Carroll, 1984, DIS 60: 236-41.

Perrimon, Mohler, Engstrom, and Mahowald, 1986, Genetics 113: 695-712.

**phenotype:** Female-sterile locus affecting late oogenesis.

Eggs of mutants lack proteinaceous yolk and collapse; ultrastructurally abnormal chorion at anterior end and especially at base of respiratory filaments. No abnormality detectable in chorion protein synthesis. Uptake of the three yolk proteins by *yl* oocytes is severely reduced, although the proteins accumulate in the hemolymph.

**Yp: Yolk protein**

Three yolk proteins, YP1, YP2, and YP3, are synthesized in the fat body and ovarian follicle cells of wild-type adult female flies (Gelti-Douka *et al.*, 1974; Kambysellis, 1977; Bownes and Hames, 1978; Bownes, 1979; Brennan *et al.*, 1980, 1982; Postlethwait and Shirk, 1981). These proteins are the major tyrosine-sulfonated proteins in female flies (Bauerle and Huttner, 1985). After their synthesis, the yolk proteins are secreted into the hemolymph and transported to the egg, where they are converted into the mature form and packaged in the yolk granules (Warren *et al.*, 1979; Brennan *et al.*, 1982). Fat body cells produce approximately equal amounts of YP1, YP2, and YP3 mRNA and protein, but follicle cells synthesize considerably less YP3 transcript and gene product (Barnett *et al.*, 1980; Brennan *et al.*, 1982; Williams and Bownes, 1986). Ovaries transplanted from females into male hosts produce some YP mRNA and protein, but female fat cells transplanted into male hosts do not (Kambysellis, 1977; Postlethwait *et al.*, 1980). The three YP proteins are of similar molecular weight [approximately 44,700-47,000 daltons (Bownes and Hames, 1977; Hames and Bownes, 1978; Warren and Mahowald, 1979; Bownes, 1982)], but have different isoelectric points (Warren and Mahowald, 1979). Each protein is encoded by a single copy, X-linked gene, *Yp1*, *Yp2*, or *Yp3* (Barnett *et al.*, 1980). Regulation occurs by means of 20-hydroxyecdysone (involved in the accumulation of *Yp* transcripts in the fat body of females) and juvenile hormone (involved in the development of ovarian follicles) (Postlethwait and Handler, 1979; Jowett and Postlethwait, 1980; Bownes, 1982a, 1982b, 1986). Male and female larvae and adult males do not normally produce YPs. Some yolk protein, however, is produced in males injected with 20-hydroxyecdysone; juvenile hormone does not induce YP synthesis in male flies (Postlethwait *et al.*, 1980; Bownes and Nothiger, 1981; Bownes, 1982; Bownes *et al.*, 1983a). The products of the sex-determining genes, *ix*, *tra*, *tra2*, and *dsx* may influence the expression of the yolk protein genes (Bownes *et al.*, 1983b; Belote, Handler, Wolfner, Livak, and Baker, 1985, Cell 40: 339-48; Kraus *et al.*, 1988). *X/X* flies carrying *tra/tra*, *tra2/tra2*, or *dsx<sup>D</sup>/dsx* do not produce detectable amounts of yolk protein, but intersexes carrying *ix/ix*, *dsx/dsx*, or *dsx<sup>D</sup>/+* do synthesize YPs (although in reduced amounts) (Bownes and Nothiger, 1981; Bownes *et al.*, 1983b).

**Yp1****location:** 1-30.**discoverer:** Postlethwait, 80c.**phenotype:** Structural gene for the yolk protein YP1 found in recently-emerged female flies. Protein migrates at different rates in SDS-polyacrylamide gels when encoded by the electrophoretic variants  $Yp1^F$  (fast) and  $Yp1^S$  (slow), alleles that are female fertile and produce normal amounts of YP1.  $Yp1^{ts1}$ , which maps near the *Yp1* locus and is believed to be an allele, produces a slow-migrating translation product that is present in reduced amounts in the hemolymph and the ovaries (Bownes and Hodson, 1980); this mutant is female sterile.**alleles:**  $Yp1^F$  (=  $Yp1^{LC}$ ),  $Yp1^S$  (in Canton-S and Oregon-R stocks), and  $Yp1^{ts1}$ . The  $Yp1^{ts1}$  allele is a female sterile mutant [synonym = *fs(1)1163* (Bownes and Hodson, 1980)]. It is homozygous female sterile at 18° and homo- and heterozygous female sterile at 29°, producing flaccid eggs and reduced amounts of yolk protein at the high temperature (Bownes and Hodson, 1980).  $Yp1^{ts1}$  is female sterile over *Df(1)C52*, a deficiency for the *Yp1* locus (Postlethwait and Shirk, 1981).**cytology:** *Yp1* has been located in 8F-9B by *in situ* hybridization of cloned DNA to the salivaries (Barnett *et al.*, 1980; Riddell *et al.*, 1981); cytological location between 9A and 9B since found between the X breakpoints of  $T(1;Y)B52 = T(1;Y)9A;YL$  and  $T(1;Y)J2a = T(1;Y)9B;YS$ .**molecular biology:** The gene for YP1 has been cloned from Canton-S wild type and its nucleotide sequence obtained (Barnett *et al.*, 1980; Hovemann *et al.*, 1981; Hovemann and Galler, 1982; Hung *et al.*, 1982; Hung and Wensink, 1981, 1983; Riddell *et al.*, 1981). *Yp1* is 1635 bp long and present as a single copy, with a short exon followed by a very short intron (76 bp) and a long exon (Hung and Wensink, 1981, 1983). It is transcribed in a proximal to distal direction. The length of the transcript is about 1559 nucleotides plus poly(A) tail; the protein predicted from the nucleotide sequence is made up of 439 amino acids. The mutant  $Yp1^{ts1}$  has been cloned and sequenced (Saunders and Bownes, 1986); the mutant protein was found to differ from the wild-type protein by an amino acid substitution (isoleucine to asparagine) at position 92.Transformation experiments indicate that two enhancer sequences upstream from *Yp1* determine its tissue specificity (fat body or follicle cells) (Garabedian *et al.*, 1985, 1986; Shepherd *et al.*, 1985; Tamura, Kunert, and Postlethwait, 1985, Proc. Nat. Acad. Sci. USA 82: 7000-04).A *Yp1-Adh* fusion gene has been used to transform an *Adh*<sup>-</sup> chromosome; adult females (but not adult males or male and female larvae) expressed enzymatically active ADH (Aprison *et al.*, 1989). *tra2*<sup>ts2</sup> homozygotes with two X chromosomes show expression of the fusion gene only when they are raised at 16°, the temperature at which they are morphologically female and produce yolk proteins. Endogenous yolk protein genes show the same pattern of temperature expression as the fusion gene in females homozygous for *tra2*<sup>ts</sup> (Belote, Handler, Wolfner, Livak, and Baker, 1985, Cell 40: 339-48).**Yp2****location:** 1-29.5.**discoverer:** Postlethwait, 79a.**phenotype:** Structural gene for the yolk protein YP2 found in recently-emerged female flies. Protein migrates at different rates in SDS-polyacrylamide gels when encoded by the electrophoretic variants  $Yp2^F$  (fast) and  $Yp2^S$  (slow), alleles that are female fertile and produce normal amounts of YP2. A mutant  $Yp2^M$  (=  $Yp2^{12-1245}$ ) is female fertile but lays fewer eggs than normal (Mohler, Postlethwait, and Shirk) and does not contain yolk protein in the hemolymph or ovaries.**alleles:**  $Yp2^F$  (in Canton-S and Oregon-R stocks),  $Yp2^S$  [=  $Yp2^{Po}$  (Postlethwait and Jowett, 1980)], and  $Yp2^M$ , [induced by Mohler and believed to be a mutant allele (Mohler, 1977, Genetics 85: 259-72; Mohler and Carroll, 1984, DIS 60: 236-41; Tamura *et al.*, 1985)].**cytology:** *Yp2* has been located in 8F-9B by *in situ* hybridization (Barnett *et al.*, 1980; Riddell *et al.*, 1981); cytological location between 9A and 9B since found between the X breakpoints of  $T(1;Y)B52 = T(1;Y)9A;YL$  and  $T(1;Y)J2a = T(1;Y)9B;YS$ .**molecular biology:** The gene for YP2 has been cloned from Canton-S wild type and its nucleotide sequence obtained (Barnett *et al.*, 1980; Hovemann *et al.*, 1981; Hovemann and Galler, 1982; Hung *et al.*, 1982; Riddell *et al.*, 1981). *Yp2* is 1614 bp long (1225 bp distant from *Yp1*) and is present as a single copy, with a short exon followed by a very short intron (68 bp) and a long exon (Hung and Wensink, 1983). It is transcribed in a distal to proximal direction (opposite from the transcription direction of *Yp1*). There are two transcripts of 1614 and 1698 nucleotides in length. The protein predicted from the nucleotide sequence is made up of 442 amino acids. *Yp1* and *Yp2* show about 53% sequence identity (Yan *et al.*, 1987). The site of tyrosine sulfonation has been identified in this secretory protein (Baeuerle *et al.*, 1988); it is similar in amino acid composition and secondary structure to known tyrosine sulfonation sites in vertebrates.**Yp3****location:** 1-44.**discoverer:** Postlethwait, 79g.**phenotype:** Structural gene for the yolk protein YP3 found in recently-emerged female flies. Protein migrates at different rates in SDS-polyacrylamide gels when encoded by the electrophoretic variants  $Yp3^F$  (fast) and  $Yp3^S$  (slow), alleles that are female fertile and produce normal amounts of YP3.  $Yp3^{RI}$ , which maps close to the *Yp3* locus, has no detectable YP3 protein in the hemolymph or ovary, but is not female sterile (Postlethwait and Jowett, 1980; Postlethwait and Shirk, 1981).**alleles:**  $Yp3^F$  (=  $Yp3^{CB}$ ),  $Yp3^S$  (in Canton-S and Oregon-R stocks), and  $Yp3^{RI}$ , which behaves like a *cis*-acting regulatory variant and was found by Laurie-Ahlberg in wild stock RI14 (Postlethwait and Shirk, 1981).**cytology:** *Yp3* has been located in 12B-C by *in situ* hybridization (Barnett *et al.*, 1980; Riddell *et al.*, 1981); cytological location between 12A6-7 and 12D3, the region deleted from *Df(1)HA92 = Df(1)12A6-7;12D3*.**molecular biology:** The gene for YP3 has been cloned from Canton-S wild type and its nucleotide sequence obtained (Barnett *et al.*, 1980; Hovemann *et al.*, 1981;

Hovemann and Galler, 1982; Hung *et al.*, 1982; Hung and Wensink, 1981; Riddell *et al.*, 1981; Garabedian *et al.*, 1987; Yan *et al.*, 1987). *Yp3* is 1624 bp long and present as a single copy. It has two small introns and is transcribed in a distal to proximal direction (Yan *et al.*, 1987). The transcript is about 1499 nucleotides plus poly(A) tail in length; the protein predicted from the nucleotide sequence is made up of 420 amino acids. The mutant *Yp3<sup>R1</sup>* produces no translatable message in females, but carries normal amounts of transcripts that hybridize to the *Yp3* gene probe (Postlethwait and Shirk, 1981). The overall amino acid sequence identity of the three yolk protein genes is 43% (Garabedian *et al.*, 1987). *Yp1* and *Yp3* show about 53% identity in their amino acid sequences; *Yp2* and *Yp3* show about 48% identity. These identical sequences occur mainly in translated regions (Yan *et al.*, 1987).

Two small regions identical to the *Yp1* fat body enhancer region have been found in *Yp3* flanking sequences (Garabedian *et al.*, 1987).

**yrt: yurt**

**phenotype:** The regulatory gene *zeste* interacts with the white locus as well as with the bithorax and decapentaplegic complexes, changing the phenotypic expression of these loci.  $z^1$  was the first mutant allele identified (Gans, 1948, 1953); the homo- or hemizygotes of this neomorphic mutant show a lemon yellow eye color when carrying two paired copies of  $w^+$  or of the rightmost  $w^+$  alleles [as in  $z^1 w^+/z^1 w^+$  females or  $z^1/Y$  males with a  $w^+$  duplication (Jack and Judd, 1979)].  $z^1 w^+/Y$  males without the duplication,  $z^1/z^1$  females heterozygous for a  $w$  allele belonging to one of the right-hand (*zeste*-suppressing) subloci, or  $z^+/z^1$  females are wild type. An

intralocus duplication for a right sublocus of white produces mottling in  $z^1$  males.  $z^1$  eye color develops autonomously in mosaics and in eye-disk transplants. It is not affected by the number of Y chromosomes in the genotype. A third chromosome mutant *wo* interacts with  $z^1$  or  $z^{58g}$  to lighten eye color, producing  $z/z;wo/wo$  white-eyed females and  $z/Y;wo/wo$  males with a slight deviation from wild-type eye color (Rayle, 1969, DIS 44: 98; Kaufman *et al.*, 1973).  $z^1$  has no effect on the expression of the white gene in ocelli, testes, or larval Malpighian tubules.

The first  $z^a$  mutant was also identified by Gans. These mutants are wild type in  $z^a/Y$  males and  $z^a/z^a$ ,  $z^a/Df(1)z$ , and  $z^+/z^a$  females. The heteroallelic combination of  $z^1/z^a$ , however, results in yellow-eyed flies. Complementation between  $w^{sp}$  and other white alleles does not occur in  $z^a$  mutants, although it does occur in  $z^+$  or  $z^1$  flies (Babu and Bhat, 1980).  $z^a$ -type alleles, including  $z^{ae(bx)}$ , as well as the partial revertant of  $z^1$ ,  $z^{1IG3}$ , enhance the mutant phenotype of certain heteroallelic combinations of *BXC* alleles that show transvection (partial complementation) when paired;  $z^+$  and  $z^1$ , however, do not affect these *BXC* alleles (Kaufman *et al.*, 1973; Gelbart and Wu, 1982; Mariani *et al.*, 1985; Pirrotta *et al.*, 1987). All *zeste* mutant alleles tested enhance certain heteroallelic mutant combinations that show transvection in *dpp* (Gelbart and Wu, 1982).

The  $z^{op}$  mutants (Lifschytz and Green, 1984), unlike  $z^1$ , require only one copy of  $w^+$  for expression of a *zeste* eye color in homo- and hemizygotes. Heterozygotes over  $z^+$  are *zeste* if they have two copies of  $w^+$ , but are wild type if there is only one copy.

Another mutant,  $z^{v77h}$ , requires only one copy of  $w^+$  in males. The eyes are brown variegated in hemi- and homozygous  $z^{v77h}$  females and  $z^{v77h}/Y$  males, but wild type in homozygous  $z^{v77h} Dp(1;1)w^{+2}$  females and  $z^{v77h} Dp(1;1)w^{+2}/Y$  males, this allele responding to an increase in  $w^+$  dosage in a manner contrary to that of  $z^1$  (Green, 1984).

Diepoxy-butane-induced mutations (including multilocus deletions) have been generated in an attempt to obtain a null allele of *zeste* (Goldberg *et al.*, 1989). Some of the females that were completely deficient for  $z$  [*Df(1)z-deb3/Df(1)z-deb3*, for example] survived and were fertile, indicating that the product of the *zeste* gene is not required for viability or female fertility.

**alleles:** *Zeste* mutants and rearrangements are described in the following table. Deficiencies for *zeste* are listed as rearrangements. See end of text for more detailed descriptions of certain alleles.

allele	origin	discoverer	ref <sup>α</sup>	comments
<b>z<sup>1</sup></b>	spont	Gans, 46b	5-9, 10-13, 16, 17	eye color wild type in males; lemon yellow at 25°, mottled yellow and brownish red at 19° in homozygous females
<b>z<sup>1-35</sup></b>		Jack	11	no detectable DNA rearrangements
<b>z<sup>1-42</sup></b>		Jack	11	no detectable DNA rearrangements

<sup>β</sup> Synonym: *e(bx)*.

**cytology:** Located in salivary chromosome band 3A3 on the basis of its inclusion in  $Df(1)w^{258-11} = Df(1)3A3-4;3C2-3$  and  $Df(1)64C = Df(1)3A3-4;3C2-3$  (Gans, 1953, Judd, Shen, and Kaufman, 1972, *Genetics* 71: 139-56), but not in  $Df(1)K95 = Df(1)3A3-6;3B1$ . Also located in 3A3 by *in situ* hybridization to  $In(1)z^{ae(bx)}$  (Mariani *et al.*, 1985).

**molecular biology:** The wild type allele of *zeste* and some of the *zeste* mutants have been cloned and the cDNA sequenced (Mariani *et al.*, 1985; Gunaratne *et al.*, 1986; Pirrotta *et al.*, 1987). Cloning has been accomplished by microdissection of the salivary 3A1-4 region followed by microcloning and chromosome walking; also by "transposon tagging" of the locus with *P* elements, recovering the sequences flanking the 3A3-4 *P* insertion. Probes from the 3' or 5' end of the gene were used to isolate cDNA clones; the length of the longest clone was just over 2300 nucleotides (Pirrotta *et al.*, 1987). No detectable DNA rearrangements were found in many of the mutants (Gunaratne *et al.*, 1986). A transcript of 2.2-2.4 kb was found at all postzygotic stages of development in wild type and most mutant individuals; shorter transcripts were found in  $z^{ae(bx)}$ ,  $z^{\pi 1}$ , and  $z^{v77h}$ . Transcription is most abundant in maternal RNA; it declines during larval growth, but increases again in third instar larvae and pupae (Pirrotta *et al.*, 1988). The gene is transcribed along the *X* from distal to proximal. The  $z^+$  transcript includes three exons and two introns; no differences in exon size or position could be detected in the RNA of the mutants  $z^1$ ,  $z^{op6}$ , or  $z^a$ . *P* factor mediated germ-line transformation to wild-type eye color was carried out in a  $z^1 Dp(1;1)w^+$  strain (Gunaratne *et al.*, 1986); in other transformation experiments, yellow-eyed transformants were produced by injecting  $z^{op6}$  DNA in a *P* element vector into a  $y z^a$  strain (Pirrotta *et al.*, 1987).

The *zeste* protein predicted from the nucleotide sequence of wild type *zeste* cDNA has an amino terminal region with both basic and acidic residues, a second region that is acidic, a third region with few basic or acidic residues but many glutamines and alanines, and a carboxy terminal region with many basic and acidic residues (Pirrotta *et al.*, 1987). The protein binds directly to specific DNA sequences of the white, Ultrabithorax, decapentaplegic, Antennapedia, and engrailed regulatory regions (Benson and Pirrotta, 1987, 1988; Biggin *et al.*, 1988; Mansukhani *et al.*, 1988). Anti-*zeste* antibodies interact with approximately 60 specific bands in polytene chromosomes; this number is drastically increased by heat shock (Pirrotta *et al.*, 1988).

**other information:** Inversions, translocations, and transpositions with breaks in 3C3, induced as derivatives of  $z^1$  chromosomes carrying tandem duplications of  $w^+$ , result in a range of *zeste* phenotypes in males and females, the eye colors being *zeste*, *zeste* variegated, *zeste* halo, and wild type (Green, 1967, 1984). *E(z)* and *Su(z)* loci have been described (Green, 1967; Kalisch and Rasmuson, 1974, *Hereditas* 78: 97-104; Persson, 1976, *Hereditas* 82: 111-20).

**$z^1$**

**phenotype:** Two synapsed copies of  $w^+$  required for expression of *zeste* eye color (Gans, 1953). Ocelli wild type in color, as are testes and larval Malpighian tubules. Supports transvection at *Ubx* but not at *dpp*.

**molecular biology:** Comparison between the sequences of  $z^+$  and  $z^a$  shows many polymorphisms concentrated in the middle, repetitive part of the gene (Pirrotta *et al.*, 1987). There are no changes in the 5' flanking region or in the untranslated leader. Most of the changes do not affect the predicted amino acid sequence since they are in the introns or in the third position of the codons; the change from A to T (Lys to Met in the middle repetitive part of the protein) is believed to have an important effect on the properties of the mutant product (Pirrotta *et al.*, 1987).

**$z^{11G3}$**

**phenotype:** Partial revertant of  $z^1$  showing wild-type eye color in hemizygous males and homozygous females (Gans, 1953). Almost complete complementation of  $z^1$  eye color. Does not support transvection at *dpp* or *Ubx*.

**molecular biology:** The sequence of  $z^{11G3}$  is identical to that of  $z^1$  except that three nucleotides have been deleted, removing a tyrosine from the amino acid sequence (Pirrotta *et al.*, 1987).

**$z^a$**

**phenotype:** Hemizygous males and homozygous females said to be wild type in eye color (Gans); however, on closer inspection they are seen to have a diluted eye color that becomes brown with age (Pirrotta *et al.*, 1987).  $z^1/z^a$  females have *zeste* eyes;  $z^a w^{DZL}/z^a w^{ch}$  females have light brown eyes. Does not support transvection at *dpp* or *Ubx*.

**molecular biology:** No detectable rearrangements except for a DNA insertion (about 15 kb) of unknown significance (Gunaratne *et al.*, 1986).

**$z^{ae(bx)}$**

**phenotype:** Mostly wild type, but slight eye color variegation in homozygous females (Lewis, 1959, *DIS* 33: 96).  $z^1/z^{ae(bx)}$  females *zeste*. Does not support transvection at *dpp* or *Ubx*.

**molecular biology:** Lacks about 800 nucleotides of the *zeste* coding region, but otherwise the 5' half of the mutant gene is normal (Pirrotta *et al.*, 1987). The transcript of 1.4-1.8 kb (Mariani *et al.*, 1985; Gunaratne *et al.*, 1986) ends shortly after the 3A3 breakpoint of the inversion [breakpoint placed on molecular map of *zeste* at about +2.0 kb, the origin being the first *EcoRI* site in clone CS1014 (Gunaratne *et al.*, 1986)].

**$z^{op6}$**

**phenotype:** Eye color *zeste* in hemizygous males and homozygous females with only one copy of  $w^+$ ; homozygous females with two copies of  $w^+$  also *zeste*. Heterozygous  $z^+/z^{op6}$  females wild type if one copy of  $w^+$ , but *zeste* if two copies;  $z^{op6}$  reverts to weaker alleles after EMS or X rays (Lifschytz and Green, 1984).

**molecular biology:** Carries all the polymorphisms in the  $z^1$  sequence as well as the change from Lys to Met; also a C to T mutation causing a proline to leucine change in the middle region of the protein, increasing its hydrophobic nature (Pirrotta *et al.*, 1987).

**$z^{\pi 1}$**

**phenotype:** Hemizygous males and homo- or hemizygous females almost wild type in eye color. Supports transvection at *Ubx* (Pirrotta *et al.*, 1987).

**molecular biology:** *P* element insertion at coordinate 0 on

molecular map of Mariani *et al.* (within 10 kb of this origin and in the same orientation as the coordinates of Gunaratne *et al.*) plus a deletion of about 300 nucleotides (Pirrotta *et al.*, 1987); otherwise, coding region like that of  $z^+$ .

### $z^{v77h}$

**phenotype:** Eye color diluted, turning brownish with age in hemizygous males and hemi- and homozygous females with a normal complement of  $w^+$  genes.  $z^{a/2} z^{v77h}$  females are wild type;  $z^{1/2} z^{v77h}$  females are zeste;  $z^{v77h}$  hemizygous males and homozygous females carrying a  $w^+$  duplication in each X are wild type.

**molecular biology:** Carries deletion of about 320 nucleotides and addition of seven nucleotides in the first exon; P element was probably inserted, followed by excision of the P and the flanking deletion (Pirrotta), the deletion removing the AUG start codon.

$z^m$ : see  $w^{zm}$

### \*Z: *Zerknittert*

**location:** 1-5.5.

**references:** Grüneberg, 1931, Biol. Zentralbl. 51: 219-25. 1934, DIS 2: 8.

**phenotype:** Wings may be crumpled or incompletely unfolded, but majority overlap wild type. Viability 10% wild type. RK3.

**z2:** see under *ANTC*

### Z600

**location:** 3-[42].

**references:** Schultz and Butler, 1989, Genes Dev. 3: 232-42.

Schultz, Schlomchik, Cherbas, and Cherbas, 1989, Dev. Biol. 131: 515-23.

**phenotype:** Member of cluster of genes that includes *Eip28/29* and *Gdl*. Believed to play role in processes of early development.

**cytology:** Located in 71C3-D4 (Schultz and Butler, 1989).

**molecular biology:** Gene cloned, partially sequenced, and a 600-nucleotide transcript (missing sequences from the 5' end) detected in zygotes (Schultz *et al.*, 1989; Schultz and Butler, 1989). *Z600* is located upstream to the neighboring gene *Gdl<sup>M</sup>* and overlaps it. The *Z600* gene is expressed abundantly in very early embryos and again at a lower level in adults; the transcript is expressed at a higher level in oviposited eggs than in ovaries. The gene is 1780 bp long, with three exons of 453, 295, and 506 bp and two introns of 56 and 410 bp.

### zip: zipper

**location:** 2-107.6.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus and Kluding,

1983, DIS 59: 158-60.

Nüsslein-Volhard, Wieschaus and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Côté, Preiss, Haller, Schuh, and Jäckle, 1987, EMBO J. 6: 2793-2801.

Zhao, Côté, Jähmig, Haller, and Jäckle, 1988, EMBO J. 7: 1115-19.

**phenotype:** The wild-type allele of *zipper* is expressed in the nervous system during development and was believed to encode an integral membrane protein necessary for normal axon patterning (Zhao *et al.*, 1988); however it has more recently been shown to encode the heavy chain of cytoplasmic myosin (Kierhart). The mutants are embryonic lethals; abnormalities include a small hole in the ventral thorax, distortion of ventral denticle rows, and defects in head involution and dorsal closure (Nüsslein-Volhard *et al.*, 1984; Côté *et al.*, 1987). These defects vary in different alleles and in different embryos from the same egg laying (Côté *et al.*, 1987). The nervous system of mutant embryos also differentiates abnormally, showing local defects in the fasciculation pattern of axons (Zhao *et al.*, 1988), as indicated by antibody stains for neurons and their axons. These CNS abnormalities can be detected after germ band shortening and, together with the molecular data, suggested that neurological rather than epidermal defects are the primary ones in *zip* mutants (Côté *et al.*, 1987).

**alleles:** *zip<sup>1</sup>* (isolation number ID16), a strong allele showing severe cuticular and neurological defects, *zip<sup>2</sup>* (isolation number IIF107), a weaker allele, and 16 discarded alleles have been reported.

**cytology:** Located in 60E9-F1 since uncovered by *Df(2R)gsb = Df(2R)60E9-10,60F1-2*, but not by *Df(2R)SB1 = Df(2R)60E10-F1,60F5*.

**molecular biology:** The 60E9-60F1 region of 2R was cloned by microdissection and the clones were used to start a chromosome walk (Côté *et al.*, 1987). On the molecular map, the *zip* region lies between the proximal breakpoint of *Df(2R)gsb* at -55 to -49 kb ("- values to the left) and the proximal breakpoint of *Df(2R)SB1* at 0 to +3.5 kb ("+" values to the right). A transcript of 2.4 kb was demonstrated by northern blot analysis. The transcript accumulates in the mesodermal-neuroblast region (not in the ectoderm) at the extended germ band stage, but becomes restricted to neural tissue (brain and ventral nerve cord) from the time of germ band shortening up to hatching, not appearing in the precursor cells of the cuticle (Côté *et al.*, 1987).

*zip* cDNA has been sequenced and the putative amino acid sequence of the protein determined (Zhao *et al.*, 1988). There is a single open reading frame of 1500 bp which encodes a polypeptide of 500 amino acids with several domains, including a putative signal sequence and a transmembrane domain.

**other information:** Shown to be the same as *Mhc-c*, and is a synonym thereof (Kierhart).

- phenotype:** Structural gene for glucose 6-phosphate dehydrogenase (Zwischenferment of Warburg) [G6PD (E.C. 1.1.1.49)], the first enzyme in the oxidative part of the pentose phosphate shunt. Electrophoretic variants  $Zw^A$  and  $Zw^B$  have been described in *Drosophila melanogaster* (Young *et al.*, 1964; Young, 1966). The G6PD produced by  $Zw^A$  shows faster migration in starch gel (Young *et al.*, 1964) or acrylamide gel (Peeples, Barnett, and Oliver, 1967, *J. Hered.* 58: 243-45) than that produced by  $Zw^B$ . A  $Zw^A/Zw^B$  female shows fast- and slow-migrating bands but no hybrid band of intermediate mobility (Young *et al.*, 1964; Steele *et al.*, 1968; Hori and Tanda, 1980, *Jpn. J. Genet.* 55: 211-23). The B variant in both homo- and heterozygotes is characterized by a double band and shows more heat stability than the A variant (Steele *et al.*, 1968). A dominant sex-linked modifier of the electrophoretic mobility of G6PD,  $M(G6PD)$ , has been described by Komma (1968, *Biochem. Genet.* 1: 229-37). A regulatory element that affects the activity level of G6PD has been reported by Itoh and Hori (*Jpn. J. Genet.* 60: 441-53). The molecular weight of the A variant of G6PD approximates 147,000 and that of the B variant 317,000 according to Steele *et al.* (1968), who used the electrophoretic starch gel method and observed that the B form can dissociate and produce some A-like form. Lee, Langley, and Burkhart (1978, *Anal. Biochem.* 86: 697-706), using gel-filtration chromatography, reported that the B variant has a molecular weight of 240,000. A subunit molecular weight for the purified enzyme was estimated by Lee *et al.* to be 55,000 and by Hori and Tanda to be 69,000, as if the slow B variant represented a tetramer and the fast A variant a dimer of single polypeptides (Hori and Tanda, 1980; Miyashita *et al.*, 1986). Significant amounts of the enzyme are found in the fat body and the intestine of *Drosophila melanogaster* larvae (Cochrane and Lucchesi, 1980, *Genetics* 94: s20). Enzyme levels are raised by dietary sucrose or D-glycerate (Geer, Kamiak, Kidd, Nishimura, and Yemm, 1976, *J. Exp. Zool.* 195: 15-31; Geer, Woodward, and Marshall, 1978, *J. Exp. Zool.* 203: 391-402; Cavener and Clegg, 1981; Cochrane, Lucchesi, and Laurie-Ahlberg, 1983, *Genetics* 105: 601-13). A maternal form of G6PD can be detected up to the early pupal stage (Gerasimova and Smirnova, 1979). Total G6PD activity increases during the larval period, reaches a peak during the third larval instar, drops during pupation, and increases again in the adult (Bijlsma and Van der Meulen-Bruijns, 1979, *Biochem. Genet.* 17: 1131-44; Williamson and Bentley, 1983). The enzyme shows a characteristic staining pattern in imaginal disks (Cunningham, Smith, Makowski, and Kuhn, 1983, *Mol. Gen. Genet.* 191: 238-43).
- Males with one dose of  $Zw^+$  and females with two doses have about the same amount of G6PD activity, *i.e.* show dosage compensation for enzyme activity (Seecof *et al.*, 1969; Gvozdev *et al.*, 1971; Bowman and Simmons, 1973; Faizullin and Gvozdev, 1973; Williamson and Bentley, 1981). Females heterozygous for a  $Zw$  deficiency show a corresponding reduction in enzyme activity; males and females with an extra dose of  $Zw^+$  show increased enzyme activity (Seecof *et al.*, 1969; Maroni and Plaut, 1973; Stewart and Merriam, 1975). Contribution of each dose of G6PD to the level of enzyme activity is the same in triploid females as in diploid females (Lucchesi and Rawls, 1973).
- A number of low- and null-activity mutations have been induced at the  $Zw$  locus. The mutant alleles are fully viable (Gvozdev *et al.*, 1976; Hughes and Lucchesi, 1977; Bijlsma, 1980; Lucchesi *et al.*, 1979), but the larvae do not grow as well as wild type on a minimal

amino-acid diet lacking fatty acids and whole nucleic acids (Geer *et al.*, 1974). Null alleles at the *ry* locus are also viable, but double mutant combinations of  $Zw^-;ry^-$  do not survive (Lucchesi and Manning, 1988). Although  $Pgd^-$  flies are lethal,  $Zw^-Pgd^-$  flies carrying null alleles for both G6PD, the first enzyme in the pentose phosphate shunt, and 6PGD, the last enzyme, are viable, presumably because the toxic 6-phosphogluconate is not produced (Hughes and Lucchesi, 1977, 1978; Geer *et al.*, 1979; Lucchesi *et al.*, 1979).

Many natural populations throughout the world are polymorphic for the A and B variants (Oakeshott,

Chambers, Gibson, Eanes, and Willcocks, 1983, *Heredity* 50: 67-72). Rare variants from a number of North American populations have been screened by sequential electrophoresis of starch and acrylamid gels to detect molecular heterogeneity (Eanes, 1983, 1984; Eanes and Hey, 1986); the G6PD activity of these lines and also of induced mutants has been measured (see the following table).

**alleles:** The following table includes electrophoretic (wild-type), low activity, and null alleles at the *Zw* locus. (Synonyms for the  $Zw^+$  alleles,  $Zw^A$  and  $Zw^B$ , use terminology for allozyme variants from DIS 53: 117).

<sup>β</sup> >A = faster than *Zw<sup>A</sup>*; <A = slower than *Zw<sup>A</sup>*; >B = faster than *Zw<sup>B</sup>*; <B = slower than *Zw<sup>B</sup>*; % = percent of *Zw<sup>A</sup>* G6PD activity; null = no G6PD activity.

<sup>γ</sup> P-element insertion at 18D12-13 (Eanes and Hey, 1986).

**cytology:** Placed in 18D12-13 by *in situ* hybridization (Eanes and Hey, 1986).

**molecular biology:** A clone containing the G6PD gene sequence (hybridizing to salivary region 18D) was obtained from a *Drosophila melanogaster* genomic library (Ganguly *et al.*, 1985) and its translation product found to be a polypeptide identical to that of the

monomeric subunit of G6PD (molecular weight 55,000). A transcriptional map of the gene shows three introns, dividing the protein-coding region into four exons (Fouts *et al.*, 1988). The transcript is 2.0 kb long and there is one copy of the gene per X chromosome in both males and females (Ganguly *et al.*, 1985). The complete nucleotide sequence of *Zw<sup>+</sup>* DNA and the predicted

amino acid sequence are given by Fouts *et al.* (1988). The sequence of Oregon-R cDNA differs from Canton-S genomic DNA at three sites which do not change the predicted amino acid sequence. The 5' end of the mature mRNA is at nucleotide -289. The first ATG of the transcription unit is at position 1 and the second ATG at position 592; both start sites would result in a protein with a subunit molecular weight of about 55,000, the value predicted by Lee *et al.* (1978). The sequence upstream from each of these sites is GT-rich.

*Drosophila melanogaster* G6PD is not similar to the human enzyme for the first 42 amino acid residues, but about 65% identity exists throughout the sequence, especially near the N-terminal region and near the central part of the protein (Fouts *et al.*, 1988).

Germline transformation of a  $Zw^{nl}$  strain was carried out using a  $Zw^+$  vector. All transformations produced active G6PD enzyme even when the transduced gene was relocated to an autosome, but in an autosomal site no dosage compensation was observed in males (Fouts *et al.*, 1988).

**other information:** The activity of G6PD is influenced by factors on the second and third chromosomes (Laurie-Alberg *et al.*, 1980; Tanda and Hori, *Jpn. J. Genet.* 58: 591-606; Miyashita *et al.*, 1986). The suggestion of Giesel (1976, *Biochem. Genet.* 14: 823-33) that  $Zw$  regulates structural genes on the autosomes has not been supported by studies of the mobility or activity of G6PD in *Drosophila melanogaster* (Lucchesi *et al.*, 1979).

## ADDENDUM

**Gad: Glutamic acid decarboxylase (J.C. Hall)**

**location:** 3-[15].

**origin:** From molecular cloning, based on cross-hybridization with feline GAD-encoding gene.

**references:** Jackson, Newby, and Kulkarni, 1990, *J. Neurochem.* 54: 1068-78.

**phenotype:** The structural gene for glutamic acid decarboxylase. *Gad* probes detect putative GAD-encoding 3.1-kb mRNA, from 4-8 h of embryogenesis to adulthood; a 2.6-kb RNA was also found, in embryos and pupae only; *in situ* hybridization detects the RNA(s) in widely, but not uniformly, distributed CNS cortical regions (of adult heads and larvae), with no detectable signals in non-neural tissues.

**cytology:** *Gad* cDNA probe hybridized to 64A3-5; adults heterozygous for *Df(3L)HR277 [= Df(3L)63B12;64B12]* and a normal third chromosome display a 30-45% reduction in GAD levels.

**molecular biology:** Sequence of cross-hybridizing cDNA clones predicts a 510-amino-acid protein with overall sequence identity to feline coding material of *ca.* 50% (after alignment of *Drosophila* sequence with residues 81-585 of cat GAD); *in vitro* translation of *Drosophila* cDNA leads to *ca.* 57-kd protein (would correspond to a 510-residue polypeptide); this was immunoprecipitable and Western-blotable with anti-rat-GAD, though the latter experiments also found a 76-kd band.

**other information:** *Gad* cDNA probe did not cross hybridize with *Ddc* clone, though the sequences of these two genes indicate a region of sequence similarity in their coding regions (corresponding to pyridoxal-phosphate-binding region).

**ggy: groggy (J.C. Hall)**

**location:** 3-between *cu* and *sr* (based on mapping of physiological defects).

**origin:** Induced by ethyl methanesulfonate.

**references:** Timpe, Moats, Jan, and Jan, 1987, *Neurosci. Abstr.* 13: 578.

**phenotype:** Found as heat-sensitive adult paralytic; in physiological experiments on larvae, recordings from neuromuscular junctions show spontaneous depolarizations at room temperature, which probably result from anomalous spontaneous firing of motor neurons (*e.g.*, kainic acid, which blocks evoked junctional potentials, also blocks the spontaneous ones); patch-clamp experiments reveal no abnormalities of potassium-dependent-A or delayed-rectifying currents.

**Gtd: Glucose-tasting-defective (J.C. Hall)**

**location:** 1-(*v-f*, closer to *v*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Rodrigues, Sathe, Pinto, Balakrishnan, and Siddiqi, 1991, *Mol. Gen. Genet.* 226: 265-766.

**phenotype:** Isolated after feeding-preference enrichment, against positive glucose response, of descendants of mutagenized flies. Subsequent detailed testing revealed enhanced attraction to NaCl in feeding-preference test, NaCl tolerance in ingestion test, relative indifference to sucrose, and higher than normal threshold for quinine avoidance; all of these phenotypes semi-dominant. Gustatory responses of larvae normal. No alteration in

electrophysiologically measured response of peripheral (labellar) neurons to NaCl; causes lethality of males hemizygous for the mutation who also carry duplication for normal allele.

**cytology:** Maps to 10E1 or 11A7, based on inclusion in *Df(1)KA6 = Df(1)10E1-2;11A7-8* but not in *Df(1)m259-4 = Df(1)10C2-3;10E1-2* or *Df(1)m30 = Df(1)10E2;11A6-7*; in fact, females carrying either of the latter two deficiencies in heterozygous combination with *Gtd* are near-normal in sucrose and quinine responses (*i.e.*, closer to wild type than *Gtd/+*); yet, *Gtd* over either *Df(1)*v*-L2 = Df(1)9F13;10A1* or *Df(1)N105 = Df(1)10F7;11D1* leads to *Gtd/+*-like responses; *Gtd/y<sup>+</sup>Yv<sup>+</sup>#3 (9F4;10E3-4)* males die as second-instar larvae, whereas the *y<sup>+</sup>Yv<sup>+</sup>* duplication (9F4;10A1) does not effect such synthetic lethality; the X factor responsible for the lethality (in conjunction with the larger duplication) was inseparable from *Gtd* locus.

**other information:** Fails to complement nearby *gustD* mutations with respect to (recessive-type) quinine tolerance; when heterozygous with *gustC*, which is closely linked, flies show reduced response to sucrose that is more severe than in tests of either homozygous or hemizygous type; complements *gustB* in behavioral assays (*re* homozygous-type responses); three revertants of *Gtd/y<sup>+</sup>Yv<sup>+</sup>#3* lethal interaction also reverted with respect to sucrose-indifference phenotype.

**iav: inactive (J.C. Hall)**

**location:** 1-18.8 (*iav<sup>1</sup>*), 20.7 (*hypoB<sup>1</sup>*).

**synonym:** *hypoB*.

**references:** Kaplan, 1977, *DIS* 52: 1.

Homyk and Sheppard, 1977, *Genetics* 87: 95-104.

Homyk, 1977, *Genetics* 87: 105-28.

O'Dell and Burnet, 1986, *DIS* 63: 107-08.

O'Dell, Coulon, David, Papin, Fuzeau-Braesch, and Jallon, 1977, *Comptes Rendus Ser. III* 305: 199-202.

O'Dell and Burnet, 1988, *Heredity* 61: 199-207.

O'Dell, Burnet, and Jallon, 1989, *Heredity* 62: 373-81.

**phenotype:** *iav<sup>1</sup>* noted (Kaplan, 1977) to be extremely inactive as adult, with normal external morphology; population of mutants remains quiet and spread out evenly in a container; will walk or fly when container disturbed, but settles into inactivity soon afterward. *iav<sup>2</sup>* noted (Homyk and Sheppard, 1977) to be inactive and difficult to arouse for flight (and, when it does, seems to hover and fixate on objects); to jump and fly abnormally short distances; to exhibit slow running or climbing ability and optomotor response; to be debilitated after mechanical shock (especially in adults more than two weeks old). Gynandromorph analysis of *iav<sup>2</sup>* adult behavioral impairments suggests primary focus could be neural (Homyk, 1977). Open-field activity tests of *iav<sup>1</sup>* and *iav<sup>2</sup>* (O'Dell and Burnet, 1988) showed both to exhibit reduced speed as well as amount of locomotion (the former meaning number of squares in the activity chambered visited/unit time, the latter the proportion of time spent moving); male activity levels higher than for females (also found for wild-type); lower than wild-type levels of activity at all ages between time of eclosion and approximately one-month; yet, unlike wild type, speed and amount of activity increase (in tests of *iav<sup>2</sup>*) in parallel between days 1 and 2 of adulthood (reaching a much lower than normal plateau). In tests of homozygous *iav<sup>1</sup>*

and *iav*<sup>2</sup> females (with normal males), mating propensity reduced and courtship durations extended, though such females showed normal compositions of cuticular hydrocarbons and were highly attractive to courting males (O'Dell et al., 1989); mutant males with normal females exhibited slightly reduced mating success; mutant males crossed with mutant females had very low mating success rate. Lower than normal octopamine levels, especially in extracts from adult heads (O'Dell et al., 1987), with dopamine and norepinephrine levels apparently normal.

**alleles:** *iav*<sup>1</sup>, spontaneous (Kaplan, 1977), *iav*<sup>2</sup>, *iav*<sup>3</sup>, induced by ethyl methanesulfonate [originally *hypob*<sup>1-3</sup> (Homyk and Sheppard, 1977)].

**other information:** Allelism of *iav*<sup>1</sup> to *hypob*<sup>1</sup> shown by O'Dell and Burnet (1986) in open field tests of heterozygotes; they also note that both mutations are recessive.

### ***irreC: irregular chiasm-C (J.C. Hall)***

**location:** 1-1.7 (from cytology, association with *rst*; *irreC*<sup>1</sup> does map between *y* and *cv*).

**references:** Boschert, Ramos, Tix, Technau, and Fischbach, 1990, *J. Neurogenet.* 6: 153-71.

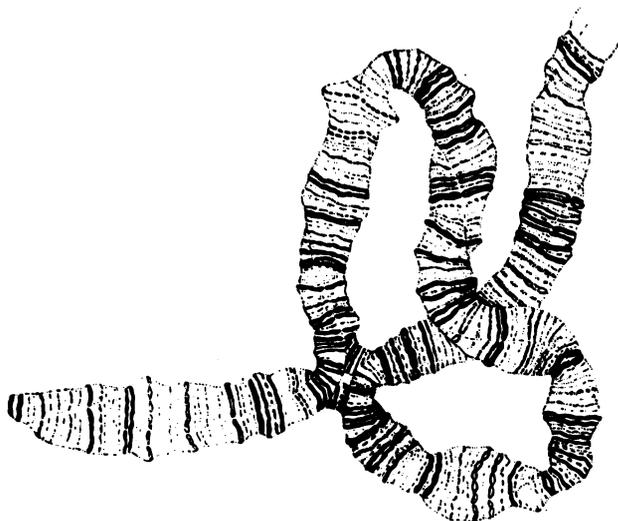

**phenotype:** In optic ganglia, fiber tracts from the medulla to the lobula plate penetrate lobula neuropile instead of projecting through second optic chiasm; occasionally, ectopic bundles of axonal fibers penetrate lobula-plate neuropile; in most severely deformed individuals, lobula and lobula plate are partly fused. In first optic chiasm, fibers from lamina are misrouted, taking detour around posterior medulla neuropile, penetrating the latter at variable positions on its inner (posterior) face from which positions the fiber tracts turn around and form normal-appearing terminals in retinotopic locations. Gynandromorph analysis showed that eye genotype does not induce optic lobe phenotypes. It also appears as if first- (or second-) chiasm defect does not induce that in the second (or first); among several mutant individuals analyzed (cf. variable expressivity under alleles), there is no correlation between the anatomical abnormalities in these two locations (though there is high correlation between defective first or second chiasm in left and right

sides of head). Optic lobe pioneer axons [larval neurons, which persist into adulthood and can be seen following path of first optic chiasm, and may guide newly growing fibers during formation of imaginal visual system (Tix, Minden, and Technau, 1989, *Development* 105: 739-46)] are displaced in *irreC* pupae, with their axons having followed ectopic pathways.

**alleles:** *irreC*<sup>1</sup> (*P*-element induced as *irreC*<sup>UB883</sup>) shows 94% penetrance for optic-lobe defects; good viability and fertility; expressivity highly variable (e.g., anatomical abnormalities can appear in only first but not second chiasm, or vice versa, or in only left or right side of the head). *IrreC*<sup>2</sup> (X ray induced as *irreC*<sup>IR34</sup>) shows high penetrance for optic-lobe abnormalities, but variable expressivity; females homozygous for this inversion (see below) do not lay eggs and have rudimentary egg chambers (likely not due to lesion in region 3C, owing to fertility of synthetic deletion described under cytology).

**cytology:** Located in 3C4-5. *irreC*<sup>1</sup> has a *P* element inserted in 3C (also in 2EF and 4D); *irreC*<sup>2</sup> is associated with *In(1)2A;3C3-6*, with anatomical defects inseparable from the inversion. The following deletions uncovered *irreC* mutation(s): *Df(1)JC19 = Df(1)2F6;3C5*, *Df(1)N8 = Df(1)3C2-3;3E3-4*, *Df(1)w258-42 = Df(1)3A4-6;3C5-6*, and *Df(1)N71h = Df(1)3C4;3D3-4*; the nearest complementing deletions tested were *Df(1)258-45 = Df(1)3B2-3;3C2-3* and *Df(1)N69h9 = Df(1)3C6;3D1*. Females heterozygous for *Df(1)w258-42/Df(1)N8* are *irreC*-like in their optic lobe anatomy (as well having white and roughest eyes, and seem no worse so than mutant homozygotes or hemizygotes; such females are also fertile).

**other information:** Associated with the closely linked *rst* locus. Whereas two mutant *rst* alleles (including *rst*<sup>6</sup>) lead to no apparent abnormalities in optic chiasms (cf. Meyerowitz and Kankel, 1978, *Dev. Biol.* 62: 112-42), and *irreC*<sup>1</sup> causes no eye roughening, this mutation over *Df(1)rst vt* leads to rough eyes; some *irreC*<sup>2</sup> flies show weak eye roughening, and that allele over *rst*<sup>6</sup> exhibits rough eyes but normal optic lobes.

Le Calvez, 1948, Bull. Biol. France Belg. 82: 97-113.

## CHROMOSOMES

**IDENTIFYING SYMBOLS.** The standard chromosome sequence or arrangement is the one on which the standard genetic map and the standard polytene chromosome map are based. Chromosome breakage and reunion can give rise to new chromosome sequences; i.e., chromosome aberrations.

As the number of interacting breaks increases, there is a geometrical increase in the number and complexity of possible rearrangements. Rather than a descriptive name and symbol for every type, chromosome aberrations are classified as deficiencies, duplications, inversions, rings, translocations, and transpositions; these are abbreviated *Df*, *Dp*, *In*, *R*, *T*, and *Tp*, respectively. Deficiencies, inversions, rings, and certain duplications and transpositions are intrachromosomal; translocations and other duplications and transpositions are interchromosomal. The abbreviation is followed parenthetically by an indication of the chromosome or chromosomes involved, and then by a specific designation which identifies the particular rearrangement. A brief arbitrarily chosen specific designator is preferred to a lengthy descriptive one. As with mutant symbols, aberration symbols are italicized and do not contain subscripts, or spaces.

**Translocations.** Translocations are rearrangements in which nonhomologous chromosomes interchange segments and thus involve at least two breaks. No distinction is made in the symbol between simple reciprocal and more complex translocations, nor are the involved arms indicated in the parenthetical chromosomal information. Participating chromosomes are separated by semicolons and listed in the following order: 1 (*X*), *Y*, 2, 3, and 4 [e.g., *T(1;Y;3)127*, *T(1,2,4)<sup>w</sup>D2*, and *T(1,4)B<sup>S</sup>*]. The chromosomal information (within parentheses) is aligned on the left margin, the different classes being ordered

numerically according to this information (e.g., 1;2, 1;2;3, 1;2;4, 1;3, etc., the *Y* falling between 1 and 2). Within chromosomal classes, translocations are arranged alphabetically according to specific designation. Individual elements of a translocation are denoted by the superscripts *P*, *D*, and *M*. *P* (proximal) refers to the source of the centromere of the element, *D* (distal) to the source of a terminus of different origin from the centromere, and *M* (medial) to the source of any material intercalated between *D* and *P*; segments are designated in the order *P*, *M*, and *D* [e.g.,  $2^P X^D$  from *T(1;2)Bld*,  $2^P 3^M X^D$  of *T(1;2;3)Din*]. This is a departure from previous practice according to which the order was reversed.

**Rings.** Rejoining of breaks in opposite arms of the same chromosome may give rise to a ring-shaped chromosome. In ring designations the symbol is followed in parentheses by the chromosome involved and then by a specific designation; e.g., *R(1)1*. Ring-shaped *Y* chromosomes are described as *Y* derivatives in the section on special chromosomes.

**Inversions.** Intrachromosomal aberrations that are not rings and that have at least one section whose map order (either cytological or genetic) is inverted with respect to adjacent regions are designated inversions. In the case of multiple-break intrachromosomal rearrangements, the distinction between inversions and transpositions often becomes ambiguous. An intrachromosomal rearrangement that can be partitioned into a duplicated and a deficient product by exchange with a normal-sequence chromosome is designated a transposition even though it may carry an inverted segment; otherwise, it is designated an inversion. Inversions may involve one arm (paracentric) or both arms (pericentric) of a chromosome; they are symbolized by the abbreviation *In* followed parenthetically by the chromosome arm

or arms involved and then by a specific designation; e.g., *In(2L)Cy*, *In(2LR)bw<sup>V1</sup>*. *In(1LR)* designates pericentric X-chromosome inversions rather than *Inp(1)*, which was formerly used, and *1L* is implied in *In(1)*. Sometimes one break of a simple autosomal inversion is in the pericentric heterochromatin and is not positioned with respect to the centromere, so that whether the inversion is paracentric or pericentric is indeterminate. In such cases, the parenthetical information consists of chromosome number with no arm designation. Recombination between similar inversions may produce viable recombinant inversions with the left end of one and the right end of the other. Superscripts *L* and *R* are used to identify the sources of the two ends; for example; *In(2R)Cy<sup>L</sup>bw<sup>VR</sup>DeIR*.

A segment inserted into a new location is in inverted order if its numerical order in salivary-gland-chromosome terminology is inverted with respect to the adjacent segments; it is in dyscentric order if its polarity with respect to the centromere is altered. When a segment from a right arm is inserted into a right arm or left into left, the inverted order is dyscentric; but in left-to-right and right-to-left insertions, the two terms are discordant, the inverted order being eucentric instead of dyscentric.

**Transpositions.** In this revision, the definition of transposition has been extended beyond that employed by Bridges to include interchromosomal as well as intrachromosomal rearrangements; i.e., we use the transposition category to designate insertional translocations. Transpositions are three-break rearrangements in which a chromosomal segment is removed from one chromosomal region and inserted into another; intrachromosomal transpositions are equivalent to the interchange of two chromosomal segments. The ambiguous distinction between some transpositions and inversions has already been discussed. Among interchromosomal rearrangements, the term transposition is reserved for that class of aberrations in which a segment is deleted from one chromosome and inserted into another, such that a reciprocal duplication and deficiency are generated by random assortment. Reciprocal interchanges of segments between nonhomologous chromosomes are classified as translocations. In the chromosomal designation of transpositions, the donor chromosome precedes the recipient; e.g., *Tp(2;3)P*, *Tp(3;1)ry<sup>35</sup>*.

**Deficiencies.** The term deficiency is applied both to deficient chromosomes and deficient genotypes; the distinction between the two is not absolute and the symbol *Df* is used to designate both. A deficient chromosome is one from which a segment, either terminal or interstitial, is missing; whereas, a deficient genotype is one that is hypodiploid or hypotriploid by virtue of having fewer than two or three doses, respectively, of a particular chromosome segment. Deficient chromosomes or deficient genotypes may be produced by induced deletion of segments, by reciprocal translocation between sister or homologous chromatids, as segregants from transpositions, or by recombination between inversions with similar but offset breakpoints. In addition, deficient genotypes may be constructed by combining elements of rearrangements (e.g., reciprocal translocations with similar but offset breakpoints as in the method of segmental aneuploidy). Deficient chromosomes, but not deficient

genomic constructs, are included in this revision. The symbol *Df* is followed by the parenthetical indication of the chromosome arm involved and then by a designator of the specific deficiency. In past editions, deficiencies for genes have been treated as alleles; here we abandon that practice by avoiding superscripts in the specific designations [e.g., *Df(2R)vg-B* not *Df(2R)vg<sup>B</sup>*; *Df(3L)st3* not *Df(3L)st<sup>3</sup>*]; when the deficiency is not named after the deleted gene, however, the superscript is retained [e.g., *Df(1)sc<sup>8</sup>*, not *Df(1)sc8*]. Deficiencies recovered as revertants of dominant mutants are simply denoted as deficiencies for the gene involved. Unless otherwise indicated, deficiencies are assumed to be hemizygous or homozygous lethal. The advent of restriction mapping and nucleotide sequencing has revealed intragenic deletions; these are not treated as deficiencies, but as mutations; at least two adjacent loci must be removed before a chromosome is considered a deficiency.

**Duplications.** Chromosomes that carry an additional chromosome segment derived either from a sister chromatid, a homologous chromosome or a nonhomologous chromosome are termed duplications and abbreviated *Dp*. As with deficiencies, the distinction can be made between duplicated chromosomes and duplicated genomes, and only the former are described herein. Duplicated chromosomes are formed as the reciprocal product of several of the deficiency-generating events; e.g., reciprocal interchanges between sisters or homologues, segregants from transpositions, and recombinants between inversions with offset breakpoints. In addition, deletion of the majority of a chromosome can generate a small centric element which may be carried as a free duplication. Certain *Y* duplications carrying marker gene(s) are described as *Y* derivatives in the section on special chromosomes. The symbol for duplication follows the same plan as that used for transpositions; the parenthetical chromosomal information contains the chromosome of origin of the duplicated segment listed first followed, after a semicolon, by the recipient chromosome; e.g., *Dp(3;1)O5*, *Dp(1;1)y<sup>bl</sup>*. When the duplicated segment is carried as a free centric element, the letter *f* (free) follows the semicolon within the parentheses; e.g., *Dp(1;f)101*. A small chromosome segment duplicated *in situ* may be referred to as a repeat, even though it is still symbolized as a duplication; e.g., *Dp(1;1)B*. When the duplicated regions are in the same order, the term tandem repeat is sufficient to specify accurately the new chromosome if the limits of the duplicated segment are known. When these regions are inverted with respect to each other, two reversed repeats are possible, making it necessary to specify which end of the segment is at the axis of symmetry of the repeat; i.e., ABCCBD or ACBBBD. Failure to make such a distinction has given rise to ambiguous descriptions. Recombinations within tandem repeats can lead to formation of triplications and in successive steps to tandem repeats of order higher than three. Such high-order repeats are also symbolized *Dp*, with the number of repeats indicated in the parenthetical chromosomal designation, i.e., *Dp(1;1)* = duplication, *Dp(1;1;1)* = triplication, and so forth.

**Combinations of rearrangements.** The elementary categories of chromosome aberrations are not mutually exclusive, and some aberrations combine several of them. In such cases the symbol used is the one that

stands highest in the following ranking:  $T > \text{interchromosomal } Tp > R > In > \text{intrachromosomal } Tp > Dp > Df$ . This is especially so when the components are inseparable. A complicated rearrangement may be separable genetically into its simpler component aberrations, which are usually sufficiently designated with the distinguishing symbol of the original aberration. When, however, the original is named after a phenotype associated with one of the component aberrations, designation of the other component with the symbol of the mutant is inappropriate. A rearrangement superimposed upon another rearrangement may be given a name, which more often than not refers to the entire complex since the newly induced aberration is likely to be inseparable from the original; e.g.,  $In(2LR)SMI$  is a large pericentric inversion superimposed upon  $In(2L)Cy + In(2R)Cy$ . Component rearrangements of synthetic combinations of aberrations are occasionally referred to individually, connected with a plus sign; for example,  $In(1)sc^{\delta} + In(1)dl-49$  or  $In(2L)Cy + In(2R)Cy$ . Collecting terms in much the same way as algebraic factoring to further abbreviate the symbol is legitimate; e.g.,  $In(1)sc^{\delta} + dl-49$  and  $In(2L+2R)Cy$ . Formerly, chromosomes with more than one inversion were symbolized  $Ins( )$ ; we use instead  $In( )$  for both singly and multiply inverted chromosomes since the presence of more than one inversion is indicated by the specific designation; e.g.  $In(1)sc^{S1L}sc^{8R} + S$ .

In describing a chromosome, inclusion of several types of information is often desirable; e.g., sequence and gene content. Such categories are separated by a comma followed by a space; e.g.,  $In(1)dl-49, y w B$ , which designates an *X* chromosome carrying the delta-49 inversion, the recessive markers yellow and white, and the dominant marker Bar. Marker genes are listed in the order of the standard genetic map irrespective of their order on the chromosome in question. Three categories of information may be necessary to describe some special chromosomes; e.g.,  $YSX.YL, In(1)EN+dl-49, y B$ , where, besides gene content and sequence, it is informative to designate an abnormal combination of complete chromosome elements.

**DESCRIPTIVE SYMBOLS.** In addition to identifying symbols just discussed, aberrations are given alternative descriptive symbols indicating points of breakage on the chromosome map; breakpoints are listed in numerical order according to the limits within which they must lie. Each major euchromatic arm as seen in salivary-gland-chromosome preparations is divided into 20 numbered divisions; the heterochromatic complement displays linear differentiation in mitotic prophase and has been subdivided into 61 segments, designated h1 through h61 by Gatti and Pimpinelli (e.g., 1983, Chromosoma 88: 349-73 for the *Y* chromosome). The euchromatic map is numbered sequentially from 1 through 102, with heterochromatic segments h1-h61 interspersed as follows:  $YL-YS = h1-h17-h18-h25$ ;  $YL-XR = 1-20 h26-h32-h33-h34$ ;  $2L-2R = 21-40 h35-h37-dh38-h46 41-60$ ;  $3L-3R = 61-80 h47-h52-h53-h58 81-100$ ;  $4 = h59-h61 101-102$ ; centerpoints indicate centromere positions. Each numbered division on the salivary map is divided into six subdivisions designated by the letters A through F, each of which begins with a heavily staining band; within the lettered subdivisions, the bands are numbered individually. Thus the complete designation of a particular band

consists of its numbered division, its lettered subdivision, and its number; e.g., 3C2. Positions of breakpoints are designated according to the bands between which or the region or regions within which they are known to lie; for example, if a break lies between bands 3C2 and 3C7, its position is designated 3C2-7; for the sake of brevity, the redundant information 3C is omitted from the second half of the notation. Less accurately determined breakpoints may be given less specific designations; e.g., 3C or 3. An example of the total designation, both identifying and descriptive, is as follows:  $Tp(2;3)P = Tp(2;3)58E3-F2;60D14-E2;96B5-C1$ , items of chromosomal information being separated by semicolons without spaces. Breakpoints are listed in order. Often heterochromatic breakpoints are determined only in polytene preparations; in this case they are designated according to polytene locations 20F, 40, 41, 80, 81, 101 for *X*, *2L*, *2R*, *3L*, *3R*, and *4*, respectively; when prophase determinations have been made h1-h61 designations are employed. *X*-heterochromatin breaks are given arbitrarily as 20F. Apparent terminal deficiencies carry a single breakpoint designation. Descriptions of incompletely analyzed rearrangements incorporate the known information.

Descriptive symbols are used simply as a shorthand method for providing information about the aberration; they supplement rather than substitute for the identifying symbols. We have attempted to give breakpoints according to the revised salivary gland chromosome maps published by C. B. and P. N. Bridges rather than according to C. B. Bridges's original maps, in which individual bands were not numbered. No special notation is used to designate doublet bands; the member of the doublet closer to the breakpoint alone is listed.

Breaks rejoin cyclically to produce chromosome aberrations (e.g., A with B and B with A) and multiple breaks may rejoin in one or more cycles. Thus four breaks may interact to form one four-break rearrangement or two two-break rearrangements. A complex rearrangement consisting of two or more simple cyclic rearrangements is indicated in the descriptive symbol; e.g.

$$T(2;3)OR72 = T(2;3)19E;29F + In(2LR)24F;54B$$

or

$$T(1;2)C314 = T(1;2)5D;40-41 + T(1;2)9D;51D + T(1;2)20;56F.$$

The order in which the component rearrangements are listed in complex descriptive symbols follows the hierarchy according to which the identifying symbol is determined. For a rearrangement superimposed upon a preexisting rearrangement a similarly compound designation is used except that the plus symbol is replaced by the word on. If one of the new associations of the preexisting rearrangement is broken by the superimposed aberration, then the descriptive symbol is written as though the entire aberration occurred at one time rather than stepwise. An example is:  $T(1;4)w^{m52b13}$ , which was superimposed upon  $In(1)rst^2$ , is designated

$$T(1;4)2A2-3;3C3-4;20B;101$$

since 20B, which was originally adjacent to 3C3, has

become associated with 2A2 and 3C3 with 101. A cyclic rearrangement was produced involving both the preexisting breakpoints and the subsequently occurring ones; i.e., the symbol cannot be written as the old and the new cyclic rearrangements.

**NEW ORDERS.** In an aberration having only two breakpoints, the new order follows unambiguously from the descriptive symbol. In heterochromatic rearrangements, however, an ambiguity in the position of the breakpoint with respect to the centromere may lead to ambiguities in order. Thus, for example, *T(1;2)8F;40-41* has chromosome 2 broken into two pieces, one extending from 21 to 40 and the other from 41 to 60. Since it is not known which piece is centric, it is not possible to state to which portion of chromosome 2 the acentric portion of the X extending from 1 to 8F is attached. With three or more breakpoints more than one new order is possible; specifying the breakpoints is therefore not sufficient to describe the aberration. We have adopted the following conventions for specifying sequences of aberrations. The sequence of each chromosome involved in an aberration is specified from one end to the other according to salivary gland chromosome terminology. Points of breakage and reunion are indicated by vertical bars, and segments between these points are designated by the most extreme band known to be included at each end, separated by a dash. Thus the order of

$$Tp(2;3)P = T(2;3)58E3-F2;60D12-E2;96B5-C1$$

is represented as follows:

21 - 58E3|60E2 - 60F;  
61 - 96B5|60D14 - 58F2|96C1 - 100.

Were the order of the inserted segment 60D14 - 58F2 not known, the segment would have been included within parentheses; i.e.,

61 - 95B5|(58F2 - 60D14)|96C1 - 100;

hierarchies of ambiguities are represented by parentheses within parentheses. Salivary terminology is not italicized except when part of an aberration symbol, either identifying or descriptive. Use of information on order depends only on remembering that chromosome 1 extends from 1 through 20, with the centromere and the proximal heterochromatin in 20F in polytenes or h26-h34 in prophase chromosomes, the Y chromosome from h1 through h25 with the centromere between h17 and h18, chromosome 2 from 21 through 60 with the centromere between 40 and 41, chromosome 3 from 61 through 100 with the centromere between 80 and 81 and chromosome 4 from 101 through 102 with the centromere in 101D. The first breakpoint in *Tp(2;3)P* is listed as 58E3-F2; the first segment indicated in the sequential formula goes through band 58E3, and the inserted segment begins with 58F2. Nothing is implied about the position of the intervening bands 58E4 to 58F1; unless they are specifically described as missing, they are assumed to exist in association with one or the other or both fragments produced by the break. Information on new order is written as follows: each chromosomal element starts at the free end with the lower value and the elements are listed in

ascending order, Y falling between 20 and 21.

When desirable, the centromere position is designated with a centerpoint; in special cases where centromeres and breakpoints coincide, as is frequently true with ring-X chromosomes, the centerpoint replaces the vertical line.

Rings are differentiated from rod-shaped chromosomes by vertical bars at the beginning and end of the element; the circle is broken for linear designation at the breakpoint with the lowest numerical value; e.g., |1A4 - 20.20F - 20A1| for *R(1)2*. In multiple-break rearrangements in which there is a break in autosomal heterochromatin whose position with respect to the centromere is ambiguous, the new order may be written in two ways depending on the position assumed for the heterochromatic break. In such cases, we have usually assumed (for the sake of supplying the remainder of the new order) that the heterochromatic break is in region 40 for breaks in chromosome 2 and 80 for breaks in chromosome 3.

**FORMAT.** The chromosome aberrations are now listed in alphanumerical order according to symbol, which is in bold face. Names, where necessary, are listed (also in bold face) with cross-references to symbols; synonymic names and symbols appear in italics with cross-references to current symbols. Each aberration description is written in the following format:

**symbol: name**

**cytology:** The descriptive symbol as discussed above.

**new order:** As discussed in the preceding paragraphs.

**origin:** The inducing agent is listed; aberrations recovered from untreated parents are listed as spontaneous or naturally occurring, depending on whether recovered as a single occurrence or repeatedly.

**discoverer:** Name, date.

**synonym:** Alternative symbols or names, or both.

**references:** Sources of descriptions of the aberrations listed in this section, although bibliographic information may appear under other categories as well.

**genetics:** Effects of the aberration on the expression of genes near the breakpoints and phenotypic effects not yet attributable to known genes are described. Genes known to be present or absent in duplications and deficiencies indicated. Segregational and recombinational behavior may also be described. Descriptions of aneuploid derivatives are also included in this category.

**molecular biology:** In long genomic walks in extensively studied regions, the molecular coordinates of rearrangement breakpoints have been determined. These are generally given in terms of kilobases from the origin, which may be a rearrangement breakpoint, the insertion point of a transposable element, or an arbitrarily chosen restriction site. Directionality of molecular coordinates are usually, but not invariably, concordant with that of the cytological map.

**other information:** In rare instances, information not fitting into other categories is included here.

Groups of rearrangements that share common features or names are tabulated wherever feasible rather than being listed as separate entries. Their distinguishing features are represented in columns whose orders approximate that of the categories of information listed in full entries.

deficiency	cytology	genetics
<b>Df(1)18-80</b>	{19F3;19F4}	<i>flil<sup>-</sup>-l(1)19Fe<sup>-</sup></i>
$\alpha$	Proximal breakpoint located by Yamamoto and Miklos (1987) between 19E3 and 19E4 instead of 19E6 and 19E7 (Schalet and Lefevre, 1976). The corrected breakpoint is consistent with the viability of <i>Df(1)16-3-35</i> when heterozygous with <i>Df(1)A118 = Df(1)19E4-5;19E8</i> .	
$\beta$	Also see Rahman and Lindsley, 1981, Genetics 99: 49-64.	
$\gamma$	<i>Df(1)17-137bb<sup>L-158</sup></i> females are phenotypically <i>bb</i> and more than 50% of them show <i>eo</i> .	
$\delta$	See Baird, Schalet, and Wyman, 1990, Genetics 126: 1045-59.

genetics: Deficient for *lfl-l(1)20Bb* and duplicated for *sc*.

*Df(1)59*: see *Df(1)ras59*

**\*Df(1)60b**

origin: X ray induced.

discoverer: Mackensen.

references: 1935, J. Heredity 26: 163-74 (fig.).

genetics: Deficient for *f* but not *fw* or *r*.

**Df(1)62d18**

cytology: *Df(1)3B1-2;3C6-7*.

origin: X ray induced.

discoverer: Judd, 62d18.

references: Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

genetics: Deficient for *l(1)3Bb-rst* but not *N*.

molecular biology: Left breakpoint localized to an approximately 4 kilobase restriction fragment fifty kilobases to the left of the origin of a 160 kb walk (Gunaratne, Mansukhani, Lipari, Liou, Martindale, and Goldberg, 1986, Proc. Nat. Acad. Sci. USA 83: 701-05).

**Df(1)62g18**

cytology: *Df(1)3A1-2;3A4-5*.

origin: X ray induced.

discoverer: Judd, 62g18.

references: Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 265-82.

Honisch and Campos-Ortega, 1982, DIS 58: 76-77.

genetics: Deficient for *gt - l(1)3Ac* but not *l(1)3Ad*. Embryos hemizygous for the deficiency show defects of the cuticle, central nervous system, and head due to absence of the *gt* locus (Honisch and Campos-Ortega, 1982). Germ-line clones lethal (García-Bellido and Robbins, 1983, Genetics 103: 235-47).

**Df(1)64c4**

**cytology:** *Df(1)3A3-4;3C2-3*.

**origin:** X ray induced.

**discoverer:** Judd, 64c4.

**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 265-82.

**genetics:** Deficient for all known loci between *z* and *w*. Also deficient for *w* but not for *z*. Male lethal in embryo.

**molecular biology:** Left breakpoint localized to a 4 kilobase BamHI restriction fragment near the origin of a 160-kb walk (Gunaratne, Mansukhani, Lipari, Liou, Martindale, and Goldberg, 1986, Proc. Nat. Acad. Sci. USA 83: 701-05).

**Df(1)64c18**

**cytology:** *Df(1)2E1-2;3C2*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**references:** Craymer and Roy, 1980, DIS 55: 200-04.

Gvozdev, Gerasimova, Kovalev, and Ananiev, 1977, DIS 52: 67-68.

Perrimon, Engstrom, and Mahowald, 1984, Genetics 108: 559-72.

1985, Genetics 111: 23-41.

**genetics:** Deficient for *pn - w*.

**Df(1)64f1**

**cytology:** *Df(1)3A9-B1;3B2-3*.

**origin:** X ray induced.

**discoverer:** Abrahamson, 64f1.

**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 365-82.

Young and Judd, 1978, Genetics 84: 723-42.

**genetics:** Deficient for *l(1)3Ba*, *per* and *l(1)3Bb* but not *l(1)3Ag* or *l(1)3Bd*. Larval lethal (Judd). Cell lethal in cuticle and in germ-line clones. (Ripoll and García-Bellido, 1979, Genetics 91: 443-53).

**molecular biology:** Right breakpoint 82-85 kb distal to the *w<sup>a</sup>* copia insertion point (Pirrota, Hadfield, and Pretorius, 1983, EMBO J. 2: 927-34; Reddy, Zehring, Wheeler, Pirrota, Hadfield, Hall, and Rosbash, 1984, Cell 38: 701-10).

**Df(1)64j4**

**cytology:** *Df(1)3A8-9;3B1-2*.

**origin:** Found in stocks in separable combination with *Df(1)w<sup>258-45</sup>*.

**discoverer:** Judd, 64j4.

**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 265-82.

Young and Judd, 1978, Genetics 88: 723-42.

**genetics:** Deficient for *l(1)3Ag* and *l(1)3Ba* but not *l(1)3Ae* or *l(1)3Bb*. Also removes *per* (Bargiello and Young, 1984, Proc. Nat. Acad. Sci. USA 81: 2142-46; Bargiello, Jackson, and Young, 1984, Nature 312: 752-54; Reddy, Zehring, Wheeler, Pirrota, Hadfield, Hall, and Rosbach, 1984, Cell 38: 701-10). Cell lethal in cuticle (Ripoll and García-Bellido, 1979, Genetics 91: 443-53). Germ-line clones lethal (García-Bellido and Robbins, 1983, Genet-

ics 103: 235-47).

**molecular biology:** Right breakpoint between 89 and 98 kb distal to the *w<sup>a</sup>* copia insertion point (Pirrota, Hadfield, and Pretorius, 1983, EMBO J. 2: 927-34).

**Df(1)65j26**

**origin:** X ray induced.

**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 365-82.

García-Bellido and Ripoll, 1973, Nature 273: 399-400.

**genetics:** Deficient for *gt-l(1)3Ac*. Male lethal in embryo but cell viable in cuticle (Ripoll and García-Bellido, 1979, Genetics 91: 443-53).

**Df(1)70**

**cytology:** A series of four distally located deficiencies; breakpoints tabulated below.

**origin:** Induced by mutator gene *mu*.

**references:** Green and Lefevre, 1972, Mutat. Res. 16: 59-64.

<sup>β</sup> Male sterile in combination with *y<sup>+</sup>Ymal<sup>+</sup>* (Rahman and Lindsley, 1981).

<sup>γ</sup> *Df(1)A58/Df(1)A118* survives (Schalet and Lefevre, 1976) and shows *vao*.

<sup>δ</sup> *Df(1)16-3-35/Df(1)A118* survives (Schalet and Lefevre, 1976) and shows *shakB* (Baird).

**\*Df(1)A1:** see **Tp(1;4)A1**

**\*Df(1)A12:** see **T(1;2;4)A12**

**Df(1)ac: Deficiency (1) achaete**

**origin:** X ray induced simultaneously with a detachment of an attached X marked with *y*.  
**references:** Muller, 1954, DIS 28: 146-47.  
**genetics:** Deficient for *ac* and probably *y*. Male viable.

**Df(1)arth: Deficiency (1) arthritic**

**origin:** X ray induced in *In(1)sc<sup>S1L</sup>sc<sup>8R</sup>In(1)dl-49* chromosome.  
**discoverer:** Schalet.  
**references:** Fleming, DeSimone, and White, 1989, Mol. Cell Biol. 9: 719-25.  
**genetics:** Deficient for *arth-ac* but not *sc*. Male and female viable.

**Df(1)At127**

**cytology:** *Df(1)1E3-4;2A2-3*.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.  
**genetics:** Deficient for *l(1)1EFa-l(1)1EFj*.

**Df(1)B: Deficiency (1) Bar**

**cytology:** *Df(1)15F9-16A1;16A6-7* superimposed on *Dp(1;1)15F9-16A1;16A7-B1*. All of the left 16A section and all but 16A7 of the right 16A section is included in the deficiency. Sutton (1943), confirmed by Peterson and Laughnan (1963), included *f* as if the left breakpoint were more distal than indicated.

**new order:**

1 - 15F9|16A7 - 20.

**origin:** X ray induced in B chromosome.

**discoverer:** Demerec, 34a.

**synonym:** *Df(1)B263-20*.

**references:** Sutton, 1943, Genetics 28: 97-107 (fig.).  
 Peterson and Laughnan, 1963, Proc. Nat. Acad. Sci. USA 50: 126-33.

Laughnan, 1970, Mol. Gen. Genet. 108: 93-96.

**genetics:** Reversion of B. Deficient for *f-B*. Male lethal.

**Df(1)B12-Df(1)B264**

**origin:** X ray induced.

<sup>β</sup> Synonym: *Df(1)g<sup>HA92</sup>*. Deficiency uncovers *mus(1)101* (Mason *et al.*, 1981).  
<sup>γ</sup> Listed as *Df(1)HC163* by Craymer and Roy, 1980.  
<sup>δ</sup> Deficiency lost according to Craymer and Roy, 1980.  
<sup>ε</sup> Lethal segregant from *Df(1)HC163* or *Df(1)RC40* (Lawlor, 1980).  
<sup>ζ</sup> Synonym: *Df(1)fw<sup>HF368</sup>*.

**Df(1)Hk. Deficiency (1) Hyperkinetic**

**cytology:** *Df(1)9A;9C.*  
**origin:** X ray induced.  
**discoverer:** Schlimgen and Kreber.  
**synonym:** *Df(1)Hk<sup>ΔR2</sup>*.  
**references:** Stern and Ganetsky, 1989, J. Neurogenet. 5: 215-28.  
**genetics:** Deficient for *Hk.*

**Df(1)HM: Deficiency (1) Hycanthon Methanesulfonate**

**origin:** Induced by hycanthon methanesulfonate.

<sup>β</sup> The zero coordinate used in locating the molecular lesions in the Notch deficiencies is the first Eco R1 site in Canton-S DNA proximal to the 3C7 breakpoint of In(1)N<sup>76b8</sup> (Kidd *et al.*, 1983); it is 1.1 kb to the right of the zero coordinate used by Artavanis-Tsakonis *et al.*, 1983.

<sup>γ</sup> Lacks Sgs-4 sequences (McGinnis *et al.*, 1980).

<sup>δ</sup> 3C7 not deleted but appears thinner than normal (Grimwade *et al.*, 1985).

<sup>ε</sup> Later reexamination of chromosomes of males from lines carrying w<sup>ch</sup> and marked N<sup>264-39</sup> revealed the presence of 3C7 (Welshons).

<sup>ζ</sup> Cell lethal and lethal in germ-line clones (Ripoll and Garcia-Bellido, 1979, Genetics 91: 443-53).

<sup>η</sup> 50 Notch mutations originating independently in In(1)cm-df = In(1)3D;6D + Df(1)6D;6F (a derivative of the unstable X Uc-1<sup>UD15</sup>) showed this apparently identical X chromosome deficiency (New order: 1A1 - 3C7 | 6D - 3D | 6F - 20). Results from *in situ* hybridizations with 20 of these deficiencies indicated a deletion of 10 kb of the sequences from the 3' end of Notch had occurred (Johnson-Schlitz and Lim, 1987). The break position of these Notch deficiencies is within the 2.2 kb Eco R1 fragment with the next 3'-most clone (Kidd *et al.*, 1983), which corresponds to the region between N<sup>264-40</sup> and spl in the genetic map.

***Df(1)sc<sup>8</sup>: Deficiency (1) scute-8***

**cytology:** *Df(1)1A1;1B2*.  
**origin:** Spontaneous in *In(1)sc<sup>8</sup>*.  
**discoverer:** Noujdin.  
**references:** 1935, Zool. Zh. 14: 317-52.  
 Baker, 1973, Dev. Biol. 33: 429-40.  
 Deak, I.I., Bellamy, Bienz, Dubuis, Fenner, Gollin, Rähmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81.  
**genetics:** Deficient for *cin*, *l(1)1Ac*, *y*, *ac*, *Hw*, and *ewg*

(Deak *et al.*, 1982). Male lethal, dies as late embryo; larva nearly complete (Poulson, 1940, J. Expt. Zool. 83: 271-325) but little or no muscular movement (Wright, 1970, Advances in Genetics 15: 262-85).

***\*Df(1)sc<sup>8</sup>25b - \*Df(1)sc<sup>8</sup>WO***

A series of derivatives of either *In(1)sc<sup>8</sup>* or *In(1)sc<sup>8LEN<sup>R</sup></sup>* that have lost spontaneously the distal euchromatic segment of *In(1)sc<sup>8</sup>*, with or without the loss of adjacent X heterochromatin. The material lost may be replaced with *YS* by means of exchange between *YS* and the heterochromatic segment of the X removed distally by *In(1)sc<sup>8</sup>*; alternatively, the X terminus may not be capped by a recognizable element. The material lost is required for viability; this requirement can be met by either *In(1)EN<sup>R</sup>* or *y<sup>+</sup>Y*.

**discoverer:** Lindsley (except for *Df(1)sc8-M* which was discovered by Mather, 1937).

**synonym:** *sc<sup>8</sup>c.p.X* [*In(1)sc<sup>8</sup>* derivatives] or *sc<sup>8</sup>ENc.o.X* [*In(1)sc<sup>8LEN<sup>R</sup></sup>* derivatives].

**Df(1)sc10-1**

**cytology:** *Df(1)1B1-2;1B2-3*.

**new order:**

1A – 1B1|1B14 – 1B3|1C1 – 20;

1B2 missing.

**origin:** X-ray-induced derivative of  $In(1)ac^3 = In(1)1B2-3;1B14-C1$ .

**discoverer:** Sturtevant, 1930.

**references:** 1935, DIS 3: 15.

1936, Genetics 21: 444-66.

García-Bellido, 1979, Genetics 91: 491-520.

Villares and Cabrera, 1987, Cell 50: 415-24.

**genetics:** Mutant for *ac* and *sc*; male viability low. The adults, which occasionally eclose, lack macro- and microchaetae, except those of the eye and wing margin. Homozygous cell clones in wing lack neurons except along anterior margin (Schubiger and Palka, 1985, Dev. Biol. 108: 399-410).

**molecular biology:** No deletion detected in cloned *ac* region (Campuzano, Carramolino, Cabrera, Ruíz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38). Sequence data indicate that there is a C to T change in nucleotide 669, a C to G change in nucleotide 1143 that converts Ser 101 to Arg, and a C to T change in nucleotide 1147 that generates a stop codon (Villares and Cabrera, 1987).

**\*Df(1)sc15**

**origin:** X ray induced.

**discoverer:** Muller.

**references:** Patterson and Muller, 1930, Genetics 15: 495-577.

Dubinín, 1933, J. Genet. 27: 443-64.

**genetics:** Mutant for *sc*; deficient for *y* and *ac*. Apparently, *y*<sup>+</sup> and *ac*<sup>+</sup> loci were inserted into an autosome and subsequently lost. Originally tested as an allele of *sc* only. Male lethal.

**Df(1)sc19:** see *Tp(1;2)sc*<sup>19</sup>

**Df(1)sc-B57**

**references:** González, Romani, Cubas, Modolell, and Campuzano, 1989, EMBO J. 8: 3553-62.

**genetics:** Deficient for *ASC* and *l(1)1Bb*.

**molecular biology:** Shown to have left breakpoint between *y* and *ac* and right breakpoint just to the right of that of *Df(1)260-1*.

**Df(1)sc-Fah: Deficiency (1) scute of Fahmy**

**cytology:** *Df(1)1A8-B1;1B2-3*.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl) aminophenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 74.

**genetics:** Probably mutant for *sc*. Male viable; homozygous female lethal.

**Df(1)sc-J4:** see *T(1;3)sc*<sup>J4</sup>

**Df(1)sd72b: Df (1) scalloped**

**cytology:** *Df(1)13F1;14B1*.

**origin:** X ray induced.

**discoverer:** Lefevre, 72b26.

**synonym:** *Df(1)sd*.

**references:** Craymer and Roy, 1980, DIS 55: 200-04.

Ganetzky and Wu, 1982, Genetics 100: 597-614.

Martin and Lefevre, 1981, Chromosoma 82: 237-47.

**genetics:** Deficient for *sd* but not for *bas*. Extreme *sd* phenotype over *RpII215*<sup>Ubl</sup>.

**Df(1)Si: Deficiency (1) Simmons**

**origin:** Induced by hybrid dysgenesis.

**references:** Simmons, Raymond, Culbert, and Laverty, 1984, Genetics 107: 49-63.

<sup>β</sup> 10A1-2 breakpoint mapped to a restriction fragment at -2.7 to -1.3 kb (Hafen, Kasler, Edström, and Rubin, 1987, Science 236: 55-63); see molecular biology under *sev* for coordinates).

<sup>γ</sup> Lethal in germ-line clones (García-Bellido and Robbins, 1983, Genetics 103: 235-47).

<sup>δ</sup> γ ray induced in *T(1;Y)B149*.

**Df(1)V51: Deficiency (1) Valencia**

**cytology:** *Df(1)19E1-2;19E3-4*.  
**origin:** X ray induced.  
**references:** Valencia, 1970, DIS 45: 37-38.

**\*Df(1)vB: Deficiency (1) vermilion of Bridges**

**origin:** Spontaneous.  
**discoverer:** Bridges, 16e9.  
**references:** 1919, J. Gen. Physiol. 1: 645-56.  
**genetics:** Deficient for *v*. Genetic map shortened 1-3 units.

**Df(1)VE624**

**cytology:** *Df(1)7E4;8B*.  
**discoverer:** Lefevre.  
**references:** Perrimon, Engstrom, and Mahowald, 1989,

Genetics 121: 333-52.

**Df(1)VE696**

cytology: *Df(1)19F1;20F.*

discoverer: Lefevre.

references: Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52.

**Df(1)vt: Deficiency (1) verticals**

cytology: *Df(1)3C2-3;3C6-7* inferred from Young and Judd's figure 1 (1978).

references: Young and Judd, 1978, Genetics 88: 723-42.

genetics: Deficient for *rst-vt*.

**Df(1)w<sup>m4L</sup>rst<sup>3R</sup>**: see *In(1)w<sup>m4L</sup>rst<sup>3R</sup>*

**Df(1)w<sup>m4L</sup>w<sup>mJR</sup>**: see *In(1)w<sup>m4L</sup>w<sup>mJR</sup>*

**Df(1)w<sup>ma</sup>N: Deficiency (1) white-marbled Notch**

cytology: *Df(1)3C2-3;3E2-3.*

origin: X ray induced.

references: Lefevre and Moore, 1968, Genetics 58: 557-71.

genetics: Deficient for *rst, spl, dm,* and *N*. Heterozygous females viable and fertile. Eyes "white-marbled" (like *w<sup>sp</sup>*).

**Df(1)w<sup>mJL</sup>rst<sup>3R</sup>**: see *In(1)w<sup>mJL</sup>rst<sup>3R</sup>*

**Df(1)w26d: Deficiency (1) white**

cytology: Deletion of 3C2-6 + interband 3C6-7; 3C1 "fused" to 3C7, forming a thick band.

origin: *Df(1)w67k30* + *Df(1)fa-swb* recombinant.

references: Keppy and Welshons, 1977, Genetics 85: 497-506.

1980, Chromosoma 76: 191-200.

genetics: Deficient for *w, rst,* and *vt*. *fa<sup>swb</sup>* phenotype absent although *fa<sup>swb</sup>* can be recovered as a recombinant product from *Df(1)w26D*.

**Df(1)w55j**

cytology: *3C2;3C2.*

origin: Unequal recombination in *w<sup>a/w</sup> a<sup>4</sup>* female.

references: Green, 1959, Heredity 13: 303-15.

1963, Z. Indukt. Abstamm. Vererbungsl. 94: 200-14.

Goldberg, Paro, and Gehring, EMBO J. 1: 93-98.

genetics: Homozygous viable. Deficient for *w<sup>sp</sup>* and *w<sup>e</sup>* sites.

molecular biology: Copia insertion near breakpoint.

**Df(1)W61**

cytology: *Df(1)10B8;10E1-2.*

genetics: Deficient for *RplI215*.

**Df(1)w62g26: see Tp(1;2)w<sup>+62g</sup>**

**Df(1)w63b: see Df(1)N63b**

**Df(1)w64b: see T(1;2)w<sup>+64b</sup>**

**Df(1)w64c**

cytology: *Df(1)2D6-E1;3C2-3.*

origin: X ray induced.

discoverer: Lefevre, 64c18.

references: Stewart and Merriam, 1974, Genetics 76: 301-09.

Craymer and Roy, 1980, DIS 55: 200-04.

genetics: Deficient for *pn, gt,* and *w*.

**Df(1)w64d: see In(1)w<sup>-64d</sup>**

**Df(1)w67**

origin: Derived from mutable *w<sup>8</sup>*, except for X-ray-induced *Df(1)w67k30*.

<i>Df(1)w-DZL-3</i>	3B4-5;3C1-2	1	<i>l(1)3Bf<sup>-</sup>-w<sup>-</sup></i>
<i>Df(1)w-DZL-14<sup>β δ</sup></i>	3C1-2;3C7-9	1, 2, 3	<i>w<sup>DZL</sup>-N<sup>-</sup></i>

<sup>α</sup> 1 = Bingham, 1980, Cold Spring Harbor Symp. Quant. Biol. 45(2): 519-25; 2 = Bingham, Levis, and Rubin, 1981, Cell 25: 693-704; 3 = Zachar and Bingham, 1982, Cell 30: 529-41; 4 = Bingham and Zachar, Cell 40: 819-25.  
<sup>β</sup> *Df(1)w-DZL-2* begins at or very near the right-hand FB segment of the *w<sup>DZL</sup>* transposon, removing sequences at or near the transposon insertion and extending to the right (away from *w*) for several hundred kilobases, leaving the *w* locus, the unique sequence, and the left-hand FB segment of the *w<sup>DZL</sup>* transposon (Bingham and Zachar, 1985, Cell 40: 819-25). The left breakpoint of *Df(1)w-DZL-14* lies between coordinates +8.0 and +10.6, with 0 the site of the copia insertion in *w<sup>a</sup>* (Levis, Bingham, and Rubin, 1982, Proc. Nat. Acad. Sci. USA 79: 564-68).  
<sup>γ</sup> Associated with *w<sup>DZL</sup>*; removes sequence at/or near the *w<sup>DZL</sup>*.  
<sup>δ</sup> TE insertion and extending proximally (Bingham and Zachar, 1982). Associated with *w<sup>+</sup>*; lacks most of *w<sup>DZL</sup>* TE (Zachar and Bingham, 1982).

**Df(1)w-m49a:** see *Tp(1;3)w<sup>m49a</sup>*

**\*Df(1)w-m53a:** see *Tp(1;2)w<sup>m53a</sup>*

**Df(1)w-N14a: Deficiency (1) white to Notch**

**cytology:** *Df(1)2C8-9;3E3-4*.  
**origin:** X ray induced.  
**discoverer:** Lefevre.  
**genetics:** Deficient for *usp-slc*.

**Df(1)w-N71a**

**cytology:** *Df(1)3A4-6;3C10-11*.  
**origin:** Spontaneous in crossover experiment involving *Df(1)N-5419/w* females.  
**discoverer:** Lefevre.  
**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56. Craymer and Roy, 1980, DIS 55: 200-04.  
**genetics:** Deficient for *l(1)3Ad*.

**Df(1)w-NFM20**

**cytology:** *Df(1)3C1-2;3C7-D1* (Bingham).  
**references:** McGinnis, Farrell, and Beckendorf, 1980, Proc. Nat. Acad. Sci. USA 77: 7367-71.  
**genetics:** Deficient for *w*, *N*, and *Sgs-4*.  
**molecular biology:** Lacks *w* and *Sgs-4* sequences.

**Df(1)w-r: Deficiency (1) white-recombinant**

**origin:** Regular product of unequal exchange between 3C1-2 (or 3) of a  $w^a$ ,  $w^{a2}$ , or  $w^{rdp}$  chromosome and the 3A or 3C-D region of a specific homologue.

deficiency	cytology	ref <sup>α</sup>	genetics
<b>Df(1)w-rG</b>	3A3-4;3C1-2	1	$z^+ w^-$ (or $w$ ) $rst^+$
<b>Df(1)w-rJ1</b> <sup>β</sup>	3A1-2;3C2-3	2, 3, 4, 5	$gt^+ tko^- w^-$ (or $w$ ) $rst^+$ ; embryonic lethal and lethal in germ-line clones <sup>γ</sup>
<b>Df(1)w-rJ2</b>	3A8-9;3C2-3	2, 3, 4, 5	$l(1)3Ag^+ l(1)3Ah^- w^-$ (or $w$ ) $rst^+$ ; embryonic lethal
<b>Df(1)w-rJ3</b> <sup>δ</sup>	3C1-2;3C12-D1	2, 3	$w^-$ (or $w$ ) $-dm^-$ (or $dm$ )

<sup>α</sup> 1 = Green, 1959, Genetics 44: 1243-56; 2 = Judd, 1961, Genetics 46: 1687-97; 3 = Judd, 1964, DIS 39: 59-60; 4 = Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56; 5 = Kaufman, Shannon, Shen, and Judd, 1975, Genetics 79: 265-82.

<sup>β</sup> Survives as  $w$  female when heterozygous with  $Df(1)w^{m4L} rst^{3R}$ ; such females display reduced crossing over and increased nondisjunction for all pairs of homologues. Deletes *per* locus (Bargiello and Young, 1984, Proc. Nat. Acad. Sci. USA 81: 2142-46).

Molecular biology: 3A3-4 (left or distal) breakpoint localized to an approximately 4-kb restriction fragment 2-6 kb to the left of the origin of a 160-kb walk in the vicinity of  $z$  (Gunaratne, Mansukhani, Lipari, Liou, Martindale, and Goldberg, 1986, Proc. Nat. Acad. Sci. USA 83: 701-05).

<sup>γ</sup> According to Garcia-Bellido and Robbins, 1983, Genetics 103: 235-47.

<sup>δ</sup> Survives as  $w$  female when heterozygous with  $Df(1)w258-45$ ,  $Df(1)w-rJ1$ , or  $Df(1)w-rJ2$ .

$\alpha$  The number preceding the hyphen designates the intergenic interval in which the break has occurred, and the numbers following the hyphen represent independent occurrences.

$\beta$  1 = Campos, Grossman, and White, 1985, *J. Neurogenet.* 2: 197-218; 2 = Mason, Voelker, Rosen, Campos, White, and Lim, 1986, *DIS* 63: 164-65; 3 = Ruiz-Gómez and Modolell, 1988, *Genes Dev.* 1: 1238-46; 4 = Voelker.

$\gamma$  DNA coordinates from Caramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-91 and Campuzano, Carramolino, Cabrera; Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 3227-38. Origin (coordinate 0) is the distal EcoRI site within the *sc*<sup>S2</sup> molecular deficiency ("+" values to the left, "-" values to the right). *Df(1)yT2-623* and *Df(1)yT2-696* have multiple breakpoints. The unstable chromosome ends lose approximately 75 base pairs per generation (Biessman and Mason, 1988, *EMBO J.* 7: 1081-86). The presented data represent the extents of the deficiencies as of 1985.

$\delta$  Broken within *su(s)*.

$\alpha$  1 = Gans, 1953, *Bull. Biol. Fr. Belg. Supp.* 38: 1-90; 2 = Gelbart, 1971, Ph.D. Thesis, Univ. of Wisconsin; 3 = Goldberg, Colvin, and Mellin, 1989, *Genetics* 123: 145-55.

$\beta$  Experiments of Goldberg *et al.*, 1989, show that females without a *zeste* locus are fertile and of normal or near normal fecundity.

**Df(1)ZWD5**

**cytology:** Band at 3C in *Df(1)ZWD5/+* salivaries wedge-shaped indicating small deficiency.

**origin:** Irradiation of  $z^1$  males.

**references:** Smolik-Utlaut and Gelbart, 1987, Genetics 116: 285-98.

**genetics:** Homozygous lethal. Notch wing in *Df(1)ZWD5/+*.

*Df(Y)bb*: see *Ybb*<sup>-</sup>

**Df(YL) and Df(YS)**

**origin:** X ray or  $\gamma$  ray induced in  $B^S Y y^+$  (Lindsley *et al*, 1972; Hazelrigg *et al*, 1982) or  $y^+ Y$  (Brosseau, 1960);  $\gamma$  ray induced in  $y^+ Y$  (Schwartz).

**genetics:** Recovered as male-sterile Y chromosomes; presence of deficiencies established by cytological examination of prophase and metaphase figures. Missing fertility factors in deficiencies of Brosseau, Hazelrigg *et al.*, and Schwartz indicated.

$\alpha$  Many Y deficiencies are also Y-autosome translocations. Three-break translocations that have lost a segment between two Y chromosome breakpoints are listed with three breakpoints, the last one being the autosomal breakpoint of the translocation (for example, *Df(YL)A78=B<sup>S</sup>Xh;h10;87B*), whereas deficiencies that are independent of the Y-autosome-translocation breakpoints are listed with two deficiency breakpoints plus two translocation breakpoints when known (for example, *Df(YL)A80=B<sup>S</sup>Xh;h7 + h21;35B*). New orders of these rearrangements are provided with description of the like-designated Y-autosome translocations. Deficiencies unassociated with translocations are listed with two breakpoints (for example, *Df(YL)B2=h3;h8*).

$\beta$  1 = Brosseau, 1960, Genetics 45: 257-74; 2 = Gatti and Pimpinelli, 1983, Chromosoma 83: 349-73; 3 = Hazelrigg, Fornili, and Kaufman, 1982, Chromosoma 87: 535-59; 4 = Kennison; 5 = Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethman, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84.

$\gamma$  Occurs in chromosome carrying two noncontiguous deletions, one in YL and the other in YS (for example, *Df(YL)A29* and *Df(YS)A29*).

<b>Df(2L)ade2-2</b>	<i>Df(2L)25F2-3;26DE</i>
<b>Df(2L)ade2-3</b>	<i>Df(2L)26A;26B5-6</i>

**Df(2L)Adh78**

**cytology:** *Df(2L)35B1;35D5-7*.  
**origin:** Spontaneous in dysgenic strain T-007; selected as ADH null on 1-penten-3-ol.  
**discoverer:** Bencze.  
**synonym:** *Df(2L)17813*.  
**references:** Ashburner, Tsubota, and Woodruff, 1982, *Genetics* 102: 401-20.  
**genetics:** Deficient for *l(2)35Ba-l(2)35Dg*.

**Df(2L)AdhnBR41**

**origin:** Induced by ENU.  
**discoverer:** Lee.  
**genetics:** Deficient for *l(2)34Fa-Adh*.

**Df(2L)al: Deficiency (2L) aristaless**

**cytology:** *Df(2L)21B8-C1;21C8-D1*.  
**origin:** X ray induced.  
**discoverer:** E. B. Lewis, 1940.  
**references:** 1945, *Genetics* 30: 147-51.  
 Korochkina and Golubovsky, 1978, *DIS* 53: 197-200.  
 Nüsslein-Volhard, Wieschaus and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82.

**genetics:** Deficient for *al*, *ex*, *ush* and *ds* but not for *lgl*, *net*, or *S*. Homozygotes lethal, heterozygotes Minute. Heterozygotes with *In(2LR)al*<sup>8</sup> survive poorly; escapers have reduced aristaes, broad thoraces, arched wings, incomplete veins, and large eyes (Koroshkina and Golubovsky, 1978).

**Df(2L)ARR1**

**cytology:** *Df(2L)35A3-4;35B9-C1*.  
**new order:**  
 21 – 35A3-4|YLY|y<sup>+</sup> ac<sup>+</sup>|YS|35B9-C1 – 60.  
**origin:** X-ray-induced reconstitution of chromosome 2 from *Y<sup>P</sup>2<sup>D</sup>* of *T(Y;2)A80* and *2<sup>P</sup>Y<sup>D</sup>* of *T(Y;2)R15*.  
**references:** Woodruff and Ashburner, 1979, *Genetics* 92: 117-32.  
 Gubb, Shelton, Roote, McGill, and Ashburner, 1984, *Chromosoma* 91: 54-64.  
**genetics:** Deficient for *el-Su(H)*; includes *Adh*. Carries *y<sup>+</sup>ac<sup>+</sup>* from *T(Y;2)R15*.

**Df(2L)ast: Deficiency (2L) asteroid**

**origin:** γ ray induced.  
**references:** Roberts, Brock, Rudden, and Evans-Roberts, 1985, *Genetics* 109: 145-56.  
**genetics:** Deficient for *ast*.

**cytology:** *Df(2L)22E2-4;22F4-23A1*.  
**origin:** X ray induced.  
**references:** Spencer, Hoffmann, and Gelbart, 1982, Cell 28: 451-61.  
**genetics:** Deficient for the entire *dpp* locus.

**Df(2L)E:** see **T(2;3)E**

**Df(2L)E53**

**cytology:** Not visibly deficient.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** T.R.F. Wright, 1983.  
**genetics:** Deficient for *l(2)36Fc* and *msl-1*, but not for

*l(2)36Fb*, *l(2)36Fd*, or *l(2)36Fe*. Lethal over *Df(2L)TW3*, *Df(2L)E71*, *Df(2L)M36F-S6*, and *Df(2L)M36F-S5*; viable over *Df(2L)TW119*.

**Df(2L)E55**

**cytology:** *Df(2L)37D2-E1;37F5-38A1*.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85.

Brittnacher and Ganetzky, 1983, Genetics 103: 659-73.  
 Nüsslein-Volhard, Wieschaus and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**genetics:** Deficient for *ref(2)P* and *spi*. Lethal over *Df(2L)TW330*, *Df(2L)VA15*, *Df(2L)VA20*, *Df(2L)VA22*, *Df(2L)VA23*, *Df(2L)VA25*, *Df(2L)TW9*, *Df(2L)TW12*, *l(2)37Da*, *l(2)37Db*, *l(2)37Fa*, *l(2)37Fb*, *l(2)37Fc*, and *l(2)37Fd*. Viable, but shows non-transparent wing phenotype over *Df(2L)TW150*, *Df(2L)TW84*, and *Df(2L)OD16*.

**Df(2L)E66: Deficiency (2L) Enhancer of variegation**

**cytology:** *Df(2L)25F2-3;26A1-B1*.  
**origin:** *P*-element induced mutagenesis.  
**references:** Locke, Kotarski, and Tartof, 1988, Genetics 120: 181-98.  
**genetics:** Enhances position-effect variegation of *In(1)w<sup>m4</sup>*. Recessive lethal.

**Df(2L)E71**

**cytology:** *Df(2L)36F2-6;37C6-D1*.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85.

Belote and Lucchesi, 1980, Genetics 96: 165-86.  
 Wright, Beermann, Marsh, Bishop, Steward, Black, Tomsett, and Wright, 1981, Chromosoma 83: 45-58.

**genetics:** Deficient for *msl-1 - fs(2)TW1* (Wright, 1983) but not for *dl* or *l(2)37Da*. Lethal over *Df(2L)M36F*, *Df(2L)E53*, *l(2)36Fc*, *l(2)36Fd*, *l(2)36Fe*, and *Df(2L)SD<sup>rv77</sup>*.

**Df(2L)E110**

**cytology:** *Df(2L)25F3-26A1;26D3-11*.  
**origin:** *P*-element induced mutagenesis.  
**references:** Locke, Kotarski, and Tartof, 1988, Genetics 120: 181-98.  
**genetics:** Enhances position-effect variegation of *In(1)w<sup>m4</sup>*. Recessive lethal.

**Df(2L)E(SD): Deficiency (2L) Enhancer of Segregation Distorter**

**origin:** γ ray induced in *SD-5* chromosome.  
**references:** Ganetzky, 1977, Genetics 86: 321-55.  
**genetics:** Deficient for *l(2)40Fa - l(2)40Ff*. Partial revertant of *Sd*.

<sup>α</sup> 1 = Angel; 2 = Ashburner, Detwiler, Tsubota, and Woodruff, 1983, *Genetics* 104: 405-31; 3 = Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, *DIS* 55: 193-95; 4 = Ashburner and Harrington, 1984, *Chromosoma* 89: 329-37; 5 = G. Johnson; 6 = Woodruff and Ashburner, 1979, *Genetics* 92: 117-32.

**Df(2L)esc10**

**cytology:** *Df(2L)33A8-B1;33B2-3* (G. Richards).  
**origin:** γ ray induced.  
**references:** Struhl, 1981, *Nature* 293: 36-41.  
 Frei, Baumgartner, Edström, and Noll, 1985, *EMBO J.* 4: 979-87.  
 Frei, Schuh, Baumgartner, Burri, Noll, Jürgens, Seifert, Nauber, and Jäckle, 1988, *EMBO J.* 7: 197-204.  
**genetics:** Deficient for *esc* but not for *sal*. Homozygotes viable and extreme *esc* when mother *esc<sup>+</sup>/esc<sup>-</sup>*, but lethal in first larval instar with homeotic transformation of segments when mother *esc<sup>-</sup>/esc<sup>-</sup>*. Heterozygotes with *esc<sup>2</sup>*, *esc<sup>4</sup>*, *esc<sup>5</sup>*, *esc<sup>6</sup>*, *esc<sup>8</sup>*, or *esc<sup>9</sup>* show same extreme phenotypes as homozygotes.  
**molecular biology:** Embryos deficient for *esc* show indiscriminate expression of segment-specific homeotic genes (Struhl and Akam, 1985, *EMBO J.* 4: 3259-64). Distal breakpoint mapped to the DNA at about -310 to -290 kb and proximal breakpoint mapped at about +70 kb

("-" values to right, "+" values to left) in the F walk of Frei *et al.*, 1985.

**Df(2L)esc-P2-0**

**cytology:** *Df(2L)33A1-2;33B1-2*.  
**origin:** Hybrid dysgenesis.  
**discoverer:** Struhl.  
**references:** Jürgens, 1988, *EMBO J.* 7: 189-96.  
 Frei, Schuh, Baumgartner, Burri, Noll, Jürgens, Seifert, Nauber, and Jäckle, 1988, *EMBO J.* 7: 197-204.  
**genetics:** Deficient for *sal* and *esc*.  
**molecular biology:** Distal breakpoint mapped to the DNA at about -476 to -442 kb (Frei *et al.*, 1985).

**Df(2L)esc-P3-0**

**cytology:** *Df(2L)33A1-2;33E*.  
**origin:** Hybrid dysgenesis.  
**discoverer:** Struhl.  
**references:** Jürgens, 1988, *EMBO J.* 7: 189-96.  
 Frei, Schuh, Baumgartner, Burri, Noll, Jürgens, Seifert, Nauber, and Jäckle, 1988, *EMBO J.* 7: 197-204.  
**genetics:** Deficient for *sal* and *esc*.

**Df(2L)F**

**cytology:** Deficient for heterochromatin between *lt* and the secondary constriction.  
**origin:** γ-ray-induced reconstitution of chromosome 2 by detachment of compound second chromosomes.  
**references:** Hilliker and Holm, 1975, *Genetics* 81: 705-21.  
 Hilliker, 1976, *Genetics* 83: 765-82.  
**genetics:** *M* and *lt<sup>+</sup>* phenotypes. Deficient for lethal loci *l(2)40Fa* and *l(2)40Fd* (Hilliker, 1976).  
**other information:** Two such deficiencies recovered.

*Df(2L)FB15* : see *Df(2L)L138D*

**Df(2L)fn: Deficiency (2L) formaldehyde induced**

**origin:** Formaldehyde induced. Selected as ADH null on 1-penten-3-ol.  
**discoverer:** Sofer.

**origin:** X ray induced in *SD-72* chromosome.  
**references:** Brittnacher and Ganetzky, 1983, Genetics 103: 659-73.  
**genetics:** Deficient for *l(2)36Fb*, *Tft*, and *hk*, but not *M(2)36F*. Lethal over *Df(2L)M36F-S5*, *Df(2L)M36F-S6*, *Df(2L)TW158*, *Df(2L)TW130*, and *l(2)36Fb-Dox*.  
**molecular biology:** Proximal breakpoint between -52.15 and -50.55 kb (see deficiency map under *l(2)37* for coordinates).

**Df(2L)hk39**

**cytology:** *Df(2L)36F6-37A1;37D1-2*.  
**origin:** X ray induced in *SD-Roma* chromosome.  
**references:** Brittnacher and Ganetzky, 1983, Genetics 103: 659-73.  
**genetics:** Deficient for *Tft* and *hk* but not *l(2)37Db*. Lethal over *Df(2L)Sd57* and *Df(2L)Sd77*.

**Df(2L)hk-UC1**

**origin:** X ray induced in Canton-S.  
**discoverer:** Gibbs and Marsh.  
**genetics:** Deficient for *l(2)31Ba - Dox-A2* but not for

*l(2)37Bg.*

**molecular biology:** Right breakpoint at -56.75 to -54.95 to the left of *Ddc* (-0.06 to +3.76).

**Df(2L)hk-UC2**

**origin:** From 15 generations of repeated backcrossing of Canton-S males to M strain females homozygous for *nub b rdo hk pr cn*.

**discoverer:** Gibbs and Marsh.

**references:** Eveleth and Marsh, 1986, Nucleic Acid Res. 4: 6169-83.

**genetics:** Deficient for *hk-l(2)37Cb - l(2)37Cc* but not for *l(2)37Cd*.

**molecular biology:** Right breakpoint at +8.15 to +10.95 to the right of *Ddc* (-0.06 to +3.76).

**Df(2L)J: Deficiency (2L) Jammed**

**origin:** X ray induced as *J* revertants.

**synonym:** *Df(2L)J-der; Df(2L)J-rv.*

<sup>β</sup> Lethal over *da*.

**Df(2L)JK12**

**cytology:** *Df(2L)37D2-E1;38A8-C1* (Kennison).

**origin:** γ ray induced.

**discoverer:** Kennison.

**genetics:** *pr<sup>-</sup>l(2)37Dc<sup>-</sup>Bl<sup>+</sup>*; lethal in combination with *T(Y;2)H174 = T(Y;2)YS;37D* and *Df(2L)TW158 = Df(2L)37B2-8;37E2-F4*.

**Df(2L)L**

**cytology:** *Df(2L)38B;40*.

**origin:** Segmental deficiency comprising the *Y<sup>P2D</sup>* element of *T(Y;2)P7 = T(Y;2)h9-10;38b* and the *2<sup>PYD</sup>* element of *T(Y;2)B190 = T(Y;2)40*.

**synonym:** *T(Y;2)P57<sup>L</sup>B190<sup>R</sup>*.

**references:** Khesin and Leibovitch, 1978, Mol. Gen. Genet. 162: 323-28.

Chernyshev, Leibovitch, and Khesin, 1980, Mol. Gen. Genet. 178: 663-68.

**genetics:** Deficient for *His*. Variegated *w* position effect in *Dp(1;3)w<sup>vco</sup>* weakened in *Df(2L)L/ +* flies.

**Df(2L)L138D**

**cytology:** *Df(2L)39A;39D-E*, with indeterminate quantities of *Y* heterochromatin intercalated between the chromosome-2 breakpoints.

**origin:** γ-ray-induced reconstitutions of chromosome 2 from the *Y<sup>P2D</sup>* element of *T(Y;2)L138* and the *2<sup>PYD</sup>* element of *T(Y;2)B209, T(Y;2)B251, or T(Y;2)H54*. Deficient for most but not all of the tandemly repeated Histone genes.

**discoverer:** J. Siegel.

**references:** 1981, Genetics 98: 505-29.

**genetics:** Deficient for *His*.

deficiency	2 <sup>P</sup> Y <sup>D</sup> component

Wright.
- $\beta$  Derived from *Dp(2;Y)G*.

**Df(2L)PR7F**

**cytology:** In 2L heterochromatin just distal to the centromere.  
**discoverer:** Hilliker.  
**references:** Brittnacher and Ganetzky, 1984, Genetics 107: 423-34.

**Df(2L)prd1.25: Deficiency (2L) paired**

**cytology:** *Df(2L)33B6-7;33E1-2 + T(Y;2)21;40*.  
**discoverer:** Nüsslein-Volhard.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.  
 Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.  
**genetics:** Deficient for *prd*.

**Df(2L)prd1.7**

**location:** *Df(2L)33B2-3;34A1-2*.  
**discoverer:** Nüsslein-Volhard.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

genetics: Deficient for *prd*.

molecular biology: Distal breakpoint mapped to the DNA (Frei, Baumgartner, Edström, and Noll, 1985, EMBO J. 4: 979-87).

**Df(2L)prd2.27:** see **Tp(2;3)prd<sup>2.27</sup>**

**Df(2L)prd5.12:** see **Tp(2;Y)prd<sup>5.12</sup>**

**Df(2L)Prl: Deficiency (2L) Proxless**

cytology: *Df(2L)32F1-3;33F1-2* (Ashburner).

discoverer: B.S. Baker.

references: Jürgens, 1988, EMBO J. 7: 189-96.

Frei, Schuh, Baumgartner, Burri, Noll, Jürgens, Seifert, Nauber, and Jäckle, 1988, EMBO J. 7: 197-204.

genetics: Associated with *Prl*. Deficient for *prd*, *sal* (Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82), and *nub* but not *b* (Ashburner).

molecular biology: Distal breakpoint mapped to the DNA at about -430 to -400 kb (Frei *et al.*, 1988).

**Df(2L)prx**

origin: X ray induced.

discoverer: Simpson.

**Df(2R)42**

**cytology:** *Df(2R)42C3-8;42D2-3*.

**origin:** Probably X ray induced. Found on chromosome with *vg<sup>S</sup>*.

**discoverer:** Bridges, 36b.

**references:** Morgan, Bridges, and Schultz, 1938, Year Book - Carnegie Inst. Washington 37: 304-9.

**genetics:** Deficient for no tested loci. Homozygous lethal.

**Df(2R)43A**

**cytology:** *Df(2R)43A2;43B1*.

**Df(2R)44CE**

**cytology:** *Df(2R)44C;44E1-4*.

**discoverer:** Yannopoulos.

**references:** Hooper and Scott, 1989, Cell 59: 751-65.

**genetics:** Deficient for *tuf*.

**Df(2R)173**

**cytology:** Not visible.

**origin:** Induced by ethyl methanesulfonate.

**references:** Duttagupta and Shellenbarger, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 25-33.

**genetics:** Includes *l(2)56Fa*, *l(2)56Fb*, and *M(2)56F*.

**Df(2R)193A**

**cytology:** *Df(2R)44C;44C*.

**Df(2R)A**

**cytology:** Deficient for about half of the 2R heterochromatin including *rl* (Hilliker, 1976).

**origin:**  $\gamma$ -ray-induced reconstitution of chromosome 2 by detachment of compound second chromosomes (Hilliker and Holm, 1975).

**references:** Hilliker and Holm, 1975, Genetics 81: 705-21. Hilliker, 1976, Genetics 83: 765-82.

**genetics:** Deficient for *rl*. Complements *Df(2R)M41A4* and *Df(2R)M41A8* but not *Df(2R)M41A10* (Hilliker, 1976).

**other information:** Thirty-three such deficiencies recovered.

**Df(2R)A'**

**cytology:** Deficient for most of the 2R heterochromatin including *rl*. Extends distal to *Df(2R)A* and *Df(2R)A''* (Hilliker, 1976).

**origin:**  $\gamma$ -ray-induced reconstitution of chromosome 2 by detachment of compound second chromosomes (Hilliker and Holm, 1975).

**references:** Hilliker and Holm, 1975, Genetics 81: 705-21. Hilliker, 1976, Genetics 83: 765-82.

**genetics:** Deficient for *rl* and *M(2)41A*. Lethal over *Df(2R)M41A4*, *Df(2R)M41A8*, and *Df(2R)M41A10* (Hilliker, 1976).

**Df(2R)A''**

**cytology:** *Df(2R)41* (heterochromatin). Deficient for about two-thirds of the 2R heterochromatin including *rl*. Extends distal to *Df(2R)A* (Hilliker, 1976).

**origin:**  $\gamma$ -ray-induced reconstitution of chromosome 2 by detachment of compound second chromosomes (Hilliker and Holm, 1975).

**references:** Hilliker, 1976, Genetics 83: 765-82.

Ganetzky, 1977, Genetics 86: 321-55.

**genetics:** Deficient for *rl*. Complements *Df(2R)M41A4* and *Df(2R)M41A8* but not *Df(2R)M41A10* (Hilliker, 1976).

**\*Df(2R)a-ba2: Deficiency (2R) arc-broad angular**

**cytology:** *Df(2R)58D5-6;58D7-8*.

**origin:** Spontaneous.

**discoverer:** Goldschmidt.

**references:** 1945, Univ. Calif. (Berkeley) Publ. Zool. 49: 363-73, 388-89.

**genetics:** Associated with *a<sup>ba2</sup>*.

**Df(2R)AA21: see In(2R)AA21**

**Df(2R)B**

**cytology:** Deficient for less than half of the 2R heterochromatin not including *rl* (Hilliker, 1976).

**origin:**  $\gamma$ -ray-induced reconstitution of chromosome 2 by detachment of compound second chromosomes (Hilliker and Holm, 1975).

**references:** Hilliker and Holm, 1975, Genetics 81: 705-21. Hilliker, 1976, Genetics 83: 765-82.

**genetics:** Not deficient for *rl*. Complements *Df(2R)M41A4* and *Df(2R)M41A8* but not *Df(2R)M41A10*.

**Df(2R)Ba**

**cytology:** *Df(2R)60E3;60E6*

**origin:**  $\gamma$  ray induced.

**discoverer:** Moscoso del Prado.

**synonym:** *Art<sup>2</sup>*, *Ba<sup>MP</sup>*.

**references:** Sunkel and Whittle, 1987, Wilhelm Roux's Arch. Dev. Biol. 196: 124-32.

Cohen, Brönnner, Küttner, Jürgens, and Jäckle, 1989, Nature 338: 432-34.

Cohen and Jürgens, 1989, EMBO J. 8: 2045-55.

**genetics:** Deficient for *Ba*; entire putative transcription unit deleted. Heterozygote shows partial transformation of arista to tarsal segments. Dominant phenotype suppressed in either *Pcl<sup>10</sup>* or *Df(2R)en28* heterozygotes. *Df(2R)Ba/+* shows almost complete suppression of the extra-sex combs phenotypes of *Pc<sup>4/+</sup>*, *Pc<sup>T7/+</sup>*, *Pcl<sup>10/+</sup>*, *Pcl<sup>11/+</sup>*, *Antp<sup>Scx/+</sup>*, *Msc/+*, and *Msc<sup>T3/+</sup>*.

**molecular biology:** Deleted for the region from approximately coordinate 90 kb through 180 kb and beyond on the molecular map of Cohen *et al.*

**Df(2R)Ba4: Deficiency (2R) Brista**

**cytology:** *Df(2R)60D1-2;60F5*.  
**origin:** EMS-induced.  
**references:** Sunkel, 1983, Ph.D. Thesis, University of Sussex.  
**genetics:** Deficient from *sp* to 2R tip. Heterozygotes have missing legs, and abnormal eye facets. Lethal over *Ba*.

**Df(2R)Ba-MP (J. Kennison)**

**cytology:** *Df(2R)60E3-4;60E5-6*.  
**origin:** X ray induced.  
**discoverer:** Moscoso del Prado.  
**synonym:** *Scnp*<sup>AL</sup>; *Art*<sup>2</sup>; *Dll*<sup>MP</sup>.  
**genetics:** Recessive lethal. Heterozygotes show partial transformation of arista to tarsal segments.  
**molecular biology:** Deletion removes the entire *Ba* coding region [Cohen, Brönnner, Küttner, Jürgens, and Jackle, 1989, Nature (London), 338: 432-34].

**Df(2R)BP7**

**cytology:** *Df(2R)57E;58A1*.  
**origin:** Constructed from *T(2;3)P49 = T(2;3)57D;81F* and *T(2;3)BTD73 = T(2;3)58A1;81F*.  
**references:** Schejter, and Shilo, 1989, Cell 56: 1093-1104.  
**genetics:** Does not complement lethal mutations of *Egfr*.

**Df(2R)bw<sup>AL</sup>Cy<sup>R</sup>:** see *In(2R)bw<sup>AL</sup>Cy<sup>R</sup>*

**Df(2R)bw<sup>VDe1L</sup>Cy<sup>R</sup>:** see *In(2R)bw<sup>VDe1L</sup>Cy<sup>R</sup>*

**Df(2R)bw<sup>VDe2L</sup>Cy<sup>R</sup>:** see *In(2R)bw<sup>VDe2L</sup>Cy<sup>R</sup>*

**Df(2R)bw5: Deficiency (2R) brown**

**cytology:** *Df(2R)59D10-E1;59E4-F1*.  
**origin:** Spontaneous.  
**discoverer:** Mohr, 31k28.  
**references:** Wright, 1970, Advances in Genetics 15: 262-85.  
**genetics:** Deficient for *bw*. Homozygous lethal in embryo (Tsai, 1955, Genetics 40: 601).

**Df(2R)bw-D23**

**cytology:** *Df(2R)59D4-5;60A1-2* (Richards).  
**origin:** X ray induced.  
**synonym:** *Df(2R)bw<sup>Drv23</sup>*; *Df(2R)bw<sup>D+R23</sup>*.  
**references:** Simpson, 1983, Genetics 105: 615-32.  
**genetics:** Deficient for *bw* but not for *twi*.

**Df(2R)bw-D31**

**cytology:** *Df(3R)59B6-8;60A8-16* (Richards).  
**origin:** X ray induced.  
**synonym:** *Df(2R)bw<sup>Drv31</sup>*; *Df(2R)bw<sup>D+R31</sup>*.  
**references:** Simpson, 1983, Genetics 105: 615-32.  
**genetics:** Deficient for *bw* and *twi*.

**Df(2R)bw-GY**

**cytology:** *Df(2R)59B;59E*.  
**origin:** Recovered as apparent recombinant from a test cross of a dysgenic-type male that was heterozygous for a maternally derived *dp b cn bw* second chromosome and paternally derived autosome extracted from a natural population and capable of promoting male recombination. An MRF (Male Recombination Factor) chromosome, *MRF23.5*, was utilized. The duplication was recovered from a male heterozygous for *MRF23.5*.  
**references:** Yannopoulos, Stamatis, Zacharopoulou, and Pelecanos, 1981, Mutat. Res. 83: 383-93.

**genetics:** Deficient for *bw*.

**Df(2R)bw-K**

**cytology:** *Df(2R)59D2-5;59E1-3*.  
**origin:** Spontaneous.  
**references:** Koliantz, 1971, DIS 46: 52.  
**genetics:** Deficient for *bw*.

**\*Df(2R)bw-R40: Deficiency (2R) brown-Rearranged**

**cytology:** *Df(2R)59C5-6;59E2-3*.  
**origin:** X ray induced.  
**discoverer:** Slatis.  
**references:** 1955, Genetics 40: 5-23.

**Df(2R)bw-S46**

**cytology:** *Df(3R)59D8-11;60A7* (Richards).  
**origin:** X ray induced.  
**references:** Simpson, 1983, Genetics 105: 615-32.  
**genetics:** Deficient for *bw* but not *twi*.

**Df(2R)C113**

**cytology:** *Df(2R)41A;41A*.  
**references:** Tano, 1966, Jpn. J. Genet. 41: 299-308.  
**genetics:** Deficient for *l(2)41Ae*. Complemented by *M(2)41A* and *M(2)39F* but not by *Df(2R)r110A*.

**Df(2R)CA53**

**cytology:** *Df(2R)43E6;44B5-9*.  
**origin:**  $\gamma$  ray induced.  
**discoverer:** Durrant.  
**genetics:** Deficient for *cn*. Ocelli small in heterozygotes.

**Df(2R)CA58**

**cytology:** *Df(3R)43A3;43F6*.  
**origin:**  $\gamma$  ray induced.  
**discoverer:** Ashburner.

**Df(2R)CC2**

**cytology:** *Df(2R)57C3;57C6*.  
**origin:**  $\gamma$  ray induced.  
**references:** O'Donnell, Boswell, Reynolds, and Mackay, 1989, Genetics 121: 273-80.  
**genetics:** Deficient for *l(2)57Cb-Pu*.

**Df(2R)cn: Deficiency (2R) cinnabar**

**origin:** Most deficiencies recovered as apparent *cn* double recombinants from test crosses of dysgenic-type males that were heterozygous for a maternally derived *dp b cn bw* second chromosome and paternally derived autosomes extracted from natural populations and capable of promoting male recombination. Rearranged derivatives occurred both singly and in clusters. Two MRF (Male Recombination Factor) chromosomes, *MRF23.5* and *MRF31.1*, were utilized. Most deficiencies of MRF origin were recovered from males heterozygous for *MRF23.5*; *1b* and *2b* recovered from males heterozygous for *MRF31.1*.

<sup>$\beta$</sup>  Arose simultaneously with *vg<sup>11</sup>*.

**\*Df(2R)M58F**

**cytology:** *Df(2R)57F11-58A1;58F8-59A1*.

**origin:** Spontaneous.

**discoverer:** Bridges, 23g15.

**synonym:** *\*Df(2R)M-l*.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 231.

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**genetics:** Deficient for *px*, *l(2)Su(H)*, *M(2)58F*, and probably *a*. Homozygote dies in egg stage; eggs recognizable by thin chorion (Li, 1927, Genetics 12: 1-58).

**Df(2R)M60E**

**cytology:** *Df(2R)60E2-3;60E11-12*.

**origin:** X ray induced.

**discoverer:** Schultz, 33a7.

**synonym:** *Df(2)M-33a*; *Df(2R)M-c33a*; *M(2)115*.

**references:** Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**genetics:** Deficient for *M(2)60E*. Homozygous lethal. Fairly strong *M* with good viability in combination with *Binsn* and *In(2LR)bw<sup>v32g</sup>* (Campos-Ortega and Waitz, 1978, Wilhelm Roux' Arch. Entwicklungsmech. Org.

184: 155-70).

**Df(2R)MP1**

**cytology:** *Df(2R)57C1-2;57D1-2*.

**origin:**  $\gamma$  ray induced.

**references:** O'Donnell, Boswell, Reynolds, and Mackay, 1989, *Genetics* 121: 273-80.

**\*Df(2R)Np: Deficiency (2R) Notopleural**

**cytology:** *Df(2R)44F1-2;45E1-2* (Bridges).

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 33b20.

**references:** Bridges, Skoog, and Li, 1936, *Genetics* 21: 788-95 (fig.).

Li, 1936, *Peking Nat. Hist. Bull.* 11: 39-48.

**genetics:** Not deficient for *cn*, *blo*, or *en*. *Df(2R)Np/T(2;3)dp* lethal.

**Df(2R)Ore-R: Deficiency (2R) Oregon-R**

**cytology:** *Df(2R)60F2-3;60F5*.

**origin:** Naturally occurring in Oregon-R stock but not in Oregon-R-C stock (Roberts, 1974, *Genetics* 77: s54-55).

**discoverer:** Bridges, 3615.

**genetics:** No detectable phenotypic effect in homozygote.

**Df(2R)P: Deficiency (2R) Pale**

**cytology:** *Df(2R)58E3-F1;60D14-E2*.

**origin:** Aneuploid segregant from *Tp(2;3)P/ +*.

**Df(2R)P32**

**cytology:** *Df(2R)43A3;43A6* (Sinclair).

**references:** Schüpbach, and Wieschaus, 1989, *Genetics* 121: 101-17.

**genetics:** Uncovers *tor*, *scra*, *mat(2)cellIRE43*.

**Df(2R)PC4**

**cytology:** *Df(2R)55A;55F* (Jürgens).

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82.

Schüpbach and Wieschaus, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 302-17.

**genetics:** Deficient for *thr*, *stau*, *Pcl* (Jürgens, 1985, *Nature* 316: 153-55); also for *Bc*, *Dox1*, *ff*, and *wt* (Deng and Rizki, 1988, *Proc. Int. Congr. Genet.*, 16th, p. 192).

**Df(2R)PC18**

**cytology:** *Df(2R)57B16-17;57C6-7*.

**origin:**  $\gamma$  ray induced.

**references:** O'Donnell, Boswell, Reynolds, and Mackay, 1989, *Genetics* 121: 273-80.

**genetics:** Deficient for *l(2)57Ba-Pu*.

**Df(2R)PC29**

**cytology:** *Df(2R)55C1-2;56B1-2*.

**Df(2R)PC66**

**cytology:** *Df(2R)55D2-E1;55E3-4*.

**Df(2R)Pcl: Deficiency (2R) Polycumblike**

**genetics:** Deficient for *Pcl*. When heterozygous with wild type, flies carrying the *Pcl* deficiency show transformation of second and third legs to first legs.

**Df(3L)brm11: Deficiency (3L) brahma**

cytology: *Df(3L)71F;72D* (Kennison).  
 origin: Induced by P-M hybrid dysgenesis.  
 discoverer: Kennison and Tamkun, 1987.  
 genetics: *brm<sup>-th</sup>*. Lethal in combination with *Df(3L)st-g24 = Df(3L)72D1-2;73A9-10* but survives in combination with *Df(3L)st-e4 = Df(3L)72D5-10;73A5* and *Df(3L)st-b11 = Df(3L)72D7-9;73D1-2*.

**Df(3L)Cat: Deficiency (3L) Catalase**

cytology: *Df(3L)75C1-2;75F1*.  
 origin:  $\gamma$  ray induced.  
 synonym: *Df(3L)Cat<sup>DH104</sup>*.  
 references: Mackay, Hollar, and Bewley, 1986, Genetics 113: s31.  
 Bewley, Mackay, and Cook, 1986, Genetics 113: 919-38.  
 genetics: Deficiency heterozygotes show dosage effect for catalase activity.

\***Df(3L)D**: see **T(Y;2;3)D**

**Df(3L)DTS5-3**

cytology: *Df(3L)72F3-4;73E2-F1* (Ashburner).  
 origin: X-ray-induced reversion of dominant effect of *l(3)73Ai* selected at 29°.  
 discoverer: Faithfull.  
 synonym: *Df(3L)DTS-5<sup>R+3</sup>*.  
 genetics: Deficient for *l(3)73Ai*.

**Df(3L)DTS5-4**

cytology: *Df(3L)72D3-6;73B6-C4 + T(Y;3)CA16* (broken at 90B-C).  
 origin: X-ray-induced revertant of dominant effect of *l(3)DTS-5*.  
 discoverer: Faithfull.  
 synonym: *Df(3L)DTS-5<sup>R+4</sup>; Df(3L)st<sup>A</sup>*.  
 references: Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91 (listed here incorrectly as *Df(3L)DTS-5<sup>R+3</sup>*).  
 genetics: Deficient for *l(3)73Ai*, *st* and *tra* but not for *as* or *th*.

**Df(3L)E**

origin: X ray induced.  
 genetics: Homozygous lethal.

α Deficient for *Sod*.  
β No major rearrangements of 68A-C, but a small aberration, possibly a deficiency, in 68A proximal to 68A2.

**\**Df(3L)h100.390: Deficiency (3L) hairy***

cytology: *Df(3L)66D2-5;66D14-E1*.  
origin: X ray induced.  
discoverer: Alexander.  
references: Ward and Alexander, 1957, Genetics 42: 42-54.  
genetics: Deficient for *h*.

***Df(3L)h-i22***

cytology: *Df(3L)66D10-11;66E1-2*.  
origin: X ray induced.  
discoverer: Belote.  
references: Ingham, Pinchin, Howard, and Ish-Horowicz, 1985, Genetics 111: 463-86.  
genetics: Deficient for *h* and the chorion protein genes on 3L (*Cp-15*, *Cp-16*, *Cp-17*, and *Cp-18*), and *abd* but not *se*. Homozygous lethal.

**Df(3L)Hn: Deficiency (3L) Henna**

**cytology:** *Df(3L)66A;66B*.  
**origin:** X ray induced simultaneously with *T(2;3)Hn = T(2;3)53E-54A;77A;94F;96A*.  
**discoverer:** Van Atta, 30k.  
**references:** 1932, Am. Nat. 66: 93-95.  
 1932, Genetics 17: 637-59.  
 Lewis, 1956, DIS 30: 130.  
**genetics:** Mutant or deficient for *Hn*. Homozygous lethal.

**Df(3L)in61: Deficiency (3L) inturned**

**cytology:** *Df(3L)76F;77D*.  
**references:** Arajärvi and Hannah-Alava, 1969, DIS 44: 73-74.  
**genetics:** Deficient for *in*.

*Df(3L)JK18*: see *Df(3L)kto2*

**\*Df(3L)K: Deficiency (3L) of Krivshenko**

**cytology:** *Df(3L)61A;61C1-2*; an apparent terminal deficiency.  
**origin:** Probably X ray induced.  
**discoverer:** Krivshenko, 5614.  
**synonym:** *Df-3L<sup>K</sup>*.  
**references:** 1959, DIS 33: 95.

**Df(3L)kto2: Deficiency (3L) kohtalo**

**cytology:** *Df(3L)76B1-2;76D5* (Ashburner).  
**origin:** Induced by P-M hybrid dysgenesis.  
**discoverer:** Kennison, 1987.  
**synonym:** *Df(3L)JK18*.  
**genetics:** Deficient for *kto* and *ash1*.

**Df(3L)l3**

**cytology:** *Df(3L)68A8-B1;68B4-C1*. Status of 68A7 not clear.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Campbell, Hilliker, and Phillips, 1986, Genetics 112: 205-15.  
**genetics:** Includes *l(3)68Ba-l(3)68Be*. Not deficient for *Sod*.

**Df(3L)lxd: Deficiency (3L) low xanthine dehydrogenase**

**references:** Schott and Finnerty, 1983, Genetics 104: s62-63.  
 Schott, Baldwin, and Finnerty, 1986, Biochem. Genet. 24: 509-27.

**Df(3L)Ly: Deficiency (3L) Lyra**

**cytology:** *Df(3L)70A2-3;70A5-6*.  
**origin:** X ray induced.  
**discoverer:** Dubinin, 1929.  
**references:** Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301.  
**genetics:** Associated with the mutant, *Ly*. Lethal in combination with *Df(3L)M69E*.

**Df(3L)Ly2**

**cytology:** *Df(3L)70A2-3;70A5-6*. Same as *Df(3L)Ly* (Zhimulev and Feldman, 1982).  
**origin:** Spontaneous (possibly caused by male recombination inducer).  
**references:** Waddle, 1977, DIS 52: 3.  
 Zhimulev and Feldman, 1982, DIS 58: 152.  
**genetics:** Deficient for *Ly*. Phenotype of *Ly<sup>2</sup>* similar to *Ly* except that eyes tend to be rougher.

**\*Df(3L)M69E**

**cytology:** Probably includes bands in 70A.  
**origin:** X ray induced.  
**discoverer:** Demerec, 33j25.  
**synonym:** *\*Df(3L)M-h33j*.  
**references:** 1935, DIS 3: 27.  
 Coyne, 1935, DIS 4: 59.  
 Mossige, 1938, Hereditas 24: 110-16.  
**genetics:** Deficient for *M(3)69E*; lethal homozygous and in combination with *Df(3L)Ly*.

*\*Df(3L)M-h33j*: see *Df(3L)M69E*

**Df(3L)Mg26: Deficiency (3L) Mglinetz**

**cytology:** *Df(3L)66C;66D*.  
**origin:**  $\gamma$  ray induced.  
**references:** Mglinetz, 1972, Genetika (Moscow) 8: 82-92.

**Df(3L)Mg27**

**cytology:** *Df(3L)61C;66D*.  
**origin:**  $\gamma$  ray induced.  
**references:** Mglinetz, 1972, Genetika (Moscow) 8: 82-92.

**\*Df(3L)Mz: Deficiency (3L) from Minute (2) z stock**

**cytology:** Loss of several bands from tip of *3L(61A)*.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 36h28.  
**references:** CP627.

*Df(3L)N<sup>264-6</sup>*: see *T(1;3)N<sup>264-6</sup>*

**Df(3L)P20: Deficiency (3L) Pasadena 20**

**cytology:** *Df(3L)67F;68E3-4*.  
**origin:** Recombinant from *Tp(3;3)P20/ +*.  
**references:** Lewis, 1980, DIS 55: 207-08.  
**genetics:** *Df(3L)P20/ +* flies slightly Minute and seem to have reduced fertility in females.

Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**genetics:** Deficient for *Scr* and *ftz*. Complements all *Antp* alleles tested.

**molecular biology:** Proximal breakpoint between coordinates +170 and +180 on DNA map of region 84B1-2 (Garber *et al.*, 1983).

**Df(3R)10-65**

**cytology:** *Df(3R)81F;81F*.

**genetics:** Deficient for *l(3)81Fa-l(3)81Fb*.

*Df(3R)10d77-7*: see *Df(3R)Tpl4*

*Df(3R)25g77*: see *Df(3R)Tpl5*

*Df(3R)30c76*: see *Df(3R)Tpl10*

**\*Df(3R)89EF**

**cytology:** *Df(3R)89D7-E1;90A2-3*.

**origin:** Synthetic. Made by combining the 4<sup>P</sup>3R<sup>D</sup> element of one *T(3;4)* with the 3R<sup>P4</sup><sup>D</sup> element of another.

**discoverer:** Dubovsky and Kelstein.

**references:** 1936, Eksperim. Med. No. 11: 65-84.

Kelstein, 1938, Biol. Zh. (Moscow) 7: 1145-69.

Pipkin, 1959, Texas Univ. Publ. 5914: 69-88.

**genetics:** One of a series of deficiencies for the middle of 3R synthesized and carefully studied by Dubovsky and Kelstein. Deficient for abdominal components of *BXC*. Heterozygous male has rotated genitalia which may be feminized both in structure and color, has sex combs. Heterozygous female sterile.

**Df(3R)109**

**references:** Casanova, Sánchez-Herrero, and Morata, 1986, Cell 47: 627-36.

**genetics:** Deficient for *Ubx* and *iab2* but not *iab5-7*.

*Df(3R)148.5*: see *Df(3R)Cha-M1*

**Df(3R)159.22**

**cytology:** *Df(3R)87E3-4;87E6-8*.

**origin:** Induced by diepoxybutane.

**references:** Nagoshi and Gelbart, 1987, Genetics 117: 487-502.

**genetics:** Deficient for *l(3)87Ee-l(3)87Ef*.

**molecular biology:** Distal breakpoint 3-8 kb proximal to the distal breakpoint of *Df(3R)Ace-HD1* at 72.5 - 77.8 kb (DNA walk of Bender, Spierer and Hogness, 1983, J.

Mol. Biol. 168: 17-33).

*Df(3R)229*: see *Df(3R)E-229*

**Df(3R)293**

**cytology:** *Df(3R)87E;88A*.

**references:** Parkhurst, Harrison, Remington, Spana, Kelley, Coyne, and Corcas, 1988, Genes Dev. 2: 1205-15.

**Df(3R)A41**

**cytology:** *Df(3R)84B1-2;84D1-2*.

**origin:** X ray induced.

**discoverer:** Abbott, 1985.

**references:** Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48.

Whetten, Organ, Krasney, Cox-Foster, and Cavener, 1988, Genetics 120: 475-84.

**genetics:** Deficient for *Antp* but not for *ftz*.

**molecular biology:** Left breakpoint at about +140 kb on the molecular map of Cavener *et al.*, (1986).

**Df(3R)A113**

**cytology:** *Df(3R)100A-B;100F*.

**references:** Van Vactor, Krantz, Reinke, and Zipursky, 1988, Cell 52: 281-90.

**Df(3R)Ace-HD1: Deficiency (3R) Acetylcholinesterase**

**cytology:** *Df(3R)87E3-4;87E5-6*.

**origin:** Hybrid dysgenesis.

**references:** Nagoshi and Gelbart, 1987, Genetics 117: 487-502.

**genetics:** Deficient for *Ace-l(3)87Ee*; does not fully remove *Ace* activity, but behaves as recessive *Ace* lethal.

**molecular biology:** Proximal breakpoint between +49 and +50.5 kb; distal breakpoint between +72.5 and +77.8 kb (DNA walk of Bender, Spierer, and Hogness, 1983, J. Mol. Biol. 168: 17-33).

**Df(3R)Aldox<sup>n1</sup>: Deficiency (1) Aldehyde oxidase**

**cytology:** *Df(3R)89A1-2*.

**origin:** Spontaneous.

**references:** Langhout and van Breugel, 1985, DIS 61: 181.

**genetics:** Deficient for *Aldox*.

*Df(3R)Antp<sup>73b+RX1</sup>*: see *Df(3R)Antp-X1*

*Df(3R)Antp<sup>rA75</sup>*: see *Df(3R)Antp6*

**Df(3R)Antp1P: Deficiency (3R) Antennapedia**

**cytology:** *Df(3R)84B3;84D1-2 + In(3R)84B3;85C2-3*.  
**origin:** Deficient recombinant between *In(3R)Antp<sup>rv1P</sup>* (also a transposition) and a normal sequence.  
**discoverer:** Green.  
**synonym:** *Df(3R)Antp<sup>+R1P</sup>*.  
**references:** Lewis, Kaufman, and Denell, 1980, DIS 55: 85-87.  
 Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.  
**genetics:** Deficient for the distal portion of the 84B1-2 doublet and reverted for *Antp*; deficient for *roe* (Lewis *et al.*, 1980).

**Df(3R)Antp2**

**cytology:** *Df(3R)84B2;84D3*.  
**synonym:** *Df(3R)Antp<sup>RA60</sup>*.  
**origin:** X ray induced.  
**references:** Abbott and Kaufman, 1986, Genetics 114: 919-42.  
**genetics:** Not *Antp* over wild-type. Complements *Antp<sup>23</sup>* and *Antp<sup>1</sup>*.

**Df(3R)Ant6**

**cytology:** *Df(3R)84B2;84C6*.  
**synonym:** *Df(3R)Antp<sup>RA75</sup>*.  
**origin:** X ray induced.  
**references:** Abbott and Kaufman, 1986, Genetics 114: 919-42.  
**genetics:** Not *Antp* over wild type. Complements *Antp<sup>23</sup>* and *Antp<sup>1</sup>*.

**Df(3R)Antp7**

**cytology:** *Df(3R)84B1-2;84D*.  
**origin:** Induced by ethyl methanesulfonate in *Antp<sup>NS</sup>*.  
**discoverer:** Struhl.  
**synonym:** *Df(3R)Antp<sup>NS+RC7</sup>* (Struhl, 1981; Garber *et al.*, 1983).  
**references:** Struhl, 1981, Nature 292: 635-38.  
 Garber, Kuroiwa, and Gehring, 1983, EMBO J. 2: 2027-36.  
**genetics:** Deficient for *Antp* but not for *ftz* or *Scr* (Struhl 1981; Riley, Carroll, and Scott, 1987, Genes and Development 1: 716-30).  
**molecular biology:** Proximal breakpoint 154 kb to the left of the proximal breakpoint of *In(3R)Hu* (Garber *et al.*, 1983).

**Df(3R)Antp17**

**cytology:** *Df(3R)84A6;84D13-14* (Baker); *84B1;84D11-12* (Lewis *et al.*, 1980).  
**origin:** X ray induced in *Antp<sup>NS</sup>*.  
**synonym:** *Df(3R)Antp<sup>NS+R17</sup>* (Duncan and Kaufman, 1975).  
**references:** Duncan and Kaufman, 1975, Genetics 80: 733-52.  
 Lewis, Kaufman, and Denell, 1980, DIS 55: 85-87.  
 Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.  
 Wakimoto, Lewis, and Kaufman, 1980, DIS 55: 140-41.  
 Seeger, Haffley, and Kaufman, 1988, Cell 55: 589-600.  
**genetics:** Deficient for *Scr-roe*; includes *Est-C* (Ohnishi and Voelker, 1982, DIS 58: 120). Associated with dominant reduced-sex-comb phenotype. Fails to complement the recessive lethality of *Scr<sup>Msc</sup>*, *Antp*, and *Scx*. Embryonic lethal with *Df(3R)Scx*. Male heterozygotes

semisterile (Kaufman).  
**molecular biology:** Distal (84D13-14) breakpoint located at -31 kb (Baker and Wolfner; 0 point = Hind III site in *αTub84D*, "+" values to the right, "-" values to the left).

**Df(3R)Antp72: see In(3R)Antp<sup>rv72</sup>**

**Df(3R)Antp-Scx: see Df(3R)Scx2**

**Df(3R)Antp-X1**

**cytology:** *Df(3R)83F4-84A1;84B1-2 + Df(3R)84B6-C1;84C5-6*; deficiencies for two noncontiguous segments juxtaposed by *In(3R)Antp<sup>73b</sup>* = *In(3R)84B1-2;84C5-6*.  
**new order:** 61-83F4|84B6-84B2|84C6-100.  
**origin:** X-ray-induced in *In(3R)Antp<sup>73b</sup>*.  
**synonym:** *Df(3R)Antp<sup>73b+RX1</sup>* (Cavener *et al.*, 1986); *Df(3R)Antp<sup>73b+RX3</sup>* (Hazelrigg and Kaufman, 1983).  
**references:** Hazelrigg and Kaufman, 1983, Genetics 105: 581-600.  
 Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.  
 Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48.  
**genetics:** Deficient for *Antp*; shows reduced-sex-comb phenotype. Marked with *Ki*.  
**molecular biology:** Distal breakpoint at about +156 kb in the molecular map of Cavener *et al.*, 1986 (ref. #2).  
**other information:** Isolated independently of *Df(3R)Antp-X2* (Hazelrigg and Kaufman, 1983).

**Df(3R)Antp-X2**

**cytology:** *Df(3R)83F4-84A1;84B1-2 + Df(3R)84B6-C1;84C5-6*; deficiencies for two noncontiguous segments juxtaposed by *In(3R)Antp<sup>73b</sup>* = *In(3R)84B1-2;84C5-6*.  
**new order:** 61-83F4|84B6-84B2|84C6-100.  
**origin:** X-ray-induced in *In(3R)Antp<sup>73b</sup>*.  
**synonym:** *Df(3R)Antp<sup>73b+RX2</sup>* (Cavener *et al.*, 1986); *Df(3R)Antp<sup>73b+RX4</sup>* (Hazelrigg and Kaufman, 1983).  
**references:** Hazelrigg and Kaufman, 1983, Genetics 105: 581-600.  
 Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.  
**genetics:** Deficient for *Antp*; shows reduced-sex-comb phenotype. Marked with *red e*.

**Df(3R)awd7: Deficiency (3R) abnormal wing disks.**

**references:** Biggs, Tripoulas, Dearolf, and Shearn, 1988, Genes Dev. 2: 1333-43.  
**genetics:** Deficient for *awd* and both flanking transcription units.

**Df(3R)awd21**

**cytology:** Deficient for 100C-D.  
**references:** Biggs, Tripoulas, Hersperger, Dearolf, and Shearn, 1988, Genes Dev. 2: 1333-43.  
**genetics:** Deficient for *awd*.

**Df(3R)β2t: see In(3R)Scr<sup>MscL</sup> Antp<sup>BR</sup>**

**Df(3R)Bd: Deficiency (3R) Beaded**

**cytology:** *Df(3R)97D;97F-98A*.  
**origin:** X ray induced.  
**discoverer:** P. Lewis.  
**synonym:** *Df(3R)Ser<sup>+82f24</sup>*.

**genetics:** Fails to complement lethality of *Bd*<sup>3</sup>; also slightly enhances *nd* on the X chromosome. Deficient for *ro* and *Bd*.

**Df(3R)bxd100: Deficiency (3R) bithoraxoid**

**cytology:** *Df(3R)89B5-6;89E2-3*.  
**origin:** Aneuploid recombinant from *Tp(3;3)bxd*<sup>100</sup>/+.  
**discoverer:** E. B. Lewis.  
**references:** Struhl, 1982, Genetics 102: 737-49.  
**genetics:** Deficient for *ss*<sup>a</sup>, *bx*, and *Ubx*; mutant for *bxd*.

**Df(3R)bxd110: see Tp(3;3)bxd<sup>110</sup>**

**Df(3R)by: Deficiency (3R) blistery**

**origin:** X ray induced.  
**references:** Kempfues, Raff, Raff, and Kaufman, 1980, Cell 21: 445-51.  
 Kempfues, Raff, and Kaufman, 1983, Genetics 105: 345-56.

$\alpha$  Original strain (*dsx<sup>D</sup>* or *dsx<sup>Mas</sup>*) indicated in superscript.

$\beta$  1 = Baker, Hoff, Kaufman, Wolfner, and Hazelrigg, 1991, Genetics 127: 125-38; 2 = Baker and Ridge, 1980, Genetics 94: 383-423; 3 = Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48; 4 = Duncan and Kaufman, 1975, Genetics 80: 733-52; 5 = Jones and Rawls, 1988, Genetics 120: 733-42; 6 = Kaufman.

$\gamma$  Proximal (84C1-3) breakpoint estimated to be at about +26 to +27 kb, based on location of 84C1-2 breaks of *T(2;3)Ta<sup>1</sup>* at +34 kb and *Df(3R)Scx<sup>2</sup>* at +41 kb (Baker and Wolfner, 1988, Genes Dev. 2: 477-89). Also deficient for *hat* and *nac*.

$\delta$  Part of 84E1-2 fused with part of 84F11-12. Proximal breakpoint at about -4kb on the molecular map of Cavener *et al.*, 1986.

$\epsilon$  Deficient for *Su(var)304* as well as *dsx<sup>D</sup>* (Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, Mol. Gen. Genet. 202: 481-87).

$\zeta$  Broken within 85A1-3, deleting centromere proximal but not centromere distal material (B.S. Baker; Jones and Rawls, 1988).

$\eta$  Proximal breakpoint at about +134 kb on the molecular map of Cavener *et al.*, 1986.

**Df(3R)e: Deficiency (3R) ebony**

origin: *Df(3R)e-G* chromosomes were  $\gamma$  ray induced, other deficiencies X ray induced.

references: Wustmann, Szidonya, Taubert, and Reuter, 1989, Mol. Gen. Genet. 217: 520-27.  
Bang, Hartenstein, and Posakony, 1991, Development 111: 89-104.  
genetics: Deficient for *H*.

**Df(3R)hh: Deficiency (3R) hedgehog**

cytology: *Df(3R)92F11-14;94E2-5*.  
origin:  $\gamma$  ray induced.  
synonym: *Df(3R)hh-GR2*.  
references: Mohler, 1988, Genetics 120: 1061-72.  
genetics: Deficient for *hh*.

**Df(3R)Hu: Deficiency (3R) Humeral**

cytology: *Df(3R)84A6-B1;84B3-6 + Df(3R)84D4-5;84F1-2*; deficiencies for two non-contiguous deletions juxtaposed by *In(3R)Hu*.  
new order:  
61 - 84A6|84D4 - 84B6|86C5 - 84F2|86C6 - 100.  
origin: Induced by ethyl methanesulfonate in *In(3R)Hu*.  
synonym: *Df(3R)Hu<sup>rvX1</sup>*; *Df(3R)Hu<sup>+RX1</sup>*.  
references: Hazelrigg and Kaufman, 1983, Genetics 105: 581-600.  
Cavener, Ottelson, and Kaufman, 1986, Genetics 114: 111-23.  
genetics: Deficient for *Antp* and *Hu* but not *ftz*. Male heterozygote shows reduced sex comb phenotype.  
molecular biology: Proximal end of the deficiency at +88; "+" values to the right, "-" values to the left. (Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, Cell 35: 763-76).

**Df(3R)I9**

cytology: *Df(3R)92B1-3;92C1-3*.  
genetics: Deficient for *l(3)SB65*.

**cytology:** *Df(3R)87A;87C*.  
**origin:** X ray induced.  
**references:** Mukhina and Zhimulev, 1980, *DIS* 55: 209.

**Df(3R)MSu2: Deficiency (3R) Minute Suppressor**

cytology: *Df(3R)100F3-5*.

origin: X ray induced.

references: Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, Mol. Gen. Genet. 202: 481-87.

genetics: Exhibits a Minute phenotype and dominant suppression of variegated-type position effect.

other information: The genetic map position and the inferred moderate phenotype are at odds with the location of the deficiency at 100F3-5.

<sup>β</sup> DNA coordinates from 85A map (Jones and Rawls, 1988, Genetics 120: 733-42) ("+" values to right, "-" values to left or centromere end of map). Proximal breakpoints of deficiencies 5, 16, and 19; distal breakpoint of deficiency 25.

<sup>γ</sup> Distal breakpoint of *Df(3R)p13* molecularly mapped to the DNA (Tautz *et al.*, 1987).

<sup>δ</sup> Includes *Dhod* (Porter and Rawls, 1984, Mol. Gen. Genet. 193: 27-32).

<sup>ε</sup> Uncovers *hb*.

<sup>ζ</sup> Deficient for *pum* (Lehman and Nüsslein-Volhard, 1987, Nature 329: 167-70).

**Df(3R)P2: Deficiency (3R) Pasadena**

cytology: *Df(3R)89D9-E1;89E2-3*.

origin: X ray induced.

discoverer: E.B. Lewis.

references: 1980, DIS 55: 207-08.

genetics: Deficient for *abx-iab*<sup>3</sup>. Genetically similar to *Df(3R)Ubx109*.

molecular biology: Right breakpoint 75-81 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>* (Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96).

**Df(3R)P9**

cytology: *Df(3R)89D9-E1;89E4-5*.

origin: X ray induced.

discoverer: E.B. Lewis.

references: 1978, Nature 276: 565-70.

1980, DIS 55: 207-08. Jiménez and Campos-Ortega, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 370-73.

Morata, 1982, Am. Zool. 22: 57-64.

Levine, Hafen, Garber, and Gehring, 1983, EMBO J. 2: 2037-46.

Hafen, Levine, and Gehring, 1984, Nature 307: 287-89.

genetics: Deficient for entire *BXC*; uncovers *tuh-3* (Kuhn, Woods, and Andrew, 1984, DIS 60: 134-35). Homozygotes die in late embryonic or early larval stages, showing transformation of metathorax and anterior first abdominal segment to mesothorax (Lewis, 1978; Hayes, Sato, and Denell, 1984, Proc. Nat. Acad. Sci. USA 81: 545-49) and transformation of posterior meso- and metathorax to prothorax (Hayes *et al.*, 1984; Ganger, Fehon, and Schubiger, 1985, Nature 313: 395-97).

When incubated at 18°, homozygous *Df(3R)P9* embryos do not complete germ band shortening but *Df(3R)P9/Dp(3;3)P5* heterozygotes go through normal development (Ganger and Schubiger, 1984, DIS 60: 108-09). *Df(3R)P9/+* flies show reduced male pigmentation on AB5 and AB6, are sterile, and have deformed genitalia; *Df(3R)P9/Mcp* flies are partially fertile. *Df(3R)P9/Df(3R)Ubx109* larvae have a short tracheal trunk between AB7 and AB8 and a posterior spiracle in AB8 (Lewis, 1978).

**molecular biology:** Right breakpoint 225-230 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rvl</sup>* (Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96).

<sup>β</sup> Heterozygotes with *In(3R)sbd<sup>17</sup>* viable and *sbd*; heterozygotes with *In(3R)sbd<sup>12</sup>*, *sbd<sup>13</sup>*, *sbd<sup>18</sup>*, and *In(3R)sbd<sup>21</sup>* lethal with adult escapers that are *sbd*.

<sup>γ</sup> Heterozygotes with *In(3R)sbd<sup>17</sup>* viable and *sbd*; heterozygotes with *sbd<sup>32</sup>* lethal with adult escapers that are *sbd*. Uncovers *pnr*

(Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95).

♂ Crossing over in *X* reduced in *Df(3R)sbd105/+* females (Hinton, 1966, Genetics 55: 157-64); no effect on spontaneous male recombination (Lutkin and Baker, 1979, Mutat. Res. 61: 221-27). Uncovers *spt* and *pnr* (Jürgens *et al.*, 1984).

***Df(3R)SCB-XL2***

**cytology:** *Df(3R)84A4-5;84B1-2*.

**origin:** X ray induced.

**discoverer:** Jürgens.

**references:** Pultz, Diederich, Cribbs, and Kaufman, 1988, Genes Dev. 2: 901-20.

**genetics:** Variegating for *pb*. *Df(3R)SCB-XL2/pb<sup>-</sup>* flies show the maxillary and labial palp phenotypes of *pb* null flies.

***Df(3R)Scr: Deficiency (3R) Sex combs reduced***

**cytology:** *Df(3R)84A1-2;84B1-2*.

**origin:**  $\gamma$  ray induced.

**discoverer:** Sinclair, 1977.

**references:** Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33.

Lewis, Kaufman, and Denell, 1980, DIS 55: 85-87.

Lewis, Kaufman, Denell, and Tallero, 1980, Genetics 95: 367-81.

Lewis, Wakimoto, Denell, and Kaufman, 1980, Genetics 95: 383-97.

Wakimoto, Lewis, and Kaufman, 1980, DIS 55: 140-41.

Wakimoto and Kaufman, 1981, Dev. Biol. 81: 51-64.

Garber, Kuroiwa, and Gehring, 1983, EMBO J. 2: 2027-36.

**genetics:** Deficient for *pb-Hu* plus four lethal complementation groups proximal to *pb*. Associated with dominant reduced-sex-comb phenotype. Fails to complement the recessive lethality of *Msc*, *Antp*, and *Antp<sup>Scx</sup>*. Embryonic lethal with *Df(3R)Antp17*.

**molecular biology:** Deletes sequences to left of molecular coordinate +100, *In(3R)Hu* breakpoint being coordinate 0 in the breakpoint DNA walk of Garber *et al.*, 1983 ("+" values to the left, "-" values to the right).

***Df(3R)Scx2: Deficiency (3R) Sexcombs extra***

**cytology:** *Df(3R)84A4-5;84C1-2*. Break near C1, probably C2 or C3 (B. Baker).

**origin:** X ray induced.

**synonym:** *Df(3R)Scx<sup>W+RX2</sup>*; *Df(3R)Antp-Scx*.

**references:** Hazelrigg and Kaufman, 1983, Genetics 105: 581-600.

Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48.

Pultz, Diederich, Cribbs, and Kaufman, 1988, Genes Dev. 2: 901-20.

**genetics:** Deficient for *pb*, *ftz*, *Scx<sup>W</sup>* and *Antp*. Homozygous lethal. *Df(3R)Scx2/Df(3R)MAP2* viable and *pb*.

**molecular biology:** Distal (84C1-2) breakpoint located at about +41 kb (Baker and Wolfner, 1988, Genes Dev. 2: 477-89); 0 point = *HindIII* site in  *$\alpha$ Tub84B*, "+" values to the right, "-" values to the left).

***Df(3R)Scx4***

**cytology:** *Df(3R)84B3;84D1-2*.

**origin:** X ray induced.

**synonym:** *Df(3R)Scx<sup>W+RX4</sup>*.

**references:** Hazelrigg and Kaufman, 1983, Genetics

105: 581-600.

Cavener, Otteson and Kaufman, 1986, Genetics 114: 111-23.

Agnel, Kerridge, Vola, and Griffin-Shea, 1989, Genes Dev. 3: 85-95.

**genetics:** Deficient for *Scx<sup>W</sup>*, *Antp*, *rn*, and *roe* but not *ftz*. Homozygous lethal.

***Df(3R)SMG39: Deficiency (3R) Semenova Mglinetz Glotoff***

**cytology:** *Df(3R)90C;91D*.

**origin:**  $\gamma$  ray induced.

**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6: 165-69.

***\*Df(3R)sr: Deficiency (3R) stripe***

**origin:** X ray induced.

**discoverer:** Alexander.

**references:** Ward and Alexander, 1957, Genetics 42: 42-54.

**genetics:** Deficient for *sr*.

***Df(3R)ss: Deficiency (3R) spineless***

**cytology:** Deficient for bands in 89C-D; associated with *In(3LR)P88=In(3LR)61A;89C-D*.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**synonym:** *Df(3R)P88*.

**references:** García-Bellido, Moscoso del Prado, and Botas, 1983, Mol. Gen. Genet. 192: 253-63.

**genetics:** Deficient for *ss*.

***Df(3R)ss-a***

**cytology:** *Df(3R)89B;89D* (Holmgren).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *ss<sup>aC15</sup>*.

**references:** Struhl, 1982, Genetics 102: 737-49.

**genetics:** Deficient for *ss*. Lethal over *Df(3R)bxd100*.

***Df(3R)su(Hw)7: Deficiency (3R) Suppressor of Hairy wing***

**cytology:** *Df(3R)88A9;88B2*.

**genetics:** Deficient for *su(Hw)<sup>7</sup>*.

***Df(3R)Su9-b: Deficiency (3R) Suppressor***

**cytology:** *Df(3R)95A;97A*.

**origin:** Spontaneous.

**references:** Gonzales, Molina, Casal, and Ripoll, 1989, Genetics 123: 371-77.

**genetics:** Deficient for *M(3)96A-Pr*. Dominant lethal.

***Df(3R)Su(var)3-6: Deficiency (3R) Suppressor of variegation***

**cytology:** *Df(3R)87B1;87D11*.

**origin:** X ray induced.

**references:** Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, Mol. Gen. Genet. 202: 481-87.

Reuter, Gausz, Gyurkovics, Friede, Bang, Spierer, Hall, and Spierer, 1987, Mol. Gen. Genet. 210: 429-36.

**genetics:** Deficient for *Su(var)3-6*. Recessive lethal.

**Df(3R)SX1**

**cytology:** *Df(3R)89E;89E*.  
**origin:** X ray induced.  
**references:** Tiong, Bone, and Whittle, 1985, Mol. Gen. Genet. 200: 335-42.  
 Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**genetics:** Deficient for *iab2 - iab9*.  
**molecular biology:** Proximal breakpoint 27.5-35 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>* (Karch *et al.*, 1985).

**Df(3R)T**

**origin:** Derived from transposing element *TE86F*.

**genetics:** Deficient for *l(4)102CDA-l(4)102CDB*. *bt* phenotype no longer observed (Hochman, 1976).

**Df(4)Cat: Deficiency (4) Cataract**

**origin:** X ray induced.  
**discoverer:** Belgovsky, 1936.  
**references:** 1937, DIS 8: 7. Morgan, 1941, DIS 14: 52. Hochman, Gloor, and Green, 1964, Genetica (The Hague) 35: 109-26. Hochman, 1971, Genetics 67: 235-52.  
**genetics:** Deficient for *l(4)102EFa-sv*.

**Df(4)ci-D: Deficiency (4) cubitus interruptus-Dominant**

**origin:** X ray induced.  
**discoverer:** Ruch, 32a18.  
**references:** Bridges, 1935, Biol. Zh. (Moscow) 4: 401-20. Hochman, Gloor, and Green, 1964, Genetica (The Hague) 35: 109-26. Hochman, 1971, Genetics 67: 235-52.  
**genetics:** Deficient for *l(4)102ABb* and *l(4)102ABc*.

**Df(4)G: Deficiency (4) of Gloor and Green**

**cytology:** *Df(4)102E2-10*; tip of 4R lost and remainder of chromosome 4 capped with X-chromosomal material, including 1A (Hochman).  
**origin:** X ray induced.  
**discoverer:** Gloor and Green, 1957.  
**references:** Hochman, Gloor, and Green, 1964, Genetica 35: 109-26. Hochman, 1971, Genetics 67: 235-52. 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London,

CHROMOSOMES - DEFICIENCIES

New York, San Francisco, Vol. 1b, pp. 903-28.

**genetics:** Deficient for *l(4)102EFa-l(4)102EFf*; fails to complement *sv* and *spa*. Lethal homozygous and in heterozygous combination with *Df(4)3*, *Df(4)11*, *Df(4)12*, *Df(4)24*, and *Df(4)34*. *y*<sup>+</sup> and *ac*<sup>+</sup> linked terminally.

## DUPLICATIONS

*Doubler*: see  $Dp(1;1)B^S RMG$

$Dp(1)3C1$ : see  $Dp(1;1)w^{rG}$

***Dp(1;1)3C3***

**cytology**:  $Dp(1;1)3C2-3;3C3-5$ ; tandem duplication of right-most sites of  $w$  ( $w^e$  and  $w^{sp}$ ).

**synonym**:  $Dp3C3$ ;  $Dp(w^+R)$ ;  $Dp(w^e;w^{sp})$ .

**references**: Green, 1963, *Z. Vererbungsl.* 94: 200-14. 1967, *Biol. Zentralbl.* 86: 211-20.

Arcos-Teran, 1972, *Chromosoma* 37: 233-96.

**genetics**: Homozygotes wild type in eye color. Males and females with  $z$  and the duplication are  $z$ .

***Dp(1;1;1)3C3***

**cytology**: Triplication of right-most sites of  $w$  inferred (Green, 1967). No thickening of 3C3 visible in polytene chromosomes (Lefevre).

**origin**: From homozygous  $Dp(1;1)3C3$  females.

**synonym**:  $Tr(w^+R)$ ;  $Dp(1;1)3C3$  (triplication).

**references**: Green, 1967, *Biol. Zentralbl.* 86: 211-20.

Arcos-Teran and Beerman, 1968, *Chromosoma* 25: 377-91.

Arcos-Teran, 1972, *Chromosoma* 37: 233-96.

**genetics**: Homozygotes wild type in eye color. Males and females with  $z$  and the duplication are  $z$ .

***Dp(1;1)4E;6F***

**cytology**:  $Dp(1;1)4E2-F1;6F1-2$ . Reversed repeat.

**new order**:

1A – 6F|6F – 4E|6F – 20.

**origin**: Derived from *Uc* unstable X.

**references**: Lim, 1979, *Genetics* 93: 681-701.

**genetics**: Unstable.

**\**Dp(1;1)100: Duplication (1;1) 100***

**origin**: Spontaneous product of exchange between  $Dp(1;f)100$  and proximal heterochromatin of  $C(1)RM$ .

**\**Dp(1;1)105***

**cytology**: Metaphase X chromosome has one arm of normal length and one about 40% normal length.

**new order**:

1 – 20F·|6 – 1.

**origin**: X-ray-induced deletion of most of X euchromatin was recovered as a  $C(1)RM/Dp(1;f)105$  female, which by detachment produced  $Dp(1;1)105$  in the succeeding generation.

**discoverer**: Dobzhansky, 1930.

**references**: 1932, *Biol. Zentralbl.* 52: 493-509.

**genetics**: Contains wild-type alleles of  $y$  through  $dx$  and also probably  $bb$ .

***Dp(1;1)112***

**origin**: Spontaneous product of exchange between  $Dp(1;f)112$  and proximal heterochromatin of an attached-X.

**\**Dp(1;1)138***

**origin**: X-ray-induced deletion of most of X euchromatin that was recovered as a  $C(1)RM/Dp(1;f)138$  female, which by detachment produced  $Dp(1;1)138$  in the subsequent generations.

**discoverer**: Dobzhansky, 1930.

**references**: 1935, *Z. Indukt. Abstamm. Vererbungsl.*

68: 134-62.

**genetics**: Extends from locus of  $r$  to base of X; carries *B*. Female nearly wild type, but male has low viability and is sterile.

**\**Dp(1;1)258-46***

**cytology**:  $Dp(1;1)2B4-7;3A4-6$ ; reversed repeat (Sutton).

**new order**:

1 – 2B4|3A4 – 2B7|2B7 – 20 or

1 – 3A4|3A4 – 2B7|3A6 – 20.

**origin**: X ray induced.

**discoverer**: Demerec, 38l.

**genetics**: Originally appeared as  $w$  but reverted to  $w^+$ . No effect on *pn-gt* reported.

***Dp(1;1)Ax<sup>28a</sup>: Duplication (1;1) Abruptex***

**cytology**: Single-band duplication believed to involve 3C7 by Morgan, Schultz, and Curry (1941); identity of extra band not confirmed by Lefevre (1953, *Genetics* 38: 345-59).

**new order**:

1A – 3C7|3C7 – 20.

**origin**: X ray induced.

**references**: Morgan, Schultz, and Curry, 1941, *Year Book - Carnegie Inst. Washington* Welshons, 1971, *Genetics* 68: 259-68.

**genetics**: *Ax* phenotype.

***Dp(1;1)B: Duplication (1;1) Bar***

**cytology**:  $Dp(1;1)15F9-16A1;16A7-B$ ; a tandem duplication (Bridges, 1936, *Science* 83: 210-11; Muller, Prokofyeva-Belgovskaya, and Kossikov, 1936, *Dokl. Acad. Nauk SSSR* 1: 87-88).

**new order**:

1 – 16A7|16A1 – 20.

**origin**: Spontaneous.

**discoverer**: Tice, 13b.

**references**: 1914, *Biol. Bull.* 26: 221-30.

**genetics**: Position effect for *B*, apparently resulting from juxtaposition of 16A1 with 16A7, which may undergo mutation to less extreme forms (e.g.,  $B^i$ ). Produces normal and triplicated [ $Dp(1;1)BB$ ] products by unequal crossing over.

**\**Dp(1;1)B<sup>263-28</sup>***

**cytology**:  $Dp(1;1)15F9-16A1;16A3-4;16A6-7;16A7-B1$ .

**new order**:

1 – 16A3|16A7|16A1 – 20.

**origin**: X-ray-induced deletional derivative of  $Dp(1;1)B^i B^i = Dp(1;1)15F9-16A1;16A7-B1$ .

**discoverer**: Demerec, 34b.

**references**: Sutton, 1943, *Genetics* 28: 97-107.

**\**Dp(1;1)B<sup>263-48</sup>: see Tp(1;1)B<sup>263-48</sup>******Dp(1;1)B<sup>S</sup>-H: Duplication (1;1) Bar Stone of Hinton***

**new order**:

1A1-1B3|20F-3C2|20F|1A4-3C1|20F-16A1|102F;

position of centromere indeterminate; adjacent to either 3C1 or 3C2.

**origin**: Generated by double exchange in a  $R(1)2, In(1)w^{vC}/In(1)sc^{4L}sc^{8R}/X^{P4D}$  female, one exchange occurring between the  $B^S$  element and  $R(1)2$  and the other between  $In(1)sc^{4L}sc^{8R}$  and  $R(1)2$ .

**references**: Hinton, 1957, *Genetics* 42: 55-65.

**phenotype:** These linear derivatives of the  $w^{vC}$  ring do not undergo the somatic loss characteristic of the unstable ring; they do, however, display indications of variable levels of instability, presumably related to the degree of instability of the generating ring. This is recognized by reduced recovery and elevated primary nondisjunction in  $Dp(1;1)B^S-H/In(1)dl49$  females. Exchange between the  $B^S$  duplication and the long arm of the same chromatid regenerates single rings whose stabilities reflect those of the parental linear chromosome. Exchange between the  $B^S$  duplication and a normal homologue generates tandem-metacentric compound chromosomes [ $C(1)TM-H$ ].

**$Dp(1;1)B^S RAG$ : Duplication (1;1) Bar of Stone Reversed Acrocentric**

**cytology:**  $Dp(1;1)15F9-16A1;20$ .

**new order:**

·20|1A – 20|20 – 16A1|102F.

**origin:** Spontaneous recombinant between the distal X of a  $C(1)RA$  and  $X^{P4D}$  from  $T(1;4)B^S$ .

**discoverer:** Lindsley and Sandler.

**references:** 1963. Methodology in Basic Genetics (W. J. Burdette, ed.). Holden-Day, Inc., San Francisco, pp. 390-403.

**genetics:** Generates reversed acrocentric compound X chromosomes in  $Dp(1;1)B^S RAG/+$  female, usually by a double exchange in which one exchange occurs between the duplicated segment of one strand and the homologous region of its sister and the other between the duplication-bearing X and its normal homolog. Rate of  $C(1)RA$  generation about  $6 \times 10^{-4}$ .

**$Dp(1;1)B^S RMG$ : Duplication (1;1) Bar of Stone Reversed Metacentric**

**cytology:**  $Dp(1;1)15F9-16A1;20$ .

**new order:**

1 – 20·20 – 16A1|102F.

**origin:** Spontaneous recombinant between  $C(1)RM$  and the  $X^{P4D}$  element of  $T(1;4)B^S$ .

**discoverer:** Muller.

**synonym:** *Doubler*.

**references:** 1936, DIS 6: 8.

Lindsley and Sandler, 1963, Methodology in Basic Genetics (W. J. Burdette, ed.). Holden-Day, Inc., San Francisco, pp. 390-403.

**genetics:** Generates reversed metacentric compound X chromosomes in  $Dp(1;1)B^S RMG/+$  female by crossing over between the duplicated segment and either the X to which it is attached or the homologous X at a rate of about  $2.5 \times 10^{-4}$ .

**$Dp(1;1)B^S TAG$ : Duplication (1;1) Bar of Stone Tandem Acrocentric**

**cytology:**  $Dp(1;1)15F9-16A1;20$ .

**new order:**

·20 – 1A|20 – 16A1|102F.

**origin:** X-ray-induced recombinant between the distal heterochromatin of an X chromosome with a terminal heterochromatin segment derived from  $y^{+Y}$  and the proximal heterochromatin of the  $X^{P4D}$  element of  $T(1;4)B^S$ .

**discoverer:** Lindsley and Sandler.

**references:** 1963, Methodology in Basic Genetics (W. J. Burdette, ed.). Holden-Day, Inc., San Francisco, pp. 390-403.

**genetics:** Ineffective in generating tandem acrocentric compound X chromosomes.

**$Dp(1;1)B^S TMG$ : Duplication (1;1) Bar of Stone Tandem Metacentric**

**cytology:**  $Dp(1;1)15F9-16A1;20$  added as a second arm to  $In(1)sc^{8L}EN^R$ .

**new order:**

1A – B2|20B – 1A|20·20 – 16A1|102F.

**origin:** Spontaneous recombinant between the X in normal sequence of a  $C(1)TM$  and the  $X^{P4D}$  element of  $T(1;4)B^S$ .

**discoverer:** Lindsley and Sandler.

**references:** 1963, Methodology in Basic Genetics (W. J. Burdette, ed.). Holden-Day, Inc., San Francisco, pp. 390-403.

**genetics:** Generates tandem metacentric compound X chromosomes in  $Dp(1;1)B^S TMG/+$  female by recombination between the duplication and the base of a homolog in normal sequence, at a rate of about  $20 \times 10^{-4}$ .

**$Dp(1;1)B^S TRG$ : Duplication (1;1) Bar of Stone Tandem Ring-genic**

See  $C(1)TMB^S$  subsection in compound chromosomes.

**$Dp(1;1)bb^{DfL}Cl^R$**

**cytology:**  $Dp(1;1)4A5-B1;4D2-3 + Dp(1;1)17A6-B1;20B-C$ .

**origin:** Associated with  $In(1)bb^{DfL}Cl^R$ .

**references:** CP627.

**$Dp(1;1)bb^{DfL}y^{4R}$**

**cytology:**  $Dp(1;1)1A8-B1;4D2-3 + Dp(1;1)18A3-4;20B-C$ .

**origin:** Associated with  $In(1)bb^{DfL}y^{4R}$ .

**references:** CP627.

**$Dp(1;1;1)BB$ : Duplication (1;1;1) Bar + Bar**

**cytology:**  $Dp(1;1)15F9-16A1;16A7-B1$ ; a tandem triplication [Bridges, 1936, Science 83: 210-11 (fig.)].

**new order:**

1 – 16A7|16A1 – 16A7|16A1 – 20.

**origin:** Spontaneous through unequal crossing over in  $B/B$  female.

**discoverer:** Zeleny.

**references:** 1920, J. Exp. Zool. 30: 292-324.

Sturtevant, 1925, Genetics 10: 117-47.

**genetics:** Either or both B regions may carry a less extreme derivative of B (i.e.,  $B^iB$ ,  $BB^i$ , or  $B^iB^i$ ). Number of duplicated segments may be either increased or decreased by unequal crossing over.

**\* $Dp(1;1)Bt$ : Duplication (1;1) Branchlet**

**cytology:**  $Dp(1;1)3B2-C1;6F6-7$ ; tandem repeat (Darby).

**new order:**

1 – 6F4|3C1 – 20.

**origin:** Induced by  $^{32}P$ .

**discoverer:** Bateman, 1950.

**references:** 1950, DIS 24: 54.

1951, DIS 25: 77.

**$Dp(1;1)Bx^f$ : Duplication (1;1) Beadex-recessive**

**cytology:**  $Dp(1;1)17A;17E-F$  (E. B. Lewis).

**origin:** Spontaneous.

**discoverer:** Ives, 35k.

**references:** 1937, DIS 7: 6.

Green, 1952, Proc. Nat. Acad. Sci. USA 38: 949-53.

1953, Genetics 38: 91-105.

1953, Z. Indukt. Abstamm. Vererbungsl. 85: 435-49.

**genetics:** Duplicated for *os*<sup>+</sup>, *Bx*<sup>+</sup>, and *fu*<sup>+</sup>. Does not yield unequal crossovers as does *Bx*<sup>r49k</sup>.

**Dp(1;1)Bx<sup>r49k</sup>**

**cytology:** *Dp(1;1)17A;17C* (E. B. Lewis).

**origin:** Spontaneous.

**discoverer:** Mossige, 49k22.

**references:** 1950, DIS 24: 61.

Green, 1953, Z. Indukt. Abstamm. Vererbungsl. 85: 435-49.

Green, 1968, Mol. Gen. Genet. 103: 209-17.

**genetics:** Duplicated for *Bx*<sup>+</sup> but not for *os*<sup>+</sup> or *fu*<sup>+</sup>. Unequal crossing over yields wild types and triplications. Quadruplications have also been produced.

**Dp(1;1)Cl<sup>L</sup>y<sup>4R</sup>**

**cytology:** *Dp(1;1)1A8-B1;4A5-B1+Df(1)17A6-B1;18A3-4..*

**new order:**

1 - 4A|17A6-1B1|18A4 - 20.

**origin:** Associated with *In(1)Cl<sup>L</sup>y<sup>4R</sup>*.

**references:** CP627.

**Dp(1;1)Co: Duplication (1;1) Confluens**

**cytology:** *Dp(1;1)3C4-5;3D6-E1*; tandem duplication (Schultz, 1941, DIS 14: 54-55).

**new order:**

1 - 3D6|3C5 - 20.

**origin:** Recovered among progeny of cold-treated fly.

**discoverer:** Gottschewski, 34c.

**references:** 1935, DIS 4: 7, 14, 16.

1937, DIS 8: 12.

1937, Z. Indukt. Abstamm. Vererbungsl. 73: 131-42.

**genetics:** The *Co* phenotype arises from a duplication of the Notch locus (salivary band 3C7).

**Dp(1;1)ct<sup>7B</sup>**

**cytology:** *Dp(1;1)6F1-2;7C1-2*. Reversed repeat.

**new order:**

1 - 6F|7C - 6F|6F - 20.

**origin:** Derived from *Uc* unstable X.

**references:** Lim, 1979, Genetics 93: 681-701.

**genetics:** Unstable.

**Dp(1;1)G: Duplication (1;1) Gelbart**

**references:** Gelbart, 1971, Ph.D. Thesis.

**cytology:** *Dp(1;1)5E;7A*; reversed repeat.

**new order:**

1A - 5E|7A - 5E|5E - 20.

**synonym:** *Dp(1;1)019*.

**origin:** Induced in progeny of *hdp-b* fly (*P* factors in rearranged chromosome at *5E* and *17C*).

**references:** Engles and Preston, 1984, Genetics 107: 657-78.

**genetics:** Reverted for *hdp-b*.

**Dp(1;1)IMNB-8**

**cytology:** Inversion of segment overlapping the tandem duplication *Dp(1;1)MNB-8*.

**new order:**

1A - 16F|16F - 16A1|16A7 - 16A1|17E1 - 17A2|16F - 20.

**origin:** Spontaneous derivative of *Dp(1;1)MNB-8*.

**references:** Holmquist, 1972, Chromosoma 36: 413-52.

**genetics:** Has a *B os*<sup>+</sup> phenotype and a (*B*<sup>+</sup> *B*)(*os*<sup>+</sup> *os*) genotype.

**Dp(1;1)jnR1-A**

**cytology:** Small duplication in 6F-7A region.

**references:** Mainz, Salz, Cline, and Schedl, 1985, Cell 43: 521-29.

**genetics:** Duplicated for *Sxl*<sup>+</sup> and *l(1)7Aa*.

**Dp(1;1)jnR1-B**

**cytology:** Small duplication in 6F-7A region.

**references:** Mainz, Salz, Cline, and Schedl, 1985, Cell 43: 521-29.

**genetics:** Duplicated for *l(1)7Aa* but not *Sxl*<sup>+</sup>.

**Dp(1;1)L-B<sup>S</sup>: Duplication (1;1) Lindsley**

**origin:** Replacement of *y*<sup>+</sup> in *Dp(1;1)L-y*<sup>+</sup> with *B*<sup>S</sup> from *B*<sup>S</sup>*Yy*<sup>+</sup> resulting in the production of a *B*<sup>S</sup>(*het*) *y cv v f bb*<sup>-</sup> chromosome.

**genetics:** Carries *B*<sup>S</sup> distal to and *y cv v f bb*<sup>-</sup> proximal to the heterochromatin.

***Dp(1;1)L-y<sup>31d</sup>***

**origin:** Replacement of  $y^+$  in  $Dp(1;1)L-y^+$  with  $y^{31d}$  from *FM6* resulting in production of a  $y^{31d}$  (*het*)  $y\ cv\ v\ f\ bb^-$  chromosome.

**genetics:** Carries  $y^{31d}$  distal to and  $y\ cv\ v\ f\ bb^-$  proximal to the distal heterochromatin.

***Dp(1;1)L-y<sup>+</sup>***

**origin:** X-ray-induced recombination in a  $B^S Y y^+ / FM6 / YSX, Df(1)bb3a, y\ cv\ v\ f\ bb^-$  female resulting in a  $YSX, Df(1)bb3a, y^+ KS\ y\ cv\ v\ f\ bb^-$  chromosome.

**references:** Lindsley and Sandler, 1963, *Methodology in Basic Genetics* (Burdette, ed.). Holden-Day, Inc., San Francisco, pp. 390-403.

**genetics:** Carries  $y^+$  distal to and  $y\ cv\ v\ f\ bb^-$  proximal to the distal heterochromatin.

***Dp(1;1)lz-1: Duplication (1;1) lozenge***

**cytology:**  $Dp(1;1)8D;8F$ ; tandem duplication.

**origin:** X ray induced in  $lz^{50e} + / + lz^{y4}$  female.

**references:** Bender, 1967, *Genetics* 55: 249-54.

Peeples, Geisler, Whitcraft, and Oliver, 1969, *Genetics* 62: 161-70.

**genetics:** Partial complementation for *lz*. Hemizygous males have slightly rough eyes, thin or missing posterior postalar bristles, and good fertility; homozygous females have rougher eyes, thin or missing posterior postalar bristles, and markedly reduced fertility although secondary reproductive structures are normal. Tarsal claws are normal in both sexes.

***Dp(1;1)lz-2***

**cytology:**  $Dp(1;1)8D1+$ ; small tandem duplication.

**origin:** X ray induced in  $lz^{50e} + / + lz^{y4}$  female.

**references:** Bender, 1967, *Genetics* 55: 249-54.

Peeples, Geisler, Whitcraft, and Oliver, 1969, *Genetics* 62: 161-70.

De la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, *Genetics* 118: 499-508.

**genetics:** Partial complementation for *lz*. Duplication may include  $t^+$ .  $Dp(1;1)lz-2$  males have less rough eyes than  $Dp(1;1)lz-1$  males, normal posterior postalar bristles, and good fertility; homozygous  $Dp(1;1)lz-2$  females have moderately rough eyes, thin or missing posterior postalar bristles, and good fertility; tarsal claws normal in both sexes.

***Dp(1;1)MNB-8***

**cytology:**  $Dp(1;1)15F9-16A1;16A7-B1;17E2-F1 + Df(1)16\ E-F1;17A2-3$ ; tandem repeat with three copies of 16A1-7.

**new order:**

1A – 16E|17A3 – 17E1|16A1 – 16A7|16A1 – 20.

**origin:** Spontaneous derivative of  $Dp(1;1)NB-8$ .

**synonym:** MLD, modified long duplication.

**references:** Gabay and Laughnan, 1970, *Genetics* 65: 249-65.

Laughnan, Gabay, and Montgomery, 1971, *DIS* 47: 64. Holmquist, 1972, *Chromosoma* 36: 413-52.

**genetics:** Has a  $B\ os^+$  phenotype and a  $(B^+ os^+)$  ( $B\ os$ ) genotype. Intrachromosomal recombination in some lines results in exceptional male offspring (Peterson and Laughnan, 1964, *Genetics* 50: 275-76; Gabay and Laughnan, 1970; Laughnan *et al.*, 1971).

***Dp(1;1)NB-8***

**cytology:**  $Dp(1;1)15F9-16A1;16A7-B1;17E2-F1$ ; tandem repeat with three copies of 16A1-7.

**new order:**

1A – 17E1|16A1 – 16A7|16A1 – 20.

**origin:** Derived from  $Dp(1;1)NBB-8$  by exchange with wild type  $X$  (crossover in distal 16A1-17E2 segment of the duplication).

**synonym:** SLD, standard long duplication.

**references:** Gabay and Laughnan, 1970, *Genetics* 65: 249-65.

**genetics:** Has a  $B\ os^+$  phenotype and a  $(B^+ os^+)$  ( $B\ os$ ) genotype.

***\*Dp(1;1)NBB-8***

**cytology:**  $Dp(1;1)15F9-16A1;17E2-F1$  superimposed on  $Dp(1;1)15F9-16A1;16A7-B1$ ; four copies of 16A1-7.

**new order:**

1 – 16A7|16A1 – 17E2|16A1-16A7|16A1 – 20.

**origin:** Spontaneous in a  $B/f\ B\ os\ car$  female.

**discoverer:** Peterson and Laughnan.

**synonym:** OLD, original long duplication.

**references:** 1963, *Proc. Nat. Acad. Sci. USA* 50: 126-33.

Gabay and Laughnan, 1970, *Genetics* 65: 249-65.

**genetics:** Male viability reduced. Has a  $BB$  phenotype. Genetically it is  $(B\ os^+)$  ( $B\ os$ ).

***Dp(1;1)O19***

**cytology:**  $Dp(1;1)5E;7A$ .

**new order:**

1A – 5E|7A – 5E|5E – 20.

**origin:** Induced by hybrid dysgenesis.

**references:** Engles and Preston, 1984, *Genetics* 107: 657-78.

***Dp(1;1)pn2: Duplication (1;1) prune***

**synonym:** *TE100*.

**genetics:** Duplicated for *Pgd*.

***Dp(1;1)S93: see Tp(1;1)S93***

***Dp(1;1)sc<sup>4L</sup>sc<sup>8R</sup>***

**cytology:**  $Dp(1;1)1B2-3;1B3-4$ .

**origin:** Associated with  $In(1)sc^{4L}sc^{8R}$ .

***Dp(1;1)sc<sup>4L</sup>y<sup>4R</sup>***

**cytology:**  $Dp(1;1)1A8-B1;1B3-4 + Dp(1;1)18A3-4;h26$ .

**origin:** Associated with  $In(1)sc^{4L}y^{4R}$ .

***Dp(1;1)sc<sup>8L</sup>sc<sup>4R</sup>***

**cytology:**  $Dp(1;1)h26;h32$ .

**origin:** Associated with  $In(1)sc^{8L}sc^{4R}$ .

***Dp(1;1)sc<sup>8L</sup>sc<sup>L8R</sup>***

**cytology:**  $Dp(1;1)h30-31;h32$ .

**origin:** Associated with  $In(1)sc^{8L}sc^{L8R}$ .

***Dp(1;1)sc<sup>8L</sup>y<sup>4R</sup>***

**cytology:**  $Dp(1;1)1A8-B1;1B2-3 + Dp(1;1)18A3-4;h32$ .

**origin:** Associated with  $In(1)sc^{8L}y^{4R}$ .

***Dp(1;1)sc<sup>260-25</sup>***

**origin:** Aneuploid recombinant from  $In(1LR)sc^{260-25}$ .

***Dp(1;1)sc<sup>L8L</sup>sc<sup>4R</sup>***

**cytology:**  $Dp(1;1)h26;h30-31$ .

**origin:** Associated with  $In(1)sc^{L8L}sc^{4R}$ .

**Dp(1;1)sc<sup>L8L</sup>sc<sup>8R</sup>**

**cytology:** *Dp(1;1)1B2-3;1B3-4*.

**origin:** Associated with *In(1)sc<sup>L8L</sup>sc<sup>8R</sup>*.

**Dp(1;1)sc<sup>S1L</sup>sc<sup>4R</sup> (L. Robbins)**

**cytology:** *Dp(1;1)20F;1B3-4*. *NO* and portions of surrounding heterochromatin duplicated at 1B3-4 inferred from genetics.

**new order:**

1 – 1B3|20F|1B4 – 20F.

**origin:** *Rex*-induced reinversion of *In(1)sc<sup>S1L</sup>sc<sup>4R</sup>*.

**references:** Swanson, 1984, Ph.D. thesis, Michigan State Univ.

Robbins and Swanson, 1988, *Genetics* 120: 1053-59.

**genetics:** One of two mitotic exchange products induced by *Rex* in *In(1)sc<sup>S1L</sup>sc<sup>4R</sup>* [see also *Dp(1;1)sc<sup>S1L</sup>sc<sup>4R</sup>*]. Euchromatin and heterochromatin are restored to normal sequence except for duplication of an inverted segment of 20F containing the *NO* and adjacent material at 1B3-4. Presence of *NO* material at both ends of the chromosomes has been confirmed by examination of the *bb* phenotypes of the separated ends, with varied levels of *bb* expression observed for the ends of independently derived chromosomes. Presence of adjacent heterochromatin in the duplicated segment is inferred from the structure of *In(1)sc<sup>S1L</sup>sc<sup>4R</sup>*.

**Dp(1;1)sc<sup>S1L</sup>sc<sup>8R</sup>**

**cytology:** *Dp(1;1)1B2-3;1B3-4*.

**origin:** Associated with *In(1)sc<sup>S1L</sup>sc<sup>8R</sup>*.

**Dp(1;1)sc<sup>S1L</sup>sc<sup>L8R</sup>**

**cytology:** *Dp(1;1)h30-31;h32*.

**origin:** Associated with *In(1)sc<sup>S1L</sup>sc<sup>8R</sup>*.

**\*Dp(1;1)Th: Duplication (1;1) Theta**

**origin:** X-ray-induced detachment of *C(1)RM* with X-ray-induced deletion of most of the *X* euchromatin.

**discoverer:** Muller.

**references:** Muller and Painter, 1929, *Am. Nat.* 63: 197.

Patterson, 1930, *Genetics* 15: 141-49.

Muller, 1932, *Proc. Intern. Congr. Genet.*, 6th., Vol. 1: 213-55.

Stern, 1956, *Wilhelm Roux's Arch. Dev. Biol.* 149: 1-25.

**genetics:** Fragment of *X* chromosome, including *y*<sup>+</sup>, *sc*<sup>+</sup>,

and *bb*<sup>+</sup> attached to right of *X* centromere. Causes development of interalar bristle not ordinarily present in *D. melanogaster* (Stern, 1956).

**Dp(1;1)w: Duplication (1;1) white**

**cytology:** *Dp(1;1)3A;3C*.

**new order:**

1 – 3C|3A – 20.

**origin:** Spontaneous as a recombinant from *w<sup>ch/w<sup>sp</sup></sup>*.

**discoverer:** E. B. Lewis, 55j.

**references:** 1957, *DIS* 31: 84.

**genetics:** Loci of *w* and *rst* within duplicated section. Unequal crossing over gives normal and triplicated products. Quintuplication also produced.

*Dp(1;1)w<sup>60h21</sup>*: see *Dp(1;1)w<sup>rG</sup>*

*Dp(1;1)w<sup>60h30</sup>*: see *Dp(1;1)w<sup>rG2</sup>*

**Dp(1;1;1)w<sup>81e1</sup>**

**origin:** Spontaneous (presumably induced by recombination between FB elements).

**references:** Collins and Rubin, 1984, *Nature* 308: 323-27.

**genetics:** Mutant for *w*. Male viable and fertile.

**molecular biology:** *w<sup>c</sup>* insertion conserved and flanked on the left by two copies of the sequence duplicated in *w<sup>i</sup>* and on the right by a single copy of the sequence.

**Dp(1;1;1)w<sup>82a3</sup>**

**origin:** Spontaneous (presumably induced by recombination between FB elements).

**references:** Collins and Rubin, 1984, *Nature* 308: 323-27.

**genetics:** Mutant for *w*. Male viable and fertile.

**molecular biology:** 1 kb of DNA deleted from *w<sup>c</sup>* inversion; otherwise, rearrangement same as *Dp(1;1;1)w<sup>81e1</sup>*.

**Dp(1;1)w<sup>+1</sup>**

**cytology:** *Dp(1;1)3C1-2;4A*; tandem duplication.

**origin:** Induced by ethyl methanesulfonate.

**references:** Green and Lefevre, 1979, *Chromosoma* 74: 329-35.

Green, 1984, *Mol. Gen. Genet.* 194: 275-78.

**genetics:** Male phenotype *w<sup>+</sup>* except with *z*. Duplicated males fertile, but do not survive as well as wild-type males. Reversion to non-duplicated chromosome in males and females. *Dp(1;1)w<sup>+1</sup>*, *z* males are *z*.

**Dp(1;1)w<sup>+2</sup>**

**cytology:** *Dp(1;1)3C1-2;3C6-7* (probably); tandem duplication.

**origin:** Induced by ethyl methanesulfonate.

**references:** Green and Lefevre, 1979, *Chromosoma* 74: 329-35.

Green, 1984, *Mol. Gen. Genet.* 194: 275-78.

**genetics:** Phenotype *w<sup>+</sup>*. Males rarely survive and survivors are sterile; females are viable. Reversion to non-duplicated chromosome in females. *Dp(1;1)w<sup>+2</sup>*, *z* males are *z* (Rasmuson, Svahlin, Montell, and Olofsson, 1978, *Mutat. Res.* 54: 33-38).

**Dp(1;1)w<sup>+61e19</sup>**

**cytology:** Tandem duplication of proximal part of *w* plus transposon inserted between duplications.

**origin:** Unequal crossing over.

**synonym:** *Dp(1;1)w<sup>+R61e19</sup>*; *Dp(1;1)w<sup>+R</sup>*; "DP" (Green, 1963).

**references:** Green, 1963, *Z. Vererbungsl.* 94: 200-14.

Rasmuson and Green, 1974, Mol. Gen. Genet. 133: 249-60.  
 Rasmuson, Montell, Rasmuson, Svahlin, and Westerberg, 1980, Mol. Gen. Genet. 177: 567-70.  
 Goldberg, Sheen, Gehring, and Green, 1983, Proc. Nat. Acad. Sci. USA 80: 5017-21.  
 Fujikawa and Kondo, 1986, Genetics 112: 505-22.

**genetics:** Duplication males with *z* are *z* (Rasmuson, Svahlin, Montell, and Olofsson, 1978, Mutat. Res. 54: 33-38). *Dp(1;1)w<sup>+</sup>61e19*, *z/Dp(1;Y)y-z* males show *z* variegation. Duplication semistable, reverting to *z<sup>+</sup>*, the reversion occurring with a higher frequency in *mei-9* than in wild-type strains (Fujikawa and Kondo, 1986).

**molecular biology:** About 80 kb of DNA in proximal part of *w* duplicated (Gunaratne, Mansukhani, Lipari, Liou, Martindale, and Goldberg, 1986, Proc. Nat. Acad. Sci. USA 83: 701-05).

***Dp(1;1)w<sup>+</sup>61e19***

**cytology:** Tandem triplication thought to involve sub-locus 4 (or 4 and 5) of the *w* locus.

**origin:** Unequal crossing over.

**synonym:** *Tr(1)w<sup>+</sup>61e19*; "TR" (Green, 1963).

**references:** Green, 1963, Z. Vererbungsl. 94: 200-14.

Rasmuson and Green, 1974, Mol. Gen. Genet. 133: 249-60.

Rasmuson, Montell, Rasmuson, Svahlin, and Westerberg, 1980, Mol. Gen. Genet. 177: 567-70.

**genetics:** Triplication males with *z* are *z*.

***Dp(1;1)w<sup>a</sup>: Duplication (1;1) white-apricot***

**cytology:** *Dp(1;1)3A10-B1;3C3-5* (Gersh, 1962, Genetics 47: 1393-98).

**new order:**

1 - 3C3|3B1 - 20.

**origin:** Spontaneous from *w<sup>a</sup>/w<sup>a</sup>* female; recovered once as a recombinant and once as a presumed recombinant.

**discoverer:** Green.

**references:** 1959, Genetics 44: 1243-56.

***Dp(1;1)w<sup>a</sup>w<sup>+</sup>***

**cytology:** Tandem duplication of entire *w* locus marked by *w<sup>a</sup>* in left segment and *w<sup>+</sup>* in right segment.

**origin:** Unequal crossing over in *w<sup>a</sup>/w<sup>+</sup>* females.

**synonym:** *Dp(w<sup>a</sup>;w<sup>+</sup>)*.

**references:** Green, 1966; Genetics 54: 881-85.

1967, Biol. Zentralbl. 86: 211-20.

1969, Mol. Gen. Genet. 103: 209-17.

**genetics:** Male phenotype *w<sup>+</sup>* except with *z*.

***Dp(1;1)w<sup>i</sup>: Duplication (1;1) white-ivory***

**references:** Green, Todo, Ryo, and Fujikawa, 1986, Proc. Nat. Acad. Sci. USA 83: 6667-71 [except for *Dp(1;1;1;1)w<sup>i</sup>*].

**genetics:** Heterozygote with *Dp(1;1)z* shows *z* eye color. Eye color of *w<sup>i</sup>* duplication males and homozygous *w<sup>i</sup>* duplication females darkens with increased dosage of *w<sup>i</sup>*. Duplications unstable, reverting to *w<sup>+</sup>*.

**molecular biology:** Quantitative increase in white locus DNA (indicated by Southern blot hybridization) as *w<sup>i</sup>* dosage increased.

duplication	cytology	origin

β  
 Homozygous females are sterile.  
 Discoverer: E.B. Lewis.  
 Synonym: *Qn(1)w<sup>i</sup>*; *Dp(1;1)w<sup>i</sup>Qn*.  
 References: Bowman, 1969, Mutat. Res. 7: 409-15.

***Dp(1;1)w<sup>m51bL</sup>w<sup>m4R</sup> (L. Robbins)***

**cytology:** *Dp(1;1)20F;3C1-2*. Variable portions of *NO* duplicated at 3C1-2; inferred from genetics.

**new order:**

1 - 3C1|20F|3C2 - 20F.

**origin:** *Rex*-induced reinversion of *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>*.

**discoverer:** Robbins 87g.

**references:** Robbins and Swanson, 1988, Genetics 120: 1053-59.

**genetics:** One of two mitotic exchange products induced by *Rex* in *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>* (see also *Dp(1;f)w<sup>m51bL</sup>w<sup>m4R</sup>*). Euchromatin and heterochromatin are restored to normal sequence except for duplication of *NO* material at 3C1-2. In effect, each such chromosome is a half-tetrad containing both of the products of a single *Rex*-induced exchange. Examination of the *bb* phenotypes of the separated *NO* regions of a series of independently generated *Dp(1;1)w<sup>m51bL</sup>w<sup>m4R</sup>* chromosomes indicates that both can be mutant, both can be *bb<sup>+</sup>*, or either one can be mutant and the other wild type (Robbins).

***Dp(1;1)w<sup>rdp</sup>***

**cytology:** Tandem duplication of the proximal part of *w*.

**references:** Jack and Judd, 1978, Proc. Nat. Acad. Sci. USA 76: 1368-72.

**genetics:** Carries *w<sup>bf</sup>* in distal part of *w*. Formed by recombination between offset *roo* insertion elements in *w<sup>ric</sup>* and *w<sup>bf</sup>*, reciprocal product is *w<sup>r,def</sup>* (Davis, Shen, and Judd, 1987, Proc. Nat. Acad. Sci. 84: 174-78).

***Dp(1;1)w<sup>rdp+</sup>***

**cytology:** Tandem duplication of the proximal part of *w*.

**references:** Jack and Judd, 1978, Proc. Nat. Acad. Sci. USA 76: 1368-72.

**genetics:** No *w<sup>bf</sup>* in distal part of *w*.

***Dp(1;1)w<sup>rg</sup>: Duplication (1;1) white-recombinant of Green***

**cytology:** *Dp(1;1)3A3-4;3C1-2* or *Dp(1;1)3A4-5;3C2-3* (Gersh, 1967).

**new order:**

1 - 3C1|3A4 - 20.

**origin:** A regular product of asymmetric exchange between 3C1-2 of a *w<sup>a</sup>* or *w<sup>a2</sup>* chromosome and 3A3-4 of specific homologs. Reciprocal of *Df(1)w<sup>rg</sup>*.

**discoverer:** Green, 60h21.

**synonym:** *Dp(1;1)3C1; Dp(1;1)w<sup>60h21</sup>*.

**references:** 1961, Genetics 46: 1555-60.

Rasmuson, Montell, Rasmuson, Svahlin, and Westerberg, 1980, Mol. Gen. Genet. 177: 567-70.

**genetics:** Complementary (maroon) eye color in males resulting from interaction between markers *w<sup>sp</sup>* and *w<sup>17G</sup>*. Unstable; duplication stocks carrying *z* produce *w<sup>+</sup>* males which, in turn, produce males with *z* eyes, white deficiencies, and transpositions of the *w* locus to other chromosomes.

***Dp(1;1)y<sup>bl</sup>*: Duplication (1;1) yellow-bristle**

**cytology:** *Dp(1;1)1B2-3;4F8-9;5D4-5* (Nicoletti, Lindsley).

**new order:**

1A - 1B2|5D4 - 4F9|1B3 - 20.

**origin:** Spontaneous.

**discoverer:** Sandler.

**references:** Sandler, Hart, and Nicoletti, 1960, DIS 34: 103-4.

**genetics:** Mutant for *y*; duplicated for *cv*. Regularly generates further rearrangements; has produced losses of the duplicated segment, which are accompanied by changes in phenotype from *y<sup>bl</sup>* to *y*-like and a translocation between the tips of *X* and *2L* accompanied by a change from *y<sup>bl</sup>* to *y<sup>+</sup>*.

**molecular biology:** Three discontinuities in DNA sequence at coordinates 40.8-41.5, 53.2-55.0, and 63.3-65.5 (Biessmann, 1985, Proc. Nat. Acad. Sci. USA 82: 7369-73).

**\**Dp(1;1)z*: Duplication (1;1) zeste**

**origin:** X ray induced.

**references:** Gans, 1953, Bull. Biol. Fr. Belg., (Suppl.)

38: 1-90.

duplication	cytology	new order	genetics
* <i>Dp(1;1)z1</i>	1E2-3;4B4-5 tandem repeat	1A-4B4 1E3-20	male lethal
* <i>Dp(1;1)z2</i>	2C10-D1;4D2-4 + 1n(1)z2		
* <i>Dp(1;1)z4<sup>α</sup></i>	2B16-C1;3B-C1	1-3B 3C1-2C1 3C1-20	male viable and fertile; female homozygote viable and semi-fertile male lethal
* <i>Dp(1;1)z8</i>	2B18-C1;4B4-5	1-4B4 2C1-20	male lethal

<sup>α</sup> 3C2-3 may also be duplicated (Gersh, 1967, Genetics 56: 309-19).

***Dp(1;1)z59d***

**cytology:** *Dp(1;1)2F5-3A1;3A4-5* (Gersh). Tandem duplication of *z*.

**new order:**

1 - 3A4|3A1 - 20.

**origin:** X ray induced in *y<sup>2</sup>su(w<sup>a</sup>)z*.

**discoverer:** Green, 59d15.

**references:** 1961, Genetics 46: 1555-60.

Gersh, 1962, Genetics 47: 1393-98 (fig.).

Jack and Judd, 1979, Proc. Nat. Acad. Sci. USA 76: 1368-72.

**genetics:** Contains *z* allele but no *w* gene. When two doses of *w<sup>+</sup>* present, *z<sup>+</sup>/Dp(1;1)z* females have orange mottled eyes while *z<sup>+</sup>/z* females have wild-type eyes (Jack and Judd, 1979).

*Dp(1;Y)IAc<sup>+</sup>*: see *l(1)IAc<sup>+</sup>Y*

Described in section on *Y* derivatives.

***Dp(1;Y)1E***

**cytology:** *YSX.YL* from which all euchromatic genes have been removed except those located in 1A through 1E.

**origin:** X ray induced.

**discoverer:** Masterson, 1961.

**synonym:** *T(1;Y)1E*; *YSsc<sup>+</sup>y.YL* (Ehrlich, 1965).

**references:** Clancy, 1964, Genetics 50: 241 (abstract).

Ehrlich, 1965, Can. J. Genet. Cytol. 7: 430-32.

Masterson, 1968, DIS 43: 61, 161.

Lucchesi and Bischoff, 1969, Genetics 61: s37-38.

**genetics:** Carries *y* and wild-type alleles of *ac - su(w<sup>a</sup>)*. Male viable and fertile (Masterson, 1968). Variegates strongly for *dor* and *dor<sup>l</sup>* (Lucchesi and Bischoff, 1969).

***Dp(1;Y)2E***

**cytology:** *YSX.YL* from which all euchromatic genes have been removed except those between 1A and 2B15 (Belyaeva *et al.*, 1982). [An additional deficiency involving *su(s)<sup>+</sup> - sta<sup>+</sup>* is reported by Rayle and Hoar (1969) in a *Dp(1;Y)2E* obtained from Clancy.]

**discoverer:** Masterson, 1961.

**synonym:** *T(1;Y)2E*.

**references:** Clancy, 1964, Genetics 50: 241 (abstract).

Masterson, 1968, DIS 43: 61, 161.

**cytology:** Second chromosome carrying fragment of *B<sup>S</sup>Yy<sup>+</sup>* with the marker *B<sup>S</sup>* attached to 2*L* tip.

**origin:** *X* ray induced in female with *B<sup>S</sup>Yy<sup>+</sup>*.

**references:** Novitski, Ehrlich, and Becker, 1971, DIS 47: 91-92.

Novitski, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b., pp. 562-68.

**Dp(1;2)B<sup>S</sup>3**

**cytology:** B<sup>S</sup> attached to 2L 0.1 unit to left of locus of *al*.  
**origin:** X ray induced in B<sup>S</sup>Yy<sup>+</sup>.  
**references:** Novitski, Ehrlich, and Becker, 1971, DIS 47: 91-92.  
**genetics:** Homozygous viable and fertile. Carries B<sup>S</sup> but no male fertility factors; probably only X-derived material translocated to 2L.

\*Dp(1;2)ct<sup>7c1</sup>: see \*Tp(1;2)ct<sup>7c1</sup>

**Dp(1;2)E1**

**cytology:** Dp(1;2)1A-F;60A.  
**references:** Jacobson, Yim, Grell, and Wobbe, 1982, Cell 30: 817-23.  
**genetics:** Carries normal alleles of y<sup>+</sup> and *su(s)*<sup>+</sup>.

**Dp(1;2)f<sup>+</sup>**

**cytology:** f<sup>+</sup> inserted near centromere of 2.  
**origin:** X ray induced.  
**references:** Shukla and Auerbach, 1980, Genet. Res. 36: 41-56.  
**genetics:** Variegates for *f*. Transposes to other chromosome sites on 2 or 4.

Dp(1;2)FN107: see Tp(1;2)sn<sup>+</sup>72d

**Dp(1;2)Hw<sup>K</sup>**

**cytology:** Dp(1;2)1B2-3;1E-F;21C2-3.  
**new order:**  
 21A - 21C2|1B3 - 1E|21C3 - 60.  
**discoverer:** Kreber.  
**references:** Craymer.  
**genetics:** Mutant for *Hw*.

**Dp(1;2)K1: Duplication (1;2) of Krivshenko**

**cytology:** Dp(1;2)1B1-3;20;29A-B; deficient for 1B3-20. Larval ganglion cells in metaphase show a rod-shaped element, believed to be distal 2L capped with the X centromere, and a J-shaped element, believed to be the X tip attached to the rest of 2 with the 2 centromere.

**new order:**

1A1 - 1B1|29B - 60;  
 20|29A - 21.

**origin:** X ray induced in Canton-S wild type.  
**synonym:** T(1;2)K1.  
**references:** Krivshenko, 1956, DIS 30: 74-76.  
**genetics:** Bipartite duplication, the 2<sup>P</sup>X<sup>D</sup> segment carrying y<sup>+</sup> and the X<sup>P</sup>2<sup>D</sup> segment carrying *bb*<sup>+</sup>. Flies hyperploid for the X<sup>P</sup>2<sup>D</sup> segment survive; flies with a normal X but homozygous for Dp(1;2)K1 die.

Dp(1;2)w<sup>+</sup>62g26: see \*Tp(1;2)w<sup>+</sup>62g26

**Dp(1;2)w<sup>+</sup>70h**

**cytology:** Dp(1;2)3A7-8;3C2-3;3IA3.  
**discoverer:** Green.  
**references:** Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.  
 Jack and Judd, 1979, Proc. Nat. Acad. Sci. USA 76: 1368-72.  
**genetics:** Covers *mit(1)15 - w*.  
**molecular biology:** Right breakpoint some 28 kb to the right of the w<sup>a</sup> copia insertion point (Pirrota, Hadfield, and Pretorius, 1983, EMBO J. 2: 927-34).

\*Dp(1;2)w<sup>m52b</sup>: see \*Tp(1;2)w<sup>m52b</sup>

\*Dp(1;2)w<sup>m53a</sup>: see \*Tp(1;2)w<sup>m53a</sup>

Dp(1;2)w-ec: see Tp(1;2)w-ec

Dp(1;2;3)pn3: see Tp(1;2;3)pn3

**Dp(1;3)51**

**cytology:** X broken distally and tip attached to centric part of 3; also broken proximally and centromere of X attached to acentric part of 3. Interstitial part of X without centromere lost. Third-chromosome breakpoint not determined.

**origin:** X ray induced.

**discoverer:** Weltman.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

**genetics:** Bipartite duplication, the 3<sup>P</sup>X<sup>D</sup> segment carrying *sc*<sup>+</sup>-*su(w<sup>a</sup>)*<sup>+</sup> and the X<sup>P</sup>3<sup>D</sup> segment carrying *bb*<sup>+</sup>.

**Dp(1;3)126**

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1930.

**references:** 1935, Z. Indukt. Abstamm. Vererbungsl. 68: 143.

**genetics:** Duplicated for *r*, *M(1)15D*, *f*, and *B* but not *sl* or *os*; variegates for *f* and *M(1)15D* (Schultz). Duplicated section inserted into chromosome 3 between *st* and *cu*. Also an inversion in 3L. Viability, fertility, and phenotype of Dp(1;3)126/+ male and female normal.

**Dp(1;3)142**

**cytology:** X broken distally and tip attached to centric part of 3; also broken proximally and centromere of X attached to acentric part of 3. Interstitial part of X without centromere lost. Third-chromosome breakpoint not determined.

**origin:** X ray induced.

**discoverer:** Weltman.

**references:** Lindsley and Sandler, 1958, *Genetics* 43: 547-63.

**genetics:** Bipartite duplication, the  $3^P X^D$  segment carrying  $sc^+ - su(w^a)^+$  and the  $X^P 3^D$  segment carrying  $su(f)^+ - bb^+$ .

**Dp(1;3)B<sup>S</sup>**

**cytology:** Duplication with  $B^S$  and some heterochromatin on 3L tip;  $B^S$  located to left of *ru*.

**origin:** X ray induced in  $B^S Y^+$ .

**discoverer:** Leigh.

**references:** Novitski, Grace, and Strommen, 1981, *Genetics* 98: 257-73.

Puro and Novitski, 1982, *DIS* 58: 126.

**genetics:** Carries  $B^S$ . Female homozygotes viable and fertile, male homozygotes viable but sterile. Used in construction of *C(3)EN* (Novitski *et al.*, 1981).

**Dp(1;3)E1**

**cytology:** *Dp(1;2)1A-F;61A*.

**references:** Jacobson, Yim, Grell, and Wobbe, 1982, *Cell* 30: 817-23.

**genetics:** Carries normal alleles of genes from the tip of X through *brc* (Voelker).

**Dp(1;3)f<sup>+</sup>71b:** see **Tp(1;3)f<sup>+</sup>71b**

**Dp(1;3)G<sup>spot</sup>:** see **Dp(1;3)w<sup>67k27</sup>**

**Dp(1;3)in<sup>61j2</sup>: Duplication (1;3) inturned**

**cytology:** *Dp(1;3)20;77B-C*. Nucleolus moved to *in* region.

**origin:** X ray induced.

**references:** Arajjarvi and Hannah-Alava, 1969, *DIS* 44: 73-74.

Hannah-Alava, 1971, *Mol. Gen. Genet.* 113: 191-203.

**genetics:** Homozygous lethal, and lethal with some *in* alleles induced by X ray. Expression of *in* variable with other *in* alleles, becoming more nearly wild type with addition of a Y (Hannah-Alava, 1971).

**Dp(1;3)JC153:** see **Tp(1;3)JC153**

**Dp(1;3)K2: Duplication (1;3) of Krivshenko**

**cytology:** *Dp(1;3)20A-B;20D-F;80-81* superimposed on *In(1)1B2-3;20B-D1*. Inferred from genetic data since salivary chromosomes do not reveal an aberration. In ganglial metaphase, chromosome 3 is a rod-shaped and a J-shaped element.

**new order:**

1A – 1B2|20B|80 – 100;

20F|80 – 61.

Tentative.

**origin:** X ray induced in *In(1)sc<sup>8</sup>*.

**synonym:** *T(1;3)K2*.

**references:** Krivshenko, 1956, *DIS* 30: 76.

**genetics:** Bipartite duplication. Irradiated *In(1)sc<sup>8</sup>* broken in distal region between  $y^+$  and  $bb^+$  and also near the centromere. Chromosome 3 broken near the centromere, whether to left or right of the centromere is not known. Tip of X chromosome with  $y^+$  and  $ac^+$  is attached to the chromosome 3 centromere, and one arm of this chromosome is attached to the X centromere. Bulk of the X chromosome is thus acentric and lost. Homozygote viable and moderately fertile.

**Dp(1;3)L<sup>spot</sup>:** see **Dp(1;3)w<sup>m49a</sup>**

**Dp(1;3)m<sup>+</sup>84f**

**cytology:** *Dp(1;3)10B;10F-11A;98*.

**new order:**

61 – 98|10B – 10F|98 – 100.

**origin:** Spontaneous.

**discoverer:** Voelker.

**genetics:** Covers *Df(1)m259-4* and therefore includes wild-type alleles of *tyl* and *RpII215* (Voelker). Exists only as the duplication (deficiency segregant lost).

**Dp(1;3)MNB-8**

**cytology:** Breaks near the two 16F regions of *Dp(1;1)MNB-8* with resulting acentric fragment inserted between 67E1 and 67E7 of 3; deficient X lost.

**new order:**

61A – 67E|16F – 16A1|16A7-

16A1|17E1 – 17A1|67E – 100.

**origin:** Spontaneous derivative of *Dp(1;1)MNB-8*.

**references:** Holmquist, 1972, *Chromosoma* 36: 413-52.

**genetics:** Carries *B os<sup>+</sup>*.

***Dp(1;3;4)7***

cytology: *Dp(3;4)62E;78D;79F;102F* + *Dp(1;3)1B;61A* from *T(1;3)sc<sup>14</sup>*

new order:

1A - 1B|61A - 62F|(78D - 79F)|102F - 101.

references: Duncan and Lewis, 1982, Symp. Soc. Dev. Biol., 40th, pp. 533-54.

phenotype: Covers homozygous lethal *Pc* mutants.

***Dp(1;4)20G1L***

cytology: Duplication for bands 1A1 to 3C2 translocated to 4. 3C1 only may be included (Gans, 1953) or 3C1 and 3C2 (Gersh, 1967).

references: Gans, 1953, Bull. Biol. Fr. Belg. (Suppl.) 38: 1-90.

Gersh, 1967, Genetics 56: 309-19.

***Dp(1;4)174***

cytology: Duplication linked with 4 but cytology not worked out.

origin: X ray induced.

discoverer: Weltman.

references: Lindsley and Sandler, 1958, Genetics 43: 547-63.

genetics: Probably bipartite duplication like *Dp(1;3)51*. Carries *sc<sup>+</sup>* but not *bb<sup>+</sup>*.

***Dp(1;4)193***

cytology: X tip attached to 4 at left end.

origin: Derived from *Dp(1;4)1021*.

synonym: *y<sup>+</sup>.spa<sup>pol</sup>*.

references: Williamson, Parker, and Manchester, 1970, Mutat. Res. 9: 287-97, 299-306.

Parker, 1970, Mutat. Res. 9: 307-32.

genetics: Carries *y<sup>+</sup>* and *ac<sup>+</sup>* as well as *ci<sup>+</sup>*, *ey<sup>+</sup>*, and *spa<sup>pol</sup>*. (Williamson *et al.*, 1970). Shows 66% segregation from the compound X in *C(1)RM* females without a Y.

***Dp(1;4)1021***

cytology: Heterochromatic left arm of 4 capped by euchromatic tip of X.

references: Parker, 1969, Mutat. Res. 7: 393-407.

Parker and Busby, 1973, Mutat. Res. 18: 33-46.

O'Tousa, 1982, Genetics 102: 503-04.

genetics: Carries *y<sup>+</sup>* and *ac<sup>+</sup>*.

***\*Dp(1;4)A1***: see ***\*Tp(1;4)A1***

***\*Dp(1;4)A12***: see ***\*Tp(1;4)A12***

***Dp(1;4)exd<sup>+</sup>*: Duplication extradenticle wild type**

discoverer: D. Falk.

references: Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

genetics: Covers *exd*.

duplication	cytology	synonym
<i>Dp(1;4)exd<sup>81h24b</sup></i>	13F;14B5-18;14E1-4;16A2	<i>Dp(1;4)81h24b</i>
<i>Dp(1;4)exd<sup>82b26c</sup></i>	13F;14D1-2;15A3-5;16A2	<i>Dp(1;4)82b26c</i>

other information: Also described as *Df(1)81h24b* and *Df(1)82b26c*.

***Dp(1;4)mg***

cytology: *Dp(1;4)2B7-C1;3C1-2;102F*.

discoverer: Green.

references: Robbins, 1977, Genetics 87: 655-84.

1980, Genetics 96: 187-200.

1984, Genetics 108: 361-75.

genetics: Covers lethals between *z* and *w*; includes *pn<sup>+</sup>* but is *w* or *w<sup>-</sup>*. *Dp(1;4)mg* hyperploids have reduced viability and homozygotes having an otherwise normal genotype are lethal. Homozygotes survive if the fly is heterozygous, homozygous or hemizygous for deficiencies in the *z-w* region. Viability of *Dp(1;4)mg* hyperploids improves at lower temperatures and in *XO* males, suggesting position-effect-variegation of the transposed genes (Robbins).

***\*Dp(1;4)N<sup>264-85</sup>***: see ***\*Tp(1;2;4)N<sup>264-85</sup>***

***\*Dp(1;4)N<sup>264-86</sup>***: see ***\*Tp(1;4)N<sup>264-86</sup>***

***Dp(1;4)r<sup>+</sup>*: Duplication (1;4) rudimentary - wild type**

cytology: *Dp(1;4)14A1-2;16A7-B1;102F2-3*.

origin: X-ray-induced derivative of *T(1;4)B<sup>S</sup> = T(1;4)15F9-16A1;16A7-B1;102F2-3* of most of the X euchromatin from the 4<sup>P</sup>X<sup>D</sup> element deleted; likely to carry genes from X terminus.

new order:

1A|14A2 - 16A7|102F2 - 101.

discoverer: Green.

synonym: *Dp(1;4)r<sup>+</sup>f<sup>+</sup>*.

references: 1963, Genetica 34: 242-53.

Jarry, 1979, Mol. Gen. Genet. 172: 199-202.

Craymer and Roy, 1980, DIS 55: 200-04.

Naguib and Jarry, 1981, Genet. Res. 37: 199-207.

Falk, Roselli, Curtis, Holliday, and Klufas, 1984, Mutat. Res. 126: 25-34.

Ganetzky, 1984, Genetics 108: 897-911.

Kulkarni, Steinlauf, and Hall, 1988, Genetics 118: 267-85.

genetics: Carries normal alleles of *exd*, *para*, *r* and *f* appended to the right end of chromosome 4. Usually lethal in two doses.

***Dp(1;4)w<sup>m5</sup>***: see ***T(1;4)w<sup>m5</sup>***

***\*Dp(1;4)w<sup>m51c</sup>***: see ***\*Tp(1;4)w<sup>m51c</sup>***

***Dp(1;4)w<sup>m65g</sup>***

cytology: *Dp(1;4)3B1-2;3C4-5;101*.

origin: X ray induced.

references: Lefevre, 1968, DIS 43: 62-63, 165.

Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56.

Robbins, 1980, Genetics 96: 187-200.

1984, Genetics 108: 361-75.

genetics: Contains wild-type alleles of *l(1)3Bb-rst*. Covers *Df(1)w<sup>m4Lrst</sup>3R* and *Df(1)w<sup>64d8</sup>* lethality. *Df(1)w<sup>258-45</sup>*; *Dp(1;4)w<sup>m65g</sup>* male zygotes are lethal in

the absence of a *Y*. Duplication shows variegation, *XO* males carrying *w* and *Dp(1;4)<sup>m65g</sup>* having almost white eyes (Robbins, 1980).

***Dp(1;4)w<sup>VD1</sup>*: Duplication (1;4)  
white-variegated of Demerec**

**cytology:** *Dp(1;4)3C1-4;101A-D*.

**origin:** X ray induced in *y*.

**discoverer:** Demerec, 33j19.

**references:** CP627.

**genetics:** Variegated for *w* but not *ci*. *X* broken between *w* and *rst*; 4 probably broken in left arm.

**\**Dp(1;f)1*: Duplication (1;free)**

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Muller.

**synonym:** *Del(1)1*.

**references:** Painter and Muller, 1929, J. Heredity 20: 287-98.

Muller and Painter, 1932, Z. Indukt. Abstamm. Vererbungsl. 62: 316-65.

**genetics:** Contains wild-type alleles of *y*, *sc*, *br*, *pn*, and *bb*.

**\**Dp(1;f)2***

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Muller.

**synonym:** *Del(1)2*.

**references:** Painter and Muller, 1929, J. Heredity 20: 287-98.

Muller and Painter, 1932, Z. Indukt. Abstamm. Vererbungsl. 62: 316-65.

**genetics:** Contains wild-type alleles of *y*, *sc*, *br*, and *bb*.

***Dp(1;f)3***

**cytology:** *Dp(1;f)1D4-E1;20D*. 4 times the size of chromosome 4 at metaphase.

**new order:**

1A – 1D3|20A – 20F.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

Grell, 1964, Genetics 50: 151-66.

Rayle and Hoar, 1969, DIS 44: 94.

Schalet and Lefevre, 1973, Chromosoma 44: 183-200.

Sandler and O'Tousa, 1979, Genetics 91: 537-51.

**genetics:** Carries wild-type alleles of *y-tw* and *wap-bb*. Includes *ABO-X* (Parry and Sandler, 1974, Genetics 77: 535-39). Disjoins regularly from *XY*, shows 3% nondisjunction from *C(1)RM*, and causes 18% nondisjunction of *In(1)dl-49* from + in *In(1)dl-49/+/Dp(1;f)3* female.

***Dp(1;f)3bb<sup>-</sup>***

**cytology:** *Dp(1;f)1D3-E1;20A-F*. 2 times size of chromosome 4 at metaphases; lacks *NO*.

**origin:** X ray induced in *Dp(1;f)3*.

**discoverer:** Parry.

**references:** Sandler and O'Tousa, 1979, Genetics 91: 537-51.

**genetics:** Deficient for *bb*.

**\**Dp(1;f)10***

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics

43: 547-63.

**genetics:** Carries wild-type alleles of *y*, *ac*, and *sc* but not *su(f)* or *bb*. Sixty-one percent nondisjunction from *XY*, 45% from *C(1)RM*, and regular disjunction of + from *In(1)dl-49* in *In(1)dl-49/+/Dp(1;f)10* female.

**\**Dp(1;f)12***

**cytology:** 3.4-4 times the size of chromosome 4 at metaphase; lacks only the distalmost part of heterochromatic segment *hD* (Cooper).

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

**genetics:** Contains wild-type alleles of *y*, *ac*, *sc*, *su(w<sup>a</sup>)*, *su(f)*, and *bb* but not *pn* or *car*. Disjoins regularly from *XY*, shows 4% nondisjunction from *C(1)RM*, and causes 19% nondisjunction of + from *In(1)dl-49* in *In(1)dl-49/+/Dp(1;f)12* female.

**\**Dp(1;f)14***

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Muller.

**synonym:** *Del(1)14*.

**references:** Painter and Muller, 1929, J. Heredity 20: 287-98.

Muller and Painter, 1932, Z. Indukt. Abstamm. Vererbungsl. 62: 316-65.

**genetics:** Contains wild-type alleles of *y*, *sc*, and *bb* but not *br*.

***Dp(1;f)18***

**cytology:** *Dp(1;f)1E4-F1;19-20*.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

Rayle and Hoar, 1969, DIS 44: 94.

Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.

**genetics:** Contains wild-type alleles of *y-l(1)1Ec* and *bb* but not *l(1)Ed* (Voelker) or *car*.

***Dp(1;f)24***

**cytology:** *Dp(1;f)1B5;19-20* (Lefevre).

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Muller.

**synonym:** *Del(1)24*.

**references:** 1932, Proc. Intern. Congr. Genet., 6th., Vol. 1: 213-55.

García-Bellido, 1979, Genetics 91: 491-520.

White, Decelles, and Endow, 1983, Genetics 104: 433-48.

**genetics:** Mutant for *sc* and carries wild-type alleles of *l(1)1Ac*, *y*, *ac*, and *l(1)Bb* but not *l(1)Ec*.

***Dp(1;f)52***

**cytology:** *Dp(1;f)1B10-C4;19-20* (Gersh). 3.7-4 times the size of chromosome 4 at metaphase; lacks only the distalmost part of heterochromatic segment *hD* (Cooper).

**origin:** X-ray-induced deletion of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

Schalet and Finnerty, 1968, DIS 43: 128-29.

**genetics:** Contains wild-type alleles of *y*, *ac*, *sc*, *su(f)*, and

*bb* but not *su(w<sup>a</sup>)*, *pn*, or *car*. Segregates normally from *XY*, shows 3% nondisjunction from *C(1)RM*, and causes 13% nondisjunction of + from *In(1)dl-49* in *In(1)dl-49/+/Dp(1:f)52*.

**Dp(1:f)60g**

**origin:** A spontaneous exchange between the distally located heterochromatin of *In(1)sc<sup>8</sup>, y<sup>31d</sup>*, and the proximal heterochromatin of a normal *X*. Occurred in a triploid female.

**discoverer:** Mohler, 60g.

**references:** 1960, DIS 34: 52.

**genetics:** Carries *y<sup>31d</sup>*, *ac<sup>+</sup>*, and probably two copies of *su(f)<sup>+</sup>* but not *car<sup>+</sup>*.

**other information:** The reciprocal product, a reversed acrocentric compound *X [C(1)RA60g]* was recovered from the same fly.

**Dp(1:f)65X<sup>C2</sup>**

**origin:** X ray induced in *R(1)2* males.

**discoverer:** Thompson, 1965.

**references:** Gethman, 1967, DIS 42: 39, 70.

**genetics:** Carries wild-type alleles of *y*, *ac*, *sc*, and *su(f)* but not *pn* or *car*. Covers deficiency of *C(1)RA60g*. Somatic unstable; mosaics frequent. Lethal in 30% of the zygotes.

**\*Dp(1:f)100**

**cytology:** Two-thirds the length of normal *X* at metaphase.

**origin:** Spontaneous deletion of most of *X* euchromatin.

**discoverer:** L. V. Morgan, 221.

**synonym:** *sc-Dp*.

**references:** 1938, Genetics 23: 423-62.

**genetics:** Contains wild-type alleles of *y-pn* and *fu-bb*. Phenotype of duplication-bearing female nearly wild type, but occipital bristles and hairs are present, eyes are a trifle smaller and rougher, and wings have straighter outer margins and sometimes scalloped inner margins. In male, duplication more than 99% lethal.

**Dp(1:f)101**

**cytology:** *Dp(1:f)2A2;20E-F* (Lefevre); *Df(1:f)2B1-2;19F5-20A* (Belyaeva *et al.*, 1982); one-fourth the length of normal *X* at metaphase.

**new order:**

1A – 2A2|20F.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Tr. Lab. Genet. (Leningrad) 9: 193-216.

1935, Z. Indukt. Abstamm. Vererbungsl. 68: 134-62.

Rayle and Hoar, 1969, DIS 44: 95.

Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.

**genetics:** Contains wild-type alleles of *y-l(1)IFc* and *bb* but not *l(1)IFd* (Voelker) or *su(f)*. With duplication, both sexes viable and wild type except for presence of occipital bristles.

**molecular biology:** DNA breakpoint (2B1-2) between coordinates 31.3 and 35.3 (Chao and Guild, 1986, EMBO J. 5: 143-50).

**\*Dp(1:f)102**

**cytology:** One-fifth the length of normal *X* at metaphase.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Biol. Zentralbl. 52: 493-509.

1935, Z. Indukt. Abstamm. Vererbungsl. 68: 134-62.

**genetics:** Contains *y<sup>+</sup>* to *rb<sup>+</sup>* inclusive and not *bb<sup>+</sup>*. Usually male lethal, but female survives and has occipital bristles, narrow parallel-sided wings, branched posterior crossveins, and heavier bristles on thorax.

**\*Dp(1:f)106**

**cytology:** Metaphase length about 4 times that of chromosome 4.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Biol. Zentralbl. 52: 493-509.

**genetics:** Contains wild-type alleles of *y*, *sc*, and *svr* but not *bb*.

**Dp(1:f)107**

**cytology:** Metaphase length about one-fifth that of a normal *X*.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Biol. Zentralbl. 52: 493-509.

**genetics:** Contains wild-type alleles of *y*, *sc*, *svr*, *su(s)* (Voelker) and *bb*.

**Dp(1:f)112**

**cytology:** *Dp(1:f)1E4-F1;19-20* (Gersh); slightly longer than chromosome 4 at metaphase.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Biol. Zentralbl. 52: 493-509.

Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.

**genetics:** Contains wild-type alleles of *y-l(1)IEc* but not *l(1)IEd* or *bb*. Both sexes viable and have occipital bristles.

**Dp(1:f)118**

**cytology:** About one-fourth the length of normal *X* at metaphase.

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Dobzhansky, 1930.

**references:** 1932, Biol. Zentralbl. 52: 493-509.

**genetics:** Contains wild-type alleles of *y*, *sc*, *svr*, *su(s)* (Voelker) and *bb* but not *kz*.

**Dp(1:f)118YM**

**cytology:** About size of chromosomes 4 at metaphase.

**origin:** Presumably same as *Dp(1:f)118*.

**references:** Yamamoto and Miklos, 1977, Chromosoma 60: 283-96.

**genetics:** Contains wild-type alleles of *y*, *sc*, and *svr* but not *bb* (Yamamoto and Miklos, 1977).

**Dp(1:f)122**

**cytology:** *Dp(1:f)1E4-F1;19-20* (Gersh).

**origin:** X-ray-induced deletion of most of *X* euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

La Volpe, La Mantis, Gargiulo, and Malva, 1984, Mol. Gen. Genet. 194: 485-88.

**genetics:** Carries wild-type alleles of *y*, *ac*, *sc*, and *bb* but not *su(w<sup>a</sup>)*, *pn*, *car*, or *su(f)*. Disjoins regularly from *XY*, shows 6% nondisjunction from *C(1)RM*, and causes 9% nondisjunction of + from *In(1)dl-49* in *In(1)dl-49/+/Dp(1:f)122*.

**Dp(1;f)134-Dp(1;f)137**

**origin:** X-ray-induced deletion of most of euchromatin from X chromosome marked with  $y^2$  or  $y^+$ .  
**discoverer:** Dobzhansky.

duplication	cytology	ref <sup>α</sup>	genetics
*Dp(1;f)134 <sup>β</sup>	deletion of most of X euchromatin	2	$y^+ -br^+$ ; not $bb^+$
Dp(1;f)135 <sup>β</sup>	deletion of most of X euchromatin	3	$y^2 -su(s)^+$ (Voelker); $bb^+$
*Dp(1;f)136 <sup>γ</sup>	metaphase length 1/4 normal X	1	$y^2 -pn^+$ ; $bb^+$
*Dp(1;f)137	metaphase length 1/5 normal X	1	$y^2 -w^+$ ; not $bb^+$

<sup>α</sup> 1 = Dobzhansky, 1932, Biol. Zentralbl. 52: 493-509; 2 = Dobzhansky, 1935, Z. Indukt. Abstamm. Vererbungsl. 68: 134-62; 3 = Sivertzev-Dobzhansky and Dobzhansky, 1933, Genetics 18: 173-92.  
<sup>β</sup> Both sexes viable and wild type except for presence of occipital bristles.  
<sup>γ</sup> Viability low; shows spread wings and occipital bristles.

**Dp(1;f)164**

**cytology:** Dp(1;f)1B;20F (Gersh). Approximate size of chromosome 4 at metaphase (Yamamoto and Miklos, 1977).

**origin:** X-ray-induced deletion of most of X euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

Yamamoto and Miklos, 1977, Chromosoma 60: 283-96.

**genetics:** Carries wild-type alleles of  $y$  and  $ac$  but not  $sc$ ,  $su(w^a)$ ,  $pn$ ,  $car$ ,  $su(f)$ , or  $bb$ . Disjoins essentially randomly from XY, shows 36% nondisjunction from C(1)RM, and does not interfere with disjunction of + from *In(1)dl-49* in *In(1)dl-49/+|Dp(1;f)164* female.

**\*Dp(1;f)167**

**cytology:** 3.7-4 times the size of chromosome 4 at metaphase; lacks only the distalmost heterochromatic segment *hD* (Cooper).

**origin:** X-ray-induced deletion of most of X euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

**genetics:** Carries wild-type alleles of  $y$ ,  $ac$ ,  $sc$ ,  $su(w^a)$ ,  $su(f)$ , and  $bb$  but not  $pn$  or  $car$ . Disjoins regularly from XY, shows 3% nondisjunction from C(1)RM, and causes 16% nondisjunction of + from *In(1)dl-49* in *In(1)dl-49/+|Dp(1;f)167* female.

**Dp(1;f)179**

**origin:** X-ray-induced deletion of most of X euchromatin.

**discoverer:** Weltman, 1954.

**references:** Lindsley and Sandler, 1958, Genetics 43: 547-63.

**genetics:** Carries wild-type alleles of  $y$ ,  $ac$ ,  $sc$ , and  $su(w^a)$  but not  $pn$ ,  $car$ ,  $su(f)$ , or  $bb$ . Disjoins regularly from XY, shows 20% nondisjunction from C(1)RM, and causes 2% nondisjunction of + from *In(1)dl-49* in *In(1)dl-49/+|Dp(1;f)179* female.

**Dp(1;f)749 - Dp(1;f)1518**

**origin:** X ray induced deletion of most of X euchromatin from *In(1)sc*<sup>δ</sup>.

**discoverer:** Krivshenko and Cooper, 1953.

**Dp(1;f)AM**

**cytology:** Dp(1;f)1C3-4;8C17-D1;9C1-2;16E1-2; 0.2 length of normal X.

**new order:**

1A - 1C3|9C1 - 8D1|16E3 - 20.

**origin:** X ray induced in *In(1)AM* = *In(1)8C17-D1;16E2-3*.

**references:** Bender and Barr, 1971, Nature (London) New

Biol. 231: 217-19.

Kalisch and Hägele, 1973, Chromosoma 44: 265-83.

**genetics:** Semilethal in males. Does not replicate its DNA in synchrony with homologous region of normal X (Kalisch and Hägele, 1973).

**\*Dp(1;f)eq: Duplication (1;free) from equational producer**

**origin:** X-ray-induced deletion of most of euchromatin from X chromosome carrying *eq*.

**discoverer:** Schultz, 34k4.

**genetics:** Contains  $y^+$  to  $pn^+$ , inclusive, and  $bb^+$ . Male fertile but rather inviable; has occipital bristles; eyes rough, wings spread, wing veins thickened. Female has occipital bristles; wings straight edged and coarse textured. Female with two duplications occasionally survives and shows extreme spread wings and rough eyes.

**Dp(1;f)GE-1**

**cytology:** *Dp(1;f)4C7;20D-F*.

**references:** Gelbart, 1971, PhD. Thesis, Univ. of Wisconsin.

**Dp(1;f)LJ: Duplication (1;free) La Jolla**

**origin:**  $\gamma$ -ray-induced deletion of most of the euchromatin from  $In(1)sc^{29} = In(1)1B;13A2-5$ .

**references:** Hardy, Lindsley, Livak, Lewis, Siversten, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.

**discoverer:** Pontecorvo.

**references:** 1942, DIS 16: 65.

**Dp(1;f)sc<sup>7.2</sup>**

**origin:** Deletion of majority of euchromatin from  $In(1)sc^7 = In(1)B4-6;5D3-6$ .

**references:** Garcia-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Carries wild-type alleles of neither *cv* nor *car*.

**\*Dp(1;f)sc<sup>260-27</sup>: Duplication (1;free) scute**

**cytology:** *Dp(1;f)1A8-B1;19F*.

**origin:** Aneuploid segregant from  $Tp(1;2)sc^{260-27}/+$ .

**Dp(1;f)sc<sup>SIL</sup>sc<sup>4R</sup> (L. Robbins)**

**cytology:** *Dp(1;f)1-1B3;20F*, inferred from genetics.

**origin:** *Rex*-induced mitotic exchange in  $In(1)sc^{SIL}sc^{4R}$ .

**references:** Swanson, 1984, Ph.D. thesis, Michigan State Univ.

Swanson, 1987, Genetics 115: 271-76.

**genetics:** One of two mitotic exchange products induced by *Rex* in  $In(1)sc^{SIL}sc^{4R}$  [see also  $Dp(1;1)sc^{SIL}sc^{4R}$ ]. Material between the two *NO* regions of  $In(1)sc^{SIL}sc^{4R}$  is deleted. Recovered at 1-5% as sterile *X/Dp* male offspring of *Rex/+* or *Rex/Rex* female by  $In(1)sc^{SIL}sc^{4R}/Y$  male crosses. Recovered as *X/Dp/Y* males at a rate of  $10^{-3}$  from crosses of *Rex/In(1)sc^{SIL}sc^{4R}* females to *X/Y* males. Independently generated  $Dp(1;f)sc^{SIL}sc^{4R}$  chromosomes recovered from *X/Dp/Y* males have different *bb<sup>Rex</sup>* phenotypes. By analogy with *Ybb<sup>Rex</sup>*, the proximal and distal heterochromatic segments are probably intact and in normal order.

**Dp(1;f)sc<sup>V2</sup>** (L. Robbins)

**cytology:** *Dp(1;f)1-1B3;20F*, inferred from genetics.  
**origin:** *Rex*-induced mitotic exchange in *In(1)sc<sup>V2</sup>*.  
**references:** Swanson, 1987, *Genetics* 115: 271-76.  
**genetics:** A *Rex*-induced mitotic exchange product of *In(1)sc<sup>V2</sup>*. Material between the two segments of the divided *NO* region of the inversion is deleted. Recovered as sterile *X/Dp* male offspring of *Rex*-bearing females and *In(1)sc<sup>V2</sup>/Y* males. By analogy with other *Rex*-generated chromosomes, the heterochromatic constitution should be normal except for *bb<sup>Rex</sup>* mutations induced during the exchange event.

**\*Dp(1;f)w<sup>m3</sup>: Duplication (1;free) white-mottled**

**cytology:** *Dp(1;f)3C-D;19-20*; breakpoints inferred from genetic data.  
**origin:** X ray induced.  
**discoverer:** Muller, 1925.  
**references:** 1930, *J. Genet.* 22: 299-334.  
**genetics:** *w/Dp(1;f)w<sup>m3</sup>* male has variegated eyes and is sterile; *C(1)RM*, *w/Dp(1;f)w<sup>m3</sup>* female has variegated eyes and is fertile.

*Dp(1;f)X<sup>c2</sup>*: see *Dp(1;f)R*

**\*Dp(1;f)y-sc: Duplication (1;free) for yellow and scute**

**origin:** X-ray-induced deletion of most of X euchromatin.  
**cytology:** Oliver, 32k21.  
**references:** 1937, *DIS* 7: 19.  
**phenotype:** Carries wild-type alleles of *y* and *sc* but not *pn*.

**Dp(1;f)y<sup>+</sup>**

**cytology:** Small fragment from tip of X.  
**references:** Roberts, 1969, *Genetics* 63: 387-404.  
**genetics:** Carries *y<sup>+</sup>*.

**Dp(1;f)w<sup>m51bL</sup>w<sup>m4R</sup>** (L. Robbins)

**cytology:** *Dp(1;f)1-3C1;20F*, inferred from genetics.  
**origin:** *Rex*-induced mitotic exchange in *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>*.  
**references:** Swanson, 1987, *Genetics* 115: 271-76.  
**genetics:** One of two mitotic exchange products induced by *Rex* in *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>* (see also *Dp(1;1)w<sup>m51bL</sup>w<sup>m4R</sup>*). Material between the two *NO* regions of *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>* is deleted. Recovered at 1-5% as sterile *X/Dp* male offspring of *Rex/+* or *Rex/Rex* female by *In(1)w<sup>m51bL</sup>w<sup>m4R</sup>/Y* male crosses. By analogy with *Dp(1;f)sc<sup>SIL</sup>sc<sup>4R</sup>/Y* and *Ybb<sup>Rex</sup>*, independent occurrences probably are *bb<sup>Rex</sup>* with the other heterochromatic segments intact and in normal order.

**Dp(1;f)z9: Duplication (1;free) zeste**

**cytology:** *Dp(1;f)3E7-F1;19-20*.  
**origin:** X-ray-induced deletion of most of euchromatin from *z*-bearing X chromosome.  
**discoverer:** Gans.  
**references:** 1953, *Bull. Biol. France Belg.*, Suppl. 38: 1-90.  
 Jack and Judd, 1979, *Proc. Nat. Acad. Sci. USA* 76: 1368-72.  
**genetics:** Contains *z* and wild-type alleles of *y* through *dm*. Eye color *zeste* in *z w<sup>+</sup>* males carrying the duplication.

**Dp(2;1)AT**

**cytology:** *Dp(2;1)5A-7A;36D1-2;37D1-2*. Duplicated for both 5A-7A and 36D-37D.  
**new order:**  
 1A – 7A|36D1-2 – 37D1-2|5A – 20.  
**references:** Marsh and Wright, 1986, *Genetics* 112: 249-65.

**Dp(2;1)B19**

**cytology:** *Dp(2;1)9B-C;24D2-5;25F1-2*.  
**new order:**  
 1A – 9B|25F1 – 24D5|9C – 20.  
**origin:** X ray induced.  
**references:** Reuter and Szidonya, 1983, *Chromosoma* 88: 277-85.  
**genetics:** Viable and female fertile. Wild type over *Df(2L)M24F11*, *Df(2L)M24F-B*, and *Df(2L)tkv3*.

**\*Dp(2;Y)R24:** see ***\*Tp(2;Y)R24***

**Dp(2;Y)Rsp: Duplication (2;Y) Responder**

**cytology:** Insertion of 2R heterochromatin into *B<sup>S</sup>Yy*<sup>+</sup>.

**origin:** Designation of several *Y* chromosomes formed by reconstitution from *T(Y;2)* males by irradiation of mature translocation-bearing sperm (Lyttle, 1984, *Genetics* 106: 423-34).

**synonym:** *RspY*.

**references:** Lyttle and Ault, 1985, *Genetics* 110: s23.

Lyttle, 1989, *Genetics* 121: 751-63.

**genetics:** Sensitivity to SD varies depending on the number of *Rsp* repeat sequences included in the reconstituted *Y*.

**Dp(2;Y)Sd: Duplication (2;Y) Segregation distorter**

**new order:**

YL|36D3 – 40F|YL·YS.

**origin:** X-ray-induced reconstitution of *Y* from *T(Y;2)b10*.

**synonym:** *Dp(2;Y)B10-4*.

**references:** Lyttle, 1984, *Genetics* 106: 423-34.

Lyttle, Brittacker, and Ganetzky, 1986, *Genetics* 114: 183-202.

Lyttle, 1986, *Genetics* 114: 203-16.

**genetics:** Carried *Sd* and *E(Sd)* as well as *B<sup>S</sup>* from *B<sup>S</sup>Y* at the end of *YL*.

**Dp(2;2)41A**

**cytology:** Tandem duplication for material in 41A.

**origin:** Spontaneous in the *In(2L)Cy* + *In(2R)Cy* chromosome of a balanced *In(2L)Cy* + *In(2R)Cy/Df(2R)M41A10* stock.

**discoverer:** Schultz, 1945.

**references:** CP627.

**genetics:** Acts as a suppressor of *Df(2R)M41A* and perhaps as a partial suppressor of *L*. Fly heterozygous for the duplication appears more stocky than normal.

**Dp(2;2)92**

**cytology:** *Dp(2;2)30B;34A*; tandem duplication.

**discoverer:** Reuter.

**references:** De la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, *Genetics* 118: 499-508.

**genetics:** Duplication for *bib*<sup>+</sup>.

**Dp(2;2)A446:** see ***Tp(2;2)A446***

**\*Dp(2;2)Adh2: Duplication (2;2) Alcohol dehydrogenase**

**cytology:** *Dp(2;2)32D3;35C1*; direct tandem duplication.

**new order:**

21A – 35C1|32D3 – 40.

**origin:** X ray induced as interchange between homologues in female.

**references:** Grell, 1969, *Genetics* 69: s23.

Nash, 1970, *Genetics* 64: 471-79.

Ashburner, 1982, *Genetics* 101: 447-59.

**genetics:** Carries *Adh<sup>F</sup>* and *Adh<sup>S</sup>*. Dominant enhancer of *H*.

**Dp(2;2)Adh3**

**cytology:** *Dp(2;2)34B1-2;35B3*; tandem repeat.

**new order:**

21 – 35B3|34B1-2 – 60.

**origin:** X ray induced as interchange between homologues in female.

**references:** Grell, 1969, *Genetics* 61: s23.

Nash, 1970, *Genetics* 64: 471-79.

Ashburner, 1982, *Genetics* 101: 447-59.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, *Genetics* 104: 405-31.

**genetics:** Duplicated for *b-Adh* in the order (*b<sup>+</sup> rk<sup>EMS</sup> el<sup>+</sup> Adh<sup>D</sup>*) (*b rk<sup>+</sup> el Adh<sup>F</sup>*); carries *rd<sup>S</sup>*. Slight suppressor of *H* (Nash, 1970; Ashburner, 1982). Suppresses *Cu* and *Cu<sup>75</sup>* (Woodruff and Ashburner, 1979, *Genetics* 92: 117-32) and the bristle phenotype of *Sco<sup>rv1</sup>* and *Sco<sup>rv11</sup>* (Ashburner *et al.*, 1983).

**Dp(2;2)AM**

**origin:** *P*-element induced mutagenesis.

**references:** Locke, Kotarski, and Tartof, 1988, *Genetics* 120: 181-98.

**genetics:** Suppresses Minute phenotype of *M(2)24F*.

**references:** Locke, Kotarski, and Tartof, 1988, Genetics 120: 181-98.

**genetics:** Carries two doses of *Su(var)2-5<sup>+</sup>* = *Su(var)205<sup>+</sup>*. Enhances position-effect variegation of

*In(1)w<sup>m4</sup>*. Recessive lethal.

***Dp(2;2)Eni*: Duplication (2;2) Enigma**

**cytology:** Complete copy of 2L appended to the end of 2R to produce 2L.2R2L chromosome. Deficient for 60D-F.

**new order:**

21 – 60D|40B – 21.

**origin:** Thought to be reciprocal crossover product of exchange generating a *F(2R)*.

**references:** Fitz-Earle, 1979, Genetics 92: s34.

Holm, 1980, Theor. Appl. Genet. 57: 247.

**genetics:** Carried in combination with *F(2R)*. Recombination between *F(2R)* and 2R of *Dp(2;2)Eni* generates a normal second chromosome and an acrocentric second chromosome that is 41 – 60D|40 – 21 and deficient for 60D-F, as reciprocal products.

***Dp(2;2)GM***: see ***Df(2L)Sco-1***

***Dp(2;2)GYL*: Duplication (2;2) of George Yannopoulos**

**cytology:** *Dp(2;2)33B1-2;35C1-3;50A1-4*.

**new order:**

21 – 50A4|35C1 – 33B2|50B5 – 60.

**origin:** Recovered as apparent *dp cn bw* double recombinant from a test cross of a dysgenic male that was heterozygous for a maternally derived *dp b cn bw* second chromosome and a paternally derived autosome extracted from a natural population and capable of promoting male recombination. A MRF (Male Recombination Factor) chromosome, *MRF23.5*, was utilized. The duplication was recovered from a male heterozygous for *MRF23.5*.

**references:** Yannopoulos, Stamatis, Zacharopoulou, and Pelecanos, 1981, Mutat. Res. 83: 383-93.

Ashburner, 1982, Genetics 101: 447-59.

Yannopoulos, Zacharopoulou, and Stamatis, 1982, Mutat. Res. 96: 41-51.

Hatzopoulos, Monastirioti, Yannopoulos, and Louis, 1987, EMBO. J. 6: 3091-96.

**genetics:** Covers *esc* (Struhl) and all loci in region 34-35 up to *l(2)35Cb*. Enhances *H* (Ashburner, 1982). Unstable, transposing and producing shorter derivatives. Homozygous viable.

**molecular biology:** Mobile element *hobo* present at or near breakpoints of GYL derivatives (Hatzopoulou, 1987).

***Dp(2;2)GYL1***

**cytology:** *Dp(2;2)33B1-2;35C1-3;50A4-B5*.

**origin:** Derivative of *Dp(2;2)GYL*.

**references:** Ashburner.

**genetics:** Covers *esc – l(2)35Cb*.

***Dp(2;2)GYL4***

**cytology:** *Dp(2;2)34A1-2;35C1-3;50A1-4*.

**new order:**

21 – 50A1|35C1 – 34A2|50A4 – 60.

**origin:** Spontaneous derivative of *Dp(2;2)GYL*.

**references:** Hatzopoulos, Monastirioti, Yannopoulos, and Louis, 1987, EMBO J. 6: 3091-96.

***Dp(2;2)GYS***

**cytology:** *Dp(2;2)34D1-2;35C1-3;50A1-4*.

**new order:**

21 – 50A1|35C1 – 34D2|50A4 – 60.

**origin:** Spontaneous derivative of *Dp(2;2)GYL*.

**references:** Ashburner, 1982, Genetics 101: 447-59.  
Yannopoulos, Zacharopoulou, and Stamatis, 1982, Mutat. Res. 96: 41-51.  
**genetics:** Distally covers lethals in region in common between *Df(2L)64j* and *Df(2L)b80e3*; proximal limit of duplication presumably same as that of *Dp(2;2)GYL*. Enhances *H*. Homozygous viable.

**Dp(2;2)GYSS**

**cytology:** *Dp(2;2)34D1-2; 35B1-2;59F1-3*.  
**new order:**  
21 – 59F2|35B1 – 34D2|59F3 – 60.  
**origin:** Spontaneous derivative of *Dp(2;2)GYS*.  
**references:** Ashburner.  
**genetics:** Covers all lethals in region in common between *Df(2L)64j* and *Df(2L)b80e3*.

**Dp(2;2;2)I**

**cytology:** Tandem triplication of 33A;40B with all members inverted.  
**new order:**  
21A – 33A|40B – 33A|40B – 33A|40B – 33A|40B – 60.  
**origin:** Induced by triethylenemelamine.  
**synonym:** *Dp(2;2)Tr-I*.  
**references:** Slizynska, 1968, Genet. Res. 11: 201-08.

**Dp(2;2;2)II**

**cytology:** Triplication of 41A;44D with only middle member inverted.  
**new order:**  
21A – 44D|44D – 41A|41A – 60.  
**origin:** Induced by nitrogen-mustard.  
**synonym:** *Dp(2;2)Tr-II*.  
**references:** Slizynska, 1968, Genet. Res. 11: 201-08.

**Dp(2;2)It<sup>+</sup>: Duplication (2;2) light - wild type**

**cytology:** Chromosome duplicated for heterochromatin between *It* and the secondary constriction.  
**origin:** γ-ray-induced detachment product of compound second chromosomes.  
**references:** Hilliker and Holm, 1975, Genetics 81: 705-21.  
**genetics:** Carries duplication for 2L heterochromatin with *It<sup>+</sup>*.

**Dp(2;2)M: Duplication (2;2) Mglinetz**

**origin:** Recovered as apparent recombinants from γ-irradiated males.  
**references:** Mglinetz, 1971, Genetika (Moscow) 7(8): 108-14.

<sup>α</sup> Tandem duplications (except for #5).  
<sup>β</sup> New order: 21 – 26C|25A3 – 24F1|26C – 60.

**Dp(2;2)M56F<sup>+</sup>2**

**cytology:** *Dp(2;2)56C-D;59C-D*; tandem repeat.  
**origin:** X ray induced.  
**synonym:** *Dp(2;2)Minute 2*.  
**references:** Nix, 1973, Mol. Gen. Genet. 120: 309-18.  
**genetics:** Suppresses *M(2)56F*. Includes site of rRNA-5S genes (Wimber and Steffensen, 1970, Science 170: 639-41). Homozygous lethal and lethal with *Dp(2;2)M56F<sup>+</sup>2*. Fertility of heterozygotes good.

**Dp(2;2)M56F<sup>+</sup>4**

**cytology:** *Dp(2;2)56E-F;58A-B*.  
**origin:** X ray induced.  
**synonym:** *Dp(2;2)Minute 4*.  
**references:** Nix, 1973, Mol. Gen. Genet. 120: 309-18.  
**genetics:** Suppresses *M(2)56F*. Left break of duplication within site of rRNA-5S genes. Homozygous lethal and lethal with *Dp(2;2)M56F<sup>+</sup>2*. Fertility of heterozygotes good.

**Dp(2;2)Mdh: Duplication (2;2) Malate dehydrogenase**

**cytology:** Tandem duplication in region of "gooseneck" in 2L.  
**origin:** X ray induced.  
**synonym:** *Dp(2;2)Mdh-2*.  
**references:** Grell, 1969, Genetics 61: s23.  
**genetics:** Carries *Mdh1*. Compensates for Minute effect of *Df(2L)Mdh*.

**Dp(2;2)MS3: Duplication (2;2) Mglinetz Semenova**

**cytology:** *Dp(2;2)47B;48E*.  
**origin:** γ ray induced.  
**references:** Mglinetz and Semenova, 1970; Genetika (Moscow) 6(8); 86-94.

**Dp(2;2)MS4**

**cytology:** *Dp(2;2)42A;55E*.  
**origin:** γ ray induced.  
**references:** Mglinetz and Semenova, 1970, Genetika

(Moscow) 6(8): 86-94.

**Dp(2;2)MS5:** see **Tp(2;2)MS5**

**Dp(2;2)MVD1-2**

**cytology:** *Dp(2;2)21E;25A1;33B*.

**references:** Irish and Gelbart, 1987, *Genes Dev.* 1: 868-79.

**Dp(2;2)NS**

**cytology:** *Dp(2;2)34A1-2;35C1-3;50B + In(2R)50B1-2;56D9-10* (Ashburner).

**new order:**

21 – 50B1|56D9 – 50B2|34A2 – 35C1|56D10 – 60.

**origin:** Spontaneous derivative of *Dp(2;2)GYL*.

**references:** Yannopoulos, Zacharopoulou, and Stamatis, 1982, *Mutat. Res.* 96: 41-51.

**Dp(2;2)Px<sup>4</sup>:** see *In(2LR)S<sup>56f</sup>*

**Dp(2;2)S: Duplication (2;2) Star**

**cytology:** *Dp(2;2)21D2-3;21E2-3*; tandem repeat.

**new order:**

21A – 21E2|21D3 – 60.

**origin:** Spontaneous as interchange between homologous chromosomes.

**discoverer:** E. B. Lewis, 39i.

**references:** 1941, *Proc. Nat. Acad. Sci. USA* 27: 31-35. 1945, *Genetics* 30: 137-66.

**genetics:** Duplicated segment contains the loci of *S* and *ast*. *ast* mutant in both members of the duplication (+ *ast* + *ast*). Duplication appears wild type when homozygous or when heterozygous with *ast*. Heterozygous with *S*, it has normal or only slightly roughened eyes. Various combinations of *S* and *ast* alleles have been introduced into the duplication. Through unequal crossing over, a triplication and a quintuplication of the region [*i.e.* *Dp(2;2;2)S* and *Dp(2;2;2;2;2)S*] have been synthesized.

**Dp(2;2)S<sup>56f</sup>**

**cytology:** *Dp(2;2)21C6-D1;22A3-B1*.

**origin:** Associated with *In(2LR)Px<sup>4</sup>*.

**references:** CP627.

**Dp(2;3)Su-en**

**cytology:** Insertion of two bands, presumably including *en<sup>+</sup>*, into 62C.

**discoverer:** Russell.

**references:** Morata, Kornberg, and Lawrence, 1983, *Dev. Biol.* 99: 27-33.

**Dp(2;3)TE35A-203:** see **Tp(2;3)TE35A-203**

**Dp(2;3)tkv3:** see **Tp(2;3)tkv3**

**Dp(2;3;3)S: Duplication (2;3;3) Synthetic  
new order:**

61A – 89D|41 – 48C|84D – 100F.

**origin:** Recombination between *T(2;3)205* and *T(2;3)P8*.

**discoverer:** Craymer, 1979.

**synonym:** *Dp(2;3;3)205<sup>P</sup>P8<sup>D</sup>*.

**genetics:** Lethal when heterozygous with normal 3. Useful in selecting duplications and deficiencies in 84D-89D.

**Dp(2;f)1: Duplication (2;free) 1**

**cytology:** *Dp(2;f)21;41* (left breakpoint tentative) superimposed on *In(2LR)40F;59E*. Small metacentric, 1/3 length of the X (Grell, 1970).

**new order:**

21|41 – 40F|59E – 60. Tentative.

**origin:** X-ray-induced derivative of *In(2LR)bw<sup>V32g</sup>*; possibly a deletion of most of the long arm.

**discoverer:** E. H. Grell, 1959.

**references:** CP627.

Grell, 1970, *Genetics* 64: 337-65.

**genetics:** Carries centromere of 2, most of the proximal heterochromatin and probably all of the loci between *bw* and the tip of 2R (Grell, 1970). Suppresses *w<sup>m4</sup>* variegation.

**Dp(2;f)Bl: Duplication (2;f) Bristle**

**cytology:** *Dp(2;f)38C;41*; considerably larger than 4 in metaphase, appearing as small compact ring. Basal region triplicated in salivaries.

**origin:** X ray induced in *Bl* male; recovered with *C(2)EN*.

**discoverer:** Novitski.

**synonym:** *R(2)Bl*.

**references:** Puro and Nokkala, 1977, *Chromosoma* 63: 273-86.

Novitski and Puro, 1978, *DIS* 53: 205-06.

Falk, 1981, *DIS* 56: 37-38.

**genetics:** Contains *Bl* but not *pr*<sup>+</sup>. May show some somatic loss (Novitski and Puro, 1978; Falk, 1981).

**Dp(2;f)rl<sup>+</sup>: Duplication (2;f) rolled**

**cytology:** Ring with heterochromatic breaks on either side of the centromere.

**origin:** X ray induced in females; recovered in crosses of irradiated females with *C(2L)RM/C(2R)RM* males.

**synonym:** *R(2)rl*<sup>+</sup>.

**references:** Hilliker, 1980, *Genetics* 90: 85-91.

**genetics:** Carries *rl*<sup>+</sup>. Mitotically unstable in neuroblast tissue.

**Dp(3;1)Tpl: Duplication (3;1) Triplolethal**

**cytology:** *Dp(3;1)* derivative of *Dp(3;Y)Tpl11*.  
**origin:** Derived from *Dp(3;Y)Tpl11* by detachment of *C(1)RM*,  $y v bb$ .  
**synonym:** *Dp(3;1)11a76*.  
**references:** Keppy and Denell, 1979, *Genetics* 91: 421-41.  
**genetics:** Covers *Tpl* region (83D-E); carried in combination with complementary deficiency.

**Dp(3;1)w<sup>+</sup>67k27:** see **Tp(3;1)w<sup>+</sup>67k27**

**Dp(3;1)w<sup>zh</sup>:** see **Tp(3;1)w<sup>zh</sup>**

**Dp(3;Y)Rg-pbx:** see **Dp(3;Y)trx<sup>D</sup>**

**Dp(3;Y)Tpl7: Duplication (3;Y) Triplolethal**

**cytology:** *Dp(3;Y)YL;82D1;83E1-2;83E4;100C6-D1-2*.  
**new order:**  $YS.YL^P|82D1 - 83E2|100D1-2 - 100F$ .  
**origin:**  $\gamma$  ray induced *Df(3R)83E1-4;100C6-D2* in  $Y^{P}3^D$  element of  $T(Y;3)B155 = T(Y;3)YL;82D1$ .  
**synonym:** *Dp(3;Y)7a77; TplY7*.  
**references:** Keppy and Denell, 1979, *Genetics* 91: 421-41.  
**genetics:** Covers *Tpl* region (83D-E); marked with  $y^+$  on *YS*.

**Dp(3;Y)Tpl11**

**cytology:** *Dp(3;Y)YS;83D4-5;84F4;99E1*.  
**new order:**  $YL.YS^P|83D5 - 84F4|99E1 - 100F$ .  
**origin:**  $\gamma$  ray induced *Df(3R)84F4;99E1* in  $Y^{P}3^D$  element of  $T(Y;3)L132 = T(Y;3)h21-Xhy^+;83D4-5$ .  
**synonym:** *Dp(3;Y)11a76; TplY11*.  
**references:** Keppy and Denell, 1979, *Genetics* 91: 421-41.  
**genetics:** Covers *Tpl* region; marked with  $B^S$  on *YL*.

**Dp(3;Y)trx<sup>D</sup>: Duplication (3;Y) trithorax-Dominant**

**cytology:** Insertion of the more proximal rearrangement point of *In(3R)trx<sup>D</sup> = In(3R)85AB;88C-E* into the *Y* chromosome.  
**origin:** X ray induced.  
**discoverer:** E.B. Lewis.  
**synonym:** *Dp(3;Y)Rg-pbx; TplYtrx<sup>D</sup>*.  
**references:** Capdevila and García-Bellido, 1981, *Wilhelm Roux's Arch. Dev. Biol.* 190: 339-50.  
**genetics:** Shows *trx<sup>D</sup>* phenotype.

**Dp(3;Y;1)M**

**cytology:** *1A1;h23-Xhy<sup>+</sup>;62AB*.  
**new order:**  $20 - 1A|h21 - h23|62A - 61A$ .  
**origin:** X-ray-induced replacement of  $y^+$  on *Dp(1;1)L-y<sup>+</sup>* by  $3^D$  of  $T(Y;3)P6 = T(Y;3)62A-B$ . (Three independent occurrences, *M1, M2* and *M3*).  
**references:** García-Bellido and Ripoll, 1973, *DIS* 50: 92. Minaña and García-Bellido, 1982, *Wilhelm Roux's Arch. Dev. Biol.* 191: 331-34.  
**genetics:** Males viable and fertile over *YL* chromosome; females homozygous lethal. Carries  $mwh^+$  and  $ve^+$ ; no variegation for  $mwh^+$  in nullo-*Y* males.

**Dp(3;2)dpp<sup>60</sup>:** see **Tp(3;2)dpp<sup>60</sup>**

**Dp(3;2)dpp<sup>66</sup>:** see **In(2L)dpp<sup>66</sup>**

**Dp(3;2)dpp<sup>80</sup>: Duplication (3;2) decapentaplegic**

**cytology:** *Dp(3;2)22F1-2;85D;86E*.  
**new order:**  $21A - 22F|85D - 86E|22F - 60F$ .  
**origin:**  $\gamma$  ray induced.  
**discoverer:** Segal.  
**references:** Gelbart.  
**genetics:** *d-III* mutant.

***Dp(3;3)Antp*<sup>50</sup>: Duplication (3;3) Antennapedia**

**cytology:** *Dp(3;3)84B1-2* + extra band immediately following 84B1-2 (Hannah-Alava).

**origin:** X ray induced.

**discoverer:** Piternick, 1950.

**references:** Bulyzhenkov and Ivanov, 1978, *Genetika* (Moscow) 14: 456-62.

Kaufman, Lewis, and Wakimoto, 1980, *Genetics* 94: 115-33.

Lewis, Kaufman, Denell and Talerico, 1980, *Genetics* 95: 367-81.

**genetics:** Mutant for *Antp*<sup>50</sup>. Homozygous lethal in first instar larvae (Bulyzhenkov and Ivanov, 1978).

***Dp(3;3)Antp*<sup>60</sup>**

**cytology:** *Dp(3;3)84B1-2* + extra band that splits 84B1-2 doublet into three thin bands.

**origin:** X ray induced.

**discoverer:** Hannah-Alava.

**references:** Bulyzhenkov and Ivanov, 1978, *Genetika* (Moscow) 14: 456-62.

Kaufman, Lewis, and Wakimoto, 1980, *Genetics* 94: 115-33.

Lewis, Kaufman, Denell, and Talerico, 1980, *Genetics* 95: 367-81.

**genetics:** Mutant for *Antp*. Homozygous lethal in first instar larvae (Bulyzhenkov and Ivanov, 1978).

***Dp(3;3)Antp*<sup>rv8</sup>**

**cytology:** Tandem *Dp(3;3)84D5-8;85F5-8* superimposed on *In(3R)84B1-2;84C5-6*.

**new order:**

61 – 84B1|84C5 – 84B2|84C6 – 85F5|84D8 – 100.

**origin:** X-ray-induced revertant of *Antp*<sup>73b</sup>.

**discoverer:** Hazelrigg.

**synonym:** *Dp(3;3)Antp*<sup>73b+RX6</sup>; *Dp(3;3)Antp*<sup>73b+RX8</sup>.

**references:** Kempfhus, Raff, Raff, and Kaufman, 1980, *Cell* 21: 445-51.

Hazelrigg and Kaufman, 1983, *Genetics* 105: 581-600.

De la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, *Genetics* 118: 499-508.

**genetics:** Fails to complement *Antp* lethality. Covers *βTub85D* and *neu*. Seems entirely possible that duplication separable from revertant.

***Dp(3;3)BK***

**origin:** X-ray induced in *Dp(3;3)S2*.

**references:** Leicht and Bonner, 1988, *DIS* 67:54-56.

***Dp(3;3)Mtn<sup>+</sup>H22: Duplication (3;3) Metallothionein***

**cytology:** *Dp(3;3)85E10;85E15* (based on *in situ* hybridization with a *Mtn* probe). Polytene chromosomes apparently normal.

**origin:** Spontaneous in population under selection for cadmium resistance.

**discoverer:** Otto and Maroni.

**synonym:** *Dp(3;3)Mtn<sup>+</sup>H22*.

**references:** Otto, Young, and Maroni, 1986, Proc. Nat. Acad. Sci. USA 83: 6025-29.

**genetics:** Homozygous viable and fertile. Shows increased tolerance to Cd ions. Can be induced to produce twice as much metallothionein RNA as wild type.

**molecular biology:** Tandem duplication of 2.2 kb including *Mtn<sup>+</sup>*. Duplicated segment starts 228 bp upstream of the transcription start site box and ends 1.4 kb downstream of the site corresponding to the end of the mRNA. Sequence analysis indicates almost exact duplication; 3' region of first repeated unit joined by a 6 bp segment to 5' region of the second unit (Otto *et al.*, 1986).

***Dp(3;3)Mtn<sup>+</sup>H46***

**origin:** Spontaneous in unselected laboratory strain carrying *cn* and *bw*.

**references:** Otto, Young, and Maroni, 1986, Proc. Nat. Acad. Sci. USA 83: 6025-29.

**synonym:** *Dp(3;3)Mtn<sup>H46</sup>*.

**molecular biology:** Involves repeat of 4.6 kb of DNA which includes the entire *Mtn* transcription unit, the boundaries of the repeat being different from those of

*Dp(3;3)Mtn<sup>+</sup>H22*.

***Dp(3;3)P5: Duplication (3;3) Pasadena***

**cytology:** *Dp(3;3)89E1-2;90A*; tandem repeat.

**discoverer:** E.B. Lewis.

**references:** Duncan, 1982, Genetics 102: 49-70.

Duncan and Lewis, 1982, Developmental Order: Its Origin and Regulation (Subtelny and Green, eds.). Alan R. Liss, Inc., New York, pp. 533-34.

**genetics:** Covers BXC and surrounding material.

***Dp(3;3)st<sup>+</sup>g18: Duplication (3;3) scarlet - wild type***

**cytology:** *Dp(3;3)72E1-2;74F4-75A1*.  
**new order:**  
 61 – 72E1|74F4 – 72E2|74F4 – 72E2|75A1 – 100.  
**origin:** X ray induced.  
**references:** Belote and McKeown, 1985, DIS 61: 33-34.  
**genetics:** Carries *st<sup>+</sup>* in a tandem, inverted duplication.

***Dp(3;3)Su<sup>8</sup>***

**cytology:** *Dp(3;3)96A;96E-F*.  
**discoverer:** Ripoll.  
**references:** De la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, Genetics 118: 499-508.  
**genetics:** Duplication of *E(spl)<sup>+</sup>*.

***Dp(3;3)Tpl: Duplication (3;3) Triplolethal***

**cytology:** *Dp(3;3)83D;84B3*; reversed repeat.  
**origin:**  $\gamma$  ray induced in *C(1)RM/T(Y;3)A109* female.  
**synonym:** *Dp(3;3)E6;Dp(3;3)83D-E;Dp(3;3)21173*.  
**references:** Denell, 1976, Genetics 84: 193-210.  
 Keppy and Denell, 1979, Genetics 91: 421-41.  
 Lucchesi and Roehrdanz, 1980, Genetics 95: 355-66.  
**genetics:** Covers *Tpl* region (83D-E). Lethal over normal 3, viable and reasonably fertile over *Tpl*-deficient 3. Cell lethal in four doses (Lucchesi and Roehrdanz, 1980).  
**other information:** Treatment of *Df(3R)83DE/Dp(3;3)Tpl* males with ethyl methanesulfonate produced three duplication chromosomes [*Dp(3;3)9k75-1*, *Dp(3;3)9k75-2*, and *\*Dp(3;3)19k75*] that are viable over normal 3's, but cytologically show the reversed repeat associated with *Dp(3;3)Tpl* (Keppy and Denell, 1979).

***Dp(3;3)VV7: Duplication (3;3) V. Velissariou***

**cytology:** *Dp(3;3)66E1;67A9*; reversed repeat.  
**new order:**  
 61A – 67A9|67A9 – 66E1|67A9 – 100.  
**origin:**  $\gamma$  ray induced.

**discoverer:** Velissariou.

**references:** Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.

***Dp(3;4)h<sup>+44</sup>: see Tp(3;4)h<sup>+44</sup>***

***Dp(3;4)ry<sup>+</sup>: Duplication (3;4) rosy - wild type***

**cytology:** *Dp(3;4)86D2-3;88B;101A-D;101F*. Appears as a ring in salivary preparations (Moscoso del Prado).  
**new order:**  
 |88B – 86D3|101F – 101A|. Tentative.  
**origin:** X-ray-induced derivative of the 4<sup>P</sup>3R<sup>D</sup> element of *T(3;4)86D = T(3;4)86D2-3;101F*.  
**discoverer:** E. H. Grell, 1960.

**references:** 1962, Z. Indukt. Abstamm. Vererbungslehre 93: 371-77.  
 Hall and Kankel, 1976, Genetics 83: 517-35;  
 Ish-Horowicz, Holden, and Gehring, 1977, Cell 121: 643-52.  
**genetics:** Carries normal alleles of *cu*, *kar*, and *ry*. Covers *Df(3R)kar3J*. Shows tendency toward somatic elimination.

***Dp(3;f)MS13: Duplication (3;f) Mglinetz Semenova***

**cytology:** *Dp(3;f)61;80*.  
**origin:**  $\gamma$  ray induced.  
**references:** Mglinetz and Semenova, 1970, Genetika (Moscow) 6(8): 86-94.

***Dp(3;f)SMG50: Duplication (3;f) Semenova Mglinetz Glotoff***

**cytology:** *Dp(3;f)69E;99A*.  
**origin:**  $\gamma$  ray induced.  
**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6(4): 165-69.  
 Mglinetz and Semenova, 1970, Genetika (Moscow) 6(8): 86-94.

***In(1)65: Inversion (1) 65***

**cytology**: *In(1)2C4-8;10A1-2*.  
**origin**: X ray induced simultaneously with, but separated from, *T(1;3)65* in y.  
**references**: Lindsley, Edington, and Von Halle, 1960, *Genetics* 45: 1649-70.  
 Voelker, Greenleaf, Gyurkovics, Wisely, Huang and Searles, 1984, *Genetics* 107: 279-84.  
**genetics**: Inseparable from y. About 1% nondisjunction and 21.8% recombination in *In(1)65/+* female; 25.9% nondisjunction and 19.7% recombination in *In(1)65/+Y* female (Grell, 1962, *Genetics* 47: 1737-54).

***In(1)78b***

**cytology**: *In(1)3A2-3;3C3-5*.  
**origin**: X ray induced in *fa<sup>swb</sup>* chromosome.  
**discoverer**: Keppy.  
**references**: Welshons and Welshons, 1985, *Genetics* 110: 465-77.  
**genetics**: Male viable. Suppresses the *fa<sup>swb</sup>* position effect but shows no mutant phenotype as a hemizygote, homozygote, or heterozygote with *Df(1)w67k30*. Distal break near z; proximal break between w and N.

***In(1)94-2A***

**cytology**: *In(1)1F-2A;5E-6A* (Lindsley).  
**origin**: Derived by recombination from *C(1)94-2A*.  
**discoverer**: Rosenfeld.  
**references**: CP627.  
**genetics**: Leads to partial stabilization of tandem ring compound X chromosome. Recoverable in derivative single ring, *R(1)9-4*. Exists in three interchangeable configurations in *C(1)TR* (e.g., Novitski and Braver, 1954, *Genetics* 39: 197-209).

***In(1)123***

**cytology**: *In(1)9E1;20F*.  
**discoverer**: Nash.  
**genetics**: Deficient for *ras*.

**\**In(1)272-13***

**references:** Sutton, 1943, *Genetics* 28: 97-107.  
**genetics:** Position effect at *B*.

***In(1)B<sup>M1</sup>: Inversion (1) Bar of Muller***

**cytology:** *In(1)16A2-5;20D-F* (Lefevre).  
**origin:** X ray induced.  
**discoverer:** Muller, 34e.  
**references:** 1935, *DIS* 3: 29.  
**genetics:** Position effect at *B*. *In(1)B<sup>M1</sup>/0* males are *bb* and variegate for *pdf* (Schalet, 1969, *DIS* 44: 87). Primary nondisjunction 0.4 and secondary 18.5%; recombination 32% in *In(1)B<sup>M1</sup>/+* and 35.4% in *In(1)B<sup>M1</sup>/+Y* female (Grell, 1962, *Genetics* 47: 1737-54). Males reared at 18° show diffuse polytene X. (Lakhotia and Mishra, 1983, *Indian J. Exp. Biol.* 20: 643-51).

***In(1)B<sup>M2</sup>***

**cytology:** *In(1)16A2-5;20F* (Sutton, 1943, *Genetics* 28: 97-107).  
**origin:** X ray induced.  
**discoverer:** Muller, 34e.  
**references:** 1935, *DIS* 3: 29.  
**genetics:** Position effect at *B*.

***\*In(1)B<sup>rv2</sup>: Inversion (1) Bar-reversed***

**cytology:** *In(1)3F8-4A1;16A2-4*; right break in right section of  $Dp(1;1)B = Dp(1;1)15F9-16A1;16A7-B1$ .  
**new order:**  
 1 – 3F8|16A2 – 16A1|16A7 – 4A1|16A4 – 20.  
**origin:** X ray induced in  $Dp(1;1)B$ .  
**discoverer:** Bishop, 1940.  
**references:** Sutton, 1943, *Genetics* 28: 100.  
**genetics:** Reversal of *B*.

***\*In(1)B<sup>rv3</sup>***

**cytology:** *In(1)15F9-16A1;16A7-B1;20A5-F*; right break between segments of  $Dp(1;1)B = Dp(1;1)15F9-16A1;16A7-B1$ .  
**new order:**  
 1 – 16A7|20A5 – 16A1|20F.  
**origin:** X ray induced in *B*.

**discoverer:** Bishop, 1940.

**references:** Sutton, 1943, *Genetics* 28: 100.

**genetics:** *B* reversion.

### ***In(1)B1-4***

**cytology:** *In(1)1A7-8;1F3-4*.

**origin:** Induced by *I-R* interaction.

**references:** Pallison, 1981, *Mol. Gen. Genet.* 183: 123-29.

**genetics:** Male lethal. Deficient for *y* and *ac*.

### ***In(1)bb<sup>Df</sup>*: Inversion (1)**

#### **bobbed-Deficiency**

**cytology:** *In(1)4D2-3;20F*; deficiency in 20F; two-thirds normal length at metaphase.

**new order:**

1 – 4D2|20F – 4D3|20F.

**origin:** X ray induced.

**discoverer:** Sivertzev-Dobzhansky and Dobzhansky, 31b.

**references:** 1933, *Genetics* 18: 173-92.

Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Right breakpoint between *rb* and *rg*. Deficient for *bb*. *In(1)bb<sup>Df</sup>/+* female produces about 2% exceptional sons from 4-strand double exchange within inverted segment. Secondary exceptions about 13%.

### ***In(1)bb<sup>DfL</sup>Cl<sup>R</sup>*: Inversion (1)**

#### **bobbed-Deficiency Left Cl-Right**

**cytology:** *In(1)4D2-3;20F<sup>L</sup>4A5-B1;17A6-B1<sup>R</sup>*; duplicated for 4B1-D2 and 17B1-20F.

**origin:** Recombinant containing left end of *In(1)bb<sup>Df</sup>* and right end of *In(1)Cl*.

**references:** Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Duplicated for *bi*, *rb*, *fu*, and *car* but not *ec*, *rg*, *f*, *os*, or *bb*. Survives as small male with less convex outer wing margins than normal and usually one or more notches at wing tips; sterile, has collapsed testes. Heterozygous female fertile, has slightly narrowed wings.

### ***In(1)bb<sup>DfL</sup>y<sup>4R</sup>*: Inversion (1)**

#### **bobbed-Deficiency Left yellow-4 Right**

**cytology:** *In(1)4D2-3;20F<sup>L</sup>1A8-B1;18A3-4<sup>R</sup>*; duplicated for 1B1-4D2 and 18A4-20F.

**origin:** Recombinant containing left end of *In(1)bb<sup>Df</sup>* and right end of *In(1)y<sup>4</sup>*.

**references:** Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Duplicated for *ac* through *rb* and *fu* through *car*. Heterozygous female has stubby posterior verticals and disarranged scutellars; outer wing margin less convex than normal; fair viability and fertility. Enhances expression of heterozygous *B*. Male lethal.

### ***In(1)br<sup>103</sup>*: Inversion (1) broad**

**cytology:** *In(1)2B3-4;3C1* (or *3C2-3*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, *DIS* 58: 184-90.

**genetics:** Break in 2B3-4 associated with lethal effect.

### **\**In(1)Br*: Inversion (1) Bridged**

**origin:** X ray induced.

**discoverer:** Muller, 2713.

**references:** 1935, *DIS* 3: 29.

**genetics:** Associated with dominant mutant, *Br*. Crossing over suppressed to right of *v*, about normal to left.

### ***In(1)C10 – In(1)C212***

<sup>β</sup> Eliminates *sc-f* recombination. Male fertile.

<sup>γ</sup> Male lethal.

<sup>δ</sup> 1 – 8F|16A1 – 11A1|8F – 11A|16A – 20.

<sup>e</sup> Eleven percent recombination between *sc* and *f*. Male lethal.

### ***In(1)CA32***

**cytology:** *In(1)4F1-2;6A*.

**origin:**  $\gamma$  ray induced.

**discoverer:** Ashburner.

**genetics:** Associated with *osp<sup>201</sup>*.

### ***In(1)ci-x*: Inversion (1) cubitus**

**cytology:** *In(1)1A;20F*.

**origin:** Spontaneous.

**references:** Muller, 1934, *DIS* 2: 90.

Brosseau, 1969, *DIS* 44: 45.

**genetics:** Homozygous viable and fertile. Associated with *y<sup>ci-x</sup>*, an extreme *y* allele. Enhances *ci*.

### ***In(1)Cl*: Inversion (1) Cl**

**cytology:** *In(1)4A5-B1;17A6-B1* (Hoover, 1938, *Z. Indukt. Abstamm. Vererbungsl.* 74: 429).

**origin:** Spontaneous in a *sc t<sup>2</sup> v sl B* chromosome.

**discoverer:** Muller, 20j.

**references:** 1928, *Genetics* 13: 279-357.

Gershenson, 1935, *J. Genet.* 30: 115-25.

Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Left break between *ec* and *bi*; right break between *os* and *fu*; *l(1)C* associated with left break (Muller). About 0.35% primary and 37% secondary exceptions. Total recombination about 1%.

**other information:** *In(1)Cl*, *sc l(1)C t<sup>2</sup> v sl B* is the *CIB* chromosome, described in the section on balancers.

### ***In(1)Cl<sup>L</sup>bb<sup>DfR</sup>*: Inversion (1) Cl-Left bobbed-Deficiency Right**

**cytology:** *In(1)4A5-B1;17A6-B1<sup>L</sup>4D2-3;20F<sup>R</sup>*; deficient for 4B1-D2 and 17B1-20F.

**origin:** Recombinant containing left end of *In(1)Cl* and right end of *In(1)bb<sup>Df</sup>*.

**references:** Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Deficient for *bi*, *rb*, *fu*, *car*, and *bb* but not *ec*, *rg*, *f*, or *os*. Both *bi* and *fu* lethal when heterozygous for *In(1)Cl<sup>L</sup>bb<sup>DfR</sup>*. Heterozygous female extreme Minute [*M(1)18C*], with abnormal wing shape; ovaries normal but female sterile. Male lethal.

***In(1)Cl<sup>L</sup>y<sup>4R</sup>*: Inversion (1) Cl-Left  
yellow-4 Right**

**cytology:** *In(1)4A5-B1;17A6-B1<sup>L</sup>1A8-B1;18A3-4<sup>R</sup>*; duplicated for 1B1-4A5, deficient for 17B1-18A3.

**origin:** Recombinant containing left end of *In(1)Cl* and right end of *In(1)y<sup>4</sup>*.

**references:** Sturtevant and Beadle, 1936, Genetics 21: 554-604.

**genetics:** Duplicated for *ac* through *ec*; deficient for *fu* but not *f*, *vb*, *os*, or *car*. Heterozygous female has irregular acrostichal rows and wings smaller and with less-convex posterior margin than normal. Enhances expression of heterozygous *B*. Male lethal.

***In(1)cm-df*: Inversion (1)  
carmine-deficiency**

**cytology:** *In(1)3D;6D + Df(1)6D;6F*.

**origin:** Derived from an unstable *X* carrying a lethal (*Uc-1<sup>UJD15</sup>*).

**synonym:** *Df(1)cm-In*.

**references:** Johnson-Schlitz and Lim, 1987, Genetics 115: 701-09.

Lim, 1988, Proc. Nat. Acad. Sci. USA 85: 9153-57.

**genetics:** Deficient for *cm*. Produces *N* deficiencies at high rate.

**molecular biology:** Chromosome carries five *hobo* transposing elements (Lim, 1988).

***In(1)ct*: Inversion (1) cut**

**origin:** X ray induced.

**genetics:** All male lethal except for *In(1)ct<sup>43aH1</sup>* and *In(1)ct<sup>J7</sup>* (semilethal). *In(1)ct<sup>3a2</sup>* and *In(1)ct<sup>J7</sup>* give extreme *ct* in combination with *ct<sup>6</sup>*.

<sup>γ</sup> New order: 1A - 7B2|11D8 - 7B5|11D9 - 20.

<sup>δ</sup> New order: 1A - 6F11|10B11 - 7B6|10B12 - 20.

***In(1)ct<sup>78</sup>***

**cytology:** *In(1)6A1-B1;6F1-2;7C1-2;19A1-4;* contains reversed repeat of 6F2 to 7C1.

**new order:**

1A1 - 6A1|19A1 - 6F2|6F2 - 7C1|  
6F1 - 6B1|19A4 - 20.

**origin:** Derived from unstable *X* chromosome with an easily mobilized *gypsy* element at *ct*.

**references:** Lim, 1979, Genetics 93: 681-701.

**genetics:** Unstable.

***In(1)ct-df*: Inversion (1)  
cut-deficiency**

**cytology:** *In(1)3D;6F + Df(1)6F;7C*.

**origin:** Derived from an unstable *X* carrying a lethal (*Uc-1<sup>UJD15</sup>*).

**synonym:** *In-Df(1)ct*.

**references:** Johnson-Schlitz and Lim, 1987, Genetics 115: 701-09.

**genetics:** Deficient for *ct*.

***In(1)D1*: Inversion (1) from  
deoxycytidine**

**cytology:** *In(1)13B;16A*.

**origin:** Induced by tritiated deoxycytidine.

**discoverer:** Kaplan, 1965.

**references:** 1966, DIS 41: 59.

**genetics:** Male lethal.

***In(1)D30***

**cytology:** *In(1)14C6-D1;15E-F*.

**synonym:** *In(1)l<sup>D30</sup>*.

**references:** Ganetzky, 1984, Genetics 108: 897-911.

**genetics:** Distal break associated with *l(1)14Dc<sup>1</sup>*.

***In(1)dl-49*: Inversion (1) delta-49**

**cytology:** *In(1)4D7-E1;11F2-4* [Painter; Hoover, 1938, Z. Indukt. Abstamm. Vererbungsl. 74: 420-34 (fig.)].

**discoverer:** Muller, 26k.

**references:** Muller and Stone, 1930, Anat. Record 47: 393-94.

Stone and Thomas, 1935, Genetica 17: 170-84.

Sturtevant and Beadle, 1936, Genetics 21: 554-604.

**genetics:** Left break between *rb* and *cv*; right between *wy* and *g*. Measures of recombination vary from 5.5% (Grell, 1962, Genetics 47: 1737-54) to about 15% (Sturtevant and Beadle, 1936); secondary exceptions from 33% (Grell, 1962) to 44% (Sturtevant and Beadle, 1936).

**other information:** Used as a balancer either with markers *y Hw m<sup>2</sup> g<sup>4</sup>* or *y w lz<sup>s</sup>* with *Hw* and *lz<sup>s</sup>* sterilizing homozygous female.

***In(1)dm75e*: Inversion (1) diminutive**

**cytology:** *In(1)3E;5E + Df(1)3C11;3E4*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**references:** Craymer and Roy, 1980, DIS 55: 200-04.

**genetics:** Deficient for *dm*.

***In(1)dor<sup>var2</sup>*: Inversion (1) deep orange**

**cytology:** *In(1)2A4-B1;12F-13F*.

**new order:**

1A - 2A4|12F - 2B1|13F - 20.

**origin:**  $\gamma$  ray induced.

**references:** Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS

58: 184-90.

**genetics:** Inversion males lethal with *Dp(1;f)18* or *Dp(1;f)112*, viable and normal with *Dp(1;f)101*,  $y^{59b}Y(2)$ , or  $y^2Y67g24.2$ . Females heterozygous for *BRC* mutants, *dor*, or *hfw* show strong position effect.

***In(1)dor*<sup>var7</sup>**

**cytology:** *In(1)2B5-6;20* + additional rearrangements between *X* and 2.

**origin:**  $\gamma$  ray induced.

**references:** Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.

**genetics:** Females heterozygous with *hfw*, *dor*, *BRC* mutants, and *sta* but not *l(1)2Bk* or *l(1)2Bl* show strong position effect.

***In(1)drp: Inversion (1) droop wings***

**cytology:** *In(1)12B;20B*.

**origin:** Spontaneous from *hi*.

**discoverer:** Ives, 48f.

**synonym:** *In(1)hi1; Inversion (1) droop*.

**references:** 1949, DIS 23: 58.

**genetics:** Associated with mutant droop wings. Male viable.

***\*In(1)dta: Inversion (1) delta wing***

**cytology:** *In(1)6B2-3;15E7-F2*.

**origin:** Induced by triethylenemelamine.

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 69.

**genetics:** Associated with *dta*. Female sterile.

***In(1)EC238***

**cytology:** *In(1)3D5-6;4C1*.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Lefevre.

**genetics:** Male lethal. Allele of *dm*.

***In(1)elav*<sup>4</sup>**

**cytology:** *In(1)1A7;1B8*.

**synonym:** *In(1)elav*<sup>G3</sup>.

**references:** Campos, Rosen, and White, 1986, Genetics 113: s27.

***In(1)EN: Inversion (1) Entire***

**cytology:** *In(1)1A;20F;20F*. At prophase, distal end carries a single heterochromatic segment about equal in size to chromosome 4; proximally, it carries a very short heterochromatic segment and as a second arm two larger heterochromatic segments (Lindsley).

**new order:**

20 – 1A|20C – 20F·20.

Tentative.

**origin:** Spontaneous opening out of *R(1)1*, *y*.

**discoverer:** Novitski.

**references:** 1949, DIS 23: 94-95.

Lindsley, 1958. Z. Indukt. Abstamm. Vererbungsl. 89: 103-22.

Lindsley and Novitski, 1959, Genetics 44: 187-96.

**genetics:** Entire chromosome, including the lethally mutable loci distal to *y*, inverted. Carries mutant alleles of *bb* at each end, which acting together produce *bb*<sup>+</sup> phenotype. Male viable and fertile.

***In(1)EN2***

**cytology:** *In(1)1A3-4;19F-20A;20F*. Inferred from origin.

**new order:**

20 – 1A3|20A – 20F·20.

Tentative.

**origin:** Spontaneous opening of *R(1)2*, *y*<sup>+</sup>.

**discoverer:** Muller.

**references:** 1956, DIS 30: 140-41.

**genetics:** Entire chromosome inverted like *In(1)EN* but carries *y*<sup>+</sup> rather than *y*.

***\*In(1)EN2B: Inversion (1) Entire 2 of Bender***

**cytology:** *In(1)1A3-4;19F-20A;20F*. Inferred from origin.

**new order:**

20 – 1A3|20A – 20F·20F.

Tentative.

**origin:** Spontaneous opening of *R(1)2*, *y* v.

**discoverer:** M. A. Bender, 55e6.

**references:** 1955, DIS 29: 69.

***\*In(1)exr: Inversion (1) extra venation***

**cytology:** *In(1)12E8-10;15D1-3*.

**origin:** Induced by triethylenemelamine.

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 70.

**genetics:** Affects *exr*.

***In(1)f*<sup>67a</sup>: Inversion (1) forked**

**cytology:** *In(1)12E;18B + In(1)15E;20*.

**origin:** X ray induced.

**synonym:** *Tp(1;1)f*<sup>67a</sup>.

**references:** Becker, 1968, DIS 43: 59.

**genetics:** Mutant for *f*. Homo- and hemizygous viable.

***In(1)f*<sup>257-4</sup>**

**cytology:** *In(1)15F2-16A1;16D2-E1*.

**origin:** X ray induced.

**discoverer:** Demerec, 33j.

**genetics:** *f* affected.

***In(1)FM3: Inversion (1) First Multiple***

**cytology:** *In(1)3E-F;16A-B;19F-20F*; superimposed on *In(1)1B2-3;20F + In(1)4D7-E1;11F2-4*.

**new order:**

1A – 1B2|20F|16B – 19F|3F – 4D7|

11F2 – 4E1|11F4 – 16A|3E – 1B3|20F.

**origin:** X ray induced in *In(1)sc*<sup>8</sup> + *In(1)dl-49*,  $y^{31d} sc^8 dm B$ .

**discoverer:** R. F. Grell, 1954.

**references:** Mislove and Lewis, 1954, DIS 28: 77.

**genetics:** Mutant for two lethals, one allelic to *l(1)1Ac* and therefore covered by  $y^+Y$  and the other covered by  $B^SY$ ; both *In(1)FM3/y^+Y/B^SY* and *In(1)FM3/B^SY y^+* males survive. The treated chromosome carried  $y^{31d}$ , but *In(1)FM3/y* variegates for yellow bristles.

**other information:** Used as a first chromosome balancer, described as *FM3* in the section on balancers.

***In(1)FM4***

**cytology:** *In(1)3C;4E-F* superimposed on *In(1)1B2-3;20F + In(1)4D7-E1;11F2-4*.

**new order:**

1A – 1B2|20F – 11F4|4E|3C – 4D7|

11F2 – 4F|3C – 1B3|20F.

**origin:** X ray induced in *In(1)sc*<sup>8</sup> + *In(1)dl-49*,  $y^{31d} sc^8$

*dm B.*

**discoverer:** R. F. Grell, 1954.

**references:** Mislove and Lewis, 1954, DIS 28: 77.

**other information:** Used as a first chromosome balancer, described as *FM4* in the section on balancers.

***In(1)FM6***

**cytology:** *In(1)15D-E;20F* superimposed on *In(1)1B2-3;20F + In(1)3C;4E-F + In(1)4D7-E1;11F2-4.*

**new order:**

1A – 1B2|20F|15E – 20F|15D – 11F4|4E|  
3C – 4D7|11F2 – 4F|3C – 1B3|20F.

**origin:** X ray induced in *In(1)FM4*,  $y^{31d} sc^8 dm B.$

**discoverer:** R. F. Grell, 55i.

**references:** Grell and Lewis, 1956, DIS 30: 70.

**other information:** Used as first chromosome balancer, described as *FM6* in the section on balancers.

***In(1)FM7***

**cytology:** *In(1)1B2-3;20F + In(1)4D7-E1;11F2-4 + In(1)15D-E;20A-E.* Salivaries of females heterozygous with *In(1)sc<sup>8</sup> In(1)dl-49* show complete synapsis, with the delta-49 region homozygous and an inversion loop from 15D-E to the chromocenter.

**new order:**

1A1-1B2|20F-20A|15D-20A|15D-11F4|4E1-  
11F2|4D7-1B3|20F.

**origin:** Crossing over in *FM6/In(1)sc<sup>8</sup> In(1)dl-49* female.

**synonym:** *FM7a.*

**references:** Merriam, 1968, DIS 43: 64.

1969, DIS 44: 101.

**other information:** Used as a first chromosome balancer, described as *FM7* in the section on balancers.

***In(1)FM7<sup>L</sup>EN<sup>R</sup>***

**origin:** Single exchange between  $y^{+YSX}$ , *In(1)FM7* and *X-YLB<sup>S</sup>*, *In(1)EN* to yield *YSX-YL*, *In(1)FM7<sup>L</sup>EN<sup>R</sup>* in which the euchromatin from the *X* terminus through *sc* is replaced by *YS*.

**discoverer:** Craymer.

**synonym:**  $y^{+YSX-YLB<sup>S</sup>}, In(1)FM7<sup>L</sup>EN<sup>R}</sup>$ .

**references:** 1974, DIS 51: 21.

**genetics:** Males and homozygous females viable and fertile. Carries  $y^{+}, y, v^{Of},$  and  $B<sup>S}</sup>$ .

***In(1)g<sup>17</sup>: Inversion (1) garnet***

**cytology:** *In(1)12B10;19F* superimposed on *In(1)1B3-4;20F<sup>L</sup>1B2-3;20F<sup>R</sup> + In(1)4D7-E1;11F2-4.*

Spradling and Mahowald, 1981, Cell 27: 203-09.

**genetics:** Mutant for *oc*. Homozygous females sterile, but sterility may not be due to mutation at *oc* since *oc*<sup>1</sup>/*oc* females are fertile (Lefevre). *Cp36* and *Cp38* are included within and 1-3 kb from the distal breakpoint of the inversion. Synthesis of chorion proteins *s36-1* and *s36-2* much reduced in homozygotes (Spradling *et al.*, 1979). Abnormal ultrastructure of chorion described by Johnson and King (1974, J. Insect Morphol. Embryol. 3: 385-95).

**molecular biology:** Sequences containing both breakpoints as well as adjacent sequences cloned. Inversion shows drastically altered pattern of differential replication of sequences surrounding 7F1-2; the 40 kb of DNA lying distal to the 7F breakpoint do not amplify as in the normal X; the remaining 50 kb, now adjacent to 8A, show somewhat reduced amplification. Sequences proximal to the 8A breakpoint do amplify in *In(1)oc*-containing follicle cells. Region 7F seems to contain a replication origin stimulated to additional rounds of replication.

**In(1)omb<sup>H31</sup>: Inversion (1)**

**optomotor blind**

**cytology:** *In(1)4C4-7;12D2-E1*.

**origin:** Induced by ethyl methanesulfonate.

**references:** Heisenberg, Wonneberger, and Gotz, 1978, J. Comp. Physiol. 124: 287-96.

Blondeau and Heisenberg, 1982, J. Comp. Physiol. 145: 321-29.

Heisenberg, 1982.

**genetics:** Associated with *omb*<sup>1</sup>, a mutant showing an optic lobe defect producing abnormal tracking behavior in homozygotes and in flies heterozygous with *Df(1)RC40*.

**In(1)ovo<sup>5</sup>: Inversion (1) ovo**

**cytology:** *In(1)4E1-2;5A1-6*.

**discoverer:** Oliver.

**synonym:** *In(1)ovo*<sup>D1rG5</sup>.

**genetics:** Mutant for *ovo*.

***In(1)para<sup>lk4</sup>*: Inversion (1) paralytic**

cytology: *In(1)13E9-14;14C7-8*.  
 references: J.C. Hall.  
 genetics: Mutant for *para*.

***In(1)pdf*: Inversion (1) podfoot**

cytology: *In(1)16B;19F-20A*.  
 origin: X ray induced.  
 discoverer: Welshons, 57h6.  
 references: 1960, DIS 34: 54.  
 genetics: Associated with *pdf*.

***In(1)pn*: Inversion (1) prune**

origin: X ray induced.  
 references: Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.  
 genetics: Mutant for *pn*.

***In(1)RF24***

cytology: *In(1)13A6;19E*.  
 origin: X ray induced.  
 discoverer: Lefevre.  
 genetics: Male lethal.

**\**In(1)rg<sup>7</sup>*: Inversion (1) rugose**

cytology: *In(1)4E;7A* (J.I. Valencia).  
 origin: X ray induced.  
 discoverer: Cantor, 46d20.  
 genetics: Mutant for *rg*.

**\**In(1)rg<sup>P</sup>***

cytology: *In(1)3C;4E* (Darby).  
 origin: Induced by <sup>32</sup>P.  
 discoverer: Bateman.  
 references: 1951, DIS 25: 77-78.  
 genetics: Mutant for *rg*.

***In(1)rst<sup>3</sup>*: Inversion (1) roughest**

cytology: *In(1)3C3-4;20F*. Right breakpoint about one-fourth the distance between the heterochromatic-euchromatic junction and the centromere, approximately between heterochromatic segments *hC* and *hD* (Cooper, 1959, Chromosoma 10: 535-88).  
 origin: X ray induced.  
 discoverer: Gruneberg, 33116.  
 references: 1935, DIS 3: 27.  
 1935, J. Genet. 31: 163-84 (fig.).  
 1937, J. Genet. 34: 169-89.  
 Spofford, 1969, Genetics 62: 555-71.

genetics: Left breakpoint between *w* and *rst*; right breakpoint to the left of *bb* [Emmens, 1937, J. Genet. 34: 191-202 (fig.); Kaufmann, 1942, Genetics 27: 537-49 (fig.)]. Variegates for *rst* with extent of mutant eye tissue decreased by *Su(var)* (Spofford, 1969); in *X/O* male variegates for *w* (Gersh, 1963, DIS 37: 81). Precise reinversions of *In(1)rst<sup>3</sup>* accompanied by reversion of phenotype reported to occur spontaneously (Gruneberg, 1935) and after X irradiation of oocytes (Novitski, 1961,

Genetics 46: 711-17) but not after irradiation of sperm (Kaufmann, 1942).

**\*In(1)rstl: Inversion (1) roughestlike**

**cytology:** Breakpoints unknown.  
**origin:** X ray induced.  
**discoverer:** Oliver, 29d3.  
**references:** 1935, DIS 3: 28.  
**genetics:** Associated with *rstl*.

**In(1)S: Inversion (1) of Sinitskaya**

**cytology:** *In(1)6F;10F10-11A1* (Brosseau, 1967).  
**origin:** X ray induced simultaneously with *In(1)sc<sup>SI</sup>*.  
**discoverer:** Sinitskaya.  
**references:** Muller and Prokofyeva, 1934, Dokl. Akad. Nauk SSSR, n.s. 4: 74-83.  
 Slizynski, 1948, DIS 22: 77.  
 Brosseau, 1967, DIS 42: 41.  
**other information:** *In(1)sc<sup>SI</sup>* + *In(1)S* used as crossover suppressors in certain balancers, e.g., *Basc*.

**In(1)S39**

**cytology:** *In(1)1D1-2;1E1*.  
**genetics:** Mutant for *su(w<sup>a</sup>)*.

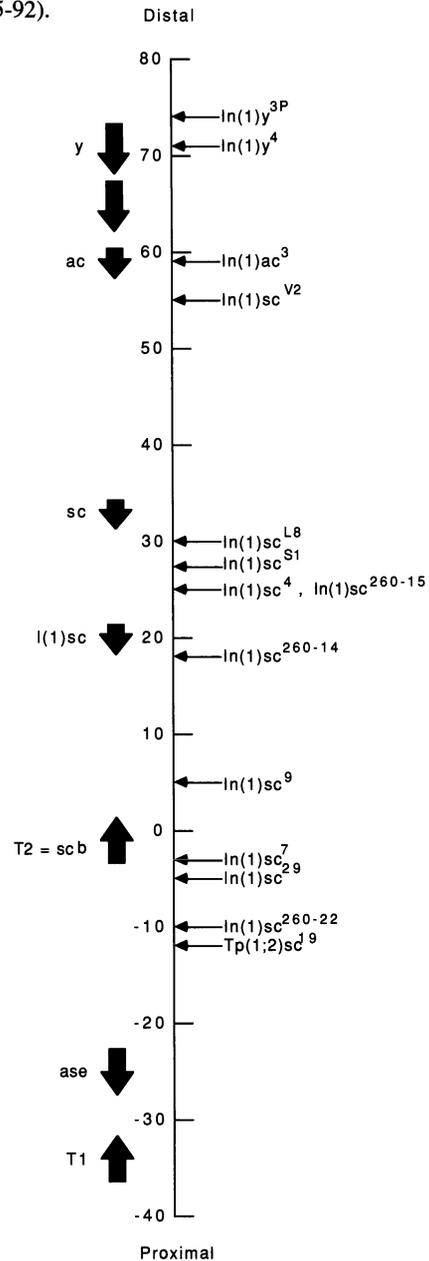

**In(1)sc<sup>1</sup>**

**cytology:** *In(1)1B3-4;6D8*.  
**genetics:** Mutant for *sc*.

**In(1)sc<sup>4</sup>: Inversion (1) scute**

**cytology:** *In(1)1B3-4;20F*. In mitotic chromosomes, the right break is to the right of and near the euchromatic-heterochromatic juncture in the heterochromatic segment h26 as defined by Gatti and Pimpinelli.  
**origin:** X ray induced in a *y* chromosome.  
**discoverer:** Agol, 1928.  
**references:** 1929, Zh. Eksp. Biol. Med. 5: 86-101.  
 1931, Genetics 16: 254-66.

 Schalet and Lefevre, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol 1b, pp. 847-902.  
 Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38.  
**genetics:** Mutant at *sc*; also carries *y*. Left break placed to the right of the  $\alpha$  subdivision of the *sc* locus and to the left of *l(1)sc* and the  $\beta$  subdivision (García-Bellido, 1979, Genetics 91: 491-520). Right break in the proximal heterochromatin between *su(f)* and *bb* (Schalet *et al.*, 1970). Proximal heterochromatin carries the *ABO-X* to *CR* region as well as the *NO* (Yedvobnick, Krider, and Levine, 1980, Genetics 95: 661-72). Maternal and zygotic interactions between *abo* and *In(1)sc<sup>4</sup>* (Malva, Labella, Manzi, Salzano, Lavorgna, De Ponti, and Graziani, 1985, Genetics 111: 487-94). *In(1)sc<sup>4</sup>/+* female produces about 6% exceptional males from 4-strand double exchange. Secondary exceptions about 4%.  
**molecular biology:** Left breakpoint between DNA coordinates +24.0 and +25.8 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the *sc $\beta$*  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, EMBO J.

1: 1185-92).

**Molecular map of *y* and *sc* inversion breakpoints** (after Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38 and González, Romani, Cubas, Modolell, and Campuzano, 1989, EMBO J. 8: 3553-62).

***In(1)sc<sup>4L</sup>sc<sup>8R</sup>: Inversion (1) scute-4 Left scute-8 Right***

**cytology:** *In(1)1B3-4;20F<sup>L</sup>1B2-3;20F<sup>R</sup>*; duplication for 1B3; mitotic chromosomes deficient for the proximal portion of h26 through the distal portion of h32 according to Gatti and Pimpinelli. About 0.6 the length of a normal X at metaphase.  
**origin:** Recombinant containing left end of *In(1)sc<sup>4</sup>* and right end of *In(1)sc<sup>8</sup>*.  
**discoverer:** Gershenson.  
**synonym:** *Df(1)bb-G*.  
**references:** 1933, J. Genet. 28: 297-313.  
 1933, Biol. Zh. (Moscow) 2: 145-59, 419-24.

Tartof, 1971, Science 171: 294-97.

Malva, Graziani, Boncinelli, Polito, and Ritossa, 1972, Nature (London), New Biol. 239: 135-37.

Tartof, 1973, Genetics 73: 613-34.

Parry and Sandler, 1974, Genetics 77: 735-39.

Peacock, Miklos, and Goodchild, 1975, Genetics 79: 613-34.

Procnier and Tartof, 1978, Genetics 88: 67-79.

**genetics:** Duplicated for the *sc* locus, carrying both *sc*<sup>4</sup> and *sc*<sup>8</sup>; deficient for *ABO-X*, *CR* and all the ribosomal RNA-complementary DNA at the *bb* locus of a normal X (Ritossa and Spiegelman, 1965; Tartof, 1971). *In(1)sc*<sup>4</sup>*sc*<sup>8</sup>/*Ybb*<sup>+</sup> males and heterozygous *In(1)sc*<sup>4</sup>*sc*<sup>8</sup> females have one *NO* (on the Y and on the normal X) and show a *bb*<sup>+</sup> phenotype. *In(1)sc*<sup>4</sup>*sc*<sup>8</sup>/*Ybb*<sup>-</sup> males and *XO* males carrying *In(1)sc*<sup>4</sup>*sc*<sup>8</sup> are lethal. Magnification or increase in rDNA multiplicity may take place in *In(1)sc*<sup>4</sup>*sc*<sup>8</sup>/*Ybb* males, changing their phenotype from *bb* to *bb*<sup>+</sup> (Tartof, 1971, 1973; Malva *et al.*, 1972). *In(1)sc*<sup>4</sup>*sc*<sup>8</sup>/*Y* males frequently show correlated meiotic drive and nondisjunction (Peacock, 1965; Peacock *et al.*, 1975), resulting in the recovery of more nullto than *In(1)sc*<sup>4</sup>*sc*<sup>8</sup>/*Y* gametes and more *sc*<sup>4</sup>*sc*<sup>8</sup> than *Y* gametes. Distorted ratios result from sperm dysfunction which is proportional to the chromosome content of the nucleus (McKee, 1984, Genetics 106: 403-22). The extent of these meiotic irregularities is dependent on Y chromosome(s) present (Peacock *et al.*, 1965) and the temperature at which meiosis occurs (Zimmering, 1963, Genetics 48: 133-38). *In(1)sc*<sup>4L</sup>*sc*<sup>8R</sup>/*T(Y;A)* and *In(1)sc*<sup>4L</sup>*sc*<sup>8R</sup>/*mal*<sup>+</sup>*Y* males sterile (McKee and Lindsley, 1987, Genetics 116: 399-407).

***In(1)sc*<sup>4L</sup>*sc*<sup>9R</sup>: Inversion (1) scute-4 Left scute-9 Right**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1B3-4;18C1*<sup>R</sup>. Duplicated for 18C1-20.

**origin:** Recombinant containing left end of *In(1)sc*<sup>4</sup> and right end of *In(1)sc*<sup>9</sup>.

**discoverer:** Muller.

**references:** 1935, Genetics 17: 237-52.

García-Bellido and Santamaria, 1978, Genetics 88: 469-86.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Deficient for *l(1)sc*. Mutant for *Hw*. Duplicated for loci to right of 18C1. Male lethal but viable in presence of *Dp(1;2)sc*<sup>19</sup> = *Dp(1;2)1B1-2;1B4-7;25-26*. Only affects larval nervous system (Villares and Cabrera, 1987, Cell 50: 415-24).

***In(1)sc*<sup>4L</sup>*sc*<sup>L8R</sup>: Inversion (1) scute-4 Left scute of Levy 8 Right**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1B3-4;20F*<sup>R</sup>. Mitotic chromosomes deficient for the proximal part of h26 through h30 (Gatti and Pimpinelli).

**origin:** Recombinant containing left end of *In(1)sc*<sup>4</sup> and right end of *In(1)sc*<sup>L8</sup>.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, Genetics 22: 87-93.

**genetics:** Deficient for *bb* and the *NO*.

***In(1)sc*<sup>4L</sup>*sc*<sup>S1R</sup>: Inversion (1) scute-4 Left scute of Sinitskaya 1 Right**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1B3-4;20F*<sup>R</sup>; deficient for the proximal part of h26 through the majority of h32 (Gatti and Pimpinelli). X at metaphase.

**origin:** Recombinant containing left end of *In(1)sc*<sup>4</sup> and right end of *In(1)sc*<sup>S1</sup>.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, Genetics 22: 87-93.

**genetics:** Deficient for *bb*. Behavior in meiosis of the male like that of *In(1)sc*<sup>4L</sup>*sc*<sup>8R</sup>.

***In(1)sc*<sup>4L</sup>*sc*<sup>V2R</sup>**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1B2-3;20F*<sup>R</sup>. Deficient for the proximal part of h26 through the distal half of h29 (Gatti and Pimpinelli).

**origin:** Single recombinant between *In(1)sc*<sup>4L</sup>*sc*<sup>8R</sup> and *In(1)sc*<sup>V1</sup>.

**discoverer:** Lindsley.

**genetics:** X-Y disjunction normal; *In(1)sc*<sup>4L</sup>*sc*<sup>V2R</sup>/*T(Y;A)* and *In(1)sc*<sup>4L</sup>*sc*<sup>V2R</sup>/*mal*<sup>+</sup>*Y* males fertile (McKee and Lindsley, 1987, Genetics 116: 399-407). Carries sufficient ribosomal cistrons to support survival and *bb*<sup>+</sup> phenotype of *XO* male. Duplicated for *sc* α region.

***In(1)sc*<sup>4L</sup>*y*<sup>3PR</sup>: Inversion (1) scute-4 Left yellow-3P Right**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1A;20F*<sup>R</sup>; duplicated for 1B1-3.

**origin:** Recombinant containing left end of *In(1)sc*<sup>4</sup> and right end of *In(1)y*<sup>3P</sup>.

**references:** García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Fully viable, *ac*<sup>+</sup> and *sc*<sup>+</sup> with weak *Hw* phenotype.

***In(1)sc*<sup>4L</sup>*y*<sup>4R</sup>: Inversion (1) scute-4 Left yellow-4 Right**

**cytology:** *In(1)IB3-4;20F*<sup>L</sup>*1A8-B1;18A3-4*<sup>R</sup>; duplicated for 1B1-3 and 18A4-20F.

**origin:** Recombinant containing left end of *In(1)sc*<sup>4</sup> and right end of *In(1)y*<sup>4</sup>.

**references:** Sturtevant and Beadle, 1936, Genetics 21: 554-604.

**genetics:** Duplicated for the loci of *ac*, *sc*, *car*, and *M(1)18C*; carries *y*<sup>1</sup> distally and the *y* locus interrupted by *In(1)y*<sup>4</sup> proximally. Both male and female look normal.

***In(1)sc*<sup>7</sup>**

**cytology:** *In(1)IB3-4;6D8* (Lefevre).

**origin:** X ray induced in a *w*<sup>a</sup> chromosome.

**discoverer:** Dubinin, 1929.

**references:** 1930, Zh. Eksp. Biol. Med. 6: 300-24.

Serebrovsky and Dubinin, 1930, J. Hered. 21: 259-65.

Dubinin, 1933, J. Genet. 27: 443-64.

Sturtevant and Beadle, 1936, Genetics 21: 554-604.

García-Bellido, 1979, Genetics 91: 491-520.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38.

**genetics:** Mutant for *sc*. Normal disjunction and 33% recombination in *In(1)sc*<sup>7</sup>/*+* female, 26% secondary nondisjunction and 27% recombination in *In(1)sc*<sup>7</sup>/*+**Y* female (Grell, 1962, Genetics 47: 1737-54). *w*<sup>a</sup> removable from the inversion by double crossing over in triploid.

**molecular biology:** Left breakpoint between DNA coordi-

ates -1.8 and -5.9 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the  $sc\beta$  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

***In(1)sc<sup>8</sup>***

**cytology:** *In(1)1B2-3;20F*. Mitotic chromosomes show break in proximal heterochromatin extremely close to the centromere in proximal part of h32 (Gatti and Pimpinelli). *NO* near left end of X.

**origin:** X ray induced.

**discoverer:** Sidorov, 1929.

**references:** 1931, *Zh. Exper. Biol. Med.* 7: 28-40.

1936, *Biol. Zentralbl.* 5: 1-26.

Noujdin, 1935, *Zool. Zh.* 14: 317-52.

Patterson and Stone, 1935, *Genetics* 20: 172-78.

Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

Baker, 1971, *Proc. Nat. Acad. Sci. USA* 68: 2472-76.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Vilares, Boronat, and Modolell, 1985, *Cell* 40: 327-38.

**genetics:** Weak mutant for *sc* and shows a *Hw* effect; variegates for *ac*, *y*, and probably *l(1)IAc* (Hess, 1962, *Verh. Dtsch. Zool. Ges., Zool. Anz., Suppl.* 26: 87-92) in *X/O* male. Left break between *ac* and *sc* because induced deficiencies for the terminal uninverted portion of *In(1)sc<sup>8</sup>* are deficient for *y* and *ac* but not *sc<sup>8</sup>* (Patterson and Stone, 1935) and because *In(1)sc<sup>8Lsc<sup>4R</sup></sup>* is deficient for *sc* (Sturtevant and Beadle, 1936); [*i.e.*, for the  $\alpha$  subdivision of the *sc* locus (García-Bellido)]. Right break between *bb* and centromere because deficiencies for terminal genes are frequently deficient for *bb* (Patterson, 1933, *Genetics* 18: 32-52) as is *In(1)sc<sup>4Lsc<sup>8R</sup></sup>* (Gershenson, 1933, *J. Genet.* 28: 297-313; Sturtevant and Beadle, 1936). *In(1)sc<sup>8/+</sup>* female produces about 3% exceptional sons from 4-strand double crossing over within the inversion and about 8.7% recombination. *In(1)sc<sup>8/+Y</sup>* female produces 19% secondary nondisjunction and 12% recombination (Sturtevant and Beadle, 1936; Grell, 1962, *Genetics* 47: 1737-54). *In(1)sc<sup>8/0</sup>* partially male lethal (Baker, 1971; Johnson, Harger, and Holm, 1979, *Genetics* 92: s54-55); variegates for *y*; *ac* enhanced.

**molecular biology:** Left breakpoint between DNA coordinates 46.8 and 47.9 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the  $sc\beta$  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

***In(1)sc<sup>8L</sup>EN<sup>R</sup>: Inversion (1) scute-8 Left Entire Right***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1A;20;20F<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)EN*.

**references:** Lindsley, 1958, *Z. Indukt. Abstamm. Vererbungsl.* 89: 103-22.

**genetics:** Carries *l(1)IA<sup>+</sup>* alleles, *y<sup>+</sup>* (or *y<sup>31d</sup>*), and *ac<sup>+</sup>* distally and *l(1)IA<sup>+</sup>* alleles, *y*, and *ac<sup>+</sup>* proximally on long arm plus heterochromatic short arm of *In(1)EN*. Carries *bb<sup>+</sup>* in distal heterochromatin derived from *In(1)sc<sup>8</sup>* and a mild allele of *bb* in proximal heterochromatin derived from *In(1)EN*.

***In(1)sc<sup>8L</sup>sc<sup>4R</sup>: Inversion (1) scute-8 Left scute-4 Right***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1B3-4;20F<sup>R</sup>*; deficient for 1B3 and duplicated for proximal portion of h26 through majority of h32. About 1.4 times the length of a normal X at metaphase.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)sc<sup>4</sup>*.

**references:** Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

García-Bellido, and Santamaria, 1978, *Genetics* 88: 469-86.

García-Bellido, 1979, *Genetics* 91: 491-520.

**genetics:** Deficient for  $\alpha$  subset of *sc* locus; duplicated for *bb<sup>+</sup>* and the *NO*. Homozygous female lethal; *In(1)sc<sup>8Lsc<sup>4R</sup>/+</sup>* female often has crippled legs. Male survives rarely and is extreme *sc* and slight *ac* (García-Bellido, 1979). Remains immobile after hatching.

***In(1)sc<sup>8L</sup>sc<sup>9R</sup>***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1B3-4;18C1<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)sc<sup>9</sup>*.

**references:** García-Bellido and Santamaria, 1978, *Genetics* 88: 469-86.

García-Bellido, 1979, *Genetics* 91: 491-520.

**genetics:** Male lethal. Deficient for  $\alpha$  subset of *sc* locus and *l(1)sc*; duplicated for loci to right of 18C1. Mutant for *Hw*.

***In(1)sc<sup>8L</sup>sc<sup>L8R</sup>: Inversion (1) scute-8 Left scute of Levy 8 Right***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1B3-4;20F<sup>R</sup>*; deficient for 1B3; mitotic chromosomes duplicated for h31 through majority of h32 (Gatti and Pimpinelli).

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)sc<sup>L8</sup>*.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, *Genetics* 22: 87-93.

**genetics:** Duplicated for the majority of the  $\alpha$  subset of the *sc* locus.

***In(1)sc<sup>8L</sup>sc<sup>S1R</sup>: Inversion (1) scute-8 Left scute of Sinitskaya 1 Right***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1B3-4;20B-D1<sup>R</sup>*; deficient for 1B3.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)sc<sup>S1</sup>*.

**genetics:** Deficient for the majority of the  $\alpha$  subset of the *sc* locus. A few extreme *sc* males survive.

***In(1)sc<sup>8L</sup>y<sup>3PR</sup>: Inversion (1) scute-8 Left yellow-3 of Patterson Right***

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1A;20F<sup>R</sup>*; duplicated for 1A-B2.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)y<sup>3P</sup>*.

**references:** Muller, 1935, *J. Hered.* 26: 469-78.

García-Bellido, 1979, *Genetics* 91: 491-520.

**genetics:** Duplicated for *y* and *ac* loci; shows variable *Hw* phenotype in the mesopleura (García-Bellido, 1979). Not deficient for *bb*. Male viable.

***In(1)sc<sup>8L y 4R</sup>*: Inversion (1) scute-8  
Left yellow-4 Right**

**cytology:** *In(1)1B2-3;20F<sup>L</sup>1A8-B1;18A3-4<sup>R</sup>*; duplicated for 1B1-2 and 18A4-20F.

**origin:** Recombinant containing left end of *In(1)sc<sup>8</sup>* and right end of *In(1)y<sup>4</sup>*.

**references:** Sturtevant and Beadle, 1936, *Genetics* 21: 554-604.

**genetics:** Duplicated for *ac*, *car*, *M(1)18C*, and *bb*. Both male and female survive and show *Hw* effect of *In(1)sc<sup>8</sup>*.

***In(1)sc<sup>9</sup>***

**cytology:** *In(1)1B3-4;18C1* (Lefevre).

**origin:** X ray induced.

**discoverer:** Levit, 1929.

**references:** 1930, Wilhelm Roux's Arch. Entwickl.-  
lungsmech. Organ. 122: 770-83.

Norton and Valencia, 1965, *DIS* 40: 40.

García-Bellido, 1979, *Genetics* 91: 491-520.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 327-38.

**genetics:** Mutant for *sc*. Left break to right of the  $\alpha$  region of the *sc* locus and *l(1)sc*; inferred from observation that *In(1)sc<sup>4L sc 9R</sup>* is lethal in male unless *Dp(1;2)sc<sup>19</sup>* is present (Muller, 1935). Right break right of *sby*, *smd*, and *coc* and left of *car*, as shown by the deficiency for *sby*, *smd*, and *coc* of *In(1)y<sup>4L sc 9R</sup>* (Norton and Valencia, 1965).

**molecular biology:** Breakpoint between DNA coordinates +5.6 and +4.7 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the *sc $\beta$*  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

*In(1)sc<sup>10</sup>*: see *In(1)ac<sup>3</sup>*

**references:** 1943, *Genetics* 28: 210-17.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 327-38.

**genetics:** Mutant for *sc* but not *y*, *ac*, or *svr*.

**molecular biology:** Breakpoint between DNA coordinates -10.9 and -11.5 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the *sc $\beta$*  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

**\**In(1)sc<sup>A</sup>*: Inversion (1) scute of Agol**

**discoverer:** Agol.

**references:** 1936, *DIS* 5: 7.

**genetics:** Mutant for *sc*; semilethal. Genetically, appears to extend from *sc* to near *r* (54.5).

***In(1)sc<sup>J1</sup>*: Inversion (1)  
scute of Jacobs-Muller**

**cytology:** *In(1)1A4-5;1B4-5*.

**discoverer:** Jacobs-Muller.

**references:** Muller, 1932, *Proc. Intern. Congr. Genet.* 6th., Vol. 1: 225.

Muller, Prokofyeva, and Raffel, 1935, *Nature* (London) 135: 253-55.

**genetics:** Mutant for *sc* and *l(1)1Ac*.

***In(1)sc<sup>L8</sup>*: Inversion (1) scute of Levy**

**cytology:** *In(1)1B3-4;20F*; inferred from genetic data. In mitotic chromosomes, right break is between h30 and h31 of Gatti and Pimpinelli. *NO* near left end of *X*.

**discoverer:** Levy, 1932.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, *Genetics* 22: 87-93.

Muller and Raffel, 1938, *Genetics* 23: 160.

Raffel and Muller, 1940, *Genetics* 25: 541-83.

Baker, 1971, *Proc. Nat. Acad. Sci. USA* 68: 2472-76.

García-Bellido, 1979, *Genetics* 91: 491-520.

Johnson, Harger, and Holm, 1979, *Genetics* 92: s54-55.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 327-38.

**genetics:** Mutant for *sc*. Left break in  $\alpha$  segment of the *sc* locus. Right break to right of *bb* because *In(1)sc<sup>4L sc L8R</sup>* deficient for *bb* (Muller *et al.*, 1937). Homozygous females sterile (Pucket and Snyder, 1973) *In(1)sc<sup>L8/0</sup>* almost completely male lethal (Baker, 1971; Pucket and Snyder, 1973, *Genetics* 74: s221) but cell viable in

gynandromorphs [Pyati, 1976, *Genetika* (Moscow) 12: 75-81]. Lethality of *XO* males believed to be due to position-effect inactivation of the ribosomal cistrons and other genes affecting viability (Baker, 1971); maternal effect suppression of this lethality reported (Johnson *et al.*, 1979).

**molecular biology:** Breakpoint between DNA coordinates +30.9 and +28.8 (Campuzano *et al.*, 1985). 0 is an arbitrarily chosen *EcoRI* site in the *sc* $\beta$  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

***In(1)sc<sup>L8L</sup>sc<sup>4R</sup>*: Inversion (1) scute of  
Levy 8 Left scute-4 Right**

**cytology:** *In(1)1B3-4;20F<sup>L</sup>1B3-4;20F<sup>R</sup>*. Mitotic chromosomes duplicated for proximal half of h26 through h30 of Gatti and Pimpinelli.

**origin:** Recombinant containing left end of *In(1)sc<sup>L8</sup>* and right end of *In(1)sc<sup>4</sup>*.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, *Genetics* 22: 87-93.

**genetics:** Duplicated for *bb* and the *NO*.

***In(1)sc<sup>L8L</sup>sc<sup>8R</sup>*: Inversion (1) scute of  
Levy 8 Left scute-8 Right**

**cytology:** *In(1)1B3-4;20F<sup>L</sup>1B2-3;20F<sup>R</sup>*; duplicated for 1B3 and mitotic chromosomes, deficient for h31 and majority of h32 (Gatti and Pimpinelli).

**origin:** Recombinant containing left end of *In(1)sc<sup>L8</sup>* and right end of *In(1)sc<sup>8</sup>*.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, *Genetics* 22: 87-93.

**genetics:** Duplicated for  $\alpha$  segment of the *sc* locus but not *bb*. Survives as *X/0* male and homozygous female.

***In(1)sc<sup>L8L</sup>sc<sup>9R</sup>***

**cytology:** *In(1)1B3-4;20F<sup>L</sup>1B3-4;18C1<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)sc<sup>L8</sup>* and right end of *In(1)sc<sup>9</sup>*.

**references:** García-Bellido, 1979, *Genetics* 91: 491-520.

**genetics:** Male lethal. Deficient for *l(1)sc<sup>1</sup>*; duplicated for loci to right of 18C1. Mutant for *Hw*.

**molecular biology:** Deficient for 23.2 kilobases of DNA in *sc* region: coordinates 5.6 to 28.8 (Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 327-38). 0 is an arbitrarily chosen *EcoRI* site in the *sc* $\beta$  segment of *ASC*; positive values to the left (Carramolino, Ruiz-Gómez, Guerro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92).

***In(1)sc<sup>L8L</sup>sc<sup>S1R</sup>*: Inversion (1) scute  
of Levy 8 Left scute  
of Sinitskaya 1 Right**

**cytology:** *In(1)1B3-4;20F<sup>L</sup>1B3-4;20F<sup>R</sup>*; mitotic chromosome deficient for h31 and majority of h32 (Gatti and Pimpinelli).

**origin:** Recombinant containing left end of *In(1)sc<sup>L8</sup>* and right end of *In(1)sc<sup>S1</sup>*.

**references:** Muller, Raffel, Gershenson, and Prokofyeva-Belgovskaya, 1937, *Genetics* 22: 87-93.

**genetics:** Homozygous viable and fertile; does not affect expression of variegation of *bw<sup>A</sup>*.

***In(1)sc<sup>S1</sup>*: Inversion (1)  
scute of Sinitskaya**

**cytology:** *In(1)1B3-4;20F*; inferred from genetic identity of left break with that of *In(1)sc<sup>4</sup>* and of right break with that of *In(1)sc<sup>8</sup>*. In mitotic chromosomes, right break is in proximal end of h32 of Gatti and Pimpinelli.

**origin:** X ray induced simultaneously with *In(1)S*.

**discoverer:** Sinitskaya, 34c.

**references:** Muller and Prokofyeva, 1934, *Dokl. Akad. Nauk SSSR* 4: 74-83.

Muller and Raffel, 1938, *Genetics* 23: 160.

**In(1)w<sup>DZL-1</sup>**

**cytology:** *In(1)2F6;3C1-2.*  
**origin:** In a *w<sup>DZL/w<sup>DZL</sup></sup>* female. Presumed to be a rearrangement generated by *w<sup>DZL</sup>*.  
**references:** Bingham, 1980, Cold Spring Harbor Symp. Quant. Biol. 45(2): 519-25.  
**genetics:** *In(1)w<sup>DZL-1/w<sup>DZL</sup></sup>* females have wild-type eye color. Viable and fertile in homo- and hemizygotes.

**In(1)w<sup>DZL-3</sup>**

**cytology:** *In(1)3C1-2;3E3-7.*  
**origin:** In a *w<sup>DZL/w<sup>DZL</sup></sup>* female. Presumed to be a rearrangement generated by *w<sup>DZL</sup>*.  
**references:** Bingham, 1980, Cold Spring Harbor Symp. Quant. Biol. 45(2): 519-25.  
**genetics:** *In(1)w<sup>DZL-3/w<sup>DZL</sup></sup>* females have wild-type eye color. Viable and fertile in homo- and hemizygotes.

**\*In(1)w<sup>G</sup>: Inversion (1) white of Goldschmidt**

**cytology:** *In(1)3C;3D-E* (Kodani).  
**origin:** X ray induced in *In(1)y<sup>G</sup> = In(1)IA;1C3-4*.  
**discoverer:** Goldschmidt.  
**references:** 1945, Univ. Calif. (Berkeley) Publ. Zool 49: 522.

**In(1)w<sup>m4</sup>: Inversion (1) white-mottled**

**cytology:** *In(1)3C1-2;20F* (Lefevre, 1976). Right breakpoint in mitotic chromosomes is to the left of *bb* in region h28 (Gatti and Pimpinelli). Appels and Hilliker (1982, Genet. Res. 39: 149-56) place the breakpoint at the distal border of the rDNA sequences.

**origin:** X ray induced.  
**discoverer:** Muller, 1929.

**references:** 1930, J. Genet. 22: 299-334.

Lefevre, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66.

Spofford and De Salle, 1978, DIS 53: 204.

Pirrotta, Hadfield, and Pretorius, 1983, EMBO. J. 2: 927-34.

Tartof, Hobbs, and Jones, 1984, Cell 37: 869-78.

**genetics:** Variegated for *w*. Left break to the left of *w*.

**molecular biology:** Left (3C1-2) breakpoint at -24.5 kb in the restriction map of the *w* locus (0 point at site of the *copia* insertion in *w<sup>a</sup>*); right (20F) breakpoint near 5' end of a Type I mobile element (Tartof *et al.*, 1984).

**other information:** A strongly variegating line has been designated *In(1)w<sup>m4h</sup>* (Reuter, Werner, and Hoffmann, 1982, Chromosoma 85: 539-51; Reuter and Szidonya, 1983, Chromosome 88: 277-85).

**In(1)w<sup>m4L</sup>rst<sup>3R</sup>: Inversion (1) white-mottled 4 Left roughest-3 Right**

**cytology:** *In(1)3C1-2;20F<sup>L</sup>3C3-4;20F<sup>R</sup>*; deficient for 3C2-3.

**origin:** Recombinant containing left end of *In(1)w<sup>m4</sup>* and right end of *In(1)rst<sup>3</sup>*.

**references:** Lefevre and Wilkins, 1966, Genetics 53: 175-87.

Lefevre, 1968, DIS 43: 141.

Lefevre and Green, 1972, Genetics 36: 391-412.

**genetics:** Deficient for *w*; position effect on *rst* (Lefevre, 1968). Males lethal, with occasional *w rst* escapers at 29°; lethality covered by *Dp(1;2)51b*.

**In(1)w<sup>m4L</sup>sc<sup>4R</sup>**

**cytology:** *In(1)3C1-2;20F<sup>L</sup>1B3-4;20F<sup>R</sup>*; carries distal heterochromatin of *In(1)w<sup>m4</sup>* and proximal heterochromatin of *In(1)sc<sup>4</sup>*.

**origin:** Recombinant containing left end of *In(1)w<sup>m4</sup>* and right end of *In(1)sc<sup>4</sup>*.

**references:** Yedvobnick, Krider, and Levine, 1980, Genetics 95: 667-721.

**genetics:** Variegated for *w*; duplicated for the *ABO-X* to *CR* region and for *l(1)sc* through *w*; carries *bb<sup>+</sup>*.

**In(1)w<sup>m4L</sup>w<sup>m51bR</sup>**

**cytology:** *In(1)3C1-2;20F<sup>L</sup>3C1-2;20F<sup>R</sup>*. Right break just proximal to the *NO*.

**origin:** Recombinant containing left end of *In(1)w<sup>m4</sup>* and right end of *In(1)w<sup>m51b</sup>*.

**references:** Appels and Hilliker, 1982, Genet. Res. 39: 149-56.

**genetics:** Variegated for *w*. Carries *ABO-X* and *CR*; deficient for the majority, if not all, of the ribosomal cistrons.

**In(1)w<sup>m4L</sup>w<sup>mJR</sup>: Inversion (1) white-mottled 4 Left white-mottled of Jonsson Right**

**cytology:** *In(1)3C1-2;20F<sup>L</sup>3C2-3;20F;102C<sup>R</sup>* deficient for 3C2 and for an undetermined portion, including the centromere, of the base of the *X*.

**new order:**

1 - 3C1|20F - 3C3|102C - 101A.

**origin:** Recombinant containing left end of *In(1)w<sup>m4</sup>* and right end of *In(1)w<sup>mJ</sup>*, which is part of *T(1;4)w<sup>mJ</sup> = T(1;4)3C2-3;20F;102C*.

**references:** Lefevre, 1963, DIS 37: 49-50.

Lefevre and Wilkins, 1966, Genetics 53: 175-87.

**genetics:** Deficient for white; males viable and therefore not deficient for any lethal. Also deficient for proximal heterochromatin, including *bb* (*XO* lethal).

**In(1)w<sup>m4rv</sup>**

**origin:** X ray induced in *In(1)w<sup>m4</sup>*.

**references:** Tartof, Hobbs, and Jones, 1984, Cell 37: 869-78.

**genetics:** Eyes *w<sup>+</sup>* (even when revertants reared at 17°).

inversion	cytology	new order
<i>In(1)w<sup>m4rv5</sup></i>	<i>3C1-2;4A;20A</i>	1A - 3C1 20 - 4A 3C2 - 4A 20
<i>In(1)w<sup>m4rv6</sup></i>	<i>1F;3C1-2;20A</i>	1A - 1F 3C2 - 20 3C1 - 1F 20
<i>In(1)w<sup>m4rv26</sup></i>	<i>3C1-2;6B;20A</i>	1A - 3C1 20 - 6B 3C2 - 6B 20

**In(1)w<sup>m51b</sup>**

**cytology:** *In(1)3C1-2;20F*; right break proximal to the *NO* (Gersh), at the junction between h29 and h30 (Gatti and Pimpinelli). Appels and Hilliker (1982, Genet. Res. 39: 149-56) place the breakpoint at the proximal border of the rDNA sequences.

**origin:** X ray induced.

**discoverer:** Baker, 51b19.

**references:** CP627.

Spofford and De Salle, 1978, DIS 53: 204.

Tartof, Hobbs, and Jones, 1984, Cell 37: 869-78.

**genetics:** Variegated for *w* and *rst*. Recombinant carrying left end of *In(1)w<sup>m51b</sup>* and right end of the 4-centric element of *T(1;4)w<sup>mJ</sup> = T(1;4)3C2-3;20F;102C* is white eyed and male viable, indicating that *In(1)w<sup>m51b</sup>*, like *In(1)w<sup>m4</sup> = In(1)3C1-2;20F*, is broken between 3C1 and 2 (Gersh).

**molecular biology:** Left (3C1-2) breakpoint is at -21 kb of the restriction map of the *w* locus (0 point at site of the *copia* insertion in *w<sup>a</sup>*); right (20F) breakpoint is at a mobile element (Tartof *et al.*, 1984).

**In(1)w<sup>m51bL</sup>w<sup>m4R</sup>**

**cytology:** *In(1)3C1-2;20F<sup>L</sup>3C1-2;20F<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)w<sup>m51b</sup>* and right end of *In(1)w<sup>m4</sup>*.

**references:** Appels and Hilliker, 1982, Genet. Res. 39: 149-56.

**genetics:** Variegated for *w* and *rst*. Carries *ABO-X* and *CR*; duplicated for the majority, if not all, of the ribosomal cistrons.

***In(1)w<sup>m53j</sup>***

**cytology:** *In(1)1A;3C3-5;20;20F;20F*. Inferred from origin.

**new order:**

20 – 3C5|20F|1A – 3C3|20.

Tentative.

**origin:** X ray induced in *In(1)EN = In(1)1A;20F;20F*.

**discoverer:** Bender, 53j.

**references:** 1955, DIS 29: 69.

**genetics:** Variegated for *w*.

***In(1)w<sup>m54l</sup>***

**cytology:** *In(1)3C3-5;20F*.

**origin:** Neutron induced.

**discoverer:** Mickey, 54l3.

**references:** 1963, DIS 38: 29.

**genetics:** Variegated for *w*.

***In(1)w<sup>m55b</sup>***

**cytology:** *In(1)1A3-4;3C3-5;20;19F-20A1;20A1-F*.

Inferred from origin. Appears as a rod in metaphase.

**new order:**

20F – 3C5|20A1|1A4 – 3C3|20F.20.

Tentative.

**origin:** X-ray-induced derivative of *R(1)2 = R(1)1A3-4;20F* opened in inverted order.

**discoverer:** M. A. Bender, 55b28.

**references:** 1955, DIS 29: 69.

**genetics:** Variegated for *w*.

***In(1)w<sup>mb</sup>: Inversion (1) white-mottled of Barnes***

**cytology:** *In(1)3C2-3;20F*.

**origin:** X ray induced.

**discoverer:** Barnes, 1965.

**references:** Lefevre, 1968, DIS 43: 62-63.

**genetics:** Variegated for *w* in both males and females as in *In(1)w<sup>md</sup>*. Variegated for *rst* and *vt* in *XO* males.

***In(1)w<sup>mJ</sup>: see T(1;4)w<sup>mJ</sup>***

***In(1)w<sup>mJL</sup>rst<sup>3R</sup>: Inversion (1) white-mottled of Jonsson Left roughest-3 Right***

**cytology:** *In(1)3C2-3;20F<sup>L</sup>3C3-4;20F<sup>R</sup>*; deficient for 3C3.

**origin:** Recombinant carrying left end of *In(1)w<sup>mJ</sup>*, which is part of *T(1;4)w<sup>mJ</sup>*, and right end of *In(1)rst<sup>3</sup>*.

**references:** Lefevre, 1963, DIS 37: 49-50.

Lefevre and Wilkins, 1966, Genetics 53: 175-87.

**genetics:** Male lethal. Variegated for *w* and *rst*.

***In(1)w<sup>mMc</sup>: Inversion (1) white-mottled of McLean***

**cytology:** *In(1)3C1-2;20F*; inferred from genetic data.

**origin:** X ray induced.

**discoverer:** McLean.

**references:** Muller, 1946, DIS 20: 68.

Tartof, Hobbs, and Jones, 1984, Cell 37: 869-78.

**genetics:** Variegates for *w* and *rst*. Complementary single recombinants between *In(1)w<sup>md</sup> = In(1)3C1-2;20F* and *In(1)w<sup>mMc</sup>* are viable, fertile, and *bb<sup>+</sup>*. Left breakpoints therefore identical and right breakpoints on the same side of *bb*.

**molecular biology:** Left (3C1-2) breakpoint is at -21 kb in the restriction map of the *w* locus (0 point at site of the

copied insertion in *w<sup>a</sup>*); right (20F) breakpoint near the 3' end of a Type I mobile element that is inserted in a ribosomal RNA gene (Tartof *et al.*, 1984).

***In(1)w<sup>vc</sup>: Inversion (1) white-variegated of Catcheside***

**cytology:** *In(1)3C1-2;20F* superimposed on *R(1)1A3-4;20F*.

**new order:**

|1A4-3C1|20F-3C2|20F|. Position of centromere indeterminate.

**origin:** X ray induced in *R(1)2*.

**discoverer:** Catcheside.

**references:** Hinton, 1955, Genetics 40: 952-61.

**genetics:** Variegates for *w*, *rst*, *spl*, and *N* but not *y*. *X/Y* male viability reduced; *X/Y/Y* male more viable. Characterized by variable degree of instability manifested by production of gynandromorphs, *X/O* males, and dominant lethals. An extreme example gave 140 females, 106 gynandromorphs, 181 *X/O* males, and 868 dominant lethals among 1295 putative ring/rod zygotes. Small ring-shaped duplications are generated infrequently (analysis by Hinton, 1955). Behavior of rod derivatives of *In(1)w<sup>vc</sup>* (Hinton, 1957, Genetics 42: 55-65) suggests generation of dicentrics through sister-strand fusion rather than exchange. Fusion postulated to occur in heterochromatin of the 3C1|20F reunion point of *In(1)w<sup>vc</sup>*. Mitotic abnormalities in cleavage of *In(1)w<sup>vc</sup>* embryos described (Hinton, 1959, Genetics 44: 923-31). Chromosome tends to become stable in stocks. Viability and fertility correlated with stability. Widely used in mosaic analysis and fate mapping (*e.g.*, García-Bellido and Merriam, 1969, J. Exp. Zool. 170: 61-76).

***In(1)w<sup>w</sup>***

**cytology:** *In(1)3B2-C1;4B4-C1*.

**origin:** Spontaneous in a mutable *z w<sup>zmmz</sup>* strain.

**references:** Kalish, 1970, Mol. Gen. Genet. 107: 336-50. 1980, DIS 55: 206-07.

**genetics:** Mutant for *w*. Reverts to *w<sup>zmmz</sup>* with reinversion of *In(1)w<sup>w</sup>*.

***In(1)y<sup>3P</sup>: Inversion (1) yellow-3 of Patterson***

**cytology:** *In(1)1B1-2;20* (Muller and Prokofyeva, 1935) or *In(1)1A8-B1;20F*. Heterochromatic break proximal to h29.

**origin:** X ray induced.

**discoverer:** Patterson, 31e25.

**references:** Muller, 1935, Genetica 17: 237-52.

Muller and Prokofyeva, 1935, Proc. Nat. Acad. Sci. USA 21: 16-26.

Sidorov, 1936, Biol. Zh. (Moscow) 5: 3-26.

García-Bellido, 1979, Genetics 91: 491-520.

Carramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell, 1982, EMBO J. 1: 1185-91.

Biessmann, 1985, Proc. Nat. Acad. Sci. USA 82: 7369-73.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38.

**genetics:** Variegated for *y* and, to a lesser extent, for *Hw*. Genetic breaks between *l(1)1Ac* and *y* and between *bb* and centromere. Inversion slightly longer than *In(1)sc<sup>8</sup>*.

**molecular biology:** The left breakpoint defines the distal limit of the *y* coding region. On the DNA map of Campuzano *et al.*, 1985, this breakpoint is at +73 and on the

DNA map of Biessmann, 1985, it lies between +36.5 and +38.3; in both maps, positive values are to the left of the origin.

***In(1)y<sup>3PL</sup>sc<sup>4R</sup>***

**cytology:** *In(1)1A;20<sup>L</sup>1B3-4;20F<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)y<sup>3P</sup>* and right end of *In(1)sc<sup>4</sup>*.

**references:** García-Bellido and Santamaria, 1978, Genetics 88: 469-86.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Male lethal. Carries *Hw* and the region covering *l(1)sc*. Deficient for *y*, *ac*, and the  $\alpha$  segment of *sc*.

**molecular biology:** Deficiency includes coding sequences for transcripts *T4*, *T5*, and *T6* (Campuzano, Carramolino, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-48).

***In(1)y<sup>3PL</sup>sc<sup>8R</sup>: Inversion (1) yellow-3 of Patterson Left scute-8 Right***

**cytology:** *In(1)1A;20<sup>L</sup>1B2-3;20F<sup>R</sup>*; deficient for 1A-B2.

**origin:** Recombinant containing left end of *In(1)y<sup>3P</sup>* and right end of *In(1)sc<sup>8</sup>*.

**references:** Muller, 1935, J. Hered. 26: 469-78.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38.

Chia, Howes, Martin, Meng, Moses, and Tsubota, 1986, EMBO J. 5: 3597-3605.

**genetics:** Deficient for *y* and *ac* but not *l(1)IAc*, *sc*, or *bb*. Male viable.

**molecular biology:** Deletes sequences encoding transcripts *T5* and *T6*.

***In(1)y<sup>3PL</sup>sc<sup>9R</sup>***

**cytology:** *In(1)1A;20<sup>L</sup>1B3-4;18C1<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)y<sup>3P</sup>* and right end of *In(1)sc<sup>9</sup>*.

**references:** García-Bellido and Santamaria, 1978, Genetics 88: 469-86.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Male lethal. Deficient for *y*, *ac*, *sc $\alpha$* , and *l(1)sc*. Mutant for *Hw*. Duplicated for *car-bb*.

***In(1)y<sup>3PL</sup>sc<sup>51R</sup>***

**cytology:** *In(1)1A;20<sup>L</sup>1B3-4;20F<sup>R</sup>*.

**origin:** Recombinant containing left end of *In(1)y<sup>3P</sup>* and right end of *In(1)sc<sup>51</sup>*.

**references:** García-Bellido and Santamaria, 1978, Genetics 88: 469-86.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Male lethal. Deficient for *y*, *ac*, and *sc $\alpha$* ; retains *l(1)sc*. Male spots in gynandromorphs deficient for *ac* and *sc*.

***In(1)y<sup>4</sup>***

**cytology:** *In(1)1A8-B1;18A3-4* (Norton and Valencia, 1965, DIS 40: 40).

**origin:** X ray induced.

**discoverer:** Serebrovsky.

**references:** Dubinin and Friesen, 1932, Biol. Zentralbl. 52: 147-62.

Sturtevant and Beadle, 1936, Genetics 21: 554-604.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38.

**genetics:** Mutant for *y*. Right break within the *y* locus (Biessmann, 1985, Proc. Nat. Acad. Sci. USA 82: 7369-

73); left break between *fu* on left and *sby*, *smd*, and *coc* on right; shown by deficiency of *In(1)y<sup>4L</sup>sc<sup>9R</sup>* for *ac*, *sc $\alpha$* , *l(1)sc*, *sby*, *smd*, and *coc* but not *l(1)IAc* or *fu* (Norton and Valencia, 1965). *In(1)y<sup>4</sup>/+* female produces about 2% exceptional sons from 4-strand double exchange in the inverted regions; *In(1)y<sup>4</sup>/+Y* female produces about 7% secondary exceptions (Sturtevant and Beadle, 1936).

**molecular biology:** Left breakpoint between DNA coordinates 70.6 and 71.6 [to right of breakpoint of *In(1)y<sup>3P</sup>* (Campuzano *et al.*, 1985)].

***In(1)y<sup>4L</sup>sc<sup>4R</sup>: Inversion (1) yellow-4 Left scute-4 Right***

**cytology:** *In(1)1A8-B1;18A3-4<sup>L</sup>1B3-4;20F<sup>R</sup>*; deficient for 1B1-3 and 18A4 through the distal portion of h26.

**origin:** Recombinant containing left end of *In(1)y<sup>4</sup>* and right end of *In(1)sc<sup>4</sup>*.

**references:** Sturtevant and Beadle, 1936, Genetics 21: 554-604.

**genetics:** Deficient for *ac*, *sc*, *car*, and *M(1)18C* but not *os* or *bb*. Heterozygous female Minute and poorly viable but fertile. Male lethal.

***In(1)y<sup>4L</sup>sc<sup>8R</sup>: Inversion (1) yellow-4 Left scute-8 Right***

**cytology:** *In(1)1A8-B1;18A3-4<sup>L</sup>1B2-3;20F<sup>R</sup>*; deficient for 1B1-2 and 18A4 through the majority of h32.

**origin:** Recombinant containing left end of *In(1)y<sup>4</sup>* and right end of *In(1)sc<sup>8</sup>*.

**references:** Sturtevant and Beadle, 1936, Genetics 21: 554-604.

**genetics:** Deficient for *ac*, *car*, *M(1)18C*, and *bb* but not *svr*; carries the distal half of the *y* locus, *y<sup>4</sup>*. Heterozygous female Minute, fertile, and poorly viable. Male lethal.

***In(1)y<sup>4L</sup>sc<sup>9R</sup>: Inversion (1) yellow-4 Left scute-9 Right***

**cytology:** *In(1)1A8-B1;18A3-4<sup>L</sup>1B2-3;18B8-9<sup>R</sup>*; deficient for 1B1-2 and 18A4-B8.

**origin:** Recombinant containing left end of *In(1)y<sup>4</sup>* and right end of *In(1)sc<sup>9</sup>*.

**references:** Norton and Valencia, 1965, DIS 40: 40.

**genetics:** Deficient for *ac*, *sc $\alpha$* , *l(1)sc*, *sby*, *smd*, and *coc* but not *l(1)IAc* or *fu-pph*. Carries the distal half of the *y* locus. Male lethal.

***\*In(1)y<sup>5</sup>***

**cytology:** *In(1)1A-B;14D* (Muller and Raffel).

**discoverer:** Patterson.

**genetics:** Mutant for *y*. Recessive lethal associated with right breakpoint.

***In(1)y<sup>65f4</sup>***

**cytology:** *In(1)1B2-3;1C1*.

**origin:** X ray induced.

**references:** Lefevre, 1968, Genetics 60: 196-97. 1970, DIS 45: 32.

**genetics:** Phenotype *y<sup>2</sup>*-like, with bristles dark and body slightly darker than *y<sup>2</sup>*. Fertile in males and females.

***In(1)y<sup>A</sup>: Inversion (1) yellow of Alexandrov***

**references:** Alexandrov, Ankina and Alexandrova, 1985,

DIS 61: 212-13.

*In<sub>1</sub>(1)<sup>K</sup>*: see *In(1)m<sup>K</sup>*

***In(1LR)l-v139*: Inversion (1LR) lethal-variegated**

cytology: *In(1LR)3C6-7*.

origin: X ray induced.

discoverer: Lindsley, Edington, and Von Halle.

references: 1960, Genetics 45: 1649-70.

Gersh, 1965, Genetics 51: 477-80 (fig.).

genetics: Variegated for w, rst, and a lethal; requires two Y chromosomes for survival; X/Y/Y male fertile. Recombinant carrying left end of the X<sup>P4D</sup> element of *T(1;4)w<sup>ms</sup> = T(1;4)3C3-4;101F1-2* and right end of *In(1LR)l-v139* variegates for w but not for rst or the lethal.

***In(1LR)sc<sup>260-25</sup>*: Inversion (1LR) scute**

**cytology:** *In(1LR)1B2-3*.  
**origin:** X ray induced.  
**discoverer:** Sutton, 39k.  
**synonym:** *Tp(1;1)sc<sup>260-25</sup>*.  
**references:** 1940, Genetics 25: 628-35 (fig.).  
**genetics:** Mutant for *sc*; variegates for *y* and *ac* but not *svr*. Genetic tests indicate loci of *l(1)IAc*, *y*, and *ac* are located at the base of *X* to the right of *bb*. Sutton judged it to be a transposition of 1A1-B2 into the proximal heterochromatin, but since this requires three breaks with one to the left of 1A1, a pericentric inversion is deemed more probable. Recombination between *In(1LR)sc<sup>260-25</sup>* and a normal sequence yields *Df(1)sc<sup>260-25</sup>* = *Df(1)1B2-3* and *Dp(1;1)sc<sup>260-25</sup>* = *Dp(1;1)1B2-3*. The deficiency is deficient for *l(1)IAc*, *y*, and *ac* (Sutton, 1940).

***In(1LR)sc<sup>V1</sup>*: Inversion (1LR) scute of Valencia**

**cytology:** *In(1LR)1A8-C3*; inferred from genetic results.  
**origin:**  $\gamma$  ray induced.  
**discoverer:** J. I. Valencia, 46h23.  
**synonym:** *Inp(1)sc<sup>V1</sup>* (*Inp* symbolized a pericentric inversion).  
**references:** Muller and Valencia, 1947, DIS 21: 69-70.  
**genetics:** Mutant for *ac* and *sc*. A single exchange between *In(1LR)sc<sup>V1</sup>* and a normal *X* chromosome produces one recombinant with the left end of *In(1LR)sc<sup>V1</sup>* that is deficient for the tip of *X*, *Df(1)sc<sup>V1</sup>*, and one with the right end of *In(1LR)sc<sup>V1</sup>* that is duplicated for the tip of *X*, *Dp(1;1)sc<sup>V1</sup>*. Left break between *ac* and *M(1)1B* based on observation that *Dp(1;1)sc<sup>V1</sup>* is duplicated for *ac*, and *Df(1)sc<sup>V1</sup>* is deficient for *ac* but not *M(1)1B*. Right break in *XR*. *Dp(1;1)sc<sup>V1</sup>* carrying *y* in normal position and *y<sup>+</sup>* in duplicated region provides an excellent marker system for right end of the *X*.

***In(Y)***

**origin:** Induced in *y<sup>+</sup>Y* by *X* rays (Brosseau, 1960) or by  $\gamma$  rays (M. Schwartz); and in *B<sup>S</sup>Yy<sup>+</sup>* by *X* rays.  
**genetics:** Male sterile; mutant sterility factors indicated in table below. Presence of inversions indicated by examination of prophase or metaphase figures.

**origin:** Spontaneous in a natural population.  
**references:** Ashburner and Lemeunier, 1976, Proc. R. Soc. London, B 193: 137-57.

**In(2L)Arp1: Inversion (2L) Aristapediod**

**cytology:** *In(2L)49A12-B3;49E5-F1*.  
**origin:** Hybrid dysgenesis.

**references:** Adler, 1984, Genetics 107: s1.  
**genetics:** Mutant for *Arp* in heterozygotes. Embryonic recessive lethal at proximal breakpoint.

**In(2L)Arp2**

**cytology:** *In(2L)49A12-B3;49E5-F1*.  
**origin:** Hybrid dysgenesis.  
**references:** Adler, 1984.  
**genetics:** Not identical to *In(2L)Arp1* (based on crosses to *vg* deletions). Recessive lethals at proximal and distal breakpoints.

**In(2L)ast: Inversion (2L) asteroid**

**cytology:** *In(2L)21E1-3;40*.  
**origin:**  $\gamma$  ray induced.  
**references:** Roberts, Brock, Rudden, and Evans-Roberts, 1985, Genetics 109: 145-56.  
**genetics:** Mutant for *ast*.

**\*In(2L)ast<sup>rv2</sup>: Inversion (2L) asteroid-reverted**

**cytology:** *In(2L)21E2-3;31*.  
**origin:** X ray induced in *ast*.  
**discoverer:** E. B. Lewis, 1942.  
**references:** 1945, Genetics 30: 158.  
**genetics:** Partial reversion of *ast*.

**In(2L)AWI**

**origin:** Accumulated on second chromosomes during repeated backcrossing, these second chromosomes coming from a lethal-carrying chromosome *AW* derived in 1967 from a wild-type cage population.  
**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

β	new order: 21 – 24D 42E – 41A 59D4 – 42E 24E1 – 40F  59D5 – 60.	

***In(2LR)bw*<sup>V1</sup>: Inversion (2LR) brown-Variiegated**

**cytology:** *In(2LR)21C8-D1;60D1-2 + In(2LR)40F;59D4-E1.*

**new order:**

21A – 21C8|60D1 – 59E1|40F – 59D4|40F – 21D1|60D2 – 60F.

**origin:** X ray induced.

**discoverer:** Muller, 1929.

**synonym:** *Ins(2LR)Pm*: *Inversion (2LR) Plum*.

**references:** 1930, J. Genet. 22: 299-334 (fig.).

Glass, 1934, J. Genet. 28: 69-112 (fig.).

1934, Am. Naturalist 68: 107-14.

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

Holm and Chovnick, 1976, Genetics 81: 293-311.

Craymer, 1981, DIS 95: 75-97.

Genetics 81: 293-311.

**genetics:** Mutant for *ds* which is included as *ds*<sup>33k</sup> in the *In(2LR)21C8-D1;60D1-2* component (Craymer, 1981); variegated for *lt*, *bw*, *mi*, and *abb*. *al*<sup>4</sup> arose after origin. Expression of *bw*<sup>V1</sup> suppressed by extra Y (Holm and Chovnick, 1976) or extra chromosome 4 (Lindsley). Double crossovers in 2L but not 2R fairly frequent. Single exchange in region 21D1-40F of 2L between *In(2LR)bw*<sup>V1</sup> and a normal sequence produces a recombinant carrying left end of normal chromosome 2, which is duplicated for 21A1-C8 and deficient for 60D2-F5. Heterozygote for this recombinant poorly viable, fertile, brown-Variiegated, Minute, and dwarf with pebbled arc wings; deficient for locus of *M(2)60E*. Reciprocal recombinant deficient for 21A1-C8 and duplicated for 60D2-F5; heterozygote poorly viable, fertile, *bw*<sup>+</sup>, Minute and giant; deficient for *al* and *M(2)21C*. Inversion heterozygote shows interchromosomal effect (Valentin, 1972, Hereditas 72: 243-54).

***In(2LR)bw*<sup>V29I</sup>**

**origin:** X ray induced.

**discoverer:** Van Atta.

**references:** 1932, Genetics 17: 637-59.

**genetics:** Variegated for *bw*. Breaks most probably just to the left of centromere and near *bw*.

***In(2LR)E1***

**cytology:** *In(2LR)34A;58F*.

**discoverer:** Ising.

***In(2LR)el<sup>6</sup>***

**cytology:** *In(2LR)35B1-3;57C3-9* (Ashburner).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Angel.

**genetics:** Associated with *el<sup>6</sup>*.

***In(2LR)Eni: Inversion (2R) Enigma***

**cytology:** Pericentric inversion.

**origin:** Recombination between *Dp(2;2)Eni/F(2R)* and standard strain.

**references:** Fitz-Earle, 1979, Genetics 91: s34.

**genetics:** *Dp(2;2)Eni/F(2R)* and additional free arms produced again through recombination.

***In(2LR)f6: Inversions (2LR) from free arms 6***

**cytology:** *In(2LR)39D3-E1;48F6-49A1*.

**origin:** X ray induced as a translocation between the 2<sup>PY</sup>D element of *T(Y;2)B238 = T(Y;2)YS;41* and *F(2R)VH1*. Subsequently reconstituted as *In(2LR)f6*.

**references:** Craymer, 1984, DIS 60: 234-36.

***In(2LR)Gla: Inversion (2LR) Glazed***

**cytology:** *In(2LR)27D;51E* superimposed on *In(2L)22D3-E1;34A8-9* (Woodruff and Ashburner, 1979, Genetics 92: 117-32).

**new order:**

21 – 22D3|34A8 – 27D|51E – 34A9|22E1 – 27D|51E – 60.

**origin:** X ray induced in chromosome containing *In(2L)t = In(2L)22D3-E1;34A8-9*.

**genetics:** Associated with *Gla*. Effective crossover suppressor; no single or double crossovers recovered to

the left of *c* (Alexander, 1952, Texas Univ. Publ. 5204: 219-26). Orange Malpighian tubules in larvae and adults heterozygous with *cn* (Ashburner).

***In(2LR)JHI***

**origin:** Accumulated on second chromosomes during repeated backcrossing. These second chromosomes come from a lethal- carrying chromosome *JH* derived in 1967 from a wild-type cage population.

**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

 Gubb, Roote, Harrington, McGill, Durrant, Shelton, and Ashburner, 1985, Chromosoma 92: 116-23.  
**genetics:** Associated with *noc<sup>4</sup>*. Autosynaptic derivatives [*LS(2)noc<sup>4</sup>*; *DS(2)noc<sup>4</sup>*] recoverable (Gubb).

**In(2LR)noc<sup>4L</sup> Sco<sup>rv9R</sup>**

**cytology:** *In(2LR)35B1-2;35D1-2;41*; deficient for 35B2-D1.  
**origin:** Recombinant between autosynaptics, *LS(2)noc<sup>4</sup>* and *DS(2)Sco<sup>rv9</sup>*.  
**discoverer:** Gubb.  
**synonym:** *Df(2L)noc<sup>4L</sup> Sco<sup>+R9R</sup>*.  
**genetics:** Deficient for *noc - l(2)35Da*. Presumably aneuploid for interval between region 41 breakpoints of parental inversions.

**In(2LR)noc<sup>7</sup>**

**cytology:** *In(2LR)35A1-4;40;46B1-2;48C6 + T(Y;2)60D7-F*.  
**new order:**  
 21A - 35A1|46B2 - 48C6|40 - 46B1|

35A4 - 40|48C6 - 60D7|Y;  
 Y|60D7 - 60F.

**origin:**  $\gamma$  ray induced.  
**discoverer:** Harrington.  
**references:** Ashburner, Aaron, and Tsubota, 1982, Genetics 102: 421-35.  
 Chia, Karp, McGill, and Ashburner, 1985, J. Mol. Biol. 186: 689-706.  
 Gubb, Roote, Harrington, McGill, Durrant, Shelton, and Ashburner, 1985, Chromosoma 92: 116-23.  
**genetics:** Associated with *noc<sup>7</sup>*.

**In(2LR)O: Inversion (2LR) of Oster**

**cytology:** *In(2LR)30E-F;50C10-D1* superimposed on *In(2L)22D1-2;33F5-34A1 + In(2R)42A2-3;58A4-B1* (Lindsley).  
**new order:**  
 20 - 22D1|33F5 - 30F|50D1 - 58A4|  
 42A2 - 34A1|22D2 - 30E|50C10 - 42A3|  
 58B1 - 60.  
**origin:** X ray induced in *In(2L)Cy + In(2R)Cy, Cy dp<sup>lv</sup> pr cn<sup>2</sup>*.

**references:** Oster, 1956, DIS 30: 145.  
**molecular biology:** 50C-D breakpoint distal to *mam*; between coordinates +25 and +29 on the chromosome walk including *mam* (Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97).  
**other information:** Used as a balancer for chromosome 2, described as *CyO* in the section on balancers.

*In(2LR)Pm*: see *In(2LR)bw<sup>V1</sup>*

*In(2LR)Pm<sup>2</sup>*: see *In(2LR)bw<sup>V32g</sup>*

**In(2LR)Pu<sup>Ly</sup>: Inversion (2LR) Punch of Lyttle**

**cytology:** *In(2LR)40B-F;57C4-6*.  
**origin:**  $\gamma$  ray induced in *SD-Roma*.  
**discoverer:** Lyttle.  
**synonym:** *In(2LR)R-3*.  
**references:** Mackay and O'Donnell, 1983, Genetics 105: 35-53.  
 O'Donnell, Boswell, Reynolds, and Mackay, 1989, Genetics 121: 273-80.  
**genetics:** Associated with *lt* at 40B-F and *Pu<sup>Ly</sup>* at 57B-C. Dominant, variegated eye color. Homozygous lethal.

**In(2LR)px<sup>52g</sup>: Inversion (2LR) plexus**

**cytology:** *In(2LR)30A;58E*.  
**origin:** X ray induced in *cn crs*.  
**discoverer:** Iyengar and Meyer, 52g.  
**references:** 1956, DIS 30: 73.  
 Meyer, 1956, DIS 30: 81.  
 1958, DIS 32: 83.  
 Craymer, 1980, DIS 55: 197-200.  
 1981, Genetics 99: 75-97.  
**genetics:** Mutant for *px*. Pericentric inversion with breakpoints between *dp* and *b* and between *px* and *sp*. Homozygous female is fertile but male is sterile. Male genitalia rotated. Sterility factor not allelic to *ab* and not covered by duplication in *bw<sup>+Y</sup>* (as is *crs*, the male sterility factor present in original chromosome).

**In(2LR)Px<sup>4</sup>: Inversion (2LR) Plexate**

**cytology:** *In(2LR)22A3-B1;60B-C<sup>L</sup>;21C8-D1;60D1-2<sup>R</sup> + In(2R)42A2-3;58A4-B1*; deficient for 60B-D1 and duplicated for 21D1-22A3.

**new order:**

21A – 22A3|60B – 58B1|42A3 – 58A4|  
42A2 – 21D1|60D2 – 60F.

**origin:** Synthetic. This chromosome is a recurrent product of recombination in region 33F-40F between *In(2LR)21C8-D1;60D1-2* from *In(2LR)bw<sup>VI</sup>* [*In(2LR)21C8-D1;60D1-2* + *In(2LR)40F;59D4-E1*] and *In(2LR)22A3-B1;60B-C* from *SM1* [*In(2L)Cy* = *In(2L)22D1-2;33F5-34A1* + *In(2LR)22A3-B1;60B-C* + *In(2R)Cy* = *In(2R)42A2-3;58A4-B1*]. Recombinant carries tip of 2L and *In(2R)Cy* from *SM1* and tip of 2R and most of 2L from *In(2LR)bw<sup>VI</sup>*. The reciprocal recombinant is *In(2LR)S<sup>56f</sup>*.

**discoverer:** Thompson.

**references:** Burdick, 1956, DIS 30: 69.

**genetics:** Deficient for *bs*, *ba*, *Pin*, *Px*, and probably *sp*; duplicated for *S*.

***In(2LR)RBR***

**origin:** Spontaneous [accumulated on second chromosome lines during repeated backcrossing of males heterozygous for each second chromosome line over *In(2LR)bw<sup>VI</sup>* to *In(2LR)bw<sup>VI</sup>/SM1* females].

**references:** Yamaguchi, Cardellino, and Mukai, 1976, Genetics 83: 409-22.

***In(2LR)Rev: Inversion (2LR) Revolute***

**cytology:** *In(2LR)40F;52D10-E1* (Bridges and Li in Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 293).

**origin:** X ray induced.

**discoverer:** Dobzhansky, 31b5.

**references:** Valentin, 1972, Hereditas 72: 243-54. 1978, Hereditas 89: 263-64.

**genetics:** Variegated for *lt* and *Rev*. Heterozygotes show no interchromosomal effect on distal X recombination (Valentin, 1978).

***In(2LR)Rev<sup>B</sup>: Inversion (2LR) Revolute of Bridges***

**cytology:** *In(2LR)40;52D5*.

**origin:** Spontaneous.

**discoverer:** Bridges, 36e22.

**synonym:** *In(2LR)Rvd*.

**references:** Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 293. Valentin, 1978, Hereditas 89: 263-64. Wargent, 1972, DIS 49: 50.

Wargent and Hartman-Goldstein, 1974, Heredity 33: 317-26.

**genetics:** Variegated for *Rev* and *lt* (Wargent, 1972, DIS 49: 50-51). Variegation enhanced by low temperature; suppressed by extra Y chromosome (Wargent). Heterozygotes show no interchromosomal effect on distal X recombination (Valentin, 1978).

***In(2LR)S<sup>56f</sup>: Inversion (2LR) Star***

**cytology:** *In(2L)22D1-2;33F5-34A1* + *In(2LR)21C8-D1;60D1-2<sup>L</sup>22A3-B1;60B-C<sup>R</sup>* + *In(2LR)40F;59D4-E1*; deficient for 21D1-22A3 and duplicated for 60B-D1.

**new order:**

21A – 21C8|60D1 – 50E1|40F – 59D4|40F – 34A1|  
22D1 – 33F5|22D1 – 22B1|60C – 60F.

**origin:** Synthetic. This chromosome is a recurrent product of recombination in region 33F-40F between *In(2LR)21C8-D1;60D1-2* from *In(2LR)bw<sup>VI</sup>* [*In(2LR)21C8-D1;60D1-2* + *In(2LR)40F;59D4-E1*] and *In(2LR)22A3-B1;60B-C* from *SM1* [*In(2L)Cy* = *In(2L)22D1-2;33F5-34A1* + *In(2LR)22A3-B1;60B-C* + *In(2R)Cy* = *In(2R)42A2-3;58A4-B1*]. Recombinant carries the tip of 2L and *In(2LR)40F;59D4-E1* from *In(2LR)bw<sup>VI</sup>* and the tip of 2R and *In(2L)Cy* from *SM1*. Reciprocal recombinant is *In(2LR)Px<sup>4</sup>*.

**discoverer:** Thompson.

**references:** Burdick, 1956, DIS 30: 69.

**genetics:** Deficient for *S*; duplicated for *Px*.

***In(2LR)S<sup>325</sup>***

**cytology:** *In(2LR)21D2-3;21D3-E2;21E2-3;41F*.

**new order:**

21A – 21E2|41 – 21D3|41 – 60.  
Tentative.

**origin:** X ray induced in *Dp(2;2)S* = *Dp(2;2)21D2-3;21E2-3*.

**discoverer:** E. B. Lewis.

**genetics:** Break in 2L either in or between duplicated segments of *Dp(2;2)S*. *In(2LR)S<sup>325</sup>/ds<sup>W</sup>* shows a *ds<sup>-</sup>/ds<sup>W</sup>* phenotype (Craymer, 1981, Genetics 99: 75-97).

***\*In(2LR)S<sup>K</sup>: Inversion (2LR) Star of Krivshenko***

**cytology:** Breakpoints near ends of 2L and 2R.

**discoverer:** Krivshenko.

**references:** 1936, DIS 5: 8.

**genetics:** Associated with *S<sup>K</sup>*.

***In(2LR)S<sup>Ly</sup>: Inversion (2LR) Star of Lyttle***

**cytology:** *In(2LR)21E-F;41*.

**origin:** X ray induced in *SD-Roma*.

**discoverer:** Lyttle.

**genetics:** Associated with *S<sup>Ly</sup>* which is located at 21E-F and shows an *S* phenotype but is somewhat more variable than *S*.

***In(2LR)Sco<sup>rv1</sup>: Inversion (2LR) Sco-revertant***

**cytology:** *In(2LR)35D1-2;44C4-5* (Ashburner).

**origin:** X ray induced in *Tp(2;2)Sco*.

**synonym:** *Sco<sup>+R1</sup>*; *l(2)br29<sup>Sco+R1</sup>*.

**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.

Craymer, 1981, Genetics 99: 75-97.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, Genetics 104: 405-31.

Ashburner and Harrington, 1984, *Chromosoma* 89: 329-37.

Gubb, Roote, Harrington, McGill, Durrant, Shelton, and Ashburner, 1985, *Chromosoma* 92: 116-23.

Gubb, Roote, McGill, Shelton, and Ashburner, 1986, *Genetics* 112: 551-75.

**genetics:** *Sco* revertant. Homozygous lethal in pupal stage. Lethal over *Sco* and most *Sco* revertants, but semilethal with *Sco*<sup>rv27</sup>. Also semilethal with *l(2)35Ba* alleles and with some *el* and *noc* alleles. Lethality maps between left breakpoints of *Df(2L)A446* and *Df(2L)A267*. Can be converted to autosynaptic form, *AS(2)Sco*<sup>rv1</sup> (Craymer, 1981). Associated with warped wing and pale scutellum phenotypes (Ashburner *et al.*, 1983).

**molecular biology:** Left DNA breakpoint at -67.1 to -68.3 kb, the origin of the map being the *EcoRI* site immediately distal to *Adh* (Chia, Karp, McGill, and Ashburner, 1985, *J. Mol. Biol.* 186: 689-706).

**other information:** Revertants of the *Sco*<sup>rv1</sup> lethal interaction with *noc*<sup>TE35A</sup> include *Tp(2;2)Sco*<sup>rv1</sup>-*DV1* (*viz*) and seven other derivatives, which are not further rearranged, designated *DV4*, *DV5*, and *DV6* (EMS induced) and *DV9*, *DV10*, and *DV11* ( $\gamma$  ray induced) (Ashburner, unpublished).

**references:** Yamazaki and Thompson, 1973, *Jpn. J. Genet.* 48: 217-29.

**genetics:** *k* value: .4885 - .7778.

#### ***In(2LR)shv*<sup>S15</sup>: *Inversion (2LR) short vein of Segal***

**cytology:** *In(2LR)22F1-2;59B*.

**origin:**  $\gamma$  ray induced.

**references:** Segal and Gelbart, 1985, *Genetics* 109: 119-43.

**genetics:** Associated with break in *shv* region at 22F1-2. Heterozygotes with *shv* are lethal, with *dpp* alleles are lethal or wild type.

#### ***In(2LR)shv*<sup>S17</sup>**

**cytology:** *In(2LR)22F1-2;41A*.

**origin:**  $\gamma$  ray induced.

**references:** Segal and Gelbart, 1985, *Genetics* 109: 119-43.

**genetics:** Associated with break in *shv* region at 22F1-2. Heterozygotes with *shv* are lethal, with *dpp* alleles are mutant or wild type.

#### ***In(2LR)SM1: Inversion (2LR) Second Multiple***

**cytology:** *In(2LR)22A3-B1;60B-C* superimposed on *In(2L)22D1-2;33F5-34A1 + In(2R)42A2-3;58A4-B1*.

**new order:**

21 - 22A3|60B - 58B1|42A3 - 58A4|42A2 - 34A1|22D2 - 33F5|22D1 - 22B1|60C - 60F.

**origin:** X ray induced in *In(2L)Cy + In(2R)Cy*.

**references:** R. F. Grell, 1953, *DIS* 27: 58.

**genetics:** The pericentric inversion, *In(2LR)22A3-B1;60B-C*, enhances balancing power of *In(2L)Cy + In(2R)Cy* since it causes the single crossover between the two *Cy* inversions to yield complementary products that are dominant lethal. Heterozygote shows interchromosomal effect; used to increase crossing-over and gene conversion in *ry* region (Chovnick, Ballantine, and Holm, 1971, *Genetics* 69: 179-209); also causes non-disjunction of compound autosomes (Lindsley and Grell, 1969, *Genetics* 61: 69-78).

**other information:** Used as a balancer for chromosome 2, described as *SM1* in the section on balancers.

#### ***In(2LR)SM1-bw*<sup>V1</sup>**

**cytology:** *In(2L)22D1-2;33F5-34A1 + In(2LR)22A3-B1;60B-C + In(2LR)40F;59D4-E1*.

**new order:**

21A - 22A3|60B - 59E1|40F - 59D4|40F - 34A1|22D2 - 33F5|22D1 - 22B1|60C - 60F.

**origin:** An *SM1* chromosome in which a double crossover replaces *In(2R)Cy* and the centromere with the inner pericentric inversion [*In(2LR)40F;59D4-E1*] from *In(2LR)bw*<sup>V1</sup>.

**references:** Kaufmann and Gay, 1970, *DIS* 45: 81.

**genetics:** Mutant for *Cy* and *bw*<sup>V1</sup>.

***In(2LR)SM5***

**cytology:** *In(2L)21D2-3;36C + In(2L)29C-E;40F + In(2R)42D;53C;58F* superimposed on *In(2L)22D1-2;33F5-34A1 + In(2LR)22A3-B1;60B-C + In(2R)42A2-3;58A4-B1*. Duplicated for regions 42A3-D and 58B1-F.

**new order:**

21A – 21D2|36C – 40F|29C – 22D2|34A1 – 36C|  
21D3 – 22A3|60B – 58B1|42A3 – 42D|42D – 42A3|  
58B1 – 58F|53C – 42D|53C – 58A4|42A2 – 40F|  
29E – 33F5|22D1 – 22B1|60C – 60F.

**origin:** X ray induced in several steps in *In(2LR)SM1*.

**discoverer:** R. F. Grell, 1955.

**references:** Mislove and Lewis, 1955, DIS 29: 75.

**genetics:** Variegated for *lt* owing to *In(2L)29C-E;40F*.

Carries *ds*<sup>55</sup> (Craymer, 1980, DIS 55: 197-200).

*In(2LR)SM5/M(2)58F* lethal (C. Hinton); probably related to break in 58F.

**other information:** Excellent balancer for all of chromosome 2, described as *SM5* in the section on balancers.

***In(2LR)SM6***

**cytology:** *In(2LR)SM1 = In(2LR)22A3-B1;60B-C + In(2LR)O = In(2LR)30E-F;50C10-D1*, both inversions superimposed on *In(2L)Cy = In(2L)22D1-2;33F5-34A1 + In(2R)Cy = In(2R)42A2-3;58A4-B1*.

**new order:**

21 – 22A3|60B – 58B1|42A3 – 50C10|  
30E – 22D|34A1 – 42A2|58A4 – 50D1|  
30F – 33F5|22D1 – 22B1|60C – 60F.

**origin:** Recombination between chromosomes derived from *SM1* and *CyO*, *Roi* chromosomes.

**discoverer:** Craymer.

**genetics:** Carries *al*<sup>2</sup> *Cy dp*<sup>lv1</sup> *cn*<sup>2P</sup> *sp*<sup>2</sup> and either *pr* (*SM6a*) or *Roi*(*SM6b*).

**other information:** Used as a balancer for chromosome 2, described as *SM6* in the section on balancers.

***In(2LR)SMG8***

**cytology:** *In(2LR)22D;42*.

**new order:**

21 – 22A3|60B – 58B1|42A3 – 50C10|  
30E – 22D|34A1 – 42A1|58A4 – 50D1|

**origin:**  $\gamma$  ray induced.

**references:** Semenova, Mglinetz, and Glotoff, 1970, *Genetika* (Moscow) 6: 165-69.

***In(2LR)SMG9***

**cytology:** *In(2LR)35B;57F*.

**origin:**  $\gamma$  ray induced.

**references:** Semenova, Mglinetz, and Glotoff, 1970, *Genetika* (Moscow) 6: 165-69.

***In(2LR)St: Inversion (2LR) Stalker***

**cytology:** *In(2LR)29D;45B-C*.

**origin:** Spontaneous in a natural population in Texas.

**references:** Stalker, 1976, *Genetics* 82: 323-47.

***In(2LR)TE35A***

**origin:**  $\gamma$  ray induced in *TE35A*.

**synonym:** *In(2LR)TE146*.

 1968, DIS 43: 140-41.  
 Valentin, 1972, Hereditas 72: 243-54.  
 genetics: Left breakpoint between *ap* and *pk*. Homozygous viable and fertile. Crossing over in 2R strongly reduced. Carries *cn*<sup>2</sup> in most laboratory stocks. Interchromosomal effect on crossing over and primary non-disjunction greater when in *cis* with *In(2L)Cy* than in *trans* (Valentin, 1972).  
 other information: Used in combination with *In(2L)Cy* as a balancer for chromosome 2.

**In(2R)Cy<sup>L</sup>bw<sup>VDe1R</sup>: Inversion (2R) Curly-Left brown-Variiegated of Demerec 1 Right**

cytology: *In(2R)42A2-3;58A4-B1<sup>L</sup>41B2-C1;59E2-4<sup>R</sup>*;  
 duplicated for 41C1-42A2 and deficient for 58B1-59E2.  
 origin: Recombinant carrying left end of *In(2R)Cy* and  
 right end of *In(2R)bw<sup>VDe1</sup>*.  
 genetics: Deficient for *M(2)58F*, *bw*, and *mi*; duplicated  
 for *Df(2R)M41A* but not *rl* or *M(2)p*.

***In(2R)Cy<sup>L</sup>bw<sup>VDe2R</sup>*: Inversion (2R) Curly-Left brown-Variegated of Demerec 2 Right**  
**cytology:** *In(2R)42A2-3;58A4-B1<sup>L</sup>41A-B;59D6-E1<sup>R</sup>*; duplicated for 41B-42A2 and deficient for 58B1-59D6.  
**origin:** Recombinant carrying left end of *In(2R)Cy* and right end of *In(2R)bw<sup>VDe2</sup>*.  
**genetics:** Deficient for *M(2)58F* and *bw* but not *mi*; duplicated for *Df(2R)M41A* but not *rl* or *M(2)p*.

***In(2R)Cy<sup>L</sup>C129<sup>R</sup>***  
**cytology:** *In(2R)42A2-3;58A4-B1<sup>L</sup>43F;56E<sup>R</sup>*. Deficient for 41B-42A2 and 58A4-59E1.  
**origin:** Recombination between *In(2R)Cy* and *In(2R)C129*.  
**references:** Nix, 1973, Mol. Gen. Genet. 120: 309-18.  
**other information:** May be used in combination with *In(2L)t* as a balancer for chromosome 2.

***In(2R)en<sup>28</sup>*: Inversion (2R) engrailed**  
**cytology:** Complex rearrangement, including *Df(2R)47B3;47B9-14 + In(2R)47B9-14;48A1-2 + Df(2R)48A1-2;48B-C1*.  
**origin:** X ray induced.  
**references:** Eberlein, 1982, Genetics 100: s21-22. Eberlein and Russell, 1983, Dev. Biol. 100: 227-37.  
**genetics:** Homozygous lethal and cell lethal. When heterozygous over *en<sup>1</sup>* or *en<sup>30</sup>*, *In(2R)en<sup>28</sup>* survives to adult stage and shows weak *en* phenotype.

***In(2R)en<sup>48</sup>***  
**cytology:** *In(2R)47F;48A3-4*.  
**origin:** X ray induced.  
**discoverer:** Kornberg.  
**references:** Kuner, Nakanishi, Ali, Drees, Gustavson, Theis, Kauvar, Kornberg, and O'Farrell, 1985, Cell 42: 309-16. Drees, Ali, Soeller, Coleman, Poole, and Kornberg, 1987, EMBO J. 6: 2803-09.  
**genetics:** Homozygous lethal. Associated with *en<sup>48</sup>*.  
**molecular biology:** Right breakpoint 10-11 kb toward the centromere from the insertion site of the *en<sup>1</sup>* transposition. (Kuner *et al.*, 1985).

***In(2R)en<sup>C2</sup>***  
**cytology:** *In(2R)47A;48A*.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Kornberg, 1981, Proc. Nat. Acad. Sci. USA 78: 1095-99. Drees, Ali, Soeller, Coleman, Poole, and Kornberg, 1987, EMBO J. 6: 2803-09.  
**genetics:** Homozygous lethal; semilethal over *en<sup>7</sup>*; *en* phenotype over *en* showing duplicated antennal segments and fused leg segments.  
**molecular biology:** Breakpoint 14 kb upstream of the *en* transcripts (Drees *et al.*, 1987).

***In(2R)G: Inversion (2R) Gallup***  
**cytology:** *In(2R)50C20;54B1* (Vassin).  
**origin:** Spontaneous.  
**discoverer:** Ives.  
**references:** 1957, DIS 31: 83.  
**genetics:** Associated with *mam<sup>1</sup>*. Crossing over in 2R reduced to about 13%.  
**molecular biology:** 50C breakpoint between coordinates -27.3 and -25.5 in the region of *mam* (Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97).

***In(2R)HNI: Inversion(2R) Hiraizumi Nakazima***  
**cytology:** *In(2R)55E;60E*.  
**origin:** Spontaneous in a wild population in Japan.  
**references:** Hiraizumi and Nakazima, 1965, DIS 40: 72. Hartl, 1980, Genetics 80: 539-47.  
**other information:** Carried along with *In(2R)NS* in *SD*-bearing chromosome.

***In(2R)IW6: Inversion (2R) Inoue Watanabe***  
**cytology:** *In(2R)42E;47C*.  
**origin:** Spontaneous in a natural population in Japan.  
**references:** Inoue and Watanabe, 1979, Jpn. J. Genet. 54: 69-82.

***In(2R)IW7***  
**cytology:** *In(2R)51B;59B*.  
**origin:** Spontaneous in a natural population in Japan.  
**references:** Inoue and Watanabe, 1979, Jpn. J. Genet. 54: 69-82.

***In(2R)JHI***  
**origin:** Accumulated on second chromosomes during repeated backcrossing to balancer chromosome. These second chromosomes come from a lethal-carrying chromosome *JH* derived in 1967 from a wild-type cage population.  
**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

 Choi, 1977, DIS 52: 88.  
 1977, Genetica 47: 155-60.

***In(2R)L5***

**cytology:** *In(2R)44A;53D*.  
**discoverer:** Ising.

***In(2R)LK1***

**cytology:** *In(2R)41A-B;57F2-58A1*.  
**origin:** X ray induced in a chromosome carrying *ix*.  
**references:** Keltner and Puro, 1978, DIS 53: 170.  
**genetics:** Homozygous viable. Males fertile and females *ix*.

***In(2R)M: Inversion (2R) of Mourad***

**cytology:** *In(2R)54F1-55A1;58F-59A*.  
**origin:** Spontaneous.  
**discoverer:** Mourad and Mallah.  
**references:** 1960, Evolution 14: 166-70.  
 Ashburner and Lemeunier, 1976, Proc. R. Soc. London, B 193: 137-57.

***In(2R)mam***

**origin:** Induced by hybrid dysgenesis in a Harwich second chromosome which has *P*-elements at 42C-D; 50C-D, and 57B.  
**references:** Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97.  
**genetics:** Mutant for *mam*.

inversion	synonym	cytology <sup>α</sup>

***In(2R)N2G***

**cytology:** *In(2R)50C-D;54D*.  
**origin:** Spontaneous in wild populations.  
**references:** Ives, 1947, Evolution 1: 42-47.  
**genetics:** *mam* allele (Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97).

***In(2R)NC: Inversion (2R) from North Carolina***

**cytology:** *In(2R)46A;49F*.  
**origin:** Spontaneous in *In(2R)NS*.  
**references:** Mettler, Voelker, and Mukai, 1977, Genetics 87: 169-76.

***In(2R)NS: Inversion (2R) from Nova Scotia***

**cytology:** *In(2R)52A2-B1;56F9-13* (Bridges and Li in Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 292-3).  
**origin:** Naturally occurring inversion.  
**discoverer:** Sturtevant, 13i (as a crossover suppressor).  
**synonym:** *In(2R)A* (Stalker, 1976, Genetics 82: 323-47); *In(2R)C* (Oshima and Watanabe, 1965, DIS 40: 88).  
**references:** Sturtevant, 1919, Carnegie Inst. Washington Publ. No. 278: 305-41.  
 1931, Carnegie Inst. Washington Publ. No. 421: 1-27.  
 Mukai, Watanabe, and Yamaguchi, 1974, Genetics 77: 771-93.  
 Inoue and Watanabe, 1979, Jpn. J. Genet. 54: 69-82.  
**genetics:** Crossing over reduced to about 1.5% between centromere and inversion and to about 0.1% between inversion and tip of chromosome. Includes *Amy* (Mukai *et al.*, 1974).  
**other information:** Found in many natural populations (e.g., Warters, 1944, Texas Univ. Publ. 4445: 129-74; Oshima and Watanabe, 1965, DIS 40: 88; Ashburner and Lemeunier, 1976, Proc. R. Soc. London, B 193: 137-57; Stalker, 1976, Genetics 82: 523-47; Choi, 1977, DIS 52: 88; Mettler, Voelker and Mukai, 1977, Genetics 87: 169-76; Knibb, 1982, Genetika 58: 213-21). Found in most *SD* chromosomes (Watanabe and Oshima, 1970, Genetics 64: 93-106).

***In(2R)PA – In(2R)PF: Inversion (2R) Pipkin***

Craymer, 1981, Genetics 99: 75-97.

1984, DIS 60: 234-36.

**genetics:** Homozygous viable, although it often contains lethals of independent origin.

**other information:** Often associated with *In(3R)P*. Useful as a balancer for *3L*. Allows only about 0.02% crossing over between *ru* and *st*. Balancers contain recessive lethals or *Me*. Balancers for all of chromosome 3 made by combining *In(3L)P* with *In(3R)P* or *In(3R)C*. Found in many wild populations (e.g., Warters, 1944, Texas Univ. Publ. 4445: 129-174; Oshima and Watanabe, 1965, DIS 40: 88; Stalker, 1976, Genetics 82: 323-47; Mettler, Voelker, and Mukai, 1977, Genetics 87: 169-76; Knibb, 1982, Genetics 58: 213-21).

***In(3L)P8: Inversion (3L) Pasadena 8***

**cytology:** *In(3L)63A-C;78F* (Craymer).

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

<i>In(3LR)C267</i> <sup><math>\alpha</math></sup>	74F;88D	
<i>In(3LR)C269</i>	78C;98F	homozygous viable; recombination practically eliminated between <i>st</i> and <i>ca</i>
<i>In(3LR)C334</i> <sup><math>\beta</math></sup>	67E;86D;91F	homozygous lethal; recombination reduced between <i>ve</i> and <i>st</i> and between <i>st</i> and <i>ca</i>

$\alpha$  Originally associated with *T(2;3)C267* (CP627).

$\beta$  new order: 61 - 67E|86D - 67E|91F - 86D|91F - 100.

***In(3LR)CA18***

**cytology:** *In(3LR)80;98B4-8*.

**origin:**  $\gamma$  ray induced.

**discoverer:** Ashburner.

**genetics:** Induced with *In(2LR)noc*<sup>7</sup>.

***In(3LR)CA25***

**cytology:** *In(3LR)61A-B;92B*.

**origin:**  $\gamma$  ray induced; occurred simultaneously with partial loss of *TE35BC-33*.

**discoverer:** Ashburner.

**references:** Gubb, Shelton, Roote, McGill, and Ashburner, 1984, Chromosoma 91: 54-64.

***In(3LR)Cx<sub>D</sub>*: Inversion (3LR) Crossover Suppressor Dichaete**

**cytology:** *In(3LR)71F;85C + In(3LR)80;84A;93F* superimposed on *In(3L)69D3-E1;70C13-D1*.

**new order:**

61A - 69D3|70C13 - 69E1|70D1 - 71F|85C - 84A|80 - 84A|93F - 85C|71F - 80|93F - 100 (Bridges).

**origin:** X ray induced in *In(3L)D*.

**discoverer:** Oliver.

**synonym:** *CxD*; *Dcx*.

**references:** Glass, 1933, J. Genet. 28: 70.

Federova, 1937, Dokl. Acad. Nauk SSSR 14: 135-38.

**genetics:** Carries *D* (separates from other inversions with frequency of 0.2%). Crossing over strongly reduced in chromosome 3 except distal half of 3L; virtually no crossing over between *st* and *e*.

**other information:** Name easily confused with what has been called *C(3)x*, which appears to be *In(3L)P + In(3R)P* (Lewis, 1956, DIS 30: 130).

***In(3LR)Dcx<sub>F</sub>*: Inversion (3LR) Dichaete crossover suppressor of Federova**

**cytology:** *In(3L)62;67* superimposed on *In(3L)69D3-E1;70C13-D1 + In(3LR)71F;85C + In(3LR)80;84A;93F*. From Federova's drawings (1937), there appears to be an inversion from about 62 to 67 in addition to a complex rearrangement, presumably *In(3LR)Cx<sub>D</sub>*.

**new order:**

61 - 62|67 - 62|67 - 69D3|70C13 - 69E1|70D1 - 71F|85C - 84A|80 - 84A|93F - 85C|71F - 80|93F - 100.

**origin:** X ray induced in *In(3LR)Cx<sub>D</sub>*.

**discoverer:** Federova.

**synonym:** *In(3LR)Cx<sub>F</sub>*; *Dcx<sub>F</sub>*; *CxF*, *D*.

**references:** 1937, Dokl. Acad. Nauk SSSR 14: 135-38.

Craymer, 1980, DIS 55: 197-200.

**genetics:** Carries *ru*, *h* and *D*. Crossing over strongly inhibited throughout chromosome 3.

***In(3LR)DI*<sup>KX12</sup> Inversion (3LR) Delta**

**cytology:** *In(3LR)67C-D;91F;92B*.

**new order:**

61 - 67C|91F - 67D|92B-100. Lacks 91F - 92B.

**origin:** X ray induced.

**discoverer:** Vässin.

**references:** Campos-Ortega.

**genetics:** Associated with *DI*.

***In(3LR)dsx*<sup>34</sup>: Inversion (3LR) doublesex**

**cytology:** *In(3LR)71F1-2;84E1-2*. Break near distal edge of 84E1-2.

**origin:** X ray induced in *dsx*<sup>M</sup>.

**discoverer:** Baker, Hoff, Kaufman, Wolfner, and Hazelrigg, 1991, Genetics 127: 125-38.

**synonym:** *In(3LR)dsx*<sup>Mas+R13</sup>.

**genetics:** Revertant of *dsx*<sup>M</sup>.

***In(3LR)dsx*<sup>36</sup>**

**cytology:** *In(3LR)76A5-7;84E1-4*.  
**origin:** X ray induced in *dsx*<sup>M</sup>.  
**discoverer:** Baker, Hoff, Kaufman, Wolfner, and Hazelrigg, 1991, Genetics 127: 125-38.  
**synonym:** *In(3LR)dsx*<sup>Mas+R23</sup>.  
**genetics:** Revertant of *dsx*<sup>M</sup>.

***In(3LR)E(spl)*<sup>rv1</sup>: Inversion (3LR) Enhancer of split-revertant**

**cytology:** *In(3LR)96F-97A,99B*.  
**origin:** X ray induced.  
**references:** Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 62-74.  
**genetics:** Revertant of *E(spl)*.

***In(3LR)f*: Inversion (3LR) free arms**

**origin:** X ray induced as reciprocal translocation between *F(3L)* and *F(3R)*. Replacement of the centromere regions with that of a normal chromosome by double recombination converts the translocation into a pericentric inversion.  
**discoverer:** Craymer, 1981.  
**references:** 1984, DIS 60: 217-18 and 234-36.

<sup>α</sup> Homozygous viable, fertile, and phenotypically wild type.  
<sup>β</sup> Wings may be somewhat flimsy, but otherwise wild type.  
<sup>γ</sup> Subsequently reconstituted as *In(3LR)* by double-crossover centromere replacement from a normal third chromosome.

***In(3LR)fkf*: Inversion (3LR) fork head**

**cytology:** *In(3LR)80;98D2-3*.  
**origin:** X ray induced.  
**references:** Jürgens and Weigel, 1988, Roux's Arch. Dev. Biol. 197: 345-54.  
**genetics:** Weak *fkf* phenotype.

***In(3LR)gv*<sup>U</sup>: Inversion (3LR) grooved**

**cytology:** *In(3LR)69C1-2;81*.  
**origin:** γ ray induced.  
**synonym:** *In(3LR)gs*<sup>U</sup>.  
**references:** Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25.  
**genetics:** Mutant for *gv*. *eyg/gv*<sup>U</sup> flies show *eyg* phenotype; *gv/gv*<sup>U</sup> flies show *eyg* and *gv* phenotype. Homozygous lethal.

***In(3LR)h*<sup>R15</sup>**

**cytology:** *In(3LR)66D14-E1;85B5-C12*.  
**origin:** X ray induced.  
**synonym:** *In(3LR)h*<sup>+15</sup>.  
**references:** Jeffery, 1979, Genetics 91: 105-25.  
 Ingham, Pinchin, Howard, and Ish-Horowitz, 1985, Genetics 111: 463-86.  
**genetics:** Homozygous lethal.  
**molecular biology:** Breakpoint located within cloned region of *h* (Holmgren, 1984, EMBO J. 3: 569-73).

***In(3LR)H159*:** see ***T(Y;3)H159***

***In(3LR)SMG32***

**cytology:** *In(3LR)64F;100F*.

**origin:**  $\gamma$  ray induced.

**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6(4): 165-69.

***In(3LR)st<sup>a27</sup>*: Inversion (3LR) scarlet**

**cytology:** *In(3LR)73A3-4;87D13-14*.

**origin:** X ray induced.

**references:** McKeown, Belote, and Baker, 1987, Cell 48: 489-99.

**discoverer:** Belote and McKeown.

**genetics:** Mutant for *st*.

**molecular biology:** Left-most breakpoint is coordinate 0 of the walk in region 73AB of McKeown and Belote ("+" values to the right, "-" values to the left).

***In(3LR)St*: Inversion (3LR) Stalker**

**cytology:** *In(3LR)77D;88D*.

**origin:** Spontaneous in a natural population.

**references:** Stalker, 1976, Genetics 82: 323-47.

***In(3LR)Sta*: Inversion (3LR) Stigmata**

**cytology:** *In(3LR)79D;94A* (Lewis).

**origin:** X ray induced in *Tp(3;2)P10*.

**discoverer:** E.B. Lewis, 1978.

**references:** Craymer, 1981, Genetics 99: 75-97. 1984, DIS 60: 234-36.

**genetics:** Associated with *Sta*. Homozygote occasionally survives. Gelbart, 1971, Ph.D. Thesis, Univ. of Wisconsin.

***In(3LR)Tl<sup>rv18</sup>*: Inversion (3LR) Toll-revertant**

**cytology:** *IN(3LR)74A;97D*.

**origin:** X ray induced.

**synonym:** *In(3LR)Tl<sup>5BRXV</sup>*.

**references:** Anderson, Jürgens, and Nüsslein-Volhard, 1985, Cell 42: 779-89.

**genetics:** Revertants of the female sterility of *Tl*; trans heterozygotes viable.

***In(3LR)TM1*: Inversion (3LR) Third Multiple**

**cytology:** *In(3L)63C;72E1-2 + In(3LR)69E;91C + In(3R)89B;97D*.

**new order:**

61 – 63C|72E1 – 69E|91C – 97D|89B – 72E2|  
63C – 69E|91C – 89B|97D – 100.

**origin:** Derived from *T(2;3)Melri*, presumably by a double crossover with exchanges in regions 72E2-80 and 81-89B, which replaced the *T(2;3)* breakpoint in 3 with *ri*.

**discoverer:** E. B. Lewis.

**references:** 1949, DIS 23: 92.  
1953, DIS 27: 58.

**genetics:** Carries *Me*, *ri*, and *sbd*<sup>1</sup>.

**other information:** Used as a balancer for chromosome 3, described as *TM1* in the section on balancers.

### *In(3LR)TM3*

**cytology:** *In(3LR)71C;94D-F + In(3LR)76C;93A + In(3LR)79E;100C* superimposed on 3<sup>PX<sup>D</sup></sup> from *T(1;3)IA8-B1;61A1-2 + In(3LR)65E;85E + In(3R)92D1-E1;100F2-3*.

**new order:**

1A1 – 1A8|61A2 – 65E|85E – 79E|100C – 100F2|  
92D1 – 85E|65E – 71C|94D – 93A|76C – 71C|  
94F – 100C|79E – 76C|93A – 92E1|100F3 – 100F5.

**origin:** Induced by repeated irradiation of the 3<sup>PX<sup>D</sup></sup> element of *T(1;3)sc*<sup>260-20</sup>, which carried *In(3LR)sep + In(3R)C, y<sup>+</sup> ri p sep bx*<sup>34e e<sup>s</sup></sup>.

**discoverer:** E. B. Lewis.

**references:** Mitchell, 1958, Cold Spring Harbor Symp. Quant. Biol. 23: 279-90.  
Lewis, 1960, DIS 34: 51.

**other information:** Used as a balancer for chromosome 3, described as *TM3* in the section on balancers.

### *In(3LR)TM6*

**cytology:** *In(3LR)M6 = In(3LR)75C;94A* superimposed on *In(3L)P = In(3L)63B8-11;72E1-2 + In(3LR)P88 = In(3LR)61A1-2;89C2-4 + In(3R)C = In(3L)92D1-E1;100F2-3*.

**new order:**

61A1|89C2 – 75C|94A – 100F2|92D1 – 89C4|  
61A2 – 63B8|72E1 – 63B11|72E2 – 75C|  
94A – 92E1|100F3 – 100F5.

**origin:** X ray induced.

**discoverer:** E. B. Lewis and F. Bacher, 66i.

**genetics:** Homozygous lethal. Deficiency for *ss* but not *bx* associated with *In(3LR)P88*.

**other information:** Used as a balancer for chromosome 3. Described as *TM6* in section on balancers.

### *In(3LR)TM6B*

**cytology:** *In(3LR)M6 = In(3LR)75C;94A* superimposed on *In(3L)P = In(3L)63B8-11;72E1-2 + In(3LR)HR33 = In(3LR)61A1-2;87B2-4 + In(3R)Hu = In(3R)84B1-2;84F4;86C7-8 + In(3R)C = In(3R)92D1-E1;100F2-3*.

**new order:**

61A1|87B2 – 86C6|84F1 – 85C5|84B6 – 84F1|  
84B3 – 75C|94A – 100F2|92D1 – 87B4|61A2 – 63B8|  
72E1 – 63B11|72E2 – 75C|94A – 92E1|100F3 – 100F5.

**references:** Craymer, 1984, DIS 60: 234-36.

**genetics:** Resembles *In(3LR)TM6* except for substitution of *In(3LR)HR33* for *In(3LR)P88* and addition of *Hu*. Usually carries *D*<sup>3</sup> or *Tb* with combinations of *e*, *ca*, *h* and *Hn*<sup>P</sup>.

**other information:** Used as balancer for chromosome 3. Described as *TM6B* in section on balancers.

### *In(3LR)TM6C*

**cytology:** Same as *In(3LR)TM6B* except for absence of *In(3LR)Hu = In(3R)84B1-2;84F4;86C7-8*.

**references:** Craymer, 1984, DIS 60: 234-36.

**genetics:** Homozygotes viable but with development delayed. Stocks may carry *cu* and *Sb* in addition to the *TM6B* markers.

**other information:** Used as balancer for chromosome 3 [less effective for centromere region than *In(3LR)TM6B*]. Described as *TM6C* in section on balancers.

### *In(3LR)TM8*

**origin:** X ray induced in *In(3L)C90 In(3R)C/+* males carrying *l(3)DTS4* in 3L.

**references:** Marsh, 1978, DIS 53: 155-56.

**genetics:** Temperature-sensitive dominant lethal, showing very few viable and fertile escapers from the DTS phenotype.

**other information:** Used as a dominant temperature-sensitive balancer for chromosome 3. Described as *TM8* in the section on balancers.

### *In(3LR)TM9*

**origin:** X ray induced in *In(3L)C90 In(3R)C/+* males carrying *l(3)DTS4* in 3L.

**references:** Marsh, 1978, DIS 53: 155-56.

**genetics:** Temperature-sensitive dominant lethal, showing very few viable and fertile escapers from the DTS phenotype.

**other information:** Used as a dominant temperature-sensitive balancer for chromosome 3. Described as *TM9* in the section on balancers.

*In(3LR)Uab*<sup>4</sup>: see *In(3LR)iab3*<sup>4</sup>

### *In(3LR)Ubx: Inversion (3LR) Ultrabithorax*

**origin:** X ray induced.

**In(3R)bx<sup>d</sup><sup>183</sup>: Inversion (3R) bithoraxoid**

**cytology:** *In(3R)89C;89E*.  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** E.B. Lewis.  
**synonym:** *bx<sup>d</sup>*<sup>17758.83</sup>.  
**genetics:** Mutant for *bx<sup>d</sup>*.

**In(3R)C: Inversion (3R)**

**Crossover suppressor**

**cytology:** *In(3R)92D1-E1;100F2-3* (Bridges and Li in Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301).  
**origin:** Naturally occurring inversion.  
**discoverer:** Sturtevant, 13f.  
**synonym:** *C3, CIIIIE; In(3R)E; In(3R)H*.  
**references:** 1913, Science 37: 990-92. 1917, Proc. Nat. Acad. Sci. USA 3: 555-58. 1926, Biol. Zentr. 46: 697-702. 1931, Carnegie Inst. Washington Publ. No. 421: 1-27. Muller, 1918, Genetics 3: 422-99.  
**genetics:** Homozygous viable. Crossing over in *3R* reduced to 1% between centromere and *ss*, to 0.2% between *ss* and *e*; no crossovers between *e* and tip of *3R* recovered except for rare doubles within inversion.  
**other information:** First inversion demonstrated genetically (Sturtevant, 1926). Used as a balancer for the region from *D1* to *3R* tip. Balancers contain *Sb, e, l(3)a*, or *l(3)e*. Balancer for all of chromosome 3 made by combining with *In(3L)P*. Found in wild populations (e.g., Oshima and Watanabe, 1965, DIS 40: 88; Ashburner and Lemeunier, 1976, Proc. R. Soc. London, B 193: 137-57; Stalker, 1976, Genetics 82: 323-47; Choi, 1977, DIS 52: 88; 1977, Genetica 47: 155-60).

**In(3R)C13 - In(3R)C289**

<sup>β</sup> Chromosome does not usually exhibit 93D puff. Transcription and *in situ* hybridization of 93D sequences occurs outside the inversion.

***In(3R)hb<sup>D1</sup>: Inversion (3R) hunchback-Dominant***

**cytology:** *In(3R)85A;88C-D* (B.S. Baker).  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Bacher.  
**synonym:** *In(3R)Rg-pbx*, *Inversion (3R) Regulator of Post-bithorax* (E.B. Lewis).

**references:** Lewis, 1968, Proc. XII Int. Congr. Genet. 2: 96-97.  
Kiger, 1973, J. Theoret. Biol. 40: 455-67.  
García-Bellido and Lewis, 1976, Dev. Biol. 45: 400-10.  
Bender, Turner, and Kaufman, 1987, Dev. Biol. 119: 418-32.  
**genetics:** Associated with *hb<sup>D</sup>* (= *Rg-pbx*) which shows a variable transformation of the halteres to wing tissue. Homozygous lethal.

***In(3R)hb<sup>D2</sup>***

**cytology:** *In(3R)84B;85A*.  
**origin:**  $\gamma$  ray induced.  
**discoverer:** Posakony.  
**genetics:** Homozygous lethal. Associated with *hb<sup>D2</sup>*. Lethal over *hb*; a few escapers.

*In(3R)hp*: see *In(3R)P*

***In(3R)HR13***

**cytology:** *In(3R)81;98E*.  
**references:** Ashburner, 1972, DIS 49: 34.

***In(3R)Hu: Inversion (3R) Humeral***

**cytology:** Double inversion - *In(3R)84B3-6;84F1-2;86C5-6* (B.S. Baker) or *84B1-2;84F4;86C7-8* (Hazelrigg and Kaufman, 1983).

**new order:**

61A – 84B3|84F1 – 84B6|  
86C5 – 84F2|86C6 – 100 (B.S. Baker).

**origin:** X ray induced.  
**discoverer:** Ruch, 1931.  
**references:** Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33.  
Garber, Kuroiwa, and Gehring, 1983, EMBO J. 2: 2027-36.  
Hazelrigg and Kaufman, 1983, Genetics 105: 581-600.  
Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, Cell 35: 763-76.  
Kuroiwa, Hafen, and Gehring, 1984, Cell 37: 825-31.  
**genetics:** Associated with *Hu*. Homozygotes survive (but at low frequency) until third instar (Hazelrigg and Kaufman, 1983).  
**molecular biology:** Left-most (proximal) breakpoint is the point of initiation (coordinate 0) of the walk of Garber *et al.*, 1983 ("+" values to the left, "-" values to the right) which is about 255 kilobases distal to the 0 coordinate of Scott *et al.*, 1983 ("+" values to the right, "-" values to the left).

***In(3R)iab2<sup>S3</sup>***

**cytology:** *In(3R)89E;93F*.  
**origin:**  $\gamma$  ray induced.  
**discoverer:** Tiong.  
**synonym:** *In(3R)abda<sup>S3</sup>*.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
Tiong, Bone, and Whittle, 1985, Mol. Gen. Genet. 200: 335-42.  
**genetics:** Associated with *iab2*. Homozygous viable and almost wild type; causes partial transformation of second abdominal segment into the first in hemizygotes.  
**molecular biology:** Left breakpoint between 24 and 28 kilobases to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3R)iab4<sup>166</sup>***

**cytology:** *In(3R)79D-E;89E*.  
**origin:** X ray induced in *Mcp*.  
**discoverer:** Von Der Ahe.  
**synonym:** *Mcp<sup>rv31166.1</sup>*.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**genetics:** Associated with *iab4*. *In(3R)iab4/Df(3R)P9* adults show fourth abdominal segment transformed into third; also lack gonads.  
**molecular biology:** Right breakpoint 76-83 kb distal to the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3R)iab6<sup>G</sup>***

**cytology:** *In(3R)89B;89E3-4*.  
**origin:** X ray induced.  
**discoverer:** Gausz.  
**synonym:** *Camel*.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**genetics:** Associated with *iab6<sup>G</sup>*. Heterozygotes have longitudinal furrow on the notum; also a dominant partial *iab5* phenotype. *iab6<sup>G/+</sup>* males lack pigment on fifth tergite and have some bristles on the sixth sternite. *iab6<sup>G/Df</sup>* shows transformations of the fifth, sixth, and seventh segments toward the fourth and a more extensive longitudinal furrow, extending into the abdomen and causing a fusion problem in the tergites.  
**molecular biology:** Right breakpoint 113-121 kilobases to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3LR)iab6<sup>Spth</sup>*: see *In(3LR)iab7<sup>Spth</sup>***

***In(3R)iab7<sup>SGA</sup>***

**cytology:** *In(3R)88C4-7;89E1-2*.  
**origin:** X ray induced.  
**discoverer:** Gyurkovics.  
**synonym:** *SGA62*.  
**references:** Awad, Gausz, Gyurkovics, and Párducz, 1981, Acta Biol. Acad. Sci. Hung. 32: 219-28.  
Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**genetics:** Associated with *iab7*. Recessive transformation of sixth and seventh abdominal segment into fifth. In heterozygotes, shows tumor-like growths of sixth tergite tissue on back of head; also partial transformation of sixth segment into fifth.  
**molecular biology:** Right breakpoint 133-139.5 kb distal to the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3R)iab7<sup>Spth</sup>***

**cytology:** *In(3R)89A;89E*.  
**origin:** X ray induced.  
**discoverer:** Kempfues.  
**synonym:** *In(3R)iab6<sup>Spth</sup>*.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**genetics:** Associated with *iab7*. Recessive transformation of sixth and seventh abdominal segment into fifth. In heterozygotes, shows tumor-like growths of sixth tergite tissue on back of head; also partial transformation of sixth segment into fifth.  
**molecular biology:** Right breakpoint 133 to 139.5 kilobases to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3R)iab9<sup>rvTab</sup>***

**cytology:** *In(3R)89E;90A + In(3R)89E;90D*.  
**new order:**  
 61 – 89E|90A – 90D|90A – 89E|90D – 100.  
**origin:** X ray induced in *In(3R)iab9*.  
**synonym:** *In(3R)Tab<sup>rv107</sup>*.  
**references:** Celniker and Lewis, 1987, Genes and Development 1: 111-23.  
**genetics:** Revertant of the *iab9<sup>Tab</sup>* phenotype. When hemizygous, shows stronger transformation of the eighth ventral setal band toward that of the seventh than does *iab9/Df(3R)P9*; also, abnormal posterior spiracles and a rudimentary ninth ventral setal band.  
**molecular biology:** Lesion associated with the 89E breakpoint lies between 185 and 187 kb on the composite restriction map of the BXC (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, Science 221: 23-29).

***In(3R)iab9<sup>Tab</sup>***

**cytology:** *In(3R)89E;90D*.  
**origin:** X ray induced in *Mcp Sab<sup>2</sup>* chromosome.  
**synonym:** *In(3R)Tab*.  
**references:** Celniker and Lewis, 1984, Genetics 107: s17. Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96. Celniker and Lewis, 1987, Genes and Development 1: 111-23.  
**phenotype:** Associated with *iab9<sup>Tab</sup>*. Homozygous lethal and lethal over *Df(3R)P9*, the embryos showing transformation of segments A8 towards A7 or A6 and A7 towards A6. Also, ninth setal belt appears as group of denticles behind eighth setal belt. *iab9/+* flies show abdominal tissue in two sets of longitudinal stripes on the mesonotum.  
**molecular biology:** Left breakpoint 188 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***In(3R)IC67-79***

**cytology:** *In(3R)85F;97F*.  
**origin:** X ray induced.  
**references:** Brosseau, 1969, DIS 44: 45.  
**genetics:** Homozygous lethal.

***In(3R)IC67-327***

**cytology:** *In(3R)82D;98E*.  
**origin:** X ray induced.  
**references:** Brosseau, 1969, DIS 44: 45.  
**genetics:** Homozygous viable and fertile. Associated with recessive rough eye phenotype.

<sup>α</sup> Deficient for 97E-F.

**In(3R)til: Inversion (3R) tailless**

**cytology:** *In(3R)85F10-86A1;100A6-B1*.

**origin:** X ray induced.

**synonym:** *til*<sup>2</sup>.

**references:** Strecker, Kongswan, Lengyel, and Merriam, 1986, Dev. Biol. 113: 64-76.

**phenotype:** Mutant for *til*. When in heteroallelic combination with *til*<sup>1</sup>, embryos lack telson but have normal eighth abdominal denticle belt and pharyngeal ridges.

**In(3R)Ubx: Inversion (3R) Ultrabithorax**

**genetics:** Associated with *Ubx* alleles.

## RINGS

***R(1)1: Ring (1)***

**cytology:** *R(1)1A;20B-C*; salivary chromosomes show deficiency for most of 1A and a duplication for 20C-D [Schultz and Catcheside, 1937, *J. Genet.* 35: 315-20 (fig.)]. Ring shaped in metaphase.

**new order:**

|1A – 20·20F – 20C|

**origin:** Spontaneous from *C(1)RM*, *y* female.

**discoverer:** L. V. Morgan, 1922.

**synonym:** *X<sup>c</sup>*; *X<sup>0</sup>*.

**references:** 1926, *Proc. Nat. Acad. Sci. USA* 12: 180-81. 1933, *Genetics* 18: 250-83.

**genetics:** Carries *y*. Male and homozygous female have reduced viability; *X/0* male lethal (Schultz, 1941, *Proc. Int. Congr. Genet.*, 7th., pp. 257-62). Somewhat unstable, tending to be eliminated during mitosis. Shows about 5 times as much somatic crossing over as rod *X* (Brown, Walen, and Brosseau, 1962, *Genetics* 47: 1573-79). Crossing over reduced in ring/rod heterozygote; only double crossovers recovered. Exceptional males result from 4-strand double crossing over in *R(1)1/+* female.

**other information:** May open out into a rod [e.g., *In(1)EN*] spontaneously in stock.

***R(1)2***

**cytology:** *R(1)1A3-4;19F-20A1*; salivary chromosomes deficient for 1A1-3 and reported to be duplicated for all of region 20 (Schultz and Catcheside, 1937; Viniika *et al.*, 1971), but duplication was not confirmed by Falk (1973). Ring shaped in metaphase.

**new order:**

|1A4 – 20·20F – 20A1|

**origin:** Spontaneous as a detachment of *C(1)RM*, *y<sup>+</sup>*.

**discoverer:** Beadle, 34b (ring nature discovered by Boche).

**synonym:** *X<sup>c2</sup>*.

**references:** Schultz and Catcheside, 1937, *J. Genet.* 35: 315-20.

Viniika, Hannah-Alava, and Arajärvi, 1971, *Chromosoma* 36: 34-45.

Falk, R, 1973, *DIS* 50: 144-45.

**genetics:** Carries *y<sup>+</sup>*. More viable than *R(1)1*; *X/0* male survives. Ordinarily, ring elimination less than 1% (Battacharya, 1950, *Proc. R. Soc. Edinburgh*, B 64: 199-215; Braver and Blount, 1950, *Genetics* 35: 98), but nearly 20% of the first progeny of 11-day-old females crossed to ring-bearing males are gynandromorphs (Hannah, 1955, *Z. Indukt. Abstamm. Vererbungslehre* 86: 600-21). Number of male nuclei in eggs of gynandromorphs varies greatly, suggesting that loss of the ring *X* may occur more than once and that it may take place as late as the ninth cleavage (Zalokar, 1980, *Cell* 19: 133-41). Crossing over reduced in ring/rod heterozygote; only double crossovers recovered. Exceptional males result from 4-strand double exchange in *R(1)2/+* female.

**other information:** Ring may open out spontaneously in stock [e.g., *In(1)EN2*].

***R(1)5A***

**cytology:** Ring shaped in mitotic figures.

**origin:** Derived from *C(1)TM5A* by meiotic exchange between arms.

**references:** Pasztor, 1967, *DIS* 42: 107.

1971, *Genetics* 68: 245-58.

**genetics:** Mitotically unstable, producing gynandromorphs and *XO* males. Duplication of *X* required for male survival; *R(1)5A/0* and *R(1)5A/Y* males not recovered; however, *R(1)5A*-bearing males survive in combination with *B<sup>S</sup>Y* or *su(f)<sup>+</sup>Y*.

***R(1)9-1***

**cytology:** Ring shaped in mitotic figures. Early prophase shows heterochromatic constitution (proceeding from normally proximal euchromatin, across the centromere to the normally distal euchromatin) to be as follows: a large segment, a well-defined constriction, a large segment, a constriction, a small segment, the centric constriction, a small segment.

**origin:** Regular product of exchange in *C(1)TMB<sup>S</sup>9-1*.

**references:** Lindsley and Sandler, 1965, *Genetics* 51: 223-45 (fig.).

**genetics:** Carries *y*. *R(1)9-1/0* male survives. On basis of origin, *R(1)9-1* is euchromatically but not heterochromatically identical with *R(1)1*.

***R(1)9-4***

**cytology:** Ring shaped in mitotic figures. Early prophase shows heterochromatic constitution (proceeding from normally proximal euchromatin, across the centromere to the normally distal euchromatin) to be as follows: a large segment, a constriction, a small segment, the centric constriction, a small segment.

**origin:** Regular product of exchange in *C(1)TMB<sup>S</sup>9-4*.

**references:** Lindsley and Sandler, 1965, *Genetics* 51: 223-45 (fig.).

**genetics:** Carries *y*. *R(1)9-4/0* male viable. Based on origin, *R(1)9-4* euchromatically but not heterochromatically identical with *R(1)1*.

***R(1)63***

**cytology:** Ring shaped in mitotic figures. Early prophase shows heterochromatic constitution (proceeding from the normally proximal euchromatin, across the centromere to the normally distal euchromatin) to be as follows: two large segments separated by an ill-defined constriction, a constriction, a small segment, the centric constriction, a small segment.

**origin:** Regular product of exchange in *C(1)TM2*.

**references:** Lindsley and Sandler, 1965, *Genetics* 51: 223-45 (fig.).

**genetics:** Carries *y*. *R(1)63/0* male survives. Based on origin, *R(1)63* is euchromatically but not heterochromatically identical with *R(1)1*; however, survival of *R(1)63/0* males suggests otherwise.

***R(1)94-2A1***

**cytology:** *R(1)1A;1F-2A;5E-6A;17F-18A;20*; duplicated for 1A-F and 18A-20.

**new order:**

|1A – 5E|1F – 1A|20·20 – 6A|18A – 20|

**origin:** Spontaneous product of *C(1)94-2A*. Possibly a product of breakage of double second-anaphase bridge formed by exchange between the arms of the compound.

**discoverer:** Armentrout, 1964.

**\*R(1)C1**

**cytology:** Ring shaped in mitotic figures.  
**origin:** Spontaneous derivative of *In(1)sc*<sup>8L</sup>*EN*<sup>R</sup>; arose by recombination between distal heterochromatic segment of *In(1)sc*<sup>8</sup> and heterochromatic short arm of *In(1)EN*.  
**discoverer:** Lindsley, 1950.  
**references:** 1958, Z. Indukt. Abstamm. Vererbungsl. 89: 103-22.  
**genetics:** Carries *y*. On basis of origin, *R(1)C1* is euchromatically identical with *R(1)I*, but it must be different heterochromatically since *R(1)C1/0* male viable.

**R(1)Ddc<sup>+</sup>**

**cytology:** *R(1)IA3-4;19F-20A1 In(1)3C1-2;20F + Ddc<sup>+</sup>* insert (near *sn*).  
**origin:** Double crossover between *R(1)2*, *In(1)w<sup>vc</sup>* and rod-X chromosome with *P*-element mediated *Ddc<sup>+</sup>* insert.  
**synonym:** *Ddc<sup>+</sup>-Ring-X*.  
**references:** Gailey, Bordne, Vallés, Hall, and White, 1987, Genetics 115: 305-11.  
**genetics:** Shows instability characteristic of *R(1)2*, *In(1)w<sup>vc</sup>*. Used to generate *Ddc* mosaics.

**R(1)I-v459**

**cytology:** *R(1)3D-F*.  
**origin:** Associated with *T(1;2;3)I-v459*.

**R(1)y<sup>4</sup>: Ring (1) yellow**

**cytology:** *R(1)IA8-B1;18A3-4*; deficient for 1A and duplicated for 18-20.  
**new order:** |1B1 – 20·20 – 18A4|  
**origin:** Regular product of exchange within inversion in *C(1)SB*; which is a *C(1)RM* heterozygous for *In(1)y<sup>4</sup>* = *In(1)IA8-B1;18A3-4*.  
**discoverer:** Sturtevant and Beadle.  
**references:** 1936, Genetics 21: 554-604.  
 Novitski and Sandler, 1956, Genetics 41: 194-206.  
**genetics:** Deficient for loci distal to *y*, duplicated for *car-bb*. Heterozygous female survives; male lethal, owing to deficiency for *l(1)IA* loci.

**R(1;Y)EN**

**cytology:** Complete *X* and *Y* chromosomes joined together in a ring.

**origin:** X-ray-induced exchange in tandem metacentric carrying a normal *X* attached to one *Y* arm and an inverted *X* to the other arm without loss of *Y* fertility factors.

**synonym:** *C(1;Y)R, EN*.

**references:** Fowler, 1971, DIS 46: 74.

Novitski and Childress, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 487-503.

Novitski and Puro, 1978, DIS 53: 205.

**genetics:** Filicidal except in certain genetic backgrounds. Not obviously unstable. Neither the *X* nor the *Y* in the ring lack any essential viability or fertility genes.

**R(Y)**

Described in section on *Y* derivatives.

*R(2)Bl*: see *Dp(2;f)Bl*

*R(2)rl<sup>+</sup>*: see *Dp(2;f)rl<sup>+</sup>*

**R(3)S1: Ring (3) Synthetic**

**cytology:** Ring shaped in mitotic figures. Duplicated for 89C-92D and deficient for terminal chromatin of 61A and 100F.

**new order:** |61A – 100F|92D – 89C|

**origin:** Synthesized from *In(3LR)P88 + In(3R)C* and a structurally normal *3* by crossing over in both the 61-89 and the 92E-100F region.

**references:** Craymer, 1984, DIS 60: 80-81.

**genetics:** Duplication of 89C-92D compensated by *Df(3R)P47 = Df(3R)89D;92A; R(3)S1/Df(3R)P47* flies have minor phenotypic abnormalities and are sterile or nearly so; a few fertile crosses carrying *Df(3R)P47* in the ring are fertile.

**other information:** Ring useful for inserting markers into *In(3R)C*.

**R(3L)**

**cytology:** Ring involving all of *3L*.

**origin:** Byproduct of synthesis of *3R3L.3R* chromosome by X ray.

**references:** Novitski and Puro, 1978, DIS 53: 205.

TRANSLOCATIONS

**\*T(1;?)sc<sup>260-23</sup>: Translocation (1;?) scute**

**cytology:** T(1;?)1B2-3; position of second break not determined.

**origin:** X ray induced.

**discoverer:** Sutton, 1939.

**references:** 1943, Genetics 28: 210-17.

**genetics:** Mutant for *sc* but not *y* or *svr*.

**T(1;Y)**

**Table I:** Translocations with breaks in X euchromatin.

**cytology:** X breaks based on salivary analysis (exceptions indicated in notes); Y breaks based on genetic data.

**origin:** X ray induced. Translocations with unlettered designations induced by Nicoletti; those with lettered designations F, G and P-W (except P12) induced by Kennison; the remainder induced by Merriam and colleagues.

**genetics:** Male viability and fertility indicated in table.

<sup>α</sup> 1 = Merriam; 2 = Merriam, Yamamoto, Stewart, Rahman, and Nicholau; 3 = Nicoletti and Lindsley, 1960, DIS 34: 95-97; 4 = Nicoletti and Lindsley, 1960, Genetics 45: 1705-22; 5 = Stewart and Merriam, 1973, DIS 50: 167-69; 6 = Stewart and Merriam, 1975, Genetics 79: 635-47; 7 = Young and Judd, 1978, Genetics 88: 723-42; 8 = Zhimulev, Belyaeva, Pokholkova, Kochneva, Fomina, Bgatov, Khudyakov, Patzевич, Semeshin, Baricheva, Aizenzon, Kramers, and Eeken, 1981, DIS 56: 192-96.

<sup>β</sup> New order:  
 $T(1;Y)2 = 1 - 5E|YS^P - YL;$   
 $20 - 19F|11F - 5E|19F - 11F|YS^D.$   
 $*T(1;Y)9 = 1A - 2C|YS^P - YL;$   
 $20 - 19F|2C - 19F|YS^D.$   
 $*T(1;Y)290 = 1A|YS^P - YL;$   
 $20F - 20A|1A - 20A|YS^D.$

<sup>γ</sup> 3C break between *N* and *dm* (Young and Judd, 1978).  
<sup>δ</sup> Variiegates for *w* and *N* (Nicoletti and Lindsley, 1960).  
<sup>ε</sup> Break locations inferred from crosses to deletions or lethals.

<sup>ζ</sup> Molecular biology: *T(1;Y)B55* maps between +33.4 and +34.9 kb and *T(1;Y)W32* maps between +95.2 and +98.7 kb (Kamb, Iverson, and Tanouye, 1987, Cell 50: 405-13). These and *T(1;Y)V7* display leg shaking owing to their disruption of the *Sh* locus (Tanouye, Ferrus, and Fujita, 1981, Proc. Nat. Acad. Sci. USA 78: 6548-52).

**Table II:** Translocations with breaks in X heterochromatin.

**cytology:** Breakpoints on the cytogenetic map of the *Y* (Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73) and the *X* heterochromatin (Gatti and Pimpinelli, unpublished) inferred from the cytogenetic data of Kennison (1981, Genetics 98: 529-48) or, in a few cases, determined by Bonaccorsi. *X* breakpoints designated *h26-h29* are distal to *bb*, those designated *h29* are within *bb* and those designated *h29-h33* are proximal to *bb*. *Y* breaks between *B<sup>S</sup>Xh* and *h17* are in *YL*; those between *h18* and *Xhy<sup>+</sup>* are in *YS* with *bb* occupying *h20*.

**origin:**  $\gamma$  ray induced using *B<sup>S</sup>Yy<sup>+</sup>*.

**discoverer:** Kennison.

**genetics:** Male viable. Fertility of males indicated in table.

$\alpha$  The heterochromatic proximal part of the X has been divided by Gatti into 9 sections, *h26-h34*, distinguishable in neuroblast chromosomes by special staining techniques; the heterochromatic Y had previously been divided (Gatti and Pimpinelli, 1983) into 25 sections, *h1-h25*. The normal position of the X centromere is at *h33-h34* and of the Y centromere at *h17-h18*.

**cytology:** *T(1;Y;3)h29-h30;h11-12;75F-76A* (*Y* breaks from Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73).  
**new order:**  
 1 – h29|h12 – Xhy<sup>+</sup>;  
 h34 – h30|76A – 61;  
 XhB<sup>S</sup> – h11|76A – 100.  
**origin:**  $\gamma$  ray induced in *B<sup>S</sup>Yy<sup>+</sup>*.  
**references:** Kennison, 1981, Genetics, 98: 529-48.  
 Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.  
**genetics:** Male viable and fertile.

**T(1;Y;3)W27**

**cytology:** *T(1;Y;3)h29-h30;h9-h10;91A + In(Y)h10;h20* (*Y* breaks from Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73).  
**new order:**  
 1 – h29|h20 – h10|h20 – Xhy<sup>+</sup>;  
 h34 – h30|91A – 100;  
 XhB<sup>S</sup> – h9|91A – 61.  
**origin:**  $\gamma$  ray induced in *B<sup>S</sup>Yy<sup>+</sup>*.  
**references:** Kennison, 1981, Genetics, 98: 529-48.  
 Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.  
**genetics:** Male viable and fertile. Males carrying *3R<sup>P</sup>Y<sup>D</sup>* and *X<sup>P</sup>3R<sup>D</sup>* from *T(1;Y;3)W27* and *Y<sup>P</sup>X<sup>D</sup>* from *T(1;Y)E15* are deficient for *kl-2* and flanking sequences (Hardy *et al.*, 1984).

**T(1;Y;4)116**

**cytology:** *T(1;Y)14D;YS + T(1;4)9C;101*.  
**new order:**  
 1 – 9C|101;  
 20 – 14D|YS<sup>D</sup>;  
 YL – YS<sup>P</sup>|14D – 9C|102.  
**origin:** X ray induced in *B<sup>S</sup>Y*.  
**discoverer:** Nicoletti.  
**references:** Nicoletti and Lindsley, 1960, Genetics 45: 1705-22.  
 1960, DIS 34: 95-97.  
**genetics:** Male viable and sterile.

**T(1;Y;4)B<sup>S</sup>: Translocation (1;Y;4) Bar of Stone**

**cytology:** A derivative of *T(1;4)B<sup>S</sup>* in which the X centromere has been replaced by a Y chromosome whose other arm (presumably YL) is derived from *y<sup>+</sup>Y*.  
**references:** Novitski and Peacock, 1970, DIS 45: 95-96.  
**genetics:** Males are viable with low fertility.

**T(1;Y;A)V63**

**cytology:** *T(1;Y;A)h26-h29;h11-12;A* (*Y* breaks from Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73).  
**new order:**  
 1 – h26|h12 – Xhy<sup>+</sup>;  
 h34 – h29|A<sup>D</sup>;  
 XhB<sup>S</sup> – h11|A<sup>P</sup>.  
**origin:**  $\gamma$  ray induced in *B<sup>S</sup>Yy<sup>+</sup>*.  
**references:** Kennison, 1981, Genetics, 98: 529-48.  
 Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.  
**genetics:** Male viable and fertile.

**T(1;2)1.10**

**cytology:** *T(1;2)4A3-4;24B*.  
**origin:** X ray induced.  
**discoverer:** Nüsslein-Volhard.  
**synonym:** *T(1;2)odd<sup>1.10</sup>*.  
**references:** Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.  
**genetics:** Male fertile. Second-chromosome breakpoint between *odd* and *slp*; neither gene mutant. The crossing scheme described should not have yielded X-autosome translocations.

**T(1;2)2A4**

**cytology:** *T(1;2)11B;33E*.  
**origin:** Induced by ethyleneimine.  
**references:** Lim and Snyder, 1968, Mutat. Res. 6: 129-37.

**\*T(1;2)7**

**origin:** X ray induced.  
**discoverer:** Bonner, 1931.  
**references:** Dobzhansky, 1935, Z. Indukt. Abstamm. Vererbungsl. 68: 134-62.  
**genetics:** X broken between *rb* and *cv*; chromosome 2 to the right of *sp*. Male and heterozygous female viable and fertile; homozygous female poorly viable and sterile. *X<sup>P</sup>2<sup>D</sup>* recoverable as an aneuploid segregant that is duplicated for the loci of *y* through *rb* but is not demonstrably deficient for 2R markers; nothing written to indicate that it is deficient for *M(2)c*.

*T(1;2)26*: see *Tp(1;2)26*

**T(1;2)27A2**

**cytology:** *T(1;2)8E;57B*.  
**origin:** Induced by ethyleneimine.  
**references:** Lim and Snyder, 1968, Mutat. Res. 6: 129-37.

*T(1;2)63i*: see *Tp(1;2)v<sup>+</sup>63i*

*T(1;2)65b*: see *Tp(1;2)v<sup>65b</sup>*

**\*T(1;2)106**

**origin:** X ray induced.  
**discoverer:** Sturtevant, 1930.  
**genetics:** Break in X chromosome near centromere to right of *f*; break in chromosome 2 near centromere, probably in 2L. Male fertile; homozygous female viable and fertile.

Crossing over and disjunction for both chromosomes *X* and 2 normal in *T(1;2)106/+* female. *T(1;2)106/+Y* female shows nondisjunction of *X*'s.

**\**T(1;2)271b***

**cytology:** *T(1;2)3C3-7;40*; inferred from figs. 15A, G, and H of Mackensen (1935).

**origin:** X ray induced.

**discoverer:** Patterson.

**synonym:** *Df(1)Del271b*.

**references:** 1932, Am. Nat. 66: 193-206.

Mackensen, 1935, J. Heredity 26: 163-74 (fig.).

**genetics:** Mutant for *N*.

***T(1;2)429.44***

**cytology:** *T(1;2)2B12-14;30B1-2*.

**discoverer:** Gelbart.

***T(1;2)A18***

**cytology:** *T(1;2)2A4;60E8-9*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Mutant for *br*.

**\**T(1;2)A61b***

**cytology:** *T(1;2)15F*; breakpoint in chromosome 2 at unknown position in left arm, which also carries an inversion. Breakpoint in *X* inferred from fig. 17G of Mackensen (1935).

**references:** Mackensen, 1935, J. Heredity 26: 163-74 (fig.).

**genetics:** Mutant for *f*.

***T(1;2)A64***

**cytology:** *T(1;2)2B7;42*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Mutant for *br*.

*T(1;2)A1125*: see *Tp(1;2)rb<sup>+</sup>71g*

**\**T(1;2)B<sup>48g</sup>*: Translocation (1;2) Bar**

**cytology:** *T(1;2)15F-16A1;33B* superimposed on *In(1)1B3-4;19F-20C1*.

**new order:**

1A1 - 1B3|19F - 16A1|33B - 60;

20F - 20C1|1B4 - 15F|33B - 21.

**origin:** X ray induced in *In(1)sc<sup>4</sup>*.

**discoverer:** Yu, 48g.

**genetics:** Position effect at *B*. Male sterile.

***T(1;2)B<sup>bd</sup>*: Translocation (1;2) Bar-baroid**

**cytology:** *T(1;2)16A1-2;48C2-3* + *In(2R)41A;47A* (Bridges in Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 291).

**new order:**

1 - 16A1|48C2 - 47A|41A - 47A|41A - 21;

20 - 16A2|48C3 - 60.

**origin:** X ray induced simultaneously with *In(2R)41-47*.

**discoverer:** Dobzhansky, 31b5.

**references:** 1932, Genetics 17: 369-92.

**genetics:** Recessive position effect for *B*. Translocation and inversion probably not separable.

***T(1;2)B27***

**origin:** Induced in a *Sh<sup>14</sup>* chromosome.

**references:** Baumann, Krah-Jentgens, Müller, Müller-Holtkamp, Seidel, Kecskemethy, Casal, Ferrus, and

Pongs, 1987, EMBO J. 6: 3419-29.

**genetics:** Associated with modified *Sh* phenotype.

**molecular biology:** Maps between 42 and 43 kb proximal to the start site of the *Sh* chromosomal walk.

***T(1;2)Ba<sup>18</sup>*: Translocation (1;2) Brista (J. Kennison)**

**cytology:** *T(1;2)3C3-7;60D-E* (J. Kennison).

**origin:** Spontaneous.

**discoverer:** Williams.

**synonym:** *Art; Dll<sup>w</sup>; Ba<sup>w</sup>*.

**references:** Cohen, Bronner, Küttner, Jürgens, and Jackle, 1989, Nature 338: 432-34.

**molecular biology:** 60D-E located on molecular map (Cohen et al., 1989).

**genetics:** Associated with *Ba<sup>18</sup>*. *2<sup>P</sup>X<sup>D</sup>* element is duplicated for the loci of *y* and *w*, deficient for *M(2)60E* and *Kr* and has the dominant *Ba* phenotype.

***T(1;2)bi<sup>D2</sup>*: Translocation (1;2) bifid**

**cytology:** *T(1;2)4C5-6;46B5-7*.

**origin:** X ray induced.

**references:** Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, Chromosoma 93: 341-46.

**genetics:** Associated with *bi*, *Qd*, and *omb*. Male lethal.

***T(1;2)Bld*: Translocation (1;2) Blond**

**cytology:** *T(1;2)1C3-4;60B12-13* + *In(2R)42A2-3;58A4-B1*.

**new order:**

1A - 1C3|60B12 - 58B1|42A3 -

58A4|42A2 - 21;

20 - 1C4|60B13 - 60F5.

**origin:** Spontaneous in *In(2R)Cy*.

**discoverer:** Burkart, 1930.

**references:** 1931, Rev. Fac. Argon. Vet. Univ. Buenos Aires 7: 393-491.

Burkart and Stern, 1933, Z. Indukt. Abstamm. Vererbungsl. 64: 310-25.

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

Morgan, Bridges, and Schultz, 1938, Year Book - Carnegie Inst. Washington 37: 307.

Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**genetics:** Associated with *Bld*. Both aneuploid segregants survive. The *2<sup>P</sup>X<sup>D</sup>* element is duplicated for *y*, *ac*, *sc*, *Hw*, *svr*, *su(s)*, *l(1)1Ab*, *su(b)*, and *M(1)1B* and deficient for *sp*, *bs*, *ba*, *Pin*, and *M(2)60E*; heterozygote extreme Plexate and slight Minute with small dark body and slow development; viability low; male sterile; female slightly fertile. *X<sup>P2D</sup>* is reciprocally duplicate deficient; heterozygous female Blond and extreme Minute [*M(1)1B*] with short, broad, occasionally downward-curved wings; ecloses 3-4 days late; male lethal, with embryos showing no organized ventral nerve cord structure but only some cell clusters in the brain lobes (Jiménez and Campos-Ortega, 1979, Nature 282: 310-12).

***T(1;2)C*: Translocation (1;2) Crossover suppressor**

**origin:** X ray induced; selected on the basis of reduced recombination in one chromosome arm.

**discoverer:** Roberts, 1964, 1965.

references: 1970, Genetics 65: 429-48.

**cytology:** T(1;2)20A-B;27-28.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Allele of l(1)20Ac.

**T(1;2)GEM224**

**cytology:** T(1;2)11A4;11C3;40-41.

**new order:**

1 - 11A4|11C3 - 11A4|41 - 60;  
21 - 40|11C3 - 20.

**discoverer:** Lefevre.

**genetics:** Mutant for fw (Kulkani and Hall, 1987, Genetics 115: 461-75).

**T(1;2)GF326**

**cytology:** T(1;2)1D4;36C.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Allele of l(1)1Dc.

**T(1;2)gl<sup>+</sup>: Translocation (1;2) giant larvae-wild type**

**cytology:** 21A1-C1 [location of l(2)gl] translocated to X tip.

**references:** Cline, 1976, Genetics 83: s16.

**T(1;2)HA37**

**cytology:** T(1;2)3A4;32A1-2.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Allele of l(1)3Ac.

**\*T(1;2)HC221**

**cytology:** T(1;2)2B11;22B.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Hemizygous lethal. Wild type over dor mutant; lethal over dor<sup>25</sup> (Lefevre).

**T(1;2)HC282**

**cytology:** T(1;2)2C1-2;32B.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Not covered by Dp(1;3)w<sup>vco</sup> or y<sup>2</sup>Y67g (Lefevre).

**T(1;2)HF326**

**cytology:** T(1;2)3C7;27E.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. N allele.

**T(1;2)HG370**

**cytology:** T(1;2)3E3-4;A (complex).

**origin:** X ray induced.

**discoverer:** Lefevre.

genetics: Male lethal. Allele of *slc*.

***T(1;2)Hw<sup>bap</sup>*: Translocation (1;2)  
Hairy-wing-bristly  
abdominal pleura**

cytology: *T(1;2)1B;21B* (Cline, 1984).

discoverer: Cline.

references: Roseland and Schneiderman, 1979, Wilhelm Roux's Arch. Dev. Biol. 186: 235-65.

Cline, 1984, Genetics 107: 231-77.

 $\gamma$  Male hyperploid for *X<sup>P</sup>2L<sup>D</sup>* element survives.  
 $\delta$  New order: 1A|41 - 30B|4B - 1A|41 - 60; 20 - 14B|12D - 14B|12D - 4B|30B - 21.

**\**T(1;2)Sy: Translocation (1;2) Stubby***

**origin:** Spontaneous.  
**discoverer:** Ives, 34j31.  
**genetics:** Associated with *Sy*. Male sterile. Probably reciprocal translocation with breaks near the base of *X* and *2L*.

***T(1;2)TE35A-217: Translocation (1;2) Transposing Element***

**cytology:** *T(1;2)20;35A-B*.  
**origin:**  $\gamma$  ray induced in *TE35A*.  
**discoverer:** Samkange (Ashburner's lab).  
**synonym:** *T(1;2)TE146-217*.

**\**T(1;2)v*<sup>267-4</sup>**

**cytology:** *T(1;2)11A7-8;36* (Sutton).  
**origin:** X ray induced.  
**discoverer:** Hoover, 35i.  
**genetics:** Mutant for *v* (breakpoint not at *v* locus). Semi-lethal. *ras*, *dwx*, *sbr*, *m*, *dy*, and *fw* not affected.

***T(1;2)V: Translocation (1;2) Valencia***

**origin:** X ray induced.  
**references:** Valencia, 1970, DIS 45: 37.

translocation	cytology	genetics
<i>T(1;2)V9-2</i>	6A2-3;38F	male sterile
<i>T(1;2)V11-2</i>	20;40-41	male fertile, homozygous viable
<i>T(1;2)V12-1</i>	11E-F;25C-D	male sterile
<i>T(1;2)V12-2</i>	12C9;40-41A	male sterile
<i>T(1;2)V101</i>	20A(C-D?);60F5	male sterile
<i>T(1;2)V153</i>	20A3-4;56F5	male sterile
<i>T(1;2)V154</i>	12A3;40-41	lethal
<i>T(1;2)V161</i>	8B4;40	lethal

**T(1;2)VE614**

**cytology:** *T(1;2)7B1-2;2L*.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Lefevre and Leeds, 1983, *Genetics* 104: s45-46.  
**genetics:** Shows strong *kf*<sup>2</sup> phenotype but has no *ct* effect.

**T(1;2)VE715**

**cytology:** *T(1;2)19E;27A*.  
**origin:** X ray induced.  
**discoverer:** Lefevre.  
**genetics:** Male lethal. *unc* allele.

**T(1;2)VE901**

**cytology:** *T(1;2)2B;25E-F*.  
**origin:** X ray induced.  
**discoverer:** Lefevre.  
**genetics:** Male lethal. Mutant for *br*.

**\*T(1;2)w<sup>13G2</sup>: Translocation (1;2) white**

**cytology:** *T(1;2)3C3-5;41;56F*; also inversion in 2R.  
**new order:**  
 1 – 3C3|41 – 56F|41 – 21;  
 20 – 3C5|56F – 60.  
 Probable.  
**origin:** X ray induced.  
**discoverer:** Gans.  
**genetics:** Variegated for *w*.

*T(1;2)w<sup>64d</sup>*: see *Tp(1;2)w-ec*

**T(1;2)w<sup>70k18.1</sup>**

**cytology:** *T(1;2)3C1;12B2-9;39E2*.  
**new order:**  
 1 – 3C1|39E3 – 60;  
 21 – 39E2|12B2 – 3C2|12B9 – 20.  
**origin:** X ray induced in *In(1)z<sup>64b9</sup>*.  
**references:** Sorsa, Green, and Beermann, 1973, *Nature* (London) *New Biology* 245: 34-37.  
**genetics:** Male viable with white eyes.

*T(1;2)w<sup>+51b7</sup>*: see *T(1;2)51b*

**\*T(1;2)w<sup>m53e</sup>: Translocation (1;2) white-mottled**

**cytology:** *T(1;2)3C3-4;20A2-3;58F8-59A1*.  
**new order:**  
 1 – 3C3|58F8 – 21;  
 20F – 20A3|3C4 – 20A2|59A1 – 60.  
**origin:** Neutron induced.  
**discoverer:** Mickey, 53e11.  
**synonym:** *T(X-2)In<sup>X and 3</sup>*.  
**references:** 1963, *DIS* 38: 29.  
**genetics:** Variegated for *w*.

**\*T(1;2)w<sup>m258-34</sup>**

**cytology:** *T(1;2)3C3-5;41A* (Demerec and Hoover).  
**origin:** X ray induced.  
**discoverer:** Demerec, 38b.  
**genetics:** Variegated for *w* but not *rst*, *fa*, or *dm*. Male viable.

**\*T(1;2)w<sup>m258-36</sup>**

**cytology:** *T(1;2)3C6-7;41A-B + T(1;2)4C2-3;41F5-6*.  
**new order:**  
 1 – 3C6|(41B – 41F5)|4C3 – 20;  
 21 – 41A|(3C7 – 4C2)|41F6 – 60.

Insertions said to be in inverted order but not specified with respect to centromere or numerical order.

**origin:** X ray induced.

**discoverer:** Demerec, 38b.

**references:** Sutton, 1940, *Genetics* 25: 534-40 (fig.).

**genetics:** Variegated for *w* and *rst* but not *pn*, *fa*, or *dm*. Male viable. Cytology predicts that each element of the translocation should survive as aneuploid but not so recorded.

**\*T(1;2)w<sup>m258-37</sup>**

**cytology:** *T(1;2)3C3-4;40-41A* (Sutton).

**origin:** X ray induced.

**discoverer:** Demerec, 33j.

**genetics:** Variegated for *w* but not *kz*, *rst*, *fa*, or *dm*.

**\*T(1;2)w<sup>m258-39</sup>**

**cytology:** *T(1;2)3C3-5;40E-F* (Demerec and Hoover).

**origin:** X ray induced.

**discoverer:** Demerec, 38e.

**genetics:** Variegated for *w* but not *pn*, *rst*, *fa*, or *dm*. Male viable.

**\*T(1;2)w<sup>m258-40</sup>**

**cytology:** *T(1;2)3C3-5;41* (Demerec and Hoover).

**origin:** X ray induced.

**discoverer:** Demerec, 38e.

**genetics:** Variegated for *w* and *rst* but not *pn*, *kz*, *fa*, or *dm*.

**\*T(1;2)w<sup>MD1</sup>: Translocation (1;2)**

**white-mottled of Dubinin**

**cytology:** *T(1;2)3B;19-20;21F*.

**new order:**

1 – 3B|21F – 60;  
 20|3B – 19|21F – 21A.

**origin:** X ray induced.

**discoverer:** Dubinin.

**references:** Sacharov, 1936, *Biol. Zh. (Moscow)* 5: 293-302.

**\*T(1;2)w<sup>VD4</sup>: Translocation (1;2)**

**white-variegated of Demerec**

**cytology:** *T(1;2)3D6-E1;40F* (Schultz).

**origin:** X ray induced.

**discoverer:** Demerec, 33k2.

**genetics:** Variegated for *N*, *rst*, *w*, and *dm*. *X/Y* male survives only rarely as *rst* with mottled eye color; *X/Y/Y* male more viable, slightly *rst*, and sterile. Variegation for *lt* in *X/X/Y* female.

*T(1;2)(w-ec)<sup>64d</sup>*: see *Tp(1;2)w-ec*

*T(1;2)w-ec*: see *Tp(1;2)w-ec*

**T(1;2)X9<sup>ts</sup>**

**cytology:** *T(1;2)2D1-2;56A1-2*.

**origin:**  $\gamma$  ray induced.

**references:** Kaufman and Suzuki, 1974, *Can. J. Genet. Cytol.* 16: 579-92.

**genetics:** Male fertile. Associated with temperature-sensitive lethal in males. *X/X* females and *X/w<sup>+</sup>Y* males are viable and normal at 22° and 29°; *X/Y* males at 29° are lethal or show escaper phenotype of net-like wing veins, etched abdominal tergites, and sexcombs on meso- and metathoracic legs.

**\*T(1;2)y<sup>260-13</sup>: Translocation (1;2) yellow**

**cytology:** *T(1;2)1A4-5;36D*.  
**origin:** X ray induced.  
**discoverer:** Sutton, 1939.  
**references:** 1943, *Genetics* 28: 210-17.  
**genetics:** Mutant for *y*.

**T(1;2)y<sup>A76b37</sup>**

**cytology:** *T(1;2)1B1-2;60F*.  
**origin:**  $\gamma$  ray induced.  
**references:** Alexandrov, Ankina, and Alexandrova, 1985, *DIS* 61: 212-13.  
**genetics:** Mutant for a *y*<sup>ca</sup>-like allele.

**T(1;2)y<sup>A79d</sup>**

**cytology:** *T(1;2)1A6-B2;23E5*.  
**origin:** Neutron induced.  
**references:** Alexandrov, Ankina, and Alexandrova, 1985, *DIS* 61: 212-13.  
**genetics:** Mutant for *y*.

**T(1;2)y<sup>R7</sup>**

**cytology:** *T(1;2)1A6-B1;49F*.  
**origin:** X ray induced.  
**references:** Roberts, 1974, *Mutat. Res.* 22: 139-44.  
**genetics:** Body color yellow. Male viable but sterile.

**\*T(1;2)y<sup>v1</sup>: Translocation (1;2) yellow-variegated**

**cytology:** *T(1;2)1A;39*.  
**origin:** X ray induced.  
**discoverer:** Schultz, 33a11.  
**genetics:** Variegated for *y*.

**T(1;2)z<sup>+</sup>: Translocation (1;2) zeste-wild type**

**origin:** X-ray-induced rearrangements in *z*-bearing X chromosomes that interfere with the *z-w* interaction.  
**genetics:** *z*<sup>+</sup> phenotype.

 20 - 3C3|54B - 41B|54C - 60.

**T(1;2)ZWD1**

**cytology:** *T(1;2)3C2-5;45C*.  
**origin:**  $\gamma$ -ray-induced.  
**references:** Smolik-Utlaut and Gelbart, 1987, *Genetics* 116: 285-98.  
**genetics:** Moles *w*<sup>+</sup> and sterile.

**T(1;2)ZWD12**

**cytology:** *T(1;2)2A;3C1-2;221A;22A;43F*.  
**origin:**  $\gamma$ -ray-induced.  
**references:** Smolik-Utlaut and Gelbart, 1987, *Genetics* 116: 285-98.  
**genetics:** Moles *w*<sup>+</sup> and sterile.

**\*T(1;2;3)58i**

**origin:** X ray induced.  
**discoverer:** Imazumi.  
**references:** 1961, *DIS* 35: 87-88.  
 1962, *DIS* 36: 80.  
 1962, *Cytologia* 27: 212-28 (fig.).  
**genetics:** Distal one-third of 2L appended to X chromosome as short arm. Also *T(2;3)* with 2R broken between *cn* and *vg* and 3L broken between *se* and *st*. Male lethal in embryo.

**\*T(1;2;3)100r20**

**cytology:** *T(2;3)35B2-3;40;80* superimposed on *Dp(1;3)3B4-C1;4B4-5;80*.  
**new order:**  
 21 - 35B2|4B4 - 3C1|80 - 100;  
 60 - 40|35B3 - 40|80 - 61.  
**origin:** X ray induced in *Dp(1;3)N<sup>264-100</sup>*.  
**discoverer:** Gersh, 1959.  
**synonym:** *\*T(2;3)100r20*.  
**references:** 1959, *Genetics* 44: 163-72.  
**genetics:** Selected as a partial reversion from white-mottled.

**T(1;2;3)220**

**cytology:** *T(1;2;3)14A;50A;75C*.  
**new order:**  
 1 - 14A|50A - 21;  
 20 - 14A|75C - 61;  
 60 - 50A|75C - 100.  
**origin:** X ray induced.  
**references:** Lindsley, Edington, and Von Halle, 1960, *Genetics* 45: 1649-70.  
**genetics:** Male viable and sterile.

**\*T(1;2;3)A149**

**cytology:** *T(1;2;3)19B1-2;20;48F;81*. Complex.  
**origin:** X ray induced.  
**discoverer:** Lefevre.  
**genetics:** Male lethal.

**\*T(1;2;3)b<sup>75.1</sup>: Translocation (1;2;3) black**

**cytology:** *T(1;2;3)1B7-8;42E;62B9*.  
**new order:**  
 61 - 62B9|1B7-8 - 20;  
 21 - 42E|1B7-8 - 1A;  
 60 - 42E|62B9 - 100.  
**origin:** X ray induced.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, *DIS* 55: 193-95.  
**genetics:** Mutant for *b* (induced by independent event).

**T(1;2;3)by<sup>35</sup>: Translocation (1;2;3) blistery**

**cytology:** Break in 3 at 85D7-12 (used to localize *by*); other breaks not given.  
**origin:** X ray induced.  
**references:** Kempthues, Raff, Raff, and Kaufman, 1980, *Cell* 21: 445-51.

genetics: Mutant for *by*.

**T(1;2;3)C232: Translocation (1;2;3)  
Crossover suppressor**

cytology: T(2;3)35D;71E; additional presence of T(1;2)20;40-41 or T(1;3)20;80-81 inferred from genetic data.

origin: X ray induced.

discoverer: Roberts, 1965.

references: 1970, Genetics 65: 429-48.

genetics: Male viable and fertile; homozygous female lethal. Recombination reduced in 2L.

**T(1;2;3)C312**

cytology: T(2;3)32C;87E; additional presence of T(1;2)20;40-41 or T(1;3)20;80-81 inferred from genetic data.

origin: X ray induced.

discoverer: Roberts, 1965.

references: 1970, Genetics 65: 429-48.

genetics: Male sterile. Recombination reduced in 2L.

**\*T(1;2;3)ct<sup>268-40</sup>: Translocation (1;2;3) cut**

cytology: T(1;2;3)7D2-3;10A5-6;21B-C;28-29;40-41;75B-C;87D;88C;92; new order not determined.

origin: X ray induced.

discoverer: Demerec, 1938.

references: Sutton, 1940, Genetics 25: 534-40 (fig.).

genetics: Mutant at *ct* but not *scp*, *cm*, *sn*, *v*, *sbr*, *dy*, *g*, *ty*, *na*, *pl*, *sd*, or *mc*. Male lethal.

**T(1;2;3)DEB1: Translocation (1;2;3)  
diepoxybutane**

cytology: T(1;2;3)20F;24F;88F.

origin: Induced by diepoxybutane.

references: Denell, Lim, and Auerbach, 1978, Mutat. Res. 49: 219-24.

**T(1;2;3)Din: Translocation (1;2;3) Dinty**

cytology: T(1;3)3C;63A + T(2;3)39D;73A (Lindsley).

new order:

1A - 3C|63A - 73A|39D - 60;

20 - 3C|63A - 61;

21 - 39D|73A - 100.

origin: X ray induced.

discoverer: Braver, 55a.

references: 1955, DIS 29: 70.

Pollock, 1963, DIS 38: 50.

genetics: Associated with *Din*. Male viable and fertile.

The two translocations should be easily separable, and *Din* is, in all probability, associated with only one.

**\*T(1;2;3)l-v216: Translocation (1;2;3)  
lethal-variegated**

origin: X ray induced.

references: Lindsley, Edington, and Von Halle, 1960, Genetics 45: 1649-70.

genetics: Variegated for a lethal; male sterile.

**T(1;2;3)l-v459**

cytology: T(1;2;3)3D-F;XR;50;80-81.

new order:

1A - 3D|50 - 21;

βF - 20F-|;

XR-80 - 61;

60 - 50-81 - 100.

Tentative.

Postulated that centromere of chromosome 3 split or double with one half capped by 2R<sup>D</sup> and the other by XR<sup>D</sup> X<sup>P</sup> in the form of a ring.

origin: X ray induced.

references: Lindsley, Edington, and Von Halle, 1960, Genetics 45: 1649-70.

genetics: Variegated for a lethal; male fertile.

**T(1;2;3)ML140**

cytology: T(1;2;3)20;40-41;80-81.

origin: X ray induced.

references: Mukhina and Zhimulev, 1980, DIS 55: 209.

genetics: Homozygous lethal.

**\*T(1;2;3)N<sup>264-74</sup>: Translocation (1;2;3) Notch**

cytology: T(1;2;3)3C10-11;20D-E;40C-D;92E6-8; 20D-E break claimed to be to the left of the nucleolus organizer (Sutton).

new order:

1 - 3C10|40D - 60;

20F - 20E|40C - 21;

61 - 92E6|20D - 3C11|92E8 - 100.

origin: X ray induced.

discoverer: Demerec, 38k.

references: Sutton, 1940, Genetics 25: 534-40 (fig.).

genetics: Variegates for *w*, *rst*, and *N* but not *kz*, *pn*, or *dm*.

**\*T(1;2;3)N<sup>264-87</sup>**

cytology: T(1;2;3)3C7-9;10A2-B1;45F-46A;59F-60A;97C-D;100E-F (Sutton).

new order:

1 - 3C7|97D - 100E|59F - 46A|10B1 - 20;

21 - 45F|3C9 - 10A2|60A - 60F;

61 - 97C|100F.

origin: X ray induced.

discoverer: Demerec, 39j.

references: Sutton, 1940, Genetics 25: 534-40.

genetics: Carries a mutant allele of *N* and normal alleles of *w*, *rst*, and *dm*.

**T(1;2;3)OR9: Translocation (1;2;3)  
from Oak Ridge**

origin: X ray induced. Selected on the basis of pseudolinkage in daughters of treated wild-type males.

discoverer: Warters, 1961.

translocation	cytology	new order <sup>α</sup>	genetics
T(1;2;3)OR9	19-20;49F;81F	1	male lethal
T(1;2;3)OR10	18A;41;73F	2	male viable but sterile

**T(1;2;3;4)l-v454: Translocation (1;2;3;4) lethal-variegated**

**cytology:** *T(1;2;3)12B;22-23;81* + *T(2;4)44F;101F*.

**new order:**

1 – 12B|81 – 61;  
20 – 12B|22 – 21;

60 – 44F|101F – 101A;

100 – 81|23 – 44F|101F – 102.

**origin:** X ray induced.

**discoverer:** Lindsley, Edington, and Von Halle.

**references:** 1960, *Genetics* 45: 1649-70.

**genetics:** Associated with *l(1)v454*. Male sterile.

**T(1;2;4)429.28**

**cytology:** *T(1;2;4)5B;56D-E;101B-C*.

**new order:**

1A – 5B|56D – 21A;  
60F – 56E|101B – 101A;  
102F – 101C|5B – 20F.

**discoverer:** Gelbart.

**\*T(1;2;4)A12: Translocation (1;2;4) from Austin**

**cytology:** *T(1;2;4)1B-C;7A;7B;13B1-5;101-102*; breakpoints in chromosomes 2 and 4 not determined (Mackensen, 1935, *Texas Univ. Publ.* 4032: frontispiece).

**new order:**

1A – 1B|13B5 – 20;  
21 – ?|(7A – 7B)|? – 60;  
101|((1C – 7A)|(7B – 13B1))|102.

**origin:** X ray induced.

**discoverer:** Patterson, Stone, Bedicheck, and Suche.

**references:** Stone, 1934, *Genetica* 16: 506-19.

Mackensen, 1935, *J. Heredity* 26: 163-74.

Patterson, Stone, and Bedicheck, 1935, *Genetics* 20: 259-79.

1937, *Genetics* 22: 407-26.

**genetics:** A section from between *sc* and *br* on the left to between *g* and *sd* on the right is inserted into chromosome 4. The *ct* locus, but not *cm*, *sn*, or *oc*, is deleted from the insertion [i.e., *Df(1)A12* = *Df(1)7A;7B*] and inserted into chromosome 2 [i.e., *Dp(1;2)A12* = *Dp(1;2)7A;7B*]. Female hyperploid for the *X<sup>P</sup>X<sup>D</sup>* element [i.e., *Dp(1;f)A12* = *Dp(1;f)1B-C;13B1-5*] survives and is claimed to be fertile. Female hyperploid for *X<sup>M</sup>* [i.e., *Dp(1;4)A12* = *Dp(1;4)1B-C;7A;7B;13B1-5;101-102*] occasionally survives and is sterile.

**\*T(1;2;4)N<sup>264-85</sup>: Translocation (1;2;4) Notch**

**cytology:** *T(1;2;4)3B4-C1;6A2-B1;60A4-5;101F-102A* [Sutton, 1940, *Genetics* 25: 534-40 (fig.)] (complex).

**new order:**

1 – 3B4|60A4 – 21;  
20 – 6B1|60A5 – 60F;  
101A – 101F|(3C1 – 6A2)|102A – 102F.

**origin:** X ray induced.

**discoverer:** Demerec, 39d.

**genetics:** Variegates for *w*, *rst*, *fa*, *dm*, *rg*, *cx*, *cv*, *rux*, and *vs* but not *pn*, *ec*, *bi*, *peb*, or *rb*. Carries normal allele of *ci* (Stern). *Dp(1;4)N<sup>264-85</sup>* = *Dp(1;4)3B4-C1;6A2-B1;101F-102A* viable in both sexes and sterile in male. Complementary *Df(1)N264-85* inviable.

**T(1;2;4)OR24: Translocation (1;2;4) from Oak Ridge**

**cytology:** *T(1;2)3C;38A* + *T(1;4)11A;102C*.

**new order:**

1 – 3C|38A – 60;  
20 – 11A|102C – 102F;  
21 – 38A|3C – 11A|102C – 101A.

**origin:** X ray induced.

**discoverer:** Warters, 1961.

**genetics:** Male viable and sterile. Produces a hyperploid

female that may carry the  $X^{P4D}$  element.

**\*T(1;2;4)w<sup>mbw</sup>V: Translocation (1;2;4)  
white-mottled  
brown-Variigated**

**cytology:** *T(1;2)12F3-4;59C4-5 + T(1;4)3C3-4;101E4-5.*

**new order:**

1 – 3C3|101E4 – 101A;

20 – 12F4|59C5 – 60;

21 – 59C4|12F3 – 3C4|101E5 – 102F.

**origin:** Neutron induced.

**discoverer:** Mickey, 53f15.

**references:** 1963, DIS 38: 30.

**genetics:** Variegated for *w*. Also claimed to variegate for *bw*, which is unusual since the *T(1;2)* is completely euchromatic.

**\*T(1;2;4)w<sup>VD2</sup>: Translocation (1;2;4)  
white-variegated  
of Demerec**

**cytology:** *T(1;2;4)3C4-5;18F;38;101A-C* (Schultz).

**new order:**

1 – 3C4|101C – 102F;101A;

20 – 18F|3C5 – 18F|38 – 21;

60 – 38|101A;101C-102F.

Tentative.

**origin:** X ray induced.

**discoverer:** Demerec, 33k27.

**genetics:** Variegated for *w* but not *rst* in male and for *w* and occasionally *rst* in female. Absence of effect on *ci* a criterion for postulating break in *4L*. Fly hyperploid for the  $4^{PX^D}$  element survives.

**T(1;2;4)y<sup>R29</sup>**

**cytology:** *T(1;2;4)1E4-F1;20;26A;35B-C;101.*

**origin:** X ray induced.

**references:** Roberts, 1974, Mutat. Res. 22: 139-44.

**genetics:** Mutant for *y* although breakpoint given is proximal to *y*. Male viable but sterile.

**T(1;2;4)z<sup>+</sup>4E7**

**cytology:** *T(1;2;4)3C7-9;56C4-D1;102A.*

**references:** Gans, 1953, Bull. Biol. Fr. Belg. Supp. 38: 1-90.

**genetics:** Phenotype *z*<sup>+</sup>.

**T(1;3)2B7**

**cytology:** *T(1;3)2B7;84A4-6.*

**references:** Belyaeva, Aizenzon, Semeshin, Kiss, Koczka, Baritcheva, Gorelova, and Zhimulev, 1980, Chromosoma 81: 281-306.

**\*T(1;3)3**

**origin:** X ray induced.

**discoverer:** Bonner, 1931.

**references:** Dobzhansky, 1935, Z. Indukt. Abstamm. Vererbungsl. 68: 143-46.

**genetics:** X chromosome broken between *rb* and *rg*; *3R* broken to the right of *ca*. Male and homozygous and heterozygous females viable and fertile. Crossing over in heterozygous female nearly absent in left end of X, rises to about normal around *ct*, and may be increased at right end. Crossing over in chromosome 3 in translocation heterozygote normal between *e*<sup>s</sup> and *ro* and reduced to two-thirds normal between *ro* and *ca*. Male carrying the  $3^{PX^D}$  element in place of a normal 3 nearly lethal;

female has narrow wings, occipital bristles, and branched posterior veins. Crossing over between normal X chromosomes about one-third of normal at left end in duplication-bearing female and nearly normal to right of *ct*.

**T(1;3)3Ac<sup>59</sup>**

**\*T(1;3)B<sup>581</sup>: Translocation (1;3) Bar**

**cytology:** *T(1;3)16A;88F*.  
**origin:** X ray induced.  
**discoverer:** E.B. Lewis, 5814.  
**references:** Ogaki, 1960, DIS 34: 97.  
 1960, Jpn. J. Genet. 35: 282.  
**genetics:** Position effect at *B*. Male sterile.

**\*T(1;3)Bb: Translocation (1;3) Bubble**

**cytology:** *T(1;3)13E;84F* (Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301).  
**origin:** X ray induced.

**discoverer:** King, 32d.

**genetics:** Associated with *Bb*. Male sterile.

**T(1;3)bi<sup>D1</sup>: Translocation (1;3) bifid**

**cytology:** *T(1;3)4C5-6;65C3-5*.

**origin:** X ray induced.

**references:** Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, Chromosoma 93: 341-46.

**genetics:** Associated with *bi*, *Qd*, and *omb*. Male lethal.

**T(1;3)bx<sup>657</sup>: Translocation (1;3) bithoraxoid**

**cytology:** *T(1;3)X;81?;89E*.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** E.B. Lewis.

**synonym:** *bx<sup>16765.7</sup>*.

**genetics:** Associated with *bx<sup>657</sup>*.

**T(1;3)C: Translocation (1;3) Crossover suppressor**

**origin:** X ray induced.

**discoverer:** Roberts, 1964, 1965.

**references:** 1970, Genetics 65: 429-48.

<b>T(1;3)GA119</b>	1E1;93A	

**T(1;3)GE222**

cytology: T(1;3)2B6;83E.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal. Mutant for *br*.

**T(1;3)GE245**

cytology: T(1;3)3C7;96. Region from 80-96 complex.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal. *N* allele.

**\*T(1;3)H: Translocation (1;3) Hairless**

discoverer: Efromson.  
references: Kamshilov, 1933, Biol. Zh. (Moscow) 2: 161-83.  
genetics: Break in X chromosome to the left of *w*; *3R* broken near *H*.

**T(1;3)h<sup>+06</sup>**

cytology: T(1;3)1B10-C1;66D14-E1.  
origin: X ray induced.  
references: Jeffery, 1979, Genetics 91: 105-25.  
genetics: Male viable but sterile. Variegates for *h*.

**T(1;3)HA14**

cytology: T(1;3)19E;80.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal. *run* allele.

**T(1;3)JA29**

cytology: T(1;3)1E5;85A.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal.

**T(1;3)JC59**

cytology: T(1;3)2F6-3A1;92F-93A.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal. Mutant for *phl*.

T(1;3)JC153: see *Tp(1;3)JC153*

**T(1;3)JK: Translocation (1;3) Jim Kennison**

cytology: T(1;3)Xh;80.  
origin: γ ray induced.  
discoverer: Kennison.

translocation	genetics
<b>T(1;3)JK1</b>	male viable and fertile; variegates for <i>Pc</i> <sup>4</sup>
<b>T(1;3)JK2</b>	male lethal
<b>T(1;3)JK3</b>	male lethal

**T(1;3)os<sup>bdw</sup>: Translocation (1;3) outstretched small eye-bending wings**

cytology: *T(1;3)16E;80C* (Nicoletti).  
origin: X ray induced.  
discoverer: Halfer, 1960.  
genetics: Associated with *os<sup>bdw</sup>*. Male sterile.

**T(1;3)P104: Translocation (1;3) Pasadena**

cytology: *T(1;3)19-20;87F-88A*.  
origin: X ray induced.  
discoverer: E.B. Lewis.

**T(1;3)pn<sup>12</sup>: Translocation (1;3) prune**

cytology: *T(1;3)2E1-2;98A1-2*.  
origin: X ray induced.  
references: Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.  
genetics: Mutant for *pn*. Male lethal.

**T(1;3)pn<sup>36</sup>**

cytology: *Tp(3;1)2E1-2;61A;62C1-2*.  
new order:  
1A|62C3 - 100;  
61A - 62C2|2E1 - 1A|2E2 - 20.  
Tentative.  
origin: X ray induced.  
references: Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.  
genetics: Mutant for *pn*.

**T(1;3)rb<sup>D1</sup>: Translocation (1;3) ruby**

cytology: *T(1;3)4C6-7;3R*.  
origin: X ray induced.  
references: Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1985, Chromosoma 93: 341-46.  
genetics: Associated with *rb*. Male lethal.

**T(1;3)RF29**

cytology: *T(1;3)3D;7D4;93F-94A* + complex autosomal rearrangement.  
origin: X ray induced.  
discoverer: Lefevre.  
genetics: Male lethal. Mutant for *dm*. Female fertile over

*FM6* (Lefevre).

**\*T(1;3)rst: Translocation (1;3) roughest**

origin: X ray induced.  
discoverer: Ball, 32b25.  
genetics: Associated with *rst*. Breakpoints in X chromosome near *w* and *bb*; position of breakpoint in chromosome 3 unknown.

**T(1;3)sc<sup>260-15</sup>: Translocation (1;3) scute**

cytology: *T(1;3)1B4-5;71C-D*.  
origin: X ray induced.  
discoverer: Demerec, 381.  
references: Sutton, 1943, Genetics 28: 210-17.  
genetics: Mutant for *sc* but not *y* or *ac*. Male sterile.

**\*T(1;3)sc<sup>260-20</sup>**

cytology: *T(1;3)1A8-B1;61A1-2*.  
origin: X ray induced.  
discoverer: Sutton, 39e.  
references: 1943, Genetics 28: 210-17.  
genetics: Mutant for *sc* but not *y*, *ac*, or *svr*. Male and homozygous female viable and fertile. The two halves of the translocation are recoverable independently. The  $X^{P3D}$  element should be deficient for *y* and *ac* but carry *sc<sup>260-20</sup>*; it presumably is male lethal but survives in heterozygous female. The  $3^{PX^D}$  element carries normal alleles of *y* and *ac* but not *sc<sup>260-20</sup>* or *svr<sup>+</sup>* and should also carry normal alleles of *ve* and *ru*.

**T(1;3)sc<sup>J4</sup>: Translocation (1;3) scute of Jacobs-Muller**

cytology: *T(1;3)1B;3A3-C2;61A* (inferred from genetic tests); 1B-3A3 lost.  
new order:  
1A1 - 1B|61A - 100;  
20 - 3C2|61A.  
origin: X ray induced.  
discoverer: Jacobs-Muller.  
references: Muller, 1932, Proc. Intern. Congr. Genet., 6th., Vol. 1: 225.  
1934, DIS 2: 60.

genetics: The section of the X chromosome from 1B through 3A was presumably inserted elsewhere in the genome; it subsequently separated from the rest of the configuration and was lost. Base of the X, presumably capped by the undemonstrable terminus of  $3L$  (i.e.,  $X^{P3D}$ ), is deficient for the tip of X through *z* and may be stocked in combination with a duplication for the tip of X, such as the  $4^{PX^D}$  element from *T(1;4)w<sup>m5</sup>* or *Dp(1;f)z<sup>9</sup>*. The  $3^{PX^D}$  segregant carries normal alleles of *l(1)Ac*, *y*, and *ac* but is not demonstrably deficient for  $3L$  factors since it is homozygous viable.  $y^+$  localizes about 4 units to the left of *ru*. *T(1;3)sc<sup>J4</sup>* restores viability of *In(1)sc<sup>V2</sup>/0* males (Baker, 1971, Proc. Nat. Acad. Sci. USA 68: 2472-76).

**\*T(1;3)sc<sup>K</sup>: Translocation (1;3) scute of Krivshenko**

discoverer: Krivshenko.  
references: Agol, 1936, DIS 5: 7.  
genetics: Mutant for *sc*. Three-break rearrangement with  $X^D$  translocated to  $3L^P$ ,  $3L^D$  translocated to  $3R^P$  and  $3R^D$  translocated to  $X^P$ .

***T(1;3)sc<sup>K3</sup>***

**cytology:** *T(1;3)1B2-3;61A1-2*.  
**origin:** X ray induced.  
**discoverer:** Krivshenko, 53j29.  
**references:** 1959, DIS 33: 95-96.  
**genetics:** Mutant for *sc*. Male fertile. Two halves of the translocation recoverable separately.  $3^P X^D$  element is viable homozygous, although males are somewhat infrequent.  $X^P 3^D$  is inviable in males and homozygous females but survives in heterozygous females.

***T(1;3)sc<sup>KA8</sup>***

**cytology:** *T(1;3)1B4-5;98+*.  
**discoverer:** Lefevre.  
**references:** Carramolino, Ruiz-Gomez, Guerrero, Cam-puzano, and Modolell, 1982, EMBO J. 1: 1185-91.  
**genetics:** Mutant for *sc*.  
**molecular biology:** X breakpoint between coordinates +13.7 and +16.7 (Carramolino *et al.*, 1982).

***T(1;3)Sh<sup>LC</sup>: Translocation (1;3) Shaker***

**cytology:** *T(1;3)16F1-2;80*.  
**origin:** X ray induced.  
**references:** Tanouye, Ferrus, and Fujita, 1981, Proc. Nat. Acad. Sci. USA 78: 6548-52.  
 Papazian, Schwartz, Tempel, Jan and Jan, 1987, Science 237: 749-53.  
**genetics:** Associated with *Sh<sup>15</sup>*.  
**molecular biology:** Maps to a *HindIII-EcoRI* fragment between +54.1 and +59.1 kb (Kamb, Iverson, and Tanouye, 1987, Cell 50: 405-13) or +53 to +55 kb (Bau-man, Krah-Jentgens, Müller, Müller-Holtkamp, Seidal, Keckemethy, Casal, Ferrus, and Pongs, 1987, EMBO J. 6: 3419-29).

***T(1;3)slu: Translocation (1;3) sluggish***

**cytology:** *T(1;3)2E;97A10*.  
**origin:**  $\gamma$  ray induced.  
**references:** Sharma, 1977, Experientia 33: 171-73.  
**genetics:** Males (semifertile) show abnormal phototactic behavior and light-dependent homosexual activity. Homozygous females sluggish and sterile. No crossing over reported in heterozygous females. Mutant phenotype recessive.

***T(1;3)SMG: Translocation (1;3) Semenova Mglinetz Glotoff***

**cytology:** *T(1;3)11A;70E*.  
**origin:**  $\gamma$  ray induced.  
**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6(4): 165-69.

***T(1;3)SP: Translocation (1;3) from São Paulo***

**origin:**  $\gamma$  ray induced. Selected as male-sterile mutations in a *y w X* chromosome.  
**discoverer:** Lindsley and Musatti, 1961.  
**genetics:** Male viable but sterile.

***T(1;3)v*: Translocation (1;3) vermilion**

**cytology:** *T(1;3)10A1-2;93B7-10* (Lefevre, 1970).  
**origin:** X ray induced in a chromosome carrying *v*.  
**discoverer:** Anderson, 1924.  
**references:** 1925, Papers Mich. Acad. Sci. 5: 355-66.  
 1926, Papers Mich. Acad. Sci. 7: 273-78.  
 1929, Z. Indukt. Abstamm. Vererbungsl. 51: 397-411.  
 Lefevre, 1970, DIS 45: 39.  
 Zhimulev, Belyaeva, Khudyakov, and Pokholkova, 1980, DIS 55: 211.  
 Zhimulev, Pokholkova, Bgatov, Semeshin, and Belyaeva, 1981, Chromosoma 82: 25-40.  
**genetics:** Inseparable from *v*. Male viable and sterile. Male sterility associated with loss of central pair of microtubules from sperm-tail axoneme [Kiefer, 1973, Genetic Mechanisms of Development (F.H. Ruddell, ed.). Academic Press, New York, London, San Francisco, pp. 47-102]. Primary nondisjunction occurs with a frequency of about 2% in heterozygous females; secondary nondisjunction is 23%. Crossing over is reduced near *v* but approaches normal on both ends of the X.

***T(1;3)v<sup>L1</sup>***

**cytology:** *T(1;3)3E1-2;90C9-11 + Df(1)10A1-2;10A4-5* (separable).

**genetics:** Mutant for *pn*. Male lethal.

***T(1;4)RF43***

**cytology:** *T(1;4)3A2-3;101-102* (complex).

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. Allele of *l(1)3Ac*.

**\**T(1;4)RF60***

**cytology:** *T(1;4)3C;101-102*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Male lethal. *N* allele.

**\**T(1;4)sc<sup>10-2</sup>: Translocation (1;4) scute***

**cytology:** *T(1;4)1A;102F + T(1;4)1D;101F*; two reciprocal *l-4* translocations, according to Schultz.

**origin:** X ray induced in *In(1)ac<sup>3</sup>*.

**discoverer:** Sturtevant, 1930.

**references:** 1934, Proc. Nat. Acad. Sci. USA 20: 515-18. 1936, Genetics 21: 444-66.

**genetics:** Mutant for *sc*. Virtually male lethal. X chromosome broken between *M(1)1B* and *br*; chromosome 4 broken proximal to *ci*. According to Schultz, both X and 4 also have breaks distal to all known loci and their termini are interchanged. *4<sup>P</sup>X<sup>D</sup>* carries X-chromosome loci from y through *M(1)1B* and was used extensively by Sturtevant (1934, 1936) in his studies on preferential segregation. The *X<sup>P</sup>4<sup>D</sup>* element survives in the heterozygous female but is an extreme Minute owing to deficiency for *M(1)1B* and is rarely fertile.

***T(1;4)sc<sup>H</sup>: Translocation (1;4) scute of Hackett***

**cytology:** *T(1;4)1B4-C3;101-102*; inferred from genetic results.

**origin:** γ ray induced.

**discoverer:** Hackett, 46a.

**references:** Muller and Valencia, 1947, DIS 21: 70.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Relatively viable and *sc* (García-Bellido, 1979).

Two halves of the translocation may be recovered separately. *X<sup>P</sup>4<sup>D</sup>* is deficient for y and *sc* but not *M(1)1B* and carries *ey<sup>+</sup>*. *4<sup>P</sup>X<sup>D</sup>* covers *Df(1)sc<sup>19</sup>* and therefore carries a normal allele of *l(1)sc*. *T(1;4)sc<sup>H</sup>/ci* is *ci<sup>+</sup>*.

**molecular biology:** X-chromosome breakpoint between coordinates +5.9 and +6.4 (Carramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell, 1982, EMBO J. 10: 1185-91).

\**T(1;4)w<sup>13</sup>*: see *Tp(1;4)A1*

***T(1;4)w<sup>70L26.5</sup>: Translocation (1;4) white***

**cytology:** *T(1;4)3C1-2;12B8-9;102F*. Ring-like chromomere complex in 3C1; remnants of band material between 3C1 and 3C2 missing (Sorsa, 1973).

**new order:**

1 – 3C1|102F – 101;

102F|12B8 – 3C2|12B9 – 20.

**origin:** X ray induced in  $In(1)z^{+64b9} = In(1)3C1-2;12B8-9$ .

**references:** Sorsa, 1973, Cold Spring Harbor Symp. Quant. Biol. 38: 601-08.

Sorsa, Green, and Beermann, 1973, Nature (London) New Biol. 245: 34-37.

**genetics:** Homo- and hemizygous viable with white eyes.

**\*T(1;4)w<sup>258-43</sup>**

**cytology:**  $T(1;4)3C3-5;102F4-5$  (Demerec).

**origin:** X ray induced.

**discoverer:** Demerec, 38k.

**genetics:** Mutant for *w* but not *kz*, *pn*, *rst*, or *fa*. Male lethal.

**\*T(1;4)w<sup>m3</sup>:** see  $T(1;4)A3$

**T(1;4)w<sup>m5</sup>: Translocation (1;4) white-mottled**

**cytology:**  $T(1;4)3C2;101F1-2$  (Pipkin and Chakrabarty, 1975, Genetics 80: s64). Duplication 1.9 times the length of 4 at metaphase.

**origin:** X ray induced.

**discoverer:** Muller, 1929.

**synonym:**  $T(1;4)m^5$ : Translocation (1;4) mottled-5;  $T(1;4)A5$ .

**references:** 1930, J. Genet. 22: 299-334.

Bolen, 1931, Am. Nat. 65: 417-22.

Grell and Day, 1970, Chromosoma 31: 434.

**genetics:** Variegates for *w* and *ci* [Dubinin, Sokolov, and Tiniakov, 1935, Biol. Zh. (Moscow) 4: 716-20]. X chromosome broken between  $l(1)3C3$  and *rst*, and chromosome 4 broken to the left of *ey*.  $4^P X^D$  added to a normal male genome produces males with 20% normal viability that are weakly fertile; added to a diploid female genome, it produces a fertile hyperploid genome; and added to a triploid intersex genome, it is virtually lethal.  $X^P 4^D$  is inviable when added to a male genome, is virtually lethal when added to a female genome, and produces rather fertile hypotriploid females when added to a triploid intersex genome (Pipkin, 1940, Texas Univ. Publ. 4032: 126-56). Griffen and Stone (1940, Texas Univ. Publ. 4032: 190-200) produced and studied a number of X-ray-induced derivatives of  $T(1;4)w^{m5}$ .

**\*T(1;4)w<sup>m11</sup>**

**cytology:**  $T(1;4)3C3-4;101A-D$ .

**origin:** X ray induced.

**discoverer:** Panshin.

Panshin, 1938, Nature 142: 837.

1941, DIS 15: 33-34.

**genetics:** Variegated for *w* but not *ci*. First rearrangement to involve, and therefore to demonstrate, existence of 4L. Panshin and Khvostova [1938; Panshin, 1938, Biol. Zh. (Moscow) 7: 837-65] produced and studied a number of X-ray-induced derivatives of  $T(1;4)w^{m11}$ .

**T(1;4)w<sup>m258-18</sup>**

**cytology:**  $T(1;4)3C4-5;101$ .

**origin:** X ray induced.

**discoverer:** Demerec, 33k.

**references:** Demerec and Slizynska, 1937, Genetics 22: 641-49.

**genetics:** Variegated for *w* and *rst* but not *pn*, *fa*, *dm*, or *ec*. Also variegated for *ci* (Stern). Male and homozygous

female viable and fertile. X chromosome broken between *rst* and *vt* (Gersh, 1965, Genetics 51: 477-80). The  $4^P X^D$  element survives as a duplication.

**T(1;4)w<sup>m258-21</sup>**

**cytology:**  $T(1;4)3E5-6;101F$  (Demerec and Hoover).

**origin:** X ray induced.

**discoverer:** Demerec, 1934.

**synonym:**  $T(1;4)w^{vD3}$ : Translocation (1;4) white-variegated of Demerec.

**references:** Hartmann-Goldstein, 1967, Genet. Res. 10: 143-59.

Cowell and Hartmann-Goldstein, 1980, Chromosoma 79: 329-40.

Kornher and Kauffman, 1986, Chromosoma 94: 205-16.

**genetics:** Variegates for *w*, *fa*, *spl*, *N*, *Sgs-4*, *dm*, and  $M(1)3E$  but not *ec* or *bi*. Also variegates for *ci* (Gersh). Low temperature increases variegation of larval Malpighian tubules and also heterochromatic appearance of the transposed euchromatin (Hartmann-Goldstein, 1967). Cytological compaction of the *Sgs-4* locus (3C11-12) enhanced at low temperature (17°C) and *Sgs-4* protein and transcript reduced in translocation heterozygotes at this temperature (Kornher and Kauffman, 1986). Males usually lethal; survivors probably *X/Y/Y*. Cell lethal in *X/0* tissue in gynandromorphs (Judd, 1953, DIS 27: 95).

**\*T(1;4)w<sup>m258-31</sup>**

**cytology:**  $T(1;4)3C3-5;102F4-17$  (Demerec and Hoover).

**origin:** X ray induced.

**discoverer:** Demerec, 37l.

**genetics:** Variegated for *w* but not *rst*. Male viable.

**\*T(1;4)w<sup>m258-53</sup>**

**cytology:**  $T(1;4)3C1-2;101E-F$ ; distal part of chromosome 4 lost. Sutton thought it a terminal deficiency of X. Evidence that chromosome 4 is involved seems equivocal, especially since, according to events postulated, the original mottled fly should have been haplo-4. Alternative interpretation is translocation between X and Y in *X/Y* sperm.

**new order:**

1A – 3C1|101E – 101A;

20 – 3C2|?

**origin:** X ray induced.

**discoverer:** Demerec, 39l.

**references:** Sutton, 1940, Genetics 25: 628-35.

**genetics:** Variegated for *w* but not *pn*, *rst*, or *spl*. Male viable. Translocation-bearing fly carries two normal fourth chromosomes.

**T(1;4)w<sup>mA</sup>: Translocation (1;4) white-mottled from Austin**

**cytology:**  $T(1;4)3C2-3;101A2-3$ .

**origin:** X ray induced.

**discoverer:** Stone.

**references:** Griffen and Stone, 1939, Genetics 24: 73.

1940, Texas Univ. Publ. 4032: 201-7 (fig.).

**genetics:** Variegated for *w*. Male viable and fertile. Second demonstration of the existence of a left arm on chromosome 4.

***T(1;4)w<sup>MD3</sup>*: Translocation (1;4) white-mottled of Dubinin**

**cytology:** *T(1;4)3C;101*.

**discoverer:** Dubinin.

**references:** Sacharov, 1936, Biol. Zh. (Moscow) 5: 293-302.

**genetics:** Variegated for *w*.

***T(1;4)w<sup>MDV4</sup>*: Translocation (1;4) white-mottled of Dubinin and Volotov**

**cytology:** *T(1;4)3C3-7;3D;101A-D*; 3C-3D missing; inferred from genetic data and from figs. 5-7 of Sacharov (1936) which indicate that the break in chromosome 4 is in the left arm.

**new order:**

1 - 3C3|101D - 102F;

20 - 3D|101A.

**discoverer:** Dubinin and Volotov.

**references:** Sacharov, 1936, Biol. Zh. (Moscow) 5: 293-302 (fig.).

**genetics:** Deficient for *N*; variegated for *w*. Male lethal. Since the 4<sup>P</sup>X<sup>D</sup> element of *T(1;4)w<sup>MDV4</sup>* survives as a duplication and carries *w<sup>MDV4</sup>*, the left break in the X chromosome is between *w* and *N*.

***T(1;4)w<sup>mJ</sup>*: Translocation (1;4) white-mottled of Jonsson**

**cytology:** *T(1;4)3C2-3;20F;102C*.

**new order:**

1 - 3C2|20F - 3C3|102C - 101A;

20|102C - 102F.

**origin:** X ray induced.

**discoverer:** Jonsson, 61i28.

**references:** Lefevre, 1963, DIS 37: 49.

Lefevre and Wilkins, 1966, Genetics 53: 175-87.

**genetics:** Variegated for *w*. The X<sup>P4</sup>D element of the translocation has become separated from the 4<sup>P</sup>X<sup>D</sup> element and lost. The 4<sup>P</sup>X<sup>D</sup> element is viable as an X/Y male but lethal as an X/O male, probably owing to deficiency for *bb*. Additional evidence for appreciable deficiency for proximal X heterochromatin is virtually random disjunction of X and Y chromosomes. 4<sup>P</sup>X<sup>D</sup> carries *ci*<sup>+</sup> but not *ey*<sup>+</sup>. The variegation of white is unorthodox because heterochromatin has been moved to the white locus rather than white moved into proximal heterochromatin.

***T(1;4)w<sup>mK</sup>*: Translocation (1;4) white-mottled of Krist**

**cytology:** Distal tip of X translocated to centromere of 4.

**origin:** X ray induced.

**references:** Breugel, 1972, Genetica 43: 25-42.

**genetics:** Variegates for *w*. Most of the homozygous females and hemizygous males have mottled eyes with large spots; a few have almost wild-type or pale eyes without large spots. More pigment at 25° than at 16°.

**\**T(1;4)w<sup>mMed</sup>*: Translocation (1;4) white-mottled of Medvedev**

**discoverer:** Medvedev, 1934.

**genetics:** Variegated for *w* and probably *rst*. Arose in *w<sup>a</sup>* and therefore has light eye color.

*T(1;4)w<sup>vD3</sup>*: see *T(1;4)w<sup>m258-21</sup>*

***T(1;4)y<sup>A74c40</sup>***

**cytology:** *T(1;4)1B1-2;101F*.

**origin:** Induced with caffeine and γ rays.

**references:** Alexandrov, Ankina, and Alexandrova, 1985, DIS 61: 212-13.

**genetics:** Mutant for *y*.

***T(1;4)z<sup>20G1</sup>*: Translocation (1;4) zeste**

**discoverer:** *T(1;4)3C1-2;102F2-4*; genetic data more in accord with breakpoint in 3C2-3 than 3C1-2.

**origin:** X ray induced in a chromosome carrying *z*.

**discoverer:** Gans.

**references:** 1953, Bull. Biol. France Belg. Suppl. 38: 1-90 (fig.).

Gersh, 1963, DIS 37: 80.

**genetics:** Suppresses *z*. The 4<sup>P</sup>X<sup>D</sup> element is poorly viable when added to male genome but viable and fertile in female; duplicated for *w* but does not cover lethality of *Df(1)w<sup>m4L</sup>rst<sup>3R</sup>* = *Df(1)3C1-2;3C3-4* (Gersh, 1963).

***T(1;4)z<sup>+</sup>***

**origin:** X-ray-induced rearrangements of *z*-bearing X chromosomes that interfere with *z-w<sup>+</sup>* interaction.

**genetics:** *z<sup>+</sup>* phenotype.

**references:** Gelbart, 1971, Ph.D. Thesis, Univ. of Wisconsin.

$\alpha$  Y breakpoints in the terminology of Gatti and Pimpinelli, 1983, whenever available.

$\beta$  Parentheses used for data from Lindsley *et al.*, 1972, that differ from data from Gatti and Pimpinelli, 1983.

$\gamma$  1 = Ashburner and Velissariou, 1980, DIS 55: 196; 2 = Baker, 1980, DIS 55: 197; 3 = Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73; 4 = Hazelrigg, Fornili, and Kaufman, 1982, Chromosoma 87: 535-59; 5 = Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, and Gould-Somero, 1972, Genetics 71: 157-84; 6 = Procnier and Dunn, 1978, Cell 15: 1087-93; 7 = Procnier and Tartof, 1976, Nature 263: 255-57; 8 = Siegel, 1981, DIS 56: 123-24; 9 = The Seattle-La Jolla Drosophila Laboratories, 1971, DIS 47, Suppl.; 10 = Velissariou and Ashburner, 1980, Chromosoma 77: 13-27; 11 = Woodruff and Ashburner, 1972, Genetics 92: 117-32.

$\delta$  New order:

- T(Y;2)A77 = B<sup>S</sup>Xh - h19|23F - 25A|23F - 21; Xhy<sup>+</sup> - h19|25A - 60.
- T(Y;2)A120 = B<sup>S</sup>Xh - h16|h21 - h16|57E - 60; Xhy<sup>+</sup> - h21|57E - 21.
- T(Y;2)B80 = B<sup>S</sup>Xh - h21|Xhy<sup>+</sup> - h21|60F; Xhy<sup>+</sup>|60F - 21.
- T(Y;2)B107 = B<sup>S</sup>Xh|29C - 47E|29C - 21; Xhy<sup>+</sup> - B<sup>S</sup>Xh|47E - 60.
- T(Y;2)B185 = YL·YS<sup>P</sup>|60F; YS<sup>D</sup>|60F - 53D|51A - 53C|34A - 51A|34A - 21.
- T(Y;2)D219 = YL<sup>D</sup>|36F - 60; YS·YL<sup>P</sup>|36E - 36A|35F - 21.
- T(Y;2)H165 = B<sup>S</sup>Xh - Xhy<sup>+</sup>|21E - 21A; Xhy<sup>+</sup>|28D - 21E|28D - 60.
- T(Y;2)L67 = B<sup>S</sup>Xh - Xhy<sup>+</sup>|25E - 40|25E - 21; Xhy<sup>+</sup>|40 - 60.
- T(Y;2)L135 = YL<sup>D</sup>·YS<sup>F</sup>|31F - 40|31F - 21; YS|40 - 60.
- T(Y;2)L137 = YL·YS<sup>P</sup>|60A - 60F; YS<sup>D</sup>|43E - 60A|43E - 21.
- T(Y;2)R145 = YL·YS<sup>P</sup>|23F - 40|23F - 21; YS<sup>D</sup>|40 - 60.
- T(Y;2)R147 = B<sup>S</sup>Xh|27E - 60 YS·YL|23 - 27E;|23 - 21.

$\epsilon$  Synonym: T(Y;2)Kr.

$\delta$  Broken within the 5S RNA gene cluster (Procnier and Tartof, 1976; Procnier and Dunn, 1978).

$\eta$  Broken just outside the 5S RNA gene cluster, proximal for T(Y;2)L139 and distal for T(Y;2)L141 (Procnier and Dunn, 1978). Completely male sterile in combination with Df(1)bb158 (Lyttle).

$\theta$  Suppresses Y loop associated with kl-3 (Bonaccorsi and Gatti).

<sup>1</sup> Cytology corrected by Davis and MacIntyre, 1988, Genetics 120: 755-66.

**T(Y;2)1 – T(Y;2)16**

origin: X ray induced.

**T(Y;2)2.31**

cytology: T(Y;2)25C;38B.

new order:

- Y<sup>P</sup>|25C - 21;
- Y<sup>D</sup>|38B - 25C|38B - 60.

origin: X ray induced.

discoverer: Nüsslein-Volhard.

synonym: T(Y;2)odd<sup>2.31</sup>.

references: Nüsslein-Volhard, Kluding, and Jürgens, 1985,

Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

genetics: Second-chromosome breakpoint between *slp* and *mid*; neither gene mutant.

**T(Y;2)4.25**

cytology: T(Y;2)24D.

origin: X ray induced.

discoverer: Nüsslein-Volhard.

synonym: T(Y;2)odd<sup>4.25</sup>.

references: Nüsslein-Volhard, Kluding, and Jürgens, 1985,

Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

genetics: Second-chromosome breakpoint between *slp* and *mid*; neither gene mutant.

**\*T(Y;2)21E**

cytology: T(Y;2)21D4-E1.

discoverer: Schultz.

references: Lewis, 1945, Genetics 30: 137-66.

genetics: Not mutant for *S* or *ast*. Chromosome 2 broken between *ds* and *S*. Both Y<sup>P2D</sup> and 2<sup>P</sup>Y<sup>D</sup> recoverable in aneuploid progeny.

**\*T(Y;2)54a**

cytology: T(Y;2)YL;59C4-6.

discoverer: Mickey, 54a.

references: 1959, Texas Univ. Publ. 5914: 99-105.

1963, DIS 38: 30.

genetics: Variegated for *bw*. Male fertile. Male hyperploid for Y<sup>P2D</sup> survives, is not variegated, and is sterile.

T(Y;2)60D-F: see *In(2LR)noc*<sup>7</sup>

**T(Y;2)429 - T(Y;2)434**

origin: X ray induced.

discoverer: Gelbart.

**T(Y;2)CyO: Translocation (Y;2) Curly Oster**

**cytology:** Translocation between *Y* and *CyO*, *l(2)DTS513<sup>DTS</sup>*. Cytology not given.

**origin:** X ray induced.

**references:** Wright and Green, 1974, DIS 51: 108-09.

**genetics:** *Cy* males carry temperature-sensitive lethal. Useful for constructing virginator stocks.

*T(Y;2)D*: see *T(Y;2;3)D*

**T(Y;2)dp<sup>61d</sup>: Translocation (Y;2) dumpy**

**origin:** X ray induced.

**discoverer:** Thompson, 61d.

**genetics:** Mutant for *dp*.

**\*T(Y;2)dp<sup>w2</sup>: Translocation (Y;2) dumpy-warped**

**origin:** X ray induced.

**discoverer:** Schalet, 55k.

**references:** Carlson and Schalet, 1956, DIS 30: 71.

Carlson, 1958, DIS 32: 117-18.

**genetics:** Variegated for *dp*.

**T(Y;2)dpp<sup>16</sup>: Translocation (Y;2) decapentaplegic**

**cytology:** *T(Y;2)22F1-2*.

**origin:** X ray induced.

**discoverer:** Spencer.

**references:** Gelbart.

**genetics:** *d-III dpp* mutant.

**T(Y;2)DTD50**

**cytology:** *T(Y;2)35D-E*.

**discoverer:** Gelbart.

**genetics:** Disrupts transvection at *dpp*.

**T(Y;2)E**

**cytology:** *T(Y;2)36D2-3* (Whittinghill, 1937, DIS 8: 82-84).

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1929.

**references:** 1930, Biol. Zentr. 50: 671-85.

1932, Z. Indukt. Abstamm. Vererbungsl. 60: 235-86.

**genetics:** Male fertile; *Df(1)sc<sup>4L</sup>sc<sup>8R</sup>/T(Y;2)E* male is sterile.

**T(Y;2)el<sup>4</sup>: Translocation (Y;2) elbow**

**cytology:** *T(Y;2)35B1*. *Y* arm not determined.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Harrington.

**references:** Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.

**genetics:** Associated with *el<sup>4</sup>*. Thought to be mutant, but not deficient, for *el* since *el<sup>4</sup>/el* is like *el/el* but less extreme than *el/Df*.

**\*T(Y;2)Elp<sup>2</sup>: Translocation (Y;2) Ellipse**

**cytology:** T(Y;2)57C9-D5.  
**origin:** X ray induced.  
**discoverer:** Angel.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.  
**genetics:** Ellipse-like eye phenotype; allelism with *Egfr*<sup>El</sup> not tested before translocation lost.

**T(Y;2)en<sup>SF32</sup>: Translocation (Y;2) engrailed**

**cytology:** T(Y;2)48A.  
**origin:** X ray induced.  
**references:** Kuner, Nakanishi, Ali, Drees, Gustavson, Theis, Kauvar, Kornberg, and O'Farrell, 1985, Cell 42: 309-16.  
**genetics:** Mutant for *en*; a lethal allele.  
**molecular biology:** Located at -2 kb on the molecular map of *en* ("- values to left, "+" values to right of *en* which is at position 0).

T(Y;2)F: see T(Y;2;3)F

**T(Y;2)GT1**

**cytology:** T(Y;2)35A4-B1.  
**origin:** γ ray induced.  
**discoverer:** Durrant.  
**genetics:** Deficient for *noc-osp*.

**T(Y;2)GT2**

**cytology:** T(Y;2)35A1-2.  
**origin:** γ ray induced.  
**discoverer:** Durrant.  
**genetics:** Deficient for *l(2)35Aa-pu*.

**T(Y;2)IC68-5**

**cytology:** T(Y;2)41F;53B.  
**new order:**  
 Y<sup>P</sup>|53B – 60F;  
 Y<sup>D</sup>|41F – 53B|41F – 21.  
**origin:** X ray induced.  
**references:** Brosseau, 1969, DIS 44: 45.  
**genetics:** Male fertile; shows dominant rough eye phenotype (allelism not determined).

**T(Y;2)J<sup>rv99</sup>: Translocation (Y;2) Jammed-revertant**

**cytology:** {T(Y;2)31B-F}. Autosomal breakpoint assumed to be at or near *J*.  
**origin:** X ray induced in *J* males.  
**synonym:** *J-der-99*.  
**references:** Salas and Lengyel, 1984, DIS 60: 243-44.  
**genetics:** Revertant of *J*.

**T(Y;2)J-D: Translocation (Y;2) J of Dobzhansky**

**cytology:** T(Y;2)40F-41A1;57F1-2 (Whittinghill, 1937, DIS 8: 82-84).  
**new order:**  
 Y<sup>D</sup> or P|40F – 21;  
 Y<sup>P</sup> or D|57F1 – 41A1|57F2 – 60.  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 1929.  
**references:** 1930, Biol. Zentr. 50: 671-85. 1932, Z. Indukt. Abstamm. Vererbungsl. 60: 235-86.  
**genetics:** Does not affect *rl*, *M(2)41A*, *stw*, *ap*, *msf*, *tk*, or *ltd*.

**T(Y;2)JL11**

**cytology:** T(Y;2)YS;56F + *In(2LR)21A;57F*.  
**new order:**  
 YL.YS|56F – 57F|21A;  
 60F – 57F|21A – 56F|YS<sup>+</sup>.  
**origin:** γ-ray-induced 2° translocation from T(Y;2)L141 = T(Y;2)56F.  
**references:** Mackay and O'Donnell, 1983, Genetics 105: 35-53. Lyttle, 1984, Genetics 106: 423-34. Mackay, Reynolds, and O'Donnell, 1985, Genetics 111: 885-904.  
**genetics:** Partially male fertile. *Pu*<sup>+</sup> translocated to YS. Normal guanosine triphosphate cyclohydrolase (GTP CH) activity (Mackay *et al.*, 1985).

**T(Y;2)JL12**

**cytology:** T(Y;2)YS;56F + *In(2LR)21A;59D*.  
**new order:**  
 YL.YS|56F – 59D|21A;  
 60F – 59D|21A – 56F|YS.  
**origin:** γ-ray-induced 2° rearrangement on T(Y;2)L141 = T(Y;2)56F.  
**references:** Lyttle, 1984, Genetics 106: 423-34.

T(Y;2)Kr: see T(Y;2)B80

**T(Y;2)Kr<sup>AK1</sup>**

**cytology:** T(Y;2)60F3-5.  
**origin:** X ray induced in *If* chromosome.  
**references:** Preiss, Rosenberg, Kienlin, Seifert, and Jäckle, 1985, Nature 313: 27-32.  
**genetics:** Mutant for *Kr*. Incomplete revertant for *If* (phenotype dependent on chromosomal background).  
**molecular biology:** Entire cloned *Kr* region (from -5 to +34) translocated onto *Y*; *EcoRI* site at origin of chromosomal walk of Preiss *et al.*, 1985.

**T(Y;2)MK2**

**cytology:** T(Y;2)25E1-3.  
**discoverer:** Kotarski.

T(Y;2)odd<sup>2.31</sup>: see *Tp(2;Y)odd*<sup>2.31</sup>

<sup>β</sup> Suppresses *SD* strongly.

***T(Y;2)TE34Ca: Translocation (Y;2) Transposing Element***

**cytology:** *T(Y;2)35D5-7*. *Y* arm not determined.  
**origin:**  $\gamma$  ray induced as partial revertant of *TE34Ca* of Ising.  
**discoverer:** Gubb.  
**synonym:** *T(Y;2)TE60*<sup>V1</sup>.  
**references:** Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.  
**genetics:** Variegates for the  $w^+$  of the transposing element. Male fertile.  
**other information:** Cytology not consistent with the insertion site of the transposing element.

***T(Y;2)TE35A***

**origin:**  $\gamma$  ray induced in *TE35A*.  
**synonym:** *T(Y;2)TE146Z*.

***T(Y;2)TW20: Translocation (Y;2) Ted Wright***

**cytology:** *T(Y;2)38A6-C1*.  
**origin:** X ray induced.  
**references:** Wright, Hodgetts, and Serald, 1976, Genetics 84: 267-85.  
**genetics:** Deficient for *pr*; carries *Tft* and *l(2)74i*.

***T(Y;2)TW124***

**cytology:** *T(Y;2)45A2-E1*.  
**origin:** X ray induced in *cn bw*.  
**references:** Wright, Hodgetts, and Serald, 1976, Genetics 84: 267-85.  
**genetics:** Variegated for *pr*.

***T(Y;2)w<sup>+</sup>Y***

Described as  $w^+Y$  (see *Y DERIVATIVES* in SPECIAL CHROMOSOMES section).

***T(Y;2;3)A147***

**cytology:** *T(Y;3)93F + T(2;3)60B;61A*.  
**origin:** X ray induced.  
**references:** Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972,

Genetics 71: 157-84.

*T(Y;2;3)b*: see *T(Y;2) - T(Y;2;3)*

***T(Y;2;3)b10-1***

**cytology:** *T(Y;2)YL;36D2-3 + T(2;3)36C10-D1;62A-B*.

**new order:**

YL<sup>D</sup>|36D3 – 60;  
 YS·YL<sup>F</sup>|36D2 – 36D1|62A – 61;  
 21 – 36C10|62B – 100.

**origin:** X-ray-induced derivative of *T(Y;2)b10*; male fertile in combination with *Dff(1)bb158*.

**references:** Lyttle, 1984, Genetics 106: 423-34.

**genetics:** 36C10-D1 breakpoint apparently inactivates *rdo*, since *T(Y;2;3)b10-1/rdo* flies exhibit a strong reduced-ocelli phenotype. Males carrying the *Y*-chromosome element capped by 36D1-2 plus region 61 are viable and fertile; therefore *Y*-chromosome breakpoint distal to *kl-5*. Females carrying remaining two elements of the translocation are marked with *B* and are sterile, presumably owing to heterozygous deficiency for region 61. This genotype, which is deficient also for 36D1-2 is deficient for *Arr1*, by *in situ* hybridization, and *I(2)36Db* but not *ninaD*; whether *kel* is included not determined (Hardy).

***T(Y;2;3)Coi<sup>rv1</sup>: Translocation (Y;2;3) Coiled-revertant***

**cytology:** *T(Y;2)22B8 + T(2;3)32F;89E-F + Tp(3;3)64C;71A;75C*.

**new order:**

Y|21 – 22B8;  
 60 – 32F|89F – 100;  
 61 – 64C|71A – 75C|64C – 71A|75C – 89E|32F – 22B8|Y.

**origin:** X ray induced.

**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.

**genetics:** Revertant of *Coi*.

**\**T(Y;2;3)D***

**cytology:** *T(Y;2;3)29F-30A1 + T(2;3)34C;78F + Df(2R)41A;41C + Df(3L)61E2-F1;62A4-6*. May also carry small inverted segment in region 41 (Whittinghill, 1937, DIS 8: 82-84).

**new order:**

Y<sup>D</sup>|30A1 – 34C|78F – 100;  
 Y<sup>F</sup>|29F – 21;  
 60 – 41C|41A – 34C|78F – 62A6|61E2 – 61A.

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1929.

**synonym:** *T(Y;2)D*.

**references:** 1930, Biol. Zentr. 50: 671-85.

1932, Z. Indukt. Abstamm. Vererbungsl. 60: 235-86.

**genetics:** Deficient for *M(2)41A* and *stw* (but not *rl*, *ap*, *msf*, *tk*, or *ltd*) in chromosome 2 and for *ru*, *aa*, and *ve* [but not *su(ve)* or *R*] in chromosome 3. The *Y<sup>F2D</sup>* element survives in hyperploids.

***T(Y;2;3)F***

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1929.

**synonym:** *T(Y;2)F*.

**references:** 1930, Biol. Zentr. 50: 671-85.

1932, Z. Indukt. Abstamm. Vererbungsl. 60: 235-86.

**genetics:** Break in 2R to right of *sp*.

**T(Y;2;3)G20**

**cytology:** *T(Y;2;3)YS;31C-D;81F;82F.*

**new order:**

YL·YS|81F – 82F|31C – 21;  
YS|31D – 60;  
61 – 81F|82F – 100.

**origin:** X ray induced.

**references:** The Seattle-La Jolla Drosophila Laboratories, 1971, DIS 47, Suppl.

Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84.

**genetics:** Male fertile over normal X.

**T(Y;2;3)H: Translocation (Y;2;3) Hilliker**

**origin:** γ ray induced.

**references:** Hilliker and Trusis-Coulte, 1987, Genetics 117: 233-44.

**genetics:** Viability and fertility of homozygotes not determined.

translocation <sup>α</sup>	cytology	new order

 $YS \cdot YL^P | 64F - 61.$

<sup>e</sup> Immediately proximal [T(Y;3)A109] or distal [T(Y;3)D85] to the *Antp* complex (Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33).

<sup>ζ</sup> Severe *bb* phenotype in combination with *Df(1)bb158* (Golic).

<sup>η</sup> The pieces 96A-97F and 97F-100 not visibly connected in chromocenter.

<sup>θ</sup> Breakpoints inferred from Bar-variegated phenotype (Craymer, 1984, DIS 60: 217).

<sup>l</sup> Carries *Cat*<sup>+</sup>.

### T(Y;3)12-4B

cytology: T(Y;3)78F.

origin: X ray induced on y<sup>+</sup>Y.

references: Novitski and Ehrlich, 1970, DIS 45: 102.

### T(Y;3)12-26M

cytology: T(Y;3)83D.

origin: X ray induced on y<sup>+</sup>Y.

references: Novitski and Ehrlich, 1970, DIS 45: 102.

### T(Y;3)15

origin: X ray induced.

cytology: T(Y;3)87B5-7.

references: Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, Mol. Gen. Genet. 202: 481-87.

Reuter, Gausz, Gyurkovics, Friede, Bang, Spierer, Hall, and Spierer, 1987, Mol. Gen. Genet. 210: 429-36.

genetics: Associated with *Su(var)3-6*.

### \*T(Y;3)42I

cytology: Break in middle of one arm of chromosome 3.

origin: X ray induced.

discoverer: Poulson.

references: 1943, DIS 17: 51.

**T(Y;3)67-325**

**cytology:** *T(Y;3)87B1-2*. Complex rearrangement.  
**origin:** X ray induced.  
**discoverer:** Brosseau.  
**references:** Ellgaard and Brosseau, 1969, *Genetics* 62: 337-41.

**T(Y;3)409**

**cytology:** *T(Y;3)87E1-2*.  
**origin:** X ray induced.  
**references:** Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, *Mol. Gen. Genet.* 202: 481-87.  
**genetics:** Associated with *Su(var)3-7*.

**T(Y;3)Antp<sup>Ns</sup>: Translocation (Y;3) Antennapedia-revertant**

**origin:** X ray induced.  
**genetics:** Revertant of *Antp<sup>Ns</sup>* [partial in *T(Y;3)Antp<sup>rv18</sup>*].

translocation	cytology	synonym	ref <sup>α</sup>	homoz. viable?

<sup>γ</sup> Male sterile as homozygote and as heterozygote with *T(Y;3)S20*.

***T(Y;3)Scr*<sup>E4</sup>: Translocation (Y;3) Sex combs reduced**

**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Kennison, 1984.  
**genetics:** Associated with *Scr*.

***T(Y;3)se*<sup>V</sup>: Translocation (Y;3) sepia-variegated**

**cytology:** *T(Y;3)66D*.  
**origin:** X ray induced.  
**references:** Jeffery, Stephans, and Giddings, 1974, Genetics 77: s32.  
**genetics:** Variegates for *se*.

**\**T(Y;3)sr*<sup>100.23</sup>: Translocation (Y;3) stripe**

**cytology:** *T(Y;3)90E2-3*.  
**origin:** X ray induced.  
**discoverer:** Alexander.  
**references:** Ward and Alexander, 1957, Genetics 42: 42-54.  
**genetics:** Mutant for *sr*.

**\**T(Y;3)st*<sup>100.126</sup>: Translocation (Y;3) scarlet**

**cytology:** *T(Y;3)73A2-3*.  
**origin:** X ray induced.  
**discoverer:** Alexander.  
**references:** Ward and Alexander, 1957, Genetics 42: 42-54.

**genetics:** Mutant for *st*.

***T(Y;3)ST1***

**cytology:** *T(Y;3)YL;69F-70A2 + In(3L)62B;74A* (Kennison).

**new order:**

YL<sup>P</sup>|69F - 62B|74A - 100.

YS.YL<sup>P</sup>|70A2 - 74A|62B - 61.

**origin:** γ ray induced in a *mwh iab9<sup>uh3</sup>* stock.

**discoverer:** Tiong.

**synonym:** *T(Y;3)I2-10-1*.

**genetics:** Duplication segregant *Dp(3;Y)ST1* includes *brm*<sup>+</sup> *th*<sup>+</sup> *st*<sup>+</sup> *tra*<sup>+</sup> *KL*<sup>+</sup> *KS*<sup>+</sup>.

***T(Y;3)Tab*<sup>rv89</sup>: Translocation (Y;3) Tab-reverted**

**cytology:** *T(Y;3)89E + In(3R)89E;90D*.

**origin:** X ray induced in *In(3R)Tab*.

**references:** Celniker and Lewis, 1987, Genes and Development 1: 111-23.

**genetics:** Revertant of the dominant *Tab* phenotype. When hemizygous, shows stronger transformation of the eighth ventral setal band toward that of the seventh than does *Tab/Df(3R)P9*; also, A7 transformed toward A5 or A6, no posterior spiracles and no ninth ventral setal band.

***T(Y;3)Ubx*<sup>21R</sup>**

**cytology:** *T(Y;3)89E*.

**origin:** X ray induced.

**synonym:** *Ubx*<sup>19649.21R</sup>.

**references:** E.B. Lewis.

**genetics:** Associated with *Ubx*<sup>21R</sup>.

***T(Y;3)Ubx*<sup>1343</sup>**

**cytology:** *T(Y;3)89E*.

**origin:** X ray induced.

**synonym:** *Ubx*<sup>31616.1343</sup>.

**references:** E.B. Lewis.

**genetics:** Associated with *Ubx*<sup>1343</sup>.

***T(Y;3)vin*<sup>101</sup>: Translocation (Y;3) vin**

**cytology:** *T(Y;3)87F12-14*.

**origin:** γ ray induced simultaneously with, but independently of, *vin*<sup>101</sup>.

**references:** Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25.

**genetics:** Homozygous lethal but viable with all *vin* deficiencies.

***T(Y;3;4)fkf*: Translocation (Y;3;4) fork head**

**cytology:** *T(Y;3;4)98D2-3;99F;101*.

**origin:** X ray induced.

**references:** Jürgens and Weigel, 1988, Roux's Arch. Dev. Biol. 197: 345-54.

**genetics:** Weak *fkf* phenotype.

*T(Y;4)*: see 4Y

Described in section on Y derivatives.

***T(Y;4)B15***

**cytology:** *T(Y;4)YL;102F*.

**new order:**

B<sup>S</sup>YL|102F - 101A;

102F|YL·YSy<sup>+</sup>.

**origin:** X ray induced using B<sup>S</sup>Yy<sup>+</sup>.

**references:** Hazelrigg, Fornili, and Kaufman, 1982, Chro-

mosoma 83: 535-59.

**genetics:** Male fertile as *X/T(Y;4)*.

***T(Y;4)ci1: Translocation (Y;4) cubitus interruptus***

**origin:** X ray induced.

**synonym:** *R<sup>1</sup>(ci)*.

**references:** Stern and Kodani, 1955, *Genetics* 40: 343-73.

**other information:** Breakpoints and position effect information not given.

*T(2;?)odd<sup>5.1</sup>*: see *Tp(2;?)5.1*

***T(2;3)3.29***

**cytology:** *T(2;3)25C;100F*.

**origin:** X ray induced.

**discoverer:** Nüsslein-Volhard.

**synonym:** *T(2;3)odd<sup>3.29</sup>*.

**references:** Nüsslein-Volhard, Kluding, and Jürgens, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 145-54.

**genetics:** Second chromosome breakpoint between *slp* and *mid*; neither gene mutant.

***T(2;3)63***

**origin:**  $\gamma$  ray induced.

**discoverer:** Hinton, 63b.

**references:** 1964, *DIS* 39: 61 (except for *T(2;3)63-5*). 1965, *Genetics* 51: 971-82.

translocation	cytology	genetics
<i>T(2;3)63-1</i>	49D-E;79B-C	homozygous viable, fertile; eyes slightly rough
<i>T(2;3)63-2</i>	27B-C;75C	homozygous lethal
<i>T(2;3)63-3<sup>α</sup></i>	40-41;80-81	homozygous lethal
<i>T(2;3)63-5</i>	40C;89E-F + <i>In(3L)69-70;79-80</i>	homozygous viable, fertile; short bristles; wings obliquely creased, ovate, often asymmetrical
<i>T(2;3)63-6</i>	59E-F;89E-F	homozygous viable, fertile; short bristles; wings obliquely creased, ovate, often asymmetrical
<i>T(2;3)63-7</i>	41C;92D-E	homozygous lethal
<i>T(2;3)63-8</i>	36E;86B	homozygous lethal
<i>T(2;3)63-9</i>	34A-B;75C	homozygous lethal
<i>*T(2;3)63-10</i>	33-34;76D-E	homozygous viable but sterile; abdominal tergites more pigmented than in wild type
<i>T(2;3)63-13</i>	24-25;94D-E	homozygous viable, fertile; variegated eye color
<i>T(2;3)63-14</i>	38A-B;69A-B	homozygous lethal
<i>T(2;3)63-15</i>	41D;64A	homozygous lethal; variegated eye color in heterozygote
<i>T(2;3)63-16</i>	41C-D;93A-B	homozygous viable, fertile; eyes slightly rough
<i>T(2;3)63-17</i>	40C;96A-B	homozygous lethal; eye color in heterozygote variegated over <i>SM5</i> but normal over <i>bw</i> or +
<i>T(2;3)63-18</i>	39B-C;80C	homozygous viable, fertile; trough-like wing posture in 90% of flies
<i>T(2;3)63-19</i>	24D-E;80C	homozygous lethal
<i>T(2;3)63-21</i>	32E;89C-E + <i>In(3LR)65B;84B</i>	homozygous lethal
<i>T(2;3)63-22</i>	40B;84D	homozygous lethal
<i>T(2;3)63-23<sup>α</sup></i>	40-41;80-81	homozygous lethal

<sup>α</sup> Inferred from genetic data because salivary chromosomes appear normal.

***T(2;3)64***

**origin:**  $\gamma$  ray induced.

**discoverer:** Hinton, 63b.

**references:** 1965, *Genetics* 51: 971-82.

<sup>α</sup> Inferred from genetic data because salivary chromosomes appear normal.

*\*T(2;3)100r20*: see *T(1;2;3)100r20*

***T(2;3)101***

**cytology:** *T(2;3)44B;83E-F* (Lewis, 1956, *DIS* 30: 130).

**discoverer:** Sturtevant.

**genetics:** Homozygous viable; male fertile and female sterile. Crossing over about normal in chromosome 2 of heterozygous female.

***\*T(2;3)103***

**discoverer:** Sturtevant.

**genetics:** Homozygous lethal. Reciprocal translocation with breaks in 2L and 3L. Crossing over in heterozygous female low in 2L, normal in 2R.

***T(2;3)108***

**cytology:** *T(2;3)37-38;52D-F;80;81* + *T(2;3)42A2-3;58A4-B1* inferred from a combination of cytological [52D-F (Lewis, 1951, *DIS* 25: 108-9)] and genetic observations.

**new order:**

21 - 37|(80 - 81)|52D - 42A3|58B1 - 60;  
61 - 80|(37 - 42A2|58A4 - 52F)|81 - 100.

**origin:** Arose in *In(2R)Cy = In(2R)42A2-3;58A4-B1*.

**discoverer:** Sturtevant.

**references:** Bahn, 1971, *Hereditas* 67: 75-78.

**genetics:** Mutant for *Rev*. Homozygous semilethal. The segregant that receives a normal chromosome 2 and the transposed element that might be designated *3L<sup>D</sup>2L<sup>P</sup>3R<sup>D</sup>* survives and is fertile. It is duplicated for the loci of *pr*, *lt*, *rl*, *tk*, and according to Lewis, for *M(2)53*, *sm*, and *hy*; not deficient for chromosome 3 genes.

***T(2;3)109***

**cytology:** *T(2;3)22F-23B;55F-56A;80* (Lewis, 1951, *DIS* 25: 108-9).

**new order:**

21 - 22F|55F - 23B|80 - 61;  
60 - 56A|80 - 100.

**discoverer:** Sturtevant.

**genetics:** Homozygous viable and wild type. Originated in *In(3R)P* but is separable from it.

***\*T(2;3)110***

**origin:** X ray induced.

**discoverer:** Sturtevant.

**genetics:** Homozygous lethal. Wings short, extended, and coiled downward in spiral. L4 and marginal veins thickened, L4 sometimes not reaching margin; posterior wing cell reduced. Posterior crossvein absent; L5 reduced and irregularly plexate. Break in 2R near *vg* and one in 3R, which carries *In(3R)P*. New order is 2L + 3L and 2R + 3R.

**\*T(2;3)135**

**cytology:** T(2;3)37;85A.  
**origin:** X ray induced simultaneously with T(1;2)l-v135.  
**references:** Lindsley, Edington, and Von Halle, 1960, Genetics 45: 1663.

**T(2;3)203**

**cytology:** T(2;3)57A5-10;84C8-D1 interband (B.S. Baker, 1985).  
**discoverer:** Ou.  
**genetics:** Transvects *Cbx Ubx*+

**T(2;3)205**

**cytology:** T(2;3)41;89D (E.B. Lewis).  
**origin:** X ray induced in *Canton-S*.  
**discoverer:** Ou.

**T(2;3)221**

**cytology:** T(2;3)22B;62F (E.B. Lewis).  
**origin:** X ray induced in *Canton-S*.  
**discoverer:** Ou.  
**references:** Craymer, 1984, DIS 60: 234-36.  
**genetics:** Discovered in association with *In(3R)221*; does not transvect *Cbx Ubx*+

**T(2;3)429 - T(2;3)445**

**origin:** X ray induced.  
**discoverer:** Gelbart.

**T(2;3)A**

**cytology:** T(2;3)39B-C;83B (Lewis, 1951, DIS 25: 108-9).  
**origin:** X ray induced in *Bl*.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 1933, Z. Indukt. Abstamm. Vererbungs. 64: 269-309.  
 Dobzhansky and Sturtevant, 1931, Carnegie Inst. Washington Publ. No. 421: 29-59.  
**genetics:** Homozygous lethal.

**\*T(2;3)A1: Translocation (2;3) from Austin**

**origin:** X ray induced.  
**references:** Patterson, Stone, Bedichek, and Suche, 1934, Am. Nat. 68: 359-69.  
 Pipkin, 1940, Texas Univ. Publ. 4032: 73-125.  
**genetics:** Homozygous viable and fertile. Chromosomes 2 and 3 broken at chromocenter. 2L attached to 3R and 3L to 2R.

**T(2;3)A1-W: Translocation (2;3) A1 of Wallace**

**cytology:** T(2;3)22;68 superimposed on *In(2L)22D1-2;33F5-34A1 + In(2R)42A2-3;58A4-B1 + In(3LR)61A-C;74;89D-E;93B;96A*.  
**origin:** Spontaneous in *In(2L)Cy In(2R)Cy; TM2*.  
**references:** Wallace, Zouros, and Krimbas, 1966, Amer. Nat. 100: 245-51.  
 Wallace, 1966, Amer. Nat. 100: 565-83.  
 Thompson, 1977, Genetics 85: 125-40.  
 1983, DIS 59: 129-30.  
**genetics:** Homozygous lethal because of the dominant markers in the component balancers *In(2L)Cy In(2R)Cy, Cy L* and *In(3LR)Ubx<sup>130</sup>, Ubx<sup>130</sup> e<sup>s</sup> (TM2)*. Segregates as a unit and suppresses recombination in chromosomes 2 and 3.

**T(2;3)A2**

**cytology:** T(2;3)46B;47F;78A.  
**new order:**  
 21 - 46B|47F - 46B|78A - 61;  
 60 - 47F|78A - 100.  
**origin:** X ray induced.  
**references:** Ashburner, 1972, DIS 49: 34.  
**genetics:** Homozygous lethal.

**\*T(2;3)A26**

**origin:** X ray induced.  
**discoverer:** Muller.  
**references:** Painter and Muller, 1929, J. Heredity 20: 287-98.  
 Muller, 1930, J. Genet. 22: 299-334.  
**genetics:** Break in 3R between *sr* and *e*.

**T(2;3)A147: see T(Y;2;3)A147**

**T(2;3)abd-A: Translocation (2;3) abdominal-A**

**origin:** X ray induced.  
**genetics:** Mutant for *abd-A*.

translocation	cytology	discoverer	ref <sup>α</sup>	molecular biology <sup>β</sup>
<b>T(2;3)abd-A<sup>517</sup>γ</b>	34-5;41;78;83-84;89E	Baker		40-45 kb

<sup>α</sup> 1 = Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96; 2 = Sánchez-Herrero, Vernós, Marco, and Morata, 1985, Nature 313: 108-13; 3 = Tiong, Bone, and Whittle, 1985, Mol. Gen. Genet. 200: 335-42.  
<sup>β</sup> Coordinates of 89E breakpoints in kilobases to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.  
<sup>γ</sup> Synonym: *iab2<sup>31616.517</sup>*.

**T(2;3)Adh1: Translocation (2;3) Alcohol dehydrogenase**

**cytology:** *T(2;3)33E9-34A1;89A3-7* (Ashburner); originally described as *T(2;3)35A;35D;89A* (Nash, 1970).

**origin:** X ray induced as a "double-crossover" in a *b<sup>+</sup>rk<sup>EMS</sup>el<sup>+</sup>Adh<sup>D</sup>/b rk<sup>+</sup>el<sup>+</sup>Adh<sup>F</sup>* female.

**discoverer:** E.H. Grell.

**synonym:** *T(2;3)DpAdh1*.

**references:** Grell, 1969, Genetics 61: s23. Nash, 1970, Genetics 64: 471-99. Ashburner, 1982, Genetics 101: 447-59.

**genetics:** Originally described as duplicated for *Adh* (Nash, 1970), but presumably has undergone spontaneous exchange and no longer carries the *Adh* duplication nor enhances *H* (Ashburner).

**T(2;3)Antp<sup>Ctx</sup>: Translocation (2;3) Antennapedia-Cephalothorax**

**cytology:** *T(2;3)35B;84B1-2 + In(2R)* (Ashburner).

**origin:** X ray induced.

**discoverer:** Duncan and E.B. Lewis.

**synonym:** *T(2;3)Ctx*.

**references:** Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, Cell 35: 763-76. Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**genetics:** Recessive lethal. Heterozygotes show transformation of dorsal head structures into dorsal thoracic structures and, occasionally, transformation of antennae into legs.

**molecular biology:** Third-chromosome breakpoint 165-166 kb distal to proximal breakpoint of *Tp(3;3)Dfd<sup>rv16</sup>*.

**T(2;3)Antp<sup>rk4</sup>: Translocation (2;3) Antennapedia-recessive**

**cytology:** *T(2;3)36C-D;84B1-2 + In(3LR)62B;98F*.

**origin:** X ray induced.

**synonym:** *T(2;3)antp<sup>Xbk4</sup>*.

**references:** Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.

Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, Cell 35: 763-76.

Abbott and Kaufman, 1986, Genetics 114: 919-42.

**genetics:** Recessive lethal without dominant phenotype.

**molecular biology:** Third-chromosome breakpoint 120 kb distal to the proximal breakpoint of *Tp(3;3)Dfd<sup>rv16</sup>*.

**T(2;3)Antp<sup>rL1</sup>**

**cytology:** *T(2;3)25F;84B2*.

**origin:** X ray induced.

**synonym:** *T(2;3)antp<sup>L1</sup>*.

**references:** Abbott and Kaufman, 1986, Genetics 114: 919-42.

**genetics:** Recessive lethal without dominant phenotype.

**T(2;3)Antp<sup>rv</sup>**

**genetics:** Revertant of *Antp*. Homozygous lethal.

<sup>γ</sup> Lethal with *Antp<sup>B</sup>*.

<sup>δ</sup> Molecular biology: Third-chromosome breakpoint 144-147 kb distal to the proximal breakpoint of *Tp(3;3)Dfd<sup>rv16</sup>* (Scott *et al.*, 1983).

*T(2;3)Antp<sup>Scx</sup>*: see *T(2;3)Scx*

**T(2;3)Antp<sup>Yu</sup>: Translocation (2;3) Antennapedia of Yu**

**cytology:** *T(2;3)22A4-5;84B2-4 + T(2;3)37B1-2;98B1-2* (Kaufman *et al.*, 1980).

**new order:**

21 - 22A4|84B4 - 98B1|37B1 - 22A5|84B2 - 61; 60 - 37B2|98B2 - 100.

**origin:** X ray induced.

**discoverer:** Yu, 1948.

**references:** 1949, Ph.D. Thesis, Calif. Inst. Tech. Lewis, 1956, DIS 30: 76.

Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33.

**genetics:** Mutant for *Antp*; associated with 84B2-4 breakpoint. Homozygous lethal.

**T(2;3)ap<sup>Xa</sup>: Translocation (2;3) apterous-Xasta**

**cytology:** *T(2;3)41F;89E8-F1* superimposed on *In(2R)42A2-3;58A4-B1 + In(3R)89C2-3;96A18-19* (Bridges in Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 294; correction by Lewis, 1951, DIS 25: 108-9).

**new order:**

21 - 41F|89E8 - 89C3|96A19 - 100; 60 - 58B1|42A3 - 58A4|42A2 - 41F|89F1 - 96A18|89C2 - 61.

**origin:** X ray induced in *In(2R)Cy; In(3R)P*.

**discoverer:** Serebrovsky, 28a.

**synonym:** *T(2;3)Xa: Translocation (2;3) Xasta*.

**references:** Serebrovsky and Dubinin, 1930, J. Hered. 21: 259-65.

Sturtevant, 1934, DIS 2: 19.

**genetics:** Dominant mutant for *ap*. Homozygote virtually lethal.

**other information:** The first X-ray-induced mutation recovered in the USSR. Useful as a balancer of 2R and 3R.

**\*T(2;3)ast<sup>rv1</sup>: Translocation (2;3) asteroid-reverted**

**cytology:** T(2;3)21E2-3;68C2-3;88D8-9.  
**new order:**  
 21A – 21E2|88D8 – 68C3|88D9 – 100;  
 61 – 68C2|21E3 – 60.  
**origin:** X ray induced in *al ast ho*.  
**discoverer:** E.B. Lewis, 1942.  
**references:** 1945, Genetics 30: 158.  
**genetics:** Associated with a reversion of *ast*. Homozygous lethal.

**\*T(2;3)ast<sup>rv3</sup>**

**cytology:** T(2;3)21E2-3;61C2-3.  
**origin:** X ray induced in *net ast dp cl*.  
**discoverer:** E.B. Lewis, 1942.  
**references:** 1945, Genetics 30: 158.  
**genetics:** Associated with reversion of *ast*. Lethal homozygous and heterozygous with *Df(2L)S4 = Df(2L)21C3-4;22B2-3*.

**T(2;3)Asx<sup>T1</sup>: Translocation (2;3) Additional sex combs**

**cytology:** T(2;3)41-42;84E-F;88B.  
**new order:**  
 21 – 41|88B – 84F|88B – 100;  
 61 – 84E|42 – 60.  
**origin:**  $\gamma$  ray induced in Oregon-R.  
**discoverer:** Tiong.  
**synonym:** T(2;3)OR-6-6-1.  
**genetics:** Associated with *Asx<sup>T1</sup>* but should be separable.

**\*T(2;3)Ata: Translocation (2;3) Arista**

**cytology:** T(2;3)40;66F-67A + T(2;3)47;81.  
**new order:**  
 21 – 40|67A – 81|47 – 60;  
 61 – 66F|40 – 47|81 – 100.  
**origin:** X ray induced.  
**discoverer:** Krivshenko, 1949.  
**synonym:** T(2;3)At (symbol preoccupied).  
**references:** 1954, DIS 28: 74-75.  
 1955, DIS 29: 73.  
**genetics:** Associated with *Ata*. Homozygous lethal.

**T(2;3)AWT1**

**cytology:** T(2;3)29F;94B.  
**origin:** Spontaneous in AW chromosome line during successive backcross programs.  
**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

**T(2;3)b: Translocation (2;3) black**

**references:** Alexandrov and Alexandrova, 1986, DIS 63: 159-61.  
**genetics:** Mutant or deficient for *b*.

translocation	cytology	origin	comments

<sup>γ</sup> Translocation parts interchangeable in *T(2;3)bw*<sup>V3</sup>, *T(2;3)bw*<sup>V4</sup>, *T(2;3)bw*<sup>V5</sup> without altering phenotype.  
<sup>δ</sup> Crossing over reduced in 2L, 2R, and base of 3R; eye color reverted to wild type but translocation remained.

\**T(2;3)bw*<sup>V30k12</sup>  
**origin:** X ray induced.  
**discoverer:** Van Atta, 30k12.  
**references:** 1932, Genetics 17: 637-59.  
**genetics:** Variegated for *bw*. Complex rearrangement with breaks in 2L near centromere, 2R near *bw*, and 3L near centromere; appears to carry an inversion in 3R.

\**T(2;3)bw*<sup>V30k13</sup>  
**origin:** X ray induced.  
**discoverer:** Van Atta, 30k13.  
**references:** 1932, Genetics 17: 637-59.  
**genetics:** Variegated for *bw*. Breaks in 2R near *c* and *bw* and in 3R near *cu*.

\**T(2;3)bw*<sup>VD</sup>: **Translocation (2;3) brown-Variegated Dichaete linked**  
**origin:** X ray induced.  
**discoverer:** Oliver, 29k24.  
**references:** 1932, Z. Indukt. Abstamm. Vererbungsl. 61: 447-88.  
**genetics:** Variegated for *bw*. Homozygous lethal.

*T(2;3)bw*<sup>VDe3</sup>: **Translocation (2;3) brown-Variegated of Demerec**  
**cytology:** *T(2;3)59D;81F*. Also an inversion in 2R.  
**origin:** X ray induced.  
**discoverer:** Demerec, 33j14.  
**genetics:** Variegates for *bw* and *mi* but not *abb*. Mutant for *Dfd*. Homozygous lethal. Gives transvection effects with certain pairs of bithorax pseudoalleles (Lewis, 1955, Am. Nat. 89: 73-89).

*T(2;3)bw*<sup>VDe4</sup>  
**cytology:** *T(2;3)59D2-4;80* (Schultz).  
**origin:** X ray induced.  
**discoverer:** Demerec, 33k22.  
**genetics:** Variegates for *bw* and *mi*. Homozygous lethal.

*T(2;3)bx*<sup>d</sup>: **Translocation (2;3) bithoraxoid**  
**origin:** X ray induced.  
**genetics:** Mutant for *bx*<sup>d</sup>.

 6 = 21-40|94D-84D|94D-99B|84B-61;  
 60-40|99B-100.

$\beta$  Involvement of chromosome 2 inferred from genetic data.  
 $\gamma$  Variegates for *ca* but not for *AcpH-1* (Morrison and MacIntyre, 1978, Genetics 83: 487-97).

**\*T(2;3)C-K: Translocation (2;3)  
 Curved of Krivshenko**

**cytology:** T(2;3)52;76;81;86.  
**new order:**  
 21-52|86-100;  
 60-52|81-76|81-86|76-61.  
**origin:** X ray induced.  
**discoverer:** Krivshenko, 5513.  
**references:** 1956, DIS 30: 74.  
**genetics:** Associated with C-K. Homozygous lethal.

**T(2;3)ca<sup>nd3</sup> Translocation (2;3) claret**

**cytology:** T(2;3)44A-B;100B.  
**origin:**  $\gamma$  ray induced.  
**references:** Sequeira, Nelson, and Szauter, 1989, Genetics 123: 511-214.  
**genetics:** Distal break near but distinct from *Ca<sup>nd3</sup>*.

**T(2;3)ca<sup>v</sup>**

**cytology:** Df(3R)81F;99C-E + T(2;3)59D;94.  
**new order:**  
 21-59D|94-99C|81F-94|59D-60;  
 61-81F|99E-100.  
**references:** Craymer, 1980, DIS 55: 199.  
**genetics:** Associated with variegation for *ca*. Possible to recover the T(2;3) without the deficiency as a consequence of double crossover. The reciprocal product not recoverable; the deficiency is too large.

**T(2;3)CA: Translocation (2;3) CAMbridge**

<sup>$\alpha$</sup>  1 = Ashburner; 2 = Ashburner, Aaron, and Tsubota, 1982, Genetics 102: 421-35; 3 = Velissariou.

**T(2;3)cb25-17**

**origin:**  $\gamma$  ray induced.  
**discoverer:** Lyttle.  
**cytology:** T(2;3)52B;99C.

T(2;3)Ctx: see T(2;3)Antp<sup>Ctx</sup>

**T(2;3)Cy<sup>rvC3</sup>: Translocation (2;3)  
 Curly-revertant**

**cytology:** T(2;3)23B3-8;72F3-4 + In(2L)22D1-2;33F5-34A1.  
**new order:**  
 21-22B3|72F4-100;  
 61-72F3|22B8-22D1-2|33F5-22D2|34A1-60.  
**origin:** X ray induced in In(2L)Cy.  
**discoverer:** Littlewood.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.  
**genetics:** Revertant of Cy.

**\*T(2;3)D**

**origin:** X ray induced.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 Dobzhansky and Sturtevant, 1931, Carnegie Inst. Washington Publ. No. 421: 29-59.  
**genetics:** Heterozygote short lived and frequently sterile, especially in female. Wings misshapen and legs short.

**T(2;3)D<sup>4</sup>: Translocation (2;3) with  
 Dichaete-4**

**cytology:** T(2;3)21D;70-71 (Lewis).  
**origin:** X ray induced.  
**discoverer:** Sigmund, 1978.  
**references:** Craymer, 1980, DIS 55: 197-200.  
**genetics:** Mutant for *D* (missing alulae) and deficient for *ds* (shortened wings with close crossveins and widely spaced posterior scutellar bristles); also body small. Homozygous lethal and lethal over *D*: T(2;3)D<sup>4</sup>/ds<sup>W</sup> shows mutant characteristics of ds<sup>W</sup>/ds<sup>W</sup>.

**T(2;3)dp<sup>5</sup>**

**cytology:** T(2;3)25A2-3;95B3-5.  
**origin:** X ray induced.  
**discoverer:** Velissariou.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.  
 Velissariou and Ashburner, 1980, Chromosoma 77: 13-27.  
**genetics:** Associated with *dp*.

**T(2;3)dp<sup>6</sup>**

**cytology:** T(2;3)25A2-3;81F.  
**origin:** X ray induced.  
**discoverer:** Velissariou.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.  
 Velissariou and Ashburner, 1980, Chromosoma 77: 13-27.  
**genetics:** Mutant for *dp*.

**T(2;3)dp<sup>D</sup>: Translocation (2;3)  
 dumpy-Dominant**

**cytology:** T(2;3)25A;95B-D (Lewis).  
**origin:** X ray induced.  
**discoverer:** E.B. Lewis, 1962.  
**references:** Del Campo, 1963, DIS 38: 32.  
**genetics:** Mutant for *dp*. Homozygous lethal.

**T(2;3)dp<sup>w1</sup>: Translocation (2;3) dumpy-warped**

**origin:** X ray induced.  
**discoverer:** Schalet, 1955.  
**references:** Carlson and Schalet, 1955, DIS 29: 71-72.  
 Carlson, 1958, DIS 32: 117-18.  
**genetics:** Apparently variegated for *dp*. Homozygous lethal.

**T(2;3)Dp-S: Translocation (2;3) with Duplication Star**

**cytology:** T(2;3)21D4-E1;81F superimposed on Dp(2;2)21D2-3;21E2-3.  
**new order:**  
 21A – 21E2|21D3 – 21D4|81F – 61;  
 60 – 21E1|81F – 100.  
**origin:** X ray induced in Dp(2;2)S, *ast ast*.  
**discoverer:** E.B. Lewis.  
**references:** 1945, Genetics 30: 137-66.  
**genetics:** Y-suppressible expression of *ast*.

**origin:**  $\gamma$ -ray-induced detachment of *C(2L)RM-SH3* *C(2R)RM-SH3* females.  
**references:** Hilliker and Holm, 1975, Genetics 81: 705-21.  
**genetics:** Lethal with *Df(2L)C*, *Df(2L)C'*, and *In(2LR)bw<sup>VI</sup>*; viable with *Df(2L)D* and *Df(2L)D'*.  
 Variegates for *lt*.

***T(2;3)E(da)*: Translocation (2;3) Enhancer of daughterless**

**cytology:** *T(2;3)41;66C*.  
**origin:** X ray induced.  
**references:** Mange and Sandler, 1973, Genetics 73: 73-86.  
**genetics:** Associated with *E(da)*.

***T(2;3)E(SD)1*: Translocation (2;3) Enhancer of Segregation Distorter**

**cytology:** *T(2;3)41;100 + Df(2L)E(SD)1 = Df(2L)40A-B;40E*.  
**origin:**  $\gamma$  ray induced.  
**references:** Ganetzky, 1977, Genetics 86: 321-55.  
**genetics:** Associated with *E(SD)*.

***T(2;3)eg<sup>spy</sup>*: Translocation (2;3) eagle-spready**

**cytology:** *T(2;3)33D4-E3;79A4-B1*.  
**origin:** X ray induced.  
**discoverer:** Puro, 1961.  
**synonym:** *T(2;3)spy*.  
**references:** 1968, DIS 43: 59.  
 Puro and Arajarvi, 1968, DIS 43: 89-90.  
 1969, Hereditas 62: 414-18.  
 Puro, 1982, DIS 58: 205-08.  
**genetics:** Homozygous viable and fertile. Mutant for *eg*.

***T(2;3)el24*: Translocation (2;3) elbow**

**cytology:** *T(2;3)35B1-3;93C3-7*.  
**origin:** Induced by ethyl methanesulfonate.  
**genetics:** Mutant for *el*.

***T(2;3)en*: Translocation (2;3) engrailed**

**genetics:** Associated with *en*.

***T(2;3)ftz<sup>Rpl</sup>*: Translocation (2;3) fushi-tarazu-regulator of postbithorax-like**

**cytology:** *T(2;3)40-41;84B1-2*.  
**origin:** X ray induced.  
**discoverer:** Duncan.  
**synonym:** *T(2;3)Rpl*.  
**references:** Weiner, Scott, and Kaufman, 1984, Cell 37: 843-51.  
 Laughon and Scott, 1984, Nature 310: 25-31.  
 Duncan, 1986, Cell 47: 297-304.

**genetics:** Heterozygotes show transformations of posterior haltere to posterior wing.

**molecular biology:** Encodes truncated protein in which the C-terminal amino acids are replaced by 10 novel amino acids (Laughon and Scott, 1984). Breakpoint on 3 lies within the homeobox of the *ftz* coding sequence.

**T(2;3)G16: Translocation (2;3) Gelbart**

**cytology:** T(2;3)35D5-7;85F6-8;87F (Ashburner).

**new order:**

21 – 35D5|85F6 – 61;  
60 – 35D7|87F – 85F8|87F – 100.

**origin:** X ray induced.

**discoverer:** Gelbart.

**references:** Ashburner, Tsubota, and Woodruff, 1982, Genetics 102: 401-20.

**genetics:** 2L break associated with l(2)35Dd.

**T(2;3)G24**

**cytology:** T(2;3)35E1-2;89A1-2;92A1-2.

**new order:**

21 – 35E1|89A2 – 92A1|89A1 – 61;  
100 – 92A2|35E2 – 60.

**origin:** X ray induced.

**discoverer:** Gelbart.

**T(2;3)G40**

**cytology:** T(2;3)34F4-5;91E5-6.

**discoverer:** Gelbart.

**genetics:** Broken proximal to *noc*.

**T(2;3)gl<sup>63d</sup>: Translocation (2;3) glass**

**origin:** γ ray induced.

**discoverer:** Ives, 63d29.

**references:** 1965, DIS 40: 35.

**genetics:** Mutant for *gl*.

**T(2;3)Gla<sup>2</sup>: Translocation (2;3) Glazed-2**

**cytology:** T(2;3)27-28;87-88.

**origin:** X ray induced.

**references:** The Seattle-La Jolla Drosophila Laboratories, 1971, DIS 47, Suppl.

**genetics:** Associated with *Gla*<sup>2</sup>.

**T(2;3)Gld<sup>d5</sup>: Translocation (2;3) Glucose dehydrogenase**

**cytology:** T(2;3)?;84C8-D1.

**references:** Cavener, Otteson, and Kaufman, 1986, Genetics 14: 111-23.

Cavener, Corbett, Cox, and Whitten, 1986, EMBO J. 5: 2939-48.

**genetics:** Mutant for *Gld*.

**molecular biology:** Distal breakpoint at about +134 kb on the molecular map of Cavener, Corbett, Cox, and Whitten.

**T(2;3)gls: Translocation (2;3) glassy**

**cytology:** T(2;3)47B;91A.

**synonym:** T(2;3)T2.

**references:** Robinson and Curtis, 1972, Can. J. Genet. Cytol. 14: 129-37.

**genetics:** Homozygotes viable and fertile, with abnormal eye. In heterozygotes T(2;3)gls/T(2;3)smg, females are more fertile than males.

T(2;3)Gr: see T(2;3)Pu<sup>Gr</sup>

**T(2;3)GT**

**origin:** γ ray induced.

**discoverer:** Durrant.

<sup>α</sup> Synonym: T(2;3)LO2 - T(2;3)LO67 ("LD" = lost).

**T(2;3)H<sup>24</sup>: Translocation (2;3) Hairless**

cytology: T(2;3)41;92F1-2.  
 references: Bang, Hartenstein and Posakony, 1991,  
 Development 111: 89-104.  
 genetics: Mutant for *H*.

**\*T(2;3)HK: Translocation (2;3) Half of Krivshenko**

cytology: T(2;3)22A;61A.  
 origin: X ray induced in female.  
 discoverer: Krivshenko, 56114.  
 references: 1959, DIS 33: 95.  
 genetics: Only the 3<sup>P</sup>2L<sup>D</sup> element recovered from the treated oocyte.

**T(2;3)Hm: Translocation (2;3) Haltere mimic**

cytology: T(2;3)29;32;88F;89E3-4.  
 new order:  
 21 - 29|88F - 61;  
 60 - 32|88F - 89E3|29 - 32|89E4 - 100.  
 origin: X ray induced.  
 discoverer: Slatis, 49b5.  
 references: Lewis, 1982, Embryonic Development: Genetic Aspects (Burger and Weber, eds.). Alan Liss, Inc., New York. Progress in Clin. Biol. Res. 85A: 269-89.  
 genetics: Associated with *Cbx<sup>Hm</sup>*.

**T(2;3)Hn: Translocation (2;3) Henna**

cytology: T(2;3)53E-54A;77A;94F;96A (Lewis).  
 new order:  
 21 - 53E|77A - 61;  
 60 - 54A|94F - 96A|77A - 94F|96A - 100.  
 Tentative.  
 origin: X ray induced.  
 discoverer: Van Atta, 30k.  
 references: 1932, Am. Nat. 66: 93-95.  
 1932, Genetics 17: 637-59.  
 genetics: Separable from *Hn*, which is associated with *Df(3L)Hn = Df(3L)66A;66B*.

T(2;3)ho5: see T(2;3)dpp<sup>3</sup>

**T(2;3)HR**

origin: X ray induced.  
 genetics: Crossover suppressor between *h* and *ri*.

translocation	cytology	ref <sup>α</sup>	homozygous viability

<sup>β</sup> Also fertile and wild type.

**T(2;3)I: Translocation (2;3) Ising**

discoverer: Ising.  
 references: Ashburner.

translocation	cytology
<b>T(2;3)I805</b>	40F;75AB + In(3R)89;94
<b>T(2;3)I806</b>	55E;66A
<b>T(2;3)I810</b>	53F;95E-F

**T(2;3)iab4<sup>45</sup>: Translocation (2;3) infraabdominal**

cytology: T(2;3)32;41;89E. Complex.  
 origin: X ray induced.  
 discoverer: R.H. Baker.  
 genetics: Mutant for *iab4*.

**molecular biology:** 89E breakpoint 78.5-82 kb to the right of right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

**T(2;3)iab6**

**origin:** X ray induced.  
**genetics:** Mutant for *iab6*.

translocation	cytology	discoverer	molecular biology <sup>α</sup>
<b>T(2;3)iab6<sup>75</sup></b>	30A-B;31D-E; 59F;89E;89F	Baker	103--108 kb

<b>T(2;3)iab6<sup>C1</sup></b>	60B;81;89E;	Crosby	108-111 kb

<sup>α</sup> Coordinates of 89E breakpoints in kilobases to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

**T(2;3)iab8<sup>rv</sup>**

**genetics:** Revertants of *iab8* in the *BXC*.

translocation	cytology
<b>T(2;3)iab8<sup>rv100</sup></b>	37E-38A;89E
<b>T(2;3)iab8<sup>rv185</sup></b>	50D;89E

**T(2;3)iab9<sup>65</sup>**

**cytology:** T(2;3)41;89E.  
**origin:** X ray induced.  
**discoverer:** R.H. Baker.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.  
Sánchez-Herrero, Vernós, Marco, and Morata, 1985, Nature 313: 108-13.  
Tiong, Bone, and Whittle, 1985, Mol. Gen. Genet. 200: 335-42.

**genetics:** Mutant for *iab9*.  
**molecular biology:** 89E breakpoint 163-166.5 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

**T(2;3)IC67-98**

**cytology:** T(2;3)24E-F;91D.  
**origin:** X ray induced.  
**references:** Brosseau, 1969, DIS 44: 45.  
**genetics:** Homozygous lethal.

**T(2;3)in<sup>60i2</sup>: Translocation (2;3) intuned**

**cytology:** T(2;3)62D-F;77B;80C. Complex translocation with inversion(s) in 3L.  
**references:** Arajarvi and Hannah-Alava, 1969, DIS 44: 73-74.  
**genetics:** Associated with *in<sup>60i2</sup>*.

**T(2;3)Ir: Translocation (2;3) Irish**

**cytology:** T(2;3)55D-E;98F.  
**origin:** γ ray induced.  
**discoverer:** Irish.  
**other information:** Induced along with *Df(2L)dpp43*.

**T(2;3)JHT1**

**cytology:** T(2;3)34C;96F.  
**origin:** Spontaneous in *JH* chromosome line during successive backcross programs.  
**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

**T(2;3)JHT2**

**cytology:** T(2;3)56F;97B.  
**origin:** Spontaneous in *JH* chromosome line during successive backcross programs.

**references:** Yamaguchi and Mukai, 1974, Genetics 78: 1209-21.

**T(2;3)L141**

**origin:** γ ray induced in *T(Y;2)L141/+* males.  
**discoverer:** Lyttle.

**T(2;3)lt<sup>m100</sup>**

cytology: T(2;3)40;97F.  
origin: X ray induced.  
references: Baker and Rein, 1962, Genetics 47: 1399-1407.  
genetics: Variegated for *lt*. Homozygous lethal.

**T(2;3)lt<sup>x13</sup>**

cytology: T(2;3)40F;97D2.  
discoverer: Wakimoto.  
references: James, Eissenberg, Craig, Dietrich, Hobson, and Elgin, 1989, Eur. J. Cell Biol. 50: 170-80.

T(2;3)M<sup>V54d</sup>: see T(2;3)MV

**\*T(2;3)Me<sup>2</sup>**

origin: X ray induced.  
discoverer: Moore, 1929.  
references: Glass, 1933, J. Genet. 28: 69-112.  
genetics: Break in 2L near centromere. Mutant for *Me*.

**\*T(2;3)Me<sup>So</sup>: Translocation (2;3) Moiré of Sytko**

discoverer: Sytko.  
references: Agol, 1936, DIS 5: 7.  
genetics: Breaks reportedly in 2R and 3R, yet mutant for *Me* in 3L.

**T(2;3)Met: Translocation (2;3) Metatarsi irregular**

origin: X ray induced.  
discoverer: Jonsson, 56a10.  
references: 1956, DIS 30: 73.  
genetics: Associated with *Met*.

***T(2;3)Mpe: Translocation (2;3) Monoplane***

cytology: *T(2;3)35B2-3;86C1-2* (Ashburner).  
origin: X ray induced.  
discoverer: Shelton.  
references: Hughes and Shelton, 1980, DIS 55: 204-05.  
Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.  
Chia, Karp, McGill, and Ashburner, 1985, J. Mol. Biol. 186: 689-706.  
McGill, Chia, Karp, and Ashburner, 1988, Genetics 119: 647-61.  
genetics: Associated with dominant *Mpe* phenotype and recessive *osp* allele. Also shows a dominant leg phenotype (thickening of the tibial-tarsal joint of the metathoracic leg). Phenotypes of leg and outstretched-wing associated with 2<sup>P3</sup>D element of the translocation. Lethal homozygous or with *Df(3R)cu40* and *Df(3R)by77*. Heterozygotes show reduced viability and partial sterility (Hughes and Shelton, 1980). *T(2;3)Mpe* heterozygous with a deletion of the entire *noc* region is *noc*<sup>+</sup> (McGill *et al.*, 1988).

molecular biology: 35B2-3 breakpoint at -103 to -106.5 bp in the molecular map of the wild-type *noc-Adh* region (McGill *et al.*, 1988) (coordinate 0 on *EcoR1* restriction site 1321 bp to the left of the start of transcription of the larval *Adh* transcript, "+" values to the right, "-" values to the left).

***T(2;3)Msc<sup>T3</sup>: Translocation (2;3) Multiple sex comb***

origin: γ ray induced.  
discoverer: Tiong.  
references: Kennison and Russell, 1987, Genetics 116: 75-86.  
genetics: Mutant for *Msc*.

**\*T(2;3)MV: Translocation (2;3) Variegated of Mickey**

**cytology:** T(2;3)43E;75C.  
**origin:** γ ray induced.  
**discoverer:** Mickey, 54d.  
**synonym:** T(2;3)M<sup>V54d</sup>.  
**references:** 1963, DIS 38: 30.  
**genetics:** Eye color variegated, more prominent in male.

**T(2;3)N**

**origin:** X ray induced.

60 – 57C1|79F – 100.

Tentative.

**origin:** X-ray-induced derivative of *T(2;3)Pu* = *T(2;3)40F-41A;70D-E + T(2;3)57B5-C1;79F*.

**discoverer:** Oliver, 32127.

**references:** 1939, Genetics 24: 82.

1941, Proc. Intern. Congr. Genet., 7th., p. 228.

**genetics:** Partial reversal of *Pu*. Homozygous lethal.

***T(2;3)Pu*<sup>W</sup>: Translocation (2;3) Punch-Wine**

**cytology:** *T(2;3)57C4-6;80*.

**origin:** X ray induced.

**discoverer:** E.B. Lewis, 55h.

**references:** Mackay and O'Donnell, 1983, Genetics 105: 35-53.

**genetics:** Mutant for *Pu*, showing dominant variegated eye color. Homozygous lethal.

***T(2;3)RBR37***

**cytology:** *T(2;3)26A;88F*.

**origin:** Spontaneous [accumulated on second chromosome lines during repeated backcrossing of *In(2LR)bw*<sup>V1/+</sup> males to *In(2LR)bw*<sup>V1/SM1</sup> females].

**references:** Yamaguchi, Cardellino, and Mukai, 1976, Genetics 83: 409-22.

***T(2;3)RBR77***

**cytology:** *T(2;3)33B;99F*.

**origin:** Spontaneous [accumulated on second chromosome lines during repeated backcrossing of *In(2LR)bw*<sup>V1/+</sup> males to *In(2LR)bw*<sup>V1/SM1</sup> females].

**references:** Yamaguchi, Cardellino, and Mukai, 1976, Genetics 83: 409-22.

***T(2;3)rg35***

**cytology:** *T(2;3)27E-F;62C2-D1*.

**origin:** γ ray induced. Sliter, Henrioh, Tucker, and Gilbert, 1989, Genetics 123: 327-36.

***T(2;3)ri*<sup>60b2</sup>: Translocation (2;3) radius incompletus**

**cytology:** *T(2;3)?;77E3-78A1*.

**origin:** X ray induced.

**references:** Arajarvi and Hannah-Alava, 1969, DIS 44: 73-74.

**genetics:** Mutant for *ri*.

***T(2;3)rn*: Translocation (2;3) rotund**

**cytology:** *T(2;3)40-41;80-81;84D8-9* (Duncan and Kaufman, 1978; B.S. Baker). Configuration is *2L-3L;2R-3R* (Puro and Kiiskilä, 1982).

**new order:**

21 – 40|80 – 61;  
60 – 41|84D8 – 81F|84D9 – 100.

Tentative.

**origin:** Probably X ray induced.

**discoverer:** Glass, 1929.

**references:** 1934, DIS 2: 8.

Muller, 1953, DIS 27: 106-7.

Carlson, 1956, DIS 30: 109.

Duncan and Kaufman, 1975, Genetics 80: 733-52.

Puro and Kiiskilä, 1982, DIS 80: 125-26.

**genetics:** Mutant for *rn*. Homozygous viable and sterile in both sexes. About 10% of the progeny of parents heterozygous for *T(2;3)rn* and chromosome 2 inversions are nondisjunctional for chromosome 2 (Muller, 1953).

*T(2;3)Rpl*: see *T(2;3)ftz*<sup>Rpl</sup>

***T(2;3)RY2***

**origin:** X ray induced.

**discoverer:** Simpson.

**genetics:** Deficient for *sna*.

**\**T(2;3)S*<sup>L</sup>: Translocation (2;3) Star of Lewis**

**cytology:** *T(2;3)21D;81;88D* (Craymer, 1984).

**new order:**

21A – 21D|81F – 88D|81F – 61;  
60 – 21D|88D – 100.

Tentative.

**origin:** X ray induced.

**discoverer:** E.B. Lewis, 1940.

**references:** 1945, Genetics 30: 137-66.

Craymer, 1984, Genetics 108: 573-87.

**genetics:** Mutant for *S*.

***T(2;3)S*<sup>M</sup>: Translocation (2;3) Star of Muller**

**cytology:** *T(2;3)21E2-3;79D2-E1* superimposed on *In(2L)22D1-2;33F5-34A1 + In(2R)42A2-3;58A4-B1*.

**origin:** X ray induced in *In(2L)Cy + In(2R)Cy*.

**discoverer:** Muller, 1928.

**references:** Painter and Muller, 1929, J. Heredity

20: 287-98.

Muller, 1930, *J. Genet.* 22: 335-57.

Morgan, Bridges, and Schultz, 1936, *Year Book - Carnegie Inst. Washington* 35: 293.

**genetics:** Mutant for *S*; also carries *Cy*.

***T(2;3)S9***

**cytology:** *T(2;3)40-41;80-81*.

**origin:** X ray induced.

**references:** Sandler, Lindsley, Nicoletti, and Trippa, 1968, *Genetics* 60: 525-58.

**genetics:** Homozygous lethal.

**\**T(2;3)Sa: Translocation (2;3) Salmon***

**origin:** X ray induced.

**discoverer:** Van Atta, 30k1.

**references:** 1932, *Am. Nat.* 66: 93-95.

1932, *Genetics* 17: 637-59.

**genetics:** Associated with *Sa*. Homozygous lethal. Break in *2L* between *pr* and centromere and in *3L* near centromere.

***T(2;3)Sb<sup>V</sup>: Translocation (2;3) Stubble-Variigated***

**cytology:** *T(2;3)41A-C;88;89B* superimposed on *In(3R)93D7-E1;98F2-6*. *In(3LR)P35 = In(3LR)65;83D-E* induced simultaneously but was separated from it by recombination.

**new order:**

21 – 41A|89B – 93D7|98F2 – 93E1|98F6 – 100;

61A – 88|89B – 88|41C – 60.

**origin:** X ray induced in *In(3R)Mo*, *Sb sr*.

**discoverer:** E.B. Lewis, 1948.

**references:** 1956, *DIS* 30: 76-77.

**genetics:** Variates for phenotype of deficiency for *Sb*, which is normal.

***T(2;3)sbd<sup>47</sup>: Translocation (2;3) stubbloid***

**cytology:** *T(2;3)41;89B10-12*.

**origin:** X ray induced.

**references:** Spillman and Nöthinger, 1978, *DIS* 53: 164-65.

**genetics:** Associated with *sbd<sup>47</sup>*. Homozygous lethal.

***T(2;3)sbd<sup>106</sup>***

**cytology:** *T(2;3)22E;89B*.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**\**T(2;3)Scar: Translocation (2;3) Scarred***

**cytology:** *T(2;3)27E;95A + In(3R)91F;96A*.

**origin:** X ray induced.

**discoverer:** Yu, 48h.

**references:** 1949, *DIS* 23: 65.

**genetics:** Associated with *Scar*.

***T(2;3)Sco<sup>rv7</sup>: Translocation (2;3) scutoid-revertant***

**cytology:** *T(2;3)35D1-2;93F11-94A4* superimposed on *Tp(2;2)Sco*.

**new order:**

21 – 35A4|(35C2 – 35C5)|35B4 – 35C1|

35B3 – 35B1|93F11 – 61;

60 – 35D2|93A4 – 100.

**origin:** X ray induced.

**discoverer:** Ashburner.

**references:** Woodruff and Ashburner, 1979, *Genetics*

92: 117-32.

Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, *DIS* 55: 193-95.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, *Genetics* 104: 405-31.

Ashburner and Harrington, 1984, *Chromosoma* 89: 329-37.

**genetics:** Homozygous lethal. Revertant for *Sco*.

***T(2;3)Sco<sup>rv13</sup>***

**cytology:** *T(2;3)35D1-2;71B1-2;81*.

**new order:**

21 – 35A4|(35C2 – 35C5)|35B4 – 35C1|35B3 – 35B1|

71B2 – 81|71B1 – 61;

60 – 35D2|81 – 100.

**origin:** X ray induced.

**discoverer:** Ashburner.

**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, *DIS* 55: 193-95.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, *Genetics* 104: 405-31.

Ashburner and Harrington, 1984, *Chromosoma* 89: 329-37.

**genetics:** Homozygous lethal. *2L* breakpoint maps between transposed *noc* allele and *sna*.

**molecular biology:** 35D1--2 breakpoint mapped to the DNA (McGill, Chia, Karp, and Ashburner, 1988, *Genetics* 119: 647-61).

***T(2;3)Scr<sup>T3</sup>: Translocation (2;3) Sex combs reduced***

**cytology:** Complex with breakpoints in at least *25C-D;84B1-2;92A* (Kennison).

**origin:**  $\gamma$  ray induced in a *mwh iab9<sup>uh3</sup>* stock.

**discoverer:** Tiong.

**genetics:** *Dfd<sup>+</sup> Scr<sup>-</sup> ftz<sup>+</sup> Antp<sup>+</sup>*; associated with *Scr<sup>T3</sup>*.

***T(2;3)Scx<sup>Wrv1</sup>: Translocation (2;3) sex combs extra revertant***

**cytology:** *T(2;3)58F1-2;84B1-2*.

**origin:** X ray induced.

**references:** Hazelrigg and Kaufman, 1983, *Genetics* 105: 581-600.

Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, *Cell* 35: 763-76.

**genetics:** Homozygous lethal; heterozygotes show reduced sex comb phenotype. Fails to complement *Antp* and certain *Scr* alleles for lethality; viable or semilethal with other *Scr* alleles.

**molecular biology:** Third-chromosome breakpoint 79 kilobases to the right of the proximal breakpoint of *Tp(3;3)Dfd<sup>rv16</sup>* (Scott *et al.*, 1983).

***T(2;3)Scx<sup>Wrv6</sup>***

**cytology:** *T(2;3)22D1;63A1-2 + T(2;3)54A1-2;80-81*. Pairing of polytene chromosomes in proximal *3R* usually disrupted.

**synonym:** *T(2;3)Scx<sup>W+RX6</sup>*.

**origin:** X ray induced.

**references:** Hazelrigg and Kaufman, 1983, *Genetics* 105: 581-600.

Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, *Cell* 35: 763-76.

**genetics:** Homozygous lethal; heterozygotes show reduced sex comb phenotype. Fails to complement *Scr* and *Antp*

for lethality.

**T(2;3)SD: Translocation (2;3)  
Segregation Distorter**

**origin:** X ray induced in SD-72 males.  
**references:** Yamazaki and Thompson, 1973, Jpn. J. Genet. 48: 217-29.  
**genetics:** Associated with SD. K values tested.

translocation	cytology	synonym
T(2;3)SD-1	25D;61E	T(2;3)SD72-9
T(2;3)SD-2	56;94	T(2;3)SD-182
T(2;3)SD-3	40-41;97	T(2;3)SD-392

**T(2;3)shv<sup>S</sup>: Translocation (2;3)  
shortvein of Segal**

**references:** Segal and Gelbart, 1985, Genetics 109: 119-43.  
**genetics:** Associated with shv alleles. Lethal over shv and other dpp lethals.

translocation	cytology	origin
T(2;3)shv S1 α	22F1-2;64E1-2	X ray
T(2;3)shv S13	22F1-2;93B8-10	γ ray

60F - 59D|88D - 87C|88D - 94D|22F - 59D|94D - 100F.  
(tentative chromocentral arrangement)

**\*T(2;3)SM2: Translocation (2;3)  
Second Multiple**

**cytology:** T(2;3)21A;40F;80-81 superimposed on In(2L)22D1-2;33F5-34A1 + In(2LR)22A3-B1;60B-C + In(2R)42A2-3;58A4-B1; position of breaks in proximal heterochromatin with respect to centromeres not determined.

**origin:** X ray induced in In(2LR)SM1.  
**discoverer:** R. F. Grell, 1953.  
**references:** Lewis and Mislove, 1953, DIS 27: 58. Mislove and Lewis, 1954, DIS 28: 77.  
**genetics:** Variegated for lt.

**other information:** The translocation impairs its general usefulness as a chromosome 2 balancer; described as SM2 (see Balancers in Special Chromosomes section).

**T(2;3)smg: Translocation (2;3) smudge**

**cytology:** T(2;3)24D;92A.  
**synonym:** T(2;3)T1.  
**references:** Robinson and Curtis, 1972, Can. J. Genet. Cytol. 14: 129-37. 1973, Genetica 44: 591-601.  
**genetics:** Homozygotes viable and fertile, with abnormal eye ("smudge" effect). Heterozygotes wild type and semisterile (Robinson and Curtis, 1973). In double heterozygotes T(2;3)gls/T(2;3)smg, females are more fertile than males (Robinson and Curtis, 1972).

**T(2;3)SMG: Translocation (2;3)  
Semenova Mglinetz Glotoff**

**origin:** γ ray induced.  
**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6: 165-69.

translocation	cytology
T(2;3)SMG41	27B;92C
T(2;3)SMG42	27F;66B
T(2;3)SMG43	26E;54D;76C;84F

**T(2;3)sna: Translocation (2;3) snail**

**cytology:** T(2;3)24B-C;35C-D;41;81. 24C-D to 35B-C inverted.

**discoverer:** Simpson.  
**synonym:** RY2.  
**genetics:** Mutant for sna. Homozygous lethal.

**T(2;3)so<sup>Drv</sup>: Translocation (2;3)  
sine-oculis**

**references:** Ashburner.  
**genetics:** so<sup>D</sup> revertant.

translocation	cytology
T(2;3)so <sup>Drv1</sup>	43B1-2;86E14-20
T(2;3)so <sup>Drv2</sup>	43B3-8;91A3-8

**\*T(2;3)sr<sup>4.2</sup>: Translocation (2;3) stripe**

**cytology:** T(2;3)30C;90C-96.  
**origin:** X ray induced.  
**discoverer:** Alexander.  
**references:** 1960, Genetics 45: 1019-22.  
**genetics:** Mutant for sr. Homozygous lethal.

**\*T(2;3)sr<sup>100.312</sup>**

**cytology:** T(2;3)40-41;90D2-E1.  
**origin:** X ray induced.  
**discoverer:** Alexander.  
**references:** Ward and Alexander, 1957, Genetics 42: 42-54.  
**genetics:** Mutant for sr. Homozygous lethal.

**T(2;3)ss<sup>a75</sup>**

**cytology:** T(2;3)36D;89C.  
**origin:** γ ray induced.  
**references:** Kaufman, 1978, Genetics 90: 579-96.  
**genetics:** Mutant for ss<sup>a</sup>.

**\*T(2;3)st<sup>100.359</sup>: Translocation (2;3) scarlet**

**cytology:** T(2;3)21C3-5;73A2-3;98F2-4.  
**new order:**  
21A - 21C3|73A3 - 98F2|73A2 - 61;  
60 - 21C5|98F4 - 100.  
**origin:** X ray induced.  
**discoverer:** Alexander.  
**references:** Ward and Alexander, 1957, Genetics 42: 42-54.  
**genetics:** Mutant for st. Homozygous lethal.

**T(2;3)Su(var)3-5: Translocation (2;3)  
Suppressor of  
variegation 3-5**

**cytology:** T(2;3)58B;86B.  
**origin:** X ray induced.  
**references:** Reuter, Dorn, Wustmann, Friede, and Rauh, 1986, Mol. Gen. Genet. 202: 481-87.

**genetics:** Associated with *Su(var)3-5*. Recessive semilethal and sterile in both males and females.

***T(2;3)Su(z)41: Translocation (2;3) Suppressor of zeste***

**cytology:** *T(2;3)40-41;80-81*.

**references:** Gelbart, 1971, Ph.D. Thesis, Univ. of Wisconsin.

**genetics:** Associated with *Su(z)*.

***T(2;3)Su(z)56***

**cytology:** *T(2;3)40-41;97F-98B*.

**references:** Gelbart, 1971, Ph.D. Thesis, Univ. of Wisconsin.

**genetics:** Associated with *Su(z)*.

***T(2;3)scx<sup>2</sup>: Translocation (2;3) super sex combs***

**cytology:** *T(2;3)41C1-2;98C-D;99A-B*.

**new order:**

21A – 41C1|99B – 100;

61 – 98C|99A – 98D|41C2 – 60.

**origin:** X ray induced.

**references:** Ingham, 1984, Cell 37: 815-23.

**genetics:** Mutant for *scx*. Homozygous lethal and lethal over *Df(2R)M41A4*.

***T(2;3)T***

**origin:** X ray induced in stage 7 or stage 14 oocytes of *T(2;3)eg<sup>SPY</sup>/+* females or *T(2;3)ap<sup>Xa</sup>/+* females.

**references:** Puro, 1982, DIS 58: 205-08.

(terminal attachment of 3L segment to 2R distal to 60F5).

$\beta$  Break in 2 and left break in 3 identical to those in *T(2;3)eg<sup>SPY</sup>*; *T(2;3)T1-53* derived from *T(2;3)eg<sup>SPY</sup>* by replacement of 61-79A4 by 61-80A1.

***T(2;3)Ta<sup>1</sup>: Translocation (2;3) thickened arista***

**cytology:** *T(2;3)51E1-2;84B1-2* (Kaufman *et al.*, 1980) or *.84C1-2* (Cavener *et al.*, 1986).

**synonym:** *T(2;3)Ta<sup>L</sup>*.

**origin:**  $\gamma$  ray induced.

**references:** Kaufman, 1978, Genetics 90: 579-96.

Kaufman, Lewis, and Wakimoto, 1980, Genetics 94: 115-33.

Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48.

Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

**genetics:** Associated with *Ta<sup>1</sup>*. Homozygous lethal. When heterozygous with *Ta<sup>2</sup>*, the translocation is viable and shows a transformation of the whole arista and antennal segments four and five into tarsus and, in males, an extreme reduction in number of sex-comb teeth on the first leg (Kaufman *et al.*, 1980). Fails to complement both *hat* and *stk* and gives rise to the same lethal "partial eclosion" phenotype (Cavener *et al.*, 1986).

**molecular biology:** Distal (84C1-2) breakpoint at +34 kb; in the 15 kb overlap of *Df(3R)Scx2* and *Df(3R)dsx2M* (Baker and Wolfner, 1988, Genes Dev. 2: 477-89; 0 point = *HindIII* site in  $\alpha$ *Tub84D*; "+" values to the right, "-" values to the left).

***T(2;3)Tab<sup>rv100</sup>: Translocation (2;3) Transabdominal-reverted***

**cytology:** *T(2;3)37F-38A;89E + In(3R)89E;90D*.

**origin:** X ray induced in *In(3R)Tab*.

**references:** Celniker and Lewis, 1987, Genes and Development 1: 111-23.

**genetics:** Revertant of dominant *Tab* phenotype. When hemizygous, shows stronger transformation of the eighth ventral setal band toward that of the seventh than does *Tab/Df(3R)P9*; also abnormal posterior spiracles and a rudimentary ninth ventral setal band.

**molecular biology:** Lesion associated with the 89E breakpoint lies between 183 and 184 kb on the composite restriction map of the BXC (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, Science 21: 23-29).

***T(2;3)Tab<sup>rv185</sup>***

**cytology:** *T(2;3)50D;89E + In(3R)89E;90D*.

**origin:** X ray induced in *In(3R)Tab*.

**references:** Celnicker and Lewis, 1987, Genes and Development 1: 111-23.

**genetics:** Revertant of dominant *Tab* phenotype. When hemizygous, shows stronger transformation of the eighth ventral setal band toward that of the seventh than does *Tab/Df(3R)P9*; also abnormal posterior spiracles and a rudimentary ninth ventral setal band.

***T(2;3)TE34Cc: Translocation (2;3) Transposing Element***

**cytology:** *T(2;3)34D1-2;80-81*.

**origin:**  $\gamma$  ray induced in *TE34Cc*.

**discoverer:** Gubb.

**synonym:** *T(2;3)TE94<sup>V1</sup>*.

**references:** Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.

**genetics:** Variegates for *w*. Lethal with *l(2)34Da*

deficiencies.

**T(2;3)TE35A**

origin:  $\gamma$  ray induced in TE35A; selected as reversion of z.  
 synonym: T(2;3)TE146Z.

**references:** 1945, Genetics 30: 137-166.  
**genetics:** Variegates for *S*, *ast*, and *ci*. Homozygous lethal. Fly with  $2^P 4^D$  element in place of one chromosome 2 survives and has extremely rough eyes.  $2^P 4^D$  is deficient for *l(2)gl* and *net* and presumably for *al*, *ex*, and *ds*. Fly hyperploid for complementary  $4^P 2L^D$  also survives.

***T(2;4)b***

**cytology:** *T(2;4)25E;102C15-D1* (Schultz and Lewis). Metaphase chromosome 4 twice normal size.  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 1929.  
**references:** 1930, Biol. Zentr. 50: 671-85. 1931, Genetics 16: 629-58.  
**genetics:** *ci* not affected. Homozygous viable and fertile. Fly hyperploid for  $4^P 2L^D$  element survives; short and thick with flattened abdomen, bulging eyes, and curved wings; both sexes sterile. Duplicated for *M(2)25A* and *dp* but not *cl*, *ey*, or *sv* (Morgan, 1946, DIS 20: 88).

***T(2;4)BIII17***

**cytology:** *T(2;4)40-41;101F*.  
**references:** Yamamoto, 1987, DIS 66: 192-93.

**\**T(2;4)bw<sup>R25</sup>: Translocation (2;4) brown-Rearranged***

**cytology:** *T(2;4)59D;101E*.  
**origin:** X-ray-induced derivative of *bw*.  
**discoverer:** Slatis.  
**references:** 1955, Genetics 40: 5-23.  
**genetics:** Associated with *bw<sup>R25</sup>*.

**\**T(2;4)c***

**cytology:** Metaphase chromosome 4 about twice normal size.  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 1929.  
**references:** 1930, Biol. Zentr. 50: 671-85. 1961, Genetics 16: 629-58.  
**genetics:** Homozygote nearly lethal; wings do not expand; fly dies early. Break in 2L between *dp* and *b*, close to *dp*. Male hyperploid for  $4^P 2L^D$  element poorly viable and sterile. No variegation for *ci*<sup>+</sup> (Stern).

***T(2;4)C: Translocation (2;4) Crossover suppressor***

**origin:** X ray induced.  
**discoverer:** Roberts.  
**synonym:** *T(2;4)2 - T(2;4)90*.  
**references:** 1972, Genetics 71: 401-15.

**T(3;4)85C**

cytology: T(3;4)85C; breakpoint in chromosome 4 not determined.

discoverer: E.B. Lewis.

references: Pipkin, 1959, Texas Univ. Publ. 5914: 69-88.

**T(3;4)86D**

cytology: T(3;4)86D2-3;101F.  
origin: Neutron induced in  $bx^{34e}e^4$ .

discoverer: E.B. Lewis.

references: Grell, 1959, Genetics 44: 421-35.  
1959, Genetics 44: 911-22.

Grell and Day, 1970, Chromosoma 31: 434.

genetics: Homozygous viable and fertile. T(3;4)86D/ci has ci effect, is enhanced by low temperature, and tends to be suppressed by extra Y chromosome. Venation of homozygote and haplo-4 is  $ci^+$ .

**T(3;4)88B**

cytology: T(3;4)88B; breakpoint in 4 not determined.

origin: X ray induced in *Ubx*.

discoverer: E.B. Lewis.

references: Grell, 1959, Genetics 44: 421-35.

genetics: Homozygous lethal. Has no position effect on *ci*.

**T(3;4)89E**

cytology: T(3;4)89E2-3;101F.

origin: X ray induced in  $ss\ bx\ Su(ss)^2$ .

discoverer: E.B. Lewis.

references: Grell, 1959, Genetics 44: 911-22.

genetics: Associated with  $bxd^{101}$ . Homozygous lethal. T(3;4)89E/ci has a ci effect, is enhanced by low temperature, and tends to be suppressed by extra Y chromosome.

T(3;4)104: see *Tp(4;3)f*

**T(3;4)429.10**

cytology: T(3;4)99B1-2;102D + *In(3R)81F;86B-C*.

origin: X ray induced.

discoverer: Gelbart.

**\*T(3;4)684**

cytology: T(3;4)67;101; breakpoints roughly estimated from figure of Dubinin and Sidorov (1935).

origin: X ray induced.

discoverer: Dubinin and Sidorov.

references: 1934, Biol. Zh. (Moscow) 3: 307-31.

1935, Biol. Zh. (Moscow) 4: 555-68 (fig.).

genetics: Position effects on both *h* and *ci*.

**T(3;4)a**

cytology: Chromosome 4 increased to about one-half length of 3L in metaphase figures.

origin: X ray induced.

discoverer: Dobzhansky, 29h.

references: 1929, Biol. Zentr. 49: 408-19.

1929, Proc. Nat. Acad. Sci. USA 15: 633-38.

1930, Genetics 15: 347-99.

genetics: Homozygous lethal. Break in 3L between *D* and *th*.

**T(3;4)A: Translocation (3;4) from Austin**

origin: X ray induced.

 Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81.  
**genetics:** Revertant of Antp<sup>Ns</sup>. Lethal homozygous and when heterozygous with ANTC mutants.

**\*T(3;4)b**

**cytology:** Chromosome 4 increased to one-half the length of 3L in metaphase figures.  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 1929, Proc. Nat. Acad. Sci. USA 15: 633-38.  
 1930, Genetics 15: 347-99.  
**genetics:** Breakpoint in 3L near th. Crossing over markedly lowered near th and somewhat so at 3L tip.

**T(3;4)BII8**

**cytology:** T(3;4)77A;101F.  
**references:** Yamamoto, 1987, DIS 66: 192-93.

**T(3;4)BII13**

**cytology:** T(3;4)93E;101F.  
**references:** Yamamoto, 1987, DIS 66: 192-93.

**T(3;4)BTD1: Translocation (3;4) Bithorax Tranvection Disrupter**

**cytology:** T(3;4)87A;102D  
**origin:**  $\gamma$  ray induced.  
**references:** Smolik-Utlaut and Gelbart, Genetics 116: 285-98.

**T(3;4)bx<sup>d</sup>101: Translocation (3;4) bithoraxoid**

**cytology:** T(3;4)89E;101F.  
**origin:** X ray induced.  
**discoverer:** E.B. Lewis.  
**references:** 1981, Developmental Biology Using Purified Genes (Brown and Fox, eds.). Academic Press, New York, Vol. 23, pp. 189-208.  
**genetics:** Mutant for bx<sup>d</sup>.

**T(3;4)c**

**cytology:** T(3;4)86B-C;101F (Lewis, 1951, DIS 25: 108-9).  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 1929, Proc. Nat. Acad. Sci. USA 15: 633-38.  
 1930, Genetics 15: 347-99.  
**genetics:** Homozygous viable and fertile. ci not affected. Crossing over much reduced near breakpoint in heterozygote and even more reduced in homozygote in some

regions (Beadle, 1932, Proc. Nat. Acad. Sci. USA 18: 160-65).

**T(3;4)C: Translocation (3;4) Crossover suppressor**

**origin:** X ray induced.  
**discoverer:** Roberts.  
**synonym:** T(3;4)I - T(3;4)90.

<sup>α</sup> Involves break between ci and the centromere (Stern, MacKnight, and Kodani, 1946, Genetics 31: 598-619).

**\*T(3;4)d**

**cytology:** Metaphase figures show barely detectable increase in size of chromosome 4.  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 1929, Proc. Nat. Acad. Sci. USA 15: 633-38.  
 1930, Genetics 15: 347-99.  
**genetics:** Homozygous lethal. ci not affected (Stern). Breakpoint in 3R between ca and M(3)99E and in 4 to the left of M(4) and ey. Apparently, 3<sup>P</sup>4<sup>D</sup> element can substitute for a normal 3, producing Minute flies. Hyperploids for 4<sup>P</sup>3<sup>D</sup> element probably also survive.

**T(3;4)DI<sup>7P</sup>: Translocation (3;4) Delta-7 of Panshin**

**origin:** X ray induced.  
**discoverer:** Panshin.  
**references:** 1935, Dolk. Akad. Nauk SSSR 4: 85-88.  
**genetics:** Chromosome 3 broken to the right of cu. Mutant for Dl; position effect that weakens dominance of cu<sup>+</sup>.

**T(3;4)e**

**cytology:** T(3;4)79E;102F (Lewis, 1956, DIS 30: 130).  
**origin:** X ray induced.  
**discoverer:** Dobzhansky, 28h.  
**references:** 1929, Biol. Zentr. 49: 408-19.  
 1929, Proc. Nat. Acad. Sci. USA 15: 633-38.  
 1930, Genetics 15: 347-99.  
**genetics:** Homozygous semilethal and female sterile. ci not affected (Stern). Crossing over normal in heterozygote except near p.

**T(3;4)E(spl)<sup>IV</sup>: Translocation (3;4) Enhancer of split-reverted**

**origin:** X ray induced.  
**genetics:** Loss of function mutants. Lethal as homo- and hemizygotes. Variable neural hypoplasia in deficiency heterozygotes.

translocation	cytology	discoverer	ref <sup>α</sup>	molecular biology <sup>β</sup>
<b>T(3;4)E(spl)<sup>IV</sup> 4<sup>γ</sup></b>	96F8-9;100F5;100B-D	Bremer	1, 2, 3	proximal to -15 kb

**\**T(3;4)K*: Translocation (3;4) of Kirssanov**

**origin:** X ray induced.  
**discoverer:** Kirssanov.  
**references:** 1933, Biol. Zh. (Moscow) 2: 447-50.

***T(3;4)l-18*: Translocation (3;4) lethal**

**origin:** X ray induced.  
**discoverer:** Gloor and Green, 1957.  
**genetics:** Variegates for *ci*. Mutant for *l(4)l02ABe*.

***T(3;4)Mg198* Translocation (3;4) Mglinetz**

**cytology:** *T(3;4)93E;101-102*.  
**origin:** <sup>32</sup>P feeding.  
**references:** Mglinetz, 1968, Genetika (Moscow) 4(8): 81-86.

***T(3;4)p<sup>42</sup>*: Translocation (3;4) pink**

**cytology:** *T(3;4)85A;101D*.  
**origin:** X ray induced.  
**references:** Kempthues, Raff, and Kaufman, 1983, Genetics 105: 345-56.  
**genetics:** Mutant for *p*.

***T(3;4)P86*: Translocation (3;4) from Pasadena**

**cytology:** *T(3;4)88B-C;101* (Lewis).  
**origin:** X ray induced.  
**discoverer:** E.B. Lewis.

***T(3;4)ry<sup>ps1149</sup>*: Translocation (3;4) rosy-purine-sensitive**

**cytology:** *T(3;4)87B;101F*. 87B-D thought to be inverted [*In(3R)81;87B-D*] so that 87D placed next to heterochromatin (Rushlow and Chovnick, 1984).  
**origin:**  $\gamma$  ray induced in *ry<sup>+11</sup>*-bearing third chromosome.  
**references:** Rushlow and Chovnick, 1984, Genetics 108: 589-602.  
 Rushlow, Bender, and Chovnick, 1984, Genetics 108: 603-15.  
 Clark and Chovnick, 1986, Genetics 114: 819-40.  
**genetics:** Homozygous lethal. Variegates for *ry* with respect to XDH content of Malpighian tubules (Rushlow *et al.*, 1984); also variegates for *snk* (Clark and Chovnick, 1986). Purine-sensitive in heterozygotes with *ry<sup>2</sup>* or *ry<sup>41</sup>* (Rushlow and Chovnick, 1984). Has break in *pic* locus and is associated with *pic<sup>-</sup>* phenotype (Clark and Chovnick, 1986).  
**molecular biology:** 3R breakpoint between 160 and 150 kb proximal to the origin of the walk, which is 6.5 kb distal to the proximal breakpoint of *In(3R)Cbx<sup>rv1</sup>*; approximately 15 kb distal to *ry* (Rushlow *et al.*, 1984).

## TRANSPOSITIONS

***Tp(1;1)7B-7E***

**cytology:** *Tp(1;1)7B5-C1;7E1-2;9C2-D1*.

**origin:** Spontaneous in an outcross of the L strain of Lim, 1979. The L strain has numerous gypsy elements which are mobilized in certain outcrosses (Jack and Judd).

**references:** Lim, 1979, *Genetics* 93: 681-701.

*Tp(1;1)303-1*: see *In(1)303-1*

***Tp(1;1)A101***

**cytology:** *Tp(1;1)11A1-2;12E8-9;18B*.

**new order:**

1 – 11A1|18B – 12E9|11A2 – 12E8|18B – 20.

**discoverer:** Lefevre.

**genetics:** Lethal at 11A1-2.

*Tp(1;1)At*: see *In(1)At*

*Tp(1;1)B<sup>263-24</sup>*: see *In(1)B<sup>263-24</sup>*

**\**Tp(1;1)B<sup>263-48</sup>: Transposition (1;1) Bar***

**cytology:** *Tp(1;1)3E2-3;15F9-16A1;20A2-3*.

**new order:**

1 – 3E2|16A1 – 20A2|3E3 – 15F9|20A3 – 20F.

**origin:** X ray induced.

**discoverer:** Bishop, 1939.

**references:** Sutton, 1943, *Genetics* 28: 99.

**genetics:** Male and homozygous female viable. Crossing over in *Tp(1;1)B<sup>263-48</sup>/+* heterozygote yields *Dp(1;1)B<sup>263-48</sup>* (new order: 1 – 3E2|16A1 – 20A2|3E3 – 20F), which is heterozygous viable and Bar. The complementary deficiency (new order: 1 – 15F9|20A3 – 20F) is heterozygous lethal.

***Tp(1;1)bi<sup>D1</sup>: Transposition (1;1) bifid***

**cytology:** Break in 4C5-6; insertion of extra band.

**origin:** X ray induced.

**references:** Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, *Chromosoma* 93: 341-46.

**genetics:** Mutant for *bi*. Male lethal.

**\**Tp(1;1)ct<sup>6a1</sup>: Transposition (1;1) cut***

**cytology:** *Tp(1;1)7B2-C1;19;20F*.

**new order:**

|1 – 7B2|(19 – 20)|7C1 – 19|20F|.

Nucleolus organizer included in transposed piece.

**origin:** X ray induced in *R(1)2*.

**references:** Hannah, 1949, *Proc. Intern. Congr. Genet.*, 8th., pp. 588-89.

Hannah-Alava, 1971, *Mol. Gen. Genet.* 113: 191-203.

**genetics:** Variegated for *ct*. Male lethal.

*Tp(1;1)f<sup>67a</sup>*: see *In(1)f<sup>67a</sup>*

***Tp(1;1)FN201***

**cytology:** *Tp(1;1)3A3-4;5D;8F*.

**discoverer:** Lefevre.

**genetics:** Mutant for *z* (*z<sup>a</sup>*-like).

*Tp(1;1)hill*: see *In(1)hill*

***Tp(1;1)L2***

**cytology:** *Tp(1;1)3A2-3;8D;10B1-2*.

**new order:**

1 – 3A2|8D – 10B1|3A3 – 8D|10B2 – 20.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Homozygous lethal. Mutant for *gt* and *lz*.

*Tp(1;1)l272-13*: see *In(1)272-13*

***Tp(1;1)lz<sup>144</sup>: Transposition (1;1) lozenge***

**cytology:** *Tp(1;1)8E;20F*. Transposition of *NO* to 8E.

**discoverer:** Green and Green, 1956.

**synonym:** *lz<sup>144A</sup>* of Ives (Green).

**references:** Hannah-Alava, 1971, *Mol. Gen. Genet.* 113: 191-203.

**genetics:** *lz<sup>s</sup>* phenotype.

***Tp(1;1)lz<sup>491</sup>***

**cytology:** *Tp(1;1)8D;20F*. Transposition of *NO* to 8D.

**discoverer:** Green and Green, 1956.

**references:** Hannah-Alava, 1971, *Mol. Gen. Genet.* 113: 191-203.

**genetics:** *lz<sup>s</sup>* phenotype. Recombination reduced in *sn-lz* and *lz-v* regions (Green).

**\**Tp(1;1)N<sup>264-63</sup>: Transposition (1;1) Notch***

**cytology:** *Tp(1;1)3C7-9;13C7-8;19F* (Hoover).

**origin:** X ray induced.

**discoverer:** Demerec, 38e.

**genetics:** Mutant for *N* but not for *w*, *rst*, or *dm*.

*Tp(1;1)sc<sup>260-25</sup>*: see *In(1LR)sc<sup>260-25</sup>*

***Tp(1;1)Si1: Transposition (1;1) Simmons***

**cytology:** *Tp(1;1)11A8-9;14D1-2;19C*.

**new order:**

1A – 11A8-9|(14D1-2 – 19C)|11A8-9 – 14D1-2|19C – 20F.

**origin:** Induced by hybrid dysgenesis.

**references:** Simmons, Raymond, Culbert, and Laverty, 1984, *Genetics* 107: 49-63.

**genetics:** Chromosome has lethal at *r* locus.

***Tp(1;1)Si2***

**cytology:** *Tp(1;1)1A1-8;14D2-E1;18F*.

**new order:**

1A1 – 8|14D2-E1 – 18F|1A1-8 – 14D2-E1|18F – 20F.

**origin:** Induced by hybrid dysgenesis.

**references:** Simmons, Raymond, Culbert, and Laverty, 1984, *Genetics* 107: 49-63.

**genetics:** Chromosome has lethal at *r* locus.

***Tp(1;1)sn<sup>S93</sup>: Transposition (1;1) singed***

**cytology:** *Tp(1;1)7B5-6;7D1;8D*.

**new order:**

1 – 7B5|7D2 – 8D|7B6 – 7D1|8D – 20.

**origin:** X ray induced.

**references:** Lefevre and Johnson, 1973, *Genetics* 74: 633-45.

**genetics:** Shows *sn* phenotype in combination with *sn<sup>3</sup>*. Male lethal. Female heterozygote viable. When the components of the transposition are separated by crossing over in the 7D2-8D region, the deficiency alone (new order: 1 – 7B5|7D2 – 20) behaves as a dominant lethal, whereas the duplication (new order: 1 – 8D|7B6 – 7D1|8D – 20) behaves as a recessive lethal.

***Tp(1;1)v<sup>N48</sup>*: Transposition (1;1) vermilion**

**cytology:** *Tp(1;1)9F;10C3-5;20*.

**origin:** Neutron induced.

**discoverer:** Schalet.

**references:** Voelker, Wisely, Huang, and Gyurkovics, 1985, *Mol. Gen. Genet.* 201: 437-45.

**genetics:** Mutant for *v*. Males viable, fertile and show additional mutant phenotypes such as rough eyes, missing bristles, and abnormal wings (Schalet). Females heterozygous for *Df(1)v64f*, *Df(1)v-L1*, and *Df(1)v-L2* are viable and show the additional mutant phenotypes described for males, but females heterozygous for *Df(1)v-L15*, *Df(1)N71*, or *Df(1)m259-4* are lethal.

3C break between *w* and *rst* (Young and Judd, 1978, *Genetics* 88: 723-42).

***Tp(1;2)25***

**cytology:** Euchromatic portion of left arm of X transposed into heterochromatic region of 2.

**discoverer:** Lindsley.

**references:** Shoup, 1967, *J. Cell Biol.* 32: 663-75.

**genetics:** Males sterile; sperm heads fail to differentiate and do not convert lysine-rich to arginine-rich histone.

***Tp(1;2)26***

**origin:** X ray induced in *R(1)2*.

**discoverer:** Pontecorvo, 1941.

**synonym:** *T(X<sup>c2</sup>;2)26*.

**references:** 1942, *DIS* 16: 65.

**genetics:** Section of X including *car* and *bb* inserted into base of 2L. Homozygous lethal.

***Tp(1;2)51b***

**cytology:** *Tp(1;2)3C1-2;3D6-E1;20A;52E*.

**new order:**

1 - 3C1|20A - 3E1|20A - 20F;  
21 - 52E|(3C2 - 3D6)|52E - 60.

**origin:** X ray induced in *In(1)w<sup>m4</sup>* = *In(1)3C1-2;20A*.

**discoverer:** Lefevre, 51b7.

**synonym:** *T(1;2)w<sup>+51b7</sup>*.

**references:** 1951, *DIS* 25: 71.

1952, *DIS* 26: 66.

Ratty, 1954, *Genetics* 39: 513-28.

Lefevre, 1970, *DIS* 45: 39.

**genetics:** Segregant *Dp(1;2)51b* = *Dp(1;2)3C1-2;3D6;52E* survives; duplicated for loci of *w*, *rst*, *spl*, *fa*, and *dm*. Duplication used to cover lethality of *N* in studies of pseudoallelism at the *N* locus (Welshons and Von Halle, 1962, *Genetics* 47: 743-59).

**\**Tp(1;2)A50b*: Translocation (1;2) from Austin**

**cytology:** *Tp(1;2)2B;15F;41*; inferred from fig. 17H of Mackensen (1935).

**new order:**

1 - 2B|15F - 20;  
21 - 41|15F - 2B|41 - 60.

**references:** Mackensen, 1935, *J. Heredity* 26: 163-74 (fig.).

**genetics:** Left break in X between *br* and *pn*; right break between *r* and *f*. Mutant for *f*.

**\**Tp(1;2)A106***

**cytology:** *Tp(1;2)6-7;12;17*; rough estimates of break-points in X from fig. 17I of Mackensen (1935); chromosome 2 broken in euchromatin of left arm.

**new order:**

1 - 6|17 - 20;  
21 - ?|12 - 17|7 - 12|? - 60.

**references:** Mackensen, 1935, *J. Heredity* 26: 163-74 (fig.).

**genetics:** Mutant for *Bx*.

**\**Tp(1;2)A124***

**cytology:** *Tp(1;2)10A;13A1-2;59*.

**new order:**

1 - 10A|13A2 - 20;  
21 - 59|(10A - 13A1)|59 - 60.

**origin:** X ray induced.

**references:** Mackensen, 1935, *J. Heredity* 26: 163-74 (fig.).

Patterson, Stone, and Bedichek, 1935, *Genetics* 20: 259-79 (fig.).

1937, *Genetics* 22: 407-26.

Pipkin, 1940, *Texas Univ. Publ.* 4032: 126-56.

**genetics:** Left break between *ras* and *v*; right break between *g* and *pl*. Male fertile. The segregant *Dp(1;2)A124* = *Dp(1;2)10A;13A1-2;59*, which is duplicated for *v<sup>+</sup>* through *g<sup>+</sup>*, survives as a fairly viable and fertile female, but male carrying *Dp(1;2)A124* dies as embryo. The complementary *Df(1)A124* = *Df(1)10A;13A1-2* survives as a fertile *X/X/Df* triploid female and as an *X/X/Df* diploid metafemale but not as an *X/Df* diploid.

**\**Tp(1;2)B<sup>DG</sup>*: Transposition (1;2) Bar of Dubinin and Goldat**

**cytology:** *Tp(1;2)4;15F-16A;20;40-41*; inferred from figure of Dubinin and Goldat.

**new order:**

1 - 4|15F - 4|20;  
21 - 40|(16A - 20)|41 - 60.

**origin:** X ray induced.

**references:** Dubinin and Goldat, 1936, *Biol. Zh.* 5: 881-84 (fig.).

**genetics:** Position effect for *B*. Male lethal.

***Tp(1;2)C84***

**cytology:** *Tp(1;2)3F;17E-F;30A*.

**new order:**

1 – 3F|17F – 20;

21 – 30A|3F – 17E|30A – 60.

**origin:** X ray induced.

**references:** Roberts, 1970, *Genetics* 65: 429-48.

**genetics:** Male viable and sterile. Recombination reduced in X and 2L.

**\**Tp(1;2)ct<sup>7c1</sup>: Transposition (1;2) cut***

**cytology:** *Tp(1;2)7B2-3;8E2-3;25C* superimposed on *R(1)1A3-4;19F-20A1*.

**new order:**

|1A4 – 7B2|8E2 – 20-20F – 20A1|;

21 – 25C|(7B3 – 8E2)|25C – 60.

**origin:** X ray induced in *R(1)2*.

**discoverer:** Hannah, 1947.

**genetics:** Mutant for *ct* but not *cm* or *sn*; male lethal.

*Tp(1;2)ct<sup>7c1</sup>/Dp(1;3)sn<sup>13al</sup>* male survives and is fertile, suggesting that lethality is associated with 7B2-3 breakpoint. The segregant *Dp(1;2)ct<sup>7c1</sup> = Dp(1;2)7B2-3;8E2-3;25C* survives; duplicated for *sn* but not *cm*; male and female have darker, roof-like wings, enlarged abdomens, and are sterile.

**\**Tp(1;2)ct<sup>14a2</sup>***

**cytology:** *Tp(1;2)7B2-4;19-20;41E1-2* superimposed on *R(1)1A3-4;19F-20A1*.

**new order:**

|1A4 – 7B2|20-20F – 20A1|;

21 – 41E1|7B4 – 19|41E2 – 60.

**origin:** X ray induced in *R(1)2*.

**discoverer:** Hannah, 1947.

**genetics:** Mutant for *ct* but not *cm*, *sn*, or *oc*. Male lethal.

*Tp(1;2)ct<sup>14a2</sup>/Dp(1;3)sn<sup>13al</sup>* male rarely survives, probably sterile.

**\**Tp(1;2)f<sup>257-15</sup>: Transposition (1;2) forked***

**cytology:** *Tp(1;2)13E9-10;15E2-3;24F* (Sutton).

**origin:** X ray induced.

**discoverer:** Demerec, 35a.

**genetics:** Mutant for *f* but not *M(1)15D* or *B*. Male lethal.

***Tp(1;2)GF325***

**cytology:** *Tp(1;2)2B7;7D;36C*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Homozygous lethal. Mutant for *br*.

**\**Tp(1;2)l-v47: Transposition (1;2) lethal-variegated***

**cytology:** *Tp(1;2)8F-9B*; heterochromatic material inserted in X; genetic results suggest linkage between X and 2.

**origin:** X ray induced.

**references:** Lindsley, Edington, and Von Halle, 1960, *Genetics* 45: 1649-70.

**genetics:** Variegated for a lethal; *gg*-like phenotype.

**\**Tp(1;2)lt<sup>m16</sup>: Transposition (1;2) light-mottled***

**cytology:** *Tp(1;2)11A;12F;22D;40B-F*.

**new order:**

1 – 11A|12F – 20;

21 – 22D|11A – 12F|40B – 22D|40F – 60.

**origin:** X ray induced.

**references:** Hessler, 1958, *Genetics* 43: 395-403.

**genetics:** Variegated for *lt*.

***Tp(1;2)m<sup>v</sup>: Transposition (1;2) miniature-variegated***

**cytology:** *Tp(1;2)7C;10F;40-41*.

**origin:** X ray induced.

**references:** Lefevre, 1969, *Genetics* 63: 589-600.

**genetics:** Deficiency segregant lethal in heterozygous female. Duplication segregant *Dp(1;2)m<sup>v</sup>* variegates for *m*; does not carry *fw*.

**\**Tp(1;2)N<sup>264-50</sup>: Transposition (1;2) Notch***

**cytology:** *Tp(1;2)3C7-9;20C1-F;22A2-3* (Hoover).

**new order:**

1 – 3C7|20F;

21 – 22A2|3C9 – 20C1|22A3 – 60.

**origin:** X ray induced.

**discoverer:** Demerec, 37k.

**references:** 1941, *Proc. Intern. Congr. Genet.*, 7th., pp. 99-103.

**genetics:** Variegates for *fa* but not *w*, *rst*, or *dm*.

***Tp(1;2)OR9: Transposition (1;2) from Oak Ridge***

**cytology:** *Tp(1;2)3A;14F;41*.

**new order:**

1 – 3A|14F – 20;

21 – 41|14F – 3A|41 – 60.

**origin:** X ray induced in *y*.

**discoverer:** Wartens, 1959.

**genetics:** Male lethal; lethality not covered by *B<sup>S<sub>w</sub></sup>+Y*; therefore, not associated with break at 3A.

***Tp(1;2)pn1: Transposition (1;2) prune***

**cytology:** *Tp(1;2)2E1-2;20A1-2;20D;43F* (Slobodyanyuk and Serov, 1983).

**new order:**

1 – 2E1|20D – 20F;

21A – 43F|20A2 – 20D|2E1 – 20A1|43F – 60F.

**references:** Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, *DIS* 55: 205.

Slobodyanyuk and Serov, 1983, *Mol. Gen. Genet.* 192: 372-77.

**genetics:** Homozygous lethal. Heterozygotes with *pn* are *pn*.

***Tp(1;2)r<sup>+</sup>75c: Transposition (1;2) rudimentary-wild type***

**cytology:** *Tp(1;2)14B13;15A9;35D-E*.

**new order:**

1 – 14B13|15A9 – 20;

21 – 35D|14B13 – 15A9|35E – 60.

**origin:** X ray induced.

**discoverer:** Lefevre.

**references:** Craymer and Roy, 1980, *DIS* 55: 200-04.

Ganetzky and Wu, 1982, *Genetics* 100: 597-614.

**genetics:** "Pebbly" eyes (Craymer and Roy, 1980) is the result of a *sl* mutation associated with the distal X breakpoint at 14B13 (Schalet, 1986, *Mutat. Res.* 163: 115-44). *Dp(1;2)* segregant covers *l(1)14Cc* (Jones and Rubin, 1990, *Neuron* 4: 711-23), probably through lethals in 15A.

***Tp(1;2)rb<sup>+</sup>71g: Transposition (1;2) ruby-wild type***

**cytology:** *Tp(1;2)3F3;5E8;23A15.*

**new order:**

1 – 3F3|5E8 – 20.

21 – 23A15|3F3 – 5E8|23A15 – 60.

**origin:** X ray induced.

**discoverer:** Lefevre.

**synonym:** *T(1;2)A1125.*

**references:** Craymer and Roy, 1980, DIS 55: 200-04.

Busson, Gans, Komitopoulou and Masson, 1983, Genetics 105: 309-25.

**genetics:** Females heterozygous for the deficiency segregant and males carrying the duplication segregant are lethal (Busson *et al.*, 1983). Duplication carries wild-type alleles of *vs* (Craymer and Roy, 1980), *l(1)5CDa* (Voelker and Wisely, 1982, DIS 58: 150-51), and *ovo* (Oliver, Perrimon, and Mahowald, 1987, Genes Dev. 1: 913-23).

***Tp(1;2)sc<sup>19</sup>: Transposition (1;2) scute***

**cytology:** *Tp(1;2)1B1-2;1B4-5;25A3-7* (Lefevre; García-Bellido, 1979).

**new order:**

1A – 1B1|1B5 – 20;

21 – 25A|(1B2 – 1B4)|25A – 60.

**origin:** X ray induced.

**discoverer:** League.

**references:** Muller, 1935, Genetica 17: 237-52.

García-Bellido and Santamaria, 1978, Genetics 88: 469-86.

García-Bellido, 1979, Genetics 91: 491-520.

**genetics:** Mutant for *sc*, showing slight suppression of scutellar chaetae (García-Bellido and Santamaria, 1978). A small subterminal piece of *X* is inserted into 2*L* one or two units to the right of *dp*. The two halves of the transposition can be recovered independently as *Df(1)sc19* and *Dp(1;2)sc<sup>19</sup>*. Homozygous clones in wing survive but fail to differentiate sensilla (Schubiger and Palka, 1985, Dev. Biol. 108: 399-410). *Df(1)sc19* is deficient for *y*, *ac*, *sc*, and *sc<sup>1</sup>* but not *l(1)1Ac*, *om*, or *M(1)1B*; it is male lethal but survives in the heterozygous female. *Dp(1;2)sc<sup>19</sup>* carries, in addition to *sc<sup>19</sup>*, normal alleles of *y*, *ac*, and *sc<sup>1</sup>*; it is viable homozygous and does not affect crossing over in 2*L*. X-ray-induced losses of *y<sup>+</sup>* from the transposed fragment are *M* and male and female sterile (Velissariou and Ashburner, 1980, Chromosoma 77: 13-27).

**molecular biology:** 1B4-5 breakpoint at coordinate -13.1 (Carramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell, 1982, EMBO J. 1: 1185-91).

***\*Tp(1;2)sc<sup>260-27</sup>***

**cytology:** *Df(1)1A8-B1;19F + T(1;2)15E;33-34;57B-C.*

**new order:**

1A1 – 1A8|19F – 20;

21 – 33|15E – 19F|1B1 – 15E|57B – 34|57C – 60.

**origin:** X ray induced.

**references:** Sutton, 1943, Genetics 28: 210-17.

**genetics:** The segregant *Df(1)sc260-27* separates as a free duplication from the segregant *Dp(1;2)sc<sup>260-27</sup>*, which carries wild-type alleles of *y* and *ac*. The transposition as a whole is mutant for *sc* and male sterile.

***Tp(1;2)sn<sup>+</sup>72d: Transposition (1;2) singed-wild type***

**cytology:** *Tp(1;2)7A8;8A5;32C;58E.*

**origin:** X ray induced.

**discoverer:** Robins, 62g26.

**synonym:** *T(1;A)pn-ec; T(1;2)w<sup>+</sup>62g26.*

**references:** Lefevre, 1963, DIS 37: 50.  
1970, DIS 45: 39.

**genetics:** No variegation for  $w^+$ . Male lethal. Deficiency segregant uncovers *pn* and *ec*; females carrying the deficiency over a normal X survive, though poorly viable and fertile. Duplication segregant does not cover *pn* (Lefevre, 1970); males carrying the duplication over a normal X are viable but sterile.

***Tp(1;2)w<sup>+</sup>64b***

**cytology:** *Df(1)5A1-2;20F* [superimposed on *In(1)w<sup>md</sup> = In(1)3C1-2;20F + T(1;2)4E3;26D7*, the latter involving the acentric ring concomitant of the *Df(1)*]. Fragment 3C2 through 5A1-2 broken into two pieces at 4E3 and the pieces, separated by an appreciable amount of proximal heterochromatin, inserted into 2L at 26D7.

**new order:**

1 – 3C1|20F – 5A2|20F;  
21 – 26D7|4E3 – 3C2|20F|5A1 – 4E3|26D7 – 60.

**origin:** X ray induced in *In(1)w<sup>md</sup>*.

**discoverer:** Lefevre, 64b13.

**references:** 1968, DIS 43: 62-63.

Craymer and Roy, 1980, DIS 55: 200-04.

**genetics:** Males carrying the transposition are viable, fertile and wild type. X0 transposition males are viable but show *w* variegation. Females heterozygous for the deficiency are poorly viable, *N*, and almost sterile. Males carrying the duplication are lethal, but hyperploid females are viable and fertile (Lefevre, 1968).

**\**Tp(1;2)w<sup>m52b</sup>: Transposition (1;2) white-mottled***

**cytology:** *Tp(1;2)1E5-F1;3C3-5;20F;40-41*.

**new order:**

1A – 1E5|20F – 3C5|20F;  
21 – 40|(1F1 – 3C3)|41 – 60.

**origin:** X ray induced in *In(1)rst<sup>3</sup> = In(1)3C3-5;20F*.

**discoverer:** Ratty, 52b12.

**references:** Lefevre, 1953, DIS 27: 57.

**genetics:** Variegated for *w*. *Dp(1;2)w<sup>m52b</sup>* survives.

**\**Tp(1;2)w<sup>m53a</sup>***

**cytology:** *Tp(1;2)3B2-C1;3C9-D1;40-41*.

**new order:**

1 – 3B2|3D1 – 20;  
21 – 40|(3C1 – 3C9)|41 – 60.

**origin:** X ray induced.

**discoverer:** Farnsworth, 53a4.

**references:** Lefevre, 1953, DIS 27: 57.

**genetics:** Variegated for *w*. The segregant *Dp(1;2)w<sup>m53a</sup>* survives and is duplicated for the loci of *w*, *rst*, and *N*. *Df(1)w-m53a* survives as Notch female; deficient for *w*, *rst*, and *N*.

***Tp(1;2)w<sup>m258-36</sup>***

**cytology:** *Tp(1;2)3C6-7;4C2-3;41A-B;41F5-6* (Demerec and Hoover).

**new order:**

1 – 3C6|(41B – 41F5)|4C3 – 20;  
21 – 41A|(3C5 – 4C2)|41F6 – 60.

Insertions said to be in inverted order but not specified with respect to centromere or numerical order.

**origin:** X ray induced.

**discoverer:** Demerec, 38b.

**references:** Sutton, 1940, Genetics 25: 534-40 (fig.).

**genetics:** Variegated for *w* and *rst* but not *pn*, *fa*, or *dm*.

Male viable. Cytology predicts that each element of the translocation should survive as aneuploid but not so recorded.

***Tp(1;2)w-ec: Transposition (1;2) white-echinus***

**cytology:** *Tp(1;2)3C1-2;3E7-8;37D*.

**new order:**

1 – 3C1|3E8 – 20;  
21 – 37D|(3C2 – 3E7)|37D – 60.

**origin:** X ray induced.

**discoverer:** Stafford, 64d20.

**synonym:** *T(1;2)(w-ec)<sup>64d</sup>; T(1;2)N<sup>St</sup>; Stafford-Notch; T(1;2)w<sup>64d</sup>; T(1;2)w-ec*.

**references:** Lefevre and Wilkins, 1966, Genetics 53: 175-87.

Lefevre and Moore, 1968, Genetics 58: 557-71.

Craymer and Roy, 1980, DIS 55: 200-04.

**genetics:** Males carrying the transposition are viable, *w*, *ec*, and *N<sup>+</sup>* (Lefevre and Wilkins, 1966). Females heterozygous for the deficiency show *N*. Neither the duplication nor the deficiency complements *w<sup>sp</sup>* (Lefevre, 1968) nor are *w ec* males or females with the duplication wild type.

***Tp(1;2)y<sup>R3</sup>: Transposition (1;2) yellow of Roberts***

**cytology:** *Tp(1;2)1B2-3;1E2-3;35F*.

**origin:** X ray induced.

**references:** Roberts, 1974, Mutat. Res. 22: 139-44.

**genetics:** Mutant for *y*. Male viable and fertile.

***Tp(1;2;3)pn<sup>3</sup>: Transposition (1;2;3) prune***

**cytology:** *Tp(1;2)12E1-2;20A;41A + Tp(1;3)2E1-2;12E1-2;80C*.

**new order:**

1A – 2E1|20A2 – 20;  
21A – 41A|12E2 – 20A1|41A – 60;  
61A – 80C|2E2 – 12E1|80D – 100.

**origin:** X ray induced.

**references:** Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.

Slobodyanyuk and Serov, 1983, Mol. Gen. Genet. 191: 372-77.

**genetics:** Mutant for *pn*. Homozygous lethal.

***Tp(1;3)20A11***

**cytology:** *Tp(1;3)5B;17D;81*.

**new order:**

1 – 5B|17D – 20;  
61 – 81|5B – 17D|81 – 100.

**origin:** Induced by ethyleneimine.

**references:** Lim and Snyder, 1968, Mutat. Res. 6: 129-37.

**genetics:** Male lethal.

**\**Tp(1;3)A1: Transposition (1;3) from Austin***

**origin:** X ray induced.

**discoverer:** Muller, 1926.

**references:** Painter and Muller, 1929, J. Heredity 20: 287-98.

**genetics:** Breakpoints in X chromosome between *dm* and *ec* and between *car* and *bb*. Midsection of X transposed to 3R. Male hyperploid for *Dp(1;3)A1* survives; duplicated for loci of *y* through *dm* as well as *bb* (Schultz).

***Tp(1;3)B<sup>S3i</sup>*: Transposition (1;3) Bar-Super inserted in chromosome 3**

**cytology:** *Tp(1;3)15F9-16A1;16A7-B1;20F;Y;66B13-C1* (Muller; Lindsley); translocation between *Dp(1;1)B = Dp(1;1)15F9-16A1;16A7-B1* and chromosome 3. X break can be shown genetically to separate *f<sup>+</sup>* from *B* and is assumed to separate the two halves of the Bar duplication.

**new order:**

1 – 16A7|20F·Y<sup>S</sup>;  
61 – 66B13|(16A1 – 20F)|66C1 – 100.  
Tentative.

**origin:** Neutron induced in *X·Y<sup>S</sup>, sc w B*.

**discoverer:** Norby.

**references:** Muller and Norby, 1949, DIS 23: 61.

**genetics:** Associated with *B<sup>S3i</sup>*. Male viable. Homozygous female lethal. Chromosome 3 containing inserted X material survives as duplication in presence of normal X chromosomes; male sterile; female fertile. Duplication segregant *Dp(1;3)B<sup>S3i</sup>* carries *bb<sup>+</sup>* (N. Scott) and has extreme *B* phenotype.

***Tp(1;3)C92***

**cytology:** *Tp(1;3)6E1-2;11D9-10;chrom3* (insertion of 6E1-2;11D9-10 into 3).

**origin:** X ray induced.

**references:** Lefevre and Peterson, 1972, DIS 48: 126-27.

**genetics:** Mutant for *sno*.

**\**Tp(1;3)ct<sup>11a</sup>*: Transposition (1;3) cut**

**cytology:** *Tp(1;3)1B;7B2-3;8E-F;84B* superimposed on *R(1)1A3-4;19F-20A1*.

**new order:**

|1A4 – 1B|8E – 7B3|8F – 20·20F – 20A1|;  
61 – 84B|(1B – 7B2)|84B – 100.

**origin:** X ray induced in *R(1)2*.

**discoverer:** Hannah, 1947.

**genetics:** Mutant for *ct* but not *y*, *ac*, *sc*, *cm*, *sn*, or *oc*. Male lethal. Female carrying *Dp(1;3)ct<sup>11a</sup>* survives and has small eyes and arc-like wings with delta-like venation; duplicated for *cm*.

**\**Tp(1;3)ct<sup>12c1</sup>***

**cytology:** *Tp(1;3)7B2-3;7D2-6;85* superimposed on *R(1)1A3-4;19F-20A1*.

**new order:**

Acad. Sci. USA 78: 6548-52.

Baumann, Krah-Jentgens, Müller, Müller-Haltkamp, Seidel, Kecskemethy, Casal, Ferrus, and Pongs, 1987, EMBO J. 6: 3419-29.

**molecular biology:** Maps between 76 and 73 kb distal to the start site of the *Sh* chromosomal walk (Baumann et al., 1987).

***Tp(1;3)m<sup>+</sup>82f*: see *Dp(1;3)m<sup>+</sup>82f***

***Tp(1;3)N<sup>50k</sup>*: Transposition (1;3) Notch**

**cytology:** *Tp(1;3)1E3-4;3C6-7;3C8-9;89A*.

**new order:**

1A1 – 1E3|3C9 – 20;  
61 – 89A|(1E4 – 3C6)|89A – 100.  
3C7-8 missing (Lefevre).

**origin:** X ray induced.

**references:** Lefevre, 1951, DIS 25: 71.  
1952, DIS 26: 66.

Ratty, 1954, Genetics 39: 513-28.

**genetics:** Mutant for *N*. The segregant *Dp(1;3)N<sup>50k</sup>* is viable and carries normal alleles of *pn*, *w*, and *rst*.

***Tp(1;3)N<sup>264-58</sup>***

**cytology:** *Tp(1;3)3B2-3;3D6-7;80D-F* (Sutton).

**new order:**

1 – 3B2|3D7 – 20;

61 – 80D|3D6 – 3B3|80F – 100.

**origin:** X ray induced.

**discoverer:** Demerec, 38d.

**synonym:** *T(1;3)w<sup>m264-58</sup>*.

**references:** 1940, Genetics 25: 618-27.

Sutton, 1940, Genetics 25: 534-40 (fig.).

Spofford, 1973, DIS 50: 98.

**genetics:** Variegates for *w*, *rst*, *N*, and its pseudoalleles (Cohen, 1962, Genetics 47: 647-59). Spofford, 1973, thinks *dm* phenotype result of extreme variegation; *dm/Dp(1;3)N<sup>264-58</sup>* males in a Suppressor-of-variegation background are *dm<sup>+</sup>*. The segregant *Df(1)N<sup>264-58</sup>* survives in heterozygous female and is deficient for *w*, *rst*, *fa*, and *dm* but not *pn* or *ec*. *Dp(1;3)N<sup>264-58</sup>* survives as both male and female.

**\**Tp(1;3)N<sup>264-100</sup>***

**cytology:** *Tp(1;3)3B4-C1;4B4-5;80* [Sutton, 1940, Genetics 25: 534-40 (fig.); Gersh, 1959, Genetics 44: 163-72].

**new order:**

1 – 3B4|4B5 – 20;

61 – 80|4B4 – 3C1|80 – 100.

**origin:** X ray induced.

**references:** Demerec, 1940, Genetics 25: 618-27.

**genetics:** Variegates for *w*, *rst*, *fa*, *dm*, and *ec* but not *pn* or *bi*. The segregant *Df(1)N<sup>264-100</sup>*, which is deficient for *N*, survives in heterozygous female. *Dp(1;3)N<sup>264-100</sup>* originally survived in female but not male; more recently, male carrying duplication found to survive (Gersh, 1959).

***Tp(1;3)O4: Transposition (1;3) of Oliver***

**origin:** X ray induced.

**discoverer:** Oliver, 29k24.

**references:** Dobzhansky and Schultz, 1934, J. Genet. 280: 373-77.

Oliver, 1937, DIS 7: 19.

**genetics:** X chromosome broken between *m* and *g* and between *f* and *car*. Center section of X then inserted into 3L. The segregant *Df(1)O4* is inviable when added to a normal male genotype, poorly viable when added to a normal female genotype, and survives well when added to a triploid intersex (2X:3A) genotype where it confers a low degree of fertility. The reciprocal segregant, *Dp(1;3)O4*, is lethal in the male, survives well in the female, and poorly in the intersexes.

***Tp(1;3)pn<sup>25</sup>: Transposition (1;3) prune***

**origin:** X ray induced.

**references:** Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.

**genetics:** Homozygous lethal. Heterozygotes with *pn* are *pn*.

transposition	cytology	orientation of inserted segment
<i>Tp(1;3)pn<sup>25α</sup></i>	2E1-2;20A1-2;70A5-6	eucentric
<i>Tp(1;3)pn<sup>26</sup></i>	2E1-2;20A1-2;70C1-2	eucentric

<i>Tp(1;3)w<sup>+</sup>3</i>	3-28	
<i>Tp(1;3)w<sup>+</sup>7</i>	3-72	

**\**Tp(1;3)w<sup>+</sup>54a4***

**origin:** X ray induced.

**synonym:** *T(1;3)54a; Dp(1;3)w<sup>+</sup>54a4*.

**references:** Lefevre, 1955, DIS 29: 73.

**genetics:** Section of X including *w<sup>+</sup>* inserted into 3.

**\**Tp(1;3)w<sup>+</sup>54c10***

**origin:** X ray induced.

**synonym:** *T(1;3)54c; Dp(1;3)w<sup>+</sup>54c10*.

**references:** Lefevre, 1955, DIS 29: 73.

**genetics:** Section of X including *w<sup>+</sup>* inserted into 3.

***Tp(1;3)w<sup>+</sup>67k***

**cytology:** *Tp(1;3)3A4-5;3E8-F1;8E5;87E17*.

**new order:**

1A - 3A4|8E5 - 3F1|8E5 - 20.  
60 - 87E17|3A5 - 3E8|87E17 - 100.

**discoverer:** Lefevre, 67k27.

**synonym:** *T(1;3)w<sup>67k27</sup>*; duplication segregant: *G spot; Tp(1;3)67k*.

**references:** Lefevre, 1970, DIS 45: 32.

Judd, Shen, and Kaufman, 1972, *Genetics* 71: 139-56.

Craymer and Roy, 1980, DIS 55: 200-04.

Gelbart and Wu, 1982, *Genetics* 102: 179-89.

**genetics:** The duplication segregant carries wild-type alleles of *l(1)3Ad* through *w* and *N* but not *ec*. It only partially suppresses *z*, leading to a brownish eye color in *z w<sup>+</sup>* flies (Gelbart and Wu, 1982).

***Tp(1;3)w<sup>c</sup>: Transposition (1;3) white-crimson***

**origin:** Believed to be effect of transposing element, the distal part of the *w* locus being moved to chromosome 3.

**references:** Green, 1969, *Genetics* 61: 429-41.

Paro, Goldberg, and Gehring, 1983, *EMBO J.* 2: 853-60.

**genetics:** Male with *w* or *Df(1)w* is *w<sup>c</sup>*. Transposition recessive to *w<sup>+</sup>*, complements *w<sup>sp</sup>*, and is mutable (Green, 1969).

transposition	genetic location of <i>w<sup>c</sup></i>	chromosome of origin	viability and fertility
<i>Tp(1;3)w<sup>c</sup>-1<sup>α</sup></i>	3-3.8	<i>w<sup>c</sup> w<sup>sp</sup></i>	homozygous lethal
<i>Tp(1;3)w<sup>c</sup>-2</i>	3-10.2	<i>w<sup>c</sup> w<sup>sp</sup></i>	homozygous viable
<i>Tp(1;3)w<sup>c</sup>-3</i>	3-46 (left of <i>ri</i> )	<i>w<sup>c</sup> w<sup>sp</sup></i>	
<i>Tp(1;3)w<sup>c</sup>-4</i>	3-92	<i>w<sup>c</sup> w<sup>-67c</sup></i>	homozygous viable but male sterile

<sup>α</sup> *In situ* hybridization of single copy *w* DNA to *Tp(1;3)w<sup>c</sup>-1* locates the transposon at 62E; transposon associated with FB elements (Paro et al., 1983).

***Tp(1;3)w<sup>m49a</sup>: Transposition (1;3) white-mottled***

**cytology:** *Tp(1;3)3A10-B1;3E2-3;80-81*.

**new order:**

1 - 3A10|3E3 - 20;  
61 - 80|(3B1 - 3E2)|81 - 100.

**origin:** X ray induced.

**discoverer:** Lefevre, 49a7.

**synonym:** *T(1;3)w<sup>mSp</sup>: Translocation (1;3) white-mottled Spotted*.

**references:** 1949, DIS 23: 59.

1951, DIS 25: 71.

Ratty, 1954, *Genetics* 39: 513-28.

**genetics:** Variegated for *w*, *rst*, and *spl*. The two elements of the translocation can be separated; *Df(1)w-m49a* survives in heterozygous female and is *N*; *Dp(1;3)w<sup>m49a</sup>* survives in both male and female and carries the loci of *w*, *rst*, *N*, and (from the cytology) presumably *dm*.

***Tp(1;3)w<sup>vco</sup>*: Transposition (1;3)  
white-variegated cobbled**

**cytology:** *Tp(1;3)2B17-C1;3C5-6;77D3-5;81* (2C1-2 may not be included in transposed region according to Lefevre).

**new order:**

1A – 2B17|3C6 – 20;  
61 – 77D3|2C1 – 3C5|81 – 77D5|81 – 100.

**discoverer:** Clausen.

**references:** Seecof, Kaplan, and Futch, 1971, Proc. Nat. Acad. Sci. USA 62: 528-35.

Bowman and Simmons, 1973, Biochem. Genet. 10: 319-31.

Lucchesi and Rawls, 1973, Genetics 73: 459-64.

Lucchesi, Rawls, and Maroni, 1974, Nature 248: 564-67.

Lefevre, 1981, Genetics 99: 461-80.

**genetics:** Insertion of small segment of X with *Pgd*<sup>+</sup>, *w*<sup>+</sup>, and *rst*<sup>+</sup> into 3 (Lucchesi and Rawls, 1973). Variegated for *w* and *rst* and apparently mutant for *in* but *eg* not affected; *in* effect probably associated with 77D3-5 break (Arajarvi and Hannah-Alava, 1969, DIS 44: 73). Each element of the translocation survives as an aneuploid. *Df(1)w-vco* is deficient for recessives from *Pgd* through *w* and *rst*. *Df(1)w-vco/Tp(1;3)w<sup>vco</sup>* is *w*, extreme *rst*, and highly infertile. *Dp(1;3)w<sup>vco</sup>* covers *Pgd*, *w*, and *rst*.

***Tp(1;3)w<sup>zh</sup>*: Transposition (1;3)  
white-zeste halo**

**cytology:** *Tp(1;3)3C2-3;3C6;61D*.

**origin:** Spontaneous derivative of *w<sup>zm</sup>* (Judd, 1975).

**references:** Judd, 1975, The Eukaryotic Chromosome (Peacock and Brock, eds.). Australian National University Press, Canberra, pp. 169-84.

Jack and Judd, 1979, Proc. Nat. Acad. Sci. USA 76: 1368-72.

Levis, Bingham, and Rubin, 1982, Proc. Nat. Acad. Sci. USA 79: 564-68.

**genetics:** Duplication segregant carries *w*<sup>+</sup>, *rst*<sup>+</sup>, and *vt*<sup>+</sup>. Deficiency segregant male lethal in absence of the duplication. *z* males and females when homozygous for *Tp(1;3)w<sup>zh</sup>* have "halo" eyes (*z* in center, *w*<sup>+</sup> on periphery) as do *z* females that are homozygous for *Dp(1;3)w<sup>zh</sup>* (Jack and Judd, 1979). *z* males homozygous for *Dp(1;3)w<sup>zh</sup>*, however, have *w*<sup>+</sup> eyes as do *z* males and females heterozygous for *Dp(1;3)w<sup>zh</sup>*. The transposition mutates frequently (Judd, 1975). Some mutations from *w<sup>zh</sup>* show changes in the amount and distribution of eye pigment; other mutations involve lethality.

**molecular biology:** According to molecular data (Levis *et al.*, 1982), the white-associated breakpoints of *Df(1)w-zh* and *Dp(1;3)w<sup>zh</sup>* are not identical. *Dp(1;3)w<sup>zh</sup>* carries sequenced beginning between the coordinates -3.2 and -1.4 and extending rightward, with 0 the site of the copia insertion in *w<sup>a</sup>*.

***Tp(1;3)ZWD10***

**cytology:** *In(1)4A;20 + Tp(1;3)3C6-7;92B*.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, Genetics 116: 285-98.

**genetics:** Male lethal.

***Tp(1;3)ZWD13***

**cytology:** *Tp(1;3)3C1-3;9B;77E + Tp(1;3)16C;20;94B*.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, Genetics 116: 285-98.

**genetics:** Male lethal.

**\**Tp(1;4)A1*: Transposition (1;4) from Austin**

**cytology:** *Tp(1;4)9B;20;101-102*.

**new order:**

1 – 9B|20;  
101|9B – 20|102.

**origin:** X ray induced.

**discoverer:** Muller, 1928.

**synonym:** *CRB*; *W13*; *T(1;4)w<sup>13</sup>*; *T(1;4)I*.

**references:** Muller and Stone, 1930, Anat. Record 47: 393-94.

Muller and Painter, 1932, Z. Indukt. Abstamm. Vererbungsl. 62: 316-65.

Painter, 1934, Genetics 19: 448-69.

**genetics:** X chromosome broken between *lz* and *ras* and between *bb* and the centromere. The *Df(1)A1 = Df(1)9B;20* segregant dies in the egg stage, showing incomplete blastoderm formation, while the *Dp(1;4)A1 = Dp(1;4)9B;20;101-102* segregant dies later in the egg stage without separation of the germ layers (Poulson, 1940, J. Exp. Zool. 83: 271-325). Males with one entire X chromosome plus either segregant die, but females with two entire X's plus either segregant survive with low fertility (Muller and Stone, 1930). Triploid intersexes with either segregant also show very low fertility (Pipkin, 1940, Texas Univ. Publ. 4032: 126-56).

**\**Tp(1;4)ct<sup>13b1</sup>*: Transposition (1;4) cut**

**cytology:** *Tp(1;4)7B2-3;20;101A-D* superimposed on *R(1)1A3-4;19F-20A1*.

**new order:**

|1A4 – 7B2|20:20F – 20A1|;  
101A|7B3 – 20|101D – 102;

Tentative.

**origin:** X ray induced in *R(1)2*.

**discoverer:** Hannah, 1947.

**genetics:** Mutant for *ct* but not *y*, *ac*, *sc*, *cm*, *sn*, or *oc*. Male lethal.

**\**Tp(1;4)N<sup>264-86</sup>***

**cytology:** *Tp(1;4)3C6-7;3C7-8;3E5-6;101F*.

**new order:**

1 – 3C7|3E6 – 20;  
101A – 101F|3C7 – 3E5|101F – 102;

band 3C7 present twice and postulated to have been derived from each of two chromatids in the sperm (Demerec and Sutton, 1940, Proc. Nat. Acad. Sci. USA 26: 532-36).

**origin:** X ray induced.

**discoverer:** Demerec, 39i.

**references:** 1940, Genetics 25: 618-27.

Sutton, 1940, Genetics 25: 534-40 (fig.).

**genetics:** Supposedly carries two *N* loci, one mutant and one variegated. Also carries a mutant allele of *rst* (*rst<sup>264-86</sup>*) and variegates for *dm* but not *w* or *ec*. Carries normal allele of *ci*<sup>+</sup> (Stern). *Dp(1;4)N<sup>264-86</sup> = Dp(1;4)3C6-7;3E5-6;101F-102* viable and fertile in both sexes; *Df(1)N264-86 = Df(1)3C7-8;3E5-6* viable in heterozygote.

***Tp(1;4)w<sup>+IV</sup>***

**cytology:** *Tp(1;4)3C2;102F*.  
**origin:** Activity of transposing element.  
**references:** Rasmuson, Montell, Svahlin, and Westerberg, 1980, *Mol. Gen. Genet.* 177: 567-70.  
 Paro, Goldberg, and Gehring, 1983, *EMBO J.* 2: 853-60.  
**genetics:** Transposition of *w<sup>spw17g</sup>* to 4; shows *w<sup>m</sup>* phenotype (Rasmuson *et al.*, 1980).  
**molecular biology:** Seems to be associated with FB sequences. Located on 4 by *in situ* hybridization of single copy *w* DNA close to telomere of 4 at 102F.

***Tp(1;4)w<sup>m51c</sup>: Transposition (1;4) white-mottled***

**cytology:** *Tp(1;4)3C1-2;3C4-7;20E-F;101*.  
**new order:**  
 1 – 3C1|20F – 3C7|20F;  
 101|(3C2 – 3C4)|101 – 102.  
**origin:** X ray induced in *In(1)w<sup>m4</sup> = In(1)3C1-2;20F*.  
**discoverer:** Lefevre, 51c20.  
**references:** 1951, *DIS* 25: 71.  
 1952, *DIS* 26: 66.  
 Ratty, 1954, *Genetics* 39: 513-28.  
**genetics:** Variegated for *w* and *rst*. Male lethal. *Dp(1;4)w<sup>m51c</sup> = Dp(1;4)3C2-3;3C4-7;101* viable and fertile; carries loci of *w* and *rst* but not *spl*.

**\**Tp(1;4)w<sup>m52b13</sup>***

**cytology:** *Tp(1;4)2A2-3;3C3-4;20F;101*.  
**new order:**  
 1 – 2A2|20F – 3C4|20F;  
 101|(2A3 – 3C3)|101 – 102.  
**origin:** X ray induced in *In(1)rst<sup>3</sup> = In(1)3C3-4;20F*.  
**discoverer:** Ratty, 52b13.  
**references:** Lefevre, 1953, *DIS* 27: 57.  
**genetics:** Variegated for *w*.

**\**Tp(2;1)260-31***

**cytology:** *Tp(2;1)9A;24;29*.  
**new order:**  
 1 – 9A|(24 – 29)|9A – 20;  
 21 – 24|29 – 60.  
**origin:** X ray induced simultaneously with *y<sup>260-31</sup>*.  
**discoverer:** Fano, 1941.  
**references:** Sutton, 1943, *Genetics* 28: 210-17.  
**genetics:** Male lethal; lethality attributable to the independent mutation to *y<sup>260-31</sup>* since *Tp(2;1)260-31, y<sup>260-31</sup>/Df(1)sc260-25* is lethal.

***Tp(2;1)429.65***

**cytology:** *Tp(2;1)20F;21D1-2;25E3-4* (tentative).  
**new order:**  
 1A – 20F|(21D2 – 25E3)|20F;  
 21A – 21D1|25E4 – 60.  
**discoverer:** Gelbart.

***Tp(2;1)B19***

**cytology:** *Tp(2;1)9B14-C1;24D2-5;25F1-2*.  
**new order:**  
 1 – 9B14|25F1 – 24D5|9C1 – 20;  
 21 – 24D2|25F2 – 60.  
**origin:** X ray induced.  
**references:** Reuter and Szidonya, 1983, *Chromosoma* 88: 277-85.  
 Semeshin and Szidonya, 1985, *DIS* 61: 148-54.  
 Szidonya and Reuter, 1988, *Genet. Res.* 51: 187-208.

**genetics:** The region transposed carried *ed-mid*.

***Tp(2;1)C121: Transposition (2;1) Crossover suppressor***

**cytology:** *Tp(2;1)20;35F;40*.  
**new order:**  
 1 – 20|(35F – 40)|20;  
 21 – 35F|40 – 60.  
**origin:** X ray induced.  
**discoverer:** Roberts, 1965.  
**references:** 1970, *Genetics* 65: 429-48.  
**genetics:** Male viable and fertile. Recombination reduced in 2L.

***Tp(2;1)C239***

**cytology:** *Tp(2;1)7A-B;36C;39E*.  
**new order:**  
 1 – 7A|36C – 39E|7B – 20;  
 21 – 36C|39E – 60.  
**origin:** X ray induced.  
**discoverer:** Roberts, 1965.  
**references:** 1970, *Genetics*, 65: 429-48.  
**genetics:** Male lethal. Recombination reduced in X chromosome. The segregant *Dp(2;1)C239 = Dp(2;1)7A-B;36C;39E* survives; carries *His* (Moore, Sinclair, and Grigliatti, 1981, *Genetics* 97: 75-76).

***Tp(2;1)DTD2: Transposition (2;1) Disrupter of Transvection at Decapentaplegic***

**cytology:** *Tp(2;1)20;22D4-5;23B1-2*.  
**new order:**  
 1 – 20|(22D5 – 23B1)|20;  
 21 – 22D4|23B2 – 60.  
**origin:** X ray induced.  
**references:** Spencer, Hoffmann, and Gelbart, 1982, *Cell* 28: 451-61.  
 Segal and Gelbart, 1985, *Genetics* 109: 119-43.  
**genetics:** Disrupts transvection at *dpp*. *Df(2L)DTD2* lacks and *Dp(2;1)DTD2* carries the entire *dpp* locus.

***Tp(2;1)l-v223***

**cytology:** *Tp(2;1)14F;41;50E*.  
**new order:**  
 1A – 14F|(41 – 50E)|14F – 20;  
 21A – 41|50E – 60.  
**origin:** X ray induced.  
**discoverer:** Lindsley, Edington, and Von Halle.  
**references:** 1960, *Genetics* 45: 1640-70.  
**genetics:** Variegated for a lethal and has defective external male genitalia; male sterile.

**\**Tp(2;1)lt<sup>m31</sup>***

**cytology:** *Tp(2;1)8F;28D;40B-F*.  
**new order:**  
 1 – 8F|28D – 40B|8F – 20;  
 21 – 28D|40F – 60.  
**origin:** X ray induced.  
**discoverer:** Hessler, 1957.  
**references:** 1958, *Genetics* 43: 395-403.  
**genetics:** Variegated for *lt*.

**\**Tp(2;1)N<sup>264-80</sup>***

**cytology:** *Tp(2;1)3C6-7;36;40 + In(1)11;20* (Sutton).  
**new order:**  
 1 – 3C6|(36 – 40)|3C7 – 11|20 – 11|20;

21 – 36|40 – 60.

**origin:** X ray induced.

**discoverer:** Demerec, 39d.

**references:** 1941, Proc. Intern. Congr. Genet., 7th., pp. 99-103.

**genetics:** Contains mutant allele of *N* but normal alleles of *w*, *rst*, *dm*, and *ec*.

**\**Tp(2;1)N*<sup>264-102</sup>**

**cytology:** *Tp(2;1)3C6-7;50E;56C* (Sutton).

**new order:**

1 – 3C6|(50E – 56C)|3C7 – 20;

21 – 50E|56C – 60.

**discoverer:** Demerec, 39l.

**genetics:** Carries mutant allele of *N* and normal alleles of *w*, *rst*, and *dm*.

***Tp(2;1)odd*<sup>1.10</sup>: Transposition (2;1) odd-skipped**

**cytology:** *Tp(2;1)4A3-4;21A;24B*.

**new order:**

1 – 4A3|(21A – 24B)|4A4 – 20;

21A|24B – 60.

**discoverer:** Nüsslein-Volhard.

**synonym:** *T(1;2)odd*<sup>1.10</sup>.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**genetics:** Deficiency segregant uncovers *odd*.

***Tp(2;1)OR19***

**cytology:** *Tp(1;2)20;51F + In(2R)42B;48E;57C*.

**new order:**

1 – 20|51F – 48E|57C – 51F|20;

21 – 42B|48E – 42B|57C – 60E.

Three break rearrangement in chromosome 2 deletes 48E-57C and inverts 42B-48E; break between 20 on X and 51F of deleted acrocentric ring.

**origin:** X ray induced.

**discoverer:** Warters, 1961.

**genetics:** Male viable and weakly fertile. Homozygous female viable. *Dp(2;1)OR19 = Dp(2;1)20;48E;57C* survives in both male and female.

**\**Tp(2;1)sc*<sup>260-26</sup>**

**cytology:** *Tp(2;1)1B4-5;41F2-3;58B2-3 + In(2LR)27D2-3;41A*.

**new order:**

1A – 1B4|41F3 – 58B2|1B5 – 20;

21 – 27D2|41A – 27D3|41A – 41F2|58B3 – 60.

**origin:** X ray induced.

**discoverer:** Sutton, 39l.

**references:** 1943, Genetics 28: 210-17.

**genetics:** Mutant for *sc* but not *y*, *ac*, or *svr*.

***Tp(2;1)Sco*<sup>rv23</sup>: Transposition (2;1) Scutoid**

**cytology:** *Tp(2;1)h29;34F1-2;35B1-D1* superimposed on *Tp(2;2)Sco*. *Dp(2;1)Sco*<sup>rv23</sup> visible in salivaries "floating" in the nucleolus (Ashburner *et al.*, 1981).

**new order:**

1 – h29|(34F2 – 35A4|(35C2 – 35C5)|34B4 – 35C1|35B3 – 35B1)|h29 – h34;

21 – 34F1|35D2 – 60.

**origin:** X ray induced in *Tp(2;2)Sco*.

**discoverer:** Littlewood.

**synonym:** *Tp(2;1)Sco*<sup>R+23</sup>.

**references:** Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.

Ashburner, 1982, Genetics 101: 447-59.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, Genetics 104: 405-31.

Ashburner and Harrington, 1984, Chromosoma 89: 329-37.

**genetics:** *Sco* revertant; homozygous lethal as transposition. *Dp(2;1)Sco*<sup>rv23</sup> homozygotes and hemizygotes are viable and fertile; the duplication covers *l(2)34Fa – l(2)35Da* but not *sna* or *lace*, which are exposed by *Df(2L)Sco23*. The duplication is mutant for *noc* and is a strong enhancer of *H*. *Df(2L)Sco23* is deficient for *l(2)34Fa – lace* and is a dominant suppressor of *H* (Ashburner, 1982).

***Tp(2;1)ZWD11***

**cytology:** *Tp(2;1)3C7;41;56F*.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, Genetics 116: 285-98.

**genetics:** Males *w*<sup>+</sup> and sterile.

***Tp(2;?)odd*<sup>5.1</sup>**

**cytology:** *Tp(2;Y)23E;24E-F*; insertion position not known.

**origin:** X ray induced.

**discoverer:** Nüsslein-Volhard.

**references:** Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

**genetics:** Transposed element carries normal alleles of *odd* and *slp*.

***Tp(2;?)shv*<sup>S28</sup>: Transposition (2;?) short vein**

**cytology:** *Tp(2;?)22F1-2;24A1-2* inserted into chromosome (chromosome arm not known).

**origin:**  $\gamma$  ray induced.

**references:** Segal and Gelbart, 1985, Genetics 109: 119-43.

**genetics:** Associated with *shv*<sup>S28</sup>. Lethal over *shv* and lethal *dpp* alleles.

***Tp(2;Y)***

**Table I:** *Tp(2;Y)b10-4-Tp(2;Y)t223*;  $\gamma$  ray induced recombinations of *Y* and chromosome 2 from *T(Y;2)*; recovered as fertile males in combination with *Df(1)bb158*.

 $\beta$  Df(2;Y)R31 carries Pu<sup>+</sup>.

**Tp(2;Y)bw<sup>+</sup>: Transposition (Y;2) brown-wild type**

**cytology:** Tp(2;YL);58F1-59A2;60E3-F1 (Gersh, 1956, DIS 30: 115; Nicoletti).

**new order:**  
 YL<sup>D</sup> | (59A2 - 60E3) | YL<sup>P</sup> - YS;  
 21 - 58F1 | 60F1 - 60F5.

**origin:** X ray induced.

**discoverer:** Dempster.

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961,

Genetics 46: 339-46.

**genetics:** *Dp(2;Y)bw<sup>+</sup>* carries loci from *bw* through *ba* but not *hv* or *M(2)60E*; it is used as a marked *Y* and referred to as *bw<sup>+</sup>Y*. *Df(2R)bw* lost.

***Tp(2;Y)C***

**cytology:** [*Tp(2;Y)41A;43*]. Breaks in *2R* just to left of 41A (Whittinghill, 1937, DIS 8: 82-84) and distal to *cn* (located in 43E by Zacharopoulou, Yannopoulos, and Stamatis, 1981, DIS 56: 166-67).

**origin:** X ray induced.

**discoverer:** Dobzansky, 1929.

**synonym:** *T(Y;2)C*; *cn<sup>+</sup>Y* [= *Dp(2;Y)C*].

**references:** 1930, Biol. Zentr. 50: 671-85.

1932, Z. Indukt. Abstamm. Vererbungsl. 60: 235-86.

Sullivan, Kitos, and Sullivan, 1973, Genetics 75: 651-61.

**genetics:** Duplication segregant *Dp(2;Y)C* carries *cn<sup>+</sup>* (Sullivan *et al.*, 1973). Translocation heterozygotes over *cn* viable and fertile, the males with wild-type and the females with *cn* eyes.

***Tp(2;Y)en<sup>SF32</sup>: Transposition (2;Y) engrailed***

**cytology:** *Tp(2;Y)48A*.

**references:** Kuner, Nakanishi, Ali, Drees, Gustavson, Theis, Kauvar, Kornberg, and O'Farrell, 1985, Cell 42: 309-16.

**genetics:** Homozygous lethal. Associated with *en<sup>SF32</sup>*.

**molecular biology:** DNA breakpoint at about -2 kb, *i.e.*, 2 kb to the left of the *en<sup>1</sup>* insertion point.

***Tp(2;Y)G***

**cytology:** *Tp(2;Y)36B5-C1;40F*; metaphase chromosomes appear normal (Morgan, Bridges, and Schultz, 1935, Year Book - Carnegie Inst. Washington 34: 287).

**new order:**

Y|(36C1 - 40F)|Y;

21 - 36B5|40F - 60.

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1929.

**references:** 1930, Biol. Zentr. 50: 671-85.

Rhoades, 1931, Genetics 16: 490-504.

Yim, Grell, and Jacobsen, 1977, Science 198: 1168-70.

Nakamura, Gay, and Contamine, 1986, Biol. Cell. 56: 227-38.

**genetics:** *Dp(2;Y)G* has normal phenotype and is fertile when hyperploid in either sex; duplicated for the loci of *M(2)36F*, *M(2)39F*, *hk*, *pr*, *Bl*, *lt*, and *bw<sup>V32g</sup>* but not *rd*; covers the deficiency segregant of *Tp(2;Y)b10-4* and includes *Sd<sup>+</sup>* and *E(SD)<sup>+</sup>* (Lyttle, 1986, Genetics 114: 203-16).

*Tp(2;Y)G-H1*: see *Dp(2;Y)H1*

*Tp(2;Y)G-H2*: see *Dp(2;Y)H2*

*Tp(2;Y)G-H3*: see *Dp(2;Y)H3*

***Tp(2;Y)G-M15***

**cytology:** *Tp(2;Y)36B5-C;37E;40F*. Heterochromatin from the *Y* inserted in the transposed segment of 2.

**origin:** X ray induced in *Tp(2;Y)G*.

**new order:**

Y|36C1 - 37E|Y|37E - 40F|Y;

21 - 36B5|40F - 60.

**references:** Nakamura, 1973, Thesis, Paris-Sud.

1978, Mol. Gen. Genet. 159: 285-92.

Nakamura, Gay, and Contamine, 1986, Biol. Cell. 56:

227-38.

**genetics:** Duplication segregant carries *M(2)36F<sup>+</sup>* - *hk<sup>+</sup>* and *pr<sup>+</sup>* - *M(2)39F<sup>+</sup>* but not *ref(2)P<sup>+</sup>*.

**\**Tp(2;Y)H***

**cytology:** *Tp(2;Y)37B1-2;40B2-3*; also an inversion in *2R* from near centromere to left of *px* (Morgan, Bridges, and Schultz, 1935, Year Book - Carnegie Inst. Washington 34: 287).

**new order:**

Y<sup>D</sup>|(37B2 - 40B2)|Y<sup>P</sup>;

21 - 37B1|40B3 - | - | - 60.

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1929.

**references:** 1930, Biol. Zentr. 50: 671-85.

Schultz and Bridges, 1932, Am. Nat. 66: 323-34.

**genetics:** Male fertile. Homozygote viable and male sterile. *Df(2L)H* survives and is deficient for *M(2)39F*, *hk*, and *pr* but not *M(2)36F* or *lt*; somewhat sterile. *Dp(2;Y)H* appears normal; duplicated for the loci for which *Df(2L)H* is deficient.

***Tp(2;Y)odd: Transposition (2;Y) odd-skipped***

**discoverer:** Nüsslein-Volhard.

**references:** Nüsslein-Volhard, Wieschaus and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

<sup>α</sup> New order: Y|(21A - 25C)|Y;  
21A|38B - 25C|38B - 60.

***Tp(2;Y)pr<sup>C5</sup>: Transposition (2;Y) purple***

**origin:** Induced by ethyl methanesulfonate.

**references:** Yim, Grell, and Jacobsen, 1977, Science 198: 1168-70.

Tobler, Yim, Grell, and Jacobsen, 1979, Biochem. Genet. 17: 197-206.

**genetics:** Variegates for *pr*.

***Tp(2;Y)prd: Transposition (2;Y) paired***

**cytology:** *Df(2L)33A1-2;34F1-2 Df(2L)33A1-2;34F1-2 + T(Y;2)33F2-3*.

**new order:**

Y|33F2 - 34F1|33A2 - 33F1|Y;

21 - 33A1|34F2 - 60.

**synonym:** *T(Y;2)prd*.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**genetics:** Deficiency segregant [*Df(2L)prd*] uncovers *prd* - *sal*.

**\**Tp(2;Y)R24***

**cytology:** *Tp(2;Y)45A;51E*.

**new order:**

Y<sup>D</sup>|(45A - 51E)|Y<sup>P</sup>;

21 - 45A|51E - 60.

**origin:** X ray induced.

**discoverer:** Slatis.

**references:** 1955, Genetics 40: 8.

**genetics:** Induced simultaneously with (but independently

of *bw*<sup>24</sup>, an isoallele of *bw*. Associated with a rough eye phenotype. *Dp(2;Y)R24*-bearing males viable and sterile.

***Tp(2;Y)Rsp: Transposition (2;Y) Responder***

**cytology:** Insertion of proximal heterochromatin of 2R into *B<sup>S</sup>Yy<sup>+</sup>* between *B<sup>S</sup>* and *kI5*.

**origin:** X-ray-induced reconstitution of intact Y and second chromosomes from *T(Y;2)cb25 = T(Y;2)B<sup>S</sup>Xh;41A*.

**references:** Lyttle, 1984, Genetics 106: 423-34.

Lyttle and Ault, 1985, Genetics 110: s23.

Lyttle, 1989, Genetics 121: 751-63.

**properties:** A series of reconstitutions that result in the insertion of variable amounts of 2R heterochromatin into *YL* and the deletion of that amount from 2R. Both 2R and Y respond independently to *SD* and in proportion to the number of *Rsp* sequences that they carry. Each of the segregants, *Dp(2;Y)Rsp (=B<sup>S</sup>RspYy+)* or *Df(2R)Rsp*, survives in the absence of the other and can be studied individually.

chromosome	cytology	genetics	$k_Y^\alpha$	$k_A^\alpha$
<i>Tp(2;Y)Rsp1</i>	<i>h38-h40</i>	<i>l(2)41Aa-</i>	0.804	
<i>Tp(2;Y)Rsp4</i>	<i>h38-h44</i>	<i>l(2)41Aa<sup>+</sup>-l(2)41Af<sup>+</sup></i>	0.956	0.593
<i>Tp(2;Y)Rsp22</i>	<i>h38-h43</i>	<i>l(2)41Aa<sup>+</sup>-r1<sup>+</sup></i>	0.961	0.514
<i>Tp(2;Y)Rsp24</i>	<i>h38-h39</i>	<i>l(2)41Aa-</i>	0.885	0.479
<i>Tp(2;Y)Rsp29</i>	<i>h38</i>	<i>l(2)41Aa-</i>	0.606	0.998
<i>Tp(2;Y)Rsp31</i>	<i>h38</i>	<i>l(2)41Aa-</i>	0.623	0.979
<i>Tp(2;Y)Rsp42</i>	<i>h38</i>	<i>l(2)41Aa-</i>	0.599	0.973

<sup>α</sup>  $k_Y$  is the k value indicating the response to *SD* of the Responder sequences inserted into the Y, whereas  $k_A$  reflects the response of the Responder sequences remaining in the reconstituted second chromosome.

***Tp(2;Y)vg<sup>76d2</sup>***

**cytology:** *Tp(2;Y)58B + Dp(2R)58B-D*.

**origin:** Caffeine and γ rays.

**references:** Alexandrov and Alexandrova, 1987, DIS 66: 185-87.

**genetics:** Mutant for *vg*.

***Tp(2;2)433.56***

**cytology:** *Tp(2;2)28D2-3;29E1-2;40-41*.

**new order:**

21 - 28D2|29E2 - 40|(28D3 - 29E1)|41 - 60.

**discoverer:** Gelbart.

***Tp(2;2)A446***

**cytology:** *Tp(2;2)35F1-2;36C1-2;49B1-7 + Df(1)35B1-3;35F1-2*.

**new order:**

21 - 35B1|36C2 - 49B1|35F2 - 36C1|49B3 - 60F.

**origin:** X ray induced.

**discoverer:** Aaron.

**synonym:** *Df(2L)A446*.

**references:** Ashburner, Aaron, and Tsubota, 1982, Genetics 102: 421-35.

Gubb, Roote, McGill, Shelton, and Ashburner, 1986, Genetics 112: 551-75.

**genetics:** *Df(2L)A446 = Df(2L)35B1-3;35F1-2* is deficient for *noc - l(2)35Eb*, and heterozygotes are semi-lethal; escapers are sterile and have a wavy-wing and small-fly phenotype. *Dp(2;2)A446* (recombinant between *Tp(2;2)A446* and a wild-type 2) is viable.

***Tp(2;2)b: Transposition (2;2) black***

**origin:** γ ray induced.

**references:** Alexandrov and Alexandrova, 1986, DIS 63: 159-61.

Alexandrova, 1986, DIS 63: 21.

**genetics:** Mutant for *b* but not for *nub* or *j*. Homozygous lethal.

**cytology:** *Tp(2;2)35A4-B1;35B3-4;35C1-2;35C5-D1* or *In(2L)35A4-B1;35C5-D1* + *In(2L)35B3-4;35C1-2*. Inferred from cytogenetic data.

**new order:**

21 – 35A4|(35C2 – 35C5)|35B4 – 35C1|35B3 – 35B1|35D2 – 60.

**origin:** X ray induced.

**synonym:** *Sco*; *Tp(2;2)Sco1* *Tp(2;2)Sco2*.

**references:** Maroni, 1980, *DIS* 55: 96-98.

Ashburner, Tsubota, and Woodruff, 1982, *Genetics* 102: 401-20.

Ashburner, Detwiler, Tsubota, and Woodruff, 1983, *Genetics* 104: 405-31.

Ashburner and Harrington, 1984, *Chromosoma* 89: 329-37.

**genetics:** Homozygous lethal. Mutant for *Sco*, with phenotype enhanced by *noc* mutations and suppressed by *noc*<sup>+</sup> duplications. *Adh<sup>F</sup>* carried on *Tp(2;2)Sco*. Gene sequence as follows: – *noc*|*rd* – *l(2)35Da*|*l(2)35Bb* – *l(2)35Cb*|*Adh* – *noc*|*sna* –.

**molecular biology:** *Adh-noc* region cloned (Chia, Karp, McGill, and Ashburner, 1985, *J. Mol. Biol* 186: 689-

706) (coordinate 0 an *EcoRI* restriction site 1321 bp to the left of the start of transcription of the larval *Adh* transcript; positive values toward the centromere). The distal breakpoint of the *Sco* rearrangement is within the *noc* gene complex between the *nocA* and *nocB* components, such that *nocB* and *nocC* are brought into juxtaposition with *sna*. The molecular coordinates are complex, in that the distal break point as judged from the uninverted portion of *noc* is between coordinates -103.3 and -102.3; as judged from the *noc-sna* junction, however, it is between coordinates -108.5 and -107.8 kb, very close to the -107.8 position. Both these breakpoints are between *nocA* and *nocB*; the *noc-Adh* transposed segment extends from -107.8 to at least +40 kb (McGill, Chia, Karp, and Ashburner, 1988, *Genetics* 119: 647-61). The proximal-most breakpoint of *Tp(2;2)Sco* is within 16 kb to the left of *sna* (Alberga).

***Choline acetyltransferase***

cytology: *Tp(2;3)41;91C*. Complex rearrangement.

origin:  $\gamma$  ray induced.

discoverer: Myers and Gelbart.

***Tp(2;3)dp: Transposition (2;3) dumpy***

cytology: *Tp(2;2)27E1-2;32E2-3;45A + Tp(2;3)34D7-E1;41;48A1;80-81* (inferred). Breakpoints listed by Bridges (CP627) have been revised by Woodruff and Ashburner, 1979, who describe a stock obtained from the Bowling Green Stock Center. Examination of the stock by standard genetic tests indicates a transposition between chromosome 2 and chromosome 3. Metaphase preparations of the balanced stock show, in addition to two normal-looking metaphase chromosomes, a long metacentric and a short submetacentric, believed to be the transposed chromosome.

new order:

21 - 27E1|32E3 - 34D7|41 - 34E1|48A1 - 60;  
61 - 80|(41 - 45A|27E2 - 32E2|45A - 48A1)|81 - 100.  
Tentative (Ashburner). Chromosome 3 breaks inferred from genetic data (Muller, 1942; Cooper, Zimmering, and Krivshenko, 1955, Proc. Nat. Acad. Sci. USA 41: 911-14)).

origin: Reportedly spontaneous.

discoverer: Nichols-Skoog, 36e16.

synonym: *In(2LR)dp*.

**genetics:** Deficiency segregant uncovers *noc-osp*.

***Tp(2;3)P*: Transposition (2;3) Pale**

**cytology:** *Tp(2;3)58E3-F2;60D14-E2;96B5-C1* (Morgan, Bridges, and Schultz, 1935, Year Book - Carnegie Inst. Washington 34: 286).  
**new order:**  
 21 – 58E3|60E2 – 60F;  
 61 – 96B5|60D14 – 58F2|96C1 – 100.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 17j16.  
**references:** 1919, Anat. Record 15: 357-58.  
 1923, Anat. Record 24: 426-27.  
 Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 184-87.  
 Li, 1927, Genetics 12: 1-58.  
 Kossikov and Muller, 1935, J. Heredity 26: 305-17.  
 Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**genetics:** Associated with *P*. Homozygote ordinarily lethal but survives in presence of *bw<sup>+</sup>Y = Dp(2;Y)YL;58F1-59A2;60E3-F1*; lethality therefore associated with 60D14-E2 breakpoint (Muller, 1942, DIS 16: 64). *Dp(2;3)P* is viable and fertile; duplicated for loci of *px*, *M(2)58f*, *crs*, *bw*, *mi*, *abb*, *pd*, *ll*, *l(2)NS*, *sp*, *bs*, and *ba* but not *a* or *M(2)60E*. Homozygous *Dp(2;3)P* (i.e., four doses of 59A2-60E3) is lethal unless one chromosome 2 is *Df(2R)P*. *Df(2R)P* with two normal third chromosomes is lethal.

**other information:** First transposition recorded in *D. melanogaster*.

***Tp(2;3)P32*: Transposition (2;3) Pasadena 32**

**cytology:** *Df(2R)41A;44C-D + T(2;3)42D-E;89D7-E1*. (Translocation involves the acentric ring produced as a concomitant of the deficiency.)  
**new order:**  
 21 – 41A|44D – 60;  
 61 – 89D7|42D – 41A|44C – 42E|89E1 – 100.  
**origin:** X ray induced in *bx<sup>34e</sup>*.  
**discoverer:** E.B. Lewis, 50i.  
**genetics:** Gives transvection effect in *Tp(2;3)P32*, *bx<sup>34e</sup>/Ubx* heterozygote. The segregant *Dp(2;3)P32* survives and is fertile and virtually wild type; duplicated for *stw*, *ap*, *tuf*, and *cn* but not *ltd*.

***Tp(2;3)prd<sup>2.27</sup>*: Transposition (2;3) paired**

**cytology:** *Tp(2;3)31B;33D-E;97C-D*.  
**discoverer:** Nüsslein-Volhard.  
**synonym:** *T(2;3)prd<sup>2.27</sup>*.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.  
 Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Quant. Biol. 50: 145-54.  
**genetics:** Deficiency segregant [*Df(2L)prd2.27*] uncovers *bsk – prd*.

***Tp(2;3)SS301* Transposition (2;3) S. Smith**

**cytology:** *Tp(2;3)21A;21D1;80F* (Ashburner *et al.*, 1980, corrected).  
**origin:** X ray induced.  
**discoverer:** Smith.  
**references:** Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95.

***Tp(2;3)TE35A-203*: Transposition (2;3) Transposable Element**

**cytology:** *Tp(2;3)34C1-2;35B;80-81* (Ashburner).  
**origin:**  $\gamma$  ray induced in *TE35A*.  
**discoverer:** Samkanje.  
**synonym:** *Tp(2;3)TE146Z*.  
**genetics:** Deficiency segregant dominant lethal.

***Tp(2;3)TE35BC-2***

**cytology:** *Df(2L)25A1-2;37A1-2 + Tp(2;3)35C1-3;80-81*.  
**new order:**  
 21 – 25A1|37A2 – 60;  
 61 – 80|(35C1 – 25A2|37A1 – 35C3)|81 – 100.  
**origin:**  $\gamma$  ray induced in *TE35BC*.  
**discoverer:** Gubb.  
**synonym:** *Tp(2;3)36R*.  
**genetics:** Variegates for *w<sup>+</sup>* of *TE35BC*. Does not cover deficiency for *rst*. Lethal with lethal *ck* alleles.

***Tp(2;3)tkv*: Transposition (2;3) thick veins**

**cytology:** *Tp(2;3)25A2-3;25D5-E1;69C*.  
**new order:**  
 21 – 25A2|25E1 – 60;  
 61 – 69C|25A3 – 25D5|69C – 100.  
**discoverer:** Szidonya.  
**references:** Szidonya and Reuter, 1988, Genet. Res. 51: 197-208.  
**genetics:** Deficiency segregant is *M* and female sterile; very weak but fertile with *SM1* or *In(2L)NS*, sterile with *SM5*.

***Tp(2;3)V*: Transposition (2;3) Valencia**

**origin:** X ray induced.  
**references:** Valencia, 1970, DIS 45: 37-38.

	transposition	cytology	new order $\alpha$	genetics (homozygotes)
	<b><i>Tp(2;3)V10-7m</i></b>	<i>26A3;26F;86E</i>	1	lethal

**Tp(2;4)X2**

**cytology:** *Tp(2;4)23D-E;24A1-2;102D*.

**synonym:** *Tp(2;4)ey<sup>D</sup>*.

**references:** Ashburner.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**genetics:** Mutant for *Alp<sup>2</sup>* and *ey<sup>D</sup>*.

**Tp(3;1)bx<sup>111</sup>: Transposition (3;1) bithoraxoid**

**cytology:** *Tp(3;1)4D;89E;90B2*.

**new order:**

1 – 4D|89E – 90B2|4D – 20;

61 – 89E|90B2 – 100.

**references:** Lewis, 1981, *Developmental Biology Using Purified Genes* (Brown and Fox, eds.). Academic Press, London, New York, San Francisco, Vol. 23, pp. 189-208.

**genetics:** Transposes rightmost part of the *BXC* to 4D. Mutant for *bx<sup>d</sup>* and *pbx*. Distinguishable from other *bx<sup>d</sup>* rearrangements by larval phenotype.

**molecular biology:** 89E breakpoint about 5 kb to the left of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>* (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, *Science* 221: 23-29).

**Tp(3;1)C152**

**cytology:** *Df(3R)88B-C;94A + T(1;3)20;90E..*

**new order:**

1 – 20|(90E – 88C|94A – 90E)|20;

61 – 88B|94A – 100.

**origin:** X ray induced.

**discoverer:** Roberts, 1965.

**references:** 1970, *Genetics* 65: 429-48.

**genetics:** Male fertile. Recombination reduced in *3R*.

**Tp(3;1)C210**

**cytology:** *Tp(3;1)7F10-8A1;76B;80*.

**new order:**

1 – 7F10|76B – 80|8A1 – 20;

61 – 76B|80 – 100.

**origin:** Lefevre.

**genetics:** Associated with *gg*.

**Tp(3;1)DEB8: Transposition (3;1) diepoxybutane**

**cytology:** *Tp(3;1)20F;70E-F;77C*.

**new order:**

1 – 20F|70F – 77C|20F;

61 – 70E|77C – 100.

**origin:** Induced by diepoxybutane.

**references:** Denell, Lim, and Auerbach, 1978, *Mutat. Res.* 49: 219-24.

**genetics:** Male fertile.

**Tp(3;1)FA11**

**cytology:** *Tp(3;1)X;84D-E;87D*.

**synonym:** *T(1;3)FA11*.

**discoverer:** Lehman.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

**genetics:** Deficiency segregant uncovers *hb – sad*.

**Tp(3;1)HF318**

**cytology:** *Tp(3;1)3A3-4;66D-E;80*.

**origin:** X ray induced.

**discoverer:** Lefevre.

**genetics:** Hemizygous lethal.

**Tp(3;1)KA21**

**cytology:** *Tp(3;1)2C9;66B;67E*.

**origin:** X ray induced.

**references:** Lefevre, 1981, *Genetics* 99: 461-80.

Oro, McKeown, and Evans, 1990, *Nature* 347: 298-361.

**genetics:** Hemizygous lethal. Mutant for *usp*.

**molecular biology:** 2C9 break results in deletion of three nucleotides in *usp<sup>2</sup>*.

**Tp(3;1)kar<sup>51</sup>: Transposition (3;1) karmoisin**

**cytology:** *Tp(3;1)20;87C7-D1;88E2-3*.

**new order:**

1 – 20|87D1 – 88E2|20;

61 – 87C7|88E3 – 100.

**discoverer:** Gelbart.

**references:** Hall and Kankel, 1976, *Genetics* 83: 517-35.

Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

**genetics:** Associated with *kar*. Deficiency segregant uncovers *ems – put* (Jürgens *et al.*, 1984). Duplication segregant includes *trx<sup>+</sup>* (Ingham, 1981, *Wilhelm Roux's Arch. Dev. Biol.* 190: 365-69).

**Tp(3;1)N<sup>264-6</sup>: Transposition (3;1) Notch**

**cytology:** Breakpoints given in CP627 revised by Ashburner and Walker (Ashburner *et al.*, 1981). *X* consists of inverted *X* and inserted third chromosome material; *3* is both inverted and deficient.

**new order:**

1 – 3C|20 – 3C|80 – 73F4|71B8 – 73A5|20F;

61A – 61F5|71B7 – 61F8|73F1 – 73B2|80 – 100.

This cytology incompatible with reported survival of aneuploid segregants.

**origin:** X ray induced.

**discoverer:** Demerec, 33k20.

**synonym:** *T(1;3)N<sup>N264-6</sup>* (CP627).

**references:** CP627.

Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, *DIS* 56: 186-91.

**genetics:** Variegates for *w* and *N*. *X/Y* male lethal; *X/Y/Y* viable and sterile. Duplication segregant viable; deficiency segregant survives and is *M. Tp(1;3)N<sup>264-6</sup>* (CP627).

**Tp(3;1)O5**

**cytology:** *Tp(1;3)4F2-3;62B-C;88A-C;92C-D* (Lewis, 1951, *DIS* 25: 108-9). *Dp(3;1)O5* similar to standard *X* in size, staining of salivaries, and early completion of replication (Lakhotia, 1970, *Genet. Res.* 15: 301-07).

**new order:**

1 – 4F2|88C – 92C|4F3 – 20;

61 – 62B|88A – 62B|92D – 100.

**origin:** X ray induced.

**discoverer:** Oliver, 29130.

**references:** 1937, *Am. Nat.* 71: 560-66.

1938, *Genetics* 23: 162.

**genetics:** Male viable and fertile. Homozygous female viable and sterile. The segregant *Dp(3;1)O5* is viable and fertile in male and female. It is duplicated for loci of *red*, *jvl*, *cv-c*, *su(Hw)*, *sbd*, *ss*, *bx*, *sr*, *gl*, *k*, and *Dl* but not *cu*, *ry*, *kar*, or *e* (Lindsley and Grell, 1958, *DIS* 32: 136; Lewis). Produces roughish eyes, spread and nicked

wings, coarse bristles, and a darkly-pigmented abdomen.

***Tp(3;1)P115: Transposition (3;1) Pasadena 115***

**cytology:** *Tp(3;1)20;89B7-8;89E7-8* (Sánchez-Herrero *et al.*, 1985).

**discoverer:** E.B. Lewis.

**references:** Morata and García-Bellido, 1976, Wilhelm Roux's Arch. Dev. Biol. 179: 125-43.

Sánchez-Herrero, Vernós, Marco, and Morais, 1985, Nature 313: 108-13.

**genetics:** The deficiency segregant, *Df(3R)P115*, includes the entire *BXC* and several neighboring genes (Sánchez-Herrero *et al.*, 1985). The duplication segregant, *Dp(3;1)P115*, carries all the wild-type alleles in the *BXC*.

***Tp(3;1)pn<sup>36</sup> Transposition (3;1) prune***

**cytology:** *Tp(3;1)1A;2E1-2;61A;62C2-3*.

**new order:**

1A|2E1 – 1A|61A – 62C1|2E2 – 20;  
61A|62C4 – 100.

**origin:** X ray induced.

**references:** Ilyina, Sorokin; Belyaeva, and Zhimulev, 1980, DIS 55: 205.

Slobodyanyuk and Serov, 1983, Mol. Gen. Genet. 191: 372-77.

**genetics:** Mutant for *pn*.

***Tp(3;1)ry<sup>35</sup>: Transposition (3;1) rosy***

**cytology:** *Tp(3;1)20;87C-E;91B-C* (Lindsley). Left breakpoint in or near *ry*.

**new order:**

1 – 20|(87E – 91B)|20;  
61 – 87C|91C – 100.

**origin:** X ray induced in *cu kar* chromosome.

**discoverer:** Schalet.

**references:** 1964, DIS 39: 62-64.

Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 1261-68.

Roehdanz, Kitchens, and Lucchesi, 1977, Genetics 85: 489-96.

**genetics:** Transposition associated with *cu*, *ry<sup>35</sup>*, and *kar*. The segregant, *Dp(3;1)ry<sup>35</sup>* is viable and fertile in male and female; duplicated for loci of *Aldox*, *Sb* and *Ubx*.

***Tp(3;1)ss<sup>V</sup>: Transposition (3;1) spineless-variegated***

**cytology:** *Tp(3;1)20;89B;100F*.

**new order:**

1 – 20|89B – 100F|20;  
61 – 89B|100F.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**genetics:** Variegated for *ss<sup>l</sup>* and mutant for *ss<sup>a</sup>*. Male viable and sterile.

***Tp(3;1)st<sup>g82</sup>: Transposition (3;1) scarlet***

**cytology:** *Tp(3;1)5B6-7;72D10-11;73B1-2;80F*; deficient for 72D11-73B1.

**new order:**

1 – 5B6|80F – 73B2|5B7 – 20;  
61 – 72D10|80F – 100.

**origin:** X ray induced.

**discoverer:** Belote.

**references:** Belote and McKeown.

**genetics:** Deficient for *st*.

***Tp(3;1)ZWD14***

**cytology:** *Tp(3;1)3C1-2;81;86B-C*.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, Genetics 116: 285-98.

**genetics:** Males *w<sup>+</sup>*; homozygous females show mottled eye color.

***Tp(3;Y)***

**origin:** X ray induced in *B<sup>S</sup>Y<sup>+</sup>*.

<sup>$\gamma$</sup>  New order: *Y<sup>D</sup>|(86C – 91A|95D – 91C|83E – 86C)|Y<sup>P</sup>*;  
61 – 83D|95D – 100.

<sup>$\delta$</sup>  Carries *Acp<sup>+</sup>*, *bv<sup>+</sup>*, and *ca<sup>+</sup>* (Morrison and MacIntyre, 1978, Genetics 88: 487-97).

***Tp(3;Y)Abd-B: Transposition (3;Y) Abdominal-B***

**cytology:** *Tp(3;Y)89C;89E1-2*.

**new order:**

Y|89C – 89E1|Y;  
61 – 89C|89E2 – 100.

**origin:**  $\gamma$  ray in *mwh* stock.

**references:** Tiong, Whittle, and Gribbin, 1987, Development 101: 135-42.

**genetics:** Mutant for *Abd-B*, *Ubx*, *abd-A*; proximal part of *Abd-B* inserted in *Y*.

**molecular biology:** Distal breakpoint at +54 kb (Bender) proximal to the *Abd-B* homeobox.

***Tp(3;Y)L131-D3***

**cytology:** *Tp(3;Y)72A-B;75C*; *y<sup>+</sup>* inserted in *3L*.

**origin:**  $\gamma$  ray-induced derivative of *T(Y;3)L131* that is no longer male-sterile in combination with *Df(1)bb158*.

**discoverer:** Kennison.

**genetics:** Duplication segregant survives and is *B<sup>S</sup>* but not *y<sup>+</sup>*.

***Tp(3;Y)P92: Transposition (3;Y) Pasadena 92***

**cytology:** *Tp(3;Y)84D9-10;85A6* on *In(3R)85B;88C*. Extra bands distally and proximally (B.S. Baker).

**new order:**

Y|84D10 – 85A6|Y;  
61 – 84D9|85A6 – 85B|88C – 85B|88C – 100.

**origin:** X-ray-induced derivative of *In(3R)hb<sup>D</sup>*.

**discoverer:** E.B. Lewis.

**references:** Duncan and Kaufman, 1975, *Genetics* 80: 733-52.

Bender, Turner, and Kaufman, 1986, *Dev. Biol.* 119: 418-32.

**genetics:** *hb<sup>D</sup>* transposed to *Y*. Duplication segregant complements the recessive lethality of *Dfd* and covers *dsx* and *p<sup>P</sup>*, but does not cover the *Dfd* eye phenotype (Duncan and Kaufman, 1975).

***Tp(3;2)BTD9***

**cytology:** *Tp(3;2)58A;81;88E*.

**new order:**

41 – 58A|88E – 81|58A – 60;

61 – 81|88E – 100F.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, *Genetics* 116: 285-98.

***Tp(3;2)C16***

**cytology:** *Tp(3;2)50E;66C;70C*.

**new order:**

21 – 50E|70C – 66C|50E – 60;

61 – 66C|70C – 100.

**origin:** X ray induced.

**discoverer:** Roberts, 1964.

**references:** 1970, *Genetics* 65: 429-48.

**genetics:** Homozygous lethal. Recombination reduced in 2R and 3L.

***Tp(3;2)C259***

**cytology:** *Tp(3;2)40-41;61E;73A*; position of breakpoint in chromosome 2 with respect to centromere not determined.

**new order:**

21 – 40|61E – 73A|41 – 60;

61A – 61E|73A – 100.

Tentative.

**origin:** X ray induced.

**discoverer:** Roberts, 1965.

**references:** 1970, *Genetics* 65: 429-48.

**genetics:** Homozygous lethal. Recombination reduced in 3L.

***Tp(3;2)ca<sup>v</sup>: Transposition (3;2) claret-variegated***

**cytology:** *Df(3R)81F;99C-E + T(2;3)59D;94*. (Translocation involves the acentric ring formed as a concomitant of the deficiency.)

**new order:**

21 – 59D|94 – 99C|81F – 94|59D – 60;

61 – 81F|99E – 100.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**synonym:** *In(3R)ca<sup>v</sup>* (CP627).

**references:** Craymer, 1980, *DIS* 55: 197-200.

**genetics:** Variegates for *ca*.

***Tp(3;2)CA20***

**cytology:** *Df(2L)34D;35C + T(2;3)45A-B;69F-70A;98E-F + T(2;3)48E-F;99E*.

**new order:**

21 – 34D|35C – 45A|98F – 99E|48F – 60F;

61 – 69F|98E – 70A|45B – 48E|99E – 100.

**references:** Gubb, Roote, Harrington, McGill, Durrant, Shelton, and Ashburner, 1984, *Chromosoma* 92: 116-23.

**genetics:** Associated with *Df(2L)TE35A-5*.

***Tp(3;2)Ctx: Transposition (3;2) Cephalothorax***

**cytology:** *Tp(3;2)35B3-4;83C9-D1;85E5-9* (E.B. Lewis; Jürgens).

**new order:**

21 – 35B3|83D1 – 85E5|35B4 – 60;

61 – 83C9|85E9 – 100.

**synonym:** *T(2;3)Ctx*.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

**genetics:** Mutant for *l(2)35Bd* and *Anp<sup>Cx</sup>*. Deficiency segregant uncovers *Scr - hb*.

**molecular biology:** Third chromosome breakpoint 165-166 kb distal to proximal breakpoint of *Tp(3;3)Dfd<sup>rv16</sup>*.

***Tp(3;2)DTD129***

**cytology:** *Dp(3;2)26F;81F;99A*.

**origin:**  $\gamma$  ray induced.

**references:** Smolik-Utlaut and Gelbart, 1987, *Genetics* 116: 258-98.

***Tp(3;2)FA12***

**cytology:** *Tp(3;2)chrom2;77A-B;80F*.

**synonym:** *T(2;3)FA12*.

**discoverer:** Lehman.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

**genetics:** Deficiency segregant uncovers *kni* and *Pc* in heterozygous embryos.

***Tp(3;2) fz<sup>C21</sup>: Transposition (3;2) frizzled***

**cytology:** *Tp(3;2)40;66B-D;70D4-7*.

**new order:**

21A – 40|66D – 70D4|40 – 60;

61 – 66B|70D7 – 100.

**origin:**  $\gamma$  ray induced.

**discoverer:** Adler.

**genetics:** Moderate *fz* phenotype. Homozygous lethal (occasional homozygotes dying as pharate adults, but most dying earlier). Viable over all other *fz* alleles.

***Tp(3;2)I702***

**cytology:** *Tp(3;2)29F;64F;77F on In(3L)63C;72E1-2*.

**new order:**

21 – 29F|77F – 72E2|63C – 64F|29F – 60;

61 – 63C|72E1 – 64F|77F – 100.

**discoverer:** Ising.

**references:** Ashburner.

***Tp(3;2)iab2<sup>P10</sup>: Transposition (3;2) infraabdominal 2 - Pasadena 10***

**cytology:** *Tp(3;2)29A-C;89C1-2;89E1-2*.

**new order:**

21 – 29A|89C2 – 89E1|29C – 60;

61 – 89C1|89E2 – 100.

**origin:** X ray induced.

**discoverer:** Shaw, 1974.

**synonym:** *Tp(3;2)P10*.

**references:** Lewis, 1978, *Nature* 276: 565-70. 1980, *DIS* 55: 207-08.

Struhl, 1981, *Nature* 293: 36-41.

1984, Nature 308: 354-57.

Morata, Botas, Kerridge, and Struhl, 1983, J. Embryol. Exp. Morphol. 78: 319-41.

Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 45: 81-96.

**genetics:** Insertion of *ss<sup>+</sup>-pbx<sup>+</sup>* and perhaps part of *iab2<sup>+</sup>* into 2L (Lewis, 1978; Struhl, 1984). Homozygous lethal in late embryo (Lewis, 1980). *Dp(3;2)P10* homozygous viable; *Df(3R)P10* heterozygous viable and *Ubx* in phenotype. It deletes all the thoracic *BXC* genes and seems to damage *iab2* (Morata *et al.*, 1983).

**molecular biology:** 89E breakpoint 35-36 kb to the right of right breakpoint of *In(3R)Cbx<sup>rv1</sup>*. (Karch *et al.*, 1985).

***Tp(3;2)iab5<sup>301</sup>: Transposition (3;2) infraabdominal 5***

**cytology:** *Tp(3;2)41;86E;89E*.

**discoverer:** R.H. Baker.

**genetics:** Mutant for *iab5<sup>301</sup>*.

***Tp(3;2)iab5<sup>843</sup>***

**cytology:** *Tp(3;2)23;81;89E3-4*.

**new order:**

21 - 23|81 - 89E3|23 - 60;

61 - 81|89E4 - 100.

**origin:** X ray induced.

**discoverer:** R.H. Baker.

**synonym:** *iab5<sup>31616.843</sup>*.

**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.

**genetics:** Mutant for *iab5*.

**molecular biology:** 89E3-4 breakpoint 93-99.5 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***Tp(3;2)iab5<sup>994</sup>***

**cytology:** *Tp(3;2)22;89B;89E;90A*.

**origin:** X ray induced.

**discoverer:** R.H. Baker.

**synonym:** *iab5<sup>31616.994</sup>*.

**genetics:** Mutant for *iab5*.

***Tp(3;2)MS6: Transposition (3;2) Mglinetz Semenova***

**cytology:** *Tp(3;2)60A;61C;64B*.

**new order:**

21 - 60A|61C - 64B|60A - 60F;

61A - 61C|64B - 100.

**origin:**  $\gamma$  ray induced.

**references:** Semenova, Mglinetz, and Glotoff, 1970, Genetika (Moscow) 6(4): 165-69.

Mglinetz and Semenova, 1970, Genetika (Moscow) 6(8): 86-94.

***Tp(3;2)MS7***

**cytology:** *Tp(3;2)21A;61A;63B*.

**new order:**

21A|61A - 63B|21A - 60;

61A|63B - 100.

**origin:**  $\gamma$  ray induced.

Mglinetz and Semenova, 1970, Genetika (Moscow) 6(8): 86-94.

***Tp(3;2)N2-27***

**cytology:** *Tp(3;2)21F-22A;35D-F;75A-B;80*.

**new order:**

21A - 21F|75B - 80|35D - 22A|35F - 60;

61 - 75A|80 - 100.

**origin:** X ray induced.

**synonym:** *T(2;3)FM27*.

**references:** Puro, Nygren, and Nuutila, 1973, DIS 50: 108.

Puro and Nygren, 1975, Hereditas 81: 237-48.

Puro, 1982, DIS 58: 205-08.

**genetics:** Homozygous lethal. Duplication segregant survives and carries wild-type alleles of *in*, *ri*, and *Pc*. Deficiency segregant is lethal.

***Tp(3;2)osp<sup>204</sup>: Transposition (3;2) outspread***

**cytology:** *Tp(3;2)35B2-3;86C2-D4;89A4-7*.

**new order:**

21 - 35B2|89A4 - 86D4|35B3 - 60;

61 - 86C2|89A7 - 100.

**origin:**  $\alpha$  ray induced.

**discoverer:** Detwiler.

**genetics:** Deficient for *noc-osp* but not *Adh*. Shows stronger *Mpe* leg phenotype than *T(2;3)Mpe*, but does not show dominant *Mpe* wing phenotype.

*Tp(3;2)P10*: see *Tp(3;2)iab2<sup>P10</sup>*

***Tp(3;2)ry<sup>+</sup>: Transposition (3;2) rosy - wild type***

**cytology:** *Tp(3;2)2L;87C2-3;88C2-3* (Gelbart). Amount of 87C2-3 material duplicated is uncertain (Gyurkovics).

**references:** Hall and Kankel, 1976, Genetics 83: 517-35.

Gausz, Bencze, Gyurkovics, Ashburner, Ish-Horowicz, and Holden, 1979, Genetics 93: 917-34.

**genetics:** With *Dp(3;2)ry<sup>+</sup>*, *Df(3R)kar<sup>3J</sup>* homozygotes or *Df(3R)kar<sup>3J</sup>/Df(3R)kar<sup>3I</sup>* heterozygotes are viable but female sterile, whereas *Df(3R)kar<sup>Sz29</sup>/Df(3R)kar<sup>3J</sup>* heterozygotes are female fertile (Ish-Horowicz).

***Tp(3;2)S485***

**cytology:** *Tp(3;2)21C;89F;96A*. 89F break believed to be outside the *BXC*.

**new order:**

21A - 21C|89F - 96A|21C - 60;

61 - 89F|96A - 100.

**origin:** X ray induced.

**discoverer:** Shaw.

**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Crosby, and Lewis, 1985, Cell 45: 81-96.

**genetics:** *Tp(3;2)S485/Df(3R)P9* flies viable and do not show more segmental transformation than *Df(3R)P9/+* flies.

**molecular biology:** 89F breakpoint 205-216 kb to the right of right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***Tp(3;2)shv<sup>S3</sup>: Transposition (3;2) shortvein***

**cytology:** *Tp(3;2)22F1-2;40C;82A;92A5-8*.

**new order:**

21A - 22F1|92A5 - 82A|40C - 22F2|40C - 60F (order of reattachment of chromocentral breaks uncertain);

61A - 82A|92A8 - 100F.

**origin:** X ray induced.

**discoverer:** Segal.

**references:** Segal and Gelbart, 1985, Genetics 109: 119-43.

**genetics:** Associated with *shv<sup>S3</sup>*. Lethal over *shv* and

lethal *dpp* alleles.

***Tp(3;2)SNS***

**cytology:** *Tp(3;2)33A;90C;92D*.

**origin:**  $\gamma$  ray induced.

**references:** Sequeira, Nelson, and Szauter, 1989, *Genetics* 123: 511-24.

**other information:** Induced at same time as *ca*<sup>5</sup>.

***Tp(3;2)Ubx*<sup>895</sup>: *Transposition (3;2) Ultrabithorax***

**cytology:** *Tp(3;2)2R;89E;90A*.

**origin:** X ray induced.

**discoverer:** R.H. Baker, 84k.

**genetics:** Associated with *Ubx*<sup>895</sup>.

***Tp(3;2)V4-8: Transposition (3;2) Valencia***

**cytology:** *Tp(3;2)43E;65F;79E-F*.

**new order:**

21 – 43E|65F – 79E|43E – 60;

61 – 65F|79F – 100.

**origin:** X ray induced.

**references:** Valencia, 1970, *DIS* 45: 37-38.

**genetics:** Homozygous lethal.

***Tp(3;2)V12-1a***

**cytology:** *Tp(3;2)55B;88B;91B*.

**new order:**

21 – 55B|88B – 91B|55B – 60;

61 – 88B|91B – 100.

**origin:** X ray induced.

**references:** Valencia, 1970, *DIS* 45: 37-38.

**genetics:** Homozygous lethal.

***Tp(3;2)XM54***

**cytology:** *Tp(3;2)chrom2;88C2-3;96B11-C1*.

**synonym:** *T(2;3)XM54*.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

**genetics:** Deficiency segregant uncovers *put* – *tld* in heterozygous embryos.

***Tp(3;3)bx<sup>100</sup>*: *Transposition (3;3) bithoraxoid***

**cytology:** *Tp(3;3)66;89B5-6;89E2-3* (89E breakpoint between *Ubx* and *bx<sup>100</sup>*).

**new order:**

61 – 66C|(89B6 – 89E2)|66C – 89B5|89E3 – 100.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**references:** 1951, Cold Spring Harbor Symp. Quant. Biol. 16: 159-74.

Lewis, 1978, *Nature* 276: 565-70.

Morata and Kerridge, 1981, *Nature* 290: 778-81.

Struhl, 1981, *Nature* 293: 36-41.

Gailey, Jackson, and Siegel, 1982, *Genetics* 102: 771-82.

Struhl, 1984, *Nature* 308: 454-57.

**genetics:** Transposes small, proximal part of the *BXC* to 3*L*. Mutant for *bx<sup>100</sup>* and *pbx* but not *bx*, *Cbx*, or *Ubx*. *Dp(3;3)bx<sup>100</sup>* survives, and is duplicated for *ss* – *Ubx* but not for *bx<sup>100</sup>*. *Df(3R)bx<sup>100</sup>* survives in the heterozygote where it shows the *Ubx* phenotype.

**molecular biology:** 89E2-3 breakpoint between 15 and 20 kb proximal to the distal breakpoint of *In(3R)Cbx<sup>rv1</sup>* (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis,

and Hogness, 1983, *Science* 221: 23-29).

***Tp(3;3)bx<sup>110</sup>***

**cytology:** *Tp(3;3)89E2-3;91D1-2;92A2-3*.

**new order:**

61 – 89E2|(91D2 – 92A2)|89E3 – 91D1|92A3 – 100.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**genetics:** Transposes the *Dl* region into the *BXC*. Mutant for *bx<sup>110</sup>* but not *bx* or *Dl*. *Df(3R)bx<sup>110</sup>* = *Df(3R)91D1-2;92A2-3*, formed by recombination with a normal chromosome in region 89E3-91D1, survives in the heterozygote where it shows the *Dl* phenotype. The complementary *Dp(3;3)bx<sup>110</sup>* is duplicated for *Dl*<sup>+</sup> and acts as a suppressor of *Dl* in *Dp(3;3)bx<sup>110</sup>/Dl*<sup>7</sup> heterozygote (Lewis).

**molecular biology:** 89E2-3 breakpoint between 20 and 30 kb proximal to the right breakpoint of *In(3R)Cbx<sup>rv1</sup>* (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, *Science* 221: 23-29).

***Tp(3;3)bx<sup>DB9</sup>***

**cytology:** *Tp(3;3)80;89E*.

**origin:** X ray induced.

**discoverer:** D. Baker.

**genetics:** Mutant for *bx<sup>110</sup>*.

***Tp(3;3)C285: Transposition (3;3) Crossover suppressor***

**cytology:** *Tp(3;3)88F;98B;99B*.

**new order:**

61 – 88F|98B – 99B|88F – 98B|99B – 100.

**origin:** X ray induced.

**discoverer:** Roberts, 1965.

**references:** 1970, *Genetics* 65: 429-48.

**genetics:** Homozygous lethal. Recombination between *st* and *ca* sharply reduced.

***Tp(3;3)C341***

**cytology:** *Tp(3;3)63C;71E;80-81*; position of right breakpoint with respect to centromere not determined.

**new order:**

61 – 63C|71E – 80|(63C – 71E)|81 – 100.

**origin:** X ray induced.

**discoverer:** Roberts, 1965.

**references:** 1970, *Genetics* 65: 429-48.

**genetics:** Homozygous viable. Recombination reduced in 3*L*.

***Tp(3;3)Dfd<sup>rv1</sup>: Transposition (3;3) Deformed-revertant***

**cytology:** *Tp(3;3)83D4-5;84A4-5;98E6-F2*.

**new order:**

61 – 83D4|84A5 – 98E6|83D5 – 84A4|98F2 – 100.

**origin:** X ray induced.

**references:** Hazelrigg and Kaufman, 1983, *Genetics* 105: 581-600.

**genetics:** Revertant of *Dfd*.

***Tp(3;3)Dfd<sup>rv16</sup>***

**cytology:** *Tp(3;3)84A4-5;86F11;87D13-14*.

**new order:**

61 – 84A4|86F11 – 87D13|84A5 – 86F11|87D14 – 100.

**origin:** X ray induced.

**references:** Hazelrigg and Kaufman, 1983, *Genetics* 105: 581-600.

Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman, 1983, Cell 35: 763-76.

**genetics:** Revertant of *Dfd*. Shows a *pic<sup>-</sup>* phenotype (Clark and Chovnick, 1986, Genetics 114: 819-40).

**molecular biology:** DNA breakpoint at 84A4-5 is coordinate 0 in the walk of Scott *et al.*

***Tp(3;3)DI<sup>III3</sup>*: Transposition (3;3) Delta**

**cytology:** *Tp(3;3)88F5-9;91A3-8;92A2*.

**new order:**

61 – 88F5|91A8 – 92A2|88F9 – 91A3|92A2 – 100.

**origin:** X ray induced.

**discoverer:** Shrons.

**references:** Vässin and Campos-Ortega, 1987, Genetics 116: 433-45.

**genetics:** Associated with *DI<sup>III3</sup>*.

***Tp(3;3)h<sup>m3</sup>*: Transposition (3;3) hairy**

**cytology:** *Tp(3;3)61E;66D2-3;66D9-10*.

**new order:**

61A – 61E|66D3 – 66D9|61E – 66D2|66D10 – 100.

**origin:** X ray induced.

**references:** Ingham, Pinchin, Howard, and Ish-Horowicz, 1985, Genetics 111: 463-86.

**genetics:** Homozygous lethal. Associated with *se* and *h*.

**molecular biology:** 66D break located at -10.8 to -9.35 kb on the DNA map of *h* (Howard, Ingham, and Rushlow, 1988, Genes Dev. 2: 1037-46); "+" values to the right, "-" values to the left. The coordinate system has 0 at the start of transcription (Rushlow).

***Tp(3;3)H<sup>57</sup>*: Transposition (3;3) Hairless**

**cytology:** *In(3R)86F7-11;97D1-2 + In(3R)95C1-2;98C5*. (Ashburner).

**new order:**

61 – 86F7|97D1 – 95C2|98C5 – 97D2|86F11 – 95C1|98C5 – 100.

**discoverer:** Gloor.

**references:** van Breugel, Ray, and Gloor, 1968, Genetika 39: 165-92.

Ashburner, 1982, Genetics 101: 447-59.

**genetics:** Associated with *H<sup>57</sup>* (van Breugel *et al.* 1968), but, presumably, *H<sup>57</sup>* and the transposition arose by independent mutational events (Ashburner, 1982) since none of the breakpoints is between 92D and 94A, the location of *H*.

***Tp(3;3)iab3<sup>277</sup>* Transposition (3;3) infraabdominal**

**cytology:** *Tp(3;3)89E;94A;96F*.

**new order:**

61 – 89E|94A – 96F|89E – 94A|96F – 100.

**origin:** X ray induced in *Mcp*.

**discoverer:** D. Baker.

**synonym:** *Mcp<sup>revB277</sup>*, *iab3<sup>B277</sup>*, *iab3<sup>DB</sup>*.

**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.

**genetics:** Mutant for *iab3*. Partial revertant of *Mcp*.

**molecular biology:** 89E breakpoint 63-64.5 kb to the right of the right breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

***Tp(3;3)iab6<sup>Vno</sup>***

**cytology:** *Tp(3;3)89E;94A;96F*.

**new order:**

61 – 89E|94A – 96F|89E – 94A|96F – 100.

**origin:** X ray induced.

**discoverer:** E.H. Grell, 56c.

**synonym:** *Tp(3;3)Vno*.

**references:** 1959, DIS 33: 94.

Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, Cell 43: 81-96.

**genetics:** Associated with *Vno* and *iab6*. Insertion at 89E separable by recombination from the deletion at 94A-96F, the *Vno* wing phenotype segregating with the deletion (Karch *et al.*, 1985). Homozygous lethal.

**molecular biology:** 89E breakpoint 108-111 kb to the right of the distal breakpoint of *In(3R)Cbx<sup>rv1</sup>*.

Schematic representation of the prophase differentiation of the Y chromosome. Solid segments are brightly fluorescing or, in the case of N banding, darkly staining; crosshatched regions are moderately fluorescing; hatched regions are dully fluorescing; and empty regions are non staining or non fluorescing. The upper diagram represents the fluorescence of Hoechst-33258-stained chromosomes; the second row depicts the quinacrine staining pattern; the third row indicates chromomycin staining; and the fourth row shows the N-banding pattern (provided by Gatti and Pimpinelli).

## NORMAL CHROMOSOME COMPLEMENT

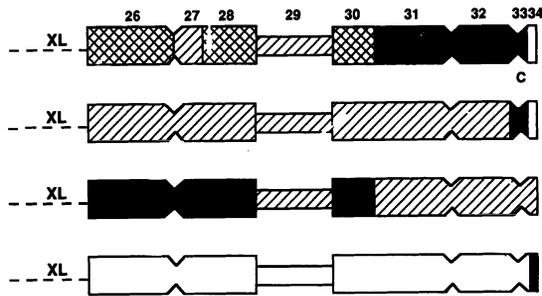

This section contains brief descriptions of the normal chromosome cytology, both in mitotic and polytene cells. Polytene maps are included as foldouts at the end of the book, and combine material from C. B. Bridges (1935, *J. Hered.* 26: 60-64; 1938, *J. Hered.* 29: 11-13), C. B. Bridges and P. N. Bridges (1939, *J. Hered.* 30: 475-76) and P. N. Bridges (1941, *J. Hered.* 32: 64-65; 299-300; 1942, *J. Hered.* 33: 403-408), and Lefevre [1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.), Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66]. In addition detailed polytene maps based on electron-microscopic examination of thin sections of polytene-chromosome squashes were presented, one numbered section at a time, by Sorsa (1988, *Chromosome Maps of Drosophila*, CRC Press, Inc., Boca Raton, Florida, Vol II). Each of the major chromosome arms is divided into twenty numbered sections, each of which is divided into six subsections, lettered A-F, and within which the bands are numbered sequentially.

Mitotic prophase cytology has been perfected by Gatti and Pimpinelli; using several fluorescent dyes, principally, Hoechst 33258, and N-banding techniques they are able to detect considerable linear differentiation of the pericentric heterochromatin, which is not amplified and thus not amenable to analysis in polytene chromosomes. The main publications dealing with prophase cytology are Gatti and Pimpinelli (1983, *Chromosoma* 88: 349-73) and Dimitri (1991, *Genetics* 127: 553-64).

### *X chromosome*

Also known as chromosome 1. Present in one dose in male and two doses in female. In mitotic figures, the X is a rod-shaped element with a nearly terminal centromere and a minute second arm designated as the right arm, XR. The left arm, XL, is divided into a distal isopycnotic euchromatic region, Xe, in which the chromatids are usually separated, and a proximal heterochromatic or heteropycnotic region, Xh, in which the chromatids are not separated. The heterochromatic region comprises one-third to one-half the DNA content of the X chromosome. Tritiated thymidine incorporation studies (Barigozzi, Dolfini, Fraccaro, Raimondi, and Tiepolo, 1966, *Exp. Cell Res.* 43: 231-34) demonstrate that the heterochromatic region is late replicating. In second meiotic prophase of spermatogenesis, on the other hand, both euchromatin and heterochromatin are visibly double. In mitotic prophase cells, the heterochromatic region can be subdivided into nine segments by means of a variety of staining procedures (Gatti and Pimpinelli); these are designated, from left to right, h26 through h34; h26 is juxtaposed to the euchromatin; the ribosomal cistrons are thought to occupy h29 and the centromere has been placed between h32 and h33. Cooper (1959, *Chromosoma* 10: 535-88) characterized the heterochromatin of aceto-orcein-stained prophase X chromosomes as comprising four major orcein-staining segments designated from right to left hA, hB, hC, and hD and separated by three secondary constrictions, the central one of which corresponds to the nucleolus organizer, *i.e.*, the site of the

*bb* locus, which comprises a tandem array of repeats encoding the 5.8 S, 18 S, and 28 S ribosomal RNA's; other than the nucleolus organizer, correspondences between Cooper's map on one hand and that of Gatti and Pimpinelli on the other have not been determined.

Schematic representation of the prophase differentiation of the pericentric heterochromatin of the X chromosome. Solid segments are brightly fluorescing or, in the case of N banding, darkly staining, crosshatched regions moderately fluorescing, hatched regions dully fluorescing, and empty regions are non staining or nonfluorescing. The upper diagram represents the fluorescence of Hoechst-33258 stained chromosomes; the second row depicts the quinacrine staining pattern; the third row indicates chromomycin staining; and the fourth row shows the N-banding pattern (provided by Gatti and Pimpinelli).

The polytene X chromosome (see foldout at end of book) extends from region 1 at the tip through region 20 at the centromere; *Xe* comprises approximately 1000 bands (1008 according to Bridges and 979 according to Sorsa), and is thought to extend at least through 20D, with 20E and F perhaps corresponding to the distalmost portion of *Xh* and residing in the chromocenter; all known genes except *bb* and possibly *su(f)* are located distal to 20E [Schalet and Lefevre, 1973, *Chromosoma* 44: 181-202; Lefevre, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66]. Several polytene landmarks given mnemonic designations by Bridges (1935, *J. Hered.* 26: 60-64) are as follows: the puff at 2B, the four brothers in 9A, the two sisters in 10A and B, the weak spot in 11A, the chains in 15B and D, the turnip in 16A-B, and the offset in 19E.

### Y chromosome

In mitotic figures, the Y chromosome appears as an entirely heterochromatic element; tritiated thymidine incorporation studies (Barigozzi, Dolfini, Fraccaro, Raimondi, and Tiepolo, 1966, *Exp. Cell Res.* 43: 231-34) show it to be late replicating. The Y is a two-armed chromosome, the short arm, YS, being about two-thirds the length of the long arm, YL. At metaphase the Y is somewhat shorter than the X chromosome. Sister chromatids are not in evidence in prophase or metaphase Y chromosomes during mitosis, but in second meiotic prophase of spermatogenesis sister chromatids are well separated. In mitotic prophase preparations the Y chromosome can, by a combination of staining procedures, be subdivided into 25 distinct segments (Gatti and Pimpinelli, 1983, *Chromosoma* 88: 349-73); they are designated h1 at the

terminus of YL through h25 at the end of YS (see diagram on the preceding page). Gatti and Pimpinelli have placed the Y male-fertility genes as follows: *kl-5* in h2-h3, *kl-3* in h4-h9, *kl-2* in h10, *kl-1* in h13-h15, *ks-1* in h21-h23, and *ks-2* in h24-h25; in addition, Su(Ste) resides in h11 (Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, *Genetics* 107: 591-610), and the ribosomal cistrons of the Y are in h20 (Gatti and Pimpinelli). Mapping of eight different satellite DNA sequences with respect to the 25 segments of the Y is described by Bonaccorsi and Lohe (1991, *Genetics* 129: 177-89). In aceto-orcein-stained prophase chromosomes Cooper (1959, *Chromosoma* 10: 535-88) reported that YS is subdivided by the nucleolus constriction into a distal segment, SB, comprising two-thirds of YS, and a proximal segment, SA, comprising the other one-third; YL is divided into three segments of approximately equal length by two constrictions, the more distal of which is the more constant landmark. From the centromere, the segments are designated LA, LB, and LC. Gatti and Pimpinelli have equated the constriction between LB and LC with their brightly fluorescing segments h8-h9 and in general find a correspondence between secondary constrictions seen in aceto-orcein- or Giemsa-stained chromosomes with brightly fluorescing blocks and not with nonfluorescing gaps in Hoechst-stained material.

The Y chromosome does not undergo polytenization. In salivary-gland preparations, Prokofyeva-Belgovskaya (1937, *Genetics* 22: 94-103) observed a small collection of bands that she attributed to the Y. However, Nicoletti and Lindsley (1960, *Genetics* 45: 1705-22) found no evidence of bands attributable to the Y chromosome in a study of *T(1;Y)*'s; their observations were confirmed in the polytene analysis of a large collection to *T(Y;A)*'s (Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, *Genetics* 71: 157-84).

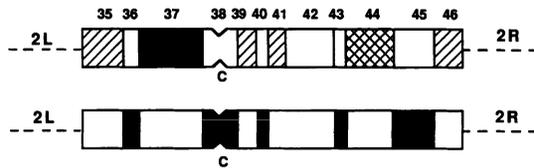

Several complex structural elements in the primary spermatocyte nucleus depend on the presence of the Y chromosome; two, designated tubuli and reticular material in electron micrographs (Meyer, Hess, and Beerman, 1961, *Chromosoma* 12: 676-716), are associated with the male-fertility genes, *kl-5* and *kl-3*, respectively (Hardy, Tokuyasu, and Lindsley, 1981, *Chromosoma* 83: 593-617). These and another associated with *ks-1* can be recognized in the light microscope (Bonaccorsi, Pisano, Puoti, and Gatti, 1988, *Genetics* 120: 1015-34). Their function is unknown.

Addition of Y chromosomes to a normal chromosome complement suppresses variegated position effects, and removal of the Y from the male enhances variegation (1933, Gowan and Gay, *Proc. Nat. Acad. Sci. USA* 19: 122-26). Two or more Y's added to the normal complement cause variegation of otherwise self-colored eyes (Cooper, 1956, *Genetics* 41: 242-64).

### Chromosome 2

In mitotic figures, chromosome 2 is less than twice the length of the X and slightly smaller than chromosome 3. It contains two euchromatic arms separated by the centromere and the pericentric heterochromatin. In acetic-orcein-stained preparations of mitotic prophase chromosomes, the pericentric heterochromatin comprises two

segments separated by the centric constriction; Gatti and Pimpinelli, utilizing Hoechst 33258 and N banding, recognize linear differentiation of the pericentric heterochromatin into twelve segments, designated from left to right h35 to h46; h42 is subdivided into 42A and 42B in some strains; the centromere is placed in h38. Dmitri (1991, Genetics 127: 553-64) has produced a cytogenetic map of the chromosome-2 heterochromatin; the *l(2)40F* loci, including *lt*, as well as *cta* and *E(SD)* are confined to segment h35 at the euchromatic-heterochromatic junction; the responder sequences, *Rsp*, comprise segment 39 in *2R*, which varies in size according to the sensitivity of the chromosome to distortion by *SD* (Pimpinelli and Dimitri, 1989, Genetics 121: 765-72); in addition, *l(2)41Ab* is located at the h39-h40 junction, *l(2)41Aa* and *rl* are in h40, and *l(2)41Ad* is in h43-h44; *l(2)41Ae* and *l(2)41Ah* are located in h46 at the heterochromatic-euchromatic junction. Dimitri has also located a number of heterochromatic breakpoints in chromosome 2.

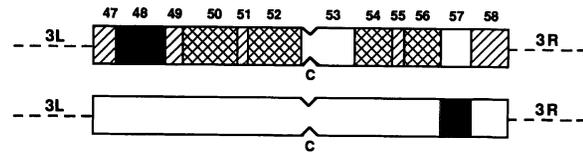

Schematic representation of the prophase differentiation of the pericentric heterochromatin of chromosome 2. Solid segments are brightly fluorescing or, in the case of N banding, darkly staining; crosshatched regions moderately fluorescing; hatched regions dully fluorescing; and empty regions are non staining or non fluorescing. The upper diagram represents the fluorescence of Hoechst-33258 stained chromosomes; the second row depicts the N-banding pattern (provided by Gatti and Pimpinelli).

In polytene preparations the left arm contains 804 bands according to Bridges and 869 as estimated by Sorsa, with an upper limit of 927; its 20 sections are numbered 21-40 from tip to centromere. Land mark regions named by Bridges (1935, J. Hered. 26: 60-64) for mnemonic purposes include the dog collar at 21C-D, the shoe buckle at 25A, the shield at 30A, the gooseneck at 31B-F; in addition, regions of the proximal half of *2L* tend to fold back on themselves, frequently imparting a convoluted conformation to this part of the chromosome; these regions are termed the spiral loop in 31B-F, the turn back in 36, and the basal loop in region 37-39. The right arm of chromosome 2 is subdivided into 20 sections labeled 41 at the centromere to 60 at the tip; it contains 1136 bands on the Bridges maps and 1009 to 1152 according to Sorsa, depending on whether doublets are considered single or double; its landmarks are the onion base at 42A, the barrel in section 47 [Lefevre, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66], goggles at 50A and B (Lefevre), the miniskirt at 50C-D (Strathern), and the huckleberry tip at 60E.

**Chromosome 3**

In mitotic figures, chromosome 3 is less than twice the length of the X and slightly larger than chromosome 2. It contains two euchromatic arms separated by the centromere and the pericentric heterochromatin. In acetic-

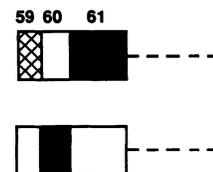

orcein-stained preparations of mitotic prophase chromosomes, the pericentric heterochromatin comprises two segments separated by the centric constriction. Gatti and Pimpinelli subdivide the third-chromosome heterochromatin into twelve sections, numbered from left to right h47 through h58; the centromere is placed in h53, but other than that no further characterization has been undertaken.

Schematic representation of the prophase differentiation of the pericentric heterochromatin of chromosome 3. Solid segments are brightly fluorescing or, in the case of N banding, darkly staining; crosshatched regions moderately fluorescing; hatched regions dully fluorescing; and empty regions are non staining or non fluorescing. The upper diagram represents the fluorescence of Hoechst-33258 stained chromosomes; the second row depicts the N-banding pattern (provided by Gatti and Pimpinelli).

In polytene preparations, the left arm of chromosome 3, *3L*, comprises twenty divisions numbered from tip to centromere 61 through 80 and containing 884 bands according to P. N. Bridges. Sorsa's estimates are considerably higher; considering doublets to be single bands he recognizes 1032 bands and considering them as two bands he enumerates 1073. The mnemonics suggested by Bridges for designating cytological landmarks on *3L* are the barrel at 61C-F, the ballet skirt at 68B-C, the Chinese lanterns, two large puffs, at 74-75, and the graded capsules in 79D-E. The twenty divisions of *3R*, numbered 81F (81A-E do not appear on polytene maps) at the centromere through 100 at the tip contain 1178 bands according to P. N. Bridges. Sorsa estimates that there are 1147 bands if doublets are treated as single bands and 1233 if they are treated as two. Bridges' landmarks for *3R* are the cucumber base in 81 to 83D, the road apple at 85F (Strathern), the duck's head at 89E-91A, and the goblet tip at 100.

**Chromosome 4**

Schematic representation of the prophase differentiation of the heterochromatin of chromosome 4. Solid segments are brightly fluorescing or, in the case of N banding, darkly staining; crosshatched regions moderately fluorescing; hatched regions dully fluorescing; and empty regions are non staining or non fluorescing. The upper diagram represents the fluorescence of Hoechst-33258 stained chromosomes; the second row depicts the N-banding pattern (provided by Gatti and Pimpinelli).

In mitotic figures, chromosome 4 is a dot-like element that is separated into two segments (*4L* and *4R*) of

grossly unequal size by a sometimes-visible centric constriction. The bulk of chromosome 4 is heterochromatic and in prophase has been differentiated into three segments designated h59, h60, and h61 by Gatti and Pimpinelli. The presence of a short left arm is indicated by its involvement in chromosome rearrangements [e.g.,  $T(1;4)_{wm}^{11}$  (Panshin and Khvostova, 1938, Biol. Zh. 7: 359-80) and  $T(1;4)_{w}^{mA}$  (Griffen and Stone, 1940, Texas Univ. Publ. 4032: 201-07)].

In polytene configurations, chromosome 4 is a short element emerging from the chromocenter. It is divided into two sections, 101 proximally and 102 distally; no reliable bands can be identified proximal to 101D, nor does any of the material in 4L polytenize (Lefevre). Hochman [1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.), Academic Press, London, New York, San Francisco, Vol. 1b, pp. 903-28], Lefevre, and Sorsa agree that the 137 bands on the detailed map of chromosome 4 produced by Slizynski (1944, J. Hered. 35: 322-25), and included in the previous edition of this work, cannot be confirmed. They estimate 40-50 bands. Note that the centromere positions of the two subtelocentric elements of the genome differ. It is on the right in the case of the X and on the left in chromosome 4.

#### **4-sim: chromosome 4 from *Drosophila simulans* (H. A. Orr)**

A single fourth chromosome from *D. simulans* was introduced into an otherwise *D. melanogaster* genome by Muller and Pontecorvo (1940, *Nature* 146: 199-200; 1940, *Science* 92: 418). Phenotypic effects of 4-sim were described by Muller and Pontecorvo (1942, *Genetics* 27: 157) and Pontecorvo (1943, *Proc. Roy. Soc. Edinburgh B* 61: 385-97; *J. Genet.* 45: 51-66). Although 4-sim/4 is apparently normal, 4-sim/4-sim homozygotes suffer decreased viability and show subtle peculiarities: flattened body, heavy trident, and reduced eyes. 4-sim/4-sim male genitalia also slightly resemble those of *D. simulans* (Muller and Pontecorvo, 1942; Coyne, 1983, *Evolution* 37: 1101-18). Some genes on 4-sim show unusual dominance relations:  $spa^{Cat}$  is not seen in 4-sim/ $spa^{Cat}$  heterozygotes. Conversely, 4-sim/*ci* shows occasional wing-vein interruptions; 4-sim/*ci*<sup>W</sup> shows more extreme cubitus-interruptus phenotype than 4/*ci*<sup>W</sup> (Uphoff, 1949, *Genetics* 34: 315-27). Appearance of *ci* is not due to the presence of a mutation at *ci*<sup>+</sup> on the single 4-sim chromosome introduced into *D. melanogaster* as Sturtevant (1946, *Genetics* 31: 259-68) suggested: *D. melanogaster ci*—*D. simulans ci*<sup>+</sup> species hybrids also occasionally show *ci* [several *D. simulans* stocks tested (Uphoff, 1949; Orr, unpublished)]. Segregation of 4-sim

and 4 is fairly regular (Muller and Pontecorvo, 1942).

4-sim/4-sim are completely sterile, whereas 4-sim/4 males are fully fertile. All female genotypes are fertile. Testes of sterile males appear normal. Meiosis occurs, but very few motile sperm are produced; about 75% of 4-sim/4-sim males produce no motile sperm at all (Orr, 1992, *Genet. Res.*). Pontecorvo (1943) claimed that sterility results from a breakdown in the last stages of spermiogenesis. The factor(s) causing sterility map to the proximal end of chromosome 4 within a large Minute deletion (Muller and Pontecorvo, 1942). Subsequent deletion and translocation mapping shows that sterility maps to 101F, 102A2-B5, or both, representing less than 15% of the cytological length of the dot chromosome. *Df(4)M101-3/4-sim* and *Df(4)M101-62f/4-sim* are male sterile; *Df(4)M101-63a/4-sim* and *Df(4)G/4-sim* are fertile (Orr, 1992). Male sterility is therefore apparently due to a single gene, dubbed *hms* (hybrid male sterile). *hms* complements all known genes in the *Df(4)M101* region and shows no interaction with testis-specific  $\beta$ -tubulin. 4-sim male sterility depends only on zygotic genotype at *hms*.

Comparisons of *D. melanogaster* and *D. simulans* polytene chromosomes were made by Kerkis (1936, *Am. Nat.* 70: 81-86), Horton (1939, *Genetics* 24: 234-43) and Patau (1935, *Naturwissenschaften* 23: 537-43). Chromosome 4 of *D. simulans* differs from that of *D. melanogaster* by a fairly long inversion, including at least 102B1-2 through 102E1-2 and probably 102E3, 4, and 5 (Horton, 1939). A darkly staining terminal ring is sometimes seen at the tip of the *D. simulans* chromosome. The proximal third of chromosome 4 from *D. simulans* tends to be narrower than the distal two-thirds. Slizynski (1941, *Proc. Roy. Soc. Edinburgh B* 61: 95-106) claimed to identify the short left arm of 4-sim and compares it with that of *D. melanogaster*; however, recent workers dispute the claim that 4L can be seen in polytene preparations. Horton (1939) never observed synapsis of chromosome 4 in salivary-gland cells of *D. melanogaster*—*D. simulans* species hybrids. Although 4-sim and 4 in the "4-sim" stock of *D. melanogaster* also do not usually pair, Slizynski (1941) found one nucleus in which the inverted segments paired. In triplo-4 larvae, the *D. melanogaster* 4' s pair and the 4-sim chromosome remains unpaired. As expected, the 4-sim chromosome from the 4-sim stock pairs normally with wild-type *D. simulans* fourth chromosomes in species hybrids (Orr, 1992). In both species hybrids and on a *D. melanogaster* genetic background, the tip of the *D. melanogaster* 4R tends to stick into the chromocenter; the tip of the *D. simulans* 4, however, is always free of the chromocenter (Horton, 1939; Slizynski, 1941).

**C(1)A**

## BALANCERS

Balancers are chromosomes that are designed to maintain a homologous chromosome or a segment thereof intact in a cross or stock. They share three properties: (1) they are multiply inverted in order to suppress recombination with homologous chromosomes; (2) they are usually lethal, sterile in one sex or the other, or exhibit low viability in the homozygous condition in order to avoid displacing their homologues in balanced stocks; and (3) they are marked in such a way that their presence in heterozygotes (and, where they survive, as homozygotes) is recognizable, usually with a combination of dominant and recessive mutant alleles. The most crucial aspect of balancers is their ability to suppress recombination, and therefore their rearranged sequence. In this treatment we arrange balancers according to chromosome; balancers with the same rearranged sequence are treated together as a single entry; different marker constitutions as indicated by identifying mnemonics or version designations are tabulated within such entries.

## X-CHROMOSOME BALANCERS

## CIB

**constitution:**  $In(1)Cl, sc\ l(1)C\ t^2\ v\ sl\ B.$

**synthesis:** Muller.

**references:** 1928, Genetics 13: 279-357.

**properties:** Male lethal. Suppresses crossing over in the X chromosome. Originally used in recovery of sex-linked recessive lethals; replaced by *Basc* for this purpose.

*complete*: see  $In(1)sc^8+dl49$

*finsky*: see  $In(1)sc^{SIL}sc^{8R}+dl49$

*FM0*: see  $In(1)sc^8+dl49$

*FM1*: see  $In(1)sc^8+dl49$

## FM3: First Multiple 3

**constitution:**  $In(1)FM3, y^{31d}sc^8\ dm\ B.$

**order:** 1A—1B2|20F|16B—19F|3F—4D7|11F2—4E1|11F4—16A|3E—1B|20F.

**synthesis:** R.F. Grell, 1954.

**references:** Mislove and Lewis, 1954, DIS 28: 77.

**properties:** Male lethal owing to presence of two multilocus deficiencies in  $In(1)FM3$ , which may be covered by  $B^SYy^+$  or by  $B^SY$  and  $y^+Y$  (Schalet). Effectively suppresses crossing over in the X chromosome. Useful for balancing sex-linked recessive, female-sterile mutants and, in combination with  $B^SYy^+$ , for balancing sex-linked recessive lethal and male-sterile mutants.

## FM4

**constitution:**  $In(1)FM4, y^{31d}sc^8\ dm\ B.$

**order:** 1A—1B2|20F—11F4|4E|3C—4D7|11F2—4F|3C—1B3|20F.

**synthesis:** R.F. Grell, 1954.

**references:** Mislove and Lewis, 1954, DIS 28: 77.

**properties:** Male viable and fertile; homozygous female viable but sterile owing to *dm*.  $In(1)FM4$  is the consequence of the approximate reinversion of  $In(1)dl49$  in  $In(1)sc^8+dl49$  and is similar in sequence to  $In(1)sc^8$  but with the transposition of 3C-4F into 11F. Unless this small transposition has an abnormally large effect on crossing over (e.g., see  $Dp(2;2)C619$ ) recombination might be expected to be frequent in  $FM4/+$  heterozygotes and especially in  $FM4/In(1)sc^8$  heterozygotes. In  $FM4/+$  heterozygotes, double crossovers with points of exchange inside or outside the 3C-11F interval produce euploid X chromosomes, and those with one point of exchange inside and one outside produce complementary duplications and deficiencies for 3C—4F. The duplication survives in either sex and exhibits a Confluens phenotype (E.H. Grell); the deficiency might survive in the heterozygote as a Notch Minute female judging from the survival of the slightly smaller  $Df(1)w^{m258-44} = Df(1)3C3-4;4D2-E1$ . Balancing properties not well determined. Some lines carry  $w^{55f}$  and in some  $y^{31d}$  replaced with  $y^+$  or  $B$  with  $f$  or  $+$ .

## FM6

**constitution:**  $In(1)FM6, y^{31d}sc^8\ dm\ B.$

**order:** 1A—1B2|20F|15E—20F|15D—11F4|4E|3C—4D7|11F2—4F|3C—1B3|20F.

**synthesis:** R.F. Grell, 55i.

**references:** Grell and Lewis, 1956, DIS 30: 71.

**properties:** Male viable and fertile; homozygous females viable but sterile owing to the presence of *dm*. Like *FM4* except for the presence of the additional  $In(1)15D-E;20A-B$ . Reservations similar to those about the balancing ability of *FM4* apply in *FM6* to the salivary chromosome region from 1B to 15D. In genotypes with a normal recombination rate, *FM6* effectively eliminates recombination in  $FM6/+$  heterozygotes but yields viable recombinants when heterozygous for such inversions as  $In(1)sc^8$ . Used for balancing sex-linked recessive lethal and sterile mutations. Does not effectively balance *cv* or *v* in stocks that are also heterozygous for  $In(2LR)SM$  and  $In(3LR)Ubx^{130}$ . Different markers have been introduced into *FM6*; they include *w* and  $dm^+$ ; the  $dm^+$  is probably a duplication introduced by a double crossover in regions 1B3—3C and 4F—11F2; *FM6, dm^+* homozygotes are fertile. In addition recessive-lethal-bearing *FM6* chromosomes have been described (e.g., Lifschytz and Falk, 1968, Mutat. Res. 6: 235-44).

## FM7

**constitution:**  $In(1)FM7, y^{31d}sc^8\ w^a\ B.$

**order:** 1A—1B2|20F—20E|15E—20A|15D—11F4|4E1—11F2|4D7—1B3|20F.

**properties:** Males and homozygous females viable and fertile. An excellent suppressor of recombination with normal-sequence X chromosomes. Commonly used in balancing, even in female fertile versions.

## SECOND-CHROMOSOME BALANCERS

### *CyO*: *Curly of Oster*

**constitution:** *In(2LR)O, Cy dp<sup>lv</sup> pr cn<sup>2</sup>*.

**order:** 21—22D|33F5—30F|50D1—58A4|42A2—34A1|22D2—30E|50C10—42A3|58B1-60.

**synthesis:** Oster.

**synonym:** *Cy, InsO5*.

**references:** 1956, DIS 30: 145.

O'Donnell, Gerace, Leister, and Sofer, 1975, *Genetics* 79: 73-83.

**properties:** More effective suppressor of crossing over in chromosome 2 than *In(2L+2R)Cy*; should be superior to *SM1* as a balancer for chromosome 2. Other markers introduced into *CyO* include *Adh<sup>NA</sup>* and *Adh<sup>NB</sup>* (O'Donnell *et al.*), *l(2)DTS100*, *l(2)DTS486*, and *l(2)DTS573* (Falke and Wright, 1972, DIS 48: 89), as well as *b, bw, esc<sup>2</sup>, pk<sup>81h</sup>, Roi, sple<sup>81h</sup>*, and others.

### *SM1*: *Second Multiple 1*

**constitution:** *In(2LR)SM1, al<sup>2</sup> Cy cn<sup>2</sup> sp<sup>2</sup>*.

**order:** 21—22A3|60B—58B1|42A3—58A4|42A2—34A1|22D2—33F5|22D1—22B1|60C—60F.

**synthesis:** R.F. Grell, 1953.

**references:** Lewis and Mislove, 1953, DIS 27: 58.

**properties:** Homozygous lethal. Viability and fertility of heterozygote excellent. Reliable balancer for all of chromosome 2, although there is an occasional double cross-over in 2R if X and 3 are heterozygous for inversions. MacIntyre and Wright (1966, DIS 41: 141-42) found no recombination between *In(2LR)SM1* and *al dp b pr cn c px sp* in females heterozygous for *In(1)sc<sup>8</sup>* and *In(3LR)Ubx<sup>130</sup>*. Nondisjunction of compound autosomes occurs in *SM1/+* females [Lindsley and Grell, 1969, *Genetics* 61 (Supplement): 69-71]; balancer shows interchromosomal effect (Parry, 1973).

### \**SM2*

**constitution:** *T(2;3)SM2, al<sup>2</sup> Cy lt<sup>v</sup> cn<sup>2</sup> sp<sup>2</sup>*.

**synthesis:** R.F. Grell, 1953.

**references:** Lewis and Mislove, 1953, DIS 27: 58. 1954, DIS 28: 77.

**properties:** Not useful as a balancer.

### *SM5*

**constitution:** *In(2LR)SM5, al<sup>2</sup> Cy lt<sup>v</sup> sn<sup>2</sup> sp<sup>2</sup>*. Series of overlapping inversions and transpositions distributed over length of chromosome (Sankaranarayanan, 1974, *Mutat. Res.* 24: 389-93).

**order:** 21A—21D2|36C-40F|29D—22D2|34A1—36C|21D3—22A3|60B—58B1|42A3—42D|42D—43A|58B1—58F|53C—42D|53C—58A4|42A2—40F|29E—33F5|22D1—22B1|60C—60F.

**synthesis:** R.F. Grell, 1953.

**references:** Mislove and Lewis, 1955, DIS 29: 75.

**properties:** Homozygous lethal. Heterozygote usually has

good viability and fertility, although may not be as good as *SM1*. Most complete balancer for chromosome 2.

### *SM6*

**constitution:** *In(1)2LR)SM6, al<sup>2</sup> Cy dp<sup>lv</sup> cn<sup>2P</sup> sp<sup>2</sup>* combination containing both *In(2LR)O* and *In(2LR)SM1*.

**order:** 21—22A3|60B—58B1|42A3—50C10|30E—22D2|34A1—42A2|58A4—50D1|30F—33F5|22D1—22B1|60C—60F.

**synthesis:** Craymer.

**references:** 1984, DIS 60: 234-36.

**properties:** Suppresses recombination over entire chromosome 2; carries *cn<sup>2P</sup>*, an amorphic derivative of *cn<sup>2</sup>*. Two versions: without *Roi* = *SM6a*; with *Roi* = *SM6b*.

## THIRD-CHROMOSOME BALANCERS

### *C(3)x*

**constitution:** *In(3L)P In(3R)P*. (Probably not the same as *Payne*).

### *LVM*

**constitution:** *In(3L)P In(3R)P, l(3)LVML pe l(3)LVMR*.

**properties:** Homozygous lethal; suppresses crossing over in chromosome 3.

### *MKRS*

**constitution:** *Tp(3;3)MKRS, M(3)76A, kar ry<sup>2</sup> Sb*.

**order:** 61—71B2|92E—93C|87F1—92E|71C—87E8|93C—100.

**synthesis:** Chovnick.

**references:** 1973, *Genetics* 76: 289-99.

Hilliker, Clark, Chovnick, and Gelbart, 1980, *Genetics* 95: 95-100.

**properties:** Homozygous lethal. Suppresses crossing over in the proximal regions of both arms of chromosome 3. Version lacking *kar* designated *MRS*.

### *TM1*: *Third Multiple 1*

**constitution:** *In(3LR)TM1, Me ri sbd<sup>1</sup>*.

**order:** 61—63|72E1—69E|91C—97D|89B—72E2|63C—69E|91C—89B|97D—100.

**synthesis:** Lewis.

**references:** 1949, DIS 23: 92.

Lewis and Mislove, 1953, DIS 27: 58.

Shearn, 1974, *Genetics* 77: 115-25.

**properties:** Homozygous lethal; suppresses crossing over in chromosome 3.

### *TM2*

**constitution:** *In(3LR)Ubx<sup>130</sup>, emc<sup>2</sup> Ubx<sup>130</sup> e<sup>s</sup>*.

**order:** 61A|96A—93B|89D—74|61C—74|89E—93B|96A—100.

**synthesis:** Lewis.

**references:** 1952, *Proc Nat. Acad. Sci. USA* 38: 953-61.

1952, DIS 26: 66.

**properties:** Homozygous lethal. Eliminates crossing over in chromosome 3 except at the end of the right arm. Does not reliably balance mutations in the vicinity of *ca*. MacIntyre and Wright (1966, DIS 41: 141-42) observed about 9% double crossing over in the unbroken segment of the left arm from 61C to 74 on the polytene map and 15% recombination between the breakpoint at 96A and *ca* in *In(3LR)Ubx<sup>130</sup>, Ubx<sup>130</sup> e/ru h th st cu sr e<sup>s</sup> Pr ca* females that were also heterozygous for an X-

chromosome inversion behaving like *In(1)sc*<sup>8</sup> and *In(2LR)SM1*; no recombination observed in other regions. Some versions also carry *p*<sup>P</sup>.

**TM3**

**constitution:** *In(3LR)TM3, y<sup>+</sup> ri p<sup>P</sup> sep l(3)89Aa bx<sup>34e</sup> e* [not *e*<sup>S</sup> according to Craymer (1980, DIS 55: 197-200)]. Some *TM3* stocks have lost *y*<sup>+</sup> (Shearn, 1980, DIS 55: 167).

**order:** 1A1—1A8|61A2—65E|85E—79E|100C—100F2|92D1—85E|65E—71C|94D—93A|76C—71C|94F—100C|79E—76C|93A—92E1|100F3—100F5.

**synthesis:** Lewis, 55g.

**references:** Mitchell, 1958, Cold Spring Harbor Symp. Quant. Biol. 23: 279-90.

Lewis, 1960, DIS 34: 53-54.

Tinderholt, 1960, DIS 34: 53-54.

**properties:** Stocks exist in which *Ser* or *Sb* and *Ser* are present in the balancer, making the *TM3* chromosome homozygous lethal. With normal *X* and *2*, all of chromosome *3* is effectively balanced; however, in the presence of *FM6* and *SM5*, crossing over between *y*<sup>+</sup> and *ri* (*i.e.*, 61A2-65E) is appreciable. Double crossovers that separate *Sb* or *Ser* from the inversion complex are rare, even in the presence of *FM6* and *SM5*.

**TM6**

**constitution:** *In(3LR)TM6, Hn<sup>P</sup> ss<sup>P88</sup> bx<sup>34e</sup> Ubx<sup>P15</sup> e* [*Ubx<sup>P15</sup>* listed as *Ubx<sup>67b</sup>* in CP627 (Craymer, 1980, DIS 55: 197-200)].

**order:** 61A|89C2—75C|94A—100F2|92D1—89C4|61A2—63B8|72E1—63B11|72E2—75C|94A—92E1|100F3—100F5.

**synthesis:** Lewis and Bacher, 66i.

**references:** CP627.

**properties:** Homozygous lethal. Suppresses crossing over in chromosome *3*. Has unbroken regions with genetic lengths of approximately 10, 15, 20, and 30 units.

**TM6B**

**constitution:** *In(3LR)TM6B, Hu e*. Carries same inversions as *TM6* except for substitution of *In(3LR)HR33* for *In(3LR)P88* and addition of *In(3R)Hu*. Exists with several marker combinations, usually carrying *D*<sup>3</sup> or *Tb* with various combinations of *ca*, *h*, and *Hn<sup>P</sup>*.

**order:** 61A1|87B2—86C6|84F1—86C5|84B6—84F1|84B3—75C|94A—100F2|92D1—87B4|61A2—63B8|72E1—63B11|72E2—75C|94A—92E1|100F3—100F5.

**synthesis:** Craymer.

**references:** 1984, DIS 60: 234-36.

**properties:** Probably most efficient balancer of chromosome *3*.

**TM6C**

**constitution:** *In(3LR)TM6C*. Carries same inversions as *TM6B* except that *In(3R)Hu* is absent. Exists with various marker combinations (including *cu* and *Sb*) in addi-

tion to those listed for *TM6B*.

**order:** 61A1|87B2—75C|94A—100F2|92D1—87B4|61A2—63B8|72E1—63B11|72E2—75C|94A—92E1|100F3—100F5.

**synthesis:** Craymer.

**references:** 1984, DIS 60: 234-36.

**properties:** Homozygous viable, although homozygotes show lower viability and longer development time than wild type. Resembles *TM6B* in balancing efficiency except that the absence of *In(3R)Hu* in *TM6C* lessens its effectiveness in the centromere region.

**TM8**

**constitution:** *In(3LR)TM8, l(3)DTS th st Sb e*.

**origin:** X ray induced in *In(3L)C90 In(3R)C, l(3)DTS4/+*.

**synthesis:** Marsh.

**properties:** Effective chromosome *3* balancer that carries dominant temperature-sensitive lethal; shows very few viable and fertile escapers from the DTS phenotype. 87C-92D-E not balanced (Duncan).

**TM9**

**constitution:** *In(3LR)TM9, l(3)DTS th st Sb e*.

**origin:** X ray induced in *In(3L)C90 In(3R)C, l(3)DTS4/+*.

**synthesis:** Marsh.

**properties:** Effective chromosome *3* balancer that carries dominant temperature-sensitive lethal; shows very few viable and fertile escapers from the DTS phenotype. 87A-92D-E not balanced (Duncan).

*winscy*: see *In(1)sc<sup>SIL</sup> sc<sup>8R</sup> + dl49*

**TMS: Third Multiple of Singson**

**constitution:** *In(3R)87A-B; 97F-98A* superimposed on *Tp(3;3)MKR5, M(3)76A kar ry<sup>2</sup> Sb P(ry<sup>+</sup>Δ2-3)99B*.

**order:** 61—71B2|92E—93C|87F—92E|71C—87A|97F—93C|87E—87B|98A—100.

**synthesis:** Singson.

**properties:** Useful in maintaining linkage between *Sb* and *A2-3* when passed through heterozygous females.

## MULTI-CHROMOSOME BALANCERS

**AM1: Autosomal Multiple 1**

**constitution:** *T(2;3)A1, Cy L Ubx<sup>130</sup>*. Reciprocal translocation between balancers *In(2L+2R)Cy* and *TM2*.

**synonym:** *A1*.

**synthesis:** Wallace, 1966.

**references:** Wallace, Zouras, and Krimbas, 1966, Am. Nat. 100: 245-51.

Wallace, 1966, Am. Nat. 100: 565-83.

Thompson, 1977, Genetics 85: 125-40.

1983, DIS 59: 129-30.

**properties:** Homozygous lethal. Suppresses crossing over in chromosomes *2* and *3*. Recombination on *2* increased in presence of *X* chromosome balancer, *In(1)sc<sup>SIL</sup> sc<sup>8R</sup> + dl49* (Thompson).

## COMPOUND CHROMOSOMES

Compound chromosomes are monocentric elements in which the material from one chromosome arm is represented twice; they contain the entire diploid complement for the arm involved. They are designated by the symbol *C* followed parenthetically by the designation of the involved arm. Gametes of compound-bearing flies generally carry two or no doses of the chromosome arm. Compound-*X* chromosomes [*C*(1)'s] exist only in females which, unless special steps are taken, carry a *Y* chromosome. Such *C*(1)/*Y* females produce patroclinous sons that inherit the *X* from their father and the *Y* from their mother and matroclinous daughters that inherit two *X*'s from their mother and a *Y* from their father (so-called non-crisscross inheritance). Compound-autosome-bearing flies usually produce no viable progeny unless crossed to flies carrying compounds for the same arm or arms.

Some compounds have arisen repeatedly from certain genotypes; they were studied collectively but not as individual occurrences. In other cases, similar compounds of independent origin were studied individually. Both general classes of compounds and compounds of unique origin are listed.

The two chromosome arms comprising a compound may join (1) by attachment of the base of one to the terminus of the other to form an acrocentric chromosome or (2) by attachment of both proximally to a single centromere to form a metacentric; the ends of either an acrocentric or a metacentric may join to form a compound ring. In addition, the component arms may be in the same sequence or one may be entirely inverted with respect to the other. Thus, the elements of a compound may pair as a spiral (the tandem configuration) or as a hairpin (the reversed configuration). Simple compounds may therefore be classified according to the conventions of Novitski (1954, *Genetics* 39: 127-40) as reversed acrocentrics, reversed metacentrics, reversed rings, tandem acrocentrics, tandem metacentrics, and tandem rings; where applicable, this classification was retained and is used in the designation of compounds.

When the component arms differ in sequence by something other than whole-arm inversion, the classification tandem or reversed becomes ambiguous. Furthermore, when the component arms are separable from each other by a single break, the terms acrocentric and metacentric are descriptive; however, when elements of the two arms become interspersed (as for example by interarm rearrangements), these terms lose meaning. Consequently, the more-complex compounds are given arbitrary symbols.

The chromosomal constitution of compounds in which the chromosome arms remain intact is designated: metacentrics, by the sequences of the component arms separated by a centerpoint (which represents the centromere); acrocentrics, by the sequence of the distal arm separated by an em dash from the sequence of the proximal arm followed by a centerpoint; rings (which are derived from acrocentrics or metacentrics) by origin. In heterozygotes, the gene content of the component arms is listed according to the same conventions, with the genes on the first arm listed in the chromosomal designation followed by those on the second arm. In homozygotes,

the genes are listed in chromosome map order. Complete designation of a compound includes its symbol, its chromosomal constitution, and the gene content of its component arms; e.g., *C*(1)*TM2*, + - *In*(1)*sc*<sup>4*L*</sup>*EN*<sup>*R*</sup>, *y cv v · sd · y sn g*. It should be emphasized that the heterozygous gene content of compounds is often highly unstable owing to homozygosis and changes in coupling relations resulting from exchange.

In compounds in which elements of the component arms have become interspersed, it is usually not feasible to designate the chromosomal constitution in terms of the component arms; rather, it is described in terms of the order of chromosome segments as seen in salivary-gland chromosomes. In heterozygotes, the gene content is listed in such a way as to indicate which genes were originally in the different component arms.

***C*(1)94-2*A***

**constitution:** Homozygous for *y*; originally heterozygous for *cv*, *sn*, *v*, *g*, and *sd*. Ring shaped in mitotic metaphase. Salivary chromosome analysis shows order to be |1A - 5E|1F - 1A · 20 - 5E|1F - 20|.

**origin:** Spontaneous (although possibly X ray induced premeiotically) derivative of *C*(1)*TR94-2*. Apparently arose through an asymmetrical or reversed exchange between the 1F region near the centromere and the 5E region near the interstitial heterochromatin of *C*(1)*TR94-2*.

**synthesis:** Rosenfeld, 1964.

**properties:** Crossing over in region 1F - 6A produces a single ring carrying *In*(1)94-2*A* = *In*(1)1F-2A;5E-6A. Reversibly convertible to other double-ring configurations by other types of exchange (e.g., Novitski and Braver, 1954, *Genetics* 39: 197-209).

***C*(1)*A*: Compound (1) of Armentrout**

**constitution:** Homozygous for *y* and probably originally heterozygous for *cv*, *sn*, *v*, *g*, and *sd*. Ring shaped in mitotic metaphase. Salivary chromosome analysis shows order to be |1A - 6F2 |6F2 - 1A|20 - 7A1|7A1 - 20 · |.

**origin:** Spontaneous stable derivative of *C*(1)*TR94*, which was originally *y cv v · sd · y sn g*. Apparently arose by a process describable as reversed crossing over in region 6F2 - 7A1. Current versions of this chromosome have apparently opened, since they are no longer ring-shaped in metaphase. Shown to have separated at 13E by Traverse and Pardue (1988, *Proc. Nat. Acad. Sci. USA* 85: 8116-20) such that the new order is 13E - 7A1| 7A1

–20·1–6F2|6F2–1|20–13E|13E–20·1–6F2|6F2–1|20–7A1|7A1–13E which are interconvertible by exchange between regions 20 and 13. The newly terminal ends at 13E have acquired moderately repeated sequences (He-T DNA) ordinarily encountered at telomeres and in the chromocenter (Traverse and Pardue). Transmission of *C(1)A* is reduced owing to the fact that half of meiotic exchanges lead to the production of dicentric chromosomes.

**synthesis:** Armentrout, 1964.

**properties:** An apparently completely stable, compound-ring-X chromosome; cannot produce single-X chromosome derivative by heterochromatic exchange. Should be the best of all compound-X chromosomes for stock purposes.

### ***C(1)DX: Compound (1) Double X***

**constitution:** *C(1)DX, In(1)dl-49–In(1)sc<sup>8</sup>, yf–y<sup>-</sup>sc<sup>8</sup>f<sup>·</sup>*

**origin:** X ray induced in *In(1)dl-49, y w flIn(1)sc<sup>8</sup>sc<sup>8</sup>B* female [stated by Muller to have been *In(1)dl-49/In(1)sc<sup>8</sup>l<sup>y</sup>3PR*, but the derivative does not carry *y<sup>3P</sup>*]. Was originally *y w f–y<sup>-</sup>sc<sup>8</sup>B<sup>·</sup>*, but by double exchange *f* became homozygous and *B* was lost.

**synthesis:** Muller.

**synonym:** The symbol :=.

**references:** 1943, DIS 17: 61-62.

Valencia, Muller, and Valencia, 1949, DIS 23: 99-102.

**properties:** A reversed acrocentric heterozygous for *In(1)dl-49*; it is useful in balancing because it is very stable, which is probably due to little interstitial heterochromatin. *y w f* detachments very rarely produced. Also produces a low incidence of homozygosis for *w*, and *y w f* versions exist. *C(1)DX/0* lethal; deficient for *bb*.

### **\**C(1)M2: Compound (1) Multiple***

**constitution:** *C(1)M2, In(1)sc<sup>7</sup>+AM–In(1)FM4<sup>·</sup>, sc<sup>7</sup>–y<sup>-</sup>sc<sup>8</sup>dmB<sup>·</sup>*

**origin:** X-ray-induced exchange between the proximal heterochromatin of *In(1)sc<sup>7</sup>+AM* and the distal heterochromatin of *In(1)FM4*.

**synthesis:** Lewis, 54h.

**synonym:** *FMA2: First Multiple Attached*.

**references:** 1958, DIS 32: 81.

### ***C(1)M3***

**constitution:** *C(1)M3, In(1)AM–In(1)FM4<sup>·</sup>, y<sup>2</sup>–y<sup>-</sup>sc<sup>8</sup>dmB<sup>·</sup>*

**origin:** Recombinant between *In(1)sc<sup>7</sup>In(1)AM* element of *C(1)M2* and *In(1)AM, y<sup>2</sup>* in triploid.

**synthesis:** Lewis, 55b.

**synonym:** *FMA3*.

**references:** 1958, DIS 32: 81-82.

**properties:** Detachment rare; useful in balancing.

### ***C(1)M4***

**constitution:** *C(1)M4, In(1)w<sup>m4</sup>+AB–FM7<sup>·</sup>, y w<sup>m4</sup>–y<sup>-</sup>w<sup>a</sup>v<sup>Of</sup>sc<sup>8</sup><sup>·</sup>*

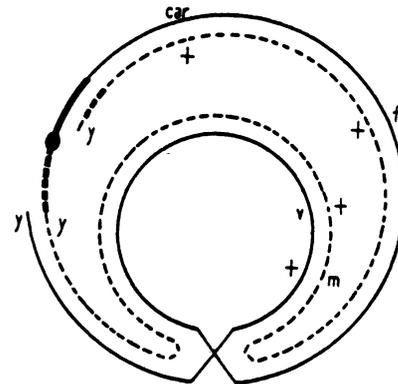

**origin:** X-ray-induced exchange between the proximal heterochromatin of *In(1)w<sup>m4</sup>+AB* and the distal heterochromatin of *FM7*.

**synthesis:** Craymer, 72e.

**references:** 1974, DIS 51: 21.

**properties:** Because of the *w<sup>m4</sup>/w<sup>a</sup>* constitution, *C(1)M4* females without a *Y* chromosome display strong variegation, those with *YS* moderate variegation, and those with

*YL* or a complete *Y* almost no variegation. Useful in maintenance of *XY*-bearing stocks without a free *Y*. Detachment rate approximately 1/15,000. A powerful enhancer of autosomal recombination, but has low viability in combination with autosomal rearrangements. Some derivatives are *y<sup>2</sup>bb<sup>-</sup>*.

### ***C(1)NB: Compound (1) of Novitski and Braver***

From Novitski and Braver, 1954, Genetics 39: 197-209.

### ***C(1)NB: Compound (1) of Novitski and Braver***

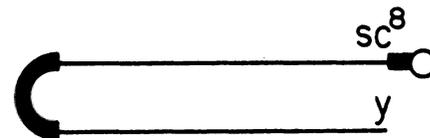

**constitution:** *C(1)NB, In(1)dl-49–In(1)sc<sup>4L</sup>EN<sup>R</sup>*; originally *y v f car·y m; In(1)dl-49* and *In(1)EN* attached proximally to a single centromere.

**origin:** Crossover between the heterochromatic short arm of *In(1)EN* and the proximal heterochromatin of *In(1)dl-49*.

**synthesis:** Novitski and Braver.

**references:** 1954, Genetics 39: 197-209 (fig.).

**properties:** Essentially a tandem metacentric heterozygous for *In(1)dl-49*. Can exist in a number of different configurations interconvertible by crossing over. Generates single rings at different frequencies, depending on configuration of the compound.

### ***C(1)RA: Compound (1) Reversed Acrocentric***

Redrawn from Sandler, 1954, Genetics 39: 923-42.

### ***C(1)RA: Compound (1) Reversed Acrocentric***

**constitution:** *C(1)RA, +–In(1)sc<sup>8</sup><sup>·</sup>*

**origin:** Spontaneous from *X·YL/In(1)sc<sup>8</sup>* either by exchange between the proximal heterochromatin of *X·YL* and the distal heterochromatin of *In(1)sc<sup>8</sup>*, or possibly by sister-strand union in one of the heterochromatic segments followed by a normal euchromatic exchange. A frequently recurring event that seems to require the presence of *YL*. More recent attempts to repeat such constructions have been unsuccessful, except in response to x irradiation.

**synthesis:** Novitski.

**synonym:** *RA*.

**references:** Novitski, 1954, *Genetics* 39: 127-40.

Sandler, 1954, *Genetics* 39: 923-42.

1958, Cold Spring Harbor Symp. Quant. Biol. 23: 211-23.

Sandler and O'Tousa, 1979, *Genetics* 91: 537-51.

**properties:** Yields frequent detachments resulting from exchange between the *Y* chromosome and the interstitial heterochromatin of the reversed acrocentric and preferential recovery of the proximal *X*. Tetrad distribution usually quite abnormal; one-exchange tetrads infrequent and no- and two-exchange tetrads frequent. Exchange frequency increased by addition of *Y* or *y*<sup>+</sup>*YL*, but tetrad distribution remains abnormal (Sandler, 1954). *YL* appended as a second arm to *C(1)RA* normalizes tetrad distribution (Sandler, 1958). Tetrad distribution is normal in more recently recovered *C(1)RA* chromosomes (Sandler and O'Tousa), reason for differences between 1954 and 1979 data is unclear. The presence of a *Y* chromosome or a free-*X* duplication as a homologue markedly increases both exchange between the elements of the compound and fecundity of compound-bearing females.

### ***C(1)RA60g***

**constitution:** *C(1)RA60g*, + - *In(1)sc*<sup>8</sup>.

**origin:** A spontaneous euchromatic event (perhaps sister chromatid union) in a triploid female heterozygous for *In(1)sc*<sup>8</sup> + *dl49*.

**synthesis:** Mohler, 60g.

**references:** 1960, *DIS* 34: 52.

Gethmann, 1979, *Genetics* 55: 673-79.

**properties:** Deficient for interstitial heterochromatin and proximal euchromatin, including *su(f)*. Requires a duplication carrying both *su(f)*<sup>+</sup> and *bb*<sup>+</sup> in order to survive. Exhibits standard distribution of tetrads in meiosis (Gethmann).

**other information:** The reciprocal exchange product, *Dp(1:f)60g*, recovered from same fly.

### ***C(1)RA85***

**constitution:** *C(1)RA85*, *y w*<sup>1118</sup> *f*<sup>5</sup> - *In(1)sc*<sup>SIL</sup> *sc*<sup>8R</sup> + *S*, *y*<sup>-</sup> *sc*<sup>8</sup> *w*<sup>r</sup> *f*<sup>5</sup>.

**origin:** Spontaneous exchange between the proximal heterochromatin of *y w*<sup>1118</sup> *f*<sup>5</sup> and the distally inverted heterochromatin of *Basc*, with subsequent loss of *B* and homozygosis of *f*<sup>5</sup>.

**references:** Mount, Green, and Rubin, 1988, *Genetics* 118: 221-34.

**properties:** A stable compound *X* chromosome.

### ***C(1)RM: Compound (1) Reversed Metacentric***

**constitution:** *C(1)RM*, + · + ·; two *X* chromosomes in normal sequence attached proximally to the same centromere; exists with many combinations of markers.

**origin:** Spontaneous. Recurs regularly by exchange between heterochromatin of the short arm of one *X*, *XYS*, or *XYL* and that of the base of the long arm of a sister or homolog. Can be induced in mature *X*·*YL*-bearing sperm (Leigh, 1972, *DIS* 48: 107). Presumably the pericentric heterochromatic constitutions of independently arising *C(1)RM* chromosomes varies.

**discoverer:** L. V. Morgan, 21b12.

**synonym:** *Attached-X*; also the symbol · =.

**references:** 1922, *Biol. Bull.* 42: 267-74.

1938, *Am. Naturalist* 72: 434-46.

**properties:** Recombination with the *Y* chromosome leads to detachments with a frequency of about 10<sup>-3</sup> in *C(1)RM/Y* females. Has been extensively used in studies of crossing over (e.g., Anderson, 1925, *Genetics* 10: 403-17; Beadle and Emerson, 1935, *Genetics* 20: 192-206; Welshons, 1955, *Genetics* 40: 918-36).

### **\**C(1)RR1: Compound (1) Reversed Ring***

**constitution:** *C(1)RR1*, + - *In(1)EN*, *y*<sup>-</sup> *sc*<sup>-</sup> - *y*; two *X* chromosomes attached by their normally distal ends to a common centromere and by their normally proximal ends to each other. Marked with *y*.

**origin:** Spontaneous derivative of *C(1)TR1*.

**synthesis:** Zimmering.

**synonym:** *RR*.

**references:** Novitski, 1954, *Genetics* 39: 127-40.

### **\**C(1)RR2***

**constitution:** *C(1)RR2*, *In(1)sc*<sup>8</sup> · *In(1)sc*<sup>SIL</sup> *EN*<sup>R</sup>; originally *y*<sup>-</sup> *cv v f* · *y m car*. *In(1)sc*<sup>8</sup> and *In(1)sc*<sup>SIL</sup> *EN*<sup>R</sup> attached proximally to a single centromere and distally at their distal heterochromatic segments.

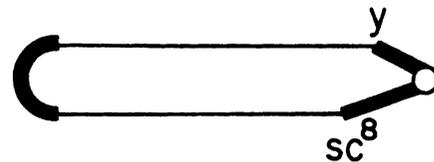

**origin:** *X* ray induced in an attached-*X* with *In(1)sc*<sup>8</sup> and *In(1)sc*<sup>SIL</sup> *EN*<sup>R</sup> attached proximally to a single centromere. Recovered as simultaneous loss of *y*<sup>+</sup> from the tip of both arms.

**synthesis:** Sandler.

**references:** 1957, *Genetics* 42: 764-82 (fig.).

1958, Cold Spring Harbor Symp. Quant. Biol. 23: 211-23.

**properties:** Tetrad distribution abnormal; one-exchange tetrads are infrequent and no- and two-exchange tetrads are frequent. Exchange frequency increased by addition of *Y* or *y*<sup>+</sup>*YL*, but tetrad distribution remains abnormal.

### ***C(1)RR2: Compound (1) Reversed Ring 2***

From Sandler, 1957, *Genetics* 42: 764-82.

### ***C(1)RR94-2F***

**constitution:** *C(1)RR94-2F*, + · + ·; two *X* chromosomes of normal sequence attached proximally to a single centromere and joined distally by a segment of heterochromatin.

**origin:** *X*-ray-induced derivative of *C(1)TR94*.

**synthesis:** Rosenfeld, 1964.

**references:** Sandler, 1965, *Nat. Cancer Inst. Monograph* No. 18: 243-72.

**properties:** Tetrad distribution more nearly normal than in *C(1)RR2*.

### ***C(1)SB: Compound (1) of Sturtevant and Beadle***

**constitution:** *C(1)SB*, + · *In(1)y*<sup>4</sup>; *In(1)y*<sup>4</sup> and a normal sequence attached proximally to a single centromere.

**origin:** Recombinant between the uninverted portion of

*In(1)y*<sup>4</sup> and *C(1)RM* in a triploid.

**synthesis:** Sturtevant and Beadle.

**references:** 1936, Genetics 21: 554-604.

Novitski and Sandler, 1956, Genetics 41: 194-206.

**properties:** A reversed metacentric heterozygous for *In(1)y*<sup>4</sup>. Meiotic behavior similar to that of a tandem metacentric. Crossing over within inversion generates single ring, *R(1)y*<sup>4</sup>.

**\*C(1)TA1: Compound (1) Tandem Acrocentric**

**constitution:** *C(1)TA1*, *In(1)sc*<sup>4</sup> - *In(1)EN*·*YL*, *y sc*<sup>4</sup> - *y*.

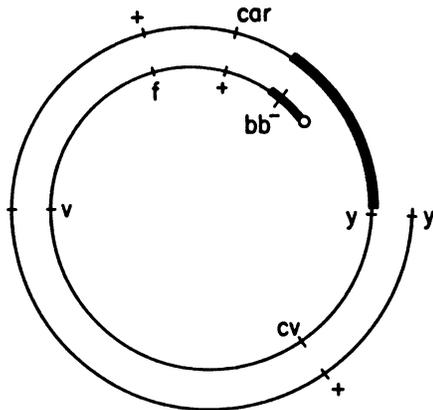

**origin:** X-ray-induced exchange between the proximal heterochromatin of *In(1)sc*<sup>4</sup> and *YS* of *YSX*·*YL*.

**synthesis:** Novitski.

**synonym:** *TA*.

**references:** 1954, Genetics 39: 127-40.

**properties:** Produces a single, centric, rod-X chromosome and either an acentric, ring-X or a tandem triple-X chromosome by recombination between the proximal and distal X chromosomes.

**C(1)TA2: Compound (1) Tandem Acrocentric 2**

From Sandler and Lindsley, 1963, Genetics 48: 1533-43.

**C(1)TA2**

**constitution:** *C(1)TA2*, + - + ·; originally *y cv f* - *y f*.

**origin:** X-ray-induced recombinant in *YSX*, *y*<sup>+</sup> *K*<sup>S</sup> *y cv v f*/*XYL*, *y car K*<sup>L</sup> female; origin required triple exchange.

**synthesis:** Sandler and Lindsley.

**references:** 1963, Genetics 48: 1533-43 (fig.).

**properties:** Generates single X chromosomes like *C(1)TA1*. Tetrad distribution about normal. *C(1)TA2/0* lethal, probably deficient for *bb*.

**C(1)TA·YL**

**constitution:** *C(1)TA*·*YL*, + - + ·, *y* - *y*·*KL*; original line segregating for *cv*, *v*, *f*, and *car*.

**origin:** Spontaneous in a *X*·*YS*, *In(1)sc*<sup>8L</sup>*EN*<sup>R</sup>, *y*<sup>+</sup> *y*/*X*·*YL*, *y cv v f car*; thought to result from an euchromatic exchange between the *X*·*YL* chromosome and the acentric ring formed by dyscentric exchange between the distal and proximal heterochromatin of the long arm of *X*·*YS*, *In(1)sc*<sup>8L</sup>*EN*<sup>R</sup>.

**references:** Merriam, 1968, Genetics 59: 351-66.

**C(1)TA·sc<sup>V1</sup>**

**constitution:** *C(1)TA*·*sc*<sup>V1</sup>, + - + ·, *y* - *y*·*sc*<sup>V1</sup> *y*<sup>+</sup>.

**origin:** Derived as a recombinant in the *B* - *car* region between *C(1)TA*·*YL* and the *X*<sup>P4D</sup> element of *T(1;4)B*<sup>SL</sup>*In(1LR)sc*<sup>VIR</sup>, *B*<sup>S</sup> *car*·*sc*<sup>V1</sup> *y*<sup>+</sup>.

**references:** Merriam, 1968, Genetics 59: 351-66.

**C(1)TM1: Compound (1) Tandem Metacentric**

**constitution:** *C(1)TM1*, + · *In(1)sc*<sup>8L</sup>*EN*<sup>R</sup>, *y Hw f*·*y*<sup>+</sup> *y f*; a normal sequence and *In(1)EN* attached proximally to a single centromere derived from *R(1)2*.

**origin:** Product of one crossover between + and *R(1)2* and one between *In(1)EN* and *R(1)2* in a +/*R(1)2*/*In(1)EN* triploid.

**synthesis:** Novitski, 1950.

**references:** Novitski and Lindsley, 1950, DIS 24: 90-91.

**properties:** Single crossover between the arms produces single-ring-X chromosome with the same structure as *R(1)2* and an acentric-rod X chromosome. Tetrad distribution about normal (Novitski, 1951, Genetics 36: 267-80; Novitski and Sandler, 1956, Genetics 41: 194-206).

**C(1)TM2**

**constitution:** *C(1)TM2*, + · *In(1)sc*<sup>4L</sup>*EN*<sup>R</sup>; originally *y cv v sd*·*y sn g*. The sequence in mitotic prophase is: the normal X euchromatin, two large heterochromatic segments, a small segment, the centromere, a small segment, the inverted X euchromatin.

**origin:** X-ray-induced exchange between the proximal heterochromatin of a normal X and *YL* of *X*·*YL*, *In(1)sc*<sup>4L</sup>*EN*<sup>R</sup>.

**synthesis:** Lindsley and Sandler, 1963.

**synonym:** *TMX y*.

**references:** 1965, Genetics 51: 223-45 (fig.).

**properties:** Recombination between the arms produces a single-ring-X chromosome and an acentric, rod-X chromosome. Meiotic behavior similar to that of *C(1)TM1*; tetrad distribution about normal.

**C(1)TM5**

**constitution:** *C(1)TM5*, *YSIn(1)EN*·+; originally *y w v B KS*·*y*.

**origin:** X ray induced in *YSX*·*YL*, *In(1)EN*, *y w v f B/XYL*·*YS*, *y*·*y*<sup>+</sup> females.

**synthesis:** Lucchesi, Mills, and Rosenbleeth.

**references:** 1965, DIS 40: 57-58.

Pasztor, 1967, DIS 42: 107.

Pasztor, 1971, Genetics 68: 245-58.

**properties:** Single exchange generates highly unstable single ring chromosomes as seen by very low recovery of ring-bearing daughters and by 16-46% gynandromorphs among single-ring-bearing progeny. Single rings apparently deficient for proximal euchromatic material, as they are male-lethal in combination with a normal Y but survive in combination with *B*<sup>S</sup>*Y* or *su(f)*<sup>+</sup>*Y*.

**C(1)TM-H: Compound (1) Tandem Metacentric of Hinton**

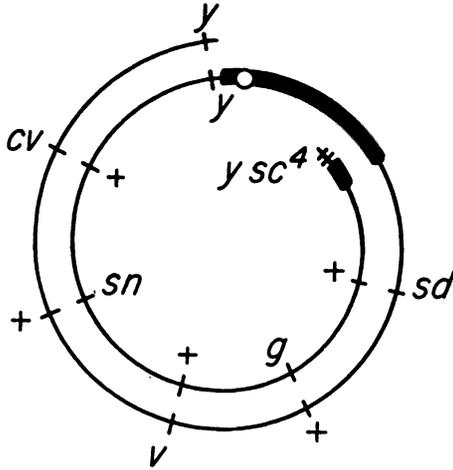

**constitution:** *C(1)TM-H*, *In(1)sc*<sup>4L</sup>*R(1)2*<sup>R</sup> [*·In(1)w*<sup>VC</sup>] + *dl49*; position of centromere indeterminate.

**origin:** Generated by exchange between the *B*<sup>S</sup> duplication of *Dp(1;1)B*<sup>S</sup>-*H* and *In(1)dl49*.

**references:** Hinton, 1957, Genetics 42: 55-65.

**properties:** These are linear derivatives of the unstable *R(1)2*, *In(1)w*<sup>VC</sup>. They exhibit variable stability as indicated by (a) their reduced recovery among the progeny

*C(1)TM-H*-bearing mothers, (b) the production of *XO* patroclinous sons, and (c) the instability of single rings produced by single exchange between the arms of the tandem metacentric.

**C(1)TM2: Compound (1) Tandem Metacentric 2**  
From Lindsley and Sandler, 1965, *Genetics* 51: 223-45.

**C(1)TMB<sup>S</sup>9-1: Compound (1) Tandem Metacentric with Bar Stone**

**constitution:** *C(1)TMB<sup>S</sup>9-1, Dp(1;1)B<sup>S</sup>TAG·In(1)sc<sup>8L</sup>EN<sup>R</sup>*; originally *B<sup>S</sup>y cv v sd·y sn g*. The sequence in mitotic prophase is: the normal *X* euchromatin, two large heterochromatic segments, a small segment, the centromere, a small segment, the inverted *X* euchromatin.

**origin:** X-ray-induced exchange between the proximal heterochromatin of *Dp(1;1)B<sup>S</sup>TAG* and *YL* of *X·YL, In(1)sc<sup>8L</sup>EN<sup>R</sup>*.

**synthesis:** Lindsley and Sandler, 1963.

**synonym:** *TMXB<sup>S</sup>9-1*; also designated as *Dp(1;1)B<sup>S</sup>TRG*.

**references:** 1965, *Genetics* 51: 223-45.

**properties:** Recombination between the arms produces a single-ring-*X* chromosome, *R(1)9-1*, and an acentric, rod-*X* chromosome. Recombination between the *B<sup>S</sup>* duplication and the homologous region of the inverted arm generates a nontransmissible tandem-ring chromosome. Meiotic behavior similar to that of *C(1)TM2*.

**C(1)TMB<sup>S</sup>9-4**

**constitution:** *C(1)TMB<sup>S</sup>9-4, Dp(1;1)B<sup>S</sup>TAG·In(1)sc<sup>8L</sup>EN<sup>R</sup>*; originally *B<sup>S</sup>y cv v sd·y sn g*. The sequence in mitotic prophase is: the normal *X* euchromatin, a large heterochromatic segment, a small segment, the centromere, a small segment, the inverted *X* euchromatin.

**origin:** X-ray-induced exchange between the proximal heterochromatin of *Dp(1;1)B<sup>S</sup>TAG* and *YL* of *X·YL, In(1)sc<sup>8L</sup>EN<sup>R</sup>*.

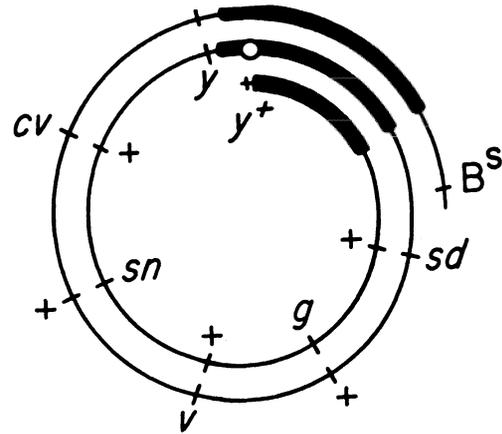

**synthesis:** Lindsley and Sandler, 1963.

**synonym:** *TMXB<sup>S</sup>9-4*; also designated as *Dp(1;1)B<sup>S</sup>TRG*.

**references:** 1965, *Genetics* 51: 223-45 (fig.).

**properties:** Recombination between arms produces single-ring-*X* chromosome, *R(1)9-4*, and an acentric, rod-*X* chromosome. Recombination between the *B<sup>S</sup>* duplication and the homologous region of the inverted

arm produces a tandem-ring chromosome that may be transmissible.

**C(1)TMB<sup>S</sup>: Compound (1) Tandem Metacentric with Bar-Stone**

From Lindsley and Sandler, 1965, *Genetics* 51: 223-45.

**\*C(1)TR1: Compound (1) Tandem Ring**

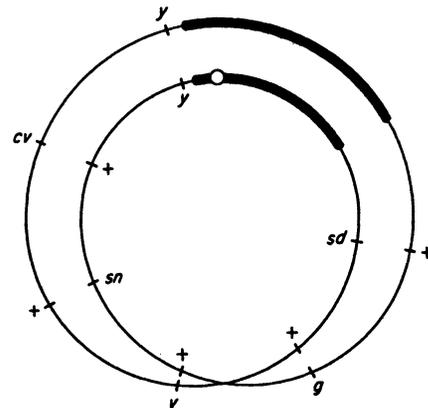

**constitution:** *C(1)TR1, In(1)sc<sup>4</sup>-In(1)EN·, y<sup>-</sup>sc<sup>-</sup>-y·.*

**origin:** Spontaneous derivative of *C(1)TA1* in which the *YL* second arm had been replaced by the *X<sup>P4D</sup>* element of *T(1;4)B<sup>S</sup> = T(1;4)15F9-16A1;16A7-B1;102F*. A product of recombination between the duplicated *B<sup>S</sup>* second arm and the homologous region of the distal element of the tandem acrocentric.

**synthesis:** Novitski.

**references:** 1954, *Genetics* 39: 127-40.

**properties:** Seems to be poorly transmissible (Novitski, 1954). Produces a centric, single-ring-*X* and either an acentric, single-ring-*X* or a tandem, triple-ring-*X* chromosome by recombination between the two elements of the compound.

**C(1)TR94: Compound (1) Tandem Ring 94**

From Sandler and Lindsley, 1967, *Genetics* 55: 645-71.

**C(1)TR94**

**constitution:**  $C(1)TR94, + \cdot In(1)sc^{4L}EN^R \cdot$ ; originally  $y$   
 $cv \ v \ sd \cdot y \ sn \ g$ .

**origin:** Regular but infrequent product of  $C(1)TMB^{S9-4}$ .  
Formed by exchange between the duplicated  $B^S$  section  
and the homologous region of the inverted arm.

**synthesis:** Sandler and Lindsley.

**references:** 1967, Genetics 55: 645-71.

**properties:** Produces a centric, single-ring- $X$  and either an  
acentric, single-ring- $X$  or a tandem, triple-ring- $X$  chromo-  
some by crossing over between the two arms of the com-  
pound. Transmission higher than that of  $C(1)TR1$ .  
Tetrad distribution about normal. Exhibits  $< 0.20\%$   
dicentric quadruple rings in mitotic metaphases (Gatti,  
Santini, Pimpinelli, and Olivieri, 1979, Genetics  
91: 255-74).

**\*C(1)VM: Compound (1) of Valencia  
and Muller**

**constitution:**  $C(1)VM, + - In(1)sc^{S1} In(1)dl-49 \cdot$ ; origi-  
nally  $y \ ac \ sc \ pn \ w \ rb \ cm \ ct^6 \ sn^3 \ oc \ ras^2 \ v \ dy \ g \ f \ car - y$   
 $sc^{S1} \ lz^s \ B \cdot$ .

**origin:** X ray induced in  $+In(1)sc^{S1} In(1)dl-49/YL$  female,  
either by exchange between the proximal heterochroma-  
tin of the normal sequence and the distal heterochromatin  
of  $In(1)sc^{S1}$  or by sister-strand union in one of the  
heterochromatic elements accompanied by normal  
euchromatic exchange. A regularly induced product in  
such females.

**synthesis:** Valencia, Muller, and Valencia.

**references:** 1949, DIS 23: 99-102.

**properties:** Essentially a reversed acrocentric in which the  
proximal element contains  $In(1)dl-49$ . Detachment by  
crossing over with a  $Y$  chromosome relatively frequent.

**C(2)EN: Compound (2) ENTire**

**constitution:**  $C(2)EN, 2R2L - 2L2R$ .

**origin:** Synthesized by first selecting a  $T(Y;2)$  with a break  
in  $YL$  of  $B^S Yy^+$  and an absolutely terminal break in  $2L$ ,  
and next transferring the terminal  $YL$  to  $C(2L)RM$  by  
recombination in a  $Dp(Y;2)/C(2L)RM/C(2R)RM$  triploid;  
the terminal  $YL$  was homozygosed to produce  
 $C(2LYL)RM, B^S$ . Irradiated  $C(2LYL)RM, B^S/C(2R)$   
females were crossed to  $C(2L); F(2R)/F(2R)$  males; this  
cross selects for progeny that receive  $C(2LYL)RM, B^S$   
plus a single copy of  $2R$  from their mothers; those with  
wider Bar eyes are putative results of a translocation  
between the base of  $2R$  from  $C(2R)RM$  and a terminal  $YL$   
of  $C(2LYL)RM$  and the surviving offspring are  
 $YL2L \cdot 2L2R/F(2R)$ ; crosses of females of this constitu-  
tion to  $C(2L)RM; C(2R)RM$  have yielded  $C(2)EN$ -bearing  
progeny as a consequence of fertilization of an ovum that  
has received a derivative homozygous (non  $B^S$ ) for the  
 $2L2R$  arm of the compound and no  $F(2R)$  by a nullo-2  
sperm. *In situ* hybridization with a telomeric probe  
reveals the presence of telomeric sequences at the junc-  
tion between  $2L$  and  $2R$  (Goldstein, Berry, and Novitski,  
1984, DIS 60: 117).

**references:** Novitski, 1977, Genetics and Biology of Dro-  
sophila (Ashburner and Novitski, eds.). Academic Press,  
London, New York, San Francisco, Vol. 1b, pp. 562-68.  
Novitski, Grace and Strommen, 1981, Genetics 98: 257-  
73.

**properties:** Provides all of chromosome 2 necessary for  
normal development.  $C(2)EN$ -bearing flies produce two

types of meiotic products with respect to chromosome 2;  
half disomic and half nullosomic. Accordingly crosses to  
normal diploids produce mainly inviable mono- and  
triplo-2 zygotes; however crosses of  $C(2)EN$  flies to each  
other produce progeny. Transmission of  $C(2)EN$  by  
males versus that from females varies from about 30% to  
very low values (see also Robbins, 1977, Genetics  
87: 67-81). This is attributed to zygote mortality by  
Novitski *et al.*; however, it may be reflected in defects in  
spermatogenesis as seen in cross sections of bundles of  
elongated sperm tails. Male transmission ratio is sensi-  
tive to the particular  $Y$  chromosome present (Strommen,  
1982, Mol. Gen. Genet. 187: 126-31). Sex-chromosome  
disjunction in both sexes influenced by  $C(2)EN$  (Falk,  
1982, Genet. Res. 41: 17-28); in  $XY/O$  males the  $XY$   
segregates preferentially from the compound; in  $X/Y$   
males and  $X/X$  females, sex chromosome nondisjunction  
is elevated with the sex chromosomes segregating pre-  
ferentially away from  $C(2)EN$ . In general,  $C(2)EN$ -bear-  
ing flies perform poorly in stocks and crosses.

**C(2;3)EN: Compound (2;3) ENTire**

**constitution:**  $C(2;3)EN, 2R2L \cdot 3L3R$ .

**origin:** Induced by irradiation of  $C(2)EN; 3R3L \cdot YS^+$   
females. Recovered as a translocation involving the cen-  
tric heterochromatin of both elements resulting in the  
replacement of one arm of  $C(2)EN$  with  $3R3L$ .

**references:** Novitski, Grace and Strommen, 1981, Genetics  
98: 257-73.

**properties:** Carries a complete haploid set of the large  
autosomes attached to a single centromere. Transmission  
by heterozygous females is reduced by nonrandom dis-  
junction of heteromorphic dyads resulting from exchange  
between the compound and a normal homologue, but it is  
high if recombination is suppressed by homologous  
inversions. Transmission by heterozygous males is low.  
Homozygous viability and fertility not indicated.

**C(3)EN: Compound (3) ENTire**

**constitution:**  $C(3)EN, 3R3L \cdot 3L3R$ .

**origin:** Synthesized by first selecting a  $T(Y;3)$  with a break  
in  $YL$  of  $B^S Yy^+$  and an absolutely terminal break in  $3L$ .  
Females heterozygous for  $B^S YL3L \cdot 3R$  and a normal  
third chromosome were irradiated and crossed to  
 $F(3L)/F(3L)/C(3R)RM$  males; one of the few surviving  
products of this cross is non-Bar and comes from fertili-  
zation of an ovum containing a half translocation  
between the base of  $3R$  of the normal third and the distal  
 $YL$  material of the  $Dp(Y;3)$  fertilized by a sperm contain-  
ing  $F(3L)$  but no  $C(3R)$ ; the  $F(3L)$  in this case was the  
 $Y^P 3L^D$  of a  $T(Y;3)$  involving breaks in  $YL$  of  $B^S Yy^+$   
and the proximal heterochromatin of  $3L$ , so that the desired  
survivor is  $3R \cdot 3L3R/y^+ YS \cdot 3L$  in constitution. One pro-  
duct of recombination between  $3L$ 's in females of the  
above constitution is  $y^+ YS \cdot 3L3R$ . Females homozygous  
for the latter derivative were irradiated and crossed to  
 $C(3L)RM; C(3R)RM$  males; surviving  $y$  offspring carried  
 $3R3L \cdot 3L3R = C(3)EN$  from the mother and no third  
chromosomal elements from the father. *In situ* hybridiza-  
tion with telomeric sequences provides no evidence for  
the presence of such sequences at the  $3L - 3R$  junction  
(Goldstein, Barry and Novitski, 1984 DIS 60: 117).

**references:** Novitski, Grace and Strommen, 1981, Genetics  
98: 257-73.

**properties:** Provides all of chromosome 3 necessary for

normal development. *C(3)EN*-bearing flies produce two types of meiotic products with respect to chromosome 3: half disomic and half nullosomic; accordingly crosses to normal diploids produce only inviable mono- and triplo-3 zygotes; however crosses of *C(3)EN* flies to each other produce progeny. Transmission of *C(3)EN* by males versus that from females varies widely depending on the particular isolations tested, from 40% relative maternal transmission in some crosses through equal recovery in others, to 30% relative paternal transmission in yet others. In general these chromosomes perform poorly in stocks and crosses.

**C(4)RM**

**constitution:** 4.4; exists with various marker combinations. Two right arms of chromosome 4 attached proximally to a single centromere.

**origin:** X ray induced.

**synonym:** *E. B. Lewis*.

**properties:** Produces haplo-4 and triplo-4 progeny in crosses to normal diplo-4 flies. Tetra-4 flies carrying two copies of *C(4)RM* exhibit but slightly reduced viability (Grell, 1972, DIS 48: 69). Segregates quasi regularly from *C(1)RM* in *C(1)RM/0*; *C(4)RM/0* females (Grell, 1963, Genetics 48: 1217-29).

**C(A): Compound (Autosomal arm)**

Autosomal compound chromosomes may be subdivided into two classes, homocompounds, consisting of two copies of the same autosomal arm attached to a common centromere, and heterocompounds in which two arms from different autosomes are connected through the centromere of one of them. These are discussed separately in the following section.

**Homocompounds:** Compound chromosomes containing two copies of an autosomal arm [*C(A)*] have been constructed for each autosomal arm, as reversed metacentrics in every case so far. The compound for a particular autosomal arm may be kept in stock either with the compound for the other arm of the same autosome [e.g., *C(AL)*; *C(AR)*] or with free arms [e.g., *C(AL)*; *F(AR)/F(AR)*]. Most compound autosome stocks are of the former constitution; outcrosses to wild type are virtually sterile, the rare survivors being triploids, triploid intersexes, and triploid metafemales (*4X3A*) thought to arise from unreduced ova (Gethmann, 1972, DIS 49: 62) or products of tetraploid oocytes (Kuznetsova and Glotoff, 1978, Genetika 14: 463-69; Kuznetsova and Balakireva, 1980, Genetika 16: 1498-1500; Kuztenova, 1983, Genetika 19: 775-78); in addition some diploid survivors contain reconstituted *2L·2R* chromosomes. Stocks of the second type are similarly unproductive when outcrossed to wild type; rare survivors carry detachments of the *C(A)* resulting from exchange between the base of the compound autosome and either the *Y* or the *X* chromosome (Chadov, 1975, Genetika 11(1): 80-90; 91-100; 1976, Genetika 12(3): 67-77; Chadov and Chadova, 1977, Genetika 13: 477-89; Chadov, Chadova and Khostina, 1983, Genetika 19: 1111-20). Once the first *C(2L)*; *C(2R)* and *C(3L)*; *C(3R)* strains were constructed (Rasmussen, 1960, DIS 34: 53), it became possible to generate additional compound chromosomes, either spontaneously or by irradiation of normal chromosome complements and by crossing to a compound-autosome-containing line to recover them in

combination with a compound for the complementary arm. Compound autosomal arms result from interchanges involving breaks on opposite sides of the centromere of two chromosomes, either homologues or sisters. The resultant chromosomes have an intact autosomal arm on one side of the centromere and a proximal segment of the other arm on the other side to which is attached the distal majority of the first arm from the sister chromatid or the homologous chromosome. Thus compound arms carry two doses of the majority of the arm but only one dose of a proximal segment of variable length, plus a proximal segment of the opposite arm. New compounds may be induced by irradiation of oocytes (Bateman, 1968, Effects of Irradiation on Meiotic Systems, International Atomic Energy Agency, Vienna, pp. 63-70) and in spermatocytes and spermatids (Leigh and Sobels, 1970, Mutat. Res. 10: 475-87). Compound autosomes with desired marker constitutions may be achieved by recombination in triploids or by inducing them anew in appropriately marked diploids; since the latter is the preferred method, most different marker combinations represent independent occurrences, and are so considered in the following table. Reconstitution of *AL·AR* from *C(AL)*; *C(AR)*, either induced or spontaneous, generates chromosomes that may be duplicated or deficient for regions adjacent to the centromere; these have been used to investigate the genetic content of pericentric regions (Baldwin and Suzuki, 1971, Mutat. Res. 11: 203-13; Hilliker and Holm, 1975, Genetics 81: 705-21). In otherwise normal genotypes *C(AL)* and *C(AR)* segregate from one another regularly in females (Grell, 1970, Genetics 65: 65-74; Holm and Chovnick, 1975, Genetics 81: 293-311); in males they segregate at random with respect to one another (Hilliker, 1981, DIS 56: 61-62; Holm and Chovnick, 1975), generating a trimodal distribution of mature sperm-head volumes; chromosome loss is indicated by the presence of micronuclei in spermatids (Hardy, 1975, Genetics 79: 231-64). Regular segregation in females can be upset by the addition of heterologous inversions or by the addition of an extra *Y* chromosome or an attached *X* (Grell, 1970), compounds that carry only heterochromatic material from the opposite arm segregate randomly in males, whereas those that contain euchromatic material from the opposite tend to segregate from the complementary compound. The table below lists a selection of compound autosomal arms that have been characterized or referenced in some way.

**Heterocompounds:** Four types of heterocompounds are possible: *C(2L · 3L)*, *C(2L · 3R)*, *C(2R · 3L)*, and *C(2R · 3R)*; the chromosomal origin of the centromere in such compounds is frequently ambiguous. Pairs of these are produced as the components of 2-3 translocations in which both breakpoints are in the pericentric heterochromatin, e.g., *C(2L · 3L)*; *C(2R · 3R)*, and they may be carried together as translocations in either the homozygous or heterozygous condition. Pairs from two different translocations, which have one autosomal arm in common can be carried in combination with a normal chromosome and a homocompound for the missing arm. The two heterocompounds and the normal compound form a tricomplex; tricomplexes are chromosome constitutions that form a triradial synaptic configuration, involving three entire autosomal arms rather than four as seen in reciprocal-translocation heterozygotes. They are maintained in stock in combination with a compound for the fourth autosomal arm. For example, a triradial synaptic configuration is formed in the constitution *C(2L · 3L)/3L · 3R/C(3R · 2L)*, and it can be maintained in the presence of *C(2R)*. Alternatively a heterocompound may be carried in homozygous condition in combination with homocompounds for the missing arms, e.g., *C(2L)*; *C(2R · 3L)/C(2R · 3L)*; *C(3R)*. New heterocompounds may be induced by crossing irradiated females to heterocompound-bearing males that can generate the complementary gametic types (Parker, 1968, Effects of Radiation on Meiotic Systems, International Atomic Energy Agency, Vienna, pp. 209-18; Puro, 1985, Genet. Res. 46: 287-307). Puro (1973, Hereditas 75: 140-43; 1985, Genet. Res. 46: 287-307) used *T(2;3)N2-29* and *T(2;3)N2-46*, which he determined to be *2L · 3L*; *2R · 3R* and *2L · 3R*; *2R · 3L* respectively, to generate all four types of tricomplex and to characterize their meiotic behaviors. Such tricomplex-bearing flies are produced by crossing *T(2;3)N2-29/T(2;3)N2-46* females to *C(2L)*; *C(2R)* or *C(3L)*; *C(3R)* males. In addition to the heterocompounds recovered from the above two translocations he recovered and characterized *C(2R · 3R)HT10* and *C(2L · 3R)HT26* from irradiated females.

**X-Y COMBINATIONS**

The X and one or both arms of the Y chromosome may be linked by recombinational events occurring in the heterochromatin. Such X-Y combinations are composed of the X, a centromere (derived from either X or Y), and either YL or YS or both. In the designation of such chromosomes, the component elements are listed in order such that the X precedes the centromere (symbolized by a center point), e.g., YSX·YL. Events that give rise to X-Y attachments are usually recurring so that the same combinations arise repeatedly; however, since the exact points of exchange differ, independent occurrences of similar combinations certainly differ from one another in heterochromatic content. Because similar X-Y combinations of independent origin are not ordinarily designated, studied, or maintained as different chromosomes, and because for most purposes, it is not important that they be distinguished, for the most part, general categories of X-Y combinations are described in the ensuing section. Where a specific combination has been studied, it is listed with the designation of its component elements followed immediately by its specific designation, e.g., X·YLC2.

The complete designation of an X-Y combination consists of the following items in the order given: chromosomal elements, sequence of the X chromosome (if other than normal), gene content. X-Y combinations that differ from one another only with respect to mutant genes or euchromatic inversions are not described separately because it is considered that such mutants and inversions can be removed from or inserted into the component X by euchromatic exchange. When X's differ by an inversion with at least one heterochromatic breakpoint, the chromosomes are described separately because they must differ in their heterochromatic constitution.

*sc*<sup>8</sup>*c.o.X*: see *YSX, In(1)sc*<sup>8</sup>

*XY*<sup>+</sup>: see *X·YL*

**X·*bw*<sup>+</sup>*YL***

**constitution:** X·(*bw*<sup>+</sup>-*ba*<sup>+</sup>) *KL*. X chromosome with prominent YL as second arm.

**origin:** Spontaneous in *y v/bw*<sup>+</sup>*Y; bw* stock.

**synthesis:** Erickson.

**synonym:** *Dp(1;Y;2)bw*<sup>+</sup>.

**references:** 1968, DIS 43: 63.

**properties:** X chromosome originally carried *y* and *v*; Y arm carries YL fertility factors with *bw*<sup>+</sup>-*ba*<sup>+</sup> inserted proximal to *KL*.

**X·YL**

**origin:** A recurrent product of exchange between the proximal heterochromatin of *C(1)RM* and either arm of the Y. Also may result from exchange between YS and the proximal heterochromatin of a normal X or the interstitial heterochromatin of *C(1)RA*. Have also been recovered as one element of *T(1;Y)'s* induced in X/Y sperm with one break in YS and the other in X heterochromatin (Kennison, 1981, Genetics 98: 529-48). May be recovered with YL marked with various euchromatic

markers, e.g., *bw*<sup>+</sup> (Erickson, 1968, DIS 43: 63), *y*<sup>+</sup>, or *B*<sup>S</sup>.

**synonym:** *XY*<sup>+</sup>.

**references:** Stern, 1926, Biol. Zentralbl. 46: 505-08.

1929, Z. Indukt. Abstamm. Vererbungslehre. 51: 253-353.

Kaufmann, 1933, Proc. Nat. Acad. Sci. USA 19: 830-38 (fig.).

**properties:** An X chromosome in normal sequence with YL appended as a second arm. May carry varying amounts of the proximal part of YS between the X and the centromere; positions of such breakpoints with respect to *bb*, *ks1*, and *ks2*, as determined by Kennison for *T(X;Y)'s* provided with entries on the translocations. Males carrying X·YL require *KS* in some form for fertility. Chromosome V-shaped in metaphase.

**other information:** A series of X-ray-induced exchanges between X·YL and *y*<sup>+</sup>*Y* replacing YL with *y*<sup>+</sup>*YL* investigated by Frankel (1968, DIS 43: 99; 1973, Genetics 74: 115-32).

**X·YLC2**

**constitution:** X·YL, *bb*<sup>-</sup> *KL*.

**origin:** Recombination between YS proximal to *bb*<sup>+</sup> and *C(1)RM* distal to *bb*<sup>+</sup>.

**synthesis:** Lindsley.

**properties:** Like X·YL but deficient for *bb*; X·YLC2/0 lethal. Shows unique behavior in double, first anaphase bridges (Novitski, 1952, Genetics 37: 270-87). Male sterile in combination with *y*<sup>+</sup>*Ymal*<sup>+</sup> (Stone, 1984, Can. J. Genet. Cytol. 26: 67-77).

**X·YL, *In(1)EN***

**constitution:** X·YL, *In(1)EN*, *y*·*KL*.

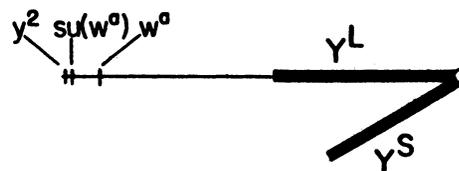

**origin:** Single euchromatic recombinant from *YSX·YL, In(1)EN/In(1)EN* female.

**properties:** An entirely inverted X chromosome with YL appended as a second arm.

**XYL**

**origin:** Detachment of *XYL·X* or *XYL·YLX* (attached X chromosomes synthesized from *XYL·YS*) by interchange with small, free-X heterochromatic duplications, i.e., *Dp(1)f*.

**references:** Lindsley and Novitski, 1959, Genetics 44: 187-96.

**XYL·YS**

From Lindsley and Novitski, 1959, Genetics 44: 187-96.

**XYL·YS**

**constitution:** *XYL·YS*; originally *y*<sup>2</sup> *su(w<sup>a</sup>) w<sup>a</sup> (bb?) KL·KS*.

**origin:** X-ray-induced detachment in *C(1)RM*, *y*<sup>2</sup> *su(w<sup>a</sup>) bb/y*<sup>+</sup>*Y* female; Y-chromosome breakpoint distal to *k15*. Also a common product of X-Y translocation induced in X/Y sperm, at least when the Y is *B<sup>S</sup>Yy*<sup>+</sup> (Kennison,

1981, Genetics 98: 529-48).

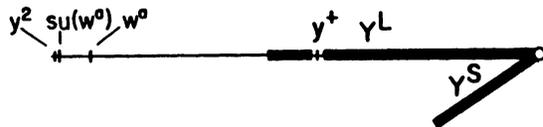

**synthesis:** Parker.

**references:** Parker and McCrone, 1958, Genetics 43: 172-86.

Lindsley and Novitski, 1959, Genetics 44: 187-96 (fig.).

**properties:** Essentially an intact Y chromosome with all of the X euchromatin appended distally to *KL*. Carries all the sex-chromosome material required for male viability and fertility.

**other information:** Several detachments of this constitution recovered (numbered 2-10T13, 2-10T15, 108-9, 112-17, and 129-11) as well as segregants from translocations with one break in X heterochromatin and one distal to *kl5* in  $B^S Yy^+$  (designated *E12*, *E17*, *F6*, *K1*, *N16*, *P9*, *V13*, and *W8*).

XYL·YS129-16

#### XYL·YS129-16

**constitution:** XYL·YS; originally  $y^2 su(w^a) w^a (bb?) y^+$  KL·KS.

**origin:** X-ray-induced detachment in *C(1)RM*,  $y^2 su(w^a) bb/y^+ Y$  female.

**synthesis:** Parker.

**references:** Parker and McCrone, 1958, Genetics 43: 172-86.

Parker, 1968, DIS 43: 156.

**properties:** Essentially an intact Y chromosome with all of the X euchromatin attached to *YL* distal to  $y^+$ . Interstitial position of  $y^+$  shown by recovery of  $y^+$  reattachment; also interstitial  $y^+$  allele shows strong variegation. The break in the  $y^+ Y$  occurs between *l(1)IAc<sup>+</sup>* and  $y^+$  (Parker, 1968). Carries all the sex-chromosome material required for male viability and fertility.

#### XYL·YS, *bb*<sup>-</sup>

**constitution:** XYL·YS,  $y v bb^- KL \cdot bb^- KS$ ; rDNA-deficient chromosome carrying most of  $B^S Ybb^-$ ; derived by detachment of the distal [*In(1)dl49*] X of *C(1)DX* and its attachment to *YL* of  $B^S Ybb^-$  with loss of  $B^S$ ; *In(1)dl49* replaced by recombination.

**synthesis:** Komma.

**synonym:** X-Y<sup>bb-</sup>.

**references:** Komma and Endow, 1986, Genetics 114: 859-74.

**properties:** A *Ybb*<sup>-</sup> chromosome with the X euchromatin attached (in normal sequence) distal to *YL*. Carries all the sex-chromosome material required for male fertility, but is deficient for bobbed.

**other information:** *bb/XYL·YS*, *bb*<sup>-</sup> females show an increase in the number of 18S + 28S ribosomal genes (magnification) in their offspring.

#### X·YS

**origin:** Recurrent product of recombination between the proximal heterochromatin of *C(1)RM* and the Y. Also recovered as one element of *T(1;Y)*'s induced in *X/Y* sperm with one break in *YL* and the other in X heterochromatin (Kennison, 1981, Genetics 98: 529-48).

**synthesis:** Kaufmann.

**references:** 1933, Proc. Nat. Acad. Sci. USA 19: 830-38.

**properties:** An X chromosome in normal sequence with *YS* appended as a second arm. May carry varying amounts of the proximal part of *YL* between X and the centromere; positions of such breakpoints with respect to *kl5*, *kl3*, *kl2*, *Su(Ste)*, and *kl1* as determined by Kennison for *T(X;Y)*'s provided with entries on the translocations. Males carrying X·YS require *KL* in some form for fertility. Chromosome J-shaped in metaphase [e.g., Janning, 1970, Mol. Gen. Genet. 107: 150-57 (fig.)].

#### X·YS, *Basc*

**constitution:** X·YS, *In(1)sc<sup>SIL</sup>sc<sup>8R</sup>+S*,  $y^{31d} sc^{S1} sc^8 w^a B \cdot y sc^+$ .

**origin:** Recovered as an X-ray-induced detachment from a *C(1)RM*, *Basc/Dp(1;Y)IE* female.

**synthesis:** Ehrlich.

**references:** 1971, DIS 46: 108.

**properties:** Homozygous females viable and fertile; males viable and fertile with normal Y but lethal with *Dp(1;Y)IE*. Suppresses crossing over in X.

#### X·YSYL

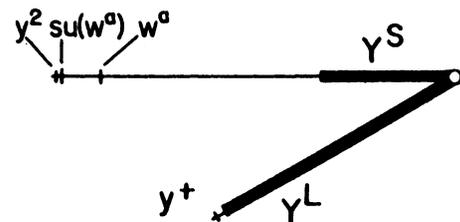

**constitution:** X·YSYL,  $y w \cdot KS KL y^+$ ; metacentric chromosome.

**origin:** X ray induced in X·YS,  $y w/y^+ YL$  male.

**references:** Johnsen, 1968, DIS 43: 158.

Johnsen and Zarrow, 1971, Mol. Gen. Genet. 110: 36-39.

**properties:** Attached XY with X in normal sequence on one side of the centromere and a complete Y on the other. X·YSYL/0 males fertile; transmission of the XY somewhat reduced.

XYS·YL

From Lindsley and Novitski, 1959, Genetics 44: 187-96.

#### XYS·YL

**constitution:** XYS·YL; originally  $y^2 su(w^a) w^a (bb?) KS \cdot KL y^+$ .

**origin:** X-ray-induced detachment in *C(1)RM*,  $y^2 su(w^a) bb/y^+ Y$  female, in which the Y breakpoint is distal to *ks2*. Also a common product of X-Y translocation induced in *X/Y* sperm, at least when the Y is  $B^S Yy^+$  (Kennison, 1981, Genetics 98: 529-48).

**synthesis:** Parker.

**references:** Parker and McCrone, 1958, Genetics 43: 172-86.

Lindsley and Novitski, 1959, Genetics 44: 187-96 (fig.).

**properties:** Essentially an intact  $y^+Y$  chromosome with all of the X euchromatin appended distally to YS. Carries all the sex-chromosome material required for male viability and fertility. YL may carry any marker available on the long arm of marked Y chromosomes, e.g.,  $y^+$ ,  $B^S$ , etc.

**other information:** Two detachments of this constitution recovered (110-8 and 115-9) as well as segregants from translocations with one break in X heterochromatin and one distal to *ks2* in  $B^S Yy^+$  (designated G7, N10, N30, P1, V4, V23, V25, V36, and Z14).

### YSX

**constitution:** YSX; originally *KS y cv v f* (Braver).

**origin:** Spontaneous derivative from YSX·YL, *In(1)EN*, *KS y·KL/sc cv v f*.

**synthesis:** Novitski.

**synonym:** *FR1: Fragment 1*.

**references:** Novitski, 1952, Genetics 37: 270-87.

Lindsley and Novitski, 1959, Genetics 44: 187-96.

Janning, 1970, Mol. Gen. Genet. 107: 150-57 (fig.).

**properties:** An X in normal sequence marked with y and with YS appended distal to *l(1)IAa*<sup>+</sup>. Reduces crossing over near y.

### YSX, *In(1)FM7*

**constitution:** YSX, *In(1)FM7*,  $y^+ KS y^- w^a v^{Of}$ .

**origin:** X-ray-induced detachment by exchange between the interstitial heterochromatin of *C(1)M4* with the short arm of  $B^S Yy^+$ .

**references:** Craymer, 1974, DIS 51: 21.

### YSX, *In(1)sc*<sup>8</sup>

**constitution:** YSX, *In(1)sc*<sup>8</sup>, *KS [l(1)IAa-ac]<sup>-</sup> sc*<sup>8</sup>.

**origin:** Infrequent product of spermatogonial exchange between YS and the distal inverted heterochromatic segment of *In(1)sc*<sup>8</sup>. The incidence increased twenty fold in genotypes undergoing ribosomal DNA magnification [e.g., *In(1)sc*<sup>8</sup>, *bb<sup>1</sup> sc<sup>8</sup>/Ybb*], but decreasing with successive generations of magnification (Ritossa, 1973, Proc. Nat. Acad. Sci. USA 70: 1050-54).

**synthesis:** Sidorov.

**synonym:** *sc*<sup>8</sup> c.o. X.

**references:** Sidorov, 1940, Bull. Biol. Méd. Exp. URSS 9: 10-12.

1941, Dokl. Akad. Nauk SSSR, Ser. Biol. 30: 248-49.

Lindsley, 1955, Genetics 40: 24-44.

Ritossa, 1973, Proc. Nat. Acad. Sci. USA 70: 1950-54.

**properties:** *In(1)sc*<sup>8</sup> with the distal uninverted euchromatic region carrying the normal alleles of *l(1)IAa* through *ac* replaced by *KS*; deficiency covered in single crossover between *in(1)sc*<sup>8</sup> and *In(1)EN*, i.e., *In(1)sc*<sup>8</sup>*EN*<sup>R</sup>. Resembles *In(1)sc*<sup>8</sup> in mitotic prophase.

### YSXX·YL

**constitution:** An X-Y combination carrying a *C(1)RA*; the distal X is YSX in normal sequence, and the proximal X is an inverted sequence with YL attached as a second arm.

**origin:** Exchange in triploid females carrying *C(1)RA*, first replacing the centromere region of the proximal X with that of YSX·YL, *In(1)EN* and then the terminus of the distal X with that of YSX.

**references:** Lindsley and Novitski, 1959, Genetics 44: 187-96.

### YSX·YL

**constitution:** YSX·YL, *KS y·YL*.

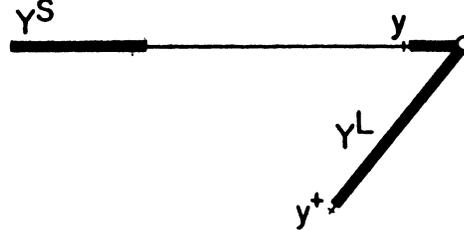

**origin:** Recombination between YSX and X·YL.

**synthesis:** Lindsley and Novitski.

**references:** 1959, Genetics 44: 187-96.

**properties:** An attached XY with the X in normal sequence.

Contains all of the sex-chromosome material required for male viability and fertility. Commonly kept in stock as YSX·YL/0 males crossed to *C(1)/0* females.

YSX·YL, *In(1)EN*

From Lindsley and Novitski, 1959, Genetics 44: 187-96.

### YSX·YL, *In(1)EN*

**constitution:** YSX·YL, *In(1)EN*, *KS y·KL y*<sup>+</sup>.

**origin:** Recovered as recombinant between the proximal heterochromatin of YSX, *In(1)sc*<sup>8</sup>*EN*<sup>R</sup> and  $y^+Y$ .

**synthesis:** Lindsley, 1949.

**references:** Lindsley and Novitski, 1960, DIS 24: 84-85.

1959, Genetics 44: 187-96 (fig.).

**properties:** Contains all of the sex-chromosome material required for male viability and fertility. Exists without the  $y^+$  marker at the end of the YL arm. A derivative with  $B^S$  at the end of YL described by Craymer (1974, DIS 51: 21); also exists with various combinations of sex-linked markers. Two X-ray-induced paracentric-inversion derivatives described by Novitski: *In(1)24*, a nearly complete inversion with one break in the normally proximal euchromatin and the other in the centric heterochromatin, and *In(1)26* with one break in 10A and one break in heterochromatin, distal or proximal not specified (Novitski, 1951, DIS 25: 122; Lindsley and Novitski, 1959, Genetics 44: 187-96).

### YSX·YL, *In(1)FM7*

**constitution:** YSX·YL, *In(1)FM7*<sup>L</sup>*EN*<sup>R</sup>,  $y^+ KS y v^{Of} \cdot KL B^S$ .

**origin:** Recombination between YSX, *In(1)FM7*,  $y^+ KS y^- w^a v^{Of}$  and YSX YL, *In(1)EN*, *KS y·KL B^S* such that the  $w^a y^-$  base of FM7 is replaced by the  $w^+ y \cdot KL$  of YSX·YL, *In(1)EN*.

**synthesis:** Craymer, 74d.

**synonym:** FM7Y.

**references:** Craymer, 1974, DIS 51: 21.

Mitchell, 1977, Genetics 87: 763-74.

**properties:** Contains all of the male fertility factors. The FM7 inversions prevents euchromatic crossovers and the  $y^+$  and  $B^S$  markers serve to detect recombinational events in the heterochromatin.

### YSXYL·

**constitution:** YSXYL·, *KS y KL*·.

**origin:** Rarely recovered recombinant between XYL· and YSX.

**synthesis:** Lindsley.

**references:** Lindsley and Novitski, 1959, *Genetics* 44: 187-96.  
Novitski and Brosseau, 1964, *Genetics* 50: 273 (abstr.).  
Donady, Seecof, and Fox, 1973, *Genetics* 73: 429-34.  
**properties:** Shows extremely reduced recovery from above

heterozygous females (Lindsley and Novitski), all zygotes carrying *YSXYL* being lethal in some autosomal backgrounds; reciprocal recombinant recovered frequently (Novitski and Brosseau; Donady *et al.*).

Y DERIVATIVES

The Y chromosome consists of a long arm (YL) and a short arm (YS); the long arm is arbitrarily taken as the left arm. Special Y chromosomes include (1) marked Y's which are used as Y tracers and (2) Y fragments, unmarked or marked, which are used as duplications or, when marked, as Y-arm tracers. Y fragments are symbolized either YL or YS plus necessary distinguishing notation, e.g., YS8. The Y chromosome may be marked by mutating the genetically demonstrable elements of the Y or by translocating normal or mutant alleles from other parts of the complement to the Y chromosome. Marked-Y chromosomes are symbolized by combining, without intervening punctuation, the symbol for the normal or mutant gene of primary marker intent with the symbol Y. If the marker is in the long arm, its symbol precedes Y (e.g.,  $y^+Y$ ); if it is in the short arm, its symbol follows Y (e.g.,  $Ybb$ ). Symbols for marked fragments combine the symbol for the appropriate Y arm with that for the marker gene, listed in order. These notations are separated by a center point when the centromere lies between them (e.g.  $YL \cdot sc^{S1}$ ); otherwise they are not separated by punctuation (e.g.,  $y^+YL$ ). The long arm of the Y carries a complex of male fertility genes, *KL*, plus an *ABO* element and *Su(Ste)*, and the short arm carries a normal allele of *bb* and an *ABO* element proximally and a complex of male fertility factors, *KS*, distally. The genetic constitution of the Y chromosome may be designated by listing the above components and the centromere in order from left to right,  $kl5^+ kl3^+ kl2^+ ABO-YL Su(Ste) kl1^+ \cdot ABO-YS bb^+ ksl^+ ks2^+$ . The genetic constitution of a marker segment is designated by listing the symbols of the most widely separated loci known to be included in it separated by an em dash, e.g.,  $bw^+ - ba^+$ . The constitution of a Y fragment may be designated by listing its genetic elements in order with any ambiguities in order enclosed within parentheses, e.g.,  $KL(bw^+ - ba^+) bb^+ KS$ . When there is a hierarchy of ambiguities in order, a hierarchy of parentheses is used, as in  $((ci^+ - spa^+)KL)bb^+ KS$ .

4Y

**constitution:**  $((ci^+ - spa^+)KL)bb^+ KS$ ; tentative.  
**origin:** X ray induced.  
**synthesis:** Edmondson, 1946.  
**synonym:** *Tp4Y*.  
**references:** Muller and Edmondson, 1957, DIS 31: 140-41.  
**properties:** Contains all known loci of chromosome 4 linked to the Y chromosome. Results from recombination between 4Y and *YSX \cdot YL* suggest that 4 is inserted into or appended to YL. Two doses of this chromosome in the absence of any other Y- or 4-derived material produce viable and fertile flies of both sexes.

\* $B^S w^+ y^+ Y$

**constitution:**  $B^S pfd^+ l(1)20Bb - su(f)^+ Pgd^A - spl^+ y^+ ac^+ KL \cdot bb^+ KS$ ; inferred from origin.  
**origin:** X-ray-induced deletion of the majority of euchromatin ( $dm^+$  through  $mal^+$ ) from the recombinant composed of the left end of  $X^{PYD}$  element of  $T(1;Y)148 = T(1;Y)2D;YL$ , which involves  $B^S Y$ , and the right end of  $XYL \cdot YS129-16$ , which carries  $y^+$  from  $y^+ Y$  between X and YL.

**synthesis:** Nicoletti.

**synonym:**  $Dp(1;Y)B^S w^+ y^+$ .

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.

**properties:** Meiotic behavior and viability apparently normal. Produces *Co* effect; covers *N*. Has in addition combined marker characteristics of  $B^S Y$  and  $y^+ Y$ .

$B^S w^+ Y$

**constitution:**  $B^S pfd^+ l(1)20Bb - su(f)^+ pn^+ - dm^+ KL \cdot bb^+ KS$ ; inferred from origin.

**origin:** X-ray-induced deletion of the majority of euchromatin ( $rb^+$  through  $mal^+$ ) from a recombinant carrying left end of the  $X^{PYD}$  element of  $T(1;Y)148 = T(1;Y)2D;YL$ , which involves  $B^S Y$ , and the right end of  $XYL \cdot YS$ .

**synthesis:** Nicoletti.

**synonym:**  $Dp(1;Y)B^S w^+$ .

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.

**properties:** Produces *Co* phenotype in  $X/B^S w^+ Y$  male and  $XX/B^S w^+ Y$  female. Covers many *N* deficiencies. *B* phenotype as in  $B^S Y$ .

$B^S y^+ Y$

**constitution:**  $B^S pdf^+ l(1)20Bb^+ - su(f)^+ y^+ ac^+ KL \cdot bb^+ KS$ .

**origin:** X-ray-induced deletion of the euchromatin ( $pn^+$  through  $mal^+$ ) from a recombinant carrying the left end of the  $X^{PYD}$  element of  $T(1;Y)148 = T(1;Y)2D;YL$ , which involves  $B^S Y$ , and the right end of  $XYL \cdot YS129-16$ , which carries  $y^+$  from  $y^+ Y$  between X and YL.

**synthesis:** Nicoletti.

**synonym:**  $Dp(1;Y)B^S y^+$ .

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.

Parker, 1968, DIS 43: 156.

**properties:** Detachments from  $C(1)RM/B^S y^+ Y$  females carry both markers ( $y^+$  and  $B^S$ ) or neither, so order not  $B^S Y y^+$  but  $B^S y^+ Y$  as given.

$B^S Y$

**constitution:**  $B^S pdf^+ l(1)20Bb^+ - su(f)^+ KL \cdot bb^+ KS$ .

**origin:** X-ray-induced deletion of the euchromatin (including  $mal^+$ ) from a recombinant carrying the left end of the  $X^{PYD}$  element of  $T(1;4)B^S = T(1;4)15F9-16A1;16A7-B1;102F$  and the right end of  $XYL \cdot YS$ .

**synthesis:** Brosseau.

**synonym:**  $YB^S, Dp(1;Y)B^S$ .

**references:** Brosseau and Lindsley, 1958, DIS 32: 116.

Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.

**properties:** Causes extreme *B* phenotype; presence readily scorable in  $+/+$ ,  $B/+$ , and  $+$  but not in *B* or  $B/B$  constitutions. Shown to carry  $pdf^+$  in addition to *B* from 16A (Grell) and  $l(1)20Bb^+$  through  $su(f)^+$  from region 20 (Schalet and Lefevre, 1973, Chromosoma 44: 183-202). Does not cover  $spa^{pol}$ . Viability and fertility of  $X/B^S Y$ ,  $X/B^S Y/B^S Y$ , and  $X/X/B^S Y$  good. Eyes of  $X/B^S Y$  detectably wider than those of  $X/B^S Y/B^S Y$ . Three euchromatic bands visible in salivary chromosomes (Nicoletti and Lindsley, 1960, Genetics 45: 1705-22). Prophase chromosomes show the presence of an extra Hochst-bright segment ( $B^S Xh$ ) appended to the end of YL and separated from it by a non-fluorescent junction gap ( $B^S Xh_j$ ) (Gatti

and Pimpinelli, 1983, *Chromosoma* 88: 349-73).

***B<sup>S</sup>Ybb<sup>-</sup>***

**constitution:**  $B^S pdf^+ l(1)20Bb^+ - su(f)^+ KL \cdot bb^- KS$ ; carries *Ybb<sup>-</sup>* deletion on *YS*.

**origin:** Derived from original *Ybb<sup>-</sup>* chromosome of Schultz by recombination with  $B^S Yy^+$ .

**synthesis:** Komma.

**references:** Endow, 1982, *Genetics* 102: 91-99.

Hawley and Tartof, 1983, *Genetics* 104: 63-80.

**properties:** *Y* chromosome deficient for most of the rDNA sequences, but carrying some sequences similar but not identical to those on *Ybb<sup>-</sup>* chromosome (Endow, 1982). Marked with  $B^S$ . Magnification induced as with *Ybb<sup>-</sup>*.

***B<sup>S</sup>Yy<sup>+</sup>***

**constitution:**  $B^S pdf^+ l(1)20Bb^+ - su(f)^+ KL \cdot bb^+ KS ac^+ - l(1)IAa^+$ .

**origin:** Recombination between  $B^S$  and  $bw^+ Yy^+$ .

**synthesis:** Brosseau.

**references:** Brosseau, 1958, *DIS* 32: 115-16.

Brosseau, Nicoletti, Grell, and Lindsley 1961, *Genetics* 46: 339-46.

Williamson, 1968, *DIS* 43: 157.

**properties:** *YL* in mitotic prophase same as that in  $B^S Y$ ; *YS* carries the Hoechst-bright segment (*Xhy<sup>+</sup>*) found on *YL* of  $y^+ Y$  (Gatti and Pimpinelli, 1983, *Chromosoma* 88: 349-73).

**other information:** Several derivatives of  $B^S Yy^+$  with newly induced mutant alleles of *y* have been described.

derivative	origin	ref <sup>α</sup>	phenotype
$B^S Yy^{61d}$	tritium	1	yellowish body, bellow bristles, wild type wings
$B^S Yy^{67}$	EMS	3	yellow body, dark bristles
$B^S Yy^{b12}$	X ray	2	wild-type body, yellow bristles

<sup>α</sup> 1 = Hughes and Hildreth, 1967, *DIS* 42: 86; 2 = Seattle-LaJolla *Drosophila* Laboratories, 1971, *DIS* 47 (supplement); 3 = Williamson, 1968, *DIS* 43: 65.

***B<sup>S</sup>Yy<sup>31d</sup>***

**constitution:**  $B^S pdf^+ l(1)20Bb^+ - su(f)^+ KL \cdot bb^+ KS ac^+ y^{31d} - l(1)IAa^+$ ; inferred from origin..

**origin:** Recombination between  $B^S Yy^+$  and  $In(1)sc^8, y^{31d} sc^8$  in a female.

**synonym:**  $Dp(1;Y)B^S y^{31d}$ .

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, *Genetics* 46: 339-46.

$B^S - Y$ : see  $y^+ Yv^+$

***B<sup>SV</sup>Y***

**origin:** Five X-ray-induced derivatives of  $B^S Y$ .

**synthesis:** Brosseau.

**synonym:**  $Dp(1;Y)B^{SV}$ .

**references:** Brosseau, 1960, *Genetics* 45: 979.

Moore, Procnier, Cross, and Grigliatti, 1979, *Nature* 282: 312-14.

**properties:** Show variegation for *B*. With a normal *X*, the eye phenotype is  $B^+$ , with *XY*, it is  $B^S$ , and with *XYL* or *YXS*, it is intermediate *B*. The enhancers of variegation,  $Df(2R)M41A1$  and  $E(var)7$ , shift the phenotype of  $B^{SV} Y$  flies toward normal (Brosseau, 1960), whereas deficiencies that wholly or partially remove *His* genes [ $Df(2L)TW65$ ,  $Df(2L)TW84$ , and  $Df(2L)TW161$ ] shift the phenotype toward  $B^S$  (Moore *et al.*).

**other information:** Eleven  $B^{SV} Yy^+$  chromosomes of independent origin (The Seattle-LaJolla *Drosophila* Laboratories, 1971, *DIS* 47, supplement) produce a larger eye phenotype in *XY/Y* males than in *X/Y* males.

***bw<sup>+</sup>Y***

**constitution:**  $KL (bw^+ - ba^+) bb^+ KS$ .

**origin:** Aneuploid segregant from  $Tp(2;Y)YL;58F1-59A2;60E3-F1$  (Gersh, 1956, *DIS* 30: 115; Nicoletti).

**synthesis:** Dempster.

**synonym:**  $Y:bw^+; Dp(2;Y)bw^+$ .

**references:** Muller, 1942, *DIS* 16: 64.

1951, *DIS* 25: 119.

1955, *DIS* 29: 146.

**properties:** A section of *2R* carrying  $bw^+$  inserted into *YL* proximal to *KL* (Baker, 1955, *DIS* 29: 101-03). Inserted segment known to carry normal alleles of *bw*, *mr*, *or*, *Fo*, *Pin*, *bs*, and *ba* but not *px*, *hy*, *crs*,  $M(2)58F$ , or  $M(2)60C$ . Males with two doses of  $bw^+ Y$  lethal.

***bw<sup>+</sup>Yy<sup>+</sup>***

**constitution:**  $KL (bw^+ - ba^+) bb^+ KS ac^+ - l(1)IAa^+$  (Baker, 1955, *DIS* 29: 101-03).

**synthesis:** Cooper.

**synonym:**  $sc^8 Ybw^+$ .

**references:** Cooper, 1951, *DIS* 26: 97.

***cn<sup>+</sup>Y***

**constitution:** Segment of *2R* carrying  $cn^+$  inserted onto *Y*.  
**origin:**  $Dp(2;Y)$  segregant from  $Tp(2;Y)C = Tp(2;Y)41A;43$ .

**references:** Sullivan, Kitos, and Sullivan, 1973, *Genetics* 75: 651-61.

**properties:** Covers *cn*.

***ct<sup>+</sup>y<sup>+</sup>Y***

**constitution:**  $KS cm^+ - ct^+ mal^+ - bb^+ (het) y^+ ac^+ KL \cdot KS$  (tentative).

**origin:** X-ray-induced deletion of the majority of the euchromatin from a recombinant carrying the left end of the  $X^F Y^D$  element of  $T(1;Y)131 = T(1;y)6E;YS$  and the right end of  $XYL \cdot YSI29-16$ .

**synthesis:** Johnson.

**synonym:**  $Dp(1;Y)ct^+ y^+$ .

**references:** Johnson and Judd, 1979, *Genetics* 92: 485-502.

Nicklas and Cline, 1983, *Genetics* 103: 617-31.

**properties:** Carries wild-type alleles of *y-ac*, *cm-ct*, and *mal-bb*.

*FR2*: see  $y^+ YL$

*Fragment 2*: see  $y^+ YL$

***l(1)1Ac<sup>+</sup>Y***

**constitution:**  $l(1)1Ac^+ KL bb^+ KS$ .

**origin:** Neutron-induced derivative of  $y^+ Y$ .

**synthesis:** Muller.

**synonym:**  $l(1)J1^+ Y$ .

**references:** Muller, 1954, *DIS* 28: 140-43.

Padilla and Nash, 1977, *Mol. Gen. Genet.* 155: 171-77.

**properties:** Like  $y^+ Y$  except that  $y^+$  and  $ac^+$ , but not  $l(1)1Ac^+$  deleted; other  $l(1)1A$  loci not tested.

$l(1)J1^+ Y$ : see  $l(1)1Ac^+ Y$

**pn<sup>-</sup>w<sup>+</sup>Y**

constitutioci: *kz<sup>+</sup>—spl<sup>+</sup> KL bb<sup>+</sup> KS*.

**pn<sup>-</sup>w<sup>+</sup>Y**

origin: X-ray-induced loss of *pn<sup>+</sup>* in *w<sup>+</sup>Y* chromosome.

synthesis: Lifschytz and Falk.

synonym: *Dp(1;Y)pn<sup>-</sup>w<sup>+</sup>*.

references: Lifschytz and Falk, 1969, *Genetics* 62: 343-52.

properties: Same as *w<sup>+</sup>Y* except for the absence of *pn<sup>+</sup>*.

**R(Y)bw<sup>+</sup>**

constitution: *KL (bw<sup>+</sup>—ba<sup>+</sup>) bb<sup>+</sup> KS*; closed to form a ring.

origin: X-ray-induced derivative of *bw<sup>+</sup>Yy<sup>+</sup>*.

synonym: *Y<sup>c</sup>bw<sup>+</sup>*; *MYR: Marked Y Ring*.

references: Oster and Lyengar, 1955, *DIS* 29: 159.

Stone, 1982, *Genetics* 102: 245-58.

properties: Ring shaped in mitotic metaphase. Lacks *y<sup>+</sup>* present in the progenitor chromosome. Introduction of *R(Y)bw<sup>+</sup>* via male into certain strains results in death of nearly all male progeny during early embryogenesis. About 10% of strains are subject to such killing of male offspring. Introduction of *R(Y)bw<sup>+</sup>* via female does not result in death of the sons (Oster, 1964, *Genetics* 50: 274). Inviability of *R(Y)bw<sup>+</sup>*-bearing embryos shown by Stone to depend on genotype of mother.

**R(Y)F: Ring Y Fillicidal**

constitution: Seven unmarked ring-Y chromosomes plus one marked with *su(f)<sup>+</sup>*.

origin: X- and  $\gamma$ -ray-induced derivatives of *B<sup>S</sup>Yy<sup>+</sup>*.

synthesis: Oster.

references: Oster, 1964, *Genetics* 50: 274 (abstr.).

Stone, 1982, *Genetics* 102: 245-58.

properties: Pre-blastoderm embryos produced by so-called ring-sensitive females and carrying *R(Y)F*, either paternal or maternal in origin, are disorganized and fail to develop; the genetic basis of maternal ring sensitivity is complex (Stone).

**R(YL)**

constitution: *KL* closed to form a ring.

origin: Selected on the basis of marker loss from singly or doubly marked *Y* chromosomes; recovery from *y<sup>+</sup>Y* requires two breaks; those recovered from *bw<sup>+</sup>Yy<sup>+</sup>* represent a rare subset of derivatives and are attributed to four breaks.

chromosome	origin	source	retains	ref <sup>α</sup>	synonym
<i>R(YL)</i>	spont	<i>y<sup>+</sup>Y</i>	<i>KL</i>	4	<i>Y<sup>cl</sup>, Y<sup>Lc</sup></i>

<i>R(YL)bb<sup>+</sup></i>	X ray	<i>bw<sup>+</sup>Yy<sup>+</sup></i>	<i>KL bb<sup>+</sup></i>	1, 3	<i>Y<sup>Lc</sup> .bb<sup>+</sup></i>

<sup>α</sup> 1 = Baker, 1955, *DIS* 29: 101-02; 2 = Baker, 1971, *Proc. Nat. Acad. Sci. USA* 68: 2472-76; 3 = Baker and Spofford, 1959, *Univ. Texas Publ.* 5914: 135-54 (fig.); 4 = Muller, 1948, *DIS* 22: 73-74.

properties: *R(YL)* does not respond to the ring sensitivity of certain maternal genotypes (Oster, 1964, *Genetics* 50: 274).

**R(YS)bw<sup>+</sup>**

constitution: (*bw<sup>+</sup>—ba<sup>+</sup>) bb<sup>+</sup> KS*; closed to form a ring.

Order of elements inferred from origin.

origin: X-ray-induced derivative of *bw<sup>+</sup>Yy<sup>+</sup>*.

synthesis: W. K. Baker.

synonym: *Y<sup>cS</sup>:bw<sup>+</sup>bb<sup>+</sup>*.

references: Baker and Spofford, 1959, *Univ. Texas Publ.* 5914: 135-54 (fig.).

properties: Ring shaped in mitotic metaphase. Lacks *y<sup>+</sup>* and *KL* from the treated chromosome. Shows some somatic and germinal instability.

**RspYy<sup>+</sup>**

constitution: *M(2)41A<sup>+</sup>—l(2)41Aa<sup>+</sup> KL bb<sup>+</sup> KS ac<sup>+</sup>—l(1)1Aa<sup>+</sup>*.

origin: X-ray-induced deletion of majority of euchromatin from *Y<sup>P</sup>2R<sup>D</sup>* element of *T(Y;2)cb25*, which has one break between *B<sup>S</sup>* and *KL* in *B<sup>S</sup>Yy<sup>+</sup>* and one proximal to *Rsp* in *2R*; retained euchromatin not characterized.

references: Lyttle and Ault, 1985, *Genetics* 110: s23.

phenotype: Two such products isolated, 9 and 11. Both appear to show preferential recovery, with *k* values >0.95, among progeny of *SD/+* males.

other information: See also *Tp(2;Y)Rsp*.

**sc<sup>V1</sup> · YS**

constitution: *l(1)1Aa<sup>+</sup>—sc<sup>V1</sup> bb<sup>+</sup> KS*; tentative.

origin: Spontaneous recombinant from *ln(1)sc<sup>V1</sup>/Y* male.

synthesis: Muller.

references: 1948, *DIS* 22: 73-74.

properties: Small, two-armed chromosome in mitotic metaphase. Survives in combination with *C(1)DX* and therefore carries *bb<sup>+</sup>*.

**sc<sup>V1</sup> · YS mwh<sup>+</sup>**

constitution: *l(1)1Aa<sup>+</sup>—sc<sup>V1</sup> bb<sup>+</sup> KS ve<sup>+</sup> mwh<sup>+</sup>*.

origin: Spontaneous derivative of *Dp(1;1)sc<sup>V1</sup>* and *T(Y;3)P6 = T(Y;3)62A-B*.

synthesis: Ripoll and Garcia-Bellido.

synonym: *Dp(1;Y;3)H*.

references: 1973, *DIS* 50: 177.

properties: Carries *YS* fertility factors plus *mwh<sup>+</sup>* and *ve<sup>+</sup>*. *y<sup>+</sup>* of the *sc<sup>V1</sup>* element variegates very strongly in *y* males; no *mwh* variegation.

**shi<sup>+</sup> Y**

origin: Deletions of the majority of the euchromatin from a recombinant comprising the left end of *T(1;Y)P12 = T(1;Y)13F1-2;YSy<sup>+</sup>* and the right end of *XYS · YLB<sup>S</sup>*.

synthesis: Poodry.

synonym: *Dp(1;Y)shi<sup>+</sup>*.

references: 1980, *DIS* 55: 210.

properties: Covers *sd*, *tc*, and *shi*; marked with *y<sup>+</sup>* and *B<sup>S</sup>*.

chromosome constitution

*shi<sup>+</sup> Y1* covers *Df(1)sd72b = Df(1)13F1;14B1* only in

the presence of *Dp(1;4)r<sup>+</sup> = Dp(1;4)14A1-2;16A1-2;102F2-3*

*\*shi<sup>+</sup> Y2*

chromosome constitution

**sh<sup>r</sup>Y3** covers *Df(1)sd72b*, but not *r* at 15A1**su(f)<sup>+</sup>Y****origin:** X ray induced in *T(1;Y;4)B<sup>S</sup>* males.**synthesis:** Wong, 1965.**synonym:** *Dp(1;Y)su(f)<sup>+</sup>*.**references:** Gethmann, 1967, DIS 42: 39.**properties:** Covers the deficiency in *C(1)RA60g* and carries *su(f)<sup>+</sup>*. *Tp4Y*: see *4Y* *TplY*: see *Dp(3;Y)Tpl* *TplYtrx<sup>D</sup>*: see *Dp(3;Y)trx<sup>D</sup>***w<sup>+</sup>y<sup>+</sup>Y****constitution:** *Pgd<sup>A</sup>—Sgs4<sup>+</sup>y<sup>+</sup>ac<sup>+</sup>KL·bb<sup>+</sup>KS*; inferred from origin and supposed constitution of *B<sup>S</sup>w<sup>+</sup>y<sup>+</sup>Y*.**origin:** X-ray-induced derivative of *B<sup>S</sup>w<sup>+</sup>y<sup>+</sup>Y*.**synthesis:** Nicoletti.**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.**properties:** Like *B<sup>S</sup>w<sup>+</sup>y<sup>+</sup>Y*, but with *B<sup>S</sup>* and *su(f)<sup>+</sup>* missing.**w<sup>+</sup>Y****constitution:** *Pgd<sup>A</sup>—Sgs4<sup>+</sup>y<sup>+</sup>KL·bb<sup>+</sup>KS*; inferred from origin. *Dp(1;Y)2D1-2;3D3-4;Y* (Judd *et al.*). Grell, R., 1971, Mol. Gen. Genet. 110: 218-37.

Baker, 1973, Dev. Biol. 33: 429-40.

**properties:** Tip of *In(1)sc*<sup>8</sup> including *l(1)IAa*<sup>+</sup> through *ac*<sup>+</sup>, but not *sc*, transferred to the tip of *YL* distal to *KL*. *YL* appears to be as long as the *X* in metaphase (Hannah); a large Hoechst-bright segment (*y*<sup>+</sup>*Xh*) appended to the end of *YL* and separated from it by a short non-fluorescent gap (*y*<sup>+</sup>*Xhj*) (Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73). Detachment studies show that *bb*<sup>+</sup> from *In(1)sc*<sup>8</sup> has not been transferred to *YL* (Parker). Has dominant *Hw* effect that produces one or more humeral microchaetae in *X/y*<sup>+</sup>*Y* male and *X/X/y*<sup>+</sup>*Y* female and one or more hairs in the membrane of the second and third posterior cells of wing (Schultz) and extra veins, especially associated with the posterior crossveins (Williamson, 1968, DIS 43: 157) in *X/y*<sup>+</sup>*Y/y*<sup>+</sup>*Y* males. *y/y*<sup>+</sup>*Y* males show some variegation for *y* without enhancers of variegation and considerable *y* variegation in the presence of *E(var)7* and *E(var)21* (Hadorn *et al.*, 1970; Grell, 1971).

**other information:** Derivatives with mutant alleles of *y* have been recovered.

<sup>α</sup> 1 = Hinton and Schmidt, 1956, DIS 30: 121; 2 = Lüning, 1953, DIS 27: 58; 3 = Meyer, 1959, DIS 33: 97.

***y*<sup>+</sup>*Ydor*<sup>+</sup>**

**constitution:** *l(1)IAa*<sup>+</sup>—*dor*<sup>+</sup> *fog*<sup>+</sup>—*su(f)*<sup>+</sup> *KS KL y*<sup>+</sup>.  
**origin:** X-ray-induced deletion in *X* euchromatin of *XYS·YL*, *y*<sup>2</sup> *su(w<sup>a</sup>) w<sup>a</sup> KS · KL y*<sup>+</sup> male.  
**synthesis:** Holm.  
**synonym:** *Dp(1;Y)dor*<sup>+</sup> *y*<sup>+</sup>.  
**references:** Holm, 1968, DIS 43: 143.  
**properties:** Reduced body size and *Hw* effect in males. Body size normal and little *Hw* effect in compound-X-bearing females with the duplication. Duplication carries mutant alleles, *y*<sup>2</sup> and *su(w<sup>a</sup>)* and a wild-type allele of *y*.

***y*<sup>+</sup>*YL***

**constitution:** *l(1)IAa*<sup>+</sup>—*ac*<sup>+</sup> *KL bb*<sup>+</sup>.  
**origin:** Spontaneous product from *YSX·YL*, *In(1)EN*, *KS y·KL y*<sup>+</sup> female.  
**synthesis:** Novitski.  
**synonym:** *FR2: Fragment 2*.  
**references:** Novitski, 1952, Genetics 37: 270-87.  
**properties:** Has subterminal centromere and extremely short second arm in mitotic metaphase. Constitution confirmed by analysis of detachments with *C(1)RA*, all of which appear to result from exchange between the interstitial heterochromatin of the compound and the *bb*<sup>+</sup>-bearing short arm of *y*<sup>+</sup>*YL* (Sandler, 1954, DIS 28: 153-54).

***y*<sup>+</sup>*Ymal*<sup>+</sup>1**

**constitution:** *l(1)IAa*<sup>+</sup>—*ac*<sup>+</sup> *KL·M(1)I8C*<sup>+</sup>—*su(f)*<sup>+</sup> *bb*<sup>+</sup> *KS*.  
**origin:** X-ray-induced euchromatic deletion in *YSX·YL*, *In(1)EN*, *y·y*<sup>+</sup>.  
**references:** Schalet, 1963, DIS 38: 82.

***y*<sup>+</sup>*Ymal*<sup>+</sup>2**

**constitution:** *l(1)IAa*<sup>+</sup>—*ac*<sup>+</sup> *KL·l(1)carot2*<sup>+</sup>—*su(f)*<sup>+</sup> *bb*<sup>+</sup> *KS*.  
**origin:** Same as *y*<sup>+</sup>*Ymal*<sup>+</sup>1.

**references:** Schalet, 1963, DIS 38: 82.

**other information:** A number of X-ray-induced *mal* or *mal*<sup>-</sup> derivatives partially characterized in table below (Schalet and Finnerty, 1968, DIS 43: 65-66; Chovnick, Finnerty, Schalet, and Duck, 1969, Genetics 62: 145-60).

derivative	characterization
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>102</sup>	deficient for <i>l(1)carot2—mal</i> ; retains <i>l(1)19Ec</i> <sup>+</sup>
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>106</sup>	noncomplementing mutation of <i>mal</i>
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>107</sup>	deficient for <i>l(1)carot2—eo</i>
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>108</sup>	deficient for <i>l(1)carot2—unc</i> ; retains <i>lfr</i> <sup>+</sup> ; breakpoint at 19E8-F1 (Schalet and Lefevre, 1973, Chromosoma 44: 183-200)
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>113</sup>	deficient for <i>sw—l(1)19Ec</i> ; retains <i>oi</i> <sup>+</sup> to the left and <i>unc</i> <sup>+</sup> to the right
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>116</sup>	complementing mutation of <i>mal</i>
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>118</sup>	deficient for <i>mal—su(f)</i> ; retains <i>mel</i> <sup>+</sup> to the left
<i>y</i> <sup>+</sup> <i>Ymal</i> <sup>126</sup>	deficient for <i>l(1)carot2—l(1)19Ff</i> ; <i>eo</i> <sup>+</sup> retained; breakpoint at 19F6-20A1 (Schalet and Lefevre)

***y*<sup>+</sup>*Yv*<sup>+</sup>**

**origin:** Two X-ray-induced losses of *B*<sup>S</sup> from *y*<sup>+</sup>*Yv*<sup>+</sup>*B*<sup>S</sup> #1 (Chovnick).  
**synonym:** *B*<sup>S</sup>*Y*.

***y*<sup>+</sup>*Yv*<sup>+</sup>*B*<sup>S</sup>**

**constitution:** *l(1)IAa*<sup>+</sup>—*ac*<sup>+</sup> *KL bb*<sup>+</sup> *KS dy*<sup>+</sup>—*l(1)9Fe*<sup>+</sup> (*KL?*) *su(f)*<sup>+</sup>—*l(1)20Bb pdf*<sup>+</sup> *B*<sup>S</sup>.  
**origin:** X-ray-induced deletion of the majority of the euchromatin from the recombinant carrying the left end of the *X<sup>P</sup>Y<sup>D</sup>* element of *T(1;Y)124 = T(1;Y)(9F;YL)* and the right end of *XYS·Y1110-8*.  
**synthesis:** Chovnick.  
**references:** Chovnick, 1968, DIS 43: 170.  
**properties:** Three independent isolations; cover *l(1)9Fe* through *v* but not *m* according to Chovnick; #3, however, covers through *dy* but not *fw* (Schalet, 1969, DIS 44: 123). Lethal in combination with *Basc* in males.

***y*<sup>+</sup>*Yy*<sup>+</sup>**

**constitution:** *l(1)IAa*<sup>+</sup>—*ac*<sup>+</sup> *KL bb*<sup>+</sup> *KS ac*<sup>+</sup>—*l(1)IAa*<sup>+</sup>.  
**origin:** X ray induced.  
**references:** Parker and Busby, 1972, Mutat. Res. 16: 49-58.  
**properties:** Carries small duplication, marked with *y*<sup>+</sup> and *ac*<sup>+</sup>, on the end of each arm. Flies with two *y*<sup>+</sup>*Yy*<sup>+</sup> chromosomes show a pronounced *Hw* phenotype.

***y*<sup>2</sup>*Y***

**origin:** X-ray- (Lefevre) or  $\gamma$ -ray-induced (Gorelova) deletions of majority of euchromatin from *XYL·YL*, *y*<sup>2</sup> *su(w<sup>a</sup>) w<sup>a</sup>*.  
**synonym:** *Dp(1;Y)y*<sup>2</sup>.

Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90.

**properties:** Covers *l(1)IAa-l(1)2Ad*; partially covers *sta* (Aizenzon and Belyaeva, 1982). Marked with *y<sup>59b</sup>*, which resembles *y<sup>1</sup>*.

**y<sup>66d</sup>**

**constitution:** *YSYL·YS, KS bb<sup>+</sup> y<sup>+</sup> KL·bb<sup>+</sup> KS* (Williamson).

**origin:** Spontaneous derivative of *XYL·YS129-16*.

**synthesis:** Parker.

**references:** Parker, 1968, DIS 43: 156.

Williamson, 1973, DIS 50: 102.

**properties:** Duplicated for *KS* and the nucleolus organizer, the two nucleoli being connected by *YL*. *y scY66d* males are fertile and show more pronounced *y* variegation than *XYL·YS129-16/0* males. *Y66d*, like *XYL·YS129-16*, does not cover *l(1)IAc*; it carries the *y<sup>+</sup>* marker in an interstitial position (Parker, 1968).

**YB<sup>S</sup>:** see **B<sup>S</sup>Y**

**Ybb**

This is a group of Y chromosomes that carry insufficient numbers of ribosomal genes to produce wild-type bristle morphology. They are characterized by having 125 or fewer ribosomal cistrons compared to 225 in wild-type Y chromosomes. Since numbers of ribosomal cistrons are unstable and subject to change by magnification or reduction, the estimates of cistron number presented here represent historical observations and need not reflect current compositions. The distinction between chromosomes designated *Ybb<sup>-</sup>* and those designated *Ybb* not always based on objective criteria; however, *Ybb* chromosomes are generally hemizygous viable whereas *Ybb<sup>-</sup>* chromosomes are generally hemizygous lethal [e.g., in *In(1)sc<sup>4L</sup>sc<sup>8R</sup>/Ybb<sup>-</sup>*] and therefore have few if any ribosomal cistrons. The original *Ybb<sup>-</sup>* was shown to have a foreshortened short arm; despite this cytological deficiency, however, derivative chromosomes with increased numbers of ribosomal genes have been recovered. Chromosomes designated in both ways are included in the following table.

chromosome	origin	discoverer	ref <sup>α</sup>	phenotype	rDNA gene #
<b>Ybb</b>	spont	Bridges, 1926	3		
<b>Ybb<sup>-</sup></b>		Schultz, 33k8	3	YS one third normal length

<sup>α</sup> 1 = Atwood, 1969, Genetics 61: 319-27; 2 = Baker, 1971, Proc. Nat. Acad. Sci. USA 68: 2472-76; 3 = CP627; 4 = Endow, 1982, Genetics 102: 91-99; 5 = Hawley and Tartof, 1985, Genetics 109: 691-700; 6 = Procnier and Williamson, 1974, Dev. Biol. 39: 198-209; 7 = Ritossa, 1968, Proc. Nat. Acad. Sci. USA 59: 1124-31; 8 = Robbins, 1981, Genetics 99: 443-59; 9 = Spear, 1974, Chromosoma 48: 159-79; 10 = Swanson, 1987, Genetics 115: 271-76; 11 = Tartof, 1973, Genetics 73: 57-71.

<sup>β</sup> Derived from the original *Ybb<sup>-</sup>*.

<sup>γ</sup> Estimated at 100 non-functional genes (Ritossa), no ribosomal genes (Spear) and 10-12 ribosomal genes, some of them with type 2 repeats (Endow).

<sup>δ</sup> Estimates of Ritossa.

<sup>ε</sup> Estimate of Tartof.

<sup>ζ</sup> Originally lethal with *In(1)sc<sup>4L</sup>sc<sup>8R</sup>*, but phenotype can be changed to almost *bb<sup>+</sup>* by magnification.

<sup>η</sup> Regularly occurring product of *Rex*-induced mitotic exchange in progeny of crosses of *Rex/+* or *Rex/Rex* females to *YSX·YL/0* males; *X/Ybb<sup>Rex</sup>* males fertile.

<sup>θ</sup> Slight *bb* according to Hawley and Tartof, but strong *bb* according to Ritossa. Suppresses *In(1)w<sup>m4</sup>* position-effect variegation.

**YKpn**

**constitution:** Y carrying the tip of *3R*, presumably *Y<sup>P3D</sup>* element of a *T(Y;3)*; Y arm not specified.

**origin:** X ray induced.

**synthesis:** Falk and Shamay.

**synonym:** *Dp(3;Y)awd<sup>+</sup>* [= *Dp(3;Y)Kpn<sup>+</sup>*].

**references:** Lifschytz and Falk, 1969, Genetics 62: 353-58.

**properties:** Carries *ca<sup>+</sup>* and *Kpn<sup>+</sup>*.

**Ymal<sup>+</sup>**

**constitution:** *KL·sw<sup>+</sup>—su(f)<sup>+</sup> bb<sup>+</sup> KS*; inferred from origin.

**origin:** X-ray-induced deletion of majority of euchromatin [*l(1)IAa<sup>+</sup>—car<sup>+</sup>*] from *YSX·YL, In(1)EN*.

**synthesis:** E. H. Grell.

**references:** Brosseau, Nicoletti, Grell, and Lindsley, 1961, Genetics 46: 339-46.

**other information:** Two such chromosomes recovered, only one of which was kept.

**Y<sup>c</sup>bw<sup>+</sup>:** see **R(Y)bw<sup>+</sup>**

*Y<sup>cl</sup>*: see *R(YL)*

*Y<sup>CL</sup>:bb<sup>+</sup>*: see *R(YL)bb<sup>+</sup>*

**YL·y<sup>+</sup>**

**constitution:** *KL·(bb<sup>+</sup>) ac<sup>+</sup>—l(1)IAa<sup>+</sup>*.

**origin:** Spontaneous recombination between *YS* and the distal heterochromatin of *In(1)sc<sup>8</sup>* in males.

**references:** Lindsley, 1955, Genetics 40: 24-44.

Ritossa, 1973, Proc. Nat. Acad. Sci. USA 70: 1950-54.

**properties:** One of seven independent cases was deficient for *bb* (Lindsley).

*YLC*: see *R(YL)*

**Yst: Y sterile**

**constitution:** *KL·bb*; in metaphases, the *Y* appears as a rod about the same length as *YL*.

**origin:** Spontaneous; recovered in a *w<sup>e</sup> bb<sup>l</sup>* female that was unexpectedly viable, *bb*, and fertile.

**synthesis:** Bridges, 1926.

**references:** CP552.

**properties:** Males with *Yst* sterile in the absence of a *YS* or a normal *Y*. *bb<sup>l</sup>/bb<sup>l</sup>Yst* females fertile and less extreme *bb* than *bb/bb<sup>l</sup>* females.

**Ysu(f)<sup>-</sup>**

**constitution:** *KL·l(1)20Ac<sup>+</sup>—sw<sup>+</sup> bb<sup>+</sup> KS*. The *Y* carries at least one dose of *bb<sup>+</sup>*.

**origin:** Spontaneous derivative of *Ymal<sup>+</sup>*.

**synonym:** *Dp(1;Y)su(f)<sup>-</sup>*.

**references:** Rahman and Lindsley, 1981, DIS 56: 108.

**properties:** Deficient for *uncl—su(f)*; carries *sw<sup>+</sup>—l(1)20Ac<sup>+</sup>*.

**YS8**

**constitution:** *bb<sup>+</sup> KS*; tentative.

**origin:** Spontaneous derivative of *bw<sup>+</sup>Yy<sup>+</sup>* recovered from *R(1)l/bw<sup>+</sup>Yy<sup>+</sup>* male.

**synthesis:** W. K. Baker.

**synonym:** *YS:bb<sup>+</sup>-8*.

**references:** Baker and Spofford, 1959, Univ. Texas Publ. 5914: 135-54.

**properties:** A small, two-armed chromosome in mitotic metaphase. Lacks *y<sup>+</sup>*, *bw<sup>+</sup>*, and *KL* present in the progenitor chromosome.

**YSy<sup>+</sup>**

**constitution:** *bb<sup>+</sup> KS ac<sup>+</sup>—l(1)IAa<sup>+</sup>*.

**origin:** Derivatives of *bw<sup>+</sup>Yy<sup>+</sup>*.

**references:** Baker, 1955, DIS 29: 101-12.

Baker and Spofford, 1959, Univ. Texas Publ. 5914: 135-54 (fig.).

AUTOSYNAPTIC CHROMOSOMES

Pericentric-inversion heterozyotes may be recovered and maintained in either of two forms (Craymer, 1981, Genetics 99: 75-97). The conventional heterosynaptic form can be converted to two reciprocal autosynaptic elements by recombination between the inverted segment and a normal homologue. In this sense autosynaptic stocks can be regarded as pericentric inversion heterozyotes in which the two breakpoints have been separated onto homologous centromeres. Craymer termed the complementary products of exchange levosynaptic (*LS*) and dextrosynaptic (*DS*) elements, as the elements carry homologous synapsed regions from the left or the right arm respectively. The levosynaptic element contains two copies of the portion of the autosome to the left of the inversion, one copy of the inversion and no copy of the segment to the right of the inversion; similarly the dextrosynaptic element carries two copies of the region to the right of the inversion, one copy of the inverted region and no copy of the region to the left of the inversion. Heterosynaptic and autosynaptic configurations are interconvertible by single exchange within the inverted segment. In general, reciprocal autosynaptic elements from the same pericentric inversion are carried together; the complex is designated  $AS( ) = LS( )/DS( )$ . Craymer describes a number of methods for generating autosynaptic complexes and indicates their utility in genetic experiments. Gubb, McGill, and Ashburner (1988, Genetics 119: 377-390) have shown how particular autosynaptic stocks can be used to select sets of independently derived *LS* and *DS* elements resulting from interarm translocations between homologous chromosomes; both  $\gamma$ -rays and hybrid-dysgenesis were used to generate such rearrangements. Such an approach selects for autosynaptic chromosomes with breakpoints in the vicinity of those of the selecting  $AS( )$ . In the  $LS( )$  and  $DS( )$  chromosomes, those designated with *D* followed by a number were  $\gamma$  ray induced; those with either *P* or *S* are from dysgenic males crossed to autosynaptic-complex-bearing females. Conventions for indicating the allelic content of autosynaptic elements are discussed by Gubb *et al.*

Molecular map of *P* (W. R. Engels)

## TRANSPOSABLE ELEMENTS

by: D. J. Finnegan

At least ten percent of the genome of *Drosophila melanogaster* is made up of transposable elements. These are all moderately repeated sequences. There are about fifty families of such elements and these may be divided into groups according to their DNA topologies and putative mechanisms of transposition.

The largest group contains the *copia*-like elements, named after one of the first elements of this type to be discovered. They are similar to retroviral proviruses and have long terminal direct repeats, LTRs, and a long open reading frame that encodes an amino acid sequence related to viral reverse transcriptases. These elements are believed to transpose by a mechanism related to a retroviral life cycle. Eighteen of the elements listed below are of this type (*17.6*, *297*, *1731*, *3S18*, *412*, *BEL*, *blood*, *copia*, *flea*, *gypsy*, *H.M.S. Beagle*, *mdg1*, *mdg2*, *micropia*, *NEB*, *opus*, *roo*, and *springer*).

Six elements, *D*, *F*, *G*, *I*, *Doc*, and *jockey*, are believed to be members of a second class of elements, sometimes called non-viral retrotransposons, that are also believed to transpose by reverse transcription of an RNA intermediate. They have an A-rich sequence at the 3' end of one strand, but no terminal repeats, and encode putative reverse transcriptases. These elements are variable in length and are often truncated at the 5' end of the strand with the A-rich sequence.

*P*, *pogo*, *hobo*, and *HB* elements have short terminal inverted repeats and are believed to transpose directly from DNA to DNA. The same may be true of *FB* and *BS* elements that have long terminal inverted repeats.

The information given below relates to specific elements, more general discussions can be found in the review by Finnegan and Fawcett [1986, *Oxford Surveys of Eukaryotic Genes* (N. McClean, ed.). Oxford University Press, Oxford, vol. 3, pp. 1-64] or in articles in "Mobile DNA" [1989, (Berg and Howe, eds.). American Society for Microbiology, Washington]. The restriction maps, terminal sequences and lengths of target-site dupli-

cations are given to aid in the identification of elements encountered during chromosome walks or in the analysis of molecular lesions associated with particular mutations. At least half of all spontaneous mutations in *Drosophila melanogaster* are due to insertions of transposable elements. The terminal sequences shown for an element that is variable in length may not be found at the ends of all copies of that element.

### 17.6

**length:** 7.4 kilobases (Saigo *et al.*, 1984).

**target site duplication:** Four base pairs (Kugimya *et al.*; Inouye *et al.*).

**copy number:** Forty (Kugimya *et al.*; 1983).

**references:** Saigo, Millstein, and Thomas, 1981, Cold Spring Harbor Symp. Quant. Biol. 45: 619-28.

Kugimya, Ikenaga, and Saigo, 1983, Proc. Nat. Acad. Sci. USA 80: 3193-97.

Saigo, Kugimya, Matsuo, Inouye, Yoshioka, and Yuki, 1984, Nature 312: 659-61.

Inouye, Yuki, and Saigo, 1986, Nature 310: 332-33.

**comments:** First described by Saigo *et al.* as a sequence inserted into histone genes and hybridizing to *297* elements. The sequence of the LTR shown here was reported by Kugimya *et al.*. A complete *17.6* element has been sequenced by Saigo *et al.* (1984); the map shown here is derived from this sequence. There are no sites for the enzymes *Ava*I, *Kpn*I, *Sac*I, *Sma*I, or *Xba*I. The sequences of the LTRs of *17.6* and *297* elements are similar. Heteroduplexes between *17.6* and *297* elements show a 1.7 kb region of homology between their right-hand ends (Kugimya *et al.*). All insertions studied so far are associated with duplications of the sequence ATAT.

**restriction map (17.6):**

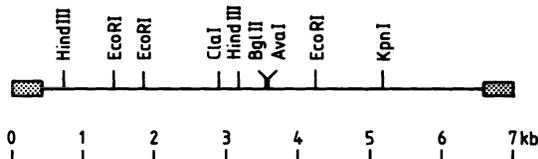

**297**

**length:** 7 kilobases (Inouye *et al.*).  
**target site duplication:** Four base pairs (Ikenaga and Saigo; Spradling and Rubin).  
**copy number:** Approximately 30 (Potter *et al.*).  
**references:** Potter, Brorein, Dunsmuir, and Rubin, 1979, *Cell* 17: 415-27.  
 Ikenaga and Saigo, 1981, *Proc. Nat. Acad. Sci. USA* 79: 4143-47.  
 Spradling and Rubin, 1981, *Ann. Rev. Genet.* 15: 219-64.  
 Kugimya, Ikenaga, and Saigo, 1983, *Proc. Nat. Acad. Sci. USA* 80: 3193-97.  
 Inouye, Yuki, and Saigo, 1986a, *Eur. J. Biochem.* 154: 417-25.  
 Inouye, Saigo, Yamada, and Kuchino, 1986b, *Nucl. Acids Res.* 14: 3031-43.  
**comments:** 297 elements were first described by Potter *et al.* but were originally identified by Wensink and Rubin as being complementary to abundant polyA RNA in tissue-culture cells. The sequence of an LTR shown below was reported by Ikenaga and Saigo. A complete element has been sequenced by Inouye *et al.* (1986a) and the restriction map shown here is based on that sequence. There are no sites for enzymes BamHI, PstI, SalI, SmaI or XhoI. Insertions are preferentially at the sequence ATAT (Spradling and Rubin). The sequences of the LTR's of 297 and 17.6 elements are similar, and heteroduplexes between these elements show a region of 1.7 kb of homology at the right-hand ends of each (Kugimya *et al.*). Inouye *et al.* (1986b) have identified a serine tRNA as the probable primer for reverse transcription.

 Shepherd and Finnegan, 1984, *J. Mol. Biol.* 180: 21-40.

Chang, Wisely, Huang, and Voelker, 1986, *Mol. Cell. Biol.* 6: 1520-28.  
 Yuki, Ishimaru, Inouye, and Saigo, 1986a, *Nucl. Acids Res.* 14: 3017-29.  
 Yuki, Inouye, Ishimaru, and Saigo, 1986b, *Eur. J. Biochem.* 158: 403-10.  
 Micard, Couderc, Sobrier, Girard, and Dastugue, 1988, *Nucl. Acids Res.* 16: 455-70.

**comments:** First described as being complementary to abundant poly(A)+ RNA in tissue culture cells (Rubin *et al.*). The sequence of the LTR shown here was reported by Will *et al.*; rare 412 elements have 571 base-pair LTRs, the first 482 base pairs of which correspond to the sequence presented (Will *et al.*). The map shown here is adapted from that published by Shepherd and Finnegan; there are no sites for the enzymes BamHI, SacI, or SalI. The sequence of a complete element has been reported by Yuki *et al.* (1986 a and b). Fourteen of the 18 bases of the putative primer binding sites of 412 and *mdg1* elements are identical, as are 27 bases adjacent to their left-hand LTRs (Will *et al.*). Yuki *et al.* (1986b) have suggested that an arginine tRNA may serve as the primer for reverse transcription of 412 RNAs. Finnegan *et al.* and Micard *et al.* have reported that the majority of 412 transcription is from right to left in tissue culture cells. This would produce antisense RNAs. Prosser and Finnegan have found that both strands of 412 are represented in polyA RNA from adults. Micard *et al.* have shown that the level of 412 transcription in tissue-culture cells is decreased in the presence of 20-hydroxyecdysone. The phenotypes of some mutations associated with 412 insertions are affected by *su(s)* mutations (Yuki *et al.*, 1986a).

 TTAAAACGGA CTTGTGTTCT GAATTGGAGT TCATCATTAC A 481

**restriction map (412):**

**1731**

**length:** 4.6 kilobases (Peronnet *et al.*).  
**target site duplication:** Five base pairs (Peronnet *et al.*).  
**copy number:** Ten (Peronnet *et al.*).  
**references:** Peronnet, Becker, Becker, d'Auriol, and Best-Belpomme, 1986, *Nucl. Acids Res.* 14: 9017-33.  
 Fourcade-Peronnet, d'Auriol, Becker, Galivert, and Best-Belpomme, 1988, *Nucl. Acids Res.* 16: 6113-25.  
**comments:** The first 1731 element was identified because its transcription in tissue-culture cells is reduced in the presence of 20-hydroxyecdysone (Peronnet *et al.*). The map, and LTR sequence shown here are taken from Peronnet *et al.*; the sequence of a complete 1731 element has been reported by Fourcade-Peronnet *et al.*; the coding capacity of this element is more closely related to that of *copia* than of longer *copia*-like elements such as 17.6. Reverse transcription of 1731 RNA may be primed by a fragment of the initiator methionine tRNA (Fourcade-Peronnet *et al.*).

**restriction map (1731):**

**3S18**

**length:** 6.5 kilobases (Bell *et al.*, 1985).

**target site duplication:** Five base pairs (O'Hare *et al.*).

**copy number:** Approximately 15 (Bell *et al.*, 1985).

**references:** Fabijanski and Pellegrini, 1982, Nucl. Acids Res. 10: 5979-91.

Mattox and Davidson, 1984, Mol. Cell. Biol. 4: 1343-53.

O'Hare, Murphy, Levis, and Rubin, 1984, J. Mol. Biol. 180: 437-55.

Bell, Bogardus, Schmidt, and Pellegrini, 1985, Nucl. Acids Res. 13: 3861-71.

**comments:** First identified as an insertion within the non-transcribed spacer of an rDNA repeat (Bell *et al.*; Fabijanski and Pellegrini). Restriction and Southern hybridization data suggest that this element is flanked by direct repeats about 500 base pairs long (Bell *et al.*). A 3S18 probe hybridized to twelve euchromatic sites and the chromocenter of polytene chromosomes from a cross between *gt<sup>1</sup>* and *gt<sup>X11</sup>* strains. The map shown here as been taken from those published by Bell *et al.* and Mattox and Davidson. There are no sites for enzymes BglII, SmaI, or XbaI. The sequences at the ends of the 3S18 and BEL elements are the same suggesting that these elements are closely related if not the same (O'Hare, unpublished). The terminal sequences are from the element associated with the *w<sup>zm</sup>* mutation (O'Hare *et al.*).

**BEL**

**length:** 7.3 kilobases.

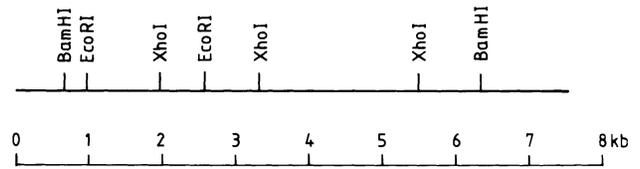

**copy number:** Twenty five.

**references:** Goldberg, Sheen, Gehring, and Green, 1983, Proc. Nat. Acad. Sci. USA 80: 5017-21.

**comments:** First described as an insertion associated with the *w<sup>a4</sup>* mutation. *In situ* hybridization experiments indicate that BEL elements are located at about twenty five sites throughout the genome, and that their distribution differs from one strain to another. The ends of this element hybridize to each other. Goldberg *et al.* have suggested that it is a *copia*-like elements, although it is not known whether the terminal repeats are direct or

inverted. The sequences at the ends of BEL and 3S18 elements are the same, suggesting that these elements are closely related if not the same (O'Hare, unpublished).

**restriction map (BEL):**

**blood**

**length:** 6 kilobases.

**target site duplication:** Four base pairs.

**copy number:** Nine to fifteen.

**references:** Bingham and Chapman, 1986, EMBO J. 5: 3343-51.

**comments:** First identified as an insertion associated with the mutation *w<sup>bl</sup>*. The putative primer binding site is similar to those for *412* and *mdg1* elements, suggesting that the primer may be an arginine tRNA.

 Yoshioka, Honma, Zushi, Kondo, Togashi, Miyake, and Shiba, 1990, EMBO J. (in press).

**comments:** First described by Finnegan *et al.* as a sequence complementary to abundant polyA+ RNA in tissue culture cells. The map is taken from the sequence of Mount and Rubin, and the sequence of the LTR is from Levis *et al.* The sequences of complete *copia* elements have been published by Mount and Rubin and by Emori *et al.* Virus-like particles containing full length *copia* RNAs have been found in tissue culture cells by Shiba and Saigo. The major protein in these particles is translated from a 2 kb spliced mRNA (Yoshioka *et al.*). The sequence of this mRNA has been determined by Miller *et al.* This protein is released from the primary translation product by autocatalytic cleavage (Yoshioka *et al.*). Kikuchi *et al.* have shown that a fragment of the initiator methionine tRNA acts as a primer for reverse transcription of *copia* RNA in these particles. Sequences essential for *copia* expression are located on either side of the major transcriptional start sites (Sneddon and Flavell).

**length:** 7 kilobases.  
**references:** Karch, Weiffenbach, Peifer, Bender, Duncan, Celnickier, Crosby, and Lewis, 1985, Cell 43: 81-96.  
**comments:** Only one *Delta88* element has been described. This is associated with the *iab8,9<sup>tuh3</sup>* mutation. It is a moderately repeated element.

**restriction map (Delta88):**

**Doc**

**length:** Variable, up to 5 kilobases (Schneuwly *et al.*).  
**target site duplication:** six to thirteen kilobases (Schneuwly *et al.*; O'Hare *et al.*).  
**references:** Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, Science 221: 23-29.  
 O'Hare, Levis, and Rubin, 1983, Proc. Nat. Acad. Sci. USA 80: 6917-21.  
 Schneuwly, Kuroiwa, and Gehring, 1987, EMBO J. 6: 201-06.  
 Driver, Lacey, Cullingford, Mitchelson and O'Hare, 1989, Mol. Gen. Genet. 220: 49-52.

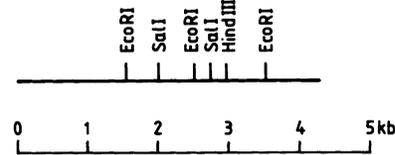

**comments:** First described as an insertion in the BXC region on a chromosome carrying the *bx<sup>3</sup>* mutation, although it is not responsible for the mutant phenotype (Bender *et al.*). The map shown here is of this element. Schneuwly *et al.* have found that *Doc* elements lie at both break points of the *Antp<sup>73b</sup>* inversion; these elements lie in inverted orientation, and the inversion probably resulted from recombination between them. The element reported by O'Hare *et al.* as being associated with the *w<sup>1</sup>* mutation is probably a *Doc* element. Driver *et al.* have cloned seven *Doc* elements and have determined the sequences at their termini; their 5' ends are variable, but their 3' ends are conserved.

Di Nocera, Digan, and Dawid, 1983, J. Mol. Biol. 168: 715-27.

Di Nocera and Casari, 1987, Proc. Nat. Acad. Sci. USA 84: 5843-47.

**comments:** First described by Dawid *et al.* as an element within a copy of the type I 28S rDNA insertion sequence. The termini shown here are of 101F, the longest *F* element to have been cloned (Di Nocera *et al.*). The map is the consensus for *F* elements (Di Nocera *et al.*). There are no sites for the enzymes ClaI, PvuI, or XhoI. The complete base sequence of a 3.5 kilobase element, *Fw*, has been reported by Di Nocera and Casari. The element *Jiminy*, which was identified within the BXC by Bender *et al.*, is probably an *F* element.

**length:** Variable (Truett *et al.*).

**target site duplication:** Nine base pairs (Truett *et al.*).

**copy number:** Thirty (Truett *et al.*).

**references:** Ising and Ramel, 1976, The Genetics and Biology of *Drosophila* (M. Ashburner and E. Novitski, eds.). Academic Press, London, Vol. 1b, pp. 947-54.

Potter, Truett, Phillips, and Maher, 1980, Cell 20: 639-47.

Truett, Jones, and Potter, 1981, Cell 24: 753-63.

Levis and Rubin, 1982, Cell 30: 543-50.

Potter, 1982, Nature 297: 201-204.

Paro, Golberg, and Gehring, 1983, EMBO J. 2: 853-60.

Smyth, Templeton and Potter, 1989, EMBO J. 8: 1887-91.

**comments:** First described as elements containing inverted repeat sequences (Potter *et al.*, 1980). The inverted repeats at the ends of *FB* elements vary in length; they are made up of different numbers of tandemly repeated sequences, with a maximum repeat length of 155 base pairs (Truett *et al.*; Potter *et al.*, 1982). The DNA between the inverted repeats also varies. The element *FB4* has been sequenced entirely (Potter *et al.*, 1982). Its restriction map and terminal sequences are shown. The only *HinfI* and *TaqI* sites marked, are those that lie in the inverted repeats. There are no sites for the enzymes *AvaI*, *BamHI*, *EcoRI*, *HpaI*, *PstI*, *SacI*, *Sall*, *SmaI*, or

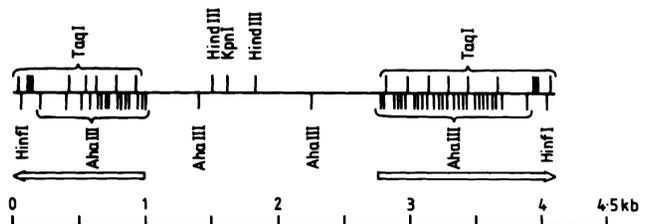

*XhoI*. Potter *et al.* (1982) have suggested that another transposable element, *HBI*, lies between coordinates 1.1 and 2.75 of *FB4*. The sequence of the central region of an *FB* element related to *FB-w<sup>c</sup>*, the element responsible for the *w<sup>c</sup>* mutation, has been determined (Smyth, Templeton and Potter). It contains two long open reading frames in one strand, and these authors suggest that they may encode functions required for transposition of *FB* elements. They have evidence that the product of the first open reading frame is a 71 kd polypeptide present in early embryos and egg chambers. *FB* elements have been found at the ends of the *TE* elements (Ising and Ramel; Paro *et al.*). The smallest known element of this type is associated with the mutation *w<sup>DZL</sup>* (Levis and Rubin).

 Mazo, Mizrokhi, Karavanov, Sedkov, Krichevskaja, and Ilyin, 1989, EMBO J. 8: 903-11.

**comments:** First described by Ilyin *et al.* (1980) as *mdg4*, a sequence complementary to double stranded RNA from tissue culture cells, and by Bender *et al.* (1983) as an insertion associated with mutations *bx*<sup>3</sup>, *bx*<sup>34e</sup>, *bx*<sup>55i</sup>, and *bx*<sup>51j</sup>. Modolell *et al.* have shown by *in situ* hybridization that *gypsy* insertions are associated with many mutations suppressed by *su(Hw)*. The *su(Hw)* product binds to an enhancer-like sequence within *gypsy*, and this

may affect the expression of adjacent genes as well as of *gypsy* itself. This is alleviated by *su(Hw)* mutations (Geyer *et al.*; Peifer *et al.*; Spana *et al.*; Mazo *et al.*). The phenotypes of some mutations caused by *gypsy* insertions are affected by *su(f)* mutations. The LTR sequence shown here was reported by Bayev *et al.*. Freund and Meselson have reported an equivalent sequence of 482 base pairs. The sequences of complete elements have been reported by Yuki *et al.* and Marlor *et al.*. The map shown here is based on those of Bayev *et al.* and Mattox and Davidson. There are no sites for the enzymes *Bam*HI or *Sall*.

**restriction map (gypsy):**

**Harvey**

**length:** 7.2 kb (Bender).  
**comments:** First described as an insertion associated with the *bx*<sup>8</sup> mutation. The results of whole genome Southern transfer experiments indicate that this element is repeated within the genome, and that the internal *Sall* fragment is conserved in length. The ends of the element hybridize to each other.

**restriction map (Harvey):**

**HB**

**length:** 1.6 kilobases (Potter, Brierly, and Potter).  
**target site duplication:** Possibly 8 bp (Potter, Brierly, and Potter).  
**copy number:** Twenty (Brierly and Potter).  
**references:** Potter, 1982, Nature 297: 201-4.  
 Brierly and Potter, 1985, Nucl. Acids Res. 13: 485-501.  
 Harris, Bailie, and Rose, 1988, Nucl. Acids Res. 16: 5991-98.  
 Henikoff and Plasterk, 1988, Nucl. Acids Res. 16: 6234.

**comments:** The first *HB* element was found as the loop sequence within the *FB* element *FB4* (Potter). Brierly and Potter have shown that *HB* sequences are rarely associated with *FB* sequences and have suggested that they constitute a separate transposable element. The chromosomal distribution of these elements is fairly stable as assayed by Southern transfer experiments. There are 29 bp inverted repeats at the ends of the two elements that have been sequenced, but part of these may comprise target site duplications (Brierly and Potter). If there is an 8 bp target site duplication then the length of the terminal repeat is 20 bp. The sequence of *HB1* contains an open reading frame of 444 bp (Potter). There is about 25% sequence identity between the amino acid sequences

encoded by *HBI* and the *Tcl* transposable element of *Caenorhabditis elegans* (Harris *et al.*; Henikoff and Plasterk). This map is taken from the sequence of *HBI*. There are no sites for the enzymes BamHI, EcoRI, SacI, SalI and XhoI.

**references:** McGinnis, Shermoen, and Beckendorf, 1983, Nucl. Acids Res. 11: 737-51.

Streck, MacGaffrey, and Beckendorf, 1986, EMBO J. 5: 3615-25.

Yannopoulos, Stamatis, Monastirioti, Haizopoulos, and Louis, 1987, Cell 49: 487-95.

Blackman, Grimaila, Koehler, and Gelbart, 1987, Cell 49: 497-505.

Lim, 1988, Proc. Nat. Acad. Sci. USA 85: 9153-57.

Blackman, Macy, Koehler, Grimaila, and Gelbart, 1989, EMBO J. 8: 211-17.

**comments:** First described by McGinnis *et al.* as being associated with the *Sgs4* allele in the strain Stromsvreten 8. The sequence and map shown are of *hobo100* (Streck *et al.*). This element contains a single long open reading frame that reads from left to right. Blackman *et al.* have identified a fully functional *hobo* element and have used it to introduce a marked element into the genome. Some

strains appear to lack *hobo* elements, whereas others have 10-50 copies. These are called "E" and "H" strains, respectively (Streck *et al.*). The frequency of *hobo* activity is elevated in some strains and in some cases is increased in the progeny of crosses between E and H strains (Yannopoulos *et al.*; Blackman *et al.*). Lim has evidence that recurring chromosome aberrations that he has found on an unstable X chromosome are due to recombination between *hobo* elements that lie at the breakpoints. The majority of strains derived from natural populations before the mid 1950's harbor few *hobo* homologous sequences. In contrast almost all present-day populations carry numerous *hobo* elements and two specific deletion-derivative elements called *Th1* and *Th2* (Periquet, Hamelin, Bigot, and Lepissier, 1989, J. Evol. Biol. 2: 223-29).

**references:** Bucheton, Paro, Sang, Pélisson, and Finnegan, 1984, Cell 38: 153-63.

Sang, Pélisson, Bucheton, and Finnegan, 1984, EMBO J. 3: 3079-85.

Fawcett, Lister, Kellett, and Finnegan, 1986, Cell 47: 1007-15.

Crozatier, Vaury, Busseau, Pélisson, and Bucheton, 1988, Nucl. Acids Res. 16: 1999-2013.

Busseau, Pélisson, and Bucheton, 1989a, Nucl. Acids Res. 17: 6939-45.

Busseau, Pélisson, and Bucheton, 1989b, Mol. Gen. Genet. 218: 222-28.

**comments:** First described by Bucheton *et al.* as insertions associated with *w* gene mutations induced by I-R hybrid dysgenesis. The base sequence of a complete *I* element has been determined by Fawcett *et al.*, and the restriction map shown here is based on this sequence. There are no sites for the enzymes BamHI, EcoRI, SacI, SalI, SmaI, or XhoI. Incomplete *I* elements that have recently inserted in the genome have deleted varying amounts from the 5' end of the sequence of a complete element (Busseau *et al.*, 1989a). Incomplete elements that have been in the genome for a long time are located in pericentromeric regions, and differ from complete elements by many base substitutions and internal or terminal deletions or both (Crozatier *et al.*). Mutations induced by I-R hybrid dysgenesis include apparent point mutations due to insertion of *I* elements and chromosome rearrangements due to recombination between *I* elements (Sang *et al.*; Busseau *et al.*, 1989b).

 .....AAGAAGAGG GTTCTTAACT

**restriction map (opus):**

**P (W.R. Engels)**

**length:** 2907 base pairs or fewer (O'Hare and Rubin). Longer elements can be produced *in vitro*.

**structure:** Perfect terminal repeats of 31 base pairs plus several internal repeat structures. Defective *P*-elements are derived from the complete 2907 base pair sequence by internal deletions of various sizes and positions (O'Hare and Rubin). Approximately 150 base pairs at each terminus are usually intact, and are thought to be needed for mobility (Mullins *et al.*).

**target site duplication:** Eight base pairs (O'Hare and Rubin).

**copy number and distribution:** (Bingham *et al.*; Kidwell; Anxolabéhère *et al.*) The older laboratory strains, dating from 1950 or earlier, have no *P* homologous sequences, and they are called "M strains." Most natural populations in North and South America and Africa are "P strains", *i.e.*, they have multiple copies of both complete and defective *P*-elements in scattered and highly variable genomic positions. The total copy number is usually 30-50. Most European and Asian populations are "M' strains," meaning that they have mostly defective *P*-elements and a different kind of regulation. The total copy number tends to be less than P strains. Australia has both P and M' strains.

Sved, Eggleston, and Engels, 1989, *Genetics* (in press).

**transposase:** Exons 0-3 (see map) encode an 87 kilodalton protein needed for both transposition and excision. The 2-3 splice is germline-specific, but this intron can be artificially removed to yield transposase in somatic cells (Karess and Rubin; Rio *et al.*; Laski *et al.*).

**insertion sites:** *P*-elements insert at random, but their distribution is not uniform. There is a strong preference for euchromatin and the 5' untranslated regions of genes.

They also tend to insert adjacent to other *P*-elements and have a slight preference for target sequences resembling GGCCAGAC. Precise insertional hotspots have been seen in several genes, suggesting that there are additional specificities not yet characterized (O'Hare and Rubin; Engels).

**regulation:** (Engels) *P* strains and *M'* strains have relatively little transposition and excision activity, and several regulatory mechanisms are thought to be involved. One of these, called the *P* "cytotype," is found only in *P* strains and has a partial maternal inheritance resulting in relative stability in *P*-elements in the progeny of *P* strain females crossed to *M* strain males. However, the elements are active in progeny from the reciprocal cross. Certain defective *P*-elements have been shown to encode a negative regulator of *P*-element activity.

**hybrid dysgenesis:** Mobilization of *P*-elements results in a syndrome of abnormal traits called hybrid dysgenesis (Kidwell *et al.*; Engels). This syndrome includes high frequencies of chromosome rearrangements and male recombination, both of which occur preferentially at the insertion sites of *P*-elements (Engels and Preston; Sved *et al.*). Elevated mutation rates result from insertion mutations and other genomic changes. At high temperatures there is considerable cell death either in the germline or in somatic tissues depending on the transposase source (Simmons *et al.*; Engels *et al.*).

**use as transformation vectors:** When *P*-elements are injected into *M* strain embryos in the presence of transposase, they will jump from the injected DNA into chromosomal locations, carrying along any sequence that has been inserted into the internal portion of the element (Rubin and Spradling). Genes transformed in this way usually display approximately normal expression and regulation. However, there is usually some position effect, the degree of which depends on the particular transformed sequence. The transposase source can be a gene coinjected with the *P* vector such as the "wings clipped" element (Karess and Rubin) or a stable genomic source such as P[ry<sup>+</sup>Δ2-3](99B) (Robertson *et al.*).

**use in mutagenesis:** Selecting *P*-element insertion mutations is useful for cloning genes through "transposon tagging" and for generating variability. The most effective approach is to mobilize defective elements with an immobile transposase source (Robertson *et al.*). The mobilized elements can be either naturally occurring defective *P*-elements or marked elements introduced by transformation (Cooley *et al.*).

**use as 'enhancer traps':** (O'Kane and Gehring) Genes with specific expression patterns can be identified by mobilization of a *P*-element carrying the β-galactosidase gene fused to the transposase promoter. The spatial and developmental pattern of β-galactosidase expression appears to depend on the surrounding sequences.

comments: This element is associated with a phenotypic revertant of the  $y^m$  mutation. It has inserted into the *gypsy* element associated with  $y^m$ . The sequence of its termini and its restriction map indicate that it is a *jockey* element.

TE

The transposable elements (*TE*) first investigated by Ising carry the loci of *w* and *rst* flanked by foldback element sequences. The original transposition was from the normal location of *w rst* to 48F on 2R; secondary and tertiary transpositions were located both by recombination and cytologically. The following table is extracted and modified from one by Ising and Block (1980, Cold Spring Harbor Symp. Quant. Biol. 45: 527-44). Here and throughout this volume we designate those transposed elements whose cytological positions have been determined according to those determinations; where the cytology has not been done we retain the original numerical designations but with a # sign to differentiate them from cytological positions.

## DEPARTURES FROM DIPLOIDY

---

The diploid chromosome complement of *Drosophila melanogaster* may be designated  $X/X; 2/2; 3/3; 4/4$  for females and  $X/Y; 2/2; 3/3; 4/4$  for males. Addition to or subtraction from either of these complements of one or more chromosomes produces a departure from diploidy. The non-diploid constitutions are designated by a name but not a symbol except as included in the name, e.g.,  $X/O$  male. Constitutions are described by listing their component chromosomes, homologous chromosomes being separated by slash bars and nonhomologous chromosomes by semicolons. When two homologous chromosomes are attached to the same centromere, components are listed without separation, e.g.,  $XX, XY$ , and  $44$ .

### **diploid metafemal**

**constitution:**  $X/X/X; 2/2; 3/3; 4/4$ ; sex chromosome constitution may also be  $XX/X$ .

**source:** Produced by triploid and compound- $X$ -bearing females. May result from two- $X$  gametes produced by nondisjunction.

**discoverer:** Bridges.

**synonym:** *superfemale*.

**references:** 1921, *Science* 54: 252-54.

1922, *Am. Nat.* 56: 51-63 (fig.).

1925, *Am. Nat.* 59: 127-37.

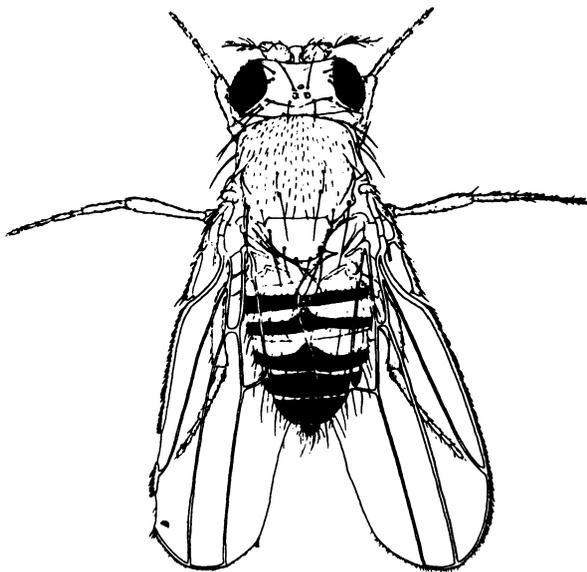

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 153-62 (fig.).

**properties:** Wings crumpled or incised on inner margin.

Rear legs often malformed. Viability low, usually less than 0.5%. Flies die mostly in late larval and pupal stages; at 25°C, puparium formation delayed 1-2 days (Brehme, 1937, *Proc. Soc. Exp. Biol. Med.* 37: 578-80). Survival increased by rearing at 20° instead of 25°; five days after oviposition most sensitive (Neeley, 1968, *DIS* 43: 83; 1969, *Genetics* 61: s43). Survivors sterile; two fertile metafemales were apparently mosaic for triploid tissue [Rolfes and Hollander, 1961, *J. Heredity* 52: 61-66 (fig.)]. Larval ovaries from metafemales transplanted into sterile diploids have produced a few progeny (Beadle and Ephrussi, 1937, *Proc. Nat. Acad. Sci. USA* 23: 356-60). Crossing over between the  $X$  chromosomes appears to be infrequent. Studies of  $C(1)RM/R(1)w^{VC} // C(1)RM/O$  mosaics (Schüpbach, Wieschaus, and Nöthiger, 1978, *Wilhelm Roux's Arch. Dev. Biol.* 184: 41-56) demon-

strate the focus of lethality to be in a region near the ventral prothoracic discs and that of female sterility to be in the external genitalia. Mosaics with diploid external genitalia and  $3X:2A$  germlines produce about three-fourths as many eggs as diploid females but only two percent of such eggs develop into adulthood, most of them failing to complete embryogenesis. Transcriptional activity of each  $X$  chromosome in  $3X:2A$  larvae, as measured by uridine incorporation by polytene chromosomes, is two-thirds that of each  $X$  in  $2X:2A$  larvae according to Lucchesi, Rawls, and Maroni (1974, *Nature* 248: 564-67) and equal to that of each  $X$  in  $2X:2A$  larvae according to Gvozdev, Leibovitch, and Ananiev (1983, *DIS* 59: 48-9). G6PD level per  $X$ -chromosome gene, as measured either by enzyme activity (Lucchesi *et al.*) or immunologically (Gvozdev *et al.*), in  $3X:2A$  animals is two-thirds that in  $2X:2A$  animals.

**other information:** The term metafemale instead of superfemale was suggested by Stern (1959, *Lancet* 12: 1088).

**diploid metafemale**

From Bridges, 1922, *Am. Nat.* 56: 51-63.

#### **haplo-4**

**constitution:**  $X/X; 2/2; 3/3; 4;$  sex chromosome constitution may also be  $X/Y$ .

**source:** Produced after occasional loss or nondisjunction of chromosome 4 during meiosis. Produced in quantity from crosses of  $C(4)RM/0$  with normal or from heterozygous  $T(2;4)$  or  $T(3;4)$  females.

**discoverer:** Bridges, 20a30.

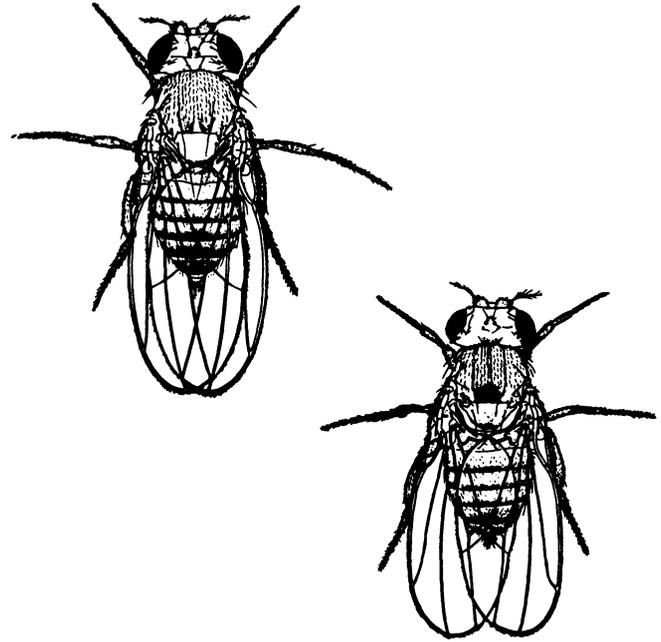

**synonym:** *Diminished*.

**references:** 1921, *Proc. Nat. Acad. Sci. USA* 7: 186-92.

1922, *Am. Nat.* 56: 51-63 (fig.).

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 135-43 (fig.).

**properties:** Minute phenotype caused by deficiency for  $M(4)$ . Pale body with prominent trident pattern on thorax. L5 often does not reach wing margin. Eclosion delayed 2-4 days. Viability erratic, usually below 80% of normal. Usually sterile. Male tends to be more viable and fertile than female.

**haplo-4**

From Bridges, 1922, *Am. Nat.* 56: 51-63.

#### **haploid**

**constitution:**  $X; 2; 3; 4.$

**source:** Recorded as patches of tissue.

**discoverer:** Bridges.

**references:** 1925, *Proc. Nat. Acad. Sci. USA* 11: 706-10.  
1930, *Science* 72: 405-6.

**properties:** Eye facets small in haploid patches. A haploid foreleg bore no sex comb; the tissue is therefore probably female, as expected on the basis of balance theory of sex determination. Gynogenetic haploid embryos are produced in crosses of normal females with homozygous  $ms(3)k81$  males; a considerable fraction of such embryos continue development to reach the final stages of embryogenesis, producing larvae with differentiated cuticles but which never hatch (Fuyama, 1986, *Genetics* 112: 237-48). That haploid embryos are females is indicated by the failure of gynogenetic haploids produced by *da* females to develop and the failure of the androcidal spiroplasma *SR*, derived from *Drosophila nebulosa* to affect such development (Fuyama, 1987, *DIS* 66: 53). Nuclear division cycle of haploid embryos protracted compared to diploids, and the syncytial blastoderm nuclei undergo an extra division to produce twice the normal density prior to cellularization (Edgar, Kiehle, and Schuberger, 1986, *Cell* 44: 365-72).

#### **intersex**

**constitution:**  $X/X; 2/2/2; 3/3/3; 4/4/4;$  presence of  $Y$  and number of fourth chromosomes variable.

**source:** Regularly found among progeny of triploid females.

**discoverer:** Bridges, 20l.

**references:** 1921, *Science* 54: 252-54.

1922, *Am. Nat.* 56: 51-63 (fig.).

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 153-62 (fig.).

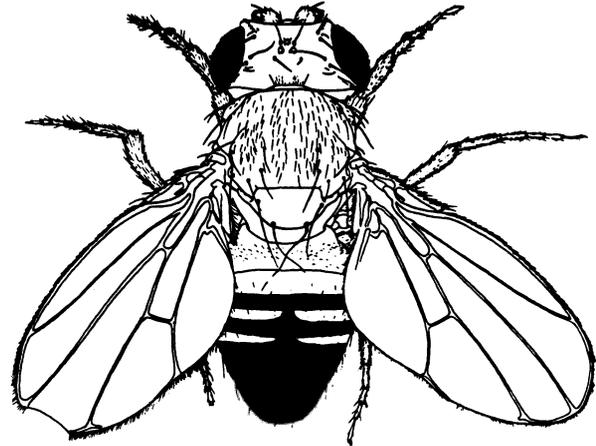

Bridges, 1939, *Sex and Internal Secretions* (E. Allen, C. H. Danforth, and C. A. Doisy, eds.). The Williams

and Wilkins Co., pp. 15-63.

**properties:** Large-bodied fly with coarse bristles, roughish eyes, and scalloped wing margins. Small hairs on surface of wing more sparsely distributed than in diploids. Usually has sex combs and a mixture of male and female genitalia; genitalia may be malelike or femalelike. Flies contain a patchy distribution of male and female tissue rather than intermediate sexuality; foreleg contains male sex-comb bristles or female bristles or both, but not bristles of intermediate position and morphology as seen in *dsx*; abdomen may consist of a sharply delineated mosaic of male and female pigmentation (Stern, 1968, *Genetic Mosaics and Other Essays*, Harvard University Press, Cambridge). This genotype is apparently unstably situated at the point of decision in sexual differentiation, and the mosaic phenotype seems to be a product of alternative sexual determination. The probability of male versus female development appears to be subject to extraneous influences. For example, Fung and Gowan (1956, *J. Exp. Zool.* 134: 515) reported that a triploid line producing intersexes with predominantly female genitalia carried several fourth chromosomes; raising intersexes at 27°-30° reported to have a feminizing effect on development (Laugé, 1969, *Ann. Embryol. Morphog.* 2: 245-69, 273-99). Gonads of triploid intersexes may be male like, female like or mosaic; *XO*- type crystals are present in spermatocytes of *XXAAA* but not *XXYAAA* intersexes; spermatocytes of the latter type can produce abnormal spermatozoa, which subsequently degenerate (Laugé, 1969, *Ann. Soc. Entomol. Fr. (NS)* 5: 253-514). Flies are uniformly sterile. Addition of sections of *X* chromosome shifts intersexes toward femaleness [Dobzhansky and Schultz, 1934, *J. Genet.* 28: 349-86 (fig.); Pipkin, 1940, *Univ. Texas Publ.* 4032: 126-56]. Addition of sections of the second or the third chromosome has not resulted in a shift of sexuality (Pipkin, 1947, *Genetics* 32: 592-607; 1960, *Genetics* 45: 1205-16). Gene activity per *X* chromosome in *2X;3A* intermediate between that of *2X;2A* or *3X;3A* and *1X;2A* as measured by enzyme activity in homogenates of adult flies (Faizullen and Gvozdev, 1973, *Genetika* 9: 106-07; Lucchesi and Rawls, 1973, *Genetics* 73: 459-64) and as measured by uridine incorporation by polytene chromosomes (Maroni and Plaut, 1973, *Chromosoma* 40: 361-77; Ananiev, Faizullen, and Gvozdev, 1974, *Chromosoma* 45: 193-201; Leibovitch, Belyaeva, and Zhimulev, 1976, *Chromosoma* 54: 349-62).

**metamale**

**constitution:** *X/Y; 2/2/2; 3/3/3; 4/4/4*; inferred from markers inherited. May also be diplo-4.  
**source:** Occurs among progeny of triploid female.  
**discoverer:** Bridges, 201.  
**synonym:** *supermale*.  
**references:** 1921, *Science* 54: 252-54.  
 1922, *Am. Nat.* 56: 51-63 (fig.).  
 Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 153-62 (fig.).  
**properties:** Male has small body and spread wings. Late hatching, poorly viable, and completely sterile. Single polytene *X* of *XY:3A* metamale incorporates 90% as much uridine as all three *X* chromosomes in triploid larvae; G6PD and 6GPD levels in metamales over 80% those of triploid females (Lucchesi, Belote, and Maroni,

**metamale**

From Bridges, 1922, *Am. Nat.* 56: 51-63.

1977, *Chromosoma* 65: 1-7).

**nullo-X**

**constitution:** *Y/Y; 2/2; 3/3; 4/4*.  
**source:** One-fourth the progeny from crosses between certain compound-*X*-bearing females [e.g., *C(1)RM/Y*] and normal males.  
**properties:** Dies as embryo (Li, 1927, *Genetics* 12: 1-58). Cleavage nuclei abnormally distributed and blastoderm not formed (Poulson, 1940, *J. Exp. Zool.* 83: 271-325). According to Scriba (1964, *Zool. Jahrb. Abt. Anat. Ontog. Tiere* 81: 435-90), migration of cleavage nuclei to surface of egg is normal, blastoderm formation irregular, and germ band development frequently incomplete.

**nullo-X nullo-Y**

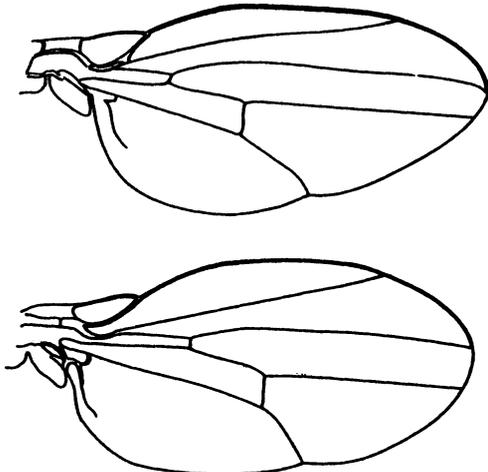

**constitution:** *2/2; 3/3; 4/4*.  
**source:** One-fourth the progeny of crosses such as *C(1)RM/0* females with *Y<sup>S</sup>X<sup>L</sup>Y<sup>L</sup>/0* males.  
**properties:** Most embryos die after 10-12 cleavages (von Borstel and Rekemeyer, 1958, *Nature* 181: 1597-98). Embryology like that of *nullo-X* (Scriba, 1964, *Zool. Jahrb. Abt. Anat. Ontog. Tiere* 81: 435-90).

*superfemale* : see *diploid metafemal*

*supermale* : see *metamale*

**tetra-4**

**constitution:** *X/X; 2/2; 3/3; 4/4/4/4*. Sex chromosome constitution may also be *X/Y*; that for chromosome 4 may be *4/4/4/4* or *44/44*.  
**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 135-43.  
 Li, 1927, *Genetics* 12: 1-58.  
 Bridges, 1935, *Tr. Dinam. Razvit.* 10: 463-74.  
 Grell, 1961, *Genetics* 46: 1177-83 (fig.).  
 Grell, 1972, *DIS* 48: 69.  
**properties:** Viability slightly reduced; 68-76% of diplo-4 sibs and 58-63% that of triplo-4 (Moore and Grell, 1972, *Genetics* 70: 567-81, 583-93). Wings of survivors longer and more pointed than normal.  
**source:** Synthesized as females homozygous for *T(1;4)w<sup>m4</sup>* + *T(1;4)B<sup>S</sup>* formed by recombination in

tetra-4

above: tetra-4; below: diplo-4

From Grell, 1961, *Genetics* 46: 1173-83.

region 3C4-15F8 between  $T(1;4)w^{m5} = T(1;4)3C3-4;101F1-2$  and  $T(1;4)B^S = T(1;4)15F9-16A1;16A7-B1;102F$  (Grell, 1961). Also recovered from progeny of crosses between males and females that carry  $C(4)RM$  (Moore and Grell).

**tetraploid**

**constitution:**  $X/X/X/X; 2/2/2/2; 3/3/3/3; 4/4/4/4$ .

**source:** Seen on a few occasions as a tetraploid daughter of a triploid female or as a patch of tetraploid gonial tissue in an otherwise diploid female. Extensive attempts to produce tetraploid males have failed. (see Novitshi, 1984, DIS 60: 157).

**discoverer:** Bridges.

**references:** 1925, *Am. Nat.* 59: 127-37.

Morgan, 1925, *Genetics* 10: 148-78.

**properties:** Recognized by production of progeny that are almost exclusively triploids and intersexes.

**triplo-4**

**constitution:**  $X/X; 2/2; 3/3; 4/4/4$ . Sex chromosome constitution may be  $X/Y$ ; that for chromosome 4 may be  $44/4$ .

**source:** Product of nondisjunction of chromosome 4. Regular product of cross between  $C(4)RM$  and normal diplo-4 flies.

**discoverer:** Bridges, 21b13.

**references:** 1922, *Am. Nat.* 56: 51-63.

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 21 (fig.), 135-43.

**properties:** Phenotypic departure from normal very slight. Body darker than normal and trident pattern subdued. Eyes small. Body and wings elongate. Preferential segregation of the different fourth chromosomes in triplo-4's described by Sturtevant (1936, *Genetics* 21: 444-66).

**triploid**

**constitution:**  $X/X/X; 2/2/2; 3/3/3; 4/4/4$ . Sex chromosome constitution may also be  $X/X/X/Y$ ,  $XX/X$ , or  $XX/X/Y$ . Triploids from stocks kept for several generations usually carry only two fourth chromosomes, i.e., diplo-4 triploids.

**source:** Spontaneous from unreduced eggs; incidence increased by treatment with cold (Bauer, 1946, *Z. Naturforsch.* 1: 35-38; Gloor, 1950, DIS 24: 82) or with colchicine (Braungart and Ott, 1942, *Sci. Counselor* 8: 105; Schultz). Produced in relatively high frequency by triploid females and by  $c(3)G/c(3)G$  females (Gowen, 1933, *J. Exp. Zool.* 65: 83-106).

**discoverer:** Bridges, 1920.

**references:** 1921, *Science* 54: 252-54.

1922, *Am. Nat.* 56: 51-63 (fig.).

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 135-43.

**properties:** Eye facets larger and hairs on surface of wings more sparsely distributed than in diploid, giving eyes and wings a coarse texture; bristles also coarse. These characteristics are diagnostic for three sets of autosomes and result from increased cell size. Body thickset. Ventral bristles between first and second pairs of legs often missing. Discernible from diploid with practice. Triploid females have the same wet weight and the same amount of DNA per fly as do diploid females (Lucchesi and Rawls, 1973, *Biochem. Genet.* 9: 41-51); however, they have fewer and larger cells than diploids (Dobzhansky, 1929, Wilhelm Roux's *Arch. Entwicklunsgmech. Org.* 115: 363-79). Perhaps owing to a reduced number of neurons, triploid females show reduced mating success when competing with their diploid sisters (Novitski and Dews, 1970, DIS 45: 101). Genetic activity per X chromosome as estimated from uridine incorporation into salivary chromosomes (Maroni and Plaut, 1973, *Chromosoma* 40: 361-77) or by G6PD and 6GPD activities (Lucchesi and Rawls) the same in diploid and triploid females; thus triploid cells with 50% more chromatin exhibit 50% more activity per cell, but as there are two-thirds as many cells in triploids as diploids, the activity per fly is the same in the two genotypes. Fertility poor owing to production of aneuploid classes of gametes. Because equal numbers of chromosomes tend to go to each pole during first meiotic division, euploid gametes are produced with lower-than-expected frequencies; gametes with one X and two sets of autosomes and with two X's and one set of autosomes far outnumber those with one X and one set of autosomes or two X's and two sets of autosomes (Bridges and Anderson, 1926, *Genetics* 10: 418-41). Triploids that carry an attached X (attached X triploids) are more fertile and produce a higher proportion of triploid progeny than free X triploids. Triploids are of necessity female and their progeny include metafemales, metamales, intersexes, triploid and diploid females, and diploid males. Crossing over is markedly increased in triploids; Sturtevant (1951, *Proc. Nat. Acad. Sci. USA* 37: 405-7) has mapped chromosome 4 in diplo-4 triploids. *B*, *Bl*, *Bx*, *Cy*, *D*, *Dfd*, *H*, *Hw*, *J*, *L*<sup>2</sup>, *Me*, and *Sb* are classifiable in a single dose in triploids. *Dl*, *G*, *N*, *bw*<sup>VI</sup>, *Px*, *S*, and all Minutes are recessive in a single dose. Two doses of *D*, *Dl*, *G*, *H*, *bw*<sup>VI</sup>, *Px*, and *Sb* produce an extreme phenotype, whereas two doses of *M* or *Me* are lethal (Schultz, 1934, DIS 1: 55).

**triploid metafemale**

**constitution:**  $X/X/X/X; 2/2/2; 3/3/3; 4/4/4$ ; third 4 may be absent.

**source:** Found among progeny of tetraploid female (Morgan). Also produced by nondisjunction of sex chromo-

somes in *C(1)RM/In(1)sc<sup>8</sup>/Y* triploid (Frost).

**discoverer:** L. V. Morgan.

**references:** 1925, *Genetics* 10: 147-78.

Frost, 1960, *Proc. Nat. Acad. Sci. USA* 46: 47-51.

**properties:** Coarse eyes, wing texture, and bristles. Resembles triploid except body smaller and eyes more bulging. Inner wing margins often incised. Using exceptional triploid females as a standard, Frost (1960) determined that triploid metafemales have 25% viability, 24-54% lay eggs (1 to 150 eggs), and about 11% of the eggs develop into adults.

### **XO male**

**constitution:** *X; 2/2; 3/3; 4/4*.

**source:** Product of primary nondisjunction of the sex chromosomes in either father or mother in cross of *X/Y* male with *X/X* female. Forms one-fourth the progeny of crosses, such as *X/X* female by *YSX·YL/0* male or *C(1)RM/0* female by *X/Y* male.

**discoverer:** Bridges.

**references:** 1916, *Genetics* 1: 1-52.

**properties:** Male morphologically normal but entirely sterile. No motile sperm produced. Spermatogenesis described by Kiefer (1966, *Genetics* 54: 1441-52) and by Meyer (1968, *Z. Zellforsch.* 84: 141-75; *Genetics* 61 Supplement: 79-92); the phenotype is the consequence of the simultaneous deletion of the six *Y*-linked fertility genes plus *Su(Ste)* and *bb*; the effects of removal of these genes one at a time have been described (Hardy, Tokuyasu, and Lindsley, 1981, *Chromosoma* 83: 593-617; Goldstein, Hardy, and Lindsley, 1982, *Proc. Nat. Acad. Sci. USA* 79: 7404-09; Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, *Genetics* 107: 591-610). The phenotype includes abnormal distribution of chromosomes and mitochondrial material at meiosis 1, the presence of micronuclei in spermatids, depression of *Ste* on the *X*, and the presence of needle-shaped proteinaceous crystals in primary spermatocytes, spermatids, and extracellularly; these phenotypes are attributable to the absence of *Su(Ste)*. Nucleoprotein structures ordinarily present in primary spermatocyte nuclei attributable to *Kl-5*, *kl-3*, and *ks-1* are missing. The outer dynein arms associated with the peripheral microtubular doublets of the axoneme are reduced or absent owing to the absence of *kl-5* and *kl-3*, and three sperm proteins in the 300-350 kd range attributable to *kl-5*, *kl-3* and *kl-2* are missing. The combined effects of these early defects lead to the general disorganization of structure as spermiogenesis continues. The contributions of *kl1*, *bb*, and *ks2* to the *XO* phenotype have not been sorted out, although their individual effects have been described.

### **XXY female**

**constitution:** *X/X/Y; 2/2; 3/3; 4/4*. Sex chromosome constitution may also be *X/XY* or *XX/Y*.

**source:** Product of either primary or secondary nondisjunction in either male or female. Also produced from cross of an *XY*-bearing parent with a normal-*X*-bearing parent. Condition usually found in compound-*X*-bearing female.

**discoverer:** Bridges.

**references:** 1916, *Genetics* 1: 1-52.

**properties:** Phenotype and fertility like those of normal female. Nondisjunction of *X* chromosomes in *X/X/Y* much higher than in *X/X* female; about 4% exceptions with two normal *X* chromosomes and much higher if *X*'s are heterozygous for inversions (Sturtevant and Beadle, 1936, *Genetics* 21: 554-604).

### **XXYY female**

**constitution:** *X/X/Y/Y; 2/2; 3/3; 4/4*. Sex constitution may also be *XX/Y/Y*, *X/XY/Y*, or *XY/XY*.

**source:** A common product of crosses such as *Y<sup>S</sup>X·Y<sup>L</sup>/Y* male by *X/Y<sup>S</sup>X·Y<sup>L</sup>* or *X/X/Y* female, or *X/Y/Y* male by *X<sup>S</sup>X·Y<sup>L</sup>/X*, *X/X/Y*, or *C(1)RM/Y* female.

**discoverer:** Stern.

**references:** 1929, *Biol. Zentr.* 49: 261-90; 727.

Cooper, 1956, *Genetics* 41: 242-64.

**properties:** Eye color mottled to varying degrees. Posterior and middle legs often malformed. Fertility and viability reduced. Gametes preponderantly *X/Y* in constitution owing to the regular segregation of both the *X*'s and the *Y*'s at the first meiotic division. Sometimes sterile.

### **XYY male**

**constitution:** *X/Y/Y; 2/2; 3/3; 4/4*. Sex chromosome constitution may also be *XY/Y*.

**source:** About one-fourth the progeny of crosses such as *X/X/Y* female by *X/Y* male, *C(1)RM/Y* female by *YSX·YL/Y* male, and *X/YSX·YL* female by *X/Y* male.

**discoverer:** Bridges.

**references:** 1916, *Genetics* 1: 1-52.

**properties:** Phenotype normal; usually fertile; with certain normal *Y* chromosomes, completely sterile (R. F. Grell). The two *Y* chromosomes tend to separate at the first meiotic division to a degree depending on the source of the *Y*'s and the *X* (Grell, 1958, *Proc. Intern. Congr. Genet.* 10th., Vol. 2: 105).

### **XYYY male**

**constitution:** *X/Y/Y/Y; 2/2; 3/3; 4/4*. Sex chromosome constitution may also be *XY/Y/Y*.

**discoverer:** Stern.

**references:** 1929, *Biol. Zentr.* 49: 261-90.

Morgan, Bridges, and Schultz, 1934, *Carnegie Inst. Wash. Year Book* 33: 274-80.

Cooper, 1956, *Genetics* 41: 242-64.

**properties:** Morphologically normal male but with mottled eyes as in *XXYY* female. Almost entirely sterile owing to the presence of three doses of *kl-3* (Kennison, 1981, *Genetics* 98: 529-48). Cooper (1956) suggests that the few offspring may result from *X/Y/Y* cysts produced by mitotic loss of a *Y* chromosome.

# SATELLITE SEQUENCES

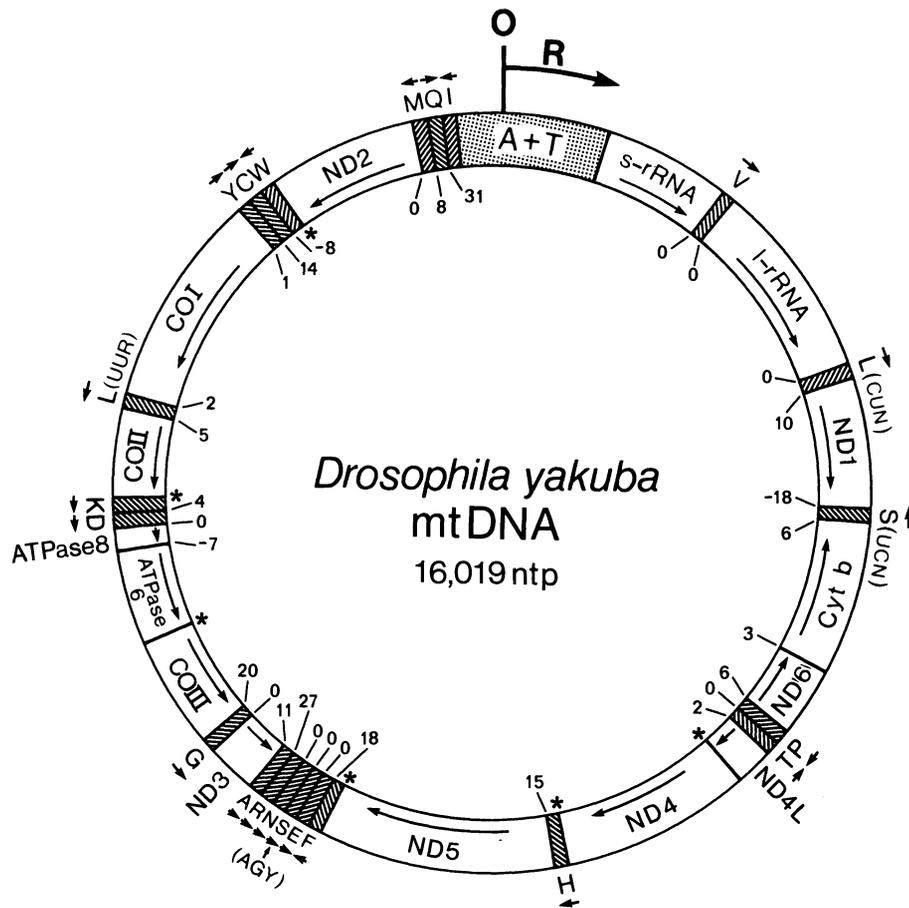

Long arrays of highly repeated simple oligonucleotide sequences with characteristic buoyant densities on cesium chloride gradients performed either with or without the action of DNA-binding antibiotics or metal ions. Comprise approximately 20% of the *Drosophila melanogaster* DNA complement. Confined to, and comprise the majority of, the pericentric heterochromatin of all chromosomes in the complement. Four satellite peaks in cesium chloride gradients can be separated from the main band, which contains the euchromatic DNA (Peacock, Brutlag, Goldring, Appels, Hinton, and Lindsley, 1973, Cold Spring Harbor Symp. Quant. Biol. 38: 405-16). These sequences do not become amplified in polytene chromosomes and remain at the diploid-cell concentration (Gell, Cohen, and Polan, 1971, Chromosoma 33: 319-44). Large clones of 1.672, 1.686, and 1.705 g/ml satellite DNA sequences in *E. coli* are unstable, but segments of 300 to 600 base pairs can be stably cloned in pBR322; it is found that samples of such clones derived from a single peak of the gradient may contain one major and several minor repeating sequences (Lohe and Brutlag, 1986, Proc. Nat. Acad. Sci. USA 83: 696-700).

buoyant density (g/ml)	sequence 5' → 3' <sup>α</sup>	density class (g/ml)	fraction of total DNA (%)
1.663	(AACAA) <sub>n</sub>	1.672	0.06
1.669	(AATAAAC) <sub>n</sub>	1.672	0.23
1.672	(AATAT) <sub>n</sub>	1.672	3.1
1.680	(AATAC) <sub>n</sub>	1.672	0.52
		1.686	
1.686	(AATAACATAG) <sub>n</sub>	1.686	2.1
1.688	(359 bp) <sub>n</sub>	1.688	5.1
1.688	(AATAGAC) <sub>n</sub>	1.686	0.24
1.689, 1.701	(AAGAC) <sub>n</sub>	1.686	2.4
1.693	(AATAG) <sub>n</sub>	1.686	0.23
	(GAGAG) <sub>n</sub>		
1.705	(AAGAG) <sub>n</sub>	1.705	5.6

<sup>α</sup> designated according to the sequence of the purine-rich strand.

The five-, seven-, and ten-base-pair repeats in such clones of either major or minor satellite sequences are quite homogeneous, displaying zero, one, or at most two deviant repeat units in stretches of approximately fifty

such units (approximately one base pair per kilobase). The sequences are not random, but conform to the pattern (RRN)<sub>m</sub>(RN)<sub>n</sub>, where R represents a purine (usually A) and N represents C, T, or G. The 1.688 g/ml satellite is complex, consisting of a 359-base-pair repeating unit. This sequence is quite variable among repeat units at about a dozen sites, but is otherwise highly conserved (Hsieh and Brutlag, 1979, J. Mol. Biol. 135: 465-81). Hsieh and Brutlag (1979, Proc. Nat. Acad. Sci. USA 76: 731-35) identified and partially purified a protein that binds specifically to the 1.688 g/ml satellite sequence. *In situ* hybridization of satellite sequences to polytene-chromosome preparation show labeling of the chromo-center, and (some at lower stringency) of a few euchromatic bands [e.g. 3C (359 bp), 7F (AATAC), 21D (AAGAG), telomeres (AAGAG) (Lohe and Roberts, 1988, Heterochromatin: Molecular and structural aspects (R.S. Verma, ed.). Cambridge University Press, Cambridge, pp. 148-86]. Hybridization of radio labeled RNA transcribed from DNA of the different buoyant-density classes to mitotic chromosomes reveals the presence of homologous sequences in the pericentric heterochromatin (Steffensen, Appels, and Peacock, 1981, Chromosoma 82: 525-41). 1.672 g/ml DNA sequences are detected at the tip and in the middle of *YL*, and in the heterochromatin of chromosome 4 and to a lesser extent at the tip of *YS* and in the centromere regions of chromosomes 2 and 3. 1.705 g/ml sequences are detected in substantial quantities at the tip and base of *YL*, the base of *YS*, and in the pericentric heterochromatin of both *2L* and *2R* and in lesser amounts at the tip of *YS*, the centromere region of the *X*, near the heterochromatic-euchromatic junction of *3R*, and in the right arm of chromosome 4. The 1.688 g/ml satellite is mostly localized to two blocks in the *X* heterochromatin, one near the middle in the vicinity of the nucleolus organizer and the other adjacent to the centromere and in a third block near the center of *YL*; it is also detected in order-of-magnitude lower amounts at the tip and base of *YL*, the nucleolus organizing region of *YS*, at the base of one arm each of chromosomes 2 and 3, and on the short arm of chromosome 4 (Peacock, Lohe, Gerlach, Dunsmuir, Dennis, and Appels, 1977, Cold Spring Harbor Symp. Quant. Biol. 42: 1121-35).

Gene map of the *Drosophila yakuba* mitochondrial genome provided by Wolstenholme. The circular molecule of 16,019 nucleotide pairs has been completely sequenced. The 13 protein genes are COI, COII, and COIII (subunits 1, 2, and 3 of cytochrome *c* oxidase), Cyt b (cytochrome b), ATPase 6 and 8 (subunits 6 and 8 of the F<sub>0</sub> ATPase complex), and ND1-ND6 and ND4L (components 1-6 and 4L of the respiratory chain NADH dehydrogenase). Each tRNA gene (hatched) is identified by the one letter amino acid code, and serine and leucine tRNA genes are also identified by the codon family (in parenthesis) that the corresponding tRNAs recognize. s-rRNA and l-rRNA indicate the small and large rRNA genes, respectively. Arrows within and outside the molecule indicate the direction of transcription of each gene. The numbers of apparently non-coding nucleotides that occur between the genes are shown at the gene boundaries on the inner side of the map. Negative numbers indicate overlapping nucleotides of adjacent genes. Asterisks identify possible incomplete termination codons (T or TA). The location of the origin of replication (O) within the A+T-rich region (dotted) and the direction of replication (R) were determined by electron microscope studies (Goddard and Wolstenholme, 1980, *Nucleic Acids Research* 8: 741-757). This map is a modification of that given by Clary and Wolstenholme (1985, *J. Mol. Evol.* 22: 252-27).

## NONCHROMOSOMAL INHERITANCE

### mitochondria

Mitochondrial DNA (mtDNA) is a covalently closed duplex circle of about 19,500 base pairs. Contained within *Drosophila* mtDNA is a region exceptionally rich in adenine + thymine. This A+T-rich region comprises 5-6 kb in *D. melanogaster*, but is shorter in related species (Fauron and Wolstenholme, 1980, *Nucleic Acids Res.* 8: 2439-52); some intraspecific variation in the length of this region is recorded; e.g., 5.9, 5.5, and 5.1 kb in three strains of *D. melanogaster*; these differences used to confirm maternal inheritance of *Drosophila* mitochondria (Fauron and Wolstenholme, 1980, *Nucleic Acids Res.* 8: 5391-5410). Mitochondria of *D. melano-*

*gaster* replaced by those of *D. mauritiana* by embryo injection (Niki, Chigusa, and Matsuura, 1989, *Nature* 341: 551-52). The origin of replication is located within the A+T-rich segment and proceeds unidirectionally around the circle, with the first strand becoming as much as 100% completed before the second strand initiates. Extensive sequencing of mtDNA of both *D. yakuba* and *D. melanogaster* has shown the two molecules to be highly homologous and to encode thirteen hydrophobic polypeptides, which have been identified as subunits of enzyme complexes associated with the inner mitochondrial membrane, a large and a small ribosomal RNA and

22 transfer RNA's. The polypeptides include cytochrome b, two subunits (6 and 8) of the ATPase, three subunits of the cytochrome c oxidase, and seven subunits of the NADH reductase complex (Chomyn, Marioeini, Cleeter, Ragan, Matsuno-Yagi, Hatefi, Doolittle, and Attardi, 1985, *Nature* 314: 592-97). These coding regions are densely packed, with few if any nucleotides separating them and in a few cases overlapping, and none of them containing introns (de Bruijn, 1983, *Nature* 304: 234-41; Wolstenholme and Clary, 1985, *Genetics* 109: 725-44; Garesse, 1988, *Genetics* 118: 649-63). The direction of replication and the order and directions of transcription of these mitochondrial genes are indicated on the diagram of the *Drosophila yakuba* mitochondria at the beginning of this section; the A+T-rich region of *D. yakuba* is considerably shorter than that of *D. melanogaster*. Mouse mitochondrial DNA contains the same genes, but the order differs from that of *Drosophila* by three inversions, and there has been some shuffling of tRNA-encoding sequences [Wolstenholme, Clary, Macfarlane, Wahleithner, and Wilcox, 1985, *Organization and Evolution of Invertebrate Mitochondrial Genomes* (Quagliariello, Slater, Palmieri, Saccone, and Kroon, eds.). Elsevier, Amsterdam, New York, Oxford, Vol. 2: pp. 61-70]. The polypeptide encoding genes use ATA, ATT, or ATG as initiation codons; ATC appears only as an internal codon. TAA is the most frequently used termination codon with ATG found in one case; some genes end in T or TA, and the stop codon is generated by polyadenylation (Garesse). UGA → tryptophan instead of stop; AUA → methionine instead of isoleucine; unlike mammalian mitochondria, AGA → serine instead of arginine as in chromosomally derived messages or stop as in mammalian mitochondria. Overall codon usage reflects the relatively high ratio of AT/CG in mitochondrial *vis-à-vis* chromosomal DNA.

### **picornaviruses**

Three small RNA viruses known as picornaviruses are found in *Drosophila melanogaster* but only two of these viruses, DAV and DPV are transmitted from females to their offspring in the egg. The third DCV, is transmitted by contamination of the surface of the egg.

**origin:** Transmitted vertically in eggs of young, naturally-infected females of both natural and lab populations (old naturally-infected females and artificially-infected females cannot transmit DAV or DPV in this way); viruses also transmitted by contact, ingestion and inoculation.

Ashburner, 1989, *Drosophila, a Laboratory Handbook*, Cold Spring Harbor Press, Cold Spring Harbor, New York, pp. 101-02.

**phenotype:** Both DAV and DPV are ribosomal viruses of 625-702 nm that are resistant to ether, ethanol, and low

pH treatment. Eggs infected with these viruses can be cured by dechlorinating them using sodium hypochlorite and transferring them to fresh medium. Unlike DCV, which kills the flies a few days after injection, the viruses DAV and DPV are not immediately pathogenic to their hosts; however, they reduce the longevity and female fertility of the infected flies. No carbon dioxide sensitivity is observed in *Drosophila* as a result of these viruses. DAV and DPV multiply in the gut, Malpighian tubules, and ovaries of *Drosophila melanogaster* and are only found in the cytoplasm (not the nucleus) of the infected cells. Molecular weights of major capsid polypeptides of the viruses are:

DAV 31,600, 41,200, 72,900

DPV 26,000, 19,400, 48,000.

Ashburner, 1989, *Drosophila, a Laboratory Handbook*, 1989, Cold Spring Harbor Press, Cold Spring Harbor, New York, pp. 101-116, 1192.

**phenotype:** Whereas normal *Drosophila melanogaster* recover in a short time after carbon dioxide anesthesia, flies belonging to certain strains suffer paralysis eventually followed by death after a short exposure to carbon dioxide. These strains were found to carry the rhabdovirus sigma (L'Héritier and Teissier, 1937). This RNA virus resembles vesicular stomatitis virus (VSV) of horses both in size (70 nm wide and 180 nm long) and shape (bullet-like); VSV and the fish rhabdoviruses PFR and SVC can multiply and produce carbon dioxide sensitivity in *Drosophila* (Brun and Plus, 1980; Teninges and Bras-Herreg, 1987). The sigma virus, however, does not multiply in any vertebrate host and normally is transmitted from *Drosophila* females to their offspring by way of the egg. The expression of sigma is correlated with the presence of the virus in nerve centers. The virus grows well in *Drosophila* tissue culture cells (Richard-Molard,

Blondel, Wyers, and Dezelee, 1984, *J. Gen. Virol.* 65: 91-99).

Carbon dioxide-sensitive sigma strains may be divided into two types: stabilized and nonstabilized. Artificial inoculation regularly leads to the nonstabilized condition. In this state, males do not transmit sensitivity to progeny but females do transmit it to part of their progeny, indicating the presence of the sigma virus in some of the eggs of infected individuals. Some flies of a nonstabilized strain achieve the stabilized state. In the stabilized state, the females transmit the virus and the stabilized condition to approximately 100% of their offspring (Fleuriet, 1980a, 1988). The stabilized males transmit the virus but not the stabilized condition to part of their progeny; electron micrographs show the virus in male germ cells (Brun and Plus, 1980).

The *ref* (refractory) mutants, found on *Drosophila* chromosomes *X*, *2*, and *3*, prevent flies from being infected by sigma. Some of the virus strains are defective and do not produce carbon dioxide-sensitivity in stabilized flies. Other mutant strains of sigma are heat sensitive and unable to infect flies at 30° (Contamine, 1973, *Mol. Gen. Genet.* 124: 233-46). Flies stabilized for one of these temperature-sensitive mutants lose their sensitivity to carbon dioxide at the restrictive temperature but can transmit the virus to their offspring.

**molecular biology:** Sigma virus from a *Drosophila* cell line was used to prepare genomic RNA (Teninges and Bras-Herreg, 1987). The sigma strain used gave a high yield of virus but was unable to establish a persistent stabilized-type infection when inoculated into *Drosophila* tissue culture cells. After preparation, the genomic RNA was purified, labelled with <sup>32</sup>P, and used to probe for mRNA in sigma-infected cells. A cDNA copy of the complete coding region of the mRNA was cloned and its nucleotide sequence and deduced amino acid sequence determined (Teninges and Bras-Herreg, 1987). There is a long open reading frame (ORF) in the nucleotide sequence starting at position 47 and ending at position 1624. The putative amino acid sequence consists of a chain of 526 amino acids. Within the long ORF is a short frame-shifted ORF (starting at position 643 and ending at position 763) which could encode a peptide of 40 amino acids. About 20% amino acid sequence identity has been established between the glycoprotein precursor of this strain of sigma virus and that of VSV (New Jersey strain).

### **SR: Sex Ratio**

**origin:** Artificially inoculated into *D. melanogaster* from SR-bearing *D. willistoni* and *D. nebulosa*.

Laugé, 1980, *The Genetics and Biology of Drosophila* (Ashburner and Wright, eds.). Academic Press, London, New York, San Francisco, Vol. 2d, pp. 33-106.

Niki, 1988, *Jpn. J. Genet.* 63: 11-21.

Ashburner, 1989, *Drosophila, a Laboratory Handbook*, 1989, Cold Spring Harbor Press, Cold Spring Harbor, New York. p. 1193.

**phenotype:** The SR or Sex Ratio phenotype found in several groups of *Drosophila* carrying spirochaete-like microorganisms now classified as spiroplasmas in their hemolymph (Williamson and Whitcomb, 1975, *Science* 188: 1018-20) and is characterized by a failure on the part of females to produce male offspring (Williamson and Poulson, 1979). Spiroplasmas are normally transmitted from female to offspring in the egg (Nikki, 1988). The SR agent can be extracted from *D. willistoni*, *D. nebulosa*, *D. paulistorum*, or *D. equinoxialis* and can be transferred by inoculation into *D. melanogaster*, and *D. simulans* (Poulson, 1963; Sakaguchi and Poulson, 1963; Ikeda, 1965; Oishi and Poulson, 1970; Watanabe and Yamada, 1977; Tsuchiyama *et al.*, 1978). Two strains of SR microorganisms, WSR from *D. willistoni* and NSR from *D. nebulosa*, are quite stable in *D. melanogaster*, the degree of stability of the infection differing among *D. melanogaster* strains. XY male offspring of females carrying the infection die as embryos. A few infected gynandromorphs with small areas of XO tissue survive, but the majority do not survive when XO cells carry the infection (Tsuchiyama *et al.*, 1978). Triploid intersexes are not killed by the SR agent, nor are females transformed by *tra*, *tra<sup>D</sup>*, *ix*, or *dsx* (Sakaguchi and Poulson, 1963; Miyamoto and Oishi, 1975). The spiroplasmas of each species of *Drosophila* carry their own viruses and these viruses can clump and lyse the spiroplasmas of related species of *Drosophila* (Oishi, 1971; Poulson and Oishi, 1973, *Genetics* 74: s216).

**other information:** The name SR was proposed by Magni (1953, *Nature* 172: 81) for *D. bifasciata* females (inseminated before capture) that produced only female offspring (Laugé, 1980) and was used by Poulson and colleagues for these maternally-transmitted cytological factors (spiroplasmas) found naturally or by infection in *Drosophila*.

# CYTOGENETIC MAP

by: Michael Ashburner

---

This is a cytogenetic map of *D. melanogaster* sorted by determined or estimated genetic map position. Estimated map positions are based on cytological positions, and where the published genetic map position is at variance with the known cytological position, an estimated map position (enclosed in brackets) is substituted for the published genetic position. There is approximate but not complete concordance between the map positions in this table and those in the individual entries in the body of this work. Loci mapped only to a chromosome, chromosome arm, or to a very long region (*e.g.*, between *v* and *f* on chromosome *I*) are excluded from this table. The other fields in the table are cytogenetic map position, gene symbol, and map index. The gene symbols in the table have been reconciled with those used in the body of the text insofar as possible; loci indicated in the table that are not represented in the text are designated with the symbol "†".

Map index has been introduced to indicate absolute physical order within well mapped regions, this order usually being determined by deletion mapping or molecular methods. The reason for doing this is that published map positions, either genetic or cytogenetic, are inadequate to indicate the absolute order in many, if not most

cases. So as to allow this order to be generated by a program, rather than by hand, genes within well mapped regions are given an index which indicates this order. The map index has three components: a numbered division (1-104; numbers 103 and 104 are for the long and short arms of the *Y* chromosome respectively); a lettered subdivision, in lower case so as to avoid confusion with cytogenetic positions, and an index number. If, within a lettered subdivision, two independent fine scale maps cannot be related with respect to each other, then the lower case letter of the index may be repeated. Examples of map indices are 1a100, 24e1000, 24ee100. If two loci have not been separated, then they will have identical index numbers. Physical relationships are indicated by the fact that within a series of map indices (that is within a division or subdivision) a locus with the numerically lower index is physically to the left of one with a higher index. The index number is enclosed with () if only *relative* order is known. Map indices are not permanent attributes of loci (at least, not until the map is "complete"). They will change as these tables are updated. Note that the sorting of loci in this table may well give an incorrect impression of physical order.

THE GENOME OF *DROSOPHILA MELANOGASTER*
