*We dedicate this book to the memory of George Lefevre in recognition of his exhaustive cytogenetic analysis of the X chromosome and in gratitude for his many helpful comments on the manuscript version of this revision prior to his untimely death in January, 1990.*

# PREFACE

---

The last twenty years have witnessed a remarkable expansion in the definition of the *Drosophila* genome. The emergence of *Drosophila* as an organism of choice for molecular-genetic investigations of eukaryotic biology has attracted a large number of talented workers to the field, and the rapid advances in molecular technology have provided new and sophisticated tools and generated novel kinds of information.

This work is a revision of "The Genetic Variations of *Drosophila melanogaster*" by D. L. Lindsley and E. H. Grell, which appeared in 1968 and was essentially a complete catalogue of mutations and chromosome rearrangements of *Drosophila melanogaster* as of the end of 1966. The present volume purports to be such a catalogue current until the end of 1989. The illustrations are primarily the work of Edith M. Wallace, the artist employed by T. H. Morgan; they were mostly drawn between 1920 and 1940. The same illustrations were used in "The Genetic Variations of *Drosophila melanogaster*" and its predecessor "The Mutants of *Drosophila melanogaster*" by Calvin B. Bridges and Katherine S. Brehme. At the time of the 1968 publication, genes were identified exclusively through the existence of mutant alleles; the only wild-type alleles considered were electrophoretic variants of a few enzymes, and the only gene for which there was any molecular information was *bb*. Amino-acid and nucleotide sequencing and the polymerase chain reaction were concepts for the future; cloning of DNA sequences had not been imagined; transposable elements, hybrid dysgenesis, and transformation were unsuspected. These technologi-

cal advances have shifted the emphasis to normal gene structure and function rather than exclusive consideration of mutant alleles. This shift in emphasis is reflected in the title of the present volume, "The Genome of *Drosophila melanogaster*." The ability to identify a gene from either its protein product or the homologous product from another species, rather than the converse, has led to the discovery of many new genes for which no variant had been previously recognized. In addition, new genes with interesting expression patterns are being discovered in enhancer-detection lines.

Interim versions of the majority of the material contained herein have appeared in the form of volumes 62, 64, 65, and 68 of *Drosophila* Information Service. This volume contains information on upwards of 4000 genes and 9000 chromosome rearrangements. There are categories of effects, little if at all represented in the 1968 edition, that have assumed major proportions in the present version. These include developmental mutations, behavioral mutations, female-sterile mutations, meiotic and mitotic mutations, Y-autosome translocations, and transposable elements; in addition, many regions of the genome have been subjected to saturation mutagenesis so that large numbers of lethally mutable loci have been identified and deficiency mapped. A major consequence of the mapping efforts, utilizing both chromosome rearrangements and *in situ* hybridization, is that the polytene map has displaced the recombination map as the more useful standard. The 1968 volume was subdivided into seven sections: Mutations, Chromosome Aberrations,

## PREFACE

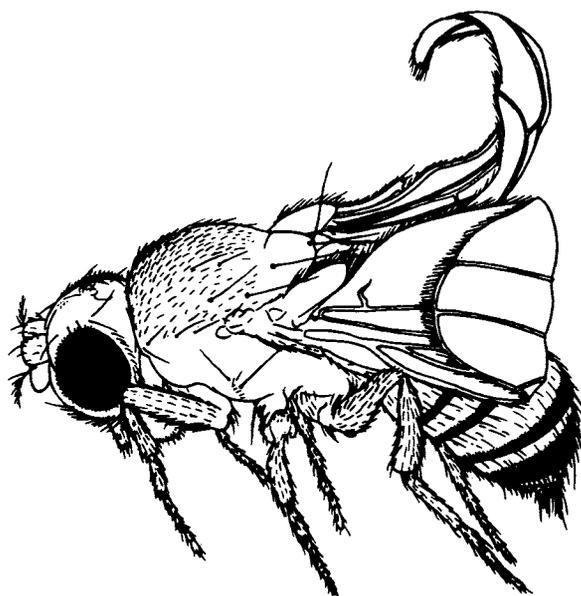

Special Chromosomes, Cytological Markers, Departures from Diploidy, Nonchromosomal Inheritance, and Wild-Type Stocks. In the present version, the section on Wild-Type Stocks has been eliminated, new sections on Transposable Elements and DNA Sequences have been added, and a molecular biology category has been added to the descriptions of genes and rearrangements if the information is available.

We are grateful to our colleagues throughout the world for their contributions and corrections to draft copies. Those who have submitted entries or sections of entries are acknowledged on the first line of the entry. Special thanks are due to a number of colleagues whose efforts on behalf of this volume have been more than substantial. In particular, Jeff Hall has provided almost all of the material on behavioral and neuronal genes; George Lefevre and especially his colleague, Catherine Coyle-Thompson, provided

massive amounts of information and corrections to the sections on X-linked lethals; Trudi Schüpbach provided descriptions of female-sterile and maternal-effect-lethal mutations. Jim Boyd and Scott Hawley provided the entries on mutagen-sensitive and meiotic mutants, respectively. Michael Ashburner has been especially helpful in keeping us supplied with his encyclopedic lists of mutations, chromosome rearrangements, and references; in addition, he has gone over the draft copies of the work and provided detailed additions and corrections. Finally, Loring Craymer and Abraham Schalet were most helpful in reviewing material and pointing out errors and omissions.

We apologize for the omissions, inconsistencies, and errors in this compilation. Every time we reread it we find new ones, but, mercifully, revision has to stop sometime.

Dan L. Lindsley  
Georgianna G. Zimm

## GENES

---

**LOCI.** When the last edition of this book was prepared, it was necessary to have two alleles of a gene in order to identify and map a locus genetically. The subsequent development of methods for identifying and mapping loci by gene-dosage manipulation and by *in situ* hybridization with cloned probes has led to the identification and cytological localization of many genes for which no allelic variability has yet been detected. Thus, genes are now recognized by virtue of a phenotypic response to the dosage of a specific circumscribed chromosome segment, by the *in situ* hybridization of a specific transcribed sequence to a polytene-chromosome band, or by the existence of allelic variation. Each locus so recognized is given a name which is descriptive of its mutant phenotype or its wild-type function. The name is concise and is preferably a simple noun or adjective; for example, cabbage, canoe, and kidney or Curly, outstretched, pink and rough. Loci recognized by virtue of the protein that they encode are named as the protein; e.g., Alcohol dehydrogenase, Actin, Calmodulin, etc.

The phenotype of flies obtained from natural populations is considered normal or wild type, and the alleles carried by such individuals, the normal or wild-type alleles. When the main characteristic of the nominate mutant allele is recognized when it is heterozygous with a wild-type allele, the mutant is considered dominant and its name begins with an upper-case letter; when the nominate allele is recessive, an initial lower-case letter is used. The names of genes specifying proteins, for many of which only the wild-type allele is known, begin with upper-case letters. Cases arise in which the same locus has received two or more names; other things being equal, the earlier-applied name is adopted.

For convenience, a symbol is assigned to each locus. This symbol is an abbreviation of the name that uniquely designates the locus in question; it combines brevity with

information. It usually begins with the same letter as the name, is always italicized, and does not contain subscripts, or spaces; e.g., *r* for rudimentary, *R* for Roughened, *ro* for rough, *rs* for rose, and *ry* for rosy. In designations of genotypes with several mutant genes, symbols of genes on the same chromosome are separated by spaces (e.g., *y w f B*); symbols of genes on homologous chromosomes are separated by a slash bar (e.g., *y w / f B*); symbols of genes on nonhomologous chromosomes are separated by semicolons and spaces (e.g., *bw; e; ey*). Names are not italicized in text.

**ALLELES.** The alternatives or alleles at a particular genetic locus are designated by the same name and symbol and are differentiated by distinguishing superscripts. The superscript notation designating alleles may take a number of different forms. A common device is an abbreviation that further characterizes the particular allele or that was used as the locus symbol before allelism was established. This practice is avoided because it has the disadvantage of preempting useful symbols and names from use as locus designations. Another unacceptable device is the use, as superscripts, of elements of the genotype in which the allele arose, since such a designation implies something more than a trivial connection between allele and element. Finally, lengthy acquisition numbers are avoided as allelic designations, since the information that they contain is of no use to the general user, and greatly exceeds what is necessary to differentiate one allele from another; in the present version, many such allelic designations have been abbreviated. In a large number of cases we have replaced complex, and to most users uninformative, superscripts with simple numeral designations; we have not, however, been consistent in this practice. Other acceptable superscripts for allelic designations are arbitrary numbers, capitalized initials of the finder or laboratory, or the date of discovery.

The numeral 1 is the implied superscript of nonsuperscripted symbols. Whereas genes in the same allelic series are designated by the same symbol but with different superscripts, mutants with similar phenotypes at different loci are not given the same symbol.

For a recessive allele of a preponderantly dominant series or a dominant allele of a predominantly recessive series, the superscripts *r* and *D*, respectively, may be used; e.g., *Hn<sup>r</sup>*, *Hn<sup>r2</sup>*, and *bw<sup>D</sup>*. Finally, for the normal allele in a series, a superscript plus sign may be used; e.g., *b<sup>+</sup>* or *B<sup>+</sup>*. The plus symbol alone implies the normal (wild-type) allele or alleles in any context, such as *y/+* or *y m fl/+*. Absence of a particular locus may be noted by use of a superscript minus sign with the symbol; e.g., *bb<sup>-</sup>*. Revertants or partial revertants of mutant alleles are designated by the superscript *rv* followed by a distinguishing number; revertants of dominant mutations that are deficiencies are treated not as alleles but as deficiencies and are accordingly not superscripted but listed with the distinguishing number.

Loci encoding specific polypeptides or transcripts require special conventions. In many instances, such loci lack recognized allelic variants, but a single wild-type allele is known; in others, polymorphisms exist in such attributes as electrophoretic mobility, abundance, or stability, or mutants affecting activity, developmental-stage specificity, or tissue specificity may occur; these are designated as alleles in the standard manner; e.g., *Adh<sup>F</sup>* and *Adh<sup>S</sup>*. Alleles specifying the absence of a particular enzyme or other protein are designated by the superscript *n* (null) followed by a distinguishing number or letter, e.g., *Adh<sup>n1</sup>* or where lack of function is inviable by *l* (lethal), e.g., *Nrg<sup>l1</sup>*. All such loci identified by virtue of their wild-type gene product are treated as dominants and are thus named and symbolized with initial upper-case letters. Since all the genes described in this compilation are *Drosophila* genes, we have not used an initial "D" to designate the *Drosophila* homologues of genes originally characterized in other species. Abbreviations for the protein and the gene are frequently identical, and both are used in most discussions. The gene symbol may be differentiated from the protein symbol by having only its initial letter capitalized and by being italicized, whereas the protein symbol is in roman capitals; e.g., ADH.

In several instances where two members of the same allelic series were formerly given different locus names, both are here included under one name; e.g., *Pm = bw<sup>V1</sup>*. In other cases, we assume allelism of mutants with similar phenotypes and genetic positions even though they have not been tested for phenotypic interaction. In such instances, the basis for the assumption is usually noted. Since the practice has not been consistent, some alleles may be described as different genes. Except in special cases, investigation of allelic interaction of sex-linked recessive lethals is not feasible; consequently, they are often given distinctive symbols where allelism may actually exist.

**TRANSFORMANTS.** Loci transposed to new chromosome locations by transposable elements are enclosed in brackets to indicate that they are not in their normal position, followed by a parenthetical indication of their new position; e.g., *[w<sup>+</sup>](35BC)* and *[ry<sup>+</sup>](sd)*. As such constructs become more complex, a complete description cannot be incorporated into the symbol. Accordingly,

our policy is to sacrifice information in order to keep the symbol as simple as possible; thus, transformants of genes of interest selected by cotransformation with a selectable marker are designated according to the gene of interest rather than the selectable marker; e.g., *[Cp16](52D)* designates an insertion of Chorion protein 16 into 52D, which was selected by cotransformation of *ry<sup>+</sup>*.

**MIMICS.** Mutants at different loci sometimes have similar phenotypic effects. Such loci may be handled in several ways. The simplest is to give each a distinctive name (e.g., vermilion, cinnabar, scarlet, karmoisin, cardinal); this method has the effect of scattering such mimics throughout the alphabetical listing. Or a common symbol followed by a distinguishing symbol may be used (e.g., *tu-1a*, *tu-1b*, *tu-2* for genes controlling production of melanotic pseudotumors). Loci encoding proteins of similar function are differentiated by arbitrary numbers (e.g., *Sgs3*, *Sgs7*, *Sgs8*), by polytene chromosome position (e.g., *Act5C*, *Act42A*, *Act57A*, etc.), or by molecular weight (e.g., *Hsp68*, *Hsp70*, *Hsp83*, etc.). Distinctive suffixes are also useful (e.g., rough, roughoid, roughish, roughex; plexus, Plexate; dachs, dachsous; maroon, maroonlike). The latter schemes frequently have the virtue of placing like phenotypes or gene functions in sequence in an alphabetical listing. Some phenotypes result from mutation at many loci in all chromosomes; these are given a common symbol followed by a parenthetical designation of the chromosome and then by a distinguishing designation. Examples of this type of mutant are the female steriles, the lethals, the Minutes, and the male steriles [e.g., *fs(2)B*, *l(1)1Ac*, *M(1)18C*, *ms(2)73d*, respectively]. We endeavor in this work to replace arbitrarily chosen distinguishing designations with polytene locations where possible. This has become feasible as the result of remarkable strides in cytogenetic mapping made possible by the selection characterization and maintenance of many deficiencies and by *in situ* hybridization.

**MODIFIERS.** The primary effect of some mutants is to cause another mutant to exhibit a more-extreme departure from normal (enhancer) or a more nearly normal phenotype (suppressor). Such mutants are symbolized *e* or *E* and *su* or *Su*, followed in parentheses by the gene modified. Designation of the particular allele modified appears as a superscript within the parentheses and alleles of the modifier gene as superscripts outside the parentheses; e.g., *su(lz<sup>34</sup>)* and *su(Hw)<sup>r</sup>*. Terms such as dilutor, exaggerator, inhibitor, intensifier, and modifier were also formerly used, but we have usually attempted to classify such genes as enhancers or suppressors.

**FORMAT.** Mutants with their descriptions are listed alphabetically according to symbol and cross-indexed according to name. Current terminology is listed in bold face. All cases of synonymy are also listed in italics with cross-references to current usage. Mutants known to be lost are preceded by an asterisk; however, mutants not preceded by an asterisk are not therefore known to be extant. Each mutant is described according to the following format:

**symbol: name (Author of entry)**

**location:** The location is indicated by the chromosome number, separated by a hyphen from the genetic position

on the chromosome. Three levels of accuracy of the genetic location are indicated, those carried to tenths of a unit being the more accurately determined; e.g., 3.0 represents a more accurate location than 3. In regions saturated for mutants, map positions may be given in hundredths, either as the result of detailed recombinational mapping or by interpolation using deficiency mapping data. Map positions enclosed in braces are inferred from cytological map position. Accuracy of a map position determination is of course dependent on the accuracy of the positions assigned to the reference markers; i.e., on the accuracy of the map. We treat the map as a rough guide to the relative positions of loci but, considered on a refined level, it may be inaccurate with respect to both position and order of genes. Intense activity in determining cytological positions in recent years is resulting in the rapid replacement of the genetic map by the cytological map as the more useful indicator of gene position.

**origin:** For induced mutants, the agent is given; mutants recovered from untreated parents or a wild population are listed as spontaneous. Isoallelic variants found as major components of stocks or populations are listed as naturally occurring alleles. Mutagenic agents are frequently abbreviated, especially in tables of alleles; abbreviations used are indicated in the accompanying table:

abbreviation <sup>α</sup>	compound
<b>CB 1246</b>	triethylmelamine

<b>TEM</b>	triethylmelamine

<sup>α</sup> CB Chester Beatty; ICR Institute for Cancer Research.

The chromosome of origin of mutations is of interest when DNA sequence is being studied; such information is not generally available, however, and is usually not included.

**discoverer:** Name, date of discovery.

**synonym:** Alternative symbol or name or both, mostly obsolete terminology.

**references:** Sources of the major descriptive material are listed, but bibliographic material may also appear in some of the other categories. The second reference to a paper in an entry is generally abbreviated to just the author's name or to name and year. Such abbreviated references not preceded by a fuller reference in the same entry are generally to unpublished information. References to CP552 refer to Carnegie Publication 552, which is "The Mutants of *Drosophila melanogaster*" by C.B. Bridges and K.S. Brehme; CP627 refers to "Genetic Variations of *Drosophila melanogaster*" by D.L. Lindsay and E.H. Grell.

**phenotype:** The most important departures from normal, which are usually those suggested by the name, are described first. Other information about the phenotype follows, and finally there may be data on viability and fertility. This revision contains considerable information on the normal functions of the genes described, including observations on stage and tissue specificity of expression; the techniques of *in situ* hybridization and immunostaining of whole embryos and sectional material have added a new dimension to phenotypic description. The last item in the phenotypic description is the rank, abbreviated RK. In this revision, we have not attempted to assign rank to mutants; however, we have retained those assignments appearing in early editions. Mutants were classified by Bridges into three different ranks according to their utility in experiments in which counts are made: RK1 mutants are easily scored; RK2 mutants are usable but less convenient; RK3 mutants have limited usefulness. An RK3 mutant may be one with good expression and viability but simply not convenient to use in counting experiments; e.g., enzyme polymorphisms. The letter A follows the rank of mutants associated with chromosome aberrations.

**alleles:** Rather than describing alleles in separate entries, as was done in previous versions, we have attempted, wherever possible, to tabulate them. Different grouping of the types of information itemized above appear as columns in the tables of alleles. When a type of information, such as phenotype, is too extensive for tabulation, subentries follow the nominate entry. The types of information included in each table are decided on a case-by-case basis, but the order of columns approximates the order in which information is included in full entries. Deficiencies may be listed in tables of alleles for the purpose of cross-referencing.

**cytology:** This category is primarily to provide the cytological location of the gene, as determined by rearranged breakpoint-associated alleles, by deficiency mapping, or by *in situ* hybridization to polytene chromosomes. It may also indicate that the mutant was induced in a rearranged chromosome or occurred in association with a *de novo* rearrangement; in tables of alleles, pre-existing rearrangements are listed by name; *de novo* rearrangements likely to have caused the mutant receive the same designation as the mutant, and are listed by breakpoints in tables and by name in the section on chromosome rearrangements.

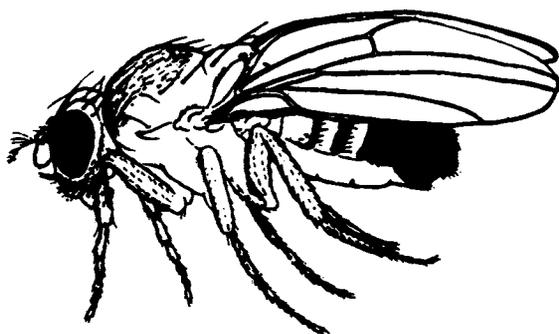

**molecular biology:** This is a new category of information that is expanding at an unprecedented rate. It includes references to the cloning, restriction mapping, sequenc-

ing, and conceptual amino-acid sequences with indicated homologies to other proteins and motifs. In allele tables, it includes sequence alterations associated with different alleles. Molecular mapping results are currently presented without regard to an established convention. Zero coordinates have frequently been chosen at sites not easily identified in a normal chromosome complement, such as a rearrangement breakpoint, the site of insertion of a transposable element, or the end of a random-shear fragment. We propose that the midpoint of an endonuclease restriction site, preferably one shown to be present in chromosomes of several independent origins, be chosen as the origin of a restriction map and that 0 marks not a nucleotide pair, but the plane of symmetry of the restriction site; ambiguity can result only from restriction site polymorphism. We also propose that when the chromosomal orientation of the map is determined, positive values extend to the right and negative values to the left so that all restriction maps have the same orientation; this

will be especially useful when adjacent restriction maps fuse. When two studies of the same region have used different sets of coordinates, we have perforce chosen the one that conforms more closely with the above conventions. No convention has been established for defining the origin of nucleotide maps of transcription units, and of course either orientation with respect to the restriction map may obtain, depending on which strand is transcribed.

**other information:** This category contains miscellaneous information that does not fit into one of the other categories.

Loci that share phenotypic and nomenclatural features (i.e., mimics) are frequently presented in a single entry in which the common information is presented once, and the information that distinguishes among loci is tabulated; the order of the columns of information roughly corresponds to the order in which the same categories of information appear in full entries.

**a: arc****location:** 2-99.2.**discoverer:** Bridges, 12e24.**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 202 (fig.).Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 212 (fig.).Bridges, 1937, *Cytologia (Tokyo)*, Fujii Jub., Vol. 2: 745-55.**phenotype:** Wings broader; bent downward in slight, even arc; edges drawn down to diamond shape. Sometimes in stock, wings are bent upward instead of downward. Crossveins closer together. RK2.**alleles:**  $a^1$ ,  $a^{ba}$  (see below),  $*a^{ba1}$ ,  $*a^{ba2}$ ,  $*a^{ba3}$ ,  $*a^{ba4}$ ,  $*a^{bad6}$ ,  $*a^{badp}$ ,  $*a^{bar}$ ,  $*a^{Ba}$ ,  $*a^{BaC}$ ,  $*a^{Bap1}$ ,  $*a^{Bap2}$ ,  $*a^{BaX}$ ,  $*a^{Bay}$  (Goldschmidt, 1945, *Univ. Calif. Berkeley Publ. Zool.* 49: 351-56, 388-89, 519; CP627), and  $*a^{M60}$  (Meyer, 1963, *DIS* 37: 50).**cytology:** Placed between 57F11 and 58E4 on the basis of its inclusion within  $Df(2R)M-1 = Df(2R)57F11-58A1;58F8-59A1$  but not  $Dp(2;3)P = Dp(2;3)58E3-4;60D14-E2;96B5-C1$  (Bridges, 1937). Likely in band 58D6 or 7 based on  $Df(2R)a-ba2 = Df(2R)58D5-6;58D7-8$ .**a: arc**

From Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 148.

 **$a^{ba}$ : arc-broad angular****origin:** Spontaneous.**discoverer:** Goldschmidt, 1934.**synonym:** Referred to as *bran: broad angular* by Goldschmidt, but shown by him to be an allele of *arc*.**references:** 1945, *Univ. Calif. Berkeley Publ. Zool.* 49: 351-56, 388-89, 519.**phenotype:** Wings broader and shorter than wild type, blunt at the tip. Frequently shows upturned posterior scutellar bristles. In combination with  $svr^{poi}$ , produces soft blistered wing. Other interactions described by Goldschmidt, 1945, table 74. Wing grows in pupal stage to full length and then retracts, possibly with histolysis [Goldschmidt, 1934, *Z. Indukt. Abstamm. Vererbungsl.* 69: 38-131 (fig.)]. RK2.**cytology:** Salivary chromosomes normal (Kodani).**other information:** Claimed to recur repeatedly in certain lines (Goldschmidt, 1945). $\alpha^1$ : see *tyr1***\*A: Abnormal abdomen****location:** 1-4.5.**discoverer:** Morgan, 11g.**synonym:** *Abnormal*.**references:** 1915, *Am. Naturalist* 49: 384-429 (fig.).

Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 27 (fig.).

**phenotype:** Tergites and sternites raggedly incomplete, exposing a thin crinkled cuticle; bristles and hairs on abdomen correspondingly eliminated. Highly variable, wild phenotype in old dry cultures.  $A/+$  less extreme than  $A/A$  and  $A$  male; homozygous female fully viable and fertile. RK2 in well-fed cultures.**alleles:**  $*A^1$  (Morgan and Bridges, 1916),  $A^{53g}$  (see below),  $A^{70}$  [allelism conjectural (Gooskov, 1971, *DIS* 46: 41)].**other information:** Lost by reversion to wild type. $A$ : see  $bw^A$ **A53g****location:** 1- (between  $y$  and  $w$ ; may not be allelic to  $A$ ).**origin:** Spontaneous.**discoverer:** Hillman, 53g.**references:** 1953, *DIS* 27: 56.1973, *Genet. Res.* 22: 37-53.1977, *Amer. Zool.* 17: 521-33.Hillman and Barbour, 1963, *Proc. Intern. Congr. Genet.*, 11th, Vol. 1: 170.**phenotype:** Epidermal foldings of abdomen abnormal. Tergite formation incomplete, ranging from loss of tergites 2-8 in extreme cases to loss of lateral part of tergite in one or more segments. Expression in  $A53g/A53g$  females  $> A53g/Y$  males  $> A53g/+$  females. Expression maternally influenced (Shafer and Hillman, 1974, *J. Insect Physiol.* 20: 223-230). Highly variable; sensitive to modifiers on  $X$ , 2, and 3, including  $E(A53g)$  on 2L. Sensitive to culture conditions; expression reduced in old cultures and under conditions of crowding, low temperature (TSP in late second and early third instar), and low humidity. Also reduced by agents that inhibit RNA or protein synthesis or oxidative phosphorylation (Hillman, Shafer, and Sang, 1973, *Genet. Res.* 21: 229-38). Supernatants from homogenates of  $A53g$ -bearing adults stimulate amino acid incorporation and aminoacylation of tRNA more than those from wild type (Rose and Hillman, 1969, *Biochem. Biophys. Res. Commun.* 35: 197-204). Mutant late pupae and adults show increased concentrations of soluble protein. Expression of biochemical phenotype correlated with that of visible phenotype (Rose and Hillman, 1973, *Genet. Res.* 21: 239-245). RK2 in young cultures.**cytology:** Deficiency analysis places  $A53g$  in 3A5 (Hillman), which is at variance with the genetic position of  $A$ . $a-3$ : see  $a(3)26$ **\*A-p: Abnormal abdomen-polygenic****location:** Polygenic.**discoverer:** Sobels, 49i.**references:** 1950, *DIS* 24: 62.1951, *DIS* 25: 75-76.1952, *Genetica* 26: 117-279 (fig.).1952, *Trans. Intern. Congr. Entomol.*, 9th, Vol. 1: 225-30.**synonym:**  $AA$ ;  $Asy$ : *Asymmetric*.

**phenotype:** Incomplete mediodorsal fusion and on-sided reduction of tergites. When more than one tergite is abnormal, spiral segmentation types are most frequent. Expression strongly dependent on environment. Penetrance and expressivity correlated (Bezem and Sobels, 1953, Koninkl. Ned. Akad. Wetenschap., Proc. Ser. C. 56: 48-61). In strains selected for penetrance of *A-p*, mediodorsal fusion or asymmetrical reduction of head and thorax also occur. RK3.

**\*a(1)48: abnormal abdomen in chromosome 1**

**location:** 1- (not located).

**origin:** Spontaneous.

**discoverer:** Zimmerman, 1948.

**references:** 1952, DIS 26: 69.

1954, Z. Indukt. Abstamm. Vererbungs. 86: 327-72 (fig.).

**phenotype:** Used to describe three X chromosomes with little or no effect of their own but which increase the incidence of abdominal malformations in crosses with *a(2)* and *a(3)*. Viability and fertility good. RK3.

**alleles:** The three chromosomes designated *\*a(1)48*, *\*a(1)50*, and *\*a(1)51* (CP627). Genetic relations not worked out.

**a(1)HM26**

**location:** 1-(y-cv).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)HM26*.

**references:** Mayoh and Suzuki, 1973, Can. J. Genet. Cytol. 15: 237-54.

**phenotype:** Missing or reduced sternites; missing or angled tergites; black specks on ventral surface of abdomen in about one-third of males at 22° and more than half of males at 17°. Viability reduced at 17° relative to that at 22°.

**a(1)HM27**

**location:** 1-(near y).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)HM26*.

**references:** Mayoh and Suzuki, 1973, Can. J. Genet. Cytol. 15: 237-54.

**phenotype:** Same as *a(1)HM26*; more severe at 17° than at 22°. Viability slightly reduced at 17° relative to that at 22°.

**\*a(2)48**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Zimmerman, 1948.

**references:** 1952, DIS 26: 69.

1954, Z. Indukt. Abstamm. Vererbungs. 86: 327-72 (fig.).

**phenotype:** Abdominal irregularities most frequently involve anterior segments. Penetrance 7%. Also shows maternal effect. Viability and fertility good. RK3.

**alleles:** Second chromosomes with some or all of these effects are *\*a(2)50*, *\*a(2)51*, and *\*A(2)51*. Genetic relations not worked out.

*a(3)26*: see *abd*

**\*a(3)48**

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Zimmerman, 1948.

**references:** 1952, DIS 26: 69.

1954, Z. Indukt. Abstamm. Vererbungs. 86: 327-72 (fig.).

**phenotype:** Only a maternal effect affecting 2.5% of progeny. Irregularities most frequently involve posterior segments of abdomen. Viability and fertility good. RK3.

*A34*: see *bw*<sup>V6</sup>

**aa: anarista**

**location:** 3-0.

**discoverer:** Bridges, 23d10.

**synonym:** *al-b: aristaless-b*.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 218.

**phenotype:** Aristae bare or tufted. Wings somewhat broader than wild type. Expression variable, overlaps wild type often in female and sometimes in male. RK3.

**cytology:** Placed between 61E2 and 62A6 on basis of its inclusion in *Df(3L)D = Df(3L)61E2-F1;62A4-6* from *T(Y;2;3)D*.

**Aa: Altered abdomen**

**location:** 1- (not located).

**origin:** X ray induced in the *In(1)dl-49, y w f* component of *C(1)DX*.

**discoverer:** Cicak, 56f.

**references:** Cicak and Oster, 1957, DIS 31: 80.

**phenotype:** Heavy deposition of melanin in tergites of females and males. *Aa* detachment-bearing males sterile. RK2A.

**cytology:** Possibly associated with a rearrangement in addition to *In(1)dl-49*.

*AA*: see *A-p*

**ab: abrupt**

**location:** 2-44.0.

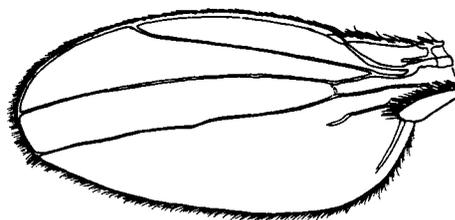

**origin:** Spontaneous.

**discoverer:** Bridges, 16j16.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 218 (fig.).

**phenotype:** Vein L5 usually stops after posterior crossvein. Scutellar bristles usually fewer. Wing effect probably acts during contraction period (Waddington). Overlaps wild type. Expression more severe in females than in males and when pupal stage takes place at 20° than at 25°. TSP during the first 10% of pupal stage. (Thompson, Bruni, Carbonaro, and Russo, 1988, DIS 67: 86). RK2.

**alleles:** *ab*<sup>1</sup>, *ab*<sup>2</sup> (see below), *ab*<sup>51g</sup>, like *ab*<sup>2</sup> in *In(2L+2R)Cy*; *\*ab*<sup>l-60h</sup>: *abrupt lethal* (CP627).

**ab: abrupt**

Edith M. Wallace, unpublished.

**ab<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** Bridges, 23g6.

**synonym:** *pt*: *parted*.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 232.

**phenotype:** Vein L5 does not reach margin. Scutellar bristles always fewer than wild type. Hairs parted down midline of thorax and abdomen. Supra-alar bristles sometimes absent. Coxae tend to be thickened. Males sterile and have rotated genitalia. *ab/ab<sup>2</sup>* resembles *ab/ab* but has a stronger bristle effect. RK2.

**abb: abbreviated**

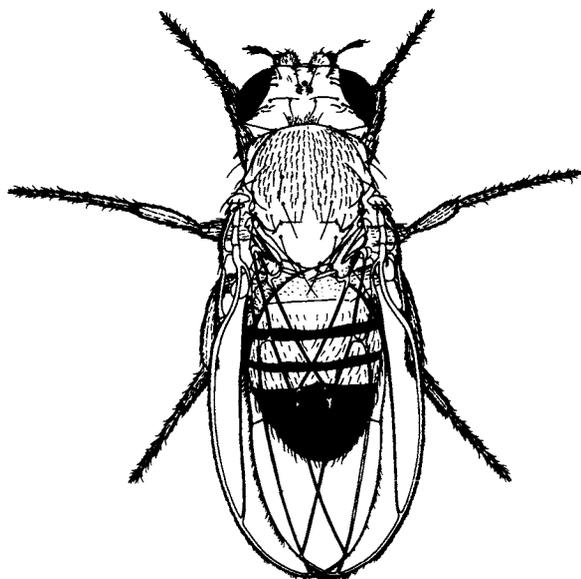

**location:** 2-105.5.

**discoverer:** Bridges, 28d6.

**references:** 1937, *Cytologia* (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Bristles smaller, especially posterior scutellars. Developmental time slightly longer than normal. Viability only slightly reduced. Classification difficult, especially in early eclosions; improves with age of culture. Enhanced by *shr* (2-2.3), making classification easy. RK3; RK2 with *shr*.

**cytology:** Placed in region between 59E2 and 60B10 by Bridges (1937) on basis of its being to the right of *In(2R)bw<sup>VDel</sup> = In(2R)41B2-C1;59E2-4* and to the left of *Df(2R)Px = Df(2R)60B8-10;60D1-2*.

**abb: abbreviated**

From Bridges and Brehme, 1944, *Carnegie Inst. Washington Publ. No.* 552: 11.

**abd: abdominal**

**location:** 3-27 (to the right of *se*).

**origin:** Spontaneous.

**discoverer:** H. A. and N. W. Timoféeff-Ressovsky.

**synonym:** *a-3*, *a(3)26*.

**references:** 1927, Wilhelm Roux's *Arch. Entwicklungsmech. Organ.* 109: 70-109.

Schäffer, 1935, *Z. Indukt. Abstamm. Vererbungsl.* 68: 336-60 (fig.).

**phenotype:** Irregular reduction of abdominal tergites, sternites, pigmentation, and bristles; more marked in females and increased by crowding and dry food (Braun, 1938, *Am. Naturalist* 72: 189-92). Schäffer's data (1935) suggest irregular dominance in heterozygote, overlapping of wild type in homozygote, and genetic modifiers. RK3.

**alleles:** *abd<sup>2</sup>*, spontaneous; recovered by Gottschewski, 1939. Partially complements *abd<sup>1</sup>*. Allelism inferred from similarity in genetic location and phenotype and incomplete complementation.

**cytology:** Placed in 66D9-E1 based on its inclusion in *Df(3L)h-i22 = Df(3L)66D9-E1* (Ingham, Pinchin, Howard, and Ish-Horowitz, 1985, *Genetics* 111: 463-86).

**Abl: Cellular abl oncogene sequence**

**location:** 3-{44}.

**origin:** Isolated from genome library using *v-abl* probe.

**synonym:** *Dash*.

**references:** Shilo and Weinberg, 1981, *Proc. Nat. Acad. Sci. USA* 78: 6789-92.

Simon, Kornberg, and Bishop, 1983, *Nature* (London) 302: 837-39.

**phenotype:** Considered to be the *Drosophila* sequence homologous to mammalian *c-abl* based both on its origin and amino acid sequence as inferred from its nucleotide sequence.

ABL protein detected at the time of germ-band shortening in the axons of the central nervous system in a bilateral symmetrical series of points that correspond to the positions of neuromeres; later, protein appears in the axons growing across the midline, but not in the cell bodies of the CNS nor in the PNS. As development proceeds, staining of the longitudinal fascicles and to a lesser extent the commissural fascicles becomes intense; staining also seen in association with axonal outgrowth of neural cells in the eye imaginal disk (Bennett and Hoffmann).

Recessive alleles in combination with *Df(3L)st-j7 = Df(3L)73A1-2;73B1-2* either die as late pupae or pharate adults with complete cuticle and roughened eyes, *Abl<sup>11</sup>*, or as short lived (5-6 days), rough-eyed adults, *Abl<sup>12</sup>* and *Abl<sup>13</sup>*. Surviving females lay few eggs, some of which develop into adults; surviving males have motile sperm, but do not mate and produce no progeny. The rough eye is a reflection of some loss of photoreceptor cells plus ommatidial fusion. In combination with a deficiency extending further to the left, e.g., *Df(3L)std11 = Df(3L)73A11-B1;73D1-2* to include the locus of *Dab*, *Abl<sup>1</sup>/Abl<sup>-</sup>* genotypes die as late embryos or early first-instar larvae with disrupted axonal organization in the ventral nerve cord (Henkemeyer, Gertler, Goodman, and Hoffmann, *Cell* 51: 821-28). CNS of doubly deficient embryos, i.e., *Abl<sup>-</sup>Dab<sup>-</sup>*, fails to form commissures and is defective in axonal outgrowth, although the PNS develops normally.

**alleles:** Three ethyl-methanesulfonate-induced recessive lethal or semilethal alleles recovered in combination with *Df(3L)st4* or *Df(3L)st-e5* by Belote, McKeown, and Hoffmann are designated *Abl*<sup>11</sup>, *Abl*<sup>12</sup>, and *Abl*<sup>13</sup>. Phenotypic descriptions given above.

**cytology:** Localized to 73B by *in situ* hybridization with genomic clone (Simon *et al.*).

**molecular biology:** Sequence isolated using *v-abl* probe from murine leukemia virus (Hoffman-Falk, Einat, Shilo, and Hoffmann, 1983, Cell 35: 393-401). cDNA and genomic sequencing (Telford, Burkhardt, Butler, and Pirrotta, 1985, EMBO J. 4: 2609-15; Henkemeyer, Bennett, Gertler, and Hoffmann, 1988, Mol. Cell Biol. 8: 843-53) reveal a gene of ten exons distributed over 26 kb of genomic DNA; the exons encode a protein of 1520 amino acids, whose sequence is more similar to mammalian *c-abl* sequence than to that of any other gene; between residues 187 and 656, which contains the tyrosine kinase essential domain, the *Drosophila* sequence is 75-85% similar to that of the human *abl* gene. 33 bp region beginning at tyrosine-416 84% homologous to mammalian nucleotide sequence and 62% homologous to *C-src* DNA from *Drosophila* (Hoffmann, Fresco, Hoffman-Falk and Shilo, 1983, Cell 35: 393-401). The polypeptide product as yet unidentified but presumed to be a protein kinase; *Drosophila* extracts do contain a tyrosine kinase activity (Simon *et al.*). The carboxy half of the ABL protein is not conserved between flies and mammals. Expression of the kinase essential domain in bacteria leads to excessive phosphorylation of proteins at tyrosine residues. Developmental Northern blots probed with 800 base-pair sequence from region of highest homology with *v-abl* reveal a 6.2 kb polyadenylated transcript in early but not late embryos, larvae or adults; most abundant in 0-4 hr embryos; absent after 8 hr (Lev, Liebovitz, Segev, and Shilo, 1984, Mol. Cell. Biol. 4: 982-84); returns in a burst of activity in early pupae.

**abnormal tergites:** see *abt*

**abnormal wings:** see *abw*

**abo: abnormal oocyte**

**location:** 2-44.0 (mapped with respect to *J*, 2-41).

**origin:** Naturally occurring allele recovered near Rome, Italy.

**references:** Sandler, Lindsley, Nicoletti, and Trippa, 1969, Genetics 64: 481-93.

Mange and Sandler, 1973, Genetics 73: 73-86.

Sandler, 1970, Genetics 64: 481-93.

1975, Israel J. Mol. Sci. 11: 1124-34.

1977, Genetics 86: 567-82.

**phenotype:** Probability of survival of embryos produced by *abo/abo* mothers reduced; male embryos more severely affected than female embryos. Both preblastoderm and postblastoderm embryonic death observed; partial rescue of postblastoderm mortality effected by pater-

nally inherited *abo*<sup>+</sup> allele; partial rescue of preblastoderm mortality by heterochromatic *ABO* elements located in *Xh* between 3/4 and 7/8 of the distance from the centromere, in *YL* region h10-11, in *YS* region h19, in *2R* proximal, and perhaps in other heterochromatic regions (Pimpinelli, Sullivan, Prout, and Sandler, 1985, Genetics 109: 701-24). Gradual loss of phenotype in homozygous *abo* stocks accompanied by increase in quantity of ribosomal DNA (Kridler and Levine, 1975, Genetics 81: 501-13). New restriction fragments appear in Hind III/Hae III double digests of such homozygous lines probed with nontranscribed spacer sequences of ribosomal genes (Graziani, Vicari, Boncinelli, Malva, Manzi, and Mariani, 1981, Proc. Nat. Acad. Sci. USA 78: 7662-64). *abo* phenotype returns with subsequent maintenance in heterozygous condition. Homozygous *abo* females exhibit moderate decrease in recombination with concomitant increase in exceptional progeny (Carpenter and Sandler, 1974, Genetics 76: 453-75).

**cytology:** Located in 31F-32E based on its inclusion in *Df(2L)J39 = Df(2L)31A-B;32E* but not *Df(2L)J27 = Df(2L)31B-D;31F* or *Df(2L)Mdh = Df(2L)30D-F;31F*. *abo*-bearing chromosomes differ from others in having a *blood* insertion sequence in 32E (Lavorgna, Malva, Manzi, Gigliotti, and Graziani, 1989, Genetics 123: 485-94).

## ABO

A series of heterochromatic elements capable of reducing the level of maternally influenced preblastoderm, but not postblastoderm, mortality among the progeny of *abo/abo* mothers; embryos that carry ABO elements survive better than those that do not (Pimpinelli, Sullivan, Prout, and Sandler, 1985, Genetics 109: 701-24). Elements identified to date and their heterochromatic locations, where known, are listed in the accompanying table. The rescuing capability of *ABO-X* approximates that of *ABO-YL + ABO-YS*. *ABO-X* apparently defective in *In(1)sc*<sup>4</sup> (Malva, Labella, Manzi, Salzano, Lavorgna, De Ponti, & Graziani, 1985, Genetics 111: 487-94). Effectiveness of *ABO-X* and *ABO-2R* appears to be enhanced by maintenance in a homozygous *abo* stock (Sullivan and Pimpinelli, 1986, Genetics 114: 885-95).

element	cytology
ABO-2R	
ABO-X	h26-28 <sup>α</sup>
ABO-YL	h10-11
ABO-YS	h19

<sup>α</sup> In region that includes proximal half of h26 and distal half of h28 (Pimpinelli, Sullivan, Prout, and Sander, 1985, Genetics 109: 701-24).

**abr: abero**

**location:** 2-83.

**origin:** Spontaneous.

**discoverer:** Bridges, 33b10.

**phenotype:** Abdominal banding etched and irregular.

Wing margins irregular. Eyes rough. Bristles and hairs sparse and disarranged. *abr*<sup>1</sup> + sometimes lacks anterior dorsocentrals. Viability usually poor. RK3.

**other information:** Not allelic to *fr* or *nw*.

**abrupt:** see *ab*

**Abruptex:** see *Ax*, listed under *N: Notch*

**\*abt: abnormal tergites**

**location:** 1-45.6.

**origin:** Induced by 2-chloroethyl methanesulfonate.

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 83.

**phenotype:** Abdomen affected to various degrees, from extreme deformation of tergites to slight abnormalities in distribution of pigment and hairs. Eyes also deformed to various degrees from gross alterations in shape to slight derangement of ommatidia. Wings vary from alterations in size, outline, and venation to small incisions of the inner margin. Most-extreme effects not always positively correlated, and all flies show several atypical characters. Males viable; fertility severely reduced. RK3.

**\*abw: abnormal wings**

**location:** 1-60.

**origin:** X ray induced.

**discoverer:** Halfer, 1963.

**phenotype:** Wing size reduced; wings upturned; L5 and crossveins absent. Plexus of veins between L3 and L4. RK1.

**abx:** see **BXC**

**ac:** see **ASC**

**Ac:** see **Cu<sup>A</sup>**

**Ac-SD:** see **Rsp**

**acc: acclinal wing**

**location:** 1-54.5.

**origin:** Induced by triethylenemelamine.

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 67.

**phenotype:** Wings upheld but slope backward at 45° angle from abdomen. Unable to fly or jump; muscles normal in gross and ultrastructural morphology. Mosaic experiment suggests possible thoracic neural etiology (Deak, 1976, J. Insect Physiol. 22: 1159-65). Viability and fertility good in both sexes. RK1.

**alleles:** One allele each induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine and by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine.

**Ace: Acetyl cholinesterase (J.C. Hall)**

**location:** 3-52.2.

**synonym:** *l(3)26*.

**references:** Hall and Kankel, 1976, Genetics 83: 517-35.

Greenspan, Finn, and Hall, 1980, J. Comp. Neurol. 189: 741-74.

Hall, Alahiotis, Strumpf, and White, 1980, Genetics 96: 939-65.

**phenotype:** The structural gene for acetylcholinesterase [AChE, acetylcholine acetyl hydrolase (EC 3.1.1.7)], the enzyme that terminates synaptic transmission by rapidly hydrolyzing the neurotransmitter acetylcholine. Biochemical analysis (*e.g.*, Zingde, Rodrigues, Joshi, and Krishnan, 1983, J. Neurochem. 41: 1243-52; Gnagey, Forte, and Rosenberry, 1987, J. Biol. Chem. 262: 13290-98; Fournier, Bride, Karch, and Bergé, 1988, FEBS Lett. 238: 333-37; Haas, Marshall, and Rosenberry, 1988, Biochemistry 27: 6453-57; Toutant, Arpagaus, and Fournier, 1988, J. Neurochem. 50: 209-18; Fournier, Bergé, Almeida, and Bordier, 1988, J. Neurochem. 50: 1158-63), indicates that the mature enzyme

contains noncovalently associated subunits of 16 and 55 kd, which are processed from a primary translation product of *ca* 70 kd such that the 16-kd moiety is from the N terminus and the 55-kd moiety is from the C terminus; two such associations are linked via disulfide bonds connecting the 55-kd polypeptides anchored to membrane via a glycoinositol phospholipid anchor covalently linked to the C termini of the 55-kd subunits. Extracts contain amphiphilic dimers and monomers as well as hydrophilic dimers and monomers, which lack the glycoinositol phospholipid anchor. Developmental profile studied by Dewhurst, McCaman, and Kaplan (1970, Biochem. Genet. 4: 499-508; see also Arpagaus, Fournier, and Toutant, 1988, Insect Biochem. 18: 539-49); total AChE activity shows a transient peak during first larval instar and rises again to a maximum in the adult. In the developing eye disc, AChE first appears in retinula cells three to four days before they are functional and when it cannot have a synaptic function; levels are reduced in retinula cells midway through pupal development, and the enzyme accumulates rapidly in the neuropils of the optic lobes of the brain and the midbrain (Wolfgang and Forte, 1989, Dev. Biol. 131: 321-30). Putative nulls are lethal at end of embryonic stage; then ultrastructural observations of CNS in such mutants suggest neural-degenerative defects (Chase and Kankel, 1988, Dev. Biol. 125: 361-80). ACE-minus tissues survive in mosaics unless enzyme absent from posterior midbrain; surviving mosaics have defective visual physiology, optomotor behavior or courtship, depending on location of mutant clone. Such clones associated with defective morphology or neuropile of various ganglia in central nervous system (Greenspan *et al.*, 1980). In heat-sensitive combinations of *Ace* mutations (Greenspan *et al.*, 1980), both membrane-bound and soluble enzyme has reduced activity (Zador, 1989, Mol. Gen. Genet. 218: 487-90).

**alleles:** Unless noted otherwise in comments column alleles are null as is *Ace<sup>1</sup>*.

<sup>α</sup> 1 = Greenspan, Finn, and Hall, 1980, J. Comp. Neurol. 189: 741-74; 2 = Hall, Alahiotis, Strumpf, and White, 1980, Genetics 96: 939-65; 3 = Hall and Kankel, 1976, Genetics 83: 517-35; 4 = Hilliker, Clark, Gelbart, and Chovnick, 1981, DIS 56: 65-72; 5 = Mortan and Singh, 1982, Biochem. Genet. 20: 179-98; 6 = Nagoshi and Gelbart, 1987, Genetics 117: 487-502; 7 = Reuter, Gausz, Gyurkovics, Friede, Bang, Spierer, Hall, and Spierer, 1987, Mol. Gen. Genet. 210: 429-36; 8 = Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 1261-68.

<sup>β</sup> More detailed description below.

**cytology:** Located in 87E3 based on its location between *Df(3R)ry1301 = Df(3R)87D2-4;87E1-2* and *Df(3R)GE41 = Df(3R)87E4* (Hall and Spierer 1986, EMBO J. 5: 2949-54).

**molecular biology:** Locus comprises ten exons and nine introns distributed within a 34-kb transcription unit (Fournier, Karch, Bride, Hall, Bergé, and Spierer, 1989, J. Mol. Biol. 210: 15-22) extending from approximately coordinates 18 to 52 kb on the molecular map of Bender, Spierer, and Hogness (1983, J. Mol. Biol. 168: 17-33) whose origin is 6.5 kb to the left of the left breakpoint of *In(3R)Cbx<sup>rv1</sup>* with positive values extending to the right. Transcription takes place from right to left. The 5' untranslated region is transcribed from exons I and II; the signal sequence is encoded in exon II, the 16-kd polypeptide by exons II, III, and IV; the 55-kd polypeptide by exons IV, V, VI, VII, VIII, and IX; the hydrophobic peptide exchanged in mature protein with a glycolipid anchor as well as the 3' untranslated region by exon X. The mature transcripts are estimated at 4.2 and 4.5 kb (Nagoshi and Gelbart, 1987, Genetics 117: 487-502). cDNA sequencing (Hall and Spierer, 1986; Fournier *et al.*, 1989) indicates mature transcript of 4291 nucleotides encoding a 650-amino-acid protein product, which displays a high degree of homology with AChE from *Torpedo californica*; however, the *Drosophila* protein carries a 38-amino-acid signal sequence lacking in *Torpedo*, and a 41-amino-acid hydrophilic sequence extending from residues 140 to 180 that is not contained in the *Torpedo* sequence; the latter is encoded by exons III and IV, and contains the site of proteolytic cleavage of the *Drosophila* AChE primary translation product.

### *Ace*<sup>I</sup>

**phenotype:** Temperature insensitive lethal; lethal in homozygotes or in combination with deficiency for *Ace*<sup>+</sup>. Lethality at end of embryonic stage. Greatly reduced levels of acetylcholinesterase. AChE-minus tissues survive in mosaics unless enzyme absent from posterior midbrain; surviving mosaics have defective visual physiology, optomotor behavior, or courtship depending on location of mutant clone. Such clones associated with defective morphology of neuropile of various ganglia in

central nervous system.

**molecular biology:** DNA insert in fifth intron (Fournier *et al.*, 1989) observed at approximately coordinate +30; separable by recombination from the *Ace*<sup>I</sup> mutation (Nagoshi and Gelbart, 1987, Genetics 117: 487-502).

### *Ace*<sup>HD1</sup>

**phenotype:** Retains some ACE activity (Nagoshi and Gelbart, 1987, Genetics 117: 487-502), but only as soluble enzyme outside CNS (Zudor *et al.*, 1986).

**molecular biology:** Deleted of promoter region and first (non-coding) exon (Fournier *et al.*, 1989).

### *Ace*<sup>J29</sup>

**phenotype:** The original allele of this complementation group. Cold sensitive lethal. Maximum survival of *Ace*<sup>J29</sup>/*Df(3R)l26d* at 27°, no survival at 18°. Exposure to 18° does not reduce AChE activity. *Ace*<sup>J29</sup> alters Km of enzyme, further implying structural gene locus.

### *Ace*<sup>J40</sup>

**phenotype:** Nearly completely lethal. Two percent survival in combination with *Df(3R)l26d* at 18°, none at 29°. Partial complementation of *Ace*<sup>J19</sup> and *Ace*<sup>J50</sup>; heat sensitive; extracts of *Ace*<sup>J40</sup> lack the 110 kilodalton molecular species, whereas *Ace*<sup>J19</sup> and *Ace*<sup>J50</sup> lack the 64 and 75 kilodalton species (Zingde, Rodrigues, Joshi, and Krishnan, 1983, J. Neurochem. 41: 1243-52). Enzyme produced by heteroallelic combinations raised under permissive conditions is thermolabile. Exposure of *Ace*<sup>J40</sup>/*Ace*<sup>J19</sup> or *Ace*<sup>J40</sup>/*Ace*<sup>J50</sup> flies to restrictive temperature during late embryonic-early larvae stage lethal; little effect on mid and late larval stages; pupal exposure causes defects in adult phototaxis and motor activity. Heat treatment of adults causes no decline in ACE activity but decrements in phototaxis (29°), and cessation of movement (31°) observed. *Ace*<sup>J40</sup> produces enzyme with altered Km.

**molecular biology:** Appears to map proximal to a DNA insert located between coordinates +43 and +48 (Nagoshi and Gelbart, 1987).

### *Ace*<sup>J44</sup>

**molecular biology:** Associated with a molecularly defined structural variation; probably loss of a *Bam* H1 site around coordinate +33 (Gausz, Hall, Spierer, and Spierer, 1986, Genetics 112: 65-78). Structural variant and mutation appear to be inseparable by recombination (Nagoshi and Gelbart, 1987).

### *Ace*<sup>Im35</sup>

**phenotype:** Hypomorphic allele. Exhibits reduced survival (< 30%) in combination with *Df(3R)l26d*. Enzyme activity in *Ace*<sup>Im35</sup>/+ heterozygotes lower than in heterozygotes for more severe alleles.

### *Ace*<sup>mr</sup>: Acetylcholinesterase-malathion resistant

**origin:** Recovered from line selected for malathion resistance.

**phenotype:** Acetylcholinesterase from homozygotes has lower K<sub>m</sub>, lower activity, and slightly increased electrophoretic mobility compared to wild type. Relation to malathion resistance unclear.

### ACE1: Amplification Control Element on chromosome 1

A sequence required for amplification in ovarian follicle cells of the cluster of chorion-protein genes located at 7F1-2 (*Cp36* and *Cp38*); provisionally located between 654 and 266 base pairs upstream from *Cp38* (Wakimoto).

### ACE3

A sequence required for amplification in ovarian follicle cells of the cluster of chorion-protein genes located at 66D11-15 (*Cp15*, *Cp16*, *Cp18* and *Cp19*); located between 615 and 187 base pairs upstream from *Cp18* (Kalfayan, Levine, Orr-Weaver, Parks, Wakimoto, deCicco, and Spradling, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 527-35).

**Acetyl choline receptor:** see *Acr*

**achaete:** see *ac* under *ASC*

**Ach:** see *emc*<sup>D</sup>

### Acp: Accessory gland protein

Genes inferred from bands on SDS polyacrylamide gels. Six polypeptides are highly polymorphic, exhibiting several electrophoretic variants; these all map to chromosome 2 and are tabulated below. Codominant expression indicates that variants are in structural genes and not attributable to differences in post-translational modification (Whalen and Wilson, 1986, Genetics 114: 77-92).

locus	genetic location	cytological location	molecular mass (kd)
<i>AcpA</i>	2-		165-70
<i>AcpB</i>	2-42.8	36D1-E4	130-140
<i>AcpC</i> <sup>α</sup>	2-53.0		125-128
<i>Acp-g1</i> <sup>α</sup>	2-13.5		145-163
<i>AcpJ</i>	2-		45
<i>AcpK</i> <sup>α</sup>	2-54.1		43

<sup>α</sup> variants include a null allele.

### Acp70A: Accessory gland peptide

**location:** 3-{40}.

**references:** Chen, Stumm-Zollinger, Aigaki, Balmer, Bienz, and Böhlen, 1986, Cell 54: 291-98).

**phenotype:** Encodes a 36-amino-acid peptide that is synthesized in the accessory gland and is transferred to the female where it represses female sexual receptivity and stimulates oviposition. The peptide contains a high concentration of basic amino acids, tryptophan and hydroxyproline as well as an unique residue of unknown nature that is encoded by a leucine codon.

**cytology:** Placed in 70A by *in situ* hybridization.

**molecular biology:** Gene cloned and sequenced; conceptual sequence indicates a hydrophobic amino-terminal signal sequence of 19 residues. mRNA for prepeptide accumulates exclusively in the male accessory gland.

### AcpH-1: Acid phosphatase 1

**location:** 3-101.1 (between *ca* and *bv*).

**discoverer:** MacIntyre, 1964.

**references:** 1966, DIS 41: 61.  
1966, Genetics 53: 461-74.

**phenotype:** Structural gene for acid phosphatase 1 [ACPH-1 (EC3.1.3.2)], the major phosphatase in adults; responsible for approximately 90% of the low-pH nucleotidase activity throughout development. Glycopro-

tein homodimer with subunit molecular weight of 50,000 daltons. Purification and biochemical characterization by Feigen, Mitrick, Johns, Postlethwait, and Sederoff (1980, J. Biol. Chem. 255: 10338-43). Serves as a reliable cytochemical marker in many tissues (Hall, 1979, Genetics 92: 437-57). Enzyme appears to be produced in nurse cells and follicular cells of ovary and transferred to oocyte through the ring canals and by pinocytosis, respectively (Sawicki and MacIntyre, 1977, Dev. Biol. 60: 1-13); maternally produced enzyme persists to third instar; paternal gene function detectable in gels after 9-10 hr of embryonic development (Yasbin, Sawicki, and MacIntyre, 1978, Dev. Biol. 63: 35-46); and after 5 hr histochemically (Sawicki and MacIntyre, 1978, Dev. Biol. 63: 47-58). Enzyme found in larvae, pupae, and adults; levels increase during adult life (Postlethwait and Gray, 1975, Dev. Biol. 47: 196-205).

**alleles:** In addition to the information tabulated below, pairwise combinations of *AcpH-1*<sup>n2</sup>, *AcpH-1*<sup>n3</sup>, *AcpH-1*<sup>n6</sup>, and *AcpH-1*<sup>n9</sup> exhibit 20-40% normal levels of cross reacting material (CRM).

<sup>α</sup> 1 = Bell, MacIntyre, and Olivieri, 1972, Biochem. Genet. 6: 205-16; 2 = Burkhart, Montgomery, Langley, and Voelker, 1984, Genetics 107: 295-306; 3 = Langley, Voelker, Leigh Brown, Ohnishi, Dickson, and Montgomery, 1981, Genetics 99: 151-56; 4 = MacIntyre, 1968, DIS 3: 60.

**cytology:** Located between 99C5 and 7 based on its deletion by *Df(3R)ca-R14 = Df(3R)99A8-9;99D1-2* but not by *Df(3R)ca-165P = Df(3R)99B2-4;99C5-6* (Frisardi and MacIntyre, 1984, Mol. Gen. Genet. 197: 403-13).

### Acr60C: Acetyl choline receptor in 60C

**location:** 2-{107}.

**references:** Shapiro, Wakimoto, Subers, and Nathanson, 1989, Proc. Nat. Acad. Sci. USA 86: 9039-43.

Onai, FitzGerald, Arakawa, Gocayne, Urquhart, Hall, Fraser, McCombie, and Venter, 1989, FEBS Lett. 255: 219-25.

**phenotype:** The structural gene encoding a Drosophila homologue of vertebrate muscarinic acetylcholine recep-

tor (mAChR). When expressed in Y1 adrenal cells it is physiologically active as measured by agonist dependent stimulation of phosphatidylinositol metabolism.

**cytology:** Placed in 60C7-8 by *in situ* hybridization.

**molecular biology:** Genomic clone isolated from library using a probes from vertebrate muscarinic acetylcholine receptor genes. Nucleotide sequences of cDNA clones reveal a long open reading frame that encodes a 788-amino-acid protein with calculated molecular weight of 84,807 (Onai *et al.*). The amino-acid sequence shows a number of features characteristic of the muscarinic/adrenergic receptor gene superfamily in vertebrates: three potential N-linked glycosylation sites (Asn 65, 84, and 87), seven putative membrane-spanning domains. It displays a high degree of amino-acid identity with vertebrate muscarinic acetylcholine receptors, ~60% overall and up to 88% in transmembrane regions; the segment between transmembrane domains 5 and 6 is considerably longer than that of vertebrate sequences; also the gene has three introns in the region.

### **Acr64B**

**location:** 3-{8}.

**synonym:** *ard*.

**references:** Hermans-Borgmeyer, Zopf, Ryseck, Hovemann, Betz, and Gundelfinger, 1986, EMBO J. 5: 1503-08.

Wadsworth, Rosenthal, Kammermeyer, Potter, and Nelson, 1988, Mol. Cell Biol. 8: 778-85.

Sawruk, Hermans-Borgmeyer, Betz, and Gundelfinger, 1988, FEBS Lett. 235: 40-46.

**phenotype:** Structural gene encoding a Drosophila homologue of a subunit of vertebrate nicotinic acetylcholine receptors (nAChR). Antibody raised against *Acr64B* fusion proteins immunoprecipitate one of two high-affinity  $\alpha$ -bungarotoxin-binding sites from detergent extracts of Drosophila head membranes (Schloss, Hermans-Borgmeyer, Betz, and Gundelfinger, 1988, EMBO J. 7: 2889-94). *In situ* hybridization localizes *Acr64B* expression to nervous tissue, especially in late embryos, pupae, and newly eclosed adults (Hermans-Borgmeyer, Hoffmeister, Sawruk, Betz, Schmitt, and Gundelfinger, 1989, Neuron. 2: 1147-56).

**cytology:** Placed in 64B by means of *in situ* hybridization.

**molecular biology:** Genomic clones identified using a *Torpedo californica* nAChR probe; these hybridize to a 3.2-kb mRNA present at high levels on developmental Northern blots in late embryos and during metamorphosis, periods of neuronal differentiation. Genomic probes used to isolate overlapping cDNA clones. The gene comprises six exons distributed over approximately seven kb of genomic sequence. The predicted mature protein after cleavage of a 24 amino-acid signal sequence, consists of 497 amino acids, has a calculated molecular weight of 57,340 and shows extensive homology to all known nAChR genes of other species along its entire amino acid sequence, conforming most closely to neuronal  $\alpha$  subunits, although it lacks the cysteine doublet at residues 201 and 202 characteristic of all other  $\alpha$  subunits. It contains four putative transmembrane domains, a potential amphipathic  $\alpha$  helix, and a canonical N-glycosylation site Asn48; however, the N-linked glycosylation site found at residue 141 in all vertebrate nAChR's is absent in *Drosophila*.

### **Acr96A**

**location:** 3-{83}.

**synonym:** *ALS: Alpha-Like Subunit*.

**references:** Bossy, Ballivet, and Spierer, 1988, EMBO J. 7: 611-18.

**phenotype:** Structural gene encoding a Drosophila homologue of a subunit of vertebrate nicotinic acetylcholine receptors (nAChR); inferred to be homologous to neuronal  $\alpha$  subunits based on the cysteine doublet at amino-acid residues 201 and 202.

**cytology:** Placed in 96A by *in situ* hybridization.

**molecular biology:** Genomic clones identified using as a probe a fragment of the chick neuronal nAChR $\alpha$ 2 gene; these hybridize to a 10.5 kb mRNA present at high levels on developmental Northern blots from late embryo to pupation, decreasing in late pupae and adults; genomic probes used to isolate overlapping cDNA clones. The gene comprises ten exons distributed over 54 kb of genomic sequence; combined nucleotide sequence from the cDNA clones defines a single long open reading frame of 1701 nucleotides bracketed by 1282 5' and 514 3' nucleotides. The ORF encodes 567 amino acids, which show 40-44% sequence conservation with mammalian neuronal nAChR  $\alpha$  subunits and with *Drosophila Acr64B* product. Structural domains homologous to those of vertebrate nAChR subunits include a cysteine doublet at residues 201 and 202 that characterizes all  $\alpha$  subunits, four transmembrane domains, two potential glycosylation sites (Asn 24 and 212) characteristic of vertebrate neuronal  $\alpha$  subunits, and an amphipathic  $\alpha$ -helical region in the C-terminal quarter of the polypeptide. In addition, the positions of four *Drosophila* introns correspond exactly to those of four of seven vertebrate AChR introns.

*Activator of SD*: see *Rsp*

### **act: actidione sensitive**

**location:** 3-90 (21 units to the right of *H*).

**origin:** Naturally occurring allele.

**references:** Marzluf, 1969, Biochem. Genet. 3: 229-38.

**phenotype:** *act/act* killed by 0.1 the concentration of actidione (cycloheximide) that *act*<sup>+</sup>-bearing strains survive.

**alleles:** Recessive allele fixed in Oregon-R and Canton-S strains. Urbana-S and Swedish-b carry *act*<sup>+</sup>.

### **Act5C: Actin in region 5C**

**location:** 1-{14}.

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Kindle, Davidson, and Sodja, 1980, Cell 19: 365-78.

Fyrberg, Bond, Hershey, Mixer, and Davidson, 1981, Cell 24: 107-16.

**phenotype:** Codes for cytoplasmic actin; transcribed throughout development; one of two actin genes transcribed in Kc cells and several other cell lines (Fyrberg, Mahaffy, Bond, and Davidson, 1983, Cell 33: 115-23). One of three actin genes expressed in the wing disc during wing development, each with its characteristic profile. Peak expression at 44h of pupal age, little or no expression at 60h rising again at 80h. 44h peak corresponds to time of maximum change in cell shape (Peterson, Bond, Mitchell, and Davidson, 1985, Dev.

Genet. 5: 219-25). Transcripts present in the preblastoderm embryo suggesting maternal transcription; during blastoderm formation, *Act5C* transcripts accumulate at the periphery of the embryo; local concentrations of transcript observed in anterior and posterior midgut rudiments in stage 13 embryos; hybridization also observed in the developing ventral nervous system. Later in embryogenesis, transcript found in all tissues but with dramatic concentrations of transcripts in the anterior and posterior midgut and the proventriculus. Exon specific probes demonstrate that transcripts containing exon 1 tend to be concentrated in anterior portions of early embryos, including the anterior midgut primordium and the proventriculus, as well as in the posterior midgut primordium; during germ-band extension, small local concentrations of exon 2 transcripts are seen in posterior and ventral regions of the embryo (Burn, Vigoreaux, and Tobin, 1989, Dev. Biol. 131: 345-55).

**cytology:** Localized to 5C2-5 based on failure of *Act5* specific probe to hybridize to either *Df(1)N73 = Df(1)5C2;5C5-6* or *Df(1)C149 = Df(1)5A8-9;5C5-6* (Sodja, Rizki, Rizki and Zafar, 1982, Chromosoma 86: 293-98).

**molecular biology:** Genomic clone restriction mapped (Fyrberg *et al.*, 1980) and partially sequenced (Fyrberg *et al.*, 1981). Comparison with cDNA clones indicates the presence of three exons, two of which are included in any cDNA (Bond and Davidson, 1986, Mol. Cell Biol. 6: 2080-88). Partial sequence (Bond and Davidson; Vigoreaux and Tobin, 1987, Genes Dev. 1: 1161-71) indicate that all protein encoding sequences reside in exon 3, that either exon 1 or exon 2 is spliced to exon 3, and that there are three transcription start sites, one in exon 1 and two in exon 2, giving rise to different 5' untranslated regions; also there are indications of at least three polyadenylation sites generating messages with 3' untranslated regions of 375, 655, and 945 nucleotides. Using discriminating 5' and 3' probes, Burn, Vigoreaux, and Tobin (1989) have shown that transcripts differing in 5' untranslated regions display different tissue specificities; no 3' specificities are seen. Exons 1 and 2 are each preceded by a functional promoter (Bond-Matthews and Davidson, 1988, Gene 62: 289-300).

### Act42A

**location:** 2-55.4 (inferred from polytene position).

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Bond, Hershey, Mixter, and Davidson, 1981, Cell 24: 107-16.

**phenotype:** Codes for cytoplasmic actin; transcribed throughout development; one of two actin genes transcribed in Kc cells and several other cell lines (Fyrberg, Mahaffy, Bond, and Davidson, 1983, Cell 33: 115-23). One of three actin genes expressed in the wing disc during wing development, each with its characteristic profile. Peak expression at 44h of pupal age, little or no expression at 60h rising again at 80h. 44h peak corresponds to time of maximum change in cell shape (Peterson, Bond, Mitchell, and Davidson, 1985, Dev. Genet. 5: 219-25).

**cytology:** Located in 42A by *in situ* hybridization.

**molecular biology:** Genomic clone =  $\lambda$ DmA3. Partial nucleotide sequence in Fyrberg *et al.* (1981).

### Act57A

**location:** 2-{93}.

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Kindle, Davidson, and Sodja, 1980, Cell 19: 365-78.

Fyrberg, Bond, Hershey, Mixter, and Davidson, 1981, Cell 24: 107-16.

**phenotype:** According to Fyrberg and Davidson, *Act57A* encodes the actin I protein isoform, which is the major actin species of larval intersegmental muscle; also encodes adult cephalic and abdominal muscle (Fyrberg, Mahaffy, Bond and Davidson, 1983, Cell 33: 115-33).

**cytology:** Localized to 57A by *in situ* hybridization.

**molecular biology:** Genomic clone =  $\lambda$ DmA4; coding region restriction mapped and partially sequenced (Fyrberg *et al.*, 1981). Intervening sequence of approximately 630 base pairs inserted in the glycine codon at amino acid position 13 (Fyrberg *et al.*, 1981).

### Act79B

**location:** 3-{47.5}.

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Kindle, Davidson, and Sodja, 1980, Cell 19: 365-78.

Fyrberg, Bond, Hershey, Mixter, and Davidson, 1981, Cell 24: 107-16.

Zulauf, Sánchez, Tobin, Rdest, and McCarthy, 1981, Nature 292: 556-58.

Sánchez, Tobin, Rdest, Zulauf, and McCarthy, 1983, J. Mol. Biol. 163: 533-51.

**phenotype:** According to Zulauf *et al.* (1981), *Act79B* appears to code for actin I, a larval muscle-specific actin. Initial translation product, which migrates as actin II, apparently acetylated to become actin I. Using probe from 3' transcribed-but-not-translated sequences, Sánchez *et al.* demonstrated two minor peaks of transcription during embryogenesis and major peaks during first and second instar and to a lesser degree in the pupa. Fyrberg, Mahaffy, Bond, and Davidson, (1983, Cell 33: 115-23) on the other hand, find *Act79B* to be expressed in adult legs and tubular muscles of thorax, including direct flight muscles, pleurosternal muscles, and muscles of various leg segments. In addition, *Act79B* is expressed in muscles that support the head and abdomen, in the scutellar pulsatile organ, and in two pairs of abdominal muscles that are present only in male flies (Courchesne-Smith, and Tobin, 1989, Dev. Biol. 133: 313-21). One of three actin genes expressed in wing development each with its characteristic developmental profile; peak activity at 80h of pupal age (Peterson, Bond, Mitchell, and Davidson, 1985, Dev. Genet. 5: 219-25).

**cytology:** Localized to 79B by *in situ* hybridization.

**molecular biology:** Genomic clone by Zulauf *et al.* (1981) and as  $\lambda$ DmA6 by Fyrberg *et al.* (1981). Coding region restriction mapped and partially sequenced by Fyrberg *et al.* (1981). Intervening sequence of 357 nucleotides within a glycine codon at position 307 (Fyrberg *et al.*, 1981). Coding sequences, intervening sequences and flanking sequences completely sequenced (Sánchez *et al.*). Encodes a 374-amino-acid 43-kd polypeptide which is 95% homologous with the product of *Act88F*

and 91% homologous with rabbit actin.

**Act87E**

**location:** 3-{52.3}.

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Kindle, Davidson, and Sodja, 1980, Cell 19: 365-78.

Fyrberg, Bond, Hershey, Mixter, and Davidson, 1981, Cell 24: 107-16.

**phenotype:** Encodes actin found in larval muscle and adult cephalic and abdominal muscle (Fyrberg, Mahaffey, Bond, and Davidson, 1983, Cell 33: 115-23).

**alleles:** No lethal alleles of *Act87E* recovered in a lethal-saturation study (Manseau, Ganetzky, and Craig, 1988, Genetics 119: 407-20).

**cytology:** Placed in 87E9-12 by *in situ* hybridization; included in *Df(3R)ry619 = Df(3R)87D7-9;87E12-F1*, but not in *Df(3R)ry1168 = Df(3R)87B15-C1;87E9-12* (Manseau *et al.*, 1988).

**molecular biology:** Genome clone restriction mapped and partially sequenced by Fyrberg *et al.* (1981). Comparison of genomic and cDNA sequence indicates a 556 nucleotide intron in the 5' untranslated region. Conceptual amino-acid sequence shows ~95% identity with other *Drosophila* actins (Manseau *et al.*, 1988).

**Act88F**

**location:** 3-57.1 (based on 41 *cu-sr* and 84 *red-e* recombinants).

**references:** Tobin, Zulauf, Sánchez, Craig, and McCarthy, 1980, Cell 19: 121-31.

Fyrberg, Kindle, Davidson, and Sodja, 1980, Cell 19: 365-78.

Fyrberg, Bond, Hershey, Mixter, and Davidson, 1981, Cell 24: 107-16.

Sánchez, Tobin, Rdest, Zulauf, and McCarthy, 1983, J. Mol. Biol. 163: 533-51.

**phenotype:** Structural gene encoding actin III; expressed only in the developing thorax, specifically in the indirect flight muscles (Fyrberg, Mahaffey, Bond, and Davidson, 1983, Cell 33: 115-23; Hiromi and Hotta, 1985, EMBO J. 4: 1681-87). The only actin expressed in indirect flight muscle (Fyrberg). Heterozygotes for null mutations or *Act88F* deficiencies are flightless; flightlessness is apparently caused by imbalance between myosin heavy chains and actin III; whereas hemizyosity for either *Mhc* or *Act88F* leads to complex myofibrillar defects and flightlessness, double hemizygotes have nearly normal fibrillar structure and are able to fly [Beall, Sepanski, and Fyrberg, 1989, Genes Dev. 3: 131-40 (fig.)]. Major peaks of transcription during pupal stage (Sánchez *et al.*, 1983). Heterozygotes and to a greater degree, homozygotes and heteroallelic heterozygotes for antimorphic alleles *Act88F<sup>4</sup>* and *Act88F<sup>5</sup>* show constitutive synthesis of heat-shock proteins, with HSP26 and HSP27 less actively synthesized than HSP22, HSP70, and HSP84; response to heat shock normal (Hiromi and Hotta).

**alleles:**

allele	origin	synonym	ref <sup>α</sup>	comments

Cell Biol. 7: 3084-91; 5 = Lang, Wyss, and Eppenberger, 1981, Nature 291: 506-08; 6 = Mahaffey, Coutu, Fyrberg, and Inwood, 1985, Cell 40: 101-10; 7 = Mogami and Hotta, 1981, Mol. Gen. Genet 183: 409-17; 8 = Okamoto, Hiromi, Ishikawa, Yamada, Isoda, Mackasa, and Hotta, 1986, EMBO J. 5: 589-96.

**cytology:** Placed in 88F by *in situ* hybridization.

**molecular biology:** Genomic clones isolated by Tobin *et al.* (1980) and by Fyrberg *et al.* (1981). Sequence analysis reveals a translated sequence accounting encoding a 374-amino-acid polypeptide of molecular weight 43 kd, which shows 95% homology with the *Act79B* gene product and 92% homology with rabbit actin. The genomic sequence shows an intron of 60 nucleotides within codon 307 (Sánchez *et al.*, 1983). Deletion analysis of upstream *cis*-acting regulatory sequences carried out by Geyer and Fyrberg (1986, Mol. Cell Biol. 6: 3388-96). Arthrin, a 55-kd protein found in indirect flight muscle shown to be an unquinated form of actin III (Ball, Karlik, Beall, Saville, Sparrow, Bullard, and Fyrberg, 1987, Cell 51: 221-28).

**Act88F<sup>4</sup>**

**phenotype:** Dominant flightless allele; actin III replaced by a truncated polypeptide of 42 kd that is stable and capable of incorporation into myofibrils; actin II reduced in homozygotes (Hiromi and Hotta, 1985). Myofibrils in indirect flight muscles of homozygotes severely deranged; sarcomere structure obliterated; indirect-flight-muscle nuclei enlarged. Skeins of morphologically normal but highly disorganized thick filaments present, but Z discs absent. Thin filaments scarce. Electron dense material of unknown origin seen in sections. Wild-type flies transformed with cloned *Act<sup>4</sup>* sequence produces both the 42-kd and the heat-shock proteins (Hiromi, Okamoto, Gehring, and Hotta, 1986, Cell 44: 293-301).

**Act88F<sup>5</sup>**

**phenotype:** Produces half normal amount of actin isoform III; shows increased synthesis of actin I, normally present in only trace amounts in indirect flight muscle. Indirect-flight-muscle nuclei enlarged and myofibrils disrupted. Heterozygotes flightless.

**Act88F<sup>6</sup>**

**phenotype:** Actin III entirely absent from indirect flight muscle in homozygotes; levels of actin II also reduced.

**Act88F<sup>7</sup>**

**phenotype:** Actin III replaced by a truncated polypeptide of 38 kd; its low concentrations on gels suggests high instability (Hiromi and Hotta, 1985).

**Act88F<sup>8</sup>**

**phenotype:** Studied only in combination with *rsd* at 95.4 on chromosome 3; not examined in *rsd*<sup>+</sup> background. Wings of homozygotes held straight up, nearly meeting over thorax; heterozygotes have wings held normally, but are nearly flightless. Electron microscopy of homozygotes reveals grossly abnormal indirect-flight-muscle structure; lack thin filaments and Z discs (Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rahmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81). Abnormal protein accumulation observed in thoraces. Actin III and its ubiquitinated derivative, arthrin, absent in *Act88F*<sup>8</sup> homozygotes (Lang *et al.*); six other polypeptides, including an indirect-flight-muscle tropomyosin isoform and two indirect-flight-muscle tropomyosin-related isoforms, markedly reduced. Homozygotes transformed with *Act88F*<sup>+</sup> show restoration to approximately normal levels of the six reduced polypeptides. Accumulation of actin III and arthrin still negative, however; the latter attributed to the failure of post-translational modification in the presence of homozygous *rsd*. Viability and fertility normal.

**molecular biology:** a null mutant; *Act88F* mRNA reduced 10-15 fold; alteration of normal sequence apparently outside the coding region; mRNA level, and to some degree, the phenotype rescuable by germ-line transformation using *Act88F* normal genomic sequence. Sequence of coding region of DNA including 60-nucleotide intron reveals differences from that of Canton-S that account for five amino-acids substitution (Mahaffey *et al.*).

**other information:** Conceivable that *Act88F*<sup>9</sup> is a wild-type isoallele with normal phenotype in the absence of *rsd*.

**actidione sensitive:** see *act*

**Actin:** see *Act*

**Actn:  $\alpha$  Actinin**

**location:** 1-1.0.

**synonym:** *l(1)2Cb*

**phenotype:** The structural gene for  $\alpha$  Actinin (Fyrberg).

Both lethal and viable alleles recovered; allelism determined by Homyk and Emerson. Viable alleles unconditionally flightless; wing position normal, but unable to fly or beat wings; jump abnormally short distances. Gynandromorph studies of *Actn*<sup>1</sup> indicate a bilateral pair of submissive foci located mid ventrally close to the embryonic midline (Homyk and Emerson). ERG normal (Homyk and Pye, 1989, J. Neurogenet. 5: 37-48). *Actn*<sup>4</sup> is a heat sensitive lethal, and when raised at low temperature, causes aberrant wing display of courting males; *Actn*<sup>1</sup>/*Actn*<sup>4</sup> jumps and flies abnormally when raised at 22° but normally when raised at 29°; temperature sensitive period for this effect in first half of pupal stage (Homyk *et al.*, 1980). Trans heterozygotes (i.e., *Actn*<sup>3</sup>, *Actn*<sup>4</sup>, *Actn*<sup>8</sup>, and *Actn*<sup>14</sup>) with *hdp-a*<sup>2</sup> also flightless. Lethal alleles die in late larval or early pupal stages; homozygous maternal germline clones produce normal ova. Polyphasic lethality of *Actn*<sup>8</sup> attributed to position effect of the inversion on arm (Perrimon, Engstrom, and

Mahowald, 1985, Genetics 111: 23-41).

**cytology:** Placed in 2C3 based on breakpoint common to three rearrangement associated lethal alleles (Lefevre). Covered by *Dp(1;3)w<sup>vco</sup> = Dp(1;3)2B17-C1;3C4-5;77D3-5;81* but not by *Dp(1;Y)w<sup>+303</sup> = Dp(1;Y)2D1-2;3D3-4* (Perrimon, *et al.*).

**ad: arcoid**

**location:** 2-60.7.

**origin:** Spontaneous.

**discoverer:** Curry, 38a2.

**references:** 1939, DIS 12: 45.

**phenotype:** Wings arched, broad, and somewhat shortened; crossveins close; scutellar groove shallow. Legs may be slightly shorter than wild type. RK3.

**add-B:** see *dmd*<sup>2</sup>

**Additional sex combs:** see *Asx*

**ade1: adenosine1**

**location:** 1-57 (right of *f*).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *ade1-1<sup>sd</sup>*.

**references:** Falk and Nash, 1974, Genetics 76: 755-766.

**phenotype:** Eclosion delayed 2 or 3 days; delay abolished by supplementation of minimal medium with adenosine or guanosine.

**ade2 (S. Henikoff and D. Nash)**

**location:** 2-17.7 [based on 73 *cl-spd* recombinants (Keizer, Nash, and Tiong, 1989, Biochem. Genet. 27: 349-53)].

**references:** Johnstone, Nash, and Naguib, 1985, Biochem. Genet. 23: 539-55.

Henikoff, Nash, Hards, Bleskan, Woolford, Naguib, and Patterson, 1986, Proc. Nat. Acad. Sci. USA 83: 3919-23.

Tiong, Keizer, Nash, Bleskan, and Patterson, 1989, *Biochem. Genet.* 27: 333-48.

**phenotype:** Purine nucleoside auxotroph supplementable with adenine, adenosine, and inosine. Eye color reddish-brown similar to rosy. Lacks detectable levels of the fourth purine *de novo* synthetic-pathway enzyme, formylglycineamide ribotide amidotransferase (FGARAT; EC 6.33.5.3). Homozygotes and heteroallelic combinations of many alleles have defective wings; the defects include reduced wing size, deranged posterior wing margins, and extra wing veins. Macrochaetae are somewhat thinner than normal and reduced in length. *ade2*<sup>5</sup>, *ade2*<sup>6</sup>, and *ade2*<sup>7</sup> are sterile, perhaps owing to general debility, when homozygous or in heteroallelic combination with one another. Only *ade2*<sup>7</sup> was not tested owing to a linked lethal. Most homozygotes and heteroallelic heterozygotes display reduced viability, with the appearance of pharate adults unable to eclose.

***ade3* (S. Henikoff and D. Nash)**

**location:** 2-20.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Nash.

**synonym:** *Gart*.

**references:** Johnstone, Nash, and Naguib, 1985, *Biochem. Genet.* 23: 539-55.

Henikoff, Nash, Hards, Bleskan, Woolford, Naguib, and Patterson, 1986a, *Proc. Nat. Acad. Sci. USA* 83: 3919-23.

Henikoff, Keene, Sloan, Bleskan, Hards, and Patterson, 1986b, *Proc. Nat. Acad. Sci. USA* 83: 720-24.

**phenotype:** Purine nucleoside auxotroph supplementable with adenine, adenosine, and inosine. Recovery of *ade3* progeny from crosses between *ade3* and *ade3/SM5* is about 1% when raised on minimal medium. Less than 3% of the normal activity purine *de novo* synthetic pathway enzyme, glycineamide ribotide transformylase [EC 2.1.2.2 (GART)]. Eye color normal.

**cytology:** 27C by means of *in situ* hybridization of cloned

sequence.

**molecular biology:** Corresponds to the cloned sequence selected by Henikoff, Keene, Tatchell, Hall, and Nasmyth [1981, *Nature* (London) 289: 37] by its ability to complement *ade8* in yeast, which codes for GART. Seven exons specify a 4.7 kb mRNA encoding the second, third, and fifth *de novo* purine biosynthetic-pathway enzyme activities, glycineamide ribotide synthetase [EC 6.3.4.13 (GARS)], aminoimidazole ribotide synthetase [EC 6.3.3.1 (AIRS)], and GART, on a 1353 amino-acid polypeptide. The first four exons also specify a 1.7 kb mRNA encoding *Gars* alone on a 434 amino acid polypeptide (Henikoff *et al.*). This smaller polypeptide is identical to the NH<sub>2</sub>-terminal portion of the larger, except for the last amino acid, as a consequence of alternative processing of the primary transcript. The *ade3* mutation is a single base transition changing a conserved glycine (found at that position in yeast *ade8*) to a serine at amino acid 1164 of the large polypeptide.

A functional pupal cuticle protein gene is found within the first intron (interrupting the GARS domain), is encoded on the other DNA strand, and is itself interrupted by a single intron between codons 4 and 5 of a 184 amino-acid open reading frame. This intronic gene (*Pcp*) is expressed primarily in abdominal epidermal cells that secrete the pupal cuticle (Henikoff, Keene, Fachtel, and Fristrom, 1986, *Cell* 44: 33-42).

**Adenine phosphoribosyl transferase:**  
see *Aprt*

**Adenylate kinase C:** see *Adk-C*

***Adh*: Alcohol dehydrogenase (M. Ashburner)**

**location:** 2-50.1.

**references:** Johnson and Denniston, 1964, *Nature* (London) 204: 906-07.

Grell, Jacobson, and Murphy, 1965, *Science* 149: 80-82.

Ursprung and Leone, 1965, *J. Exp. Zool.* 160: 147-54.

**phenotype:** Structural gene for alcohol dehydrogenase [ADH (EC 1.1.1.1)]. Natural populations are polymorphic for three electrophoretic alleles (*Adh*<sup>F</sup>, *Adh*<sup>S</sup>, *Adh*<sup>F-ChD</sup>) and for three rarer electrophoretic alleles (*Adh*<sup>US</sup>, *Adh*<sup>F'</sup>, *Adh*<sup>UF</sup>). The frequency of the *Adh*<sup>F</sup> allele increases, at the expense of *Adh*<sup>S</sup>, with increasing latitude in both northern and southern hemispheres [Johnson and Schaffer, 1973, *Biochem. Genet.* 10: 149-63; Vigue and Johnson, 1973, *Biochem. Genet.* 9: 213-27; Wilks, Gibson, Oakeshott and Chambers, 1980, *Aust. J. Biol. Sci.* 33: 575-85; Anderson, 1981, *Genetic Studies of Drosophila Populations* (Gibson and Oakes, eds.). Australian National University Press, pp. 237-50; Anderson and Chambers, 1982, *Evolution* 36: 86-96].

Confers resistance to ethanol; flies lacking ADH rapidly become intoxicated and eventually die on exposure to ethanol (Grell, Jacobson and Murphy, 1968, *Ann. N.Y. Acad. Sci.* 151: 441-45; Vigue and Sofer, 1976, *Biochem. Genet.* 14: 127-135; David, Bocquet, Arens and Fouillet, 1976, *Biochem. Genet.* 14: 989-97). However, ethanol sensitivity is complex since even *Adh* nulls are more resistant to ethanol when young than when old (Vigue and Sofer, 1976; Tsubota). *Adh*<sup>+</sup> flies are killed by low concentrations of unsaturated secondary alcohols (e.g. 1-penten-3-ol; 1-pentyn-3-ol) but not by unsaturated

turated primary alcohols (e.g. 1-penten-1-ol) (Sofer and Hatkoff, 1972, *Genetics* 72: 545-49), presumably due to the formation of toxic ketones. This allows the chemical selection of *Adh* nulls (Sofer and Hatkoff, 1972; O'Donnell, Gerace, Leister and Sofer, 1975, *Genetics* 79: 73-83). ADH may play a metabolic role independent of alcohol detoxication, i.e. in the metabolism of higher alcohols (see Winberg, Thatcher and McKinley-McKee, 1982, *Biochem. Biophys. Acta* 704: 7-16). ADH also catalyses the oxidation of acetaldehyde to acetate (Heinstra, Eisses, Schoonen, Aben, de Winter, van de Horst, van Marrewijk, Beenackers, Scharloo and Thörig, 1983, *Genetica* 60: 129-37; Moxon, Holmes, Parsons, Irving, and Doddrell, 1985, *Comp. Biochem. Physiol.* 80B: 525-35).

Specific activity of ADH changes with development, with peaks at the end of the third larval instar and about four days after eclosion (Ursprung, Sofer and Burroughs, 1970, Wilhelm Roux's *Arch. Entwicklungsmech. Org.* 164: 201-08; Dunn, Wilson and Jacobson, 1969, *J. Exp. Zool.* 171: 185-90; Leibenguth, Rammo and Dubiczky, 1979, Wilhelm Roux's *Arch. Dev. Biol.* 187: 81-88; Maroni and Stamey, 1983, *DIS* 59: 77-79; Anderson and McDonald, 1981, *Canad. J. Genet. Cytol.* 23: 305-13). Most of the activity is in the larval fat body and gut and the adult fat body (Ursprung, Sofer and Burroughs). Maternal inheritance of ADH by embryos and larvae (O'Donnell *et al.*; Leibenguth *et al.*). Half life of ADH-F *in vivo* estimated as 55.3 hours (Anderson and McDonald, 1981, *Biochem. Genet.* 19: 411-19). Not expressed in SL2 tissue culture cells, but transfected cloned gene is (Benyajati and Dray, 1984, *Proc. Nat. Acad. Sci.* 1701-05).

Ethanol tolerance usually correlated with ADH activity and polymorphic experimental populations exposed to ethanol usually show an increase in the frequency *Adh<sup>F</sup>* (McDonald and Avise, 1976, *Biochem. Genet.* 14: 347-55; Cavener and Clegg, 1978, *Genetics* 90: 629-44; van Delden, Kamping and van Dijk, 1975, *Experientia* 31: 418-19; Oakeshott, Gibson, Anderson and Champ, 1980, *Aust. J. Biol. Sci.* 33: 105-14; McDonald, Chambers, David and Ayala, 1977, *Proc. Nat. Acad. Sci. USA* 74: 4562-66). Flies carrying *Adh<sup>F</sup>* tend to be more resistant than those carrying only *Adh<sup>S</sup>* to ethanol [Kamping and van Delden, 1978, *Biochem. Genet.* 16: 541-55; Ainsley and Kitto, 1975, *Isozymes* (C. Markert, ed.). Academic Press, Vol. II, pp. 733-43; Briscoe, Robertson and Malpica, 1975, *Nature* (London) 253: 148-49].

Electrophoresis of homozygous genotypes usually reveals three interconvertible isozymes [Ursprung and Leone; Johnson and Denniston; Grell *et al.*, 1965; Ursprung and Carlin, 1968, *Ann. N.Y. Acad. Sci.* 151: 456-75; Jacobson, Murphy and Hartmann, 1970, *J. Biol. Chem.* 245: 1075-83; Jacobson and Pfuderer, 1970, *J. Biol. Chem.* 245: 3938-44; Jacobson, Murphy and Ortiz, 1972, *Arch. Biochem. Biophys.* 149: 22-35; Knopp and Jacobson, 1972, *Arch. Biochem. Biophys.* 149: 36-41; Schwartz, Gerace, O'Donnell and Sofer, 1975, *Isozymes* (C. Markert, ed.). Academic Press, Vol. I, pp. 725-51]. These vary in activity and stability, the most cathodal being more active, but less stable, than the more anodal forms. They probably result from the binding of 0, 1 or 2 moles per mole of a NAD<sup>+</sup> addition

complex with a carbonyl compound [Schwartz and Sofer, 1976, *Nature* (London) 263: 129-31; Schwartz, O'Donnell and Sofer, 1979, *Arch. Biochem. Biophys.* 194: 365-78; Winberg, Thatcher and McKinley-McKee, 1983, *Biochem. Genet.* 21: 63-80]. Feeding flies acetone, propan-2-ol, or 3-hydroxy-butanone, for example, converts isozymes to most anodal form and results in loss of enzyme activity *in vitro* and *in vivo* (Schwartz and Sofer, 1976; Papel, Henderson, van Herewege, David and Sofer, 1979, *Biochem. Genet.* 17: 533-63). ADH has been purified (Sofer and Ursprung, 1968, *J. Biol. Chem.* 243: 3118-25; Schwartz *et al.*, 1975; Thatcher, 1977, *Biochem. J.* 163: 317-23; Leigh Brown and Lee, 1979, *Biochem. J.* 179: 479-82; Juan and Gonzalez-Duarte, 1980, *Biochem. J.* 189: 105-10; Elliot and Knopp, 1975, *Methods Enzymol.* 41: 374-79; Chambers, 1984, *Biochem. Genet.* 22: 529-50). It is a homodimer with monomeric subunit molecular weight of 27500 daltons (Thatcher, 1980, *Biochem. J.* 187: 875-83); molecular extinction coefficient 4.8 X 10<sup>4</sup> liter/mol/cm (Juan and Gonzalez-Duarte, for ADH-S). Complete amino acid sequence determined by Thatcher (1980; see also Schwartz and Jornvall, 1976, *Europ. J. Biochem.* 68: 159-68; Auffret, Williams and Thatcher, 1978, *FEBS Lett.* 90: 324-26; Benyajati, Place, Powers, and Sofer, 1981, *Proc. Nat. Acad. Sci. USA* 78: 2317-21; Chambers, Laver, Campbell and Gibson, 1981, *Proc. Nat. Acad. Sci. USA* 78: 3103-07) with secondary structure predictions (Thatcher and Sawyer, 1980, *Biochem. J.* 187: 884-86; Benyajati *et al.*, 1981). Limited homology in supposed catalytic region with ribitol dehydrogenase of *Klebsiella* (Jornvall, Persson and Jeffry, 1981, *Proc. Nat. Acad. Sci. USA* 78: 4226-30).

ADH shows a broad substrate specificity but is more active (by at least a factor of 5) with secondary than primary alcohols and shows highest activity to 3-6 carbon alcohols (Sofer and Ursprung; Thatcher and Camfield, 1977, Winberg *et al.*, 1982, Chambers *et al.*). Differences in substrate specificity, kinetic constants and stability of different electrophoretic variants often reported (Anderson and McDonald, 1983, *Proc. Nat. Acad. Sci. USA* 80: 4798-802). Considerable heterogeneity in the specific activity of ADH within and between different *Adh<sup>F</sup>* and *Adh<sup>S</sup>* strains, though *Adh<sup>S</sup>* strains tend to be lower than *Adh<sup>F</sup>* [Day, Hillier and Clarke, 1974, *Biochem. Genet.* 11: 141-53, 155-65; Day and Needham, 1974, *Biochem. Genet.* 11: 167-75; Gibson, 1970, *Nature* (London) 227: 959-61; Gibson, Chambers, Wilkes and Oakeshott, 1980, *Aust. J. Biol. Sci.* 33: 479-89; Gibson and Miklovitch, 1971, *Experientia* 27: 99-100; Kreitman, 1980, *Genetics* 95: 467-75; Oakeshott, 1976, *Aust. J. Biol. Sci.* 29: 365-73; Sampsell, 1977, *Biochem. Genet.* 15: 971-88; Sampsell and Sims, 1982, *Nature* (London) 296: 853-55; Thörig, Schoone and Scharloo, 1975, *Biochem. Genet.* 13: 721-31; Vigue and Johnson; Hewitt, Pipkin, Williams and Chakrabarty, 1974, *J. Hered.* 65: 141-44; Ward, 1974, *Biochem. Genet.* 12: 449-58; Ward, 1975, *Genet. Res.* 26: 81-93; Maroni, Laurie-Ahlberg, Adams and Wilton, 1982, *Genetics* 101: 431-66; Rasmuson, Nilson and Zeppezauer, 1966, *Hereditas* 56: 313-16; Clarke, Camfield, Garvin and Pitts, 1979, *Nature* (London) 180: 517-18; Laurie-Ahlberg, Maroni, Bewley, Lucchesi and Weil, 1980, *Proc. Nat. Acad. Sci. USA* 77: 1073-77; Barnes

and Birley, 1978, *Heredity* 40: 51-57; Barnes and Birley, 1978, *Biochem. Genet.* 16: 155-65; McDonald and Ayala, 1978, *Genetics* 89: 371-88; McDonald *et al.*, 1980; Lewis and Gibson, 1978, *Biochem. Genet.* 16: 159-70]. With the exception of the studies by Thatcher and Sheikh (1981, *Biochem. J.* 197: 111-17), Winberg *et al.* (1982), McDonald, Anderson and Santos (1980, *Genetics* 95: 1013-22); Eisses, Schoonen, Aben, Scharloo, and Thörig (1985, *Mol. Gen. Genet.* 199: 76-81) and Moxon *et al.* (1985), these were all done with crude extracts and not purified enzyme. Thatcher and Sheikh find the relative thermostabilities to be ADH-S > ADH-F > ADH-n5 > ADH-D. ADH-S shows slower dissociation of NADH from NADN-enzyme complex than ADH-F (Winberg, Hovik, and McKinley-McKee, 1985, *Biochem. Genet.* 23: 205-16).

ADH is not a metalloenzyme (Place, Powers and Sofer, 1980, *Fed. Proc.* 39: 1640); but, paradoxically, is inhibited by certain metal ion chelators, *e.g.* pyrazole (Place, Powers and Sofer; Winberg *et al.*, 1982; Moxon *et al.*, 1985).

Utilization of ethanol as an energy source (van Herrewege and David, 1974, *C. Rend. Acad. Sci. Paris* 279D: 335-38; van Herrewege, David and Grantham, 1980, *Experientia* 36: 846-47; Libion-Mannaert, Deltombe-Lietaert, Lenelle-Montfort and Elens, 1976, *Experientia* 32: 22-23) depends on ADH activity (David, Bocquet, van Herrewege, Fouillet and Arens, 1978, *Biochem. Genet.* 16: 203-11). *Adh<sup>F</sup>* homozygotes usually show a better ability to survive on ethanol as a sole energy source than *Adh<sup>S</sup>* homozygotes (Daly and Clarke, 1981, *Heredity* 46: 219-26; Anderson, McDonald and Santos, 1981, *Experientia* 37: 463-64).

*Adh<sup>F</sup>* and *Adh<sup>S</sup>* homozygotes also show behavioural differences in their response to ethanol (Parsons, 1977 *Oecologia* 30: 141-46; Cavener, 1979, *Behav. Genet.* 9: 359-65; Gelan and McDonald, 1980, *Behav. Genet.* 10: 237-49; Hougonto, Lietaert, Libion-Mannaert, Feytmans and Elens, 1982, *Genetica* 58: 121-28; Parsons, 1980, *Behav. Genet.* 10: 183-90; Parsons, 1980, *Experientia* 36: 1070-71).

*D. simulans* enzyme monomers form heterodimers with those of *D. melanogaster* (E.H. Grell); *D. simulans* enzyme purified (Juan and Gonzalez-Duarte, 1981, *Biochem. J.* 195: 61-69). Sequence of *D. simulans* ADH (from DNA) similar to that of *Adh<sup>S</sup>* with following changes: ser1 → ala1; gln82 → lys82; ile184 → val184 (Bodmer and Ashburner, 1984, *Nature* 309: 425-30). *D. simulans* and *D. melanogaster* enzymes differentially regulated in hybrids (Dickenson, Rowan, and Brennan, 1984, *Heredity* 52: 215-25). The *Adh* genes from *D. orena* and *D. mauritiana* have also been sequenced (Bodmer and Ashburner), and those of *D. erecta*, *D. teissieri* and *D. yakuba* mapped with restriction enzymes (Langley, Montgomery and Quattlebaum, 1982, *Proc. Nat. Acad. Sci. USA* 79: 5631-35).

**alleles:** Large numbers of alleles have been selected and characterized. This information is summarized in the following tables: The first table describes the origins and phenotypes of the electrophoretic variants, the majority of which were isolated from natural populations; the second describes the origins and phenotypes of the null alleles; In addition 16 isolations of null alleles from four Australian locations have been described (Freeth and Gibson, 1985, *Heredity* 55: 369-74); not clear how many mutational events represented.

Zool. 160: 147-54; 24 = Wilks, Gibson, Oakeshott, and Chambers, 1980, Aust. J. Sci. 33: 375-85.

$\beta$  Numbers in parentheses inferred from phenotypic description; others represent actual measurements (Thatcher, 1980, Biochem J. 187: 875-83).

$\gamma$  Unlike *Adh*<sup>F</sup>, will oxidize dihydroorotic acid to orotic acid and sarcosine to glycine.

$\delta$  Probably identical.

$\epsilon$  Probably the same as *Adh*<sup>71k</sup>.

$\zeta$  = *Adh*<sup>F</sup>.

$\eta$  = *Adh*<sup>S</sup>.

$\gamma$	Polypeptide smaller than wild type.							
$\delta$	Polypeptide slightly larger than wild type on SDS gels and electrophoretic mobility altered on non-denaturing gels.							
$\epsilon$	Purified enzyme thermolabile; <i>Adh</i> <sup>n5</sup> flies grown at 18° show loss of both ADH activity and CRM following a shift to 30° (Tsubota); recovery on return to 18° takes several days (Vigue and Sofer; Tsubota).							
$\zeta$	Mutation in adenine ribose pocket of coenzyme binding domain; is not bound to 5' -AMP sepharose and cannot recognize NAD <sup>+</sup> (Thatcher and Retzios), <i>Adh</i> <sup>F</sup> / <i>Adh</i> <sup>n11</sup> forms an active dimer that migrates as <i>Adh</i> <sup>F</sup> / <i>Adh</i> <sup>UF</sup> (Schwartz and Jomvall; Schwartz and Sofer, Pelliccia and Sofer). Shows weak intracistronic complementation with <i>Adh</i> <sup>n6</sup> , <i>Adh</i> <sup>n7</sup> , <i>Adh</i> <sup>n12</sup> and <i>Adh</i> <sup>nA</sup> (Thatcher; Reddy <i>et al.</i> ). <i>Adh</i> <sup>n6</sup> / <i>Adh</i> <sup>n11</sup> heterozygotes display partial resistance to alcohol; hybrid enzyme activity heat labile; displays altered substrate binding properties (Pelliccia and Couper, 1984, DIS 60: 160-62).							
$\eta$	Isolated from natural population.							
$\theta$	Polypeptide shorter than normal (24 kilodaltons).							
$\iota$	<i>In vitro</i> translation product of mRNA smaller than that of wild type (Pelham and Bodmer).							
$\kappa$	Protein unstable by two-dimensional gel electrophoretic analysis.							

**cytology:** Placed in 35B3 by *in situ* hybridization.

**molecular biology:** Structural gene cloned (Goldberg, 1980, Proc. Nat. Acad. Sci. USA 77: 5794-98) and sequenced [Goldberg; Benyajati *et al.*, 1981; Haymerle, 1983, Thesis, University of Cambridge; Kreitman, 1983, Nature (London) 304: 412-17; Benyajati, Place, Wang, Pentz, and Sofer, 1982, Nucleic Acids Res. 10: 7261-72]. Partial sequence (3' end) of cDNA clone by Benyajati, Wang, Reddy, Weinberg and Sofer (1980, Nucleic Acids Res. 8: 5649-67). Variation in restriction enzyme sites within and around *Adh* (Langley *et al.*). *Adh*<sup>F</sup> alleles are polymorphic for insertion substitution changes within the 5' non-coding region intron (Kreitman, 1983). Sequence comparisons between 5' flanking regions and exons in *D. melanogaster* and *D. simulans* indicate excess polymorphism in the *D. melanogaster* 5' flanking region (Kreitman and Aguade, 1986, Genetics 114: 93-100; Aquadro, Desse, Blond, Langley, and Laurie-Ahlberg, 1986, Genetics 114: 1165-90).

Standard amino acid sequence taken to be that of ADH-S (Thatcher, 1980 with two corrections: glu25 (not gln) and an extra tryptophan at 251 (Benyajati *et al.*, 1981). Standard DNA sequence is that of *Adh*<sup>S</sup> allele from clone pSAC1 of Goldberg (Benyajati *et al.*, 1981, 1982, 1983; Haymerle); numbered from -1/+1, +1 being the 'A' of the ATG initiating codon. All changes with respect to coding strand.

Two primary transcripts: major larval transcript initiated from -69, 24 bp from a TATA box (-100 to -94); major adult transcript initiated from -766, 24 bp from a TATA box (-808 to -800). The major adult transcript is processed by the removal of an intervening sequence between -689 and -36. There are two introns within the coding sequence, from +100 to +164 and from +571 to +639. The polyA addition site is from +1028 to +1034 and the 3' end of the mRNA at +1079. (Benyajati *et al.*, 1981, 1983, Henikoff, 1983, Nucleic Acids Res.

11: 4735-52).

An 11.8 kb *SacI* restriction fragment of the *Adh*<sup>F</sup> allele shown by P-element-mediated germline transformation to contain all *cis*-acting DNA sequences necessary for correct expression (quantitative levels of mRNA and enzyme; tissue specificity; developmental switch in promoter usage)(Goldberg, Posakony, and Maniatis, 1983, Cell 34: 59-73. *In vitro* recombinants rule out the 5' flanking sequences as responsible for the two- to three-fold higher enzyme activity and increased amount of ADH protein in *Adh*<sup>F</sup> compared to *Adh*<sup>S</sup>; the only consistent differences are at three nucleotide positions, one at 1490 responsible for the electrophoretic difference and two silent third-codon substitutions at nucleotides 1443 and 1527 (Laurie-Ahlberg and Stamm, 1987, Genetics 115: 129-40); increase probably not attributable to increased levels of mRNA (Laurie and Stamm, 1988, Proc. Nat. Acad. Sci. USA 85: 5161-65). Transcript of *Drosophila* gene transfected into yeast spliced normally (Watts, Castle, and Beggs, 1983, EMBO J. 2: 2085-91). A fusion of *Adh* to the *Hsp70* promoter has been inserted into a *P* element and used in transformation experiments in *Adh* deficient flies; in such transformants *Adh*<sup>+</sup> function is under heat-shock control (Bonner, Parks, Parker-Thornberg, Mortin and Pelham, 1984, Cell 37: 979-91). Molecular information on alleles in following table.

allele	molecular biology	ref $\alpha$
<b>Adh 71k</b>	lys 192 → thr 192; pro 214 → ser 214	7

### **adp<sup>60</sup>: adipose**

**location:** 2-83.4.

**origin:** Spontaneous.

**discoverer:** Doane, 1960.

**references:** 1961, DIS 35: 78.

1963, DIS 38: 32.

1963, Proc. 23rd Ann. Biol. Coll., Oregon State Univ. Press, Corvallis, pp. 65-88.

1969, J. Exp. Zool. 171: 321-42.

**phenotype:** Adult fat body hypertrophies as cells become distorted by enormous oil globules. Lipid accumulated at expense of glycogen in fat body; yolk deposition retarded (Doane, 1963, DIS 37: 73-74; Doane, 1980, Evolution 34: 868-74). Lipid content and fatty acid profiles compared for various developmental stages in *adp<sup>60</sup>* and wild type (Teague, Clark, and Doane, 1986, J. Exp. Zool. 240: 95-104). Abnormal fat bodies visible through body wall of 6-day-old and older adults when submerged in 95% alcohol and then water. Corpus allatum of mated females hypertrophies. Females fertile but egg hatchability reduced to 45-90%, depending on residual genome; dorsal appendages of chorion convoluted or fused (King and Koch, 1963, Quant. J. Microscop. Sci. 104: 297-320); adult emergence lowered to 33-85%. (Doane, 1963, DIS. 37: 73-74). Males viable and fertile. Hetero-

zygotes show desiccation tolerance superior to that of wild type or *adp<sup>60</sup>* homozygotes (Clark and Doane, 1983, Hereditas 99: 165-75). RK3.

**cytology:** Placed in 55A-C1 based on its inclusion in *Df(2R)PC4 = Df(2R)55A;55F* but not *Df(2R)P29 = Df(2R)55C1-2;56B1-2* (Doane and Dumapias, 1987, DIS 66: 49).

### **adp<sup>fs</sup>: adipose-female sterile**

**origin:** Spontaneous.

**discoverer:** Counce, 1956.

**synonym:** *fs(2)adp: female sterile(2) adipose*.

**references:** Doane, 1959, Genetics 44: 506.

1960a, J. Exp. Zool. 145: 1-22 (fig.).

1960b, J. Exp. Zool. 145: 23-42.

1961, J. Exp. Zool. 146: 275-98.

**phenotype:** Adult fat body phenotype like *adp<sup>60</sup>*; lipid accumulated at expense of glycogen in fat body; yolk deposition in ovaries retarded; carbohydrate levels low in 8-day-old adults (Cummings and Ganetzky, 1972, DIS 30: 48. Corpus allatum hypertrophies in mated females to same degree as in *adp<sup>60</sup>*. Females completely sterile; sterility autonomous. Eggs laid by homozygotes show meiotic or mitotic abnormalities, or both, never develop beyond early cleavage stages; chorion, chorionic filaments and vitelline membrane defective in some. Males 78% fertile. Heterozygotes fertile, but females become sterile with age. Viability generally good but longevity reduced; homozygotes with selective advantage under starvation; heterozygotes superior under desiccation. Average water content of well-fed adults reduced; percentage of lipids, as a function of dry body weight, almost double that of wild type. Iodine numbers show greater degree of saturation of mutant lipid extracts than of wild type. RK3.

### **\*ae: aeroplane**

**location:** 2-55.8.

**origin:** Spontaneous.

**discoverer:** Mohr, 26k24.

**references:** Quelprud, 1931, Hereditas 15: 97-119 (fig.).

**phenotype:** Wings spread, balancers drooping. Overlaps wild type. RK3.

### **\*Ae: Aechna**

**location:** 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Belgovsky, 45a14.

**references:** 1946, DIS 20: 63.

**phenotype:** Wings spread at right angles to body axis. Homozygous lethal. RK1A.

**other information:** Reduced crossing over in the *th-e* region suggests presence of pericentric inversion.

*aea*: see *dv<sup>2</sup>*

**aeroplane:** see **ae**

### **ag: agametic**

**location:** 1-20.7.

**origin:** Spontaneous.

**references:** Engstrom, Caulton, Underwood, and Mahowald, 1982, Dev. Biol. 91: 163-70 (fig.).

**phenotype:** Maternal effect mutant; approximately 40% of gonads of progeny of homozygous females agametic. Although some eggs of homozygous females exhibit

abnormal polar granules, normal numbers of pole cells form; some pole cells abnormal with degenerating polar granules and nuclear bodies, but pole cells reach gonads at 14 hr of development and then in 40% of the gonads become necrotic and disappear; responses of right and left gonads correlated. Phenotype most pronounced at 25°, decreasing at higher and lower temperatures. Mutant not completely recessive; expression in progeny of heterozygous females half that in those of homozygotes.

**cytology:** Placed between 7B4 and 7C1 based on its position to the right of *ct* and its inclusion in *Df(1)ct268-42 = Df(1)7A5-6;7B8-C1*.

**\*agl: angle winglike**

**location:** 1- (not located).

**origin:** Recovered among descendants of flies treated with natural gas.

**discoverer:** Mickey, 49c7.

**synonym:** Originally called *angle wing* but this name preoccupied by *ang*.

**references:** 1950, DIS 24: 60.

**phenotype:** Wing bent upward in middle. Overlaps wild type. RK3.

**agn: agnostic**

**location:** 1-38.9.

**references:** Savvateeva, Korochkina, Pereslenny, and Kamyshev, 1985, DIS 61: 144.

Savvateeva, Pereslenny, Ivanushina, and Korochkin, 1985, Dev. Genet 5: 157-72.

**phenotype:** Identified as three temperature sensitive lethal mutations. Adenylate cyclase activity somewhat higher than normal at 22° and readily activated at 29°. Phosphodiesterase activity assayed in heat-pretreated homogenates higher than normal. Locomotor activity decreased and learning activity increased at 22°, like *dnc* at 29°.

**alleles:**

allele	origin	synonym
<i>agn</i> <sup>1</sup>	EMS	<i>l(1)ts398</i>
<i>agn</i> <sup>2</sup>	EMS	<i>l(1)ts622</i>
<i>agn</i> <sup>3</sup>	EMS	<i>l(1)ts980</i>

**agq: atrophie gonadique**

**location:** 2-3 polygenic.

**origin:** Recovered from natural population on French Mediterranean coast.

**references:** Periquet, 1970, DIS 45: 33.

1979, Biol. Cell. 33: 33-38.

**phenotype:** Gonads atrophic either unilaterally or bilaterally owing to pole cell degeneration. Degree of effect correlated with both temperature during the first hours of development and with the number of *agq*-derived autosomes. Pole cells, but not oocytes, thermosensitive. Responses of right and left gonads correlated. Penetrance higher in females than males.

**al: aristaless**

**location:** 2-0.4 [Golubovsky, Kulakov, and Korochkina, 1978, Genetika (Moscow) 14: 294-305].

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 213 (fig.).

Stern and Bridges, 1926, Genetics 11: 510 (fig.).

**phenotype:** Aristae strongly reduced. Postscutellars

widely separated and erect but strongly divergent. Scutellum shortened; sternopleurals irregular in size, position, and number; wings slightly bowed downward, narrowed, and pointed; first longitudinal vein raised and thickened. Tarsal claws transformed into bristle-like structures or absent; effect enhanced by presence of *th* or *ss*<sup>a40a</sup> or both [Mglinetz and Ivanova, 1975, Genetika (Moscow) 11, 4: 88-96]. Enhances transformations of *Antp*<sup>NS</sup> [Mikuta and Mglinetz, 1978, Genetika (Moscow) 14: 1578-85] and *ss*<sup>a40a</sup>; *al ss*<sup>a40a</sup> flies exhibit partial transformation of third antennal segment to basitarsus; anomalous outgrowths of distal basitarsus and foreshortening of second and third tarsal joints of thoracic legs; spineless phenotype also enhanced. *al* females exhibit reduced mating success (Burnet, Connolly, and Dennis, 1971, Anim. Behav. 19: 409-15). RK1.

**alleles:**

<sup>β</sup> *alanyl dopamine synthetase*: see *e*

**alarless**: see *alr*

***alb*: alberich**

**location:** 2-(unmapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS

66: 209-26.

**phenotype:** Maternal-effect lethal; occasional embryo lacks abdominal segments (Lehmann).

**Alcohol dehydrogenase:** see *Adh*

**ald:** *altered disjunction* (A. T. C. Carpenter)

**location:** 3-61.

**origin:** Induced by ethyl methanesulfonate.

**references:** O'Tousa, 1982, *Genetics* 102: 503-24.

**phenotype:** Homozygous females display elevated levels of nondisjunction of *X* and fourth chromosomes (9.5 and 6.0% respectively); double exceptions are predominantly *XX;0* and *0;44*, products expected from nonhomologous disjunction; behavior of large autosomes nearly normal. Exchange frequencies normal, and sex-chromosome exchange tetrads contribute to exceptional products.

**Ald: Aldolase**

**location:** 3-91.5.

**origin:** Naturally occurring polymorphism.

**references:** Voelker, Ohnishi, and Langley, 1979, *Biochem. Genet.* 17: 769-83.

**phenotype:** Structural gene for fructose-biphosphate aldolase (EC 4.1.2.13). Enzyme multimeric based on the formation of heteromultimeric bands on gels from heterozygotes for electrophoretic variants. Amino-acid sequence determined; protein is a 158-kd multimer comprising four 360-amino-acid polypeptides. Monomers show 71% identity with rabbit muscle aldolase (Malek, Suter, Frank, and Brenner-Holzach, 1985, *Biochem. Biophys. Res. Comm.* 126: 199-205). Mixed multimers of rabbit and *Drosophila* subunits able to function (Brenner-Holzach and Leuthard, 1972, *Eur. J. Biochem.* 31: 423-26). Sequence analysis suggests alternating domains of alpha helix and beta sheet; domain boundaries correspond to boundaries between exons as seen in rat-liver aldolase (Sawyer, Fothergill-Gilmore, and Freemont, 1988, *Biochem. J.* 249: 789-93).

**cytology:** Placed in 97A-B on the basis of its being between the autosomal breakpoints of  $T(Y;3)R87 = T(Y;3)97A$  and  $T(Y;3)B158 = T(Y;3)97B$ .

**alleles:** Two electrophoretic variants described; *Ald*<sup>4</sup> product migrates toward the anode more rapidly than that of *Ald*<sup>2</sup>.

**Aldehyde oxidase:** see *Aldox*

**Aldolase:** see *Ald*

**Aldox-1: Aldehyde oxidase-1**

**location:** 3-57.2 (between *red* and *sbd*).

**origin:** Naturally occurring polymorphism.

**synonym:** *Ao*.

**references:** Dickinson, 1970, *Genetics* 66: 487-96.

Warner, Watts, and Finnerty, 1980, *Mol. Gen. Genet.* 180: 449-53.

Warner and Finnerty, 1981, *Mol. Gen. Genet.* 184: 92-96.

Bogart and Bernini, 1981, *Biochem. Genet.* 19: 929-46.

**phenotype:** Structural gene for aldehyde oxidase [AO-1 (EC 1.2.3.1)]. A molybdenum-containing homodimer with subunits of 140,000-dalton molecular weight. As with other molybdenum hydroxylases, activity is inhibited by tungsten and depends on the presence of a low-molecular-weight cofactor (Warner and Finnerty).

Enzyme activity increases nonuniformly during development with step increases at pupation and midway through pupal stage. First increase appears to be controlled by a closely linked *cis*-acting element (Dickinson, 1975, *Dev. Biol.* 42: 131-40) and the latter by *Aldox-2*<sup>+</sup> (Bentley and Williamson, 1979, *Z. Naturforsch.* 34: 304-05). Control independent of that of *lpo* located 0.08 unit to the left (Dickinson and Weisbrod, 1976, *Biochem. Genet.* 14: 709-21). Enzyme activity absent in *cin* (Browder and Williamson, 1976, *Develop. Biol.* 53: 241-49) and *mal* and reduced in *lxd* (Courtright, 1967, *Genetics* 57: 25-39); cross-reacting material observed in all three genotypes (Browder, Wilkes, and Tucker, 1982, *Biochem. Genet.* 20: 111-24). These mutants presumably affect the availability of molybdenum cofactor (Warner and Finnerty). Autonomous in transplants. Enzyme composition in egg and early larva reflects maternal genotype, giving way to that of zygotic genotype during larval life. Tissue specificity varies with stage and strain (Dickinson, 1972, *Genetics* 71: s14; Cypher, Tedesco, Courtright and Kumaran, 1982, *Biochem. Genet.* 20: 315-32). Heptaldehyde serves as specific substrate (Cypher *et al.*). Differential staining for enzyme noted in different compartments of the wing imaginal disc (Kuhn and Cunningham, 1976, *Genetics* 83: s42).

**alleles:** Three electrophoretic variants superscripted 1, 2, and 3 in order of increasing mobility described by Dickinson (1970) presumably correspond to *Aldox-1*<sup>4</sup>, *Aldox-1*<sup>6</sup>, and *Aldox-1*<sup>8</sup> (1978, *DIS* 53: 117); 6 electrophoretic variants numbered in order of increasing mobility from 1 through 6 described by Langley, Tobar, and Kojima (1974, *Genetics* 78: 921-36). Correspondence of two sets of alleles unknown. Two null alleles superscripted *n1* and *n2* are homozygous viable but produce no recognizable product either in the form of enzyme activity or by the formation of heterodimers with functional gene products; however, cross-reacting material found in larval hemolymph but not in extracts of adults (Browder *et al.*, 1982). Thirteen other null alleles isolated from natural populations in Great Britain (*Aldox*<sup>nGB1</sup> to *Aldox*<sup>nGB4</sup>) and North Carolina (*Aldox*<sup>nNC1</sup> to *Aldox*<sup>nNC9</sup>); all thirteen exhibit residual enzyme activity and except for *Aldox*<sup>nGB1</sup> are *Aldox*<sup>4</sup> derivatives and fail to participate in heterodimer formation with normal gene products. *Aldox*<sup>nGB1</sup> is an *Aldox*<sup>8</sup> derivative and forms heterodimers (Burkhart, Montgomery, Langley, and Voelker, 1984, *Genetics* 107: 295-306). *lao*: low aldehyde oxidase (Collins, Duck, and Glassman, 1971, *Biochem. Genet.* 5: 1-13) considered allelic based on its phenotype and genetic position (3-56); aldehyde oxidase levels of *Aldox*<sup>n</sup>/*Aldox*<sup>lao</sup> higher than expected if *Aldox*<sup>n</sup> amorphic.

**cytology:** Placed in region between 88F9 and 89B4 on the basis of its inclusion in  $Df(3)sbd105 = Df(3R)88F9-88A1,89B4-5$  but not  $Df(3R)sbd45 = Df(3R)89B1-4;89B10-13$  (Spillmann and Nöthiger, 1978, *DIS* 53: 124). Narrowed to 89A1-2 by Langhout and van Breugel (1985, *DIS* 61: 181) on basis of reduced staining of that doublet in *Aldox*<sup>n1</sup>.

**Aldox-1<sup>Pa1</sup>**

**origin:** Polymorphic in laboratory and natural populations.

**references:** Dickinson, 1975, *Dev. Biol.* 42: 131-40.

**phenotype:** Exhibits substantial increase in enzyme

activity between late larval and early pupal stages followed by a second increase in late pupal stage. Results in relatively high pupal:adult activity ratio.

**Aldox-1<sup>Pa2</sup>**

**origin:** Polymorphic in laboratory and natural populations.  
**references:** Dickinson, 1975, Dev. Biol. 42: 131-40.  
**phenotype:** Exhibits little change in enzyme activity between late larval and early pupal stages, but there is a substantial increase in late pupal and adult stages. Results in relatively low pupal:adult activity ratio. *Aldox-1<sup>Pa1</sup>/Aldox-1<sup>Pa2</sup>* has intermediate phenotype.  
**other information:** 1.5% recombination with electrophoretic *Aldox-1* alleles recorded. The difference between *Pa1* and *Pa2* postulated to reside in a cis-acting site that exerts temporal control on gene activity.

**Aldox-1<sup>Pb1</sup>**

**origin:** Polymorphic in natural population from Lima, Peru.  
**references:** Dickinson, 1978, J. Exp. Zool. 206: 333-42.  
**phenotype:** Cytochemically, enzyme activity in paragonia uniformly distributed and high at eclosion. By end of first week of adult life enzyme accumulated into intracellular bodies giving accessory gland a spotted appearance.  
**alleles:** *Aldox-1<sup>Pb2</sup>* characterized by lower activity that remains uniformly distributed in paragonia as detected histochemically.  
**other information:** Not separated genetically from electrophoretic alleles of *Aldox-1*. *Pb1* and *Pb2* postulated to differ in a cis-acting control site with tissue-specific effects on gene activity.

**aldox2: aldehyde oxidase 2**

**location:** 2-82.9 (based on 112 *c-px* recombinants).  
**origin:** Naturally occurring polymorphism.  
**references:** Bentley and Williamson, 1979, Z. Naturforsch. 34: 304-05.  
 1980, Genetics 94: s8.  
 Meidinger and Bentley, 1986, Biochem. Genet. 24: 683-99.  
 Bentley, Meidinger, and Braaten, 1989, Biochem. Genet. 27: 99-118.  
**phenotype:** Not a structural gene for aldehyde oxidase. Homozygotes for *aldox2* fail to show increased levels of molybdoenzymes, aldehyde oxidase, pyridoxal oxidase, sulfite oxidase, and xanthine oxidase, that normally occur late in the pupal period; adult levels lower than normal. Enzyme activity less sensitive to tungsten and more responsive to molybdenum than in wild type; aldehyde oxidase activity, at least, more heat labile and pH optimum slightly more acidic than normal (Meidinger and Bentley, 1984, Genetics 107: s73). Duplication of *aldox2<sup>+</sup>* without effect on enzyme levels.  
**cytology:** Placed in region 54 based on the failure of *Y<sup>P2D</sup>* from *T(Y;2)H149 = T(Y;2)h21;54F* to cover it and its genetic map position to the right of *Amy*, which has been placed in 54A1-B1 by *in situ* hybridization.

**ale: almond eye**

**location:** 3-47.5 (located with respect to *D* and *Sb*).  
**origin:** Spontaneous in natural population.  
**references:** Golubovsky and Zakharov, 1972, DIS 49: 112.  
 Golubovsky, Ivanov, and Zakharov, 1973, Genetika (Moscow) 9(8): 168-71.

**phenotype:** In homozygotes, eye almond shaped but with normal facet development. Phenotype normal in heterozygotes with normal third but mutant when heterozygous to *D. Dfd/ale* show normal eye size, and 20% of flies show tufted vibrissae characteristic of *Dfd/+*. *ale Mc* homozygotes completely eyeless.

**other information:** Both *Dfd* and *ale* map to 47.5. No wild-type recombinants recovered among 569 tested progeny of *Dfd/ale* females. *ale* acts as a transdominant suppressor of *Dfd*.

**Ali<sup>n</sup>: Aliesterase-negative**

**location:** 3- (not located).  
**origin:** Spontaneous.  
**synonym:** *ali: aliesteraseless*.  
**references:** Ogita, 1961, Botyu-Kagaku 26: 93-97.  
 1962, DIS 36: 103.  
**phenotype:** Probably the structural gene for aliesterase [ALI (EC 3.1.1.1)]. Homozygotes for *Ali<sup>n</sup>* practically unable to hydrolyze methyl butyrate, whereas wild type shows high activity; *Ali<sup>n</sup>/+* exhibits intermediate activity. Homozygotes shown by Beckman and Johnson to lack a normally present esterase that migrates slowly on starch gel (their band F). RK3.  
**alleles:** *Ali<sup>n</sup>* is a null allele; no other variants reported.

**Alkaline phosphatase:** see **Aph and Aph-2**

*aliesteraseless:* see *Ali<sup>n</sup>*

*almond:* see *Dfd<sup>r</sup>*

**almondex:** see **amx**

*almondex-55:* see *lz<sup>K</sup>*

**almond eye:** see **ale**

**\*alo: alopecia**

**location:** 1-38.3.  
**origin:** Induced by 2-chloroethyl methanesulfonate.  
**discoverer:** Fahmy, 1956.  
**references:** 1958, DIS 32: 67.  
**phenotype:** Abdominal hairs much reduced in number; pigmentation frequently lighter and patchy. Effect very pronounced in females reared at 25° but overlaps wild type in both sexes when reared at a low temperature. Viability and fertility good in males but reduced in females. RK3.

**Alp: Abnormal leg pattern**

**location:** 2-10.  
**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.  
**phenotype:** Defined by two dominant gain-of-function alleles. Heterozygotes viable with fusion of metatarsal and second tarsal segments. *Alp<sup>1</sup>/Alp<sup>2</sup>* is pupal lethal with more extreme tarsal fusions.  
**alleles:** Two X-ray induced alleles. *Alp<sup>1</sup>* is associated with *T(2;3)XT1* and *Alp<sup>2</sup>* is associated with *T(2;4)X2*.  
**cytology:** Placed in 23F6-24A1 based on breakpoint common to translocations.

*alpha:* see *tyr-1*

**alpha methyl dopa hypersensitive:** see **amd**

**\*alr: alarless****location:** 3- (not located).**origin:** Spontaneous.**discoverer:** Steinberg, 40b.**references:** 1940, DIS 13: 51.**phenotype:** Outer postalar bristle always missing; posterior supra-alar missing in about 80% of the flies. Anterior scutellars, humerals, and notopleurals frequently duplicated. Never overlaps. Viability and fertility excellent. RK3.**ALS:** see *Acr96A***Altered abdomen:** see *Aa***altered disjunction:** see *ald***Alu: Alula****location:** 2-54.9 (Muller places *Alu* to the left of *pr*).**origin:** Spontaneous.**discoverer:** Bridges, 38a12.**references:** Curry, 1939, DIS 12: 45.**phenotype:** Heterozygote has alula fused to main wing; wings often bent, broader. May overlap wild type but intensified by cold and by heterozygous *ds* with buckling effect increased. Homozygote at 19° shows extreme buckling owing to rotation of wing and alula. Homozygote viable and resembles heterozygote. RK2.**alleles:** \**Alu*<sup>56c</sup> (CP627).**\*alw: arclike wing****location:** 2- (near *b*).**discoverer:** Sturtevant, 1948.**references:** 1948, DIS 22: 55.**phenotype:** Wings evenly bent downward at tips. Overlaps wild type. RK2.**am:** see *Dfd*<sup>r</sup>**Ama:** see *ANTC***Ama:** see *RpII*<sup>C4</sup>**Ama-1: α-amanatin resistant 1****location:** 3-19.**origin:** Recovered from natural populations from India, Malaysia, and Taiwan.**references:** Phillips, Willms, and Pitt, 1982, Can. J. Genet. Cytol. 24: 151-62.**phenotype:** Flies homozygous or heterozygous for *Ama-1* and *Ama-2* have LD<sub>50</sub> to α-amanatin 10-30 times that of wild type. Sensitivity of RNA polymerase II activity to α-amanatin same as wild type. *Ama-1* alone sufficient to confer resistance, but in three independent isolations both *Ama-1* and *Ama-2* present.**Ama-2****location:** 3-100.**origin:** Recovered from natural populations in India, Malaysia, and Taiwan.**references:** Phillips, Willms, and Pitt, 1982, Can. J. Genet. Cytol. 24: 151-62.**phenotype:** Same as for *Ama-1*.**Amalgam:** see *Ama* under *ANTC***Amanatin resistant:** see also***Amr* and *RpII*****amb: amber****location:** 1-6.8.**origin:** Induced by triethylenemelamine.**discoverer:** Fahmy, 1950.**references:** 1958, DIS 32: 67.**phenotype:** *amb* has pale yellow body color; bristles very thin and short; hairs less affected. Eyes slightly brighter red. Males sterile. Viability 10-50% wild type. RK2. *amb*<sup>2</sup> less extreme, males viable and fertile, females sterile.**alleles:** \**amb*<sup>1</sup>, *amb*<sup>2</sup> (Fahmy, 1958 and CP627). Also one allele each induced by triethylenemelamine, DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine, 2-chloroethyl methanesulfonate, and nitrogen mustard and two alleles induced by *p*-N,N-di-(2-chloroethyl)amino-phenylethylamine.**cytology:** Placed in 4C7-8 on the basis of its inclusion in *Df(1)bi-D3 = Df(1)4C5-6;4C7-8* but not *Df(1)rb41 = Df(1)4B6-C1;4C7-8* (Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1985, Chromosoma 93: 341-46).**amd: alpha methyl dopa hypersensitive****location:** 2-53.9 [.002 units (2.1 kb) to the left of *Ddc*].**synonym:** *amd*; *l(2)amd*<sup>H</sup>, *l(2)37Bk*.**references:** Sparrow and Wright, 1974, Mol. Gen. Genet. 130: 127-41.

Wright, 1977, Am. Zool. 17: 707-21.

Wright, 1987, Adv. Genet. 24: 127-222.

**phenotype:** *amd*<sup>+</sup> flies die when reared on levels of alpha methyl dopa that are not lethal to wild type; resistance proportional to the number of *amd*<sup>+</sup> loci present. Adult *amd*<sup>+</sup> females fed alpha methyl dopa become sterile and lay eggs that cannot complete embryogenesis. Dopa decarboxylase levels normal. *amd* homozygotes lethal; lethal phase at times of larval hatching, larval molts, and pupariation; larval anal organ extruded and necrotic; pupal cuticle thin and friable. Appears to play role in cuticle formation. *amd*<sup>1</sup>/*amd*<sup>6</sup> complementing adults deficient for one or more unidentified catecholamines involved in the colorless sclerotization of cuticle.**alleles:** The first seven alleles selected as alpha methyl dopa hypersensitive in the heterozygous condition; the remainder recovered as recessive lethal mutations. Interallelic complementation observed, suggesting dimeric product.

<sup>α</sup> 1 = Black, Pentz, and Wright, 1987, *Mol. Gen. Genet.* 209: 306-12; 2 = Sparrow and Wright, 1974, *Mol. Gen. Genet.* 130: 127-41; 3 = Wright, Bewley, and Seraldi, 1976, *Genetics* 84: 287-310; 4 = Wright, Black, Bishop, Marsh, Pentz, Steward, and Wright, 1982, *Mol. Gen. Genet.* 188: 18-26.

**cytology:** Placed in 37B9-C1 based on its inclusion in *Df(2L)NST* but not *Df(2L)VA17*.

**molecular biology:** Located between coordinates -4.7 and -2.42, where 0 is the axis of symmetry of the *HpaI* site near the terminus of the *Ddc* coding sequence and positive values extend to the right. Genomic sequence contains a 483-bp intron near the 5' end; the usual upstream regulatory sequences identified as well (Marsh, Erfle, and Leeds, 1986, *Genetics* 114: 453-67). A 2.0-kb *amd* transcript first detectable early in embryogenesis; reaching maximum level at 12-16 hours; low levels observed in adults; concentrated in the nurse cells of stage 8-9 oocytes; smaller transcripts with sequence homology to the 2.0-kb transcript observed in third-instar larvae. *amd* and *Ddc* transcribed from opposite strands; two regions of extensive homology between *amd* and *Ddc* detected; intron sequences and positions not conserved, although homology across intron junctions is high (Eveleth and Marsh, 1986, *Genetics* 114: 469-83). Sequence predicts a 50,481 dalton polypeptide with a slight negative charge; 38% amino acid homology with dopa decarboxylase.

***Amdr*: Alpha methyl dopa resistant**

**location:** 3- (between *h* and *tn*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bishop and Seraldi, 1981, *DIS* 56: 21.

**phenotype:** Based on two of 16 chromosomes selected for conferring resistance to α methyl dopa when heterozygous. LD<sub>50</sub> to L-α-methyl dopa for the two chromosomes is 0.325 mM for *Amdr*<sup>1/+</sup> and 0.35 mM for *Amdr*<sup>2/+</sup>, compared to 0.10 mM for wild type. Both

chromosomes are homozygous lethal, and *Amdr*<sup>1/Amdr</sup><sup>2</sup> is nearly lethal, allowing the inference of a single locus.

***amethyst*:** see *amy*

***amiel***

**location:** Autosomal.

**origin:** Spontaneous.

**synonym:** *Amiel*.

**references:** Rushton and Metcalfe, 1971, *DIS* 46: 61.

**phenotype:** Homozygous males court abnormally; wing vibrations and copulation attempts more vigorous than in wild type, but mutant males take longer to achieve copulation and have higher incidence of unsuccessful courtships. Homozygous females behave normally.

*Amiel*: see *amiel*

**Aminoimidazole ribotide synthetase:** see *ade2*

***amn*: amnesiac (J.C. Hall)**

**location:** 1-63.

**discoverer:** Sziber.

**origin:** Induced by ethyl methanesulfonate.

**references:** Quinn, Sziber, and Booker, 1979, *Nature (London)* 277: 212-14.

**phenotype:** Homozygous or hemizygous mutant flies can be conditioned to avoid odors associated with electric shocks, but effects of conditioning decay with a half life of 15 min compared to 60 min for normal. Memory decay biphasic; rapid for first hour and slow thereafter (Tully). Substitution of reward (1.0 M sucrose) for punishment (electric shock) lengthens memory span from one hour to six hours (Tempel, Bonini, Dawson, and Quinn, 1983, *Proc. Nat. Acad. Sci. USA* 80: 1482-86). Groups of *amn* flies exhibit apparently abnormal acquisition of learning in tests using visual cues (Folkers, 1982, *J. Insect. Physiol.* 28: 535-39); it appears that short-term memory is defective in the mutant (in shock-odor tests), with long-term memory being normal (Tully and Quinn, 1985, *J. Comp. Physiol.* 157: 263-77); in experiments involving "operant" conditioning, with heat as the aversive unconditioned stimulus, *amn* exhibits a small decrement in learning *per se* and subsequently has no detectable memory (Mariath, 1985, *J. Insect Physiol.* 31: 779-81). In tests of "simple learning," amnesiac individuals habituate to or are sensitized by sugar stimuli subnormally; the sensitization defect maps to the same proximal locus as that affecting associative conditioning (Duerr and Quinn, 1982, *Proc. Nat. Acad. Sci. USA* 79: 3646-50). The effects on courtship behavior or pre-exposure to fertilized females decay more rapidly in amnesiac than in normal males (Siegel and Hall, 1979, *Proc. Nat. Acad. Sci. USA* 76: 3430-34; Ackerman and Siegel, 1986, *J. Neurogenet.* 3: 111-23), but amnesiac males are defective in expressing after-effects of exposure to immature wild-type males when tested immediately after such exposure (Gailey, Jackson, and Siegel, 1982, *Genetics* 102: 771-82). Females defective in ability to be primed by courtship song (Kyriacou and Hall, 1984, *Nature (London)* 308: 62-65).

**cytology:** Placed in 19A1 based on its inclusion in *Df(1)mal12 = Df(1)19A1;20F* but not *Df(1)mal11 = Df(1)19A2-3;19E1* or *Df(1)mal3 = Df(1)19A2-3;20E-F* (Tully and Gergen, 1986, *J. Neurogenet.* 3: 33-47).

**Amplification Control Element:** see **ACE**

**Amr: Amanatin resistant**

**location:** 3- (not mapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Nishiura, 1981, *Biochem. Genet.* 19: 31-46.

**phenotype:** Heterozygotes survive 5 µg/ml α amanatin. RNA polymerase II activity in *Amr*-bearing flies resistant to α amanatin.

**alleles:** Three lines possibly containing different alleles designated *Amr*<sup>010</sup>, *Amr*<sup>018</sup>, and *Amr*<sup>106</sup>.

**other information:** Genetic analysis lacking. If it is demonstrated that this locus codes for an RNA polymerase II subunit, it will be renamed *RpII* plus a subunit designation.

**amx: almondex**

**location:** 1-27.7 [to the left of *lz* (Green and Green, 1956, *Z. Indukt. Abstamm. Vererbungsl.* 87: 708-21)].

**origin:** X ray induced.

**discoverer:** Ball, 32k20.

**phenotype:** Eyes slightly reduced, narrower below. Trident pattern stronger than in *lz*. Maternal effect lethal. Studies by Shannon [1972, *Genetica* (The Hague) 43: 244-56] show that *amx* progeny and many *amx*/+ progeny of *amx* mothers are embryonic lethals. Ovaries and egg production of *amx* females normal. General disorganization of early embryo with *amx*/+ progeny of *amx* mothers less extreme than *amx* progeny (Shannon, 1973, *J. Exp. Zool.* 183: 383-400); *amx*/+ daughters show 0.2% survival; *amx*/*Dp(I;I)lz-2* show considerably higher survival (Campos-Ortega); Lethal embryos exhibit hypertrophy of central nervous system at the expense of epidermal tissue (Lehmann, Dietrich, Jiménez, and Campos-Ortega, 1981, *Wilhelm Roux's Arch. Dev. Biol.* 190: 226-29; Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, *Wilhelm Roux's Arch. Dev. Biol.* 192: 62-74). Similarly peripheral nervous elements, the sensilla, exhibit increased numbers and abnormal morphology; cells diverted from epidermal to neurological pathway (Hartenstein and Campos-Ortega, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 210-21). Embryonic phenotype locally rescuable by injections of ooplasm from wild-type or *pcx* ova during preblastoderm stages (Campos-Ortega, La Bonne and Mahowald, 1985, *Dev. Biol.* 110: 264-67). *lzlamx* is wild type. Mosaics in *amx*/+ daughters of ±/± or *amx*/+ females show that ventral tissues are sensitive to reduced *amx*<sup>+</sup> activity; no clones of *amx* tissue found in cuticle of *amx*/+ daughters of *amx* mothers (Germeraad and Disano, 1984, *Genetics* 107: s36). RK2.

**cytology:** Located in 8D (region 8D4 through 8E2) by Green and Green (1956).

*amx*<sup>55</sup>: see *lz*<sup>K</sup>

**\*amy: amethyst**

**location:** 2- (not located).

**discoverer:** Bridges.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 218.

**phenotype:** Transparent, light-purplish eye color. RK3.

**Amy: Amylase**

**location:** 2-77.9 (based on 5039 *c-wt* recombinants).

**origin:** Polymorphic locus.

**discoverer:** Kikkawa, 1957.

**references:** Kikkawa and Abe, 1960, *Annotationes Zool. Jpn.* 33: 14-23.

Kikkawa, 1960, *Jpn. J. Genet.* 35: 382-87.

1969, *Problems in Biology: RNA in development* (Hanly, ed.). U. of Utah Press, Salt Lake City, pp. 73-109 (fig.).

Hickey and Benkel, 1986, *CRC Crit. Rev. Biotech.* (fig.).

**phenotype:** The structural gene for α-amylase [AMY (EC 3.2.1.1)]. A monomeric protein based on failure to form hybrid enzyme molecules of intermediate mobility in heterozygotes for alleles coding for electrophoretic variants. Activity mainly in midgut and hemolymph with smaller amounts in other tissues; activity found in anterior or posterior, or both, but not middle, region of midgut; three spatial patterns of adult posterior midgut activity encountered on standard medium; controlled by the trans-regulatory effect of *map* (2-80) (Abraham and Doane, 1978, *Proc. Nat. Acad. Sci. USA* 75: 4446-50); adult anterior midgut activity under regulation of another separable regulatory locus (Doane, 1980, *DIS* 55: 36-39). Larval midgut activity affected by closely linked *cis*-acting regulatory elements (Klarenberg, Kisser, Willemse, and Scharloo, 1986, *Genetics* 114: 1131-45). Amylase activity is glucose repressible (Hickey and Benkel, 1982, *Biochem. Genet.* 20: 1117-29); the degree of repression can be greater than one hundred fold in larvae and occurs at a pretranslational, probably transcriptional, level of regulation (Benkel and Hickey, 1985, *Genetics* 110: S25; 1986, *Genetics* 114: 137-44, 943-54; 1987, *Proc. Nat. Acad. Sci. USA* 84: 1337-39).

**alleles:** Eight electrophoretic variants of α-amylase have been recorded; they are numbered, in order of decreasing rates of migration toward the anode, from -1 through +7 (Doane, Treat-Clemons, Gemmill, Levy, Hawley, Buchenberg, and Paigen, 1983, *Isozymes: Curr. Top. Biol. Med. Res.* 9: 63-70). Enzymes with mobilities 2 and 3 exist in forms with different heat sensitivities: *Amy*<sup>1</sup> the most frequent allele, may be expressed at three different activity levels in different strains, 1a, 1b, and 1c in which 1a has twice the activity of 1b and 1b has twice the activity of 1c; purified α-amylases from 1a and 1c strains have identical specific activities (Treat-Clemons and Doane, 1982, *Isozyme Bull.* 15: 90-91); enzyme levels here are apparently under the control of closely linked transacting regulatory elements (Hickey, 1981, *Biochem. Genet.* 19: 783-96). A chromosome may express none, one, or two of these forms. Bahn recovered one *Amy*<sup>1,3</sup> and two *Amy*<sup>2</sup> recombinants from *Amy*<sup>1</sup>/*Amy*<sup>2,3</sup> heterozygotes and one *Amy*<sup>4,3</sup> and two *Amy*<sup>2,6</sup> recombinants from *Amy*<sup>4,6</sup>/*Amy*<sup>2,3</sup> heterozygotes. From these observations it was concluded that the *Amy* locus is duplicated and the two copies are separated by 0.008 cm; furthermore, flanking marker segregations indicated that determinants of forms 1,2 (thermostable), and 4 are to the left of those for 3 (thermostable) and 6. Conservation of res-

triction endocuclease sites in DNA from Bahn's *Amy*<sup>2,3</sup> in comparison with *Amy*<sup>1,3</sup> (from Canton-S) and *Amy*<sup>1,6</sup> (from Suyama, Japan) indicates that the determinant of form 1 is to the left of those of forms 3 and 6 in the latter two chromosomes (Gemmill, Schwartz, and Doane, 1986, Nucl. Acids Res. 14: 5337-52). *Amy*<sup>1</sup> monomorphic allele in Oregon-R has been shown to be *Amy*<sup>1,1</sup> (Hawley, 1989, Ph.D thesis, Arizona State University).

**cytology:** Placed in 54A based on *in situ* hybridization (Gemmill, Levy, and Doane, 1985, Genetics 110: 299-312).

**Amy-d: Amylase distal**

The distal member of the *Amy* repeat. Electrophoretic alleles include *Amy-d*<sup>3</sup> (thermostable). *Amy-d*<sup>6</sup> and likely *Amy-d*<sup>2</sup> (thermolabile); some chromosomes apparently lack *Amy-d* activity.

**Amy-p: Amylase proximal**

The proximal member of the *Amy* repeat. Electrophoretic alleles include *Amy-p*<sup>1</sup>, *Amy-p*<sup>2</sup> (thermostable), *Amy-p*<sup>4</sup>, probably *Amy-p*<sup>3</sup> (thermolabile), and *Amy-p*<sup>5</sup>; a null allele also exists. Allelic compositions of various strains are tabulated in the accompanying table.

<sup>β</sup> Tentative assignments.

**molecular biology:** Clones homologous to mouse α-amylase gene isolated from Maniatis library (Doane, Treat-Clemons, Gemmill, Levy, Hawley, Buchberg, and Paigen, 1983, Curr. Top. Biol. Med. Res. 9: 63-90). λDm32 hybridizes to polytene region 53CD; no homologous mRNA detected; postulated to be pseudogene. λDm65 hybridizes to 54A1-B1 and is homologous to a 1450-1500 nucleotide transcript (Gemmill, Levy, and

Doane, 1985, Genetics 110: 299-312). 15kb insert in λDm65 contains reverse repeat by restriction mapping; subclones, each containing one of the repeated sequences, injected into *Xenopus* oocytes; one subclone capable of producing isozyme 1 of α-amylase; the other capable of producing isozyme 3; confirms duplicated nature of locus (Levy, Gemmill, and Doane, 1984, Isozyme Bull. 17; 1985, Genetics 110: 313-24). Directions of transcription of the two genes divergent. (Levy, 1985, Genetics 110: 137); separated by 4 kb. Seven strains exhibiting no, one, or two electrophoretic forms of α-amylase all carry the duplication as ascertained from restriction analysis. *Amy*<sup>1c</sup> contains an approximately 10 kilobase insert some 10 kb proximal to *Amy-p*. 12% of chromosomes isolated from diverse natural populations contain large inserts in the vicinity of the *Amy* loci (Langley, Shrimpton, Yamazaki, Miyashita, Matsuo, and Aguadro, 1988, Genetics 119: 619-29). Two molecular inversions that could have arisen through interlocus exchange recorded; one had normal levels of amylase activity (Langley *et al.*) and the other was a null allele that produced reduced levels of mRNA and was insensitive to glucose repression (Hickey, Benkel, Abukashawa, and Haus, 1988, Biochem. Genet. 26: 757-68; Schwartz and Doane, 1989, Biochem. Genet. 27: 31-46). An amylase cDNA has been cloned and sequenced (Boer, and Hickey, 1986, Nucleic Acid Res. 14: 8399-8411). This sequence shows 57% identity to mouse amylase; the predicted amino-acid sequence indicates a 54.5-kd polypeptide of 493 residues, the 18 N-terminal ones of which are signal sequence; there is 55.4% amino-acid identity with mouse amylase. Upstream sequence contains a repeated motif also found in a negatively regulated mammalian gene (Hickey, Genest, and Benkel, 1987, Nucleic Acid Res. 15: 7184). Northern blots probed with this cDNA show that the glucose repression effect is at the level of amylase mRNA abundance.

**an: ancon**

**location:** 2-44 (34-54).

**discoverer:** Bridges, 30e3.

**phenotype:** Wings and legs somewhat short in *an*<sup>1</sup>; *an*<sup>2</sup> (CP627) more extreme with gnarled legs, scraggly abdominal bristles, etched sclerites; eyes small and roughish. *an*<sup>1</sup>/*an*<sup>2</sup> like *an*<sup>2</sup>.

**alleles:** *an*<sup>1</sup> and *an*<sup>2</sup>.

**anarista:** see *aa*

**ancon:** see *an*

**And: Andante (J.C. Hall)**

**location:** 1-36.2

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Konopka, R. Smith and Orr, 1976.

**references:** Jackson, Gailey, and Siegel, 1983, J. Comp.

Physiol. 151: 545-52.

**phenotype:** The normal free-running 24 hr periods of the circadian rhythms of eclosion and adult locomotor activity (in constant conditions) are lengthened by 1.5-2 hr/cycle; *And/+* heterozygotes have a period phenotype intermediate between wild-type and mutant homozygotes (Konopka, R. Smith and Orr). The phase-response curves (PRCs) for eclosion and activity rhythms, indicating light-induced phase shifts, show a similar degree of lengthening as seen in free-running periodicities. *And* rhythms are highly temperature-compensated, as are those of wild-type (Konopka *et al.*). *And* males are defective in after effects on courtship behavior that are usually induced by prior exposure to mated females or very young males (Jackson *et al.*, 1983).

**cytology:** Placed in 10E1-2;10F1. The *And* homozygote-like activity rhythm phenotype is uncovered by *Df(1)KA6 = Df(1)10E1;11A7-8* and *Df(1)KA7 = Df(1)10A9;10F6-7*, but heterozygotes involving *And* and *Df(1)N105 = Df(1)10F7;11D1*, *Df(1)RA47 = Df(1)10F1;19F9-10*, or *Df(1)m<sup>259-4</sup> = Df(1)10C2-3;10E1-2* are like *And/+* (Konopka *et al.*). The two *And*-uncovering *Df*'s just noted over wild type give normal periods. An anomaly then, is that *Df(1)HA85 = Df(1)10C1-2;11A1-2*, which uncovers *And* as it should (see above), leads to significantly longer-than-normal periods when over wild type (Konopka *et al.*).

**other information:** *And* lengthens in an additive manner, the periodicities associated with certain other rhythm mutants, *i.e.*, those which by themselves cause shorter- or longer-than-normal locomotor activity periods (*viz.*, *per<sup>S</sup>*, *per<sup>L1</sup>*, *per<sup>L2</sup>*, *Clk*). *And*, on its isolation, was associated with a *dy* wing phenotype, and the rhythm abnormality maps to the *dy-m* locus (see "cytology"); but *dy* and *m<sup>D</sup>* have normal activity rhythm periods, and *And* over either of these two visibles gives the same periods as seen in *And/+* (Konopka *et al.*); however, of four gamma-ray induced *dy*'s - *dy<sup>n1</sup>*, *dy<sup>n2</sup>*, *dy<sup>n3</sup>*, and *dy<sup>n4</sup>*, all but *dy<sup>n2</sup>* are *And*-like in their locomotor activity rhythms (Jackson, Newby, and DiBartolomeis, 1989, Neurosci. Abstr. 15: 461).

### **ang: angle wing**

**location:** 2-10.5.

**origin:** Spontaneous.

**discoverer:** Mittler and Goldberg, 48i16.

**references:** Mittler, 1950, DIS 24: 61.

**phenotype:** Wings held up from dorsal surfaces and extended outward 15-90° from the mid-dorsal line. Longitudinal dorsal median muscles 5 and 6 fused (Goldberg, 1954, Ph.D. Thesis, Ill. Inst. Technol.). No increase in expressivity with temperature. Does not overlap wild type. RK2.

*ang*: see *ano*

**angle wing:** see *ang*

*angle wing*: see *agl*

**angle winglike:** see *agl*

### **\*ano: anomogenitals**

**location:** 1-35.7.

**origin:** Induced by triethylenemelamine.

**discoverer:** Fahmy, 1952.

**synonym:** Originally symbolized *ang*, but this symbol preoccupied.

**references:** 1958, DIS 32: 67.

**phenotype:** Many bristles on head and thorax either reduced in size or absent. Thoracic and abdominal hairs appreciably fewer. External male genitalia invariably abnormal, sometimes completely absent. Melanized exudate frequently present in furrow between mesonotum and scutellum near anterior scutellar bristles. Males sterile; viability less than 10% wild type. RK3.

### **ant: antennaless**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Gordon, 1936.

**references:** 1941, DIS 14: 39.

1941, Proc. Intern. Congr. Genet., 7th. p. 131.

**phenotype:** The existence of the homeotic *ANTC* was originally proposed based on the tight linkage of the proboscipedia (*pb*). Sex combs reduced (*Scr*) and Antennapedia (*Antp*) loci. All were found to reside in a set of three doublet bands at the proximal end of section 84 (84A1,2-3,4 and 84B1,2) in the right arm of polytene chromosome 3. Subsequent genetic analyses have shown that two other homeotic loci labial (*lab*) and Deformed

(*Dfd*) are also members of the complex. The homeotic loci of the *ANTC* are involved in the specification of segmental identity in the posterior head (gnathocephalic) and anterior thoracic regions of the embryo and adult. Moreover the linear order of the homeotic loci in the complex *lab*, *pb*, *Dfd*, *Scr*, and *Antp* corresponds to the anterior posterior order of altered segments (intercalary, mandibular, maxillary, labial, and thoracic) found in animals bearing mutations in each of the resident loci. Specifically *Antp* transforms posterior T1, all of T2, and the anterior of T3, *Scr* transforms T1 and labial, *Dfd* affects the maxillary and mandibular lobes, *pb* affects the derivatives of the maxillary and labial segments and finally *lab* functions in the intercalary segment. Taken together the results of mutational analyses indicate that members of the complex are necessary to repress head development in the thorax (*Antp*) and elicit normal segmental identity in the anterior thorax (*Scr*) and posterior head (*Scr*, *Dfd*, *pb*, and *lab*). The *ANTC* is distinguished from the bithorax complex not only by virtue of the domain of action of its homeotic loci (anterior vs. posterior) but also by the residence of loci which are not homeotic in nature. Two of these fushi tarazu (*ftz*) and zerknüllt (*zen*) have been shown to affect segment enumeration (*ftz*) and the formation of dorsal structures (*zen*) in the early embryo. A third nonhomeotic gene is bicoid (*bcd*). Mutations in this locus result in female sterility and maternal effect lethality. Eggs laid by *bcd* females fail to develop normal anterior ends and instead produce mirror image duplications of structures normally produced at the posterior terminus of the embryo. In addition to these genetically defined loci there are several other "genes" which have been found in the *ANTC* by molecular mapping. The first of these is a cluster of cuticle-protein-related genes which map between the *lab* and *pb* loci. Eight small (*ca.* 1 kb) transcription units make up the cluster and all have sequence similarities to known cuticle protein genes. These "genes" are also apparently regulated by ecdysone in imaginal discs. Deletion of the entire cluster has no apparent effect on the development or cuticle morphology of embryos, larvae, or adults. The second molecularly identified "gene" is the Amalgam (*Ama*) transcription unit. The encoded protein places the gene in the immunoglobulin superfamily and like the cuticle cluster the locus can be deleted from the genome with no discernible effect on the organism.

**cytology:** Placed in the 84A1-B2 interval by the inclusion of the complex in *Df(3R)Scr* and the location of breakpoint associated inactivations of the *lab*, *pb*, *Dfd*, *Scr*, *ftz*, and *Antp* loci.

**molecular biology:** The entire complex has been cloned and has been shown to cover 335 kb of genomic DNA. The most distal transcription unit is *Antp* which covers the distal-most 100 kb of the complex and is made up of eight exons. Proximally the next 75 kb contain the *Scr* and *ftz* loci. The distal 50 kb of this interval house sequences necessary for *Scr* expression as well as the two exons of the *ftz* locus and its associated regulatory elements. The proximal 25-kb contain the three identified exons of the *Scr* transcription unit. The five exons of the *Dfd* gene are found in the central portion of the next-most-proximal 55-kb interval. The *Dfd* transcription unit covers only 11 kb of this region and it is likely that one or both of the 20-kb intervals flanking the gene are the

location of *cis*-acting regulatory elements for the locus. The next 25-kb interval contains four of the nonhomeotic transcription units which help distinguish the *ANTC* and *BXC*. The distal most is *Ama*, next *bcd*, and finally *zen* and *z2*. The *z2*, *zen*, and *Ama* transcription units are all relatively small (1-2 kb) and comprise two exons each. The *bcd* gene is somewhat larger (3.6 kb) and is made up of four exons. Immediately proximal to the *z2* transcription unit (*ca.* 1 kb from its 3' end) is the 5' end of *pb*; the latter gene extends over the next 35 kb of genomic DNA and contains nine exons. The next 25 kb of the complex contain the cuticle cluster and its eight identified transcription units. The final 25 kb are the residence of the *lab* gene which is made up of three exons.

Despite the nonhomeotic nature of three of the smaller transcription units (*zen*, *bcd*, and *ftz*) resident in the complex, these loci are tied to the larger homeotic genes of the region by the nature of their protein products. All five of the large homeotics (*Antp*, *Scr*, *Dfd*, *pb*, and *lab*) and the three small genes have a homeobox motif and their protein products are found in the nuclei of the cells in which they are expressed. Thus eight of the genes in the *ANTC* encode regulatory proteins which act as transcription factors. The *z2* gene also contains a homeobox; however, the biological significance of the gene is not known as deletions of this transcription unit have no discernible effect. The cuticle-like genes and *Ama* do not contain a homeobox.

The reasons for the clustering of these developmentally significant loci of similar function is not known. The existence of common or overlapping regulatory elements, the need to insulate regulatory sequences from position effect and the possibility of higher order chromatin structures for proper expression have all been proposed. Whatever the reason, the homeotic complex structure has a long evolutionary standing. Similar clusters are found in vertebrates, an observation consistent with a very early origin of these genes, likely predating the separation of protostomes and deuterostomes.

### **Ama: Amalgam**

**location:** 1-{47.5}.

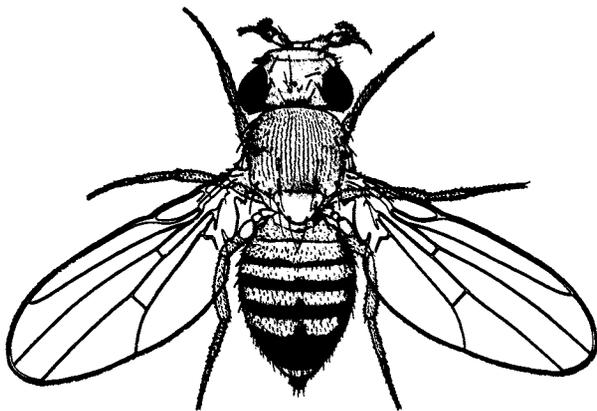

**origin:** Isolated as an unidentified third transcription unit in a 50 kb region known to harbor *bcd* and *zen*.

**references:** Seeger, Haffley, and Kaufman, 1988, Cell 55: 589-600.

**phenotype:** Antibody staining first detects Amalgam in the mesoderm during gastrulation; as neuroblasts delaminate from the ectoderm staining appears in a row of mesectodermal cells along the ventral midline of the extended germ band. Amalgam appears in the first neurons generated from the ganglion-mother cells, but not in the neuroblast precursors of these cells. Neuronal accumulation of *Ama* gene product increases during CNS development, but appears to be confined to the CNS and initially does not extend to axons exiting the CNS in segmental, intersegmental, or peripheral nerves; with time three rows of PNS-associated cells accumulate *Ama* protein; staining heavy around spiracle sensory organ and several cephalic sensory structures. Simultaneously there is a complicated temporal and spatial sequence of staining of mesodermal derivatives. Embryonic phenotype of deletion of *Ama* attributable to simultaneous deletion of *zen*; no effect of *Ama*<sup>-</sup> detectable.

**cytology:** Placed in 84A1 based on its juxtaposition with *bcd*.

**molecular biology:** Sequence of a putatively full-length cDNA clone compared with that of the corresponding genomic region reveals a gene with a 316 bp intron in the 5' untranslated region. Transcription from left to right. Conceptual amino-acid sequence indicates a protein product of 333 amino acids, the first 23 of which have the characteristics of a signal sequence. The sequence contains three internal repeats of approximately 100 amino acids each that exhibit homology to the immunoglobulin or Ig domain of vertebrates; each contains two widely spaced cysteine residues and the show 22-36% identity to one another with greatest identity found around the cysteines. There are two potential N-linked glycosylation sites in the first domain and one in the third. In addition there is a potential C-terminal membrane-attachment domain of amino acids. Comparison with sequences in the data base indicate that the Amalgam sequence is closest to members of the Ig class of proteins that act as cell-adhesion molecules.

**phenotype:** Null loss-of-function alleles result in embryonic lethality. Animals succumb at the end of embryogenesis and show homeotic transformations in the larval cuticle of the first, second, and third thoracic segments. Specifically the cuticle derived from parasegments 4 and 5 are transformed to a more anterior identity such that the posterior of the first thorax produces fragments of mouth hook material on its dorsal surface presumably owing to a new posterior labial identity, whereas the anterior of the second thorax resembles the first thorax. The anterior of the third thoracic segment is weakly transformed toward a T1-like identity. The posterior of T2 is presumably T1 like as there are no gnathal structures seen in this compartment. There are also partial loss-of-function mutations which allow survival into the larval, pupal, and adult stages. Those that allow adult survival produce animals in which the anterior of the dorsal mesothorax shows a transformation to prothorax. There are no other apparent defects associated with these lesions. Those "leaky" mutants which die in the pupal and larval stages show similar parasegmental transformations as the null alleles, except that only the parasegment 4 to 3 homeosis is generally apparent. Animals which survive to the pupal stage fail to evert their anterior spiracles resulting in a blunt appearance of the anterior pupa. This same phenotype is seen in genotypes which survive to the adult stage. These partial mutants in many cases are associated with chromosome rearrangements notably deletions which approach the locus from its distal end. Moreover these mutations have been shown to complement fully other seemingly null mutations. Subsequent molecular analyses have shown that these results are accounted for by the presence of two promoters, one, P1, distal to the other, P2. The partial mutants affect the ability of the P1 promoter to initiate transcription, while the complementing lesions inactivate P2. Null mutants affect the transcription unit and protein encoding portion of the gene which is common to both promoters (see below).

X-ray induced somatic clones of *Antp*<sup>-</sup> cells demonstrate that the locus is required in the adult for the proper development of the dorsal pro and mesothorax, and legs. The former is reduced in size presumably reflecting an anteriorward transformation while the latter are

transformed to antennae. Thus *Antp*<sup>+</sup> function is required in the embryo and adult in parasegments 4 and 5 to prevent more anterior segmental identities, specifically those normally found in the anterior thorax and head.

The *Antp* locus was initially recognized by virtue of several striking dominant gain-of-function alleles. Thirteen of these transform the antenna of the adult into a mesothoracic leg (*Antp*<sup>49</sup>, *Antp*<sup>B</sup>, *Antp*<sup>Yu</sup>, *Antp*<sup>Pw</sup>, *Antp*<sup>LC</sup>, *Antp*<sup>R</sup>, *Antp*<sup>Wu</sup>, *Antp*<sup>50</sup>, *Antp*<sup>RM</sup>, *Antp*<sup>73b</sup>, *Antp*<sup>CB</sup>, *Antp*<sup>72j</sup>, and *Antp*<sup>Ns</sup>). Three of these also have effects on the orbit of the eye and the vibrissal region of the ventral head (*Antp*<sup>RM</sup>, *Antp*<sup>72j</sup>, and *Antp*<sup>Ns</sup>). There are also two dominant alleles (*Antp*<sup>Ctx</sup> and *Antp*<sup>W</sup>) which transform portions of the head capsule (dorsal and posterior) and the eye to a dorsal mesothoracic identity. In some cases this includes the production of wing tissue in the eye. Finally, a unique dominant *Antp*<sup>Hu</sup> produces bristles on the normally bald propleurae just ventral to the mesothoracic spiracle. This latter phenotype has been interpreted as the production of sternopleural bristles on the propleurae, and thus a T1 to T2 transformation. With the exception of *Antp*<sup>Ns</sup> and *Antp*<sup>72j</sup> all these dominant lesions are associated with recessive lethality and gross chromosome rearrangements. All the breakpoints fall in the interval between the distal and proximal promoters. The dominant gain-of-function phenotype results from the misregulation of the P2 promoter by position affect or by the production of novel transcripts initiated in the newly juxtaposed sequences and spliced to the downstream *Antp* coding sequences. Both events result in the ectopic accumulation of the *Antp* protein product in the eye-antennal disc where the normal head repressive function of the gene causes the observed alteration. The recessive lethality associated with these lesions falls into the partially deficient category mentioned above. That is, these lesions show complementation with the P2 specific (*Antp*<sup>1</sup> and *Antp*<sup>23</sup>) mutations and in general show only strong parasegment 4 → parasegment 3 transformations. However, there is a gradient of this affect among the breakpoints. Those closest to P1 and furthest from P2 are the weakest, whereas those close to P2 show the strongest phenotype and earlier lethal phase. This same result is obtained with breakpoint mutations in the P2-to-P1 interval which are not associated with a dominant phenotype. Therefore this interval likely contains sequences necessary for the proper regulation of the P2 promoter.

Three of the dominant gain-of-function lesions (*Antp*<sup>Hu</sup>, *Antp*<sup>73b</sup>, and *Antp*<sup>Ns</sup>) have been reverted. The revertants are either complete nulls, thus obviating the potential for ectopic expression, or are partial mutants; the latter mutants likely remove the potential for ectopic expression by altering the juxtaposed sequences required for abnormal P2 activity.

Both *in situ* hybridization and immunostaining have been used to determine the spatio-temporal pattern of *Antp* expression. Both the protein and RNA are strongly accumulated in the ventral nerve cord and more weakly in the epidermis and mesoderm of the embryo. Protein and RNA are first detected during cellular blastoderm in a band of cells in the parasegment 4-6 anlagen. This initial spatial pattern is further elaborated at full germ-band extension. In the ectoderm *Antp* products are found starting in the region of the first thoracic segment (parasegments 3 and 4) and extending posteriorly to the level of

the seventh abdominal segment. In the mesoderm, they are found in parasegments 4-6. During germ band shortening the gene products are accumulated in the CNS from parasegment 4 (posterior T1) through to the posterior end of the ventral nerve cord. In the integument transcripts and protein are mainly restricted to the parasegments 4-5 interval although some weak expression can be seen in parasegments 3. As embryogenesis proceeds, the posterior CNS expression diminishes but is still detectable at the end of embryogenesis. The major accumulation in the CNS at this time is in the neuromeres of parasegments 4 and 5. The mesodermal expression is found in the anterior midgut; quenching of *Antp* expression is found in the posterior portion of the anterior midgut and has been shown to be dependent on the expression of *Ubx*. In later stages *Antp* protein can be detected in the leg, dorsal prothoracic, and wing discs.

<sup>α</sup> MDN = methoxy diethylnitrosamine.

**cytology:** Placed in 84B1-2 based on *Antp*'s inclusion in the overlap region between *Df(3R)Scr* and *Df(3R)A41* as well as the commonly held breakpoint of four forward, eleven gain-of-function and eighteen revertant of gain-of-function mutations (see table of alleles).

**molecular biology:** The *Antp* transcription unit lies at the distal end of the *ANTC* and is transcribed in a distal to proximal (*i.e.*, left to right) direction with respect to the right arm of the third chromosome. The locus has been identified in the DNA through the localization of breakpoints associated with both loss- and gain-of-function mutations. Additionally regulatory portions of the gene have been used to drive the expression of β galactosidase reporter constructs *in vivo* and these constructs produce spatial patterns of expression similar to those seen for the normal gene. The identified transcription unit is 100 kb long and is made up of eight exons. Exons 1 and 2 are the most distal and are found at the 5' end of RNAs initiated from the P1 promoter mentioned previously. Exon 3 is approximately 60 kb downstream of the P1 5' end and represents the leader sequences unique to transcripts initiated at the P2 promoter. The remaining five exons (E4-E8) are common to transcripts initiated at both P1 and P2. Exon 4 also encodes a leader sequence and the identified open reading frame begins in exon 5, 36 nucleotides downstream of the splice acceptor. The open

reading frame continues through exons 6, 7, and 8 ending 240 nucleotides downstream of the splice acceptor of E8. Two polyadenylation sites are used at the downstream end of E8. The first (A1) is *ca.* 875 nucleotides downstream of the 5' end of the exon; the other (A2) is *ca.* 2300 nucleotides more proximal. The two promoters coupled with the two adenylation sites result in the production of four size classes of transcript (P1/A1 = 3.2 kb, P1/A2 = 4.6 kb, P2/A1 = 3.4 kb, P2/A2 = 4.8 kb). All of these have been seen on Northern blots. There is no apparent preferential association of promoter with respect to 3' end formation. However, the two promoters do have different spatial patterns of expression. Notably the P1 promoter is seen to be strongly expressed in the anlagen of the dorsal prothoracic disc, a tissue dramatically affected by its deletion. The P2 promoter is more evenly expressed in *Antp*'s spatial domain (see below), consistent with the defects associated with its inactivation. The 3' end of the transcription unit is *ca.* 30 kb distal to the 3' end of *ftz* and 50 kb distal to the identified 5' end of *Scr*. The distance to the next most distal transcription unit from the P1 5' end is nearly 50 kb. The site of the *Antp* <sup>Hu</sup> breakpoint is in this 50 kb interval.

In addition to the transcript heterogeneity mentioned above, *Antp* also undergoes alternate splicing among the ORF-containing introns. Specifically exon 6 which encodes thirteen amino acids is found predominantly in embryonic transcripts and less frequently in imaginal disc derived RNAs. Additionally there is an alternate splice at the 3' end of exon 7, resulting in the deletion of four amino acids just upstream of the homeobox motif if the short splice is made. It appears that the long form splice is used preferentially but that all four potential protein forms are made in imaginal discs. The exon-6-less transcripts are rare in embryonic RNA. There is no apparent preferential association of alternate splicing patterns with either of the two promoters. The longest potential protein (E6 + 7L) is 378 amino acids in length, and has a predicted molecular weight of 43 kd. The homeobox motif is encoded in E8 and the opa like repeats in E5.

**bcd: bicoid**

**location:** 3-{47.5} (between *zen* and *Ama*).

**synonym:** *mum: multimorph*.

**references:** Frohnhöfer and Nüsslein-Vollhard, 1986, *Nature* (London) 324: 120-25 (fig.).

Frohnhöfer and Nüsslein-Vollhard, 1987, *Genes Dev.* 1: 603-14.

**phenotype:** Maternal-effect lethal mutations showing defective head and thorax development. Females homozygous for strong alleles produce embryos in which head and thorax are replaced by duplicated telson, including anal plates, tuft, spiracles, and flizkörper; however, no pole cells formed at the anterior end. Deletions and fusions of anterior abdominal segments and occasionally anterior abdominal segments in reversed polarity are also observed. Strong alleles amorphic based on phenotypic similarities of embryos produced by homozygous and hemizygous females. Weak alleles result in pattern defects in heads of embryos; lack only labral derivatives (median tooth, dorsal bridge); intermediate weak genotypes produce reduced head but retain normal thoracic development; intermediate strong produce further reduction of head, deletion of second and third and reduction

of first thoracic dentical belts; thoracic segments fused. Partial rescue of embryonic phenotype effected by injection of cytoplasm (5% of volume) from the anterior ends of unfertilized wild-type eggs into the anterior pole of newly fertilized eggs of *bcd* mothers; injection into ectopic sites stimulates differentiation of anterior structures at site of injection; efficiency proportional to number of *bcd*<sup>+</sup> alleles carried by cytoplasm donor. Phenocopies result from leakage of 5% of egg volume from anterior perforation of normal embryos. The distance of the head fold at gastrulation is proportional to the number of *bcd*<sup>+</sup> alleles in the maternal genotype. *bcd* mRNA appears as a flattened disc plastered to the anterior extremity of early embryos; by the time of pole cell migration it has become localized to the clear cytoplasm at the periphery, forming a cap over the anterior end of the egg and is distributed in a steeply decreasing gradient such that 90% of the RNA is in the anterior 18% of egg length; by nuclear cycle 14 the RNA begins to disappear and becomes undetectable by midway through cellularization. *bcd* protein on the other hand forms a shallower gradient in which 57% of protein is in the anterior 18% of egg length, and the gradient doesn't reach baseline until the posterior 30% of egg length; the gradient forms from two to four hours after oviposition in both fertilized and unfertilized eggs, and except during mitosis is concentrated in nuclei; diffusion postulated to account for the establishment of the protein gradient following translation from anteriorly anchored RNA. Protein levels decrease during cellularization, although some nuclear staining persists until the end of germ-band elongation. *bcd* transcript first detectable in the ovaries of *bcd* females; forms a ring around the anterior margin of the developing oocyte in stages 5 and 6; in stages 9 and 10 nurse-cell accumulation observed to be localized toward the periphery of the cyst; by stage 12 the nurse cells have emptied their contents into the oocyte and the *bcd* transcript appears as an anterior cap (St. Johnston, Driever, Berleth, Richstein, and Nüsslein-Volhard, 1989, Development Supplement: 13-19). No evidence of translation of *bcd* protein during oogenesis. Formation of the *bcd* gradient is regulated by three maternally active genes *exu*, *sww*, and *stau*; *exu* appears necessary for nurse cell accumulation; *sww* is required for anterior localization of *bcd* mRNA in the oocyte; and *stau* appears to be involved in RNA localization in the embryo. A defect in any of these functions results in little or no gradient of *bcd* activity. *bcd* in turn appears to control the activity of anterior gene activity; specifically the anterior pattern of *hb* expression is not observed and is replaced by a mirror-image posterior *hb* stripe in *bcd*<sup>-</sup> embryos (Tautz, 1988, Nature 332: 281-84; Schröder, Tautz, Seifertz, and Jäckle, 1988, EMBO J. 7: 2881-87).

**cytology:** Placed in region 84A1 on the basis of failure to be complemented by *Df(3R)9A99 = Df(3R)83F2-84A1;84B1-2*; *Df(3R)LIN*, and *Df(3R)Scr = Df(3R)84A1-2;84B1-2*, and complementation by *Df(3R)4SCB = Df(3R)84A6-B1;84B2-3*, and *Df(3R)Antp17 = Df(3R)84A6;84D13-14*.

**molecular biology:** Gene identified in an 8.7-kb genomic fragment from coordinates -42 to -33 kb of the chromosome walk of Scott, Weiner, Hazelrigg, Polisky, Pirrotta, Scalenghe, and Kaufman (1983, Cell 35: 763-76) by germ-line transformants that completely rescue the mutant phenotype (Berleth, Burri, Thoma, Bopp, Richstein, Frigerio, Noll, and Nüsslein-Volhard, 1988, EMBO J. 7: 1749-56; see also Frigerio, Burri, Bopp, Baumgardner, and Noll, 1986, Cell 47: 735-46; Kilchherr, Baumgardner, Bopp, Frei, and Noll, 1986, Nature 321: 493-97). The transcription unit comprises four exons and produces a major mRNA of 2.6 kb, which contains all four exons, and a minor 1.6-kb mRNA from which exons 2 and 3 are spliced. Splice-acceptor-site variation in the third exon leads to translation products of 489 and 494 amino acids (53.9 kd). The first exon contains a PRD repeat, consisting essentially of alternating histidines and prolines, found within a number of genes, including *prd*, expressed early in development; the 5' end of exon 3 encodes a novel homeodomain with no more than 40% amino-acid homology with other homeobox sequences; the 3' end contains a series of repeated glutamines, opa repeats. Also contains a RNA-recognition motif, mostly in exon 4 (Rebagliatti, 1989, Cell 58: 231-32). A highly acidic C-terminal domain is thought to provide transcriptional activation; the latter can be replaced with heterologous activating sequences and still display *bcd*<sup>+</sup> activity (Driever, Ma, Nüsslein-Volhard, and Ptashne, 1989, Nature 342: 149-54). The sequence responsible for the anterior localization of *bcd* RNA at the anterior embryonic pole localized to 625 nucleotides in the 3' untranslated region, which include regions capable of forming extensive secondary structure

(Macdonald and Struhl, 1988, Nature 336: 595-600). The ten residues from 138 to 147 comprise the DNA recognition helix of the *bcd* homeodomain; replacing the lysine in the ninth position of this ten-amino-acid sequence with either alanine or glutamine is sufficient to destroy recognition of *hb* sequences; in addition, the latter substitution confers a new specificity for *Anp* and *Ubx* upstream target sequences (Hanes and Brent, 1989, Cell 57: 1275-83). Bicoid protein binds to five high-affinity binding sites (consensus sequence TCTAATCCC) upstream from the *hb* transcription start site (Driever and Nüsslein-Volhard, 1989, Nature 337: 138-43). The posterior boundary of the anterior *hb* domain responds to changes in the number or affinity of these sites as well as to the dose of *bcd*<sup>+</sup> such that increases cause a more posterior and decreases a more anterior boundary (Driever, Thoma, and Nüsslein-Volhard, 1989, Nature 340: 363-67; Struhl, Struhl, and Macdonald, 1989, Cell 57: 1259-73).

**phenotype:** Null mutations act as recessive lethals. Homozygous or hemizygous animals die at the end of embryogenesis and show a spectrum of defects in the head. There are no discernible defects in the trunk. The head defects are associated with missing structures normally derived from the mandibular and maxillary segments, the dorsal lateral papillae of the maxillary sense organ, the mouth hooks, and the maxillary cirri. The remaining gnathal structures are present albeit disarranged likely due to abnormalities in the movements associated with head involution. A weak homeotic

transformation (30-50% penetrance) has also been noted in animals hemizygous for a breakpoint-associated revertant of the single dominant gain-of-function allele (*Dfd*<sup>rv1</sup>). The phenotype is an apparent transformation of the H piece and lateral-graten which appear to be replaced by cephalopharyngeal plates. This phenotype has not been observed in any other mutant genotype and the reason for its low-penetrance production by this particular allele is not known. X-ray-induced somatic clones of *Dfd*<sup>-</sup> cells have shown that the locus is also required for adult head development. These cells develop normally in the thorax and abdomen but do not form structures in the ventral anterior aspect of the head; specifically the vibrissae and maxillary palps. Clones in the dorsal posterior part of the head form ectopic bristles which have been interpreted as a head to thoracic transformation. A temperature-conditional allele has been used to define two temperature-critical periods for *Dfd*<sup>+</sup> activity. The first is during embryogenesis during segmentation and head involution, while the second occurs in the late third instar larval through mid pupal stages. These times correlate nicely with the observed cuticular defects in mutant animals and the times of peak gene product accumulation. There is a single dominant gain-of-function allele which causes defects in the ventral aspects of the adult head similar to those seen in the *Dfd*<sup>-</sup> head clones mentioned above. There are no defects seen in the posterior of the head nor does this allele cause any embryonic or larval defects as a heterozygote, homozygote, or hemizygote. This allele is associated with a group of *B104* (*roo*) insertion elements (ca. 50 kb of inserted DNA) as well as a duplication of the 3' exons of the *Dfd* transcription unit (see below). The mutant causes an extended spatial domain of expression of the locus into the eye portion of the eye-antennal disc as compared to the pattern seen in normal animals. The precise cause-effect relationship between the observed molecular defect and the mutant phenotype is not known except that partial deletion of the *B104* elements but not the 3' end duplication causes a reversion of the dominant phenotype and has no apparent effect on the wild type function of the resident *Dfd* gene. This dominant allele has been reverted and these revertants act as a simple recessive loss-of-function alleles with the one exception noted above. The *Dfd* transcript is initially detected at the blastoderm stage in a band of cells at the position of the future cephalic furrow. This RNA shows maximal accumulation from 6-12 hours of embryogenesis when it is found in the mandibular and maxillary lobes, as well as in the subesophageal region of the CNS. The amount of *Dfd* RNA diminishes through the first and second larval instars and peaks again during the third instar. At this point, it is found in the peripodial membrane cells of the eye-antennal discs. The cells which accumulate the RNA are those which have been fate mapped to give rise to the adult-head-capsule structures which are defective in *Dfd*<sup>-</sup> clones. Antibodies raised to *Dfd* protein have shown a similar pattern of accumulation to that seen for the RNA. The protein is first detected in cellular blastoderm stage in a stripe of six cells which circumscribes the embryo. As germ-band elongation proceeds and segmentation becomes evident *Dfd* protein is detected in the mandibular and maxillary lobes and a portion of the dorsal ridge. During germ-band shortening protein is no longer detect-

able in the mandibular lobe or in the anterior lateral aspect of the maxillary lobe. The process of head involution carries the *Dfd*-expressing cells interiorly where they are found in portions of the pharynx at the end of embryogenesis. *Dfd*-positive cells are also found in the subesophageal region of the CNS in the maxillary ganglion. This expression pattern has been shown to be dependent on the prior expression of the gap and pair-rule segmentation genes for its inception and on an autonomous regulatory element upstream of the *Dfd* transcription initiation site for the maintenance of *Dfd* expression into the later stages of embryogenesis. Immunostaining of imaginal discs shows *Dfd*-positive cells in the peripodial membrane of the eye-antennal discs with no detectable accumulation in the disc proper. There are also a few cells in the stalk of the labial discs which appear to accumulate *Dfd* protein. The *Dfd* cDNA driven by a heat shock promoter has been returned to flies and used to ectopically express *Dfd* protein. Animals carrying this construct subjected to heat shock produce ectopic mouth hooks and maxillary cirri in the ventral aspect of their thoracic segments, two structures missing in *Dfd*<sup>-</sup> animals. There is no phenotypic affect on abdominal pattern; however, head development is severely disrupted in heat-pulsed animals.

**cytology:** Placed in 84A4-5 by its inclusion in *Df(3R)Scr*, *Df(3R)Antp17*, and *Df(3R)Dfd13* and the location of two revertant-associated breakpoints *Dfd*<sup>rv1</sup> and *Dfd*<sup>rv2</sup>.

**molecular biology:** The *Dfd* transcription unit has been identified in the *ANTC* by its association with two *Dfd* revertant breakpoints which interrupt it and result in the recessive lethal mutant phenotype. The identified transcription unit covers 11 kb of genomic DNA and is made up of five exons. The 5'-most three exons are separated by two relatively small introns and these are separated from the 3'-most two exons by a large 7-kb intron. Transcription proceeds from proximal to distal (with respect to the chromosome centromere to telomere). This orientation is opposite to that of all the other homeotic loci in the *ANTC*. The next most proximal gene in the complex is *Ama*, the 3' end of which is just over 20 kb from the 5'

end of *Dfd*. Distally the 3' end of *Dfd* is 20 kb from the 3' end of *Scr*. The five exons sum to 2.75 kb, a figure in good agreement with the 2.8 kb transcript size seen in Northern blots. Sequence analysis of a full length cDNA shows a long open reading frame of 1758 nucleotides encoding a protein of 586 amino acids, yielding a molecular weight of 63.5 kd. The homeobox is encoded by exon four and the opa repeats are downstream in exon five.

**phenotype:** Null loss-of-function mutations result in embryonic lethality. Animals survive to the end of embryogenesis and exhibit a pair-rule mutant phenotype in the cuticle. This same phenotype is observable in animals at the beginning of segmentation of the germ band. Prior to deposition of cuticle, *ftz*<sup>-</sup> animals have two rather than three mouth (gnathocephalic) segments and five as compared to ten trunk metameres. The material deleted is derived from the even-numbered parasegments, ps2 through ps12. Similar metamer deletions/fusions are seen in the neuromeres of the ventral nerve cord of the CNS. The name of the locus derives from the phenotype and is Japanese for "segment" (*fushi*) "deficient" (*tarazu*) (*N.B.* — there is only one letter t in tarazu; it is at the start of the word *i.e.*, there is **no** second t preceding the z). Temperature-sensitive alleles of the gene have shown that the temperature-critical period for viability and phenotype falls between 1 and 4 hours of embryogenesis with the mid point of 2.5 hours at the blastoderm stage. The recovery of clones of *ftz*<sup>-</sup> cells created by X-ray-induced somatic exchange after cellular blastoderm have demonstrated that *ftz*<sup>+</sup> activity is not necessary for normal cuticular morphogenesis subsequent to this point in development. In addition to these recessive null and hypomorphic alleles there are two classes of dominant gain-of-function lesions at the *ftz* locus. The first, *ftz-Regulator of postbithorax-like*, causes a variable transformation of the posterior haltere into posterior wing. The second, *ftz-Ultra-abdominal-like*, is associated with a patchy transformation of the adult first abdominal segment toward third abdominal identity. The former (*ftz*<sup>Rpl</sup>) lesion also shows a recessive loss-of-function phenotype while the latter class (*ftz*<sup>Ual</sup>) has no discernable embryonic phenotype and is homozygous viable. The fact that these dominant alleles produce mutant phenotypes that mimic lesions in the *BXC* has been inter-

puted as demonstrating a regulatory link between the segment enumeration genes and the homeotics. alleles:

α Associated with a 5-kb insertion element in the transcribed region of *ftz*.  
β Behaves genetically as a deletion of *ftz*, *Scr*, and *Antp*.

**cytology:** Placed in 84B1-2 based on its inclusion in *Df(3R)Scr* and the 3R breakpoint of *T(2;3)ftz<sup>Rpl</sup>*, which is known to interrupt the coding region of the *ftz* transcription unit.

**molecular biology:** The localization and identification of the *ftz* transcription unit within the *ANTC* has been accomplished through the mapping of *ftz*-associated aberrations in the DNA [*ftz*<sup>11</sup> and *T(2;3)ftz<sup>Rpl</sup>*] and the rescue of *ftz*<sup>-</sup> genotypes using *P*-element mediated transformation. The transcription unit is just over 2 kb in length and is made up of two exons of 800 and 980 base pairs and a single 150-base-pair intron. The open reading frame is 1,239 nucleotides long and initiates in the (800 bp) 5' exon. Conceptual translation of the open reading frame predicts a protein of 398 amino acids with a molecular weight of 43 kd. The most prominent motifs in the protein are the homeodomain (encoded in the second exon) and a PEST domain which may be important in the dynamic pattern of *ftz* expression. Northern blots have shown that the *ftz* transcript is accumulated in early embryos starting at about 2 hours (syncytial blastoderm), peaking shortly afterwards and declining at about 4 hours. These times are coincident with the temperature-sensitive-period data noted above. The spatial pattern of RNA accumulation is first seen as a broad band at syncytial blastoderm extending from the position of the future cephalic furrow posteriorly to about 15% egg length. At cellular blastoderm this broad single band resolves into seven transverse stripes which circumscribe the embryo. These stripes disappear as gastrulation proceeds and are gone by mid gastrulation. Protein accumulation lags behind the RNA and is first detected at cellular blastoderm in the seven-stripe pattern. The position and width of the stripes indicates that *ftz* expression occurs within the even-numbered parasegmental anlagen, which are missing in *ftz*<sup>-</sup> animals. Subsequent to the ectodermal expression in the germ band, the *ftz* protein product is

again detected in the later stages of germ-band shortening, in a subset of cells in each of the segmental ganglia of the ventral nerve cord. This expression continues to the end of embryogenesis and has been shown to be important in the proper morphogenesis of a specific set of neurons repeated in each ganglion. Transformation studies have resulted in the identification of at least three *cis*-acting upstream regulatory elements necessary for normal *ftz* expression. An 1-kb fragment just upstream of the start of transcription is necessary for the establishment of the striped pattern at cellular blastoderm. Another fragment just distal to this element is needed for expression in the CNS, while about 6 kb upstream is an element necessary for the maintenance of stripes. It has also been shown that this *cis*-acting maintenance element requires the presence of *ftz* protein and therefore that *ftz* is apparently autogenously regulated in the later stages of its expression.

**lab: labial**

**location:** 3-47.5.

**references:** Diederich, Merrill, Pultz, and Kaufman, 1989, *Genes Dev.* 3: 399-414.

**phenotype:** Null mutations act as recessive embryonic lethals. Animals survive to the end of embryogenesis and have normal thoracic, abdominal, and caudal segments. However, the head is abnormal, and shows defects in derivatives of all of the gnathocephalic segments. There is no obvious homeotic transformation in these animals. Analysis of earlier stages shows abnormalities in the process of head involution. X-ray-induced clones of *lab*<sup>-</sup> cells demonstrate that *lab* function is unnecessary for the development of the adult thorax and abdomen. However, clones in the head fail to develop normally and show deletions in the maxilla and eye. Dorsally the posterior head capsule is transformed toward an apparent thoracic identity. A temperature conditional allele has been used to show a temperature critical period between 6 and 14 hours of embryogenesis. This period coincides with an interval in which head involution, a process disrupted by *lab*<sup>-</sup>, takes place. Antisera raised to *lab* protein have shown it to initially accumulated just anterior to the gnathocephalic region of the germ band at the early stages of segmentation. This protein also is found in a row of cells extending above the gnathal region in the procephalic lobe and more dorsally into the dorsal ridge. As segmentation, germ-band shortening and head involution proceed, the cells expressing the protein are involved in the process complexities of head involution. Finally at the end of morphogenesis, *lab* positive cells are found in the lateral aspects of the pharynx, the tritocerebral ganglia of the CNS, and the frontal sac. In addition to this expression in the head, *lab* protein is also found in endodermal cells at the posterior of the anterior midgut and the anterior cells of the posterior midgut. The position and movements of the cephalic cells accumulating *lab* is consistent with the interpretation that this locus is expressed in the intercalary or most anterior of the gnathal segments.

**cytology:** Placed in 84A1-2 based on its inclusion in *Df(3R)Scr* and the location of the proximal 3R breakpoints of two rearranged alleles *In(3R)lab*<sup>9</sup> and *T(3;4)lab*<sup>16</sup>. These latter two breakpoints have been located in the DNA and are known to interrupt the *lab* transcription unit.

**molecular biology:** The *lab* transcription unit is the most proximal in the *ANTC* and has been localized and identified by mapping the position of four *lab*<sup>-</sup> associated rearrangements in the DNA (*lab*<sup>9</sup>, *lab*<sup>14</sup>, *lab*<sup>15</sup>, and *lab*<sup>16</sup>) and the rescue of *lab*<sup>-</sup> animals by a minigene constructed from the transcription unit implicated by the breakpoints. The *lab* transcription unit is 17 kb in length, is made up of three exons and is transcribed from distal to proximal on the chromosome. Exons two and three are separated by a 245-bp intron and these from the 5' exon by a 13.8-kb intron. The open reading frame begins at nucleotide +239 in the first exon and extends through the third. Conceptual translation of the open reading frame predicts a protein of 629 amino acids and a molecular weight of 67.5 kd. Northern blot analysis detects a single Poly(A)<sup>+</sup> RNA of 3.0 kb, a size in good agreement with the identified exons of 1455, 416, and 935 bp. This RNA is first detected at 2-4 hours of embryogenesis and remains present through the larval and pupal stages. There is no detectable accumulation in adults. The encoded protein contains opa sequences as well as a homeodomain. The latter is encoded by sequences in exons two and three, has its closest similarity to the *pb* homeodomain, and shares with that homeobox the position of its intronic interruption.

**phenotype:** Null alleles transform the labial palps of the adult into portions of the prothoracic leg. The distal tarsal segments are present, including claws and pulvilli. The distal portion of the first tarsal segment including the sex comb in males is fused directly to the proximal portion of the femur. Thus proximal first tarsus, tibia, and distal femur are absent. Leg segments proximal to femur are not present. Hypomorphic alleles produce a labial-palp-to-antenna transformation. Generally only more distal (arista) antennal structures are seen. Extremely weak hypomorphic alleles exist which produce no ostensible phenotype as homozygotes but do reveal a weak antennal transformation in combination with a deletion or null allele. Both null and hypomorphic alleles also show an alteration in maxillary palp morphology which has been interpreted as a transformation toward an antennal identity.

**cytology:** Placed in 84A4-5 based on its inclusion in *Df(3R)Scr* and the location of eleven *pb*-associated breakpoints in this doublet (see table of alleles).

**molecular biology:** The *pb* transcription unit extends over

35 kb of DNA in the proximal portion of the *ANTC*. It is bounded distally by the z2 transcription unit and proximally by a cluster of at least eight cuticle-like genes. Neither the proximal nor distal transcripts have any demonstrable function in the fly. The transcription unit produces a single 4.3-kb mRNA which is derived from nine exons distributed over the interval. The open reading frame begins in exon two and ends in exon nine. The homeobox motif is encoded in exons four and five and is split by intron four in the same position as the homeobox is split in the labial gene. The opa sequences are in exon eight and are therefore downstream of the homeobox. Exon three is roughly equidistant between its two flanking exons and the two largest introns of the gene. This exon is 15 nucleotides long and is alternately spliced. The RNA and protein products of the gene are accumulated in the maxillary and mandibular lobes of the embryo and the labial discs of the larvae.

**phenotype:** Null mutations at the locus result in embryonic lethality. Animals die at the end of embryogenesis and show evidence of homeotic transformation in the cuticle derived from the labial and first thoracic segments. The first thorax is transformed to a second thoracic identity and the labial segment toward maxillary. This latter phenotype is seen as a duplication of the maxillary sense organs and the cirri. Deletions of the locus as well as null alleles also produce a dominant phenotype most clearly seen in males as a reduction in the number of sex-comb teeth. This reduction is indicative of a partial transformation of first leg to second, a conclusion borne out by the recovery of hypomorphic alleles of the locus which as hemizygotes allow survival to the adult stage and have no obvious effect in the embryo. These survivors show a complete transformation of ventral prothorax to mesothorax including the presence of steno-pleural bristles on the propleurae; they also show an apparent transformation of the dorsal prothorax toward a mesothoracic identity. In addition to these thoracic transformations, the labial palps are transformed toward a maxillary palp morphology. All of these adult transformations can also be seen in X-ray-induced somatic clones of *Scr*<sup>-</sup> cells. Thus *Scr* activity is needed for proper segmental identity in both the embryo and adult in the anterior-most segment of the thorax and the posterior-most metamere of the head. In the absence of *Scr* product these two segments are transformed divergently to the identity of the next most posterior and ante-

rior metamere respectively. The only other homeotic mutation to produce such a divergent homeosis is *pb*, which appears to act similarly in the adjacent maxillary and labial segments of the adult head. In addition to these loss-of-function mutations there are several gain-of-function dominant alleles. All result in a similar phenotype in adults, most clearly seen in males as the production of sex combs on the second and third thoracic legs. Additionally, strong alleles of this type (*Scr*<sup>*ScxW*</sup>, *Scr*<sup>*ScxP*</sup>, and *Scr*<sup>*ScxS*</sup>) show the loss of sternopleural bristles indicative of a more complete transformation of mesothorax to prothorax. All of these dominants are associated with genomic rearrangements and with the exception of *Scr*<sup>*ScxS*</sup> act as recessive lethals (*Scr*<sup>*Msc*</sup>, *Scr*<sup>*ScxT1*</sup>, *Scr*<sup>*ScxT2*</sup>, and *Scr*<sup>*ScxP*</sup>) or semilethals (*Scr*<sup>*ScxW*</sup> and *Scr*<sup>*ScxT3*</sup>) at the locus. Examination of animals carrying these lesions at the end of embryogenesis as heterozygotes with a normal chromosome or hemizygotes reveals no evidence of the gain-of-function transformation of T2 and T3 → T1, only the loss-of-function phenotypes described above. These phenotypic observations have been extended by showing that *Scr* protein is accumulated ectopically in the second and third leg imaginal discs in dominant gain-of-function genotypes but not in the second and third thoracic segments at any point in embryogenesis. Thus it appears that the spatial pattern of *Scr* expression is differentially regulated at these two times. Genetic analyses have shown that at least one difference lies in *Scr* imaginal expression being subject to a transvection-like effect. The gain-of-function lesions cause or allow the ectopic expression of the structural gene on the *trans*- rather than the *cis*-coupled transcription unit. This is most clearly seen in the case of *Scr*<sup>*ScxT1*</sup>, which is broken within the transcribed portion of *Scr* and is therefore incapable of making a functional gene product. *Scr* mRNA is first detected in embryos in early gastrulae in a band of cells just posterior to the cephalic furrow. Protein is not detected at this time but later during germ-band elongation; it is found in the region of the labial lobe. Subsequently, during germ-band retraction, RNA and protein are detected in the first thoracic segment with the highest concentration at the anterior border of this segment. RNA and protein are also detected in the subesophageal region of the CNS in the labial ganglion and in mesodermal cells associated with the anterior midgut. As head involution proceeds, the *Scr*-expressing cells of the labial segment are carried inside where they are found associated with the pharynx and the mouthparts at the end of embryogenesis. In the third larval instar, protein is found in the prothoracic leg discs, the dorsal prothoracic discs, the labial discs, and a small group of cells in the stalk of the antennal portion of the eye-antennal disc where it attaches to the mouthparts. In addition to this disc expression, *Scr* protein is accumulated in the subesophageal region of the CNS. This spatial pattern of expression in the epidermis is consistent with the spectrum of defects seen in *Scr*<sup>-</sup> animals and clones.

**cytology:** Placed in 84B1-2 based on its inclusion in *Df(3R)Scr*, and the common 84B1-2 breakpoints of eleven *Scr* mutations.

**molecular biology:** The *Scr* transcription unit has been identified by the localization of twelve *Scr*-associated breakpoints and the overlap junction of six deletions. Three of these approach *Scr* from its distal limit [*Df(3R)Antp7*, *Df(3R)A41*, and *Df(3R)Hu*]; the remainder delete the proximal end of the gene [*Df(3R)Dfd13*]. The identified transcription unit spans 25 kb of genomic DNA and is made up of three exons. Proceeding from 5' to 3' they are 0.5, 1.0, and 2.5 kb in length. The two introns are 6.0 and 15 kb respectively. The 3' end of *Scr* is 20 kb distal to the 3' end of *Dfd*, and the 5' end of *Scr* is 18 kb proximal to the 5' end of *ftz* and 50 kb proximal to the 3' end of *Antp*. Breakpoint associated mutations in this latter 50-kb interval all affect *Scr* function indicating that this region is important for the normal expression of the transcription unit. The sum of the three identified exons is in close agreement with the 3.9-kb mRNA detected on Northern blots. There is a single large open reading frame, which initiates in exon 2 just downstream of the splice acceptor, and terminates in exon 3 about 300 nucleotides downstream of the splice acceptor. Thus the 3' tail is just over 2 kb in length. The total open reading

frame is 1,245 nucleotides in length and encodes a protein of 413 amino acids with a predicted molecular weight of 45 kd. The homeobox motif is encoded in exon 3 and opa-like repeats are found in exon 2.

## **z2: zen-2**

**location:** 3-47.5 (inferred from close proximity to *zen*).

**synonym:** *zpr: zen pattern related*.

**references:** Rushlow, Doyle, Hoey, and Levine, 1987, *Genes Dev.* 1: 1268-79.

Pultz, Diederich, Cribbs, and Kaufman, 1988, *Genes Dev.* 2: 901-20.

**phenotype:** Simultaneous deletion of both *z2* and *pb* produces only a *pb* mutant phenotype. Thus absence of *z2* function has no discernible effect on development or morphology.

**cytology:** Placed in 84A4-5 based on its inclusion in *Df(3R)Scr* and exclusion from *Df(3R)LIN*.

**molecular biology:** The *z2* transcription unit maps 10 kb proximal to *zen* and about 1 kb distal to the transcription initiation site of *pb*. An open reading frame starts 67 bp downstream of the transcription start site in exon 1 and extends to 114 bp upstream of a consensus poly(A) addition site. The transcript produced is 1.0 kb in length and shows the same spatio-temporal expression pattern as the neighboring *zen* gene. Like *zen* conceptual translation of the *z2* open reading frame reveals the presence of a homeobox domain (encoded in exon 2). This sequence shows good similarity to the *zen* homeobox (75%), but there is little other sequence similarity found in the remainder of the proteins. The function of this locus is not known, but in light of the fact that its deletion causes no detectable effect, and *zen* mutants can be rescued by a genomic fragment which does not contain *z2*, it is likely the locus represents a pseudogene. Consistent with this conclusion is the finding that a *z2* homologue is not found in the *ANTC* of *D. pseudoobscura*.

## **zen: zerknüllt**

**Location:** 3-47.5 (between *pb* and *bcd* in the *ANTC*).

**references:** Wakimoto, Turner, and Kaufman, 1984, *Dev. Biol.* 102: 147-72.

Rushlow, Doyle, Hoey, and Levine, 1987, *Genes and Dev.* 1: 1268-79.

Rushlow, Frasch, Doyle, and Levine, 1987, *Nature* 330: 583-86.

Doyle, Harding, Hoey, and Levine, 1986, *Nature* 323: 76-9.

**phenotype:** Null mutations result in embryonic lethality and the loss of several dorsally derived embryonic structures, including the amnioserosa, optic lobe, and dorsal ridge. These animals also fail to fully extend their germ bands and go through the process of head involution. The name for the locus derives from the characteristic "wrinkled" appearance of the germ band seen in the SEM at the time of normal germ-band retraction. Hypomorphic mutations result in the absence of dorsal structures but do undergo normal gastrulation movements. A temperature-sensitive allele has been used to define the time of *zen*<sup>+</sup> action between 2 and 4 hours of embryogenesis, just prior to and overlapping the earliest observable morphogenic defects. X-ray induced somatic clones have further shown that *zen*<sup>+</sup> function is unnecessary for postembryonic development. The RNA product of *zen* is first detected at about 2 hours of development during the

eleventh to twelfth cell cycle of the syncytial blastoderm. At this early stage the RNA is found on the dorsal surface of the embryo extending around the anterior and posterior poles. As cellularization proceeds and the early events of gastrulation begin, the RNA becomes restricted to a mid-dorsal stripe of cells. These cells have been fate mapped and give rise to the amnioserosa and the lobes in the dorsal posterior of the embryonic head, *i.e.*, the structures absent in *zen*<sup>-</sup> animals. The time of appearance of *zen* RNA also correlates nicely with the temperature-sensitive-period data obtained using the conditional allele. Antisera to the *zen* protein product has been used to follow its accumulation pattern, and this analysis agrees with and expands the *in situ* results. The protein is located in the nuclei of cells expressing the gene and at cellular blastoderm is found in a mid-dorsal stripe seven cells wide and seventy cells in length. During gastrulation these cells eventually give rise to the amnioserosa, the optic lobe, and dorsal ridge; these structures continue to show *zen* protein accumulation until the end of germ-band extension at about 4 to 6 hours of development. This end point also correlates well with the end of the temperature-sensitive period of the conditional allele. The spatial pattern of *zen* expression has been shown to be dependent on the products of several of the maternally expressed genes which specify the anterior-posterior and dorsal-ventral polarity of the embryo, and *zen* would appear to lie near the end of the axis-determining pathway.

**alleles:** Seven ethyl-methanesulfonate-induced alleles, all of which have normal cytology.

**cytology:** Placed in 84B1-2 based on its inclusion in *Df(3R)Scr* and *Df(3R)SCB-XL2*.

**molecular biology:** One of a pair of regions between *pb* and *bcd* in the *ANTC* has been shown to be *zen* by *P*-element mediated transformation and rescue of a *zen*<sup>-</sup> genotype. The rescuing fragment is 4.5 kb in length and carries a single 1.3 kb transcription unit. It is composed of two exons separated by a 64-base pair intron. The start of translation is 52 base pairs downstream of the transcription start site in the first exon. The open reading frame ends 169 base pairs upstream of a poly(A) addition site in exon 2. The predicted size of mature message from genomic and cDNA sequence analysis is 1.3 kb which is in agreement with the transcript size observed on Northern blots. Conceptual translation of the open reading frame shows the presence of a homeodomain and PEST sequences, which are enriched for the amino acids serine, threonine, proline, and glutamic acid. The presence of both of these motifs correlates well with the DNA binding activity of *zen* protein and the dynamic pattern of protein accumulation seen for *zen* protein *in vivo*.

**antenna:** see *ems*

**Antennapedia:** see *Antp* under *ANTC*

**anterior open:** see *aop*

**anterobithorax:** see *abx* under *BXC*

**Antp:** see *ANTC*

**ants: antennas**

**location:** 3-49.4.

**origin:** Spontaneous.

**references:** Ribó, 1968, DIS 43: 59.

**phenotype:** Antennae modified—lengthened or reduced—especially in males. Viability good.

**aop: anterior open**

**location:** 2-12 (approximate).

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82. (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Homozygous embryos have anterior dorsal hole in epidermis. Brain and sometimes gut extrude through hole. Head involution normal. Visible during dorsal closure.

**alleles:** Six ethyl-methanesulfonate induced alleles; *aop*<sup>1</sup> and *aop*<sup>2</sup> (recovered as *IP* and *IIS*) retained.

**aor: abdominal one reduced**

**location:** 3-{85}.

**references:** González, Molina, Casal, and Ripoll, 1989, Genetics 123: 371-77.

**phenotype:** Hemizygotes lack the first abdominal segment. Histoblasts of third-instar larvae normally present in A1.

**cytology:** Placed in 96A1-7 based on its association with *In(3R)Ubx*<sup>7L</sup> = *In(3R)89E;96A1-7* and its inclusion in *Df(3R)L16* = *Df(3R)96A1-10;96E*.

**\*ap: apterous** (T.G. Wilson)

**location:** 2-55.2.

**references:** Metz, 1914, Am. Naturalist 48: 675-92.

Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 236 (fig.).

Stevens and Bryant, 1985, Genetics 110: 281-97.

1986, Genetics 112: 217-28.

**phenotype:** Wings and halteres reduced to traces. Bristles eliminated from area around wing base (including posterior notopleurals, anterior and posterior supra-alars, and anterior postalars); posterior scutellars erect when present but missing in first counts; dorsocentrals smaller and fewer; hairs on thorax sparse and irregular. Sutural furrow reduced; thorax disproportionately small. Flies small, pale, weak, and very short lived. Viability about 70% that of wild type but erratic. Both sexes sterile. RK2.

**alleles:** Apterous alleles generally fall into three groups based on phenotypic differences. Most of the characterized apterous alleles belong to the first group and have basically the *ap* or *ap*<sup>4</sup> phenotype. Some alleles (*ap*<sup>blt2</sup> and *ap*<sup>T60</sup>) have a less severe wing phenotype, being straplike. Alleles also vary in their expressivity of the precocious adult death and nonvitellogenic ovary phenotypic characters; some alleles result in a low number of escapers, similar to *ap*<sup>4</sup>, while others have an escaper percentage of as much as 50%. There is little correlation between expressivity of the wing deficiency phenotype

and either precocious adult death or nonvitellogenic ovary development, but a good correlation exists between expressivity of the latter phenotypic characters (Wilson, 1980). Generally, heterozygous combinations of these alleles do not show complementation for any phenotypic characters. Another group, represented by *ap<sup>blt</sup>*, exhibits a less severe, somewhat different phenotype; attributable to localized lysosomal cell death in the presumptive wing blade. (Sedlock, Mango, and Stevend, 1984, Dev. Biol. 104: 489-96). A third group includes two dominant alleles. The apterous locus appears to be a complex locus, containing several partially complementing groups for the wing deficiency and adult-death/female-sterility phenotypic characteristics. However, by studying the effects of a number of different temperature regimens on phenotypic expression of three different temperature-sensitive alleles, Stevens and Bryant (1986) conclude that all phenotypes are explicable in terms of changes in quantity rather than quality of gene product.

<sup>β</sup> Designation of allele with similar phenotype.

γ Phenotypes described below in separate entries.

**cytology:** Placed in salivary region 41B-C (Schultz).

### *ap<sup>4</sup>*

**phenotype:** Wings less than 10% normal length, lacking all wing blade structures. Halteres reduced to structure-less remnants less than 25% normal size. Scutellar and dorsocentral bristles sometimes missing (Butterworth and King, 1965, Genetics 52: 1153-74). Wing phenotype disc autonomous in *ap<sup>4</sup>/ap<sup>+</sup>* mosaic flies, although small patches of *ap<sup>4</sup>* wing structures are found in *ap<sup>4</sup>/ap<sup>+</sup>* mosaic wings. Haltere phenotype disc autonomous (Wilson, 1981, Dev. Biol. 85: 434-45). Adults become paralyzed about 30 hr following eclosion and die soon thereafter. Around 1% of adults are long-lived "escapers" of this phenotype (Wilson, 1980, Dev. Genet. 1: 195-204). Precocious adult-death phenotype fate-maps to proximity of Malpighian tubules, and tubule malfunctioning postulated to result in this phenotype (Wilson, 1981). Foregut of females swollen owing to accumulation of peritrophic membrane (King and Sang, 1958, DIS 32: 133). Female sterile with underdeveloped ovaries; nurse cell nuclei become pycnotic after stage 7, and stage-8 oocytes are the most advanced (King and Burnett, 1957, Growth 21: 263-80; Wilson, 1980). *ap<sup>4</sup>* ovaries develop nonautonomously when transplanted to a wild-type host (King and Bodenstein, 1965, Z. Naturforsch. 20B: 292-97). Application of juvenile hormone mimic, ZR-515, to newly eclosed *ap<sup>4</sup>* females results in vitellogenic oocytes [Postlethwait and Weiser, 1973, Nature (London) New Biol. 244: 284-85]. Membranes of vitellogenic oocytes lack microvilli and pinocytotoxic vesicles normally present; development of these structures stimulated by administration of ZR-515 (Tedesco, Courtwright, and Kumaran, 1981, J. Insect. Physiol. 27: 895-902). Corpora allata from adult *ap<sup>4</sup>* are juvenile-hormone deficient when bioassayed [Postlethwait, Handler, and Gray, 1975, The Juvenile Hormones (L.I. Gilbert, ed.), pp. 449-69]. Nonvitellogenic oocyte phenotype fate-maps to same or similar location as precocious adult death phenotype (Wilson, 1981). Escaper females develop stage-14 oocytes (King and Sang, 1958) and are fertile (Wilson, 1980). Males show immature sexual behavior and are sterile, but testes appear normal with motile sperm (King and Sang, 1958). Larval fat body histolysis delayed; this phenotype is nonautonomous as determined by transplantation experiments (Butterworth, 1972, Dev. Biol. 28: 311-25). Application of ZR-515 accelerates larval fat body histolysis in *ap<sup>4</sup>* adults (Postlethwait and Jones, 1978, J. Expt.

Zool. 203: 207-14). Ovarian acid phosphatase level low in *ap*<sup>4</sup> females and is restored after application of ZR-515 (Postlethwait *et al.*, 1975). *ap*<sup>4</sup> ovaries cultured *in vitro* are capable of yolk protein synthesis (Redfern and Bownes, 1982, Mol. Gen. Genet. 195: 181-83). *ap*<sup>4</sup>/*Df(2L)M41A-54* hemizygote has nearly normal complement of bristles but otherwise resembles *ap*<sup>4</sup> homozygote (Butterworth and King, 1965).

***ap*<sup>56f</sup>**

**phenotype:** Wing and haltere phenotype like *ap*<sup>4</sup>. Scutellar and dorsocentral bristles missing (Butterworth and King, 1965, Genetics 52: 1153-74). Rear and middle legs occasionally twisted, more frequently in female than in male. Both sexes fertile and long lived when homozygous and in combination with other *ap* alleles. *ap*<sup>56f</sup>/*M(2)S2*<sup>4</sup> have normal complement of dorsocentral and scutellar bristles (Butterworth and King, 1965).

***ap*<sup>77i</sup>**

**phenotype:** Weakest non-temperature-sensitive allele known. Wing has reasonably good wing blade development, with missing triple-row elements and posterior wing margin. Haltere less well developed but more so than *ap*<sup>4</sup>. Adults long lived and fertile. Less dominant in heteroallelic combination with *ap*<sup>4</sup>-like alleles than is *ap*<sup>56f</sup>. *ap*<sup>77i</sup>/*Df(2R)M41A4* has more severe phenotype than *ap*<sup>77f</sup> homozygotes.

***ap*<sup>78j</sup>**

**phenotype:** A temperature-sensitive allele of apterous. When raised at 22°, wing and haltere phenotype approaches wild type except for missing patches of triple-row bristles and posterior wing margin. When raised at higher temperatures, phenotype becomes more severe and resembles *ap*<sup>4</sup> at 29°. Two nonoverlapping temperature-sensitive periods in development, one in late-second to middle-third instar for wing and haltere deficiency phenotype and the other during the first day of pupal development for precocious adult death and nonvitellogenesis phenotype. Wing discs of heat-pulsed larvae failed to exhibit cell death by trypan blue exclusion.

***ap*<sup>blt</sup>: apterous-blot**

**phenotype:** Wings blistered, sometimes inflated and dark due to trapped hemolymph. Mirror-image duplication of posterior wing blade structures occurs [Waddington, 1939, Proc. Nat. Acad. Sci. USA 25: 299-307; Whittle, 1979, J. Embryol. Exp. Morphol. 53: 292-303 (fig.)]. Wing venation may be disrupted. Portions of posterior wing compartment may be transformed into anterior compartment structures, an effect like that of engrailed (*en*; 2-62.0). Despite relatively mild adult phenotype, extensive cell death observed, localized to wing pouch of imaginal discs; associated with acid phosphatase and lysosomal activity (Sedlak, Manzo, and Stevens, 1984, Dev. Biol. 104: 489-96). Clonal analysis revealed nonautonomous expression of phenotype. Heterozygotes with *ap*<sup>4</sup> or *ap*<sup>56f</sup> and hemizygotes show blistering phenotype only (Whittle). *ap*<sup>blt</sup>/*ap*<sup>73n</sup> shows transformation phenotype, and aldehyde oxidase histochemical staining of these wing discs is consistent with transformation (Whittle and Sprey, 1982, Wilhelm Roux's Arch. Dev. Biol. 191: 285-88). Much overlapping with wild type, and expressivity variable. Adults long lived and fertile.

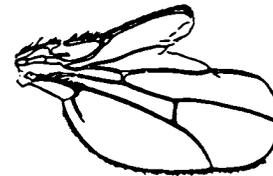

***ap*<sup>e</sup>**

**phenotype:** Homozygotes display extreme wing reduction, particularly of the posterior wing compartment. Approximately 50% of the flies have duplications of the anterior wing margin, distal costa, and triple row bristles. In wings with large amounts of wing blade, very little venation is present; however, these may often have triplications or even four copies of the anterior wing margin, some located in the posterior part of the wing. Dried hemolymph sometimes trapped between the dorsal and ventral wing surfaces giving the wing a puffy blackened appearance. This mutant therefore has duplications and deficiencies characteristic of cell death followed by regulation in the wing, but also has transformations of the posterior wing compartment to the anterior wing compartment. 8% of the flies have defective third legs, more frequently in females than in males. Halteres and scutellar bristles appear to be normal. Homozygotes viable and fertile.

***ap*<sup>trw</sup>: apterous-torn wing**

**phenotype:** Distal part of wing in homozygotes shows sawtooth pattern as if tip torn away. Expression uniform in males and females. Viability and fertility good.

**other information:** Genetic location and phenotype suggests allelism with apterous, but not tested with viable *ap* alleles.

***ap*<sup>Xa</sup>: apterous-Xasta**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 228.

***ap*<sup>Xa</sup>: apterous-Xasta**

**phenotype:** Wings reduced in length to about 70% normal; irregular in outline with a V-shaped incision with apex at L2, uniformly present giving wing a mitten-like shape with the thumb between marginal vein and L2. Excellent dominant with no overlap. Fertile and fully viable in heterozygote. Usually lethal in homozygous conditions, but occasionally ecloses very late as pale dwarf with wings and balancers like *vg*. Deep notch visible in tip of wing fold in prepupa (Waddington, 1939, Proc. Nat. Acad. Sci. USA 25: 299-307). In homozygotes and in combination with *ap*<sup>4</sup>, *ap*<sup>6</sup>, or *Df(2R)M41A4*, wings are straplike and 30-70% normal length, and haltere length is 25-50% normal; longevity and fertility like *ap*<sup>4</sup>/*ap*<sup>4</sup> except for an occasional long-lived *ap*<sup>Xa</sup>/*Df(2R)M41A4* female that may be fertile [Butterworth and King, 1965, Genetics 52: 1153-74 (fig.)]. In heterozygous combination with *ap*<sup>ID</sup>, duplications of the notum occur frequently. Wing disc cell death found in both *ap*<sup>Xa</sup>/+ (Fristrom, 1969, Mol. Gen. Genet. 103: 363-79) and *ap*<sup>Xa</sup>/*ap*<sup>ID</sup> [Postlethwait, 1978, Genetics and Biology of *Drosophila* (Ashburner and Wright, eds.), Academic Press, London, New York, San Francisco, Vol. 2C,

pp. 418-19 (fig.).

**cytology:** Shown by Sturtevant (1934, DIS 2: 19) to be associated with  $T(2;3)ap^{Aa} = T(2;3)41F;89E8-F1$  which is superimposed on  $In(2R)Cy$  and  $In(3R)P$  (Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 294; Lewis, 1951, DIS 25: 109).

*ap-c*: see *ap*<sup>2</sup>

*ap-c*: see *ap*<sup>3</sup>

*ap-d*: see *ap*<sup>4</sup>

**apang**: see **apg**

**Apart**: see **Apt**

**\*apb: apterblister**

**location:** 2-44.7.

**origin:** Ultraviolet induced.

**discoverer:** Edmondson, 49k.

**references:** Meyer, Edmondson, Byers, and Erickson, 1950, DIS 24: 59-60.

**phenotype:** Wings always notched, nearly always spread, and usually blistered but expression somewhat variable. Homozygous imagos live less than 24 hr, owing to intestinal obstructions. Abdomens characteristically turn dark grey before death because of accumulation of digested food products. Although not at same locus as *ap*, *apb*  $+/+$  *ap*<sup>4</sup>, flies show slight notching of wings and many die within a day; those that survive are fertile. *ap*<sup>5</sup> gives a similar heterozygous effect. RK2.

**Ape: Apurinic endonuclease**

**location:** 3-{47}.

**synonym:** AP3.

**references:** Kelly, Venugopal, Harless, and Deutsch, 1989, Mol. Cell Biol. 9: 965-73.

**phenotype:** Encodes an apurinic-apyrimidinic DNA endonuclease, AP3. Biochemical studies by Spiering and Deutsch (1986, J. Biol. Chem. 261: 3222-28).

**cytology:** Placed in 79C-D by *in situ* hybridization.

**molecular biology:** Isolated from a cDNA expression library using antiserum directed against human enzyme known to cross react with the Drosophila enzyme (Spiering and Deutsch). The conceptual translation product predicts a 317-amino-acid polypeptide of molecular weight 34.2 kd. Region between nucleotides 30 and 173 shows 66% homology with *recA* of *E. coli* and 42% amino-acid identity. Two helix-turn-helix domains detected in the carboxy-terminal end of the polypeptide. Northern blots identify a 1.3-kb transcript at all stages of development, but somewhat reduced in pupae and adult males; there is also transiently present, a 3.5-kb transcript in four-to-eight-hour embryos that disappears after second larval instar.

**apexless**: see **apx**

**aperA: abnormal proboscis extension reflex A (J.C. Hall)**

**location:** 1-22.1.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kimura.

**references:** Kimura, Shimozawa and Tanimura, 1986, J. Exp. Zool. 239: 393-99.

**phenotype:** Variable phenotypic defects in the sugar-induced proboscis extension reflex (PER): some *aperA*

flies cannot extend their probosces at all, whereas they are able to open the labellar lobes; some individuals extend their probosces only to the right or the left side of the body; each mutant individual seems to have a fixed phenotype, e.g., a fly which shows one-sided PER always extends its proboscis to the same side; the array of aberrant phenotypes is different under the influence of the two mutant alleles: for *aperA*<sup>1</sup>, 47.0% were unable to extend their probosces, 16% only to the left side, and the remainder extended their probosces normally; for *aperA*<sup>2</sup>: 32% could not extend their probosces, 23% could extend them only to the right side, and 22% only to the left side (the remainder behaved normally).

**alleles:** Two alleles; *aperA*<sup>1</sup> (=TT1), *aperA*<sup>2</sup> (=TT360), with the overall penetrance for the former ca. 79%; 77% for the latter.

**aperB (J.C. Hall)**

**location:** 1-0.6.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kimura.

**references:** Kimura, Shimozawa and Tanimura, 1986, J. Exp. Zool. 239: 393-99.

**phenotype:** Given sugar stimuli *aperB* flies extended their probosces, not straight forward (as does wild-type), but backward; when these mutants show a partial extension of their probosces, the direction of the extensions is normal; the expression of the *aperB* gene is sensitive to culture temperature: when the *aperB*<sup>1</sup> mutants were reared at low temperature (18° or 20°C), over 90% of the flies were normal, whereas the high culture temperature (over 25°C) caused an abnormal PER; the temperature at which the proboscis extension reflex was tested did not affect the phenotype.

**cytology:** Maps to 2D3-F3; based on its inclusion in  $Df(1)Pgd = Df(1)2D3;2F5$  but not  $Df(1)JC19 = Df(1)2F3;3C5$ ;  $w^+Y = Dp(1;Y)2D2;3D2-3$  covers *aperB*<sup>1</sup>.

**alleles:** Two alleles: *aperB*<sup>1</sup> (=TT665) and *aperB*<sup>2</sup> (=TF48), which lead to indistinguishable phenotypic defects.

**other information:** *aperB* mutations are completely recessive, and complement the closely linked *aperC* mutation.

**aperC (J.C. Hall)**

**location:** 1-0.4.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kimura.

**references:** Kimura, Shimozawa and Tanimura, 1986, J. Exp. Zool. 239: 393-99.

1986, Devel. Biol. 117: 194-203.

1987, J. Neurogenet. 4: 21-28.

**phenotype:** Sugar-induced proboscis extension nearly absent (*i.e.* no extension at all of rostrum and haustellum), but not until adults are three to six days old; this defect, which is completely recessive, wanes such that at least half of the adults behave normally again by approximately day 10-11; correlated with these behavioral changes is time-dependent degeneration and regeneration of a pair of muscles, the rostral protractors; behavioral and histological phenotypes are temperature-sensitive: 18° causes defects later in adult life, and yet there is no recovery; 29° causes lower than usual (*i.e.* 25°) proportion of adults developing the defects, and high temperature is compatible with recovery; temperature-sensitive

period is from two to four days post-eclosion.

**cytology:** Maps to 1F5-2A, based on its inclusion in  $Df(1)A94 = Df(1)1F5;2B15$  and  $Df(1)S39 = Df(1)1E4;2B11-20$  plus the fact that the X-chromosome duplication from the distal tip to 2A, from  $T(1;Y)G20$ , covers *aperC*.

**other information:** *aperC* completely recessive and complements the closely linked *aperB* mutations.

**apg: apang**

**location:** 2-7.7.

**origin:** Induced by ethyl methanesulfonate.

**references:** Shakaron and Sharma, 1983, DIS 59: 110 (fig.).

**phenotype:** Homozygotes when raised at 19° show occasional absence of one or both claws; veins L4 and L5 interrupted; fertile at 19° but become sterile when shifted to 28°; produce embryos with range of germ band abnormalities. Homozygous pupal lethal when raised at 28°; pharate adults show defective tarsal development of all six legs; condensed, poorly developed and curved metatarsus and tarsi; duplications in tibial and tarsal segments; claws absent. Temperature sensitive period first instar to early pupa.

**Aph-1: Alkaline phosphatase-1**

**location:** 3-47.3 (between *W* and *p*) (Wallis and Fox).

**references:** Beckman and Johnson, 1964, Nature 201: 321 (fig.).

1964, Genetics 49: 829-35 (fig.).

Wallis and Fox, 1969, Biochem. Genet. 2: 141-58.

**phenotype:** Locus responsible for one of several different alkaline phosphatase species [APH1 (EC 3.1.3.1)] formed during the life cycle. Specifies the enzyme that becomes active in the larval cuticle and muscle during the third instar. Electrophoretic mobility of a pupal form of the enzyme, which differs from that found in the larva, also appears to be controlled by this locus (Wallis and Fox). Dimeric nature of enzyme inferred from the presence of enzymes of hybrid mobility in larvae heterozygous for electrophoretic variants. Biochemical characterization of larval enzyme by Harper and Armstrong (1972, Biochem. Genet. 6: 75-82; 1973, Biochem. Genet. 10: 29-38; 1974, Biochem. Genet. 11: 177-80).

**alleles:** Naturally occurring alleles superscripted *F* and *S* reported by Beckman. Wallis and Fox describe *Aph<sup>A</sup>* which specifies larval enzyme migrating faster than *Aph<sup>F</sup>*, but a pupal enzyme with same characteristics as that produced by *Aph<sup>F</sup>*. *Aph<sup>0</sup>* reported by Johnson (1966, Science 152: 361-62) produces no detectable enzyme activity but causes the appearance in extracts of *Aph<sup>S</sup>/Aph<sup>0</sup>* larvae of a band migrating slightly faster than the hybrid band produced by *Aph<sup>F</sup>/Aph<sup>S</sup>* larvae. Naturally occurring alleles superscripted 2, 4, 6, and 10 characterized by Harper and Armstrong (1972, 1973, 1974); 4 is synonymous with *F* as is 6 with *S*; 2 migrates more slowly than *S* and 10 more rapidly than *F*; not clear that 10 and *A* are different. That the larval and pupal enzymes are differently modified products of the same locus is indicated by genetic inseparability and by concordance in the orders of mobilities of electrophoretic alleles (Wallis and Fox).

**Aph-2**

**location:** 2- not mapped.

**references:** Schneiderman, Young, and Childs, 1966, Science 151: 461-63.

**phenotype:** The alkaline phosphatase found in adult hindgut.

**alleles:** Two different alleles recorded superscripted *A* and *B*. Enzyme produced by *Aph-2<sup>A</sup>* homozygotes migrates more rapidly than that produced by *Aph-2<sup>B</sup>* homozygotes; enzyme produced by *Aph-2<sup>A</sup>/Aph-2<sup>B</sup>* has same mobility as that produced by *Aph-2<sup>A</sup>* homozygotes.

**apo: altered pattern orientation (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *apo<sup>S129</sup>*.

**references:** Heisenberg, 1979, Handbook of Sensory Physiology (H. Autrum, ed.). Springer-Verlag, Berlin, Vol. VII/6A, pp. 665-79.

Bülthoff, 1982, DIS 58: 31.

1982, Biol. Cybernet. 45: 63-70.

**phenotype:** Poor orientation to objects, including spots in Y-maze test; electroretinogram normal.

**app: approximated**

**location:** 3-37.5.

**discoverer:** Curry, 34a25.

**references:** 1935, DIS 3: 6.

**phenotype:** Crossveins close together; veins diverge at greater angle than wild type; effect visible in prepupal wing [Waddington, 1940, J. Genet. 41: 75-139 (fig.)]. Legs short with four-jointed tarsi; the penultimate joint characteristically swollen [Waddington, 1939, Growth Suppl. 37-44 (fig.)]. Joint between second and third tarsal segments often incomplete; invaginations or internalization of cuticle seen in tarsi 1, 3, and 4 (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57). Thickset body. Posterior scutellars farther apart than normal. Eyes smaller and flatter than normal, also bumpy. Spread wings; thickened veins. RK1.

**alleles:** *app<sup>61e</sup>* (CP627).

**cytology:** Placed in 69A2-4 on the basis of its inclusion in  $Df(3L)vin6 = Df(3L)68C8-11;69A4-5$  but not  $Df(3L)vin5 = Df(3L)68A3;69A1-2$  (Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-26).

**Appl: β-Amyloid protein precursor like (K. White; J.C. Hall)**

**Location:** 1-{0}.

**origin:** Isolated as cDNA clones derived from cloned genomic DNA in the 1B division.

**references:** Rosen, Martin-Morris, Luo, and White, 1989, Proc. Nat. Acad. Sci. USA 86: 2478-82.

Martin-Morris, and White, 1990, Dev. (In press).

**molecular biology:** A 6.5 kb transcript corresponding to the cDNA clones encodes a polypeptide that is conceptually an 886 amino acid transmembrane protein; this predicted amino-acid sequence shows strong homology in certain of its regions to the β-amyloid protein precursor protein of humans (Rosen *et al.*, 1989). Two forms of the actual protein, which is N-glycosylated, are detectable (in studies involving extracts, primary cultures, and transfected cells); an 145 kd membrane-associated precursor and a 130 kd secreted form lacking the

cytoplasmic domain inferred from sequencing (Luo, Martin-Morris, and White, 1990, J. Neurosci., in press). The source of the *Appl* transcript spans ca. 38 kb of genomic DNA; this RNA localizes to post-mitotic neurons (and apparently not to non-neuronal tissues) in all developmental stages and in adults (Martin-Morris and White, 1990). Consistent with these *in situ* hybridization data are those showing APPL protein immunoreactivity in developing neurons, concomitant with axonogenesis; this staining remains associated with differentiated neuronal cell bodies and axonal tracts (including neuropil regions) in embryos, APPL immunoreactivity is observed exclusively in post-mitotic CNS and PNS neurons (Luo *et al.*, 1990).

**other information:** The APPL-encoding gene initially suggested (Rosen *et al.*, 1989) to correspond to *vnd* (which was defined originally by embryonic neural-lethal mutations). This has been disproved, in that a terminal deletion *Df(1)78* which retains *vnd*<sup>+</sup> function removes most of the *Appl* coding sequences (Martin-Morris and White).

*apr*: see *w*<sup>a</sup>

#### **Appt: Adenine phosphoribosyltransferase**

**location:** 3-1.49 (0.13 cM to the right of *R*; estimated by Johnson and Friedman to be 3.03 units from the tip of *3L*).

**synonym:** *aprt*.

**references:** Johnson and Friedman, 1981, Science 212: 1035-36.

1983, Proc. Nat. Acad. Sci. USA 80: 2990-94.

**phenotype:** Is the structural gene for adenine phosphoribosyltransferase [APRT, AMP: pyrophosphate phosphoribosyltransferase (EC 2.4.2.7)], a homodimer with 23,000 dalton subunits. It is a purine salvage enzyme which catalyzes the synthesis of AMP from 5-phosphoribosyl-1-pyrophosphate. Flies homozygous for a null allele *Appt*<sup>1</sup> survive on 15 times the concentration of purine that wild type tolerates and show about 2% wild-type enzyme activity; *Appt*<sup>1</sup>/<sub>+</sub> exhibit about half wild-type activity. *Appt*<sup>2</sup> has 9% normal enzyme activity. The dosage response suggests that the mutant affects the structural gene for APRT.

**alleles:** Electrophoretic variants *Appt*<sup>A</sup> (more acidic) and *Appt*<sup>B</sup> (more basic) in wild-type stocks Oregon R and Canton S, respectively. *Appt*<sup>1</sup> (Duck), *Appt*<sup>2</sup> and *Appt*<sup>3</sup> (Gelbart and Chovnick) induced by ethyl methanesulfonate; *Appt*<sup>4</sup> and *Appt*<sup>5</sup> selected on purine food by Johnson and Friedman (1983).

**cytology:** Placed in 62B8-12 based on its inclusion in the region of overlap of *Df(3L)R-G7 = Df(3L)62B8-9;62F2-5* and *Df(3L)R-G2 = Df(3L)62B2-4;62B11-12* (Sliter, Henrich, Tucker, and Gilbert, 1989, Genetics 123: 327-36). *in situ* hybridization identifies 62B9 as the site of *Appt* (Johnson *et al.*).

**molecular biology:** Genomic clone isolated by chromosomally walking from sequences isolated and cloned by microdissection of region 62B from polytene chromosomes. Gene recognized by hybrid selection of an 1-kb mRNA that translated an APRT product. cDNA's have a common 5' initiation site but two different 3' polyadenylation sites. The primary transcript contains two introns, the first of which has alternative 5' sites, which are spliced to the same 3' site; one product encodes the

functional enzyme and the other a prematurely terminated and presumably nonfunctional polypeptide (Johnson and Henikoff, 1989, Mol. Cell Biol. 9: 2220-23). Conceptual amino-acid sequence predicts a polypeptide of 194 amino acids and about 20 kd in molecular weight. *Drosophila* APRT amino-acid sequence displays approximately 40% identity and nearly 80% homology with all known APRT proteins (Johnson, Edström, Burnett, and Friedman, 1987, Gene 59: 77-86).

#### **\*Apt: Apart**

**location:** 3- (between *h* and *p*).

**origin:** X ray induced.

**discoverer:** Belgovsky, 34e23.

**references:** 1935, DIS 3: 27.

**phenotype:** Wings spread widely. Viability, fertility, and separability good. Homozygous lethal. RK2A.

**cytology:** Associated with *In(3L)Apt* — no salivary analysis.

**other information:** *Apt/D* survive; therefore not an allele of *D*.

**apterblister:** see *apb*

**apterous:** see *ap*

**Apurinic endonuclease:** see *Ape*

#### **\*apx: apexless**

**location:** 1-11.3.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)aminophenylalanine.

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 83.

**phenotype:** Slightly larger fly with large eyes containing various numbers of deranged ommatidia. Wings broad and blunt; in many flies, margin removed to various degrees, from a small incision of inner margin to removal of entire inner margin, costal vein, and parts of the membrane as far as L3. Region from L3 to costal cell unaffected. Rarely L4 and 5 are interrupted. Males viable and fertile; female fertility reduced. RK3.

#### **Apx: Antennapedex (R.E. Denell)**

**location:** 1-70 (said to map 12 units to the right of *B*).

**origin:** Neutron induced.

**references:** Ginter, 1969, DIS 44: 50.

**phenotype:** Males and heterozygous females show variable expression from small additional segment on the third antennal segment to a nearly complete leg including femur, tibia, and tarsus. Arista usually present. Homozygous females lethal but *X0* males survive. Crosses involving either *Apx* males or females produce many inviable embryos.

**cytology:** Polytene X appears normal, but genetic results suggest a *T(1;3)* with breakpoints in the proximal part of *Xh* and at *Antp*.

*Apx-2*: see *Antp*

#### **ar: abdomen rotatum**

**location:** 4- (proximal to *bt*; Fung and Stern, 1951, Proc. Nat. Acad. Sci. USA 37: 403-4.

**origin:** Spontaneous.

**discoverer:** Beliajeff, 1926.

**references:** 1931, Biol. Zentralbl. 51: 701-8 (fig.). Bridges, 1935, Biol. Zh. 4: 401-20.

Marengo and Howland, 1942, *Genetics* 27: 604-11 (fig.).

**phenotype:** Abdomen twisted clockwise through 45° to 60°. No overlapping with wild type. Male external genitalia often missing. Males usually sterile; females partially fertile. Puparia not so smooth as normal; larval segmentation remains. Puparia have deep constriction near posterior end just anterior to spiracles. Existing chromosomes marked *ar* also carry *l(4)* and, in combination with *Df(4)M*, show counterclockwise rotation of male abdomen when viewed from behind (Hochman). RK2.

**alleles:** *ar*<sup>2</sup>, *\*ar*<sup>57d</sup>, and *\*ar*<sup>57g</sup> X ray induced (CP627). Ethyl methanesulfonate induced alleles superscripted *65f*, *65h*, *68i*, and *69g* described by Hochman (1971, *Genetics* 67: 235-52; 1972, *DIS* 48: 17). *ar*<sup>68i</sup> shows best viability and fertility.

**cytology:** Placed in salivary chromosome region 101E through 102B16 on basis of its inclusion in *Df(4)M* = *Df(4)101E-F;102B6-17*.

*Ar*: see *Antp*<sup>LC</sup>

**arc:** see *a*

**arch:** *arch*

**location:** 2-60.5.

**origin:** Spontaneous.

**discoverer:** Curry, 36g3.

**references:** 1937, *DIS* 7: 5.

**phenotype:** Wings curved evenly downward, both longitudinally and transversely; sometimes shorter and blunter; rarely divergent. RK2.

**arclike wing:** see *alw*

**arcoid:** see *ad*

**arctops:** see *at*

**arctus oculus:** see *at*

**ard:** see *Acr64B*

**aret:** *arrest* (*T. Schüpbach and E. Wieschaus*)

**location:** 2-48.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females often have underdeveloped ovaries which seem to lack germ cells altogether. In some females a small number of developing egg chambers is found. These never develop beyond the first few stages of oogenesis.

**alleles:** Eight, *aret*<sup>WQ</sup> = *aret*<sup>l</sup>, *aret*<sup>WH</sup>, *aret*<sup>PA</sup>, *aret*<sup>PC</sup>, *aret*<sup>PD</sup>, *aret*<sup>PE</sup>, *aret*<sup>QB</sup>, *aret*<sup>RM</sup>. Females homozygous for *aret*<sup>PC</sup> and *aret*<sup>QB</sup> usually have a number of egg chambers in their ovaries in which the nurse cells and oocyte never seem to develop beyond stage 2 or 3 of oogenesis, but the follicle cells nevertheless synthesize a tiny round chorion around the cysts. Females homozygous for *aret*<sup>PA</sup>, *aret*<sup>PD</sup> and *aret*<sup>RM</sup> usually have almost normal numbers of early stages of egg chambers in their ovaries which degenerated before yolk uptake occurs.

**cytology:** Placed in 33B3-F2, since uncovered by *Df(2L)Prl* = *Df(2L)32F1-2;33F1-2* and *Df(2L)prd1.7* = *Df(2L)33B2-3;34A1-2*.

**Argk:** *Arginine kinase*

**location:** 3-25.2.

**references:** Fu and Collier, 1981, *Genetics* 97: 537-38.

1983, *Bull. Inst. Zoo. Acad. Sinica* 22: 25.

James and Collier, 1988, *J. Exp. Zool.* 248: 185-91.

**phenotype:** Structural gene for arginine kinase [ARGK (EC 2.7.3.3)] based on gene dosage studies. Cellular and mitochondrial forms behave as if both are products of the gene. (Munneke and Collier, 1985, *Genetics* 110: s85). In 108-hour third-instar larvae, activity is high in body-wall and digestive-tract musculature; lower in brain, imaginal discs, and salivary glands; present in head, thorax, and abdomen of adults, being highest in indirect flight muscle of thorax. Activity levels increase during development reaching a peak at the pupal stage; then an abrupt decrease during the pupal stage is followed by a second increase beginning around the time of eclosion and climbing to high adult levels (James and Collier).

**cytology:** Located to 66B by segmental aneuploidy.

**Arista:** see *Ata*

**aristaleless:** see *al*

**aristaleless-b:** see *aa*

**Aristapedia:** see *Antp*<sup>LC</sup>

**Aristapedioid:** see *Arp*

**arm:** *armadillo*

**location:** 1-1.2.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Voelhard, Wieschaus, and Jürgens, 1982, *Verh. Dtsch. Zool. Ges.* 1982: 91-104.

Gergen and Wieschaus, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 49-62.

Klingsmith, Noll, and Perrimon, 1989, *Dev. Biol.* 134: 130-45.

**phenotype:** Homozygous lethal; embryonic segmentation defective by time of germ-band shortening; naked cuticle ordinarily comprising the posterior two thirds of each segment replaced by mirror-image duplication of the anteriorly situated denticle belt; strong alleles delete first denticle row in abdominal segments. May have dorsal hole in cuticle. Embryonic CNS development quasi normal (Patel, Schafer, Goodman, and Holmgren, 1989, *Genes Dev.* 3: 890-904). Autonomous at the level of single cells as shown by denticulate clones of homozygous cells in the naked cuticle of abdominal segments in *arm*<sup>+</sup> embryos (Wieschaus and Riggelman, 1987, *Cell* 49: 177-84). Clones of homozygous female germ cells arrested at stage 10 of oogenesis (Wieschaus and Noell, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 63-73). An exception is *arm*<sup>8</sup> for which progeny from homozygous germ-line clones have been recovered (Klingsmith *et al.*). Cell lethal in imaginal discs; although clones of homozygous cells not observed in adults, their formation seems to engender mirror-image duplications, which are not seen in response to homozygosing other cuticular cell lethals (Wieschaus). Transcript found with minor fluctuations in amount, in all cell types at all stages in development (Riggelman, Wieschaus, and Schedl, 1989, *Genes Dev.* 3: 96-113).

## alleles:

allele	origin	synonym	ref <sup>α</sup>	comments

<b>arm 8</b>	EMS	<i>arm H8.6</i>	1	temperature-sensitive allele

<sup>α</sup> 1 = Klingsmith, Noll, and Perrimon, 1989, Dev. Biol. 134: 130-45; 2 = Riggleman, Wieschaus, and Schedl, 1989, Genes Dev. 3: 96-113; 3 = Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

**cytology:** Located in region 2B15 by *in situ* hybridization.

Complementation with other lethals in 2B apparently not tested.

**molecular biology:** Gene isolated by transposon tagging and identified by germ-line transformation (Klingsmith, Noll, and Perrimon, 1989, Dev. Biol. 134: 130-45). Genomic sequences identify a single 3.2-kb transcript; two classes of cDNA's isolated which have different first exons spliced to six common exons; the first exons are 500 base pairs apart, so that exon 1 of one transcript is within the first intron of the other; they also show slightly different 3' polyadenylation sites. The mature transcript contains an open reading frame of 2529 nucleotides, which encodes a predicted 843-amino-acid, 91.1-kd acidic protein with an isoelectric point of 5.86. The conceptual amino-acid sequence contains no indication of either a signal or a transmembrane sequence; it does contain a 23-amino-acid glycine-rich sequence, which lacks charged amino acids, near the C terminus. In addition, internally there are 12.5 tandem repeats of a 42-amino-acid sequence with a consensus sequence to which the various repeats show 28 to 80% identity.

*arp-1*: see *ss<sup>aSp</sup>*

**Arp: Aristapedloid (P. Adler)**

**location:** 2-67 (inseparable from *vg*)

**origin:** Hybrid dysgenesis.

**references:** Adler, 1984, Genetics 107: s1.

Adler, Charlton, and Brunk, 1989, Dev. Genet. 10: 249-60.

Brunk and Adler, 1990, Genetics 124: 145-56.

**phenotype:** Homozygous lethal. Two dramatic dominant phenotypes: One is a partial transformation of arista to tarsus, the other is the loss or reduction in size of medially located macrochaetae on the dorsal thorax. Both phenotypes show high penetrance but variable expressivity.

**alleles:** *Arp<sup>1</sup>* and *Arp<sup>2</sup>*.

**cytology:** Both alleles associated with *In(2R)49A12-B3;49E5-F1* with P-derived sequences at either end. Deficiency analysis shows that lethality common to the two alleles associated with the 49A12-B3 breakpoint and thus localizes *Arp*. Both alleles revert by reinversion in dysgenic (1/200) and control (1/2000) crosses.

**other information:** Concluded to be homeotic gain-of-function alleles of *Su(z)2* (Brunk and Adler).

**arr: arrow**

**location:** 2-66.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Additional denticle bands anterior and posterior to normal denticle bands, especially in ventral midline. Strongest at 18°.

**alleles:** Nine ethyl-methanesulfonate-induced alleles; *arr<sup>1</sup>* and *arr<sup>2</sup>* (recovered as *IB* and *IIV*) retained.

**Arr1: Arrestin 1**

**location:** 2-{53}.

**references:** Smith, Shieh, and Zuker, 1990, Proc. Nat. Acad. Sci. USA 87: 1103-07.

Hyde, Mecklenburg, Pollock, Vihtelic, and Benzer, 1990, Proc. Nat. Acad. Sci. USA 87: 1108-12.

LeVine, Smith, Whitney, Malicki, Dolph, Smith, Burkhart, and Zuker, 1990.

**phenotype:** Encodes a Drosophila homologue of mammalian arrestin, a protein that interacts stoichiometrically with activated rhodopsin, inhibiting its ability to interact with the G protein, transducin, thus terminating the visual response. ARR1 presumed to be the 41-kd protein that is phosphorylated by exposure to light in the presence but not the absence (i.e., *ninaE* flies) of rhodopsin. Expression first detected in late pupae, when other genes involved in phototransduction are also first expressed. Transcript localized to photoreceptor cells of the compound eye, the ocelli, and the larval light sensitive organ.

**cytology:** Placed in 36D1-2 by *in situ* hybridization.

**molecular biology:** Sequence isolated from an eye specific genomic library produced by subtractive hybridization with cDNA from body and *eya* flies. The genomic clone identifies an 1.4-1.5-kb transcript in late pupae. Sequencing of genomic and cDNA clones indicates a primary transcript with four exons separated by introns of 421, 233, and 60 nucleotides; the conceptual amino-acid sequence indicates a protein of 364 residues that displays 42-45% amino-acid identity with bovine and human arrestins. Drosophila arrestin, however, lacks the 30 C-terminal amino acids, which share homology with  $\alpha$ -transducin in human and bovine arrestins.

**Arr2**

**location:** 3-{26}.

**references:** Yamada, Takeuchi, Komori, Kobayashi, Sakai, Hotta, and Matsumoto, 1990, Science 248: 483-86.

Levine, Smith, Whitney, Malicki, Dolph, Smith, Burkhart, and Zuker, 1990.

**phenotype:** Encodes a second Drosophila homologue of mammalian arrestin, a 49-kd (or 46-kd) protein that is phosphorylated by exposure to light in wild type but not in *ninaE* flies which lack rhodopsin in photoreceptor cells 1-6, nor *norpA* flies which are deficient in phospholipase C activity. Phosphorylation dependent on the presence of  $Ca^{++}$ , whose intracellular levels are regulated by phospholipase C. Expression first detected in late pupae, when other genes involved in phototransduction are also first expressed. *Arr2* expression is approximately seven times that of *Arr1*. In the adult, transcript localized to photoreceptor cells of the compound eye and the ocelli.

**cytology:** Placed in 66D10-11 by *in situ* hybridization

(Levine *et al.*).

**molecular biology:** Sequence isolated by screening an expression library with a monoclonal antibody raised to the *Drosophila* 49-kd protein (Yamada *et al.*) or with a synthetic oligonucleotide based on partial amino-acid sequence (LeVine *et al.*). Also apparently isolated as autonomous head-specific clones by Levy, Ganguly, Ganguly, and Manning (1982, *Dev. Biol.* 94: 451-64). The sequence identifies a single transcript of 1.8 kb (or 1.65 kb) on Northern blots; the conceptual amino-acid sequence indicates a protein of 401 amino acids, a calculated molecular mass of 44,972 daltons, and an isoelectric point of 8.9. ARR2 shares 206 residues with ARR1, and 181 with bovine arrestin; 146 residues are conserved in all three polypeptides. ARR2 shares with bovine arrestin virtually identical hydropathy plots and potential glycosylation sites but differs in being basic (pI = 8.9) rather than an acidic (pI = 6.0). The carboxy terminus of ARR2 displays only partial homology to the sequence of the proposed rhodopsin binding site of  $\alpha$ -transducin; also, the arrestin sequences that resemble the adenosine diphosphate-ribosylation sites of transducin are not found in ARR2.

**Ars: Arylsulfatase**

**references:** MacIntyre, 1974, *Isozyme Bul.* 7: 23-24.

**phenotype:** Inferred as structural gene for arylsulfatase [ARS (EC 3.1.6.1)] on basis of response of enzyme level to gene dosage.

**cytology:** Placed in 74A-79D by segmental aneuploidy.

**art: aristatarsia**

**location:** 3- (not mapped; modifying factors on chromosome 2).

**origin:** Spontaneous.

**discoverer:** Ouweneel, 69e.

**references:** 1970, *DIS* 45: 35.

**phenotype:** In homozygotes, arista replaced by tarsus-like structure. Penetrance more than 70%. Complements *ss*<sup>a</sup> but enhances *Antp*<sup>B</sup> in heterozygous condition; penetrance of *Antp*<sup>B</sup>/+ less than 1%, of *Antp*<sup>B</sup>/*art* more than 60%; *Antp*<sup>49</sup> also enhanced.

**arth: arthritic**

**location:** 1-0.0 [between *ewg* and *y* (Fleming)].

**references:** Schalet and Roberts, 1973, *DIS* 50: 23.

**phenotype:** Legs weak with pigmented joints; tarsal segments frequently askew with claws fused; movements somewhat uncoordinated. Brownish-black pigment present at joints of over 90% of males, most frequently in meso- and metathoracic legs between femur and tibia but sometimes between coxa and trochanter or proximal to coxa.

**cytology:** Placed in 1A5-8 based on arthritic phenotype of males carrying *Df(1)y15 = Df(1)1A4-5;1A8-B1* in combination with *l(1)1Ar*<sup>+</sup>*Y*. Included in *Df(1)sc*<sup>19</sup>, whereas *ewg* is not (Schalet).

**as: ascute**

**location:** 3-46.

**origin:** Spontaneous.

**discoverer:** Bridges, 16j21.

**references:** Bridges and Morgan, 1923, *Carnegie Inst. Washington Publ.* No. 327: 170.

**phenotype:** In *as*<sup>1</sup>, front of scutellum elevated, with partial obliteration of transverse furrow; deep chested. Bub-

ble in scutellum or midline of thorax; dried black exudate, often at each side of scutellum, may appear at any of the sutures of head and thorax; black deformed lump behind cheek. Wings droop at sides. Overlaps wild type. RK3.

**alleles:** *\*as*<sup>1</sup>, *\*as*<sup>2</sup> (CP627), *as*<sup>hg</sup>.

**cytology:** Placed in region 72D3-73A5 by Velissariou and Ashburner, 1981, *Chromosoma* 84: 173-85.

**as<sup>hg</sup>: ascute-hängende**

**origin:** Spontaneous.

**references:** Franke, 1934, *DIS* 2: 9.

Gottschewski, 1935, *DIS* 4: 15.

**phenotype:** Wings held laterally downward, ends occasionally resting on legs; eyes small and knobby. RK2.

**ASC: achaete-scute complex**

**location:** 1-0.0.

**references:** García-Bellido, 1979, *Genetics* 91: 491-520.

Carramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-91.

Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell, 1985, *Cell* 40: 327-38.

Dambly-Chaudière and Ghysen, 1987, *Genes Dev.* 1: 297-306.

Ghysen and Dambly-Chaudière, 1988, *Genes Dev.* 2: 495-501.

**phenotype:** The achaete-scute complex (ASC) produces a number of transcripts whose translation gene products function in the specification of diverse sensilla and their centrally projecting neurons. Insertions of transposable elements and rearrangement breakpoints in ASC result in the loss of certain subsets of bristles (both macrochaetae and microchaetae) and other sensilla, including their associated accessory cells, such as those forming sockets and peripheral neurons; these lesions, with few exceptions, occur outside of transcribed regions. The complex was subdivided into four components based on the sites of lesions causing mutant phenotypes by García-Bellido (1979); they are, from left to right, *ac*, *sc $\alpha$* , *l(1)sc*, and *sc $\beta$* ; a fifth component, *sc $\gamma$* , has been identified by Dambly-Chaudière and Ghysen (see also Ghysen and Dambly-Chaudière). Four genes that function in neurogenesis, and thus comprise ASC, are *ac*, *sc* (in the *sc $\alpha$*  region), *l(1)sc*, and *ase* (in the *sc $\gamma$*  region); some lesions in *sc* affect sex determination and are currently denoted *sis-b*. *ac*, and *ase* function in the genesis of both larval and adult peripheral nervous-system elements; *l(1)sc* functions in central-nervous-system development. *Hw* alleles are dominant gain-of-function mutations in ASC; unlike loss of function mutations, at least two *Hw* mutations have foreign sequences inserted into structural genes of ASC (Campuzano, Balcells, Villares, Carramolino, García-Alonzo, and Modolell, 1986, *Cell* 44: 303-12). Deficiencies for most regions of the complex are hemizygous and homozygous viable; however, deficiency for *l(1)sc* is lethal. Interestingly, *sc* rearrangements with breakpoints in the *sc $\alpha$*  region have their second breakpoints in pericentric heterochromatin, whereas those broken in the *sc $\beta$*  region have euchromatic second breakpoints (García-Bellido, 1979). Different segments of ASC tend to affect different subsets of bristles in the adult, as will be described in entries to follow; detailed descriptions of these bristle patterns are given by Dubinin (1933, *J. Genet.* 27: 446) and García-Bellido (1979). ASC

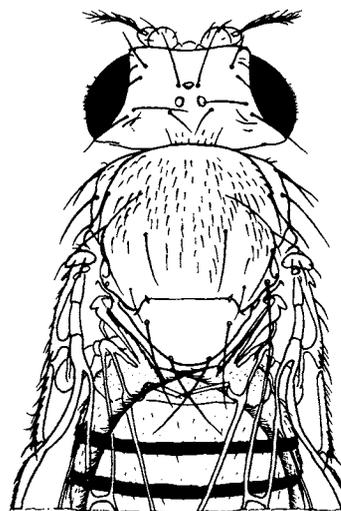

deficiencies also result in absences of campaniform and trichoid sensilla (García-Bellido and Santamaria, 1978, *Genetics* 88: 469-86). In larvae, *ASC* specifies neurons innervating peripheral sensory organs plus another class of neurons of uncertain (perhaps proprioceptive) function, but not chordotonal-organ-innervating neurons; here too, different components of *ASC* specify different and sometimes overlapping subsets of pattern elements (Dambly-Chaudière and Ghysen). Double hemizygotes for *ASC* and *da* [*Df(1)260-1/+; Df(2L)J27/+*] or *ASC* and *Df(4)M101-62f* show loss of macrochaetae, which none of the single hemizygotes does (Dambly-Chaudière, Ghysen, Jan, and Jan, 1988, *Roux's Arch. Dev. Biol.* 197: 419-23). Homozygous *ASC* deficiencies tend to counteract the embryonic effects of deficiencies for the neurogenic loci; *i.e.*, they cause a partial return to epidermigenesis (Brand and Campos-Ortega, 1988, *Roux's Arch. Dev. Biol.* 197: 447-56). In the following treatment of *ASC*, *ac*, *ase*, *Hw*, *l(1)sc*, *sc*, and *sis-b* are discussed in turn; a general discussion of phenotype of each element is followed by a table of alleles, after which specific aspects of various alleles are described.

**cytology:** Placed in 1B1-7 based on its being positioned to the right of the left breakpoint of  $ln(1)y^{3P} = ln(1)1B1-2;20F$  and to the left of the left breakpoint of  $Tp(1;2)sc^9 = Tp(1;2)1B1-2;1B4-7;25-26$ . The region has been subdivided by rearrangement breakpoints in the following order:  $ln(1)y^{3P}$ ,  $ln(1)y^4$ , *ac*,  $ln(1)sc^8$ , *sc $\alpha$* ,  $ln(1)sc^{L8}$ ,  $ln(1)sc^{S1}$ ,  $ln(1)sc^4$ , *l(1)sc*,  $ln(1)sc^9$ , *sc $\beta$* , *Df(1)sc19*, *sc $\gamma$* , *Df(1)260.1*.

**molecular biology:** Most of the complex has been cloned and restriction mapped in a chromosome walk of over 100 kb (Campuzano *et al.*); insertions and rearrangement breakpoints associated with different *sc* mutations located on restriction map. The coordinate system designates 0 as an arbitrarily chosen *EcoRI* site in the *sc $\beta$*  region with positive values extending to the left (Carramolino, Ruiz-Gómez, Guererro, Campuzano, and Modolell, 1982, *EMBO J.* 1: 1185-92). Sequence variation in *ASC* region of chromosomes isolated from natural populations investigated by Aguadé, Miyashita, and Langley (1989, *Genetics* 22: 607-15). Nine different transcription units, originally designated T1 to T9, identified in the *ASC* region. Four of these, T5, T4, T3, and T8 (formerly T1a), appear to be responsible for the neurogenic functions of the complex and correspond to *ac*, *sc*, *l(1)sc*, and *ase*, respectively; they are transcribed from left to right and encode members of the helix-loop-helix class of proteins, which are able to bind, as dimers, to DNA. In addition, the *ac*, *sc*, and *l(1)sc* transcripts share a 15-nucleotide acidic C-terminal sequence (Villares and Cabrera, 1987, *Cell* 50: 415-24; Alonso and Cabrera, 1988, *EMBO J.* 7: 2585-91; González, Romani, Cubas, Modolell, and Campuzano, 1989, *EMBO J.* 8: 3553-62). Transcription unit T2 is found in the *sc $\beta$*  region; its protein product and spatial pattern of expression rule out a neurogenic function and therefore membership in *ASC*.

### **ac: achaete**

**phenotype:** *ac* specifies the formation of the anterior and posterior dorsocentral, the posterior supra-alar (as does *sc*), the anterior vertical bristle, and in addition the acrostichal rows of microchaetae on the notum. Absence of bristles accompanied by absence of associated socket and

**ac: achaete**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 12.

underlying centrally projecting neuron (Stern, 1938, *Genetics* 23: 172-73). In addition mutant alleles of *ac* tend to remove the interocellar hairs and the hairs on the surface of the eye and a restricted subset of the campaniform sensilla on the wing blade (Leyns, Dambly-Chaudière and Ghysen, 1989, *Roux's Arch. Dev. Biol.* 198: 227-32). Trichomes are not affected. *ac* deficiencies, *e.g.*,  $ln(1)y^{3PL}sc^{8R}$ , survive as fully mobile and fertile adults (García-Bellido, 1979, *Genetics* 90: 491-529). A series of terminal deficiencies approaching the *ac* coding sequence from the left a few hundred base pairs at a time, when tested in heterozygotes with  $ln(1)y^{3PL}sc^{8R}$  or *Df(1)sc19*, cause, with few exceptions, progressive loss of chaetae as the amount of deleted material increases; response of anterior verticals erratic. First effects of deficiencies noted with chromosomes broken 10 kb upstream of the transcription start site. Despite loss of most of the DNA upstream from the transcribed region, the phenotypes associated with these deletions still suppressed by *emc* and *h* (Ruiz-Gómez and Modolell, 1987, *Genes Dev.* 1: 1238-46). Deficiencies for *ac* act as suppressors of *h* (Sturtevant, 1970, *Dev. Biol.* 21: 48-63), whereas extra doses of  $ac^+$  enhance expression of *h* (Moscoso del Prado and García-Bellido, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 242-51). Longitudinal stripes of expression on either side of the midline during gastrulation become internalized and segmented into four longitudinal rows of clusters of expressing cells at half-segment intervals. *ac* RNA undetectable in germ band at time of germ-band shortening. Several regions of high expression seen in cephalic region. Also expressed in posterior midgut rudiment (Romani, Campuzano, and Modolell, 1987, *EMBO J.* 6: 2085-92; Cabrera, Martínez-Arias, and Bate, 1987, *Cell* 50: 425-33). In third-instar larvae, expression in wing imaginal disks restricted to regions where precursors of cuticular organs specified by *ac* are known to reside (Romani, Campuzano, Macagno, and Modolell, 1989, *Genes Dev.* 3: 997-1007).

Hered. 21: 259-65 7 = Sutton, 1943, Genetics 28: 210-17; 8 = Weinstein, 1918, Genetics 3: 133-72.

**cytology:** Placed in 1B1-2 based on its position between left breakpoints of *In(1)y<sup>4</sup> = In(1)1A8-B1;18A3-4* and *In(1)sc<sup>8</sup> = In(1)1B2-3;20F*.

**molecular biology:** The *ac* transcription unit, designated T5 by Campuzano *et al.* is located from kb 59 to 58, and transcription is from left to right. cDNA and genomic sequences of the putative *ac* transcribed region determined by Villares and Cabrera (1987, Cell 50: 415-24); the transcription unit of 911 nucleotides is without introns and specifies a 201-amino-acid polypeptide of 22.7 kd.

**ac<sup>1</sup>**

**phenotype:** Hypomorphic; phenotype of homozygous females weaker than in hemizygous females (García-Bellido, 1979, Genetics 91: 491-520). Posterior dorso-central bristles missing; also posterior supra-alar and anterior vertical bristles frequently missing. Anterior dorso-centrals displaced anteriorly (Claxton, 1969, Genetics 63: 883-96). García-Bellido (1979) finds anterior dorso-central bristles more strongly decreased than posterior dorso-centrals. Hairs usually fewer near position of posterior dorso-centrals; interocellar hairs invariably fewer, typically absent. Eyes partly devoid of hairs. Trichomes unaffected. Limited nonautonomy near the borders of somatic spots with respect both to numbers and positions of bristles and hairs (Stern, 1954, Am. Sci. 42: 212-47; Roberts, 1961, Genetics 46: 1241-43; Claxton, 1976, Genet. Res. 27: 11-22). *ac* partially suppresses *h*; *Hw/ac* = *Hw*/+ (Sturtevant, 1969).

**molecular biology:** A deficiency extending from a point between kb 64.9 and 63.5, which is approximately 5 kb upstream from the presumptive *ac* transcription unit, to the left to approximately kb 82. (Campuzano, Carramolino, Cabrera, Ruíz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38).

**\*ac<sup>2</sup>**

**phenotype:** Since *ac<sup>2</sup>* and *sc<sup>3</sup>* were for practical purposes inseparable by crossing over, the effect of *ac<sup>2</sup>* alone could not be assessed. The double mutant removed all bristles except scutellars and postdorso-centrals. *ac<sup>2</sup>/ac<sup>2</sup>* and *ac<sup>2</sup>/+* suppress *h* (Sturtevant). Viability of males low; females nearly inviable. RK2.

**cytology:** Salivary chromosomes normal (Schultz).

**ac<sup>3</sup>**

**synonym:** Called *ac<sup>2</sup>* by Dubinín, the earlier *ac<sup>2</sup>* with *sc<sup>3</sup>* having been omitted from the series, *sc<sup>10</sup>, sc<sup>11</sup>* (Sturtevant and Schultz, 1931, Proc. Nat. Acad. Sci. USA 17: 265-70).

**phenotype:** Posterior and usually anterior dorso-centrals lacking; other bristles wild type. Hairs removed from areas across rear and front edges of thorax, through mid-dorsal area, and between ocelli. *ac<sup>3</sup>* even in *ac<sup>3</sup>/+* heterozygotes exerts strong suppression on *h* (Sturtevant, 1970, Dev. Biol. 21: 48-61). RK2A.

**cytology:** Inseparable from *In(1)ac<sup>3</sup> = In(1)1B2-3;1B14-C1* (Muller, Prokofyeva, and Raffel, 1935, Nature (London) 135: 253-55).

**molecular biology:** Left breakpoint of *In(1)ac<sup>3</sup>* at DNA coordinate +59 near the transcription start site of the *ac* transcript; transcript levels substantially reduced in both embryos and pupae; the *l(1)sc* transcript but not the *sc* transcript also reduced (Campuzano, Carramolino, Cabrera, Ruíz-Gómez, Villares, Boronat, and Modolell, 1985, Cell 40: 327-38).

**ac<sup>3B</sup>**

**phenotype:** Low level of absence of dorso-central bristles as well as microchaetae. Bristles normally removed by *sc* mutations not missing.

**molecular biology:** A *gypsy* insert in the *ac* region of *ASC* at +63.7; in addition there is a 0.5 kb insert in the *sc<sup>β</sup>* region at approximately -5.0 to -6.5, which shows sequence homology with the *gypsy* LTR.

**other information:** *ac<sup>3B</sup>* is a derivative of *sc<sup>3B</sup>*, which originally displayed a *sc<sup>1</sup>*-like phenotype. The original phenotype is no longer present and a weak achaete phenotype appears instead. Apparently a *gypsy* element originally inserted between -5.0 and -6.5 has excised, leaving a 0.5 kb remnant and resulting in reversion of the *sc* phenotype, and a new *gypsy* has inserted at 63.7, about 4 kb upstream from the *ac* transcription unit, to produce the present *ac* phenotype. Level of *ac* transcript reduced. *ac<sup>3B</sup>* complements *ac<sup>1</sup>* (García-Bellido, 1979, Genetics 91: 491-520).

**ase: asense**

**location:** 1-0.0.

**references:** Ghysen and Dambly-Chaudière, 1988, Genes Dev. 2: 495-501.

González, Romani, Cubas, Modolell, and Campuzano, 1989, EMBO J. 8: 3553-62.

**phenotype:** *ase<sup>1</sup>* (formerly *sc<sup>2</sup>*) shown to be a molecular deletion including the *ase* transcription unit. *ase* embryos lack a subset of peripheral neurons (Dambly-Chaudière and Ghysen, 1987, Genes Dev. 1: 297-306); third-instar larvae show disrupted optic-lobe development; in adults almost all abdominal chaetae are removed as are the extra chaetae induced by *Tft*. Abdomen tends to be swollen; wings poorly expanded; viability of homozygous and hemizygous females low (García-Bellido, 1979, Genetics 91: 491-520). Gene expression first detectable in the neural primordium, presumably in the neuroblasts. In later embryos, RNA is detected in most cells of the CNS primordium as well as in the labrum, optic lobe rudiment, procephalic neurogenic region, and the posterior midgut rudiment. Expression lasts into germ-band retraction. Also expressed sparsely in third-instar larvae; scarce in imaginal disks except for

one large cell cluster in each leg disk; strong in the CNS, especially in a cap of cells over each optic lobe, which are destined to generate ganglion mother cells of the lamina and medulla; expression also seen in inner anlagen of optic lobes, which give rise to cells of the medulla and lobula complex. Otherwise expression in brain and ventral ganglion occurs in isolated clusters of cells and single cells. Expression thought to identify actively proliferating cells (González *et al.*).

**cytology:** Placed in 1B4-7, the 22-kb region defined as *scy* by Dambly-Chaudière and Ghysen (1987), based on its being included in the apparently terminal deficiency *Df(1)260.1 = Df(1)1B4-6* but in neither *Df(1)sc19 = Df(1)1B1-2;1B4-5* nor in the terminal duplication afforded by the  $4^P X^D$  element of *T(1;4)sc^H*.

**molecular biology:** Both cDNA and genomic clones isolated and sequenced (González *et al.*); 1596 ORF encodes a protein of 486 amino acids; in addition to the helix-loop-helix motif, it contains a centrally located acidic region and a proline-rich region near the N terminus; it lacks the N-terminal acidic domain characteristic of the other three *ASC* transcripts. The protein also contains PEST and *opa* sequences. The genomic sequence is without introns. *ase<sup>1</sup>* mutation is a small deletion from coordinates -11.5 to -30 kb that includes the *ase* transcription unit, which is located at approximately coordinate -25 kb.

### Hw: Hairy wing

**references:** Campuzano, Balcells, Villares, Carramolino, García-Alonzo, and Modolell, 1986, Cell 44: 303-312. García-Alonzo and García-Bellido, 1986, Wilhelm Roux's Arch. Dev. Biol. 193: 259-64. Balcells, Modolell, and Ruiz-Gómez, 1988, EMBO J. 7: 3899-3906.

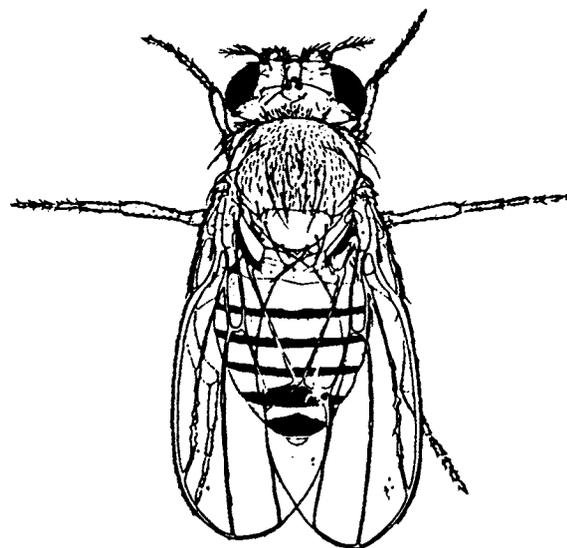

**phenotype:** Gain of function alleles of *ASC*, which lead to the development of supernumerary bristles and hairs in all segments of the fly: in the prefrons, postfrons, postgena, and occipital regions of the head; in the preepisternum, episternum, anepisternum, scutum, scutellum, postnotum, wingblade, legs, humerus, and halteres of the thorax; and in the tergites, pleura, and sternites of the abdomen. Phenotype suppressed by three doses of *h<sup>+</sup>* (Botas, Moscoso del Prado, and García-Bellido, 1982, EMBO J. 1: 307-10) and enhanced by *h*, *emc*, and *pyd* (Neel, 1941, Genetics 26: 52-58; Moscoso del Prado and García-Bellido, 1984, Wilhelm Roux's Arch Dev. Biol. 193: 242-45). Numbers of super numerary bristles reduced in *da<sup>+</sup>* hemizygotes (Dambly-Chaudière, Ghysen, Jan and Jan, 1988, Roux's Arch Dev. Biol. 97: 419-23).

**Hw: Hairy wing**

Edith M. Wallace, unpublished.

### *Hw<sup>1</sup>*

**phenotype:** Males and heterozygous females have extra bristles on the head (especially occipitals), the notum and the mesopleurae; also extra bristles, including sensory ones and campaniform sensilla (Palka, Schubiger, and Hart, 1981, Nature 294: 447-49), along longitudinal veins and in membrane of wing. Classifiable in a single dose in triploids (Schultz, 1934, DIS 1: 55). Homozygous females more extreme; 110 extra chaetae on wing vs. 49.5 for *Hw<sup>1</sup>/+*; 11 on scutellum and postnotum vs. 0.7 in *Hw/+* (García-Bellido and Merriam, 1971, Proc. Nat. Acad. Sci. USA 68: 2222-26). Number of extra bristles inversely correlated with temperature (Ohn and Sheldon, 1970, Genetics 66: 517-40). *Hw<sup>1</sup>/Hw<sup>1</sup>* females exhibit 40-80% wild-type viability and are agametic steriles; clones of homozygous germinal cells in *Hw/+* females capable of producing progeny (García-Bellido and Robbins, 1983, Genetics 103: 235-47); however, García-Alonzo and García-Bellido claim that their strain is no longer homozygous female sterile. Viability and fertility of *Hw<sup>1</sup>/Y* males and *Hw<sup>1</sup>/+* females good. *Hw<sup>1</sup>/Hw<sup>1</sup>* and  $\pm$  autonomous in somatic clones until 8 hr before puparium formation; altering cellular genotype after that time is without effect owing to perdurance (García-Bellido and Merriam). X-ray-induced full and partial revertants are frequently mutant for *ac* (García-Alonzo and García-Bellido). RK1 as male or heterozygous female.

**cytology:** Claimed by Demerec and Hoover (1939, Genetics 24: 68) to be associated with duplication for the 1B1-2 doublet; however restriction mapping of *ASC* fails to confirm this claim (Campuzano *et al.*). Many rearrangements with breakpoints in distal portion of *sc* com-

plex have a weak *Hw* effect, especially as indicated by microchaetae on the mesopleurae; duplications for rearranged scute loci have enhanced effects; duplications of *Hw*<sup>+</sup> without phenotypic effects except that they suppress *h* (Botas *et al.*).

**molecular biology:** Carries a *gypsy* insert near the midpoint of the *ac* structural gene (T5) as well as a 2.6 kb insert (*Sancho 2*) located 8.5 kb to the left of the *gypsy*. Transcript 5 shortened from 1.1 kb seen in wild type to 0.9 kb; initiation normal; termination takes place in insert. Developmental Northern blots show peak accumulations in early embryos and early pupae; this transcript, which contains only the 5' half of the normal T5, is still functional in that no *ac* bristles are removed; it is present in many fold excess at all developmental stages examined (Campuzano *et al.*). The distribution of expressing cells in the wing disk is much less localized than in wild type (Balcells *et al.*).

### *Hw*<sup>2</sup>

**phenotype:** Females homozygous for *Hw*<sup>2</sup> show only occasional extra hairs along wings. Overlaps wild type. RK3A.

**cytology:** Salivary chromosome analysis by Schultz (Morgan, Schultz, and Curry, 1941, Year Book - Carnegie Inst. Washington 40: 284) shows small inversion of the region from 1A3 through 1B1 *i.e.*, associated with  $In(1)Hw^2 = In(1)1A2-3;1B1-2$ .

### *Hw*<sup>49c</sup>

**phenotype:** More extreme than *Hw*<sup>1</sup>. Homozygous female has doubling and tripling of many bristles, three or four extra dorsocentral bristles per side, extra wing veins, gap in posterior crossvein, and extra hairs on vein L2 and in wing cells. Width of mesonotum in region between dorsocentral bristles increased leading to increased numbers of acrostichal rows as well as extraneous extra microchaetae (Gottlieb, 1964, Genetics 49: 739-60); many lack one or more ocellar or postvertical macrochaetae (Stoddard, 1972, DIS 48: 137-38). Heterozygous female has normal bristles, extra hairs on L2 and L3 and in wing cells, and often an extra free vein from posterior crossvein; also extra acrostichal rows. *Hw*<sup>49c</sup> male much like homozygous female but bristle duplication less extreme. Low degree of non autonomy reported at junction between *Hw*<sup>49c</sup>/*Hw*<sup>49c</sup> and +/- twin spots (Gottlieb). Male and heterozygous female fertile; homozygous female sterile. Revertants of *Hw*<sup>49c</sup> lose their dominant phenotypes; however they remain *sc* and may exhibit a weak *ac* phenotype or be lethal in combination with *Df(1)sc*<sup>19</sup> (García-Alonzo and García-Bellido). Not suppressed by *su(Hw)*. *Hw*<sup>49c</sup> and *Oce* act synergistically in removing head bristles but cancel each others effects on thorax in *Hw/Oce* females (Stoddard). *ac*, *sc*, and *l(1)sc* transcripts considerably more abundant than in wild type; also more generally expressed in wing disks than normal (Balcells *et al.*). RK1.

**cytology:** Associated with  $In(1)1B;2B3-4$ , with one breakpoint between 14.8 kb and 13.5 kb in the walk of Campuzano *et al.* and the other between 111 kb and 122 kb in the walk of Chao and Guild (Balcells *et al.*).

**other information:** Three X-ray-induced revertants of *Hw*<sup>49c</sup>, all of which lack ectopic chaetae, characterized by Balcells *et al.*; *Hw*<sup>49c-rv1</sup> is associated with  $T(1;3)1B;95A$ ; its breakpoint in region 1B is in the same

restriction fragment as that of  $In(1)Hw^{49c}$ . *Hw*<sup>49c-rv4</sup> is associated with  $T(1;2)1B;21A$ ; its 1B breakpoint is between *sc* and *l(1)sc* in 26.8 kb to 25.0 kb. *Hw*<sup>49c-rv5</sup> is associated with an eight-base-pair deletion in the *sc* coding region; it produces a polypeptide containing the first 114 amino acids of the *sc* translation product followed by 53 nonsense amino acids; the truncated polypeptide retains the basic region but not the helices of the helix-loop-helix motif. A null allele of *sc*.

### *Hw*<sup>59g</sup>

**phenotype:** Extra vertical, dorsocentral, and scutellar bristles. Suppression of *sc* with  $su(Hw)^2$  does not suppress *Hw*<sup>59g</sup>.

### *Hw*<sup>685</sup>

**references:** Ruiz-Gómez and Modolell, 1987, Genes Dev. 1: 1238-46.

Balcells, Modolell, and Ruiz-Gómez, 1988, EMBO J. 7: 3899-3906.

**phenotype:**  $Df(1)Hw^{685}/Df(1)sc^{19}$  generates lateral clusters of microchaetae on the scutellum and promotes differentiation of extra sensilla campaniformia on the dorsal radius of the wing, of microchaetae or other sensilla on wing vein 3, and occasional microchaetae on wing vein 2. Slight increases in numbers of microchaetae on notum as well. Displays a very weak achaete effect despite presumed homozygous deficiency for *ac*.

**cytology:** Claimed to be associated with terminal deficiency,  $Df(1)yT1b-685$ , which was broken at 45.4 kb to 43.9 kb. That this determination may be in error is suggested by the observation: (1) that no other terminal  $Df(1)yT1b$ , including two others broken in the same restriction fragment, shows a hairy-wing effect; (2) terminal deficiencies induced in *mu2* females are unstable losing about 75 base pairs per generation (Biessman and Mason, 1988, EMBO J. 7: 1081-86); yet *Hw*<sup>685</sup> appears to be stable, and (3) *Hw*<sup>685</sup> does not appear to be completely deficient for *ac*.

### *Hw*<sup>bap</sup>: Hairy wing-bristly abdominal pleura

**phenotype:** Nearly all abdominal segments have on the pleurae two rows of bristles, which are the same size as those on the sternites. Mutant-bearing flies have a row of bristles arising immediately posterior to each pigment band that are shorter than other tergite bristles.

**cytology:** Associated with the  $2^P X^D$  element of  $T(1;2)Hw^{bap} = T(1;2)1B;21B$ .

### *Hw*<sup>BS</sup>

**phenotype:** Spontaneous derivation of *Hw*<sup>1</sup> with slightly weaker phenotype.

**molecular biology:** Contains an 8 kb insert near the distal LTR in the *gypsy* element that is inserted in T5, the presumptive *ac* transcript, in *Hw*<sup>1</sup>. The identity of this sequence is unknown, but its internal 1.7 Pst1 fragment is repeated fifteen times in the genome of *Hw*<sup>BS</sup> and Oregon R. The developmental profile of the *Hw*<sup>BS</sup> T5 transcript is similar to that of *Hw*<sup>1</sup> (Campuzano *et al.*).

### *Hw*<sup>Ua</sup>

**phenotype:** Weak *Hw* phenotype in heterozygous females. Phenotype only slightly enhanced by suppressing the pre-existing *sc*<sup>1</sup> allele with  $su(Hw)^2$  (García-Alonzo and García-Bellido).

**molecular biology:** Complete *copia* element inserted into

T4, the presumed *sc* structural gene, about one third of the distance from termination of the transcription unit. The *Hw<sup>Ua</sup>* transcript, which carries the 5' two-thirds of the presumptive *sc* and terminates in *copia*, is present in excess in early larvae but not in crawling larvae or early pupae (Campuzano *et al.*).

### *l(1)sc*: lethal at scute

**synonym:** *l'sc*.

**references:** Muller, 1935, *Genetica* 17: 237-52.

García-Bellido, 1979, *Genetics* 91: 491-520.

Jiménez and Campos-Ortega, 1987, *J. Neurogenet.* 4: 179-200.

**phenotype:** Deficiency from which existence of *l(1)sc* inferred, *i.e.*, *In(1)sc<sup>4Lsc9R</sup>*, embryonic lethal. Volume of embryonic ventral nerve cord slightly reduced; posterior commissures thinner than in wild type; longitudinal connectives virtually lacking. Concomitant deletions for *scα* or *scα* and *ac* cause more severe CNS disruptions, although by themselves these deletions have no observable CNS effects; simultaneous deletion of the *scγ* region also enhances the CNS disruptions (Jiménez and Campos-Ortega). Transiently expressed at periphery of syncytial blastoderm; late blastoderm shows paired dorsolateral and ventrolateral longitudinal stripes of expression, the latter being coincident with the presumptive neurogenic ectoderm. During germ-band expression, *l(1)sc* expression seen in many cell clusters over most of the ectoderm; segmental distribution becomes apparent both internally and externally. *l(1)sc* expression seen in many foci in the head region and in the posterior midgut rudiment (Romani, Campuzano, and Modolell, 1987, *EMBO J.* 6: 2085-92; Cabrera, Martínez-Arias, and Bate, 1987, *Cell* 50: 425-33). Little if any expression in later stages, except in the central nervous system (Romani, Campuzano, Macagno, and Modolell, 1989, *Genes Dev.* 3: 997-1007).

**molecular biology:** The gene encodes a 258-amino-acid, 29-kd polypeptide with a helix-loop-helix motif in the N-terminal end and a 15-residue C-terminal acidic domain (Alonso and Cabrera, 1988, *EMBO J.* 7: 2585-91). Transcription unit between coordinated 19.9 and 17.8 kb.

**other information:** Inferred from the inviability of *In(1)sc<sup>4Lsc9R</sup> = In(1)1B3-4;19F-20CI<sup>L</sup>1B2-3;18B8-9<sup>R</sup>* [left break of *In(1)sc<sup>9</sup>* in doubt], except in the presence of *Dp(1;2)sc<sup>19</sup>*. No mutant recovered (García-Bellido).

### *sc*: scute

**phenotype:** Specifies the differentiation of numerous macrochaetae on the head and thorax as well as microchaetae on the tergites: anterior, medial, and posterior orbital, posterior vertical, ocellar, and postvertical bristles on the head plus humeral, presutural, anterior and posterior notopleural, anterior supra-alar, sternopleural, anterior and posterior postalar, and anterior and posterior scutellar bristles on the mesothorax; also participates with *ac* in specifying the anterior vertical, posterior supra-alar, and anterior dorsocentral bristles; specifies the majority of the campaniform sensilla on the wing blade (Leyns, Dambly-Chaudière and Ghysen, 1989, Wilhelm Roux's Arch. Dev. Biol. 198: 227-32). Males deficient for *sc*, *i.e.*, *In(1)sc<sup>8Lsc4R</sup>*, are poorly viable and catatonic; homozygous deficient females lethal; males deficient for both *ac* and *sc*, *i.e.*, *In(1)y<sup>3PLsc4R</sup>*, are lethal (García-

Bellido, 1979, *Genetics* 91: 491-520). *sc* deficiencies suppress the phenotype of *emc*; extra doses of *ASC* enhance the *emc* phenotype (Moscoco del Prado and García-Bellido, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 242-51).

**alleles:** Numerous alleles described, all but one of which are associated either with chromosome rearrangements with one breakpoint in region 1B or with inserts of foreign DNA. All but two chromosomal lesions with *sc* effects map proximal to the presumptive *sc* transcription unit; two inversions with breakpoints just distal to the transcription unit have slight effects; proximal lesions map to either side of *l(1)sc*, and strength of expression is inversely correlated with the molecular distance between the lesion and the scute transcription unit. Proceeding from right to left, lesions remove bristles from the mesonotum in a roughly hierarchical fashion in the following order: scutellars, (postverticals, ocellars, sternopleurals, anterior and medial orbitals, postalars), anterior notopleurals, (posterior orbitals, postverticals, anterior supra-alar) (presuturals, orbitals), with those enclosed in parentheses tending to be removed together (see Ghysen and Dambly-Chaudière, 1988, *Genes Dev.* 2: 495-501). Transcription first observed in early gastrula in regions with neurogenic potential, but before any overt evidence of neurogenesis apparent. As development proceeds, a complex temporal and spatial program of expression, mostly in neurogenic precursor cells ensues; expression ceases during the period of germ band shortening (Cabrera, Martínez-Arias, and Bate, 1987, *Cell* 50: 425-33; Romani, Campuzano, and Modolell, 1987, *EMBO J.* 6: 2085-92). In third-instar larvae, expression in wing disks is confined to restricted subsets of cells known to correspond to regions giving rise to precursors of cuticular sense organs that are under control of *sc* (Romani, Campuzano, Macagno, and Modolell, 1989, *Genes Dev.* 3: 997-1007).

<sup>β</sup> DNA coordinates from Carramolino, Ruiz-Gómez, Guerrero, Campuzano, and Modolell (1982, EMBO J. 1: 1185-91) and Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell (1985, Cell 40: 3227-38). 0 defined as the more distal EcoRI site within the *sc*<sup>52</sup> molecular deficiency; positive values extend to the left. Where known, restriction fragment interrupted by the 1B breakpoint of *sc* rearrangements indicated.

**cytology:** Placed in 1B3 based on its location between the left breakpoints of *In(1)sc*<sup>8</sup> = *In(1)1B2-3;20F* and *In(1)sc*<sup>4</sup> = *In(1)1B3-4;20F*.

**molecular biology:** *sc* assigned to transcript T4 of Campuzano, Carramolino, Cabrera, Ruiz-Gómez, Villares, Boronat, and Modolell (1985, Cell 40: 3227-38); the *sc* transcription unit is transcribed from left to right and occupies DNA coordinates approximately 34 to 32 kb. A series of terminal deletions approaching the *sc* transcription unit from the left were placed in heterozygous combination with *In(1)sc*<sup>8L</sup>*sc*<sup>4R</sup>, among other *sc* deficiencies, and the phenotypes assessed (Ruiz-Gómez and Modolell, 1987, Genes Dev. 1: 1238-46). The majority of deficiencies between coordinates 55 and 38 kb showed significant but weak *sc* phenotypes; those ending within 4-5 kb of the transcription start caused stronger phenotypic effects, removing first posterior supra-alar, and then posterior notopleural bristles (see also Ghysen and Dambly-Chaudière, 1988, Genes Dev. 2: 495-501). cDNA and genomic sequences of the *sc* transcribed region determined by Villares and Cabrera (1987, Cell 50: 415-24); the transcription unit of 1430 nucleotides is without introns; the longest open reading frame encodes a 345-amino-acid polypeptide of 38.1 kd. Contains both the helix-loop-helix motif and the C-terminal acidic region characteristic of *ac* and *l(1)sc*.

**sc**<sup>1</sup>

**phenotype:** Causes loss or marked reduction in number of scutellar, coxal, ocellar, first and second orbital, anterior notopleural, postvertical, tergal, and sternal bristles. Bristle sockets missing; bristle cells absent 19 hr after pupation, when normally present [Lees and Waddington, 1942, DIS 16: 70-70a; 1943, Proc. Roy. Soc. (London), Ser. B 131: 87-110]. Suppressed by *su(Hw)* and *su(Hw)*<sup>2</sup>. RK1.

**other information:** Revertable by X rays (Green, 1961, Genetics 46: 671-82).

*sc*<sup>2</sup>: see *ase*

**\**sc*<sup>3</sup>**

**phenotype:** Most bristles affected, principally ventrals, orbitals, verticals, postverticals, ocellars, humerals, presuturals, notopleurals, supra-alars, postalars, sternopleurals, abdominals, and anterior dorsocentrals; scutellars and postdorsocentrals usually present. Viability of male low; female virtually lethal. RK2.

**cytology:** Salivary chromosomes appear normal (Morgan, Bridges, and Schultz, 1935, Year Book – Carnegie Inst. Washington 34: 290).

***sc*<sup>3-1</sup>**

**phenotype:** Partial reversion from *sc*<sup>3</sup>. Homozygous females show reduced viability; hemizygous females lethal (García-Bellido, 1979, Genetics 91: 491-520). RK2.

**\**sc*<sup>3B</sup>: scute-3 of Bridges**

**phenotype:** Like *sc* but does not affect anterior notopleurals. Suppressed by *su(Hw)*<sup>2</sup> (Lee, 1973, Aust. J. Biol. Sci. 26: 903-09). RK1.

**other information:** Some stocks currently labelled *sc*<sup>3B</sup> are reverted for *sc* but are now *ac*<sup>3B</sup>.

***sc*<sup>4</sup>**

**phenotype:** Extreme scute. Bristles of head, except anterior verticals, absent. Only posterior notopleurals and alars remain on sides of mesothorax; abdominals, ventrals, coxals, and scutellars also missing. Slight variegation for *Hw*. RK1A.

***sc*<sup>5</sup>**

**phenotype:** Sternital and scutellar bristles reduced in number; others rarely affected. *sc*<sup>5</sup>/*sc*<sup>6</sup> is practically wild type. RK1.

***sc*<sup>6</sup>**

**phenotype:** Slight *sc*; removes coxals, ocellars, first and second orbitals, postverticals, and anterior notopleurals. Scutellars and sternitals not affected. RK1.

**cytology:** No inversion.

***sc*<sup>7</sup>**

**phenotype:** Like *sc* but anterior notopleurals not affected. *sc*<sup>7</sup> tends to suppress expression of *h* (Steinberg, 1942, DIS 16: 68). RK1A.

**other information:** *w*<sup>a</sup> separable from *sc*<sup>7</sup> by exchange in triploid female.

***sc*<sup>8</sup>**

**phenotype:** Slight *sc*; supra-alars, sternopleurals, or other bristles sometimes affected. Extra bristles may be present. Shows *Hw* effect and may be recognized in heterozygote, homozygote, or male by presence of one or more hairs on anterior mesopleural region. The *Hw* effect interacts strongly with *h* to produce extremely hairy wings (Steinberg, 1942, DIS 16: 68). *sc*<sup>8</sup>/*0* male nearly lethal; survivors show variegation for *y* and *ac*; lethality suppressed by a Y chromosome, partially suppressed by parts of the Y (Hess, 1962, DIS 36: 74-75; 1963, Verhandl. Deut. Zool. Ges., Zool. Anz. Suppl. 26: 87-92). RK2A.

*sc*<sup>8</sup> *c.o.* *X*: see *Df(1)sc*<sup>8</sup>

*sc*<sup>8</sup> *ENc.o.* *X*: see *Df(1)sc*<sup>8</sup>

***sc*<sup>9</sup>**

**phenotype:** Like *sc* but scutellars always absent. Abdomen swollen and wings poorly expanded, like *sc*<sup>2</sup>. RK2A.

*sc*<sup>10</sup>: see *ac*<sup>3</sup>

***sc*<sup>10-1</sup>**

**phenotype:** Like *sc*<sup>3</sup> but more extreme; most extreme viable *sc* allele. Viability low. RK2A.

**cytology:** Originally thought to be associated with a minute deficiency (Schultz); not confirmed by molecular analysis.

**molecular biology:** Sequence data reveal a silent C→T transition at nucleotide 669, a C→G transversion at nucleotide 1143 causing ser<sup>161</sup>→arg<sup>161</sup>, and a C→T transition in nucleotide 1147 resulting in a stop codon; (first nucleotide of initial ATG codon at nucleotide 660) (Villares and Cabrera, 1987, Cell 50: 415-29).

*sc*<sup>11</sup>: see *ac*<sup>3</sup>

**\**sc*<sup>12</sup>**

**phenotype:** First and second orbitals reduced or absent; other head bristles, posterior scutellars, and coxals also affected. Also shows achaete effect. Viability of homozygous female low. RK2.

**\**sc*<sup>13</sup>**

**phenotype:** Like *sc* but scutellars invariably absent and ocellars, postverticals, and first and second orbitals less frequent. Anterior and posterior dorsocentrals also absent, as are thoracic hairs, because of *ac*<sup>4</sup>. Viability low. RK2.

**\**sc*<sup>15</sup>**

**phenotype:** Originally allelic to *sc* and semilethal in male. Subsequently, allelic to *y*, *ac*, and *sc*, and male lethal. Lethal form exaggerates other *ac* and *sc* alleles in heterozygote. RK2A.

**cytology:** Presumably associated with *Df(1)sc*<sup>15</sup>; break-points unknown.

**other information:** Apparently, *y*<sup>+</sup> and *ac*<sup>+</sup> were inserted elsewhere in the genome (as in *sc*<sup>19</sup> or *sc*<sup>V1</sup>), became separated from the left end of *X*, and were lost.

***sc*<sup>19</sup>**

**phenotype:** Scutellar bristles absent and sternitals reduced. RK1A.

***sc*<sup>28</sup>**

**phenotype:** Strong scute; not suppressed by *su(Hw)*<sup>2</sup>.

***sc*<sup>29</sup>**

**phenotype:** Similar to *sc*<sup>7</sup>. Viable and fertile. RK2A.

***sc*<sup>49c</sup>**

**other information:** Overlooked at the time *Hw*<sup>49c</sup> was described. Possibly of subsequent spontaneous origin.

***sc*<sup>52c</sup>**

**other information:** Association with *In(1)sc*<sup>52c</sup> (break-points unknown) inferred, since *sc*<sup>52c</sup> has been inseparable from *ras v*.

**sc<sup>67b5</sup>**

phenotype: Strong scute; not suppressed by *su(Hw)*<sup>2</sup>.

**sc<sup>260-14</sup>**

phenotype: Both sexes viable and fertile. RK2A.

**sc<sup>260-15</sup>**

phenotype: Male sterile. Viability reduced. RK2A.

**\*sc<sup>260-16</sup>**

phenotype: *sc<sup>260-16</sup>/sc* overlaps wild type. Lethal homozygous and hemizygous. RK2.

cytology: Salivary chromosomes normal.

**\*sc<sup>260-17</sup>**

phenotype: Male and homozygous female viable and fertile. RK2A.

**\*sc<sup>260-18</sup>**

phenotype: Male sterile. RK2A.

**\*sc<sup>260-20</sup>**

phenotype: Male and homozygous female viable and fertile. RK2A.

**sc<sup>260-22</sup>**

phenotype: Both sexes viable and fertile. RK2A.

**\*sc<sup>260-23</sup>**

phenotype: Both sexes viable. RK3A.

**sc<sup>260-25</sup>**

phenotype: Variegates for *y*, *ac*, and probably *l(1)Ia*c but not for *svr*; more extreme than *sc<sup>V1</sup>*. Homozygous lethal. RK2A.

**\*sc<sup>260-26</sup>**

phenotype: Viability reduced in male. Male fertile. RK2A.

**\*sc<sup>260-27</sup>**

phenotype: Male viable but sterile. RK2A.

**\*sc<sup>260-29</sup>**

phenotype: Male viable but sterile. RK2A.

**\*sc<sup>A</sup>: scute of Agol**

phenotype: Similar to *sc*. Viability low. RK2A.

**\*sc<sup>B1</sup>: scute of Brande**

phenotype: Similar to *sc*. Viability good. RK2A.

**sc<sup>B57</sup>**

phenotype: Embryo displays reduced numbers of CNS and PNS neurons.

**sc<sup>D1</sup>: scute of Dobzhansky**

phenotype: Weak *sc*. RK2.

cytology: Salivary chromosomes apparently normal (Schultz).

**sc<sup>D2</sup>**

phenotype: Slight *sc*. RK2.

**sc<sup>Fah</sup>: scute of Fahmy**

phenotype: Bristles (principally orbitals, verticals, post-verticals, and ocellars) missing. Scutellars and postdorsocentrals left nearly intact. Male viable and fertile; female homozygous lethal. *sc<sup>Fah</sup>/sc* has only occasional absence of postvertical or ocellar bristles. RK2A.

**sc<sup>H</sup>: scute of Hackett**

phenotype: Similar to *sc* but more extreme. RK2A.

**sc<sup>J4</sup>**

phenotype: Scute and achaete effects. RK3A.

**\*sc<sup>K</sup>: scute of Krivshenko**

phenotype: Similar to *sc* but semilethal in male and lethal in homozygous female. RK2A.

**sc<sup>L3</sup>: scute of Levy**

phenotype: In addition to scute, it has a spoon-like wing caused by a mutation to the right of *sc*. Viable. Suppressed by *su(Hw)*<sup>2</sup> (Lee, 1973, Aust. J. Biol. Sci. 26: 903-09). RK2.

**sc<sup>L6</sup>**

phenotype: Moderate scute; suppressed by *su(Hw)*<sup>2</sup> (Lee, 1973, Aust. J. Biol. Sci. 26: 903-09)

**sc<sup>L8</sup>**

phenotype: Similar to *sc<sup>4</sup>* but more extreme. Homozygous female sterile. RK2A.

**sc<sup>S1</sup>: scute of Sinitskaya**

phenotype: Rather extreme *sc* allele; slight *Hw* effect; hairs often removed from abdomen and wings. Homozygous female sterile and low in viability. Male fertile and fairly viable. RK2A.

**sc<sup>S2</sup>**

phenotype: Similar to *sc<sup>7</sup>*. RK1A.

**\*sc<sup>So</sup>: scute of Sytko**

phenotype: Like *sc*; viability of homozygous female low. RK2.

**sc<sup>V1</sup>: scute of Valencia**

phenotype: Extreme scute and achaete. Viability low. RK2A.

**sc<sup>V2</sup>**

phenotype: Both achaete and scute variably affected. Some tendency for extra or twin bristles. Abdominal bristles markedly fewer both dorsally and ventrally. Male and homozygous female viable and fertile. RK2A.

**sis-b: sisterless b (T. W. Cline)**

location: 1-0.0.

synonym: *sc<sup>3-1</sup>*.

references: Cline, 1988, Genetics 119: 829-62.

Torres and Sánchez, 1989, EMBO J. 8: 3079-86.

Cline, 1989, Cell 59: 231-34.

phenotype: Original hypomorphic allele recovered as a reversion of *sc<sup>3</sup>* to nearly wild-type *ac* and *sc* phenotype in hemizygote and homozygote; originally designated *sc<sup>3-1</sup>* by Sturtevant, renamed *sis-b* by Cline. Locus also characterized by dominant effects of deficiencies and duplications of the *ASC* region, and later by mutant alleles *sc<sup>10-1</sup>* and *Hw<sup>49c</sup>* that affect *ASC* functions more than *sis-b* functions. *sis-b* reduces viability of homozygous females and hemizygous females are lethal; yet hemizygous males fully viable. Dominant synergistic female-specific lethal interactions with loss-of-function alleles of *Sxl*, *sis-a*, and/or maternal *da*; magnitude of viability effects depends on genetic background and inversely correlates with background effects on male-lethal effects; interactions temperature dependent, generally more extreme at higher temperatures. Female via-

bility effects suppressed by gain-of-function *Sxl<sup>M1</sup>* allele, and by duplications of *Sxl<sup>+</sup>* or *sis-a<sup>+</sup>*. Duplication of *sis-b<sup>+</sup>* male-lethal in combination with duplication of *Sxl<sup>+</sup>* and/or *sis-a<sup>+</sup>*, more so at lower temperatures. Male lethality of duplication combinations suppressed by *Sxl<sup>-</sup>*. Phenotype of 2X;3A intersexes strongly dependent on dose of *sis-b<sup>+</sup>*. The dose-dependent interactions of this gene identify it as a positive regulator of *Sxl<sup>+</sup>* and part of the numerator of what is referred to as the X/A balance, the primary sex-determination signal. This is a character it shares with *sis-a*.

**cytology:** Located in 1B3, based on its location between the left breakpoints of  $In(1)sc^8 = In(1)B2-3;20F$  and  $In(1)sc^4 = In(1)B3-4;20F$ .

**molecular biology:** Activity mostly (but not entirely) confined to a region of approximately 24 kb as determined by Cline (1988), which includes the scute-alpha member of the ASC, and is known to encode one (T4) or possibly two (also T7) transcripts. Location refined further by Torres and Sánchez (1989) to the 8.3 kb fragment between the breakpoint of  $In(1)sc^{L8}$  distally and the breakpoint of  $Df(1)yT2-650$  proximally, a region containing only transcription unit T4; however, there are uncertainties connected with this assignment:  $Df(1)yT$  rearrangements are reported to be highly unstable, losing 75 base pairs per generation (Biessmann and Mason, 1988, EMBO J. 7: 1081-86), the assay used to assess *sis-b* function was not always sufficient to establish whether wild-type levels of *sis-b* activity were present. Molecular characterization of  $sc^{10-1}$  and  $Hw^{49c}$  indicates that *sis-b* function requires protein encoded by the *sc* transcription unit; nevertheless, it seems worthwhile to retain both gene names for the time being, since different regulatory information, and perhaps even somewhat different protein activities, are involved in sex determination versus neurogenesis.

**ascutex:** see *asx*

**asense:** see *ase* under **ASC**

**ash1: absent, small, or homeotic discs**

**location:** 3-46.

**references:** Shearn, 1974, Genetics 77: 115-25.

Shearn, Hersperger, and Hersperger, 1987, Roux's Arch. Dev. Biol. 196: 231-42 (fig.).

**phenotype:** Most alleles homozygous lethal; stage of lethality variable. Surviving and pharate adults display transformations including haltere to wing, first and third legs to second leg, genitalia to leg or antenna; *ash1<sup>8</sup>* and *ash1<sup>10</sup>* show transformation of posterior to anterior wing margin. Homeotic transformations also seen in clones of homozygous cells in otherwise heterozygous flies. Larvae homozygous for *ash1<sup>12</sup>*, a severe allele, displays a high incidence of failure to form imaginal disks, especially antennal, genital, haltere, and wing disks.

**alleles:**

Shearn, Hersperger, and Hersperger, 1987, Roux's Arch. Dev. Biol. 196: 231-42 (fig.).

**phenotype:** Most alleles homozygous lethal; stage of lethality variable. Surviving and pharate adults display transformations similar to those indicated for *ash1<sup>1</sup>*.

**alleles:**

allele	origin	synonym	comments
<i>ash2<sup>1</sup></i>	NNG	<i>703</i>	L2-L3 lethal
<i>ash2<sup>2</sup></i>	NNG	<i>1803R</i>	prepupal lethal
<i>ash2<sup>3</sup></i>	EMS	<i>R0631</i>	pupal-adult lethal
<i>ash2<sup>4</sup></i>	EMS	<i>SE420</i>	
<i>ash2<sup>5</sup></i>	EMS	<i>SH536</i>	prepupal-pupal lethal

**cytology:** Placed in 96A1-25 based on its inclusion in  $Df(3R)96A1-7;96A20-25$  associated with  $In(3R)Ubx^{7L}ats^R$  (González, Molina, Casal, and Ripoll, 1989, Genetics 123: 371-77).

**asp: abnormal spindle**

**location:** 3-85.2 (based on 64 *hh<sup>1</sup>-tx* recombinants).

**origin:** Induced by ethyl methanesulfonate.

**references:** Ripoll, Pimpinelli, Valdivia and Avila, 1985, Cell 41: 907-12.

González, Molina, Casal, and Ripoll, 1989, Genetics 123: 371-77.

**phenotype:** Cold-sensitive recessive semilethal; 12% survive to adulthood at 25°; most larvae with small or absent imaginal discs; delayed development; survivors with nicked wings and rough eyes. Males sterile at 18° and fertile at 25°; produce abundant MI nondisjunction; females sterile. Larval neuroblasts frequently polyploid, especially when held at 18°. Phenotype enhanced by duplication for 97B, i.e., the  $Y^{P3D}$  element of  $T(Y;3)B158 = T(Y;3)B^S Xh;97B$ , but not that of  $T(Y;3)R71 = T(Y;3)h1-2;97B$

**cytology:** Localized to 96A21-B10 between third chromosome breakpoints of  $T(Y;3)A117 = T(Y;3)h24;96A21-25$  and  $T(Y;3)B197 = T(Y;3)h3;96B1-10$ .

**L-aspartate: 2-oxyglutarate aminotransferase:** see **Got**

**ast: asteroid**

**location:** 2-1.3 (0.02 unit to right of S).

**origin:** Spontaneous.

**discoverer:** E. B. Lewis, 38b.

**synonym:**  $S^r$ : *Star-recessive*.

**references:** 1938, DIS 10: 55.

1942, Genetics 27: 153-54.

1945, Genetics 30: 137-66.

1951, Cold Spring Harbor Symp. Quant. Biol. 16: 159-

74 (fig.).

**phenotype:** Eyes small and rough. Veins L2, L3, L4, and L5 do not always extend to margin. Overlaps wild type rarely. *S* +/+ *ast* has very small eyes with fused facets; veins L2 to L5 incomplete at tip. *S ast/ + ast* has slightly larger eye than *S +/+ ast*. *S ast/ + +* resembles *S +/+ +*. *S +/+ ast* and *ast/ast* partially suppress *px* and *net*. Eyes of *ast/ E(S)* rough. RK2.

**alleles:** \**ast*<sup>2</sup> and *ast*<sup>3</sup> show eye but not wing effect of *ast* (CP627). *ast*<sup>4</sup>, \**ast*<sup>5</sup>, and *ast*<sup>X</sup> homozygotes look normal but enhance expression of *S* in heterozygotes (Lewis, 1951). Three reversions of *ast* superscripted \**rv1*, \**rv2*, and \**rv3* (Lewis, 1951). *ast*<sup>v</sup> is variegating allele associated with *T(2;4)21E2-3;101* (Lewis, 1951).

**cytology:** Placed in the 21E1-2 doublet on the basis of its being included in the synthetic deficiency derived by combining the *Y*-centric portion of *T(Y;2)21E = T(Y;2)21D4-E1* and the 2-centric portion of *T(2;4)ast<sup>v</sup> = T(2;4)21E2-3;101* (Lewis, 1945). See also Roberts, Brock, Rudden, and Evans-Roberts, 1985, Genetics 109: 145-56.

**\**asx*: *ascutex***

**location:** 1-26.

**origin:** Spontaneous.

**discoverer:** Bridges, 24b14.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 218.

**phenotype:** Furrow between scutellum and thorax much shallower; scutellum inflated. Body color pale. Legs have blackened leaky joints. Character less extreme in old dry cultures. Viability 60% wild type. RK3.

***Asx*: Additional sex combs**

**location:** 2-72.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Jürgens.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82. Jürgens, 1985, Nature 316: 153-55.

Breen and Duncan, 1986, Dev. Biol. 118: 442-56 (fig.)

**phenotype:** *Asx*/+ males have extra sex-comb teeth on meso- and metathoracic legs (e.g., *Asx*<sup>6</sup> → 11.8 sex-comb teeth per prothoracic, 0.5 per mesothoracic, and 0.2 per metathoracic leg). Homozygote embryonic lethal. Abdominal denticles in head and thoracic segments; abdominal segments 1-7 transformed into more posterior segments. With respect to the degree of transformation to more posterior structures, *Df(2R)trix/Df(2R)trix* > *Df(2R)trix/Asx*<sup>5</sup> > *Asx*<sup>5</sup>/*Asx*<sup>5</sup>, indicating that *Asx*<sup>5</sup> is hypomorphic mutation. Similar genotypes derived from *Df(2R)trix/Asx*<sup>5</sup> oocytes achieved by means of pole-cell transplantatiton display more severe transformation than their counterparts above derived from mothers carrying one dose of *Asx*<sup>+</sup> (Breen and Duncan). In double mutant combinations with *Pcl*, *Psc*, or *Scm* shows strong posterior transformation of all segments and failure of head involution. The presence of *BXC*<sup>+</sup> required for expression of phenotype.

**cytology:** Placed in 51A1-B4 based on its being deleted by both *Df(2R)trix = Df(2R)51A2-4;51B3-6* and *Df(2R)L+48 = Df(2R)51A1;51B4*.

**Asy:** see *A-p*

**Asymmetric:** see *A-p*

**\**at*: *arctus oculus***

**location:** 2-60.1.

**origin:** Spontaneous.

**discoverer:** Fernandez Gianotti, 42g28.

**synonym:** *bar eye*; *arctops*.

**references:** 1943, DIS 17: 48.

1944, DIS 18: 45.

1945, Rev. Inst. Genet. Fac. Agron. Vet. Univ. Buenos Aires 2(14): 171-77.

1948, DIS 22: 53.

**phenotype:** Eyes similar to *B* but with more facets. Classification, fertility, and viability excellent. RK1.

***At*: Attenuated**

**location:** 1- (in the *B* region).

**origin:** Induced with soft X rays in *In(1)sc<sup>SIL</sup>sc<sup>8R</sup>+dl-49, sc<sup>S1</sup>sc<sup>8</sup>B*; associated with loss of *B* phenotype.

**discoverer:** Valencia and Valencia, 1949.

**references:** 1949, DIS 23: 64.

**phenotype:** In *At*/+ females, wings incised medially and laterally, usually have one large central blister. *At/At* females have badly crumpled, blistered, and sometimes poorly developed wings. Wings of *At* males tend to be more like those of *At*/+ females, although many fall somewhere between *At*/+ and *At/At* in phenotype. Thus there is evidence for only a slight dosage compensation for *At*. This mutant is similar to some Beadex alleles, but allelism not tested. Both males and homozygous females viable and fertile. RK1A.

**cytology:** Associated with *In(1)At = In(1)16A4-5;18C4-6;20A2-3*.

***Ata*: Arista**

**location:** Not located.

**origin:** X ray induced.

**discoverer:** Krivshenko, 1949.

**synonym:** *At* (symbol preoccupied).

**references:** 1954, DIS 28: 74-75.

1955, DIS 29: 73.

**phenotype:** Lateral branches of arista reduced, especially branches extending upward from central axis and situated at base of arista. Axis of arista often abnormal. Wings have small transparent spots distally. Homozygous lethal. Heterozygous viability and fertility comparatively high. RK2A.

**cytology:** Associated with *T(2;3)Ata = T(2;3)40;66F-67A + T(2;3)47;81*.

***Atpα: (Na<sup>+</sup> + K<sup>+</sup>) ATPase α subunit*****location:** 3-{70}.**references:** Lebovitz, Takeyasu, and Fambrough, 1989, EMBO J. 8: 193-202.**phenotype:** Structural gene for the α or catalytic subunit of Na<sup>+</sup> K<sup>+</sup> ATPase (ouabain sensitive). Immunofluorescence microscopy with a monoclonal antibody demonstrates high concentrations of αATPase in adult muscle, nervous tissue, and Malpighian tubules; strong immunofluorescence observed in brain, optic lobes, photoreceptor cells of retina, and ventral thoracic neuromere. Flies heterozygous for *Df(3R)r1-G6* which lacks *Atpα*, are sluggish and less tolerant of physical stress than normal.**cytology:** Placed in 93B by *in situ* hybridization. Included in *Df(3R)r1-G6 = Df(3R)93A2-B1;93E-F*.**molecular biology:** cDNA clones isolated by probing a late-pupal and six-hour embryonic cDNA libraries with probes from the homologous gene from chicken. All tissues and all stages tested produce three homologous transcripts of 3.6, 3.8, and 4.8 kb, with the 4.8-kb species being the most abundant, except in the adult thorax where all are equally abundant. The sequence reveals an open reading frame encoding a polypeptide of 1038 amino acids; the conceptual sequence is 75-80% homologous to other α subunits. Genomic clones contain more than 10 kb of intron sequence.**atrophy gonadique:** see *agg****ats: abnormal tarsi*****location:** 3- (not localized).**origin:** Spontaneous in a third chromosome carrying three non-overlapping paracentric inversions.**references:** Sierra and Comendador, 1984, DIS 60: 244-45(fig.)**phenotype:** Homozygotes exhibit different degrees of tarsal aplasia; most frequently second, third, and fourth tarsal joints missing; less frequently the fifth tarsal joint arises from tibia; often a rudimentary tarsal appendage arises from tibia or the fifth tarsal joint. Homozygous males and females sterile. Adult and preadult survival reduced; more than 50% of imago die during the first day.**Attenuated:** see *At****aub: aubergine (T. Schüpbach)*****location:** 2-39.**origin:** Induced by ethyl methanesulfonate.**references:** Schüpbach and Wieschaus.**phenotype:** Female sterile; homozygous females lay eggs which are of variable shapes; in the most extreme cases, the eggs are longer than the normal, more pointed at the posterior end, and lack dorsal appendages, resembling eggs produced by the dominant female-sterile mutation *Fs(2)G*.**alleles:** *aub*<sup>OC</sup> = *aub*<sup>1</sup>, *aub*<sup>AHN</sup>, *aub*<sup>HN</sup>.**augenwulst:** see *awu****aur: aurora*****location:** 3-53.**synonym:** *early-A; frühe2*.**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.**phenotype:** Maternal-effect lethal. Embryos abnormal

from nuclear cycle 9 onward. Multiple spindles assemble in long arrays with shared centrosomes. Polyploid nuclei develop with multiple centrosomes. Larval mitosis not investigated (Glover and Nüsslein-Volhard).

**alleles:** Three ethyl-methanesulfonate-induced alleles, *aur*<sup>1</sup>, *aur*<sup>2</sup>, and *aur*<sup>3</sup> recovered as *074, 175, and 287*.**cytology:** Placed in 87A7-B2 based on inclusion in the region of overlap of *Df(3R)E229 = Df(3R)86F6-7;87B1-2* and *Df(3R)kar-D1 = Df(3R)87A7-8;87D1-2*.***\*aw: awry*****location:** 1-32 (not allelic to *wy*).**origin:** Induced by ingested radiophosphorus.**discoverer:** Bateman, 1949.**references:** 1950, DIS 24: 54.  
1951, DIS 25: 77.**phenotype:** Wings upcurled, slightly wavy, convex, opaque, or vestigial-like. Variable; overlaps wild type. Viability about 50% wild type. Not enhanced in presence of *y*, as is *dvr* (1-28.1). RK3.***\*aw-b: awry-b*****location:** 1-38 to 39.**origin:** Induced by ingested radiophosphorus.**discoverer:** Bateman, 1950.**synonym:** *aw*<sup>2</sup>.**references:** 1950, DIS 24: 54.  
1951, DIS 25: 77.**phenotype:** Like *aw*. Good expression at 25°. Viability 10% that of wild type. Most males fail to eclose. RK3.***awd: abnormal wing disc (A. Shearn)*****location:** 3-102.9 (based on mapping of *awd*<sup>K</sup>).**origin:** *P* mutagenesis.**discoverer:** Dearolf, 1983.**references:** Dearolf, Hersperger, and Shearn, 1988, Dev. Biol. 129: 159-68.

Dearolf, Tripoulas, Biggs, and Shearn, 1988, Dev. Biol. 129: 169-78.

Biggs, Tripoulas, Hersperger, Dearolf, and Shearn, 1988, Genes Dev. 2: 1333-43.

**phenotype:** Homozygotes die in late third larval instar; wing discs variably hypoplastic; other discs appear grossly normal. Trypan blue staining reveals cell death in wing disc, either in area of presumptive wing blade, or scattered throughout disc; other discs reveal lesser amounts of cell death later in development than in wing discs. Extensive lipid vacuolization in larval ventral ganglion, brain lobes, and proventriculus. Mutant discs exhibit slow growth when transplanted into wild-type hosts; normal discs in mutant hosts grow normally. Metamorphosis of eye-antennal, wing, and leg discs when transplanted into normal larvae severely restricted; few or no adult structures develop; mutant ovaries do not survive transplantation to wild-type hosts; however, transplanted *awd* pole cells capable of producing both *awd*<sup>+</sup> and *awd*<sup>awd</sup> progeny. Epidermal clones nearly lethal and with thin, short, bent bristles and hairs when induced early; survive in reduced numbers and size when induced late.**alleles:** Five *P*-induced alleles and twelve revertants of *awd*<sup>K</sup> reported but only a subset of them identified in

publications; some revertants listed under *Df(3R)awd*.

**cytology:** Placed in 100C-D by *in situ* hybridization.

**molecular biology:** Locus cloned by transposon tagging and restriction mapped. 850 base pair transcript detected by northern analysis. Rescue of mutant phenotype achieved by germ-line transformation. Transcript detected by northern analysis, abundantly in larval and less abundantly in adult tissues as well as in cultured cells. Sequencing shows exon 1 = ~130 nucleotides, intron 1 = ~250 nucleotides, and exon 3 = ~300 nucleotides. Sequence determined by Biggs *et al.* indicates a protein of 153 amino acid residues and 16-17 kd in molecular weight. Gel-filtration experiments of embryonic extracts indicate that the AWD protein is present in cells in a 100 kd species. The conceptual amino acid sequence shows 78% identity and 95% similarity to that of the human metastasis inhibiting factor, NM23 (Rosengard, Krutzsch, Shearn, Biggs, Barker, Inger, Margulies, King, Liotta, and Steeg, 1989, *Nature* 342: 177-80). Both sequence and activity (Shearn) indicate that the protein is a nucleoside diphosphate kinase.

### *awd<sup>K</sup>*

**phenotype:** An antimorphic allele; no phenotypic effects, either when homozygous or heterozygous; however, it is a dominant conditional lethal, which is lethal in combination with *pn*, i.e., *pn/Y; awd<sup>K</sup>/+* males or *pn/pn; awd<sup>K</sup>/+* females. *awd<sup>K</sup>* does not interact with any other eye-color mutant. Interacts lethally with all standard alleles of *pn* tested; however, *pn<sup>ts-ek</sup>* insensitive to *awd<sup>K</sup>* at permissive temperatures, whereas nine other temperature-sensitive alleles of *pn* are insensitive under all conditions. Lethal phase of *pn; awd<sup>K</sup>* genotypes begins in early second larval instar and lasts until after the time that normal larvae pupate. Using *pn<sup>ts-ek</sup>*, the temperature-sensitive period of the *pn* component of the lethal interaction determined to begin in second instar and last until eclosion. *pn; awd<sup>K</sup>* sons of *pn* mothers appear to die earlier than those of *pn<sup>+</sup>* mothers, suggesting a maternal effect of *pn<sup>+</sup>*, which is revealed in the presence of *awd<sup>K</sup>* (Hackstein, 1971, *Mol. Gen. Genet.* 111: 371-76). Fate mapping in *pn/pn<sup>+</sup>; awd<sup>K</sup>/+* gynandromorphs places

the focus of the lethal interaction in the midventral part of the blastoderm, not a focus of pteridine biosynthesis. *awd<sup>K</sup>* eye disks transplanted into *pn* hosts develop autonomously as do the reciprocal transplants (Grell, 1958, *DIS* 32: 123-24). The levels of *awd* transcript are normal in (1) *pn*, (2) *awd<sup>K</sup>/+*, and (3) *pn; awd<sup>K</sup>/+* flies; however, only the first two genotypes accumulate normal levels of the AWD polypeptide, the last having little or none, despite the presence of one copy of *awd<sup>+</sup>*. *pn; awd<sup>K</sup>/+* larvae die in early third instar, whereas those that are *pn; awd<sup>K</sup>/+/+* die at the end of L3.

**other information:** Allelism of *awd<sup>K</sup>* demonstrated by two observations. First induced revertants of *awd<sup>K</sup>*, as recovered on the basis of their failure to interact lethally with *pn*, are lethal in all pairwise combinations (Lifschytz and Falk, 1969, *Genetics* 62: 353-58) and in combination with *awd<sup>b3</sup>*. Second transformants carrying an *awd* homologous sequence isolated from homozygous *awd<sup>K</sup>* DNA are able to rescue *awd<sup>b3</sup>* lethality and are able to kill *pn* in the presence of homozygous *awd<sup>+</sup>* (Biggs *et al.*).

**awry:** see *aw*

### *awu: augenwulst*

**location:** 2-53.7 (based on mapping of *awu<sup>2</sup>* by Carfagna and Melen).

**origin:** Spontaneous.

**discoverer:** Rosin, 1951.

**references:** Volkart, 1959, *DIS* 33: 100.

**phenotype:** Eyes deformed; in most extreme expression, deeply indented at middle of anterior margin where invaginating integument forms a pad-like swelling with bristles. Expression variable, often asymmetrical. Overlaps wild type. Heterozygote occasionally has minor effects. Good viability. RK3.

**alleles:** \**awu<sup>1</sup>*; *awu<sup>2</sup>*, spontaneous (1971, Carfagna and Melen, *DIS* 47: 38). Shows more dominance than *awu*.

**Ax:** see under *N*

### *Axs: Aberrant X segregation* (A.E. Zitron and S. Hawley)

**location:** 1-56 (not separated from *f* in 80 recombinants between *v* and *car*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Zitron, and Hawley, 1989, *Genetics* 122: 801-21.

**phenotype:** Dominant meiotic mutant that affects distributive pairing; disrupts meiotic segregation of non-exchange chromosomes in females. Has no effect on the frequency of exchange. Loss of function mutation at a dosage sensitive locus; *Axs<sup>+</sup>* duplication can rescue mutation in *trans*. Specific to female meiosis. In *Axs/Axs/Y* females, X-chromosomes nondisjunction is accompanied by random disjunction of the *Y* rather than directed disjunction from the *X*'s as observed in *+/+/Y* females. *Axs* homozygotes increase X nondisjunction many fold; parallel but lesser effects observed on autosomal disjunction.

**cytology:** Associated with a small chromosome aberration at 15D1.

**b: black (M. Ashburner)**

location: 2-48.5.

**phenotype:** Black pigment on body and tarsi and along wing veins. Reflectance of cuticle 40% that of wild type (Pedersen, 1982, Carlsberg Res. Comm. 47: 391-400). Heterozygote somewhat darker than wild type, especially on trident, but never confused with homozygote. Body color darker at low temperature (Sherald, 1981, Mol. Gen. Genet. 183: 102-06). Puparium lighter than wild type. Not easily classified in newly emerged flies (Waddington, 1941, Proc. Zool. Soc. London Ser. A. 111: 173-80). Tyrosinase formed in adult flies (Horowitz). Fails to synthesize beta-alanine (Hodgetts, 1972, J. Insect Physiol. 18: 937-47), and feeding or injection of beta-alanine to *b* produces normal phenotype [Jacobs, 1974, J. Insect Physiol. 20: 859-66; Hodgetts, Hodgetts and Choi, 1974, Nature (London) 252: 710-11]. Also corrected by feeding 6-azauracil (Pedersen, 1982, Hereditas 97: 329); feeding 6-azathymine produces weak *b* phenocopy which is suppressed by *Su(b)* (Pedersen). ERG normal [Hotta and Benzer, 1969, Nature (London) 22: 354-56]. Puparial case structurally abnormal with wide, diffuse, exocuticular lamellae and indistinct endocuticular fibrils (Jacobs, 1978, Insect Biochem. 8: 37-41). Pupae UV sensitive (Jacobs 1978). Suppressed by *su(b)* (Sherald, 1981, Mol. Genet. 181: 102-106) and *Su(b)* (Pedersen); enhanced by *sp*<sup>2</sup> (Gubb) and *su(r)* (Pedersen). *su(r) su(b) b* is enhanced black; *su(r) b* not enhanced by feeding 6-azauracil (Pedersen). Possibly structural gene for beta-ureidopropionase (EC 3.5.1.6; Sherald). RK1 in aged flies.

β Lighter than *b*<sup>1</sup>.

γ Diepoxyoctane.

δ Induced simultaneously with *r*k 81*f*2.

ε Synonym = *b*<sup>B</sup>; homozygous lethal, said to be associated with *Df(2L)35C;35D*, but this was almost certainly a misinterpretation of ectopic pairing (Ashburner).

**cytology:** Placed in region 34D4-6 (Ashburner).

β: see *Tyr2*

**B: Bar**

**location:** 1-57.0.

**origin:** Spontaneous in a female.

**discoverer:** Tice, 13b.

**references:** 1914, Biol. Bull. 26: 221-30 (fig.).

Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 66 (fig.).

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 29-33.

**phenotype:** Eye restricted to narrow vertical bar of about 90 facets in the male and 70 facets in the female, as contrasted with normal numbers of about 740 for males and 780 for females [Sturtevant, 1925, Genetics 10: 117-47 (fig.)]. Homozygous female fully viable. *B*/*B* female has about 360 facets and shows indentation terminating in horizontal fissure on anterior margin of eye, producing a kidney-shaped eye. *B*/*B* and *B*/*B* completely separable from wild type; in some genetic backgrounds, *B*/*B* overlaps *B*/*B* slightly. Classifiable in single dose in triploids by slight anterior nick in eye (Schultz, 1934, DIS 1: 55); is useful in the recognition of triploids. Variegated position effect derivatives of *B*<sup>S</sup>(*B*<sup>SVY</sup>) exhibit nonmutant phenotypes in *XY* males but narrow eyes in *XY*Y males; other enhancers of variegation, *M(2)S10* and *E(var)7*, also shift phenotype toward normal (Brosseau, 1960, Genetics 45: 979). Eyes of female heterozygous for a deficiency for *B* and a normal *X* are normal (Sutton, 1943, Genetics 28: 97-107). Log of facet number inversely proportional to temperature of development (Hersh, 1930, J. Exp. Zool. 57: 283-306).

Nonautonomous over short distances (Sturtevant, 1932, Proc. Intern. Congr. Genet., 6th, Vol. 1: 304-7). Facet development enhanced in organ culture by addition of wild type cephalic complexes [Kuroda and Yamaguchi, 1956, Jpn. J. Genet. 31: 97-102 (fig.)]. Disc size reduced; morphogenetic furrow absent; deep cleft at anterior margin of preommatidial cell clusters. Only four to five rows of clusters. Those at cleft edge look mature (Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29). Cell death observed in anterior presumptive ommatidium-forming region of eye disc [D. Fristrom, 1969, Mol. Gen. Genet. 103: 363-79; 1972, Mol. Gen. Genet. 115: 10-18; Michinomae and Kaji, 1973, Jpn. J. Genet. 49: 353-71 (fig.); Michinomae, 1974, Jpn. J. Genet. 49: 353-71; 1976, Jpn. J. Genet. 51: 315-26 (fig.)]; high acid phosphatase levels characteristic of liposomal activity seen at same time (Michinomae, 1974, 1976). Reduction in facet number, increase in acid phosphatase activity, and cell death inhibited in larvae grown on medium supplemented with acetamide or lactamide (Kaji, 1954, Annot. Zool. Jpn. 27: 194-200; Fristrom, 1972; Michinomae and Kaji, 1973; Michinomae, 1974, 1976). Double amides more effective than single (DeMarinis and Sheibley, 1968, DIS 43: 138). Facet development responds strongly to environmental factors around 60 hr after oviposition (Luce, Quastler, and Chase, 1951, Genetics 36: 488-99). Pigmented but non-faceted part of eye shows retinulae and dioptic apparatus lacking, but rudimentary ommatidia present, consisting of hypertrophied accessory cells (Wolsky and Huxley, 1936, Proc. Zool. Soc. London 485-89). Introduction of *B* into a strain of flies characterized by jumping in response to a sudden decrease in light intensity nearly eliminates response; response rescued by increasing facet number

$\alpha$  1 = Brosseau, 1960, Genetics 45: 979 and the report of the Seattle-La Jolla Drosophila Laboratories, 1971, which appeared as an unbound supplement to DIS 47; 2 = Brosseau, 1967, DIS 42: 38; 3 = Brosseau, 1969, DIS 44: 45; 5 = Childress, 1973, Mol. Gen. Genet. 121: 133-38; 6 = CP552; 7 = CP627; 8 = Kaplan, 1969, DIS 44: 45; 9 = Novitski, 1970, DIS 45: 87-88.

$\beta$  The phenotype of females carrying the allele in heterozygous combination with +. <*B* = less extreme than *B*/+; >*B* = more extreme than *B*/+, etc.

$\gamma$  Viability of males hemizygous and, where testable, of females homozygous for the allele. Where tested the lethal alleles are cell lethal in cuticular spots.

$\delta$  + = loss of tandem duplication or triplication to produce normal sequence.

through lactamide feeding during larval development (Nakashima-Tanaka and Matsubara, 1980, Jpn. J. Genet. 55: 275-82). RK1A.

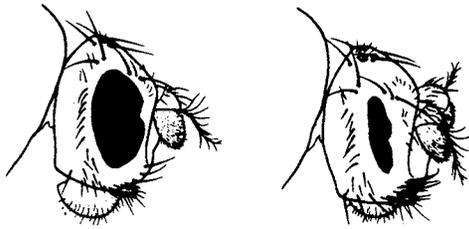

**alleles:** Derivatives of *B* with altered phenotypes, including reversions to normal phenotype have been given allelic designations. These derivatives are summarized in the accompanying table. Unless otherwise indicated, fuller descriptions are found in CP627. See table for allelic information.

**cytology:** Located in 16A1-2. Associated with *Dp(1;1)B = Dp(1;1)15F9-16A1;16A7-B1*.

**molecular biology:** Region cloned by transposon tagging from hybrid-dysgenesis-induced *B* reversion (Tsubota, Rosenberg, Szostak, Rubin, and Schedl, 1989, Genetics 122: 881-90). Analysis of genomic DNA reveals presence of *roo* element at the junction between 16A7 and 16A1, indicating that original duplication may have arisen by unequal recombination between *roo* elements inserted at 16A1 and 16A7. Three hybrid-dysgenesis-induced partial revertants have *P*-element inserts close to

the junction as does *B*<sup>3</sup>. Breakpoints of *B*, *B*<sup>M1</sup>, *B*<sup>M2</sup>, and *B*<sup>bd</sup> span a region of approximately 37 kb.

**other information:** Since *B* is a tandem duplication, *B* homozygotes may give rise to a nonduplicated chromosome (reversal to normal phenotype) and a triplicated chromosome (*i.e.*, double Bar = *BB*) as reciprocal products of unequal crossing over (Sturtevant and Morgan, 1923, Science 57: 746-47; Gabay and Laughnan, 1973, Genetics 75: 485-95). From successive unequal crossovers in attached X's, Rapoport (1940, Zh. Obshch. Biol. 1: 235-70; 1941, DIS 15: 36-37) was able to accumulate as many as 7 or 9 Bar regions in a single chromosome. Bar is the first recorded instance of position effect. Presumably results from the new band association 16A7-16A1 and can be reversed by rearrangements that separate these bands. Also the first case of *cis-trans* position effect, two 16A7-16A1 associations in the same chromosome producing greater facet reduction than one association in each of two homologous chromosomes.

**B: Bar**

Left: heterozygous female. Right: hemizygous male. From Sturtevant and Beadle, 1939. An Introduction to Genetics, Saunders, p. 24.

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**ba: balloon**

From Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 148.

**phenotype:** Wings at first inflated with hemolymph to produce blisters and vesicles; venation weak, plexus like; wings smaller, warped, discolored, and divergent. Effect caused by inadequate contraction of epithelium after inflated state of pupal wing [Waddington, 1940, J. Genet. 41: 75-139 (fig.)]. Sensitive to temperature. RK3 above 25°; RK2 at 19° or below.

**alleles:**  $*ba^2$  (CP627).

**cytology:** Located in 60C5-D2 based on inclusion within  $Df(2R)Px = Df(2R)60B8-10;60D1-2$  and within  $Df(2R)Px^2 = Df(2R)60C5-6;60D9-10$  (Bridges, 1937).

**other information:** May be part of a pseudoallelic complex with *bs* and *Px*.

$ba^2$ : see *blo*

$ba^{33f26}$ : see *blo*

**Ba: Brista**

**location:** 2-107.8 (0.8 unit to right of *sp*).

**synonym:** *Dll*: Distal-less.

**references:** Sato, 1984, DIS 60: 180-82 (fig.)

Sunkel and Whittle, 1987, Wilhelm Roux's Arch. Dev. Biol. 196: 124-32.

Cohen and Jürgens, 1989, EMBO J. 8: 2045-55.

**phenotype:** Null alleles are recessive embryonic lethals, with dominant developmental defects of distal appendages. Lethal embryos lack certain sensilla, including Keilin's organs, and antennal, maxillary, labial, and labral sense organs, all of which are thought to correspond to vestiges of the distal sensilla of rudimentary larval appendages. No other embryonic sensilla are affected, nor are the neurons innervating the rudimentary appendages detectably abnormal. In homozygous-viable or pharate-adult-lethal hypomorphic alleles defects are found in all appendages represented by the above larval structures. Heterozygotes for lethal alleles are characterized by transformations of distal antennal segments (*i.e.*, AII, AIII, and arista) to mesothoracic leg and by variable loss of distal leg segments, depending on severity of allele. Transformation in the case of  $Ba^1$  sensitive to low-temperature pulses throughout larval development, whereas the TSP for leg truncation is at end of the third larval instar. Clones of homozygous  $Ba^-$  cells incapable of contributing to any but the coxal segment of the legs, and for the most part, the first antennal segment; in the relatively infrequent cases, in which  $Ba^-$  clones involve distal antennal segments,  $Ba^-$  portions, which always include at least the arista, are absent, and  $Ba^+$  portions develop normally indicating cellular autonomy.

β					Coordinates estimated from figure of Cohen <i>et al.</i> ; origin undefined; positive values extend to left.
γ					Differs from other tested alleles in showing some dominance in combination with two + alleles.
δ					Differs from other tested alleles in being embryonic rather than pupal lethal in combination with <i>Ba</i> <sup>3</sup> and <i>Ba</i> <sup>9</sup> .

**cytology:** Placed in 60E5-6 based on its inclusion in *Df(2R)Ba = Df(2R)60E3;60E6* and on common breakpoints of *Ba* rearrangements.

**molecular biology:** Region isolated in a chromosome walk of 180 kb (Cohen, Jürgens, and Jäckle, 1989, Nature 338: 432-34). *Ba* lesions extend over a region of 38 kb. A single transcription unit detected that is homologous to transcripts of ~2.5 and ~3.4 kb which hybridize to restriction fragments extending over 25 kb of genomic sequence; three exons identified; sequence of genomic fragments hybridizing transcript indicate the presence of a putative homeodomain that is interrupted by an intron between residues 44 and 45 as is the homeodomain of *lab*.

### *Ba*<sup>1</sup>

**phenotype:** Homozygous lethal; dies in first instar and has normal morphology. Heterozygote shows antenna-to-leg transformation; entire arista and part of third antennal segment transformed to distal metathoracic leg structures. Expression temperature sensitive; transformation complete at 19°; phenotype normal at 29°. *Ba/Df(2R)Ba4* shows abnormal segmentation both dorsally and ventrally and loss of head structures; antennal, maxillary, and labial segments affected. "H" piece malformed or absent as are Keilin's organs in all three thoracic segments. Recessive to two doses of 60D-F.

### *Ba*<sup>3</sup>

**phenotype:** *Ba*<sup>3</sup>/+ wild type; *Ba*<sup>3</sup>/*Ba*<sup>1</sup> fail to eclose; pharate adults lack third antennal segment; second segment transformed to leg; distal arista normal. Legs lack all structures distal to tibiae; tibiae enlarge and bear ectopic bristles; no remaining leg bristles are bracted.

### *Ba*<sup>5</sup>

**phenotype:** *Ba*<sup>5</sup>/+ like *Ba*<sup>1</sup>/+. *Ba*<sup>5</sup>/*Ba*<sup>5</sup> and *Ba*<sup>5</sup>/*Ba*<sup>1</sup> are late embryonic lethals; show loss of antennae, maxillary, and labial sense organs, as well as the "H" piece and Keilin's organs from all three thoracic segments. Occasional abnormalities in setal bands of segments posterior to prothorax; setal bands or spinules may be deleted or adjacent bands fused. Posterior end of larva normal.

### *Ba*<sup>9</sup>

**phenotype:** Recessive allele. Homozygotes show partial transformation of antennae to legs as well as deletions of some leg structures. Tarsal tissue, sometimes including claws, develops in place of arista and part of third antennal segment. Third segment usually contains patchwork of incompletely differentiated leg tissue; first and second segments normal. Leg effects distal to mid tibia; legs proximal to mid tibia normal. In extreme cases number

of tarsal segments reduced to two or three; basitarsus and distal tibia may be missing; in most extreme cases claws may also be missing. In the case of mild expression abnormal bristle patterns, including polarity reversal, occur around basitarsus-tibia joint, where there may also develop cuticular hyperplasia. Penetrance greater in females than males, in antennae than legs, and in metathoracic than other legs. *Ba*<sup>1</sup>/*Ba*<sup>M</sup> die as pharate adults with extreme malformations of antennae and legs.

### *Ba*<sup>12</sup>

**phenotype:** *Ba*<sup>12</sup>/+ wild type; recessive lethal. Heterozygote exhibits nearly complete suppression of extra-sex-combs phenotype of *Pc*<sup>4</sup>/+.

### \**bal*: bandy legged

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Ströher, 1958.

**references:** Mainx, 1958, DIS 32: 82.

**phenotype:** Legs extremely shortened and crippled. All parts of legs from femur to tarsi shortened, broadened, and irregularly curved. Deformities most extreme in metathoracic legs. Movement unsteady and tottering. Manifestation increased by selection. Viability poor, especially in males; fertility good. RK2.

**bas: bang sensitive (J.C. Hall)**

**location**: 1-50.7 (based on 31 *m-f* recombinants).

**origin**: Induced by ethyl methanesulfonate.

**references**: Grigliatti, L. Hall, Rosenbluth, and Suzuki, 1973, *Mol. Gen. Genet.* 120: 107-14.

Ganetzky and Wu, 1982, *Genetics* 100: 597-614.

**synonym**: *bas-A*.

**phenotype**: Striking culture vial sharply on hard surface immobilizes *bas* flies for 30-40 seconds. Rapid recovery followed by refractory period of an hour. Suppressed by *nap<sup>ts</sup>* at permissive temperatures; at temperatures above 37.5° *bas* flies quickly paralyzed; no detectable physiological abnormalities at neuromuscular junction in *bas* larvae (Ganetzky and Wu). In experiments on photoreceptor function, recovery of prolonged depolarization afterpotentials (induced by strong blue light) abnormally slow following exposure to orange light (Homyk and Pye, 1989, *J. Neurogenet.* 5: 37-48).

**cytology**: Included in neither  $Dp(1;4)r^+ = Dp(1;4)13F;16A1-2$  nor  $Df(1)sd72b = Df(1)13F1-14B1$ ; therefore *bas* to the left of 13F1. Placed in 12F by Homyk.

**other information**: Jan and Jan (1978, *Proc. Nat. Acad. Sci. USA* 75: 515-19) erroneously termed what is now *bss<sup>1</sup>* a *bas* allele.

*bas-B*: see *bss*

*Bashed*: see  $Mhc-m^5$

**basket**: see **bsk**

**bat: bat**

**location**: 2-71.0.

**discoverer**: Bridges, 22j26.

**synonym**: *ext-b: extended-b*.

**phenotype**: Wings extended and bent backward. RK2.

**\*baton: baton**

**location**: 2-52.

**phenotype**: Abdomen elongated with defective plates; eye resembles  $L^4$ . Extremely inviable; most homozygotes die in larval and pupal stages, appearing as elongated corpses. Heterozygote shows some eye effect. RK3.

**baz: bazooka**

**location**: 1-56.7.

**origin**: Induced by ethyl methanesulfonate.

**references**: Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 296-307.

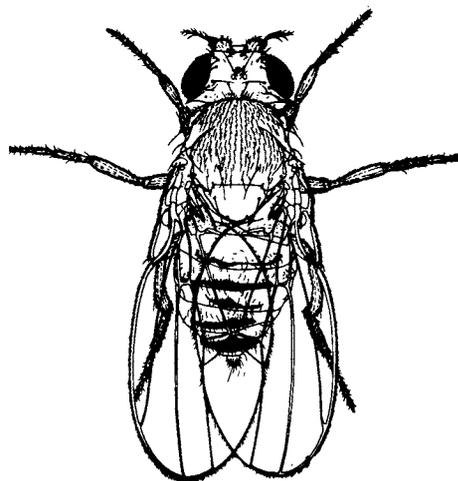

Wieschaus and Noell, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 63-73.

**phenotype**: Homozygous lethal, large dorsal and ventral hole in embryo. Homozygous *baz* germ-line clones undergo oogenesis, but the heterozygous progeny produced display major reductions in viability (Wieschaus

and Noell).

**alleles**: Three alleles,  $baz^1 = D9$ ,  $baz^2 = K7$ , and  $baz^3 = i^1$ .

**cytology**: Placed in 14A1-B1, or 14E1-F6, or 15A6-16A2 based on its being covered by  $Dp(1;4)exd^+82b = Dp(1;4)14A1-2;14B5-18 + 14E1-4;16A1-2$  but not included in  $Df(1)r-D17 = Df(1)14F6;15A6$ .

**an extreme bobbed**

Edith M. Wallace, unpublished.

**bb: bobbed (K.D. Tartof and R.S. Hawley)**

**location**: 1-66.0 (Bridges) and on *YS* (Stern, 1927; Cooper, 1959, *Chromosoma* 10: 535-88). Proximal to *ks-1* and *ks-2* (Kennison, 1981, *Genetics* 98: 529-48).

**origin**: Many alleles. In laboratory stocks, *bb* mutants may arise spontaneously or inadvertently while selecting for mutagen-induced mutations at other loci. *bb* mutations may be induced at high frequency by carcinogenic hydrocarbons such as 7,12-dimethyl benz[ $\alpha$ ]anthracene (DMBA) (Fahmy and Fahmy, 1969, *Nature* 224: 1328-29; 1970, *Mutat. Res.* 9: 239-43) or multifunctional alkylating agents such as triethylenemelamine (Tartof). Mutations of the X chromosome *bb* locus may be specifically induced genetically in four different ways. First, alterations of the X chromosome *bb* locus may occur *bb* in males or females carrying the aberrant chromosome  $Ybb^-$ . These are high frequency ( $10^{-2}$ - $10^{-1}$ ) events and may be observed as either stable reversions from *bb* to  $bb^+$  (magnification: Ritossa, 1968, *Proc. Nat. Acad. Sci. USA* 60: 509-16; Komma and Endow, 1986, *Genetics* 114: 859-74) or as mutations ( $10^{-3}$ - $10^{-2}$ ) from  $bb^+$  to *bb* or from *bb* to  $bb^1$  (reduction: Tartof, 1973, *Cold Spring Harbor Symp. Quant. Biol.* 38: 491-500; Tartof, 1974, *Proc. Nat. Acad. Sci. USA* 71: 1272-76; Locker and Prud'homme, 1973, *Mol. Gen. Genet.* 124: 11-19). It has been suggested that both magnification and reduction may be the result of unequal sister-chromatid exchanges occurring at the X chromosome *bb* locus in the germ line of  $X/Ybb^-$  males (Tartof, 1974); evidence for this is from studies of ring-X *bb* chromosomes (Endow, Komma, and Atwood, 1984, *Genetics* 108: 969-83); alternatively, a model of excision and reintegration of circular molecules rDNA has been proposed by Ritossa [1972, *Nature* (London), *New Biol.*

240: 109-11]. *C(1)RM* stocks carrying *Ybb*<sup>-</sup> accumulate modifiers that suppress the *bb* phenotype (Marcus, Zitron, Wright, and Hawley, 1986, *Genetics* 113: 305-19). Second, in males carrying *mei-41*, *bb*<sup>+</sup> mutates to *bb* at a frequency of 10<sup>-3</sup>-10<sup>-2</sup> (Hawley and Tartof, 1983, *Genetics*, 104: 63-80). *mei-41* does not induce reversions of *bb* to *bb*<sup>+</sup> as does *Ybb*<sup>-</sup> nor does it induce *bb* mutations on the *Y*. Third, when males carrying certain XY chromosomes are mated to females heterozygous for *Rex*, free *Y* chromosomes carrying *bb* mutants are generated at high frequency (10<sup>-2</sup>; Robbins, 1981, *Genetics* 99: 443-59). Fourth, hybrid dysgenic crosses may also generate *bb* (Thompson and Woodruff, 1980, *Proc. Nat. Acad. Sci. USA* 77: 1059-62). Despite such high frequency genetic mutations, homozygous stocks of *bb*<sup>2</sup>, *bb*<sup>4</sup>, *bb*<sup>6</sup>, and *bb*<sup>8</sup> have been maintained for 10 years with no evidence of reversions (Tartof). Unless otherwise stated, the origin of most *bb* mutations is unclear.

**discoverer:** Sturtevant, 20b.

**references:** Stern, 1927, *Z. Indukt. Abstamm. Vererbungsl.* 44: 187-231.

Ritossa, Atwood, and Spiegelman, 1966, *Genetics* 54: 819-34.

Ritossa, 1976, *Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 801-47.

**phenotype:** Three phenotypes are associated with bobbed mutants: thinning and shortening of bristles, etching of the abdomen, and, in extreme cases, lethality. Of these phenotypes, bristle size and lethality are the most reliable. These phenotypes are somewhat variable from fly to fly and the bristle abnormality may be obscured by such mutations as *f*, *sn*, and *ty* to name a few. *bb/0* males, and *bb/In(1)sc<sup>4L</sup>sc<sup>8R</sup>* females have phenotypes similar to, but more extreme than, that of homozygous females. *bb/Y* males are wild type, owing to presence of a normal allele of *bb* in *YS*; *bb/bb/Y* females are similarly normal in phenotype. Viability is variable. Ritossa, Atwood, and Spiegelman (1966) showed that *bb* contains about half as many ribosomal RNA genes (rDNA) as *bb*<sup>+</sup>. They conclude that the *bb* locus is the site of ribosomal RNA synthesis and interpreted *bb* mutations as partial deletions of the locus. They postulated that in *bb* flies the rate of protein synthesis is limited by the amount of ribosomal RNA, and the *bb* phenotype results in part because normal bristle production requires maximum protein synthesis on the part of the trichogen cells during a particular interval in development. The rate of rRNA synthesis is reduced in *bb* (Mohan and Ritossa, 1970, *Dev. Biol.* 22: 495-512; Mohan, 1975, *Genetics* 81: 723-38; Shermoen and Kiefer, 1975, *Cell* 4: 275-80)

**alleles:** Many independent occurrences of *bb* have been recovered and designated without a superscript; consequently, alleles designated as *bb* are often unrelated. We redesignate Sturtevant's original *bb*<sup>5</sup> as *bb*<sup>1</sup>, but, given the propensity for *bb* alleles to change spontaneously and the ambiguities of labeling, it is unlikely that any particular *bb* stock contains the original allele. The same arguments apply to *Ybb* originally described by Bridges. The accompanying tables summarize the specifically desig-

nated *bb* alleles on both the *X* and the *Y* chromosomes.

 $\delta$  A regular product of *Rex*-induced mitotic exchange in progeny of crosses of *Rex*<sup>+</sup> or *Rex*/*Rex* females to *YSX*•*YL*/0 males; *X*/*Ybb<sup>Rex</sup>* males are fertile.

**cytology:** Shown to be to the right of 20E-F by Schalet and Lefevre [1976, Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, vol. 1b, pp. 848-902)]. The *bb* locus lies approximately in the center of the proximal heterochromatin and accounts for about one-third of its length, or about  $3.2 \times 10^6$  bp. The nucleolus organizer, located between heterochromatic regions *hB* and *hC* (Cooper, 1959), = *h29* of Gatti and Pimpinelli, and the rDNA are probably the same (Ritossa, Atwood, and Spiegelman, 1966). Presence of *bb*<sup>+</sup> on *Y* chromosome postulated by Burlingame and demonstrated by Stern (1927). This *bb*<sup>+</sup> is located on *YS* proximal to *ks-1* and *ks-2* (Kennison, 1981); it is located in the Hoechst-33258 dully fluorescing segment of *YS* designated *h20* by Gatti and Pimpinelli (1983, Chromosoma 88: 349-73). The rDNAs of the *X* and *Y* chromosomes combine to form a single nucleolus in which the rDNA components of each chromosome can be discerned by electron microscopy (Schultz, 1965, Brookhaven Symp. Biol. 18: 116-47).

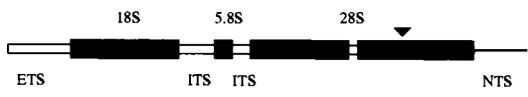

Positions of *X*-chromosome inversion breakpoints with respect to the rDNA. Thin line represents euchromatin and shaded box represents ribosomal DNA.

**molecular biology:** The *X* and *Y* chromosome *bb* loci each contain approximately 225 rRNA genes organized as a large tandem array of transcription units separated by nontranscribed spacers. (Ritossa *et al.*, 1966, Tartof, 1973, Genetics 73: 57-71). Copy number of *Y*-linked sequences varies over a six-fold range in *Y* chromosomes sampled from a natural population (Lyckegeard and Clark, 1989, Proc. Nat. Acad. Sci. USA 86: 1944-48). Sequences of nontranscribed spacers and external tran-

scribed spacers determined (Simeone, deFalco, Macino, and Boncinelli, 1982, Nucleic Acid Res. 10: 63-72; Simeone, LaVolpe, and Boncinelli, 1985, Nucleic Acid Res. 13: 1089-1101). There are three kinds of repeating units in the array as defined by digestion with the restriction enzyme, *EcoRI*. The first class is the functional 11-kb gene containing an external transcribed spacer followed by the sequence encoding 18S rRNA and then an internal transcribed spacer within which is the sequence encoding 5.8S rDNA; this is followed by the sequence encoding 28S rRNA, which is interrupted by a short transcribed spacer and finally there is a long non-transcribed spacer (White and Hogness, 1977, Cell 10: 177-92; Wellauer and David, 1977, Cell 10: 193-212; Pellegrini, Manning, and Davidson, 1977, Cell 10: 213-24). A second class is composed of repeats that contain a 0.5- to 5-kb insert known as Type I (White and Hogness; Wellauer and Dawid). The third class of repeats possesses a different insertion, Type II (Dawid, Wellauer, and Long, 1978, J. Mol. Biol. 126: 749-68). Type I and Type II insertions are located at different but nearby sites within the 28S coding region (Rioha, Miller, Woods, and Glover, Nature (London) 1981, 290: 749-53; see also Rae, 1981, Nucleic Acids Res. 9: 4997-5010). Type I and Type II containing genes appear to be transcriptionally inactive under normal conditions (Long and Dawid, 1979, Cell 18: 1185-96; Long, Rebert, and Dawid, 1980, Cold Spring Harbor Symp. Quant. Biol. 45: 667-72) and are intermingled at random with the noninsert-bearing genes throughout the array (Tartof and Dawid, 1976, Nature 263: 27-36; Hawley and Tartof, 1983, J. Mol. Biol. 163: 499-503). During magnification, however, all types of sequences appear to be transcribed (deCicco and Glover, 1983, Cell 32: 1217-25; Labella, Vicari, Manzi, and Graziani, 1983, Mol. Gen. Genet. 190: 487-93). The ribosomal genes of only one homolog are amplified in polytene nuclei of both males and females (Endow, 1980, Cell 22: 149-55).

A single rDNA gene is inserted ectopically into euchromatic locations by *P*-element transformation capable of high-level transcription in polytene chromosomes and micronucleolus formation; also able to partially alleviate effects of partial deletions of *bb* (Karpen, Schaefer, and Laird, 1988, Genes Dev. 2: 1745-63).

Map of basic repeating unit of ribosome DNA. Thick segments represent rDNA sequences; segments of intermediate width represent internal (ITS) and external (ETS) transcribed spacer sequences. Thin line represents non-transcribed (NTS) spacer sequences. Inverted triangle denotes positions of type I and type II inserts.

*X* and *Y* chromosome rDNA differ from each other in three important respects. (1) 65-70% of the *X* rDNA contains Type I-bearing genes (Wellauer, Dawid, and Tartof, 1978, Cell 14: 269-78). The *Y* contains type-I repeats detectable by *in situ* hybridization to metaphase chromosomes (Hatsumi and Endow, 1990); however, the major

type-I class is greatly reduced in amount in *Y* chromosomes (Tartof and Dawid, 1979, *Nature* 263: 27-30; Komma, Glass and Endow, 1990). (2) Yagura, Yagura, and Muramatsu (1979, *J. Mol. Biol.* 133: 533-47) showed that the 18S RNA transcribed from *X* rDNA differs from that of the *Y* by at least one base substitution. (3) Coen, Thoday, and Dover (1982, *Nature* 295: 564-68) found that the 5' end of the nontranscribed spacer is different in *X* and *Y* rDNA. These data indicate that there is little, if any, interchange of rDNA between *X* and *Y* chromosomes. However, rDNA is apparently responsible for regular pairing and segregation of *X* and *Y* chromosomes in males (McKee and Karpen, 1990, *Cell* 61: 61-72).

**other information:** Exchange between *Xh* and the *Y* chromosome at the bobbed locus results in *YSXh* and *X·YL* products that arise at a frequency of about  $2 \times 10^{-4}$  (for review, see Lindsley, 1955, *Genetics* 40: 24-44; Hawley and Tartof, 1983, *Genetics* 104: 63-80). Orientation of the *X* rDNA cluster has no effect on the frequency of exchange (Maddern, 1981, *Genet. Res.* 38: 1-7). Similar events occur in females [Williamson and Parker, 1976, *Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Vol. 1b, pp. 701-20]. Recombination events involving rDNA sequences of *X* chromosomes and *X* and *Y* chromosomes investigated using restriction-fragment-length polymorphisms (Williams, Kennison, Robbins, and Strobeck, 1989, *Genetics* 122: 617-24).

### **Bb: Bubble**

**location:** 1- (not located) or 3-48.

**origin:** X ray induced.

**discoverer:** R. L. King, 32d.

**synonym:** *Balloon*.

**phenotype:** Wings of heterozygous female smaller, trimmed, and inflated. Bubble in first posterior cell. In extreme cases and usually in males, the wing is a small inflated sac. Sexual difference in expression may indicate that *Bb* is on the *X*. Female fertile; male entirely sterile; therefore, homozygous females not obtainable. RK3A.

**cytology:** Associated with *T(1;3)Bb = T(1;3)13E;84F* (Morgan, Bridges, and Schultz, 1937, *Year Book - Carnegie Inst. Washington* 36: 301).

### **BB: Bar + Bar**

**origin:** Spontaneous through unequal crossing over in *B/B* (see description of *B*).

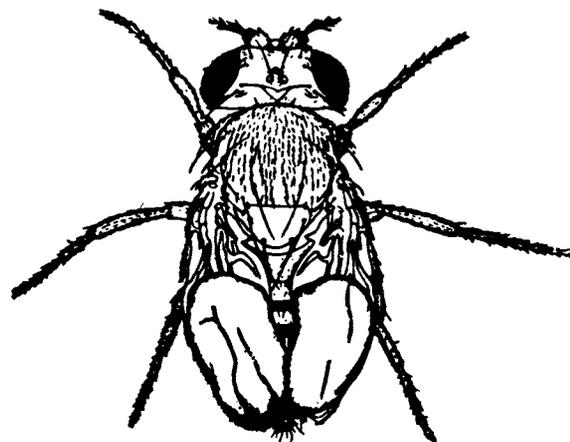

**discoverer:** Zeleny.

**synonym:** *Bar double*; *Ultra-bar*; *double Bar*.

**references:** 1920, *J. Exp. Zool.* 30: 292-324 (fig.).

Sturtevant, 1925, *Genetics* 10: 117-47 (fig.).

**phenotype:** Eye more reduced than in *B*. Facet numbers are 25, 29, and 45 in *BB/BB* female, *BB* male, and *BB/+* female, respectively. Median ocellus lacking or strongly

**Bb: Bubble**

From Bridges and Brehme, 1944, *Carnegie Inst. Washington Publ. No. 552*: 23.

reduced (Lefevre, 1941, *DIS* 14: 40). Optic disc reduced (Power, 1942, *Genetics* 27: 161); deep cleft anteriorly; cell clusters at cleft look mature (Renfranz and Benzer, 1989, *Dev. Biol.* 136: 411-29). RK1A.

**alleles:** Different alleles of *B* that are not involved in gross chromosome aberrations can be combined in all pair-wise combinations by means of unequal crossing over in heterozygous females. Described combinations are *\*BB<sup>i</sup>*, *\*B<sup>i</sup>B*, and *B<sup>i</sup>B<sup>i</sup>* (Sturtevant, 1925, *Genetics* 19: 117-47); *\*B<sup>i40b</sup>B<sup>i40b</sup>* (Steinberg, 1942, *DIS* 16: 53); *\*BB<sup>3</sup>*, *BB<sup>36b</sup>*, and *BB<sup>L</sup>* (Muller).

**cytology:** Associated with a tandem triplication of the region duplicated in *Dp(1;1)B = Dp(1;1)15F9-16A1;16A7-B1* [Bridges, 1936, *Science* 83: 210-11 (fig.)].

### **Bc: Black cells**

**location:** 2-80.6.

**origin:** Induced by ethyl methanesulfonate.

**references:** Grell, 1969, *DIS* 44: 46.

Rizki, Rizki, and Grell, 1980, *Wilhelm Roux's Arch. Dev. Biol.* 188: 91-99 (fig.).

**phenotype:** Quadrate crystalline bodies in crystal cells of hemolymph replaced by amorphous melanotic mass. Black cells appear in 11-hour embryos in *Bc/Bc* and in late first-instar larvae in *Bc/+*. Crystal cells replaced by black cells during first instar in *Bc/+*. Numerous black cells visible through the integument of larvae, pupae, and of head, thorax, and abdomen in adults. *Bc/Bc* larvae have no phenol oxidase activity and larval hemolymph fails to darken upon exposure to air; *Bc/+* intermediate between *+/+* and *Bc/Bc* in these respects. *Bc/Bc* adults viable and fertile when separated from a closely linked simultaneously recovered lethal. RK1 in larvae; RK2 in pupae and adults.

**cytology:** Placed in 55A based on its inclusion in *Df(2R)PC4 = Df(2R)55A;55F* but not *Df(2R)Pd-w5 = Df(2R)55A-B;55C* (Deng and Rizki, 1988, *Genome* 30, Suppl. 1: 192).

**other information:** Suppressed by some *lz* alleles (Rizki and Rizki, 1981, *Genetics* 97: s90). *Dox-A1* and *Phox* reside in the same cytological interval.

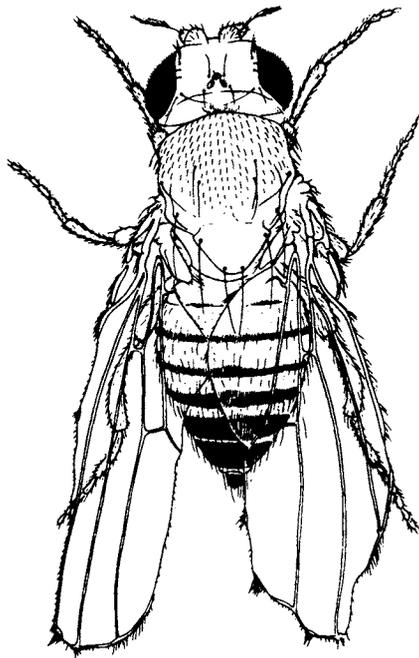

**bch: branch**

**location:** 3-46 (approximately).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Jürgens, Wieschus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.  
**phenotype:** Homozygous lethal; incomplete fusion of denticle bands.

*bd*; see *ra*<sup>2</sup>

**\*bd: balding**

**location:** 2-56.1 (between *Bl* and *L*).  
**origin:** Spontaneous.  
**discoverer:** Ives, 71j25.  
**synonym:** *bald* (preoccupied).  
**references:** 1972, DIS 49: 38.  
**phenotype:** Semicircular, medial bald spot on thorax, about one-third width of thorax. Very little variation at 25°. RK1.

**Bd: Beaded**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 152.

**Bd: Beaded**

**location:** 3-91.9 [based on 102 *ro-ca* and 182 *Pr-ca* recombinants in crosses involving *Bd*<sup>S</sup> (Curry, 1939, DIS 12: 46)].  
**references:** Dexter, 1914, Am. Nat. 48: 712-58.  
 Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 37, 152 (fig.).  
 Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 45.  
 Fleming, Scottgale, Diederich, Artavanis-Tsakonas, 1990, (manuscript).  
**phenotype:** Originally recovered alleles were recessive lethal with a dominant incised-wing phenotype; *Bd*<sup>1</sup> was very weak and highly variable when first recovered, but

gained expressivity with selection; subsequently isolated alleles were stronger. Wings reduced by marginal excision both anteriorly and posteriorly. Phenotype of *Bd*<sup>1</sup>/*Bd*<sup>1</sup>/+ extreme (Peter Lewis). Expression and interaction studied by Goldschmidt and Gardner [1942, Univ. Calif. (Berkeley) Publ. Zool. 49: 103-24]. Expression of *Bd*<sup>1</sup>, *Bd*<sup>3</sup>, and *Bd*<sup>S</sup> suppressed by *H* (DIS 9) and *Ax* alleles (Bang). In combination with several different Minutes, causes incomplete development of anal and genital imaginal discs in males and less frequently in females (Goldschmidt, 1948, Proc. Nat. Acad. Sci. USA 34: 245-52; Sturtevant, 1949, Proc. Nat. Acad. Sci. USA 35: 311-13). *Bd*<sup>S</sup> (originally designated *Ser: Serrate*) homozygous viable; initially thought to be homozygous lethal, but lethality removable by recombination (Belt, 1971, DIS 46: 116). The closely linked recessive lethal persists in many *Bd*<sup>S</sup>-bearing chromosomes. Recessive lethal alleles, which lack the dominant wing phenotype, recovered as revertants of *Bd*<sup>S</sup> (symbolized *Bd*<sup>Srv</sup>) or selected on the basis of their failure to complement the lethality of *Bd*<sup>3</sup> (symbolized *Bd*<sup>r</sup>). Allelism of *Bd*<sup>r1</sup> (originally designated *std: serratoid*) inferred from enhanced wing incising in heterozygotes with *Bd*<sup>S</sup> and genetic map position similar to that of *Bd*<sup>S</sup>; homozygous viability unknown. Cuticle preparations of embryos homozygous for *Bd*<sup>S</sup> revertants reveal lack of germband retraction, improper deposition of cuticle, lack of head and thoracic structures, lack of Filzkörper, and in severe cases, only a remaining patch of cuticle (either ventral or dorsal). Central-nervous-system defects revealed by anti-horseradish peroxidase preparations include breaks in the longitudinal and/or commissure nerve tracts, twisted or unretracted nerve tracts, only a single nerve tract, and occasionally only the presence of groups of staining cells scattered throughout the embryo (Fleming, *et al.*). Each *Bd*<sup>Srv</sup> allele displays the whole range of embryonic phenotypes but the proportions of individuals with a particular phenotype varies between alleles.

Genet. 2: 45; 11 = Ohnishi, 1950, DIS 24: 61.

<sup>β</sup> More detailed description follows.

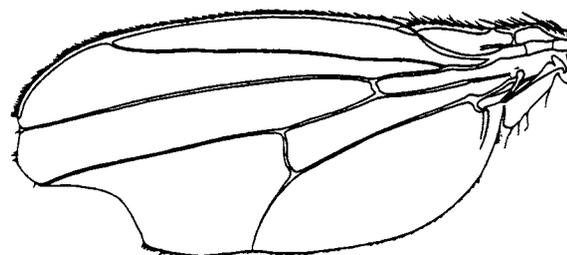

**cytology:** Placed in 97F by *T(2;3)Bd<sup>Srv3</sup>* = *T(2;3)56E;97F*, *In(3R)Bd<sup>Srv2</sup>* = *In(3R)97F;98C*, *Df(3R)Ser* = *Df(3R)97D;97F-98A1*, and *T(Y;3)128* = *T(Y;3)97F;YS*. Also *in situ* chromosomal studies displayed hybridization at 97F.

**molecular biology:** An 85 kb walk and Southern analysis showed that *Bd<sup>G</sup>* and *Bd<sup>S</sup>* contain molecular lesions in the 97F region (*Bd<sup>S</sup>* contains a 5.5 kb repeated DNA sequence, and *Bd<sup>G</sup>* has a complex rearrangement). Two major transcripts of 5.5 and 5.6 kb appear to differ at their 5' ends. Sequencing of two overlapping cDNAs produced a sequence of 5561 base pairs that contained a large open reading frame of 4329 nucleotides. Conceptual translation indicates a protein of 1404 amino acids that contains a signal peptide, a region of sequence homology to the neurogenic locus *Delta*, a partial EGF-like repeat, 14 EGF-like repeats with interruptions in the 4th, 6th, and 10th repeats, a transmembrane domain, and an intracellular domain of ~160 amino acids. Analyzing whole mount *in situs* using probes that recognize both transcripts, revealed a complex and dynamic pattern of embryonic mRNA expression in the head segments; the dorsal, ventral, and lateral epidermis in the thorax and abdomen; the proventriculus, and hindgut; the trachea; and a reiterated array of cells in the CNS. Expression appears to be limited to tissues of ectodermal origin (Fleming *et al.*, 1990).

**other information:** *Bd/In(3R)C*, *l(3)a* was the first described case of a balanced lethal [Muller, 1918, Genetics 3: 422-99 (fig.)].

### *Bd<sup>S</sup>*: Beaded-Serrate

**phenotype:** Wings of *Bd<sup>S/+</sup>* and *Bd<sup>S/Df(3R)Ser</sup>* notched at tip; deepest notch at second posterior cell. In triploids, one dose of *Bd<sup>S</sup>* overlaps wild type. *Bd<sup>S</sup>* is homozygous viable; initially thought to be homozygous lethal, but lethality removable by recombination (Belt, 1971, DIS 46: 116); the closely linked recessive lethal persists in

### *Bd<sup>S</sup>*: Beaded-Serrate

Edith M. Wallace, unpublished.

many *Bd<sup>S</sup>*-bearing chromosomes. Homozygous *Bd<sup>S</sup>* produces extreme incision of wing margins especially in second posterior cell (Belt, 1971). As with other *Bd* alleles expression suppressed by *H* and *Ax* (Bang).

*bdw*: see *os<sup>bdw</sup>*

### \**be-3*: benign tumor in chromosome 3

**location:** 3-25.

**origin:** Spontaneous.

**discoverer:** Stark, 16k.

**references:** 1919, Proc. Nat. Acad. Sci. USA, 5: 573-80 (fig.).

Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 179 (fig.).

Stark and Bridges, 1926, Genetics 11: 249-66.

Stark, 1935, DIS 4: 62.

**phenotype:** Melanotic tumors appear in larvae and persist in adults. Subject to modification by genetic factors. Nonlethal. RK3.

**Beaded:** see *Bd*

**Beadex:** see *Bx*

**Beadexoid:** see *Bxd*

**Bearded:** see *Brd*

**bef:** beta lobes fused

**location:** 1- (not located).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *bef<sup>BG17b</sup>*.

**references:** Heisenberg, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.), pp. 373-90.

**phenotype:** Beta lobes of mushroom bodies (in anterior supraesophageal ganglion) are fused across midline. Mutant isolated on basis of this morphological defect in strain with aberrant visual responses and optic lobes, but genetic etiology of aberrant mushroom bodies is apparently separable from X-chromosome factor(s) causing the visual defects.

**bel:** belle (M.T. Fuller)

**location:** Just proximal to *p*.

**synonym:** *l(3)L3; ms(3)neo30*.

**references:** Bender, Turner, and Kaufman, 1987, Dev. Biol. 119: 418-32.

Jones and Rawls, 1988, Genetics 120: 733-42.

Deuring, Wolf, Schuske, Cooley, Spradling, and Fuller, (unpublished).

**phenotype:** Recessive larval lethal. Homozygous null individuals hatch, but remain as first instar larvae until their death several days later.

allele	synonym	origin	ref <sup>α</sup>	phenotype
<b>bel<sup>1</sup></b>	EMS	belle <i>b3</i>	1	larval lethal
<b>bel<sup>2</sup></b>	EMS	belle <i>b10</i>	1	larval lethal

<b>bel<sup>6</sup></b>	EMS	belle <i>pr134</i>	1	larval lethal
<b>bel<sup>7</sup></b>	P	<i>ms(3)neo30</i>	2	male sterile <sup>β</sup>

<sup>α</sup> 1 = Bender, Turner, and Kaufman, 1987, Dev. Biol. 119: 418-32; 2 = Deuring, Wolf, Schuske, Cooley, Spradling, and Fuller, (unpublished).

<sup>β</sup> Male sterile with defects in meiosis and spermatid differentiation. Hemizygotes are more extreme than homozygotes, and poorly viable if raised at 18°. Female fertile, but hemizygous females sterile and produce eggs with weak chorion.

**cytology:** Placed in region 85A4-6 on the basis of the position of the P-element insert in *bel<sup>7</sup>*, and on the basis of being uncovered by *Df(3R)p7* but not *Df(3R)p5*.

**molecular biology:** The 4 kb *bel* transcript is present in unfertilized eggs, embryos, larvae, pupae, and adult males and females; it encodes a protein of 781 amino acids with a central core region of 414 residues that is highly homologous to *vasa* (Deuring *et al.*, unpublished). Based on this core homology, the *bel* gene product is a member of the DEAD box family and is likely to be a nucleic-acid-dependent ATPase.

**bellyache:** see *bly*

**ben:** *bendless* (J. Hall; R. Wyman)

**location:** 1-45.0 (1.2 cM to the left of *na*).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *nj-262*; *nonjumper-262*.

**references:** Thomas, 1980, Neurosci. Abstr. 6: 742.

Thomas and Wyman, 1982, Nature (London) 298: 650-51.

Thomas and Wyman, 1983, Cold Spring Harbor Symp. Quant. Biol. 48: 641-53.

1984, J. Neurosci. 4: 530-38.

**phenotype:** Adults have an aberrant startle response; they do not jump when presented with a lights-off stimulus. The cervical giant fiber, a brain neuron, has abnormal morphology. The normal giant fiber terminates in the thorax at a synapse onto the motoneuron innervating the tergo-trochanteral (TT) muscle (= jump muscle). In *ben*, this synapse is abnormal or absent. The normal lateral bend of the giant fiber toward the TT motoneuron in the mesothoracic neuromere is absent; the axon usually terminates at the midline with fine branches extending from its tip. Latency of response of the TT muscle to stimulation of the giant fiber is abnormally long, and muscles cannot follow stimulation at rates above 5 Hz. Rhabdomeres of the photoreceptor cells in the ommatidia heart shaped in cross section with indentation centrally oriented rather than round as is normal. Furthermore, the axons from photoreceptor cells R7 and R8 fail to make the right-angle turn into the optic medulla after traversing the lamina (Benzer). *ben* flies choose visible over ultraviolet wave lengths whereas wild-type flies make the opposite choice (Benzer).

**alleles:** Six ethyl-methanesulfonate-induced alleles; all are jumpless; all but *ben<sup>1</sup>* have normal giant-fiber physiology (Tanouye).

allele	discoverer	synonym

<b>ben<sup>5</sup></b>	Tanouye	<i>ben<sup>1561</sup></i>
<b>ben<sup>6</sup></b>	Tanouye	<i>ben<sup>1682</sup></i>

**other information:** *ben/Df(1)HA92* said to be indistinguishable from *ben/ben*, indicating that the mutation is amorphic (Thomas and Wyman, 1983).

**cytology:** Located within salivary gland chromosome region 12A6-B based on its inclusion in *Df(1)HA92 = Df(1)12A6-7;12D3* (Thomas and Wyman, 1984), but not the segmental deficiency *Y<sup>P</sup>X<sup>D</sup>B166/X<sup>P</sup>Y<sup>D</sup>B89 = Df(1)12A-B;12B9-C1* (Tanouye).

*ben(2)gcn*: see *bgn*

*bending wings*: see *os<sup>bdw</sup>*

**bendless:** see *ben*

**benign gonial cell neoplasm:** see *bgn*

**benign tumor in chromosome 3:** see *be-3*

**bent:** see *bt*

**bent scutellars:** see *bsc*

**\*ber:** *berrytail*

**location:** 1-52.4.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 67.

**phenotype:** Abdomen narrow, ending in a berry-like protrusion carrying defective genitalia. Wings opaque, with areas of deranged hairs (some with cut inner margins and interrupted or abnormally positioned longitudinal veins). Anterior scutellars often acutely bent; eyes occasionally misshapen. Males sterile and viability about 40% wild type. RK3.

*Bercel*: see *Fs(3)Sz4*

*beta*: see *Tyr2*

**beta lobes fused:** see *bef*

**bf:** *brief*

**location:** 3-95.

**origin:** Spontaneous.

**discoverer:** Curry, 38i3.

**references:** 1939, DIS 12: 45.

**phenotype:** Fly small; bristles Minute like. Classification perfect; viability fair. Male completely sterile; female with low fertility. RK3.

**Bg:** *Bag*

**location:** 1-51.6 (to the right of *sd*).

**origin:** Spontaneous.

**discoverer:** Bridges, 33d22.

**phenotype:** Heterozygous female with wings shorter and blunter, shortened L5, extra veins or gaps near anterior

crossvein, and inflated bag centering in first basal cell. Frequently overlaps wild type. Lethal in male. RK2 as a lethal; RK3 as a dominant.

**alleles:** Lost alleles described in CP627: \**Bg*<sup>1</sup>, \**Bg*<sup>2</sup>, \**Bg*<sup>49h</sup>, and \**Bg*<sup>52c</sup>.

**cytology:** Probably in 13C, based on *Bg*-like variegation of  $Tp(1;3)ras^v = Tp(1;3)9E;13C;81F$ .

**other information:** Possibly an allele of *Bb*, although published information suggests that *sd* lies between *Bb* and *Bg*.

### ***bgn*: benign gonial cell neoplasm**

**location:** 2- (between *dp* and *b*).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *ben(2)gcn*.

**references:** Gateff, 1981, DIS 56: 191.

**phenotype:** Gametocyte differentiation defective; gonial proliferation unchecked; gonads of both males and females become engorged with gonial cells. Ovarioles appear sausage like; testes smaller than normal. Autonomous in transplants of young adult ovaries and testes into body cavity of wild-type females.

### ***bh*: baldhead**

**location:** 3-81.

**origin:** Spontaneous.

**references:** Robertson, 1973, DIS 50: 24 (fig.).

**phenotype:** Ocelli and associated bristles absent; wings shortened. Both sexes sterile.

### ***bhe*: broad head (C. Nüsslein-Volhard)**

**location:** 2-0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**phenotype:** Embryonic lethal; embryos have incompletely involuted heads. In double mutants with *Pc*-like mutants, abdominal transformations occur. At least one *bhe* allele fails to complement *l(2)gl*, which is a larval lethal (Kennison).

**alleles:** *bhe*<sup>1</sup> (formerly *bhe*<sup>1J</sup>) and *bhe*<sup>2</sup> (formerly *bhe*<sup>1M</sup>).

**cytology:** Placed in 21A on basis of being covered by terminal 2L duplications that cover *l(1)gl*.

### ***bi*: bifid**

**location:** 1-6.9.

**discoverer:** Morgan, 11k.

**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 28 (fig.).

**phenotype:** Longitudinal veins fused at base of wing into bifid stalk. L3 delta-like at tip; L4 often incomplete at tip. Wing margins often excised at tip of L4. Wings spread in proportion to their shortness. High temperature enhances and low temperature produces overlapping of wild type. Stronger in male than in female. Hypomorphic allele; females heterozygous for *bi* and a deficiency for *bi* have outspread, crumpled, and very flimsy wings with an extreme bifid fusion of the basal regions of the longitudinal wing veins (Craymer and Roy, 1980, DIS 55: 204). Enhances *Bx* alleles as well as *sd*, *cp*, and *vg*<sup>np</sup> (Waletzky). RK1.

**alleles:** \**bi*<sup>35</sup> (CP627).

**cytology:** Placed in 4C5-6 based on its inclusion in  $Df(1)rb13 = Df(1)4C5-6;4D3-E1$  but not in  $Df(1)GA56 = Df(1)4C5-6;4D1$ , as well as the *bi* phenotype of

$T(1;2)bi^{D2} = T(1;2)4C5-6;46B5-7$  and  $T(1;3)bi^{D1} = T(1;3)4C5-6;65C3-5$ . (Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, Chromosoma 93: 341-46).

### ***bib*: big brain**

**location:** 2-34.7.

**references:** Lehmann, Dietrich, Jiménez, and Campos-Ortega, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 226-29.

Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 62-74.

**phenotype:** Recessive embryonic lethal, a neurogenic mutant. Homozygotes fail to form ventral, lateral, and most of the cephalic epidermis. Central nervous system hypertrophied by recruitment of presumptive epidermal cells, but exhibiting considerable architectural normality. Most epidermal sense organs can be recognized in electron microscope preparations; chordotonal organs prevalent but with abnormal structures, perhaps owing to disrupted attachment. Supernumerary peripheral elements formed by recruitment of presumptive epidermal cells [Hartenstein and Campos-Ortega, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 210-21 (fig.)]. Cuticular clones of cells homozygous for *bib*<sup>1</sup> or *bib*<sup>6</sup> exhibit normal development (Dietrich and Campos-Ortega, 1984, J. Neurogenet. 1: 315-32). Effects on central nervous system intermediate with respect to mutations at other neurogenic loci. Insensitive to changes in dosage of other neurogenic genes (de la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, Genetics 118: 499-508).

**alleles:** Eight alleles with similar phenotypes.

allele	origin	discoverer	synonym	ref <sup>α</sup>
<i>bib</i> <sup>1</sup>	EMS	Nüsslein-Volhard and Wieschaus	<i>bib</i> <sup>ID05</sup>	1, 2, 3

<i>bib</i> <sup>7</sup>	X ray	Campos-Ortega	<i>bib</i> <sup>FX1</sup>	3
<i>bib</i> <sup>8β</sup>	X ray	Lehmann	<i>bib</i> <sup>C7A</sup>	3

<sup>α</sup> 1 = Dietrich and Campos-Ortega, 1984, J. Neurogenet. 1: 315-32; 2 = Hartenstein and Campos-Ortega, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 210-21 (fig.); 3 = Lehmann, Jiménez, Dietrich and Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 190: 226-29.

<sup>β</sup> Associated with *In(2L)30A9;30F*.

**cytology:** Placed in region 27D-31E based on the lethal phenotype of the deficient segregant from  $T(Y;2)B231$  in combination with *bib*.  $In(2L)bib^8 = In(2L)30A9;30F$  further restricts position to 30A9-F (Campos-Ortega).

**molecular biology:** Gene cloned and sequenced; conceptual amino-acid sequence indicates a gene product with 700 amino acids. The predicted *bib* product shows significant sequence similarity to a family of transmembrane proteins, some of which form channels permeable to small molecules (Rao, Jan, and Jan, 1990, Nature 345: 163-67).

***bic*: bicaudal**

**location:** 2-67.0 (inferred from cytological position; maps to 68 with respect to *Bl* and *L*, but penetrance problems introduce uncertainty).

**origin:** Spontaneous.

**references:** Bull, 1966, J. Exp. Zool. 161: 221-42 (fig.).

Nüsslein-Volhard, 1977, Wilhelm Roux's Arch. Dev. Biol. 183: 249-68 (fig.).

1979, Symp. Soc. Dev. Biol. 37: 185-211 (fig.).

**phenotype:** Homozygous *bic* females produce variable numbers of eggs that fail to hatch (e.g., 25-50%). *bic/Df(2R)vg<sup>B</sup>* females produce higher embryonic mortality. Males of either genotype are normal. A wide array of developmental anomalies observed among arrested embryos. Many fail to show outward signs of initiation of development, although in at least some zygotes nuclear divisions can be demonstrated. Others show replacement of anterior embryonic segments by a mirror-image set of posterior segments. The majority of these bicaudal embryos are symmetrical with opposing sets of the two to five posterior-most segments; mirror-imaged structures include denticle belts, posterior spiracles, Malpighian tubules, genital disc, and posterior midgut invagination. Polar cells form at the original but not the duplicated posterior end. Asymmetrical bicaudal embryos such as 3/6 or 3/7 have fewer duplicated than original posterior segments. Other embryos have the head replaced by posterior abdominal structures or show abnormal development of the cephalopharyngeal apparatus. Finally, some embryos are foreshortened and seem to lack internal segments. Maximum production of bicaudal embryos occurs in the first eggs produced by females developing at 28°-29°. The incidence of bicaudal embryos falls rapidly during the first 60 hr after eclosion. Incidence of bicaudal embryos and nondeveloping eggs depends on genotype: *bic/Df(2R)vg<sup>B</sup>* > *bic/Df(2R)vg<sup>D</sup>* > *Df(2R)vg<sup>B</sup>/+* > *bic/bic* > *bic/+* = 0.

**alleles:** *bic<sup>44</sup>* (Basel).

**cytology:** Placed between 49D3 and 49E6 based on the absence of normal allele in *Df(2R)vg<sup>B</sup>* = *Df(2R)49D3-4;50A* and *Df(2R)vg<sup>D</sup>* = *Df(2R)49C1-2;49E2-6*.

***BicC*: Bicaudal C**

**location:** 2-52.0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Jürgens, 1982, Verh. Dtsch. Zool. Ges. 91-104.

Mohler and Wieschaus, 1986, Genetics 112: 803-22.

**phenotype:** A maternal-effect semilethal; the majority of embryos produced by *BicC/+* mothers given rise to normal larvae a minority fail to hatch and vary in phenotype. Double-abdomen embryos have a normal posterior end and the anterior end replaced by mirror image series of posterior segments, e.g. A8-A4|A4-A8 to A8-A6|A6-A8; they need not have the same number of segments on either side of the reversal of polarity, the duplicated portion having fewer segments; generally more segments seen ventrally than dorsally. Less severely affected embryos may be headless, or with reduced mouth parts, or even normal appearing but failing to hatch. The incidence and severity of abnormal embryos vary with genetic background and temperature, the incidence being highest at 25° and decreasing at lower and higher temperatures. The majority of the embryos produced by

*BicC/BicD* trans heterozygotes are abnormal. Homozygotes are abnormal. Homozygous *BicC* females sterile, germ-cell differentiation blocked at the beginning of vitellogenesis. Follicle cells do not invade between oocyte and nurse cells; they do synthesize a chorion which remains open ended like a chalice or a cup; such eggs never fertilized.

**alleles:** Five ethyl-methanesulfonate-induced alleles; *BicC<sup>3</sup>* and *BicC<sup>5</sup>* more severe than the others.

**cytology:** Placed in 35D4-E6 based on the sterility of females carrying *BicC* and heterozygous for *Df(2L)osp29* = *Df(2L)35B3;35E6* but not *Df(2L)75c* = *Df(2L)35A1-2;35D4-7* (Mohler and Wieschaus).

***BicD***

**location:** 2-52.91 (to the right of *dl*; based on an estimated four recombinants between *dl* and *BicD* out of 4,000 tests).

**references:** Nüsslein-Volhard, Wieschaus, and Jürgens, 1982, Verh. Dtsch. Zool. Ges. 91-104.

Mohler and Wieschaus, 1986, Genetics 112: 803-22.

Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78.

Suter, Romberg, and Steward, 1989, Genes Dev. 3: 1957-68.

Wharton and Struhl, 1989, Cell 59: 881-92.

**phenotype:** A maternal-effect semilethal; substantial numbers of embryos produced by *BicD/+* mothers give rise to normal larvae; the remainder fail to hatch and vary in phenotype. The array of phenotypes encountered is the same as that produced by *BicC/+* females. The incidence and severity of abnormal embryos vary with genetic background and temperature, the incidence being highest at 18°, and decreasing at higher temperatures. *BicD* homozygotes, either homoallelic or heteroallelic, and *BicC/BicD* heterozygotes are female fertile, although producing eggs with fused or reduced chorionic appendages; the majority of their embryos are abnormal and the influence of temperature, if any, obscure. *BicD/+* duplication-bearing females produce few if any abnormal embryos, whereas *BicD/Df(2L)TW119* females produce more abnormal embryos than *BicD/+*, i.e., with respect to the severity of phenotype, *BicD/0* > *BicD/+* > *BicD/+* > *BicD/+*; however, simply a deficiency of *BicD* product does not account for the abnormal phenotype, since embryos produced by females carrying one dose of *BicD<sup>+</sup>* over a deficiency develop normally. Embryos produced by homozygous *BicD* females display symmetrical patterns of *cad<sup>+</sup>* polypeptide distribution during early development (Mlodzik and Gehring, 1987, Cell 48: 465-78).

Abnormal embryo production by *BicD/+* females enhanced by the heterozygosity for the mutant allele of or deficiency for *l(2)49*; Mohler and Wieschaus speculate that *l(2)49* is an allele of *bic*. In addition, eg, *stau*, *tor*,

and *trk*, maternal-effect mutants that affect early anterior but not posterior development, act as dominant enhancer of *BicD*; other maternal-effect mutants ineffective.

Bicaudal embryos exhibit nanos protein at both anterior and posterior poles and the absence of hunchback protein in both ends of the embryo; embryos produced by *BicD*<sup>1</sup>/*BicD*<sup>2</sup>;*osk/osk* females do not express *nos*; display a burst of anterior, *bcd*-dependent *hb* expression not seen in bicaudal embryos, which is correlated with a dramatic expansion of *kni* expression (abdominal) and failure to express *Kr* (thorax and anterior abdomen). *BicD* expressed early in oogenesis; in wild type, protein first appears in the cytoplasm of all cells in 16-cell cysts in the middle of the germarium; upon entering the vitellarium, protein begins to accumulate in the oocyte and continues to do so for as long as observations are possible. The early embryos produced by such females show uniform distribution of *BicD* protein, which becomes localized to the cortical cytoplasm at blastoderm formation; anterior-to-posterior distribution remains uniform. Protein disappears at gastrulation. In *BicD*<sup>1</sup>/*BicD*<sup>2</sup> females protein accumulation in the oocyte is precocious and greater than normal and the adjacent nurse cells may become visibly depleted; in the embryo, the protein appears to be concentrated as a cap over the anterior third and uniformly less concentrated in the remainder of the embryo. *BicD*<sup>rv1</sup> females display extreme concentration of product in the presumptive oocyte and virtually none in the nurse cells; however, the presumptive oocyte never develops as an oocyte but remains nurse-cell like until the cyst degenerates.

**alleles:**

<sup>α</sup> 1 = Mohler and Wieschaus, 1986, Genetics 112: 803-22; 2 = Suter, Romberg, and Steward, 1989, Genes Dev. 3: 1957-68. 3 = Wharton and Struhl, 1989, Cell 59: 881-92.

**cytology:** Placed in 36C2-D1 based on its inclusion in *Df(2L)TW137 = Df(2L)36C2-4;37B9-C1*, but not *Df(2L)VA18 = Df(2L)36C4-D1;37C2-D1* (Steward and Nüsslein-Volhard).

**molecular biology:** The gene has been cloned and sequenced (Suter, Romberg, and Steward, 1989, Genes Dev. 3: 1957-68; Wharton and Struhl, 1989, Cell 59: 881-92); identified by transformation rescue of *BicD*<sup>rv1</sup> female sterility. Two transcripts found in early embryos of 3.6 and 4.0 kb (Wharton and Struhl; 3.8 and 4.4 kb according to Suter *et al.*), which differ only in their 3' untranslated regions; transcription occurs from right to left. Gene contains at least eight exons; encodes a polypeptide of 782 amino acids and ~89 kd molecular mass; pI = 4.93. Sequence similar to that of the C-terminal half of myosin-heavy-chain polypeptides, and similar coiled-coil molecules, which contain long α helices that form double- or triple-chain coils. These species contain an underlying heptad amino-acid repeat in which residues one and four are generally hydrophobic; about

half of the *BicD* protein comprises such heptad repeats.

**other information:** Mohler and Wieschaus describe a polygenic strain, designated YC67 that parallels the behavior of *BicD* in all respects except that it is unmappable.

**BicF**

**location:** 3- (unmapped).

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Dominant maternal effect giving bicaudal embryos in some genetic backgrounds (*e.g.*, with *ln(2LR)O*, *Cy l(2)DTS513*). High temperatures and short egg shape may enhance this effect. Homozygous phenotype is probably collapsed eggs.

**bie: bientot (T. Schüpbach)**

**location:** 2-97.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect female-sterile mutant; homozygous females lay eggs which show no visible signs of development when observed under transmitted light in a stereo microscope. These eggs are defective in fertilization or very early embryonic development. *bie*<sup>PV</sup> sometimes gives rise to embryos which form irregular blastoderms and develop abnormally, producing fragmented pieces of cuticle.

**alleles:** Three, *bie*<sup>1</sup> - *bie*<sup>3</sup> isolated as *RD*, *PV*, and *SD*, respectively.

**bifid:** see *bi*

**big brain:** see *bib*

**Billa:** see *Fs(2)Sz2*

**bip: bipolar oocyte**

**location:** 3-10.

**origin:** Induced by ethyl methanesulfonate.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Female sterile; no eggs laid. Oocytes often have nurse-cell clusters at both ends (15 nurse cells altogether). Mature oocytes can have micropiles at both ends, no dorsal appendages and no polarity.

**bis: bistre**

**location:** 1-21+ (T. K. Johnson).

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)aminophenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 67.

**phenotype:** Very dark brown eye color; ocelli also dark.

Wings frequently unexpanded. Males sterile, but homozygous females fertile (T. Johnson). Viability varies from less than 10% to 70% wild type. RK2A.

**cytology:** Placed between 7B5 and 9 by Lefevre.

**\*Bit: Bitten**

**location:** 3- (not located; crossing over between *ru* and *th* almost completely suppressed).

**origin:** X ray induced.

**discoverer:** Lefevre, 48g5.

**references:** 1949, DIS 23: 58.

**phenotype:** Inner margin of wing indented. Wings, nor-

mally folded, appear to have had a bite taken out of the back. Marginal hairs present unlike *N* and *ct*. Flight is impeded, although little wing area lost. Homozygous lethal. RK1A.

**cytology:** Associated with *In(3L)Bit*; breakpoints not determined.

**bithorax:** see *bx* under *BXC*

**Bithoraxlike:** see *Ubx* under *BXC*

**bithoraxoid:** see *bx* under *BXC*

**Bitten:** see *Bit*

**\*bk: buckled**

**location:** 1-59.8.

**origin:** Induced by *p*-N,N-di-(2-chloroethyl)aminophenylethylamine (CB. 3034).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 83.

**phenotype:** Wings slightly altered in shape and frequently divergent; membranes warped between longitudinal veins. Veins slightly thickened at wing margins. Eye shape slightly altered. Scutellar bristles frequently abnormal, either inserted in base atypically, bent, or duplicated. Males viable and fertile. RK3.

**alleles:** \**bk*<sup>2</sup> (CP627).

**Bkd: Blackoid**

**location:** 2-65 (Braun).

**origin:** Spontaneous.

**discoverer:** Goldschmidt, 1938.

**phenotype:** Body color black in homozygote, distinctly darker than wild type in heterozygote. RK2.

**alleles:** \**Bkd*<sup>1</sup> (spontaneous, Goldschmidt, 1938); *Bkd*<sup>M</sup> (induced by ethyl methanesulfonate + formaldehyde, Marsh and Mack, 1985, DIS 61: 214); allelism of *Bkd*<sup>M</sup> inferred from phenotype and position between *cn* and *c*.

**\*bkl: buckledlike**

**location:** 1-59.9.

**origin:** Induced by *D*-*p*-N,N-di-(2-chloroethyl)aminophenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 83.

**phenotype:** Wings slightly divergent with membranes warped between longitudinal veins, which themselves are often slightly thickened. Abnormally-shaped eyes, frequently compressed dorsoventrally. Both sexes viable and fertile. RK3.

**other information:** Probably a complementing allele of *bk*. One X-ray-induced allele.

**Bl: Bristle**

**location:** 2-54.8 (crossing over may be reduced).

**origin:** Spontaneous.

**discoverer:** R. L. King, 25d11.

**references:** 1927, Biol. Bull. 53: 465-68.

**phenotype:** Bristles one-half to two-thirds normal length, blunt, thicker, and beaded in outline. Posterior scutellars often cross and adhere to body. Eyes somewhat larger and rougher. Overlaps wild type when reared at 20° (Ashburner). Probably affects nature of bristle secretion, particularly outer layer [Lees and Waddington, 1942, DIS 16: 70; Lees and Picken, 1945, Proc. Roy. Soc. (London), Ser. B 132: 396-423 (fig.)]. Viability of

heterozygote is good but erratic; homozygotes usually lethal; survivors female sterile with roughish eye character. RK1 as dominant.

**alleles:** \**Bl*<sup>30</sup> and \**Bl*<sup>31</sup> (Plough and Ives, 1935, Genetics 20: 42-69).

**cytology:** Between 38A6 and 38E9 based on inclusion within *Df(2L)TW2 = Df(2L)37D2-E1;38E6-9* but not *Df(2L)TW9 = Df(2L)37E2-F4;38A6-C1* or *Df(2L)TW158 = Df(2L)37B2-8;37E2-F4* (Wright, Hodgetts, and Sberald, 1976, Genetics 84: 267-85).

**\*bla: bladderwing**

**location:** 1-43.2.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)aminophenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 67-68.

**phenotype:** Wings grossly deformed, small, and normally full of fluid. Eyes slightly abnormal in shape. Males fertile; females sterile. Viability about 50% wild type. RK3.

**Bla:** see *nw*<sup>B</sup>

**black:** see *b*

**Black cells:** see *Bc*

**black leg:** see *bleg*

**Blackoid:** see *Bkd*

**bladderwing:** see *bla*

**Blastoderm-specific gene:** see *Bsg*

**bhc: blocked (T. Schüpbach)**

**location:** 2-43.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female-sterile; homozygous females often have underdeveloped ovaries which seem to lack germ cells altogether. In some females a small number of developing egg chambers is found; may contain abnormal numbers of nurse cells, and never develop beyond the first few stages of oogenesis.

**alleles:** *bhc*<sup>WE</sup> = *bhc*<sup>1</sup>, *bhc*<sup>HM</sup>.

**bld: bald**

**location:** 3-48.1 (in *3R* to the left of *Ki*).

**origin:** Induced by ethyl methanesulfonate; detected by the presence of X-ray-induced somatic spots in the progeny of treated males.

**references:** García-Bellido and Dapena, 1974, DIS 50: 179.

1974, Molec. Gen. Genet. 128: 117-30.

**phenotype:** Homozygous lethal (lethal may be independently induced); not cell lethal. In homozygous cuticular spots, chetae, trichomes and cuticle appear depigmented and transparent; trichomes long, thin, and wooly. RK1 as a marker for cuticular clones.

**Bld: Blond**

**location:** 1- or 2- (associated with rearrangement).

**origin:** Spontaneous in chromosome containing *In(2R)Cy*.

**discoverer:** Burkart, 1930.

**references:** 1931, Rev. Fac. Agron. Vet. Univ. Buenos Aires 7: 393-491.

Burkart and Stern, 1933, Z. Indukt. Abstamm.

Vererbungs. 64: 310-25 (fig.).

**phenotype:** Bristles of heterozygote are gleaming yellow at tips and for varying lengths of more basal regions. Hairs not much paler and bristles of abdomen only slightly affected. Larval mouth parts wild type. No overlap. ERG normal [Hotta and Benzer, 1969, *Nature* (London) 222: 354-56]. Viability and fertility excellent. Most available *T(1;2)Bld* chromosomes carry a lethal in *2R*; lethal easily separated from translocation by recombination in *T(1;2)Bld/In(2R)Cy* females.

**cytology:** Associated with *T(1;2)Bld* = *T(1;2)1B13-C1;60B12-13* (Lefevre).

**other information:** *Bld* phenotype associated with the  $2R^{DX^P}$  element of the translocation.

**Ble: Barlike eye**

**location:** 3-94.

**origin:** X ray induced.

**discoverer:** Crowell, 57i.

**references:** Meyer, 1958, DIS 33: 97.

**phenotype:** Eye shape indistinguishable from Bar. Expression of *Ble*<sup>+</sup> varies, best at 26°. Excellent expression in homozygote at all temperatures. *Ble/Ble* in combination with *B* results in an extremely narrow eye. RK1.

**other information:** If *Ble* represents a transposition of the Bar locus to chromosome 3, the flanking loci of *f*<sup>+</sup> and *od*<sup>+</sup> have not been transposed. Also against transposition is absence of sexual dimorphism that dosage compensation of *B* should produce in such a case.

**\*bleg: black leg**

**location:** 3- (near *p*).

**discoverer:** Bridges, 16b23.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 158.

**phenotype:** Legs black; body color pallid; wings flimsy. RK3.

**blistered: see bs**

**Blisterlike: see Bsl**

**blistery: see by**

**blo: bloated**

**location:** 2-58.5.

**origin:** Recovered among descendants of heat-treated flies.

**discoverer:** Ives, 33f26.

**synonym:** Originally referred to as *ba*<sup>2</sup>: *balloon* and *ba*<sup>33f26</sup>.

**references:** Plough and Ives, 1934, DIS 1: 33.

1934, DIS 2: 10.

1935, DIS 3: 6.

Bridges, Skoog, and Li, 1936, *Genetics* 21: 788-95.

**phenotype:** Wings spread, crumpled, and vesiculated; wing shows irregular plexus of extra veins. In extreme cases, wings unexpanded. Occasional hooked or wavy bristles. Developmental studies by Waddington [1939, *Proc. Nat. Acad. Sci. USA* 25: 299-307 and 1940, *J. Genet.* 41: 75-139 (fig.)] show intervein material spongy and veins swollen with inadequate contraction after inflated stage of pupal wing. Droplets of hemolymph often become clothed with cells liberated from epithelium and remain along basal processes. Does not overlap wild type but has poor viability and hatches later. RK2.

**cytology:** Not included within and does not recombine with (0/1098) *Df(2R)Np* = *Df(2R)44F1-2;45E1-2* (Bridges, Skoog, and Li, 1936).

**blocked: see bic**

**Blond: see Bld**

**blot: see ap**<sup>blt</sup>

**\*blt: ballet**

**location:** 1- (not located).

**origin:** X ray induced.

**discoverer:** Iyengar.

**references:** 1962, DIS 36: 38.

**phenotype:** Wings one-third the normal length, stretched outward and slightly upward; wing tip broadened; venation markedly altered as in fused. Male viability impaired; females almost completely lethal. RK2.

**blt: see ap**<sup>blt</sup>

**\*blu: blunt**

**location:** 3- (near *ru*).

**origin:** Spontaneous.

**discoverer:** Walbrunn, 46j23.

**references:** 1947, DIS 21: 71.

**phenotype:** Wings slightly shorter and broader than normal, giving a squared appearance. Sometimes difficult to classify. RK3.

**Blunt short bristle: see Bsb**

**bly: bellyache**

**location:** 1-28.3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Eberl and Hilliker, 1988, *Genetics* 118: 109-20.

**phenotype:** Recessive lethal. Dispersed or poorly formed Malpighian tissue and often a yolk plug; cuticle appears normal.

**alleles:** Two putative alleles, *bly*<sup>1</sup> and *bly*<sup>2</sup>; isolated as *l(1)EH290* and *l(1)EH740a*.

**\*bn: band**

**location:** 3-72.

**origin:** Spontaneous.

**discoverer:** Morgan, 12g.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 79 (fig.).

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 215 (fig.), 218.

**phenotype:** Trident pattern and scutellum darker with dark transverse band across anterior portion of mesonotum. Thorax vacuolated; hairs on thorax sparse and directed medially in bowed lines. RK2.

**bo: bordeaux**

**location:** 1-12.5.

**discoverer:** Nazarenko.

**phenotype:** Eye color dark wine; not completely separable from wild type. Transplantation indicates *bo* may be nonautonomous (Ephrussi and Beadle, 1937, *Genetics* 22: 65-75). Larval Malpighian tubules bright yellow (Beadle, 1937, *Genetics* 22: 587-611). RK3.

**other information:** CalTech stock, *bo v*, contains *w* alleles. Schalet thinks *bo* is a dark allele of *w*; *bo/w*<sup>a</sup> looks like dark allele of *w* series.

**bobbed:** see *bb*

**bobbed on the Y chromosome:** see *bb<sup>Y</sup>*

**bod:** *bowed*

**location:** 3-48.3.

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 35b20.

**references:** 1937, DIS 7: 6.

**phenotype:** Wings bowed downward over abdomen with curvature along both axes; curvature occasionally reversed. Wings somewhat smaller than wild type. Whole fly smaller and humpy; eyes slightly bulged. Overlaps wild type slightly. Viability 75% wild type. RK3.

*Bojla:* see *Fs(3)Sz5*

**\*bord:** *bordered*

**location:** 1-70.

**origin:** Spontaneous.

**discoverer:** Bridges, 1916.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 220.

**phenotype:** Wings smaller and slightly extended; venation ragged; veins bordered by darker bands. Viability poor; classification unreliable. RK3.

**bordeaux:** see *bo*

**bordered:** see *bord*

**\*bos:** *bordosteril*

**location:** 3-0.0.

**origin:** Spontaneous.

**discoverer:** Fabian, 1941.

**references:** 1948, *Arch. Julius Klaus-Stift. Vererbungsforsch. Sozialanthropol. Rassenhyg.* 23: 512-17.

**phenotype:** Eye color dark brownish red, darkens with age. Malpighian tubules and testis sheaths colorless. Male fertile; female sterile. RK2.

**other information:** Possibly an allele of *she*.

**boss:** *bride of sevenless*

**location:** 3.90.5 (just proximal to *Pr*).

**references:** Reinke and Zipursky, 1988, *Cell* 55: 321-30.

**phenotype:** Homozygotes lack photoreceptor cell R7; phenotype indistinguishable from that of *sev*. Mosaic studies demonstrate that *boss<sup>+</sup>* activity required in R8 and in no other photoreceptor cell for the normal development of the R7 cell in the same ommatidium. *boss<sup>+</sup>* R8 cell cannot rescue R7 development in adjacent ommatidia.

**alleles:** Sixteen alleles induced by X rays, ethyl methanesulfonate, and hybrid dysgenesis.

**cytology:** Placed in 96F5-14 by deficiency mapping.

**bot:** *botch* (*T. Schüpbach*)

**location:** 2-20.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect female-sterile mutant; embryos from homozygous mothers do not hatch and show irregular segmentation, variable segment fusions, and holes in cuticle.

**alleles:** *bot<sup>Q1</sup>* = *bot<sup>i</sup>*.

*Botond:* see *Fs(3)Sz6*

**\*bow:** *bow wings*

**location:** 1- (not located).

**discoverer:** Bridges, 12h15.

**references:** Morgan and Bridges, 1916, *Carnegie Inst. Washington Publ. No. 237*: 46 (fig.).

**phenotype:** Wings curved downward over abdomen and also sideways, like bowl of a spoon. Overlaps wild type. RK3.

**Bow:** *Bowed* (*M. Ashburner*)

**location:** 2-55.1.

**origin:** Induced with ethyl methanesulfonate.

**discoverer:** Detwiler.

**phenotype:** Wings of heterozygotes at 45° to body axis; macrochaetae, especially scutellars, with hooked tips.

**cytology:** Cytologically normal (Ashburner).

**bow-legged:** see *bwl*

**bowed:** see *bod*

**Bowed:** see *Bow*

*bp:* see *bul<sup>bp</sup>*

**br:** see *BRC*

**\*Br:** *Bridged*

**location:** 1- (right half; crossing over suppressed to the right of *v*).

**origin:** X ray induced.

**discoverer:** Muller, 2713.

**references:** 1935, DIS 3: 29.

**phenotype:** Plexus-like wings with extra crossveins bridging longitudinals. L4 bent. Wings arched. Male lethal. RK3A.

**cytology:** Associated with *In(1)Br*.

*Br:* see *Sp*

**brachymacrochaetae:** see *brc*

**brahma:** see *brm*

**braille:** see *brl*

*bran:* see *a<sup>ba</sup>*

*Bran:* see *a<sup>Ba</sup>*

**branch:** see *bch*

**Branchlet:** see *Bt*

**\*brb:** *broad abdomen*

**location:** 1-52.9.

**origin:** Induced by styrylquinoline (CB. 3086).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 83.

**phenotype:** Fly with broad abdomen and slightly shortened thorax and wings. Wings frequently slightly divergent. Eyes small and dull red with reflection spots. Bristles slightly shortened and lying flatter on thorax. Males and females viable and fertile. RK2.

**alleles:** One allele induced by *L-p-N,N-di-(2-chloroethyl)amino-phenylalanine*.

**brc: brachymacrochaetae**

**location:** 1-0.0 [no recombinants with *sc* among 6746 sons; placed between *su(s)* and *tw* by duplication analysis (Maddern, 1972, DIS 49: 40); placed just proximal to *tw* between *l(1)1Da* and *l(1)1Dc*, by Voelker, using terminal deficiencies].

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 68.

**phenotype:** One or more thoracic bristle much reduced in size; scutellars and dorsocentrals most frequently affected. Occasional bristles duplicated. Extra-bristle phenotype enhanced by duplications for the tip of X with breakpoint between *su(s)* and *tw* (Maddern, 1972, DIS 49: 40). Good viability and fertility in both sexes. *brc*<sup>6</sup>, a lethal allele, causes pupal death with substantial pupal histolysis, especially at anterior end (Eberl, Hilliker, and Voelker, 1988, DIS 67: 36).

**alleles:** Majority of alleles are lethal.

**BRC: Broad Complex**

**location:** 1-0.28 (left of *dor*); mapped to 1-0.43 based on 15 crossovers between *npr*<sup>4</sup> and *y*, 36 between *npr*<sup>4</sup> and *w*, and 159 between *npr*<sup>4</sup> and *ec* (Belyaeva *et al.*).

**synonym:** *o.c.c.*: overlapping complementation complex; *ecs*: ecdysone sensitivity (Zhimulev, Belyaeva, Fomina, Protopopov, and Bolshakov, 1987, Chromosoma 94: 492-504).

**references:** Belyaeva, Aizenzon, Semeshin, Kiss, Koczka, Baritcheva, Gorelova, and Zhimulev, 1980, Chromosoma 81: 281-306.

Belyaeva, Protopopov, Baritcheva, Semeshin, and Izquierdo, 1987, Chromosoma 95: 295-310.

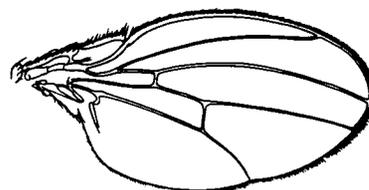

Kiss, Beaton, Tardiff, Fristrom, and Fristrom, 1988, Genetics 118: 249-57.

**genetics:** The Broad Complex resides in the early ecdysone-induced puff at the left end of the X chromosome; it comprises a number of mutations with complicated phenotypic and complementation characteristics. Russian investigators originally defined four mutually complementing, lethally mutable loci, which function in ecdysone-dependent induction of metamorphosis: *br* = broad, *rbp* = reduced bristles on palpus, *l(1)2Bc*, and *l(1)2Bd*. Based on amorphic mutations, defined on the basis of having equivalent phenotypes in homozygous and hemizygous females, Kiss *et al.* define two complementation groups: *br* [comprising *br*, *rbp*, and *l(1)2Bd*

(Belyaeva *et al.*)] and *l(1)2Bc;npr* alleles are non-complementing. In the following treatment we retain the subdivisions as defined by Belyaeva *et al.*; however, as the molecular structure of the complex becomes understood, simpler terminology will be indicated.

**cytology:** Placed in 2B5 based on its deletion by *Df(1)S39* = *Df(1)1E3-4;2B5* and by the deficiency within *Dp(1;Y)S280* = *Df(1)2B4-5;2B6-7*; *Df(1)S39/Dp(1;Y)S280* males die as puffless third-instar larvae (Belyaeva, Vlassova, Biyasheva, Kakpakov, Richards, and Zhimulev, 1981, Chromosoma 84: 207-19).

**molecular biology:** Region entered by transposon tagging (Chao and Guild, 1986, EMBO J. 5: 143-50) and by microdissection (Galcerán, Jiménez, Edström, and Izquierdo, 1986, Insect Biochem. 16: 249-54). Chromosomal walk of 230 kb includes polytene bands 2B1-6; coordinate 0 defined as the most distal point of the walk, with positive values extending to the right. Mutational lesions are spread over 50 kb and are confined to two disjunct regions, the distal one is between 100 and 115 kb and the proximal is between 150 and 175 kb (Sampedro, Galcerán, and Izquierdo, 1989, Mol. Cell Biol. 9: 3588-91); both *br* and *l(1)2Bc* lesions are found in the proximal group. The region is transcriptionally complex; transcripts from the distal region seem unrelated to *BRC* function, whereas, the proximal region produces an array of transcripts that display alternative initiation and termination sites as well as alternatively spliced exons which show stage specificity, with constitutive and early transcripts originating at coordinate 143 kb and late transcripts at 165 kb (Galcerán, Llanos, Sampedro, Pongs, and Izquierdo, 1990, Nucleic Acids Res. 18: 539-45).

**br: broad**

Edith M. Wallace, unpublished.

**br: broad**

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 145, 220 (fig.).

**phenotype:** The *br* complementation group contains both amorphic and hypomorphic mutant alleles; amorphic alleles cause early prepupal developmental arrest; hypomorphic alleles cause late pupal or pharate adult developmental arrest or are viable. Null alleles display normal larval development but prevent elongation and eversion of discs giving rise to appendages in the pupal stage. Wings of the viable allele, *br*<sup>1</sup>, somewhat broader than normal; about 80% of normal length, with round full tip; crossveins closer together. Shape difference visible in middle prepupal stage immediately after eversion [Waddington, 1939, Proc. Nat. Acad. Sci. USA 25: 299-307; 1940, J. Genet. 41: 75-139 (fig.)]. A haplo-insufficient locus in that heterozygosity for a deficiency including the

THE GENOME OF *DROSOPHILA MELANOGASTER*

*br* locus leads to a slight *br* phenotype (Craymer and Roy, 1980, DIS 55: 200-04); furthermore, the deficiency in combination with *br*<sup>1</sup> or *br*<sup>3</sup> leads to drastic reduction in viability, especially at 18°, and an extreme phenotype among survivors, including reduced palpi characteristic of *rbp* alleles, short rounded wings with interrupted veins, and malformed third legs, *i.e.*, shortened and thickened femora and tibiae as well as misshapen basitarsi. The malformed-leg syndrome is enhanced by heterozygosity for *Sb* or *sbd* alleles (Beaton, Kiss, Fristrom, and Fristrom, 1988, Genetics 120: 453-64). *br*<sup>16</sup>/+ and *Df(1)S39*/+ display slight dominance of *br* effects in the presence of *Rpl1215*<sup>Ubi</sup> (Mortin and Lefevre, 1981, Chromosoma 82: 237-47).

***l(1)2Bd***

**phenotype:** Males and homozygous females display normal phenotype and viability; however, in heterozygous combination with deficiencies or *npr* mutations, *l(1)2Bd* acts as a temperature-sensitive lethal; completely lethal at 29°; at 25° or 18° most individuals die in late pupal stage, and survivors have faded wings, swollen abdomen, and reduced bristle number on palpi.

## alleles:

allele	origin	synonym	ref <sup>α</sup>	comments
<i>l(1)2Bd<sup>1</sup></i>	EMS	<i>l(1)t252</i>	1, 2, 3, 4	hypomorph

<sup>α</sup> 1 = Aizenzon and Belyaeva, 1982, DIS 58: 3-7; 2 = Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90; 3 = Belyaeva, Aizenzon, Semeshin, Kiss, Koczka, Baritcheva, Gorelova, and Zhimulev, 1980, Chromosoma 81: 281-306; 4 = Kiss, Beaton, Tardiff, Fristrom and Fristrom.

**npr1: nonpupariating**

**phenotype:** Hemizygous male larvae fail to pupariate, although they survive 10-15 days after their normal sibs have pupariated. Four-day-old larvae appear normal as do their imaginal discs; normal ecdysteroid levels achieved. Discs become abnormal beginning on the sixth day; peripodial membrane becomes enormously distended and highly distorted; partially evaginated structure becomes visible in the disc lumen; do not undergo detailed morphological changes characteristic or metamorphosis, either *in situ* or in transplants into normal larvae [Fristrom, Fekete, and Fristrom, Wilhelm Roux's Arch. Dev. Biol. 190: 11-21 (fig.)]. Both salivary glands and fat bodies fail to undergo histolysis *in situ* or *in vitro*. Mutant flies able to produce ecdysone, but tissues unable to respond normally. In gynandromorphs, the female tissue forms a puparium, whereas *npr1* male tissue remains larval; no adults survive (Kiss, Szabad, and Major, 1978, Mol. Gen. Genet. 164: 77-83; Kiss, Bencze, Fodor, Szabad, and Fristrom, 1975, Nature 262: 136-38). Implantation of wild-type ring glands into *npr1* larvae does not rescue pupariation; however implanted wild-type or *npr1* ring glands are able to rescue *npr3* larvae [Kiss, Szabad, Belyaeva, Zhimulev, and Major, 1980, Development and Neurobiology of Drosophila (Siddiqi, Babu, Hall, and Hall, eds.) Plenum Press, New York and London, pp. 163-81]. No maternal effect of either *npr1*<sup>3</sup> or *npr1*<sup>4</sup> (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14). *npr1*<sup>6</sup> homozygous and hemizygous larvae die without exhibiting any sign of ecdysone-inducible puff formation; culture of salivary glands in 20-OH ecdysone produces partial development of some early, but none of late ecdysone-inducible puffs, and extraneous puff appears at 75CD (Belyaeva, Vlassova, Biyasheva, Kakpakov, Richards, and Zhimulev, 1981, Chromosoma 84: 207-19). *npr1*<sup>+</sup> gene product also required for regression of the intermolt 68C glue puff [Belyaeva, *et al.* (*npr*<sup>6</sup>); Crowley, Mathers and Meyerowitz, 1984, Cell 39: 149-56 (*npr*<sup>3</sup>)] and for the transcription of the three 68C glue protein genes (Crowley *et al.*).

**rbp: reduced bristles on palpus**

**phenotype:** Late pupal lethal; most animals reach the pharate adult stage. *rbp*<sup>2</sup> homozygotes and males survive with fewer than normal bristles on the palpus; when raised at 29°, females exhibit faded wings and swollen abdomens; when raised at 18° males have faded wings. *rbp*<sup>2</sup>/*Df(1)RA19* females virtually lethal; females carrying *rbp*<sup>2</sup> and any of the other *rbp* alleles are completely viable when reared at 18°, but at higher temperatures most die and escapers have reduced bristles on the palpus, shortened bristles on the scutellum, shrivelled or swollen abdomen shrivelled wings and eyes with crumpled surface.

**\*brd: broadened**

**location:** 1-33.

**origin:** X ray induced.

**discoverer:** Muller, 26127.

**references:** 1935, DIS 3: 29.

**phenotype:** Wings expanded. Viability 20% wild type. RK3.

**Brd: Bearded (M. Leviten)**

**location:** 3-42 (between *G1* and *th*).

**phenotype:** Causes production of supernumerary chaetae and sensilla at or near normal positions. *Brd*<sup>1</sup> homozygotes survive and exhibit more severe phenotypes than heterozygotes. *Brd*<sup>1</sup>/*+* = *Brd*<sup>1</sup>/*Df(3L)Brd*. *Brd* alleles affect all classes of adult sensory organs. *Brd*<sup>1</sup> strongly affects macrochaetae and other imaginal-disc sensilla (*i.e.*, trichoid, campaniform, basiconic), but only mildly increases microchaete density. *Brd*<sup>3</sup> and other alleles produce more severe microchaete phenotypes, in both disc and histoblast derived tissues, as well as exhibiting the *Brd*<sup>1</sup> phenotypes. In addition to sensillum multiplication, *Brd*<sup>1</sup> homozygotes also exhibit bristle loss, with

anterior orbitals absent (>90%) and a less frequent loss of ocellar macrochaetae (<5%). This bristle loss occurs in other *Brd* genotypes and is most severe for *Brd*<sup>3</sup> homozygotes. The combination of sensilla multiplication and loss phenotypes is made more severe by loss-of-function mutations at Notch and neuralized, and are decreased in the presence of three wild-type copies of these genes. The ethyl-methanesulfonate-induced point revertants of *Brd*<sup>1</sup> tested (*Brd*<sup>rv1-4</sup>) are homozygous viable, viable in *trans* to *Brd* deficiencies, and display no mutant phenotypes in either situation.

**alleles:** Alleles other than *Brd*<sup>1</sup> are primary or secondary derivatives of *Brd*<sup>1</sup>. *Brd*<sup>rv5</sup> and *Brd*<sup>rv6</sup> are revertants of *Brd*<sup>3</sup>, and the *Brd*<sup>Prv</sup> alleles are revertants of *Brd*<sup>P1</sup>.

**other information:** Possibly *Hi* was a *Brd* allele.

**\*bre: bright eye**

**location:** 1-24.6.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 68.

**phenotype:** Eye color brighter red. Wings shorter, often crumpled or waved. Abdomen disproportionately large. Male viability and fertility good; females have reduced fertility. Not easily classified. RK3.

**alleles:** One allele induced by methyl methanesulfonate.

**brevis:** see *bv*

**brh: brown head**

**location:** 2-61.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Defect in head involution; denticle bands abnormal.

**alleles:** Two retained, *brh*<sup>1</sup> and *brh*<sup>2</sup> isolated as *IB* and *IID*; plus six discarded alleles.

**bri: bright**

**location:** 2-54.3.

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 34b23.

**references:** Beadle and Ephrussi, 1937, Am. Naturalist 71: 91-95.

**phenotype:** Eye color bright red, like *cn*<sup>2</sup> or *v*<sup>2</sup>; difficult to separate from wild type. Malpighian tubules pale yellow (Beadle, 1937, Genetics 22: 587-611). RK3.

**bride of sevenless:** see *boss*

**Bridged:** see *Br*

**Bristled:** see *Sp*

**brl: braille (M.P. Scott)**

**origin:** Enhancer trap P-element mutagenesis.

**discoverer:** L.E. Rost and M.P. Scott, 1989.

**phenotype:** Recessive mutation with complete penetrance and variable expressivity. Strongest phenotypes include partial to full transformation of one or both eyes into antennae. Less severe adult phenotypes include excess bristles under the eyes, duplication of the more anterior set of scutellar bristles (macrochaetae), and a spoon-like curvature of the wings. Homozygotes are viable and fertile.

**cytology:** P-element insertion in 60B-C; mobilization of the P-element restored wild-type morphology.

**molecular biology:** Gene cloned by plasmid rescue from bacterial sequences in the P-element.

**other information:** Presumed additional alleles obtained by mobilization of P-element. All are recessive lethals that die during early larval stages.

**brm: brahma (J.A. Kennison)**

**location:** 3-43.0.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1983.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Dominant suppressor of *Pc* and *Pcl* alleles. Recessive embryonic lethal with strong maternal contribution. Maternal effect lethality is non-rescuable even by two wild-type zygotic alleles. There is a single 5.5 kb mRNA present throughout development with the greatest amounts in the unfertilized egg and early embryo. *brm*<sup>1</sup> isolated as a dominant suppressor of the antennal to leg transformation associated with a *Pc*<sup>2</sup> *Anp*<sup>Ns</sup> double heterozygote.

**alleles:** Fifteen alleles induced by ethyl methanesulfonate, three alleles induced by gamma irradiation, and four alleles induced by hybrid dysgenesis.

**cytology:** Placed in 72A3-5 based on *in situ* hybridization to salivary gland chromosomes.

**\*brw: broader wing**

**location:** 1-39.8.

**origin:** X ray induced.

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 83.

**phenotype:** Wings broad and rounded at the tips. Males show reduced viability and are sterile. RK3.

**bs: blistered**

**location:** 2-107.3.

**origin:** Spontaneous.

**discoverer:** Bridges, 11k16.

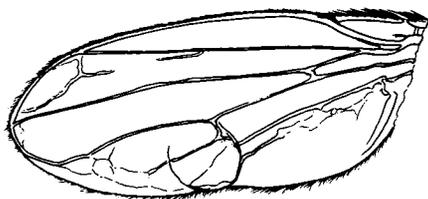

**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 155 (fig.).  
Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 219 (fig.).

**phenotype:** Wings blistered, small, pointed; venation thick and plexus-like with branches from and parallel to L5 beyond second crossvein, where there is a semidominant free vein effect. Temperature sensitive. RK2 at 19°; RK3 at 25°.

**alleles:** *bs*<sup>2</sup>, *bs*<sup>3</sup>, *\*bs*<sup>4</sup>, *bs*<sup>8</sup>, *\*bs*<sup>52d</sup>, *\*bs*<sup>54j</sup>, *\*bs*<sup>bl</sup>, *\*bs*<sup>38i</sup>, *bs*<sup>cy</sup>, *\*bs*<sup>P</sup>, and *bs*<sup>PP</sup> (CP627).

**cytology:** Located between 60C5 and 60D2, based on its inclusion within *Df(2R)Px = Df(2R)60B8-10;60D1-2* and within *Df(2R)Px<sup>2</sup> = Df(2R)60C5-6;60D9-10* (Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55).

**other information:** May be part of a pseudoallelic complex with *ba* and *Px*.

***bs*<sup>2</sup>: blistered-2**

Edith M. Wallace, unpublished.

***Bsb*: Blunt short bristle**

**location:** 3-100.6 (based on distribution of *Bsb* among 387 crossovers between *ro* and *ca* from *Bsb/ca ro* females).

**origin:** Induced by ethyl methanesulfonate.

**references:** B.S. Baker, 1980, DIS 55: 197.

**phenotype:** Bristles markedly shortened; sharply tapered at tip resembling sharpened pencil under compound microscope. Excellent cell marker. Bristles reduced to very short stubs in *Pr Bsb* heterozygotes. Homozygous lethal; viability and fertility of heterozygote excellent.

**cytology:** Salivary-gland chromosomes normal.

**\*bsc: bent scutellars**

**location:** 1-1.1.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 68.

**phenotype:** One or more scutellars bent on themselves in form of inverted V. Other bristles irregularly bent. Eyes slightly smaller. Wings slightly abnormal in shape. Male viability about 50% wild type; fertility much reduced. RK3.

**alleles:** One allele each induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine and D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine.

***Bsg*: Blastoderm-specific gene**

Three loci identified in a differential screen of a genomic library with labeled blastoderm cDNA plus competing amounts of unlabeled preblastoderm cDNA; localized by *in situ* hybridization to polytene chromosomes.

locus	genetic location	cytological location	synonym	ref <sup>α</sup>
<b><i>Bsg25D</i></b>	2-{16}	25D3		2, 3
<i>Bsg75C</i>	3-{45}	75C1-2	<b>term</b>	1, 3
<b><i>Bsg99D</i></b>	3-{101}	99D4-8		3

<sup>α</sup> 1 = Balderelli, Mahoney, Salas, Gustavson, Boyer, Chang, Roark, and Lengyel, 1988, Dev. Biol. 125: 85-95; 2 = Boyer, Mahoney, and Lengyel, 1987, Nucleic Acids Res. 15: 2309-25; 3 = Roark, Mahoney, Grahm, and Lengyel, 1985, Dev. Biol. 109: 476-88.

***Bsg25D***

**molecular biology:** Genomic subclone hybridizes to overlapping 2.7-, 3.0-, and 4.5-kb mRNA's on Northern blots. The two larger transcripts present in 0-8 hr embryos; whereas the 2.7-kb transcript is found only in the blastoderm stage. The 2.7- and 4.5-kb messages encode the same polypeptide; they come from a transcript with three exons, the first two of which are shared, and the third of which differs between the two in the length of its 3' untranslated region. The conceptual amino-acid sequence contains 741 amino acids and contains a 96-amino-acid domain with 22% identity to c-fos and a 21-amino-acid domain that resembles repeated actin-binding segments of tropomyosin.

***Bsh*: see *Mhc-m*<sup>5</sup>**

***bsk*: basket**

**location:** 2-33.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Homozygous lethal; embryos have large dorsal anterior hole.

**alleles:** Three, *bsk*<sup>1</sup>, *bsk*<sup>2</sup>, and *bsk*<sup>3</sup>, isolated as *IIIJ*, *IIP*, and *\*IL*.

**cytology:** Placed in 31B-32A based on its inclusion in *Df(2L)J27 = Df(2L)31B-E;32A*.

**bsp: brown spots**

**location:** 2-40.6.

**origin:** Spontaneous.

**references:** Di Pasquale, 1959, DIS 33: 128.

Di Pasquale and Zambruni, 1963, DIS 37: 73 (fig.).

1965, DIS 40: 80.

1966, DIS 41: 119.

1967, DIS 42: 74.

**phenotype:** Spots of brown pigment appear in integument of *bsp/bsp* females only after they have mated. Di Pasquale and Zambruni (1963) showed that copulation with any male, sterile or fertile, triggers formation of brown spots in cuticle and brown masses in tissues. Courtship without copulation ineffective; virgin females never show brown spots. Simulated copulation with a glass needle, with or without accessory-gland fluid, leads to phenotype. Mating of etherized females less effective in inducing brown spot formation. No phenotype in males. Penetrance of 60-80%; viability excellent. RK3.

**bss: bang senseless (J.C. Hall)**

**location:** 1-54.6.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *bas*<sup>MW1</sup>: *bang sensitive*.

**references:** Jan and Jan, 1978, Proc. Nat. Acad. Sci. USA 75: 515-19.

Ganetzky and Wu, 1982, Genetics 100: 597-614.

**phenotype:** Mechanical shock or vortexing induces paralysis lasting for 2-3 minutes; heterozygous female are paralyzed for 40-50 seconds. Homozygotes and hemizygotes have abnormally prolonged release of neurotransmitter at larval neuromuscular junctions, which is associated with multiple firing of action potentials in the nerves; behavioral and electrophysiological phenotypes suppressed by *nap*<sup>ts</sup> at its permissive (low) temperature.

**alleles:** *bss*<sup>1</sup> (formerly *bas*<sup>MW1</sup>) and *bss*<sup>2</sup> phenotypically alike.

**cytology:** Placed between 14B5 and 14B13 based on its being deleted by *Df(1)81112h = Df(1)14B5-18;15A6-11* (Steller) but not carried by *Dp(1;2)r<sup>+</sup>75c = Dp(1;3)14B13;15A9;35D-E* (Ganetzky and Wu).

**other information:** Separable by recombination from *eas*, which causes a similar phenotype and to which *bss* is closely linked.

**bt: bent**

**location:** 4-1.4 [mapped in diplo-4 triploids by Sturtevant (1951, Proc. Nat. Acad. Sci. USA 37: 405-7)].

**origin:** Spontaneous.

**references:** Muller, 1914, J. Exp. Zool. 17: 325-36.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 216 (fig.), 219.

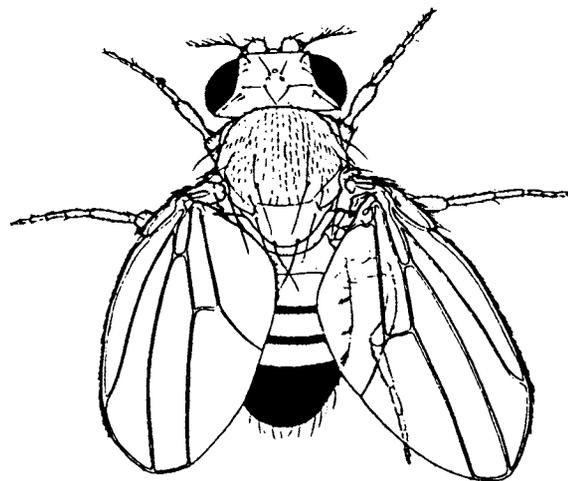

Bridges, 1935, Biol. Zh. 4: 401-20.

**phenotype:** Wings held out at base and bent sharply backward. Rear legs often lumpy at first tarsal joint. May have one to four "preleg" or "first ventral" bristles on ventral surface of thorax anterior to first pair of legs, in

space otherwise devoid of bristles or hairs. Overlaps wild type at 25°, very much at 19°, and little if any at 29° (Metz, 1923, Proc. Soc. Exp. Biol. Med. 20: 305-10). RK2 at 28°.

**cytology:** Tentatively placed in 102B10-E9 between *Df(4)M4 = Df(4)101E-F;102B9-10* and *Df(4)G = Df(4)102E2-10;tip* (Hochman, 1971, Genetics 67: 235-52).

**other information:** First mutant found on chromosome 4.

**bt: bent**

From Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 216.

**bt<sup>D</sup>: bent-Dominant**

**origin:** X ray induced.

**discoverer:** Schultz, 33a11.

**references:** Bridges, 1935, Biol. Zh. 4: 401-20.

**phenotype:** When found, *bt<sup>D</sup>/+* showed regularly divergent wings with some angular bend near base. Legs lumpy at low temperature. Preleg bristles present as in *bt*. Homozygous lethal. Fails to complement *l(4)2* and *l(4)23* [Hochman, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 903-28]. RK3 as lethal.

**other information:** Balanced stocks in existence today show only preleg bristle character and recessive lethality (Lewis).

**\*Bt: Branchlet**

**location:** 1- (rearrangement).

**origin:** Induced by <sup>32</sup>P.

**discoverer:** Bateman, 1950.

**references:** 1950, DIS 24: 54.

1951, DIS 25: 77.

**phenotype:** Heterozygous female has posteriorly directed branchlet on posterior crossvein as well as other extra venation. Abdominal segments often poorly chitinized. Male lethal. RK3A.

**cytology:** Associated with *Dp(1;1)Bt = Dp(1;1)3B2-C1;6F6-7*.

**other information:** Phenotype may be *Co* effect in 3C7 or more likely *dx* in region 6.

**btd: buttonhead****location:** 1-31.**origin:** Induced by ethyl methanesulfonate.**references:** Wieschaus, Nüsslein-Volhard and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307 (fig.)**phenotype:** Homozygous lethal; head involution incomplete.**cytology:** Localized to 8A5-9A1 by segmental aneuploidy.**btdl: buttonheadlike****location:** 1-65.**origin:** Induced by ethyl methanesulfonate.**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20.**phenotype:** Mouthparts sclerotized but not completely internalized; the head is often open. A fraction of *btdl*<sup>1</sup>/+ females have bristled growths on the head; those in eye region resemble eye-to-antenna transformations.**alleles:** *btdl*<sup>1</sup> and *btdl*<sup>2</sup> isolated as *l(1)EH564* and *l(1)EH793*.**cytology:** Placed in 18B4-19A1 based on its being covered by *X<sup>P</sup>Y<sup>D</sup>B50* from *T(1;Y)18B4-11;YL* but not by *Ymal*<sup>+</sup>, which carries 18F3-19A1 to 20F from the X.**\*bu: bulging****location:** 1-58.**origin:** X ray induced.**discoverer:** Muller, 2618.**references:** 1935, DIS 3: 29.**phenotype:** Eyes rough and bulging. Semilethal. RK3.*bu*: see *Hn*<sup>r2</sup>*bu-w*<sup>61j</sup>: see *vs*<sup>61j</sup>**Bubble:** see **Bb***bubble wing*: see *vs*<sup>61j</sup>**buckled:** see **bk****buckledlike:** see **bkl****bul: bulge****location:** 3-43.6.**origin:** Spontaneous.**discoverer:** Spencer, 36d28.**references:** 1937, DIS 7: 6.

Curry, 1939, DIS 12: 45.

**phenotype:** Eyes very large and bulging; facets rounded, in irregular rows, and some quite large. Wing margin heavy; end of wing somewhat squared off to L3. RK3.**cytology:** In 72E4-5 (Velissariou and Ashburner, 1981, Chromosoma 84: 173-85).**bul<sup>bp</sup>: bulge-bumpy****origin:** Spontaneous.**synonym:** *bp*.**references:** E. H. Grell, 1955, DIS 29: 72.**phenotype:** About one-half the eye surface erupted into irregular yellowish blisters. Facets larger than normal in nonblistered areas. Homozygotes occur with 1% of expected frequency. Surviving homozygotes vigorous and male fertility high; females lay eggs abundantly, but only rarely does an egg hatch. RK3.**bul<sup>D</sup>: bulge-Dominant (E.H. Grell)****origin:** Induced by ethyl methanesulfonate.**phenotype:** Eyes rough with large facets in both heterozygote and homozygote. Good viability.**bulging:** see **bu****\*buo: burnt orange****location:** 2-57.1.**origin:** Spontaneous.**discoverer:** T. Hinton and Kleiner, 1941.**references:** Hinton, 1942, DIS 16: 48.**phenotype:** Eye color bright orange-brown. Malpighian tubules colorless in larva (Brehme and Demerec, 1942, Growth 6: 351-56). RK2.**other information:** Not an allele of *cn*. Allelism with *ltd* (2-56) apparently never tested.**bur: burgundy****location:** 2-55.7.**origin:** Ultraviolet induced.**references:** Meyer and Edmondson, 1949, DIS 23: 60.**phenotype:** Eye color dull, darkish brown (like *pr*), brilliant orange in combination with *cn*. *bur*<sup>gua</sup> supplementable by guanosine but not other ribonucleosides or nucleic acid bases; inosine-5'-monophosphate dehydrogenase activity reduced compared to normal (Johnston, Nash, and Naguib, 1985, Biochem. Genet. 23: 539-55). Classification and viability excellent. Fertility of females good; of males, variable. RK1.**alleles:** *bur*<sup>2</sup> (CP627) and *bur*<sup>gua</sup>.**cytology:** In 42B1-3 (Johnstone).**other information:** *bur* not allelic to *lt*, *ltd*, or *pr*. Allelism of *bur*<sup>gua</sup> inferred from map position of 2-54 and phenotype.**bur<sup>gua</sup>****origin:** Induced by ethyl methanesulfonate.**synonym:** *gua2-1*.**phenotype:** Recessive auxotroph for guanosine; supplementable by 3.2 mM of guanosine but not by other ribonucleosides or nucleic acid bases. Homozygotes have dark red eyes; this character segregates with the nutritional requirement. Inosine dehydrogenase activity of *bur*<sup>gua</sup> larval extracts an order of magnitude lower than that of wild type (Johnston, Nash, and Naguib, 1985, Biochem. Genet. 23: 539-55).**burnt orange:** see **buo****buttonhead:** see **btd****buttonheadlike:** see **btdl****bv: brevis****location:** 3-102.7 (recalculated from Sturtevant, 1956, Genetics 41: 118-23).**discoverer:** Bridges, 33e25.**phenotype:** Bristles uniformly short and stubby. Body chunky. Hatches late but viability excellent. RK1.**cytology:** Tentatively placed in distal to 100B7-8 by Frisardi and MacIntyre (1984, Mol. Gen. Genet. 197: 403-13) based on the retention of *bv*<sup>+</sup> by *Df(3R)ca48 = Df(3R)98F14;100B7-8*.

**bw: brown**

**location:** 2-104.5.

**discoverer:** Waaler, 19j15.

**references:** 1921, Hereditas 2: 391-94.

Dreesen, Johnson, and Henikoff, 1988, Mol. Cell Biol. 8: 5206-15.

Sullivan and Sullivan, 1975, Biochem. Genet. 13: 603-13.

Mount, 1987, Nature (London) 325: 487.

**phenotype:** Eye color light brownish wine on emergence, darkening to garnet. Red pigments lacking. Xanthommatin mostly replaced by dihydroxanthommatin (Phillips, Forrest, and Kulkarni, 1973, Genetics 73: 45-56). Pigment granules present but somewhat smaller than in wild type. Adult testes and vasa colorless. Larval Malpighian tubules pale yellow (Beadle, 1937, Genetics 22: 587-611). Produces white eyes in combination with *v*, *cn*, or *st*. Eye color autonomous when transplanted into wild-type host (Beadle and Ephrussi, 1936, Genetics 21: 230). RK1.

**alleles:** Mutant alleles of *bw* are listed in the accompanying table and their phenotypes compared to those of alleles described below. More complete descriptions in CP627 unless otherwise indicated.

<sup>α</sup> The phenotype column lists the allele described below that the allele listed resembles; *bw*<sup>5</sup> is homozygous lethal, but other *bw*<sup>5</sup>-like alleles are not.

<sup>β</sup> Ives, 1968, DIS 43: 64.

<sup>γ</sup> Valadé del Rio, 1983, Genet. Iberica, 35: 47.

<sup>δ</sup> Trippa, Loverre, and Cichetti, 1980, Genetics 95: 399-412.

**cytology:** Placed between 59E1-2 or the 59E2-3 interband by examination of *In(2LR)bw*<sup>85f4</sup> = *In(2LR)30A;59E2-3* (Nash and Tiong) and by *in situ* hybridization of a brown (Dreesen, *et al.*, 1988).

**molecular biology:** The genomic locus as well as cDNAs have been cloned and sequenced. The genomic region contains six small introns. The *bw* mutation is an insertion of about 8 kb of unknown origin into the coding portion of the locus. In the heads of newly eclosed wild-type flies there are two major transcripts of 2.8 and 3.0 kb that differ as a consequence of alternative poly(A) addition and encode the same predicted protein of 675 amino acids. The 8 kb *bw* insertion results in termination of transcription to give two truncated poly(A<sup>+</sup>) transcripts (Dreesen, *et al.*, 1988).

**other information:** Uptake studies indicate that *bw*, like *w*, blocks the transport of guanine and xanthine, likely pteridine precursors (Sullivan and Sullivan, 1975). Sequence comparisons between the predicted *bw*- and *w*-encoded proteins show that they are similar to one another and to subunits of active transport family members (Mount, 1987; Dreesen, *et al.*, 1988).

**bw<sup>4</sup>**

**origin:** Spontaneous.

**discoverer:** Mohr, 31k28.

**phenotype:** Homozygotes have normal eye color; in heterozygotes with other alleles, red pigment is reduced. *bw*<sup>4</sup>/*bw*<sup>5</sup> is purpleoidlike. *bw*<sup>4</sup>/*bw* like *bw* but darker. RK3.

**bw<sup>5</sup>**

**origin:** Spontaneous.

**discoverer:** Mohr, 31k28.

**phenotype:** *bw*<sup>5</sup>/*bw*<sup>4</sup> is purpleoidlike (see *bw*<sup>4</sup>); *bw*<sup>5</sup>/*bw*<sup>5</sup> is light yellowish brown; *bw*<sup>5</sup>/+ is wild type; *bw*<sup>5</sup>/*bw*<sup>5</sup> is lethal. RK2A.

**cytology:** Shown to be a deficiency based on failure to hybridize *in situ* with clones derived from this region (Dreesen, Johnson, and Henikoff).

**bw<sup>6</sup>**

**origin:** Spontaneous.

**discoverer:** Farmer, 1974.

**references:** 1977, Heredity 39: 297-303.

Farmer and Fairbanks, 1986, DIS 63: 50-51.

**synonym:** *Su(w<sup>co2</sup>)<sup>+</sup>*; *Su(w<sup>coJ</sup>)<sup>+</sup>*.

**phenotype:** A subliminal recessive allele of *bw*; homozygotes are wild type in all combinations except in flies that are homozygous or hemizygous for *w<sup>co2</sup>*, which are like *bw* or *w<sup>co</sup>*. *bw*<sup>6</sup>/*bw*<sup>4</sup> suppresses *w<sup>co2</sup>*, but all other heterozygotes between *bw*<sup>6</sup> and *bw* alleles which were tested did not suppress. RK1 in combination with *w<sup>co2</sup>*.

*bw*<sup>6lj</sup>: see *vs*<sup>6lj</sup>

**bw<sup>a</sup>: brown-amber**

**origin:** Spontaneous.

**discoverer:** R. C. King, 48f15.

**references:** Poulson and King, 1948, DIS 22: 54.

**phenotype:** Eye color light brownish yellow. Adult testes and vasa colorless. Larval Malpighian tubules slightly paler yellow than wild type. *bw*<sup>a</sup>/*bw* gives eye color slightly lighter than *bw*. RK1.

**\*bw<sup>A</sup>: brown-Auburn**

**origin:** X ray induced.

**discoverer:** Dubinin.

**synonym:** *A*; *Pm*<sup>DI</sup>.

**references:** Dubinin and Heptner, 1935, J. Genet.

30: 423-46 (fig.).

Dubinín, 1936, Biol. Zh. (Moscow) 5: 851-74.

**phenotype:** Nearly uniform brown but with extra *Y* chromosome shows strong variegation. Homozygote usually lethal. RK1A.

**cytology:** Associated with  $In(2R)bw^A = In(2R)A1;59D$ .

### ***bw<sup>D</sup>*: brown-Dominant**

**origin:** Spontaneous.

**discoverer:** T. Hinton, 1940.

**references:** 1940, DIS 13: 49.

1942, DIS 16: 48.

Slatís, 1955, Genetics 40: 246-51.

**phenotype:** Eye color varies with age from purple to brown. Shows slight variegation in combination with *st* (Slatís, 1955). Wings pebbled.  $bw^D/+$  shows nearly a 100-fold reduction in pteridine levels; no accumulation of *bw* RNA detectable.  $bw^D/bw^{VI} > bw^D/+ > bw^D/bw^D$  in severity of effect (Henikoff, and Dreesen, 1989, Proc. Nat. Acad. Sci. USA 86: 6704-08). Variegation suppressed by extra *Y* chromosomes (Brosseau, 1959, DIS 33: 123). Homozygote viable and fertile. Larval Malpighian tubules bright yellow (Brehme and Demerec, 1942, Growth 6: 351-56). RK1A.

**alleles:**  $bw^{D114}$ , X ray induced (Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-285).

**cytology:** Schultz reports an extra band in 59E that tends to pair with a band in the homolog, suggesting a duplication of one band from 59E. Slatís (1955) reports insertion of three or four bands, probably of heterochromatic origin. Reverts to wild type when extra bands separated from *bw* locus (Hinton and GoodSmith, 1950, J. Exp. Zool. 114: 103-14). Examination of stained metaphase preparations reveals a block of heterochromatin in the approximate position of  $bw^D$  (Dimitri and Pimpinelli).

**other information:** Since 1950 some and perhaps all lines of  $bw^D$  have undergone a secondary event that removed a portion of the coding region of the *brown* gene, generating a null allele (Dreesen and Henikoff).

### ***\*bw<sup>ptm</sup>*: brown:pteridine modifier**

**origin:** Naturally occurring allele.

**synonym:** *ptm*.

**references:** Clancy, 1967, DIS 42: 57.

**phenotype:** Undetectable in wild-type background. In  $w^{sar}$  or  $w^{cf}$  flies that are at the same time *v*, *cn*, or *st*, the amount of red eye pigment in  $+/+ > +/bw^{ptm} > bw^{ptm}/bw^{ptm}$ .

### ***bw<sup>R</sup>*: brown-Rearranged**

**origin:** X-ray-induced derivatives of *bw* or  $bw^+$ .

**discoverer:** Slatís, 48k16.

**references:** 1955, Genetics 40: 5-23.

**phenotype:** These rearranged derivatives exhibit variegated phenotype in combination with *+*. Mostly homozygous lethal; survivors have brown eyes.

**alleles:** These derivatives and those associated rearrangements are listed in the accompanying table. More complete descriptions in CP627.

**cytology:** All associated with chromosome rearrangements with one breakpoint in 59DE and one in proximal heterochromatin.

<sup>α</sup> Polytene analysis unavailable where breakpoints not indicated.

### ***bw<sup>V1</sup>*: brown-Variegated**

**origin:** X ray induced.

**discoverer:** Muller, 1929.

**synonym:** *Pm*: *Plum*.

**references:** 1930, J. Genet. 22: 299-334 (fig.).

Glass, 1934, J. Genet. 28: 69-112 (fig.).

1934, Am. Naturalist 68: 107-14.

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Eye color like *bw* or *pr*, mottled with darker spots that deepen in red color with age. With *st* or *v*, has pale orange ground with dark orange spots.  $bw^{V1}/bw$  shows sharply reduced levels of transcript from both the  $bw^+$  allele in *cis* with the rearrangement and the *bw* allele on the homologous second chromosome (Henikoff, and Dreesen, 1989, Proc. Nat. Acad. Sci. USA

86: 6704-08). Extra *Y* chromosome, as with other variegated browns, suppresses brown color, giving red eye sparsely speckled or spotted with darker spots. Amount of wild-type eye color also responds to fourth-chromosome constitution;  $4/C(4) > C(4) = 4/4 > 4/0$ , with the first approaching wild type and the latter nearly *bw* (Lindsley and Rokop). Larval Malpighian tubules normal (Glass, Brehme). Generally lethal homozygous and in combination with other brown-Variategateds. Heterozygotes fully viable and fertile. RK1A.

**alleles:** Other variegated alleles of *bw*, all of which are associated with X-ray-induced chromosome aberrations, are listed in the accompanying table. More complete descriptions in CP627.

**cytology:** Associated with  $In(2LR)bw^{VI} = In(2LR)21C8-D1;60D1-2 + In(2LR)40F;59D4-E1$  (Schultz and Bridges).

*bw-b*: see *ca*

*bwn<sup>G</sup>*: see *ca<sup>G</sup>*

***bx*:** see ***BXC***

***bx<sup>D</sup>*:** see ***Ubx*** in ***BXC***

***Bx*: Beadex**

**location:** 1-59.4.

**phenotype:** Male and homozygous female with Beaded-like wings; long, narrow, and excised along both margins; fully viable. Heterozygous female less extreme and overlaps wild type. Some venation abnormality. Development studied by Goldschmidt [1935, Biol. Zentr. 55: 535-54 (fig.)]. According to Waddington (1940), embryological effect is same as that of *vg*. RK2 (RK3 as *Bx/+*).

<sup>β</sup> Size of DNA insert in *Bx* region.  
<sup>γ</sup> Phenotypes described below.

**cytology:** Placed in 17C2-3 based on the position of break-points of hybrid-dysgenesis-induced *hdp* mutants (Engels and Preston, 1981, Cell 26: 421-28).

**molecular biology:** 49kb, including the *Bx* locus, cloned and restriction mapped by Mattox; 0 coordinate defined as *Sma*I site within a 1.8 kb *Bam* HI fragment within or very close to the *Bx* coding sequence; positive values to the right. Six mutants differ from wild type in having different segments of DNA inserted into the same 0.4kb restriction fragment (-2.0 to -1.6). *Bx<sup>2</sup>* has two gypsy elements inserted in opposite orientation at coordinates -0.5 and -1.5. Hybrid-dysgenesis-induced mutations, *Bx<sup>9</sup>* and *Bx<sup>15</sup>*, are imprecise excisions of the P factor, which is inserted at coordinate -0.8 in the Π2 X chromosome and is without phenotypic effect. *Bx<sup>9</sup>* deletion includes 1.2kb of flanking DNA including -0.8 to -2.0, and *Bx<sup>15</sup>* deletion of 2.0kb includes -1.3 to +0.4 (Mattox and Davidson, 1984, Mol. Cell. Biol. 4: 1343-53).

**other information:** Interpreted by Lifschytz and Green (1979, Mol. Gen. Genet. 171: 153-59) as mutation in *cis*-acting control element causing overproduction of *hdp-a* gene product. Tandem duplication of *Bx<sup>+</sup>* and *hdp-a<sup>+</sup>* has recessive *Bx* effect (e.g., *Bx<sup>r</sup>*); tandem tripllication and quadruplication have dominant *Bx* effects in combination with a normal X, but not in combination with *hdp-a* or a *Bx* deficiency (Lifschytz and Green, 1979). Amorphic or extreme hypomorphic *Bx* mutations and deficiencies for *Bx* act as trans suppressors of *Bx*. Suppression used by Lifschytz and Green to select null alleles or deficiencies from treated + or *Bx<sup>3</sup>* chromosomes; seven derivatives of *Bx<sup>3</sup>* and those of *Bx<sup>+</sup>* described; all have *hdp-a* effects as well.

***Bx<sup>2</sup>*: Beadex-2**

Edith M. Wallace, unpublished.

***Bx<sup>2</sup>***

**phenotype:** Wings of males and homozygous females narrowed by marginal excision. Wings often bubbly and ragged. Homozygous female fully viable. *Bx<sup>2/+</sup>* less extreme; overlaps wild type. Classifiable in a single dose in triploids (Schultz, 1934, DIS 1: 55). RK1 (RK3 as *Bx<sup>2/+</sup>*).

***Bx<sup>3</sup>***

**phenotype:** Extreme allele usually without the bubbles in the wing. Shortened L5 a constant character (few *Bx<sup>2</sup>* show this). Wings more pointed than *Bx<sup>2</sup>* and hairs at tip of wing clumped. Third-instar larvae show 20-40 degenerating cells in area of wing disk corresponding to future wing margin (D. Fristrom, 1969, Mol. Gen. Genet. 103: 363-79). Scalloping visible in prepupal

wing bud [Waddington, 1940, *J. Genet.* 41: 75-139 (fig.)].  $Bx^3$  in heterozygous combination with a  $Bx$  deficiency or  $hdp-a$  has normal wing phenotype (Lifschytz and Green, 1979, *Mol. Gen. Genet.* 171: 153-59).  $Bx^3/+$  fully separable. RK1.

### $Bx^J$ : *Beadex of Jollos*

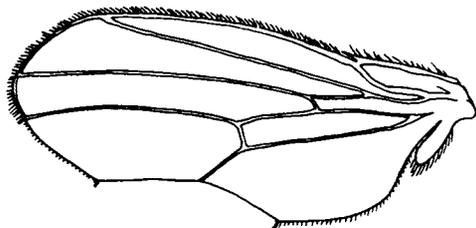

**phenotype:** Wings reduced to slender strip; only posterior cell present at tip.  $Bx^J/+$  have half and  $Bx^J/Bx^J$  one third the normal number of cells in membrane of wing. Femur shortened or legs otherwise abnormal, especially third pair. Halteres abnormal. Homozygous female viable. Interacts with  $bi$  to give more nearly normal wings. The only dominant  $Bx$  allele not suppressed by a  $Bx$  deficiency [e.g.,  $In(1)Cl^{Ly}4R$ ] or  $hdp$  (Lifschytz and Green, 1979, *Mol. Gen. Genet.* 171: 153-59). Embryology like  $Bx$  [Goldschmidt, 1935, *Biol. Zentr.* 55: 535-54; Waddington, 1940, *J. Genet.* 41: 75-139 (fig.)]. Clonal analysis of wing disk development indicates massive cell loss during third larval instar. Clones of  $Bx^+$  cells in  $Bx^J/+$  wings that reach the margin but are confined to the dorsal or ventral surface often cause reconstitution of both surfaces and appearance of marginal elements derived from both surfaces (Santamaria and García-Bellido). RK1. 1975, Wilhelm Roux' Arch. Entwickl.-mech. Organ. 178: 233-45.

### $Bx^r$ : *Beadex-recessive*

**phenotype:**  $Bx^r/+$  is normal. Male and homozygous female show less extreme narrowing of wings than  $Bx$ . Anterior crossvein short and thickened and that region blistered. May overlap wild type in old crowded cultures at 25°, more extreme at 19°. RK3A.

**cytology:** Associated with  $Dp(1;1)Bx^r = Dp(1;1)17A;17E-F$  (Green, 1953, determined by E.B. Lewis). Recessive  $Bx$  effects are due not to an altered gene but to increased dosage of the normal allele.

**other information:**  $Bx/Dp(1;1)Bx^r$  produces recombinants of genotype  $Bx^+Bx$  and  $BxBx^+$ , which are more extreme than  $Bx$ . Same holds for  $Bx^2/Dp(1;1)Bx^r$ .

### $Bx^{r49k}$ : *Beadex-recessive 49k*

From Green, 1953, *Z. Indukt. Abstamm. Vererbungsl.* 85: 435-49.

### $Bx^{r49k}$

**phenotype:** Slight scalloping of posterior wing margin only; overlaps wild type. RK3A.

**cytology:** Associated with  $Dp(1;1)Bx^{r49k} = Dp(1;1)17A;17C$  (E.B. Lewis).

**other information:** This duplication undergoes unequal crossing over readily and forms triplications and quadruplications. Duplication is recessive; triplication is dominant. Phenotypic interaction with  $Bx$  same as for  $Bx^r$ .

## **BXC: *Bithorax Complex* (I. Duncan)**

The bithorax complex (BXC) is a gene cluster that functions to assign unique identities to body segments in the abdomen and posterior thorax (Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, *Science* 221: 23-29). Most, perhaps all, BXC functions are expressed within parasegments, metameric units composed of the posterior compartment of one segment and the anterior compartment of another. Complementation studies indicate that the BXC is organized into three large functionally integrated regions, known as the *Ultra-bithorax* (*Ubx*), *abdominal-A* (*abd-A*), and *Abdominal-B* (*Abd-B*) domains. Apparent point mutations have been recovered that totally inactivate each of these domains. The *Ubx* domain functions primarily to assign identities to parasegments 5 and 6 (PS5 and PS6), the *abd-A* domain functions in PS7-PS13, and the *Abd-B* domain functions in PS10-PS14. Each BXC domain contains subregions that are responsible for the assignment of identities to specific compartments or parasegments. The *Ubx* domain contains two major subregions. These are the *anterobithorax-bithorax* (*abx-bx*) region, which specifies PS5 identities, and the *bithorax-postbithorax* (*bxd-pbx*) region, which specifies PS6 identities. Molecular studies indicate that most or all *Ubx* domain functions are executed by a family of homeodomain-containing *Ubx* proteins. The *abx-bx* and *bxd-pbx* subregions appear to *cis*-regulate the expression of these proteins in PS5 and PS6, respectively. *abd-A* and *Abd-B* functions are also executed by homeodomain-containing proteins. The *abd-A* and *Abd-B* domains each contains parasegment- or segment-specific subregions which have been named *infra-abdominal* (*iab*) regions. Each *iab* region is named according to the anterior compartment of the segment or parasegment whose identity is specifically abolished by mutations in that region. For example, *iab2* mutations cause a transformation of the anterior second abdominal segment (A2) toward A1, and *iab3* mutations cause transformations of anterior A3 (and more posterior segments) toward A2. The *iab2*, *iab3*, and *iab4* subregions are contained within the *abd-A* domain whereas the *iab5* through *iab9* regions are located within the *Abd-B* domain. Some evidence suggests that the *bxd-pbx* region and some of the *iab* regions may be bifunctional and affect the expression of both adjacent BXC domains. Remarkably, the order of subregions within the complex is the same as the order of the parasegments or segments that each affects. Although it is not known whether this correlation has functional significance, two mutations (*Uab<sup>1</sup>* and *Cbx<sup>1</sup>*) that change the relative order of BXC regions alter the spatial expression of BXC products.

### ***abd-A: abdominal-A* (I. Duncan)**

**phenotype:** Null alleles are recessive lethal. Homozygous larvae show transformations of the ventral and dorsal setal belts of A2 through A8 toward A1. These transformations are complete in A2 through A4, but are incomplete more posteriorly. Partial Keilin's organs composed of monohairs occur variably on all segments from A1 through A7. In the adult cuticle, homozygous *abd-A* mitotic recombination clones are completely transformed to A1 in segments A2 through A4 and show characteristics of A1 to A4 in segments A5 to A7.

**phenotype:** Heterozygotes for null alleles show weak anteriorly-directed transformations of A5, A6, and A7. In the male, this results in the presence of a tiny extra tergite in A7 and a loss of pigmentation on the A5 tergite. Heterozygotes are partially to completely sterile in both sexes, but are fertile if a duplication for the BXC [such as *Dp(3;5)P5* or *Dp(3;1)P68*] is present. Hemizygotes and homozygotes are lethal; embryos lack posterior spiracles

and filzkörper, have the ventral setal bands of A6, A7 and A8 transformed toward A5 or A4, and develop rudimentary chitinized plates in posterior A8.

Peifer and Bender, 1986, EMBO J. 5: 2293-2303.

**phenotype:** Homozygotes show variable transformations of the anterior-most portion of the third thoracic segment (T3) toward the corresponding part of T2. Homozygotes also show variable transformations of posterior T2 to posterior T1. The latter effect is enhanced by low temperature. Partially complements and shows transvection with *bx*<sup>1</sup>, *bx*<sup>3</sup>, and *bx*<sup>34e</sup>. *abx/pbx* has the posterior portion of the distal segment of the haltere very slightly transformed into wing tissue; *abx/pbx*<sup>2</sup> is similar if heterozygous for a rearrangement that suppresses transvection.

thoracic segment (T3) transformed toward corresponding region of second (T2). The extent of this transformation is allele dependent and is most extreme in *bx*<sup>3</sup> and weakest in *bx*<sup>4</sup>. Although the transformations caused by most *bx* alleles are uniform, those caused by *bx*<sup>1</sup> and *bx*<sup>34eprv</sup> are highly variable. At 17°C several *bx* alleles show weak and variable transformations of posterior T2 to posterior T1. *bx*<sup>3</sup>, *bx*<sup>8</sup>, and *bx*<sup>G</sup> over *pbx* show a very slight *pbx* effect (as described for *abx*) if heterozygous for a rearrangement that suppresses transvection.

**phenotype:** Homozygotes show transformation of the anterior first abdominal segment (A1) to the corresponding region of the third thoracic segment (T3). In addition, *bx* homozygotes have posterior T3 and posterior A1 transformed toward posterior T2. Hemizygotes for the stronger *bx* alleles show (with variable expression) formation of one or a pair of well-developed thoracic legs and, rarely, an extra haltere on A1; the frequency of these abdominal halteres is greatly enhanced in hemizygotes for *bx*<sup>9</sup> *iab2*<sup>K</sup>. The A1 legs in *bx* hemizygotes contain underdeveloped posterior compartments, indicating that posterior A1 is partially transformed toward thorax.

<sup>α</sup> Bender, Akam, Karch, Beachy, Peifer, Spierer, Lewis, and Hogness, 1983, Science 221: 23-29; Bender, Weiffenbach, Karch, and Peifer, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 173-80.

<sup>β</sup> Type is as described by Bender *et al.*, 1985.

- I Strong *bx<sup>d</sup>* (Hemizygotes): Transformation of posterior portion of haltere towards wing, loss of A1 tergite, and appearance of T3 legs on A1. Ventral setal belt of A1 is transformed toward that of T3, and ventral pits appear on abdominal segments A1 to A7, inclusive.
- II Intermediate *bx<sup>d</sup>* (Hemizygotes): Transformation of posterior portion of haltere toward wing, replacement of A1 tergite by post-notal tissue as in (I), no extra legs. A1 setal belt is intermediate between A1 and T3 type belts. Ventral pits on all abdominal segments.
- III Weak *bx<sup>d</sup>* (Hemizygotes): Only two *bx<sup>d</sup>* effects remain: A1 tergite is slightly reduced in hemizygote but not in homozygote, and ventral pits are formed on A1 to A7, inclusive, in the hemizygote and on A1 in the homozygote. These weak alleles when homozygous survive to adults and appear wild type.

and Hogness, 1983, Science 221: 23-29.

Casanova, Sánchez-Herrero, and Morata, 1985, J. Embryol. Exp. Morphol. 90: 179-196.

White and Akam, 1985, Nature 318: 567-69.

**phenotype:** *Cbx<sup>1</sup>/+* has a strong transformation of the posterior region of the second thoracic segment (T2) toward the corresponding region of the third (T3), and a weak and variable transformation of anterior T2 toward anterior T3. The *Cbx<sup>1</sup>* homozygote differs in having a stronger, but still variable, transformation of anterior T2 toward T3. *Cbx<sup>1</sup>/Ubx* has a slight enhancement of the *Ubx* phenotype (see also *su-Cbx*). *Cbx<sup>2</sup>* has both anterior and posterior regions of T2 moderately transformed toward T3. *Cbx<sup>Hm</sup>* affects only the wing, which is strongly transformed to haltere. Flies carrying two doses of *Cbx<sup>Hm</sup>* plus a normal allele have a virtually complete transformation of wing to haltere (as figured in Lewis,

1982). *Cbx<sup>2</sup>* and *Cbx<sup>Hm</sup>* have inseparable recessive *bx<sup>d</sup>* effects. *Cbx<sup>3</sup>/+* transforms anterior portions of T2 variably toward anterior T3. It has no effect in posterior T2. For an overview of the effects of *Cbx* mutants on specific structures see Table 1: Lewis, 1982.

Bender, Weiffenbach, Karch, and Peifer, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 173-80.

**phenotype:** *Hab*/+ has the third thoracic segment (T3) and first abdominal segment (A1) variably transformed toward the second abdominal segment (A2), occasionally resulting in the loss of one or both metathoracic legs and one or both halteres; an A2 type tergite and sternite appear on T3; but A1 is only weakly transformed toward A2. Strongly enhanced when mother is from stock of *Df(3R)red-P93, l(3)tr Sb/In(3L)P + In(3R)P18, Me Ubx*.

**alleles:**

Duncan, 1987, Annual Review of Genetics 21: 285-391.

**phenotype:** Adult homozygotes or hemizygotes show transformations of A2 toward A1. The known alleles cause only partial transformations. Wheeler's organs (A2 structures) are reduced or absent and A2 tergite bristles are reduced in size. These alleles do not affect the larval cuticle pattern.

**alleles:**

Duncan, 1987, Annual Review of Genetics 21: 285-319.

**phenotype:** Hemizygotes show strong transformations of A5, A6, and A7 toward A4. In males, the A5 and A6 tergites show a loss of pigmentation and an unpigmented A4-type tergite develops in A7. Both A6 and A7 show the development of sternites with bristles. Heterozygotes show a small A7 tergite in the male. Two gain-of-function alleles recorded. *iab7*<sup>Spth</sup> (split thorax) heterozygotes display a longitudinal furrow in the mesothorax; *iab7*<sup>SGA</sup> heterozygotes causes abdominal structures to develop in the back of the head (Awad, Gausz, Gyurkovics, and Párducz, 1981, Acta Biol. Acad. Sci. Hung. 32: 219-28; Kuhn and Packert, 1988, Dev. Biol. 125: 8-18).

**alleles:** Seven alleles induced by X rays.

Celniker and Lewis, 1987, *Genes. Dev.* 1: 111-23.

Duncan, 1987, *Annual Review of Genetics* 21: 285-319.

**phenotype:** Adult homozygotes or hemizygotes show absent or defective genitalia and analia in both sexes. Adults homozygous or heterozygous for *iab9*<sup>65</sup> show in addition a partial transformation of A6 toward A7. Embryos hemizygous for *iab9* mutations show the development of a zone of naked cuticle and a rudimentary ninth abdominal setal belt posterior to the eighth abdominal setal belt. Posterior spiracles are absent in *iab9*<sup>65</sup> and *iab9*<sup>48</sup> hemizygotes and are defective in *iab9*<sup>Uab1</sup>, *iab9*<sup>tuh-3</sup>, and *iab9*<sup>Tab</sup> hemizygotes. *iab9*<sup>65</sup> and *iab9*<sup>48</sup>, but not the other *iab9* mutations, cause transformations of the A8 setal belt (located in anterior A8) toward A7.

***Mcp*: Miscaldastral pigmentation (E.B. Lewis)**

**location:** 3-58.5 (to the right of *iab4*; to the left of *iab6*).

**origin:** Spontaneous.

**discoverer:** Crosby.

**synonym:** *Male chauvinist pigmentation*.

**references:** Lewis, 1978, *Nature* 276: 565-70.

Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, *Cell* 43: 81-96.

Duncan, 1986, *Cell* 47: 297-309.

**phenotype:** *Mcp* homozygotes have the fourth (A4) and fifth (A5) abdominal segments transformed to a state intermediate between A5 and A6. Similar, but weaker, transformations occur in *Mcp*<sup>1</sup>/+ heterozygotes. *Mcp*<sup>1</sup> can be scored in males by dark pigmentation of the A4 tergite and in females by an effect on the orientation of the lateral bristles of the A4 tergite.

***Tab*: Transabdominal (E.B. Lewis)**

**location:** 3-58.8.

**origin:** X ray induced.

**discoverer:** E.B. Lewis.

**synonym:** *Net*: Neo-ectopic tergite; *Eat*: Ectopic abdominal tergite; *Comma*-like.

**references:** Celniker and Lewis, 1984, *Genetics* 107: s17.

Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, *Cell* 43: 81-96.

Celniker and Lewis, 1987, *Genes Dev.* 1: 111-23.

**phenotype:** Heterozygous adults have a pair of laterally disposed longitudinal stripes of tissue on the second thoracic segment (T2) probably corresponding to tissue from the dorsal sixth (A6) and/or seventh (A7) abdominal segments. These ectopic stripes of tissue are entirely

black in males but only partially pigmented in females. *Tab*<sup>+</sup> flies are virtually sterile, and have a thin seventh tergite in males. Fertility is partially restored in the presence of a duplication for *BXC*, such as *Dp(3;1)P68*. When hemizygous, *Tab* embryos have a reduction of the posterior spiracles and filzkörper, and a tiny ninth abdominal ventral setal belt that appears as a small row of denticles posterior to the A8 setal belt.

**cytology:** Associated with *In(3R)Tab = In(3R)89E;90D*.

**molecular biology:** The inversion puts the 90D region into the *BXC* at +188 kb., in the presumed *iab9* region (see Karch *et al.*, 1985).

### **Uab: Ultraabdominal (E.B. Lewis)**

**location:** 3-58.8.

**references:** Kiger, 1976, *Dev. Biol.* 50: 187-200.

Davis and Kiger, 1977, *Dev. Biol.* 58: 114-23.

Lewis, 1978, *Nature* 276: 565-70.

Lewis, 1982, *Embryonic Development: Genes and Cells* (Burger, ed.). Alan Liss, Inc., New York, pp. 269-88.

Karch, Weiffenbach, Peifer, Bender, Duncan, Celniker, Crosby, and Lewis, 1985, *Cell* 43: 81-96.

**phenotype:** *Uab*<sup>1</sup>, *Uab*<sup>2</sup>, and *Uab*<sup>4</sup> cause A1 to transform toward A2. *Uab*<sup>5</sup> causes A1 and A2 to transform toward A3. *Uab*<sup>1</sup> is an intra-complex inversion with a breakpoint in the *bx*d region, *Uab*<sup>2</sup> is associated with a *Uab* mutation, the *Uab*<sup>4</sup> breakpoint is an *iab-3* mutation, and the *Uab*<sup>5</sup> breakpoint is a weak *bx*d mutation. Reversion studies show that *Uab*<sup>1</sup>, *Uab*<sup>4</sup>, and *Uab*<sup>5</sup> cause abnormal expression of *abd-A* domain functions in A1.

Mann and Hogness, 1990, *Cell* 60: 597-610.

**phenotype:** Larvae homozygous and hemizygous for strong *Ubx* mutants, such as the *Ubx*<sup>1</sup>-type, have the ventral setal bands or "hooklets" of the first abdominal segment (A1) and T3 transformed toward those of T2; dorsally, the hair patterns of posterior T2 and posterior T3 are transformed toward posterior T1; Keilin organs with 2 hairs appear on A1; ventral pits appear on segments A1 thru A7; two extra sets of anterior spiracles appear, one on T3 and one on A1. Homozygotes die, usually as tiny third-instar larvae, but occasionally grow to a normal-sized third-instar larvae and may pupate. Homozygotes of some weaker alleles, such as *Ubx*<sup>61d</sup>, survive to adult stage and show weak *bx*, *bx*d, and *pbx* effects, especially in the haltere, and A1 is generally reduced.

**bx<sup>d</sup>**: see **BXC**

**bx<sup>d</sup>**: see *Ubx* in **BXC**

**\*Bxd: Beadexoid**

**location**: 1-45.

**origin**: Spontaneous.

**discoverer**: Goldschmidt.

**references**: 1945, Univ. Calif. (Berkeley) Publ. Zool. 49: 507, 520.

**phenotype**: Like a strong *Bx*. RK2.

**Bxl**: see *Ubx* in **BXC**

**by: blistery**

**location**: 3-48.7.

**origin**: Spontaneous.

**discoverer**: Glass, 33a.

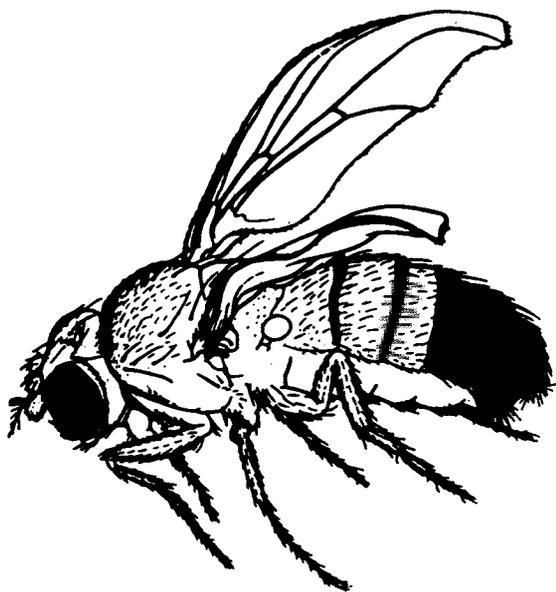

**references**: 1934, DIS 2: 8.

**phenotype**: Wings blistered in subterminal region; wing surface dusky and warped. Thorax humpy. RK1.

**alleles**: \**by*<sup>46h</sup> (CP627) like *by* but without thoracic effect.

**cytology**: Placed in 85D11-E3 based on its inclusion in *Df(3R)by62 = Df(3R)85D11-14;85F6* and *Df(3R)by416 = Df(3R)85D10-12;85E1-3* (Kemphues, Raff, and Kaufman, 1983, Genetics 105: 345-56).

**bz**: see *mal*<sup>bz</sup>

**c: curved**

From Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 165.

**c: curved**

**location:** 2-75.5.

**phenotype:** Wings thin textured, divergent, uplifted at base, and curved downward throughout their length. RK1.

**alleles:**

**cytology:** Placed in 52D3-9 based on its inclusion in *Df(2R)KL9 = Df(2R)52D3;52D7-9* (Davis and MacIntyre).

*C*<sup>K</sup>: see *C-K*

*C-abl*: see *Abl*

*C-erb*: see *Egfr*

**\*C-K: Curved of Krivshenko**

**location:** 2- or 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Krivshenko, 5513.

**references:** 1956, DIS 30: 74.

**synonym:** *C*<sup>K</sup>.

**phenotype:** Wings are thin textured, slightly divergent, uplifted basally, and then curved downward. Homozygous lethal. RK2A.

**cytology:** Associated with *T(2;3)C-K = T(2;3)52;76;81;-*

86.

**other information:** Probably allele of *Rev*.

**C(): Crossover suppressor**

The terminology originally used for dominant suppressors of crossing over. These effects were found to be rearrangements and are so treated here. The symbol *C* in this context has been dropped except where included under synonymy.

**\*c(1)a: crossover suppressor for chromosome 1**

**location:** One factor in *X* and probably several autosomal modifiers.

**origin:** Spontaneous.

**discoverer:** Bridges, 1916.

**references:** Bonnier, 1923, Hereditas 4: 81-110.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 220.

**phenotype:** Reduces recombination between *v* and *f* from 23 to 15% and between *w*<sup>e</sup> and *v* from 31% to 10%. *c(1)a* was probably the cause of a secondary nondisjunction frequency of 15-30%. RK3.

**other information:** Validity of phenotypic description seems dubious. Probably an inversion.

*C(2)R*: see *In(2R)NS*

*C(2;3)*: see *In(2L)t*

*C(2L)HR*: see *In(2L)t*

*C(2L)T*: see *In(2L)t*

**c(3)G: crossover suppressor in chromosome 3 of Gowen**

**location:** 3-57.4 (1.0 to the left of *sbd*<sup>2</sup>, 4.0 to the right of *cv-c*).

**phenotype:** Eliminates meiotic crossing over in homozygous females. First-division nondisjunction and chromosome loss frequent (30% for *X*, 2, and 3; 20% for 4); second division normal; exceptions more frequent at 25° than at 19°. Production of triploids and intersexes 300-500 times normal. Egg hatch very low. Synaptonemal complexes absent from oocytes (Meyer), and both duration of meiotic prophase and number of 16-cell cysts per germarium reduced in *c(3)G/c(3)G* females (Smith and King, 1969, Genetics 60: 335-51). Meiotic loss of ring chromosomes increased in *c(3)G* females (Sandler, 1961, Nat. Cancer Inst. Monogr. 18: 243-73). No meiotic effects in homozygous males. In *c(3)G/+* females, both intergenic recombination (Hinton, 1966, Genetics 53: 157-64) and the subset of intragenic recombination accompanied by recombination of flanking markers (Carlson, 1972, Genet. Res. 19: 129-32) increased. Somatic pairing (Semjenov, 1979, Tsitologiya 21: 1353-55) and somatic crossing over (Le Clerc, 1946, Science 103: 553-54) normal in *c(3)G* homozygotes;

however, reported to be deficient for one of two X-ray-induced reactions leading to mitotic exchange (Handle, 1974, *Molec. Gen. Genet.* 128: 233-39). Heterochromatic interchanges inducible in oocytes of homozygous females by X irradiation (Roberts, 1969, *Genetics* 47: 387-408; Würigler, Graf, Ruch, Beck, and Steiner, 1978, *Arch. Genet.* 51: 217-42). Oocytes of homozygous females show increased sensitivity to X irradiation and lack the normally observed fractionation effect (Watson, 1969, *Mutat. Res.* 8: 91-100; 1972, *Mutat. Res.* 14: 299-307); Watson (1972) also reports increased sensitivity of *c(3)G*-bearing sperm from *c(3)G/+* males to translocation induction. RK3.

<sup>β</sup> Severity of phenotype vis-à-vis *c(3)G*.

γ Fourteen other alleles recovered in same experiment.

**cytology:** Placed in region 89A2-5 on the basis of its inclusion in *Df(3R)c3G2 = Df(3R)89A2-3;89B4-5* (Hughes, Nelson, Yanuk, and Szauter).

***c(3)G*<sup>68</sup>**

**phenotype:** Effects slightly more severe than in *c(3)G*. Meiotic recombination absent; first-division nondisjunction and loss high (40% for X, 2, and 3; 30% for 4). Low level of nondisjunction in second meiotic division. Oocytes of homozygous females lack synaptonemal complex (Carpenter).

***c(3)G*<sup>OR28</sup>**

**phenotype:** Hypomorphic allele. Homozygous females show polarized reduction of recombination to 4.3% between *y* and *f* with greatest reduction distally. X-chromosome nondisjunction temperature sensitive; 16.7% at 25°; reduced to 10.2% in oocytes exposed to 17° during metaphase I and anaphase I; no X-chromosome loss at either temperature. Synaptonemal complex reduced in quantity and abnormal in structure. *c(3)G*<sup>OR28</sup>/*Df(3R)sbd*<sup>105</sup> females exhibit no recombination and 32% X-chromosome nondisjunction.

***ca: claret***

**location:** 3-100.7.

**references:** Sequeira, Nelson, and Szauter, 1989, *Genetics* 123: 511-24.

Yamamoto, Komma, Shaffer, Pirrotta, and Endow, 1989, *EMBO J.* 8: 3543-52.

**phenotype:** Eye color ruby. With *cn*, eye color is deep reddish yellow; with *bw*, translucent brownish yellow (Mainx, 1938, *Z. Indukt. Abstamm. Vererbungsl.* 75: 256-76). Larval Malpighian tubes colorless (Beadle,

1937, *Genetics* 22: 587-611). Eye color autonomous when larval optic disk from *ca* is transplanted into wild type or *v*. Wild-type disk in *ca* not entirely autonomous (Beadle and Ephrussi, 1936, *Genetics* 21: 230); *ca* flies produce less *v*<sup>+</sup> substance than wild type (Clancy, 1942, *Genetics* 27: 417-40). Uptake of radio-labeled kynurenine by larval Malpighian tubules greatly reduced; uptake by developing eyes nearly normal (Sullivan and Sullivan, 1975, *Biochem. Genet.* 13: 603-13). Presence of 4-O-glucosyl-N-acetyldopamine, possibly a detoxification product of dopamine, reported by Okubo (1958, *Med. J. Osaka Univ.* 9: 327-37). Slightly narrow body and pointed wing. RK1.

**alleles:** Some alleles are mutant for two closely spaced genes and are *ncd ca* double mutants; these alleles are designated *ca*<sup>nd</sup> in the following table.

<sup>α</sup> 1 = Bridges and Morgan, 1923, *Carnegie Inst. Wash. Publ. No.* 327: 219 (fig.); 2 = CP627; 3 = Davis, 1969, *Genetics* 61: 577-94; 4 = Frisardi and MacIntyre, 1984, *Mol. Gen. Genet.* 197: 403-13; 5 = Gossi and Moree, 1971, *DIS* 46: 40; 6 = Gossi, Kreisman, and Moree, *DIS* 48: 15; 7 = Lewis and Gencarella, 1952, *Genetics* 37: 600-01; 8 = Sequeira, Nelson, and Szauter, 1989, *Genetics* 123: 511-24; 9 = Yamamoto, Komma, Shaffer, Pirrotta, and Endow, 1989, *EMBO J.* 8: 3543-52.

**cytology:** Placed in region 99B5-9 based on its inclusion in both  $Df(3R)ca46 = Df(3R)98F14;99B5-9$  and  $Df(3R)L127 = Df(3R)99B5-6;99E4-F1$  (Frisardi and MacIntyre, 1984, Mol. Gen. Genet. 197: 403-13). Placed in 99B8-10 by *in situ* hybridization (Yamamoto *et al.*).

**molecular biology:** Region cloned in a 160-kb chromosome walk from 99C6-8 to 99B8-10 (Yamamoto *et al.*). A 7.4 kb mRNA detected on Northern blots with sequence from this region is the putative *ca* transcript; it is reduced or absent in  $ca^1$ ,  $ca^{34}$ ,  $ca^{nd1}$ , and  $ca^{nd7}$ , but present in *ncd* RNA. The 7.4-kb RNA is transcribed from left to right and its 5' end is very close to that of a transcription unit on the opposite strand that generates a 2.2-kb mRNA thought to encode the *ncd* product. All five *ncd ca* chromosomes tested have the same or similar 2.6-kb deletions for the 5' region shared by the two transcription units; the *P* element insert of  $ca^{34}$  resides in this segment.

### ***ca<sup>v</sup>*: claret-variegated**

**origin:** X ray induced.

**discoverer:** E. B. Lewis.

**phenotype:**  $ca^v/ca$  slightly variegated. Can be confused with wild type.  $ca^v/ca^{nd1}$  females produce normal progeny. Homozygous lethal. RK3A.

**cytology:** Associated with  $T(2;3)ca^v = T(2;3)59D;81F;94;99C-E$  (Craymer, 1980, DIS 55: 199).

### ***cab*: cabbage (J.C. Hall)**

**location:** 1-(not localized).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Sziber.

**references:** Aceves-Piña and Quinn, 1979, Science 206: 93-96.

**phenotype:** Blocked or impaired in learning, with respect to several types of conditioning tests used on groups of flies or on individuals, including those involving electric shocks (Booker and Quinn, 1981, Proc. Nat. Acad. Sci. USA 78: 3940-49) or exposure to flies (mated females, immature males) that in wild type induce poor courtship subsequently (Gailey, Jackson, and Siegel, 1982, Genetics 102: 771-82). *cab* flies may be generally debilitated, and tests involving habituation or sensitization to sugar stimuli gave unreliable results (Duerr and Quinn, 1982, Proc. Nat. Acad. Sci. USA 79: 3646-50).

### ***cac*: cacophony (J.C. Hall)**

**location:** 1-36.6.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schilcher, 1976, Behav. Biol. 17: 187-96. 1977, Behav. Genet. 7: 251-59.

Hall, Siegel, Tompkins, and Kyriacou, 1980, Stadler Genet. Symp. 12: 43-82.

Kulkarni and Hall, 1987, Genetics 115: 461-75.

Wheeler, Kulkarni, Gailey, and Hall, 1989, Behav. Genet. 19: 503-28.

**phenotype:** Males court abnormally with poor mating success and aberrant courtship song, which includes pulses of tone that are polycyclic, rather than monocyclic or tricyclic, within wild-type pulses and have increased amplitude. Some *cac* pulses, however, are quasi-normal in their cycle numbers (Wheeler *et al.*, 1989); these, as well as many of the polycyclic pulses, have essentially normal

intra-pulse frequencies; other *cac* pulses exhibit anomalous modulations, and these show multiple peaks in the intra-pulse spectra, unlike wild type. Mating success of wingless mutant males is still worse than that of wingless wild-type males, which is correlated with genetic separability of song abnormalities from deficit in mating performance. Female courtship appears to be unaffected by *cac*; but general locomotor activity of males or females is subnormal. *cac* is recessive for generally abnormal behavior and for courtship song defects in *tra/tra* flies (Kulkarni, Hall, and Schilcher).

**cytology:** Placed in 11A2 based on the failure of  $Df(1)HF368 = Df(1)11A2;11A9$  to complement *cac* in  $Df(1)HF368/cac$ ; *tra/tra* flies, and the normal courtship song of *cac* males carrying  $Dp(1;3)v^{+74c} = Dp(1;3)9E2;11B1-2$ .

**other information:**  $l(1)11Aa$  fails to complement both *cac* and *nbaA*; however *cac* and *nbaA* complement, and *cac* flies exhibit normal visual behavior and visual system physiology (Kulkarni and Hall, 1987). Chromosome rearrangements with breakpoints in 11A and which are lethal in combination with  $l(1)11Aa$  also fail to complement *cac* and *nbaA* [ $ln(1)A78$ ,  $ln(1)A97$ ,  $ln(1)N66$ , and  $Tr(1;1)A101$ ]. Complementation tests for *cac* carried out in diplo-X individuals transformed into phenotypic males by *tra*.

### ***cact*: cactus (T. Schüpbach)**

**location:** 2-52 (between *b* and *pr*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal mutant; embryos from homozygous mothers appear "ventralized"; at differentiation they form only a narrow strip of dorsal cuticle, whereas ventral setal belts are expanded and encircle in irregular fashion most of the embryonic periphery. At gastrulation the germband hardly extends at all, and the posterior midgut invaginates close to the posterior pole. Cephalic furrow is more pronounced than in wildtype.

**cytology:** Placed in 35E6-36A9 between the right break of  $Df(2L)osp29 = Df(2L)35B1-3;35E6$  and the left break of

*Df(2L)H20 = Df(2L)36A8-9;36E1-2.*

**cad: caudal**

**location:** 2-{55}.

**references:** Mlodzik, Fjose, and Gehring, 1985, EMBO J. 4: 2961-69 (fig.).

Levine, Harding, Wedeen, Doyle, Hoey, and Radomska, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 209-33 (fig.).

Macdonald and Struhl, 1986, Nature 324: 537-456 (fig.).  
Hoey, Doyle, Harding, Wedeen, and Levine, 1986, Proc. Nat. Acad. Sci. USA 83: 4809-13.

Mlodzik and Gehring, 1987, Cell 48: 465-78.

**phenotype:** Homozygous lethal; homozygous *cad* embryos from *cad*<sup>+</sup> moths develop into nearly normal first-instar larvae, which, however, lack cuticular structures of the external terminalia, e.g., the anal tuft, parts of the anal pads and the terminal sense organs. Distribution of *cad*<sup>+</sup> gene product in such embryos indistinguishable from that in their *cad*<sup>+</sup> and +/+ sibs, evidently maternally derived. *cad*<sup>+</sup> offspring from *cad/cad* oogenic cysts indistinguishable from those from *cad*<sup>+</sup> cysts; larvae lack portions of the eighth abdominal segment and sometimes parts of the fourth and less frequently other even-numbered abdominal segments; frequently they develop into normal adults. *cad/cad* embryos from homozygous *cad* cysts display variably abnormal segmentation; head and anterior thorax normal; many posterior segments deleted with T2 and odd-numbered abdominal segments more resistant to deletion; most of eighth abdominal segment and terminalia (but not some parts of posterior spiracles) deleted; replaced by small plates of sclerotized cuticle resembling mouth hooks. Maternal germ-line transcription of the *cad*<sup>+</sup> gene demonstrated by the detection of transcript in oocytes and nurse cells; transcripts uniformly distributed in early embryos; in the syncytial blastoderm transcripts disappear from the anterior end of the embryo and an anterior-posterior gradient develops with heaviest concentration posteriorly. The cellular blastoderm shows a band of hybridization three to five cells wide encircling the embryo .13 to .19 of the distance from posterior to anterior end; label is internalized during gastrulation and is seen in hind gut, midgut, and Malpighian tubules. Immunocytochemical observations detect no *cad* polypeptide until the stage 5 or 6 embryo. In the syncytial blastoderm there is dramatic accumulation of *cad* polypeptide in the same antero-posterior gradient as observed for transcript; the polypeptide localizes strongly to nuclei during interphase. The same gradient develops over time in unfertilized eggs. Subsequent collapse of the gradient into a posteriorly disposed circumferential band follows the behavior of transcript. Embryos produced by homozygous *BicD* or *bcd* females display an uniform distribution of *cad*<sup>+</sup> product, which subsequently becomes restricted to symmetrically disposed anterior and posterior rings of *cad* polypeptide. During gastrulation *cad*<sup>+</sup> polypeptide persists in a position suggesting a fifteenth parasegment, in the posterior midgut and Malpighian tubules, in six narrow bands at double segment intervals, in pairs of neuromeres initially in parasegments 1-14, later in thorax and anterior abdomen, and in portions of the genital disc, possibly precursors of the analia. In third instar larvae transcripts are also found in germ cells of both sexes and in the

presumptive hind gut and analia of the genital disc. The *cad* gene product can increase the level of *ftz* transcription in the posterior half of the embryo by interacting with multiple copies of a TTTATG consensus sequence located in the zebra-stripe element of the *ftz* promoter (Dearolf, Topol, and Parker, 1989, Nature 341: 340-42).

**alleles:** Four ethyl-methanesulfonate-induced alleles described by Macdonald and Struhl: *cad*<sup>1</sup>, *cad*<sup>2</sup>, *cad*<sup>3</sup>, and *cad*<sup>4</sup>.

**cytology:** Localized to 38E5-6 by *in situ* hybridization.

**molecular biology:** Locus initially identified and gene isolated on basis of homeobox homology. Genomic clones isolated and sequenced; two exons separated by an intervening sequence of 10.5 kb. The homeobox begins 14 base pairs from the beginning of the 3' exon. 2.4 kb maternal mRNA detected in 0-4 hr embryos and a 2.6 kb zygotic mRNA at cellular blastoderm. mRNA's differ in both initiation and termination sites; exons identical in the two. The polypeptide is characterized by a number of homopolymeric repeats: 10/10 His/Ala, 6/7 His, 10/12 Ser, 15/20 gly/val and 20/27 Asn in the 5' exon and 11/11 Arg in the 3' exon.

**\*cal: coal**

**location:** 3-59.5.

**origin:** Spontaneous.

**discoverer:** Grout, 47120.

**references:** Ives, 1948, DIS 22: 53.

**phenotype:** Black body color similar to *e*<sup>4</sup>. Viability reduced slightly. RK2.

**Cal: Calmodulin**

**location:** 2-{67}.

**discoverer:** Yamanaka.

**references:** Yamanaka, Sangstad, Hanson-Painton, McCarthy, and Tobin, 1987, Nucleic Acids Res. 15: 3335-48.

Smith, Doyle, Maune, Munjaal, and Beckingham, 1987, J. Mol. Biol. 196: 471-85.

**phenotype:** The structural gene of the calcium-binding protein, calmodulin (148 amino acids, 17000 daltons).

**cytology:** Located in region 49A by *in situ* hybridization (E.B. Lewis).

**molecular biology:** Genomic clone isolated from library using electric eel cDNA probe. Gene comprises four exons separated by three introns of 3400 to 4300 base pairs in length, exon 1 consists of 5' untranslated region and the initiator ATG; exon 2 encodes amino-acid residues 1 to 58.3; exon 3 residues 58.3 to 139.3 and exon 4 residues 139.3 to 148 plus the 3' untranslated region. Sequence highly conserved among eukaryotic species. Transcripts of 1.65 and 1.9 kb found at intermediate levels in embryos, high levels in larvae, and low levels in adults.

**capu: cappucino** (*T. Schüpbach*)

location: 2-8.

origin: Induced by ethyl methanesulfonate.

references: Manseau and Schüpbach, 1989, *Genes Dev.* 3: 1437-52.Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal. Homozygous females lay eggs which sometimes (5-10%) have a "pointed cap" (cappucino) of dorsal appendage material sitting over the anterior end of the egg, instead of two distinct dorsal appendages. Such eggs are similar to eggs formed by the female-sterile mutation *fs(1)K10* but the extent of dorsal appendage material on *capu* eggs is much more variable than that of *fs(1)K10* eggs. No polar granules are found in such eggs. Mutant females produce embryos lacking polar granules, pole cells, and normal abdominal segmentation. In combination with *Bic-D*, however, abdominal segmentation does develop in the anterior half of the embryo. Improper localization of abdominal determinants also indicated by the lack of posterior localization of *vasa* protein. Cellularization of the blastoderm irregularly defective, with nuclei of different sizes and densities. Resemble embryos formed by other grandchildless-knirps-like mutations, such as *vasa* or *tudor*, but in addition, some of the embryos from *capu* also appear dorsitized. Mosaic studies demonstrate germ-line function of *capu*.

**alleles:** Four, *capu*<sup>1</sup> to *capu*<sup>4</sup> isolated as *RK*, *G7*, *H3*, and *H8*, respectively.

**car: carnation**

location: 1-62.5.

origin: X ray induced.

discoverer: Patterson, 28c20.

references: 1934, *DIS* 1: 31.

**phenotype:** Eye color dark ruby. Body shape and proportions seem rounded. With *st*, eye color is yellow-brown; with *bw*, brownish yellow to brown (Mainx, 1938, *Z. Indukt. Abstamm. Vererbungsl.* 75: 256-76). Malpighian tubes pale yellow in mature larva (Beadle, 1937, *Genetics* 22: 587-611) but hard to distinguish from wild type before third instar. Eye color autonomous in transplant into wild-type host (Beadle and Ephrussi, 1936, *Genetics* 21: 230). *car dor* is pupal lethal and shows reduced recovery in gynandromorphs with male parts *car dor* (Nash, 1971, *DIS* 47: 73). *car lt* also lethal, dies as larva when mother *car;lt/+* or *car/+;lt* and as pupa when mother *car/+;lt/+* (Nickla, 1977, *Nature* 268: 638-39); lethal focus domineering; fate maps to ventral nervous system (Nickla, Lilly, and McCarthy, 1980, *Experientia* 36: 402-05). Brain histology abnormal [McCarthy and Nickla, 1980, *Experientia* 36: 1361-63 (fig.)].

**alleles:** \**car*<sup>2</sup> and *car*<sup>26-48</sup> (CP627).

**cytology:** Shown to lie in doublet 18D1-2 by deficiency analysis (J.I. Valencia).

**caramel:** see *cml***cardinal:** see *cd***carmine:** see *cm***carminoid:** see *cmd***carnation:** see *car***Casein kinase:** see *CklI***cast: ojos castaños**

location: 1-36.

origin: Spontaneous in dysgenic cross.

references: Valdé del Rio and Costas, 1982, *DIS* 58: 210.

**phenotype:** Eye color chestnut brown in both sexes. *cast*-bearing strain reverts with low frequency and generates mutations at other loci as well.

**Cat: Catalase**

**location:** 3-47.0 (assuming that strain differences in catalase level represent allelic differences at the *Cat* locus).

**references:** Lubinski and Bewley, 1977, *Genetics* 86: s39. 1979, *Genetics* 91: 723-42.

Bewley, Nahmias, and Cook, 1983, *Dev. Genet.* 4: 49-60.

Mackay and Bewley, 1989, *Genetics* 122: 643-52.

**phenotype:** The structural gene for catalase [CAT(EC 1.11.1.6)]. Two peaks of activity, the smaller in late third instar larvae just prior to puparium formation and the larger during metamorphosis; coincident with the two major peaks of ecdysone titer. High specific activity in larval Malpighian tubules, gut, and fat body; higher in adult abdomen than in thorax or head. Purification and characterization of enzyme by Nahmias and Bewley (1984, *Comp. Biochem. Physiol.* 77B: 355-64). Amorphic and hypomorphic mutants are hemizygous viable on normal medium; however those with the lowest levels of catalase activity exhibit severely reduced viability (i.e., less than 2% normal levels). All mutants show increased sensitivity to the presence of hydrogen peroxide in the medium.

**alleles:** No electromorphs detected among 50 inbred laboratory strains. Bewley, MacKay, and Cook (1986, *Genetics* 113: 919-38) describe two strains that differ from the majority of strains in their levels of catalase; one exhibits a reduction in activity to 0.47 X normal, with a disproportionate reduction during third instar, and the other displays a 1.5 fold increase in activity; the differences are attributable to differences in the rates of enzyme synthesis. The difference maps between *st* and *cu* at 3-47.0, which is within or near the 75D-F interval within which *Cat* resides. Thus these activity differences may be attributable to allelic variation at the *Cat* locus.

origin: Induced by ethyl methanesulfonate.

references: Heisenberg, Borst, Wagner, and Byers, 1985, J. Neurogenet. 2: 1-30.

phenotype: Ellipsoid body and central body of central brain abnormally flat and broad; learning abnormal in tests using olfactory stimuli.

alleles: *ccb*<sup>1</sup> and *ccb*<sup>2</sup> (formerly *ccb*<sup>KS127</sup> and *ccb*<sup>KS145</sup>).

**ccd: central complex deranged (J. Hall)**

location: 1-15.

origin: Induced by ethyl methanesulfonate.

references: Heisenberg, Borst, Wagner, and Byers, 1985, J. Neurogenet. 2: 1-30.

phenotype: Ellipsoid body of central brain abnormally flat and broad; fiber number in inter-hemispheric commissure of brain reduced (in white pupae); abnormal larval and adult learning in tests using olfactory stimuli; activity in open-field locomotor test reduced.

**ccw: concave wing**

location: 1-23.4.

origin: Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

discoverer: Fahmy, 1953.

references: 1958, DIS 32: 68.

phenotype: Wings shorter and narrower with L3 and L4 shifted toward each other, occasionally truncated. Wing membrane depressed in center into slight concavity, giving slight scooped effect. Not easily classified. RK3.

**other information:** One allele induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine.

**cd: cardinal**

location: 3-75.7.

origin: Spontaneous.

discoverer: Johnson, 19k24.

references: Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 217 (fig.).

phenotype: Eye color yellowish vermilion, changing toward wild type with age. Drosoperin content of eyes about 85% normal (Gearhart and MacIntyre, 1970, Anal. Biochem. 37: 21-25). Phenoxazinone synthetase activity about 39% wild type; accumulates 3-hydroxykinurenine (Phillips, Forrest, and Kulkarni, 1973, Genetics 73: 45-56; Sullivan, Grillo, and Kitos, 1974, J. Exp. Zool. 188: 225-34). Ocelli white, showing no effect of age. Accumulates a blue-fluorescent compound termed cardinalic acid (xantherenic acid 8-O-β-O-glucoside) (Ferre, Mensua, and Jacobson, 1985, DIS 61: 71). Eye color autonomous in transplant of larval optic disk into wild type, *ca*, *cn*, *st*, or *v* larval host (Beadle and Ephrussi, 1936, Genetics 21: 230). Larval Malpighian tubes bright yellow; not distinguishable from wild type. RK2.

alleles: *cd*<sup>3</sup> [persistent allele in Amherst population (Ives, 1970, Evolution 24: 507-18)]; *cd*<sup>79i</sup> and *cd*<sup>81d</sup> isolated from a natural population by Najera (1985, DIS 61: 215) and *\*cd*<sup>63</sup> (CP627).

cytology: Placed in 94A-E based on segmental hypoploid

from  $T(Y;3)D100 = T(Y;3)94A$  and  $T(Y;3)B27 = T(Y;3)94E$  (Jones, 1971, DIS 47: 90).

**cd<sup>wo</sup>: cardinal-white ocelli**

**discoverer:** Bridges, 12f21.

**synonym:** *wo*.

**references:** 1920, Biol. Bull. 38: 231-36.

Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 66.

**phenotype:** Ocelli colorless. Eye color wild type. Modifies  $w^e$  to a lighter and less yellow tone.  $cd/cd^{wo}$  has normal eye color but white ocelli (Jones, 1971, DIS 47: 90). RK2.

*Cd*: see *Cu*

**Ce: Cell**

**origin:** Spontaneous.

**location:** 4- (not located).

**discoverer:** Green.

**references:** 1952, DIS 26: 63.

**phenotype:** Ocelli reduced or absent; ocellar and scutellar bristles absent; interocellar microchaetae disrupted but frontals normal; postverticals short, thick, often with an adventitious pair between the normally placed postvertical bristles. Wing veins L3 and L4 converge, giving wing phenotype much like *fu* although wing phenotype variable. Homozygous lethal; lethality occurs during embryonic period (Hochman). Shown to be a segment polarity gene; homozygous embryos exhibit loss of the naked cuticle in the posterior half of each segment plus the anterior margin of the adjacent segment; most dorsal pattern elements also eliminated, leaving a lawn of fine hairs. Engrailed-antibody staining fails to detect a subset of CNS neurons in *Ce* homozygotes that are normally stained in wild-type embryos (Patel, Schafer, Goodman, and Holmgren, 1989, Genes Dev. 3: 890-904). No maternal requirement of  $Ce^+$  for either oogenesis or embryonic phenotype (Orenic, Chidsey, and Holmgren, 1987, Dev. Biol. 124: 50-56). Lethal phenotype of *Ce* not complemented by *l(4)I7* or by induced revertants of the wing phenotype of  $ci^D$  (Orenic *et al.*); pupal lethal in combination with  $ci^D$  [Hochman, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 902-28]. RK3.

**alleles:** *l(4)I7* renamed  $Ce^1$ : Cell recessive; homozygous and heterozygous with  $Ce^2$  has the same phenotype as  $Ce^2/Ce^2$ . *Scn* may also be allelic to *Ce* (Hochman).

$Ce^{r2}$	X ray		1, 5, 6	no dominant phenotype

<sup>α</sup> 1 = CP627; 2 = Glass, 1939, DIS 12: 47; 3 = Green, 1952, DIS 26: 63; 4 = Green, 1959, DIS 33: 94; 5 = Hochman, Goor, and Green, 1964, Genetica 35: 109-26; 6 = Orenic, Chidsey, and Holmgren, 1987, Dev. Biol. 124: 50-56.

**cytology:** Placed in salivary chromosome region 101E through 102B16, based on the inclusion of both  $Ce^1$  and  $Ce^2$  within *Df(4)M = Df(4)101E-F;102B6-17*.

**other information:** Based on (a) position, (b) homozygous phenotype, and (c) complementation results, *Ce* and  $ci^D$

postulated to be part of a single complex (Orenic *et al.*).

**ceb: central brain deranged (J.C. Hall)**

**location:** 1-23.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg.

**phenotype:** Extra lobe, in adult brain, of approximately 400 coiled Kenyon-cell fibers next to calyx of mushroom bodies; olfactory learning in adults slightly reduced; memory is normal.

**cytology:** Located in 7F1-8A5.

**Cec: Cecropin**

**location:** 3-{101}.

**references:** Kylsten, Samakovlis, and Hultmark, 1990, EMBO J. 9: 217-24.

**phenotype:** Three structural genes for three very similar cecropin proteins (cecropin *A1*, *A2*, and *B*), bacteriotoxic proteins that are induced in adults in response to bacterial infection. All three cecropin genes are coordinately induced by injection of bacteria, although the *B* gene is expressed at a much lower level. Levels appreciable within one hour, peak at 6 hours and have generally returned to base line by 24 hours. Cecropins also induced by ingested bacteria.

**cytology:** Placed in 99E by *in situ* hybridization.

**molecular biology:** Isolated from genomic library using homologous cloned sequence from *Sarcophaga peregrina*. Two neighboring clones found to encode three functional cecropin genes and two apparent pseudogenes, the order being *A1*,  $\Psi 1$ , *A2*,  $\Psi 2$ , and *B*. Each gene is interrupted by a short intron in the coding sequence; *CecA1* and *CecA2* encode the same peptide and differ from *Sarcophaga* sarcotoxin 1A at five residues in the signal sequence; *CecB* differs from *A1* and *A2* by ten amino acid replacements, five in the signal sequence. cDNA's from all three genes recovered indicating that all are transcribed. *CecA1* and *CecA2* are transcribed off of the same strand and *CecB* is transcribed off the other.

**cel: celibate (J.C. Hall)**

**location:** 1-48.5.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Lindsley.

**references:** Hall, Siegel, Tompkins, and Kyriacou, 1980, Stadler Genet. Symp. 12: 43-82.

**phenotype:** Males court females vigorously but rarely attempt to copulate and even less frequently achieve genital contact; females apparently unaffected by the mutation.

**central body defect:** see *cbd*

**central brain deranged:** see *ceb*

**central complex broad:** see *ccb*

**central complex deranged:** see *ccd*

**\*cf: cleft**

**location:** 1-65.6.

**origin:** Spontaneous.

**discoverer:** Bridges, 14j28.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 55 (fig.).

**phenotype:** Wings smaller and somewhat spread. L3 split just beyond first crossvein; extra crossveins and branches.

Gap in L4 beyond second crossvein. Males sterile. Viability good. RK2.

*cf*: see *cff*

*Cf*: see *Px<sup>Cf</sup>*

**cf1: Chorion factor 1**

**location:** 1-{0.5}.

**references:** Shea, King, Conboy, Mariani, and Kafatos, 1990, *Genes Dev.* 4: 1128-40.

**phenotype:** Encodes a protein that binds the promoter region of *Cp15*.

**cytology:** Placed in 2C4-8 by *in situ* hybridization.

**molecular biology:** Gene cloned and sequenced.

**cf2**

**location:** 2-{13}.

**references:** Shea, King, Conboy, Mariani, and Kafatos, 1990, *Genes Dev.* 4: 1128-40.

**phenotype:** Encodes a protein that binds the promoter region of *Cp15*.

**cytology:** Placed in 25A5-8 by *in situ* hybridization.

**molecular biology:** Gene cloned and sequenced.

*Cf-3*: see *Dl<sup>Cf-3</sup>*

***cff*: control of female fertility**

**location:** 1-39.09 (0.09 unit to the right of *dnc*).

**origin:** Spontaneous.

**synonym:** *cf* (preoccupied).

**references:** Salz and Kiger, 1984, *Genetics* 108: 377-92.

**phenotype:** *cff* is a specific cis-acting enhancer of the female-sterile phenotype of *dnc<sup>1</sup>*, without effect on phosphodiesterase activity. The number of progeny per female measured as 0 in *dnc<sup>1</sup> cff/dnc<sup>1</sup> cff*, 2.3 in *dnc<sup>1</sup> cff/dnc<sup>M14</sup> cff<sup>+</sup>*, and 30 in *dnc<sup>1</sup> cff<sup>+</sup>/dnc<sup>M14</sup> cff*.

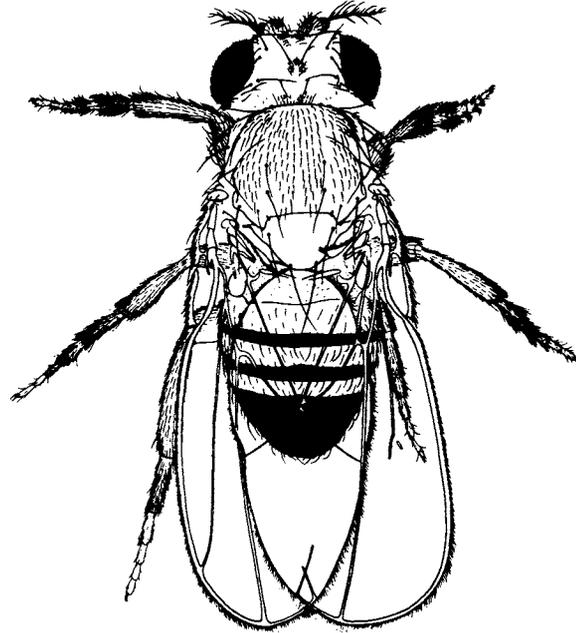

***cg*: comb gap**

**location:** 2-71.1.

**origin:** Spontaneous.

**discoverer:** Bridges, 25k16.

**phenotype:** Sex combs of male extremely large. Number of sex comb teeth increased from 10 to 18; number of bractless bristles increased; width of distal portion of basitarsus increased 1.6 fold; total number of bristles on basitarsus increased in both sexes (Datta and Mukherjee, 1968, *Proc. XII Int. Congr. Genet.* 1: 146; 1971, *Genetics* 68: 269-86). Some distortion and shortening of legs. Wings show gap in vein L4 between posterior crossvein and margin. Wings slightly curved. Effects result from a combination of overgrowth and irregular folding of imaginal rudiments during the pupal period. Strong exaggeration in compound homozygotes with genes such as *d*, *fj*, *ds*, and *ss<sup>a</sup>*. Double heterozygote for *cg* and *ci* often shows gap in L4 (Waddington, 1952, *J. Genet.* 51: 243-58). Double heterozygote *en cg/++* has slight degree of L4 interruption and thinning at low temperature. Triple heterozygote *en cg/++; ci/+* has L4 interruption in half the flies (House, 1961, *Genetics* 46: 871). *ci<sup>W</sup>* interacts strongly with *cg*. *cg/+; ci<sup>W</sup>/+* resembles *ci<sup>W</sup>/ci<sup>W</sup>* (House, 1953, *Genetics* 38: 669-70). Sex-comb phenotype enhanced by *sn* or *Pc/Scx* (Datta and Mukherjee, 1968, *Proc. XII Int. Congr. Genet.* 1: 146). Females sterile. Oogenesis highly irregular (Beatty, 1949, *Proc. Roy. Soc. Edinburgh B* 63: 249-70). RK2.

**cg: comb gap**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 40.

***Cg*: Collagen**

Fifteen of thirty clones, isolated from a genomic library using a chicken-derived pro $\alpha$ 2(I) collagen clone, define at least ten different sequences that can be differentiated by (1) their positions in the genome, (2) their restriction maps, (3) the numbers and sizes of mRNA's with which they hybridize on Northern blots, and (4) the developmental profiles of the various mRNA's (LeParco, Cecchini, Knibiehler, and Mirre, 1986, *Biol. Cell* 56: 217-26). The genes tabulated below are differentiated according to their estimated position on the polytene map based on *in situ* hybridization. Two of these loci (*Cg19-20* and *Cg25C*) had been identified previously and are described in more detail following the table.

locus	genetic location	synonym	mRNA sizes (kb)
<b><i>Cg9E</i></b>	1-{32}		1.3, 6.3
<b><i>Cg10AB</i></b>	1-{34}		1.3, 2.3
<b><i>Cg16-17</i></b>	1-{58}		0.7, 1.6, 2.7
<b><i>Cg19-20</i></b>	1-{65}		3.8, 4.3
<b><i>Cg25C</i></b>	2-{15}	<i>DCg1</i>	6.4
<b><i>Cg42DE</i></b>	2-{57}		
<b><i>Cg63-64</i></b>	3-{15}		1.6
<b><i>Cg98F99A</i></b>	3-{101}		
<b><i>Cg-C<sup>α</sup></i></b>			

<sup>α</sup> At least five separable sequences in the chromocenter; the probe that identifies these sequences does not contain rDNA sequences.

***Cg19-20***

**location:** 1-{65}.

**references:** Natzle, Monson, and McCarthy, 1982, *Nature* 296: 368-71.

**phenotype:** Encodes a type IV collagen, the major component of basement membrane. Transcripts accumulate during ecdysis in wandering hematocytes, indicating that hematocytes contribute to extra cellular matrix deposition

(Knibiehler, Mirre, Cecchini, and LeParco, 1987, Dev. Biol. 196: 243-47).

**cytology:** *In situ* hybridization  $^3\text{HcRNA}$  from pDCg2 to polytene chromosomes identifies complementary sequences in region 19E-20B.

**molecular biology:** Identified by means of a genomic clone (pDCg2) selected from a *Drosophila melanogaster*  $\lambda$  library using a cDNA probe for chicken pro $\alpha$ 2(I) collagen. Developmental profile of RNA hybridizing to pDCg2 shows peak during larval stage; little hybridization at other stages.

### Cg25C

**location:** 2-{15}.

**synonym:** *DCgI*.

**references:** Natzle, Monson, and McCarthy, 1982, Nature 296: 368-71.

Monson, Natzle, Friedman, and McCarthy, 1982, Proc. Nat. Acad. Sci. USA 79: 1761-65.

LeParco, Knibiehler, Cecchini, and Mirre, 1986, Exp. Cell. Res. 163: 405-12 (Fig.).

**phenotype:** Structural gene for a type IV basement-membrane collagen. Expression first detected following germ-band shortening in cells of both somatic and visceral mesodermal origin, specifically in mesoblasts (hemocytes) and fat-body cells (Mirre, Cecchini, LeParco, and Knibiehler, 1988, Development 102: 369-76). Translation takes place in embryonic mesoblasts and larval fat-body cells, and is deposited extracellularly in basement membranes surrounding skeletal and visceral muscles (LeParco, Bevic, Knibiehler, Mirre, and Cecchini, 1989, Insect Biochem. 19: 789-802).

**cytology:** Placed in 25C by *in situ* hybridization.

**molecular biology:** Identified by means of a genomic clone selected from a *Drosophila melanogaster*  $\lambda$  library using a cDNA probe for chicken pro $\alpha$ 2(I) collagen. *Drosophila* probe hybridizes to a 6.4 kb mRNA which shows peak during larval stages preceded by a small peak in late embryonic stages; cDNA and genomic sequence studies (Cecchini, Knibiehler, Mirre, and LeParco, 1987, Eur. J. Biochem. 165: 587-93; Blumberg, MacKrell, Olson, Kurkinen, Monson, Natzle, and Fessler, 1987, J. Biol. Chem. 262: 5947-50; Blumberg, MacKrell, and Fessler, 1988, J. Biol. Chem. 263: 18328-37) reveal that the gene comprises nine relatively large exons interrupted by eight relatively small introns (unlike mammalian homologues, which have numerous small exons separated by large introns). The complete cDNA sequence encodes an 1775 amino-acid protein including a signal peptide. Both N-terminal and C-terminal nonhelical domains involved in intermolecular junctional complexes share homology with mammalian type IV collagens, whereas the triple helical region shows little homology. The triple helical region comprises repeating sequences of Gly X Y tripeptides typical of such regions; similarly to other type IV collagens, the Y residues of the Gly X Y tripeptides show preference for lysines and prolines; furthermore, the positions of 11/22 interruptions of the tripeptide-repeat sequences in the *Drosophila* protein correspond nearly exactly to those of such nonhelical segments of the mammalian triple-helical domain, although there is no conservation of length or sequence of such interruptions. The C-terminal nonhelical domain displays 58% amino-acid identity and 76% similarity to its counterparts in human

and mouse type IV collagen. In all three sequences this region is composed of two homologous halves, A and B; all six segments each contain six completely conserved cysteins. Intraspecific homology between the A and B segments is considerably less than interspecific homology between A segments or B segments, indicating an ancient origin of the duplication.

### cgd: congested

**location:** 1-40 (37.6 and 41.7 in two determinations).

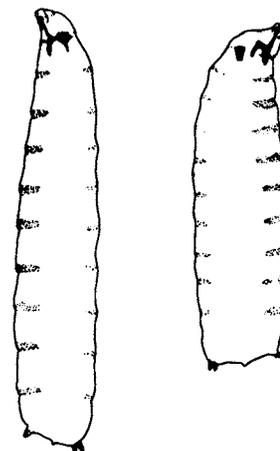

**origin:** Induced by ethyl methanesulfonate.

**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20 (fig.).

**phenotype:** Hemizygous lethal; first instar larvae unable to escape egg shell. Gut often poorly differentiated; cuticle phenotype variable - some normal, some with abnormal (e.g. fused) segments. Frequent holes in cuticle or absence of regions of cuticle.

**alleles:** Two.

**cytology:** Placed in 11B12-12C7.

### ch: chubby

Left: wild-type larva. Right: *chubby* larva. From Dobzhansky and Duncan, 1933, Wilhelm Roux' Arch. Entwicklungsmech. Organ. 130: 109-30.

### ch: chubby

**location:** 2-73.8 (based on mapping of *ch*<sup>76F</sup>; Rizki and Rizki, 1981, J. Hered. 72: 78-81).

**origin:** Spontaneous.

**discoverer:** Bridges, 17j26.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 222.

**phenotype:** Adults, pupae, and larvae thickset and short. Difficult to distinguish from wild type. Chubby larvae shorter than wild type at hatching [Dobzhansky and Duncan, 1933, Wilhelm Roux's Arch. Entwicklungsmech. Organ. 130: 109-30 (fig.)]. RK3.

**alleles:** *ch*<sup>76F</sup>, spontaneous (Rizki and Rizki, 1981).

*Ch*<sup>V</sup>: see *Kg*<sup>V</sup>

### \*ch-b: chilblained-b

**location:** 1-23.8.

**discoverer:** Moriwaki, 39e22.

**references:** 1939, DIS 12: 50.

**phenotype:** Tarsi conglutinated. RK3.

**cha: chaff** (*T. Schüpbach*)

**location:** 2-84.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal mutant; embryos from homozygous mothers form a fragmented cuticle with variable holes and head defects.

**alleles:** *cha*<sup>HB</sup> = *cha*<sup>1</sup>.

**Cha: Choline acetyltransferase** (*J.C. Hall*)

**location:** 3-64.6.

**synonym:** *Cat*.

**references:** Hall, Greenspan, and Kankel, 1979, *Soc. Neurosci. Symp.* 4: 1-42.

Greenspan, 1980, *J. Comp. Phys.* 137: 83-92.

**phenotype:** Probable structural gene for choline acetyltransferase [ChAT, acetyl CoA-choline-O-acetyltransferase (EC 2.3.1.6)], which has been purified and whose molecular weight approximates 67 kilodaltons (Slemmon, Salvaterra, Crawford and Roberts, 1982, *J. Biol. Chem.* 257: 3847-52); monoclonal antibodies prepared and inhibit enzyme (Crawford, Slemmon, and Salvaterra, 1982, *J. Biol. Chem.* 257: 3853-56); homozygotes and hemizygotes for either of the original two non-conditionally mutant alleles, *Cha*<sup>11</sup> or *Cha*<sup>12</sup>, show no detectable enzymatic activity as late embryos, which is when the mutants die; other non-conditional lethals at the locus not tested for lethal stage or ChAT activity; either of two temperature sensitive alleles, *Cha*<sup>ts1</sup> or *Cha*<sup>ts2</sup>, causes a variety of phenotypic defects when hemizygous or homozygous: reduced viability at 25° and death at 29° (*Cha*<sup>ts1</sup>), reduced viability at 18° and death at 22° or above (*Cha*<sup>ts2</sup>) plus gradual but reversible decline of enzymatic activity and of acetylcholine levels following transfer of low-temperature reared *Cha*<sup>ts</sup> adults to 29-30° or above (Greenspan, 1980; Salvaterra and McCaman, 1985, *J. Neurosci.* 5: 903-10); correlated with decrements in these biochemical parameters (reversible on lowering temperature), are heat-induced abnormalities of general mobility, male courtship ability, plus electroretinogram (Greenspan, 1980), landing response (Gorczyca and Hall, 1985, *Neurosci. Abstr.* 11: 512), and of several elements of physiological responses made by thoracic indirect flight muscles following stimulation of giant fiber pathway, implying that certain interneuronal synapses in this pathway are cholinergic (Gorczyca and Hall, 1984, *J. Neurogenet.* 1: 289-313); whereas wild type exhibits two molecular forms of ChAT activity after isoelectric focusing, homogenates of *Cha*<sup>ts1</sup> lead to a single form, and of *Cha*<sup>ts2</sup> to two forms shifted to higher-than-normal pI (Salvaterra and McCaman, 1985); these two conditional *Cha* mutations also cause ChAT activity to have accentuated thermolability in vitro (Greenspan, 1980; Salvaterra and McCaman, 1985). Immunohistochemical staining of ChAT reveals wide distribution in CNS; this staining is strong in *Cha*<sup>ts1</sup> at permissive temperature but diminishes after *in-vivo* heat treatment (Gorczyca and Hall, 1987, *J. Neurosci.* 7: 1361-69); *Cha*<sup>ts2</sup> staining is poor even at permissive temperature and diminishes after heating the flies (Gorczyca and Hall, 1987). *In situ* hybridization to tissue sections detected transcriptional activity in most neuronal elements of the

cell-rich areas of the cortical regions of the cerebrum and optic lobes; however, some cells in the lamina including the amacrine neurons showed no label. Highest expression is seen in laminar monopolar-cell region, and the cerebral cortical rind, and to a lesser degree, over cortical cells of medulla-lobula, the antennal sensory neurons, and the reticular-cell layer of the compound eye (Barber, Sugihara, Lee, Vaughn, and Salvaterra, 1989, *J. Comp. Neurol.* 280: 533-43). Immunolocalization of ChAT in the adult cephalic ganglion reveals weak staining in the lamina corresponding to the synaptic layer of photoreceptor cells 1-6 of the ommatidia, three layers of strong reaction corresponding to the synaptic layers in the medulla, and labeling of four layers in the lobula (Ikeda and Salvaterra, 1989, *J. Comp. Neurol.* 280: 283-90). In *Cha*<sup>ts1</sup> staining seen at 19° but disappears by 120 hours after shift to 30°; *Cha*<sup>ts2</sup> shows reduced staining at 19° and none after 80 hours at 30°.

<sup>β</sup> Fails to complement *l(3)91Ca*, *l(3)91Cb*, *Cha*, and *l(3)91Cd*.

<sup>γ</sup> Fails to complement both *Cha* and *l(3)91Cb*.

**cytology:** Placed in 91C7-D2 based on common breakpoints of *Cha*<sup>1</sup> rearrangements and on its absence from *Df(3R)Cha9 = Df(3R)91C7;92A8-9* and from *Df(3R)Cha12 = Df(3R)91A;91D1-2*.

**molecular biology:** 3' end of coding sequence recovered as a cDNA clone prepared from mRNA isolated from adult heads; sequence determined (Itoh, Slemmon, Hawke, Williamson, Morita, Itakura, Roberts, Shively, Crawford, and Salvaterra, 1986, *Proc. Nat. Acad. Sci. USA* 83: 4081-85). The *Drosophila* enzyme produced from complete *Cha* cDNA expressed in *Xenopus* oocytes, leads to active Chat (McCaman, Carbini, Maines, and Salvaterra, 1988, *Mol. Brain Res.* 3: 107-14).

**chaeta:** see *cht*

**chaetelle:** see *chl*

**chaff:** see *cha*

**chal: chalice** (*T. Schüpbach*)

**location:** 2-37.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females show abnormalities in late oogenesis. Follicle cells do not

migrate centripetally between nurse cells and oocyte. They do synthesize a chorion which remains open ended (like a chalice, or cup). Such eggs are usually not laid and remain unfertilized.

**alleles:** *chal*<sup>1</sup> to *chal*<sup>3</sup> isolated as *WP*, *HC*, and *QC*, respectively. *chal*<sup>2</sup> produces eggs of normal morphology which remains unfertilized.

**chaoptic:** see *chp*

**\*che: cherub**

**location:** 2-62.0.

**origin:** Ultraviolet induced.

**discoverer:** Meyer, 48g.

**references:** Meyer and Edmondson, 1951, DIS 25: 71.

**phenotype:** Wings short, papery, and downcurved with short, broad alulae. Males sterile. Homozygotes short lived; balanced stock *cn che bw spl In(2L+2R)Cy, al<sup>2</sup> Cy cn<sup>2</sup> L<sup>4</sup> sp<sup>2</sup>* has a generation time 30% longer than normal. RK3.

**alleles:** \**che*<sup>2</sup> and \**che*<sup>3</sup> in CP627.

**chic: chickadee (T. Schüpbach)**

**location:** 2-23.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; nurse cell contents are not transported into the egg, and homozygous females lay tiny eggs, which remain unfertilized.

**alleles:** *chic*<sup>1</sup> to *chic*<sup>3</sup> recovered as *WC*, *WF*, and *WK*.

**chif: chiffon (T. Schüpbach)**

**location:** 2-53 (between *b* and *pr*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile, homozygous females lay eggs which have thin, fragile chorions and remain unfertilized.

**alleles:** *chif*<sup>1</sup> to *chif*<sup>4</sup>, recovered as *WD*, *QV*, *QW*, and *WF* respectively.

**cytology:** Placed in 35E6-A9 between the right break of *Df(2L)osp29 = Df(2L)35B1-3;35E6* and the left break of *Df(2L)H20 = Df(2L)36A8-9;36E1-2*.

**chilblained-b:** see *ch-b*

**chl: chaetelle**

**location:** 2-60.8.

**discoverer:** Bridges, 33a4.

**references:** Beatty, 1949, Proc. Roy. Soc. Edinburgh B 63: 249-70.

**phenotype:** Bristles very small. Wing venation slightly plexuslike, exaggerates *px* when combined with it. Body size small. Rotated genitalia in many males. Blunt-tipped abdomen. Females infertile, but ovary and oocytes appear normal. RK2.

**chlorotic:** see *svr*

**cho: chocolate**

**location:** 1-5.5 [right of *ec*; (Lefevre, 1970, DIS 45: 40)].

**origin:** X ray induced.

**discoverer:** Weigle, 1955.

**references:** Sturtevant, 1955, DIS 29: 75.

**phenotype:** Eye color brown with whitish highlights. Paler than *se*, less purplish than *pn*. In *cho*<sup>2</sup> 2-amino-4-hydroxypterine absent; isoxanthopterin II present in excess (McKay, 1972, DIS 48: 62). Malpighian tubes of

larvae and adults contain brown pigment like *red*. Larvae easily distinguished from wild type. Malpighian tube color autonomous in mosaic larvae [Falk, Orevi, and Menzel, 1973, Nature (London) New Biol. 246: 19-20]. Brown pigment of Malpighian tubes absent when *cho* is combined with *v*, *cn*, or *st*, mutations which prevent formation of brown eye pigment. Eye color of *cho v* is yellowish, but *cho g* cannot be distinguished from *g*. Separability, viability, and fertility excellent. RK1.

**alleles:** *cho*<sup>2</sup> (CP627).

**cytology:** Placed in 3F on the basis of being included in *Df(1)GA102 = Df(1)3D5;3F7-8*, but not *Df(1)w64d = Df(1)3C2;3E8*.

Reinke, Krantz, Yen, and Zipursky, 1988, Cell 52: 291-301.

**phenotype:** The structural gene encoding chaoptin, a 160 kd glycoprotein localized to the extracellular membrane surface of photoreceptor cells and their axonal projections to the optic ganglia. Protein first identified by a monoclonal antibody (MAb24B10). Antigen first appears behind the morphogenetic furrow during differentiation of the eye imaginal disk. Defective alleles, *chp*<sup>1</sup> and *chp*<sup>2</sup>, recognized by reduced levels of antigen. Rhabdomeres of mutant photoreceptor cells highly deranged or nearly absent in homozygotes and hemizygotes for *chp*<sup>1</sup> or *chp*<sup>2</sup>, respectively; also close apposition of adjacent retinular cells partially disrupted. Gene product postulated to play role in cell surface interactions necessary for correct alignment of the microvilli that form the rhabdomeres.

**cytology:** Located in 100B6-9 by *in situ* hybridization, uncovered by *Df(3R)til-e = Df(3R)10A5;100C1* but not by *Df(3R)ca48 = Df(3R)98F14;100B7-8*.

**molecular biology:** Genomic clone isolated using synthetic oligonucleotide probe; clone hybridizes to a 4.3 kb polyadenylated transcript in head-derived RNA, which is absent from body RNA. Same sequence isolated by Levy and Manning (1982, Dev. Biol. 94: 465-76) using poly-A+ head RNA. Both cDNA and genomic sequences determined; eleven introns, eight of which are in the translated region, varying from 509 (intron 1) to 49 (intron 6) base pairs. Two CATT boxes but no TATA box found 5' to the transcription initiation site. Open reading frame with conceptual amino sequence of 1134 amino acids; first 29 amino acids have features of signal sequences; otherwise there is no membrane spanning domain, although chaoptin shown to be an integral membrane protein. Mature polypeptide of 127 kd with fourteen potential N-linked glycosylation sites. 90% of the

sequence comprises 41 tandemly arranged repeats of average residue number 24, with periodically disposed hydrophobic amino acids separated by hydrophilic ones; repeats occur in three large blocks separated by short unique regions; homologous to repeats occurring in three other known polypeptides including the Toll gene product in *Drosophila*.

**\*chr: chromosome**

**location:** 1- (not located).  
**origin:** Spontaneous.  
**discoverer:** Bridges, 13115.  
**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 74.  
**phenotype:** Body color brownish yellow or tan. Abdominal bands clear yellow. RK3.

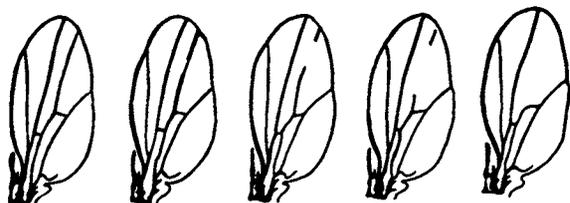

**cht: chaeta**

**location:** 2-65.6 (located in relation to *po*, *sca*, and *vg*).  
**origin:** Isolated from a line selected for high scutellar-bristle number.  
**references:** MacBean, McKenzie, and Parsons, 1971, Theor. Appl. Genet. 41: 227-35.  
**phenotype:** *cht/cht* averages 1.64 scutellar bristles more than *cht/+* (6.04 vs. 4.40).

**chubby: see ch**

**chy: chunky**

**location:** 2- (between 8 and 28).  
**origin:** Spontaneous.  
**discoverer:** Bridges, 38b10.  
**phenotype:** Body short and heavy set. Wings shorter than wild type. Difficult to classify. RK3.

**ci: cubitus interruptus**

Wings showing from no interruption (extreme left) to complete absence (extreme right) of the cubital vein. From Stern and Kodani, 1955, Genetics 40: 343-73.

**ci: cubitus interruptus**

**location:** 4-0 [most proximal mutant in 4 (Sturtevant, 1951, Proc. Nat. Acad. Sci. USA 37: 405-7)].  
**phenotype:** Vein L4 shows one or more gaps both distal and proximal to posterior crossvein, generally nonterminal. Anterior crossvein shortened or absent. Other gaps and scattered branch veins in region of crossveins. At 19°, nearly all flies have a mutant phenotype; at 25°, there is slight overlap with wild type; at 30°, virtually all flies are wild type. Dosage effect such that *ci*0 haplo-4's are more extreme than *ci/ci* diplo-4's, which are more extreme than *ci/ci/ci* triplo-4's. Suppressed by *su(Hw)*<sup>2</sup> (Kotarski). For interactions of *ci* with *en*, *H*, *ve*, and *cg*, see House (1953, Genetics 38: 199-214, 309-27; 1955, Anat. Record 122: 471; 1959, Genetics, 44: 516; 1961, Genetics, 46: 871). Expression of *ci* sensitive to genetic background; selection possible for more and less extreme phenotypes (House and Yeatts, 1962, Genetics

47: 960); contribution of chromosome 2 more important than that of 3 (House and Pernaveau, 1971, Genetics 68: s29). Phenotypic effect visible in prepupa by absence of the longer longitudinal vein. RK1 at 19° and higher rank with higher temperatures.

**alleles:** Two types of alleles: mutant alleles tabulated below and described in more detail following the table; wild-type isoalleles described separately.

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments <sup>β</sup>
<i>ci</i> <sup>1</sup>	spont	Terentieva, 30b		1, 5, 6	gypsy insert
<i>ci</i> <sup>36</sup>	spont	Curry, 36l		2	4.0 kb insert
<i>ci</i> <sup>57</sup>	X ray	Hochman, 57g		3	800 bp deletion
<i>ci</i> <sup>D</sup>	X ray	Ruch, 32a18		1	molecular rearrangement
<i>ci</i> <sup>D-G</sup>		Gloor		4	
<i>ci</i> <sup>W</sup>	spont	Wallace, 36d20	<i>It: Interrupted</i>	2	4.0 kb insert <sup>γ</sup>
<sup>α</sup>					
1 = Bridges, 1935, Biol. Zh. (Moscow), 4: 401-20; 2 = CP627; 3 = Hochman, 1971, Genetics 67: 235-52; 4 = Scharloo, 1963, DIS 38: 32; 5 = Terentieva, 1931, Eksperim. Biol. 7: 187-90 (fig.); 6 = Tiniakov and Terentieva, 1933, Genetics 18: 117-20 (fig.).					
<sup>β</sup>					
Molecular results from Kotarski.					
<sup>γ</sup>					
Different from the insert in <i>ci</i> <sup>36</sup> .					

**cytology:** Placed in salivary chromosome region 101F2-102A5, on the basis of its inclusion in *Df(4)M*<sup>63a</sup> = *Df(4)101F2-102A1;102A2-5*.

**molecular biology:** Region cloned and restriction mapped by Locke and Kotarski; all molecular lesions indicated in the table occur in the same 5.8 kb *Bgl*I fragment. This fragment hybridizes to a 2.0 kb RNA that shows peak concentrations in late pupae.

**other information:** The expression of *ci*<sup>+</sup> can be altered in direction of *ci* by certain chromosome rearrangements that have one break in vicinity of *ci* locus. Rearranged fourth chromosomes carrying a mutant allele of *ci*, *R(ci)*, may also show altered expression of gene [Stern and Kodani, 1955, Genetics 40: 343-73 (fig.)]. *R(ci)* and *R(ci*<sup>+</sup>) terminology not retained here; interaction with *ci* included in descriptions of aberrations involving chromosome 4.

**\*ci<sup>+2</sup>: cubitus interruptus-wild-type isoallele**

**origin:** On fourth chromosome carrying *ey*<sup>2</sup>.  
**references:** Stern and Schaeffer, 1943, Proc. Nat. Acad. Sci. USA 29: 361-67.

**phenotype:** Homozygote wild type at 14° and 26°. *ci*<sup>+2</sup>/*Df(4)M* wild type at 26°; shows some thinning and interruption of L4 at 14°. *ci*<sup>+2</sup>/*ci* wild type at 26°; at 14°, fewer flies show thinning or interruption of L4 than *ci*<sup>+C</sup>/*ci*. *ci*<sup>+2</sup>/*ci*<sup>W</sup> shows significantly greater amount of thinning and interruption of L4 than *ci*<sup>+C</sup>/*ci*<sup>W</sup>. RK3.

**alleles:** *ci* isoalleles superscripted \*+2, +3, and \*+C described by Stern and Schaeffer (1943), +5 by Hochman (1961, Evolution 15: 239-46). Relative strengths are +C > +5 > +3 > +2.

**ci<sup>D</sup>: cubitus interruptus-Dominant**

**phenotype:** Wings show interruptions of L4 in two places: proximal to and distal to anterior crossvein. L5 also shows distal interruption. L3 and L5 thick. Considerable plexus effect and knotting of veins. Wings broader, warped or concave upward, regularly extended, and bent backward. Alula fused with and in same plane as blade of wing. Black dried haemolymph from axillary spiracle. Slight scalloping of inner wing margin, with

hairs and tufts. Direction and extent of temperature effects depends on genetic background (Scharloo). In general, no overlapping of wild type. Inviabile in combination with *Ax/Ax* or *Ax/Y* (House and Lutes, 1975, Genetics 80: 542-43). *H/+* inhibits scalloping of *ci<sup>D</sup>* but greatly enhances L4 interruption (House, 1959, Genetics 44: 516). Fully dominant in triplo-4's (Sturtevant, 1936, Genetics 21: 448). Two doses of *ci<sup>D</sup>* reduce survival of triplo-4 flies (Parker, 1969, Mutat. Res. 7: 393-407). Homozygotes lethal in embryo (Hochman, 1971, Genetics 67: 235-52). Embryonic segment polarity disrupted; anterior portions of segments with their denticle belts duplicated in mirror-image fashion; posterior portions missing; each segment almost entirely covered with denticles (Nüsslein-Volhard and Wieschaus, 1980, Nature 287: 795-801). Fine hairs eliminated from dorsal abdominal segments; replaced with clear cuticle and socketed denticles (Orenic, Chidsey, and Holmgren, 1987, Dev. Biol. 124: 50-56). Embryonic CNS relatively normal (Patel, Schafer, Goodman, and Holmgren, 1989, Genes Dev. 3: 890-904). Genotype of oocyte with respect to *ci<sup>D</sup>* without effect on phenotype of progeny (Orenic *et al.*). *ci<sup>D</sup>/l(4)102ABc* dies as embryo, *ci<sup>D</sup>/l(4)102ABb* as embryo or larva; in *ci<sup>D</sup>/Ce<sup>2</sup>* death usually delayed until pupal stage (Hochman, 1971). Survival of *ci/ci<sup>D</sup>/Df(4)M101-63a* argues for nonallelism or pseudoallelism of *ci* and *ci<sup>D</sup>* (Hochman, 1971). RK1.

**alleles:** *ci<sup>D-G</sup>*, a less severe derivative of *ci<sup>D</sup>*, recovered as a recombinant between *ci<sup>D</sup>* and *spa<sup>pol</sup>* (CP627). *ci<sup>D-l</sup>* is a revertant of the *ci* phenotype in combination with either  $\pm$  or *ci*, which has retained the lethal phenotype (Puro). Ten similar revertants induced by  $\gamma$  rays isolated by Orenic *et al.*; three were cytologically normal and seven were translocations with breakpoints in or near the chromocenter. *ci<sup>Drv</sup>* [*ci<sup>D-l</sup>* of Haavisto (see Puro, 1982, DIS 58: 205)] reverted for *ci* phenotype but not for recessive lethality; complements *ci*.

**cytology:** Salivary study by Bridges revealed no chromosomal aberration.

**other information:** Not allelic with *ci*, at least with respect to its lethality, since *ci<sup>D</sup>/Df(4)M101-63a* survives, whereas *ci/Df(4)M101-63a* is mutant (Hochman, 1965, DIS 40: 60). Based on location, phenotype, and complementation, *ci<sup>D</sup>* and *Ce* postulated to be part of a single complex (Orenic *et al.*).

### *ci<sup>W</sup>*: *cubitus interruptus* of Wallace

**phenotype:** Homozygote is extreme *ci* type. Wings sometimes almost twice normal width, arlike, and virtually lack veins. Often present is a well-organized pattern of venation in which the posterior crossvein flows smoothly into L5. Legs lumpy, sex combs larger than normal, antennae enlarged, eyes smaller, and extra bristles present. Heterozygote shows gap in L4 in 80% of flies. *ci<sup>W</sup>* enhanced by *H*, *en*, and *Cy* (House, 1953, Genetics 38: 669-70; 1959, Genetics 44: 516) and by *Tp(4;Y)* (Benner, 1972, Genetics 71: s4). Temperature effect described by House (1955, Genetics 40: 576). RK2.

### *cin*: *cinnamon*

**location:** 1-0 ( $1.7 \times 10^{-3}$  unit to the left of *y*; Padilla and Nash, 1977, Mol. Gen. Genet. 155: 171-77).

**references:** Baker, 1973, Dev. Biol. 33: 429-40.

**phenotype:** *cin/Y* and *cin/cin* embryos of *cin/cin* mothers almost completely lethal; rare surviving adults have

reddish-brown eyes; both survival and normal eye pigmentation affected by the presence of *cin<sup>+</sup>* in either the mother or the zygote; however, *cin* progeny of *cin<sup>+</sup>* mothers exhibit mutant phenotype when raised on 0.02% allopurinol (Padilla and Nash, 1977, Mol. Gen. Genet. 155: 171-77). Survival of the double mutant *cin<sup>3</sup>v* is also sensitive to allopurinol (Bentley and Williamson, 1982, DIS 58: 23). Mosaic and transplantation analysis (Nissani and Fellingner, 1978, Dev. Biol. 65: 117-27) indicate that the maternal effect of *cin<sup>+</sup>* on eye color requires the presence of *cin<sup>+</sup>* in the oocyte, whereas *cin<sup>+</sup>* in ovarian mesoderm contributes to the maternal effect on viability. Affected progeny lack activity for four different molybdenum hydroxylases—all known to require a molybdenum-containing cofactor for catalytic function. These are aldehyde oxidase (Bentley and Williamson, 1982, Can. J. Genet. Cytol. 24: 1-9), pyridoxal oxidase, xanthine dehydrogenase (Browder and Williamson, 1976, Dev. Biol. 53: 241-49), and sulfite oxidase (Bogaart and Bernini, 1981, Biochem. Genet. 19: 929-46). Inactivity of xanthine dehydrogenase accounts for the eye color phenotype. Level of low-molecular-weight molybdenum cofactor severely reduced. *cin* progeny of *cin* mothers CRM negative for pyridoxal oxidase (Warner, Watts, and Finnerty, 1980, Mol. Gen. Genet. 180: 449-53). Aldehyde oxidase CRM found in hemolymph of *cin<sup>1</sup>* (100%) and *cin<sup>9</sup>* (60%) larvae and in extracts of *cin<sup>9</sup>* (32%) adults. Both alleles show about 70% normal quantities of xanthine dehydrogenase CRM (Browder, Wilkes, and Tucker, 1982, Biochem. Genet. 20: 111-24). Eye color expression nonautonomous in gynandromorphs (Padilla and Nash, 1977).

**alleles:** All alleles induced by ethyl methanesulfonate except the spontaneous *cin<sup>2</sup>* and perhaps *cin<sup>B</sup>*.

<sup>α</sup> 1 = Baker, 1973, Dev. Biol. 33: 429-40; 2 = Bentley and Williamson, 1979, Can. J. Genet. Cytol. 21: 457-71; 3 = Courtright, 1976, Genetics 83: s17; 4 = Courtright, unpublished; 5 = Hickey and Singh, 1982, DIS 58: 74-76; 6 = Mohler, 1977, Genetics 85: 259-72; 7 = Padilla and Nash, 1977, Mol. Gen. Genet. 155: 171-77.

<sup>β</sup> Males carrying this allele produce *cin<sup>+</sup>* sons in crosses to *C(1)RM*, *cin y* females.

<sup>γ</sup> Males carrying this allele produce *cin* sons in crosses to *C(1)RM*, *cin y* females. Males carrying other alleles produce no sons from such crosses.

<sup>δ</sup> *cin lk* considered to be a hypomorphic or leaky allele of *cin*; it produces low levels of aldehyde oxidase and xanthine dehydrogenase activity and is genetically very close to yellow; however, *cin<sup>1</sup>/cin lk* are wildtype both with respect to eye color and enzyme

activity and may not therefore be an allele.

**cytology:** Duplication analysis by Padilla and Nash place *cin* distal to *arth* and proximal to *l(1)J1*.

**other information:** Four complementation groups described by Baker; a fifth observed by Warner.

**cinnabar:** see *cn*

**cinnamon:** see *cin*

**ck: crinkled (M. Ashburner)**

**location:** 2-51.0 (estimated).

**discoverer:** Bridges, 30c30.

**synonym:** *l(2)br27*, *l(2)35Ca*, D group of O'Donnell *et al.* (1977).

**references:** O'Donnell, Mandel, Kraus, and Sofer, 1977, *Genetics* 86: 553-66.

Ashburner, Tsubota, and Woodruff, 1982, *Genetics* 102: 401-20.

Gubb, Shelton, Roote, McGill, and Ashburner, 1984, *Chromosoma* 91: 54-64 (fig.).

**phenotype:** Recessive lethal or semilethal. *ck* embryos exhibit denticles thickset and forked; hairs basally fused; sensory hairs blunt [Nüsslein-Volhard, Wieschaus, and Klüding, (fig.)]. Hemizygous survivors, or survivors among heteroallelic combinations that partially complement for viability, have stubbly chaetae, multiple trichomes, and feathery aristae (Gubb *et al.*). Variable expression of a wavy, crinkled wing phenotype. Cell viable in clones of adult epidermis; bristle and hair phenotypes autonomous; useful as a cell marker in *2L* for clonal analysis (Struhl).

**alleles:** 13 named alleles, all but *ck<sup>1</sup>* induced by ethyl methanesulfonate. Four additional EMS-induced alleles, including one weak allele, isolated by Nüsslein-Volhard, Wieschaus, and Klüding (1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82).

allele	isolation #	ref <sup>α</sup>	phenotypic class <sup>β</sup>
<i>ck<sup>1</sup></i>

<sup>α</sup> 1 = Ashburner, Tsubota, and Woodruff, 1982, *Genetics* 102: 401-20; 2 = Gubb, Shelton, Roote, McGill, and Ashburner, 1984, *Chromosoma* 91: 54-64; 3 = Maroni (unpublished); 4 = O'Donnell, Mandel, Kraus, and Sofer, 1977, *Genetics* 86: 553-66.

<sup>β</sup> Class 1 survival at 1% or less, class 2 at 5%, and class 3 greater than 10% expected value.

**cytology:** Placed in 35B10-C1 based on its inclusion in *Df(2L)64j = Df(2L)34D1-2;35B9-C1 and Df(2L)fr30 = Df(2L)34C6-7;35B9-C1*, but not in *Df(2L)AR-R1 = Df(2L)35A3-4;35B9-C1*.

**other information:** Allelism of *l(2)35Ca* and *ck* inferred from similarities in phenotype and map position. Insertion TE35B between 35B9 and 35C1 results in a class 2 *ck* allele (Gubb *et al.*).

**CkII α: Casein kinase II, α subunit**

**location:** 3-{47}.

**references:** Saxena, Padmanabha, and Glover, 1987, *Mol. Cell. Biol.* 7: 3409-17.

**phenotype:** The structural gene for the catalytic subunit of casein kinase II (CKII). CKII is a cyclic-nucleotide-independent, Ca<sup>2+</sup> and calmodulin-insensitive protein kinase. It phosphorylates serine and threonine residues of a broad range of nuclear and non-nuclear proteins with functions in development, cell division, and oncogenesis. It exists as a 130,000 molecular weight α<sub>2</sub>β<sub>2</sub> tetramer. Purification of the *Drosophila* enzyme described by Glover, Shelton, and Brutlag (1983, *J. Biol. Chem.* 258: 3258-65).

**molecular biology:** cDNA sequence isolated by antibody screening of a λgt11 expression library. Nucleotide sequence shows an open reading frame encoding a 336-amino-acid polypeptide with strong homology to calf thymus CKIIα and homology to the yeast homologue; also shows weak homology to the yeast *Cdc28* gene. *Drosophila CkII α* and β can rescue casein kinase II deficient yeast (Glover).

**cytology:** Placed in 80A by *in situ* hybridization (Glover).

**CkII β: Casein kinase II, β subunit**

**location:** 1-{36}.

**references:** Saxena, Padmanabha, and Glover, 1987, *Mol. Cell. Biol.* 7: 3409-17.

**phenotype:** The structural gene for the autophosphorylated, regulatory β subunit of casein kinase II (CKII).

**molecular biology:** cDNA sequence isolated by antibody screening of a λgt11 expression library. Nucleotide sequence shows an open reading frame encoding a 215-amino-acid polypeptide with strong homology to calf thymus CKIIβ and homology to the yeast homologue. Genomic sequence reveals five introns in the protein-coding region and at least one more upstream from the initiating ATG (Saxena, Carney, Bruley, and Glover, 1989, *Genetics* 122: s25). *Drosophila CkII α* and β can rescue casein kinase II deficient yeast (Glover).

**cytology:** Placed in 10E by *in situ* hybridization (Glover).

**cl: clot**

**location:** 2-18.83 (Kotarski, Pickert, and MacIntyre, 1983, *Genetics* 105: 371-86).

**origin:** Spontaneous.

**discoverer:** Bridges, 27a3.

**phenotype:** Eye color dark maroon to sepialike with age, is less extreme than *sepia*. Severely deficient in one of three enzyme activities required for the conversion of dihydroneopterin triphosphate to pyrimidiazepine, a precursor of the drosopterin (Wiederrecht, Paton, and Brown, 1984, *J. Biol. Chem.* 259: 2195-2200). Claimed to accumulate 2-amino-4-hydroxypteridine, biopterin, sepiapterin, and xanthopterin (Nikla, 1972, *Can. J. Genet. Cytol.* 14: 105-11). Eye color autonomous when larval optic disk is transplanted into wild-type host (Beadle and Ephrussi, 1936, *Genetics* 21: 230). Larval Malpighian tubes pale yellow, distinguishable from wild type (Brehme and Demerec, 1942, *Growth* 6: 351-56). RK1.

**alleles:** *cl<sup>2</sup>* (CP627). *cl<sup>3</sup>* and *cl<sup>4</sup>* induced by ethyl methanesulfonate in *CyO* (Kotarski, Pickert, and MacIntyre, 1981, *DIS* 56: 191); *cl<sup>CA1</sup>* associated with *T(1;2)cl<sup>CA1</sup>* (Ashburner, Faithfull, Littlewood, Richards, Smith, and Velissariou, 1980, *DIS* 56: 186).

**cytology:** Placed in salivary chromosome bands 25E1-2 (Ashburner and Velissariou, 1980, DIS 55: 196).

**claret:** see *ca*

**\*cld: cloudy**

**location:** 2-96 to -101.

**origin:**  $\gamma$  ray induced.

**discoverer:** Wallbrunn, 61j6.

**references:** 1964, DIS 39: 59.

**phenotype:** Wings opaque from fluid between upper and lower membranes; occasionally, fluid forms small blisters. Males sterile; females highly infertile. RK2.

**cleft:** see *cf*

*clf*: see *wtw<sup>clf</sup>*

**cli: clift (C. Nüsslein-Volhard)**

**location:** 2-17.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

**phenotype:** Embryonic lethal. Defect in head involution. No segmental movements. Shows abdominal transformations in combination with *Pc*-like mutants.

**alleles:** Two.

**\*Cli: Clipped wings**

**location:** 1- (to the left of *f*).

**discoverer:** Agol.

**references:** 1936, DIS 5: 7.

**phenotype:** Dominant wing mutant (no description given). Viable in male and homozygous female. RK3.

**Clift:** see *Cli*

*clip wing*: see *dp<sup>o2</sup>*

**clipped:** see *cp*

**Clipped wings:** see *Cli*

**Clipt:** see *Cpt*

**Clk: Clock (J.C. Hall)**

**location:** 1-1.4 (0.015 map units to the right of *per<sup>o1</sup>*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Konopka and Orr.

**references:** Dushay, Konopka, Orr, Greenacre, Kyriacou, Rosbash and Hall, 1990, Genetics 125: 557-78.

**synonym:** *Clk-6*.

**phenotype:** The normal 24 hour period of the circadian rhythms of adult locomotor activity and of eclosion are shortened by approximately 1.5 hours. *Clk/+* heterozygotes have a period phenotype intermediate between wild-type and mutant homozygotes. The period of the phase-resetting response of the activity rhythm is shortened by 1-2 hours per cycle; adults entrain well to 12 hour light: twelve hour dark cycles, but evening peak of locomotor activity is advanced relative to wild-type; courtship song rhythms of mutant males have essentially normal one-minute periods. Temperature compensation of circadian period is normal ( $Q_{10}$  approximately equal to 1.0), in tests of locomotor activity rhythms.

**cytology:** Series of deletions and duplications running from X distal tip to white; all failed to uncover and ameliorate effects of *Clk*.

**other information:** *Clk* is close enough to *per<sup>o1</sup>* mutation so that it could be allele of the period gene; however, *Clk/per<sup>o1</sup>* indistinguishable from *Clk/+*.

**\*clm: clumpy marginals**

**location:** 1-32.6.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3205).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 68.

**phenotype:** Irregularly bent marginal hairs, especially on posterior border of wings. Bristles stiff and frequently bent or split. Viability and fertility of males good. Homozygous females reduced in viability and fertility. RK2.

**other information:** One allele each induced by 2-chloroethyl methanesulfonate and DL-p-N,N-di-(2-chloroethyl)amino-phenylalanine.

**clo: close down (T. Schüpbach)**

**location:** 2-77.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female-sterile; homozygous females contain egg chamber which degenerate before yolk uptake. Occasionally normal egg chambers are found which take up yolk and form eggs. Such eggs often have fused dorsal appendages and remain unfertilized.

**alleles:** *clo<sup>1</sup>* to *clo<sup>3</sup>* isolated as *WG*, *WK*, and *WU*.

**Clock:** see *Clk*

**close down:** see *clo*

**clot:** see *cl*

**cloudy:** see *cld*

**cloven thorax:** see *clv*

**club:** see *cb*

**clubfoot:** see *cbf*

**club wing:** see *clw*

**clumpy marginals:** see *clm*

**clt: cricklet**

**location:** 2-96.

**origin:** Induced by ethyl methanesulfonate.

**references:** Shirras and Bownes, 1989, Proc. Nat. Acad. Sci. USA 86: 4559-63.

**phenotype:** Yolk protein synthesis reduced approximately twenty fold in homozygous females; such females are also defective in the synthesis of larval-serum protein 2 (LSP2) although LSP2 synthesis in larvae is unaffected. Adult fat body normal in morphology and in other secretory functions. Larval fat body persists into adult stage; oocyte development arrested in previtellogenic stage. Methoprene, a juvenile hormone analogue, which stimulates fat-body synthesis of yolk and vitellogenesis in starved wild-type females, has no effect in *clt* females; however, ovarian transplant experiments indicate that *clt* females have sufficient JH concentrations to promote oogenesis. Ecdysone, on the other hand, stimulates LSP2 and yolk-protein synthesis in *clt* females, but has no effect on larval-fat-body regression or oogenesis.

**\**clv-1: cloven thorax no. 1***

**location:** 1-0.0.  
**origin:** X ray induced.  
**discoverer:** Muller, 19h.  
**references:** 1935, DIS 3: 29.  
**phenotype:** Thorax often has long cleft; partially dominant. Semilethal at low temperature; viable at high temperature. RK3.

**\**clv-2***

**location:** 1-42.0.  
**origin:** X ray induced.  
**discoverer:** Muller, 26111.  
**references:** 1935, DIS 3: 29.  
**phenotype:** Thorax has longitudinal cleft, sometimes half thorax. One wing often reduced or like *vg*. Partially dominant. Semilethal. RK3.  
**alleles:** \**clv-2*<sup>52b</sup> completely recessive (CP627). \**clv-2*<sup>D</sup> [formerly *Clv*<sup>3</sup> (Maroni, 1968, DIS 43: 60)] is a fully dominant allele associated with *T(1;2)clv-2*<sup>D</sup>.  
**cytology:** Placed in 11A7-8 based on association of *clv-2*<sup>D</sup> with *T(1;2)11A7-8;27E2-3* (Kirschbaum).

*Clv*<sup>3</sup>: see *clv-2*<sup>D</sup>

***clw: club wing***

**location:** 1-21 (same as *sn*; inferred from instability correlated with that of *sn*<sup>49s</sup>).  
**origin:** Presumably induced by *P*-factor in chromosome isolated from natural population; arose simultaneously with *sn*<sup>49s</sup>.  
**references:** Golubovsky and Zakharov, 1979, Genetika (Moscow) 15: 1599-1609.  
 1980, DIS 55: 49-55.  
 Zakharov and Golubovsky, 1980, Genetika (Moscow) 16: 1603-12.  
 Zakharov and Yurchenko, 1984, Genetika (Moscow) 20: 266-73.  
 Yurchenko, Zakharov, and Golubovsky, 1984, Mol. Gen. Genet. 194: 279-85.  
**phenotype:** Wings fail to expand; retain pupal conformation. Penetrance low, 11% in males and 0.6% in homozygous females; inversely related to temperature; penetrance in *XO* males less than in *XY* males. Unstable, *clw sn*<sup>49s</sup> can mutate to wild type, either unstable (*i.e.*, can regenerate *clw sn*<sup>49s</sup>) or stable, or to a stable *clw*<sup>+</sup> with an unstable *sn* phenotype of intermediate strength. Interpreted as owing to an insertional sequence between *clw* and *sn*.  
**cytology:** Placed in 7D based on its presumed contiguity with *sn*. Since it may have been carried in by a transposon, there may not be a normal allele at this position in wild-type chromosomes.  
**other information:** May be allelic to *cb*.

***cm: carmine***

**location:** 1-18.9.  
**origin:** Spontaneous.  
**discoverer:** Mohr, 27d27.  
**references:** 1927, Z. Indukt. Abstamm. Vererbungsl. 45: 403-5.  
**phenotype:** Eye color translucent dark ruby. With *st*, eye color deep orange; with brown, slightly lighter than *bw* alone. Larval Malpighian tubes very pale yellow. RK1.

**alleles:**

<sup>β</sup> Arose in a stock carrying a transposable element in *ct* and reverts spontaneously; inserted element neither *P* nor *gypsy* (their *mdg4*).

**cytology:** Located in 6E5-6 (CP627; Lefevre, 1981, Genetics 99: 461-80).

*cm*: see *cmp*

***Cm: Crimp***

Edith M. Wallace, unpublished.

**\**Cm: Crimp***

**location:** 3-43.5.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 28a28.  
**phenotype:** Heterozygote has crimped wings ruffled on rear edge. Classification good in first 4 days' hatch, then *Cm* overlaps wild type progressively. Better at 25° than at 19°. Homozygous lethal. RK2 as lethal; RK3 as dominant.

***Cma: Comma***

**location:** 3-57.5 (between *jvl* and *sbd*).  
**origin:** X ray induced.  
**discoverer:** Lewis, 1971.  
**references:** Craymer, 1980, DIS 55: 197.  
**phenotype:** *Cma*<sup>+</sup> has a pair of comma-like depressions at the anterior edge of the dorsal mesothorax similar to those of some *dp* alleles, intumed dorsocentral bristles, a *sr*-like phenotype, and a soft-appearing cuticle. *Cma*<sup>+</sup> imparts dominance to the vortex effects of *dp*, *dp*<sup>v</sup>, *dp*<sup>ov</sup>, and *dp*<sup>olv</sup> alleles. *Cma*<sup>+</sup> flies flightless, have abnormal myofibrils of indirect flight muscles (Mogami). Homozygous lethal. RK1.  
**cytology:** Location in 88C-F inferred from its map position and its survival in combination with *Df(3R)sbd*<sup>105</sup> = *Df(3R)88F9-89A1;89B4-5* and the failure of a synthetic deficiency to the left that includes 88C to include *jvl* (Craymer).

**cmd: carminoid**

location: 3-68.2.

origin: Spontaneous.

references: Mostashfi and Koliantz, 1970, DIS 45: 34.

phenotype: Eye color resembles that of *cm*.*cMdh*: see *Mdh1**cMhc-1*: see *Mhc-c***cml: caramel**location: 2-71.2 (said to complement *sf* and *ake*).

origin: Spontaneous.

references: Ribó, 1968, DIS 43: 59.

phenotype: Eye color brownish orange at eclosion, darkens with age but not as dark as *se*. Produces orange eye in combination with *cn*. RK1.**cmp: crumpled**

location: 3-93.

origin: Spontaneous.

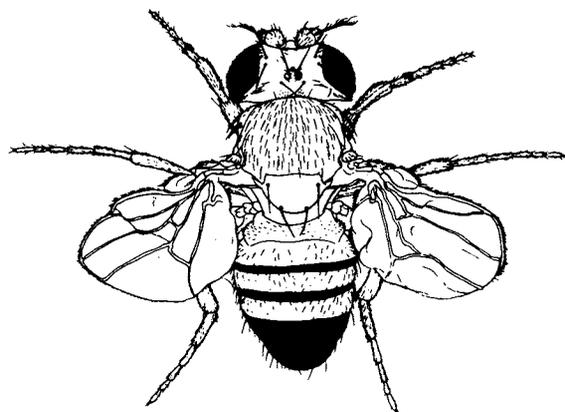

discoverer: Bridges, 22d2.

synonym: *cm*.

references: Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 247.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 223.

phenotype: Wings about two-thirds normal size and greatly crumpled or blistered. Marginal hairs irregularly clumped. Legs irregularly shortened and gnarled. Bristles somewhat short and thick. Posterior scutellars slightly divergent. Branches of aristae bent anteriorly near middle, with apices parallel to main axes of aristae. Viability and fertility may be low. RK3.

**cmp: crumpled**

Edith M. Wallace, unpublished.

**\*cmt: comet**location: 3-57.2 (based on 35 *cu-sr* recombinants).

origin: Induced by ethyl methanesulfonate.

references: García-Bellido and Dapena, 1973, DIS 50: 179.

1974, Mol. Gen. Genet. 128: 117-30 (fig.).

phenotype: Homozygous lethal; however, clones of homozygous cells survive in cuticle. Wing cells like *mwh* but with fewer trichomes per cell and smaller angles between trichomes. Less distinct in tergites but accom-

panied by loss of pigment.

**cn: cinnabar**

location: 2-57.5.

origin: Spontaneous.

discoverer: Clausen, 20i8.

references: 1924, J. Exp. Zool. 38: 423-36.

phenotype: Eye color bright red, like *v* or *st*. Ocelli colorless. Eye color darkens with age, but ocelli remain colorless. Larval Malpighian tubes pale yellow (Beadle, 1937, Genetics 22: 587-611). *cn* defective in ommochrome synthesis; blocks conversion of kynurenine to 3-hydroxykynurenine, which has been identified as the *cn*<sup>+</sup> hormone (Butenandt, Weidel, and Schlossberger, 1949, Z. Naturforsch. 4b: 242-44). *cn* homozygotes devoid of kynurenine 3-hydroxylase activity (Ghosh and Forrest, 1967, Genetics 55: 423-31). Enzyme activity proportional to the number of doses of *cn*<sup>+</sup>; *cn*<sup>+</sup> therefore concluded to be the structural gene for kynurenine 3-hydroxylase (EC 1.14.13.9) (Sullivan, Kitos, and Sullivan, 1973, Genetics 75: 651-61). Also *cn* defective in the uptake of kynurenine by eye discs and Malpighian tubules, where it is normally converted to 3-hydroxykynurenine (Sullivan, Grillo, Kitos, 1974, J. Exp. Zool. 188: 225-34). Nonautonomous in development of pigment of transplanted eye disks (Beadle and Ephrussi, 1936, Genetics 21: 230); however, ethyl methanesulfonate-induced mutants recovered as mosaics in homozygous *red* background (Paton and Sullivan, 1978, Biochem. Genet. 16: 855-65); furthermore, even though *st* has no detectable 3-hydroxykynurenine, it is able to rescue *cn* in transplants (Phillips, Simmons, and Bowman, 1970, Biochem. Genet. 4: 481-87). Enzyme activity developmentally regulated with a peak of activity in early third instar and a five-fold higher peak in the second half of pupal development (Sullivan *et al.*). Heterozygotes in all pairwise combinations of 13 ethyl methanesulfonate-induced alleles exhibit mutant phenotype (Paton and Sullivan, 1978). RK1.**alleles:**

**cop: copper**

**location:** 1-43.3.

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 68.

**phenotype:** Brownish red eye color. Best classification in newly emerged flies. Occasionally, wings show cutaway inner margins. Excellent viability and fertility in both sexes. RK2.

**other information:** Two alleles induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine.

**Cor: Corroded eye**

**location:** 3- (not located).

**origin:** X ray induced.

**discoverer:** Muller.

**references:** 1946, DIS 20: 66.

**phenotype:** *Cor*<sup>+</sup> shows slight irregular flecking of eye. In combination with *v*, expression enhanced, producing

patchy diminution in color, especially near posterior margin of eye, giving impression that color was washed or eaten away, especially from deeper layers; regions of surface often blackened. Homozygote not described. RK2.

**corkscrew:** see *csw*

**corrugated wing:** see *corr*

**\*corr: corrugated wing**

**location:** 2-36.

**origin:** Spontaneous.

**discoverer:** Mayeda, 61g.

**references:** 1963, DIS 38: 31.

**phenotype:** Wings wrinkled and wavy, reduced to three-fourths normal size. Whole wing corrugated at 20°, only posterior third at 25°. Good classification. RK2.

**Corroded eye:** see *Cor*

**corrugated wing:** see *corr*

**cort: cortex (T. Schüpbach)**

**location:** 2-49.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal mutant; homozygous females lay eggs in which a narrow halo of clear cytoplasm appears in the cortex around the time when nuclei would be expected to migrate to the periphery, but no cellularization takes place.

**alleles:** Two, *cort*<sup>1</sup> and *cort*<sup>2</sup>, isolated as *QH* and *RH*.

**cos: costa (P. Simpson)**

**location:** 2-57.4.

**synonym:** *cos2*.

**references:** Whittle, 1976, Dev. Biol. 51: 257-68.

Grau and Simpson, 1987, Dev. Biol. 122: 186-200 (fig.).

Simpson and Grau, 1987, Dev. Biol. 122: 201-09 (fig.).

**phenotype:** Homozygotes, hemizygotes, and heteroallelic heterozygotes for class I alleles die as embryos with a normal cuticular phenotype. When derived from homozygous ovarian clones, however, abnormal deletion-duplication patterns in each segment are observed; posterior rows of abdominal denticles are replaced by mirror-image duplications of the anterior rows, including the segmental boundary, which is thereby duplicated; thoracic denticle belts missing; *cos*<sup>1</sup> especially severely affected in this regard, including loss of entire segments. Heterozygotes derived from homozygous ovarian clones show slightly abnormal segmental patterning. Flies heterozygous for class I alleles or *cos* deficiencies and at the same time heterozygous for *Cos* alleles display pattern duplications of wings and halteres. Class II alleles are hemizygous lethal but homozygous viable. They display wing and haltere duplications indistinguishable from those found for *cos*<sup>1</sup>/*Cos*<sup>1</sup> heterozygotes as described by Whittle. Flies heterozygous for class III alleles and *Cos* show moderately reduced viability and occasional wing duplications; flies homozygous for class III alleles show reduced viability and have wild-type phenotype, but enhance the pattern duplications associated with *Cos*<sup>+</sup>; hemizygotes for class III alleles or heterozygotes with class I alleles are lethal or nearly so in the presence of *Cos*, the survivors invariably exhibiting pattern duplications of wings and halteres.

**alleles:** Severity of class I and II alleles estimated as follows:  $cos^3 > cos^2 > cos^1 = cos^4 = cos^5 > cos^6 > cos^7$  Similarly for class III alleles:  $cos^{V5} \geq cos^{V4} = cos^{V1} \geq cos^{V3} \geq cos^{V2}$ .

α Synonym: *cos2*<sup>W1</sup>.

β Found to exist in various laboratory stocks.

**cytology:** Placed in 43B2-C3 on the basis of its inclusion in the region of overlap of *Df(2R)pk78k = Df(2r)42E3;43C3* and *Df(2R)ST1 = Df(2R)43B2-C1;43E1-8*.

**Cos: Costal (P. Simpson)**

**location:** 2-67.2.

**synonym:** *Epa: Epalette; Cos1*.

**references:** Whittle, 1976, Dev. Biol. 51: 257-68.

Grau and Simpson, 1987, Dev. Biol. 122: 186-200 (fig.).

Simpson and Grau, 1987, Dev. Biol. 122: 201-09 (fig.).

**phenotype:** Mirror-image duplications of wings and halteres; duplications of wing begin in mid-costal region and may include entire anterior compartment; posterior compartments unaffected, even when transformed into anterior compartments in *en* homozygotes. Penetrance of *Cos* higher when maternally than when paternally inherited. Class I alleles are homozygous viable and display pattern duplications in both heterozygotes and homozygotes. Penetrance and expressivity variable and may overlap wild type. Class II alleles are lethal when homozygous or in heteroallelic combination with one another; they sometimes display pattern duplications in heterozygotes. Class III alleles are homozygous lethal and have no dominant phenotype. Flies heterozygous for alleles of any of the three classes display the phenotype when simultaneously heterozygous for lethal alleles or deletions of *cos*; the heterozygous expression of *Cos* is dependent on the number of *cos*<sup>+</sup> alleles present, with the severity of wing duplication decreasing as the number of *cos*<sup>+</sup> alleles increases from one to three. Flies heterozygous for *Cos* and homozygous or hemizygous for some viable alleles of *cos* die as pharate adults and display pattern duplications in the anterior compartment of every body segment. Homozygotes of class II and III alleles die as embryos with abnormal cuticular patterns; failure to develop of variable extents of the anterior end of the embryo, *i.e.* head or head and thorax, as well as mirror image duplications of anterior denticle belts of abdominal segments, or more frequently simply disturbed denticle polarity. Embryos that are simultaneously homozygous for *cos*<sup>V</sup> alleles and *Cos*<sup>3</sup> are more severely affected, with some exhibiting a bicaudal phenotype. *cos*<sup>V1</sup> *Cos*<sup>2</sup>/*Df(2R)CA58* flies survive poorly, but show pattern duplications in the anterior compartments of all seg-

ments. Revertants of *Cos* are viable and wild type in phenotype; as they are presumably null alleles, *Cos* mutations are presumed to be gain of function alleles.

**cp: clipped**

Edith M. Wallace, unpublished.

**cp: clipped**

**location:** 3-45.3.

**discoverer:** Mainx, 34g.

**references:** 1936, Z. Indukt. Abstamm. Vererbungslehre 71: 303-4 (fig.).

Pollitzer, 1937, DIS 8: 91.

**phenotype:** Wing margins snapped, most often along marginal vein. At 19°, character slighter but completely penetrant. Shows partial dominance in combination with Minutes (Sinclair and Suzuki, 1979, Genetics 91: s117; V. Walker). Most stocks carry closely linked modifiers; has reduced viability when phenotype is good (Craymer). RK2.

**alleles:** *cp*<sup>SS305</sup> and *cp*<sup>SS307</sup> X ray induced (Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95).

**cytology:** Placed between the breakpoints of *T(Y;3)L131 = T(Y;3)75D4-5* (V. Walker) and *T(2;3)spy = T(2;3)33D4-E3;79A4-B1* (Puro, 1983, Hereditas 62: 414-18).

**Cp15: Chorion protein**

**location:** 3-{26.5} (based on *in situ* hybridization).

Located between *Cp18* and *Cp19*.

**synonym:** *S15*: Shell.

**references:** Spradling, Digan, Mahowald, Scott, and Craig, 1980, Cell 19: 905-14.

Spradling, 1981, Cell 27: 193-201.

Griffin-Shea, Thireos, and Kafatos, 1982, Dev. Biol. 91: 325-36.

Levine and Spradling, 1985, Chromosoma 92: 136-42.

Wong, Pustell, Spoerel, and Kafatos, 1985, Chromosoma 92: 124-35.

**phenotype:** The second of four chorion-protein genes in a 6-kb sequence; encodes S15-1, a chorion protein estimated at 15,000 daltons by Waring and Mahowald (1979, Cell 16: 599-607) and 9700 daltons by Petri, Wyman, and Kafatos (1976, Dev. Biol. 49: 185-99). Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**alleles:** Probably the locus for which Yannoni and Petri (1980, Wilhelm Roux's Arch. Entwicklungsmech. Organ. 189: 17-24) detected electrophoretic variants by isoelectric focusing.

**cytology:** Localized to 66D11-15 by *in situ* hybridization. Less than 1 kb from *Cp18*.

**molecular biology:** Gene cloned and sequenced (Levine and Spradling; Wong *et al.*). Transcription unit estimated to be 515 nucleotides by Levine and Spradling and 590 by Wong *et al.*; contains a 71 nucleotide intron four codons downstream from the translation initiation site. Direction of transcription the same as for *Cp16*, *Cp18* and *Cp19*. The conceptual polypeptide, which contains a signal peptide and a putative signal-peptide cleavage site, contains 115 residues and the mature chorion protein 97 residues for a calculated molecular weight of 9934 (Wong *et al.*) or 9467 (Levine and Spradling). Flanking sequences examined for putative regulatory sequences. Located in a chromosome region that is amplified approximately 60 fold as a series of nested bidirectional replication forks spanning approximately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire region under the control of *ACE3*, a *cis*-acting sequence between 615 and 187 base pairs upstream from *Cp18* (Kalfayan, Levine, Orr-Weaver, Parks, Wakimoto, deCicco, and Spradling, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 527-35), and at least four amplification-enhancing regions (AERs) located one base pair downstream from each of the four second-chromosome chorion-protein genes (Delidakis and Kafatos, 1989, EMBO J. 8: 891-901).

### **Cp16**

**location:** 3-{26.5} (based on sequence proximity to *Cp15* and *Cp18*).

**synonym:** *S16*.

**references:** Griffin-Shea, Thireos, and Kafatos, 1982, Dev. Biol. 91: 325-36.

**phenotype:** The fourth of four chorion-protein genes in a 6-kb sequence; encodes S16-1, a 16,000-dalton chorion protein. Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**cytology:** Placed in 66D11-15 based on sequence proximity to *Cp15* and *Cp18*. Approximately 1 kb from *Cp19*.

**molecular biology:** Identified on genomic clone selected with cDNA probe for *Cp15*. S1 nuclease digest of DNA-mRNA hybrid indicates presence of small intron toward one end of gene. Located in a chromosome region that is amplified approximately 60 fold as a series of nested bidirectional replication forks spanning approxi-

mately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire region under the control of *ACE3*, a *cis*-acting sequence between 615 and 187 base pairs upstream from *Cp18* (Kalfayan, Levine, Orr-Weaver, Parks, Wakimoto, deCicco, and Spradling, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 527-35), and at least four amplification-enhancing regions (AERs) located one base pair downstream from each of the four second-chromosome chorion-protein genes (Delidakis and Kafatos, 1989, EMBO J. 8: 891-901). Transcriptionally most active during stages 13 and 14.

### **Cp18**

**location:** 3-{26.5} (based on *in situ* localization).

**synonym:** *S18*.

**references:** Spradling, Digan, Mahowald, Scott, and Craig, 1980, Cell 19: 905-14.

Spradling, 1981, Cell 27: 193-201.

Griffin-Shea, Thireos, and Kafatos, 1982, Dev. Biol. 91: 325-36.

Levine and Spradling, 1985, Chromosoma 92: 136-42.

Wong, Pustell, Spoerel, and Kafatos, 1985, Chromosoma 92: 124-35.

**phenotype:** The first of four chorion-protein genes in a 6-kb sequence; encodes S18-1 estimated at 18,000 daltons by Waring and Mahowald (1979, Cell 16: 599-607) and 15,600 by Petri, Wyman, and Kafatos (1976, Dev. Biol. 49: 185-99). Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**cytology:** Localized to 66D11-15 by *in situ* hybridization. Less than 1 kb from *Cp15*.

**molecular biology:** Gene cloned and sequenced (Levine and Spradling; Wong *et al.*). Transcription unit estimated to be 650 nucleotides by Levine and Spradling and 825 by Wong *et al.*; contains a 176 nucleotide intron five codons downstream from the translation initiation site. Direction of transcription the same as for *Cp15*, *Cp16* and *Cp19*. The conceptual polypeptide, which contains a signal peptide and a putative signal-peptide cleavage site, contains 172 residues and the mature chorion protein 156 residues for a calculated molecular weight of 15517 (Wong *et al.*) or 15027 (Levine and Spradling). Flanking sequences examined for putative regulatory sequences. Located in a chromosome region that is amplified approximately 60 fold as a series of nested bidirectional replication forks spanning approximately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire region under the control of *ACE3*, a *cis*-acting sequence between 615 and 187 base pairs upstream from *Cp18* (Kalfayan, Levine, Orr-Weaver, Parks, Wakimoto, deCicco, and Spradling, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 527-35), and at least four amplification-enhancing regions (AERs) located one base pair downstream from each of the four second-chromosome chorion-protein genes (Delidakis and Kafatos, 1989, EMBO J. 8: 891-901).

### **Cp19**

**location:** 3-{26.5} (based on sequence proximity to *Cp15* and *Cp18*).

**synonym:** *S19*.

**references:** Griffin-Shea, Thireos, and Kafatos, 1982, Dev. Biol. 91: 325-36.

Wong, Pustell, Spoerel, and Kafatos, 1985, Chromosoma

92: 124-35.

**phenotype:** The third of four chorion-protein genes in a 6-kb sequence; encodes S19-1, a chorion protein estimated at 19,000 daltons by Waring and Mahowald (1979, Cell 16: 599-607) and 17,500 by Petri, Wyman, and Kafatos (1976, Dev. Biol. 49: 185-99). Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**cytology:** Placed in 66D11-15 based on sequence proximity to *Cp15* and *Cp18*. Approximately 1 kb from *Cp16* on one side and less than 1 kb from *Cp15* on the other.

**molecular biology:** Gene cloned and sequenced (Wong *et al.*). Transcription unit estimated to be 742 nucleotides contains a 89 nucleotide intron five codons downstream from the translation initiation site. Direction of transcription the same as for *Cp15*, *Cp16* and *Cp18*. The conceptual polypeptide, which contains a signal peptide and a putative signal-peptide cleavage site, contains 173 and the mature chorion protein 156 residues for a calculated molecular weight of 16722 daltons. Flanking sequences examined for putative regulatory sequences. Located in a chromosome region that is amplified approximately 60 fold as a series of nested bidirectional replication forks spanning approximately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire region under the control of *ACE3*, a *cis*-acting sequence between 615 and 187 base pairs upstream from *Cp18* (Kalfayan, Levine, Orr-Weaver, Parks, Wakimoto, deCicco, and Spradling, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 527-35), and at least four amplification-enhancing regions (AERs) located one base pair downstream from each of the four second-chromosome chorion-protein genes (Delidakis and Kafatos, 1989, EMBO J. 8: 891-901).

**alleles:** Electrophoretic variants identified by isoelectric focusing (Yannoni and Petri, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 301-03).

### **Cp36**

**location:** 1-{23} (based on *in situ* localization).

**synonym:** *S36*.

**references:** Spradling and Mahowald, 1979, Cell 16: 589-98.

Spradling, Waring, and Mahowald, 1979, Cell 16: 609-16.

Spradling and Mahowald, 1980, Proc. Nat. Acad. Sci. USA 77: 1096-1100.

Spradling, 1981, Cell 27: 193-201.

**phenotype:** The structural gene for s36-1, a 36,000-dalton chorion protein. Synthesis primarily during stages 12 and 13 (Waring and Mahowald, 1979, Cell 16: 599-607) and during stages 11 and 12 (Petri, Wyman, and Kafatos, 1976, Dev. Biol. 49: 185-99). Approximately 1,000 daltons cleaved from primary translation product to yield mature protein (Spradling *et al.*, 1980). Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**alleles:** Two-dimensional gels reveal electrophoretic variants, which we designate *Cp36<sup>a</sup>* and *Cp36<sup>b</sup>*. Null allele, *Cp36<sup>nl</sup>* [formerly *fs(1)cor-36*] produces no 36,000-dalton chorion protein (Digan, Spradling, Waring, and Mahowald, 1979, ICN-UCLA Symposium 14: 171-81).

**cytology:** Localized to 7F1-2 by *in situ* hybridization. Less than 1 kb distal to *Cp38*.

**molecular biology:** Resides on the same transcription unit as *Cp38*; separated by 1414 bp; gene 1100 bp in length and contains a small 5' intron (Wakimoto); nascent transcripts contain a ribonucleoprotein particle at each splice junction (Olsheim, Miller, and Beyer, 1985, Cell 43: 143-51). Abundantly transcribed producing polyadenylated mRNA in follicle cells surrounding stage-12 and -13 oocytes. Abundance markedly reduced in *In(1)oc = In(1)7F1-2;8A1-2* homozygotes. Located in a chromosome region that is amplified approximately 14-16 fold as a series of nested bidirectional replication forks spanning approximately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire region under the control of *ACE3*, a *cis*-acting sequence between 654 and 266 base pairs upstream from *Cp38* (Wakimoto). Amplification disrupted by *In(1)oc = In(1)7F1-2;8A1-2*; female sterility results in homozygotes. Electron-microscope characterization of transcription unit, including length, polymerase II density, and discrete termination site by Olsheim, Miller, and Beyer (1986, EMBO J. 5: 3591-96).

### **Cp38**

**location:** 1-{23} (based on *in situ* localization).

**synonym:** *S38*.

**references:** Spradling and Mahowald, 1979, Cell 16: 589-98.

Spradling, Waring, and Mahowald, 1979, Cell 16: 609-16.

Spradling, Digan, Mahowald, Scott, and Craig, 1980, Cell 19: 905-14.

Spradling and Mahowald, 1980, Proc. Nat. Acad. Sci. USA 77: 1096-1100.

Spradling, 1981, Cell 27: 193-201.

**phenotype:** Structural gene for s38-1, a 38,000-dalton chorion protein. Synthesis primarily during stages 12 and 13 (Waring and Mahowald, 1979, Cell 16: 599-607) and during stages 11 and 12 (Petri, Wyman, and Kafatos, 1976, Dev. Biol. 49: 185-199). 2,000 to 3,000 daltons cleaved from primary translation product to yield mature protein (Spradling *et al.*, 1980). Temporal and spatial distribution of expression described by Park and Spradling (1987, Genes Dev. 1: 497-509).

**alleles:** Isoelectric focusing resolves two electrophoretic forms of s38-1 which may be designated *Cp38<sup>a</sup>* and *Cp38<sup>b</sup>*.

**cytology:** Localized to 7F1-2 by *in situ* hybridization. About 1 kb proximal to *Cp36*.

**molecular biology:** Resides on the same transcription unit as *Cp36*; separated from it by 1414 bp; gene 1516 bp in length and contains a small 5' intron (Wakimoto); nascent transcripts contain a ribonucleoprotein particle at each splice junction (Olsheim, Miller, and Beyer, 1985, Cell 43: 143-51). Abundantly transcribed producing polyadenylated mRNA in follicle cells surrounding stage-12 and -13 oocytes. Abundance markedly reduced in *In(1)oc = In(1)7F1-2;8A1-2* homozygotes. cDNA and approximately 200 kb of genomic sequences in the region of *Cp38* cloned and restriction mapped. Direction of transcription is toward the centromere. Located in a chromosome region that is amplified approximately 14-16 fold as a series of nested bidirectional replication forks spanning approximately 100 kb in the follicle cells surrounding maturing oocytes; amplification of the entire

region under the control of *ACE3*, a *cis*-acting sequence between 654 and 266 base pairs upstream from *Cp38* (Wakimoto). Amplification disrupted by *In(1)oc* = *In(1)7F1-2;8A1-2*; female sterility results in homozygotes. Electron-microscope characterization of transcription unit, including length, polymerase II density, and discrete termination site by Olsheim, Miller, and Beyer (1986, EMBO J. 5: 3591-96).

### **Cp70**

**location:** 1-{0}.

**references:** Yannoni and Petri, 1984, Dev. Biol. 102: 504-08.

**phenotype:** The structural gene for a 70-dalton minor component of the chorion.

**alleles:** Two electrophoretic alleles known.

**cytology:** Placed in 2B3-6 based on its inclusion in *Df(1)S39* = *Df(1)1E1-2;2B5-6*, but not in *Df(1)sta* = *Df(1)1E1-2;2B3-4* (Peterson and Petri, 1986, DIS 63: 158).

### **\*cpl: cupola**

**location:** 1-0.0 (no crossing over with *sc* in 584 males).

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1959, DIS 33: 83-84.

**phenotype:** Small, inviable fly. Wings shorter and curved to form canopy over abdomen with tips converging toward mid-dorsal line. Head and eyes slightly deformed. Abdominal tergites abnormal; from irregular pigmentation to absence or gross deformation of the sixth and seventh tergites. Males sterile. RK3.

### **\*Cpt: Clipt**

**location:** 2-43.7.

**origin:** Spontaneous.

**discoverer:** Sturtevant, 26b18.

**phenotype:** Bristles short, like those of *Sb*. Homozygous lethal. Male sterile. RK1.

### **\*cpw: canopy wing**

**location:** 1-2.5 [not between *w* and *vt* (Lefevre and Green, 1972, Chromosoma 36: 391-412)].

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 69.

**phenotype:** Wings short and very broad; longitudinal veins frequently do not reach wing margin and often diverge. Eyes large and slightly rough. Head bristles reduced in number (ocellars most frequently affected). Thorax broad, one or more bristles occasionally absent; hairs more widely separated, with noticeable hairless areas. Males sterile. Viability 40% wild type. RK3.

*cq*: see *rk*<sup>4</sup>

### **\*cr: crisp**

**location:** 1- (not located).

**discoverer:** Agol.

**references:** 1936, DIS 5: 7.

**phenotype:** Bristles like forked. RK2.

**other information:** Not an allele of *f* or *sn*.

### **CR: Compensatory Response (K. Tartof)**

**location:** 1-{66}. *CR* is located in the centric heterochromatin of the *X* chromosome distal to the tandem array of ribosomal RNA genes (rDNA). It lies between the heterochromatic breakpoints of *sc*<sup>4</sup> (distally) and *w*<sup>md</sup> and *rst*<sup>3</sup> (proximally).

**origin:** Absence or dysfunction of this otherwise wild-type locus is detected by deletions or rearrangements of the heterochromatic interval indicated above.

**references:** Tartof, 1971, Science 171: 294-97.

Spear and Gall, 1973, Proc. Nat. Acad. Sci. USA 70: 1359-63.

Procunier and Tartof, 1978, Genetics 88: 67-79.

**synonym:** *cr*<sup>+</sup>.

**phenotype:** In females there are about 250 tandemly arrayed rRNA genes in each of the two *X* chromosome. However, when only a single *X* is present, as in *X/O* males or *X/In(1)sc*<sup>4L</sup>*sc*<sup>8R</sup> females, there are approximately 400 rRNA genes per *X*. This phenomenon, referred to as "compensation", results from the disproportionate replication of rDNA in somatic cells of adults and is controlled by the *CR* locus. *CR* is novel in that it exhibits both *trans* and contiguous-*cis* acting properties. It acts in *trans* to detect the presence of its partner locus in the homologue, and if that partner locus is absent, it acts in *cis* to drive the disproportionate replication of those rRNA genes that are contiguous with it. The observed disproportionate rDNA replication may occur primarily in polytene nuclei. *CR* is not required for the "magnification" or "reduction" of germ line rDNA.

**cytology:** Placed in 20F based on its location between the proximal breakpoints of *In(1)sc*<sup>4</sup> to the left and *In(2)rst*<sup>3</sup> and *In(1)w*<sup>md</sup> to the right. This places *CR* in h26-29 on the heterochromatic map of Gatti and Pimpinelli.

### **\*Cr-2: Cream in chromosome 2**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Bridges, 13i15.

**references:** 1919, J. Exp. Zool. 28: 337-84.

Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 239 (fig.).

**phenotype:** Specific dilutor of *w*<sup>e</sup>. *w*<sup>e</sup>; *Cr-2/Cr-2* has a pale-cream eye color. *w*<sup>e</sup>; *Cr-2/+* has eye color between eosin and cream. RK3.

### **\*cr-3: cream in chromosome 3**

**location:** 3-36.5.

**origin:** Spontaneous.

**discoverer:** E. M. Wallace, 14b27.

**references:** Bridges, 1919, J. Exp. Zool. 28: 337-84.

Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 112 (fig.).

**phenotype:** Homozygote has slightly diluted eye color. Eye color of *w*<sup>e</sup>; *cr-3* cream. Larval Malpighian tubes of *w*<sup>e</sup>; *cr-3* white, those of *cr-3* bright yellow (Brehme and Demerec, 1942, Growth 6: 351-56). RK3.

### **\*cr-a: cream-a**

**location:** Autosomal, not located.

**origin:** Spontaneous.

**discoverer:** Bridges, 13g15.

**references:** 1916, Genetics 1: 147.

1919, J. Expt. Zool. 28: 337-84.

**phenotype:** Strong specific dilutor of *w*<sup>e</sup>. RK3.

**\*cr-b**

**location:** 2-24.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 14c10.  
**references:** 1916, *Genetics* 1: 149.  
 1919, *J. Exp. Zool.* 28: 337-84.  
 Bridges and Morgan, 1919, *Carnegie Inst. Washington Publ. No. 278*: 245 (fig.).  
**phenotype:** Specific dilutor of  $w^e$ . RK3.

**\*cr-c**

**location:** 2- (near *S*).  
**origin:** Spontaneous.  
**discoverer:** Bridges, 16g13.  
**phenotype:** Weak specific dilutor of  $w^e$ . RK3.

**cra: crack (C. Nüsslein-Volhard)**

**location:** 2-77.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82.  
**phenotype:** Embryonic lethal. Defect in head involution. Shows abdominal transformations in combination with *Pc*-like mutants.  
**alleles:** Two.

**cramped:** see *crm*

**cramped-like:** see *crm*<sup>2</sup>

**crb: crumbs**

**location:** 3-82.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95 (fig.).  
**phenotype:** Homozygous lethal; many small holes in cuticle.  
**alleles:** Six; one weak.  
**cytology:** Placed in 95E-96A; covered by  $Y^{P_3D}$  element from  $T(Y;3)HI73 = T(Y;3)Xhy^+$ ; 95E but not  $T(Y;3)G73 = T(Y;3)YL;96A$ .  
**molecular biology:** Tentatively identified as a putative neurogenic gene based on hybridization of a cDNA clone with partial homology to *N* and *Dl* to 95F (Knust, Dietrich, Tepass, Bremer, Weigel, Vässin, and Campos-Ortega, 1987, *EMBO J.* 6: 761-66).

**CRB:** see  $T(1;4)A1$

**crc: cryptocephal**

**location:** 2-55.  
**origin:** Spontaneous.  
**discoverer:** Hadorn, 1942.  
**synonym:**  $l(2)crc$ .  
**references:** Hadorn and Gloor, 1943, *Rev. Suisse Zool.* 50: 256-61.  
 Gloor, 1945, *Arch. Julius Klaus-Stift. Vererbungsforsch. Sozialanthropol. Rassenhyg.* 20: 209-56.  
 Fristrom, 1965, *Genetics* 52: 297-318.  
 Sparrow and Chadfield, 1985, *Dev. Genet.* 5: 103-14 (fig.)  
**phenotype:** Homozygotes frequently die as larvae; failure to eliminate chitinous mouthparts at the larval molt frequently results in larvae with supernumerary mouth parts; homozygotes undergo pupation but rarely eclose from puparia. Imaginal head is not everted from thorax.

Except for slightly reduced eyes and shortened legs, wings, and thoracic bristles, the head and thorax are fully differentiated; frequently fail to pass gas bubble to anterior retro-opercular position, thus failing to provide space for head eversion. Head eversion is inhibited by integument being more rigid than normal. Mutant integument contains more glucosamine than normal; Sparrow and Chaddfield unable to confirm (1982, *Dev. Genet.* 3: 235-45). Feeding glucosamine to wild-type larvae produces a phenocopy very similar to  $l(2)crc$ . Abdomen often shows no differentiation, and internal organ development is arrested at pupal stage. Lethality suppressed by  $su(crc)l$  (Sparrow, 1981, *Genet. Res.* 38: 297-314). RK3.

**cytology:** Placed in 39C2-D12 based on its inclusion in  $Df(2L)TW12 = Df(2L)37E2-F4;39D12$  but not in  $Df(2L)TW1 = Df(2L)38A7-B1;39C2-3$  or  $Df(2L)TW2 = Df(2L)37D2-E1;38E6-9$  (Wright, Hodgetts, and Sherald, 1976, *Genetics* 84: 267-85).

**cream underscored:** see *cru*

**creased:** see *cs*

**creeper:** see  $rk^4$

**crib: cribble (T. Schüpbach)**

**location:** 2-{57}.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Schüpbach and Wieschaus.  
**phenotype:** Maternal-effect lethal mutant; Embryos from homozygous females cellularize irregularly at the blastoderm stage. Further development is very abnormal; at final differentiation embryos form only fragmented pieces of cuticle.  
**alleles:**  $crib^{HD} = crib^1, crib^{PA}, crib^{RS}$   
**cytology:** Placed in 42C1-43F8, since uncovered by  $Df(2R)pk78s = Df(2R)42C1-7;43F5-8$ .

**cricketlet:** see *clt*

**Crimp:** see *Cm*

**crinkled:** see *ck*

**\*crip: cripple**

**location:** 2- (between *pr* and *cn*).  
**discoverer:** Komai, 1924.  
**references:** 1926, *Genetics* 11: 280-93.  
 1927, *Mem. Coll. Sci. Univ. Kyoto, Ser. B* 2: 211-57.  
**phenotype:** Middle and hind legs twisted and shortened. Thirty percent penetrance. RK3.

**cripA: crippled-A (J.C. Hall)**

**location:** 1-1.8.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Homyk and Sheppard, 1977, *Genetics* 87: 95-104.  
**phenotype:** Adults walk slowly in uncoordinated manner, dragging one or more legs; legs weak and unable to support normal posture; flies weak; males court feebly and move wings up and down slowly instead of vibrating them.

**cytology:** Proximal to 2B11 owing to its not being deleted by *Df(1)RA19 = Df(1)IE3-4;2B11-12* nor carried by the terminal duplication  $y^2Y67g = Dp(1;Y)2B6-7$  (Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbertova, Kramers, and Zhimulev, 1982, DIS 58: 184-90).

### **cripB** (J.C. Hall)

**location:** 1-8.8.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

**phenotype:** Adults walk in uncoordinated manner; normal jumping difficult to induce; legs move to abnormal position during tethered flight; roughened eye phenotype.

### **cripC** (J.C. Hall)

**location:** 1-57 (approximate).

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. and Gen. Genet. 177: 553-65.

**phenotype:** Running, climbing, jumping are uncoordinated and generally abnormal; all such defects seemingly caused by stiffness of legs (nonbending at tibia-tarsal joints); mutant males court in uncoordinated manner with abnormal wing display, e.g., extension of both wings simultaneously; wing beat abnormal in tethered flight, as is position of legs.

**crisp:** see *cr*

### **\*crk: crooked setae**

**location:** 1-60.1.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 69.

**phenotype:** Bristles thin and slightly shortened; occasional missing scutellar. Acrostichals deranged. Abdominal hairs of female frequently missing; tergites occasionally abnormal. Classification difficult. Viability and fertility good. RK3.

**other information:** One allele induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine.

### **\*crm: cramped**

**location:** 1-1.48 (based on *crm<sup>sa</sup>* mapping 0.02 unit to the left of *w*).

**origin:** Induced by P32.

**discoverer:** Bateman.

**synonym:** *sta<sup>P</sup>: stubarista* from P32; *cramped-like* (*crm<sup>2</sup>*).

**references:** 1951, DIS 25: 78. 1953, DIS 27: 55.

**phenotype:** Antennae swollen, arista short, and branches fewer than in wild type. Wings slightly divergent and in some alleles nicked. Males have small extra sex combs on second tarsal segment of prothoracic legs and less frequently on basitarsal segments of mesothoracic and rarely metathoracic legs. *crm<sup>sa</sup>;Pc/+* males have large sex combs on all six basitarsi and small sex combs on all second tarsal segments in many flies. One or both post-ventricles lacking and other bristles occasionally missing or doubled. Body slightly darkened. Fertility of both males and females reduced, females more severely than males. Strength of sterilizing effect allele dependent. Females generally sterile; surviving *crm<sup>1</sup>* females have

rudimentary ovaries with no oocytes beyond stage 7 (Shannon, Kaufman, Shen, and Judd, 1972, DIS 48: 92); males of *crm<sup>2</sup>* and *crm<sup>7</sup>* partially fertile, other alleles male sterile. Viability variably reduced depending on crowding in culture; *crm<sup>4</sup>*, *crm<sup>7</sup>* are semilethal alleles, *crm<sup>6</sup>* die in late third instar; survivors eclose on days 11-13; rarely survive in combination with a deficiency (Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56; Shannon *et al.*, 1972).

**alleles:** Independently discovered and named mutants with the same phenotype and map position have been designated *l(1)zw<sup>9</sup>*, *sa*: sparse arista, and *swa*: swollen antennae. These are now designated alleles of *crm*. Designated alleles are tabulated below.

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>crm<sup>1</sup></i>	32 P	Bateman	<i>sta<sup>P</sup></i>	1

<sup>α</sup> 1 = CP627; 2 = Gersh, 1967, Genetics 56: 309-19; 3 = Lefevre; 4 = Rayle, 1968, DIS 43: 62; 5 = Rayle and Green, 1969, Genetica 39: 497-507; 6 = Shannon, Kaufman, Shen, and Judd, 1972, DIS 48: 92.

<sup>β</sup> Allelism inferred from missing-bristle phenotype of escapers; could be allelic to *l(1)3Bf* instead.

**cytology:** Placed in the left edge of or to the left of 3C1 based on the failure of *Df(1)wr-J1 = Df(1)3A1-2;3C2-3* but not *Df(1)X2 = Df(1)2F6-3A1;3B5-C1* to complement *crm<sup>1</sup>* (Judd, Shen, and Kaufman, *ibid.*) and the failure of *Df(1)w70e7 = Df(1)3B5-C1;3C1-2* [Sorsa, Green, and Beermann, 1973, Nature (London) New Biol. 245: 34-37] to delete *crm*.

### **crn: crooked neck**

**location:** 1-{0.95}.

**synonym:** *l(1)2Fa*.

**references:** Gvozdev, Gerasimova, Kovalev, and Ananiev, 1977, DIS 52: 67-68.

Perrimon, Engstrom, and Mahowald, 1984, Genetics 111: 23-41 (fig.).

**phenotype:** Hemizygous embryos from heterozygous mothers show twisted phenotype; *crn<sup>3</sup>/Df(1)64c18* and *crn<sup>4</sup>/Df(1)64c18* exhibit a similar but more extreme phenotype, suggesting that they are hypomorphic. Both alleles lethal in female germ-line clones.

<sup>β</sup> HMS = hycanthon methanesulfonate.

Failure of HMS-induced mutants to complement both *crn*<sup>3</sup> and *crn*<sup>7</sup> established allelism among the three series.

**cytology:** Placed in 2F1 based on its inclusion in *Df(1)278.4B1 = Df(1)2E3-F3;3A5-B4* but not *Df(1)2F1-3A4*.

**molecular biology:** Localized by transformation to a subclone of a component cosmid of a 200 kb walk initiated from microdissected polytene chromosomes. *crn* 65-70 kb to the right of the arbitrarily chosen initiation point of the walk; probes from the region identify a 2.1 kb transcript on Northern blots (Haenlin, Steller, Pirrotta, and Mohier, 1985, Cell 40: 827-37).

**Crn: Crown**

**location:** 3-46.8 (0.1 map unit to left of *in*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** E.H. Grell

**phenotype:** Dark trident pattern in heterozygote. Homozygous lethal.

*cro*: see *ptg*<sup>3</sup>

*crooked*: see *fw*<sup>c</sup>

**crooked neck:** see *crn*

**crooked setae:** see *crk*

**Crossover suppressor:** see *C()*

**crossveinless:** see *cv*

*crown*: see *ptg*<sup>3</sup>

**crs: cru sterile**

**location:** 2- (between *px* and *bw*).

**discoverer:** Muller.

**references:** 1951, DIS 25: 119.  
1955, DIS 29: 146.

**phenotype:** Male sterile. RK2.

**cytology:** Located between 58E3 and 59A2 on basis of sterility in combination with *Df(2R)P + Dp(2;Y)bw<sup>+</sup> = Df(2R)58E3-F1;60D14-E2 + Dp(2;Y)Y<sup>L</sup>;58F1-59A2;60D14-E2* (Muller, 1955).

**other information:** Male sterility formerly associated with but separable from *cru*.

**crt: crumpled tips**

**location:** 1-40.3 (7.3 units from *v*, based on 3035 flies).

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1952.

**references:** 1959, DIS 33: 84.

**phenotype:** Wing tips frequently shriveled, pleated, or crumpled and often turned up or down. Wings vary from completely unexpanded to wild type. Viability and fertility good in both sexes. Failure of *crt*<sup>2</sup> to produce homozygous germ-line clones reported by Perrimon, Engstrom, and Mahowald (1989, Genetics 121: 333-52). RK2.

**alleles:** *crt*<sup>2</sup>, induced by ethyl nitrosourea by Scott (PhD Thesis, 1987, University of California, San Diego), considered to be allelic based on similarity in phenotype and genetic position. Twelve other alleles: One each induced by X rays, triethylenemelamine, 2-fluoroethyl methane-sulfonate, and L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine; two induced by *p*-N,N-di-(2-chloroethyl)-amino-phenylethylamine; three each induced by S-2-chloroethylcysteine, and DL-*p*-N,N-di-(2-chloroethyl)-amino-phenylalanine.

**cytology:** Placed in region 11F2 through 12A2 based on its inclusion in *Df(1)C246 = Df(1)11D1-2;12A1-2* but not *Df(1)wy2 = Df(1)11A6-12;11F2-4* (Scott).

**cru: cream underscored**

**location:** 2-52.5.

**origin:** Spontaneous.

**discoverer:** Bridges, 20a5.

**phenotype:** Specific dilutor of *w<sup>e</sup>* and *P*. Slight dominant but used as a recessive. Originally thought to be male sterile, but this was caused by a factor in 2R, *crs*. Larval Malpighian tubes of *w<sup>e</sup>*; *cru* colorless; those of +; *cru* bright yellow (Brehme and Demerec, 1942, Growth 6: 351-56). RK3.

**cytology:** Not uncovered by *Df(2L)64j = Df(2L)34D1-2;35B9-C1*, *Df(2L)75c = Df(2L)35A1-2;35D4-7*, or *Df(2L)fn1 = Df(2L)34F4-35A1;35D5-7*. Presumably proximal to 35D5 (Woodruff and Ashburner, 1979, Genetics 92: 117-32).

**crumbs:** see *crb*

**crumpled:** see *cmp*

**crumpled tips:** see *crt*

**crumpled wings:** see *cwl*

**cru sterile:** see *crs*

**cryptocephal:** see *crc*

**cs: creased**

**location:** 1-56.

**origin:** X ray induced.

**discoverer:** K. C. Atwood, 41i.

**references:** 1942, DIS 16: 47.

**phenotype:** Wings longitudinally creased in first posterior cell from distal end of L3 virtually to anterior crossvein. Fertility and viability good. RK1.

**alleles:** *cs*<sup>53</sup> (CP627).

**csk: costakink**

**location:** 1-33.0.

**phenotype:** Most alleles are lethal; originally described on basis of a single surviving semilethal allele which

displayed smaller eyes, with wings slightly reduced in size and abnormally held, with the costal vein frequently kinked near L2. Not fully penetrant; male viability and fertility good; female fertility reduced to about 50% wild type. Survivors of other semilethal or nearly lethal alleles display similar phenotype (Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720). Lethal allele *csk*<sup>33</sup>, functions in homozygous germ-line clones, but has no maternal effect (Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52). Fate maps, as a bilateral domineering mutant, to a broad region of the neurogenic ectoderm posterior to the metathoracic ganglion; in addition a nonautonomous focus in the wing disc gives rise to crumpled turned up wings (Bgatov, Zharkikh, and Zhimulev, 1984, Mol. Gen. Genet. 196: 110-16).

<sup>α</sup> 1 = Fahmy, 1958, DIS 32: 69; 2 = Geer, Lischwe, and Murphy, 1983, J. Exp. Zool. 225: 107-18; 3 = Lefevre, 1981, Genetics 99: 161-80; 4 = Lefevre and Watkins, 1986, Genetics 113: 869-95; 5 = Lefevre and Wiedenheft, 1974, DIS 51: 83; 6 = Zhimulev, Belyaeva, Pokholkova, Kotcheva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baricheva, Aizenzon, Kramers, and Eeken, 1981, DIS 56: 192-96; 7 = Zhimulev *et al.*, 1981, Chromosoma 82: 25; 8 = Zhimulev, Belyaeva, Pokholkova, Kochneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baricheva, Aizenzon, Kramers, Eeken, 1982, DIS 58: 210-14; 9 = Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987,

Biol. Zentralbl. 106: 699-720.

**cytology:** Allelism inferred from observation that both samples of alleles map to the region of overlap between *Df(1)v-L1* and *Df(1)v-L2*. Survivors carrying semilethal alleles exhibit *csk* phenotype. Some surviving heteroallelic combinations display late eclosion and small pale bristles.

### **csw: corkscrew**

**location:** 1-{0.55}.

**synonym:** 1(1)2Db.

**references:** Perrimon, Engstrom, and Mahowald, 1985, Genetics 111: 23-41 (fig.).

**phenotype:** Hemizygotes die at the larval-pupal transition; dissected third-instar larvae display small imaginal disks. Larval neuroblast cells show low mitotic index, but chromosome morphology appears normal. Homozygous germ-line clones produce inviable embryos with U-shaped or twisted phenotypes, which are unaffected by paternal genotype or developmental temperature. *csw*<sup>6</sup> is viable and fertile with rough eyes.

### **alleles:**

<sup>α</sup> 1 = Dura, Randsholt, Deatrck, Erk, Santamaria, Freeman, Freeman, Weddell, and Brock, 1987, Cell 51: 829-39; 2 = Lefevre, 1981, Genetics 99: 461-80; 3 = Lefevre and Watkins, 1986, Genetics 113: 869-95; 4 = Perrimon, Engstrom, and Mahowald, 1985, Genetics 111: 23-41.

**cytology:** Placed in 2D3-4 based on its inclusion in *Df(1)pn38 = Df(1)2D3-4;2E3* but not *Df(1)Pgd-kz = Df(1)2D3-4;2F5*.

### **ct: cut**

**location:** 1-20.0.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 35, 223 (fig.).

Lefevre and Johnson, 1973, Genetics 74: 633-45.

Johnson and Judd, 1979, Genetics 92: 485-502.

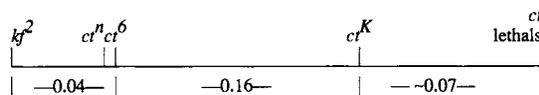

Jack, 1985, Cell 42: 869-76.

**phenotype:** *ct* mutations fall into three nonoverlapping phenotypic classes: kinked femur, cut wings, and lethal. Kinked-femur mutants are small with slightly dark, dull, red eye color; femurs kinked; wings seldom expand following eclosion, or when they do expand they are opaque and abnormal in shape; flies seem unable to move normally and die on the food soon after eclosion. Cut-wing mutants variably affect wing shape and head capsule development; phenotypic effects include incised wing margins with the tips usually cut to points, missing or ventrally displaced vibrissae, deformed antennae, *e.g.*, flattened and embedded with arista concave forward,

smaller kidney-shaped eyes, warped abdominal bands, and fine bristles. Most lethal alleles survive as clones of homozygous epidermal cells (Demerec). Developmental study of *ct*<sup>6</sup> by Waddington [1939, Proc. Nat. Acad. Sci. USA 25: 299-308; 1940, J. Genet. 41: 75-139 (fig.)] shows wing bud narrower than wild type as early as just after eversion of wing in early pupa. Cell death observed in prepupal wing bud (D. Fristrom, 1969, Mol. Gen. Genet. 103: 363-79). Clones of *ct*<sup>6</sup> cells in internal areas of wing blade normal in size; marginal clones much reduced in size indicating cell death. Homozygous clones in either dorsal or ventral membrane must reach margin in order to produce incision, 100/127 marginal clones unassociated with gaps; when gaps are produced, they affect both wing surfaces even though clone confined to a single surface. Both dorsal and ventral chaetal elements at the edges of such gaps may show the markers of such clones (Santamaria and Garcia-Bellido, 1975, Wilhelm Roux's Arch. Entwicklungsmech. Org. 178: 233-45). Lethal alleles fall into three groups, based on their complementation characteristics: cutless, group I, and group II. Lethal alleles *ct*<sup>C145</sup>, *ct*<sup>JA124</sup>, and *ct*<sup>149</sup> exhibit polyphasic lethality from late embryo to pharate adult (Johnson and Judd, 1979). Lethal embryos characterized by posterior defects in spiracles; no Keilin's organs, and abnormal maxillary complex (Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307). Group II and to a slightly lesser degree group I lethals fail to differentiate external sensory neurons in the peripheral nervous system; the presumptive external sensory neurons of the embryonic peripheral nervous system and their support cells are transformed into chordotonal neurons with their support cells; the transformed organs are chordotonal both in morphology and antigenic specificity. Same effect seen in the adult sensory organs in mosaics; embryonic effect differs from that seen in adults in that embryos lack peripheral sensory structures, e.g., Keilin's organs, whereas such structures persist, though reduced in size, in adult tissue. The numbers and positions of peripheral neurons is normal. CNS structure and function appear normal. No discernable effect of absence of *ct* function in the maternal germ line. Effect of *ct* mutations on PNS differentiation cell autonomous. [Bodmer, Barbel, Sheperd, Jack, Jan, and Jan, 1987, Cell 51: 293-307 (fig.)] Antibodies to *ct* protein specifically bind to nuclei of presumptive external sensory organ cells including those of the antennamaxillary organ and external sensory organs in spiracles, but not to nuclei of chordotonal organs; antibody staining also seen in some neurons with multiple dendritic arborizations and in cells lining the Malpighian tubules (Blochlinger, Bodmer, Jack, Jan, and Jan, 1988, Nature 333: 629-35).

Kinked-femur, cut-wing, and cutless alleles are mutually complementing: group I lethals complement kinked-femur but not cut-wing alleles; and group II lethals are noncomplementing; all combinations of lethal alleles are lethal. The different phenotypic classes of alleles occupy discrete and separate regions of the complex, with the order from left to right being, kinked femur, cut wing, group I lethals, and group II lethals; cutless alleles have not been mapped. Kinked femur, cut, and group-I-lethal mutations are associated with chromosome aberrations or insertions of transposable elements,

whereas group II lethals appear to be point mutations. *ct*<sup>6</sup>, *ct*<sup>68E</sup> (= *ct*<sup>67s?</sup>), *ct*<sup>78a</sup>, and *ct*<sup>K</sup> suppressed by *su(Hw)*<sup>2</sup>; *dvr*<sup>2</sup> enhances *ct*<sup>6</sup> and inhibits its complete suppression by *su(Hw)*<sup>2</sup>; *su(Hw)*<sup>2/+</sup> shows slight dominant suppression of wing phenotype of *ct*<sup>K</sup> (Lee, 1973, Aust. J. Biol. Sci. 26: 903-09). *ct*<sup>6</sup> and *ct*<sup>K</sup> strongly enhanced by *su(s)*; *su(s)* *ct*<sup>K</sup> lethal (Johnson) but rescued by *su(Hw)*<sup>2/+</sup> (Craymer). *ct*<sup>6</sup> the most commonly used allele.

Genetic fine structure map of the cut locus

**alleles:** *ct* is among the most mutable X-linked genes; several large-scale mutagenesis experiments have yielded many alleles, the majority of which are lost. The majority of induced *ct* alleles are lethal, or associated with chromosome rearrangements, or both. X-ray-induced alleles superscripted \*2a2, \*2a3, \*2c1, \*3a2, \*3b1, 4b1, \*4c1, \*6a1, \*7a1, \*7a2, \*7b2, \*7c1, \*7c2, \*9b1, \*9b2, \*10a1, \*10b1, \*10c1, \*11a, \*12a1, \*12a2, \*12c1, \*12c2, \*13a2, \*13b1, \*14a1, \*14a2, \*14a3, \*14b1, \*14b2, \*14c1, 15b1, and \*15b4 described by Hannah (Proc. Int. Congr. Genet. 8th, 1949, 588-89; 1971, Mol. Gen. Genet. 113: 191-203; CP627). Of a similar set of 28 alleles with superscripts between \*268-1 and 268-42 induced with X rays by Demerec or Hoover (CP552 and 627), only *Df(1)ct*<sup>268-42</sup> persists. Early alleles superscripted \*2 through \*21 (CP552 and 627) are lost with the exception of *ct*<sup>6</sup>. Other early alleles are superscripted \*34a, \*34b, \*36b, \*41c23, \*41i30 (CP552 and 627), \*43aH1, 46l, \*50e, \*62a, \*62f, \*do-vg, \*n4, \*n36, and \*So (CP627). Information on *ct* alleles that persist or that have been described since CP627 and on *kf*: kinked femur, which is a member of the cut complex, is tabulated below. *ct*<sup>cl</sup>: cut-cutless complements various non-lethal *ct* alleles but fails to complement lethal alleles except *ct*<sup>HA46</sup> (Lefevre and Leeds, 1983, Genetics 104: s45-46). A derivative of *ct*<sup>6</sup> (termed *Uc*: Unstable chromosome) studied by Lim (1979, Genetics 93: 681-701) and *ct*<sup>MR2</sup> derived from a hybrid dysgenic cross involving *MR-h12* on chromosome 2 by Gerasimova (1981, Mol. Gen. Genet. 184: 544-547) are highly unstable. The instability is manifest as increased incidence of lethal mutations, many of which are associated with chromosome aberrations broken in 6F (Lim), high reversion frequencies often accompanied by mutation at other loci. (Gerasimova, 1983, Mol. Gen. Genet. 190: 390-93; Gerasimova and Ilyin, 1984, DIS 60: 111-112) to either stable, unstable (most frequent, →10<sup>-4</sup> mutations to *ct*), or superunstable (least frequent, → around 50% *ct* mutants) alleles, and to other *ct* alleles, which in turn may be unstable or superunstable. In both instances the *gypsy* sequence [called *L* by Lim, Simmons, Raymond, Cox, Doll, and Culbert (1983, Proc. Nat. Acad. Sci. USA 80: 6624-27) and *mdg4* by Gerasimova, Ilyin, Mizrokhi, Semjonova, and Gregoriev (1984, Mol. Gen. Genet. 193: 488-92)] is inserted into the *ct* locus. The *gypsy* sequence appears to be mobilized and transposed into other parts of the *ct* locus to produce new *ct* alleles or, when *ct* undergoes reversion, to other posi-

Dev. Biol. 193: 296-307; 26 = Tchurikov, Gerasimova, Johnson, Barbakar, Kenzior, and Georgiev, 1989, Mol. Gen. Genet. 219: 241-48.

<sup>β</sup> f = kinked femur; u = unexpanded wings; w = cut wings; a = deformed antennae; v = displaced or missing vibrissae; b = fine bristles; l = lethal; (u) = unstable; (su) = superunstable.

- γ Coordinate system of Jack; origin at site of *gypsy* insertion of *ct*<sup>6</sup>. Coordinates used by Tchurikov *et al.* place *ct*<sup>6</sup> insertion at -118 kb; here converted to those of Jack by the addition of 118 kb.
- δ *ct*<sup>cl</sup> = cut-cutless; *ct*<sup>cl1</sup> and *ct*<sup>cl2</sup> recovered as *l(1)VA39* and *l(1)VE829* respectively; isolation number of *kf*<sup>3</sup> = VE614.
- ε Derivatives of *ct*<sup>MR2</sup> in which an additional transposable element is inserted in the left end of the *gypsy* element associated with *ct*<sup>MR2</sup>: *ct*<sup>MRpN1a</sup>, *ct*<sup>MRpN7</sup>, *ct*<sup>MRpN17</sup>, *ct*<sup>MRpN19</sup>, and *ct*<sup>MRpN26</sup> have *jockey* inserts in one position and in one orientation; *ct*<sup>MRpN10</sup>, *ct*<sup>MRpN20A</sup>, *ct*<sup>MRpN22</sup>, *ct*<sup>MRpN23</sup>, and *ct*<sup>MRpN30</sup> have *jockey* inserts in a slightly different position and in the opposite orientation; *ct*<sup>MRIK1</sup>, and *ct*<sup>MRILD1</sup> have *Hercules* inserts in different sites in the same region.
- ζ Additional information detailed below.

tions on the chromosomes where new mutants arise. Other types of transposing elements also appear to be mobilized in these two situations (*e.g.* Gerasimova, Matyunina, Ilyin, and Georgiev, 1984, *Mol. Gen. Genet.* 194: 517-22).

In the accompanying table of alleles, those superscripted *L* were recovered by Lim and colleagues; *L* followed by an even number designates a cut-wing allele, and *L* followed by an odd number a group-I lethal allele; alleles designated as weak cut wings have more nearly entire wing margins and lack head-capsule defects. Alleles superscripted *MR* are derived, either primarily or secondarily from hybrid-dysgenesis crosses by Gerasimova and her colleagues; those designated by *MR* followed by a number display the strong *ct*<sup>6</sup>-like wing phenotype; those designated *MRpN* are less extreme with multiple small incisions in the wing margin. *ct*<sup>MR2</sup> can revert or partially revert by excision of, or insertion of other elements (*e.g.* *Jockey* or *Hercules*), into the *gypsy* insert responsible for *ct*<sup>MR2</sup> (Leigh, Brown, Ross, Alphey, Flavell, and Gerasimova, 1989, *Mol. Gen. Genet.* 218: 203-13; Tchurikov, Gerasimova, Johnson, Barbakar, Kenzior, and Georgiev, 1989, *Mol. Gen. Genet.* 219: 241-48). Unstable revertants are able to generate new *ct* derivatives, retain the *gypsy* LTR of *ct*<sup>MR2</sup> (Mizrokhi, Obolenkova, Priimägi, Ilyin, Gerasimova and Georgiev, 1985, *EMBO J.* 4: 3781-87).

**cytology:** Placed in 7B1-2 by *in situ* hybridization.

**molecular biology:** Two hundred kilobases of DNA from the cut region cloned and restriction mapped (Jack, 1985, *Cell* 42: 869-76). Coordinate 0 is the site of the *gypsy* insert in *ct*<sup>6</sup>; coordinates 0 to -60 extend to the left and 0 to +140 to the right; all sequences hybridize to 7B1-2. Kinked-femur effects map in the -60 to -14 kilobase region, and cut-wing effects, many of which are known to result from *gypsy* inserts, to -6 to +19.3. Group I lethals cluster in the +71 to +73.5 region, and most of them contain *gypsy* inserts; group II mutants do not contain *gypsy* inserts and are thought to lie to the right of coordinate +100. 8,217 base pairs of cDNA clones sequenced; transcribed from over 70 kb of genomic sequence from coordinates approximately 80 to 150, which contain lethal I and lethal II regions. Transcription is from left to right. Sequence reveals long open reading frame encoding a putative protein of 2,175 amino acids with molecular mass of 240 kd. Principle among the features of the amino-acid sequence is a 60-residue homeodomain homologue, which although the most divergent of *Drosophila* homeobox sequences shows identity at the nine residues that are invariant in all homeodomains. In addition there are three 60-residue repeats showing 55-68% identity to each other which are not homologous to repeats found in other proteins; there are also four stretches of polyglutamate aspartate and a number of runs rich in single amino acids (Blochlinger *et al.*).

### *ct*<sup>71g</sup>

**molecular biology:** A molecular inversion with one break-point between DNA coordinates -35.8 and 33.2 and the other between +4.1 and +4.8.

### *ct*<sup>JC20</sup>

**molecular biology:** A molecular deletion beginning between coordinates -1.7 and +1.0 and extending to the left beyond -60, the extent of the cloned region. Deletes material of both kinked-femur and cut-wing regions of the complex.

### *ct*<sup>k</sup>

**phenotype:** Classified as a group-I lethal because homozygotes show reduced viability, and only 10% of fewer heterozygotes with other lethal alleles survive; survivors have weakly cut wings, as well as fine bristles, and enlarged and deformed humeral callus, not seen in other cut-wing mutants.

### *ct*<sup>cl</sup>: cut-cutless

**references:** Leeds and Lefevre, 1983, *Genetics* 104: s45-46.

**phenotype:** Acts as a lethal allele in combination with deficiencies for *ct*; phenotype normal in combination with viable *ct* alleles. Homozygotes have reduced viability and show thoracic protuberances (Schalet). Heterozygotes of *ct*<sup>cl</sup> with lethal alleles of *ct* die or eclose in small numbers; an exception is *ct*<sup>cl/ct</sup><sup>HA46</sup>, which exhibits normal survival.

### *ct*<sup>IS1</sup> (A. Schalet)

**phenotype:** Lethal; a member of cut Lethal II group, maps proximal to *ct*<sup>C145</sup> (Jack, 1985). Not suppressed by *su(Hw)*<sup>2</sup> (Schalet). *ct*<sup>IS1/+</sup> males, frequently show thoracic protuberances (Schalet).

### *ct*<sup>IS2</sup> (A. Schalet)

**phenotype:** Almost complete lethal; survival less than 1%. Not suppressed by *su(Hw)*<sup>2</sup>; cut-cutless type of mutant in that *ct*<sup>IS2</sup> fails to complement lethal alleles, *e.g.* *ct*<sup>IS1</sup>, but complements *kf*<sup>2</sup>, *ct*<sup>6</sup> and *ct*<sup>S</sup>. Rare surviving males and females are fertile with normal wings, but usually show thoracic protuberances in the region of the presutural and notoplural bristles as are also seen in heterozygotes of *ct*<sup>IS1</sup>, *Df(1)ct*<sup>J4</sup> or *Df(1)ct*<sup>J6</sup>.

### *kf*<sup>2</sup>

**molecular biology:** An approximately 18 kilobase deletion extending from a point between coordinates -35.8 and -33.2 to a point between -18.5 and -14.0.

### *cta*: concertina (T. Schüpbach)

**location:** 2-{54.8}.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal, female sterile: Embryos from homozygous mothers gastrulate abnormally; no posterior midgut formed; the germ band does not advance to the dorsal side of the embryo, but as it

expands, it is thrown into a series of folds at the ventral side of the embryo. Anterior midgut appears to develop normally. The phenotype is reminiscent of the zygotic embryonic lethal mutation folded gastrulation (*fog*). At final differentiation, the embryos from *cta* mothers have a fairly normal array of thoracic and abdominal segments with morphologically normal denticle belts. Defective head skeleton seen in larvae.

**alleles:**

<i>cta</i> <sup>2</sup>	EMS	<i>cta</i> <sup>PC</sup>
<i>cta</i> <sup>3</sup>	EMS	<i>cta</i> <sup>PG</sup>
<i>cta</i> <sup>4</sup>	EMS	<i>cta</i> <sup>QB</sup>
<i>cta</i> <sup>5</sup>	EMS	<i>cta</i> <sup>RC</sup>

**cytology:** In heterochromatic region of 2L, since uncovered by *Df(2L)PR31*.

***ctl*: coatless**

**location:** 1-25.8.

**origin:** Induced by ethyl methanesulfonate.

**references:** Eberl and Hilliker, 1988, *Genetics* 118: 109-20.

**phenotype:** Hemizygous lethal; distinct yolk plug indicating poorly developed gut; variably incomplete Malpighian tubules; poorly differentiated cuticle; mouthparts abnormal.

***ctt*: contorted**

**location:** 1-0.3.

**origin:** Induced by ethyl methanesulfonate (CB. 1528).

**discoverer:** Fahmy, 1956.

**references:** 1959, *DIS* 33: 84.

**phenotype:** Wings shorter than normal and abnormally shaped, frequently curved either convexly or concavely. Eyes rough and slightly altered in shape. Bristles thinner and straggly; orbitals frequently reduced or absent. Male genitalia frequently slightly twisted and abnormal. Males fertile; females sterile. RK2.

***cu*: curled**

**location:** 3-50.0.

**origin:** Spontaneous.

**discoverer:** Morgan, 15115.

**references:** Morgan and Bridges, 1923, *Carnegie Inst. Washington Publ. No. 327*: 152 (fig.).

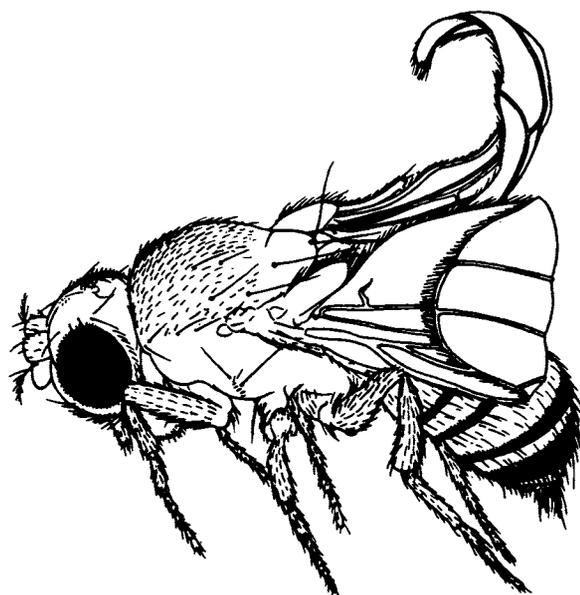

Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 215 (fig.), 223.

Whittinghill, 1937, *DIS* 7: 22.

**phenotype:** Wings curved upward throughout length and slightly divergent. Body color dark. Postscutellars erect and crossed. Good nutrition of larvae enhances curled character as does high temperature in last day of pupal life. (Nozawa, 1956, *Jpn. J. Genet.* 31: 321-26). RK1.

**alleles:** *\*cu*<sup>100.69</sup>, *\*cu*<sup>100.384</sup>, and *\*cu*<sup>300.215</sup> (CP627); *cu*<sup>5J</sup> associated with *In(3R)84F11-12;86D1-E2* (Ashburner, 1981, *DIS* 56: 190).

**cytology:** Located in 86D1-4 based on the absence of *cu*<sup>+</sup> from *Df(3R)M86D = Df(3R)86D1;86D4* (Ashburner, 1981, *DIS* 56: 189).

***cu*: curled**

From Bridges and Morgan, 1923, *Carnegie Inst. Washington Publ. No. 327*: 152.

**\**Cu*: Curl**

**location:** 2-54.6 (0.1 unit to the right of *pr*).

**origin:** X ray induced.

**discoverer:** Bateman, 1954.

**synonym:** *Cd*: *Coildex*; *Coi*: *Coiled*.

**references:** 1955, *DIS* 29: 69.

**phenotype:** Similar to *Cy* but wing curvature more extreme; wings opaque and greyish. Anterior margin of wing invaginated at point where L1 meets wing margin. When expression is weakest, it appears only as a slight wave in the wing margin. In 10-15% of the flies, wings also curve downward over flanks before curling upward. In *y*; *Cu*<sup>54</sup> flies, curvature reduced to a shallow spoon. *Cu*<sup>54</sup> epistatic to *Cy*. RK2.

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	homozygote phenotype
<i>*Cu</i> <sup>1</sup>	spont.	Ives		5	viable
<i>Cu</i> <sup>2</sup>	EMS	Grell			viable, does not complement <i>stw</i>
<i>Cu</i> <sup>3</sup>		Ish-Horowicz, 1976	<i>Cd</i> <sup>2</sup>	2	lethal
<i>*Cu</i> <sup>54</sup>	X ray	Bateman, 1954	<i>Cd</i>	2	lethal
<i>Cu</i> <sup>57</sup>	X ray	Carlson, 57g	<i>Coi</i>	3	viable; complements <i>stw</i> <sup>β</sup>
<i>Cu</i> <sup>75</sup>	X ray	Ashburner	<i>Coi</i> <sup>75</sup>	1	viable
<i>*Cu</i> <sup>A</sup>	spont.	Fernandez Gianotti	<i>Ac</i>	4	viable

<sup>α</sup> 1 = Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, *DIS* 55: 193-95; 2 = Bateman, 1955, *DIS* 29: 69; 3 = Carlson, 1960, *DIS* 34: 48; 4 = Fernandez Gianotti, 1948, *DIS* 22: 53; 5 = Ives, 1948, *DIS* 22: 53.

<sup>β</sup> Viability and fertility of *Cu*<sup>57</sup> excellent; phenotype extreme.

**other information:** Allelism of *Cd*, *Coi*, and *Cu* inferred from similarity of phenotype and of genetic position (54.6-56.6). *Cd* (= *Cu*<sup>54</sup>) and *Coi* (= *Cu*<sup>57</sup>) declared to be allelic based on renewed mapping of *Coi* just to the right rather than to the left of *pr* in agreement with the published position of *Cd* (Ashburner and Woodruff, 1979, *Genetics* 92: 117-32). Both *Cu*<sup>57</sup> and *Cu*<sup>75</sup> suppressed by *Dp(2;2)Adh3* (Ashburner and Woodruff). *Cu* and

*Cu*<sup>57</sup> shown to be in 2R based on their being recoverable in *C(2R)* but not *C(2L)* compounds (E.H. Grell).

**Cu-3: Curl in chromosome 3**

**location:** 3-66.0.  
**origin:** Spontaneous.  
**discoverer:** Erickson and Meyer, 51c.  
**synonym:** *Cur*: *Curl* preoccupied.  
**references:** Meyer, 1952, DIS 26: 66.  
**phenotype:** Heterozygote has curly wings with parchment-like texture resembling *Cy*. Homozygous lethal. RK2.

**cu-X: curled-X**

**location:** 1- (not located but not allelic to *cx*).  
**origin:** Spontaneous in *In(1)dl-49+B<sup>M1</sup>*, *y sc v*.  
**discoverer:** Krivshenko, 57j29.  
**references:** 1956, DIS 32: 80.  
**phenotype:** Males have wings that are bent upwards and diverge slightly. *cu-X* is never expressed in females. It represents a mutation whose phenotypic expression is sex limited. Expressed equally well in males with and without a Y chromosome. RK2.

**cubitus interruptus: see ci**

**cuff: cutoff (T. Schüpbach)**

**location:** 2-61.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Schüpbach and Wieschaus.  
**phenotype:** female-sterile; homozygous females often have underdeveloped ovaries which seem to lack germ cells altogether. In some females, a small number of developing egg chambers is found; these never develop beyond the first few stages of oogenesis.  
**alleles:** *cuff*<sup>1</sup> to *cuff*<sup>3</sup> isolated as *WL*, *QQ*, and *WM* respectively.

**cui: curvi**

**location:** 2-23.4 (1.4 to the right of *Sp* and 0.5 to the right of *lys*).  
**origin:** Spontaneous.  
**discoverer:** Nicoletti.  
**synonym:** *curved*.  
**references:** 1957, DIS 31: 84.  
**phenotype:** Distal half of wing curved upward. Viability and expressivity very good. RK1.

**cup: cup (T. Schüpbach)**

**location:** 2-23.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Schüpbach and Wieschaus.  
**phenotype:** Female-sterile; homozygous females show abnormalities in late oogenesis. Follicle cells do not migrate centripetally between nurse cells and oocyte. They do synthesize a chorion which remains open ended (like a chalice, or cup). Such eggs are usually not laid and remain unfertilized.  
**alleles:** Thirty seven alleles; *cup*<sup>1</sup> to *cup*<sup>37</sup> (isolated as *WQ*, *PB1*, *PB53*, *PF21*, *PF63*, *PH69*, *PL11*, *PN14*, *PS73*, *PV36*, *PW3*, *PV76*, *QD57*, *QJ9*, *QJ36*, *QJ65*, *QK4*, *QK12*, *QK24*, *QL54*, *QM66*, *QR55*, *QR56*, *QV7*, *QV50*, *QW45*, *RC11*, *RG6*, *RH13*, *RH24*, *R177*, *RM12*, *RN61*, *RS2*, *RS42*, *RS50*, and *RU45* respectively).

**cupola: see cpl**

**cur: curvoid**

**location:** 3-30.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 33c14.  
**phenotype:** Wings divergent and curved down. Resembles *c*. Viability erratic. RK3.

**cv: crossveinless**

From Weinstein, A., 1920, Proc. Nat. Acad. Sci. USA 6: 625-39.

**cut off:** see *cuff*

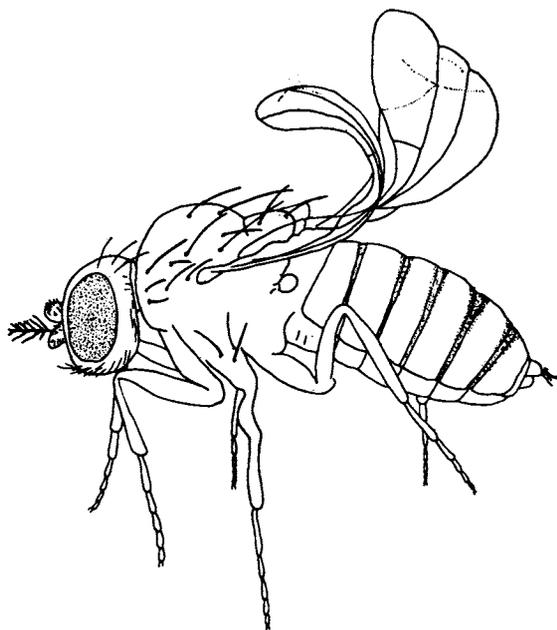

**cv: crossveinless**

**location:** 1-13.7.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 1912.  
**references:** 1920, Proc. Nat. Acad. Sci. USA 6: 660-63. Weinstein, 1920, Proc. Nat. Acad. Sci. USA 6: 625-39 (fig.).  
**phenotype:** Crossveins absent or traces only present. Veins L3 and L4 slightly delta at tips. Classifiable in unexpanded wings. Wing effects due to excessive contraction in the pupal period, obliterating the cavity which should normally remain between the epithelia to form the vein (Waddington, 1940, J. Genet. 41: 75-139). RK1.  
**alleles:** \**cv*<sup>68</sup> induced by ethyl methanesulfonate (Hayman and Maddern, 1969, DIS 44: 50).  
**cytology:** Located in polytene region 5B [Lefevre, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66].

**cv-2: crossveinless on chromosome 2****location:** 2-96.2.**origin:** Spontaneous.**discoverer:** Nicoletti, 62j.**phenotype:** Anterior and posterior crossveins absent. RK1.**alleles:** Found segregating in several natural populations (Boyer, Parris, and Milkman, 1973, *Genetics* 75: 169-75).**cytology:** Salivary chromosomes normal.**\*cv-b: crossveinless-b****location:** 3-65.**origin:** Spontaneous.**discoverer:** Bridges, 24k8.**phenotype:** Crossveins reduced or absent. May overlap wild type. RK3.**cv-c: crossveinless-c****location:** 3-54.1 (0.5 units to the right of *red*, Craymer).**origin:** Spontaneous.**discoverer:** Stern, 25g13.**references:** 1934, DIS 1: 35-36.**phenotype:** Posterior crossvein usually absent or greatly reduced. Anterior crossvein usually present but often detached. Eye flattened or with vertical shallow furrow. Legs weak, especially tarsal joints. Occasionally overlaps wild type. RK2.**cytology:** Placed in 88B-C based on its inclusion in the synthetic deficiency with *3R* proximal derived from  $T(Y;3)P102 = T(Y;3)87B2-3$  and *3R* distal derived from  $T(3;4)P86 = T(3;4)88B-C;101$  (Bernstein) as well as in the duplication from  $T(1;3)O5 = T(1;3)4F2-3;62B-C;88A-C;92C-D$  (Lindsley and Grell, 1958, DIS 32: 136).**cv-d: crossveinless-d****location:** 3-65.**origin:** Appeared among progeny of ether-treated flies.**discoverer:** Duncan, 34c.**references:** 1935, DIS 4: 7.**phenotype:** Posterior crossvein absent or reduced to an oblique fragment or bar parallel to L5. Anterior crossvein sometimes detached. RK2.**other information:** Possibly an allele of *cv-b*.**cve: crossveinless effect**

This is a term used by Milkman for alleles anywhere in the genome which affect the formation of crossveins. Not strictly a gene locus designation.

**cvl-5: crossveinless like****location:** 3-48.1 [based on 55 crossovers between *st* and *cu* (Thompson, 1967, DIS 42: 41)].**origin:** The major component in a line selected by Mohler (1965, *Genetics* 51: 641-51) for crossveinless-like phenotype.**references:** Thompson, 1967, *Genetics* 56: 13-22.**phenotype:** Removes crossveins. Complex response to heat shock described by Thompson (*ibid*).**cvl-6: crossveinless like 6****location:** 1-59.1 (2.4 map units to the right of *f*).**origin:** Major component of a line selected by Mohler for crossveinless-like phenotype.**references:** Mohler, 1965, *Genetics* 51: 641-51.**phenotype:** Removes crossveins. Developmental sequence differs from that of *cv* and *cvl-5*; longitudinal veins form in time and manner expected of wild type; *cvl-6* differs in that the wings begin vein development with a joining of the wing surfaces through the crossvein region; partial repair is accomplished by a secondary developmental sequence, including withdrawal of cell processes joining the wing surfaces at this position and subsequent reorganization of a crossvein around this gap (Mohler and Swedberg, 1964, *Genetics* 50: 1403-19).**\*cvw: convex wing****location:** 1-58.2.**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).**discoverer:** Fahmy, 1953.**references:** 1958, DIS 32: 69.**phenotype:** Wings slightly shortened and arched convexly. Variable and may overlap wild type. Tergites in some females have serrated edges or are grossly deformed. Viability and fertility good in both sexes. RK2.**cwi: crumpled wings****location:** 1-{0.5}.**references:** Zhimulev, Belyaeva, Fomina, Protopopov, and Bolshakov, 1986, *Chromosoma* 94: 492-504.**phenotype:** Crumpled wings?**cytology:** Placed in 2B7-10.**cx: curlex****location:** 1-13.6.**origin:** Spontaneous.**discoverer:** R. L. King, 1927.**phenotype:** Wings bent upward for posterior two-thirds of length; anterior one-third warped; margin kinked. Wings not spread. RK2.**cytology:** Placed in polytene region 5A-B by Lefevre.*cx*: see *c(3)G***cx<sup>tg</sup>: curlex-twisted genitalia****origin:** Spontaneous.**discoverer:** Curry, 37c19.**phenotype:** Wings always divergent, usually 45° from axis. Basal one-third of wing wavy but less so than in *cx*; posterior two-thirds of wing curled slightly upward or downward. Genitalia of nearly all males rotated, usually 45° counterclockwise. Flies dwarfish. Viability irregular. Male sterile. RK2.*cx-b*: see *wy*<sup>2</sup>**cxb: calyx bulging (J.C. Hall)****location:** 2-73.**origin:** Induced by ethyl methanesulfonate.**synonym:** *cxb*<sup>N71</sup>.**references:** Heisenberg, Borst, Wagner, and Byers, 1985, *J. Neurogenet.* 2: 1-30.**phenotype:** Calyces of mushroom bodies in dorsal brain of adult are enlarged and have abnormal shape; peduncles and lobes (projecting from these calyces) small or missing; ellipsoid body of central brain also aberrant in morphology; learning abnormal, in tests using olfactory stimuli.*CxD*: see *In(3LR)CxD**CxF,D*: see *In(3LR)DcxF*

**Cy: Curly**

From L. Ward, 1923, *Genetics* 8: 276-300.

**Cy: Curly**

**location:** 2-6.1 (removed from *In(2L)Cy* and located by Tinderholt).

**origin:** Spontaneous.

**discoverer:** L. Ward, 20c.

**references:** 1923, *Genetics* 8: 276-300 (fig.).

**phenotype:** Wings curled upward; rarely overlaps wild type at 25°, but frequently overlaps at 19°. Curvature caused by the unequal contraction of the upper and lower epithelia during the drying period following emergence from the pupa case (Waddington, 1940, *J. Genet.* 41: 75-139). Flightless but thoracic innervation normal (Chiarodo, Reing, and Saranchak, 1971, *J. Expt. Zool.* 178: 325-30). Expression decreased by larval crowding, increased by increased temperature during pupal development (Nozawa, 1956, *Jpn. J. Genet.* 31: 161-71). Classifiable in single dose in triploids. Usually homozygous lethal but may emerge as dwarf with more extreme wing character. Effective lethal phase late embryo-early larva (Kidwell, 1972, *J. Hered.* 63: 100). RK1A.

**alleles:** *Cy<sup>M</sup>*: Curly of Meyerowitz; *Cy<sup>rv76</sup>*, X-ray-induced reversion of *Cy* in *CyO* (Wright, Hodgetts, and Serald, 1976, *Genetics* 84: 267-85).

**cytology:** Placed in 22F4-23B2 on the basis of its being lethal in combination with *Df(2L)DTD2 = Df(2L)22D4-5;23B1-2* but not *Df(2L)DTD48 = Df(2L)22E2-4;22F-23A1* (Spencer, Hoffman, and Gelbart, 1982, *Cell* 28: 451-61). Ordinarily inseparable from *In(2L)Cy = In(2L)22D1-2;33F5-34A1*, although it was separated by Tinderholt (1961, *DIS* 35: 47).

**other information:** *Cy* removed from *In(2L)Cy* still causes a local reduction in crossing over in the *ed-cl* region (Sederoff).

**Cyclic GMP dependent protein kinase:** see *Pkg*

**Cyclic AMP Phosphodiesterase-2:** see *dnc*

**CycA: Cyclin A**

**location:** 3-{37}.

**synonym:** *l(3)68Ea; l(3)rsg11*.

**references:** Whitfield, González, Sánchez-Herrero, and Glover, 1989, *Nature* 338: 337-40.

Lehner and O'Farrell, 1989, *Cell* 56: 957-68.

**phenotype:** Encodes cyclin, a molecule involved in the cell cycle; the pattern of transcription reflects this. Maternal message uniformly distributed in newly laid egg, but becomes more concentrated in the cortex prior to peripheral nuclear migration. At the time of cellularization of the blastoderm, zygotic message is produced. Cyclin A accumulates in the interphase cytoplasm of cellularized embryos, but relocates to the nuclear region early in prophase and is completely degraded during metaphase. A functional cyclin A gene is required for continued cell division after exhaustion of maternally provided cyclin A. Message confined to dividing tissues in brain and imaginal disks in larvae.

**alleles:**

<sup>α</sup> 1 = Akam, Roberts, Richards, and Ashburner, 1978, *Cell* 13: 215-25; 2 = Hoogwerf, Akam, and Roberts; 3 = Lehner and O'Farrell, 1989, *Cell* 56: 957-68.

**cytology:** Placed in 68E by *in situ* hybridization; included in *Df(3L)vin3 = Df(3L)68C5-6;68D6* but not *Df(3L)vin2 = Df(3L)67F2-3;68E3-4*.

**molecular biology:** Sequence isolated from a genomic library using a synthetic oligonucleotide based on conserved sequences of known cyclin genes. Detects a 2.3 kb transcript that is abundant in pre-cellularization embryos and in adult females; a 2.5 kb zygotically derived transcript appears after cellularization (Akam *et al.*). These transcripts are 2.5 and 3.0 kb respectively according to Lehner and O'Farrell. Akam *et al.* report three other transcripts detectable in pupae, of which one persists into adulthood. Lehner and O'Farrell report the sequence of a cDNA that contains a long open reading frame that encodes a 491-amino-acid protein, which displays 50% amino-acid identity to clam cyclin A and 34% identity to clam cyclin B.

**CycB: Cyclin B**

**location:** 2-{100}.

**references:** Whitfield, González, Sánchez-Herrero, and Glover, 1989, *Nature* 338: 337-40.

**phenotype:** Encodes cyclin, a molecule involved in the cell cycle; the pattern of transcription reflects this. Maternal message uniformly distributed in newly laid egg, but becomes concentrated at the posterior pole at the time of polar-nucleus migration; also evident in the cortex of the syncytial blastoderm. Larval message concentrated in the testis.

**cytology:** Placed in 59A by *in situ* hybridization.

**molecular biology:** Sequence isolated from a genomic library using a synthetic oligonucleotide based on conserved sequences of known cyclin genes. Detects a 2.3

kb transcript that is abundant in pre-cellularization embryos and in adult females; a 2 kb transcript is found in adult males.

**Cyclin A:** see *CycA*

**Cyclin B:** see *CycB*

**Cyd: Curlyoid**

**location:** 3- (rearrangement).

**discoverer:** Jollos.

**references:** Curry, 1939, DIS 12: 46.

**phenotype:** Wings curled upward in heterozygote, only slightly so in some flies; wings slightly reduced in size and dusky. *In(3R)P,Cyd/+* has 2- to 3-day developmental delay (Craymer). Homozygous lethal. RK3.

**cytology:** Associated with *In(3R)P*; no other aberration present (Craymer).

*cyl*: see *rk<sup>cyl</sup>*

**Cyt-b: Cytochrome-b homologue**

**location:** 2-{52}.

**synonym:** *TU36B*.

**references:** Levin, Boychuk, Croniger, Kazzaz, and Rozek, 1989, Nucleic Acids Res. 17: 6349-67.

**phenotype:** Encodes a cytochrome-b homologue that is expressed specifically in muscles; expression is concordant with that of *Mhc*.

**cytology:** Placed in 36B based on its juxtaposition to *Mhc*.

**molecular biology:** cDNA's cloned and sequenced; gene shown to have one intron. mRNA transcribed off of

opposite strand from *Mhc*; poly(A) addition sites 99 nucleotides apart. Contains an open reading frame of 1242 nucleotides able to encode a polypeptide of 414 amino acids of 47 kd. Sequence shows 17.6% identity and 41% homology with yeast cytochrome-b2.

**Cyt-c1 and Cyt-c2: Cytochrome c**

**location:** 2-{52}.

**origin:** Isolated from a Charon-4 library using mouse cytochrome-c gene sequence as a probe.

**references:** Limbach and Wu, 1985, Nucleic Acids Res. 13: 631-44.

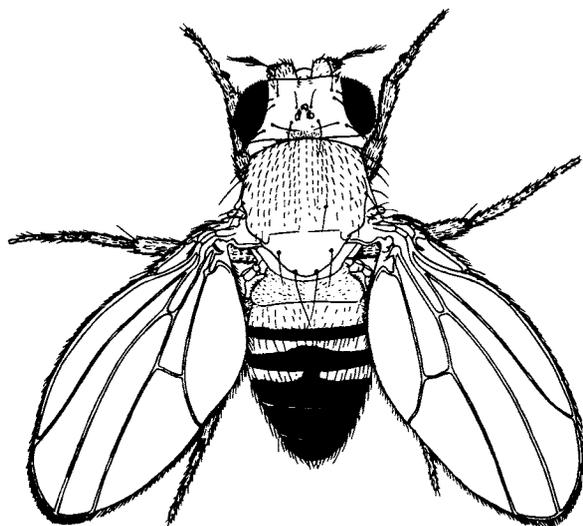

**phenotype:** Apparently the structural genes for two cytochrome-c type enzymes, which differ from each other in 32/107 amino-acid residues. *Cyt-c1* (sequence D3) expressed at constant, but relatively low, level throughout development; *Cyt-c2* (sequence D4) expressed at varying, but relatively high, levels throughout development. Amino acid sequence also given in Handbook of Biochemistry and Molecular Biology: Proteins (Fasman, ed.) CRC Press, Cleveland, Vol. 3, pp. 282-83.

**cytology:** Placed in 36A10-11 by *in situ* hybridization.

**molecular biology:** Sequences located within a 4 kb region of DNA. Sequence analysis indicates that both can encode functional cytochrome-c proteins. *Cyt-c* genomic clones also isolated, using *Manduca sexta* cDNA clone as probe, and sequenced by Swanson, Zieminn, Miller, Garber, and Margoliash (1985, Proc. Nat. Acad. Sci. USA 82: 1964-68).

**d: dachs****location:** 2-31.0.**origin:** Spontaneous.**discoverer:** Morgan and Bridges, 12k22.**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 216 (fig.).Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 212 (fig.), 223.

**phenotype:** Similar to *ff*. Tarsi four jointed instead of five jointed owing to failure of joint formation between second and third tarsal segments (Tokunaga and Gerhart, 1976, *Genetics* 83: s76); joint remnants sometimes persist beneath the cuticle (Held, Duarte, and Derakhshanian, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 145-57). Legs short and held close to body. Femur, tibia, and tarsae foreshortened [Tokunaga and Gerhart; Mikuta and Mglinetz, 1979, *Genetika (Moscow)* 15: 624-32]. Probability of failure of joint formation proportional to degree of foreshortening of second tarsal segment (Tokunaga and Gerhart). Joint failure phenotype can extend into *d/+* tissue adjacent to *d/d* clones (Tokunaga and Gerhart). Number of longitudinal rows of bristles in second basitarsus unaffected, but number of bristles per row reduced (Held, 1979, *Wilhelm Roux's Arch. Dev. Biol.* 187: 105-27). Leg effects enhanced by *ss<sup>a</sup>* and *ss<sup>aB</sup>* (Villem, 1945, *Genetics* 30: 26-27). Wings smaller than wild type, narrowed, with L2 and L3 joined near anterior crossvein; distance between crossveins smaller and crossveins sometimes absent. Angle between L2 and L5 greater than normal. Eyes small and rough. Posterior scutellar bristles erect. Viability erratic. Frequently sterile. Enhances transforming effects of *Antp<sup>Ns</sup>* (Mikuta and Mglinetz, 1979) and *pb*; labial legs in *d*; *pb* flies show failure of joint formation [Kaurov, 1978, *Genetika (Moscow)* 14: 306-12]. RK2.

*d<sup>1</sup>*: see *Df(2L)d***D: Dichaete**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 127.

*D*: see *Lvp-D***D: Dichaete****location:** 3-40.7.**origin:** Spontaneous.**discoverer:** Bridges, 15a3.**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 127 (fig.).

**phenotype:** Wings extended uniformly at 45° from body axis and elevated 30° above (occasionally sharply down-cast and dragging). Alulae missing. Dorsocentrals and some other bristles reduced in number (Sturtevant, 1918, Carnegie Inst. Washington Publ. No. 264; Plunkett, 1926, *J. Exp. Zool.* 46: 181-244). Head often deformed or split in postvertical region. Halteres turned down. Homozygous lethal. Nearly lethal in combination with *ey<sup>D</sup>* (Sobels, Kruijt, and Spronk, 1951, *DIS* 25: 128). Partially suppressed by *sc* alleles that remove postverticals (*sc*, *sc<sup>4</sup>*, *sc<sup>6</sup>*, *sc<sup>7</sup>*) but not by others (*sc<sup>2</sup>*, *sc<sup>5</sup>*) (Sturtevant). Classifiable in triploids. RK2A.

**alleles:** *D<sup>3</sup>* and *D<sup>E</sup>* less severe derivatives of *D* (CP627). *D<sup>4</sup>* X ray induced, associated with *T(2;3)21D;70-71* (Craymer, 1980, *DIS* 55: 197).

**cytology:** Inseparable from *In(3L)D = In(3L)69D3-E1;70C13-D1* (Bridges in Morgan, Bridges, and Schultz, 1937, *Year Book - Carnegie Inst. Washington* 36: 301). Tentatively placed in 70C13-D1 based on breakpoint common to *In(3L)D* and *T(2;3)D<sup>4</sup>*.

Murre, McCaw, Vässin, Caudy, Jan, Jan, Cabrera,

Buskin, Hauschka, Lassar, Weintraub, and Baltimore, 1989b, Cell 58: 537-44.

**phenotype:**  $da^+$  performs multiple roles during development. Maternally supplied  $da^+$  is required in female embryos as a positive activator of the gene, Sex-lethal (*Sxl*), the key binary switch gene for the sex determination pathway. Also,  $da^+$  expression is required in the somatic gonad of adult females for proper egg membrane formation, and hence for the survival of all progeny regardless of their sex. Embryonic expression of  $da^+$  is required in both sexes for the formation of the peripheral nervous system (PNS) and parts of the central nervous system (CNS). And, during larval and/or pupal stages,  $da^+$  may be required for the growth and/or differentiation of cells that form the adult cuticle.

Amorphic alleles ( $da^2$ ,  $da^3$ ,  $da^5$ , etc.) are recessive lethals, with a lethal period which is predominantly embryonic (Cronmiller and Cline, 1987; Caudy *et al.*, 1988a). In addition, the hypomorphic allele,  $da^1$  (originally called *da*), is hemizygous [ $da^1/Dff(2L)da^-$ ] lethal (Mange and Sandler, 1973), and  $da^1$  homozygotes die when they undergo the first half of embryonic development at 29° (Cline, 1976). Death appears to be a consequence of dosage compensation defects (Cline, 1983a; Gergen, 1987). Viability of  $da^1$  homozygotes is improved by the presence of extra X or Y heterochromatin in either the parental female or her progeny (Sandler, 1972; Mason, 1973). Temperature-sensitive lethality of the  $da^1$  zygotic lethal effect is not affected by the *Sxl* genotype (Cline, 1980).  $da^+$  is not required in the germline, since  $da^-(da^2/da^3)$  pole cells produce fertile gametes; however, mitotic recombination failed to yield significant  $da^-(da^2$  or  $da^3)$  somatic clones, suggesting  $da^+$  may be essential during epidermal development (Cronmiller and Cline, 1987). Embryos, homozygous for lethal *da* alleles, have a reduced CNS, lack all peripheral neurons, and have no external sensory structures (Caudy *et al.*, 1988a). Adult flies heterozygous for a deletion of the achaete-scute (*ASC*) genes and simultaneously heterozygous for *Df(da)* (also  $da^2/+$  or  $da^5/+$ ) exhibit characteristic bristle defects (Dambly-Chaudière *et al.*, 1988). Hemizygosity for  $da^+$  reduces the number of supernumerary bristles in *Hw* mutants (Dambly-Chaudière *et al.*, 1988).

In addition to its zygotic phenotype,  $da^1$  exhibits two separable maternal effects. There is a female-specific maternal effect: At 22° and 25°, homozygous  $da^1$  females produce no daughters, while at 18°, they produce approximately 20% as many daughters as sons (Cline, 1976). At 29°,  $da^1$  displays a sex-nonspecific maternal effect. Homozygous females are reversibly sterile; they lay eggs that show little or no development (Cline, 1976). Sterility of  $da^1$  females at high temperature results from a defect in the somatic gonad rather than in the germline, since  $da^-$  germ cells in wild-type ovaries produce normal eggs which support full viability of sons (Cronmiller and Cline, 1987).

The female-specific maternal effect has a temperature-sensitive period which includes the last 60 hr of oogenesis and the first 3 hr of development (Cline, 1976). This maternal effect is also observed in crosses of  $da^1$  females to *D. simulans* males (Watanabe and Yamada, 1977). The female-lethal maternal effect is autonomous to the germline, as demonstrated by transplantation of

$da^1$ , or  $da^2/da^3$  pole cells into + hosts (Cline, 1983b; Cronmiller and Cline, 1987). Female zygotes from  $da^1$  mothers at 25° die as embryos. Such lethal female embryos show consistent abnormalities in midgut formation, and in about 50% of the abnormal embryos, shortening of the germ band fails, while anus and posterior spiracles open on the dorsal surface behind the head segments (Counce). Female embryos from  $da^1$  mothers also show consistent defects in the CNS, which is either reduced in width or shows abrupt bends or twists; abnormally formed gut often extends into the CNS (Caudy *et al.*, 1988a). The majority of daughters of  $da^1$  mothers surviving at 18° are morphologically abnormal, often missing structures from one or more imaginal discs or abdominal histoblasts, and frequently with duplication of structures (Cline, 1976).

Though it was reported that daughters of homozygous  $da^1$  females could be rescued by cytoplasmic injection (Bownes *et al.*, 1977), the apparent rescue was subsequently found to result from nonspecific effects that may have slowed the early development of females who are on the threshold of surviving (Cline, 1984; see also Muir and Bell, 1987). Gynandromorphs can survive the lethal maternal effects, but there is no localized lethal focus. Diplo-X tissue develops abnormally alongside normally developing haplo-X tissue. Survival of the mosaics and their average fraction of diplo-X tissue increases with decreasing temperature (Cline, 1976).

The  $da^1$  maternal effect masculinizes escaper daughters that are homozygous for *mle* (Cline, 1984) and masculinizes triploid intersex (XXAAA) progeny (Cline, 1983a). Females heterozygous for *Sxl* alleles that lead to male development develop as sterile males, mosaic intersexes, or sterile females (depending on the *Sxl* allele), when produced by  $da^1$  mothers (Cline, 1984). The  $da^1$  female lethal maternal effect is unaffected by *tra* or *dsx* (Bell, 1954; Colainne and Bell, 1968). However, daughters of  $da^1/da^1$  mothers are almost fully rescued by a single zygotic dose of *Sxl<sup>MI</sup>* and to a limited degree by a duplication for *Sxl<sup>+</sup>* (Cline, 1978). Conversely, zygotic *Sxl<sup>-</sup>* enhances the *da* maternal effect. Females with reduced *Sxl* dose (*Sxl<sup>-</sup>/+*) fail to survive from  $da^1/da^1$  mothers at the semipermissive 18° (Cline, 1978). A strong dominant *da* maternal effect [ $da^1/+$ , *Df(2L)da/+*, or  $da^2/+$  mothers] is observed when female progeny are doubly heterozygous for *Sxl<sup>-</sup>* and *sis-a<sup>-</sup>* (Cline, 1986, Genetics 113: 641-63; Cronmiller and Cline, 1986, 1987). The maternal effect of  $da^1$  is made semidominant also by *E(da)* (*cis* or *trans* to  $da^1$ ) in the mother (Mange and Sandler, 1973; see also Cline, 1980). The zygotic  $da^+$  dose itself does not affect expression of *Sxl<sup>+</sup>* sex determination function (Cronmiller and Cline, 1986).

#### alleles:

allele	origin	synonym	ref. <sup>α</sup>	comments	molecular data
$da^1$	spont		1	(= <i>da</i> ); viable; temperature sensitive hypomorph; strong daughterless maternal effect above 22°; lethal with <i>Df</i> or amorphic alleles; lethal at 29°	900 bp insertion of middle repetitive DNA in untranslated leader
$da^2$	EMS		2	apparent amorph; recessive lethal; lethal	normal Southern

<sup>α</sup> 1 = Bell, 1954, *Genetics* 39: 958-59; 2 = Cronmiller and Cline, 1987, *Cell* 48: 479-87; 3 = Caudy, Grell, Dambly-Chaudière, Ghysen, Jan, and Jan, 1988, *Genes Dev.* 2: 843-52; 4 = Cronmiller, Schedl, and Cline, 1988, *Genes Dev.* 2: 1666-76; 5 = Brand and Campos-Ortega, 1988, *Roux's Arch. Dev. Biol.* 197: 457-70; 6 = Caudy, Vässin, Brand, Tuma, Jan, and Jan, 1988, *Cell* 55: 1061-67.

**cytology:** Placed in 31E based on localization by *in situ* hybridization of *da*<sup>7</sup> *P*-element insertion (Cronmiller, Schedl, and Cline, 1988).

**molecular biology:** The genomic region was cloned by transposon tagging from *da*<sup>7</sup> (Cronmiller, Schedl, and Cline, 1988) and by chromosome walking (Caudy *et al.*, 1988b). Approximately 30-kb walks were restriction mapped; the *da* transcription unit was localized by the demonstration of altered transcripts on Northern blots of *da*<sup>1</sup> and *da*<sup>7</sup> RNAs and by mapping rearrangements of several mutant alleles within a 6-kb genomic region. Two transcripts are detected by Northern analysis, 3.2 and 3.4-3.7 kb; both transcripts are present in male and female adults and at all stages of development [including unfertilized eggs (Cronmiller)], although the smaller transcript is enriched in unfertilized eggs and in 0-2.5 hr embryos. cDNA sequence analyses revealed a single intron, approximately 1.5 kb, located upstream of the initiating AUG. The inferred amino acid sequence predicts a protein of 710 aa, with a molecular weight of 74,000 daltons. From the amino acid sequence, the *da* protein is a member of the Helix-Loop-Helix family of DNA binding proteins. Within this family, the most extensive sequence similarity exists between *da* and the human kE2 enhancer binding protein, E12, where the two proteins are 78% identical over 93 amino acids (Murre *et al.*, 1989a). *In vitro*, *da* protein and E12 form heterodimers and bind to DNA (Murre *et al.*, 1989b). The predicted *da* protein also includes two short (27 aa) regions of similarity to the *bcd* protein, one being the His-Pro repeat that is also present in *prd*.

*da*: see *dar*

### **Dab: Disabled**

**location:** 3-[44].

**synonym:** *dab*.

**references:** Gertler, Bennett, Clark, and Hoffmann, 1989, *Cell* 58: 103-13.

**phenotype:** A dominant enhancer of the lethal phenotype of genotypes deficient in *Abl* function. *Abl*<sup>1</sup>/*Abl*<sup>-</sup>, which ordinarily survive to late pupal or adult stages, die as late embryos or early larvae with abnormal CNS development when heterozygous for *Dab* mutants or deficiencies; such *Dab*<sup>-</sup> or *Dab*<sup>-</sup> heterozygotes are normal in the presence of *Abl*<sup>+</sup>. Double mutant embryos, *Abl*<sup>-</sup> *Dab*<sup>-</sup>, are lethal and have few or no proper longitudinal or commissural axons in the CNS. Homozygous *Dab*<sup>-</sup> in the presence of *Abl*<sup>+</sup> results in reduced survival with intermediate levels of CNS disruption.

**alleles:** Two ethyl-methanesulfonate-induced alleles, *Dab*<sup>1</sup> and *Dab*<sup>2</sup>, isolated as *M2* and *M29*, mimic the effects of *Dab* deficiencies; not allelic to *l(3)73Bc*.

**cytology:** Placed in 73B2-3 based on the enhanced *Abl* phenotype of *Abl*<sup>11</sup>/*Df(3L)st100.62* = *Df(3L)72F3-7;73B3* but not *Abl*<sup>11</sup>/*Df(3L)st-j7* = *Df(3L)73A1-2;73B1-2* (Henkemeyer, Gertler, Goodman, and Hoffmann, 1987, *Cell* 51: 821-28).

**dachs:** see *d*

**dachsous:** see *ds*

### **dal: daughterless abnormal oocyte like**

**alleles:** 2-44 (not separated from *abo*).

**references:** Sandler, 1977, *Genetics* 86: 567-82.

**phenotype:** External phenotype normal. Shows reduced survival in heterozygous combination with deficiency. Maternal effect embryonic lethal with relative survival of sons less than that of daughters. Maternal effect more severe at 25° than at 19°. Maternal effect reduced by presence of *Y* or *Xh* in zygotes. Presence of *dal*<sup>+</sup> allele increases survival of offspring of *abo* mothers.

**cytology:** Placed in 31F-32E based on inclusion in *Df(2L)J-der-39* = *Df(2L)31A-B;32E* but not *Df(2L)J27* = *Df(2L)31B-D;31F* or *Df(2L)Mdh-1J* = *Df(2L)30D-F;31F*.

**other information:** Complements *abo*, *hup*, and *wd*<sup>2</sup>.

### **\*dar: darky**

**location:** 1-0 (no crossovers with *sc* in 547 flies).

**origin:** X ray induced.

**discoverer:** Fahmy, 1956.

**synonym:** *da*; preoccupied.

**references:** 1959, *DIS* 33: 84.

**phenotype:** Small, heavily melanized flies. Sometimes wings curl upward. Male sterile; viability about 15% wild type; late eclosing. RK2.

### **\*dark: darkener of white-eosin**

**location:** Autosomal.

**discoverer:** Bridges, 13i23.

**references:** 1916, *Genetics* 1: 148.

1919, *J. Exp. Zool.* 28: 347.

**phenotype:** Specific partial suppressor of *w*<sup>e</sup>. RK3.

**daughterless abnormal oocyte like:** see *dal*

**db: dark body**

location: 3-45.

references: Chovnick and Talsma, 1966, DIS 41: 58.

phenotype: Body color darker than normal. Male rarely survives, dies in late pupal stage as pharate imago.

Female weakly fertile. RK2.

alleles:

allele	origin	discoverer	comments
<i>db 1</i>	spont		male lethal, female viable
<i>db 2</i>	ENU	Belote	both sexes lethal
<i>db 4</i>	ENU	Belote	both sexes viable
<i>db 5</i>	ENU	Belote	male lethal, female viable
<i>db 83e</i>	X ray	Belote	male lethal, female viable
<i>db 83l</i>	X ray	Belote	male lethal, female viable

*db*<sup>4</sup> viable in heterozygous combination with *db*<sup>1</sup>, *db*<sup>5</sup>, and deficiencies for *db*; however male lethal in combination with *db*<sup>2</sup> (Belote). *db*<sup>2</sup> complements other lethals in vicinity and may be an antimorphic allele (Belote).

cytology: Placed in 73C2-D1 by deficiency analysis (Belote).

other information: Possibly allelic to *du*.

**db1: dichaeete-beadex-lethal**

location: 1-23.0.

origin: I-factor induced.

references: Ellison, 1981, Mol. Gen. Genet. 183: 123-29.

phenotype: Produces a phenotype resembling the double mutant *Bx/+; D/+* at 20°; lethal at 25°.

other information: Reverts at frequency between  $10^{-3}$  and  $10^{-2}$ .

*DCgl*: see *Cg25C*

**dcm: dark carmine**

location: 1- (between *y* and *w*).

origin: Spontaneous.

references: Aguado, Galán-Estella, and González-Gulián, 1988, DIS 67: 109.

phenotype: Eye color dark carmine. *dcm;st* eyes orange.

*Dcx*: see *In(3LR)CxD*

*DcxF*: see *In(3LR)DcxF*

**\*dd: displaced**

location: 1-24.3.

discoverer: Bridges, 31d7.

phenotype: Antennae sunken into shortened head; eyes also deformed. Females often sterile. RK2.

cytology: Locus lies between 7C4 and 8C2 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book

- Carnegie Inst. Washington 41: 191). Further restricted to 7F through 8C2 on the basis of its genetic location to the right of *oc* which is in 7F-8A.

*dd*<sup>3</sup>: see *ddl*

**Ddc: Dopa decarboxylase (T.R.F. Wright and J. Hirsh)**

**location:** 2-53.9+ (.025 centimorgans to the right of *hk* at 53.9 and .002 centimorgans to the right of *amd*).

**discoverer:** Wright, 1974.

**references:** Wright, Bewley, and Sherald, 1976, *Genetics* 84: 287-310.

Wright, Beerman, Marsh, Bishop, Steward, Black, Tomsett, and Wright, 1981, *Chromosoma* 83: 45-58.

Wright, Black, Bishop, Marsh, Pentz, Steward, and Wright, 1982, *Mol. Gen. Genet.* 188: 18-26.

**phenotype:** Structural gene for dopa decarboxylase [DDC, 3-4-dihydroxy-L-phenylalanine-carboxylase (EC 4.1.28)] which catalyzes the decarboxylation of dopa to dopamine (Lunan and Mitchell, 1969, *Arch. Biochem. Biophys.* 132: 450-56) and 5-hydroxytryptophan to serotonin (5-hydroxytryptamine) but not tyrosine to tyramine (Livingstone and Tempel, 1983, *Nature* 303: 67-70). Native DDC isolated from mature larvae is a homodimer with subunit molecular weight 54 kd (Clark, Pass, Venkataraman, and Hodgetts, 1978, *Mol. Gen. Genet.* 162: 287-97). Distinct DDC isoforms are generated in the CNS and hypoderm by alternate splicing of the *Ddc* primary transcript; the CNS isoform differs by the addition of 35 amino acids at the amino terminus (Morgan, Johnson, and Hirsh, 1986, *EMBO J.* 5: 3335-42). The predicted subunit molecular weights of these are 57.1 and 53.4 kd, respectively. DDC requires pyridoxal-5-phosphate for activity and is strongly inhibited by heavy-metal ions and the sulfhydryl reagent, N-ethylmaleimide. Initial velocity constants determined by Black and Smarrelli (1986, *Biochim. Biophys. Acta* 870: 31-40). The dopamine produced by DDC is necessary to effect sclerotization of the cuticle, being further metabolized both to N-acetyldopamine and N-β-alanyldopamine, which after oxidation to their respective quinones, crosslink cuticular proteins. Thus in adults and white prepupae more than 90% of the DDC activity is located in the epidermis (Lunan and Mitchell, 1969; Scholnick, Morgan, and Hirsh, 1983, *Cell* 34: 37-45). Some DDC activity (~5%) is found in the central nervous system of white prepupae and adults where it produces the neurotransmitters dopamine and serotonin [Wright, 1977, *Amer. Zool.* 17: 707-21; Livingstone and Tempel, 1983; White and Vallés, 1985, *Molecular Basis of Neural Development* (Edelman, Gell, and Cowan (eds.). John Wiley and Sons, N.Y., pp 547-63)]. The limited amounts found in the ovaries (Wright, Steward, Bentley and Adler, 1981, *Dev. Genet.* 2: 223-35) and proventriculus (Wright and Wright, *Proc. Int. Congr. Genet.*, 15th, 1978, Part I, p. 615) are localized in associated neural ganglia (Konrad and Marsh, 1987, *Dev. Biol.* 122: 172-85). Five peaks of DDC activity evident during development: at the end of embryogenesis, the two larval molts, pupariation, and eclosion (Marsh and Wright, 1980, *Dev. Biol.* 80: 379-87; Kraminsky, Clark, Estelle, Gietz, Sage, O'Conner, and Hodgetts, 1980, *Proc. Nat. Acad. Sci. USA* 77: 4175-79). The largest peak, which occurs at pupariation, is induced by a coincident ecdysone peak of the

molting larvae (Marsh and Wright, 1980) and has been shown to be attributable to a rapid increase in translatable DDC mRNA following administration of 20-OH-ecdysone (Kraminsky *et al.*, 1980). Ecdysone induces *Ddc* expression in the mature larval epidermis within two to four hrs (Kraminsky, *et al.*, 1980; Clark, Doctor, Frisstrom, and Hodgetts, 1986, *Dev. Biol.* 114: 141-50). Since cycloheximide addition is sufficient to largely abolish this induction, it appears that this response is an indirect action of ecdysone. A different response of *Ddc* to ecdysone occurs in cultured imaginal discs; *Ddc* induction occurs only subsequent to withdrawal of the hormone (Clark *et al.*, 1986).

Most mutations in *Ddc* are homozygous or hemizygous lethal. The effective lethal phases of the first eight lethal alleles, *Ddc*<sup>nl</sup>-*Ddc*<sup>ns</sup>, were almost identical. As hemizygotes over *Df(2L)TW130* almost all mortality is late embryonic with actively moving larvae, exhibiting unpigmented cephalopharyngeal apparatuses and denticle belts, unable to hatch. When homozygous there is a fairly uniform shift in effective lethal phases with mean mortalities from all eight alleles in the cross of *Ddc*<sup>nl</sup>/*CyO* × *Ddc*<sup>nl</sup>/*cn bw* being 13.6% embryonic, 14.1% larval, and 4.8% pupal (Wright and Wright, 1978). Many larvae hemizygous for lethal alleles, or homozygous deficient for *Ddc*, when mechanically released from the egg membranes, continue development to the 3rd larval instar and to the pharate adult stage.

Genotypes which produce individuals with drastically reduced DDC activities (~0.5-5% of wild type) exhibit an "escaper" phenotype characterized by incomplete pigmentation and sclerotization of the cuticle; developmental time can be prolonged for as many as four or five days; puparia are easily scored showing melanization at each end of the greenish-gray pupa case; adults often die or get stuck in the food within 24 hr of eclosion; macrochaetae may be very thin, long, and straw-colored or colorless; the whole body remains light, *i.e.*, doesn't take on its normal pigmentation; abdominal markings are apparent but do not darken; upon aging a few hours wing axillae become melanized similar to the phenotype of *sp*, leg joints also become melanized perhaps due to the phenoloxidase wound reaction brought on by ruptures of weakened cuticle; flies walk on tibiae rather than tarsi, but leg movements appear to be coordinated (Wright, Bewley, and Sherald, 1976). Genotypes that produce flies exhibiting the "escaper" phenotype include heteroallelic intragenic complementing heterozygotes with less than 5% of the expected number of survivors (Wright, Bewley, and Sherald, 1976), hemizygotes of the *ts* allele *Ddc*<sup>ts2</sup> raised continuously at 22° or 25°, or homozygotes for *Ddc*<sup>ts1</sup> or *Ddc*<sup>ts2</sup> exposed to the restrictive temperature 30° for 24- or 48-hour pulses at the end of the pupal stage (Wright).

*Ddc* temperature-sensitive mutants have been reported to show reduced learning after a three-day period at the restrictive temperature (Tempel, Livingstone, and Quinn, 1984, *Proc. Nat. Acad. Sci. USA* 81: 3577-81). However, these results cannot presently be reproduced by other investigators (see Tully, 1987, *Trends in Neurosci.* 10: 330-35; Hirsh, 1989, *Dev. Genet.* 10: 232-38). It is possible that this lack of reproducibility is due to the accumulation of genetic modifiers. In homozygous deficient larvae normally-serotonin-containing neurons

lack immunologically detectable serotonin but display normal levels of uptake of exogenously supplied serotonin (Valles and White, *J. Neurosci.* 6: 1482-91).

Further studies of these *Ddc*<sup>-</sup> larvae, on which catecholamine histofluorescence studies were performed, revealed novel neuronal subsets lighting up, which become fluorogenic earlier than the wild-type-like neurons in the mutant CNS (Budnik, Martin-Morris, and White, 1986, *J. Neurosci.* 6: 1482-91). Certain serotonin-containing nerve fibers in developing larvae are still able to reach their normal targets in *Ddc*<sup>-</sup> animals (which therefore are intrinsically serotonin-minus), but there is anomalous extra branching associated with the incoming fibers (Budnik, Wu, and White, 1989, *J. Neurosci.* 9: 2866-77). *Ddc* mosaics generated by crossing a transduced *Ddc*<sup>+</sup> insert into *R(1)w*<sup>VC</sup> (Gailey, Bordne, Valles, Hall, and White, 1987, *Genetics* 115: 305-11). Such adult mosaics used to reveal no absolute requirement of DDC in any particular portion of epidermis or CNS, but there was low recovery of gynandromorphs with large *Ddc*<sup>-</sup> patches. Larval mosaics show that DDC-positive neurons always contain serotonin, but some serotonin-positive cells (which were near DDC<sup>+</sup>) have no detectable enzyme protein; hence, the serotonin phenotype can be nonautonomous (Valles and White, 1990).

In addition to the naturally occurring alleles, *Ddc*<sup>RE</sup>, *Ddc*<sup>RS</sup>, and *Ddc*<sup>+4</sup>, which are described separately, three surveys of natural populations for *Ddc* variants have been reported. Estelle and Hodgetts (1984, *Mol. Gen. Genet.* 195: 434-41) measured DDC levels in 109 strains isogenic for second chromosomes isolated independently by Bewley (1978, *Biochem. Genet.* 16: 769-75) from collections at Raleigh, NC, Bloomington, IN., and Webster Groves, MO. (WGM). Two (WGM) strains (including *Ddc*<sup>+4</sup>) had increased activities and two had reduced activities when compared with a Canton-S control. Marsh and Wright report DDC activities from twelve different wild-type strains maintained in laboratories for many years. Relative to Oregon-R (*Ddc*<sup>C</sup>) females, they ranged from a low of 68% for Urbana males to a high for Canton-S females (180%) and males (130%) with most strains with activities between Oregon-R and Canton-S. Aquadro, Jennings, Bland, Laurie-Ahlberg, and Langley (1984, *Genetics* 107: s3) surveyed forty-six second chromosome lines isolated from five natural populations for restriction fragment variations in the 80kb region surrounding *Ddc* and for adult DDC activity. No consistent pattern of association between level of DDC activity and restriction site haplotype was apparent although the lines showed a two-fold variation in DDC activity. Two lines with 5kb and 1.5kb inserts within an intron and at the 5' end of *Ddc* showed normal adult DDC activities.

The temperature-sensitive periods causing lethality for *Ddc*<sup>ts2</sup> homozygotes are primarily during embryogenesis and late in the third larval instar. Heat shocks, 30° for 24 or 48 hr, during metamorphosis do not increase lethality significantly but produce adults with the extreme "escaper" phenotype. DDC in extracts from adult *Ddc*<sup>ts1</sup> and *Ddc*<sup>ts2</sup> homozygotes is significantly more thermolabile than that from wild-type controls. DDC from *Ddc*<sup>ts1/+</sup> heterozygotes is much less labile showing a biphasic inactivation curve. *Ddc*<sup>ts2/+</sup> DDC is no more thermolabile than wild-type DDC (Wright, unpublished

data).

Genotypes with reduced levels of DDC activity, e.g. *Ddc*<sup>n5</sup>/*Ddc*<sup>n8</sup> and *Ddc*<sup>n1</sup>/*Ddc*<sup>n8</sup> with less than 4% DDC activity, are not more sensitive to dietary alpha methyl dopa nor are genotypes with increased levels of DDC activity more resistant (Marsh and Wright, 1986, *Genetics* 112: 249-65). In fact, the reverse may be true: reduced DDC, more resistant; increased DDC, more sensitive.

**alleles:** The numbered superscripts of many of the alleles were previously preceded by n to indicate null; the n's have been removed, but the numbers retained.

<sup>β</sup> Specific DDC activity of newly eclosed adult *CyO/Ddc* heterozygotes expressed as a percentage of appropriate *CyO+* controls.

<sup>γ</sup> Expanded description below.

**cytology:** *In situ* hybridization with cloned *Ddc* placed the *Ddc* gene in or very close to 37C1-2 (Hirsh and Davidson, 1981, *Mol. Cell Biol.* 1: 475-85). The distal breakpoint of *Df(2L)VA17* breaks in 37C1,2 deleting the proximal part of the band (Wright *et al.*, 1981), and at the DNA level this breakpoint is located in the first intron of *Ddc* deleting the 5' (proximal) exon (Gilbert, Hirsh, and Wright, 1984, *Genetics* 106: 679-94). The smallest deficiency that completely deletes *Ddc* is *Df(2L)TW130*.

**molecular biology:** *Ddc* was cloned by a two-step screen, first screening for genes encoding hypodermally expressed mRNA's and then screening these clones by *in situ* hybridization (Hirsh and Davidson, 1981, *Mol. Cell Biol.* 1: 475-85). The sequence of *Ddc* and flanking DNA has been determined by the Hirsh and Marsh laboratories, as shown in the Genbank entries DRODDC and DRODDCG, respectively. (Primary references: Morgan *et al.*, 1986; Eveleth, Geitz, Spencer, Nargan, Hodgetts, and Marsh, 1986, *EMBO J.* 5: 2663-72). Whereas these entries are in general agreement, there are several differences, including several that affect the predicted reading frames. The open reading frame given in DRODDC shows conservation with the periwinkle tryptophan hydroxylase sequence (Genbank entry CTRTPDC) in several regions, where the DRODDCG sequence indicates alternate reading frames. *Ddc* encompasses four exons, labelled A, B, C, and D, of which B, C, and D are protein encoding. The major mRNA encoded by *Ddc* is in the hypoderm, a 2.1-kb mRNA containing all four exons. As mentioned above, these mRNA's encode different DDC isoforms. A different pattern of *Ddc* exons is predicted in the exon B-C region by Eveleth *et al.*, but these predictions are not consistent with the functional expression analyses in Morgan *et al.* (1986).

*Ddc* and *amd* share high levels of sequence identity; their 3' ends are separated by a sequence of 2 kb, which contains another transcription unit (Eveleth and Marsh, 1986, *Nucleic Acids Res.* 114: 6169-83; Black, Pentz, and Wright, 1987, *Mol. Gen. Genet.* 209: 306-12).

Using the same 7.5 kb *Pst* restriction enzyme fragment that straddles the *Ddc* gene but using different *P* element vector constructs, both Scholnick, Morgan, and Hirsh (1983, *Cell* 34: 37-45) and Marsh, Gibbs, and Timmons (1985, *Mol. Gen. Genet.* 198: 393-403) have effected germline transformation of *Ddc*<sup>+</sup> DNA which rescues *Ddc* mutant homo- and hemizygotes. All except two of the total of 16 transformed strains examined showed

approximately normal levels of DDC activity along with normal tissue and temporal expression of the transposed *Ddc* genes. One strain had the expected level of DDC activity at pupariation but unexpectedly low levels in both sexes of newly emerged adults, and the other strain gave elevated DDC activities at all stages (Marsh, Gibbs, and Timmons, 1985). Of the two X-linked transformants, one was dosage compensated (Scholnick, Morgan and Hirsh, 1983) and the other was not (Marsh, Gibbs and Timmons, 1985).

*P*-element germline integration (Scholnick *et al.*, 1983; Marsh *et al.*, 1985) initially defined essential *Ddc* regulatory sequences to lie within 2.5 kb of 5' and 1 kb of 3' flanking DNA. These studies were extended by analyses of deletions (Hirsh, Morgan, and Scholnick, 1986, *Mol. Cell Biol.* 6: 4548-57; Scholnick, Bray, Morgan, McCormick, and Hirsh, 1986, *Science* 234: 998-1002) and by the detection of promoter sequences conserved between the *Ddc* genes from *D. melanogaster* and *D. virilis* (Bray and Hirsh, 1986, *EMBO J.* 5: 2305-11). These data indicate that sequences farther than 98 base pairs from the RNA transcription start site are not required for normal temporal regulation of *Ddc* expression in the hypoderm and implicate sequences between -106 and -38 as being necessary for this regulation. This region contains a number of sequence elements conserved between the two evolutionarily related *Ddc* genes. In a wild-type larval CNS (Beall and Hirsh, 1987, *Genes Dev.* 1: 510-20; Konrad and Marsh, 1987, *Dev. Biol.* 122: 172-85), *Ddc* is expressed in approximately 85 serotonergic neurons, and in another approximately 45 neurons previously identified as containing catecholamines (Budnick, Martin-Morris, and White, 1986, *J. Neuroscience* 6: 3682-91) which are presumably dopaminergic neurons. In addition, there is a low level of expression in a network consisting of a subset of glial cells (Beall and Hirsh, 1987). All *cis* elements necessary for neuronal expression of *Ddc* are contained within the 2,200 base pairs of *Ddc* 5' flanking sequences (Bray, Johnson, Hirsh, Heberlein, and Tjian, 1988, *EMBO J.* 7: 177-88). At least two separate regions are required for normal expression of *Ddc* in the CNS: a distal CNS-enhancer region, extending from ~1000 to 1600 upstream of the transcription start point (Beall and Hirsh, 1987; Johnson and Hirsh, 1989, *Genes Dev.* 3: 676-86) and a small proximal element I, at -60 (Scholnick *et al.*, 1986; Bray *et al.*, 1988; Bray, Burke, Brown, and Hirsh, 1989, *Genes Dev.* 3: 1130-45). The distal enhancer contains most if not all of the information controlling cell specificity of *Ddc* expression in the CNS (Johnson and Hirsh, 1989) whereas element I is required for *Ddc* expression in all *Ddc*-expressing neurons. The protein NTF (Neurogenic-element-binding transcription factor) binds to the CNS-specific element I in the proximal promoter (Bray *et al.*, 1988, 1989), and a number of binding factors are found within the distal enhancer (Johnson and Hirsh, 1989). NTF and the factor cf1a, which binds to dopamine-cell-specific regulatory elements in the distal enhancer, have been cloned (Bray *et al.*, 1989; Dynlacht, Attardi, Admon, Freeman, and Tjian, 1989, *Genes Dev.* 3: 1677-88; Johnson and Hirsh, 1990, *Nature* 343: 467-70). cf1a encodes a POU homeodomain protein.

***Ddc<sup>C</sup>: Dopa decarboxylase-C***

**origin:** Made isogenic by homozygosing single first, second, and third chromosomes from the Oregon-R6 isogenic strain from Yale University.

**phenotype:** DDC activity and resistance to dietary alpha methyl dopa in the normal range for Oregon-R derived stocks. This strain was put through the same genetic manipulations as *Ddc<sup>RE</sup>* and *Ddc<sup>RS</sup>* so it could serve as a valid control for those strains.

**cytology:** Normal.

***Ddc<sup>DE1</sup>: Dopa decarboxylase Differential Expression 1***

**discoverer:** K. Wade.

**references:** Bishop and Wright, 1987, Genetics 115: 477-91.

**phenotype:** Hemizygous adults (9% of expected eclose) exhibit an extreme "escaper" phenotype (see *Ddc* above) except macrochaetae are normally pigmented suggesting that *Ddc<sup>DE1</sup>* is differentially active in the epidermis *vis-a-vis* the bristle-forming cells. Pupa cases of *Ddc<sup>DE1</sup>* homo- and hemizygotes are wild type. DDC activity in newly eclosed adult *Ddc<sup>DE1</sup>* homozygotes is  $4.4 \pm 0.2\%$  and in hemizygotes is  $0.6 \pm 0.1\%$  of wild-type controls. Homozygous late embryos have  $4.8 \pm 2.3\%$  activity. In striking contrast homozygous white prepupae have  $46.5 \pm 2.8\%$  DDC activity. However, central nervous systems dissected from these *Ddc<sup>DE1</sup>* homozygous white prepupae show a tissue specific difference having  $4.8 \pm 2.3\%$  DDC activity compared to wild-type CNS. Specific DDC activity in *Ddc<sup>DE1</sup>* homozygotes ranges significantly more than two times DDC levels in *Ddc<sup>DE1</sup>/Df(2L)TW130* hemizygotes.

DDC from *Ddc<sup>DE1</sup>* homozygotes, crawling third instar larvae and adults, is less thermostable *in vitro* in comparison to controls. Late *Ddc<sup>DE1</sup>/Ddc<sup>DE1</sup>* embryos (16-20 hr) have no detectable mature 2.0 kb *Ddc* RNA and have reduced levels of the 2.3 kb RNA. The precise reason for the differential expression has yet to be established but is not due to position effect variegation (Bishop and Wright, 1987, Genetics 115: 477-91). *Ddc<sup>DE1</sup>* phenotype rescued by a 7.5kb transformant of *Ddc<sup>+</sup>* DNA.

***Ddc<sup>lo1</sup>: Dopa Decarboxylase low-1***

**discoverer:** T.R.F. Wright.

**references:** Wright, Black, Bishop, Marsh, Pentz, Steward, and Wright, 1982, Mol. Gen. Genet. 188: 18-26;

**phenotype:** Some hemizygous adults exhibit the incomplete sclerotization "escaper" phenotype. Not temperature sensitive: hemizygotes being equally viable at 18°, 25°, and 30° (40-56% of expected). DDC from *Ddc<sup>lo1</sup>* hemizygotes is not more thermolabile *in vitro* than that from wild type. Heterozygous *Ddc<sup>lo1</sup>/CyO* have about 77% wild type specific DDC activity and *Ddc<sup>lo1</sup>* homozygotes have 15-30% activity.

**cytology:** No visible aberration. No detectable difference in the DNA (>50bp).

***Ddc<sup>RE</sup>: Dopa decarboxylase-R<sup>E</sup>***

**origin:** Natural variant; Canton-S-like on the basis of restriction enzyme site polymorphisms. Originally reported as being EMS-induced in Oregon-R but probably a Canton-S contaminant. Made coisogenic with *Ddc<sup>C</sup>* strain.

**discoverer:** Sherald.

**references:** Marsh and Wright, 1986, Genetics 112: 249-65.

**phenotype:** Dual phenotype of elevated DDC activity and increased resistance to dietary alpha methyl dopa relative to Oregon-R derived controls (*Ddc<sup>C</sup>*). Specific DDC activity of newly eclosed adults 158% and DDC crossreacting material (CRM) 156% of the *Ddc<sup>C</sup>* control. LD<sub>50</sub> for alpha methyl dopa is ~0.4 mM vs. ~0.2 mM for the *Ddc<sup>C</sup>* control. Gene dosage studies with *Ddc<sup>+</sup>* and *l(2)amd<sup>+</sup>* demonstrate that increased resistance to alpha methyl dopa is not the result of increased DDC activity. Thus, the dual phenotype is inferred to arise from a coordinated increase in *Ddc<sup>+</sup>* activity and *l(2)amd<sup>+</sup>* activity produced either by accumulated changes in a genetic element (or elements) in the close proximity to the *Ddc* and *amd* genes.

**cytology:** No visible difference apparent: not a duplication at either the cytological level or at the DNA level.

***Ddc<sup>RS</sup>: Dopa decarboxylase-R<sup>S</sup>***

**origin:** Variant isolated from a *sp<sup>2</sup> bs<sup>2</sup>* stock. Made coisogenic with *Ddc<sup>C</sup>* strain.

**discoverer:** Sherald.

**phenotype:** Dual phenotype of elevated DDC activity and increased resistance to dietary and methyl dopa relative to Oregon-R derived controls (*Ddc<sup>C</sup>*). Specific DDC activity of newly eclosed adults 141% and DDC crossreacting material (CRM) 137% of the *Ddc<sup>C</sup>* control. Interpretation of phenotype identical to that for *Ddc<sup>RE</sup>*.

**cytology:** No visible difference apparent: not a duplication at either the cytological level or at the DNA level.

***Ddc<sup>+4</sup>: Dopa decarboxylase +4***

**origin:** Natural variant in a second chromosome extracted from a Webster Groves, Missouri (WGM) population and made isogenic using marked balancer chromosomes (Bewley, 1978, Biochem. Genet. 16: 769-75).

**references:** Estelle and Hodgetts, 1984, Mol. Gen. Genet. 195: 434-41.

**phenotype:** No visible phenotype: *Ddc<sup>+4</sup>* overproduces DDC activity at embryonic hatching, the second to third instar molt, and at adult eclosion relative to a Canton-S control: 141%, 150%, and 118% respectively; in contrast, underproduces DDC at pupariation: 50%. These temporal differences are found in epidermis but not in neural tissues where DDC activities are normal. DDC CRM at pupariation and adult eclosion are 49% and 140% respectively of Canton-S CRM. No difference was found in the electrophoretic mobility of non-denatured and denatured DDC molecules. DDC mRNA is 140%, 52%, and 148% of Canton-S at embryonic hatching, pupariation, and adult eclosion respectively indicating that the temporal phenotype is reflected in mRNA levels.

**molecular biology:** *Ddc<sup>+4</sup>* DNA was cloned and examined by acrylamide gel electrophoresis of restriction fragments. Six small restriction length polymorphisms and one restriction site polymorphism exist between *Ddc<sup>+4</sup>* and Canton-S DNA. Five of these differences occur in the 5' untranslated leader sequence of the DDC mRNA or in the 4.5 kb of DNA upstream of the transcription start site. Some DNA sequence data have been acquired (Spencer and Hodgetts, unpublished data).

**ddd: defective dorsal discs (A. Shearn)**

**location:** 3-18.0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Shearn, Rice, Garen, and Gehring, 1971, Proc. Nat. Acad. Sci. USA 68: 2594-98.

Wurst, Hersperger, and Shearn, 1984, Dev. Biol. 106: 147-55.

Simcox, Wurst, Hersperger, and Shearn, 1987, Dev. Biol. 122: 559-67.

**phenotype:** Homozygous larvae perish between the first larval instar and the prepupal stage; dorsal thoracic imaginal discs, *i.e.* of the pronotum, mesonotum, and metanotum reduced to 3% or less of normal size; all other imaginal discs develop normally. Mutant larvae support the growth of wild-type wing discs; mutant wing discs show very little development in wild-type larval. Mutant cells develop normally in wing discs that contain mixtures of mutant and wild-type cells, as produced by nuclear or cellular transplantation into blastoderms or by somatic exchange. Mutant leg discs transplanted into wild-type hosts can transdetermine to wing development. Studies of temperature-sensitive genotypes indicate that *ddd*<sup>+</sup> product is not required for normal wing development during embryogenesis. No evidence for a maternal effect in either conditional mutants raised under permissive conditions and switched to restrictive temperatures or in germ-line-transplants of mutant cells into wild-type hosts.

**alleles:** Thirteen alleles induced by ethyl methanesulfonate by Shearn.

**dec-1: defective chorion 1**

**location:** 1-20.7 (based on 69 *ct-oc* and 93 *ct-sn* recombinants; combined data of Lineruth *et al.*).

**references:** Gans, Audit and Masson, 1975, Genetics 81: 683-704.

Komitopoulou, Gans, Margaritis, Kafatos, and Masson, 1983, Genetics 105: 897-920.

Lineruth and Lambertsson, 1985, Wilhelm Roux's Arch. Dev. Biol. 194: 436-39.

Lineruth, Lambertsson, and Lindberg, 1985, Mol. Gen. Genet. 201: 375-78.

Lineruth and Lambertsson, 1986, Mol. Gen. Genet. 205: 213-16.

Bauer and Waring, 1987, Dev. Biol. 121: 349-58.

**phenotype:** Females homozygous for *dec-1*<sup>2</sup> produce few eggs; chorion thin and fragile, often lost during ovoposition; dorsal appendages much reduced, often absent; chorion appears vacuolated and permits uptake of neutral red. Mosaic studies with *dec-1*<sup>2</sup> demonstrate that it is a somatically active gene [Wieschaus, Audit, and Masson, 1981, Dev. Biol. 92-103 (fig.)]. Mature egg shell shows lack of organization within the endochorion and accumulation of electron dense material in the vitelline membrane of stage-14 egg chambers. No abnormalities detected in stage-10 oocytes. Three protein products of gene detected; the primary translation product of 130 kd found in stage-10 follicles; this appears to be quickly processed into an 85-kd product, which is in turn processed into a 67-kd protein in stage 13 and 14 egg shells (Bauer and Waring); these products measured as 92, 82, and 76 kd, respectively, by Lineruth and Lambertsson (1985). All three proteins absent in *dec-1* mutants, and they vary coordinately in molecular weight in natural variant alleles.

**alleles:** Three molecular-weight variants found among strains from natural populations; each variant affects all three forms of the gene product. The majority of strains are as characterized: strains labeled Israel and Krasnodar produce slightly smaller polypeptides, and strains labeled Alma Ata, Frunze, and Shahrinay produce polypeptides that are even smaller (Lineruth, Lambertsson, and Lindberg, 1985, Mol. Gen. Genet. 201: 375-78). These wild-type alleles are designated *dec-1*<sup>+1</sup>, *dec-1*<sup>+2</sup>, and *dec-1*<sup>+3</sup> respectively.

<sup>α</sup> 1 = Bauer and Waring, 1987, Dev. Biol. 121: 349-58; 2 = Gans, Audit, and Masson, 1975, Genetics 81: 683-704; 3 = Komitopoulou, Gans, Margaritis, Kafatos, and Masson, 1983, Genetics 105: 897-920; 4 = Lineruth and Lambertsson, 1986, Mol. Gen. Genet. 205: 213-16; 5 = Mohler and Carroll, 1984, DIS 60: 236-41.

**cytology:** Placed in 7C1-3 based on its inclusion in *Df(1)ct<sup>4bl</sup> = Df(1)7B2-4;7C3-4* but not in *Df(1)ct<sup>268-42</sup> = Df(1)7A5-6;7B8-C1*.

**molecular biology:** Region isolated in a chromosome walk from the proximal breakpoint of *Df(1)ct<sup>4bl</sup>* (Hawley and Waring, 1988, Genes Dev. 2: 341-49); coordinate 0 placed at *EcoRI* site just proximal to above breakpoint with positive values extending to the left. Sequence from 0 to 6.6 kb (which includes *ct<sup>4bl</sup>* breakpoint) is complementary to an abundant poly(A)<sup>+</sup> RNA of 4.0 kb from stage-8 to stage-11 follicles and a less abundant one of 5.8 kb from stage-11 and stage-12 follicles. cDNA's indicate that both messages have a common transcription start site, share several small introns, and that transcription is from right to left. A segment is apparently spliced out of a large exon present in the 5.8-kb message to generate the 4.0-kb message, which contains sufficient coding capacity to encode the 130 kd protein. *Df(1)ct<sup>4bl</sup>* removes the 3' end of the transcript beginning at approximately the site of the 4.0-kb RNA-specific splice donor. Preliminary sequence determination indicates a N-terminal signal sequence. A 200-base-pair deletion between coordinates 1.9 and 2.7 differentiates the Shahri-nau from the Canton-S wild-type allele and accounts for the molecular weight differences between their protein products.

## **dec-2**

**location:** 1-23.1.

**discoverer:** D. Mohler.

**synonym:** *fs(1)C2*.

**phenotype:** Homozygous females rarely ovoposit. Eggs have thin chorion with thin respiratory appendages.

**cytology:** Placed in 7E10-8A5.

**del: deadlock (T. Schüpbach)**

**location:** 2-{54}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female-sterile; homozygous *del<sup>1</sup>* females often have underdeveloped ovaries which seem to lack germ cells altogether. In some females a small number of developing egg chambers are found. These never develop beyond the first few stages of oogenesis. Females homozygous for *del<sup>2</sup>* and *del<sup>3</sup>* have normal numbers of developing egg chambers of all stages in their ovaries. The eggs produced by the females very frequently have fused dorsal appendages, or lack dorsal appendages altogether, and remain unfertilized.

**alleles:** *del<sup>1</sup>* to *del<sup>4</sup>* are isolated as *WK*, *HN*, *PS*, and *WH*, respectively.

**cytology:** Placed in 37F5-39F1, since uncovered by *Df(2L)TW65 = Df(2L)37F5-38A1;39E2-F1*.

**origin:** Spontaneous.  
**discoverer:** Nichols-Skoog, 35k27.  
**phenotype:** Posterior crossveins detached from longitudinals at one or both ends and may be absent. Wings occasionally folded back under or folded flat at middle. Eyes sometimes rough and bulging. Wings slightly spread. Bristles tend to break; scutellars occasionally doubled. RK3.

**Detached:** see *Dt*

**dev: devenir**

**location:** 3-40.9.  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Kennison, 1983.  
**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.  
**phenotype:** Isolated as a dominant suppressor of *Pc* mutations. Associated with recessive larval lethality. Lowered survival and loss of humeral bristles in combination with *D<sup>3</sup>* may indicate allelism with *Dichaete*, but it is difficult to ascertain.  
**alleles:** Two alleles induced by ethyl methanesulfonate.  
**cytology:** Placed in 70C2-D3 based on its inclusion within *Df(3L)fz-CAL5 = Df(3L)70C2;70D3* and exclusion from *Df(3L)fz-M21 = Df(3L)70D2-3;71E4-5*.

**\*df: defective**

**location:** 1-32.5.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 1513.  
**phenotype:** Head bristles around ocelli missing. Viability poor. RK3.

**\*dfa: deformed antennae**

**location:** 1-13.9.  
**origin:** Induced by 2-chloroethyl methanesulfonate.  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 84.  
**phenotype:** Wings short, broad, either convex or concave, and abnormally held. Eyes small, dark, and rough. Bristles short, stiff, and occasionally bent. Trident pattern more pigmented. Abnormal antennae and arista. Males viable and fertile. Females sterile. RK2.

**Dfd:** see *ANTC*

**\*dfi: deformed eye**

**location:** 3- (near *D*).  
**origin:** Recovered among descendants of heat-treated flies.  
**discoverer:** Ives, 32c.  
**synonym:** *rough III*.  
**references:** Plough and Ives, 1934, DIS 1: 34. 1935, Genetics 20: 42-69.  
**phenotype:** Eyes roughish, reduced, and misshapen. Overlaps wild type. Female sterile; poorly viable. RK3.

**deflected wing:** see *dfw*

**deformed antennae:** see *dfa*

**\*dft: deformed tergites**

**location:** 1-33.7.  
**origin:** Induced by 2-chloroethyl methanesulfonate.  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 84.  
**phenotype:** Small fly with small, slightly rough eyes. Wings slightly divergent or upheld, abnormally shaped with occasional incision of the inner margin. Bristles slightly thinner and shorter with one or both postscutellars frequently absent, and a dorsocentral occasionally missing. Abdominal segmentation deformed to various degrees; abdominal hairs fewer and deranged. Males poorly fertile; viability about 50% wild type. RK2.

**degenerated spermatheca:** see *dg-a*

**dfw: deflected wing**

**location:** 1-21.6.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine.

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 84.

**phenotype:** Wings slightly divergent and upheld to various degrees, often twisted on their axes. Inner margins frequently incised; occasionally, wing membranes separated by fluid. Eyes slightly smaller. Males viable and fertile. Females sterile; viability reduced. RK2.

**alleles:** One X-ray-induced allele.

**dg: Don Giovanni (J.C. Hall)**

**location:** 1- (between *y* and *cv*).

**origin:** Spontaneous in Canton-S stock.

**discoverer:** Gailey.

**references:** Gailey, Jackson, and Siegel, 1984, Genetics 106: 613-23.

Gailey and Siegel, 1989, Anim. Behav. 38: 163-89.

**phenotype:** Males not conditioned by courtship of fertilized females, apparently because they fail to elicit the appropriate cues from them (Gailey and Siegel, 1989); this means, further, that after a *dg* male courts a fertilized female, a wild-type male will not show the usual depressed courtship of this female; yet if the fertilized female is first courted by a wild-type male, a *dg* male will exhibit depressed courtship of her; females fertilized by *dg* males do not effectively modify subsequent courtships directed at them by any male type (Gailey and Siegel, 1989). *dg* males can, in general, learn, *i.e.* also in artificial test situations such as those using shocks and odorants (Siegel, Hall, Gailey, and Kyriacou, 1984, Behav. Genet. 14: 425-52) or involving females to which quinine is applied (Ackerman and Siegel, 1986, J. Neurogenet. 3: 111-23).

**\*dg-a: degenerated spermatheca**

**location:** 3-75.5.

**origin:** Spontaneous.

**discoverer:** Collins, 21a.

**references:** Wexelsen, 1928, Genetics 13: 389-400 (fig.).

**phenotype:** Adult females show degeneration and pigmentation of epithelial cells of spermathecae 24 hr or more after eclosion. Viability and fertility good. Penetrance 100%. RK3.

**dgl: double glazed**

**location:** 2-{51}.

**references:** McGill, Chia, Karp, and Ashburner, 1988, Genetics 119: 647-61.

**cytology:** Placed in 34C4-35C5 based on its inclusion in the *Sco* transposition.

*dh*: see *eg*<sup>2</sup>

**\*dhm: dark hairy margins**

**alleles:** 3-43.2 (proximal to *th*).

**origin:** Spontaneous.

**references:** Barker and Hollingdale, 1970, DIS 45: 39.

**phenotype:** Wings darker than wild type, have hairy margins and thick veins; increased numbers of abdominal and scutellars bristles. Viability and fertility good.

**other information:** *l(3)DTS5* may be allelic to *dhm* (Ashburner).

**Dhod: Dihydroorotate dehydrogenase**

**alleles:** 3-48.0 (no recombinants with *p*<sup>P</sup> among 11,618 offspring of heterozygous mothers).

**references:** Rawls, Chambers, and Cohen, 1981, Biochem. Genet. 19: 115-27.

Porter and Rawls, 1984, Mol. Gen. Genet. 193: 27-32.

**phenotype:** Likely to be the structural gene for dehydroorotate dehydrogenase, which catalyzes the fourth enzymatic step of *de novo* pyrimidine biosynthesis [DHODEHase (EC 1.3.3.1)]. Homozygotes for null alleles display less than 3% normal levels of enzyme activity; heterozygotes have half-normal levels; flies with three normal alleles show increased levels. Enzyme appears to be monomeric; no interallelic complementation among null alleles. Enzyme activity located in outer surface of inner mitochondrial membrane in other species; also mitochondrial in *Drosophila*. Homozygotes for null alleles exhibit wing truncation, irregular lengths and distribution of hairs on wing margin, deformed posterior legs, and female sterility, as seen in *r* and *r-l*. Viability normal. Phenotype suppressed, but enzyme level not restored, by *su(r)*. Null mutants suppress eye mottling characteristic of *r-l* in doubly mutant genotypes.

**alleles:** A naturally occurring variant designated *Dhod*<sup>low</sup> produces but 25% of normal DHODEHase activity. Twelve EMS-induced null or nearly null alleles are designated *Dhod*<sup>1</sup> through *Dhod*<sup>12</sup>. *Dhod*<sup>2</sup> and *Dhod*<sup>12</sup> are hypomorphic, exhibiting weak wing effects and female fertility. In addition, *Dhod*<sup>13</sup> and *Dhod*<sup>14</sup> were X ray induced by Vincent (originally designated *Dhod*<sup>V7</sup> and *Dhod*<sup>V10</sup>); the former was associated with *In(3R)Dhod*<sup>13</sup> = *In(3R)85A;89B*. *Dhod*<sup>15</sup> induced by hybrid dysgenesis as *Dhod*<sup>C2</sup>.

**cytology:** Placed in 85A4-5 based on its inclusion in the region of overlap of *Df(3R)V2* = *Df(3R)84E6-9;85A3-5* and *Df(3R)G1* = *Df(3R)85A4-5;85A6-11*; coordinates -49 to +19 (Jones and Rawls, 1988, Genetics 120: 733-42).

**molecular biology:** Included in a 145-kb walk carried out by Jones and Rawls (0 coordinate chosen as the proximal end of the initiating lambda clone, with positive values to the right). A putative 0.8-kb *P* insertion associated with *Dhod*<sup>15</sup> located between coordinates 14.4 and 14.9 kb; the inversion associated with *Dhod*<sup>13</sup> is broken at 14 kb. Genomic sequence hybridizes to a 1.5-kb transcript that is most abundant in early embryos, moderately abundant in mid embryos, mid pupae and adults; lowest in mid-larval stages; some stages display a 1.6-kb transcript as well; transcribed from right to left. Partial sequence shows homology to bacterial DHODEHase in the 3' end but no discernable homology in the 5' end (Jones, Kirkpatrick, and Rawls, 1989, Mol. Gen. Genet. 219: 397-403).

**\*di: dimorphos**

**location:** 1- (near spindle attachment).

**origin:** Spontaneous.

**discoverer:** Harnly, 32d10.

**references:** 1935, J. Exp. Zool. 72: 75-99 (fig.). 1940, DIS 13: 49.

**phenotype:** Specific lengthener of *vg* wings, especially in males (*di*; *vg* female much like *vg*). At higher temperatures, eyes small and rough, and wings of both sexes approach wild type. RK2 in *vg* male.

**dib: disembodied**

**location:** 3-12.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95 (fig.).

**phenotype:** Homozygous lethal; no differentiation of cuticle and head skeleton.

**alleles:** Three. *dib*<sup>1</sup>, *dib*<sup>2</sup>, and *dib*<sup>3</sup>, isolated as *10F*, *10K*, and *10L*.

**cytology:** Placed in 62D-64C; uncovered by terminally-deficient segregant from *T(2;3)D11 = T(2;3)?;64B-C* but not covered by *Dp(3;Y)H141 = Dp(3;Y)61B;62D*.

*dibro*: see *fr*<sup>di</sup>

**dic: dicephalic**

**location:** 3-46.0.

**origin:** Spontaneous.

**references:** Lohs-Schardin, 1982, Wilhelm Roux's Arch. Dev. Biol. 191: 28-36 (fig.).

**phenotype:** A semidominant maternal-effect mutant with low penetrance. Homozygous *dic* females and, to a lesser extent, *dic/+* heterozygotes exhibit variable numbers of abnormal follicles and abnormal oocytes. During vitellogenesis, the oocyte occupies a position in the middle of or lateral to the nurse cells rather than posterior to them; the fifteen nurse cells distribute themselves into two clusters, one at each end of the follicle, instead of remaining together anteriorly, as normally occurs. The larger cluster tends to be located anteriorly. One or several nurse cells may become detached from remainder of cyst [Frey, Sander, and Gutzeit, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 388-93 (fig.)]. Pole-cell transplantation experiments show that the *dic* phenotype results if either the germ line or the soma or both are homozygous for *dic* (Frey and Gutzeit, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 527-31). Chorionic respiratory processes irregular in shape and frequently point toward oviduct rather than germarium, as usually occurs. Eggs of *dic* females form micropyle at both ends, and they are less uniform in size and more irregular in shape than eggs from normal females. Embryonic development restricted to eggs of nearly normal shape. Blastoderm appears normal but no pole cells form. Head furrows and head lobes seen at both ends of embryo. Embryos secreting larval cuticle display (1) anterior denticle belt patterns at both ends, (2) a single abnormal polarity gradient, or (3) posterior pattern elements at both ends; segment showing polarity switch varies. The relative frequencies of these three classes agree with hypothesis that the two ends of the egg develop independently with P (anterior development) = 0.9 for both ends.

**Dichaete:** see *D*

**dichaete-beadex-lethal:** see *dbl*

**Difl: Drosophila-interferon-like-protein**

**location:** 3-{27}.

**discoverer:** Garen.

**phenotype:** Homologous to mouse  $\alpha 2$  interferon.

**cytology:** Localized to 67A8-10 by *in situ* hybridization.

*dihedral*: see *eg*<sup>2</sup>

**Dihydroorotate dehydrogenase:** see *Dhod*

**dil: dilute**

**location:** 2-57.

**origin:** Spontaneous.

**discoverer:** Bridges, 32f22.

**phenotype:** Dilutes *bw* to pale yellowish brown and *we*<sup>e</sup>, *w*<sup>e2</sup>, and *w*<sup>bl</sup> to paler grades. RK3.

**\*dil-3: dilute in chromosome 3**

**location:** 3- (not located).

**discoverer:** Bridges, 1519.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 151.

**phenotype:** Eye color like maroon, overlaps wild type. RK3.

**\*dil-w<sup>a</sup>: dilutor of white-apricot**

**location:** 3- (not located).

**discoverer:** Weinstein.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 218.

**phenotype:** Lightens *w*<sup>a</sup>. RK3.

**dilute:** see *dil*

**dilute in chromosome 3:** see *dil-3*

*dilute ocelli*: see *po*<sup>2</sup>

*Dilute-1*: see *bw*<sup>V291</sup>

**diminutive:** see *dm*

**Dimethylnitrosoamine demethylase:** see *Dmnd*

**dimorphos:** see *di*

**\*Din: Dinty**

**location:** Unknown; associated with a rearrangement.

**origin:** X ray induced.

**discoverer:** Braver, 55a.

**references:** 1955, DIS 29: 70.

Pollock, 1963, DIS 38: 50,

**phenotype:** In male and heterozygous female, central portion of vein L2 interrupted. Posterior supra-alar bristles absent in 95-99% of females and 97-99.5% of males. Anterior postalar bristles absent in 6-11% of females and 2-6% of males. Wings divergent. Viable and fertile in male and heterozygous female; homozygous lethal. RK2.

**cytology:** Associated with *T(1;2;3)Din = T(1;3)3C;63A + T(2;3)39D-73A*.

*Dint-1*: see *wg*

**Dinty:** see *Din*

**Dip-A: Dipeptidase-A**

**location:** 2-55.2 (based on 74 *pr-cn* recombinants).

**origin:** Naturally occurring polymorphism.

**references:** Voelker and Langley, 1978, *Genetica* 49: 233-36.

Ohnishi and Voelker, 1981, *Biochem. Genet.* 19: 75-85.

**phenotype:** Structural gene for dipeptidase A [DIP-A (EC 3.4.14.?)], a dimeric molecule based on the formation of hybrid enzymes in heterozygotes for electrophoretic variants. Enzyme molecular weight estimated at approximately 117,000 daltons by gel filtration (Leigh Brown). Substrate specificities determined by Laurie-Ahlberg (1982, *Biochem. Genet.* 20: 407-24). The only *Drosophila* peptidase with glycyl-L-isoleucine-ase activity. Occurs at high levels in the larval midgut.

**alleles:** In order of increasing anodal migration in 12% starch gel electrophoresis designated *Dip-A*<sup>2</sup>, *Dip-A*<sup>4</sup>, and *Dip-A*<sup>6</sup>. Null alleles superscripted *nNC1*, *nNC2*, *nGB1*, *nGB2*, and *nGB3* recovered from natural populations (Voelker, Langley, Leigh Brown, Ohnishi, Dickson, Montgomery, and Smith, 1980, *Proc. Nat. Acad. Sci. USA* 77: 1091-95). *Dip-A*<sup>nGB2</sup>/*Dip-A*<sup>nGB3</sup> shows partial complementation producing *Dip-A*<sup>2</sup> migration rate (Barkhart, Montgomery, Langley, and Voelker, 1984, *Genetics* 107: 295-306).

**cytology:** Placed in 41A at heterochromatic-euchromatic junction of 2R based on its inclusion in *Df(2R)M-S2*<sup>4</sup>, in which no loss of euchromatic bands can be detected; the locus is not included in *Df(2)M-S2*<sup>8</sup> or *Df(2)M-S2*<sup>10</sup>, the latter of which has been shown to be deficient for the majority of 2R heterochromatin.

**Dip-B: Dipeptidase B**

**location:** 3-53.6 (Laurie-Ahlberg, 1982).

**references:** Ohnishi and Voelker, 1981, *Biochem. Genet.* 19: 75-85.

**phenotype:** Structural gene for dipeptidase B [DIP-B (EC 3.4.14.?)], which is virtually monomorphic in natural populations but which differs in electrophoretic mobility from dipeptidase-B variants in *D. simulans*. Substrate specificities determined by Laurie-Ahlberg (1982, *Biochem. Genet.* 20: 407-24).

**alleles:** *Dip-B*<sup>4</sup> is the common allele; *Dip-B*<sup>6</sup>, a slow variant, and *Dip-B*<sup>10NC25</sup>, a nearly null allele, isolated from natural populations (Laurie-Ahlberg, 1982).

**cytology:** Localized to 87F13-88C2 based on the absence of *D. melanogaster* enzyme from hybrids between *D. melanogaster* and *D. simulans* when the *melanogaster* genome carries *Df(3R)red*<sup>31</sup> = *Df(3R)87F12-14;88C1-3*.

**Dip-C: Dipeptidase-C**

**location:** 3-{50-51}.

**references:** Ohnishi and Voelker, 1981, *Biochem. Genet.* 19: 75-85.

**phenotype:** Structural gene for dipeptidase C [DIP-C (EC 3.4.14.?)], for which no genetic variants are known but which differs in electrophoretic mobility from dipeptidase-C in *D. simulans*. Specific for dipeptides with carboxy proline (Laurie-Ahlberg, 1982, *Biochem. Genet.* 20: 407-24).

**cytology:** Localized to 87B6-9 based on the presence of the *D. melanogaster* enzyme in hybrids between *D. melanogaster* and *D. simulans* when the *melanogaster* genome carries *Df(3R)T45* = *Df(3R)86;87B5-6* but not

when it carries *Df(3R)E-079* = *Df(3R)86F1-2;87B8-10*. None of the three lethal complementation groups (*e*<sup>180</sup> and <sup>280</sup>*e*<sup>227</sup>, and *e*<sup>078</sup>) also defined by those two deficiencies is associated with *Dip-C* function.

**Dipeptidase-A:** see *Dip-A*

**Diphenol oxidase:** see *Dox*

**Dipp: Defective in phototaxis plasticity**  
(J.C. Hall)

**location:** 1-not mapped.

**references:** Willmund and Ewing, 1982, *Anim. Behav.* 30: 209-15.

Willmund, Emanns, Eusmann, and Ross, 1984, *J. Insect Physiol.* 30: 431-36.

**phenotype:** Fails to display long-lasting modification of visual responses (*e.g.*, light/dark choices) that are usually induced by exposure to strong blue light; prolonged depolarizing afterpotential (PDA) of photoreceptor cells, usually induced by such exposure, decays rapidly in the dark, unlike wild type, in which PDA is stable; in optomotor behavior, *Dipp*<sup>1</sup> still shows some responses to moving stimuli after PDA induced, whereas *Dipp*<sup>2</sup>, as does wild type, has such responses switched off by induction of PDA.

**alleles:** Possibly two mutant alleles, *Dipp*<sup>1</sup> and *Dipp*<sup>2</sup>.

**other information:** The two mutations here do not complement, given their dominance; yet, they have not been mapped meiotically, so they could be non-allelic.

**dipp-: defective in phototaxis plasticity**  
(J.C. Hall)

**origin:** Induced by ethyl methanesulfonate.

**references:** Willmund, Emanns, Eusmann, and Ross, 1984, *J. Insect Physiol.* 30: 431-36.

Speck, Mutz, Ohl, and Spatz, 1984, *J. Insect Physiol.* 30: 437-40.

**phenotype:** A series of sex-linked non-complementing, mutants with similar phenotypes. Homozygotes fail to display long-lasting decrement in visual response (*i.e.*, light-dark choices) that are usually induced by exposure to strong blue light; prolonged depolarizing afterpotentials of photo receptors occur normally; other aspects of physiological phenotype described in individual entries, which follow.

**dipp-3**

**location:** 1-(not localized; said not to be mappable to a single X-chromosome interval).

**phenotype:** Photoreceptors show subnormal sensitivity, in electroretinogram recordings, after blue light exposure followed by dark adaptation. ERG responses to flickering light (400 or 600 nm) suggest that the two central photoreceptors in each facet are abnormal in their response (Speck, Mutz, Ohl, and Spatz, 1984, *J. Insect Physiol.* 30: 437-40). Fast phototaxis responses show subnormal sensitivity after some kinds of pretreatment.

**dipp-4**

**location:** 1-(*v*-centromere).

**phenotype:** Photoreceptors show somewhat aberrantly high sensitivity, in electro-retinogram recordings, to various wave lengths of light. ERG light-on transient smaller than normal (Speck, Mutz, Ohl, and Spatz, 1984, *J. Insect Physiol.* 30: 4337-40). Fast phototaxis responses show

subnormal sensitivity after exposure to blue light followed by dark adaptation.

**dipp-5**

**location:** 1-(*cv-f*).

**phenotype:** ERG response to flickering light normal (Speck, Mutz, Ohl, and Spatz, 1984, *J. Insect Physiol.* 30: 437-40). Fast phototaxis responses show subnormal sensitivity after exposure to blue light followed by dark adaptation.

**dipp-6**

**location:** 1-(not localized; no recombinants from *y cho cv v f/dipp-6* exhibit normal phenotypes as if several factors responsible for mutant behavior of *dipp-6* strain.

**phenotype:** Photoreceptors show subnormal sensitivity, in electroretinogram recordings, after blue light exposure followed by dark adaptation. Fast phototaxis generally defective. Mutant females exhibit defective mating kinetics (Willmund and Ewing, 1982, *Anim. Behav.* 30: 209-15).

**dipp-7**

**location:** 1-(*cv-v*).

**phenotype:** Photoreceptors show subnormal blue-green light sensitivity, in electroretinogram recordings, after blue light exposure followed by dark adaptation. Fast phototaxis generally defective.

**dipp-8**

**location:** 1-(*cv-f*).

**phenotype:** Fast phototaxis generally defective.

*Dipr*: see *rn*

**\*dis: distorted eye**

**location:** 1-23.

**origin:** Recovered among progeny of natural-gas-treated fly.

**discoverer:** Mickey, 49b5.

**references:** 1951, *DIS* 25: 74.

**phenotype:** Whole or part of eye roughened. Sometimes bristles absent or doubled. Wings may be roughened with nicked margins and plexus veins. Expressivity variable. RK3.

**cytology:** Salivary chromosomes appear normal.

**Disabled:** see *Dab*

**discless:** see *dsl*

**disco: disconnected** (J.C. Hall and H. Steller)

**locus:** 1-53.1.

**discoverer:** K. Fischbach and M. Heisenberg.

**references:** Steller, Fischbach, and Rubin, 1987, *Cell* 50: 1139-53 (fig.).

Dushay, Rosbash, and Hall, 1989, *J. Biol. Rhythms* 4: 1-27.

Zerr, Hall, Rosbash, and Sibicki, 1990, *J. Neurosci.* 10: 2749-62.

**phenotype:** Compound eyes are disconnected from optic ganglia in most mutant individuals, but approximately 5-10% have superficially normal eye-brain connections. Photoreceptor cells initially present but degenerate progressively with age; axons of photoreceptor cells which are still present form plexus beneath the eye. Focus of gene function fate maps to a point well anterior to the focus of either the eye or optic lobe (Fischbach).

Adult defect arises as consequence of a defect in the larval visual nerve (Bolwig's nerve) which fails to connect with its target cells in the central nervous system; subsequently, owing to loss of the pioneer function of Bolwig's nerve, reticular axons fail to innervate their target cells in the developing optic lobes leading to massive degeneration of the optic ganglia during the early pupal stages (Steller and Rubin). Slight disarray of embryonic peripheral nervous system detectable; occasional errant neurons seen. Developing CNS appears normal, but adult brain is abnormal in that certain lateral neurons, which normally express *per* are either absent or do not express *per* (Zerr *et al.*). Larval reacts normally to all stimuli except light. All alleles display significantly reduced viability; death occurs in late pupal stages as pharate adults. In tests of circadian rhythms, eclosion and adult locomotor activity are essentially arrhythmic (Dushay *et al.*). Cyclical expression of *per* protein, which normally occurs in eyes and brain, is fairly robust in *disco*, whether eyes connected to the brain or not (Zerr *et al.*); hence this eye rhythm may be autonomous, *i.e.*, given absence of CNS neuronal staining in mutant adults.

**alleles:** Four ethyl-methanesulfonate-induced alleles: *disco*<sup>1</sup> (Fischbach) and *disco*<sup>2</sup>, *disco*<sup>3</sup> and *disco*<sup>4</sup> (Steller); all alleles show reduced viability.

**cytology:** Placed in 14B3-4 on the basis of its being included in *Df(1)82c3k = Df(1)14B3-4;14E* but not *Df(1)80g7d = Df(1)14B3-4;14C6-8*; not covered by *Dp(1;2)r<sup>+</sup>75c = Dp(1;2)14B13;15A9;35D-E*. *Dp(1;4)r<sup>+</sup>* and *Dp(1;4)80g7d* cover *disco*-induced arrhythmicity (Dushay *et al.*).

**other information:** Not allelic to *bss* or *eas*, two closely linked behavioral mutants in 14B4-13; order = *disco eas bss*.

**\*dk: dark**

**location:** 3- (not located).  
**discoverer:** Clausen, 20g.  
**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 235.  
 Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 223.  
**phenotype:** Eye color maroon. Overlaps wild type. RK3.

**\*dkb: dark bubbly**

**location:** 2- (to the left of *vg*).  
**discoverer:** Bridges, 38d25.  
**phenotype:** Thorax has dark bubbly longitudinal streak. RK3.

**dke: dark eye**

**location:** 2-73.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 38c11.  
**phenotype:** Eye color soft, dull, and dark, like *sf*. *sfi dke* is wild type. RK2.

**Dke: Darkened eye**

**location:** 2- (not located).  
**origin:** X ray induced.  
**discoverer:** Hendrix, 1963.  
**references:** 1964, DIS 39: 58.  
**phenotype:** In heterozygotes, eye facets roughened with black-spotted pigmentation, varying from light spotting near margin of eye to heavy pigmentation covering one-half of the eye. A bleached area sometimes appears adjacent to the pigmentation. Effect usually symmetrical. Homozygous lethal. RK3.  
**cytology:** Salivary chromosomes appear normal (Peacock).

**\*dki: darker legs**

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1954.  
**synonym:** *thl-d: thick legs darker*.  
**references:** 1959, DIS 33: 85.  
**phenotype:** Extra pigment in body and legs. Legs slightly shortened, especially in female. Wings small and divergent. Eye shape altered. Viability good in both sexes; female fertility reduced. RK3.

**dl: dorsal**

**location:** 2-52.9.  
**synonym:** *mat(2)dorsal*.  
**references:** Nüsslein-Volhard, 1979, Symp. Soc. Dev. Biol. 37: 185-211 (fig.).  
 1979, INSERM Symp. 10: 69-82 (fig.).

 Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78.  
**phenotype:** Embryos produced by homozygous *dl* females form normal cellular blastoderm but at gastrulation develop into yolk-filled tube of dorsal hypoderm. Hair pattern of cuticle characteristic of dorsal hypoderm; ventral structures, such as denticle belts, lacking. Normally, dorsal infoldings occupy entire circumference of embryo. Evidence of anterior-posterior differentiation includes

possible mouth armature structures anteriorly, small spiracles posteriorly, and orientation of hairs. The periodicity of stripes of *ftz* expression in pre gastrulation embryos, as revealed by antibody staining, displays the pattern normally characteristic of the dorsum circumferentially in embryos produced by *dl* females (Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32. Embryos produced by *dll/dl* and *dll/Df(2L)TW137* indistinguishable, suggesting *dl* to be amorphic. Penetrance complete; expression constant. Embryos of *dl*<sup>2</sup> females lack all structures normally derived from the ventral half of the egg, including mesoderm, endodermal gut, ventral nervous system, and ventral hypoderm.

*dl*<sup>1</sup> and to a lesser extent *dl*<sup>2</sup>, females produce embryos with reduced capacity for neurogenesis in response to an absence of *dl* function (Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 317-26). *dl* germ line dependent; homozygous germ-line clones produce dorsalized embryos (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48).

Embryos of *dll*+ females produced at 29° develop into comparatively normal-looking larvae; they mainly lack internal organs, such as mesoderm and parts of the anterior and posterior gut; often ventral hypoderm including denticle belts reduced; phenotype sensitive to genetic background. At 22°, *dll*+ females produce normal embryos. Developmental fate of ventrally located cells on cellular blastoderm apparently shifted to that of more dorsally located cells. The phenotype of embryos produced by *dll/dl* females partially rescued by the injection of wild-type cytoplasm but not RNA (Santamaria and Nüsslein-Volhard, 1983, EMBO J. 2: 1695-99; Anderson and Nüsslein-Volhard, 1944, Nature 34: 225-27).

Developmental profiles show transcript to be present only in ovaries and pre-cellular-blastoderm stages of embryogenesis. *In situ* hybridization indicates that ovarian transcript accumulates in nurse cells from stage 5 to 11; number of transcripts per genome equivalent in these polytene cells remains low and constant until stage 10, at which time there is a dramatic increase in the relative numbers of transcripts. After a lag of one or two nuclear divisions, transcript begins to accumulate in the oocyte; by stage 12 there is little detectable transcript in the nurse cells. It appears as though the nurse-cell transcript is transferred to the oocyte and thus to the embryo; transcript seems to be uniformly distributed in stage 14 oocytes (Steward, Ambrosio, and Schedl).

*dl* protein is uniformly distributed throughout cytoplasm of early embryo; in the syncytial blastoderm a gradient of expression is achieved by the graded transport of *dl* protein into nuclei, with the highest nuclear concentrations found ventrally; protein remains cytoplasmic dorsally. Maternal dorsalizing mutants prevent nuclear localization and ventralized embryos show dorsal as well as ventral nuclear localization (Steward, Zusman, Huang, and Schedl, 1988, Cell 55: 487-95; Rushlow, Han, Manley, and Levine, 1989, Cell 59: 1165-77; Steward, 1989, Cell 59: 11179-88; Roth, Stein, and Nüsslein-Volhard, 1989, Cell 59: 1189-1202).

<sup>α</sup> 1 = Nüsslein-Volhard, 1979, Symp. Soc. Dev. Biol. 37: 185-211; 2 = Nüsslein-Volhard, 1979, INSERM Symp. 10: 69-82; 3 = Schüpbach and Wieschaus, 1989, Genetics 121: 101-17; 4 = Steward, McNally, and Schedl, 1984, Nature 311: 262-65; 5 = Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78; 6 = Szabad, Erdélyi, Hoffmann, Szidonya, and Wright, 1989, Genetics 122: 823-35; 7 = Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**cytology:** Placed in 36C2-D1 based on its inclusion in *Df(2L)TW137 = Df(2L)36C2-4;37B9-C1* but not *Df(2L)VA18 = Df(2L)36C4-D1;36F-37A*. Further confined to 36C by breakpoints common to *In(1)dl<sup>H</sup>* and *In(1)dl<sup>T</sup>*.

**molecular biology:** Genomic clone isolated by Steward, McNally, and Schedl (1984, Nature 311: 262-65). A 14 kb transcription unit encodes a 2.8 kb poly-adenylated transcript; transcription proceeds from right to left; transcript contains two and probably three introns, a 1 kb intron down stream from a 5 kb intron. A 2.3 HindIII-SstI restriction fragment from the 3' exon contains the breakpoints of both *In(2)dl<sup>H</sup>* and *In(2L)dl<sup>L</sup>* (Steward, Ambrosio, and Schedl, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 223-38). The cDNA sequence indicates that the dorsal protein has 678 amino acids and a molecular weight of 75,450 daltons; the NH<sub>2</sub> terminal portion of the conceptual amino-acid sequence reveals a high level of homology with the *c-rel* proto-oncogene. The C-terminal portion has regions in common with *N* and *en* (Steward, 1987, Science 238: 692-94; 1989, Cell 59: 1179-88; Rushlow, Han, Manley, and Levine, 1989, Cell 59: 1165-77).

**other information:** Expression of *twi* prevented in embryos produced by *dl* females (Thisse, Stoetzel, El Messal, and Perrin-Schmidt, 1987, Genes Dev. 1: 709-15).

*dl*: see *dpl*

**DI: Delta**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 197.

**DI: Delta**

**location:** 3-66.2.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 197-201 (fig.).

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 75 (fig.).

Vässin and Campos-Ortega, 1987, Genetics 116: 433-45. Alton, Fechtel, Terry, Miekle, and Muskavitch, 1988, Genetics 118: 235-45.

**phenotype:** A haplo-insufficient member of the group of neurogenic genes originally described on the basis of its dominant phenotype. Several classes of alleles designated by Vässin and Campos-Ortega based on the phenotype of heterozygous adults: Amorphic and strong hypomorphic alleles display wing veins widened at their junctions with the margin to form delta-like structures; in addition, they show irregular thickening of vein 2, and wings frequently held in divergent attitude; fusion of ommatidia may give rise to disruptions in regular hexagonal array of eye facets; ocelli are slightly enlarged; additional bristles are present on head, thorax, and abdomen; homozygotes die as embryos. Rare antimorphic alleles display the above phenotype in exaggerated form with irregular widening of all longitudinal wing veins, enlarged deltas, regularly divergent wings, smaller rougher eyes, larger and often fused ocelli, and further increase in the numbers of extra bristles; in addition, tarsal joints 2 to 4, but not 5 are fused; homozygotes are embryonic lethals. Rare recessive alleles show low levels of survival as homozygotes or trans heterozygotes with more severe alleles; survivors usually display a less extreme version of the phenotype exhibited by heterozygotes for amorphic alleles; however, some combinations are wild type in appearance and others (e.g., the antimorphs) are lethal. The embryonic lethality of homozygotes displays the typical neurogenic phenotype with neural hyperplasia accompanied by epidermal aplasia; most or all cells of the neurogenic ecto-

derm recruited into the neurogenic pathway. Transplantation of homozygous *Dl* pole cells demonstrate *Dl* expression during oogenesis (Dietrich and Campos-Ortega, 1984, J. Neurogenet. 1: 315-32). *Dl* classed as non-autonomous in that single cells from the neurogenic ectoderm of *Dl*<sup>-</sup> embryos are capable of giving rise to both neural and epidermal derivatives when transplanted into the neurogenic region of wild-type embryos, suggesting that *Dl*<sup>-</sup> cells are capable of responding normally to information from neighboring cells (Technau and Campos-Ortega, 1987, Proc. Nat. Acad. Sci. USA 84: 4500-04). Transcription in cellular blastoderm seen in the ventrolateral neurogenic ectoderm, with a ventral-to-dorsal gradient of expression, corresponding to the gradient of neurogenic capabilities of the neurogenic ectoderm. During gastrulation a metameric pattern of expression appears, disappears, and reappears; as development proceeds complicated spatial and temporal specificities of expression ensue (Vässin *et al.*, 1987).

Interactions with other neurogenic mutations complex; *Dl* mutations suppress the *spl*-enhancing effect of *E(spl)* (Shepard, Boverman, and Muskavitch, 1988, Genetics 122: 429-38) and the expression of *Ax* (Sirén and Portin, 1989, Genet. Res. 54: 23-26); severe alleles fail to survive in heterozygotes with *E(spl)* loss-of-function alleles [Lehmann, Dietrich, Jiménez, and Campos-Ortega, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 226-29 (fig.)] especially when *E(spl)* is maternally inherited. Expression of *Dl*<sup>+</sup> observed to be partially suppressed by duplications for *E(spl)*<sup>+</sup> (Vässin, Vielmetter, and Campos-Ortega, 1985, J. Neurogenet. 2: 291-308), yet, de la Concha, Dietrich, Weigel, and Campos-Ortega (1988, Genetics 118: 499-508) report that extra doses of *E(spl)*<sup>+</sup> enhance the neurogenic phenotype of *Dl*<sup>-</sup>. *Dl*<sup>+</sup> and *Dl*<sup>-</sup> phenotypes are suppressed by heterozygous and homozygous deficiencies for *H*, respectively. For example, *H*<sup>-</sup> is able to suppress the phenotypic effects of *Dl*<sup>9P</sup>, either in *Dl*<sup>9P</sup>/+ or in *Dl*<sup>9P</sup>/*Dl*<sup>9P</sup> genotypes; *Dl*<sup>9P</sup>/*Dl*<sup>9P</sup> is cell lethal in both the eye and the cuticle; *Dl*<sup>9P</sup> *H*<sup>2</sup>/*Dl*<sup>9P</sup> *H*<sup>2</sup> cells, on the other hand, develop nearly normally (Dietrich and Campos-Ortega, 1984). Expression of *Dl* enhanced by duplications for *N*<sup>+</sup> or *H*<sup>+</sup>, and three doses of *Dl*<sup>+</sup> enhance expression of *N*<sup>-</sup> and *neu*<sup>-</sup>, but reduce the severity of the *mam*<sup>-</sup> phenotype. de la Concha, *et al.* have incorporated many of these observations into a model of neurogenic-gene interaction. *Dl* alleles interact synergistically with certain Minutes, producing extreme phenotypes and drastically lowered viability (Schultz, 1929, Genetics 14: 366-419); *Dl*<sup>Of</sup> enhances *spa*<sup>Cat</sup> (Tsukamoto, 1956, DIS 30: 79).

β Phenotypes described more fully below.

γ Associated with *T(2;3)*.

**cytology:** Placed in 92A2 based on its inclusion in both *Df(3R)Bxd<sup>110</sup> = Df(3R)91D;92A2* and *Df(3R)DI-KX12 = Df(3R)92A2;92A4*.

**molecular biology:** Two chromosomal walks carried out in the region (Vässin, Bremer, Knust, and Campos-Ortega, 1987, *EMBO J.* 6: 3431-40; Kopczynski, Alton, Fechtel, Kooh, and Muskavitch, 1988, *Genes Dev.* 2: 1723-35);

coordinate 0 of the Kopczynski *et al.* walk is at approximately -20 kb on the Vässin *et al.* walk; in both coordinate systems, positive values extend to the left. Lesions associated with *Dl* mutations found between 75 and 100 kb on the Vässin *et al.* coordinates and between 95 and 127 kb on that of Kopczynski *et al.*; probes from this region identify two major transcripts of 4.5 or 4.6 and 5.4 kb; in addition, Kopczynski *et al.* report four minor transcripts. Probing of cDNA with genomic restriction fragments indicate that both major transcripts comprise four exons spread over 25 kb of chromosomal DNA. The smaller transcript is found in ovaries and in 0-2 hour embryos and is presumably maternal in origin; the larger one accumulates maximally in 2-6 hour embryos. Conceptual amino acid sequence indicates a protein of 832 amino acids which contains a signal sequence (residues 1-25), an extracellular domain, which included nine EGF-like repeats (residues 26-595), a transmembrane domain (residues 596-617), and an intracellular domain (residues 618-832); it also contains five consensus asparagine-linked glycosylation sites at residues 98, 137, 167, 421, and 649 (Kopczynski *et al.*).

### *Dl*<sup>6B</sup>

**phenotype:** Like *Dl*<sup>1</sup> except that severity of phenotype in homozygous embryos temperature sensitive. At 18° there is patchy neuralization of cephalic and ventral ectoderm; expression more severe at 25° and extreme at 29°. Temperature-sensitive period between pole-cell formation and mesodermal segmentation. Clone of ommatidia homozygous for *Dl*<sup>6B</sup>, normal when reared under permissive conditions; in flies raised at 29°C, however, ommatidial pattern severely disturbed, producing scarring of the eye surface; ommatidia appear larger than normal and interommatidial bristles missing; homozygous mutant facets contain more than a normal complement of retinula cells-up to 13; cytodifferentiation apparently normal. Cuticular clones exhibit elaboration of extra bristles at bristle-forming sites [Dietrich and Campos-Ortega, 1984, *J. Neurogenet.* 1: 315-32 (fig.)].

### *Dl*<sup>B107</sup>

**phenotype:** The most severe antimorphic allele (Vässin and Campos-Ortega, 1987). All components of the phenotype of heterozygosity for a *Dl* deletion are present in a drastically increased manner in heterozygotes for *Dl*<sup>B107</sup> (or for *Dl*<sup>FE30</sup> or *Dl*<sup>FE32</sup>). All wing veins are irregularly widened, veins 3 and 5 being broadened along their whole lengths (same for vein 2 in *Dl*<sup>FE30</sup> and *Dl*<sup>FE32</sup>) and are occasionally incised posteriorly; the deltas formed at the wing margins are larger and the wings are held spread with complete penetrance. The eyes are smaller and rougher. There is also a severe disturbance of the normal bristle pattern on the head, thorax, and abdomen owing to a further increase in the number of bristles. The ocelli are larger and often fused together, thus forming a half circle. Finally, tarsal segments 2 to 4 are fused, but segment 5 is never found to be affected.

### *Dl*<sup>vi</sup>: Delta viable

**phenotype:** Three alleles survive as homozygotes (Vässin, and Campos-Ortega, 1987). Slight delta-like thickenings at posterior tips of wing veins 2, 3, 4 and 5; roughening of eye. *Dl*<sup>vi</sup> homozygotes also show shortening and frequent fusion of tarsal segments. A few homozygous

embryos fail to hatch, showing patchy neuralization in cephalic and ventral territories. *Dl*<sup>vi/+</sup> normal. *Trans* heterozygotes with dominant alleles show extreme wing, eye, and tarsal abnormalities; *Dl*<sup>vi</sup> lethal in combination with *Dl*<sup>F30</sup>, *Dl*<sup>F32</sup>, *Dl*<sup>E50-2</sup>, and *Dl*<sup>B107</sup> (Vässin, and Campos-Ortega, 1987).

### *dlg1*: discs large

**location:** 1-34.82.

**synonym:** *l(1)10Bf*.

**references:** Stewart, Murphy, and Fristrom, 1972, *Dev. Biol.* 27: 71-83.

Gateff, 1978, *Biol. Rev.* 53: 123-68.

1978, *Science* 200: 1448-59.

Kiss, Szabad, and Major, 1978, *Mol. Gen. Genet.* 164: 77-83.

Perrimon, 1988, *Dev. Biol.* 127: 392-407.

Woods and Bryant, 1989, *Dev. Biol.* 134: 222-35.

**phenotype:** Late larval lethal; prolonged larval stages with bloated larvae attempting pupariation around day 15; some cuticular tanning, but no adult cuticular structures formed. During early larval development, the imaginal discs are smaller than those of normal larvae of the same age and are misshapen, but as the larvae continue to survive after the normal pupariation time, the discs continue to grow. They become large, amorphous, and solid, containing three times the normal numbers of cells at ten days of age; they also experience substantial cell death. By eleven days, wing and haltere discs may fuse; also first and second leg discs fuse with ventral ganglion of the CNS; great enlargement of optic lobes of brain also takes place. Discs, but not brains, transplanted into adults grow rapidly displaying invasive growth; they do not differentiate when transplanted into larvae for metamorphosis. Homozygous tissues do not survive, nor do gynandromorphs (one with male abdominal tissue vs. 66 expected). It is possible to produce homozygous germ-line clones (Perrimon). *dlg1* embryos generated from such clones display defects in morphogenesis and neurogenesis; most tissues are defective; partial rescue achieved by a paternal *dlg1*<sup>+</sup> contribution, in the form of either a normal X or a v<sup>+</sup>Y.

<sup>β</sup> More complete description following molecular biology.

**cytology:** Placed in 10B8 based on its inclusion in *Df(1)DA622 = Df(1)10B8;10D2* but not *Df(1)m13 = Df(1)10B8;11A3-5*.

**molecular biology:** Region contained in a 60-kb walk initiated from the junction fragment of *Df(1)m13*. A 5.1 kb putative *dlg1* cDNA clone isolated (Woods and Bryant); it hybridizes to genomic fragments extending over 25 kb; antisense probe detects five different mRNA species in Northern blots; these species altered or absent in various *dlg1* mutants; the direction of transcription is from left to right. Late third instar larvae have transcripts to 6.0 and 5.5 kb; they are reduced in two-day pupae and a 1.9 kb transcript appears; it disappears in three-day pupae and the 6.0 and 5.5-kb species become more abundant and a 5.0-kb species appears. Adult females show five distinct mRNA species of 6.0, 5.5, 5.0, 4.0 (ovary specific), and 1.9 kb; only the two largest bands are seen in adult males. 0-4 hour embryos contain the 5.0 and at lower level the 5.5 kb transcripts; at 6-12 h these levels reduced and the 6.0 kb RNA appears; all species are barely detectable at end of embryogenesis; 5.5 and 6.0-kb species appear in the first larval instar becoming abundant in the third instar.

### *dlg1*<sup>2</sup>

**phenotype:** Homozygotes fail to survive when raised at 25°; when raised at 18° however, 37% survival attained; hemizygous females show 65-70% survival at 18°, but are also lethal at 25°. Survival at 18° nearly complete in heterozygotes with *dlg1*<sup>5</sup> and *dlg1*<sup>18</sup>, and survival at 25° is 4% and 95% respectively. Embryos produced by matings between surviving *dlg1*<sup>2</sup> flies raised at 18° show but 4% hatchability at 18°, and such crosses are completely sterile at 25°; however in crosses of homozygous *dlg1*+2 females to *dlg1*<sup>+</sup> males, rescue of heterozygous daughters nearly complete at either 18° or 25° and is somewhat reduced at 29°. Abnormal embryos produced by *dlg1*<sup>2</sup> females show failure of dorsal closure, and head involution. The maternal effect of *dlg1* is germ-line specific, since embryos produced by homozygous clones in heterozygous mothers are indistinguishable from those produced by homozygous mothers (Perrimon, 1988, Dev. Biol. 127: 392-407).

### *dlg2*

**location:** 1-24.9.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)d.lg.-2*.

**references:** Gateff, 1978, Biol. Rev. 53: 123-68. 1978, Science 200: 1448-59.

**phenotype:** Imaginal disc neoplasm with invasive mode of growth. Brains enlarged, but do not display neoplastic

growth.

*Dll*: see *Ba*

### *dlmd*: dorsal-longitudinal-muscle-defective (J.C. Hall)

**location:** 3-18 to 19 (approximately 8 cM. to left of *h*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Wang, Keng, Hsu, and Tan, 1989, J. Neurogenet. 6: 27-39.

**phenotype:** Flightless; wings held in normal position; walking, jumping, overall viability said to be normal; dorsal-longitudinal muscles (DLMs) degenerate, usually observed most readily at periphery of fibers; in degenerative areas, muscle Z lines disappear. DLM degeneration begins in late pupae, becoming more pronounced in newly eclosed adults (this progressive atrophy quantified for four of the alleles in homozygous condition: 3, 14, 23, 26); physiology of giant-fiber nerve pathway (which in part ends at DLMs) is essentially normal, though muscle-cell resting potential in mutant flies is lower than normal, and membrane excitability is accentuated.

**alleles:** *dlmd*<sup>23</sup>, *dlmd*<sup>30</sup>, *dlmd*<sup>17</sup>, *dlmd*<sup>26</sup>, *dlmd*<sup>14</sup>, *dlmd*<sup>3</sup>, listed in order of decreasing penetrance for flightlessness, which ranges from 80-100%; also *dlmd*<sup>23</sup>/+ almost thoroughly flightless; other alleles, over +, lead to 50-70% adults unable to fly.

**other information:** *dlmd*<sup>17</sup> mutation was the only one mapped meiotically; others said to be allelic by lack of *inter se* complementations in flight tests; *dlmd*<sup>23</sup> seems not knowable as allelic, given its nearly complete dominance.

### *dlv*: deltoid veins

**location:** 1-25.9.

**origin:** Induced by S-2-chloroethylcysteine.

**discoverer:** Fahmy, 1957.

**references:** 1959, DIS 33: 85.

**phenotype:** Wings small, abnormal, with margin occasionally incised, and frequently either divergent or slightly upheld. Extra venation, especially at junctions between longitudinal and costal veins, giving Delta-like formations. In extreme cases, wings grossly deformed and blistered. Excess melanization throughout body. Eyes dark, small, and slightly rough. Total body size reduced. Both sexes viable and fertile. RK1.

**alleles:** One allele induced by S-2-chloroethylcysteine.

### *Dly*: Delayed recovery (W.B. McCrady)

**location:** 3-52.7 (2.7 units to right of *cu*).

**origin:** Natural population.

**discoverer:** McCrady, 1959.

**references:** McCrady and Sulerud, 1964, Genetics 50: 509-26.

Clark, McCrady, and Fielding, 1979, Genetics 92: 503-10.

**phenotype:** Recovery from CO<sub>2</sub> exposure for 15 min at 14°C of most *Dly/Dly* flies occurs between one and four hr, although many never recover, compared to less than 15 min for wild-type. *Dly*/+ flies recover between 15 min and one hr post-exposure. Percent of flies recovering decreases with increasing temperatures at time of exposure to CO<sub>2</sub> and with length of exposure. Exposure of *Dly/Dly* flies to 28° during development rescues them but not their *Dly*-bearing progeny from delayed recovery. *Dly* strains carry cytoplasmic factors which can transmit

CO<sub>2</sub> sensitivity by injection. Cytoplasmically transmissible factor reduced by successive backcrossing, but *Dly* strains remain CO<sub>2</sub> sensitive. *Dly* strains show partial resistance to suprainfection by sigma virus.

**dm: diminutive**

**location:** 1-4.0.

**origin:** Spontaneous by insertion of gypsy (Modolell, Bender, and Meselson, 1983, Proc. Nat. Acad. Sci. USA 80: 1678-82).

**discoverer:** Nichols-Skoog, 33j9.

**references:** 1935, DIS 3: 10.

**phenotype:** Bristles and body small and slender. Viability excellent. Females sterile. Oocyte cyst development abnormal; nurse-cell nuclei swell in stage 7, subsequently becoming pycnotic (King and Burnett, 1957, Growth 21: 263-80); cuboidal follicle cells covering developing oocyte in stage 8 fail to show normal growth and degenerate rather than becoming columnar (King and Vanoucek, 1960, Growth 24: 333-38). Chambers degenerate around stage 8; phenotype of homozygous *dm* less severe than that of *dml Df(1)dm* (King and Vanoucek). RK1.

**alleles:** \**dm*<sup>264-58</sup> (CP627); *dp*<sup>ls</sup>.

**cytology:** 3D5 (Lefevre, 1981, Genetics 99: 461-80).

*dmd*: see *pch*

**Dmnd: Dimethylnitrosamine demethylase**

**location:** 2-64.7.

**references:** Waters, Shigemi, Simms, and Nix, 1984, Biochem. Biophys. Res. Comm. 123: 907-13.

**phenotype:** Different strains differ with respect to presence or absence of this activity.

**cytology:** Placed in 48A-49D.

*Dmras64B*: see *Ras2*

**dn: doughnut**

**location:** 3-50.

**origin:** Spontaneous.

**references:** Wallbrunn, 1942, DIS 16: 54. Wright, 1946, DIS 20: 68.

**phenotype:** Eye of *se dn* has unpigmented spot (in middle or toward posterior) at emergence from puparium. Spot gradually darkens; after 2 days, eyes appear sepia. Difficult to detect with wild-type eye color, appears as slightly lighter red spot, which disappears after 2 days. Viability low; many die as pupae at 25°. Viability nearly normal at 17° but character not detectable. Both sexes highly infertile; testes about one-third normal length. Spermathecae very small. External genitalia of both sexes often abnormal. RK3.

**DNase-1: Deoxyribonuclease-1**

**location:** 3-61.8 (based on 83 *bx-sr* recombinants).

**references:** Grell, 1976, Genetics 83: s28-29.

Detwiler and MacIntyre, 1978, Biochem. Genet. 16: 1113-34.

**phenotype:** The structural gene for DNase 1, one of an estimated 7 or more DNase species (Boyd, 1964, Biophys. Biochem. Acta 171: 103-12). Active on native DNA at acid pH (optimum = 4.8) and in the presence of EDTA. Heterozygotes for electrophoretic alleles show two bands on gels indicating monomeric nature of enzyme. Activity of paternally inherited allele demonstr-

able in 0- to 1-hr embryos. Activity fluctuates during embryogenesis, is low during larval stages, rises precipitously just before pupation, and falls after eclosion (Detwiler and MacIntyre, 1978). DNase-1 activity isolated with lysosomal fraction of embryo homogenates (Detwiler and MacIntyre, 1980, Insect Biochem. 10: 255-63). Flies homozygous for hypomorphic allele are small with reduced viability; maturation of ovaries delayed for several days after eclosion; recombination normal (Grell, 1976). Homozygotes for the hypomorphic allele *DNase1<sup>lmn</sup>* accumulate low-molecular-weight, low-thermal-stability DNA, especially in the ovaries; Feulgen-positive vesicles visible in maturing oocytes near chorionic appendages (Stone, Dower, Hauseman, Cseko and Sederoff, 1983, Can. J. Genet. Cytol. 25: 129-38).

**alleles:** Naturally occurring alleles designated *F*, *I*, and *S* by Grell are probably same as those subsequently designated *A*, *B*, and *C* by Detwiler and MacIntyre (1980); we adopt *F*, *I*, and *S*. Young adult flies homozygous for *DNase1<sup>F</sup>* or *DNase1<sup>I</sup>* exhibit two bands on gels; *DNase1<sup>S</sup>* homozygotes show one (Grell, 1976). *DNase1<sup>lo</sup>* (Grell, 1976) induced by ethyl methanesulfonate is hypomorphic. Also mentioned by Detwiler and MacIntyre (1978, 1980) are three hypomorphic alleles isolated by J. Stone, including *DNase<sup>lmh</sup>*, and eight null alleles, including *DNase1<sup>n324</sup>*, isolated by Detwiler.

**cytology:** Placed between 90C2 and 90F based on the absence of any electrophoretic allele on *Df(3R)P14 = Df(3R)90C2-D1;91A2-3* or on the *Y<sup>P3D</sup>* element of *T(Y;3)B116 = T(Y;3)YL;90E* (Detwiler and MacIntyre, 1978).

**other information:** Hyperploidy for 30F-35BC and 67C-70C as well as 88C-91B caused greater than 50% increase in acid deoxyribonuclease activity (MacIntyre, 1974, Isozyme Bull. 7: 23).

**DNase2**

**location:** 3-45.9 (between *st* and *in*).

**references:** Grell, 1976, Genetics 83: s28-29.

**phenotype:** The structural gene for a deoxyribonuclease that is active on heat-denatured DNA at pH 8.5. Causes the appearance of two bands on polyacrylamide gels. Null allele without detectable phenotypic effect.

**alleles:** A naturally occurring null allele designated *DNase2<sup>nl</sup>* removes both bands.

**other information:** There is evidence for two other alkaline deoxyribonuclease genes. One produces a band on denatured substrate at pH 8.5 and is localized to *3L* on the basis of different mobilities in *D. melanogaster* and *D. simulans* (Grell, 1976). The other is located in 97F-100F based on increased alkaline DNase activity in hyperploids for that region (MacIntyre, 1974, Isozyme Bull. 7: 23); segmental aneuploidy failed to identify the other two regions as affecting DNase levels (MacIntyre, 1974).

**dnc: dunce (R. Davis; J.C. Hall)**

**location:** 1-3.9 [about five-eighth the recombinational distance from *w* to *ec* (Salz, and Kiger, 1984, Genetics 108: 377-92); however, as it is adjacent to *dm* (1-4.0), it is assigned a map position of 3.9].

**origin:** Induced by ethyl methanesulfonate (all alleles except *dnc<sup>CK</sup>*, which was X ray induced).

**discoverer:** Byers.

- references:** Dudai, Jan, Byers, Quinn, and Benzer, 1976, Proc. Nat. Acad. Sci. USA 73: 1684-86.

 Salz and Kiger, 1984, Genetics 108: 377-92.

**phenotype:** Gene encodes a cAMP-specific phosphodiesterase. Mutants blocked or impaired in learning, with respect to several of the conditioning tests used on groups of flies or larvae or on individual adults, *e.g.*, those involving odors and electric shocks or sugars (Aceves-Piña and Quinn, 1979, Science 206: 93-96; Tempel, Bonini, Dawson, and Quinn, 1983, Proc. Nat. Acad. Sci. USA 80: 1482-86; see also Aceves-Piña, Booker, Duerr, Livingstone, Quinn, Smith, Sziber, Tempel, and Tully, 1983, Cold Spring Harbor Symp. Quant. Biol. 48: 831-40), visual stimuli (Folkers, 1982, J. Insect Physiol. 28: 535-39), or various elements of courtship (with respect to tests on mutant males or females, summarized by Hall, 1984, Dev. Genet. 4: 355-78); also, *dnc*<sup>M14</sup> males have reduced reproductive fitness after exposure to and courtship of immature females, *i.e.* when mutant males are put, post training, with mixed female/young male populations (Gailey, Siegel, and Hall, 1985, Genetics 111: 795-804). *dnc* females display an increased frequency of mating; it is suggested that this could account for their 50% normal longevity (Bellen and Kiger, 1987, Genetics 115: 153-60). *dnc* males are not conditioned to avoid virgin females by sequestration with such females in the presence of quinine; wild type males are (Ackerman and Siegel, 1986, J. Neurogenet. 3: 111-23). *dnc* mutants apparently learn normally, or nearly so, in certain experiments but have abnormally short memory (*e.g.*, Dudai, 1979, J. Comp. Physiol. 130: 271-75; Mariath, 1985, J. Insect Physiol. 31: 779-87); more specifically, modifications of original shock-odor testing system reveal that *dnc* is defective in short term memory, with long-term memory similar to wild type (Tully and Quinn, 1985, J. Comp. Physiol. 157: 263-77); *dnc/+* females also memory deficient (Dudai, 1983, Proc. Nat. Acad. Sci. USA 80: 5445-48). Whereas *dnc* adults seem normal in several general behaviors (Dudai *et al.*, 1976), the mutant displays aberrant "centrophobic" behavior [*i.e.*, transient avoidance of the center of an arena displayed by normal adults (Gotz and Biesinger, 1985, J. Comp. Physiol. 156: 319-27, 329-37)]. Mosaic studies suggest that the focus of *dnc/+* function is the brain, even though some learning responses demonstrated by headless flies (Aceves-Piña, *et al.*). Sensory fatigue associated with an adult mechanosensory neuron, as measured by bristle stimulation, occurs more rapidly than normal in *dnc* (allele not specified) (Corfas and Dudai, 1990, J. Neurosci. 10: 491-99). There is an increased number of mushroom-body axonal fibers in young adults expressing *dnc*<sup>1</sup> or *dnc*<sup>M11</sup>, which, unlike wild type, decreases over the next few days (Balling, Technau, and Heisenberg, 1987, J. Neurogenet. 4: 65-73). Mutations or deletions of the locus reduce or eliminate one form of cyclic AMP phosphodiesterase (EC 3.1.4.17) activity; caffeine, an inhibitor of this enzyme, decreases visual learning performance of normal adults and of *dnc*<sup>1</sup> as well, suggesting that the biochemical effects of the drug and the mutation

are not identical (Folkers and Spatz, 1984, J. Insect Physiol. 30: 957-65). The effects of *dnc* mutations on heat stability or K<sub>m</sub> of this activity indicate that the locus codes for this enzyme (Kauvar, 1982, J. Neurosci. 2: 1347-58; Davis and Kauvar); *dnc* variants also lead to increased levels of cyclic AMP (summarized by Davis and Kauvar, 1983), more specifically, such that most of the excess is in free (vs. bound) nucleotide; both fractions exist in whole-fly homogenates (Friedrich, Solti, Gyurkovicz, 1984, J. Cell. Biochem. 26: 197-203). *dnc*<sup>M11</sup> affects the level of phosphorylation of the regulatory subunit of the cyclic-AMP-dependent kinase (Dévay, Pintér, Yalcin, and Friedrich, 1986, Neurosci. 18: 193-203). Levels of regulatory subunit of cAMP-dependent protein kinase tend to be higher than normal in *dnc*<sup>1</sup> and *dnc*<sup>2</sup> (Muller and Spatz, 1989, J. Neurogenet. 6: 95-114). *dnc*<sup>M11</sup> flies exhibit increased levels of expression of *copia* (Yun and Davis, 1989, Nucleic Acids Res. 17: 8313-26).

*dnc* alleles cause varying degrees of female sterility; oocytes of females homozygous for amorphic alleles rarely reach maturity, and for the most part are not oviposited; 90% of the few that are oviposited are fragile, lacking a chorion. That this phenotype is somatic in origin is demonstrated by the observation that homozygous germline clones produce morphologically normal eggs; some of these eggs undergo a few abortive nuclear divisions, but they never reach an identifiable stage of oogenesis. The maternal-effect lethality partially suppressible by *rut*, which reduces adenylate cyclase activity. The earliest defect seen in the embryos produced by *dnc rut* females occurs soon after fertilization and affects DNA replication and mitosis, prevents nuclear migration, and leads to large polyploid nuclei; a later defect prevents cleavage nuclei from migrating into, or dividing in, the posterior region of the egg, affecting the developmental behavior or fate of blastoderm cells. The few surviving offspring of double-mutant females show frequent developmental abnormalities of the second and third thoracic, and the first five abdominal segments; these include deficiencies, duplications, and transformation of structures; some 15% of the daughters of such females lack one or both ovaries (Livingstone, Sziber, and Quinn, 1984, Cell 37: 205-15; Bellen, Gregory, Olsson, and Kiger, 1987, Dev. Biol. 121: 432-44; Bellen and Kiger, 1988, Roux's Arch. Dev. Biol. 197: 258-68).

<i>dnc</i> <sup>ML</sup>	EMS			amorph

α Associated with *T(1;3)dnc*<sup>CK</sup> = *T(1;3)3C-D4;63C*.  
 β *dnc*<sup>M11</sup> maps 0.04 map unit to the left of the other *dnc* alleles. Also, two molecularly defined "iso-alleles", resulting from transposon insertions at the locus that may have accompanied intragenic recombination events, have been characterized at high resolution (Pittler and Davis, 1987, Mol. Gen. Genet. 208: 325-28).

**cytology:** Placed in 3C11-D4, with exons 1 and 2 at 3C11 and exons 3-13 in 3D4 (Chen, Malone, Beckendorf, and Davis, 1987, Nature 329: 721-24). Claimed to be uncovered by *Df(1)N64i16* = *Df(1)3C2-3;3D4-5*, but not

*Df(1)N64j15* = *Df(1)3C3-5;3D3-4* (Kiger and Golanty, 1977, *Genetics* 85: 609-22).

**molecular biology:** Both cDNA and genomic DNA cloned and sequenced (Davis and Davidson, 1984, *Mol. Cell. Biol.* 4: 358-67; Chen *et al.*). Genomic DNA at the locus identified in part by intragenic recombination events and following RFLPs as markers (see Pittler, Salz, and Davis, 1987, *Mol. Gen. Genet.* 208: 315-24 for further information on such recombination and putative gene conversion events). Gene comprises 13 exons, with exons 1 and 2 being separated from the remainder by an intron of 79 kb; this intron contains at least two and perhaps four genes, including *Pigl* (transcribed from the opposite strand) and *Sgs4* plus another developmentally regulated transcript (transcribed off the same strand as *dnc*); *sam* may also be encoded within the 79 kb intron (Chen, Malone, Beckendorf, and Davis, 1987, *Nature* 329: 721-24). A probe from the region of exon 6 identifies polyadenylated RNA's of 9.5, 7.4, 7.2, 7.0, 5.4, and 4.2 kb in RNA from adult flies; exons 1 and 2 share homology with the 9.5 kb mRNA and at least one of about 7.2 kb. The 5.4 kb species found in all developmental stages; the 9.6-, 7.4-, 7.2-, and 7.0-kb species found in late embryos and beyond; the 4.5-kb species found in early embryos and adults but not elsewhere (Davis and Davidson, 1986, *Mol. Cell. Biol.* 6: 1464-70). cDNA clones representing part of transcript contains an open reading frame that could define a 40,000 dalton polypeptide; the deduced amino acid sequence exhibits greater than 50% sequence identity with bovine Ca<sup>2+</sup>/calmodulin-dependent cyclic nucleotide phosphodiesterase; lesser and more restricted regions of homology seen with cAMP-dependent protein kinase and *Aplysia californica* egg-laying hormone precursor. Genomic clones reveal the presence of five introns in the sequence containing this open reading frame (Chen, Denome, and Davis, 1986, *Proc. Nat. Acad. Sci. USA* 83: 9313-17).

**other information:** *Df(1)N71h24/Df(1)dm75e19* females survive, even though they are completely deleted for some five bands, including 3D4; such females are defective in learning and are sterile. *dnc*<sup>M11</sup>-induced sterility partly suppressed by *rut* (Livingstone *et al.*, 1984), and this phenotype of the double mutant used to select two new purported *rut* alleles, one of which (*rut*<sup>2</sup>) also suppresses learning defects associated with *dnc*<sup>M14</sup> (Feany, 1990, *Proc. Nat. Acad. Sci. USA* 87: 2795-99).

### **Doa: Darkener of apricot**

**location:** 3-99.

**references:** Rabinow and Birchler, 1989, *EMBO J.* 8: 879-89.

**phenotype:** Homozygous larval lethal, but in heterozygotes causes the *copia* insertion allele *w*<sup>a</sup> and some of its revertants to produce more pigment than usual; not only in the eye, but in the ocelli, testis sheath, and Malpighian tubules as well; enhances *w*<sup>sp55</sup> resulting in less than normal pigmentation; other tested alleles not affected. Flies carrying three copies of the wild-type allele of *Doa* lighten *w*<sup>a</sup> and darken *w*<sup>sp55</sup>. *Doa* also darkens *z w*<sup>a</sup> in homozygous females. Heterozygotes for *Doa*<sup>1</sup> or *Doa*<sup>2</sup> and *Doa*<sup>6</sup> or *Doa*<sup>7</sup> survive rarely, and when they do, *w*<sup>a</sup> is darkened to nearly wild-type color; *w*<sup>sp55</sup> reacts in the

opposite manner, becoming nearly white; eyes of escapers have disarranged facets. Males of these heteroallelic combinations involving *Doa*<sup>6</sup> are sterile despite having motile sperm; females and both sexes involving *Doa*<sup>7</sup> are weakly fertile.

**dor: deep orange**

**location:** 1-0.3.

**origin:** X ray induced.

**discoverer:** E.D. King.

**references:** Merrell, 1947, *Am. Naturalist* 81: 399-400.

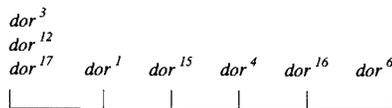

Counce, 1956, *Z. Indukt. Abstamm. Vererbungsleh.* 87: 443-61 (fig.).

Bischoff and Lucchesi, 1971, *Genetics* 69: 453-66.

**phenotype:** *dor* mutants affect a number of developmental processes; severity of effect increases with increasing developmental temperature. Eye color orange, shade depending on allele and temperature. *dor* reduces eye pigmentation in combination with either *cn* or *v* or with *bw*, indicating reduction in both drospterins and xanthommatin. Biochemical analyses show xanthommatin and five drospterins to be reduced to different degrees in *dor*; levels, but not relative proportions, change according to temperature of development (Counce, 1957, *Experientia* 13: 354; Puckett and Petty, 1980, *Biochem. Genet.* 18: 1221-28). Reciprocal transplantation experiments show that eye color is autonomous (Hadorn and Counce). *dor* females produce no progeny in crosses to *dor* males at 25°, although some allelic combinations able to produce progeny at 18°; and a few *dor*/+ daughters are produced in crosses to + males. Germ-line clones homozygous for the lethal allele *dor*<sup>28</sup> produce collapsed eggs (Perriman, Egstrom, and Mahowald, 1989, *Genetics* 121: 333-52). The lethal embryos produced by *dor* mothers reach gastrulation or beyond (Hildreth and Lucchesi, 1967, *Dev. Biol.* 15: 536-52; Counce, 1969, *DIS* 44: 101-82). Maternal effect shown to be germ line autonomous by both ovarian (Garen and Gehring, 1972, *Proc. Nat. Acad. Sci. USA* 69: 2982-85) and pole-cell transplantation (Marsh, van Deusen, Wieschaus, and Gehring, 1977, *Dev. Biol.* 56: 195-99). Maternal lethal effect rescuable by injections into preblastoderm embryos of cytoplasm from

unfertilized eggs of normal females (Garen and Gehring, 1972); *dor*<sup>+</sup> substance present during early stages of vitellogenesis but not detected in yolk of cellular blastoderm embryos (Marsh *et al.*, 1977). Abnormalities of *dor* cells in culture eliminated by extracts of normal post- but not pregastrulation embryos (Kuroda, 1977, Dev. Growth Differ. 19: 57-66). *dor* males show variable extents of gonadal dysgenesis depending on culture conditions and genotypic background; abnormalities range from failure of testes to attach to genital ducts to failure of one attached testis to elongate (Lucchesi, Counce, and Hildreth, 1968, J. Exp. Zool. 168: 437-50). Viability and longevity of *dor* homozygotes and hemizygotes variably reduced depending on allele and temperature; *dor*<sup>1</sup> larvae develop melanotic pseudotumors (Stark, 1918, J. Exp. Zool. 27: 509-29; Oftedal, 1953, Z. Indukt. Abstamm. Vererbungsl. 85: 408-22) and midgut occlusion (Russell, 1940, J. Exp. Zool. 84: 363-79), dying in late third instar (Bischoff and Lucchesi, 1971). *dor/dor*<sup>1</sup> lethal at 29° (Belyaeva, Aizenzon, Semeshin, Kiss, Koczka, Baritcheva, Gorelova, and Zhimulev, 1980, Chromosoma 81: 281-306). *dor* in combination with *ry*, *ry*<sup>2</sup> (Lucchesi, 1968, Genetics 59: 37-44) and *car* (Nash, 1971, DIS 47: 73) causes lethality in pupal stage. Recovery of gynandromorphs with *dor car* male sectors less than in controls; bilateral gynandromorphs not observed, but distribution of male tissue resembles that of control (Grell, 1976). *dor* behaves as a semilethal in combination with *pd* and with *cn bw* (Lucchesi, 1968).

**alleles:** Mutants can be arranged in a linear sequence of increasing strengths; heterozygotes between different pairs of alleles show intermediate phenotypes; no evidence of interallelic complementation (Bischoff and Lucchesi, 1971). Recombinational mapping by Bischoff (1973, DIS 50: 172) established the order illustrated.

Genetic fine structure map of the **deep orange** locus.

**origin:** Spontaneous.

**discoverer:** Bridges, 36c28.

**phenotype:** Bristles very short and slender, nearly as small as *ss*. Males entirely sterile; testis shape normal. Sper-

**dow:** downy

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 64.

miogenesis arrested shortly after meiosis; nebenkern formation abnormal; spermatids degenerate after slight elongation [Kiefer, 1973, Genetic Mechanisms of Development (F.H. Ruddle, ed.). Academic Press, New York, London, and San Francisco, pp. 47-102]. Spermatocyte nuclei exhibit reduced amounts of Y-chromosome-dependent structures (Kiefer, 1973). Viability good. RK2.

### **Dox-A1: Diphenol oxidase A1 subunit**

**location:** 2-{80.6}.

**references:** Deng and Rizki, 1988, Genome 30, Suppl. 1: 192.

**phenotype:** Enzyme detectable in embryos at ten hours and remains throughout development and adult life. A1 band more intense than those of subunits A2 and A3.

**alleles:** Monomorphic in *D. melanogaster*, but two bands present in *D. melanogaster* X *D. simulans* hybrids.

**cytology:** Placed in 55A based on its inclusion in *Df(2R)PC4 = Df(2R)55A;55F* and *Df(2R)Pcl11B = Df(2R)54F6-55A1;55C1-3* but not *Df(2R)Pcl-W5 = Df(2R)55A-B;55C*. as detected in *D. melanogaster* X *D. simulans* hybrids. *Bc* and *Phox* occupy the same cytological interval.

### **Dox-A2: Diphenol oxidase A2 subunit**

**location:** 2-53.9.

**synonym:** *l(2)37Bf<sup>+</sup>*.

**references:** Pentz, Black, and Wright, 1986, Genetics 112: 823-41.

Pentz and Wright, 1986, Genetics 112: 843-59.

Wright, 1987, Adv. Genet. 24: 127-222.

**phenotype:** The structural gene for the A2 component of phenol oxidase, which utilized diphenol substrates. Developmentally regulated; levels low until just prior to pupariation; dramatic rise to maximum at puparium formation, followed by reduced, but still high, levels throughout pupal stage, again decreasing at eclosion (Geiger and Mitchell, 1966, J. Insect Physiol. 12: 755-

65). Heterozygotes for lethal alleles show reduced diphenol oxidase activity; homozygotes die as first instar larvae; dead larvae do not turn black. One homozygous *Dox-A2<sup>1</sup>* escaper reaching pharate adult stage was liberated from the pupa case; it was chalk white, devoid of any cuticular pigment; cell lethal; no homozygous clones observed for any of the lethal alleles.

**alleles:** Most alleles are larval lethals; *Dox-A2<sup>mfs1</sup>* homozygotes are also lethal, but hemizygotes display 60% normal adult viability and, although diphenol oxidase activity is normal, females and males are sterile.

<sup>α</sup> 1 = Pentz, Black, and Wright, 1986, Genetics 112: 823-41; 2 = Wright, Black, Bishop, Marsh, Pentz, Steward, and Wright, 1982, Mol. Gen. Genet. 188: 18-26.

**cytology:** Localized to a region between 14.3 and 16.8 kilobases long in 37B10-13 between the right-hand breaks of *Df(2L)hk-UC1* and *Df(2L)OD15*.

**molecular biology:** Genomic clone isolated in a chromosome walk through the *Ddc* region. The 1.7 kb transcription unit is processed to an 1.66 kb mRNA which encodes a basic protein of 56 kD made up of 494 amino acids. A single mRNA is present at varying levels throughout development.

### **Dox3**

**location:** 2- [placed between *rdo* and *M(2)36F* by Rizki; however, placed to the right of *pr* by Pentz and Wright].

**discoverer:** Rizki.

**references:** Rizki and Rizki, 1985, Genetics 110: s98.

Rizki, Rizki and Bellotti, 1985, Mol. Gen. Genet. 201: 7-13.

**phenotype:** Apparently the structural gene of the A<sub>3</sub> component of phenol oxidase.

**alleles:** Electrophoretic variants exist.

**cytology:** Placed in 36D1-E4 based on its location in the region common to *Df(2L)H20 = Df(2L)36A89;36E3-4* and *Df(2L)M-HS5 = Df(2L)36D1-E1;36F1-37A1*. However, placed to the right of 37D1-2 by Pentz and Wright based on the failure of the following overlapping deficiencies to delete it: *Df(2L)H20 = Df(2L)36A7-10;36E4-F1*, *Df(2L)TW203 = Df(2L)36E4-F1;37B9-C1*, and *Df(2L)TW130 = Df(2L)37B9-C1;37D1-2* (Wright, 1987, Adv. Genet. 24: 127-222).

### **dp: dumpy**

**location:** 2-13.0.

**references:** Carlson, 1959, Genetics 44: 347-73 (fig.).

Southin and Carlson, 1962, Genetics 47: 1017-26 (fig.).

Grace, 1980, Genetics 94: 647-62.

**phenotype:** *dp* alleles have variable effects on wing length and shape and on the thoracic cuticle. Presence of wing phenotype indicated by *o* = oblique in the allelic designation and of thoracic phenotype by *v* = vortex or *cm* = comma. The wing effect is an oblique truncation affecting the margins of the first and second posterior cells in

weak alleles and reducing wings to approximately half normal length in extreme genotypes, where the truncation is more nearly perpendicular to the long axis of wing. Margins remain intact; angle between veins L2 and L5 increased, and intercrosvein distance decreased. Phenotype resembles rudimentary. Thoracic phenotype comprises five types of hypodermal irregularities: first vortices, second vortices, commas, pre-episternal pits, and posterior invagination; all five have the form of pits, eruptions, or raised pits of the cuticle (Metcalf, 1970, Genetics 65: 627-54). First vortices are hypodermal pits or eruptions located posterolaterally on the scutum; they disrupt the acrostichal rows, resulting in surrounding whorls of microchaete. Second vortices are located anterolaterally on the scutum and resemble first vortices morphologically. Commas are comma-shaped depressions at the anterior margin of the scutum. The pre-episternal pit is in the pre-episternal plate immediately anterior to the sternopleural chaetae, which sometimes exhibit disturbed orientation (Metcalf, 1969, DIS 44: 91). The posterior invagination occurs between the laterotergite plate and the metanotum (Metcalf, 1969); different alleles exhibit different combinations of these traits. Musculature attached to disturbed regions of the cuticle often degenerates (Metcalf, 1970). Some alleles show reduced body size and small weak legs (*dp<sup>h</sup>*, *dp<sup>obw</sup>* females, *dp<sup>olv</sup>/dp<sup>ov</sup>*). Phenotypic expression enhanced by increased temperature during development; wing and thorax effects show dominance when heterozygotes exposed to increased temperatures at 12-16 and 8-10 hr of pupal life, respectively (Blanc and Child, 1940, Physiol. Zool. 13: 65-72). Normal larvae fed 6-azauracil produce adults with oblique phenocopies; 6-azauracil feeding suppresses *dp* (Rizki and Rizki, 1965, Science 150: 222-23), *su(r)* enhances the oblique phenotype (Stroman, 1974, Hereditas 78: 157-68). The four genotypes studied [*dp<sup>o2</sup>*, *dp<sup>ovN</sup>*, *dp<sup>v2</sup>*, and *dp<sup>v</sup>*; *e(dp<sup>v</sup>)*] show increased orotate phosphoribosyl transferase activity during third larval instar and enhanced incorporation of labeled glucose into chitin (Blass and Hunt, 1980, Mol. Gen. Genet. 178: 437-42). Many alleles are lethal when homozygous; they are identified by *l* in the allelic designation. Lethal stages vary among alleles, e.g., *dp<sup>olv</sup>* is embryonic lethal; *dp<sup>lv1</sup>*, and *dp<sup>lv1</sup>* die at the egg-larval boundary; *dp<sup>lm</sup>* homozygotes die primarily at larval ecdysis between the first and second larval instar with some death at hatching and at ecdysis of second-instar larvae; *dp<sup>obm</sup>* homozygotes die mostly at hatching but a few die during first and second larval instars (Metcalf, 1971, Genet. Res. 17: 173-83).

In *Me/+* heterozygotes, many *dp* alleles show a dominant oblique effect when heterozygous for *dp<sup>+</sup>* and *dp*; *dp<sup>v</sup>* is an exception (Carlson, 1959). *dp<sup>v</sup>* homozygotes normal; show thoracic phenotype only if third chromosomes homozygous for *e(dp<sup>v</sup>)*.

**alleles:** One, two, or three of the phenotypic attributes of *dp* (*o*, *l*, or *v*) may be expressed in an allele, and alleles are classified according to which attributes they exhibit; the information is generally included in the superscript designation; the order *olv* is roughly in accord with map order. As a rule, the heteroallelic combination of any two alleles exhibits only phenotypic features common to the two alleles [e.g., *dp<sup>o</sup>/dp<sup>v</sup>* is normal, and *dp<sup>ov</sup>/dp<sup>lv</sup>* exhibits thoracic but not wing abnormalities (Carlson,

1959)]. Partial complementations between some pairs of *olv* and *l* or *lv* alleles are exceptions to this rule (Carlson, 1959; Grace, 1980). Identified alleles are tabulated below.

discontinuously distributed alleles; *o* and *olv* alleles found in several clusters, other phenotypic classes confined to a single cluster.

*Dp*: see *Dr*

***dpl*: duplicated legs**

**location:** Not located.

**origin:** Derived from ethyl-methanesulfonate-treated flies.

**synonym:** *dl*.

**references:** Mglinetz, 1979, Ontogenez 10: 602-08.

Mglinetz and Ivanov, 1980, Ontogenez 11: 277-85.

**phenotype:** Some 6.7% of the flies of this strain show duplicated tarsi and in some instances tibiae; primarily involves mesothoracic legs. Distribution of bristles on leg and its duplicate agree with polar coordinate model (French, Bryant, and Bryant, 1976, Science 193: 969-81) of regeneration and duplication initiated in region of cell death. Phenotype resembles that of heat-pulsed *su(f)<sup>ls726</sup>*. Produces duplicated antennal legs in combination with *ss<sup>ak</sup>*, and both leg and its duplicate four jointed in combination with *ff* (Mglinetz, 1980, Ontogenez 11: 542-44). No genetic analysis reported.

**dpp: decapentaplegic (W.M. Gelbart)**

**location:** 2-4.0.

**discoverer:** E. Novitski (original *ho* mutation). R. Tung and W. Gelbart (original multi-disk *dpp* mutation).

**synonym:** *ho*, *blk*, *shv*, *DPP-C*, *Hin-d*, *Tg*.

**references:** Spencer, Hoffmann, and Gelbart, 1982, *Cell* 28: 451-61 (fig).

Segal and Gelbart, 1985, *Genetics* 109: 119-43 (fig).

Irish and Gelbart, 1987, *Genes Dev.* 1: 868-879 (fig).

St. Johnson, Hoffman, Blackman, Segal, Grimalia, Padgett, Irick, and Gelbart, 1990, *Genes Dev.* 4: 1114-27.

**phenotype:** *dpp* is a complex locus affecting numerous developmental events. Mutations fall into three major genetic and phenotypic groupings: called shortvein (***shv***), Haplo-insufficiency (***Hin***) and imaginal disk-specific (***disk***). Each group maps to a different region of the *dpp* gene. *Hin*-region mutations have two distinguishing features: they are defective in normal dorsal-ventral patterning of the embryo, and they generally fail to complement mutations of the *shv* and *disk* types. *shv*-region mutations all show recessive defects in longitudinal wing vein formation. *disk*-region mutations exhibit pattern deletions in the adult epidermal derivatives of the imaginal disks. The phenotypes of most *shv/disk* heterozygotes suggest partial or full complementation of the *shv* and *disk* lesions. Within each of the three major groupings, several phenotypic classes of alleles have been identified. Complementation between certain combinations of *dpp* alleles is transvection sensitive (Gelbart, 1982, *Proc. Nat. Acad. Sci. USA* 79: 2636-40).

The genetic properties of the several classes of *dpp* mutations are outlined below. For a given class, the prototypical recessive phenotypes are inferred from examinations of trans heterozygotes for two different alleles of that class. This procedure obviates possible complications due to the frequent association of *dpp* mutations with gross chromosomal rearrangements. Particular allelic combinations may deviate from the prototypical descriptions.

***Hin*-region**

***emb*:** Embryonic lethal mutation. Homozygous viable, but recessive lethal in combination with *hin-r* alleles, and, in the latter background, exhibits the same weakly ventralized phenotype as *hin-r* homozygotes. Completely complements all *shv*- and *disk*-region mutations. The sole *emb* allele is associated with a small deletion in *Hin*-region.

***Hin*:** Haplo-insufficient mutations. *Hin/+* heterozygotes exhibit dominant embryonic lethality with the same weakly ventralized phenotype as *hin-r* homozygotes. Dominant lethality is rescued by duplication of *dpp*<sup>*Hin+*</sup>. Homozygotes are defective in gastrulation and die as embryos with completely ventralized cuticle. In general, *Hin* alleles do not complement any other *dpp* mutations. However, *Hin* alleles associated with small deletions or point mutations exhibit transvection effects in heterozygotes with small deletions or insertions in the *shv* and *disk*-regions. *Hin* mutations are considered the null alleles of the *dpp* gene. *Hin* alleles are associated with breakpoints, small deletions or point mutations in the *Hin*-region.

***Hin-Df*:** Haplo-insufficient mutations which behave identically to breakpoint *Hin* mutations, except that *Hin-Df*

lesions are gross deletions removing the entire *dpp* gene and adjacent vital loci.

***hin-r*:** Recessive mutations behaving as milder versions of the *Hin* lesions. In homozygotes, *hin-r* mutations exhibit embryonic lethality with weak ventralization effects (identical to *emb/hin-r* or *Hin/+* heterozygotes). All *hin-r* mutations engender temperature-sensitive mutant phenotypes when heterozygous with *shv*- and *disk*-region mutations. Phenotypes elicited in heterozygotes with small deletions, or insertions in the *shv* and *disk* regions are transvection sensitive. All *hin-r* mutations are cytologically normal and show no alterations in their restriction maps. Some have been associated with point mutations in the *Hin*-region.

***shv*-region**

***shv-lc*:** Recessive larval-lethal shortvein alleles which complement all *disk*-region mutations. Exhibit mutant phenotypes in heterozygotes with all *shv*, *Hin*, and *hin-r* mutations. Mutations generally associated with rearrangement breakpoints.

***shv-lnc*:** Recessive larval-lethal shortvein alleles which do not complement *disk*-region mutations. Also exhibit mutant phenotypes in heterozygotes with all *shv*, *Hin*, and *hin-r* mutations. Mutations generally associated with rearrangement breakpoints.

***shv-p*:** Recessive shortvein alleles surviving at least to pharate adult. Only two alleles are known; one (*s11*) is adult viable; exhibits strong venation defects, and variable head capsule defects, including loss of palps, and misarranged vibrissae. Allelic to all *shv*, *Hin*, and *hin-r* mutations. Complement all *disk*-region mutations. Both alleles are associated with rearrangement breakpoints.

***shv-w*:** Recessive viable and fertile shortvein alleles exhibiting only venation defects. Associated with small deletions of the *shv*-region. Venation phenotype allelic to all *shv*, *Hin*, and *hin-r* mutations. *shv-w/Hin*, and *shv-w/hin-r* mutant phenotypes are transvection sensitive. Only two alleles are known; both are associated with small deletions in the *shv*-region.

***Tg*:** A dominant gain-of-function allele in which the tegula on the wing appears duplicated. *Tg/+* wings are held out and down. Distinct in phenotype from heldout (*d-ho*) homozygotes. *Tg* completely complements all *dpp* mutations. The dominant effects of *Tg* can be reverted by superimposing *shv*, *Hin*, or *hin-r* mutations on the *Tg* chromosome. The one *Tg* allele is associated with a rearrangement breakpoint in or near the *shv*-region.

***disk*-region**

***disk-blk*:** Recessive viable and fertile allele in which the only mutant phenotype is loss of 80-90% of ommatidia in eye; hence this allele was designated *blink* by Sparrow (unpublished). Exhibits mutant eye phenotypes in heterozygotes with *disk-III*, *disk-V*, *Hin*, and *hin-r* mutations. Can exhibit transvection effects. The one *disk-blk* allele is associated with a small deletion within the *disk*-region.

***disk-ho*:** Recessive viable and fertile alleles in which the only mutant phenotypes are heldout wings and loss of the Sc25 on the dorsal base of the wing. Heldout phenotype displayed in heterozygotes with all *disk*-region mutations except *d-blk*, and with *Hin* and *hin-r* mutations. Can exhibit transvection effects. In addition to the one mutant allele listed here, which is associated with a small deletion within the *disk*-region, several cytologically normal *disk-ho* alleles have been associated with mobilization of

*hobo* mobile elements residing in the *disk*-region.

*disk-II*: Recessive viable alleles. Homozygotes exhibit reductions in wing blade, haltere and male genitalia. Elicit mutant phenotypes in heterozygotes with all *disk*-region mutations except *d-blk*, and with *Hin* and *hin-r* mutations. Mildest class of *disk*-region alleles associated with rearrangement breakpoints.

*disk-III*: Recessive viable alleles. Homozygotes exhibit multiple pattern abnormalities in epidermis of head, thorax, and terminalia. Structures absent or reduced include labial palps, arista, eye, wing blade, capitellum of haltere, tarsal claws, male terminalia, and female analia. Elicit mutant phenotypes in heterozygotes with all *disk*-region mutations, and with *Hin* and *hin-r* mutations. Intermediate class of *disk*-region alleles associated with rearrangement breakpoints.

*disk-V*: Recessive early pupal lethal alleles. Homozygous larvae have greatly reduced imaginal disks. Elicit mutant phenotypes in heterozygotes with all *disk*-region mutations and with *Hin* and *hin-r* mutations. Most severe class of *disk*-region alleles associated with rearrangement breakpoints.

*t*: Recessive larval-lethal alleles. Allelic to all *disk*, *Hin*, and *hin-r* mutations. The only two known alleles of this class behave identically to *disk-V* lesions, except for the earlier recessive lethal period. Tentatively classified as part of the *disk*-region. These two mutations are associated with breakpoints which map between the two tRNA<sup>tyr</sup> genes residing at the *Hin*—*disk-V* boundary. Hence the *t* designation is used to describe these alleles.

α This mutation was induced upon *dpp hr4*, complicating its mutant classification.

β Broken in 22F of the normal distal 2L copy of *dpp* and in 22C of the *Dp(2;2)dpp d21* insertion into 52F.

**cytology:** Localized to 22F1-2 based on common breakpoints of numerous mutant rearrangements and *in situ* hybridization of cloned *dpp* DNA.

**molecular biology:** These phenotypic classes fall into discrete regions of the *dpp* map. The order of these groups on the chromosome from (distal to proximal) is:

[*shv-w, shv-p*] *shv-lc shv-lnc* [*Hin, hin-r*] *t disk-V disk-III disk-II disk-ho*

Several alternatively initiated and alternatively spliced transcripts encode a single 588-amino-acid long polypeptide which is a member of the transforming growth factor-β family of secreted factors (Padgett, St. Johnston, and Gelbart, 1987, Nature 325: 81-84). The open reading frame encoding the *dpp* polypeptide is contained in two exons located entirely within the *Hin*-region. Transcripts are localized dorsally at blastoderm in the dorsal ectodermal region during early germ band elongation and in two stripes, one dorsal and one lateral during late germ band extension and germ band shortening. Also expressed in two blocks in the embryonic visceral mesoderm (St. Johnston and Gelbart, 1987, EMBO J. 6: 2785-91). For proper ontogeny of normal *disk*-region functions *dpp* is required and expressed just anterior to the A/P compartment boundary in imaginal disks (Posakony *et al.*, 1990, submitted).

#### **dpt: depilated**

**location:** 3- (not mapped).

**origin:** Spontaneous.

**references:** DeAngelis, 1972, DIS 49: 39.

**phenotype:** Loss of thoracic and head bristles during first week of adult life. Hairs unaffected. Penetrance 100%; viability excellent.

#### **\*dpy: dumpoidy**

**location:** 3- (right arm near 90).

**origin:** Spontaneous.

**discoverer:** Vilee, 40a.

**phenotype:** Wings obliquely truncated and reduced in length; marginal vein intact. No vortices or whorls of bristles on thorax. Suppressed by *Cy* and *Gla*, made dominant by *Me*. Overlaps wild type slightly. RK2.

*dq*: see *L dq*

#### **\*dr: droopy**

**location:** 2-71.2 (to the left of Lobe).

**origin:** Ultraviolet induced.

**discoverer:** Meyer and Edmondson, 49c.

**references:** 1949, DIS 23: 60.

**phenotype:** Wings spread wide apart and droop down-

ward, like *c*, often crumple and drag in food. Alula broad and short. Viability at hatching fair; females tend to die before males. Penetrance 100%. Fertility good. RK2.

**other information:** Not allelic to *c*.

*dr*: see *drw*

#### **Dr: Drop**

**location:** 3-99.2.

**phenotype:** Heterozygotes have extremely reduced numbers of facets, 1-10 in the case of *Dr<sup>1</sup>* and *Dr<sup>A</sup>*; ~30 facets coalesce to give shiny, dark red appearance in *Dr<sup>Mio</sup>*; five to seven rhabdomeres per ommatidium section; some rhabdomeres fuse. Developing eye disc reduced in size; morphogenetic furrow uneven; few clusters of presumptive photoreceptor cells; arrangement disturbed; microvillar caps blurred and diffuse (Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29).

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<b>Dr<sup>1</sup></b>	X ray	Krivshenko, 54c25	<i>Dp</i>	2	homozygous lethal

#### **drb: dark red brown**

**location:** 3-47.7 (may be rearrangement; *st-p* crossing over 50% of normal).

**origin:** Spontaneous.

**discoverer:** Rosin, 48b.

**references:** 1951, DIS 25: 75.

**phenotype:** Eye color dark red-brown at 18° and dark red at 28°. *drb/+* darker than wild type at 18° but not at 28°. RK2(A).

#### **drd: drop dead (J.C. Hall)**

**location:** 1- (between *v* and *f*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Hotta and Benzer, 1972, Nature (London) 240: 527-35.

Hotta and Benzer, 1973, Genetic Mechanisms of Development (F.H. Ruddle, ed.). Academic Press, New York, London, and San Francisco, pp. 129-67 (fig.).

Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89.

**phenotype:** After normal development and normal behavior of young adults, flies begin to walk in uncoordinated manner and rapidly die (all dead by approximately ten days posteclosion); before death, there are gross holes in brain; mosaic experiment suggests primary defect is in brain. Second allele (*drd<sup>2</sup>*) causes similar effects with rapid death of population 9-11 days post eclosion plus reduced female fertility.

**alleles:** *drd<sup>1</sup>* (Hotta and Benzer), *drd<sup>2</sup>* (Homyk *et al.*).

**other information:** Not allelic to any of six adult-lethal (*adl*) genes mapping between *v* and *f*.

**drg: dregs** (*T. Schüpbach*)

**location:** 2-38.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Schüpbach and Wieschaus.  
**phenotype:** Maternal-effect lethal mutant; embryos from homozygous mothers form a fragmented cuticle with variable holes and head defects.  
**alleles:** *drg*<sup>1</sup> isolated as *HC*.

*Drl*: see *so*<sup>D</sup>  
**droop wings:** see *drp*

**droopy:** see *dr*  
**droopy wing:** see *drw*

**Drop:** see *Dr*  
**drop dead:** see *drd*

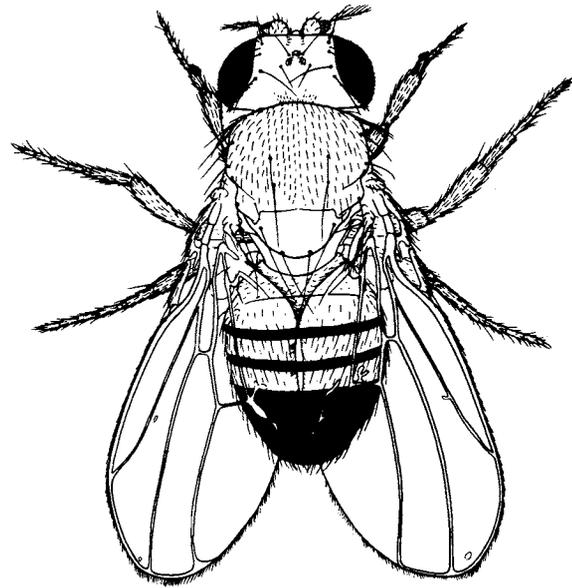

**Droplet:** see *so*<sup>D</sup>  
**Drosophila-interferon-like-protein:** see *Difl*  
**Drosulfakinin:** see *Dsk*

**\*drp: droop wings**  
**location:** 1- (rearrangement).  
**origin:** Spontaneous.  
**discoverer:** Ives, 48f.  
**references:** 1949, DIS 23: 58.  
**cytology:** Associated with *In(1)drp = In(1)12B;20B*.

**\*drw: droopy wing**  
**location:** 1-52.3.  
**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine.  
**discoverer:** Fahmy, 1953.  
**synonym:** Symbol originally *dr*, which was preoccupied.  
**references:** 1958, DIS 32: 69.  
**phenotype:** Small fly with drooping wings. Chitin of abdomen irregularly ridged and pigmented. Hairs deranged. Males infertile; viability 10% wild type. RK3.

**ds: dachsous**  
**location:** 2-0.3.  
**phenotype:** Wings shorter, blunter, and broader; crossveins uniformly very close together. Abdomen and legs chunky. Slight dominance of close crossveins. Stronger alleles may exhibit enhanced dominance, reduced viability, female sterility, delayed emergence, widely spaced scutellar bristles, and erect costal bristles. Strong interaction with *d*, *ffj*, and *cg*; double homozygotes often have excessive growth of thoracic parts and sometimes conversion of one organ into another {e.g., hypertrophy of notum, duplication of wings and antennae, and transformations of tarsus to arista, eye to antenna or palpus, or wing to notum [Waddington, 1943, J. Genet. 45: 29-43 (fig.); 1962, New Patterns in Genetics and Development, Columbia University Press, pp. 208-15 (fig.)]}. Tarsal shortening enhanced by homozygous *ss*<sup>a</sup> and *ss*<sup>ab</sup> (Vilée, 1945, Genetics 30: 26-27). RK1.

Indukt. Abstamm. Vererbungsl. 50: 113-200 (fig.); 9 = Roberts, Brock, Rudden, and Evans-Roberts, 1985, Genetics 109: 145-56; 10 = Stern and Bridges, 1926, Genetics 11: 511.  
<sup>β</sup> *ds* = dachsous-wide classified as RK1 as heterozygote.

**cytology:** Analysis by E.B. Lewis (1945, Genetics 30: 137-66) indicates that *ds* is located in 21D1-2 or possibly slightly to the left in the last band of 21C. Placed in 21C8-D1 by deficiency analysis [Golubovsky, Kulakov, and Korochkina, 1978, Genetika (Moscow) 14: 294-305] and in 21D1-2 by deficiency analysis by Roberts *et al.*

**dsh: dishevelled**  
**location:** 1-34.05.  
**references:** Perrimon and Mahowald, 1987, Dev. Biol. 119: 587-600 (fig.).  
 Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52.  
**phenotype:** Most alleles lethal, but *dsh*<sup>1</sup>, although poorly viable as homozygous females or hemizygous males,

appears to be fully viable when heterozygous to a deficiency for the region, suggesting that the reduced viability is unrelated to *dsh*. *dsh*<sup>1</sup> flies have deranged thoracic hairs, divergent and blistered wings, and ellipsoid eyes. Leg bristles, hairs, and bracts display high frequencies of abnormal polarity; extra joints or joint primordia found frequently in the first and second tarsal joints of the first and second pairs of legs; of 270 ectopic joints, 268 displayed inverted polarity [Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57 (fig.)]. Males and females fertile, males weakly so. Homozygotes and hemizygotes for the lethal alleles die as second- to early-third-instar larvae when derived from heterozygous mothers; when derived from homozygous germ-line clones, on the other hand, embryos with segment-polarity defects result; only ventral cuticle is present, covered with a lawn of setae; lack dorsal cuticle, posterior spiracles and filzkörper material. At six to seven hours maxillary and labial segments appear to be missing and parasegmental boundaries do not form; cell death apparent in vicinity of tracheal pits, which subsequently fuse; segmental boundaries fail to form; organization of central nervous system seems normal. Loss of cells of posterior segment compartments leads to discontinued production of *en*<sup>+</sup> product. Viability of *dsh*<sup>1</sup>/*dsh*<sup>3</sup>, for example, when derived from homozygous *dsh*<sup>3</sup> oogenic clones, is normal, indicating that *dsh*<sup>1</sup> is wild type for the early function.

**cytology:** Placed in 10B3-8 based on its inclusion in *Df(1)N71 = Df(1)10B5;10D4* but not in *Df(1)DA622 = Df(1)10B8;10D2*.

**Dsk: Drosulfakinin**

**location:** 3-{47}.

**references:** Nichols, Schnewly, and Dixon, 1988, J. Biol. Chem. 263: 12167-70.

**phenotype:** Encodes a Drosophila homologue of the vertebrate neuropeptide, cholecystokinin (CKK), which the authors dub drosulfakinin (DSK). *In situ* hybridization of antisense probes detects *Dsk* transcripts in regions of the adult brain, specifically the protocerebrum.

**cytology:** Placed in 81F by *in situ* hybridization.

**molecular biology:** Genomic clones isolated with synthetic probe based on the highly conserved C-terminal pentapeptide of vertebrate CKK and gastrin and cockroach leucosulfakinin peptides. cDNA clones corresponding to one class of recovered genomic clones detect a single poly(A)<sup>+</sup> RNA of about 800 nucleotides on Northern blots. cDNA sequence indicates a protein product of 128 amino acids with a potential signal

sequence (residues 2-18) and two drosulfakinins, DSK-I (residues 101-110) and DSK-II (residues 113-127); these as well as a third sequence, DSK-0 (residues 63-70), are flanked by consensus pro-hormone processing sites and contain C-terminal glycyl residues, potential amidation sites. DSK-I and DSK-II sequences display identity with five of eight C-terminal residues of vertebrate cholecystokinin. DSK-0 represents a novel peptide.

**dsl: discless**

**location:** 1-35.

**synonym:** *l(1)dsl*.

**references:** Kiss, Bencze, Fekete, Fodor, Gausz, Maróy, Szabad, and Szidonya, 1976, Theor. Appl. Genet. 48: 217-26.

**phenotype:** Larval lethal; no disc tissue detected either by dissection of mature larvae or by serial sectioning of young larvae. *dsl* tissue does not survive in gynandromorphs nor in homozygous ovarian clones. No mitotic figures found in larval brain cells (Gatti and Baker, 1989, Genes Dev. 3: 438-53).

**dsp: dispersed**

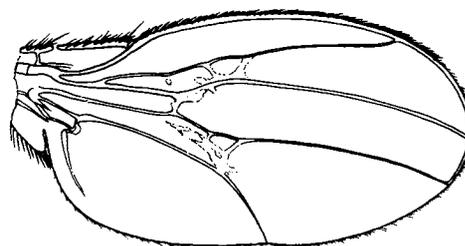

**location:** 1-55.6.

**origin:** Induced by ethyl methanesulfonate.

**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20.

**phenotype:** Recessive lethal; embryonic cuticle normal; Malpighian tubules dispersed.

**cytology:** Placed in 15A4-F2 based on its being covered by *Dp(1;3)j<sup>+</sup>71b = Dp(1;3)15A4;16C2-3;80-81* and mapping genetically to the left of *f* at 15F1-2.

**dsr: disrupted**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 71.

***dsr: disrupted*****location:** 2-90.**origin:** Spontaneous.**discoverer:** Curry, 38a28.**phenotype:** Wings have plexus of extra and doubled veins at anterior and posterior crossveins and at L3 and L4. L3 and L4 spread wide apart. Wing slightly wider and warped. At 25°, overlaps wild type; at 19°, no overlap but viability reduced to 60% wild type. RK3.*Dsrc*: see *C-src***\**dss: disturbed segmentation*****location:** 1-27.3.**origin:** Spontaneous.**discoverer:** Fahmy, 1954.**references:** 1959, DIS 33: 85.**phenotype:** Extremely abnormal abdomen with segmentation grossly deformed, very few hairs, and disturbed pigmentation. Occasionally some bristles shortened. Eyes reduced in size and sometimes abnormal in shape. Males fertile; viability about 10% wild type. Females sterile. RK3.***dsx: double sex (B. J. Taylor)*****location:** 3-48.1.**references:** Hildreth, 1965, *Genetics* 51: 659-78.Baker and Ridge, 1980, *Genetics* 94: 383-423.Baker and Belote, 1983, *Ann. Rev. Genet.* 17: 345-93.Nöthiger, Leuthold, Andersen, Gerschwiler, Gruter, Keller, Leist, Roost, and Schmid, 1987, *Genet. Res.* 50: 113-23.Baker and Wolfner, 1988, *Genes Dev.* 2: 477-89.Burtis and Baker, 1989, *Cell* 56: 997-1010.**phenotype:** The *dsx* gene regulates sexual differentiation of somatic tissues. Null alleles convert chromosomally male and female flies into sterile intersexes of similar phenotype. Dominant alleles (e.g., *dsx<sup>D</sup>*, *dsx<sup>M</sup>*, *dsx<sup>T</sup>*) transform females into intersexes when heterozygous with a normal allele, and into phenotypic males when homozygous or heterozygous with a *dsx*-null allele or deficiency, but they have no effect in males. Most alleles at *dsx* affect both sexes; however, some alleles affect only one sex. The recessive allele *dsx<sup>II</sup>* converts males into intersexes and is complemented by dominant *dsx* alleles and recessive alleles that affect only females (*dsx<sup>22</sup>*) (Baker and Ridge; Nöthiger *et al.*, 1987). Double-mutant combinations of *dsx* null mutations with loss-of-function alleles at *tra*, *tra2*, and *ix* result in a doublesex phenotype (Mukherjee and Hildreth, 1971, *Genetica* 42: 338-52; Baker and Ridge; Nöthiger *et al.*, 1987). Double-mutant combinations of *dsx<sup>D/+</sup>* with null alleles of *tra* and *tra2* convert females into phenotypic males or with *ix* into more male-like intersexes (Baker and Ridge; Nöthiger *et al.*, 1987). The dose of *dsx* alleles can alter the phenotype; triploid female flies *dsx<sup>D/+/+</sup>* are sterile and with a weak external *dsx* phenotype (Gowen and Fung, 1957; Nöthiger *et al.*, 1987); diploid female flies that are *dsx<sup>D/+</sup>*, but also carry a *dsx<sup>+</sup>* duplication *Tp(3;Y)P92* are sterile but female in appearance (Nöthiger *et al.*, 1987). Germline sexual differentiation is not dependent on *dsx<sup>+</sup>* function; only the chromosomal constitution determines the sex of transplanted *dsx<sup>M/+</sup>*, *dsx<sup>I</sup>*, *dsx<sup>D/+</sup>*, and *dsx<sup>D/dsx<sup>I</sup></sup>* germ cells (Nöthiger, Roost, and Schüpbach, 1980, DIS 55: 118; Schüpbach,1982, *Dev. Biol.* 89: 117-27). The *dsx<sup>+</sup>* gene does not appear to encode any vital functions (Baker and Ridge). The normal body size differences between male and female flies is maintained in *dsx*-null mutants (Hildreth) and in females heterozygous for *dsx<sup>D/+</sup>*, *dsx<sup>D/dsx<sup>I</sup></sup>* (Fung and Gowen, 1957; Baker and Ridge) and *dsx<sup>M/+</sup>* (Nöthiger *et al.*, 1987). The sexcomb bristles on the prothoracic basitarsus in both sexes of *dsx*-null homozygotes (Hildreth; Mukherjee, and Hildreth; Baker and Ridge) and female *dsx<sup>D/dsx<sup>I</sup></sup>* (Nöthiger *et al.*, 1987) are intermediate in number, morphology, and position compared with the sexcomb bristles in normal males and the transverse row bristles in normal females. The central sexcomb bristle is retained in *dsx*-null mutants (Hildreth). In *dsx*-null mutants, the pigmentation of the fifth tergite is intermediate between the completely pigmented male and the posteriorly pigmented female tergite, whereas the sixth tergite is darkly pigmented (Hildreth; Baker, and Ridge). Female flies that are *dsx<sup>D/+</sup>* or *dsx<sup>M/+</sup>* are similar to *dsx* homozygotes (Fung and Gowen, 1957; Duncan and Kaufman, 1975, *Genetics* 80: 733-52; Baker and Ridge; Nöthiger *et al.*, 1987). Male *dsx* flies have a seventh tergite and sternite with bristles (Hildreth; Baker, and Ridge). Female flies heterozygous for dominant alleles and either *dsx<sup>I</sup>* or *dsx* deficiencies have the male number of tergites and sternites with the male pattern of pigmentation (Duncan and Kaufman, 1975; Baker and Ridge; Nöthiger *et al.*, 1980; Nöthiger *et al.*, 1987). By clonal analysis, the action of *dsx* has been shown to be cell autonomous in the differentiation of the sexcombs and pigmentation of the abdominal tergites; *dsx<sup>+</sup>* is required until the end of the larval period for the proper sexual differentiation of the sexcombs and into the pupal period, close to the time of the termination of divisions of the abdominal histoblasts, for proper sexual differentiation of the abdominal histoblasts and for proper sexual differentiation of the abdomen (Baker and Ridge). Both male and female genitalia are formed in *dsx* null mutant flies and in female flies heterozygous for dominant alleles (Fung and Gowen, 1957; Hildreth, 1965; Epper, 1981, *Dev. Biol.* 88: 104-14; Nöthiger *et al.*, 1987); a second penis differentiates with a reduced aedeagus and parameres within the female vaginal area (Hildreth). In *dsx<sup>D/+</sup>* females, the development of the female genitalia and second penis are very similar to that of *dsx*-null flies, whereas in *dsx<sup>M/+</sup>* females the female genitalia are more severely reduced (Gowen and Fung, 1975; Baker and Ridge; Nöthiger *et al.*, 1980; Epper, 1981; Nöthiger *et al.*, 1987). Male genitalia from *dsx* null flies and females heterozygous for *dsx* dominant alleles contain all elements except a basal apodeme but other external structures such as the penis and accessory elements are reduced and not as well formed (Fung and Gowen, 1957; Hildreth; Epper, 1981). The internal duct systems develop but can vary between dual female and male ducts and a single poorly differentiated duct (Hildreth); a similar range of phenotypes for the internal ducts is found in *dsx<sup>D/+</sup>* (Fung and Gowen, 1957) and *dsx<sup>M/+</sup>* (Nöthiger *et al.*, 1980). Based on fate mapping and analysis of the morphogenesis of the *dsx<sup>D/+</sup>* genital disc, the female genitalia and second penis are generated from the female genital primordium, and the male genitalia from the male genital primordium and the production of both types of genitalia in *dsx* flies results from derepression of both

genital primordia (Epper, 1981; Epper, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 280-84). The intersexual analia differentiate as lateral plates, which are smaller than normal male lateral anal plates and do not have the ventral anal plate found in females (Hildreth; Baker, and Ridge; Epper, 1981). The bristle pattern is rather male-like but with one clearly identifiable long dorsal bristle that is female (Epper, 1981). The gonads are often rudimentary, but occasionally female *dsx*-null as well as *dsx<sup>D/+</sup>* flies have well developed ovaries and eggs (Hildreth, Fung, and Gowen, 1957; Schüpbach, 1982; Bownes, Dempster, and Blair, 1983, J. Embryol. Exp. Morph. 75: 241-57) whereas in male *dsx*-null flies, the gonads are poorly developed and no sperm are formed (Hildreth; Schüpbach, 1982). Female and male *dsx* flies and female *dsx<sup>D/+</sup>* flies make yolk protein but in amounts less than for normal females (Postelthwait, Bownes, and Jowett, 1980, Dev. Biol. 79: 379-87; Ota, Fukunaga, Kawabe, and Oishi, 1981, Genetics 99: 429-41). In *dsx<sup>D/+</sup>* females less yolk protein synthesis occurs compared to normal females; little or no yolk protein mRNA is made in the rudimentary gonads, but measurements from adult flies show that from an initially low level yolk protein transcripts increase to nearly wild-type levels but without efficient conversion into protein (Bownes, Dempster, and Blair, 1983). The male-specific transcripts 316, 355a, and 355b, made by the male accessory gland, are also produced in male flies rendered intersexual by the mutation *dsx<sup>11</sup>*, which does not affect female flies; in addition, females that are *dsx<sup>D/+</sup>* or *dsx<sup>M/+</sup>* express the male-specific transcripts, although at reduced levels (Chapman and Wolfner, 1988, Dev. Biol. 126: 195-202). Females homozygous for *dsx* do not exhibit male courtship behaviors (McRobert and Tompkins, 1985, Genetics 111: 89-96; B. Taylor, unpublished). These *dsx* females do not make 7, 11 dienes, and 7 monoenes compared to normal females (Jallon, 1984, Behav. Genet. 14: 441-78); they elicit less courtship than *dsx<sup>+</sup>* females from control males (McRobert and Tompkins, 1985). Female flies that are *dsx<sup>D/+</sup>* or *dsx<sup>M/+</sup>* also fail to express male courtship behaviors (Duncan and Kaufman, 1975; B. Taylor, unpublished). Males homozygous for *dsx* court but show reduced levels of courtship directed toward females and young males and greater-than-normal levels of courtship directed at mature males (McRobert and Tompkins, 1985). Mature *dsx* males make some pheromonal substances (Jallon, 1984) and elicit more courtship than *dsx<sup>+</sup>* males from control males (McRobert and Tompkins, 1985). Female flies homozygous for *dsx*-null alleles or mutant for *dsx* dominant alleles do not make the male-specific abdominal muscle unlike their male siblings (B. Taylor, unpublished).

<sup>α</sup> 1 = Baker and Belote, 1983, Ann. Rev. Genet. 17: 345-97; 2 = Baker, Hoff, Kaufman, and Hazelrigg, 1990, Genetics in press; 3 = Baker and Wolfner, 1988, Genes Dev. 2: 477-9; 4 = Denell and Jackson, 1972, DIS 48: 44-45; 5 = Duncan and Kaufman, 1975, Genetics 80: 733-52; 6 = Gowen and Fung, 1957, Heredity 11: 397-402; 7 = Hildreth, 1965, Genetics 51: 659-78; 8 = Mischaikow, 1959, DIS 33: 99; 9 = Nöhiger, Leuthold, Andersen, Gerschwiler, Gruter, Keller, Leist, Roost, and Schmid, 1987, Genet. Res. 50: 113-23; 10 = Nöhiger, Roost, and Schüpbach, 1980, DIS 55: 118; 11 = Puro, 1964, DIS 39: 64-65; 12 = Nagoshi and Baker, 1990, Genes Dev. 4: 89-97.

**cytology:** Placed in 84E1-2 based on breakpoints common to rearrangements associated with revertants of dominant alleles; located between the distal breakpoint of *Df(3R)Antp17 = Df(3R)84B1-2;84D11-12* (Baker et al., 1990) and the third chromosome breakpoint of *T(2;3)Es = T(2;3)48A3-4;84E3-4*.

**molecular biology:** Analysis of transcripts from the *dsx* region shows both male- and female-specific transcripts (Baker and Wolfner, 1988). Male-specific transcripts of approximately 3.8 and 2.8 kb are present in larvae and adults, with an additional 0.7 kb transcript in adult males (Baker and Wolfner, 1988; Burtis and Baker, 1990, Cell 56: 997-1010). The female-specific transcript around 3.5 kb is present in larvae and adults (Baker and Wolfner; Burtis and Baker). Based on mapping and sequencing of cDNA clones there are three common 5' exons, one female specific 3' exon, and two male specific 3' exons. The conceptual proteins encoded by the male and female *dsx* mRNA's contain 549 and 427 amino acids respectively (Burtis and Baker). Male and female *dsx* transcripts also differ with respect to the 3' polyadenylation site (Burtis and Baker). Within the female exon are six repeats of thirteen nucleotides found 3' to the acceptor site for the female exon (Burtis and Baker). Four dominant mutations (*dsx<sup>D</sup>*, *dsx<sup>M</sup>*, *dsx<sup>S</sup>*, and *dsx<sup>T</sup>*) have been mapped and sequenced and found to have lesions 3' to the acceptor site in the female exon but do not disrupt the intron or the acceptor site (Baker and Wolfner; Nagoshi and Baker, 1990, Genes Dev. 4: 89-97). Three of the dominant mutations (*dsx<sup>D</sup>*, *dsx<sup>M</sup>*, and *dsx<sup>T</sup>*) are insertions of repetitive elements and one, *dsx<sup>S</sup>*, is a small deletion. Using sex-specific probes, female flies heterozygous for a dominant allele have been shown to make both male- and female-specific *dsx* mRNA's, whereas females carrying a dominant allele in combination with a *dsx* deficiency make only the male-specific mRNA (Nagoshi and Baker). Chromosomally female flies that are homozygous for the hypomorphic *Sxl*<sup>2593</sup> or *tra* and *tra2* null mutations produce only the male-specific *dsx* transcript whereas *ix* mutant females make female-specific *dsx* transcript of normal size and abundance (Nagoshi and Baker). Male flies that overexpress a *Hsp-tra* cDNA that

produces only the female-specific *tra* mRNA make the female-specific *dsx* mRNA and are transformed into phenotypic females (McKeown, Belote, and Boggs, 1988, Cell 53: 887-95).

**\*Dt: Detached**

**location:** 2-10.

**discoverer:** Bridges, 17e11.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 224.

**phenotype:** Vein L2 fails to reach margin in 60% of flies. Homozygote not known. RK3.

**other information:** Bridges considered this a possible effect of *S* or requiring *S* as an enhancer as it was found in a *S* stock and apparently was never separated from *S*.

**\*dta: delta wing**

**location:** 1- (rearrangement).

**origin:** Induced by triethylenemelamine.

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 69.

**phenotype:** Wings widely outspread, frequently drooping in homozygous female. Viability good; female sterile. RK2A.

**cytology:** Associated with *In(1)dta = In(1)6B2-3;15E7-F2*.

*dTKR*: see *Tkr*

*dtv*: see *thv<sup>d</sup>*

**\*du: dunkel**

**location:** 3-47.

**origin:** Spontaneous.

**discoverer:** Hadorn, 49e15.

**references:** Hadorn and Fritz, 1950, Arch. Julius Klaus-Stift. Vererbungsforsch. Sozialanthropol. Rassenhyg. 25: 504-8.

**phenotype:** Body color dark, sootylike. Wings blistered. Viability almost normal at 25°, greatly reduced at 18°. Males fertile; females sterile. Ovaries and eggs normal size and morphology. Insemination of females normal (motile sperm in spermathecae and receptaculum). Either eggs from *du* females not fertilized or zygotes die before blastoderm formation. *du* ovaries behave autonomously as implants in normal hosts, and wild-type ovaries are fertile in *du* hosts. RK2 at 25°.

**other information:** Not an allele of *by* or *cu*; possibly an allele of *db* (3-44.8)

**dumpoidy:** see *dpv*

**dumpy:** see *dp*

**dunce:** see *dnc*

**dunkel:** see *du*

**duplicated legs:** see *dpl*

**dusky:** see *dy*

**dusky body:** see *dwb*

**\*dv: divergent**

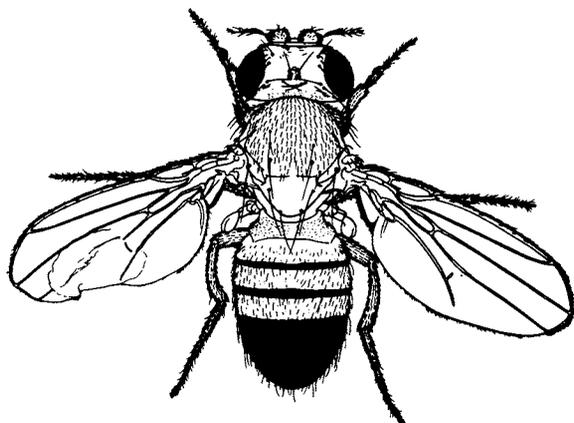

**location:** 3-20.0.

**origin:** Spontaneous.

**discoverer:** Bridges, 17f13.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 182 (fig.).

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet.

**dv: divergent**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 182.

2: 58 (fig.).

Mohr, 1937, DIS 8: 12.

**phenotype:** Wings spread, smaller, and have slight venation disturbances. Both sexes rather infertile. *dv/Df(3L)Vn* progeny of homozygous *dv* mothers practically lethal, although the same genotype from other crosses survives (Mohr and Mossige, 1943, Avh. Nor. Vidensk.-Akad. Oslo, Mat.-Naturvidensk. Kl. No. 7: 1-51). RK2.

**alleles:** *dv*<sup>2</sup> described as *aea* by Valade del Rio (1983, DIS 59: 161); same phenotype and map position as *dv*.

**cytology:** Salivary chromosome locus placed between 64C12 and 65E1 on basis of its inclusion in *Df(3L)Vn = Df(3L)64C12-D1;65D2-E1* (Mohr, 1938, Avh. Nor. Vidensk.-Akad. Oslo, Mat.-Naturvidensk. Kl. No. 4: 1-7).

**dv2**

**location:** 2-71.

**origin:** Spontaneous.

**references:** Aguado, Galán-Estella, and González-Gulián, 1988, DIS 67: 109.

**phenotype:** Wings adopt a divergent orientation with respect to the longitudinal-axis of the body when at rest.

**dvr: divers**

**location:** 1-28.1 (located using *dvr*<sup>2</sup>).

**phenotype:** Has shorter, darker wings; postscutellars bowed in; body size small; sterility high; semilethal. In combination with yellow-bodied *y* alleles, gives strongly curled wings with slight outward twist; with *f*, gives crumpled wings, with *sc*, almost lethal. RK3.

allele	origin	discoverer	ref <sup>α</sup>
<i>dvr</i> <sup>1</sup>	iodine <sup>β</sup>	Sacharov, 1932	1, 3, 5
<i>dvr</i> <sup>2</sup>	spont	Curry, 37k17	1
<i>dvr</i> <sup>84</sup>	heat <sup>γ</sup>	Green, 84k24

<sup>α</sup> 1 = CP627; 2 = Muller, 1946, DIS 20: 67; 3 = Sacharov, 1936, Biol. Zh. 5: 537-40 (fig.); 4 = Sacharov, 1937, DIS 8: 81.

<sup>β</sup> Recovered among progeny of iodine-treated male.

<sup>γ</sup> Recovered among progeny of female exposed to 37° as first instar larva.

**cytology:** Placed to the right of 8D8-9 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book - Carnegie Inst. Washington 41: 191).

**dvr<sup>2</sup>**

**phenotype:** Practically wild type. With *y*<sup>2</sup>, wings tightly curled; with *y*, wings spirally curled. RK2 with *y*.

**dvr<sup>84</sup>**

**phenotype:** Produces divers phenotype when hemizygous in *y*<sup>2</sup> or *In(1)y<sup>3PLsc</sup>8R* (i.e., *y<sup>-</sup>ac<sup>-</sup>*), but not *y<sup>+</sup>* males; *y<sup>2</sup> dvr<sup>84</sup>/y<sup>59b</sup>y* males are *y<sup>+</sup>* and *dvr* in phenotype. Homozygous females that are *y<sup>2</sup>* or *y<sup>2</sup>*; *tra* exhibit normal phenotype.

**dvr<sup>s</sup>: divers-subliminal**

**phenotype:** Wild type either alone, heterozygous to *dvr*<sup>2</sup>, or in combination with *y. y dvr<sup>s</sup>/y dvr<sup>2</sup>*, on the other hand, has wings distinctly curly or wavy, usually as in typical Cy, but other effects noted in *dvr* flies not evident. RK3.

**\*dvw: divergent wings**

**location:** 1-13.3.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine.

**discoverer:** Fahmy, 1953.

**references:** 1959, DIS 33: 85.

**phenotype:** Sex-limited character. Males late hatching; wings divergent, occasionally upheld with inner margins frequently cut away to various degrees. Bristles short and stiff. Homozygous females normal. RK1 in males.

**\*dw: dwarf**

**location:** 3-50.

**origin:** Spontaneous.

**discoverer:** Bridges, 13k12.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 101.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 58 (fig.).

**phenotype:** Body weight 76% that of heterozygous sibs. Females usually sterile (3 of 63 gave a few offspring). RK3.

**dw-24E: dwarf in salivary chromosome section 24E**

**location:** 2-13.

**synonym:** *dw-24F*.

**references:** 1941, DIS 14: 49.

**phenotype:** Body small; abdomen narrow and misshapen. Body surface dull, as if not properly dried. Eyes dull in color and smallish. Wings close textured, small, and tend to droop; crossveins close. Bristles slender. Low viability and fertility. RK3.

**alleles:**

**cytology:** Placed in 24E2-F1 based on its inclusion in *Df(2L)dp-h25 = Df(2L)24E2-3;25B2-5* but not in *Df(2L)dp-h19 = Dp(2L)24E5-F1;24F7-25A1* (Szidonya and Reuter, 1988, Genet. Res. 51: 197-208).

**\*dw-b: dwarf-b**

**location:** 3-12.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 20b5.  
**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 182, 228, 231 (fig.).  
**phenotype:** Flies about 70% as heavy as wild type. RK3.

**\*dw-sc: dwarf with scute**

**location:** 1-0.7.  
**origin:** Spontaneous (arose with *sc* and separated).  
**discoverer:** Bridges, 16a22.  
**phenotype:** Small body. Viability erratic. RK3.

**dwarf unexpanded:** see *dwu*

**dwarfex:** see *dwx*

**dwarfish:** see *dwh*

**dwarfoid:** see *dwf*

**dwarp:** see *svr*

**\*dwf: dwarfoid**

**location:** 1-13.3.  
**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine.  
**discoverer:** Fahmy, 1955.  
**references:** 1959, DIS 33: 85.  
**phenotype:** Flies small. Males fertile; viability about 50% wild type. Homozygous females show extreme expression. Fertility and viability low. RK2.

**dwg: deformed wings**

**location:** 1-1.47.  
**phenotype:** Most alleles lethal, dying during the first larval instar; the semilethal allele, *dwg*<sup>7</sup>, ceases development from the second instar on, with a few individuals surviving to adulthood. Lethal alleles (*dwg*<sup>4</sup>, *dwg*<sup>5</sup>, *dwg*<sup>6</sup>, and *dwg*<sup>8</sup>) can be recovered as males in combination with variegating duplications, *Dp(1;3)N*<sup>264-58</sup>, *Dp(1;3)w*<sup>m49a</sup>, and *Dp(1;4)w*<sup>m65g</sup>; have rough reduced dark eyes, sparse vibrissae, often missing orbital, ocellar, and vertical bristles, thickened wing veins, and incised inner wing margins; such males with a *Y* are fertile; *XO* males are not recovered at 25°. Of these alleles only *dwg*<sup>7</sup> survives as *XO* tissue in gynandromorphs; homozygous germ-line clones in females fail to produce eggs (Garcia-Bellido and Robbins, 1983, Genetics 103: 235-47). *dwg*<sup>1</sup> recorded as having broad, round tipped wings, with occasional marginal incisions and sometimes grossly deformed in shape and venation; extremely fine bristles, and small occasionally rough eyes. Surviving males with any allele are sterile.

<sup>β</sup> Spontaneous in the paternal X chromosome of a cross between wild-type males and *mei-9* females, such that the F<sub>1</sub> females were *dwg/mei-9*.

**cytology:** Placed in 3B5 by Judd, Shen, and Kaufman (1972, Genetics 71: 139-56).

**other information:** Allelism of *dwg*, *l(1)zw5*, and *ves* inferred from similarity in genetic location and phenotype (Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56).

**dwh: dwarfish**

**location:** 3- (not located).  
**origin:** Spontaneous.  
**discoverer:** Bridges, 30d16.  
**phenotype:** Small body. Wings disproportionately broad; eyes irregularly knobby and somewhat dull in color; legs weak and slightly crippled. RK3.

*dwp*: see *svr*

**\*dwu: dwarf unexpanded**

**location:** 1-58.3.  
**origin:** Induced by 2-chloroethyl methanesulfonate.  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 85.  
**phenotype:** Extremely inviable dwarf; wings frequently fail to expand completely. Males fertile if they survive to breed. RK3.

**dwx: dwarfex**

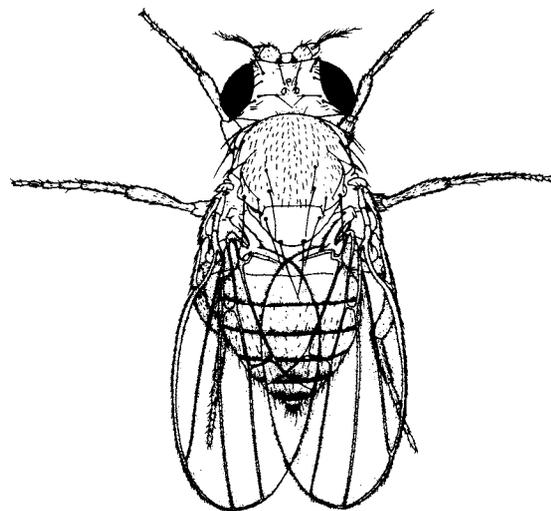

**location:** 1-33.2.  
**discoverer:** Bridges, 33c31.  
**phenotype:** Body small. Wing texture coarse; marginal hairs slightly disarranged. Classification sometimes difficult. RK3.

*dwx*<sup>mn</sup>: see *mn*

**dx: deltex****location:** 1-17.0.**origin:** Spontaneous.**discoverer:** Bridges, 22h26.**references:** Morgan, Bridges, and Schultz, 1931, Year Book - Carnegie Inst. Washington 30: 410.**phenotype:** Veins show thickenings and terminal deltas; resembles *Dl* in third chromosomes except fully viable, fertile, and easily classified. Nearly suppressed by *su(dx)*, *Su(dx)*, and *Su(dx)*<sup>2</sup>. RK2.**alleles:** An allele called *dx<sup>fl</sup>* recovered from natural population by Berg (see Golubovsky, 1983, DIS 59: 42-43) is actually a double mutant also carrying a *P*-factor induced *Sxl<sup>f</sup>* allele (Belote). Another allele *dx<sup>SIM</sup>* was obtained by Schalet.**cytology:** Demerec and Sutton show locus to be between 6A3-4 and 6F10-11 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book - Carnegie Inst. Washington 41: 191).**dx<sup>st</sup>: deltex-sterile****origin:** Spontaneous change of *dx* to *dx<sup>st</sup>*.**discoverer:** Bridges, 31a3.**phenotype:** Veins heavy, confluent, and dilated at junctions; strong deltas at tips. Wings spread wide; margins and tips snipped and nicked. Ocelli sometimes fused with disturbance of hairs and bristles in the region. Acrostichals irregular. Male sterile. Less abnormal phenotype and fertile with *Su(dx)*. RK2.**dy: dusky****location:** 1-36.2 (to the right of *m*).**origin:** Spontaneous.**discoverer:** Bridges, 1611.**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 35 (fig.), 224.

Slatis and Willermet, 1954, Genetics 39: 45-58.

Dorn and Burdick, 1962, Genetics 47: 503-18.

**phenotype:** Wings smaller than normal but of nearly wild-type shape, dusky in color. Cell expansion inhibited in prepupal as well as pupal period (Waddington, 1940, J. Genet. 41: 75-139). Partially suppressed by *su(f)* (Dudick, Wright, and Brothers, 1974, Genetics 76: 487-510). RK1.**alleles:** *\*dy<sup>2</sup>*, *\*dy<sup>3</sup>*, *\*dy<sup>31d</sup>*, *\*dy<sup>58k</sup>*, *\*dy<sup>60k</sup>*, *\*dy<sup>61a</sup>*, *\*dy<sup>62b</sup>*, *\*dy<sup>286-9</sup>*, *\*dy<sup>ala</sup>* (CP627); *\*dy<sup>73</sup>* (Green, 1975, Mutat. Res. 29: 77-84) presumably induced by insertion of a transposable element; apparently reverted coincidentally with appearance of the mutable *m* allele *m<sup>fl</sup>*.**cytology:** Located at 10E2 (Lefevre, 1981, Genetics 99: 461-80).**other information:** The mutant *And*, a rhythmic variant, has a *dy* phenotype and some newly isolated *dy*'s exhibit aberrant (long-period) circadian rhythms.**\*dyb: dusky body****location:** 1-44.6.**origin:** Induced by ethyl methanesulfonate.**discoverer:** Fahmy, 1958.**references:** 1959, DIS 33: 85.**phenotype:** Dusky body color and browner eyes. Eye and wing shapes slightly altered. Males viable and fertile; females sterile. RK2.**dy: dusky**

Edith M. Wallace, unpublished.

**e: ebony**

**location:** 3-70.7.

**discoverer:** E. M. Wallace, 12b15.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 50 (fig.).

**phenotype:** Body color varies from shining black to slightly darker than wild type, depending on allele. Puparia much lighter than wild type. Classifiable throughout larva period by darkened color of spiracle sheaths (Brehme, 1941, Proc. Nat. Acad. Sci. USA 27: 254-61). Viability lowered to about 80% wild type. Heterozygotes for dark alleles have slightly darker body color than normal. For interaction with other body color mutants, see Waddington (1941, Proc. Zool. Soc. London, Ser. A 111: 173-80). Postulated to encode  $\beta$ -alanyl dopamine synthetase, a 90-kd enzyme that requires ATP and  $MgCl_2$  to catalyze the formation of N- $\beta$ -alanyl dopamine from  $\beta$  alanine and dopamine;  $\beta$  alanyl dopamine absent from newly eclosed *e* flies (Wright, 1987, Adv. Genet. 24: 127-222);  $\beta$  alanine and dopamine accumulate in pupae and pharate adults, dopamine to twice normal levels, in *e* and *e<sup>11</sup>* homozygotes; levels return to normal in older adults (Hodgetts, 1972, J. Insect Physiol. 18: 937-47; Hodgetts and Konopka, 1973, J. Insect Physiol. 19: 1211-20). Unable to utilize  $\beta$  alanine in tanning of puparium. Labeled  $\beta$  alanine or uracil injected into *e* pupae remains in hemocoel, not incorporated into pupal case as in +; light-colored pupa result; *e*/+ intermediate in these respects. Only newly emerged + adults incorporate uracil or  $\beta$  alanine into cuticle; *e* flies and older + flies do not;  $\beta$  alanine toxic to the latter two types (Jacobs, 1968, Biochem. Genet. 1: 267-75). Defect in tanning leads to spongy cuticle which responds to  $\beta$  alanine administration (Jacobs, 1980, Biochem. Genet. 18: 65-76). Phenylthiocarbamide inhibits development of *e<sup>11</sup>* homozygotes more than wild type; reverse is true for inhibition by silver chloride; heterozygotes intermediate in both cases. Mixtures of the two inhibitors affect heterozygotes to a greater extent (Kroman and Parsons, 1960, Nature 186: 411-12). Electroretinograms of *e* flies abnormal; lamina potential reduced or absent (Hotta and Benzer, 1969, Nature 222: 354-56). Threshold for phototaxis 200-fold higher than that for wild type; high sensitivity (retinulae 1-6) optomotor threshold 500 times normal and high acuity (retinulae 7 and 8) optomotor threshold ten times normal [Heisenberg, 1972, Information Processing in the Visual Systems of Arthropods (R. Wehner, ed.). Springer-Verlag, Berlin, Heidelberg, and New York, pp. 265-68]. *e* flies more sensitive to polarized light than wild type (Heisenberg, 1972). Abnormal distribution of uptake of <sup>3</sup>H-GABA by the lamina ganglionaris described by Campos-Ortega (Cell Tissue Res. 147: 415-31). Reduced mating success compared to wild type (Rendel, 1951, Evolution 5: 226-30). Courtship frequently aborts owing to mismounting by male [Crossley and Zuill, 1970, Nature (London) 225: 1064-65]; relative mating success increased in dark (Kyriacou, 1981, Anim. Behav. 29: 462-71) but not according to Crossley (1970, DIS 45: 170). Courtship shows deficiency in wing vibration; low proportion of sine song and long intrapulse interval; *e*/+ outsings +/+ (Kyriacou, Burnet, and Connolly, 1978, Anim. Behav. 26: 1195-1206). RK1.

**alleles:** Changes at *e* not known to be associated with

deficiency for the locus tabulated below. *e<sup>1</sup>* inseparable from *In(3R)C*; stocks labeled as carrying *e*, but not *In(3R)C*, for the most part carry *e<sup>4</sup>* (Craymer).

<sup>α</sup> 1 = Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. 327: 59, 99, 184; 2 = CP627; 3 = Ives, 1965, DIS 40: 55; 4 = Scalenghe and Ritossa, 1976, Atti Accad. Lincei 13: 439-528; 5 = Stern, 1926, Z. Indukt. Abstamm. Vererbungsl. 41: 198-215; 6 = Villee, 1941, DIS 14: 40; 7 = Villee, 1942, Univ. Calif. Berkeley, Publ. Zool. 49: 137; 8 = Ward and Alexander, 1957, Genetics 42: 42-54; 9 = Zurcher, 1963, Genetics 34: 1-33 (fig.).

<sup>β</sup> Probably independent of *e* mutation.

**cytology:** Placed in 93D2-6 by D'Alessandro, Ritossa, and Scalenghe (1977, DIS 52: 46) based on its being the position of the breakpoint common to a number of *e* rearrangements. Probably at the left end of this region based on *Df(3R)e671 = Df(3R)93B5-7;93D3* (Korge, 1972, DIS 48: 20) and *Df(3R)e-H5 = Df(3R)93B10-13;93D2-3* (Henikoff, 1980, DIS 55: 61-62).

**E74: Ecdysone-inducible gene encoded in region 74 (W.A. Segraves)**

**location:** 3-{45}.

**synonym:** *Eip74EF*.

**references:** Burtis, 1985, PhD Thesis, Stanford University. Janknecht, Taube, Lüdecke and Pongs, 1989, Nucleic Acids Res. 17: 4455-64.

Burtis, Thummel, Jones, Karim and Hogness, 1990, Cell 61: 85-99.

Thummel, Burtis and Hogness, 1990, Cell 61: 101-11.

**phenotype:** Encodes an ecdysone-inducible gene associated with the early puff at 74E-F. Periodic expression of the gene follows, by approximately one hour, pulses of ecdysone occurring during development; two periods of expression occur independently of ecdysone pulses, one at the end of embryogenesis and one at the end of pupal development. Return to base line levels of expression requires protein synthesis and presumably results from repression by ecdysone-induced gene products; *in situ* hybridization to larvae detects transcription of *E74* in most tissues, both imaginal and strictly larval.

**alleles:** Two mutant alleles selected by Burtis (1985); one dies in the pharate-adult stage, whereas the other is a prepupal lethal, showing defects in larval shortening and cuticular tanning; a low frequency of defective prepupae

reach the pharate adult stage.

allele	origin	discoverer	synonym	comments
<b>E74<sup>1</sup></b>	X ray	Burtis, 1985	<i>E74<sup>x1001</sup></i>	pharate adult lethal; <i>T(2;3)29A-C;74E-F</i> <sup>α</sup>
<b>E74<sup>2</sup></b>	EMS	Burtis, 1985	<i>E74<sup>e3109</sup></i>	prepupal lethal

<sup>α</sup> Broken in first intron of the long transcript.

**cytology:** Placed in early ecdysone-inducible puff at 74E-F by *in situ* hybridization.

**molecular biology:** The gene is 6 kb in length; three different transcripts produced by transcription from right to left. The long transcript comprises eight exons and is dispersed over all 6 kb; the mature message encodes a protein of 829 amino-acids and 87.1 kd. The other two transcripts are shorter and are initiated from promoters 300 base pairs apart in the fifth of seven introns of the long transcript; they have four exons, the last three being the same as those of the long transcript; thus the proteins share their C-terminal sequences but have different N-terminal ends; both short transcripts encode the same polypeptide of 833 amino acids and 94.7 kd. The sequences indicate a polypeptide with an acidic N terminus and a basic C terminus separated by a region of homopolymeric repeats. A segment of 84 amino acids in the C-terminal end shows 50% identity with a similarly situated sequence in the protein encoded by the human *c-ets-2* oncogene. Thummel *et al.* demonstrate that *E74* is transcribed at 1.1 kb per minute such that an hour is required from the time of ecdysone stimulation until the first mature transcripts are produced.

### **E75 (W.A. Segraves)**

**location:** 3-{46}.

**synonym:** *Eip75*.

**references:** Segraves, 1988, PhD Thesis, Stanford University.

Feigl, Gram, and Pongs, 1989, *Nucleic Acids Res.* 17: 7167-78.

Segraves and Hogness, 1990, *Genes Dev.* 4: 204-19.

**phenotype:** Encodes an ecdysone-inducible gene associated with the early puff at polytene position 75B. Periodic expression occurs in response to ecdysone pulses occurring at specific times during development; regression of puff and reduction of *E75* expression in third instar does not occur in the presence of cycloheximide, and presumably depends on ecdysone-induced gene products.

**alleles:** 28 alleles recovered by Segraves (1988), falling into two groups, one displaying early lethality (early larval for the combinations examined) and one displaying pharate-adult lethality.

<sup>α</sup> Breaks in the long transcription unit immediately downstream from the first exon.

<sup>β</sup> Breaks immediately downstream from the first exon of the *E75 A* transcription unit; chromosome has an associated, possibly complex, inversion from 67B to the base of 3R.

<sup>γ</sup> Removes the entire *E75* gene and eliminates the 75B puff.

<sup>δ</sup> Lost.

**cytology:** Placed in early ecdysone-inducible puff at 75B by *in situ* hybridization.

**molecular biology:** 350 kb from 75B region cloned and used to identify two overlapping ecdysone-responsive transcription units; *E75 A* and *E75 B*. The *E75 A* unit contains six exons spread over 50 kb, and gives rise to mRNA's of 4.9 or 5.7 kb by use of alternate polyadenylation sites within the final exon. The *E75 B* unit begins within the second intron of *E75 A* and contains five exons, the final four of which are shared with *E75 A*, and produces mRNA's of 5.2 and 6.0 kb. The polypeptides encoded by the two thus contain different N termini and a common C terminus. The *E75 A* polypeptide contains 266 unique and 971 shared amino acids for a molecular weight of 132 kd; the *E75 B* polypeptide contains 422 + 971 amino acids and has a molecular weight of 151 kd. The conceptual amino acid sequence exhibits striking homology to the steroid receptor superfamily of proteins. The homology is restricted to the DNA-binding and hormone-binding domains of the proteins. The two polypeptides differ most significantly in that the *E75 A* protein contains both of the characteristic zinc fingers of the steroid-receptor-like DNA-binding domain, whereas the *E75 B* protein contains only one. A third type of *E75* cDNA has been reported, which closely resembles the *E75 A* mRNA except for the substitution of novel sequences for the first *E75 A* exon (Feigl *et al.*, 1989). This would result in the production of an *E75* protein with the same DNA-binding and hormone-binding domains as the *E75 A* protein, but with a different amino terminus. These novel sequences are transcribed from an exon 50 kb upstream of the *E75 A* promoter, which defines the > 100 kb *E75 C* transcription unit (Segraves, unpublished).

**E(2)Bic:** see *E(Bic)*

### **E(A<sup>53g</sup>): Enhancer of abnormal abdomen-53g**

**location:** 2-6 (between *al* and *dp*).

**origin:** Spontaneous.

**references:** Thalmann, 1974, *DIS* 51: 22.

**phenotype:** Extreme intensification of *A53g* phenotype;

flies nearly denuded of tergites. Does not enhance *S*, and *E(S)*, which maps in same region, does not enhance *A53g*.

*E(Arp)*: see *Ba*<sup>10</sup>

***E(B): Enhancer of Bar***

**location:** 1-57.3.

**origin:** Spontaneous.

**discoverer:** Bonnier and Nordenskiöld.

**synonym:** *i*; *I: Intensifier of Bar*; *Eb: Exaggeration of Bar*.

**references:** 1942, DIS 16: 47.

Bonnier, Nordenskiöld, and Bågman, 1943, *Hereditas* 29: 113-33 (fig.).

Rasmuson, 1948, *Proc. Intern. Congr. Genet.*, 8th. pp. 645-46.

**phenotype:** *E(B)* heterozygous with any *B* allele, including *B*<sup>+</sup>, produces flies similar in phenotype to homozygotes for that allele. *B* +/+ *E(B)* eyes have 80-90 facets, but *B E(B)/++* eyes have only 40. Homozygous lethal. RK2(A).

**cytology:** Salivary chromosomes appear normal, but there is occasional indication of deficiency for faint bands 16A5 and 6.

**other information:** Reduces *B-fu* crossing over about 40%.

***E(Bic)***

**location:** 2-64.0.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *E(2)Bic*.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Roux's Arch. Dev. Biol.* 193: 267-82.

Mohler and Wieschaus, 1986, *Genetics* 112: 803-22.

**phenotype:** An incompletely penetrant dominant female-sterile mutation; heterozygous females produce 60% apparently unfertilized eggs. In heterozygotes with *Bic-C* or *Bic-D*, *E(Bic)* causes a substantial increase in the incidence of double-abdomen embryos, but *E(Bic)/+* females produce normal embryos.

*e(bx)*: see *z<sup>ebx</sup>*

***E(bx): Enhancer of bithorax***

**location:** 3- (to the left of R).

**origin:** X ray induced.

**discoverer:** E. B. Lewis.

**synonym:** *En-bx*.

**phenotype:** Enhances expression of *bx<sup>34e</sup>*, *bx<sup>3</sup>*, and *Ubx/+*. Lethal homozygous. RK2.

***E(da): Enhancer of daughterless***

**location:** 2-55 (inferred from rearrangement breakpoint).

**origin:** X ray induced.

**references:** Mange and Sandler, 1973, *Genetics* 73: 73-86.

**phenotype:** One dose of *E(da)* in *da/+* females, in either coupling or repulsion with *da*, reduces the number of daughters among their progeny; without effect in *da/+* males. *da E(da)/SMI* females are daughterless. Effect enhanced by reduced heterochromatic content of progeny (Mange and Sandler, 1973). Maternal effect of *E(da)* strong at 29° but absent at 17° (Cline 1980, *Genetics* 96: 903-26). *Sxl<sup>fl</sup>/+;da E(da)/+* females produce no *Sxl<sup>fl</sup>/+* daughters at 29° (Cline, 1980). *E(da)/abo* females produce normal sex ratios; show zygotic

suppression of the maternal effect of homozygous *abo* (Mange and Sandler, 1973).

**cytology:** Associated with *T(2;3)E(da) = T(2;3)41,66C*. Sandler and Mange (1973) suppose *E(da)* to be a consequence of the break in 2R.

***e(dp<sup>v</sup>): enhancer of dumpy-vortex***

**location:** 3-40.4.

**origin:** Spontaneous.

**discoverer:** Bridges, 16h7.

**synonym:** *vo-3: vortex in chromosome 3*.

**references:** 1919, Bridges and Mohr, *Genetics* 4: 283-306 (fig.).

1923, Bridges and Morgan, *Carnegie Inst. Washington Publ. No. 327*: 168.

1925, Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 41-43 (fig.).

**phenotype:** Normal. In combination with *dp<sup>v</sup>*, produces one or two pairs of pits or volcano-like protrusions on thorax; hairs and bristles arranged in whorls. RK3.

**\**E(f): Enhancer of forked***

**location:** 2-86.5.

**origin:** X ray induced.

**discoverer:** Belgovsky, 37c4.

**synonym:** *1-f: Intensifier of forked*.

**references:** 1937, DIS 8: 7.

1938, *Izv. Akad. Nauk SSSR, Ser. Biol.* 1017-36.

1940, DIS 13: 52.

1944, *Zh. Obshch. Biol.* 5: 325-56.

**phenotype:** Homozygote has short, twisted bristles intermediate between *f* and *Bl*; postscutellars often pale; viability and fertility reduced. Heterozygote is wild type. *fl/+*; *E(f)/+* slightly more extreme than *f. fl/f*; *E(f)/+* has an extreme forked phenotype and hairs are forked. *fl/f*; *E(f)/E(f)* rarely survives. RK3.

**cytology:** Salivary chromosomes normal.

***e(fa<sup>swb</sup>): enhancer of facet-strawberry***

**location:** 1-1.5 (no recombination with *w<sup>a</sup>*).

**origin:** Spontaneous.

**discoverer:** Keppy.

**synonym:** *e(fa<sup>swb</sup>) fa<sup>swb</sup>* which was originally designated *fa<sup>swb-h</sup>: facet-strawberry-hairy*.

**references:** Welshons and Welsons, 1986, *Genetics* 113: 337-54.

**phenotype:** By itself *e(fa<sup>swb</sup>)* is wild type in phenotype; when in *cis* with *fa<sup>swb</sup>*, either in homozygous or hemizygous condition, it produces narrow, rough, glossy eyes, bowed tibiae on the metathoracic legs, and a proliferation of microchaetae. *e(fa<sup>swb</sup>) fa<sup>swb</sup>/fa<sup>g</sup>* have glossy phenotype; *fa<sup>swb</sup>/fa<sup>g</sup>* have facet phenotype.

**cytology:** Postulated to be an inversion of bands 3C2 and 3 on the basis of its elimination of *w<sup>a</sup>-rst* recombination and its normal appearing polytene banding pattern.

**\**e(g): enhancer of garnet***

**location:** 1-5.9.

**discoverer:** Payne and Denny, 1921.

**synonym:** *m(g): modifier of garnet*.

**references:** 1921, *Am. Naturalist* 55: 377-81.

**phenotype:** Apparently wild type but, in combination with *g*, produces a more orange eye than *g* alone. RK3.

*E(H)*: see *Su(H)*

***E(lz): Enhancer of lozenge***

**location:** 3-64.0 (between *sr* and *Dl*).  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Grell.  
**phenotype:** Dominant enhancer of lozenge; no effect observed in absence of *lz*. Homozygous viable.

**\**E(M99E): Enhancer of Minute (3) 99E***

**location:** 3- (near spindle attachment).  
**origin:** Spontaneous.  
**discoverer:** Bridges.  
**synonym:** *E(M3g)*.  
**phenotype:** Specific intensifier of shortness of bristles of *M(3)99E*. RK3.

**\**e(N<sup>8</sup>): enhancer of Notch-8***

**location:** 3- (not located).  
**origin:** Spontaneous.  
**discoverer:** Mohr, 181.  
**references:** 1923, Z. Indukt. Abstamm. Vererbungsl. 32: 108-232 (fig.).  
**phenotype:** Produces slight nicking of wings. Enhances *N<sup>8</sup>*. RK3.

***E(Pc): Enhancer of Polycomb (R. Denell)***

**location:** 2-61.9 (0.1 cM to the left of *en*).  
**origin:** Induced by ethyl methanesulfonate.  
**synonym:** *l(2)28-28-12*.  
**references:** Russel and Eberlein, 1979, Genetics 91: s109. Sato, Russel, and Denell, 1983, Genetics 105: 357-70. Sato, Hayes, and Denell, 1984, Dev. Genet. 4: 185-98.  
**phenotype:** Although *E(Pc)* heterozygotes are cuticularly normal as larvae and adults, the mutation acts zygotically as a dominant enhancer of the adult homeotic syndrome of flies heterozygous for Polycomb mutations or *Df(3L)Pc-MK*. The locus is haplo-abnormal, as heterozygous deficiencies of the *E(Pc)* locus have an equivalent effect. Heterozygosity for *E(Pc)* or a deficiency also enhances the adult homeotic syndrome of Polycomblike mutation or deficiency heterozygotes, and renders the normally recessive mutations *esc* and *l(4)29* slightly pseudodominant, but has no effect on phenotypes associated with *Antp<sup>Ns</sup>*, *Antp<sup>73b</sup>*, *Antp<sup>Scx</sup>*, *Antp<sup>EfW15</sup>*, *Scr<sup>Msc</sup>*, *Cbx*, *Ubx*, *bx<sup>34e</sup>* or *abx bx<sup>3</sup> pbx* heterozygotes. *E(Pc)* is a recessive lethal mutation; homozygotes and hemizygotes die as late embryos or larvae, which appear cuticularly normal. *E(Pc)* has dominant maternal as well as zygotic effect on the severity of the embryonic homeotic syndrome of *Pc<sup>3</sup>* or *Df(3L)Pc-MK* homozygotes. Zygotic homozygosity for *E(Pc)* also enhances the embryonic effects of *Pcl<sup>W4</sup>*, *Pcl<sup>W5</sup>*, and *Pcl<sup>W6</sup>*, and *E(Pc)*; *l(4)29* doubly homozygous embryos from heterozygous mothers show incomplete head involution, presumably due to a cryptic homeotic effect.

**cytology:** Placed in 48A3-6 based on its inclusion in *Df(2R)en30 = Df(2R)48A3-4;48C6-8* and *Df(2R)en-A = Df(2R)47D3-4;48A5-6*.

***E(Pc)-a***

**location:** 3- (near *Dl*).  
**discoverer:** E.B. Lewis and Chang.  
**references:** Eberlein, 1984, Genetics 107: s26.  
**phenotype:** Homozygous lethal; heterozygotes show partial transformation of legs 2 and 3 to first leg and occasionally of first and fourth abdominal segments to second and fifth, respectively. Phenotype enhanced by combina-

tion with *Pc* or *E(Pc)*.

**\**e(S): enhancer of Star***

**location:** 3- (between 0 and 10; perhaps an allele of *ru* or *R*).  
**origin:** Spontaneous.  
**discoverer:** Bridges, 16k18.  
**synonym:** *S-i: intensifier of Star*.  
**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 175 (fig.).  
**phenotype:** By itself, homozygous *e(S)* has normal eyes. *S/+*; *e(S)/e(S)* has eyes smaller and rougher than *S/+*, although overlapping somewhat; abdomen bulbous; body color darkish. RK3.

***E(S): Enhancer of Star***

**location:** 2-6 [claimed to lie between left break of *In(2L)Cy* and locus of *Cy*].  
**discoverer:** Bridges, 30a27.  
**phenotype:** *E(S)/+* normal, *E(S)/E(S)* gives slight roughening of eye. *E(S)/+* strongly reduces size and increases roughness of *S/+* and *S<sup>2</sup>/+* eyes; imparts dominance to *ast/+*, *ast<sup>2</sup>/+*, *ast<sup>3</sup>/+*, and *ast<sup>4</sup>/+* (Lewis, 1945, Genetics 30: 137-66). *S/+ + E(S)* occasionally emerges as a late-eclosing giant. RK3A.  
**cytology:** Arose in *In(2L)Cy = In(2L)22D1-2;33F5-34A1*. Placed in 22D3-E1 on the basis of enhancement of *S* by a duplication for the interval (Gelbart).

***E(sd): Enhancer of scalloped***

**location:** Autosomal.  
**origin:** Spontaneous.  
**discoverer:** R. M. Valencia, 1963.  
**references:** 1965, DIS 40: 37.  
**phenotype:** Almost completely removes wings of *sd<sup>SP</sup>*; not tested with other alleles of *sd*. No interaction with *Bx* or *Bx<sup>r</sup>*. RK2.

***E(Sd): Enhancer of Segregation Distorter***

**location:** 2-55.  
**origin:** Found on *SD* chromosomes.  
**references:** Ganetzky, 1977, Genetics 86: 321-55.  
**phenotype:** In the presence of *E(SD)*, either in coupling or repulsion, *Sd* characterized by *k* values of  $> .95$ . Deletion of *E(SD)* reduces *k* values to .65-.75. Non-*SD* chromosomes carry either no allele or a nonenhancing allele. *E(Sd)* in the absence of *Sd* able to cause differential recovery of *Rsp<sup>+</sup>* and *Rsp<sup>-</sup>* chromosomes (Sharp; Temin).  
**cytology:** Located in proximal heterochromatin of 2L. Deleted by three deficiencies for *lt*, *Df(2L)ESD1*, *Df(2L)ESD3*, and *Df(2L)ESD36*.

***e(sei): enhancer of seizure***

**location:** 3-39.0.  
**origin:** Spontaneous.  
**references:** Kasbekar, Nelson, and Hall, 1987, Genetics 116: 423-31.  
**phenotype:** In the homozygous condition, it lowers the temperature threshold of two temperature-sensitive alleles of *sei*. *sei<sup>ts2</sup>*, which is a dominant paralytic at 40°, a recessive paralytic at 38° and nonparalytic at 35°, becomes a dominant paralytic at 38° and displays a recessive hyperactive uncoordinated phenotype at 35° in the presence of homozygous, but not heterozygous *e(sei)*. Homozygous *sei<sup>ts1</sup>* which is normal at 35° becomes

paralyzed at that temperature in the presence of homozygous *e(sei)*. Flies homozygous for *e(sei)* by itself, when their container is tapped lightly, become hyperactive and unable to crawl up the sides of the container to the top. *e(sei)* flies exhibit spontaneous neuronally stimulated firing of the dorsal longitudinal muscle and greatly enhances such firing of *sei*<sup>ts2</sup>. Also *e(sei)* does not affect saxitoxin binding by membrane extracts as do *sei* mutations.

**cytology:** Placed in 69A4-B5 based on its inclusion in *Df(3L)vin7 = Df(3L)68C8-11;69B4-5* but not *Df(3L)vin6 = Df(3L)68C8-11;69A4-5* or *Df(3L)vin5 = Df(3L)68A2-3;69A1-3*.

***E(spl)*: Enhancer of split**

**location:** 3-89.

**phenotype:** Locus involved in the differentiation of the neural ectoderm into neuroblasts and epidermoblasts. Increased levels of gene product favor epidermal differentiation, whereas decreased levels favor neuronal differentiation. Locus originally identified by the split-enhancing feature of a dominant gain-of-function mutation. Loss of function mutations are lethals and are described separately. A weak hypomorphic allele described as *gro* (*groucho*) is also described below. *E(spl)* causes *spl/+* to display a split phenotype and elicits a more extreme phenotype in *spl/spl* and *spl/Y*. The *spl*-enhancing effect of *E(spl)*<sup>1</sup> is suppressed in flies heterozygous for *Dl* (Shepard, Boverman, and Muskavitch, 1989, Genetics 122: 429-38). With respect to enhancement, *+/+/+ < +/E(spl) < E(spl)/+/+ < E(spl)/E(spl)*, in accord with expectations from a hypermorphic allele; duplication for *E(spl)*<sup>+</sup> achieved with *Dp(3;3)M95A<sup>+</sup>16*. In the absence of *spl*, *E(spl)* causes slight roughening of the eyes; furthermore, depending on parental constitution, varying percentages of embryos display defects in central- and peripheral-nervous-system development and irregular cuticular defects. A fraction of these fail to develop; percentages vary from 25% neural hypoplasia and 8% embryonic mortality in crosses between homozygous *E(spl)* parents to 100% death and 78% neural hypoplasia when both parents are *E(spl)/Dp(3;3)M95A<sup>+</sup>*. Both of these effects are sensitive to maternal genotype. That *E(spl)* is not simply a hypermorph is indicated by the fact that although *+/Df(3R)Espl* is viable, *E(spl)/Df(3R)Espl* is virtually lethal, especially when the deficiency is maternally inherited. Embryos homozygous for loss-of-function alleles vary in phenotype from weak to very strong neural hyperplasia, with concomitant aplasia of the epidermal sheath. Heterozygotes for stronger hypomorphic alleles may show terminal thickening of wing veins L4 and L5,

and may have adventitious vein segments in the posterior wing membrane. Double heterozygotes for *E(spl)* loss-of-function alleles and either *N* or *Dl* are lethal. In the adult, increasing levels of *E(spl)* function result in increasing levels of split enhancement and in decreased numbers of sensilla as measured by the number of costal bristles on the wing. Conversely, decreased *E(spl)* function results in larger eyes and more sensilla plus ectopic sensory neurons appearing in the wing blade, especially along the posterior margin. Hemizygoty for *E(spl)*<sup>+</sup> completely suppresses *spl*. Three doses of *E(spl)*<sup>+</sup> increase the severity of the effects of the absence of function of *Dl*, reduce the severity of the absence of function of *N*, *neu* and *mam* and are without effect on the phenotype of *bib*<sup>-</sup>; conversely, absence of function of *E(spl)* is not affected by hyperploidy for any of the neurogenic loci or by loss of *H* function; from this De la Concha *et al.* infer that *E(spl)* is positively controlled by *N* and negatively controlled by *H* and *Dl*. Unlike the results using other neurogenic mutants, single vitally stained cells taken from the neurogenic ectoderm of *E(spl)*<sup>-</sup> embryos and transplanted into wild-type host embryos fail to give rise to clones containing epidermal cells; only neuronal elements are produced. This observation is interpreted to indicate that the *E(spl)*<sup>+</sup> product serves a receptor rather than a signalling function (Technau and Campos-Ortega, 1987, Proc. Nat. Acad. Sci. USA 84: 4500-04).

**alleles:** One true mutant allele is the original dominant *E(spl)* and it is likely a double mutant; a number of recessive lethals recovered either as reversions of *E(spl)*, designated *E(spl)*<sup>rv</sup> and mostly associated with chromosome rearrangements, or as mutations designated *E(spl)*<sup>r</sup> that fail to complement *Df(3R)Espl-3*, a cytologically visible deficiency that contains more than eleven transcription units. These lethals display variable levels of neural hyperplasia and are treated as alleles in the literature; however interactions among them in *trans* heterozygotes lead to complex complementation patterns, and in general, the mutations have not been associated with particular transcription units.

<sup>α</sup> 1 = Knust, Bremer, Vässin, Ziemer, Tepass and Campos-Ortega, 1987, Dev. Biol. 122: 262-73; 2 = Knust, Tietze and Campos-Ortega, 1987, EMBO J. 6: 4113-23; 3 = Preiss, Hartley and Artavanis-Tsakonas, 1988, EMBO J. 7: 3917-27; 4 = Welshons, 1956, DIS 30: 157-58; 5 = Ziemer, Tietze, Knust and Campos-Ortega, 1988, Genetics 119: 63-74.

**cytology:** Placed in 96F11-14 based on its inclusion in *Df(3R)ro82b = Df(3R)96F11-14;97F3-11* but not *Df(3R)Tl-Q = Df(3R)97A1;97D* (Preiss et al.).

**molecular biology:** Region isolated in two independent walks both initiated from the same cloned sequence: a 150-kb walk (Knust, Tietze and Campos-Ortega, 1987, EMBO J. 6: 4113-23) with an *EcoRI* site just to the right of the initiating clone designated as coordinate 0 and positive values to the right and an 80-kb walk (Preiss, Hartley and Artavanis-Tsakonas, 1988, EMBO J. 7: 3917-27) with a *Xho* site just to the right of the initiating clone designated as the 0 coordinate and positive values to the left. The *Xho* site appears to be approximately 2.5 kb to the left of the *EcoRI* site; accordingly changing the sign and subtracting 2.5 kb from the Preiss et al. coordinates approximates the Knust et al. coordinates which are used here. Lesions of twelve different mutations identified within 36 kb from -15 to +21 kb of the walk. At least 11 transcripts detected in this region; they are numbered m1 through m11 in order from proximal to distal; coordinate 0 is between transcription units m4 and m5. All of these transcription units are expressed at some level during embryogenesis and several are expressed maternally as well. *In situ* hybridization of cDNA or genomic probes for nine of the eleven transcribed regions to developing embryos reveal complex temporal and spatial patterns of expression; four of the transcripts m4, m5, m7 and m8 exhibit virtually identical expression patterns, which accord with expectation for neurogenic genes; transcript first appears in late blastoderm, most intensely the neurogenic ectoderm, a ventrolateral stripe several cells wide on either side of the embryo. They are also expressed in several other neural primordia such as the stomatogastric nervous system and the optic lobes; transcripts subsequently become restricted to epidermal primordia; m9 and m10 are strongly and ubiquitously expressed in the embryo as well as maternally. Among the mutants with lesions within the 36-kb region are *gro* which appears to be an allele of *E(spl)*, and *Pr* alleles which do not. Sequence determined for m4, m5, m7 and m8 (Klämbt, Knust, Tietze and Campos-Ortega, 1989, EMBO J. 8: 203-10); m5, m7

and m8 are highly homologous to one another and share significant homology with proteins of the helix-loop-helix variety such as those encoded by *da*, *emc*, T3, T4, T5 and T8 of *ASC* and vertebrate *myc*; m4 is completely different from the other three and from known sequences in databases. The genomic sequences of all four lack introns and all encode hydrophilic polypeptides; specific information on each is as follows: m4 is a 1.1-kd mRNA that encodes a 152 (or 141 depending on start codon) amino-acid, 19-kd hydrophilic polypeptide with pI = 5.5; m5 is 1.0 kb and encodes a 19.9-kd polypeptide of 178 amino-acids, pI = 10.16; m7 is an 1.5 kb mRNA encoding a 186 amino-acid, 20.5-kd polypeptide, pI = 10.2 and m8, which is 1.0 kd in length, encodes a polypeptide of 179 amino acids and molecular weight of 19.7 kd, pI approximately equal to 10. The genomic sequence of m8 is modified in *E(spl)*; there is an 84-nucleotide deletion upstream from the putative m8 promoter plus a 483-nucleotide deletion that removes the last 56 codons from the message; the next 27 base pairs are in frame and append nine ectopic amino-acids to the truncated polypeptide; these are followed by a 60-base-pair insertion the first three nucleotides of which are a stop codon; then there is a ten-nucleotide deletion followed by wild-type sequence. Klämbt et al. have shown that the abnormal m8 region is responsible for the *E(spl)* phenotype; transformation with a genomic segment containing m8 and little else leads to genotypes with strong split suppressing effects. Transformation with a segment including the transcription unit for m9 and m10 is able to rescue lethality of seven presumed lethal point mutations of *E(spl)*, of *E(spl)/Df(3R)Espl* and the phenotype of *Df(3R)Espl/gro*; it does not, however, fully rescue the neural hyperplasia associated with some molecular deficiencies (Preiss et al., 1989). The genomic sequence corresponding to the transcription unit has been sequenced; the two transcripts share a common uninterrupted open reading frame, differing only in the length of their 3' untranslated region. The conceptual amino-acid sequence contains 719 residues with predicted molecular weight of 78,928 daltons; there is no evidence of either a signal sequence or transmembrane regions; three clusters of residues rich in proline seen in the amino-terminal half of the molecule in residues 3-19, 120-208 and 273-421, the carboxy-terminal half contains four or five repeating motifs of 43 to 47 residues. In database searches, the 340 carboxy-terminal amino-acids display 39% homology and 21% identity to  $\beta$  transducin, the G protein involved in signal transduction in the retina; homology is also detected to several other  $\beta$ -G proteins and to the yeast cell-cycle gene, *CDC4*.

### *E(spl)*<sup>2</sup>

**synonym:** *gro*: *groucho*.

**phenotype:** Homozygotes have clumps of extra bristles above each eye which give impression of bushy eyebrows; also extra bristles on the humerus. Top of head tends to be malformed; ocelli often enlarged and run together. In selected stocks, penetrance approaches 100%, but is low in unselected stocks. Concluded to be an allele of *E(spl)* on the basis of the visible phenotype of heterozygotes with lethal presumed point mutations at *E(spl)*; however, it does not cause neural hypertrophy and is wild type in combination with *E(spl)*<sup>1</sup>.

**molecular biology:** The chromosome containing the *gro* mutation contains two inserts, one of ~4 kb between coordinates -4.8 and -3.8 kb and a much smaller one at approximately +11.5 detected by Preiss *et al.*. The larger of the two is independent of the *gro* mutation since *Df(3R)Pr4*, which deletes the region into which the segment is inserted, does not uncover *gro*; a similar argument for the independence of the insert at 11.5 can be made since *gro* is rescued by transformation with a segment from 12.7 to 23.1 (Preiss *et al.*).

***e(tu-K): enhancer of tumor K***

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Burnet and Sang.

**references:** 1964, Genetics 49: 223-35.

**phenotype:** Homozygote produces a significant increase in the penetrance of *tu-K* in both untreated flies and those treated in ways known to increase tumor incidence in *tu-K*. RK3.

***E(tuh-1): Enhancer of tumorous head-1***

**location:** 3- (not mapped; near *BXC*).

**references:** Kuhn and Dorgan, 1974, Genetics 77: s37.

**phenotype:** Increases penetrance by 8% and expressivity by 91% for the tumorous-head trait. Acts in *trans* to *iab8,9<sup>tuh3</sup>* to increase maternal effect of *tuh1* on transformation of head to abdominal structures (Kuhn, and Packert, 1988, Dev. Biol. 125: 8-18).

***E(var)7: Enhancer of variegation***

**location:** 2- (not located).

**origin:** X ray induced.

**discoverer:** Schultz.

**phenotype:** *E(var)7*<sup>+</sup> has no phenotype of its own but enhances variegation, e.g., *w<sup>m4</sup>* is made much lighter and variegation for *rst* appears in males. Variegated position effects do not respond uniformly to *E(var)7*. RK2(A).

**cytology:** May be small abnormality in 25A (Schultz).

***E(var)21***

**discoverer:** Schultz.

**references:** Hadorn, Gsell, and Schultz, 1970, Proc. Nat. Acad. Sci. USA 65: 633-37.

**phenotype:** Produces large patches of yellow bristles in combination with *E(var)7* in *y/y<sup>+</sup>Y* males.

***E(var)25F to 100C-F***

A series of enhancers of variegation inferred from the effects of segmental deficiencies and duplications on the phenotype of *In(1)w<sup>m4</sup>*. All but *E(var)33A-D*, which is a triplo enhancer, are haplo enhancers. Three other triplo enhancers have been associated with haplo suppressors of variegation: *Su(var)2-5 = Su(var)205*, *Su(var)7* and *Su(var)9*.

***E(var)300 series***

Three ethyl-methanesulfonate-induced dominant enhancers of variegation (Sinclair, Mottus, and Grigliatti, 1983, Mol. Gen. Genet. 191: 326-33). Cause substantial reduction in eye pigment of *In(1)w<sup>m4</sup>*-bearing flies; less to no effect on *w<sup>m57b</sup>*, *w<sup>mj</sup>*, and *w<sup>mMc</sup>*; all three enhance *bw<sup>VDe2</sup>* and *Sb<sup>V</sup>* (Sinclair, Lloyd, and Grigliatti, 1989, Mol. Gen. Genet. 216: 328-33).

locus	location
<i>E(var)301</i>	3-49.3
<i>E(var)302</i>	3-36.6
<i>E(var)303</i>	3-34.7

***E(var)c101***

**location:** 3-54 [based on 3.7% recombination with 89C2-3 breakpoint of *T(2;3)ap<sup>Xa</sup>* (Reuter, Werner and Hoffmann, 1982, Chromosoma 85: 539-51)].

**origin:** Spontaneous in *T(2;3)ap<sup>Xa</sup>*.

**references:** Reuter and Wolff, 1981, Mol. Gen. Genet. 182: 516-19.

**phenotype:** Produces white eyes with occasional single red facets in combination with *w<sup>m4h</sup>*.

***E(w<sup>a</sup>): Enhancer of white-apricot***

**location:** 2-105.1 (4.6 units to the right of *px*; to the left of *sp*).

**origin:** Spontaneous.

**discoverer:** Scandlyn.

**references:** Von Halle, 1969, DIS 44: 119.

**phenotype:** Heterozygote dilutes *w<sup>a</sup>* to pale yellow. Homozygote with *w<sup>a</sup>* is white. Enhances *w<sup>a1</sup>* and *w<sup>a4</sup>*. Also enhances *w<sup>Sp55</sup>* and *w<sup>h</sup>* (Birchler, 1986, Genetics 113: s47) but not *w<sup>a2</sup>*, *w<sup>a3</sup>*, *w<sup>bf</sup>*, *w<sup>Bwx</sup>*, *w<sup>cf</sup>*, *w<sup>ch</sup>*, *w<sup>co</sup>*, *w<sup>col</sup>*, *w<sup>e</sup>*, or *w<sup>sp</sup>*; enhances phenotype of *w<sup>a1</sup>/w<sup>bf</sup>*. No effect on eye color in presence of *w<sup>+</sup>*; and no interaction with other eye-color mutants. Enhancement dominant to two doses of the normal allele in *w<sup>a</sup>/bw<sup>+</sup>Y;E(w<sup>a</sup>)/+*. Homozygous males sterile; homozygous females partially fertile. RK3.

**cytology:** Placed to the left of 60B10 based on the *E(w<sup>a</sup>)/+*-like phenotype of *E(w<sup>a</sup>)/Df(2L)Px* [= *Df(2R)60B8-10:60D1-2*].

***\*e(w<sup>e</sup>): enhancer of white-eosin***

**location:** 1-32.

**origin:** Spontaneous.

**discoverer:** Green, 55b21.

**synonym:** *en-w<sup>e</sup>*.

**references:** 1957, DIS 31: 81.

1959, Heredity 13: 303-15.

**phenotype:** Enhances certain intermediate alleles of *w*;

e.g.,  $w^{aE}$ ,  $w^e$ ,  $w^{e2}$ ,  $w^h$ , and  $w^{X16}$ ; three of these shown to have transposable element *DOC* inserted at the same place; two have *pogo* ( $w^e$  and  $w^{e2}$ ) and one has *roo* ( $w^h$ ) inserted in the *DOC* element. Produces a nearly white eye color. No effect on  $w^a$ ,  $w^{a2}$ ,  $w^{a3}$ ,  $w^{a4}$ ,  $w^{bf}$ ,  $w^{ch2}$ ,  $w^{co}$ ,  $w^{col}$ , or  $w^{sat}$ . Suppresses *lz<sup>K</sup>* and *gypsy* containing mutants *lz<sup>1</sup>*, *f<sup>1</sup>*, *f<sup>5</sup>*, and *bx<sup>34e</sup>* (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97).  $e(w^e)$  flies occasionally have *px*-like venation or shortened wings, or both. Homozygous females sterile. RK2.

**alleles:** A second spontaneous allele with similar phenotype and map position recovered by Schalet.

$e(w^{8d})$ : see *su(f)*

### ***e(y)*: enhancer of yellow**

A series of sex-linked recessive mutations that modify the expression of  $y^2$ , a *gypsy*-induced allele; these mutations do not modify the expression of other *gypsy*-induced mutations. Recovered from hybrid dysgenic crosses in which the transposable element, *Stalker* plus, in some cases, *P* were mobilized. The new mutations fall into six complementation groups; they were localized by recombinational analysis and by *in situ* hybridization using the transposable sequences as probes; (Georgiev and Gerasimova, 1989, Mol. Gen. Genet. 220: 121-26).  $y^2$  suppressed by *su(Hw)*<sup>2</sup>; however, the effects of all *e(y)* mutations on bristle color persist in the presence of *su(Hw)*<sup>2</sup>.

locus	genetic location	cytological location	comments <sup>α</sup>
<b><i>e(y)1</i></b>	1-57.9	16B	head and thorax bristles yellow; microchaetae yellow; female sterile
<b><i>e(y)2</i></b>	1-36.2	10C	head and thorax bristles yellow; microchaetae yellow; short stocky body; wings separated; eyes small; facets altered; bristles shortened
<b><i>e(y)3</i></b>	1-62.2	18C-D	head and thorax bristles yellow; microchaetae yellow; thin bristles; female sterile; reduced viability
<b><i>e(y)4</i></b>	1-58.1	16B	thorax macro- and microchaetae yellow; causes yellow bristles on $y^+$ flies; males but not females have short thin bristles
<b><i>e(y)5</i></b>	1-59.2	17C	$y^+$ flies have shortened, thin, yellow, transparent macro- and microchaetae on thorax and abdomen; female sterile
<b><i>e(y)6</i></b>	1-37.2	10F	$y^+$ flies have pale yellow body, wings, and bristles; male sterile; reduced viability

<sup>α</sup> Effect on phenotype of  $y^2$  unless otherwise indicated; no effect on phenotype of  $y^+$  unless so indicated.

**alleles:** Independent recovery of mutations at several of the loci recorded; those with *P*-element inserts generally unstable, reverting to wild type or in some cases generating novel alleles; those with *Stalker* inserts stable.

Phillips and Shearn, 1990, Genetics 125: 91-101.

Jones and Gelbart, 1990, in press.

**phenotype:** Locus named after original gain-of-function allele  $E(z)^1$  (Kalisch and Rasmuson); subsequently designated *polycombeotic* (*pco*) (by Phillips and Shearn) based on phenotype of lethal homozygotes. Loss of function alleles recovered as (a) recessive lethal mutations (b) reversions of  $E(z)^1$  and (c) reversions of the antimorphic allele,  $E(z)^{59}$ . Reduction of  $E(z)^+$  activity leads to suppression of the *z* eye color, whereas gain-of-function alleles are dominant enhancers of *zeste* eye color [i.e.,  $z w^+/Y$ ;  $E(z)^1/+$  males have brownish eyes as do  $z w^+/z^+ w^+$ ;  $E(z)^1/+$  females].  $E(z)^{59}$  an antimorphic allele, is a dominant suppressor of *z* [i.e.  $z w^+$ ;  $E(z)^{59}/+$  females have orange eyes]. Hemizygoty for  $E(z)^+$  produces a very mild suppression of the *z* eye color. No effects on eye color in  $z^+$  or  $z^a$  backgrounds, and effects on eye color not specific to a particular *w* allele. Reduction of  $E(z)^+$  activity also allows ectopic expression of the segment identity genes of the Antennapedia and bithorax gene complexes, resulting in homeotic transformations. This latter effect defines  $E(z)$  as a Polycomb-group locus.  $E(z)^{61}$  displays temperature-sensitive suppression of *z* eye color and homeotic phenotypes. At 22°,  $z w^{ts}/Y$ ;  $E(z)^{61}/Df(3L)E(z)^-$  males have orange eyes and no homeotic transformations. At 29°, such males have wild-type red eyes and die as pharate adults with strong homeotic transformations of the mesothoracic and metathoracic legs toward the prothoracic state. Embryos produced by  $E(z)^{61}$  homozygous females at 29°C die with homeotic transformations of most segments toward the eighth abdominal segment. Even two copies of paternally contributed  $E(z)^+$  does not rescue viability of these embryos. Complete lack of zygotically produced  $E(z)^+$  results in early pupal lethality and small imaginal disks. Larval brain squashes from individuals homozygous for an amorphic allele reveal a very low mitotic index; metaphase chromosomes irregularly condensed and fragmented (Gatti and Baker, 1989, Genes Dev. 3: 438-53).

**alleles:** With the exception of the first four alleles, which are gain-of-function dominant suppressors of *zeste*, and  $E(z)^{60}$ , which is an antimorphic dominant suppressor of

zeste, all alleles listed below are presumably hypomorphic and amorphic alleles, which can act as dominant suppressors of zeste and are homozygous lethal.

Gen. Genet.* 218: 559-64.

<sup>β</sup> Heat sensitive alleles.

**cytology:** Placed in 67E3-4 based on its inclusion in the region of overlap of *Df(3L)Ez6 = Df(3L)67E1-2;67E3-5* and *Df(3L)Ez3 = Df(3L)67E3-4;67E6-7*, as well as on the breakpoint to *T(2;3)E(z) 65 = T(2;3)21C1-2;67E3-4*.

**molecular biology:** Region cloned by Jones. P-element mediated germline transformation of 9 kb fragment of DNA rescues all mutant phenotypes. Single 2.5-kb transcript expressed throughout development but most abundant in maternal mRNA. Approximately 1 kb proximal and in opposite transcriptional orientation to *hay* transcription unit.

**ea: easter**

**location:** 3-57 (between *jvl* and *sbd*).

**references:** Anderson and Nüsslein-Volhard, 1984, *Nature* 311: 223-27 (fig.).

1986, *Symp. Soc. Dev. Biol.* 44: 177-94.

*Gametogenesis and the Early Embryo* (J. Gall, ed.). Alan R. Liss, New York, pp. 177-94.

Chasan and Anderson, 1989, *Cell* 56: 391-400.

**phenotype:** Maternal effect lethal; both recessive loss-of-function and dominant gain-of-function alleles female sterile. Embryos produced by females homozygous for recessive alleles are dorsalized; lack ventral and lateral elements similar to embryos produced by *dll/dll* females; dorsal folds extend around circumference of embryo; lateral head fold and ventral furrow fail to form; germ band does not extend, and cuticle forms a tube with dorsal characteristics throughout. Degree of dorsalization proportional to level of *ea* expression as demonstrated by hypomorphic and temperature-sensitive alleles. Temperature sensitive period as demonstrated by *ea*<sup>14</sup> from the time of pole-cell formation to gastrulation; developmental Northern blots demonstrate the presence of transcript in the ovaries and increased levels during the first four hours of embryonic development followed by a marked decline between hours four and six. Partial rescue of mutant phenotype achieved by injection of cytoplasm or poly-A+ RNA from wild-type embryos or embryos from females homozygous for other dorsal-group mutants; spatial source of donor cytoplasm unimportant; degree of rescue reduced with distance from site of injection; complete rescue producing viable and fertile adults achievable with injection of purified *ea*<sup>+</sup> mRNA. *rw*, a zygotically active member of the dorsal group of genes, is not expressed in such embryos (Thisse, Stoetzel, El Messal, and Perrin-Schmidt, 1987, *Genes Dev.* 1: 709-15); furthermore strong alleles allow *zen* expression ventrally where it is not normally observed (Rushlow, Frasch, Doyle, and Levine, 1987, *Nature* 330: 583-86); periodicity of *ftz* stripes slightly disrupted in embryos from *ea* mothers (Carroll, Winslow, Twombly, and Scott, 1987, *Development* 99: 327-32). Females

heterozygous for fully penetrant dominant alleles are sterile; the offspring of *ea*<sup>D3</sup>/+ females display ventralization or lateralization as indicated by lateral extension of the denticle bands; patches or rings of denticles may encircle the embryo; however, the mesoderm, the most ventral pattern element, is not increased; dorsal structures such as filzkörper, antennal and maxillary sense organs are absent; field of dorsal hairs greatly reduced. *ea*<sup>D2</sup>/+ females are lateralized, producing embryos that lack presumptive mesoderm and have no ventral furrow, show dorsoventrally symmetrical folding at gastrulation with the lateral head fold encircling the embryo, and do not undergo germ band extension. Injection of *ea*-deficient embryos with 200 times the quantity of mRNA required for complete rescue does not cause ventralization, indicating that gain of function alleles are not merely hypomorphic in nature.

**alleles:** The only dorsal-group gene, other than *Tl*, that mutates at substantial frequency to dominant alleles; dominant alleles designated *ea*<sup>D</sup>.

<sup>α</sup> 1 = Chasan and Anderson, 1989, Cell 56: 391-400; 2 = Erdélyi and Szabad, 1989, Genetics 122: 111-27; 3 = Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**cytology:** Placed in 88F2 by *in situ* hybridization (Chasan and Anderson).

**molecular biology:** Locus identified in a chromosome walk by transposon tagging; restriction fragment harboring sites of P insertion recognizes mRNA of 1.5 kb. Shown to be the *ea* message by rescuing embryos of *ea* mothers by injection of hybrid selected message. cDNA selected from 0-3 hr embryo library by above restriction fragment shown to be full length by rescue of embryos with *in vitro* transcription product. Sequence of cDNA indicates a polypeptide of 392 amino-acids, 43,070 daltons, and containing a putative signal sequence. The N-terminal 127 residues show no homology with any

known protein; the remaining residues, however, share homology with many extracellular serine proteases of the trypsin superfamily; in conserved segments of the catalytic domain there is 50% amino-acid identity, and over the entire catalytic domain, 30% identity.

### **eag: ether-a-go-go (J.C. Hall)**

**location:** 1-50.0 (1-45.3 according to Homyk and Grigliatti, 1983, Dev. Genet. 4: 77-97).

**origin:** All alleles induced by ethyl methanesulfonate.

**references:** Kaplan, 1969, DIS 44: 45.

Kaplan and Trout, 1969, Genetics 61: 399-409.

Ganetzky and Wu, 1983, J. Neurogenet. 1: 17-28.

**phenotype:** Abnormal leg shaking under ether anaesthesia; aberrant, repetitive firing of action potentials in larval nerves; potassium currents abnormal in larval muscles (Wu, Ganetzky, Haugland and Lin, 1983, Science 220: 1076-1078). *eag Sh* double mutants display greatly increased level of spontaneous neuronal activity and extreme behavioral phenotypes (Burg and Wu, 1989, Dev. Biol. 131: 505-14).

**alleles:** *eag*<sup>1</sup>; *eag*<sup>4PM</sup>, weak behavioral abnormalities but is abnormal physiologically; *eag*<sup>101</sup>, hyperactive, flies and jumps well when raised at 22°, flies poorly or not at all when raised at 29°. (Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65); TSP during pupal stage (Homyk and Grigliatti, 1983, Dev. Genet. 4: 77-97). *eag*<sup>102</sup>, also causes accentuated jumping ability (Homyk *et al.*).

**cytology:** Located in 12F6-13A4 based on uncovering by *Df(1)RK2 = Df(1)12D2-E1;13A2-5*, by *Df(1)RK3 = Df(1)12E2-6;13A6-11*, by *Df(1)RK4 = Df(1)12F5-6;13A9-B1*; and by *Df(1)RK5 = Df(1)12E10-11;13A8-B1*; not uncovered by *Df(1)KA9 = Df(1)12E2-3;12F5-13A1* (Kreber and Ganetzky).

**molecular biology:** Region very close to, and likely to include, the locus cloned by Drysdale and Ganetzky (1985, Neurosci. Abstr. 11: 788).

**other information:** *eag* mutations interact synergistically with Shaker mutations, *i.e.*, double mutants are severely abnormal both behaviorally and physiologically (Ganetzky and Wu, 1983).

**eagle:** see *eg*

**early:** see *eay*

**early:** see *lds*

**early C:** see *elyC*

**early-A:** see *aur*

### **eas: easily shocked (J.C. Hall)**

**location:** 1-53.5.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *PC80, RH11*.

**references:** Benzer, 1971, J. Amer. Med. Assoc. 218: 1015-22.

Ganetzky and Wu, 1982, Genetics 100: 597-614.

**phenotype:** Brief paralysis following exposure to mechanical shock; this phenotype suppressed by *nap*<sup>ts</sup> mutation at its permissive temperature; release of neurotransmitter at larval neuromuscular junction is apparently normal.

**alleles:** Two mutant alleles: *eas*<sup>1</sup> and *eas*<sup>2</sup>.

**cytology:** Placed in 14B5-18 based on its inclusion in *Df(1)81h246 = Df(1)14B15-18;14E* but not in

*Df(1)82a2y = Df(1)14B5-18;15A3-4* (Steller).

**other information:** Separable by recombination from *bss* (which causes similar phenotype), to which *eas* is closely linked.

**easter:** see *ea*

**eay:** *early* (*T. Schüpbach*)

**location:** 2- {86}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal or female-sterile mutant; homozygous females lay eggs which show no visible signs of development when observed under transmitted light in a stereo microscope; defective in fertilization or very early embryonic development.

**alleles:** Seven alleles *eay*<sup>1</sup> through *eay*<sup>7</sup>, originally designated *OP*, *AWG*, *AWH*, *HL*, *PI*, *PQ*, and *SJ* respectively.

**cytology:** Placed in 55A-F since uncovered by *Df(2R)PC4 = Df(2R)55A;55F*.

*eb*: see *s*<sup>eb</sup>

**eb:** *extra bristles*

**location:** 2-32.

**origin:** Spontaneous.

**references:** Mostashfi and Koliantz, 1969, *DIS* 44: 51.

**phenotype:** Increased bristle number on mesonotum and scutellum; average of two extra scutellar and two extra mesonotal bristles.

*Eb*: see *E(B)*

*ebonized*: see *s*<sup>eb</sup>

**ebo:** *ellipsoid body open* (*J.C. Hall*)

**location:** 1-0.6.

**origin:** Induced by ethyl methanesulfonate.

**references:** Heisenberg, Borst, Wagner, and Byers, 1984, *J. Neurogenet.* 2: 1-30.

**phenotype:** Ellipsoid body of central brain abnormally flat and broad; learning normal in tests using olfactory stimuli.

**ebony:** see *e*

**ec:** *echinus*

**location:** 1-5.5.

**origin:** Spontaneous.

**discoverer:** Bridges, 1916.

**phenotype:** Eyes large and bulging. Eye surface rough; facets large. Wings rather short and broad. Body thick-set. Tends to remove dorsocentrals (posterior more than anterior) and posterior notopleurals; may also add dorsocentrals anterior to anterior dorsocentrals whether or not posterior bristles removed (Sturtevant). Reduces number of mesopleural hairs in *h* homozygotes (Sturtevant, 1969, *Dev. Biol.* 21: 48-61). *ec* is visible in *+ec/ec* triploids (Gersh). RK1.

**cytology:** 3E8 or F1 [Lefevre, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, p. 59].

**ecd:** *ecdysone*

**location:** 3-1.5.

**references:** Garen, Kauvar, and Lepesant, 1977, *Proc. Nat. Acad. Sci. USA* 74: 5099-103.

Redfern and Bownes, 1983, *Mol. Gen. Genet.* 189: 432-40.

**phenotype:** Temperature-sensitive recessive lethal. At 29°, the nine-fold increase in β-ecdysone content during embryogenesis occurs normally in *ecd* homozygotes. Accompanied by normal increases in dopa-decarboxylase and dopamine acetyltransferase activity (Marsh and Wright, 1980, *Dev. Biol.* 80: 379-87). The four-fold increase during the first larval instar is reduced to 40% of normal; the additional twelve-fold increase normally occurring at pupariation eliminated. Embryonic development of *ecd* at 29° normal, but first larval molt delayed and death usually occurs by end of second instar; shift down to 20° at mid second instar produces full yield of adult progeny. Larvae shifted from 20° to 29° midway through third instar fail to pupate and survive as larvae for up to 3 weeks; ring gland, salivary glands, and brain of nonpupariating larvae are smaller than wild type; such ring glands cultured *in vitro* secrete ecdysone at lower than normal levels. Effects of 29° on third instar reversible by ecdysone feeding or by shift down to 20° within 3-5 days of shift up; after that imaginal disks cannot differentiate; *ecd* imaginal disks develop normally at 29° when implanted in a wild-type host. A heat pulse during larval development results in cell death with consequent abnormalities in emerging adults. At 29°, third instar larvae exhibit abnormally low dopadecarboxylase activity (Kraminsky, Clark, Estelle, Gietz, Sage, O'Connor, and Hodgetts, 1980, *Proc. Nat. Acad. Sci. USA* 77: 4175-79); Marsh and Wright) and high urate oxidase activity (Krase and Friedman, 1979, *Genetics* 91: s62-63); ecdysone feeding effects normal levels. Transfer to restrictive conditions at the beginning of the pupal stage leads to death as pharate adults and to the elimination of mechanosensory chaetae; Non-sensory chaetae and other sensilla not affected. Chaetae loss is autonomous as seen in homozygous clones produced by somatic exchange and in *ecd* discs passed through metamorphosis in wild type hosts under restrictive conditions (Sliter, 1989, *Development*, 106: 347-54). Sensitivity to restrictive temperature disappears in 24 hour pupae. *ecd* fails to block midpupal increase in ecdysone titer (Marsh and Wright). Shifting newly emerged *ecd* adults to 29° results in drastically reduced ecdysone titers and sterilizes both males and females; reversible by shift back to 20°; temperature-sensitive periods and therefore the times that ecdysone is required for embryonic development, chorion formation, and vitellogenesis are 1-2 days before oviposition, 24 hr prior to oviposition, and prior to stage 7, respectively (Audit-Lamour and Bussin, 1981, *J. Insect Physiol.* 27: 829-37).

**alleles:** In addition to *ecd*<sup>1</sup> described above, *ecd*<sup>2</sup>, a non-conditional, ethyl-methanesulfonate-induced allele recovered by Sliter, Henrich, Tucker, and Gilbert (1989, *Genetics* 123: 327-36).

**cytology:** Placed in 62C4-D5 based on its inclusion in *Df(3L)R-R2 = Df(3L)62B2-4;62D3-5* but not *Df(3L)R-G5 = Df(3L)62A10-B1;62C4-D1* (Sliter *et al.*).

**Ecdysone-dependent gene:** see *Edg*

**Ecdysone-inducible:** see **E74**

**Ecdysteroid-inducible polypeptide encoded in 55BD:** see **Eip55BD**

**echinoid:** see **ed**

**echinus:** see **ec**

**ecl:** **echinus like**

**location:** 1- {8} [to the left of *fl(1)302*].

**origin:** Induced by ethyl methanesulfonate.

**references:** Steinmann-Zwicky, 1988, EMBO J. 7: 3889-98.

**phenotype:** Like *ec*.

**cytology:** Placed in 4C5-E1 based on its inclusion in *Df(1)rb13 = Df(1)4C5-6;4D3-E1*. Not included in *Df(1)rb23* or *Df(1)rb34* both of which overlap the left end of of *Df(1)rb13* and include *rb* and *peb* as does *Df(1)rb13*.

**Eco: Extra combs**

**location:** 2-84.

**discoverer:** Duncan.

**phenotype:** Sex combs formed on second and third pairs of legs; middle leg transformed to first leg; fifth and sixth tergites transformed to sixth and seventh, respectively. Clonal analysis indicates late activity.

**alleles:** Hypomorphic and amorphic alleles and deletions have been identified.

**ecs:** see **BRC**

**ed: echinoid**

**location:** 2-11.0.

**origin:** Spontaneous.

**discoverer:** Bridges, 31a16.

**phenotype:** Eyes large and rough. Easily classified, although not as extreme as *ec*. *Su(S)/ed* is echinoid in phenotype (Gelbart). RK1.

**cytology:** Placed in 24D3-4 on the basis of its inclusion in the region of overlap of *Df(2L)ed-Szl = Df(2L)24A3-4;24D3-4* and *Df(2L)M24F-11 = Df(2L)24D3-4;25A2-3* (Szidonya and Reuter, 1988, DIS 67: 77-79; 1987, Genet. Res. 210: 429-36).

**Edg: Ecdysone-dependent gene**

Four genes identified in a differential screen of a genomic library with cDNA isolated from imaginal discs pulsed with 20-hydroxyecdysone, 20-HE (Fechtler, Natzle, Brown, and Fristrom, 1988, Genetics 120: 465-74). All of these genes accumulate transcripts in imaginal disc tissue, beginning at six to nine hours, following a six-hour 20-HE pulse, but not in the absence or continual presence (except *Edg64CD*) of 20-HE; mRNA's of all four enriched in membrane-bound polysome fractions of imaginal discs. Translation product from hybrid selected mRNA of *Edg78E*, but not the other three, reacts with polyclonal antibodies prepared against purified pupal cuticle proteins.

--------------	------------------	----------------------	------------------

**ee: extra eye (W.K. Baker and J.C. Hall)**

**location:** 2-18.0 (between *dp* and *spd*).

**origin:** Spontaneous.

**discoverer:** Aaverhoff.

**references:** Marcey and Stark, 1985, Dev. Biol. 107: 180-97.

Baker, Marcey and McElwain, 1985, Genetics 111: 67-88.

**phenotype:** Flies from extra eye stocks show pattern duplications of head morphology in varying degrees; small duplications may appear as a few extra orbital bristles, whereas extreme expression involves well-formed, supernumerary, compound eyes on the vertex with associated orbital structures; ectopic eye is a mirror-image partial duplication of the ipsilateral eye. Occasionally, ocelli may be duplicated and rarely the antennae; a line of mirror-image symmetry often can be recognized between normal structures and their duplicated counterparts; structural deficiencies, particularly in the occipital region, are common. Penetrance is temperature sensitive (72% at 29° and 25°, 43% at 19°); temperature-sensitive periods in mid-embryogenesis and mid-first instar. There is no evidence of cell death in eye-antenna imaginal disc; first evidence of disc hyperplasia in late third instar. Fine-structure anatomy and physiology of photoreceptors in extra eyes appear normal; electroretinograms suggest that photoreceptors in extra eyes can make functional synaptic connections, although neuroanatomical studies show receptor-central-nervous-system innervations only rarely; the rare supernumerary antennae, however, have receptor cells whose axons innervate the ventral brain.

**cytology:** No recombination has been observed between *ee* and a *P*-element insertion at 26D1-2.

**other information:** *ee* is incompletely penetrant, being influenced profoundly by apparent enhancer mutations on 1, 2, and 3; it behaves as a partial dominant when appropriate enhancers are made homozygous; *P* elements also serve as enhancers (Marcey). Penetrance is temperature-sensitive, being higher at 25° than at 19°; temperature-sensitive periods occur at mid-late embryogenesis and at early first instar.

**\*ef: elfin**

**location:** 1- (rearrangement).

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1952.

**references:** 1959, DIS 33: 86.

**phenotype:** Small fly with slightly excess melanization.

Wings proportionally smaller, slightly altered in shape, and warped. Abdominal tergites often broken and abnormally pigmented. Males viable but sterile. RK3A.

**cytology:** Associated with *T(1;2)ef = T(1;2)14C8-D1;2R*.

**Ef1α1: Elongation factor 1α #1**

**location:** 2-{64}.

**synonym:** *F1*.

**references:** Walldorf, Hovemann, and Bautz, 1985, Proc. Nat. Acad. Sci. USA 82: 5795-99.

Hovemann, Richter, Walldorf, and Cziepluch, 1988, Nucleic Acids Res. 16: 3175-94.

Shepherd, Walldorf, Hug, and Gehring, 1986, Proc. Nat. Acad. Sci. USA 86: 7520-21.

**phenotype:** Encodes an  $\alpha$  unit of the heterotrimeric protein, elongation factor 1, which promotes the binding of aminoacyl-tRNA to ribosomes. Originally isolated on the basis of its displaying 5 to 10 fold overexpression in females versus males. *Ef1 $\alpha$ 1* is expressed throughout development. The rate of protein synthesis in *Drosophila* declines with age; this has been attributed to impaired binding of aminoacyl-tRNA to ribosomes, which is promoted by elongation-factor 1 (EF1); transcription of elongation factor-1 mRNA shown to decrease with age; by fifteen days following emergence the level of EF1 mRNA is but a few percent that of newly emerged adults (Webster and Webster, 1984, *Mech. Ageing Dev.* 24: 335-42). Transformation with *Ef1 $\alpha$ 1* under the control of heat shock promoter increased the mean life span from 38.2 to 45.1 days at 25° and from 21.1 to 29.8 days at 29° (Shepherd *et al.*).

**cytology:** Placed in 48D by *in situ* hybridization.

**molecular biology:** Investigations of genomic and cDNA clones indicate a gene with 60-base pair untranslated minixon separated from the main body of the gene by an 1.3-kb intron. The single open reading frame encodes a polypeptide of 463 amino-acids; the sequence is highly conserved; it displays 90% homology with *EF1 $\alpha$ 1* and not much less with *EF1 $\alpha$*  from the brine shrimp and humans, indicating early separation of *Ef1 $\alpha$ 1* and *Ef1 $\alpha$ 2* during the evolution of *Drosophila*.

### **Ef1 $\alpha$ 2**

**location:** 3-{102}.

**synonym:** *F2*.

**references:** Walldorf, Hovemann, and Bautz, 1985, *Proc. Nat. Acad. Sci. USA* 82: 5795-99.  
Hovemann, Richter, Walldorf, and Cziepluch, 1988, *Nucleic Acids Res.* 16: 3175-94.

**phenotype:** Encodes an  $\alpha$  unit of the heterotrimeric protein, elongation factor 1; isolated by homology with *Ef1 $\alpha$ 1*. Expressed primarily in pupae; low levels of mRNA detectable in third-instar larvae and adults.

**cytology:** Placed in 100E by *in situ* hybridization.

**molecular biology:** Gene comprises five exons separated by introns of 1.24, 0.45, 0.45 and 0.08 kb. Encodes a polypeptide one amino-acid shorter than that of *EF1 $\alpha$ 1* and 90% homologous thereto.

### **Ef2**

**location:** 2-{54}.

**references:** Grinblat, Brown, and Kafatos, 1989, *Nucleic Acids Res.* 17: 7303-14.

**phenotype:** Encodes elongation factor 2 (EF2), which catalyzes the GTP-dependent translocation of tRNA from the aminoacyl to the peptidyl site of the ribosome; also catalyzes hydrolysis of GTP. Expression becomes detectable by four hours of development and persists into adulthood.

**cytology:** Placed in 39E-F by *in situ* hybridization.

**molecular biology:** Clone selected from embryonic cDNA library probed sequence from *mys*, which encodes the *Drosophila* homologue of  $\beta$  integrin, or position specific antigen (PS3); comparison of the sequence with the published sequences, however, revealed close nucleotide homology with hamster EF2. Longest open reading frame encodes an 844-amino-acid polypeptide of about 95 kd. Shows 85% identity with hamster EF2 except between residues 240 and 274 and between 90 and 100; displays

sequence similarity to other GTP binding proteins including EF1 $\alpha$ 1 in three domains in the N-terminal third, probably involved in GTP binding and GTPase activity; another segment in the N-terminal end and two in the carboxy-terminal end are shared only among elongation factors. The genomic sequence comprises four exons, the first of which is short and largely untranslated; the second contains the GTP-binding domains and one elongation factor specific domain, and the fourth most of the remaining shared domains. Northern blots detect a single mRNA of 3.1 kb.

### **eg: eagle**

**location:** 3-47.3.

**phenotype:** Wings extended. Hairs on thorax somewhat disarranged. Dark pattern on thorax. Viability varies among alleles; *eg*<sup>2</sup> females sterile. RK2.

**alleles:**

Schejter and Shilo, 1989, *Cell* 56: 1093-1104.

**phenotype:** Encodes the *Drosophila* homolog of epidermal growth factor receptor protein. Mutations with three different phenotypes and described under three different names shown to be alleles of *Egfr*. *Elp* (Ellipse) is a dominant eye shape and texture mutant; *flb* (faint little ball) is an embryonic lethal causing dorsalized embryos, and *top* (torpedo) is a maternal-effect lethal causing ventralized embryos; each of these classes is described in detail at the end of the entry; *in situ* hybridization with transcript-specific probes reveals uniform distribution of transcript during embryogenesis; in larvae, hybridization confined to mitotic tissues and not seen in cells with polytene chromosomes (Kammermeyer and Wadsworth, 1987, *Development* 100: 201-10). Transcript concentrated in cells of the central nervous system and gonial cells in adults.

**alleles:** Price *et al.* have subsumed the embryonic lethal alleles (*flb*) under the symbol for the maternal-effect-lethal alleles (*top*). We further consolidate both along with the dominant visible alleles (*Elp*) under the symbol

*Egfr* as *Egfr<sup>f</sup>*, *Egfr<sup>t</sup>*, and *Egfr<sup>E</sup>* alleles respectively.

<sup>α</sup> 1 = Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95; 2 = Baker and Rubin, 1989, Nature (London) 150-53 (fig.); 3 = Grell, 1960, DIS 34: 50; 4 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-83; 5 = O'Donnell, Boswell, Reynolds, and Mackay, 1989, Genetics 121: 273-80; 6 = Price, Clifford and Schüpbach, 1989, Cell 56: 1085-92; 7 = Schejter and Shilo, 1989, Cell 56: 1093-1104.

**cytology:** Genomic clone hybridizes to 57F.

**molecular biology:** Genomic sequence isolated using a probe homologous to kinase domain of the v-erbB oncogene protein. cDNA clones isolated from 3-12 hr cDNA library. Sequence comparisons of cDNA and genomic clones reveal the presence of four 3' exons separated by three small introns; these are separated from two distant 5' exons by a long (i.e., 45 kb) intron. Three different splicing patterns in the 5' region each associated with a different 3' polyadenylation site generate three different transcripts. Conceptual amino-acid sequence suggests a 42-base-pair signal sequence followed by a 769-nucleotide extracellular putative EGF-binding domain with twelve potential N-linked glycosylation sites and 68

cystein residues, a 31-residue hydrophobic transmembrane region, and a 566-nucleotide cytoplasmic kinase domain with but 13 cysteines. The overall amino-acid homology with human epidermal-growth-factor receptor is 41% in the extracellular domain and 55% in the kinase domain. The ligand-binding domain contains three cysteine-rich regions, which share homology with each other and with two such regions present in human EGF receptor.

### *Egfr<sup>E</sup>*

**synonym:** *Elp: Ellipse*

**references:** Grell, 1960, DIS 34: 50.

Baker and Rubin, 1989, Nature (London) 150-53 (fig.).

**phenotype:** Eyes of *Egfr<sup>E/+</sup>* heterozygotes rough and more oval than wild type; also display a slight disturbance of the wing-vein pattern. Homozygotes have smaller eyes with many fewer ommatidia and some regions lack them entirely; those ommatidia that are formed contain the normal number and arrangement of cells; the regions without ommatidia contain cells that resemble pigment cells and mechanosensory bristles; only about one tenth the normal number of preommatidial cell clusters differentiate behind the morphogenetic furrow. *Egfr<sup>E</sup>* in heterozygous combination with a deficiency or null mutation for *Egfr* is normal in phenotype indicating that *Egfr<sup>E</sup>* alleles are hypermorphic.

### *Egfr<sup>f</sup>*

**synonym:** *flb: faint little ball*

**origin:** Recovered as embryonic lethals (*Egfr<sup>f1</sup>* to *Egfr<sup>f23</sup>*) as mutations that fail to complement the female sterile effect (*Egfr<sup>f24</sup>* to *Egfr<sup>f35</sup>*) or the wing-vein defect (*Egfr<sup>f36</sup>* to *Egfr<sup>f38</sup>*) of *Egfr<sup>t</sup>* or, as revertants of *Egfr<sup>E</sup>* (*Egfr<sup>f39</sup>* to *Egfr<sup>f43</sup>*).

**references:** Nüsslein-Volhard, Wieschaus and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-83.

Schejter and Shilo, 1989, Cell 56: 1093-1104.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Embryos form a ball of dorsal hypoderm with the internal organs extruded anteriorly. Ventral cuticle absent or strongly reduced. First visible in extended-germ-band stage. Cells at the anterior and posterior ends of the embryo form clumps and slough off; very few head and gnathal cells remain. Substantial ectodermal cell death observed; germ band retraction fails to take place. Ultimately, cuticle formation produces mostly dorsal and lateral cuticular elements with but a narrow strip of denticles midventrally. Hypomorphic alleles initiate but do not complete germ-band retraction; they show intermediate phenotypes with wider denticle bands and in weak alleles some head and telson structures are formed as well. No maternal effect as shown by pole-cell transplantation.

### *Egfr<sup>t</sup>*

**synonym:** *top: torpedo*.

**references:** Schüpbach, 1987, Cell 49: 699-707.

Price, Clifford and Schüpbach, 1989, Cell 56: 1085-92.

**phenotype:** Maternal-effect lethal. Homozygous females lay eggs that are long and pointed at both ends. Such eggs often have only one fused dorsal appendage; also there is an increase in the number of follicle cells that give rise to the main body of the chorion at the expense of those ordinarily contributing to the operculum and dor-

sal appendages. *Egfr*<sup>1</sup> alleles are completely recessive and fully penetrant in homozygous females; the embryos never hatch. Homozygous and hemizygous adult flies exhibit incomplete fourth veins, absence of the anterior crossvein, rough eyes, loss of ocelli and ocellar bristles, and the loss of sensory bristles from the thorax. Changes in the embryonic pattern become visible at the beginning of gastrulation. Around the circumference of the embryo, 40% of the cells invaginate on the ventral side and form mesoderm; these cells become organized into two ventral furrows which are lost in later stages, and a mass of mesodermal cells fills the ventral half of the embryo. The only cuticle structure differentiated is a strip of dorsal hypoderm flanked by bands of ventral setae; lateral and ventral sides are made up of mesoderm. The head is reduced but filzkörper and spiracles are visible posteriorly. Experiments with germline mosaics produced by pole cell transplantation indicate that the mutant gives rise to ventralized eggs and embryos by interfering with processes taking place in somatic cells rather than germinal tissue. The mutant phenotype was only produced in mosaics in which wild-type germ cells were surrounded by *Egfr*<sup>1</sup> follicle cells and not by the reverse cell arrangement. *Egfr*<sup>1</sup> blocks dorsalization caused by *fs(1)K10*, but not that produced by *dl* females.

**egl: egalitarian** (*T. Schüpbach*)

**location:** 2-105.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile. Defect in cell fate detectable in anterior germarium. In contrast to wild-type, in all *egl* alleles all sixteen cells per cyst enter pachytene; subsequently all sixteen revert to nurse-cell morphology and behavior (Carpenter). Egg chambers increase in volume along the ovariole, but do not take up yolk. No chorion is formed. *BicD*<sup>1</sup> females simultaneously heterozygous for *egl*<sup>1</sup> or *egl*<sup>2</sup> fail to form double-abdomen embryos (Mohler and Wieschaus, 1986, *Genetics* 112: 803-22).

**alleles:** Five alleles; *egl*<sup>1</sup> through *egl*<sup>5</sup>, originally isolated as WU, RC, PB, Pr, and PV, respectively.

**cytology:** Placed in 59D8-60A2, since uncovered by *Df(2R)bw-S46 = Df(2R)59D8-11;60A7*, and by *Df(2R)bw-D23 = Df(2R)59D4-5;60A1-2*.

**Egon: Embryonic gonad**

**location:** 3-{47}.

**origin:** Isolated from genomic library using a *kni* zinc-finger probe.

**references:** Rothe, Nauber, and Jäckle, 1989, *EMBO J.* 8: 3087-89.

**phenotype:** Expression detected in embryonic gonad but not in other tissues or at other stages of development.

**cytology:** Placed in 79B by *in situ* hybridization.

**molecular biology:** Nucleotide sequence indicates an open reading frame encoding a polypeptide of 373 amino acids with a 1421-nucleotide intron between codons 26 and 27. The first 90 amino acids, which contain the zinc-finger domain, show 80% and 86% similarity to the products of *kni* and *knrl*, respectively; the three proteins share a 19-amino-acid motif, the *kni* box, just downstream from the zinc-finger domain. These polypeptides share features with vertebrate steroid hormone receptors; their putative ligand-binding domains exhibit a low level of similarity.

**Eip55BD: Ecdysteroid-inducible polypeptide encoded in 55BD**

**location:** 2-{86}.

**synonym:** *Eip40*.

**references:** Cherbas, Cherbas, Savakis, and Koehler, 1981, *Am. Zool.* 21: 743-50.

**phenotype:** The structural gene for a 40 kilodalton polypeptide (EIP40) whose concentration in Kc cells increases detectably beginning 30-60 min following administration of ecdysteroid hormone and reaching a maximum after 4-6 hr (Savakis, Demetri, and Cherbas, 1980, *Cell* 22: 665-74).

**molecular biology:** cDNA clone pKc252 isolated and used to select genomic clones from Maniatis library.

**cytology:** *In situ* hybridization localizes sequence to 55BD.

**Eip71CD**

**synonym:** *Eip28/29*.

**location:** 3-{42}.

**references:** Cherbas, Cherbas, Savakis, and Koehler, 1981, *Am. Zool.* 21: 743-50.

Savakis, Koehler, and Cherbas, 1984, *EMBO J.* 3: 235-43.

Cherbas, Schulz, Koehler, Savakis, and Cherbas, 1986, *J. Mol. Biol.* 189: 617-31.

Schulz, Cherbas, and Cherbas, 1986, *Proc. Nat. Acad. Sci. USA* 83: 9428-32.

**phenotype:** The structural gene for 28 and 29 kilodalton (as determined by gel mobility) polypeptides (EIP28, EIP29) whose concentration in Kc cells increases detectably beginning at 30-60 min and reaches a maximum at 4-6 hr following ecdysteroid administration (Savakis, Demetri, and Cherbas, 1980, *Cell* 22: 665-74). Each protein exists in three isoforms with different pI's, possibly owing to acetylation.

**molecular biology:** cDNA clone pKC252 isolated and used to select genomic clones. Hybrid selected mRNA translation products include both EIP28 and EIP29. Sequence analysis reveals the presence of four exons,  $\delta$ ,  $\alpha$ ,  $\beta$ , and  $\gamma$  from 11743 to -1627, -628 (or -640) to -435, -324 to -64, and -4 to +406 respectively. All contain coding information. Two primary transcripts are produced by alternate splicing; 75% use the consensus splice donor sequence of exon  $\alpha$  and 25% an alternate donor site twelve bases upstream, encoding a polypeptide internally deleted for four amino acids: Tyr Lys Arg Met. Since EIP28 is two charges more basic than EIP29, it is concluded to be encoded by the longer message, which specifies a conceptual sequence of 28,218 Daltons, and EIP29 is encoded by the shorter message producing a product of 27,640 Daltons.

**cytology:** *In situ* hybridization localizes sequence to 71C3-D2.

*Eip75*: see *E75*

**el: elbow** (*M. Ashburner*)

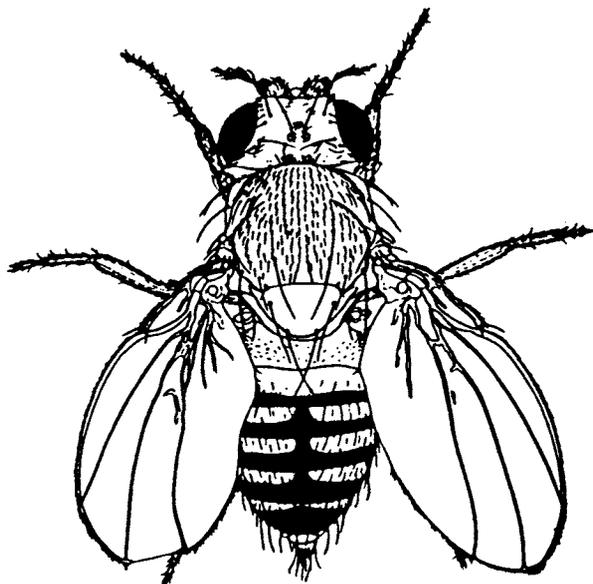

**location:** 2-50.0.

**discoverer:** E. M. Wallace, 35d1.

**references:** Bridges and Brehme, 1944.

**phenotype:** Wings extended and bent backward, often warped and shortened; sometimes blistered and nicked. Alulae reduced in size with reduced number of marginal

Temperature-sensitive allele; partially complements  $el^1$  at 25° but not at 29°.

### el: elbow

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 75.

bristles—may fuse with wing blade. Venation reduced by terminal shortening of L5 and of crossveins. Halteres reduced, often to stubs. Eye size decreased (variable, even with strong alleles). Weak alleles may overlap wild type and show only a reduction in number of marginal bristles on alulae. Some alleles may be semilethal when hemizygous. Class (i) alleles enhance *Sco*, are semilethal with alleles of *l(2)35Ba* and show a weak *noc* phenotype when heterozygous with strong *noc* alleles or *noc* deletions. Class (ii) alleles do not interact with these loci. All alleles more extreme when hemizygous; strong alleles nearly apterous.

Robinow and White, 1988, Dev. Biol. 126: 294-303.

**phenotype:** Embryonic lethal, or in the case of viable and ostensibly hypomorphic alleles, displays poor jumping and flying ability plus aberrant visual physiology and behavior. No morphological abnormalities visible in sections of dying embryos (*elav*<sup>1</sup>, *elav*<sup>2</sup>, or *elav*<sup>3</sup>); however, whole-mount embryos show periodic interruptions in the longitudinal connectives of the CNS and missing commissures especially the posterior ones (Jiménez and Campos-Ortega). *elav*<sup>ts1</sup> allows survival to adult stage at 19°-25° but viability is reduced and adults usually die soon after eclosion; viability after rearing at 30° is very low and newly emerged adults show poor coordination and die soon; this temperature-sensitive allele also causes morphological abnormalities in the brain, especially in the visual system (after postembryonic shift from 19° to 30° or even following all development at low-temperature); optic chiasma is abnormal and second order optic lobe (medulla) is rotated to aberrant position (Campos *et al.*, 1985); when *elav*<sup>ts1</sup> raised at 30°, surface of eye is rough and photoreceptor layer abnormal in sections (Campos *et al.*, 1985). Another temperature-sensitive allele *elav*<sup>19</sup> also induces abnormalities of visual system (Homyk *et al.*, 1985); rearing at 29° or high-temperature pulses delivered to pupae, raised otherwise at 20°, causes vacuolization of photoreceptors and disorganization of rhabdomeres; high-temperature rearing or pupal pulsing induces severe optic lobe defects (absence of size reduction); electroretinograms of this mutant, raised at high-temperature, are missing light-on and light-off transient spikes (also seen after low-temperature rearing) and have reduction of ERG photoreceptor potential; amplitude of this potential also deteriorates as does deep pseudopupil when adults treated at high-temperature after low-temperature rearing; mosaic analysis (Campos *et al.*, 1985) of *elav*<sup>1</sup> reveals autonomously induced defects in eye morphology, but no effects on other imaginal disc derivatives, and suggests both directly induced defects in optic lobe development,

as well as inductively caused CNS defects mediated through expression of this mutation in the eye (i. e., such that the visual system's ganglia are genotypically normal). Lethal "focusing" in these mosaics suggests influence of gene on derivatives of ventral blastoderm. In studies of viable alleles, *elav*<sup>19</sup> and *elav*<sup>20</sup>, both of which are temperature-sensitive, flying and jumping ability shown to be especially aberrant after rearing at 29°C; wing position also aberrant; *elav*<sup>ts1</sup> most severe, including having no optomotor response when raised at high (or even low) temperature; temperature-sensitive period for aberrant wing posture in *elav*<sup>19</sup> extends from larval to pupal period (Homyk and Grigliatti). An antibody specific to neuronal nuclei fails to stain neurons of *elav*-deficient embryos; however, the quantity of antigen does not respond to the number of *elav*<sup>+</sup> genes present (Bier, Ackerman, Barbel, Jan and Jan, 1988, Science 240: 913-16). *elav* transcripts detected in all postmitotic neurons, from their birth; not seen in embryonic or larval neuroblasts. Also seen in larval eye discs, adult retinas and Johnston's organ of the antennae.

**cytology:** Placed in 1B5-9 based on the proximal breakpoint of *ln(1)elav*<sup>4</sup> = *ln(1)IA6-B1;IB5-9*, which interrupts the *elav* gene.

**molecular biology:** Probing Northern blots with a 4.8-kb genomic subclone spanning the *ln(1)elav*<sup>4</sup> breakpoint identifies 4.7, 5.4, and 6.1-kb transcripts; the 5.4-kb RNA is seen in 0-6-hr embryos and the 4.7 and 6.1-kb RNAs in 6-18-hr embryos; no transcripts seen in larvae and two very low abundance RNAs of similar size to the

embryonic RNAs seen in pupae; adult heads contain 5.4 and 6.1-kb transcripts; all three transcribed from right to left. A genomic clone encompassing the region homologous to the 4.7 and 6.1 but not all of the 5.4-kb transcript able to rescue lethality of *elav*. Sequence analysis of genomic and partial-length cDNA clones indicate an open reading frame specifying a complete polypeptide of 483 amino acids and 50.76 kd. The coding sequence contains two introns of 1289 and 2208 nucleotides. The conceptual translation product contains three repeats of a pair of sequences previously defined as RNA-binding consensus sequences, an octopeptide, RNP1, and an appropriately spaced hexapeptide, RNP2, suggesting that this protein is involved in the RNA metabolism of neurons. In addition, a palindromic sequence is seen 5' to the transcription unit and GAGA motifs are found 5' to the transcription unit, and in the second intron. Eleven copies of a putative zeste-protein-binding sequence are found in the vicinity.

**elbow:** see *el*

**elf:** *extra lamina fiber* (J.C. Hall)

**location:** 1- between *v* and *f*.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *H37; opm37*.

**references:** Heisenberg and Gotz, 1975, J. Comp. Physiol. 117: 127-62.

**phenotype:** An extra large fiber profile is found in each cartridge of lamina (first order optic lobe); adults exhibit defective phototaxis and optomotor responses (e.g., higher than normal light intensities needed for vigorous responses); light-off transient spike of electroretinogram weak.

**other information:** Morphological difference from normal may no longer exist in adult lamina (Meinertzhagen).

**elfin:** see *ef*

*Elf-1* : see *Ntf*

**ellipsoid body open:** see *ebo*

**elliptical rough:** see *elr*

**Elongation factor:** see *Ef*

*Elp* : see *Egfr<sup>E</sup>*

**\*elr:** *elliptical rough*

**location:** 1-25.1.

**origin:** X ray induced.

**discoverer:** Fahmy, 1956.

**references:** 1960, DIS 34: 49.

**phenotype:** Eyes slightly elliptical and rough. Wings slightly broader. Both sexes viable and fertile. RK2.

**other information:** Two other alleles: one induced by X rays, one by L-p-N, N-di-(2-chloroethyl)amino-phenylalanine.

**elyC:** *early C*

**location:** 3-(unmapped).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Nüsslein-Volhard.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Embryos produced by

homozygous females show abnormal development during early cleavage and cease development soon thereafter.

alleles: Two, *elyC*<sup>1</sup> and *elyC*<sup>2</sup>, isolated as 043 and 230.

**Embryonic gonad:** see *Egon*

**embryonic lethal, abnormal vision:** see *elav*

***emc*: extra macrochaetae (H.M. Ellis)**

location: 3-0.

references: Botas, Moscoso del Prado, and García-Bellido, 1982, EMBO J. 1: 307-10.

Moscoso del Prado and García-Bellido, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 242-45.

García-Alonso and García-Bellido, 1988, Roux's Arch. Dev. Biol. 197: 328-38.

Ellis, Spann, and Posakony, 1990, Cell 61: 27-38.

Garrell and Modolell, 1990, Cell 61: 39-48.

**phenotype:** Hypomorphic alleles, or amorphic alleles when heterozygous with a hypomorphic allele, cause formation of extra macrochaetae. Severely hypomorphic combinations also cause formation of extra microchaetae. Amorphic alleles when homozygous result in embryonic lethality. Amorphic alleles when heterozygous with a normal third chromosome result in the appearance of ectopic chaetae in the occipital and premandibular regions. Extra chaetae in *emc* mutant flies appear on the head and notum (weak alleles) as well as on the wing blade, pleura, post-scutellum, tergites and legs in more severe allelic combinations. In severely hypomorphic allelic combinations extra campaniform sensilla occasionally appear on the wing blade. Reduction of wild-type *emc* function also causes the presence of extra bits of wing vein. A dominant *emc* allele (*emc*<sup>D</sup>) causes a reduction in the number of macrochaetae on the head and notum. *emc*<sup>D</sup> is homozygous viable; *emc*<sup>D</sup> homozygotes are more mutant than *emc*<sup>D/+</sup> individuals. The L4 and L5 wing veins are shortened in *emc*<sup>D</sup> homozygotes but only rarely in *emc*<sup>D/+</sup> heterozygotes. The insufficiency produced by *emc* can be titrated by altering the dosage of *ASC*; increased function of *ASC* produced by gain-of-function mutations (*Hw*) can be titrated by altering the dosage of *emc*<sup>+</sup>.

<sup>ε</sup> These experiments utilized Birmingham 2; delta 2-3.

**cytology:** Placed in 61D1-2 on the basis of *in situ* hybridization with *P*-element probes to revertible *P*-element induced *emc* null alleles.

**molecular biology:** The *emc* locus encodes a 2.3-kb transcript (interrupted by a single intron of 1.9-kb) that is present at all stages of development. Peak levels of transcript accumulation occur in 6-16 hour embryos and late third instar larvae and early pupae. *emc* transcripts appear in ovaries as well as female somatic tissue. Transcripts are also present in adult males. *emc* transcripts are present throughout the embryo at all stages from early cleavage through germ band extension. In third-instar larvae, *emc* transcripts are found in all tissues but are more abundant in the imaginal discs. RNA distribution is relatively homogeneous throughout the wing disc. *emc* cDNA clones contain a single long open reading frame capable of encoding a protein of approximately 22 kd. Analysis of the derived sequence of the *emc* protein shows that it is a member of the helix-loop-helix (HLH) family of proteins, but lacks the DNA binding motif characteristic of this group of proteins.

***ems*: empty spiracles**

location: 3-53.

origin: Induced by ethyl methanesulfonate.

references: Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95 (fig.). Dalton, Chadwick, and McGinnis, 1989, Genes Dev. 3: 1940-56 (fig.).

**phenotype:** Embryonic lethal. Embryos display loss of filzörper in the posterior spiracles; posterior ends of longitudinal tracheal trunks incomplete. Failure of head involution; many cuticular structures that normally derive from the procephalic and mandibular lobes of the head missing; embryonic antennal organs missing. *ems* protein first appears as an anterior ring around the syncytial blastoderm at a position just anterior to that of *Dfd*; it is five to six cells wide dorsally and 10-12 cells wide ventrally; at gastrulation the ring is just anterior to the cephalic furrow. As gastrulation proceeds expression becomes patchy and confined to specific groups of cells. The protein is nuclear in localization. The metameric pattern of *ems* expression commences at the beginning of germ-band extension; protein first appears in a group of

cells in each segment, which subsequently elongates and splits into two clusters of *ems*-positive cells in regions destined to give rise to tracheal pits, neuroblasts and epidermis. In the eighth abdominal segment, a large patch of *ems*-positive cells forms just posterior to the tracheal pit and presumably correspond to the primordia of the posterior spiracles and the filzkörper; a similar patch is formed anteriorly in embryos produced by *bcd* mothers. For a detailed discussion of the expression pattern see Dalton *et al.*

**alleles:** Five alleles induced with ethyl methanesulfonate by Jürgens *et al.*

allele	synonym	comments
<i>ems</i> <sup>1</sup>	7D99	
<i>ems</i> <sup>2</sup>	9H83	amorphic allele; stop codon at residue 161
<i>ems</i> <sup>3</sup>	9Q64	stop codon at residue 141
<i>ems</i> <sup>4</sup>	10A	hypomorphic allele

**cytology:** Placed in 88A1-2 by *in situ* hybridization.

**molecular biology:** Gene isolated on basis of homology to *eve* homeo domain. Northern blots with genomic fragment detect a 2.3-kb transcript that reaches peak abundance during 6-12 hr of embryonic development, and with substantial expression throughout embryonic development as well as in the third larval instar and pupal stages. Nucleotide sequence of a 2.2-kb cDNA and a portion of genomic sequence reveals the presence of an ~300 nucleotide intron just upstream of the homeo domain. The longest open reading frame could encode a polypeptide of 494 amino-acid residues; amino acids 1-384 contain 80 proline residues; residues 99-359 contain 12% glutamines. The C-terminal end contains a 24-amino-acid segment with 62% glutamic and aspartic acid residues. The homeo-domain sequence is quite divergent from other published homeobox sequences, exhibiting less than 50% identity.

***en: engrailed* (T.Kornberg)**

**location:** 2-62.

**references:** Eker, 1929, *Hereditas* 12: 217-22.

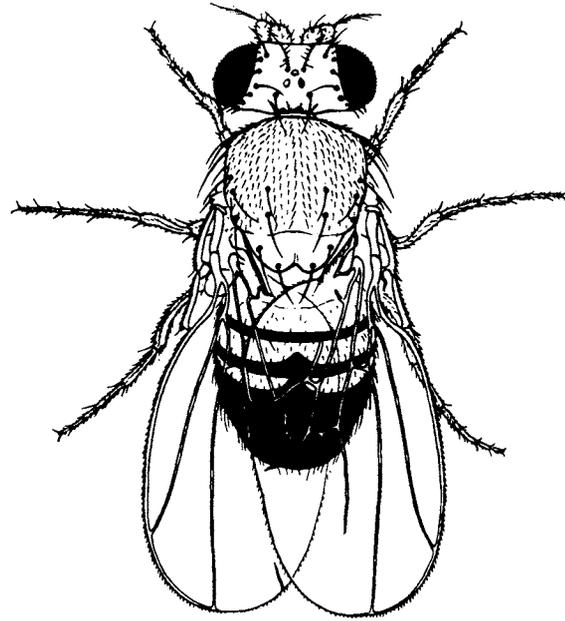

Nüsslein-Volhard and Wieschaus, 1980, *Nature* 287: 795-801.

Kornberg, 1981, *Proc. Nat. Acad. Sci. USA* 78: 1095-99.

Eberlein and Russell, 1983, *Dev. Biol.* 100: 227-37.

**phenotype:** Four classes of alleles, all recessive.

(1) *en*<sup>1</sup>. Viable hemizygous and homozygous; fertile. Longitudinal cleft extends from rear border of scutellum forward, may be reduced to median nick or posterior flattening of scutellum. Wings larger, broader, and thin textured with spatulate end; venation and distribution of sensilla abnormal in posterior wing compartment. Variable duplication of anterior triple row bristles on posterior margin; alula reduced, with costal-like bristles. In males, extra sex comb often present (Brasted, 1941, *Genetics* 26: 347-73), smaller than normal, and in mirror-image position in posterior compartment. Duplications of transverse rows in female prothoracic leg, extra bristles in mesothoracic and metathoracic tarsi (García-Bellido, and Santamaria, 1972, *Genetics* 72: 87-104; Lawrence, Struhl, and Morata, 1979, *J. Embryol. Exp. Morph.* 51: 195-208). Action of *en*<sup>1</sup> is autonomous except for scutellar cleft (Tokunaga, 1961, *Genetics* 46: 157-76; Stern and Tokunaga, 1968, *Proc.*

***en: engrailed***

From Eker, 1929, *Hereditas* 12: 217-22.

*Nat. Acad. Sci. USA* 60: 1252-59; García-Bellido, and Santamaria, 1972, *Genetics* 72: 87-104). Clones of *en* cells of posterior compartment origin fail to respect anterior-posterior compartment border in wing disc as do *mwh* clones in wing discs of *en*<sup>1</sup> homozygotes (Morata and Lawrence, 1975, *Nature* 255: 614-17; Morata and Lawrence, 1976, *Dev. Biol.* 50: 321-37). *en* abnormalities are associated with posterior compartment structures only, except for scutellar cleft. Restriction of glucose-6-phosphate dehydrogenase, 6-phosphogluconate dehydrogenase (Cunningham, Smith, Makowski, and Kuhn, 1983, *Mol. Gen. Genet.* 191: 238-43) and of a protein recognized by monoclonal antibody PS2 (Brower, 1984, *Nature* 310: 496-98; 1987, *EMBO J.* 5: 2649-56) to posterior compartment of wing disc altered by *en*<sup>1</sup>. Interaction with *ci*, *cg*, *sx* (House, 1953, *Genetics* 38: 200-15; House, 1953, *Genetics* 38: 309-27; House, 1961, *Genetics* 46: 871; Mukherjee, 1965, *Genetics* 51: 285-304; Datta and Mukherjee, 1971, *Genetics* 68: 269-86) and *fu* (Fausto-Sterling and Smith-Schiess, 1982, *EMBO J.* 1: 827-33) partially increase phenotype. No suppression by *su(Hw)*.

(2) Lethal alleles with normal cytology. Embryonic lethal. Anterior margin of each segment defective. Pair rule defects in naked cuticle of T1, T3, A2, A4, A6, A8 result in pair-wise fusion of adjacent segments. Autonomous effects in adult cuticular clones observed in posterior compartment of proboscis, thorax, abdomen, and genitalia. *en*<sup>lethal</sup> clones are without effect in anterior compartments and in eye-antennal region (Kornberg, 1981, *Proc. Nat. Acad. Sci. USA* 78: 1095-99; Kornberg, 1981, *Dev. Biol.* 86: 363-72; Lawrence and Struhl, 1982, *EMBO J.* 1: 827-33). The *en*<sup>1</sup>/*en*<sup>lethal</sup> heterozygote characterized by wing abnormalities only; disruption of anterior crossvein, gap in vein IV, and occasional socketted bristles on posterior margin. In some combinations complementation is complete or nearly so (Condie and

Brower, 1989, Dev. Biol. 135: 31-42). No maternal effect (Lawrence, Johnston and Struhl, 1983, Cell 35: 27-34).

(3) Deficiencies and lethal alleles with inversion or translocation breakpoints. Embryonic lethal. Embryonic segment defects slight and variable. Alleles of this class in heterozygous combination with *en*<sup>1</sup> produce adults more extreme than *en*<sup>1</sup>. For example, in *en*<sup>1</sup>/*en*<sup>2</sup>, legs are truncated, the tarsi reduced to densely bristled stumps; wings are greatly enlarged and spatulate with greater disruption of veins IV and V; higher penetrance of socketed bristles along the posterior margin. Extreme scutellar cleft. At 29°, duplication of anterior compartment bristles in mirror-image symmetry in posterior compartment of second antennal segment (Morata, Kornberg, and Lawrence, 1983, Dev. Biol. 99: 27-33).

(4) Non-lethal alleles with breakpoints. Hemizygous viable, embryos normal. Heterozygous with other allele classes, variable gaps in wing veins IV and V. Variable reductions or deletions in male and female genitalia (Epper and Sanchez, 1983, Dev. Biol. 100: 387-98). Scutellum may also be affected.

<sup>β</sup> Origin of molecular coordinates defined as the insertion site in *en*<sup>1</sup>; minus values to the left.

**cytology:** Placed in 48A3-4, based on two inversion and eleven translocation breakpoints.

**molecular biology:** 225 kb of genomic DNA proximal to *tRNA-Met2* at 48B5-7 (Poole, Kauvar, Drees, and Kornberg, 1985, Cell 40: 37-43) was used to locate *en* rearrangements. Gene also isolated directly from genomic library using *Ubx* homeobox probe (Fjose, McGinnis, Gehring, 1985, Nature 313: 284-89). *en*<sup>1</sup> is associated with a 7-kb insertion of a middle-repetitive DNA element (defined as molecular coordinate 0 with negative values to the left). Lethal breakpoints span the *en*<sup>1</sup> insertion from -35 kb proximally to +10 kb distally; non-lethal breakpoints are at +15 to +35 (Kunner, Nakanishi, Ali, Drees, Gustavson, Theis, Kauvar, Kornberg and O'Farrell, 1985, Cell 42: 309-16). Subclones from -20 to -12 detect transcripts of 1.4, 2.7 and 3.6 kb on Northern blots of RNA from embryos (high abundance), larvae, and pupae (low abundance), but not from adults; the abundance of the 2.7-kb species is ten times that of the other two in all stages investigated. Sequence determinations reveal a 1700-nucleotide open reading frame within which a polypeptide of 562 amino-acids and approximately 60 kd is encoded. The initial transcript contains introns of 1.1 and 0.28 kb, the latter one being 3' to the first and interrupting a homeobox encoding domain. The homeobox sequence diverges significantly from those at *ftz*, *Antp*, and *Ubx*, the latter displaying closer homology to human homeobox sequences than they do to the *en* homeo domain. In addition, in the 5' end of the gene there is a concentration of the repeating CAA and CAG as well as other single-amino-acid runs throughout the sequence (Poole, Kauvar, Drees, and Kornberg, 1985,

Cell 40: 37-43). Transcription occurs from the right to left (Drees, Ali, Soeller, Coleman, Poole, and Kornberg, 1987, EMBO J. 6: 2803-09). *en* protein binds to clusters of sequences located upstream from the *en* transcription-start site; both *en* and *ftz* gene products compete for the consensus sequence TCAATTAAT (Desplan, Theis, and O'Farrell, 1985, Nature 318: 630-35; Jaynes and O'Farrell, 1988, Nature 336: 744-49; Desplan, Theis, and O'Farrell, 1988, Cell 54: 1081-90). Shown to form stable polyprotein DNA-binding complex with other soluble proteins in the nucleus (Gay, Poole, and Kornberg, 1988, EMBO J. 4291-97). The developmental and spatial program of *en* expression determined by immunolocalization of its protein product (DiNardo, Kuner, Theis, and O'Farrell, 1985, Cell 43: 59-69; Karr, Weir, Ali, and Kornberg, 1989, Development 105: 605-12). Engrailed protein is first detectable in Western blots in the precellular blastoderm; at the initiation of cellularization a low level of protein distributed uniformly in embryo; as cellularization proceeds, the protein becomes concentrated in the second and fifth sixths of the egg length; subsequently stripes become more numerous and narrower, filling the central third of the embryo with stripes, first in even-numbered segments and then in every segment. At the onset of gastrulation; the cellular blastoderm exhibits fourteen one-cell-wide stripes of *en* expression; each stripe defines the anlagen of the posterior compartment of a metameric segment and the anterior parasegment boundary. At full germ-band extension *en* expressed in labial, maxillary, mandibular primordia, in three thoracic, and nine abdominal segments. Cell movements in head and tail regions lead to complex distributions of expressing cells. Subsets of cells in the ventral nervous system also seen to be expressing *en* at ten hours of development. As expected for a DNA-binding protein, *en* antigen accumulates in nuclei. In third-instar larvae *en* expression observed in presumptive posterior compartments of imaginal discs and in discrete cells in the ventral ganglion of the larval brain (Brower, 1987, EMBO J. 5: 2649-56). Expression of *en* positively controlled by *ftz*, *eve*, and *prd*; modulated by *h*, *odd*, *opa*, and *run* (Weir, and Kornberg, 1985, Nature 318: 433-39; Harding, Rushlow, Doyle, Hoey, and Levine, 1986, Science 233: 953-59; Howard, and Ingham, 1986, Cell 44: 947-57; DiNardo, and O'Farrell, 1987, Genes Dev. 1: 1212-25; Ingham, Baker, and Martinez-Arias, 1988, Nature 331: 73-75; Martinez-Arias, and White, 1988, Development 102: 325-28).

Academic Press, London, New York, San Francisco, Vol. 1b, pp. 847-902; 10 = Zusman, Coulter, and Gergen, 1985, DIS 61: 217-18.

**cytology:** Placed in 20A1-2 based on its inclusion in  $Df(1)B12 = Df(1)I9E1;20A1-2$  and  $Df(1)JC4 = Df(1)20A1;20E-F$ .

*Epa*: see *Cos1*

**Epidermal growth factor receptor homologue:** see *Egfr*

**eq: equational producer**

**location:** 1- (to the right of *car*, probably heterochromatic).  
**origin:** X ray induced.

**discoverer:** Schultz, 33a2.

**references:** Morgan, Bridges, and Schultz, 1934, Year Book - Carnegie Inst. Washington 33: 280.

**phenotype:** Produces 1-2% equational nondisjunction of X's in male, producing both X/X and nullo-X, nullo-Y sperm. Original *eq* male when crossed to attached-X female produced 89/289 equational exceptional X/X daughters. Claimed to generate *bb*-deficient Y chromosomes. More recent experiments (Valentin, 1984, Hereditas 101: 115-17) produce an order of magnitude fewer equational exceptions from males; none from homozygous females.

**cytology:** Both salivary and mitotic chromosomes appear normal.

**eq1: equatorial-less (J.C. Hall)**

**location:** 2-right arm near *bw*.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Ransom.

**references:** Campos-Ortega, 1980, Current Topics in Developmental Biology 15: 347-71.

**phenotype:** Recessive lethal; in homozygous mutant clones in mosaic eyes, ommatidia lack one, two, or three photoreceptor cells from among two specific outer cells in a given facet ( $R_1, R_6$ ) and a specific inner cell ( $R_7$ ).

**alleles:** Two mutant alleles, *eq1*<sup>1</sup> and *eq1*<sup>2</sup> (published as *eq1*<sup>lff40</sup> and *eq1*<sup>lff225</sup>, respectively), the latter of which is more severe in its effects, often removing three photoreceptors from each facet instead of one or two.

**cytology:** Not uncovered by  $Df(2R)bw^5$ .

**er: erupt**

**location:** 3-71 (60.7 to 80.7; not an allele of *k*).

**origin:** Spontaneous.

**discoverer:** Glass, 1941.

**references:** 1943, DIS 17: 50.

1944, Genetics 29: 436-46.

1957, Science 126: 683-89 (fig.).

**phenotype:** Exhibits eruption of underlying hypodermis in center of one or both eyes. Eruption may be segmented and have hairs. Less extreme expression produces derangement of central or anterior-central facets. Eruption may occur as encroachment of chitin with bristles and hairs into anterior edge of eye. Extra tissue derived

from eye portion of eye-antennal disk (Aubele, 1968, DIS 43: 139). RK2.

**other information:** Alleles of at least five different strengths present in different wild stocks. Present in many wild stocks in suppressed condition.

**\*Er: Erect**

**location:** 3-50.

**origin:** Spontaneous.

**discoverer:** Neel, 41c9.

**references:** 1942, DIS 16: 50.

**phenotype:** Posterior scutellars at greater than normal angle with body, vary from slight effect to conditions in which bristles stand at right angles to scutellum. In latter case, bristles usually appear warped and twisted. Wings incompletely expanded and crinkled to varying degrees. RK3.

*Erased*: see *en*<sup>Es</sup>

*Erect*: see *Er*

*erect wing*: see *ewg*

**err: erratic (T. Schüpbach)**

**location:** 2-40.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal effect lethal; embryos from homozygous mothers have variable cuticular defects and holes.

**alleles:** *err*<sup>1</sup>, isolated as *err*<sup>RE</sup>.

**cytology:** Placed in 31B-32A based on lethality over  $Df(2L)J27 = Df(2L)31B-D;31F-32A$ .

*erupt*: see *er*

**es: ether sensitive**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Tinderholt.

**references:** Kidd, 1963, DIS 37: 49.

**phenotype:** Hypersensitive to diethyl ether and chloroform. Homozygotes killed by exposure to doses of these agents harmless to normal flies. Sensitivity probably affected by modifiers. A male sterility factor seems to be associated but may be separable. Viability of homozygote about 70% that of *es/SMI* and remains low in strains selected for less sensitivity. Not sensitive to carbon dioxide. RK3.

*Es*: see *en*<sup>Es</sup>

**esc: extra sex combs**

**location:** 2-{47}.

**discoverer:** Slifer, 40e2.

**references:** 1942, J. Exp. Zool. 90: 31-40 (fig.).

Struhl, 1981, Nature (London) 293: 36-41 (fig.).

**phenotype:** Distal portions of second and third legs weakly transformed into first leg and wing blade into haltere; transformation partial and variable in hypomorphic allele, *esc*<sup>1</sup>. Sex combs may be present on all six legs of male; at least one extra sex comb present in majority of males. Expression affected by culture conditions. When expressivity high, extra transverse bristle rows appear between sixth and eighth longitudinal rows of bristles, mainly on distal portion of basitarsus and tibia of second and third legs in both sexes; accompanied by shortening of affected

leg segments. Sex comb development autonomous in mosaics produced by somatic crossing over [Tokunaga and Stern, 1965, *Dev. Biol.* 11: 50-81 (fig.)]. For interactions with *Pc* and *Scx* see Hannah-Alava [1958, *Genetics* 43: 878-905 (fig.)]. Leg effects autonomous in homozygous clones of hypomorphic or amorphic alleles. Studies with amorphic alleles demonstrate that *esc* offspring of *esc*/+ mothers express the leg transformation, but *esc* zygotes produced by *esc* mothers die as newly hatched larvae that exhibit drastic homeotic transformations. All abdominal and thoracic and some head segments are transformed into eighth abdominal segments. The effects of the maternal insufficiency partially overcome by the presence in the zygote of a paternally derived *esc*<sup>+</sup> allele, more so by two paternally derived *esc*<sup>+</sup> alleles. Larvae with one paternal *esc*<sup>+</sup> range between normal and transformed phenotype; those with two frequently develop into adults, more than half of which show patchy transformations in abdominal and thoracic segments to more posterior segments. Temperature-shift experiments with the temperature-sensitive allele, *esc*<sup>17</sup> (i.e., on the *esc/esc* progeny of *esc*<sup>17</sup>/*esc* mothers when crossed to *esc* fathers) indicate that *esc*<sup>+</sup> product is required only around the time of gastrulation, as that is the only temperature-sensitive period (Struhl and Brower, 1982, *Cell* 31: 285-92). In the presence of extreme *BXC* deficiencies (including *abdA*<sup>-</sup>, *AbdB*<sup>-</sup>, and *abdA*<sup>-</sup> *AbdB*<sup>-</sup>) which transform the eighth abdominal segment to more anterior segments, *esc*<sup>+</sup> product insufficiency in the zygote causes all segments to develop as the eighth abdominal segment would develop under the influence of the *BXC* genotype in the presence of *esc*<sup>+</sup> product (Struhl, 1981; Struhl and White, 1985, *Cell* 43: 507-19). In the *esc*<sup>-</sup> embryo produced by *esc*<sup>2</sup>/*esc*<sup>10</sup> parents, *Ubx* transcription is normal early in development, but following gastrulation transcripts appear in ectodermal and mesodermal derivatives of all fourteen parasegments rather than being restricted to parasegments 6-12 as in wild-type (Struhl and Akam, 1985, *EMBO J.* 4: 3259-64). *esc*<sup>-</sup> embryos display reduced levels of *Antp* protein to levels below those of wild-type in all segments of the nervous system (Carroll, Laymon, McCutcheon, Riley, and Scott, 1986, *Cell* 47: 113-22).

<sup>α</sup> 1 = CP627; 2 = Hannah and Strömnaes, 1955, *DIS* 29: 121-23; 3 = Slifer, 1942, *J. Exp. Zool.* 90: 31-40; 4 = Struhl, 1981, *Nature* (London) 293: 36-41; 5 = Struhl and Brower, 1982, *Cell* 31: 285-92.

<sup>β</sup> Erroneously designated a dominant allele in CP627.

**cytology:** Placed in 33B1-2 based on *Df(2L)esc10*, a 380-bp deletion (coordinates -315 to +65) deficient for those two bands (G. Richards).

**molecular biology:** Region cloned by walking from sequences cloned from microdissected chromosomes (Frei, Baumgartner, Edström and Noll, 1985, *EMBO J.* 4: 979-87). Transformation experiments restrict locus to a 12-kb fragment from around coordinate -70 kb (0 = left end of a 44-kb *EcoRI* fragment from the walk; negative values to the left); the 12-kb fragment detects a single transcript of 1.8-kb, which is most abundant in follicles and 0-4 hr embryos, but is drastically reduced in later stages. Genomic sequences homologous to the transcript lie entirely within the segment from -67.8 to -64.6 kb. cDNA's identify the 3' end and a 364-base-pair intron, but not the 5' end of the transcript; transcription from right to left (Frei, Bopp, Burri, Baumgartner, Edström and Noll, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 127-34).

**Esm: Enhancer-of-split mimic**

**location:** 3-{81}.

**references:** Knust, Dietrich, Weigel, Tepass, Vässin, Bremer, and Campos-Ortega, 1987, *J. Neurogenet.* 4: 145-46).

**cytology:** Tentatively placed in 95F.

**molecular biology:** May carry *EGF*-like repeats.

**Est-6: Esterase 6**

**location:** 3-35.9 [based on 334 recombinants between *h* and *th* (Franklin, 1971, *DIS* 47: 113)].

**discoverer:** Wright, 61h.

**synonym:** *Est-D*.

**references:** 1963, *DIS* 37: 53.

1963, *Genetics* 48: 787-801 (fig.).

**phenotype:** The structural gene for the nonspecific carboxylesterase, [EST-6 (EC 3.1.1.1)]. One of the ten positively migrating esterases demonstrable with  $\alpha$ -naphthyl acetate and Fast Blue BB after starch gel electrophoresis of homogenates. Molecular weight determinations on purified enzyme indicate that the active enzyme is a 62,000 to 65,000 dalton glycoprotein monomer (Mane, Tepper, and Richmond, 1983, *Biochem. Genet.* 21: 1019-40). Substrate specificities to different esters explored by Danford and Beardmore (1979). Specific EST-6 activity during development shows a prominent transient peak during second larval instar and shows a male-specific rise in activity beginning 36-48 hr after eclosion; males reach level double that of females (Sheehan, Richmond, and Cochrane, 1979, *Insect Biochem.* 9: 443-50); similar high levels found in male-like triploid intersexes (Aronsham and Kuzin, 1974, *Zh. Obsch.* 35: 926-33) and *X/X;tra/tra* (Johnson, 1964, *Genetics* 50: 259). High concentrations of EST-6 found in ejaculatory duct; at mating, male level depleted and female level enhanced; transfer of activity from male to

*Est-6<sup>0</sup>* female detected early during copulation, prior to the transfer of sperm, indicating that *EST-6* is a component of seminal fluid (Richmond, Gilbert, Sheehan, Gromko, and Butterworth, 1980, *Science* 207: 1483-85). Enzyme levels in flies carrying different X chromosomes from natural populations in combination with constant autosomal complement vary suggesting X-linked modifiers (Tepper, Richmond, and Terry, 1981, *Genetics* 97: s103). In *D. melanogaster* X *D. simulans* hybrid males that carry a *D. melanogaster* X chromosome, the level of the *D. melanogaster* enzyme is reduced compared to that of the *D. simulans* enzyme; hybrid females have equivalent activities of the two enzymes (Korchkin, Aronshtam, and Matveeva, 1974, *Biochem. Genet.* 12: 9-24). Electrophoretic mobility reduced modestly from 1.10 to 1.08 for *Est-6<sup>F</sup>* and from 1.0 to 0.98 for *Est-6<sup>S</sup>* by *m(Est-6)* on the third chromosome (Cochrane and Richmond, 1979, *Biochem. Genet.* 17: 167-83).

**alleles:** Allelic variation in *Est-6* is expressed in electrophoretic mobility (complicated by heterogeneity for *m(Est-6)* on chromosome 3), thermal stability, and level of activity. The same alleles have been designated differently by different authors. The accompanying table attempts to define the equivalences. Some use electrophoretic mobility relative to that of *Est-6<sup>S</sup>* = 1.00 in designating alleles. Relative mobility estimates vary within and among gels; also relations between mobilities on starch and acrylamide are nonlinear; consequently, similar but not identical estimates may not represent real differences.

<sup>α</sup> 1 = Cochrane and Richmond, 1979, *Genetics* 93: 461-78; 2 = Franklin, 1971, *DIS* 47: 113; 3 = Johnson, 1964, *J. Hered.* 55: 76-8; 4 = Rodinó and Danieli, 1972, *DIS* 48: 77; 5 = Triantaphyllidis and Christodoulou, 1973, *Biochem. Genet.* 8: 383-90; 6 = Trippa, Scozzari, Costa, and Danieli, 1979, *Egypt. J. Genet.* 8: 295-302.

<sup>β</sup> Contains insert of 412.

<sup>γ</sup> Requires 3-4 times normal incubation time to detect activity.

**cytology:** Placed in 69A1-5 based on its inclusion within *Df(3L)vin-5 = Df(3L)68A3;69A1-2*, but not *Df(3L)vin-6 = Df(3L)68C8-11;69A4-5* (Akam, Roberts, Richards, and Ashburner, 1978, *Cell* 13: 215-25). Further localized to 69A by *in situ* hybridization (Oakeshott, Collet, Phillis, Nielsen, Russell, Chambers, Ross, and Richmond, 1987, *Proc. Nat. Acad. Sci. USA* 84: 3359-63).

**molecular biology:** Gene isolated by screening a cDNA library with oligonucleotide probes based on tryptic-peptide amino-acid sequences (Oakeshott *et al.*). The 1.85-kb cDNA clone sequence is contained within a 2.3-kb *EcoRI-BamHI* genomic fragment. One strand of the cDNA clone hybridizes to mRNA's of 1.68 and 1.83 kb. Developmental profiles of transcripts concordant with that of *EST-6*; transcripts absent in *Est-6<sup>0</sup>* adults. Conceptual amino acid sequence of larger transcript suggests a signal peptide of 21 amino acids followed by 527 residues of the mature protein (59,380 daltons); potential glycosylation sites at residues -2, 21, 399, 435, and 485. Contains an eight-residue sequence with strong similarity to the consensus of active sites of nine other eukaryotic esterases.

### **Est-9**

**location:** 2- (probably right arm based on apparent homology to and position of *Est-9* in *Drosophila pseudoobscura*).

**references:** Loukas, 1981, *DIS* 56: 85.

**phenotype:** The apparent structural gene of an esterase whose detection depends on the presence of 1-leucyl-β-naphthylamide in addition to α-naphthyl acetate as substrate.

**alleles:** *Est-9<sup>F</sup>* and *Est-9<sup>S</sup>* detected.

### **Est-A: Esterase A**

**location:** Not located.

**references:** Mizianty and Case, 1972, *J. Heredity* 62: 345-47.

**phenotype:** The most anodally migrating esterase band; migrates considerably in advance of *EST-C*. Activity weak in standard gel system.

**alleles:** *Est-A* inferred from absence of band from Swedish-C wild stock; *EST-A* band present in Oregon-R. Presence and absence segregate as a single genetic character.

### **Est-C**

**location:** 3-47.7 [to the left of *p* (Ohnishi and Voelker, 1979, *Jpn. J. Genet.* 54: 203-209); 0.006 from *Odh* (Mukai and Voelker, 1977, *Genetics* 86: 175-85)].

**references:** Beckman and Johnson, 1964, *Hereditas* 51: 212-20 (fig.).

**phenotype:** Specifies *EST-C* (EC 3.1.1.1), the next-to-most rapidly migrating of six anodally migrating esterases detectable with α-naphthyl acetate and Fast Blue BB following starch gel electrophoresis. Enzyme a monomer. Putative null alleles homozygous viable, consistent with failure to find lethal complementation group within the interval.

**alleles:** Selected from natural populations. Since they were isolated from the same population, either *Est-C<sup>nNC1</sup>* and *Est-C<sup>nNC4</sup>*, or *Est-C<sup>nNC2</sup>* and *Est-C<sup>nNC3</sup>*, or *Est-C<sup>nGB1</sup>* and *Est-C<sup>nGB2</sup>* could represent reisolates of the same allele.

**cytology:** Placed in 84D3-5 on the basis of its position between *Df(3R)Scx4 = Df(3R)84B1-2;84D3-4* and *Df(3R)D7 = Df(3R)84D3-5;84F1-2* (Cavener, Otterson, and Kaufman, 1986, *Genetics* 114: 111-23).

**Etd: Eye tissue determiner**

**location:** 1-23 (approximate).

**origin:** Spontaneous.

**references:** Gethman, 1971, *Mol. Gen. Genet.* 114: 144-55.

**phenotype:** Removes lower half of eye.

**Eth: Ether resistant (J.C. Hall)**

**location:** 3-61.

**origin:** Strain produced by 29 generations of selection.

**references:** Ogaki, Nakashima-Tananka, and Murakami, 1967, *Jpn. J. Genet.* 42: 387-94.

Gamo, Ogaki, and Nakashima-Tanaka, 1979, *Jpn. J. Genet.* 54: 229-34.

Gamo, Nakashima-Tanaka, and Ogaki, 1980, *Jpn. J. Genet.* 55: 133-40.

**phenotype:** The major determinant in a selected strain that is more resistant than usual to killing effects of ether vapors administered to adults; resistance dominant to sensitivity; minor factors on chromosomes 1 and 4; *Eth*-bearing strain also relatively resistant to killing effects of chloroform or halothane; these phenotypes are dominant and semidominant, respectively; chloroform resistance due to major factor on chromosome 1 and a minor one on chromosome 2; halothane resistance caused by major factor on third chromosome (not known if same locus as that responsible for most of the ether resistance), and minor components on chromosomes 1 and 2; halothane resistance also seen with respect to anesthesia, and genetic difference for this maps to chromosome 1.

**ether-a-go-go:** see *eag*

**ether sensitive:** see *es*

*Etre*: see *Fs(2)Sz4*

**Ets2: Ets-2 proto-oncogene homologue**

**location:** 2-{100}.

**references:** Pribyl, Watson, McWilliams, Ascione, and Papas, 1988, *Dev. Biol.* 127: 45-53.

**phenotype:** Encodes a *Drosophila* homologue to the *ets* gene from the avian erythroblastosis retrovirus E26. mRNA constitutively present in all developmental stages, with elevated levels of expression in 0-9-hr embryos and pupae.

**cytology:** Placed in 58A-B by *in situ* hybridization.

**molecular biology:** Genomic clone isolated using restriction fragment from a *Drosophila Ets* clone previously

derived from Schneider cells. The sequence shows homology to the last two exons of chicken *ets* or mammalian *ets-2* (as does *v-ets* from E26) with an intron of 63 base pairs separating the two exons; the intron is smaller in size, but identical in position to that of *ets* genes in other species. *Ets* sequences detect a single 4.7-kb mRNA on Northern blots. Between *Drosophila Ets* and *v-ets*, there is 71% homology at the nucleotide level and 91% at the predicted amino-acid level; these figures with respect to human *ets-2* are 76% and 94%.

**eve: even skipped**

**location:** 2-58.

**references:** Nüsslein-Volhard and Wieschaus, 1980, *Nature (London)* 287: 795-801 (fig.).

Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82 (fig.).

Nüsslein-Volhard, Kluding, and Jürgens, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 145-54 (fig.).

**phenotype:** Homozygous lethal; embryos homozygous for a null allele or a deficiency fail to undergo segmentation and their ventral surfaces are covered by a lawn of short denticles pointed toward the midline; denticles in the anterior region show thoracic characteristics suggesting that segmental identities persist in the absence of segmentation. All derivatives of gnathal segments are missing, such as maxillary sense organs, cirri, mouth hooks, labial sense organs and the mandibular parts of the cephalopharyngeal skeleton; the labrum, antennal sense organs, and a rudimentary skeleton are the only remains of the larval head. Posteriorly, anal plates and some sensory organs persist as do remnants of spiracles, filzkörper, and tufts. Homozygotes and hemizygotes for hypomorphic alleles display pair-rule segmentation defects. Denticle bands and adjacent naked cuticle of the prothoracic, metathoracic and even-numbered abdominal segments removed; some naked cuticle of the adjacent segment removed as well (i.e., the odd numbered parasegments are removed). Combinations of alleles with *Df(2R)eve* raised at different temperatures can achieve an array of phenotypes between these extremes. Expression of *eve* is first detected at the eleventh nuclear division following fertilization; at this stage, *eve* protein is uniformly distributed among the nuclei, both at the periphery and deep within the egg; by the thirteenth nuclear division, the anterior one-third of the embryo is devoid of detectable protein; over the next 20 minutes, the antibody staining in the posterior two-thirds of the embryo becomes concentrated in seven transverse stripes four or five cells wide separated by stripes three to four cells wide with lower levels of staining. By the time of germ-band elongation, the seven stripes have become narrowed and sharply defined and seven new weakly expressing stripes, one to two cells wide, appear between the major stripes; during germ-band elongation all stripes gradually disappear. As *eve* stripes become more sharply defined so too do *ftz* stripes, no longer overlapping *eve* stripes, but forming a complementary pattern. At the same time, a group of expressing cells appears at the posterior end of the germ band; these cells form a ring around the anal plate during germ-band shortening. Also during germ-band shortening, a specific subset of sixteen neurons in each hemisegment of the CNS expresses *eve* product as does a row of cell clusters on either side of the

dorsal midline; lateral to these clusters are curious rings of weakly staining cells; the dorsal cells do not appear to be neuronal (Frasch, Hoey, Rushlow, Doyle, and Levine, 1987, *EMBO J.* 6: 749-59; Frasnch and Levine, 1987, *Genes Dev.* 1: 981-95). In homozygous *eve*<sup>1</sup> embryos switched to restrictive temperature during neurogenesis, four specifically studied *eve*-expressing neurons in each hemisegment are found to persist; two of them develop normally, but two send axonal processes to abnormal destinations [Doe, Smouse, and Goodman, 1988, *Nature (London)* 333: 376-78]. Frasnch and Levine observe that segmentation-gene-mutations generally have reciprocal effects on the expression of *eve* and *ftz*, leading them to postulate that their promoters respond reciprocally to the same positional cues. *eve* concluded to be an early pair-rule gene, since its expression is modified by gap-gene mutations, but not by most other pair-rule gene mutations nor by segment-polarity gene mutations. Three pair-rule genes do influence *eve* expression: in either *eve* or *h* genotypes, *eve* expression is reduced and in *run* embryos *eve* is overexpressed (Frasch and Levine, 1987). In *eve* embryos, *en* stripes do not appear (Macdonald, Ingham, and Struhl, 1986, *Cell* 47: 721-34). *Ubx* protein is detected at high level in odd-numbered parasegments from 7 through 13 rather than in every parasegment from 6 through 12 (Martinez-Arias, and White, 1988, *Development* 102: 325-38). *ftz* stripes are disrupted in regularity of position, size, and timing (Carroll and Scott, 1986, *Cell* 45: 113-26).

**alleles:**

<i>eve</i> <sup>1</sup>	EMS	ID19	1, 2, 3, 5	temperature-sensitive allele; 121 arg → his
<i>eve</i> <sup>2</sup>	EMS	IIR59	1, 2, 3, 5	weak allele; 75 thr → ile
<i>eve</i> <sup>3</sup>	EMS	R13	1, 4, 5	strong allele; → no <i>eve</i> protein
<i>eve</i> <sup>4</sup>	X ray	3.77.17	1, 5	intermediate allele; molecular deletion → frame shift → 134 C-terminal residues replaced by 79 extraneous ones

<sup>α</sup> 1 = Frasnch, Warrior, Tugwood, and Levine, 1988, *Genes Dev.* 2: 1824-38; 2 = Nüsslein-Volhard and Wieschaus, 1980, *Nature (London)* 287: 795-801 (fig.); 3 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82 (fig.); 4 = Nüsslein-Volhard, Kluding, and Jürgens, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 145-54 (fig.); 5 = Tearle and Nüsslein-Volhard, 1987, *DIS* 66: 209-26.

**cytology:** Placed in 46C3-11 based on *Df(2R)eve* = *Df(2R)46C3-4;46C9-11*.

**molecular biology:** Gene isolated based on homology to known homeobox sequences (Macdonald *et al.*, 1986; Frasnch *et al.*, 1987). Probing Northern blots with the genomic sequence identifies a single RNA species of 1.4 kb whose expression is strong during early embryogenesis, persisting at declining levels until first instar. Sequence data reveals the presence of a 71-bp intron between the initiating AUG and the homeobox; the conceptual amino-acid sequence defines a basic 40-kd polypeptide of 376 amino acids with a 60-amino acid homeobox domain extending from residue 70 to 130; the homeobox sequence shows only about 50% identity with those of previously sequenced homeoboxes. Repeats of the trinucleotide GCX are found in positions 564-608 producing a polyalanine sequence, as is also seen in *en*,

*N*, and *cad*. Promoter fusion experiments utilizing a *LacZ* reporter gene identify promoter elements for stripe 1 (tentative), stripe 3, and stripes 2 and 7 within 8 kb of upstream sequence; in addition a target for an autoregulatory function of *eve* protein identified in this region (Goto, Macdonald, and Maniatis, 1989, *Cell* 57: 413-22; Harding, Hoey, Warrior, and Levine, 1989, *EMBO J.* 8: 1205-12). *eve* protein shown to repress *Ubx* transcription *in vitro* (Biggin and Tjian, 1988, *Cell* 58: 433-40); in DNA footprint studies *eve* protein can be shown to bind to specific sequences 5' to both *en* and *eve*, but the sequences in the two genes do not appear to have features in common [Hoey and Levine, 1988, *Nature (London)* 332: 858-61].

**ewg: erect wing (J.C. Hall)**

**location:** 1-0.0.

**references:** Deak, 1978, *Dev. Biol.* 66: 422-41.

Fleming, Zusman, and White, 1983, *Dev. Genet.* 3: 347-63.

Fleming, DeSimone, and White, 1989, *Mol. Cell Biol.* 9: 719-25.

**phenotype:** Viable allele causes wings to be held upright; wing posture phenotype shows incomplete penetrance. Dorso-ventral flight muscles often absent, especially when the mutation is heterozygous with a deficiency. Ultrastructure of tergal depressor of trochanter jump muscle normal. Flies hemizygous for lethal alleles die either just prior to hatching of the larva from the egg or immediately thereafter; mosaic analysis of certain lethal alleles suggests primary defect in developing muscles; however, *in situ* studies of transcription reveal that expression is confined to the nervous system and not the muscles (Fleming *et al.*, 1989).

**alleles:** Survival of lethal alleles in combination with *ewg*<sup>1</sup> variable and temperature-sensitive *ewg*<sup>11</sup> complements at least partially *ewg*<sup>4</sup>, *ewg*<sup>7</sup>, *ewg*<sup>10</sup>, and *ewg*<sup>12</sup>.

<sup>α</sup> 1 = Fleming, Zusman, and White, 1983, *Dev. Genet.* 3: 347-63; 2 = Fleming, DeSimone, and White, 1989, *Mol. Cell Biol.* 9: 719-25; 3 = Lefevre, 1981, *Genetics* 99: 461-80; 4 = Lefevre and Watkins, 1986, *Genetics* 113: 869-95.

**cytology:** Placed in 1A7-8 based on inclusion in *Df(1)SJ1a* = *Df(1)1A1-3;1A8-B1* but not *Df(1)SJ1d* = *Df(1)1A1-*

3;1A6-B1. To the right of *cin*, which is in the same interval and separated from *ewg* by the breakpoint of *T(1;4)cin*.

**molecular biology:** Region cloned by an extension of the chromosome walk of Campuzano *et al.* (Cell 40: 327-38). Gene localized to a 9.5-kb segment at approximately 140 to 150 kb on the molecular map by means of germ-line-transformant rescue of lethal alleles of *ewg*. Probing developmental Northern blots with this sequence reveals a collection of at least five transcripts ranging in size from 3.7 to 6 kb; transcription is most pronounced in six-to-twelve hour embryos with subsets of these transcripts appearing in 0-6 hr embryos and in adults (Fleming, DeSimone, and White, 1989, Mol. Cell Biol. 9: 719-25).

**ex: expanded**

From Stern and Bridges, 1926, Genetics 11: 503-30.

**ex: expanded**

**location:** 2-0.1.

**origin:** Spontaneous.

**discoverer:** Bridges, 17k21.

**references:** Stern and Bridges, 1926, Genetics 11: 514 (fig.).

**phenotype:** Wings extremely wide and large, sometimes curved and divergent. Effect produced in prepupal wing, probably by influence on cell division (Waddington, 1940, J. Genet. 41: 75-139). Eyes slightly reduced in size and roughish. Body large. RK2.

**alleles:** \**ex*<sup>2</sup> (Mickey, 1950, DIS 24: 60).

**cytology:** Salivary chromosome location in or near 21C3 (Lewis, 1945, Genetics 30: 137-66). Between 21C2 and 8 by deficiency analysis [Golubovsky, 1979, Genetika 14: 294-305 (fig.)].

*Exaggeration of Bar*: see *E(B)*

**exb: extreme bar**

**location:** 3-47.4.

**origin:** Occurred with *TE#68*.

**discoverer:** Ising.

**Phenotype:** Very narrow eyes (smaller than *B/B*); no ocelli.

**exd: extradenticle**

**location:** 1-54.

**origin:** Induced by ethyl methanesulfonate.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307. Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Homozygous lethal; meso- and metathoracic segments resemble prothorax; first abdominal like posterior abdominal segments. In combination with *Pc*-like mutants shows abdominal transformations.

**alleles:** Two. *exd*<sup>1</sup> and *exd*<sup>2</sup>, isolated as *XP* and *YO*.

**cytology:** Placed in 14A1-B1 based on inclusion in the region of overlap of *Df(1)sd72b = Df(1)13F1;14B1* and *Dp(1;4)r<sup>+</sup> = Dp(1;4)14A1-2; 16A1-2; 102F2-3*.

**\*exi: exiguous**

**location:** 1-51.5.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1958, DIS 32: 70.

**phenotype:** Small fly with rather dusky body color. Not easily classified. Viability and fertility good in male, slightly reduced in female. RK3.

**exo: exocephalon**

**location:** 1-58.

**origin:** Induced by ethyl methanesulfonate.

**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20.

**phenotype:** Sex-linked recessive lethal; variably differentiated cuticle; complete failure of head involution with well developed head structures on exterior of the embryo. Many embryos slightly twisted with defective ventral denticle patterns.

**alleles:** *exo*<sup>1</sup> and *exo*<sup>2</sup> isolated as *l(1)EH354* and *l(1)EH406*.

**cytology:** Placed in 16C2-18B11 between breakpoints of *Dp(1;3)j<sup>+</sup>71b = Dp(1;3)15A4;16C2-3;80-81* and *T(1;Y)B50 = T(1;Y)18B4-11*.

**expanded:** see *ex*

**\*exr: extra venation**

**location:** 1- (associated with *In(1)exr*).

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 70.

**phenotype:** Eyes slightly rough and smaller than normal. Wings have irregularly distributed extra vein tissue. Males viable and fertile; females viable but sterile. RK3A.

**cytology:** Associated with *In(1)exr = In(1)12E8-10;15D1-3*.

**\*ext: extended**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Ströher, 1958.

**references:** Mainx, 1958, DIS 32: 82.

**phenotype:** Wings held out at about a 75° angle from body axis, are wavy, and gradually curve downward. Distal parts of wings often crumpled and folded. Halteres normal. Function of wings reduced. Viability and fertility good. RK3.

**Ext: Extras**

**location:** 1-15.2.

**discoverer:** Schultz, 3318.

**phenotype:** Heterozygous female has thickened, branched, and extra veins. Overlaps wild type. Lethal in male. RK3.

**cytology:** Tentatively placed in 7C-E on the basis of *Ext* phenotype of segmental deficiency (Merriam and colleagues).

**exu: exuperantia (T. Schüpbach)**

**location:** 2-93.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 302-17.

Mlodzik, DeMontrion, Hiromi, Kraus, and Gehring, 1987, Genes Dev. 1: 603-14.

Fronhöfer and Nüsslein-Volhard, 1987, Genes Dev. 1: 880-90.

Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal mutant; embryos from homozygous mothers lack anterior-most head structures. Instead they form an inverted posterior midgut and proctodeal region at their anterior end. Cephalic furrow at gastrulation is shifted towards anterior. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48). Causes shift in blastoderm fate map as indicated by *ftz* expression; thoracic stripes broadened and shifted anteriorly; abdominal stripes narrowed and compressed posteriorly (Mlodzik *et al.*). Eggs produced by *exu* mothers appear to have a more uniform distribution of *bcd*<sup>+</sup> product, i.e., less concentration anteriorly (Fronhöfer and Nüsslein-Volhard).

**cytology:** Placed in 56F-57B by segmental aneuploidy (Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26).

**alleles:** *exu*<sup>1</sup> - *exu*<sup>4</sup> isolated as *PJ*, *QR*, *SB*, and *SC*, respectively.

**ey: eyeless**

**location:** 4-2.0 (located by recombination in diplo-4 triploids by Sturtevant, 1951, Proc. Nat. Acad. Sci. USA 37: 405-7).

**origin:** Spontaneous.

**discoverer:** Hoge, 14e.

**references:** 1915, Am. Naturalist 49: 47-49.

Bridges, 1935, Biol. Zh. 4: 401-20 (fig.).

**phenotype:** Eye size variably reduced depending on allele (see table); expressivity more variable for some alleles than for others. Tetragonal packing of facets and face-centered tetragonal bristle lattice (*ey*<sup>R</sup>) in place of hexagonal array of wild type [Hartman and Hayes, 1971, J. Hered. 62: 41-43 (fig.)]; associated with a failure of the horizontal secondary pigment cell to expand to give rise to the horizontal boundaries between ommatidia [Ready, Hanson, and Benzer, 1976, Dev. Biol. 53: 217-40 (fig.)]. Some *ey*<sup>2</sup> flies show duplications of antennae or antennal segments with or without duplication of arista; extra maxillary structures also observed (Shatouri, 1963, Caryologia 16: 431-37). Optical disks reduced in size [(*ey*<sup>1</sup>) Richards and Farrow, 1922, Proc. Oklahoma Acad. Sci. 2: 41-45; (*ey*<sup>2</sup>) Medvedev, 1935, Z. Indukt. Abstamm. Vererbungslehre 70: 55-72 (fig.); 1935, Tr. Inst. Genet. Akad. Nauk SSSR 10: 119-51; Steinberg, 1944, Proc. Nat. Acad. Sci. USA 30: 5-13; (*ey*<sup>4</sup>) Chen, 1929, J. Morphol. 47: 135-99]. Degenerating cells abundantly observed in the optic disks of third-instar larvae of *ey*<sup>2</sup> [Fristrom, 1969, Mol. Gen. Genet. 103: 363-79 (fig.); Ransom, 1979, J. Embryol. Exp. Morphol. 53: 225-35]. Expressivity sensitive to genetic background [(*ey*<sup>4</sup>) Spofford, 1956, Genetics 41: 938-59; (*ey*<sup>1</sup>, *ey*<sup>2</sup>, *ey*<sup>4</sup>, *ey*<sup>K</sup>) Hunt and Burnet, 1969, Genet. Res. 13: 251-65]. Phenotype also responds to developmental temperature, larval density, and composition of medium. Eye size reported to increase with increased temperature in *e*<sup>1</sup> (Baron, 1935, J. Exp. Zool. 70: 461-90) and *ey*<sup>K</sup> (Sang and Burnet, 1963, Genetics 48: 1683-99) but to decrease in *ey*<sup>W</sup> (Meyer, 1959, DIS 33: 97). Phenotype less extreme in flies raised under crowded conditions at 18° but not 25° (Sang and Burnet, 1963; see also Chester, 1971, DIS 46: 62-63). Eye size of four alleles increased by cholesterol deprivation and decreased by dietary deficiencies in thiamine or RNA (Hunt and Burnet, 1969). Larval feeding of lactamide to *ey*<sup>2</sup> causes decreased eye size, which is of opposite sign from its effect on *B* (Grant and Rapport, 1980, DIS 55: 53); no such effect of lactamide on *ey*<sup>K</sup> observed by Sang and Burnet (1963). *ey*<sup>2</sup> flies exhibit normal visual orientation in Y maze (Bülthoff, 1982, DIS 58: 31). *ey*<sup>2</sup>, *ey*<sup>4</sup>, and *ey*<sup>K</sup> in combination with *eyg* (3-35.5) results in almost complete curtailment of eye development and synthetic lethality, with the major lethal crisis at the end of the pupal stage and a minor lethal phase at pupation; rare surviving adults have brain in anterior thorax [Hunt, 1970, Genet. Res. 15: 29-34 (fig.)].

**alleles:** *ey*<sup>2</sup> is the most frequently used allele. Four lethal alleles, formerly *l(4)10* = *l(4)33*, assigned to the *ey* locus by Hochman (1971, Genetics 62: 235-52); they produce a low incidence of escapers with reduced eyes and but partially complement *ey*<sup>R</sup>.

*ey*<sup>D</sup>: eyeless-Dominant

Left: head. Right: first pair of legs.

From Patterson and Muller, 1930, Genetics 15: 495-577.

***ey*<sup>D</sup>: eyeless-Dominant**

**origin:** X ray induced.

**discoverer:** Muller, 27k.

**references:** Patterson and Muller, 1930, Genetics

15: 495-577 (fig.).

Bridges, 1935, Biol. Zh. 4: 401-20.

1935, Tr. Dinam. Razvit 10: 463-73.

**phenotype:** Eyes of heterozygotes small, outline irregular, displaced toward top and rear. Head large, often with duplicated antennae or ocelli. Basitarsus broadened distally and incompletely separated from second tarsal segment owing to interruptions of the intersegmental membrane. Polarity of bract-bristle arrangement locally reversed in regions of membrane gaps [Poodry and Schneiderman, 1976, Wilhelm Roux's Arch. Dev. Biol. 180: 175-88 (fig.)]. 27-48 sex-comb teeth disposed in more-or-less parallel longitudinal rows in males; number of transverse-bristle rows increased in females (Stern and Tokunaga, 1967, Proc. Nat. Acad. Sci. USA 57: 658-64). Extra leg joints tend to form as mirror-image duplications proximal to the normal joint between the first and second tarsal joints (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57). Clones of *ey*<sup>+</sup> tissue in *ey*<sup>D/+</sup> background exhibit *ey*<sup>D/+</sup> phenotype (Stern and Tokunaga, 1967), but both *ey*<sup>+</sup> leg disks transplanted into *ey*<sup>D</sup> hosts and the reciprocal transplant develop autonomously (Tokunaga, 1970, Dev. Biol. 18: 401-13). *ff ey*<sup>D</sup> flies have but three tarsal joints (Postlethwaite and Schneiderman, 1975, Annu. Rev. Genet. 7: 381-433). Fully dominant in triplo-4 flies (Sturtevant, 1936, Genetics 21: 448). Eye size of *B; ey*<sup>D/+</sup> males larger than of *B* alone. Produces extreme phenotype in combination with *D*. *D/+; ey*<sup>D/+</sup> almost completely lethal (Sobels, Kruijt, and Spronk, 1951, DIS 25: 128). Homozygous lethal; two lethal crises, one during first or second larval instar and the other just prior to or during pupal stage. Cell degeneration observed in optic disks of homozygous second-instar larval (Ransom, 1979, J. Embryol. Exp. Morphol. 53: 225-35). Larvae which are unable to pupate rescuable by injection of  $\alpha$ -ecdysone (Arking, 1969, J. Exp. Zool. 171: 285-96). Homozygotes reaching pupal stage lack adult derivatives of eye-antennal disks; adult derivatives are formed by *ey*<sup>D/ey<sup>D</sup> eye-antennal disks transplanted into wild-type hosts; brain present but number of cortical cells severely reduced (Arking, Putnam, and Schubiger, 1975, J. Expt. Zool. 193: 301-12). RK2.</sup>

**cytology:** Salivary chromosomes show duplication of about a dozen bands inserted into middle of fourth chromosome as a reversed repeat. Source of duplication unknown (Bridges, 1935) but suggested to be 4L (Hochman, 1971, Genetics 67: 235-52).

**other information:** May not be an allele of *ey*.

*ey*<sup>opt</sup>: see *Opt*

***eya*: eyes absent**

**location:** 2-.

**origin:** Viable allele *eya*<sup>1</sup> spontaneous; other alleles X-ray induced or induced by ethyl methansulfonate.

**references:** Sved, 1986, DIS 63: 169 (fig.).

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** Eye facets completely absent in strong alleles; other aspects of head development appear normal; antennae and ocelli, which also arise from eye-antenna disc, present. Eye portion of disc markedly reduced; no morphogenetic furrow or putative photoreceptor-cell clusters seen; little or no staining with monoclonal antibodies that normally stain presumptive photoreceptor cells.

**alleles:** More than 40 alleles obtained (Leiserson, 1990); most of them are homozygous lethal. Some alleles are temperature-sensitive.

**cytology:** Located in 26E. Associated with *In(2L)eya* = *In(2L)22D;34B*.

**molecular biology:** Gene cloned, the region involved spanning seven breakpoint alleles.

**other information:** Used by several groups in subtractive hybridization protocols for the isolation of eye-specific cDNA's.

**\*Eye: Eyeless dominant in chromosome 2**

**location:** 2-62.7.

**origin:** Probably ultraviolet induced.

**discoverer:** Edmondson, 51g.

**synonym:** *ey-II<sup>D</sup>*.

**references:** 1952, DIS 26: 60.

**phenotype:** Eyes may be greatly reduced in size with frequent doubling of antennae. Overlaps wild type, especially in old vials. Recessive in triploids. *Eye/+*; *ey<sup>D</sup>/+* has smaller eyes than either alone. Homozygous lethal. RK3.

**eye gone:** see *eyg*

**eye missing:** see *eym*

**Eye tissue determiner:** see *Etd*

**eyeless:** see *ey*

**Eyeless dominant in chromosome 2:** see *Eye*

**eyelisch:** see *eyh*

**Eyeluf:** see *Eyl*

**eyes absent:** see *eya*

**eyes reduced:** see *ld<sup>eyr</sup>*

**eyg: eye gone**

**location:** 3-37.5 [between 37 and 38, to the right of *Est-6* (Roberts and Malpica, 1972, DIS 49: 40)].

**origin:** Spontaneous.

**discoverer:** Ives, 40g20.

**references:** 1942, DIS 16: 48.

**phenotype:** Eyes and head much smaller than normal. Considerable pupal mortality, probably from inability to push open pupa cases. Adults normal in viability and productivity. Character subject to genetic modifiers and possibly environmental influences. Expression varies

from complete absence of facets to formation of about 100 facets. Homozygotes show reduced larval and pupal survival (Inoue, 1980, DIS 55: 206). Lethal in combination with *ey*; phenotype described under *ey* [Hunt, 1970, Genet. Res. 15: 29-34 (fig.)]. RK2.

**alleles:** *eyg<sup>64e</sup>*, X ray induced, slightly dominant (Mittler, 1967, DIS 42: 38).

**cytology:** Placed in 69C on the basis of its exclusion from *Df(3L)vin<sup>7</sup>* = *Df(3L)68C8-II;69B3-CI* and its mutant phenotype in combination with *In(3LR)gs<sup>U</sup>* = *In(3LR)69B5-C4;8I* (Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25).

**eyh: eyelisch**

**location:** 3-58 (0.47 units from *Sb* but order unspecified).

**origin:** Spontaneous.

**references:** Kalisch, 1980, DIS 55: 206-07.

**phenotype:** Eyes variably reduced. 7.5% of flies have no eyes; 0.3% of females and 5.6% of males overlap wild type. The proportion of completely eyeless flies increases dramatically and there is no overlap with wild type when *eyh* is combined with *eyg* or *ey*. RK3.

**\*Eyl: Eyeluf**

**location:** 1-18.

**origin:** Spontaneous.

**discoverer:** Marzluf.

**phenotype:** One or both eyes reduced in size. Expression varies from slight reduction to absence of eye. Sometimes extraneous materials protrude through eye; frequently, one or more duplicated antennae present. Penetrance incomplete; viability good. In aged and crowded cultures, both penetrance and expressivity increased. Third chromosome carries important modifiers affecting penetrance, and different wild-type and mutant stocks carry different modifiers. Penetrance lower at 18° than at 25°. RK3.

**eym: eye missing**

**location:** 3-67.9.

**origin:** Spontaneous.

**references:** Inoue, 1980, DIS 55: 206.

**phenotype:** Eyes almost completely absent in homozygotes. Heterozygotes with a wild-type chromosome but with *eyg* (3-37.5) show variable reduction in eye size. Homozygotes have normal larval but reduced pupal survival. Fertile. RK1.

*eyr*: see *ld<sup>eyr</sup>*

**f: forked**

**location:** 1-56.7.

**origin:** Spontaneous.

**discoverer:** Bridges, 12k19.

**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 58 (fig.).

**phenotype:** Macrochaetae, microchaetae, and trichomes affected to various degrees depending on allele—short, gnarled, and bent with ends split or sharply bent. Extreme effect of  $f^{36a}$  on trichomes makes it the most useful allele as a cell marker in cuticular spots produced by somatic exchange. Treatment with methylurea causes normal bristle formation (De Marinis). Developmental studies [Lees and Waddington, 1942, Proc. Roy. Soc. (London) Ser. B 131: 87-110 (fig.); Lees and Picken, 1945, Proc. Roy. Soc. (London), Ser. B 132: 396-423 (fig.)] show nature of pupal bristle secretion is affected. Suppression by  $su(f)$  and  $su(Hw)^2$  allele specific.  $f^1$  and  $f^5$  suppressed by  $su(Hw)$ ,  $e(w^e)$ ,  $su(f)$ , and  $su(pr)$ , enhanced by  $su(s)$  and  $su(w^a)$  (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97). RK1.

**alleles:** Can be classed as weak with macrochaetae slightly bent, moderate with both macrochaetae and microchaetae clearly affected, strong with macrochaetae and microchaetae strongly gnarled, and extreme with chaetae and trichomes strongly affected. Descriptions of phenotypes are such as to make classification highly subjective. Bridges (1938, DIS 9: 46-47; see also CP552) lists 14 lost alleles of diverse origin not included here, and Belgovsky (1940, DIS 13: 47-48) lists 35  $f^B$  alleles induced by X rays in  $In(1)sc^8$  or  $In(1)B^{M2}$ , of which 33 are lost and not included here. Included in the table are deficiencies which have been erroneously given allelic designations in the past.

**cytology:** Localized to 15F1-3 on the basis of  $Df(1)f^{257-5} = Df(1)15E7-F1;15F2-4$ . Polytene analysis completed on some alleles.

**molecular biology:** Region cloned using *gypsy* insertion into the  $f^1$  allele (Parkhurst and Corces, 1985, Cell 41: 429-37) and  $f^5$  (McLachlan, 1988, J. Mol. Cell. Biol. 6:1-6).  $f$  alleles from the right pseudoallelic series of Green ( $f$ ,  $f^5$ ,  $f^{36a}$ ) have DNA inserts within a 5.4 kb segment of DNA. The forked phenotype as well as the accumulation of RNAs can be rescued by *P*-element mediated germline transformation with a 6.1 kb SaII-XhoI fragment. There are four transcripts encoded within this DNA region: polyadenylated 4.3 kb, 2.4 kb, 1.9 kb, and 1.4 kb RNAs present only during mid to late pupal stages. Transcripts are reduced or missing in mutants. Transcripts in the  $f^1$  mutant return to wild-type levels when combined with the  $su(Hw)$  or  $su(f)$  mutations (see McLachlan).

**other information:** Green (1955, Proc. Nat. Acad. Sci.

USA 41: 375-79; 1956, Proc. Nat. Acad. Sci. USA 42: 73-77) showed the forked mutants can be assigned to either of two pseudoallelic series, *f* is a member of the right series. Back mutations to *f*<sup>+</sup> occur spontaneously, and their incidence is not increased by X rays (Green, 1959, Proc. Nat. Acad. Sci. USA 45: 16-18; Lefevre and Green, 1959, Genetics 44: 769-76).

**f: forked**

Edith M. Wallace, unpublished.

**f<sup>1</sup>**

**molecular biology:** A member of the right hand group of alleles. Contains a gypsy insert in a 3.8 kb *Eco*RI restriction fragment (Parkhurst and Corces) and 3.2 kb from a particular *Sal*I restriction site (McLachlan, 1986, J. Mol. Cell. Biol. 6: 1-6). Orientation of gypsy element opposite that of the gene.

**f<sup>3</sup>**

**molecular biology:** A member of the left hand group of alleles shown to contain an insert of 6 kb, but to the right of *f*<sup>1</sup>, according to the orientation on the chromosome as determined by Parkhurst and Corces (McLachlan, 1986, J. Mol. Cell. Biol. 6: 1-6).

**f<sup>3N</sup>**

**phenotype:** Expression similar to *f* but unlike *f*, does not respond to *su(f)*. Characterized by a high spontaneous reversion rate ( $\sim 2 \times 10^{-5}$ ); rate may be further increased by a closely linked *cis*-dominant mutator allele, *Mu(f<sup>3N</sup>)*, (5 $\times$ ; Woodruff, 1975, Genet. Res. 25: 163-77), by X rays (20 $\times$ ; Green, 1977, Mutat. Res. 43: 305-08), and by mustard gas (Woodruff, Bowman, and Simmons, 1972, Mut. Res. 15: 86-89). RK1.

**molecular biology:** A member of the left hand group of alleles. Shown to contain a 2.8 kb tandem repeat, but to the right of *f*<sup>1</sup> according to the orientation on the chromosome as determined by Parkhurst and Corces (McLachlan). A revertant of *f<sup>3N</sup>* retains the repeated sequence.

**f<sup>5</sup>**

**molecular biology:** A member of the right hand group of alleles; contains two gypsy inserts, one which is similar or identical to that of *f*<sup>1</sup> and the other which is closer to the *Sal*I restriction site (1.2 kb); orientation is the same. In addition *f*<sup>5</sup> contains a 4.4 kb insert in a restriction fragment to the left of that carrying the *f*<sup>1</sup> gypsy insert; it is located approximately 4.7 kb to the left of the reference *Sal*I site (McLachlan).

**f<sup>36a</sup>**

**molecular biology:** A member of the right-hand group of alleles. Contains a 3.0 kb insertion 2.5 kb to the right of the reference *Sal*I site (McLachlan).

**f<sup>56e</sup>**

**molecular biology:** A molecular deletion detected by Parkhurst and Corces but not by McLachlan; in the 3.8 *Eco*RI fragment studied by Parkhurst and McLachlan.

**f<sup>+ih</sup>: forked-wild type in heterochromatin**

**origin:** X ray induced simultaneously with *f*<sup>X</sup>.

**synonym:** *f*<sup>m</sup>: *forked-mottled* = *f*<sup>X</sup>*f*<sup>+ih</sup>.

**phenotype:** *f*<sup>+ih</sup> with any *f* allele has normalizing effect.

Patches of bristles and occasionally whole fly is wild type. An extra Y chromosome enhances the normalizing effect. RK2A.

**cytology:** Salivary chromosomes appear normal (J.I. Valencia).

**molecular biology:** The inserted segment contains the entire 40 kb walk of McLachlan.

**other information:** Apparently, *f*<sup>+ih</sup> is all or part of the normal allele of *f* transposed to the proximal heterochromatin of the X chromosome, where it variegates. The sequences remaining in the original position behave as a hypomorphic allele of *f*, *f*<sup>X</sup>. Oster, Erlich, and Muller (1957, DIS 31: 141-44) argue that the sum of sequences inserted in the heterochromatin plus those remaining behind exceeds the normal sequential content of *f*<sup>+</sup>.

**f<sup>B15</sup>**

**origin:** X ray induced in *B*<sup>M2</sup> male.

**phenotype:** Shows variegated expression of *f*. More extreme in combination with *E(f)*. RK2A.

**cytology:** Genetic data indicate that the mutation is associated with a reinversion of the *B*<sup>M2</sup> inversion. *B*<sup>M2</sup> phenotype reverted.

**f<sup>B27</sup>**

**origin:** X ray induced in *B*<sup>M2</sup> male.

**phenotype:** Males have mostly normal bristles, a few reduced like a Minute, rarely forked. *f*<sup>B27</sup>/*f* are mosaic for forked. *f*<sup>B27</sup>/*f*<sup>B27</sup> females rarely survive; those that do sometimes have reduced bristles or notched wings, or both, and are sterile. More extreme in combination with *E(f)*. RK3A.

**f<sup>X</sup>: forked from X irradiation**

**origin:** X ray induced, simultaneously with *f*<sup>+ih</sup>.

**synonym:** *f*<sup>m</sup>: *forked-mottled* = *f*<sup>X</sup>*f*<sup>+ih</sup>.

**discoverer:** Muller.

**phenotype:** A medium *f*. Suppressed by *su(f)*. Behaves as a hypomorphic allele (Oster, Erlich, and Muller, 1958, DIS 32: 144-45). RK1.

**molecular biology:** Restriction map indistinguishable from

that of *f<sup>1</sup>* (McLachlan).

*F2*: see *Efl α 2*

**fa**: see *N*

*fa<sup>swb-h</sup>*: see *e(fa<sup>swb</sup>)*

*facetious*: see *rg<sup>P</sup>*

**factor for male fertility**: see *fmf*

**fai**: *faint*

**location**: 2-61.

**origin**: Induced by ethyl methanesulfonate.

**references**: Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.)

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype**: Homozygous larval lethal. Unpigmented cuticle and mouth parts.

**alleles**: Six, two of which are weak; *fai<sup>1</sup>* and *fai<sup>2</sup>* (isolated as IIA and IIV) retained.

*faint little ball*: see *Egfr*

**faint sausage**: see *fas*

*faintoid*: see *gs*

**fap**: *female abdomen pattern*

**location**: 3-0.5 (to the left of *mwh*; Robertson and Riviera, 1972, DIS 48: 21).

**origin**: Spontaneous.

**references**: Robertson and Louw, 1966, DIS 41: 154-55 (fig.).

Robertson, Briscoe, and Louw, 1977, Genetica 47: 73-77.

**phenotype**: Female-specific recessive that removes black pigment from the sixth and seventh tergites when homozygous; heterozygotes exhibit intermediate phenotype at 18°.

**alleles**: Natural populations highly polymorphic at this locus with at least six alleles (Robertson and Riviera, 1972).

**cytology**: Polytene chromosomes normal (Slyzinska).

*Farkas*: see *Fs(3)Sz8*

*fas*: see *rg<sup>P</sup>*

**fas**: *faint sausage*

**location**: 2-68.

**origin**: Induced by ethyl methanesulfonate.

**references**: Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.)

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype**: Embryonic lethal; embryos have poorly developed cuticle with necrotic patches and an abnormal head. First visible in extended-germ-band stage.

**alleles**: Four, out of which two are retained, *fas<sup>1</sup>* and *fas<sup>2</sup>* (isolated as IC and IIA).

**Fas1**: *Fasciclin I*

**location**: 3-{58}.

**origin**: Isolated from *Drosophila* embryonic cDNA libraries using a fasciclin I probe from grasshopper.

**references**: Zinn, McAllister, and Goodman, 1988, Cell 53: 577-87 (fig.).

**phenotype**: Expression confined to neurons. In 12-14 h embryos high levels of fasciclin I are detectable in two commissural axon bundles (fascicles) per segment, a thick one in the posterior commissure and a thin one in the anterior commissure. In addition high expression is seen in two clusters of neuronal cell bodies per hemisegment as well as in the intersegmental and segmental nerve axons. Finally, fasciclin I is detected on the surface of all peripheral neurons. Postulated to be involved in neuron recognition during growth cone guidance. Flies deficient in *FasI* function are fully viable and CNS development apparently is normal.

**cytology**: Placed in 89D by *in situ* hybridization to polytene chromosomes. Deleted by *Df(3R)Ubx<sup>109</sup>* = *Df(3R)89D1-2;89E1-2*.

**molecular biology**: Apparently full-length cDNA clone of 3.0 kb isolated and sequenced. Conceptual amino-acid sequence indicates a protein similar in size to the 638-amino-acid, 70 kd fasciclin I from grasshoppers; it is 48% homologous to the grasshopper protein. Contains a putative signal sequence, but no convincing transmembrane domain. Concluded to be an extrinsic membrane protein since it is isolated with the membrane fraction. Mature protein composed of four homologous domains of approximately 150 amino acids each, followed by 20-25 C-terminal residues.

**Fas3**: *Fasciclin III*

**location**: 2-{53}.

**origin**: Identified by screening a cDNA expression library with monoclonal antibodies directed against embryonic CNS and shown to identify proteins expressed on the cell surface of a restricted subset of cells of the embryo, including specific cells of the developing central nervous system.

**references**: Gauger, Glicksman, Saltino, Condie, Schuberger, and Brower, 1987, Development 100: 237-44.

Patel, Snow, and Goodman, 1987, Cell 48: 975-88 (fig.).

Snow, Bieber, and Goodman, 1989, Cell 59: 313-23.

**phenotype**: Monoclonal-antibody staining reveals a complex sequence of temporal and spatial expression of *Fas3*. It is expressed on segmentally repeated patches of cells during neurogenesis and outside the developing CNS on segmentally repeated stripes in the epidermis at the segmental grooves, on patches of epithelial cells near the stomodeal and proctodeal invaginations, on the visceral but not the somatic mesoderm, and on the luminal surface of the salivary gland epithelium; expression is highest where fasciclin-III-positive cells contact one another. After germ-band extension transiently expressed on segmentally repeated patches of neuroepithelial cells and specific underlying neuronal lineages; by the end of germ band retraction fasciclin-III is expressed in repeated stripes across all body segments. At hour 12 fasciclin is detected on a subset of three axon bundles (fascicles) in the anterior commissure and two in the posterior commissure of each segment; generally, however it's not expressed on the axons of these neurons that exit CNS, specifically on the longitudinal fascicles. Expression of *Fas3* in transfected cultured cells promotes their adhesion to each other, but not to nonexpressing cells (Snow, *et al.*). The monoclonal antibodies used in the isolation of fasciclin identify four closely related membrane glycoproteins of 80, 66, 59, and 46 kd molec-

ular weight; all depend on the presence of *Fas3*<sup>+</sup> for their presence.

**cytology:** Placed in 36E1 by *in situ* hybridization to polytene chromosomes. In the region of overlap of *Df(2L)H20 = Df(2L)36A7-10;36E4-F1* and *Df(2L)V18 = Df(2L)36C4-D1;37C2-5*.

**alleles:** A null mutation, *Fas3*<sup>nl</sup>, has been isolated (Elkins).

**molecular biology:** cDNA's cloned and sequenced; conceptual amino acid sequence indicates a mature polypeptide, following cleavage of a 20-amino-acid signal sequence, of 488 amino acids of calculated molecular mass of 53.6 kd. It comprises a putative 326-amino-acid extracellular domain, a 24-amino-acid transmembrane domain, and a 138-amino-acid intracellular domain. The extracellular domain contains four potential N-linked glycosylation sites, and the intracellular domain contains a single tyrosine residue, two potential phosphorylation sites, and an *opa*-repeat sequence (a second such sequence found in the 3' untranslated region).

**fat:** see *ft*

**Fat body protein:** see *Fbp*

**faulty chaetae:** see *fc*

**\*fb: fine bristle**

**location:** 1-1.0.

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 70.

**phenotype:** Thin, slightly shortened bristles. Occasional scalloping of wing margins. Delayed emergence. Good viability and fertility in both sexes. RK3.

**fbr: fine bristles**

**location:** 1-3.3.

**origin:** Spontaneous (appears to be unstable).

**references:** Golubovsky, 1978, DIS 53: 122.

**phenotype:** Bristles reduced in length and diameter.

**other information:** Transmission in crosses irregular; possibly associated with a transposable element. Possibly allelic to *dm* or *slc*.

**Fbp1: Fat body protein 1**

**location:** 3-{41}.

**synonym:** *P1*.

**references:** Lepesant, Kejzlarova-Lepesant, and Garen, 1978, Proc. Nat. Acad. Sci. USA 75: 5570-74.

Lepesant, Levine, Garen, Kejzlarova-Lepesant, Rat, and Somme-Martin, 1982, J. Appl. Mol. Genet. 1: 371-83.

Paco-Larson, Nakanishi, Levine, and Garen, 1986, Dev. Genet. 7: 197-203.

Deutsch, Laval, Lepesant, Maschat, Pourrain, and Rat, 1989, Dev. Genet. 10: 220-31.

**phenotype:** Encodes P1 polypeptide, which accumulates in the fat body of third-instar larvae; not detectable at earlier stages or in other tissues. Expression stimulated by the increased ecdysone level characteristic of third-instar larvae; function of the protein product uncertain (Deutch *et al.*, 1989).

**cytology:** Located in 70D1-2 by *in situ* hybridization to the salivary chromosomes.

**molecular biology:** *Fbp1* cloned and its nucleotide

sequence determined (Lepesant, *et al.*, 1982); gene shows a simple molecular structure and organization, with very short introns interrupting transcribed sequences coding for unique mRNA. The putative P1 polypeptide of 1,030 amino acids has a presumptive N-terminal signal peptide; since no extracellular P1 product is detectable in the hemolymph, the signal peptide may serve to compartmentalize the protein within the fat-body cell. The sequence also contains two aspartic + asparagine stretches of 11 or 12 amino acids (Deutch *et al.*, 1989). A transcript is not detected until the second larval molt; at this time, it is restricted to the fat body (Lepesant *et al.*, 1982; Paco-Larson *et al.*, 1986). A peak in the accumulation of transcript occurs at the time of puparium formation and is followed by its disappearance after the early pupal stage; the rise and fall follows by several hours that of the larval serum proteins, which are also fat-body specific in their expression. *Fbp1* expression completely inhibited in *ecd-1*<sup>ts</sup> flies shifted to restrictive temperature following the second larval molt or in *dor*<sup>lit87</sup> third-instar larvae; expression rescued by administration of 20-hydroxyecdysone. Germ-line transformation experiments demonstrate that 138 but not 80 base pairs upstream from the transcription start site are sufficient to impart complete temporal, spatial, and hormonal regulatory control of transcription.

**Fbp2: Fat body protein 2**

**location:** 2-{35}.

**synonym:** *P6*.

**references:** Langer-Safer, Levine, and Ward, 1982, Proc. Nat. Acad. Sci. USA 79: 4381-85.

Lepesant, Levine, Garen, Lepesant-Kejzlarova, Rat, and Somme-Martin, 1982, J. Appl. Mol. Genet. 1: 371-83.

Paco-Larson, Nakanishi, Levine, and Garen, 1986, Dev. Genet. 7: 197-203.

Deutsch, Laval, Lepesant, Maschat, Pourrain, and Rat, 1989, Dev. Genet. 10: 220-31.

**phenotype:** Gene detected in the larval fat body of *Drosophila melanogaster*. Function of the protein product uncertain (Deutch *et al.*, 1989).

**cytology:** Located in 30B by *in situ* hybridization to the salivary chromosomes.

**molecular biology:** *Fbp2* cloned, and its nucleotide sequence determined (Lepesant, 1982). The gene has an unusually high methionine content (20%); conceptual amino acid sequence shows significant similarity to that of *Drosophila* alcohol dehydrogenase, which lacks methionine. A transcript is not detected until the second larval molt, when it is restricted to the fat body (Lepesant *et al.*, 1982; Paco-Larson *et al.*, 1986). As in *Fbp1*, a peak in the accumulation of transcript occurs at the time of puparium formation and is followed by its disappearance after the early pupal stage; apparently not sensitive to the removal or addition of ecdysone during the third larval instar.

**Fat body protein:** see *Fbp*

**\*fc: faulty chaetae**

**location:** 1-0.9.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 70.

**phenotype:** Short, thin bristles. About one-third of flies show either absence or duplication of one scutellar bristle. Viability and fertility good in both sexes. RK2.  
**other information:** Possibly allelic to *kz*.

**fch: fragile chorion**

**location:** 3-55.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.  
**phenotype:** Maternal effect; chorion very thin or nonexistent.  
**alleles:** Two, *fch*<sup>1</sup> and *fch*<sup>2</sup> (isolated as 055 and 267).

**fcl: foreclosed**

**location:** 1-(between 57.8 and 59.1).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20.  
**phenotype:** Embryonic lethal; no internal organogenesis; prominent central yolk plug; dorsal closure may be incomplete; head involution partial; germ band contraction incomplete. No cuticle evident in cuticle preparations, but mouth parts and spiracles visible. Embryos exhibit considerable movement.  
**alleles:** Two putative alleles *fcl*<sup>1</sup> and *fcl*<sup>2</sup> (isolated as *l(1)EH244b* and *l(1)EH523*).  
**cytology:** Placed in 16C2-18B11 based on the failure of  $Dp(1;3)f^{+71b} = Dp(1;3)15A4;16C2-3;80-81$  and  $X^P Y^D B5O = X^P Y^D 18B4-11$  to cover it.

**\*fd: furled**

**location:** 1-(rearrangement).  
**origin:** Induced by <sup>32</sup>P.  
**discoverer:** Bateman, 1949.  
**references:** 1950, DIS 24: 54.  
 1951, DIS 25: 77.  
**phenotype:** Like vestigial but with immovable mouth parts and fully extended proboscis. Dies early, perhaps owing to failure to ingest. Viability at eclosion good. RK3A.  
**cytology:** Associated with  $T(1;3)fd = T(1;3)7A;86E + In(3R)89C;96A$  (Darby).

**fdg: fibrillar dysgenesis**

**location:** 1-55.0  
**origin:** Induced by ethyl methanesulfonate.  
**synonym:** *l(1)fdg*.  
**references:** Newman, and Wright, 1983, Dev. Genet. 3: 329-45 (fig.).  
**phenotype:** Embryonic lethal at 32-30°; larval-pupal lethal at lower temperatures. Mutant embryos exhibit abnormal distribution of muscle fiber elements and organelles. Also abnormal Z-body alignment.

**female abdomen pattern:** see *fap*

**female lethal 302:** see *fl(1)302*

**Female lethal:** see *Sxl*

**female sterile:** see *fs( )*

**Female sterile:** see *Fs( )*

**femaleless:** see *fle*

*fes:* see *fs(2)B*

*fes(2)K:* see *fs(2)K*

**ff: fluff**

**location:** 1-57.7.  
**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**discoverer:** Fahmy, 1955.  
**references:** 1959, DIS 33: 86.  
**phenotype:** Extremely fine short bristles. Wings slightly rounded at tips. Males and females viable and fertile; eclosion delayed. RK3.  
**other information:** One allele induced by nitrogen-mustard.

**\*fft: fused filament**

**location:** Not located.  
**origin:** Spontaneous.  
**discoverer:** Robertson and Reeve.  
**references:** 1954, DIS 28: 78.  
**phenotype:** Chorionic filaments of eggs laid by *fft* females usually fused into a single structure. A few normal eggs also laid. Hatchability reduced and variable. RK3.

*fg:* see *spd*<sup>fg</sup>

**\*fi: frail**

**location:** 1-53.  
**origin:** Recovered among progeny of flies treated with Janus green.  
**discoverer:** Muller, 28e20.  
**references:** 1935, DIS 3: 30.  
**phenotype:** Wings nearly as small as *m*, thin and frail. Bristles fine. Fly weak. Viability 10-30% wild type. RK3.

**fiber loop:** see *flo*

**fibrillar dysgenesis:** see *fdg*

**\*fil: fine lash**

**location:** 1-56.8.  
**origin:** Induced by L-p-N,N-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1953.  
**references:** 1959, DIS 33: 86.  
**phenotype:** Thin, slightly shorter bristles. Eyes reduced in size; posterior border very close to orbital bristles. Both sexes viable and fertile. RK3.  
**other information:** Two alleles induced by ethyl methanesulfonate.

**filzig:** see *flz*

**fin: finer**

**location:** 1-29.6.  
**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).  
**discoverer:** Fahmy, 1954.  
**references:** 1959, DIS 33: 86.  
**phenotype:** Fly slightly smaller than normal with shorter, thinner bristles. Delayed eclosion. Males viable but sterile. RK3.

**fine bristle:** see *fb*

**fine bristles:** see *fbr*

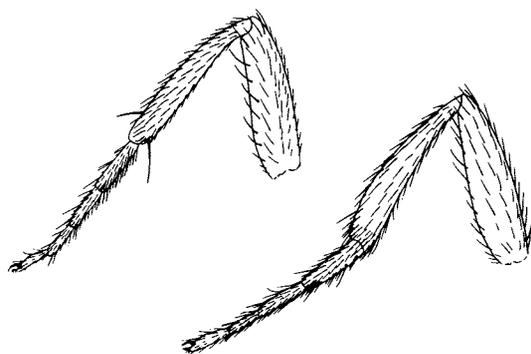

**fine chaetae:** see *fnc*

**fine lash:** see *fil*

**fine macros:** see *fm*

**finer:** see *fin*

**fizzy:** see *fzy*

**fj: four jointed**

Edith M. Wallace, unpublished.

**fj: four jointed**

**location:** 2-81.5.

**origin:** Spontaneous.

**discoverer:** Schultz, 31d1.

**phenotype:** Similar to *d*. Tarsi four instead of five jointed.

Legs short and stocky, owing to failure of joint formation between second and third tarsal segments (Tokunaga and Gerhart, 1976, *Genetics* 83: s76). Femur, tibia, and tarsae foreshortened [Tokunaga and Gerhart, 1976; Mikuta, 1979, *Genetika (Moscow)* 15: 624-32]. Probability of joint failure proportional to degree of shortening of second tarsal segment (Tokunaga and Gerhart, 1976). Joint failure phenotype can extend into *ff*/*ff* clones (Tokunaga and Gerhart, 1976). Leg chaetae show irregularities in the relative orientation of sockets and bracts (Held, Duarte, and Derakhshanian, 1986, *Wilhelm Roux's Arch. Dev. Biol.* 195: 145-57). Enhanced by *ss<sup>a</sup>* and *ss<sup>ab</sup>* [Villem, 1945, *Genetics* 30: 26-27; Mglinetz and Ivanov, 1976, *Genetika (Moscow)* 12: 87-94] and by *pb* [Kaurov, Ivanov, and Mglinetz, 1978, *Genetika (Moscow)* 14: 306-12]; also influenced by *Antp<sup>Ns</sup>* (Mikuta and Mglinetz). *ff ey<sup>D</sup>* flies have but three tarsal joints (Postlethwait and Schneiderman, 1975, *Ann. Rev. Genet.* 7: 381-433). Development similar to that of *dachs* [Waddington, 1943, *J. Genet.* 45: 29-43 (fig.)]. Wings shorter and broader with crossveins conspicuously closer together; veins diverge at greater angle (Tokunaga, Michinomae, Sizemore, and Gerhart, 1978, *Genetics* 88: s98). Effect visible in pupal wing (Waddington, 1940, *J. Genet.* 41: 75-139). Eyes smaller, ellipsoid, coarse textured; head foreshortened. RK2.

**alleles:** *\*ff<sup>40e</sup>* (Ives, 1941, *DIS* 14: 39) showed more extreme but more variable venation anomalies than *ff<sup>1</sup>*.

**cytology:** Placed in 55B-C based on its inclusion in *Df(2R)11B = Df(2R)54F6-55A1;55C1-3* and *Df(2R)Pcl-w5 = Df(2R)55A-B;55C* (Deng and Rizki, 1988, *Genome* 30, Suppl. 1: 192).

**Fk:** see *Hex-C*

**fkh: fork head**

**location:** 3-95.

**references:** Jürgens and Weigel, 1988, *Wilhelm Roux's Arch. Dev. Biol.* 197: 345-54.

Weigel, Jürgens, Küttner, Seifert, and Jäckle, 1989, *Cell* 57: 645-58.

**phenotype:** Embryonic lethal. *fkh<sup>+</sup>* appears to be required in the most anterior and posterior regions of the embryo; in amorphic mutants homeotic transformation effects the appearance of post-oral head structures in these terminal domains. The ectopic head structures are sometimes associated with thoracic structures anteriorly and anterior tail structures posteriorly. Thus *fkh* mutations produce transformations directed to the center involving structures normally found in different parasegments. Anteriorly, esophagus and proventriculus, derivatives of the ectodermal stomodaeum, are absent but not the pharynx or the hypopharyngeal organ, which resides on the anterior surface of the embryo; parts of the head skeleton are distorted; other parts apparently normal. Salivary glands absent. Posteriorly, anal pads and Malpighian tubules, derivatives of the ectodermal proctodaeum, are absent; replaced by anterior tail structures and post-oral head structures; supernumerary anal sensilla and dorsal hairs also present. Anterior and posterior *fkh* domains are beyond the regions controlled by *ANTC* and *BXC*, respectively; however ectopic expression of *ANTC* and *BXC* expression can occur in the *fkh* domains of *fkh* but not *fkh<sup>+</sup>* embryos. No maternal effect. Homozygous *fkh* clones in adult cuticle completely normal in structure indicating no requirements for *fkh<sup>+</sup>* in imaginal disk development. *In situ* hybridization reveals transcript in two terminal domains shortly before blastoderm cellularization occupying 5% embryonic length anteriorly and 15% posteriorly. *fkh* protein first detected in posterior domain at the end of syncytial blastoderm and the anterior domain at the beginning of cellularization. Expression continues in the derivatives of the ectodermal stomodaeum and proctodaeum throughout gastrulation. In addition *fkh* protein is detected in the midgut, the salivary glands, the central nervous system, and the yolk cells.

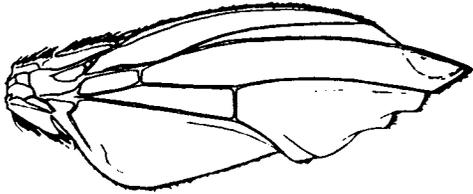

**alleles:**

allele	origin	ref <sup>α</sup>	comments
<i>fkh<sup>1</sup></i>	EMS	1	nonsense mutation in codon 254
<i>fkh<sup>2</sup></i>	EMS	2	in frame deletion of codons 233-237; 17 bp deletion + 2 bp insertion
<i>fkh<sup>3</sup></i>	EMS	2	nonsense mutation in codon 63
<i>fkh<sup>4</sup></i>	X ray	2	weak allele; <i>T(2;3)38;98D2-3</i>
<i>fkh<sup>5</sup></i>	X ray	2	weak allele; <i>T(Y;3;4)98D2-3;99F;101</i>
<i>fkh<sup>6</sup></i>	X ray	2	out of frame deletion of codons 8-10 + 2 bp of codon 11
<i>fkh<sup>7</sup></i>	X ray	2	deletion of ca. 90 kb
<i>fkh<sup>8</sup></i>	X ray	2	weak allele; <i>In(3LR)80F;98D2-3</i>

<sup>α</sup> 1 = Jürgens, Wieschaus, Nüsslein-Volhard and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95; 2 = Jürgens and Weigel, 1988, *Wilhelm Roux's Arch. Dev. Biol.* 197: 355-59.

**molecular biology:** Region cloned in a 120 kb walk. Identity of *fkh* gene confirmed by *P*-mediated germ-line transformation. 4.2 kb transcript observed in Northern blots; 4002 base pairs of cDNA sequence determined; direction of transcription from right to left; breakpoints of *fkh* rearrangement located downstream from the gene. Sequence reveals an uninterrupted open reading frame of

1530 base pairs, encoding a 510-residue polypeptide of calculated molecular weight of 54.3 kd; antibody staining reveals the restriction of *fkh* protein to nuclei. No significant sequence similarity to known proteins detected in computer search of databases. A second transcript, distal to fork head (*dfk*), which is transcribed from left to right, lies less than 500 base pairs to the right of *fkh*.

**fl: fluted**

Edith M. Wallace, unpublished.

**fl: fluted**

**location:** 3-59.7+ (Kuhn, Woods and Andrew, 1984, DIS 60: 134-35).

**origin:** Spontaneous.

**discoverer:** Redfield, 211.

**phenotype:** Wings creased lengthwise and dark. Overlaps wild type slightly at 25° but not at 19°. RK3.

**alleles:** \**fl*<sup>2</sup>, spontaneous, Spencer, 36d15.

*Fl*: see *Sxl*

**fl(1)302: female lethal 302**

**location:** 1-{9} (to the right of *ect*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Steinmann-Zwicky.

**references:** 1988, EMBO J. 7: 3889-98.

**phenotype:** Homozygous females die in larval or pupal stages. Male viable.

**cytology:** Placed in 4C5-E1 based on its inclusion in *Df(1)rb13 = Df(1)4C5-6;4D3-E1*. Not included in *Df(1)rb23* and *Df(1)rb27* which overlap the left end of *Df(1)rb13* but have not been characterized cytologically.

**fla: flateye**

**location:** 1-2.4 [no evidence for such in *w-spl* interval (Lefevre and Green, 1972, Chromosoma 36: 391-412)].

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 70.

**phenotype:** Smaller fly with smaller and less curved eyes. Wings extremely variable, from normal through incised margins to crumpled vestigial stumps. Not easily classified. Viability and fertility good in males but reduced in females.

**flap wing:** see *flw*

**flare:** see *flr*

**flateye:** see *fla*

*flb*: see *Egfr*

**fle: femaleless**

**location:** 3-45 (mapped with respect to *mwh* and *red*).

**origin:** Spontaneous.

**synonym:** *fle(3)100*.

**references:** Inouchi, Okuno, Oishi, and Watanabe, 1983, Jpn. J. Genet. 58: 525-30.

Okuno, Satou, and Oishi, 1984, Jpn. J. Genet. 59: 237-47.

**phenotype:** Homozygous females die; males survive. Lethal effect late. Dosage compensation normal as determined by tritiated uridine labeling of polytene chromosomes. No interaction with *tra* in *fle/tra* heterozygotes.

**fli-385: flightless-385 (J.C. Hall)**

**location:** 1-ca. 0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

**phenotype:** Adults cannot fly or even beat wings; induced simultaneously with a *fli* allele; not allelic to *fliA* or *fliB*.

**fli: flightless (J.C. Hall)**

A series of ethyl-methanesulfonate-induced, sex-linked mutations selected by Homyk *et al.*. All were crudely mapped; complementation tests were performed among *fli*, *fliA*, and other behavioral mutants recovered in the screens and mapping to the same interval. In this way eleven *fli* loci, designated *fliA* through *fliK*, were identified. Allelism tests with *fli* mutants not carried out.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

Homyk and Grigliatti, 1983, Dev. Genet. 4: 77-97.

Homyk and Emerson, 1988, Genetics 119: 105-21.

*fliA*: see *Actn*

**fliB**

**location:** 1-0.0.

**phenotype:** Flightless and beats wings poorly after rearing at 17°; weak flier after rearing at 22°; jumps abnormally short distances when raised at restrictive temperature. TSP late larval early pupal.

**fliC**

**location:** 1-19.9.

**phenotype:** Flight and other behaviors impaired; for one allele (*fliC*<sup>1</sup>), raising at 22° leads to weak flight though normal appearance; rearing at 29° causes drooped wing position (often bilaterally asymmetrical), poor flying, weak locomotion, inadequate wing display of courting males; TSP for flightlessness in first half of pupal stage. *fliC*<sup>2</sup> allele nearly lethal at 29°; rearing at 22° leads to good survival but weak flight; both alleles have lethal maternal effect. *fliC*<sup>1</sup> females sterile.

**alleles:** Two mutant alleles: *fliC*<sup>1</sup> and *fliC*<sup>2</sup>. ERG normal (Homyk and Pye, 1989, J. Neurogenet. 5: 37-48).

**cytology:** Placed in 7B2-C1; in the region of overlap of *Df(1)ct-J6 = Df(1)6E1;7C1* and *Df(1)ct4B1 = Df(1)7B2-4;7C3-4* (Homyk and Emerson, 1988, Genetics 119: 105-21).

**fliD**

**location:** 1-25.5.

**phenotype:** When raised at 17°, adults are weak fliers; when raised at 22°, bristles are small and adults cannot

fly and cannot jump normally; lethal when raised at 29°. ERG normal (Homyk and Pye, 1989, J. Neurogenet. 5: 37-48). TSP a restricted period in early pupa.

**cytology:** Placed in 8C-9B1; not deleted by *Df(1)KA14* = *Df(1)7F1-2;8C6* or *Df(1)v-L15* = *Df(1)9B1-2;10A1-2*. Females carrying *fliD* in heterozygous combination with *Df(1)C52* = *Df(1)8E;9C-D* and raised at 29° exhibit partially impaired flying and hopping ability which could indicate location of the gene at the 8E breakpoint; however, *Df(1)C52/±* females also show abnormal movement after development at 29°.

### **fliE**

**location:** 1-26.8.

**phenotype:** Flightless when raised at 17°; weak flight after rearing at 22°; jumping ability poor after rearing at restrictive temperature. TSP first half of pupal stage. ERG normal (Homyk and Pye, 1989, J. Neurogenet. 5: 37-48).

### **fliF**

**location:** 1-29.1.

**phenotype:** Flightless, jumping ability poor; mosaic analysis suggests primary defect could be in muscles (Homyk, 1977, Genetics 87: 105-28). In *fliF*<sup>2</sup> and *fliF*<sup>3</sup>, indirect flight muscles have relatively mild abnormalities of z bands and myofibrils. Reduced amounts of at least two high-molecular-weight proteins from indirect flight muscles [Deak, Rahmi, Bellamy, Bienz, Blumer, Fenner, Golin, Ramp, Reinhardt, Dubendorfer, and Cotton, 1980, Development and Neurobiology of Drosophila (Siddiqi, Babu, Hall, and Hall, ed.). Plenum Press, New York and London, pp. 183-92; Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rahmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81].

#### **alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>fliF</i> <sup>1</sup>	EMS	Homyk		2	
<i>fliF</i> <sup>2</sup>	EMS		696 = <i>gmp</i> <sup>1</sup>	1	
<i>fliF</i> <sup>3</sup>	EMS		628 = <i>gmp</i> <sup>2</sup>	1	

<sup>α</sup> 1 = Deak, Rahmi, Bellamy, Bienz, Blumer, Fenner, Golin, Ramp, Reinhardt, Dubendorfer, and Cotton, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, ed.). Plenum Press, New York and London, pp. 183-92; 2 = Homyk and Sheppard, 1977, Genetics 87: 95-104.

### **fliG**

**location:** 1-32.67.

**references:** Zhimulev, Belyaeva, Pokolkova, Kotchneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baricheva, Aizenzon, Kramers, and Eeken, 1981, DIS 56: 192-96.

1982, DIS 58: 210-14.

Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720; 1987, DIS 66: 194-97.

**phenotype:** Flight and other behaviors impaired. One allele, *fliG*<sup>1</sup>, allows for weak flight; another, *fliG*<sup>2</sup>, leads to almost no flight ability and weak running or climbing (Homyk, 1977, Genetics 87: 105-28); wings abnormal in appearance (intrinsically and in terms of positions in which they are held); male fertility reduced; sex combs reduced. All alleles are nearly lethal when reared at 18° and cause poor viability when raised at 25°. Not allelic to *fliC*, *fliD*, *fliE*, *fliF*, or *fliG*, or to *sdby*.

**cytology:** Placed in the 9F11-12 interband or in the left

edge of 9F12 based on its being uncovered by *Df(1)v-L3* = *Df(1)9F10;10A7-8* but not by *Df(1)v-M6* = *Df(1)9F11-12;10A1-2* and mapping to the left of *v* (Zhimulev *et al.*, 1981, 1987).

**alleles:** Four mutant alleles: *fliG*<sup>1</sup>, *fliG*<sup>2</sup>, *fliG*<sup>3</sup> (= *fliG*<sup>B186</sup>), and *fliG*<sup>4</sup> (= *fliG*<sup>dp324</sup>), all cold-sensitive lethals or semilethals. The first two described by Homyk and Sheppard, the latter two by Zhimulev *et al.*; *fliG*<sup>4</sup> induced in *v*<sup>+</sup>*Yy*<sup>+</sup>.

*fliH*: see *hdp-a*

### **fliI**

**location:** 1-66.5.

**phenotype:** Both viable and lethal alleles isolated. Viable alleles are recessive and flightless; wing position normal; jumping abilities variously impaired depending on allele. Temperature-sensitive alleles show temperature-sensitive period to be during first half of pupal stage. Rearing *fliI*<sup>1</sup> and *fliI*<sup>2</sup> at 17° leads to weak flight and at 22° to flightlessness. Indirect-flight-muscle fibers wavy with amorphous internal structures; myofilaments disorganized; z bands and myofibrils abnormal; thin filaments often aggregated into bundles with striations (not seen in wild type). Mosaic analysis with *fliI*<sup>5</sup> suggests primary defect in thoracic muscles (Koana and Hotta, 1978, J. Embryol. Exp. Morphol. 45: 123-43). Trans heterozygotes with *sdby* are flightless. Lethal alleles die in larval or pupal stages. Maternal effect lethal; progeny produced from homozygous female germline clones of severe alleles (e.g., *fliI*<sup>14</sup>) are not rescuable by normal allele of paternal origin; abnormal folding during gastrulation; mesoderm invagination abnormal; only patches of epidermis present at later stages; embryos from clones homozygous for weaker alleles (e.g. *fliI*<sup>22</sup>) were more nearly normal in appearance.

**cytology:** Placed in the distal half of 19F based on deficiency mapping with deficiencies of unknown polytene breakpoints (Perrimon, Smouse, and Miklos, 1989, *Genetics* 121: 313-31).

*flilJ*: see *elav*

***flIK***

**location:** 1-30.1.

**synonym:** *l(1)9Fc*.

**phenotype:** Flying and jumping ability poor or absent; mutants tend to be generally inactive, including poor courtship; both alleles lead to stress-sensitive paralysis and are temperature sensitive, in that rearing at 29° leads to severe weakness and early death. Temperature sensitive throughout most of development. ERG normal (Homyk and Pye, 1989, *J. Neurogenet.* 5: 37-48).

<sup>α</sup> 1 = Homyk, Szidonya, and Suzuki, 1980, *Mol. Gen. Genet.* 177: 553-65; 2 = Lefevre, 1981, *Genetics* 99: 461-80; 3 = Lefevre and Watkins, 1986, *Genetics* 113: 869-95; 4 = Zhimulev, Belyaeva, Pokolkova, Kotchneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baritcheva, Aizenzon, Kramers, and Eeken, 1981, *DIS* 56: 192-96; 5 = Zhimulev, Pokholkova, Bgatov, Semeshin, and Belyaeva, 1981, *Chromosoma* 82: 25-40.

**cytology:** Placed in 9F3-5 based on inclusion in *Df(1)HC133 = Df(1)9B9-10;9F2-5* but not *Df(1)ras-P14 = Df(1)9E1-2;9F3-4* (Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987, *Biol. Zentralbl.* 106: 699-720; 1987, *DIS* 66: 194-97).

***flightless*:** see *flit*

***flight defective*:** see *flit*

***flight reduced*:** see *flrd*

***flipper*:** see *flp*

**\**flil*: flyless**

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** Cercos, 41g15.

**references:** Andres, 1943, *DIS* 17: 48.

**phenotype:** Wings apparently normal, but fly cannot keep them spread and cannot fly more than a few inches. RK3.

***flo*: fiber loop (J.C. Hall)**

**location:** 2-58 (1% recombination with *cn*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg and Fishbach.

**synonym:** *flo*<sup>N115</sup>.

**phenotype:** Looped axon fiber present in axonal columns in distal part of medulla (second order optic lobe); nearly full penetrance (Heisenberg).

*flp*: see *flw*

**\**flp*: flipper**

**location:** 2-27 (based on location of *flp*<sup>hd</sup>).

**origin:** Spontaneous.

**discoverer:** Mohr, 18h5.

**references:** Bridges and Mohr, 1919, *Genetics* 4: 304.

**phenotype:** Wings fail to expand, remain compact, very dark, extended, and curved slightly downward. Fly a wizened dwarf. Body surface dull and dark. Both sexes sterile. RK3.

***flp*<sup>hd</sup>: flipper-hood**

**origin:** X ray induced.

**discoverer:** M. Simmons, 1972.

**references:** Craymer, 1980, *DIS* 55: 198.

**phenotype:** Like *flp* but fertile in both sexes. *flp*<sup>hd</sup>/<sub>1</sub> + tends to have dusky, corrugated wings. RK3 as dominant; RK1 as recessive.

**other information:** Allelism inferred from location (27 vs 30) and phenotype.

***flr*: flare**

**location:** 3-38.8 (with respect to *h* and *th*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Garcia-Bellido and Dapena, 1974, *Mol. Gen. Genet.* 128: 117-30.

**phenotype:** Chaetae and trichomes in thorax and abdomen abnormally shaped. Chaetae have rudimentary sockets, and shaft is frequently crooked and branched. Trichomes transformed into multiple short outgrowths which appear as swellings on wing cells and as rosettes in abdominal cuticle cells. Homozygotes are zygotic lethals but cell viable; homozygous clones may have reduced survival in thorax but not in abdomen. Excellent marker for homozygous *3L* clones.

**alleles:** Three alleles: *flr*<sup>1</sup>, *flr*<sup>2</sup>, and *flr*<sup>3</sup>. Lethal in all pairwise combinations.

***flrd*: flight reduced (J.C. Hall)**

A series of ethyl-methanesulfonate-induced, sex-linked mutants with reduced flying ability recovered by Homyk *et al.*. All were crudely mapped; complementation tests were performed among *flit*, *flrd*, and other behavioral mutants recovered in the same screens and mapping to the same interval. In this way 17 *flrd* loci, designated *flrdA* through *flrdR* (no K or Q) were identified; two others were not mappable. Allelism tests with *flit* mutants

were not performed.

**references:** Homyk and Sheppard, 1978, *Genetics* 87: 95-104.

Homyk, Szidonya, and Suzuki, 1980, *Mol. Gen. Genet.* 177: 553-65.

#### ***firdA***

**location:** 1- 1.2.

**phenotype:** Flight weak; small amplitude of wing beats. Not allelic to *firdB* or *firdC*.

#### ***firdB***

**location:** 1- 1.1.

**phenotype:** Flight weak; females may be more impaired than males; small amplitude of wing beats; jumping ability subnormal.

#### ***firdC***

**location:** 1- 4.0.

**phenotype:** Flight weak; adults seem generally feeble, including poor jumping ability; 10-30% of adults fail to inflate wings normally; even when wings inflated, males seldom extend them fully when courting.

#### ***firdD***

**location:** 1- 28.1.

**phenotype:** Weak flight when raised at 29°; flightless when raised at 22°; wing beats have small amplitude and wing behavior of courting males is aberrant; impaired jumping ability when raised at either temperature; mosaic analysis suggests primary defect could be in muscles (Homyk, 1977, *Genetics* 87: 105-28).

#### ***firdE***

**location:** 1- 39.9.

**phenotype:** Weak flight; adults often fail to retract wings properly and walk holding one or both wings at 90° angle to body axis.

#### ***firdF***

**location:** 1- 42.2.

**phenotype:** Flightless; jumping ability poor; mosaic analysis suggests primary defect could be in muscles (Homyk and Sheppard, 1977).

#### ***firdG***

**location:** 1- 44.6.

**phenotype:** Weak flight; males may be more impaired than females; no wing beats; general locomotor activity weak, including poor jumping ability; adults begin dying around 10 days post eclosion; homozygous mutant females do not lay eggs (which is not necessarily due to same variant as that causing behavioral defects).

#### ***firdH***

**location:** 1-51.0.

**phenotype:** Weak to very weak flight; small amplitude of wing beats in flight; weak jumping ability; all alleles lead to decreased viability, flying ability, or both when raised at higher temperatures; mutations are heat-sensitive male steriles, and at least one allele, *firdH*<sup>3</sup>, causes abnormalities of wing movements in courtship after rearing at 29°. TSP of *firdH*<sup>3</sup> second and third larval instars (Homyk and Grigliatti, 1983, *Dev. Genet.* 4: 77-97).

**alleles:** Four mutant alleles: *firdH*<sup>1</sup>, *firdH*<sup>2</sup>, *firdH*<sup>3</sup>, and *firdH*<sup>4</sup>; *firdH*<sup>2</sup> (*firdH*<sup>2xk</sup>) originally designated *firdK*.

#### ***firdJ***

**location:** 1- 51.0.

**phenotype:** Very weak flight. Mosaic analysis suggests primary defect in thoracic muscles [Homyk, 1977, *Genetics* 87: 105-28 (described these as *firdI* rather than *firdJ*)].

*firdI*: see *l(1)adl16*

*firdK*: see *firdH*<sup>2</sup>

#### ***firdL***

**location:** 1- 62.5.

**phenotype:** Weak flight; generally somewhat inactive.

#### ***firdM***

**location:** 1- 23.6.

**phenotype:** Weak flight and jumping; adults generally somewhat inactive; some such individuals have poor landing response.

#### ***firdN***

**location:** 1-38.0.

**phenotype:** Weak flight and jumping ability; more severe phenotype, including poor wing usage in male courtship, after rearing at 29°. Wings held up and out when raised at 29°. TSP for wing posture restricted to late third instar; that for flightlessness begins in second instar and extends until near end of pupal stage.

#### ***firdO***

**location:** 1- 45.3.

**phenotype:** Weak to poor flying ability; *firdO*<sup>1</sup> is most severe of three alleles; wings tend to be held in aberrant positions, including by courting males (all alleles).

**alleles:** Three mutant alleles: *firdO*<sup>1</sup>, *firdO*<sup>2</sup>, and *firdO*<sup>3</sup>.

#### ***firdP***

**location:** 1- 44.6.

**phenotype:** Flight and jumping ability weak; adults become uncoordinated briefly after mechanical shock.

**other information:** Complements *firdG* although mapping to the same position.

#### ***firdQ***

**location:** 1- 56.7.

**phenotype:** Weak flying and jumping ability; wing beating in flight has small amplitude; adults generally somewhat inactive.

#### ***fird-R***

**location:** 1- 58.6.

**phenotype:** Flight weak; generally somewhat inactive; some of the mutant individuals have melanotic spot under cuticle, near wing (not known to be due to same genetic change as that affecting flight).

#### ***fird-393: flight reduced-393 (J.C. Hall)***

**location:** 1- not localized.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, *Genetics* 87: 95-104.

**phenotype:** Very weak flight; small amplitude of wing beats in flight; usage of wings by courting males abnormal.

**other information:** Position of mutation or mutations responsible for aberrant phenotypes said not to be resolvable.

**flrd-397 (J.C. Hall)**

**location:** 1- not localized.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.  
**phenotype:** Weak flight; usage of wings by courting males abnormal.  
**other information:** Position of mutation or mutations responsible for aberrant phenotypes said not to be resolvable.

**flt: flight defective (J.C. Hall)**

A series of ethyl-methanesulfonate-induced X-chromosome mutants isolated by Koana and Hotta (1978, J. Embryol. Exp. Morphol. 45: 123-43). All were crudely mapped and complementation tests performed among those mapping in the same interval. In this way 15 loci were identified and designated *fltA* through *fltO*. They were not tested for allelism with other collections of sex-linked flightless mutants such as *fli* or *flrd*; many cases of allelism between these series are likely.

**fltA**

**location:** 1- between *y* and *cho*.  
**phenotype:** Impaired flight; jumping ability nearly normal.

**fltB**

**location:** 1- between *cho* and *cv*.  
**phenotype:** Impaired flight; jumping ability nearly normal.

**fltC**

**location:** 1- between *cv* and *v*.  
**phenotype:** Impaired flight, but when raised at 24°, some individuals fly normally; when raised at 29°, all are completely flightless; jumping ability nearly normal.

**fltD**

**location:** 1- between *cv* and *v*.  
**phenotype:** Completely flightless; reduced jumping ability. Mosaic analysis suggests primary focus in thoracic muscles.  
**other information:** Complements *flrdD*, *gmp*, and *sdby*.

**fltE**

**location:** 1- between *cv* and *v*.  
**phenotype:** Impaired flight; jumping ability normal.

**fltF**

**location:** 1- between *cv* and *v*.  
**phenotype:** Impaired flight; unable to take off from a surface; severely impaired jumping ability.

**fltG**

**location:** 1- between *cv* and *v*.  
**phenotype:** Impaired flight; *fltG* has near-normal jumping ability; *fltG*<sup>2</sup> is normal in this behavior.  
**alleles:** Two mutant alleles: *fltG*<sup>1</sup> and *fltG*<sup>2</sup>.

**fltH**

**location:** 1- between *v* and *f*.  
**phenotype:** Completely flightless; normal jumping ability; wavy myofibrils in flight muscles, with larger than normal diameter; thick and thin filaments sometimes disorganized with deficient Z bands; sarcomere length abnormal; mosaic analysis suggests primary defect in thoracic muscles.

**fltI**

**location:** 1- between *v* and *f*.  
**phenotype:** Impaired flight; jumping ability nearly normal.

**fltJ**

**location:** 1- between *v* and *f*.  
**phenotype:** Impaired flight; unable to take off from a surface; normal jumping ability.  
**alleles:** Three mutant alleles: *fltJ*<sup>1</sup>, *fltJ*<sup>2</sup>, and *fltJ*<sup>3</sup>, the latter two weaker than the first.

**fltK**

**location:** 1- between *v* and *f*.  
**phenotype:** Completely flightless; reduced jumping ability.

**fltL**

**location:** 1- between *v* and *f*.  
**phenotype:** Completely flightless; normal jumping ability.

**fltM**

**location:** 1- between *f* and centromere.  
**phenotype:** Impaired flight; jumping ability nearly normal.

**fltN**

**location:** 1- between *f* and centromere.  
**phenotype:** Impaired flight; jumping ability nearly normal.

**fltO:** see *fliI*

**flu: fluorouracil response**

**location:** 3- not mapped.  
**origin:** Naturally occurring polymorphism.  
**references:** Duke and Glassman, 1968, Nature 220: 588-89.  
 O'Byrne-Ring and Duke, 1980, Biochem. Genet. 18: 717-26.  
**phenotype:** Resistant strain, *flu*<sup>r</sup>, resistant to at least 0.0035% FU and shows resistance to FUDR as well. Sensitive strain, *flu*<sup>s</sup> exhibits over 90% mortality following exposure to 0.0008% FU (6 × 10<sup>-5</sup> M). Thymidilate synthetase levels of resistant strains four times those of sensitive strains.  
**alleles:** Two alleles described: *flu*<sup>r</sup> and *flu*<sup>2</sup> designating resistant and sensitive alleles.

**Flu: Flutter (J.C. Hall)**

**location:** 1-37.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rahmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81.  
**phenotype:** Flies heterozygous for one of the mutant alleles, *Flu*<sup>1</sup>, have reduced flight ability, impaired jump response, and relatively slight disturbances in morphology of Z bands and myofibrils of indirect flight muscles; these *Flu*<sup>+</sup> flies are also like Hyperkinetic (*Hk*) mutants in terms of agitated behavior after etherization; *Flu*<sup>1</sup>/*Flu*<sup>1</sup> flies are more severely affected with respect to flight and *Hk*-like phenotype; *Flu*<sup>2</sup> is recessive in regard to flight and shaking defects; *Flu*<sup>1</sup> studied for indirect flight muscle proteins and has reduced amounts of at least two high-molecular-weight materials.  
**alleles:** Two mutant alleles: *Flu*<sup>1</sup> and *Flu*<sup>2</sup>.

**fluff:** see *ff*

**fluorouracil response:** see *flu*

**fluted:** see *fl*

**Flutter:** see *Flu*

**flw: flap wing (J.C. Hall)**

**location:** 1-31.

**references:** Deak, 1977, J. Embryol. Exp. Morphol. 40: 35-63.

Deak, Rahmi, Bellamy, Bienz, Blumer, Fenner, Gollin, Ramp, Reinhardt, Dubendorfer, and Cotton, 1980, Development and Neurobiology of *Drosophila*, (Siddiqui, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 183-92.

**phenotype:** Wings held in lateral position, instead of dorsally, and parallel to substrate as in wild type; thorax has darkened longitudinal stripe; anterior scutellar bristles sometimes missing or doubled; eyes bulging and slightly roughened; head compressed; third antennal joint shortened; unable to fly; jumping ability poor; fibrillar muscles of thorax (dorsoventrals, dorsolongitudinals) are variably abnormal, ranging from disorganized to missing; tergal depressor of trochanter jump muscle is normal in light microscope; behavioral and muscular phenotypes affected by *flw*<sup>2</sup> may be due to primary defect in muscle primordia, concluded from mosaic experiment (Deak, 1977); at least two *flw* alleles (*flw*<sup>3</sup> and *flw*<sup>4</sup>) cause reduced amount of a particular protein from indirect flight muscles (same molecule as that affected by *hdp*, *int*, *rsd*, and *up* mutations) (Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rahmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81). *flw* is not allelic to *gmp*.

**alleles:**

allele	origin	discoverer	synonym
<i>flw</i> <sup>1</sup>		Waletsky, 1937	<i>flp</i>
<i>flw</i> <sup>2</sup>		Hanratty	
<i>flw</i> <sup>3</sup>	EMS		<i>flw</i> <sup>671</sup>
<i>flw</i> <sup>4</sup>	EMS		<i>flw</i> <sup>725</sup>
<i>flw</i> <sup>5</sup>	EMS		<i>flw</i> <sup>942</sup>

**cytology:** Placed in 9C on the basis of its inclusion in *Df(1)N110 = Df(1)9B3-4;9D1-2* but not *Df(1)C52 = Df(1)8E;9C-D* (Craymer and Roy, 1980, DIS 55: 200-04).

**flyless:** see *fll*

**flz: filzig**

**location:** 2-59.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.)

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal; denticles and hairs of larvae have abnormal fuzzy texture. Mouth hooks poorly developed.

**alleles:** Five, *flz*<sup>1</sup> and *flz*<sup>2</sup> (isolated as *IP* and *IIG*) retained.

**cytology:** Placed in 44F-46D by segmental aneuploidy.

**\*fm: fine macros**

**location:** 1-66.1.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 86.

**phenotype:** Small fly with narrow abdomen and extremely

short, thin bristles. Males fertile; viability about 50% wild type. RK3.

**other information:** Possibly allelic to *lf* or *lfl*.

**fmf: factor for male fertility**

**location:** 1- 0.5 (more than 0.008 but less than 0.189 cM to right of *dor*).

**origin:** Locus inferred from infertility of males deficient for 2B7-12, i.e., *Df(1)st472/ly<sup>2</sup>Y67g = Df(1)2B6-8;2B11-12/Dp(1;Y)1A1;2B6-7*.

**references:** Aizenzon and Belyaeva, 1982, DIS 58: 3-7.

Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 190.

**phenotype:** Males poorly viable and sterile.

**cytology:** Inferred position 2B7-12.

**Fmrf: FMRF amide homologous precursor**

**location:** 2-{59}.

**references:** Nambu, Murphy-Erdosh, Andrews, Feistner, and Scheller, 1988, Neuron 1: 55-61.

**phenotype:** Encodes the precursor polypeptide that is processed to generate a nonapeptide, DPKQDFMRFamide, that shares homology with the FMRFamide neuropeptide from molluscs. Gene appears to be expressed from late embryogenesis through the adult stage (see also White, Hurteau, and Punsal, 1986, J. Comp. Neurol. 247: 430-38).

**cytology:** Placed in 46C by *in situ* hybridization; proximal to *Df(2R)eve1.27 = Df(2R)46C3-4;46C9-11*.

**molecular biology:** Clones isolated from library using an oligonucleotide probe based on the putative amino-acid sequence of the nonapeptide, which had been isolated. Gene encodes a single 1.7 kb message; cDNA clones sequenced; conceptual amino-acid sequence indicates a precursor protein of 347 amino acids; the sequence contains a putative signal sequence, five copies of DPKQDFMRF as well as ten additional peptides exhibiting various degrees of relatedness. Each peptide is flanked by single arginine cleavage sites and ends contain a carboxy-terminal glycine that can serve as the substrate for amidation.

**\*fnc: fine chaetae**

**location:** 1-34.9.

**origin:** Induced by S-2-chloroethylcysteine (CB. 1592).

**discoverer:** Fahmy, 1957.

**references:** 1959, DIS 33: 86.

**phenotype:** Extremely fine, short bristles. Body parts disproportionately reduced; reduction least marked on head and most marked on abdomen. Wings broad and slightly rounded at tips, occasionally with incisions of margin. Eyes slightly brighter red than normal. Males viable but sterile. RK3.

**fo: folded**

**location:** 1-63.

**discoverer:** Grossman, 1932.

**references:** 1934, DIS 1: 30.

**phenotype:** Wings remain unexpanded in a varying percentage of flies. Balancers shriveled; postscutellars bent forward. Overlaps wild type. RK3.

**Fo: Forkoid**

**location:** 2-107 (between *or* and *sp*).

**origin:** X ray induced.

**discoverer:** Mohler, 58c18.

**references:** 1960, DIS 34: 52.

**phenotype:** Heterozygote shows reduction in size of bristles and weak forking of head and posterior thoracic bristles. Using *Dp(2;3)P*, it may be shown that the expression of *+/+Fo < +/Fo < +/Fo/Fo; +/Fo/Fo* shows extreme forking of all bristles and is sterile. Homozygous lethal. *Fo* interacts with *f* alleles to produce extreme *f* bristles. RK1.

**alleles:** *Fo*<sup>1</sup> and *Fo*<sup>2</sup>; the latter induced by Angel with ethyl methanesulfonate; allelism based on phenotype and map position (1.4% to right of *bw*).

**cytology:** Located between 58E3 and 60B10, on basis of its inclusion in *Dp(2;3)P = Dp(2;3)58E3-F2;60D14-E2;96B5-C1* but not in *Df(2R)Px = Df(2R)60B8-10;60D1-2* (Mohler) or in the deficiency for the tip of 2R derived from *T(1;2)Bld = T(1;2)IC3-4;60B12-13* (Armentrout).

*focal melanosis*: see *me*

**fog: folded gastrulation**

**location:** 1-65.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307. Zusman and Wieschaus, 1985, Dev. Biol. 111: 359-71. Perrimon, Smouse, and Miklos, 1989, 121: 313-31.

**phenotype:** Hemizygous lethal; the cellular blastoderm apparently normal and gastrulation begins at normal time. No posterior midgut formed; germ band does not elongate onto dorsal side of embryo but it is thrown into a series of transverse ventral folds. Older embryos often twist around the longitudinal axis for one complete turn; many exhibit an anterodorsal hole through which the brain protrudes and a split in the posterior CNS and protrusion of the midgut. Hemizygous deficiency gives same phenotype. No effect of maternal genotype; homozygous germ line clones make eggs capable of supporting normal embryonic development. Fate mapping localizes *fog* lethal focus to the posterior pole most likely in presumptive posterior-midgut or proctodaeum cells.

**alleles:**

**cytology:** Localized to 20A-B.

**\*fol: folded wings**

**location:** 2-39.

**origin:** Spontaneous.

**discoverer:** Goldschmidt, 1937.

**phenotype:** Expanded wing folded. Overlaps wild type. RK3.

**folded:** see *fo*

**folded gastrulation:** see *fog*

**folded wings:** see *fol*

**for: foraging**

**location:** 2-10.

**origin:** Naturally occurring variants.

**references:** DeBelle, Hilliker, and Sokolowski, 1987, Behav. Genet. 17: 620-21. 1989, Genetics 123: 157-63.

**phenotype:** The major gene responsible for foraging strategy of feeding larvae. Larvae from so-called sitter strains move about 6.5 cm in five minutes while feeding on a yeasted surface, whereas those from so-called rover strains travel some 17 cm; heterozygotes are rovers. Several X-ray induced reversions of the dominant rover phenotype shown to be non-complementing lethals which map to 10 on chromosome 2, thus localizing a major behavioral locus.

**alleles:** Two alleles thus defined, *for*<sup>R</sup>, the rover allele, and *for*<sup>S</sup>, the sitter allele.

**cytology:** Placed in 24A3-C5 based on the lethality of the noncomplementing lethal alleles in combination with *Df(2L)ed-Sz = Df(2L)24A3-4;24D3-4* but not with *Df(2L)ed = Df(2L)24C3-5;25A1-4*.

**fr: fringed**

**location:** 2-80.

**origin:** Spontaneous.

**discoverer:** Bridges, 22c30.

**references:** 1938, DIS 9: 48.

**phenotype:** Wings often spread; wing margins snipped; bristles irregular and fringelike. Eyes small and rough. Midline of abdomen at slight angle to longitudinal axis of fly. Much variability in expression; safest criterion is wing margin irregularity. Viability and fertility variably reduced depending on allele. Character less extreme at low temperature.

**alleles:** Four spontaneous alleles recorded.

**fragile chorion:** see *fch*

**frail:** see *fi*

**Frd: Freckled**

**location:** 2-102.4 (2.1 units to the left of *bw*).

**origin:** X ray induced.

**discoverer:** M. G. Davis, 1961.

**references:** Erlich, 1963, DIS 37: 47.

Barigozzi, 1963, Proc. Intern. Congr. Genet., 11th., Vol. 1: 207.

1965, DIS 40: 64.

**phenotype:** Pupa and young fly characterized by accumulation of dark pigment; in older fly, pigment becomes concentrated in black specks scattered through body, head, and legs. Deposition of electron-dense material in nucleus and cytoplasm of fat cells begins during pupal stage; pericardial cells of adult become filled with electron-opaque granules and vacuoles (Perotti and Bairati, 1968, J. Insect Path. 10: 122-38). The occasional weak manifestation of the *Frd* phenotype transmitted from *Cy/Frd* males to their *Cy* offspring and their descendents led Barigozzi and Gira (1968, Genet. Res. 11: 141-50) to postulate an extra chromosomal component of the *Frd* phenotype. Homozygous lethal. RK2.

**frh: fruh (T. Schüpbach)**

**location:** 2-62.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach, and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal mutant; homozygous females lay eggs which show no visible signs of development when observed under transmitted light in a stereo microscope; defective in fertilization or very early embryonic development. *frh*<sup>3</sup> and *frh*<sup>6</sup> sometimes give rise to embryos which form irregular blastoderms and develop very abnormally, producing fragmented pieces of cuticle.

**alleles:** Six; *frh*<sup>1</sup> through *frh*<sup>6</sup> (isolated as *RO*, *HM*, *PH*, *PM*, *SB*, and *APL* respectively).

**fringed:** see *fr*

**frizzled:** see *fz*

**fru: fruitless (J.C. Hall)**

**location:** 3-62.0.

**origin:** X ray induced.

**synonym:** *fruity*.

**references:** Gill, 1963, DIS 38: 33.

1963, Am. Zool. 3: 507.

Hall, 1978, Behav. Genet. 8: 125-41.

Hall, Siegel, Tompkins, and Kyriacou, 1980, Stadler Genet. Symp. 12: 43-82.

**phenotype:** Males court but do not mate with females; *fru* males court other males (especially when such flies also are homozygous for *fru*) and stimulate vigorous courtship on the part of *fru* or wild-type males. Mutant males

produce volatile compounds different from those generated by normal males, on criteria of gas chromatography and bioassays of behavioral effects of these compounds; females appear to be unaffected by *fru*, which is not allelic to *sr*.

**cytology:** Placed in 90C to 91A, based on uncovering by *Df(3R)P14*.

**other information:** Not allelic to *sr*.

**fs(1)-: female sterile on chromosome 1**

There have been three concerted searches for female sterile mutations on the X chromosome. The first to be reported is that of Gans, Audit, and Masson (1975, Genetics 81: 683-704), the second is by Mohler (1977, Genetics 85: 259-72), the third is by Komitopoulou, Gans, Margaritis, Kafatos, and Masson (1983, Genetics 105: 897-920). These series of mutants are designated *fs(1)A*, *fs(1)M*, and *fs(1)K* respectively. In designating loci the order of priority is *A>M1-M63>K*; e.g., all alleles of mutants first recovered (Gans *et al.*) are designated *fs(1)A-*, and the nominate allele is the one with the lowest acquisition number; alleles found by Audit are numbered, consecutively, alleles of Mohler are designated by the superscript M, and those by Komitopoulou by K. Allelism among these mutants has been incompletely tested; the number of loci is certainly lower than the tables indicate.

In addition to these extensive searches there are other female sterile mutants whose designations are more *ad hoc*.

**fs(1)5:** see *yl*

**fs(1)5e**

**location:** 1-37.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Perez-Chiesa, Cintron, and Morales, 1985, DIS 61: 215.

**phenotype:** Homozygous females sterile; males fertile. 95% of heterozygous females are fertile when reared at 25°, but only 5% are fertile when reared at 29°, or when reared at 25° but shifted for three days to 29°. Eggs produced are permeable to neutral red and burst when dechorionated in a 3% sodium hypochlorite solution.

**Fs(1)10A**

**location:** 1-33.52.

**synonym:** *hfs*: *haplo female sterile*.

**references:** Lefevre, 1969, Genetics 63: 589-600.

Zhimulev, Pokholkova, Bgatov, Semeshin, and Belyaeva, 1981, Chromosoma 82: 25-40.

**phenotype:** Locus inferred from the infertility of females heterozygous for vermilion deficiencies.

**cytology:** Placed in 10A8 by deficiency analysis; included in *Df(1)v<sup>65b</sup> = Df(1)9F12-23;11A8-9* and *Df(1)RA37 = Df(1)10A5-6;10B17-C1* but not *Df(1)v<sup>L3</sup> = Df(1)9F10;-*

10A7-8 or *Df(1)KA7 = Df(1)10A8-9;10F10*.

*fs(1)11* to *fs(1)14*: see *otu*

***fs(1)29***: see *yl*

***fs(1)42***

**location**: 1-13.3.

**origin**: Induced by ethyl methanesulfonate.

**discoverer**: Denell, 1971.

**references**: Rizzo and King, 1977, *J. Morphol.* 152: 329-40 (fig.).

**phenotype**: Viability and longevity normal. Oogenesis in homozygous females proceeds through stage 8; chambers then degenerate. Dying follicle cells seen in chambers at all positions in ovarioles; profollicle cells also die in germaria and clusters of cystocytes delayed in achieving full complement of covering follicle cells. Egg chambers in vitellarium contain about 60% the normal number of follicle cells; these have greater lateral dimensions, and their nuclei and nucleoli are larger than normal. Follicular envelope of mutant chambers often contains gaps through which projections from cystocytes protrude.

*fs(1)117*: see *yl*

*fs(1)205*: see *yl*

*fs(1)209*: see *otu*

***fs(1)288***

**origin**: Induced by ethyl methanesulfonate.

**references**: Waring, DiOrio, and Hennen, 1983, *Dev. Biol.* 100: 452-63.

**cytology**: Placed in 12A6-D3 based on its inclusion in *Df(1)HA92 = Df(1)12A6-7;12D3*.

*fs(1)445*: see *yl*

*fs(1)1001*: see *otu*

*fs(1)1163*: see *Ypl<sup>ts1</sup>*

*fs(1)1304b*: see *otu*

*fs(1)1396*: see *otu*

*fs(1)1401*: see *otu*

***fs(1)1867***

**location**: 1-62.9 (0.4 cM to the right of *car*).

**origin**: Induced with ethyl methanesulfonate.

**references**: Wieschaus, 1979, *Cell Lineage, Stem Cells, and Cell Determination* (Le Douarin, ed.), Elsevier/North Holland Biomedical Press, pp. 291-302. Szabad and Szydony, 1980, *Development and Neurobiology of Drosophila* (Siddiqui, Babu, Hall, and Hall, eds.), Plenum Press, New York, pp. 95-108.

**phenotype**: Homozygotes and hemizygotes exhibit delayed development and Minute-like or missing bristles; eclosion delayed about four days compared to heterozygous sibs; gynandromorphs delayed in development in proportion to quantity and independent of the quality of *fs(1)1867* tissue. Homozygous females sterile, never lay eggs; ovarioles develop normally until stage 10 after which degeneration and resorption occurs. Oocytes in *fs(1)1867* ovaries transplanted into wild-type hosts unable to develop, but *fs(1)1867* oocytes in wild-type ovaries do develop. *fs(1)1867* follicle cells fail to become columnar; defect concluded to be follicular.

*fs(1)4077*: see *otu*

***fs(1)A*: female sterile of Audit**

A series of ethyl-methanesulfonate-induced sex-linked recessive female sterile mutations first reported by Gans, Audit, and Masson (1975, *Genetics* 81: 683-704). The mutants were apportioned to the following phenotypic classes: Class I - females produce few if any eggs; Class II - females produce morphologically abnormal eggs; and Class III - females lay numerous normal appearing eggs. Class III is subdivided into IIIA for cases where fertilization by a sperm carrying the normal allele of the mutant for which the mother is homozygous rescues the eggs and produces an offspring and IIIB in which a sperm bearing a normal allele is unable to effect rescue. All classes have been described briefly by Gans *et al.*; Class II mutants have been described in more detail by Komitopoulou, Gans, Margaritis, Kafatos, and Masson [1983, *Genetics* 105: 897-920 (fig.)], and Class IIIB by Zalokar, Audit, and Erk [1975, *Dev. Biol.* 47: 419-32 (fig.)]. Information on mapping, allelism, and phenotypic class of these mutant presented in following table followed by phenotypic descriptions from above references.

<sup>α</sup> Mutants allelic to previously recognized or more recently renamed loci are listed as alleles of those loci. For newly recognized loci the numbers of subsequently identified alleles in the A, K, and M series are indicated.

### ***fs(1)A59***

**phenotype:** Eggs show limited flaccidity; chorion with slightly shortened dorsal appendages. Mosaic analysis with *fs(1)A59<sup>KI</sup>* shows normal allele to function in somatic tissue (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

### ***fs(1)A97***

**phenotype:** Homozygous females sterile at 29° but not 16°. Produce haploid embryos at 29° which form abnormal blastoderms.

### ***fs(1)A99***

**phenotype:** Cold sensitive; death occurs during larval stage; normal development at 29°.

### ***fs(1)A107***

**phenotype:** Development ceases late in embryogenesis.

### ***fs(1)A117***

**phenotype:** Embryogenesis arrested at various stages; low fecundity.

### ***fs(1)A120***

**phenotype:** Embryogenesis arrested at various stages; dependent on culture medium. Somatic-cell-specific function (Wieschaus, Audit, and Masson, 1981, Dev. Biol. 88: 92-103).

### ***fs(1)A125***

**phenotype:** Low fecundity; dorsal appendages fused; partially fertile at 16° and 23°.

### ***fs(1)A147***

**phenotype:** No initiation of development; fine structure of chorion normal.

### ***fs(1)A180***

**phenotype:** Fertile at 16° and 23°. Mosaic analysis suggests that normal allele functions in somatic tissue (Wieschaus, Audit, and Masson, 1981, Dev. Biol. 88: 92-103). Chorion ultrastructure normal (Komitopoulou, Gans, Margaritis, Kafatos and Masson, 1983, Genetics 105: 897-920).

### ***fs(1)A214***

**phenotype:** No evidence of cleavage; Feulgen-positive material accumulates during first two hr. No evidence that fertilization takes place regularly. (Figured by Zalokar, Audit, and Erk, 1975, Dev. Biol. 47: 419-32). *fs(1)A214*<sup>2</sup> fertile at 16° but not 29°.

### ***fs(1)A248***

**phenotype:** Adult phenotype normal but females retain eggs. *fs(1)A248*<sup>2</sup> females fertile at 16°.

### ***fs(1)A273***

**phenotype:** Chorion appendages of *fs(a)A273<sup>KI</sup>* females show abnormal size and shape. About 5% of eggs produce adults. Mosaic results ambiguous (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

### ***fs(1)A321***

**phenotype:** Homozygous females have short bristles; lay flaccid eggs.

### ***fs(1)A330***

**phenotype:** Time of developmental failure varies - at fertilization, blastoderm formation, gastrulation, or in embryo. Such development as does occur is abnormal.

### ***fs(1)A331***

**phenotype:** Various times of developmental arrest.

### ***fs(1)A383***

**phenotype:** Embryos apparently normal but few larvae hatch. Many eggs of *fs(1)A383*<sup>2</sup> females cease mitosis during first hour, forming a few polyploid nuclei; others reach blastoderm which displays a peculiar mosaicism of an area with large swollen nuclei sharply separated by a line of pycnotic nuclei from an area with nuclei having more condensed chromatin. Occasionally two such areas in succession divided by lines girdling egg. Preblastoderm mitoses diploid and synchronous.

**fs(1)A387**

**phenotype:** Embryos fail late in development; some rescue by fertilization with sperm carrying normal allele.

**fs(1)A426**

**phenotype:** Embryonic development arrested at various times during development at 29°; some adult survival at 16°.

**fs(1)A427**

**phenotype:** Phenotype of adults normal, but females retain eggs.

**fs(1)A436**

**phenotype:** Development fails at advanced stage of embryogenesis. Rescue effected by fertilization with sperm carrying normal allele.

**fs(1)A456**

**phenotype:** Mosaic analysis shows normal allele to function in somatic tissue. Chorion ultrastructure normal (Komitopoulou, Gans, Margaritis, Kafatos, and Masson, 1983, *Genetics* 100: 897-920).

**fs(1)A457**

**phenotype:** Haploid development to abnormal blastoderm or gastrula stages. Nuclei smaller than normal and their numbers in blastoderm may exceed 10,000. In at least one case a Y chromosome was seen suggesting proliferation of paternal pronucleus. Few develop to late embryonic stages.

**fs(1)A462**

**phenotype:** Adults normal but females retain eggs; partially fertile at 16°. Clones of homozygous germinal cells in heterozygous female produce oviposited eggs (Wieschaus, Audit, and Masson, 1981, *Dev. Biol.* 88: 92-103).

**fs(1)A473**

**phenotype:** Eggs partially devoid of chorion; females fertile at 16° and 23°. Mosaic studies show gene function to be specific to soma (Wieschaus, Audit, and Masson, 1981, *Dev. Biol.* 88: 92-103; Perrimon and Gans, 1983, *Dev. Biol.* 100: 365-73).

**fs(1)A475**

**phenotype:** Mutant females lay eggs at 23° but not at 29°. Fertilization with sperm carrying normal allele produces some progeny at 23°.

**fs(1)A476**

**phenotype:** Development arrested in late embryo; rescue occurs with sperm carrying normal allele.

**fs(1)A508**

**phenotype:** Adults display twisted bristles and delayed development. Eggs produced by homozygous females vary in size, often smaller than normal.

**fs(1)A543**

**phenotype:** Adults have short wings; homozygous females retain eggs at 29° but are fertile at 16°.

**fs(1)A572**

**phenotype:** Early blastoderm apparently normal; later at nuclear elongation nuclei appear constricted and some forced out of peripheral layer and into deeper regions of the egg. Excessive numbers of blastoderm nuclei

(>10,000), but not due to haploidy. Gastrulation appears normal; development arrested at time of first muscular contractions. Difficulties of nuclear separation in early cleavage stages observed.

**fs(1)A1001**

**phenotype:** Adults normal in appearance. Females retain eggs but are partially fertile at 16°. Mosaic results at 29° indicate mutant interferes with somatic function of normal allele.

**fs(1)A1010**

**phenotype:** Development arrested in second and third cleavage; in metaphase, excessive numbers of punctiform and filamentous chromosomes; spindles appear normal. A few escapers appear at 16°-18°; many are agametic.

**fs(1)A1024**

**phenotype:** Offspring of homozygous mothers usually die in late pupal stages; about 30% escapers have unexpanded wings and die within a few days of eclosion.

**fs(1)A1042**

**phenotype:** Development arrested in second and third cleavage; in metaphase, excessive numbers of punctiform and filamentous chromosomes; spindles appear normal. A few escapers appear at 16°-18°; many are agametic.

**fs(1)A1059**

**phenotype:** Egg development and chorion morphology of *fs(1)A1059<sup>K1</sup>* females at 19° normal. At 29° chorion resembles that of previously identified chorion-protein-gene-amplification-defective mutants [*fs(1)K451* and *fs(1)K1214*]. At 29° follicle cells show at least a three-to-five-fold suppression of amplification of the chorion-protein genes on both the X and third chromosomes compared to 24° (Komitopoulou, Kouyanou, and Kafatos, 1986, *Dev. Genet.* 7: 75-80).

**alleles:** Although not explicitly stated, it seems that lack of complementation has been demonstrated in the following combinations: *fs(1)A1059<sup>1</sup>/fs(1)A1059<sup>K1</sup>* (Komitopoulou), *fs(1)A1059<sup>2</sup>/fs(1)A1059<sup>M1</sup>*, and *fs(1)A1059<sup>K1</sup>/fs(1)A1059<sup>M1</sup>* (Mohler).

<sup>α</sup> 1 = Gans, Audit and Masson, 1975, *Genetics* 81: 683-704; 2 = Komitopoulou, Gans, Margaritis, Kafatos, and Masson, 1983, *Genetics* 105: 897-920; 3 = Mohler and Carroll, 1984, *DIS* 60: 236-41;

**fs(1)A1074**

**phenotype:** At 29° eggs fail to develop; at 23° development ceases during embryogenesis or larval or even pupal stages. Some rescue at 23° by fertilization with sperm carrying the normal allele.

**fs(1)A1140**

**phenotype:** Preblastoderm formed more or less normally, but nuclei irregularly placed within periplasm; many polyploid mitoses. Gastrulation abnormal; death precedes onset of muscular movement.

***fs(1)A1187***

**phenotype:** Homozygous females fertile at 16° but not at 29°. Blastoderm abnormal containing haploid nuclei.

***fs(1)A1242***

**phenotype:** Eggs arrest after a few nuclear divisions; have polyploid groups of chromosomes or deeply stained masses of chromatin. Mosaic studies indicate germ-line function of normal allele (Perrimon and Gans, 1983, *Dev. Biol.* 100: 365-73).

***fs(1)A1245***

**phenotype:** Viability reduced when raised at 29° and development delayed 1-3 days depending on allele. Oogenesis normal until stage 11-12 of King [stage 9 for *fs(1)A1245*<sup>3</sup>]. Appendages of chorion absent. Mosaic analysis using *fs(1)A1245*<sup>2</sup> suggest germ line function of gene (Perrimon and Gans, 1983, *Dev. Biol.* 100: 365-73).

***fs(1)A1304***

**phenotype:** Most egg chambers of homozygous females degenerate after King stage 6; a few cysts escape to produce stage 14 oocytes which are retained in the ovariole. Vitellogenesis severely inhibited and uptake of protein from the hemolymph apparently impaired. (Khipple Mulligan and Rasch, 1980, *J. Exp. Zool.* 212: 343-54). Nucleoli of nurse cells morphologically aberrant (Khipple Mulligan and King, 1976, *Int. J. Insect. Morphol. Embryol.* 5: 127-35). Oocytes grow at reduced rate and become covered by multiple layers of follicle cells, which secrete abnormal egg coverings (Khipple Mulligan and King). Phenotype insensitive to ecdysone administration and pole-cell-transplantation in studies by Lamnissou and Galti-Douka (1986, *Dev. Genet.* 6: 239-46), (Khipple Mulligan and Rasch). Mosaic studies by Wieschaus, Audit, and Masson (1981, *Dev. Biol.* 88: 92-103) indicate that the gene functions in the germ line, presumably in the nurse cells.

***fs(1)A1371***

**phenotype:** Homozygous females produce few offspring at 29°; at 16° nuclei begin to degenerate in preblastoderm stage leading to irregular blastoderm and irregular gastrula. Claimed to be an allele of *fs(1)1059*<sup>K1</sup> and *fs(1)1059*<sup>M1</sup> by Mohler and Carroll (1984, *DIS* 60: 236-41) but phenotype is not concordant with such a claim.

***fs(1)A1459***

**phenotype:** Homozygous females produce progeny at 16° but not at 29°. Blastoderm develops normally at 29°, but at nuclear elongation stage, nuclei move irregularly from surface into periplasm; nuclei degenerate, cell wall formation irregular.

***fs(1)A1509***

**phenotype:** Blastoderm and early gastrulation normal; orifice of midgut remains widely separated from cephalic furrow, intervening space filled with yolky ooplasm covered with a layer of flat epithelium; area may subsequently evert exposing internal organs. Cyst-like diverticles formed within embryo. Developmental arrest at time of first muscular contractions. Primary defect is failure of germ band elongation.

***fs(1)A1526***

**phenotype:** Few nuclear divisions resulting in polyploid groups of chromosomes or in deeply stained masses of chromatin.

***fs(1)A1528***

**phenotype:** Most eggs remain unfertilized.

***fs(1)A1559***

**phenotype:** Developmental arrest in late embryo; a few larvae hatch.

***fs(1)A1561***

**phenotype:** Mosaic studies indicate somatic function of normal allele (Perrimon and Gans, 1981, *Dev. Biol.* 100: 365-73).

***fs(1)A1578***

**phenotype:** Most eggs remain unfertilized.

***fs(1)A1621***

**location:** 1-11.7.

**origin:** Induced with ethyl methanesulfonate.

**synonym:** *liz*; *snf*.

**references:** Gans, Audit, and Masson, 1975, *Genetics* 81: 683-704.

Gollin and King, 1981, *Dev. Genet* 2: 203-18.

Perrimon and Gans, 1983, *Dev. Biol.* 100: 365-73.

Steinmann-Zwicky and Nöthiger, 1985, *Cell* 42: 877-87.

Cline, 1988, *Genetics* 119: 829-62

Oliver, Perrimon, and Mahowald, 1988, *Genetics* 120: 159-71.

Steinmann-Zwicky, 1988, *EMBO J.* 7: 3889-98.

**phenotype:** Homozygous females viable but semisterile; males normal. Young females produce ova which can be fertilized and develop normally into adults. Older females cease production of oocytes, producing at first only pseudo nurse cells and subsequently tumorous germlaria containing hundreds or thousands of cells of apparently germinal origin. Tumorigenesis takes place earlier at higher temperatures. *fs(1)A1621/Df(1)C159* hemizygous for mutant; more temperature sensitive; the germ-line phenotype more severe than in homozygote but viability seems unaffected (Gollin and King). Mosaic studies suggest that gene function is germ line autonomous (Wieschaus *et al.*; Perrimon and Gans); however, the leakiness of the mutant phenotype introduced an element of ambiguity, raising the possibility of a somatic contribution to oogenesis as well. Interactions with *Sxl* alleles studied by Cline (1989), Steinmann-Zwicky (1988), and Oliver *et al.* (1988). Fertility of *fs(1)A1621* homozygotes is rescued by the presence of *Sxl*<sup>M1</sup>. *Trans* heterozygotes of *fs(1)A1621* or *Df(1)HC244* with *Sxl*<sup>f1</sup> show very low viability when *fs(1)A1621* is inherited from the female; survivors are sterile and show patchy transformations to maleness, such as sex-comb bristles and pigmentation of tergites 5 and 6. Viability of heterozygotes produced by the reciprocal cross also reduced but less so; surviving heterozygotes display reduced fertility. Viability effects appear to arise mostly from a maternal effect of the gene, whereas masculinizing and sterility effects result from decreased zygotic expression. The maternal effect of *fs(1)A1621* also reduces survival of *Sxl*<sup>f1/+</sup> daughters; survival is cold sensitive. The

presence of *Sxl<sup>M1</sup>* rescues *fs(1)A1621/Sxl<sup>fl</sup>* females; *Df(1)HC244*, *Sxl<sup>M1</sup>/Sxl<sup>fl</sup>* are viable and fertile without male transformations. *Sxl<sup>M1</sup>* is also able to rescue *Sxl<sup>fl</sup>/+* from the maternal effect of *fs(1)A1621/+*, and *fs(1)A1621* is able to rescue male viability and fertility of *Sxl<sup>M1</sup>* in *fs(1)A1621 Sxl<sup>M1</sup>* double mutants. In contrast to the *sis* genes, which also interact with *Sxl*, the zygotic dose of *fs(1)A1621* has little or no influence on the sexual phenotype of 2X;3A animals; moreover, *fs(1)A1621* interacts little if at all with *sis-a*. Thus although *fs(1)A1621<sup>+</sup>* clearly has a positive involvement in *Sxl<sup>+</sup>* functions, its precise placement in the sex determination hierarchy is currently unclear. It has been suggested that it is involved in the positive autoregulatory aspect of *Sxl* function that maintains female development. Females heterozygous for *fs(1)A1621* and either *ovo<sup>D1</sup>*, *ovo<sup>D2</sup>*, or *ovo<sup>D3</sup>* have ovarian tumors (Oliver, Pauli, and Mahowald, 1990, Genetics 125: 535-50).

**cytology:** Placed in 4F7-12 based on its inferred inclusion in *Df(1)HC244 = Df(1)3E8;4F11-12* but not *Df(1)A113 = Df(1)3D6;4F7-8* (Steinmann-Zwicky, and Nöthiger, 1985; Cline, 1988).

**fs(1)BP**

**location:** 1-32.67.

**discoverer:** Bgatov.

**phenotype:** Adults normal; fertility lesion not characterized.

**alleles:** Six; *fs(1)BP<sup>1</sup>* to *fs(1)BP<sup>6</sup>* isolated as *F58*, *F129*, *F403*, *F417*, *F456*, and *F469*, respectively.

**cytology:** Placed in 9F3-5 based on inclusion in *Df(1)HC133 = Df(1)9B9-10;9F2-5* but not *Df(1)ras-P14 = Df(1)9E1-2;9F3-4* (Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720; 1987, DIS 66: 194-97).

*fs(1)cor-36*: see *Cp-36<sup>nl</sup>*

**fs(1)C**

A small series of ethyl-methanesulfonate induced mutants produced and partially characterized by D. Mohler and A. Carroll (1984, DIS 60: 236-41).

**fs(1)de: female sterile (1) defective eggs**

A subset of hybrid-dysgenesis-induced, X-linked female-sterile mutations that are characterized by the production of morphologically abnormal eggs that fail to hatch [Orr, Galanopoulos, Romano, and Kafatos, 1989, Genetics 122: 847-58 (fig.); see also Galanopoulos, Orr, Szabad and Kafatos, 1989, Dev. Genet. 10: 87-97 (fig.)]. The loci are numbered from 1 through 17 with alleles of *fs(1)del* designated by lower case letters in the superscript. The X chromosomes in these lines harbor multiple P elements, thus complicating cytological localization.

No case of allelism with previously identified sex-linked female sterile mutations and one case of allelism to a known lethal mutation in the *BRC* detected. Various defects in respiratory appendages and chorionic architecture described in above references.

**fs(1)h: female sterile (1) homeotic**

**location:** 1-21.65 (0.05 cM to the left of *mys*).

**synonym:** *l(1)7Da*; *fsh*.

**references:** Gans, Audit, and Masson, 1975, Genetics 81: 683-704.

Zalokar, Audit, and Erk, 1975, Dev. Biol. 47: 419-32 (fig.).

Gans, Forquignon, and Masson, 1980, Genetics 96: 887-902.

Forquignon, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 132-38.

Digan, Haynes, Mozer, Dawid, Forquignon, and Gans, 1986, Dev. Biol. 114: 161-69.

**phenotype:** Many mutant alleles at this locus are nonconditional lethals, but there are three temperature-sensitive hypomorphic alleles. *fs(1)h<sup>1</sup>* is the weakest of these and many of the phenotypic studies have been carried out on it and on *Df(1)C128*, which is deficient for the locus. Temperature-sensitive genotypes display two periods of sensitivity to elevated temperature; one is during oogenesis and affects embryonic development and the other is during the pupal stage and affects adult survival. Adult survival of *fs(1)h<sup>1</sup>* homozygotes and *fs(1)h<sup>1</sup>/Df(1)C128* heterozygotes is normal at 20° and 25°, but 10% and 0 respectively at 28.5°. As mentioned above, the TSP for lethality is the pupal stage. *fs(1)h<sup>15</sup>* shown to be lethal in germ-line clones (Perrimon, Engstrom, and Mahowald, 1984a, Dev. Biol. 105: 404-14). Fertility of *fs(1)h* homozygotes and *fs(1)h/Df(1)C128* temperature sensitive with the former becoming completely sterile at 29° and the latter at 25°; temperature-sensitive periods for *fs(1)h/Df(1)C128* females during pregastrulation embryogenesis and perhaps late oogenesis. Eggs laid at restrictive temperatures exhibited normal preblastoderm development, although about half the nuclei are haploid; nuclear behavior during blastoderm formation disrupted and development arrested in blastoderm or early gastrulation. Larvae and adults surviving semi-permissive temperatures display homeotic anomalies; dead embryos, and newly hatched larvae frequently have missing thoracic

and anterior abdominal segments; surviving adults exhibit a sex ratio skewed in favor of males and frequently show missing halteres and less frequently third legs; effects are more severe in progeny of *fs(1)h/Df(1)C128* than homozygous *fs(1)h* females, in daughters than sons, and at 25° than 23°; small areas of homeotic transformations of anterior metathoracic to anterior mesothoracic structures also seen. The maternal effect of *fs(1)h* interacts synergistically with *Ubx*<sup>130</sup>, *Df(3R)red*, and *trx*, but not *bx*<sup>3</sup> or *pbx*.

**alleles:** Most alleles are nonconditional lethals; fine structure mapping places two nonconditional alleles tested distal to the three tested conditional alleles. Relative strengths of the mutant alleles estimated as follows: *Df(1)C128* = *fs(1)h*<sup>5</sup> = *fs(1)h*<sup>4</sup> > *fs(1)h*<sup>18</sup> > *fs(1)h*<sup>3</sup> > *fs(1)h*<sup>8</sup> > *fs(1)h*<sup>17</sup> > *fs(1)h*<sup>2</sup> > *fs(1)h*<sup>6</sup> > *fs(1)h*<sup>1</sup>, the last three being conditional.

Res. 163: 115-44.

<sup>β</sup> Origin of molecular coordinates a *SacI* site just proximal to the proximal breakpoint of *Df(1)C128* = *Df(1)7D1;7D5-6*, positive values to the left.

**cytology:** Localized to 7D1-5 based on its inclusion in *Df(1)C128* = *Df(1)7D1;7D5-6*.

**molecular biology:** Region cloned in an 120 bp chromosome walk from a genomic clone shown to be deleted by *Df(1)C128*. Southern blots identify lesions associated with four alleles, which map to positions 39 to 51 kb distal to the proximal breakpoint of *Df(1)C128*. Poly(A)<sup>+</sup>RNAs migrating as a doublet at 7.6 kb and a band at 5.9 kb are transcribed from this region in ovaries; these transcripts are present in 0 to 4 h embryos but are not detectable at later stages. During pupal stages a 2.4 kb transcript is detected. The largest RNAs are derived from a 20-kb chromosomal region encompassing the sites of all mapped *fs(1)h* alleles. The *fs(1)h* transcription unit is less than 500 base pairs distal to that of *mys*.

## *fs(1)K10*

**location:** 1-0.5 (based on 191 recombinants between *y* and *w*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Wieschaus, Marsh, and Gehring, 1978, Wilhelm Roux's Arch. Dev. Biol. 184: 75-82 (fig.).

Wieschaus, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 89-94 (fig.).

**phenotype:** Homozygous females lay eggs with hyperplasia of the anterior chorionic appendages to form a collar around the micropile. Pole-cell-transplantation studies demonstrate chorionic phenotype to depend on germ-line genotype; pattern of overlying follicle cells apparently depends on cues from oocyte. *In situ* hybridization and antibody staining indicate that expression is confined to the primary oocyte and that the protein product is sequestered in the oocyte nucleus (Prost, Deryckere, Roos, Haenlin, Pantesco, and Mohier, 1988, Genes Dev. 2: 891-900). Eggs of mutant females seldom fertilized; those that are exhibit abnormalities of gastrulation with the anterior ends showing dorsal patterns of development both ventrally and laterally. Some larvae produced with dorsal cuticular pattern covering entire circumference; last few segments have normal ventral hypoderm pattern. Ventralizing mutants *grk* and *top* both epistatic to the dorsalizing effects of *fs(1)K10* (Schüpbach, 1987, Cell 49: 699-707). Germ-line mosaics produced by mitotic exchange indicate *fs(1)K10* activity required during oogenesis (Marsh, Wieschaus, and Gehring, 1976, Experientia 32: 803). Ovarian clones of homozygous cells useful in investigating kinetics of oogenesis (Wieschaus and Szabad, 1979, Dev. Biol. 68: 29-46).

**alleles:** Four ethyl-methanesulfonate-induced alleles; *fs(1)K10*<sup>1</sup> isolated by Wieschaus *et al.* (1978); *fs(1)K10*<sup>2</sup>, *fs(1)K10*<sup>3</sup>, and *fs(1)K10*<sup>4</sup> isolated as *fs(1)M9* by Mohler (Mohler, and Carroll, 1984, DIS 60: 236-41).

**cytology:** Placed 2E2-F1 based on its being deleted by *Df(1)278* = *Df(1)2E2-F3;3A5-B4* but not *Df(1)2F1;3A4*. (Perrimon, Engstrom, and Mahowald, 1984, Genetics 108: 559-72).

**molecular biology:** Region cloned in a 200-kb chromosomal walk initiated from cloned sequences from microdissected polytene region 2E2-F1 (Haenlin, Steller, Pirrotta and Mohier, 1985, Cell 40: 827-37). *fs(1)K10* mutants rescuable by transformation with a 5-kb sequence. This sequence detects mRNA molecules of four different sizes on Northern blots; all have apparently the same initiation sites; species of 3.1 and 2.8 kb have different polyadenylation sites and both have had an 854-bp intron removed; a 4.0-kb species retains the intron and has the same polyadenylation site as the 3.1 kb molecule; a low-abundance mRNA of 6.0 kb retains the intron and extends beyond the known polyadenylation sites. The 3.1 and 2.8 messages are expressed in the ovaries and early embryos; the two larger transcripts are more generally expressed. Transcription from left to right (Haenlin, Roos, Cassab, and Mohier, 1987, EMBO J. 6: 801-07). Sequencing of cDNA clones yields a conceptual polypeptide of 463 amino acid residues of 51.5 kd and an isoelectric point of pH 11.2; the molecule has three domains: the amino terminal domain up to residue

225 contains seven eight-residue repeats with consensus sequence GlnGlnGlnHisProSerPro and variants thereof; the middle domain of ca. 112 amino acids is apolar, containing 37% proline; the carboxyterminus contains a helix-turn-helix motif in residues 390-418 (Prost *et al.*).

***fs(1)K79–fs(1)K1563: Female sterile of Komitopoulou***

A series of ethyl-methanesulfonate-induced, sex-linked-recessive female-sterile mutants reported by Komitopoulou, Gans, Margaritis, Kafatos, and Masson (1983, Genetics 105: 897-920). The same classification scheme as used in the *fs(1)A* series was employed for *fs(1)K* mutants. Only class II mutants have been characterized. Information on mapping, allelism, and phenotypic class are presented in the accompanying table; additional phenotypic description follows the table.

<sup>α</sup> Mutants allelic to previously recognized or more recently renamed loci are listed as alleles of those loci.

***fs(1)K79***

**phenotype:** Actually *fs(1)K79* females, either homozygous or hemizygous, are fertile, but their eggs display short and fragile dorsal appendages.

***fs(1)K93***

**phenotype:** Homozygous females produce flaccid eggs, which readily take up neutral red.

***fs(1)K163***

**phenotype:** Survival severely reduced and development delayed; wings short and thin. Eggs of homozygous females flaccid; embryogenesis blocked at various stages; rescue effected by sperm carrying normal allele.

***fs(1)K254***

**phenotype:** Pupal lethal at 29°; female survival reduced at 23° and 25°. Female fertility reduced at 23° and abolished at 25° and 29°. Eggs of homozygous females have short thin dorsal appendages; ultrastructure of chorion abnormal; chorion defects not temperature sensitive. Mosaic analysis shows gene to function in somatic tissue (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

***fs(1)K451***

**phenotype:** Reduced viability, especially of females; abnormalities of posterior legs, also especially in females. *fs(1)K451/Df(1)g-l* does not survive. Homozygous females produce eggs with short thin dorsal appendages and ultrastructurally defective chorions. All major chorion proteins underproduced owing to failure of chorion protein gene amplification. *Cp* genes on the third chromosome more severely affected than those on the *X* (Orr, Komitopoulou, and Kafatos, 1984, Proc. Nat. Acad. Sci. USA 81: 3773-77). In mosaic experiments *fs(1)K451* behaves as a locus required in both somatic and germinal tissues (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

***fs(1)K524***

**phenotype:** At 29° eyes rugose and bristles short and fine; abdominal etching as well at 20°. Ovaries extremely atrophied, resembling ovaries without germ cells; however, occasional stage 14 cysts encountered.

***fs(1)K741***

**phenotype:** Viability good; ovaries atrophied at 29°. Female fertile at 23°.

**\**fs(1)K811***

**phenotype:** Low fecundity; dorsal appendages of chorion may be fused; chorion ultrastructurally normal.

***fs(1)K1134***

**phenotype:** Follicular development arrested at stage 8; transformation of larval to adult fat body appears to be blocked. May be a juvenile hormone deficiency.

***fs(1)K1193***

**phenotype:** Viability normal; homozygous females produce somewhat flaccid eggs. Development rarely proceeds to pupal stage. Mosaic studies indicate that gene functions in germ line (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

***fs(1)K1214***

**phenotype:** Viability and fecundity of homozygous females reduced; sterility virtually complete, but a few progeny escape. Dorsal appendages of chorion short and thin. All major chorion proteins underproduced owing to a defect in amplification of *Cp* genes on both the *X* and chromosome 3 (Orr, Komitopoulou, and Kafatos, 1984, Proc. Nat. Acad. Sci. USA 81: 3773-77). Mosaic analysis indicates somatic function of gene (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

***fs(1)K1221***

**phenotype:** Oogenesis normal but mature eggs retained by homozygous female.

***fs(1)K1274***

**phenotype:** Viability good at 29° but ovaries of homozygous females severely atrophied, probably with tumorous follicles. At 25° cysts contain 16 nurse cells and no oocyte; females fertile when raised at 23°. Mosaic studies indicate germ-line function of gene (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

***fs(1)K1563***

**phenotype:** Viability normal; eggs produced by homozy-

gous females have thin, short dorsal chorionic appendages at 29° but not 23°; sterile at both temperatures; partially dominant at 29°. Chorion ultrastructurally abnormal. Mosaic studies indicate somatic function for gene (Perrimon and Gans, 1983, Dev. Biol. 100: 365-73).

*fs(1)L186-fs(1)L211*: see *yl*

***fs(1)M: female sterile of Mohler***

A series of ethyl-methanesulfonate-induced sex-linked-recessive female-sterile mutants reported by Mohler (1977, Genetics 85: 259-72; Mohler and Carroll, 1984, DIS 60: 236-41). The mutants were mapped and tested for complementation. The accompanying table lists the complementation groups.

$\alpha$  The number of alleles for each complementation group recovered by Mohler.

$\beta$  Allelism to previously named or recently renamed loci; e.g., *fs(1)M5* alleles fail to complement *fs(1)A147*; Mohler's three alleles are accordingly designated *fs(1)A147<sup>M1</sup>*, *fs(1)A147<sup>M2</sup>*, and *fs(1)A147<sup>M3</sup>*.

$\gamma$  *fs(1)*-bearing ova from homozygous females rescued by fertilization with *fs(1)<sup>+</sup>*-bearing sperm.

$\delta$  1 = Zhimulev, Belyaeva, Pokholkova, Kotcheneva, Fomina, Bgatov, Khudyakov, Patzevitch, Semeshin, Baritcheva, Aizenzon, Kramers, and Eeken, 1981, DIS 56: 192-96; 2 = Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720.

### ***fs(1)N: female sterile (1) of Nasrat***

**location:** 1-0.0 (closely linked to *sc*).

**origin:** Induced by an unspecified chemical mutagen.

**discoverer:** Nasrat, 1952.

**references:** Counce and Ede, 1957, J. Embryol. Exp. Morphol. 5: 404-21 (fig.).

Degelmann, Hardy, Perrimon, and Mahowald, 1986, Dev. Biol. 115: 479-89 (fig.).

**synonym:** *fs(1)<sup>nas</sup>*.

**phenotype:** Maternal lethal. Developmental study of *fs(1)N<sup>1</sup>* by Counce and Ede. Eggs of *fs(1)N/fs(1)N*

females will not support development of normal embryos. About half the eggs contain little or no yolk; development may or may not begin in such eggs but never progresses beyond a highly abnormal cleavage. In eggs containing more yolk, major effect is on synchrony of cleavage and blastoderm mitoses. Twenty percent of these embryos cease development before blastoderm formation. The remainder have abnormal blastoderms and aberrant gastrulation. Final pattern of damage determined by degree of abnormality of earlier stages, but some embryos show larval differentiation. A few of the

least abnormal embryos may emerge but never move about or feed. Formation of polar granules abnormal. RK3.

**alleles:** Homozygous *fs(1)N*<sup>12</sup> females produce embryos with defects in anterior and posterior development (Degelmann *et al.*). Head involution fails; anterior endodermal derivatives are deficient and the absence of pharyngeal musculature causes collapse of the cephalo-pharyngeal apparatus. Embryos lack all posterior endodermal derivatives as well as structures characteristic of abdominal segments 8 to 10 usually, but have six abdominal denticle belts, and occasionally partial seventh or seventh and eighth. In addition, posterior midgut, hindgut, Malpighian tubules, filzkörper, spiracles, anus, anal pad, and anal tuft absent; lateral tracheal trunks end blindly, usually in the sixth segment; posterior disorganization of CNS seen. Pole cells form abnormally and seldom migrate to form the gonad; posterior blastoderm nuclei fail to cellularize and the centrosome position *vis à vis* the blastoderm nuclei erratic; remarkably free of microtubules. Six rather than seven stripes of *ftz* transcription seen in blastoderm, with the sixth stripe wider than normal and separated from the fifth by a wider-than-normal space. At gastrulation neither posterior midgut invagination nor proctodeal invagination occur normally.

**cytology:** No detectable chromosomal rearrangements (Slizynska). Placed in 1E1-2A by Peréz-Chiesa.

***fs(1)ne*: female sterile (1) no eggs**

A subset of hybrid-dysgenesis-induced, X-linked female-sterile mutations that are characterized by the oviposition of few if any eggs [Orr, Galanopoulos, Romano, and Kafatos, 1989, Genetics 122: 847-58 (fig.); see also Galanopoulos, Orr, Szabad, and Kafatos, 1989, Dev. Genet. 10:87-97 (fig.)]. The loci are numbered between 1 and 13 with alleles designated by lower case letters in the superscript. The X chromosomes in these lines harbor multiple P elements thus complicating cytological localizations. No case of allelism with previously identified sex-linked female sterile mutations detected. Various defects in respiratory appendages and chorionic architecture of hand dissected eggs described in above refer-

ences.

***fs(1)Ya*: female sterile of Young**

**location:** 1-[between *l(1)zw7* and *l(1)zw5*; to the right of *fs(1)Yb*].

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Young.

**references:** Young and Judd, 1978, Genetics 88: 723-42.

Lin and Wolfner, 1989, Mol. Gen. Genet. 215: 257-65.

**phenotype:** Homozygous females completely sterile; lay normal numbers of eggs. Eggs remain vacuolated after deposition. No evidence of syngamy (Zalokar, Audit, and Erk, 1975, Dev. Biol. 47: 419-32).

**alleles:** Expression female germ-line autonomous (Perri-mon, Engstrom, and Mahowald, 1986, Genetics 113: 695-712); no expression detectable in daughters of *tud* females (Lin and Wolfner). Transcript detectable in nurse cells and oocyte as early as stage 7; evenly distributed throughout cytoplasm of 0-2 h embryos, but not detectable later (Lin and Wolfner).

<sup>α</sup> 1 = Gans, Audit and Masson, 1975, Genetics 105: 897-920; 2 = Mohler and Carroll, 1984, DIS 60: 236-41; 3 = Young and Judd, 1978, Genetics 88: 723-42.

**cytology:** Placed in 3B4-6 by deficiency mapping.

**molecular biology:** Identified on the basis of homology with a 2.4-kb female-specific transcript within a 32-kb walk through region 3B4-6. Germ-line transformants with an 8.5-kb fragment of wild-type DNA with homology to only the above transcript rescue fertility of both *fs(1)Ya* and *fs(1)Yb* females. Transcription unit shown to be 2.7 kb long and to be transcribed from left to right (Lin and Wolfner).

***fs(1)Yb***

**location:** 1-[between *l(1)zw7* and *l(1)zw5*; to the left of *fs(1)Ya*].

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Young.

**references:** Young and Judd, 1978, Genetics 88: 723-42.

**phenotype:** Homozygous females semisterile; lay reduced

numbers of eggs, most of which remain vacuolated after deposition; a few develop into normal-appearing adults. Mutation without effect on males.

**alleles:** *fs(1)Yb*<sup>1</sup>, *fs(1)Yb*<sup>2</sup>, and *fs(1)Yb*<sup>3</sup> recovered as *fs(1)Y*<sup>1</sup>, *fs(1)Y*<sup>3</sup>, and *fs(1)Y*<sup>7</sup>, respectively.

**cytology:** Placed in 3B4-6 by deficiency mapping.

*Fs(2)1*: see *Fs(2)M*

*fs(2)3A-fs(2)308A*: see *fs(2)HO3-fs(2)HO308*

### ***fs(2)A***

A series of mutants that have been subjected to complementation and physiological analysis but not mapped genetically.

**origin:** Induced by ethyl methanesulfonate.

**references:** Bakken, 1973, *Dev. Biol.* 33: 100-22 (fig.).

### ***fs(2)A1***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch.

**alleles:** Two alleles recovered among 79 second-chromosome female-sterile mutants analyzed.

### ***fs(2)A2***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch. First cleavage division normal; subsequent divisions often contain extra chromosomes; both clumped and scattered chromosomes observed. Some eggs have large spherical masses of fragmented chromosomes. No peripheral migration of nuclei.

**alleles:** Seven alleles recovered among 79 mutants analyzed.

### ***fs(2)A3***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch.

### ***fs(2)A4***

**phenotype:** Homozygous females anatomically normal; seem to be ovulation deficient since they accumulate normal-appearing stage-14 oocytes in their ovarioles.

**alleles:** 39 alleles recovered among 79 mutants analyzed.

### ***fs(2)A5***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch.

### ***fs(2)A6***

**phenotype:** Homozygous females anatomically normal but do not oviposit; ovaries may be abnormal.

### ***fs(2)A7***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch. Abnormal cleavage figures seen after the fourth division. Peripheral migration of nuclei restricted to only a part of the egg surface. Many blastoma nuclei large and reticulate; others small and condensed. Yolk nuclei clumped and unevenly disposed.

### ***fs(2)A8***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch.

### ***fs(2)A9***

**phenotype:** Homozygous females anatomically normal; lay eggs with fragile chorions, which do not hatch. Some eggs reach syncytial blastema but not cellular blastoderm formation; blastema nuclei unequal in size, irregularly shaped, and sometimes pycnotic. Distribution over egg surface nonuniform.

**alleles:** Two alleles among 79 mutants analyzed.

### ***fs(2)A10***

**phenotype:** Homozygous females anatomically normal; seem to be ovulation deficient since they accumulate stage-14 oocytes in their ovarioles.

### ***fs(2)A11***

**phenotype:** Homozygous females anatomically normal. Distribution of nuclei in syncytial blastema irregular. Oldest embryos show abnormal gastrulation.

### ***fs(2)A12***

**phenotype:** Homozygous females anatomically normal; lay foreshortened eggs with truncated anterior tip and short fat chorionic filaments. Eggs similar to stage-11 oocytes, some with adhering follicle and nurse cells. A few eggs lack stainable chromatin; most have one to three large spherical masses of fragmented chromosomes or tripolar spindles and abnormally elongated mitotic figures.

**alleles:** Six alleles among 79 analyzed mutants.

### ***fs(2)A13***

**phenotype:** Homozygous females anatomically normal, lay eggs that do not hatch. Eggs have abnormal cleavage figures, multipolar spindles, nonuniformity of chromosome contraction during anaphase, mitotic asynchrony, and uneven distribution of mitotic figures through ooplasm. In some, no mitotic figures are recognizable; only large masses of fragmented chromosomes or amorphic clumps are seen.

### ***fs(2)A14***

**phenotype:** Homozygous females anatomically normal; lay eggs that do not hatch. Most eggs display meiotic metaphase II chromosomes, without visible spindle fibers, and a sperm head lying close by. Oocyte chromosomes may be scattered or regularly grouped.

### ***fs(2)A15***

**phenotype:** Homozygous females have small abnormally organized ovaries; ovaries approximately 200 μm long; no ovariole formation; no organized follicles; no recognizable oocytes. Nuclei of different sizes and shapes but not in groups expected from cystocyte divisions; some are pycnotic.

### ***fs(2)A16***

**phenotype:** Homozygous females have small (400-600 μm long) abnormally organized ovaries. Ultrastructural studies by King and Buckles (1980, *DIS* 55: 74-75) reveal that oogonial cysts appear to be normal; surrounded by wedge-shaped follicle cells but not separated by interfollicular stalks so that the conventional moniliform vitellarium is not observed. Posterior end of ovariole filled with fusing follicles.

**fs(2)A17**

**phenotype:** Homozygous females have smaller-than-normal ovaries with nurse cell nuclei arrested in stage 4. Follicle cells continue normal differentiation for some time before degenerating. Vitellogenesis defective; oocyte arrests in stage 7. Transplantation experiments (Postlethwait and Handler, 1978, *Dev. Biol.* 67: 202-13) show that *fs(2)A17* ovaries develop autonomously in wild-type hosts and that *fs(2)A17* hosts support vitellogenesis in implanted normal and *ap* ovaries.

**alleles:** Six alleles among 79 analyzed mutants.

**fs(2)A18**

**phenotype:** Most egg chambers of homozygous females arrested in stage 7; no evidence of vitellogenesis. Height of follicular columnar epithelium increased. Posterior half of ovarioles filled with degenerating stage-8-sized egg chambers. Transplantation experiments (Postlethwait and Handler, 1978, *Dev. Biol.* 67: 202-13) show that *fs(2)A18* is ovary autonomous when transplanted into a wild-type host but nonautonomous when transplanted into a *fs(2)A17* host. *fs(2)A18* hosts support some vitellogenesis of + and *ap* implants.

*fs(2)adp*: see *adp*<sup>fs</sup>

**fs(2)B: female sterile (2) of Bridges**

**location:** 2-5.

**origin:** Spontaneous.

**discoverer:** Bridges, 29c25.

**synonym:** *fes*.

**references:** King, Sang, and Leth, 1961, *Exp. Cell. Res.* 23: 108-17 (fig.).

King, Koch, and Cassens, 1961, *Growth* 25: 45-65 (fig.).

Koch and King, 1964, *Growth* 28: 325-69 (fig.).

King, 1969, *Nat. Cancer Inst. Monogr.* 31: 323-45.

**phenotype:** External morphology and sexual behavior normal (Burnet, Connolly, Kearney, and Cook, 1973, *J. Insect Physiol.* 19: 2421-31). Males fertile; females sterile. After rearing on glucose diet mutant females are less receptive to copulation attempts and more vigorously courted than wild-type virgins (Cook and Connolly, 1976, *J. Insect Physiol.* 22: 1727-35). Germaria of ovaries of homozygous females larger than normal; cysts contain 3 times the normal number of cells; metaphase figures found throughout germarium. Just over half the oogonia undergo complete cleavage with the loss of ring canal connections to other cells; remaining cells in small clusters with tenuous connections (Johnson and King, 1972, *Biol. Bull.* 143: 525-47). Vitellaria subdivided into a series of sausage-shaped cell aggregates, each surrounded with an ill-defined follicular epithelium and filled with hundreds to thousands of mitotically active oogonia-like cells [King, Burnett, and Staley, 1957, *Growth* 21: 239-61 (fig.)]. These cells occasionally differentiate into cells resembling nurse cells, which may have polytene chromosomes, and rarely into oocytes. *fs(2)B* ovaries transplanted into wild-type hosts in late larval stages and reciprocal transplants develop autonomously (Clancy and Beadle, 1937, *Biol. Bull.* 72: 47-56; Klug, Bodenstein, and King, 1968, *J. Exp. Zool.* 167: 151-56). The cells of the corpus-allatum corpus-cardiacum complex of homozygous *fs(2)B* females appear to be prevented from releasing their hormone products and undergo degenerative changes; these effects

reversible by vitellogenic activity of wild-type ovary implanted into the abdomen of the *fs(2)B* female (King, Aggarwal, and Bodenstein, 1966, *J. Exp. Zool.* 161: 151-76; Aggarwal and King, 1971, *J. Morphol.* 134: 437-46). Abdominal fat cells of *fs(2)B* females 1.5 times size of those in wild type. They resemble male fat cells in having more fat and less glycogen than those of normal females; return to normal size and composition following implantation of wild-type ovary (Butterworth and Bodenstein, 1968, *J. Exp. Zool.* 167: 207-18). *fs(2)B* ovaries show reduced levels of thymidylate synthetase (Carpenter, 1973, *Genetics* 75: 113-22). RK3.

*Fs(2)D*: see *Fs(2)G*

**Fs(2)D10**

**location:** 2 (unmapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Tearle and Nüsslein-Volhard, 1987, *DIS* 66: 209-26.

**phenotype:** Dominant female sterile. Development ceases before cellularization of blastoderm; syncytial nuclear division appears normal.

*Fs(2)D-M*: see *Fs(2)M*

**fs(2)E: female sterile (2) Edmondson**

**origin:** A series of nine ultraviolet-induced mutations at different loci.

**references:** Edmondson, 1952, *DIS* 26: 61-62. 1960, *DIS* 34: 49. CP627.

mutation	genetic location	synonym	phenotype

<sup>α</sup> Dorsal appendages of chorion convoluted or fused (King and Koch, 1963, *Quant. J. Microscop. Sci.* 104: 297-320).

**fs(2)eo: female sterile (2) early oogenesis (T. Schüpbach)**

A group of female-sterile mutations on the second chromosome which affect early stages of oogenesis (before yolk uptake). They were all induced by ethyl methanesulfonate, and recovered in screens by Schüpbach and Wieschaus (1989, *Genetics* 121: 110-17).

locus	genetic location	synonym	phenotype
<i>fs(2)eo1</i>	2-30	<i>fs(2)eoPV30</i>	few if any egg chambers; early oogenic arrest
<i>fs(2)eo2</i>	2-54	<i>fs(2)eoPL3</i>	few if any egg chambers; early oogenic arrest
<i>fs(2)eo3</i> <sup>α</sup>	2-{54}	<i>fs(2)eoRV64</i>	many degenerating egg chambers
<i>fs(2)eo4</i>	2-64	<i>fs(2)eoPB6</i>	egg chambers with variable

<b><i>fs(2)eo7</i></b>	2-105	<i>fs(2)eoPP22</i>	few if any egg chambers; early oogenic arrest

<sup>α</sup> Placed in 36E4-38A7 on the basis of its inclusion in *Df(2L)TW50 = Df(2L)36E4-F1;38A6-7*.

### ***Fs(2)G: Female sterile (2) of Grell***

**location:** 2- (not located).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** E. H. Grell, 65e.

**synonym:** *Fs(2)D*.

**references:** Yarger and King, 1971, *Dev. Biol.* 24: 166-77 (fig.).

**phenotype:** Heterozygous females raised at 25° or 30° completely sterile; minimal development noted of zygotes resulting from eggs of females raised at 20°; heterozygous males fertile. Ten percent as many egg chambers as normal, and 10% of chambers have fewer than 16 cells, generally lacking an oocyte. Ovaries of heterozygous females developing at 30° frequently fail to attach to oviducts. At 25° and 30°, heterozygous females take one day longer to develop than controls; viability of *Fs(2)G/+* females 70-75% at 20° and 25°, 5% at 30°. Wings of heterozygotes normal at 20°, frequently incised at 30°, greatly reduced and crumpled at 30°. Bristles short; thorax broad and flattened with air bubbles under cuticle. RK3.

### ***fs(2)HO: female sterile (2) of Hardy and Orevi***

A series of female-sterile mutations isolated from a sample of lethal-free ethyl-methanesulfonate treated second chromosomes produced by Hardy and Orevi.

mutation	synonym	ref <sup>α</sup>
<b><i>fs(2)HO3</i></b>	<i>fs(2)3A</i>

<b><i>fs(2)HO297</i></b>	<i>fs(2)297A</i>	
<b><i>fs(2)HO308</i></b>	<i>fs(2)308A</i>	

<sup>α</sup> 1 = Postlethwait and Handler, 1976, *Dev. Biol.* 67: 202-13.

**phenotype:** Females homozygous for all four mutants dealt with by Postlethwait and Handler have oogenesis aborted at early previtellogenic stages, are ovary autonomous in transplants into wild-type females, and support vitellogenesis in implanted wild-type ovaries.

### ***fs(2)K: female sterile (2) of Kikkawa***

**location:** 2-100.

**origin:** Spontaneous.

**discoverer:** Kikkawa, 1960.

**synonym:** *fs(2)K*.

**references:** 1960, DIS 34: 51.

**phenotype:** Female sterile; male fully fertile. RK3.

### ***fs(2)lto: female sterile (2) late oogenesis (T. Schüpbach)***

A group of female-sterile mutations on the second chromosome which lead to defects in later stages of oogenesis (during yolk uptake, chorion synthesis, or egg laying). They were all ethyl methanesulfonate induced and isolated in screens by Schüpbach and Wieschaus (1989, *Genetics* 121: 101-17).

<i>locus</i>	genetic location	synonym	phenotype
<b><i>fs(2)lto1</i></b>	2-51	<i>fs(2)ltoPN48</i>	Homozygous females lay eggs with fragile chorions, which remain unfertilized.
<b><i>fs(2)lto2</i></b>	2-[54] <sup>α</sup>	<i>fs(2)ltoHD43</i>	Homozygous females lay collapsed eggs.
<b><i>fs(2)lto3</i></b>	2-[54] <sup>α</sup>	<i>fs(2)ltoRE57</i>	Homozygous females lay eggs which often lack dorsal appendages, and appear more pointed at the posterior end.
<b><i>fs(2)lto4</i></b>	2-62	<i>fs(2)ltoQB3</i>	Homozygous females lay tiny eggs, which remain unfertilized.
<b><i>fs(2)lto5</i></b>	2-[86] <sup>β</sup>	<i>fs(2)ltoDF6</i>	Homozygous females lay short eggs.

<sup>α</sup> In *Df(2L)TW50 = Df(2)36E4-F1;38A6-7*.

<sup>β</sup> In *Df(2R)PC4 = Df(2)55A;55F*.

### ***Fs(2)M: Female sterile (2) of Meyer***

**location:** 2- [between *al* (2-0.4) and *dp* (2-13.0), (Szabad, Erdélye, Hoffman, Szidonya, and Wright, 1989, *Genetics* 122: 823-35)].

**origin:** X ray induced.

**synonym:** *Fs(2)I*, *Fs(2)D-M*.

**references:** Meyer, 1966, DIS 41: 167.

**phenotype:** Sterile *Fs(2)M/+* females deposit very few, mostly flaccid eggs that never bear dorsal chorionic appendages (Szabad, Erdélye, Hoffman, Szidonya, and Wright, 1989, *Genetics* 122: 823-35). Flies slightly reduced in size with discernably reduced eyes. *Fs(2)M/Cy* females show less curled wings than *+/Cy* (Craymer).

### ***fs(2)OW: female sterile (2) of Oshima and Watanabe***

A series of up to 34 different complementation units isolated from a natural population 3 times during the year; as many as 7 more isolated from cage populations. The loci inferred are numbered from 101 to 107, 202 to 217, and 801 to 812 from the natural population and c1 to c7 from the population cage. Complementation testing was the only procedure to which these recessive female-sterile mutants were submitted. The designator *OW* did not appear in the original publication.

**origin:** Spontaneous.

**references:** Oshima and Watanabe, 1973, *Genetics* 74: 351-61.

*fs(2)Q342*: see *Vm26A2*

### ***Fs(2)Sz: Female sterile (2) of Szabad***

A series of ethyl-methanesulfonate-induced dominant-female-sterile mutations on the second chromosome described by Szabad, Erdélye, Hoffmann, Szidonya, and Wright (1989, *Genetics* 122: 823-35). Meiotic mapping

possible in germ-line-independent and incompletely penetrant mutants; remainder mapped mitotically. X-ray- or EMS-induced revertants usually recessive lethals; complementation analysis of revertants identify 13-15 loci. The mutants named for Hungarian families that vanished by the beginning of the 14th century, as indicated in the following table.

locus	name	location	comments <sup>α</sup>
<b>Fs(2)Sz1</b>	Barsa	2-( <i>nub-stw</i> )	little or no embryogenesis
<b>Fs(2)Sz2</b>	Billa	2-( <i>nub-lt</i> )	little or no embryogenesis (Reuter)
<b>Fs(2)Sz3</b>	Dorog	2L	dorsal appendages reduced
<b>Fs(2)Sz4</b>	Etre	2-71.4	thin chorion; not germ line dependent (Wright)
<b>Fs(2)Sz5</b>	Himca	2L	pre-pronuclear-fusion arrest
<b>Fs(2)Sz6</b>	Hont	2-( <i>al-dp</i> )	meiotic defects (Wright)
<b>Fs(2)Sz7</b>	Ketel	2-( <i>lt-sca</i> )	meiotic defects
<b>Fs(2)Sz8</b>	Kompolt	2-( <i>al-dp</i> )	abnormal nuclear divisions
<b>Fs(2)Sz9</b>	Tarhos		abnormal nuclear divisions
<b>Fs(2)Sz10</b>	Tekele	2-( <i>al-nub</i> )	abnormal nuclear divisions
<b>Fs(2)Sz11</b>	Told	2-( <i>nub-sca</i> )	15% of embryos→head defects
<b>Fs(2)Sz12</b>	Ugra	2-18	agametic; germ line independent
<b>Fs(2)Sz13</b>	Vaja	2-15.1	Incompletely penetrant; variable head defects; may be <i>BicD</i> allele

<sup>α</sup> Phenotype of eggs laid by *Fs(2)Sz/+* females; parentheses indicate origin of alleles not found in Szeged.

**fs(2)TLM: female sterile (2) of Trippa, Louverre, and Micheli**

**location:** 2-89.7 (between *L* and *Pin*).

**origin:** Spontaneous.

**references:** Trippa, 1977, DIS 52: 3 (fig.).

Trippa, Loverre, and Michele, 1977, DIS 52: 75.

Trippa, Loverre, and Cicchetti, 1980, Genetics 95: 399-412 (fig.).

Trippa, Loverre, and Cicchetti, 1980, J. Exp. Zool. 214: 277-85.

**phenotype:** Homozygous females sterile, produce no eggs, have underdeveloped ovaries; fewer ovarioles than normal; vitellogenesis apparently absent. One third of homozygous males sterile; remainder show normal fecundity, become sterile during first week of life. Testes abnormally shaped and reduced in size.

**fs(2)TW1: female sterile (2) Ted Wright 1**

**location:** 2-54 (estimated from cytological location).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** T.R.F. Wright in saturation studies of the *Df(2L)130* region.

**phenotype:** Eggs produced by homozygous females show no visible signs of development (Schüpbach, and Wieschaus, 1989, Genetics 121: 101-17).

**alleles:** Eight independent occurrences recovered by Wright, four more by Schüpbach.

**cytology:** Placed between 37C2 and 37D1 on the basis of its inclusion in the region of overlap of *Df(2L)36F2-6;37C6-D1* and *Df(2L)VA12 = Df(2L)37C2-D1;38B2-C1*.

**Fs(2)X10**

**location:** 2 (unmapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Dominant female sterile, gives cup-like eggs.

**Fs(2)Y12**

**location:** 2 (unmapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Semidominant female sterile, gives cup-like eggs.

**fs(3)6m45**

**location:** 3- (not mapped).

**discoverer:** Rice.

**references:** Bownes and Hames, 1978, J. Embryol. Exp. Morphol. 47: 111-20.

**phenotype:** Oocytes of homozygous females show no signs of vitellogenesis. Yolk proteins accumulate in hemolymph. *fs(3)6m45* ovaries transplanted fail to take up yolk proteins and are nonvitellogenic. Wild-type ovaries take up yolk protein and develop normally in *fs(3)6m45* host.

<sup>α</sup> 1 = Snyder, Galanopoulos, and Kafatos, 1985, Genetics 110: 53; 2 = 1986, Proc. Nat. Acad. Sci. USA 83: 3341-45.

**fs(3)108-17**

**phenotype:** Eggs of homozygous females have short thin chorionic respiratory appendages. Endochorionic structures disrupted; chorionic protein levels normal.

**fs(3)110-8**

**phenotype:** Eggs of homozygous females deficient in the first-deposited inner endochorionic layers; early chorion proteins deficient, although transcript levels appear normal.

**fs(3)272-9**

**phenotype:** Egg shells produced by homozygous females extremely disrupted. Deficiency of endochorionic material. All six chorion proteins and their mRNA's present at reduced levels; deficiency in the level of chorion-gene amplification in follicle cells.

**alleles:** Two; *fs(3)272-9<sup>1</sup>* recovered by Nüsslein-Volhard; *fs(3)272-9<sup>2</sup>* EMS induced by Lindsley; originally designated *fs(3)SD78*.

**fs(3)293-19**

**phenotype:** Eggs of homozygous females defective in late-deposited outer layers of endochorion; endochorionic material deficient. Late-gene expression as measured by mRNA or protein levels defective; deficiency in the level of chorion-gene amplification in follicle cells.

**fs(3)350-7**

**phenotype:** Eggs of homozygous females have short thin chorionic respiratory appendages; endochorion structure disrupted; chorionic-protein levels normal.

***fs(3)A***

A series of mutants that have been subject to complementation and phenotypic analysis but have not been mapped genetically.

**origin:** Induced by ethyl methanesulfonate.

**references:** Baaken, 1973, *Dev. Biol.* 33: 100-22 (fig.).

***fs(3)A1***

**phenotype:** Oocyte development normal through stage 7, then arrested. Every ovariole has the normal number of 6 follicles. No vitellogenesis. Very little degeneration seen. Effects of mutant not affected by transplantation of *fs(3)A1* ovaries into wild-type hosts; *fs(2)A1* hosts support vitellogenesis of implanted wild-type ovaries poorly (Postlethwait and Handler, 1978, *Dev. Biol.* 67: 202-13).

**alleles:** Two alleles recovered.

***fs(3)A2***

**phenotype:** Homozygous females morphologically normal; lay eggs that do not hatch.

***fs(3)A3***

**phenotype:** Same as *fs(3)A2*.

***fs(3)A4***

**phenotype:** Same as *fs(3)A2*.

***fs(3)A5***

**phenotype:** Homozygous females morphologically normal; oocytes contain mature eggs but ovoposition does not take place.

***fs(3)A6***

**phenotype:** Same as *fs(3)A5*.

***fs(3)A7***

**phenotype:** Same as *fs(3)A5*.

***fs(3)A8***

**phenotype:** Same as *fs(3)A5*.

**alleles:** Two alleles recovered.

***fs(3)A9***

**phenotype:** Same as *fs(3)A5*.

***fs(3)A10***

**phenotype:** Ovaries ~180  $\mu$ m long; appear immaturely developed rather than malformed. Ovariole formation proceeds halfway down the ovary; stage 3 or 4 the most mature follicles seen. Posterior half of ovary contains degenerating egg chambers.

***fs(3)A11***

**phenotype:** Homozygous females morphologically normal; lay eggs that lack all discernable chromatin and fail to hatch.

***fs(3)A12***

**phenotype:** Same as *fs(3)A11*.

***fs(3)A13***

**phenotype:** Homozygous females produce eggs that appear to develop normally for the first 10 hr following fertilization but fail to hatch.

***fs(3)A14***

**phenotype:** Mostly the same as *fs(3)A11*; a few eggs produced by homozygous females contain large amorphous chromatin bodies; one embryo observed to reach syncytial blastema stage.

***fs(3)A15***

**phenotype:** Fertilized eggs of homozygous females have tripolar spindles, longitudinally split metaphase plates with too many chromosomes, precocious pulling of some chromosomes to poles, and numerous anaphase bridges. Some eggs had 1-3 large spherical or fragmented chromosomes.

***fs(3)A16***

**phenotype:** Ovaries of homozygous females show retardation of oocyte growth; stage 7 oocytes smaller than nurse cells; many egg chambers begin degenerating at stage 7. Some continue to grow, and nurse cells and follicle cells differentiate normally, but follicle is dwarfed.

***fs(3)A17***

**phenotype:** A few ovaries produce one or two yolky oocytes and the rest of the posterior half is filled with degenerating egg chambers. Most ovaries show very long slender stage-10 and stage-11 chambers. The globular appearance of the ooplasm suggests that many are degenerating.

***Fs(3)Apc***

**location:** 3- 39.5 (63/81 the distance of *h* to *th*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Szabad and Erdélye.

**references:** Szabad and Hoffman, 1989, *Dev. Biol.* 131: 1-10.

**phenotype:** Majority of eggs produced by *Fs(3)Apc/+* females collapse; 1-5% not flaccid. Respiratory appendages of chorion rudimentary as in the anterior chorion. When fertilized, resulting embryos rarely develop cuticular derivatives. Follicle cells in ovarioles fail to migrate between the oocyte and nurse cells. Mutant does not successfully revert. Germ-line chimaeras demonstrate that *fs(3)Apc* is follicle-cell autonomous.

***fs(3)G2***

**phenotype:** Females almost sterile; produce rare surviving progeny. Oogenesis incomplete, usually stops in early phases of vitellogenesis. Most (89%) follicles contain 32 cells instead of normal 16 as a result of an extra oogonial division. The 32 cells of an incipient cyst enclosed in two chambers in 6% of the cases. Position of oocyte in follicle abnormal in 28% of cases. Males partially sterile. Viability low. RK3.

***fs(3)G3***

**phenotype:** Oogenesis incomplete; most follicles stop development during yolk deposition (after stage 9). Males fertile. RK3.

***fs(3)G5***

**phenotype:** Oogenesis incomplete; ovarioles contain excessive numbers of follicles, which usually stop developing at or before stage 9. Males fertile. RK3.

***fs(3)H: female sterile (3) of Handler***

**location:** 3- (not mapped).

**origin:** Two complementing mutants, *fs(3)H23* and *fs(3)H172*, induced by ethyl methanesulfonate.

**discoverer:** Handler.

**references:** Postlethwait and Handler, 1978, *Dev. Biol.* 67: 202-13.

***fs(3)H23***

**phenotype:** Follicles cease development at early previtellogenetic stage; the few vitellogenic follicles that do appear are highly abnormal. Ovary autonomous in transplants, but some vitellogenesis induced by administration of juvenile hormone analogue, ZR-515. *fs(3)H23* females support vitellogenesis in implanted wild-type ovaries.

***fs(3)H172***

**phenotype:** Oocytes occasionally begin vitellogenesis, but process halts prematurely and only rarely do mature oocytes develop. Mature follicles look normal. Ovary autonomous in transplants into wild-type host and supports vitellogenesis in implanted wild-type ovaries.

***fs(3)HO: female sterile (3) of Hardy and Orevi***

A series of female-sterile mutations isolated from a sample of lethal-free, ethyl-methanesulfonate-treated third chromosomes produced by Hardy and Orevi.

mutation	genetic location	synonym	ref <sup>α</sup>
<i>fs(3)HO5A</i> <sup>β</sup>	3-46.3	<i>fs(3)jfl</i> <sup>5A</sup>	1

<sup>α</sup> 1 = Nishida, 1980, Jpn. J. Genet. 55: 427-39 (fig.); 2 = Postlethwait and Handler, 1978, Dev. Biol. 67: 202-13.

<sup>β</sup> Isolated from same mutagen-treated chromosome along with *ms(3)HO5A* and *ms(3)HO5B*.

***fs(3)HO5A***

**phenotype:** Homozygous females do not lay eggs; oocyte development arrested in a previtellogenetic stage. Attachment of ovaries to oviduct fragile. Germania filled with polytene cells; no vitellana.

**cytology:** Polytene chromosomes normal.

***fs(3)HO5B***

**phenotype:** Homozygous females lay fertilized eggs, which fail to develop. Maternal effect lethal.

**cytology:** Polytene chromosomes normal.

***fs(3)HO29***

**phenotype:** Oocytes exhibit abortive vitellogenesis. Mutant effect is ovary autonomous in transplants into wild-type hosts and mutant females support development of implanted wild-type ovaries.

***fs(3)HO115***

**phenotype:** Oocyte development arrested in late previtellogenesis. Mutant-effect ovary autonomous in transplants into wild-type hosts and mutant females support vitellogenesis in implanted wild-type ovaries.

***fs(3)HO127***

**phenotype:** Similar to that of *fs(3)HO115*.

***fs(3)HO133***

**phenotype:** Similar to that of *fs(3)HO115*.

***fs(3)K1***

**location:** 3- (not mapped).

**discoverer:** Mohler.

**references:** King and Mohler, 1975, Handbook of Genetics

(R.C. King, ed.). Plenum Press, New York, and London, Vol. 3, pp. 83.

**phenotype:** Homozygous females produce eggs with abnormal dorsal chorionic appendages.

***Fs(3)Sz: Female sterile (3) of Szeged***

A series of ethyl-methanesulfonate-induced dominant or incompletely dominant female-sterile mutations on the third chromosome described by Erdélye and Szabad (1989, Genetics 122: 111-27). X-ray- or EMS-induced revertants identify 27-34 loci. The mutants are named for Hungarian families that vanished by the beginning of the 14th century, as indicated in the following tables.

locus	Table I: Complete Dominants		comments <sup>α</sup>
	name	location	
<b><i>Fs(3)Sz1</i></b>	<b><i>Apc</i></b>	3-39.5	incomplete anterior egg coverings; flaccid eggs with rudimentary chorionic appendages
<b><i>Fs(3)Sz2</i></b>	<b><i>Avar</i></b>	3-36.3	agametic; retains eggs
<b><i>Fs(3)Sz3</i></b>	<b><i>Baksa</i></b>	3L	eggs fertilized, but sperm pronuclei do not divide and there is no development
<b><i>Fs(3)Sz4</i></b> <sup>β</sup>	<b><i>Bercel</i></b>	3-( <i>ru-h</i> )	only chitin granules in embryos
<b><i>Fs(3)Sz5</i></b>	<b><i>Bojla</i></b>	3L	eight sperm nuclei along A-P axis
<b><i>Fs(3)Sz6</i></b>	<b><i>Botond</i></b>	3L	eggs fertilized, meiosis completed, but no further development
<b><i>Fs(3)Sz7</i></b> <sup>β</sup>	<b><i>Damasa</i></b>	3L	eggs fertilized, meiosis completed, but usually no further development
<b><i>Fs(3)Sz8</i></b>	<b><i>Farkas</i></b>	3-( <i>ru-sr</i> )	several divisions of pronuclei without fusion
<b><i>Fs(3)Sz9</i></b>	<b><i>Gerec</i></b>	3-( <i>h-th</i> )	pronuclei approach but no fusion or division
<b><i>Fs(3)Sz10</i></b>	<b><i>Hodos</i></b>	3-( <i>ru-h</i> )	several divisions of pronuclei without fusion
<b><i>Fs(3)Sz11</i></b>	<b><i>Horka</i></b>	3R	pronuclei approach but no fusion or division
<b><i>Fs(3)Sz12</i></b> <sup>γ</sup>	<b><i>Huba</i></b>	3L	pronuclei may or may not divide; no fusion; cleavage may or may not occur
<b><i>Fs(3)Sz13</i></b>	<b><i>Jutas</i></b>	3R	meiotic figures among cleavage nuclei
<b><i>Fs(3)Sz14</i></b> <sup>δ</sup>	<b><i>Kavar</i></b>	3L	head lesions in embryos; some posterior structures present
<b><i>Fs(3)Sz15</i></b>	<b><i>Keled</i></b>	3-( <i>cu-sr</i> )	poorly formed cuticle fragments in 50% of the embryos
<b><i>Fs(3)Sz16</i></b>	<b><i>Keve</i></b>	3-( <i>h-th</i> )	mid abdominal segments missing
<b><i>Fs(3)Sz17</i></b>	<b><i>Kun</i></b>	3-( <i>e-ca</i> )	sperm but not egg pronuclei divide a few times
<b><i>Fs(3)Sz18</i></b>	<b><i>Laborc</i></b>	3L	1-3 large nuclei (probably sperm pronuclei)
<b><i>Fs(3)Sz19</i></b>	<b><i>Palat</i></b>	3-( <i>ru-h</i> )	head lesions
<b><i>Fs(3)Sz20</i></b>	<b><i>Pilis</i></b>	3-( <i>sr-e</i> )	poorly formed cuticle fragments in 50% of embryos
<b><i>Fs(3)Sz21</i></b>	<b><i>Tevel</i></b>	3-( <i>h-th</i> )	head lesions
<b><i>Fs(3)Sz22</i></b> <sup>δ</sup>	<b><i>Tomaj</i></b>	3-( <i>h-th</i> )	sperm pronuclei may or may not divide but no fusion or further development
<b><i>Fs(3)Sz23</i></b>	<b><i>Tonuz</i></b>	3R	sperm but not egg pronuclei divide a few times
<b><i>Fs(3)Sz24</i></b>	<b><i>Varas</i></b>	3-( <i>ru-h</i> )	sperm but not egg pronuclei divide a few times
<b><i>Fs(3)Sz25</i></b>	<b><i>Zerind</i></b>	3R	sperm but not egg pronuclei divide a few times
<b><i>Fs(3)Sz26</i></b>	<b><i>Zombor</i></b>	3-( <i>h-th</i> )	several divisions of pronuclei without fusion

locus	name	location	comments $\alpha$
<b>Fs(3)Sz27 Kartal</b>		3-( <i>cu-ca</i> )	areas without nuclei in syncytial blastoderm; cleavage abnormalities
<b>Fs(3)Sz28 Levente</b>		80.7	no development after syncytial blastoderm; cleavage abnormalities
<b>Fs(3)Sz29 Purdur</b>		3-( <i>ru-cu</i> )	eggs fertilized, meiosis completed, but no development
<b>Fs(3)Sz30 Rosd</b>		3-( <i>cu-sr</i> )	head lesions
<b>Fs(3)Sz31 Vencellin</b>		28.1	head lesions
<b>Fs(3)Sz32 Zolta</b>		3-( <i>cu-sr</i> )	eggs rudimentary and flaccid; follicle cell epithelium ventralized during oogenesis

$\alpha$  Phenotype of eggs laid by *Fs(3)Sz/+* females.

$\beta$  Two mutant alleles.

$\gamma$  Four mutant alleles.

$\delta$  Three mutant alleles.

### ***fs(3)T: female sterile (3) of Tabriz***

**location:** 3-108.6.

**origin:** Spontaneous.

**references:** Mostashfi and Koliantz, 1972, DIS 48: 104.

**phenotype:** Homozygous females sterile and exhibit a pinkish eye color.

### ***fs(4)34***

**location:** 4- (not mapped).

**origin:** Spontaneous.

**discoverer:** Hochman, 64d.

**references:** 1972, DIS 48: 17.

**phenotype:** Viability of homozygotes normal; males fertile; females sterile. As originally described by Hochman, ovaries morphologically normal; females can be inseminated and can oviposit, but eggs fail to develop. In subsequent work, King and Buckles (1980, DIS 55: 74-75) report altered phenotype with oogenesis arrested in the germarium, where there are large numbers of oogenia not organized into cysts anteriorly and a solid plug of profollicle cells posteriorly.

**cytology:** Induced in neither *Df(4)M = Df(4)101E-F;102B6-17* nor *Df(4)G = 102E2-10*; tip (Hochman, 1974, Cold Spring Harbor Symp. Quant. Biol. 38: 581-89); probably lies between.

*fsh*: see *fs(1)h*

### ***ft: fat***

**location:** 2-12.0.

**origin:** Spontaneous.

**discoverer:** Mohr, 20b15.

**references:** 1923, *Studia Mendeliana* (Brunae). pp. 266-87.

1929, *Z. Indukt. Abstamm. Vererbungsl.* 50: 113-200 (fig.).

Bryant, Huettner, Held, Ryerse, and Szidonya, 1988, *Dev. Biol.* 129: 541-54.

**phenotype:** Viable alleles characterized using *ft*<sup>1</sup>. Abdomen short and fat. Thorax broad. Wings short and broad with crossveins much closer together than normal. Scutellum shortened; scutellar bristles far apart. Viability good. Second- and third-instar larvae, particularly when there is little yeast in the food, show vacuoles in cytoplasm of salivary gland cells. Two waves of vacuole formation; vacuoles may be membrane-bound lipoprotein bodies (Chandhuri, 1969, DIS 44: 118). Tip of X disfigured, possibly as a result of several small puffs intermingled with hard, nonpuffed bands. In about 1% of

larvae, salivary glands distally expanded and crooked [Slizynski, 1964, *Cytologia* (Tokyo), 29: 330-36 (fig.)]. Lethal alleles characterized in study of *ft*<sup>8</sup> (formerly *fd* = floppy disc) by Bryant *et al.*. *ft*<sup>8</sup> classified as an amorphic mutation based on the similarity in lethal phenotype of *ft*<sup>8</sup>/*ft*<sup>8</sup> and *ft*<sup>8</sup>/*Df(2L)M25A-11*. Larvae characterized by imaginal-disc hyperplasia such that mutant discs are much larger and more convoluted than wild type; the disc remains a single epithelial layer but in the highly convoluted proximal regions, of the wing disc at least, the columnar cells give way to cuboidal epithelial cells, which are deficient in cytoskeletal elements. Pupariation is delayed 3.2 days in mutants and the discs contain 122,000 cells at the end of nine days compared to 50,000 cells in wild type discs, which attain full growth at 5 days. Disc phenotype autonomous in transplants into adult hosts. Occasional mutant pupae reach the pharate-adult stage so that adult structures can be studied. Abdomens normal; eyes often swollen and may be split into two parts; extra head bristles; distal parts of antennae and legs may be missing; wings often fail to evaginate. Legs most severely affected; joints short and thick; missing tarsal joints and claws and tarsal fusions; increased bristle densities with deviant chaetal polarities; frequent outgrowths and ingrowths of cuticle; the latter giving rise to cuticle bound vesicles within the legs.

### **alleles:**

### ***fu: fused***

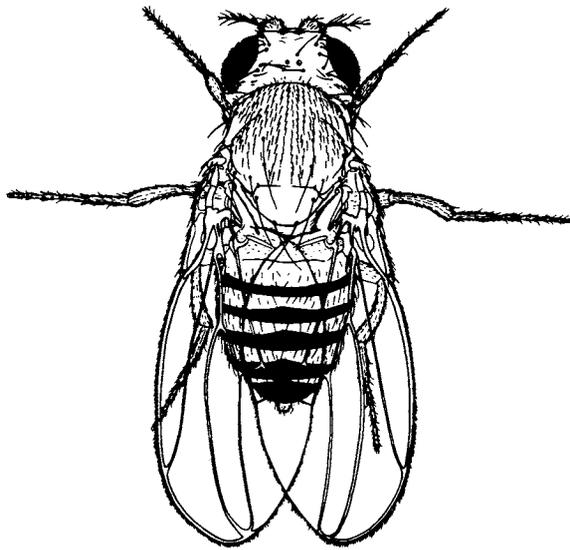

**location:** 1-59.5.

**origin:** Spontaneous.

**discoverer:** Bridges, 12k4.

**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 55-58 (fig.).

Lynch, 1919, *Genetics* 4: 501-33.

**fu: fused**

Edith M. Wallace, unpublished.

King, 1970, Ovarian Development in *Drosophila melanogaster*, Academic Press, New York, London.

Busson, Limbourg-Bouchon, Mariol, Preat, and Lamour-Isnard, 1988, Roux's Arch. Dev. Biol. 197: 221-30.

**phenotype:** Veins L3 and L4 fused from base to beyond anterior crossvein with elimination of anterior crossvein and first basal cell. L3 and L4 fused at tip; this fusion may reach back to basal cell. L3 may be thickened and branched to varying degrees; L4 may be partially or completely absent. Mosaic wings in which the posterior compartment is nearly entirely *fu/fu* may develop normally; alternatively, patches of + tissue in a *fu* wing may develop a *fu* phenotype (Fausto-Sterling, 1978, Dev. Biol. 63: 358-69). Wings usually extended; flightless owing to cuticle defect (Deak). Ocelli reduced or absent; bristles of ocellar region small or absent. Eyes small and slightly rough. Phototactic response normal (Benzer, 1967, Proc. Nat. Acad. Sci. USA 58: 1112-19). Anterior scutellar bristles reduced in number and scutellum shortened. Female late to eclose and has decreased longevity. Ovaries histologically normal at eclosion but with half the normal number of ovarioles (Beatty, 1949, Proc. Roy. Soc. Edinburgh, B 63: 249-70); fecundity 4% normal. Developing egg chambers may fuse or become tumorous with age (King, Burnett, and Staley, 1957, Growth 21: 239-61 (fig.)). All aspects of phenotype respond in a coordinated fashion to experimental manipulation (Wust and Hanratty, 1979, Can. J. Genet. Cytol. 21: 335-46). Proportion of tumorous egg chambers increases by 6% per day. Females raised at 18° show only 10% the tumor development of those raised at 25°. Tumor formation also enhanced by presence of YS (King, 1969, Nat. Cancer Inst. Monogr. 31: 323-45). Ovarian effects in females carrying *fu* and a deficiency for *fu* [i.e. *In(1)Cl<sup>Ly</sup>4R = In(1)A5-B1;17A6-B1<sup>L</sup>1A8-B1;18A3-4<sup>R</sup>*] are more extreme than those in *fu* homozygote (King, 1959, DIS 33: 142-43; 1970). Alleles vary in strength; measures of

ovarian tumor formation revealed that  $fu^1 = fu^{14} > fu^7 > fu^{13} > fu^{11} = fu^{12}$  [Smith and King, 1966, J. Nat. Cancer Inst. 36: 445-63 (fig.)]. *fu/fu* ovaries transplanted into *fu<sup>+</sup>* hosts develop autonomously in regard to fertility (Clancy and Beadle, 1937, Biol. Bull. 72: 47-56; Sobels, 1950, Experientia 6: 139-40) and tumor formation (Smith, Bodenstein, and King, 1965, J. Exp. Zool. 159: 333-36). The few normal-appearing eggs that are laid by *fu/fu* females produce adults only if they have been fertilized by *fu<sup>+</sup>*-bearing sperm (Lynch, 1919, Genetics 4: 501-33). Eggs fertilized by *fu*- or Y-bearing sperm, with rare exceptions (Counce), develop into embryos that become abnormal 5-5½ hr after fertilization. Lethal embryos exhibit incompletely penetrant segment polarity defects in which the anterior denticle-belt-bearing half of each segment shows mirror-image duplication replacing the naked cuticle of the posterior half; more pronounced in thoracic segments; penetrance in right and left hemisegments at the same level is not necessarily correlated. (Nüsslein-Volhard and Wieschaus, 1980, Nature 287: 795-801, Gergen and Wieschaus, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 49-62). Elimination of regions of dorsal pattern and occasional head defects are also observed. *fu* eggs from *fu/+* mothers develop normally. Segment polarity defects autonomous in mosaics (Gergen and Wieschaus). Heterozygous daughters from homozygous mothers on the other hand, often have abnormal abdominal segmentation and, as embryos, have abnormal musculature. This is a maternal effect not found in the reciprocal cross, and it is temperature sensitive (Armstrong and Sobels). RK1.

**alleles:** No complementation observed in 120 heteroallelic combinations (Wurst and Hanratty).

Washington Publ. 237: 55-58 (fig.); 15 = Nüsslein-Volhard and Wieschaus, 1980, Nature 287: 795-801; 16 = Perrimon and Mahowald, 1987, Dev. Biol. 119: 587-600; 17 = Smith and King, 1966, J. Nat. Cancer Inst. 36: 445-61 (fig.); 18 = Wrust and Hanratty, 1979, Can. J. Genet. Cytol. 21: 335-46.

<sup>β</sup> Phenotype as determined by Busson *et al.* with respect to wing phenotype, viability, fecundity and maternal effect respectively; W = weak, I = intermediate, S = strong. Wing phenotype, veins L3 and L4 fused only proximally = W, at several points = I, all along length = S. Viability as the ratio of the number of fused flies to wild type in *fu*/<sup>+</sup> X *fu*/<sup>Y</sup>: 0.75-1.0 = W, 0.5-0.75 = I, 0.25-0.5 = S. Fecundity as the ratio of eggs laid by *fu*/<sup>fu</sup> versus *fu*/<sup>+</sup> sisters: 0.5-1.0 = W, 0.25-0.5 = I, 0-0.1 = S. Maternal effect on segmentation as percent of embryos with all segments entirely duplicated: 0-25% = W, 25-70% = I, 70-100% = S.

<sup>γ</sup> azm = azo-mustard.

<sup>δ</sup> Phenotype described below.

**cytology:** Placed in 17C3-D2 based on its inclusion in *Df(1)fu-H4 = Df(1)17C3-7;17D1-2* (Busson, Limbourg-Bouchon, Mariol, Preat and Lamour-Isnard, 1988, Roux's Arch. Dev. Biol. 197: 221-30).

**molecular biology:** Included in a 250-kb walk from 17C to 17E; no alterations in restriction map were observed for 12/12 viable *fu* alleles nor for the three pupal-lethal alleles listed in the allele table. *Df(1)fu-Z4* determined to be deficient for 40-kb; a cosmid covering this region when injected into embryos effects partial rescue of the maternal effect of homozygosity for *fu* in some 2% of embryos; similar results obtained from a 14-kb subclone. Two adjacent *Eco*RI subclones identify four transcripts on Northern blots of mRNA from 0-4 hr embryos of 1.3 and 1.6 kb for the more distal fragment and 2.5 and 3.5 kb for the more proximal fragment; the *fu* transcript or transcripts not identified (Mariol, Preat and Limbourg-Bouchon, 1987, Mol. Cell. Biol. 7: 3244-51).

**phenotype:** Homozygous and hemizygous females and hemizygous males die in pupal stage; lethality suppressible by *Su(fu)*. *fu*<sup>31</sup>/*fu*<sup>41</sup> and *fu*<sup>31</sup>/*Y* have all segments entirely duplicated; lack mouth hooks and some have no head. *fu*<sup>31</sup>/<sup>+</sup> embryos from such clones exhibit very low paternal rescue; small correction of segmental phenotype, low hatch, and preadult mortality (Busson, Limbourg-Bouchon, Mariol, Preat and Lamour-Isnard, 1988, Roux's Arch. Dev. Biol. 197: 221-30).

### **fu**<sup>33</sup>

**phenotype:** A temperature-sensitive allele. *fu* wing-vein phenotype occurs at all temperatures; ocelli absent when raised at 22° but not at 17°. TSP for absence of anterior ocellus from second instar through pupal stage, for posterior ocelli restricted to late third instar and early pupal stage. Flightless when raised at 22° or 29° but not at 17°; wings held horizontally perpendicular to body at 29°. Musculature abnormal when raised at restrictive temperatures [Homyk and Grigliatti, 1983, Dev. Genet. 4: 77-97 (fig.)].

### **fu**<sup>40</sup>

**phenotype:** *fu*<sup>40</sup>/*Y* sons of *fu*<sup>40</sup>/<sup>+</sup> mothers die as late pupae or newly emerged adults; lethality suppressible by *Su(fu)*. *fu* embryos produced by homozygous germ-line clones are mostly lethal (70%); those that hatch mostly achieve adulthood (Perrimon and Mahowald, 1987, Dev. Biol. 119: 587-600).

### **Fuc: alpha-Fucosidase**

**location:** 3-35.5 [based on 45 recombinants between *h*(26.5) and *st* (44.0) (Repp)].

**phenotype:** Structural gene for alpha fucosidase (EC 3.2.1.51). A diffuse intermediate zone of activity in *Fuc*<sup>F</sup>/*Fuc*<sup>S</sup> heterozygotes suggests multimeric nature of enzyme (MacIntyre). Flies heterozygous for a null allele and a deficiency for *Fuc* are viable and fertile (Bond).

**alleles:** *Fuc*<sup>F</sup> and *Fuc*<sup>S</sup> are naturally occurring alleles; also one null allele, *Fuc*<sup>nl</sup>, induced by ethyl methanesulfonate (Bond).

**cytology:** Placed between 67F2 and 68D6 on the basis of its inclusion in the region deleted by *Df(3L)vin2 = Df(3L)67F2-3;68D6* (Bond).

*Fuh*: see *Fum*

### **fum: fused mushroom bodies (J.C. Hall)**

**location:** 2- (not mapped).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg and Fischbach.

**phenotype:** Beta lobes of mushroom bodies in dorsal brain are fused at the midline; penetrance incomplete.

### **Fum: Fumarase**

**location:** 1-19.9.

**synonym:** *Fuh*: Fumarate hydratase.

**references:** Madhavan and Ursprung, 1973, Mol. Gen. Genet. 120: 379-80.

**phenotype:** The structural gene for fumarase [FUM; L-malate hydro-lyase (EC 4.2.1.2)]. Enzyme level observed depends on genetic background (Laurie-Ahlberg, Maroni, Bewley, Lucchesi, and Wier, 1980, Proc. Nat. Acad. Sci. USA 77: 1073-77). Enzyme levels higher in females than in males in midlarval, pupal, and

pharate-adult stages; female levels drop and are surpassed by male levels in older adults (Whitney and Lucchesi, 1972, *Insect Biochem.* 2: 367-70). Head and thorax have higher activities than abdomen (Pipkin, Chakrabarty, and Bremner, 1977, *J. Hered.* 68: 245-52). Activity equally distributed between mitochondrial and cytoplasmic fractions (Pipkin *et al.*).

**alleles:** Two electrophoretic alleles, *Fum<sup>F</sup>* and *Fum<sup>S</sup>*, found in natural populations. (Designated *Fum<sup>6</sup>* and *Fum<sup>4</sup>* by Research Triangle Park Group, 1978, *DIS* 53: 117).

**cytology:** Placed in 5C-6C11 by method of segmental aneuploidy (Pipkin *et al.*).

**furled:** see *fd*

**furrowed:** see *fw*

**fused:** see *fu*

**fused filament:** see *fft*

**fused mushroom bodies:** see *fum*

**fuzzy:** see *fy*

**fw: furrowed**

**location:** 1-36.85 (Lefevre, 1970, *DIS* 40: 45).

**origin:** Spontaneous.

**discoverer:** Duncan, 14k.

**references:** 1915, *Am. Naturalist* 49: 575-82.

Morgan and Bridges, 1916, *Carnegie Inst. Washington Publ. No. 237*: 80.

Nachtsheim, 1919, *Z. Indukt. Abstamm. Vererbungsl.* 20: 118-56.

**phenotype:** Eyes with vertical fold and furrows. Head and scutellum shortened. Bristles gnarled and shortened, especially the postscutellars. Best classification character is short, blunt notopleurals. RK2. Phenotype can become nearly wild type on inbreeding (Lefevre).

**alleles:** Most information on *fw* alleles tabulated below. Descriptions of special phenotypic features differing from those described above for *fu<sup>1</sup>* are detailed separately following the table.

β Only differences from the basic *fu<sup>1</sup>* phenotype indicated.  
γ Phenotype described separately below.

**cytology:** Placed in 11A4 (Lefevre, 1981, *Genetics* 99: 461-80).

**\*fw<sup>2</sup>**

**phenotype:** Extreme *fw*. Female sterile. RK2A.

**fw<sup>34e</sup>**

**phenotype:** Originally showed eye surface medium folded; bristles much gnarled. Schultz and Curry report that stock in 1940 showed gnarled bristles and eye small but no vertical fold. RK2.

**fw<sup>49c</sup>**

**phenotype:** Eyes furrowed; distal portions of arisal branches hooked; wings divergent and often stringy; scutellar groove reduced. Bristles split, bent, and often erect; acrostichal hair pattern distributed with whorls and naked areas. Late hatching, poorly viable, and mostly sterile. *fw<sup>49c</sup>/fw* phenotypically intermediate but more like *fw/fw* than *fw<sup>49c</sup>/fw<sup>49c</sup>*. RK3.

**fw<sup>59</sup>**

**phenotype:** Eyes rough and creased; facets irregular, 15% fewer than normal. Eyes browner than normal; pterine concentration reduced in the eyes and, except for isoxanthopterin, increased in testis sheath. Riboflavin accumulates in Malpighian tubules. Large bristles of head and thorax short, thick, angled, blunt, and occasionally reduced to stumps. Arista thick with contorted and supernumerary branches. Scutellum small with groove between it and thorax reduced. Hatchability and larval development normal; larval anal plates swollen and surrounded by melanotic halo. Melanotic anal region persists in pupa; pupa also has melanotic spots elsewhere that may result in nonpigmented areas on the imaginal integument. Extrusion of anterior and posterior spiracles in prepupa incomplete. Many *fw<sup>59</sup>* flies die either after 24-30 hr of pupal development or at the time of eclosion. Fecundity of female reduced owing to reduced number of ovarioles. RK2.

**fw<sup>60</sup>**

**phenotype:** Like *fw<sup>59</sup>* but with lower penetrance and expressivity. RK2.

**\*fw<sup>w</sup>: furrowed-weak**

**phenotype:** Affects only bristles, particularly the scutellars and postalar. Eyes normal. Normal fertility and viability. RK2.

**fw<sup>wr</sup>: furrowed-wrinkled**

**synonym:** *wr*.

**phenotype:** Eye surface in folds. Some bristles shortened, thickened, or curved; many doubled and may be fused. Viability low. RK2.

**fw<sup>d</sup>: four wheel drive (M. Fuller)**

**location:** 3- {0}.

**discoverer:** Wolf, 1988.

**synonym:** *ms(3)neol*.

**origin:** P-element insert marked with neomycin resistance, from the single element mobilization screen of Cooley and Sprading, 1988.

**references:** Wolf and Fuller, unpublished.

**phenotype:** Recessive male sterile. Failure of cytokinesis after meiosis I and meiosis II in males, usually resulting in onion stage early spermatids with four equal sized nuclei associated with a single, large mitochondrial derivative. Cells in meiosis II contain two spindles. Females fertile.

**cytology:** Placed in 61A1-C4 based on its inclusion in *Df(3L)emc-E12 = Df(3L)61A;61D3* but not in *Df(3L)Ar14-8 = Df(3L)61C3-4;62A8*.

*fx*: see *fa<sup>fx</sup>*

**\*fy: fuzzy**

**location:** 2-33.

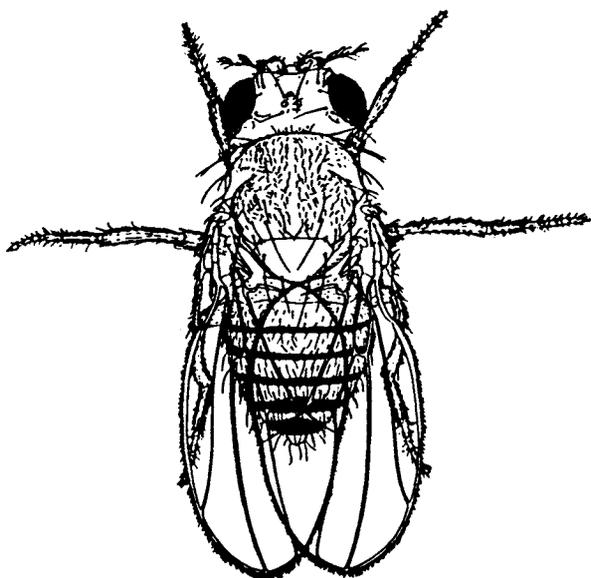

**origin:** Spontaneous.

**discoverer:** Ives, 39a.

**references:** 1940, DIS 13: 49.

**phenotype:** Hairs on abdomen and thorax irregular and directed toward midline. Hairs on wing margins erect. Hairs on legs also show abnormal polarities (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57). Resembles *fz*. Fertility and viability below normal. RK2.

**alleles:** A possible second allele, *fy<sup>2</sup>*, described by Grell (1969, DIS 44: 46-47) but maps to 2-24.1.

**fz: frizzled**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 85.

**fz: frizzled**

**location:** 3-41.7.

**origin:** Spontaneous.

**discoverer:** Bridges, 38b18.

**references:** Adler, Charlton, and Vinson, 1987, Dev. Genet. 8: 99-119.

**phenotype:** Hairs on thorax directed irregularly toward midline. Thoracic bristles also inturned and often wavy. Postverticals may turn outward. Hairs on wing edge and feet nearly erect; trichomes on wings of flies carrying weaker alleles tend to form swirls rather than lying parallel to one another and pointing distally; stronger alleles

can cause random orientation of trichomes. Polarity of chaetae deranged in characteristic ways on wings, notum, halteres, legs, tergites, and sternites; *fz M<sup>+</sup>* clones in *M/+* wings cause derangement of polarity in *M/+* cells surrounding clone (Gubb and García-Bellido, 1982, J. Embryol. Exp. Morphol. 68: 37-57). In a wild-type background clones of wing cells homozygous for *fz* alleles that cause eye roughening, but not of those without effect on eye texture, cause adjacent normal trichomes in regions distal, anterior, and posterior, but not proximal to the clone, to orient toward the clone rather than distally as they normally do; no effect on trichomes on opposite surface of the wing (Vinson and Adler, 1987, Nature 329: 549-51). Wing may be reduced. A low level of doubling of trichomes and splitting of chaetae observed. Sex combs may be irregular. Most alleles cause eyes to be rough. Two weak alleles, *fz<sup>24</sup>* and *fz<sup>34</sup>* and two neomorphic alleles, *fz<sup>13</sup>* and *fz<sup>20</sup>*, have normal eye textures. Extra leg joints tend to form as mirror-image duplications proximal to the normal joints on tarsal segments one to four. Also polarities of bristles, hairs, and bracts on legs abnormal (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57). RK2.

**alleles:** Most alleles fit into a hypomorphic to amorphic series with many hemizygotes displaying a more severe phenotype than homozygotes. Four strong alleles are lethal in homozygotes; three are associated with chromosome rearrangements (*fz<sup>3</sup>*, *fz<sup>26</sup>* and *fz<sup>30</sup>*) and one with a normal sequence (*fz<sup>14</sup>*); they complement one another in all pairwise combinations and survive in combination with *fz* deficiencies; therefore lethality is not associated with the *fz* locus.

<sup>β</sup> Phenotypic analysis according to Adler *et al.*; the first letter scores thoracic-bristle phenotype and the second wing-hair disorientation (S = strong, M = moderate, W = weak); the third letter indicates viability (V) or lethality (L).

<sup>γ</sup> Lethal alleles complement each other as well as *fz* deficiencies indicating three of the four lethal chromosomes are rearranged; they complement each other.

**molecular biology:** Genomic sequence isolated by transposon tagging. A single 4-kb mRNA identified in Northern blots of pupal RNA. A full-length cDNA contains a single long open reading frame which encodes a 581-amino-acid polypeptide. The N terminus contains a putative signal sequence. Following a long N-terminal

region, there are seven strongly hydrophobic regions typical of transmembrane domains three of which contain a proline residue. No striking homologies to other polypeptide sequences found in databases (Vinson, Conover and Adler, 1989, Nature 338: 263-64).

**cytology:** Placed in 70D6-7 based on commonality of breakpoints in *In(3L)fz*<sup>3</sup> and *In(3L)fz*<sup>4</sup> (Ashburner *et al.*). Adler places *fz* in 70D4-5 based on *in situ* hybridization of *P*-element probe to polytene chromosomes of *fz*<sup>34</sup>.

**fz 13**

**phenotype:** A neomorphic allele causing severe disruption of trichome orientation in the costal wing cell, a region little affected by most alleles; phenotype of homozygote more severe than that of hemizygote. Also unlike other alleles, homozygous clones of *fz*<sup>13</sup> cells in the wing do not affect orientation of trichomes in surrounding normal cells. A third notable feature of *fz*<sup>13</sup> is that it is without effect on eye texture.

**fz 20**

**phenotype:** Like *fu*<sup>13</sup>.

**fzy: fizzy**

**location:** 2-51.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

**phenotype:** Homozygous lethal; ventral outside and central nervous system degenerate.

**alleles:** Eight; *fzy*<sup>1</sup> and *fzy*<sup>2</sup> (isolated as *IB* and *IH*) retained.

**g: garnet****location:** 1-44.4.**discoverer:** Bridges, 15b19.**synonym:** *salmon*.**references:** Bridges, 1916, *Genetics* 1: 151.

**phenotype:** Eye color brownish, darkening with age; both pteridine and ommochrome pigments variably reduced in different alleles, giving rise to such descriptions as deep purplish ruby, pinkish, brownish, yellowish ruby, orange, etc. Nolte (1959, *Heredity* 13: 233-41) measured both pigments spectroscopically for *g* alleles ( $g^1, g^2, g^3, g^4$ ) and detected subtle differences. Hexter (1963, *Proc. Nat. Acad. Sci. USA* 50: 372-79) claims  $g^1, g^2, g^3$ , and  $g^4$  indistinguishable phenotypically but  $g^{53d}$  to be orange eyed and easily separable. Earlier authors claims  $g^2$  lighter than  $g^1$ . Pigmentation of Malpighian tubules also reduced (Brehme and Demerec, 1942, *Growth* 6: 351-56). Eye color ( $g^2$ ) autonomous in transplants into wild type host (Beadle and Ephrussi, 1936, *Genetics* 21: 225-47).

**cytology:** Placed in 12B6-7 (Lefevre, 1976, *Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, p59.

**other information:** Alleles separable by conversion;  $g^{53d}$  to the left of  $g^2$ .

**G: Gull**

From Mohr, 1929, *Z. Indukt. Abstamm. Vererbungsl.* 50: 113-200.

**G: Gull****location:** 2-12.0.**origin:** Spontaneous.**discoverer:** Mohr, 19k23.**references:** 1923, *Studia Mendeliana* (Brunae), pp. 266-87 (fig.).1927, *Proc. Intern. Congr. Genet.*, 5th., Vol. 2: 1136.1929, *Z. Indukt. Abstamm. Vererbungsl.* 50: 113-200 (fig.).

**phenotype:** Wings large, held out from sides at 45-90° angle, curved downward, and somewhat pointed. Vein L1 thickened; crossveins closer together, sometimes broken. Thoracic and vertical bristles duplicated in majority of flies. *G/ft* has exaggerated *ft* phenotype. Partially

inhibited by *ds/+* and much inhibited by *ds/ds*. Homozygous lethal. RK2.

**cytology:** Placed in 24D3-8 based on its inclusion in *Df(2L)M = Df(2L)24D3-4;25A2-3* but not in *Df(2L)dp-h28 = Df(2L)24D7-8;24F7-25A1* (Szikony and Reuter, 1988, Genet. Res. 51: 197-208).

**other information:** Causes local shortening of map by about 1.1 units. Is a deficiency for or an allele of *ft*.

***G<sup>rv</sup>*: Gull-reverted**

**origin:** Spontaneous derivative of *G*.

**discoverer:** Bridges, 1930.

**phenotype:** Does not show *G* phenotype. Allelic to *ft* but does not exaggerate *ft*. Lethal in combination with *G*. RK2.

***G* protein: see *Gα* and *Gβ***

*g2*: see *Tkr*

*g-l*: see *sno*

*g, Inh*: see *g<sup>X</sup>*

***Gα*: G protein α subunit**

*G* proteins belong to a family of membrane-associated guanine nucleotide-binding proteins that couple specific receptors for extracellular signals to specific intracellular effectors, thus regulating the activity of these effectors. When not interacting with the receptor, *G* proteins are usually in the form of a heterotrimer made up of  $\alpha$ ,  $\beta$ , and  $\gamma$  subunits, with the  $\alpha$  subunit bound to GDP. Upon activation by the receptor, the  $\alpha$  subunit exchanges GDP for GTP, dissociates from the  $\beta$ - $\gamma$  subunits, and interacts with the effector. Afterwards GTP is hydrolyzed, and the heterotrimer of  $\alpha$ ,  $\beta$ , and  $\gamma$  subunits is formed again. In *Drosophila melanogaster*, three genes coding for different  $\alpha$  subunits have been identified.

gene	location	$\alpha$ subunit encoded	ref <sup><math>\alpha</math></sup>	cytology
<i>G α 47A</i> <sup><math>\beta</math></sup>	2-[60]	G <sub>o</sub> 1, G <sub>o</sub> 2	1, 5-7	47A
<i>G α 60A</i>	2-[106]	G <sub>s</sub>	2, 6	60A

<sup>$\beta$</sup>  Synonym: *dgo* (Yoon *et al.*, 1989).

<sup>$\gamma$</sup>  Synonym: *DGα1* (Provost *et al.*, 1989).

***Gα47A*: G protein α subunit at 47A**

**phenotype:** Encodes a *G* protein  $\alpha$  subunit that is expressed mainly in the nervous system (DeSousa *et al.*, 1989; Thambi *et al.*, 1989) and shows homology to mammalian *Goα*. Low levels of this *G* protein are found in the embryo until completion of germband shortening; then high levels begin to be expressed in the neuropil (Wolfgang, *et al.*, 1990).

**molecular biology:** The gene has been cloned using rat, bovine, and human cDNA as probes. Genomic, cDNA and putative amino acid sequences have been obtained (DeSousa *et al.*, 1989; Thambi *et al.*, 1989; Yoon *et al.*, 1989). Three transcripts have been identified, a 3.8-4.2 kb transcript expressed at high levels in heads and bodies

of adults, a 5.3-6 kb transcript expressed at high levels in the heads only, and a 3.4-3.5 kb transcript found in bodies (Thambi *et al.*, 1989; Yoon *et al.*, 1989). Transcripts are also found in embryos, larvae, and pupae. The mRNA occurs abundantly in the cell bodies of neurons in the cortex of the brain and the thoracic ganglia; a low level of mRNA is found in nurse cells and oocytes (De Sousa *et al.*, 1989). Two classes of cDNA that differ in DNA sequences in the 5'-noncoding region and the 5'-most part of the coding region are generated by the splicing together of seven exons. The first exon in the splice differs in length and location in the two classes; the last six exons are identical in both classes (Yoon *et al.*, 1989). This alternative splicing results in the encoding of two proteins 354 amino acids long that differ in seven amino acids in the amino terminal region (De Sousa *et al.*, 1989; Thambi *et al.*, 1989; Yoon *et al.*, 1989). Transcripts corresponding to both classes of cDNA are found in the central nervous system (De Sousa *et al.*, 1989). Membrane preparations from *Drosophila melanogaster* heads contain high levels of a pertussin toxin (PTX) substrate with 82% sequence identity to vertebrate *G* proteins that are modified similarly by PTX (De Sousa *et al.*, 1989; Thambi *et al.*, 1989).

***Gα60A*: G protein α subunit at 60A**

**phenotype:** Encodes a stimulatory *G* protein  $\alpha$  subunit with high homology to mammalian *Gsα* that is responsible for the coupling of extracellular receptors to adenylate cyclase and an increase in the second messenger cAMP (Quan *et al.*, 1989). The protein is expressed at low levels until completion of germband shortening; then high levels begin to be expressed in the neuropil (Wolfgang *et al.*, 1990).

**molecular biology:** The gene has been cloned from head DNA using bovine cDNA as a probe. The genomic, cDNA and putative amino acid sequences determined (Quan *et al.*, 1989; Quan and Forte, 1990). The gene is 4.5 kb long. Transcripts are most abundant in the central nervous system; mRNAs were also isolated (using PCR) from whole flies and bodies (Quan and Forte, 1990). There are 9 exons separated by 8 introns, the introns showing a size variation of 56 bp to 1.4 kb. Alternate splicing at the 3' end of intron 7 produces transcripts that encode a long or short *G* protein  $\alpha$  subunit. The cDNAs differ by the inclusion or deletion of nine nucleotides at the exon 7-8 junction. The long or short protein products differ by inclusion or deletion of three amino acids and the substitution of a Ser in the long protein and for a Gly in the short protein (Quan and Forte, 1990). The apparent molecular weights of these two forms are 51,000 and 48,000 daltons.

***Gα65A*: G protein α subunit at 65A**

**phenotype:** Encodes a *G* protein  $\alpha$  subunit displaying sequence homology to mammalian *Giα* that inhibits adenylate cyclase activity. The *G* protein is uniformly distributed in oocytes, becomes restricted to the posterior pole of the embryo during early cleavage and is lost during the blastoderm stage (Wolfgang *et al.*, 1990).

**molecular biology:** The gene has been cloned using bovine transducin  $\alpha$  subunit cDNA as a probe; the genomic, cDNA, and putative amino acid sequences were determined. There are five exons separated by four introns. A major 2.3 kb transcript and a minor 1.7 kb

transcript have been identified. These transcripts, first isolated in very young embryos, are most abundant in the embryonic and pupal stages. The gene encodes a G protein  $\alpha$  subunit with amino acid sequences showing 77-78% identity to the sequences in bovine inhibitory G proteins; an isoleucine in the *Drosophila* protein, however, has been substituted for a cysteine in the vertebrate proteins (Provost *et al.*, 1989).

### **Gal: $\beta$ -Galactosidase**

**location:** 2-[20].

**references:** Kotarski, Pickert, and MacIntyre, 1983, *Genetics* 105: 387-407.

Knipple and MacIntyre, 1984, *Mol. Gen. Genet.* 198: 75-83.

Fargnol, Hyde, and Sofer, 1985, *Genetics* 110: s7.

**phenotype:** Inferred to be the gene that codes for the enzyme  $\beta$  galactosidase [B-GAL (EC 3.2.1.23)] because of response of the enzyme level to gene dosage. A null strain (*Gal<sup>ng</sup>*) does not survive on medium containing lactose (Fargnol *et al.*, 1985), but the Bethyie wild-type strain shows more than 95% survival on lactose medium. Induction in cell culture by hormone studied by Best-Bellpomme, Courgen, and Rambach (1978, *Proc. Nat. Acad. Sci. USA* 75: 6102-06).

**alleles:** *Gal<sup>n1</sup>* and *Gal<sup>n2</sup>* (Knipple and MacIntyre, 1984), *Gal<sup>ng</sup>* (Fargnol *et al.*, 1985).

**cytology:** Placed in 26A8 since located between autosomal breakpoints of *T(Y;2)H69 = T(Y;2)26A7-8* and *T(Y;2)D211 = T(Y;2)26B3-5* and uncovered by *Df(2L)GpdhA = Df(2L)26D7-E1;26A8-9* but not by *Df(2L)c17 = Df(2L)26D7-E1;26A7-8* (Knipple and MacIntyre, 1984).

**gap:** see *gp*

### **Gapdh1: Glyceraldehyde dehydrogenase 1**

**location:** 2-[57].

**references:** Tso, Sun, Wu, 1985, *J. Biol. Chem.* 260: 8820-28.

**phenotype:** One of two genes (*Gapdh1* and *Gapdh2*) that code for the enzyme glyceraldehyde-3-phosphate dehydrogenase [G3PD (EC.1.2.12)]. These genes are expressed in almost all cells, especially those that undergo a high rate of glycolysis.

**cytology:** Glyceraldehyde 1 has been located at 43E-F by *in situ* hybridization to the salivaries.

**molecular biology:** *Gapdh1* has been cloned and its nucleotide and deduced amino acid sequences determined. *Gapdh1* and *Gapdh2* show a striking degree of identity in their coding regions but are entirely different in their 5' and 3' flanking regions. Since, for the enzymes encoded by these genes, there are only eight amino acid residue differences in a total of 332 residues, Tso *et al.* suggest that the two genes have arisen by duplication and translocation events. The transcription initiation site and the polyadenylation site of *Gapdh1* have been determined; the gene is transcribed from left to right and its transcript is present in adult flies. In its -30 bp region, *Gapdh1* resembles many RNA polymerase II transcribed promoters in the lack of a sequence homologous to the TATA box. No introns are found in its coding region.

### **Gapdh2: Glyceraldehyde dehydrogenase 2**

**location:** 1-[54].

**references:** Tso, Sun, Wu, 1985, *J. Biol. Chem.* 260: 8820-28.

Sun, Lis, and Wu, 1988, *Genes Dev.* 2: 743-53.

**phenotype:** Another gene that codes for the enzyme glyceraldehyde-3-phosphate dehydrogenase (see *Gapdh1*). The level of expression of *Gapdh2* has been found to be regulated developmentally (Sun *et al.*, 1988).

**cytology:** Glyceraldehyde 2 has been located at 13F by *in situ* hybridization to the salivaries.

**molecular biology:** *Gapdh2* has been cloned and its nucleotide and deduced amino acid sequences determined. As in *Gapdh1*, the transcription initiation site and the polyadenylation sites of *Gapdh2* have been determined. The promoter region of *Gapdh2* (unlike that of *Gapdh1*) contains a consensus TATA box sequence as well as a CAAT box sequence (Tso *et al.*, 1985). There is an intron located in the 5' noncoding region, but no other intervening sequences. There are two distinct regulatory regions, URS1 and URS2, in the first 145 bp of the 5' flanking region of *Gapdh2*. URS1 acts throughout development to activate transcription; URS2 acts along with URS1 to activate transcription in larval and adult stages, but represses transcription in Schneider cells and perhaps some embryonic stages (Sun *et al.*, 1988).

**garnet:** see *g*

**Gart:** see *ade3*

**gastrulation defective:** see *gd*

**gat: gate (J.C. Hall)**

**location:** 2-60.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jackson, 1983, *J. Neurogenet.* 1: 3-15.

**phenotype:** Eclosion of flies is poorly synchronized in light-dark cycle; eclosion becomes arrhythmic in constant darkness; fluctuations of male's courtship song interpulse intervals define a sloppy rhythm or are arrhythmic (Jackson and Kyriacou).

**other information:** Allelic to *psi-2*, based on aberrant short-term rhythms of courtship song in *gat/psi-2* males (Kyriacou).

### **G $\beta$ 13F: G protein $\beta$ subunit at 13F**

**location:** 2-[54].

**references:** Yarfitz, Provost and Hurley, 1988, *Proc. Nat. Acad. Sci. USA* 85: 7134-38.

**phenotype:** This gene encodes one isoform of the G protein  $\beta$  subunit in *Drosophila melanogaster*. After the G protein  $\alpha$  has interacted with the effector, the  $\beta$ - $\gamma$  subunits reassociate with the  $\alpha$  subunit and bring the  $\alpha$  subunit to its specific receptor.

**cytology:** Located at 13F by *in situ* hybridization to the salivaries.

**molecular biology:** Gene cloned using bovine transducin  $\beta$  subunit cDNA as a probe, and the genomic, cDNA and the putative amino acid sequences determined. There is an open reading frame (ORF) of 1023 bases which codes for a predicted protein of 340 amino acids showing more than 80% identity to the corresponding mammalian proteins. The *Drosophila* protein is unique at 15% of the amino acid positions. Transcripts of 5.2, 4.2, 3.3, 3.0 and 1.9 kb are expressed from mid-embryo through adult

stages, the highest level of expression being in late embryos and pupae. Expression is low in larvae and can hardly be detected in adults. Early embryos also show transcripts of 3.1, 2.5 and 2.0 kb. In adult flies there is more mRNA in the heads than in the bodies. Restriction mapping and DNA sequencing indicate the absence of introns in the presumptive coding region of the gene; however, at least two introns are present in the 5' noncoding region and there is evidence for alternative splicing in this region.

**gcd: giant cell defect (J.C. Hall)**

**location:** 1-48.  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Heisenberg.

**phenotype:** Cellular cortex of central brain shows one giant cell body lateral to base of each calyx (bulges located relatively dorsally and at posterior edge of cortex); penetrance of this phenotype approximately 85%.

**gd: gastrulation defective**

**location:** 1-36.78.  
**origin:** Induced by ethyl methanesulfonate.  
**synonym:** *fs(1)A573*, *fs(1)M18*.  
**references:** Gans, Audit, and Masson, 1975, *Genetics* 81: 683-704.  
 Anderson and Nüsslein-Volhard, 1984a, *Nature (London)* 311: 223-27.  
 1984b, *Pattern Formation (Malacinski and Bryant, eds.)*. Macmillan, New York. pp. 269-89.

 Anderson, Bokla, and Nüsslein-Volhard, 1985, *Cell* 42: 791-98.

**phenotype:** Maternal-effect lethal; embryos produced by homozygous females exhibit hyperplasia of dorsal cuticular elements and aplasia of ventral elements; phenotype of strong alleles, e.g. *gd<sup>7</sup>*, indistinguishable from that of *dl*. Weaker alleles display some ventral elements. Gastrula exhibits excessive furrowing both dorsally and ventrally [Zalokar, Audit, and Erk, 1975, *Dev. Biol.* 47: 419-32 (fig.)]. Polarity of the egg shell unaffected. Temperature-sensitive period of temperature-sensitive alleles begins several hours prior to ovoposition and persists until 1.5 h after fertilization. Five of eight mutants classed as weak on the basis of filzkörper development; these five tend to be more dorsalized in posterior than in anterior parts of the embryo, as the setal bands become progressively narrowed posteriorly. *gd<sup>7</sup>/gd<sup>7</sup>*; *Toll/+* females produce lateralized embryos; most ventral and dorsal pattern elements missing; lateral cephalic furrow seen both dorsally and ventrally, and ventral setae formed at all dorsal-ventral positions.

Biol.* 47: 419-32 (fig.).  
<sup>β</sup> *gd<sup>6</sup>* complements *gd<sup>3</sup>* and partially complements *gd<sup>2</sup>*.  
<sup>γ</sup> Pattern of *ftz* protein stripes in homozygous females identical to that of other maternal dorsalizing mutants (Carroll, Winslow, Twombly, and Scott, 1987, *Development* 99: 327-32).

**cytology:** Placed in 11A1-7, since uncovered by *Df(1)KA10 = Df(1)11A1;11A7-8* (Tearle and Nüsslein-Volhard, 1987, *DIS* 66: 209-26).

**\*Gd: Gulloid**

**location:** 3-78.  
**origin:** Spontaneous in *Dp(2;3)P*.  
**discoverer:** Bridges, 22g26.  
**phenotype:** *Gd/+* wings shorter, blunter, slightly more spread, and have crossveins closer together than wild type. Homozygous lethal. RK3A.  
**cytology:** Inseparable from *Dp(2;3)P = Dp(2;3)58E3-F2;60D14-E2;96B5-C1*.

**Gdh: Glutamate dehydrogenase**

**location:** 3-81.7 (between *hh* and *tx*).  
**references:** Caggese, dePinto, and Ferrandino, 1982, *Biochem. Genet.* 20: 449-60.  
 Novak and Piechowska, 1986, *DIS* 63: 102-04, 104-07.  
**phenotype:** Structural gene for NAD<sup>-</sup> dependent glutamate dehydrogenase [GDH (EC1.4.1.4)], which comprises six 57,000 dalton subunits. Enzyme activity inducible by addition of glutamate to medium. Nearly all larval activity can be isolated with the mitochondria.  
**alleles:** *Gdh<sup>F</sup>* and *Gdh<sup>S</sup>* identified; heterozygote produces broad band on cellulose acetate gel.

*Gdh*: see *Gpdh*

**gdl: gonadal**

**location:** 3-{42}.  
**references:** Schultz and Butler, 1989, *Genes Dev.* 3: 232-42.  
 Schultz, Schlomchik, Cherbas, and Cherbas, 1989, *Dev. Biol.* 131: 515-23.  
**phenotype:** Member of cluster of overlapping genes; *gdl* is proximally overlapped by *Eip28/29* and distally by *Z600*. The function of the *gdl* gene in the germ lines of both males and females is unknown at present (Schultz and Butler, 1989).

**cytology:** Located in 71C3-D4 (Schultz and Butler, 1989).  
**molecular biology:** Gene cloned and partially sequenced. *gdl* is expressed in either of two modes (male or female). There are four transcripts, both due to different transcription initiation sites and multiple polyadylation sites at their 3' ends. *gdl<sup>M</sup>* transcripts are first detectable during late larval development, appear at higher levels in pupae, and occur abundantly in the testes of adults, being 1200 and 1500 nucleotides long; *gdl<sup>F</sup>* transcripts are found in adult ovaries, early embryos and Kc cells, are 1000 and 1300 nucleotides long. and have the same terminal exons as *gdl<sup>M</sup>* transcripts. A common ORF occurs in all four transcripts. None of these transcripts are found in male or female animals lacking a germ line. In each mode, the

longer transcript is the result of a polyadenylation site within the 5' exon of *Eip28/29*. The two genes *Eip28/29* and *gdl* do not share coding DNA. Transformation experiments indicate that *gdl* can be expressed outside its normal overlapping gene environment.

*Gdt-3*: see *Gpdh<sup>H</sup>* and *Gpdh<sup>L</sup>*

### \**ge*: genitalless

**location:** 1-0.1.

**origin:** Induced by methyl methanesulfonate (CB. 1540).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 70.

**phenotype:** External male genitalia absent or grossly deformed. Bristles fine; wings often small and deformed. Tergites abnormal; abdomen frequently contains melanotic tumors. Males viable but sterile. RK3.

*Gerec*: see *Fs(3)Sz9*

*gespleten*: see *gv*

### *gfA*: giant fiber A (J.C. Hall; R.A. Wyman)

**location:** 1- 62 (between *f* and the centromere).

**origin:** Induced by ethyl methanesulfonate.

**references:** Thomas, 1980, Neurosci. Abstr. 6: 742.

Thomas and Wyman, 1984, J. Neurosci. 4: 530-38.

**phenotype:** Adults have an aberrant startle response; they do not jump when presented with a lights-off stimulus. The dorso-longitudinal indirect flight muscles (DLMs) are abnormally driven by the giant fiber pathway neurons (see entry for *ben*). DLMs are driven at long and variable latencies after brain stimulation. Morphology of the giant fiber and its response to stimulation is normal. The motor neuron of the tergotrochanteral (jump) muscle is driven normally by the giant fiber. The physiological defect in *gfA* is probably located at the synapses between the peripherally synapsing interneuron (PSI) and the DLM motor neurons in the thoracic ganglion. *gfA* complements *pas*.

**alleles:**

allele	discoverer	synonym
<i>gfA</i> <sup>1</sup>	Thomas	<i>nj-54</i>
<i>gfA</i> <sup>2</sup>	Thomas	<i>nj-75</i>
<i>gfA</i> <sup>3</sup>	Tanouye	4-22-09

<i>gfA</i> <sup>5</sup>	Baird	<i>nj-520</i>
<i>gfA</i> <sup>6</sup>	Baird	<i>nj-522</i>

**cytology:** Located between 18A5 to 18D1-2, based on uncovering by *Df(1)JA27 = Df(1)18A5;18D1-2*.

**other information:** *gfA*<sup>1</sup>/*Df(1)JA27* is said to be indistinguishable from *gfA*<sup>1</sup>/*gfA*<sup>1</sup> (Thomas and Wyman, 1984). Physiological effects of *gfA*<sup>1</sup> and *gfA*<sup>2</sup> are ostensibly the same.

### *gg*: goggle

**location:** 1-23.1 (no crossovers with *oc* among 4300 flies).

**phenotype:** Eyes protruding and bulging, placed far back on a narrow head. Facets very large in rough areas. Wings smaller with fringed marginal hairs; dusky; pebbly appearance caused by large cells. Bristles coarse and irregular; hairs sparse and irregular, especially on abdomen. Body small in late counts. Viability reduced. Females usually sterile; males usually fertile. RK3.

### alleles:

### *gl*: glass

**location:** 3-63.1.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 188 (fig.).

Morgan, Bridges and Sturtevant, 1925, Bibliog. Genet. 2: 214.

Pak, Grossfield and White, 1969, Nature (London) 222: 351-54.

Moses, Ellis and Rubin, 1989, Nature (London) 340: 531-36.

**phenotype:** Null mutations of *glass* remove photoreceptor cells in all of the three organs in which they occur. The mutants have compound eyes that are reduced in size and elliptical or diamond shaped; the texture is glassy from fused facets and irregular surface. Ocelli are flattened and lack pigment; there is no ocellar neuropil (Moses *et al.*, 1989). In larvae, the visual Bolwig organs are absent in *gl*<sup>2</sup>, but present in *gl*<sup>3</sup>. Neither mutant expresses chaoptin (Moses *et al.*, 1989). Color of compound eyes and Malpighian-tubules variably reduced depending on

allele. In the presence of the dimorphic sex-linked modifier, *msd(gl)<sup>d</sup>*, males have more pigment than females, whereas males have the same eye color as females when they carry the monomorphic allele *msd(gl)<sup>m</sup>* [Birchler, 1984, Genet. Res. 44: 125-32]. *dsx* homozygotes of either *X* constitution but especially *XX* produce more pigment than *dsx<sup>+</sup>* (Smith and Lucchesi, 1969, Genetics 61: 607-18); however *msd(gl)* was not controlled by Smith and Lucchesi. Pigmentation increases with increased developmental temperature. At high or very low levels of pigment production the sexual dimorphism disappears. Weak alleles have small smooth eyes and normal pigment levels in both sexes. Mild alleles have eyes reduced to two-thirds normal size and approximately 20% normal eye-pigment levels and male levels approximately 2X female levels. Moderate alleles reduce eye size to half normal and pigment to about 5% normal levels with male levels approximately 3X those of females. Strong alleles have eye area less than half normal, and eyes are virtually colorless in both sexes (Smith and Lucchesi). The optic lamina is virtually nonexistent and the medulla is very small and disorganized in *gl<sup>1</sup>*; the lamina and medulla are both small and disorganized in *gl<sup>2</sup>* and *gl<sup>3</sup>* [Meyerowitz and Kankel, 1978, Dev. Biol. 62: 112-42 (fig.)]. Mosaic studies using *gl<sup>3</sup>* show that the *gl* genotype of the eye, rather than that of the optic lobe, determines the axon array of the optic lobe (Meyerowitz and Kankel, 1978). Structures of individual neurons studied by S.H. Garen and Kankel (1983, Dev. Biol. 96: 445-56). Retinula cells of the mutant are irregular and rhabdomeres are lacking; the electroretinogram shows no response to light (Pak, Grossfield and White, 1969). *gl* flies are nonphototactic and males exhibit depressed courtship activity [Merrell and Underhill, 1956, Genetics 41: 469-85; Hall, Tomkins, Kyriacou, Siegal, Von Schilcher and Greenspan, 1980, Developmental Neurobiology of *Drosophila* (Siddiqi, Babu Hall and Hall, eds.). Plenum Press, New York, pp. 425-56]. Wing beat frequency increased (Williams and Reed, 1944, Am. Nat. 78: 214-23).

Calif. Publ. Zool. 49: 137;
- <sup>β</sup> Associated with *T(2;3)gl<sup>63d</sup> = T(2;3)47B;91A* (Robinson and Curtis, 1972, Can. J. Cytol. Genet. 14: 129-37).
- <sup>γ</sup> Lethal allele.
- <sup>δ</sup> Associated with *In(3R)gl<sup>BX6</sup>* (Moses *et al.*, 1989).

**cytology:** Located in 91A1-2 since all the DNA in the central restriction map of a wild-type *gl* genomic clone lies within this polytene band; also *In(3R)gl<sup>BX6</sup>* and *T(2;3)gl<sup>63d</sup>* appear to have breakpoints within this region (Moses *et al.*, 1989).

**molecular biology:** The glass gene was cloned by chromosome walking and the limits of the *gl<sup>2</sup>* gene determined by *P*-element mediated germline transformation (Moses *et al.*, 1989). The probe from one of the transforming fragments (9,954 bp) hybridized to a 3.0 kb poly(A)<sup>+</sup> RNA in the heads of adult flies. All of the viable alleles tested affect only this transcript, believed to be that of glass, which is first detected in the early third larval instar, and remains to the adult stage in which it is head-specific. There are five exons and four introns. The 9,954 bp fragment has been sequenced and the predicted sequence of a protein of 604 amino acids determined. The protein encoded by the *gl* transforming fragment includes five zinc-finger repeats similar to those of the *Kr* protein but some sequences (Ser-Gln-Ser) have not been found in other zinc-finger proteins. Another fragment was obtained that extends further toward the centromere end of the chromosome and does not rescue glass gene function. The mutant *gl<sup>WG1</sup>* deletes about 600 bp near the centromere end of the *gl* transforming fragment; *gl<sup>1</sup>*, *gl<sup>2</sup>*, *T(2;3)gl<sup>63d</sup>*, and *In(3R)gl<sup>BX6</sup>* show breaks within the next region. The weak allele *gl<sup>3</sup>* inserts about 2.5 kb and the allele *gl<sup>60j</sup>* inserts more than 30 kb into the third region, and *gl<sup>BX3</sup>* removes about 4.5 kb from the distal end of the transforming fragment. All of these alleles are viable. The lethal alleles *gl<sup>B16</sup>* and *gl<sup>BX7</sup>* occupy the DNA distal to glass at 91A1-2 as well as the distal part of the *gl* transforming fragment, deleting about 20 and 18.5 kb respectively.

**GI: Glued**

**location:** 3-41.4 [0.9 unit from *Ly* (Mossige, 1935, DIS 4: 59; 1938, Hereditas 24: 110-16)].

**references:** Plough and Ives, 1934, DIS 1: 31-4.

Plough, 1934, DIS 2: 34-5.

Plough and Ives, 1935, Genetics 20: 42-69 (fig.).

Harte and Kankel, 1982, Genetics 101: 477-501 (fig.)

Swaroop, Paco-Larson and Garen, 1985, Proc. Nat. Acad. Sci. USA 82: 1751-55.

Swaroop, Sun, Paco-Larson and Garen, 1986, Mol. Cell

Biol. 6: 833-41.

Swaroop, Swaroop and Garen, 1987, Proc. Nat. Acad. Sci. USA 84: 6501-05.

**phenotype:** Eyes rough, smaller, and oblong; facets rounded; surface smooth and shiny like *gl*. Pattern, as indicated by staining with monoclonal antibodies, abnormal in the posterior eye disk (Renfrenz and Benzer, 1989, Dev. Biol. 136: 411-29). Architecture of the optic ganglia severely deranged; attributable to the mutant genotype of the overlying eye tissue (Meyerowitz and Kankel, 1978, Dev. Biol. 62: 112-42). Structures of individual neurons studied by S.H. Garen and Kankel (1983, Dev. Biol. 96: 445-56). Somatic-crossover studies and temperature-shift experiments with *Gl<sup>rv30</sup>*, a temperature-sensitive allele, suggest that *Gl<sup>+</sup>* gene product is required in mid third instar; abnormal retinula fiber projections first observed in late third instar [Harte and Kankel, 1983, Dev. Biol. 99: 88-102 (fig.)]. No electro-retinogram [Grossfield, 1975, Handbook of Genetics (R.C. King, ed.). Plenum Press, New York and London, Vol. 3, p. 690]. Bristles generally shortened slightly and straighter than normal. Viability and fertility of heterozygote good. With respect to severity of expression *Df(3L)Gl2/+* = wild type; *Gl/+/+* = very weak Glued; *Gl/+* = weak Glued; *Gl/+* = Glued; *Gl/Gl/+* = few extreme Glued survivors, *Gl/Df(3L)Gl<sup>-</sup>* = *Gl/Gl* = lethal (Harte and Kankel). RK1.

**alleles:** In addition to *Gl<sup>1</sup>*, which occurred spontaneously among the progeny of heat treated flies (Ives, 31f5), both Harte and Kankel (1982) and Garen, Miller, and Paco-Larson (1984, Genetics 107: 645-55) induced a number of new mutations and rearrangements at the locus; these fall into two general classes: (1) new lethal alleles in which the dominant phenotype is weak or absent, and (2) revertants of *Gl<sup>1</sup>* induced by either ionizing radiation, ethyl methanesulfonate, or hybrid dysgenesis. 17 ethyl-methanesulfonate-induced lethal mutants are lethal in combination with either *Gl<sup>1</sup>* or *Df(3L)Gl2* and appear to be point mutations, since they complement lethals in flanking loci. The time of death varies.

allele	synonym	ref <sup>α</sup>	<i>Gl<sup>1</sup>/Df(3L)Gl2</i> lethal period
α			1 = Garen, Miller, and Paco-Larson, 1984, Genetics 107: 645-55; 2 = Harte and Kankel, 1982, Genetics 101: 477-501; 3 = Plough and Ives, 1934, DIS 1: 31-4.
β			Surviving homozygotes produced at both 18° and 29°; homozygous stock can be established at 18° but not 29°; in crosses to wild type, homozygous males fertile at both temperatures and eggs maturing at 18° but not at 29° able to produce progeny (Harte and Kankel, 1982).
γ			<i>Gl<sup>22</sup></i> complements or partially complements other lethal alleles of <i>Gl</i> : <i>Gl<sup>22</sup>/Gl<sup>1</sup></i> lethal at 29°; eyes extreme Glued, bristles reduced and wings small and outheld at 18°; enhances phenotype of <i>Gl<sup>118</sup></i> and <i>Gl<sup>16</sup></i> . * <i>Gl<sup>121</sup></i> also complemented.
δ			<i>Gl<sup>120</sup>/Gl<sup>13</sup></i> rarely survive as feeble adults.

Approximately one-fourth (22/96) revertants of *Gl* induced by X or γ irradiation fail to complement one or more flanking lethals and are therefore presumed to be deficiencies; those induced by ethyl methanesulfonate and hybrid dysgenesis on the other hand complement all flanking lethals. Phenotypic revertants induced by ionizing radiation and ethyl methanesulfonate remain lethal in heterozygous combination with either *Gl* or *Df(3L)Gl2* and with each other; revertants tested in combination with *Df(3L)Gl2* die during the first larval instar. The majority of hybrid-dysgenesis-induced revertants (67/78) are viable in heterozygous combination with *Df(1)Gl2* and most *Gl<sup>1</sup>* alleles, whereas they are lethal in combination with *Gl<sup>1</sup>*, *Gl<sup>19</sup>*, and *Gl<sup>110</sup>*; 7/67 are viable in all the above combinations and 4/67 are inviable in all combinations. Available phenotypic observations on *Gl<sup>rv</sup>/+* summarized in accompanying table.

**cytology:** Placed in 70C2 on basis of *in situ* hybridization of cloned sequence (Garen *et al.*, 1984).

**molecular biology:** The Glued locus was cloned by P-element insertion in 70C2 as a chromosome marker (Swaroop *et al.*, 1986). The dominant *Gl* allele differs from *Gl<sup>+</sup>* in the presence of the transposon *roo* near the 3' end of the transcribed region, resulting in the formation of a truncated 5.1 kb transcript instead of the 6 kb transcript of *Gl<sup>+</sup>* (Swaroop *et al.*, 1985). The normal transcript has been found in about all of the tissues of *Gl<sup>+</sup>* homozygotes. The complete cDNA sequence of *Gl<sup>+</sup>* contains an open reading frame encoding 1319 amino acids (Swaroop *et al.*, 1987). There are five exons, two of them in the 5' untranslated region. One of the introns interrupting the Glued ORF encodes at least two polyadenylated transcripts. The Glued polypeptide

predicted from the sequence encoded by the ORF has extensive  $\alpha$ -helical internal domains (Swaroop *et al.*, 1987). Similar in sequence and structure to those of filamentous proteins of other species.

*gl-l*: see *gl*<sup>41e</sup>

**Gla: Glazed**

**location:** 2- (rearrangement).

**references:** Morgan, Bridges, and Schultz, 1936, Year Book - Carnegie Inst. Washington 35: 293.

**phenotype:** Eye reduced to one-fourth normal area and narrowed to a point ventrally. Eye color generally diluted but with some black patches. Ommatidia coalesce into gleaming, smooth sheet. Malpighian tubes of larva somewhat lighter than wild type; difficult to classify (Brehme and Demerec, 1942, Growth 6: 351-56). Abdomen of heterozygous female fails to distend with eggs; fertility impaired (Craymer, 1980, DIS 55: 200). Homozygous lethal. RK2A.

**cytology:** Associated with *In(2LR)Gla = In(2LR)27D;51E*, superimposed on *In(2L)t = In(2L)22D3-E1;34A8-9*.

**Gld: Glucose dehydrogenase**

**location:** 3-48 (based on 30 *st-cu* recombinants).

**synonym:** *Go*: Glucose oxidase.

**references:** Cavener, 1980, Biochem. Genet. 18: 927-37. Cavener and MacIntyre, 1983, Proc. Nat. Acad. Sci. USA 80: 6268-88.

Whetten, Organ, Krasney, Cox-Foster, and Cavener, 1988, Genetics 120: 475-84.

**phenotype:** The structural gene for FAD glucose dehydrogenase [GLD (EC1.1.99.10)]. The formation of a hybrid band in *Gld<sup>F</sup>/Gld<sup>S</sup>* heterozygotes indicates a dimeric enzyme. Molecular weight given as 110,000 daltons. Gene expressed during pupal stages of both sexes; enzyme found in pupal stage 3-4 moulting fluid where it modifies puparium cuticle. *Gld* also expressed in the ejaculatory duct of males; genital disc transplantation experiments indicate that GLD expression in ejaculatory duct is autonomous (Cavener); enzyme transferred from males to females during copulation. Lethality of null alleles in the pupal stage observed; *Gld<sup>n</sup>* flies can be rescued by pre-eclosion excision of pupal operculum.

**alleles:** Two naturally occurring electrophoretic alleles, *Gld<sup>F</sup>* and *Gld<sup>S</sup>* and five EMS-induced null alleles *Gld<sup>n1</sup>* - *Gld<sup>n5</sup>*.

$\alpha$  1 = Cavener and MacIntyre, 1983, Proc. Nat. Acad. Sci. USA 80: 6268-88; 2 = Cavener, Otteson and Kaufman, 1986, Genetics 114: 111-13; 3 = Lewis, Kaufman, Denell, and Tallierico, 1980,

Genetics 95: 367-81.

$\beta$  Measured in *Gld<sup>n</sup>/Df(3R)Antp17*.

$\gamma$  1% wild-type enzyme activity in pupae and adult males. *Gld<sup>2</sup>* through *Gld<sup>5</sup>* lethal in all pairwise combinations except that *Gld<sup>2</sup>* partially complements *Gld<sup>4</sup>* and *Gld<sup>5</sup>*.

**cytology:** Placed in 84D on the basis of its being in the region of overlap between *Df(3R)A41 = Df(3R)84B1-2;84D1-2* and *Df(3R)dsx29 = Df(3R)84D2-3;84F8-10* (Cavener, Otteson and Kaufman, 1986, Genetics 114: 111-23).

**molecular biology:** Structural gene cloned from EMBL-4 Oregon-R genomic library (Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48). Clones identified by locating deficiency and translocation breakpoints delimiting *Gld*. A 2.8 kb poly(A) RNA transcript identified with temporal and spatial expression similar to that of *Gld*. Expression of *Gld* induced immediately before larval and pupal moults. The three 5' exons of the gene have been sequenced and the start sites for transcription and translation identified (Whetten *et al.*, 1988). The first exon contains 335 nucleotides; the second exon contains the *Gld* translation start codon. The putative amino acid sequence at the amino terminus has three serine-alanine tandem repeats and numerous cysteine residues. The *Gld* lethal phenotype was rescued by *P*-element-mediated germline transformation (Whetten *et al.*, 1988).

**gleam:** see *gm*

**\*gli: glide**

**location:** 1-38.0.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 70.

**phenotype:** Wings held horizontally at right angles to body. Pigmentation of tergites frequently interrupted along mid-dorsal line; tergites occasionally show a nick in the posterior border. Males sterile; viability about 70% wild type. RK2.

**glisten:** see *gn*

**glossy:** see *lz*

**glossy like:** see *sno*

**Glt: Glutactin**

**location:** 2-{30}.

**references:** Fessler and Fessler, 1989, Annu. Rev. Cell Biol. 5: 309-39.

**phenotype:** Encodes an acidic sulfated glycoprotein of basement membranes.

**cytology:** Placed in 29D by *in situ* hybridization.

**molecular biology:** Gene sequenced and found to code for a 1024-residue polypeptide that has a signal peptide, a major amino domain of 600 residues with the coding region interrupted by one intron, and an acidic carboxyl domain. Amino and carboxyl domains separated by 13 threonine residues; four O-sulfated tyrosines present. The protein preferentially binds Ca<sup>++</sup> in the presence of excess Mg<sup>++</sup>.

**Glu:  $\beta$ -Glucuronidase**

**location:** 3-{101}.

**references:** Langley, S.D., Wilson, Gross, and Finnerty, 1983, J. Biol. Chem. 258: 7416-24.

**phenotype:** May or may not be a structural gene for  $\beta$ -D-Glucuronidase (EC 3.2.1.31). The enzyme is a glycoprotein and exists in two chromatographically separable forms. Form I is membrane bound, has a pI of 8.0 - 8.5, and can be irreversibly inactivated by either incubation at 55° for 20 min or by incubation at 37° in the presence of 6M urea; form II exists in both membrane-bound and free states, has a pI of 4.5, and is resistant to inactivation by the above treatments. The two are kinetically similar, having similar  $K_m$  and  $V_{max}$  and are precipitated by antibody raised against form II.

**alleles:** *Glu<sup>H</sup>* has high activity owing to the presence of both forms I and II; *Glu<sup>L</sup>* has the same level of form II activity but lacks form I and exhibits low activity. Heteroallelic genotypes exhibit intermediate levels of form I activity. Observations suggests that *Glu<sup>H</sup>* may be a duplication or *Glu<sup>L</sup>* is an amorphic mutant in a duplicate gene.

**cytology:** Placed in 98F-100F by gene dosage studies.

Homyk and Emerson, 1988, Genetics 119: 105-21.

**phenotype:** Flight is defective; indirect flight muscles have relatively mild abnormalities of Z-bands and myofibrils; mosaic analysis suggests that thoracic nerves or muscles could be primary site of mutant defect. All alleles lead to reduced amount of at least two high molecular-weight proteins from indirect flight muscles.

**alleles:** Three mutant alleles: *gnd<sup>1</sup>*, *gnd<sup>2</sup>*, *gnd<sup>3</sup>*.

**other information:** Could be allelic to *fltM*, *fltN*, *fltO*, *flrdR*, or *flrdQ*.

**gnu: giant nuclei**

**location:** 3-42.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Freeman, Nüsslein-Volhard, and Glover, 1986, Cell 46: 457-68.

**phenotype:** Maternal-effect lethal. Embryos produced by homozygous or hemizygous females exhibit normal levels of DNA synthesis, but do not display normal nuclear division; a small number of giant nuclei formed. Cytoplasmic elements such as centrosomes, microtubules, and actin appear to attempt to follow the normal developmental program, demonstrating that control of nuclear and cytoplasmic components of syncytial nuclear divisions can be uncoupled.

**cytology:** Placed in 70D2 or 70E4-8 on the basis of its inclusion in *Df(3L)jz-m21 = Df(3L)70D2-3;70E4-5* but not *Df(3L)jz-d21 = Df(3L)70D3;70E3-8*.

*Go:* see *Gld*

**Go: Gold tip**

**location:** 2-64.3 (57.5 to 71.1; between *cn* and *cg*).

**origin:** Spontaneous.

**discoverer:** Sturtevant, 1948.

**references:** 1948, DIS 22: 55.

**phenotype:** Tips of many bristles and hairs pale and curved. Bristles often short (tips broken off?). Wild-type bristles sometimes have pale tips, thus interfering with positive classification. Lethal when homozygous. Expression best at low temperatures. RK2.

**goggle:** see *gg*

**Gold tip:** see *Go*

**gonadal:** see *gdl*

**gooseberry:** see *gsb*

**Got1: Glutamate oxaloacetic transaminase**

**location:** 2-75 (between *L* and *nw<sup>D</sup>*).

**synonym:** Designated *Got2* by Band (1975) and also by Cavener and Clegg (1976).

**references:** Band, 1975, Genetics 80: 761-71.

Cavener and Clegg, 1976, J. Hered. 67: 313-14.

Grell, 1976, Genetics 83: 753-64.

Chase and Kankel, 1987, J. Neurobiol. 18: 15-41.

**phenotype:** The structural gene for the more rapidly anodally migrating of two glutamate oxaloacetic transaminases [GOT1 (EC 2.6.1.1) = L-aspartate: 2-oxoglutarate aminotransferase] found in *Drosophila*.

**alleles:** Two alleles described by Grell, *Got1<sup>M</sup>*, monomorphic in all stocks examined and *Got1<sup>lo</sup>* an ethyl methanesulfonate-induced allele with low activity; *Got1<sup>lo</sup>* homozygotes normal in viability and fertility.

**cytology:** Located at 52D9-15.

**Got2**

**location:** 2-4.8 [based on 70 *al-cl* recombinants (Cavener and Clegg)].

**references:** Band, 1975, Genetics 80: 761-71.

Cavener and Clegg, 1976, J. Hered. 67: 313-14.

Grell, 1976, Genetics 83: 753-64.

Chase and Kankel, 1987, J. Neurobiol. 18: 15-41.

**phenotype:** The structural gene for the more slowly anodally migrating of the two glutamate oxalacetic transaminases. Enzyme is a dimer based on formation of a hybrid molecule.

**alleles:** The most common allele is designated *Got1* by Band, *Got2<sup>4</sup>* by Voelker and Langley (1978, DIS 53: 117), and *Got2<sup>M</sup>* by Grell; we establish *Got2<sup>1</sup>* as the designation.

Kalm, Weaver, DeMarco, MacIntyre, and Sullivan, 1989, Proc. Nat. Acad. Sci. USA 86: 5020-24.

**phenotype:** The structural gene for α glycerol-3-phosphate dehydrogenase (NAD<sup>+</sup>) [α GPDH (EC 1.1.1.8)], a homodimer with subunit molecular weight 31700 (Collier, Sullivan, and MacIntyre, 1976, Biochim. Biophys. Acta 429: 316-23). Purification and structural analysis of enzyme by Niesel, Bewley, Miller, Armstrong, and Lee (1980, J. Biol. Chem. 255: 4073-80). Three isozymes designated GPDH-1, GPDH-2, and GPDH-3 in order of decreasing rate of migration toward the anode (Wright and Shaw, 1968, Biochem. Genet. 3: 343-53). The three forms respond alike to electrophoretic alleles, null alleles, and dosage of *Gpdh*<sup>+</sup> (Bewley, Rawls, and Lucchesi, 1974, J. Insect. Physiol. 20: 153-75); all three are products of the same structural gene for developmental profile (see Bewley, 1981, Dev. Genet. 113-29). GPDH-1 first appears in late pupae and is present in high concentration in the adult thorax where it functions to provide energy for flight muscles; GPDH-2 also appears in late pupae and is present in low concentration throughout the fly; GPDH-3 is present throughout the life cycle; it is concentrated in the larval fat body (Reichsteiner, 1970, J. Insect. Physiol. 16: 1179-92) and the adult abdomen (Wright and Shaw); GPDH-1 and GPDH-3 present in equal amounts in adult head. Product of paternally inherited allele first appears at 22 hr, just

before hatching of larva (Wright and Shaw). GPDH-1 is stable at 50° but decays at 57°; GPDH-3 is labile at 50° (Bewley *et al.*). Studies by Bewley and Luccesi indicate the presence of a heat-labile RNase-resistant factor in crude larval extracts able to convert GPDH-1 into GPDH-2 and GPDH-3 but not *vice versa*; GPDH-3 lacks three C-terminal amino acids present on GPDH-1 (Niesel, Bewley, Miller, Armstrong, and Lee, 1980, J. Biol. Chem. 255: 4073-80). Homozygotes for null alleles are fertile, show reduced viability, and are unable to sustain flight (O'Brien and MacIntyre, 1972, Genetics 71: 127-38); ultrastructural integrity of flight muscle sarcosomes degenerates prematurely [O'Brien and Shimada, 1974, J. Cell Biol. 63: 864-82 (fig.)]. Homozygous stocks maintained for 25 generations regain the ability to fly despite continued absence of GPDH activity (O'Brien and Shimada).

**alleles:** Natural populations are polymorphic for electrophoretic variants as well as for regulatory elements that determine enzyme level; induced electromorphs have also been recovered. These variants are tabulated first.

allele	synonym	origin	mobility
<b>Gpdh<sup>A</sup></b>	<i>Gpdh<sup>2</sup></i> , <i>Gpdh<sup>F</sup></i> , <i>Gpdh<sup>R</sup></i>		Fast
<b>Gpdh<sup>B</sup></b>	<i>Gpdh<sup>A</sup></i> , <i>Gpdh<sup>S</sup></i>		Slow
<b>Gpdh<sup>C</sup></b>	$\alpha$ <i>Gpdh-1<sup>CC</sup></i>	EMS( <i>Gpdh<sup>B</sup></i> )	Slower
<b>Gpdh<sup>D</sup></b>			
<b>Gpdh<sup>H</sup></b> $\alpha$			
<b>Gpdh<sup>L</sup></b> $\alpha$			
<b>Gpdh<sup>P</sup></b>		EMS( <i>Gpdh<sup>B</sup></i> )	
<b>Gpdh<sup>UF</sup></b>		spont	Faster

$\alpha$  *Gpdh<sup>H</sup>* and *Gpdh<sup>L</sup>* determine high versus low rates of accumulation of GPDH-3 in both larvae and adults (Bewley, Dev. Genet. 2: 113-192). Bewley attributes this polymorphism to a separate regulatory gene, *Gdt-3*, but we prefer to designate the alternatives as alleles of *Gpdh* based on Bewley's finding that their effect is *cis* acting and his inability to separate them from *Gpdh* genetically. *Gpdh<sup>H</sup>* has been found in association with both *Gpdh<sup>A</sup>* (*Gpdh<sup>HA</sup>*) and *Gpdh<sup>B</sup>* (*Gpdh<sup>HB</sup>*), whereas *Gpdh<sup>L</sup>* has been found only with *Gpdh<sup>A</sup>* (*Gpdh<sup>LA</sup>*). The physical properties of the enzymes produced under the control of these two regulatory elements are identical (Shaffer and Bewley, 1983, J. Biol. Chem. 258: 10027-33). Control postulated at the level of transcription (Wilkins, Shaffer, and Bewley, 1982, Dev. Genet. 3: 129-42).

**cytology:** Placed in 25F5 by deficiency analysis (Kotarski, Pickert and MacIntyre, 1983, Genetics 105: 371-86) and

in 26A (distal) by *in situ* hybridization to the salivaries (Cook *et al.*, 1986).

**molecular biology:** Genomic and cDNA clones of the gene have been isolated (Cook *et al.*, 1985, 1986, 1988), and the genomic and predicted amino acid sequences determined (Cook *et al.*, 1988; Kalm *et al.*, 1989). The transcript of *Gpdh<sup>+</sup>* is about 4.9 kb in length and is composed of eight exons interrupted by seven introns. There is a tandem duplication of a portion of the coding region. The duplication is truncated at the 5' end and is polymorphic in natural populations [Koga, Kusakabe, Tajima, Harada, Bewley and Mukai, 1988, Proc. Japan Acad. 64 (B): 9-12]. The DNA sequence data predict three transcripts, each differing in the 3' untranslated region (Cook *et al.*, 1988). Poly(A) site selection may occur in exon 6, exon 7, or exon 8, producing mRNAs of different size ranges from alternate splicing pathways and producing three different isozymes (GPDH-1, GPDH-2, GPDH-3) differing in the amino acid sequences at their COOH-terminal ends although encoded by the same structural gene (Skuse and Sullivan, 1985; Cook *et al.*, 1988). Each transcript and each isozyme is tissue-specific in its expression. The amino acid sequence at the COOH terminal end of GPDH-3 is Asn-His-Glu-His-Met-COOH; the sequence of GPDH-1 is extended by the three amino acid sequence Glu-Asn-Leu-COOH. *Xenopus laevis* oocytes injected with poly(A)+ RNA from *Drosophila melanogaster* direct synthesis of two immunologically-related proteins, a 32-kd protein from *Gpdh<sup>+</sup>* and a 34-kd protein from a CRM-null *Gpdh* mutant (Wright *et al.*, 1985).

**other information:** A series of *Gpdh-Gpo* double mutants were constructed by Davis and MacIntyre (1988, Genetics 120: 755-66); four of these mutants were found to be viable and flightless; two others were allele-dependent synthetic lethals. A *trans* acting regulatory element tightly linked to the *Gpdh* locus has been isolated in a natural population of *Drosophila melanogaster* in Tasmania (Gibson, Wilks, Cao and Freeth, 1986, Experientia 42: 191-92). Flies homozygous for second chromosomes carrying the element (designated *H31*) have half the GPDH activity of normal homozygotes.

There are a number of spontaneous and induced amorphic and hypomorphic alleles. These are tabulated also.

$\alpha$  1 = Bewley, DeZurille, and Pagelson, 1980, Mol. Gen. Genet. 178: 301-308; 2 = Burkhart, Montgomery, Langley, and Voelker, 1984, Genetics 107: 295-306; 3 = Kotarski, Pickert, Leonard, LaRosa, and MacIntyre, 1983, Genetics 105: 387-407; 4 = Lee, Niesel, and Bewley, 1980, Biochem. Genet. 18: 1003-18; 5 = Mukai and Cockerham, 1977, Proc. Nat. Acad. Sci. USA 74: 2514-17; 6 = Racine, Langley, and Voelker, 1980, Environ. Mutagen. 2: 167-77.

$\beta$  Cross reacting material measured by a) rocket immunoelectrophoresis (numerical values), b) immunoprecipitation (++) or c) radioimmune assay (+).

$\gamma$  Activity measured in some studies (numerical values); merely noted in others (+ or -).

$\delta$  Mobility measurable directly in mutants with residual enzyme activity and indirectly in nulls that form an active heterodimer. + = heterodimer formed but mobility not noted. - = no active heterodimer.

$\epsilon$  *Gpdh* <sup>JH253</sup> and *Gpdh* <sup>JH254</sup> probably independent recoveries of same mutant.

**Gpo:  $\alpha$ -Glycerophosphate oxidase**

location: 2-75.5.

references: O'Brien and MacIntyre, 1972, Biochem Genet. 7: 141-61.

O'Brien and Gethmann, 1973, Genetics 75: 155-67.

Davis and MacIntyre, 1988, Genetics 120: 755-66.

phenotype: The structural gene for sn-glycerol-3-

phosphate oxidoreductase [ $\alpha$ GPO (EC 1.1.99.5)], a 100,000 dalton protein localized on the inner mitochondrial membrane.

alleles: *Gpo* mutants were induced by ethyl methanesulfonate; a hypomorphic allele *Gpo* <sup>n318</sup> and an almost null mutant *Gpo* <sup>n322</sup> were recovered (Davis and MacIntyre, 1988), both viable but flightless.

**cytology:** Localized to 52C9-D3 by deficiency analysis (Davis and MacIntyre) since included in *Df(2R)WVG = Df(2R)52A4-B1;52D7-E1* but in neither *Df(2R)XTE18 = Df(2R)51E3-4;52C9-D1* nor *Df(2R)KL9 = Df(2R)52D3;-52D7-9*.

**other information:** A series of *Gpdh-Gpo* mutants were constructed (Davis and MacIntyre, 1988); four of these mutants were viable but flightless; two others were allele-dependent synthetic lethals.

**Gpt: Glutamate pyruvate transaminase**

**location:** 1-42.6.

**references:** Leigh Brown and Voelker, 1980, *Biochem. Genet.* 18: 303-09.

**phenotype:** Structural gene for glutamate-pyruvate transaminase [GPT (EC 2.6.1.2)]. Molecular weight is 87,000 daltons, and similar to the enzyme from other sources, it is most likely dimeric in structure (Leigh Brown, 1980, *DIS* 55: 82-84). Homozygotes exhibit three bands of activity on starch gels, which could represent different degrees of binding of a pyridoxal phosphate ligand to the enzyme.

**alleles:** Three alleles designated *Gtp*<sup>2</sup>, *Gtp*<sup>4</sup>, and *Gtp*<sup>6</sup> in order of increasing electrophoretic mobility in starch gel.

**cytology:** Placed in region 11F1 through 12A2 based on its inclusion in *Df(1)C246 = Df(1)11D;12A1-2* but not *Df(1)N12 = Df(1)11D1-2;11F1-2*.

**\*gr: gracile**

**location:** 1-36.4.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1959, *DIS* 37: 86.

**phenotype:** Small fly with narrow abdomen. Wings frequently held atypically, either upward or downward. Very inviable, many dying less than 24 hr after eclosion; males sterile. RK3.

*gr*: see *grt*

*gra*: see *grn*

**gra: gravel**

**location:** 1-28.5.

**origin:** Spontaneous.

**references:** Thompson, 1973, *DIS* 50: 59 (fig.).

**phenotype:** Eye texture rough owing to irregularly arranged and roughened facets. Suppresses *ve*, making veins L2, L3, and usually L4 complete; in *ve*<sup>+</sup> flies produces extra vein segments in the marginal, distal, and second and third posterior cells.

**gracile:** see *gr*

**grain:** see *grn*

**grandchildless:** see *gs*

**grandchildless on chromosome 2 of Mariol:**  
see *gs(2)M*

**gravel:** see *gra*

**\*gre: green body color**

**location:** 1- (not located).

**origin:** Spontaneous.

**discoverer:** Bridges, 13e.

**references:** Morgan and Bridges, 1916, Carnegie Inst.

Washington Publ. No. 237: 73.

**phenotype:** Body color tinged greenish black with marked trident pattern. Overlaps wild type. RK3.

**other information:** Possibly an allele of *ptg*.

**grg: giant ring gland**

**location:** 1-17.0.

**origin:** Induced by triaziquone.

**synonym:** *l(1)grg*.

**references:** Klose, 1980, *Wilhelm Roux's Arch. Dev. Biol.* 189: 57-67.

**phenotype:** Recessive lethal; third larval instar protracted. Ring gland enlarged, and neurosecretory cells of brain abnormal. Ecdysteroid levels low; not correctable by exogenous hormone.

**grk: gurken**

**location:** 2-30.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach, 1987, *Cell* 49: 699-707.

**phenotype:** Maternal-effect lethal. Wild-type allele required for normal dorsoventral pattern in the egg. In mutants, the ventral regions of the chorion and the embryo are expanded at the expense of the dorsal regions. The pattern of the chorion is altered, a second micropyle and a small patch of operculum-like material often forming at the posterior pole in extremely mutant eggs; fewer cells contribute to the dorsal appendage, which is usually shifted posteriorly, but more follicle cells contribute to the main body of the chorion. In the embryo the major increase in cell mass occurs in the mesoderm as an invagination on the ventral side during early gastrulation. Analysis of mosaic females in which germ cells and sister nurse cells are of different genotype indicate that *grk* mutations act only in the germ line.

**alleles:**

allele	synonym	phenotype of eggs and embryos
<i>grk</i> <sup>1</sup>	<i>grk</i> <sup>DC</sup>	intermediate and strong
<i>grk</i> <sup>2</sup>	<i>grk</i> <sup>HG</sup>	weak and intermediate
<i>grk</i> <sup>3</sup>	<i>grk</i> <sup>HK</sup>	intermediate and strong
<i>grk</i> <sup>4</sup>	<i>grk</i> <sup>HL</sup>	intermediate and strong
<i>grk</i> <sup>5</sup>	<i>grk</i> <sup>QI</sup>	mostly intermediate, but can vary from weak to strong
<i>grk</i> <sup>6</sup>	<i>grk</i> <sup>WG</sup>	mostly intermediate but can vary from weak to strong

**cytology:** Placed in 29C.

**grn: grain**

**location:** 3-47.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *gra*.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95 (fig.).

**phenotype:** Homozygous lethal; filzkörper or embryo not elongated; head skeleton defective.

**alleles:** Two.

*gro*: see *E(spl)*<sup>2</sup>

**grooved:** see *gv*

**grooveless:** see *gvl*

**grotle:** see *grt*

*groucho*: see *E(spl)*<sup>2</sup>

**grounded**: see *gnd*

**grt: grotle**

**location**: 1-64 [Recombination tests by Roberts and Hewitt place *grt* 15.3 cM to the right of *f*; however, it is to the left of *ot* at 1-65.7, since it is not covered by *y*<sup>+</sup>*Ymal106* which does cover *ot* (Schalet, 1972, DIS 49: 36)].

**origin**: Spontaneous.

**synonym**: *gr* (preoccupied).

**references**: Roberts and Hewitt, 1969, DIS 44: 49.

**phenotype**: Homozygotes and heterozygotes have wing abnormalities with variable expression. Extreme expression, wings with fluid-filled sac covering 75% of wing area, leaving wings crumpled when sac bursts; weak expression, small blisters and incised margins of posterior cells on wings. Penetrance complete.

**cytology**: Distal to region 19 based on failure of *y*<sup>+</sup>*Ymal*<sup>106</sup> to cover *grt* (Schalet, 1972, DIS 49: 36; Schalet and Lefevre, 1973, Chromosoma 44: 183-202).

*gs*: see *gv*

**gs: grandchildless**

**location**: 1-21 (less than 1cM to the right of *ct*).

**origin**: Induced by ethyl methanesulfonate.

**references**: Thierry-Mieg, Masson, and Gans, 1972, C.R. Hebd. Seances. Acad. Sci. Ser. D 175: 2751-54.

Thierry-Mieg, 1976, J. Microsc. Biol. Cell 25: 1-6.

**phenotype**: Homozygous females normal in appearance. When oogenesis in such females proceeds at 28.5° 80-85% of the eggs cease development before the blastoderm stage. Most embryos reaching gastrulation continue development normally except for the frequent absence of pole cells; 11-15% of surviving adult progeny have agametic gonads; if the maternal females are also homozygous for an X-linked modifier, *mod*, the incidence of agametic survivors increases to 60-65%. Oogenesis at 10° leads to 62% hatch and 6-10% agametic, which is decreased to <3% in the presence of homozygous *mod*. Outcome not influenced by genotype of father. The temperature-sensitive period for survival of zygotes produced by *mod gs* females is monophasic extending from stages 9 to 14 of oocyte development, whereas that for agametic gonads is diphasic with one sensitive period at stages 6-7 and the other more severe period from stages 10-14; stages 7-9 temperature insensitive. The histology of agametic gonads of both males and females resemble those produced by ultra-violet irradiation of embryonic pole cells (Lauge, Sauphanov, and Randrianandrianina, 1977, C.R. Hebd. Seances Aca. Sci. Ser. D 284: 1187-89).

**gs(1)N26**

**location**: 1-33.8.

**origin**: Induced by ethyl methanesulfonate.

**references**: Niki and Okada, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 1-10 (fig.).

Niki, 1984, Dev. Biol. 103: 182-89 (fig.).

**phenotype**: Fecundity and fertility of homozygous females low; mortality of sons higher than that of daughters. Fraction of surviving progeny agametic depends on temperature of oogenesis; 93% agametic at 25°, 56% agametic at 18°. In eggs produced at 25° migration of nuclei to posterior pole abnormal; almost no pole cells

produced in half the embryos. Polar granules present in posterior egg cytoplasm, defects in failure of nuclear migration.

**gs(1)N41**

**location**: 1-39.6.

**origin**: Induced by ethyl methanesulfonate.

**synonym**: *gs(1)N441*.

**references**: Nikki and Okada, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 1-10 (fig.).

**phenotype**: Fecundity and fertility of homozygous females normal. 71% and 19% agametic progeny when females raised at 25° and 18°, respectively. Peripheral migration of nuclei at blastoderm formation normal; pole cell formation inhibited. Temperature sensitive period extends from stages 9-13 of oocyte development.

**gs(2)M: grandchildless on chromosome 2 of Mariol**

**location**: 2- (between *S* and *Sp*).

**origin**: Induced by ICR-170.

**references**: Mariol, 1981, Mol. Gen. Genet. 181: 505-11.

**phenotype**: At 28.5°, homozygous females lay normal numbers of eggs but about 20% fail to hatch and about 40% die just after hatching; these mostly lack pole cells. A fraction of the surviving embryos are also devoid of pole cells and develop into adults with agametic gonads. Abnormalities most frequent in 8-12-day-old females. Paternal genotype without influence. At 16°, 75% of eggs hatch and develop into normal fertile adults. Last four days of oogenesis at 28.5° temperature insensitive. Incidence of agametic progeny increases with successive generations of homozygosity of mothers from one to four, constant thereafter; one generation of heterozygosity returns level to ground state.

**gsb: gooseberry**

**location**: 2-107.6.

**origin**: Induced by ethyl methanesulfonate.

**references**: Nüsslein-Volhard and Wieschaus, 1980, Nature (London) 287: 795-801 (fig.).

Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82 (fig.).

Bopp, Burri, Baumgartner, Frigerio and Noll, 1986, Cell 47: 1033-40.

Baumgartner, Bopp, Burri and Noll, 1987, Genes Dev. 1: 1247-67.

Côte, Preiss, Haller, Schuh, Kienlin, Seifert, and Jäckle, 1987, EMBO J. 6: 2793-801.

Perrimon and Mahowald, 1987, Dev. Biol. 119: 587-600.

**phenotype**: Homozygous lethal; embryos show segment-polarity defects. The posterior portion of each segment is deleted and the anterior portion duplicated in mirror image fashion; the ventral segments are almost entirely covered with denticles, the posterior fraction of which point anteriorly. Segment boundaries persist normally and segments maintain their individuality. The mutants show alterations in the identity of neurons, both underneath and outside the modified ectoderm (Patel, Schafer, Goodman, and Holmgren, 1989, Genes Dev. 3: 890-904); posterior commissures are almost totally absent.

**alleles**: No point mutations were obtained in embryonic lethal screens by Nüsslein-Volhard *et al.*, 1984, or Côte *et al.*, 1987.

**cytology:** Placed in 60E9-F1 (Nüsslein-Volhard *et al.*, 1984) since uncovered by *Df(2R)gsb = Df(2R)60E9-10;60F1-2*.

**molecular biology:** Wild-type *gsb* function provided by two closely-linked duplicated genes, the proximal *gsb-p* (=BSH4) and the distal *gsb-d* (=BSH9) (Bopp *et al.*, 1986; Baumgartner *et al.*, 1987; Côté *et al.*, 1987). These *gsb* genes were mapped by microdissection and microcloning of bands in the 60E9-60F1 region followed by chromosome walking from the proximal breakpoint of *Df(2R)SBI* to the distal breakpoint of *Df(2R)gsb*. The *gsb-p* transcript is made up of five exons and is transcribed in the opposite direction from the two-exon *gsb-d* transcript. The almost complete DNA sequence and corresponding amino acid sequence of the putative protein has been obtained for the two *gsb* genes (Baumgartner *et al.*, 1987). The longest open reading frame of *gsb-p* would encode a protein of 452 amino acids; the longest ORF of *gsb-d* would encode a protein of 427 amino acids.

### **Gsl: Glutamine synthetase I**

**location:** 2-{0}.

**references:** Scalenghe and Ritossa, 1976, Atti Accad. Naz. Lincei. Cl. Sci. Fis. Nat. Rend. 13: 439-538.

Caizzi and Ritossa, 1983, Biochem. Genet. 21: 267-85.

Caggese, Caizzi, Bozzetti, Barsanti, and Ritossa, 1988, Biochem. Genet. 26: 571-84.

**phenotype:** Structural gene for glutamine synthetase I [GS (EC 6.3.1.2)] in *Drosophila melanogaster*. The enzyme catalyzes the formation of glutamate and ammonia by cleaving ATP into ADP and phosphate (Caggese *et al.*, 1988). The GSI protein was purified from *Drosophila* larvae (Scalenghe and Ritossa, 1976; Caggese and Ritossa, 1983); it is a multimer of two subunits (MW 43,000 and 64,000) (Caggese and Ritossa, 1983); the 43,000 dalton protein is usually the more abundant. The molecular weight for the complete enzyme is apparently 380,000. A fast electrophoretic variant (*Gsl<sup>f</sup>*), an intermediate and common electrophoretic variant (*Gsl<sup>c</sup>*), and a slow electrophoretic variant (*Gsl<sup>s</sup>*) have been found. Hybrids between variants show a strongly stained intermediate band (Caggese *et al.*, 1988). The GSI protein but not the GSII protein is found in the epidermis of *Drosophila* (Scalenghe and Ritossa, 1976).

**alleles:**

**cytology:** Located in 21B3-6 since between proximal breakpoints of *Df(2L)PMI = Df(2L)21A1;21B3-5* and *Df(2L)PMG = Df(2L)21A1-2;21B4-6*.

**molecular biology:** *Gsl* and *GsII* show partial DNA identity with each other and with the DNA from the hamster (De Pinto, Caggese, Prezioso, and Ritossa, 1987, Biochem. Genet. 25: 821-36).

**other information:** Mutations in *Gsl* do not affect the

GSII enzyme (Caggese *et al.*, 1988).

### **GsII: Glutamine synthetase II**

**location:** 1-{34}.

**references:** Scalenghe and Ritossa, 1976, Atti Accad. Naz. Lincei. Cl. Sci. Fis. Nat. Rend. 13: 439-538.

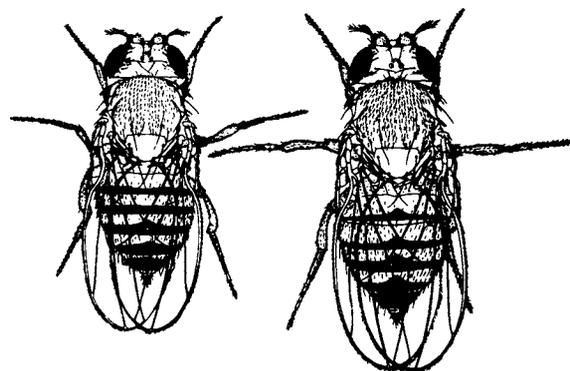

Caggese, Caizzi, Grieco, Bozzetti, and Ritossa, 1986, Mol. Gen. Genet. 204: 208-13.

De Pinto, Caggese, Prezioso, and Ritossa, 1987, Biochem. Genet. 25: 821-36.

**phenotype:** Structural gene for glutamine synthetase II. Completely separable from glutamine synthetase I by DEAE chromatography. The GSII protein was purified from adult *Drosophila* (Scalenghe and Ritossa, 1976) and was isolated by sequence identity with the hamster gene (De Pinto *et al.*, 1987). The enzyme is a multimer of a single subunit (MW 42,000). The complete enzyme has an approximate molecular weight of 360,000 and differs from the GSI enzyme in both subunit molecular weight and in isoelectric point. 90% of glutamine synthetase activity is due to GSII, which is the most abundant adult form.

**cytology:** Located in 10B8-11 by *in situ* hybridization. Variation in the dose of a chromosomal segment from 9F3 to 10C1-2 results in proportional variation in the amount of the GSII enzyme without influencing the amount of GSI (Caggese *et al.*, 1986).

**molecular biology:** Shows partial DNA identity with *Gsl* and with the hamster gene (De Pinto *et al.*, 1987).

### **gt: giant**

Left: wild type female. Right: *giant* female.

From Bridges and Gabritschevsky, 1928, Z. Indukt. Abstamm. Vererbungsl. 46: 231-47.

### **gt: giant**

**location:** 1-0.9 (0.04 cM to the left of *tko*).

**origin:** Spontaneous.

**discoverer:** Gabritschevsky, 25i2.

**references:** Bridges and Gabritschevsky, 1928, Z. Indukt. Abstamm. Vererbungsl. 49: 231-47 (fig.).

Gabritschevsky and Bridges, 1928, Z. Indukt. Abstamm. Vererbungsl. 49: 248-84.

Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

Narachi and Boyd, 1985, Mol. Gen. Genet. 199: 500-06.

Petschek, Perrimon and Mahowald, 1987, Dev. Biol. 19: 175-89.

Mohler, Eldon and Pirrotta, 1989, EMBO J. 8: 1539-48.

**phenotype:** Larval development 4 days longer than normal resulting in giant larvae, pupae, and imagoes. Adult weight 1.7 times normal; increased size caused by increase in cell size and not cell number [Simpson and Morata, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall and Hall, eds.). Plenum Press, New York and London, pp. 129-40]. Pupariation delayed owing to delayed increase in ecdysteroid titers; level reached at pupariation lower than normal; pupal interval of normal length (Schwartz, Imberski, and Kelly, 1984, Dev. Biol. 103: 85-95). Not all genetically giant flies show the giant character, the rest have normal size; distribution sharply bimodal. Percentage giant greatest in well-fed cultures, also raised by modifying action of *bb<sup>11</sup>*. Penetrance of viable alleles enhanced in heterozygotes with lethal alleles and deficiencies; viability decreased (Kaufman, 1972, Genetics 71: s28-29). Abnormalities in DNA metabolism found in homo- or heteroallelic third instar *gt* females (Narachi and Boyd, 1985). Salivary gland chromosomes of double thickness in some cells (Bridges, 1935, J. Heredity 26: 60-64). Feulgen staining shows extra round of DNA synthesis; polytene chromosome can be analyzed in *gt/Df* larvae (Kaufman, 1972, Genetics 71: s28-29). Embryos carrying lethal giant mutations have defects in the anterior and the posterior domains (Petschek *et al.*, 1987; Mohler *et al.*, 1989). Posterior compartment of the labial segment deleted from blastoderm; cell death at germ-band elongation deletes anterior compartments of abdominal segments 5-7. Posterior-compartment structures of A5-7 in the peripheral nervous system fuse in mature embryos (Petschek and Mahowald). Hemizygotes for lethal alleles, *gt<sup>13z</sup>* and *gt<sup>X11</sup>*, fail to hatch (Kaufman, 1973, Genetics 74: s133); denticle belts of the fifth through the seventh abdominal segments partially or completely absent; internally corresponding neuromeres absent; eight abdominal neuromeres disconnected from remainder. Head does not complete involution, shows characteristic "buttonhead" phenotype with ventral skeleton extruded from the anterior end of the larva (Mohler *et al.*, 1989), pharynx and pharyngeal chitinized sclerites shorter, and brain lobes somewhat smaller than normal; extensive cell death in epidermal and neural components of embryo (Honisch and Campos-Ortega, 1982, DIS 58: 76-77). Effect cell autonomous in mosaic embryos. (Gergen and Wieschaus, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 49-62). Germline clones viable (García-Bellido and Robbins, 1983, Genetics 103: 235-47). *gt* stocks (homo- or heteroallelic) show an increase in the frequency of spontaneous mutations, including deletions of *y* and *w* loci (Green, 1982, Proc. Nat. Acad. Sci. USA 79: 5367-69); these stocks also synthesize DNA of a reduced molecular weight and show many single-strand and double-strand breaks, suggesting abnormalities in DNA metabolism (Narachi and Boyd, 1985). RK3.

**alleles:** In addition to those tabulated, Wieschaus, Nüsslein-Volhard, and Jürgens (1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307) report eight embryonic lethal alleles, of which four are weak; these exhibit defects in head and in fifth through seventh abdominal

segments.

<sup>α</sup> 1 = Bridges and Gabritschevsky, 1928, Z. Indukt. Abstamm. Vererbungsl. 49: 231-47 (fig.); 2 = Dutttagupta, Das, and Dutta, 1984, DIS 60: 90-91; 3 = Gabritschevsky and Bridges, 1928, Z. Indukt. Abstamm. Vererbungsl. 49: 248-84; 4 = García-Bellido and Robbins, 1983, Genetics 103: 235-47; 5 = Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56; 6 = Kaufman, 1972, Genetics 71: s28-29; 7 = Liu and Lim, 1975, Genetics 79: 601-11; 8 = Mohler, Eldon and Pirrotta, 1989, EMBO J. 8: 1539-48; 9 = Petschek, Perrimon and Mahowald, 1987, Dev. Biol. 19: 175-89.

<sup>β</sup> Associated with two inserts of DNA into the *gt* locus, one near +17 and the other near +32 on the molecular map (Mohler *et al.*, 1989).

<sup>γ</sup> N-methyl-N<sup>1</sup>-nitro-N-nitrosoguanidine.

<sup>δ</sup> *Tp(1;1)2 = Tp(1;1)3A2;8D;10B1*; weak lethal allele induced by irradiation (Mohler *et al.*, 1989).

**cytology:** Placed in 3A2 by Judd, Shen, and Kaufman, 1972, Genetics 71: 139-56; and Lefevre, 1981, Genetics 99: 461-80; later placed in 3A1 by Mohler *et al.*, 1989.

**molecular biology:** Rearrangement breakpoints associated with *gt* were positioned on the genomic clone map of Mariani, Pirrotta, and Manet (1985, EMBO J. 4: 2045-52). Mohler *et al.*, 1989, report confirmation of the cloning of *gt* by partial rescue with *P*-elements. The region from +18 to +21 on the molecular map is practically identical to a 1.9 kb RNA expressed in 2- to 4-hour embryos but barely detectable in 4- to 6-hour embryos; this region is included in the DNA fragment used in the complete rescue of the abdominal segmentation defects of the giant mutant *gt<sup>X11</sup>* (Mohler *et al.*, 1989). Sequencing of the cDNA of *gt* suggests that the gene encodes a novel protein that shows identity to *opa* but not to other pattern-forming genes (Eldon and Pirrotta, 1989).

**other information:** Used by Bridges (1935) in the construction of salivary chromosome maps. Preliminary evidence of interallelic complementation with respect to phenotype and viability presented by Dutttagupta, Das, and Dutta (1984, DIS 60: 90-91).

**\*Gt2: Giant in chromosome 2**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Bridges, 14i28.

**phenotype:** Heterozygote normal but, in presence of

homozygous *gt3*, gives giant, male-sterile flies. Homozygous lethal. RK3.

**\*gt3: giant in chromosome 3**

**location:** 3-64.

**origin:** Spontaneous.

**discoverer:** Bridges, 14i28.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 120 (fig.).

**phenotype:** Body size much larger than normal. Late hatching. Entirely sterile in male. Giant character produced only in flies homozygous for *gt-3* and heterozygous for *Gt-2*. RK3.

**gt4**

**location:** 2-24.0.

**origin:** Spontaneous.

**discoverer:** Bridges, 30b14.

**phenotype:** Giant flies hatch very late. Viability variable but around 15% wild type. RK3.

**\*gtd: giantoid**

**location:** 1-0.5.

**origin:** Spontaneous.

**discoverer:** Bridges, 21c12.

**references:** Bridges and Gabritschewsky, 1928, Z. Indukt. Abstamm. Vererbungsl. 46: 232 (fig.).

**phenotype:** Body size larger, especially head. Late hatching. Viability erratic, about 50% wild type. Separation difficult in females, easier in males. RK3.

**gua1: guanosine requiring**

**location:** 1-31.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *gual-1<sup>ts</sup>*.

**references:** Falk and Nash, 1974, Genetics 76: 755-56.

**phenotype:** A temperature-sensitive guanosine auxotroph. Hemizygous viability on guanosine-free medium reduced at 25°; virtually lethal at 29° although completely supplementable at that temperature. Normal allele thought to function in the conversion of inosinic acid to guanic acid.

**cytology:** Placed in 9D1-E1 by deficiency analysis; temperature sensitive on minimal medium in combination with *Df(1)ras-v = Df(1)9D1-2;10A2-3*, but not *Df(1)v<sup>64f</sup> = Df(1)9E7-8;10A2-3* or *Dp(1;2)v<sup>63i</sup> = Dp(1;2)9D4-E1;10A11-B1;56A* (Johnson, Woloshyn, and Nash, 1979, Mol. Gen. Genet. 174: 287-92). This small region carries in addition *pur1*, *ras*, and lethals, which fail to complement the other three loci (Nash, Woloshyn, and Janca, 1979, Genetics 92: s87).

**gus: gustatory (J. C. Hall)**

A series of ethyl-methanesulfonate-induced taste mutants selected by Tompkins *et al.*, 1979. All mutants were crudely mapped and complementation tests performed between those mapping to the same interval.

**references:** Tompkins, Cardoza, White, and Sanders, 1979, Proc. Nat. Acad. Sci. USA 76: 884-86.

mutant	location	alleles
<i>gusA</i>	1- (v - f)	<i>gusA<sup>Q1</sup></i> , <i>gusA<sup>Q2</sup></i> , <i>gusA<sup>Q3</sup></i> , <i>gusA<sup>Q4</sup></i>
<i>gusC</i>	1- (cv - v)	<i>gusC<sup>N10</sup></i>
<i>gusD</i>	1- (v - f)	<i>gusD<sup>N9</sup></i> , <i>gusD<sup>N12</sup></i>
<i>gusE</i>	1- (v - f)	<i>gusE<sup>N1</sup></i>

**gusA**

**phenotype:** Attracted to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>), unlike wild type, which is repelled; normal aversion to sodium chloride (NaCl). One allele, *gusA<sup>Q1</sup>*, leads to cold-sensitive phenotype, in that larvae or adults, raised at 22°, show the aberrant attraction to quinine, but when raised at higher temperatures, these animals show normal behavior; the temperature-sensitive period of *gusA<sup>Q1</sup>* is during embryogenesis (Tompkins, 1979, Dev. Biol. 73: 174-77).

**other information:** Not allelic to *gusD* or *gusE*.

*gusB*: see *gustC*

**gusC**

**phenotype:** Attracted to sodium chloride (NaCl), unlike wild type, which is repelled; normal aversion to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>).

**gusD**

**phenotype:** Attracted to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>) and to sodium chloride (NaCl), unlike wild type, which is repelled by both.

**other information:** Not allelic to *gusA* or *gusE*.

**gusE**

**phenotype:** Attracted to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>) and to sodium chloride (NaCl), unlike wild type, which is repelled by both; larval chemosensory behavior normal; is cold-sensitive, such that exposure of third larval instar to 22° (but not higher temperatures) results in aberrantly responding adults (Tompkins, 1979, Dev. Biol. 73: 174-77).

**other information:** Not allelic to *gusA* or *gusD*.

*gusF*: see *gustB*

**gust: gustatory defective (J.C. Hall)**

Another series of ethyl-methanesulfonate-induced taste mutants that affect the fly's responses to attractants and repellents. All mutants were crudely mapped and complementation tests performed between those mappings to the same interval. Complementation tests with *gus* mutants were also performed. Sodium chloride (NaCl) elicits responses from two sensory neurons (L1 and L2) in each taste sensillum; another sensory neuron (S) involved in response to sugars (Siddiqi, Joshi, Arora, and Rodrigues, 1989, Genome 31: 646-51). A fourth neuron is inhibited by sodium chloride (NaCl) and sugars (Arora *et al.*, 1987).

Sci. 87B: 147-60; 4 = Siddiqi, Joshi, Arora, and Rodrigues, 1989, Genome 31: 646-51; 5 = Siddiqi and Rodrigues, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall.), Plenum Press, New York, pp. 347-59.

<sup>β</sup> Cytological location between 6C11 and 6E4-5 (Siddiqi *et al.*, 1989).

### gustA

**phenotype:** Insensitive to pyranose sugars (C<sub>7</sub>H<sub>12</sub>O<sub>6</sub>), but shows normal response to fructose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) and normal aversion to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>) and sodium chloride (NaCl). Receptor defective mutant (Siddiqi *et al.*, 1989). One type of sense hairs on the labellum shows reduced physiological responses to pyranoses (Rodrigues and Siddiqi, 1981, Mol. Gen. Genet. 81: 406-08); another type of sense hairs is insensitive to the normal inhibition by pyranose sugars.

### gustB

**phenotype:** Originally said to be "indifferent" to sodium chloride (NaCl), but now known to give positive responses (greater than wild type) to this salt in the feeding preference test which consist of behavioral (proboscis extension) and physiological (labellar recording) responses (Arora). Responds normally to sucrose (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>) and quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>). In this mutant, the S neuron, usually involved in the sugar response, is excited by sodium chloride (NaCl) (Arora *et al.*, 1987). Two forms of alpha-glucosidase activity (enriched in tarsal leg segments relative to other tissues in wild type) are lower than normal in two of the *gustB* alleles (unspecified) (Bhavsar, Rodrigues, and Siddiqi, 1983, J. Biosci. 5: 279-87).

**cytology:** Placed in 10E1 since included in *Df(1)m259-4 = Df(1)10C2-3;10E1-2* and *Df(1)KA6 = Df(1)10E1;11A7-8* (Arora *et al.*, 1987).

**other information:** Allelic to *gusF* of Tompkins, Cardoso, White, and Sanders (1979, Proc. Nat. Acad. Sci. USA 76: 884-86).

### gustC

**phenotype:** Originally said to be "indifferent" to sodium chloride (NaCl), but now known to give responses (greater than wild type) to this salt in the feeding preference test (Arora). Indifferent to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>), and sucrose (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>). Also at least one allele (*gustC*<sup>x2</sup>) leads to lower amounts of two forms of alpha-glucosidase activity that are normally found in the legs [and are enriched in the tarsi of these appendages in wild type (Bhavsar *et al.*, 1983)].

**other information:** Allelic to *gusB* (Tompkins *et al.*, 1979).

### gustD

**phenotype:** Insensitive to quinine (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>), but shows normal responses to sucrose (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>) or to sodium chloride (NaCl); both alleles are heat-sensitive, in that rearing at 28°C leads to aberrant responses of adults, but development at low temperature leads to normal-behaving flies; levels of leg-specific alpha-glucosidases are normal or nearly so (Bhavsar *et al.*, 1983).

**other information:** Not allelic to *gusA*, *gusB*, *gusD*, or *gusE*.

### gustE

**phenotype:** No attraction to sodium chloride (NaCl) in feeding tests (*gustE*<sup>v86</sup>); response to potassium chloride (KCl) is the same as in wild type.

### gustF

**phenotype:** Electrophysical sensitivity to both sodium chloride (NaCl) and potassium chloride (KCl) reduced; behavioral characteristics not tested by Siddiqi *et al.*, (1989).

### gustM

**phenotype:** Insensitive to sodium chloride (NaCl) and quinine sulfate (C<sub>20</sub>H<sub>24</sub>N<sub>2</sub>O<sub>2</sub>) in proboscis extension responses (i.e. these substances fail to inhibit the sugar-induced reflex); further behavioral testing, however, reveals abnormally prolonged drinking of salt solutions and attraction to quinine; sugar responses normal.

**cytology:** The mutant is located at 93D and associated with *In(3R)AFA (86C4-5;93D1-2)*; the behavioral abnormalities are uncovered by *Df(3R)e-N12 (93B1-2;93D6-7)*, *Df(3R)e-GC9 (93B11-13;93D9-10)*, and *Df(3R)e-D7 (93C3-6;93F5-8)*, implying that the righthand inversion breakpoint is responsible.

### GustR

**phenotype:** Attracted to sodium chloride (NaCl) but not potassium chloride (KCl); shows reduced attraction to all sugars. L1 neurons involved in sodium chloride (NaCl) response (Siddiqi *et al.*, 1989).

### GustS

**phenotype:** Attracted to sodium chloride (NaCl) but not potassium chloride (KCl); shows reduced attraction to all sugars.

**gustatory:** see *gus*

**gustatory defective:** see *gust*

### \*gv: grooved

**location:** 3-37.3 (based on its position of 0.2cM to the left of *eyg*).

**origin:** Spontaneous.

**discoverer:** Ives, 43128.

**references:** 1946, DIS 20: 65.

**synonym:** *gs: gespleten*.

**phenotype:** A longitudinal medial groove in thorax; in extreme individuals, thorax nearly cleft. Eyes reduced, sometimes missing. Irregular and often extra alar bristles. Viability and fertility good. RK1.

allele	origin	discoverer	synonym	ref <sup>α</sup>

β	Associated with	$ln(3LR)gv^u = ln(3LR)69C1-2;81$ ; homozygous lethal.		

**cytology:** Placed in 69C on the basis of its exclusion from  $Df(3L)vin^7 = Df(3L)68C8-11;69B3-C1$  and the *gv* phenotype of  $gv/ln(3LR)gv^u = ln(3LR)69B5-C4;81$  (Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25).

### ***gvl: grooveless***

**location:** 4-0.2 [in diplo-4 triploids (Sturtevant, 1951, Proc. Nat. Acad. Sci. USA 37: 405-7)].

**origin:** Spontaneous.

**discoverer:** Bridges, 33e10.

**references:** 1935, Biol. Zh. (Moscow) 4: 401-20.

**phenotype:** Short transverse groove between scutellum and thorax is nearly eliminated; no overlap with wild type. Black scars appear on scutellar groove at sides, in pleural region, and behind sternopleurals. Viable and fertile. RK1.

### ***gy: gouty legs***

**location:** 4-0.2.

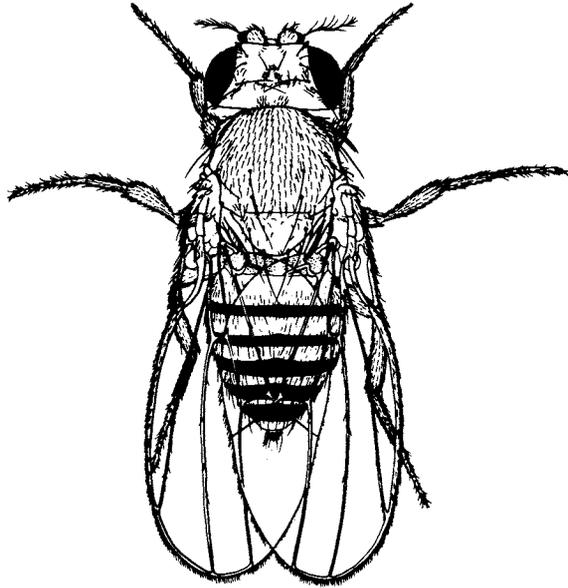

**origin:** Spontaneous.

**discoverer:** Muller.

**references:** 1965, DIS 40: 36.

**phenotype:** Legs shortened and thickened, especially the metatarsi of the hind legs, which are often swollen. Usually classifiable; viability and fertility good.  $gy/ey^D$  is *gy*. RK2.

**cytology:** Tentatively placed at 102B10-E9 between  $Df(4)M4 = Df(4)101E-F;102E2-10$  and tip (Hochman, 1971, Genetics 67: 235-52).

**phenotype:** The pair-rule gene hairy regulates the development of alternate segments in the embryo as well as the spatial expression of another pair-rule gene fushi tarazu (Holmgren, 1984; Carroll *et al.*, 1988; Rushlow *et al.*, 1989). A later phenotypic expression of hairy, the adult bristle pattern, is established during larval and pupal

stages (Nüsslein-Volhard and Wieschaus, 1980; Ingham *et al.*, 1985a, 1985b). In the embryo, *h* mutations delete the posterior part of each odd-numbered segment, weak alleles deleting less than a whole segment and strong alleles deleting regions greater than one segment. In mutant adults, extra microchaetae are found along wing veins, L2 more so than L4 or 5, and on wing membrane; also on dorsal and ventral scutellum and top of head. Extra sensilla present on longitudinal wing veins in a gradient in which sensilla are concentrated proximally and hairs distally; intermediate structures found in the middle (Spivey and Thompson, 1984, Genetics 107: s102). Extra acrostichal row on either side of midline between dorsocentral bristles (Claxton, 1971, DIS 46: 133); also occupy thin arch of cuticle connecting ventral scutellum and pleurae. Microchaetae found on mesopleurae (mean of 13 in males and 20 in females versus none in wild type) and pteropleurae (Murphy, 1972, J. Exp. Zool. 179: 51-62). Used by García-Bellido and Ferrus (1975, Wilhelm Roux's Arch. Dev. Biol. 178: 337-40) to provide cuticular markers on pleurae for fate mapping. Additional hair-forming cells present in 19-hr pupa (Lees and Waddington, 1942, DIS 16: 70). Autonomous expression in clones produced prior to the last eight hr of larval life; clones produced during the last eight hr before pupation exhibit normal phenotype; attributable to perdurance of wild-type gene product (García-Bellido and Merriam, 1971, Proc. Nat. Acad. Sci. USA 68: 2222-26). Reduced *ac*<sup>+</sup> function as in *ac*<sup>3</sup> or *ac*<sup>3/+</sup> suppresses *h* phenotype; extra doses of *ac*<sup>+</sup> enhance *h* expression and can render *h* partially dominant (Sturtevant, 1969, Dev. Biol. 21: 48-61; Botas, Moscoso del Prado, and García-Bellido, EMBO J. 1: 307-10). Three doses of *h*<sup>+</sup> suppress *Hw* (Botas, *et al.*). *h* expression also enhanced by combination with rearrangements that place the *ac-sc* region in juxtaposition with substantial quantities of heterochromation (Green, 1960, Proc. Nat. Acad. Sci. 46: 524-28). Interactions with *sc* alleles detailed by Sturtevant (1969). *h*<sup>2</sup> less severe than and partially complements *h*<sup>1</sup> (Sturtevant). As with *ci*<sup>+</sup>, expression of *h*<sup>+</sup> may be altered in the direction of *h* by rearrangements with breakpoints in the vicinity of the *h* locus (Dubinin and Sidorov, 1934, Biol. Zh. 3: 307-31; see also Jeffrey, 1979, Genetics 91: 105-25). Unlike the *ci* case, however, rearranged *h* chromosomes do not show evidence of altered gene action (Stern, 1944, DIS: 18:56).

<sup>β</sup> Result of *gypsy* insertion (Holmgren, 1984).

<sup>γ</sup> Phenotype described separately; alleles also described in *h*<sup>20</sup>.

<sup>δ</sup> Regulatory mutation causing alterations in hairy expression in cellular blastoderm that result in a partial version of the wild-type pattern (Howard *et al.*, 1988).

**cytology:** Placed in 66D15 on the basis of the *h* phenotypes of many rearrangements with breakpoints between 66D14 and 66E1 (Jeffrey, 1979). Placed in 66D9-11 by Ingham *et al.* (1985) based on the left breakpoint of *T(2;3)h<sup>m1</sup> = T(2;3)66D9-11;41A*.

**molecular biology:** The hairy region was tagged and cloned with the transposing element *gypsy* (Holmgren, 1984) and with *P* elements (Ish-Horowicz *et al.*, 1985). Cloned genes were able to rescue *h* segmentation mutants when introduced into flies by *P*-element transposition (Rushlow *et al.*, 1989). The gene hairy encodes a major transcript of 2.1 to 2.3 kb that is expressed at high levels in 2-4 hr embryos but at lower levels later (Ish-Horowicz *et al.*, 1985; Rushlow *et al.*, 1989) and a minor 2.0 kb transcript that is expressed at low levels in 2-4 hr embryos but at higher levels in larvae and adults. Two other transcripts, 1 kb and 3 kb, have been reported during larval life (Ish-Horowicz *et al.*, 1985); the time of expression and chromosomal origin of these RNAs indicate that they are involved in hairy bristle function. All RNAs are transcribed from distal to proximal and must differ at their 5' ends. Genomic and cDNA sequences have been obtained (Rushlow *et al.*, 1989); they show that the hairy transcription unit is interrupted by two introns. The gene encodes a 337 amino acid protein, which contains a helix-loop motif (Rushlow *et al.*, 1989), and functions both in segmentation in the embryo and bristle patterning in the adult. The protein is found in cell nuclei and is localized in eight distinct regions of the early embryo (Carroll *et al.*, 1988); the major protein stripes are located in the posterior and adjacent anterior parts of alternate segment primordia. There are striking patterns of nuclear protein distribution during larval and pupal imaginal disc development with transient hairy expression in the eye, leg, and wing discs (Carroll and Whyte, 1989).

**other information:** *h*<sup>1</sup> shown to recombine with and lie to the right of *h*<sup>2</sup> (Sturtevant; Rasmussen).

*h*<sup>13</sup>

**synonym:** *h*<sup>s</sup>, hairy-subliminal.

**phenotype:** Homozygote nearly lethal but has no *h* phenotype. Heterozygote with *h* and *h*<sup>2</sup> also wild type. *h*<sup>s</sup>/+ has extra hairs on wings, head, pleurae, halteres, and occasionally on scutellum if also heterozygous for certain *X*-chromosome inversions that variegate for *Hw*, including *In(1)sc*<sup>8</sup>, *In(1)sc*<sup>51</sup>, and *In(1)y*<sup>3P</sup>. Presence of *y*<sup>+Y</sup> also induces extra hairs. RK3.

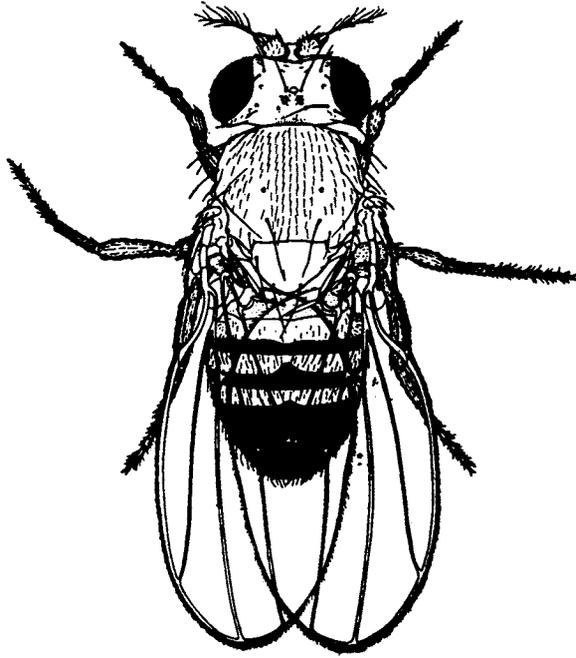

*h*<sup>20</sup>

**synonym:** *h*<sup>brr</sup>, hairy-barrel.

**phenotype:** Homozygous lethal. Newly hatched larvae lack denticle belts of alternate segments; *i.e.* the prothoracic, metathoracic and even numbered abdominal segments; naked cuticle missing from mesothorax and odd numbered abdominal segments (a member of the pair-rule class of Nüsslein-Volhard and Wieschaus). Pattern

of persisting segments often slightly irregular.

**alleles:** Eight embryonic lethal alleles, including four with weak expression, reported by Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding (1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95).

**H: Hairless**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 161.

**H: Hairless**

**location:** 3-69.5.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 161 (fig.).

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 170 (fig.), 227.

Nash, 1965, Genet. Res. 6: 175-89.

Bang, Hartenstein, and Posakony, 1990, Development, in press.

**phenotype:** Bristles, especially postverticals and abdominals, missing in heterozygous *H* flies. Bristle sockets present at some sites, not at others. Expressed most distinctly on head; occipital; post vertical and ocellar bristles affected. Bristles of antennae and vibrissae show mutant phenotype much less frequently. Sockets without shafts also found on thorax, scutellum, abdominal tergites, external genitalia, wings, and legs. No shaftless sockets appear on the bracted costa of the wing. Some 40% of bristle organs located on distal part of femur differentiate neither shaft nor bract; bracts absent whenever shaft missing but present when shaft present; abnormally short shaft may be accompanied by normal-sized bract (from description of *H*<sup>2</sup>, by Tobler, Rothenbühler, and Nöthiger, 1973, *Experientia* 29: 370-71). Veins L4 and L5 do not reach wing margin; occasionally true of L2 also. Eyes larger than wild type; body color somewhat paler. Lees and Waddington [1942, *Proc. Roy. Soc. (London)*, Ser. B. 131: 87-110 (fig.)] show that trichogen

cell forms a socket instead of a bristle shaft at some sites. Phenotypic expression of *H* responds linearly to dosage of *Su(H)*<sup>+</sup> in region 35B6-10 on the left arm of chromosome 2. The number of microchaetae in *H*/+ flies varies from approximately 35 in the presence of a single dose of 35B6-10 to fewer than 10 in the presence of four doses (Ashburner, 1982, *Genetics* 64: 471-79). Interactions with other mutants studied by House (1953, *Genetics* 38: 199-215, 309-27; 1959, *Genetics* 44: 516; 1955, *Anat. Record* 122: 471; 1959, *Anat. Record* 134: 581-82). *H* suppresses wing notching of *N*, *fa*, *fa*<sup>no</sup>, and *nd*, enhances *Ax*; also *H* enhances eye effect of *spl*, and removes more bristles in combination with *spl* (House, Von Halle). Reduction in the number of copies of the wild-type allele of *H* decreases the mutant phenotype of heterozygous *N* and *Dl* flies, but increase in the number of copies of the wild-type allele of *H* enhances the mutant phenotype of heterozygous *N*, *Dl*, and *E(spl)* flies (Vässin, Vielmetter, and Campos-Ortega, 1985, *J. Neurogenet.* 2: 291-308). *H* shows some superadditive interaction with *en*, *ci*, *ci*<sup>W</sup>, and *ci*<sup>D</sup> relative to degree of L4 interruption. L2 interruption augmented in combinations with *ve* and *ri*; L3 interruption augmented in combinations with *ve* and *tt*. Triploid, *H*/+/, intermediate between wild type and *H*/+. *H*/*H*/+ most extreme type with bristles absent from head, thorax, and abdomen [Gowen, 1933, *Am. Nat.* 67: 178-80 (fig.)]. Homozygous lethal. *H* null homozygotes die during larval and pupal stages (Bang *et al.*). Animals surviving to pharate adult are completely devoid of macrochaetes and microchaetes on the head and notum, with occasional "double sockets" remaining on the abdominal tergites. Bristles on the legs significantly resistant to loss of *H*<sup>+</sup> function; many "double sockets" and some normal bristles remain on the legs of *H* null homozygotes. In regions of the notum exhibiting bristle "loss" in adult *H* mutants, macrochaete and microchaete primary precursor cells undetectable (Bang *et al.*). RK1.

Zool. 46: 181-244; 14 = Van Breugel, Ray, and Gloor, 1968, Genetica 39: 165-92; 15 = Vässin, Vielmetter, and Campos-Ortega, 1985, J. Neurogenet. 2: 291-308.
- $\beta$  Occurred simultaneously with, but independently of  $Tp(3;3)H^{57c} = Tp(3;3)86F7-11;95C1-2;97D1-2;98C5$ .
- $\gamma$  Fuller phenotypic description follows.
- $\delta$  Affects number of sternopleural bristles (Gallego *et al.*, 1982).

**cytology:** Located in 92E12 to 92F1-2 on the basis of the right breakpoint of  $Df(3R)H-KX2$  (Campos-Ortega) and the third chromosome breakpoint of  $T(2;3)H^{KX1}$  (Bang, Hartenstein, and Posakony, 1990, Development, in press).

### $H^{16}$

**phenotype:** Recessive allele of Hairly (formerly called Hairless-recessive). Homozygotes have nearly all bristles and hairs substituted by double and triple abnormal sockets; veins L4 and L5 fail to reach margin.  $H^{16}/H$  lethal, probably in pupal stage; few escapers short lived with extreme Hairless phenotype; all bristles and hairs suppressed or substituted by abnormal sockets; wings reduced; veins L2, L4 and L5 abnormal.

### $H^{22}$

**phenotype:** Less severe than  $H^{16}$ . Almost completely recessive. Heterozygotes most frequently wildtype in phenotype, but occasionally a "double socket" appears on the head in the position of a postvertical macrochaete or on the abdominal tergites. Homozygotes display a much stronger and more extensive mutant phenotype than  $H$  null heterozygotes. Many head and notum macrochaetes and approximately 50% of notum microchaetes missing; remaining 50% exhibit a spectrum of "double socket" phenotypes. Homozygotes also exhibit loss of wing vein tissue from L4 and L5. Approximately 50% of flies carrying  $H^{22r}$  *in trans* to a  $H$  null allele die as pharate adults. The remainder survive to eclosion, but are short-lived and exhibit extensive loss of both macrochaetes and microchaetes on the head, notum, and abdominal tergites; only 20% of the notum microchaetes remain, all with a completely transformed "double socket" phenotype.

$H$ : see *Lvp*

### **$H2.0$ : Homeobox 2.0**

**location:** 2-.

**references:** Barad, Jack, Chadwick, and McGinnis, 1988, EMBO J. 7: 2151-61.

**phenotype:** Encodes a novel, tissue-specific homeobox. A large deletion including  $H2.0$  is homozygous lethal, but the lethality may not be due to the homeobox gene. Although the structure of most organs as well as the epidermis appears to be normal in these lethal embryos, the midgut forms a balloon like yolk-filled sac.

**cytology:** Located in 26B1-3 by *in situ* hybridization to the salivaries.

**molecular biology:** Gene cloned from a library of Oregon-R genomic DNA using a *Scr* probe. The nucleotide sequence of the cDNA and the presumed amino acid

sequence were determined. A single major transcript of 1.85 kb is present throughout development, beginning at 6 hr of embryogenesis and becoming abundant between 6 and 24 hours. The cDNA includes a single methionine codon and an open reading frame of 1257 nucleotides with a highly divergent homeobox. There is a M or opa repeat near the center of the ORF with 21 CAX triplets coding for histidine and glutamine. The predicted protein is made up of 410 amino acids. This homeobox shows less than 40% identity to the *eve* and *z2* homeoboxes.

Tissue-specific expression of  $H2.0$  was first detected at embryonic stage 10 at the flexure point between the posterior midgut invagination and the extended germ band. In stage 11, the homeobox is expressed in the visceral mesoderm in continual bands on either side of the midline from the posterior midgut invagination to the anterior midgut invagination. It is later detected in all cells destined to form the visceral musculature and especially in all cells of the splanchnopleura. Ectodermal expression occurs in a restricted lateral part of the posterior compartment of each segment. A line of  $H2.0$  expressing cells connects each patch of ectodermal expression with the expression in the splanchnopleura. No expression was observed in the gut ectoderm or the somatic mesoderm.

### **\**ha*: hair bristles**

**location:** 1-22.7.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 70.

**phenotype:** Small fly with extremely fine, short bristles. Males viable and fertile. Females less viable and highly infertile. RK3.

$H37$ : see *elf*

$Hab$ : see *BXC*

### ***Had*: $\beta$ -Hydroxy-acid-dehydrogenase**

**location:** 1-54.4 (between *sl* and *r*).

**references:** Borack, Water, and Sofer, 1971, DIS 46: 43.

Borack, 1974, Experientia 30: 31.

Tobler and Grell, 1978, Biochem. Genet. 16: 333-42.

**phenotype:** Thought to be the structural gene for  $\beta$  Hydroxy acid dehydrogenase (L- $\beta$ -hydroxyacid: NAD oxidoreductase, E.C 1.1.1.45). The enzyme is a dimer, based on the formation of hybrid enzyme in *D.simulans* X *D. melanogaster* hybrids, of molecular weight 6.3 X 10<sup>4</sup> daltons. Purification and biochemistry by Borak and Sofer. Activity high in Malpighian tubules, less in muscles, intestine, and fat body; absent from brain, salivary gland, and imaginal disks. (Borak, 1972, DIS 48: 73). Activity peaks at 72 hr after hatching, then declines through larval and pupal stages, and increases to stable maximum level at 6 days of adult life (Tobler and Grell). Enzyme expendible; hemizygotes and homozygotes for null allele survive normally (Tobler and Grell).

**alleles:** Three electrophoretic variants  $Had^F$ ,  $Had^I$  and  $Had^S$ , with fast intermediate, and slow mobility described by Borack *et al.*; an ethyl-methanesulfonate-induced inactive allele,  $Had^{m1}$ , described by Tobler and Grell.

**hat: half out**

**location:** 3-{47}.

**references:** Cavener, Otteson, and Kaufman, 1986, *Genetics* 114: 111-23.

**phenotype:** Pharate adults appear morphologically normal, but only partially eclose. Heads and thoraxes may emerge, but fail to complete emergence. Not complemented by *T(2;3)Ta<sup>1</sup>*.

**alleles:**

alleles	origin	discoverer	synonym
<i>hat<sup>1</sup></i>	EMS	Denell	<i>l(3)d1</i>
<i>hat<sup>2</sup></i>	EMS	Kaufman	<i>l(3)k1</i>
<i>hat<sup>3</sup></i>	EMS	Kaufman	<i>l(3)k13</i>
<i>hat<sup>4</sup></i>	EMS	R. Lewis	<i>l(3)r8</i>

**cytology:** Located in 84C1-2 since not complemented by *T(2;3)Ta<sup>1</sup> = T(2;3)51E1-2;84C1-2*. Unlike *stk*, *hat* is not included in *Df(3R)Scx2 = Df(3R)84A4-5;84C1-2*.

**hau: haunted**

**location:** 3-48.4.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95 (fig.).

**phenotype:** Homozygous lethal; only head skeleton visible in homozygous embryo; no differentiation of cuticle.

**alleles:** Four.

**hay: haywire**

**location:** 3-34.4.

**origin:** Induced by ethyl methanesulfonate

**synonym:** *ms(3)nc2*.

**references:** Fuller, 1986, *Proc. Soc. Dev. Biol.* 74: 19-41. Regan and Fuller, 1988, *Genes and Development* 2: 82-92.

**phenotype:** The original allele, *hay<sup>nc2</sup>*, is homozygous male sterile; some derivative alleles are recessive lethal. Homozygous *hay<sup>nc2</sup>* males display defects in meiosis, flagellar elongation, and nuclear shaping. *hay<sup>nc2</sup>* also

male sterile in *trans* heterozygotes with recessive male-sterile alleles of  $\beta$  *Tub85D* or with *wrl<sup>nc4</sup>* suggesting a role for the haywire product in microtubule function. Deficiencies of *hay* are fertile in heterozygous combination with the above interacting mutations, indicating that the extragenic failure *hay<sup>nc2</sup>* to complement is based on a poison product mechanism. This feature was used to select alleles (*hay<sup>nc2rv1-8</sup>*) that revert the failure of *hay<sup>nc2</sup>* to complement  $\beta 2t^n$  (=  $\beta$  *Tub85D<sup>n</sup>*).

**alleles:**

**phenotype:** Homozygotes for null alleles of *hb* (class I alleles of Lehmann and Nüsslein-Volhard) are embryonic lethals of the gap type. Gastrulation abnormal; no cephalic fold; cell death evident at 6 hr later becoming

extensive, predominantly in the neuroectoderm; germ band extension curtailed at 50% of embryonic length. After germ band shortening embryos lack thoracic and labial segments; cephalopharyngeal skeleton present but poorly formed; head involution fails. Seventh and eighth abdominal segments fused by the deletion of parasegment 13; A1 segment 1.5 times normal width, with eight to ten deranged denticle rows compared to the normal number of four, and a widened region of naked cuticle. Filzkörper material reduced; posterior spiracles fail to evert. Three ventral ganglia absent; gap appears between suboesophageal region of ventral nerve cord and more posterior trunk ganglia. Extreme mutants display a reduced number of stripes of *ftz* expression at cellular blastoderm; the first stripe is widened and followed by a narrowed gap of nonexpression preceding the second stripe; the last pair of stripes are fused (Carroll and Scott, 1986, Cell 45: 113-26). Hypomorphic alleles display variably less severe disruption depending on allele ( $hb^{Drv6} = hb^{b2} = hb^{e21} > hb^{b7} > hb^{Drv9}$ ), the least severe,  $hb^{Drv9}$  lacking only T2. Class II alleles (Lehmann and Nüsslein-Volhard) resemble the null alleles except that some or all of the prothorax and A7 are retained. The class III allele retains the labial segment as well. Class IV alleles lack only the mesothoracic segment. Class V mutants exhibit segment transformations as well as gaps and are described separately below. Temperature sensitive period of  $hb^{ts1}$  during first four hr of development.  $hb/+$  offspring produced from homozygous oogenic clones develop normally; homozygous embryos resulting from such clones display enhanced zygotic phenotype; gnathal, thoracic, and the first three abdominal segments replaced by two or three segments of abdominal identity in mirror image relation to the more posterior abdominal segments; weak alleles without maternal effect; extra doses of  $hb^+$  in female without effect on phenotype of  $hb$  offspring. The anterior zone of  $hb$  expression extended posteriorly by six additional cells in the absence of  $Kr^+$ ; conversely the zone of  $Kr$  expression expanded anteriorly by six to eight cells in  $hb$  mutants; posterior zone appears insensitive to  $Kr$  constitution (Jäckle, Tautz, Schuh, Seifert, and Lehmann, 1986, Nature 324: 668-70).  $hb^+$  appears to set the boundaries of *Ubx* expression (White and Lehmann, 1986, Cell 47: 311-21); zone of *Ubx* expression expanded in both anterior and posterior directions in  $hb$  mutant embryos at the stage of full germ band elongation; segmental disposition of expression characteristically deranged prior to the advent of cell death. Although *Ubx* expression in the ventral nerve chord at the stage of fully shortened germ band extends from parasegments 5-13, *Ubx* protein detected in parasegments 1, 7-12 and 14 in  $hb^{12}$ , 3 and 7-14 in  $hb^1$ , and head to parasegment 1 plus parasegments 7-12 and 14 in  $hb^7$  (White and Lehmann). Phenotypic effects of *ftz* and  $hb$  in double mutants additive in thorax and anterior abdomen, but more severe than expected in head and posterior regions.

β Described more fully below.

**cytology:** Placed by cytological mapping in 85A3-B1 (Tautz *et al.*, 1987) or in 85A5-7;85B2-3 (Bender *et al.*, 1987; Lehmann, and Nüsslein-Volhard, 1987).

**molecular biology:** Genomic sequences that include the gene *hb* cloned by chromosome walking (Tautz *et al.*, 1987; Bender *et al.*, 1988); gene also sequenced. Two embryonic mRNAs were identified (Tautz *et al.*, 1987), one of 2.9 kb and another of 3.2 kb; the larger is present in the maternal RNA and persists during the first eight hours of embryonic development, whereas the smaller is detected only between the second and sixth hours. The two primary transcripts are transcribed from the same strand and have identical exons; the 3.2 kb mRNA has a 5' exon of 500 nucleotides separated from exon 2 by a 3.2 kb intron, and is separated from the 3' exon by a short intron; the same splice acceptor site is utilized in both messages. The experiments of Bender *et al.* (1988) identified five embryonic transcripts in two discrete classes; one class includes transcripts of 2.6 and 2.8 kb that are expressed only during embryogenesis with their highest level at 2-4 hr; and the other class includes transcripts of 3.0, 3.2, and 3.5 kb that accumulate to their highest levels over the first eight hours of embryogenesis, but are also present in adult females and males. The 5' to 3' direction of transcription of all five transcripts was found to be from distal to proximal along the chromosome. Primer extension and S1 protection experiments

indicate the presence of two distinct promoters and three polyadenylation sites; transcripts from the upstream promoter are found in adults (males and females) as well as in 0-12 hr embryos (Bender *et al.*, 1988). Maternal message is uniformly distributed at the time of egg deposition, but in stage 8 embryos, a gradient decreasing posterior is visible (Foe and Alberts, 1983, *J. Cell Sci.* 61: 31-70). Zygotic message first seen in stage 11 in the anterior 45% and the posterior 25% of the embryo; message subsequently disappears from the two poles of the embryo and becomes distributed in three and then two stripes in the anterior region; in general, the regions of *hb* message do not overlap those of *Kr* message. An overlap in protein distribution is shown by *hb* and *Kr* (Gaul and Jäckle, 1989, *Development* 107: 651-62). The proteins encoded by *hb* (and *Kr*) show sequence-specific DNA binding to sites upstream of the two *hb* promoters (Stanojević *et al.*, 1989; Treisman and Desplan, 1989). The posterior-group gene *nos* suppresses the activity of *hb* in the posterior half of the body; if both *nos* and *hb* are absent, the embryo is normal (Hülskamp *et al.*, 1989; Struhl, 1989).

**hb<sup>6</sup>**

**phenotype:** *hb<sup>6</sup>/hb<sup>6</sup>* embryos lack meso- and metathorax, but nine abdominal segments are formed, the most anterior being T2 transformed into A1 and the next the normal A1.

**hb<sup>7</sup>**

**phenotype:** Homozygous embryos lack labium and all thoracic segments; head and gnathal segments transformed into posterior abdominal segments as is A1. Expressed only in homozygotes, not in hemizygotes; *hb<sup>7</sup>/Df(3R)hb* displays class III phenotype. Lethality of *hb<sup>7</sup>* homozygotes not rescued by *Dp(3;Y)P92* which is able to cover the other alleles; attempts to implicate a linked lethal mutation negative.

**hb<sup>11</sup>**

**phenotype:** As in the case of *hb<sup>7</sup>*, resembles a class I mutant, but with transformation of gnathal and first abdominal segments into posterior abdominal segments. Expression in homozygotes more extreme than in hemizygotes.

**hb<sup>D1</sup>: hunchback-Dominant**

**phenotype:** A gain-of-function mutation; viable both in heterozygous and homozygous condition. Phenotype resembles that of *pbx*; insensitive to additional doses of *hb<sup>+</sup>* but suppressed by extra doses [e. g., five copies of *BXC<sup>+</sup>* (Lewis)]; enhanced in heterozygous combination with null alleles of *ftz*.

**cytology:** Associated with *In(3R)hb<sup>D1</sup> = In(3R)85B;88C*. The inversion is lethal homozygous, but lethality covered by duplication for 88C breakpoint; *hb<sup>D1</sup>* associated with proximal breakpoint.

**hb<sup>D2</sup>**

**phenotype:** Homozygous lethal; lethal when heterozygous to *hb* null alleles (e.g. *hb<sup>12</sup>*). Has two dominant phenotypes: 1) homeotic transformation of parasegment six to parasegment five, resembling that produced by *bx* and *pbx*; 2) a pair-rule segmentation defect, consisting of partial deletion of even-numbered abdominal segments, principally A2 and A4. Homozygote shows more extreme

expression of both phenotypes; penetrance and expressivity of first effect enhanced in double heterozygous combination with null alleles of *ftz* (e.g. *hb<sup>D2</sup>/ftz<sup>714</sup>*); second phenotype enhanced by *Df(2R)eve*, such that only a few adult escapers of the doubly heterozygous genotype are observed. Also has a recessive phenotype, revealed either when homozygous or heterozygous to an *hb* null allele; deletion of parasegment 13 and reduction of filzkörper; labial and thoracic segments normal. Thus, affects posterior, but not anterior, domain of *hb<sup>+</sup>* function. Viable in *trans* to some hypomorphic alleles that do not affect parasegment 13 (e.g. *hb<sup>6</sup>*).

**cytology:** Associated with *In(3R)hb<sup>D2</sup> = In(3R)84B;85A*.

Breakpoint of associated inversion approximately 1 kb upstream of transcription start for 3.2 kb transcript.

**Hdl: Haplo-diplo lethal**

**location:** 1-[43].

**references:** Merriam, Yamamoto, Stewart, Rahman, and Nicolau, 1986, unpublished.

**phenotype:** Females with one dose of the normal allele and males with two are almost completely lethal; escapers normal in phenotype.

**alleles:** No mutant alleles known.

**cytology:** Localized to 12A by segmental aneuploidy.

**hdp: heldup**

At least three different genetic entities appear to have been designated *hdp* on the basis of similarity of phenotype and map position to the now-lost *hdp* of Fahmy (1958, *DIS* 32: 70). Deak (1977, *J. Embryol. Exp. Morphol.* 40: 35-63) so designated *wup-A* of Hotta and Benzer [1972, *Nature* (London 240: 527-35)]. Lifschytz and Green (1979, *Mol. Gen. Genet.* 171: 153-59) selected reversions and suppressors of *Bx*, both of which had a held-up phenotype and were so designated. Engels and Preston (1981, *Cell* 26: 421-28) selected P-factor induced sex-linked mutants with held-up wings; 93% are associated with chromosome rearrangements with one breakpoint in 17C2-3; the other 7% are not associated with rearrangements and act as suppressors of *Bx*; the latter group of mutants complement both the other 93% of mutants recovered by Engels and Preston and those described by Deak. We resurrect the name *wupA*: wingsupA for the mutants studied by Deak; we designate the *Bx* suppressors *hdp-a* and the mutants associated with 17C2-3 breakpoints *hdp-b*. In addition Fahmy (1956, *DIS* 32: 74) describes *rwg*: reduced wings, a mutant with the same map position and a slightly different phenotype from other held-up-like mutants; we arbitrarily designate it an *hdp-a* allele.

**hdp-a**

**location:** 1-59.4 (0.0045 unit to the left of *Bx* based on separation of *Bx<sup>3</sup>* and *hdp-a*).

**synonym:** *hld*: heldwing (Deak, Bellany, Bienz, Dubuis, Fenner, Gollin, Rähmi, Ramp, Reinhardt, and Cotton, 1982, *J. Embryol. Exp. Morphol.* 69: 61-81); *ftiH* (Homyk, 1977, *Genetics* 87: 105-28; Homyk and Shepard, 1977, *Genetics* 87: 95-104).

**phenotype:** Wings held up to various degrees; may overlap wild type. *hdp-a* alleles act as dominant suppressors of *Bx* in either *cis* or *trans* (Lifschytz and Green, 1979, *Mol. Gen. Genet.* 171: 153-59). Lifschytz and Green consider *hdp-a* mutants to be hypomorphic or amorphic alleles of

a gene that is under *cis* control of  $Bx^+$ ;  $Bx$  mutants cause overproduction  $hdp-a^+$  product.

$\gamma$  1 = Engels and Preston, 1981, Cell 26: 421-28; 2 = Fahmy, 1958, DIS 32: 67-77; 3 = Homyk and Emerson, 1988, Genetics 119: 105-21; 4 = Lifschytz and Green, 1979, Mol. Gen. Genet. 171: 153-59.

$\delta$  Shows partial complementation over *hdp-a*<sup>2</sup>.

$\epsilon$  Representative of 7% of the *hdp*-like mutants spontaneously generated by hybrid dysgenesis in an X chromosome that carries a P factor inserted at 17C2-3. These alleles associated with P-factor excision.

**cytology:** Placed in 17C2-3 on the basis of perfect correlation between *hdp-a* mutation in a dysgenic cross and the loss of a P element from 17C2-3 (Engels and Preston, 1981, Cell 26: 421-28).

**other information:** Relation between *hdp-a* and *hdp-b* unclear, they are in the same polytene bands but complement each other completely. They are separated by  $Bx$  (Mattox).

### *hdp-b*

**location:** 1-59.4 (inferred from polytene position).

**origin:** Induced by hybrid-dysgenesis in an X chromosome with a P-factor in 17C2-3.

**references:** Engels and Preston, 1981, Cell 26: 421-28.

**phenotype:** Same as *hdp-a*, except that there is no interaction with  $Bx$ .

**alleles:** 93% of the hybrid-dysgenesis-induced *hdp*-like mutants in an X chromosome in which a P factor resides at 17C2-3 are *hdp-b* alleles.

**cytology:** All dysgenesis induced *hdp-b* alleles, are associated with rearrangements with one breakpoint in 17C2-3.

### *her*: hermaphrodite (G.S. Carson)

**location:** 2-52.9 (between *b* and *pr*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Baker and Belote, 1983, Ann. Rev. Genet. 17: 345-93.

**phenotype:** Original allele was recovered as a recessive temperature-sensitive lethal with low homozygous viability (3-7% of the viability *her*/+) at 29° C and near-normal viability at 18° C in both sexes. Surviving 29° C homozygotes have small bodies, rough eyes, incised wings, and etched abdominal tergites. XX homozygotes surviving at 29° C are intersexual, with partially formed sexcombs, male-colored abdominal patches, and rudimentary male and female external genitalia. XY escapers have female-like sixth abdominal sternite bristles, but otherwise appear sexually normal. *her/her* flies of both sexes raised at 18° C are morphologically normal and fertile; however, XX homozygotes exhibit reversible temperature-dependent sterility when mated at 29° C. Homozygous females exert a mild maternal effect upon the sexual phenotype of *her*/+ offspring which develop at 29° C; females show abnormal basitarsal bristle arrangement and patches of male abdominal pigmentation; males show female basitarsal bristles among sexcomb teeth and the presence of sixth sternite bristles.

**alleles:** *her*<sup>2</sup>, spontaneous on *In(2LR)SM1,Cy*.

**cytology:** Placed between 36B4 and 36C2-4 as a result of its complementation by *Dp(2;Y)B106* and *Dp(2;Y)B108* = *Dp(2;Y)35F;36DE*, *Dp(2;Y)H1* = *Dp(2;Y)36B4;40F* + *Df(2L)37F4;39C2* and *Dp(2;Y)H3* = *Dp(2;Y)36B4;40F* + *Dp(2L)38B2;39E2* and its exclusion from *Df(2L)TW137* = *Df(2;Y)36C2-4;37B9-C1* and *Dp(2L)TW50* = *Df(2;Y)36E4-F1;38A6-7*.

**molecular biology:** Tritiated uridine incorporation in third instar salivary gland chromosomes suggests X chromosome transcriptional activity is reduced in *her/her* larvae compared with heterozygous siblings.

*Hex-3*: see *Hex-C*

### *Hex-A*: Hexokinase A

**location:** 1-29.2.

**synonym:** *Hex-A,B*.

**references:** Voelker, Langley, Leigh Brown, and Ohnishi, 1978, DIS 53: 200.

Moser, Johnson, and Lee, 1980, J. Biol. Chem. 255: 4673-79.

**phenotype:** The structural gene for hexokinases A, B1, and B2 (EC 2.7.1.1). The enzyme is monomeric and of molecular weight 47,000  $\pm$  3000 for HEX-A and 48,000  $\pm$  3000 for HEX-B1 and HEX-B2. The three forms of the enzyme are immunologically identical but exhibit pI values of 5.1, 5.3, and 5.5 respectively upon isoelectric focusing, and these values covary in allelic variants. All three forms are found in the adult, but HEX-A is absent from larval preparations; HEX-A mainly localized in adult flight muscle. Three forms modified products of same structural gene. For purification and biochemical characterization see Moser *et al.*

**alleles:** Electrophoretic variants *Hex-A*<sup>2</sup> which migrates more slowly than *Hex-A*<sup>4</sup>.

**cytology:** Localized to 8D4-E1 (Voelker).

**Hex-C**

**location:** 2-74.5 (Mukai and Voelker, 1977, Genetics 86: 175-85).

**synonym:** *Fk*: Fructokinase; *Hex-3*.

**references:** Jelnes, 1971, Hereditas 67: 291-93.

Fox and Madhavan, 1971, DIS 46: 42.

Madhavan, Fox, and Ursprung, 1972, J. Insect. Physiol. 18: 1523-30.

Moser, Johnson, and Lee, 1980, J. Biol. Chem. 255: 4673-79.

**phenotype:** The structural gene for hexokinase-C [HEX-C (EC 2.7.1.1)]. The enzyme is a monomer of estimated molecular weight 42,000 ± 3,000 (Moser *et al.*) or 35,000 (Leigh Brown in Racine, Langley, and Voelker, 1980, Environ. Mutagen. 2: 167-77). Activity present in all developmental stages except freshly laid eggs; restricted to fat body in larvae, but present in many organs in adult. Weakly active or inactive in cell line (Deber, 1974, Wilhelm Roux's Arch. Entwicklungsmech. Org. 174: 1-9). HEX-C activity not necessary for survival; null mutants viable (Burkhart, Montgomery, Langley and Voelker, 1984, Genetics 107: 295-306). Purification and biochemical characterization of enzyme described by Moser *et al.*.

**hfw: halfway**

**location:** 1-0.4 [0.008 map units to right of *dor* (Aizenzon and Belyaeva, 1982, DIS 58: 3-7)].

**phenotype:** Recessive lethal; for some alleles, development arrested in third instar, the anterior half initiating puparium formation while the posterior half remains larval. Extent of development influenced by administration of ecdysone and by temperature; pupariation occasionally completed at 18°. Some alleles yield a few survivors with characteristic wing abnormalities and occasionally swollen abdomens.

**alleles:** Seven alleles, superscripted 1-7.

Mohler, 1988, Genetics 120: 1061-72.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.

**phenotype:** A segment polarity type of embryonic lethal. Homozygous embryos have the posterior naked portion of the ventral surface of each segment deleted and replaced by a mirror image of the anterior denticle belts. Embryos appear to lack segmental boundaries. In strong alleles, there is no obvious segmentation; the larvae are approximately 40% the length of the wild-type larvae, and there is a lawn of denticles arranged in a number of whorls on the ventral surface as a result of loss of naked cuticle. In intermediate alleles, naked cuticle is also lost from the ventral region, but the lawn of denticles is arranged in segmental arrays in mirror-image symmetry. The weak alleles show fusions that delete the naked cuticle usually between abdominal segments 1 and 2 and 6, 7, and 8 (Mohler, 1988). Temperature shift experiments with a temperature-sensitive allele (viable and normal at 18°, and mutant at 25°) indicate two phases of *hh* activity at 25°, the first during early embryogenesis (3-6 hr of development) and the second during the late larval and early pupal stages (4-7 days of development).

<sup>α</sup> 1 = Ives, 1950, DIS 24: 58. 2 = Jürgens, Wieschaus, and Nüsslein-Volhard, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95; 3 = Mohler, 1988, Genetics 120: 1061-72; 4 = Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.

**cytology:** Placed in 94E by segmental aneuploidy. Placed in 94D10-E5 based on breakpoint common to four *hh* rearrangements (Mohler, 1988).

### **hh1**

**phenotype:** A weak hypomorphic allele that is not complemented by other *hh* alleles. Eye of homozygote small and narrow with about 150 facets. Eye disc size reduced; deep cleft at anterior edge cell; clusters at cleft look mature (Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29).

### **\*hi: high**

**location:** 2- (not located).

**origin:** Found in Florida natural population.

**discoverer:** Ives, 1943.

**references:** 1943, Genetics 28: 77.

1950, Evolution 4: 236-52.

**phenotype:** Male homozygous for *hi* produces sperm containing 10 times normal frequency of mutations. Heterozygous *hi/+* causes a mutation rate 2-7 times normal. Ratio of sex-linked lethal to visible mutations about 8 to 1. Inversions associated with about 5% of mutations. RK3.

**cytology:** Salivary chromosomes normal.

**other information:** Homozygous *hi* constructed by crossing two balanced lethal stocks, *11 hi/Cy X 12 hi/Cy*. Since these stocks have developed a common lethal, it is now difficult to obtain *hi* homozygotes.

### **\*Hi: Hirsute**

**location:** 3-{rearrangement}.

**origin:** X ray induced.

**discoverer:** Bishop, 1939.

**phenotype:** All bristles except postscutellars and postdorsocentrals multiplied, especially on head and anterior thorax. Eyes smaller and facets irregular. Homozygous lethal. RK2A.

**cytology:** Associated with *In(3LR)Hi = In(3LR)71A;91F*.

**other information:** Possibly the same as *Brd*.

### **Hia: Hiatus**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Bridges, 29b12.

**phenotype:** Terminal interruption of L2. More obvious in heterozygous male than in heterozygous female. Homozygous viable. RK3.

**Hid:** see *term*

**high:** see *hi*

**Himca:** see *Fs(2)Sz5*

**Hin-d:** see *dpp*

**hindsight:** see *hnt*

### **hir: heterochromatic-recombination-inducer**

**location:** 2- (left end of 2L).

**references:** Hiraizumi, 1980, Genetics 94: s45-46.

**phenotype:** Females homozygous for *hir* in combination with certain cytoplasmic constitutions show increased recombination between *lt* and *Rsp*. Effect decreases with maternal age. *hir* without effect in males.

### **His: Histone**

**location:** 2-55 [between *l(2)crc* and *lt*].

**references:** Pardue, Kedes, Weinberg, and Bernstiel, 1977, Chromosoma 63: 135-51.

Lifton, Goldberg, Karp, and Hogness, 1977, Cold Spring Harbor Symp. Quant. Biol. 42: 1047-51.

**phenotype:** *His* refers collectively to five structural genes (*His1*, *His2a*, *His2b*, *His3*, and *His4*) for the five different histones (H1, H2A, H2B, H3, and H4). H2A, H2B, H3 and H4 participate in equimolar quantities in the formation of histone octomers, which form the protein core of nucleosomes. H1 associates with DNA between nucleosomes. The ratio of H1 to nucleosome core histones is higher in the salivary glands of larvae than in the cells of young embryos (Holmgren, Johansson, Lambertsson, and Rasmusson, 1985, Chromosoma 93: 123-31). For primary structure of H2B see Elgin, Schilling, and Hood (1979, Biochemistry 18: 5679-85). The expression of the histone genes changes in mid-embryogenesis (Ambrosio and Shedl, 1985, Dev. Biol. 111: 220-31; Ruddell and Jacobs-Lorena, 1986, Proc. Nat. Acad. Sci. USA 82: 3316-19). The egg chambers contain a variable and low level of mRNA during nurse cell polytenization; however, at the end of stage 10, all the nurse cells accumulate histone mRNA which is turned over to the growing oocytes as the nurse cells degenerate. Heterozygosity for full or partial deficiency of the histone genes suppresses variegation (*B<sup>SV</sup>*, *Sb<sup>v</sup>*, *w<sup>md</sup>*); duplications without effect on level of variegation (Moore, Sinclair, and Grigliatti, 1983, Genetics 105: 327-44). Transcription not repressed by heat shock (Spradling, Pardue, and Penman, 1977, J. Mol. Bio. 109: 559-87).

**cytology:** Localized to polytene bands 39D3 through 39E1-2 and possibly 39D2 as well by *in situ* hybridization of sea urchin histone messenger RNA (Pardue *et al.*). Orphan sequences homologous to *His2B* and *His3* detected outside the tandem array but not localized further (Childs, Maxson, Cohn, and Kedes, 1981, Cell 23: 651-63).

**molecular biology:** The five histone genes are deployed in the order *His1 His3 His4 His2a His2b* in a tandemly

repeating unit that is represented in 100-200 copies per haploid complement. Units of 5.0 and 4.75 kb are found depending on whether or not there is a 250 base-pair insertion in the spacer region between *His1* and *His3* (Matsuo and Yamazaki, 1989, *Nucleic Acids Research* 17: 225-38); the 5 kb units are present from one to four times more frequently than 4.8 kb units, depending on the particular strain (Strausbaugh and Weinberg, 1982, *Chromosoma* 85: 489-505). Magnification and compensation of histone gene sequences in *Df(2L)TW161* described by Chernyshev, Bashkirov, and Khesin (1980, *Mol. Gen. Genet.* 178: 663-68) and Chernyshev (1982, *Mol. Biol. Moscow* 16: 593-603). The repeating unit has been cloned, and the relative positions and directions of transcription of the five histone genes have been determined by Lifton *et al.* A 68 base-pair segment between *His3* and *His4* specifically binds the B transcription factor (Parker and Topol, 1984, *Cell* 36: 357-69). Sequence analysis by Goldberg (1979, PhD. Thesis, Stanford University) reveals the absence of introns. Among the first genes to be transcribed, transcription beginning 90 minutes after oviposition; transcription rates and message stability are high in early embryogenesis when the rate of DNA synthesis is maximal and both decrease markedly as development proceeds (Anderson and Lengyel, 1980, *Cell* 21: 717-27). When *Drosophila* tissue culture cells are heat shocked, H2B protein synthesis is increased, but H1, H2A, H3, and H4 protein synthesis is decreased (Farrell-Towt and Sanders, 1984, *Mol. Cell Biol.* 4: 2676-85). Histone messages non polyadenylated (Burkhardt and Birmstiel, 1978, *J. Mol. Biol.* 18: 61-79). Regular development of nucleosomes with respect to repeating sequence of histone genes studied by means of nuclease sensitivity (Samal, Worcel, Louis, and Schedl, 1981, *Cell* 23: 401-10). Bands, interbands, and puffs in the polytene chromosomes are recognized by a monoclonal antibody to an epitope in the carboxy-terminal tail of *His1* (Hill, Watt, Wilson, Fifis, Underwood, Tribbick, Geysen, and Thomas, 1989, *Chromosoma* 98: 411-21).

**other information:** One H2A-like sequence variant has been found (Donahue, Palmer, Condie, Sabatini, and Blumenfeld, 1986, *Proc. Nat. Acad. Sci. USA* 83: 4744-48). Within the H3 gene, the average nucleotide difference within a chromosome was 52% of that within a population (Matsuo and Yamazaki, 1989, *Genetics* 122: 87-97).

*Hiv*: see *L(1)7C*

**Hirsute**: see *Hi*

**hk: hook**

**location:** 2-53.9.

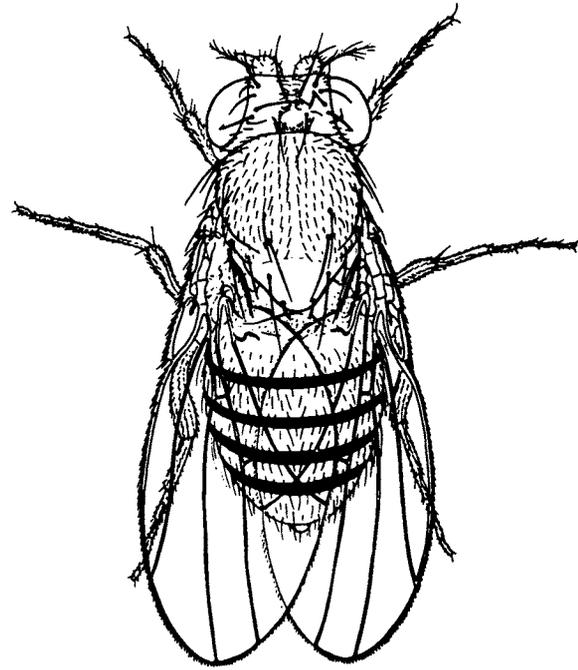

**origin:** Spontaneous.

**discoverer:** Mohr, 24a4.

**references:** 1927, *Hereditas* 9: 169-79 (fig.).

**phenotype:** Bristles nearly all hooked at tip or blunted, some bent at right angles. Scutellars and verticals especially affected. Acrostichal hairs fewer and outer rows separated. Eyes slightly roughened. Wings usually divergent and may be smaller. Body sometimes small and chunky. Less extreme expression at 19°, especially the wing character, but classification reliable. RK2.

**alleles:** *hk*<sup>2</sup> (Bridges, 33a31) spontaneous and less extreme than *hk*<sup>1</sup>. *hk*<sup>127</sup> and *hk*<sup>131</sup> X ray induced (Wright,

**hk: hook**

From Mohr, 1927, *Hereditas* 9: 169-79.

Hodgetts, and Sherald, 1976, *Genetics* 84: 267-85).

**cytology:** Located to 37B10-14 by deficiency analysis (Wright, Beermann, Marsh, Bishop, Seward, Black, Tomsett, and Wright, 1981, *Chromosoma* 83: 45-58). *Df(2L)130/Df(2L)203 = Df(2L)37B9-C1;37D1-2/Df(2L)36E4-F1;37B9-C1* survives and is *hk* in phenotype (Wright *et al.*).

**Hk: Hyperkinetic** (J.C. Hall)

**location:** 1-30.1.

**references:** Kaplan and Trout, 1969, *Genetics* 61: 399-409.

Ikeda and Kaplan, 1974, *Amer. Zool.* 14: 1055-66.

Thompson, 1977, *DIS* 52: 2.

Kaplan, 1979, *Psychological Survey* (Connolly, ed.).

Allen and Unwin, London, Vol. 2, pp. 90-109.

Stern and Ganetzky, 1989, *J. Neurogenet.* 5: 215-28.

**phenotype:** Isolated as a dominant allele that induces ether-induced leg shaking in flies (Kaplan and Trout, 1969); later, hyperkinetic alleles showed recessive behavior, both in regard to the adult leg shaking phenotype and to the larval electrophysiological phenotype (Stern and Ganetzky, 1989). The vigorous leg shaking of flies can be induced by nitrogen or triethylamine, as well as ether, but not by chloroform (Ganetzky and Wu, 1982, *Genetics* 100: 597-614); ether also induces rhythmic bursts of impulses in certain cells of the thoracic ganglia of adults (summarized by Ikeda and Kaplan, 1974). The "patch clamp" experiments on neurons from *Hk* larvae reveals inward currents of unusually high conductance (Sun and Wu, 1985, *Neurosci. Abstr.* 11: 787). In *Hk* larvae, the amplitude and duration of the post synaptic response to a brief high frequency nerve stimulation is increased up to the level characteristic of *Sh* mutants (Stern and Ganetzky, 1989). Shadow stimuli induce jump response, which maps to the head in mosaic experiment (Kaplan, 1979). *Hk* can overcome heat-induced paralytic

effects of *para*<sup>ts</sup> (i.e. stobe light stimuli to the double mutant elicit jumps). *Hk*-induced leg shaking suppressed by *nap*<sup>ts</sup> at its relatively low permissive temperature (Ganetsky and Wu, 1982). Courtship performed by *Hk* males is abnormal (Burnet, Eastwood, and Connolly, 1974, *Behav. Genet.* 4: 227-35). Lifespan is shorter than normal and rate of oxygen consumption is greater than normal in *Hk* (Trout and Kaplan, 1970, *Exper. Geront.* 5: 83-93). Mutant focus of life-shortening effect maps to ventral anterior part of thorax as does leg shaking (Trout and Kaplan, 1982). Mutant shows weak orientation to spots in Y-maze test (Bulthoff, 1982, *Biol. Cybernet* 45: 63-7).

**alleles:**

**Hmg: Hmg-CoA-reductase**

**location:** 3-{81}.

**references:** Gertler, Chiu, Richter-Mann, and Chin, 1988, *Mol. Cell Biol.* 8: 2713-21.

**phenotype:** Encodes 3-methylglutaryl coenzyme A (HMG CoA) reductase, the rate-controlling enzyme for cholesterol synthesis in mammals. In *Drosophila melanogaster*, the enzyme is not regulated by sterols (Brown, Havel, and Watson, 1983, *J. Biol. Chem.* 258: 8512-15; Silberkang, Havel, Friend, McCarthy, and Watson, 1983, *J. Biol. Chem.* 258: 8503-11); it synthesizes mevalonate for the production of nonsterol isoprenoids which are needed for growth and differentiation. The enzyme is found in cultured Kc and Schneider cells.

**cytology:** Located in 95A.

**molecular biology:** The gene was cloned and its nucleotide and putative amino acid sequences determined (Gertler *et al.*, 1988). An open reading frame of 2,748 bp encodes a polypeptide of 916 amino acids similar to hamster HMG CoA reductase; the C-terminal region showing 56% identical residues and the N-terminal region 32 to 60% identical residues. A 4 kb transcript was found in early embryos, increased in abundance in late embryos, and was expressed at low levels in larvae, pupae, and adults; a 3.2 kb transcript was found at low levels in third-instar larvae, but increased in abundance in pupae and adults. Schneider cell fed mevalonate showed a reduction both in the 4 kb transcript and in enzyme activity.

**hmr: hybrid male rescue**

**location:** 1-31.8

**origin:** Spontaneous in the Ukraine, USSR.

**references:** Hutter and Ashburner, 1987, *Nature* 327: 331-33.

**phenotype:** Rescues *D. melanogaster* / *simulans* hybrid males that would not survive in the absence of the gene. Hybrid males that carry both *hmr* and a duplication (thought to be *hmr*<sup>+</sup>) are lethal, so the rescue is considered recessive. The hybrids are sterile. Hybrid females from the reciprocal cross show low viability. *D. melanogaster* / *mauritanica* and *D. melanogaster* / *sechellia* hybrid males also rescued. The rescue of *D. melanogaster* / *simulans* and *D. melanogaster* / *mauritanica* males by *hmr* almost complete at 18°; at 25° *D. melanogaster* / *mauritanica* male rescue is good, but *D. melanogaster* / *simulans* males is poor at this temperature. At 18° only one third of the *D. melanogaster* / *sechellia* males are rescued.

**cytology:** Located in bands 9D1-2;9E1-2. No chromosome abnormalities are shown.

*hn*<sup>3</sup>: see *Hn*<sup>r2</sup>

**Hn: Henna**

**location:** 3-23.0

**phenotype:** A recessive eye color mutant, amorphic alleles of which show slight dominance. The first allele described, being associated with a deficiency, was homozygous lethal, and therefore only the slight dominant phenotype of homogenously dark, dull brown eye color could be scored; thus the dominant symbol *Hn* was applied. All subsequent alleles homozygous viable, exhibiting dark brown sepia-like or clot-like eyecolor in homozygous flies. Red pteridine eye pigments, drosopterin, reduced and sepiapterin accumulates; sepiapterin reductase levels reduced (Barthelmess and Robertson, 1970, *Genet. Res.* 15: 65-86). Eye color of *Hn*<sup>r</sup> and *Hn*<sup>r3</sup> autonomous in transplants of optic disk into wild-type hosts (Beadle and Ephrussi, 1936, *Genetics* 21: 230). Larval Malpighian tubes bright yellow as in wild type (Beadle, 1937, *Genetics* 22: 587-611). RK1 or 2 as homozygote.

**hop: hopscotch**

**location:** 1-34.6 (between *dsh* and *dlg*).

**references:** Perrimon and Mahowald, 1986a, Dev. Biol. 118: 28-41.

1986b, Symp. Soc. Dev. Biol. 44: 221-35.

**phenotype:** The wild-type allele of *hop* is required for the continued cell division of all diploid cells as well as the establishment of the normal array of segments. Most of the mutants are homozygous late zygotic (L-P) lethals; one mutant is a larval lethal; two other mutants have some adult survivors (hemizygous males being morphologically normal, but 40% of the homozygous females and 85% of the hemizygous females showing major defects). Most of the heteroallelic females are lethal, with the following exceptions:

genotype	percent viable
<i>hop</i> <sup>29</sup> / <i>hop</i> <sup>25</sup>	12%
<i>hop</i> <sup>3</sup> / <i>hop</i> <sup>25</sup>	16%
<i>hop</i> <sup>14</sup> / <i>hop</i> <sup>25</sup>	40%
<i>hop</i> <sup>12</sup> / <i>hop</i> <sup>25</sup>	68%
<i>hop</i> <sup>27</sup> / <i>hop</i> <sup>25</sup>	100%
<i>hop</i> <sup>32</sup> / <i>hop</i> <sup>25</sup>	100%
<i>hop</i> <sup>33</sup> / <i>hop</i> <sup>25</sup>	100%

All viable heteroallelic combinations are female sterile, failing to produce eggs or laying abnormal eggs that are small, with a clear chorion and with chorionic filaments absent or partially fused (Perrimon and Mahowald, 1986a). There is a maternal effect on thoracic and abdominal segments, the most extreme embryos

[produced from homozygous *l(1)hop* germline clones that have not received a paternal copy of *hop*<sup>+</sup>] showing defects in the posterior spiracles and in segments T2 (denticle belt deleted). T3, A4, and A5 (segment missing) and A8 (segment reduced in size); the least extreme mutant embryos from germline clones show defects in segment A5. Defects visible in early segmentation stages. The extent of the defects is dependent on the strength of the maternal alleles and the paternal contribution. Wild-type sperm can rescue all defects, except those in A5. A few of the rescued progeny hatch and develop into adults.

**hp: humped****location:** 3- (rearrangement).**origin:** Spontaneous.**discoverer:** Bridges, 31a22.**phenotype:** Thorax shortened and strongly humped with thoracoscutellar groove almost absent. Eyes sharply reduced, may be absent at 29°. Bristles Minute-like and occasionally missing. Viability 10% wild type. RK3A.**cytology:** Associated with *In(3R)P* (Craymer).**\*hpa: hyperantenna****location:** 1-50.1.**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).**discoverer:** Fahmy, 1954.**references:** 1959, DIS 33: 86.**phenotype:** Antennae enlarged or have duplicated parts, sometimes an extra antennal base near the eye. Grossly deformed head and eyes. Wings have rounded tips and incised inner margins. An occasional bristle absent or shorter. Phenotype variable; minimal expression shown by slightly altered eye shape and blunt wing tips. Males viable and infertile; females sterile. RK3.**Hpb: Hydroxyphenyl-buten-1****location:** 2- (chromosomal location tentative).**origin:** Induced by ethyl methanesulfonate.**references:** Kikuchi, 1973, Nature 243: 36-38.**phenotype:** Flies carrying *Hpb-1* are attracted to compounds that repel wild type. The strongest of these is 4-(0-Hydroxyphenyl)3-buten-2-one, where 71% of mutant bearing flies respond positively and 67% of wild type flies negatively to the stimulus, an odds ratio of approximately 5. Slightly lower differentials are seen with eleven among 63 other compounds tested.*Hr*: see *dsx*<sup>D</sup>**Hrb1: hnRNA-binding protein 1 (S. Haynes)****location:** 3-{98}.**origin:** Isolated from a cDNA library using *pen* repeat probe.**references:** Haynes, Raychaudhuri and Beyer, 1990, Mol. Cell. Biol. 10: 316-23.

Haynes, Rebbert, Mozer, Forquignon, and Dawid, 1987, Proc. Natl. Acad. Sci. USA 84: 1819-23.

**phenotype:** Homology to the mammalian A and B hnRNP proteins based on amino acid sequence inferred from nucleotide sequence.**cytology:** Placed in 98D-E by *in situ* hybridization. Located 15 kb distal of *fkh*.**molecular biology:** Genomic clone isolated from Maniatis library (partial sequence); cDNA clones from ovarian, embryonic and pupal libraries (complete sequences). Eight transcripts are produced by use of the alternative promoters, exons, and splice acceptor sites; these transcripts can encode four protein isoforms. Transcripts are expressed throughout development with highest levels in ovaries, early embryos, and pupae.**Hrb2: hnRNA-binding protein 2 (S. Haynes)****origin:** Isolated from a cDNA library by homology with *Drosophila Hrb1* gene.**references:** Haynes, Raychaudhuri, Johnson, Amero, and Beyer, 1990, Mol. Biol. Rep. 14: 93-4.**phenotype:** Homology to the mammalian A and B hnRNP

proteins based on amino acid sequence inferred from nucleotide sequence.

**cytology:** Placed in 87F by *in situ* hybridization.**molecular biology:** Genomic clone isolated from Maniatis library (partial sequence); cDNA clones from ovarian, and embryonic libraries (complete sequences). Two transcripts (2.2 and 1.7 kb) are produced by use of alternative polyadenylation sites. Transcripts are expressed throughout development with highest levels in ovaries, early embryos, late larvae and early pupae.**Hsc70: Heat-shock-cognate 70**Three gene sequences that share homology with *Hsp70* as demonstrated by *in situ* hybridization to polytene chromosomes and subsequent sequence determination. Although their transcription is developmentally regulated, it is temperature independent. Sequence analysis of the amino terminus reveals 70-80% identity between *Hsp70* and its three cognates. Unlike *Hsp70*, the *Hsc70* genes carry sequences in the 5' non-coding region that encode three additional amino acids. In *Hsc70-1*, the codon specifying amino acid 66 is interrupted by an 1.7 kb insertion; in *Hsc70-2*, the codon specifying amino acid 55 is also interrupted by an insertion (Craig *et al.*, 1983). *Hsc70-4* and *Hsp70*, however, have no insertions in the region coding for amino acids 1-101.

<sup>β</sup> Between *ry* and *pic*.**Hsp: Heat-shock protein**Exposure of cells to pulses of elevated temperature initiates the heat-shock response. A restricted subset of genes, the *Hsp* genes, is activated and the majority of transcription and translation is shut-down. However, mitochondrial- and histone-gene activities persist (Spradling, Pardue, and Penman, 1977, J. Mol. Biol. 109: 559-87). This response follows a pulse of 36° to 40°; treatments above 40° inhibit all activity and lead to death; treatments of 30°-35° induce heat-shock-protein synthesis without repressing normal protein synthesis (Tissières, Mitchell, and Tracy, 1974, J. Mol. Biol. 84: 389-98). Similar response inducible by other stressful treatments. The response may be elicited at all stages of the life cycle and in cultured cells. Stage specific phenocopies result from heat shocking early stages of *Drosophila* development [Mitchell and Petersen, 1982, Heat Shock from Bacteria to Man (Schlesinger, Ashburner, and Tissières, eds.). Cold Spring Harbor Laboratory, New York, pp. 345-52]. In polytene cells existing puffs regress and a novel group quickly appears [33B, 63C, 64F, 67B, 70A, 87A, 87C, 93D, 95D (Ashburner, 1970, Chromosoma 31: 356-76; Tissières *et al.*, 1974)]. Activation of transcription of *Hsp* genes apparently involves the sequential binding of two or more protein factors in vicinity of TATA box (Wu, 1984, Nature (London) 309: 229-34). Binding sites for these proteins are multiple short upstream sequence elements called HSEs or heat shock consensus elements (Pelham, 1982, Cell

30: 517-28; Xiao and Lis, 1988, *Science* 239: 1139-42). Polymerase II dissociates from most chromosome regions and accumulates at the new puff sites (Bonner and Kerby, 1982, *Chromosoma* 85: 93-108). 3H-uridine incorporation ceases at its usual positions and commences at new puff sites. Preexisting polysomes disaggregate and within a few minutes a new population of polysomes appears containing newly transcribed mRNA; this RNA hybridizes to some of the heat-shock puffs. The effects of heat shock may be abrogated to some degree by pre-treatment with a pulse of a slightly lower temperature (Mitchell, Moller, Petersen, and Lipps-Sarmiento, 1979, *Dev. Genet.* 1: 181-92 Peterson and Mitchell, 1981, *Proc. Nat. Acad. Sci. USA* 78: 1708-11). For reviews of the heat-shock response see Ashburner and Bonner (1978, *Cell* 17: 241-54) and Heat Shock from Bacteria to Man (cited above). The different heat-shock genes are designated by the molecular weights in kilodaltons of the polypeptides they produce: *Hsp22*, *Hsp23*, *Hsp26*, *Hsp27*, *Hsp68*, *Hsp70* and *Hsp83*.

### **Hsp22 - Hsp-G3**

**phenotype:** There are seven closely related heat-shock genes at 67B (Ayme and Tissières, 1985; Pauli, Arrigo, Vasquez, Tonka, and Tissières, 1989, *Genome* 31: 671-76). In addition to the four small heat-shock genes previously identified (*Hsp22*, *Hsp23*, *Hsp26*, and *Hsp27*), three more genes (*Hsp-G1*, *Hsp-G2*, and *Hsp-G3*, formerly called *Gene1*, *Gene2*, and *Gene3*) have been found clustered within 15 kb of DNA at the same 67B cytological location. All seven genes are heat-shock inducible in almost all cells at the stages tested (Ayme and Tissières, 1985). The genes are also transcribed during certain developmental stages in the absence of heat shock (Sirotkin and Davidson, 1982, *Dev. Biol.* 89: 196-210). Pauli *et al.* (1989) report that the maximum accumulation of developmental rRNA in a majority of these small heat-shock genes occurs in the white pupae stage; in *Hsp-G2*, however, a small transcript is found in embryos, first and second instar larvae, and young pupae; and a larger transcript in the pupal and adult stages of males (Pauli and Tonka, 1987, *J. Mol. Biol.* 198: 235-40; Pauli, Tonka, and Ayme-Southgate, 1988, *J. Mol. Biol.* 200: 47-53). In absence of stress, the expression of *Hsp26* has been observed in spermatocytes, nurse cells, epithelium, imaginal discs, proventriculus, and neurocytes (Glaser, Wolfner, and Lis, 1986, *EMBO* 5: 747-54). Transcripts of *Hsp26* and *Hsp27* accumulate in adult ovaries, apparently originating in nurse cells (Zimmerman, Petri, and Meselson, 1983, *Cell* 32: 1161-70).

**alleles:** A mutant allele of *Hsp27* that produces small amounts of a large, heat-induced transcript has been cloned and found to contain a defective *P*-element (Eissenberg and Elgin, 1987, *Genetics* 115: 333-40).

**molecular biology:** All of the small heat-shock genes are located on the same 15 kb fragment. The order from distal to proximal is *Hsp-G3*, *Hsp-G2*, *Hsp22*, *Hsp26*, *Hsp-G1*, *Hsp23*, *Hsp27*, with *Hsp22*, *Hsp-G1*, and *Hsp-G3* transcribed from one strand and the remainder transcribed from the other (Corces, Holmgren, Freund, Morimoto, and Meselson, 1980, *Proc. Nat. Acad. Sci. USA* 77: 5390-93; Voellmy, Goldschmidt-Clermont, Southgate, Tissières, Levis, and Gehring, 1981, *Cell* 23: 261-70; Szauter and Pardue, 1982, *Genetics* 100: s67 68; Ayme and Tissières, 1985; Pauli *et al.*, 1989). Genomic and putative amino acid sequences obtained from all seven genes (Ingolia and Craig, 1982, *Proc. Nat. Acad. Sci. USA* 79: 2360-64; Southgate, Ayme, and Voellmy, 1983, *J. Mol. Biol.* 165: 35-57; Ayme and Tissières, 1985; Pauli and Tonka, 1987; Pauli *et al.*, 1988). Activation of the small heat-shock genes by stress depends on consensus sequences upstream of the transcription start sites. A third and larger transcript is induced by heat shock in *Hsp-G2*; this transcript extends through *Hsp22* to the 3' end of the latter gene (Pauli *et al.*, 1988). Heat-shock proteins 22, 23, 26, and 27 are encoded by the corresponding genes; protein products of the other three heat-shock genes have not been identified yet, although the amino acid sequences have been estimated from genomic sequences. All seven genes show homologies, both to each other, and to a lesser extent, to mammalian lens protein, the  $\alpha$ -crystallins. There is considerable upstream sequence identity between heat-shock genes expressed strongly in ovaries [i.e., *Hsp26*, *Hsp27*, and the larger heat-shock gene *Hsp83* (Xiao and Lis, 1988, *Science* 239: 1139-42)]. Peaks in *Hsp26* and *Hsp28* mRNA are correlated with peaks in ecdysteroid titres in mid-embryogenesis pupariation, and mid pupation (Thomas and Lengyel, 1986, *Dev. Biol.* 115: 434-38).

### **Hsp68**

**phenotype:** The structural gene for the 68,000 dalton heat-shock protein (HSP68).

**molecular biology:** The gene has been cloned and restriction mapped; it is represented but once in the genome (Holmgren, Livak, Morimoto, Freund, and Meselson, 1979, *Cell* 18: 1359-70). Thermal stability tests indi-

cates that there is about 15% sequence divergence between *Hsp68* and *Hsp70*. The mRNA of *Hsp68* is 2.1 kb in length; there are no introns in the genomic sequence.

### **Hsp70**

**phenotype:** The structural genes that code for the 70,000 dalton heat-shock protein (HSP70), the most abundant of the heat-shock proteins. HSP70 returns to preshock levels more rapidly than other heat-shock proteins following return to 25° (DiDomenico, Bugaisky, and Lindquist, 1982, Proc. Nat. Acad. Sci. USA 79: 6181-85). The protein becomes concentrated in nuclei during heat shock; disperses to cytoplasm during recovery; returns to nucleus upon further heat shock (Velazquez and Lindquist, 1984, Cell 36: 655-62). Appears not to be expressed in the testis in response to heat-shock stimulation (Bonner, Parks, Parker-Thornberg, Mortin, and Pelham, 1984, Cell 37: 979-91). Deletion of either the 87A7 or the 87C1 sequences does not eliminate the HSP70 heat-shock response; simultaneous deletion of both sequences does eliminate the HSP70 heat-shock response (Ish-Horowitz *et al.*, 1979).

**molecular biology:** mRNA for a 70 kilodalton heat-shock protein hybridizes to both 87A and 87C on the salivaries (Spradling, Pardue, and Penman, 1977, J. Mol. Biol. 109: 559-87). Several clones isolated from each region and sequences determined. There are two copies of *Hsp87A*, and three copies of *Hsp87C* (Holmgren, Livak, Morimoto, Freund, and Meselson, 1979, Cell 18: 1359-70). Restriction maps of clones from the two regions differ slightly (Artavanis-Tsakonis, Steward, Gehring, Mirault, Goldschmidt-Clermont, Moran, and Tissières, 1978, Cell 14: 921-29). Two copies of *Hsp70* coding sequence at 87A arranged in divergent order with ATG codons separated by about 1700 nucleotide pairs (Goldschmidt-Clermont, 1980, Nucleic Acids Res. 8: 235-52). Sequence between the two determined (Mason, Torok, Kiss, Karch, and Udvardy, 1982, J. Mol. Biol. 156: 21-35). At 87° two copies separated by about 1000 nucleotides pairs are transcribed in the proximal to distal direction; the third sequence, about 38,000 nucleotide pairs proximal to the other two, is transcribed in the opposite direction (Ish-Horowitz and Pinchon, 1980, J. Mol. Biol. 142: 231-45; Mason *et al.*, 1982). The proximal copy of *Hsp70* at 87C sequenced by Ingolia, Craig, and McCarthy (1980, Cell 21: 669-79). Sequence 5' to *Hsp70* coding sequences compared (Mason *et al.*, 1982). Between the single proximal and two distal *Hsp70* genes at 87C lie several repeated sequences designated  $\alpha$ ,  $\beta$ , and  $\gamma$ . *Hsp70* exhibits 48% homology with *dnaK*, a heat-shock gene in *E. coli* (Bardwell and Craig, 1984, Proc. Nat. Acad. Sci. USA 81: 848-52). 74% homology with the yeast *Hsp70* genes, and 85% homology with mouse *Hsp70* genes (Moran, Chauvin, Kennedy, Korri, Lowe, Nicholson, and Perry, 1983, Can. J. Biochem. Cell Biol. 61: 488-99). Activation of transcription on exposure to heat shock is carried out by upstream consensus elements or HSEs (see introduction) as indicated by deletion analyses of *Hsp70* (Pelham, 1982, Cell 30: 517-28; McGarry and Lindquist, 1985, Cell 42: 903-11). Determination of sequence requirements by *P*-element germline transformation (Cohen and Meselson, 1984, Proc. Nat. Acad. Sci. USA 81: 5509-13). The HSE for *Hsp70*

was thought to be a 14-bp element, (Pelham, 1982); however, a very low level of heat-shock expression was obtained with two copies of the 14-bp HSE in flies carrying the *Hsp70-lacZ* hybrid gene. Recently, a HSE made up of contiguous arrays of inverted repeats of a 5-bp unit, -GAA-, has been proposed (Amin, Ananthan, and Voellmy, 1988, Mol. Cell Biol. 8: 3761-69; Xiao and Lis, 1988, Science 239: 1139-42; Perisic, Xiao, and Lis, 1989, Cell 59: 797-806); the *Drosophila melanogaster* *Hsp70* gene has four arrays of three or four 5-bp units each (Perisic, Xiao, and Lis, 1989).

### **Hsp83**

**phenotype:** The structural gene for the 83,000 dalton heat-shock protein (HSP83). During development, the gene is expressed at high levels in the absence of heat shock in many tissues, especially ovaries where it apparently originates in nurse cells (Zimmerman, Petri, and Meselson, 1983, Cell 32: 1161-70). During heat shock, however, the expression level is only raised several fold (Xiao and Lis, 1989, Mol. Cell Biol. 9: 1746-53). Deletion of sequences upstream from the coding region eliminates normal developmental expression and results in regulation of *Hsp83* in a manner similar to that of *Hsp70* which is activated only in response to heat shock.

**molecular biology:** The sequence, which is unique, has been cloned, restriction mapped, and sequenced (Hackett and Lis, 1983, Nucleic Acids Res. 11: 7011-30; Blackman and Meselson, 1986, J. Mol. Biol. 188: 499-515). The mRNA is 2.6 kb in length; no introns found in genomic sequence. The expression of the gene during normal development (in the absence of heat shock) was thought to be due to the affinity of three overlapping, 14-bp heat shock consensus elements for a *trans*-acting heat shock factor (Xiao and Lis, 1986, Mol. Cell Biol. 6: 3200-06). Deletion mutants carrying the multiple HSEs, however, lost most of their developmental expression, but responded to heat shock like *Hsp70*. Recently Xiao and Lis (1989, Mol. Cell Biol. 9: 1746-53) have proposed that regulation of *Hsp83* is the result of a single array of eight 5-bp units (-GAA). Upstream regions necessary for expression of ovarian development carry a 7-bp sequence CGTTTTG and multiple copies of the shorter sequence GTTTT (Xiao and Lis, 1989). A peak in *Hsp83* mRNA is correlated with a peak in ecdysteroid titre in mid-embryogenesis, pupariation, and mid-pupation (Thomas and Lengyel, 1986, Dev. Biol. 115: 434-38).

### **Hsr93D: Heat-shock RNA at 93D**

**location:** 3-71 (based on cytological position with respect to *e*).

**synonym:** *hsr $\omega$* .

**references:** Bonner and Pardue, 1976, Cell 8: 43-50.

Mohler and Pardue, 1984, Genetics 106: 249-65.

Garbe, Bandena, Alfano, and Pardue, 1986, J. Biol. Chem. 261: 16889-94.

Bandena, Garbe, Traverse, Lakhotia, and Pardue, 1989, J. Cell Biol. 108: 2017-28.

Garbe, Bandena, and Pardue, 1989, Genetics 122: 403-

15.

Lakhotia, 1989, *Genome* 31: 677-803.

**phenotype:** A sequence that responds to heat shock by generation of a large puff in polytene chromosomes. The 93D region transcribes mRNA that apparently is not translated. *Hsr93D* is active in almost all cells in *Drosophila melanogaster*; the activity is greatly increased by heat shock (Bonner and Pardue, 1976) and is induced independently by benzamide (Lakhotia and Mukherjee, 1970, *DIS* 45: 108). The inducibility of the locus is selectively repressed by a combination of heat shock with another inducer, by rearing larvae at 10°, by heterozygous deficiency for 93D or by treating wild-type salivaries with beta-alanine (Lakhotia, 1989). The 93D heat shock mRNA is predominately polyA<sup>-</sup> in the cytoplasm, whereas nuclear transcripts are both polyA<sup>+</sup> and polyA<sup>-</sup> (Lengyel, Randson, Graham, and Pardue, 1980, *Chromosoma* 80: 237-52). Heat-shock response in homozygous deficiencies for *Hsr93D* is indistinguishable from normal except for the absence of the 93D puff and transcripts.

**cytology:** Placed between 93D4 and 93D9 by deficiency mapping.

**molecular biology:** Transcribed region of the genome cloned and sequenced (Walldorf *et al.*, 1984; Garbe and Pardue, 1986; Garbe *et al.*, 1986 1989). Shown by *Tacql* digestion to comprise a 10-12 kilobase tandem array of 280 nucleotide repeat sequences. Transcripts produced following heat shock complementary to *Tacql* repeat sequence but not to flanking sequences. There are three overlapping transcripts, all from the same start site. The largest transcript,  $\omega 1$ , is limited to the nucleus and is composed of about 3 kb of unique regions followed by 7-17 kb of short tandem repeats (Bendena *et al.*, 1989). The second transcript,  $\omega 2$ , also nuclear, contains the first 2-3 kb of the unique region. The cytoplasmic transcript,  $\omega 3$ , has the same sequence as  $\omega 2$  minus an intron of about 700 bp (Garbe *et al.*, 1986). All three transcripts are produced in nonstressed cells, but the transcript level is increased significantly when the cells are heat shocked. Drugs such as benzamide that increase puffing, lead to large increase in the  $\omega 1$  transcript. There are no long open reading frames (Garbe *et al.*, 1989). Although *Hsr93D* does not encode any known heat-shock protein, there is some evidence that the cytoplasmic mRNA  $\omega 3$  contains a very small open reading frame (ORF  $\omega$ ) that would encode 23 to 27 amino acids and is conserved in *D. melanogaster*, *D. pseudoobscura*, and *D. hydei* (Fini, Bendena, and Pardue, 1989, *J. Cell Biol.* 108: 2045-57; Garbe *et al.*, 1989).

**Hsr  $\alpha$   $\beta$** 

**location:** 3-51 (based on cytological location).

**references:** Lis, Prestidge, and Hogness, 1978, *Cell* 14: 901-19.

Livak, Freund, Schweber, Wensink, and Meselson, 1978, *Proc. Nat. Acad. Sci. USA* 75: 5613-17.

Hackett and Lis, 1981, *Proc. Nat. Acad. Sci. USA* 78: 6196-6200.

**phenotype:** Repeated sequences that are transcribed in response to heat shock. Not translated.

**cytology:** Localized to 87C1.

**molecular biology:** A series of tandemly repeating units, each comprising an  $\alpha$  (0.49 kb) and a  $\beta$  (1.10 kb), located

between the proximal two, divergently oriented, *Hsp70* gene sequences in 87C. There are several tandem arrays separated by nontranscribed spacer regions. In some of the elements  $\beta$  is replaced by  $\gamma$  (0.87 kb), which is homologous to sequences 5' to all five *Hsp70* genes.

*HsrW*: see *Hsr93D*

**hth: homothorax**

**location:** 3-48.

**origin:** Induced with ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95 (fig.).

**phenotype:** Homozygous lethal. Thoracic segments of embryo similar to one another; morphology of denticle bands intermediate between that of normal first and second thoracic segments.

**cytology:** Placed in 85E-86B by segmental aneuploids.

*Hu*: see *Antp<sup>Hu</sup>* under *ANTC*

*Huba*: see *Fs(3)Sz12*

**Humeral patch:** see *Hup*

**humped:** see *hp*

**humpy:** see *hy*

**hunchback:** see *hb*

**hup: hold-up**

**location:** 2-44 (probably to the left of *abo* based on failure of 8 recombinants between *da* and *hup* to separate *hup* from *abo*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Sandler, 1977, *Genetics* 86: 567-82.

Lindsley, D.E., Goldstein, and Sandler, 1980, *DIS* 55: 84-85.

**phenotype:** Nearly completely penetrant upheld wing. Homozygotes viable and semisterile in both sexes. Lethal in combination with deficiency. Mortality of zygotes produced by *hup* mothers increased by the presence of a paternally inherited Y chromosome but not by the quantity of paternally derived X heterochromatin. Maternal effect at 25° more severe than at 19°. Fertility also temperature sensitive; spermatids of sterile males show micronuclei and occasional double basal bodies and axonemes.

**cytology:** Placed in 31F-32E based on inclusion in *Df(2L)J39 = Df(2L)31A-B;32E* but not *Df(2L)J27 = Df(2L)31B-D;31F* of *Df(2L)Mdh-2J = Df(2L)30D-F;31F*.

**other information:** Complements *abo*, *dal*, and *wd*<sup>2</sup>.

**Hup: Humeral patch**

**location:** 1-{20}.

**references:** Merriam, Yamamoto, Stewart, Rahman, and Nicolau, unpublished.

**phenotype:** A haplo-sensitive site on the X chromosome. Patch on either side of the thorax including the humeral bristles appears extended as a knobby outgrowth.

**cytology:** Placed in 7C by segmental aneuploidy.

**hv: heavy-vein**

**location:** 2-104.0.

**discoverer:** Curry, 36115.

**phenotype:** Veins thick and knotty, especially at ends of

crossveins; posterior crossvein oblique and may show break in middle; extra crossveins sometimes present. Wings broad, thick, dark, warped, divergent, and droopy. Eyes small and bulging. Posterior scutellars blunt, short, and crossed. Overlaps wild type at 25° but useful at 19°. RK2.

**\*Hv: Hooked-veins**

**location:** 1-66.

**discoverer:** Tanaka, 35a4.

**references:** 1935, DIS 4: 16.

1936, DIS 5: 8.

1937, DIS 8: 11.

**phenotype:** Heterozygous female shows small branches from posterior crossvein and L5. Eyes small and rough.

Homozygous female lethal. RK3A.

**cytology:** Associated with *In(1)Hv*.

**Hw:** see **ASC**

**Hx: Hexaptera**

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Herskowitz, 47j.

**references:** 1949, Genetics 34: 10-25 (fig.).

**phenotype:** Expression same in *Hx/+* and *Hx/Hx*, varies from absence of a detectable difference from normal through various intermediate types to presence of large appendage on prothorax. Entire abnormal structure may remain beneath exoskeleton. Appendage varies from small amorphous mass to highly differentiated wing. May also produce haltere- and leg-like appendages. Penetrance same in homozygote and heterozygote; prothorax to mesothorax transformation, enhanced by crowding and by high temperature (at 20°, male 1.5 and female 3.3%; at 25°, male 6.5 and female 24.2%); and affected by genotype, *e.g.*, suppressed by *In(2L+2R)Cy* and by *In(2LR)bw<sup>VI</sup>*. RK3.

**hy: humpy**

**location:** 2-93.3.

**origin:** Spontaneous.

**discoverer:** Bridges, 18j22.

**references:** 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Thorax strongly ridged with commas anteriorly and two pairs of vortices. Wings obliquely truncated to one-half normal length. An irregular contraction of larval muscles at time of pupation (Waddington, 1941, Proc. Zool. Soc. London Ser. A 111: 181-88). Viability low and erratic. Both sexes highly infertile. RK2.

**cytology:** Placed in region 57 on basis of its being to the right of *In(2R)NS = In(2R)52A2-B1;56F9-13* and to the left of *Df(2R)M-1 = Df(2R)57F11-58A1;58F8-59A1* (Bridges, 1937).

**Hydroxy acid dehydrogenase:** see *Had*

**Hydroxphenyl buten-1:** see *Hpb*

**hyperantenna:** see *hpa*

**Hyperkinetic:** see *Hk*

**hy: humpy**

Edith M. Wallace, unpublished.

**hypoA: hypoactive-A (J.C. Hall)**

**location:** 1-1.0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

**phenotype:** Inactive; difficult to arouse for flight; runs and climbs slowly; jumps and flies abnormally short distances; slow optomotor response; debilitated after mechanical stress.

**hypoB:** see *iav* (in addendum)

**hypoC (J.C. Hall)**

**location:** 1-44.3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

Homyk, 1977, Genetics 87: 105-28.

O'Dell and Burnet, 1988, Heredity 61: 199-207.

O'Dell, Burnet and Jallon, 1989, Heredity 62: 373-81.

**phenotype:** Relatively inactive (Homyk and Sheppard, 1977); difficult to arouse for flight; flies abnormally slow (hovers and fixates on object while flying); runs and climbs slowly; slow optomotor response. Jumping ability very poor (O'Dell and Burnet, 1988). Mosaic analysis (Homyk, 1977) suggests primary defect could be in central nervous system or in muscles. In open field activity chamber tests (O'Dell and Burnet, 1988), moves as much as wild-type initially (0-10 minutes) but becomes less active later (10-20 minutes); both speed and amount of movement affected (*e.g.* in aging tests, both metrics increase in parallel from day 1 to 16 of adulthood, whereas wild types show near-maximal levels of activity as young adults, with slow decline during subsequent one month). When homozygous in females, causes reduced mating propensity and extended courtship durations (O'Dell *et al.*, 1989).

**alleles:** *hypoC<sup>1</sup>*, *hypoC<sup>2</sup>*.

**hypoD:** see *slrp*

***hypoE*** (J.C. Hall)

**location:** 1-39.2.

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk, Szidonya, and Suzuki, 1980, *Molec. Gen. Genet.* 177: 553-65.

O'Dell and Burnet, 1988, *Heredity* 61: 199-207.

O'Dell, Burnet and Jallon, 1989, *Heredity* 62: 373-81.

**phenotype:** Subnormal activity (Homyk *et al.*, 1980); requires extensive agitation to induce movements and becomes inactive more quickly than normal when agitation ceases; males inactive in courtship. Jumping ability very poor (O'Dell and Burnet, 1988). In open field chamber tests (O'Dell and Burnet, 1988), speed of locomotion (number of squares entered/unit time) reduced but not the amount (proportion of time spend moving); amount of speed changes in wild-type-like

manner with advancing adult age (*cf. hypoC*) When *hypoE* homozygous in females, their receptivity to male courtship and mating attempts is essentially the same as for wild-type females (O'Dell *et al.*, 1989).

**other information:** Complements the closely linked *comt* mutations.

***hypoF*:** see *rdgB*

***hypoG*** (J.C. Hall)

**location:** 1-50.8.

**references:** Homyk, Szidonya, and Suzuki, 1980, *Molec. Gen. Genet.* 177: 553-65.

**phenotype:** Subnormal activity, similar to that caused by *hypoE*, except *hypoG* more abnormal, including decreasing and relatively quick cessation of wing beats in flight plus weak optomotor response.

*i*: see *E(B)*

*I*: see *E(B)*

*I-f*: see *E(f)*

*iab*: see *BXC*

***iav*: inactive (J.C. Hall)**

**location:** 1-18.8.

**references:** Kaplan, 1977, DIS 52: 1.

O'Dell and Burnet, 1986, DIS 63: 107-08.

**phenotype:** Morphology normal; adults extremely inactive; population of mutants remains quiet and spread out evenly in a container; will walk or fly when container disturbed, but settles into inactivity soon after a disturbance; gene could be allelic to *hypoB* since *hypoB/iav* flies showed a marked reduction in activity for twenty generations (O'Dell and Burnet, 1986). Fertile. RK1.

**cytology:** Located in 7A5-7C1.

*Ic D*: see *bw*<sup>VD</sup>

***Idh*: Isocitrate dehydrogenase**

**location:** 3-25.4 [based on Ohnishi and Voelkers mapping of *Idh<sup>F</sup>* vs *Idh<sup>S</sup>* to a position between *ju* and *se* (1982, DIS 58: 121); Fox (1970, DIS 45: 35) mapped same alternatives to 27.1].

3-27.2 [based on Bentley, Meidinger, and Williamson's (1983, Biochem. Genet. 21: 725-33) mapping of *Idh<sup>nGB1</sup>* vs *Idh<sup>+</sup>* to a position between *h* and *th*].

**synonym:** *Idh-NADP*.

**references:** Fox, D.J., 1971, Biochem. Genet. 5: 69-80.

Williamson, Krochko, and Bentley, 1980, Comp. Biochem. Physiol. 65B: 339-43.

Kuhn and Cunningham, 1986, Dev. Genet. 7: 21-34.

**phenotype:** Term for the structural gene or genes for NADP<sup>+</sup>-dependent isocitrate dehydrogenase [threo-D-isocitrate: NADP<sup>+</sup> oxydoreductase (decarboxylating)]; [IDH(E.C 1.1.1.42)]. Studies of purified enzyme (Williamson) indicate it to have a molecular weight of 110,000 and to be a dimer of subunits with molecular weights 60,000 and 50,000. Whether these are products of one or of two closely linked genes is uncertain; formation of a hybrid dimer in *Idh<sup>F</sup>/Idh<sup>S</sup>* heterozygotes suggests a single locus, but the mapping results outlined above are suggestive of two. Only maternally derived enzyme present during most of embryogenesis with vigorous zygotic production beginning just prior to hatching (Wright and Shaw, 1970, Biochem. Genet. 4: 385-94); peak activity reached in third larval instar after which the level falls until just prior to eclosion when it rises once more (Fox, 1971, Biochem. Genet. 5: 69-80). Activity found in all tissues, but especially high in larval fatbody and the sperm pump of adult males and to a lesser extent in the larval and adult midgut and the seminal receptacle and spermathecae (Fox, Conscience-Egli, and Abächerli, 1972, Biochem. Genet. 7: 163-75). Staining activity distributed nonuniformly in the following imaginal discs: eye-antenna, all thoracic discs, and genital, plus in larval gut, adult ovaries, and internal male genitalia. Staining patterns formed gradually in eye-antennal and wing disks. IDH staining pattern and intensity changed in third instar larvae as ommatidia are differentiated. When the tissue type is transformed by homeotic genes, the IDH pattern is altered in a specific

way (Kuhn and Cunningham, 1986). Labial discs, histoblasts, and salivary glands stain uniformly; clypeus-labrum disc, imaginal foregut cells and imaginal ring of hind gut show no activity (Cunningham and Kuhn, 1981, Insect Biochem. 11: 277-85).

<sup>α</sup> 1 = Bentley, Meidinger, and Williamson, 1983, Biochem. Genet. 21: 725-33; 2 = Burkhart, Montgomery, Langley, and Voelker, 1984, Genetics 107: 295-306; 3 = Fox, 1970, DIS 45: 35; 4 = Fox, 1971, Biochem. Genet. 5: 69-80; 5 = Fox, 1972, DIS 48: 20; 6 = Langley, Voelker, Leigh Brown, Ohnishi, Dickson, and Montgomery, 1981, Genetics 99: 151-56; 7 = Voelker, Langley, Leigh Brown, Ohnishi, Dickson, and Montgomery, and Smith, 1980 Proc. Nat. Acad. USA 77: 1091-95.

<sup>β</sup> 24% wild-type levels of CRM; kinetic properties of residual activity indistinguishable from those of wild type.

**cytology:** Placed in region 66B-D by Voelker and Ohnishi (Burkhardt, Montgomery, Langley and Voelker, 1984, Genetics 107: 295-306).

***if*: inflated**

**location:** 1-55.

**references:** Brower, Wilcox, Piovant, Smith, and Reger, 1984, Proc. Nat. Acad. Sci. USA 81: 7485-89.

Wilcox, Brown, Piovant, Smith, and White, 1984, EMBO J. 3: 2307-13.

Bogaert, Brown, and Wilcox, 1987, Cell 511: 929-40.

Leptin, Aebersold, and Wilcox, 1987, EMBO J. 6: 1037-43.

Brower and Jaffe, 1989, Nature (London) 342: 285-87

Brown, King, Wilcox, and Kalfatos, 1989, Cell 59: 185-95.

**phenotype:** Structural gene for the α-subunit of position specific integrin 2 (PS2), a large transmembrane protein (Bogaert *et al.*, 1987). The β-subunit can associate with either of the two α-subunits, PS1 or PS2 (Brower *et al.*, 1984; Wilcox, Brown, Piovant, Smith, and White, 1984, EMBO J. 3: 2307-13). Both α and β integrin are expressed in embryonic and larval tissues. In early development, PS2 is found in the mesoderm, localized to muscle attachments (Bogaert *et al.*, 1987). Later, PS1 is expressed in the presumptive dorsal epithelium of the third instar imaginal wing discs; also, PS2 is found in the ventral epithelium, both integrins being important for the joining of the dorsal and ventral surfaces of the wing blade (Brower and Jaffe, 1989). Null mutations cause embryonic lethality (Wilcox, DiAntonio, and Leptin). In the mutant *if<sup>1</sup>*, the adult wing is inflated with lymph and smaller than normal; venation is defective. Wings later become dry and blistered.

---------	--------	------------	------------------	----------

<sup>α</sup> 1 = Brower and Jaffe, 1989, Nature (London) 342: 285-87; 2 = Curry, 1939, DIS 12: 45; 3 = Schalet, Leigh, and Paradi, 1983, Proc. Int. Congr. Rad. Res. 7th, pp. c4-12; 4 = Weinstein, 1918, Genetics 3: 157.

<sup>β</sup> Further descriptions below.

**cytology:** Located in 15A1-5 by *in situ* hybridization of cloned DNA (Bogaert *et al.*, 1987).

**molecular biology:** The gene encoding the PS2  $\alpha$ -subunit has been cloned, genomic and cDNA sequences obtained (Bogaert *et al.*, 1987). The predicted N terminus of the PS2  $\alpha$ -subunit is part of a 4182-bp open reading frame that encodes a 1394 amino acid protein of 154 kd; the *Drosophila* N-terminal sequences show identity to the sequences of both the heavy and light chains of  $\alpha$ -subunits of the vertebrate fibronectin receptor family (Bogaert *et al.*, 1987; Leptin *et al.*, 1987). The C-terminal region of the *Drosophila*  $\alpha$ -subunit that shows no identity to the vertebrate  $\alpha$ -subunit is characterized by the presence of multiple serine repeats.

*if*<sup>3</sup>

**phenotype:** Longitudinal veins thickened, especially at wing base. Anterior crossvein thickened. *if*<sup>3</sup>/*if*<sup>3</sup> flies show reduced levels of PS2 integrin on the surfaces of some imaginal disc cells (especially in the ventral region), but levels of this integrin in muscle, salivary glands, and most other tissues seem to be normal (Brower and Jaffe, 1989). Adult wings typically show large round wing blisters, but the penetrance of this phenotype in homo- and hemizygotes is variable. *if*<sup>3</sup>/*if*<sup>3</sup>*k27e* flies show an increase in penetrance (from 15-20% in homozygotes to 60-70% in the heteroalleles); penetrance is reduced in *if*<sup>3</sup>/*if*<sup>3</sup>*k27e* flies by low temperature and crowding (Brower and Jaffe, 1989).

*if*<sup>N</sup>

**other information:** Allele induced simultaneously with a *f* mutation (Schalet *et al.*, 1983).

### ***If*: Irregular facets**

**location:** 2-107.6 [0.6 unit to the right of *sp*, according to Ives; inseparable from *Kr* by recombination in 2589 opportunities. (Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Dev. Biol. 104: 172-86)].

**origin:** Spontaneous.

**discoverer:** Casey, 65116.

**references:** Ives, 1967, DIS 42: 39.

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** In heterozygote, eye area about one-half normal; narrow and pointed ventrally; facets irregular and often missing across middle of eyes, sometimes fused or absent in ventral portion. In homozygote, eyes are narrow slits with smooth glossy surface. In the eye disk of late third instar larvae, fairly large number of cell clusters in irregular arrangement, especially in ventral half of disk (Renfranz and Benzer, 1989). Viability and fertility good. RK1.

**cytology:** Placed in 60F3 on the basis of the concordant reversion of *If* and induction of *Kr*<sup>API</sup> associated with a molecularly, but not cytologically, discernable deletion of *Kr*<sup>+</sup>. (Preiss, Rosenberg, Kienlin, Seifert, and Jäckle, 1985, Nature 313: 27-32).

### ***Ifm*: Indirect flight muscle (J.C. Hall)**

A collection of ethyl-methanesulfonate-induced autosomal dominant flight-defective mutants characterized by Mogami and Hotta (1981, Mol. Gen. Genet. 183: 409-17). Heterozygotes frequently hold wings up. Fine structure examination of myofibrils reveals abnormalities in every case, and in some cases particular proteins missing from three-dimensional gels of homozygotes. Specific features detailed in the following entries.

*Ifm*(2)3 : see *Mhc*

#### ***Ifm*(2)11**

**location:** 2-56 (just to right of *pr*).

**phenotype:** 10% of homozygotes hold wings erect. Myofibrils have thin or ruptured A bands; may appear faint.

**other information:** Fails to complement *Ifm*(2)3 even though it maps to a separate second-chromosome region.

*Ifm*(3)1 : see *Act88F*

*Ifm*(3)2 : see *Act88F*

*Ifm*(3)3 : see *Tm2*

*Ifm*(3)4 : see *Act88F*

#### ***Ifm*(3)5, *Ifm*(3)6**

**location:** 3-55 (between *red* and *ss*).

**phenotype:** Homozygotes for *Ifm*(3)5 and *Ifm*(3)6 display characteristic departures from wild-type protein patterns in two-dimensional gels (Mogami and Hotta, 1981). *Ifm*(3)5 homozygotes lack myofibrils; *Ifm*(3)6 homozygotes have opaque strings of myofibrils. Both mutants are flightless as heterozygotes. The myofibrils of *Ifm*(3)6 heterozygotes are frayed.

**other information:** *Ifm*(3)5 and *Ifm*(3)6 are recombinationally inseparable.

*Ifm*(3)7 : see *Act88F*

### **\**im*: interrupted margin**

**location:** 1-3.1.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 86-87.

**phenotype:** Wing margin nicked to various degrees with costal vein frequently interrupted. Extra wing venation often present and occasionally anastomoses, giving a plexus, particularly at the wing apex. Eyes smaller and sometimes slightly rough. Bristles thin. Males small, late eclosing; viability reduced. Female sterile. RK3.

### ***Imp-E*: Inducible membrane-bound polysomes-Early**

**origin:** From imaginal disc cultures treated with 20-hydroxyecdysone.

**references:** Natzle, Hammonds, and Fristrom, 1986, J. Biol. Chem. 261: 5575-83.

Natzle, Fristrom, and Fristrom, 1988, Dev. Biol. 129: 428-38.

**phenotype:** Name given to three genes encoding transcripts associated with membrane-bound polysomes in imaginal discs and expressed only in response to 20-hydroxyecdysone (20 HOE). Expression studied both *in vitro* and *in vivo*. *Imp-E* denotes three "early" genes

involved in elongation of appendage-forming regions of the imaginal discs by means of epithelial-cell rearrangements (Natzle *et al.*, 1988).

**cytology:** Three *Imp-E* genes have been isolated; their cytological location as determined by *in situ* hybridization is shown in the following table.

gene	location	cytology
<i>Imp-E1</i> <sup>α</sup>	3-[26]	66C
<i>Imp-E2</i>	3-[6]	63E
<i>Imp-E3</i>	3-[48]	84E

<sup>α</sup> Present in single copy.

**molecular biology:** Genes cloned by use of a hybridization screen for ecdysone inducible expression in imaginal discs (Natzle *et al.*, 1986). *Imp-E1* probe detects a 7.5 kb transcript in cultured imaginal discs treated with 20-HOE as well as in imaginal discs from third instar larvae and white pupae, where transcript occurs in leg, wing, haltere, and genital discs, but not in the ommatidial region of the eye-antennal discs (Natzle *et al.*, 1988). The transcript accumulates rapidly after 20-HOE treatment, but no transcript is found without ecdysone. *In vivo*, the 7.5 kb transcript can be detected, not only in larvae in the imaginal discs, but also (after pupariation) in glial cells around the brain. The gene product is believed to be involved in cell rearrangements in the epithelium of imaginal discs and in the glial layers (Natzle *et al.*, 1988).

#### *Imp-L: Imp-Late*

**origin:** From imaginal disc cultures treated with 20-hydroxyecdysone.

**references:** Natzle, Hammonds, and Fristrom, 1986, J. Biol. Chem. 261: 5575-83.

Osterbur, Fristrom, Natzle, Tojo, and Fristrom, 1988, Dev. Biol. 129: 439-44.

**phenotype:** *Imp-L* encoding transcripts associated with membrane-bound polysomes in imaginal discs and expressed only in response to 20-hydroxyecdysone (20 HOE). Expression studied both *in vitro* and *in vivo*. *Imp-L* denotes three "late" genes involved in the eversion to the exterior of the elongated regions of discs by means of local changes in cell shape (Osterbur *et al.*, 1988).

**cytology:** Three *Imp-L* genes have been isolated; their cytological location as determined by *in situ* hybridization is shown in the following table.

gene	location	cytology
<i>Imp-L1</i>	3-[40]	70A
<i>Imp-L2</i> <sup>α</sup>	3-[12]	64B
<i>Imp-L3</i>	3-[21]	65B

<sup>α</sup> Present in single copy.

**molecular biology:** Genes cloned by use of a hybridization screen for ecdysone-inducible expression is found in imaginal discs (Natzle *et al.*, 1986). *Imp-L3* probe detects a 3.0 kb transcript in cultured imaginal discs treated with 20-HOE as well as in third instar larvae and pupae (maximum transcript accumulation occurring just after pupation). *In vivo*, the 3.0 kb transcript can be detected in cells of the peripodial epithelium (precursors of head and thorax epithelium) and later in the imaginal histoblasts (precursors of the adult abdominal epithelium) (Osterbur *et al.*, 1988). The gene product may be involved in the flattening of the epithelial cells in preparation for fusion into a

contiguous sheet.

#### *in: inturred*

**location:** 3-46.75 (Arajärvi and Hannah-Alava, 1969, DIS 44: 73-4).

**origin:** Spontaneous.

**discoverer:** Bridges, 26k20.

**references:** Gubb and García-Bellido, 1982, J. Embryol. Exp. Morphol. 68: 37-57.

**phenotype:** Hairs and bristles on thorax and abdominal tergites, directed irregularly toward midline; trichomes and chaetae on mesonotum coordinately misdirected (Toney and Thompson, 1980, *Experientia* 36: 344-45). Marginal hairs of wing stand out from wing margin; trichomes on wing blade no longer directed in parallel with longitudinal veins; frequently divergent therefrom. 50-60% of trichome-bearing cells express duplicated or rarely triplicated trichomes. Wings slightly spread and tend to be long and narrow. Somatic clones of homozygous cells in wing described by Gubb and García-Bellido. Incomplete extra leg joints tend to form as mirror-image duplications proximal to the normal joints on tarsal segments three and four (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57). RK1.

*In-ho*: see *ho*<sup>40</sup>

#### *inaA: inactivation-no-afterpotential-A (J. Hall)*

**location:** 2-44 (between *Sp* and *B1*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakefield, ed.). Elsevier, New York, pp. 67-99.

**phenotype:** Mutant eyes lack the prolonged depolarizing afterpotential (PDA) that is induced in wild-type R1-6 photoreceptors by a bright or prolonged blue light stimulus, which photoconverts a large fraction of rhodopsin in these photoreceptors to metarhodopsin; *inaA*-induced phenotype differs from that observed in *nina* mutants because the R1-6 photoreceptors of *ina* mutants are inactivated after the blue stimulus, *i.e.*, are insensitive to subsequent blue light stimuli; an orange light stimulus, which cancels the PDA of wild type by photoconverting metarhodopsin back to rhodopsin, restores the R1-6 cell sensitivity of *ina* mutants.

**alleles:** One allele isolated as *P226*.

**inaB** (J.C. Hall)

**location:** 2-14 (between *S* and *Sp*).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakefield, ed.). Elsevier, New York, pp. 67-99.  
**phenotype:** Same basic phenotype as *inaA*; also, *inaB* lacks on and off transient spikes of electroretinogram (ERG).  
**alleles:** Two mutant alleles *inaB*<sup>1</sup> and *inaB*<sup>2</sup>, formerly *P222* and *P223*.  
**cytology:** Located in 25CD-28B. Normal allele carried by *Y*<sup>P</sup>*2*<sup>D</sup> element of *T(1;Y)H52 = T(1;Y)28B*, but not by that of *T(1;Y)D6 = T(1;Y)25C-D* (Pye).

**inaC** (J.C. Hall)

**location:** 2-82 (distal to *L*).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakefield, ed.). Elsevier, New York, pp. 67-99.  
**phenotype:** Same basic phenotype as *inaA*; also, *inaC* lacks off transient of ERG, and (in such physiological recordings) there is a slow return to baseline potential at stimulus offset.  
**alleles:** Eight; *InaC*<sup>1</sup> - *InaC*<sup>3</sup> isolated by Pak as *P207*, *P209*, and *P234*; *InaC*<sup>4</sup> - *InaC*<sup>8</sup> isolated in Merriam's laboratory as *US2167*, *US3741*, *US3841*, *US4173*, and *US4186*.

**inaD** (J.C. Hall)

**location:** 2-101.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakefield, ed.). Elsevier, New York, pp. 67-99.  
**phenotype:** Semi-dominant mutant of visual physiology, such that the phenotype (re PDA) of heterozygote similar to that produced by other *ina* homozygotes; *inaD* homozygotes exhibit ERG response that decays to baseline during bright light stimulus, and off transient is absent.  
**alleles:** One mutant allele, isolated as *P215*.  
**cytology:** Located between 58F1 and 60F1, based on coverage by *bw*<sup>+</sup> duplication in *bw*<sup>+</sup>*Yy*<sup>+</sup>.

**inaE** (J.C. Hall)

**location:** 1 (unlocalized).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakefield, ed.). Elsevier, New York, pp. 67-99.  
**phenotype:** Same basic eye-physiology phenotype as in *inaA*, *inaB*, and *inaC*; one allele (at least, *i.e.* *inaE*<sup>1</sup>) causes age-dependent photoreceptor degeneration.  
**alleles:** Two mutant alleles; *inaE*<sup>1</sup> and *inaE*<sup>2</sup> isolated as *N125* and *P19*.

**inactive:** see *iav*

**\*inb: incised balloon**

**location:** 2-55.  
**origin:** Spontaneous.  
**discoverer:** Neel, 41d9.  
**references:** 1942, DIS 16: 50.  
**phenotype:** Wings held at 45° angle to body. Wing margins incised, varying from slight nicks to extreme reduc-

tion to small fluid-filled sacs. RK2.

**cytology:** Salivary chromosomes normal.

**\*Ind: Indented**

**location:** 2-63.  
**origin:** Spontaneous.  
**discoverer:** Cole, 40e.  
**references:** Whittinghill and Parker, 1945, Genetics 30: 27-28.  
 Whittinghill, 1947, DIS 21: 72.  
**phenotype:** Eye usually kidney shaped with indentation anteriorly; shape sometimes normal but facets irregular. Often indented posteriorly as well as anteriorly, sometimes dividing eye into two spots or with only upper lobe persisting. Rarely eyeless. More extreme at 28° than at 25°. RK2.

**indented thorax:** see *int*

**Inr: Insulin receptor**

**location:** 3-{72}.  
**references:** Petruzzelli, Herrera, Garcia, and Rosen, 1985a, Cancer Cells: 115-21.  
 1985b, J. Biol. Chem. 260: 16072-75.  
 Nishida, Hata, Nishizuka, Rutter, and Ebina, 1986, Biochem. Biophys. Res. Commun. 141: 474-81.  
 Petruzzelli, Herrera, Arenas-Garcia, Fernandez, Birbaum, and Rosen, 1986, Proc. Nat. Acad. Sci. USA 83: 4710-14.  
 Fernandez-Almonacid and Rosen, 1987, Mol. Cell Biol. 7: 2718-27.  
**phenotype:** Encodes the insulin-binding (α) and insulin-dependent protein tyrosine kinase (β) subunits of the insulin receptor of *Drosophila melanogaster*. In *Drosophila* cell lines the insulin receptor contains insulin-binding α subunits of 110 or 120 kd, a 95-kd β subunit that is phosphorylated on tyrosine in response to insulin, and a 170-kd protein that may be an incompletely processed receptor. All of the components are processed from a proreceptor, joined by disulfide bonds, and exposed on the cell surface (Petruzzelli *et al.*, 1985a, 1985b, 1986; Fernandez-Almonacid and Rosen, 1987). Subunits in man and in *Drosophila* are similar both in molecular structure and in insulin-binding and protein tyrosine kinase activities; the latter activity is detected only during certain embryonic periods in *Drosophila*.  
**cytology:** Located in 93E by *in situ* hybridization of cloned DNA (Rosen and Young; confirmed by Chovnick); single copy gene.  
**molecular biology:** *Inr* has been cloned using human α- and β-subunit-specific probes (Nishida *et al.*, 1986; Petruzzelli *et al.*, 1986); nucleotide and deduced amino acid sequences of the kinase domain of the β subunits have been obtained. Fourteen clones hybridized to the human α subunit; two clones hybridized to the human β

subunit. A cDNA probe detects mRNA's of 8.6 and 11 kb. The 86-kb mRNA is relatively frequent in oocytes and early embryos whereas the 11-kb message is more prevalent in later embryos, in the developing nervous system and in imaginal discs (Garofalo and Rosen, 1988, Mol. Cell Biol. 8: 1638-47).

### **int: indented thorax**

**location:** 1-43.5.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Ghysen.

**references:** Deak, 1977, J. Embryol. Exp. Morphol. 40: 35-63.

Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rähmi, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81 (fig.).

Homyk and Emerson, 1988, Genetics 119: 105-21.

**phenotype:** 80-85% of *int* flies hold wings ventrolaterally, 10% hold them vertically and the remainder maintain normal wing position. In many flies mesonotum indented to variable degree and at various positions; 85% in flies raised at 29° and 45% when raised at 18°. More extreme expression in *y* flies; partially dominant in *y* genotypes. Fate mapping indicates focus in presumptive thoracic musculature. Indirect flight muscle structure badly deranged, Z-bands disappear as muscles degenerate; also lose a 54k protein. *int/int* adults flightless and unable to jump; *int/+* adults normal.

**alleles:** *int*<sup>1</sup>, *int*<sup>2</sup>, *int*<sup>3</sup> and *int*<sup>4</sup> mentioned in Deak *et al.*

**other information:** Claimed to be allelic to *up* (1-43.5) by Deak *et al.*, 1982 but earlier mapping data of Deak not reconciled; therefore tentatively considered to be a separate locus.

### **intro: introvert**

**location:** 1-66.

**references:** Schalet and Lefevre, 1973, Chromosoma 44: 183-202.

Schalet and Lefevre, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 847-902.

Lefevre and Watkins, 1986, Genetics 113: 869-95.

Schalet, 1986, Mutat. Res. 163: 115-44.

Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31.

Schlösser, Boschert, and Fischbach, unpublished data.

**phenotype:** Many mutants exhibit a pupal lethal phase, although some are larval lethals. [The name "introvert" is derived from abnormality of some hemizygous pupae in which the head remains inverted within the thorax

(Schlösser *et al.*)]. Pupal-phase mutants do not contract at the beginning of pupation, remaining slender like larvae. Eye development very rudimentary. Germline clone analysis shows variable lethal phenotypes, including collapsed eggs (Perrimon *et al.*).

Academic Press, London, New York, San Francisco, Vol. 1b, pp. 847-902.

<sup>$\beta$</sup>  Most flies exhibit a pupal lethal phase like *intro*<sup>12</sup> and *intro*<sup>13</sup>. However, those males and females that eclose and mate appear normal and are fertile (Schalet, 1986). Viability of heterozygotes with *intro*<sup>12</sup> or *intro*<sup>13</sup> is low (5% or less).

**cytology:** Located in 20A (Lefevre and Watkins, 1986).

### **inv: invected**

**location:** 2-{62} (located immediately to the left of *en*).

**synonym:** *engrailed-related*.

**references:** Poole, Kauvar, Drees, and Kornberg, 1985, Cell 40: 37-43.

Coleman, Poole, Wier, Soeller, and Kornberg, 1987, Genes Dev. 1: 19-28.

Drees, Ale, Soeller, Coleman, Poole, and Kornberg, 1987, EMBO J. 6: 2803-09.

**phenotype:** Although a developmental role for *inv* is indicated by hybridization, experiments with embryonic and larval cells using cDNA probes, the function in development of the protein encoded by *inv* is not known (Coleman *et al.*, 1987). No mutant alleles were reported.

**cytology:** Located in 48A.

**molecular biology:** DNA spanning the *en* locus was cloned by DNA walking using a collection of *en* mutants of known cytology (Poole *et al.*, 1985). Two clones obtained from this region indicated the presence of another gene located 17 kb proximal to *en*. Unlike *en*, this gene (*inv*) is transcribed from left to right (Poole *et al.*, 1985; Coleman *et al.*, 1987). Nucleotide sequences and presumed amino acid sequences were obtained. *inv* shows striking sequence identity to *en* (52 out of 60 amino acids identical) at the carboxy-terminal end in a 117-amino-acid region containing homeobox sequences; however, no sequence similarities were observed elsewhere in the presumed protein-coding region, which is similar in size in both genes (1740 bp in *inv* and 1656 bp in *en*). *inv* has four exons of 1588, 6, 161, and 694 bp

and three introns; the first intron, the second exon, and the second intron span about 26 kb, the third intron (417 bp) splits the homeobox. Genomic DNA probes from *inv* hybridized to transcripts of 3.4, 2.7, and 1.2 kb (Poole *et al.*, 1985; Drees *et al.*, 1987); the 2.7-kb transcript is believed to represent the mature invected mRNA (Coleman *et al.*, 1987). This mRNA is thought to encode a 576-amino acid protein of about 60 kd. cDNA probes specific to *inv* and *en* were used for *in situ* hybridization to sections from embryos, larvae, and imaginal discs. Both genes were expressed in the posterior developmental compartment of embryonic and larval cells, as well as in the hindgut, clypeolabrum and neural ganglia, but *inv* expression appeared at a later period than *en* expression (Coleman *et al.*, 1987).

**inturned:** see *in*

**invected:** see *inv*

*It*: see *ci*<sup>W</sup>

***ix*: intersex**

**location:** 2-60.5.

**origin:** Spontaneous.

**discoverer:** L. V. Morgan, 1943.

**references:** Morgan, Redfield, and Morgan, 1943, Year Book - Carnegie Inst. Washington 42: 171-74.  
Kroeger, 1959, Arch. Entwicklungsmech. Organ. 151: 301-22 (fig.).

Baker and Belote, 1983, Annu. Rev. Genet. 17.

McRobert and Tompkins, 1985, Genetics 111: 89-96.

**phenotype:** Females changed into sterile intersexes with a set of reduced male and a set of irregular female external genitalia. Gonads also mixed. They have no sex combs; pigmentation of abdomen intermediate between male and female. A large mass of chitinized tissue protrudes from

vaginal opening. Homozygous males look normal but behave like intersexes (McRobert and Tompkins, 1985). They court young males as much as normal males do, and occasionally court females; however, they are attractive to normal mature males. Heterozygous *ix/+* males court females and young males, but seldom court mature males. The *ix* locus acts with the *dsx* female function to allow somatic differentiation in females (Nagoshi, McKeown, Burtis, Belote, and Baker, 1988, Cell 53: 229-36).

***ix*<sup>2</sup>**

**origin:** Ultraviolet induced.

**discoverer:** Meyer, 50k.

**synonym:** *tom*: *tomboy*.

**references:** Meyer and Edmondson, 1951, DIS 25: 73.

Meyer, 1958, DIS 32: 83.

**phenotype:** Females homozygous for *ix*<sup>2</sup> have male-like pigmentation of posterior tergites, rudimentary ovaries, and are sterile. Expression extreme and viability reduced at 27°; at 17°, expression less extreme and viability greater. Homozygous males appear normal but have nonmotile sperm. RK2.

**other information:** The possibility that the male sterility is at another locus has not been excluded.

***ix*<sup>3</sup>**

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Duncan.

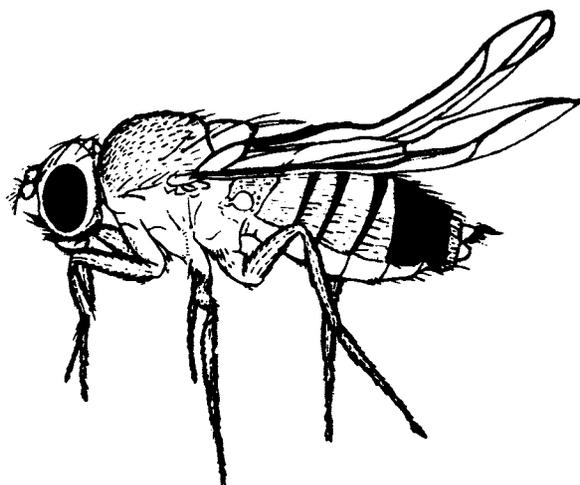

**synonym:** *ix*<sup>D100.36</sup>.

**references:** Nagoshi, McKeown, Burtis, Belote, and Baker, 1988, Cell 53: 229-36.

<sup>β</sup> Wing bends sharply upward in vicinity of anterior crossvein in extreme cases, with a small dark blot near vein L3 at level of deflection. Anterior crossveins may be reduced or absent.

**cytology:** Placed in 34E2. Within *Df(2L)b82a2* = *Df(2L)34D2-4;34E1-2* and *Df(2L)fn7* = *Df(2L)34E2-4;35B3-5*, but not in *Df(2L)b82a1* or *Df(2L)el80fl* = *Df(2L)34E2-4;35C3-5* (Ashburner).

**J: Jammed**

**location:** 2-41.0.

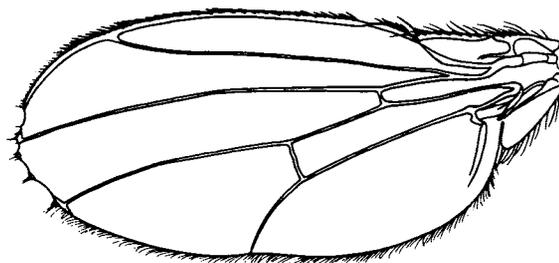

**origin:** Spontaneous.

**discoverer:** Bridges, 23d3.

**phenotype:** Wings often compressed into narrow strips, sometimes filled with fluid. Alula larger and square tipped with clumped bristles and bare regions. Alula modification is characteristically least likely to overlap wild type. Completely overlaps wild type at 19°, almost never at 28° or 30°. Not lethal when homozygous; viability, as in heterozygote, about 70% wild type. Classifiable in single dose triploids (Schultz, 1934, DIS 1: 55). RK1 at 28°-30°; RK2 at 25°.

**alleles:** *J*<sup>1</sup> and *J*<sup>34e</sup> (Duncan); like *J*<sup>1</sup> but produces more vigorous stock; RK1 at 28°. Two X-ray-induced revertants *J*<sup>rv99</sup> and *J*<sup>rv272</sup> are not deficient for flanking markers; *J*<sup>rv99</sup> is associated with *T(Y;2)J*<sup>rv99</sup> (Salas and Lengyel, 1984, DIS 60: 243-44).

**cytology:** Salivary chromosomes apparently normal (Bridges in Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301). Placed in 31B-F on basis of region common to deficiencies recovered as revertants of *J* (Sandler, 1977, Genetics 86: 567-82).

**Jag: Jagged**

Edith M. Wallace, unpublished.

**Jag: Jagged**

**location:** 2-54.9 (0.1 unit from *Bl*).

**discoverer:** L. V. Morgan, 34b20.

**phenotype:** *Jag*<sup>+</sup> has end of wing cut off; better in early counts and above 25°. *Jag/Jag* has reduced and roughened eyes and extremely jagged wings. RK2 as heterozygote; RK3 as homozygote.

**Jammed:** see *J***jan: janus**

**location:** 3-99D (close to *Sryβ*).

**synonym:** *Y*.

**references:** Yanicostas, Vincent, and Lepesant, 1989, Mol. Cell Biol. 9: 2526-35.

**phenotype:** Two partially overlapping genes, *janA* and *janB*, regulate the expression of somatic sex differentiation. *janA* is expressed in a complex way in both males and females; *janB* is only expressed in males (Yanicostas *et al.*, 1989).

**molecular biology:** Genomic and cDNA clones were isolated and nucleotide and deduced amino acid sequences obtained. The genomic and cDNA sequences showed that both *janA* and *janB* contain a single long open reading frame. Both genes are transcribed in the same direction; the 5' end of the *janB* mRNA maps within the 3' untranslated region of the *janA* transcribed sequence, the

overlapping region being 118 bases long. Some other attributes are listed in the following table:

gene	transcripts		predicted protein	
	size (kb)	sex	amino acids	mol. wt.
<i>janA</i>	1.1	males	115	12 kd
	0.95	males		
	0.8	males and females		
<i>janB</i>	0.84	males	140	15 kd

The cDNA sequences of *janA* suggests the existence of alternative transcript structures which have not been definitely determined yet. The size difference between the 0.8 kb and the 0.95 kb transcripts is the result of a difference in length of their poly(A) tails. The male-specific 0.95 kb *janA* transcript and the male-specific *janB* transcript are only expressed in germ line tissues, but the non-sex-specific 0.8 kb *janA* transcript is known to be expressed in both germ line and somatic tissues since detected in germ-line-less as well as normal adults. 37% of the amino acid residues of the two janus genes are identical at homologous positions and the last two 3' introns of both genes are located at identical positions with respect to their protein-coding sequences, suggesting that *janA* and *janB* originated from a duplication of an ancestral transcription unit.

**jaunty:** see *j*

**jaunty x:** see *jyx*

**javelin:** see *ju*

**javelinlike:** see *jvl*

**\*je:** *jelly*

**location:** 3-46.

**origin:** Spontaneous; arose simultaneously with *mussed* (3-50).

**discoverer:** Mohr, 37121.

**references:** Mossige, 1939, DIS 12: 47.

**phenotype:** Dark pinkish eye color. RK1.

**Jon: Jonah**

A complex family of about 20 genes distributed at widely dispersed sites on the chromosomes of *Drosophila melanogaster* and expressed only in the midgut of larvae and adults. The function of the gene products are not known. The genes are found in small clusters at different chromosomal sites, as indicated in the following table.

genes (single or clustered)	location	cytology <sup>α</sup>	number of genes at site
<i>Jon25B</i> <sup>β</sup>	2-113	25B	3
<i>Jon44E</i>	2-158	44E	1
<i>Jon65A</i> <sup>β</sup>	3-120	65A	4
<i>Jon66C</i> <sup>β</sup>	3-126	66C	2
<i>Jon99C1</i> <sup>γ</sup>	3-1101	99C	2
<i>Jon99C2</i> <sup>βγ</sup>	3-1101	99C	3
<i>Jon99F</i>	3-1101	99C	2

<sup>α</sup> As indicated by *in situ* hybridization to the salivaries (Carlson and Hogness, 1985, Dev. Biol. 108: 341-54). A weak site at 67B was also identified by long exposure to the label but no genomic clones were identified (Wolfner, 1980, Ph.D thesis, Stanford University). Six gene clusters listed have repeats (direct, inverted, or both).

<sup>β</sup> Described in detail at the end of text.

<sup>γ</sup> Allelic variants at 99C. Synonym: *JonC* α and *JonC* β.

**origin:** From cDNA clones from the poly(A)<sup>+</sup> RNA of third instar larvae before the beginning of larvae metamorphosis. Sites identified by *in situ* hybridization with the reference cDNA probe.

**references:** Akam and Carlson, 1985, EMBO J. 4: 155-61.

Carlson and Hogness, 1985a, Dev. Biol. 108: 341-54.

Carlson and Hogness, 1985b, Dev. Biol. 108: 355-68.

**phenotype:** The *Jon* genes are expressed in various regions of the larval midgut (AMG, MMG, PMG) during all the larval stages (Akam and Carlson, 1985); expression disappears at pupation, but reappears in the adult midgut shortly after eclosion and remains throughout adult life.

**molecular biology:** Genomic clones and subclones carrying *Jonah* genes from different chromosomal sites were constructed and isolated (Carlson and Hogness, 1985a, 1985b), revealing a family of imperfectly repeated genes. *Jonah* mRNA is abundant during all three larval instars and in the adult life, but different *Jonah* RNA's show spatial and temporal differences (Akam and Carlson, 1985; Carlson and Hogness, 1985a). The mature mRNA is about 910 bp in length and encodes a 28 kd translation product whose function has not been determined (Carlson and Hogness, 1985b).

**Jon25B**

**molecular biology:** mRNA hybridizes strongly to larvae, weakly to adults (Carlson and Hogness, 1985b).

**Jon65A**

**molecular biology:** Weak identity to other *Jonah* genes. mRNA hybridizes to both anterior and middle midgut of larvae (Akam and Carlson, 1985; Carlson and Hogness, 1985b).

**Jon66C**

**molecular biology:** mRNA hybridizes to larvae only (Carlson and Hogness, 1985b).

**Jon99C2**

**molecular biology:** Shows considerable identity to many other *Jonah* genes. mRNA hybridizes strongly to anterior part of the posterior midgut of larvae (Akam and Carlson, 1985; Carlson and Hogness, 1985b).

**jpl:** see *gfa*

**ju:** *juniper*

**location:** 3-91.09 (between *se* and *e*).

**origin:** Wild population from Yugoslavia.

**references:** Lenicek and Sesta, 1986, DIS 63: 163.

**phenotype:** Flies have opened wings, oriented at an angle of 65° with respect to the longitudinal axis, and 10-30° with respect to the horizontal axis. Homozygotes show decreased flying ability and move from place to place by jumping.

**Jutas:** see *Fs(3)Sz13*

**ju:** *javelin*

**location:** 3-19.2 (0.9 unit to left of *dv*).

**discoverer:** Mohr, 31j29.

**references:** 1937, DIS 8: 12.

Mohr and Mossige, 1943, Skrifter Norske Videnskaps-Akad. Oslo, I: Mat.-Naturv. Kl., No. 7. 51 pp. (fig.).

**phenotype:** All bristles and hairs cylindrical, instead of tapered, with small enlargement before tip. Cell autonomous and useful as a marker for epidermal clones (Morata and Ripoll, 1975, Dev. Biol. 42: 211-21). RK2.

**alleles:**  $ju^1$  and  $ju^{70b}$ .

**cytology:** Placed between 64C12 and 65E1 on the basis of its inclusion in  $Df(3L)Vn = Df(3L)64C12-D1;65D2-E1$ .

***ju1: javelinlike***

**location:** 3-56.7.

**origin:** Spontaneous.

**discoverer:** Ives, 4012.

**references:** 1942, DIS 16: 48.

**phenotype:** Resembles  $ju$  but bristles sometimes more crooked. Viability and productivity somewhat lower than normal. RK2.

***\*jyx: jaunty-x***

**location:** 1-24.

**origin:** Spontaneous.

**discoverer:** Bridges, 14112.

**phenotype:** Wings curved up at tips. Viability about 60% wild type. RK3.

**k: kidney**

From Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 77.

**k: kidney**

**location:** 3-64.

**origin:** Spontaneous.

**discoverer:** Bridges, 12f26.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 72 (fig).

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 214 (fig.), 227.

**phenotype:** Eye size reduced by indentation of front margin. Tuft of vibrissae and hairs below eye. Penetrance varies with allele as does expression; moderate alleles overlap wild type significantly. RK3.

allele	origin	discoverer	ref <sup>α</sup>	phenotype
<i>k</i> <sup>1</sup>	spont	Bridges, 12f26	1, 4	moderate
<i>*k</i> <sup>2</sup>	spont	Goldschmidt, 1927	2	moderate
<i>k</i> <sup>3</sup>	spont	Gottschewski, 1937	2	weak
<i>k</i> <sup>6b</sup>	spont	G.L. Lee	3	strong
<i>k</i> <sup>D</sup>	spont	Puro, 60c11	5	β

<sup>α</sup> 1 = Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 72 (fig.); 2 = Gottschewski and Ma, 1937, Z. Indukt. Abstamm. Vererbungsl. 73: 584-97; 3 = Lee, G.L., 1972, DIS 48: 18; 4 = Morgan, Bridges, and Sturtevant, 1925, Bibliogr. Genet. 2: 214 (fig.), 227; 5 = Puro, 1964, DIS 39: 65.

β Derivative of *k*<sup>1</sup>; phenotype described separately below.

***k*<sup>D</sup>: kidney-Dominant**

**phenotype:** Eyes of heterozygote reduced at anterior edges. Expression variable; in extreme cases, eye size about one-third normal. *k*<sup>D</sup>/*k* more extreme. Eyes of homozygote reduced about as much as *k*<sup>D</sup>/*k* but occasionally one or both eyes missing; antennae usually slightly deformed with thickened aristae. RK1.

***kar*: karmoisin**

**location:** 3-51.7.

**phenotype:** Eye color like *st* but less bright. Ocelli white. Eyes contain 29% wild-type brown pigment (Nolte, 1954, J. Genet. 52: 111-26). Larval Malpighian tubes of *kar*<sup>1</sup> but not *kar*<sup>2</sup> considerably lighter than wild type; difficult to classify in living larvae (Brehme and Demerec, 1942, Growth 6: 351-56). Phenoxazinone synthetase level subnormal in mutants; maybe a structural gene for this enzyme; 3-hydroxykynurenine accumulates (Sullivan, Kitos, and Sullivan, 1974, J. Exp. Zool. 188: 225-34). RK1.

**cytology:** Placed in 87C8 by Gausz, Bencze, Gyurkovics, Ashburner, and Ish-Horowicz (1979, Genetics 93: 917-34).

**alleles:** Many deficiencies have been given allelic designa-

tions in the past; they are tabulated under *Df(3R)kar*. Alleles believed unaccompanied by deficiencies are summarized in the accompanying table.

Roark, Mahoney, Graham, and Lengyel, 1985, Dev. Biol. 109: 476-88.

**phenotype:** Homozygous lethal; embryo open dorsally.

**alleles:** Two.

**cytology:** Placed in 99A-100A.

***kdn*: knockdown (J.C. Hall)**

**location:** 1- (between *cv* and *v*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Christensen.

**references:** Ganetzky and Wu, 1982, Genetics 100: 587-614.

**phenotype:** Temporary paralysis following mechanical shock; sensitive only to initial shock, refractory thereafter. The bang-sensitive phenotype is suppressed by *nap*<sup>ts</sup> at its permissive temperature; the electrophyl-

siology of the larval neuromuscular junction appears normal.

**alleles:** One mutant allele, called *kdn*<sup>PC64</sup>.

**other information:** Could be allelic to *rex*.

**kdu: kudu**

**location:** 2-{22}.

**origin:** Hybrid dysgenesis.

**references:** Berg and Spradling, 1989.

**phenotype:** Recessive female-sterile mutation; eggs have fused or thin membranes.

**cytology:** Placed in 28A.

**\*ke: kidney eye**

**location:** 1-28.6.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 87.

**phenotype:** Eyes small and extremely rough; anterior border indented, giving a kidney shape. Wings small, abnormal, outspread, or upheld. Veins thick and often interrupted or fail to reach wing margin, which is usually incised. Deformed antennae. Bristles straggly; occasionally, one is missing. Flies short lived; 50% die less than 24 hr after eclosion. Sterile, probably because they are too weak to mate. RK3.

**kel: kelch**

**location:** 2-{53}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Schüpbach.

**references:** Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78.

**phenotype:** Recessive female sterile. Nurse cell cytoplasm not incorporated in oocyte. Small eggs "open" at anterior pole since egg membranes are not deposited around whole oocyte.

**cytology:** Located in 36E4; included in *Df(2L)H20* = *Df(2L)36A8-9;36E3-4* and *Df(2L)TW330* = *Df(2L)36E4-F1;37D1-2*.

**Kf1: Kynurenine formamidase 1**

**location:** 3-{62-70}.

**references:** Moore and Sullivan, 1975, Biochem. Biophys. Acta 397: 486-77.

1978, Biochem. Genet. 16: 619-34.

**phenotype:** The structural gene for one of the two forms of kynurenine formamidase found in *Drosophila melanogaster* [arylformylamine amidohydrolase (EC 3.5.1.9)]. Formamidase I is a dimer of 34,000 subunit molecular weight, which catalyzes the conversion of N-formylkynurenine to kynurenine. Biochemical characterization by Moore and Sullivan.

**cytology:** Localized to 91B-93F by dosage response to segmental aneuploidy.

**Kf2**

**location:** 2-{13-21}.

**references:** Moore and Sullivan, 1975, Biochem. Biophys. Acta 397: 468-77.

1978, Biochem. Genet. 16: 619-34.

**phenotype:** Structural gene for the second form of kynurenine formamidase in *Drosophila melanogaster*. Formamidase II is monomeric with a molecular weight of 31,000. Amino acid compositions of formamidase I and II are virtually indistinguishable, suggesting that they are duplicate genes. They do not interconvert in vitro. The supposed duplicate nature of the coding sequence postulated as the explanation of the inability to recover mutants defective in the conversion of N-formylkynurenine to kynurenine.

**cytology:** Dosage studies in segmental aneuploids place the structural gene in 25A-27E.

**\*Kg: Kugel**

**location:** 3-47.5 [changed from 48.2 in order to lie 0.1 unit to left of *Ki*; as determined using *Kg*<sup>V</sup> (Craymer, 1980, DIS 55: 199)].

**origin:** Spontaneous.

**discoverer:** Benz, 1953.

**references:** 1956, Rev. Suisse Zool. 63: 208-16.

**phenotype:** Larva, pupa, and adult shorter and thicker than normal. Most striking in pupa. Homozygote more extreme than heterozygote. Homozygote viability 68% of wild type and fertility somewhat reduced. RK2.

**Kg<sup>V</sup>: Kugel of Valencia**

**origin:** X ray induced.

**discoverer:** Valencia, 1964.

**synonym:** *Ch*<sup>V</sup>: Chubby of Valencia.

**references:** 1968, DIS 43: 60.

Craymer, 1980, DIS 55: 198.

**phenotype:** Larvae, pupae, and adults short and thickset; especially easy to score preadult stages. Homozygous males viable and fertile.

**Ki: Kinked**

**location:** 3-47.6 [Location in 3R demonstrated by mitotic recombination. (Merriam and García-Bellido, 1972, DIS 44:51) and by recovery in newly induced *C(3R)RM* but not *C(3L)RM* chromosomes (Lütolf, 1971, Experientia 27: 1357)].

**origin:** Spontaneous.

**discoverer:** R. F. Grell, 571.

**references:** 1958, DIS 32: 80.

**phenotype:** All bristles and hairs of heterozygote shortened and twisted. Resembles *sn*. Viability and fertility excellent; classification easy. Homozygote has more extreme bristle and hair effects. Expression much reduced in flies raised at 18° (Hardy). *Ki*<sup>+</sup> an excellent marker for cuticular clones in *Ki*/+ heterozygotes. Viability somewhat reduced but fertility near normal. RK1 as heterozygote.

**alleles:** *Ki*<sup>72</sup> induced by ethyl methanesulfonate (García-Bellido and Dapena, 1974, Mol. Gen. Genet. 128: 117-30).

**cytology:** Placed in 83DE by deficiency analysis (Roehrdanz and Lucchesi, 1980, Genetics 95: 355-66).

**other information:** Very closely linked to the triplo-lethal region of 83DE; attempts to revert *Ki* by deletion unsuccessful (Kaufman, 1978, Genetics 90: 579-96), and *Ki*

frequently deleted simultaneously with *Tpl* (Roehrdanz and Lucchesi).

**Kin: Kinesin**

**location:** 2-[78].

**discoverer:** Christensen.

**references:** Saxton, Porter, Cohn, Scholey, Raff, and McIntosh, 1988, Proc. Nat. Acad. Sci. USA 85: 1109-13.

Yang, Saxton, and Goldstein, 1988, Proc. Nat. Acad. Sci. USA 85: 1864-86.

Scholey, Heuser, Yang, and Goldstein, 1989, Nature 338: 355-57.

Yang, Laymon, and Goldstein, 1989, Cell 56: 879-89.

**phenotype:** Encodes a protein from *Drosophila* that behaves similarly in its effect on movement of microtubules and is antigenically similar to the heavy chain kinesin of squid and sea urchin (Saxton *et al.*, 1988). The *Drosophila* kinesin is found in embryos, larvae, adults, and tissue culture cells. Flies deficient for *Kin* survive through early embryogenesis (Saxton).

**molecular biology:** Antiserum recognizing the heavy chain of *Drosophila melanogaster* kinesin was employed in the isolation of cDNA clones. The complete nucleotide and predicted protein sequence of a 3.8 kb cDNA clone were obtained (Yang *et al.*, 1988, 1989); this clone produced a protein synthesized *in vitro* that, like heavy chain kinesin in other organisms, binds to microtubules in the presence of the non-hydrolyzable analogue of ATP, AMP-PNP, but not in the presence of ATP or 0.1 M KCl. The cDNA is 3547 nucleotides long and has one long open reading frame; the predicted protein has a molecular weight of 110,428 daltons and is made up of 975 amino acids. Analysis of the protein indicates the presence of a 50 kd globular amino-terminal domain with sites for microtubule and nucleotide binding (the motor domain), a 50-60 kd  $\alpha$ -helical coiled-coil stalk region, and a short carboxy-terminal region that is also globular and interacts with light chains (Yang *et al.*, 1989). These structural elements show good correlation with the corresponding structure of mammalian, squid, and sea urchin kinesin heavy chains observed under the electron microscope (Amos, 1987, J. Cell Science 87: 105-11; Hirakawa, Pfister, Yorufuji, Wagner, Brady, and Bloom, 1989, Cell 56: 867-78; Scholey *et al.*, 1989).

**Kinked:** see *Ki*

**kinked femur:** see *kf* under *ct*

**kis: kismet (J.A. Kennison)**

**location:** 2-0 (between *net* and *art*).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1984.

**synonym:** *Su(Pc)21AB*.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Isolated as a dominant suppressor of *Pc* alleles. Homozygous lethal. Duplications for *kismet*

strongly enhance the dominant *Pc* phenotypes. *kismet* mutations suppress the antennal transformations of *Antp<sup>B</sup>*, *Antp<sup>73b</sup>*, and *Antp<sup>Ns</sup>*, as well as the transformations caused by ectopic expression of *Antp* protein under the control of a heat-inducible promoter. *kismet* mutations in mitotic clones induced during larval stages transform the fifth abdominal segment into a more anterior segmental identity.

**alleles:** Eight alleles induced by ethyl methanesulfonate [including three on *Dp(2;Y)L124*], two by gamma irradiation, and one associated with an insertion of a *P*-element derived *ry* vector.

**cytology:** Located in 21B6-7 based on its failure to complement *Df(2L)net - PMF = Df(2L)21A1;21B7-8* and *Df(2L)net - PMC = Df(2L)21A1;21B6-7* but not *Df(2L)net - PM47C = Df(2L)21A1;21B6-7*.

**kis<sup>S</sup>: kismet-Spradling**

**origin:** *P*-element-induced insertion.

**discoverer:** Spradling.

**other information:** *ry<sup>+</sup>* transformant that fails to complement *kismet* mutations for viability. Failure to complement *kismet* mutations is revertable at high frequency in the presence of *P*-element transposase.

**\*kk: kinky**

**location:** 1-42.

**origin:** Spontaneous.

**discoverer:** Philip.

**references:** 1937, DIS 8: 10.

**phenotype:** Bristles slightly bent or forked. RK3.

**other information:** May be an allele of *fw*.

**kkv: krotzkopf verkehrt**

**location:** 3-49.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95 (fig.).

**phenotype:** Homozygous lethal; head skeleton crumbled; denticle bands narrower; embryo rarely inverted in egg case.

**alleles:** Twenty including one weak and one temperature sensitive.

**KL: Male fertility complex in the long arm of the Y chromosome**

**synonym:** Mutants in the Y-linked male-fertility genes have in the past been symbolized *ms(Y)* followed by an identifying symbol; this convention fails to indicate allelic relations among independently recovered Y-linked sterile mutants. Accordingly, mutant terminology now uses the symbol of the fertility gene involved with the particular allele designated by the previously used identifying symbol as a superscript. *e.g.*, *ms(Y)G9* now is *kl-3<sup>G9</sup>*

**references:** Brosseau, 1960, Genetics 45: 257-74.

Kennison, 1981, Genetics 98: 529-48.

1983, Genetics 103: 219-34.

Hazelrigg, Fornili, and Kaufman, 1982, Chromosoma 87: 535-59.

Gatti and Pimpinelli, 1983, Chromosoma 88: 349-73.

Bonaccorsi, Pisano, Puoti, and Gatti, 1988, Genetics 120: 1015-34.

The male fertility complex of the long arm of the Y chromosome, originally called *K1* by Stern (1929, Z.

Indukt. Abstamm. Vererbungsl. 51: 253-353) and subsequently called *KL* by Brosseau comprises four male-fertility genes designated *kl-1*, *kl-2*, *kl-3*, and *kl-5* (*kl-4* described by Brosseau, has not been confirmed). These loci have been defined by complementation analysis (Brosseau), by segmental aneuploidy (Kennison) and by cytological localization of male-sterile, *Y*-chromosome breakpoints (Gatti and Pimpinelli).

### *kl-1*

**phenotype:** Males deficient or mutant at *kl-1* are sterile. One allele of Brosseau's, probably *kl-1*<sup>B13</sup>, studied by Kiefer, produces motile sperm which are transferred to females but do not reach the female sperm-storage organs; substantial amounts of sperm degeneration observed [Kiefer, 1969, Genetics 61: 157-66 (fig.)]. The spermatogenic lesion resembles the late phenotypes of other sterile mutants suggesting that the primary departure from normality has been overlooked. Cross sections of sperm tails nonuniform within a cyst and the number of tails at various levels in a bundle varies. The minitubules, which fill the interstices among the individualized sperm tails of mature bundles, not formed. [Hardy, Tokuyasu, and Lindsley, 1981, Chromosoma 83: 593-617 (fig.)].

**alleles:** In addition to the alleles tabulated, Williamson (1972, Mol. Gen. Genet. 119: 43-47) reported fifteen non-complementing and five complementing alleles, all induced by ethyl methanesulfonate.

β Induced on the same chromosome with *kl-5*<sup>G16</sup>.

γ Induced on the same chromosome with *kl-3*<sup>G17</sup>.

**cytology:** *Y-h14*.

### *kl-2*

**phenotype:** Males deficient or mutant for *kl-2* are sterile; primary ultrastructural lesion not identified. Such sterile males lack a 300-325 kilodalton sperm polypeptide thought to be a structural component of the axoneme (Goldstein, Hardy, and Lindsley, 1982, Proc. Nat. Acad. Sci. USA 79: 7404-09; Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610).

**alleles:** In addition to the alleles tabulated, Williamson (1972, Mol. Gen. Genet. 119: 43-47) reported five

ethyl-methanesulfonate induced complementing alleles.

β Listed as involving either *kl-2* or *kl-4*.

**cytology:** *Y-h10*.

### *kl-3*

**phenotype:** Males mutant for *kl-3* fail to assemble the outer dynein arms associated with the peripheral nine microtubule doublets of the sperm-tail axoneme [Hardy, Tokuyasu, and Lindsley, 1981, Chromosoma 83: 593-617 (fig.)]. Such males also fail to produce a *kl-3*-specific 300-325 kilodalton sperm polypeptide presumed to be a component of the outer dynein arms (Goldstein, Hardy, and Lindsley, 1982, Proc. Nat. Acad. Sci. USA 79: 7404-09). Such mutants display an exceedingly low level of fertility at 25° but not at 18° immediately upon eclosion, but not thereafter (Kennison, 1983, Genetics 103: 219-34). Deficiencies for *kl-3* are completely sterile, and in addition to the above mutant phenotype, they fail to elaborate the loops (ribbon-like structure) observed in the primary spermatocyte nuclei of normal males by light microscopy and the reticular material ordinarily observed by electron microscopy in spermatocyte nuclei (Hardy *et al.*, 1981). The *kl-3* loops are visible in living spermatocytes and in fixed cells stained with the protein-specific dye CBB; these loops are also demonstrated by the polyclonal antibody Sph-155 but do not react with monoclonal antibody S5 (Bonaccorsi *et al.*, 1988).

**alleles:** In addition to the alleles tabulated, Williamson (1972, Biol. Gen. Genet. 119: 43-47) reported 23 non-complementing and nine complementing alleles induced by ethyl methanesulfonate.

<sup>α</sup>	1 = Brosseau, 1960, Genetics 45: 257-74; 2 = CP627; 3 = Hazelrigg, Fornili and Kaufman, 1982, Chromosoma 87: 535-59; 4 = Kennison, unpublished information; 5 = Kennison, 1983, Genetics 103: 219-34.				
<sup>β</sup>	Induced on the same chromosome with <i>kl-1</i> <sup>G17</sup> .				

**cytology:** *Y-h7*.

**kl-4**

Existence inferred by Brosseau (1960, Genetics 45: 257-74) on the basis of the failure of a *kl-3*<sup>-</sup> *Y* to complement a *kl-5*<sup>-</sup> *Y* for male fertility. No single site mutant or breakpoint interrupting *kl-4* alone reported by Brosseau, Kennison (1983, Genetics 103: 219-34), Hazelrigg, Fornili and Kaufman (1982, Chromosoma 87: 535-59), or Gatti and Pimpinelli (1983, Chromosoma 88: 349-73). Williamson (1972, Mol. Gen. Genet. 119: 43-47), on the other hand reported seven noncomplementing and seven complementing alleles induced by ethyl methanesulfonate.

**kl-5**

**phenotype:** Males mutant for *kl-5* fail to assemble the outer dynein arms associated with the A tubules of the peripheral doublets of the sperm tail axoneme [Hardy, Tokuyasu, and Lindsley, 1981, Chromosoma 83: 593-617 (fig.)]. Such males also fail to produce *kl-5*-specific 300-325 kilodalton sperm polypeptide considered to be a component of the outer arms (Goldstein, Hardy, and Lindsley, 1982, Proc. Nat. Acad. Sci. USA 79: 7404-09). *kl-5* mutants exhibit very low level of fertility at 25° but not at 18° and in young but not older males (Kennison, 1983, Genetics 103: 219-34). Deficiencies for *kl-5* completely sterile, and in addition to the mutant phenotype they fail to produce aggregates of tubuli normally seen in thin sections of primary spermatocyte nuclei (Hardy *et al.*). Within the *kl-5* fertility region of the spermatocyte nucleus, a loop-forming site has been demonstrated by its reaction with the monoclonal antibody S5 (Bonaccorsi *et al.*, 1988). These loops are stained with the protein-specific dye CBB, but are not visible in living preparations.

**alleles:** In addition to the alleles tabulated, Williamson (1972, Mol. Gen. Genet. 119: 43-47) reported 26 non-complementing and 9 complementing alleles induced by ethyl-methanesulfonate.

<sup>α</sup> 1 = Ayles, Sanders, Kiefer, and Suzuki, 1973, Dev. Biol. 32: 239-57; 2 = Brosseau, 1960, Genetics 45: 257-74; 3 = CP627; 4 = Goldstein, Hardy, and Lindsley, 1982, Proc. Nat. Acad. Sci. USA 79: 7405-09; 5 = Hazelrigg, Fornili, and Kaufman, 1982, Chromosoma 87: 535-59; 6 = Kennison, unpublished information.

<sup>β</sup> Induced on same chromosome with *kl-1*<sup>G16</sup>.

<sup>γ</sup> Produces normal quantities of its high-molecular-weight polypeptide at restrictive temperature; however, outer-arm assembly defective.

**cytology:** *Y-h1-2* and *h3*.

**klis: klarsicht**

**location:** 3-0.0.

**discoverer:** Nüsslein-Volhard.

**phenotype:** Maternal effect mutant; without effect on viability or fertility of homozygotes. Homozygous females produce eggs with clear distinction between yolk and germ layers. Facilitates *in vivo* observation of developmental processes.

**kmA: killer of males**

**location:** 2-45.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pierre, 1972, DIS 48: 16.

**phenotype:** Homozygous males die during embryogenesis.

**kmB**

**location:** 2-20.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pierre, 1972, DIS 48: 16.

**phenotype:** Homozygous males die during embryogenesis.

**kn: knot**

**location:** 2-72.3.

**discoverer:** Nichols-Skoog, 31h1.

**references:** Díaz-Benjumea, Gaitán, and García-Bellido, 1989, Genome 31: 612-19.

**phenotype:** Veins L3 and L4 shifted closer together in region of anterior crossvein, which is either extremely thick or eliminated by regional fusion of L3 and L4. Frequently, extra crossvein between L3 and L4 near end of wing. Shift in positions of sensilla and extra chaetae accompanies shift in vein positions. Wing narrowed. Head narrowed and flattened, so the long axis of eye is at oblique angle. May overlap wild type at high temperatures and in late counts. Best at 19°. RK2.

**cytology:** Located in 51C-E (MacIntyre).

**kni: knirps**

**location:** 3-{46}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard and Wieschaus, 1980, Nature (London) 287: 795-801 (fig.).

Rothe, Nauber, and Jäckle, 1989, *EMBO J.* 8: 3087-94.

**phenotype:** Zygotic gap gene whose mutants are homozygous lethal; their denticle belts in segments one through seven are fused into a single field (Nüsslein-Volhard and Wieschaus, 1980), but the head, thorax, eighth abdominal segment, and tail region appear normal. Embryos homozygous for a strong *kni* mutant show a wide band of *ftz* staining instead of the normal number of *ftz* stripes (Carroll and Scott, 1986).

**alleles:** The following alleles are listed by Tearle and Nüsslein-Volhard, 1987:

allele	origin	synonym	comments
<i>kni</i> <sup>1</sup>	EMS	<i>kni</i> <sup>5F</sup>	
<i>kni</i> <sup>2</sup>	EMS	<i>kni</i> <sup>7G</sup>	strong

α Also see Nauber *et al.*, 1988.

**cytology:** Placed in 77E1-2 by *in situ* hybridization of cloned DNA to salivaries (Nauber *et al.*, 1988). Included in *Df(3L)ri79c = Df(3L)77B-C;77F-78A* (Jürgens *et al.*, 1984).

**molecular biology:** The 77E1 region was microcloned and used to start a chromosome walk (Nauber *et al.*, 1988). Breakpoints of chromosomal aberrations involving *kni* were located on the molecular map. Two transcripts of 2.2 and 2.5 kb were identified; the smaller transcript is expressed transiently at the blastoderm stage, but the larger one continues to be expressed after gastrulation. These transcripts are not present in embryos homozygous for *kni*<sup>FC13</sup>, a small molecular deletion of 2 kb. Genomic and cDNA sequences and predicted amino acid sequences were determined (Nauber *et al.*, 1988). Analysis of the DNA sequences showed three exons interrupted by two introns of 733 bp and 214 bp. A protein of 429 amino acids would be encoded by the single open reading frame of 1,287 bp. This protein shows similarity in the N terminus to proteins of the vertebrate nuclear hormone receptor family (Nauber *et al.*, 1988). The zinc-finger domain of *knirps* and its amino-acid motif, the *kni* box, show 80-88% identity with the corresponding domains of *egon* and *knrl*, two genes that also map in the 77-79 region [Oro, Ong, Margolis, Posakony, McKeown, and Evans, 1988, *Nature* (London) 336: 493-96; Rothe *et al.*, 1989].

**knickkopf:** see *knk*

**knirps:** see *kni*

**knirps-related:** see *knrl*

**knk:** *knickkopf*

**location:** 3-49.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.*

193: 283-95 (fig.).

**phenotype:** Homozygous lethal; head skeleton defective; denticle bands narrowed; embryo rarely inverted in egg case.

**alleles:** Four, including one weak and one temperature-sensitive allele.

**cytology:** Placed in 85E1-10 based on its inclusion in *Df(3R)GB104 = Df(3R)85D11-13;85E10* and *Df(3R)by62 = Df(3R)85D11-14;85E16* but not *Df(3R)by416 = Df(3R)85D10-12;85E1-2*.

**\*kno:** *knobbyhead*

**location:** 1-63.9.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1951.

**references:** 1958, *DIS* 32: 70.

**phenotype:** Abnormal head with one or both eyes irregularly shaped, often drastically reduced in size. Occipital region frequently has hairy tufts, often carried on protuberances. Males highly infertile; viability about 10% wild type. RK2.

**other information:** One allele induced by D-1:6-dimethanesulfonyl mannitol (CB. 2511).

**knockdown:** see *kdn*

**knot:** see *kn*

**knrl:** *knirps-related*

**location:** 3-{46}.

**origin:** Isolated from a genomic library using a human retinoic acid receptor cDNA probe (Oro *et al.*, 1988) or a *Drosophila kni* zinc-finger probe (Rothe *et al.*, 1989).

**references:** Oro, Ong, Margolis, Posakony, McKeown, and Evans, 1988, *Nature* (London) 336: 493-96.

Rothe, Nauber, and Jäckle, 1989, *EMBO J.* 8: 3087-94.

**phenotype:** Expressed maternally at low levels in very early stages; expression increases during early embryogenesis and continues in larvae and adults (in contrast to *kni*, which is first expressed zygotically and does not continue beyond embryonic stages) (Oro *et al.*, 1988; Rothe *et al.*, 1989).

**alleles:** No loss-of-function alleles isolated.

**cytology:** Located in 77E1-2 by *in situ* hybridization; location not distinguishable by this technique from that of *kni*.

**molecular biology:** Gene cloned and sequenced (Oro *et al.*, 1988). One clone of 3,505 bp contains an open reading frame encoding 647 amino acids showing 85% identity with the predicted *knirps* gene product and 47% identity with the human retinoic acid receptor. The genes *knrl*, *kni*, and *egon* show more than 80% sequence identity in the first part of the zinc-finger domain and share a *kni* box downstream from this domain (Rothe *et al.*, 1989). In the carboxyl-terminal region, however, there is little sequence similarity between *knrl* and the other receptors.

**phenotype:** The wild-type allele of Krüppel controls the development of the thoracic and abdominal segments of *Drosophila*; homozygous mutants show a gap in the larval pattern in these regions (Nüsslein-Volhard and Wieschaus, 1980; Knipple, *et al.*, 1987). *Kr*<sup>+/+</sup> adult sometimes has thoracic malformation; a leg or a wing may be absent; penetrance low. Heterozygous larvae show small defects in denticle bands of thorax and abdomen as do heterozygous deficiencies for *Kr*; penetrance about 80%. Homozygotes are embryonic lethal. *Kr*<sup>1</sup> homozygotes exhibit shortened germ band of but three to four segments with three to four tracheal pits; visible beginning at 7h of embryogenesis; head and gnathal segments apparently normal. At later stages only three to four abdominal and thoracic segments clearly visible; normal telson and segments 8 and 7 followed by enlarged sixth, a rudimentary fifth and apparently mirror image sixth segment. Weak and intermediate mutant alleles lack the mirror-image duplications (Gaul and Jäckle, 1987, Trends Genet. 3: 127-30). Ventral chain of ganglia disconnected; tracheal system defective; Malpighian tubules missing; salivary glands normal. Homozygotes for hypomorphic alleles display more nearly complete segmentation. Homozygous *M*<sup>+</sup> *Kr* clones develop normally in all parts of adult cuticle of *M*<sup>+</sup> flies. Metamorphic potential of *Kr*/*Kr* embryos cultured in female abdomens restricted in that wing-disc-derived structures not observed. Germline clones of homozygous

*Kr* cells capable of normal oogenesis; no maternal effect of *Kr*<sup>+</sup> observed. Requirement for *Kr*<sup>+</sup> function apparently restricted to early embryogenesis. *Kr* affects *ftz* producing abnormal intensity and spacing of *ftz* stripes in thorax and anterior abdomen (Carroll and Scott, 1986, Cell 45: 113-26).

**alleles:** Twentyfour alleles are listed in the following table. Deficiencies are listed in the rearrangement section.

<sup>α</sup> 1 = Gaul, Redemann, and Jäckle, 1989, Proc. Nat. Acad. Sci. USA 86: 4599-4603; 2 = Harbecke and Janning, 1989, Genes Dev. 3: 114-22; 3 = Preiss, Rosenberg, Kienlin, Seifert, and Jäckle, 1985, Nature (London) 313: 27-32; 4 = Redemann, Gaul, and Jäckle, 1988, Nature (London) 332: 90-92; 5 = Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

<sup>β</sup> S = Strong alleles: segments T1-3 and A1-5 deleted; A6 and sometimes A7 and 8 duplicated with reverse polarity. I = Intermediate alleles: segments T1-3 and A1-4 deleted; duplicated segments not observed. W = Weak alleles: segments T2 and 3 and A1 deleted; A2-4 variably deleted depending on allele. MT = Malpighian tubules.

<sup>γ</sup> Approximate extents of molecular deletions on coordinates of Preiss *et al.*, 1985; amino acid substitutions in zinc-finger region (Gaul *et al.*, 1989) as indicated by sequence analysis.

<sup>δ</sup> Recovered as revertants of *If*.

**cytology:** Placed in 60F3 based on proximal breakpoint of *In(2R)Kr*<sup>UR1</sup> and the 2R breakpoint of *T(Y;2)Kr*<sup>AK1</sup>; mutant phenotype associated with five *Kr* deficiencies (Preiss *et al.*, 1985).

**molecular biology:** *Kr* was cloned by microdissection from the salivary band 60F3 followed by chromosome walking. A physical map was constructed from 50 kb of the *Kr* region in a series of overlapping clones (Preiss *et al.*, 1985). *Kr*<sup>+</sup> activity contained in a 4 kb subsegment (approximate coordinates +5 to +9) was identified by the region of overlap between molecular deletions *Kr*<sup>11</sup> and *Kr*<sup>15</sup>. DNA sequencing indicates a single open reading frame of 1,398 bp split by a 372 kb intron and encoding a putative protein of about 466 amino acids (Rosenberg *et al.*, 1986). The protein shares structural elements with the DNA-binding zinc-finger domain of TFIIIA, a *Xenopus* transcription factor [Schuh *et al.*, 1986; Gaul *et al.*, 1987; Stanojevic *et al.*, 1989, Nature (London)

341: 331-35]. This gene product binds to the sequence AAGGGGTAA, the binding sites being located upstream of the *hb* promoter (Stanojevic *et al.*, 1989; Treisman and Desplan, 1989). One cloned segment rescues *Kr* embryos when injected and identifies a 2.5 kb blastoderm-specific polyadenylated RNA (Preiss *et al.*, 1985). Injection of anti-sense RNA into wild-type embryos produces *Kr/Kr* phenocopies (Rosenberg *et al.*, 1985). Transcripts are first detected at the syncytial blastoderm stage, and can be demonstrated at the cellular blastoderm in the central part of the embryo (Knipple *et al.*, 1985). In the absence of *hb* expression, the *Kr*<sup>+</sup> transcript domain extends anteriorly up to segment A3 (Jäckle *et al.*, 1986); in the absence of *kni* expression, the extent of this domain is posterior to its normal boundary. At the start of gastrulation, an anterior transcript domain appears between head and thorax. Later, the transcripts are restricted to certain cells of the the brain and nervous system, to the mesoderm, and to the Malpighian tubules (Knipple *et al.*, 1985). At the beginning of germ-band shortening, there is a very low level of transcript accumulation throughout the embryo. The protein domain of *Kr* involves the activity of maternal effect genes and two adjacent gap genes, *hb* and *kni* (Gaul *et al.*, 1987). The *Kr* protein can be detected in the middle of the embryo (by antibody staining) at syncytial blastoderm and is demonstrated in a wide band of increasing density during cellular blastoderm (Gaul and Jäckle, 1987, 1989). Antibody staining is strongest in the center of the domain, growing weaker toward the anterior and posterior margins. The band in the middle of the embryo decreases in width at the end of cellularization and two more protein domains have been established as a stripe and a posterior cap. Domains of protein expression in *hb* and *Kr* overlap in wild-type embryos (Gaul and Jäckle, 1989) as do the protein domains of *Kr* and *kni* [Hülskamp, Pfeifle, and Tautz, 1990, *Nature* (London) 346: 577-80].

**krotzkopf verkehrt:** see *kkv*

### **KS: Male fertility complex on the short arm of the Y chromosome**

**synonym:** see *KL*.

**references:** Brosseau, 1960, *Genetics* 45: 257-74.

Kennison, 1981, *Genetics* 98: 529-48.

1983, *Genetics* 103: 219-34.

Hazelrigg, Formili, and Kaufman, 1982, *Chromosoma* 87: 535-59.

Gatti and Pimpinelli, 1983, *Chromosoma* 88: 349-73.

The male fertility complex of the short arm of the Y chromosome, originally called *K2* by Stern (1929, *Z. Indukt. Abstamm. Vererbungsl.* 51: 253-353) and subsequently called *KS* by Brosseau (1960, *Genetics* 45: 257-74), contains two complementing units designated *ks-1* and *ks-2*.

#### **ks-1**

**phenotype:** Males deficient for *ks-1* sterile. Cross sectional profiles of sperm tails in coiled bundles abnormal in outline; minute tubules ordinarily present among individualized spermtails in coiled bundles missing; replaced by membrane bound vesicles [Hardy, Tokuyasu, and Lindsley, 1981, *Chromosoma* 83: 593-617 (fig.)]. Within the *ks-1* fertility region of the spermatocyte nucleus, a loop-forming site has been demonstrated by

antibody staining using the monoclonal S5 (Bonaccorsi *et al.*, 1988). The loops are not visible in living preparations, but like the *kl-5* loops, can be stained with the dye CBB.

**alleles:** In addition to the alleles tabulated, Williamson (1972, *Mol. Gen. Genet.* 119: 43-47) reported 26 non-complementing and nine complementing alleles induced by ethyl methanesulfonate.

allele	origin		discoverer	synonym	ref <sup>α</sup>

**cytology:** *Y-h21* and *h23*.

#### **ks-2**

**phenotype:** Males deficient for *ks-2* are sterile. The earliest departure from normal spermiogenesis is the abnormal alignment of the axoneme with the furrow demarcating the two halves of the nebenkern. Subsequent development of the major and minor mitochondrial derivatives and their interactions with endoplasmic reticulum grossly abnormal [Hardy, Tokuyasu, and Lindsley, 1981, *Chromosoma* 83: 593-617 (fig.)].

**alleles:** In addition to the tabulated alleles, Williamson (1972, *Mol. Gen. Genet.* 119: 43-47) reported eleven noncomplementing and eleven complementing alleles induced by ethyl methanesulfonate.

**cytology:** *Y-h25*.

**KS63:** see *mud*

#### **kto: kohtalo (J.A. Kennison)**

**location:** 3-46.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1983.

**references:** Kennison and Tamkun, 1988, *Proc. Nat. Acad. Sci. USA* 85: 8136-40.

**phenotype:** Isolated as a dominant suppressor of *Pc* mutations. Also suppresses *Pcl* alleles as well as *Msc*, *Mrt*, and *Antp*<sup>Scx</sup>. Associated with recessive larval lethality.

THE GENOME OF *DROSOPHILA MELANOGASTER*

**alleles:** One mutant allele, called *kto*<sup>1</sup>.

**cytology:** Placed in 76B1-76D5 based on *Df(3L)kto2 = Df(3L)76B1-2;76D5* (Ashburner).

**kudu:** see *kdu*

**kug:** *kugelei*

**location:** 3-47.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Nüsslein-Volhard.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Female sterile. Mature eggs not laid and almost round.

**alleles:** Nineteen alleles.

**Kugel:** see *Kg*

**Kun:** see *Fs(3)Sz17*

**kurz:** see *kz*

**Kynurenine formamidase:** see *Kf*

**kz:** *kurz*

**location:** 1-0.9.

**discoverer:** Stern, 26a23.

**references:** Stern, 1930, Z. Indukt. Abstamm. Vererbungsl. 53: 279-86.

1934, DIS 1: 35.

Haenlin, Stellar, Pirrotta, and Mohier, 1985, Cell 40: 827-37.

**phenotype:** In the viable allele *kz*<sup>1</sup>, bristle are shorter and finer, like a slight Minute (Stern, 1930, 1934). Postscutellars often absent. Mutant hatches somewhat late. Viability fair; both sexes fertile. Recessive lethal alleles are slow to develop. First or second instar larvae stop developing; larvae may survive up to one week in arrested state (Perrimon *et al.*, 1984). All lethal alleles are cell lethal in germ-line clones. *kz*<sup>1</sup> females, heterozygous for a deficiency for the locus or for a lethal allele, emerge occasionally, but only after a delay of several days (Perrimon *et al.*, 1984).

<sup>β</sup> HMS = hycanthon methanesulfonate.

<sup>γ</sup> Discoverer: Sobels.

**cytology:** Placed in polytene band 2E3 by Lefevre (1981, Genetics 99: 461-80) and in 2E1-3 by Gvozdev (*et al.*, 1977).

**molecular biology:** The gene *kurz* was located in a clone microdissected from the 2E2-2F3 region of the salivary chromosomes; this clone (*cos9*), containing a 43 kb insert, was able to rescue the lethal mutant *kz*<sup>23</sup>; viable non-*FM7* males were produced from a cross between heterozygous *kz*<sup>23</sup>/*FM7* females and males carrying the cosmid on an autosome (Haenlin *et al.*, 1985).

**L: Lobe**

location: 2-72.0.

**phenotype:** Variable reduction in eye size of heterozygotes and homozygotes as well as in homozygous viability, depending on allele. Most extreme allele,  $L^2$ , exhibits reduced eyes in heterozygote and tiny eyes and poor viability in homozygote; classifiable in single dose in triploids (Schultz, 1934, DIS 1: 55).  $L^1/+$  have slightly reduced eyes with nick in anterior edge and the lower half of eye reduced more than upper; overlaps wild type; eyes of homozygote much smaller and less variable; bipartite eyes occasionally formed.  $L^r$  shows weakest expression, with the heterozygote indistinguishable from wild type and the homozygote with small kidney-shaped eyes at 25°, but overlapping wild type at 19°. Tested alleles ( $L^4$ ,  $L^B$ ,  $L^d$ ,  $L^r$ ) exhibit reduced expression at 19° compared to 25°. Expression enhanced ( $L^1$ ,  $L^2$ ,  $L^4$ ) in combination with Minutes [ $M(2)58F$ ,  $M(3)69E$ ,  $M(3)95A$ ] (Dunn and Coyne, 1935, Biol. Zentr. 55: 385-89). Reduced numbers of cells enter into formation of eye disks ( $L^2$ ,  $L^4$ ,  $L^5$ , Steinberg, 1944, Proc. Nat. Acad. Sci. USA 30: 5-13); reduced size of cephalic complex detectable in 24-hr larva, but subsequent growth rate is similar to wild type ( $L^4$ , Medvedev, 1935, Z. Indukt. Abstamm. Vererbungsl. 70: 55-72; Tr. Inst. Genet. Akad. Nauk. SSSR 10: 119-51).

<sup>β</sup> Strength of phenotypic expression, graded with respect to standard phenotypes  $L^1$ ,  $L^2$ , and  $L^r$ .

<sup>γ</sup> In  $In(2L+2R)Cy$ , therefore only heterozygote testable. Sectors of ommatidia replaced by chitin and bristles; lower half of head also reduced at 25°. Lower half of eye apparently produced from fewer than the normal nine or ten presumptive ommatidium-producing cells. Temperature-sensitive period for ommatidium formation first and second instars; third instar as well for head reduction.

**cytology:** Placed in 51A2-B1 based on its inclusion in

$Df(2L)L4 = Df(2L)51A2;51A12-B1$  (Baker and Ridge, 1980, Genetics 94: 383-423).

**l: lethal**

Some gene functions are dispensable to survival of flies in culture, whereas others are vital to survival such that amorphic alleles are lethal. Intermediate degrees of dispensability and hypomorphic alleles lead to intermediate situations. Whether a vital locus is named according to the phenotype of a hypomorphic allele or an escaper from a usually lethal genotype, or as a lethal is largely an accident of circumstance. Add to this uncertainty the recent practice of naming lethal mutants according to their lethal phenotype rather than as lethals, and the inconsistencies of nomenclatural usage become severe. In this revision, when a specific phenotype, either in the adult or an immature stage, can be associated with a mutation, that phenotype is used in its designation; otherwise, more general terms such as "lethal" are applied. In this regard, stage of death is not necessarily considered a specific phenotype.

In this revision an attempt is made to generate some order in the nomenclature for lethal alleles, which have heretofore been designated in a most capricious manner. Inasmuch as the cytological map has developed into such an exquisite instrument for gene localization, the method of indicating lethal loci currently used by Wright for the lethals in regions 37B and C has been adopted insofar as possible to the entire genome. Lethals are named according to the lettered subdivision of the polytene map that they occupy; separate loci are differentiated by lower case letters, e.g.,  $l(1)IAa$ , and  $l(1)IAb$ , etc. for lethals in region 1A; in case a lettered subdivision has more than 26 lethal complementation groups,  $l(1)Az$  will be followed by  $l(1)Aaa$ ,  $l(1)Abb$ , etc. Since cytogenetic mapping is imperfect, this system of nomenclature cannot be expected to be perfect; there are bound to be instances where the lethal name misidentifies the position of the locus, being slightly off in most cases, but seriously so in a few. The order in which loci within a subdivision are named is arbitrary, although when the linear order is known, it may be reflected in the locus designations; however, **alphabetical order is not a reliable indication of map order!** Where the cytological information is available, lethal loci in a lettered subdivision are tabulated in bold face according to lettered subdivision and their alternative designation(s) indicated in body type. Lethal mutations named according to their more specific phenotypes are tabulated according to lettered subdivision in body type and their current designation in bold face in the column headed "synonym", e.g.,  $l(1)IAa = l(1)EC1$  and  $l(1)IAe = ewg$ . Tabulations of loci in a lettered subdivision are generally followed by tabulations of the known alleles at each locus. Lethals named according to their more specific phenotypes are described and their alleles listed under the more specific name and not with the lethals. Where the cytological locations are unavailable, lethals are listed as in "Genetic Variations of *Drosophila melanogaster*", but where possible, groups of lethals with some aspect in common are designated alike and tabulated. As cytological determinations and complementation tests are made, additional lethals can be renamed according to cytological conventions and non-complementing lethals listed under the same locus sym-

bol. The column designated "comments" contains a variety of information. The notations represented by upper case letters indicate the lethal phase: E = embryonic; L1, L2, L3 = larval instars; EP = early pupa; LP = late pupa; A = adult; PP = polyphasic. In the case of X-chromosome lethals, notations with a slash bar are from Perrimon (e.g. Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14; 1989, Genetics 121: 333-52). The letters preceding the slash bar indicate the lethal phase; the letters following the slash bar indicate the behavior of homozygous oogenic clones in otherwise heterozygous females: NME = no maternal effect, i.e., the lethal phenotype of males produced by homozygous germ-line clones is indistinguishable from that of males produced by heterozygous mother; ME = maternal effect; MER = maternal effect partially rescued by paternal +; VME = variable maternal expression; AO = abnormal oogenesis; L = lethal. Rearrangements listed as associated with lethals are described under the appropriate rearrangement type, usually with breakpoints indicated.

For those numbered divisions in which saturation mutagenesis has been carried out, the lethal tabulations are followed by tables of the deficiency mapping results for the region. Cytological localizations of deficiency breakpoints are presented even though some are at variance with the genetic data. The orders indicated cannot be completely accurate, since all lethals have not been tested with all indicated deficiencies.

**l(1)**

Lethal mutations on the X chromosome are among the easiest to recover and the least convenient to characterize genetically. Accordingly they comprise the most represented and least characterized subset of lethal mutations. There are doubtlessly numerous instances of undetected allelism and therefore, in the following treatment, the number of named loci must substantially exceed the number actually represented.

**\*l(1)1: lethal (1) 1**

**location:** 1-1.1.

**origin:** Spontaneous.

**discoverer:** Rawls, 12b.

**references:** 1913, Biol. Bull. 24: 115-24.

Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 31.

**other information:** First recessive lethal found in *D. melanogaster*.

**l(1)1A**

Eight lethally mutable loci tentatively identified in region 1A; these include the former *l(1)J1* of Jacobs-Muller, *pch*, *cin*, *ewg*, and *arth*. Order established by deficiency mapping by Fleming, Schalet, Lim, and White; Complementation tests between mutants described by Maddern and the remainder not carried out; allelic relations arbitrarily assigned.

***l(1)1Bb***

**phenotype:** Homozygous clones in eyes display swelling and vacuolization of pigment cells (alleles designated MM2 and TE10). Deletion for *l(1)1Bb* enhances central-nervous-system and eye effects of ASC deficiencies (Jiménez and Campos-Ortega, 1987, J. Neurogenet. 4: 179-200; González, Romani, Cubas, Modolell, and Campuzano, 1989, EMBO J. 8: 3553-62).

<sup>α</sup> 1 = Eberl, Hilliker, and Voelker, 1988, DIS 67: 36; 2 = Lefevre, 1981, Genetics 99: 461-80; 3 = Lefevre and Watkins, 1986, Genetics 113: 869-95.

<sup>β</sup> Lefevre's and Voelker's mutants have arbitrarily been declared alleles, since all of Lefevre's are lost and the alternative is to postulate two loci, one of which Lefevre sampled four times and the other of which Voelker mutated three times.

**I(1)1D**

Region 1D contains three lethally mutable loci, one of which is *brc*.

$\alpha$  For coordinates in the *y* to *sc* region, (1) see Fleming, DeSimone, and White (1989, Mol. Cell Biol. 9: 719-25) when values are > 100, (2) see Ruiz-Gómez and Modolell (1987, Genes Dev. 1: 1238-46), when values are < 100. 0 is defined as the more distal *EcoR1* site within the *sc*<sup>32</sup> molecular deficiency; positive values extend to the left. For coordinates in the *elav* region, see Campos, Rosen, Robinson and White (1987, EMBO J. 6: 425-31). 0 is defined as the *BamHI* site closest to the proximal breakpoint of *In(1)elav*<sup>4</sup>; positive values extend to the right. The *Df(1)yT* series comprises terminal deficiencies that were induced in a *mu2* background; such deficiencies are unstable and lose about 75 terminal nucleotides per generation (Biessman and Mason, 1988, EMBO J. 7: 1081-86); hence the above determinations represent the situation prior to 1987.

## *l(1)2A*

At least six lethally mutable loci, including *sta*. Two loci identified by Belyaeva and Aizenzon; their *l(1)BA11* arbitrarily assigned to *l(1)2Ac*, but complementation tests not performed; when these are done the locus designation is likely to change. Their *l(1)BA12* assigned to the *l(1)2Ad* locus on the basis of its localization to the right of *Dp(1:f)101* and to the left of *sta*. These lethals placed between 2A2 and 2B4 by Aizenzon and Belyaeva. Schalet records spontaneous lethals at two loci within *Df(1)HA18*, *l(1)13-80* and *l(1)4-134*, and Kramers *et al.* record an HMS-induced allele of the latter *l(1)HM31*; allelism tests of these mutants to known alleles of *l(1)2Ab*, *l(1)2Ac*, and *l(1)2Ad* have not been carried out.

***l(1)2B***

Two collections of lethals in region 2B (Lefevre; Belyaeva *et al.*) have been complementation tested *inter se*, but have not been tested against each other. Lefevre identifies eleven complementing groups, whereas Belyaeva *et al.* identify nine plus two or three others that are identified here as alleles of *l(1)2A* loci but could lie in 2B. Where a single lethal complementation group from each series occupies the same region as defined by deficiency mapping, they are treated as a single locus. Lethal alleles of *br* and *dor* are included in both collections. Belyaeva *et al.* identify a complex of complementing lethals (designated *o.c.c.* = overlapping complementation complex) that includes the lethal alleles of *br*, and which is not recognized by Lefevre. These are tabulated below as *l(1)2Ba* to *l(1)2Bd*; *l(1)2Bad* alleles fail to complement four mutually complementing lethals and *l(1)2Bab* fails to complement *l(1)2Ba* and *l(1)2Bb*. The loci identified by Lefevre in the *br-dor* region and which he places in 2B4-12 have been equated arbitrarily to the complementing complex, which Belyaeva *et al.* place in 2B3-8; future crosses will determine the rectitude of this assignment. These lethals are described with the broad complex (*BRC*). In addition, Schalet (1983, DIS 59: 107) describes three complementation groups between the breakpoints of *y<sup>2</sup>Y67g19.1* and *Dp(1;3)w<sup>vco</sup>*; not tested against *l(1)2Bj* through *l(1)2Bt*. *arm*, selected by Wieschaus, Nüsslein-Volhard and Jürgens, has not been tested in combination with any of the others.

*l(1)2Fb*<sup>14</sup> fails to complement *l(1)2Fb*<sup>21</sup>; Gvozdev's alleles arbitrarily assigned to this locus although complementation with Lefevre's alleles not tested; could equally well be allelic to *l(1)2Fd*.

***l(1)2Fc***

**phenotype:** Lethal phase second or third larval instars; few eggs produced by homozygous germ-line clones in young *l(1)2Fc*<sup>1/+</sup> but not *l(1)2Fc*<sup>2/+</sup> females; clones in older females of both genotypes exhibit previtellogenic arrest.

### **l(1)3Ac**

**phenotype:** Tight alleles [*l(1)3Ac*<sup>9</sup>, *l(1)3Ac*<sup>12</sup>, *l(1)3Ac*<sup>23</sup>, *l(1)3Ac*<sup>33</sup>] are polyphasic, dying during L2, L3, and post puparial stages; cell viable. Semilethal alleles [*l(1)3Ac*<sup>2</sup> and *l(1)3Ac*<sup>6</sup>] die as pupae; escapers have rough eyes, shriveled or blistered wings, and crippled metathoracic legs; phenotype of *X0* more extreme than that of *XY* males. *XY* escapers fertile but females sterile [*l(1)3Ac*<sup>2</sup>/*l(1)3Ac*<sup>2</sup> and *l(1)3Ac*<sup>2</sup>/*l(1)3Ac*<sup>6</sup>] or nearly so [*l(1)3Ac*<sup>6</sup>/*l(1)3Ac*<sup>6</sup>]. The latter females sterile in crosses to *l(1)3Ac*<sup>6</sup> males, but produce heterozygous daughters when outcrossed (Shannon, Kaufman, Shen, and Judd, 1975, Genetics 72: 615-38). In line freed of *l(1)3Ba*<sup>4</sup> (Robbins), *l(1)3Ac*<sup>14</sup> survives as epidermal clones and as oogenic clones, which produce lethal zygotes (García-Bellido and Robbins, 1983, Genetics 103: 235-47).

**molecular biology:** Likely included in the chromosome walk of Mariani, Pirrotta, and Manet (1985, EMBO J. 4: 2045-52).

Res. 24: 1-10; 6 = Liu and Lim, 1975, Genetics 79: 601-11.

<sup>β</sup> MZI = maternal-zygotic interaction; demonstrated in males carrying mutant allele from heterozygous mother and variegating allele in a paternally derived duplication (Robbins, 1983, Genetics 103: 633-48).

### *l(1)3Ae*

**phenotype:** Alleles tested [*l(1)Ae<sup>2</sup>*, *l(1)Ae<sup>3</sup>*, *l(1)Ae<sup>6</sup>*, *l(1)Ae<sup>8</sup>*, *l(1)Ae<sup>10</sup>*, *l(1)Ae<sup>11</sup>*] die in post puparial stage, but growth slowing starts at various earlier stages; tested alleles survive in hemizygous condition in gynandromorphs; hemizygous eyes rough. Pharate adults dissected from *l(1)3Ae<sup>1</sup>* and *l(1)Ae<sup>5</sup>* pupae show rough eyes, sparse microchaetae, and incomplete dorsal midline; XY but not XO males of both rescued by *Dp(1;4)w<sup>m65g</sup>*, exhibiting phenotype of dissected pharate adults described above (Shannon, Kaufman, Shen, and Judd, 1972, Genetics 72: 615-38).

<sup>α</sup> 1 = Lim and Snyder, 1974, Genet. Res. 24: 1-10; 2 = Liu and Lim, 1975, Genetics 79: 601-11.

<sup>β</sup> MZI = maternal-zygotic interaction; demonstrated in males carrying mutant allele from heterozygous mother and variegating allele in a paternally derived duplication (Robbins, 1983, Genetics 103: 633-48). Survival of duplication-bearing males cold sensitive; *l(1)3Ag/w<sup>+</sup>Y* males yield frequent meiotic nondisjunction.

### *l(1)3Ah*

**phenotype:** Lethal alleles [*l(1)3Ah<sup>7</sup>*, *l(1)3Ah<sup>9</sup>*, *l(1)3Ah<sup>11</sup>*] die at the egg-larval boundary; *l(1)3Ah<sup>16</sup>* and *l(1)3Ah<sup>12</sup>* die shortly after hatching. Cell viable, but gynandromorphs show reduced survival. *l(1)3Ah<sup>6</sup>* semilethal with biphasic lethal expression in early larval and imago stages; escapers have rough eyes and are male fertile; inviable in combination with deficiency or lethal alleles (Shannon, Kaufman, Shen, and Judd, 1972, Genetics 72: 615-38). *l(1)3Ah<sup>13</sup>* viable in epidermal but not female germ-line clones (García-Bellido and Robbins, 1983, Genetics 103: 235-47).

***l(1)3Bb***

**phenotype:** Tested alleles die without growth in first larval instar [*l(1)3Bb<sup>4</sup>*, *l(1)3Bb<sup>6</sup>*, *l(1)3Bb<sup>7</sup>*] or grow slightly [*l(1)3Bb<sup>1</sup>*, *l(1)3Bb<sup>5</sup>*]. Few reach second instar but fail to grow further. All survive as XY but not as XO males in presence of either *Dp(1;4)w<sup>m65g</sup>* or *Dp(1;3)w<sup>m49a</sup>*. Survive as gynandromorphs when only tergites and occasionally wing tissue mutant; mutant tissue etched, lacks bristles, and deformed in the case of wing tissue (Shannon, Kaufman, Shen, and Judd, 1972, Genetics 72: 615-38). *l(1)3Bb<sup>1</sup>* and *l(1)3Bb<sup>4</sup>* viable in epidermal clones; only *l(1)3Bb<sup>1</sup>* survives in oogenic clones, and they produced viable zygotes (García-Bellido and Robbins, 1983, Genetics 103: 235-47).

<sup>α</sup> 1 = Judd, Shen, and Kaufman, 1972, *Genetics* 71: 139-56; 2 = Kraemers, Schalet, Paradi, and Huizer-Hoogteyling, 1983, *Mutat. Res.* 107: 187-201; 3 = Lefevre, 1981, *Genetics* 99: 461-80; 4 = Lefevre and Watkins, 1986, *Genetics* 113: 869-95; 5 = Lim and Snyder, 1974, *Genet. Res.* 24: 1-10; 6 = Liu and Lim, 1975, *Genetics* 79: 601-11.

<sup>β</sup> MZI = maternal-zygotic interaction; demonstrated in males carrying mutant allele from heterozygous mother and variegating allele in a paternally derived duplication (Robbins, 1983, *Genetics* 103: 633-48).

### ***l(1)3Bd***

**phenotype:** *l(1)3Bd*<sup>1</sup> males die either without growth in L1 or following protracted growth to full sized L2 stage. *l(1)3Bd*<sup>3</sup> males die as full-size L1 or variable-size L2 stage. XY but not XO males survive with slightly rough eyes and are fertile in presence of *Dp(1;4)w*<sup>m65g</sup>, *Dp(1;3)w*<sup>m49a</sup>, and *Dp(1;3)N*<sup>264-58a</sup>. Mutant tissue does not survive in gynandromorphs (Shannon, Kaufman, Shen, and Judd, 1972, *Genetics* 72: 615-38), nor in epidermal or female germ-line clones (García-Bellido and Robbins, 1983, *Genetics* 103: 235-47).

<sup>β</sup> MZI = maternal-zygotic interaction; demonstrated in males carrying mutant allele from heterozygous mother and variegating allele in a paternally derived duplication (Robbins, 1983, *Genetics* 103: 633-48).

<sup>γ</sup> Spontaneous in the paternal X chromosome of a cross between wild-type males and *mei-9* females, such that the F<sub>1</sub> females were *l(1)3Bd/mei-9*.

### ***l(1)3Bf***

**phenotype:** Most mutant larvae survive to L2 stage; L2 survivors grow slowly and reach half normal size before dying. XY but not XO males survive in combination with *Dp(1;4)w*<sup>m65g</sup>, *Dp(1;3)w*<sup>m49a</sup>, and *Dp(1;3)N*<sup>264-58a</sup>; lack varying numbers of orbital, ocellar, and vertical bristles; occasionally wing veins thickened; fertile. Mutant tissue [*l(1)3Bf*<sup>5</sup>, *l(1)3Bf*<sup>6</sup>, *l(1)3Bf*<sup>7</sup>] does not survive in gynandromorphs (Shannon, Kaufman, Shen, and Judd, 1972, *Genetics* 72: 615-38). *l(1)Bf*<sup>5</sup> lethal in both epidermal and oogenic clones (García-Bellido and Robbins, 1983, *Genetics* 103: 235-47).

### ***l(1)3C3***

**location:** 1-1.6 (between *w* and *rst*).

**origin:** Synthetic.

**discoverer:** Lefevre and Wilkins.

**references:** 1964, *Genetics* 50: 264.

**phenotype:** Male lethal. *l(1)3C3/w* is normal. RK2.

**cytology:** The consequence of deleting 3C3 through 3C6, a region postulated to contain duplicated loci (Lefevre and Green, 1972, *Chromosoma* 36: 391-412). Originally associated with the deficiency for band 3C3 alone obtained as a single recombinant carrying the left end of *T(1;4)w*<sup>mJ</sup> = *T(1;4)3C2-3;20;102C* and the right end of *In(1)rst*<sup>3</sup> = *In(1)3C3-5;20B*. That result attributed to the combined effects of the deficiency for 3C3 and a position effect on 3C5-6, neither of which is lethal by itself (Lefevre and Green).

### ***l(1)3C-D***

3C contains two named lethally mutable loci, *crm* and *N*. 3D contains one lethally mutable locus.

<sup>α</sup> Coordinates in 3B1-2 from Bargiello and Young (1984, Proc. Nat. Acad. Sci. USA 81: 2142-46); coordinates in 3B1-2 to 3C2-3 from Pirrotta, Hadfield, and Pretorius (1983, EMBO J. 2: 927-34); coordinates in 3C2-7 from Kidd, Lockett, and Young (1983, Cell 34: 421-33); and coordinates in 3D from Davis and Davidson (1986, Mol. Cell Biol. 6: 1464-70).

### *I(1)5CDa*

**location:** 1-15.1 (Voelker and Wisely, 1982, DIS 58: 150-51).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)E12* (or *l(1)E7* by label mixup?).

**references:** Suzuki, Piternick, Hayashi, Tarasoff, Baillie, and Erasmus, 1967, Proc. Nat. Acad. Sci. USA 57: 907-12.

Tarasoff and Suzuki, 1970, Dev. Biol. 23: 492-509.

**phenotype:** Development protracted and adults sterile when reared at 22°; protracted even more but adults fertile when reared at 17°. Sensitive to 29° at all stages of development. Lethality in midpupal stage. Shift down prior to lethal phase improves survival.

**cytology:** Placed in 5C5-D6 on the basis of its inclusion in *Df(1)N73 = Df(1)5C2;5D56* but not in *Df(1)C149 = Df(1)5A8-9;5C5-6*.

**other information:** *l(1)E12* mapped to 35.4 by Tarasoff and Suzuki and to 15.1 by Voelker and Wisely. Could Voelker and Wisely have received a mislabeled stock of *l(1)E7* (1-15.2) from Vancouver?

### \**I(1)6*

**location:** 1-0.4.

**origin:** Spontaneous.

**discoverer:** Bridges, 14d9.

**references:** 1916, Genetics 1: 149.

**phenotype:** Rare survivors interpreted as recombinants led Bridges to place *l(1)6* 0.4 unit to the left of *y*.

### *I(1)6D*

Eight lethally mutable loci identified, but not ordered

by Lefevre.

***l(1)7C: Dominant Lethal in 7C***

location: 1-{22}.

origin: Inferred from the haploinviability of deficiencies for 7C.

synonym: *Hiv*.

references: Lefevre and Johnson, 1973, Genetics 74: 633-45.

cytology: Placed in 7C5-9 on the basis of the failure to recover *ct sn* deficiencies and on the failure of deficiencies for *ct* to extend to the right beyond 7C4 and of a *sn* deficiency to extend to the left beyond 7D1.

***I(1)7C***

Eight lethally mutable loci, only one of which has more than a single allele, identified by Lefevre.

**\**l(1)8***

**location:** 1-21.3 (19.0 to 23.6).

**discoverer:** Sobels.

**references:** Gloor, 1962, Rev. Suisse Zool. 69: 409-63 (fig.).

**phenotype:** Larvae lethal in third instar, survive up to 10 days. Testes and lymph glands degenerate. Imaginal disks develop normally after transplantation. Protein metabolism disturbed; free amino acids and peptides abnormally high. RK2.

***l(1)8A***

Four lethally mutable loci including *oc*. *l(1)8Aab* of Schalet fails to complement both *l(1)8Aa* and *l(1)8Ab*.

**I(1)9A, I(1)9E**

Four complementation groups between 9E1 and 9E8 identified by Janca, Woloshyn, and Nash, (1986, Genetics 112: 43-64); three identified by Lefevre (Lefevre and Watkins, 1986, Genetics 113: 869-95); complementation studies by Janca *et al.* show that only *ras* and *I(1)9Ed*

identified by both studies.

<sup>α</sup> 1 = Janca, Woloshyn, and Nash, 1986, Genetics 112: 43-64; 2 = Lefevre and Watkins, 1986, Genetics 113: 869-95.

<sup>β</sup> Haplospecific alleles survive as males or homozygous females, but die in heterozygous combination with a deficiency for the locus.

**I(1)9F**

Alleles recovered and characterized by three groups: allelism between mutants from the different collections partially carried out by Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva (1987, Biol. Zentralbl. 106: 699-720). As many as seven lethally mutable loci, including *sesB*, *fliK*, and *sbr*, identified. Deficiency map based largely on the work of Zhimulev *et al.* are labeled *I(1)BP* after Belyaeva and Pokholkova; those identified by Geer *et al.* are labeled *I(1)G*; the remainder were identified by Lefevre. Janca, Woloshyn, and Nash isolated three mutants in different complementation groups in 9E7-9F11 and four in two complementation groups in 9F10-10A2, but no complementation tests carried out with other lethal mutations in 9F and therefore not included in tabulations.

**I(1)9Fe**

**alleles:** All alleles lethal except *I(1)9Fe*<sup>12</sup>, which is viable and of normal phenotype in both homozygous and heterozygous condition. However, flies heterozygous for *I(1)9Fe*<sup>12</sup> and any lethal allele except *I(1)9Fe*<sup>1</sup> or for a

deficiency for *l(1)9Fe* show irregularly missing bristles, especially humerals; *l(1)9Fe*<sup>1</sup> complements *l(1)9Fe*<sup>12</sup>.

***l(1)10A***

Four independent mutation searches have been carried out in this region. Most mutants have been tested against the first group of three loci identified by Lefevre (1971, Genetics 67: 497-513), but there are indications of as many as five additional loci as inferred from the results of within-search complementation tests. In general mutants recovered in different searches have not been tested against one another. *rtv* has not been tested for complementation by other mutants in region 10A. Presumptive loci originally identified by Zhimulev *et al.* are labeled *l(1)BP* after Belyaeva and Pokholkova; those identified by Geer *et al.* are labeled *l(1)G*; the remainder were identified by Lefevre.

### *l(1)10Ad*

One of two loci in the region of overlap between *Df(1)RA37* and *Df(1)v-13*. Allelism of *l(1)10Ad*<sup>1</sup> with Russian alleles and with HMS-induced alleles established by Zhimulev *et al.* *l(1)10Ad*<sup>23</sup> and *l(1)10Ad*<sup>24</sup> designated alleles on basis of deficiency mapping and complementation of *l(1)10Ae*<sup>1</sup>. *l(1)10Ae*<sup>20</sup> fails to complement the Russian alleles, but according to Geer *et al.* does complement *l(1)10Ad*<sup>21</sup> and *l(1)10Ad*<sup>22Y</sup>, which are not mentioned in the Russian papers.

<sup>β</sup> Tentative order: 1—5C|73F—77A|22A—60;20—14B|13B—14B|10A—13B|10A—5D|77A—61;21—22A|73F—100.

<sup>γ</sup> Segment from 3C12 to 20A4 highly rearranged and inserted into 3L at 64B; additional breaks recorded in 9D-E, 10B7-12, 11A7, and 15B-C.

***l(1)10B***

Complementation and deficiency mapping of the lethals in 10B have been carried out by Sponaugle, who determined relations among mutant alleles produced by Lefevre, Geer *et al.*, and Voelker.

**l(1)10C**

Searches of Lefevre, of Geer *et al.*, and of Voelker *et al.* extend into this region. 10C is subdivided into two regions by the *Df(1)v-N48* breakpoint. Of four lethally mutable loci in the more distal region, 10C1-5, *RpII215* is 0.02 map units to the left of *l(1)10Cc* (5X2/63,658) other pairs of loci have not been separated by recombination: *RpII215-tyl* (0/8,606), *tyl-l(1)10Cc* (0/81,402), and *l(1)10Cc-l(1)10Cd* (0/144,897); the fifth locus, *nod*, was tested for complementation, but not by recombination (Voelker, Wisely, Huang, and Gyurkovics, 1985, *Mol. Gen. Genet.* 201: 437-45).

### *l(1)11D-F*

The product of saturation mutagenesis and deficiency mapping in the region encompassed by *Df(1)C246* carried out by N. Scott (1987, Ph.D. thesis, University of California, San Diego).

***l(1)14-l(1)15***

Two studies using lethal mutations in this region have been reported; neither was interested in the lethals *per se*, and the mutants reported in one study were never tested against those in the other, and no case of allelism was reported in either study. *para* is the only genetic landmark common to the two studies. Recent studies by Steller (unpublished) provide more information on rela-

tive positions of loci in 14B-C. Embryonic lethal mutations *baz* and *exd* map to this region, but allelism with the lethals tabulated not tested.

### I(1)16Fa

**phenotype:** Major lethal phase in early pupae. Cell lethal in somatic mosaics in the hypoderm of the adult; also lethal in female germ-line mosaics.

### I(1)16Fb

**phenotype:** Major lethal phase in late pupae. Somatic clones of homozygous tissue in adult hypoderm show small bristles, slightly disoriented, unpigmented cuticle, and plexate veins. Gynandromorphs show vibrating appendages in the mutant territory. Germ-line mosaics show a maternal effect since the eggs produced by mutant ovarioles never develop beyond the gastrula stage, irrespective of the zygotic genotype.

### I(1)16Fc

**phenotype:** Major lethal phase in the first larval instar. Somatic mosaics in the adult hypoderm show normal differentiation. Gynandromorphs show vibrating appendages in the mutant territory; also uncoordinated movement on the mutant side. Germ-line mosaics show a maternal effect since the eggs produced by mutant ovarioles never develop beyond the gastrula stage, irrespective of the zygotic genotype.

***l(1)16Fd***

**phenotype:** Major lethal phase in early pupae. Somatic mosaics in the adult hypoderm show fewer and smaller bristles and smooth ommatidia. Lethal in germ-line mosaics.

***l(1)16Fe***

**phenotype:** Major lethal phase in second larval instar. Somatic mosaics in the adult hypoderm show normal cuticle. Gynandromorphs exhibit vibrating appendages and abnormal wing position in the mutant side. Germ-line clones normal.

***l(1)18F-19A***

***l(1)19C-D***

Four lethally mutable loci identified by Schalet and Lefevre [1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, vol. 1b, pp. 847-902]. Three lethally mutable loci identified in an independently derived sample (Lefevre and Watkins, 1986, Genetics 99: 869-95). Complementation tests between the two sets of mutants not performed; allelism between lethals in the

two groups arbitrarily assigned.

***l(1)19Ec***

**phenotype:** Mutant embryos from heterozygous females exhibit no defects in central or peripheral nervous systems; *l(1)19Ec*<sup>1</sup> and *l(1)19Ec*<sup>18</sup> are lethal in germ-line clones, whereas *l(1)19Ec*<sup>8</sup> and *l(1)19Ec*<sup>25</sup> germ-line clones exhibit a paternally rescuable maternal effect. Embryonic phenotype includes head and dorsal-closure defects, and most embryos are twisted (Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31).

### ***l(1)19Fb***

**phenotype:** Pupal lethal; embryonic central nervous system (CNS) and peripheral nervous system (PNS) normal. Eggs derived from homozygous germ-line clones have variably defective chorions. The few embryos that develop are U-shaped owing to defective germ-band retraction; have severe head defects (Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31).

*l(1)48j*: see *mys*

### \**l(1)52*

**location:** 1- (to the right of *B*).

**discoverer:** Sobels.

**references:** Gloor, 1962, Rev. Suisse Zool. 69: 409-63 (fig.).

**phenotype:** Larvae die in second instar. Growth retarded. Histology of nervous system, testes, and imaginal disks abnormal. Number of nuclei in salivary glands increased. Amino acids and peptides increased. Transplanted testes and imaginal disks autonomously lethal. RK2.

### *l(1)55*

**location:** 1-0.

**discoverer:** Burdick, 55a.

**references:** 1956, DIS 30: 69. 1957, DIS 31: 86.

**phenotype:** Rare surviving males misinterpreted by Burdick as crossovers to the left of *y* leading him to place *l(1)55* at -0.6. Heterozygote claimed to have viability about 1.5 times normal. Not allelic to *l(1)IAc<sup>1</sup>*. RK2.

### *l(1)55a*

**location:** 1-5.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz, 1978, Dev. Biol. 66: 571-78 (fig.).

**phenotype:** Temperature-sensitive lethal; few *l(1)55*-bearing males develop at 27°; lethal-bearing males surviving either temperature regime display arrest of spermatogenesis. At 18-22° a variable number of cysts continues to support gonial proliferation producing giant cysts with hundreds of spermatogonia, most of which degenerate.

### *l(1)63*

**location:** 1-0.3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz, 1978, Dev. Biol. 66: 571-78 (fig.).

**phenotype:** Temperature-sensitive lethal. Surviving *l(1)63*-bearing males raised under permissive conditions exhibit precocious spermatocyte maturation in some cysts of four and eight cells; other cysts produce sixteen primary spermatocytes. Shifting such males to 27° causes mitotic arrest leading to disappearance of gonial cells within two or three days and of primary spermatocytes after four or five days. Homozygous females raised at

18° phenotypically normal but sterile. Mutant tergites found in gynandromorphs raised at 27°; half-and-half gynandromorphs formed from embryos shifted from permissive to restrictive conditions 48 hr after oviposition; facet number in mutant eyes and bristles in mutant tissue reduced, indicating mitotic arrest.

*l(1)76*: see *dor<sup>l2</sup>*

### \**l(1)184*

**location:** 1- (rearrangement).

**origin:** X ray induced.

**discoverer:** Lindsley, Edington, and Von Halle.

**references:** 1960, Genetics 45: 1649-70.

**phenotype:** Almost completely lethal. The few survivors have dark, rough eyes. RK2A.

**cytology:** Associated with *T(1;3)l-184 = T(1;3)18A;81*.

### \**l(1)272-13*

**location:** 1- (rearrangement).

**origin:** X ray induced.

**discoverer:** Demerec, 1940.

**references:** Sutton, 1943, Genetics 28: 210-217.

**phenotype:** Lethal. *l(1)272-13/sc* is scute. RK2A.

**cytology:** Associated with *In(1)l-272-13 = In(1)1A6-B1;11A7-8;11F2-12A1;18A4-B1*.

### *l(1)1074<sup>ts</sup>*

**location:** 1-16.3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Datson and Brink, 1978, Aust. J. Biol. Sci. 31: 73-91.

Brink, 1979, Aust. J. Biol. Sci. 32: 597-606.

**phenotype:** Temperature-sensitive mutant of a gene whose product is required several times during development. The temperature-sensitive periods are towards the end of oogenesis in homozygous females, from the sixth to twelfth hour of embryogenesis and again during larval and early pupal development in mutant offspring. Embryological abnormalities first evident during gastrulation and eventually result in the breakdown of organogenesis and the absence of normal muscular contractions. Fragments of mutant gastrulae transplanted into larvae fail to show evidence of the cuticular differentiation seen in transplanted wild-type fragments. X-ray-induced mutant clones formed normally in abdominal histoblasts, but didn't survive in imaginal discs.

### *l(1)2269*

**location:** 1-unmapped.

**origin:** Induced by ethyl methanesulfonate.

**references:** Gateff, 1978, Biol. Rev. 53: 123-68.

1978, Science 200: 1448-59.

**phenotype:** Causes malignant neuroblastoma of the adult optic neuroblasts and ganglion mother cells; also displays intermediate imaginal disc neoplasm with compact mode of growth.

### *l(1)3063*

**location:** 1-0.8 (0/569 recombinants with *pn*).

**origin:** X ray induced.

**references:** Imaizumi, 1967, DIS 42: 78.

**phenotype:** Embryonic lethal; dies in second half of embryogenesis.

*l(1)Ab*: see *r*

***l(1)Ac*<sup>1</sup>**

**origin:** X ray induced simultaneously with *sc*<sup>J1</sup>.  
**discoverer:** Jacobs-Muller.  
**references:** Muller, 1932, Proc. Intern. Congr. Genet., 6th., Vol. 1: 225.  
 Muller, 1935, Genetica 17: 237-52.  
**phenotype:** Lethal. Not cell lethal (Ephrussi, 1934, Proc. Nat. Acad. Sci. USA 20: 420-22). One recorded surviving male had rough eyes and was sterile. RK2A.  
**cytology:** Probably in 1A6. Associated with *In(1)sc*<sup>J1</sup> = *In(1)1A4-5;1B4-5* (Muller, Prokofyeva, and Raffel, 1935, Nature 135: 253-55).

***l(1)adi: lethal (1) adult***

A series of ethyl-methanesulfonate-induced mutants identified by virtue of their reduced life span upon being shifted from their developmental temperature of 22° to 29° shortly after eclosion. Most are temperature-sensitive lethals with preimaginal as well as adult lethal phases; as such they identify a subset of lethally mutable genes whose functions are required both during development and for the maintenance of adult viability; in general, they have not been tested for allelism with unconditional lethals nearby. Others are unconditionally lethal in the adult stage and are either completely viable during development or are semilethal during development at one or both temperatures.

<sup>α</sup> 1 = Homyk and Sheppard, 1977, Genetics 87: 95-104; 2 = Homyk, Sinclair, Wong, and Suzuki, 1979, Genetics 91: s49-50; 3 = Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89; 4 = Homyk, Szidonia, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65; 5 = Laffelaar and Grigliatti, 1984, Dev. Genet. 4: 199-210; 6 = Shellenbarger and Cross, 1979, Dev. Biol. 71: 308-22.

<sup>β</sup> The period during which adults die in days after eclosion at 29°; control flies survive well beyond 25 days at that temperature.

***l(1)adi1***

**phenotype:** Temperature shift and pulse experiments delineate two major temperature sensitive periods, one during the second half of embryogenesis and the other at the time of pupation. Fate mapping revealed separate mesodermal foci for leg paralysis, and examination of embryos developing at 29° indicated abnormalities in muscle development (Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89).  
**cytology:** Located in 7D11-22 based on its inclusion in

*Df(1)HA11* (Lefevre).

***l(1)adi2***

**phenotype:** Fate mapping suggests presence of bilateral domineering foci located in or near the subesophageal ganglion responsible for both hypoactivity and lethality at 29° (Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89).

***l(1)adi3***

**phenotype:** Severely debilitated in phototaxis and geotaxis shortly after shift of adults raised at 22° to 29° (Laffelaar and Grigliatti, 1984, Dev. Genet. 4: 199-210).

***l(1)adi4***

**phenotype:** Gradual loss of phototaxis and geotactic abilities during three days following shift of adults raised at 22° to 29° (Laffelaar and Grigliatti, 1984, Dev. Genet. 4: 199-210).

***l(1)adi13***

**phenotype:** Motor, geotactic, and phototactic behavior severely debilitated at 22°, but lifespan shortened only when shifted to 29° (Laffelaar and Grigliatti, 1984, Dev. Genet. 4: 199-210).

***l(1)adi16***

**phenotype:** The normal pattern of behavioral loss associated with aging in *Drosophila* was contracted exactly in parallel with the contraction of the life span in *l(1)adi16*<sup>1</sup> flies, suggesting that mutations at this locus accelerate aging (Laffelaar and Grigliatti, 1984, Dev. Genet. 4: 199-210). *l(1)adi16*<sup>3</sup> (formerly *firdl*) adults show weak flight, general activity and reduced life span at 25°.

**alleles:**

*l(1)crn*: see *crn*

### *l(1)DC*: lethal (1) of David Cross

Twelve complementing heat-sensitive lethals which develop at 22° but not at 29°; phenotypic information available on three.

**discoverer:** Cross.

**references:** Shellenbarger and Cross, 1979, Dev. Biol. 71: 308-22.

### *l(1)DC371*

**phenotype:** Males raised at 22° fertile, but become sterile after eight days at 28°. Sterile males have motile sperm, which are not transmitted to females.

### *l(1)DC836*

**phenotype:** Males raised at 22° survive, but die when held at 28° following eclosion.

### *l(1)DC1112*

**phenotype:** Males raised at 22° eclose but die prematurely at either permissive or restrictive temperature.

### *l(1)dd*: lethal (1) discs degenerate

A group of late larval-early pupal lethals that exhibit degeneration of imaginal discs at the normal time of pupation. None of those tested is able to survive in male tissue in gynandromorphs (all but *dd10* and *dd11* tested). All have been found by Baker, Smith, and Gatti to be mitotic mutants; they argue that the maternal genotype supports cell division in the embryo, and that disc proli-

feration represents the first instance of zygotically controlled cell division; thus the defects in these mutants do not affect phenotype until late in development (Baker, Smith, and Gatti, 1982, Proc. Nat. Acad. Sci. USA 79: 1205-09; Gatti, Pimpinelli, Bove, Baker, Smith, Carpenter, and Ripoll, Proc. Int. Cong. Genet. 15th, 1983, Vol. 3, pp. 193-204; Gatti and Baker, 1989, Genes Dev. 3: 438-53).

<sup>β</sup> Fuller discussion follows.

### *l(1)dd3*

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion cells three times that of controls; chromosomes highly condensed as seen in colchicine-treated cells; 20% of metaphases polyploid; chromosome fragmentation common; no anaphase figures seen (Gatti and Baker, 1989, Genes Dev. 3: 438-53). Homozygous cells in ovary lethal (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14).

### *l(1)dd4*

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion cells three times that of controls; 20% of metaphases polyploid; very few anaphase figures seen. No maternal effect of homozygosis in ovarian clones on phenotype of offspring (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14). *l(1)dd4<sup>S</sup>* recovered as a mutation on the paternal X in a cross of homozygous *mei-9* females by normal males [isolated as *l(1)08/20*]. Ordinarily dies just prior to eclosion, but in dry cultures, both males and females eclose and have good viability, but are almost completely sterile. Wings are held up, some bristles on head and thorax (especially scutellars) are absent; abdomen mutant effects similar to those of *bb*. Females heterozygous for *l(1)dd4<sup>S</sup>* and a deficiency are almost completely lethal.

**cytology:** Placed in 12A-C based on the failure of *Y<sup>PX</sup>D<sup>B166</sup>X<sup>PY</sup>D<sup>B136</sup>* to complement the lethality of *l(1)dd4<sup>S</sup>*. *Dp(1;Y)g<sup>+</sup>* covers lethal, sterile, and visible effects in males; *Dp(1 f)LJ9* covers lethal effect, but only

partially covers visible effects.

***l(1)dd9***

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion reduced; chromosomes unevenly condensed, appear fuzzy; sister chromatids often closely apposed; heterochromatic regions elongated; tetraploid cells and some chromosome breakage seen (Gatti and Baker, 1989, Genes Dev. 3: 438-53). No maternal effect of homozygosis in ovarian clones on phenotype of offspring (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14).

***l(1)dd10***

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion cells three times that of controls; mitotic chromosomes more highly condensed than normal; 30% of metaphases polyploid; chromosome fragmentation common; no anaphase figures seen (Gatti and Baker, 1989, Genes Dev. 3: 438-53). Homozygous cells in ovary lethal (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14).

***l(1)dd11***

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion cells and chromosome condensation normal; 43.5% of metaphases polyploid; cells containing 500 to 1000 chromosomes encountered; some chromosome fragmentation seen (Gatti and Baker, 1989, Genes Dev. 3: 438-53). Homozygous cells in ovary lethal (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14).

***l(1)dd12***

**phenotype:** Discs missing or degenerate; mitotic index of larval ganglion cells reduced; chromosomes swollen and unevenly condensed; few metaphases polyploid; no chromosome fragmentation seen (Gatti and Baker, 1989, Genes Dev. 3: 438-53). Homozygous cells in ovary lethal (Perrimon, Engstrom, and Mahowald, 1984, Dev. Biol. 105: 404-14).

***l(1)dh1: lethal (1) discs heterogeneous***

**location:** 1-27.5.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)d.het.-1*.

**references:** Kiss, Bencze, Fekete, Fodor, Gausz, Maróy, Szabad, and Szidonya, 1976, Theor. Appl. Genet. 48: 217-26.

**phenotype:** Pupal lethal; imaginal leg discs small, remaining imaginal discs normal in size and structure.

***l(1)dh2***

**location:** 1-57.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)d.het.-2*.

**references:** Kiss, Bencze, Fekete, Fodor, Gausz, Maróy, Szabad, and Szidonya, 1976, Theor. Appl. Genet. 48: 217-26.

**phenotype:** Pupal lethal; leg discs degenerated; remaining imaginal discs of normal size and structure. Chromosomes in larval ganglion cells irregularly condensed, often displaying coiled and banded appearance; in addition, chromatid breaks and extremely hyperploid or tetraploid cells are frequently observed (Gatti, Pimpinelli, Bove, Baker, Smith, Carpenter, and Ripoll, Proc. Int.

Cong. Genet. 15th, 1983, Vol. 3, pp. 193-204; Gatti and Baker, 1989, Genes Dev. 3: 438-53).

***l(1)dn: lethal (1) discs normal***

A group of late larval and early pupal lethals in which the imaginal discs appear normal at the time that pupation normally occurs. The ability of the discs of these mutants to differentiate in a normal hormonal milieu has been examined in both gynandromorphs and when transplanted into larvae that are then allowed to undergo metamorphosis.

<sup>γ</sup> Cell division normal (Gatti and Baker, 1989, Genes Dev. 3: 438-53).

### *l(1)ds10*

**phenotype:** Discs small, folding rudimentary; ring gland normal size.

### *l(1)ds11*

**phenotype:** Discs very small, no folding; ring gland small; pupariation accelerated by implantation of wild-type ring glands.

### *l(1)ds12*

**phenotype:** Discs very small, no folding; ring gland small.

### *l(1)ds13*

**phenotype:** Discs small, folding rudimentary; ring gland small.

### *l(1)E7<sup>ts</sup>*

**location:** 1-15.2 (1.5 units to the right of *cv*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Suzuki, Piternick, Hayashi, Tarasoff, Baillie, and Erasmus, 1967, Proc. Nat. Acad. Sci. USA 57: 907-12.

Tarasoff and Suzuki, 1970, Dev. Biol. 23: 492-509.

**phenotype:** Males, but not homozygous females, able to develop at 29°; females die as embryos or young larvae; males die as late pupae or young imagos. TSP of males lasts from midpupal into early adulthood. Females sensitive during first 40 hr as well as from 60-75 hr and again during pupation. Mutant females homozygous for *tra* respond to high temperature as do *tra*<sup>+</sup> females.

*l(1)E12*: see *l(1)5CDA*

### *l(1)E25<sup>ts</sup>*

**location:** 1-15.5 (1.8 units to the right of *cv*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Suzuki, Piternick, Hayashi, Tarasoff, Baillie, and Erasmus, 1967, Proc. Nat. Acad. Sci. USA 57: 907-12.

Tarasoff and Suzuki, 1970, Dev. Biol. 23: 492-509.

**phenotype:** Hatchability of eggs deposited by *l(2)E25<sup>ts</sup>* females inversely related to length of maternal exposure to 29°; no hatch after 12-15 hr at 29°. Heat effect reversible by cooling for the first few hours after ovoposition. Exposure of paternal male to restrictive temperatures without effect. Newly fertilized eggs placed at 29° produce larvae that arrest in second instar; later shift up causes later arrest. Lethal polyphasic.

### *l(1)E34<sup>ts</sup>*

**location:** 1-20.7 (7.0 units to the right of *cv*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Suzuki, Piternick, Hayashi, Tarasoff, Baillie, and Erasmus, 1967, Proc. Nat. Acad. Sci. USA 57: 907-12.

Tarasoff and Suzuki, 1970, Dev. Biol. 23: 492-509.

**phenotype:** Late pupal lethal; flies raised at 29° form eye and bristle pigments and wings but fail to eclose. Rates of development heterogeneous. TSP begins at time of initiation of pupation.

### *l(1)EN: lethal (1) from Eugene Nonautonomous*

**origin:** X ray induced.

**references:** Novitski, 1963, DIS 37: 53.

**phenotype:** A series of sex-linked recessive lethals selected by virtue of the survival of hemizygous lethal-bearing cells in gynandromorphs. Free amino acid concentrations in lethal-bearing immature stages estimated by means of paper chromatography; differences from wild type reported (see also CP627).

locus	genetic location	lethal phase	amino acid phenotype <sup>α</sup>	comments
<i>l(1)EN1</i>	1-46	L1-P	ALA,tyr	salivary glands and gastric ceca small; fat body missing in L3

### *l(1)ER<sup>ts</sup>: lethal (1) endoplasmic reticulum*

**location:** 1-18.

**origin:** Induced by ethyl methanesulfonate.

**references:** Fullilove and Woodruff, 1974, Dev. Biol. 38: 291-307 (fig.).

**phenotype:** Embryonic development arrested prior to gastrulation at 29°; hatching delayed approximately two hr at 25° but development normal. Embryos produced by *l(1)ER<sup>ts</sup>* females held at 29° arrested prior to gastrulation; this TSP lasts until 8 hr after fertilization. Hatching of eggs produced by such females delayed 2 hr at 21°

compared with eggs from wild-type females. Second TSP occurs during the first three days of larval life; larvae developing at 29° arrest as fully-developed pupae which fail to eclose. Electron-microscope observations made on arrested embryos; show abnormal distributions of nuclei, cytoplasm, and yolk; rough endoplasmic reticulum abnormal.

***l(1)ESHS: lethal (1) of Eeken, Sobels Hyland, and Schalet***

**origin:** MR induced. Recovered among the progeny of males whose fathers carried *MR-h12* and who inherited from their mothers *In(1)dl49*, *y w f* (experiment 1/), *y mei-9<sup>a</sup> mei-41<sup>D5</sup>* (experiments 2/ and D), or Berlin-K wild type (experiments 20/, 24/, 28/, and 32/) X chromosomes. P-element sequence inserts detected by *in situ* hybridization to polytene X chromosomes in those mutants whose acquisition numbers are followed by an asterisk, but not in those followed by double asterisks.

**references:** Eeken, Sobels, Hyland, and Schalet, 1985, *Mutat. Res.* 150: 261-75.

**cytology:** Lethals in regions covered by X duplications; subjected to more or less complete deficiency mapping, but complementation mapping with respect to previously mapped lethal mutations not generally done. Those few shown not to complement known lethal mutations are listed with the appropriate loci; the remainder are arranged below in relation to the duplications and deficiencies against which they were tested and in their order along the chromosome. Allelism tests among *l(1)ESHS* mutants mapping to the same cytological interval not invariably performed; such allelism as discerned indicated by more than a single isolation designation for a locus. As allelism of *l(1)ESHS* mutants to known loci is determined, they will be removed from this list and appended to the allelic lists of said loci. Polytene analysis revealed no case of gross chromosome rearrangement.

### \***I(1)ff: lethal (1) formalin food**

**location:** 1- (not located).

**origin:** Induced by formaldehyde.

**discoverer:** Auerbach.

**synonym:** *Lff11*.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 148: 416-36 (fig.).

**phenotype:** Develops to late embryonic stage; at 22 hr (normal hatching time), shows vigorous muscular movements but is unable to break through vitelline membrane. Muscular activity persists several hours, but hatching does not occur; cell degeneration begins at about 25 hr. Differentiation abnormal in several ways: pharyngeal apparatus reduced and distorted; brain forms irregular mass; constriction forms behind head; segmentation distorted; body wall usually incomplete dorsally. RK2.

### **I(1)FM**

Several lethal mutations have been recorded in *FM6* or *FM7*; they have not been further characterized.

### **I(1)HM: lethal (1) of Helen Mayo**

A series of cold-sensitive sex-linked recessive lethal mutations induced by ethyl methanesulfonate. Cold-sensitive lethals are defined as exhibiting >20% survival at 22° and none at 17°, and cold-sensitive semilethals as exhibiting >30% survival at 22° and <13% at 17° (Mayoh and Suzuki, 1973, Can. J. Genet. Cytol. 15: 237-54; Falke and Wright, 1975, Genetics 81: 655-82).

### **I(1)J: lethal (1) of János Szidonia**

Thirty-nine complementing heat-sensitive lethals which develop at 22° but not at 29°.

**discoverer:** Szidonia.

**references:** Shellenbarger and Cross, 1979, Dev. Biol. 71: 308-22 (fig.).

### **I(1)J413**

**location:** 1-between *g* and *f*.

**phenotype:** Males raised at 22° become sterile and lack motile sperm after six days at 28°. No postmeiotic cysts found in sterilized males. Basal third of testis contains debris; distal two-thirds accumulate primary spermatocytes.

### **I(1)J770**

**phenotype:** Males raised at 22° survive but die when held at 28° following eclosion.
