### **I(1)J1024**

**location:** 1-19.3.

**phenotype:** Males raised at 22° become sterile and lack motile sperm after six days at 28°. Testicular contents disorganized in sterile males; dispersed but well-condensed sperm heads present. Thought to be blocked in spermatid elongation.

### **I(1)J1649**

**phenotype:** Males raised at 22° survive but die when held at 28° following eclosion.

### **I(1)J1660**

**phenotype:** Males raised at 22° fertile, but become sterile after eight days at 28°; sterile males have motile sperm, which are not transmitted to females.

### **I(1)J1674**

**phenotype:** Males raised at 22° fertile, but become sterile after eight days at 28°; sterile males have motile sperm, which are not transmitted to females.

### **I(1)J1743**

**phenotype:** Males raised at 22° survive but die when held at 28° following eclosion.

*l(1)J1<sup>259</sup>*: see *Df(1)259*

### \***I(1)jl: lethal (1) jawless**

**location:** 1-14.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, Heredity 6: 403-7.

**phenotype:** Dies during first larval instar. Mouth parts poorly formed and sometimes absent. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

*l(1)L5*: see *RpII215*

**\*I(1)m: lethal (1) malignant**

location: 1- (not located).

origin: Induced by mustard gas.

synonym: *l-mal*.

references: El Shatoury, 1955, Arch. Entwicklungsmech. Organ. 147: 496-522 (fig.).

El Shatoury and Waddington, 1957, J. Embryol. Exp. Morphol. 5: 143-52 (fig.).

phenotype: Cells originating from lymph glands in late third instar first spread to and cause destruction of imaginal buds and later may move along ventral nerve cord to attack posterior fat bodies and testes. The tumor cells eventually become melanotic after destruction of various healthy tissues. Death occurs in late larval or early pupal stages. RK2.

**I(1)M**

A series of sex-linked recessive lethals induced by ethyl methanesulfonate by Bryant and Zornetzer (1973, Genetics 75: 623-37). They were characterized with respect to lethal stage and survival in gynandromorphs.

mutant	genetic location	lethal stage	Gynandromorphs

**I(1)M41**

location: 1-36.0.

origin: Induced by methyl methanesulfonate.

references: Lim, 1970, DIS 45: 73-74.

other information: Putative spontaneous revertants reported by Lim.

**I(1)Mb and I(1)Mc: lethal (1) Madrid**

A series of 89 ethyl-methanesulfonate-induced sex-linked recessive lethal mutations studied in genetic mosaics, both in gynandromorphs and epidermal clones (Ripoll, 1977, Genetics 86: 357-76). Epidermal phenotypes of subset in which male tissue had distinctive phenotype or in which gynandromorphs failed to survive described following table.

mutant	genetic location	lethal stage	relative viability of gynandromorphs	epidermal clones
<b>I(1)Mb7</b>	1-7	E	0.04	
<b>I(1)Mb8</b>	1-60	E-L	0	lethal

<sup>α</sup> Fails to complement g.

**I(1)Mb7**

phenotype: All bristles transparent, smaller than normal; glassy eyes; arista almost branchless.

**I(1)Mb16**

phenotype: Bristles and trichomes normal. 30% of clones split into several spots of similar size, which together add up in area to the area of control spots. Split clones found only in spots induced more than 48 hr before puparium formation.

**I(1)Mb24**

phenotype: Bristles small and unpigmented; wing trichomes about half normal size. As a consequence of reduced cell size, the area occupied by a clone does not correspond to that expected for its number of cells.

**I(1)Mb28**

phenotype: Bristles of the wing margin small and unpigmented. Clones in the wing blade extremely elongated. Whereas control clones are 5-10 times longer than wide, with irregular borders, clones of cells monozygous for the lethal are 30-50 times longer than wide, with smooth borders. This phenotype found only in clones induced more than 48 hr before puparium formation.

***l(1)Mb38***

**phenotype:** External genitalia do not evaginate when male or mosaic; normal structures remain within the abdomen. Other structures, when male, evaginate normally.

***l(1)Mc1***

**phenotype:** Rounded wings, about one-third shorter than normal. Rough and bulgy eyes.

***l(1)Mc28***

**phenotype:** Bristles smaller than normal. Wing trichomes small; occasionally clones of cells without epidermal processes appear. Behaves as expected for a mutation decreasing mitotic rate.

***l(1)Mc39***

**phenotype:** Very thin bristles, shorter than normal; abdomen almost completely devoid of bristles.

***l(1)Mc51***

**phenotype:** Several (2-6) trichomes per cell in wing disc derivatives. Only 75% of the individual cells show this phenotype.

***l(1)Mc56***

**phenotype:** Wings coiled dorsally.

***l(1)ml: lethal (1) melanomalike***

**location:** 1-10.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, *Heredity* 6: 403-7.

Oster and Sobels, 1956, *Am. Nat.* 90: 55-60.

**phenotype:** Larvae die in third instar. At death, they have internal melanotic masses (usually one or two, sometimes as many as ten). RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, *Genetics* 36: 580).

***\*l(1)mt: lethal (1) midget***

**location:** 1-2.5.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, *Heredity* 6: 403-7.

**phenotype:** Dies as undersized third-instar larva. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, *Genetics* 36: 580).

***l(1)nc: lethal (1) nutritionally conditional***

Three mutants that are lethal on Burnett and Sang's defined casein medium (1963, *J. Insect. Physiol.* 9: 553-62) but can be rescued by addition of yeast extract to the medium.

**origin:** Induced by ethyl methanesulfonate.

**references:** Vyse and Nash, 1969, *Genet. Res.* 13: 281-87. Vyse and Sang, 1971, *Genet. Res.* 18: 117-21.

<sup>α</sup> Associated with *In(1)I625 = In(1)3F;20C*.

<sup>β</sup> Female sterile---probably a rudimentary allele.

***\*l(1)nd: lethal (1) no differentiation***

**location:** 1- (not located).

**origin:** Induced by mustard gas.

**references:** El Shatoury, 1955, *Arch. Entwicklungsmech. Organ.* 147: 523-38 (fig.).

**phenotype:** Some or all imaginal buds fail to differentiate during larval third instar, apparently as a result of abnormal proliferation of imaginal disk mesoderm. Death in pupal or prepupal stage. RK2.

***\*l(1)ne: lethal (1) nonevaginates***

**location:** 1-0.1.

**origin:** Induced by urethane.

**discoverer:** Vogt, 1949.

**references:** 1951, *DIS* 25: 76.

Florschütz-de Waard and Faber, 1952, *DIS* 26: 99.

Faber, Sobels, Florschütz-de Waard, and Oppenoorth, 1954, *Z. Indukt. Abstamm. Vererbungslehre* 86: 293-321 (fig.).

**phenotype:** Lacks imaginal thoracic hypoderm. Cephalic complex and thoracic imaginal disks fail to evaginate. The unaffected abdominal hypoderm develops but ends anteriorly in a free edge that folds back on itself and forms a darkly-pigmented ring around the pupa. Genital disk capable of normal evagination but vasa deferentia do not connect to testes, which do not spiralize. Death occurs 3-5.5 days after prepupal formation. Pupae darker than normal with sticky, irregular surface and distinctly meandering tracheal trunks. RK2.

***\*l(1)nib: lethal (1) no imaginal buds***

**location:** 1- (not located).

**references:** El Shatoury and Waddington, 1957, *J. Embryol. Exp. Morphol.* 5: 143-52 (fig.).

**phenotype:** Dies in third larval instar. Imaginal buds small or absent. Excessive proliferation of stomach epithelium leads to occlusion of gut. Proliferations degenerate into melanotic masses. RK2.

***l(1)P1: lethal (1) of Parkash***

**location:** 1-52.

**origin:** Recovered from thymidine-fed flies.

**references:** Parkash, 1969, *DIS* 44: 51.

**phenotype:** *l(1)P1* males completely lethal when reared at 16° and viable when reared at 26°; lethal period at larval-pupal transition. Homozygous females survive either temperature.

***l(1)P2***

**location:** 1-42.3.

**origin:** Recovered from thymidine-fed flies.

**references:** Parkash, 1971, *DIS* 46: 67.

**phenotype:** Mutant males survive rearing at 16° but not 26°.

***l(1)P3***

**origin:** Recovered from thymidine-fed flies.

**references:** Parkash, 1971, *DIS* 46: 67.

**phenotype:** Mutant males die when reared at 16° but survive rearing at 26° and are sterile.

***\*l(1)rr: lethal (1) ring gland rudimentary***

**location:** 1-0.3.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, *Heredity* 6: 403-7.

**phenotype:** Dies during third larval instar. Larvae live 15-30 days but do not become giant. Ring gland abnormally small, probably causing failure to undergo third molt. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

**\*l(1)S9**

**location:** 1- (to the right of *car*).

**origin:** Spontaneous.

**discoverer:** Auerbach.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 149: 256-66 (fig.).

**phenotype:** Almost all embryos deformed at anterior end, where there is usually some undigested yolk. Death occurs in embryonic, larval, and pupal stages. Primary abnormality is distribution of cleavage nuclei, which causes blastoderm to be fragile at its anterior end. RK2.

**l(1)sc:** see **ASC**

**\*l(1)sd: lethal (1) scheiben defekt**

**location:** 1-17.9.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** M. J. Fahmy.

**references:** Schnitter, 1961, Rev. Suisse Zool. 68: 345-418 (fig.).

**phenotype:** Dies during transition from larva to prepupa. Some larvae form puparia but do not differentiate further. Pattern of damage complex; most severe defects found in certain imaginal disks. Several larval organs abnormal, especially the salivary glands. RK2.

**\*l(1)te: lethal (1) tracheae enlarged.**

**location:** 1-0.3.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, Heredity 6: 403-7.

**phenotype:** Dies during third larval instar. Main tracheal tubes greatly enlarged, sometimes lack functional posterior spiracles. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

**\*l(1)tl: lethal (1) tracheae lacking**

**location:** 1-59.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, Heredity 6: 403-7.

**phenotype:** Dies during first larval instar. Main tracheal tubes absent, although small side branches present. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

**\*l(1)tr: lethal (1) tracheae ramified**

**location:** 1-56.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**references:** Oster, 1952, Heredity 6: 403-7.

**phenotype:** Dies during first larval instar. Main tracheal tubes thick and have numerous side branches. RK2.

**cytology:** Salivary chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

**\*l(1)trs: lethal (1) tracheae stretched**

**location:** 1-8.0.

**origin:** Ultraviolet induced.

**discoverer:** McQuate, 1951.

**synonym:** *l(1)ts* (preoccupied).

**references:** Oster, 1952, Heredity 6: 403-7.

**phenotype:** Dies during first larval instar. Larvae very large for this stage and all tracheal tubes very thin, suggesting that they grow more slowly than larvae and thus become stretched. RK2.

**cytology:** Salivary gland chromosomes normal (Valencia and McQuate, 1951, Genetics 36: 580).

**\*l(1)ts: lethal (1) temperature sensitive**

**location:** 1-8.

**discoverer:** Falbo and Ré.

**references:** 1945, DIS 19: 45, 57.

**phenotype:** Inviabile in cultures grown at 23° but shows more than 50% survival in cultures grown at 26.5°. RK3.

**l(1)ts1**

**location:** 1-1.9.

**origin:** Induced with ethyl methanesulfonate.

**references:** Fausto-Sterling, Wiener, and Digan, 1979, J. Exp. Zool. 200: 199-210.

**phenotype:** Maternal-effect lethal. Homozygous females raised or aged at 28° produce embryos that fail to develop (incomplete dorsal closure, abnormal midgut formation) regardless of zygotic genotype. Females raised at 18° produce viable embryos. Viable embryos placed at 28° die as late pupae and are insensitive to maternal genotype. TSP for maternal effect after stage 7 of oogenesis; pupal TSP lasts 2.5 days.

**l(1)ts**

Lethals recovered as temperature-sensitive alleles by workers in several different laboratories. Some are mapped, and most have been scored for survival in patches of homozygous cuticular tissue. In general complementation tests among these lethals or between these lethals and other X-linked lethal mutations were not carried out. These names are transitional and likely to be changed if any of the mutants is further characterized.

Biol. 178: 247-75; 8 = Simpson and Schneiderman, 1976, Wilhelm Roux's Arch. Dev. Biol. 179: 215-36; 9 = Woodruff and Gander, 1974, Mut. Res. 25: 337-45.

$\beta$  t.s. indicates that the incidence of X-ray-induced *sn* clones in *y/l(1)ts sn* females compared to the recovery of *y* clones (Arking) or of *y* clones in *y/l(1)ts/sn* females compared to the recovery of *sn* clones (Russell) is significantly lower in flies raised at 29° than in those raised at 22°; non t.s. indicates no significant difference.

$\gamma$  Survivors at permissive temperature are female sterile.  
 $\delta$  Phenotypes described more fully below.  
 $\epsilon$  *l(1)ts120* and *l(1)1891* not allelic.  
 $\zeta$  *l(1)ts613* and *l(1)1082* not allelic.  
 $\eta$  See *su(f)*.  
 $\theta$  Survivors male sterile.  
 $\iota$  Cold sensitive.

### *l(1)ts66*

**phenotype:** Selected as a temperature-sensitive lethal in the presence of theophylline; hypersensitive to theophylline at 29°, but not at 25°. Mutant males contain lower levels of cyclic nucleotide phosphodiesterase than wild type and normal levels of adenylyl cyclase. Exhibit increased motor activity at 29°; movements uncoordinated; flight and both phototaxis and geotaxis impaired. Unable to learn (Savvateeva and Kamyshev, 1981, Pharmacol. Biochem. Behav. 14: 603-11; Savvateeva, Pereslenny, Ivanushina, and Korochkin, 1985, Dev. Genet. 5: 157-72).

### *l(1)ts504*

**phenotype:** Temperature-sensitive pupal lethal. Heat pulses of one-to-three days duration applied during larval stages delay pupariation and cause duplications and deficiencies of imaginal structures in surviving adults. Similarly, rarely surviving gynandromorphs exhibit duplicated and missing structures; heterozygous females from the same cross that are malformed interpreted as cryptic gynandromorphs in which the male tissue has died. Epidermal clones of homozygous tissue very reduced in number and size in the head and thorax, but do not differ from controls in the abdomen (Simpson and Schneiderman, 1975, Wilhelm Roux's Arch. Dev. Biol. 178: 247-75).

### *l(1)ts1126*

**phenotype:** Temperature-sensitive, cell-autonomous lethal mutant. Exposure of first- and second-instar larvae to 29° retards growth and delays pupariation, but adults eventually formed are normal. Exposure of third-instar larvae to 29° does not delay pupariation, but results in the production of smaller-than-normal flies. Late third-instar pulses cause delayed eclosion, and absence of the black pigment band as well as reduced bristle number and size in the tergites of survivors. Homozygous clones substantially reduced in size in the wing by heat pulses during early instars and in tergites by pulses at the end of the larval stage. In gynandromorphs that pupate at normal times *l(1)ts1126/0* compartments are smaller than normal; in gynandromorphs exhibiting delayed development, compartment sizes are normal [Simpson and Morata, 1980, Developmental Neurobiology of Drosophila (Siddiqi, Babu, Hall, and Hall, eds.), Plenum Press, New York and London, pp. 129-39]. All effects explained by a reduced rate of cell division in mutant cells (Simpson and Schneiderman, 1976, Wilhelm Roux's Arch. Dev. Biol. 179: 215-36).

### *l(1)ts1251*

**phenotype:** A temperature-sensitive cell lethal; also a temperature-sensitive male sterile mutation. Larvae subjected to 29° during the latter part of the third larval instar produce pharate adults that display duplicated or missing structures or both typically resulting from cell death. Some 5% also exhibit transformation of the humeral disc into a heterotypic structure consisting proxi-

mally of foreleg tissue (coxa through first tarsal segments on basis of chaetotaxy) and distally of antennal tissue, *i.e.*, arista (Arking, 1978, Genetics 88: s4-5).

**\*l(1)TS-45: lethal (1) no. 45 of T. Shiom**

**location:** 1-5.8.

**origin:** X ray induced.

**discoverer:** Shiom, 52f.

**references:** 1954, DIS 28: 78.

Imaizumi and Shiom, 1955, Arch. Biol. (Liège) 66: 483-87.

**phenotype:** Dies before hatching. No visible morphological abnormality. Heterozygote of *l(1)TS-45/Basc* has average of 612 eye facets compared to only 402 in *+Basc*. Accumulation of urea or carbamides in larvae of heterozygote; these compounds presumably tend to normalize the Bar phenotype. RK2.

**\*l(1)TS-56**

**location:** 1-1.5.

**origin:** X ray induced.

**discoverer:** Shiom, 52f.

**references:** 1954, DIS 28: 78.

**phenotype:** Lethal in late embryonic stage. Development of tracheae, other chitinized parts, and body segments abnormal. RK2.

**l(1)TW: lethal (1) of Ted Wright**

A series of six ethyl-methanesulfonate-induced mutants that have reduced survival when raised at 17° compared with that when raised at 25°; the differences in survival at the two temperatures vary substantially among replicate crosses.

locus	genetic location	synonym	lethal stage	comments
<i>l(1)TW1</i>	1-26.3		L	female sterile at 16°, few eggs
<i>l(1)TW2</i>	1-41.8	<i>sno</i>		
<i>l(1)TW3</i>	1-2.5		P	females fertile; ether sensitive
<i>l(1)TW4</i>	1-48.4		LP	females fertile; metathoracic legs abnormal
<i>l(1)TW5</i>	1-63.8	<i>l(1)carot14</i>	LP	females sterile; abnormal abdomen, indented wings at 16°
<i>l(1)TW6</i>	1-37.1	<i>nod<sup>8</sup></i>	E	females sterile at 16°, meiotic nondisjunction

**l(1)v: lethal (1) variegated**

**origin:** X ray induced.

**references:** Lindsley, Edington, and Von Halle, 1960, Genetics 45: 1649-70.

**phenotype:** A series of sex-linked recessive lethals that die as *XO* males but survive as *XY* males and homozygous females. All are associated with chromosome rearrangements with one breakpoint in the X chromosome and one in pericentric heterochromatin, of either the X or an autosome; interpreted as position-effect variegation of vital loci. In some cases the viability of *XY* males is further reduced by the known enhancers of variegation,

*Df(2R)M41A10* and *Evar7*. The lethals associated with reciprocal translocations are male sterile, owing to a failure of sperm head elongation.

<sup>α</sup> Homozygous females have blistered wings and duplicated anterior scutellar and postalar bristles.

<sup>β</sup> *XY* males have *gg*-like phenotype but with peripheral darkening of eye color. Associated with insertion of an unspecified segment of heterochromatin into 8F-9B; linkage tests suggest chromosome-2 origin.

<sup>γ</sup> Homozygous females survive and have fewer and smaller bristles.

<sup>δ</sup> *XYX* males viable and fertile; show strong variegation for *w* and *rst*. Recombinant carrying the left end of the *X<sup>P</sup>4<sup>D</sup>* element to *T(1;4)w<sup>ms</sup>* and the right end of *ln(1LR)-v139* is variegated for *w* but not for *rst* and is male viable.

<sup>ε</sup> Viability of *XXY>XX*; homozygous females frequently lacking dorso-central bristles.

<sup>ζ</sup> Variegates for absence of external genitalia.

<sup>η</sup> Surviving *XO* males have rough reduced eyes.

<sup>θ</sup> Variegates for *w*.

<sup>ι</sup> *XY* males have rough eyes and deformed wings and wing veins.

**\*l(1)w**

**location:** 1-66.

**discoverer:** Schubel, 1934.

**references:** 1934, Am. Nat. 68: 278-82.

**phenotype:** Males survive; homozygous females die. RK3.

**other information:** Probably a lethal allele of *bb*.

**\*l(1)X2: lethal (1) X ray induced**

**location:** 1- (near forked).

**origin:** X ray induced.

**discoverer:** Auerbach.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 148: 437-51 (fig.).

**phenotype:** Embryos die in advanced stage of development. They live beyond normal hatching time, move actively, but do not hatch. Embryo distorted; head material not involuted and pharyngeal material external; body wall has disarranged segmentation in medial region. Mutant disrupts mechanism controlling mitosis in early

stages of gastrulation, occasionally as early as blastoderm formation. RK2.

**cytology:** Salivary chromosomes normal.

### \*I(1)X10

**location:** 1-0.0 (near *sc*).

**origin:** X ray induced.

**discoverer:** Auerbach.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 149: 247-58 (fig.).

**phenotype:** Variation in expression of factors discontinuous. There are three types of lethal embryos; some may survive into larval stage. Type 1 stops development after formation of a cap of undifferentiated cells. Type 2 has limited differentiation, often the nervous tissue exclusively, but no organ formation. Type 3 survives beyond normal hatching time, has no gross abnormalities, but does not hatch. RK2.

### \*I(1)X20

**location:** 1- (near *sc*).

**origin:** X ray induced.

**discoverer:** Auerbach.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 149: 101-14 (fig.).

**phenotype:** Four types of defective embryos produced. Types 1 and 2 reach late stage of development and are alive at time larvae normally hatch. Type 1 has a complete nervous system but incomplete hypoderm. Type 2 has hypoderm but a deficient nervous system. Types 3 and 4 stop developing at early stages. Type 3 has no development beyond gastrulation, and type 4 forms no blastoderm. RK2.

### \*I(1)X27

**location:** 1-63.4.

**origin:** X ray induced.

**discoverer:** Auerbach.

**references:** Ede, 1956, Arch. Entwicklungsmech. Organ. 149: 88-100 (fig.).

**phenotype:** Embryos alive in a late stage of development at normal hatching time but do not hatch. Degeneration begins at about 25 hr. Germ band irregular at beginning of gastrulation, apparently the result of defective ventral furrow formation. Consequently, hindgut is open dorsally, nervous system irregularly developed, and ventral nerve cord interrupted in region of midgut. Other abnormalities from different causes are: (1) gut remains sac-like, (2) ectoderm remains unsegmented, and (3) musculature of body wall is underdeveloped. RK2.

### I(1)Y

A series of sex-linked recessive lethals induced by ethyl methanesulfonate by Bryant and Zornetzer (1973, Genetics 75: 623-37). They were characterized with respect to lethal stage and survival in gynandromorphs.

mutant	lethal stage	Gynandromorphs		
		relative survival (%)	amount of male tissue (%)	phenotype of male tissue
<i>I(1)Y8</i>	L1	0		
<i>I(1)Y12</i>	E	3	12	wings incompletely expanded
<i>I(1)Y80</i>	E	20	21	+
<i>I(1)Y107</i>	L1	2	15	abnormal bristles
<i>I(1)Y110</i>	LP	6	17	degenerated ommatidia

The following table refers to a number of series of sex-linked-lethal mutations induced or spontaneous, many of which were mapped genetically, and some of which were analysed cytologically. Virtually all have long since been discarded; they are cited here for completeness of the record (see also CP627).

**I(2)24EF**

A series of mutants recovered by virtue of their lethal phenotype in combination with *Df(2L)M24F* by Roy, Manna, and Duttagupta (1984, J. Biosci. 6: 87-95). Not tested against alleles recovered by Szidonya and Reuter. Deficiencies inferred by failure to complement more than a single complementation group not detected cytologically. The order of loci *a*, *b*, *c*, and *d* with respect to each other, but not their polarity, inferred from these deficiencies; the order of the remaining loci with respect to both *a* through *d* and each other unknown. Despite the presence of *dw-24E* and *dp* in region monitored, the authors report recovery of no visible mutations.

<sup>α</sup> Search of Szidonya and Reuter (1988, Genet. Res. 51: 197-208).  
<sup>β</sup> Search of Roy, Manna, and Duttgupta (1984, J. Biosci. 6: 87-95).  
 Variants common to the two searches occupy the same lines in the table.

***l(2)25***

The entire region screened extensively for lethal mutations by Szidonya and Reuter (1988, Genet. Res. 51: 197-208). In addition, the region deleted by *Df(2L)GpdhA*, which is deficient for 25E through 26A has yielded seventeen lethally mutable loci in the region (Kotarski, Pickert, and MacIntyre, 1983, Genetics 105: 371-86). Complementation tests have not been carried out between mutations isolated in the two screens.

***l(2)25A & B***

Nine lethally mutable loci, the most distal of which is *slf*.

**l(2)25Ca**

**location:** 2-15}.

**origin:** Induced by ethyl methanesulfonate; selected as dominant temperature-sensitive, dominant cold-sensitive lethal, or recessive lethal mutations.

**references:** Suzuki and Procnier, 1969, Proc. Nat. Acad. Sci. USA 62: 369-76.

Rosenbluth, Ezell, and Suzuki, 1972, Genetics 70: 75-86.

Szidonya and Reuter, 1988, Genet. Res. 51: 197-208.

**phenotype:** Heterozygotes for dominant temperature-sensitive alleles lethal or nearly so when raised at 29° but survive at 25°; +/- heterozygotes survive development at 29°. Heterozygotes for dominant cold-sensitive alleles lethal or nearly so when raised at 17° but survive at 22°; adults insensitive to 17°. Heat-sensitive period 18-24 hr after ovoposition; lethal phase varies, but most frequently at 75-90 hr for heat-sensitive alleles and late in development, but highly variable for cold-sensitive alleles. Heterozygotes for alleles selected as recessive lethals are mostly not dominant temperature-sensitives.

<sup>α</sup> 1 = Rosenbluth, Ezell, and Suzuki, 1972, Genetics 70: 75-86; 2 = Suzuki and Procnier, 1969, Proc. Nat. Acad. Sci. USA 62: 369-76; 3 = Szidonya and Reuter, 1988, Genet. Res. 51: 197-208.

**other information:** Interallelic complementation of heat-sensitive alleles observed at 25°; complementation map circular with a tail. Circular complementation map also observed for cold-sensitive alleles at 22°. Cold-sensitive alleles fail to complement heat-sensitive allele **l(2)25Ca<sup>3</sup>**. Alleles selected as recessive lethals form a linear complementation map with dominant heat-sensitive alleles (Szidonya and Reuter, 1988).

**l(2)25E**

Seven lethally mutable loci including midline (*mid*). Isolated in a saturation study of the region uncovered by *Df(2L)GpdhA* by Kotarski, Pickert, and MacIntyre (1983, Genetics 105: 371-86). The mutation study of Szidonya and Reuter (1988, Genet. Res. 51: 197-208) also extends into the region. The deficiency maps from the two studies are highly concordant; however, there have been no complementation crosses between mutants from the two studies. Although each study groups six loci together as **l(2)25Ea** to **l(2)25Ef**, there is no reason to believe that they have been designated in the same order; nevertheless, we have designated them *Ea* and *Ea*, *Eb* and *Eb*, etc. with the understanding that complementation tests are required in order to establish that the primed and nonprimed alleles are in fact allelic.

**I(2)35Ba**

**phenotype:** *l(2)35Ba<sup>1</sup>* may escape in combination with deficiency for the locus; escapers are weak elbow in phenotype if deficiency includes *el*, but not if it does not. All alleles express weak elbow in combination with *el<sup>1</sup>*; heteroallelic escapers [*i.e.*, *l(2)35Ba<sup>4</sup>* in combination with other alleles] are weak elbow. Semilethal with *In(2LR)Sco<sup>rv1</sup>* and *Sco<sup>rv27</sup>*; also show weak *noc* phenotype in combination with strong *noc* alleles.

$\alpha$  Origin of coordinates at *EcoRI* site 5' to *Adh*; coordinates are negative in the direction of the telomere and positive in the direction of the centromere (McGill, Chia, Karp, and Ashburner, 1988, Genetics 119: 647-61) and are not necessarily correlated with cytological breakpoints.

**I(2)36**

references: Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78.

**I(2)36A**

Five lethally mutable loci, including *Mhc*; map order not determined.

<sup>β</sup> Breakpoint not localized with respect to neighboring lethal mutations.

***l(2)37***

More than eighty lethal alleles at 37 loci, including *Dox-A2*, *Amd*, and *Ddc*, in the region uncovered by *Df(2L)TW50 = Df(2L)36E4-F2;38A6-7* recovered and deficiency mapped by Wright, Bewley and Sherald (1976, Genetics 84: 287-310). Detailed analysis of those under *Df(2L)TW130 = Df(2L)37B9-C1;37D1-2* presented in other work involving 204 mutants (Wright, Beerman, Marsh, Bishop, Steward, Black, Tomsett, and Wright, 1981, Chromosoma 83: 45-58). Additional mutants in more proximal part of region 37 recovered and analyzed by Gay and Contamine. Allelic information for this region are as yet incomplete.

***l(2)37A***

Three complementation groups represented by one ethyl-methanesulfonate-induced allele each; recovered by Wright and coworkers (Wright, Bewley, and Sherald, 1976, Genetics 84: 287-310).

### *l(2)37Ca*

**phenotype:** *l(2)37Ca*<sup>ts1</sup>/*Df(2L)TW130* eclosed adults at 25° have incompletely sclerotized thoracic cuticle, which deforms when the indirect flight muscles contract; wings rarely completely expanded. X-ray-induced abdominal clones hemizygous for the amorphic allele *l(2)37Ca*<sup>4</sup>, produce bristles one-third wild-type size.

***l(2)37Cf***

**phenotype:** Lethality occurs as pharate adults. Third-instar larvae of 13 of 14 alleles examined display enlarged brains—up to eight times normal volume; greatest in presumptive optic center (Hankins and Wright). Brain fragments transplanted into normal adults show uncontrolled proliferation and metastatic invasion of other tissues (Gateff). Escapers [*l(2)37Cf*<sup>1</sup>-/*l(2)37Cf*<sup>ts3</sup>] lethargic and sterile in both sexes [Wright, 1987, Results and Problems in Cell Differentiation (W. Hennig, ed.). Springer-Verlag, Berlin, Heidelberg, pp. 95-120]. Homozygous females [*l(2)37Cf*<sup>ts2</sup>] retain eggs in ovaries (Schüpbach).

***l(2)37D-E***

Eleven lethally mutable loci identified, ten in 37D and one in 37E. In addition to the alleles identified below, Wright, Bewley, and Sherald (1976, Genetics 84: 287-310) report seven mutants between the right break of *Df(2L)TW130* and the left break of *Df(2L)TW2* (designated *E27*, *E29*, *E56*, *E107*, *E137*, *E142M*, and *E151*) plus four between the left breakpoint of *Df(2L)TW2* and the right breakpoint of *Df(2L)TW158* (designated *E12*, *E34*, *E68*, and *E144M*) that were not tested for complementation.

<sup>α</sup> Coordinates of restriction fragments containing the genes and breakpoints in question; 0 is the axis of symmetry of the *HpaI* site near the terminus of the *Ddc* coding sequence. The origin of this set of coordinates is approximately 950 base pairs to the left of that used by Hersh and Wright, and their coordinates have been adjusted accordingly.

<sup>β</sup> Breakpoint not localized with respect to neighboring lethal mutations.

<sup>γ</sup> TU = transcription unit.

**I(2)39a**

**location:** 2-50 (right of *BI* ?).

**origin:** Spontaneous.

**discoverer:** Curry, 39a.

**references:** 1939, DIS 12: 45.

**I(2)40F**

Twenty-eight ethyl-methanesulfonate-induced recessive lethal mutations that are not complemented by *Df(2L)C'*, which is thought to delete only 2L heterochromatin (Hilliker, 1976, Genetics 83: 765-82). All seven loci are localized to heterochromatic segment h35 (Pimpinelli).

***I(2)41A***

A series of 85 ethyl-methanesulfonate-induced recessive lethal mutations comprising seven complementation groups, including *rl*, *uex*, and *M(2)41A*, detected by virtue of their inability to complement *Df(2R)M41A* and other deficiencies for the proximal heterochromatin of 2R. All mutants occupy but a single complementation group, and no mutant alleles of *M(2)41A*, which lies in the region, were recovered (Hilliker, 1976, Genetics 83: 765-82).

<b><i>I(2)41Ab</i><sup>4</sup></b>	<i>I(2)EMS45-91</i>

***I(2)41Ae***

**phenotype:** Heterozygotes not Minute. Complementation map shaped like a figure eight and highly complex. Four heteroallelic combinations exhibit partial complementa-

tion: *l(2)41Ae*<sup>10</sup>/*l(2)41Ae*<sup>15</sup> shows 17% survival, *l(2)41Ae*<sup>10</sup>/*l(2)41Ae*<sup>19</sup> 8% survival, *l(2)41Ae*<sup>9</sup>/*l(2)41Ae*<sup>28</sup> 10% survival, and *l(2)41Ae*<sup>21</sup>/*l(2)41Ae*<sup>28</sup> 21% viability. The remaining combinations exhibit non-complementation or complete complementation. In spite of the fact that among alleles *l(2)41Ae*<sup>35</sup> to *l(2)41Ae*<sup>40</sup>, there is only one noncomplementing pair of alleles, *l(2)41Ae*<sup>35</sup> and *l(2)41Ae*<sup>36</sup>, these mutants are designated alleles of *l(2)41Ae* on the basis of their inclusion in *Df(2R)M41A-4*, *Df(2R)M41A-8*, *Df(2R)M41A-10*, and *Df(2R)M41A-50j* and the extensive complementation characteristic of *l(2)41Ae* alleles.

***l(2)41Af***

A single mutation that deficiency maps to the same region as *M(2)41A* and *l(2)41Ae*, but complements all alleles of the latter, and exhibits no Minute phenotype.

allele	synonym
<b><i>l(2)41Af1</i></b>	<i>l(2)EMS4--72</i>

***l(2)41Ah***

Located very close to the heterochromatic-euchromatic junction of 2R. Complementation map circular, with the majority of mutants falling into a single complementation group that is complemented by only three of the thirty alleles. *l(2)41Ah*<sup>8</sup>/*l(2)41Ah*<sup>12</sup> survives and has wings uniformly spread from the body at a 45° angle; *l(2)41Ah*<sup>3</sup>/*l(2)41Ah*<sup>12</sup> survivors have in addition misshapen, unpigmented or absent ocelli. *l(2)41Ah*<sup>31</sup> to *l(2)41Ah*<sup>34</sup> not tested against the remaining alleles; designated alleles because they are mutually noncomplementing, and they are included in *Df(2R)M41A-4*, *Df(2R)M41A-8*, and *Df(2R)M41A-10*, but not *Df(2R)M41A-50j*.

***l(2)52***

Nine lethally mutable complementation groups identified in the region uncovered by *Df(2R)WMG* = *Df(2R)52A2-B4;52D7-E1* and one in the region uncovered by *Df(2R)KL32* = *Df(2R)52C5-D1;52E2-5*,

but not by *Df(2R)WMG*. Two additional complementation groups inferred from the lethality of overlapping deficiencies. Eight of the nine uncovered by *Df(2R)WMG* were also uncovered by *Df(2R)XTE18* = *Df(2R)51E3-4;52C9-D1*, and were not further studied (Davis and MacIntyre, 1988, Genetics 120: 755-66).

***l(2)52ACa-l(2)52ACh***

Eight complementation groups identified but not further characterized.

***l(2)52Da***

**location:** 2-{75}.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** Group 1.

**alleles:** Nine.

**cytology:** Placed in 52D3 based on its inclusion in *Df(2R)KL9* = *Df(2R)52D3;53D7-9* but not *Df(2R)KL69* = *Df(2R)52D2-3;52D9-E1*.

***l(2)52Db***

**location:** 2-{75}.

**alleles:** None recovered.

**cytology:** Inferred to be in 52D7-9 based on the inviability of the heterozygote between *Df(2R)KL9* = *Df(2R)52D3;-53D7-9* and *Df(2R)KL69* = *Df(2R)52D3;52D9-E1* but not of that between *Df(2R)KL9* and *Df(2R)WMG* = *Df(2R)52A4-B2;53D7-E1*.

***l(2)52Dc***

**location:** 2-{75}.

**alleles:** None recovered.

**cytology:** Inferred to be in 52D6-E1 based on the inviability of the heterozygote between *Df(2R)l30* = *Df(2R)52D6-7;52E1* and *Df(2R)KL69* = *Df(2R)52D3;-52D9-E1*.

***l(2)52Ea***

**location:** 2-{75}.

**origin:** Induced by ethyl methanesulfonate.

**alleles:** Two.

**cytology:** Placed in 52D9-E5 based on its inclusion in *Df(2R)KL32* = *Df(2R)52C5-D1;52E2-5* but not *Df(2R)KL69* = *Df(2R)52D3;52D9-E1*.

### l(2)54

**location:** 2-41 (not separated from *J*: 2-41.0).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Sandler, 1976.

**references:** 1977, Genetics 86: 567-82.

**phenotype:** Recessive lethal.

**cytology:** Located to 31B-F based on its inclusion in *Df(2L)J-der-27 = Df(2L)31B-D;31F*.

**other information:** Not allelic to *da* or *mfs(2)48*.

### l(2)55i

**location:** 2-55.0 (probably to the left of the centromere).

**origin:** Spontaneous.

**discoverer:** Burdick, 55i.

**references:** 1956, DIS 30: 69.

Mukai and Burdick, 1959, Genetics 44: 211-32.

1960, Genetics 45: 1581-93.

Schnick, Mukai, and Burdick, 1960, Genetics 45: 315-29.

Mukai and Burdick, 1961, Japan J. Genetics 36: 97-104.

**phenotype:** Larvae hatch but die before pupation. Females heterozygous for *l(1)55i* have higher fecundity than homozygous, wild-type females. The lethal is therefore not eliminated from laboratory populations. RK3.

### l(2)56a

**location:** 2-90.

**origin:** Spontaneous.

**discoverer:** Burdick, 56a.

**references:** 1956, DIS 30: 69.

**phenotype:** Homozygous lethal; heterozygote shows normal viability. RK3.

**other information:** Crossing over normal.

### l(2)56F

A series of mostly recessive lethals recovered based on their lethality in combination with *Df(2R)l73* (cytology normal) and *Df(2R)017 = Df(2R)56F5;56F15* [Shellenbarger and Duttgupta, 1978, Mutat. Res. 52: 395-407; Duttgupta and Shellenbarger, 1980, Development and Neurobiology of Drosophila (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 25-33]. Four complementation groups within *Df(2R)017* but not *Df(2R)l73* (not further described) plus five sites uncovered by both deficiencies, which are separable by complementation analysis, but arbitrarily considered to represent three gene loci, two of which have complementing alleles, and the third of which interacts in *trans*

with the other two. Except for the fact that *l(2)56Fa* maps to the left of *M(2)56F* and the inference that *l(2)56Fb* lies between them, nothing known of order of loci.

locus	genetic location		cytological location		included in	excluded from	synonym

<b>l(2)56Fg</b>	2-92.3	56F5-15	<i>Df(2R)017</i>	<i>Df(2R)l73</i>			

### l(2)56Fa

**phenotype:** Recessive lethal; no phenotype in heterozygote, except when heterozygous to *l(2)56Fb* in which case short thin bristles are observed.

**alleles:** Nine alleles, two complementing and seven non-complementing. Shown to map to the left of *M(2)56F* by recombination.

### l(2)56Fb

**location:** Position between *l(2)56Fa* and *M(2)56F* provisional; based on interactions with mutants at both loci.

**synonym:** *l(2)l2*.

**phenotype:** A single allele, which is lethal in homozygotes but produces an extreme Minute, semilethal phenotype in trans heterozygotes with *Df(2R)017* and *Df(2R)l73*. Complements all other *l(2)56F* mutants for viability; interacts with the the noncomplementing alleles of *l(2)56Fa* and *M(2)56F* to produce a Minute-like phenotype in the case of *l(2)56Fa* and an enhanced Minute phenotype in combination with *M(2)56F*. Trans heterozygotes of *l(2)56Fb* with the complementing alleles of the other two loci are wild type.

### \*l(2)57

**origin:** Spontaneous.

**discoverer:** Paik.

**references:** 1960, Evolution 14: 293-303.

**other information:** A series of 11 lethals selected from Korean wild populations.

### l(2)57

Two lethal-saturation studies carried out in the region; tests against *Df(2R)D17 = Df(2R)57B5;58B1-2* or against smaller deficiencies including *Pu* and *tud* in 57C were carried out by O'Donnell, Boswell, Reynolds, and Mackay, (1989, Genetics 121: 273-80); they recovered 76 lethal mutations identifying sixteen complementation groups between 57B17 and 57F6; in addition, there were fourteen mutations outside this region, but still uncovered by *Df(2R)D17*. The second study by Schejter and Shilo (1989, Cell 56: 1093-1104) identified eight complemen-

tation groups among sixteen lethal mutations uncovered by *Df(2R)PK1 = Df(2R)57C5,57F6*, the region containing *Egfr*. Few complementation crosses were carried out between mutations from the two screens.

**I(2)57CD**

Three complementation groups were identified by Schejter and Shilo in 57C5-D9, the region of overlap between *Df(2R)PK1* and *Df(2R)PI12*; O'Donnell *et al.* identified five complementation groups in the same region, and no complementation tests have been carried out. Until they are, these mutations are considered independently of those of O'Donnell *et al.*

**I(2)64**

**location:** 2-70.

**origin:** X ray induced.

**references:** Ytterborn, 1967, Hereditas 58: 165-90.

**phenotype:** Homozygous lethal. Allele frequency maintained in experimental populations in higher-than-expected frequencies; this "overdominance" effect lost in later generations (Ytterborn, 1968, Hereditas 60: 33-71).

**cytology:** Polytene configuration normal.

**I(2)74I**

**location:** 2R.

**origin:** Spontaneous.

**references:** Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85.

**I(2)85**

**location:** 2-54.8.

**origin:** X ray induced.

**references:** Ytterborn, 1967, Hereditas 58: 165-90.

**phenotype:** Homozygous lethal; eliminated from experimental populations less rapidly than expected.

**cytology:** No aberrations observed.

**\*I(2)1076**

**location:** 2-15 (about 40 units from *Bl*).

**origin:** Spontaneous.

**discoverer:** Ives, 49h.

**references:** 1951, DIS 25: 70.

**phenotype:** Lethal homozygous and in combination with *In(2L)Cy*. RK3.

**\*I(2)1323**

**location:** 2-55 (0/162 crossovers with *Bl*).

**origin:** Spontaneous.

**discoverer:** Ives, 51g.

**references:** 1951, DIS 25: 70.

**phenotype:** Lethal homozygous and in combination with *In(2L)Cy* + *In(2R)Cy*. RK3.

**l(2)1542**

**location:** 2-unmapped.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Gateff, 1978, *Biol. Rev.* 53: 123-68.  
 1978, *Science*, 200: 1448-59.  
**phenotype:** Causes malignant neuroblastoma of the adult neuroblasts and ganglion mother cells; also displays intermediate imaginal disc neoplasm with compact mode of growth.

**l(2)a**

**location:** 2-64.7.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 16a15.  
**references:** Bridges and Morgan, 1919, *Carnegie Inst. Washington Publ. No. 278*: 286, 302.  
**phenotype:** Almost completely lethal; body color of rare survivor pale. RK3.

**l(2)ax**

**location:** 2-106.9.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 19b28.  
**references:** 1937, *Cytologia (Tokyo)*, Fujii Jub., Vol. 2: 745-55.  
**phenotype:** Lethal in very early larval stage. RK3.  
**cytology:** Located in 60B on salivary chromosome by Bridges but not included in *Df(2R)Px = Df(2R)60B8-10;60D1-2*.

**l(2)ay**

**location:** 2-8.3.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 30d5.

**l(2)B**

**location:** 2- [in 2L of *In(2L)t*].  
**discoverer:** Bridges, 1930.

**l(2)bl: lethal (2) bluter**

**location:** 2-43.8.  
**origin:** X ray induced.  
**discoverer:** Käfer, 50b.  
**references:** Benz, 1953, *DIS* 27: 55.  
 1957, *Z. Indukt. Abstamm. Vererbungsl.* 88: 78-114 (fig.).  
**phenotype:** Lethal at end of pupal stage. Homozygotes make emerging movements, but puparia have abnormally thick protein layer so that imaginal hypodermis is punctured in attempt to eclose. Hemolymph is lost, and flies die. Apparently-normal homozygotes may be obtained by artificially opening puparium. Occasionally, a fly spontaneously escapes puparium without serious injury. Differences in content of free amino acids and peptides between *l(2)bl* and wild type can be distinguished in third-instar larvae, prepupae, and early pupae. RK3.

*l(2)Bld*: see *l(2)36Da*

**l(2)bw: lethal (2) with brown**

**location:** 2-104.  
**origin:** Spontaneous in *bw<sup>2b</sup>mr* chromosome.  
**discoverer:** Curry, 36i.  
**cytology:** Salivary chromosomes seem to show slight deficiency or disturbance in 59C and D (Bridges).

*l(2)C*: see *l(2)49Dc*

**l(2)CA6**

**location:** 2-distal to *Df(2L)64j*.  
**synonym:** *l(1)br6*.  
**references:** Woodruff and Ashburner, 1979, *Genetics* 92: 133-49.  
**alleles:** Three ethyl-methanesulfonate-induced alleles (*SF3*, *SF24*, *SF27*).

**l(2)cg: lethal (2) with comb gap**

**location:** 2-15 (between *dp* and *cl*).  
**origin:** Spontaneous.  
**discoverer:** Nichols-Skoog, 33d19.  
**references:** Curry, 1939, *DIS* 12: 46.

### ***l(2)gd1: lethal (2) giant discs***

**location:** 2-47.7.

**origin:** Spontaneous.

**references:** Bryant, 1969, *DIS* 44: 47.

Bryant and Schubiger, 1971, *Dev. Biol.* 24: 233-63.

**phenotype:** Pupariation delayed, up to nine days in crowded cultures; pupariation is but one day in uncrowded cultures. Discs continue to grow, becoming very large with long delays. Mutant discs transplanted into normal larval hosts metamorphose; cuticular patterns normal but bristles and to a greater degree sensillae and bracts missing; unguis missing from tarsal claws; tarsi two jointed. Mutant discs yield low incidence of trans-determination.

**cytology:** Chromosomes normal (Ashburner).

### ***l(2)gd2***

**location:** 2-10.4 (Jürgens).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(2)gd-l*.

**references:** Gateff, 1977, *DIS* 52: 4.

**phenotype:** Lethal shortly after pupation; imaginal discs two to four times normal size. Usually display abnormal shapes and folding patterns; occasionally appear normal. Metamorphosed fragments in normal larval hosts exhibit hair patterns; occasional single bristles seen; often only naked cuticle forms.

### ***l(2)gl: lethal (2) giant larvae***

**location:** 2-0.0.

**synonym:** *lgl*.

**references:** Hadorn, 1937, *Proc. Soc. Exp. Biol. Med.*

36: 632-34.

1937, *Proc. Nat. Acad. Sci. USA* 23: 478-84.

1938, *Rev. Suisse Zool.* 45: 425-29.

Vogt, 1947, *Z. Naturforsch* 26: 292-94.

Gateff and Schneiderman, 1974, *Wilhelm Roux's Arch. Dev. Biol.* 176: 23-65.

Gateff, 1978, *Biol. Rev. Cambridge Phil. Soc.* 53: 123-68.

Mechler, McGinnis, and Gehring, 1985, *EMBO J.* 4: 1551-57.

**phenotype:** Homozygotes undergo embryogenesis and the first three larval instars; larvae reach normal maximum size; then for some alleles most homozygotes fail to pupate, becoming bloated and 1.5-2 times normal size, whereas for others the majority form prepupae but fail to progress into morphogenesis. Ring gland small and appears immature in third-instar larvae (Scharrer and Hadorn, 1938, *Proc. Nat. Acad. Sci. USA* 24: 236-42); third-instar *l(2)gl* larvae implanted with a normal ring gland pupate but do not metamorphose; injection of ecdysone elicits the same result (Karlson and Hanser, 1952, *Z. Naturforsch* 76: 80-83); thus a deficiency of hormones from the ring gland is probably one, but not the only, result of *l(2)gl*. Homozygotes that die as prepupae have underdeveloped corpora allata and prothoracic glands, whereas larval lethals have underdeveloped prothoracic glands but normal corpora allata (Korochkina and Nazarova, 1977, *Chromosoma* 62: 175-90). Prothoracic glands contain approximately 1% the normal quantity of smooth endoplasmic reticulum (Aggarwal and King, 1969, *J. Morph.* 129: 171-99). Alleles range from 98% larval and 2% pupal death to 18% larval and 82% pupal death (Gateff, Golubovsky, and Sokolova, 1977, *DIS* 52: 128-29). In the most extreme phenotypes (+++), the larval brain and optic lobes become enlarged and disorganized and the imaginal discs large and clumped; when discs of such larvae are transplanted into wild-type-female abdomens, they form large contained tumors, whereas transplanted optic primordia from larval brains form invasive neuroblastomas, which grow rapidly, killing the host within 7-14 days; they can be serially cultured in adult abdomens (Gateff and Schneiderman, 1974). These observations have led to *l(2)gl*'s being designated a *Drosophila* oncogene. Intermediate alleles (++) exhibit moderately enlarged brain and discs, which show enhanced growth when transplanted into wild-type females and death of host is delayed. In weak alleles (+) the brain and discs are small and rudimentary and grow slowly in transplants. One allele normal in disc morphology and behavior in transplants (-). The lethal phase is not well correlated with the phenotypic expression.

Most abundant transcription noted in early (0-6 h) embryos and late third-instar larvae, with the smaller transcript more abundant in embryos and the larger in larvae (Mechler, McGinnis, and Gehring). Immunocytochemistry shows localization of *l(2)gl* product at cell surfaces, specifically at the interfaces between proliferating cells (Klämbt and Schmidt, 1986, *EMBO J.* 5: 2955-61; Klämbt, Müller, Lützelshwab, Rossa, Totzke, and Schmidt, 1989, *Dev. Biol.* 133: 425-36; Lützelshwab, Klämbt, Rossa, and Schmidt, 1987, *EMBO J.* 6: 1791-97). During later embryogenesis relatively high amounts of *l(2)gl* protein is detected in pole cells and cells of the

<sup>β</sup> DNA coordinates with respect to an arbitrarily chosen origin close to the tip of 2L; positive values to the right. Most tested alleles are molecular deficiencies with one breakpoint distal to the origin of the 40 kb walk and the other as indicated in the table. Only *l(2)gl*<sup>52</sup>, which has a 10 kb insertion, and *l(2)gl*<sup>275</sup>, in which 7.9 kb have been deleted and replaced by an insert of 6.5 kb, are exceptions.

developing nervous system; specifically neurons in the peripheral nervous system undergoing axogenesis express the protein. Monoclonal antibodies specifically stain junctions between mammalian cells in culture as though they are recognizing either membrane or intercellular-matrix proteins (Klämbt *et al.*, 1989).

Ten-to-eleven-day-old larvae homozygous for larval-lethal alleles exhibit remarkably few puff sites, only 63BC and occasionally 88D and 89B; however, heat shock induced puffs develop normally (Ashburner, 1970, Chromosoma 31: 356-76). Homozygotes able to form prepupae exhibit more nearly normal puffing patterns; puffing in response to administration of ecdysone also appears normal (Richards, 1976, Wilhelm Roux's Arch. Dev. Biol. 179: 339-48).

**alleles:** A high incidence of mutant alleles found in natural populations in the Soviet Union (Golubovsky and Sokolova, 1973, DIS 50: 124). More than fifty independent alleles recorded.

**cytology:** Placed in 21A3-4 by *in situ* hybridization (Mechler, McGinnis, and Gehring).

**molecular biology:** Region from tip of 2L cloned and a 40 kb walk and restriction mapping carried out. Coordinate 0 at the left end of the walk, with positive coordinate values extending to the right toward the centromere. A transcribed region between coordinates 7.3 and 19.4 kb, which is interrupted or deleted by every *l(2)gl* allele tested, is able to rescue *l(2)gl* homozygotes by transformation (Opper, Schuler, and Mechler, 1987, Oncogene 1: 91-96); it produces transcripts of 4.3 and 5.5-6 kb in length, which originate from the same sequence through alternative splicing. The larger RNA encodes a polypep-

ptide of 1114 amino acids and approximately 130 kd, whereas the smaller one contains only the 708 N-terminal residues of the larger for a molecular weight of 780 kd. Comparison of genomic and cDNA sequences show *l(2)gl* to contain ten exons and to comprise two major blocks of coding exons, the core segment, comprising predominantly exons IV and V, which encodes the majority of the smaller polypeptide and the N-terminal portion of the larger one, and the tail segment comprising exons VII and VIII, which encodes the C-terminal portion of the larger polypeptide. Alternative splicing takes place in and around exon VI (Jacob, Opper, Metzroth, Phannavong, and Mechler, 1987, Cell 50: 215-25). The conceptual sequence of the 130 kd protein shares many features with mammalian cell adhesion proteins, specifically members of the vertebrate cadherin family of proteins, suggesting a function in cell to cell interaction (Lützeltschwab *et al.*, 1987; Klämbt *et al.*, 1989). *l(2)gl* protein lacks the transmembrane domain found in cadherins, but it does have an internally located signal sequence near the N-terminus. It contains four kinds of sequences that show 30 to 40% homology, and half that level of identity with similar sequences in mammalian cadherins (*e.g.* L-CAM): sequence A of some 60 residues has three characteristically spaced N-glycosylation sites; sequence B is around 140 amino acids in length with two cysteine residues and all N-glycosylation sites conserved; sequence C is 70 residues in length and has a high concentration of negative charges; and sequence D contains 45 residues and is positively charged. The sequence of L-CAM can be represented as cytoplasmic domain-transmembrane domain-B—A-C-D— and that of *l(2)gl*

as AA-B-AD—CC-D—.

**other information:** At least one allele of *bhe* (broad head) fails to complement *l(2)gl* alleles and is covered by duplications for the 2L terminus (Kennison).

### ***l(2)H: lethal (2) of Humphrey***

**location:** 2-50.

**origin:** Spontaneous.

**discoverer:** Humphrey, 32k.

**references:** Dunn, 1934, DIS 1: 30.  
1935, DIS 4: 9.

**phenotype:** Usually dies as pupa; 10-15% of flies survive and look normal but are weak. Homozygote usually sterile when inbred but fertile in outcrosses. RK3.

### ***l(2)hst: lethal (2) histolytic***

**location:** 2-56.

**origin:** X ray induced.

**discoverer:** Thompson, 59k.

**phenotype:** Homozygote dies in early pupal stage. Heterozygous viability good. RK3.

### ***l(2)K: lethals from Kofu-Katsunama, Japan***

**origin:** Repeatedly isolated from natural population in Kofu-Katsunama, Japan.

**references:** Watanabe and Oshima, 1970, Genetics 64: 93-106.

### ***l(2)M: lethal (2) from Mohr***

**location:** 2- (between *dp* and *b*).

**origin:** Spontaneous.

**discoverer:** Bridges, 33118.

*l(2)Mad51<sup>n-</sup>*: see *l(2)S*

*l(2)Mass38<sup>x-</sup>*: see *l(2)S*

### ***l(2)mat: lethal (2) maternal***

**location:** 2- (near *pr*).

**origin:** Spontaneous.

**discoverer:** Redfield, 23b.

**references:** 1924, Am. Naturalist 58: 566-69.  
1926, Genetics 11: 482-502.

**phenotype:** Homozygous females produce 1 daughter to 5.5 sons. Abnormal sex ratio caused by inviability of

females. *l(2)mat* does not seem to be allelic to *da*, which has a similar effect. RK3.

### ***l(2)mbn: lethal (2) malignant blood neoplasm***

**origin:** Induced by ethyl methanesulfonate.

**references:** Gateff, 1977, DIS 52: 4.

1978, Biol. Rev. Cambridge Philos. Soc. 53: 123-68.

1978, Nature 200: 1448-59.

**phenotype:** Hyperplasia of cellular components of larval hemolymph; cell counts 30-40 times normal; cells resemble immature plasmatocytes. In premortal stages the larval tissues have mostly disintegrated and larvae appear to be sacks filled with blood cells. Cells do not proliferate when transplanted to normal larvae.

### ***l(2)me: lethal (2) meander***

**location:** 2-72 (71-73).

**origin:** Spontaneous.

**discoverer:** Hadorn, 44g20.

**synonym:** *lme*.

**references:** 1947, Exptl. Biol. Symp., Vol. 2: 177-95, Cambridge Univ. Press.

1947, DIS 21: 68.

Schmid, 1949, Z. Indukt. Abstamm. Vererbungslehre 83: 220-53 (fig.).

Chen and Hadorn, 1954, Rev. Suisse Zool. 61: 437-51.

1955, Rev. Suisse Zool. 62: 338-47.

**phenotype:** Larvae do not grow normally, die while small. Body length remains relatively shorter than tracheal stems, which become convoluted in a meandering manner. Salivary glands reach 30% normal size; pharyngeal development normal. Intestines lack proteolytic enzymes. RK3. Homozygotes show altered charged tRNA<sup>Glu</sup> isoacceptor pattern. Kubli (1978, Rev. Suisse Zool. 85: 790) suggests a deletion for *tRNA-Glu* and *HexC*.

### ***l(2)mr<sup>2</sup>: lethal (2) with morula***

**location:** 2-70.

**origin:** Spontaneous.

**discoverer:** Bridges, 25k24.

### ***l(2)MV: lethal (2) of Mglinetz and Vikulova***

**location:** 2-82 (not separated from *wt*).

**references:** Mglinetz and Vikulova, 1977, Genetika 13: 1318-20.

**phenotype:** Homozygotes die after head eversion at 29°, but viable and fertile adults produced at 17° and 25°. Transplanted mutant disks into wild-type hosts develop normally.

### **\**l(2)NS: lethal (2) Nova Scotia***

**location:** 2-107.0 [to the right of *l(2)ax* and to the left of *sp*].

**discoverer:** Bridges, 23j31.

**references:** 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Lethal when larvae are about 2 mm long. Development of tracheae and other chitinized parts abnormal. RK3A.

**cytology:** Exists only as *In(2R)NS, px l(2)NS sp*. Salivary chromosome locus in 60B10-12 on the basis of its inclusion in *Df(2R)Px = Df(2R)60B8-10;60D1-2* but not in the *2R<sup>PX</sup>D* element of *T(1;2)Bld = T(1;2)1C3-4;60B12-13* (Bridges).

***l(2)pm: lethal (2) polymorph***

**location:** 2-30.3.

**origin:** X ray induced.

**discoverer:** Käfer, 50b.

**references:** Benz, 1953, DIS 27: 55.

1957, Z. Indukt. Abstamm. Vererbungs. 88: 78-114 (fig.).

**phenotype:** Flies die throughout larval and pupal stages. Larvae do not contract before pupation; hence, pupae are long and thin. Imagos often cryptocephalic. Chief characteristic is a severe muscular dystrophy. Protein metabolism extremely disturbed. In larval stage, free amino acids and one peptide are in abnormally high concentration. Prepupae only slightly different from normal in this respect. Occasional survivors viable and fertile. RK3.

**\**l(2)pup: lethal (2) pupal***

**location:** 2-47.

**origin:** Spontaneous.

**discoverer:** Ives, 38j25.

**references:** 1945, Genetics 30: 175.

1945, DIS 19: 46.

**phenotype:** Dies during middle or late pupal stage. External anatomy appears normal except for heavy melanization of wings and legs. RK3.

***l(2)R: lethal (2) of Redfield***

**location:** 2- [in 2L with *In(2L)l*].

**discoverer:** Redfield, 1933.

***l(2)S: lethal (2) of Seto***

A series of late larval and pupal lethals recovered and examined developmentally by Seto. All are lost; more thorough phenotypic descriptions may be found in the references.

**references:** 1954, J. Exp. Zool. 126: 17-32.

1954, Am. Nat. 88: 373-78.

1956, J. Hered. 47: 21-27 (fig.).

1957, DIS 31: 160-62.

1958, DIS 32: 157-58.

1961, DIS 35: 94-95.

1963, DIS 37: 128-229.

***l(2)Su(H): lethal (2) from Suppressor of Hairless***

**location:** 2-99.

**origin:** Spontaneous.

**discoverer:** Bridges, 3717.

**cytology:** Located in salivary region 58A1 through 58F8 on the basis of its inclusion in *Df(2R)M-1 = Df(2R)57F11-58A1,58F8-59A1*.

***l(2)Stn: lethal (2) of Steinmetz***

**location:** 2-50.

**origin:** Naturally occurring.

**discoverer:** Steinmetz.

**references:** Liebenguth and Steinmetz, 1976, Biochem. Genet. 14: 299.

**phenotype:** Late pupal lethal; pigmentation of eyes and cuticular tissues retarded.

**cytology:** Not included in *Df(2L)64j*, *Df(2L)75c*, or *Df(2L)fn1* (Woodruff and Ashburner, 1979, Genetics 92: 117-32).

**\**l(2)T: lethal (2) of Thompson***

**origin:** Spontaneous in normal chromosome of *SM1/+* heterozygote.

**discoverer:** Thompson, 1956, 1957.

**synonym:** *l(2)56i24* through *l(2)57h10*.

**other information:** A series of 13 independently-occurring and genetically-located lethals.

*l(2)Wau55<sup>n-</sup>*: see *l(2)S*

*l(3)I*: see *l(3)a*

*l(3)26*: see *Ace<sup>1</sup>*

***l(3)36d10***

**location:** 3- (close to *D*, or rearrangement).

**origin:** Spontaneous.

**discoverer:** Bridges, 36d10.

**\**l(3)36d24***

**location:** 3- (near centromere).

**origin:** Spontaneous.

**discoverer:** Bridges, 36d24.

**references:** 1937, DIS 7: 13.

Bridges and Bridges, 1938, Genetics 23: 111-14.

**l(3)62**

Lethals in thirteen complementation groups isolated in the region uncovered by  $Df(3L)R-R2 = Df(3L)62B2-4;62D3-5$  (Sliter, Henrich, Tucker, and Gilbert, 1989, Genetics 123: 327-36).

<sup>α</sup> Cooley, Kelly, and Spradling, 1988, Science 239: 1121-28.

**l(3)62Bg**

**phenotype:** Locus displays *ca* 80 times the mutation rate of most of the other loci in the region, and it is relatively more sensitive to γ irradiation than to EMS mutagenesis than other loci (by a factor of six); in addition, none of the alleles is associated with a gross chromosome rearrangement. Hemizygotes are arrested in the first larval

instar, where they remain robust and active. One allele temperature sensitive; developmental arrest takes place shortly after shift up in temperature at several stages.

**I(3)67**

Results of saturation mutagenesis experiments in the region uncovered by *Df(3L)AC1 = Df(3L)67A2;67D11-13* plus additional saturation of its region of overlap with *Df(3L)29A6 = Df(3L)66F3;67B1* (Leicht and Bonner, 1988, Genetics 119: 579-93).

**I(3)67A**

Five complementation groups of unknown order; two are included in the cytologically invisible deficiency, *Df(3L)e146*, whose position in 67A is undetermined.

**l(3)68**

A collection of chemically-induced lethals in the region flanking the 68C *glu* gene cluster on chromosome three (Crosby and Meyerowitz, 1986, Genetics 112: 785-802). They have been mapped with deficiencies as well as recombinationally. The order of loci reflects the map order of the mutants except for *l(3)68Am*, which has not been recombinationally mapped. Hoogwerf, Akam, and Roberts (unpublished) have extended the analysis through 68F. An independent sample of chemically-induced lethal mutations uncovered by *Df(3L)lxd9* was selected and complementation mapped by Campbell, Hilliker, and Phillips (1986, Genetics, 112: 205-15). The latter sample of mutants has not been tested against those of Crosby and Meyerowitz, and the breakpoints of *Df(3L)lxd9* and the *lxd* locus are the only points shared by the analysis with the other two. Since gene order was determined using recombination by Crosby and Meyerowitz, their map is used as standard; the findings of Campbell, Hilliker, and Phillips are noted in the deficiency map of the region.

### l(3)70Aa

Four interallelic complementation groups as follows: (alleles 5 and 7) (allele1) (allele3) (allele4); alleles 2 and 6 are noncomplementing except that *l(3)70Aa*<sup>6</sup> complements *l(3)70Aa*<sup>4</sup> at 30°.

### l(3)72A-D (J.A. Kennison)

Twenty one lethally mutable loci, including *arl*, *brm* and *th* defined by complementation analysis of 95 ethylmethanesulfonate-induced recessive lethal mutations uncovered by *Df(3L)th102* (Kennison and Brizuela).

locus	genetic location	cytological location	included in	excluded from	synonym

<sup>α</sup> Coordinates in kilobases from the left breakpoint of *In(3L)st-a27*.

### *l(3)80F-81F*

A series of ethyl-methanesulfonate-induced lethals detected by failure to complement proximal heterochromatic deficiencies in *3L* or *3R*, which resulted from detachments, *i.e.*, reconstitutions of normal third chromosomes, from irradiated *C(3L)RM/C(3R)RM*-bearing females; a large set of such proximal heterochromatic deficiencies was employed in deficiency mapping of these lethals (Marchant and Holm, 1988, Genetics 120: 519-32).

***l(3)84Da***

phenotype: Hemizygotes for *l(3)84Da*<sup>1</sup> semilethal when the test deficiency extends distally as far as 84F6-7 [e.g. *Df(3R)dsx29*] and lethal when the deficiency extends as far as 84F16 [e.g. *Df(3R)dsx2D*]. *l(3)84Da*<sup>2</sup> not extensively tested for this behavior.

<sup>α</sup> *Df(3R)Scx2* and *Df(3R)dsx2M* overlap by ten kb and the *trans* heterozygote is lethal. *T(2;3)Ta<sup>L</sup>* breakpoint is in the 10 kb segment and may define a lethally mutable locus between *stk* and *hat*.

### I(3)85A

A series of eight lethally mutable loci, all but one of which were first recorded in a saturation mutagenesis screen of the region uncovered by *Df(3R)p25* (Bender, Turner, and Kaufman, 1986, *Dev. Biol.* 119: 418-32). Either ethyl methanesulfonate or diepoxybutane used as the mutagenic agent. Two more loci inferred from the lethality of overlapping deficiencies by Jones and Rawls (1988, *Genetics* 120: 733-42). The right most of these loci is that of *hb*; the rest were previously unrecorded. Deficiency analysis of Bender *et al.* updated by Jones and Rawls with additional deficiencies.

***l(3)85Ea***

**phenotype:** *l(3)85Ea*<sup>1</sup> is a heat-sensitive allele. At 20° about half the expected number of homozygotes eclose, the remainder dying as pharate adults; those that emerge are sterile, ovaries failing to mature, testes appearing morphologically normal; they also exhibit other slight abnormalities such as extra sex-comb teeth and defective wing margins. At 22° all flies die as pharate adults with greatly reduced heads, often with duplicated antennal and palpal structures. No metamorphosis accompanies development at 25°; the eye disc is virtually missing, whereas the wing and haltere discs are severely hyperplastic; disc effects autonomous in transplants. Temperature-shift experiments demonstrate a temperature-sensitive period lasting from the beginning of the second instar until the end of pupation. The 24-hr pulses of 27° during development reveal that the various phenotypic consequences of homozygosity for this allele have different TSP's. *l(3)85Ea*<sup>1</sup> wing discs used to demonstrate that extra cellular proliferation is insufficient to induce transdetermination (Shearn, Martin, Davis, and Hersperger, 1984, Dev. Biol. 106: 135-46). Density of gap junctions in hyperplastic imaginal wing discs markedly reduced (Ryerse and Nagel, 1984, Dev. Biol. 105: 396-403); in shift-up experiments, reduction in gap junctions precedes the onset of tissue hyperplasia (Ryerse and Nagel, 1985, Wilhelm Roux's Arch. Dev. Biol. 194: 480-86). Cell death also observed in wing discs as early as twelve hours following application of restrictive temperature (Sedlak, 1986, Dev. Genet 6: 199-212). Mitosis normal (Gatti and Baker, 1989, Genes Dev. 3: 438-53).

**alleles:** In addition to those listed below a series of *P*-element induced alleles recovered by Cheney.

***l(3)87***

Three different studies have identified forty lethally-mutable loci in 87A-E. 87A and 87B with five and thirteen loci respectively (Gausz, Gyurkovics, Bencze, Awad, Holden, and Ish-Horowicz, 1981, Genetics 98: 775-89); 87C with four loci (Gausz, Bencze, Gyurkovics, Ashburner, Ish-Horowicz, and Holden, 1979, Genetics 93: 917-34); and 87D and E with seven and eleven loci respectively (Hilliker, Clark, and Chovnick, 1980, Genetics 95: 95-110). Included among these loci are *pic* in 87D and *Ace* in 87E.

**l(3)87Ca**

**phenotype:** Most extreme hemizygous phenotype is embryonic lethality, even though homozygous *Df(3R)kar3J*, which lacks the locus entirely, dies during the first larval instar (Ish-Horowicz, Holden, and Gehring, 1977, *Cell* 12: 643-52). First instar larvae have transparent Malpighian tubules; autonomous in transplants. Two alleles isolated on the basis of their dominant suppression of ectopic sex-comb teeth in *Pc*<sup>4/+</sup> males (Kennison and Tamkun, 1988, *Proc. Nat. Acad. Sci. USA* 85: 8136-40).

**references:** Gausz, Bencze, Gyurkovics, Ashburner, Ish-Horowicz, and Holden, 1979, *Genetics* 93: 917-34.

**l(3)87De**

**phenotype:** Escapers resemble *MesB*, but without the abdomen effect. Interacts with *MesB* in *trans* heterozygotes (Skinner, Cole, and Chovnick).

<sup>α</sup> 1 = Hilliker, Clark, and Chovnick, 1980, Genetics 95: 95-110; 2 = Hilliker, Clark, Gelbart, and Chovnick, 1981, DIS 56: 65-72.

**l(3)87Df (A. Chovnick)**

**location:** Maps immediately to the left of, and is contiguous with *ry* DNA.

**references:** Chovnick, Gelbart, McCarron, Osmond, Candido, and Baillie, 1976, Genetics 84: 233-55.

Hilliker, Clark, Chovnick, and Gelbart, 1980, Genetics 95: 95-110.

Hilliker, Clark, Gelbart, and Chovnick, 1981, DIS 56: 65-72.

Clark and Chovnick, 1986, Genetics 114: 819-40.

Dutton and Chovnick, 1990, submitted.

**phenotype:** *l(3)87Df*<sup>1</sup> and *l(3)87Df*<sup>2</sup> hemizygotes completely lethal. *l(3)87Df*<sup>3</sup> cold-sensitive, conditional lethal. Surviving cold-sensitive mutants, and underexpression variants generated by *P*-element transformation, display a phenotypic syndrome that can include delayed development, abnormal bristle morphology and female sterility. Using these phenotypes, defects in "early" and "late" *l(3)87Df*<sup>1</sup> expression can be identified. *l(3)87Df*<sup>1</sup> function is required in embryos, early larvae, late pupae, and during oogenesis phenocritical periods, which coincide with peaks of *l(3)87Df*<sup>1</sup> transcript accumulation. Phenotypic and molecular analyses suggest that the *l(3)87Df*<sup>1</sup> gene probably encodes a ribosomal protein. Genetic and molecular mapping place *l(3)87Df*<sup>1</sup> immediately to the left of the *rosy* locus.

**l(3)87Eb**

**phenotype:** Lethal in all homoallelic and heteroallelic combinations except two: *l(3)87Eb*<sup>8</sup> shows 4% and 15% survival in combination with *l(3)87Eb*<sup>2</sup> and *l(3)87Eb*<sup>5</sup>, respectively; phenotypes normal. *l(3)87Eb*<sup>6</sup> allelism inferred from deficiency mapping; allele lost before others recovered.

<sup>α</sup> Molecular coordinates from Spierer, Bender, and Spierer (1983, J. Mol. Biol. 168: 35-50) and Gausz, Hall, Spierer, and Spierer, 1986, Genetics 112: 65-78). Origin 6.5 kb distal to left breakpoint of *ln(3R)Cbx<sup>rv1</sup>* (Bender, Spierer, and Hogness, 1983, J. Mol. Biol. 168: 17-33).

**I(3)88Aa**

**location:** 3-50.3.

**origin:** Induced by N-methyl-N'-nitro-N-nitrosoguanidine.

**synonym:** *I(3)2004*.

**references:** Shearn, Rice, Garen, and Gehring, 1971, Proc. Nat. Acad. Sci. 68: 2594-98.

**phenotype:** Homozygous larvae die in third instar; discs reported as missing, probably rudimentary (see Szabad and Bryant, 1982, Dev. Biol. 93: 240-56). Mitotic chromosomes fuzzy and swollen; 27% of cells polyploid; chromosome breaks observed (Gatti and Baker, 1989, Genes Dev. 3: 438-53).

**cytology:** Placed in 87F12-88B1 on the basis of inclusion in *Df(3R)red31* = *Df(3R)87F12-14;88B2-3* but not *Df(3R)red-P93* = *Df(3R)88A10-B1;88C2-3*.

**I(3)88Ab**

**location:** 3-51.1.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *I(3)K43*.

**references:** Shearn, Rice, Garen, and Gehring, 1971, Proc.

Nat. Acad. Sci. USA 68: 2594-98.

Szabad and Bryant, 1982, Dev. Biol. 93: 240-56.

**phenotype:** Homozygous larvae contain rudimentary imaginal discs, but disc primordia do not grow during larval development; testes and ovaries smaller than normal, and cell number in central nervous system reduced. Mutant gonads do not survive metamorphosis when implanted into wild-type larvae. Homozygous cuticular clones appear to develop normally, but abdominal clones reduced in frequency and size compared to control clones. Mutant larvae support growth of implanted wild-type discs. Normal gene product postulated to be required for cell proliferation; survival of somatic epidermal clones attributed to perdurance. Larval ganglia exhibit extremely low mitotic index; chromosomes irregularly condensed and chromosome breakage observed (Gatti and Baker, 1989, Genes Dev. 3: 438-53); salivary chromosomes appear normal.

$\alpha$  More detailed description below.

**cytology:** Placed in 88A12-B1 on the basis of its inclusion in *Df(3R)red-P52 = Df(3R)88A12-B1;88B4-5* but not *Df(3R)red-P93 = Df(3R)88A10-B1;88C2-3*.

**molecular biology:** Region of gene contained in a 400 kb cosmid walk; position narrowed to 50 kb between the proximal breakpoint of *Df(3R)red-P52* and the distal breakpoint of an overlapping more proximal inversion *Df(3R)293 = Df(3R)87E;88A*.

***l(3)88Ab<sup>2</sup>***

**phenotype:** Homozygous females weakly fertile; produce eggs with grossly defective chorions; thin, missing most appendages and permeable. All chorion proteins reduced in abundance; chorion gene amplification reduced to 10% wild-type level (Snyder, Galanopoulos, and Kafatos, 1986, Proc. Nat. Acad. Sci. USA 83: 3341-45). Heterozygotes with lethal alleles more extreme and sterile.

***l(3)89A-B***

Based on fine structure deficiency mapping of Hughes, Nelson, Yanuk, and Szauter (unpublished). The region of overlap between this study and that of Tiong, Bone, and Whittle in regions 89B-E have not been reconciled; they are treated separately here.

**origin:** Induced by ethyl methanesulfonate.

**references:** Ivy, 1981, Ph.D. Thesis, University of California, San Diego.

**phenotype:** Homozygotes die as embryos; cell lethal in cuticular clones. Heterozygous males display approximately 4% nondisjunction of both sex and fourth chromosomes; diplo-chromosome exceptions more frequent than nullo-chromosome exceptions. Slight evidence for autosomal nondisjunction and second-division sex-chromosome nondisjunction in males and sex- and fourth-chromosome nondisjunction in females.

**l(3)91F-92A**

Two independent saturation studies carried out by groups at Köln and Bloomington, using different deficiencies for both selection and mapping of lethal mutations; the ambiguities resolved by Lehmann using complementation and deficiency mapping to a common set of deficiencies. The order *l(3)91Fa nos l(3)91Fb l(3)91Fe l(3)91Ff l(3)92Aa Dl* also determined by recombination.

***l(3)93***

Eighteen loci that have mutated to 60 lethal alleles plus one locus inferred from the lethality of heterozygotes for a pair of overlapping deficiencies. Mutations were induced with a variety of mutagenic agents and selected on the basis of inviability in combination with either *Df(3R)e-Gp4 = Df(3R)93B11-13;93D7-9* or *Df(3R)e-H4 = Df(3R)93C3-6;93F6-8*, and therefore are confined to the region 93B11 to 93F8. The region also contains the locus of ebony and the 93D heat-shock locus; none of the mutants affected the heat-shock gene, but the locus inferred from the inviability of heterozygotes for two overlapping deficiencies, *l(3)93De*, appears to be responsible for the heat-shock puff (Mohler and Pardue, 1984, Genetics 106: 249-65).

### ***I(3)109***

**location:** 3-36.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Ferrus and Kankel, 1981, Dev. Biol. 85: 485-504.

**phenotype:** Homozygous lethal; cell viable; homozygous cells 2-3 times normal size.

### ***I(3)1215***

**location:** 3-50.6.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Shearn.

**references:** Bryant, Girton, and Martin, 1980, Insect Biology in the Future (M. Locke and D.S. Smith, eds.). Academic Press, New York, pp. 517-42 (fig.). Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 145-57.

**phenotype:** Homozygotes die as pharate adults. Discs giving rise to segmented appendages develop abnormally; legs much shorter than normal; normal numbers of foreshortened segments with reduced numbers of bristles. Tibias of all legs show mirror-image duplication of distal elements with inverted polarity with indications of incipient joint development at the plane of symmetry; other segments not so affected although some pattern deficiencies and bristles with reversed polarity are observed. Tarsi unsegmented. Antennal joints either abnormal or absent; second segment with reduced number of bristles.

### ***I(3)a***

**location:** 3-81.6.

**origin:** Spontaneous in *In(3R)C*.

**discoverer:** Morgan, 111.

**synonym:** *I(3)l*.

**references:** Muller, 1918, Genetics 3: 422-99.

**phenotype:** Lethal homozygous. Reduced recovery of *M(3)95A*-bearing daughters from *In(3R)C*, *l(3)a/-M(3)95A* females (Schultz). RK3.

**other information:** Results of Bridges interpreted to show allelism to *M(3)95A*<sup>3</sup> (3-79.7); may have been related to maternal effect described by Schultz. Position based on crosses by Muller (1918), in which he used *l(3)a* separated from *In(3R)C*.

### ***l(3)ac: lethal (3) accessory***

**location:** 3- (midregion).

**discoverer:** Schultz, 25g.

**phenotype:** Enhances maternal effect of *In(3R)C*, *l(3)a* on recovery of *M(3)95A* daughters from *M(3)95A/In(3R)C*, *l(3)a* mothers (Schultz). RK3.

### ***l(3)AFA***

**location:** 3-72 [*l(3)AFA7*].

**origin:** Induced by ethyl methanesulfonate in *In(3R)AFA*.

**references:** Caggese, Caizzi, Morea, Scalenghe, and Ritossa, 1979, Proc. Nat. Acad. Sci. USA 76: 2385-89.

**cytology:** Placed in 93C3-E2 based on inclusion in *Df(3R)e-D7* and *Df(3R)e-F1*.

**other information:** Two lethals *l(3)AFA7* and *l(3)AFA17*; allelism not ascertained; also not tested against *l(3)93* lethals of Mohler and Pardue.

### ***l(3)AM1***

**origin:** Induced by ethyl methanesulfonate.

**references:** Seecof, 1977, Am. Zool. 17: 577.

**phenotype:** Nearly dominant lethal; only 4% of *l/l* plus *l/+* genotypes survive. Defective in myogenesis; embryo homogenates in culture display normal axon growth but reduced nucleus; axon ratio suggests myogenesis reduced.

### **\**l(3)blo-l: lethal (3) bloated larvae***

**location:** 3- (to the left of *p*).

**discoverer:** Bridges, 25k7.

**references:** Chen, 1929, J. Morphol. 47: 135-99.

**phenotype:** Larvae become very large and transparent, die in the prepupal stage. Growth of imaginal disks irregular. RK2.

### ***l(3)bt: lethal (3) brain tumor***

**references:** Gateff, 1981, 7th European Drosophila Research Conference Abstracts, p. 42.

**phenotype:** Heat sensitive; at 29° third-instar larvae develop brain tumors and die either before or after pupation. Optic neuroblasts and their derivatives, the ganglion mother cells, proliferate. Brain enlarged and malformed; grow in malignant fashion when transplanted into normal hosts. TSP 0-12 hours of embryonic life.

### ***l(3)ds: lethal (3) discs small***

A series of late-larval, early-pupal lethals characterized by having small imaginal discs; isolated by Shearn and Garren (1974, Proc. Nat. Acad. Sci. USA 71: 1393-97). Originally designated *l(3)B*, but renamed *ds* to conform to the terminology for the same types of mutants recovered on the X chromosome.

locus	genetic location	origin	synonym	can differentiate	α	can support differentiation	β
<i>l(3)ds1</i>	68.0	EMS	<i>l(3)B1</i>			no

<i>l(3)ds16</i>	49.0	ICR	<i>l(3)B16</i>				
<i>l(3)ds17</i>	44.1	ICR	<i>l(3)B17</i>				

α Test of the ability of suspensions of embryonic cells transplanted first into adult hosts for proliferation and then into larval hosts for metamorphosis to differentiate into adult cuticular structures.

β Test of ability of mutant larvae to act as hosts for the differentiation of wild-type imaginal discs. Wild-type discs transplanted into *l(3)ds5* hosts, but not into *l(3)ds1* hosts, can grow and differentiate when subsequently transplanted back into wild-type third-instar larvae.

γ Discless.

### ***l(3)dsi: lethal (3) discless***

A series of late-larval, early-pupal lethals characterized by the absence of imaginal discs; isolated by Shearn and Garren (1974, Proc. Nat. Acad. Sci. USA 71: 1393-97). Originally designated *l(3)A*, but renamed *dsi* to conform to the terminology for the same types of mutants recovered on the X chromosome.

<i>l(3)dsi9</i>	3-74.3	ICR170	<i>l(3)A9</i>				
<i>l(3)dsi10</i>	3-		<i>l(3)A10</i>	no		yes	

α Test of the ability of suspensions of embryonic cells transplanted first into adult hosts for proliferation and then into larval hosts for metamorphosis to differentiate into adult cuticular structures.

β Test of ability of mutant larvae to act as hosts for the differentiation of wild-type imaginal discs.

### ***l(3)DTS: lethal (3) Dominant Temperature Sensitive***

A group of ten ethyl-methanesulfonate-induced dominant-temperature-sensitive mutations on the third chromosome; heterozygotes are lethal when raised at 29°, but survive rearing at 22°. Only *l(3)DTS2* viable as homozygote at 22° (Holden and Suzuki, 1973, Genetics 73: 445-58). Only *l(3)DTS4* expressed dominant lethality in one dose in triploids.

locus	genetic location	phenotype	lethal phase at 29°
<i>l(3)DTS1</i>	3-78	Minute-like at 22°	LP-A
<i>l(3)DTS2</i>	3-33.4		EP

<i>l(3)DTS5</i> <sup>β</sup>	3-44.3		P( <i>hfw</i> -like)
<i>l(3)DTS6</i>	<i>st-p</i> <sup>P</sup>	Minute-like at 22°	P

locus	genetic location	phenotype	lethal phase at 29°
<b><i>l(3)DTS7</i></b>	3-42.3		P
<b>*<i>l(3)DTS8</i></b>	3-55.5		
<b>*<i>l(3)DTS9</i></b>		dominant female sterile	
<b>*<i>l(3)DTS10</i></b>		dominant female sterile	

$\alpha$  More detailed description follows.  
 $\beta$  See *l(3)73Ai*.

***l(3)DTS3***

Heterozygous larvae raised at 29° arrested at the third larval instar for up to two weeks; exhibit grossly hypertrophied ring glands due to the growth of the prothoracic gland cells. The nuclei possess polytene chromosomes which are as large as those of salivary gland nuclei; their banding pattern is similar but not identical to that of salivary gland polytene chromosomes, but the puffing patterns are quite different. Salivary gland chromosomes also hypertrophy and lack the normal ecdysone-induced puffs. Chromosomes in both tissues respond to administration of ecdysone by producing the characteristic set of puffs (Holden and Ashburner, 1978, Chromosoma 68: 205-27). At 29° imaginal discs unable to evert *in situ*; however evert normally if cultured in the presence of ecdysterone or in wild-type hosts. Implantation of a single wild-type ring gland rescues lethality (Holden, Walker, Maroy, Watson, White, and Gausz, 1986, Dev. Genet. 6: 153-62).

***l(3)DTS-1165***

**origin:** Induced by ethyl methanesulfonate in *TM2*.  
**discoverer:** Suzuki.  
**references:** Falke and Wright, 1972, DIS 48: 89-91.  
**phenotype:** Among progeny of *TM2*, *l(3)DTS-1165/Sb* by Oregon R crosses raised at 30° no lethal-bearing progeny survive when lethal inherited from father, but survival of lethal heterozyotes is 4% when lethal inherited from mother.

**\**l(3)e: lethal (3) with ebony***

**location:** 3- (not located).  
**origin:** Spontaneous in *In(3R)C, e*.  
**discoverer:** Schultz.  
**phenotype:** Dies as fully-developed, normal-appearing imago unable to eclose. RK3A.

***l(3)ET: lethal (3) Elaine Tasaka***

A series of ethyl-methanesulfonate-induced temperature-sensitive mutations induced by Tasaka and Suzuki (1973, Genetics 74: 509-20). Genetically mapped, but individual positions not given; most clustered between *st* and *Sb*. Heat-sensitive and cold-sensitive mutants as well as alleles sensitive to both high and low temperatures reported.

$\alpha$  Placed in 90C1-91A2 based on inclusion in *Df(3R)sr*.

***l(3)gl: lethal (3) giant larvae***

**origin:** Induced with ethyl-methanesulfonate.

**references:** Gateff, 1977, DIS 52: 4.

1978, Biol. Rev. 53: 123-42.

1978, Science 200: 1448-59.

**phenotype:** Late larval lethal; larvae bloated, enlarged; transparent owing to reduced fat body. Third larval instar may be prolonged for up to one week. Imaginal discs represent transplantable benign and lethal neoplasms; brain develops a malignant neuroblastoma. Penetrance incomplete.

**\**l(3)hd: lethal (3) head defect***

**location:** 3- (not located).

**discoverer:** Bridges, 1924.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 230.

**phenotype:** Dies in pupal stage with black, tumor-like growth in head. RK3.

*l(3)Lh*: see *l(3)80F*

***l(3)LVML: lethal (3) L. V. Morgan Left***

***l(3)LVMR: lethal (3) L. V. Morgan Right***

Recessive lethal alleles associated with *In(3L)P* and *In(3R)P* respectively in the *LVM* balancer (Craymer, 1980, DIS 55: 197-204).

***l(3)mbn: lethal (3) malignant blood neoplasm***

**origin:** Induced by ethyl-methanesulfonate.

**references:** Gateff, 1977, DIS 52: 4.

1978, Biol. Rev. 53: 123-42.

1978, Science 200: 1448-59.

**phenotype:** Lethal at pupariation; larvae appear bloated

owing to having 150 times as many free hemocytes as normal; these can encapsulate and melanize larval tissue.

### ***l(3)nc99Eb***

**location:** 3-54.2.

**references:** Warmke, Krevz, and Falkenthal, 1989, *Genetics* 122: 139-51.

**phenotype:** Homozygous lethal; heterozygous flightless; interacts semilethally with heterozygous deficiency for *Mlc2*, i.e., *Df(3R)99D3-E3*.

### ***l(3)PL: l(3) Payne Left***

**location:** 3- (left arm).

**origin:** Spontaneous in *3L* carrying *In(3L)P*.

### ***l(3)PR: l(3) Payne Right***

**location:** 3-90.2.

**origin:** Spontaneous in *In(3R)P*.

**phenotype:** Homozygous lethal; lethal in combination with *M(3)96CF*. RK3.

*l(3)QIII*: see *M(3)80*

### ***l(3)R***

A series of late larval lethal mutations that complement one another in all pairwise combinations; not mapped; screened for antigens with 16 different antisera on double diffusion plates (Roberts and Evans-Roberts, 1976, *Mol. Gen. Genet.* 148: 57-64).

### ***l(3)R12***

**location:** 3-[51].

**origin:** Induced by ethyl methanesulfonate.

**references:** Caggese, Caizzi, Morea, Scalenghe, and Ritossa, 1979, *Proc. Nat. Acad. Sci. USA* 76: 2385-89.

**cytology:** Placed in 87A6-D5 based on its failure to complement *Df(3R)kar-D2 = Df(3R)87A6-7;87D4-5*. Not checked for complementation with known *l(3)87* mutants.

*l(3)Rh*: see *l(3)81F*

### ***l(3)S1: lethal (3) of Schalet***

**location:** 3-51 (to the left of *kar*).

**origin:** X ray induced in a *kar*<sup>2</sup> chromosome.

**discoverer:** Schalet.

**other information:** Placed to the left of *l(3)S2* on the basis of its exclusion from *Df(3R)ry*<sup>76</sup>, which is deficient for *l(3)S2* and loci to the right.

### ***l(3)S1<sup>a</sup>***

**origin:** X ray induced in a *kar*<sup>2</sup> chromosome.

**discoverer:** Schalet.

**other information:** Allelism with *l(3)S1* tentative and based on similarity in interaction with *Df(3R)ry*<sup>76</sup>.

### ***l(3)S2***

**location:** 3-51.5 [between *l(3)S1* and *kar*].

**origin:** X ray induced in a *kar*<sup>2</sup> chromosome.

**discoverer:** Schalet.

**references:** Schalet, Kernaghan, and Chovnick, 1964, *Genetics* 50: 1261-68.

**other information:** Placed between *l(3)S1* and *kar* on the basis of its inclusion in *Df(3R)ry*<sup>76</sup> but not *Df(3R)ry*<sup>29</sup>, *Df(3R)ry*<sup>33</sup>, or *Df(3R)ry*<sup>36</sup>. None of these deficiencies includes *l(3)S1* and all include *kar* and genes to its right.

*l(3)S3*: see *l(3)87Da*

### ***l(3)S4***

**location:** 3-52.1 (to the right of *pic*).

**origin:** X ray induced in a *kar*<sup>2</sup> chromosome.

**discoverer:** Schalet.

**references:** Schalet, Kernaghan, and Chovnick, 1964, *Genetics* 50: 1261-68.

**phenotype:** Homozygous lethal, but there are a few, relatively normal-appearing survivors that are mostly females. RK3.

**other information:** Placed to the right of *ry* by recombination and to the right of *pic* on the basis of its survival in combination with *ry*<sup>35</sup>, which behaves as though it were deficient for *ry* and *pic*. Placed to the left of *l(3)S5* by recombination.

*l(3)S5*: see *l(3)87Db*

*l(3)S6*: see *l(3)87Eb*

### ***l(3)S7***

**location:** 3-53 [to the right of *l(3)26*].

**origin:** X ray induced in a *kar*<sup>2</sup> chromosome.

**discoverer:** Schalet.

**references:** Schalet, Kernaghan, and Chovnick, 1964, *Genetics* 50: 1261-68.

**alleles:** Five alleles recovered; *l(3)S7*<sup>2</sup> - *l(3)S7*<sup>5</sup> originally designated *l(3)S7*<sup>a</sup> - *l(3)S7*<sup>d</sup>. *l(3)S7*<sup>1</sup> but not *l(3)S7*<sup>2</sup> or *l(3)S7*<sup>3</sup> complemented by an undescribed *red* deficiency.

**other information:** Placed to the right of *l(3)26* on the basis of its exclusion from *Df(3R)ry*<sup>66</sup>, which includes *l(3)26* and loci to its left.

### ***l(3)SG: lethal (3) of Shearn and Garen***

Recessive lethal third-chromosome mutations in ninety-four loci isolated by Shearn and Garen (or occasionally by Shearn: *SG4*, *SG5*, *SG6*, *SG16*, *SG28*, *SG30*, *SG35*, *SG44*, *SG64*, *SG68*, *SG70*) mostly selected to be late larval or prepupal lethals. For simplicity they are designated numerically in their genetic map order; those that are unmapped continue the list at the end according to isolation number. As these loci become cytologically mapped or otherwise named, their *SG* designations will

THE GENOME OF *DROSOPHILA MELANOGASTER*

sink to synonymy.

### I(3)SG8

**phenotype:** Homozygous larvae never form puparia; imaginal discs never exceed size seen in late second instar, neither do they grow when transplanted into normal adult female abdomens nor differentiate when transplanted back into wild-type larval hosts for metamorphosis (Shearn, Hersperger, Hersperger, Pentz, and Denker, 1978, Genetics 89: 355-70).

**alleles:** All alleles noncomplementing.

### I(3)SG13

**phenotype:** Homozygous larvae contain rudimentary imaginal discs, but disc primordia do not grow during larval development; testes and ovaries smaller than normal, and cell number in central nervous system reduced. Mutant gonads do not survive metamorphosis when implanted into wild-type larvae. Homozygous cuticular clones appear to develop normally. Mutant larvae support growth of implanted wild-type discs. Normal gene product postulated to be required for cell proliferation; survival of somatic epidermal clones attributed to perdurance. Larval ganglia exhibit extremely low mitotic index; chromosomes irregularly condensed; extensive chromosome fragmentation observed frequently (Gatti and Baker, 1989, Genes Dev. 3: 438-53); salivary chromosomes appear normal.

<b><i>l(3)SG26</i><sup>3</sup></b>	<i>l(3)E26</i>

***l(3)SG29***

**phenotype:** Homozygous larvae do not form puparia; imaginal discs never attain size of those in young third-instar larvae. Mutant discs transplanted into wild-type female abdomens decrease in size and disappear during the first three days; however, in transplanted mixtures of wild-type and mutant embryonic cells allowed to pass through metamorphosis, mutant cells appear in cuticular derivatives from all discs. Wild-type discs transplanted into mutant larvae are capable of reduced growth and of differentiation upon retransplantation into wild-type larvae. Alleles with more extreme effects (*i.e.*, larval death in early second instar) and less severe effects (pharate adults that do not eclose) noted (Shearn, Hersperger, Hersperger, Pentz, and Denker, 1978, Genetics 89: 355-70).

**alleles:** Interallelic complementation not observed; heteroallelic combinations exhibit phenotypes intermediate between those of the two homozygotes.

***l(3)SG56***

**references:** Shearn, Hersperger, Hersperger, Pentz, and Denker, 1978, Genetics 89: 355-70.

Pentz and Shearn, 1979, Dev. Biol. 70: 149-70 (fig.).

Cheney, Miller, Lang, and Shearn, 1984, Proc. Nat. Acad. Sci. USA 81: 6422-26.

**phenotype:** 78% of mutant larvae reach third instar; development delayed, and larvae never pupariate; rather they remain alive on surface of food for up to 22 days. Larvae form melanotic masses. Imaginal disc growth retarded and development abnormal, with substantial cell death; growth rate of mutant discs, but not their ability to differentiate, partially restored when transplanted into normal larval host; mutant larvae defective in support of growth of implanted wild-type discs, but do not prevent their subsequent differentiation upon retransplantation into normal larvae. Homozygous mutant clones in a wild-type background were induced at control frequencies; however, sizes of mutant clones produced earlier, but not those produced later, were smaller than control clones; differentiation of cuticular elements normal in small clones, but in large thoracic clones produced in a *M* background cuticular development abnormal (Pentz and Shearn). Ganglion mitosis normal according to Gatti and Baker (1989, Genes Dev. 3: 438-53), disturbed according to Pentz. *l(3)SG56*<sup>26</sup> homozygotes lethal when raised at 27° but survive as fertile adults when reared at 20°; shifting such adult females to 27° demonstrates that *l(3)SG56* is a maternal-effect lethal and a female sterile; egg production decreases with time, and those eggs that are produced exhibit abnormal cellularization and fail to hatch; temperature effect reversible by shift down. Two-dimensional gel electrophoresis analysis of proteins from mutant tissue at restrictive vs. permissive temperatures shows reduction in levels of three proteins and a concomitant increase of three related proteins; two other proteins are absent from mutant tissue at restrictive temperatures; mutant postulated to be defective in post-translational modification of a small subset of proteins crucial to normal cell division, cell motility, and formation of adult hairs and bristles (Cheney, *et al.*).

**alleles:** No complementation between alleles observed. *l(3)SG56*<sup>6</sup> hypomorphic; completes metamorphosis but dies as pharate adult without striking morphological defects. *l(3)SG56*<sup>26</sup> heat sensitive.

***l(3)SG67***

**phenotype:** Homozygotes pupariate, but do not metamorphose; imaginal discs never exceed in size those of late second-instar larvae. Mutant eye-antennal and wing discs transplanted into adult wild-type female abdomens are never recovered after seven days in culture; they decrease in size and disappear during first three days. Mutant larvae permit reduced growth of implanted wild-type discs and do not interfere with their subsequent development in normal hosts (Shearn, Hersperger, Hersperger, Pentz, and Denker, 1978, *Genetics* 89: 355-70). Larval ganglion cells exhibit extremely low mitotic index and weak effects on chromosome condensation; chromosomes thin and elongated (Gatti and Baker, 1989, *Genes Dev.* 3: 438-53).

**alleles:** All alleles noncomplementing.

***l(3)tl: lethal (3) tumorous larvae***

**location:** 3- to the left of *R* (3-1.4).

**origin:** Spontaneous.

**references:** Peterson and Gardner, 1965, *Genetics* 52: 465-66.

Kobel and Breugel, 1967, *Genetica* 38: 305-27.

Zhimulev and Lychev, 1972, *Genetika (Moscow)* 8(6): 51-55.

Zhimulev, Belyaeva, and Lychev, 1974, *Genetika (Moscow)* 10(10): 73-79 (fig.).

Zhimulev, Belyaeva, and Lychev, 1976, *Chromosoma* 55: 121-26.

**phenotype:** Homozygous larvae fail to pupate and live beyond normal time of pupation. Hemolymph contains an overabundance of blood cells as well as melanotic pseudotumors. Fat bodies and parts of gut disintegrate. Salivary nuclei contain nucleolus-like bodies six to seven times normal size; polytene chromosomes short, thick, and diffuse, especially the male X; bands appear to fuse. Mutant eye-antennal discs allowed to metamorphose in normal larvae produce some normal adult structures.

***l(3)tr: lethal (3) translucida***

**location:** 3-20 (18.1 to 22.0).

**origin:** Spontaneous.

**discoverer:** Hadorn, 40116.

**references:** 1947, *Expt. Biol. Symp.*, Vol. 2: 177-95, Cambridge Univ. Press.

1947, *DIS* 21: 68.

1956, *Cold Spring Harbor Symp. Quant. Biol.* 21: 363-

73 (fig.).

**phenotype:** Larvae become bloated and transparent from accumulation of abnormal amount of hemolymph. Concentration of amino acids in hemolymph higher than normal; concentration of proteins reduced. Pupation delayed one day (25°); dwarfed pupae formed in inflated puparia; death follows pupation or completion of imaginal differentiation of head and thorax; abdomen never metamorphoses. After transplantation into normal hosts, imaginal disks develop normally; ovaries also develop normally and are fully capable of producing viable eggs [Sobels, 1950, *Experientia* 6: 139-40 (fig.)]. In pure oxygen, frequency and extent of imaginal differentiation strongly increased [Sobels and Nijenhuis, 1953, *Z. Indukt. Abstamm. Vererbungslehre* 85: 579-92 (fig.)]. RK3.

**cytology:** Salivary chromosomes normal (Rosin).

**l(3)W**

**location:** 3- (right arm).

**origin:** Spontaneous in 3R carrying *In(3R)P*.

**l(3)XaR**

**location:** 3-91.8.

**other information:** Used to balance *T(2;3)ap<sup>Xa</sup>*.

**l(4)102**

The following represents the results of extensive searches for mutations on chromosome 4, largely carried out by Hochman. Mutants can be examined for their ability to complement *Df(4)M4* and *Df(4)G*; those that complement both deficiencies are assumed to be located between them, although it is possible that some are located proximal to *Df(4)M4*.

***l(4)102CDa***

**alleles:** A highly mutable locus. The 35 alleles designated *a* through *hh* by Hochman; alleles *b*, *k*, and *ii* die in the larval stage and are mutually partially complementing; a fourth complementation group comprises alleles *f*, *h*, and *t*, which are larval lethals. The remaining 29 alleles are embryonic lethals and are noncomplementing. Allele *c* fails to complement *l(4)102CDB* alleles as well.

***l(4)102EFc* (R. Denell)**

**references:** Hochman, Gloor, and Green, 1964, *Genetica* 35: 109-26.

Gehring, 1970 *DIS* 45: 103.

Hochman, 1971, *Genetics* 67: 235-52.

Duncan, 1982, *Genetics* 102: 49-70.

Sato, Russell, and Denell, 1983, *Genetics* 105: 357-70.

**phenotype:** Homozygotes from heterozygous mothers die as pupae (Hochman). Those that reach the pharate-adult stage show partial homeotic transformations of first and second antennal segments into proximal leg structures, meso- and metathoracic legs into prothoracic legs, as well as posteriorly directed transformations of features of the abdominal hypoderm and of parovaria into spermathecae in females. All three pairs of legs distorted, with tarsal segments swollen and sometimes fused with missing claws; some abnormalities of derivatives of the antennal disc and of the dorsal prothorax also present (Gehring; Duncan). Heterozygous adults normal, except that males also heterozygous for a deficiency or mutation of *E(Pc)* occasionally develop sex-comb teeth on meso- and metathoracic legs (Sato *et al.*). Heterozygous and homozygous larvae from heterozygous mothers normal; homozygotes from transplanted homozygous ovaries die as late embryos with a complex homeotic syndrome. Head involution incomplete, and portions of head develop abdominal-like denticles. All thoracic segments partially transformed to resemble the first abdominal segment, and more posterior segments may develop cuticular features characteristic of the eighth abdominal segment. Heterozygotes from homozygous ovaries sometimes die as late embryos displaying relatively mild homeotic effects of the head and mesothorax or slightly incomplete head involution or both, but often hatch and die during larval or pupal stages. Rarely, adults eclose, often with appendages that are crippled or are missing owing to failure of imaginal-disc evagination (Denell). Most embryos produced by oocytes hemizygous for *l(4)102EFc*<sup>3</sup> and *l(4)102EFc*<sup>4</sup>, achieved by pole-cell transplantation, fail to form cuticle, even with a wild-type paternal complement; a few of the latter genotype produce enough cuticle to reveal extensive defects in segmentation; setal belts usually missing or transformed; head involution fails; anterior hole present in most embryos (Breen and Duncan, 1986, *Dev. Biol.*

118: 442-45).

**cytology:** Placed in 35D3-4 by Ashburner.

**lacquered:** see **lac**

**Lam:** **Laminin**

**location:** 2- {17}.

**origin:** Gene identified by screening a  $\gamma$ -gt11 cDNA expression library, constructed from early embryonic mRNA, with monoclonal antibodies against Drosophila laminin.

**references:** Gruenbaum, Landesman, Drees, Bare, Saumweber, Paddy, Sedat, Smith, Benton, and Fisher, 1988, J. Cell Biol. 106: 585-96.

**phenotype:** The structural gene for nuclear lamin. Translated as a prolamin of apparent molecular mass of 76-kd, which is quickly processed to a 74-kd species, presumably by proteolysis. The processed polypeptide is assembled into the nuclear envelope, where it becomes phosphorylated and again attains a mass of 76 kd (Smith, Gruenbaum, Berrios, and Fisher, 1987, J. Cell Biol. 105: 771-90).

**molecular biology:** Original cDNA clone identified two transcripts of 2.8 and 3.0 kb; although they encode identical polypeptides, they display differential expression profiles on developmental Northern blots. They are equally abundant during oögenesis, but in the early embryo the 2.8-kb species is four times more abundant than the 3.0-kb species; the latter increases in intensity until the two are again equally abundant at mid gastrulation; by 7.5 h, only the 3.0-kb molecule persists. Full length cDNA clones of both have been recovered and sequenced; their differences reside in the lengths of their untranslated 3' regions. The gene encodes a polypeptide of 621 amino acids and calculated molecular mass of 70,974. Amino-acid sequence shows approximately 35% identity with human laminin; shows secondary structural features characteristic of intermediate filament proteins; contains a segment with 49% sequence identity with hamster vimentin.

**Lam-: Laminin**

Three genes encode the three subunits of Drosophila laminin, which associate to form a cruciform molecule in which the carboxy-terminal ends are alpha helical and associate with one another and whose amino-terminal ends are free to form three short arms of the cross.

locus	genetic location	cytological location <sup>α</sup>	molecular weight

<b><i>Lam-B1</i></b>	2- {33}	28D	220 kd
<b><i>Lam-B2</i></b>	3- {34}	67C	180 kd

$\alpha$  localized by *in situ* hybridization.

**references:** Fessler, Campbell, Duncan, and Fessler, 1987, *J. Cell Biol.* 105: 2383-91.

Montell and Goodman, 1988, *Cell* 53: 463-73.

**phenotype:** The three genes are coordinately expressed with little or no transcript detectable prior to germ-band elongation. At eight hr, expression detected in the mesoderm and to a lesser extent in a subset of the ectoderm, including the epidermis. In the developing CNS grains associated with certain glial elements; no transcript seen after 18 hr. Immunocytochemical observations in embryos show laminin to be localized to basement membranes surrounding internal organs and muscles, in the underlying hypodermal epithelium and in the nervous system; also in basement membranes of larvae and adults. In the developing CNS, high levels are seen in the mesectodermal strand, in a pair of mesodermal cells near the segment border, in and around axon pathways, and in glial cells. Neurons and glia of the PNS also show abundant laminin immunoreactivity [Montell and Goodman, 1989, *J. Cell Biol.* 109: 2441-53 (fig.)].

### Lam-B1

**molecular biology:** All three genes cloned. *LamB1* sequenced; conceptual amino acid sequence of 1784 residues comprises six domains: starting from the C-terminus, domains I and II separated by a short stretch termed  $\alpha$  comprise 67 kd are largely  $\alpha$  helical, show 25% and 22% homology with mouse B1 subunit, respectively, and comprise the segment of the chain that associates with the A and B2 subunits. The  $\alpha$  region has 27 amino acids including six cysteines and eight glycines; it shows 36% homology with the mouse  $\alpha$  sequence; five of the six cysteines and five of the eight glycines are conserved. Domains III (44 kd) and V (30 kd) contain eight and five cysteine-rich repeats that exhibit homology with epidermal growth factor; they are 54% and 53% homologous with the mouse polypeptide, respectively. Domains IV (25 kd) and VI (28 kd) show 58% and 26% homology with mouse, respectively and have been postulated to be collagen-binding domains.

### Lam-B2

**molecular biology:** Sequence determined (Chi and Hui, 1989, *J. Biol. Chem.* 264: 1543-50; Montell and Goodman, 1989, *J. Cell Biol.* 109: 2441-53). Conceptual amino acid sequence contains 1639 residues. Domain structure similar to that of LAM-B1, except that LAM-B2 lacks the 27 amino acid cysteine-rich  $\alpha$  domain that separates domains I and II in LAM-B1. There is also a large deletion in domain V and seven rather than eight EGF repeats in domain III; five more EGF repeats reside in domain V. Shows higher homology to mouse LAM-B2 than to *Drosophila* LAM-B1.

### Lap-A: Leucine aminopeptidase A

**location:** 3-98 (near *Lap-D*; no recombination yet observed).

**references:** Beckman and Johnson, 1964, *Hereditas* 51: 221-30.

Walker and Williamson, 1980, *Insect Biochem.* 10: 535-41.

Walker, Williamson, and Church, 1981, *Biochem. Genet.* 19: 47-60.

**phenotype:** Structural gene for leucine aminopeptidase A [LAP-A(E.C.3.4.1.1)], one of six such enzymes revealed by starch-gel electrophoresis. More anodally migrating than LAP-D; molecular weight 280,000 daltons; pH optimum 6.7. Enzyme apparently monomeric; no hybrid molecules formed in heterozygotes for electrophoretic variants. Appears 12 hrs after oviposition; found in larvae and pupae but not adults. Localized in larval hemolymph; not induced by substrate feeding.

**alleles:** Naturally occurring alleles: *LapA<sup>F</sup>*, *LapA<sup>S</sup>*, *LapA<sup>0</sup>*; fast, slow, and null alleles respectively.

### Lap-D: Leucine aminopeptidase D

**location:** 3-98.3 (Falke and MacIntyre).

**references:** Beckman and Johnson, 1964, *Hereditas* 51: 221-30 (fig.).

Falke and MacIntyre, 1966, *DIS* 41: 165-66.

Walker and Williamson, 1980, *Insect Biochem.* 10: 535-41.

Walker, Geer, and Williamson, 1980, *Insect Biochem.* 10: 543-46.

Walker, Williamson, and Church, 1981, *Biochem. Genet.* 19: 47-60.

**phenotype:** Structural gene for leucine aminopeptidase D [LAP-D(E.C.3.4.1.1)], one of six such activities revealed by starch-gel electrophoresis and a staining with L-leucil-B-naphthylamide and Fast Black K salt; enzyme monomeric; molecular weight = 280,000 daltons; pH optimum 7.6; may be Zn metalloenzyme. Found in larvae and pupae, but not adults; highest in young larvae. Localized to larval midgut where levels are induced by dietary substrate.

**alleles:** Three alleles mentioned in literature, *LapD<sup>F</sup>* and *LapD<sup>S</sup>* plus an unnamed, uncharacterized one alluded to by Sakai, Tung, and Scandalios (1968, *Genetics* 60: 219-20). *Lap-D<sup>F</sup>/Lap-D<sup>S</sup>* produce equal amounts of slowly and rapidly migrating LAP D and no enzyme of intermediate mobility.

**Larval serum:** see *Lsp*

**Larval visceral protein:** see *Lvp*

**late hatching:** see *lh*

### Lcp: Larval cuticle protein

A series of genes encoding electrophoretically separable proteins extractable from the cuticles of third-instar larvae, but not other stages. Four immunologically related proteins are encoded by a cluster of genes on 2R

and another cluster of three unrelated to the preceding four, but related to each other, located on 3L. Designated numerically in order of increasing mobility on non-denaturing gels of encoded polypeptide, with the exception of *Lcp10*.

Nat. Acad. Sci. USA 79: 7430-34.

**Lcp1-4**

**phenotype:** Encode larval cuticle proteins CP1, CP2, CP3, and CP4 (alternatively L<sub>3</sub>CP<sub>1</sub> to L<sub>3</sub>CP<sub>4</sub>); molecular weights 17.5, 17.5, 9 and 13 kd respectively. Each has a 15-residue signal peptide.

<i>Lcp4<sup>1</sup></i>	population	1	

<sup>α</sup> 1 = Fristrom, Hill, and Watt; 2 = Snyder, Kimbrell, Hunkapiller, Hill, Fristrom, and Davidson, 1982, Proc. Nat. Acad. Sci. USA 79: 7430-34.

**molecular biology:** These four genes and a pseudogene are clustered within 7.9 kb of DNA located in region 44D. The genes are arranged in numerical order along the chromosome, but polarity with respect to the centromere is not known. Each gene is approximately 0.5 kb in length; *Lcp1* and *Lcp2* are separated by 2.9 kb, *Lcp2* and *Lcp3* by 0.87 kb, and *Lcp3* and *Lcp4* by 1.6 kb. All four genes contain a short intron between the third and fourth codon of the signal peptide. *Lcp1* and *Lcp2* show 91% amino acid homology, *Lcp3* and *Lcp4* show 85%, and between these two pairs there is approximately 60% homology (Snyder, Hirsh, and Davidson). A putative pseudogene, whose sequence suggests origin via unequal crossing over between *Lcp1* and *Lcp2*, found between these two genes, 500-600 bp from *Lcp2*. Transcription of *Lcp1*, *Lcp1psi* and *Lcp2*, takes place off of the opposite strand and divergently from that of *Lcp3* and *Lcp4* (Snyder, Hunkapiller, Yuen, Silvert, Fristrom, and Davidson). *Lcp2<sup>F</sup>* gene product has been shown to differ from that of the more common *Lcp2<sup>S</sup>* allele by two amino acid substitutions; *Lcp3<sup>nl</sup>* contains a 7.3 kb DNA insertion, identified as H.M.S. Beagle, located within the TATA box (Snyder, Kimbrell, Hunkapiller, Hill, Fristrom and Davidson).

**Lcp5**

**alleles:** *Lcp<sup>+</sup>* is the commonly encountered allele; the other alleles are infrequent. Electrophoretic variants, when homozygous, may reveal two bands, one at the new position and one at the original position; these alleles are designated *r* for residual. Others leave no residual band and are designated *nr*.

**ld: loboid**

**location:** 3-102 [between *ca* and *bv* (Lewis, 1956, DIS 30: 130)].

**origin:** Spontaneous.

**discoverer:** Curry, 39a.

**references:** 1939, DIS 12: 45.

**phenotype:** Eyes resemble *L/+*. Malformation of eyes ranges from slight dorsoventral seam across middle of eye to a more extreme effect in which growth of anterior part is completely inhibited in most-extreme cases. Antenna-like outgrowth frequent where growth of eyes is suppressed. Tends to overlap wild type. In the presence of a sex-linked modifier, *opht* [*opht*; *ld* designated *ld<sup>oph</sup>* by Kobel (1968, *Genetica* 39: 329-44)] *ld* flies show homeotic transformation of eye to wing tissue (Ouweneel, 1969, Wilhelm Roux's Arch. Entwicklungsmech. Org. 164: 1-114 and 14-36; 1970, 166: 76-88; 1970, *Genetica* 41: 1-20). RK3.

**cytology:** Tentative; placed in 99C-F based on its genetic localization.

**\**ld<sup>eyr</sup>*: loboid-eyes reduced**

**origin:** Found among flies grown on food containing copper sulfate.

**phenotype:** Eyes vary from normal to absence of ommatidia. Shows some degree of dominance; many heterozygotes have some eye abnormality, usually a nick in anterior region of one or both eyes; an abnormal growth of wing tissue may be associated with the nick. *ld<sup>eyr</sup>*; *ey<sup>4</sup>* flies have very small heads, usually without ommatidia. Viability greatly reduced. RK2.

**lds: lodestar**

**location:** 3-47.

**synonym:** *early*.

**references:** Tearl and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal. In nuclear cycles 9-10, multiple complex anaphase spindles share several centrosomes. Multiple groups of chromosomes are often directed to same pole. Elongated polyploid nuclei develop. Mitotic abnormalities in larval brain cells (Gatti).

**alleles:** Four alleles, *lds<sup>1</sup>*-*lds<sup>4</sup>*, isolated as 042, 072, 098, and 298.

**cytology:** Placed in 88D13-14 (Ashburner).

**lea: leak**

**location:** 2-3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**phenotype:** Embryonic lethal. Head involution incomplete. In combination with *Pc*-like mutants, abdominal transformations occur.

**alleles:** Two, *lea<sup>1</sup>* and *lea<sup>2</sup>*, isolated as 25 and IIS.

**cytology:** Placed in 21F2-22B1 based on its inclusion in *Df(2L)S2 = Df(2L)21C6-D1;22A6-B1* but not *Df(2L)S3*

*= Df(2L)21D2-3;21F2-22A1*.

**leg:** see *run*

**leg tumor:** see *Igt*

**\**lem: lemon***

**location:** 1-17.5.

**origin:** Spontaneous.

**discoverer:** E. M. Wallace, 12h.

**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 48 (fig.).

**phenotype:** Body color pale yellow with dark trident and black bristles. Wings and veins pale yellow. Easily distinguished from wild type, viability about 70% wild type, and most flies sterile. RK3.

**Les: Lesbian (J.C. Hall)**

**location:** Complex genetic etiology.

**origin:** Isolated from a series of related, balancer-containing strains (used to maintain the *Fs(2)B* mutation).

**references:** Cook, 1975, *Nature* 254: 241-42.

**phenotype:** Females exhibit male-like courtship, including unilateral wing display, directed at other females; courtship bouts relatively short; not all females of the strain show the anomalous behavior; these behaviors have been observed in females of other strains (Cook, 1981, *Z. Naturforsch.* 36C: 475-83).

**\**Lg*: Large**

**location:** 1-27.  
**origin:** Induced by P<sup>32</sup>.  
**references:** Bateman, 1950, DIS 24: 55.  
**phenotype:** Heterozygote large, late eclosing, with visibly smaller hairs; viability excellent. Tendency toward shortening of L4 and L5, missing postvertical bristles, and islands of vein tissue on either side of L2. Homozygous lethal. RK2.

**\**lgh*: long haired**

**location:** 1-20.7.  
**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 87.  
**phenotype:** Small fly; size reduction most noticeable in head and thorax. Wings short and slightly altered in

shape. Anterior thorax frequently dented in the mid-dorsal line. Hairs deranged; bristles long and scraggly. Abdomen nearly always abnormally pigmented, ranging from no melanization of tergites 5-7 to small, irregular, under-pigmented patches on these tergites. Male viability about 25% wild type. Males sterile. RK3.

*lgl* : see *l(2)gl*

*lglG* : see *ovo*<sup>Drv22</sup>

**\**lgt*: leg tumor**

**location:** 2- (not located).  
**origin:** Spontaneous.  
**discoverer:** Spencer, 36c20.  
**references:** 1937, DIS 7: 14.  
**phenotype:** Black tumor growth inside thorax ventrally at bases of posterior legs. Sterile in both sexes; poor viability. RK3.

***lh*: late hatching**

**location:** 1-57.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 31d6.  
**phenotype:** Slow-developing semigiant. RK3.

*LHP* : see *Lsp2*

***Lhr*: Lethal hybrid rescue**

**location:** 2-95 (in *Drosophila simulans*).  
**origin:** Spontaneous.  
**references:** Watanabe, 1979, Jpn. J. Genet. 54: 325-31. Takamura and Watanabe, 1980, Jpn. J. Genet. 55: 405-08.  
**phenotype:** When *Drosophila simulans* carries *Lhr*, classes of hybrids between *D. simulans* and *D. melanogaster* that do not ordinarily survive are recovered. Crosses of *D. melanogaster* females by *D. simulans* males, which ordinarily produce only daughters, produce sons and daughters in a 1:1 ratio. Crosses of *D. simulans* females to *D. melanogaster* males, which ordinarily produce only sons, produce 86% sons and 14% daughters. Crosses of *C(1)RM* - bearing *D. melanogaster* females to *D. simulans* males, which normally produce only sons, yield a few daughters when the *D. simulans* males carry *Lhr*.

**light:** see *lt*

**lightoid:** see *ltd*

**limited:** see *lm*

***lin*: lines (C. Nüsslein-Volhard)**

**location:** 2-59.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.  
**phenotype:** Embryonic lethal; small anterior portion of each segment deleted; A8, spiracles, and anal plates absent. Head abnormal.  
**alleles:** Three alleles, *lin*<sup>1</sup>-*lin*<sup>3</sup>, isolated as 5E, IIF, and IIV.  
**cytology:** Tentatively placed in 44F-46D.

**lix: little Isoxanthopterin****location:** 1-23.**origin:** Spontaneous.**discoverer:** Hessler, 1959.**references:** 1960, DIS 34: 50.

Hubby, 1962, Genetics 47: 109-14.

**phenotype:** Most likely the structured gene for dihydropterin oxidase. Flies indistinguishable from wild type; dissected testis sheath dark yellow-orange, but this character is not dependable for classification; causes striking changes in compounds that fluoresce in ultraviolet light on paper chromatograms of testes. Isoxanthopterin content of testis sheath greatly reduced. No detectable dihydropterin oxidase activity (Ordoño, Silva, and Ferré, 1988, DIS 67: 63). A blue fluorescent compound not otherwise detected in *D. melanogaster* (the *lix* substance) is present. Drosopterins present in the testis sheath, and quantities of sepiapteridine, biopterin, "Compound A," and a "riboflavinlike" compound are elevated. The colored pteridine gives testis sheath its darker color. Pteridine accumulation in testis sheath alone is affected. RK3.

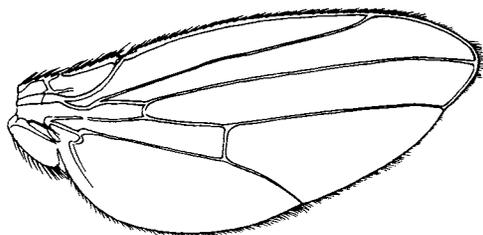

**cytology:** Placed in 7D10-F2 based on its inclusion in *Df(1)RA2 = Df(1)7D10;8A4-5* but not *Df(1)KA14 = Df(1)7F1-2;8A6* (Silva, Escriche, Ordoño, and Ferré).

Bridges, 1937, Cytologia (Tokyo, Fujii Jub., Vol. 2: 745-55.

**phenotype:** Wings narrowed at tips and slightly divergent. Eyes slightly smaller than normal and bulging; head narrow. Waddington finds wing effect detectable in middle pupal stage. RK3.

**cytology:** Placed in region between 59E2 and 60B10 on the basis of its being to the right of *In(2R)bw<sup>VDel</sup> = In(2R)41B2-C1;59E2-4* and to the left of *Df(2R)Px = Df(2R)60B8-10;60D1-2*.

**II<sup>2</sup>: lanceolate-2**

Edith M. Wallace, unpublished.

**II<sup>2</sup>****origin:** Spontaneous.**discoverer:** Bridges, 23d25.

**phenotype:** Wings pointed and narrow. Eyes small and bulging. Head narrow. Wing shape first seen in early contraction stage of wing development (23-hr pupa at

25°) (Waddington, 1939, Proc. Nat. Acad. Sci. USA 25: 303). More extreme and more useful than *II*. RK2.

*IIb*: see *l(3)89Ea***Im: limited****location:** 2-50.**origin:** Spontaneous.**discoverer:** Bridges, 29125.

**phenotype:** Sternites small, rounded, or irregular; bristles sparse. Females sterile. RK3.

**cytology:** Not included in *Df(2L)64j = Df(2L)34E5-F1;35C3-D1* (E. H. Grell).

**\*Ime: lame****location:** 1-47.8.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.**references:** 1959, DIS 33: 87.

**phenotype:** Legs weak, frequently deformed, and generally shortened as a result of reduction in length of tarsal segments. Wings atypically shaped and abnormally held. Flies so crippled they cannot move; they die soon after eclosion. RK3.

*Ime*: see *l(2)me**Lms*: see *kl-***Lobe:** see **L****loboid:** see **ld****lobula-plateless:** see **lop****lon: longevity****location:** 1-21.7.**origin:** Induced by ethyl methanesulfonate.

**references:** King, Bahns, Horowitz, and Larramendi, 1978, Int. J. Insect Morphol. Embryol. 7: 359-75.

**phenotype:** Homozygotes and hemizygotes exhibit delay in eclosion of four days; become paralyzed at nine to ten days of age and die on day eleven or twelve.

**cytology:** Distal to the breakpoint of *T(1;Y)B138*, which is in 7F6-8.

**long haired:** see **lgh****lop: lobula-plateless (J.C. Hall)****location:** 2-ca. 70.**origin:** Induced by ethyl methanesulfonate.**synonym:** *N684*.**discoverers:** Heisenberg and Fischbach.

**references:** Fischbach and Heisenberg, 1984, J. Exp. Biol. 112: 65-93.

Bülthoff and Buchner, 1985, J. Comp. Physiol. 156: 25-34.

Helfrich, 1986, J. Neurogenet. 3: 321-43.

**phenotype:** Lobula plate (third-order optic ganglion) missing most of its usual neuropile (Fischbach and Heisenberg, 1984), including an absence of most "small-field" visual neurons; but the giant fibers of this lobe remain; certain of these (*i.e.* "VS"-cells) enter the neuropile of a more peripheral lobe (the medulla), as opposed to their orthodox (more central) targets; optomotor roll and pitch responses to movements in the visual field are weak or absent. Visually mediated stimulus-specific labelling (in 2-deoxyglucose experiments) does not occur in lobula

plate, though it is normal in the mutant's lamina (first order optic lobe) and medulla (Bülthoff and Buchner, 1985). Circadian rhythms of locomotor activity are quite robust and have normal *ca.* 24 hours free-running periodicities (Helfrich, 1986).

**alleles:** One mutant allele, *lop*<sup>1</sup> (= *lop*<sup>N684</sup>).

**lot** (J.C. Hall)

**location:** 1-unlocalized.

**synonym:** *lot-235*.

**origin:** Induced by ethyl methanesulfonate.

**references:** Falk and Atidia, 1975, *Nature* 254: 325-26.

**phenotype:** Like *Lot* but non-allelic and recessive.

**Lot** (J.C. Hall)

**location:** 1-55.5 (to left of *f* between 55.5 - 56.0).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *Lot-94*.

**references:** Falk and Atidia, 1975, *Nature* 254: 325-26.

Atidia and Baker, 1974, *DIS* 51: 72.

Falk, 1979, *J. Insect Physiol.* 25: 87-91.

**phenotype:** Adults consume solutions of sodium chloride 10X more concentrated than will wild type; largely due to fact that *Lot/Lot* > *Lot/+* > *+/+* in liquid consumption; named *Lot* (Genesis 19 v 26) based on a perceived reduction in aversion to salt. Subsequently found that the amount of NaCl that had to be added to 0.1 M sucrose to switch preference from 0.1 M to 0.01 M sucrose same as wild type (Falk, 1979, *J. Insect Physiol.* 25: 87-91).

**alleles:** *Lot*<sup>1</sup>, semidominant; *Lot*<sup>r</sup> (= *Lot114*), completely recessive.

**Lsp1: Larval serum protein 1**

Genes encoding three related polypeptides that combine in random hexamers to form LSP1, a heterogenous larval serum protein of 450,000 to 480,000 daltons (Wolfe, Akam, and Roberts, 1977, *Eur. J. Biochem.* 79: 47-53). LSP1 synthesized in fat body; appears early in third instar attaining peak levels at the white prepupal stage; level begins to decline at mid-pupal stage reaching base line about four days into adult life (Roberts, Wolfe, and Akam, 1977, *J. Insect Physiol.* 23: 871-78). Highly homologous to one another and all three share amino-acid homology with LSP2. Antigenically related as well but antisera to LSP1 polypeptides do not crossreact with LSP2 (Brock and Roberts, 1980, *Eur. J. Biochem.* 106: 129-35).

**Lsp1 $\alpha$ : Larval serum protein-1  $\alpha$  chain**  
(D.B. Roberts)

**location:** 1-39.5 (27/47 of the distance from *v* to *g*).

**discoverer:** Evans-Roberts, 1977.

**references:** Roberts, Wolfe, and Akam, 1977, *J. Insect Physiol.* 23: 871-78.

McClelland, Smith and Glover, 1981, *J. Mol. Biol.* 153: 257-72.

Roberts and Evans-Roberts, 1979, *Nature* 280: 691-92.

Ghosh, Chatterje, Bunick, Manning and Lucchesi, 1989, *EMBO J.* 8: 1191-96.

**phenotype:** Codes for the  $\alpha$  polypeptide of LSP1; molecular weight 83,000 (Brock and Roberts, 1980, *Eur. J. Biochem.* 106: 129-35).

**alleles:** Electrophoretic variants isolated from natural populations: *Lsp1 $\alpha$ <sup>F</sup>*, *Lsp1 $\alpha$ <sup>SI</sup>*, and *Lsp1 $\alpha$ <sup>S2</sup>*.

**cytology:** Localized to 11A7-9 by *in situ* hybridization (Smith *et al.*). Included in *Df(1)HF368* = *Df(1)11A2;11B9* but not *Df(1)v65b* = *Df(1)9F13-10A1;11A7-8* (Roberts and Evans-Roberts).

**molecular biology:** The *Lsp1 $\alpha$*  gene has been cloned; the cloned DNA cross hybridizes to the *Lsp1 $\beta$*  and  $\gamma$  genes; encodes a 2.85 kb polyadenylated mRNA (Smith *et al.*); clone DNA partially characterized and shows that the gene has a short intervening sequence of about 50 bp 400 nucleoties from the 5' end (McClelland *et al.*). 1.5 kb at 5' end of gene sufficient for normal control of tissue and stage specificity (Yedvobnick and Levine, 1982, *Nature* 297: 239-41). Transformants carrying the bacterial *Cat* gene linked to 377 base pairs of upstream sequence from *Lsp1 $\alpha$*  express CAT with the same developmental and tissue specificity as the endogenous *Lsp1 $\alpha$*  gene (Delaney, Sunkel, Genova-Seminova, Davies, and Glover, 1987, *EMBO J.* 6: 3849-54).

**other information:** Although X-linked *Lsp1 $\alpha$*  is not dosage compensated (Roberts and Evans-Roberts); however when relocated by transformation to an autosomal site or to an ectopic site on the X, the gene does show dosage compensation (Ghosh *et al.*, 1989).

**Lsp1 $\beta$**  (D.B. Roberts)

**location:** 2-1.9 (4/28 of the distance from *al* to *dp*).

**references:** Roberts, Wolfe, and Akam, 1977, *J. Insect Physiol.* 23: 871-78.

Roberts and Evans-Roberts, 1979, *Genetics* 93: 663-79.

Smith, McClelland, White, Addison, and Glover, 1981, *Cell* 23: 441-49.

McClelland, Smith, and Glover, 1981, *J. Mol. Biol.* 153: 257-72.

Brock and Roberts, 1981, *Chromosoma* 83: 159-68.

**phenotype:** Codes for the polypeptide of LSP1 $\beta$ ; a phosphorylated polypeptide of molecular weight 80,000 (Brock and Roberts, 1980, *Eur. J. Biochem.* 106: 124-35).

**alleles:** Naturally occurring electrophoretic variants: *Lsp1 $\beta$ <sup>+</sup>* (the predominant allele), *Lsp1 $\beta$ <sup>F</sup>* and *Lsp1 $\beta$ <sup>n</sup>*, a null allele.

**cytology:** Located to 21D3-5 by *in situ* hybridization (Smith *et al.*).

**molecular biology:** The *Lsp1 $\beta$*  gene has been cloned; the cloned DNA cross hybridizes to the *Lsp1 $\alpha$*  and  $\gamma$  genes; encodes a 2.85 kb polyadenylated mRNA (Smith *et al.*); cloned DNA partially characterized; shows a short intervening sequence of about 50 bp 400 nucleotides from the 5' end of the gene (McClelland *et al.*). Transformants carrying the bacterial *Cat* gene linked to 471, but not 66, base pairs of upstream sequence from *Lsp1 $\beta$*  express CAT with the same developmental and tissue specificity as the

endogenous *Lspβ* gene (Delaney, Sunkel, Genova-Seminova, Davies, and Glover, 1987, EMBO J. 6: 3849-54).

**other information:** *Dp(2;2;2;2)S* probably carries five copies of the *Lsp1β* gene (Brock and Roberts).

### **Lsp1γ (D.B. Roberts)**

**location:** 3-1.4 (2/15 of the distance from *Dp(1;3)sc<sup>J4</sup>* to *ve*).

**references:** Roberts, Wolfe, and Akam, 1977, J. Insect Physiol. 23: 871-78.

Roberts and Evans-Roberts, 1979, Genetics 93: 663-79.

McClelland, Smith, and Glover, 1981, J. Mol. Biol. 153: 257-72.

**phenotype:** Codes for the γ chain of LSP1; a phosphorylated polypeptide of molecular weight 77,000 (Brock and Roberts, 1980, Eur. J. Biochem. 106: 129-35).

**alleles:** In addition to *Lspγ<sup>+</sup>*, four null alleles recorded: *Lspγ<sup>01</sup>*, *Lspγ<sup>02</sup>*, *Lspγ<sup>03</sup>*, and *Lspγ<sup>04</sup>*. *Lsp2<sup>F</sup>* said to be homozygous lethal (Brock and Roberts, 1980, Eur. J. Biochem. 106: 129-35).

**cytology:** Localized to 61A1 by *in situ* hybridization (Smith *et al.*); 61A1-3 (Brock); uncovered by the deficiency generated by *T(Y;3)S50* (Roberts and Evans-Roberts).

**molecular biology:** The *Lsp1γ* gene has been cloned; cloned DNA cross hybridizes to the *Lsp1α* and β genes; encodes a 2.85 kb polyadenylated mRNA (Smith *et al.*); cloned DNA partially characterized; shows short intervening sequence of about 50 bp 400 nucleotides from the 5' end of the gene (McClelland *et al.*).

### **Lsp2: Larval serum protein-2 (D.B. Roberts)**

**location:** 3-37 (3/17 of the distance from *vin* to *gv*).

**discoverer:** Akam, 1977.

**synonym:** *Pt-1, LHP*.

**references:** Hubby, 1963, Genetics 48: 871.

Roberts, Wolfe, and Akam, 1977, J. Insect Physiol. 23: 871-78.

Akam, 1977, D. Phil. Thesis, Oxford University.

Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25.

Akam, Roberts, and Wolfe, 1978, Biochem. Genet. 16: 101-19;

Lepesant, Levine, Garen, Lepesant-Kejzlarova, Rat, and Somme-Martin, 1982, J. Mol. Appl. Genet. 1: 371-83.

Paco-Larson, Nakanishi, Levine, and Garen, 1986, Dev. Genet. 7: 197-203.

Paco-Larson, Nakanishi, Levine, and Garen, 1986, Dev. Genet. 7: 197-203.

**phenotype:** Codes for LSP2, a glycosylated polypeptide of 80,000 molecular weight (Brock and Roberts, 1980, Eur. J. Biochem. 106: 129-35) and one of the major serum proteins of third-instar larvae; a homohexamer of molecular weight 450,000 with subunit molecular weight of 78-83 X 10<sup>3</sup> daltons. LSP2 appears during the third larval instar and levels increase until midway through the pupal stage; then levels decline reaching base line early in adult life. Transcription detectable only in third-instar fat body, ecdysone dependent; in presence of temperature-sensitive *ecd*, *Lsp2* transcription off at restrictive temperature; resumes following ecdysterone administration or shift to permissive temperature;

juvenile hormone blocks ecdysterone stimulation.

**alleles:** Naturally occurring alleles, *Lsp2<sup>F</sup>* and *Lsp2<sup>S</sup>*.

**cytology:** Localized to 68E3-4 by deficiency mapping (Akam *et al.* 1978); 68E by *in situ* hybridization (Lepesant *et al.*).

**molecular biology:** The *Lsp2* gene has been cloned (Lepesant *et al.*).

### **lt: light**

**location:** 2-55.0.

**references:** Bridges, 1931, Eos 7: 229-48.

de Zulueta, 1931, Eos 7: 249-53.

**phenotype:** Eye color yellowish pink-lighter at high temperature, darker at low. Ocelli colorless; Drosoterins drastically reduced; no maternal effect on eye pigmentation (Nickla, 1972, Can. J. Genet. Cytol. 14: 105-11). When combined with *st*, eye color only slightly lighter than with *lt* alone; with *bw* it is clear yellow, pinkish in old flies (Schultz and Dobzhansky, 1934, Genetics 19: 344-64; Mainx, 1938, Z. Indukt. Abstamm. Vererbungsl. 75: 256-76). Eye color autonomous in mutant optic discs transplanted into wild-type hosts (Beadle and Ephrussi, 1936, Genetics 21: 230). Larval Malpighian tubes colorless in *lt* offspring of *lt* mothers; some color in tubes if mother is *lt/+*. The quantity of yellow pigment, composed primarily of riboflavin, in Malpighian tubes exhibits parallel maternal effects in larvae, pupae, and adults (Nickla, 1972, Can. J. Genet. Cytol. 14: 391-96); the amount of such pigment increases with maternal age for both *lt/+* and *lt/lt* parental females (Nickla, 1973, Can. J. Genet. Cytol. 15: 437-42). *lt stw* homozygotes completely inviable (Purdom); however, *lt stw<sup>3</sup>* homozygotes have good viability. *car lt* double mutants are also invariably lethal; the time of death varying from the third larval instar to late pupa, depending on the number of normal alleles of either gene carried by the mother (Nickla, 1977, Nature 268: 638-339). Lethal focus of the lethal interaction as measured in *car/+; lt/lt, car/0; lt/lt* gynandromorphs is in ventral nervous tissue (Nickla, Lilly, and Brown, 1980, Experientia 36: 402-03); larval brain histologically abnormal (McCarthy and Nickla, 1980, Experientia 36: 1361-62).

**cytology:** Located in 40F; proximal to the secondary construction on 2L (Hilliker and Holm, 1975, Genetics 81: 705-21). Placed in h35 of 2L heterochromatin (Pimpinelli).

**molecular biology:** Region cloned by transposon tagging; lesions of some mutations characterized (Wakimoto).

***It*<sup>m</sup>: light mottled**

A series of X-ray induced light-variegated chromosome rearrangements (Hessler, 1958, Genetics 43: 395-403). Some have a mixture of light and wild-type ommatidia and are classified as pale; others have a mixture of wild-type and occasional darker ommatidia and are classified as dark.

allele <sup>α</sup>	phenotype	cytology
<i>It</i> <sup>m1</sup>	pale	<i>T(2,3)40B-F;63E-F</i>

<sup>α</sup> <sup>β</sup> All alleles except *It*<sup>m29</sup> and *It*<sup>m100</sup> lost (CP627). Also see data on previous *It* table.

***It*<sup>V</sup>: light variegated**

**origin:** X ray induced as part of the construction of *SM5*.  
**references:** Mislove and Lewis, 1955, DIS 29: 75.

***It*<sup>d</sup>: lightoid**

**location:** 2-{59}.

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 36d6.

**phenotype:** Eye color clear, light, translucent yellowish pink. Resembles *It* but is lighter, darkens with age. Ocelli colorless; larval Malpighian tubes colorless. Deficient in ommochrome synthesis. Lack detectable levels of 3OH kynurenine despite normal levels of kynurenine hydroxylase activity; administration of 3 hydroxykynurenine without effect (Phillips, Simmons, and Dowman, 1970, Biochem. Genet. 4: 481-87; Sullivan, Kitos, and Sullivan, 1973, Genetics 75: 651-61). Exhibits reduced levels of phenoazinone synthetase, an enzyme involved in the condensation of 3OH kynurenine molecules to xanthommatin, as do other mutants deficient in ommochrome synthesis (Phillips, Forrest, and Kulkarni, 1973, Genetics 73: 45-56). Uptake of kynurenine, which is produced in the fat body, by the Malpighian tubes, where it is converted to 3-hydroxykynurenine, is defective; similar defect seen in eye discs (Sullivan and Sullivan, 1975, Biochem. Genet. 13: 603-13). Sullivan and Sullivan postulate that *It*<sup>d</sup> is a transport mutant that prevents the substrate kynurenine from reaching the sites of its conversion to ommochrome. Phenotypic interaction with other eye-color mutants examined by Rudy and Carvalier (1971, J. Hered. 62: 131-34) and by Silva and Ménsua, 1985, DIS 61: 156); produces nearly white eyes when combined with either *rb* or *g*.

**cytology:** Placed in 44E-46E based on inclusion in *Dp(2,3)eve*<sup>1.18</sup> = *Dp(2,3)44B;46D-E*; *chrom3* (Hooper) but not in *Dp(2,3)P32* = *Dp(2,3)41A;42D-E;44C-D;-89D7-E1* (Lewis) or *Df(2R)44CE* = *Df(2R)44C;44E1-4* (Hooper).

***It*<sup>37b</sup>**

**origin:** Spontaneous.

**discoverer:** Poulson, 37b.

**references:** Poulson and King. 1948, DIS 22: 55.

**phenotype:** Eye color of newly hatched adult bright red like *v*, darkens to a color like *pr* in old flies. Ocelli colorless; larval Malpighian tubes colorless. Viability excellent. RK1.

***luc*: luckenhaft (T. Schüpbach and E. Wieschaus)**

**location:** 2-65.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect female sterile: Embryos from homozygous females form cellular blastoderms with local defects; embryos form cuticle with big holes, variable head defects and segment fusions.

**alleles:** *luc*<sup>OG</sup> = *luc*<sup>I</sup>, *luc*<sup>QA</sup>, *luc*<sup>RN</sup>

***Lvp*: Larval visceral protein**

Three genes that are clustered in an 8 kb segment of DNA and lie 11 kb from the second-chromosome *Lcp* gene cluster (Snyder and Davidson, 1983, J. Mol. Biol. 166: 101-18). The order of the genes is *LvpH*--1.7kb--*LvpD*--1.1kb--*LvpL*, with *LvpH* being closest to the *Lcp* cluster. *LvpH* and *LvpL* are transcribed off of the same

strand as *Lcp1* and *Lcp2*, and *LcpD* off of the same strand as *Lcp3* and *Lcp4*. Three genes are completely sequenced and are 50-60% homologous in DNA sequence; they encode polypeptides of approximately 500 amino acids, which contain apparent signal peptide sequences but lack hydrophobic regions indicating that they are secreted rather than being membrane proteins; each has a sequence of 12 amino acids similar to known calcium binding domains of other proteins. The genes are coordinately transcribed in abundance in young larvae and adults, but not in late larvae when *Lcp* genes are transcribed; whereas *Lcp* genes are transcribed in the larval cuticle, *Lvp* transcripts are found in the larval viscera. The time and place of *Lvp* transcription suggests a possible digestive function of the gene products.

locus	genetic location	cytological location	comments
<i>LvpD</i>	2-59.4	44D	353 bp intron at 1322-1323
<i>LvpH</i>	2-59.4	44D	
<i>LvpL</i>	2-59.4	44D	62 bp intron at 145-146

### *lxd*: low xanthine dehydrogenase

**location:** 3-34.5.

**references:** Keller and Glassman, 1964, *Genetics* 49: 663-68.

1964, *DIS* 39: 61.

Schott, Baldwin, and Finnerty, 1986, *Biochem. Genet.* 24: 509-27.

**phenotype:** Homozygotes exhibit little or no activity of four molybdenum hydroxylases, *i.e.*, 25% normal levels of xanthine dehydrogenase (XDH) activity (Keller and Glassman), 12% normal aldehyde oxidase (AO) activity (Courtright, 1967, *Genetics* 57: 25-39), no pyridoxal oxidase (PO) (Keller and Glassman) and 5-10% normal levels of sulfite oxidase (SO) (Bogaart and Bernini, 1981, *Biochem. Genet.* 19: 929-46) (2% according to Schott, Baldwin and Finnerty). Residual activity of AO and XDH thermolabile (Schott, Baldwin and Finnerty). These reduced activities not accompanied by comparable reductions in the levels of crossreacting material (CRM) indicating that the structural genes for the enzymes are still being expressed (Glassman, Shinoda, Duke, and Collins, 1968, *Ann. N.Y. Acad. Sci.* 151: 263-73; Browder, Wilkes, and Tucker, 1982, *Biochem. Genet.* 20: 111-24 and 125-32; Warner, Watts, and Finnerty, 1980, *Mol. Gen. Genet.* 180: 449-53). *lxd*<sup>+</sup> postulated to be involved in production of an enzyme cofactor (Glassman *et al.*, 1968); dietary molybdenum shown to increase specific activity of AO and XDH in flies homozygous for some, but not all, *lxd* alleles (Duke, Rushing, and Glassman, 1975, *Biochem. Genet.* 13: 53-64). *lxd* homozygotes shown to have only 10% normal molybdenum cofactor activity (Schott, Baldwin, and Finnerty). Tungsten, a known antagonist of molybdenum cofactor, shown to mimic *lxd* in wild type (Warner and Finnerty, 1981, *Mol. Gen. Genet.* 184: 92-96) and to exacerbate the effects of *lxd* (Bentley, Williamson, and Oliver, 1981, *Can. J. Genet. Cytol.* 23: 597-609). The maternal effects of *cin* and *mal* are suppressed in *cin lxd* and *mal lxd* offspring of *cin*<sup>+</sup> and *mal*<sup>+</sup> mothers respectively; dietary molybdenum counteracts the suppression; *lxd* also suppresses complementation between various pairs of partially complementing *mal* alleles (Courtright, 1975,

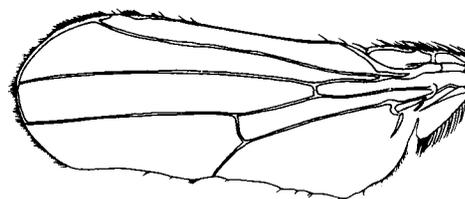

*Mol. Gen. Genet.* 142: 231-38). Dietary tungsten produces brown eye color in *lxd* flies, which normally have red eyes; used to select new *lxd* alleles (Bentley, Williamson, and Oliver); allopurinol used in the same way (Schott, Baldwin, and Finnerty).

**alleles:** All alleles non complementing.

### Ly: Lyra

From Bridges and Brehme, 1944, *Carnegie Inst. Washington Publ. No. 552*: 118.

### Ly: Lyra

**location:** 3-40.5.

**origin:** X ray induced.

**discoverer:** Dubinin, 1929.

**references:** Coyne, 1935, *DIS* 4: 59.

Morgan, Bridges, and Schultz, 1937, *Year Book - Carnegie Inst. Washington* 36: 301.

**phenotype:** Lateral margins of wings excised, giving narrowed shape; angle between veins L2 and L5 reduced. Bristles shortened and stubby; postscutellars frequently missing. Eyes somewhat deformed with tufted vibrissae. Abdomen dark and narrow with rear edge of tergites raised. Homozygous lethal. *Ly/Df(3L)M69E* is lethal. Modification of wings first visible as marginal scalloping of prepupal wing buds; wing fold narrower (Waddington, 1939, *Proc. Nat. Acad. Sci. USA* 25: 304; 1940, *J. Genet.* 41: 75-139). RK1A.

**alleles:** *Ly*<sup>2</sup> like *Ly*<sup>1</sup> but with rougher eyes; spontaneous (Waddle, 1977, DIS 52: 3). Associated with same deficiency as *Ly*<sup>1</sup> (Zhimulev and Feldman, 1982, DIS 58: 152).

**cytology:** Placed in 70A3-5 on the basis of its association with *Df(3L)Ly = Df(3L)70A2-3;70A5-6* (Bridges).

**lys: lysine**

**location:** 2-22.9.

**origin:** Spontaneous.

**discoverer:** E. H. Grell, 1957.

**references:** 1960, DIS 34: 50. 1961, Genetics 46: 925-33.

**phenotype:** Larvae, pupae, and adults contain a higher concentration of lysine than wild type. Accumulation of lysine is postulated to result from block in its degradation. Flies homozygous for *lys* occasionally have faintly reddish fat cells, especially in thorax. This effect enhanced by starvation, by combining *lys* with *rc*, *rc*<sup>2</sup>, or *cho*. RK3.

**lz: lozenge**

**location:** 1-27.7.

**references:** Gottschowski, 1936, Zool. Anz. Suppl. 9: 586-91.

Clayton, 1958, Genetics 43: 261-73 (fig.).

Clayton, 1959, Genetics 44: 1041-52 (fig.).

**phenotype:** Many alleles with a wide range of phenotypes. Homozygous males have eyes size variably reduced and often ovoid in shape. Surface with fused facets producing a roughened glistening appearance (= glossy), or smooth with pigment either uniformly distributed or concentrated at periphery of the eye (= spectacle). Eye pigment variably reduced, and Malpighian tubes slightly lighter than normal (Brehme and Demerec, 1942, Growth 6: 351-56). Tarsal claws reduced to different extents by different alleles. Spermathecae and parovaria (= accessory glands) often missing in homozygotes with abnormal parovaria seen in some heterozygous females (Anderson, 1945). Females often sterile, but sterility appears to be primarily an ovarian defect, since some genotypes which lack parovaria and spermathecae are female fertile. Some alleles lack the class of hemocytes called crystal cells, or at least lack the crystalline inclusions of those cells; the inclusions can be shown to comprise prophenoloxidase, and flies lacking crystal cells are deficient in phenol oxidase activity and suppress the phenotype of *Bc*. Five of fifteen alleles tested (*lz*<sup>36f17</sup>, *lz*<sup>46</sup>, *lz*<sup>D</sup>, *lz*<sup>rf8</sup>, and *lz*<sup>s</sup>) suppress *Bc* and lack crystal cells and phenol oxidase activity (Rizki and Rizki, 1981, Genetics 97: s90); postulated that *lz*<sup>+</sup> crucial to differentiation of crystal cells, and is not a structural gene for any of the five phenol oxidase moieties. Peeples, Geisler, Whitcraft, and Oliver report defective phenol oxidase

activity in *lz*<sup>8</sup> (1969, Biochem. Genet. 3: 563-69) *lz*<sup>64j</sup>, *lz*<sup>66c</sup>, *lz*<sup>s</sup>, and *lz*<sup>y4</sup>, but not in *lz*<sup>50e</sup>, or *lz*<sup>K</sup> (1969, Genetics 62: 161-70); Warner, Grell, and Jacobson (1974, Biochem. Genet. 11: 359-65) found no phenol oxidase activity in *lz*<sup>rf8</sup>, but normal levels in *lz*<sup>1</sup> and *lz*<sup>8</sup>.

<sup>γ</sup> More detailed phenotype description below.

**cytology:** Placed in 8D8-9 (Lefevre, 1976, Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66).

**other information:** The *lz* region has been subdivided into four recombinationally separable groups of alleles (Green and Green, 1949, Proc. Nat. Acad. Sci. USA. 35: 586-91; 1956, Z. Indukt. Abstamm. Vererbungsl. 87: 708-21); recombination is observed between but not within groups. Not all alleles have been mapped. The total genetic length of the region is 0.14 cM. Double mutants produced by recombination all have the extreme phenotype of *lz<sup>s</sup>*. Mitotic exchange between *lz<sup>36</sup>* and *lz<sup>y4</sup>* reported by Tokunaga (1973, Mol. Gen. Genet. 125: 109-18).

### *lz<sup>1</sup>*

**origin:** Spontaneous; contains gypsy insert (Modolell, Bender, and Meselson, 1983, Proc. Nat. Acad. Sci. 80: 1678-82).

**discoverer:** Bridges, 16b12.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 230.

Green and Green, 1956, Z. Induktive Abstammungs-Vererbungsl. 87: 708-21.

**phenotype:** Eye narrower than wild type and ovoid. Irregular facets in some areas cause rough patches; areas of fused facets appear as smooth patches. Eye color appears normal but, in combination with *st*, slight reduction in red pigment detectable. Tarsal claws reduced. Developmental study by Waddington and Pilkington (1942, DIS 16: 70) shows failure of middle cell layer of optic disk to penetrate between cells of outer layer; surface thus covered with primary pigment cells. Females sterile. Parovaria and spermathecae absent; some *lz/+* females have abnormal parovaria (Anderson, 1945, Genetics 30: 280-96). Suppressed by *su(f)<sup>6</sup>* (Schalet, 1970, Genen. Phaenen 14: 16-17), *su(Hw)<sup>2</sup>*, *e(w<sup>e</sup>)<sup>s</sup>*, and *su(pr)<sup>e3</sup>*; enhanced by *su(s)<sup>3</sup>* and *su(w<sup>a</sup>)* (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97). Phenol oxidase activity increased from 17% to 71% normal (Snyder and Smith, 1976, Biochem. Genet. 14: 611-17). RK1.

### *lz<sup>3</sup>*

**phenotype:** Eye size sharply reduced; surface smooth. Optic disk of mature larva and prepupa two-thirds normal size (Chen, 1929, J. Morphol. 47: 135-99). Red pigment greatly reduced; color yellowish brown, cream colored in combination with *v*. Tarsal claws vestigial. Homozygous females lack parovaria and spermathecae and are sterile; *lz<sup>3</sup>/+* females lack parovaria and many have abnormal spermathecae [Anderson, 1945, Genetics 30: 280-96 (fig.)]. Unaffected by *su(f)<sup>6</sup>* (Schalet, Snyder, and Smith, 1976, Biochem. Genet. 14: 611-17). RK1.

### *lz<sup>34</sup>*

**phenotype:** Eye phenotype intermediate between *lz* and *lz<sup>3</sup>*. Surface of eye has large areas of fused facets with a few normal facets (Clayton, 1957, Genetics 42: 28-41); eye color dark red with small yellowish spots. Larval Malpighian tubes slightly lighter than normal; variable (Brehme and Demerec, 1942, Growth 6: 351-56). Tarsal claws reduced. Spermathecae and parovaria absent from homozygous females, which accumulate stage 14 oocyte and are quite infertile; some *lz<sup>34</sup>/+* females have abnormal parovaria (Anderson, 1945, Genetics 30: 280-96). Eye effect, but not other aspects of phenotype, enhanced by *spa<sup>e(lz)</sup>*; eye converted from a glossy to a spectacle phenotype (Beeson and Bender, 1975, J. Exp. Zool. 193: 177-90). In the presence of *su(lz<sup>34</sup>)*, *lz<sup>34</sup>* flies have virtually normal eyes. Beeson and Bender were unable to confirm previous observations of Bender and Green (1960, Genetics 45: 1563-66) that *su(lz<sup>34</sup>)* increases the fecundity of *lz<sup>34</sup>* females. Unaffected by *su(f)<sup>6</sup>* (Schalet) or *su(Hw)<sup>2</sup>*; however suppressed by *su(pr)* and enhanced by *su(s)* and *su(w<sup>a</sup>)* (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97). RK1.

### *\*lz<sup>35</sup>*

**phenotype:** Eyes reduced and diamond shaped; color opaque brown. Homozygous females sterile. *lz<sup>35</sup>/lz* females fertile. RK1.

**lz<sup>37</sup>**

**phenotype:** Eye size reduced. Areas of irregular facets in posterior region of eye; eye color normal. Enhanced by *su(f)*<sup>6</sup> (Schalet, 1970, Genen. Phaenen 14: 16-17); also enhanced by *su(Hw)*<sup>2</sup> and *su(s)* (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, Genetics 119: 391-97). Phenol oxidase level decreased from 94% to 58% of normal (Snyder and Smith, 1976, Biochem. Genet. 14: 611-17). RK1.

**lz<sup>48f</sup>**

**origin:** Induced by mustard gas.  
**discoverer:** Lindsley, 48f.  
**references:** Green and Green, 1956, Z. Indukt. Abstamm. Vererbungsl. 87: 708-21.  
**phenotype:** Unaffected by *su(f)*<sup>6</sup> (Schalet).

**\*lz<sup>49h</sup>**

**phenotype:** Eye size sharply reduced; surface smooth; red pigment distributed over entire eye. Tarsal claws normal. Spermathecae and parovaria present and normal in females, which are fertile. Complements all *lz* alleles tested except *lz*<sup>50e</sup>.

**lz<sup>50e</sup>**

**phenotype:** Like *lz*<sup>49h</sup>. Eyes reduced in size and almond shaped; no indication of facets; covered with indentations, giving a pock-marked appearance. Hairs on eye surface sparse or absent; eye surface glossy with many large black or brown flecks. Tarsal claws normal. Females fertile; spermathecae and parovaria present and normal. *lz*<sup>50e</sup>/*lz* has normal eyes except for a few flecks. Complements most other *lz* alleles except *lz*<sup>49h</sup>, *lz*<sup>52c</sup>, and those associated with rearrangements or deficiencies. Unaffected by *su(f)*<sup>6</sup> (Schalet). RK1.

**\*lz<sup>52c</sup>**

**origin:** Recovered among progeny of male fed H<sub>3</sub>BO<sub>3</sub> and exposed to thermal neutrons.  
**phenotype:** Eyes mottled, yellowish brown, darker at rim; facets fused. Males semisterile with missing tarsal claws, although pulvilli and endopodia normal. Third antennal segment slightly reduced. *lz*<sup>52c</sup>/*lz*<sup>50e</sup> females resemble *lz*<sup>50e</sup>. RK1.

**\*lz<sup>59</sup>**

**phenotype:** Eyes reduced in size and ovoid; facets fused; surface slightly rough and almost or completely hairless; color light brown with darker, slightly reddish rim; almost colorless in combination with *v*. Tarsal claws practically absent as in *lz*<sup>cl</sup>. Males sterile, (possibly associated with X-autosome translocation), transmit no motile sperm to females; therefore, homozygous females not observed. *lz*<sup>59</sup>/*lz*<sup>37</sup> females intermediate between the two mutants in eye phenotype, have reduced tarsal claws, and are weakly fertile. RK2.

**lz<sup>61f</sup>**

**phenotype:** Facets completely fused; eye color dark, but pigment unevenly distributed and concentrated at margin. Females found to be fertile by Burdicks, but were sterile when studied by Schwalm, Bender, and Klinge (1970, DIS 45: 91) who studied the ultrastructure of eggs produced by homozygous females. *lz*<sup>61f</sup>/*lz* females more nearly normal than either mutant; facets disrupted and fused only in posterior third of eye; also fertile. RK1.

**lz<sup>63</sup>**

**phenotype:** Eye shape oval; color brown, darkest at margin; surface smooth and glossy. Viability and fertility of both sexes good. RK1.

**lz<sup>63f</sup>**

**phenotype:** Eye size moderately reduced; surface smooth; color brownish with darker margin. Tarsal claws and pulvilli strongly reduced. Spermathecae and parovaria absent; female reproductive capability strongly reduced. *lz*<sup>63f</sup> complements *lz*<sup>50e</sup> but not *lz*<sup>34</sup>, *lz*<sup>D</sup>, or *lz*<sup>61f</sup> (Klingele). Spermathecal number of *lz*<sup>63f</sup>/*lz*<sup>K</sup> 0-3. RK1.

**lz<sup>71a</sup>**

**phenotype:** Phenol oxidase activity severely reduced; further reduced in presence of *su(f)* (Snyder and Smith), 1976, Biochem. Genet. 14: 611-17.

**\*lz<sup>cl</sup>: lozenge-clawless**

**origin:** Appeared as a male from an ovary treated *in vitro* with CuSO<sub>4</sub>.  
**phenotype:** Eyes narrow and small without facets; surface has rough spots; color amber, both pteridines and ommochromes affected, darker at rim. Tarsal claws absent. Third antennal segment reduced; sensilla on antennae abnormal. Phenotype similar in both sexes. Females infertile and lack spermathecae and parovaria. Autonomous in transplants. RK1.

**lz<sup>D</sup>: lozenge-Dominant**

**phenotype:** Males and homozygous females resemble *lz*<sup>S</sup>. Heterozygous females sometimes have roughened eyes. Apparent dominance shown by H. Bender to be caused by the presence of *spa*<sup>el(z)</sup>; heterozygous expression additionally enhanced by presence of *In(2LR)bw*<sup>V1</sup>.

**lz<sup>g</sup>: lozenge-glossy**

**phenotype:** Eyes smaller than wild type; surface glossy from fused facets; a few normal facets also present; color dark blood red, bright red in combination with *st* or *v*. Larval Malpighian tubes slightly lighter than normal (Brehme and Demerec, 1942, Growth 6: 351-56). Tarsal claws reduced. Spermathecae and parovaria absent from homozygous females, which have reduced fertility; *lz*<sup>g</sup>/*+* females tend to have abnormal parovaria [Anderson, 1945, Genetics 30: 280-96 (fig.)]. RK1.

**other information:** *lz*<sup>g</sup>/*lz*<sup>S</sup> provided probably the first recorded case of intra-allelic recombination (Oliver, 1940, Proc. Nat. Acad. Sci. USA 26: 452-54; 1940, DIS 13: 73).

**\*lz<sup>gl</sup>: lozenge-glued**

**phenotype:** Eyes of male reduced and roughened like *Gl*; color dark; female eyes somewhat less extreme. *lz*<sup>gl</sup>/*lz* intermediate between *lz*<sup>gl</sup> and *lz* and sterile. Homozygous females fertile. RK1.

**lz<sup>K</sup>: lozenge of Krivshenko**

**synonym:** *amx*<sup>55</sup>: *almondex-55*; *lz*<sup>k</sup>.

**phenotype:** Eyes narrow and moderately rough; facets irregular; eyes of homozygous females more nearly normal than those of males. Tarsal claws normal. Females fertile; spermathecae and parovaria present. Interactions of *lz*<sup>K</sup> with other *lz* alleles described by Green [1961, Genetics 46: 1169-76 (fig.)]. Unaffected by *su(f)*<sup>6</sup> or *su(Hw)*<sup>2</sup>; however suppressed by *su(pr)* and enhanced by *su(s)* and *su(w<sup>a</sup>)* (Rutledge, Mortin, Schwarz, Thierry-

Mieg, and Meselson, 1988, *Genetics* 119: 391-97). RK1.

**\**lz<sup>M58</sup>*: lozenge of Meyer**

**phenotype:** Eyes small and oval; surface glossy; color brownish. Tarsal claws missing. Homozygous females moderately fertile, although spermathecae absent; *lz<sup>M58</sup>/lz<sup>s</sup>* also fertile. RK1.

***lz<sup>s</sup>*: lozenge-spectacled**

**phenotype:** Eye size reduced, narrower than normal; no true facets; whole eye has glossy surface; color yellow-brown with darker rim, creamy in combination with *v*. Tarsal claws vestigial. Homozygous females lack spermathecae and parovaria and are sterile. *lz<sup>s</sup>/+* females tend to have abnormal parovaria (Anderson, 1945, *Genetics* 30: 280-96). RK1.

**other information:** *lz<sup>s</sup>/lz<sup>s</sup>* provided probably the first recorded case of intra-allelic recombination (Oliver, 1940, *Proc. Nat. Acad. Sci. USA* 26: 452-54; 1940, *DIS* 13: 73).

***lz<sup>y4</sup>*: lozenge in yellow-4**

**phenotype:** Similar to *lz<sup>s</sup>* but eye color redder. Homozy-

gous females lack spermathecae and parovaria and are sterile; *lz<sup>y4</sup>/+* females have abnormal parovaria and tend to lack spermathecae and parovaria (Anderson, 1945, *Genetics* 30: 280-96). RK1.

*lz-l*: see *rstl*

**\**lzl*: lozengelike**

**location:** 1-11.

**discoverer:** Oliver, 29k24.

**references:** 1935, *DIS* 3: 28.

**phenotype:** Eyes rough. Both sexes fertile. RK3.

**other information:** Possibly an allele of *rg* (1-11.0).

Many spontaneous reversions of *ovo<sup>DI</sup>* result in a phenotype similar to that originally reported for *lzl* (Busson, Gans, Komitopoulou and Masson, 1983, *Genetics* 105: 309-25; Oliver, Perrimon, and Mahowald, 1987, *Genes Dev.* 1: 913-23; Mével-Ninio, Mariol, and Gans, 1989, *EMBO J.* 8: 1549-58). The *lzl* alleles derived from the *ovo<sup>DI</sup>* chromosome are characterized by rough or glazed eyes. All alleles are semidominant and cold sensitive. These mutations are likely to be new alleles of *lzl*. This cannot be tested as the original *lzl* allele was lost.

**m: miniature**

From Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237.

**m: miniature**

location: 1-36.1

**phenotype:** Wing size reduced, only slightly longer than abdomen and with normal proportions. Angle between L2 and L5 reduced. Wings dark gray and less transparent than normal. Wing cells smaller than normal (Dobzhansky, 1929, Arch. Entwicklungsmech. Organ. 115: 363-79). In poor cultures, wings may become divergent and stringy. Cell expansion inhibited in prepupae and pupae [Waddington, 1940, J. Genet. 41: 75-139 (fig.)]. Different *m* mutants complement slightly; *m/dy* is wild type.

RK1.

<sup>β</sup> More complete description below.

**cytology:** Placed in 10E1-2 by Lefevre [Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 31-66].

**other information:** The miniature-dusky region has been subdivided into four recombinationally separable sites (Dorn and Burdick, 1962, Genetics 47: 503-18).

***m*<sup>D</sup>: miniature-Dominant**

**phenotype:** Wings of homozygote smaller than *m/m*. *m*<sup>D</sup>/<sub>+</sub> wings intermediate between homozygote and wild type. Viability 20-50% normal in males and 5% in homozygous females; most die in embryo. Fertility low in homozygous females. Wing size of *m*<sup>D</sup>/*m* and *m*<sup>D</sup>/*dy* intermediate between *m*<sup>D</sup>/<sub>+</sub> and *m*<sup>D</sup>/*m*<sup>D</sup>. RK2.

***m*<sup>I</sup>: miniature-intermediate**

**origin:** Stable spontaneous derivative produced repeatedly by *m*<sup>μ</sup>.

**phenotype:** Wing length intermediate between that of *m*<sup>μ</sup> and wild type. Resembles *dy*<sup>73</sup> but complements *dy*<sup>73</sup> and is mutant in combination with *m*<sup>μ</sup>. Phenotype more extreme in combination with *Df(1)m-fw*.

***m*<sup>K</sup>: miniature of Krivshenko**

**phenotype:** Variegated-type position effect; enhanced by *In(2LR)Rev<sup>B</sup> = In(2LR)40;52C-E*; *In(1)m<sup>K</sup> = In(1)10E;20B*; in turn enhances *Rev<sup>B</sup>* (Wargent and Hartmann-Goldstein, 1974, Heredity 33: 317-26).

***m<sup>μ</sup>***

**origin:** A spontaneous derivative of *dy*<sup>73</sup>, which was accompanied by reversion of *dy*<sup>73</sup>.

**phenotype:** A strong allele that mutates at an inordinately high rate, both germinally and somatically, to two different states, *m<sup>i</sup>* and *m<sup>s</sup>*.

***m<sup>s</sup>*: miniature-subliminal**

**origin:** Stable spontaneous derivative produced repeatedly by *m<sup>μ</sup>*.

**phenotype:** Hemizygotes, homozygotes, and heterozygotes with *dy*<sup>73</sup> are wild type. In heterozygous combination with either *m<sup>μ</sup>* or *Df(1)m-fw* displays a *dy*-like phenotype.

**M: Minute**

Minutes are a class of genes, which, when the wild-type allele is present in hemizygous condition (not including X-linked Minutes in males), produce a characteristic phenotype consisting of short slender bristles and delayed development. That is, heterozygotes for deficiencies or loss of function alleles of these loci exhibit the Minute phenotype. Many of the early Minutes were mapped crudely, and those with similar map positions were seldom tested for complementation. As most of these Minutes have long since been lost, experimental establishment of allelism is not possible. Furthermore the results of deficiency analysis are also ambiguous; a Minute phenotype of a deficiency heterozygote indicates the presence of "at least one," not "only one" *M* gene. Given these uncertainties, tentative designations of allelism have been made, with the caveat that complementation tests have not or cannot be done. Furthermore inviability of *trans* heterozygotes does not invariably indicate allelism (Moscoso del Prado and Ripoll, 1983, Genet. Res. 42: 59-63). The existence of a Minute locus more frequently inferred from the phenotype of a deficiency heterozygote than a point mutant. Trans-acting suppressors turn out to be duplications of the locus on the *M<sup>+</sup>* homologue (Schultz, Baker, 1972, DIS 49: 59; Broderick and Roberts, 1982, Genetics 102: 71-74). Phenotype of flies heterozygous for two different Minutes no more extreme than that of the more extreme mutant of the combination (Schultz, 1929, Genetics 14: 366-419); however, see *M(3)65F* and *M(3)69E*. Homozygotes and hemizygotes for mutant alleles are late embryonic or early larval lethals (reviewed by Wright, 1970, Adv. Genet. 15: 262-85). *M/+* triploids are normal in phenotype, whereas *M/M+* triploids are lethal (Schultz). Heterozygotes often display secondary effects such as small body size, large and somewhat rough eyes, missing arista, thin-textured wings with tendency to plexus venation, missing bristles (usually postverticals), and low fertility, especially in females. The developmental delay exhibited by *M/+* individuals is attributable to increased cell cycle times compared to that of wild type; this feature is autonomous such that *+/+* cells produced by mitotic exchange in an *M/+* fly proliferate more rapidly than the surrounding cells, leading to increased size of *M<sup>+</sup>* clones, and facilitating ascertainment of mitotic recombination events (Morata and Ripoll, 1975, Dev. Biol. 42: 211-21); this observation was interpreted by Stern (1936, Genetics 21: 625-730) as increased incidence of somatic crossing over in the *M*-bearing chromosome arm of *M/+* flies. Overgrowth of *M<sup>+</sup>* clones

used extensively in somatic genetic studies of development. Most Minutes enhance dominance of such venation characters as *px* and *net* or of such bristle characters as *sc*. Dominant lethal effects are frequent, in combination with *Dl*, *J*, and occasionally *D*. At least one Minute locus shown to encode a ribosomal protein (Kongsuwan, Yu, Vincent, Frisardi, Rosbash, Lengyel, and Merriam, 1985, Nature 317: 555-58), and presumably most if not all the others do as well. A consequent reduction in the rate of protein synthesis is postulated to lengthen the cell cycle and to limit the rate of bristle elaboration, which is postulated to require maximum rates of synthesis (Atwood).

Since many Minute loci have been named according to the lettered subdivision of the polytene map to which they have been localized, this revision attempts to standardize that mode of designation for all confirmed loci. Further restriction of designations to single lettered subdivisions should accompany revised localizations.

*m-like*: see *dy*<sup>31d</sup>

*M-pro*: see *T(1;4)M-pro*

**M(1)**

The following table summarizes the Minute loci inferred to exist on the X chromosome on the basis of the phenotypes of females carrying mutations or deficiencies. The loci included are confirmed; others that have been claimed, but not confirmed are included among the entries that follow the table.

locus	genetic location	cytological location	included in	excluded from	synonym	ref <sup>α</sup>

Res. 163: 115-44; 6 = Schultz, 1929, Genetics 14: 366-419; 7 = Scott, 1987, Ph.D. Thesis, University of California at San Deigo; 8 = Voelker.

**M(1)1B**

**discoverer:** Patterson.

**synonym:** *Vi: Viability*.

**references:** 1932, Z. Indukt. Abstamm. Vererbungsl. 60: 125-36.

**phenotype:** Heterozygous deficiency for locus is extreme Minute of low viability. In Patterson's work, the nonappearance of Minutes led him to postulate a factor for viability (*Vi*). Eclosion delayed 76 hr (Ferrus, 1975, Genetics 79: 589-99). RK3A.

**alleles:** Single ethyl-nitrosourea-induced mutant allele recovered by Voelker in a screen for lethals in the vicin-

ity of *su(s)*. Lethality occurs between the first larval instar and pupation (Eberl, Hilliker, and Voelker, 1988, DIS 67: 36).

**molecular biology:** Both the recessive lethality of *M(1)1B<sup>B46</sup>* and the Minute phenotype of *Df(1)su(s)83* are rescued by a *P*-element transformant containing a 10 kb fragment of genomic DNA from immediately to the left of the *su(s)* gene. *M(1)1B* function is apparently encoded by a ~3.5 kb message (Voelker, Huang, Wisely, Sterling, Bainbridge, and Hiraizumi, 1989, Genetics 122: 625-42).

**cytology:** Associated with the *X<sup>P</sup>2R<sup>D</sup>* element of *T(1;2)Blid = T(1;2)1C3-4;60B12-13* when the *2R<sup>P</sup>X<sup>D</sup>* element is replaced by a normal second chromosome.

***M(1)3E: Minute (1) in region 3E***

**location:** 1-{5}.

**discoverer:** Demerec, 1938.

**references:** Demerec, Kaufman, Fano, Sutton, and Sansome, 1942, Year Book - Carnegie Inst. Washington 41: 191.

**phenotype:** Identified on basis of slight Minute phenotype, barely distinguishable from wild type, associated with deficiencies that include region 3E. RK3A.

**cytology:** Found and located in salivary chromosome bands 3E3-4 on the basis of slight *M* phenotype of females heterozygous for *Df(1)N264-76 = Df(1)3B4-C1;3E4-5* and non-*M* phenotype of females heterozygous for *Df(1)N264-38 = Df(1)2D3-4;3E2-3* and *Df(1)N264-117 = Df(1)3A6-7;3E2-3*. Also identified in a segmental deficiency scan of the *X* by Merriam and colleagues.

***M(1)4BC: Minute (1) in region 4BC***

**location:** 1-{6,8}.

**discoverer:** Demerec, 1938.

**references:** Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book - Carnegie Inst. Washington 41: 191.

**phenotype:** Strong Minute; easily distinguishable from wild type. RK2A.

**cytology:** Inferred to be in salivary gland chromosome region 4B5 through 4C6 on the basis of extreme *M* phenotype of females heterozygous for *Df(1)N<sup>264-73</sup> = Df(1)3C3-4;4C6-7* versus slight *M* phenotype [*M(1)3E*] of *Df(1)N<sup>264-42</sup> = Df(1)3C4-5;4B4-6*. However, no minute phenotype observed in a segmental - deficiency scan of 3F through 4F by Merriam and Colleagues. As *M(1)4BC* was inferred only deficiencies including both 3E and 4BC, perhaps deficiency for 4BC acts as an enhancer of *M(1)3E*; however Merriam and colleagues fail to report such an enhancement.

***M(1)5A***

**phenotype:** Identified by extreme Minute phenotype and very low viability of segmental deficiencies for 5A6-13.

**other information:** Possibly the same as the lost *M(1)30*, a spontaneous deficiency, which included *cv* at 5B, recovered by Schultz (1929, Genetics 14: 366-419).

***M(1)5D6A***

**other information:** Considered the same as the lost spontaneous Minute, *M(1)30* (CP627; Lefevre, 1973, Cold Spring Harbor Symp. Quant. Biol. 38: 591-99; Merriam *et al.*); *M(1)30* was associated with *Df(1)M30*, which included *cv* at 5B.

***M(1)8F***

**origin:** Spontaneous.

**phenotype:** Readily classified Minute found between *lz* and *v* (Schalet, 1986, Mutat. Res. 163: 115-44).

**cytology:** Since the proximal breakpoint of *Df(1)lz5*, which is *M<sup>+</sup>*, is listed as 8F-9A (CP627), and the cytology of another *M<sup>+</sup>* deficiency *Df(1)C52* is listed as *Df(1)8F3-9D6* (Mason, Green, Shaw, and Boyd, 1981, Mutat. Res. 81: 329-43), *M(1)8F* is probably located at 8F1-2 (Schalet, 1986).

***M(1)11F***

**phenotype:** Identified on the basis of the slightly finer bristles and protracted development of *Df(1)C246/+* females (Craymer and Roy, 1955, DIS 55: 204).

**other information:** Tentatively equated to *M(1)k* by Craymer and Roy; however, genetic map position of *M(1)k* discordant with cytological position of *Df(1)C146*; also *M(1)k* described as strong Minute.

***M(1)14C***

**origin:** Spontaneous.

**phenotype:** Moderate Minute.

**cytology:** Located in the 14B13 to 14D1-2 interval since allelic to *Df(1)r75c = Df(1)14B13;15A9* but not to *Df(1)r-D1 = Df(1)14D1-2;15D1-2* (Schalet, 1986, Mutat. Res. 163: 115-44).

***M(1)15D***

**phenotype:** Eclosion delayed 35 hr (Ferrus, 1975, Genetics 79: 589-99).

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>
<i>M(1)15D<sup>1</sup></i>	spont	Bridges, 24B24	<i>M(1)o</i>	1
<i>M(1)15D<sup>2</sup></i>	spont	Spencer, 32i28	<i>M(1)o<sup>Sp</sup></i> <i>M(1)Sp</i>	1, 2, 3

<sup>α</sup> 1 = CP627; 2 = Spencer, 1935, DIS 3: 28; 3 = Spencer, 1937, DIS 7: 14.

***M(1)18C***

**phenotype:** Heterozygous females have Minute bristles. Lethal in males. Viability and fertility low. Pupation delayed about 42 hr at 25° (Brehme). Wing cells smaller than normal (Brehme, 1941, J. Exp. Zool. 88: 135-60). RK2.

### M(2)

Fifteen second-chromosome Minute loci considered to be well established and localized are tabulated below; additional information provided in entries that follow the table. Several described Minutes that are less well established are also included among the subsequent entries.

locus	genetic location	cytological location	included in	excluded from	synonym	ref <sup>α</sup>

### M(2)21AB

**location:** 2-0.0 (3.8 cm to the left of *shv*).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *Su(z)5*.

**references:** Persson, 1976, Hereditas 82: 57-62.

1977, DIS 52: 1.

**phenotype:** Body size and bristles reduced in heterozygotes; irregular facets in upper half of eye. Heterozygous females virtually sterile at temperatures above 18°; surviving offspring frequently have missing legs or halteres, somewhat narrowed wings, and reduced bristles. Homozygotes lethal. Selected on the basis of a dominant suppressor of *zeste* phenotype. Characterized by relatively frequent reversions of all features of the phenotype save homozygous lethality. One such revertant found to be deficient for the tip of *2L*, suggesting a gain of function rather than haplo insufficiency as the nature of the mutation (Kennison).

**cytology:** Salivary-gland chromosomes appear normal. Placed in 21A-B on the basis of complementation by *M(2)21AB* of *Df(2L)al*, *Df(2L)S2*, and *Df(2L)S3*, the recovery of 0/196, 0/284, and 0/642 recombinants with *net*, *al*, and *ex*, respectively, and a position 3.8 cM from *shv*; complements *l(2)gl*.

### M(2)21C

**phenotype:** Identified by virtue of the extreme Minute phenotype of *Df(2L)al/+*.

### M(2)24F

**phenotype:** Medium Minute with good characteristics.

About two days delay in puparium formation (Dunn and Mossige, 1937, Hereditas 23: 70-90). RK2.

**alleles:** Three alleles are listed in the following table.

allele	origin	discoverer	synonym	ref <sup>α</sup>
<b>M(2)24F<sup>1</sup></b>	spont	Schultz	<i>M(2)z</i>	2
<b>M(2)24F<sup>2</sup></b>	X ray	Green	<i>M(2)z G1</i>	1
<b>M(2)24F<sup>3</sup></b>	X ray	Green	<i>M(2)z G2</i>	1

<sup>α</sup> 1 = Persson, 1977, DIS 52: 1; 2 = Schultz, 1929, Genetics 14: 366-419.

### \*M(2)25C

**origin:** X ray induced.

**discoverer:** Schultz, 33a12.

**phenotype:** Small-bristled Minute with heavy body. Classification good. Viability and fertility fairly good. RK2.

*M(2)29*: see *M(2)56F*

**M(2)30A**

**location:** 2-40.5 [based on cytological position immediately to the left of *J*(2-41); originally mapped to 46±5].

**phenotype:** *M(2)30A*<sup>1</sup> is a medium Minute with delayed hatching. 50% of females and 10% of males show abnormal abdomen effect. Most females sterile and remainder produce few progeny. RK3(A).

**alleles:** Four presumptive alleles, but no complementation studies done. Allelism based on similarity of genetic positions of *M(2)30A*<sup>1</sup> = 46±5, *M(2)30A*<sup>2</sup> = 43, and *M(2)30A*<sup>3</sup> = 46±5; also both *M(2)30A*<sup>1/+</sup> and *M(2)30A*<sup>4/+</sup> described as female sterile.

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<b>*M(2)30A</b> <sup>1</sup>	spont	Bridges, 20b25	<i>M(2)e</i>	2	moderate allele
<b>*M(2)30A</b> <sup>2</sup>	spont	Bridges, 24i16	<i>M(2)t</i> , <i>M(2)e</i> <sup>1</sup>	1	weak allele
<b>M(2)30A</b> <sup>3</sup>	X ray	Schultz, 34k21	<i>M(2)S11</i> , <i>M(2)e</i> <sup>S</sup>	1	moderate allele
<b>M(2)30A</b> <sup>4</sup>	X ray	Sandler	<i>M(2)fs</i>	3	

<sup>α</sup> 1 = CP627; 2 = Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 231; 3 = Sandler, 1977, Genetics 86: 567-82.

**cytology:** Placed in 30A based on inclusion in *Df(2R)J4* = *Df(2R)31A-B;31F-32A*, but not in *Df(2R)J2* = *Df(2R)31B;32A*. Also distal to the breakpoint of *T(Y;2)LS2* = *T(Y;2)30F-31A*.

**other information:** Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero (1972, Genetics 71, 157-84) placed *M(2)e* in 28D-29F, where reexamination of the data suggests no *M* locus exists; their *M(2)LS3* presumably corresponds to *M(2)e* = *M(2)30A*.

*M(2)33a*: see *Df(2R)M60E*

**M(2)36F**

**phenotype:** Medium to strong Minute. Eclosion of heterozygous deficiency delayed 30 hr (Ferrus, 1975, Genetics 79: 589-99).

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<b>*M(2)36F</b> <sup>1</sup>	spont	Bridges, 23g12	<i>M(2)m</i>	1, 2	strong Minute
<b>*M(2)36F</b> <sup>2</sup>	spont	Schultz, 24i28	<i>M(2)m</i> <sup>S</sup> , <i>M(2)s</i>	1, 4	medium Minute
<b>*M(2)36F</b> <sup>3</sup>	X ray	Schultz, 33b3	<i>M(2)m</i> <sup>S13</sup> , <i>M(2)S13</i>	1	strong Minute
<b>M(2)36F</b> <sup>4</sup>	X ray	Green	<i>M(2)m</i> <sup>G</sup>	3	
<b>M(2)36F</b> <sup>5</sup>	X ray	Green	<i>M(2)H</i> <sup>G</sup>	3	

<sup>α</sup> 1 = CP627; 2 = Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 231; 3 = Persson, 1977, DIS 52: 1; 4 = Schultz, 1929, Genetics 14: 366-419.

**cytology:** Originally assigned its present chromosomal position on the basis of its extreme phenotype and that of the combination *Df(2L)G/Dp(2;Y)H* plus its genetic map position estimated to be 2-54 by Bridges, even though the appropriate complementation tests not performed. Allelisms inferred from similarities in genetic map positions: *M(2)36F*<sup>2</sup> = 54.5; *M(2)36F*<sup>3</sup> = 50; *M(2)36F*<sup>3</sup> complemented by *Dp(1;Y)G*, but not by *Dp(1;Y)H*; *M(2)36F*<sup>4</sup> fails to complement *Df(2L)M36-56* and *M(2)36F*<sup>5</sup> fails to complement *Df(2L)M36F-S5*.

*M(2)38b*: see *M(2)44C*

**M(2)39F**

**phenotype:** Originally identified on the basis of the weak Minute phenotype of heterozygotes for the *Df(2L)H* segregant from *Tp(2;Y)H* = *Tp(2;Y)37B1-2;40B2-3*.

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>
<b>*M(2)39F</b> <sup>1β</sup>	X ray	Schultz, 33a9	<i>M(2)H</i> <sup>S5</sup> , <i>M(2)SS</i>	1, 2
<b>M(2)39F</b> <sup>2γ</sup>	X ray	Schultz, 33b7	<i>M(2)H</i> <sup>S12</sup> , <i>M(2)S12</i>	1

<sup>α</sup> 1 = CP627; 2 = Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85.

<sup>β</sup> Originally complemented *M(2)36F*; current stocks labelled *M(2)H*<sup>S5</sup> do not; they are *Df(2L)M36F-S5* (Wright, Hodgetts, and Sherald, 1976, Genetics 84: 267-85).

<sup>γ</sup> Allelism inferred from weak phenotype and inseparability from *pr*.

**\*M(2)40c**

**location:** 2-65±5.

**origin:** Spontaneous.

**discoverer:** Ives, 40c.

**references:** 1941, DIS 14: 39.

**phenotype:** Medium Minute with probable eye effect. RK2.

**cytology:** Crossing over normal. Genetic map position of 65±5 places *M(2)40c* in the vicinity of *vg*. Tentatively placed in the region deleted by the segmental deficiency formed from *T(Y;2)D19* and *T(Y;2)G53* [= *Df(2R)48E;50A*] [Pasztor, 1976, Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 185-206]; this region encroached upon from the right by *Df(2R)vgC* = *Df(2R)49B2-3;49E1-F1*, which has no Minute phenotype, thus restricting the tentative position of *M(2)40c* to 48E-49B.

**alleles:** Besides the original allele, a second allele, *M(2)40c*<sup>2</sup> (= *M(2)40c*<sup>G</sup>), tentatively identified as an allele by genetic map position, X ray induced by Green (Persson, 1977, DIS 52: 1).

**M(2)41A**

**phenotype:** Medium Minute. Originally identified by virtue of Minute phenotype of *Df(2R)M41A10*; most recurrences shown to be deficiencies. Eclosion of heterozygous deficiency delayed 13 hr (Ferrus, 1975, Genetics 79: 589-99).

**alleles:** Formerly listed alleles of *M(2)41A* known to be deficiencies by virtue of failing to complement mutants in adjacent loci are listed with the deficiencies.

allele	origin	discoverer	synonym	comments
<b>M(2)41A</b> <sup>1</sup>	X ray	Schultz, 33a	<i>M(2)S2</i> <sup>3</sup> , <i>M(2)S3</i>	no <i>b-pr</i> recombination
<b>M(2)41A</b> <sup>2</sup>	X ray	Schultz, 32k31	<i>M(2)S2</i> <sup>9</sup> , <i>M(2)S9</i>	

**cytology:** Placed in 41A, *i.e.*, in the proximal heterochromatin of 2R, based on the normal polytene configuration but reduced amount of heterochromatin at the base of 2R in ganglion prophase figures of *Df(2R)M41A10*.

**M(2)44C**

**phenotype:** Extreme Minute with small bristles and compact body. Viability varies with modifiers. *M(2)44C/stw* is non-*stw*; *M(2)44C/M(2)p* is viable. RK3.

**cytology:** Tentatively placed in 44C based on its genetic

map position, and the Minute phenotype of the segmental deficiency between *T(Y;2)B26* and *T(Y;2)H136* [= *Df(2R)43E-F;44C*], but not of *Df(2R)cn9* = *Df(2R)42E;44C*.

**alleles:** *M(2)44C*<sup>1</sup> is the original spontaneous allele isolated by Curry (33b18); a second allele, *M(2)44C*<sup>2</sup> X ray induced by Green (Persson, 1977, DIS 52: 1).

*M(2)47*: see *M(2)56F*

*M(2)50J*: see *Df(2R)M41A50J*

*M(2)51*: see *M(2)56F*

### *M(2)53*

**origin:** X ray induced (occurred as a mosaic).

**discoverer:** Schultz, 33a2.

**phenotype:** Bristles very small; arista often reduced; venation plexus like. Ecloses 24 hr late (Ferrus, 1975, Genetics 79: 589-99). Viability about 70% of wild type and variable. Fertility good. RK2.

**cytology:** Salivary chromosomes apparently normal.

**other information:** May be the same as *RpA1*.

### *M(2)56CD*

**phenotype:** Bristles extremely small. Abnormal abdomen effects in 90% of females and 40% of males. RK2.

**other information:** The first Minute found in chromosome 2.

### *M(2)56F*

**phenotype:** Moderate Minute; expression enhanced when heterozygous to *l(2)56Fb*; enhances expression of *cp* (Schultz, 1929, Genetics 14: 366-419) and suppresses extra-sex-comb phenotype of *Msc* and *Pc* (Sinclair, Suzuki, and Grigliatti, 1981, Genetics 97: 581-606).

**alleles:** Identified through recovery of *M(2)56F*<sup>1</sup>, which although cytologically normal fails to complement mutant alleles that complement each other, *l(2)56Fa*, *l(2)56Fb*, and *M(2)56F*; accordingly *M(2)56F*<sup>1</sup> considered a deficiency [*Df(2R)173*]. *M(2)56F*<sup>4</sup> and *M(2)56F*<sup>5</sup> lethal in combination with *Df(2R)017* and *Df(2R)173*, but survive as homozygotes exhibiting Minute-like bristles; enhance Minute phenotype when heterozygous to other *M(2)56F* alleles and to each other, except that *M(2)56F*<sup>4</sup> and *M(2)56F*<sup>7</sup> complement.

### *M(2)58F*

**phenotype:** Identified by the strong Minute phenotype of *Df(2R)M58F*. Heterozygosity for null allele as represented by the deficiency characterized by a two-day delay in eclosion (at 25°) owing to delay in puparium formation (Dunn and Mossige, 1937, Hereditas 23: 745-55); delay 19 hr according to Ferrus (1975, Genetics 79: 589-99). Eyes somewhat rough; veins often show plexus; abdominal sclerites often abnormal; ocelli often reduced. Viability 80-90% wild type and fertility low. Presumed mutant allele, *M(2)58F*<sup>1</sup>, displays 13 hr delay in puparium formation at 25° (Brehme, 1939, Genetics 24: 131-61); slight delay in time of second larval molt. Viability, fertility, and classification excellent. Homozygote lethal in first larval instar.

**alleles:** *M(2)58F*<sup>1</sup> (formerly *M(2)l'* or *M(2)l*<sup>2</sup>), spontaneous with apparently normal polytene chromosomes, Schultz (26a7); *M(2)58F*<sup>2</sup>, γ ray induced, with Minute phenotype suppressed by *SM5*, as if this Minute lies within the 58B-F segment duplicated in *SM5* (Kennison: *M* located between *Pu*<sup>2</sup> and *Pin*<sup>B</sup>).

### *M(2)60E*

**phenotype:** Fairly strong Minute; slow development; good viability and fertility [description based on *Df(2R)M60E* = *Df(2R)60E2-3;60E11-12*]. Eclosion of *Df(2R)M60E/+* delayed 49 hours (Ferrus, 1975, Genetics 79: 589-99).

**M(3)65F**

**origin**: X ray induced.

**discoverer**: Schultz, 33a12.

**phenotype**: Extreme Minute with fine bristles and small body. RK3.

**other information**: Considered to be allelic to *M(3)69E* [*M(3)h* in CP627] on the basis of lethality of the *trans* heterozygote; however, Moscoso del Prado and Ripoll (1983, Genet. Res. 42: 59-63) demonstrated that the two Minutes occupy different cytological positions, thus rendering fallible the rule that double Minute genotypes are no more severe in phenotype than the more severe member of the pair, and suggesting some caution in concluding allelism based on lethality of *trans* heterozygotes.

**M(3)67C**

**phenotype:** Moderate alleles have good heterozygous viability; extreme alleles very late eclosing [45 hr according to Ferrus (1975, Genetics 79: 589-99)] with poor viability, and females usually sterile. Viability further reduced in presence of *su(f)* alleles (Girton, Langer, Cejka, 1986, Roux's Arch. Dev. Biol. 195: 334-37).

**alleles:** Most assignments of allelism based on map positions in the vicinity of 3-30; *M(3)67C*<sup>4</sup> through *M(3)67C*<sup>7</sup> assigned on the basis of complementation results (Moscoso del Prado, 1983, Genet. Res. 42: 59-63; Persson, 1977, DIS 52: 1).

<sup>β</sup> Tentative assignments; these two recessive lethal alleles fail to complement each other, and *M(3)67C*<sup>9</sup> fails to complement *M(3)67C*<sup>4</sup>.

**M(3)69E**

**phenotype:** Moderate alleles have good viability and fertility; puparium formation delayed two days (Dunn and Mossige, 1937, Hereditas 23: 70-90; Ferrus, 1975, Genetics 79: 589-99). Extreme alleles have low viability, flimsy or waxy wings with plexus effects along vein L2 and at posterior crossvein; eyes may be small and rough.

**alleles:** *M(3)69E*<sup>4</sup> and *M(3)69E*<sup>5</sup> both lethal in *trans* heterozygotes with *M(3)69E*<sup>1</sup>, but see *M(3)66A*; allelism of *M(3)69E*<sup>2</sup> and *M(3)69E*<sup>3</sup> inferred from genetic map positions. *Df(3L)M69E* considered an allele in CP627.

**M(3)76A**

**origin:** X ray induced.

**discoverer:** Schultz, 33a6.

**phenotype:** Slight Minute; overlaps wild type; in existing lines bristles appear normal, but recessive lethal effect at 44.3 remains. RK3.

**M(3)80**

**synonym:** *M(3)Q-III*, *M(3)LS4 Q-III*.

**phenotype:** Originally identified by virtue of the Minute

phenotype of the segmental deficiency for 79E5 to the chromocenter. An EMS-induced temperature-sensitive allele recovered and described by Sinclair, Suzuki, and Grigliatti (1981, Genetics 97: 581-606). Heterozygotes raised at 22° normal in phenotype; those raised at 29° display small bristles, rough eyes, prolonged developmental time, reduced viability, and interact with several unrelated mutations; at 29° but not at 22°, in the presence of *M(3)80/+*, *vg/+* and *cp/+* exhibit reduced viability and incomplete wing margins; enhances *J<sup>34e</sup>/+*, *Ly/+*, *Dfd/+*, and *DI<sup>D</sup>/+* such that they are lethal or weakly viable; also suppresses extra-sex-comb phenotypes of *PC* and *Msc*. These effects are similar to those shown by other minutes at all temperatures. The temperature sensitive periods of these effects reflect the time of action of the modified genes (Sinclair, Grigliatti, and Kaufman, 1984, Genet. Res. 43:257-75). *M(3)80* homozygotes reared at 22° display moderate small bristle and rough eye phenes, as well as prolonged development; homozygotes lethal when reared at 29°. Homozygous females fertile, but switching to 29° blocks egg production; males at 22° are poorly fertile and become sterile upon switching to 29°. Temperature-pulse experiments yield a number of abnormal phenotypes which differ depending on the stage and duration of the pulse; described by Sinclair *et al.*

**other information:** As there is apparently but a single mutant allele, we designate it *M(3)80*<sup>1</sup>, sinking to synonymy the specific designation *Q-III*, used by the authors. May be the same as *Rp21*.

**M(3)82BC**

**origin:** X ray induced.

**discoverer:** Schultz, 33a3.

**phenotype:** Extreme Minute with small body. Low viability and fertility. RK3.

**M(3)85E**

**other information:** Identified by virtue of the Minute phenotype of the segmental deficiency produced between *T(Y;3)G42* and *T(Y;2)L17* [*Df(3R)85E2-4;86A*] and equated to *M(3)S31* (Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84). *M(3)S31* subsequently shown to lie in 86D (Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91), and this Minute deficiency mapped to 85E2-F1 and renamed *M(3)LS5* (Kempthues, Raff, and Kaufman, 1983, Genetics 105: 345-56).

**M(3)86D**

**phenotype:** Fine-bristled Minute with medium viability. RK3.

**other information:** Identified by virtue of Minute phenotype of *Df(3R)M86D = Df(3R)86D1;86D4*; no mutant alleles identified. This Minute erroneously designated *M(3)S35* (Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84).

**M(3)95A**

**phenotype:** Strong Minute; eclosion delayed 40 hours (Ferrus, 1975, Genetics 79: 589-99).  
**alleles:**

**cytology:** Placed in 95A1 by Broderick and Roberts and in 94D-E by Vässin.

**M(3)96A**

**phenotype:** Heterozygotes for *3<sup>P</sup>Y<sup>D</sup>G73 Y<sup>P</sup>3<sup>D</sup>H173* display slender bristles; viability and developmental time, however, normal.

**M(3)96C**

**phenotype:** Medium Minute of excellent viability. Eclosion delayed 31 hr (Ferrus, 1975, Genetics 79: 589-99). *M(3)96C<sup>2</sup>* reported to show plexus effect along vein L2 and at posterior crossvein. RK2.

**alleles:** Allelism based on similarity of genetic map positions which put *M(3)96C<sup>1</sup>* at 87± and *M(3)96C<sup>2</sup>* at 84.5.

**M(3)96CF**

**phenotype:** Extreme Minute; very small bristles; late eclosing; females sterile or of very low fertility; males have fair viability and fertility. *M(3)96CF<sup>2</sup>* described as having broad wings with plexus of veins and somewhat abnormal abdominal bands.

**alleles:** Allelism of *M(3)96CF<sup>1</sup>* and *M(3)96CF<sup>2</sup>* inferred from genetic map positions of 90.2 and 90±10, respectively.

<sup>α</sup> 1 = Spencer, 1937, DIS 7: 14.

**M(3)99B**

**origin:** Spontaneous.

**discoverer:** Bridges, 19b8.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 206-7 (fig.).

**phenotype:** Bristles slender and shorter than wild type. Somewhat late hatching. Heterozygous deficiency for *M(3)99B* also displays rough eyes and slightly plexate

wings (Kongsuwan, Dellavalle, and Merriam, 1986, Genetics 112: 539-50). RK2.

**other information:** First Minute found.

**M(3)99D**

**phenotype:** Identified by the phenotype of heterozygotes for a synthetic deficiency; no mutant alleles identified. Strong Minute; small bristles, slightly abnormal wings; eclosion delayed two to three days (Kongsuwan, Dellavalle, and Merriam, 1986, Genetics 112: 539-50). *M(3)99D/+* females produce smaller than normal eggs; 10-15% of embryos fail to hatch often displaying fusion and partial deletion of segments posterior to A3 (Kongsuwan, Yu, Vincent, Frisardi, Rosbash, Lengyell, and Merriam, 1985, Nature 317: 555-58).

**molecular biology:** Encodes the large ribosomal subunit 49. Transformants carrying 2.1 kb of upstream and 0.6 kb of downstream sequence in addition to the entire coding sequence of *rp49* suppress the mutant phenotype, including the maternal effect, of heterozygous deficiencies for *M(3)99D* (Kongsuwan *et al.*, 1985).

**M(3)99E**

**phenotype:** Identified by virtue of moderate Minute phenotype of heterozygotes for a synthetic deficiency (Kongsuwan, Dellavalle, and Merriam, 1986, Genetics 112: 539-50).

**other information:** Designated *M(3)j* by Kongsuwan, Dellavalle, and Merriam, despite the fact that *M(3)j* was originally recorded as having a strong phenotype. Localized just proximal to the segmental deficiency for 99F-100B designated by Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero (1972, Genetics 71: 157-84) as deleting *M(3)j<sup>+</sup>*; Kongsuwan *et al.* found no Minute phenotype associated with deficiencies for that region. Most likely *M(3)j* corresponded to a mutant or deficiency for *M(3)99D* or *M(3)100CF*, both of which are recorded as having strong Minute phenotypes. The description of heterozygotes for deficiencies for *M(3)99E* correspond more closely to that for *M(3)g*.

**M(3)100CF**

**phenotype:** Identified by virtue of the strong Minute phenotype of heterozygotes for terminal deficiency for the region distal to 100C; very few escapers (Kongsuwan, Dellavalle, and Merriam, 1986, Genetics 112: 539-50). Reuter, Dorn, Wustmann, Friede, and Rauh (1986, Mol. Gen. Genet. 202: 481-87) describe *su(var)3-12*, which maps to 3-100.2, is associated with a Minute, and is deficient for 100F3-5.

**other information:** The distal segment of *3R* tentatively associated with a Minute by Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero (1972, Genetics 71: 157-84) on the basis of their failure to recover terminal deficiencies and the published genetic position of *M(3)g* at 3-106.2; Kongsuwan, Dellavalle, and Merriam (1986, Genetics 112: 539-50) followed suit, placing *M(3)g* distal to *M(3)j*; however, phenotypic considerations suggest the allelic correspondences presented in the table of third-chromosome Minutes.

Several Minute mutations in the third chromosome that

were never located and are no longer available are tabulated below:

mutant	origin	discoverer	ref <sup>α</sup>	comments

### **M(4)101**

**location**: 4-0.

**references**: Hochman, 1974, Cold Spring Harbor Symp. Quant. Biol. 38: 581-89.

**phenotype**: Medium Minute; viability good; development protracted; eclosion delayed 33 hr (Ferrus, 1975, Genetics 79: 589-99). *M(4)101/++* triplo-fours are non-Minute (Mohr, 1933, Hereditas 17: 317-32). Homozygous mutants die in embryonic stage (Farnsworth, 1951, Genetics 36: 550). RK2.

**alleles**: Formerly designated alleles nearly all deficiencies; only *M(4)101<sup>57g</sup>* has normal polytenes and fails to uncover mutations in neighboring loci (Hochman, Gloor, and Green, 1964, Genetics 35: 109-26).

**cytology**: Placed in 101F2-102A5 on the basis of *Df(4)M101-63a = Df(4)101F2-101A1;101A2-5* (Hochman).

*M(B)*: see *su(B)*

***m(Est6)*: modifier of Esterase 6**

location: 3-56.7.

origin: Spontaneous.

synonym: *m-est*, *M-est*.

references: Cochrane, 1976, Genetics 83: s16.

Cochrane and Richmond, 1979, Biochem. Genet. 17: 167.

phenotype: Two alleles; the dominant allele arbitrarily designated *m(Est6)*<sup>+</sup>. *m(Est6)* decreases the electrophoretic mobility of the products of some alleles, but not of others. Also modifies leucine amino peptidase, but not twelve other tested enzymes. Thought to change charge rather than conformation. Evidence that sialylation not involved.

*M(g)*: see *e(g)*

***M(G6PD)*: Modifier of Glucose 6 Phosphate Dehydrogenase**

location: 1-65.

origin: Spontaneous.

synonym: *M*<sup>Zw</sup>.

references: Komma, 1968, Biochem. Genet. 1: 229-37.

phenotype: A dominant modifier of the electrophoretic mobility of G6PD encoded by both *Zw*<sup>A</sup> and *Zw*<sup>B</sup>. Mobility faster in presence of *M(G6PD)* than in *M(G6PD)*<sup>+</sup> homozygotes.

*m(GPDH)*: see *r(αGPDH)*

***M(Sd)*: Modifier of *Sd***

location: 2-57 (right of *Rsp*; near *cn*).

origin: Spontaneous.

references: Hiraizumi, Martin, and Eckstrand, 1980, Genetics 95: 693-706.

phenotype: Enhances segregation distortion in genotypes heterozygous for *Sd*, *M(Sd)*, and *Rsp*<sup>s</sup>; not the same as *E(Sd)*. Causes high levels of male infertility in genotypes that are heterozygous for *Sd* and *M(Sd)* and homozygous for *Rsp*<sup>s</sup>; those males that are fertile produce very few offspring.

***ma*: maroon**

location: 3-49.7.

origin: Spontaneous.

discoverer: Bridges, 12c13.

references: 1918, Proc. Nat. Acad. Sci. USA 4: 316-18.

Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 53 (fig.).

phenotype: Eye color dull ruby, approaching wild type with age; classification slow. Larval Malpighian tubes pale yellow (Beadle, 1937, Genetics 22: 587-611). Eye color autonomous in transplant into wild-type host (Beadle and Ephrussi, 1936, Genetics 21: 230). Wild-type levels of aldehyde oxidase and xanthine dehydrogenase activity (Hickey and Singh, 1982, DIS 58: 74.)

alleles: *ma*<sup>49</sup>, spontaneous (Oftedal, 1951, DIS 25: 69). RK2.

**\**Ma*: *Ma dominigene***

location: 1- (not located).

origin: Spontaneous.

discoverer: Goldschmidt, 1935.

references: Gardner, 1942, Univ. Calif. (Berkeley) Publ. Zool. 49: 95.

phenotype: In combination with *Ma*, *vg/+* is strongly scalloped. RK3.

***mab*: malformed abdomen**

location: 3- {47}.

phenotype: Tergites and sternites show defects in cuticle.

Homozygous viable at 18° (wild-type) and 25° (mutant); lethal at 28° (Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81).

allele	origin	discoverer	synonym	ref <sup>α</sup>
<i>mab</i> <sup>1</sup>	EMS	R. Lewis	<i>Ebmab</i> <sup>1</sup>	1, 2

***mah*: mahogany**

location: 3-88.

discoverer: Beadle, 36b26.

references: Beadle and Ephrussi, 1937, Am. Nat. 71: 91-95.

phenotype: Eye color translucent brown in young flies, changing toward wild type and becoming dark brown with age. Eyes contain 77% normal red pigment and 102% normal brown pigment (Nolte, 1955, J. Genet. 53: 1-10). Larval Malpighian tubes wild type in color (Beadle, 1937, Genetics 22: 587-611). RK3.

***mal*: maroonlike**

location: 1-64.8 (Schalet, 1963, DIS 38: 82).

references: Chovnick, Finnerty, Schalet, and Duck, 1969, Genetics 62: 145-60.

Finnerty, Duck, and Chovnick, 1970, Proc. Nat. Acad. Sci. USA. 65: 939-46.

**phenotype:** Brownish eye color resulting from reduction in the red (drosoperin) pigments. Larval Malpighian tubes short, bloated, irregularly formed, and contain yellow to orange pteridine globules (Schwinck, 1960, DIS 34: 105). *mal* is nonautonomous for eye color in mosaics with wild-type tissue (Glassman, 1957, DIS 31: 121-22) and in transplants of *mal* eyes into wild-type hosts (Ursprung, 1961, Z. Vererbungsl. 93: 119-25). Activities of three molybdo-enzymes reduced or absent: aldehyde oxidase = AO (Courtright, 1967, Genetics 57: 25-39), pyridoxal oxidase = PO (Forrest, Hanley, and Lagowski, 1961, Genetics 46: 1455-63), and xanthine dehydrogenase = XDH (Forrest, Glassman, and Mitchell, 1956, Science 124: 725-26; Glassman and Mitchell, 1959, Genetics 44: 153-62). Measurements of cross reacting material (*e.g.*, Browder, Wilkes, and Tucker, 1982, Biochem. Genet. 20: 111-24, 125-32) show 75% and 50% normal levels of AO CRM in larval hemolymph and adult extracts respectively and 105% normal level of XDH CRM (see also Warner, Watts, and Finnerty, 1980, Mol. Gen. Genet. 180: 449-53). Activity of a fourth molybdo-enzyme, sulfite oxidase, is unaffected by *mal* (Bogart and Bernini, 1981, Biochem. Genet. 19: 929-46). Furthermore, unlike mutants in genes thought to be involved with the function of molybdenum cofactor, *e.g.* *cin* and *lxd*, the effects of *mal* not alleviated by administration of molybdenum; XDH cross reacting material (CRM) isolated from *mal* flies contains molybdenum (Andres, 1976, Eur. J. Biochem. 62: 591); *mal* flies contain high levels of molybdenum cofactor by Neurospora nitrate reductase activation assay (Warner and Finnerty, 1981, Mol. Gen. Genet. 184: 72-96). Accumulation of enzyme substrates (Forrest, Glassman, and Mitchell, 1956; Glassman and Mitchell, 1959; Glassman and McLean, 1962, Proc. Nat. Acad. Sci. USA 48: 1712-18) may account for the reported increase in uricase activity (Friedman, 1970, Genetics 68: s22). The absence of XDH activity renders *mal* flies sensitive to exogenously supplied purine (Glassman, 1965, Fed. Proc. 24: 1243), which has been used in selective schemes (Finnerty *et al.*, 1970); the cell autonomy of *mal* with respect to AO activity provides the basis of a staining procedure for differentiating *mal* from *mal*<sup>+</sup> tissue in mosaics (Janning, 1972, Naturwissenschaften 59: 516-17). *mal* offspring of *mal*<sup>+</sup> mothers appear normal in both eye color and Malpighian-tube morphology (Glassman and Mitchell, 1959; Schwinck, 1960); *mal*<sup>+</sup> activity observed in germ line as AO activity (Marsh and Wieschaus, 1977, Dev. Biol. 60: 396-403) and maternally inherited XDH activity in *mal* offspring detectable until second day of pupal stage (Browder and Williamson, 1976, Dev. Biol. 53: 241-49). Maternal effect suppressed if offspring are also homozygous for *lxd* (Courtright, 1975, Mol. Gen. Genet. 142: 231-38). Interallelic complementation in females of constitution *mal*<sup>1</sup>/*mal*<sup>F1</sup>; eye color and Malpighian-tube morphology appear normal, but XDH activity about 10% normal (Glassman and Mitchell, 1959; Schwinck, 1960); complementation not seen in flies raised at 29° and reduced in flies that are also homozygous for *lxd* (Courtright, 1975, Mol. Gen. Genet. 142: 231-38); physical properties of XDH and AO altered in different heteroallelic combinations (Finnerty, McCarron, and Johnson, 1979, Mol. Gen. Genet. 172: 37-43; Finnerty and Johnson, 1979, Genetics

91: 696-722). *mal*<sup>1</sup>, *mal*<sup>F1</sup>, and *mal*<sup>F3</sup> complement for eye color in all pairwise combinations; however, *mal*<sup>F1</sup>/*mal*<sup>F3</sup>/*mal*<sup>1</sup> is mutant. *mal* and *ry* extracts complement to produce XDH activity (Glassman, 1962, Proc. Nat. Acad. Sci. USA 48: 1491-97); they do not complement intercellularly *in vivo*, however, since reciprocal eye-disk or Malpighian-tube transplants reported to behave autonomously with respect to drosoperin formation (Schwinck, 1960; 1963, DIS 38: 87).

<sup>β</sup> Complementation groups for eye color.

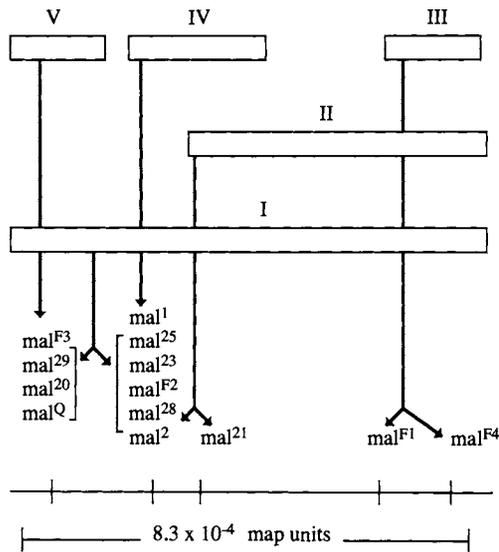

<sup>γ</sup> *mal*<sup>F1</sup> does not complement *mal*<sup>1</sup> when kept at 29°-30° throughout development; complementation occurs provided development proceeds at 25° during either of the two critical periods: the third quarter of the third larval instar or the middle of the pupal stage (Schalet, 1971, Mol. Gen. Genet. 110: 82-85).

<sup>δ</sup> CB3007 = DL-p-N,N-di-(2-chloroethyl)aminophenylalanine. CB3025 = L-p-N,N-di-(2-chloroethyl)aminophenylalanine. CB3051 = ?

**cytology:** Placed in 19D2-3 based on its inclusion in the region of overlap of *Df(1)16-2-19 = Df(1)19A5;19D3* and *Df(1)16-3-35 = Df(1)19D2-3;19E34*.

**other information:** The alleles of *mal* have been mapped both by complementation for eye color and by recombination. Five complementation units have been defined (Chovnick, Finnerty, Schalet, and Duck, 1969, Genetics 62: 145-60), and *mal*<sup>C2</sup> said to define a sixth (Bentley and Williamson, 1982, Can. J. Genet. Cytol. 24: 11-17). There is but a single lethal complementation group in

heteroallelic combinations raised on purine-enriched medium. Recombinational mapping utilized purine sensitivity to select for *mal*<sup>+</sup> recombinants (Finnerty *et al.*, 1970). Maps co-linear.

Complementation map of *mal* alleles (groups I to V above) compared to genetic map; relative positions of mutants in each complementation group with respect to genetic map indicated (modified from Duck and Chovnick, 1974, *Genetics* 79: 459-66). Program by D. Conner.

**Mal: Malformed**

**location:** 2-44-50 (between *stw* and *cn*; Bridges inferred two loci, one near right end of 2R and one on chromosome 4).

**origin:** Spontaneous.

**discoverer:** Steinberg, 36k13.

**references:** 1937, *DIS* 7: 15, 20.

Baker and Tsai, 1977, *Dev. Biol.* 57: 221-25 (fig.).

**phenotype:** Heterozygote has either malformed pit in middle of eye or, more often, nick at front edge of eye and has bristle- or antenna-like outgrowth; outgrowth determined to be mirror image duplication of part of the orbital region including the orbital and fronto-orbital bristles; several sequential duplications sometimes observed. Penetrance low in heterozygote; supposedly enhanced by addition of extra brewer's yeast to medium. Homozygote shows larger nick and antennal outgrowth with up to 100% expression in *pr Mal* stock. RK3.

**mam: master mind (J.C. Hall)**

**location:** 2-70.3.

**synonym:** *N-2G*.

**references:** Lehmann, Dietrich, Jiménez, and Campos-Ortega, 1981, *Wilhelm Roux's Arch. Dev. Biol.* 190: 226-29.

Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, *Roux's Arch. Dev. Biol.* 192: 62-74.

Campos-Ortega, 1985, *Trends Neurosci.* 8: 245-50.

Smoller, Friedel, Schmid, Bettler, Lam and Yedvobnick, 1990, *Genes Dev.* 4: 1688-1700.

**phenotype:** Homozygous embryonic lethal; embryos display neural hyperplasia with compensatory epidermal hypoplasia; caused by failure of most ventral ectodermal cells to differentiate as epidermal cells rather than neuroblasts, as seen in *N*, *amx*, *bib*, *neu*, *Dl*, and *E(spl)*; *mam* tends to have less extreme neural hyperplasia than mutants at the other neurogenic loci. A similar diversion of cells from epidermigenic into neurogenic pathways seen to generate supernumerary peripheral nerve cells (Hartenstein and Campos-Ortega, 1986, *Roux's Arch. Dev. Biol.* 195: 210-21 (fig.)). When *mam* expressed in female germ cells and the ensuing embryos, neural hyperplasia is enhanced, but *mam*<sup>+</sup> embryos from oocytes are normal [Jiménez and Campos Ortega, 1982, *Roux's Arch. Dev. Biol.* 191: 1901-201 (fig.)]. Homozygous clones in the eye display irregular ommatidial pattern characterized by lack of interommatidial bristles, enlarged facets with supernumerary retinular cells and reduced numbers of pigment cells; in the cuticle, clones homozygous for *mam*<sup>2</sup> are devoid of bristles [Dietrich and Campos-Ortega, 1984, *J. Neurogenet.* 1: 315-32 (fig.)]. *mam*<sup>1</sup> (formerly *N-2G*) heterozygotes occasionally exhibit apical wing nicking; not recorded for other alleles. Phenotype of homozygotes for null allele reduced by duplications for normal alleles of other neurogenic loci, *N*, *neu*, *Dl*, *E(spl)*, and *H*, but not *amx* or *bib* (de la Concha, Dietrich, Weigel, and Campos-Ortega, 1988, *Genetics* 118: 499-508).

<sup>α</sup> 1 = Dietrich and Campos-Ortega, 1984, J. Neurogenet. 1: 315-32; 2 = Hartenstein and Campos-Ortega, 1986, Roux's Arch. Dev. Biol. 195: 210-21; 3 = Ives, 1943, DIS 17: 50; 4 = Ives, 1957, DIS 31: 83; 5 = Jiménez and Campos-Ortega, 1982, Roux's Arch. Dev. Biol. 191: 191-201; 6 = Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, Roux's Arch. Dev. Biol. 192: 162-74; 7 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Roux's Arch. Dev. Biol. 193: 267-82; 8 = Smoller, Friedel, Schmid, Bettler, Lam and Yedvobnick, 1990, Genes Dev. 4: 1688-1700; 9 = Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97 (fig.).

<sup>β</sup> "deltas" refers to the presence of delta-like widenings of the veins 2, 3, and 4 at the margins of the wings of heterozygotes. "nicks" refers to terminal notching of the wing margins of heterozygotes; penetrance 100% for *mam*<sup>1</sup>, about 25% for other alleles.

<sup>γ</sup> Eight alleles induced by hybrid dysgenesis in Harwich second chromosomes, which has *P*-elements at 42C-D, 50C-D, and 57B.

<sup>δ</sup> 0 coordinate = the insertion point of the defective *P*-element at 50C-D in the Harwich strain; positive values to the right.

<sup>ε</sup> Frameshift → product with first 377 residues normal followed by 69 amino acids from frameshifted sequence before termination after residue 446.

**cytology:** Maps at 50C20-23, by virtue of *P*-element insertion at this site, in *mam*<sup>40</sup>; consistent with this is the fact that *mam*<sup>1</sup> is associated with *In(2R)G* = *In(2R)50C19;54B1*; and that *mam*<sup>35</sup> = *T(2;3)mam*<sup>35</sup> = *T(2;3)50C20-23;67* (Campos-Ortega).

**molecular biology:** Gene isolated by chromosome walking, physical mapping of breakpoints, and transposon tagging (Weigel, Knust, and Campos-Ortega, 1987, Mol. Gen. Genet. 207: 374-84; Yedvobnick, Smoller, Young, and Mills, 1988, Genetics 118: 483-97). Locus delimited to ca. 70 kb, within which *mam*-mutant lesions mapped over a 45 kb interval (cf. Weigel *et al.*; 1987

Smoller *et al.*, 1990). This region is rich in opa repeats (first noted by Weigel *et al.*, 1987), and regions encoding them are portions of *mam* exons; these are all contained within a 6.3 kb cDNA, cloned from an 8-12 hour library (Smoller *et al.*, 1990) probed with "unique-ORF"-containing (non-*opa*) genomic probes. Genomic sequence comprises seven exons (312, 127, 1010, 2073, 286, 1090, and 1435 bp) spanning 67 kb; transcription from left to right. Northern blots and *in situ* hybridizations (Smoller *et al.*, 1990) reveal complex patterns of *mam* mRNA expression: a maternal transcript; four embryonic ones (6.5-8.5 kb), two of which appear earlier than the other two, with all four waning by L1; transcripts return in late L3/early pupation; ubiquitous spatial expression in embryos seen during germ-band elongation, with neural-restricted signals observed later. Sequencing of the 6.3 kb cDNA revealed a 4788 bp ORF and predicts an 1596-amino-acid protein; there are 21 poly-Gln runs within the ORF, four poly-Gly, three poly-Asn, and one poly-Ala run; there are also 47 Gly-Gly doublets and three Gly-Val runs; the predicted protein contains relatively few charged residues. Antibodies generated using *mam*-fusion proteins detect a polypeptide of predicted size on Western blots and a nuclear signal in Schneider S2 cells and in whole mounts of early embryos (Smoller *et al.*, 1990).

**other information:** *N-2G* considered an allele based on its failure to complement other *mam* alleles and on the embryonic phenotype of such non-complementing *trans* heterozygotes. Interacts with *dx*, in that the great majority of *dx*<sup>ENU</sup>/*Y*; *mam*<sup>10</sup>/*+* zygotes die as pupae (Xu and Artavanis-Tsakonas, 1990, Genetics 126: 665-77).

#### *mam*: mandarin

**location:** 3-50.5.

**origin:** Spontaneous.

**references:** Aparisi and Nájera, 1987, DIS 66: 13-14. 1988, DIS 67: 4-5, 5-6.

**phenotype:** Eye color bright orange.

#### *manikin*: see *mn*

#### *many abdominal discs*: see *mad*

#### *map*: midgut amylase pattern (*W.W. Doane*)

Two closely linked genes that determine the pattern of alpha-amylase activity in three contiguous segments of the anterior portion of the adult midgut (gene *mapA*) and two segments of the posterior portion of the adult midgut (gene *mapP*). The short non-digestive middle midgut is without amylase activity in any genotype. *mapP* has three known alleles and *mapA* appears to have five since all 15 possible haplotypes have been reported (Doane, 1980, DIS 55: 36-39). In most cases, the pattern observed in the larval midgut is different from that seen in the adult of the same genotype. A pattern in which all three anterior segments and both posterior segments exhibit enzyme activity is designated 123-12 and one with no activity 000-00. The pattern observed is affected both by nutrition and adult age; for example, in some strains a 123-00 pattern may change to a 123-12 pattern at approximately 14 days of age in adults; in other strains, this change does not occur (Doane, Treat-Clemons, Gemmill, Levy, Hawley, Buchberg, and Paigen, 1983, Isozymes: Current Topics in Biological and Medical Research 9: 63-90). [Additional, as yet unnamed, genetic factors

control amylase patterns in the anterior midgut and posterior midgut of larvae (Treat-Clemons and Doane, 1983, *Isozyme Bull.* 16: 66; Klarenberg, Visser, Willemse, and Scharloo, 1986, *Genetics* 114: 1131-45); one is a *cis*-regulator of amylase activity in the anterior midgut and is located within 0.1 cM of *Amy* (Klarenberg *et al.*, 1986).

**mapA: Anterior midgut amylase pattern**

**location:** 2-82 (based on 7 recombinants between *Amy* and *mapA*).

**synonym:** *map-AMG*.

**references:** Doane, 1980, *DIS* 55: 36-39.

**phenotype:** The anterior adult midgut is divided into three segments which express discrete patterns of amylase activity.

**alleles:** Different *mapA* alleles exhibit enzyme activity in different combinations of the three segments of the anterior midgut. Presence of activity in the three regions is designated, from anterior to posterior, 1, 2, and 3; absence or near absence of activity in any region is designated 0; these notations appear as three-digit superscripts in *mapA* allelic designations: *mapA*<sup>000</sup>, *mapA*<sup>100</sup>, *mapA*<sup>103</sup>, *mapA*<sup>120</sup>, and *mapA*<sup>123</sup>.

**mapP: Posterior midgut amylase pattern**

**location:** 2-79 [based on 433 recombinants between *Amy* and *wt* (Klarenberg *et al.*, 1986); *mapP* also shown to lie to the left of *mapA* by crossovers between them (Doane, 1980) and to the left of *nw* (Doane, 1987, *DIS* 66: 49).

**synonym:** *map* (Abraham and Doane, 1978); *map-PMG* (Doane, 1980).

**references:** Abraham and Doane, 1978, *Proc. Nat. Acad. Sci. USA* 75: 4446-50.

Doane, 1980, *DIS* 55: 36-39.

Klarenberg, Visser, Willemse, and Scharloo, 1986, *Genetics* 114: 1131-45.

Doane, Treat-Clemons, Gemmill, Levy, Hawley, Buchberg, and Paigen, 1983, *Isozymes: Current Topics in Biological and Medical Research* 9: 63-90.

Treat-Clemons and Doane, 1983, *Isozyme Bull.* 16: 66.

Doane, 1987, *DIS* 66: 48.

Thompson and Doane, 1988, *J. Cell Biol.* 107: 331a.

Doane, Thompson, Norman, and Hawley, 1990, *Isozymes: Structure, Function, and Use in Biology and Medicine, Prog. Clin. Biol. Res.* 344: 19-48.

**phenotype:** Determines the level of amylase activity, amylase protein and amylase RNA in the posterior midgut. *Trans* regulation of amylase activity observed in adults (Abraham and Doane, 1978; Doane *et al.*, 1983, Klarenberg *et al.*, 1986) and in larvae of some strains (Treat-Clemons and Doane, 1983), but not others (Klarenberg *et al.*, 1986); nutritional control of *Amy* gene expression by dietary glucose repression, which is strain-specific in its magnitude (Hickey and Benkel, 1982, *Biochem. Genet.* 20: 1117-29), affects the level of amylase activity systemically in both the posterior midgut and the anterior midgut and can affect amylase activity patterns (Thompson and Doane, 1988; Doane *et al.*, 1990); similarly, dietary maltose, which is digested to glucose, can affect amylase activity patterns (Klarenberg *et al.*, 1986).

**alleles:** Two discrete regions of the larval and adult posterior midgut can express amylase activity on cornmeal-molasses-yeast food or a yeast diet with glucose containing sugars. Presence of activity in the anteriormost

region of the posterior midgut is designated 1 in the superscript, and activity in the region just behind the first region is designated 2; absence of activity in either region is designated 0. The following alleles have been recorded by Doane (1980): *mapP*<sup>00</sup>, *mapP*<sup>10</sup>, and *mapP*<sup>12</sup> [synonyms *map*<sup>A</sup>, *map*<sup>B</sup>, and *map*<sup>C</sup>, respectively (Abraham and Doane, 1978)].

**Map205: Microtubule-associated protein 205 kd**

**location:** 3- {105}.

**references:** Goldstein, Laymon, and McIntosh, 1986, *J. Cell. Biol.* 102: 2076-87.

**phenotype:** Encodes a 205 kd microtubule-associated protein, which by immunostaining can be localized to cytoplasmic microtubules and to the mitotic spindle.

**cytology:** Placed in 100E-F by *in situ* hybridization.

**molecular biology:** Genomic sequence isolated by screening an expression library with antibody. The genomic sequence hybridizes to a 6 kb mRNA on Northern blots.

**mar: metaphase arrest**

**location:** 3-{84}.

**origin:** X ray induced.

**references:** González, Molina, Casal, and Ripoll, 1989, *Genetics* 123: 371-77.

**phenotype:** Hemizygotes die as third-instar larvae; cells in larval brain have highly condensed X-shaped chromosomes, a mitotic index twice that of wild type, and a thirty-fold reduction in the ratio of anaphases to metaphases. Only about 1% of cells are tetraploid, the remainder remaining diploid. Complements *asp*, which is just to the left.

**cytology:** Placed in 96B based on its association with *T(Y;3)B97 = T(Y;3)h3;96B*, as indicated by the *mar* phenotype of *T(Y;3)B197Df(3R)L16 = Df(3R)96A1-10;96E*.

**Mar: Margin**

**location:** 2-72.

**origin:** Induced by ethyl methanesulfonate.

**references:** Whittle, 1977, *DIS* 52: 2.

**phenotype:** Heterozygotes exhibit scalloping of wing margins; have gaps in triple row and double row of bristles and marginal hairs; wing outline sometimes ragged. Similar to *Bx*<sup>G</sup>; penetrance incomplete. Homozygous lethal.

**marionette:** see *mrn*

**maroon:** see *ma*

**maroonlike:** see *mal*

**Mas:** see *dsx*<sup>M</sup>

**Masculinizer:** see *dsx*<sup>M</sup>

**master mind:** see *mam*

**mat(2)cell: maternal lethal (2) cellularization defects (T. Schüpbach)**

A series of ethyl methanesulfonate-induced maternal-effect-lethal female-sterile mutations on the second chromosome, which all result in the same phenotype. Embryos from homozygous females show variable defects in cellularization at the blastoderm stage; they form cuticles with holes, variable head defects, and segment fusions.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

***mat(2)N: maternal lethal (2) Notchlike***  
(T. Schüpbach)

**location:** 2- {97}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal, female sterile.

Embryos from homozygous mothers form only a piece of dorsal cuticle, similar to the zygotic lethal Notch (*N*).

**alleles:**

allele	origin	synonym
<i>mat(2)N<sup>1</sup></i>	EMS	<i>mat(2)N<sup>RA</sup></i>
<i>mat(2)N<sup>2</sup></i>	EMS	<i>mat(2)N<sup>QI</sup></i>
<i>mat(2)N<sup>3</sup></i>	EMS	<i>mat(2)N<sup>RQ</sup></i>

**cytology:** Placed in either 57B5-14, or in 57D8-58B, since uncovered by *Df(2R)D17 = Df(2R)57B5;58B1-2*, but not by *Df(2R)PL3 = Df(2R)57B20;59D8-9* (cytology according to O'Donnell, Boswell, Reynolds, and MacKay, 1989, Genetics 121: 273-80).

**other information:** All three alleles are semilethal over *Df(2R)D17*.

***mat(2)syn: maternal lethal (2) syncytial blastoderm arrest*** (T. Schüpbach)

A series of EMS-induced maternal-effect lethal mutations on the second chromosome, which all result in the same phenotype: Homozygous females lay eggs in which a narrow halo of clear cytoplasm appears around the time when nuclei would be expected to migrate to the egg periphery, but no cellularization takes place.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

<i>mat(2)synRE48</i>	2-24		
<i>mat(2)synSE10</i>	2-41		

***mat(3)1***

**location:** 3-54.8.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Rice.

**references:** Rice and Garen, 1975, Dev. Biol. 43: 277-86 (fig.).

Regenass and Bernard, 1978, Mol. Gen. Genet. 164: 85-91.

1980, Wilhelm Roux's Arch. Dev. Biol. 188: 127-32.

**phenotype:** Maternal-effect lethal; embryos produced by homozygous females produce pole cells, but syncytial blastoderm fails to cellularize. Pole cells from defective *mat(3)1/+* embryos of *mat(3)1* mothers functional when transplanted into normal hosts (Regenass and Bernard).

***mat(3)3***

**location:** 3-45.3.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Rice.

**references:** Rice and Garen, 1975, Dev. Biol. 43: 277-86 (fig.).

**phenotype:** Maternal-effect lethal; embryos produced by homozygous females produce pole cells, but syncytial blastoderm fails to cellularize completely; the posterior-dorsal 30% of the surface fails to form cells and is separated from the remainder of the blastoderm surface by a belt of incompletely cellularized nuclei. Mutant phenotype expressed in females kept at 29°; females kept at 25° are fertile and produce normal offspring; temperature-sensitive period during the last 12 hr of oogenesis.

*mat(3)6*: see *spg*

**maternal haploid:** see *mh*

**maternal lethal:** see *mat*

**matt brown:** see *mtb*

**\*mb: minus bar**

**location:** 3-43.4.

**discoverer:** Nordenskiöld, 33a30.

**references:** 1934, DIS 2: 7.

**phenotype:** Modifies Bar in such a way that *B/B* resembles

*B/+*, and *B/+* appears almost wild type; *B* male modified to resemble *B*<sup>1</sup>. Homozygous female highly infertile. RK3.

***mbd*: mushroom body-deranged (J.C. Hall)**

**location:** 1-56.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *mbd*<sup>K565</sup>.

**references:** Heisenberg, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 373-90.

Technau and Heisenberg, 1982, Nature (London) 295: 405-07.

Borst and Heisenberg, 1982, J. Comp. Physiol. 147: 479-84.

**phenotype:** Most axons in peduncles of mushroom bodies in dorsal brain absent; no detectable lobes associated with these bodies (cf. alpha, beta, and gamma lobes of wild-type); posterior calyces of mushroom bodies enlarged. During post-larval mushroom body regeneration (on the first day of pupation), axons roll up at periphery of brain; other parts of mutant brains appear normal. Mushroom body abnormalities are variable; most behaviors of mutant adults are normal, including basic ability to discriminate between different odors; in tests using olfactory stimuli, learning in third larval instar is normal, but olfactory learning in mutant adults is aberrant (Heisenberg, Borst, Wagner and Byers, 1985, J. Neurogenet. 2: 1-30). Penetrance of the morphological phenotype diminishes rapidly under normal culturing, but does not wane when maintained in heterozygous condition.

**cytology:** Maps within 17A-18A2, based on uncovering by *Df(1)N19*.

***mbm*: mushroom-body-miniature (J.C. Hall)**

**location:** 2-{0} (inferred from cytology; also, maps to distal 2L meiotically).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** H. Heisenberg and K. Fishbach (from mutagenized second chromosome provided by C. Nüsslein-Volhard).

**synonym:** *mus*: *mushroom-bodies-small*, a preempted symbol.

**references:** Heisenberg, Borst, Wagner and Byers, 1985, J. Neurogenet. 2: 1-30.

**phenotype:** Abnormally small calyces associated with mushroom bodies in dorsal brain; peduncles and lobes are thin or missing, owing to degeneration of Kenyon cell fibers during third larval instar; these defects are essentially limited to mutant females. Mushroom bodies appear nearly normal in brains of *mbm* males. Osmotropy (re odor discrimination) is essentially normal in females; mutant females (larvae or adults) are defective in learning tests involving odors, electric shock, or sugar, whereas males are normal or less defective.

**cytology:** Maps to 21B8-D1, because *mbm* is uncovered by *Df(2L)al = Df(2L)21B8-C1;21C8-D1*.

**alleles:** Three mutant alleles: *mbm*<sup>N337</sup>, *mbm*<sup>K1</sup>, *mbm*<sup>K7</sup> (see "other information").

**other information:** All three *mbm* alleles, when heterozygous with *Df(2L)al*, lead to stronger mutant phenotypes than mutant homozygotes or heteroallelic combinations; *mbm*<sup>K1</sup>/*mbm*<sup>K7</sup> causes a very weak (i.e., near normal) mushroom body defect. *mbm*<sup>K1</sup> and *mbm*<sup>K7</sup> are from stocks originally termed *Df(2L)net*<sup>K1</sup> and *Df(2L)net*<sup>K7</sup>;

each of these turns out not to be a deletion, i.e. they appear to be cytologically normal, but the former is mutant for *net*, *mbm* and a vital gene, as is the latter, though the lethal here complements that on the *K1* chromosome. In both of these stocks, the various abnormalities are separable by recombination.

***mbmB*: mushroom-body-miniature-B (J.C. Hall)**

**location:** 2-31.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *rem*: *reduced-mushroom-bodies*; *mbmB*<sup>N806</sup>.

**references:** Heisenberg, Borst, Wagner and Byers, 1985, J. Neurogenet. 2: 1-20.

**phenotype:** Phenotype similar to that of *mbm*, but less extreme, and mushroom body defect occurs in both males and females; learning is weak in tests using olfactory stimuli.

***mbmC*: mushroom-body-miniature-C (J.C. Hall)**

**location:** 2-35.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *opa*: *olfactory pathway*, a preempted symbol; *mbmC*<sup>N28</sup>.

**references:** Heisenberg, Borst, Wagner and Byers, 1985, J. Neurogenet. 2: 1-30.

**phenotype:** Phenotype similar to that of *mbm*; also, the pair of antennal lobes differ in volume in most *mbmC* adults (i.e. left smaller than right, or vice versa); learning very poor in tests of females, using olfactory stimuli.

**\**mbs*: miniature blistered**

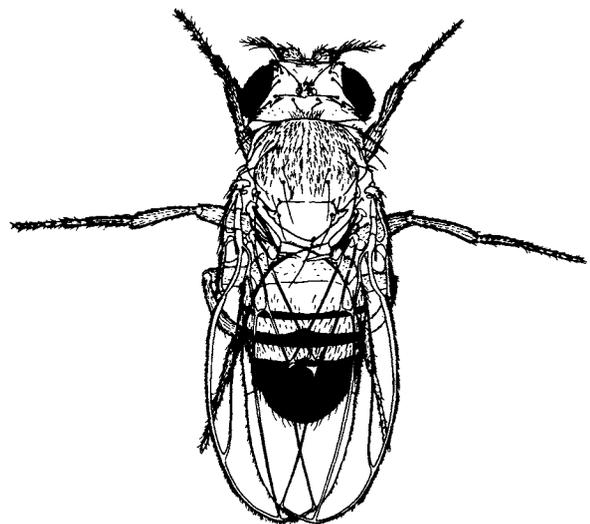

**location:** 2-56.

**origin:** Spontaneous.

**discoverer:** Neel, 41c13.

**references:** 1942, DIS 16: 51.

**phenotype:** Wings small, curled, blistered, and plexate. Bristle positions irregular and bristles often bent and twisted. Viability and fertility poor. RK3.

**mc: microchaete**

Edith M. Wallace, unpublished.

**mc: microchaete**

location: 1-54.0.

origin: X ray induced.

discoverer: Demerec, 28f20.

synonym: *tb-53*.

references: 1935, DIS 3: 13.

**phenotype:** Hairs on thorax fewer than wild type, more irregular, and frequently doubled. Bristles smaller, more sparse on scutellum, and occasionally on head. Eyes rough. Wings ovoid and short; marginal bristles disarranged. Abdominal sclerites ridged. RK1.

**\*mc<sup>2</sup>**

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

discoverer: Fahmy, 1955.

synonym: *mc-like*.

references: 1958, DIS 32: 71.

**phenotype:** Thoracic hairs irregularly distributed, occasionally reduced in number. Bristles small, sparse on scutellum. Eyes small and rough. Wings ovoid and short. Tergites in female sometimes disarranged. Viability and fertility good in both sexes. *mc<sup>2</sup>/mch* is wild type. RK2.

**other information:** Allelism inferred from location of *mc<sup>2</sup>* at 52.1 and from phenotype.

**Mc: Microcephalus**location: 3-59.0 (about 0.2 unit to the right of *bx*).

origin: Spontaneous.

references: Bateman, 1944, DIS 18: 40.

1945, DIS 19: 47.

**phenotype:** Eyes of heterozygote small or absent. Scutellars curve upward. Viability and fertility good. Homozygote usually more extreme than heterozygote but not reliably distinguishable. *ale Mc* homozygotes completely eyeless; fertile except when crossed to each other (Golubovsky and Zakarov, 1972, DIS 49: 112). Viability of homozygote varies from 100 down to 40%. RK1A.

**cytology:** Associated with a minute tandem repeat of one or more bands in 89E7-11; partially restores fertility to *Df(3R)P9* heterozygotes [Lewis, 1978, Nature (London) 276: 565-70]. Duplication appears to include at least a portion of the *AbdB* segment of *BXC* (Struhl and White, 1985, Cell 43: 507-19).

*mc-like*: see *mc<sup>2</sup>***\*mch: minute chaetae**

location: 1-52.0.

origin: Induced by methyl methanesulfonate (CB. 1540).

discoverer: Fahmy, 1956.

references: 1959, DIS 33: 87.

**phenotype:** Extremely short, fine bristles. Hairs and body also small; delayed eclosion. Male viable and fertile. *mch/mc<sup>2</sup>* is wild type. RK2.

**other information:** One allele each induced by CB. 1246, CB. 1356, and CB. 3026.

**Mcp:** see *BXC***\*md: melanotic lesions**

location: 3-38.0.

origin: Found in experiments using benzopyrene.

discoverer: Gowen, 1933.

**phenotype:** Lesions occur in many places throughout head,

thorax, and abdomen. RK3.

**\*mdg: midgoid**

location: 1-64.7.

origin: Induced by D-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

discoverer: Fahmy, 1955.

references: 1958, DIS 32: 71.

**phenotype:** Small in all dimensions; frequently underpigmented. Male infertile; viability about 20% wild type. RK3.

**Mdh1: Malate dehydrogenase**

location: 2-37.2.

**synonym:** *Mdh2* (Grell, 1969, DIS 44: 47); *MdhD* (Johnson and Schaeffer, 1973, Biochem. Genet. 10: 149-63); *sMdh* (Hay and Armstrong, 1976, Insect Biochem. 6: 367-76); *cMdh* (Voelker, Ohnishi, and Langley, 1979, Biochem. Genet. 17: 947-56).

references: Grell, 1969, DIS 44: 47.

O'Brien, 1969, DIS 44: 42, 113.

1973, Biochem. Genet. 10: 191-205.

Johnson and Schaeffer, 1973, Biochem. Genet. 10: 149-63.

Voelker, Ohnishi, and Langley, 1979, Biochem. Genet. 17: 947-56.

**phenotype:** The structural gene for the cytoplasmic, NAD-dependent malate dehydrogenase = (S)-Malate: NAD<sup>+</sup> oxidoreductase [MDH1 (EC 1.1.1.37)]. Extracts from homozygotes produce two bands of activity plus a lighter, more electronegative band on gels; heterozygotes produce hybrid bands, indicating that the enzyme is a dimeric molecule. Subunit molecular weight estimated at 30,000 Daltons. Not necessary for survival, since *Mdh1<sup>n1</sup>/Df(2L)J* is viable. Purification and biochemical characterization carried out by McReynolds and Kitto (1970, Biochim. Biophys. Acta 198: 165-75), Hay and Armstrong (1976, Insect Biochem. 6: 367-76), and Alhlotis (1979, Comp. Biochem. Physiol. 62B: 375-80).

**alleles:** For the electrophoretic variants, the Research Triangle Park conventions (1978, DIS 53: 117) are used; superscript 4 designates the most common allele; superscripts <4 migrate more slowly and >4 more rapidly than the most common allele. Null alleles all derivatives of *Mdh1<sup>4</sup>*.

**phenotype:** Locus inferred from the rescue of males hyperploid for the distal fourth of the X chromosome, which are normally inviable, by substitution of *Df(1)HC244 = Df(1)3E8;4F11-2* for the normal X. Lethality of the duplication observed in *Sxl*<sup>+</sup> males but survival of such males carrying *Sxl*<sup>fl</sup> reported.

**cytology:** Placed in 4A based on inclusion of the inferred gene in *Df(1)cho2 = Df(1)3E;4A* but not *Df(1)cho5 = Df(1)3D;4A*.

**\*me: focal melanosis**

**location:** 1-29.0.

**origin:** X ray induced.

**discoverer:** Gowen, 1928.

**references:** 1934, *Arch. Pathol.* 17: 638-47 (fig.).

1934, *Cold Spring Harbor Symp. Quant. Biol.* 2: 128-36 (fig.).

**phenotype:** Melanotic degeneration occurs at junction of tibia and femur. Lethal at end of pupal stage or shortly after eclosion. RK2.

**Me: Moirè**

**location:** 3-19.2 (to the left of *ju*; based on location of *Me*<sup>65d</sup>).

**synonym:** *Mo*.

**phenotype:** Eye has watered-silk, shimmering, iridescent pattern owing to a ring of six flecks around normal fleck. Eye color brownish and translucent; 79% normal red pigment and 85% normal brown pigment (Nolte, 1955, *J. Genet.* 53: 1-10). Larval Malpighian tubes considerably lighter in color than normal but mutant classifiable with difficulty (Brehme and Demerec, 1942, *Growth* 6: 351-56). Contains a modifier of dominance of *dp* such that *dp/+*; *Me/+* has truncated wings. Classifiable in single

dose in triploids (Schultz, 1934, *DIS* 1: 55). Homozygous lethal. *Me/In(3L)P* is viable. RK1A.

**cytology:** Placed in region 64C12-65E1 on the basis of its inclusion in *Df(3L)Vn = Df(3L)64C12-D1;65D2-E1* (Mohr, 1938, *Avh. Nor. Vidensk.-Akad. Oslo, Mat. Naturvidensk. Kl. No. 4: 1-7*). Associated with *In(3L)P = In(3L)63C;72E1-2* (Morgan, Bridges, and Schultz, 1937, *Year Book - Carnegie Inst. Washington* 36: 301).

**\*meg: megaoculus**

**location:** 1-61.9.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, *DIS* 32: 71.

**phenotype:** Eyes large, abnormally shaped, and rough. Wings abnormally shaped and sometimes extremely small. Wing surface irregularly curved. Inner margin removed to various degrees and venation abnormal. Viability good; both sexes infertile. RK2.

**other information:** One allele induced by CB. 3025.

**mei-1: meiotic mutant 1 (J. Valentin)**

**location:** 3-45-55.

**references:** Valentin, 1973, *Hereditas* 75: 5-22.

Baker, Carpenter, Esposito, Esposito, and Sandler, 1976, *Ann. Rev. Genet.* 10: 53-134.

**phenotype:** Reduces exchange on the X chromosome in females by approximately 50% but has little or no effect on autosomal recombination. Recombination is decreased most severely in the central region of the X with more normal frequencies occurring proximally and distally. X chromosome nondisjunction is increased only slightly in *mei-1* females, while the fourth chromosomes disjoin quite regularly.

Carpenter, 1982, *Proc. Nat. Acad. Sci. USA* 79: 5961-65.

**phenotype:** *mei-9* alleles confer sensitivity to mutagens as a consequence of a defect in excision repair (Boyd *et al.*, 1976; Nguyen and Boyd, 1977). This defect in DNA repair is also manifested by a high frequency of mitotic chromosome breakage and instability (Baker *et al.*, 1978; Gatti, 1979). For example, larval neuroblasts of *mei-9/Y* males display a high frequency of spontaneous chromosome breaks in both the eu- and heterochromatin (Gatti, 1979). Females homozygous for *mei-9* show greatly reduced levels of meiotic exchange. However, the residual exchanges are distributed as in wild-type and chiasma interference is maintained. *mei-9* is thus considered to be defective in the exchange process itself, rather than in the establishment of the preconditions for exchange (Carpenter and Sandler, 1974). *mei-9<sup>a</sup>* and *mei-9<sup>b</sup>* have also been assayed with respect to their effects on gene conversion at the *rosy* locus (Carpenter, 1982). Although neither allele reduces the frequency of gene conversion events, both produce post-meiotic segregation events (*i.e.*, mosaic progeny) at high frequency. Thus, the recombinational phenotype of *mei-9* involves two components, namely a decrease in the frequency of heteroduplex repair and a decrease in the frequency of reciprocal exchange. At the ultrastructural level, both synaptonemal complex morphology and the number and distribution of recombination nodules are normal in *mei-9* females (Carpenter, 1979); but see Boyd *et al.* (1976). As a consequence of the decreased frequency of reciprocal exchange, *mei-9* females display greatly elevated frequencies of meiotic nondisjunction and chromosome loss (Baker and Carpenter, 1972). Meiotic chromosome behavior in males is not affected. Nor is there any effect of *mei-9* on spontaneous recombination in males (Lutken and Baker, 1979). Neither hypermutable to alkylation nor deficient in excision repair (Smith and Dusenberry, 1988, *Mechanisms and Consequences of DNA Damage Processing*, Alan R. Liss, Inc., pp. 251-55).

**alleles:** Baker and Smith (1979) demonstrated that the *mus-110<sup>AT1</sup>*, *mus-110<sup>AT2</sup>*, and *mus-110<sup>AT3</sup>* mutations (Smith 1976) are alleles of *mei-9*. These mutations have been renamed as *mei-9<sup>A1</sup>*, *mei-9<sup>A2</sup>*, and *mei-9<sup>A3</sup>*, respectively. *mei-9<sup>L1</sup>*, also known as *mut<sup>159</sup>*, was identified by Graf *et al.* (1979).

Mason, Scobie, and Yamamoto, 1989, *Mol. Gen. Genet.* 215: 190-99.

**phenotype:** *mei-41* alleles confer sensitivity to mutagens as a consequence of a defect in a caffeine-sensitive post-replication repair pathway (Boyd and Setlow, 1976; Boyd *et al.*, 1976; Boyd and Shaw, 1982). This defect in DNA repair is also manifested by a high frequency of mitotic chromosome breakage and instability (Baker *et al.*, 1978; Gatti, 1979). *mei-41<sup>1</sup>* not hypermutable to alkylation nor defective in excision repair; yet *mei-41<sup>D12</sup>* displays hypermutability to alkylation and defective alkylation excision repair (Smith and Dusenberry, 1988, *Mechanisms and Consequences of DNA Damage Processing*, Alan R. Liss, Inc., pp. 251-55). Allelism based on lack of complementation (Mason, Scobie, and Yamamoto, 1989, *Mol. Gen. Genet.* 215: 190-99). Most alleles of *mei-41* also reduce female fertility and in some cases are female-sterile as homozygotes. Females homozygous for the more fertile alleles of *mei-41* exhibit reduced levels of meiotic exchange. The observed reductions in exchange are not uniform, but rather are most extreme in distal regions. Chiasma interference is also diminished (Carpenter and Sandler, 1974; Baker and Hall, 1976). These reduced levels of exchange allow for high frequencies of meiotic loss and nondisjunction (see Baker and

Hall, 1976). Ultrastructural analysis of pachytene in *mei-41* and *mei-41*<sup>2</sup> females demonstrates a reduced number of late recombination nodules which are distributed in a fashion that parallels residual exchange events (Carpenter, 1979). Over half of those nodules which are observed are morphologically abnormal and are associated with unusual regions of relatively uncondensed chromatin. Stocks in which *mei-41* is carried in the male are frequently observed to carry or acquire a *bb* mutation on the *mei-41*-bearing X chromosome (Hawley and Tartof, 1983). Several alleles of *mei-41* have also been shown to inhibit rDNA magnification in the male germline (Hawley and Tartof, 1983; Hawley *et al.*, 1985). Moreover, *mei-41* males undergoing magnification also produce a high frequency of X-Y exchanges which result from one break within the X-chromosome rDNA cluster and the other at any of a large number of sites on the Y chromosome (Hawley and Tartof, 1983).

**alleles:** More than fifty alleles of this locus have been recovered. This includes the *mus-103* and *mus-104* mutations which were shown by Mason *et al.* (1989) to be allelic to *mei-41*. The most commonly used alleles are listed in the table below. A fine structure map of the locus is presented in Mason *et al.* (1989).

Carpenter, 1984, Cold Spring Harbor Symp. Quant. Biol. 49: 23-29.

Carpenter, 1989, Genome 31: 74-80.

**phenotype:** Females homozygous for *mei-218* exhibit reduced levels of meiotic exchange. The residual exchanges are distributed such that the probability of euchromatic exchange becomes more nearly proportional to the polytene-chromosome length (Baker and Carpenter, 1972; Carpenter and Sandler, 1974; Baker and Hall, 1976). This relaxation of the normal constraints on the distribution of euchromatic exchange is clearly demonstrated by the ability of *mei-218* females to allow exchange between the normally achiasmatic fourth chromosomes (Sandler and Szauter, 1978). *mei-218* does not, however, permit exchanges to occur in heterochromatic intervals (Carpenter and Baker, 1982). Ultrastructural analysis of pachytene in *mei-218* and *mei-218*<sup>6-7</sup> females demonstrates a reduced number of late recombination nodules (to about 8% of normal), which are distributed in a fashion that parallels the residual exchange events (Carpenter, 1979, 1989). Many of the nodules which are observed are morphologically abnormal. There is also some evidence that early recombination nodules may be either fewer in number or more ephemeral in *mei-218* females (Carpenter, 1989). Although *mei-218* alleles reduce the frequency of reciprocal meiotic exchange, the absolute frequency of gene conversion at the *rosy* locus is two-fold elevated relative to wild-type controls (Carpenter, 1982, 1984). Moreover, co-conversion distances are shorter than those recovered from controls or from *mei-9* females (Carpenter, 1984). Thus the function of this locus is required for the generation of reciprocal exchanges and not for gene conversion (Carpenter, 1984). The reduced levels of reciprocal exchange which are characteristic of *mei-218* females allow for high frequencies of meiotic loss and nondisjunction (see Baker and Hall, 1976). Nondisjunction occurs at the first meiotic division and only nonexchange chromosomes nondisjoin (Carpenter and Sandler, 1974). All assays for an effect of *mei-218* on mitotic chromosome behavior in males or on somatic chromosome behavior are negative (Baker and Carpenter, 1972; Baker *et al.*, 1978; Lutken and Baker, 1979; Gatti, 1979).

**alleles:** There are two well characterized alleles of this locus: *mei-218* (Baker and Carpenter, 1972) and *mei-218*<sup>6-7</sup> (Baker *et al.*, 1978).

*mei-195*: see *mei-41*

***mei-251* (R.S. Hawley)**

**location:** 1- unlocated.

**references:** Baker and Carpenter, 1972, Genetics 71: 255-86.

Baker, Carpenter, Esposito, Esposito, and Sandler, 1976 Annu. Rev. Genet. 10: 53-134.

Baker and Hall, 1976, The Genetics and Biology of *Dro-*

sophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

Gatti, 1979, Proc. Nat. Acad. Sci. USA 76: 1377-81.

Carpenter and Baker, 1982, Genetics 101: 81-89.

**phenotype:** Females homozygous for *mei-251* exhibit reduced levels of meiotic exchange (to approximately 80% of control levels). The residual exchanges are distributed such that the probability of euchromatic exchange becomes more nearly proportional to polytene-chromosome length (Baker and Carpenter, 1972; Carpenter and Sandler, 1974; Baker and Hall, 1976). Both X and fourth chromosomal nondisjunction are slightly elevated, presumably as a consequence of decreased recombination. Cytological analysis of larval-neuroblast metaphases reveals no increase in spontaneous mitotic chromosome breakage in the presence of *mei-251* (Gatti, 1979).

*mei-254*: see *nod*<sup>a</sup>

***mei-352* (R.S. Hawley)**

**location:** 1- unmapped.

**origin:** Induced by ethyl methanesulfonate.

**references:** Baker and Carpenter, 1972, Genetics 71: 255-86.

Baker, Carpenter, and Ripoll, 1978, Genetics 90: 531-78.

Baker and Hall, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

Carpenter and Baker, 1982, Genetics 101: 81-89.

Gatti, 1979, Proc. Nat. Acad. Sci. USA 76: 1377-81.

Sandler and Szauter, 1978, Genetics 90: 699-712.

**phenotype:** *mei-352* females exhibit near normal levels of meiotic exchange but the distribution of crossover events is abnormal (*i.e.*, exchanges are more uniformly distributed per unit length than they are in wild-type). This relaxation of the normal constraints on the distribution of euchromatic exchange is clearly demonstrated by the ability of *mei-352* females to allow exchange between the normally achiasmate fourth chromosomes (Sandler and Szauter, 1978). *mei-352* does not, however, permit exchanges to occur in heterochromatic intervals (Carpenter and Baker, 1982). It remains to be demonstrated that the reduced fertility and the exchange phenotype are the consequence of the same mutational lesion. Although no increase in spontaneous chromosome aberrations was observed upon direct cytological examination of larval neuroblasts (Gatti, 1979), the *mei-352* mutation was shown to increase mitotic chromosome instability approximately three-fold when assayed genetically (Baker *et al.*, 1978). This suggests that the *mei-352*<sup>+</sup> gene product is required both during meiosis and mitosis.

**\**mei-1029* (R.S. Hawley)**

**location:** 3- unlocated.

**references:** Szauter, 1984, Genetics 106: 45-71.

**phenotype:** Females homozygous for *mei-1029* show reduced levels of meiotic recombination and an abnormal distribution of residual recombination events. X and fourth chromosomal nondisjunction are elevated and occur at the first meiotic division. The observed X chromosome nondisjunction primarily results from the nondisjunction of nonexchange chromosomes.

**\**mei-B* (R.S. Hawley)**

**location:** Unlocated, probably 2.

**references:** Bridges, 1915, J. Exp. Zool. 19: 1-21.

Bridges, 1929, Carnegie Inst. Wash. Publ. 399: 63-83.

Baker and Hall, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

**phenotype:** Females homozygous for *mei-B* exhibit reduced levels of meiotic exchange (to approximately 33% of control levels). The reduction in exchange is most severe in distal intervals (Baker and Hall, 1976). The effects of this mutation on disjunction were not examined. However its low fertility suggests that nondisjunction may be frequent.

***mei-G17***

**location:** 2- (distal third of 2R).

**origin:** Induced with ethyl methanesulfonate.

**references:** Gethmann, 1974, Genetics 78: 1127-42.

**phenotype:** A male-specific and chromosome specific meiotic mutant. Homozygous males, but not females, exhibit elevated frequencies of nondisjunction of second and sex but not third or fourth chromosomes. The incidence of X-Y nondisjunction varies from 4-6%, with nullo-sex-chromosome offspring greatly outnumbering X-Y bearing offspring; nondisjunction seems to occur in the first meiotic division. Among regular progeny, X-bearing genotypes are recovered in excess of Y-bearing genotypes. The frequency of second-chromosome exceptions varies, depending on the Y chromosome present, from 0.25 (*B<sup>S</sup>Y*) to 1.0 (normal Y) exceptions per parental male; this difference is attributable to variable recoveries of nullo-2 but not diplo-2 offspring. Generally the products of nullo-2 sperm are recovered more frequently than those of diplo-2 sperm. Sex-chromosome exceptions are more frequent in products of second-chromosome nondisjunction than in progeny that are regular for chromosome 2; furthermore, XX;0 and 0;22 products are recovered much more frequently than XX; 22 and 0;0 products.

**mei-G87**

**location:** 3- (approximately half way between *al* and *b*).

**origin:** Induced with ethyl methanesulfonate.

**references:** Gethmann, 1974, *Genetics* 78: 1127-42. 1984, *Genetics* 107: 65-77.

**phenotype:** A chromosome-specific but not sex-specific meiotic mutant; causes both reductional and equational nondisjunction of chromosome 2 in both males and females. In females, equational nondisjunction is independent of exchange, but reductional exceptions are primarily derived from non-exchange tetrads. In crosses of *mei-G87* males to *C(2)EN* females, in which half the exceptions are recoverable, 6-10 exceptions per thousand eggs were recovered; in the reciprocal cross, in which all the diplo-2 exceptions are theoretically recoverable, there were 1-2 exceptions per thousand eggs. In primary spermatocytes, a low incidence of cases in which the chromatids of one pair of autosomes have separated are observed.

**mei-I1**

**location:** 3-1.8 (1/15 the distance between *ru* and *h*).

**origin:** Induced with ethyl methanesulfonate.

**references:** Ivy, 1981, PhD thesis, University of California, San Diego.

**phenotype:** Homozygous males produce 43-49% gametes exceptional for sex chromosomes and 39-44% exceptional for chromosome 4. Sex and fourth chromosomes misassort independently. Consistently produce an excess of nullo-X-nullo-Y over XY-bearing gametes, but nullo-4 and diplo-4 gametes equally frequent. Nondisjunction confined to first meiotic division. Chromosomes 2 and 3 also give high frequencies of nondisjunction; appear to disjoin randomly based on chromosome analysis of secondary spermatocytes. Primary spermatocytes show mostly univalents; MII appears normal except for the non-haploid complements resulting from MI chromosome misbehavior. Spermatids often contain micronuclei, and nullo exceptions are more frequent than diplo exceptions, both indicative of chromosome loss.

**cytology:** Placed in 61A-62B1 based on the ability of  $Y^{P_3^D}$  of  $T(Y;3)D8 = T(Y;3)60A10-B1$  but not  $Y^{P_3^D}$  of  $T(Y;3)A114 = T(Y;3)61A$  to cover both the genetic and cytological effects of *mei-I1*.

**mei-I3**

**location:** 3- (unmapped).

**origin:** Induced with ethyl methanesulfonate.

**references:** Ivy, 1981, PhD thesis, University of California, San Diego.

**phenotype:** In males homozygous for this mutation, all chromosomes nondisjoin at meiosis I and reciprocal meiotic products are recovered with unequal frequencies. Furthermore, the X chromosomes nondisjoin at meiosis II. The meiotic behaviors of the sex and fourth chromosomes are positively correlated, *i.e.*, more double exceptions were recovered than expected; among double exceptions, however, nonhomologues behave independently. Homozygous females virtually sterile owing either to *mei-I3* or to a closely linked independent mutation.

**\*mei-O81**

**location:** 3- (unmapped).

**origin:** Natural population.

**references:** Sandler, Lindsley, Nicoletti, and Trippa, 1968, *Genetics* 60: 525-58.

**phenotype:** Male-specific recessive meiotic mutant. Apparently causes nondisjunction of all chromosomes; 5.0% for sex chromosomes, 7.8% for fourth chromosomes, and 0.78% double nondisjunction. Failure of homologous pairing seen in primary spermatocytes.

**cytology:** Polytene chromosomes normal.

**\*mei-S8**

**location:** 2-79.7.

**origin:** Natural population.

**references:** Sandler, Lindsley, Nicoletti, and Trippa, 1968, *Genetics* 60: 525-58.

**phenotype:** Male-specific recessive meiotic mutant. Causes high nondisjunction of chromosome 4, but has no effect on the sex chromosomes. Nullo-4 exceed diplo-4 gametes. Cytological examination of primary spermatocytes reveals nondisjunction of chromosome 4 in the first meiotic division.

**cytology:** Polytene chromosomes normal.

**mei-S51 (R.S. Hawley)**

**location:** Synthetic with at least one component on each large autosome.

**references:** Robbins, 1971, *Mol. Gen. Genet.* 110: 144-66. Sandler, Lindsley, Nicoletti, and Trippa, 1968, *Genetics* 60: 525-558.

**phenotype:** Females homozygous for *mei-S51* exhibit reduced exchange and high frequencies of nonhomologous disjunction, particularly with respect to the X and fourth chromosomes (XX <-> 44 segregations are frequent). In addition *mei-S51* decreases the frequency of secondary nondisjunction in structurally normal XXY females and increases the frequency of nondisjunction in X inversion heterozygotes. Robbins (1971) proposed that *mei-S51* disrupts a number of aspects of chromosome pairing and alignment prior to metaphase and therefore both reduces exchanges and prevents proper partner choice within the distributive system.

**mei-S282 (R.S. Hawley)**

**location:** 3-5.

**origin:** Spontaneous.

**references:** Sandler, Lindsley, Nicoletti, and Trippa, 1968, *Genetics* 60: 525-58.

Parry, 1973, *Genetics* 73: 465-86.

Sandler, Romans, and Figenshow, 1974, *Genetics* 77: 299-307.

Baker and Hall, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

Baker, Carpenter, and Ripoll, 1978, *Genetics* 90: 531-78.

**phenotype:** Females homozygous for *mei-S282* exhibit reduced levels of meiotic exchange. The residual exchanges are distributed such that the probability of euchromatic exchange becomes more proportional to unit length (Parry, 1973; Baker and Hall, 1976). This relaxation of the normal constraints on the distribution of euchromatic exchange is clearly demonstrated by the ability of *mei-S282* females to allow exchange on the

normally achiasmatic fourth chromosome (Sandler and Szauter, 1978). The reduced levels of reciprocal exchange which are characteristic of *mei-S282* females allow for high frequencies of meiotic loss and nondisjunction (see Baker and Hall, 1976). Nondisjunction occurs at the first meiotic division and only nonexchange chromosomes nondisjoin (Parry, 1973). The *mei-S282* mutation also causes mitotic chromosome instability (Baker *et al.*, 1978) when assayed genetically. This suggests that the *mei-S282*<sup>+</sup> gene product is required both during meiosis and mitosis.

***mei-S332* (R.S. Hawley)**

**location:** 2-95.

**origin:** Spontaneous.

**references:** Sandler, Lindsley, Nicolletti, and Trippa, 1968, *Genetics* 60: 525-58.

Baker and Hall, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

Davis, 1971, *Mol. Gen. Genet.* 113: 251-72.

Sandler, Romans, and Figenshow, 1974, *Genetics* 77: 299-307.

Hardy, 1975, *Genetics* 79: 231-64.

Davis, 1977, *DIS* 52: 100.

Baker, Carpenter, and Ripoll, 1978, *Genetics* 90: 531-78.

Goldstein, 1980, *Chromosoma* 78: 79-111.

**phenotype:** *mei-S332* is a semidominant autosomal mutation that increases nondisjunction of all chromosomes to the same extent in both sexes. Although female recombination is normal, *mei-S332* causes high frequencies of equational nondisjunction in both sexes as well as chromosome loss (Davis, 1971; Goldstein, 1980). In the male germline sister chromatid associations are generally normal during prophase I and metaphase I. However, by telophase I sister chromatids have frequently undergone precocious separation (Goldstein, 1980). The equational exceptions produced by *mei-S332* males and females presumably result from precociously separated sister chromatids going to the same pole at anaphase II. Goldstein (1980) has also suggested that "in the case of *mei-S332*, chromosomes which lag in the second meiotic division are usually lost and most of the genetically observed loss in *mei-S332* occurs in the second meiotic division." The hypothesis that lagging chromatids are often lost at anaphase II is consistent with Hardy's observation that *mei-S332* has micronuclei present at the early spermatid stages (Hardy, 1975). Thus *mei-S332* presumably defines a function required for sister chromatid cohesion. Sandler *et al.* (1974) have shown that ring chromosomes are frequently converted into dominant lethals in *mei-S332* females, presumably resulting from an impaired ability to resolve sister ring chromosomes at anaphase II. Baker *et al.* (1978) have also shown that mitotic chromosome instability is elevated in the presence of *mei-S332*. They suggest that the function of the *mei-S332*<sup>+</sup> locus is to delay the separation of sister chromatids at all divisions. Because the sole *mei-S332* allele is viable, they have further suggested that either this allele is leaky or that there are overlapping or redundant functions that can compensate for this defect.

**cytology:** Placed in 58A-E by Davis (1971, 1977); further confined to 58B by deficiency mapping (Kerrebrock and

Orr-Weaver).

*mei-W5*: see *pal*

*mei-W22*: see *c(3)G*

***mei-W68* (R.S. Hawley)**

**location:** 2-94.

**references:** Baker, Carpenter, Esposito, Esposito, and Sandler, 1976, *Ann. Rev. Genet.* 10: 53-134.

Baker, Carpenter, and Ripoll, 1978, *Genetics* 90: 531-78.

**phenotype:** Females homozygous for *mei-w68* show a complete absence of meiotic recombination (Baker, unpublished data). Ultrastructural studies of pachytene reveal an absence of chromosome condensation and little synaptonemal complex (Carpenter, cited in Baker *et al.*, 1976). A less severe allele (*mei-w68*<sup>L1</sup>-Lindsley) reduces exchange to approximately 60% of control levels and also alters the distribution of residual exchanges. Analysis of mitotic chromosome behavior (Baker *et al.*, 1978) suggests that the *mei-w68*<sup>+</sup> gene product is also required in mitotic cells.

**meiotic-:** see *mei-*

***mel*: melanized**

**location:** 1-64.1.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1953.

**references:** 1958, *DIS* 32: 71.

**phenotype:** Body color darker than normal, especially in thorax; trident pronounced. Eye color dull red. Wing tips frequently curve upward. Classification rather difficult, best in young flies. Viability and fertility good in both sexes. RK3.

**cytology:** Placed in 19C2-3 by Schalet and Lefevre [1976, *Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1B, pp. 847-902].

**phenotype:** Abdominal tergites have slight transverse wrinkles; perhaps thorax darker than normal; flies somewhat smaller with slightly broader wings; eyes of males slightly rough, wings of females variably wrinkled or

curled.

**cytology:** Placed in 19D2-E1 based on *mell* phenotype of heterozygotes between *Df(1)16-3-35 = Df(1)19D2-3;19E6-7* and *Df(1)mel8 = Df(1)18F4-5;19E1*.

**Men: Malic enzyme**

**location:** 3-51.73 [based on 91 recombinants between *kar* (3-51.7) and *ry* (3-52.0)].

**synonym:** *Mdh-NADP*.

**references:** Franklin and Rumball, 1971, DIS 47: 37. Voelker, Ohnishi, Langley, Gausz, and Gyrukovics, 1981, Biochem. Genet. 19: 525-34.

**phenotype:** Structural gene for malic enzyme = (S)-Malate: NADP+ oxidoreductase [MEN (EC 1.1.1.40)], a tetramer with subunit molecular weight of 58,000 (Lee, Langley, and Burkhart, 1978, Anal. Biochem. 86: 697-296) or 67,250 (Geer, Krochko, Oliver, Walker, and Williamson, 1980, Comp. Biochem. Physiol. 65B: 25-34). Biochemical characterization by Geer, *et al.*, (1980). Enzyme known to provide NADP for lipogenesis; levels in larvae increased by dietary carbohydrate and decreased by dietary lipid. Levels normally high in early third-instar larvae, reducing to half in late third instar, rising again in ageing adults. Highest specific activity found in larval fat body and, among cellular fractions, in the cytosol (Geer, Krochko, and Williamson, 1979, Biochem. Genet. 17: 867-79). Histochemical staining of larval imaginal discs reveals enzyme activity localized to nervous elements, including ommatidial precursors, the morphogenetic furrow, and the optic nerve in the eye antennal disc; and the chordotonal organ and the nerve traversing the leg discs; wing, haltere, labial, and genital discs unstained; however genital disc derivatives, the ejaculatory duct and paragonia in males and oviducts of females are stained in adults (Finkbohner, Cunningham, and Kuhn, 1985, Wilhelm Roux's Arch. Dev. Biol. 194: 217-23). Staining of morphogenetic groove absent in *D. simulans* and in *simulans-melanogaster* hybrids except when such hybrids contain two copies of *3R* from *D. melanogaster* and none from *D. simulans* (Kuhn and Sprey, 1987, Genetics 115: 277-81). All null alleles tested survive and are fertile in combination with *Df(3R)ry3l*, which lacks *Men*<sup>+</sup> (Voelker *et al.*). The NADPH/NADP ratio in such null genotypes is one-seventh that of wild type (Geer *et al.*, 1979). Presence of an extra dose of the region from 8D10-12 to 9A1-2 results in an approximately 25% increase in MEN activity (Williamson and Bentley, 1983, Genetics 103: 649-58).

<sup>α</sup> 1 = CP627; 2 = Hilliker, Clark, and Chovnick, 1981, DIS 56: 64-72; 3 = Hilliker, Clark, Chovnick, and Gelbart, 1980, Genetics 95: 95-110; 4 = Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 1261-68.

**cytology:** Placed in 87D4-8 based on its inclusion in *Df(3R)ry1608 = Df(3R)87D4-6;87E1-2* but not *Df(3R)ry74 = Df(3R)87D8;87D12*.

**other information:** All alleles complement *mesB*.

**mesB**

**location:** 3-51.9.

**discoverer:** Schalet.

**references:** Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 121-68.

Hilliker, Clark, Chovnick, and Gelbart, 1980, Genetics 95: 95-110.

**phenotype:** Wings outspread at about 45° from mid-line. Trident dark; occasional thoracic bristle duplication. Subtly abnormal abdomen. Semilethal. RK3.

**alleles:** Existence of thirteen alleles recorded by Skinner, Cole, and Chovnick. *mesB* alleles only partially comple-

ment alleles of *l(3)87De*.

**cytology:** Placed in 87D8-12 based on its inclusion in the region of overlap of *Df(3R)ry74 = Df(3R)87D8;87D12* and *Df(3R)kar-IG27 = Df(3R)87B3-5;87D6-12*.

**other information:** Interacts in *trans* with *l(3)87De* (Skinner, Cole, and Chovnick).

**messy:** see *mes*

**\*Met: Metatarsi irregular**

**location:** 2- or 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Jonsson, 56a10.

**references:** Lüning, 1956, DIS 30: 73.

**phenotype:** First and second tarsal joints fused and swollen with extra hairs. Male sex combs enlarged. Fully penetrant when balanced with *Cy*; however, *Met/ss* is wild type or nearly so. RK2A.

**cytology:** Associated with *T(2;3)Met*.

*Met*: see *Rst(1)JH*

**Metallothionein:** see *Mtn*

**metaphase arrest:** see *mar*

*Mex156*: see *Sxl*

**\*mf: macrofine**

**location:** 1-5.5.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 71.

**phenotype:** Fly slightly smaller than normal with short, thin, bristles. Male viable and fertile. Female slightly delayed in eclosion and reduced in viability. RK3.

**Mfcp: Myofibrillar contractile protein**

**location:** 3 {50-51}.

**references:** Bernstein, Glenn, and Emerson, 1981, Genetics 97: s10.

**phenotype:** Structural genes for several contractile polypeptides of approximately 22,500 daltons molecular weight that initiate expression at the fusion stage of myogenesis (Bernstein and Donady, 1980, Dev. Biol. 79: 388-98).

**cytology:** Placed in 87B by *in situ* hybridization.

**molecular biology:** Genes cloned, presumably by differential screen of pre- and post-fusion stages of myocytes in culture.

**mfd: myofibrillar-defective (J.C. Hall)**

**location:** 1- {38}.

**phenotype:** Deletion of salivary segment 11A6-7 leads to inability to jump or fly, hemizygoty for this variant

allows viability, and the phenotypic defects induced by the deletion are recessive; myofibrils or thoracic muscles shortened; spots are missing in two dimensional gel analysis of proteins from fibrillar and tubular muscles; these differences from wild type apparently due to blocking of phosphorylation of proteins in these muscles; such proteins are very likely myosins that become phosphorylated during the first day after eclosion (in wild-type), in parallel with the gradual development of flying and jumping ability (Hiromi, Ohmura, Masaki, Hirose and Hotta).

**cytology:** Maps to 11A6-7; synthetic deletion, constructed using *T(1;Y)*'s, is the only *mfd* variant.

**mfs(2)31: male-female-sterile (2) in region 31**

**location:** 2-41.35 [based on 23 recombinants between *J* (2-41.0) and *msf(2)31* with *da* (2-41.3) as a middle marker].

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *mfs48*.

**references:** Sandler, 1977, Genetics 86: 567-82.

Lindsley, Goldstein, and Sandler, 1980, DIS 55: 84-85.

**phenotype:** Homozygotes have short thin bristles; relative viability 25% at 25°; hemizygotes lethal. Both males and females sterile at 25° but some fertility observed in flies raised at 23°. Males raised at 28.5° have no motile sperm and some spermatids have micronuclei, and occasionally two basal bodies and axonemes are observed.

**cytology:** Placed in 31B-32A based on its lethality in combination with *Df(2L)527 = Df(2L)31B-D;31F-32A*

**mfs(2)350**

**location:** 2-50.7.

**references:** Fukunaga, 1980, J. Hered. 71: 349-52.

**phenotype:** Homozygous males and females sterile in certain cytoplasmic constitutions, fertile in others. Gonads rudimentary, although some males have normal testes without motile sperm.

*mfs(2)7601*: see *Dox-A2*<sup>*mfs1*</sup>

**mfs(3)73A**

**location:** 3- {45}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Hoffmann.

**cytology:** Placed in 73A10-B1 between the right breakpoints of *Df(3L)st7P* and *Df(3L)st-g24*.

**mfs(3)G: male-female-sterile of Gill**

**location:** 3-59.

**origin:** X ray induced.

**discoverer:** Gill, 59a.

**synonym:** *fs(3)4*<sup>59a</sup>.

**references:** 1960, Anat. Record 138: 351.

1961, Ph.D. Thesis, Yale Univ.

1962, DIS 36: 37.

1963, J. Exp. Zool. 152: 251-77 (fig.).

**phenotype:** Oogenesis incomplete; follicles usually cease development early in vitellogenesis (at or before stage 9); occasional breakthrough produces adult fly. Primary compound chambers in which two, occasionally three, incipient cysts are enclosed occur in about 10% of the cases. Male sterile. Adult fat body hypertrophied; body size reduced. Occasionally, metathoracic legs with tibiae more curved than normal and tarsi crooked. Viability low. RK3.

**mgr: merry-go-round**

**location:** 3-51.3.  
**origin:** X-ray induced.  
**references:** González, Casal, and Ripoll, 1988, J. Cell Sci. 89: 39-47.  
**phenotype:** Most characteristic abnormality is appearance of mitotic and meiotic figures in which all the chromosomes are arranged in a circle. Other mutant traits include metaphase arrest, polyploid cells, postmeiotic cysts with 16 nuclei, and spermatids carrying four times the normal complement of chromosomes. The circular mitotic figures (CMF's) are caused by monopolar spindles. The wild-type allele of *mgr* apparently is necessary for correct centrosome behavior.

**mgt: midget**

**location:** 1-48.7.  
**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).  
**discoverer:** Fahmy, 1954.  
**references:** 1958, DIS 32: 71.  
**phenotype:** Small fly with delayed eclosion. Not easily classified. Male fertile and viability about 20% wild type. Expression more extreme in female and viability further reduced. RK3.  
**other information:** One allele each induced by CB. 3025 and X rays; two alleles induced by CB. 1506.

**mh: maternal haploid**

**location:** 1-.  
**origin:** Induced by ethyl methanesulfonate.  
**synonym:** *fs(1)A1182*.  
**references:** Gans, Audit, and Masson, 1975, Genetics 81: 683-704.  
 Zalokar, Audit, and Erk, 1975, Dev. Biol. 47: 419-32.  
 Santamaria and Gans, 1980, Nature (London) 287: 143-44.  
 Santamaria, 1983, Dev. Biol. 96: 285-95.  
**phenotype:** Homozygous *mh* females are fertile at 18° but at 25° they are sterile; irrespective of the males used in cross, nuclei of developing embryos appear to be X-bearing and haploid. 183/200 eggs developed to blastoderm; gastrulation was abnormal; 22 embryos gave evidence of segmentation and muscular movement. Nuclei from such embryos injected into normal early embryos are capable of developing into patches of tissue, some of which produce structures of normal number and size and are presumably diploid, some of which produce increased numbers of smaller-than-normal structures and are presumably haploid, and a few of which are mixed. Haploid tissue with female phenotype found in basitarsus, tergites, and terminalia. Nuclear division cycles of haploid embryos 2.1 min. longer than wild type; such embryos undergo an extra nucleus division in the syncytial blastoderm, possibly to achieve a proper nuclear: cytoplasmic ratio prior to cellularization (Edgar, Kichle, and Schuberger, 1986, Cell 44: 365-72). Haploid cell cultures established from 25° embryos (Debec, 1978, Nature 274: 255-56). Haploid cells and their diploidized derivatives lack centrioles (Debec, Szöllösi, and Söllöcs, 1982, Biology of the Cell 44: 133-38).

**Mhc: Muscle myosin heavy chain**

**location:** 2-52.  
**origin:** A number of mutants have been induced by ethyl methanesulfonate.  
**references:** Mogami and Hotta, 1981, Mol. Gen. Genet. 183: 409-17.

 Kazzaz and Rozek, 1989, Dev. Biol. 133: 550-61.  
**phenotype:** Structural gene for the heavy chain of muscle myosin (MHC). Heterozygotes for dominant flightless mutant alleles are characterized by erect wings and disrupted myofibrils in the indirect flight muscles. Segmental-deficiency heterozygotes for the locus are also flightless with disrupted myofibrils. Flight can be rescued in heterozygotes for most alleles by addition of a second *Mhc*<sup>+</sup> allele to the complement, or by making the fly simultaneously hemizygous for *Act88F* [Beall, Sepanski, and Fyrberg, 1989, Genes Dev. 3: 131-40 (fig.)].  
**alleles:** Of five ethyl-methanesulfonate-induced alleles that are lethal as homozygotes, three have 9-10 kb inserts with some apparently similar restriction sites (Mogami and Hotta; Mogami *et al.*). Three other ethyl-methanesulfonate-induced mutants, which are homozygous viable, are judged to be allelic based on the failure to obtain recombinants between them and the lethal alleles; as yet no molecular characterization available.

<sup>β</sup> Viability notations refer to homozygotes.

$\gamma$  Fuller description follows "molecular biology".

**cytology:** Placed in 36A7-C1 on the basis of its inclusion in *Df(2L)H20 = Df(2L)36A7-10;36E4-F1* but not in *Df(2L)H68 = Df(2L)36B2-C1;37A1-B1* (Steward and Nüsslein-Volhard, 1986, Genetics 113: 665-78); located in 36B by *in situ* hybridization to salivaries (Bernstein *et al.*, 1983; Rozek and Davidson, 1983).

**molecular biology:** *Mhc* is a single copy gene in *Drosophila melanogaster* (in contrast to mammals, chickens, and nematodes which have families of myosin heavy chain genes). The *Drosophila Mhc* gene has been cloned and the complete nucleotide sequence of the genomic DNA and the derived amino acid sequence of the MHC protein obtained (Bernstein *et al.*, 1983, 1986; Rozek and Davidson, 1983, 1986; George *et al.*, 1989). The gene has a complex exon structure that, by means of regulated alternative RNA splicing, enables it to produce a variety of larval and adult muscle isoforms. Its 21 kb transcription unit contains 19 exons, 14 single-copy exons and five other exons that are tandemly repeated [two copies of exon 3 (Wassenberg *et al.*, 1987), four of exon 7, three of exon 9, five of exon 11, and two copies of exon 15 (George *et al.*, 1989; Hess *et al.*, 1989)]. In the clones studied by George *et al.* (1989), the repeated exons are spliced in a mutually exclusive manner, so that only one form of each exon set is included. Exon 18 shows differential splicing by inclusion or exclusion of the exon in pre-mRNA; it is expressed mainly in the thorax of late pupae and adults. Coding sequences for the ATP binding domain have been located in exon 4 (Wassenberg *et al.*, 1987; George *et al.*, 1989); the hydrophobic region next to the ATP-binding domain is encoded by alternative exons 3a/3b as well as by exon 4. Northern blots show transcripts of 6.1 and 6.6 kb in larval stages and transcripts of 6.1, 6.6, and 7.1 kb in adult stages. Positions of the 5' introns are conserved in flies, vertebrates, and nematodes (Wassenberg *et al.*, 1987; George *et al.*, 1989). Fusion genes have been constructed using the 5' end of the *E. coli lac-z* gene introduced into the genome by *P*-element gene transfer, and the transformed flies stained for expression of the fusion protein to identify sequences involved in muscle-specific expression (Hess *et al.*, 1989). The results indicate that these elements are located 450 nucleotides upstream and 2095 nucleotides downstream of the transcription initiation site.

### Mhc: Muscle myosin heavy chain map

From figure supplied by Bernstein and Kronert. Program by D. Conner.

**Mhc<sup>1</sup>**

**phenotype:** Homozygous embryos show no movement; unable to hatch; ultrastructural observations show complete lack of thick filaments in muscles. Heterozygotes display nearly a 50% reduction in the numbers of thick filaments in indirect flight muscles and the tergal-depressor-of-the-trochanter muscle, resulting in disruption of the normal regular array of thick and thin filaments in these muscles. Other less regularly organized muscles, although having reduced numbers of thick filaments, appear to function adequately in *Mhc*<sup>1/+</sup> flies (O'Donnell and Bernstein, 1988, *J. Cell Biol.* 107: 260-12).

**molecular biology:** 101 base pair deletion which removes most of exon 5 and the intron that precedes it. The splice-donor site of exon 4 rather than that of exon 5 appears to interact with the exon-6 splice-acceptor site (O'Donnell and Bernstein, 1988). Deletion generates a nonsense mutation, which likely results in production of an unstable truncated protein.

**Mhc<sup>5</sup>**

**phenotype:** 20% of heterozygotes display indented thorax and erect wings and are flightless; the remainder have normal phenotype but fly poorly. Homozygotes display erect wing phenotype. Judged to be antimorphic since not rescued by addition of *Dp(2;3)osp*<sup>3</sup>. *Mhc*<sup>5</sup> interaction in double heterozygotes with other flightless mutants observed by Homyk and Emerson (1988, *Genetics* 119: 105-21). Heterozygous viability severely reduced in combination with hemizygous *hdp*<sup>2</sup>, *int*<sup>3</sup>, *up*<sup>101</sup>; or *up*<sup>x</sup>; rare escapers have gnarled legs, walk poorly, and die within two days of eclosion. Females doubly heterozygous for *Mhc*<sup>5</sup> and *hdp*<sup>2</sup>, *int*<sup>3</sup>, *up*<sup>101</sup>; or *up*<sup>x</sup> have normal viability but are completely flightless and display abnormal wing posture.

**Mhc<sup>6</sup>**

**phenotype:** Heterozygotes fly moderately well and display normal wing posture; hemizygotes flightless and occasionally have abnormal wing posture. Double heterozygotes with *hdp*<sup>101</sup>, *hdp*<sup>102</sup>, *int*<sup>3</sup>, *up*<sup>101</sup>; or *up*<sup>x</sup>; but not *hdp*<sup>2</sup>, much more nearly flightless than *Mhc*<sup>6/+</sup>; wing posture normal.

**Mhc<sup>7</sup>**

**phenotype:** Indirect flight muscles accumulate little or no MHC, have no thick filaments, and show no organized myofibrils. The four smaller cells of the tergal depressor of the trochanter muscle (TDT) display reduction in thick filament number and myofibril size; large TDT cells unaffected. Flies jump 33% as well as wild type. Leg muscle MHC found in normal amounts (O'Donnell *et al.*, 1989).

**Mhc<sup>8</sup>**

**phenotype:** Heterozygotes display indented thorax and erect wings. Judged to be antimorphic since not rescued by addition of *Dp(2;3)osp*<sup>3</sup>. *Mhc*<sup>8</sup> interaction in double heterozygotes with other flightless mutants observed by Homyk and Emerson (1988, *Genetics* 119: 105-21). Heterozygous viability severely reduced in combination with either heterozygous or hemizygous *hdp*<sup>2</sup>, *int*<sup>3</sup>, and *up*<sup>101</sup>; lethal in *up*<sup>x</sup>/Y males. No interaction with the following: *hdp*<sup>3</sup>, *hdp*<sup>4</sup>, *hdp*<sup>5</sup>, *hdp*<sup>101</sup>, *hdp*<sup>102</sup>, *up*<sup>2</sup>, *up*<sup>3</sup>, or *up*<sup>102</sup>.

**Mhc<sup>9</sup>**

**phenotype:** Indirect flight muscles accumulate little or no MHC, have no thick filaments, and show no organized myofibrils. The four smaller cells of the TDT display reduction in thick filament number and myofibril size; large TDT cells unaffected. Flies jump 59% as well as wild type. Leg muscle MHC found in normal amounts (O'Donnell *et al.*, 1989).

**Mhc<sup>10</sup>**

**phenotype:** Indirect flight muscles accumulate little or no MHC, have no thick filaments, and show no organized myofibrils. All 32 TDT cells lack thick filaments and lack myofibril organization. Flies cannot jump. Leg muscles accumulate 55% normal amounts of MHC (O'Donnell *et al.*, 1989).

**molecular biology:** Mutation within 3' splice acceptor of exon 15a that encodes the central region of the MHC hinge (Collier, Kronert, O'Donnell, Edwards, and Bernstein, 1990, *Genes Dev.* 4: 885-95).

**Mhc<sup>11</sup>**

**phenotype:** Indirect flight muscles accumulate little or no MHC, have no thick filaments, and show no organized myofibrils. No apparent effect on TDT; unique among alleles in being capable of jumping. Leg muscle MHC found in normal amounts (O'Donnell *et al.*, 1989).

**Mhc<sup>12</sup>**

**phenotype:** Indirect flight muscles accumulate little or no MHC, have no thick filaments, and show no organized myofibrils. The four smaller cells of the TDT display reduction in thick filament number and myofibril size; large TDT cells unaffected.

**Mhc<sup>13</sup>**

**phenotype:** A dominant flightless mutation; in homozygotes but not heterozygotes, the myofibrils of dorsolateral indirect flight muscles, although displaying normal morphology at eclosion, degenerate with time so that each cell is composed of a narrow strip of material connected to a bulged-out region. Some areas of the cells contain over-contracted sarcomeres and others show arrays of thick and thin filaments splayed throughout the cytoplasm. Abnormal morphology is recessive. Unlike the situation with other *Mhc* mutations, the dominant flightlessness of *Mhc*<sup>13</sup> not rescued by the addition of a second dose of *Mhc*<sup>+</sup>.

**Mhc<sup>16</sup>**

**phenotype:** Heterozygotes display indented thorax and erect wings; flightless; hemizygotes semilethal, very inactive, have weak mesothoracic legs which are generally folded beneath the thorax; die prematurely after eclosion. Judged to be antimorphic since not rescued by addition of *Dp(2;3)osp*<sup>3</sup>. *Mhc*<sup>16</sup> interaction in double heterozygotes with other flightless mutants observed by Homyk and Emerson (1988, *Genetics* 119: 105-21). Heterozygous viability severely reduced in combination with hemizygous *hdp*<sup>2</sup>, *int*<sup>3</sup>, *up*<sup>101</sup>; or *up*<sup>x</sup>; rare escapers have gnarled legs, walk poorly, and die within two days of eclosion.

Young, Pesacreta, Rose, and Kiehart, 1991, Development 111: 1-14.

**phenotype:** Encodes a 205 kilodalton myosin heavy chain found in Drosophila cell lines and all Drosophila developmental stages. Antibodies raised against this protein crossreact, but weakly with muscle myosin heavy chain. First appears in preblastoderm embryos; diffusely distributed until syncytial blastoderm at which time localization to cortex and pole cells observed; at cleavage furrow, canals at the time of cellularization; transiently present at points of invagination during gastrulation (Young *et al.*, 1987, 1991).**cytology:** Localized to 60E9 by *in situ* hybridization (Jones and Young).**molecular biology:** A 50 kb walk that includes the 20.5 kb transcription unit for the gene is cloned; *in vitro* transcription and translation yields a 205 kd protein that reacts specifically with anti-cytoplasmic-myosin serum. Hybridizes with at least 2 *ca.* 6.3 kilobase messages on Northern blots that result from a differential splice at the 5' end of the gene (Kiehart *et al.*, 1989; Ketchum *et al.*, 1990).**other information:** Appears to be allelic with *zipper*. An EMS-induced allele (*Mhc-c*<sup>1</sup>) produces a truncated myosin heavy chain on Western blots and fails to complement *zip*<sup>1</sup> and *zip*<sup>2</sup>. Western blots also indicate *zip*<sup>2</sup> fails to accumulate myosin heavy chain.**mi: minus****location:** 2-104.7.**discoverer:** Biddle, 281.**references:** Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.**phenotype:** Bristles almost as small as hairs; hairs reduced in number and size. Body size small. Eclosion delayed. Viability low and erratic. Female entirely sterile; male fertile. RK2.**cytology:** Locus is in 59D6-E4 of salivary gland chromosome (Schultz) on the basis of its being between the right breakpoints of *In(2R)bw*<sup>VDe1</sup> = *In(2R)41B2-C1;59E2-4* and *In(2R)bw*<sup>VDe2</sup> = *In(2R)41A-B;59D6-E1*.**\*mib: miniature bristles****location:** 1-8.7.**origin:** X-ray induced.**discoverer:** Fahmy, 1956.**references:** 1959, DIS 33: 88.**phenotype:** Short, thin bristles. Body slightly darker than normal, particularly thorax and posterior border of tergites. Wings occasionally upheld and inner margins frequently incised. Male viable and sterile. <sup>α</sup> 1 = Kotarski, Pickert, and MacIntyre, 1983, Genetics 105: 371-86.  
2 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82; 3 = Szidonya and Reuter, 1989, Genet. Res 51: 197-208.<sup>β</sup> Allelism inferred from deficiency mapping, not complementation mapping.**cytology:** Placed in 25D7-F3 based on its inclusion within the region of overlap between *Df(2L)c11* = *Df(2L)25D7-E1;25E6-F3* and *Df(2L)GpdhA* = *Df(2L)25D7-E1;26A8-9*.**midget:** see *mgt***midgoid:** see *mdg***midgut amylase pattern:** see *map***midline:** see *mid***min: mini****location:** 2-90.**references:** Procnunier and Tartof, 1975, Genetics 81: 515-23.

Procnunier and Dunn, 1978, Cell 15: 1087-93.

**phenotype:** The locus encoding the genes for 5S RNA. Heterozygous deficiency for the region is normal in phenotype; however, *min* mutants, although normal in phenotype when heterozygous or homozygous, express a phenotype indistinguishable from *bb* when hemizygous. Ordinarily, the haploid complement carries approximately 165 copies of 5S genes; in *min*-bearing chromosomes this number is reduced to approximately 80; according to Procnunier and Tartof, this number is increased by compensation to 265 in hemizygotes for the normal allele. Eclosion of *min* hemizygotes delayed about two days; also show reduced viability which is more severe at 29° than at 25°.**alleles:** *min*<sup>0</sup> spontaneous (Procnunier and Tartof). *min*<sup>1</sup> and *min*<sup>2</sup>, induced by triethylenemelamine (Procnunier and Dunn).

**cytology:** Placed in 56E-F by *in situ* hybridization in one of the earliest uses of that technique (Wimber and Stefensen, 1970, Science 170: 639-41); Szabo notes two bands of label, at 56F1-2 and 56F6-7 (1974, J. Cell Biol. 63: 341). Also located between the breakpoints of  $T(Y;2)L139 = T(Y;2)56E$  and  $T(Y;2)L141 = T(Y;2)56F$ ;  $T(Y;2)L62 = T(Y;2)56E-F$  is broken within the tandem array of sequences with approximately 80 copies on either side.

**molecular biology:** Region contains a tandem array of 380-base-pair repeats, each comprising 120 base pairs of gene and 170 base pairs of spacer sequence; the spacer is 33% GC and the gene 57% GC (Hershey, Condad, Sodja, Yen, Cohen, Davidson, Ilgen, and Carbon, 1977, Cell 11: 585-98). Segments of tandem array cloned and restriction mapped (Artavanis-Tsakonas, Schedl, Tschudi, Pirrotta, Steward, and Gehring, 1977, Cell 12: 1057-67; Tschudi and Pirrotta, 1980, Nucleic Acid Res. 8: 441-51); variation in restriction maps attributable to variable numbers (4-7) of a tandemly repeated heptamer in the spacer region plus occasional other restriction site polymorphisms. In addition some strains appear to have a continuous array of repeats, whereas others appear to contain a segment with a number of restriction sites that separates the array into two subsegments of approximately equal size (Junakoric, 1980, Nucleic Acid Res. 8: 3611-22). Nucleotide sequence and proposed secondary structure of 5S RNA provided by Behnamon and Jordan (1976, FEBS Lett. 62: 146-46) and Thompson, Wegnez, and Hearst (1981, J. Mol. Biol. 147: 417-36). Following heat shock, 5S RNA synthesis is reduced and an abnormal product with 55 extra nucleotides appended to the 3' end appears instead; may be a precursor that does not get processed (Rubin and Hogness, 1975, Cell 6: 207-13). Linker-scanning mutation studies reveal five regions important for normal transcription; one between -39 and -26, presumably involved in polymerase binding, and four internal sequences at 3-18, 37-44, 48-61, and 79-98 (Sharp and Garcia, 1988, Mol. Cell. Biol. 8: 1266-74).

*Mio*: see *Dr<sup>Mio</sup>*

**Mir: Mirabile (M. Muskavitch)**

**location:** 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Muskavitch.

**phenotype:** Mirror-image duplication of tergite structure.

Microchaetae are eliminated from the anterior portion of the tergite and replaced by a duplication consisting of an anteriorly oriented row of macrochaetae and the darkly pigmented cuticle normally found in the posterior portion of the tergite. Fat body and oenocytes underneath the tergite are also duplicated with mirror-image symmetry (Madhavan and Madhavan).

**alleles:** Original allele dominant and revertable by X ray mutagenesis suggesting that this allele constitutes a gain-of-function mutation. Animals heterozygous for any one of seven independent X- ray-induced revertant alleles, designated *Mir<sup>rv1</sup>* through *Mir<sup>rv7</sup>*, and a wild-type allele exhibit wild-type tergite structure.

**cytology:** Associated with  $T(1;3)Mir$  with the new order 1 - 20F|81F - 64C|94A - 81F|94A-100F; 20F|64C - 61A (Gelbart). Analysis of segregation behavior of the phenotype in relation to the components of an X ray-induced detachment of  $T(1;3)Mir$  indicates that the mutation maps to the third chromosome.

**other information:** Not allelic to disembodied, hedgehog, pointed, rhomboid or shrew as assessed on the basis of lethal complementation tests employing representative alleles of these five loci.

**\**mis*: misproportioned**

**location:** 1-1.3.

**origin:** Induced by 1:4-dimethanesulfonybut-2-yne (CB. 2058).

**discoverer:** Fahmy, 1951.

**references:** 1938, DIS 32: 71.

**phenotype:** Abdomen deformed: in male, large and broad; in female, tergites abnormal and hairs disarranged. Wings shortened in both sexes. Bristles thin. Body color rather pale. Eclosion slightly delayed. Male viability and fertility normal; female viability 50% wild type. RK3.

**other information:** One allele each induced by CB. 1540 and CB. 3034.

***misformed*:** see *msf*

***misheld wings*:** see *mwi*

***misp*: misstep (T. Schüpbach)**

**location:** 2-59.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *misp<sup>RQ</sup>*.

**references:** Schüpbach and Wieschaus.

**phenotype:** Maternal-effect lethal, female sterile. Embryos from homozygous mothers do not hatch. In cuticle preparations they show irregular segmentation and variable segment fusions.

***misproportioned*:** see *mis*

***missing*:** see *msg*

***misstep*:** see *misp*

***mit*: mitotic loss inducer**

**location:** 1-57 (between *f* and *Bx*).

**origin:** Spontaneous.

**references:** Gelbart, 1974, Genetics 76: 51-63.

**phenotype:** Mosaics produced by loss of maternal or paternal chromosomes in  $F_1$  of homozygous *mit* females; progenies of *mit* males normal. Chromosome loss (*X* or 4) usually occurs at third or fourth mitotic division of the

zygote, producing mosaic patches of intermediate size. Rod-X chromosomes lost as frequently as rings, but neither XY, nor Y chromosomes eliminated frequently by *mit*. Relative frequencies of observed loss of maternal and paternal X chromosomes depend on the markers carried rather than the parental origin of the X's. Double mosaic gynandromorphs indicative of independent loss of homologous chromosomes in different lineages. No increase in meiotic nondisjunction or chromosome loss observed. *mit* stocks show good viability and fertility, though modifiers reducing frequency of mosaics tend to accumulate. *mit*-induced gynandromorphs useful in constructing morphogenetic fate maps.

**cytology:** Placed in 16A6-F8 since *mit* is proximal to *f* (in 15F) and not included in *Df(1)B263-20 = Df(1)15F9-16A1;16A6-7* or in *Dp(1;1)Bxr = Dp(1;1)17A;17E-F*.

### *mit(1): mitotic (1)*

A group of fourteen loci identified as temperature-sensitive lethal mutations (Baker) that exhibit, at semirestrictive temperatures, elevated frequencies of clones of homozygous *mwh* cells in the wings of surviving *mit(1);mwh/+* males and of *y* clones and *y//mwh* twin spots in the abdomens of *y mit(1);Dp(1;3)sc<sup>J4</sup>*, *y<sup>+</sup> mwh/+* males. The presence of large clones is consistent with origin via mitotic exchange, mitotic nondisjunction of both homologues, or mutation; twin spots are not expected to result from somatic mutation; only mitotic nondisjunction produces *y Sb<sup>+</sup>* clones in *Dp(1;3)sc<sup>J4</sup>*, *y<sup>+</sup> Sb/+*. Preponderance of small clones suggests origin via chromosome breakage. Mitotic chromosome morphology examined in larval ganglion cells of *mit(1)* males. *inter se* allelism tests have not been performed.

locus	genetic location	phenotype
<i>mit(1)2</i>	1-15.3	small clones; few twin spots; 1.16% chromatid breaks
<i>mit(1)3</i>	1-46.1	small clones; twin spots; 1.63% chromatid and isochromatid breaks
<i>mit(1)4</i>	1-28.0	large clones; twin spots; chromosomes undercondensed
<i>mit(1)5</i>		large clones; twin spots; 2.46% chromatid and isochromatid breaks
<i>mit(1)6</i>	1-34.9	small clones; few twin spots; chromosomes normal
<i>mit(1)7</i>	1-15.7	large clones; few twin spots; 1.47% chromatid, isochromatid breaks, and exchanges
<i>mit(1)8</i>		large clones; few twin spots; 1.72% chromatid and isochromatid breaks
<i>mit(1)9</i>		small clones; few twin spots; 1.13% chromatid, isochromatid breaks, and exchanges
<i>mit(1)10</i>	1-1.4	large clones; few twin spots; chromosomes normal
<i>mit(1)11</i>	1-21.4	small clones; few twin spots; 0.9% chromatid and isochromatid breaks
<i>mit(1)12</i>		large clones; few twin spots; 0.99% chromatid and isochromatid breaks
<i>mit(1)13</i>	1-36.0	large clones; <i>y Sb<sup>+</sup></i> clones; 1.68% chromatid and isochromatid breaks
<i>mit(1)14</i>	1-49.0	small clones; <i>y Sb<sup>+</sup></i> clones; 7.20% chromatid and isochromatid breaks
<i>mit(1)15</i>	1-1.2	large clones; <i>y Sb<sup>+</sup></i> clones; mitotic nondisjunction

### *mit(1)15*

**synonym:** *abe; l(1)zw10*.

**phenotype:** Semilethal as males or homozygous females; surviving flies have reduced roughened eyes, bristles on the head and thorax sometimes missing, abnormal wings with thin texture and thickened veins; both sexes sterile.

Up to 100 fold increase in the incidence of *mwh* clones per wing in *mit15;mwh/+* flies raised at sub-restrictive temperature. Half of all metaphases in larval ganglion cells are hyperploid for one or more chromosomes; hyperploidy for nearly all combinations of sex chromosomes and autosomes are observed. Chromosome breakage seen in less than 2% of cells. Cytological observations in *mit(1)15<sup>15</sup>*, *mit(1)15<sup>3</sup>* and *mit(1)15<sup>4</sup>* at either restrictive or permissive temperature.

**\**ml*: minutelike**

**location:** 3-46.  
**discoverer:** Mohr, 24c3.  
**synonym:** *sb*: *short-bristle*.  
**references:** 1924, Br. J. Exp. Biol. 2: 189-98 (fig.).  
**phenotype:** Bristles small, as in Minute. Late hatching and poorly fertile. RK3.  
**alleles:** \**ml*<sup>2</sup> (Nichols-Skog, 36c); spontaneous; allelism inferred from phenotype and location on third chromosome.

***Mlc1*: Myosin light chain**

**location:** 3- {95}.  
**references:** Falkenthal, Parker, Mattox, and Davidson, 1984, Mol. Cell. Biol. 4: 956-65.  
 Falkenthal, Parker, and Davidson, 1985, Proc. Nat. Acad. Sci. USA 82: 449-53.  
**phenotype:** Encodes the myosin alkali light chain (MLC-ALK), so called because it dissociates from MHC only at high pH. Expressed during periods of myogenesis: late embryo, larvae, late pupae, and adults; not expressed in early embryos or in early pupae during histolysis of larval muscle.

**cytology:** Placed in 98B on basis of *in situ* hybridization.  
**molecular biology:** Genomic clones isolated by screening genomic library with cDNA from stages of active myogenesis. Sequence analysis of genomic and cDNA clones indicates the presence of six exons separated by introns varying in length from 59 to 986 nucleotides; five polyadenylation signals detected within and downstream from the sixth exon; postulated to account for the variation in transcript size. Differential splicing produces one transcript with all six exons, which has a stop codon in exon 5 and one that lacks exon 5 and has the stop codon in exon 6; these generate polypeptides that differ in fourteen C-terminal amino acids; the former is found in both larvae and pupae, whereas the second is found only in pupae. Open reading frames imply a polypeptide of 155 amino acids; the inferred amino-acid sequence reveals a region of especially high homology with one of the three Ca<sup>2+</sup> binding domains of chicken MLC-ALK.

***Mlc2***

**location:** 3- {102}.  
**synonym:** *Ifm(3)99Eb*.  
**references:** Parker, Falkenthal, and Davidson, 1985, Mol. Cell. Biol. 5: 3058-68.  
 Warmke, Krevz, and Falkenthal, 1989, Genetics 122: 139-51.  
**phenotype:** Encodes a myosin light chain homologous to chicken MLC2. Expression abundant in late embryo, first and third larval instars, late pupae and adults; no expression in early embryos or early pupae. Phosphorylation of the polypeptide determined to be necessary for filament assembly (Hayashi and Hotta, 1982, Dev. Growth Differ. 24: 417).  
**alleles:** One allele recovered as a dominant flightless

mutant in combination with a closely linked recessive lethal, *l(3)99Df<sup>1</sup>* by Merriam (Warmke *et al.*). Heterozygous deficiency for the locus also flightless.

**cytology:** Placed in 99E1-3 by *in situ* hybridization.  
**molecular biology:** Genomic clone independently isolated by screening genomic libraries with cDNA from stages of active myogenesis by Parker *et al.* and by Toffenetti, Mischke, and Pardue (1987, J. Cell Biol. 104: 19-28) and by screening with blastoderm cDNA by Roark, Mahony, Graham, and Lengyel (1985, Dev. Biol. 109: 476-88). Sequence determination from genomic and overlapping cDNA clones reveals alternative transcription start sites 67 and 55 nucleotides upstream from the first codon as well as two termination sites 109 and 259 nucleotides 3' to the stop codon; also there is no TATA box. Two introns, one of 699 nucleotides between amino-acid residues 1 and 2 and the other of 169 nucleotides between residues 82 and 83; these intron positions are conserved in rat MLC2. Northern blots reveal two abundant mRNA's of 1.1 and 1.4 kb plus a minor transcript of 2.7 kb; *in vitro* translation of hybrid-selected mRNA yields polypeptides of 17 and 26 kilodaltons; amino-acid sequence inferred from the nucleotide sequence suggests high Ca<sup>2+</sup> binding affinity; also the serine that is phosphorylated in mammalian MLC2 is conserved in the *Drosophila* polypeptide, but is not known to be the site of phosphorylation. As in several vertebrate muscle proteins, *Drosophila* MLC2 has an acylated amino terminus (Toffenetti *et al.*).

**other information:** A series of alleles recovered on the basis of semilethality in combination with a deficiency for 99D3-E3 and behaving as dominant flightless mutations turn out to map to the same complementation group at 3-54.2 in region 88; the locus is designated *l(3)nc99Eb* by Warmke *et al.*

***Mlc-c*: Myosin alkali light chain cytoplasmic**  
 (D.P. Kiehart)

**location:** 1- {14}.  
**references:** Chang, Edwards, and Kiehart, in preparation.  
**phenotype:** The structural gene for the alkali light chain of non-muscle myosin (whose other subunits are encoded by *Mhc-c* and *sqh*).  
**cytology:** Localized to 5A6 by *in situ* hybridization of genomic clones.  
**molecular biology:** Cloned using oligonucleotides corresponding to partial peptide sequence of purified non-muscle myosin light chain. A cDNA detects a 1.3 kb transcript at all developmental stages and encodes a 16 kd protein with 60-70% identity to vertebrate smooth-muscle-myosin alkali light chain.

***mle*: maleless**

**location:** 2-55.2 (just distal to *ap* based on deficiency mapping).  
**references:** Fukunaga, Tanaka, and Oishi, 1975, Genetics: 81: 135-41.  
 Tanaka, Fukunaga, and Oishi, 1978, Genetics 84: 257-66.  
**phenotype:** Homozygous males die, but homozygous females survive. Males produced by homozygous females die during the third larval instar, whereas those produced by heterozygous females are late pupal lethals. Females transformed into phenotypic males (*tra*) or intersexes (*dsx*) unaffected by *mle*, *i.e.* *mle* acts only upon

single-X-bearing flies. No interaction with *msl-1* or *msl-2* (Belote, 1983, Genetics 96: 165-86). *mle*<sup>4</sup> males surviving at 18° are sterile, small, and slow developing. Concluded to be defective in dosage compensation in males based on decreased levels of X-linked-enzyme activities (G6PD, 6GPD, FUM, β-HAD) but not autosomally encoded enzymes (ADH, AO, GPDH, IDH) in homozygous *mle*<sup>4</sup> male larvae and escaping adults, e.g. β-HAD. The incorporation of labeled uridine by the polytene X chromosome relative to that of 2R is lower than normal in *mle*<sup>4</sup> males (Belote and Lucchesi, 1980, Nature 285: 573-75); steady-rate level of *Sgs4* mRNA incompletely compensated in *mle*<sup>4</sup> and *mle*<sup>4</sup>*mle*<sup>6</sup> male larvae (Breen and Lucchesi, 1986, Genetics 112: 483-91). Polytene X chromosome of *mle* males appears narrower and more densely stained than that of control males. Few homozygous *mle* gynandromorphs survive; XO patches small, with small bristles, and mostly confined to abdomen (Uenoyama, Uchida, Fukunaga, and Oishi, 1982, Genetics 102: 223-31). *mle* pole cell transplanted into wild-type hosts incapable of undergoing normal spermatogenesis (Bachiller and Sánchez, 1986, Dev. Biol. 118: 379-84). Homozygous (and to a lesser extent heterozygous) *mle* females that are heterozygous for *Sxl*<sup>F1</sup> (Uenoyama, Fukunaga, and Oishi, 1982, Genetics 102: 233-43; Skripsky and Lucchesi, 1982, Dev. Biol. 94: 153-64) or are the surviving progeny raised at 17° of homozygous *da* mothers (Cline, 1982, Genetics 100: 641-63) develop as intersexes.

β Allelism confirmed by Ashburner.

γ Allelism inferred from map position at 2-55.2.

**cytology:** Placed in 42A2-8 as it is uncovered by *Df(2R)nap9 = Df(2R)42A (?)* (Kreber).

**molecular biology:** Locus cloned by Kuroda, Kernan, Kreber, Ganetzky, and Baker. Molecular analyses of *nap* and *mle* indicate that the same open reading frame encodes *mle*<sup>+</sup>, *nap*<sup>+</sup> and *nap*<sup>ts</sup> activities.

**other information:** *mle* alleles fail to complement the paralysis caused by *nap* alleles, indicating that *nap* and *mle* are allelic (Kernan and Ganetzky).

**mle3**

**location:** 3-25.8.

**references:** Uchida, Uenoyama, and Oishi, 1981, Jpn. J. Genet. 56: 523-27.

**phenotype:** Homozygous males exhibit delayed development; survive as larvae for ten days. Ten-day-old male larvae have small undeveloped imaginal discs, which, however, when transplanted into wild type larvae are capable of undergoing nearly complete (wing, leg) or partial (eye-antenna) differentiation; few homozygous *mle* gynandromorphs survive; XO patches small, with small bristles, and mostly confined to abdomen [Uenoyama, Uchida, Fukunaga, and Oishi, 1982, Genetics 102: 223-31(fig.)]. No interaction with *mle*. Females transformed into phenotypic males (*tra*, *tra2*) or intersexes (*dsx*) unaffected by *mle3*, i.e. *mle3* acts only upon single-X-bearing flies. Females heterozygous for *Sxl*<sup>F1</sup> and homozygous (and to a lesser extent heterozygous) for *mle3* show signs of intersexual development; effect less severe when mothers homozygous for *mle3* [Uenoyama, Fukunaga, and Oishi, 1982, Genetics 102: 233-43 (fig.)]. Staining of polytene X chromosome of *mle3* males similar to that of *mle* males (Lucchesi, Skripsky, and Tax, 1982, Genetics 100: s42; Okuno, Satou, and Oishi, 1984, Jpn. J. Genet. 59: 237-47).

β 4 = Uchida, Uenoyama, and Oishi, 1981, Jpn. J. Genet. 56: 523-27. Cell autonomous; clones homozygous for mutant are deleterious (Bachiller and Sánchez, 1989).

*mll*: see *mle*

**mmy: mummy**

**location:** 2-16.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82; Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26. (fig.).

**phenotype:** Embryonic lethal; mouth parts and denticles

poorly differentiated.

**alleles:** Five including one temperature-sensitive and one weak allele. *mmy*<sup>1</sup> and *mmy*<sup>2</sup> (isolated as *IK* and *IL*) retained.

*mMdh*: see *Mdh2*

**mn: manikin**

**location:** 1-38.4.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine.

**discoverer:** Fahmy, 1954.

**synonym:** *dwX*<sup>mn</sup>.

**references:** 1959, DIS 33: 88.

**phenotype:** Fly small with narrow abdomen. Reduction in size may be bilaterally asymmetrical and may affect abdomen and thorax independently. Male viability reduced; flies rarely survive more than 48 hr. Sterile, probably owing to reduced vigor. RK3.

**alleles:** One X-ray-induced allele.

**mnb: minibrain (J.C. Hall)**

**location:** 1-58.2 (apparently part of "Sh complex").

**origin:** Induced by ethyl methanesulfonate or from hybrid dysgenesis.

**discoverer:** M. Heisenberg (from a mutagenized X provided by J. Merriam).

**synonym:** *min*.

**references:** Fischbach and Heisenberg, 1984, J. Exp. Biol. 112: 65-93.

Heisenberg and Wolf, 1984, Vision in Drosophila: Genetics of Microbehavior, Springer-Verlag, Berlin, pp. 207, 209, 227.

Heisenberg, Borst, Wagner, and Byers, 1985, J. Neurogenet. 2: 1-30.

Helfrich, 1986, J. Neurogenet. 3: 321-43.

**phenotype:** Brain mass approximately half normal, including smaller than normal optic lobes and reduction in cell number (Fischbach and Heisenberg, 1984; Heisenberg and Wolf, 1984); exceptions: neuropile of the lamina optic ganglion appears normal in size and general morphology, and peduncle of mushroom body has apparently normal number of fibers; *mnb* flies take abnormally long to eclose (*i.e.*, emergence *per se* from the pupal case is a slow process); behaviorally, *mnb* leads to relatively subtle behavioral defects, such as mild leg shaking under ether (see "other information"), absence of learning in tests using olfactory stimuli (Heisenberg *et al.*, 1985), and aberrant visual fixation. In tests of locomotor activity rhythms (Helfrich, 1986), singly mutant *mnb* adults are basically normal, but a high proportion of *mnb so* double mutants show complex rhythmicities (dual circadian periodicities) with about 20% being arrhythmic (3 times greater than wild type). Other behaviors, such as basic optomotor responses (M. Heisenberg, unpublished) and male courtship song (Kulkarni and Hall, 1987, Genetics 115: 461-475), are normal; physiologically, *mnb*--when linked to *reduced optic lobes* and *small optic lobes* mutations--has been tested for effects on electroretinogram, which have diminished amplitudes of light-on and light-off transient spikes in the triple mutant (Coombe, 1986, J. Comp. Physiol. 159: 655-665).

**alleles:** Two alleles: *mnb*<sup>1</sup> (Heisenberg) induced by ethyl methanesulfonate and *mnb*<sup>2</sup> originally designated *mnb*<sup>UB913</sup>, produced by hybrid dysgenesis and has a P-

element insertion in 16EF.

**cytology:** Located in 16E3-F3 based on coverage of *mnb*<sup>1</sup> by proximal X duplication in *Dp(1;3)JC153* = *Dp(1;3)16E3-4;17AB;99D*, but failure to be covered by duplication segregating from *T(1;Y)B55* = *T(1;Y)16F2-3* or *T(1;Y)W32* = *T(1;Y)16F3-4*; females carrying the deletion segregating from *Tp(1;3)JC153* plus the X<sup>PYD</sup> element of *T(1;Y)W32*, with *mnb*<sup>1</sup> being on the homologous X, have the mutation's effects uncovered.

**other information:** Seems to be allelic to *Sh*, given map position and *mnb*-associated leg shaking (A. Ferrus and M. Heisenberg, unpublished); yet, *Sh* mutations do not lead to any grossly aberrant brain morphology, and *Sh*<sup>5</sup> plus *Sh*<sup>14</sup> complement *mnb*<sup>1</sup> with regard to anatomical defects caused by the latter (M. Heisenberg, unpublished); *mnb*<sup>1</sup> also complements lethal alleles of 3 genes mapping just distally to *Sh* alleles (see Tanouye, Lam, and Iverson, 1986, Ann. Rev. Neurosci. 9: 255-76), *i.e.*, *l(1)16Fa*, *l(1)16Fb* and *l(1)16Fc*; an X-linked enhancer of *mnb* has been identified, which causes lethality when expressed along with the latter (M. Heisenberg, unpublished); the former maps near *cv* and (when in combination with *mnb*<sup>1</sup>) leads to death late in pupation (mutants can be "rescued" by opening the pupal case).

**mo: micro-oculus**

**location:** 1-6.7.

**origin:** Induced by DL-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 72.

**phenotype:** Eyes small. Wings narrow and frequently pleated longitudinally with irregular hairs, giving slight opacity. Body size slightly reduced. Not easily classified. Viability and fertility good in both sexes. RK3.

**other information:** Two alleles each induced by CB. 3007 and CB. 3026; four induced by CB. 1528; one each induced by CB. 1506, CB. 1540, CB. 1592, and CB. 3025.

**\*moo: moorish**

**location:** 3-48.3.

**origin:** X ray induced.

**discoverer:** Thompson.

**synonym:** *mo* (preoccupied).

**references:** 1959, DIS 33: 99.

**phenotype:** Body color black. Homozygous lethal in male; female viability about 10% normal. RK3.

**Moonrat:** see *Mrt*

**moorish:** see *moo*

**mor:** *moira* (J.A. Kennison)

**location:** 3-58.1 (based on 18 recombinants between *jvl* and *sbd*<sup>2</sup>).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1983.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Isolated as a dominant suppressor of the antenna-to-leg transformation in a *Pc*<sup>2</sup> *Antp*<sup>Ns</sup> double heterozygote. Strongly suppresses the antennal transformation in an *Antp*<sup>Ns</sup> heterozygote, but does not suppress the antennal transformation in a strain containing a heat-shock driven Antennapedia cDNA. Also behaves as a dominant suppressor of *Pc* and *Pcl* mutations. All alleles associated with a common recessive embryonic lethality. Mitotic clones induced during larval growth lead to transformation of haltere tissue to wing tissue. *Ubx*<sup>130</sup>/*mor* has low frequency of haltere to wing transformation.

**alleles:**

**cytology:** Placed in 89A11-B4 based on its inclusion in *Df(3R)sbd105 = Df(3R)88F9-89A1;89B9-10* but not in *Df(3R)Po4 = Df(3R)88F7-89A1;89A11-13* nor *Df(3R)sbd45 = Df(3R)89B4;89B10* (Hughes, Nelson, Yanuk, and Szauter).

**morula:** see *mr*

**Mos**

**location:** 3-.

**origin:** Spontaneous.

**references:** Golubowsky and Zakharov, 1979, Genetika 15: 1798-1808.

**phenotype:** Dominant factor on third chromosome that reduces dorsocentral, scutellar, and occasionally other thoracic bristles; penetrance 30-50%, higher in the presence of unstable *sn*<sup>+</sup> alleles. Causes increased rates of mutation of unstable *sn*<sup>+</sup> in both germ line and soma.

**other information:** Probably a manifestation of hybrid dysgenesis.

**\*mot-28: mottled**

**location:** 3-46.0.

**origin:** Found among progeny of males given supersonic treatment.

**discoverer:** Hersh, 28i19.

**references:** Hersh, Karrer, and Loomis, 1930, Am. Nat. 64: 552-59.

Hersh, 1934, DIS 1: 30.

Surrarer, 1935, Genetics 20: 357-62 (fig.).

1938, Genetics 23: 631-46 (fig.).

1940, DIS 13: 51.

**phenotype:** Eyes mottled with patches of dark brown or black on wild-type background. Sensitive to temperature. Always mottled at 18°, almost never above 25°. Temperature-effective period is 25-35 hr after beginning of pupation. Mottling more easily seen in presence of *v*, also manifested in *w* homozygotes (Schultz). RK1 at 18°; RK3 above 25°.

**\*mot-32l**

**location:** 1- (not located).

**origin:** X ray induced.

**discoverer:** Oliver, 32l28.

**references:** 1937, DIS 7: 19.

**phenotype:** Eye color mottled in female only. RK3.

**\*mot-36e**

**location:** 3- [left arm, with *In(3L)P*].

**discoverer:** Bridges, 36e11.

**references:** 1937, DIS 7: 12.

**phenotype:** Eyes mottled with translucent spots and roughness. Bristles twisted and stubby; hairs irregular. Wing venation plexoid around posterior crossvein. Female sterile. Enhances somatic crossing over in first, second, and third chromosomes. RK3.

**Mot-K: Mottled of Krivshenko**

**location:** 2- or 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Krivshenko, 54c25.

**synonym:** *Mo*<sup>K</sup>.

**references:** 1954, DIS 28: 75.

1955, DIS 29: 76.

**phenotype:** Eyes liberally mottled with dark color on wild-type background; character barely noticeable in young flies but striking in older ones; number and size of spots variable. Homozygous lethal. Viability and fertility of heterozygotes good. RK2A.

**cytology:** Associated with *T(2;3)Mot-K = T(2;3)41;60D;80-81*.

**mottled:** see *mot*

**mottler of white:** see *mw*

**mp: microptera**

**location:** 3-0.0.

**discoverer:** Serebrovsky, 40g8.

**references:** 1941, DIS 15: 19.

**phenotype:** Wings small and spoonlike; veins irregular. Tarsi four jointed (rarely 3 or 5); joints 3 and 4 usually fused. Antennae shortened. Ecloses somewhat late. Viability and fertility low. RK2.

**Mp20: Muscle protein 20 kd**

**location:** 3-{68}.

**references:** Ayme-Southgate, Lasko, French, and Pardue, 1989, J. Cell Biol. 108: 521-31.

**phenotype:** Encodes a 20-kd protein, that is not detected in the asynchronous oscillatory flight muscles, but is found in most, if not all, other muscles (the synchronous muscles).

**cytology:** Placed in 49F9-13 based on *in situ* hybridization and deficiency mapping.

**molecular biology:** Identified in a cDNA library produced from pulsating cultured myotubes and prehybridized with mRNA from Schneider cells. The cDNA clones identify two myotube-specific transcripts of 0.9 and 1.0 kb, the

difference residing in the 3' untranslated region. Southern blots indicate that the gene is not a member of a multigene family. The coding sequence contains two introns, one of 140 nucleotides between codons 10 and 11, and the other of 67 nucleotides between codons 121 and 122. The open reading frame encodes a polypeptide of 184 amino acids with a molecular mass of 20,166 daltons. Two stretches of twelve amino acids match the proposed consensus sequence for the calcium binding site of calcium-binding proteins are found between residues 20-31 and 93-104. No other significant sequence homologies were found in the protein data base.

**Mpl: Monoplane**

**location:** 3-[50].

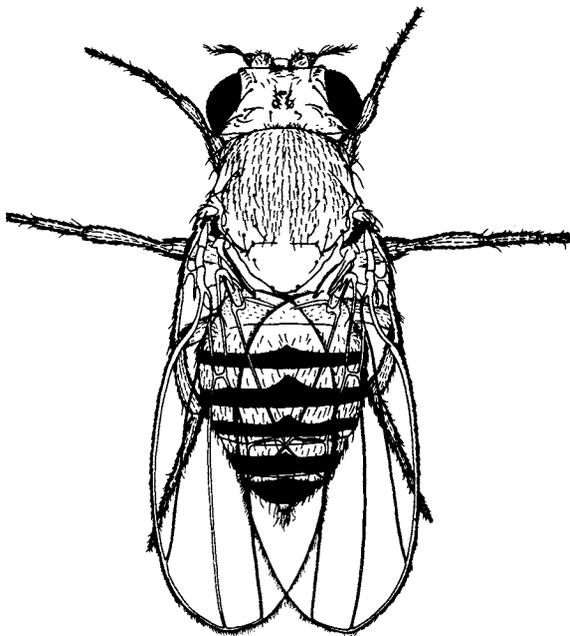

**origin:** X ray induced.

**discoverer:** Shelton.

**references:** Hughes and Shelton, 1980, DIS 55: 204.

**phenotype:** Wings held out at 90° from body axis; tibial-tarsal joint of metathoracic legs swollen. Homozygotes exhibit reduced viability and sterility; heterozygous viability also reduced. Partially suppresses expression of *ey*.

**cytology:** Associated with 3R breakpoint of  $T(2;3)Mpl = T(2;3)35B2-3;86C1-2$  (Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velisariou, and Walker, 1981, DIS 56: 186-91).

**mr: morula**

**mr: morula**

**location:** 2-106.7.

**discoverer:** Bridges, 13c8.

**references:** Bridges and Morgan, 1919, Carnegie Inst. Wash. Publ. No. 278: 230 (fig.).

Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Eyes rough. Bristles irregularly reduced in size and number. Abdominal sclerites often smaller. Developmental study by Lees and Waddington [1942, Proc. Roy. Soc. (London), Ser. B 131: 87-100] shows that effect on bristles results from general slowing of bristle growth. Female entirely sterile, has under-

developed ovaries. At 19°, bristles nearly normal and eyes nearly wild type. RK2 at 25° and above.

**cytology:** Placed in salivary chromosome region between 59E2 and 60B10 based on its being to the right of  $In(2R)bw^{VDel} = In(2R)41B2-C1;59E2-4$  and to the left of  $Df(2R)Px = Df(2R)60B8-10;60D1-2$  (Bridges, 1937).

**mr<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** Bridges, 25k24.

**phenotype:** Less extreme than *mr*. Nearly wild type at 19°. Female entirely sterile. Oogenesis normal through stage 4; then compound nurse cell chromosomes fall apart and degenerate. Karyosome of oocyte also disappears. Oogenesis does not proceed beyond sixth stage (King, 1964, Royal Entomol. Soc. London Symposium 2, Insect Reproduction, pp. 13-25). RK2 at 25° or above.

**MR: Male Recombination**

**location:** 2-54 [(between *Tft* and *pr*; 2/10 *Tft-pr* crossovers between *Tft* and *MR* (Slatko and Green, 1980, Biol. Zentralbl. 99: 149-55)].

**origin:** Spontaneous.

**synonym:** *Mister*; *MRF*.

**phenotype:** A series of second chromosomes isolated from natural populations in diverse regions of the globe that, in crosses of *MR*-bearing males to laboratory-strain females, but not in the reciprocal crosses, produce dysgenic progeny. Such progeny transmit the *MR* chromosome at reduced levels compared with the homologous second chromosome; abnormalities in spermiogenesis including failure of individualization observed in dysgenic males account for 70% of the deficiency in recovery of *MR* (Matthews, 1981, Genetics 97: 95-111). Increased levels of gonial recombination observed in both sons (Hiraizumi, 1971, Proc. Nat. Acad. Sci. USA 68: 268-700) and daughters [demonstrated in *c3G* females by Sinclair and Green (Mol. Gen. Genet. 170: 219-24)]; mitotic crossing over in wing disks unaffected (Thompson and Woodruff, 1980, Genetica 49: 77-80). Both sons and daughters exhibit increased rates of spontaneous mutations, both lethal (Slatko and Hiraizumi, 1973, Genetics 75: 643-49) and at some but not all specific loci (e.g., Green, 1977, Proc. Nat. Acad. Sci. USA 74: 3490-93); the latter types of mutants usually unstable, undergoing further mutation either to more extreme alleles or back to wild type; increased mutation rates observed when combined with *mei9* and *mei41* (1981, Mutat. Res. 83: 191-200). All classes of chromosome rearrangements produced by dysgenic progeny, but with preferential points of breakage (Yannopoulos, Stamatis, Zacharopoulou, and Pelecanos, 1983, Mutat. Res. 108: 185-202); also shown in some cases to promote gonadal aplasia, especially at higher temperatures (Stamatis, Yannopoulos, and Pelecanos, 1981, Genet. Res. 38: 125-35); metaphase I of meiosis normal, but bridges and fragments observed in anaphase I and anaphase II in dysgenic males (Henderson, Woodruff and Thompson, 1973, Genetics 88: 93-107; Yannopoulos, 1978, Genet. Res. 239-47). Gross deletion of X-chromosome material induced by *MR* shown to involve an array of breakpoints, which, by *in situ* hybridization, are free of P-element sequences; postulated to arise through illegitimate mitotic exchange (Green, Yamamoto, and Miklos, 1987, Proc. Nat. Acad. Sci. USA 84: 4533-37). The majority of the activity in

several of the isolates maps to a site between *Tft* and *pr* on the left arm of chromosome two, but when that site removed residual activity remains in the genome. Mappability of the major effect to the same site in independent isolates suggests the presence of an element that is able to promote transposition but that itself is unable to transpose. Circumstantial evidence indicates that the element is *P* and that in addition to a functional *P* element, *MR* second chromosomes also carry defective *P*'s. Males inheriting two doses of *MR* from *mei-S332* fathers crossed to *C(2)EN/0* females not discernably different from males with one dose; two doses of *MR* inherited from the mother are inactive (Green and Slatko, 1979, *Mutat. Res.* 62: 529-39).

<sup>β</sup> Also carries *Sd*.

### **mrn: marionette (Fuller)**

**location:** 3-42.6 (between *Ly* and *th*).

**synonym:** *nc16*, *l(3)E35*.

**references:** Fuller, 1986, *Gametogenesis and the Early Embryo*, (G.J. Gall, ed.). *Proc. Soc. Dev. Biol.* 44, pp 19-41.

Robertson and Fuller, unpublished.

Irick and Cherbas, unpublished.

**phenotype:** Recessive larval lethal. Individuals heterozygous for certain combinations of alleles reach late third instar but do not pupate; they have small discs and small brains. The original allele *nc16*, is associated with a dominant enhancer of the *B2t<sup>n</sup>*-tubulin mutation, suggesting a role for the gene in microtubule function. The dominant enhancer and the lethal mutation associated with *nc16* were not separated in 82 recombinants between *Ly* and *th*. None of the other alleles are dominant enhancers of *B2t<sup>null</sup>* (Robertson and Fuller, unpublished).

**alleles:**

<sup>β</sup> a = Larval lethal, isolated as dominant enhancer of tubulin mutants. b = Larval lethal, isolated as lethal under *Df(3L)BK10*. c = Lethal phase not yet established, isolated as lethal under *Df(3L)BK10*.

**cytology:** Placed in 71D-F, based on its being uncovered by *Df(3L)BrdR6* and *Df(3L)BK10*, but not *Df(3L)878.3*.

### **Mrt: Moonrat (J.A. Kennison)**

**location:** 3-79.7 (based on 211 recombinants between *e<sup>s</sup>* and *ca*).

**origin:** Spontaneous.

**discoverer:** Kennison.

**phenotype:** Heterozygote shows partial transformation of anterior wing to posterior (triple row bristles replaced by double row bristles in patches). A network of extra veins appears in the anterior compartment, beginning at the distal edge in the least affected flies, and covering the entire anterior compartment in the more extreme cases. Wing blade expanded anteriorly at the distal edge. Wing blade expansion and extra veins resemble phenotypes seen in *en<sup>1</sup>* homozygotes in the presence of Minute mutations. Bubbles often form in the wing blade. More rarely, a mirror-image outgrowth from the anterior edge is present. Mirror-image duplications sometimes appear in halteres. Legs sometimes appear deformed (similar to phenotype of *en<sup>lethal</sup>* clones induced in the larva). Dominant phenotypes strongly temperature-sensitive. Penetrance greater than 99% at 18° (with strong expressivity) but only 30-40% at 29° (with very weak expressivity). Shows paternal effect. Penetrance greater when mutant allele inherited from father than when inherited from mother. *Mrt/+* indistinguishable from *Mrt/+*.

*ms*: see *msc*

### **ms(1)1 to 16: male sterile (1)**

A series of ethyl-methanesulfonate-induced mutations at the base of the X chromosome (Geer, Bowman, and Tyl, 1979, *J. Exp. Zool* 209: 387-93).

### **ms(1)1**

**phenotype:** Few motile sperm; none transferred; morphology normal until coiling stage; however, some axoneme degeneration evident; some failure of individualization. Axoneme stability defective (Dybas, Tyl, and Geer, 1981, *J. Exp. Zool.* 216: 299-310).

**cytology:** Placed in 19F1-20B based on its being covered by  $y^+Ymal126$  (19F1-20A2 to the base) but not by  $y^+Ymal107$  (20A1-B to the base) (Geer, Bowman, and Tyl, 1979, J. Exp. Zool. 209: 387-94).

**other information:** Possibly allelic to *ms(1)20A*. *ms(1)12* maps to same region; some males have motile sperm, but no transmission to female; may be allelic.

**ms(1)4**

**phenotype:** No sperm motility. Few cysts reach coiling stage; paracrystalline material of major mitochondrial derivative diffuse and differentiation of the derivative irregular; crystallization initiated late and within the matrix of the mitochondrion rather than at a point of contact with the endoplasmic reticulum (Dybas, Tyl, and Geer, 1981, J. Exp. Zool. 216: 299-310).

**cytology:** Placed in 18F-19E1; covered by *Ymal*<sup>+2</sup> (18F to 20F) but not  $y^+Ymal102$  (19C3-E1 to 20F) (Geer, Bowman, and Tyl, 1979, J. Exp. Zool. 209: 387-94).

**other information:** Possibly allelic to *ms(1)19E*.

**ms(1)6S**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Shadholt.

**references:** Habliston, Stanley, and Bowman, 1977, J. Ultrastruct. Res. 60: 221-34 (fig.).

- phenotype:** Anatomy of the reproductive system of *ms(1)6S* males normal; however few or no motile sperm. Spermiogenesis defective; some centrioles fail to form basal bodies, reducing the numbers of axonemes formed; basal body fails to make normal attachment to nucleus; mitochondria fuse irregularly but do elongate and elaborate paracrystalline material; large cytoplasmic units with multiple mitochondrial derivatives but few if any axonemes seen in cross sections; isolated cytoplasmic elements with or without single axonemes also observed, defective acrosome formation; chromatin condensation, nuclear elongation, and formation of microtubules around elongating nucleus abnormal.

**ms(1)7**

**phenotype:** Males viable but sterile; motile sperm produced and transmitted to females in normal numbers. Sperm fertilize eggs, but development fails. Spermiogenesis ultrastructurally normal (Dybas, Tyl, and Geer, 1981, J. Exp. Zool. 216: 299-310).

**cytology:** Placed in 19E6-F1 based on its being covered by  $y^+Ymal113$ , which extends from the base of the X to 19E6-8 but not by  $y^+Ymal108$ , which extends to 19E8-F1 (Geer, Bowman, and Tyl, 1979, J. Exp. Zool. 209: 387-94).

**other information:** Possibly allelic to *ms(1)19Fa*. *ms(1)10*, mapped to same region, also had motile sperm transferred to female; possibly allelic.

**ms(1)10A**

**location:** 1-33.44.

**phenotype:** Spermiogenesis blocked at or before coiling stage. Abnormal associations of major mitochondrial derivatives with endoplasmic reticulum give rise to multiple foci of paracrystalline-material formation (Dybas, Harden, Machnicki, and Geer, 1983, J. Zool. 226: 293-302).

<sup>α</sup> 1 = Geer, Lischwe, and Murphy, 1983, J. Exp. Zool. 225: 107-18; 2 = Zhimulev, Belyaeva, Pokholkova, Kochneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baricheva, Aizenzon, Kramers, and Eeken, 1982, DIS 58: 210-14. 3 = Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720. 4 = 1987, DIS 66: 194-97.

**cytology:** Placed in 10A1-5 based on its inclusion in *Df(1)v-L1 = Df(1)9F13;10A4-5* but not in *Df(1)v-L2 = Df(1)9F13;10A1* (Zhimulev *et al.*).

**ms(1)14**

**phenotype:** Spermiogenesis appears normal, but late degeneration seen. Some sperm enter seminal vesicles and are transferred to females.

**cytology:** Placed in 19E8-20A2; covered by  $y^+Ymal108$  (19E8-F1 to 20F) but not by  $y^+Ymal107$  (20A1-B to the base) (Geer, Bowman, and Tyl, 1979, J. Exp. Zool. 209: 387-94).

**other information:** Possibly allelic to *l(1)19F6*; *ms(1)3* maps to same region, has few motile sperm which are transferred to females; may be allelic.

**ms(1)16**

**phenotype:** Few spermiogenic cysts reach coiling stage; multiple associations of mitochondrial derivative with endoplasmic reticulum producing multiple foci of paracrystalline material elaboration; improper elongation of major mitochondrial derivative or failure of paracrystalline-body formation. Individualization of sperm defective; cellular degeneration obvious; axonemes defective with gaps in the circular arrays of outer microtubular doublets. Cysts with half or twice the normal number of spermatids observed (Dybas, Tyl, and Geer, 1981, J. Exp. Zool. 216: 299-310).

**cytology:** Placed in 20B-F based on its inclusion in *B<sup>S</sup>Y* (Geer, Bowman, and Tyl, 1979, J. Exp. Zool. 209: 387-94).

**other information:** Possibly allelic to *ms(1)20B*.

**ms(1)19 and 20**

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Jakobovitz, 1978, Mol. Gen. Genet. 161: 275-84.

***ms(1)202***

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Meyer, 1977, *Chromosoma* 64: 371-92 (fig.).

**phenotype:** Meiosis I proceeds to metaphase and rarely anaphase; undivided co-oriented bivalents move irregularly toward the poles; more than 32 nuclei per cyst, frequent micronuclei; many cysts do not undergo meiosis. First division spindles tetrapolar, resemble two parallel bipolar spindles.

***ms(1)244***

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Meyer, 1977, *Chromosoma* 64: 371-92 (fig.).

**phenotype:** Shape of primary-spermatocyte nuclei highly irregular, with evaginated pockets, which sometimes contain chromosomes. Multipolar spindles observed; entire bivalents rather than dyads pass to pole at first meiotic anaphase; second division generally arrested, but some cysts with more than 32 nuclei observed. Nuclear size highly variable; micronuclei present. Mutant males exhibit shaking upon etherization.

***ms(1)401***

**location:** 1-58.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Hareven, 1977, *Dev. Biol.* 276: 276-94 (fig.).

**phenotype:** Primary spermatocytes appear to accumulate; nuclei appear creased; nucleoli fragmented. Some elongating spermatids produced, but development arrested early. In *XO* males primary spermatocytes do not attain full size, and the intermediate-sized nucleolated spermatocytes accumulate; nuclear creases fail to form.

**cytology:** Claimed to be fertile in combination with  $y^2Y67g$  (probably 67g19.1, which carries 20A3-20F).

***ms(1)413***

**location:** 1-25.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Hareven, 1977, *Dev. Biol.* 276: 276-94 (fig.).

Brick, Lifschytz, and Friedlander, 1979, *J. Ultrastruct. Res.* 66: 151-63 (fig.).

**phenotype:** Males carrying the mutation are sterile; exhibit

shaking behavior with intermittent proboscis extension. Meiosis appears to be arrested, but the cellular changes associated with spermiogenesis continue, including mitochondrial aggregation, nuclear condensation and elongation, cellular elongation, and coiling. Spermatocytes do not divide, but develop directly into spermatids with one nucleus and four axonemes; mitochondria cluster prematurely in the primary spermatocyte but do not form a nebenkern in the spermatid. No chromosome condensation or spindle formation in the spermatocytes. Irregular distribution of nuclear-envelope annuli, condensed chromatin, and perinuclear microtubules in the spermatids, basal bodies do not associate with nucleus.

**alleles:** Three mutations with similar location 4-5 units to the right of *ct* and shared somatic and germinal phenotypes presumed to be allelic: *ms(1)413*<sup>1</sup>, *ms(1)413*<sup>2</sup> [synonym = *ms(1)682*], and *ms(1)413*<sup>3</sup> [synonym = *ms(1)RD11*].

***ms(1)516***

**location:** 1-38.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Hareven, 1977, *Dev. Biol.* 276: 276-94 (fig.).

Lifschytz and Meyer, 1977, *Chromosoma* 64: 371-92 (fig.).

**phenotype:** First meiotic divisions normal in both cell morphology and bivalent structure; second meiotic divisions appear monastral but bipolar; both centrioles pass to the same pole at the second meiotic division producing one daughter nucleus with two basal bodies associated and one with none. Dyads move to the poles as highly condensed bodies with sister centromeres remaining associated; spermatids display numerous micronuclei and nebenkerne of nonuniform size. Occasional apparently normal cysts encountered. Spermiogenesis proceeds albeit abnormally.

**cytology:** Claimed to be fertile in combination with *Dp(1;3)sn*<sup>12a1</sup>, which does not include the region to which the mutant maps.

***ms(1)RA40***

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Meyer, 1977, *Chromosoma* 64: 371-92 (fig.).

**phenotype:** 90% of cysts in division in early anaphase I; apparently pause there as anaphase proceeds normally producing 32 diploid spermatids with nuclei and nebenkerne of uniform size and developing to a normal onion stage. In rare anaphase II divisions chromosomes appear to pass to the poles at random. Diploid spermatids have two centriolar bodies, usually both attached to the nuclear membrane; detached centriolar bodies also seen; centriolar bodies, whether attached or detached, undergo same morphological transformations as in normal males.

***ms(1)RD7***

**origin:** Induced by ethyl methanesulfonate.

**references:** Lifschytz and Hareven, 1977, *Dev. Biol.* 276-94 (fig.).

Lifschytz and Meyer, 1977, *Chromosoma* 64: 371-92 (fig.).

**phenotype:** Meiotic figures rare; those that are observed display abnormal chromosome behavior in both meiotic divisions. Bivalent rather than dyads pass to first ana-

phase poles. First meiotic divisions mostly abnormal with monastral, deformed diastral and multipolar spindles; second-division chromosome constitutions but not second-division spindles observed. Spermatid cysts contain fewer than 64 but more than 32 cells; two types of spermatid nuclei observed: some with 0-4 detached centrioles in cytoplasm of early spermatids in which centriolar bodies plus axonemes held together in vicinity of nucleus; others exhibit one centriole of a pair attached to nucleus and the other detached but close by.

**ms(1)RD15**

**origin:** Induced by ethyl methanesulfonate.  
**references:** Lifschytz and Hareven, 1977, Dev. Biol. 276-94 (fig.)  
**phenotype:** Meiosis appears to be held up at prometaphase of the first division; few metaphases or first anaphases encountered; twice as many cysts in division as normal with 90% in first prometaphase; tri- and sometimes tetrapolar spindles observed in M1. Second divisions not observed; cysts contain a maximum of 32 cells. Spermatid differentiation proceeds to an extent similar to that of *XO* males.

**ms(1)RD33**

**location:**  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Lifschytz and Hareven, 1977, Dev. Biol. 276-94 (fig.)  
**phenotype:** Spermatid development arrested at a stage slightly earlier than that observed in *XO* males; in *ms(1)RD33/0* males, however, development arrested before completion of primary-spermatocyte growth.

**ms(Y)**

Male-sterile mutations on the *Y* chromosome that have been mapped are designated according to the *Y*-fertility gene affected: *kl-1*, *kl-2*, *kl-3*, or *kl-5* on *YL* and *ks-1* or *ks-2* on *YS*.

**ms(Y)hd: male sterile (Y) hybrid dysgenesis**

Thirteen sterile *Y* chromosomes recovered from hybrid dysgenic crosses; Southern blots probed with P sequences reveal male specific bands not seen in the original P strain; complementation tests not carried out to determine locus affected (Schafer and Nahmias, 1985, Mol. Gen. Genet. 200: 182-84).

**ms(2)1: male sterile (2) 1**

**location:** 2-65.5.  
**origin:** Ultraviolet induced.  
**discoverer:** Meyer, 48c.  
**references:** Meyer, Edmondson, Byers, and Erickson, 1950, DIS 24: 60.  
**phenotype:** Male sterile; female fertile. Sperm present but not motile. RK3.

**ms(2)2**

**location:** 2-44.0 (Meyer).  
**origin:** Spontaneous.  
**discoverer:** Muller, 1951.  
**synonym:** *ms*.  
**references:** Meyer, 1959, DIS 33: 97.  
**phenotype:** Homozygous male completely sterile; female fairly fertile. RK3.

**ms(2)3R**

**location:** 2-51.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Romrell, Stanley, and Bowman, 1972, J. Ultrastruct. Res. 38: 563-77.  
 Laughran, Stanley, and Bowman, 1976, J. Ultrastruct. Res. 56: 21-30 (fig.).

**phenotype:** Meiosis in homozygous mutant males characterized by apparent failure of the normally occurring incomplete cytokinesis so that all four meiotic products are seen in one spherical cell. Incomplete cytokinesis and ring-canal formation occur normally during meiosis; however, furrow membranes subsequently fuse and disintegrate; double-membrane fragments and ring canals found freely floating in spermatid cytoplasm. All the mitochondria coalesce into a single nebenkern, which subsequently divides into two and may subdivide into as many as eight mitochondrial derivatives. Elongation appears to take place in separate cytoplasmic units of four spermatids each in which mitochondrial derivatives vary in size and may associate with the endoplasmic reticulum or more than one axoneme, forming like numbers of foci of crystallization. Later stages show massive degeneration.

**ms(2)10R**

**location:** 2-84.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Romrell, Stanley, and Bowman, 1972, J. Ultrastruct. Res. 38: 578-90.

**phenotype:** Spermatid elongation limited; the endoplasmic sheath surrounding the axoneme opens out producing linear rather than circular arrays of microtubular doublets in cross sections of elongating spermatids. Mitochondrial derivatives may be large and irregular in shape with multiple contact points with endoplasmic reticulum and correspondingly multiple foci of crystallization.

**ms(2)73d**

**location:** 2- (between *b* and *Sd*).  
**origin:** Spontaneous in *In(2L)Cy*; separable.  
**references:** Hartl, 1980, Genetics 96: 685-96.  
**phenotype:** Homozygous males have immature, unelongated spermatid bundles.

**ms(2)E**

A series of complementing male-sterile mutations induced by ultraviolet light (Edmondson, 1951, DIS 26: 61).

locus	genetic location	synonym

**Ms(2)M: Male sterile (2) of Meyer**

**location:** 2- (just to the right of *cn*).  
**origin:** X ray induced.  
**references:** Meyer, 1966, DIS 41: 167.

**phenotype:** Heterozygous males sterile; heterozygous females fertile.

### ***ms(3)10R***

**location:** 3-.

**origin:** Induced by ethyl methanesulfonate.

**references:** Wilkinson, Stanley, and Bowman, 1974, *J. Ultrastruct. Res.* 48: 242-58.

**phenotype:** Spermiogenesis of homozygous mutant males defective; nuclear elongation variable owing to variably reduced numbers of perinuclear microtubules; absence of perinuclear microtubules associated with irregular condensation of chromatin beneath the nuclear envelope. Evidence for folding in axonemes leading to more than 64 profiles in transverse sections of spermatid bundles. Cross sections of elongating spermatid bundles revealed deranged axonemes with linear rather than circular arrays of the nine pairs of microtubules, with the doublets either still associated with the endoplasmic reticulum or free; mitochondrial derivatives multiply associated with endoplasmic reticulum with up to four foci of deposition of paracrystalline material instead of the normal one.

### ***ms(3)HO5A: male sterile (3) of Hardy and Orevi***

**location:** 3-45.9.

**origin:** Induced by ethyl methanesulfonate simultaneously with *fs(3)HO5A*, *fs(3)HO5B*, and *ms(3)HO5B*.

**synonym:** *ms(3)ml*<sup>5A</sup>.

**references:** Nishida, 1980, *Jpn. J. Genet.* 55: 427-39 (fig.).

**phenotype:** Testes rudimentary; germ-cell development arrested in immature primary-spermatocyte stage; few cysts escape to produce spermatids. A more advanced stage of development attained, including production of motile sperm, in the presence of a recessive suppressor on chromosome 2.

**other information:** Possibly *fs(3)HO5A* and *ms(3)HO5A* are the same mutant and should be designated *ms(3)HO5A*.

### ***ms(3)HO5B***

**location:** 3-.

**origin:** Induced by ethyl methanesulfonate simultaneously with *fs(3)HO5A*, *fs(3)HO5B*, and *ms(3)HO5A*.

**synonym:** *ms(3)ms2*<sup>5A</sup>.

**references:** Nishida, 1980, *Jpn. J. Genet.* 55: 427-39 (fig.).

**phenotype:** Spermatogenesis proceeds to coiling stage, but no motile sperm produced.

### ***ms(3)K81***

**location:** 3-91.3.

**origin:** Spontaneous.

**synonym:** *ph: paternal haploid*.

**references:** Fuyama, 1984, *Jpn. J. Genet.* 59: 91-96. 1986, *Genetics* 112: 237-48.

1986, *Genetics* 114: 495-509.

**phenotype:** Homozygous males produce motile sperm capable of fertilizing eggs, but defective in pronuclear function. Development of fertilized eggs initiated; arrested after several nuclear divisions in three-fourths of the embryos, the remainder developing beyond blastoderm and proving to be haploid upon cytological examination. Nuclear division cycle protracted compared to wild type, and the syncytial blastoderm nuclei undergo an extra division to produce twice the normal density prior to cellularization (Edgar, Kiehle, and Schuberg, 1986,

Cell 44: 365-72). A small fraction of the eggs diploidize and yield viable daughters, mostly by fusion of products of the first meiotic division (85%); fusion of products of second meiotic division rare or nonexistent. Incidence of gynogenetic diploids becomes appreciable in crosses to a stock designated G9 by Fuyama (1986, *Genetics* 114: 495-509).

**cytology:** Placed in 97D2-6 on the basis of the sterility of *ms(3)K81/Df(3R)ro-XB3* males [=Df(3R)97D2-3;97D5-6].

*ms(3)KK<sup>D</sup>*: see *βTub85D*

### ***ms(3)m1***

**location:** 3-45.9.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nishida, 1980, *Jpn. J. Genet.* 55: 427-39.

**phenotype:** Homozygous males have rudimentary testes exhibiting degenerating cysts of spermatocytes and cysts arrested early in development. Homozygous females also have rudimentary gonads, but Nishida attributes this to an independent but closely linked mutation; only the male sterility is suppressed by *su(msm1)*.

### ***ms(3)m2***

**location:** 3- (near centromere).

**origin:** Induced by ethyl methanesulfonate.

**references:** Nishida, 1980, *Jpn. J. Genet.* 55: 427-39.

**phenotype:** Homozygous males sterile; small coiled testes with elongated spermatid cysts.

*ms(3)nc2*: see *hay*

### ***ms(3)nc3***

**location:** 3-47.0.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *nc3*.

**references:** Fuller, 1986, *Proc. Soc. Dev. Biol.* 74: 19-41.

**phenotype:** Fails to complement certain *βTub* mutant alleles for male fertility although mapping to another site. Male fertility of homozygotes not determined. *ms(3)nc3/+* males fertile.

**cytology:** Located at 77E-F.

*ms(3)nc4*: see *wrl*

### ***ms(3)nc32***

**location:** 3-82.9.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *nc32*.

**references:** Fuller, 1986, *Proc. Soc. Dev. Biol.* 74: 19-41.

**phenotype:** Fails to complement certain *βTub85D* mutant alleles for male fertility although mapping to another site; *βTub85D* synthesis, meiosis, and spermatid differentiation are normal in these sterile trans-heterozygotes. *ms(3)nc32/ms(3)nc32* males fail to enter meiosis and show no spermatid differentiation. Testes from these males contain gonial cells, primary spermatocyte cysts, and cysts with abnormal cells. Adult male homozygotes show no *βTub85D* synthesis. *ms(3)nc32/+* males fertile.

**cytology:** Located in 95F-96A.

*ms(3)nc33*: see *αTub84D*

*ms(3)neol*: see *fwd*

***ms(3)sa: male sterile (3) spermatocyte arrest*****location:** 3-44 (Kemphues).**origin:** Spontaneous.**synonym:** *ms(3)VO45*.**phenotype:** Primary spermatocytes arrested premeiotically but apparently after attaining full size; testes become filled with mature primary spermatocytes.**cytology:** Located at 78A3;79E1-2 (Fuller).*ms2*: see *ms(2)E***\**msc: melanoscutellum*****location:** 1-52.6.**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).**discoverer:** Fahmy, 1954.**synonym:** *ms* (preoccupied).**references:** 1958, DIS 32: 72.**phenotype:** Extra pigmentation confined to scutellum. One or more thoracic bristles duplicated. Eyes slightly more oval than normal. Wings slightly abnormal in shape and position. Characters not always penetrant. Viability and fertility good in both sexes. RK3.**other information:** One allele each induced by CB. 1506 and CB. 3025; two induced by CB. 3007.*Msc*: see *Scr*<sup>*Msc*</sup> under *ANTC****msd(gl): modifier of sexual dimorphism of glass*****location:** 1-0.96.**origin:** Spontaneous.**references:** Birchler, 1984, Genet. Res. 44: 125-32.**phenotype:** Two alleles; homozygous *gl* males carrying the allele that we designate *msd(gl)*<sup>*d*</sup> (dimorphic) have brick-red eyes, whereas *msd(gl)*<sup>*d*</sup>; *gl* females' eyes are lemon yellow. In the presence of *msd(gl)*<sup>*m*</sup> (monomorphic), however, both *gl* males and females have the lighter eye color. Thus allelic differences are discernable only in males; females, either normal or homozygous for *tra* do not respond to *msd(gl)* genotype. Males carrying duplications for the *msd(gl)* locus show that *msd(gl)*<sup>*d*</sup> is dominant to *msd(gl)*<sup>*m*</sup> and that the eye colors of males with one or two doses of the dimorphic allele are indistinguishable. In *gl*<sup>+</sup> flies, the *msd(gl)* constitution is without phenotypic consequence. Not an allele of *zeste*.**cytology:** Located in 3A8-C2 based on the presence of *msd(gl)*<sup>*d*</sup> in *Dp(1;2)w*<sup>+</sup>70h = *Dp(1;2)3A7-8;3C2-3*.***msf: misformed*****location:** 2-55.2 (originally located at 55.6 but arbitrarily placed at 55.2 to be consistent with cytological indication that it is to the left of *pk*).**discoverer:** Bridges, 30b8.**references:** Curry, 1939, DIS 12: 46.**phenotype:** Eyes misshapen. Wings short and crumpled; legs shortened. Characteristics variable and overlap wild type. RK3.**cytology:** Placed between 41A and 42A3 on the basis of its inclusion in *Df(2R)bw*<sup>*VDe2LCy*</sup><sup>*R*</sup> = *Df(2R)41A-B;42A2-3* (Schultz). Certainly included in *Df(2R)M41A-vg11* = *Df(2R)40F-41A1;42A19-B1* (Morgan, Schultz, Bridges, and Curry, 1939, Carnegie Inst. Wash. Year Book 38: 275).**\**msg: missing*****location:** 2- (not located).**origin:** Spontaneous.**discoverer:** Mossige, 50b4.**references:** 1951, DIS 25: 69.**phenotype:** Bristles greatly reduced or missing. In extreme cases, almost like *sv*. Female sterile; male sparingly fertile. RK2.***msl-1: male-specific lethal*****location:** 2-53.3.**references:** Belote and Lucchesi, 1980, Genetics 96: 165-86.**phenotype:** Homozygous male embryos hatch but die as much as twelve days later in larval or prepupal stages; females and heterozygous males survive; phenotype slightly more severe in sons of homozygous than of heterozygous mothers. Viability of two-X individuals that develop as phenotypic males (*tra2*) or intersexes (*dsx*) is unaffected by *msl-1*, indicating that the one-X condition is required for *msl-1* lethality. No interaction with *mle* or *msl-2* (Belote, 1983, Genetics 105: 881-96). Females heterozygous for *Sxl*<sup>*fl*</sup> and homozygous for *msl-1* show signs of intersexual development [Skripsky and Lucchesi, 1982, Dev. Biol. 94: 153-64 (fig.)]. Pole cells from *msl-1* male embryos capable of undergoing normal spermatogenesis when transplanted into wild-type hosts (Bachiller and Sánchez, 1986, Dev. Biol. 118: 379-84). Concluded to be defective in dosage compensation in males based on decreased levels of X-linked-enzyme activities (G6PD, 6GPD, FUM) but not autosomally encoded enzymes (ADH, AO, GPDH, IDH) in homozygous *msl-1*<sup>*1*</sup> and *msl-1*<sup>*2*</sup> male larvae when compared with non-*msl-1* controls (Belote and Lucchesi, 1980, Nature 285: 573-75).**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>msl-1</i> <sup><i>1</i></sup>	EMS	Belote		1, 2	amorph
<i>msl-1</i> <sup><i>2</i></sup>	EMS	Belote	<i>msl-1</i> <sup><i>b</i></sup>	1, 2	less severe allele

<sup>α</sup> 1 = Belote and Lucchesi, 1980, Genetics 96: 165-86. 2 = Uenoyama, Uchida, Fukunaga, and Oishi, 1982, Genetics 102: 223-31.**cytology:** Placed in 36F7-37B8 based on its inclusion in *Df(2L)TW3* = *Df(2L)36F7-37A1;37B2-8*.***msl-2*****location:** 2-9.0.**references:** Belote and Lucchesi, 1980, Genetics 96: 165-86.**phenotype:** Homozygous male embryos hatch but die as much as fourteen days later in larval or prepupal stages; females and heterozygous males survive; no maternal effect. Viability of two-X individuals that develop as phenotypic males (*tra2*) or intersexes (*dsx*) is unaffected by *msl-1*, indicating that the one-X condition is required for *msl-1* lethality. No interaction with *mle* or *msl-1* (Belote, 1983, Genetics 105: 881-96). Few homozygous *msl-2*<sup>*2*</sup> gynandromorphs survive; *XO* patches small, with small bristles, and mostly confined to abdomen (Uenoyama, Uchida, Fukunaga, and Oishi, 1982, Genetics 102: 223-31). Pole cells from *msl-2* male embryos capable of undergoing normal spermatogenesis when transplanted into wild-type hosts (Bachiller and Sánchez, 1986, Dev. Biol. 118: 379-84). Females heterozygous

for *Sxl<sup>fl</sup>* and homozygous (and to a lesser extent heterozygous) for *mst-2* show signs of intersexual development; effects greater when mother homozygous for *mst-2* [Uenoyama, Fukunaga, and Oishi, 1982, Genetics 102: 233-43 (fig.); Skripsky and Lucchesi, 1982, Dev. Biol. 94: 153-64 (fig.)]. Concluded to be defective in dosage compensation in males based on decreased levels of X-linked-enzyme activities (G6PD, 6GPD, FUM) but not autosomally encoded enzymes (ADH, AO, GPDH, IDH) in homozygous *mst-2<sup>1</sup>* male larvae when compared with non-*mst* controls (Belote and Lucchesi, 1980, Nature 285: 573-75).

<sup>β</sup> Tissue-specific expression.

#### Mst26Aa

**phenotype:** Expressed in males, but not in females; also expressed in the germ-cell-free sons of *tud* females as well as in XX individuals that are homozygous for *dsx*, *ix*, *tra2*, or *tra*. 1986, Presence of *tra2<sup>+</sup>* activity in XX flies during a part of the third larval instar is sufficient to repress expression of *Mst26Aa* and prevent accessory-gland development; absence of *tra2<sup>+</sup>* activity during that period leads to accessory-gland formation and the production of *Mst26Aa* transcript.

**molecular biology:** Transcribed from the same strand as *Mst26Ab*, the transcription terminating 20 base pairs 5' to the initiation of *Mst26Ab* transcription. 0.9 kilobase transcript has a 56-base-pair intron between the first and second nucleotides of codon 12. Open reading frame encodes a 265-amino-acid polypeptide. Conceptual amino-acid sequence reveals a region in which 11 of 17 amino acids are identical to the egg-laying hormone of the sea hare *Aplysia californica*.

#### Mst26Ab

**phenotype:** Expressed in males, but not in females; also expressed in the germ-cell-free sons of *tud* females as well as in XX individuals that are homozygous for *dsx*, *ix*, *tra2*, or *tra*. Presence of *tra2<sup>+</sup>* activity in XX flies during a part of the third larval instar is sufficient to repress expression of *Mst26Ab* and prevent accessory-gland formation and the production of *Mst26Ab* transcript.

**molecular biology:** Transcription begins 20 base pairs downstream from the termination of transcription and on the same strand as *Mst26Aa*. 0.5 kilobase transcript sequence reveals intron of 61 base pairs between the first and second nucleotides of codon 11. Open reading frame encodes a 90-amino-acid polypeptide.

#### Mst51F

**phenotype:** Expressed in normal and X0 males, as well as in the XX pseudomales or intersexes homozygous for *dsx*, *ix*, *tra2*, or *tra* and in the germ-cell-free sons of *tud* females.

#### Mst87F

**phenotype:** Expressed in normal and X0 males, but not in the XX pseudomales homozygous for *dsx*, *ix*, *tra2*, or *tra* nor in the germ-cell-free sons of *tud* females.

**molecular biology:** Sequence analysis shows that the gene comprises two exons of 79 and 338 base pairs separated by a 91-base-pair intron. A 165 base pair open reading frame is in the second and larger exon. Conceptual amino acid sequence reveals repeated motifs of Cys Cys Gly Pro or Cys Gly Pro such that Cys, Gly, and Pro comprise 38, 29, and 20% of the amino acids present. 102 base pairs of upstream sequences suffice to specify the gene's specific expression characteristics, *i.e.*, premeiotic transcription and postmeiotic translation separated by three days of development (Kuhn, Schäfer, and Schäfer, 1988, EMBO J. 7: 447-54).

#### Mst95E

**phenotype:** Expressed in males, but not in females; also expressed in the germ-cell-free sons of *tud* females as well as in XX individuals that are homozygous for *dsx*, *ix*, *tra2*, or *tra*. Presence of *tra2<sup>+</sup>* activity in XX flies during a part of the third larval instar is sufficient to repress expression of *Mst95E* and prevent accessory-gland development; absence of *tra2<sup>+</sup>* activity during that

period leads to accessory-gland formation and the production of *Mst95E* transcript.

**mt<sup>A</sup>**: see *tu-bw*

*mt*: see *mul*

**\*mtb: matt brown**

**location**: 1-3.6.

**origin**: Induced by ethyl methanesulfonate (CB. 1528).

**discoverer**: Fahmy, 1956.

**references**: 1959, DIS 33: 88.

**phenotype**: Eye color flat and browner than normal with greatly reduced reflection spots. Wing position varies from slightly to completely outspread, sometimes upheld. Male sterile; viability about 30% wild type. RK2.

*mTml*: see *Tm2*

*mTmlI*: see *Tml*

**Mtn: Metallothionein (G. Maroni)**

**location**: 3-48.8.

**references**: Lastowski-Perry, Otto, and Maroni, 1985, J. Biol. Chem. 260: 1527-1530.

Maroni, Otto and Lastowski-Perry, 1986, Genetics 112: 493-504.

**phenotype**: Codes for metallothionein, a metal binding protein. Inducible by ingestion of Cu or Cd (but not Zn) ions. In larvae, it is expressed mainly in the midgut. No point mutations are available, but *Dp(3;3)Mtn<sup>+</sup>H<sup>22</sup>* shows increased tolerance to Cd.

**cytology**: 85E10-15 based on *in situ* hybridization and its inclusion in *Df(3R)by10* but not in *Df(3R)γB104* (Maroni *et al.*).

**molecular biology**: Restriction maps and sequences of genomic and cDNA clones are available. The gene size is 631 bp; this includes 120 bp of coding sequence and a 365 bp intron. It shows similarity to the mammalian metallothioneins both at the amino-acid and nucleotide sequence level. Metal-inducible promoter useful in molecular constructs (Bunch, Grinblat, and Goldstein).

**\*mu: mussed**

**location**: 3-50.

**origin**: Spontaneous.

**discoverer**: Mohr, 37121.

**references**: Mossige, 1939, DIS 12: 47.

**phenotype**: Wings thin textured. Dorsal surface of thorax arched. RK1.

**mu1: mutator**

**location**: 3-57.

**origin**: Spontaneous.

**synonym**: *mt*; *mu* (preoccupied).

**references**: Green, 1970, Mutat. Res. 10: 353-63.

Green and Lefevre, 1973, Mutat. Res. 16: 59-64.

Gold and Green, 1974: Mol. Gen. Genet. 135: 245-55.

**phenotype**: Homozygous and hemizygous females exhibit increased rates of sex-linked visible and lethal mutations (*e.g.*,  $y^2 \rightarrow y^+$  = 1/2500; more rarely mutations to intermediate or more extreme alleles; also  $f^{3N}$  reversions and  $w^a \rightarrow w$ ); heterozygous females display slightly elevated rates of mutation; about half of mutants occur as clusters indicating premeiotic origin. Lethal mutations frequently associated with deficiencies of one to several bands. Mutation rates not elevated in males.  $y$  - *sn* recombina-

tion reduced 30% in *mul* homozygous and 25% in *mul/+* heterozygous females; also females but not males display elevated frequencies of nondisjunction. Effects of 100r on the induction of sex-linked lethals significant in *mul* but not + females (Gold and Green, 1975, Genetics 80: s35). The incidence of  $y$  and  $f^{36}$  clones is five times control values in *mul/mul* and ten times control in *mul/Df(3R)sbd105* females (Martensen and Green, 1976, Genetics 83: s47).

**cytology**: Placed in 88F9-89B10 based on its inclusion in *Df(3R)sbd105 = Df(3R)88F9-88A1;89B9-10*.

**mu2**

**location**: 3-[1.5].

**origin**: Spontaneous.

**discoverer**: Green, 1977.

**references**: Mason, Strobel, and Green, 1984, Proc. Nat. Acad. Sci. USA 81: 6090-94.

**phenotype**: Irradiation of females homozygous for *mu2* with low doses of X rays produces substantial numbers of terminal deficiencies for all chromosome arms, [see for example *Df(1)yT*]; irradiation of heterozygous females produces frequencies of deficiencies intermediate between those obtained from homozygous *mu2* and wild-type females. Extents of deficiencies limited only by the ability to recover them in viable offspring. Incidence of terminal losses linear with dose; such deficiencies visible cytologically and can be shown by *in situ* hybridization to lack sequences characteristically present at the termini of chromosome arms. Irradiation of *mu2* females does not increase the incidence of either interstitial deficiencies or sex-linked lethal mutations. Irradiation of *mu2* males does not increase the frequency of deficiencies.

**cytology**: Placed in polytene section 62, (Biessmann).

**molecular biology**: Newly formed chromosome ends unstable; lose approximately 75 base pairs per generation (Biessmann and Mason, 1988, EMBO J. 7: 1081-86).

**Mu(f<sup>3N</sup>): Mutator forked-3N**

**location**: 1-56.7-59.4 (between *f* and *Bx*).

**references**: Woodruff, 1975, Genet. Res. 25: 163-77.

**phenotype**: A dominant cis-acting enhancer of the reversion rate of  $f^{3N}$ ; thought responsible for reported instability of  $f^{3N}$ . Ineffective in reverting other alleles and in increasing the rate of sex-linked lethal mutations.

**\*mu-F: mutability factor from Florida**

**location**: 2- (not located).

**origin**: Spontaneous in Florida wild stock.

**discoverer**: Demerec, 1936.

**references**: 1937, Genetics 22: 469-78.

**phenotype**: Homozygote shows increase in lethal and visible mutation rate. Factor acts during development of germ cells in both male and female. Description resembles that of *MR*. RK3.

**mud: mushroom body defect (J.C. Hall)**

**location**: 1-50 [(Heisenberg, 1980), but cytology implies 1-[47]].

**references**: Heisenberg, 1980, Development and Neurobiology of Drosophila, (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 373-90.

Technau and Heisenberg, 1982, Nature 295: 405-07.

**phenotype**: Neuropile of mushroom bodies (usually in dorsal brain) is missing (Heisenberg, 1980); penetrance for

this anatomical phenotype (on which criterion the mutant was isolated) *ca.* 90%. Calyces that should innervate pedunculi and lobes of mushroom bodies are enlarged, as are antennal lobes in anterior brain. At sites of calyces, large numbers of thin axons form distinct lobes outside main neuropile of brain. Viability of mutant females poor, and they are sterile as well. Development of mushroom bodies apparently normal until pupation, when "reconstruction" of this bilaterally paired brain entity (this process being a normal feature of wild-type metamorphosis) is aberrant (Technau and Heisenberg, 1982). Supernumerary neuroblasts observed in the larval brain, owing to anomalous proliferation of such cells post-embryonically.

**cytology:** maps to 12E9-11 (Fischbach), based on its inclusion in *Df(1)KA9 = Df(1)12E2-3;12F5-13A1* but in neither *Df(1)g-1 = Df(1)12A;12E9-11* nor *Df(1)RK5 = Df(1)12E9-11;13A9-B1*.

*mud*: see *mudl*

**Mud: Muddled**

**location:** 1- (rearranged).

**discoverer:** E.H. Grell.

**phenotype:** Heterozygote has rough eyes with fused facets; eye color brownish. Hemizygous males have low viability but are fertile.

**cytology:** Associated with *In(1)Mud = In(1)3C3-4;5A6-B1*.

**other information:** Not allelic to *Sc*<sup>2</sup>.

**mudl: mudlike**

**location:** 3-50.5.

**origin:** Spontaneous.

**synonym:** *mud*.

**references:** Aparisi and Nájera, 1988, DIS 67: 4-5 and 5-6.

**phenotype:** Eye color grayish brown.

**mul: multiple**

**location:** 1-0.0 (between *l(1)Ca* and *tw*).

**phenotype:** Eyes rough and oval. Wings weak and held out. Bristles occasionally missing or disarranged. Body may show abnormal protuberances covered with hairs. Female sterile. After a few generations in stock, *mul*<sup>1</sup> showed only the eye abnormality. RK2.

**alleles:**

**\*mur: murrey**

**location:** 1-14.3.

**origin:** Spontaneous as one mosaic male.

**discoverer:** E. H. Grell, 57c.

**references:** 1957, DIS 31: 81.

**phenotype:** At 25°, eye color reddish purple, bristles very small, and body size reduced. At 17°, eye color and body size normal but bristles rather small. Original mosaic male transmitted only an X containing *mur*. He was mated to his daughters to produce homozygous *mur* females. *mur/mur* female and *mur* male are sterile. RK3.

*murky*: see *mk*

*murrey*: see *mur*

*mus*: see *mbm*

**mus: mutagen sensitive**

A series of mutants selected on the basis of their enhanced sensitivity to various mutagenic treatments. The nomenclatural conventions employed depart somewhat from those of other mutants that share a particular phenotype. *mus* followed by a number between 101 and 199 indicates a mutation on the X chromosome, 201-299 on the second chromosome, and 301-399 on the third chromosome; thus *mus101* [formerly redundantly designated *mus(1)101*] represents the first locus identified on the X. Some allelic designations begin with an upper-case letter indicating the laboratory in which the allele was selected; D = University of California, Davis, A = Emory University in Atlanta, B = University of British Columbia.

**mus101 (J.B. Boyd)**

**location:** 1-44.2 [0.2 cM to the left of *g* (Schalet)].

**references:** Boyd, Golino, Nguyen, and Green, 1976, Genetics 84: 485-506.

Boyd and Setlow, 1976, Genetics 84: 507-26.

**phenotype:** Survival of homozygous and hemizygous larvae hypersensitive to exposure to methyl methanesulfonate, nitrogen mustard, 2-acetylaminofluorene, and gamma rays. Partially deficient in post-replication repair (Boyd and Setlow, 1976; Brown, and Boyd, 1981, Mol. Gen. Genet. 183: 356-62); nitrogen-mustard mutagenesis abolished; *mus101*<sup>+</sup> implicated in recovery from DNA crosslinking (Graf, Green, and Würzler, 1979, Mutat. Res. 63: 101-12). Displays hypermutability to alkylating

agents; defective in alkylation repair pathway (Smith and Dusenberg, 1988, Mechanisms and Consequences of DNA Damage Processing, Alan R. Liss, Inc., pp. 251-55). Increases X-ray-induced post-meiotic chromosome loss (Cooper and Zimmering, 1981, Mutat. Res. 81: 345-56). Mutants inhibit premeiotic rDNA magnification in males (Hawley, Marcus, Cameron, Schwartz, and Zitron, 1985, Proc. Nat. Acad. Sci. USA 82: 8095-99). *mus101* function required for chorion-gene amplification (Snyder, Galanopoulos, and Kafatos, 1986, Proc. Nat. Acad. Sci. USA 83: 3341-45). Homozygotes for female-fertile allele exhibit elevated meiotic nondisjunction (Boyd *et al.*, 1976). Causes mitotic chromosome instability (*mus101*<sup>D1</sup>, Baker and Smith, 1979, Genetics 92: 833-47), and defective mitotic condensation of heterochromatin (*mus*<sup>ts1</sup>, Gatti, Smith, and Baker, 1983, Science 221: 83-85).

<sup>β</sup> Spontaneous in the paternal X chromosome in a cross of wild-type males to *mei-9* females such that the F<sub>1</sub> female was *mus101*<sup>SM</sup>/*mei9*.

**cytology:** Located in 12A6-D3 (Mason, Green, Shaw, and Boyd, 1981, Mutat. Res. 81: 329-43).

***mus102* (J.B. Boyd)**

**location:** 1-0.5 (Smith, 1976).

**references:** Boyd, Golino, Nguyen, and Green, 1976, Genetics 84: 485-506.

Smith, 1976, Mol. Gen. Genet. 149: 73-85.

**phenotype:** Survival of homozygous and hemizygous larvae hypersensitive to exposure to methyl methanesulfonate, formaldehyde (Alexandrov, Alexandrova, and Ankina, 1982, DIS 58: 12-13), and gamma rays. No evidence of hypermutability to alkylation nor defects in excision repair functions (Smith and Dusenberg, 1988, Mechanisms and Consequences of DNA Damage Processing, Alan R. Liss, Inc., pp. 251-55). Homozygous females fertile; exhibit elevated frequencies of nondisjunction. Increases frequency of *mwh* clones in *mwh*<sup>+</sup> wings; also increases incidence of isochromatid breaks in the heterochromatin and euchromatin of mitotic cells, with breaks occurring 1.4-1.6 times more frequently in females than males (Gatti, 1979, Proc. Nat. Acad. Sci. USA 76: 1377-81).

### *mus304* (J.B. Boyd)

**location:** 3-46 (between *st* and *cu*).

**references:** Boyd, Golino, Shaw, Osgood and Green, 1981, *Genetics* 97: 607-23.

**phenotype:** Larval survival hypersensitive to exposure to methyl methanesulfonate and nitrogen mustard. Neither hypermutable to alkylating agents nor defective in alkylation repair pathway; however, defective in UV-damage repair pathway (Smith and Dusenberg, 1988, *Mechanisms and Consequences of DNA Damage Processing*, Alan R. Liss, Inc., pp. 251-55). When fertile, homozygous females exhibit uniformly decreased recombination along the X chromosome (Green, 1982, *Biol. Zentralbl.* 101: 223-26). Partially deficient in post-replication repair (Boyd and Shaw, 1982, *Mol. Gen. Genet.* 186: 289-94) and excision (Boyd and Harris, 1981, *Chromosoma* 97: 607-23); DNA synthesis modified (Boyd and Shaw).

**alleles:**

allele	origin	discoverer	comments
<i>mus304</i> <sup>D1</sup>	EMS	Boyd	female fertile
<i>mus304</i> <sup>D2</sup>	EMS	Boyd	female sterile

### *mus306* (J.B. Boyd)

**location:** 3-56 (between *cu* and *sr*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Boyd, Golino, Shaw, Osgood and Green, 1981, *Genetics* 97: 607-23.

**phenotype:** Larval survival sensitive to exposure to methyl methanesulfonate. Displays hypermutability to alkylating agents; defective both in alkylation and UV excision repair pathways (Smith and Dusenberg, 1988, *Mechanisms and Consequences of DNA Damage Processing*, Alan R. Liss, Inc., pp. 251-55). Homozygotes fertile. Partially excision deficient (Boyd and Harris, 1981, *Chromosoma* 97: 607-23).

**alleles:** One allele, *mus306*<sup>D1</sup>.

### *mus307* (J.B. Boyd)

**location:** 3-59 (between *cu* and *sr*).

**references:** Boyd, Golino, Shaw, Osgood and Green, 1981, *Genetics* 97: 607-23.

**phenotype:** Larval survival hypersensitive to exposure to X rays (Oliveri, Harris, and Boyd, 1990, *Mutat. Res.* 235: 25-31), methyl methanesulfonate, and nitrogen mustard. Homozygotes fertile. Modified DNA synthesis (Boyd and Shaw, 1982, *Mol. Gen. Genet.* 186: 289-94).

**alleles:** One allele, *mus307*<sup>D1</sup>.

### *mus308* (J.B. Boyd)

**location:** 3-55 (between *cu* and *sr*).

**references:** Boyd, Golino, Shaw, Osgood and Green, 1981, *Genetics* 97: 607-23.

**phenotype:** Larval survival hypersensitive to exposure to X rays (Oliveri, Harris, and Boyd, 1990, *Mutat. Res.* 235: 25-31), and nitrogen mustard. Partially deficient in post-replication repair (Boyd and Shaw, 1982, *Mol. Gen. Genet.* 186: 289-94) and excision (Boyd and Harris, 1981, *Chromosoma* 97: 607-23); DNA synthesis modified (Boyd and Shaw). Displays hypermutability to alkylating agents; defective both in alkylation and UV excision repair pathways (Smith and Dusenberg, 1988, *Mechanisms and Consequences of DNA Damage Processing*, Alan R. Liss, Inc., pp. 251-55). Defective in levels of nuclease 3, which is apparently active in the repair of DNA cross links (Boyd, Sakaguchi, and Harris, 1990, *Genetics* 125: 813-19).

location: 1-30.9.

references: 1946, DIS 20: 88-89.

Gelbart, 1971, Genetics 68: s22.

Birchler, 1986, Genetics 113: s47.

Birchler, Hiebert, and Rabinow, 1989, Genes Dev. 3: 73-84.

phenotype: Normal by itself. A specific dilutor of *w<sup>a</sup>* and other intermediate alleles at the *w* locus. Eyes assume a lighter mottled appearance. Affects *w<sup>a</sup>* and seven other intermediate alleles (Gelbart), including *w<sup>ad</sup>*, *w<sup>bf</sup>*, *w<sup>h</sup>*, *w<sup>sp55</sup>*, and *z w<sup>zm</sup>* (Birchler); without effect on other intermediate alleles. Sensitive alleles are insertion alleles as determined by Zachar and Bingham (1982, Cell 30: 529-41); at least six different transposable elements involved. Insensitive *w* alleles are not insertion mutants. Expression not affected by dosage of *Y* chromosome (Oster, 1957, DIS 31: 150). RK1.

**mwg: microwing**

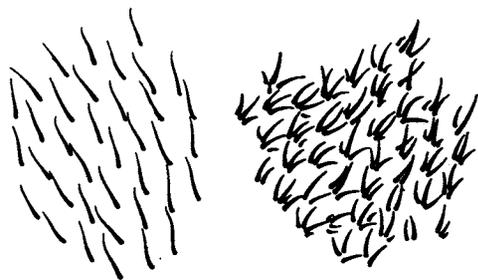

location: 2- (left arm).

origin: Spontaneous.

references: Moran and Neeley, 1971, DIS 46: 43.

phenotype: Wings reduced in size, extending slightly beyond scutellum; only proximal regions of veins obvious; wings usually curled or curved at posterior margins, often filled with fluid. Halteres slightly shorter than nor-

mal. Homozygous females fully fertile.

**mwh: multiple wing hairs**

Wing hairs. Left: wild type. Right: *mwh*.

A. Di Pasquale, unpublished.

***mwh*: multiple wing hairs**

**location:** 3-0.3 [between *fap* and *ru* (Robertson and Rivera, 1972, DIS 48: 21; Roberts and Evans-Roberts, 1979, Genetics 93: 663-79). See also Strommer and Falk (1980, DIS 56: 196)].

**origin:** Spontaneous.

**discoverer:** di Pasquale, 50l.

**references:** 1951, DIS 25: 70.

1952, Rend. Ist. Lombardo Sci. Lettere, Ser. B 85: 1-8.

Peyer and Hadorn, 1965, Arch. Julius Klaus-Stift. Vererbungsforsch. Sozialanthropol. Rassenhyg. 40: 19-26 (fig.).

**phenotype:** Affects the trichomes (hairs) of all body regions in the same general way: An increase in the number of elements is correlated with a reduction in length and a disturbance of orientation. Arista and bracts are included in this pattern; bristles and other sensilla are not. Wing cells contain groups of 2-7 hairs instead of one hair per cell as in wild type; causes supernumerary trichomes over entire integument, but tufts of trichomes only in wing blade (Ouweneel, 1970, Genetica 41: 1-20); may be supernumerary hairs and sensilla on halteres (Ouweneel and van der Meer, 1972, Wilhelm Roux's Arch. Entwicklunsgmech. Org. 172: 149-61). Also causes disruption of polarity in legs, wings, and halteres; may disrupt orientation of hairs on leg without affecting their numbers (Bryant and Schneiderman, 1969, Dev. Biol. 20: 263-90); trichomes on wings tend to diverge from vein L3 rather than parallel it as in wild type (Gubb and García-Bellido, 1982, J. Embryol. Exp. Morphol. 68: 37-57). *mwh/+* develop *mwh* phenotype following heat shock at or just prior to the time of cell-hair-extrusion (Mitchell and Petersen, 1984, Genetics 107: s74). Transplants of mutant wing disks to wild-type hosts develop autonomously (Ursprung and Hadorn, 1962, Dev. Biol. 4: 40-60). Widely used as a cell marker in the analysis of cuticular clones. The frequency of *mwh* spots after somatic recombination in *mwh/+* flies increases with increase in the temperature at which the larvae and pupae are raised (Graf, 1986, DIS 63: 65). RK1.

**cytology:** Placed in 61E2-62A3 (Roberts and Evans-Roberts).

**\**mwh<sup>semi</sup>*: multiple wing hairs-semi**

**origin:** Spontaneous derivative of *mwh*.

**discoverer:** di Pasquale, 51e.

**phenotype:** Like *mwh* except that the groups of wing hairs are restricted to wing margins. Cells of wing surface between second and fifth longitudinal veins have single hair with only an occasional group. *mwh<sup>semi</sup>/mwh* is like *mwh<sup>semi</sup>/mwh<sup>semi</sup>*. RK1.

**\**mwi*: misheld wings**

**location:** 1-0.4.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1958, DIS 32: 72.

**phenotype:** Wings diverge upward and outward at various angles. Eye shape oval. Viability and fertility good in male and reduced in female. RK2.

***Myb*: Myb proto-oncogene sequence**

**location:** 1- {50}.

**origin:** Isolated from genomic library using the c-myb sequence as probe.

**references:** Katzen, Kornberg, and Bishop, 1985, Cell 41: 449-56.

**phenotype:** Considered to be the *Drosophila* homologue of avian c-myb. Open reading frame identified to date encodes a polypeptide exhibiting 73% homology with chicken c-myb protein.

**molecular biology:** Cloned region of homology (probably < half the total) sequenced; 67% identity (253/375 residue) with chicken c-myb nucleotide sequence. *Drosophila C-myb* appears to lack two upstream exons present in chicken; the portion cloned comprises a single open reading frame, lacking two introns present in the homologous genomic sequence of the chicken. Homologous transcripts of 3.8 (predominantly) and 3.0 kb found in *Drosophila* embryos.

**cytology:** Probe hybridizes to the 13E-F boundary.

***Myc*: Myc proto-oncogene sequence**

**location:** 2- {58}.

**origin:** Isolated from a genomic library using N-myc probe from human neuroblastoma.

**references:** Voss, Strand, Anderson, Nystrom, Spiver, and McDonald, 1986, Genetics 113: s37.

**cytology:** Located to 44A by *in situ* hybridization.

**molecular biology:** Homologous to a major 7 kb transcript as well as six less abundant transcripts ranging in size from 2-5 kb.

***Myofibrillar contractile protein*:** see *Mfcp*

***myofibrillar defective*:** see *mfd*

***Myosin heavy chain*:** see *Mhc*

***Myosin heavy chain-cytoplasmic*:** see *Mhc-c*

***Myosin light chain*:** see *Mlc*

***mys*: myspheroid**

**location:** 1-21.7.

**references:** Rizki, 1956, J. Exp. Zool. 131: 203-22 (fig.).

Wright, 1958, Proc. Intern. Congr. Genet., 10th., Vol. 2: 323.

1960, J. Exp. Zool. 143: 77-99 (fig.).

Leptin, Bogaert, Lehman, and Wilcox, 1989, Cell

56: 401-08.

**phenotype:** Structural gene for the  $\beta$  subunit of position-specific integrins 1 and 2, PS1 and PS2. Twenty-hour embryos (25°) show middorsal herniation of brain and midgut, or both; abnormal somatic, visceral, and pharyngeal muscles; and incomplete morphogenesis of yolk-filled midgut. Development of embryo normal up to 13 hr, even in embryos produced from homozygous germ-line clones (Wieschaus and Noell, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 63-73). Between 13 and 14.5 hr the first muscular contractions occur, while basement membrane is incomplete. This results in dorsal rupture of hypoderm and retraction of myogenic elements of somatic and pharyngeal muscles into spheroidal masses. Continuation of myogenesis produces spheroidal muscles with a cortex of disoriented fibrillae surrounded by a medulla of nucleated sarcoplasm. Homozygous clones of *mys*<sup>11</sup> on either surface of the wing lead to separation of the two surfaces of the membrane and the formation of blisters in the vicinity of the clone [Brower and Jaffe, 1989, Nature (London) 342: 285-87]. Western blots with antibodies specific to the  $\beta$  subunit of *Drosophila* PS integrins detects no  $\beta$  integrin in *mys*<sup>10</sup>, *mys*<sup>11</sup>, and *Df(1)C128*; in addition, PS1 $\alpha$  is not cleaved properly in these genotypes, nor do  $\alpha$  chains become localized in mutant embryos. PS $\beta$  expression in wild type is diffuse in early embryos, becoming localized between the mesodermal and ectodermal layers at the extended-germ-band stage; also seen at interfaces between epidermal cells and deep in the intersegmental grooves where intersegmental muscles attach. In late embryos antibody staining is seen at basal surface of entire gut epithelium and is also concentrated at muscle attachment sites.

Genet., 10th, Vol. 2: 323; 8 = Wright, 1960, J. Exp. Zool. 143: 77-99 (fig.); 9 = Wright, 1968, Proc. Int. Congr. Genet., 12th, Vol. 1: 141.

**cytology:** Placed in 7D1-6 based on its inclusion in *Df(1)C128 = Df(1)7D1;7D5-6*.

**molecular biology:** Gene localized in an eighty-kilobase walk by virtue of the *roo* insert associated with *mys*<sup>9</sup>; the position of the insert is in a 1.7 kb restriction fragment between 21.7 and 23.4 kb distal to the first *Sma*I site proximal to *Df(1)C128*, which is designated as the 0 coordinate. *mys*<sup>2</sup>, *mys*<sup>5</sup> and *mys*<sup>8</sup> have no gross molecular lesion (Digan *et al.*). Sequences from this region identify a 4.4-kb mRNA on Northern blots; cDNA clones provide a sequence accounting for a message of such length; the conceptual amino-acid sequence contains a 23-amino acid N-terminal signal sequence and a single 23-amino-acid hydrophobic membrane-spanning domain, and specifies an 846-amino-acid polypeptide of 90 kd following removal of the signal sequence; there are six consensus sites for glycosylation of asparagine residues. The molecule contains 56 cystein residues arranged into cystein-rich motifs characteristic of the vertebrate family of  $\beta$  integrins. Overall it displays 45% identity with chicken  $\beta$  integrin with substantial segments in both the intracellular and extracellular domains showing up to 95% identity (MacKrell, Blumberg, Haynes, and Fessler, 1988, Proc. Nat. Acad. Sci. USA 85: 2633-37).

**N: Notch (W.J. Welshons)**

The Notch locus is involved in the differentiation of the ectoderm and is found in band 3C7. It includes phenotypically distinct regions *Ax*, *Co*, *fa*, *l(1)N*, *N*, *nd*, and *spl*. The wild-type allele of Notch is essential for the proper development of the neurogenic region, appearing to direct some ectodermal elements into the epidermal pathway of development. The expression of the Notch phenotype depends on the dosage of  $N^+$ , two doses in females and one in males being essential to produce wild-type flies. The mutant expression of *N*, characterized by notched wings as well as vein and microchaetal abnormalities (Mohr, 1919, *Genetics* 4: 285-82), is found in  $N/N^+$  females. *l(1)N* mutants, on the other hand, do not show a Notch phenotype over  $N^+$  and are lethal with *N* (Poulson, 1968, *Proc. Int. Congr. Genet.*, 12th, Vol. 1: 143). *Ax* mutants show dominant wing and bristle phenotypes distinct from *N* (Foster, 1975, *Genetics* 81: 99-120; Portin, 1975, *Genetics* 81: 121-33). *Co* is a duplication that affects wing veins when expressed in homo- and hemizygotes. The recessive visible mutants *fa* and *spl* affect the surface of the eye; in heterozygotes with *N*, the eyes are rough. Another recessive visible mutant *nd* (which includes  $fa^{no} = nd^3$ ) shows notched-wings, thickened veins, and interaction with *N* (Bauer, 1943, *Z. Indukt. Abstamm. Vererbungsl.* 81: 374-90; Welshons and Von Halle, 1962, *Genetics* 47: 743-59; Welshons, 1965, *Science* 150: 112-29).

The expression of  $N^+$  during neurogenesis has been examined by *in situ* hybridization (Hartley, Xu, and Artavanis-Tsakonas, 1987, *EMBO J.* 6: 3407-17) and by antibody staining (Kidd, Baylies, Gasic, and Young, 1989, *Genes Dev.* 3: 1113-29; Johansen, Fehon, and Artavanis-Tsakonas, 1989, *J. Cell Biol.* 109: 2428-40). The protein is expressed in cells destined for neural and epidermal lineages and also in mesodermal cells. Later Notch expression is restricted to the neuroblasts and their derivatives, the neurons and nerve processes.

The use of temperature-sensitive mutants, especially *l(1)N<sup>ts</sup>*, has identified the TSP's for numerous defects at Notch (Shellenbarger and Mohler, 1975, *Genetics* 81: 143-62; 1978, *Dev. Biol.* 62: 432-46). Complementation between alleles can be understood as due to the spatial or temporal separation of defects in the course of development. The defects occur throughout developmental stages from embryo to late pupa.

Notch mutants, recessive lethals, and visibles alter activities of four enzymes of the mitochondrial respiratory chain (Thörig, Heinstra and Scharloo, 1981, *Mol. Gen. Genet.* 182: 31-38; 1981, *Genetics* 99: 65-74; Thörig and Scharloo, 1982, *Genetics* 57: 219-23).

Construction of germ line mosaics homozygous for an *N* mutant reveal the existence of a maternal component of Notch expression (Jiménez and Campos-Ortega, 1982, *Wilhelm Roux's Arch. Dev. Biol.* 191: 191-201), and Notch transcripts can be detected in unfertilized eggs (Artavanis-Tsakonis, Muskavitch, and Yedvobnick, 1983, *Proc. Nat. Acad. Sci. USA* 80: 1977-81). Furthermore, *N* expression is generalized and not confined to tissues affected by mutant alleles; phenotypic effects, therefore, seem to be context-specific (Hartley *et al.*, 1987).

The Notch locus in *D. hydei* shares many similarities with the locus in *D. melanogaster* (Van Breugel, 1971, *Genetica* 42: 25-41; Van Breugel and Van Zyll

Langhout, 1983, *Genetics* 103: 197-217).

The components of Notch are described in separate entries on the following pages.

**cytology:** Placed in 3C7 since heterozygotes for a mutation or a deficiency involving this band show the Notch phenotype (Slizynska, 1938, *Genetics* 23: 29-99; Demerec, 1939, *Proc. Int. Congr. Genet.*, 7th, pp. 99-103; Demerec, Kaufman, Fano, Sutton, and Sansome, 1942, *Year Book - Carnegie Inst. Washington* 41: 191). High resolution *in situ* hybridization and computer-aided optical microscope data collection and image analysis indicate that coding portions and introns of the Notch gene are contained in 3C7. DNA 5' to the transcription start site lies in the interband distal to 3C7 (Rykowski, Parmelee, Agard, and Sedat, 1988, *Cell* 54: 461-72). Relation to *Co* illustrated by three *T(1;Y)*'s with breakpoints in 3C: *T(1;Y)D7*, *T(1;Y)R38*, and *T(1;Y)W17*. The segmental duplication formed from *T(1;Y)D7* and *T(1;Y)R38* is *Confluens* in phenotype; the corresponding deficiency is normal. The segmental deficiency formed from *T(1;Y)R38* and *T(1;Y)W17* is Notch in phenotype and the corresponding duplication is normal. In addition to *T(1;Y)R38*, two other translocations separate *Co* and *N*; *T(1;Y)R30* and *T(1;Y)J100* (Merriam and colleagues). Many *N* mutants have normal cytology. Translocations and inversions with a breakpoint at or near 3C7 also yield *N* mutants, some of which variegate for *N* and loci linked to it. Notch alleles identified as point mutations, inversions, translocations and transpositions are described in the mutant section as *N* and *l(1)N*, while *N* deficiencies are described in the deficiency section as *Df(1)N*.

Deficiencies and inversions with a breakpoint in Notch can also recombine with mutant sites such that a systematic recombinational analysis will identify the lesion at Notch on the genetic map (Welshons, 1974, *Genetics* 76: 775-94; Welshons and Keppy, 1981, *Mol. Gen. Genet.* 181: 319-24).

**molecular biology:** Molecular cloning techniques have yielded a physical map of Notch in which a 37-40 kb transcription unit contains sequences homologous to a 10.5-11.7 kb poly(A)<sup>+</sup> RNA; the DNA sequence of this transcription unit has been determined (Kidd, Lockett, and Young, 1983, *Cell* 34: 421-33; Wharton, Johansen, Xu, and Artavanis-Tsakonas, 1985, *Cell* 40: 567-81; Yedvobnick, Muskavitch, Wharton, Halpern, Paul, Grimwade, and Artavanis-Tsakonas, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 841-54; Kidd, Kelley, and Young, 1986, *Mol. Cell. Biol.* 6: 3094-3108; Kidd and Young, 1986, *Nature* 323: 89-91; Kelley, Kidd, Berg, and Young, 1987, *Mol. Cell Biol.* 7: 1545-48; Kelley, Kidd, Deutsch, and Young, 1987, *Cell* 51: 539-48; Ramos, Grimwade, Wharton, Scottgale, and Artavanis-Tsakonas, 1989, *Genetics* 123: 337-48). Except for portions of the two largest intervening sequences, the 5' and 3' ends of the gene have been mapped, and the location of nine exons have been determined. The major Notch transcript encodes a stable 350 kd transmembrane glycoprotein (2,703 amino acids) which is expressed throughout development. The protein includes extracellular epidermal growth factor-like repeats with cysteines that probably form intramolecular disulfide bonds; different X chromosomes display frequent silent nucleotide substitutions in the EGF-like repeat region (Hartley *et al.*, 1987; Kelley *et al.*, 1987; Artavanis-Tsakonas, 1988, *TIG*

4: 97-100; Kidd *et al.*, 1989; Johansen *et al.*, 1989).

P-element-mediated rescue of the homozygous lethal and heterozygous visible phenotypes of the mutants  $N^{5419}$  and  $N^{60g11}$  was accomplished with about 40 kb of genomic DNA carried in a Notch cosmid vector (Ramos *et al.*, 1989). A 15-kb "minigene" of cDNA lacking most introns but carrying all the 10.2 kb exons was able to rescue *nd* and partially rescue *fa<sup>swb</sup>* and *spl*, although it could not rescue *fa<sup>g</sup>* and *fa<sup>no</sup>*.

The zero coordinate used in locating the molecular lesions in the various Notch alleles is the first *EcoRI* site in Canton-S DNA proximal to the 3C7 breakpoint of *In(1)N<sup>76b8</sup>* (Kidd, Kelley, and Young, 1986, Mol. Cell Biol. 6: 3094-108; Kidd, Lockett, and Young, 1983, Cell 34: 421-33); it is 1.1 kb to the right of the zero coordinate used by Artavanis-Tsakonis *et al.*, 1983.

**other information:** Combined genetic and physical information is presented in the map of Notch.

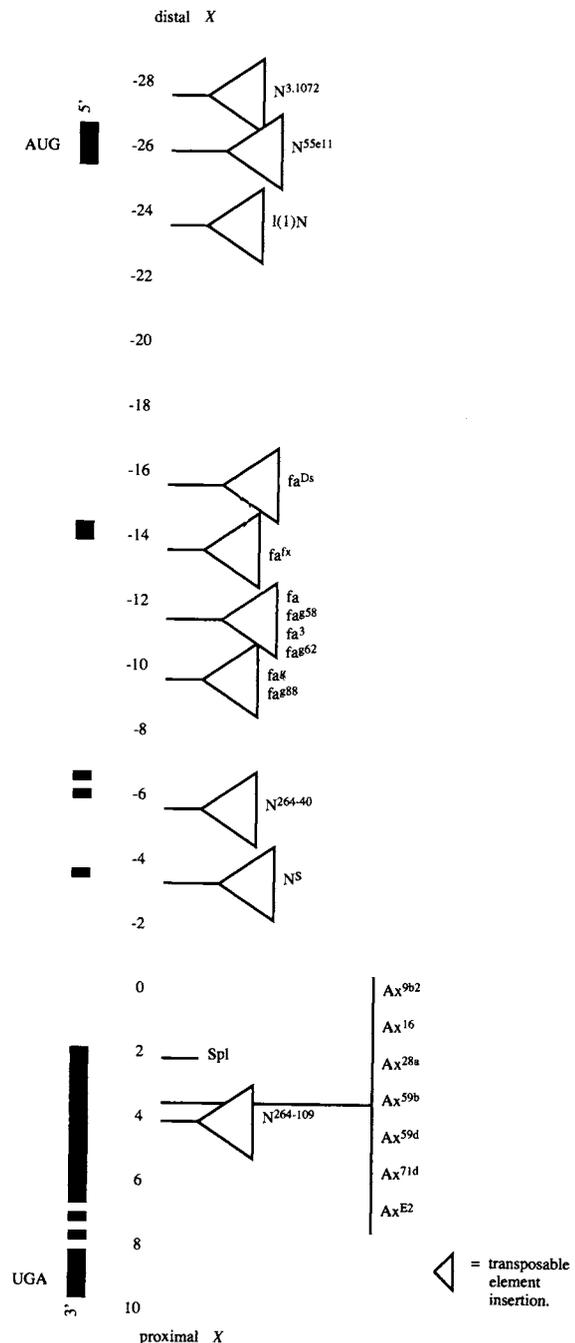

**Ax: Abruptex (W.J. Welshons)**

**location:** 1-3.0.

**phenotype:** Homozygous females and males show shortened L5 vein, usually also L4, L2, and sometimes L3. Wings shortened, arched, and thin. Costal bristles clumped and frayed; costal veins thickened. Thorax shows midfurrow with rearranged hair directions; hairs on thorax and head fewer, with clear patches and streaks. Male genitalia often rotated. *Ax/+* females show short L5 in half of the flies and sparse hair pattern on thorax. Lower temperature (19°) markedly decreases expression, and higher temperature enhances it. Some *Ax* alleles enhance *N* expression in *Ax/N* heterozygotes, but others suppress the dominant *N* phenotype. For example, *Ax/N<sup>g</sup>* approaches wild type in all characteristics. No wing-vein interruption in *Ax/+* at 18° and 26°, and enhancement by *H* occurs so that *Ax/Y;H/+* and *Ax/Ax;H/+* are nearly lethal at 26° (House, 1959, Anat. Record 134: 581-82). *Ax/Ax;ci<sup>D</sup>/+* and *Ax/Y;ci<sup>D</sup>/+* are lethal or nearly so at 26°. At 22°, males survive and show enhanced wing-vein interruption and more missing bristles. At 26°, wing-vein interruption approaches 100% in *Ax/+;ci<sup>D</sup>/+* (House and Lutes, 1975, Genetics 80: s42-43).

Wing nicking is suppressed in *Ax/N<sup>55e11</sup>* at 25°, and *Ax* venation is weakly expressed; *Ax/Ax;Dp(1;2)51b/+* shows weak *Ax* venation (Portin, 1975, Genetics 81: 121-33). Nearly lethal when reared at 29°; temperature-sensitive period early pupa (Portin and Sirén, 1976, Hereditas 84: 109-16). In heterozygotes of *Ax* with the recessives at Notch at 18° and 25°, there is neither expression of the recessive nor *Ax*-type venation. At 29°, only *Ax/fa<sup>no</sup>* shows some weak expression of the recessive, and all heterozygotes except *Ax/nd<sup>2</sup>* show some *Ax* venation (Portin, 1977, Hereditas 87: 77-84). *Ax* interacts with alleles *Ax<sup>9</sup>*, *Ax<sup>59b</sup>*, *Ax<sup>71d</sup>*, *Ax<sup>16</sup>*, and *Ax<sup>E2</sup>* (see appropriate entry). RK2 in males.

**alleles:** Three classes of *Ax* mutations can be distinguished: Some alleles (*Ax<sup>16</sup>*, *Ax<sup>71d</sup>* and *Ax<sup>E2</sup>*) in heterozygous combination with *N* enhance the wing-incision phenotype; others (*Ax<sup>1</sup>* and *Ax<sup>9</sup>*) suppress wing incision of *N* and in turn display suppression wing-vein gapping by *N*; yet another class (*Ax<sup>59b</sup>* and *Ax<sup>59d</sup>*) are homozygous lethal. Notch-enhancing and Notch-suppressing alleles are homozygous viable, but lethal in heterozygous

**Notch transcription and molecular map**  
Data modified from maps of M. Young. Program by D. Conner.

combination with each other. Phenotypic, cytological, and fine-structure mapping descriptions of these alleles appear below.

<sup>β</sup> Background on which mutation induced.

<sup>γ</sup> Mutants partially sequenced; each correlated with single amino acid substitutions within six adjacent EGF-homologous elements of the *N* protein; all have Gly at residue 2057 characteristic of Oregon R rather than Ser of Canton S (Kelley *et al.*, 1987).

<sup>δ</sup> Both alleles show changes in cysteine (cysteine to glycine in Ax<sup>59b</sup>, cysteine to tyrosine-serine in Ax<sup>59d</sup>). Developmental studies of Young have shown that Ax<sup>59d</sup> is a larval lethal and Ax<sup>59b</sup> is a pupal lethal (Kelley *et al.*, 1987).

### Ax<sup>1</sup>

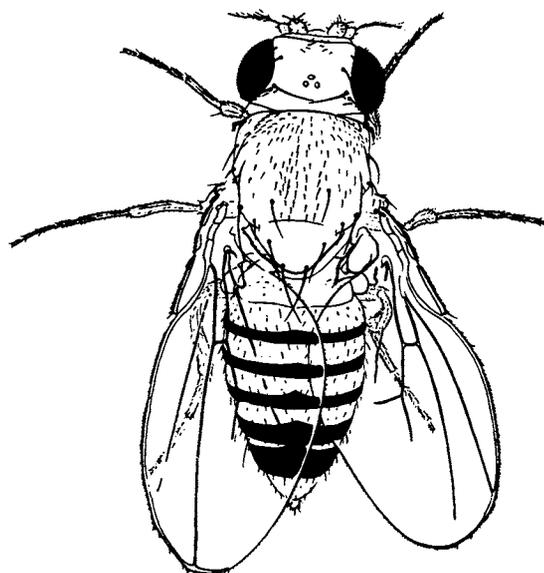

**phenotype:** Temperature-sensitive lethal; male viable at 25° but nearly lethal at 29°. Ax<sup>1</sup>/Ax<sup>E2</sup> semilethal at 25° and lethal at 29°. Temperature-sensitive period for lethality of Ax<sup>1</sup> at beginning of pupal stage; of Ax<sup>1</sup>/Ax<sup>E2</sup> at end of third instar and into early pupal stage.

**cytology:** A single-band duplication, presumed to be for 3C7 by Schultz (Morgan, Schultz, and Curry, 1941, Year Book - Carnegie Inst. Washington 40: 283). Lefevre, Ratty, and Hanks (1953, Genetics 38: 345-59), on the other hand, argue against a duplication for 3C7 on the basis of equal X-ray-induced mutability to *N* in Ax and +. Molecular information also incompatible with the presence of a duplication.

**molecular biology:** Asparagine replaced by isoleucine at residue 986 in EGF repeat #25; AAT → ATT (Kelley *et al.*, 1987).

### Ax<sup>9</sup>

**phenotype:** Viable in both sexes but poorly fertile or sterile. Bristle loss and vein interruptions are more extreme at 29°. Heterozygotes of Ax<sup>9</sup> with Ax<sup>1</sup> and Ax<sup>E1</sup> are viable, but Ax<sup>9</sup> is inviable with Ax<sup>71d</sup>, Ax<sup>16</sup>,

**Ax: Abruptex**

From Mohr, 1932, Proc. Intern. Congr. Genet., 6th, Vol. 1: 190-212.

and Ax<sup>E2</sup> (negative complementation). The lethality associated with negative complementation is suppressed by 23 lethal Notch alleles as well as by alleles of *Dl* and *mam* (Xu, Rebay, Fleming, Scottgale, and Artavanis-Tsakonas). When heterozygous with *N* mutants, phenotypes of Ax and *N* tend toward normal, but there is temperature sensitivity for suppression of wing nicks (Foster, 1975; Portin, 1975). Ax<sup>9</sup> complements every recessive visible on the Notch map at 18° to 29° (Portin, 1977, Hereditas, 87: 77-84); with Ax<sup>59b</sup> and Ax<sup>59d</sup>, it is semilethal. Negative complementation is eliminated by *Dp(1;2)51b* and results in a strong Ax phenotype (Portin, 1975). The fate map for negatively complementing heteroallelic Ax<sup>9</sup>/Ax<sup>E2</sup> suggests a focus of lethality in tissue close to hypodermal sites of central thoracic structures; in surviving gynandromorphs, negative complementation for morphological defects is autonomous (Portin, 1977, Genetics, 86: 309-19).

**molecular biology:** Mutation results in an amino acid change from aspartic acid to valine at residue 948 in EGF repeat #24; GAC → GTC (Kelley *et al.*, 1987).

### Ax<sup>16</sup>

**phenotype:** Homozygotes resemble Ax<sup>1</sup>. Ax<sup>16</sup> is less fertile than alleles Ax<sup>E2</sup>, Ax<sup>71d</sup>, and Ax<sup>9</sup> (Portin, 1975), and temperature sensitive for the bristle and wing effects of Ax (Foster, 1975). In heterozygotes with Notch, Ax is expressed and the Notch wing effect is enhanced (Foster, 1975; Portin, 1975). At 29°, heterozygotes with *N* are lethal. In Ax<sup>16</sup>/*N*<sup>264-40</sup> heterozygotes, the TSP for lethality is in the second instar, and for Ax-morphological effects, it is in the third instar (Foster, 1973, 1975). In heterozygotes with recessive visibles at Notch, all are complementary at 18° and 25°; at 29°, there are mild indications of noncomplementarity with *nd* and *nd*<sup>2</sup> (Portin, 1977). Heteroalleles Ax<sup>16</sup>/Ax<sup>E2</sup> and Ax<sup>16</sup>/Ax<sup>71d</sup> are viable (Foster, 1975; Portin, 1975); Ax<sup>16</sup>/Ax<sup>E1</sup> is inviable (negative heterosis) and heterozygotes with Ax<sup>9</sup> and Ax<sup>1</sup> are lethal (negative complementation) (Foster, 1975; Portin, 1975), but *Dp(1;2)51b* restores viability (Portin, 1977). Heterozygotes with the

lethal alleles  $Ax^{59b}$  and  $Ax^{59d}$  are lethal and mostly inviable upon the addition of  $Dp(1;2)51b$  (Portin, 1975, 1977).

**cytology:** Salivary chromosomes are normal (Foster, 1975).

**molecular biology:** Mutation involves a change from glycine to alanine in residue 1174 in EGF-like repeat #29; GGA → AGA (Kelley *et al.*, 1987).

**other information:** On the genetic map of Notch, probably between  $N^{264-40}$  and  $N^{Co}$  based on the failure to obtain recombinants between  $Ax^{16}$  and  $Ax^9$  (Foster, 1975).

#### **$Ax^{59b}$**

**phenotype:** Homozygotes and hemizygotes semilethal at 22°; lethality approximates 100% at 25°. Lethal in heterozygotes with  $N$  mutants but viable and fertile with recessive visibles at Notch.  $Ax^{59b}/Ax^{59b}; Dp(1;2)51b/+$  are poorly viable and infertile, and mutant phenotype is enhanced.  $Ax^{59b}/+; Dp(1;2)51b/+$  females have diminished mutant expression compared to  $Ax^{59b}/+$  females which in turn are similar to males  $Ax/Y; Dp(1;2)51b/+$ . In heterozygotes with  $spl$  at 25°, the eye is reduced in size but is larger than in  $spl/spl$ , and eye roughness varies from very mild to undetectable. The report by Welshons that  $Ax^{59b}/spl$  did not express the split phenotype was an error caused by uncontrolled temperature variation. In *cis* heterozygotes,  $spl Ax^{59b}/++$ , expression of split is enhanced compared to  $Ax^{59b}/spl$ ; the eyes are rough and reduced in size. No such enhancement is seen when  $fa^g$  is coupled to  $Ax^{59b}$ , and in  $Ax^{59b}/fa^g$ , the expression of the recessive is very mild and frequently nonpenetrant (Welshons, 1971).  $Ax^{59b}$  is semilethal with  $Ax^9$  and lethal with alleles  $Ax^{16}$ ,  $Ax^{E2}$ ,  $Ax^{71d}$ ,  $Ax^1$ , and the addition of  $Dp(1;2)51b$  to heterozygotes of  $Ax^{59b}$  with  $Ax^9$  and  $Ax^1$  restores viability (Portin, 1975). The temperature sensitivity of the  $Ax^{59b}$  phenotype is strongest at 25°; mutant expression decreases at both 18° and 29°, with the least mutant expression at 29° (Portin, 1981, Hereditas 94: 93-98). At 18°, there is complementarity with all recessive visibles at Notch and strong  $Ax$  expression in every case except when heterozygous with  $fa^g$ . At 29°, all heterozygotes are noncomplementary with the exception of  $nd$ ;  $Ax$  expression is diminished. At 29°, homozygotes or hemizygotes with  $Dp(1;2)51b$  are more viable than at 18° or 25° (Portin, 1977). At 25°, wing-vein interruption and bristle loss increases with an increased dose of the mutant gene (Portin, 1981, Hereditas 95: 247-51). Somatic crossing over yields twin spots on cuticular surface of flies, indicating that  $Ax^{59b}$  is not a primary cell lethal (Portin, 1980).

**cytology:** Salivary chromosomes normal (Welshons).

**molecular biology:** Cysteine replaced by glycine at residue 972 in EGF repeat #24; TGC → GGC (Kelley *et al.*, 1987). Some  $Ax^{59b}$  strains have acquired an eleven-base-pair deletion leading to chain termination downstream of the substitution at residue 972, which is independent of the  $Ax^{59b}$  lesion. Such double mutants show a typical  $N$  phenotype (Kelley *et al.*, 1987).

**other information:**  $Ax^{59b}$  placed on the map of the Notch locus between  $spl$  and  $nd^2$ ;  $Ax^{59d}$  placed between  $spl$  and  $N^{Co}$  (Welshons).

#### **$Ax^{71d}$**

**phenotype:** Homozygous, viable, phenotype like  $Ax^1$ . Viable with alleles  $Ax^{E2}$  and  $Ax^{16}$ , and lethal with  $Ax^1$  and  $Ax^9$  (negative complementation), but viability restored by  $Dp(1;2)51b$ . There is no obvious effect on the Notch phenotype in heterozygotes with  $N^8$  or  $N^{55el1}$ , but  $Ax$  phenotype is expressed. In heterozygotes with  $Ax^{E2}$ , the mutant phenotype is weakly expressed; heterozygotes with lethal alleles  $Ax^{59b}$  and  $Ax^{59d}$  are lethal.  $Ax^{71d}$  is complementary with recessive alleles at Notch at 18°, 25°, and 29°. The mutant expression of  $Ax$  tends to increase with increasing temperature except that  $Ax^{71d}/nd^2$  at 29° has no  $Ax$  expression.

**molecular biology:** Mutation involves a change from serine to isoleucine at residue 1088 in EGF repeat #27; AGT → ATT (Kelley *et al.*, 1987).

#### **$Ax^{75c}$**

**phenotype:** Recessive lethal like alleles  $Ax^{59b}$  and  $Ax^{59d}$ .  $Ax^{75c}/+$  is temperature sensitive for pleiotropic effects; the variation in mutant expression with temperatures of 18°, 25°, and 29° resembles that of  $Ax^{59b}$  and  $Ax^{59d}$  with some variation in detail (Portin, 1981, Hereditas 94: 93-98). The  $Ax$  mutant phenotype increases with increasing dose of the allele (Portin, 1981, Hereditas 95: 247-51).

#### **$Ax^{E1}$**

**phenotype:**  $Ax^{E1}/+$  females at 20.5° have gaps in wing veins and a reduction in number of ocellar and postvertical bristles. Semilethal as hemizygote or homozygote. Heterozygotes  $Ax^{E1}/Ax^9$  are viable and phenotypically intermediate:  $Ax^{E1}/Ax^{E2}$  and  $Ax^{E1}/Ax^{16}$  are inviable (negative heterosis).  $Ax^{E1}$  is inviable with most  $N$  mutants, but heterozygotes with  $N^{264-103}$  (a temperature-sensitive mutant) survive at 22° but not at 29°.

**cytology:** Salivary chromosomes are normal.

**other information:** On the map of Notch to the right of  $fa^{no}$  and probably close to  $spl$  based on failure to obtain recombinants between  $Ax^{E1}$  and  $spl$ .

#### **$Ax^{E2}$**

**phenotype:** Homozygous viable, phenotype like  $Ax^1$ . Temperature sensitive for morphological phenotypes (Foster, 1975) but stable for viability (Portin and Sirén, 1976). Viable in heterozygotes with  $N$ ; Notch-wing phenotype is enhanced. At 18° and 25°, complementary in heterozygotes with recessive alleles at Notch; at 29°,  $spl$  and  $nd^2$  are weakly expressed (Portin, 1977, Hereditas 87: 77-94). Heterozygotes  $fa^{no} spl Ax^{E2}/+++$  are like  $spl/spl$  with suppression of wing-vein gaps;  $fa^{no}++/+ spl Ax^{E2}$  and  $+spl Ax^{E2}/+++$  show mild expression of  $spl$  (Foster, 1975).  $Ax^{E2}$  is viable with alleles  $Ax^{71d}$  and  $Ax^{16}$ , lethal with lethal alleles  $Ax^{59b}$  and  $Ax^{59d}$  and with  $Ax^{E1}$ ,  $Ax^9$ , and  $Ax^1$  (Foster, 1975; Portin, 1975), and the lethality with  $Ax^1$  is more pronounced at 29° (Portin and Sirén). In  $Ax^{E2}/Ax^1$ , the TSP for lethality is monophasic from the end of the third instar to early pupa (Portin and Sirén, 1976). In  $Ax^{E2}/Ax^9$ , the focus of lethality is close to hypodermal sites of ventral thoracic structures, and in surviving gynandromorphs, the negative interaction between alleles is autonomous (Portin, 1977, Genetics 86: 309-19).

**cytology:** Salivary chromosomes are normal (Foster, 1975).

**molecular biology:** Histidine replaced by tyrosine at residue 1167 in EGF-like repeat #29; CAT → TAT (Hartley, Xu, and Artavanis-Tsakonas, 1987, EMBO J. 6: 3407-17; Kelley *et al.*, 1987).

**other information:**  $Ax^{E2}$  is placed on the genetic map of Notch close to and to the right of *spl* (Foster).

### $Ax^{J14}$

**phenotype:** Male lethal, mutant phenotype similar to  $Ax^1$ . Lethality is covered by  $Dp(1;2)51b$  and  $Dp(1;2)w^{64d}$ , and males with the duplication show the  $Ax$  phenotype. When lethality is covered by  $w^+Y$ , males have normal wing venation but lack ocellar bristles. In heterozygotes with  $fa^{12}$ , females survive exhibiting a strong  $Ax$  phenotype and rough eyes.

**cytology:** Salivary chromosomes normal.

### $Ax^S$ (A. Schalet)

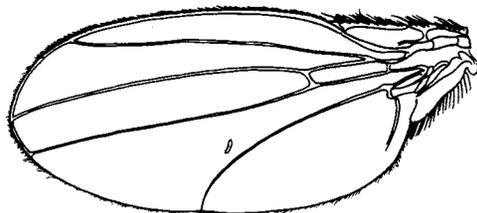

**phenotype:** Male and female homozygotes lethal.  $Ax^S/+$  males and females show sparse thoracic hairs.  $Ax^S/Ax$  similar to  $Ax/Ax$ , viability strongly reduced.  $Ax^S/N^S$  is lethal. Not suppressed by  $su(Hw)^2$ .

**molecular biology:** No detectable change in restriction map (Kidd *et al.*, 1983).

### $Ax^{tsl}$

**phenotype:**  $Ax$  phenotype 100% penetrant in heterozygotes at 18° and 29°; homozygous lethal at 29° and semilethal at 18°. Surviving homozygotes have a stronger  $Ax$  expression than in heterozygotes. Lethal with  $N$  mutants at 29° and semilethal with  $Ax^{59d}$ .  $Ax$  in phenotype and complementary with recessive visibles at Notch at 18° and noncomplementary at 29°.

**other information:** On the genetic map of the Notch locus to the right of *spl*.

**Co: Confluens**

Edith M. Wallace, unpublished.

### **Co: Confluens** (W.J. Welshons)

**location:** 1-3.0 [distal to  $N$ ; not separated by recombination, but separated by  $T(X;Y)$  breakpoints (Merriam and colleagues)].

**origin:** Recovered among progeny of cold-treated fly.

**discoverer:** Gottschewski 34c.

**references:** 1935, DIS 4: 7, 14, 16.

1937, Z. Indukt. Abstamm. Vererbungsl. 73: 131-42.

1937, DIS 8: 12.

**phenotype:** Veins irregularly thickened, especially toward tips, which are usually deltas and fused broadly to marginal vein. Stronger expression in males than in females.  $Co/N^8$  wild type except for slightly thicker L3 vein.  $Co/Ax$  like  $Ax/+$ . RK1A.

**cytology:** Associated with a tandem duplication,  $Dp(1;1)Co = Dp(1;1)3C4-5;3D6-E1$  (Schultz, 1941, DIS 14: 54-55). Result of duplication of 3C7, deficiency for

which gives Notch (Morgan, Schultz, and Curry, 1941, Year Book - Carnegie Inst. Washington 40: 283). Relation to  $N$  illustrated by three  $T(1;Y)$ 's with breakpoints in 3C:  $T(1;Y)D7$ ,  $T(1;Y)R38$ , and  $T(1;Y)W17$ . The segmental duplication formed from  $T(1;Y)D7$  and  $T(1;Y)R38$  is Confluens in phenotype; the corresponding deficiency is normal. The segmental deficiency formed from  $T(1;Y)R38$  and  $T(1;Y)W17$  is Notch in phenotype and the corresponding duplication is normal. In addition to  $T(1;Y)R38$ , two other translocations appear to separate  $Co$  and  $N$ :  $T(1;Y)R30$  and  $T(1;Y)J100$  (Merriam and colleagues).

**other information:** Reversion to wild type occurs in  $Co/Co$  by unequal crossing over.

### **fa: facet** (W.J. Welshons)

**location:** 1-3.0.

**phenotype:** Facet mutants affect the texture of the eye and in some cases cause slight to moderate wing nicks. Until now some recessive mutations with wing nicking but with normal eye texture have been designated as alleles of *fa* based upon their not being complemented by  $N$  mutants; in this treatment their designations have been changed to *nd*: notchoid, since they fail to complement *nd* mutants and like *nd* alleles, they complement *fa* alleles. All *fa* alleles complement *spl*, another eye-texture mutant in the  $N$  locus.

**alleles:** Two general phenotypes: the facet phenotype has rough eyes owing to irregularities in size, shape and arrangement of ommatidia; eye color is uniform and wild type. The glossy phenotype also displays irregular facets, but the eye surface is smooth and pigment distribution may be uneven. Most of the alleles tabulated below are described in separate entries to follow.

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments <sup>β</sup>
$fa^1$	spont	Bridges, 14b		7, 10, 13, 14	<i>opus</i> at -11.9 to -11.2; weak allele; temperature sensitive; nicked wings; not dosage compensated
$fa^3$	spont <sup>γ</sup>	Welshons		7, 10, 13	<i>springer</i> at -11.9 to -11.2; intermediate allele; not temperature sensitive; dosage compensated
* $fa^{do-vg}$	spont			4, 6	wild type as hemi- and homozygote; <i>fa</i> with <i>fa hopper</i> at -15.0 to -14.2
$fa^{Ds\delta}$	spont	Green		10	<i>flea</i> at -13.8 to -13.0; strong allele; not dosage compensated

<sup>β</sup> Insertion of copia-like elements designated *flea*, *hopper*, *springer*, and *opus* into restriction fragments placed with respect to a zero point defined as the first *EcoRI* site proximal to the left breakpoint of *In(1)N*<sup>76b8</sup>. "*flea*" represents a derivative of *flea* in which 3 kb are replaced with 1.5 kb of foreign sequence (Kidd and Young, 1986).

<sup>γ</sup> Occurred in *nd*-bearing X.  
<sup>δ</sup> *Ds* = *Drosophila simulans*.

<sup>ε</sup> Phenotype like *fa*<sup>8</sup>. Insertion in *N* intervening sequence.  
<sup>ζ</sup> *fa*<sup>swbBG</sup> is not *fa*<sup>swb</sup>; it does not carry the *fa*<sup>swb</sup> deletion; it is possibly a mislabeled *fa*<sup>862</sup>, since it contains the same insert at exactly the same nucleotide.

**molecular biology:** With the exception of *fa*<sup>swb</sup>, the *fa* alleles that have been studied have *copia*-like inserts in a 0.1 kb region of the second intron of the Notch gene (in *fa* of *Drosophila simulans* the insert is in the 3' end of the first intron). Five glossy-like alleles (*fa*<sup>fx</sup>, *fa*<sup>8</sup>, *fa*<sup>858</sup>, *fa*<sup>862</sup>, *fa*<sup>swbBG</sup>) have the same element inserted, whereas each of three facet-like alleles (*fa*<sup>1</sup>, *fa*<sup>3</sup>, *fa*<sup>Ds</sup>) has a different inserted element (see allele table). In every case the orientation of the inserted element is such that they are transcribed in the opposite direction to that of Notch.

***fa*<sup>1</sup>**

**phenotype:** Eyes of all males moderately rough owing to irregularity in size, shape, and arrangement of facets. Not dosage compensated; eyes of females less rough than those of males with about 10% overlap of wild type. Eye roughness of the females varies from nearly normal at 18° to marked at 29°; pupal stage temperature sensitive

(Shellenbarger and Mohler, 1975, Genetics 81: 143-62). Eye abnormality caused by overgrowth of secondary pigment cells, which compresses cones and causes overlying corneal facets to bulge (Waddington and Pilkington, 1942, DIS 16: 70). Wings have apical nicks in 0.25% of males and 0-5% of females. *N/fa*<sup>1</sup> has rough eyes of *fa*<sup>1</sup> as well as a Notch phenotype

***fa*<sup>3</sup>**

**phenotype:** Eyes equally rough in both sexes; wings not notched. Eyes rougher than in *fa* males but not glossy as in *fa*<sup>8</sup>; heterozygotes *fa*<sup>3</sup>/*fa*<sup>8</sup> are rough, not glossy (Welshons).

***\*fa*<sup>do-vg</sup>: facet-dominigene for vestigial**

**phenotype:** By itself, it is wild type. *fa*<sup>do-vg</sup>/*fa*<sup>1</sup> shows rough eye character of *fa*<sup>1</sup>. *fa*<sup>do-vg</sup>/*fa*<sup>do-vg</sup>; *vg/+* produces some wing notching. Presumed by Goldschmidt to enhance dominance of *vg* and thus termed a "dominigene". RK3.

***fa*<sup>fx</sup>: facet-frostex**

**phenotype:** Strong echinus-like eyes, darkening with age with glistening frosted appearance. Homozygous females sterile, but sterility may be separable from *fa*<sup>fx</sup> (Kaplan and Hayes, 1967, DIS 42: 38).

***fa*<sup>g</sup>: facet-glossy**

**phenotype:** Eyes have facets more irregular than *fa*, but surface is smoothed, giving a glossy effect. Equal mutant expression in both sexes. Pigment distribution may be uneven, contributing to an impression of altered eye color. No wing effect. Eyes of *fa*<sup>g</sup>/*fa*<sup>1</sup> intermediate between the two homozygotes. Complementary with *spl*, *fa*<sup>no</sup>, *nd*, and *nd*<sup>2</sup> (Welshons, 1965, Science 150: 1122-29). RK1.

***fa*<sup>958</sup>**

**phenotype:** Large, rough eye with semiglazed surface and irregular pigment distribution causing a patchy red color. About 2/3 flies have incisions of the inner wing margin. Viable and fertile as a male, reduced fertility in females (Fahmy, 1958, DIS 34: 49).

***fa*<sup>962</sup>**

**phenotype:** Like *fa*<sup>8</sup> and cannot be distinguished from it. In heterozygotes with *N* mutants and in *fa*<sup>862</sup>/*fa*<sup>8</sup>, the *fa*<sup>8</sup> phenotype is exhibited; *fa*<sup>862</sup>/*fa*<sup>1</sup> has a *fa*<sup>1</sup> phenotype, and *fa*<sup>862</sup>/*spl* is wild type.

***\*fa*<sup>1</sup>: facet-lethal**

**phenotype:** *fa*<sup>1</sup>/*fa*<sup>1</sup> resembles *fa*<sup>1</sup>/*fa*<sup>1</sup>; not notched. Homozygous lethal. RK2.

***fa*<sup>12</sup>**

**phenotype:** A male-lethal allele of Notch. Females nearly wild type but show occasional slight traces of Notch. Full complementation with *spl* but interacts with *fa*<sup>8</sup> showing rough irregular eyes.

***fa*<sup>swb</sup>: facet-strawberry**

**phenotype:** In males, eyes are rough with a variable tendency to be glossy; with *fa*<sup>8</sup> and *fa*<sup>862</sup>, eyes are very rough, but mutant condition is not as extreme as that found in homozygous glossy-eyed mutants. In heterozygotes with *fa*<sup>1</sup>, eyes are slightly rough, overlapping wild type; with *spl*, the eyes are wild type.

The *fa*<sup>swb</sup> allele, like *fa*<sup>1</sup>, is not dosage compensated,

and the mutant condition is poorly expressed in females.  $fa^{swb}/fa^{no}$  has slight deltas at junction of longitudinal veins with marginal veins;  $fa^{swb}$

complements  $nd$  and  $nd^2$ ; and in heterozygotes of  $fa^{swb}$ ,  $N^{55el1}$  and  $N^{264-40}$ , the eyes are glossy and the Notch phenotype is enhanced, resulting in reduced viability and fertility; with the temperature-sensitive  $N^{60g11}$ , heterozygotes are less mutant, viable, and fertile. In double mutants,  $fa^{swb}fa^g$ , the males have  $fa^g$ -like eyes; and wing veins are thickened and delta like at tips; they resemble  $fa^{no}$  males except that wings are seldom notched. The wing-venation effect is less extreme in homozygous females (Welshons and Keppy, 1975, Genetics 80: 143-55; Keppy and Welshons, 1977, Genetics 85: 497-506).

**cytology:** Deficiency for interband between 3C6 and 7, causing these bands to fuse (Keppy and Welshons, 1977).

**molecular biology:** Caused by a deficiency of 800 base pairs in the restriction fragment —26.2 to —25.0 (Grimwade, Muskavitch, Welshons, Yedvobnick, and Artavanis-Tsakonas, 1985, Dev. Biol. 107: 503-19; this is 67 base pairs upstream from the start of transcription of Notch. Deletes the 3' end of the locus immediately to the left of  $N$  (Kidd, Kelley, and Young, 1986, Mol. Cell. Biol. 6: 3094-3108).

**other information:** Removal of the region of 3C2-5 from the vicinity of  $fa^{swb}$ , either by deletion or inversion results in suppression of  $fu^{swb}$ ; also affected by spontaneously arising, cis-acting enhancer [ $e(fa^{swb})$ ] and suppressor [ $su(fa^{swb})$ ] mutations, both of which map to the 3C2-5 region. (Welshons and Welshons, 1986).

### ***l(1)N: lethal (1) Notch (W.J. Welshons)***

**location:** 1-3.0.

**phenotype:** There are four phenotypic varieties of  $l(1)N$  alleles: (1) Those that are lethal with  $N$  and wild type with the recessive visibles [see  $l(1)N^1$ ]; (2) Those that are lethal with  $N$  but not wild type with the recessive visibles [see  $l(1)N^2$ ,  $l(1)N^3$ ]; (3) Alleles whose heterozygotes with  $N^+$  have a phenotype not recognized as Notch [see  $l(1)N^B$ ], or (4) Alleles that are temperature sensitive for lethality and do not express a Notch phenotype in heterozygotes with  $N^+$  [see  $l(1)N^{ts}$ ]. The embryological defects in  $l(1)N^1$  are related to those in  $N$ ; the development in  $l(1)N^B$  is sufficiently normal to escape embryonic lethality (Poulson, 1967, 1968).

<sup>α</sup> 1 = Arnheim, 1967, Genetics 56: 253-63; 2 = Kelley, Kidd, Berg, and Young, 1987, Mol. Cell Biol. 7: 1545-48; 3 = Kidd, Lockett, and Young, 1983, Cell 34: 421-33; 4 = Lehmann, Jiménez, Dietrich, and Campos-Ortega, 1983, Wilhelm Roux's Arch. Dev. Biol. 192: 62-74; 5 = Poulson, 1967, DIS 42: 81; 6 = Poulson, 1968,

Proc. Int. Congr. Genet., 12th, 1: 143; 7 = Shellenbarger, 1972, DIS 48: 55; 8 = Shellenbarger and Mohler, 1975, Genetics 81: 143-62; 9 = Shellenbarger and Mohler, 1978, Dev. Biol. 62: 432-46; 10 = Welshons, 1965, Science 150: 1122-29.

**β** P-element insertion at 5' end of Notch transcription unit within 0.1 kb of transcription start site.  $l(1)N/+$  = wild type;  $l(1)N/N$  and  $l(1)N/Y$  = embryonic lethal. Most heterozygous combinations with recessive visibles not tested.

**γ** Temperature shifts of mature larvae result in most ommatidial cells becoming photoreceptors (Cagan and Ready, 1989, Genes Dev. 3: 1099-1112).

### ***l(1)N<sup>1</sup>***

**phenotype:**  $l(1)N^1/+$  females are wild type;  $l(1)N^1/N$  females and  $l(1)N^1/Y$  males are lethal;  $l(1)N^1/Y;Dp(1;2)51b$  males are *Co*-like. Heterozygotes with recessive visibles at Notch are wild type. Developmental defects in  $l(1)N^1/Y$  males are more limited than in  $N/Y$  males and the defects are confined to the anterior ectoderm (Poulson, 1967; 1968). Like  $N$  mutants,  $l(1)N^1$  mutants are defective as embryos (Shellenbarger and Mohler, 1975, 1978).

**molecular biology:**  $l(1)N^1$  is associated with a 8.5 kb insertion between coordinates -24.2 and -23.0 about 2.3 kb to the right of the insertion associated with  $N^{55el1}$  (Kidd *et al.*, 1983).

### ***l(1)N<sup>2</sup>***

**phenotype:**  $l(1)N^2/+$  females are wild type;  $l(1)N^2/N$  females and  $l(1)N^2/Y$  males are lethal. Heterozygotes with  $fa$  and  $fa^g$  are *fa*-like; with  $nd$ , they have *nd*-like wings and small eyes; with  $nd^3$ , they are viable, fertile and *nd^3*-like. Developmental defects in  $l(1)N^2/Y$  males and time of lethal effect same as in  $l(1)N^1/Y$ . Some  $l(1)N^2/l(1)N^{ts1}$  females survive to late pupal stage (Shellenbarger and Mohler, 1975).

### ***l(1)N<sup>3</sup>***

**phenotype:** Same as  $l(1)N^2$ .

### ***l(1)N<sup>B</sup>***

**phenotype:**  $l(1)N^B$  females have small eyes, fewer mesonotal bristles, and, sometimes, bald areas on the thorax (Welshons, 1965). The dominant bristle effect is more extreme in  $l(1)N^B/Y;Dp(1;2)51b$  males than in  $l(1)N^B/+$  females. Heterozygotes with  $fa$  have *fa*-like eyes and, frequently, nicked wings; with  $nd^3$ , they show notched wings and thickened veins; with  $nd^3$ , they are viable, fertile, and *fa*-like.  $l(1)N^B/Y$  males die during early larval life (Poulson, 1967).  $l(1)N^B/l(1)N^{ts1}$  females die before pupation (Shellenbarger and Mohler, 1975). Bristle effect autonomous in  $l(1)N^B$  cells; homozygous mutant cells survive in mosaics (Arnheim, 1967).

### ***l(1)N<sup>69e</sup>***

**phenotype:**  $l(1)N^{69e}/l(1)N^{69e}$  and  $l(1)N^{69e}/Df(1)N-8$  females are lethal at 18° and 29°;  $l(1)N^{69e}/+$  heterozygotes are almost always wild type.  $l(1)N^{69e}$  homozygotes die before pupation, but  $l(1)N^{69e}/l(1)N^{ts1}$  heterozygotes survive until the pupal stage.

### ***l(1)N<sup>ts1</sup>***

**phenotype:**  $l(1)N^{ts1}/+$  females are wild type at 18° and 29°, while  $l(1)N^{ts1}/Df(1)N-8$  females are lethal at 29°, but a few escapers are found at 18°.  $l(1)N^{ts1}$  homozygotes are viable at 18°, but lethal at 29°. If homo- and hemizygotes kept at 18°C until eclosion are transferred to 29°C and kept at this temperature for six days, they gra-

dually become flightless and show gross histological changes in the flight muscles (Vikki and Portin, 1987, William Roux's Arch. Dev. Biol. 196: 12-15). Heterozygotes show recessive visible defects at 18°, but not at 29°.  $l(1)N^{ts1}/l(1)N^2$  and  $l(1)N^{ts1}/l(1)N^3$  females survive until the late pupal stage at 29°. When heat pulses are given to pupae prior to sensillum-precursor-cell-determination, extra sensilla are produced; when given after sensillum-precursor-cell determination, the precursor cells form neurons only, not accessory cells (Hartenstein and Posakony, 1990, Dev. Biol. 142: 13-30).

***l(1)N<sup>ts2</sup>***

**phenotype:** Similar to  $l(1)N^{ts1}$  except for occasional survival of homozygotes to the pupal stage at 29° and weaker expression of recessive visible defects in heterozygotes at this temperature.

***N: Notch (W.J. Welshons)***

**location:** 1-3.0.

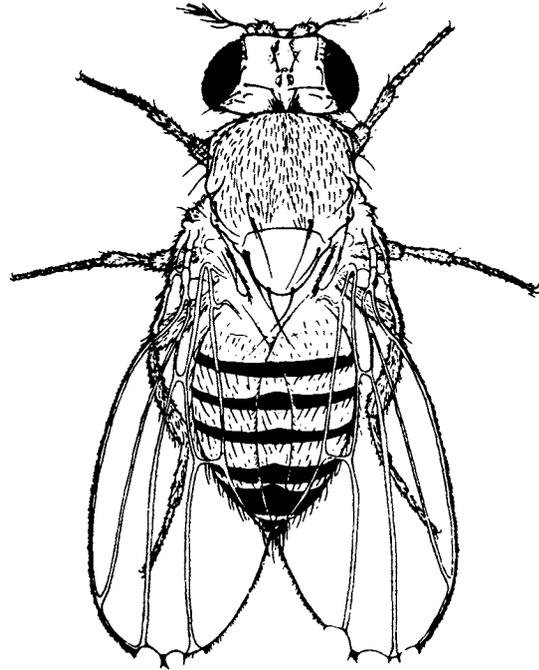

**phenotype:** Mutant alleles are characterized by the following types of expression: Wings of heterozygotes incised at tips and often along edges; veins L3 and L5 thickened; thoracic microchaetae crowded and irregularly distributed (Mohr, 1919, Genetics 4: 275-82; 1923, Z. Indukt. Abstamm. Vererbungsl. 32: 108-232). Males and homozygous females are lethal. In some *N* mutants, the phenotype is mild and varies in one or more of its typical features, but such *N*'s can usually be identified by phenotypes expressed when heterozygous with recessive visible eye and wing mutants that also occur at Notch.

Females  $N/N^+$  are Notch; females  $N/N^+;Dp(1;2)51b$  (representing a duplication for the Notch locus) are wild type. In the hemizygous male,  $N/Y$  is lethal, whereas  $N/Y;Dp(1;2)51b$  is viable and phenotypically normal; the wild phenotype is dependent upon the presence of the normal dosage of 3C6-7 for each sex. An extra dose of 3C6-7 [as in  $Dp(1;2)51b$  or  $Dp(1;1)Co$ ] causes the expression of the dominant phenotype Confluens (*Co*); thus  $N^+/N^+;Dp(1;2)51b$  females and  $N^+/Y;Dp(1;2)51b$  males are *Co*-like (Welshons, 1965). Deficiency mapping places *Co* to the left of *N* (Merriam).

Homozygotes and hemizygotes for all *N* mutants suffer the same embryological defects. In developing embryos, the pattern of differentiation of anterior and ventral embryonic ectoderm is aberrant; both presumptive hypoderm and presumptive neuroblasts develop as neuroblasts, resulting in embryos with a hypertrophied central nervous system lacking ventral and ventral-lateral hypoderm [Poulson, 1939, DIS 12: 64-65; 1940, J. Exp. Zool. 83: 271-325; 1950, Biology of Drosophila (M. Demerec, ed.). Wiley, New York, pp.168-274; 1967, DIS 42: 81; Wright, 1970, Adv. Genet. 15: 305-15]. Sensillum differentiation in peripheral nervous system of embryos also abnormal (Hartenstein and Campos-Ortega, 1986, Roux's Arch. Dev. Biol. 195: 210-21). In mosaic embryos ( $N/N^+$  and  $N/0$  cells), the  $N/0$  cells never give rise to hypoderm within the neurogenic region (Hoppe and Greenspan, 1986, Cell 46: 773-83). However, single  $N/0$  cells transplanted to  $N^+$  recipient embryos can give rise to hypoderm (Technau and Campos-Ortega, 1987, Proc. Nat. Acad. Sci. USA 84: 4500-04).

**alleles:** Notch mutants and rearrangements (other than deficiencies) are described in the following tables, the first listing the extant alleles and the second the lost alleles.

(Alleles that are also given a separate description are superscripted "#"). Notch deficiencies are listed only as chromosome rearrangements.

***N<sup>8</sup>***

Mohr, 1924, Z. Induktive Abstammungs-Verebungslehre 32: 118.

***N<sup>55e11</sup>***

**phenotype:** A weak Notch. Deltas on wing veins are most reliable character for classification. Lethal when heterozygous with  $nd^3$ ,  $N^{60g11}$ , and  $N^{Co}$ . In homozygotes and hemizygotes hyperplasia of central nervous system extreme; embryonic peripheral nervous system abnormal with sensilla undifferentiated (Hartenstein and Campos-Ortega, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 210-21).

**molecular biology:** Lesion in Notch caused by a 3.5 kb insertion in the vicinity of coordinate -26, "+" values to the right, "-" values to the left (Kidd *et al.*, 1983).

***N<sup>60g11</sup>***

**phenotype:** Wings seldom notched; veins thickened; deltas at tips.  $N^{60g11}/+$  heterozygotes have normal eyes at 29° and a disrupted facet arrangement at 21°. With increasing temperature, rough eye phenotype diminishes and Notch mutant characteristics are expressed. TSP for disrupted facets is in the third instar.  $N^{60g11}/N^{60g11}Dp(1;2)51b7$  females are viable at 29°; survival sharply decreased at 20-23°; TSP for lethality in middle of embryonic stage.  $N^{60g11}/fa$  flies have eyes like *fa*. Semilethal with  $nd^3$ . Viability poor with *nd*.

***N<sup>64d6</sup>***

**phenotype:** Typical Notch.  $N^{64d6}spl$  flies cannot be distinguished from  $N^{64d6}spl^+$  flies. When *spl* is coupled to  $N^{64d6}$ , *spl* is not enhanced by *E(spl)*.

<sup>α</sup> See references following Table I.

<sup>β</sup> 1 = Variegation for *fa* in *N/fa*; 2 = Variegation for *spl* in *N/spl*; 3 = Developmental abnormalities of male same as in *Df(1)N-8*; 4 = *XYY* male viable but sterile; *XY* male lethal; 5 = A few males, normal in phenotype, survive; 6 = Male viable and mottled for *w* and *rsr*.

### N<sup>66h26</sup>

**phenotype:** The Notch inversion *N<sup>66h26</sup>* (synonym: *In(1)w<sup>8x</sup>N<sup>66h26</sup>*), with breakpoints in *w* and *N*, was derived from *Df(1)N-8* and is unstable in crosses involving a *w<sup>a</sup>fa<sup>8</sup>rb* stock, giving rise to *N<sup>+</sup>* revertants such as *w<sup>8x1</sup>N<sup>+</sup>* and *w<sup>8x2</sup>N<sup>+</sup>* (Welshons and Keppy, 1981; Grimwade *et al.*, 1985). Recombination between *w* and *N*, which does not occur in *N<sup>66h26</sup>*, does take place in these reversions, indicating that reversion to *N<sup>+</sup>* is

accompanied by reinversion of *In(1)N<sup>66h26</sup>*. The *w<sup>8x1</sup>N<sup>+</sup>* derivative of *N<sup>66h26</sup>* is also unstable in crosses involving the *w<sup>a</sup>fa<sup>8</sup>rb* stock, generating (stepwise) various mutant and wild-type Notch alleles (Grimwade *et al.*, 1985). *Df(1)w79*, another derivative of *N<sup>66h26</sup>*, is deficient for both *N* and *w* (Welshons and Keppy, 1981).  
**molecular biology:** The lesion associated with the 3C7 breakpoint of *N<sup>66h26</sup>* lies between -24.6 and -19.4 kb.

- N<sup>68j</sup>**  
**phenotype:** Typical Notch. *N<sup>68j</sup>/+* females have wings excised at the tips; *N<sup>68j</sup>/spl* females are *spl*. *N<sup>64j</sup>* flies carrying *Dp(1;1)Co* are almost wild type. Mutant males with *w<sup>+</sup>Y* are viable (Hayman and Maddern, 1969).
- N<sup>68j1</sup>**  
**phenotype:** Typical Notch. *N<sup>68j1</sup>/Df(1)N-8* females are lethal at 29° and 18°; Notch-wing phenotype shows little or no response to temperature (Shellenbarger and Mohler, 1975).
- N<sup>69c</sup>**  
**phenotype:** Shows variable Notch-wing expression depending on temperature. Lethal in homozygotes and in heterozygotes with *Df(1)N-8* at 29° and 18°. *N<sup>69c</sup>/+* heterozygotes show greater expression of Notch-wing at 18° than at 29° (Shellenbarger and Mohler, 1975).
- N<sup>76b8</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C7-9 breakpoint lies between -2.2 and -1.3 kb on the physical map of Notch (Kidd *et al.*, 1983).  
**other information:** Recombinational analysis indicates that the Notch locus distal to *spl* is in normal sequence.
- N<sup>77c17</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C7-9 breakpoint lies between -0.1 and 7.0 kb.  
**other information:** *N<sup>77c17</sup>* does not recombine with *N<sup>60g11</sup>* (Welshons).
- N<sup>80j9</sup>**  
**phenotype:** Typical Notch. Genetically unstable, giving rise spontaneously to six independent *N<sup>+</sup>* revertants. The *N<sup>+</sup>10* revertant is rather unstable (Grimwade *et al.*, 1985).  
**molecular biology:** The lesion associated with the 3C7-9 breakpoint of the inversion lies between -24.6 and -19.4 kb.
- N<sup>81k3</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** This allele lies between -26.9 and -25.3 kb and seems to involve a deletion of 500 bp (Grimwade *et al.*, 1985).
- N<sup>81k6</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C6-9 breakpoint of the inversion lies between +5.5 and +7.0 kb.
- N<sup>81k8</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** This allele affects the restriction pattern of two regions at the same time (Grimwade *et al.*, 1985), the first mapping between -10.6 and -9.5 kb and the second between -26.9 and -23.7 kb. Sequences between the fragments are unchanged as if *N<sup>81k8</sup>* is an intralocus inversion.
- N<sup>81k9</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C6-9 breakpoint of the translocation lies between -25.3 and -23.7 kb.
- N<sup>81k10</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** Mutant phenotype thought to be caused by position effect from the juxtaposition of the Notch DNA sequence and heterochromatin at 20A3-F (Grimwade *et al.*, 1985).
- N<sup>81l1</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C5-9 breakpoint of the inversion lies between -19.4 and -9.5 kb.
- N<sup>81l3</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** This allele lies between +0.9 and +3.7 kb and seems to involve a small deletion of 2200 bp (Grimwade *et al.*, 1985).
- N<sup>81l5</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C5-9 breakpoint lies between 0 and +7.0 kb.
- N<sup>81l9</sup>**  
**phenotype:** Typical Notch.  
**molecular biology:** The lesion associated with the 3C3-3D3 breakpoint lies between -16.7 and -9.5 kb.
- N<sup>264-40</sup>**  
**phenotype:** Typical Notch. Male embryos show developmental abnormalities like those of *Df(1)N-8* (Poulson, 1939). Lethal with *nd<sup>3</sup>*.  
**molecular biology:** Lesion associated with a 0.4 kb insertion between -6.2 and -5.6 kb on the physical map of Notch (Kidd *et al.*, 1983).
- N<sup>264-47</sup>**  
**phenotype:** Typical Notch. Male embryos show developmental abnormalities like those of *Df(1)N-8* (Poulson, 1939). Lethal with *nd<sup>3</sup>*.  
**other information:** *N<sup>264-47</sup>/spl* heterozygotes produce nonrecombinant *N<sup>+</sup>* chromosomes with relatively high frequency (Welshons, 1958, Proc. Nat. Acad. Sci. USA 44: 254-58).
- N<sup>264-66</sup>**  
**phenotype:** Wing-notching weak and rarely visible. *N<sup>264-66</sup>/fa* heterozygotes variegates for *fa*. Some *N<sup>264-66</sup>/Y* males are viable and have cream-colored eyes with spots of normal red pigment.
- N<sup>264-103</sup>**  
**phenotype:** Temperature-sensitive Notch allele. *N<sup>264-103</sup>/nd<sup>3</sup>* females are viable at 22° and lethal at 29°, with a long, possibly polyphasic, TSP beginning in the embryonic stage. *N<sup>264-103</sup>/spl* females show eye-facet disarray, notching, bristle-number variation, and tarsal-segment fusion, the TSP being in the third instar (Foster, 1973). *N<sup>264-103</sup>/spl* variegates for *spl*; *N<sup>264-103</sup>/fa* is *fa*.
- N<sup>264-107</sup>**  
**phenotype:** Typical Notch.  
**other information:** The *N<sup>264-107</sup>* chromosome carries another Notch mutant site, *l(1)N*, at the distal end near *N<sup>55e11</sup>* (Welshons, 1965).

**N<sup>264-109</sup>**

**phenotype:** Typical Notch except for semilethality with *nd*<sup>3</sup>.

**molecular biology:** Lesion associated with a 14.8 kb insertion between +3.7 and +4.4 kb on the physical map of Notch (Kidd *et al.*, 1983).

**N<sup>Co</sup>**

**phenotype:** Wing tips seldom notched; veins thickened, with deltas. Acrostichal rows irregular. *N<sup>Co</sup>nd*<sup>3</sup> heterozygotes lethal; rare survivors sterile and weak. *N<sup>Co</sup>/+* females show thickened wing veins (a Confluens-like phenotype) more frequently than nicked or notched wings. Also, *N<sup>Co</sup>* heterozygous females with an extra dose of 3C6-7 [*Dp(1;1)Co* or *Dp(1;2)51b*] or hemizygous males with *Dp(1;2)51b* have an enhanced Confluens-like wing phenotype.

**N<sup>hdA171</sup>**

**phenotype:** Typical Notch.

**molecular biology:** Lesion associated with a 6.3 kb insertion between -28.4 and -27.1 kb on the physical map of Notch. *N<sup>hdA171</sup>* is the most distal of the dominant Notch alleles and is thought to be caused by a defective *P*-element (Grimwade *et al.*, 1985).

**N<sup>hdC8</sup>**

**phenotype:** Typical Notch.

**molecular biology:** Lesion associated with a 5.2 kb insertion between +2.7 and +3.7 kb, the insertion carrying moderately repetitive DNA sequences (Grimwade *et al.*, 1985).

**N<sup>J24</sup>**

**phenotype:** Typical Notch. Lethal with *nd*<sup>3</sup>.

**N<sup>M</sup>: Notch Mischiakow**

**phenotype:** Wings notched at tips and occasionally at sides; veins thickened, with deltas. Eyes slightly smaller than normal; occasionally one eye extremely small.

**molecular biology:** The Notch locus in the reverted chromosome *N<sup>+M</sup>* contains an insertion homologous to the FB4 foldback element (Grimwade *et al.*).

**N<sup>Nic</sup>: Notch Nicoletti**

**phenotype:** Typical Notch. Lethal with *nd*<sup>3</sup>. Cell lethal in tergites and dorsal mesothorax (Ripoll and Garcia-Bellido, 1979, *Genetics* 91: 443-53).

**N<sup>S</sup>: Notch Schalet**

**synonym:** *l(1)16-178*.

**phenotype:** Weak Notch. *N<sup>S</sup>/Ax<sup>S</sup>* is lethal.

**molecular biology:** Lesion associated with a five kb insertion between +3.5 and +2.90 kb on the physical map of Notch (Kidd *et al.*, 1983).

***nd*: notchoid (W.J. Welshons)**

**location:** 1-3.0.

**phenotype:** Wings notched and veins thickened. The notching is found mostly on anterior and posterior margins and is the result of cell death (Thompson and Spivey, 1984, *Genet. Res.* 44: 201-69). Homozygotes are viable and fertile in both sexes. *N/nd*<sup>1</sup> heterozygotes are partially viable and relatively infertile (Portin, 1977) and show notched and straplike wings and small eyes. About 10% of *fa/nd*<sup>1</sup> flies have small notches in one or both wings. *nd*<sup>3</sup>/*nd*<sup>1</sup> heterozygotes have slightly thick-

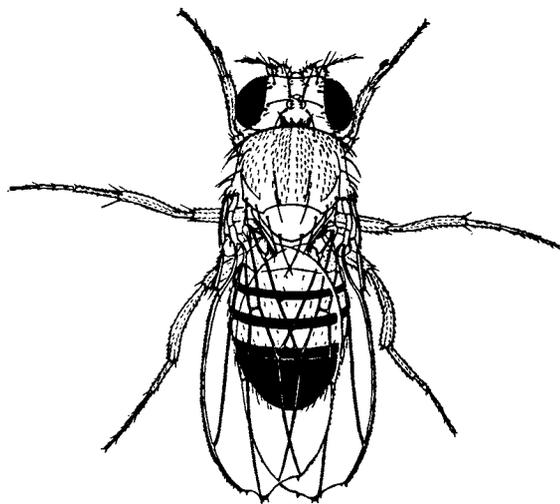

ened wing veins with deltas; *spl/nd*<sup>1</sup> heterozygotes lack a few bristles (like *spl/+*) and their eyes are sometimes smaller than normal and roughened. *spl nd*<sup>1</sup> males have rough eyes, *nd*-like wings, and irregular, bushy sex combs.

<sup>α</sup> 1 = Bauer, 1943, *Z. Indukt. Abstamm. Vererbungsl.* 81: 374-90. 2 = Fahmy, 1958, *DIS* 32: 72; 3 = Foster, 1973, *Genetics* 73: 435-38; 4 = Glass, 1933, *J. Genet.* 27: 233-41; 5 = Kelley, Kidd, Berg, and Young, 1987, *Mol. Cell Biol.* 7: 1545-48; 6 = Kidd, Lockett, and Young, 1983, *Cell* 34: 421-33; 7 = Portin, 1977, *Hereditas* 87: 77-84; 8 = Shellenbarger and Mohler, 1975, *Genetics* 81: 143-62; 9 = Welshons, 1965, *Science* 50: 1122-29; 10 = Welshons, 1971, *Genetics* 68: 259-68; 11 = Welshons, 1974, *Genetics* 76: 775-94; 12 = Welshons and Von Halle, 1962, *Genetics* 76: 775-94.

**cytology:** Salivary chromosomes are normal (Fahmy).

*nd*<sup>0</sup> (= *fa*<sup>n</sup>)

From Glass, 1933, *J. Genet.* 27: 233-41.

***nd*<sup>0</sup>**

**synonym:** *fa*<sup>n</sup>: facet-notched.

**phenotype:** Wings have apical nicks or notches in 90-100% of males, but only 8% of homozygous females. Eyes not rough. *fa/nd*<sup>0</sup> is wild type. Viability and fertility excellent. RK2 in male.

**cytology:** *nd*<sup>0</sup> is on an *In(1)dl-49* chromosome, and has not been separated from the inversion.

**nd<sup>1</sup>**

**phenotype:** *nd<sup>1</sup>* is temperature-sensitive. In homozygotes at 29°, the eyes are rough and reduced in size, there is extreme wing notching, and wing veins are thick; at 25°, the abnormalities are less severe, and at 18°, the eyes are normal and the wings are nicked. At 29°, heterozygotes with *fa*, *fa<sup>8</sup>*, and *spl* are complementary (Foster, 1973; Shellenbarger and Mohler, 1975). *nd<sup>1</sup>/Y;E(spl)<sup>r19</sup>/+* males have severely reduced and crumpled wings (Xu, Rebay, Fleming, Scottgale, and Artavanis-Tsakonas). Wing development also affected in *nd<sup>1</sup>/Y;mam<sup>10</sup>/+* males. *nd<sup>1</sup>* and *mam<sup>10</sup>* double heterozygotes are wild type. Wing notching is suppressed in *nd<sup>1</sup>/Y* males by *Dll+*.

**molecular biology:** *nd<sup>1</sup>* maps at the 3' end of the Notch locus and carries a three bp insertion in the opa repeat producing an extra glutamine and a missense mutation resulting in a threonine to isoleucine change (Xu *et al.*).

**nd<sup>2</sup>**

**phenotype:** *nd<sup>2</sup>/nd<sup>2</sup>* and *nd<sup>2</sup>/nd<sup>1</sup>* flies resemble *nd<sup>1</sup>* homozygotes; *nd<sup>2</sup>/nd<sup>3</sup>* heterozygotes are noncomplementary (Welshons). The *nd<sup>2</sup>* allele is temperature sensitive; in homozygotes at 29°, the eyes are small and rough (*spl*-like), wings have extreme notches, wing veins are thickened, tarsi are shortened, and the mutants are semilethal as late pupae; at 25°, the abnormalities are much less severe; at 18°, the eyes are slightly *spl*-like, wings are nicked, wing veins are incomplete, some bristles are missing, and the mutants are semilethal as late pupae. At 29°, *fa/nd<sup>2</sup>* heterozygotes have nicked wings, *spl/nd<sup>2</sup>* heterozygotes are *spl*-like, and *nd<sup>4</sup>/nd<sup>2</sup>* heterozygotes resemble *N/+* (Shellenbarger and Mohler, 1975). Similar wing abnormalities in *nd<sup>1</sup>/Y;E(spl)<sup>r19</sup>/+* and *nd<sup>2</sup>/Y;E(spl)<sup>r19</sup>/+* males. The temperature-sensitive rough-eye phenotype of *nd<sup>2</sup>* is enhanced by *E(spl)/+* (Xu *et al.*).

**molecular biology:** *nd<sup>2</sup>* maps proximal to *nd<sup>1</sup>* at the 3' end of Notch and shows a deletion of one bp.

**nd<sup>3</sup>**

**synonym:** *fa<sup>no</sup>*: facet-notchoid.

**phenotype:** Wings of both sexes notched at ends of L3 and L4 veins; wing veins enlarged and delta-like at tips. Mild mutant expression often limited to wing-vein effect. Mutant expression diminished at high temperature (Shellenbarger and Mohler, 1975, Genetics 81: 143-62). Heterozygotes show extremely weak dominance. *nd<sup>3</sup>/N* almost completely lethal; survivors are sterile and have an exaggerated Notch phenotype. *nd<sup>3</sup>/fa* closely resembles wild type. Heterozygotes with *fa<sup>8</sup>* and *spl* are complementary; with *nd* and *nd<sup>2</sup>*, heterozygotes are noncomplementary with a mild mutant expression of *nd<sup>3</sup>*-like wings. Up to 5% of *nd<sup>3</sup>* males from aged cultures show hyper- and hypodeveloped external genitalia (Kroeger, 1960, J. Morphol. 107: 227-32).

**nd<sup>3.1072</sup>**

**phenotype:** Viable when homo- or hemizygous; shows adult wing nicking. Lethal when heterozygous with *N* deficiencies. Phenotype similar to *nd*.

**molecular biology:** Associated with 1.2 kb *P*-element insertion within 0.1 kb of *N* transcription start site (Kelley *et al.*, 1987). Unlike *nd* and *nd<sup>2</sup>*, occupies left end of genetic map.

**nd<sup>3.1072rv</sup>**

**phenotype:** Wild-type revertant of *nd<sup>3.1072</sup>*. Viable in combination with *N* deficiencies.

**molecular biology:** Retains 200 bp of the original 1.2 kb *P*-element insertion (Kelley *et al.*, 1987).

**nd<sup>4</sup>**

**synonym:** *fa<sup>no69</sup>*.

**phenotype:** Temperature sensitive and semilethal in homozygotes; wing phenotype more extreme and survival greater at 18° than at 29°. *nd<sup>4</sup>/+* lethal at both temperatures.

**nd<sup>ts69d</sup>**

**phenotype:** Like *nd<sup>ts69j</sup>* (see below).

**nd<sup>ts69f</sup>**

**phenotype:** Like *nd<sup>ts69j</sup>* (see below).

**nd<sup>ts69j</sup>**

**phenotype:** Temperature-sensitive semilethal. Homozygotes express weak notches, mild deltas, and extra bristles at both 18° and 29°; both homozygotes and hemizygotes show significantly better survival at 18° than at 29°. *nd<sup>ts69j</sup>/+* heterozygotes have normal wings at 18° and 29°. *Df(1)N-8/nd<sup>ts69j</sup>* heterozygotes have significantly better survival at 18° than at 29°.

**nd<sup>ts70j</sup>**

**phenotype:** In general, *nd<sup>ts70j</sup>* homozygotes and heterozygotes resemble the other *N<sup>ts</sup>* mutants. *nd<sup>ts70j</sup>* homozygotes, however, are wild type at 18° and some *nd<sup>ts70j</sup>/+* heterozygotes have notched wings at 29°.

**spl (W.J. Welshons)**

**location:** 1-3.0.

**origin:** X ray induced.

**discoverer:** Dubinin.

**synonym:** *shd; fa<sup>3</sup>*.

**references:** Serebrovsky and Dubinin, 1930, J. Heredity 21: 259-65.

Agol, 1931, Genetics 16: 262.

Foster, 1973, Dev. Biol. 32: 282-96.

Shellenbarger and Mohler, 1975, Genetics 81: 143-62.

Hartley, Xu, and Artavanis-Tsakonas, 1987, EMBO J. 6: 3407-17.

Kelley, Kidd, Deutsch, and Young, 1987, Cell 51: 539-48.

Cagan and Ready, 1989, Genes Dev. 3: 1099-1112.

Shephard, Broverman, and Muskavitch, 1989, Genetics 122: 429-38.

**phenotype:** In homozygotes, eyes are rough and small, bristles are often doubled or split (sometimes missing). Hemizygotes show a more extreme reduction in eye size as well as an increase in facet and bristle abnormalities (Shephard *et al.*, 1989). Both eye and bristle abnormalities occur at all temperatures from 18° to 29°, an exception being a *spl* stock from Novosibirsk, Russia, that shows temperature sensitivity (Mglinetz, 1980, DIS 55: 107-08). The bristle phenotype is caused by an extra division of an initial bristle-forming cell (Lees and Waddington, 1943, Proc. R. Soc. London, B 131: 87-110; Van Breugel and Van der Aart, 1979, Dev. Biol.

186: 267-71). A few bristles (sockets remaining) are usually removed from the posterior border of tergites in *spl*/+ heterozygotes (Welshons). The eye abnormalities are the result of abnormal differentiation of photoreceptors at the morphogenetic furrow (Cagan and Ready, 1989). Heterozygotes with the other recessive visibles at Notch are almost normal except for *spl*/*nd*<sup>2</sup> flies; the latter are *spl*-like at 29° (Shellenbarger and Mohler, 1975). Another temperature-sensitive effect is shown by *N*<sup>264-103</sup>/*spl* flies, which have abnormal eye facets at 28-29° but are almost wild type at 20-22° (Foster, 1973, Dev. Biol. 32: 282-96). The *spl* phenotype can be enhanced by *E(spl)*/+ or *E(spl)*/*E(spl)*. *spl*/+;*E(spl)*/+ flies resemble *spl*/*spl* flies; *spl*/*spl*; *E(spl)*/+ and *spl*/*Y*; *E(spl)*/+ flies show a very extreme mutant phenotype (Shephard *et al.*, 1989). *spl*/*Y*; *E(spl)*<sup>R19</sup>/+ males and *spl*/+;*E(spl)*<sup>R19</sup>/+ females show *spl* and *Ax*-like phenotypes (Xu *et al.*). The *spl* phenotype is reduced in *mam* heterozygotes. When, however, *spl* is coupled to a *N* point mutant, as in *N*<sup>64d6</sup> *spl*/+ +;*E(spl)*/+, the phenotype is not *spl* (Welshons, 1971) split behaves autonomously in mosaics in regard to both eye and bristle phenotypes (Stern and Tokunaga, 1968, Proc. Nat. Acad. Sci. USA 60: 1252-59). The *spl* phenotype becomes dominant if *spl* is coupled, in *cis*, to lethal *Ax* alleles. Thus *Ax spl*/++ is *spl*, while +*spl*/++ is wild type (Welshons, 1971; Kelley *et al.*, 1987).

**alleles:** Three alleles have been reported: *spl*, \**spl*<sup>2</sup>, *spl*<sup>66c29</sup>.

**cytology:** Salivary chromosomes normal. Placed in 3C7 on the basis of the interaction of split with Notch.

**molecular biology:** *spl* cloned and sequenced. Located on the molecular map of *N* to the right of *fa*<sup>8</sup> at about +2 kb. It is a missense mutation in the fourteenth EGF-like repeat in the extracellular domain of the putative *N* protein and involves a change from thymine to cytosine causing an isoleucine-to-threonine substitution at residue 578 (Hartley *et al.*, 1987; Kelley *et al.*, 1987).

### \**spl*<sup>2</sup>

**origin:** Spontaneous.

**discoverer:** Gottschewski, 1935.

**phenotype:** Resembles *spl* except for smaller eyes.

*N-2G*: see *mam*

### \**N-b*: *Notch-b*

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Mann, 1921.

**synonym:** *Notch 2*.

**references:** 1923, Genetics 8: 27-36.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 232.

**phenotype:** Resembles Notch. Wing nicked in about 10% of heterozygous flies. Homozygote probably lethal. RK3.

**other information:** Possibly a *vg* or *mam* allele.

### *na*: *narrow abdomen*

**location:** 1-45.2.

**origin:** X ray induced.

**discoverer:** H. M. Miller, 34c.

**references:** 1934, DIS 2: 9.

1935, DIS 4: 9.

Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn,

Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.

**phenotype:** Abdomen long and cylindrical in both sexes. Viability low; female fertility low. Ovaries in juvenile condition (Brehme). RK2.

**cytology:** Placed in 12E1-13A5 on the basis of its inclusion in *Df(1)KA9 = Df(1)I2E1;13A5*.

### \**na*<sup>2</sup>

**origin:** Ultraviolet induced.

**discoverer:** Edmondson, 51g.

**references:** 1952, DIS 26: 60.

**phenotype:** Like *na*. RK2.

### *Na-CP*: *Na-channel-protein*

**location:** 2-{107}.

**references:** Ashburner.

**phenotype:** Structural gene for sodium-channel protein.

**cytology:** Placed in 60E.

### *nac*: *neuronally-altered-carbohydrate* (*F. Katz*)

**location:** 3-{48}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Katz, Moats, and Jan, 1988, EMBO J. 7: 3471-77.

**phenotype:** Mutants show alteration or loss of a normally neuron-specific glycoconjugate; staining by anti-HRP antibodies in imaginal and adult neural tissue is eliminated. At 25° the mutant flies are viable and fertile; *nac/nac* females, however are sterile at 18°. Under heat stress (37° for five minutes) they show abnormal jittery behavior. Developmental abnormalities, including defects in the assembly of the ommatidia and in the formation of the wing, appear at 18° in the homozygous offspring of heterozygous parents. Maternal effect embryos show loss of the anti-HRP glycan determinant and are lethal.

**cytology:** Located in 84F4-84F12.

**naked cuticle:** see *nkd*

**nanos:** see *nos*

### *nap*<sup>ts</sup>: *no action potential* (*J.C. Hall; M. Kernan*)

**location:** 2-56.2.

**origin:** Induced by ethyl methanesulfonate.

**references:** Wu, Ganetzky, Jan, Jan, and Benzer, 1978, Proc. Nat. Acad. Sci. USA 75: 4047-51.

Stern, Kreber, and Ganetzky, 1990, Genetics 124: 133-43.

Elkins and Ganetzky, 1990, J. Neurogenet. 6: 207-19.

Nelson and Wyman, 1990, J. Neurobiol. 21: 453-69.

Budnick, Zhong, and Wu, 1990, J. Neurosci. 10: 3754-68.

**phenotype:** Larvae or adults become rapidly paralyzed when exposed to 37° and rapidly recover on return to lower temperatures. Rearing stocks chronically at room temperature or above causes *nap*<sup>ts</sup> to "adapt" such that

higher temperatures (> 40°) are required for paralysis (Kyriacou and Hall, 1985). Experiments involving one-time rearing at low temperature caused *nap<sup>ts</sup>* to paralyze at relatively low temperatures (Nelson and Wyman, 1990). Axonal conduction (but not synaptic transmission) fails in larvae at high temperatures (Wu *et al.*, 1978; Wu and Ganetzky, 1980), but action potentials in the giant fiber (GF) pathway of adults are not blocked at temperatures up to 43° (Elkins and Ganetzky, 1990; Nelson and Wyman, 1990), though the latency from brain stimulation to response of thoracic muscles are aberrantly long, even at low temperatures (Nelson and Wyman, 1990), and this long-latency disappears as the temperature is raised to 35° (Elkins and Ganetzky, 1990). "Following frequency" of *nap<sup>ts</sup>* thoracic muscle responses (*re.* GF pathway stimulation) reduced at elevated temperatures, an effect which can be reversed by injection of 4-aminopyridine (Nelson and Wyman, 1990). At permissive temperatures, refractory period for elicitation of a series of action potentials is abnormally long (Ganetzky and Wu, 1980); at these low temperatures, *nap<sup>ts</sup>* suppresses effects of "hyperexcitability" mutations such as *Sh*, *bas*, *bss*, *eas*, *Hk*, *kdn*, and *tko* (Ganetzky and Wu, 1982, Genetics 100: 597-614). *nap<sup>ts</sup>* is unconditionally lethal (Ganetzky and Wu, 1980) in a double mutant with *para<sup>ts1</sup>* (death occurring during 1st larval instar) and the viability of other *para*; *nap<sup>ts</sup>* combinations is poor (Ganetzky, 1984); two doses of *para<sup>+</sup>* (in males) suppresses high-temperature paralysis of *nap<sup>ts</sup>* (Stern *et al.*, 1990). In mosaic experiments, cuticular clones of *para<sup>ts1</sup>* in a *nap<sup>ts</sup>* background (after low-temperature development) have non-functioning sensory cells, probably due to lack of nerve conduction which, however, did not cause any anatomical abnormalities involving the central projections of these sensory neurons (Burg and Wu, 1986). Another developmental study, examining larval nerve terminal innervating body-wall muscles (Budnik *et al.*, 1990), showed slight reduction in the extent of branching caused by *nap<sup>ts</sup>* at permissive temperature; the increase in branching (and higher than normal number of varicosities on motor-neurites) induced by an *eag Sh* double mutant was suppressed by *nap<sup>ts</sup>* (*re.* low-temperature rearing). *nap<sup>ts</sup>* in combination with *tipE* leads to poor viability at permissive temperature for both mutants (Ganetzky, 1986, J. Neurogenet. 3: 19-31; Jackson, Wilson, and Hall, 1986, J. Neurogenet. 3: 1-17). *nap<sup>ts</sup>* is, at permissive temperature, hypersensitive to blocking effects of tetrodotoxin (TTX) on action potentials (Ganetzky and Wu, 1980); brain membrane extracts of *nap<sup>ts</sup>*, assayed at low or high temperatures, have subnormal levels of tetrodotoxin (Kauvar, 1982) or saxitoxin (Jackson *et al.*, 1984) binding activity; the latter study reports that there are no qualitative alterations of this binding activity (kd is normal). Cultured neurons from *nap<sup>ts</sup>* larvae are 4 to 5-fold more resistant than wild-type cells to killing effects of veratridine, irrespective of temperature (22° vs 35°) (Suzuki and Wu 1984, J. Neurogenet. 1: 225-38), but TTX has no effects on these mutant cells, whose general growth characteristics are also normal (Wu, Suzuki and Poo, 1983, J. Neurosci. 3: 1888-99). The mutation does not seem to modify the expression of sodium currents in embryonic neurons (O'Dowd and Aldrich, 1988, J. Neurosci. 8: 3633-43). Exposure of *nap<sup>ts</sup>* males to high temperature causes

arrest of oscillator underlying rhythmic component of courtship song (Kyriacou and Hall, 1985); in experiments on conditioned courtship, *nap<sup>ts</sup>* males learn normally but have shortened memory spans, and *nap<sup>ts</sup>* suppresses *Sh*-induced decrements in courtship learning (Cowan and Siegel, 1984, J. Neurogenet. 1: 333-44; 1986, J. Neurogenet. 3: 187-201).

**alleles:**

allele	origin	synonym	discov/ref <sup>α</sup>	comments
<i>nap<sup>ts1</sup>β</i>	EMS		2	temperature-sensitive paralysis when homo- or hemizygous; male viable when homozygous; lethal with <i>para<sup>ts1</sup></i>
<i>nap<sup>ts2</sup></i>	HD	<i>nap<sup>hd9</sup></i>	1	fails to complement <i>nap<sup>ts1</sup></i> paralysis; no P element insertion male viable when homozygous

<i>nap<sup>rv1</sup></i>	γ ray	<i>nap<sup>tsrev1</sup></i>	1	male lethal in homozygotes or with <i>mle</i> ; homozygous females not temperature sensitive; reduction in temperature sensitivity with <i>nap<sup>ts1</sup></i> and <i>para<sup>ts1</sup></i>

α 1 = Kernan and Ganetzky; 2 = Wu, Ganetzky, Jan, Jan, and Benzer, 1978, Proc. Nat. Acad. Sci. USA 75: 4047-51.  
 β Homozygous *nap<sup>1</sup>* flies paralyzed at lower temperature than *nap<sup>1</sup> Df(2R)nap* flies (Kernan and Ganetzky). Paralysis of homozygotes suppressed by *para<sup>+</sup>* duplications (Stern and Ganetzky).  
 γ *T(2;3)nap<sup>7</sup> = T(2;3)42A2-7;80-81.*

**cytology:** Located in 42A2-8, since uncovered by *Df(2R)nap9* (R. Kreber).

**molecular biology:** Locus cloned by Kuroda, Kernan, Kreber, Ganetzky, and Baker. Molecular analyses of *nap* and *mle* indicate that the same open reading frame encodes *mle<sup>+</sup>*, *nap<sup>+</sup>* and *nap<sup>ts</sup>* activities.

**other information:** The paralysis of *nap* is not complemented by *mle* alleles, thus *nap* appears to be allelic to *mle* (Kuroda, Kernan, Kreber, Ganetzky, and Baker). Germline transformation and analysis of mutations also show that *nap<sup>ts</sup>* is a gain-of-function mutation of *mle*.

**nbA: night blind A (J.C. Hall)**

**location:** 1-36.6.

**synonym:** *nonB*; *omp18*; *P18*.

**references:** Heisenberg and Gotz, 1975, *J. Comp. Physiol.* 98: 217-241.

Heisenberg and Buchner, 1977, *J. Comp. Physiol.* 117: 127-62.

Heisenberg, 1979, *Handbook of Sensory Physiology* (H. Autrum, ed.). Springer-Verlag, Berlin, Vol. 7, pp. 665-79.

Bülthoff, 1982, *Biol. Cybernet.* 45: 63-70.

1982, *DIS* 58: 31.

Kulkarni and Hall, 1987, *Genetics* 115: 461-75.

Homyk and Pye, 1988, *J. Neurogenet.* 5: 37-48.

**phenotype:** Higher than normal light-intensity thresholds needed for optomotor or phototactic responses (Heisenberg and Götz, 1975). More specifically, high-acuity optomotor responses (ability to respond to relatively narrow moving stripes) relatively normal, but high-sensitivity flies (ability to respond to moving stimuli in dim light conditions) are impaired, hence, a "night-blind" phenotype (Heisenberg). In "slow phototaxis/Y-tube" tests (using ordinary white fluorescent light), mutant adults were extremely subnormal and in fact preferred the dark-arm of the Y (Kulkarni and Hall, 1987). Light-on and light-off transient spikes of electroretinogram reduced in amplitude, possibly absent (Heisenberg, 1979; Homyk and Pye, 1989). Weak orientation to spots in Y-maze test (Bülthoff, 1982). *nbA* mutation may define an essential gene, because *nbA*<sup>3</sup>/*l(1)11Aa*<sup>1</sup> heterozygotes lack ERG transients (Homyk and Pye) and are severely defective in phototaxis (Kulkarni and Hall, 1987).

**alleles:**

allele	origin	discoverer	synonym
<i>nbA</i> <sup>1</sup>			
<i>nbA</i> <sup>2</sup>	EMS	Heisenberg	<i>nbA</i> <sup>H18</sup> ; <i>omp18</i>
<i>nbA</i> <sup>3</sup>	EMS	Heisenberg	<i>nbA</i> <sup>H47</sup> ; <i>omp47</i>
		Eichenberger	<i>nbA</i> <sup>EE171</sup> ; <i>ldg</i>

**cytology:** Placed in 11A2. Consistent with the non-complementation of *l(1)11Aa*<sup>1</sup> is that *nbA*<sup>3</sup> has its ERG (Homyk and Pye, 1989) and phototaxis (Kulkarni and Hall, 1987) defects uncovered by *In(1)A78*, *In(1)A97*, or *Tp(1;1)A101*, which have common breakpoints in 11A2 and fail to complement *l(1)11Aa* lethals (Homyk and Pye; Lefevre, 1981). Hence, *nbA* maps to 11A2. Included in *Df(1)RC29*, a cytologically invisible deletion that removes *l(1)11Aa*, *gd*, *tsg*, and *fw* (see Kulkarni and Hall, 1987, and Homyk and Pye, 1989 for further details).

**other information:** The *ldg* (lamina-degeneration) designation for one of the alleles of this gene (*nbA*<sup>3</sup>) turned out to be a misnomer. *nbA* was also once called *nonB* (no-on-transient-B) [Pak, 1975, *Handbook of Genetics* (King, ed.). Plenum Press, New York, Vol. 3, pp. 703-33], but this designation was subsequently dropped. Possible complexity of the genes in the 11A2 region is suggested by the failure of not only *nbA*, but also the very closely linked *cac* courtship song mutation to complement *l(1)11Aa* and the (lethal) breakpoints in 11A2 (Kul-

karni and Hall, 1987; also see **cytology**). *cac* seems otherwise unrelated to *nbA* (Kulkarni and Hall, 1987), in that this song mutant has normal vision (behaviorally and physiologically), *nbA* males sing normally, and the two kinds of mutation complement each other for both phenotypes (tested in a homozygous *tra* background, with regard to courtship song).

**ncd: non-claret disjunctional**

**location:** 3-100.7 (to the left of *ca*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Davis, 1969, *Genetics* 61: 577-24.

Sequeira, Nelson, and Szauter, 1989, *Genetics* 123: 511-24.

Yamamoto, Komma, Shaffer, Pirrotta, and Endow, 1989, *EMBO J.* 8: 3543-52.

Endow, Henikoff, and Niedziela, 1990, *Nature (London)* 345: 81-83.

McDonald and Goldstein, 1990, *Cell* 61: 991-1000.

**phenotype:** Disjunction in homozygous females abnormal; incidence of nondisjunction of all chromosome pairs in the first meiotic division and of meiotic and early-cleavage mitotic loss of maternally inherited chromosomes is high. X-chromosome recombination normal among both regular and exceptional progeny. Behavior of nonhomologues correlated; doubly disomic and doubly nullosomic ova more frequent than expected (Davis). Similar in action to *ca* of *D. simulans* (Sturtevant, 1929, *Z. Wiss. Biol. Abt. A* 135: 323-56). Two thirds of mitotic loss of chromosomes in progeny of *ncd* mothers takes place in the first zygotic division; one third takes place subsequently. The majority of X-chromosome loss (85-95%) is of the maternally inherited X but there is also appreciable loss of the paternally inherited X as well (Sequeira *et al.*). Somatic loss of X and 4 correlated (Portin, 1978, *Heredity* 41: 193-203). Cytological description of meiotic behavior in *D. simulans ca* females (Wald, 1936, *Genetics* 21: 264-81) includes abnormal first meiotic spindle, second meiotic arrest, and dispersal of chromosomes into multiple micronuclei; micronuclei also observed in *ncd* females (Roberts). Spindles frequently multipolar in first meiotic division (Puro) and in early-embryo nuclear divisions, and nuclei remain close together in center of egg (Kimble and Sandstedt, 1981, *Genetics* 978: s97). Kimble and Church (1981, *J. Cell Sci.* 62: 301-18) observed four classes of metaphase I configurations: (1) two or more spindles (2) abnormally wide spindles with widely separated bivalents (3) unipolar spindles, and (4) normal spindles; the first three comprise 80% of configurations. Approximately 20% of eggs of *ncd*<sup>1</sup> females asymmetrical or with more than two appendages (Kimble and Church). Hinton and McEarchen (1963, *DIS* 37: 90) reported a haploid-diploid mosaic. *ncd* ovaries transplanted into normal host behave autonomously (Roberts, 1962, *DIS* 36: 120). Chromosome segregation normal in *ncd* males.

**alleles:** Most *ncd* mutations recovered simultaneously with *ca* mutations; the double mutants are designated *ca<sup>nd</sup>* in the claret entry; they are caused by a single lesion affecting both transcription units, and are inseparable.

<sup>α</sup> 1 = Kennison; 2 = Lewis and Gencarella, 1952, Genetics 37: 600-01; 3 = O'Tousa and Szauter, 1980, DIS 55: 119; 4 = Sequeira, Nelson, and Szauter, 1989, Genetics 123: 511-24; 5 = Yamamoto, Komma, Shaffer, Pirrotta, and Endow, 1989, EMBO J. 8: 3543-52.  
<sup>β</sup> Discoverer: Steiner.

**cytology:** Using *in situ* hybridization, *ncd* was placed in 99B8-10 by Yamamoto *et al.* (1989) and in 99B-C by McDonald and Goldstein (1990).

**molecular biology:** Region cloned in a 160-kb chromosome walk from 99C6-8 to 99B8-10 (Yamamoto *et al.*, 1989); the presumed *ncd* gene was later cloned and identified by PCR (McDonald and Goldstein, 1990). Transformation with a 0.9-kb fragment that contains the site of insertion of the *P* element in *ca<sup>34</sup>* rescues the *ncd* phenotype. This fragment hybridizes to a 2.2-kb mRNA that is abundant in adult ovaries but not in the ovary-minus carcasses nor in males. The transcript is absent in *ncd<sup>1</sup>* and *ncd<sup>7</sup>*, but is present in *ncd<sup>2</sup>*, *ca<sup>1</sup>*, and *ca<sup>34</sup>*. The 2.2-kb mRNA is transcribed from right to left and its 5' end is very close to that of a transcription unit on the opposite strand that generates a 7.4-kb mRNA thought to encode the *ca* product. All five *ncd ca* chromosomes tested have the same or similar 2.6-kb deletions for the 5' region shared by the two transcription units: *ncd<sup>2</sup>*, which is *ca<sup>+</sup>*, fails to show the deficiency, and is presumed to be a point mutation. Nucleotide and putative nucleic acid transcripts have been obtained by Endow *et al.* (1990) and McDonald and Goldstein (1990). The cDNA is 2294 nucleotides in length, has a single open reading frame, and is predicted to encode a 75,795-dalton protein 685 amino acids in length (McDonald and Goldstein, 1990). The amino acid sequence shows significant similarity in its carboxy-terminal domain to the motor amino-terminal domain of kinesin heavy chain (Endow *et al.*, 1990; McDonald and Goldstein, 1990), but the non-motor domains of the proteins encoded by *ncd* and *Kin* are not similar. Biochemical properties of the presumed *ncd* protein were tested and found to be similar to those of kinesin, suggesting that *ncd* encodes a kinesin-like protein.

***ncn*: nurse cell number**

**location:** 3-68.  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Nüsslein-Volhard.

**synonym:** *ncn-1*.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.

**phenotype:** Female sterile; no eggs laid. Follicles have increased numbers of nurse cells and are often tumorous.

**alleles:** *ncn<sup>018</sup>* and *ncn<sup>077</sup>*.

***nd*:** see *N*

***ndl*:** *nudel*

**location:** 3-17.

**synonym:** *mat(3)2*; *mel(3)5*.

**references:** Rice, Ph.D. Thesis, Yale University.

Anderson and Nüsslein-Volhard, 1984, Nature 311: 223-27.

**phenotype:** Maternal effect mutation producing totally dorsalized embryos. Spacing of transverse stripes of *ftz* protein altered in mutant embryos (Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32).

**alleles:** *ndl<sup>1</sup>* through *ndl<sup>7</sup>* recovered as *ndl<sup>046</sup>*, *ndl<sup>093</sup>*, *ndl<sup>111</sup>*, *ndl<sup>133</sup>*, *ndl<sup>169</sup>*, *ndl<sup>260</sup>*, and *ndl<sup>rm2</sup>*.

***Ndw*:** *Nicked wing*

**location:** 3-87.2.

**origin:** Treatment with DNA of nuclear polyhedrosis virus from *Galleria melonella*.

**references:** Shandala, 1985, Tsitol. Genet. 19: 179-83.

**phenotype:** Homozygous lethal. Wings nicked in heterozygotes. Maximum penetrance of wing phenotype at 16°, minimum at 28°; TSP in larval period.

**\**ne*:** *nicked eye*

**location:** 2- (not located).

**references:** Kiil, 1946, DIS 20: 66.

**phenotype:** Eye margin nicked. Overlaps wild type. RK3.

**other information:** Probably an allele of *L*.

*ne*: see *fs(1)ne*

**\**Ne*:** *Nelson's mutant*

**location:** 3-31.

**references:** Gowan and Nelson, 1942, Science 96: 558-59.

Gowan, 1961, Sex and Internal Secretions (Young and Corner, eds.). The Williams and Wilkins Co., Baltimore, Vol. 1, pp. 27-28.

Belote and Lucchesi, 1980, Genetics 96: 165-86.

**phenotype:** Female progeny from *Ne* mothers are embryonic lethals.

***neb*:** *nebbish (M. Fuller)*

**location:** 2-

**discoverer:** Wolf, 1988.

**origin:** Recovered in a single P-element screen by Berg, McKearn and Spradling, but has not yet been shown to be associated with the insert.

**synonym:** *sl(2)ry3*.

**references:** Wolf and Fuller, unpublished.

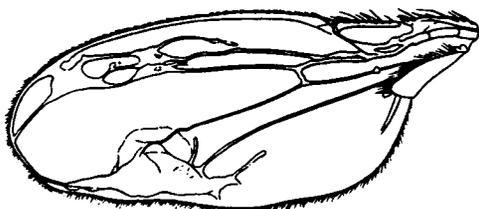

**phenotype:** Recessive late lethal. Some homozygotes survive until the pupal period, but very few eclose. Squash preparations of pupal testes reveal that the mitochondrial derivative (*nebenkern*) fails to elongate during spermatid differentiation. Flagellar axonemes are assembled. Onion stage early spermatids appear normal.

**nec: necrotic**

location: 2-{56}.

references: Ashburner.

cytology: Placed in 43A1-3.

**neither inactivation nor afterpotential: see nina****Nelson's mutant: see \*Ne****neshner: see nr****net: net**

Edith M. Wallace, unpublished.

**net: net**

location: 2-0.0.

**phenotype:** Wing veins form plexus-like net; first posterior cell between L3 and L4 widens toward tip; branch missing from posterior crossvein; all veins fused at base of wing, like *bi*. According to Waddington [1940, J. Genet. 41: 75-139 (fig.)], spaces form between epithelial layers owing to inadequate contraction during pupal period; spaces later fuse and form extra veins (Diaz-Benjumea, González-Gaitán, and García-Bellido, 1989, Genome 31: 612-19).

RK1.

**alleles:** Six net alleles [not including *Df(2L)net62*] are described in the following table.

 Schneuwly, Shortridge, Larrivee, Ono, Ozaki, and Pak, 1989, *Proc. Nat. Acad. Sci. USA* 86: 5390-94.  
**phenotype:** Strong blue light leads to anomalously small degree of photoreceptor inactivation, and the prolonged depolarizing afterpotential PDA (seen after such treatment of wild-type photoreceptor cells) degrades rapidly following blue-light exposure reaching baseline levels within a few seconds; only the six outer photoreceptors (R1-R6) in each eye facet are aberrant physiologically (Larrivee *et al.*, 1981). Rhodopsin levels are much lower than normal in these outer cells; altered gene dosage of

*ninaA*<sup>+</sup> does not effect changes in rhodopsin levels; *ninaA*'s mutant phenotypes are not suppressed by feeding on retinoid (*e.g.* vitamin A-enriched) media.  
**alleles:** With respect to defective PDA, *ninaA*<sup>2</sup> > *ninaA*<sup>1</sup> > *ninaA*<sup>3</sup>.

α Schneuwly, Shortridge, Larrivee, Ono, Ozaki, and Pak, 1989, *Proc. Nat. Acad. Sci. USA* 86: 5390-94.  
 β Shieh, Stamnes, Seavello, Harris, and Zuker, 1989, *Nature* 338: 67-70.

**cytology:** Placed in 21D4-E2, by *in situ* hybridization (Shieh *et al.*, 1989). Included in *Df(2L)ast4 = Df(2L)21D1-2;21E1-2* but not *Df(2L)ast6 = Df(2L)21E1-2;21E2-3*.

**molecular biology:** *ninaA* has been cloned, the nucleotides sequenced, and deduced amino acid sequences determined (Shieh *et al.*, 1989; Schneuwly *et al.*, 1989). It encodes a 237-amino acid protein with 40% sequence identity to the vertebrate cyclosporin A-binding protein, cyclophilin, that is involved in the activation of T-lymphocytes. Cyclophilin shown to be a peptidylprolyl *cis-trans*-isomerase that catalyzes rate-limiting steps in the folding of a number of proteins *in vitro*.

**ninaB (J.C. Hall)**

**location:** 3-53.5.  
**references:** Pak, 1979, *Neurogenetics: Genetic Approaches to the Nervous System* (Breakfield, ed.). Elsevier/North-Holland, New York, pp. 67-99.  
 Stephenson, O'Tousa, Scavarda, Randall, and Pak, 1982, *The Biology of Photoreceptors* (Cosens and Vince-Prue, ed.). Cambridge University Press, England, pp. 471-95.  
**phenotype:** Superficially like *ninaA* in aberrant visual physiology, but all eight photoreceptors in each eye facet affected by *ninaB*; can be restored to wild-type phenotype by dietary supplement of retinal but not by other retinoids.

**alleles:**

Montell and Rubin, 1988, Cell 52: 757-72.

Stowe and Davis, 1990, Cell Tissue Res. 260: 431-34.

**phenotype:** Basic physiological and rhodopsin-depleted phenotypes like those of *ninaB* or *ninaD* mutants, except that amplitude of prolonged depolarizing afterpotential and rhodopsin levels are not so severely depressed, and these phenotypes cannot be rescued by vitamin A (or other retinoid) feeding. Decreased rhodopsin content is due to reduction in diameter of the rhabdomeres; the microvilli are shorter than normal and have reduced cytoskeletal electron-dense regions (Matsumoto *et al.*, 1983). In particular, the central axial filament of the microvillus is absent (*ninaC*<sup>5</sup>) or greatly reduced (*ninaC*<sup>2</sup>, *ninaC*<sup>3</sup>). Actin immunoreactivity retained in the villi of flies homozygous for these alleles (Stowe and Davis). The mutant phenotype can be rescued using P-element mediated germ line transformation.

**alleles:** At least ten ethyl-methanesulfonate-induced alleles.

α Appears to be null allele.

**cytology:** Located in 28A1-3; included in synthetic deletion constructed using *T(Y;2)R147 = T(Y;2)B<sup>S</sup>Xhj;27E* and *T(Y;2)R50 = T(Y;2)h1-2;28B*.

**molecular biology:** The *ninaC* gene was cloned, sequenced and the eye-specific amino-acid sequences deduced (Montell and Rubin, 1988). The locus was expressed as two extensively overlapping mRNAs of 3.6

and 4.8 kb found in late pupae and adults; the RNAs code for a 132 kd protein (made up of 1135 amino acids) and a 174 kd protein (made up of 1501 amino acids) found in the rhabdomeres of the photoreceptor cells. Near the N terminus of both proteins is a putative protein kinase domain joined to a domain homologous to the globular head of the myosin heavy chain. The upstream DNA region contains an eleven-base-pair region in common with *ninaE* and *Rh2* (Mismer, Michael, Laverty, and Rubin, 1988, Genetics 120: 173-80).

**other information:** *ninaC* appears to be inseparable from *Sp* (2-22.0), though no *ninaC* mutations cause Sternopleural-like defects.

**ninaD (J.C. Hall)**

**location:** 2-57.

**origin:** Induced by ethyl methanesulfonate.

**references:** Pak, 1979, Neurogenetics: Genetic Approaches to the Nervous System (Breakfield, ed.). Elsevier/North-Holland, New York, pp. 67-99.

Stephenson, O'Tousa, Scavarda, Randall, and Pak, 1982, The Biology of Photoreceptors (Cosens and Vince-Prue, ed.). Cambridge University Press, England, pp. 471-95.

Johnson and Pak, 1986, J. Gen. Physiol. 88: 651-73.

**phenotype:** Basic physiological and rhodopsin-depleted phenotypes like those of *ninaB* mutants (*e.g.* rhodopsin levels reduced in all three classes of photoreceptors); *ninaD* mutants can be rescued by dietary supplement of vitamin A and several other retinoids. Measurements of light-induced "quantum bumps" (the basic "units" of the photoreceptor potential) in *ninaD*<sup>2</sup> (rhodopsin content, 10<sup>-2</sup> X wild-type) showed these responses to be basically normal (implying that, since extensive inter-rhodopsin molecular interactions are likely to be extremely rare, such interactions are not necessary for generation and adaptation of the bumps); yet, bump amplitudes approximately 4X normal (Johnson and Pak, 1986).

**alleles:** Five ethyl-methanesulfonate-induced alleles.

 Washburn and O'Tousa, 1989. J. Biol. Chem. 264: 15464-66.

**phenotype:** *ninaE*<sup>+</sup> encodes the opsin moiety of the major rhodopsin, RH1, which occupies the rhabdomeres of the outer six photoreceptor cells R1-R6 in each ommatidium of the adult fly. This rhodopsin is also expressed in the larval light sensitive organs (Zucker *et al.*, 1985; Pollack and Benzer, 1988). RH1 is a 39 kd basic protein (Pak and Nichols, 1985, J. Biol. Chem. 260: 12670-74). Homozygous *ninaE* mutants display severe depletion of rhodopsin from the outer photoreceptors, shown microspectrophotometrically and physiologically (Scavarda *et al.*, 1983; Johnson and Pak, 1986; also see below), as well as by absence of R1-6 staining with an anti-(*Drosophila*)rhodopsin MAb (de Couet and Tanimura, 1987, Eur. J. Cell Biol. 44: 50-56). Electroretinograms demonstrate that the prolonged depolarizing afterpotential (PDA) is absent; also, the sustained corneal-negative light-coincident response is reduced in some alleles and nearly wild type in amplitude in others. Physiological measurements of light-induced "quantum bumps" in three *ninaE* mutants (whose RH1 decrements range from 10<sup>-2</sup> to 10<sup>-6</sup> of wild-type) indicate that these responses—at the level of a given bump—are basically normal (implying that interactions among rhodopsin molecules are not likely to be critical for generation and adaptation of these "basic units" of photoreceptor potential (Johnson and Pak, 1986); bump amplitudes were higher than normal (more so in the more severe of the three mutants). Increased and decreased dosages of *ninaE*<sup>+</sup> cause higher than normal and lower than normal rhodopsin levels (Scavarda *et al.*, 1983). Some mutants, when heterozygous to wild type, show less than 50% of the normal rhodopsin level (*e.g.*, *ninaE*<sup>7</sup>/+ yields 35% of the normal level); in heterozygotes of *ninaE*<sup>5</sup>, *ninaE*<sup>6</sup>, and *ninaE*<sup>7</sup>, the basic photoreceptor potential, as seen in electroretinograms, may be reduced. In mutant homozygotes, the cross-sectional area of rhabdomeres 1-6 is smaller than normal; in some mutants (*ninaE*<sup>1</sup>, *ninaE*<sup>3</sup>, *ninaE*<sup>7</sup>, and *ninaE*<sup>8</sup>), an age dependent, light-independent degeneration of R1-6 rhabdomeres (but not cell bodies) is observed; in the case of severe alleles like *ninaE*<sup>1</sup> (see other information) or *ninaE*<sup>17</sup>, the rhabdomeres are present at eclosion, but degenerate rapidly thereafter (*e.g.*, Stark and Sapp, 1987, O'Tousa *et al.*, 1989); degeneration is cell autonomous in mosaics (Stark, Srygley, and Greenberg, 1981, DIS 56: 132-33).

<sup>β</sup> Same nonsense mutation and polymorphisms as *ninaE*<sup>1</sup> (Washburn and O'Tousa, 1989).

**cytology:** Placed in 92B6-7 based on its inclusion in *Df(3R)jo11 = Df(3R)92B5-6;92B7-8* (O'Tousa *et al.*, 1985).

**molecular biology:** Genomic clone isolated by cross homology to a bovine opsin-encoding cDNA (O'Tousa *et al.*, 1985; Zuker *et al.*, 1985). Opsin-encoding subclone identified by transformation of *ninaE* mutant homozygotes. Nucleotide sequence contains an open reading frame interrupted by four introns with consensus splicing sequences; the conceptual amino acid sequence, which comprises 373 amino acids, indicates the presence of seven putative membrane-spanning domains and several glycosylation sites. Probing of northern blots reveals the presence of an 1.5-1.7 kb eye-specific transcript, which is abundant throughout the depth of the retina (Pollock and Benzer, 1988). Three separable *cis*-acting control regions in the *ninaE* promoter extending from -120 to +61 have been identified by Mismar and Rubin (1987, Genetics 116: 565-78), the first two appearing to be quantitative regulatory elements, the third affecting tissue-specificity of the promoter. There is an eleven-base-pair sequence in common with *ninaC* and *Rh2* (Mismar, Michael, Laverty, and Rubin, 1988, Genetics 120: 173-80). The first two regions have the properties of enhancers required for normal promoter expression (Mismar and Rubin, 1989, Genetics 121: 77-87), although they do produce a *ninaE* expression pattern in a truncated *Hsp70* promoter. As is the case for other opsins, putative phosphorylation sites are located near the C terminus of *Drosophila* RH1 protein; however, removal of the relevant Ser and Thr residues by site-specific mutagenesis such that a premature termination codon is placed at amino-acid position 356, and transformation of

that construct into a *ninaE*<sup>-</sup> host (Ozaki, Zuker, Pak, and Rubin, 1986, Neurosci. Abstr. 12: 639) led to light-induced physiological response of R1-6 indistinguishable from those of fully rescued control transformants (Zuker *et al.*, 1988). The amount of rhodopsin phosphorylation in the engineered mutant was approximately half normal.

**other information:** In one clean use of a *ninaE* variant to eliminate responses of R1-6 photoreceptors, turn-on of *per* gene expression in nuclei of such cells (which requires exposures of the flies to light-dark transitions) was normal in *ninaE*<sup>17</sup> (Zerr, Hall, Rosbash, and Siwicki, 1990, J. Neurosci. 10: 2749-62). A number of studies of this general sort have been carried out on the double mutant, *ort ninaE* (recovered as *ora*<sup>JK84</sup>); *ort* by itself is known to cause deficits in ERG light-on and light-off transient spikes (O'Tousa *et al.*, 1989). The application of "*ora*" have usually been aimed at using it as a R1-6-removing tool for behavioral (*e.g.*, Coombe, 1984, J. Comp. Physiol. 155: 661-72) or physiological (*e.g.*, Stark, Schilly, Christianson, Bone, and Landrum, 1990, J. Comp. Physiol. 166: 429-36) experiments. Many of the abnormalities, such as assessments of visual pigment content (most classically, Harris, Stark, and Walker, 1976, J. Physiol. 256: 415-39) are probably attributable to the *ninaE* component only; this includes an explicit demonstration that rhabdomere degeneration (Stark and Sapp, 1987, J. Neurogenet. 4: 227-40) is caused by *ninaE* (O'Tousa *et al.*, 1989), similar to that caused by any other severe *ninaE* mutation. But certain effects of "*ora*" on visually mediated behaviors, such as decrements in male courtship (Markow and Manning, 1980, Behav. Neurobiol. 29: 276-80), the absence of blue-light influenced phototaxis (Willmund and Fischbach, 1977, J. Comp. Physiol. 118: 261-71), or the absence of R1-6-dependent optomotor responses (Heisenberg and Buchner, 1977, J. Comp. Physiol. 117: 127-62) could be affected by both factors.

### **NK1 (M. Nirenberg)**

**location:** 3-{72}.

**references:** Kim and Nirenberg, 1989, Proc. Nat. Acad. Sci. USA 86: 7716-20.

**phenotype:** Homeobox gene expressed in embryos in several types of striated muscle cells and in some cells in the ventral nervous system. Fewer transcripts were detected in the central nervous systems (CNS) of larvae, pupae, and adults. No transcripts were detected in 0-3 hour embryos.

**cytology:** Located at 93E3-5 close to *NK3* and *NK4*.

**molecular biology:** Sequence analysis of cloned cDNA and genomic DNA (7,609 nonoverlapping bp) revealed four exons. One major species of poly A<sup>+</sup> RNA from embryos 2.9 kb in length was detected. NK1 protein contains 661 amino acid residues and it is rich in S, A, P, and H. The amino acid sequence of the homeobox is closely related to the H-40 homeobox of the honeybee, *Apis mellifera* (Walldorf, Fleig, and Gehring, 1989, Proc. Nat. Acad. Sci. USA 86: 9971-75) and chicken CHox3 homeobox (Rangini *et al.*, 1989, Gene 76: 61-74). NK1 protein contains alternating repetitive, H/P residues (a

paired repeat similar to those of *prd* and *bcd* proteins), and contains regions rich in H/Q, S/P, S/T, repetitive A, and repetitive G residues. NK1 also contains an acidic domain before the homeobox. Intron 3 is located within the homeobox between codons for homeobox amino acid residues 44 and 45. Homeobox genes cloned from monkey and rat DNA contain homeobox amino acid sequences identical to that of NK1 (52 amino acid residues compared).

### **NK2 (M. Nirenberg)**

**location:** 1-{0.0}.

**references:** Kim and Nirenberg, 1989, Proc. Nat. Acad. Sci. USA 86: 7716-20.

Nakayama, Nakayama, Kim, and Nirenberg, unpublished.

**phenotype:** *NK2* is a homeobox gene whose expression starts at the blastoderm stage during cell membrane formation (2.5-3.25-hour embryos) in the region that gives rise to the ventral nervous system. *NK2* transcripts detected in the ventral nervous system at later stages of embryonic development. *NK2* transcripts also found in the midgut starting at 12 hours of embryonic development and thereafter during embryonic development. *NK2* mRNA also found in larvae and pupae but the abundance of the mRNA is lower than that of embryos. *NK2* mRNA is expressed in the central nervous system of the adult.

**cytology:** Located at 1C.

**molecular biology:** Sequence analysis of *NK2* cDNA and part of the cloned genomic DNA (3033 nonoverlapping bp) showed that *NK2* is a homeobox gene with two exons. *NK2* is a basic protein with 723 amino acid residues and relatively high levels of A, S, H, G, and P with localized regions of alternating acidic and basic amino acid residues, and with regions of abundant S/T and P, or H, Q, and P, with repetitive A residues, pest sequences, an acidic domain, and an alternating H/A repeat. Northern analysis revealed one species of poly A<sup>+</sup> RNA 3.5 kb in length.

### **NK3 (M. Nirenberg)**

**location:** 3-{72}.

**references:** Kim and Nirenberg, 1989, Proc. Nat. Acad. Sci. USA 86: 7716-20.

Webber, Kim, Guo, and Nirenberg, unpublished.

**phenotype:** Homeobox gene expressed transiently during embryonic development in some mesodermal cells (foregut and hindgut visceral muscle cells). *NK3* poly A<sup>+</sup> RNA was not detected in 0-3-hour embryos, but was found in low abundance in RNA from 3-6-hour embryos. The abundance was maximum in RNA from 6-12-hour embryos and then declined during further embryonic development.

**cytology:** Located at 93E1-3 close to homeobox genes *NK4* and *NK1*.

**molecular biology:** Genomic DNA fragments were cloned that contain both *NK3* and *NK4* homeobox genes. *NK3* and *NK4* homeobox regions are separated by approximately 7.5 kb in genomic DNA. Sequence analysis of cloned *NK3* cDNA and genomic DNA revealed two exons separated by a short intron. *NK3* protein consists of 374 amino acid residues and contains S/T rich regions and several regions rich in acidic and basic amino acid residues. Northern analysis revealed one species of *NK3* poly A<sup>+</sup> RNA, approximately 1.5 kb in length.

**NK4 (M. Nirenberg)**

**location:** 3-{72}.

**references:** Kim and Nirenberg, 1989, Proc. Nat. Acad. Sci. USA 86: 7716-20.

Rajni, Kim, Guo, and Nirenberg, unpublished.

**phenotype:** The *NK4* homeobox gene is first expressed in 3-hour embryos; no *NK4* mRNA is detected in embryos at earlier stages of development. *NK4* mRNA is detected only in mesodermal cells. The transcripts are most abundant in 3-9-hour embryos; the mRNA decreases in abundance thereafter.

**cytology:** Located at 93E1-3 close to homeobox genes *NK3* and *NK1*.

**molecular biology:** The homeobox sequences of *NK4* and *NK3* are separated in genomic DNA by approximately 7.5 kb. Sequence analysis of cloned *NK4* cDNA and genomic DNA revealed three exons. *NK4* is a basic protein (41,192 M<sub>r</sub>) with 371 amino acid residues, and has relatively high levels of S, Q, A, and P. *NK4* protein contains a homeobox that is not closely related to any known homeobox protein, contains pest sequences, Q repeats, and regions with abundant H and Q, or S, T, and P. One major species of poly A<sup>+</sup> RNA was detected, 1.7 kb in length.

**nkd: naked cuticle**

**location:** 3-47.3.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Kluding, Nüsslein-Volhard, and Wieschaus, 1983, DIS 59: 157-58.

Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

Arias, Baker, and Ingham, 1988, Development 103: 157-70.

**phenotype:** Denticle bands partially deleted. Embryonic lethal. Terminal phenotype partly due to cell death after germ band shortening (Martinez-Arias).

**alleles:** Six ethyl-methanesulfonate-induced alleles.

**cytology:** Located in 75D-76B; uncovered by *T(Y;3)LI31<sup>D</sup>LI4<sup>P</sup>* = *T(Y;3)75D1;76B5-10* (Nüsslein-Volhard).

**nmd: no mitochondrial derivative (M. Fuller)**

**location:** 2-.

**discoverer:** Wolf, 1988.

**origin:** Recovered in a single P-element screen by Berg, McKearn and Spradling. The male sterile mutation has not yet been shown to be associated with the insert.

**synonym:** *ms(2)ry4*.

**references:** Wolf, Madder, Bonneville and Fuller, unpublished.

**phenotype:** Recessive male sterile. Onion stage early spermatids in homozygous males either lack or have only tiny mitochondrial derivatives. Flagellar axonemes

elongate without mitochondrial derivatives. Mitochondria present in polar primary spermatocytes, but degenerate prior to meiosis in mature primary spermatocytes. Females are fertile.

**cytology:** The transposable element is inserted at 31.

**no action potential:** see *nap*<sup>ts</sup>

**no bridge:** see *nob*

**no distributive disjunction:** see *nod*

**nob: no bridge (J.C. Hall)**

**location:** 1-12.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg.

**references:** Heisenberg, Borst, Wagner, and Byers, 1985, J. Neurogenet. 2: 1-20.

Bouhouche and Vaysse, 1991, J. Neurogenet.

**phenotype:** Protocerebral bridge between left and right sides of adult brain seems disintegrated into two or more glomeruli; fiber number in interhemispheric commissure of white pupa reduced; learning is poor in "arena paradigm" tests of adults, using sugar and odorants (Heisenberg *et al.*, 1985); larval learning test using electric shocks and odorants gave approximately half the normal score (Heisenberg, unpublished). Locomotor activity of mutant adults is abnormal (spontaneous walking speed, regarding forward strides of legs, is slow), and in flight, there is reduced frequency of flight starts, altered "object response" and reduced occurrences of "body saccades" (Heisenberg). Adults exhibit aberrant habituation of proboscis-extension reflex (Bouhouche and Vaysse, 1991).

**alleles:** One mutant allele, called *nob*<sup>KS49</sup>.

**cytology:** Placed in 4F5-12 (Heisenberg).

**noc: no ocelli**

**location:** 2-{50}.

**discoverer:** Ashburner.

**phenotype:** The genetic complexity of *noc* is indicated by phenotypic as well as molecular data (McGill *et al.*, 1988). Mutants are characterized by partial or complete absence of ocelli and their associated bristles. Strong *noc* alleles lack all three ocelli and have fewer interocellar microchaetae; ocellar and interocellar bristles are absent; anterior postalar and notopleural bristles may not be present; postvertical bristles are crooked, an adventitious pair often occurring between a normal pair. Weak alleles may overlap wild type in phenotype, the flies having smaller ocelli and an aberrant pattern of interocellar microchaetae. Male and female homozygotes are viable and fertile. Penetrance and expressivity is stronger in males and in flies that emerge later. While a homozygous deletion of the entire *noc* region is lethal, distal or proximal regions can be homozygously deleted without causing lethality. Some *noc* alleles and deficiencies are lethal with *In(2L)Sco<sup>rv1</sup>*, whose 2L breakpoint lies within *noc*, while other alleles are viable with the *Sco* inversion.

**alleles:** Mutants and rearrangements are listed in the table. *noc* deficiencies are described in the rearrangement section.

Mol. Biol.* 186: 689-706; 7 = Gubb, Roote, Harrington, McGill, Durrant, Shelton, and Ashburner, 1985, *Chromosoma* 92: 116-23; 8 = McGill, Chia, Karp, and Ashburner, 1988, *Genetics* 119: 647-61.

<sup>β</sup> From the molecular map of the wild-type *noc-Adh* region (McGill *et al.*, 1988); coordinate 0 an *EcoRI* restriction site 1321 bp to the left of the start of transcription of the larval *Adh* transcript; "+" values to the right, "-" values to the left.

<sup>γ</sup> Lethal or semilethal with *In(2LR)Sco<sup>rv</sup>*.

<sup>δ</sup> Inversion in *T(Y;2)60D7-F*.

<sup>ε</sup> Synonym: *TE146*.

<sup>ζ</sup> Phenotype of *Sco* enhanced by deletion and suppressed by duplication of the *noc* gene (McGill *et al.*, 1988).

**cytology:** Placed in 35B1-2 on the basis of its inclusion in *Df(2L)A178 = Df(2L)35B1-2;35B2-3* but not in *Df(2L)A48 = Df(2L)35B2-3; 35D5-7*.

**molecular biology:** The DNA region associated with *noc* can be defined by the mapping of breakpoints of *noc* mutants which locate *noc* approximately between -117 and -62 kb on the molecular map of the wild-type *noc* -

*Adh* region (McGill *et al.*, 1988). If, however, *Sco* (a rearrangement in which the *noc* gene has been transposed from 35B to 35D) is considered to be an antimorphic allele of *noc* and is included in the locus, the *noc* region will be enlarged and will be located approximately between -117 and -24.6 kb. This region, almost 100 kb in estimated total length, is not thought to be continuous, but to be functionally divided into at least three components, the two distal ones (*nocA* and *nocB*) resulting in a mutant phenotype when deleted and the proximal one (*nocC*) resulting in a *noc*<sup>+</sup> phenotype when deleted (McGill *et al.*, 1988). Breakpoints of *Sco* revertants are only found in *nocB* and *nocC*. *Tp(2;3)Mpe*, which shows a *noc*<sup>+</sup> rather than a *noc* phenotype over deletions for the entire *noc* locus, has its 2L breakpoint between *nocA* and *nocB* (McGill *et al.*, 1988).

***nod*: no distributive disjunction (R.S. Hawley)**

**location:** 1-36.

Zhang and Hawley, 1990, *Genetics* (submitted).

**phenotype:** Females homozygous for *nod* alleles exhibit high frequencies of meiotic chromosome loss and nondisjunction at meiosis I. Most *nod*-induced nondisjunctional events involve nonexchange chromosomes. For example, in *nod/nod* females nondisjunction frequencies for the always nonexchange fourth chromosomes approaches 90% (the vast majority of gametes are nullo-4 ova), whereas nonexchange X chromosomes apparently disjoin at random. Both the frequency of exchange and the disjunction of exchange bivalents was shown to be normal in *nod/nod* females. Thus, with respect to its role in meiosis, the *nod*<sup>+</sup> function appears to be limited to the distributive segregation system. Based on an analysis of secondary nondisjunction in *nod<sup>a</sup>/nod<sup>a</sup>* females, Carpenter concluded that the *nod* defect does not impair the process of partner choice within the distributive system, but rather specifically impairs the disjunctional process. Nonexchange chromosomes derived from *nod<sup>a</sup>/nod<sup>a</sup>* mothers also undergo nondisjunction, and presumably loss, at meiosis II. In addition, chromosomes derived from *nod<sup>a</sup>/nod<sup>a</sup>* mothers are mitotically unstable. *nod*-induced mitotic chromosome loss is restricted to maternal nonexchange chromosomes and does not exert any discernible effect on meiosis in males or on mitotic chromosome stability (Baker *et al.*, 1978). Although none of the existing *nod* alleles is lethal or female sterile, the dosage-sensitive antimorphic mutation *l(1)TW6* (Wright, 1973) is argued to be allelic to *nod* on the basis of three lines of evidence. First, *l(1)TW6/+* females display a meiotic phenotype that is virtually identical to that exhibited by *nod<sup>a</sup>/nod<sup>a</sup>* females. Second, the two loci map to the same position on the X chromosome (Wright, 1973; Baker). Third, a γ-ray induced revertant of *l(1)TW6* was shown to be a recessive *nod* allele (New and Hawley).

1982, *Biol. Cybernet.* 45: 63-70.

1982, *Biol. Cybernet.* 45: 71-77.

**phenotype:** Poor orientation in tests involving fixation on objects or movements to and from in a "choice" experiment between two identical objects (*i.e.*, flies in an arena). Normal response to spots in a Y-maze test. Mutants make rapid continuous changes in their visual gaze instead of sporadic changes as in wild type.

**alleles:** One mutant allele, called *nofA<sup>S100</sup>* (Heisenberg and Wolf, 1979, *J. Comp. Physiol.* 130: 113-30).

*nofC*: see *norpA*

**nofD (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 31.

1982, *DIS* 58: 32-33.

1982, *Biol. Cybernet.* 45: 63-70.

1982, *Biol. Cybernet.* 45: 71-77.

**phenotype:** Poor orientation to objects, including spots in Y-maze test; electroretinogram normal.

**alleles:** One mutant allele, *nofD<sup>B11</sup>*.

*nofE*: see *sol<sup>16</sup>*

**nofF (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 31.

1982, *Biol. Cybernet.* 45: 63-70.

**phenotype:** Same phenotype as *nofD* or *nofE*.

**alleles:** One mutant allele, *nofF<sup>S71</sup>*.

**nofG (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 31.

**phenotype:** Same basic phenotype as *nofA* in relation to visual objects. Electroretinogram normal.

**alleles:** One mutant allele, *nofG<sup>S13</sup>*.

**nofI (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 32-33.

1982, *Biol. Cybernet.* 45: 63-70.

**phenotype:** Poor orientation to spots in Y-maze test. Eye color brownish; screening pigment in photoreceptors disrupted. Irregularities in pattern of rhabdomere endings. Electroretinogram normal.

**alleles:** One mutant allele, *nofI<sup>B3</sup>*.

**nofK (J.D. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 32-33.

1982, *Biol. Cybernet.* 45: 63-70.

**phenotype:** Same phenotype as *nofI*.

**alleles:** One mutant allele, *nofK<sup>B6</sup>*.

**nofL (J.C. Hall)**

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Bülthoff, 1982, *DIS* 58: 32-33.

1982, *Biol. Cybernet.* 45: 63-70.

**phenotype:** Same phenotype as *nofI*.

**alleles:** One mutant allele, *nofL<sup>B7</sup>*.

**non-claret disjunctional: see *ncd***

**nonA: no on or off transient-A (J.C. Hall)**

**location:** 1-52.3 (Pak); 1-56 (Heisenberg) (the former location more consistent with Kulkarni *et al.*, 1988, and with cytology).

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *Positive spike II* group (Benzer); *x14* (Pak), *opm2* (Heisenberg).

**references:** Hotta and Benzer, 1970, *Proc. Nat. Acad. Sci. USA* 67: 1156-63.

Pak, Grossfield, and Arnold, 1970, *Nature* 227: 518-20.

Jones and Rubin, 1990, *Neuron* 4: 711-23.

Besser, Schnabel, Wieland, Fritz, Stanewsky, and Saumweber, 1990, *Chromosoma*, in press.

**phenotype:** Defective optomotor responses and phototaxis, with the former being especially defective (Heisenberg, 1972; Heisenberg and Buchner, 1977; Kulkarni *et al.*, 1988). Poor orientation behavior in Y-maze (Bülthoff, 1982a, b). *nonA<sup>5</sup>* flies exhibit specific lack of responses

to front-to-back moving visual stimuli, whereas reaction to back-to-front motion is intact (Heisenberg, 1972). Physiologically, there are reduced or absent light-on and light-off transient spikes in electroretinogram, whereas photoreceptor potential is normal (Hotta and Benzer, 1970; Pak *et al.*, 1970; Heisenberg, 1971; Kulkarni *et al.*, 1988; Jones and Rubin, 1990). Larval visual response (*re* negative phototaxis) normal [Hotta and Keng, 1984, Animal Behavior: Neurophysiological and Ethological Approaches (Aoki *et al.*, eds.). Springer-Verlag, Berlin, pp. 49-60]. Courtship song is abnormal, as influenced by one, possibly two, mutant alleles; *nonA*<sup>9</sup> (originally *diss*) males produce abnormal song, regarding pulses relatively late in trains of such song sounds (each one resulting from a bout of wing vibration); the abnormalities are polycyclicity (Kulkarni *et al.*, 1988) and anomalous intra-pulse frequency components (Wheeler *et al.*, 1989); pulses early in trains, or throughout short ones, are nearly normal; courtship hum sounds manifest irregular sine waves, though their fundamental frequencies are normal (Wheeler *et al.*, 1989). *nonA*<sup>9</sup> by itself is also an optomotor-defective/ERG-abnormal mutant (Kulkarni *et al.*, 1988) and fails to complement other mutant alleles with regard to these visual phenotypes (Rendahl, Kulkarni, and Hall, unpublished); but these heterozygotes, in a homozygous *tra* genetic background, sing normally (with the possible exception of *nonA*<sup>2</sup>/*nonA*<sup>9</sup>, Rendahl *et al.*, unpublished), as do males hemizygous for alleles isolated as visual mutants.

**cytology:** Placed in 14C1-2, by *in situ* hybridization, using a cDNA probe (von Besser *et al.*, 1990). Covered by *Dp(1;2)r<sup>+</sup>75c = Dp(1;2)14B13;15A9;35D-E*; not included in *Df(1)81k21e = Df(1)14C1-2;15A5* (Jones and Rubin, 1990, Neuron. 4: 711-23).

**molecular biology:** Cloned from two very different starting points. Genetic one: beginning with a probe hybridizing to proximal 14B, and by walking in the proximal direction, the distal breakpoints of *Dp(1;2)r<sup>+</sup>75c* and *Df(1)81k21e* were localized at approximately +64 kb and +84 kb, respectively, on the coordinates of Steller (Jones and Rubin, 1990). Two overlapping genomic fragments from a portion of this interval rescued *nonA*<sup>5</sup>- and *nonA*<sup>9</sup>-associated ERG defects (Jones and Rubin, 1990) and the song defects of the latter as well (Rendahl *et al.*, unpublished). Genomic probes from within the "rescuing region" detected 4-, 3-, and 2.8-kb transcripts (Jones and Rubin, 1990), which are relatively constant in abundance through the life cycle (though the last of these was at relatively lower concentrations in embryos; also see von

Besser *et al.* for embryo results). Same kind of probes led to cDNAs (from adult head library), one of which when sequenced predicts a *ca.* 700-amino-acid-basic protein (Jones and Rubin, 1990) that contains "RNP" RNA binding motifs (von Besser *et al.*, 1990). No homologs found in a data-base search. The gene was also cloned serendipitously by a completely independent method. A particular monoclonal antibody raised against embryonic chromatin (Frasch and Saumweber, 1989, Chromosoma 97: 272-81), which appears to react specifically with a protein in polytene chromosome puffs, was used to isolate clones from an expression library (von Besser *et al.*, 1990); the sequence of one such clone predicts the same protein as that described by Jones and Rubin. *In situ* hybridization to embryos with a cDNA probe detects fairly ubiquitous spatial expression of the transcript(s) (von Besser *et al.*, 1990). This kind of expression is also seen using an anti-NONA monoclonal antibody to stain sections throughout the life cycle (Rendahl, Jones, and Hall, unpublished), with the additional fact that the nervous system is included in the many tissues so expressing and that the subcellular localization appears to be nuclear. The gene comprises five exons and is transcribed from left to right. Analysis of the mRNAs expressed from *nonA* indicates the transcript complexity includes alternative splicings and protein products that differ in approximately 35 C-terminal amino acids (Jones and Rubin, 1990; von Besser *et al.*, 1990). Truncation of both the predicted protein forms (I and II) by oligonucleotide directed mutagenesis followed by transformation, leads to no rescue of *nonA* ERG defects; whereas a stop codon that prematurely terminates only form II does so rescue (Jones and Rubin, 1990).

**other information:** Mosaic analysis (Hotta and Benzer, 1970) suggested that ERG defects map to photoreceptors; but too few gynandromorphs were analyzed to rule out an optic-lobe "focus", which is more likely to be the focus for visual-movement-response abnormalities (especially those reported by Heisenberg, 1972). Two genomic clones, whose distal endpoints are just distal to *nonA*-rescuing DNA fragments, rescue each of two non-allelic lethals [*l(1)14Cc*, and *l(1)14Ca*] that map to the same cytogenetic interval as does *nonA*; transformation with overlapping genomic clones indicates an order from left to right of *l(1)14Cc l(1)14Ca nonA* (Jones and Rubin, 1990). Both lethals complement the ERG defects of *nonA*<sup>5</sup> (Jones and Rubin, 1990) and complement the song abnormality of *nonA*<sup>9</sup> (Kulkarni and Hall, unpublished).

*nonB*: see *nba*

#### *nonC* (J.C. Hall)

**location:** 1- (not localized).

**origin:** Induced by ethyl methanesulfonate.

**references:** Heisenberg, 1979, Handbook of Sensory Physiology (Antrum, ed.). Springer-Verlag, Berlin, Vol. VII/6A, pp. 665-79.

Bülthoff, 1982, DIS 58: 31.

1982, Biol. Cybernet. 45: 63-70.

**phenotype:** Defective phototaxis and optomotor responses; no light-on or light-off transients in electroretinogram, probably due to defect in photoreceptor cells *per se*; abnormal orientation to spots in Y-maze test.

**alleles:** Two mutant alleles, *nonC*<sup>1</sup> (=X37), *nonC*<sup>2</sup>

(=X72).

**none: no ocelli; narrow eyes**

**location:** 3-

**discoverer:** Shearn.

**references:** Stark, Srivastava, Carlson, and Garment, 1984, DIS 60: 191-93 (fig.).

**phenotype:** No ERG or deep pseudopupal in *none/none* flies. In the compound eye, corneal facets are fused and corneal hairs displaced, but corneal nipples are present. There is an all-glial cell mass in the peripheral retina and there are no rhabdomeres or optic cartridges as in the wild-type fly. In the ocellar area, only remnants of the ocellar lenslets can be observed.

**other information:** *none* mutants resemble *Gl* mutants in regard to morphology of the compound eye (Harte and Kankel, 1982, Genetics 101: 477-501) and absence of an ERG.

**nonpupariating 3: see npr3**

**norpA: no receptor potential A (J.C. Hall)**

**location:** 1-6.5.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Pak, Grossfield, and Arnold; Hotta and Benzer; Heisenberg (all independently).

**synonym:** *nofC*; *x12*, *x13*, *x16*, *x24*.

**references:** Hotta and Benzer, 1970, Proc. Nat. Acad. Sci. USA 67: 1156-63.

**phenotype:** Structural gene for phospholipase-C (PLC; specifically, phosphatidyl inositol 4.5 biphosphate phosphodiesterase). *norpA* mutants are blind and have no (or reduced) light-elicited photoreceptor potentials (*re*: electroretinograms) in the compound eyes and ocelli. Adults

homozygous or hemizygous for severe alleles are completely blind, whereas those carrying weaker alleles have amplitude-subnormal ERGs induced by light (Ostroy and Pak, 1974, BBRC 59: 960-66; Wilson and Ostroy, 1987a). Light-induced behavior (negative phototaxis) of larvae also absent under influence of severe alleles [Markow, 1981, Behav. Neur. Biol. 31: 348-53; Hotta and Keng, 1984, Animal Behavior: Neurophysiological and Ethological Approaches (Aoki *et al.*, eds.). Springer-Verlag, Berlin, pp. 49-60]. A decrease in the amount of rhodopsin occurs under influence of severe alleles (Ostroy, 1978), though this was largely blocked when the mutant flies were reared and kept in constant darkness (Zinkl *et al.*, 1990), and precedes an age-dependent degeneration of adult photoreceptors (Wilson and Ostroy, 1987b), which is accentuated at high temperatures (Zinkl *et al.*, 1990). Severe mutants show no pigment granule migration with light adaptation (Lo and Pak, 1981). Electrophysiological as well as behavioral phenotypes are present in the youngest flies tested, long before the degenerative changes become apparent. There are zipper-like membrane specializations on plasmalemma of *norpA* retinula cells (Alawi, Jennings, Grossfield, and Pak, 1972, Adv. Exp. Med. Biol. 24: 1-21; Stark, Sapp, and Carlson, 1988, J. Neurogenet. 5: 49-59). Microvillar membranes of the photoreceptor-cell rhabdomeres are severely depleted in six-day-old *norpA*<sup>7</sup> adults [Hiro-sawa and Hotta, 1982, The Structure of the Eye (Hollifield, ed.). Elsevier, New York, pp. 45-53]. *norpA* mutants show polypeptide differences with respect to eye proteins on 1-d or 2-d gels [Ostroy and Pak, 1973, Nature (London) 243: 120-21; Hotta, 1979]. The mutation blocks light-induced phosphorylation of three eye-specific proteins (Matsumoto *et al.*, 1982); one of these proteins has been identified as R1-6 opsin (Nichols and Pak); blockage of this phosphorylation is most complete in severely blind *norpA* alleles, less so in *norpA* alleles with measurable ERGs. Phospholipid kinase (diglyceride kinase) activity is nearly absent in *norpA* mutants, as is phosphorylation of the photoreceptor phospholipid, phosphatidic acid (Yoshioka *et al.*, 1983). Hydrolysis of phosphatidyl-inositol 4.5-biphosphate, liberation of the inositol triphosphate product, and activity of PLC are only 2-3% normal (Inoue *et al.*, 1985, 1988), under the influence of a severe allele (*norpA*<sup>7</sup>) and are about 10% of normal in *norpA*<sup>9</sup>, decreasing another five-fold (as does heat-sensitive blindness) after shift to 28° (Inoue *et al.*, 1985, 1988). *so* (sine oculis) removes about 90% of PLC activity, whereas a *norpA* mutation can remove substantially more (Inoue *et al.*, 1985; Yoshioka, Inoue, and Hotta, 1985, J. Biochem. 97: 1251-54); this would seem to jibe with the provisional demonstration, by *in situ* hybridization, of a low level of *norpA* expression (however, this was not shown to be specifically a gene product) in the optic lobes and central brain (Bloomquist *et al.*, 1988).

<sup>α</sup> 1 = Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, Chromosoma 93: 341-46; 2 = Bloomquist, Shortridge, Schneuwly, Perdew, Montell, Steller, Rubin, and Pak, 1988, Cell 54: 723-33; 3 = Bülthoff, 1982, DIS 58: 31; 4 = Bülthoff, 1982, DIS 58: 32; 5 = Deland and Pak, 1973, Nature (London) New Biol. 244: 184-86; 6 = Harris and Stark, 1977, J. Gen. Physiol. 69: 261-91; 7 = Hirotsawa and Hotta, 1982, The Structure of the Eye (Hollifield, ed.) Elsevier, New York, pp. 45-53; 8 = Hotta and Masai, 1991, J. Neurogenet., in press; 9 = Ostroy and Pak, 1973, Nature (London), New Biology 243: 120-21; 10 = Ostroy and Pak, 1974, Biochim. Biophys. Acta 368: 259-68; 11 = Pak, Grossfield, and Arnold, 1970, Nature (London) 227: 518-20; 12 = Stark, Chen, Johnson, and Frayer, 1983, J. Insect Physiol. 29: 123-31.

<sup>β</sup> Alleles classified arbitrarily into four groups based on the electroretinogram amplitudes:

I = no ERG; II = very small (<3mV) ERG, even with high intensity stimuli; III = intermediate ERG; IV = ERG amplitudes approaching

that of wild type ERGs when intense stimuli are used.

<sup>γ</sup> Fixation defective; isolated on basis of poor orientation to spots in a Y-maze test and originally designated *nofC* mutations (Bülthoff, 1982). Exhibit defective visual response in a freely walking test. ERG's light sensitivity severely reduced and there are no light-on or light-off transient spikes.

<sup>δ</sup> Recovered as allele specific suppressors of *rdgB*<sup>9</sup> (Harris and Stark, 1977, see also Stark, Chen, Johnson, and Frayer, 1983, J. Insect Physiol. 29: 123-31).

**cytology:** Located at 4B6-C1 by *in situ* hybridization (Bloomquist *et al.*, 1988); lies between the cytologically indistinguishable distal breakpoints of *Df(1)rb*<sup>41</sup> and *Df(1)bi*<sup>D2</sup> at 4B6-C1.

**molecular biology:** Gene cloned and sequenced (Bloomquist *et al.*, 1988). Encodes a 7.5 kb RNA expressed in the head. Putative *norPA* protein of 1095 amino acid residues shows extensive sequence similarity to a phospholipase C (PLC) amino acid sequence from bovine brain (Bloomquist *et al.*, 1988). Report of a decrement in an eye-specific diacylglyceride kinase activity (diacylglyceride being produced as a result of PLC action) in *norPA* (Yoshioka, Inoue, and Hotta, 1984, Biochem. Biophys. Res. Comm. 119: 389-95) is not readily explainable by other enzymatic studies of the mutant, which are consistent with the clone and sequence data. Note that the PLC decrements are correlated with physiological severities of various *norPA* mutations, whereas DGK reductions are not (Inoue *et al.*, 1988).

**other information:** *norPA* mutations have been used to assess the role of "basic vision" in complex behaviors such as courtship and circadian rhythms. Initiation of courtship and beginning of mating are prolonged in mutant males (Markow and Manning, 1980, Behav. Neur. Biol. 29: 276-80; Tompkins, Gross, Hall, Gailey, and Siegel, 1982, Behav. Genet. 12: 295-307), but *norPA* females appear to mate more readily than normal females (Tompkins *et al.*, 1982; Markow and Manning, 1982, DIS 58: 104-05). Blind *norPA* adults can respond to light changes, with regard to their cyclically changing locomotor activity in 12h:12h light:dark (LD) cycles, and in terms of being entrained to exhibit free-running circadian rhythms of activity after transfer from LD to constant darkness (Konopka, 1980, Neurosci. Abstr. 6: 706; Dushay, Rosbash, and Hall, 1989, J. Biol. Rhythms 4: 1-27); yet, the free running periodicities were about 1 hour shorter than control values (Dushay *et al.*, 1989). Experiments involving turning on *per*-gene expression in adult photoreceptors, which requires exposure (of wild-type) to light-dark transition, is normal in two severe *norPA*'s (Zerr, Hall, Rosbash, and Siwicki, 1990, J. Neurosci. 10: 2749-62). Pressure injections of PLC into eye during ERG recordings does not ameliorate defective *norPA* physiology (Zinkl *et al.*, 1990). Rhabdomere turnover rhodopsin cycling rhythms (Stark, Sapp, and Schilly, 1988, J. Neurocytol. 17: 499-509) are damped or absent in *norPA* (Zinkl *et al.*, 1990).

### **nos: nanos**

**location:** 3-66.2.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Lehmann.

**references:** Nüsslein-Volhard, Frohnhöfer, and Lehmann, 1987, Science 238: 1675-81.

Lehmann, 1988, Development 104 (Suppl.): 17-27.

Hülskamp, Schröder, Pfeifle, Jäckle, and Tautz, 1989,

Nature (London) 338: 629-32.

Irish, Lehmann, and Akam, 1989, Nature (London) 338: 646-48.

Struhl, 1989, Nature (London) 338: 741-44.

**phenotype:** Maternal-effect lethal. Mutant embryos lack abdominal segments, but have normal pole cells and pole plasm; no posterior activity in pole plasm. Transport or diffusion of the *nos* gene product from the posterior of the embryo seems to be essential for development of the wild-type abdominal pattern. Presence of the *nos* protein represses the activity of the gene product encoded by the *hb* maternal transcript in the posterior half of the embryo (Hülkamp *et al.*, 1989; Irish *et al.*, 1989; Struhl, 1989). Eggs deficient for both *hb* and *nos*, when fertilized by *hb*<sup>+</sup> sperm, develop into normal embryos and subsequently into viable flies.

**alleles:** Four alleles, three strong and one weak (Wang and Lehmann, 1989).

**cytology:** Located in 91F-92A.

**molecular biology:** *nos* has been cloned (Lehmann) and a maternal transcript identified (Wang and Lehmann, 1989).

**\*Np: Notopleural**

**location:** 2-58.7 to 60.2 (between *cn* and *en*; inseparable from *blo*).

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 33b20.

**references:** Bridges, Skoog, and Li, 1936, Genetics 21: 788-95 (fig.).

Li, 1936, Peking Nat. Hist. Bull. 11: 39-48.

**phenotype:** Notopleural, humeral, presutural, and pretarsal bristles shorter and blunter than normal. Wings short and broad. Female produces few or no progeny. Viability fair. Development retarded. More extreme at 19° than at 25°, also more extreme in female. Lethal over *T(2;3)dp*. Homozygous lethal. RK2A.

**cytology:** Locus lies between 44F1 and 45E2 on the basis of its association with *Df(2R)Np = Df(2R)44F1-2;45E1-2* (Bridges).

*npr*<sup>1</sup>: see *BRC*

*npr*<sup>2</sup>: see *BRC*

***npr3: nonpupariating 3***

**location:** 1-65.8.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(1)npr-3; l(1)d.deg.12*.

**references:** Kiss, Bencze, Fodor, Szabad, and Fristrom, 1976, Nature (London) 262: 136-38.

Kiss, Szabad, and Major, 1978, Mol. Gen. Genet. 164: 77-83.

Kiss, Szabad, Belyaeva, Zhimulev, and Major, 1980, Development and Neurobiology of Drosophila (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York and London, pp. 163-81.

**phenotype:** Male lethal; continues development through larval stage, but does not pupariate. Imaginal discs are very small and structureless; ring glands are normal in size on eighth to tenth day of larval life. Puparium formation can be induced by implantation of wild-type ring glands.

***nr: nesh***

**location:** 2-28.3 (26.5 cM to left of Bristle).

**origin:** Isolated from isofemale lines carrying eagle that were derived from natural populations in California.

**references:** Prout and Green, 1986, DIS 63: 169.

**phenotype:** Identical to *eg*; *nr* and *eg* combined are *eg* in phenotype.

***nrd: neural disrupted***

**location:** 2- {7}.

**origin:** Differential screen of genomic clones using cDNA probes prepared from neural and non-neural cells.

**references:** Neumann and Mahowald.

**phenotype:** Embryonic lethal typified by an enlarged brain, irregular ventral nerve cord formation, and disorganized peripheral ganglia; these defects first appear in 10-12 hour embryos and include a delay in germband contraction and a failure of head involution. The CNS of mutant embryos fails to complete the normal condensation that leads to compact paired cerebral hemispheres and a ventral ganglion. In late mutant embryos, the brain, which has protruded dorsally through a hole in the cuticle, remains extended and flattened against the vitelline membrane and the ventral neuromeres are extended posteriorly; discontinuities or thinnings of the ventral nerve cord can frequently be observed. Normal development of the mouth parts and cephalopharyngeal apparatus is disrupted.

**cytology:** Located in 23A1-3 by *in situ* hybridization of cloned DNA.

**molecular biology:** Gene (selectively expressed in neural cells) cloned; 2.3 kb transcript obtained both maternally and in 10-18 hour old embryos. Transcript remains in larval, pupal, and adult stages. Non-neural specific 1.3 and 0.9 kb RNAs are transcribed off the opposite strand. The 2.3 kb transcript is expressed in neural cultures as well as *in vivo*.

### **Nrg: Neuroglian**

**location:** 1-23.6.

**synonym:** *l(1)7Fa*.

**references:** Bieber, Snow, Hortsch, Patel, Jacobs, Traquina, Schilling, and Goodman, 1989, *Cell* 59: 447-60. Hortsch, Bieber, Patel, and Goodman, 1990, *Neuron* 4: 697-709.

**phenotype:** Encodes a protein that is likely to play a role in neural and glial cell adhesion in the developing *Drosophila* embryo. Widely expressed in the embryo, particularly on the surfaces of a large subset of neurons and glia that interact with and adhere to one another along the dorsal surface of the developing CNS and within the peripheral nerve roots; the protein can be detected along neuronal axons, but not cell bodies. Three polypeptides of 155, 167, and 180 kd are detected on Western blots; deglycosylation experiments reduce these to a single 155 kd band; removal of N-linked high-mannose oligosaccharides causes a shift to about 162 kd. It is also expressed in a number of non-neuronal tissues such as trachea, hindgut, salivary gland and muscle. Recessive alleles are embryonic lethals and show little or no evidence of Neuroglian expression; the overall structure of the CNS and PNS, and in particular the peripheral nerve roots and CNS axon pathways develop in a relatively normal way in lethal embryos.

**alleles:** Neuroglian has been identified with a previously isolated lethal mutation of which ten alleles have been described.

<sup>α</sup> 1 = Bieber, Snow, Hortsch, Patel, Jacobs, Traquina, Schilling and Goodman, 1989, *Cell* 59: 447-60; 2 = King, Mohler, Riley, Storto, and Nicolazzo, 1986, *Dev. Genet.* 7: 1-20; 3 = Lefevre, 1981, *Genetics* 99: 461-80; 4 = Lefevre and Watkins, 1986, *Genetics* 113: 869-95.

**cytology:** Placed in 7F by *in situ* hybridization; by deficiency analysis placed in the region common to *Df(1)KA14 = Df(1)7F1-2;8C5* and *Df(1)RA2 = Df(1)7D10;8A4-5*.

**molecular biology:** A Neuroglian-specific antibody was used to screen an embryonic cDNA expression library; cDNA's corresponding to a 5.1 kb transcript were recovered and localized to 7F on polytene chromosomes. Encodes two different proteins by tissue-specific alternative splicing, which differ in their cytoplasmic domains; the longer form is restricted to the surface of neurons in the CNS and some support cells in the PNS. The shorter

form is more widely expressed in other cells and tissues. Northern blots probed with sequences specific to each of the polypeptides reveal transcripts of 5.5 kb for the short form and 5.7 and 7.6 kb for the long form. Sequence analysis reveals that Neuroglian is an integral membrane glycoprotein that is a member of the immunoglobulin superfamily. The extracellular portion of the protein consists of six immunoglobulin C2-type domains followed by five fibronectin type III domains. It is closely related to vertebrate neural adhesion molecules, most extensively to mouse L1.

### **nrs: narrow scoop**

**location:** 1-54.2.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, *DIS* 33: 88.

**phenotype:** Wings narrow and slightly shorter than normal; frequently scooped. Slightly thinner bristles. Eyes large and dull red. Eye and body colors darken with age. Viability and fertility good in male; fertility low in female. RK2.

### **Nrt: Neurotactin (J.C. Hall)**

**location:** 3-{45}.

**origin:** Molecular cloning, starting with monoclonal-antibody screening of expression library.

**references:** de la Escalera, Bockamp, Moya, Piovant, and Jiménez, 1990, *EMBO J.* 9: 3593-3601.

Barthalay, Hipeau-Jacquotte, de la Escalera, Jiménez, and Piovant, 1990, *EMBO J.* 9: 3603-09.

Hortsch, Patel, Bieber, Traquina, and Goodman, 1990, *Development* 110: 1327-40.

**phenotype:** Three monoclonal antibodies selected because of binding to presumptive imaginal neurons within the larval central nervous system (CNS) (de la Escalera *et al.*, 1990) and an additional one found by virtue of binding to neuronal surfaces in embryos (Hortsch *et al.*, 1990) detected the same *ca.* 135 kd protein on Western blots of homogenates from embryos, late larva, and pupae. The membrane-bound material is called neurotactin (NRT) because of its expression at points of interneuronal cell contact. Antibody staining (de la Escalera *et al.*, 1990, Hortsch *et al.*, 1990) shows concentration of the protein in dorsal and ventral portions of embryonic blastoderm (where staining appears cell surface-limited), all over gastrulating embryos (although Hortsch *et al.*, 1990, imply a somewhat more restricted expression pattern), in the "proliferating" CNS (including neuroblasts and their progeny) of stage 10-11 embryos, and in regions of contact between neuroblasts. In visceral mesoderm (stage 13), non-neuronal expression diminishes, although it is seen on fat body cells and the "dorsal vessel"; intense staining continues in embryonic CNS (but is relatively weak in axons of motor neurons); PNS expression is evident as well (seemingly restricted to sensory cells that send out multiple dendritic projections, and, in fact, PNS cell-body signals are weaker than on dendrites); cell-surface expression apparent in the various expressing tissues during mid-embryogenesis; in early L1, NRT signals decay but reappear in CNS (in optic formation centers and in neuron clusters and associated axons in ventral cord); the protein's expression persists in imaginal neurons through mid-pupal stage, wanes as such cells com-

plete maturation, and is undetectable in adults. L3 imaginal discs are NRT positive (e.g. on developing chordotonal neurons of leg discs and in developing photoreceptor cells plus their axons, posterior to the morphogenetic furrow). Cell culture studies, including electron-microscope observations (Barthalay *et al.*, 1990), suggest further that NRT is a "contact molecule" between neurons or epithelial cells; there is uniform expression along intercellular contact areas; non-adhesive Schneider-2 cells, transfected with *Nrt* cDNA, do not become self adhesive, but these cells bind to a subpopulation of embryonic cells.

**cytology:** Placed in 73C1-2 by *in situ* hybridization (de la Escalera *et al.*, 1990; Hortsch *et al.*, 1990). Embryos deficient for this region do not stain with anti-NRT monoclonal antibodies (de la Escalera *et al.*, 1990; Hortsch *et al.*, 1990).

**molecular biology:** cDNAs cloned from expression libraries (de la Escalera *et al.*, 1990; Hortsch *et al.*, 1990). Such clones, when used in Northern blots, detected three or more transcripts, whose expression patterns are different during the course of embryogenesis (Hortsch *et al.*, 1990), and which exhibit a later "peak" in early pupae (de la Escalera *et al.*, 1990); the larger RNA species appear to be so because of more 3' untranslated nucleotides (de la Escalera *et al.*, 1990). *In situ* hybridizations (Hortsch *et al.*, 1990) revealed temporal/spatial expression patterns similar to those seen immunohistochemically. Sequencing of a complete cDNA (de la Escalera *et al.*, 1990; Hortsch *et al.*, 1990) predicts an 846-amino-acid polypeptide [which would, as a core protein, be ca. 93 kd, though actual measurements of its size indicate 120 kd (Barthalay *et al.*, 1990)]. There is one predicted transmembrane region, and details of which monoclonal antibodies can stain simple whole-mounted embryos vs. permeabilized ones (de la Escalera *et al.*, 1990), as well as biochemical analyses (epitope mapping), using antibodies raised against *Nrt*-fusion protein constructs (Hortsch *et al.*, 1990), are consistent with the protein's being inserted into membranes, with the N-terminus cytoplasmic and the C-terminus extracellular. Data-base comparisons (de la Escalera *et al.*, 1990; Hortsch *et al.*, 1990) indicate similarity of portion of NRT's extracellular domain to cholinesterases, including product of *Drosophila Ace* locus; this NRT region is also similar to *Drosophila glutactin* and to rat thyroglobulin. NRT apparently lacks the "landmark" serine residue that would indicate it to have actual esterase activity (Hortsch *et al.*, 1990).

**other information:** Embryos homozygous for either of the two *Nrt*<sup>-</sup> deletions used by de la Escalera *et al.* (1990) [*Df(3L)st-k10* = *Df(3L)73A3-4;73D1-2* and *Df(3L)73A11-B1;73D1-2*] do not exhibit any "extra" gross abnormalities of the CNS. Deletion of regions just distal to *Nrt* [i.e. *Df(3L)st100.62* = *Df(3L)72F3-7;73B3* or *Df(3L)st-e5* = *Df(3L)?;73A9-10*] leads to defects in axonal patternings (because of the absence of the *abl* and *dab* genes in 73B, cf. Gertler, Bennet, Clark, and Hoffman, 1989, Cell 58: 103-113), but the further removal of *Nrt*<sup>+</sup> does not make this phenotype worse (de la Escalera *et al.*, 1990).

*Ns*: see *Antp*<sup>Ns</sup>

### **Ntf: Neurogenic element binding transcription factor**

**location:** 2-{83}.

**synonym:** *Elf-1: Element I binding activity.*

**references:** Bray, Burke, Brown and Hirsh, 1989, Genes Dev. 3: 1130-45.

Dynlacht, Attardi, Admon, Freeman, and Tjian, 1989, Genes Dev. 3: 1677-88.

**phenotype:** Gene encodes at least three isoforms of a protein that binds to upstream sequences of *Ddc*, *en*, *ftz*, and *Ubx*. The proteins share epitopes as recognized by two monoclonal antibodies. Expression first detected in 4- to 8-hour embryos, peaking from 8 to 12 hours and declining from 12 to 16 hours; NTF protein detected in nuclei of ectodermal derivatives; seen in all epidermal cells and changing subsets of neurons in the developing central nervous system.

**cytology:** Placed in 54F1-2 by *in situ* hybridization.

**molecular biology:** Protein purified by DNA-affinity chromatography using promoter sequences derived from *Ddc*, *Ubx*, or both. Three prominent polypeptides recovered (140, 120, and 83 kd); the purified proteins shown to bind to specific neurogenic control regions upstream from *Ddc*, *ftz*, and *Ubx* by DNA footprinting and to stimulate transcription of these genes *in vitro*. Northern blots of embryonic RNA detect mRNA's of 7.4 and 10.6 kb. cDNA clones isolated by screening an expression library either with monoclonal antibody (Bray *et al.*) or with synthetic oligonucleotides (Dynlacht *et al.*). Three different cDNA's identified by Bray *et al.* Presumed to arise as a result of alternative splicing; one of these encodes a polypeptide of 1063 residues and approximately 116 kd. The conceptual amino acid sequence contains several polyglutamine stretches (OPA repeats) in the N-terminal half; it shows no evidence of homeobox or zinc-finger domains; there is weak homology, however, to the helix-loop-helix motifs of *myoD* and myogenin.

### **\*Nu: Nude**

**location:** 2- or 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Sutton, 41a27.

**phenotype:** Many bristles missing from head and thorax; postscutellars, notopleurals, verticals, and postverticals usually present. Homozygous lethal. RK2A.

**cytology:** Associated with  $T(2;3)Nu = T(2;3)24;36-37;-39-40;73-74;75-76;77-78;81-82;85-86;89-90$ .

### **nub: nubbin**

**location:** 2-47.0.

**origin:** Spontaneous.

**discoverer:** Mickey, 48e10.

**references:** 1949, DIS 23: 61.

**phenotype:** Wings very small, opaque, curved spoonlike up or down; inflated at eclosion. Wing margins interrupted. Only one vein (L2 or L3) present. Halteres somewhat reduced. Viability excellent. RK1.

**cytology:** Placed in 33F1-5. Not included in *Df(2L)64j* = *Df(2L)34E5-F1;35C3-D1* (E. H. Grell).

### **nub<sup>2</sup>**

**origin:** Probably X ray induced.

**discoverer:** R. F. Grell, 56f1.

**references:** 1956, DIS 30: 71.

**phenotype:** Wings small and spoonlike but less extreme than *nub*. Patches of dried blood on wings. Veins L1 to L4 almost indiscernible; L5 and alula frequently absent. Viability and fertility excellent. RK1.

### *nub*<sup>62d</sup>

**origin:** X ray induced.

**discoverer:** Seiger, 62d.

**references:** 1963, DIS 37: 53.

Abbadessa and Burdick, 1963, DIS 37: 54.

**phenotype:** Wings very small and spoonlike. RK1.

### *Nuc: Nuclease*

**location:** 3-38.2.

**references:** Angelosanto and Boyd, 1976, Genetics 83: s2.

**phenotype:** Structural gene for a desoxyribonuclease active at alkaline pH and correlated with the appearance of a puff in the salivary glands of third instar larvae.

**alleles:** Two electrophoretic variants, *Nuc*<sup>1</sup>, and *Nuc*<sup>2</sup>, were found in laboratory stocks.

**cytology:** Located in 68D-70A (Y-autosome translocations); puffing activity correlated positively with level of DNase activity in salivaries during last 24 hours of larval development.

### *nuc1: nucleoside auxotroph 1*

**location:** 2-104.

**synonym:** *pyr2*.

**references:** Naguib and Nash, 1976, Mol. Gen. Genet. 147: 13-21.

**phenotype:** Nucleoside auxotroph; responds to dietary ribonucleosides.

**alleles:** *nuc1*<sup>1</sup> (= *pyr2-1*); *nuc1*<sup>2</sup> (= *pyr2-2*).

**Nuclease:** see *Nuc*

**nucleoside auxotroph 1:** see *nuc1*

**Nude:** see *Nu*

**nudel:** see *ndl*

### *numb: numb*

**location:** 2- {35}.

**references:** Uemura, Shepherd, Ackerman, Jan, and Jan, 1989, Cell 58: 349-60.

**phenotype:** The *numb* gene must be able to function in the *Drosophila* embryo in order for the peripheral sensory neurons to acquire their correct identity. In the mutants, the precursors of neurons and glial cells in the external sensory (es) organs are, for the most part, transformed into nonneural support cells; some of the es organs are duplicated. Transformation of neuron precursors into nonneural cells also occurs in the chordotonal (ch) organs. Precursors of the multiple dendrite (md) neurons undergo similar changes. Muscle development is abnormal in *numb* mutant alleles; some muscles are fewer in number than in wild type and show pattern changes (Uemura *et al.*).

**alleles:** Three mutant alleles have been identified, all apparently nulls since the neuronal phenotype of homozygotes is indistinguishable from that of hemizygotes.

allele	origin	molecular biology
<i>numb</i> <sup>1</sup>	HD	P-element at 30B
<i>numb</i> <sup>2</sup>	DEB	
<i>numb</i> <sup>3</sup>	DEB	

**cytology:** Located in 30A-C since *numb*<sup>1</sup> is not complemented by a deletion in this region; excision of the P-element at 30B leads to a reversion of the mutant phenotype.

**molecular biology:** 50 kb of genomic DNA flanking the insertion of a transposon, pUCHsneo, cloned by the plasmid rescue method and a chromosome walk. Two transcripts of 3.1 and 3.5 kb result from alternative splicing of *numb*, the first mRNA being maternal in origin and the second zygotic. cDNA clones from the 5' end of the maternal transcript and from the entire zygotic transcript have been sequenced. The zygotic DNA shows a single open reading frame. From these cDNA sequences, a 56 kd maternal protein and 61 kd zygotic protein have been predicted. Both maternal and zygotic products have putative zinc finger domains and are very basic. A 60 kd protein can be detected by anti-*numb* antibodies in very young (0-1 hr and 3-5 hr) *numb*<sup>+</sup> embryos; a larger protein (65 kd) can be detected by this antibody in older *numb*<sup>+</sup> embryos (11-13 hr and 15-17 hr). Homozygous *numb*<sup>1</sup> embryos fail to show either protein. Uemura *et al.* suggest that these proteins may be involved in nucleic acid binding.

*Nup*: see *Mhc*<sup>16</sup>

**nurse cell number:** see *ncn*

### \**nw: narrow*

**location:** 2-79.6 (Rizki *et al.*, 1980; see *nw*<sup>D</sup>); 2-79.3 (Doane and Clark, 1984; see *nw*<sup>2</sup>).

**phenotype:** Wings long, narrow, and somewhat pointed. Low viability and fertility in both sexes. At 25°C, may overlap wild type; at 19°, nearly all flies approach wild type but have longer wings. RK2.

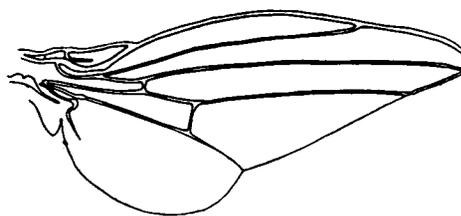

**alleles:**

allele	origin	discoverer	ref <sup>α</sup>

Genet. 2: 227; 5 = Payne, 1924, Genetics 9: 327-42; 6 = Rizki, Rizki, and Grell, 1980, Wilhelm Roux's Arch. Dev. Biol. 188: 91-99.

<sup>β</sup> Synonym: *lance*.

**cytology:** Placed in 54A-55A.

***nw*<sup>2</sup>: narrow 2**

From Payne, 1924, Genetics 9: 327-42.

***nw*<sup>2</sup>**

**phenotype:** Wings like *nw*, long, narrow, and somewhat pointed. Classification easier in females. Slight notching or tufting of marginal hairs on tip of wings. Both sexes nearly sterile. Ovaries tumorous at eclosion [King, Burnett, and Staley, 1957, Growth 21: 239-61 (fig.); King, 1964, Roy. Entomol. Soc. (London) Symp. Insect Reproduction, pp. 13-25]. Oogonia proliferate asynchronously within ovariole; follicle development inhibited [Beatty, 1949, Proc. R. Soc. Edinburgh, B 63: 249-70 (fig.)]. RK2.

***nw*<sup>B</sup>: narrow-Blade**

**phenotype:** Wings of *nw*<sup>B</sup>/+ long and narrow; variable but does not overlap wild type. Female fertility reduced. Homozygote and *nw*<sup>B</sup>/*nw*<sup>2</sup> heterozygote lethal. RK2.

***nw*<sup>D</sup>: narrow-Dominant**

**phenotype:** Wings of heterozygote longer and narrower than normal. Expression variable and sometimes approaches wild type. Viability of *nw*<sup>D</sup>/+ low. Homozygous lethal, as is *nw*<sup>D</sup>/*nw*<sup>2</sup>. RK2.

***NX*: Notch Xasta**

**location:** 3- (between *st* and *Dfd*; 44.0-47.5).

**origin:** X ray induced.

**discoverer:** Ohnishi, 49116.

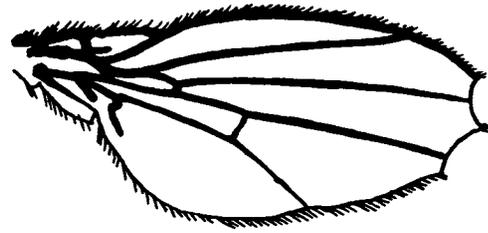

**references:** 1950, DIS 24: 61.

1951, DIS 25: 79.

Schalet, 1960, DIS 34: 55.

**phenotype:** Resembles Notch but more extreme. Homozygote resembles *ap*<sup>Xa</sup>. Viability of heterozygote fair;

homozygote semilethal. Enhanced by *D1* and suppressed by *H*. Combination of *NX* and *ap*<sup>Xa</sup> produces small wings, like *vg*, and lower viability. RK2 as heterozygote.

***ny*: notchy**

From Grüneberg, 1929, Biol. Zentralbl. 49: 680-94.

***ny*: notchy**

**location:** 1-32.

**origin:** X ray induced.

**discoverer:** Grüneberg, 28j29.

**references:** 1929, Biol. Zentralbl. 49: 680-94 (fig.).

1934, DIS 2: 8.

**phenotype:** Wing tips slightly nicked. Expression variable; overlaps wild type in some females and most males. Viability about 70% wild type. RK3.

**cytology:** Placed in 10B5-18 based on its inclusion in *Df(1)N71* = *Df(1)10B5;10D4* but not *Df(1)DA662* = *Df(1)10B8;10D2*.

**\*ob: oblique****location:** 1-37.2.**origin:** Spontaneous.**discoverer:** Neel, 41f30.**references:** 1942, Genetics 27: 532.

1942, DIS 16: 51.

**phenotype:** Wings obliquely truncated from inner margin outward. Venation disturbed. Viability about 20% wild type. RK3.**obl: oblique wings****location:** 1-60.1.**origin:** Induced by triethylenemelamine (CB. 1246).**discoverer:** Fahmy, 1953.**references:** 1958, DIS 32: 72.**phenotype:** Wings slightly upheld and outspread; small blister occasionally present. Body color slightly darker. Male viability and fertility good; female viability about 40% wild type and fertility reduced. RK2.**other information:** One allele induced by CB. 1506.**oblique:** see **ob****oblique wings:** see **obl****obt: obtuse****location:** 3-77.5.**discoverer:** E. M. Wallace, 35g1.**phenotype:** Wings shorter and blunter but overlap wild type slightly. Thorax somewhat humpy; body chunky; eyes slightly bulging. RK3.**cytology:** Not in 94A-E (Jones, 1971, DIS 47: 90).**oc: ocelliless**

"Edith M. Wallace, unpublished."

**oc: ocelliless****location:** 1-23.1.**synonym:** *otd: orthodenticle*.**references:** Wieschaus and Noell, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 63-73.

Finkelstein, Smouse, Capaci, Spradling, and Perrimon, 1990, Genes Dev. 4: 1516-27.

**phenotype:** Ocelli completely absent. Bristles in ocellar area and on top of head irregular and more numerous; postverticals usually absent. Eyes somewhat reduced and body size dwarfed. Phototaxis normal (Benzer, 1967, Proc. Nat. Acad. Sci. USA 58: 1112-19). Viability about 90% wild type. *oc* and deficiencies for *oc* show partial dominance to *oc*<sup>+</sup>; ocelli placed somewhat far back on head and slight indentation apparent between postvertical bristles (Craymer and Roy, 1980, DIS 55: 204). Eggs from *oc*<sup>1</sup> homozygotes have defective chorions and abnormal beta yolk spheres (Johnson and King, 1974, Int. J. Insect. Morphol. Embryol. 3: 385-95). Sterility is due to the presence of *In(1)oc*, one breakpoint of which

disrupts *oc*, and the other of which interferes with amplification of the chorion-protein genes *Cp36* and *Cp38* (Spradling and Mahowald, 1981, Cell 27: 203-09). *oc*<sup>1</sup> in heterozygous combination with non-complementing lethal alleles survives and is female fertile. *Ubl*/+ enhances dominance of *oc*; *Df(1)RA2*/+ exhibit delayed hatch and an *oc* phenotype; *oc*<sup>2</sup>/+ display strong *oc* phenotype, and *oc*<sup>1</sup>/*oc*<sup>1</sup> are lethal in combination with *Ubl*/+ (Mortin and Lefevre, 1981, Chromosoma 82: 237-47). Lethal alleles (recovered as *otd: orthodenticle*) die as embryos; all denticles in anterior abdominal segments point posteriorly; defects at ventral midline; head defects. Also cause embryonic neural defects (Finkelstein *et al.*, 1990): In developing ventral cord, commissures within each segment appear fused. At the cellular level, certain ventral unpaired medial (VUM) neurons do not seem to migrate ventrally (as do the normal VUMs at approximately 14 hours of embryogenesis) and are absent from most segments. Other "midline-associated" neurons are missing as well in *otd*-type embryos. Homozygous germ-line clones survive in females; homozygosity for lethal alleles in germ-line clones without effect on survival of heterozygous offspring or on phenotype of hemizygotes (Wieschaus and Noell). Putative *oc* transcript abundant in embryos, peaking between 4 and 13 hours, before and coincident with neural-developmental defects observed in central nervous system of embryos hemizygous for lethal alleles; there is also putative maternally derived *oc* mRNA (which could be alternately spliced form of the "major" transcript). Northern signals weaken in L1 and L2, are still detectable in early pupae, but are absent in late pupae and adults. *In situ* hybridization reveals earliest embryonic expression at cellular blastoderm; later, signals seen in a longitudinal strip along ventral midline, then in "head region" and in developing ventral cord.

**alleles:** Except for *oc*<sup>1</sup>, alleles are lethal; alleles *oc*<sup>2</sup> through *oc*<sup>5</sup> non complementing; *oc*<sup>6</sup> and *oc*<sup>7</sup> complement *oc*<sup>1</sup> but not one another.

<sup>α</sup> 1 = Bedichek, 1934, DIS 2: 9; 2 = Lefevre, 1981, Genetics 99: 461-80; 3 = Lefevre; 4 = Wieschaus and Noell, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 63-73; 5 = Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

β More detailed description follows.

**cytology:** Placed in 8A1-2 on the basis of its assignment to the proximal breakpoint of *In(1)oc* = *In(1)7F1-2;8A1-2*.

**molecular biology:** DNA in region 8A1-2 amplifies in *oc*<sup>1</sup> under the influence of *In(1)oc* (Spradling and Mahowald). Identified by Finkelstein *et al.*, (1990), within approximately 80 kb of cloned material from the region of the distal breakpoint of *In(1)oc*. A 4 kb *EcoRI* fragment detects a 4.7 kb transcript; this was designated

as *oc* mRNA because of its embryonic expression pattern. Sequence of a cDNA clone predicts a 670-amino-acid protein with various repeats of single amino acids (e.g. Gly, Ser, Gln), pairs of amino acids (e.g. alternating Gly-Val), and a tandemly-duplicated 19-mer. There is also a "paired-group"-like homeodomain relatively near the N-terminus.

**other information:** Relationship of *oc* to *otd* indicated by co-mapping (cf. Spradling and Mahowald, 1981; Wieschaus *et al.*, 1984) and the failure of *otd*-type alleles to complement *oc* (Finkelstein *et al.*, 1990). Moreover, *otd*<sup>+</sup> females have altered adult bristle pattern in ocellar region, similar to that exhibited by homozygotes for the weak allele *oc*<sup>db</sup> (Finkelstein *et al.*, 1990).

***oc*<sup>db</sup>: ocelliless-disturbed bristles**

**phenotype:** Ocelliless; ocellar, interocellar, and postvertical bristles variably extra, missing, or misplaced with about 80% penetrance; acts as a non complementing *oc* allele.

*o.c.c.*: see *BRC*

***Ocd*: Out cold (J.C. Hall)**

**location:** 1-55.

1979, *Hereditas* 90: 93-101.

1986, *Hereditas* 104: 313-16.

**phenotype:** Dominant cold-sensitive, reversible paralytic; heterozygous mutant females begin uncoordinated behavior (progressively: abnormal leg movements, leg stretching, wing fluttering) on shift from 25° to 18-20°; paralysis eventually occurs, and recovery is gradual on shift back to higher temperatures; critical temperature to include the debilitations is ca. 2° lower from *Ocd*<sup>7</sup> than for other alleles; also males hemizygous for *Ocd*<sup>7</sup> have better viability than those expressing the other alleles, with *Ocd*<sup>4</sup> being the most severely affected *i.e.*, nearly lethal (*Ocd*<sup>4</sup> also causes near lethality when heterozygous with any of the other alleles); at 25°, mutant males walk in reeling manner and fall over frequently; none can fly, and attempts to coax jumps (to initiate flight) cause the males merely to fall over when touched; these phenotypes also seen in homozygotes and heteroallelic combinations; certain of the homozygous mutant females (e.g. *Ocd*<sup>2</sup> and *Ocd*<sup>3</sup>) hold their wings in drooped position; also seen in *Ocd*<sup>1</sup> males; this phenotype also observed in *Ocd*<sup>2</sup>/<sub>+</sub> and *Ocd*<sup>3</sup>/<sub>+</sub> females, which also walk in unsteady manner; other alleles, when heterozygous, allow for seemingly normal behavior at 25°, except that their legs shake under etherization (with *Ocd*<sup>4</sup> causing the strongest aberrant shaking). Abrupt, anomalous changes in Arrhenius activation energy of the mitochondrial enzyme, succinate cytochrome c reductase, are seen at temperatures close to those which induce paralysis (Søndergaard, FEBS Lett. 51: 126). Two-dimension gels of mitochondria isolated from *Ocd*<sup>1</sup> contain an additional polypeptide not seen in extracts of wild-type (Søndergaard, 1986).

**cytology:** Placed in 13F10-16A2 because the severe effects of any mutant allele are ameliorated in males hyperploid for *Dp(1;4)r*<sup>+</sup> (13F10-16A2 appended to chromosome 4).

**alleles:** Seven mutants; concluded, not from problematical

complementation tests, but by failure of wild-type recombinants to be recovered from heteroallelic *Ocd* combinations. *Ocd*<sup>1</sup> (Søndergaard, Nelson, and Smillic, 1975, FEBS Lett. 51: 126-29) through *Ocd*<sup>7</sup> (Søndergaard, 1979).

***Oce*: Ocellarless**

**location:** 1-5.7.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 72.

**phenotype:** One or both ocellar bristles, frequently postverticals, missing; other bristles, especially the scutellars, sometimes absent. *Oce/Oce* females lack 90% of postvertical and ocellar macrochaetae and 10-40% of anterior dorsocentrals; *Oce*/<sub>+</sub> females lack 60-80% of ocellars and 90-95% of postverticals but show minimal loss of dorsocentral bristles; in *Hw*<sup>49c</sup>/*Oce* females *Oce* appears to be epistatic to *Hw*<sup>49c</sup> in the thoracic region (10% missing dorsocentrals) and additive in the head with 95% missing postverticals and 100% missing ocellars (Stoddard, 1972, DIS 48: 137-38). Wings frequently positioned abnormally, have incised margins; effect more marked in homozygous females. Bristle effect dominant. Good viability and fertility in both sexes. RK1.

**other information:** One allele induced by each of the following: CB. 3025, CB. 1592, CB. 1540, and CB. 1528.

***ocelliless*: see *oc***

**\**ocr*: ochracea**

**location:** 2-0.

**discoverer:** Serebrovsky, 40g25.

**references:** 1941, DIS 15: 19.

**phenotype:** Eye color lighter at eclosion, darkening with age. RK1.

***Octanol dehydrogenase*: see *Odh***

***Ocr*: Octopamine receptor (J.C. Hall)**

**location:** 3-{100}.

**origin:** Molecular cloning (using a putatively homologous clone from human and by synthesis of appropriate oligonucleotide probes).

**synonym:** *Tyr-dro*.

**references:** Arakawa, Gocayne, McCombie, Urquhart, Hall, Fraser, and Venter, 1990, *Neuron* 4: 343-54.

Saudou, Amlaiky, Plassat, Borrelli, and Hen, 1990, *EMBO J.* 9: 3611-17.

**phenotype:** Independent cDNAs were cloned into expression vectors and transfected into CHO-1 (Arakawa *et al.*, 1990) or Cos-7 (Saudou *et al.*, 1990) cells. Membranes from such cells had high-affinity binding activity to the adrenergic receptor agonist yohimbine; other agonists or antagonists used to compete with this substance showed the octopamine analog, synephrine, to have the highest agonist affinity, higher than octopamine itself; these results along with others which showed greater affinity of the cloned/transduced protein for yohimbine and chlorpromazine than for metoclopramide, suggested that this *Drosophila* receptor is an "octopamine-1" subtype (Arakawa *et al.*, 1990). Membranes preparations from the Cos-cell transfectants also had high affinity for yohimbine, and tyramine (e.g. greater than octopamine), suggesting to Saudou *et al.* (1990) that this *Drosophila*

gene encodes a tyramine receptor. Stably transfected mouse cell lines were also made (Saudou *et al.*, 1990); additions of monoamines to them (*e.g.* tyramine, octopamine) do not by themselves lead to changes in cAMP levels, but forskolin-elicited cAMP increases were reduced by added tyramine (which was more effective than octopamine). Rough anatomical localization revealed a head-enriched mRNA (3.6 kb: Arakawa *et al.*, 1990; 3.5 kb: Saudou *et al.*, 1990).

**cytology:** Mapped to 99A10-B1 by *in situ* hybridization (Arakawa *et al.*, 1990).

**molecular biology:** A cDNA encoding human brain  $\beta_2$ -adrenergic receptor used in low stringency hybridizations to clone a *Drosophila* genomic fragment, partial sequence analysis of which revealed homology to adrenergic receptors (Arakawa *et al.*, 1990). A similar approach, starting with degenerate oligonucleotides corresponding to sequences found in vertebrate receptors, led to an independent genomic clone (Saudou *et al.*, 1990). Complete sequencing of head cDNAs, hybridizing to these genomic clones (Arakawa *et al.*, 1990; Saudou *et al.*, 1990), reveals a 601-amino-acid "G-protein-coupled" type of receptor protein, with highest homology to  $\alpha_2$ -adrenergic receptor subtypes, containing seven putative membrane-spanning regions and a N-terminal signal sequence.

**other information:** Saudou *et al.* (1990) call their form of the gene *Tyr-dro* (based on their different results from, and interpretation of, pharmacological experiments; see above).

*od*: see *os*<sup>o</sup>

### **odd: odd skipped**

**location:** 2-8.

**references:** Nüsslein-Volhard and Wieschaus, 1980, *Nature* 287: 795-801 (fig.).

Nüsslein-Volhard, Kluding, and Jürgens, 1985, *Cold Spring Harbor Symp. Quant. Biol.* 50: 145-54.

**phenotype:** Embryonic lethal; posterior part of the denticle band and adjacent naked cuticle replaced by mirror-image duplication of the anterior part of the denticle band and adjacent naked cuticle in T2, A1, A3, A5, and A7. Pole-cell-transplantation experiments indicate that *odd*<sup>+</sup> not maternally required. Positional expression of *ftz* unaffected (Carroll and Scott, 1986, *Cell* 54: 113-26). However, stripes of *en* expression are broader than normal in even-numbered, but of normal width in odd-numbered parasegments; *Ubx* expression is consequently low in broader-than-normal stripes in even-numbered parasegments (Martinez-Arias and White, 1988, *Development* 102: 325-38).

**odd skipped:** see *odd*

### **Odh: Octanol dehydrogenase**

**location:** 3-49.2.

**discoverer:** Ursprung.

**references:** Ursprung and Leone, 1965, *J. Exp. Zool.* 160: 147-54.

Courtright, 1966, *DIS* 41: 59.

Courtright, Imberski, and Ursprung, 1966, *Genetics* 54: 1251-60.

**phenotype:** The structural gene for octanol dehydrogenase [ODH (EC. 1.1.1.73)], a multimer of 109,000 molecular weight (Sieber, Fox, and Ursprung, 1972, *FEBS Lett.* 26: 274-76); evidence for tetrameric structure in other *Drosophila* species (Pipkin, 1969, *Genetics* 63: 405-18); immunologically unrelated to ADH (Courtright, 1968, *DIS* 43: 144). Preferred substrates are long-chain primary alcohols, with lesser activity on short-chain and branched-chain primary alcohols; inactive on secondary alcohols (Bremner, Douglas, and Ogonji, 1971, *DIS* 47: 93-94). Enzyme activity higher in adults than in larvae or pupae (Debec, 1974, *Wilhelm Roux's Arch. Dev. Biol.* 174: 1-9); mobility also increases from larvae to pupae to adults (Hewitt, 1974, *Genetics* 77: s30-31). *Odh*<sup>+</sup> not a vital gene; homozygotes for null allele, *Odh*<sup>nNC1</sup>, viable and fertile (Voelker, Langley, Leigh-Brown, Ohnishi, Dickson, Montgomery, and Smith, 1980, *Proc. Nat. Acad. Sci. USA* 77: 1091-95).

**alleles:** Existing alleles recovered from natural populations; designated according to their migration rate toward the cathode in agar gel electrophoresis. *Odh*<sup>F</sup> the predominant allele; the incidence of *Odh*<sup>S</sup> in populations decreases with distance from the equator (Oakeshott, Gibson, Wilcocks, and Chambers, 1983, *Theoret. Appl. Genet.* 65: 191-96).

allele	synonym <sup>α</sup>	ref <sup>β</sup>	comments
<b>Odh<sup>F</sup></b>	<i>Odh<sup>M</sup></i>	1, 2	fast allele
<b>Odh<sup>nNC1</sup></b>		3	null allele
<b>Odh<sup>R</sup></b>		1	rare allele
<b>Odh<sup>S</sup></b>	<i>Odh<sup>L</sup></i>	1, 2	slow allele

<sup>α</sup> Because Costa *et al.* used a different gel system in which migration was anodal, the designations *F* and *S* were not descriptive; accordingly they use *M* = most common allele, *L* = less common allele, and *R* = rare allele, which encodes a polypeptide whose anodal migration is slower than that produced by *Odh*<sup>F</sup>.

<sup>β</sup> 1 = Costa, Danieli, and Rodino, 1977, *DIS* 52: 92; 2 = Courtright, Imberski, and Ursprung, 1966, *Genetics* 54: 1251-60; 3 = Voelker, Langley, Leigh-Brown, Ohnishi, Dickson, Montgomery, and Smith, 1980, *Proc. Nat. Acad. Sci. USA* 77: 1091-95.

**cytology:** Localized to 86D1-4 based on its inclusion in *Df(3R)M86D* = *Df(3R)86D1;86D4* (Clark, 1983, *Biochem. Genet.* 21: 375-90).

*odsy*: see *os*

*Of*: see *Dl<sup>Of</sup>*

**\*Off: Off**

**location:** 2-82.

**origin:** Spontaneous.

**discoverer:** Bridges, 23e14.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 232.

**phenotype:** Some bristles missing in heterozygotes, especially from side of abdomen; basal rings remain as in *H.* Homozygote lacks more bristles. Eyes large, creased, and roughened. RK2.

**other information:** Agrees with *abr* in locus and description; may have been an allele.

**ogre: optic ganglia-reduced (J.C. Hall)**

**location:** 1-18.8.

**references:** Niklas and Cline, 1983, *Genetics* 103: 617-631.

Lipshitz and Kankel, 1985, *Dev. Biol.* 108: 50-77.

Watanabe and Kankel, 1990, *Genetics* 126: 1033-44.

**phenotype:** Original allele (*ogre*<sup>1</sup>) recovered on the basis of simple lethality (Niklas and Cline, 1983); viable mutant (*ogre*<sup>2</sup>) isolated with respect to inability of adults to orient to vertical line of black-white contrast (Lipshitz and Kankel, 1985); optic lobes generally disorganized, as seen in adults expressing the viable allele, or in late pupae/pharate adults expressing a lethal allele; such lethals (all except *ogre*<sup>2</sup>) cause the behavioral and anatomical abnormalities just noted when heterozygous with viable allele; viability associated with one of these heteroallelic types, *i.e.*, *ogre*<sup>1</sup>/*ogre*<sup>2</sup> is poor, especially when reared at 18°C (*vs* 29°C); temperature shift experiments using this combination implies gene action in late larval stage; hemizyosity for lethal alleles causes development to cease in late larval-pupal stages, when parts of CNS appear abnormal (*e.g.*, holes in sections of brain and thoracic ganglia, with severe defects appearing in the optic lobe formation centers); holes in CNS are also seen in "escapers", *e.g.*, rare adults hemizygous for alleles other than *ogre*<sup>2</sup>, or heterozygous for *ogre*<sup>1</sup> and *ogre*<sup>2</sup>; mosaic analysis suggests that CNS defects are due to action of this gene in those developing tissues (Lipshitz and Kankel, 1985).

**alleles:** Five mutant alleles, four of which are embryonic lethal.

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>ogre</i> <sup>1</sup>	EMS	Niklas	<i>l(1)jnL3</i>	3

<sup>α</sup> 1 = Kankel and Lipshitz, 1981, *Proc. 7th Int. Symp. Div. Biophys. The Taniguchi Foundation* (Y. Hotta, ed.), pp. 215-38; 2 = Lipshitz and Kankel, 1985, *Dev. Biol.* 108: 56-77; 3 = Niklas and Cline, 1983, *Genetics* 103: 617-31; 4 = Schalet, 1986, *Mutat. Res.* 163: 115-44; 5 = Watanabe and Kankel, 1990, *Genetics* 126: 1033-44.

<sup>β</sup> *vcb* = viable contrast blind.

**cytology:** Placed in 6E2-4 based on its inclusion in *Df(1)Sxl-bt = Df(1)6E2;7A6* but not *Df(1)HA32 = Df(1)6E4-5;7A6*.

**molecular biology:** Isolated (Watanabe and Kankel, 1990) by walking distally from clone mapping to 6E4-5. Walk crosses distal breakpoints of *Df(1)HA32 (= ogre<sup>+</sup>)* and of *Df(1)Sxl-bt (= ogre<sup>-</sup>)*, which are 70 kb apart. Five tran-

scripts from this interval were detected on Northern blots of RNA from embryos and larvae; one mRNA of 2.9 kb was reduced in abundance in larvae hemizygous for *ogre*<sup>1</sup>; precise mapping of the *ogre*<sup>5</sup> deletion indicated it would be missing at least part of this 2.9 kb transcript (and two other RNAs, including an 1.35 kb species). Transformation with a 12.5 kb genomic fragment, which should include the source of the 2.9 kb mRNA, rescues *ogre*-associated lethality and the optic lobe abnormalities that can be seen in pharate adults expressing *ogre*<sup>1</sup>; these transformants, in an *ogre*<sup>5</sup> genetic background, exhibit restoration of the entire 2.9 kb, but only part of the 1.35 kb mRNA. cDNAs were cloned from embryonic libraries, and sequencing of the largest insert (2.45 kb) indicated that it can encode the entire protein, a 362-amino-acid polypeptide; features of the conceptual translation product include a putative membrane spanning region and a potential glycosylation site; there were no significant similarities, in data bases, to the *ogre* sequence.

**okr: okra (T. Schüpbach)**

**location:** 2-1.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females lay eggs which are of variable shapes; in the most extreme cases, the eggs are longer than normal, more pointed at the posterior end, and lack dorsal appendages, resembling eggs produced by the dominant female-sterile mutation *Fs(2)D*.

**alleles:** Two, *okr<sup>RU</sup> = okr<sup>1</sup>*, *okr<sup>WS</sup> = okr<sup>2</sup>*.

**olfA: olfactory-A (J.C. Hall)**

**location:** 1-21.0 (from cytology; maps between *ct* and *sn* meiotically).

**origin:** Induced by ethyl methanesulfonate.

**references:** Rodrigues and Siddiqi, 1978, *Proc. Indian Acad. Sci. B* 87: 140-60.

Rodrigues, 1980, *Development and Neurobiology of Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 361-69.

Venard and Pichon, 1984, *J. Insect Physiol.* 30: 1-5.

Venard, Antony, and Jallon, 1989, *Neurobiology of Sensory Systems* (Singh and Strausfeld, eds.). Plenum Press, New York, pp. 377-85.

Ayyub, Paranjape, and Siddiqi, 1990, *J. Neurogenet.* 6: 243-62.

**phenotype:** Larvae and adults are relatively poorly repelled by aldehydes (Rodrigues, 1980; benzaldehyde usually employed in the relevant Y-tube/olfactometric tests); strongest allele, in this regard is *olfA<sup>x1</sup>*, and yet it still detects these odorants (Ayyub *et al.*, 1990). Responses to ethyl acetate, acetone, acetic acid, and ethanol are normal (first of these tested in adults and larvae, the latter three only in larvae). In odor-induced jump assay, mutants show about half-normal frequency

of such responses (Ayyub *et al.*, 1990). Electroantennogram recordings from adults indicate somewhat reduced response to benzaldehyde, but normal ones to butanol and butyl acetate (Venard and Pichon, 1984). The physiological defect seen, with benzaldehyde as the stimulus, involves a biphasic dose-response curve (Venard *et al.*, 1989), as if there are two kinds of antennal receptors for this substance, only one of them being affected by *olfA*.

<i>olfA</i> <sup>x25</sup>	Ayyub	3

<sup>α</sup> 1 = Rodrigues, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 361-69. 2 = Ayyub, Paranjape, and Siddiqi, 1990, J. Neurogenet. 6: 243-62.

**cytology:** Maps to 7B8-D1 (Ayyub *et al.*, 1990), based on its inclusion in the region of overlap of  $Dp(1;2)sn^+72d = Dp(1;2)6C;7C9-D1$  and  $Dp(1;3)sn^{13al} = Dp(1;3)7A8;-8A5$  and its complementation by  $Df(1)ct268-42 = Df(1)7A5-6;7B8-C1$ .

**other information:** Original group of these mutations reported initially by Rodrigues and Siddiqi (1978), but not then noted as "*olfA*" (see Rodrigues, 1980, and subsequent references listed above). *olfA* alleles complement the closely linked *olfC* and *olfE* mutations.

***olfB*: olfactory-B (J.C. Hall)**

**location:** 1-{0.5}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Rodrigues.

**references:** Rodrigues and Siddiqi, 1978, Proc. Indian Acad. Sci. B 87: 147-60.

Rodrigues, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 361-69.

Ayyub, Paranjape, Rodrigues, and Siddiqi, 1990, J. Neurogenet. 6: 243-62.

**phenotype:** Similar phenotype to *olfA* (Rodrigues, 1980), but subnormal responses of larvae or adults to aldehydes [benzaldehyde and formaldehyde plus salicylaldehyde as well (Ayyub *et al.*, 1990)] seen only after rearing at 28° (permissive temperature in these tests, first performed by Rodrigues, 1980, extended by Ayyub *et al.*, 1990, was 22°). Larvae and adults grown at non-permissive temperature normal in responses to ethyl acetate, acetic acid, ethanol and acetone (Ayyub *et al.*, 1990). Physiological responses of antennae to aldehydes briefly noted to be normal by Siddiqi [1984, Genetics, New Frontiers (Chopra, Sharma, Joshi, and Bansal, eds.). Oxford and IBH Publishing Co., New Delhi, Vol. III, pp. 243-61].

**alleles:** One mutant allele, *olfB*<sup>x4</sup>.

**cytology:** Maps to 2B17-C2 (Ayyub *et al.*, 1990), based on complementation by  $Df(1)w-vco$  (2C1;3C5) but not by  $Dp(1;3)w^{vco}$  (2B17-C1;3C5-6;77D3-5;81).

**other information:** Complements *olfA*, *olfE*, and *olfF*. The one extant mutant allele, now known as *olfB*<sup>x4</sup>, originally reported by Rodrigues and Siddiqi (1978), but not then called *olfB* (see Rodrigues, 1980).

***olfC*: olfactory-C (J.C. Hall)**

**location:** 1-21.0. (from cytology, meiotically maps between *cv* and *sn*, closer to the latter).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Rodrigues.

**references:** Rodrigues and Siddiqi, 1978, Proc. Indian Acad. Sci. B 87: 147-60.

Rodrigues, 1980, Development and Neurobiology of *Drosophila* (Siddiqi, Babu, Hall, and Hall, eds.). Plenum Press, New York, pp. 361-69.

Tompkins and Hall, 1981, Z. Naturforsch 36c: 694-96.

Mane, Tompkins, and Richmond, 1983, Science 222: 419-21.

Venard and Pichon, 1984, J. Insect Physiol. 30: 1-5.

Curcillo and Tompkins, 1987, Behav. Genet. 17: 81-86.

Venard, Antony, and Jallon, 1989, Neurobiology of Sensory Systems (Singh and Strausfeld, eds.). Plenum Press, New York, pp. 377-85.

Ayyub, Paranjape, Rodrigues, and Siddiqi, 1990, J. Neurogenet. 6: 243-62.

**phenotype:** Adults show poor responses to acetates and acetone, and have diminished responses to some alcohols, in tests involving Y-tube olfactometer (Rodrigues, 1980). Odor-induced jump assays on *olfC*<sup>x3</sup> and *olfC*<sup>x17</sup> adults (Ayyub *et al.*, 1990) gave results paralleling those using olfactometer (whereby these mutants are in one of two different "acetate defective" categories; see alleles). Larvae respond abnormally to acetates and normally to aldehydes (Rodrigues, 1980). Electroantennograms (EAGs) recorded from adults show *olfC* to exhibit diminished responses of olfactory receptors to acetates (Venard and Pichon, 1984) and to 2-butanone as well (Venard *et al.*, 1989). Similar physiological [Siddiqi, 1984, Genetics: New Frontiers (Chopra, Sharma, Joshi, and Bansal, eds.). Oxford and IBH Publishing Co., New Delhi, Vol. III, pp. 243-61], and also behavioral (Rodrigues, 1980), experiments involving pairs of odorants, *e.g.* ethyl and iso-amyl acetate, suggested more than one independent "channel" for the reception of these substances. In SEM observations (Venard *et al.*, 1989) mutant antenna seems to have normal number and distribution of the three kinds of sensilla on the anterior face of the funiculus (from where EAGs recorded). Electrophoresis of triton extracts of antennae generates an extra band of esterase activity in *olfC*, which is found in neither wild-type nor in mutant thoraces and abdomens (Venard *et al.*, 1989). *olfC* males fail to have their courtship of wild-type males inhibited by high concentrations of volatile compounds (unlike normal males, which are inhibited). Mutant males court other males with abnormally high vigor yet court females with subnormal intensity (Tompkins *et al.*, 1981). Further studies showed that the mutant courts immature males vigorously (as do wild-type males), and this wanes as the courtee ages, but not to the same extent as in normal pairings; the inappropriately high levels of *olfC* courtships directed at maturing males includes all sex behaviors except attempted copulation (Curcillo and Tompkins, 1987). An inability of mutant males to discriminate between recently mated and virgin females was reported by Mane *et al.* (1983), who also showed that *olfC* males can detect, 6 hours post insemination, a difference between females mated to *Est-6*<sup>0</sup> males *vs.* males carrying a non-null allele of this gene (the latter kind of mated females were said to be relatively inhibi-

tory to male courtship); these experiments suggested that the enzyme encoded by *Est-6* turns a "pre-anti-aphrodisiac" compound, cis-vaccenyl acetate, which is transferred from males to females during copulation into a further, or the actual aphrodisiac, cis-vaccenyl alcohol; some elements of such results and inferences (Mane *et al.*, 1983) have been called into question (Vander Meer, Obin, Zawistowski, Sheehan, and Richmond, 1986, *J. Insect Physiol.* 32: 681-86; Scott and Richmond, 1987, *J. Insect Physiol.* 33: 363-69) but argued by others [Ferveur, Cobb, and Jallon, 1989, *Neurobiology of Sensory Systems* (Singh and Strausfeld, eds.). Plenum Press, New York, pp. 377-85, pp. 397-409] to still have force, at least insofar as an anti-aphrodisiac role for cis-vaccenyl acetate goes.

**alleles:**

<i>olfC<sup>x2</sup></i>	Rodrigues	reduced attraction to both ethyl and iso-amyl acetate
<i>olfC<sup>x3</sup></i>	Rodrigues	reduced attraction to both ethyl and iso-amyl acetate
<i>olfC<sup>x5</sup></i>	Rodrigues	normal response to ethyl acetate; reduced to iso-amyl acetate
<i>olfC<sup>x10</sup></i>	Rodrigues	like <i>olfC<sup>x2</sup></i> and <i>olfC<sup>x3</sup></i>
<i>olfC<sup>x13</sup></i>	Rodrigues	not mentioned anymore by Ayyub <i>et al.</i> (1990)
<i>olfC<sup>x14</sup></i>	Ayyub	like <i>olfC<sup>x5</sup></i>
<i>olfC<sup>x17</sup></i>	Ayyub	like <i>olfC<sup>x5</sup></i>

**cytology:** Maps to 7D1-6 (Ayyub *et al.*, 1990); *olfC<sup>x3</sup>* and *olfC<sup>x17</sup>* uncovered by *Df(1)C128 = Df(1)7D1;7D5-6*.

**other information:** Originally isolated (Rodrigues and Siddiqi, 1978) in the same "then-unnamed" manner as *olfA*, *olfB* and *olfD* (the latter = *sbl*). *olfC<sup>x3</sup>* over *olfC* deletion behaves with same poor responses to acetates as does homozygous mutant; however, *olfC<sup>x17</sup>* female hemizygotes defective in responses to both ethyl and iso-amyl acetates, whereas, this allele in homozygous females allows for normal responses to ethyl acetate. Mutagenesis of *olfC<sup>x17</sup>* led to some strains with "stronger" acetate-based olfactory deficit than the starting mutant. In one of these called *olfC<sup>x17-1a</sup>*, responses to iso-amyl acetate worse than in *olfC<sup>x17</sup>*, and the new strain also shows reduction in responses to benzaldehyde; both of these abnormalities covered by *Dp(1;2)sn<sup>+</sup>72d = Dp(1;2)6C;7C9-D1* and uncovered by *Df(1)ct-J4 = Df(1)7A2-3;7C1*, apparently placing this novel genetic defect in 7A2-C1, a region separate from *olfC*.

*olfD*: see *sbl*

***olfE: olfactory-E* (J.C. Hall)**

**location:** 1-{21.0}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Ayyub.

**references:** Hasan, 1989, *J. Genet.* 68: 139-46.

Ayyub, Paranjape, Rodrigues, and Siddiqi, 1990, *J. Neurogenet.* 6: 243-62.

Hasan, 1990, *Proc. Nat. Acad. Sci. USA* 87: 9037-41.

**phenotype:** Larvae and adults show reduction in responses to benzaldehyde in petri-plate-based and Y-tube olfactometric assays, respectively. In odor-induced-jump assay (using benzaldehyde), mutants jump less than half as often as normal flies.

**allele:** There is one extant allele, *olfE<sup>x26</sup>*.

**cytology:** Best estimate of location is 7C9;7D1 (Ayyub *et al.*, 1990; Hasan, 1989, 1990). The gene is covered by *Dp(1;2)sn<sup>+</sup>72d = Dp(1;2)7B1;8A5*. It is also covered by *Dp(1;3)sn<sup>13a1</sup> = Dp(1;3)6C5;7C9;79E* and uncovered by *Df(1)C128 = Df(1)7D1;7D5-6*, rearrangements that overlap according to molecular data.

**molecular biology:** Cloned by Hasan (1989, 1990) using chromosomal walking beginning with *sn*-region probes. Southern-blot mapping of proximal breakpoint of *Dp(1;3)sn<sup>13a1</sup>* and the distal breakpoint of *Df(1)C128* defines a 25 kb interval that includes *olfE* (see cytology). A 5.4 kb transcript detected with a probe relatively near (but distal to) the 7D9 breakpoint of *Dp(1;3)sn<sup>13a1</sup>*, is believed to represent *olfE* mRNA (Hasan, 1990). This transcript is found throughout the life cycle; it is in the head and bodies of adults. Another mRNA of 1.7 kb hybridizes to probes that detect the 5.4 kb transcript. A 14 kb genomic fragment that includes the 5.4 kb transcript partially rescued olfactory defects. In jump assays, more normal phenotypes were obtained, when the DNA insert was homozygous; in Y-tube tests, homozygosity was required for any appreciable rescue.

**other information:** *olfE* complements *olfA*, *olfB*, and *olfF*. The closely-linked mutants *olfA* and *olfE* are both impaired in their responses to benzaldehyde.

***olfF: olfactory-F* (J.C. Hall)**

**location:** 1-{1}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Ayyub.

**references:** Ayyub, Paranjape, Rodrigues, and Siddiqi, 1990, *J. Neurogenet.* 6: 243-62.

**phenotype:** Compared to wild-type flies, *olfF* adults require a higher concentration of benzaldehyde for detection in Y-tube olfactometer (e.g. no response at a dilution of 10<sup>-5</sup>, which readily repels wild-type flies). Mutant shows normal responses to acetates, propionic acid and butanol. *olfF/Df(1)w-vco* females are fertile.

**alleles:** There is one extant allele, *olfF<sup>x267</sup>*.

**cytology:** Located in 2E1-3C2 since uncovered by *Df(1)64c18 = Df(1)2E1-2;3C2*.

**other information:** *olfF* complements *olfA*, *olfB*, and *olfE*.

*olive-2*: see *sp*

*olv<sup>D</sup>*: see *dp<sup>D</sup>*

**\*om: ommatidia**

**location:** 1-0.1 (to the right of *sc*).

**origin:** X ray induced in (or with) *ac<sup>3</sup>*.

**discoverer:** Muller.

**references:** Muller, Prokofyeva, and Raffel, 1935, *Nature* 135: 253-55.

Muller, 1935, *DIS* 3: 30.

**phenotype:** Ommatidia disarranged, giving a slight eye roughness difficult to classify. RK3.

**cytology:** Thought by Muller to be in or very close to 1C1.

***omb: optomotor-blind* (J.C. Hall)**

**location:** 1- {7.5}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg.

**synonym:** *omb<sup>H31</sup>*; *opm31*.

**references:** Heisenberg, Wonneberger, and Wolf, 1978, *J. Comp. Physiol.* 124: 287-96.

Blondeau and Heisenberg, 1982, *J. Comp. Physiol.*

145: 321-29.

Bausenwein, Wolf, and Heisenberg, 1986, *J. Neurogenet.* 3: 87-109.

Pflugfelder, Schwartz, Roth, Poeck, Sigl, Kerscher, Jonschker, Pak, and Heisenberg, 1990, *Genetics* 126: 91-104.

**phenotype:** Adults expressing *omb*<sup>1</sup>, the only allele studied in phenotypic detail, are impaired in optomotor turning responses in tests involving tethered or freely moving flies (Heisenberg *et al.*, 1978; Blondeau and Heisenberg, 1982; Kulkarni, Steinlauf, and Hall, 1988, *Genetics* 118: 267-285; Dushay, Rosbash, and Hall, 1989, *J. Biol. Rhythms* 4: 1-27). The mutant is also aberrant in orientation to vertical stripe (Heisenberg *et al.*, 1978). More detailed examination of "yaw torque" optomotor responses show that *omb*<sup>1</sup> is restricted in responses to stimulation of "frontal visual field", with mutant behavior summarized as retaining "object responses" but missing "large field responses" (Bausenwein *et al.*, 1986). The mutant is relatively normal in "lift/thrust" response to vertical pattern movement and in regard to landing response elicited by front-to-back horizontal motion. Slow phototaxis, using Y-tube, was markedly subnormal (Dushay *et al.*, 1989). Giant arborizing fibers in lobula plate. Since isolation and the original histological examinations, anatomical abnormalities have become more pronounced, *e.g.*, the optic lobes remain in "pre-imaginal" orientation in some *omb* adults, *viz.*, long axis of medulla optic ganglia oriented more frontally than in wild-type (Blondeau and Heisenberg, 1982); other behavioral abnormalities: *omb* shows anomalous avoidance reaction, *i.e.*, "antifixation" to objects in Y-maze test (Bulthoff, 1982, *Biol. Cybernet.* 45: 63-70); courting males exhibit diminished tracking responses of and turning responses to moving females (Cook, 1980, *Biol. Cybernet.* 37: 41-51; Tompkins, Gross, Hall, Gailley, and Siegel, 1982, *Behav. Genet.* 12: 295-307). Visual stimulus-induced metabolic activity in the optic lobes (monitored by distribution of radioactive 2-deoxyglucose) is normal, suggesting that basic structure and function of ganglia distal to lobula plate is normal (Bulthoff and Buchner, 1985, *J. Comp. Physiol.* 156: 25-34). Without effect on locomotor activity rhythm (Helfrich, 1986, *J. Neurogenet.* 3: 321-43).

**alleles:** Only one viable allele, *omb*<sup>1</sup> (isolated as *omb*<sup>H31</sup>). A number of lethal rearrangements with breakpoints in 4C5-6 uncover *omb* along with other closely linked mutations.

**cytology:** Placed in 4C5-6 based on its inclusion in *Df(1)GA56 = Df(1)4C5-6;4D1* and *Df(1)rb13 = Df(1)4C5-6;4D3-E1* but not *Df(1)ovo6 = Df(1)4C5-6;4E2-3* or *Df(1)ovo7 = Df(1)4C5-6;4E2-3* (Pflugfelder *et al.*, 1990). Associated with *In(1)omb = In(1)4C4-7;12D2-E1*.

**molecular biology:** Located in an 340-kb walk initiated from polytene bands microdissected from 4B-C (Pflugfelder *et al.*, 1990). Seven *omb*<sup>-</sup> breakpoints identified in a 80-kb subsegment; in distal-to-proximal order, they are *T(1;3)bi*<sup>D1</sup>, *Tp(1;1)bi*<sup>D1</sup> (which contains a 30 kb insert within the *omb* region), *T(1;2)bi*<sup>D2</sup>, *In(1)omb*, *Df(1)GA56*, *Df(1)rb13*, and *Df(1)rb5*; these are spread over a distance of 80 kb. The distal breakpoint of *Df(1)ovo7* (which is *omb*<sup>+</sup>) is 15 kb proximal to that of *Df(1)rb5* (which is *omb*<sup>-</sup> and was mapped within 4C5-6

by Southern blots, though no cytological breakpoints for it are given). Northern blot probes (Pflugfelder *et al.*, 1990), encompassing all breakpoints that cause an *omb* phenotype, detected two transcripts that could be associated with the *omb* function. T3 (6 kb) and T7 (an approximately 2-kb smear); the genomic sources of these RNAs are 80 kb apart; they are most prominent in mid-embryos, late L3, early pupae, and adults; another fainter transcript (T7'), with a similar developmental profile, comes from a more proximal region to the right of the *In(1)omb* breakpoint. There are also several additional low-abundance embryonic/pupal transcripts that map between two relatively distal *omb*<sup>-</sup> breakpoints. Various cDNAs have been cloned, including those representing T3 and T7; the modest amount of sequencing done, as of Pflugfelder *et al.* (1990), revealed no significant matches.

**other information:** Two EMS-induced lethals with no physically detectable lesions within the relevant portion of the walk noted above fail to complement *bi*, *Qd*, *lac*, *omb*, and *l(1)bi*, the designation applied to the lethality of several of the rearrangements in the region; these complementation groups overlap the distal 20 kb of the *omb* region. The lethals are designated *l(1)omb*<sup>282</sup> and *l(1)omb*<sup>3198</sup> by Pflugfelder *et al.* (1990), but the law of parsimony suggests that they be designated *l(1)bi*<sup>1</sup> and *l(1)bi*<sup>2</sup>, respectively. Other observations suggesting that the *omb* region is genetically complex (Pflugfelder *et al.*, 1990) are exemplified by the fact that *l(1)bi*<sup>1</sup>/*Qd* females have lacquered wings.

#### **ome: omega**

**location:** 3-36.

**origin:** Induced by ethyl methanesulfonate.

**references:** Chihara and Kimbrell, 1986, *Genetics* 114: 393-404.

**phenotype:** In the presence of homozygous *omega*, larval cuticle protein 5 migrates more slowly, irrespective of the *Lcp5* alleles present; migration of the residual *Lcp5* bands also altered. *omega*<sup>+</sup> product postulated to play a role in modifying the *Lcp5* gene product.

#### **oml: ommatidiless**

**location:** 1-31.

**origin:** X ray induced.

**discoverer:** Ritterhoff.

**references:** Biggin, 1969, *DIS* 44: 49.

**phenotype:** Expression varies from normally shaped eyes with displaced facets to complete absence of eyes; variable penetrance; ventral part of eye most often affected. 10% of flies show palps in epidermis that replaces missing eye tissue; 5% show reduced head, fused ocelli, and abnormal antennae.

#### **omm: ommatoreductum**

**location:** 1-12.8.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1953.

**references:** 1958, *DIS* 32: 72.

**phenotype:** Some peripheral ommatidia absent, frequently in an irregular manner, giving a rough eye and a notched border. Shape of head abnormal; head bristles deranged or absent. Palps absent or deformed. Thoracic bristles deranged. Wings often unexpanded. Good viability and fertility in both sexes. RK2.

**other information:** One allele each induced by CB. 1246,

CB. 1522, CB. 1592, CB. 1528; two alleles induced by CB. 3026.

**ommatidia:** see *om*

**ommatidiless:** see *oml*

**ommatoeductum:** see *omm*

**\*On: Open**

**location:** 3-26.

**origin:** X ray induced.

**discoverer:** Tanaka, 36c26.

**references:** 1937, DIS 7: 21.  
1937, DIS 8: 11.

**phenotype:** Wings spread. Homozygous viable. RK2.

**\*op: opaque**

**location:** 1-50.

**origin:** X ray induced.

**discoverer:** H. M. Miller, 33k.

**references:** 1934, DIS 2: 9.  
1935, DIS 3: 14.  
1935, DIS 4: 10.

**phenotype:** Wings opaque and whitish, usually divergent and slightly convex. Viability and fertility good in male, poorer in female. RK3.

**opa: odd paired**

**location:** 3-48.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

**phenotype:** Deletes alternate metasegments, as defined by a line separating the anterior from the posterior parts of the anterior compartments; portions of denticle bands of T2, A1, A3, A5, and A7 and naked cuticle of T3, A2, A4 and A6 missing. Pattern of *Ubx* protein distribution in the double-sized units reveals them to be composite, the anterior half being derived from an odd-numbered parasegment and the posterior half from an even-numbered parasegment (read metasegment) (Ingham and Martinez-Arias, Nature 324: 592-97). Without discernable effect on *ftz* expression (Carroll and Scott, 1980, Cell 45: 113-26). However, exhibits loss of *en* product with a consequent increase in *Ubx* expression in even-numbered parasegments (Martinez-Arias and White, 1988, Development 102: 325-38).

**alleles:** Nine ethyl methanesulfonate-induced alleles, *opa*<sup>1</sup>-*opa*<sup>9</sup>, isolated as *5H*, *7N*, *9C*, *9O*, *13D*, *E8*, *IIC*, *IIP*, and *T* (Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69).

**cytology:** Placed in 82A-E; between autosomal breakpoints of *T(Y;3)J17 = T(Y;3)Xhy<sup>+</sup>;82A* and *T(Y;3)D107 = T(Y;3)h7;82E*.

**opaque:** see *op*

**\*opb: opaque broad**

**location:** 1-28.3.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 88.

**phenotype:** Short, broad, and opaque wings with slightly

convex or concave membranes. Slightly brownish eye color. Legs short with long segments frequently bowed. Abdomen slightly abnormal in shape; genitalia deformed. Males fertile; viability about 10% wild type. Females sterile. RK3.

**Open:** see *On*

**\*oph: ophthalmopedia**

**location:** 2-45.

**origin:** Spontaneous.

**discoverer:** Gordon, 1934.

**references:** 1936, J. Genet. 33: 25-60.  
1941, DIS 14: 39.

**phenotype:** In extreme form, an appendage grows from eye; in less extreme form, eye is kidney shaped. Expression sensitive to genetic and environmental modification. Effect caused by enlargement and abnormal folding of eye-forming portion of optic disk in late larvae [Waddington and Pilkington, 1943, J. Genet. 45: 44-50 (fig.)]. Disc development autonomous in reciprocal transplants with wild type (Abaturova and Ginter, 1968, Genetika 4(11): 58-64); partial *oph* disks display reduced mutant development when transplanted into wild-type hosts (Ginter and Abaturova, 1969, Genetika 5(10): 38-43). RK3.

**oph: ophthalmoptera**

**location:** 1-5.

**origin:** Spontaneous.

**references:** Ouweneel, 1970, Genetica 41: 1-20.

**phenotype:** A semidominant enhancer of *ld* and *Dfd*<sup>r</sup> and perhaps other eye-shape mutants. In the presence of *oph*, flies bearing the above mutants produce wing-like outgrowths in the eye. Expression more extreme at 17° than at 29°; temperature sensitive period in second- and third-instar larvae (Postelthwaite, 1974, Dev. Biol. 36: 212-17).

*opm24*: see *t*<sup>H24</sup>

*opm37*: see *elf*

*opm47*: see *nbA*

*opm52*: see *norpA*

**Opt: Ophthalmoptera**

**location:** 2-68 (based on progeny testing of 32 *Bl-c* recombinants from *Opt<sup>B</sup>/Bl c* females).

**phenotype:** A homeotic modifier of *ey*<sup>2</sup> and possibly other small-eye mutants (e.g., *ey<sup>D/+</sup>*). In the presence of *Opt*,

*ey*<sup>2</sup> flies exhibit protrusions of wing tissue from the region of the eye; development is normal at 17°, but homeotic transformation is observed at 29°; the temperature-sensitive period is during the second larval instar [Postlethwait, 1974, *Dev. Biol.* 36: 212-17 (fig.)]. Protrusions from the anterior portion of the eye have the triple row of bristles characteristic of the anterior wing margin; the fronto-orbital region of the head produces bristles with bracts characteristic of the costa in the proximal wing (Postlethwait).

**alleles:**

*ora*: see *ort*

Double mutant *ort<sup>1</sup> ninaE<sup>1</sup>* described as *ora<sup>JK84</sup>*; components separable by recombination.

**ora transientless:** see *ort*

**ord: orientation disruptor (R.S. Hawley)**

**location:** 2-103.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Baker and Hall, 1976, *The Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 352-434.

Mason, 1976, *Genetics* 84: 545-72.

Baker, Carpenter, and Ripoll, 1978, *Genetics* 90: 531-78.

Goldstein, 1980, *Chromosoma* 78: 79-111.

**phenotype:** In females homozygous for *ord*, exchange is strongly reduced. In both males and females, *ord* causes

a dramatic increase in both reductional and equational nondisjunction as assayed genetically. In male meiosis, Goldstein observed abnormal sister-chromatid associations during prophase as well as precocious sister-chromatid separation, followed by random disjunction during anaphase I. "The bulk of the first division misbehavior consists of sister chromatids' disjoining from one another, a process which normally occurs only during the second meiotic division" (Goldstein). *ord* also elevates the frequency of mitotic chromosome misbehavior (Baker *et al.*, 1978). "A substantial proportion of this mitotic instability can be accounted for by a hypothesis in which *ord* causes precocious sister-chromatid separation, followed by random disjunction, in somatic as well as germline cells" (Goldstein). Thus the *ord* locus likely specifies a function required for sister-chromatid cohesion during most or all cell divisions.

**cytology:** Placed in 59B-D by Mason (1976). Further confined to 59D4-10 by deficiency analysis (Miyazaki and Orr-Weaver).

**ort: ora transientless (J.C. Hall)**

**location:** 2-66.4.

**origin:** Induced by ethyl methanesulfonate.

**references:** Koenig and Merriam, 1977, *DIS* 52: 50-51.

O'Tousa, Leonard, and Pak, 1989, *J. Neurogenet.* 6: 41-52.

**phenotype:** Electroretinogram lacks on-transient, and shows either no off-transient or a delayed one, occurring 100-150 milliseconds after the light coincident photoreceptor potential is elicited. Rhodopsin levels, prolonged depolarizing afterpotentials, and rhabdomere structure are normal in R1-6 photoreceptors of *ort* eyes, unlike the case of *ninaE* single or double mutants (see allele tables of *ort* and *ninaE*).

**alleles:**

allele	discoverer	synonym	ref <sup>α</sup>	comments

<sup>α</sup> 1 = Koenig and Merriam, 1977, *DIS* 52: 50-51; 2 = O'Tousa, Leonard, and Pak, 1989, *J. Neurogenet.* 6: 41-52.

**cytology:** Located at 92A4-B1 (O'Tousa *et al.*, 1989).

Uncovered by *Df(3R)I2 = Df(3R)92A4-11;92D2-8*; complemented by *Df(3R)B16 = Df(3R)92A11-B1;92E10-F2*.

**other information:** *ort<sup>1</sup>* has been placed to the left of *ninaE<sup>1</sup>* by recombinational separation of the two genes (O'Tousa *et al.*, 1989) as well as by cytological location. (For further discussion of these genes, see *ninaE*).

**orthodenticle:** see *otd*

**os: outstretched small eye**

**location:** 1-59.2.

**origin:** X ray induced.

**discoverer:** Abrahamson, 1953.

**synonym:** *odsy*.

**references:** Verderosa and Muller, 1954, Genetics 39: 999.

**phenotype:** Wings held virtually at right angles to body. Eyes small and rounded. *os/os<sup>o</sup>* has wing effect but eyes normal. *os/os<sup>s</sup>* has eye effect but wings normal. RK1.

**cytology:** Localized to 17A5-6 (Laughnan).

**other information:** Originally considered two separate loci, *od*: outstretched and *sy*: small eye, Muller proposed a single gene based on the recovery of a mutant with both phenotypes, which was not resolvable into two components by recombination as well as on the failure to recover recombinants between *od* and *sy* in *trans* heterozygotes (Verderosa and Muller).

***os<sup>bdw</sup>*: outstretched small eye-bending wings**

**origin:** X ray induced.

**discoverer:** Halfer, 1960.

**synonym:** *bdw*.

**phenotype:** Wings divergent and drooping, size and shape normal. Males sterile. RK2A.

**cytology:** Associated with *T(1;3)os<sup>bdw</sup> = T(1;3)16E;80C*.

***os<sup>o</sup>*: outstretched small eye-outstretched**

Edith M. Wallace, unpublished.

***os<sup>o</sup>*: outstretched small eye-outstretched**

**origin:** X ray induced.

**discoverer:** Muller, 1930.

**synonym:** *od*.

**references:** 1930, J. Genet. 22: 303 (fig.).  
1935, DIS 3: 30.

Verderosa and Muller, 1954, Genetics 39: 999.

**phenotype:** Wings extremely divergent, often at right angles to body. *os<sup>o</sup>/os<sup>s</sup>* is wild type. RK1.

***os<sup>s</sup>*: outstretched small eye-small eye**

**origin:** Spontaneous.

**discoverer:** Bridges, 19g3.

**synonym:** *sy*.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 236.

**phenotype:** Eyes small and rounded, high on the head but not bulging. RK1.

***osa*: osa (J.A. Kennison)**

**location:** 3-60.0.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1983.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Isolated as a dominant suppressor of the antenna to leg transformation in *Pc<sup>2</sup> Antp<sup>Ns</sup>* double heterozygotes. Also acts as a dominant suppressor of *Antp<sup>Ns</sup>*, *Pc* and *Pcl* alleles. Recessive embryonic lethality associated with all alleles. Also fails to complement *In(3R)Antp<sup>rv1</sup>* for viability.

**alleles:** Four from ethyl methanesulfonate and three from P-M hybrid dysgenesis.

**cytology:** 90B1-90D1 based on its inclusion within the transposed segment of *Tp(3;3)S462 = Tp(3;3)64C-E;89D1-2;90D1* but not within the transposed segment of *Tp(3;1)bxdl11 = Tp(3;1)AD;89E;90B2* and its failure to complement *In(3R)Antp<sup>rv1</sup> = In(3R)81F;90B-C*.

**\**osh*: outshifted**

**location:** 1-33.0 (no crossover with *v* in 997 chromosomes).

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 73.

**phenotype:** Wings shortened and often slightly divergent. Body and wings pale in color. Eyes somewhat smaller and browner than normal. Viability and fertility good in both sexes. RK2.

***osk*: oskar**

**location:** 3-48 (distal to *p* and *hb*).

**references:** Lehmann and Nüsslein-Volhard, 1986, Cell 47: 141-52.

**phenotype:** Homozygous females normally viable and fecund; homozygous males fertile. Embryos produced by homozygous females lack pole plasm and fail to produce pole cells; abdominal region remains unsegmented and eventually dies. Temperature-sensitive period for the germ-line effect is the last six hours of oogenesis and for abdominal development the last twelve to fourteen hours (*osk<sup>s</sup>*). Homozygous *osk* germ cells autonomous in pole cell transplants. Polar cytoplasm from unfertilized eggs or normal embryos capable of rescuing pole cell formation if injected at the posterior extremity of the early embryo and abdominal segmentation, to the extent of producing viable but sterile adults, if injected into the posterior half of preblastoderm embryos. Embryos produced by homozygous *BicD*; *osk* females are indistinguishable from those produced by *osk* alone suggesting that *osk<sup>+</sup>* product is required for the formation of bicaudal embryos; also required for the early anterior-posterior gradient of *hb* expression (Tautz, 1988, Nature 332: 181-84).

**alleles:** Nine ethyl-methanesulfonate-induced alleles.

**ota1: olfactory-trap-abnormal-1 (J.C. Hall)**

**location:** 1-43.

**origin:** Induced by ethyl methanesulfonate.

**references:** Woodard, Huang, Sun, Helfand, and Carlson, 1989, Genetics 123: 315-26.

**phenotype:** Poor odor responses in tests involving an olfactory trap; entry into such traps was subnormal when odorant was food medium or ethyl acetate. Phenotype also subnormal in odor-induced jump responses (using ethyl acetate, propionic acid, or benzaldehyde as stimulant). Electroretinogram abnormal; very weak light induced depolarization and no light-on or light-off transients.

**cytology:** Maps to 12A6-13A5, owing to coverage of both olfactory and ERG defects by *Dp(1;f)LJ9*.

**ota2: olfactory-trap-abnormal-2 (J.C. Hall)**

**location:** 1-between *y* and *cv* (nearer to former).

**origin:** Induced by X-rays or ethyl methanesulfonate.

**references:** Woodard, Huang, Sun, Helfand, and Carlson, 1989, Genetics 123: 315-26.

**phenotype:** Abnormal trap-entry kinetics (*cf. ota1*), with food medium or ethyl acetate as stimulant (*ota2*<sup>1</sup> isolated using former, *ota2*<sup>2</sup> using latter). In odor induced jump tests *ota2*<sup>1</sup> responded normally to ethyl acetate, propionic acid, and benzaldehyde; but *ota2*<sup>2</sup> gave subnormal responses to the first two of these stimulants. ERG normal (both alleles).

**alleles:** Two alleles, *ota2*<sup>1</sup> (X-rays) and *ota2*<sup>2</sup> (formerly *ota4*). Allelism determined only by trap-entry behavior of the double heterozygote, *i.e.* no mapping data on *ota2*<sup>2</sup>.

**cytology:** Proximal to 1B14, because *ota2* not covered by *y*<sup>2</sup>*Y611* (duplicated from X distal tip to the site just noted).

**Ota3: Olfactory-trap-abnormal-3 (J.C. Hall)**

**location:** 1-( not localizable; see **other information**).

**origin:** Induced by ethyl methanesulfonate.

**references:** Woodard, Huang, Sun, Helfand, and Carlson, 1989, Genetics 123: 315-26.

**phenotype:** Abnormal trap-entry kinetics with ethyl acetate as stimulant (*cf. ota1*). In odor-elicited jump tests, subnormal responses occurred to ethyl acetate and propionic acid but not to benzaldehyde. ERG normal. Uppercase-ness of this gene's symbol stems from at least partial dominance associated with *Ota3*/+ females' trap-entry behavior.

**other information:** A map position for *Ota3* was not indicated by testing segregants from *y cv v flOta3* heterozygotes. Genetic origin of *Ota3* may be more complicated;

*Ota3* phenotype may not be the result of a single X-linked mutation.

**ota5: olfactory-trap-abnormal-5 (J.C. Hall)**

**location:** 1-unlocalized.

**origin:** Induced by ethyl methanesulfonate.

**references:** Woodard, Huang, Sun, Helfand, and Carlson, 1989, *Genetics* 123: 315-26.

**phenotype:** Males exhibit abnormal trap-entry kinetics with ethyl acetate as stimulant; not as subnormal (in these behavioral tests) as are the other *ota* genes. In odor-elicited jump tests with ethyl acetic or propionic acid as stimuli, however, *ota5* shows the same degree of impairment as *ota2*<sup>2</sup>, and like *ota2*<sup>2</sup>, shows normal jump responses to benzaldehyde. ERG normal. Homozygous *ota5* females behaved normally in the behavioral tests described.

**ota7: olfactory-trap-abnormal-7 (J.C. Hall)**

**location:** 1-between *y* and *cv* (nearer to former).

**origin:** Induced by ethyl methanesulfonate.

**references:** Woodard, Huang, Sun, Helfand, and Carlson, 1989, *Genetics* 123: 315-26.

**phenotype:** Abnormal trap-entry kinetics (*cf.* *ota1*) with ethyl acetate as stimulant. This phenotype is semi-dominant, as indicated from similar testing of *ota7/+* females. Odor-induced jump responses normal. ERG abnormal. The photoreceptor potential begins anomalously to decay to baseline soon after normal light-on transient appears; then renewed (cornea-negative) depolarization is observed (all of these dynamics observed during 0.5 second stimulus). Finally, a normal light-on transient is observed. The abnormal ERG phenotype, which co-segregates with subnormal trap-entry kinetics, is recessive.

**cytology:** Located proximal to 1B14, because the recessive ERG abnormality is not covered by *y*<sup>2</sup>*Y611*.

*otd*: see *oc*

**otu: ovarian tumor (R. King)**

**location:** 1-23.2.

**references:** King, Bahns, Horowitz, and Larramendi, 1978, *Int. J. Insect Morphol. Embryol.* 7: 359-75.

King and Riley, 1982, *Dev. Genet.* 3: 69-89.

King, Mohler, Riley, Storto, and Nicolazzo, 1986, *Dev. Genet.* 7: 1-20.

King and Storto, 1988, *BioEssays* 8: 18-24.

Mulligan, Mohler, and Kalfayan, 1988, *Mol. Cell. Biol.* 8: 1481-88.

**phenotype:** Homozygous females defective in proliferation, differentiation, or maturation of the germ line, depending on the level of activity of the particular allele. So-called quiescent alleles (QUI) produce ovarioles lacking in germ cells; oncogenic alleles (ONC) produce cystocytes that continue dividing and form tumors; differentiated alleles (DIF) produce chambers containing only "pseudonurse" cells (PNCs) or nurse cell/oocyte (NC/O) syncytia. In these, transport of nurse cell cytoplasm to the oocyte is inhibited and chambers are arrested at a pseudo-12 stage [Bishop and King, 1984, *J. Cell Sci.* 67: 87-119 (fig.)]. Mutant nurse cells that fail to pump their cytoplasm into the oocytes are also unable to form a system of actin microfilament bundles in their cortical cytoplasm during stage 10B (Storto and King, 1988, *Dev. Genet.* 9: 91-120). The proportions of ovarioles with the

different phenotypes appear to reflect the level of function of the particular allele; homozygotes are less severely affected than hemizygotes (80% of ovarioles of females carrying *otu*<sup>1</sup>, *otu*<sup>4</sup>, *otu*<sup>5</sup>, or *otu*<sup>7</sup> in combination with an *otu* deficiency lack germ cells, whereas 5% of the ovarioles of homozygotes lack germ cells); similarly, the levels of function of certain alleles decline as the developmental temperature is raised. Thus *otu*<sup>1</sup> behaves like a DIF allele at 18°, an ONC allele at 23°, and a QUI allele at 28°.

The ovarian tumors which give the mutant gene its name are made up of large numbers of single cystocytes and small numbers of clones of 2-4 interconnected cells [King, 1979, *Int. J. Insect Morphol. Embryol.* 8: 297-309 (fig.)]. Most cystocytes undergo complete cytokinesis, and there are defects in the construction and functioning of the polyfusomal system during the cycles of cystocyte divisions [Storto and King, 1989, *Dev. Genet.* 10: 70-86 (fig.)]. *Drosophila* nurse cells normally undergo nine or ten cycles of DNA replication (Mulligan and Rasch, 1985, *Histochemistry* 82: 233-47), and the chromatids dissociate so that each nucleus is filled with a jumbled mass of oligotene threads. In *otu* PNCs, the chromatids remain in register, generating banded polytene chromosomes [Dabbs and King, 1980, *Int. J. Insect Morphol. Embryol.* 9: 215-29 (fig.)]. Homologues pair and rearrangement configurations can be discerned [King, Riley, Cassidy, White, and Paik, 1981, *Science* 212: 441-43 (fig.)]. The largest polytenes have undergone 12 cycles of endonuclear replication (Rasch, King, and Rasch, 1984, *Histochemistry* 81: 105-10). The banding pattern of PNC polytenes is similar to that of the polytenes from larval salivary gland cells (Sinha, Mishra, and Lakhota, 1987, *Chromosoma* 95: 108-16; Heino, 1989, *Chromosoma* 97: 363-73).

At 25°, *otu*<sup>11</sup> behaves as an ONC allele, the cells dividing to form tumors, but at 18°, homozygous females produce oocytes that reach a pseudo-14 stage, contain beta yolk spheres and can undergo early embryogenesis. In the case of DIF alleles such as *otu*<sup>4</sup>, females generate pseudo-12 eggs which lack beta yolk spheres and never initiate development. When *otu*<sup>11</sup> is combined with alleles from the QUI class such as *otu*<sup>2</sup>, the heteroallelic females are sterile. Heteroalleles between *otu*<sup>11</sup> and certain DIF alleles show various degrees of fertility [Storto and King, 1987, *Roux's Arch. Dev. Biol.* 196: 210-21 (fig.)]. *otu*<sup>11</sup>/*otu*<sup>14</sup> females are fully fertile although the nurse cells, unlike those of wild-type females, contain banded chromosomes (Storto and King, 1988).

Oocyte differentiation is destabilized in certain *otu* alleles; for example, the presumptive oocytes in about 20% of *otu*<sup>7</sup> homozygotes resemble nurse cells in their polytenization, although they lag behind the remaining nurse cells by at least one replication cycle [King, Rasch, Riley, O'Grady, and Storto, 1985, *Histochemistry* 82: 131-34 (fig.)]. Germ line autonomy has been demonstrated for *otu*<sup>3</sup>, *otu*<sup>4</sup>, and *otu*<sup>7</sup> (Wieschaus, Audit, and Masson, 1981, *Dev. Biol.* 88: 92-103; unpublished work cited in King *et al.*, 1986).

**alleles:** 21 alleles are listed in the following table. Heteroallelic combinations usually produce intermediate

phenotypes, but some show partial complementation.

<sup>α</sup> 1 = Gans, Audit, and Masson, 1975, *Genetics* 81: 683-704; 2 = King, Mohler, Riley, Storto, and Nicolazzo, 1986, *Dev. Genet.* 7: 1-20; 3 = King and Riley, 1982, *Dev. Genet.* 3: 69-89; 4 = Mohler and Carroll, 1984, *DIS* 60: 236-41; 5 = Mulligan, Mohler, and Kalfayan, 1988, *Mol. Cell. Biol.* 8: 1481-88.

<sup>β</sup> P-elements in *otu*<sup>18</sup>, *otu*<sup>20</sup>, and *otu*<sup>21</sup> are of molecular sizes 2.9, 0.6, and 0.5 kb, respectively (Kalfayan, Walsh, Ousley, and Nishiharu, unpubl.).

**cytology:** Placed in 7F1 based on its inclusion in *Df(1)KA14 = Df(1)7F1-2;8C6* and its mapping genetically 0.4 cM to the left of *l(1)7Fa*<sup>10</sup> which is also placed in 7F1 (King *et al.*, 1986).

**molecular biology:** Identification of *otu* sequences based on the insertion of transposable sequences in the same *EcoRI* restriction fragment of a lambda clone from 7F1 into each of four hybrid-dysgenesis-induced *otu* alleles and the correlation between excision of these sequences and restoration of fertility in revertants of *otu18* and *otu19*. *otu17* contains a deletion of 2 kb in the restriction fragment distal to the fragment altered in the insertional alleles (Mulligan *et al.*, 1988). The *otu* gene is at least 4.6 kb long and is subdivided into seven introns and eight exons. The first and sixth introns are large (534 and 583 b, respectively); the others range in size from 53 to 68 b. The first exon specifies an untranslated leader which contains the ribosomal binding sites. The *otu* gene encodes at least two ovary-specific and four testis-specific mRNAs. The major ovarian message is 3.2 kb, while a minor message is 4.0 kb. The 3.2 kb mRNA, which is transcribed from exons 2 through 8, specifies a proline-rich protein, 811 amino acids long. Exons 2-6 encode segments of 76, 33, 51, and 46 amino acids, respectively. The largest exon (number 7) encodes 415 amino acids, while the eighth exon specifies 58 amino acids at the carboxyl end of the protein and a trailer which contains the binding site for the polyadenylating enzyme (Mulligan *et al.*, 1988; Steinhauer, Walsh, and Kalfayan, 1989, *Mol. Cell. Biol.*, 9: 5726-32).

Mével-Ninio, Mariol, and Gans, 1989, *EMBO J.* 8: 1549-58.

**phenotype:** All *ovo* alleles fully penetrant for female sterility; no male function for *ovo*<sup>+</sup> known. Lack of zygotic activity results in complete absence of germ-line cells in

adult female; reduction in numbers of germ cells first evident during early gastrulation. Homozygotes for weaker alleles produce germ cells, but oogenesis defective; egg chambers may degenerate prior to vitellogenesis or proceed through oogenesis and be oviposited, depending on allele; laid eggs are permeable to neutral red and never develop. Heterozygotes for two of the dominant alleles phenotypically similar to homozygotes for weak recessive alleles. Ovarian tumors formed in females carrying *ovo*<sup>D3</sup> in heterozygous combination with the hypomorphic alleles, e.g., *ovo*<sup>D1rv20</sup>, or with *fs(1)A1621*. The *ovo*<sup>D2</sup> mutation is partially suppressed by many *Sxl* alleles. *ovo*<sup>D1/+</sup> females produce no eggs; extensively utilized in the selection of *ovo*<sup>+</sup> germ-line clones.

**alleles:** Recessive alleles, mostly recovered as revertants of dominant alleles, usually but not always, simultaneously mutant for *svb* or *lzl*; some *svb* alleles also simultaneously mutant for *ovo*; *ovo* proximal to *svb* and distal to *rg* by deficiency analysis. Many revertants are homozygous lethal owing to their being simultaneously mutant for *svb*. The *lzl* eye phenotype is cold sensitive and semi-dominant. Most revertants are amorphic in that, when tested in heterozygous combination with *ovo*<sup>D1rv22</sup> or *ovo*<sup>D1rv23</sup>, they have atrophic ovaries, with no egg chambers observable.

<sup>α</sup> 1 = Busson, Gans, Komitopoulou, and Masson, 1983, Genetics 105: 309-25; 2 = Komitopoulou, Gans, Margaritis, Kafatos, and Masson, 1983, Genetics 105: 897-920; 3 = Mével-Ninio, Mariol, and Gans, EMBO J. 8: 1549-58; 4 = Oliver, Perrimon, and Mahowald, 1987, Genes Dev. 1: 913-23.

<sup>β</sup> Mutant alleles associated with *ovo*<sup>D</sup> revertants; coordinates from chromosomal walk of Mével-Ninio *et al.*; origin designated as *SalI* site just to the left of the *gypsy* insert of *ovo*<sup>D1rv30</sup>; positive values to the right.

**cytology:** Placed in 4E2 based on its inclusion in *Df(1)ovo6* = *Df(1)4C5-6,4E2-3* and *Df(1)bi-DL3* = *Df(1)3C7-12,4E1-2* but not *Df(1)bi-DL5* = *Df(1)3C7-12,4E1-2* (Oliver).

**molecular biology:** 32 kb of wild-type DNA containing *ovo*<sup>+</sup> has been cloned, using the transposing element *gypsy* as a tag; the position of the *ovo* locus was limited distally on the molecular map by the proximal breakpoint of *Df(1)bi-D2* = *Df(1)4B6-C1,4D7-E1* between coordinates -5 and -4 (Mével-Ninio *et al.*, 1989). Reversions of the dominant alleles *ovo*<sup>D1</sup> and *ovo*<sup>D3</sup> to recessive *ovo* alleles occurred in crosses to females carrying *gypsy* and the majority of these revertants carried insertions of *gypsy* and/or *copia* and other transposable elements; eleven spontaneous revertants contained a *gypsy*-element insert and one *copia* insert at coordinate 0.9; of the seven *gypsy*-induced revertants of *ovo*<sup>D1</sup>, four inserted in one orientation were associated with *lzl* mutations and the three inserted in the opposite orientation were not; *gypsy*-induced revertants of *ovo*<sup>D3</sup> were *lzl*<sup>+</sup> irrespective of orientation.

**p: pink**

**location:** 3-48.0 (proximal to *hb* and *dsx*).

**phenotype:** Eye color varies from pink to dull ruby with purplish tone depending on allele. Larval Malpighian tubules colorless. Color autonomous in *p<sup>P</sup>* optic disk allowed to undergo metamorphosis in a wild-type host (Beadle and Ephrussi, 1936, *Genetics* 21: 230).

**alleles:** Mutant alleles of *p* are listed in the following table, their phenotype in regard to eye color included if described in the literature.

*P6*: see *Fbp2*

**P37 (J. C. Hall)**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Deland and Pak.

**references:** Heisenberg and Götz, 1975, *J. Comp. Physiol.* 98: 217-41.

**phenotype:** Fast phototaxis not completely absent at high light levels. Optomotor response half as strong as in wild type. In flight, response to movement from front to back is disturbed. Poor fixation.

**P43 (J. C. Hall)**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Deland and Pak.

**references:** Heisenberg and Götz, 1975, *J. Comp. Physiol.* 98: 217-41.

Hall, 1982, *Quart. Rev. Biophys.* 15: 223-479.

**phenotype:** Holes in optic lobes and brain; lamina abnormal, but with general structure preserved (Pak, Heisenberg and Hengstenberg). Defective phototaxis and optomotor responses. No fixation. No light-on or light-off transient spikes.

**P48 (J. C. Hall)**

**location:** 1-.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Deland and Pak.

**references:** Heisenberg and Götz, 1975, *J. Comp. Physiol.* 98: 217-41.

**phenotype:** Variable. Rotatory optomotor response almost as big as in wild type, but absent when striped pattern used.

**pa: patulous**

**location:** 2-101.0.

**origin:** Spontaneous.

**references:** Edmondson and Meyer, 1949, *DIS* 23: 61.

**phenotype:** Wings spread wide apart. Excellent viability; fair fertility. RK1.

**cytology:** Placed in 58F2-60E2 on the basis of its being covered by *Dp(2;3)P* from *Tp(2;3)P = Tp(2;3)58E3-F2;60D14-E2;96B5-C1*.

 Baker and Hall, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 351-434.

**phenotype:** Behaves as a recessive meiotic mutant in males; causes the loss of paternally-derived chromosomes among the progeny of homozygous males. Different chromosomes are lost at different rates. Loss may occur in the zygote and affect the whole body or during early mitotic divisions giving rise to mosaicism. The site responsible for the sensitivity of the X chromosome to *pal* has been located at or near the X centromere. *pal*<sup>+</sup> function seems to be necessary during meiosis for normal transmission of paternal chromosomes in the early divisions of the fertilized egg.

**cytology:** Located in either 28C-D or 29F-30F since it is uncovered by *Dp(2;Y)B231 = Dp(2;Y)27C;31E* and is not deleted by deficiencies for 27D-28C, 28D-29F, 30F-31D, and 31C-D in segmental aneuploids (Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, Genetics 71: 157-84).

**other information:** Mosaics with large patches can be generated by early chromosome loss in the progeny of *pal* males and allows the construction of fate maps of the blastoderm.

**par: paralog**

**location:** 1-1.4.

**origin:** Recovered after ethyl methanesulfonate treatment of a  $\nu^{24}$  chromosome; may have been spontaneous in the stock.

**discoverer:** Gans.

**synonym:** *fs(1)A1122<sup>ts</sup>*.

**references:** Gans, Audit, and Masson, 1975, Genetics 81: 683-704.

Zalokar, Audit, and Erk, 1975, Dev. Biol. 47: 419-32.

Thierry-Mieg, 1982, Genetics 100: 209-37.

**phenotype:** Recessive temperature-sensitive female-sterile mutant. At 29°, homozygous females have small ovaries and abnormal egg chambers, the few eggs that are laid dying before hatching; at 23° *par* females are viable and fecund, but 60% of their progeny die without forming a complete blastoderm and the remainder form a blastoderm lacking in pole cells and develop into sterile adults with cuticular defects; at 16°, only 20-30% of the progeny of *par* females are agametic and few of these show cuticular defects. May act as a dominant enhancer of *spl* causing a *spl* phenotype in *par spl/FM3* heterozygotes. A modifier *Su(par)* (mapping to right of  $\nu$  on X) decreases in a semidominant way the frequency of agametic flies (from 95-100% to 51-61%) and abdominal defects (from 26-49% to 5-14%) (Thierry-Mieg, 1982). The temperature-sensitive period is restricted to the mother's lifespan and the frequency of progeny defects is independent of the genotype of the zygote. The mutation interacts zygotically *in trans* with loci in the neighboring regions 3A2, 3A3, 3C1-2, 3C4, and 3C6-8. When  $z^a$  and/or  $w^a$  (wild-type eye color) are combined with *par*, a zygotic semidominant temperature-sensitive interaction takes place resulting in  $z^a par$  heterozygotes that are brown-eyed and  $z^a par w^a$  heterozygotes that are white-eyed. Interactions between *par* and *N* are also reported by Thierry-Mieg, 1982, such as the zygotic dominant suppression of Notch wing in *par N<sup>+</sup>/par<sup>+</sup> N<sup>-</sup>* females (the Notch mutants being *Df(1)N-8* and *Df(1)N-264-105* but not *N<sup>264-69</sup>*, a point mutant). An interaction between *par* and a deficiency for 3A2 results in almost complete sterility in females with a paternal *par X* and in aging females with a maternal *par X*.

**alleles:** One temperature-sensitive allele, *par<sup>X1122</sup>* (Gans et al., 1975).

**cytology:** Placed in 3B3 based on its inclusion in both *Df(1)64f1 = Df(1)3A9-B1;3B2-3* and *Df(1)w258-45 = Df(1)3B2-3;3C2-3*.

**other information:** Probably represents a new complementation group in the *z-w* region since allelism tests at 23° and 29° show full complementation for all *par* characteristics by *l(1)3Bb [l(1)zw6]*, *l(1)3Bc [l(1)zw12]*, and *l(1)3Bd [l(1)zw7]* (Thierry-Mieg, 1982).

**para: paralytic (J.C. Hall)**

**location:** 1-52.1 (between *m* and *f*; Homyk and Pye, 1989).

**origin:** Induced by ethyl methanesulfonate or hybrid dysgenesis.

**discoverer:** R. Williamson.

**phenotype:** Exposure to 29-30° causes rapid paralysis that is quickly reversed on shift to 22-25°. Larvae are paralyzed, too, at somewhat higher temperatures. Flies of some *para* strains seem sluggish at lower temperatures. When these mutants are still paralyzed (*i.e.* at high temperatures), they appear to retain many of their "vital functions," their heart still beats (Grigliatti, Suzuki and Williamson, 1972), and they quickly regain normal behavior when shifted to 22° after several hours at 29° (Suzuki *et al.*, 1971); in fact, after a less prolonged exposure (30 min) to high temperature, the still-heated mutant flies regain weak mobility and are even able to right themselves and walk (Suzuki *et al.*, 1971). *para<sup>ts1</sup>/+* adults become paralyzed at 40° within one min [10 min required to paralyze wild-type (Hall, 1973, *DIS* 50: 103-04)]. *para<sup>ts1</sup>* larvae stop "tracking" at high temperature (Wu, Ganetzky, Jan, Jan and Benzer, 1978, *Proc. Nat. Acad. Sci. USA* 75: 4047-51). *para<sup>ts1</sup>* is nearly unconditionally lethal when uncovered by a deletion or other *para*-locus aberration, whereas other alleles lead to reduced viability (unconditional) when heterozygous with chromosomal aberrations at the locus (Ganetzky, 1984). Action potentials in larval nerves are reversibly heat-sensitive (Wu and Ganetzky, 1980), and the same can be inferred for at least some adult neurons (indicated by brain stimulation and recording of responses in thoracic muscles [Siddiqi and Benzer, 1976, *Proc. Nat. Acad. Sci. USA* 73: 3253-57; Benshalom and Dagan, 1981, *J. Comp. Physiol.* 144: 409-17]). Other "excitable phenomena," such as the electroretinogram responses and synaptic transmission, appear to be normal in *para<sup>ts</sup>* adults at high temperature (Suzuki *et al.*, 1971; Siddiqi and Benzer, 1976); also *para<sup>ts1</sup>* does not block action potentials in the cervical giant fiber at high temperature (Nelson and Baird, 1985, *Neurosci. Abstr.* 11: 313) in contrast to results of recording from larval motor neurons (Wu and Ganetzky, 1980); other studies of the giant fiber pathway (involving adult mosaics bilaterally split, externally, for *para<sup>ts1</sup>* and *para<sup>+</sup>*) indicate that at least certain elements of the pathway (if not the giant fiber itself) fail to fire action potentials at elevated temperature (Benshalom and Dagan, 1981), and recordings from mosaics of this type also suggest "functional coupling" between left and homologous right sides of this giant fiber pathway (Benshalom and Dagan, 1985, *J. Comp. Physiol.* 156: 13-23). *para<sup>ts1</sup>* causes first larval instar death when in combination with *nap<sup>ts</sup>* (Wu and Ganetzky, 1980; Ganetzky, 1984); similar lethality occurs when *para<sup>+</sup>* dosage is decreased in a *nap<sup>ts</sup>* background (Ganetzky, 1984). Other *para* alleles, in combi-

nation with *nap<sup>ts</sup>*, lead to reduced viability, with *para<sup>ts115</sup>* having the strongest effect, followed by *para<sup>ST76</sup>* and *para<sup>ST109</sup>* (Ganetzky, 1984). In combination with the *tipE* mutation, *para* mutations again cause decreased viability, but the allele-specific interactions are different from those of the series just noted [*i.e.* with respect to *nap<sup>ts</sup>* (Ganetzky, 1986)]. Surviving *para*; *tipE* double mutants are weak, and show accentuated heat-sensitivity (in regard to mobility and nerve conduction); *para* alleles are dominant for behavioral defects in a homozygous *tipE* background (Ganetzky, 1985). In adults doubly mutant for *para<sup>ts1</sup>* and *nap<sup>ts</sup>*, sensory cells (developing from imaginal discs in mosaics) appear to have no nerve conduction (Burg and Wu, 1984, *Neurosci. Abstr.* 10: 513). In mosaics involving *para* mutations only one allele (*para<sup>ST109</sup>*) causes all legs to be either paralyzed or normal in different individual gynandromorphs (Siddiqi and Benzer), in contrast to independent paralysis of legs in mosaics constructed with respect to *para<sup>ts1</sup>* [Grigliatti *et al.*, 1972; Siddiqi and Benzer, 1978, *Genetic Mosaics and Cell Differentiation* (Gehring, ed.), Springer-Verlag, Berlin, pp: 259-305]. These results (and others, Benshalom and Dagan, 1985, for example), reveal poor correlation of the externally mutant genotype (in mosaics) and behavioral or physiological malfunctions [consistent with internal (no doubt neural) "foci" for *para*'s action]. In other studies, *para<sup>ts1</sup>* mosaics with mutant heads (scored externally) usually are immobile at high temperature, but maintain normal posture (Suzuki *et al.*, 1971; Grigliatti *et al.*, 1972). Exposure of *para<sup>ts1</sup>* males to high temperature causes arrest of the oscillator underlying rhythmic component of courtship song (Kyriacou and Hall, 1985). At permissive temperatures, *para<sup>ts1</sup>* neurons (unlike those influenced by *nap<sup>ts</sup>*) seem normal, except that there is slightly increased resistance of cultured *para<sup>ts1</sup>* larval neurons to killing effects of veratridine, shift to high temperature causing that resistance to increase (Suzuki and Wu, 1984, *J. Neurogenet.* 1: 225-38). Other pharmacological studies (tetrodotoxin sensitivity of action potentials or binding assays involving that toxin) have revealed no *para*-induced abnormalities (Ganetzky and Wu, 1980; Kauvar, 1982, *Molec. Gen. Genet.* 187: 172-73). It was reported (based on injection of *para<sup>ts1</sup>* adults with picrotoxin and the ensuing inhibition of paralysis at high temperatures) that the mutation is involved in a generalized augmentation of inhibition mediated by gamma-amino-butyric acid [Williamson, Kaplan and Dagan, 1974, *Nature (London)* 252: 224-26] but further physiological data (involving administration of picrotoxin) dispute this hypothesis. *para<sup>ts1</sup>* is reported to cause an anomalous inflection point in Arrhenius plots, with respect to activity of the mitochondrial enzyme succinate cytochrome c reductase, at a temperature close to that which induces paralysis (Søndergaard, 1976, *Hereditas* 82: 51-56).

**alleles:** Mutant alleles of *para* are included in the following table.

<sup>β</sup> Marked reduction in number of embryonic neurons in cell culture expressing sodium currents in these alleles (O'Dowd, Germeraad, and Aldrich, 1987, Soc. Neurosci. Abstr. 13: 91; 1989, Neuron 2: 1301-11).

**cytology:** Located at 14C7-8 by *in situ* hybridization; included in *Df(1)80-Df(1)82* (Falk *et al.*, 1984) and covered by *Dp(1;4)r<sup>+</sup> = Dp(1;4)14A1-2; 16A1-2; 102F2-3*.

**molecular biology:** Genomic DNA from the *para* region was cloned from a library of *para*<sup>hd2</sup> using P element DNA as a probe (Loughney and Ganetzky, 1985, Neurosci. Abstr. II: 782). The P element in this mutant was found to reside in a 4.5 kb *EcoRI* fragment; the 14C6-D1 breakpoint of *In(1)D30* (which behaves as *para*<sup>-</sup>) is also within this 4.5 kb fragment. Another *para*<sup>-</sup> inversion breakpoint, 14C7-8 [in *In(1)para*<sup>lk4</sup>], has been localized to a site approximately 20 kb distal to the 4.5 kb fragment. Seven other alleles were distributed over a region of 45 kb. The locus includes a minimum of 26 exons. The complete nucleotide sequence of five *para* cDNAs was obtained. There are 5461 nucleotides in one open reading frame (Loughney *et al.*, 1989). Sequence

analysis of the cDNAs indicates that *para* encodes a protein with extensive amino acid identity to membrane spanning domains in the rat, implicating the sodium channels (Loughney and Ganetzky, 1988; Loughney *et al.*, 1989) in *Drosophila* neurons. The *para* transcript appears to produce several subtypes of the sodium channel by alternative splicing.

**phenotype:** *Pc*<sup>+</sup> may be considered a negative regulator of the bithorax complex (*BXC*) and the Antennapedia complex (*ANTC*), with a decreasing gradient of activity from anterior to posterior. When homozygous or hemizygous, *Pc* mutants are late embryonic lethals. Embryos with at least one dose of the *BXC* show incomplete head development and caudad transformations, the thoracic and first seven abdominal segments being partially transformed into the eighth abdominal segment (Lewis, 1978; Denell, 1982; Haynie, 1983, Dev. Biol. 100: 399-411; Denell and Frederick, 1983, Dev. Biol. 97: 34-47). This homeotic effect in homozygotes is enhanced by increasing the dosage of the *BXC*. Transformations involve brain and ventral nerve cord as well as epidermis (Jiménez and Campos-Ortega, 1981). *Pc*<sup>+</sup> alleles in the mother weaken the homeotic effect (Denell, 1982; Lawrence, Johnson, and Struhl, 1983, Cell 35: 27-34). *Pc*<sup>2</sup>/*Pc*<sup>2</sup> or *Pc*<sup>3</sup>/*Pc*<sup>3</sup> clones induced in leg and eye-antennal tissue during larval development also show similar posteriorly-directed transformations (Struhl, 1981; Duncan and Lewis, 1982).

*Pc*<sup>+</sup> flies carrying at least one dose of the *BXC* show

caudad transformations, *i.e.* partial conversion of wings into halteres and of anterior abdominal segments into more posterior ones. Some *Pc* heterozygotes show phenotypes characteristic of *ANTC* mutants, *i.e.* partial conversion of antennae into legs and of second and third legs into first legs (with sex combs in males) (Hannah-Alava, 1958; Duncan, 1982). The frequency of wing transformations varies directly with the *BXC* dosage, but does not seem to be changed by variation in *ANTC* dosage (Duncan and Lewis, 1982; Botas *et al.*, 1982). The number of abdominal transformations, however, varies inversely with the doses of the *BXC* while it increases as the doses of the *ANTC* are increased (Duncan, 1982; Duncan and Lewis, 1982).

Other changes observed in *Pc*<sup>+</sup> flies include a transformation of ventral to dorsal wing (Tiong; Sato *et al.*, 1983), elevated, divergent, or crinkled wings, terminal gaps in the L4 wing vein, bent humeral or notopleural bristles, and defective sternopleural bristles, all abnormalities being less extreme in males than in females (sometimes absent in males). When doubly heterozygous with *Antp*<sup>Y<sup>u</sup> and *Antp*<sup>B</sup>, *Pc* enhances *Antp*. The expression of all *Pc* mutant heterozygotes (including deficiencies for the locus) is enhanced by the second chromosome dominant, *E(Pc)* (Sato *et al.*, 1983, 1984). *Pc*<sup>3</sup>/*Pc*<sup>3</sup>/*Dp*(1;3;4)7 flies (carrying a *Pc*<sup>+</sup> duplication) show stronger leg and wing transformations than *E(Pc)*<sup>+</sup>/*Pc*<sup>3</sup>/*Pc*<sup>3</sup> flies (Duncan and Lewis, 1982; Sato *et al.*, 1983).</sup>

**alleles:** In addition to the alleles described in the following table, six more alleles with a *Pc* phenotype were induced by EMS in males carrying three doses of the *BXC* (Botas *et al.*, 1982). Mapping data and noncomplementation with *Df*(3L)*Pc* confirmed the allelism. All of the alleles listed in the table show partial transformations of second and third legs into first legs in *Pc*<sup>+</sup> heterozygotes, and, in the case of *Pc*<sup>T5</sup>, in homozygotes (Sato *et al.*, 1983).

- <sup>β</sup> Sex combs of males are larger and resemble those of *Scx*.
- <sup>γ</sup> Homozygous viable?
- <sup>δ</sup> Two kb deletion.
- <sup>ε</sup> Enhances extra sex combs phenotype of *Pc*<sup>4</sup>.
- <sup>ζ</sup> Cytology: *In(3L)76C;78B + In(3L)78C-D;78E5-6*.

**cytology:** Located in 78D7-8 by molecular methods and in 78E by deficiency mapping (Duncan and Lewis, 1982); uncovered by *Df(3L)Pc = Df(3L)78D12;79A4-C1* of Jürgens (Haynie, 1983, Dev. Biol. 100: 399-411).

**molecular biology:** *Pc* region cloned from salivaries (Paro, Lauer, and Hogness) by microexcision. Breakpoints of rearrangements associated with mutant alleles located on the molecular map (Paro *et al.*, 1984). Three transcripts found by Paro, Zink, Messmer, Franke, and Roddewig (Crete, 1988), a 2.5 kb transcript found throughout development, a 2.0 kb maternal and zygotic transcript, and a 1.0 kb transcript abundant in third instar larvae. The polycomb protein binds to 60 sites on the salivary chromosomes, including those of the *ANTC*, *BXC*, and *Pc*-group genes (Zink and Paro, 1989).

**other information:** Later embryonic stages of homozygous *Pc* embryos show a decline in the transcript levels of *Antp* and *Ubx* and a depression in *Antp* protein expression in the nervous system (Wedeen, Harding, and Levine, 1986, Cell 44: 739-48; Carroll, Laymon, McCutcheon, Riley, and Scott, 1986, Cell 47: 113-22).

***pcb*: posterior cell blister (F. Waddle).**

**location:** 1-1.2.

**origin:** Spontaneous.

**discoverer:** Waddle, 1985.

**phenotype:** Blistering in one or both wings, usually in second posterior cell, but may be elsewhere. Wings tend to be warped upward around affected area. RK1.

***pch*: parched**

**location:** 1-0.0.

**synonym:** *dmd*; *doomed*.

**references:** Benzer, 1971, J. Am. Med. Assoc. 218: 1015-22.

Flanagan, 1977, Genetics 85: 587-607.

Kimura, Shimozawa, and Tanimura, 1985, J. Insect Physiol. 31: 573-80.

**phenotype:** *pch*<sup>2</sup> flies appear normal at eclosion but commence dying immediately; all dead within 12 hr. *pch*<sup>2</sup> progeny recovered about 60% as frequently as expected owing to pre-eclosion mortality in the pupal stage. Approximately 15% of *pch*<sup>2</sup> individuals die before late

pupa, 25% in late pupa, and 60% during first 24 hr after eclosion. Adults exhibit uncoordinated leg movement and then lose use of legs. In gynandromorphs, only *pch*<sup>2</sup> tissue shows loss of leg coordination; such mosaics are doomed. *pch*<sup>2</sup> flies killed by light etherization but not by prolonged CO<sub>2</sub> narcosis. Fate mapping by method of focusing locates focus of lethal action to thoracic neural ganglia and not to thoracic musculature.

Adult *pch*<sup>3</sup> and *pch*<sup>4</sup> flies have higher rates of water loss than wild-type flies, the rapid water loss causing early death in a desiccated environment. In an attempt to compensate for the loss, the mutants drink much more water than wild-type flies. Even dead *pch* flies lose water more rapidly than their wild-type counterparts, suggesting that a defect in the integument rather than in the digestive or trachea-spiracle systems is the source of the abnormality. *pch* larvae and pupae are not affected by desiccation. The survival of flies mosaic for *pch*<sup>+</sup> and *pch*<sup>0</sup> in a desiccated environment depends on the ratio of wild-type to mutant cuticle. No difference in the chemical composition of the cuticle between *pch*<sup>3</sup> and the wild type detected. The relationship between mutants isolated as parched and doomed remains unclear, considering the reported differences in fate-mapping results (Flanagan vs. Kimura *et al.*).

**alleles:** Mutations recovered under a number of lethal designations including the adult-lethal mutants called *dmd* and *pch*. Complementation tests by Tanimura and Shimozawa show that *dmd* fails to complement *pch*<sup>3</sup>, and Schalet demonstrated that several of the lethal alleles listed below fail to complement *dmd = pch*<sup>2</sup>.

<sup>β</sup> Complementation with *pch<sup>2</sup>* in every instance.

<sup>γ</sup> From DNA-injected egg.

<sup>δ</sup> Spontaneous in the paternal X chromosome of a cross between wild-type males and *mei9* females, such that the F<sub>1</sub> females were *pch/mei9*.

**cytology:** Provisionally the most distal locus on the X chromosome. Located in the interval between 1A1 and 1B1 since uncovered by *Df(1)260-1 = Df(1)1A1;1B4-6* and covered by *Df(1)sc19 = Df(1)1B2;1B4*.

*Pch*: see *pyd*

### *Pcl*: Polycomblike

**location:** 2-84.

**discoverer:** Duncan.

**references:** Duncan and Lewis, 1982, Symp. Soc. Dev. Biol., 40th, pp. 533-34.

Duncan, 1982, Genetics 102: 49-70.

Sato, Russell, and Denell, 1983, Genetics 105: 357-70.

Jürgens, 1985, Nature (London) 316: 153-55.

Kennison and Russell, 1987, Genetics 116: 75-86.

**phenotype:** *Pcl*<sup>+</sup>, like *Pc*<sup>+</sup>, may be considered a negative regulator of the *BXC* and the *ANTC*. Strong *Pcl* mutant alleles (*Pcl*<sup>1</sup>, *Pcl*<sup>2</sup>) are homozygous lethal, hemizygous lethal, and lethal with each other, the embryos having partial posteriorly-directed transformations of the abdominal segments (segment 1 into segment 2 and segments 2-7 into more posterior segments). These mutants are strong enhancers of *Pc*<sup>3</sup>, showing *Pc*-like transformations in embryos, and are indistinguishable from *Pcl* deficiencies in complementation behavior. Extreme posteriorly-directed segmental transformations are found in *Pcl*<sup>1</sup>/*Df(2R)Pcl11B*; *Pc*<sup>3</sup>/*Pc*<sup>3</sup> lethal embryos (Duncan, 1982); these embryos are considerably more abnormal than the *Pc*<sup>3</sup> homozygotes that are *Pcl*<sup>+</sup>. *Pcl*/*Pcl* embryos that are also homozygous for *Asx*, *Psc*, or *Scm* show strong posteriorly-directed transformations of the entire body pattern; the triple mutant *Psc Asx Pcl* has a tandem array of posterior abdominal segments including four abdominal denticle bands in the head region (Jürgens, 1985). *Pcl*<sup>1</sup>/*Pcl*<sup>1</sup> clones in the second through the sixth abdominal tergites also show caudal transformations; similar clones in the wing often appear to be partially transformed into haltere tissue.

Weak *Pcl* alleles (*Pcl*<sup>3</sup>, *Pcl*<sup>4</sup>) survive, at least through eclosion, either as homozygotes or as heterozygotes with strong or weak *Pcl* alleles (Duncan, 1982). *Pcl*<sup>1</sup>/*Pcl*<sup>3</sup> and *Pcl*<sup>1</sup>/*Pcl*<sup>4</sup> show segmental transformations characteristic of *Pcl*<sup>+</sup> flies, i.e. antenna to leg, second and third leg to first leg, wing to haltere, and posteriorly-directed abdominal transformations (the most frequent abnormality). Increasing the dosage of the *BXC* in *Pcl*<sup>1</sup>/*Pcl*<sup>4</sup> heterozygotes suppresses the posteriorly-directed transformations, but enhances the transformations from

*leg2* and *leg3* to *leg1*; increasing the dosage of the *ANTC* enhances both types of transformations (Duncan, 1982). *Pcl*<sup>1</sup>/*Pcl*<sup>3</sup> females, which die before or soon after eclosion, show a conversion of parovaria to spermathecae. Both strong and weak *Pcl* alleles are viable as heterozygotes (*Pcl*/+) and may show partial abdominal and leg transformations, the abnormalities increasing in *Pcl*/+; *Pcl*/+ flies or when *Pcl*/+ is combined with *E(Pc)*.

<sup>β</sup> Strong interaction with *Pc*<sup>3</sup>.

<sup>γ</sup> Homozygotes almost wild type; weakly temperature-sensitive for leg transformations at 29°C.

<sup>δ</sup> Partial transformation of legs 2 and 3 to leg 1. Enhances wing to haltere transformation in *en*<sup>1</sup>/*en*<sup>28</sup> (Eberlein, 1984).

<sup>ε</sup> *In(2R)55A;57A*.

**cytology:** Located between 55A and 55C1 since *Pcl* is included in *Df(2R)Pcl-W5 = Df(2R)55A-B;55C* as well as in *Df(2R)Pcl7B = Df(2R)54E8-F1;55B9-C1* and *Df(2R)Pcl11B = Df(2R)54F6-55A1;55C1-3* (Duncan, 1982; Sato et al., 1983). These deficiencies act as enhancers of *Pc*<sup>3</sup> and show a strong *Pcl* phenotype.

*pco*: see *E(z)*

### *Pcp*: Pupal cuticle protein

**location:** 2-20 (based on site of *ade3*).

**origin:** Sequence analysis of *ade3*.

**synonym:** *Pcpgart*; *Gart* intronic gene.

**references:** Henikoff, Keene, Fechtel, and Fristrom, 1986, Cell 44: 33-42.

**phenotype:** Apparently encodes pupal cuticle protein since in 11 hr prepupae, the *Pcp* mRNA is found primarily in the abdomen in epidermis involved in cuticle formation. The pupal cuticle protein itself has not been identified.

**cytology:** Placed in 27C.

**molecular biology:** Computer analysis of *ade3* sequences located *Pcp* in an open reading frame of 184 amino acids in a nested arrangement on the noncoding strand within the first *ade3* intron (interrupting the GARS domain). The *Pcp* gene is made up of single copy DNA and contains its own intron between codons 4 and 5. Its cDNA sequence shows strong homology to regions of the genes *Lcp1* to *Lcp4* (Snyder, Hirsh, and Davidson, 1981, Cell 25: 165-77; Snyder, Hunkapiller, Yuen, Silvert, Fristrom, and Davidson, 1982, Cell 29: 1027-40). A 0.9 kb transcript was detected primarily, if not exclusively, in prepupal stage (Henikoff *et al.*, 1986).

**pcv: posterior crossvein**

**location:** 3-.

**origin:** X ray induced.

**references:** Puro, 1982, DIS 58: 205-08.

**phenotype:** Posterior crossvein incomplete. Wings slightly divergent. Not an allele of *cv-d* since *pcv/cv-d* is wild type.

**cytology:** Associated with *In(3LR)pcv = In(3LR)65B-C;92A*.

**pcx: pecanex**

**location:** 1-0.9.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Engstrom (*pcx*); Romans [*mel(1)R1*].

**synonym:** *fs(1)pcx; mel(1)R1*.

**references:** Romans, 1973, Genetics 74: s233.

Romans, Hodgetts, and Nash, 1976, Can. J. Genet. Cytol. 18: 773-81.

Mahowald, 1983, Time, Space, and Pattern in Embryonic Development (Jeffrey, Rand, and Raff, eds.). Alan R. Liss, Inc., New York, pp. 349-63.

Perrimon, Engstrom, and Mahowald, 1984, Genetics 108: 559-72.

Haenlin, Steller, Pirrotta, and Mohler, 1985, Cell 40: 827-37.

La Bonne and Mahowald, 1985a, Dev. Biol. 110: 264-67.

1985b, Genetics 110: s83.

La Bonne, Sunitha, and Mahowald, 1989.

**phenotype:** Maternal-effect-lethal mutation; homozygous mutant females crossed to mutant males produce lethal embryos showing hypertrophy of the central nervous system at the expense of the epidermis, a small patch of dorsal cuticle remaining but no ventral cuticle. This embryonic phenotype (as well as the reduced eye phenotype of viable *pcx* adults) resembles that of *amx*. Homozygous *pcx* lethal embryos can be rescued genetically; some mutant females (but not *pcx*<sup>1</sup> homozygotes) crossed to wild-type males produce viable adult *pcx*/+ female offspring (Romans *et al.*, 1976; Perrimon *et al.*, 1984); the *pcx*/Y male offspring are lethal. *pcx*/+ heterozygous females, which are fertile, crossed to viable *pcx*/Y males (also fertile) produce viable adult males (*pcx*/Y and +/Y) and viable adult females (*pcx*/*pcx* and *pcx*/+) (Romans *et al.*, 1976). Homozygous *pcx* lethal embryos can be partially rescued almost up to hatching by preblastoderm microinjection of wild-type or *amx* ooplasm (La

Bonne and Mahowald, 1985a). Germ line clonal analysis demonstrates the germ-line dependency of the *pcx* embryonic lethal phenotype (Perrimon *et al.*, 1984).

<sup>α</sup> 1 = Mohler and Carroll, 1984, DIS 60: 236-41; 2 = Perrimon, Engstrom, and Mahowald, 1984, Genetics 108: 559-72; 3 = Romans, Hodgetts, and Nash, 1976, Can. J. Genet. Cytol. 18: 773-81.

**cytology:** Located in 2E2 since included in *Df(1)pn38 = Df(1)2D3-4;3E3* but not *Df(1)dor2T = Df(2B6;2E1-2*.

**molecular biology:** *pcx* cloned and transcripts identified (tentatively by Haenlin *et al.*, 1985; confirmed by La Bonne *et al.*, 1989). These mRNAs include a rare 9 kb transcript and minor 3.7 and 2.3 kb transcripts; they are detected early (at a low level) in 0-1 hr embryos. The level is highest in 5-10 hr embryos; lower levels persist throughout pupal and adult life (La Bonne *et al.*, 1989). Nucleotide and predicted protein sequences of the 3' portion of the locus have been determined; these sequences suggest that *pcx* encodes a large transmembrane protein (La Bonne *et al.*).

**other information:** Named for its phenotypic resemblance to *amx*.

**pd: purpleoid**

**location:** 2-106.4.

**origin:** Spontaneous.

**discoverer:** Bridges, 16h31.

**references:** 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55.

**phenotype:** Eye color dark pink or maroon, like *pr* but less extreme. Semidominant; eye color of heterozygote duller than wild type; color autonomous in larval optic disk transplanted into wild-type host (Beadle and Ephrussi, 1936, Genetics 21: 230). Malpighian tubes wild type (Beadle, 1937, Genetics 22: 587-611). Semilethal with *dor* (Lucchesi, 1968, Genetics 59: 37-54). RK2.

**cytology:** Placed in region between 59E2 and 60B10 by Bridges (1937) on the basis of its being to the right of *In(2R)bw<sup>VDel</sup> = In(2R)41B2-C1;59E2-4* and to the left of *Df(2R)Px = Df(2R)60B8-10;60D1-2*.

**pdf: pod foot**

**location:** 1-57.0.

**origin:** X ray induced.

**discoverer:** Welshons, 57h6.

**references:** 1960, DIS 34: 54.

**phenotype:** Terminal tarsus swollen in one or more legs. Classification, viability, and fertility good. RK2A.

**cytology:** Associated with *In(1)pdf = In(1)16B;19F-20A*. Tentatively placed in 16A and at 57.0 since *pdf* is covered by *B<sup>S</sup>Y* but not by *Ymal<sup>+</sup>2*.

**Pdr: Purpleoider**

**location:** 3-46.

**origin:** Spontaneous.

**discoverer:** Bridges, 22f20.

**phenotype:** The combination *pd/pd; Pdr/+* gives lighter, yellower eye color than *pd* alone. *pd/+; Pdr/Pdr* has eye color like *pd/pd*. *pd/pd; Pdr/Pdr* is lethal. *Pdr/Pdr* is rosier than wild type. *Pdr/Pdr* and *pd/pd; Pdr/+* Malpighian tubes normal (Brehme and Demerec, 1942, Growth 6: 351-56). RK3.

**\*pe: pett**

**location:** 3- (not located).

**origin:** Spontaneous in *In(3L)P*.

**discoverer:** Mohr, 38k30.

**references:** 1939, DIS 12: 47.

**phenotype:** Body small. Eyes small and rough. Viability good; female fertility low. RK2A.

**Pearl:** see *PI*

**peb: pebbled**

**location:** 1-7.5+. Mapped by recombination as proximal to *rb* (Schalet, 1986).

**discoverer:** Dubinin.

**references:** Schalet, 1986, Mutat. Res. 163: 115-44.

Oliver, Perrimon, and Mahowald, 1988, Genetics 120: 159-71.

Steinmann-Zwicky, 1988, EMBO J. 7: 3889-98.

**phenotype:** Eyes markedly rough at 28°-30°, slightly rough (like *S*) at 25°, and wild type at 19°. RK2 (28°-30°).

**alleles:** Two spontaneous lethal alleles, *peb*<sup>2</sup> and *peb*<sup>3</sup> isolated as *l(1)10-75* and *l(1)20-41*, (Schalet *et al.*, 1986).

**cytology:** Placed in salivary chromosome region 4C5-7 since included in *Df(1)ovo7 = Df(1)4C5-6;4E2-3* and *Df(1)rb46 = Df(1)4A3-6;4C6-7* (Oliver *et al.*, 1988).

**pebble:** see *pbl*

**pebbled:** see *peb*

**pebbly:** see *pby*

**Pec: Pupilla eccentrica**

**location:** 3-65.

**origin:** Spontaneous in a sex-linked lethal stock kept at 26°.

**references:** Parkash, 1970, DIS 45: 35.

**phenotype:** Temperature-sensitive change in the appearance of the pupilla of the eye. At 26°, this pigment-free circular area is enlarged to a diameter of about 2/5 of the long axis of the eye and is demarcated clearly from the pigmented area; it contains scattered pigment spots. The pigmented part of the eye varies in color from dull red to light brown and the surface of the eye is somewhat rough; ocelli are colorless. As the temperature is lowered, the size of the pupilla is reduced and its boundary becomes blurry until at 16° the eye resembles wild-type. The temperature-sensitive period for development of the *Pec* phenotype seems to be the first day of pupal life.

**pecanex:** see *pcx*

**pelle:** see *pil*

**pentagon:** see *ptg*

**pep: peppercorn (T. Schüpbach)**

**location:** 2-{104}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females contain many small egg chambers in their ovaries, which seem blocked in early stages of oogenesis. Follicle cells nevertheless synthesize a very small, round chorion around these egg chambers, giving them the appearance of small round peppercorns.

**alleles:** *pep*<sup>QW</sup> = *pep*<sup>1</sup>.

**cytology:** Placed in 59D8-60A7, since uncovered by *Df(2R)bw-S46 = Df(2R)59D8-11,60A7*.

**Pepck: Phosphoenolpyruvate-carboxykinase**

**references:** Gundelfinger, Hermans-Borgmeyer, Grenningloh, and Zopf, 1987, Nucleic Acids Res. 15: 6745.

**phenotype:** Structural gene for the enzyme phosphoenolpyruvate-carboxykinase in *Drosophila melanogaster*.

**molecular biology:** A cDNA clone of *Pepck* has been isolated and found to encode a polypeptide that is 64% identical to the rodent and 62% identical to the avian enzyme precursors. The predicted *Drosophila* protein consists of 747 amino acid residues.

**peppercorn:** see *pep*

**per: period (J.C. Hall; M. Young)**

**location:** 1-1.4 (between *z* and *w*).

**origin:** Induced by ethyl methanesulfonate or nitrosoguanidine.

**discoverer:** Konopka.

**phenotype:** The *per* gene is essential for biological clock functions and determines the period length of circadian and ultradian rhythms. The *per* mutants are characterized by aberrant rhythms involving eclosion and locomotor activity (Konopka and Benzer, 1971) and may change the rhythmic component of the male courtship song (Crossley, 1988; Ewing, 1988; Kyriacou and Hall, 1980, 1986, 1988). These mutants also affect the rhythm of the larval heartbeat (Dowse, Ringo, and Kyriacou; Livingstone, 1981, *Neurosci. Abstr.* 7: 351), the level of tyrosine decarboxylase [Livingstone and Tempel, 1983, *Nature* (London) 303: 67-70], and fluctuations in membrane potentials in larval salivary glands (Weitzel and Rensing, 1981, *J. Comp. Physiol.* 143: 229-35), modulate intercellular junctional communication (Bargiello *et al.*, 1987), and alter the location of neural secretory cells in the brain (Konopka and Wells, 1980, *J. Neurobiol.* 11: 411-15).

In wild-type flies the period length is about 24 hr. In general, increases in *per*<sup>+</sup> dosage lead to shortened circadian rhythms and decreases lead to lengthened circadian rhythms (Baylies *et al.*, 1987; Côté and Brody, 1986; Hamblen *et al.*, 1986; Smith and Konopka, 1981, 1982; Young *et al.*, 1985). Females heterozygous for *per*<sup>+</sup> and a deletion of the locus or a *per*<sup>0</sup> allele show longer-than-normal periods.

*per* flies can be classified on the basis of their circadian rhythms as: (1) Cryptic period mutants (*per*<sup>0</sup>, *per*<sup>-</sup>) which have a 10-15 hr (ultradian) period and appear

arrhythmic except in special algorithmic tests (Dowse *et al.*, 1987); (2) Long period mutants (*per*<sup>L</sup>), 29 hr; (3) Long-period variable mutants (*per*<sup>Lvar</sup>), which in homozygotes or heterozygotes are arrhythmic but in combination with certain partial deletions of the *per* locus result in a 30-34 hr period. (Konopka, 1987); (4) Short period mutants (*per*<sup>S</sup>), 19 hr; (5) Short period variable mutants (*per*<sup>Svar</sup>), some flies having a 20 hr period and the others a normal 24 hr period for locomotor activity.

In temperature-change experiments on *per*<sup>S</sup> and *per*<sup>L1</sup>, the locomotor activity periods were found to be nearer to 24 hr at low temperatures, but to diverge further from normal upon heating (Konopka, Pittendrigh, and Orr; Hamblen, Ewer, and Hall). *per*<sup>L2</sup> shows lengthening of the periods at high temperatures.

The mutant types affecting circadian rhythms (*per*<sup>0</sup>, *per*<sup>L</sup>, and *per*<sup>S</sup>) may cause similar kinds of changes in the rhythmic fluctuations in courtship song intersperse intervals (IPIs) of the male (Crossley, 1988; Ewing, 1988; Kyriacou and Hall, 1980, 1986, 1988). *per*<sup>0</sup> mutants show nonrhythmic variations in the interval between pulses of wing vibration.

Neural studies show that transplantation of *per*<sup>S</sup> brains into *per*<sup>01</sup> adult hosts causes some of the hosts to be "rescued"; *i.e.* to show short-period circadian rhythms for locomotor activity (Handler and Konopka, 1979). Octopamine synthesis occurs at subnormal rates in *per*<sup>01</sup> brains, with a corresponding decrease in the enzyme tyrosine decarboxylase (Livingstone and Tempel, 1983); less severe decrements in tyrosine decarboxylase are found in *per*<sup>S</sup> and *per*<sup>L1</sup> flies.

Physiological studies show that *per* mutations can affect the level of gap junctional communication among cells in a tissue (Bargiello *et al.*, 1987). In salivary glands the *per*<sup>0</sup> and *per*<sup>L1</sup> mutations cause a lowering of the level of junctional communication, while *per*<sup>S</sup> gives a level of communication higher than wild type. Because electrical synapses are composed of gap junctions, *per* may influence circadian behavioral rhythms through altered conductances at the synapse (Bargiello *et al.*, 1987).

Mosaic analysis of *per*<sup>S</sup> mutants indicates that the gene influences the brain with respect to aberrant locomotor rhythms (Konopka, Wells, and Lee, 1983, *Mol. Gen. Genet.* 190: 284-88); *per*<sup>01</sup> and *per*<sup>02</sup> (and, to a lesser degree, *per*<sup>S</sup>) are said to cause anomalous photonegative behavior in light-response tests (Palmer, Kendrick, and Hotchkiss, 1985, *Ann. N.Y. Acad. Sci.*, pp 323-24), but in general are not defective in visual responses (phototaxis tests, optomotor behavior, and electroretinogram) according to Dushay and Hall.

**alleles:** Ten mutant alleles of *per* are described in the table below. *per*<sup>01</sup>, *per*<sup>02</sup>, and *per*<sup>03</sup> may be the same allele originating at different times, (all three carry the same nonsense or stop codon); *per*<sup>04</sup> is a different allele. See rearrangement section for *T(1;4)JC43* which shows circadian rhythms with a long period.

alleles	origin	discoverer	ref <sup>α</sup>	comments	molecular data
<i>per</i> <sup>-β</sup>			1-7, 9, 25	multiple periods; short ultradian rhythms; hyperactive flies	deletion of 10 kb
<i>per</i> <sup>01γ</sup>	EMS	Konopka, Benzer	1-10, 12-14, 16-27	multiple periods; short ultradian rhythms	nonsense mutation in exon 4
<i>per</i> <sup>02</sup>	EMS	Smith, Konopka	5-7, 19, 23, 26	multiple periods; short ultradian rhythms	same nonsense codon as <i>per</i> <sup>01</sup>
<i>per</i> <sup>03</sup>	EMS	Konopka	6, 7, 26	multiple periods; short ultradian rhythms	same nonsense codon as <i>per</i> <sup>01</sup>
<i>per</i> <sup>04</sup>	EMS/NNG	Konopka	6, 21, 26	multiple periods; short ultradian rhythms; hyperactive flies	<i>per</i> <sup>01</sup> nonsense codon absent
<i>per</i> <sup>L1δ</sup>	EMS	Konopka, Benzer	3, 4, 6, 7, 10-13	circadian rhythms; long period	nucleotide substitution in exon 3
<i>per</i> <sup>L2δ</sup>	EMS	Orr	16, 23, 26 9, 23	circadian rhythms; long period	
<i>per</i> <sup>Lvar</sup>	EMS/NNG	Konopka	7, 11	circadian rhythms; variable long period	
<i>per</i> <sup>s</sup>	EMS	Konopka, Benzer	3, 4, 6, 8, 10, 12, 13	circadian rhythms; short period	nucleotide substitution in exon 5
<i>per</i> <sup>svar</sup>	NNG	Konopka	15, 16, 23, 26 7	circadian rhythms; variable short period

<sup>β</sup> Includes deficiencies for the *per* locus such as *Df(1)TEM202/Df(1)64j4* or *Df(1)62d18/Df(1)64j4*.  
<sup>γ</sup> *per*<sup>0</sup> listed as *per*<sup>o</sup> in many references.  
<sup>δ</sup> Synonym: *per*<sup>L1</sup> = *per*<sup>1</sup>;  
*per*<sup>L2</sup> = *per*<sup>12</sup>.

**cytology:** Located in 3B1-2 since *per*<sup>0</sup> mutations are uncovered by a variety of deletions in the *zeste-white* region, including *Df(1)64j4* = *Df(1)3A8-9;3B1-2*, *Df(1)62d18* = *Df(1)3B1-2;3C6-7*, *Df(1)64f1* = *Df(1)3A9-B1;3B2-3* and *Df(1)TEM* = *Df(1)3B1-2;3C3-5* and are covered by *w*<sup>+</sup>*Y* and *Dp(3;1)w*<sup>+</sup>*67k27*. The 3B1-2 breakpoint of *T(1;4)JC43* = *T(1;4)3B1-2;3E3-4;102D* "partially" inactivates *per*<sup>+</sup>, making circadian eclosion arrhythmic (Smith and Konopka, 1981; Young and Judd, 1978); in regard to circadian locomotor activity; however, some *T(1;4)JC43/per*<sup>0</sup> females are weakly rhythmic and have a long period while the rest are arrhythmic. A synthetic deletion of the *X* between 3B1-2 and 3C2 (the 4<sup>P</sup>*X*<sup>D</sup> segment of *T(1;4)JC43* and the *X*<sup>P2</sup><sup>D</sup> segment of *T(1;2)RC45*) leads to the same array of long-period/arrhythmic individuals when heterozygous with *per*<sup>01</sup> (Smith and Konopka, 1981).

**molecular biology:** The *per* locus and its environs have been cloned by chromosomal walking/jumping (Bargiello and Young, 1984) and by micro-excision (Reddy *et al.*, 1984) and the genomic *per* DNA sequenced (Citri *et al.*, 1987; Jackson *et al.*, 1986) Sequencing data and immunochemical studies suggest that the gene product is a proteoglycan (Bargiello *et al.*, 1987; Jackson *et al.*, 1986; Reddy *et al.*, 1986; Shin *et al.*, 1985). Four types of transcripts have been reported (4.5 kb, 0.9 kb, 2.7 kb, and 1.7 kb) from the region of the *per* locus. The 4.5 kb transcript class is complex, comprising three messages produced by

differential splicing which differ in their 3' sequences (Yu *et al.*, 1987b). The 4.5 kb transcript class almost certainly codes for the *per* gene product (Bargiello *et al.*, 1984; Bargiello and Young, 1984; Bayles *et al.*, 1987; Citri *et al.*, 1987; Hamblen *et al.*, 1986; Young *et al.*, 1985; Yu *et al.*, 1987a,b). Three types of cDNA (A, B, and C), corresponding to three species of 4.5 kb RNA, have been cloned and their sequences compared (Citri *et al.*, 1987). In type A cDNA (the eight-exon type and the most abundant), the first (5'-most) and the last exon (to the right of the stop codon) are noncoding; exon 5 encodes a Threonine-Glycine repeat with 17-23 pairs of alternating Thr-Gly residues (Citri *et al.*, 1987; Jackson *et al.*, 1986; Reddy *et al.*, 1986; Shin *et al.*, 1985) and is polymorphic in different wild-type strains (Yu *et al.*, 1987a); *in vitro*-effected deletion of the Thr-Gly repeat in transformation experiments does not appear to affect circadian rhythms, but causes shorter than normal song rhythm periods (Yu *et al.*, 1987a). 4.5 kb RNA has been found in the brain and ventral ganglia of developing *per*<sup>+</sup> individuals (James *et al.*, 1986; Liu *et al.*, 1988; Lorenz, Hall, and Rosbash; Saez and Young, 1988) as well as in adult heads (Bargiello *et al.*, 1987; James *et al.*, 1986; Liu *et al.*, 1988; Saez and Young, 1988); it can also be detected in the salivary glands of *per*<sup>+</sup> embryos and larvae (Bargiello *et al.*, 1987), but is not found in individuals that lack the *per* locus. The *per* gene product has been demonstrated immunologically in *per*<sup>+</sup> embryos in

the midline of the nervous system, in salivary glands, in *per*<sup>+</sup> pupae in the optic lobes of the brain and thoracic gland/corpora allata, and, in *per*<sup>+</sup> adults, in the brain, eyes, gut, male and female reproductive tissues, Malpighian tubules, and most appendages (Bargiello *et al.*, 1987; Liu *et al.*, 1988; Saez and Young, 1988; Siwicki, Eastman, Petersen, Rosbash, and Hall, 1988, Neuron 1: 141-50). Studies involving anti-*per* antibodies show that *per*<sup>01</sup> embryos, larvae, pupae, and adults are "null" at the protein level [in that peptides used to generate the antibodies were downstream of the relevant stop codon (Bargiello *et al.*, 1987; Saez and Young, 1988; Siwicki *et al.*, 1988)]; *per*<sup>04</sup> adults are antigenically null, whereas *per*<sup>L1</sup> adults stain poorly and *per*<sup>s</sup> adults stain normally (Siwicki *et al.*, 1988). Expression of *per* in adults (embryonic expression bypassed) has been studied by temporal manipulation experiments in which a *Hsp70* promoter has been fused to the *per* gene and the fusion gene turned on in adults only [Ewer, Rosbash, and Hall, 1988, Nature (London) 333: 82-84]. Inducing the expression of *per* after development is completed is necessary for the manifestation of the phenotype; earlier induction of the gene is not necessary or helpful. Circadian rhythmicity can be restored to some of the *per*<sup>-</sup> and *per*<sup>0</sup> mutants by *P*-element-mediated transformation with DNA fragments homologous to all or part of the 4.5 kb RNA species (Bargiello *et al.*, 1984; Baylies *et al.*, 1987; Hamblen *et al.*, 1986; Young *et al.*, 1985; Zehring *et al.*, 1984). "Restored" periodicities tend to be longer than normal (Baylies *et al.*, 1987), except when *per*<sup>0</sup> flies are transformed with a particular 13.2 kb DNA fragment carrying all the coding information flanked by 3.7 kb of 5' and 2.0 kb of 3' sequences (Citri *et al.*, 1987). In the latter case, the periodicity and *per*<sup>+</sup> penetrance of the transformed flies resembles that of normal wild-type individuals. In the transformation experiments of Baylies *et al.*, 1987, period length was shown to be correlated with abundance of *per* RNA. Transformed flies also show a restoration of cell-to-cell junctional communication. Levels of gap junctional communication are also correlated with abundance of *per* RNA (Bargiello *et al.*, 1987).

The 0.9 kb transcript, located adjacent to the 4.5 kb transcript, does not seem to be involved in the rescue of the clock functions in *per*<sup>-</sup> and *per*<sup>0</sup> mutants (Bargiello and Young, 1984; Bargiello *et al.*, 1984; Hamblen *et al.*, 1986). In *per*<sup>+</sup> flies, however, this transcript shows oscillations in its abundance, being higher at midday than at midnight; in *per*<sup>0</sup> mutants these oscillations do not occur (Reddy *et al.*, 1984).

Nothing is known at present about the 2.7 kb and the 1.7 kb transcripts. DNA sequences from *per* mutants have been compared and single base-pair changes found in *per*<sup>L</sup> (T→A; Val<sup>245</sup>→Asp), *per*<sup>s</sup> (G→A; Ser<sup>589</sup>→Asn), and *per*<sup>0</sup> (C→T; Gln<sup>464</sup>→Amber) (Baylies *et al.*, 1987; Yu *et al.*, 1987b). In the *per* mutation associated with *T(1;4)JC43* flies, the 4.5 kb transcript has been replaced by a 11.5 kb transcript (Bargiello and Young, 1984; Jackson *et al.*, 1986; Reddy *et al.*, 1984).

**other information:** *per*<sup>01</sup> is complemented by *l(1)3A* and *l(1)3B* mutants nearby (Young and Judd, 1978; Smith and Konopka, 1981). The mutant *per*<sup>01</sup> of *D. melanogaster* can be rescued (i.e. made to show rhythmic behavior) by transformation with a hybrid gene carrying the coding region of the *D. pseudoobscura per*

gene (Peterson, Hall, and Rosbash, 1988, EMBO J. 7: 3939-47).

#### ***pers*: persimmon**

**location:** 3- (left arm).

**origin:** X ray induced.

**discoverer:** Demerec, 3712.

**references:** 1940, DIS 14: 40.

**phenotype:** Eye color dull orange. Larval Malpighian tubes colorless (Brehme, 1942, Genetics 27: 133). Viability and fertility good. RK2A.

**cytology:** Associated with *In(3L)pers = In(3L)63C2-5;73B2-5*.

***petit*:** see *pe*

#### ***Pfd*: Pufdi**

**location:** 2-70.8.

**discoverer:** Brierley, 1935.

**references:** Shull, 1937, DIS 8: 10.

1938, Proc. Michigan Acad. Sci. 23: 647-49.

Baker, 1950, Am. Naturalist 84: 51-70.

**phenotype:** Wings spread; fluid often accumulates between membranes. Degree of wing divergence inversely correlated with temperature; wings more divergent in male. In transfers from 19° to 31°, temperature-effective period begins 6-8 hr before eclosion in male and 4-6 hr before eclosion in female and ends with eclosion. In transfers from 31° to 19°, the temperature-sensitive period begins 8-10 hr before eclosion and ends 2-4 hr before eclosion (P. H. Baker, 1950). Homozygous lethal. RK2.

#### ***Pfk*: Phosphofructokinase**

**location:** 2-85.2.

Lucchesi, Hughes, and Geer, 1979, Curr. Top. Cell. Reg. 15: 143-54.

Gutierrez, Christensen, Manning, and Lucchesi, 1989, Dev. Genet. (Amsterdam) 10: 155-61.

**phenotype:** Structural gene for 6-phosphogluconate dehydrogenase [6PGD (E.C. 1.1.1.44)], the last enzyme in the oxidative part of the pentose phosphate shunt. The electrophoretic variants  $Pgd^A$  and  $Pgd^B$  have been described in *Drosophila* (Kazanian *et al.*, 1965; Young, 1966),  $Pgd^A$  migrating faster in starch gel than  $Pgd^B$ .  $Pgd^A/Pgd^B$  heterozygous females produce a hybrid band of intermediate mobility. The enzyme 6PGD is a dimer. Its molecular weight was reported by Kazanian [1966, Nature (London) 212: 197-98] to be about 79,000; Williamson, Krochko, and Geer (1980, Biochem. Genet. 18: 87-101), using 6PGD (purified) isolated from  $Pgd^A$  homozygotes, found its molecular weight to be 105,000, and that it contains a mixture of equal amounts of subunits having molecular weights of 55,000 and 53,000. Enzyme activity is highest in early third instar larvae and lowest in late third instar larvae and 3-day old pupae, with intermediate levels in 4-day old pupae, newly eclosed adults, and 5-day old adults (Williamson *et al.*, 1980). The enzyme is found mainly in the fat body (Cochrane and Lucchesi, 1980, Genetics 94: s20).

Males with one dose of  $Pgd^+$  and females with two doses have about the same amount of 6PGD, *i.e.* show dosage compensation for enzyme activity (Seecof *et al.*, 1969; Gerasimova and Ananiev, 1972, DIS 48: 93; Bowman and Simmons, 1973, Biochem. Genet. 10: 319-31; Faizullin and Gvozdev, 1973, Mol. Gen. Genet. 126: 233-45). Females heterozygous for a  $Pgd$  deficiency show a corresponding reduction in enzyme activity, while males and females with an extra dose of  $Pgd^+$  show increased enzyme activity.

A number of lethal and semilethal  $Pgd$  mutants have been induced in  $Pgd^A$  or  $Pgd^B$  (Bewley and Lucchesi, 1975, Genetics 79: 451-66; Gvozdev, Gostimsky, Gerasimova, Dubrovskaya, and Braslavskaya, 1975, Mol. Gen. Genet. 141: 269-75; Hughes and Lucchesi, 1977, Science 196: 1114-15; Gvozdev, Gerasimova, Rostovsky, Kogan, and Braslavskaya, 1978, DIS 53: 143; Lucchesi *et al.*, 1979). The lethals ( $Pgd^n$ ) show no enzyme activity unless covered by a  $Pgd^+$  duplication such as  $w^+Y$ ; the semilethals ( $Pgd^{lo}$ ) show low enzyme activity and are completely lethal when heterozygous with  $Pgd$  lethals. Flies carrying null alleles for both 6PGD, the first enzyme in the pentose phosphate shunt, and 6PGD, the last enzyme, are viable, presumably because the toxic 6-phosphogluconate is not produced (Lucchesi *et al.*, 1977).  $Pgd^n/Y$  males can be rescued by dietary supplements of fructose and linoleate that minimize 6-phosphogluconate production (Hughes and Lucchesi, 1978, Biochem. Genet. 16: 469-75).

**alleles:** The following table includes electrophoretic (wild-type), semilethal and lethal alleles of  $Pgd$ . [Synonyms for  $Pgd^+$  alleles ( $Pgd^A$ ,  $Pgd^B$ ) use terminology for allozyme variants from DIS 53: 117].

allele	origin	discoverer	synonym	ref <sup>α</sup>	genetics
$Pgd^A$	spont	Young	6- $Pgd^4$	6,12	viable, fertile; fast variant
$Pgd^B$	spont	Young	6- $Pgd^8$	6,12	viable, fertile; slow variant
$Pgd^I$		Lucchesi	6- $Pgd^6$		viable, fertile; intermediate variant
$Pgd^{lo1} \beta$		Young	$Pgd^-$	1, 2, 10	semi-lethal,

allele	origin	discoverer	synonym	ref <sup>α</sup>	genetics
$Pgd^{lo2}$	EMS	Lucchesi		10	female sterile, low 6PGD activity
$Pgd^{lo3}$	EMS	Lucchesi		10	semi-lethal, female sterile, low 6PGD activity

<sup>β</sup>  $Pgd^{lo1}/Pgd^{n1}$  females are lethal;  $Pgd^{n1}/Y$  males are lethal, except for a few escapers.

<sup>γ</sup> Induced in  $Pgd^A$ .

<sup>δ</sup> Induced in  $Pgd^B$ .

<sup>ε</sup> HMS = hycanthon methanesulfonate.

**cytology:** Located in 2D3 or 2D4 (Gerasimova and Ananiev, 1972, DIS 48: 93; Gvozdev, Gostimsky, Gerasimova, Dubrovskaya, and Braskavskaya, 1975, Mol. Gen. Genet. 141: 269-75; Slobodyanyuk and Serov, 1983, Mol. Gen. Genet. 191: 372-77) based on the following: (1)  $Pgd$  is uncovered by  $Df(1)Pgd-kz = Df(1)2D3-4;2F5$  but not by  $Df(1)2D6;3C2$  (Lefevre; Seecof *et al.*, 1969) and is covered by  $w^+Y$  (2D1;3D4 inserted in Y); (2) It maps to the left of  $pn$  (located by Lefevre in 2D5-6). Whereas  $Pgd^A/Pgd^B$  heterozygotes show three isozyme bands on starch gels, deficiency heterozygotes show only one band and their 6PGD level is correspondingly reduced (Gerasimova and Ananiev, 1972; Gvozdev *et al.*, 1975).

**molecular biology:** Using a cDNA clone of the rat 6PGD as a probe, Christensen and Lucchesi (1984, Genetics 107: s20; Gutierrez *et al.*, 1989) isolated a *Drosophila* clone (14.7 kb fragment) hybridizing to 2D6, the approximate cytological location of *Pgd*. Another clone hybridizing to 2C1-E3 was obtained by Brock. The lethal *Pgd*<sup>-</sup> phenotype was rescued by germline transformation (Gutierrez *et al.*, 1989). A single *Pgd*<sup>+</sup> gene transduced to an autosomal site showed higher enzyme activity in males than in females, as would be expected if sequences responsible for dosage compensation had been transduced into the *Pgd*<sup>-</sup> host.

**Pgi: Phosphoglucose isomerase**

**location:** 2-58.6 (Voelker *et al.*, 1980).

**references:** Lee, 1979, J. Biol. Chem. 254: 6375.

Voelker, Langley, Leigh-Brown, and Ohnishi, 1978, DIS 53: 200.

Voelker, Langley, Leigh-Brown, Ohnishi, Dickson, Montgomery, and Smith, 1980, Proc. Nat. Acad. Sci. USA 77: 1091-95.

Laurie-Ahlberg, Wilton, Curtsinger, and Emigh, 1982, Genetics 102: 191-206.

Burkhart, Dickson, Montgomery, Langley, and Voelker, 1984, Genetics 107: 295-306.

**phenotype:** Structural gene for the glycolytic enzyme phosphoglucose isomerase [PGI (E.C. 5.3.1.9)]. There are two electrophoretic variants (fast and slow); also a deficiency for the locus which is CRM negative and probably homozygous lethal (Lee, 1979).

**alleles:** Two *Pgi*<sup>+</sup> alleles [*Pgi*<sup>4</sup> (fast) and *Pgi*<sup>2</sup> (slow)] and one *Pgi*<sup>-</sup> allele (*Pgi*<sup>n<sup>C80</sup></sup>) have been reported. Out of a total of 716 alleles collected in North Carolina, one null allele was recovered (Langley *et al.*, 1981).

**Pgk: Phosphoglycerate kinase**

**location:** 2-5.9 (between *al* and *dp*) (Voelker *et al.*, 1979).

**references:** Chew and Cooper, 1973, Biochem. Genet. 8: 267-70.

Voelker, Ohnishi, and Langley, 1979, Biochem. Genet. 17: 769-83.

Laurie-Ahlberg, Wilton, Curtsinger, and Emigh, 1982, Genetics 102: 191-206.

**phenotype:** Structural gene for 3-phosphoglycerate kinase [3-PGK (E.C. 2.7.2.3)]. Three electrophoretic variants (fast, intermediate, slow) isolated by Chew and Cooper (1973), the heterozygotes showing no hybrid band; two electrophoretic variants isolated by Voelker *et al.* (1979).

**alleles:** Three *Pgk*<sup>+</sup> alleles, *Pgk*<sup>3</sup> (fast), *Pgk*<sup>2</sup> (intermediate), *Pgk*<sup>1</sup> (slow) of Chew and Cooper (1973). No null alleles reported out of a total of 702 alleles collected in North Carolina (Langley *et al.*, 1981).

**cytology:** Located between 22D and 23C since included in the 2<sup>D</sup> segregant of *T(Y;2)G146 = T(Y;2)h23;23B-C* but not of *T(Y;2)R136 = T(Y;2)h3;h7;22D*.

**Pgm: Phosphoglucomutase**

**location:** 3-43.4 (between *th* and *st*; Hjorth, 1970) or 3-43.6 (between *G1* and *st*; Trippa *et al.*, 1970, 1971).

**references:** Hjorth, 1970a, DIS 45: 39.

Trippa, Danieli, Costa, and Scozzari, 1977, DIS 52: 74.

Voelker, Ohnishi, and Langley, 1979, Biochem. Genet. 17: 769-83.

**phenotype:** Structural gene for the glycolytic enzyme phosphoglucomutase [PGM (E.C. 2.7.5.1)], a monomeric protein of 56,000 daltons. Two frequently-occurring electrophoretic variants were isolated and studied by Hjorth (1970a,b) and Trippa *et al.* (1970, 1971). Later five low-frequency variants were found by Trippa's group (see references in table of alleles). One null allele found in a total of 431 alleles collected in Great Britain (Langley, Voelker, Leigh-Brown, Ohnishi, Dickson, and Montgomery, 1981, Genetics 99: 151-56).

**alleles:** The seven *Pgm*<sup>+</sup> alleles identified by Trippa's group are listed in the following table. The most common allele has been designated *Pgm*<sup>4</sup> in accordance with the convention of Voelker *et al.* (1979). The slower-migrating alleles are given superscript numbers below four while the faster-migrating alleles have numbers above four.

allele	synonym	ref <sup>α</sup>	comments
<i>Pgm</i> <sup>1β</sup>	<i>Pgm E</i> ; <i>Pgm</i> <sup>0.55</sup>	2, 3, 5	slowest migration on gel
<i>Pgm</i> <sup>2β</sup>	<i>Pgm B</i> ; <i>Pgm</i> <sup>0.70</sup> ; <i>Pgm</i> <sup>2</sup>	1-6	frequency 0.8 - 20.7%
<i>Pgm</i> <sup>3</sup>	<i>Pgm F</i> ; <i>Pgm</i> <sup>0.85</sup>	2, 3, 5	
<i>Pgm</i> <sup>4γ</sup>	<i>Pgm A</i> ; <i>Pgm</i> <sup>1.00</sup> ; <i>Pgm</i> <sup>1</sup>	1-6	frequency 79.3 - 99.2%

 Santamaría, Deatrick, and Randsholt, 1989, *Roux's Arch. Dev. Biol.* 198: 65-77.

**phenotype:** A member of the Polycomb group of genes; seems to be the only one that is strongly required both maternally and zygotically for normal embryonic development. Two mutagenic events are necessary to produce null mutations, suggesting that the locus is complex, and in fact molecular determinations indicate that the locus comprises a direct repeat. Single-event mutations are viable as males and homozygous females; such mutations produce transformations similar to those of known dominant gain-of-function mutants in the *ANTC* and *BXC*, *i.e.*, transformation of wings to halteres, second and third legs to first legs, and anterior abdominal segments to more posterior segments (mutants may also show loss of the humerus). Two-event lethal mutations die in mid embryogenesis and completely lack ventral and abdominal epidermal derivatives; they show transformations of most of the segments toward the eighth abdominal segment (Dura *et al.*, 1988). There is an alteration in the pattern of axon pathways in the CNS. The axons fail to form commissures or connectives but instead form large bundles in the middle of each hemiganglion (Smouse *et al.*, 1988). Trans heterozygotes between viable and lethal alleles or between viable alleles and a deficiency for *ph* die in late embryogenesis and exhibit posteriorly directed transformations; *i.e.* viable alleles are haplo insufficient. Dura *et al.* (1987) postulate that mutations can occur in either or both of the repeated sequences such that  $-/+ = +/- = -/+ =$  viable mutant constitutions ( $-/+$  not stated to be mutant);  $-/+ = +/- =$  late embryonic lethals; and  $-/- =$  mid-embryonic-stage lethals.

The  $ph^+$  product is required autonomously in imaginal cells. A total lack of  $ph^+$  function prevents viability of the cuticular derivatives of these cells, but amorphic *ph* clones induced in late third instar survive. *ph* has a strong maternal effect on segmental identity and epidermal development that cannot be rescued by a single paternally supplied dose of  $ph^+$  in the zygote (Dura *et al.*, 1988).

The expression of *ph* is inversely related to dosage of the *ANTC* and the *BXC*; the gene interacts with *Pc*, *Pcl*, and *esc* (Dura *et al.*, 1985). At the shortened germ band stage (but not at the blastoderm stage), *ph* seems to be involved in the regulation, not only of the homeotic genes *Scr* and *Ubx*, but also in the regulation of the segmentation genes *ftz*, *eve*, and *en* (Dura and Ingham, 1988).

**alleles:** Almost 50 mutant alleles of polyhomeotic have been isolated, 41 of them being viable as adults and the rest ( $ph^{500}$  -  $ph^{505}$ ) lethal.

<sup>α</sup> 1 = Dura, Brock, and Santamaría, 1985, *Mol. Gen. Genet.* 198: 213-20; 2 = Dura, Deatrick, Randsholt, Brock, and Santamaría, 1988, *Roux's Arch. Dev. Biol.* 197: 239-46; 3 = Dura, Randsholt, Deatrick, Erk, Santamaría, Freeman, Freeman, Weddell, and Brock, 1987, *Cell* 51: 829-39; 4 = Perrimon, Engstrom, and Mahowald, 1985, *Genetics* 111: 23-41.

<sup>β</sup> Viable over deficiencies for *ph*. (Dura *et al.*, 1987).

<sup>γ</sup> Chromosome mutant for *ph* and *wapl* but not for the intervening *Pgd*; probably carries an inversion with breaks in *ph* and *wapl* (Dura *et al.*, 1987); *ph*<sup>3</sup> separable from the associated *Tp(1;1)2E-F;5B-C;19F-20* (Dura *et al.*, 1985).

<sup>δ</sup> Carries *In(1)2D;13-14*.

<sup>ε</sup> Lethal derivative of *ph*<sup>209</sup>.

<sup>ζ</sup> Extra row of bristles on wing margin; structures like vaginal plates in sixth and seventh sternites of female abdomen (Dura *et al.*, 1988).

**cytology:** Placed in 2D3-4; uncovered by *Df(1)JA52 = Df(1)2C10-D1;2D3-4* and *Df(1)pn38 = Df(1)2D3-4;2E3* (Perrimon *et al.*, 1985; Dura *et al.*, 1987); *Df(1)Pgd-kz = Df(1)2D3-4;2F5* is broken within *ph* sequences; not covered by *Dp(1;1)dorY18T = Dp(1;1)1A;2D1-2*.

**molecular biology:** The *ph* gene was localized within a 240 kb chromosome walk, using deficiencies and mutations that result from chromosome rearrangements. Hybridization analyses indicate that *ph* contains a large, highly-conserved direct but not quite contiguous repeat, each element of which contains an opa sequence, and

each is transcribed (Freeman, Randsholt, Deatrick, and Brock). One repeat, distal to the distal breakpoint of *Df(1)Pgd-kz = Df(1)2D3-4;2F5*, is unbroken and contains molecular deletions in mutant alleles, *ph*<sup>2</sup>, *ph*<sup>4</sup>, *ph*<sup>10a</sup>, and *ph*<sup>401</sup>. The proximal element is interrupted by an unrelated sequence and is deleted by *Df(1)Pgd-kz*; mutant alleles *ph*<sup>3</sup> and *ph*<sup>7</sup> contain inserted sequences in the proximal repeat element; *ph*<sup>409</sup>, and *ph*<sup>410</sup> have breakpoints in the element. A restriction site polymorphism is found in the 1.95 kb fragment separating the repeat components (Dura *et al.*, 1987). All of the *ph* lesions map within a 20 kb region between the distal breakpoint of *Df(1)pn38* and the proximal breakpoint of *Df(1)JA52*. DNA fragments from coordinates 122 to 149 on the molecular map of the 2C1-2 to 2E1-2 region (0 being the distal point of the walk) hybridize to two major embryonic poly(A)<sup>+</sup> RNA's of 6.4 and 6.1 kb (Dura *et al.*, 1987).

*phase-angle3*: see *psi3*

**Phb: Photophobe**

location: 2R.

origin: Induced by ethyl methanesulfonate in a *sev*<sup>LY3</sup> strain.

references: Ballinger and Benzer, 1988, Proc. Nat. Acad. Sci. USA 85: 3960-64.

phenotype: Dominant mutation that reverses the color-choice behavior of *sev*<sup>LY3</sup> mutants - *i.e.* *sev*<sup>LY3</sup>; *Phb*/+ flies, like wild-type flies, prefer UV over green light, while *sev*<sup>LY3</sup>;+/+ flies prefer green over UV. When tested in a T-maze for preference between darkness and green light (550 nm), both wild type and *sev*<sup>LY3</sup> flies show positive phototaxis, while *sev*<sup>LY3</sup>; *Phb*/+ and *sev*<sup>LY3</sup>; *Phb/Phb* flies show negative phototaxis. Similarly, tests in a countercurrent apparatus for movement toward and movement away from white light indicate marked preference of wild-type flies for light and of *sev*<sup>LY3</sup>; *Phb*/+ flies for darkness. Both the positive phototactic response of *sev*<sup>LY3</sup> and the negative phototactic response of *sev*<sup>LY3</sup>; *Phb*/+ flies increase with age, reaching a maximum at 4-6 days. The interaction between *Phb* and *sev* is allele specific, as is indicated in the following table:

genotype	phototaxis
<i>sev</i> <sup>d2</sup> ; <i>Phb</i> /+	+
<i>sev</i> <sup>E1</sup> ; <i>Phb</i> /+	+
<i>sev</i> <sup>E4</sup> ; <i>Phb</i> /+	+
<i>sev</i> <sup>E5</sup> ; <i>Phb</i> /+	+
<i>sev</i> <sup>f31E</sup> ; <i>Phb</i> /+	+
<i>sev</i> <sup>LY3</sup> ; <i>Phb</i> /+	-
<i>sev</i> <sup>P3</sup> ; <i>Phb</i> /+	-
<i>sev</i> <sup>x3</sup> ; <i>Phb</i> /+	+

Photoreceptor cell R7, missing in all of the *sev* alleles, was not restored in any mutant combination of *Phb* and *sev*.

**Phenol oxidase**: see **Phox**

**phl: pole hole**

location: 1-0.5.

synonym: *l(1)2Fe*; *l(1)ph*.

phenotype: The wild-type allele of *phl* seems to be involved in the setting up of positional values in embryos and also in the proliferation of diploid cells in imaginal disks (Ambrosio, Perrimon, and Mahowald, 1988). *phl* mutants are recessive early-pupal lethals, which display very small imaginal disks. Embryos derived from germline clones and lacking *phl*<sup>+</sup> activity show the "torso" or "pole hole" phenotype; structures at the anterior and the posterior end (spiracles, anal tufts, and the entire eighth abdominal segment) fail to develop (Perrimon *et al.*, 1984; Ambrosio, Mahowald, and Perrimon, 1988). The fate map of the blastoderm is shifted posteriorly and fewer segments with more cells result. A partial rescue of these mutants has been obtained with *phl*<sup>+</sup> sperm (Ambrosio, Engstrom, and Mahowald); all structures posterior to abdominal segment seven are missing (Perrimon and Mahowald, 1986).

**location:** 2-80.6.

**references:** Batterham and McKechnie, 1980, Genetica 54: 121-26.

Batterham, 1981, Genetics 97: s8.

Batterham and Chambers, 1981, DIS 56: 18-19.

**phenotype:** Structural gene for a phenol oxidase component other than A1, A2, or A3. [PHOX (E.C. 1.10.3.1)]. It is a tyrosinase, oxidizing mono- and o-diphenols. Three electrophoretic variants have been described by Batterham and McKechnie (1980), but no null alleles. The molecular weight of the native enzyme is 108,000 daltons. PHOX is believed to be a dimer with a subunit molecular weight of 54,000 (Batterham and Chambers, 1981).

**alleles:** *Phox<sup>F</sup>* (fast), *Phox<sup>I</sup>* (intermediate), and *Phox<sup>S</sup>* (slow). *Phox<sup>I</sup>* is the most common allele in Australasia, occurring with a minimum frequency of 0.85 (Batterham, 1981). No alleles affecting activity levels have been demonstrated, although the possible allelism between *Phox* and the mutant *Bc* [with the same genetic location as *Phox* (2-80.6)] has been suggested (Treat-Clemons and Doane, 1984, DIS 60: 17-42; Wright, 1987, Adv. Genet. 24: 127-222).

**other information:** *tyr1* and *lz<sup>3</sup>* show no PHOX activity (Wright, 1987).

**phr: photorepair**

**location:** 2-56.8 (between *pr* and *c*).

**origin:** Spontaneous in a standard laboratory stock.

**references:** Boyd and Harris, 1985, Genetics 110: s85. 1987, Genetics 116: 233-39.

**phenotype:** Deficient in photorepair of pyrimidine dimers; partially deficient in excision repair. Since *phr/phr* larvae show little or no photoreactivation after exposure to short wavelength UV light, the *phr<sup>+</sup>* function is thought to play a significant role in UV resistance.

**pi: pied**

**location:** 2-17.

**origin:** Spontaneous.

**discoverer:** Hamly, 38k31.

**phenotype:** Eyes like *S* but more extreme, smaller, and rougher; facets jumbled. Wings larger, flimsy, arched, and fringed. Male usually sterile, have abnormal genitalia. Viability erratic, varying from 20 to 80%. RK3.

**pic: piccolo**

**location:** 3-52.1 (distal to *ry* and *snk*).

**synonym:** *l(3)87D*.

**references:** Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 1261-68.

Hilliker, Clark, and Chovnick, 1980, Genetics 95: 95-110.

Hilliker, Clark, Gelbart, and Chovnick, 1981, DIS 56: 65-72.

Clark and Chovnick, 1986, Genetics 114: 819-40.

**phenotype:** Lethal or semilethal as homozygotes or heteroallelic heterozygotes. Survivors show the *pic* visible phenotype, *i.e.* short and thin or missing thoracic bristles, abnormal tergite morphology (as in *bb*), and, occasionally, wing defects.

**alleles:** One semilethal and 32 lethal alleles have been identified. Six of the lethals show some interallelic complementation for viability, but not for the visible phenotype.

**discoverer:** Goldschmidt.

**references:** 1953, *J. Exp. Zool.* 122: 53-96 (fig.).

**phenotype:** Produces setae of varying numbers and sizes on the sixth sternite of normal male and of X/X; *tra/tra* female. Effect enhanced by presence of *pil3* and also by Y chromosome of *tra* stock. RK3.

***pim:*** *pimples*

**locations:** 2-30.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1983, DIS 59: 158-60.

1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**phenotype:** Homozygous lethal in embryo. Cuticle poorly differentiated with necrotic patches. Head abnormal.

**cytology:** Located in 31B-32A (Nüsslein-Volhard *et al.*, 1984); uncovered by  $Df(2L)J27 = Df(2L)31B-D;31F-32A$ .

**alleles:** Only one allele was reported by Nüsslein-Volhard *et al.* (1984).

***Pin:*** *Pin*

**location:** 2-107.3 (to the right of *sp*).

**phenotype:** Thoracic bristles, especially dorso-centrals and scutellars, shortened and thick at base, sharply tapered at tip. This bristle phenotype is stronger in homozygotes than heterozygotes in the homozygous-viable allele *Pin*<sup>1</sup>.

**alleles:** Five *Pin* alleles have been described. Phenotypes of the homozygous lethal alleles follow the table.

allele	origin	discoverer	ref <sup>α</sup>
<i>Pin</i> <sup>1</sup>	spont	Ives, 39a9	4
<i>Pin</i> <sup>2</sup>	spont	Grell, 57b	3
<i>Pin</i> <sup>B</sup>	EMS	Bacher, 66	1
<i>Pin</i> <sup>Tac</sup>	spont	Weiskettel, 57l	5
<i>Pin</i> <sup>Yt</sup>	spont	Grell, 57e	2

<sup>α</sup> 1 = Craymer, 1980, DIS 55: 197-200; 2 = Grell, 1957, DIS 31: 81; 3 = Grell, 1960, DIS 34: 50; 4 = Ives, 1940, DIS 13: 50; 5 = Kadel, 1958, DIS 32: 80.

**cytology:** Located between 60C5 and 60D2 since *Pin*<sup>2</sup> is lethal over  $Df(2R)Px = Df(2R)60B8-10;60D1-2$  or  $Df(2R)Px^2 = Df(2R)60C5-6;60D9-10$ .

***Pin*<sup>2</sup>**

**phenotype:** Thoracic bristles of *Pin*<sup>2</sup>/+ flies very short at normal room temperature, but wild type at 17°. Homozygotes almost lethal, the few survivors having virtually no thoracic bristles. *Pin*<sup>2</sup>/*Pin* mutants have smaller bristles than *Pin*<sup>2</sup>/+ and lower viability. *Pin*<sup>2</sup>/*Pin*<sup>Yt</sup> is lethal, as are  $Df(2R)Px/Pin^2$ ,  $Df(2R)Px^2/Pin^2$ , and  $Df(2R)Px^4/Pin^2$ . *Pin*<sup>2</sup>/+ flies carrying *bw*<sup>+</sup>*Y* have longer bristles than *Pin*<sup>2</sup>/+ but shorter than wild type.

***Pin*<sup>B</sup>:** *Pin-Bacher*

**phenotype:** Thoracic bristles of *Pin*<sup>B</sup>/+ flies are pale yellow, thin and twisted (like *Pin*<sup>Yt</sup>/+ flies but more extreme). *Pin*<sup>B</sup>/*Pin*<sup>1</sup> has only vestiges of chaetae on the thorax; also has soft, watery-appearing cuticle. Homozygotes lethal.

***Pin*<sup>Tac</sup>:** *Pin-Tack*

**phenotype:** Thoracic bristles of *Pin*<sup>Tac</sup>/+ flies very small at 22°, but almost wild type at 18°. Older females hold wings in abnormal position. Homozygous lethal.

***Pin*<sup>Yt</sup>:** *Pin-Yellow-tip*

**phenotype:** Thoracic bristles of *Pin*<sup>Yt</sup>/+ flies are pale yellow, thin, and slightly twisted distally; cuticle appears soft. Homozygous lethal and lethal over *Pin*<sup>1</sup> and *Pin*<sup>2</sup>; survives in combination with  $Df(2R)Px$  and resembles *Pin*<sup>Yt</sup>/+.

***pink:*** see *p*

*pinkoid*: see *lt<sup>pk</sup>*

### *pip*: *pipe*

**location**: 3-47.

**origin**: Induced by ethyl methanesulfonate.

**references**: Anderson and Nüsslein-Volhard, 1984, *Nature* (London) 311: 223-27.

Anderson, Bokla, and Nüsslein-Volhard, 1985, *Cell* 42: 791-98.

Carroll, Winslow, Trombly, and Scott, 1987, *Development* 99: 327-32.

**phenotype**: Maternal-effect lethal; homozygous females are sterile. As in the mutant *dl*, lethal embryos produced by *pip* females lack ventral and lateral elements; all cells differentiate like the dorsal-most cells of normal embryos (Anderson and Nüsslein-Volhard, 1984). Dorsalization is also observed in the pattern of *ftz* stripes in *pip* embryos (Carroll *et al.*, 1987). Embryos are not rescued by injection of wild-type cytoplasm; injection of cytoplasm from ventralized embryos of *Tl<sup>5/+</sup>* females, however, partially restores the *pip<sup>+</sup>* embryonic pattern, resulting in differentiation of filzkörper in 25-40% of the treated *pip* embryos (Anderson *et al.*, 1985).

**alleles**: The alleles *pip<sup>1</sup>* and *pip<sup>2</sup>* recovered as *pip<sup>286</sup>* and *pip<sup>664</sup>*.

### *pk*: *prickle*

**location**: 2-55.3.

**discoverer**: Ives, 38k.

**references**: 1947, *DIS* 21: 68-69.

Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, *DIS* 56: 186-91.

Gubb and García-Bellido, 1982, *J. Embryol. Exp. Morphol.* 68: 37-57.

**phenotype**: Polarity pattern of wing, haltere, and notum altered in mutants. Chaetae of triple row on anterior wing slanted anteriorly instead of posteriorly. Trichomes near L2 vein arranged in counterclockwise whorl on right wing blade, in clockwise whorl on left blade; trichomes in anterior wing occasionally duplicated (Gubb and García-Bellido, 1982). On the notum, the posterior acrostichals are irregularly erect and whorled. Occasionally, extra dorsocentral and scutellar bristles appear at temperatures above 23°. Mutant flies slightly larger than wild type. Gubb and García-Bellido (1982) describe somatic clones of homozygous *pk* cells.

**alleles**: All alleles viable and *pk* over *Df(2R)pk78k*, indicating no lethal alleles at locus (Gubb and García-Bellido, 1982).

The three protein kinase gene families that have been characterized in *Drosophila*, *Pka*, *Pkc*, and *Pkg*, are described in the following sections.

### *Pka*: *Protein kinase-cAMP*

*Drosophila* c-AMP-dependent protein kinase has been purified from the bodies of adult flies; the enzyme is made up of catalytic and regulatory subunits (Foster, Guttman, Hall, and Rosen, 1984, *J. Biol. Chem.* 259: 13049-55). The catalytic subunit has a molecular weight of 40,000 and the regulatory subunit a molecular weight of 52,000 or 58,000 (based on electrophoretic mobilities in sodium dodecyl sulfate-polyacrylamide gels). This enzyme was found in all developmental stages of *Drosophila melanogaster*. Another c-AMP-dependent protein kinase occurs in larvae and during the first half of pupation, but not in embryos and adults. Genes encoding the protein found throughout the lifetime of *Drosophila* have been identified by molecular methods (Foster *et al.*, 1988; Kalderon and Rubin, 1988). These genes are very similar in their amino acid sequences to their mammalian counterparts. A description of the genes follows.

#### *Pka-C1*

**references**: Foster, Higgins, and Jackson, 1988, *J. Biol. Chem.* 263: 1676-81.

Kalderon and Rubin, 1988, *Genes Dev.* 2: 1539-56.

**phenotype**: Encodes one of the isoforms of the catalytic subunit form of *Pka*.

**molecular biology**: *Pka-C1* has been cloned using mammalian probes and its nucleotide and putative amino acid sequences determined (Foster *et al.*, 1988; Kalderon and Rubin, 1988). This gene shows 82% overall sequence identity to the c-AMP-dependent protein kinase catalytic

gene in mouse. *Pka-C1* is the source of at least four different transcripts (Kalderon and Rubin, 1988). The coding portion of the gene contains no introns and encodes a protein of 352 amino acids. An insertion of two amino acids not found in bovine and mouse enzymes has been located near the N terminus of the protein; 273 of the remaining 350 amino acids are identical to those of the bovine and mouse enzymes (Foster *et al.*, 1988).

**other information:** 11 additional *Drosophila melanogaster* DNA clones whose sequences are similar to that of *Pka-C1* within the kinase domain have been identified by nucleic acid hybridization. cDNAs have been obtained for ten of the genes involved (Kalderon and Rubin, 1988). The putative protein products of two genes (*Pka-C2* and *Pka-C3*) show 45% and 49% amino acid identity to the corresponding mouse protein kinase.

**Pka-R1**

**references:** Kalderon and Rubin, 1988, *Genes Dev.* 2: 1539-56.

**phenotype:** Encodes the type I regulatory subunit form of *Pka*.

**molecular biology:** A cAMP-dependent protein kinase regulatory subunit gene has been cloned using mammalian probes and its nucleotide and putative amino acid sequences determined (Kalderon and Rubin, 1988). *Pka-R1* is the source of at least three distinct transcripts that originate from different promoters that are spliced to a common coding region. The gene encodes at least three putative RI polypeptide products; it shows 71% amino acid identity to the mammalian RI subunit. Only the RNA class that encodes a full-length RI protein can be detected at all stages of development.

**other information:** There are two separate genes transcribed in opposite orientation to *Pka-R1* within the first and largest intron; the function of these genes is unknown.

**Pkc: Protein kinase-c**

The protein kinase C (PKC) enzyme in *Drosophila* is encoded by a gene family made up of three genes which are expressed primarily in adult flies. The deduced amino acid sequences of these genes are quite similar to each other and those of the mammalian PKC family (Schaeffer *et al.*, 1989).

**Pkc1: Protein kinase-c1**

**references:** Rosenthal, Rhee, Yadegari, Paro, Ullrich, and Goeddel, 1987, *EMBO J.* 6: 433-41.

Schaeffer, Smith, Mardon, Quinn, and Zuker, 1989, *Cell* 57: 403-12.

**phenotype:** Structural gene for protein kinase C (PKC) that is expressed primarily in the brain of adult flies.

**molecular biology:** *Pkc1* has been isolated from Oregon-R DNA clones identified by using bovine PKC cDNA probes and its nucleotide sequence and predicted amino acid sequence obtained (Rosenthal *et al.*, 1987). A single open reading frame from the combined sequences of two overlapping cDNAs encodes a 657-amino acid, 75-kd protein with extensive similarity to bovine, rat, and human protein kinase C. This *Drosophila melanogaster* PKC, like the mammalian forms, carries an amino-terminal cysteine-rich repeat region. The carboxy-

terminal region of the *Pkc1* protein shows about 88% identity to the corresponding region of the mammalian PKC proteins. *Pkc1* contains 13 coding exons of 32-623 pb and at least one untranslated 5' exon. Introns range in size from 54 to more than 8000 bp. The coding regions of *Pkc1* in Oregon-R and Canton-S strains differ by 15 silent changes and one change at amino acid 428 (from isoleucine to methionine); in addition, there are three insertion-deletion changes in the 5' untranslated region. Transcripts of about 4.3, 4, and 2 kb (equally abundant) are found in the head of adult flies, but were not found in 0-3 hr embryos (Rosenthal *et al.*, 1987). Transcription occurs in most neurons of the adult head, including photoreceptor cells (Schaeffer *et al.*, 1989).

**other information:** Molecular data indicate that *Pkc1* lies approximately 20 kb from *Pkc2*, another PKC gene with 53E cytological location (Schaeffer *et al.*, 1989).

**Pkc2: Protein kinase-c2:**

**references:** Schaeffer, Smith, Mardon, Quinn, and Zuker, 1989, *Cell* 57: 403-12.

**phenotype:** Structural gene for protein kinase C (PKC); expressed primarily in photoreceptors of adult flies.

**molecular biology:** *Pkc2* has been isolated from Oregon-R DNA clones identified by using bovine PKC cDNA probes and its nucleotide sequence and predicted amino acid sequence obtained (Schaeffer *et al.*, 1989). There is a single open reading frame which encodes a 700 amino acid protein that is similar to other PKCs. The protein encoded by *Pkc2*, like the mammalian forms of the enzyme, carries an amino-terminal cysteine-rich repeat region. The carboxy-terminal region of the *Pkc2* protein (ATP binding site and catalytic domain) shows a high degree of identity to the corresponding region of mammalian PKC proteins. Transcripts are expressed in head (not body) tissue of adult flies. A 2.5 kb transcript accumulates in late pupal stages during the terminal differentiation of photoreceptor cells; it is found in both compound eyes and ocelli of wild type individuals (Schaeffer *et al.*, 1989).

**Pkc3: Protein kinase-c3**

**references:** Schaeffer, Smith, Mardon, Quinn, and Zuker, 1989, *Cell* 57: 403-12.

**phenotype:** Structural gene for protein kinase C (PKC); expressed primarily in adult flies.

**molecular biology:** *Pkc3* has been isolated from Oregon-R DNA clones identified by using bovine PKC cDNA probes and its nucleotide sequence and predicted amino acid sequence obtained (Schaeffer *et al.*, 1989). There is a single open reading frame which encodes a 634 amino acid protein that shows 61% identity to the mammalian PKC (Ono, Fujii, Ogita, Kikkawa, Igarashi, and Nishizuka, 1988, *J. Biol. Chem.* 263: 6927-32); the *Pkc3* protein, however, diverges markedly from that of *Pkc1*, *Pkc2*, and the classical mammalian PKC genes in its amino-terminal region. *Pkc3* encodes a major 5.5 kb transcript that is found throughout development, although in reduced amounts in embryos; two other transcripts (4.3 and 4.5 kb) show increased embryonic expression. Adult transcription occurs in the cell bodies of the brain (Schaeffer *et al.*, 1989).

**Pkg: Protein kinase-cGMP**

Genes in *Drosophila melanogaster* encoding products related (by sequence comparison) to cGMP-dependent protein kinases of mammals have been isolated by using a *Drosophila* cAMP-dependent protein kinase catalytic subunit gene as a probe.

**Pkg1**

**references:** Kalderon and Rubin, 1989, J. Biol. Chem. 264: 10738-48.

**phenotype:** Encodes a product with putative cGMP-dependent binding and kinase domains that is 14% larger than the corresponding mammalian enzyme. It is believed to bind cGMP and to undergo changes enabling its catalytic site to interact with appropriate substrates. This gene is unusually polymorphic in various *Drosophila* stocks. The role of the gene and its enzyme in the organism as a whole is unknown at present.

**molecular biology:** *Pkg1* cloned and three cDNAs isolated with the genomic DNA as a probe; DNA and putative protein sequences determined (Kalderon and Rubin, 1989). A fragment that is part of the cGMP-dependent protein kinase gene (or a close homolog) was also cloned and sequenced (Foster, Higgins, and Jackson 1988, J. Biol. Chem. 263: 1676-81). There are four introns (one in the coding region, another in the regulatory domain, and two in the catalytic domain); the first intron is about 2 kb long. One major transcript of 2.8 kb was found in all developmental stages examined; this transcript is found mainly in the head in adult flies. The protein product differs from the bovine lung sequence at the amino terminus; it shows 61% identity to the mammalian enzyme in the putative cGMP binding domain and 70% identity in the kinase domain; both domains are arranged in consecutive order on the same polypeptide as in the mammalian cGMP-dependent protein kinase.

**Pkg2**

**references:** Kalderon and Rubin, 1989, J. Biol. Chem. 264: 10738-48.

**phenotype:** Encodes products with putative cGMP-dependent protein kinase activities (indicated by sequencing data obtained for all but two of the predicted proteins). The role of the gene and its enzymes in the organism as a whole is unknown at present.

**molecular biology:** Multiple cDNA clones were isolated and the sequence of representative cDNAs and the corresponding genomic DNAs determined (Kalderon and Rubin, 1989). There are three major RNA species of different sizes (4.6, 4.4, and 3.6 kb). The protein product shows 64% identity to the bovine lung cGMP-dependent protein kinase; one of the *Drosophila* products contains an additional 384 amino acids at the extreme amino terminus. All three of the major *Pkg2* transcripts can be detected throughout development. There are seven introns, three of which are located within two nucleotides of the corresponding introns in *Pkg1*; the positions of these introns do not correspond to the boundaries of the domains in the encoded proteins.

**\*pkh: pinkish**

**location:** 2-100.

**discoverer:** Bridges, 14g27.

**references:** 1919, J. Exptl. Zool. 28: 365.

Bridges and Morgan, 1919, Carnegie Inst. Washington

Publ. No. 278: 247 (fig.).

**phenotype:** Specific dilutor of  $w^e$ . RK3.

**pl: pleated**

**location:** 1-47.9.

**origin:** X ray induced.

**discoverer:** Moore, 31c15.

**references:** 1935, DIS 3: 27.

**phenotype:** Wings folded lengthwise in pleats. Overlaps wild type at 25°, more extreme at 19°. RK3.

**cytology:** Placed in salivary chromosome region 13B2-F17 on the basis of its being included in *Dp(1;f)A12 = Dp(1;f)1B-C;13B1-5* but not in the proximal part of the *X* derived from *T(1;4)A4 = T(1;4)13F6-14A1;102F* (inferred from Patterson, 1938, Am. Nat. 72: 193-206, also frontispiece of Texas Univ. Publ. 4032).

*pl*: see *pld*

**\*Pl: Pearl**

**location:** 2-6.

**origin:** Spontaneous.

**discoverer:** Rosin, 1948.

**references:** 1951, DIS 25: 75.

1952, Rev. Suisse Zool. 59: 261-68.

Nef, 1958, Z. Indukt. Abstamm. Vererbungslehre 89: 272-319 (fig.).

**phenotype:** Heterozygote has pearl-like nodes in wings. Wing margins often snapped; venation disturbed. Bristle pattern defective. Eyes small and rough. At 28°, at least one of these characters always present; at 18°, phenotype virtually normal. Viability good; fertility of male slightly reduced. Fraction of cells die in all imaginal disks. In wing disks, dead cells surrounded by epithelial cells and produce pearl-like structures in adult wing. Homozygote dies as pupa (Tschanz). RK2.

**PL: Polygenic Locus**

A genetic locus consisting of one or more closely linked genes at which allelic substitutions contribute to variance in a specified quantitative character such as the number of sternopleural bristles (Thompson and Thoday, 1974, Heredity 33: 430-37). The symbol *PL* is followed parenthetically by the chromosome involved and then by a symbol for the locus. A table of polygenic loci from the data of Thoday and his colleagues follows:

locus	location	synonym	ref <sup>α</sup>
<i>PL(1)sp</i> S1 <sup>β</sup>	1-2.4		3, 6
<i>PL(1)sp</i> S2	1-51.5		3, 6
<i>PL(2)L4a</i> γ	2-72.5		5
<i>PL(2)sp</i> G1	2-27.5		1, 6
<i>PL(2)sp</i> G2	2-47.5		1, 6
<i>PL(2)sp</i> S3	2-41.1	<i>ll</i>	3, 6

**ple: pale**

**location:** 3-18.8.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Jürgens, Wieschhaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.  
 Budnick and White, 1987, J. Neurogenet. 4: 309-14.  
 Neckameyer and Quinn, 1989, Neuron 2: 1167-75.  
**phenotype:** Homozygous lethal in embryo. Mutant embryos have unpigmented cuticle and head skeleton. Catecholamine levels reduced or absent (Budnick and White, 1987).  
**alleles:**

allele	synonym	comments
<b>*ple 1</b>	<i>*ple 7F</i>	
<b>ple 2</b>	<i>ple 70</i>	
<b>*ple 3</b>	<i>*ple 11F</i>	temperature-sensitive
<b>ple 4</b>	<i>ple 14A</i>	

**cytology:** Located in 65A-E based on segmental aneuploidy produced by Y-3 translocations.  
**other information:** *ple* may encode tyrosine hydrolase since *ple* and *Th* both map to 65B. The ability of *Th* DNA to rescue *ple* mutants has not been tested.

**pleated:** see *pl*

**Plexate:** see *Px*

**plexus:** see *px*

**pII: pelle**

**location:** 3-92.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Anderson and Nüsslein-Volhard, 1984, Nature (London) 311: 223-27.  
 Müller-Holtkamp, Knipple, Seifert, and Jäckle, 1985, Dev. Biol. 110: 238-46.  
 Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32.  
**phenotype:** Maternal-effect lethal; homozygous females sterile. As in the mutant *dl*, lethal embryos produced by *pII* females lack ventral and lateral elements (Anderson and Nüsslein-Volhard, 1984). Extreme *pII* embryos consist of a long, hollow tube with dorsal cuticular structures (Müller-Holtkamp *et al.*, 1985). Dorsalization is also observed in the pattern of *ftz* stripes in *pII* embryos (Carroll *et al.*, 1987). Injection of wild-type cytoplasm into *pII* embryos partially restores the normal embryonic pattern of development (Müller-Holtkamp *et al.*, 1985).  
**cytology:** Located in 97F.

**pn: prune**

**location:** 1-0.8.  
**references:** Beadle and Ephrussi, 1936, Genetics 21: 230.  
 Demerec, Kaufman, Fano, Sutton, and Sansome, 1942, Year Book-Carnegie Inst. Wash. 41: 191.  
 Nolte, 1959, Heredity 13: 233-41.  
 Lifschytz and Falk, 1969, Genet. Res. 14: 53-61.  
 Orevi and Falk, 1975, Mutat. Res. 33: 193-200.  
 Ilyina, Sorokin, Belyaeva, and Zhimulev, 1980, DIS 55: 205.  
 Teng, Bender, Engele, Tsubota, and Venkatesh, 1991, Genetics 128: 373-80.  
**phenotype:** Eye color of newly emerged flies transparent brownish red, becoming brownish purple with age. The eyes of *pn* males have about 25% as much drosopterin (red pigment) as the eyes of wild-type males (Gearhart and MacIntyre, 1970, Anal. Biochem. 37: 21-25); the concentrations of xanthopterin and sepiapterin (brown

pigments) are increased to about 110% of wild-type (Nolte, 1959). Control of drosoplerin synthesis seems to be related to the activity of the enzyme GTP cyclohydro-lase (Evans and Howell, 1979, *Biochem. Genet.* 16: 13-26). The *pn* eye color is autonomous in larval optic disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936). Larval Malpighian tube color is normal (Brehme and Demerec, 1942, *Growth* 6: 351-56).

Standard *pn* mutants are homo- and hemizygous viable in a wild-type background, but show a lethal interaction with the third chromosome dominant *awk<sup>K</sup>* (Lifschytz and Falk, 1969; Orevi, 1973, *DIS* 50: 77). Some temperature-sensitive *pn* mutants (*pn<sup>ts-e</sup>*), however, are insensitive to the killing action of *awk<sup>K</sup>*; one

temperature-sensitive mutant (*pn<sup>ts-ek</sup>*) is insensitive to *awk<sup>K</sup>* at permissive temperatures (18°, 22°), but sensitive to *awk<sup>K</sup>* at restrictive temperatures (25°, 29°) (Orevi, 1973, *DIS* 50: 80; Orevi and Falk, 1975). The TSP for the eye color phenotype occurs during the late pupal stage, while the TSP for the *pn* component of the *pn-awk<sup>K</sup>* interaction begins at the late pupal stage and lasts until eclosion (Orevi and Falk, 1975). Homo- and hemizygous *pn* deficiencies and other chromosomal rearrangements have been induced by Ilyina *et al.* (1980), as indicated in the allele table.

**alleles:** Eye color like *pn<sup>1</sup>* except when otherwise indicated. Alleles interact lethally with *awk<sup>K</sup>* except for those affected by temperature (Orevi and Falk, 1975).

<sup>β</sup> For new orders, see rearrangement listing in the chromosome section.

<sup>γ</sup> Synonym: *se-like 62*.

<sup>δ</sup> *pn<sup>27-9</sup>/pn<sup>68b</sup>* flies are wild type in eye color and insensitive to *awd<sup>K</sup>* (Wagenberg and Burdick, 1969).

<sup>ε</sup> 40 temperature non-sensitive mutants indistinguishable from standard *pn* alleles (Orevi and Falk, 1975).

<sup>ζ</sup> Nine *pn<sup>ts-e</sup>* alleles, all insensitive to *awd<sup>K</sup>* at all temperatures. Eye color light brown at 25° and 29°, wild type at 18° and 22° (Orevi and Falk, 1975).

<sup>η</sup> One allele, *pn<sup>ts-ek</sup>*, sensitive to *awd<sup>K</sup>* at 25° and 29°, but insensitive at 18° and 22°. Eye color light brown at 25° and 29°, wild type at 18° and 22° (Orevi and Falk, 1975).

**cytology:** Located in 2E2-3 since included in *Df(1)pn7a = Df(1)2E1-2;3A4* and *Df(1)pn38 = Df(1)2D3-4;2E3* (Ilyina *et al.*, 1980). Previously located at 2D5-6 by Demerec and Sutton (Demerec *et al.*, 1942) and by J.I. Valencia.

**pnr: pannier**

**location:** 3-58.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**phenotype:** Homozygous lethal. Dorsal anterior of embryo open.

**alleles:** Two alleles, *pnr<sup>1</sup>* and *pnr<sup>2</sup>*, recovered as *pnr<sup>7G</sup>* and *pnr<sup>9L</sup>*.

**cytology:** Placed in 89B9-10 since uncovered by *Df(3R)sbd45 = Df(3R)89B4;89B10* but not by *Df(3R)sbd105 = Df(3R)88F9-89A1;89B9-10* (Hughes, Nelson, Yanuk, and Szauter).

**pnt: pointed**

**location:** 3-79.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

Mayer and Nüsslein-Volhard, 1988, Genes Dev. 2: 1496-1511.

**phenotype:** Homozygous lethal. Zygotic expression in embryo. Head skeleton of embryo pointed; median part of all denticle bands deleted. CNS broad and less dense than wild type. Sensory organs (maxillary, antennal, and Keilin's organs) spread.

**alleles:** Two alleles, *pnt<sup>1</sup>* and *pnt<sup>2</sup>*, recovered as *pnt<sup>8B</sup>* and *pnt<sup>9J</sup>*.

**cytology:** Located in 94E; covered by *Y<sup>P3D</sup> of T(Y;3)B27 = T(Y;3)94E* but not *T(Y;3)R13 = T(Y;3)94E*.

**po: pale ocelli**

**location:** 2-65.2.

**origin:** Spontaneous.

**discoverer:** Bridges, 38d1.

**phenotype:** Ocelli virtually colorless; some pigment bordering inner margins. Eye color slightly brighter than wild type. RK2.

**\*po<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** Bridges, 20j13.

**synonym:** *do: dilute ocelli*.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 224.

**phenotype:** Ocelli pale. RK3.

**Po: Pyridoxal oxidase**

**location:** 3-57.1 (0.08 unit to left of *Aldox*).

**synonym:** *lpo*.

**references:** Collins and Glassman, 1969, *Genetics* 61: 833-39.

Dickinson and Weisbrod, 1976, *Biochem. Genet.* 14: 709-21.

**phenotype:** The structural gene for the enzyme, pyridoxal oxidase [PO (EC 1.2.3.8)]; molecular weight approximately 225,000 daltons. Enzymatic characterization by Hanley (1980, *Mol. Gen. Genet.* 180: 455-62). Substrate specificities explored by Cypher, Tedesco, Courtright, and Kumaran (1982, *Biochem. Genet.* 20: 315-32). As PO is a molybdenum-containing protein (Warner and Finnerty, 1981, *Mol. Gen. Genet.* 184: 92-96), its activity is absent from *cin*, *mal*, and *lxd* flies, but cross reacting material is present in the latter two (but not the former) genotypes (Warner, Watts, and Finnerty, 1980, *Mol. Gen. Genet.* 180: 449-53). Enzyme activity present in all major organs except cardia, crop, imaginal discs, ovarian follicle cells, paragonia, pericardial cells, and wreath cells (Cypher *et al.*, 1982). Developmental profile shows dramatic increase in activity beginning in late pupa and continuing into adult life (Dickinson and Weisbrod, 1976). The nearly amorphic allele, *Po<sup>lpo</sup>*, exhibits 2% normal activity; little if any cross reacting material is detectable in *Po<sup>lpo</sup>*.

**alleles:** In addition to *Po<sup>lpo</sup>*, electrophoretic variants *Po<sup>S</sup>* (common) and *Po<sup>F</sup>* (rare) have been recorded (Dickinson and Weisbrod, 1976). *In(3R)LVM* reported to carry a hypomorphic allele, *Po<sup>LVM</sup>*.

**cytology:** Placed in 89A1-3 based on its inclusion in *Df(3R)Po3 = Df(3R)89A1-2;89A11-13* but not *Df(3R)c3G2 = Df(3R)89A2-3;89A4-5* (Hughes, Nelson, Yanuk and Szauter).

**other information:** Name changed from *lpo* to *Po* in order to conform to terminology for other structural genes for enzymes.

**pod: podgy**

**location:** 2-55.

**references:** Ashburner, 1991, DIS 69.

**pod foot: see pdf**

**\*podG: podoptera of Goldschmidt**

**location:** Multifactorial.

**origin:** Spontaneous.

**discoverer:** Goldschmidt, 1943.

**references:** 1945, *Science* 101: 389-90.

1945, *J. Morphol.* 77: 71-103 (fig.).

Goldschmidt, Hannah, and Piternick, 1951, *Univ. Calif. Publ. Zool.* 55: 67-294.

**phenotype:** Wing transformation into legs varies from

almost wild type to three-jointed, leg-like appendages. Penetrance of 1-2% was increased to 2-4% by selection. Scalloped, blistered, and unexpanded wings and various abnormalities of legs are pleiotropic effects. RK3.

**other information:** Podoptera may be similar to tetraltera effects.

**podgy: see pod**

**\*podH: podoptera of Hannah**

**location:** Multifactorial (principal factor on chromosome 2).

**origin:** Spontaneous.

**discoverer:** Hannah, 1943.

**references:** Goldschmidt, Hannah, and Piternick, 1951, *Univ. Calif. Publ. Zool.* 55: 67-294.

**phenotype:** Wings transformed into leg-like appendages. Legs characteristically changed and parts often duplicated. Average penetrance of 2.5% increases to 5% in selected lines. Somatic elimination of X chromosome produces more than 2% gynandromorphs. RK3.

**other information:** Claimed to have a maternally inherited component.

**\*podK: podoptera of Kellen-Piternick**

**location:** Multifactorial.

**origin:** Spontaneous.

**discoverer:** Kellen-Piternick, 1944.

**references:** Goldschmidt, Hannah, and Piternick, 1951, *Univ. Calif. Publ. Zool.* 55: 67-294.

**phenotype:** Like *podG*. Wings sometimes replaced by palpus-like structure. Average penetrance 30% in *X/X/Y* females and *X/Y* males. Females without *Y* or *Y<sup>L</sup>* do not show podoptera phenotype. Rough eyes, notched wings, and absence of postverticals occur. RK3.

**\*podM: podoptera in M(3)w-124**

**location:** Multifactorial.

**origin:** Spontaneous.

**discoverer:** Kellen-Piternick, 1944.

**references:** Goldschmidt, Hannah, and Piternick, 1951, *Univ. Calif. Publ. Zool.* 55: 67-294.

**phenotype:** Wings transformed into leg-like structures. Penetrance of 15% in selected stocks is increased by presence of *Y<sup>L</sup>*. RK3.

**pol: see spa<sup>pol</sup>**

**pole hole: see phl**

**poliert: see spa<sup>pol</sup>**

**polo: polo**

**location:** 3-46.

**references:** Sunkel and Glover, 1988, *Jour. Cell Sci.* 89: 25-38.

**phenotype:** Maternal-effect mitotic mutation and male meiotic mutation. The wild type allele functions in the early embryo and in the imaginal and neuroblast cells of the larva. About 7% of *polo<sup>1</sup>* homozygotes (offspring of

*polo*<sup>1</sup>/+ females mated to *polo*<sup>1</sup>/+ or *polo*<sup>1</sup>/*polo*<sup>1</sup> males) survive to adulthood, but most of them die as late third instar larvae, their imaginal disks and neuroblast cells failing to proliferate. *polo*<sup>2</sup> homozygotes (offspring of *polo*<sup>2</sup>/+ females mated to *polo*<sup>2</sup>/+ males) never eclose, dying as early third-instar larvae. Some *polo*<sup>1</sup>/*polo*<sup>2</sup> heterozygotes (less than 7%) survive, but show very abnormal cuticle formation in the abdominal tergites.

Offspring of surviving *polo*<sup>1</sup>/*polo*<sup>1</sup> females die very early in development, the embryos showing an abnormal distribution of nuclei that fail to cellularize and then become polyploid before breaking down. Spindles of these embryonic nuclei are highly branched and have broad, barrel-shaped poles. In third instar larvae homozygous for *polo*<sup>1</sup>, many of the neuroblast cells show mitotic abnormalities. In anaphase, the chromosomes are often in a circular arrangement and may or may not be polyploid or aneuploid; these chromosomes, however, are never fragmented and seem to undergo normal condensation. In anaphase, chromosomes frequently lie in a random orientation at one or both poles.

Surviving *polo*<sup>1</sup>/*polo*<sup>1</sup> males are fertile, but often show meiotic abnormalities. Many of the meiotic spindles are irregular in shape and structure and a high frequency of nondisjunction occurs, mostly in the second meiotic division.

**alleles:**

alleles	origin	discoverer	comments
<i>polo</i> <sup>1</sup>	EMS	Nüsslein-Volhard	recessive semilethal; a few survivors
<i>polo</i> <sup>2</sup>	HD	Karess	recessive lethal

**cytology:** Located in 76B2-77C (from Ashburner).

**polymorph:** see *ade2*

**polyphene:** see *pyp*

**polyphene 61:** see *pph*

**polyphenic:** see *pph*

**polyubiquitin:** see *Ubi-p*

**ponte thermosensible:** see *pts*

**\*pop: popeye**

**location:** 1-0.4.

**origin:** Induced by *p*-N,N-di-(2-chloroethyl)amino-phenylbutyric acid (CB. 1348).

**discoverer:** Fahmy, 1952.

**references:** 1958, DIS 32: 73.

**phenotype:** Eyes small, round, bulging, and rough. Often some central ommatidia protrude. Small body. Wings short, broad, and frequently blistered. Male sterile; via-

bility less than 10% wild type. RK3.

**porc: porcupine**

**location:** 1-59.

**origin:** Hybrid dysgenesis.

**references:** Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52.

**phenotype:** Homo- and hemizygous lethal that affects segmentation pattern. *porc/Y* embryos from *porc/porc* germline clones show a segment polarity phenotype; *porc/+* progeny from the germline clones become normal females.

**cytology:** Located in 16E-17B from meiotic position.

**\*port: port**

**location:** 3- (not located).

**discoverer:** Morgan, 14c.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 125.

**phenotype:** Eye color slightly diluted. RK3.

**\*port-b: port-b**

**location:** 3- (not located).

**discoverer:** Bridges, 1911.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 214.

**phenotype:** Eye color maroon. RK3.

**posterior cell blister:** see *pcb*

**posterior crossvein:** see *pcv*

**Posterior sex combs:** see *Psc*

**postverticalless:** see *pvt*

**Pox: Paired box**

Two tissue-specific *Drosophila* paired box genes, *Pox-m* and *Pox-n*, both lacking homeodomains, are described in subsequent sections. No mutants have been discovered.

**references:** Bopp, Jamet, Baumgartner, Burri, and Noll, 1989, EMBO J. 8: 3447-57.

**molecular biology:** Genomic libraries of *Drosophila melanogaster* were screened with paired box probes from the *prd* gene and the two *gsb* genes (Frigerio, Burri, Bopp, Baumgartner, and Noll, 1986, Cell 47: 735-46; Baumgartner, Bopp, Burri, and Noll, 1987, Genes Dev. 1: 1247-67). The genes *Pox-m* and *Pox-n* were isolated and analyzed; they were found to share DNA and putative amino acid sequences with the paired box regions of *prd* and the two *gsb* genes. *Pox-m* and *Pox-n*, however, have no homeodomains. Both genes are believed to be controlled by *prd*, which has both paired- and homeodomains (Bopp *et al.*, 1989). The proteins of both *Pox-m* and *Pox-n* are located in the cell nucleus and may belong to the same regulatory cascade as the other paired domain genes.

**Pox-m: Paired box-meso**

**location:** 3-{48}.

**phenotype:** *Pox-m* shows tissue-specific, segmentally-repeated expression in the somatic mesoderm, starting at germ band extension. Transcripts are observed posterior to the parasegmental grooves (restricted to the mesodermal layer). The protein has been observed by immunostaining in the somatopleura that gives rise to the somatic

musculature, but is not found in the splanchnopleura and the mesectodermal cells (Jamet). Groups of cells in the clypeolabrum, the cephalic mesoderm, and the primordia of the telson and the proctodeum also express *Pox-m*.

**cytology:** Located in 84F11-12 by *in situ* hybridization to the salivaries. The distal breakpoint of *Df(3R)dsx5* is located at 84F11-12 in the intron of the *Pox-m* gene.

### ***Pox-n: Paired box-neuro***

**location:** 2-{48}.

**phenotype:** *Pox-n* shows tissue-specific, segmentally-repeated expression in the central and peripheral nervous system at about 5 hr after fertilization. Transcripts are apparently expressed in neural precursors of the peripheral and the central nervous system. Cells expressing this gene seem to be clonally related.

**cytology:** Located in 52C9-52D3 by *in situ* hybridization to polytene chromosomes. It is uncovered by *Df(2R)WVG = Df(2R)52C4;52E3* (Gelbart) and is located between the distal breakpoint of *Df(2R)XTE-18* at 52C9-D1 and the proximal breakpoint of *Df(2R)KL-9* at 52D3.

**molecular biology:** The *Pox-n* gene has an intron with the paired domain preceding the region encoding the helix-turn-helix motif (Bopp *et al.*, 1989).

### ***Pp1: Protein phosphatase 1***

**location:** 3- and 1- (see **molecular biology**).

**references:** Dombrádi, Axton, Glover, and Cohen, 1989, Eur. J. Biochem. 183: 603-10.

**phenotype:** Encodes a protein phosphatase 1 catalytic subunit that shows a high degree of similarity to rabbit protein phosphatase 1 $\alpha$  in its enzymatic and physiochemical characteristics and has a predicted protein sequence that is 92% identical to that of rabbit PP-1 $\alpha$ .

**cytology:** The major site of *Pp1* has been placed at 87B6-12 by *in situ* hybridization to the polytene chromosomes. In addition, three secondary sites have been demonstrated at 96A2-5, 9C1-2, and 13C1-2.

**molecular biology:** A 1.2-kb cDNA clone carrying the full coding sequence of *Drosophila Pp1* was isolated from a *Drosophila* head library using a 0.76-kb rabbit PP-1 $\alpha$  cDNA as a probe. The nucleotide and predicted amino acid sequences of this *Drosophila Pp1* were determined. A polypeptide of 302 amino acids with a molecular mass of 34.5 kd is encoded. The sequence of the 1.2-kb cDNA contains an open reading frame of 906 nucleotides flanked by 5' and 3' noncoding sequences. Abundant transcripts of 1.6 kb and 2.5 kb were detected in embryos, larvae, pupae, and adults. Another cDNA clone of 0.6 kb was isolated from the *Drosophila* head library with the same probe, and was found to hybridize to 9C1-2, indicating that there are at least two transcriptionally active *Pp1* genes in *Drosophila melanogaster*.

### **\**pph: polyphenic***

**location:** 1-60.8 (originally located at 61.0 but genetic location arbitrarily interchanged with that of *sby* for consistency with cytological observations).

**origin:** Induced by D-1:6-dimethanesulfonyl mannitol (CB. 2511).

**discoverer:** Fahmy, 1959.

**synonym:** *pph-61: polyphene 61*.

**references:** 1964, DIS 39: 58.

**phenotype:** Body small. Eyes brighter than normal. Wing

size and shape slightly altered. Scutellar bristles occasionally kinked. Both sexes viable; fertility of homozygous female low. RK3.

**cytology:** Not included in deficiency for 18A4 through 18B8 produced by combining left end of *ln(1)y*<sup>4</sup> = *ln(1)1A8-B1;18A3-4* and right end of *ln(1)sc*<sup>9</sup> = *ln(1)1B2-3;18B8-9* (Norton and Valencia, 1965, DIS 40: 40).

*pph-61* : see *pph*

### ***pr: purple***

**location:** 2-54.5.

**references:** Bridges, 1919, J. Exp. Zool. 28: 264-305.

Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 169.

Mainz, 1938, Z. Indukt. Abstamm. Vererbungsl. 75: 256-76.

Yim, Grell, and Jacobson, 1977, Science 198: 1168-70.

Tobler, Yim, Grell, and Jacobson, 1979, Biochem. Genet. 17: 197-206.

Dorsett and Jacobson, 1982, Biochemistry 21: 1238-43.

Wiederreect and Brown, 1984a, J. Biol. Chem. 259: 14121-27.

Wiederreect, Paton, and Brown, 1984b, J. Biol. Chem. 259: 2195-2200.

Searles and Voelker, 1986, Proc. Nat. Acad. Sci. USA 83: 404-08.

**phenotype:** Eye color ruby at hatching, darkening to purplish ruby with age [Sturtevant and Beadle, 1939, An Introduction to Genetics, W.B. Saunders Co., Philadelphia and London, p. 64 (plate I)]; orange in combination with *st*, reddish brown in combination with *bw* (Mainz, 1938). *pr* eye color autonomous in larval optic disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936, Genetics 21: 230). Larval Malpighian tubules wild-type in color (Beadle, 1937, Genetics 22: 587-611). Mutants deficient in pteridines (Hadorn and Mitchell, 1951, Proc. Nat. Acad. Sci. USA 37: 650-65; Wilson and Jacobson, 1977; Yim *et al.*, 1977); sepiapterin and the drosopterins are markedly reduced relative to wild type in *pr*<sup>1</sup> and *pr*<sup>bw</sup> (Wilson and Jacobson, 1977; Dorsett and Brown, 1982), the effect being greater in *pr*<sup>bw</sup> than in *pr*<sup>1</sup>. The enzyme sepiapterin synthase A, which is involved in early steps leading to the synthesis of the drosopterins (Wiederreect *et al.*, 1984a, 1984b), is most active in wild-type *Drosophila* in late pupae and young adults when sepiapterin accumulation begins and the eyes become pigmented (Krivi and Brown, 1979, Biochem. Genet. 17: 371-90). When *pr*<sup>+</sup> has been translocated into the Y chromosome [*Y*(*pr*<sup>CS</sup>), the *Y*(*pr*<sup>CS</sup>, *cn/pr*<sup>C4</sup> *cn* flies show a variegated eye color (Yim *et al.*, 1977; Tobler *et al.*, 1979) and the mutant late larvae and early pupae show a reduction in sepiapterin synthase A activity as compared to both wild-type and *pr*<sup>1</sup> (Tobler *et al.*, 1979). The suppressors *su(s)*<sup>2</sup> and *su(pr)*<sup>e3</sup> restore the pyrimidine level of *pr*<sup>1</sup> and *pr*<sup>bw</sup> to that of wild-type or nearly wild-type (Wilson and Jacobson, 1977; Yim *et al.*, 1977).

**alleles:** *pr* mutants and rearrangements (other than

deficiencies) are described in the following table:

allele	origin	discoverer	ref <sup>α</sup>	eye color	cytology
<i>pr</i> <sup>1β</sup>		Bridges, 12b20	1-4, 6, 14	reddish-purple

<sup>β</sup> *pr*<sup>1</sup> and *pr*<sup>bw</sup> suppressed by *su(s)*<sup>2</sup> and *su(pr)*<sup>e3</sup> (see "phenotype").

<sup>γ</sup> Homozygous lethal.

<sup>δ</sup> *pr*<sup>s</sup>/*pr*<sup>s</sup> females sterile, males fertile; viability of males and females good. *pr*<sup>s</sup>/*+* and *pr*<sup>s</sup>/*pr*<sup>1</sup> females fertile.

**cytology:** Placed in 38B5-C2 based on its inclusion in the region of overlap of *Df(2L)pr2b = Df(2L)38B5-C1;38D2-E1* and *Df(2L)pr-A20 = Df(2L)38A3-4;38B6-C1*.

**molecular biology:** The transposable element 412 is inserted in cytological interval 38B4-6 in *pr*<sup>1</sup> and *pr*<sup>bw</sup>, as indicated by hybridization of cloned 412 to salivary squashes (Searles and Voelker, 1986).

**Pr: Prickly**

From Muller, 1930, J. Genet. 22: 299-334.

**Pr: Prickly**

**location:** 3-90.0.

**references:** Muller, 1930, J. Genet. 22: 299-334 (fig.). 1935, DIS 3: 30.

Knust, Tietze, and Campos-Ortega, 1987, EMBO J. 6: 4113-23.

**phenotype:** Bristles very short; tips thin and twisted. Post-dorsocentrals and scutellars usually missing; dark granule present beneath normal bristle location. Homozygote has low viability. *Pr*<sup>K</sup> complements some dominant traits of *E(spl)* and is in turn enhanced by it, showing severe defects and loss of bristles.

**alleles:**

allele	origin	ref <sup>α</sup>	molecular biology <sup>β</sup>
<i>Pr</i> <sup>1</sup>	X ray	1, 2	-4.5 to 0
<i>Pr</i> <sup>K</sup>		2	-4.5 to 0
<i>Pr</i> <sup>Lγ</sup>	spont	1, 2	-4.8 to -3.8

<sup>α</sup> 1 = CP627; 2 = Knust, Tietze, and Campos-Ortega, 1987, EMBO J. 6: 4113-23.

<sup>β</sup> The positions of DNA polymorphisms; relation to mutations unclear. DNA coordinates (kb) of the walk in region 96F8-13 where *E(spl)* has been mapped ("+" values to the right, "-" values to the left).

<sup>γ</sup> Partial revertant of *Pr*<sup>1</sup>. Bristles of *Pr*<sup>L/+</sup> about one-third normal length (longer than bristles of *Pr*<sup>1/+</sup>). *Pr*<sup>L</sup> homozygote viable with small vestiges of bristles. *Pr*<sup>L/H</sup> resembles *Pr*<sup>1/+</sup>.

**cytology:** Located in 96F8-13 from molecular data; also located in 96F10-97C1.

**\*pra: prawny abdomen**

**location:** 1-15.2.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 88.

**phenotype:** Thorax narrow. Abdomen slender, often flexed between fourth and fifth segments. Wings short, rather broad, and often held atypically. Eclosion delayed. Viability about 15% wild type. RK3.

**prat: pratfall (T. Schüpbach)**

**location:** 2-98.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal effect lethal; embryos from homozygous mothers do not hatch. In cuticle preparations they show irregular segmentation and variable segment fusions.

**alleles:** *prat*<sup>PD</sup> = *prat*<sup>1</sup>.

**cytology:** Placed in 57B4-14 or in 57D8-58B (Schüpbach and Wieschaus, 1989).

**prawny abdomen:** see **\*pra**

**prd: paired**

**location:** 2-45.

**references:** Nüsslein-Volhard and Wieschaus, 1980, Nature (London) 287: 795-801.

Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54.

Frigerio, Burri, Bopp, Baumgartner, and Noll, 1986, Cell 47: 735-46.

Kilchherr, Baumgartner, Bopp, Frei, and Noll, 1986, Nature (London) 321: 493-99.

**phenotype:** The wild-type allele of *prd* is required for normal segmentation in embryos and larvae. Mutant alleles and deficiencies show no maternal effects and are embryonic lethals with half the normal number of segmental units. In strong mutants, the anterior part of segments T1, T3, A2, A4, A6, and A8 and the posterior part of T2, A1, A3, A5, and A7 (*i.e.*, odd-numbered parasegments) are deleted (Nüsslein-Volhard *et al.*, 1985). Weak mutants such as *prd*<sup>2</sup> show small and less regular segmental deletions. Structures missing in *prd* mutants include: derivatives of the mandibular segments, labial sense organs, anterior prothorax, posterior mesothorax, anterior metathorax, and alternating posterior and anterior abdominal segments, including the telson and the posterior lateral sense organs (Nüsslein-Volhard *et al.*, 1985). No head fold visible at gastrulation. Experiments with a temperature-sensitive mutant indicate that the TSP occurs during the cellular blastoderm stage (Nüsslein-Volhard *et al.*, 1985; Kilchherr *et al.*, 1986).

**alleles:** *prd* mutants and rearrangements (except for deficiencies) are described in the following table.

allele	origin	synonym	ref <sup>α</sup>	comments
<i>prd</i> <sup>1</sup>	EMS		4	
<i>prd</i> <sup>2</sup>	EMS		4	
<i>prd</i> <sup>3</sup>	X ray	<i>prd</i> <sup>2.27</sup>	3, 5	<i>Tp(2;3)31B;33D-E;97C-D</i>

<i>prd</i> <sup>10</sup>	EMS	<i>prd</i> <sup>IIN</sup>	7	temperature sensitive
<i>prd</i> <sup>11</sup>	EMS	<i>prd</i> <sup>IIV</sup>	7	weak allele
<i>prd</i> <sup>12</sup>	X ray	<i>prd</i> <sup>X3</sup>	7	strong allele

<sup>α</sup> 1 = Frigerio, Burri, Bopp, Baumgartner, and Noll, 1986, Cell 47: 735-46; 2 = Kilchherr, Baumgartner, Bopp, Frei, and Noll, 1986, Nature (London) 321: 493-99; 3 = Nüsslein-Volhard, Kluding, and Jürgens, 1985, Cold Spring Harbor Symp. Quant. Biol. 50: 145-54; 4 = Nüsslein-Volhard and Wieschaus, 1980, Nature (London) 287: 795-801; 5 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82; 6 = Sander, Lohs-Schardin, and Baumann, 1980, Nature (London) 287: 841-43. 7 = Tearle and Nüsslein-Volhard, 1987, DJS 66: 209-69.

<sup>β</sup> Larva moves in egg case, but fails to hatch. 45% of embryos show holes in the larval cuticle and/or lateral fusion of denticle belts (Sander *et al.*, 1980).

**cytology:** Located in 33C1-2 by *in situ* hybridization; included in *Df(2L)prd1.25 = Df(2L)33B6-7;33E2-3* as well as in *Df(2L)prd1.7 = Df(2L)33B2-3;34A1-2* (Nüsslein-Volhard *et al.*, 1985).

**molecular biology:** *prd*<sup>+</sup> and *prd*<sup>4</sup> have been cloned by microdissection of salivaries and chromosome walking and restriction-mapped to the DNA at +170 to +180 kb by Kilchherr *et al.* (1986) [coordinate 0 at distal end of a 41 kb *EcoRI* fragment; "+" values to the right, "-" values to the left (Frei, Baumgartner, Edström, and Noll, 1985, EMBO J. 4: 979-87)]. One transcript of 2.5 kb was detected in *prd*<sup>+</sup> embryos; two transcripts of 2.5 and 3.6 kb were detected in embryos from *prd*<sup>4</sup>/*prd*<sup>+</sup> parents; a 1.1 kb insertion was found in the mutant DNA (Kilchherr *et al.*, 1986). The 2.5 kb transcript is absent in oocytes, peaks in 2-4 hr embryos, and disappears after gastrulation.

The *prd*<sup>+</sup> gene was sequenced by Frigerio *et al.* (1986) and the amino acid sequence of a putative *prd*

protein (613 amino acids) determined. The longest open reading frame is interrupted by a 356 bp intron after the first 22 amino acids. The 1.1 kb insertion in the *prd*<sup>4</sup> DNA has also been sequenced by Frigerio *et al.* Two domains shared with the two closely-linked genes at the *gsb* locus (Bopp, Burri, Baumgartner, Frigerio, and Noll, 1986, Cell 47: 1033-40; Baumgartner, Bopp, Burri, and Noll, 1987, Genes and Development 1: 1247-67).

During the syncytial blastoderm stage in paired embryos, a transcript pattern of 7 bands, with a periodicity corresponding to two primordial segments, appears (Kilchherr *et al.*, 1986). By the time the embryos have reached the cellular blastoderm stage, an additional band appears posterior to band 7, band 1 is narrowed, and bands 2-7 have split, resulting in a 14-banded transcript pattern with single segment periodicity. *prd* is first expressed in a pattern similar to that of *ftz*, *h*, and *eve* (pair-rule genes). However, it shares domains with segment-polarity genes such as *bcd* (Bopp *et al.*, 1986). Expression of *en* absent with a consequent increase of *Ubx* expression in odd-numbered parasegments (Martinez-Arias and White, 1988, Development 102: 325-38).

**pre: presto** (*T. Schüpbach*)

**location:** 2-54.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal-effect lethal; homozygous females lay eggs in which periplasmic clearing occurs, but no signs of cellularization are observed.

**alleles:** Two: *pre*<sup>1</sup> and *pre*<sup>2</sup> isolated as *PL* and *ADF* respectively.

**cytology:** Placed in 36E4-37C1 based on its inclusion in both *Df(2L)TW50 = Df(2L)36E4-F1;38A6-7* and *Df(2L)TW137 = Df(2L)36C2-4;37B9-C1*.

**Pre-intermolt gene 1:** see *Pig1*

**presto:** see *pre*

**prickle:** see *pk*

**Prickly:** see *Pr*

**proboscipedia:** see *pb*

**prong:** see *pg*

**Pros35: Proteasome 35**

**location:** 3-{59}.

**references:** Haass, Pesold-Hurt, Multhaup, Beyreuther, and Kloetzel, 1989, EMBO J. 8: 2373-79.

**phenotype:** Encodes the 35 kd proteasome subunit of *Drosophila melanogaster*. The proteasome is strongly expressed in the central nervous system of embryos and the heart muscle and epithelial cells of the stomach and ovary of adults and is localized in the cytoplasm in some cells and/or the nucleus in others.

**cytology:** *Pros35* was located by *in situ* hybridization at the border of 89F/90A. It is a single copy gene.

**molecular biology:** The gene was cloned and its nucleotide sequence and deduced amino acid sequence obtained; the primary translation product is a 31.4 kd protein. This protein is encoded by a mRNA of about 1100 nucleotides which seems to be present in very low abun-

dance. The cDNA is 999 bp long and there is a single open reading frame encoding 279 amino acids. The 35 kd protein subunit carries a consensus sequence for a potential tyrosine phosphorylation site; this subunit may be involved in the regulation of the complete multicatalytic proteinase complex.

**Protein kinase:** see *Pk*

**proximalless:** see *pxl*

**prune:** see *pn*

**Ps: Pigmentless**

**location:** 2-57.5 (inseparable from *cn*).

**origin:** X ray induced.

**discoverer:** Krivshenko, 56115.

**references:** 1959, DIS 33: 95.

**phenotype:** Black strips on last abdominal segments of female reduced; expression variable. Male unaffected. Homozygous lethal. RK2.

**cytology:** Salivary chromosomes apparently normal.

*Ps2a*: see *if*

**Psc: Posterior sex combs**

**location:** 2-67.

**origin:** Induced by ethyl methanesulfonate; isolated as embryonic lethal with head defects (Jürgens, 1985).

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Jürgens, 1985, Nature (London) 316: 153-55.

Wu, Jones, Lasko, and Gelbart, 1989, Mol. Gen. Genet. 218: 559-64.

**phenotype:** *Psc*<sup>+</sup> is another gene that may be considered a negative regulator of the *BXC* or the *ANTC*. The mutant is homo- and hemizygous lethal, the embryos showing partial transformation of head and thorax into abdomen and of abdominal segments 1-7 into more posterior ones. *Psc/Psc* embryos that are also homozygous for *Asx*, *Pcl*, or *Scm* show stronger posteriorly-directed transformations; the triple mutant *Psc Asx Pcl* has a tandem array of posterior abdominal segments including four abdominal denticle bands in the head region (Jürgens, 1985). *Psc/+* males may have sex combs on second and third legs. The gene suppresses *z*<sup>1</sup> eye color, which becomes orange-maroon; it is lethal with *Su(z)2*<sup>1</sup> and *Su(z)2*<sup>5</sup> and semiviable with *Su(z)2*<sup>4</sup> (Wu *et al.*, 1989). *Psc* and *Su(z)2* are both members of the *Su(z)2* complex.

**alleles:** One allele isolated: *Psc*<sup>INN</sup> = *Psc*<sup>1</sup>.

**cytology:** Located in 49D3-E5 since included in *Df(2R)vg-B* = *Df(2R)49D3-4;49F15-50A2-3* and *Df(2R)vg-D* = *Df(2)49C1-2;49E4-5*; at odds with the above determination is the failure of *Df(2R)vg-C* = *Df(2R)49B2-3;49E7-F1* to uncover *Psc* (Jürgens, 1985).

**psi2: phase-angle2 (J. C. Hall)**

**location:** 2-72.0.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jackson, 1983, J. Neurogenet. 1: 3-15.

**phenotype:** Semidominant; emerges prematurely in light-dark cycle. Eclosion and locomotor activity rhythms have abnormally long periods (about 25-26 hr instead of normal 24 hr). Mutant males have abnormally long periods of courtship song rhythms (Kyriacou); phenotype recessive. Mutant males also show abnormal conditioning in courtship tests (Jackson, Gailey, and Siegel, 1983,

J. Comp. Physiol. 151: 545-52).

**cytology:** Located in 49E7-50A2, based on uncoverage of song rhythm defect by *Df(2R)vg-B* = *Df(2R)49D3-4;49F15-50A2* and complementation of this defect by *Df(2R)vg-C* = *Df(2R)49B2-3;49E7-F1* (Kyriacou and Clarkson).

**other information:** May be allelic to quasi-arrhythmic mutant *gat*, based on similar map positions and lengthened song rhythm periods in *psi2/gat* males (Jackson and Kyriacou).

**psi3 (J. C. Hall)**

**location:** 3- (to right of and close to *Sb*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Jackson, 1983, J. Neurogenet. 1: 3-15.

**phenotype:** Semidominant; emerges prematurely in light-dark cycle. Eclosion rhythm exhibits abnormally long period (about 25 hr), as do males in their rhythmic courtship singing behavior (Kyriacou). Mutant males show abnormal conditioning in courtship tests (Jackson, Gailey, and Siegel, 1983, J. Comp. Physiol. 151: 545-52).

**pt: platinum**

**location:** 1-23.1.

**origin:** Deuteron induced.

**discoverer:** Hildreth, 51h.

**references:** Hildreth, 1953, DIS 27: 56.

King, Mohler, Riley, Storto, and Nicolazzo, 1986, Dev. Genet. (Amsterdam) 7: 1-20.

**phenotype:** Body color very pale yellow, almost colorless. Bristles colorless and translucent except for dark bases. Male sterile and short lived. Tyrosinase forms in adult (Horowitz and Fling). One allele (*pt*<sup>2</sup>) is a zygotic lethal; another (*pt*<sup>4</sup>) is female sterile (King *et al.*, 1986); shown to be a maternal-effect lethal rescuable by a normal paternal allele (Mohler and Carrol, 1984, DIS 60: 236-41).

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>pt</i> <sup>1</sup>	deuteron	Hildreth	<i>pa</i>	1	viable
<i>pt</i> <sup>2</sup>	X ray	Lefevre	<i>l(1)JC28</i>	2, 3	lethal (zygote)
<i>pt</i> <sup>3</sup>	EMS	Lefevre	<i>l(1)VA70</i>	3	viable

**cytology:** Located in the 7F region since included in *Df(1)7F1-2;8C6*; maps to the left of *oc*, which is located at 8A1-2.

*pt*: see *ab*<sup>2</sup>

*Pt-1*: see *Lsp*<sup>2</sup>

*pta*: see *sld*<sup>pta</sup>

*ptc*: see *tuf*

**ptd: parted**

**location:** 1-52.7.

**origin:** Induced by nitrosoguanidine.

**references:** Kaufman, 1969, DIS 44: 44.

**phenotype:** Wings held at 45° angle from body and slightly elevated. In young flies, the wing tips are usually curved up; in old cultures and old flies, the wings are usually shrivelled. The shrivelled condition (but not the cup-

ping) does not occur at 18°. Males viable and fertile, females viable and sterile.

*Ptd*: see *Bx*<sup>J</sup>

**\*pte: pterygion**

**location:** 1-1.4.

**origin:** Induced by 1:4-dimethanesulfonylbut-2-yne (CB. 2058).

**discoverer:** Fahmy, 1951.

**references:** 1958, DIS 32: 73.

**phenotype:** Wings shortened, usually spread, and slightly drooping. Eyes misshapen and somewhat rough. Abdomen disproportionately large. Eclosion slightly delayed and viability about 20% wild type. RK3.

**other information:** Possible allele of *dwg*.

**ptg: pentagon**

**location:** 1-23.2.

**phenotype:** Thoracic trident darker than wild-type, especially the pentagonal spot just anterior to the scutellum; more extreme at 19°C. Hard to classify in young flies.

**alleles:** Six pentagon alleles are listed in the following table. (*ptg*<sup>2</sup>, *ptg*<sup>3</sup>, and *ptg*<sup>4</sup> are also given a separate description).

allele	origin	discoverer	synonym	ref <sup>α</sup>
<i>ptg</i> <sup>1</sup>		Bridges, 2218		
<i>ptg</i> <sup>2</sup>		L.V. Morgan, 24j21		4
<i>ptg</i> <sup>3</sup>		Kaliss, 351	<i>cro:crown</i>	1, 3
<i>ptg</i> <sup>4</sup>	spont	Curry, 38b8

<i>ptg</i> <sup>6</sup>	EMS	Craymer	<i>ptg</i> <sup>M1.33</sup>	
<i>ptg</i> <sup>7β</sup>	EMS	Helfand, Carlson	<i>ptg</i> <sup>3D18</sup>	2

<sup>α</sup> 1 = Felsenstein, 1937, DIS 7: 21; 2 = Helfand and Carlson, 1989, Proc. Nat. Acad. Sci. USA 86: 2908-12; 3 = Kaliss, 1937, DIS 7: 6,18; 4 = Morgan, L.V., 1935, DIS 3: 14.

<sup>β</sup> Fertility of homozygotes low; response to odor of benzaldehyde reduced.

**cytology:** Located in salivary region 8A5 by Lefevre (1981, Genetics 99: 461-80). Included in the X chromosome insertion of *ct*<sup>+</sup>-*ptg*<sup>+</sup> in *Dp(1;2)sn*<sup>+</sup>*72d* = *Dp(1;2)7A8;8A5;32C;58E*.

**ptg<sup>2</sup>**

**phenotype:** Pentagonal spot sharper and darker than in *ptg*<sup>1</sup>. Scutellum often dark and prongs of tridents may be dark also.

**ptg<sup>3</sup>**

**phenotype:** Trident darker than in *ptg*<sup>1</sup>; dark color extends to head, sides, and abdomen.

**other information:** Occasionally reverts to wild type or weak *ptg*. Allelism with *ptg* shown by Bridges.

**ptg<sup>4</sup>**

**phenotype:** Darkness of pentagon intermediate between that of *ptg*<sup>1</sup> and *ptg*<sup>2</sup>.

*ptm*: see *bw*<sup>ptm</sup>

**pts: ponte thermosensible**

**location:** 3- (near *se* at 3-26.0).

**origin:** Spontaneous in *se/se* strain.

**references:** Picard, 1973, Mol. Gen. Genet. 123: 363-68. Anxolabehere, 1980, Genetica 51: 161-65.

**phenotype:** Temperature-sensitive recessive female sterile (Picard, 1973). When homozygous *pts* females are kept

at 30°, their eggs fail to hatch or hatch in very small numbers at either 20° or 30°; when the females are kept at 20°, the eggs hatch at 20° but not at 30°. *pts/pts* females kept at an intermediate temperature (25°) are fertile, but their eggs take longer to develop than at the permissive temperature (Anxolabehere, 1980). Heterozygous females kept at either 20° or 30° hatch eggs at either temperature; their productivity is greater than that of homozygotes at 20° (Picard, 1973). The temperature-sensitive periods occur at the beginning of oogenesis (for laying) and from 36-60 hr of larval life (for hatching).

**pu: pupal**

**location:** 2-51.

**synonym:** *pads-b*.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 232.

Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91.

**phenotype:** Wings unexpanded or incompletely expanded; more extreme at 19°. Extreme alleles show erect and crossed postscutellar bristles and a distorted thoracic cage (Ashburner). *Df(2L)A400/Df(2L)el*<sup>4D</sup>*A80*<sup>P</sup>, a homozygous *pu* deficiency, is barely viable; escapers are *pu*.

**alleles:** All alleles are cytologically normal.

allele	origin	discoverer	synonym	ref <sup>α</sup>	25° phenotype
<i>pu</i> <sup>1β</sup>	spont	Duncan, 20d		1, 3	strong

Genetics 121: 273-80.

O'Donnell, McLean, and Reynolds, 1989b, Dev. Biol. 10: 273-86.

**phenotype:** The structural gene for guanosine triphosphate 7,8-8,9-dehydrogenase = GTP cyclohydrolase [GTP CH (EC 3.5.4.16)], which catalyzes the first step in pteridine biosynthesis, the conversion of GTP to dihydroneopterin with the release of formic acid; GTP CH activity proportional to the number of *Pu*<sup>+</sup> alleles. Purification and characterization by Weisberg and O'Donnell (1986, J. Biol. Chem. 261: 1453-58); the active complex has an apparent molecular mass of 575,000 daltons comprised of 39,000-dalton subunits. Developmentally regulated with a short-lived activity peak at or shortly before eclosion; 80-90% of activity found in the head; activity not detectable in embryos. Dominant alleles are embryonic lethal as homozygotes and in heterozygotes produce dilute purple eye color; Appear to be antimorphic in that GTP CH activity in heterozygotes reduced to less than the 50% normal levels observed in deficiency heterozygotes, at least in adult tissues, and is but 80% normal in genotypes that carry, in addition to the mutant allele, two doses of *Pu*<sup>+</sup>. Most are associated with a chromosome rearrangement with one breakpoint in 57 and the other in or near centric heterochromatin. A few recessive alleles are viable and fertile and exhibit reduced GTP CH activity in the head but normal or near-normal levels in prepupae and adult body; however, the majority are embryonic lethals and have reduced activity in prepupae, adult body, and head when heterozygous with viable alleles; rare lethal alleles are defective in neither eye-pigment production nor in postembryonic enzyme activity. Viable alleles complement lethal alleles for viability, at least partially; in combination with each other and with lethal alleles they display a wide range of eye pigmentation;

some pairs of lethal alleles complement fully or partially for both viability and eye color; prepupal enzyme levels are variably reduced in these combinations in ways that are uncorrelated with survival; heteroallelic survivors are fertile; heteroallelic survival markedly reduced or absent when reared at 16°.

Homozygous deficiencies [*Df(2R)F36*] die as fully formed larvae, but prior to hatching; mouth parts and setae completely unpigmented; setae and sensory structures poorly differentiated; cuticle thin and fragile; head involution and differentiation frequently incomplete, beginning at the time of germ-band shortening. Class II mutants display variably similar phenotypes as do class III alleles, but to a less severe extent. 50% of class V mutants die before blastoderm, the remaining 50% dying during late embryogenesis, but with fully pigmented mouth parts and setae and with normal head development; fusions and deletions of abdominal denticle belts, or the normal number of belts, but all of identically abnormal structure, retaining only the two posterior setal rows; preblastoderm nuclear divisions asynchronous, abnormally distributed in embryos, and nuclei misshapen (Reynolds and O'Donnell, 1987, Genetics 116: s14). Embryos homozygous for class IV alleles resemble class V mutants, but with additional features characteristic of class II embryos, including unpigmented setae and mouth parts. In crosses of class V bearing genotypes to *Df(2R)F36/+*, the *Df(2R)F36/Pu* embryos resemble class V embryos when the deficiency is maternally inherited and deficiency homozygotes when the *Pu* allele is maternally inherited.

**alleles:** In the following table, recessive alleles are superscripted "r" and revertants "rv". *Pu* deficiencies are listed as rearrangements.

<sup>β</sup> 14 = Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-69.  
More complete description below.

**cytology:** Placed in 57C5-6 based on its inclusion in both  
*Df(2R)F36* = *Df(2R)57B16-17;57C6-7* and

*Df(2R)P112 = Df(2R)57C4;57D8-9*; also placed in 57C by *in situ* hybridization to the salivaries (McLean, Boswell, and O'Donnell, 1990, Genetics 126: 1007-19).

**molecular biology:** Genomic clones of region recovered and mutants shown to cause alterations over a 30 kb segment. The region encodes at least 16 developmentally regulated transcripts (O'Donnell *et al.*, 1989b). Northern analysis reveals a 1.7 kb polyadenylated transcript that is abundant in the head and a 9 kb transcript that is transcribed off the same strand, overlaps the 1.7 kb sequence and is expressed at all stages (McLean and O'Donnell, 1987, Genetics 116: s52). The 1.7 kb transcript, which gives rise to a 39 kd polypeptide, is missing from three eye-specific *Pu* mutants (McLean, Lipsky, and O'Donnell, 1979, Genetics 122: s44).

**other information:** Mutations at this locus comprise a complex of viable and lethal, recessive and dominant, complementing and noncomplementing alleles with different stage and tissue specific defects. A complementation map has been constructed, but recombinational fine structure has not been determined.

### *Pu*<sup>2</sup>

**phenotype:** Eye color of *Pu*<sup>2/+</sup> purplish, resembling *pr*; GTP CH activity reduced to less than 50% normal levels, in prepupae, adult body, and adult head, *i.e.* lower than observed in deficiency heterozygotes. Activity 80% normal in genotypes that carry, in addition to *Pu*<sup>2</sup>, two doses of *Pu*<sup>+</sup>; Homozygous lethal with death occurring in the embryonic stage; slight transient dilution of eye color in such heterozygotes at eclosion.

### *Pu*<sup>K5-2</sup>

**phenotype:** Slightly dominant eye-color phenotype. Survives in heterozygous combination with *SMI*, but behaves as a dominant lethal or displays delayed development in combination with most other second chromosomes tested.

### *Pu*<sup>r1</sup>

**phenotype:** Homozygous viable recessive allele. GTP CH activity moderately reduced in prepupae and nearly normal in adult bodies of homozygotes; activity appears to be virtually absent in adult heads. Slight transient dilution of eye color in freshly emerged heterozygotes.

### *Pu*<sup>r331</sup>

**phenotype:** Homozygous viable recessive allele. GTP CH activity in *Pu*<sup>r331</sup>/*Pu*<sup>+</sup> same as wild type; somewhat reduced in homozygotes.

### *Pu*<sup>rP43</sup>

**phenotype:** Homozygous lethal; however, GTP CH activity in heterozygotes nearly normal. In heteroallelic combination with *Pu*<sup>rZ19</sup> the enzyme produced is unstable at 53°; other combinations produce relatively heat-stable enzyme.

### *Pu*<sup>SHC</sup>

**phenotype:** Similar to but less severe than that of *Pu*<sup>K5-2</sup>. Apparent dominant lethal effects more severe when inherited maternally than when inherited paternally.

### *pub*: *pubescent*

**location:** 1-63.

**origin:** Induced by P<sup>32</sup>.

**discoverer:** Bateman, 1950.

**references:** 1950, DIS 24: 55.

**phenotype:** Hairs and bristles *M*-like; black pigment on terminal abdominal segments nearly absent; male sterile. Tendency toward short, fat, gnarled legs; shortened L2; posterior nicking of wings. After several generations, only bristle effect and male sterility remained. RK3.

### \**Pub*: *Pub*

**location:** 1- (rearrangement).

**discoverer:** P. Farnsworth.

**references:** Lefevre, 1954, DIS 28: 75.

**phenotype:** Eye size of heterozygote variably reduced, ranging from something like *B*<sup>1/+</sup> to wild type. Eyes of homozygote greatly reduced, similar to double Bar. Interacts with *B* to give small, glazed, almost facetless eyes. RK2A.

**cytology:** Associated with *ln(1)Pub*; breakpoints unknown.

### *pubescent*: see *pub*

*Pudur*: see *Fs(3)Sz29*

### *puf*: *puff*

**location:** 2-58.

**origin:** Spontaneous.

**discoverer:** Nichols-Skoog, 35k19.

**phenotype:** Wings puffed or blistered; effect centering in third posterior cell; wings warped and creased longitudinally along vein L3. Penetrance usually 90-100% in female and 20-40% in male. RK3.

**other information:** Possibly an allele of *blo* (Ashburner).

### *Pufdi*: see *Pfd*

### *puff*: see *puf*

### *pum*: *pumilio*

**location:** 3-48.5.

**origin:** Induced by ethyl methanesulfonate.

**references:** Lehmann and Nüsslein-Volhard, 1987, Nature (London) 329: 167-70.

Nüsslein-Volhard, Frohnhofer, and Lehmann, 1987, Science 238: 1675-81.

**phenotype:** Wild-type allele of *pum* involved in development of the abdomen (embryos) and of the imaginal disks (larvae or pupae), perhaps having a function in signal transport. Embryos derived from *pum/pum* females (strong allele) form two instead of eight abdominal segments; head, thorax, and telson are normal. Pole cells are formed by the *pum* embryos and these cells function normally when transplanted into otherwise sterile embryos. There is no paternal rescue. Partial rescue of the *pum* abdominal phenotype (at the site of the injection) can be obtained with cytoplasm from the posterior pole of (1) wild-type embryos or (2) *pum* embryos. When *pum* is combined with *tsl* (mutant in which the abdominal region is placed next to the pole plasm), a rescue of abdominal segments may occur. *pum* opposite a deficiency or another *pum* allele results in a recessive zygotic visible phenotype; *pum* adult flies have additional postalar, dorso-central, and scutellar bristles and reduced viability.

**alleles:** The first *pum* allele, *pum*<sup>12</sup>, was recovered in a screen for maternal-effect mutations (Nüsslein-Volhard, Jürgens, Anderson, and Lehmann) and 12 more alleles were located on the basis of failure to complement the maternal phenotype (Lehmann, Frohnhofer, Anderson, Mayer, and Nüsslein-Volhard). All were induced by

ethyl methanesulfonate; most are semilethal and have abnormal bristles when homozygous.

**cytology:** Placed in region 85C-D since included in *Df(3R)p-XT9 = Df(3R)84F14;85C-D* but not in *Df(3R)p-XT103 = Df(3R)82A;85C1-2*.

**pun: puny**

**location:** 1-41.1.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1950.

**references:** 1958, DIS 32: 73.

**phenotype:** Body small. Wings slightly shorter than normal. Eyes occasionally deformed. Eclosion delayed. Both sexes fertile; viability about 50% wild type. RK3.

**other information:** One allele each induced by CB. 1356 and CB. 3025.

**Punch:** see *Pu*

**punt:** see *put*

**puny:** see *pun*

**pupal:** see *pu*

**Pupal cuticle protein:** see *Pcp*

**Pupilla excentrica:** see *Pec*

**pur: purplish ruby**

**location:** 3-39.5.

**origin:** Spontaneous in a natural population in Spain.

**references:** Aparisi and Najera, 1987, DIS 66: 12-13.

Najera and Aparisi, 1987, DIS 66: 191.

1988, DIS 67: 4-5, 5-6.

**phenotype:** Eye color purplish ruby. Red pigment at 75% wild-type level and brown pigment at 122% normal level.

**pur1: purine requiring**

**location:** 1-32.35.

**origin:** Induced by ethyl methanesulfonate.

**references:** Falk and Nash, 1974, Genetics 76: 755-66.

Johnson, Woloshyn, and Nash, 1979, Mol. Gen. Genet. 174: 287-92.

Nash, Woloshyn, Mehl, and Janca, 1981, Can. J. Genet. Cytol. 23: 411-23 (fig.).

**phenotype:** Purine nucleoside auxotroph; lethal on unsupplemented medium at 29° and poorly viable at 25°; rescuable by adenosine or guanosine supplementation. Slight oblique truncation of the wing occasionally observed as a small concavity of the wing margin at the distal end of vein L4 in *pur1* males and females; *pur1/Df(1)ras* females display stronger expression; hairs on wing margin regularly disposed, unlike *r*.

**alleles:** Two alleles, *pur1*<sup>1</sup> and *pur1*<sup>2</sup>; development of *pur1*<sup>1</sup> but not *pur1*<sup>2</sup> delayed when supplemented with adenosine; guanosine supports normal development of both.

**cytology:** Placed in 9E1-4 on the basis of its inclusion in the region of overlap between *Df(1)rasP14 = Df(1)9E1-2;9F3-4* and *Dp(1;2)9E1;10A11;56A* (Zhimulev, Pokholkova, Bgatov, Semeshin, and Belyaeva, 1981, Chromosoma 82: 25-40).

**other information:** *pur1* is but one of four types of mutations belonging to an interrelated complex involved some way in purine metabolism: *ras*, a nonauxotrophic eye-color mutation; two purine auxotrophs, *pur1* and *gual*, which complement *ras* and one another; *ras-l*, lethal mutations that fail to complement completely the other three types; genetic map order not determined. The complex shares many genetic features with rudimentary.

**Pur-r: Purine-resistant (A. Chovnick)**

**location:** 2-82 (approximate).

**discoverer:** Duck, 1973.

**origin:** Induced by ethyl methanesulfonate.

**references:** Dutton and Chovnick, 1990, Mol. Gen. Genet. 220: 172-76.

**phenotype:** Exhibits elevated resistance to purine [7H-imidazo (4,5-d) pyrimidine] in association with normal levels of xanthine dehydrogenase. Also confers resistance to 2,6-Diaminopurine. *Pur-r* is associated with elevated activity of adenosine deaminase (ADA); however, gene dosage experiments are inconsistent with the notion that *Pur-r* represents the structural locus for ADA, and indicate instead that *Pur-r* encodes a negative regulator of ADA. This view is supported by biochemical studies, which indicate that *Pur-r*<sup>+</sup> encodes a thermolabile component that inhibits ADA activity, presumably analogous to the ADA-binding protein known in mammalian systems (Daddona and Kelley, 1980, Mol. Cell Biochem. 29: 91-101).

**purple:** see *pr*

**purpleoid:** see *pd*

**Purpleoider:** see *Pdr*

**purplish ruby:** see *pur*

**put: punt**

**location:** 3-58.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**phenotype:** Homozygous lethal in embryo. Dorsal part of embryo open.

**cytology:** Located in 88C3-E2 based on ability of aneuploid segregants of both *Tp(3;1)XM54 = Tp(3;1)20;87C7-D1;88E2-3* and *Tp(3;2)kar51 = Tp(3;2)88C2-3;96B11-C1* to cover it.

**\*pvt: postverticalless**

**location:** 1-20.9.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 88.

**phenotype:** Wings either divergent or slightly held up. Thoracic hairs sparse, and one or both postvertical bristles

tles almost invariably absent. Shape of head and eyes varies from almost normal to anteroposterior flattening of head and deep grooving of eyes. Male viable and fertile; female sterile. RK2.

**\*pw: pink wing**

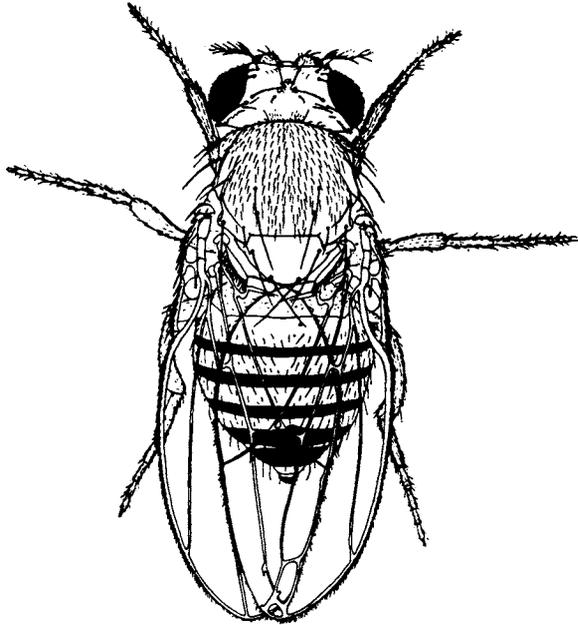

**location:** 2-14.  
**discoverer:** Bridges, 20b17.  
**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 213.  
 1931, *Eos* 7: 229-48.  
**phenotype:** Eye color like pink. Wings shorter than normal and crumpled. Viability low. RK3.

**\*Pw: Pointed wing**

**location:** 3-94.1.  
**discoverer:** Bridges, 21c29.  
**references:** Bridges and Morgan, 1923, *Carnegie Inst. Wash. Publ. No.* 327: 238 (fig.).  
**phenotype:** Wings narrowed slightly at tips; extra venation near tips of L3 and L4. Homozygous lethal. RK3.  
**other information:** Not an allele of *Bd* (3-93.8).

**pwc: pink wing c**

**location:** 2-79.  
**discoverer:** Bridges, 31c18.  
**phenotype:** Eye color lighter than normal. Wings short and blunt. Overlaps wild type. RK3.

**Pw: Pointed wing**

**pwn: pawn**

**location:** 2-55.4 [between *pk* and *cn* (Ashburner *et al.*, 1981)].  
**origin:** Induced by ethyl methanesulfonate.  
**references:** García-Bellido and Dapena, 1973, *DIS* 50: 179.  
 1974, *Mol. Gen. Genet.* 128: 117-30.  
 Lawrence and Morata, 1976, *Dev. Biol.* 50: 321-37.  
 Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, *DIS* 56: 186-91.

Gubb and García-Bellido, 1982, *J. Embryol. Exp. Morphol.* 68: 37-57.

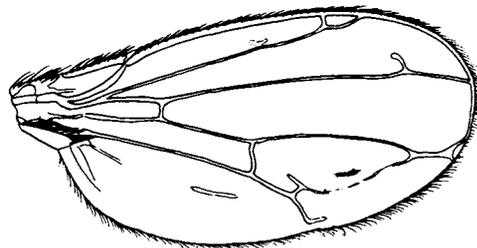

**phenotype:** Homozygous semilethal as zygote (survival 2%); escapers have dark brown eyes and show tanning of cornea cuticle (García-Bellido and Dapena, 1973). Cell viable in homozygous clones, which have truncated bristles with pale tips and pin-shaped trichomes with basal spurs and thin, transparent hairs (García-Bellido, 1973, 1974; Lawrence and Morata, 1976). Useful as cell marker.

**cytology:** Located in 42E3-43C3; included in *Df(2R)pk78k = Df(2R)42E3;43C3* (Ashburner *et al.*, 1981).

**px: plexus**

**location:** 2-100.5.  
**references:** Bridges and Morgan, 1919, *Carnegie Inst. Wash. Publ. No.* 278: 251.  
 Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 212, 233.  
 Waddington 1940, *J. Genet.* 41: 75-139.  
 Thompson, 1974, *Heredity* 33: 389-401.

**phenotype:** Wings have network of extra veins, especially towards tips and margins; L4 vein bent near tip. Semi-dominant with some Minutes. Suppressed by *S* (Bedichek, 1936, *DIS* 4: 24); suppresses expression of *ve* (Thompson, 1973, *DIS* 50: 59). Venation effect caused by inadequate contraction of wing during pupal stage, leaving spaces between epithelial layers (Waddington, 1940). Vein patterns of *px* flies studied in lines selected for increased or decreased expression (Thompson, 1974).

**px: plexus**

From "Edith M. Wallace, unpublished."

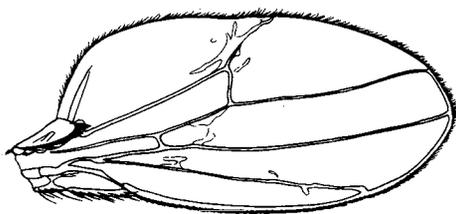

**alleles:** Phenotype same as *px*<sup>1</sup>.

No.* 278: 251; 2 = Craymer, 1980, *DIS* 55: 197-200; 3 = Gooskov, 1971, *DIS* 46: 41; 4 = Iyengar and Meyer, 1956, *DIS* 30: 73; 5 = Meyer, 1954, *DIS* 28: 77; 6 = Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 212, 233; 7 = Villee, 1942, *Univ. Calif. Publ. Zool.* 49: 125-84; 8 = Williams, 1956, *DIS* 30: 80.

**cytology:** Placed in 58F on the basis of its inclusion in *Df(2R)M-1 = Df(2R)57F11-58A1;58F8-59A1* and *Dp(2;3)P* from *Tp(2;3)P = Tp(2;3)58E3-F2;60D14-E2;96B5-C1* [Bridges, 1937, *Cytologia* (Tokyo), Fujii *Jub. Vol.* 2: 745-55]. Also, *In(2LR)px*<sup>32g</sup> =

*In(2LR)30A;58F-59B* (Lewis) is mutant for *px*.

**Px: Plexate**

From "Edith M. Wallace, unpublished."

**Px: Plexate**

**location:** 2-107.2 (approximate).

**origin:** Spontaneous.

**discoverer:** Bridges, 22f6.

**references:** 1937, *Cytologia*, Fujii Jub. Vol. 2: 745-55.

Díaz-Benjumea, González-Gaitán, and García-Bellido, 1989, *Genome* 31: 612-19.

**phenotype:** Wing veins of heterozygote with plexuslike or deltalike thickenings, most often near posterior crossvein, and free fragments of vein, most often in third posterior cell; L4 vein bent near margin. Wings smaller and narrower than wild type and dusky textured. Closely resembles *bs*. Expression more extreme in female; enhanced by cold (19°). Homozygous *Df(2R)Px* lethal as embryo (Li, 1927, *Genetics* 12: 1-58); *Df(2R)Px2* cell lethal (Ripoll and García-Bellido, 1979, *Genetics* 91: 443-53). Mutants associated with deficiencies near tip of 2R.

**alleles:** Eight (Díaz-Benjumea *et al*, 1989).

**cytology:** A haplo-insufficient locus; placed in 60C6-D1 on basis of the region of overlap between *Df(2R)Px2* = *Df(2R)60C5-6;60D9-10* and *Df(2R)Px* = *Df(2R)60B8-10;60D1-2*.

**other information:** May be part of a pseudoallelic complex with *ba* and *bs*.

**pxl: proximalless**

**location:** 2R (5 units proximal to *bw*).

**discoverer:** Ransom.

**phenotype:** Temperature-sensitive lethal. Male and female sterile. Lacks proximal region of the retinal photoreceptors.

**pyd: polychaetoid**

**location:** 3-39.

**origin:** Spontaneous.

**discoverer:** Spencer, 39h31.

**synonym:** *Pch*; *xvt*.

**references:** Spencer, 1935, *DIS* 3: 28.

1937, *DIS* 7: 15.

Neel, 1939, *Genetics* 24: 81.

1941, *Genetics* 26: 52-68.

1943, *Genetics* 28: 49-68.

**phenotype:** Extra bristles present in homozygote at or near almost all normal bristle locations but most frequently in dorsocentral and scutellar regions. Heterozygote in some stocks occasionally shows extra bristles, especially vibrissae. Character expressed better at low temperatures and in large flies. Combinations with *h* and *Hw* generally superadditive for bristle number. RK3.

**alleles:** In addition to *pyd*<sup>1</sup>, there are two mutants that resemble the original allele, both in chromosome location and bristle phenotype; they have been named *pyd*<sup>xvt</sup> (synonym: *xvt*) and *pyd*<sup>66</sup>. *pyd*<sup>xvt</sup> appeared in an Australian line selected for an increased number of scutellar bristles (Miller and Fraser, 1968, *Aust. J. Biol. Sci.* 21: 61-74; Fraser, Erway, and Brenton, 1968, *Aust. J. Biol. Sci.* 21: 75-87; Fraser, 1970, *Genetics* 65: 305-09). *pyd*<sup>66</sup> appeared in a Spanish line selected for an increased number of dorsocentral bristles; also shows many verticals, orbitals, scutellars, interocellars, sternopleurals, and abdominals (Ménsua, 1972, *DIS* 49: 40), the mutant phenotype occurring with a high penetrance.

**Pyk: Pyruvate kinase**

**location:** 1-[43].

**references:** Rust and Collier, 1985, *J. Hered.* 76: 39-44.

**phenotype:** Structural gene for the glycolytic enzyme pyruvate kinase [PYK (EC 2.7.1.40) = ATP: pyruvate phosphotransferase]. Enzyme activity low in larvae and pupae, but it increases in young adults, becoming relatively stable in two-day-old flies. Most of the pyruvate kinase activity of adults is found in the thorax.

**cytology:** Located in the 12A-C region of the X chromosome on the basis of the dosage sensitivity of the region for pyruvate kinase as shown by segmental aneuploids.

*pym*: see *ade2*

**\*pyp: polyphene**

**location:** 1-53.5.

**origin:** Spontaneous.

**discoverer:** Bridges, 37l26.

**phenotype:** Wings spread, yellowish, and have uneven surface. Trace of extra vein in third posterior cell near second crossvein. Eyes rough, pitted, bulging, and smaller than wild type. Trident more darkly pigmented in male. Female sterile. Viability about 70% wild type. RK3.

*pyr2*: see *nuc1*

**Pyridoxal oxidase:** see *Po*

**Pyruvate kinase:** see *Pyk*

**pys: polychaetous**

**location:** 2-52.

**discoverer:** Curry, 37k15.

**phenotype:** Extra or double bristles present; most easily seen are scutellars, dorsocentrals, orbitals, and vibrissae. Extra bristles on scutellum curve upward. Overlaps wild type at 19°C; classification good at 28°-30°. RK3.

**\*Q: Queer wing****location:** 2- (not located).**discoverer:** E. M. Wallace, 1931.**phenotype:** Wings irregularly incised; marginal bristles irregular. Heterozygote has low penetrance; homozygote better. RK3.**Qd: Quadroon****location:** 1-6.8.**origin:** Spontaneous.**references:** Thompson, 1959, DIS 33: 99.**phenotype:** Broad dark band on margins of all abdominal tergites, giving abdomen superficial appearance of uniform darkness. Viability of heterozygous female normal, of homozygous female < 10% normal, and of male 30% normal. *Qd/Df(1)bi4* exhibit homozygous *Qd* phenotype as well as *bi*-like phenotype; *Qd/bi* and *Qd/+* are normal with respect to *bi* (Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1986, Chromosoma 93: 341-46). RK2.**cytology:** Placed in 4C5-6 based on its inclusion in *Df(1)rb13 = Df(1)4C5-6;4D3-E1* and the localization of the X break in *T(1;3)bi<sup>D1</sup> = T(1;3)4C5-6;65C3-5* (Banga *et al.*, 1986).**qf: quetas-finas****location:** 3-60.7.**origin:** Spontaneous.**references:** Ribo, 1968, DIS 43: 59.**phenotype:** Macro- and microchaetae thinner and shorter; low fertility; viability good.**qs: quicksilver****location:** 1-39.5 (based on mapping of *qs*<sup>2</sup>).**references:** Craymer, 1984, DIS 60: 234-36.

Wieschhaus, Nüsslein-Volhard, and Jürgens, 1984,

Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

Wright, 1987, Adv. Genet. 24: 127-222.

Pentz, Black, and Wright, 1990, Biochem. Genet. 28: 151-71.

**phenotype:** Recessive embryonic lethal; denticles and mouthparts unpigmented; cell viable in gynandromorphs causing depigmentation of cuticle, including chaetae; viability reduced owing to weakened cuticle. Used as marker in the analysis of mosaic embryos (Gergen and Wieschhaus, 1985, Dev. Biol. 109: 321-35). *qs*<sup>1</sup>, *qs*<sup>2</sup>, and *qs*<sup>3</sup> hypomorphic in that expression varies with temperature and nutrition; some survival when reared on enriched medium; survivors smaller than normal and incompletely pigmented with a yellowish tinge; some extremely pale with bristles with very little pigmentation and with wings that when expanded are glassy clear and very fragile. The extremely pale *qs*<sup>2</sup>/*Y* never exhibit melanotic wound reaction, and puparia underpigmented. *qs* embryos derived from homozygous germ-line clones do not hatch and exhibit head defects and abnormalities of germ-band shortening; heterozygous embryos from such clones exhibit 75% survival; homozygous clones behave as meiotic mutant yielding 8% patroclinous males (Wieschhaus and Noel, 1986, Wilhelm Roux's Arch. Dev. Biol. 195: 63-73). Phenol oxidase activity of any surviving *qs* flies significantly depressed, in some cases being undetectable; all three components, A1, A2, and A3, coordinately reduced; activator activity normal. Phenol oxidase deficiency leads to significant accumulations ofcatecholamine pools in *qs*<sup>2</sup> males 60 to 80 min after eclosion: three-to-eight-fold increases in N- $\beta$ -alanyldopamine and N-acetyldopamine and two-fold increases in dopamine (Pentz, Black, and Wright).**alleles:**

***r*: rudimentary**

**location:** 1-54.5 [Revised to 55.6 by Colaianne and Bell (1972, DIS 48: 20-21) and to 55.3-55.4 by Nørby (1970, DIS 45: 41) based on large scale measurements of *r-f* recombination].

**phenotype:** Homozygotes and hemizygotes are pyrimidine auxotrophs (Nørby, 1969, *Hereditas* 66: 205-14). A complex locus encoding a 220 kd polypeptide containing the first three enzyme activities in the pyrimidine synthetic pathway: glutamine-dependent carbamyl phosphate synthetase [CPS (EC.2.7.2.5)] (Jarry and Falk, 1974, *Mol. Gen. Genet.* 135: 113-22), aspartate transcarbamylase [ATC (EC.2.1.3.2)] (Nørby, 1969), and dihydroorotase [DHO (EC.3.5.2.3)] (Rawls and Fristrom, 1975, *Nature* 255: 738-40). Probably exists as a homomultimer. These three activities cosediment and copurify (Brothers, Tsubota, Germeraad, and Fristrom, 1978, *Biochem. Genet.* 16: 321-32); also the developmental profiles of the three activities are the same, maximal in the egg, dropping until the time of hatching, increasing again during the first larval instar, and then leveling off at a low level (Mehl and Jarry, 1978, *Dev. Biol.* 67: 1-10); high activity in egg attributable to maternal expression. Wings of homozygous females and hemizygous males obliquely truncated posteriorly; phenotype varies from wings that are wrinkled and blistered and do not extend beyond the tip of the abdomen to normal, with intermediate phenotypes having wings truncated to various degrees but not wrinkled or blistered, or normal wings with irregularly spaced marginal hairs. Wing cells smaller than normal (Fausto-Sterling and Hsieh, 1975,

*Dev. Biol.* 51: 269-81); oblique truncation attributed to cell death in distal portion of presumptive wing blade (Fausto-Sterling, 1980, *J. Exp. Zool.* 213: 383-90).

Homozygous females usually sterile when crossed to *r* male; occasionally give a few offspring, virtually all daughters plus a few exceptional males, when outcrossed. *r*<sup>39</sup> females produce many malformed eggs and unfertilized eggs with normal morphology; ovarian development often retarded or fails; yolk deposition affected; lethal effect in progeny results from generalized disturbance in differentiation 13-16 hr after fertilization at 25°; surviving embryos hatch late and may produce larvae that neither move nor feed (Counce, 1956, *Z. Indukt. Abstamm. Vererbungsl.* 87: 482-92). Eggs produced by *r*<sup>9</sup> parents fail to hatch, but can be rescued by the injection of preblastoderm eggs with cytoplasm from either fertilized or unfertilized wild-type eggs or with pyrimidine nucleosides (Okada, Kleinman, and Schneiderman, 1974, *Dev. Biol.* 37: 55-62). *r/0* tissue in gynandromorphs produced by *r/r* females confined to abdomen; no such constraint when produced by *r/+* females (Fausto-Sterling, 1971, *Dev. Biol.* 26: 452-63). Mosaic studies of Falk (1977, *Dev. Biol.* 58: 134-47) indicate nonautonomy of *r*<sup>+</sup> within the wing and the ovary, and that normal wing and ovarian development depend on pyrimidine synthesis within those organs. Female-sterile but not truncated-wing aspect of phenotype partially alleviated by administration of cytidine during development (Bahn, 1970, DIS 45: 99); administration of 6-azauracil or 6-azauridine, competitive inhibitors of pyrimidine synthesis, causes rudimentary phenocopies [Rizki and Rizki, 1965, *Science* 150: 222-23; Strømman, Bahn, Nørby, and Sick, 1973, *Hereditas* 73: 239-46 (fig.)].

Sex-linked recessive mutants selected on the basis of inability to survive on medium deficient in pyrimidines all map to the rudimentary locus; the majority have the rudimentary phenotype, but some are phenotypically normal and are designated subliminal alleles in the following table. Subliminal alleles exhibit strongly depressed survival on pyrimidine-free medium; standard alleles do not survive in the absence of pyrimidine; relative survival of *r/+* heterozygotes varies from 5 to 70% depending on severity of allele (Falk and Nash, 1974, *Mol. Gen. Genet.* 131: 339-49).

<sup>α</sup> Carlson (1971) ordered 45 alleles by means of genetic recombination; the order, from left to right, of alleles thus localized is represented by numbers in bold face. In some publications these numbers are used as allelic designations.

<sup>β</sup> 1 = Agol, 1936, DIS 5: 7; 2 = Azou, Mehl, and Jarry, 1981, Dev. Publ. No. 237: 25 (fig.); 25 = Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 234; 26 = Nørby, 1970,

Hereditas 66: 205-14; 27 = Oliver, 1939, DIS 12: 48; 28 = Osgood, 1983, Genetics 104: s55; 29 = Rawls and Porter, 1979, Genetics 93: 143-61; 30 = Rohr, 1962, DIS 36: 39; 31 = Schalet, 1985, Genetics 110: s99; 32 = Thompson, 1969, DIS 44: 44; 33 = Tsubota, Ashburner, and Schedl, 1985, Mol. Cell. Biol. 5: 2567-74.

$\gamma$  Complementation results according to Carlson (1972), Rawls and Porter (1979) and Falk (1976, Mol. Gen. Genet. 148: 1-8; Falk, McCaughin, and Cogley, 1977, Genetics 85: 765-77); arabic numbers are the equivalent of Roman numerals used by Carlson; upper case letters used by Rawls and Porter, and by Falk, where A of Rawls and Porter corresponds to C of Falk and to 1 of Carlson, B of Rawls and Porter to 3 of Carlson, C of Rawls and Porter to B of Falk to 6 of Carlson, and D of Rawls and Porter to A of Falk to 7 of Carlson. Lines with seven + or - symbols from Carlson (many confirmed by Rawls and Porter); lines with four + or - symbols from Rawls and Porter only; and lines with but three are from Falk.

$\delta$  Subliminal alleles exhibit normal-wing phenotype and female fertility, but survive very poorly on pyrimidine deficient medium. Fully mutant derivatives of subliminal alleles induced with EMS by Falk and deBoer (1980, Mol. Gen. Genet. 180: 219-24): six from  $r^{pyr1}$ , thirteen from  $r^{pyr2}$ , sixteen from  $r^{pyr3}$ , 21 from  $r^{pyr4}$ , and 29 from  $r^{pyr11}$ .

$\epsilon$  More detailed description below.

**cytology:** Tentatively placed in 15A1 by Lefevre [Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, pp. 32-66] and in 15A1-2 on the basis of *in situ* hybridization (Rawls, Freund, Jarry, Louis, Seagraves, and Schedl, 1986, Mol. Gen. Genet. 202: 493-99).

**molecular biology:** *r* transcription unit selected using a hamster *pyr1-3* probe; walk in either direction produced 90 kb of cloned sequence from 14F-15A region (Seagraves, Louis, Schedl, and Jarry, 1983, Mol. Gen. Genet. 189: 34-40). Genomic probe hybridizes to a 7.3 kb polyadenylated RNA, which is large enough to encode the 220 kd polypeptide. Direction of transcription from left to right, beginning with the domain for DHO on the left, continuing through the domain for CPS in the middle and ATC on the right; the region transcribed is approximately 12.5 kb in length and contains at least three introns, one of which is over 4 kb in length.

**other information:** Fine structure of the locus examined by both recombination and complementation (Carlson, 1971, Genet. Res. 17: 53-81). Carlson defines seven complementing regions, whereas Fahmy and Fahmy (1959, Nature 184: 1927-29) recognized six, Green (1963, Genetica, 34: 242-53) at least three, Falk (1976, Mol. Gen. Genet. 148: 1-8) three, and Rawls and Porter (1979, Genetics 93: 143-61) four. Region D of Rawls and Porter corresponds to regions VII and C of Carlson and Falk respectively, and identifies the DHO domain; region C of Rawls and Porter corresponds to regions VI and B of Carlson and Falk and identifies the CPS domain; and region D of Rawls and Porter corresponds to region I and C of Carlson and Falk and identifies the ACT domain. The genetic map and the complementation map are roughly colinear. Noncomplementing alleles map to both the 5' and 3' ends of the gene (Carlson's numbers 5 and 6 at the 5' end and numbers 35, 37, and 42-45 at the 3' end, where numbers refer to approximate linear order of alleles on the genetic map). Complementation maps constructed using wing phenotype and survival on unsupplemented medium not identical (Falk, 1976).

### $r^{CS1}$ : rudimentary-cold sensitive

**phenotype:** Homozygotes raised at 16° are lethal, at 20° are rudimentary, and at 25° are wild type in phenotype; the same results are observed in  $r^{CS1}/Df(1)r-D17$  and  $r^{CS1}/r^1$  heterozygotes;  $r^1$  is deficient for DHO only. Heterozygotes with  $r^{11}$ , which is deficient for CPS, are rudimentary at all temperatures, and heterozygotes with  $r^{29}$  and  $r^{38}$ , which lack ATC activity, are wild type at all temperatures. Cold-sensitive periods during embryogenesis and during organogenesis in the early pupal stage; larval stages cold stable. Activities of DHO iso-

lated from early embryos cold sensitive; CPS exhibits reduced activity at all temperatures; ATC cold stable (Azou, Mehl, and Jarry, 1981, Dev. Biol. 84: 157-63).

### **R: Roughened**

**location:** 3-1.4.

**discoverer:** E. M. Wallace, 35i.

**phenotype:** Eyes of *R/+* rough, have some large dark facets. Photoreceptor cell 7 frequently absent (Carthew). Male genitalia frequently rotated and male sometimes sterile; viability about 80% wild type. Homozygote semi-lethal; wings spread. Thorax short; acrostichal hairs deranged, some missing; eyes small. Homozygous female fertile. RK1.

**alleles:**  $R^2$ , a hybrid-dysgenesis-induced revertant of *R*, which is hemizygous lethal (Sliter, Henrich, Tucker and Gilbert, 1989, Genetics 123: 327-36).

**cytology:** Placed in 62B8-12 based on reversion of *R* by  $Df(3L)R-G2 = Df(3L)62B2-4;62B11-12$  and  $Df(3L)R-G7 = Df(3L)62B8-9;62F2-5$  (Sliter, Henrich, Tucker, and Gilbert, 1989, Genetics 123: 327-36).

**other information:** Recently determined to be an allele of *Rap1* (Hariharan).

### \* $R^{51b}$

**origin:** Recovered among progeny of female treated as embryo with cold shock.

**discoverer:** Mickey, 51b21.

**references:** 1951, DIS 25: 74.

1951, Genetics 36: 565-66.

**phenotype:** Eyes of heterozygote small, oblong, and rough; facets and eye hairs irregular. Viability good. Homozygote lethal.  $R^{51b}/R$  has very small eyes, much fusion of facets, and resembles *gl* and *Gl*. RK1.

$R^3-55.4$ : see *M(GPDH)*

$R^3(+)$ : see *T(2;3;4)ci+3*

$R^{26}-43$ : see *M(ADH)*

### **r-l: rudimentary-like**

**location:** 3-70.4 (based on 240 *gl-e* recombinants).

**references:** Lastowski and Falk, 1980, Genetics 96: 471-78.

Rawls, 1980, Mol. Gen. Genet. 178: 43-49.

Rawls, 1981, Mol. Gen. Genet. 184: 174-79.

Conner and Rawls, 1982, Biochem Genet. 20: 607-19.

**phenotype:** Encodes a polypeptide with the enzyme activities that catalyze the fifth and sixth steps of *de novo* pyrimidine synthesis: orotate phosphoribosyl transferase [OPRT (EC. 2.4.2.10)] and orotidylate decarboxylase [ODC (EC. 4.1.1.23)] respectively. Thought to exist as a homodimer (Rawls, 1979, Comp. Biochem. Physiol. 62B: 207-16). The first three enzyme activities encoded

by *r* and the fourth by *Dhod*. OPRT and ODC activities drastically reduced except that OPRT moderately reduced in *r-l*<sup>K7</sup> and ODC above normal in *r-l*<sup>K6</sup>. All mutants accumulate orotic acid, the substrate of ODC. Flies hemizygous or homozygous for mutants at this locus resemble *r* in that they have obliquely truncated wings with deranged marginal hairs and virtual female sterility; they differ from *r* in having faintly mottled eyes and severely impaired viability (viability of hypomorphs moderately reduced). *r* is epistatic to *r-l* in that *r*; *r-l* flies display the *r* rather than the *r-l* phenotype, suggesting that mottled eyes and reduced viability are the consequence of orotic acid accumulation rather than pyrimidine deficiency.

<sup>α</sup> 1 = Conner and Rawls, 1982, Biochem. Genet. 20: 607-19; 2 = Las-towski and Falk, 1980, Genetics 96: 471-78; 3 = Rawls, 1980, Mol. Gen. Genet. 178: 43-49; 4 = Rawls, 1981, Mol. Gen. Genet. 184: 174-79.

**cytology:** Tentatively placed in 93B4-13 based on its inclusion in *Df(3R)e-R6 = Df(3R)93B4-5;94A5-16* (B.S. Baker) and *Df(3R)e-R1 = Df(3R)93B3-5;93D2-4* (B.S. Baker) but not *Df(3R)e-F2 = Df(3R)93A6-B1;93D7-10* (Mohler and Pardue) = *Df(3R)93B8-13;93F9-10* (Scalenghe and Ritossa).

***r(αGPDH): regulator of α glycerol phosphate dehydrogenase***

**location:** 3-55.4.

**origin:** Spontaneous.

**synonym:** *m(GPDH)*, *r*<sup>3-55.4</sup>.

**references:** King and McDonald, 1982, DIS 58: 91-92. 1983, Genetics 105: 55-69.

**phenotype:** Recessive allele of a locus that affects levels of αglycerol phosphate dehydrogenase activity. In the presence of the dominant allele, which we designate *r(αGPDH)*<sup>+</sup>, αGPDH levels in the adult are 60% higher than they are in *r(αGPDH)* homozygotes; the increase is observed in the thorax but not the abdomen. Rates of enzyme synthesis the same in the two genotypes; differences in activity attributed to reduced rates of degradation in the presence of *r(αGPDH)*<sup>+</sup>; no evidence for conformational differences in αGPDH. Not a general regulator of enzyme activity; however one rapidly migrating polypeptide is much more abundant in *r(αGPDH)* homozygotes than in the presence of *r(αGPDH)*<sup>+</sup>. Larvae carrying *r(αGPDH)*<sup>+</sup> have 25% lower levels of αGPDH activity than *r(αGPDH)* homozygotes.

***r(ADH)***

**location:** 3- (between *h* and *th*).

**origin:** Naturally occurring allele.

**synonym:** *r*<sup>26-43</sup>.

**references:** King and McDonald, 1987, Genetics 115: 693-99.

**phenotype:** *r(ADH)* homozygotes exhibit approximately 70% of the level of alcohol dehydrogenase seen in heterozygotes and *r(ADH)*<sup>+</sup> homozygotes; parallel differences in the levels of immunologically cross-reacting material (CRM) also observed. The effect of *r(ADH)* is constant over development and is not attributable to differences in charge, conformation, or rate of synthesis of ADH. Activities of GPDH and PGI levels insensitive to *r(ADH)* genotype.

***ra: rasé***

**location:** 3-97.3.

**origin:** Spontaneous.

**discoverer:** Beadle, 34d.

**references:** 1935, DIS 4: 10.

**phenotype:** Bristles and hairs small and irregularly absent, especially from head and thorax. Viability good; developmental time normal. RK2.

**cytology:** Associated with *ln(3R)P* (Craymer).

***\*ra<sup>2</sup>***

**origin:** Spontaneous in *ln(3R)P*.

**discoverer:** Mossige, 36k21.

**synonym:** *bd: bald*.

**references:** 1937, DIS 8: 9.

**phenotype:** Homozygote lacks all head bristles and some scutellars. Heterozygote has extra anterior scutellars in about 30% of flies. RK2A.

**cytology:** Occurred in and probably inseparable from *ln(3R)P = ln(3R)89C2-4;96A18-19*.

***\*rab: rabbit***

**location:** 1-58.

**origin:** Induced by P<sup>32</sup>.

**references:** Bateman, 1950, DIS 24: 55.

**phenotype:** Hairs on mesonotum near dorsocentral bristles turned inward toward midline. Air bubbles occasionally in thorax, beneath dorsocentrals, and scutellum. Wings rarely held up. Viability and fertility normal. RK2(A).

**other information:** Slight disturbance of crossing over proximally.

***rad201: radiation sensitive***

**location:** 2-59.9.

**synonym:** *rad(2)201*<sup>G1</sup>.

**references:** Levina, Malinovsky, and Zakharov, 1980, Genetika (Moscow) 16: 285-89.

Khromykh and Zakharov, 1981, Genetika (Moscow) 17: 658-66.

Khromykh, 1981, Genetika (Moscow) 17: 667-76.

Tikhomirova and Rasheva, 1983, Genetika (Moscow) 19: 628-34.

**phenotype:** Survival of homozygous larvae more sensitive to exposure to γ radiation than controls; chromosome- and chromatid-aberration induction increased over control but ratio of the two types same as control. X-ray-induced X-chromosome loss in immature oocytes greater in *rad201* than in control; mature oocytes show no effect of *rad201*. Post-treatment hyperthermia enhances the effect of irradiation in mature oocytes and control imma-

ture oocytes, but not in immature oocytes of *rad201*.

**radioresistant:** see *rar1*

**radius incompletus:** see *ri*

**raf:** see *phl*

**rag: rags** (*T. Schüpbach*)

**location:** 2-32.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schupbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal effect lethal; embryos from homozygous mothers form a fragmented cuticle with large ventral holes and head defects.

**alleles:** One: *rag<sup>QI</sup>* = *rag<sup>1</sup>*.

**\*rag: ragged**

**location:** 3-37 (Steinberg).

**discoverer:** Charles, 1932.

**references:** Dunn, 1934, *DIS* 1: 30.

**phenotype:** Hairs missing from sections of wing margin. RK3.

**rags:** see *rag*

**\*rai: raisin**

**location:** 3-17 (Stanley).

**origin:** Spontaneous.

**discoverer:** Hersh.

**references:** 1953, *DIS* 27: 55.

**phenotype:** Eye color deep brown, like *se*. Ecdysis delayed 1 or 2 days. RK2.

**raised:** see *rsd*

**raised wing:** see *rw*

**raisin:** see *rai*

**ral:** see *r-l*

**rap: retina aberrant in pattern** (*J.C. Hall*)

**location:** 1- {7.5}.

**references:** Karpilov, Kolodkin, Bork, and Venkatesh, 1989, *Genes Dev.* 3: 1834-44.

**phenotype:** Eyes grossly abnormal: rough surface texture, and deep pseudopupil (DPP) has anomalous appearance; finer level observations show ommatidia to be aberrant in size, shape, and alignment; in sections, numbers of photoreceptor cells per ommatidium vary greatly, and positions of such cells plus rhabdomere arrangements are altered. Developmentally, recruitment of presumptive photoreceptors behind morphogenetic furrow in third larval instar eye disc is abnormal: *e.g.*, arrangement of five-cell preclusters is very disorganized, and the normal increase in numbers of cells within clusters does not occur, so that, in regions where eight-cell clusters are found in wild-type, there are small clusters in *rap*, intermingled with others than can have >8 cells; cell bodies of developing photoreceptor cells do not become apically positioned in the disc, as in wild-type. Temperature-shift experiments on *rap<sup>4</sup>* show a temperature-sensitive period for roughened eye is in third larval instar. Mosaic experiments, involving induced mitotic recombination in *rap<sup>1</sup>/+* larvae, showed that normal adult ommatidia always had a *rap<sup>+</sup>* R8 cell, whereas R1-7 could readily be genotypically *rap<sup>1</sup>* in such facets; also, certain pheno-

typically mutant ommatidia, near borders separating mutant and wild-type tissue, contained all *rap<sup>+</sup>* cells (in clusters of 3, 4, 6, or 8 photoreceptor cells).

<i>rap<sup>2</sup></i>	P			hypomorph?
<i>rap<sup>3</sup></i>	P			amorph
<i>rap<sup>4</sup></i>	P		<i>rap<sup>R22ts</sup></i>	temperature-sensitive hypomorph <sup>α</sup>

<sup>α</sup> Rearing at 17° leads to normal eye-surface morphology (albeit 36% penetrance of *rap<sup>1</sup>*-like DPP phenotype); rearing at 29° causes all flies to have relatively mild eye roughening.

**cytology:** Maps to 4C7-16, based on its inclusion in *Df(1)rb<sup>13</sup>* = *Df(1)4C5-6;4D3-E1* but not *Df(1)rb<sup>1</sup>* = *Df(1)3F6-4A1;4C7-8* or *Df(1)JC70* = *Df(1)4C15-16;5A1-2*.

**other information:** *rap<sup>1</sup>* was shown to complement the nearby rough-eye mutation, *rg*.

**Rap1: Ras3**

**location:** 3- 1.4 (based on mapping of *R*).

**origin:** Isolated from genome library using v-Ha-ras probe.

**synonym:** *Dras3*, *Ras3*.

**references:** Neuman-Silberberg, Scheifer, Hoffmann, and Shilo, 1984, *Cell* 37: 1027-33.

**cytology:** Cloned sequence hybridizes to 62B.

**molecular biology:** Transcripts of 1.5, 1.9, and 2.9 kb detected (Lev, Kimchie, Hessel, and Segev, 1985, *Mol. Cell. Biol.* 5: 1540-1542); larger transcript present throughout development; shorter ones more abundant during embryogenesis.

**other information:** Isolated as a *Ras* homologue, but recently found to share high homology with human *Rap*.

**rapid exhaustion:** see *rex*

**rar1: radioresistant**

**location:** 1- (not mapped).

**origin:** Spontaneous in line selected for radioresistance.

**references:** Nöthel, 1980, *DIS* 55: 208-09.

Nöthel, 1981, *Mutat. Res.* 80: 105-20.

Nöthel, 1982, *Mutat. Res.* 103: 87-90.

Nöthel and Abdalla, 1982, *Mutat. Res.* 92: 123-32.

**phenotype:** Semidominant; reduces sensitivity of prestage-14 vitellarial oocytes to the dominant- and recessive-lethal-inducing effects of X irradiation or exposure to ethyl methanesulfonate. 1.3 X the dose to produce a given effect in controls required to produce the same effect in *radl* (*i.e.*, Dose Reduction Factor = 1.31). Effect of mutation inhibited by caffeine.

**rar2**

**location:** 2- (near centromere).

**origin:** Spontaneous in line selected for radioresistance.

**references:** Nöthel, 1980, *DIS* 55: 208-09.

Nöthel, 1981, *Mutat. Res.* 80: 105-20.

Nöthel, 1982, *Mutat. Res.* 103: 87-90.

**phenotype:** Semidominant; produces relative resistance of immature oocytes to X-ray and ethyl-methanesulfonate induction of dominant and sex-linked recessive lethals (Dose Reduction Factor = 1.31) and X-chromosome loss (Dose Reduction Factor = 1.72).

***rar3***

**location:** 3-49.8.

**origin:** Spontaneous in line selected for radioresistance.

**references:** Nöthel, 1980, DIS 55: 208-09.

Nöthel, 1981, Mutat. Res. 80: 105-20.

Nöthel, 1981, Mutat. Res. 84: 291-304, 305-13, 315-19.

Nöthel, 1982, Mutat. Res. 103: 87-90.

**phenotype:** Recessive mutant conferring resistance to the genetic effects of irradiation on oögonia and immature oocytes. Confers a dose reduction factor of 1.58 on the induction of dominant lethals, nondisjunction of major chromosomes and homologous exchange; and of 1.87 on the induction of sex-linked recessive lethals. Without effect on male germ line or somatic cells. Resistant to ethyl methanesulfonate as well.

***ras: raspberry***

**location:** 1-32.35 (Lefevre).

**phenotype:** Defective in pteridine synthesis; eye color dark ruby. Appears to affect the level of guanosine triphosphate cyclohydrolase activity; *ras* alleles exhibit increased activity compared to wild type at pupariation, but decreased activity at eclosion (Evans and Howell, 1979, Biochem. Genet. 16: 13-26). Not a purine auxotroph. Color autonomous in larval optic disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936, Genetics 21: 230). *ras/ras<sup>1</sup>* display *ras* eye color. Larval Malpighian tubes nearly wild type; not useful for classification (Brehme and Demerec, 1942, Growth 6: 351-56). *ras* is but one of four types of mutations belonging to an interrelated complex involved some way in purine metabolism: *ras*, a nonauxotrophic eye-color mutant; two purine auxotrophs, *pur1* and *gual*, which complement *ras* and one another; and *ras<sup>1</sup>*, lethal alleles that fail to complement completely the other three types.

The complex shares genetic features with rudimentary.

USA 67: 1101-08; 5 = Janca, Woloshyn, and Nash, 1986, Genetics 112: 43-64; 6 = Johnson, Woloshyn, and Nash, 1979, Mol. Gen. Genet. 174: 287-92; 7 = Lefevre 1981, Genetics 99: 461-80; 8 = Lefevre and Watkins, 1986, Genetics 113: 869-95; 9 = Muller, 1935, DIS 3: 30; 10 = Nash and Janca, 1983, Genetics 105: 957-86.

<sup>β</sup> Complements *ras<sup>2</sup>* eye color but not lethality of other *ras<sup>1</sup>* alleles.

<sup>γ</sup> Survives weakly as homozygous female, but completely lethal as male and hemizygous female.

**cytology:** Placed in 9E1-4 on the basis of its inclusion in the region of overlap between *Df(1)ras-P14* = *Df(1)9E1-2;9F3-4* and *Dp(1;2)9E1;10A11;56A* (Zhimulev, Pokholkova, Bgatov, Semeshin, and Belyaeva, 1981, Chromosoma 82: 25-40).

***Ras1: Ras proto-oncogene sequence***

**location:** 3- {49}.

**origin:** Isolated from genomic library using v-Ha-ras probe.

**synonym:** *Dras1*.

**references:** Neuman-Silberberg, Scheifer, Hoffmann, and Shilo, 1984, Cell 37: 1027-33.

**phenotype:** Codes for a polypeptide of 21.6 kilodaltons; residues 1-121 and 137-64 exhibit 75% homology with vertebrate H-ras protein.

**alleles:** Loss-of-function mutations are homozygous lethal; enhance *sev* and *Egfr<sup>E</sup>* in heterozygotes (M. Simon).

**cytology:** Cloned sequence hybridizes to 85D.

**molecular biology:** Gene cloned and sequenced. Contains four introns. Open reading frame in cDNA codes for 189 amino acids corresponding to a polypeptide of 21 kilodaltons. Transcripts of 1.3 and 2.0 kb detected by Lev, Kimchie, Hessel, and Segev (1985, Mol. Cell. Biol. 5: 1540-42); the larger persists throughout development, the smaller being primarily in unfertilized eggs and embryos.

***Ras2***

**location:** 3- {15}.

**origin:** Isolated from genome library using v-Ha-ras probe.

**synonym:** *Dras2, Dmras64B*.

**references:** Neuman-Silberberg, Scheifer, Hoffmann, and Shilo, 1984, Cell 37: 1027-33.

Moser, Marlör, Parkhurst, and Corces, 1985, Mol. Cell. Biol. 5: 885-89.

**phenotype:** Encodes a 22.7 kilodalton, 195 amino acid, polypeptide, p21.

**cytology:** Cloned sequence hybridizes to 64B.

**molecular biology:** Entire gene sequenced. Contains two more amino-terminal codons than the homologous gene from humans and four fewer than the yeast gene. *Drosophila*, human, and yeast sequences highly homologous up to amino-acid residue 90, less so for the next 80 amino acids, and not at all for residues 170-190. *Ras2* contains two introns in positions different from those in the homologous human gene. Appears to produce transcripts of 1.6, 2.1, and 2.6 kb, which are present in the same proportions throughout development (Wadsworth, Madhavan, and Bilodeau-Wentworth, 1985, Nucl. Acids

Res. 13: 2153-70; Mozer, Marlo, Parkhurst, and Corces, 1985, Cell. Biol. 5: 885-89). Claimed by Lev, Kimchie, Hessel, and Segev (1985, Mol. Cell. Biol. 5: 1540-42) to produce transcripts of 1.4 and 1.8 kb, the larger of which is expressed at all stages and the smaller in unfertilized eggs and early embryos.

**raw: raw**

**location:** 2-19.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Homozygous lethal; dorsal closure and cuticle differentiation defective.

**alleles:** *raw*<sup>1</sup> and *raw*<sup>2</sup> recovered as IG and IIF.

**rb: ruby**

**location:** 1-7.5.

**discoverer:** Bridges, 14j18.

**phenotype:** Eye color clear ruby, white in combination with *w*<sup>a</sup>, orange with *st*, and brownish red with *bw* (Mainx, 1938, Z. Indukt. Abstamm. Vererbungsl. 75: 256-76). Development of pigment autonomous in *rb* eye disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936, Genetics 21: 230). Larval Malpighian tubes pale yellow (Beadle, 1937, Genetics 22: 587-611). RK1.

**alleles:**

allele	origin	discoverer	ref <sup>α</sup>

**cytology:** Located in 4C6 based on the overlap of *Df(1)rb13 = Df(1)4C5-6;4D3-E1* and *Df(1)rb46 = Df(1)4A3-6;4C6-7* (Banga, Bloomquist, Brodberg, Pye, Larrivee, Mason, Boyd, and Pak, 1983, Chromosoma 93: 341-46).

*rbc*: see *rc*

**rb1: reduced bristle**

**location:** 2-82.3.

**origin:** Spontaneous; natural population.

**references:** Watanabe, 1969, Jpn. J. Genet. 44: 15-22.

Watanabe and Oshima, 1970, Genetics 64: 93-106.

**phenotype:** Homozygotes show reduced dorsal bristles; both sexes fertile, but development delayed by 1.5 days

and viability reduced.

*rbp*: see *BRC*

**rc: red cells**

**location:** 2-36.8 (between *d* and *J*).

**origin:** Spontaneous.

**discoverer:** E. B. Lewis, 1946.

**synonym:** *rbc*: red blood cells.

**references:** 1950, DIS 24: 59.

Jones and Lewis, 1957, Biol. Bull. 112: 220-24 (fig.).

Grell, 1961, Genetics 46: 925-33.

**phenotype:** *rc/rc* normal; in *lys rc/lys rc*, fat cells of head and thorax acquire brownish red pigment. Effect most prominent in one or more rows of pigmented cells along mid-dorsal line of thorax just beneath chitin. Pigment is ommochrome since *lys rc bw* cells are pigmented, whereas *v; lys rc* cells are colorless except in kynurenine-fed flies. RK3.

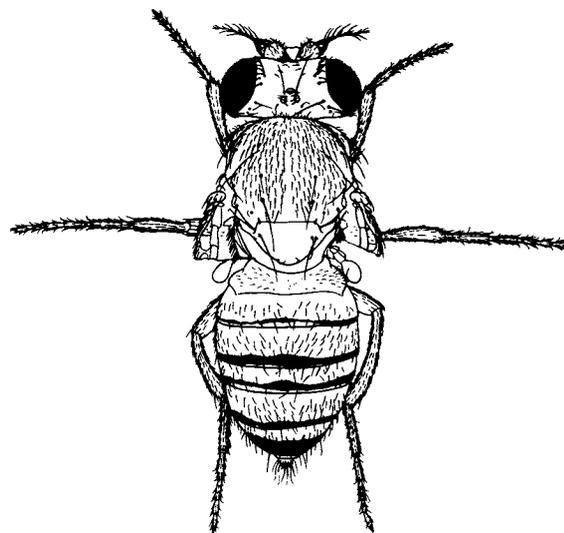

**rc<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** R. F. Grell, 1957.

**references:** Grell, 1961, Genetics 46: 925-33.

**phenotype:** Wild type at 25° on standard medium; at 17°, a few red fat cells are visible. Early third instar larvae placed on glucose-agar medium produce flies with numerous red cells. *lys rc<sup>2</sup>* has red cells under any conditions. RK3.

**rd: reduced**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 157.

**rd: reduced**

**location:** 2-51.2.

**origin:** Spontaneous.

**discoverer:** Bridges, 17g15.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 233-35.

**phenotype:** Bristles reduced in length and thickness, sometimes twisted; best seen on sternopleurals; male more extreme than female (*rd*<sup>1</sup>); female may have abnormal abdominal banding (*rd*<sup>s</sup>). Males fertile, but females may

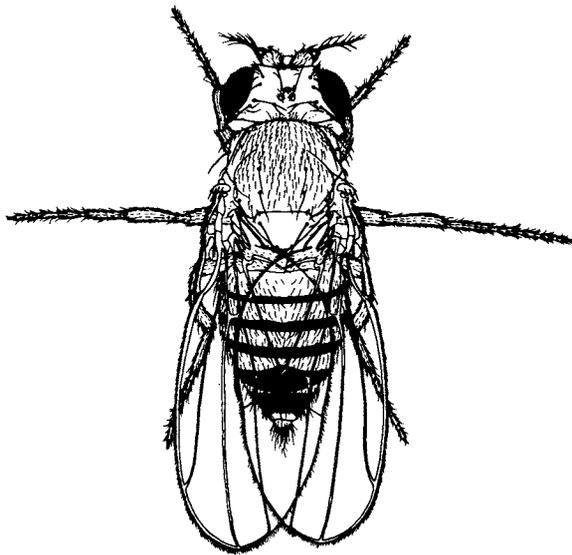

be sterile (*rd*<sup>1</sup>) (Lynch, 1919, Genetics 4: 501-33).  
**alleles:**

<sup>α</sup> 1 = Angel, Ashburner, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186; 2 = Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 233-35.

<sup>β</sup> *rd*<sup>9</sup> is lethal in combination with *Df(2L)osp18* and *Df(2L)TE35BC-3* but not with *Df(2L)nNXF1* or *Df(2L)A72*; complemented by all known lethal mutants in the region.

**cytology:** Placed in 35C2-5 based on its inclusion in *Df(2L)osp18* = *Df(2L)35B1-2;35C4-5* but not *Df(2L)el81i1* = *Df(2L)34E1-2;35C2-3*; also claimed to lie within deficiencies that include bands from 35B but not 35C [*Df(2LA215; Df(2L)A400, Df(2L)Sco-1*].

***rd*<sup>s</sup>: reduced-scraggly**

Edith M. Wallace, unpublished.

***RD(1): Recovery Disrupter (1)***

**location:** 1-62.9 [10% of the distance between *car* and *su(f)*].

**origin:** Found in a chronically irradiated population obtained from B. Wallace.

**discoverer:** Hanks, 1957.

**references:** Novitski and Hanks, 1961, Nature 190: 989-90.

Erickson and Hanks, 1961, Am. Naturalist 95: 247-50.

Hanks, 1964, Genetics 50: 123-30.

**phenotype:** Males containing this factor, *RD(2)*, and certain other factors produce approximately 67% female and 33% male progeny. The effect is not produced by zygotic mortality but by a mechanism that operates during meiosis, leading to fragmentation of the *Y* chromosome and production of fewer than 64 sperm heads per sperm bundle (Erickson, 1965, Genetics 51: 555-71). The effect is maximal at 25° and less pronounced at both

18° and 27°. Viability good but fertility reduced in both sexes. RK3.

***RD(2)***

**location:** 2- (not located).

**origin:** Found in a chronically irradiated population obtained from B. Wallace.

**discoverer:** Hanks, 1960.

**references:** Novitski and Hanks, 1961, Nature 190: 989-90.

**phenotype:** Males with this factor, *RD(1)*, and certain other factors produce about 67% female progeny. RK3.

**\**rdb: reddish brown***

**location:** 1-21.7.

**origin:** Induced by methyl methanesulfonate (CB. 1540).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 89.

**phenotype:** Eye color deep reddish brown. Wings frequently curve slightly upward at tips. Body somewhat small. Male sterile. Viability about 30% wild type. RK3.

***rde: reduced eye***

**location:** 1-20 (inferred from Fig. 1 of Homyk and Shepard and the known map position of *hypoB*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.

Homyk, 1977, Genetics 87: 105-28.

**phenotype:** Selected on basis of reduced ability to fly; other behavioral traits normal; also exhibits reduced eye size and frequently missing palpi.

***rdgA: retinal degeneration A (J.C. Hall)***

**location:** 1-26.3.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *receptor degeneration-1* (Hotta and Benzer, 1970); *x35* (Pak).

**references:** Hotta and Benzer, 1970, Proc. Nat. Acad. Sci. USA 67: 1156-63.

Harris and Stark, 1977, J. Gen. Physiol. 69: 261-91.

Johnson, Frayer, and Stark, 1982, J. Insect Physiol. 28: 23-42.

Stark and Carlson, 1985, Int. J. Insect Morphol. Embryol. 14: 243-54.

**phenotype:** Photoreceptors degenerate during first week of adult life, although electroretinogram is small at time of eclosion when photoreceptors are morphologically normal; exception: *rdg*<sup>1</sup> which is already aberrant then (Stark and Carlson, 1985); degeneration of outer photoreceptors (R1-6) in each eye facet is more severe (*i.e.*, is essentially complete) than that of inner two cells (R7,8), with the most severe central-cell degeneration caused by *rdgA*<sup>1</sup> and *rdgA*<sup>2</sup>, *rdgA*<sup>4</sup> being less severe, and *rdg*<sup>3</sup> still less (Harris and Stark, 1977); the ocelli degenerate, too, with *rdgA*<sup>1</sup> causing particularly severe effect (Johnson *et al.*, 1982); degeneration of compound eye photoreceptors is not light- or temperature-dependent (Harris and Stark, 1977); such degeneration is photoreceptor-autonomous in mosaics (Hotta and Benzer, 1970; Harris and Stark, 1977); degenerating photoreceptor axon terminals, especially those projecting from R1-6 into the lamina optic ganglion, are phagocytosed by glia in that optic lobe (Stark and Carlson, 1985); in general, though, the gross and internal structure of the lamina seems quite

normal, even after photoreceptor degeneration caused by most severe *rdgA* alleles is complete (Meyerowitz and Kankel, 1978, Dev. Biol. 62: 112-42; Johnson *et al.*, 1982; Stark and Carlson, 1985); two polypeptide spots in 2-d gel analysis of eye-specific proteins are reduced in intensity under influence of *rdgA*<sup>4</sup> [Hotta, 1979, Mechanisms of Cell Change (Ebert and Okada, eds.). John Wiley, New York, pp. 169-82]; *rdgA* mutations said to cause hypoactive behavior, and one of them also leads to shaking on exposure to ether plus premature death after exposure to 29° (Homyk, Pye and Pak, 1981, Genetics 97: s50).

**cytology:** Placed in 8A4-C6 based on its inclusion in *Df(1)KA14 = Df(1)7F1-2;8C6* but not *Df(1)RA2 = Df(1)7D10;8A4-5*.

Stark, Chen, Johnson, and Frayer, 1983, J. Insect Physiol. 29: 123-31.

Stark and Carlson, 1985, DIS 61: 162-64.

**phenotype:** Photoreceptors in each facet of compound eye show light-induced degeneration; morphology is essentially normal on eclosion, but maintenance of mutant adults on diurnal light regime causes severe degeneration within approximately one week (Harris and Stark, 1977); the cell bodies and axons of photoreceptors begin to look ultrastructurally abnormal after three days (Stark and Carlson, 1982); the various *rdgB* mutations tend to cause the outer photoreceptors (R1-6) in each facet to degenerate more than the inner two cells (R7,8), such that *rdgB*<sup>9</sup> and *rdgB*<sup>1</sup> have R7,8 preserved in nearly all ommatidia, *rdgB*<sup>6</sup> and *rdgB*<sup>8</sup> retain most central cells,

and *rdgB*<sup>7</sup> plus *rdgB*<sup>5</sup> show progressively worse degeneration of R7,8 with *rdgB*<sup>5</sup> retaining these cells in only 10% of the facets according to Harris and Stark (1977); degeneration of R7,8 not confirmed, however, by Stark *et al.* (1983). After R1-6 have degenerated and the central cells have or have not, depending on the allele, R7,8 retain at least quasi-normal function as indicated by electroretinograms (Stark, 1977, J. Comp. Physiol. 115: 47-59); degeneration is photoreceptor autonomous in mosaics (Hotta and Benzer, 1970; Harris and Stark, 1977); autonomous in mixed ommatidia at the electron-microscope level (Hofbauer and Campos-Ortega, 1976, Wilhelm Roux's Arch. Dev. Biol. 179: 275-89); ultrastructural details of degeneration include electron-dense cytoplasm with liposomes, lysosome-like bodies, myeloid bodies and vacuoles, and electron-dense reticulum and degenerate mitochondria, electron opaque photoreceptor axons lacking synaptic vesicles and containing seemingly none of the typical presynaptic structures (Stark and Carlson, 1982). Degenerating photoreceptors are associated with degeneration in the first order optic ganglion (the lamina), though the second order medulla is spared (Stark *et al.*, 1983); high temperature treatments accelerate degeneration, whereas homozygosity for an *AcpH-1*-null mutation delays it slightly (Harris and Stark, 1977). After rearing of *rdgB* animals in room light, the R1-6 cells are physiologically non-functional at eclosion (revealed by ERGs), in spite of apparently normal cellular structure (Harris and Stark, 1977). Prolonged depolarizing afterpotentials (induced by strong blue light) are abnormally short-lived and cannot be reversed by orange light, unlike the response of wild-type (Harris and Stark, 1977); degeneration of the photoreceptors is dramatically retarded by rearing in the dark followed by maintenance of adults under this condition (Harris and Stark, 1977); the same retardation of the mutations' effects occur when an *rdgB* mutation is linked to an ERG-minus *norPA* mutation (Harris and Stark, 1977), although degeneration does eventually occur in the double mutants (Stark *et al.*, 1983); three *norPA* mutations were induced based on their inhibition of *rdgB*-induced degeneration (Harris and Stark, 1977), with two of the new mutations leading to very small ERGs but the third, *norPA*<sup>sull</sup>, allowing for apparently normal retinal physiology (also see Stark *et al.*, 1983); this mutation revealed as a *norPA* allele, based on uncoverage of its degeneration-suppressing effects by an ERG-minus *norPA* mutation (Harris and Stark, 1977); *norPA*<sup>56</sup>'s suppressing effects are allele-specific, to the extent that *rdgB*<sup>9</sup>-induced degeneration is retarded (and this was the *rdgB* allele used to isolate this suppressor), but the effects of another allele, *rdgB*<sup>1</sup>, are not (Harris and Stark, 1977); *ort*<sup>1</sup> *ninaE*<sup>1</sup> (formerly *ora*<sup>JK84</sup>), an opsin-deficient genotype, also blocks light induced degeneration of receptor cells in *rdgB*<sup>9</sup> (Stark and Carlson, 1985, DIS 61: 162-64). Two *rdgB* alleles (unspecified) are associated with premature death of adults exposed to 29° (Homyk, Pye and Pak, 1981, Genetics 97: s50); further indications of pleiotropic action of this gene come from isolation of a hypoactive *rdgB* allele [originally *hypoF* (Homyk, Szidonya and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65)]; this mutation (mapping between *v* and *f*, as does *rdgB*) was shown to be an *rdgB* allele by Homyk and is now called *rdgB*<sup>23</sup>; it causes adults to be somewhat inactive in their

general movements and their jumping ability to be weak; there are no light-on or light-off transient spikes in the ERG, and optomotor responses are eliminated; two polypeptide spots observed in two-dimensional gel analysis of eye-specific proteins are reduced in intensity in an *rdgB* mutant -- the same spots as affected by *rdgA* [(Hotta, 1979, Mechanisms of Cell Change (Ebert and Okada, eds.). John Wiley, New York, pp. 169-82)].

**cytology:** Placed in 12A6-D3 based on its inclusion in *Df(1)HA92 = Df(1)12A6-7;12D3* (Deak, Bellamy, Bienz, Dubuis, Fenner, Gollin, Rähmni, Ramp, Reinhardt, and Cotton, 1982, J. Embryol. Exp. Morphol. 69: 61-81).

**other information:** *rdgB* mutations, especially those causing R1-6-specific degeneration (notably *rdgB*<sup>9</sup>), frequently used in experiments aimed at assessing behavioral and physiological significance of light input through central photoreceptors only; hence, phototaxis mediated by R7,8 (Jacob, Willmund, Folkers, Fischbach and Spatz, 1977, J. Comp. Physiol. 118: 261-71; Broda and Willmund, J. Insect Physiol. 27: 789-92; Hu and Stark, 1980, J. Comp. Physiol. 135: 85-95; Miller, Hansen and Stark, 1981, J. Insect Physiol 27: 813-19); optomotor responses eliminated by degeneration of R1-6 (Heisenberg and Buchner, 1977, J. Comp. Physiol. 117: 127-62); visual learning not impaired; intensity discrimination less acute than in wild type; no positive indication of color discrimination (Bicker and Reichert, 1978, J. Comp. Physiol. 127: 29-38). Visual pigment specific to outer photoreceptors (Harris, Stark and Walker, 1976, J. Physiol. 256: 415-39); absence of physiological effects of *rdgB* on ocelli (Hu, Reichert and Stark, J. Comp. Physiol. 126: 15-24); and physiological effects of a *trp* mutation on the central photoreceptors (Chen and Stark, 1983, J. Insect Physiol. 29: 133-40).

**\*rdm: reduced macros**

**location:** 1-59.8.  
**origin:** Induced by 2-fluoroethyl methanesulfonate (CB. 1522).  
**discoverer:** Fahmy, 1957.  
**references:** 1959, DIS 33: 89.  
**phenotype:** Most bristles thin and short. Eye shape slightly abnormal. Body short; wings short, broad, and frequently pleated. Male fertile. Viability about 10% wild type. RK3.

**rdο: reduced ocelli**

**location:** 2-53.  
**origin:** Spontaneous.  
**discoverer:** E. M. Wallace, 37113.  
**phenotype:** Ocelli small and colorless, often missing, leaving top of head smooth and sometimes pigmented. Hairs between ocelli fewer than wild type. Eye surface irregular. RK2.  
**alleles:** *rdο*<sup>2</sup>, spontaneous, Bridges, 38b10.  
**cytology:** Placed in 36E4-F1 based on its inclusion in the region of overlap of *Df(2L)TW203 = Df(2L)36E4-F1;37B9-C1* and *Df(2L)H20 = Df(2L)36A8-9;36E4-F1* (Wright).

**\*rdp: reduplicated**

**location:** 1-34.7.  
**discoverer:** Hoge-Richards, 12k.  
**references:** Hoge, 1915, J. Exp. Zool. 18: 241-97.  
**phenotype:** At low temperatures, most flies have malformed or branched legs, often with mirror image reduplication. At 25°, most flies normal. RK3.

**\*rdt: reduced thorax**

**location:** 1-54.4.  
**origin:** Induced by *p*-N,N-di-(2-chloroethyl)amino-phenylethylamine (CB. 3034).  
**discoverer:** Fahmy, 1955.  
**references:** 1959, DIS 33: 89.  
**phenotype:** Head and thorax disproportionately small compared to abdomen. Wings short, reaching only to tip of abdomen; frequently incompletely expanded or misheld. Male shows reduced viability and usually sterile. RK3.

**re: reduced eyes**

**location:** 3- (not located).  
**origin:** Spontaneous.  
**discoverer:** Rapoport.  
**references:** 1940, Dokl. Acad. Nauk SSSR 27: 1030-32.  
**phenotype:** Eye size reduced from the normal 750 to about 180 facets. Reduction more extreme in combination with *B*; some flies have no facets and are sterile. RK2.

*re*: see *rey*

**\*re-b: reduced eyes-b**

**location:** 3-45.  
**origin:** Spontaneous.  
**discoverer:** Whittinghill, 53g.  
**references:** Schacht, 1954, DIS 28: 78.  
**phenotype:** Eyes reduced in 80% of homozygotes. Expression varies independently in each eye from absence of facets to wild type. RK2.  
**other information:** Possibly allelic to *re*.

**rea: rearranged tergites****location:** 1-25.4.**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).**discoverer:** Fahmy, 1954.**references:** 1958, DIS 32: 73.**phenotype:** Tergites highly abnormal, partly missing, and have different segments united. Expression variable. Viability and fertility inversely related to tergite abnormality. RK2.**other information:** One allele induced by CB. 3025.**rec: recombination defective (R.F. Grell)****location:** 3-58 (between 57.0 and 58.2).**references:** Grell, 1978, Proc. Nat. Acad. Sci. USA 75: 3351-54.

Grell and Generoso, 1980, Chromosoma 81: 339-48.

Grell, 1984, Genetics 108: 425-33.

Grell, 1985, Aneuploidy (Dellarco, Voytek, and Hollaender, eds.). Plenum Press, New York and London, pp. 317-36.

**phenotype:** Recombination in homozygous females drastically reduced; total cross over between *y* and *f* in the *X* chromosome reduced from 56% to 2% with distal recombination being more severely affected than proximal. *X* nondisjunction increased from virtually 0 to 27%. In *rec*<sup>1</sup>/*rec*<sup>2</sup>, females show a similar reduction for ten regions between *al* and *sp*, where crossing over decreases to 9.1%, corresponding to 9% of normal. The number of progeny per homozygous female is reduced 75%; attributed to lethality of nondisjunctional products arising from distributive pairing between noncrossover heterologues. Phenotype of *rec*/+ is the same as wild-type; *rec*<sup>1</sup> and *rec*<sup>2</sup> homozygotes and hemizygotes have equivalent effects on recombination.**alleles:**

allele	origin	discoverer	synonym	comments
<i>rec</i> <sup>1</sup>	EMS	R.F. Grell & E.E. Generoso, 72k	<i>rec-1</i> <sup>6</sup>	null allele
<i>rec</i> <sup>2</sup>	EMS	R.F. Grell & E.E. Generoso, 74d	<i>rec-1</i> <sup>16</sup>	null allele
<i>rec</i> <sup>3</sup>	EMS	R.F. Grell & E.E. Generoso, 74i	<i>rec-1</i> <sup>26</sup>	temperature sensitive allele <sup>α</sup>

<sup>α</sup> See below for description.**cytology:** Placed in 88F9-89B4 based on its inclusion in *Df(3R)sbd105* = *Df(3R)88F9-89A1;89B9-10* (Lewis, 1948, DIS 22: 72-73) but not *Df(3R)sbd45* = *Df(3R)89B3-4;89B10-11* (Grell, 1984, Genetics 108: 425-43).**other information:** Not allelic to *c(3)G*, since *rec* and *c(3)G* fully complement, also unlike *c(3)G*, *rec* has no discernable effect on the synaptonemal complex.**rec<sup>3</sup>****phenotype:** At 17° recombination in *rec*<sup>3</sup>/+, *rec*<sup>3</sup>/*rec*<sup>3</sup>, and *rec*<sup>3</sup>/*Df(3R)sbd105* is elevated. At 25°, the homozygote and the heterozygote display normal values, but recombination in the hemizygote is significantly reduced. At 31°, *rec*<sup>3</sup>/+ remains normal but *rec*<sup>3</sup>/*rec*<sup>3</sup> recombination is drastically reduced. The hemizygote is sterile above 28°. In *rec*<sup>2</sup>/*rec*<sup>3</sup> females which show the most extreme temperature responses, application of the restrictive temperature at sequential days during development at 25° shows control value activity to be reduced only withtreatment on days six and seven, and more precisely during a 36-hour period beginning at the time of pro-oocyte formation between 126 and 132 hours and terminating at 162 hours. This 36-hour period coincides with the boundaries of the S period as well as those of the heat-sensitive period for enhancing recombination in the normal genotype [Grell and Day, 1974, Mechanisms in Recombination (R. F. Grell, ed.). Plenum Press, New York and London, pp. 327-49]. Activity of the *rec* gene product in the range of 17° to 31° shows a sharp decline between 28° and 31° typical of a protein denaturation curve. If denaturation of a *rec* protein by the restrictive temperature marks its active phase, then recombination must terminate at the end of S, when the restrictive temperature becomes ineffective. Electron microscopy of serially sectioned oocyte nuclei from *rec*<sup>2</sup>/*rec*<sup>3</sup> females maintained at the restrictive or at the permissive temperature reveals synaptonemal complexes indistinguishable in length and fine structure, implicating recombination and not synapsis as the target of the *rec* gene product.**Receptor:** see *Rsp***receptor degeneration:** see *rdg***recombination defective:** see *rec***Recovery Disrupter:** see *RD***red: red Malpighian tubules****location:** 3-53.6.**origin:** Spontaneous.**discoverer:** Muller, 49a.**synonym:** *bw-l*: brown-like.**references:** Oster, 1954, DIS 28: 77-78.

Aslaksen and Hadorn, 1957, Arch. Julius Klaus-Stift. Vererbungsforsch. Sozialanthropol. Rassenhyg. 32: 464-69.

**phenotype:** Malpighian tubes of larva and adult rusty red. Eye color brown, darkening with age. *kar*<sup>2</sup>, *red* flies have orange eyes (Henikoff, 1979, Genetics 93: 105-15); *cn*; *red* colorless (Paton and Sullivan, 1975, Genetics 80: s63). Malpighian tubes of *v*; *red* and *cn*; *red* are colorless and tubes of *bw*; *red* are red; therefore, pigment an ommochrome. Eyes contain less drosoperin and isoxanthopterin and more of the other pteridines than normal. Eye color autonomous in *red* eye disks transplanted into wild-type host. Wild-type Malpighian tubes acquire some red pigment after transplantation into *red* hosts. RK1.**cytology:** Placed in 88B1-3 based on its inclusion in *Df(3R)red21* = *Df(3R)88B1-2;88B2-3* (Spillman and Nöthiger, 1978, DIS 53: 163).**red blood cells:** see *rc***red cells:** see *rc***red Malpighian tubules:** see *red***red wine:** see *rwi***reddish brown:** see *rdb***reduced:** see *rd***reduced bristle:** see *rbl***reduced eye:** see *rde*

**ref: refractaire**

Mutants at several loci that interfere with the normal multiplication of some strains of sigma virus, as indicated by delayed acquisition of CO<sub>2</sub> sensitivity following viral injection. They are designated *ref* followed by parenthetical indication of the chromosome on which they reside and then a locus designating letter; the permissive or normal allele is designated by superscript *o* indicating standard allele from Oregon-R; restrictive alleles are superscripted with a letter indicating origin: *b* = Belinga; *e* = ebony stocks; *h* = Hikone; *m* = Moiré stock; *n* = Nagasaki; *p* = Paris. Except for the case of *ref(3)O*, in which the restrictive allele is dominant, permissive and restrictive alleles are codominant.

<sup>β</sup> Mechanism inferred to be affected.

**ref:** see *rfr*

**ref(2)P**

synonym: *ref*.

**phenotype:** *ref(2)P<sup>p</sup>* is the first refractaire mutant found and the most thoroughly studied. Allele frequency about 0.2 in Paris population and approaches the same incidence in caged populations with or without the presence of sigma virus (Fleuriet, 1980, Genetics 95: 459-65; 1981, Genetics 97: 415-25). Refractaire phenotype expressed in cultured cells (Richard-Molard, 1975, Arch. Virol. 47: 139-46) and in imaginal disks transplanted into stably infected hosts (Bernard, 1968, Exp. Cell Res. 50: 117-26). Inhibition of viral multiplication increases with increased doses of *ref(2)P<sup>p</sup>*, with added doses of *ref(2)P<sup>o</sup>* having an antagonistic effect (Nakamura, 1978, Mol. Gen. Genet. 159: 285-92). Strains of sigma virus

capable of multiplication in restrictive strains can be selected; *P<sup>+</sup>* virus strains multiply in *ref(2)P<sup>p</sup>* hosts, whereas *P<sup>-</sup>* strains do not; no such distinction in *ref(2)P<sup>o</sup>* hosts. Also 5-FU-induced host-adapted strains of virus (haP) capable of replication in *ref(2)P<sup>p</sup>*; many are temperature sensitive, suggesting that *ref(2)P<sup>p</sup>* interacts with a viral protein (Coulon and Contamine, 1982, Virology 123: 381-92). Males homozygous for null alleles sterile; elongating spermatids display degeneration of axonemes (Dezelee, Bras, Contamine, Lopez-Ferber, Segretain, and Teninges, 1989, EMBO J. 8: 3437-46).

**alleles:** In addition to naturally occurring *ref(2)P<sup>p</sup>* and *ref(s)P<sup>o</sup>*, X-ray-induced (Nakamura) and three hybrid-dysgenesis-induced null alleles, *ref(2)P<sup>hd1</sup>*, *ref(2)P<sup>hd2</sup>*, and *ref(2)P<sup>hd3</sup>* (Contamine, Petitjean, and Ashburner, 1989, Genetics 123: 525-33).

**cytology:** Placed in 37E2-F4 based on its being localized between *Df(2L)TW158 = Df(2L)37B2-8;37E2-F4* and *Df(2L)TW12 = Df(2L)37E2-F4;39D1-2*.

**molecular biology:** *ref(2)P* cloned (Contamine, Petitjean and Ashburner, 1989, Genetics 123: 525-33). Genomic DNA isolated by transposon tagging; sequencing indicates a structural gene with three exons and conceptual amino-acid sequence of 599 residues containing internal PEST repeats and interesting structural motifs, such as zinc fingers and amphiphilic helices; no homology with known proteins (Dezelee, Bras, Contamine, Lopez-Ferber, Segretain, and Teninges, 1989, EMBO J. 8: 3437-46).

**refrangent:** see *rfr*

**regulator of αglycerol phosphate dehydrogenase:** see *r(αGPDH)*

**Regulator of bithorax:** see *trx*

**Regulator of post bithorax:** see *hb*

**rem:** see *mbmB*

**rem: remnants (T. Schüpbach)**

location: 2-32.

origin: Induced by ethyl methanesulfonate.

references: Schupbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal effect lethal; eggs laid by females homozygous for *rem<sup>1</sup>* show no visible sign of development when observed under transmitted light in stereomicroscope; eggs derived from *rem<sup>2</sup>* often allow embryonic development; those embryos form fragmented cuticle with variable holes and head defects.

**alleles:** *rem<sup>1</sup>* and *rem<sup>2</sup>* recovered as A and HG.

**cytology:** Located in 30A-C since included in *Df(2L)30A;C*.

**Resistance ( ): see Rst( )**

**Responder: see Rsp**

**ret: reticent (T. Schüpbach)**

location: 2-62.

origin: Induced by ethyl methanesulfonate.

references: Schupbach and Wieschaus.

**phenotype:** Maternal effect lethal; embryos from homozygous mothers develop into larvae with no visible cuticular abnormalities, but do not hatch out of the egg case.

alleles:  $ret^{PK} = ret^1$ .

**\*ret: reticulated**

location: 1- (rearrangement).

origin: Induced by L-p-N,N-(2-chloroethyl)aminophenylalanine (CB. 3025).

discoverer: Fahmy, 1953.

references: 1958, DIS 32: 73.

phenotype: Wing veins increased to anastomosing reticulated areas. Wings shortened, deformed, and blistered. Eyes large and rough. Postvertical bristles usually absent. Male sterile; viability about 20% wild type. RK2A.

cytology: Associated with  $T(1;2)ret = T(1;2)20A5-B2;2R$ .

**reticent:** see *ret*

**reticulated:** see *\*ret*

**retina aberrant in pattern:** see *rap*

**retinal degeneration:** see *rdg*

**retroactive:** see *rtv*

**Rev: Revolute**

location: 2- (rearrangement).

origin: X ray induced.

discoverer: Dobzhansky, 31b5.

phenotype: Wings of heterozygote spread at 45° from midline; edges curled, giving spoon shape. Sense organs along veins enlarged. Eyes mottled in *Rev/lt*. Homozygote viable and fertile, somewhat more abnormal than heterozygote. Phenotype suppressed by extra Y's, probably a variegated position effect. RK2A.

cytology: Associated with  $In(2LR)Rev = In(2LR)40F;52D10-E1$  [Bridges and Li, in Morgan, Bridges, and Schultz (1936, Year Book – Carnegie Inst. Washington 35: 293)].

**Rev<sup>B</sup>: Revolute of Bridges**

origin: Spontaneous as a single homozygous female in a culture with no heterozygote.

discoverer: Bridges, 36e22.

synonym: *Rvd: Revolutoid*.

references: Morgan, Bridges, and Schultz, 1936, Year Book – Carnegie Inst. Washington 35: 293.

phenotype: Wings spread and curved. A variegated position effect based on enhanced phenotype by rearing at low temperature and Y suppressibility (Wargent, 1972, DIS 49: 50-51). Expression suppressed by  $In(1)m^K$ , and variegation of  $m^K$  enhanced by  $In(2LR)Rev^B$  (Wargent and Hartmann-Goldstein, 1974, Heredity 33: 317-26); incidence of chromosomes heterochromatinized in vicinity of breakpoints shows parallel interactions (Hartmann-Goldstein and Wargent, 1975, Chromosoma 52: 349-62). Homozygous lethal;  $Rev/Rev^B$  viable (E. B. Lewis). RK2A.

cytology: Associated with  $In(2LR)Rev^B = In(2LR)40F;52D5$  (Wargent).

**Revolute:** see *Rev*

**Revolutoid:** see *Rev<sup>B</sup>*

**rex: rapid exhaustion (J.C. Hall)**

location: 1-17.0.

origin: Induced by ethyl methanesulfonate.

references: Grigliatti, Hall, Rosenbluth and Suzuki, 1973,

Mol. Gen. Genet. 120: 107-14.

Homyk, Sinclair and Suzuki, 1979, Genetics 91: s49-50.

phenotype: Adults briefly paralyzed after movement, especially when they are induced to move rapidly; recovery occurs within one min, followed by uncoordinated movements and a period refractory to induction of further paralysis of at least one hr (Grigliatti *et al.*, 1973); *rex* is temperature sensitive for lethality, *i.e.*, as induced by holding adults about ten days at 29° (Homyk *et al.*, 1979); also there are semi-lethal effects on development [*i.e.*, *ca.* 50% viability after rearing at 29° (Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89)]. *rex* also hypersensitive to killing effects of caffeine (Homyk *et al.*, 1979). Causes an abnormally slow recovery from blue-light induction of prolonged depolarizing afterpotential (PDA) of photoreceptors; recovery induced rapidly by orange light (Homyk and Pye). Mosaic analysis of leg paralysis induced by *rex* suggests mesodermal (possibly muscle) foci, separate focus for each leg (Homyk *et al.*, 1986).

cytology: Placed in 7C1-4 based on its inclusion in  $Df(1)ct4b1 = Df(1)7B2-4;7C3-4$  but not in  $Df(1)ct268-42 = Df(1)7A5-6;7B8-C1$  or  $Df(1)ct-J4 = Df(1)7A2-3;7C1$  (Homyk).

alleles: One mutant allele, sometimes called *rex<sup>ts</sup>* (Homyk *et al.*, 1979).

**Rex: Ribosomal exchange (L. Robbins)**

location: 1-66 [proximal to *su(f)* (Rasooly)].

origin: Spontaneous? Discovered in  $Df(1)w^{rJ1}$  bearing chromosome.

references: Robbins, 1981, Genetics 99: 443-59.

Swanson, 1984, Ph.D. dissertation, Michigan State University.

Swanson, 1987, Genetics 115: 271-76.

phenotype: Semi-dominant, maternal-effect locus which causes an early mitotic exchange between blocks of rDNA in 1 to 10% of the offspring of *Rex*-bearing females. *Rex* affects chromosomes with two separated, complete or partial ribosomal-DNA regions, such as *YSX.YL* or  $In(1)sc^{SILsc^{4R}}$ . Chromosomes having separated blocks of heterochromatin that do not both include ribosomal genes, such as  $In(1)w^{m4}$ , are insensitive. Affected chromosomes may pair in either spiral or hairpin configurations; the former results in loss of the intervening material (*e.g.*,  $Ybb^{Rex}$ ,  $Dp(1;f)sc^{SILsc^{4R}}$ ,  $Dp(1;f)w^{m51bl_w^{m4R}}$ , the latter in the inversion of that material ( $Dp(1;1)sc^{SILsc^{4R}}$ ,  $Dp(1;1)w^{m51bl_w^{m4R}}$ ) (Robbins and Swanson, 1988, Genetics 120: 1053-59). Exchanges usually occur early enough to yield whole-body recombinant genotypes, but a minority of events yield half-half mosaics. The exchange event generally results in partial deletion of rDNA (Robbins).

**\*rey: rough eye**

location: 1-0.6 (from combined measurements on *rey*,  $rey^2$ , and  $rey^3$ ).

phenotype: Eyes extremely small and rough in male, less extreme in female. Areas of thorax often underdeveloped, sometimes hemithoracic. ( $rey^2$ ). Homozygous female viable and infertile ( $rey^3$ ).

alleles: Complementation tests not performed; allelism

inferred from similarity of phenotype and map position.

**cytology:** Outside of region 1E1-2B9 based on complementation of *rey<sup>3</sup>* by both *Df(1)sta = Df(1)ID3-E1;2A* and *Df(1)RA19 = Df(1)IE3-4;2B9-10* (Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, DIS 58: 184-90).

**other information:** Not recognized as such in recent studies of polytene region 2 by Lefevre or by Perrimon.

**\*rf: roof wings**

**location:** 2-81.

**discoverer:** Bridges, 1921.

**references:** Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 233.

**phenotype:** Wings rotated on long axis so that inner margins are raised and costal margins lowered. Overlaps wild type. RK3.

**rf<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** Redfield, 1926.

**references:** Franke, 1933, Ph.D. Thesis, Univ. Berlin.

**phenotype:** Like *rf*. RK3.

**Rf: Roof**

**location:** 3-59.

**origin:** Spontaneous.

**discoverer:** Waddington, 38a.

**references:** 1939, DIS 12: 48-49.

**phenotype:** Wing position normal at eclosion, becomes rooflike in 12-hr imagos. RK1.

**cytology:** Tentatively placed in 89C-90E based on the observation that a third chromosome deficiency combining the left portion of *T(Y;3)L142 = T(Y;3)89C* and the right portion of *T(Y;3)B116 = T(Y;3)90E* has a *Rf*-like phenotype (Rendel, 1977, DIS 52: 86).

**\*Rf-c: Roof-c**

**location:** 3- (to the left of *se*).

**discoverer:** Bridges, 20a1.

**references:** Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 228 (fig.).

**phenotype:** Wings slanted at roof-like angle. RK3.

*rfd*: see *sas*

**rfr: refringent**

**location:** 1- 67.9[to the left of *ot* at 1-65.7, since it is not covered by *y<sup>+</sup>Ymal106* which does cover *ot* (Schalet, 1972, DIS 49: 36)].

**origin:** Induced by D-*p*-N,N-di-(2-chloroethyl)aminophenyl-alanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**synonym:** *ref* (preoccupied).

**references:** 1959, DIS 33: 89.

**phenotype:** Wing surface yellowish and iridescent; occasionally, one or both wings held out; inner margins may

be incised. Expression more extreme in male than in female. Male viable and fertile; female has reduced viability and is sterile. RK2.

**alleles:** One allele each induced by CB.3026 and CB. 3034.

**rg: rugose**

**location:** 1-11.0.

**references:** Renfranz and Benzer, 1989, *Dev. Biol.* 136: 411-29.

**phenotype:** Eyes variably rough depending on strength of allele; stronger alleles display reduced viability. Additional traits include wings thin, curled upward (*rg<sup>P</sup>*), margins somewhat frayed (*rg<sup>I</sup>*); eclosion delayed (*rg<sup>7</sup>*); body pale (*rg<sup>P</sup>*).

**\*rgt: reduced pigment**

**location:** 1-11.5.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)aminophenylalanine (CB. 3025).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 89.

**phenotype:** Characteristic pigmentation of fifth tergite reduced or absent in male. Body color yellowish. Eyes bright red. Male sterile. RK2.

**rh: roughish**

**location:** 2- 54.7[on 2R based on its recovery in newly generated C(2R) chromosomes and placed distal to *ap* (2-55.2) on the basis of its being complemented by *Df(2R)M41A4* (Hilliker, Gibson, Yeomans, and Holm, 1977, DIS 52: 32)].

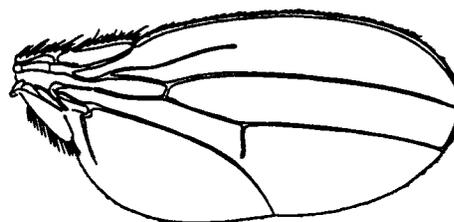

**origin:** Spontaneous.

**discoverer:** Bridges, 21a3.

**phenotype:** Eyes moderately rough. At 19°, bristles slightly wavy and wings broad. RK2.

*rh*: see *gl<sup>3</sup>*

*Rh1*: see *ninaE*

**Rh2: Rhodopsin 2****location:** 3- {65}.**references:** Cowman, Zuker, and Rubin, 1986, Cell 44: 705-10.**phenotype:** Encodes the opsin moiety of the rhodopsin specific to the ocelli. Not expressed in the eye nor is it expressed in Bolwig's organ, the larval photoreceptor [Pollock and Benzer, 1988, Nature (London) 333: 779-82)]. *Rh2* under the control of the *ninaE* promoter in a *ninaE* background functions in R1-6 cells (Zuker, Mismar, Hardy, and Rubin, 1988, Cell 55: 475-82) but with different spectral characteristics and physiology (Feiler, Harris, Kirschfield, Wehrkan, and Zuker, 1988, Nature (London) 333: 737-41). RH2 is a 381-amino-acid protein that is 67% homologous to the opsin found in R1-6 encoded by *ninaE*, but only 35% homologous to RH3 and RH4.**cytology:** Located in 91D1-2 by *in situ* hybridization.**molecular biology:** Genomic clone isolated by cross homology with a clone containing the *ninaE* gene. Sequence analysis indicates the presence of three introns, the position of the second of which is shared with that of the fourth intron of *ninaE*; positions of the other introns are not conserved. The conceptual amino-acid sequence reveals many features that characterize opsins: seven hydrophobic domains separated by hydrophilic sequences, a putative retinal-binding site in the seventh transmembrane domain, a glycosylation site in the extra cytoplasmic face, and a series of potential phosphorylation sites in the C-terminal region. Head specific transcription depends on elements between -183 and -112 (Mismar, Michael, Laverty, and Rubin, 1988, Genetics 120: 173-80); contains an eleven-base-pair sequence common to *ninaC* and *ninaE* (Mismar *et al.*).**Rh3****location:** 3- {70}.**references:** Zuker, Montell, Jones, Laverty, and Rubin, 1987, J. Neurosci. 7: 1550-57.**phenotype:** Encodes the opsin moiety of a rhodopsin specific to the rhabdomere of the seventh photoreceptor cell. Also expressed in Bolwig's organ [Pollock and Benzer, 1988, Nature (London) 333: 779-82)]. Transcript first appears during the last 48 hr of the pupal stage and is found in newly eclosed adult heads. RH3 is a 383 amino acid protein that is 35% homologous to the opsins found in R1-6 encoded by *ninaE* and in ocelli encoded by *Rh2* but 72% homologous to the *Rh4*-encoded protein.**cytology:** Located in 92D1 by *in situ* hybridization.**molecular biology:** Genomic clone isolated by hybridization to oligonucleotide probes containing sequences highly conserved between *ninaE* and *Rh2*. The gene contains no introns. The conceptual amino-acid sequence reveals features characteristic of opsin molecules (see *Rh2*).**Rh4****location:** 3- {45}.**references:** Montell, Jones, Zuker, and Rubin, 1987, J. Neurosci. 7: 1558-66.**phenotype:** Encodes the opsin moiety of a rhodopsin specific to the rhabdomere of the seventh photoreceptor cell; *Rh3* and *Rh4* are expressed in nonoverlapping subsets of ommatidia; the distribution of the two types of R7 cells within the eye is irregular. Transcript first appearsduring the last 48 hr of the pupal stage and is found in newly eclosed adult heads. Also expressed in Bolwig's organ [Pollock and Benzer, 1988, Nature (London) 333: 779-82)]. RH4 is a 378 amino acid protein that is 35% homologous to the opsins found in R1-6 encoded by *ninaE* and in the ocelli, encoded by *Rh2*, but 72% homologous to the *Rh3*-encoded protein.**cytology:** Located in 73D3-5 by *in situ* hybridization.**molecular biology:** Genomic clone isolated by hybridization to the *Rh3* gene. Sequence analysis reveals the presence of a single 9.0 kb intron, which subdivides the gene into exons of 676 and 719 nucleotides. The conceptual amino-acid sequence reveals features characteristic of opsin molecules (see *Rh2*).*RH11*: see *eas**rho*: see *ve**Rho*: see *Lcp10***Rhodopsin:** see *Rh**rhomboid*: see *ve***ri: radius incompletus**

From Edith M. Wallace, unpublished.

**ri: radius incompletus****location:** 3-46.8. (Arajarvi and Hannah-Alava, 1969, DIS 44: 73).**phenotype:** Vein L2 interrupted. Wings slightly warped and blunt. Acts during contraction period in *D. simulans*, inhibiting fusion of small spaces into a vein (Waddington, 1940, J. Genet. 41: 75-139). RK1.**alleles:**

**rk:** *ricketts* (*M. Ashburner*)

**location:** 2-48.8 (immediately to the right of *j*).

**phenotype:** Strong alleles have legs, especially metathoracic ones, flattened and bent. Femora and tibiae bowed in middle; first two tarsal joints shortened, bent, and flattened; last three tarsal joints almost fused. Wings unexpanded, resembling those of *pu*. Posterior scutellar bristles erect and crossed. Viability may be reduced. Weak alleles do not show the leg phenotype, or they overlap wild type; may have partially expanded wings and normal posterior scutellar bristles. Even strong alleles more extreme when hemizygous with *rk* deficiencies.

<sup>β</sup> Additional description below.

**cytology:** Placed in 31E1-5 based on its inclusion in *Df(2L)b-L = Df(2L)34D3;34E3-5* and *Df(2L)el82fl = Df(2L)34E1-2;35C3-5*, but not *Df(2L)b82a2 = Df(2L)34D1-2;34E1-2*.

**rk**<sup>4</sup>

**phenotype:** Wings unexpanded, spread, and drooping. Posterior legs malformed. Both sexes fully viable and fertile. *rk*<sup>4</sup> male mates with wild-type female only if wings removed from female. Viability 60% of wild type.

**rk**<sup>5</sup>

**phenotype:** Wings sometimes fully expanded and held out.

**rk**<sup>6</sup>

**phenotype:** Legs weak, wings unexpanded. Viability higher at higher temperature.

**rk**<sup>cyl</sup>

**phenotype:** Abdomen cylindrical; terminal segments thickened; halteres small and melanotic; legs like those of *bal*, but less deformed. Viability low but fertility good.

**rl:** *rolled*

**location:** 2-55.1 [between centromere and *stw* (Sturtevant); 0.03 unit to the left of *stw* (Tano, 1966, J. J. Genet. 41: 299-308)].

**phenotype:** Most alleles lethal. The viable allele, *rl*<sup>1</sup>, has wing edges rolled downward; margins somewhat frayed; L4 interrupted distal to posterior crossvein. Eyes small, dark, and rough. Most extreme at 26°, less extreme above and below that temperature (Lakovaara, 1963, Proc. Intern. Congr. Genet., 11th., Vol. 1: 175). Temperature sensitive period for eye phenotype during larval stages with most sensitive stage about 60 hr after hatching, *i.e.*, at the beginning of the third-instar (Hackman and Lakovaara, 1966, DIS 41: 92). Effects of dosage of *rl* and *rl*<sup>+</sup> on eye pigment deposition investigated by Lakovaara (1966, Hereditas 56: 1-19). *rl*<sup>1</sup> lethal in combination with all lethal alleles except *rl*<sup>6</sup>, with which it is fully viable and exhibits a *rl* phenotype. Hemizygotes for lethal alleles, except for *rl*<sup>6</sup>, die as third-instar larvae completely devoid of imaginal disks; when heterozygous for *rl*<sup>1</sup> or *rl*<sup>6</sup>, the lethal alleles lead to pupal lethality (Hilliker, 1976, Genetics 83: 765-82).

**cytology:** Placed in 41A on the basis of its inclusion in *Df(2R)M41A10 = Df(2R)41A* (Morgan, Schultz, and Curry, 1941, Year Book - Carnegie Inst. Washington 40: 284). Further restricted to the middle of the proximal heterochromatin on the basis of its inclusion in *Df(2R)A* but not *Df(2R)B* (Hilliker, 1976, Genetics 93: 765-82).

**\*rlu: rolled up**

**location:** 1- (rearrangement).  
**origin:** Spontaneous in *In(1)sc<sup>S1</sup>+dl-49*.  
**discoverer:** Reddi.  
**references:** 1963, DIS 37: 53.  
**phenotype:** Wings rolled. Good viability and fertility. RK2A.

**rm: rimy**

**location:** 1-48.1.  
**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**discoverer:** Fahmy, 1956.  
**references:** 1958, DIS 32: 74.  
**phenotype:** Eyes often dull brownish red with conspicuous white hairs between ommatidia. Wings longitudinally pleated. Viability and fertility good. RK2.  
**other information:** One allele each induced by CB. 1540 and CB. 1592.

*rm*: see *rmp*

**Rm: Ring magnifier**

**location:** Autosomal; not mapped.  
**origin:** Spontaneous.  
**references:** Endow, Komma, and Atwood, 1984, Genetics 108: 969-83.  
**phenotype:** Existence of such a mutant inferred from the behavior of ring chromosomes in magnifying genotypes in different autosomal backgrounds. In the absence of *Rm*, magnifying conditions cause the meiotic loss of *bb*-bearing ring chromosomes from *R(1)*, *bb/Ybb<sup>-</sup>* males, as detected by both a shift in the sex ratio among the progeny and the production of offspring with no paternally inherited sex chromosome; some *bb<sup>r</sup>* (bobbed-reduced) offspring are observed, but there are no *bb<sup>m</sup>* (bobbed magnified) offspring. In the presence of *Rm*, the incidence of ring-chromosome loss is elevated and *bb<sup>m</sup>* offspring occur. Postulated that sister-chromatid exchange outside of the ribosomal cistrons correlated with magnifying sister-chromatid exchanges within the ribosomal cistrons may occur in the presence of *Rm* but not *Rm<sup>+</sup>*.

**Rm2: Ring magnifier on chromosome 2**

**location:** 2-48.  
**origin:** Spontaneous.  
**discoverer:** Komma and Atwood.  
**references:** Endow, Komma, and Atwood, 1984, Genetics 108: 969-83.  
**phenotype:** Dominant mutant that permits recovery of magnified *bb* alleles in ring chromosomes. Also increases incidence of dicentric rings as seen in the primary spermatocyte division. Postulated to engender sister chromatid exchanges outside the ribosomal DNA.

**Rm4**

**location:** 4-.  
**origin:** Spontaneous.  
**discoverer:** Komma.  
**phenotype:** Similar to that of *Rm2*.

**\*rmp: rumped**

**location:** 1-14.4.  
**origin:** Induced by *L-p-N,N-di-(2-chloroethyl)amino-phenylalanine* (CB. 3025).

**discoverer:** Fahmy, 1955.  
**synonym:** *rm* (preoccupied).  
**references:** 1959, DIS 33: 89.  
**phenotype:** Wings variably unexpanded. Bristles deranged; postverticals frequently crossed. Derangement of bristles correlated with degree of wing abnormality. Viability and fertility good in both sexes. RK2.

**rn: rotund (S. Kerridge)**

**location:** 3-47.6 [from location of *rn<sup>3</sup>* (Puro and Nygrén, 1975, Hereditas 81: 237-48); distal to *roe* (Agnel *et al.*)].  
**references:** Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.  
 Kerridge and Thomas-Cavallin, 1988, Roux's Arch. Dev. Biol. 197: 19-26.  
 Agnel, Kerridge, Vola, and Griffin-Shea, 1989, Genes Dev. 3: 85-95.

**phenotype:** All alleles are viable as homozygotes. Both males and females are sterile; sterility is not germ line dependent. Two transcripts from the rotund region of *Drosophila* show similar positional specificities in imaginal disc tissues. Adult defects are restricted to homologous distal parts of the appendages, *i.e.*, the antennae, legs, wings, halteres, and proboscis. In the antenna the basal capsule is missing and the third antennal segment is reduced in size; all other antennal and eye disc derivatives are normal. In all three pairs of legs abnormalities caused by the lack of *rn<sup>+</sup>* product are localized specifically in the tarsus; instead of five individual tarsal segments, a single tarsus-like segment differentiates. The distal claw and proximal leg articulations (tibia, femur, trochanter, and coxa) are unaffected. Incomplete and duplicated joints seen at the presumptive positions of the tarsus 1-2 and 4-5 joints; intermediate joints virtually absent (Held, Duarte, and Derakhshanian, 1986, Wilhelm Roux's Arch. Dev Biol. 195: 145-57). Of the wing disc derivatives, the medial and distal costa are fused and the corresponding region in the posterior wing, the alula, is smaller, making the wing as a whole appear shorter; distal wing and mesonotum are formed as in wild type. Vein L5 and to a lesser extent L2 interrupted (*rn<sup>3</sup>*). Specific and localized deficiencies of labial and haltere disc derivatives are also evident. Genital and abdominal patterns are indistinguishable from wild-type patterns; however, seminal receptacles shorter than in wild-type females. Examination of the imaginal discs from third-instar *rn* larvae shows localized cell death in regions determined from fate maps to give rise to distal appendage parts (Cavallin).

**alleles:** No interallelic complementation detectable.

<sup>α</sup> 1 = Agnel, Kerridge, Vola, and Griffin-Shea, 1989, *Genes Dev.* 3: 85-95; 2 = Carlson, 1956, *DIS* 30: 70, 109; 3 = Glass, 1934, *DIS* 2: 8; 4 = Kerridge, 1981, *Mol. Gen. Genet.* 184: 519-25; 5 = Puro and Nygrén, 1975, *Hereditas* 81: 237-48.  
<sup>β</sup> More detailed description below.

**cytology:** Placed in 84D3 on the basis of its inclusion in the region of overlap between *Df(3R)dsx10M* = *Df(3R)84D3;84F1* and *Df(3R)Scx4* = *Df(3R)84B1-2;84D3-4*. The heterozygote between the two deficiencies survives and is rotund in phenotype.

**molecular biology:** Gene localized within a 70 kb walk on the basis of the clustering of restriction-fragment-length differences associated with *rn* mutations. Mutational lesions are arrayed over a 50 kb region from -6.5 to +44 kb. 0 is defined as the distal breakpoint of *Df(3R)Scx4*, positive values extending to the right. Two transcripts identified from the region, a 5.3 kb transcript hybridizing to a genomic fragment from 23.8 to 34.4 kb which accumulates steadily from the embryonic stage until the end of pupation and a 1.7 kb transcript between coordinates 6.3 and 12.0 kb, which appears during the third larval instar and peaks during the first two days of pupation. Both sequences are transcribed from left to right. Spatial distribution of expression of the two sequences in white prepupae highly concordant. Found in the distal-forming regions of the wing, haltere, leg, and labial discs. Aepithelial cells of the wing discs thought to contribute to thoracic musculature also exhibit expression as does a narrow strip of tissue in the genital disc destined to give rise to the internal ducts.

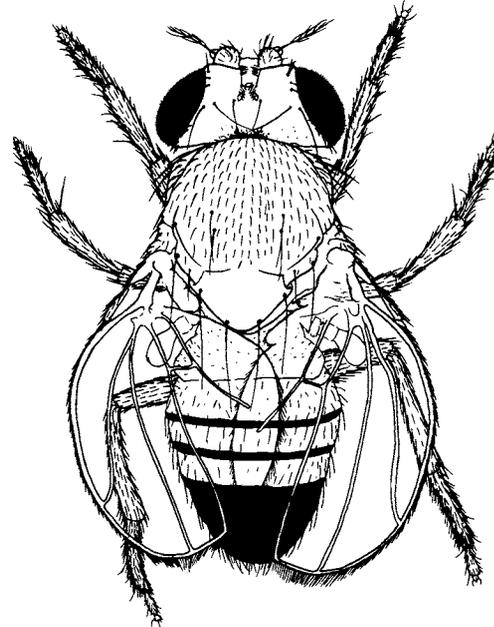

***rn*<sup>D</sup>: rotund-Dominant**

**synonym:** *Dipr*: Distal into proximal.

**phenotype:** Dominant mutation with complete penetrance and high expressivity. In *Dipr/+* flies the distal wing blade reduced to two-thirds normal length; triple row replaced by two to three rows of irregularly sized bristles resembling those found on costa; occasionally these bristles may be bracted as are those of proximal costa. Posterior row of marginal bristles absent distally. Venation in proximal portion of wing irregular and crowded but more nearly normal distally. Trichomes of wing blade organized into whorls. Capitellum of haltere covered with small adventitious bristles and sometimes pedicellar-like sensilla. Pleura, coxa, trochanter, femur, tibia, and fifth tarsal segment unaffected; other tarsal segments reduced; tarsal segments two to four variably fused; ectopic sex combs form on second tarsal segment in 70-90% of forelegs. Basal cylinder of antenna reduced or missing; replaced by bristle elements at third-segment-arista junction resembling those on third segment. Proboscis con-

tains five to seven rows of pseudotracheae rather than normal twelve; replaced by bristles laterally. Kerridge suggests transformation of distal into more proximal appendage elements. Homozygotes survive and are more extreme.

**other information:** Probably a hypermorphic allele of *rn*. X-ray-induced revertants designated *Dipr*<sup>+R1</sup>-*Dipr*<sup>+R9</sup> (lacking +R3 and +R6); the three that are visibly deleted are deficient for the more distal inversion realignment of chromosome segments.

**snRNA: small nuclear RNA**

RNA molecules ranging in size from about 100 to 300 nucleotides, which in association with polypeptides comprise a family of nuclear ribonucleoprotein (snRNP) complexes. The polypeptides are recognized by antibodies produced by patients with systemic lupus erythematosus; in *Drosophila* such sera recognize a 26 kd polypeptide, which is conserved between flies and mammals, as well as an 18 kd polypeptide (Wooley, Cone, Tartof, and Chung, 1982, *Proc. Nat. Acad. Sci. USA* 79: 6762-66). Significant sequence homology is found between *Drosophila* snRNA molecules and those isolated from mammals. Some snRNA genes have been cloned and sequenced, but as yet not localized by *in situ* hybridization; in other cases, the RNA's have been isolated and

complementary genomic sequences located by hybridization to polytene chromosomes. Where *in situ* hybridizations have been carried out, single snRNA species hybridize to a fixed number of specific sites, and with the exception of 39B no two hybridize to the same site.

<sup>α</sup> 1 = Alonso, Jorcano, Beck, and Spiess, 1983, J. Mol. Biol. 169: 691-705; 2 = Mount and Steitz, 1981, Nucl. Acids Res. 9: 6351-68; 3 = Saluz, Schmidt, Dudler, Altwegg, Stumm, Zoltinger, Kubli, and Chen, 1983, Nucl. Acids Res. 11: 77-90; 4 = Wooley, Cone, Tartof, and Chung, 1982, Proc. Nat. Acad. Sci. USA 79: 6762-66.

**other information:** Since the numerical designations applied by Saluz *et al.* are generally offset from those of the mammalian numbering system, we here reconcile the two systems by renumbering the *Drosophila* snRNA species.

### tRNA: transfer RNA

As many as 90 different tRNA sequences have been identified in the *Drosophila melanogaster* genome, each being present in from eight to twelve copies. tRNA species have been differentiated and designated according to the chromatographic mobility of their aminoacylated derivatives and without regard to their anticodon content (White, Tener, Holden, and Suzuki, 1973, Dev. Biol. 33: 185-95). The number of isoacceptor forms resolvable by column chromatography varies from two for histidine to eleven for asparagine. Several forms show evidence of post-transcriptional modification in that an earlier form ( $\delta$ ) decreases during development while a form that elutes from the column at reduced ionic strength ( $\gamma$ ) displays a concomittant increase (White, Tener, Holden, and Suzuki, 1973, J. Mol. Biol. 74: 635-51). The several copies of a particular isoform need not occur together on the chromosome, although numerous cases of clustering of copies of the same isoform as well as of different tRNA's have been recorded. In cases of clustered tRNA genes, transcription may take place in both directions. Dosage compensation has been observed for *tRNA-Ser4* (Birchler, Owenby, and Jacobson, 1982, Genetics 102: 525-37) as well as in the case of *tRNA-Val3b* in heterozygotes for *Df(3R)Antp17 = Df(3R)84A6;84D13-14* [Tener, Hayashi, Dunn, Delaney, Gillam, Grigliatti, Kaufman, and Suzuki, 1980, Transfer RNA (Abelson, Schimmel, and Söll, eds.). Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, pp. 295-

307]; however, these observations are based on specific amino acylation activity and need not reflect increased transcription from 12D-E or 84D alone. In the table below, each of the isoforms is listed and, where available, the cytological locations, as determined by *in situ* hybridization with purified samples or cloned sequences, are indicated; where localizations do not specify isoform, a numerical designation is omitted. In only a few cases has crossreaction in *in situ* hybridizations been ruled out by competition experiments. Where the numbers of copies are indicated, these are minimum estimates based on cloned segments from the regions involved; other indications of copy number are available from grain counts in autoradiograms; for example the grain-number ratio in 84D:90B-C:92D for tRNA-Val3b is 6:3:1 (or 5:4:1) and in 42A:42E:50B:62A:63B for tRNA-Lys2 is 5:3:1:1:1 (Tener *et al.*, 1980). Sequencing, where indicated, has been performed either on purified tRNA samples or on cloned DNA sequences.

Renfranz, and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** Homozygotes have rough eyes; slightly smaller and narrower than wild type. Approximately normal numbers of facets but arrangement irregular; frequently have fewer and sometimes more than eight retinula cells; some facets missing such that three ommatidial bristles juxtaposed; other facets fused (Stemm-Tegethoff and Dicke, 1974, Theoret. Appl. Genet. 44: 262-65; Ready *et al.*). Fiber pathways through lamina and into medulla in considerable disarray; optic chiasma between the two replaced by parallel fibers; laminar cartridge and medullar columns deranged, ventral epithelial nuclear row absent; medulla displaced from normal position and rotated anteriorly. Mosaic studies demonstrate that phenotype is eye autonomous; *i.e.*, the genotype of the eye dictates that of the underlying nervous elements. Expression, as determined by *in situ* hybridization found in the eye-antenna imaginal disk, especially in the region of the morphogenetic furrow, as well as in a specific area of the brain. No evidence of embryonic expression (Saint, Kalionis, Lockett, and Elizur, 1988, Nature (London) 334: 151-54). RK1.

#### alleles:

<sup>α</sup> 1 = Bridges and Morgan, 1923, Carnegie Inst. Wash. Publ. No. 327: 93 (fig.). 2 = Brosseau, 1970, DIS 45: 100; 3 = Puro, 1980, DIS 58: 205; 4 = Puro and Nygrén, 1982, Hereditas 81: 231-48; 5 = Saint, Kalionis, Lockett, and Elizur, 1988, Nature (London) 334: 151-54 (fig.); 6 = Tomlinson, Kimmel, and Rubin, 1988, Cell 55: 771-84.

<sup>β</sup> Contains a >10 kb insertion homologous to *412* in intron 1 (Tomlinson *et al.*, 1988).

<sup>γ</sup> Contains a P-element insertion in exon 3 (Tomlinson *et al.*, 1988). P-element excised in a revertant of this allele.

**cytology:** Placed in 97D1-9 based on its inclusion in *Df(3R)ro-XB3 = Df(3R)97D1-2;97D9*. Restricted to 97D5-7 by *in situ* hybridization (Tomlinson *et al.*, 1988).

**molecular biology:** Gene or part thereof isolated from a genomic library using a 33 base-pair homeobox consensus sequence as a probe. Isolated homeobox sequence shows 57 and 58% homology to those of *Antp* and *Scr* (Saint *et al.*). The complete *ro* gene was isolated by Tomlinson *et al.* (1988) by P-element transposon tagging. A mutant *ro*<sup>π13</sup> was rescued by transformation with an 8.6 kb genomic fragment carrying the gene. The *ro* locus contains three exons and two introns and the transcription unit spans about 4.3 kb. The homeobox domain is encoded in exon 2 and *opa*-like repeats are encoded in exons 1 and 3. The complete sequence of the *ro* gene was obtained, and the putative sequence of its 350-amino-acid homeobox protein determined (Tomlinson *et al.*, 1988).

*ro*-63: see *un*<sup>3</sup>

### rod: rough deal

**location:** 3-105.1 (to right of *ca*).

**origin:** Induced by hybrid dysgenesis (*rod*<sup>H4.8</sup>) or γ rays (*rod*<sup>X1-4</sup>).

**references:** Karess and Glover, 1989, J. Cell Biol. 109: 2951-61.

**phenotype:** Mutants show mitotic abnormalities in larval neuroblasts; there is a high frequency of both aneuploid cells and abnormal anaphase figures, with lagging chromatids, anaphase bridges, and stretched chromatid arms. Abnormal chromosome behavior also occurs in the second meiotic anaphase in male meiosis, although motile sperm are produced. All surviving homozygous females and 90% of surviving homozygous males are sterile and have roughened eyes, sparse abdominal bristles, and notched wings.

#### alleles:

allele	% abnormal anaphases	%homozygous viable
<i>rod</i> <sup>H4.8</sup>	20.2	25
<i>rod</i> <sup>X-1</sup>	42.5	0
<i>rod</i> <sup>X-2</sup>	20.7	27
<i>rod</i> <sup>X-3</sup>	15.0	49
<i>rod</i> <sup>X-4</sup>	13.9	73

**cytology:** Placed in 100B5-D1 based on the presence of the normal allele in *Dp(3;1)48 (=Df(3R)ca48) = Dp(3;1)100B7-8;100F* as well as in *Df(3R)ill-e = Df(3R)100A1-2;100B5-9* and *Df(3R)Kpn-A =*

*Df(3R)100D1;100E* and a synthetic deficiency for 100D-F.

### **roe: roughened eye**

**location:** 3-47.6 [proximal to *rn* (Agnel, Kerridge, Vola, and Griffin-Shea, 1989, Genes Dev. 3: 85-95)].

**references:** Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23 (fig.).

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** Produces a slight roughening of the eye owing to the irregular disposition of the facets; interommatidial bristles lost from posterior portion of the eye. Extreme expression in mutant/deficiency heterozygotes and more so in deficiency homozygotes; enhanced roughening and posterior loss of ommatidial bristles; in addition the eye is reduced in size and remaining interommatidial bristles are clumped. RK1.

**alleles:** All alleles appear to be hypomorphic in that the phenotype of mutant/deficiency is more severe than of homozygous mutants.

<i>roe</i> <sup>1</sup>	spont	Markowitz, 61g		1, 2	
<i>roe</i> <sup>2</sup>	EMS	Grigliatti		1	
<i>roe</i> <sup>3</sup>	EMS	Grigliatti	<i>roe</i> <sup>5.15</sup>	1	

<sup>α</sup> 1 = Lewis, Kaufman, Denell, and Talerico, 1980, Genetics 95: 367-81; 2 = Markowitz, 1963, DIS 38: 31.

**cytology:** Placed in 84D2 based on its inclusion in *Df(3R)D6 = Df(3R)84D2-3;84F13-16* but not *Df(3R)dsx10M = Df(3R)84D3;84F1-2*. *Df(3R)D6/Df(3R)Scx4*, which is deficient for both *roe* and *rn*, survives with an extreme *roe* phenotype.

### **Roi: Rough eye**

**location:** 2- [left arm, not separated from *ln(2L)t*].

**origin:** Spontaneous in *ln(2L)t*.

**discoverer:** Ives, 47k18.

**references:** 1952, DIS 26: 65.

1956, DIS 30: 72.

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** Eye facets of *Roi/+* irregularly rounded, sometimes enlarged; eyes sometimes bulge. *Roi/Roi* lethal; *Roi/S* viable. Acts as a partial suppressor of *B* (E. H. Grell). Viability good. RK2A.

**cytology:** Tentatively placed in 36F7-37B8 on the basis of its failure to survive in heterozygous combination with *Df(2L)TW3 = Df(2L)36F7-37A1;37B2-8* (Voelker and Langley, 1978, DIS 53: 185).

### **rol: reduced optic lobes (J.C. Hall)**

**location:** 1-52.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Heisenberg.

**references:** Wolf and Heisenberg, 1986, Nature (London) 323: 154-56.

Coombe, 1986, J. Comp. Physiol. 159: 655-65.

Heisenberg and Wolf, 1988, J. Comp. Physiol. 163: 373-88.

**phenotype:** Relatively proximal portion of optic lobes, except for lamina, reduced in volume to approximately 40-50% normal; less severe reduction than in *sol*; *rol sol* double mutant has extremely small visual system (connecting eye to central brain), whose volume is some 12% of normal (Wolf and Heisenberg, 1986) and whose lobula plate optic ganglion is absent (Heisenberg, unpublished);

a triple mutant, with *mnb* added to the two just noted, has diminished amplitudes of light-on and light-off transient spikes in electroretinogram (Coombe, 1986). Behavioral experiments reported for *rol sol* [a single mutant involving only the former exhibits only subtle defects in visual behavior (Heisenberg, unpublished)]; the double mutant is blind in terms of standard optomotor responses to rotating vertical stripes, but it can respond to the positions of landmarks by making turning maneuvers (Wolf and Heisenberg, 1986); these optic-lobe-depleted flies can make use of the magnitudes, though not the directions, of moving patterns to stabilize the panorama presented to them; they do so apparently by sampling the optomotor torque value which has the effect of putting them in optomotor balance; thus, it is concluded that the double mutant's visual orientation is an operant behavior (Wolf and Heisenberg, 1986); same conclusion arrived at in experiments testing this double mutant's visually mediated course control during tethered flight (Heisenberg and Wolf, 1988).

**allele:** One allele, *rol*<sup>1</sup>, isolated as *rol*<sup>KS221</sup>.

**\*rp: rotated penis**

**location:** 3-41.7.

**origin:** Spontaneous.

**discoverer:** Bridges, 29c15.

**references:** Morgan, Sturtevant, and Bridges, 1929, Year Book – Carnegie Inst. Washington 28: 339.

**phenotype:** As viewed from behind, external genitalia of male rotated counterclockwise from 0° to 270°, usually about 180°; overlaps wild type in 30% of flies. Eyes rough. Fly small; legs weak; tergites ridged; abdomen narrowed. Male sterile, even when genitalia not rotated. RK3.

**Rp21: Ribosomal protein 21**

**location:** 3-{47}.

**references:** Biessmann, Kuger, Schropfer, and Spindler, 1981, Chromosoma 82: 493-503.

Kay, Zhang, and Jacobs-Lorena, 1988, Mol. Gen. Genet. 213: 354-58.

**phenotype:** Cloned *Rp21* DNA encodes a ribosomal protein of 26,000 daltons (Kay *et al.*, 1988). When transformed into the *Drosophila* germ line using *P* elements, the *Rp21* gene is expressed in the transgenic flies as an increase in the level of the corresponding mRNA.

**cytology:** *Rp21* located in 3L at 80 by *in situ* hybridization of the transformed copy to the salivaries.

**molecular biology:** Gene coding for an abundant small RNA cloned by Biessman *et al.* (1981) and Kay *et al.* (1988) (see discussion under phenotype). Although mapped to the same region as *M(3)80*, the transformed *Rp21* gene did not complement this Minute (Kay *et al.*, 1988).

*Rp49*: see *M(3)99D*

**RpA1: Ribosomal protein A1**

**location:** 2-{78}.

**references:** Kay and Jacobs-Lorena, 1985, Mol. Cell. Biol. 5: 3583-92.

Qian, Zhang, Kay, and Jacobs-Lorena, 1987, Nucl. Acids Res. 15: 987-1003.

Qian, Hongo, and Jacobs-Lorena, 1988, Proc. Nat. Acad. Sci. USA 85: 9601-05.

**phenotype:** Encodes protein homologous to "A" family of eucaryotic ribosomal proteins involved in the initiation and elongation steps of protein synthesis (Qian *et al.*, 1987). mRNA of the *RpA1* gene is regulated at the level of translation; it is associated with polysomes during oogenesis and late embryonic stages (Kay and Jacobs-Lorena, 1985). An antisense *RpA1* gene (carrying a heat shock promoter), transformed into the fly genome, disrupts oogenesis and results in female sterility (Qian *et al.*, 1988).

**cytology:** Located in 53C1-6 by *in situ* hybridization to the salivaries (Socolitch). Single copy gene indicated.

**molecular biology:** Cloned DNA sequence coding for *RpA1* protein identified; complete nucleotide sequence and deduced amino acid sequence determined (Qian *et al.*, 1987). *RpA1* gene has no introns. The amino acid sequence of *RpA1* shows significant identity to the amino acid sequences of the r-proteins of rat, shrimp, and yeast;

all of these r-proteins are acidic.

**other information:** Not allelic to *M(2)53*.

**RpII140: RNA polymerase II-140 kd subunit**

**location:** 3- {54}.

**origin:** Recovered by cross hybridization with yeast gene clone.

**synonym:** *wimp*.

**references:** Faust, Renkawitz-Pohl, Falkenburg, Gasch, Bialojan, Young, and Bautz, 1986, EMBO J. 5: 741-46.

**phenotype:** The structural gene for the 140-kd subunit of RNA polymerase II [RNA nucleotidyl transferase (EC 2.7.7.6)]. The gene is highly conserved judging from shared sequence homology with the yeast 150-kd subunit gene.

**alleles:** Mutants selected by Mortin, (1990, Proc. Nat. Acad. Sci. USA 87: 4864-68) as extragenic suppressors of *RpII215<sup>K1</sup>*.

**cytology:** Placed in 88A-B by *in situ* hybridization.

**molecular biology:** Clone isolated from a genomic library using as a probe the gene for the yeast 150-kd subunit of RNA polymerase II. Antibodies raised to a fusion protein made in an expression vector react with *Drosophila* RNA polymerase II, and the fusion protein has spots in common with RNA polymerase II in peptide maps. Polyadenylated RNA of 3.9 kb transcribed by gene; very little space for untranslated sequences. High degree of homology in conceptual amino-acid sequence between yeast and *Drosophila* subunits.

**RpII215: RNA polymerase II-215 kd subunit**

**location:** 1-35.66 [based on 320 recombinants between *v* and *m* (Greenleaf *et al.*, 1980)].

**synonym:** *l(1)L5*.

**references:** Greenleaf, Borsett, Jiamachello, and Coulter, 1979, Cell 18: 13-22.

Greenleaf, Weeks, Voelker, Ohmishi, and Dickson, 1980, Cell 21: 785-92.

Greenleaf, 1983, J. Biol. Chem. 258: 13403-06.

**phenotype:** The structural gene encoding the 215 kd subunit of RNA polymerase II [RNA nucleotidyl transferase (EC 2.7.7.6)]. This subunit highly conserved as inferred from the cross reaction of antiserum from the large subunit of calf RNA polymerase II with enzyme isolated from *Drosophila* as well as that from yeast and wheat germ (Carrol and Stollar, 1983, J. Mol. Biol. 170: 777-90); also amino-acid sequence homology detected with the β' subunit of *E. coli* RNA polymerase (Biggs, Searles, and Greenleaf, 1985, Cell 42: 611-21). Dosage compensated at the level of transcription (Faust, Penkawitz-Pohl, Falkenberg, Gasch, Biabjah, Young, and Bautz, 1986, EMBO J. 5: 741-46).

**alleles:** Most alleles are recessive lethals; however several viable alleles and others with dominant phenotypes are described at the end of this entry. These alleles all enhance expression of *Ubx* in *RpII215/+* heterozygotes with the effect of + (no effect) < *RpII215<sup>H1</sup>* < *RpII215<sup>7</sup>* < *RpII215<sup>K2</sup>* < *RpII215<sup>4</sup>* < *RpII215<sup>Ubl</sup>*. Heteroallelic combinations of these mutants produce either a reduced effect when *RpII215<sup>Ubl</sup>* is involved or no effect in other combinations.

Gen. Genet. 201: 437-45.

<sup>γ</sup> Haplosppecific lethals survive, at least with a low frequency, as homozygotes, but are lethal as hemizygotes.

<sup>δ</sup> Lethal derivatives of *RpII215*<sup>4</sup> that retain alpha-amanitin resistance.

<sup>ε</sup> Derivatives of *RpII215*<sup>4</sup> chosen for reduced resistance to alpha amanitin.

<sup>ζ</sup> P-element insertion in 10B-C.

**cytology:** Placed in 10C2-5 based on its being in the region of overlap between *Df(1)m259 = Df(1)10C2-3;10E1-2* and *Df(1)vN48 = Df(1)9F;10C3-5* (Voelker, Wisely, Huang, and Gyurkovic, 1985, Mol. Gen. Genet. 201: 437-45).

**molecular biology:** Region cloned and restriction mapped (Searles, Jockerst, Bingham, Voelker, and Greenleaf, 1982, Cell 31: 585-92) and a 7 kb transcript identified as that encoding *RpII215* polypeptide (Ingles, Biggs, Wong, Weeks, and Greenleaf, 1983, Proc. Nat. Acad. Sci. USA 80: 3396-3400); four exons separated by three relatively small introns; 5' exon of 500 bp followed by 600 bp intron; the next three introns larger (2.3, 2.1, and 1.8 kb)

separated by introns of 100 and 50 bp. 0 coordinate of walk is *SstI* site within the small 5' exon of *RpII215*; polarity with respect to chromosome not determined. *RpII215* transcript extends from 0.2 at the 5' end to -7.2; first large exon sequenced (Biggs, Searles, and Greenleaf, 1985, Cell 42: 611-21).

### *RpII215*<sup>4</sup>

**synonym:** *RpII215*<sup>C4</sup>.

**references:** Greenleaf, Borsett, Jiamachello, and Coulter, 1979, Cell 18: 13-22.

Greenleaf, Weeks, Voelker, Ohnishi, and Dickson, 1980, Cell 21: 785-92.

Mortin, Kim, and Huang, 1988, Genetics 119: 863-73.

**phenotype:** This allele was selected as an amanitin resistant mutation; *RplI215*<sup>4/+</sup> females produce equal amounts of amanitin-sensitive and -resistant enzyme and are themselves amanitin resistant. Generally a viable allele, but survival in combination with *RplI215*<sup>63</sup> and *RplI215*<sup>86</sup> reduced, and with *RplI215*<sup>51</sup> and *RplI215*<sup>78</sup> survival is zero. RNA polymerase isolated from embryos homozygous for this allele is 250 times less sensitive to inhibition by alpha amanitin than that from wild type; resistance attributable to reduced amanitin binding; otherwise RNA polymerase normal in all respects except that there is some reduction in activity in the presence of Mg<sup>2+</sup>; stable to thermal denaturation (Coulter and Greenleaf, 1982, J. Biol. Chem. 157: 1945-52). Flies carrying both *RplI215*<sup>4</sup> and *RplI215*<sup>+</sup> display an Ultrabithorax-like phenotype, with enlarged halteres, and an enhancing effect on expression of *Ubx* [Greenleaf *et al.*, 1980; Voelker, Wisely, Huang, and Gyurkovics, 1985, Mol. Gen. Genet. 201: 437-45 (fig.)]. Measurements of haltere size in *TM6/+* females of various constitutions produced the following: *4/+/+* > *4/+* > *4/4/+* > *4/4* = *4/0* = *+/+*. The haltere effect of *RplI215*<sup>4</sup> is abolished in heteroallelic combination with *RplI215*<sup>7</sup>, *RplI215*<sup>H1</sup>, and *RplI215*<sup>K2</sup>. *RplI215*<sup>4</sup> decreases the *Ubx* effect of *RplI215*<sup>Ubl</sup>. Heterozygotes also exhibit increased numbers of duplicated bristles in *Dll/+* (Mortin *et al.*). Males carrying *RplI215*<sup>4</sup> on their X plus a normal allele on *Dp(1;Y)B*<sup>S<sup>-</sup>v<sup>+</sup>y<sup>+</sup></sup> are nearly sterile, and those carrying the normal allele instead on *Dp(1;2)v*<sup>65b</sup> are sterile (Voelker *et al.*).

***RplI215*<sup>7</sup>**

**synonym:** *RplI215*<sup>C11-138</sup>, *Ubl*<sup>C11</sup>.

**references:** Voelker, Wisely, Huang, and Gyurkovics, 1985, Mol. Gen. Genet. 201: 437-45.

Mortin, Kim, and Huang, 1988, Genetics 119: 863-73.

**phenotype:** Cold-sensitive lethal; survives at 28° with nearly wild-type viability, but is lethal at lower temperatures. Surviving males are fertile, whereas homozygous females are sterile. Displays slight increase in haltere size in *RplI215*<sup>7/+</sup>; *Ubx/+* females. Lethal in combination with *RplI215*<sup>Ubl</sup>. *Ubx* effect inhibited in *trans* heterozygotes with other interacting alleles. In viable heterozygotes, causes an increase in the number of duplicated bristles in *Dll/+* and, in males carrying a duplicated normal allele, produces sex combs on the middle legs.

***RplI215*<sup>106</sup>**

**synonym:** *Ubl*<sup>h</sup>.

**references:** Mortin and Lefevre, 1981, Chromosoma 82: 237-47.

**phenotype:** Homozygous lethal; *RplI215*<sup>106</sup>/*RplI215*<sup>106</sup> females with a duplication for *RplI215*<sup>+</sup> display about 50% normal viability, and are fertile when crossed to wild type, but nearly sterile in crosses to *RplI215*<sup>Ubl</sup> males with a duplication for *RplI215*<sup>+</sup>; all surviving progeny of the latter cross display a hyperabdominal-like phenotype; the females lack metathoracic legs and/or halteres in addition to having extra abdominal tissue; this phenotype barely detectable in offspring of crosses to normal males.

***RplI215*<sup>109</sup>**

**synonym:** *Ubl*<sup>m</sup>.

**references:** Mortin and Lefevre, 1981, Chromosoma 82: 237-47.

**phenotype:** Homozygous lethal; *RplI215*<sup>109</sup>/*RplI215*<sup>109</sup>/*Dp(1;1)RplI215*<sup>+</sup> females display about 50% normal viability, are fertile when crossed to wild type, but fertility only 50% normal in crosses to *RplI215*<sup>Ubl</sup>/*Dp(1;1)RplI215*<sup>+</sup> males; offspring from the latter cross have darkened eyes, thin bristles, and are sterile.

***RplI215*<sup>H1</sup>**

**phenotype:** Homozygous and hemizygous viable. Exhibits slight enhancement of *Ubx* when heterozygous to + but not in heteroallelic combination with any of the interacting mutant alleles; it decreases the enhancing effects of *RplI215*<sup>Ubl</sup>. Increases the number of duplicated bristles of *Dll/+* in all genotypes.

***RplI215*<sup>K1</sup>**

**phenotype:** Temperature-sensitive recessive lethal; flies survive at 19° but not at 29°. Although not displaying the *Ubx*-enhancing effect in combination with +, it does inhibit the effect of *RplI215*<sup>4</sup> at 29° but not at 25° or 19°.

***RplI215*<sup>K2</sup>**

**phenotype:** Homozygous and hemizygous viable; homozygous females sterile. Exhibits slight enhancement of *Ubx* when heterozygous to + but not in heteroallelic combination with any of the interacting mutant alleles; it decreases the enhancing effects of *RplI215*<sup>Ubl</sup>. Increases the number of duplicated bristles of *Dll/+* in all genotypes. Temperature-sensitive period for effects on both *Ubx* and *Dl* from third larval instar until mid-pupal stage.

***RplI215*<sup>ts</sup>**

**synonym:** *Ubl*<sup>ts</sup>.

**references:** Mortin and Kaufman, 1982, Mol. Gen. Genet. 187: 120-25.

Mortin and Kaufman, 1984, Dev. Biol. 103: 343-54 (fig.).

**phenotype:** Encodes a heat labile RNA polymerase subunit, as measured *in vitro* (Coulter and Greenleaf, 1982, J. Biol. Chem. 157: 1945-52) and by sterilizing effects on females and lethal effects on embryos. Females shifted from 22° to 29° become sterile, although their eggs laid during the first 24 hr appear normal morphologically; after 24 hr, embryonic development is visibly abnormal. Embryonic abnormalities include holes in the ventral cuticle and abnormal pharyngeal structures. Partial rescue of the sterility can be achieved by shifting newly laid eggs to 22° or by fertilization of eggs of *RplI215*<sup>ts</sup> females with wild-type sperm; the degree of rescue decreases as the time that the females have been held at 29° increases. Abnormalities of embryos dying despite rescue attempts mimic the phenotypes of pair-rule and segment-polarity mutants; surviving adults resemble *Hab* in lacking one or both halteres and metathoracic legs. In *RplI215*<sup>ts</sup>/*+* or *RplI215*<sup>ts</sup>/*0* gynandromorphs, the *RplI215*<sup>ts</sup>/*0* tissue appears to occupy more territory than expected, as though it had a proliferative advantage over the *RplI215*<sup>ts</sup>/*+* tissue (Mortin, Perrimon, and Bonner, 1985, Mol. Gen. Genet. 201: 437-45).

**RpII215<sup>Ubl</sup>: Ultrabithorax-like**

**synonym:** *Ubl*.

**references:** Mortin and Lefevre, 1981, *Chromosoma* 82: 237-47.

Mortin, Kim, and Huang, 1988, *Genetics* 119: 863-73.

**phenotype:** Homozygous and hemizygous lethal. Heterozygotes mimic *Ubx* in adding several hairs to and enlarging the capitellum of the haltere; females homozygous for *RpII215<sup>Ubl</sup>*, surviving by virtue of a duplication for *RpII215<sup>+</sup>*, more severely affected with capitellum approximately three times the size of that observed in *RpII215<sup>Ubl/+</sup>* and with two or more rows of bristles; about 10% normal viability; poorly fertile in crosses to wild type; sterile when crossed to *RpII215<sup>Ubl</sup>* males with a duplication of *RpII215<sup>+</sup>*. Similarly males with one mutant and one normal allele are more extreme than females with one mutant and two normal alleles. Acts as a dosage sensitive enhancer of *Ubx*, transforming halteres into wing-like structures; enhancement by *RpII215<sup>Ubl/RpII215<sup>Ubl/+</sup></sup>* > *RpII215<sup>Ubl/+</sup>* > *RpII215<sup>Ubl/+/+</sup>*. *RpII215<sup>Ubl/+</sup>* interacts with heterozygotes for *bx<sup>3</sup>* and *bx<sup>7</sup>* but not *bx<sup>1</sup>* to produce enlarged capitellum, and with *bx<sup>d100</sup>* to transform halteres into wing-like structures; extra doses of *Ubx<sup>+</sup>* counteract the enhancing effects of *RpII215<sup>Ubl</sup>*. A second interaction with *Ubx/+* is the production of miscadestral-like pigmentation. *Ubx* enhancement by *RpII215<sup>Ubl</sup>* reduced in *trans* heterozygotes with other interacting alleles (Mortin *et al.*). Furthermore in *RpII215<sup>Ubl/+//RpII215<sup>Ubl/0</sup></sup>* gynandromorphs, the *X0* tissue is without any *RpII215<sup>Ubl</sup>* phenotype, displaying neither enlarged halteres nor enhancement of *Ubx* expression, whereas the *XX* tissue exhibits both enlarged halteres and *Ubx* enhancement (Mortin, Perrimon, and Bonner, 1985, *Mol. Gen. Genet.* 201: 437-45). *RpII215<sup>Ubl/+</sup>* also display increased frequencies of duplicated bristles in *Dll/+*, and in some crosses causes *Sb/+* flies to exhibit shortened and broadened wings whose longitudinal veins fail to reach the margin (Mortin *et al.*). *RpII215<sup>Ubl</sup>* in heterozygous combination with deficiencies for either *ct* or *sno* is lethal and with lethal alleles of *ct* produces a strong cut phenotype; produces a mutant phenotype of allele specific severity in heterozygous combination with deficiencies for or lethal alleles of *br*, *N*, *dm*, *slc*, *bi*, *oc*, *m*, *sd*, and *sw*; interacts with heterozygotes for mutant alleles of *oc*, *sno*, and *sw*, but not the others; no interaction with *dor*, *sn*, *ras*, or *g* deficiencies. Influence of the maternal genotype apparent since patroclinous *RpII215<sup>Ubl/Y</sup>* and *RpII215<sup>Ubl/0</sup>* males from non mutant mothers survive at 20% the expected rate; they are phenotypically normal but are sterile (Voelker *et al.*).

**\*rs: rose**

**location:** 3-35.0.

**phenotype:** Eye color translucent purplish pink and ocelli colorless immediately after hatching; darken with age becoming sepia like, at least in the case of *rs<sup>66j</sup>*. Further, *rs<sup>66j</sup>* displays markedly decreased xanthopterin levels, reduced drosoppterins, and higher than normal levels of sepiapterin and bioppterin (Thörig and Scharloo, 1971, *DIS* 46: 40). *rs* very clear when combined with *v* (Akam), also interacts strongly with *ltd* (Silva and Mensua, 1985, *DIS* 51: 156). Larval Malpighian tubes pale yellow (Brehme and Demerec, 1942, *Growth* 6: 351-56).

**alleles:**

allele	origin	discoverer	ref <sup>α</sup>	comments
<i>*rs<sup>1</sup></i>	spont	Bridges, 23c10	1	male sterile; RK2
<i>rs<sup>2</sup></i>	spont	Bridges, 35d5		fertile; RK1
<i>rs<sup>66j</sup></i>	spont		2	heat sensitive

<sup>α</sup> 1 = Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 234; 2 = Thörig and Scharloo, 1971, *DIS* 40: 46.

**cytology:** Placed 67F3-68A3 on the basis of its inclusion in *Df(3L)vi<sup>2</sup>* = *Df(3L)67F2-3;68D6* but not *Df(3L)vi<sup>5</sup>* = *Df(3L)68A3;69A1-2* (Akam, Roberts, Richards, and Ashburner, 1978, *Cell* 13: 215-26).

**\*rsc: reduplicated sex combs**

**location:** 1- (between *y* and *cv*).

**origin:** X ray induced.

**discoverer:** Yanders, 56f6.

**references:** 1957, *DIS* 31: 85.

**phenotype:** Sex combs present on all six legs of males. Overlaps wild type in crowded cultures. Wings droop. Male fertile; viability only 15% wild type. Female lethal. RK2.

**other information:** Possible allele of *ph*.

**rsd: raised**

**location:** 3-95.4 (Ives); location in *Act88F<sup>8</sup> rsd* stocks more proximal (Mahaffey *et al.*, 1985).

**origin:** Spontaneous.

**discoverer:** Ives, 40i5.

**synonym:** *mod: modification*.

**references:** 1945, *DIS* 19: 46.

1947, *DIS* 21: 69.

Lang, Wyss, and Eppenberger, 1981, *Nature* (London) 291: 506-08.

Mahaffey, Coutu, Fyrberg, and Inwood, 1985, *Cell* 40: 101-10.

**phenotype:** Wings held straight up, nearly meeting over thorax. Appears to interfere with processing of certain muscle proteins (Mahaffey *et al.*). *rsd* strains analyzed in recent years also carry *Act88F<sup>8</sup>*. Viability and fertility normal. RK1.

**other information:** *Act88F<sup>8</sup> rsd* referred to as *Act88F<sup>8</sup> mod = rsd* by Mahaffey *et al.*

**rsi: reduced size**

**location:** 1-0.28 (no crossovers with *br* in 1038 flies).

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1954.

**references:** 1959, *DIS* 33: 89.

**phenotype:** Body small; eclosion delayed; viability reduced. RK3.

**cytology:** Not in *Df(1)RA19* = *Df(1)1E3-4;2B9-10* or *Df(1)sta* = *Df(1)1D3-E1;2A* (Belyaeva, Aizenzon, Kiss, Gorelova, Pak, Umbetova, Kramers, and Zhimulev, 1982, *DIS* 58: 184-90).

**other information:** One allele each induced by CB. 1506 and CB. 3026.

**Rsp: Responder**

**location:** 2-56.61 (based on 122 *pr-cn* recombinants).

**synonym:** *Ac-SD: Activator of SD* (Hiraizumi and Nakazima).

*Dr: Director* (Hartl).

*Receptor* (Sandler and Carpenter).

**references:** Hartl, 1974, *Genetics* 76: 477-86.  
 Ganetzky, 1977, *Genetics* 86: 321-55.  
 Brittnacher and Ganetzky, 1984, *Genetics* 107: 423-34.  
 Wu, True, and Johnson, 1989, *Nature* (London) 341: 248-51.

**phenotype:** The region of the chromosome upon which *Sd* acts to cause dysfunction of sperm that receive it; the sensitivity of *Rsp* is unaffected by its position in the genome, being equally responsive to *Sd* either in repulsion or coupling with *Sd*, or when located ectopically as in *Dp(2;f)Rsp* (Brittnacher and Ganetzky, 1989, *Genetics* 121: 739-50) or in *Dp(2;Y)Rsp* (Lyttle and Ault, 1985, *Genetics* 110: s23; Lyttle, 1989, *Genetics* 121: 751-63).

**alleles:** Both sensitive and insensitive alleles occur, and evidence of their existence appeared in the earliest articles on *Sd*. By monitoring the relative recoveries of homologous second chromosomes from males carrying *Dp(2;Y)B10-4 = Dp(2;Y)YL;36D2-3;40F*, in which *Sd* and *E(Sd)* are transposed from the base of *2L* into *YL*, Lyttle, Brittnacher, and Ganetzky (1986, *Genetics* 114: 183-202) were able to assign relative sensitivities to the *Rsp* alleles carried by different laboratory chromosomes; Hiraizumi and Martin had made similar assessments based on the different degrees of distortion in response to heterozygosity to an *SD* chromosome. The degree of distortion as seen in genotypic ratios among the progeny of *Sd/+* males depends on the sensitivity differential of *Rsp* on the two homologues.

**alleles:**

allele	synonym	ref <sup>α</sup>	comments
<i>Rsp<sup>i</sup></i>	<i>Rsp, Rsp<sup>ins</sup></i>		insensitive
<i>Rsp<sup>116β</sup></i>		2	
<i>Rsp<sup>132β</sup></i>		2	
<i>Rsp<sup>s</sup></i>	<i>Rsp<sup>+</sup>, Rsp<sup>s2</sup></i>	3, 4	sensitive
<i>Rsp<sup>si</sup></i>	<i>Rsp<sup>s3</sup></i>	3, 4	intermediate sensitivity
<i>Rsp<sup>ss</sup></i>	<i>Rsp<sup>s1</sup></i>	1, 3, 4	super sensitive

<sup>α</sup> 1 = Brittnacher and Ganetzky, 1984, *Genetics* 197: 423-34; 2 = Ganetzky, 1977, *Genetics* 86: 321-55; 3 = Hiraizumi, Martin, and Eckstrand, 1980, *Genetics* 95: 693-706; 4 = Lyttle, Brittnacher and Ganetzky, 1986, *Genetics* 114: 183-202.

<sup>β</sup> X-ray-induced derivatives of *Rsp<sup>s</sup>* (Ganetzky).

**cytology:** Placed in 41A proximal to *Df(2R)M41*, *Df(2R)B*, and *Df(2R)A'* based on the observation that these deficiencies, all of which include the most proximal known lethally mutable locus on *2R*, distort in *Df/Sd* males. Other proximal deficiencies have lost sensitivity to *Sd* [*Df(2R)A''*] (Ganetzky; Sharp, Hilliker, and Holm, 1985, *Genetics* 110: 671-88). X-ray-induced deficiencies for *Rsp* delete the most proximal *2R* lethal loci (Ganetzky). Insensitive chromosomes are characterized by the absence of *2R* heterochromatic region h39; there is also one fewer n-band brought about by fusion of n bands in h38 and h40; supersensitive Responders are characterized by a duplication of h39 and a wholly heterochromatic pericentric inversion (Pimpinelli and Dimitri, 1989, *Genetics* 121: 765-72).

**molecular biology:** Responder activity correlated with the dosage of a tandemly arrayed 120-base-pair, AT-rich repeat that maps to the base of *2R* and is transposed to the *Y* in *Yrsp<sup>s</sup>* chromosomes of Lyttle. In one case in which reduced sensitivity is transposed to the *Y* leaving residual activity on *2R*, repeated sequences are found on both elements of the transposition (Wu, Lyttle, Wu and Lin,

1988, *Cell* 54: 179-89).

**other information:** In flies without *SD*, deletion of the *Rsp* region results in flies (both male and female) that are less fit than *Rsp<sup>+</sup>* flies (Wu *et al.*, 1989).

***rss: reduced scutellars and sternitals***

**location:** 1-17.4.

**origin:** Spontaneous in a selection line for reduced bristle number.

**references:** Sheldon and Evans, 1984, *Aust. J. Biol. Sci.* 37: 277-301.

**phenotype:** Shows specific reduction in the number of scutellar bristles without appreciable effect on other microchaetae. Also shows a reduction in the number of sternital microchaetae.

***rst: roughest***

**location:** 1-2.2 (based on 132 *w-spl* recombinants).

**phenotype:** Eyes rough and bulging; facets irregular in size and arrangement.

**alleles:** X-ray-induced *rst* mutations associated with chromosome rearrangements; those induced by ethyl methanesulfonate appear to be point mutations, although some also affect *vt*; *rst<sup>6</sup>* appears to be a point mutation that does not affect *vt*, is not rearranged and has normal viability in both sexes.

**cytology:** Placed in 3C5 by Lefevre and Green (1972, *Chromosoma* 36: 391-412); formerly placed in 3C4, which apparently does not exist.

***Rst: Resistance***

A term used to denote genes that confer resistance to the killing effects of insecticides and other noxious agents. The symbol *Rst* is followed by parenthetical designation of the chromosomal location of the gene and then by an indication of the insecticide. Both dominant and recessive genes for insecticide resistance are conceivable. Several investigators have exposed populations to insecticides for numerous generations and selected resistant lines. In most cases, the genetic basis of resistance is multigenic, and unless a major factor has been identified, these strains are not included in this list.

***Rst(1)JH: Resistance (1) Juvenile Hormone*****location:** 1-35.4.**origin:** Induced by ethyl methanesulfonate.**synonym:** *Met: Methoprene tolerant.***references:** Arking and Vlach, 1970, *J. Insect Physiol.* 22: 1143-51.Wilson, 1985, *Genetics* 100: s84.Wilson and Fabian, 1986, *Dev. Biol.* 118: 190-201.**phenotype:** Semidominant mutation conferring 50-100 fold increase in resistance to juvenile hormone III or its analogue methoprene over that of wild type. Also resistant to methoprene-induced tumors and abnormalities in adult cuticle; action of *Rst(1)JH* autonomous in gynandromorphs. Authors speculate that gene may affect juvenile-hormone receptor.**alleles:** Six ethyl-methanesulfonate-induced, X-linked mutations resistant to juvenile hormone reported by Arking and Vlach (now lost); resistance factors varied from 1.4 to 21.5 by their methods. Presumed to be alleles of the mutation described by Wilson and Fabian.**cytology:** Placed in 10C2-D4 based on increased survival of flies raised on methoprene food when *Rst(1)JH* combined with *Df(1)M259-4 = Df(1)10C2;10E2* and *Df(1)N71 = Df(1)10B5;10D4*, compared to *Rst(1)JH/+*.***Rst(1)mth: Resistance (1) malathion*****location:** Thought to be polygenic.**references:** Sing and Morton, 1981, *Can J. Genet. Cytol.* 23: 355-69.**phenotype:** Both larvae and adults show resistance to malathion.***Rst(1)str: Resistance (1) streptomycin*****location:** 1- (not mapped).**synonym:** *str-R.***references:** Lambertsson and Rasmuson, 1971, *Hereditas* 69: 299.**phenotype:** Dominant; ribosomes from homozygotes and hemizygotes bind about one-tenth the amount of streptomycin bound by wild-type ribosomes. Resistant flies appear to lack one ribosomal protein found in wild type.***Rst(2)amd: Resistance (2) alpha methyl dopa*****location:** 2- (not mapped).**references:** Sparrow and Wright, 1974, *Mol. Gen. Genet.* 130: 127-41.Sherald and Wright, 1974, *Mol. Gen. Genet.* 133: 35-36.**phenotype:** Partially dominant; resistant to levels of alpha methyl dopa in the medium that are lethal to wild type.***Rst(2)DDT: Resistance (2) DDT*****location:** 2-65 (64.5-66).**origin:** Naturally occurring allele.**discoverer:** Tsukamoto and Ogaki, 1953.**synonym:** *RI<sup>DDT</sup>: Resistance to Insecticide-DDT;*  
*RI<sup>II</sup>: Resistance to Insecticide on chromosome 2.***references:** 1954, *Botyu-Kagaku* 19: 25.Tsukamoto, 1958, *DIS* 32: 87.Kikkawa, 1961, *Ann. Rept. Sci. Works, Fac. Sci., Osaka Univ.* 9: 1-20.Ogaki, Nakashima-Tanaka, and Murakami, 1967, *Jpn. J. Genet.* 42: 387-94.**phenotype:** *Rst(2)DDT* is a major dominant gene responsible for the phenotype of a line selected for resistance to DDT. Median lethal dose of DDT for *Rst(2)DDT* lines is about 4000 µg/cc of medium; that for sensitive lines is50-100 µg/cc. Also resistant to BHC (benzene hexachloride) and organophosphorus insecticides such as parathion and malathion. Median lethal dose of parathion is 2 ppm for resistant line and 0.08 ppm for sensitive. Sensitive to phenylthiourea (Ogita, 1958, *Botyu-Kagaku* 2: 188-204) and phenylthiocarbamide (Däuring and Sunner, 1971, *Hereditas* 68: 115-22). Shows maternal effect in that progeny of *Rst(2)DDT/+* female crossed to *+/+* male are more resistant than those of reciprocal cross. Larva more resistant than adult. RK3.**other information:** Possible to select new resistant alleles by growing the offspring of irradiated wild-type flies on parathion (Kikkawa, 1968, *DIS* 43: 161).***Rst(3)amd: Resistance (3) alpha methyl dopa*****location:** 3- (between *h* at 25.6 and *th* at 43.2).**origin:** Induced by ethyl methanesulfonate.**references:** Bishop and Sherald, 1981, *DIS* 56: 21-22.**phenotype:** Homozygous lethal. LD<sub>50</sub> concentration of α methyl dopa for heterozygotes more than three times that of wild type.**alleles:** Two alleles (PR40 and PR45) exhibiting weak complementation for lethality.*Rst(Eth):* see *Eth****Rst(3)FU: Resistance (3) Fluorouracil*****location:** 3- (not mapped).**origin:** Spontaneous.**references:** Duke and Glassman, 1968, *Nature (London)* 220: 588-89.**phenotype:** Partially dominant; homozygote survives 0.003% fluorouracil, whereas 0.0008% lethal to most strains.***\*Rst(3)ns: Resistance (3) nicotine sulfate*****location:** 3-49.5.**origin:** Spontaneous.**discoverer:** Tsukamoto, 1954.**references:** 1955, *Botyu-Kagaku* 20: 73.1956, *Botyu-Kagaku* 21: 71.1958, *DIS* 32: 87.**phenotype:** Median lethal dose to homozygote is 600 ppm of nicotine sulfate added to culture medium (from first instar larva through eclosion); to heterozygote, it is 300 ppm; to susceptible strains, 40 ppm. RK3.***\*rstl: roughestlike*****location:** 1- (rearrangement).**origin:** X ray induced.**discoverer:** Oliver, 29d3.**synonym:** *lz-1: lozenge-like.***references:** 1935, *DIS* 3: 28.**phenotype:** Eyes rough; more extreme than *lz*. Viability low. RK2A.**cytology:** Associated with *In(1)rstl*; breakpoints unknown.***\*rt: rotated abdomen*****location:** 3-37 (based on location of *rt*<sup>2</sup>).**discoverer:** Bridges, 18g28.**references:** Bridges and Morgan, 1923, *Carnegie Inst. Washington Publ. No. 327*: 190 (fig.).Morgan, Bridges, and Sturtevant, 1925, *Bibliog. Genet.* 2: 54 (fig.).**phenotype:** Abdomen twisted clockwise through 60° to

90°, as viewed from behind. Both sexes sterile. Viability low. RK2.

**cytology:** Placed in 68C8-11 based on inclusion in *Df(3L)vin7 = Df(3L)68C8-11;69B4-5* but not *Df(3L)vin6 = Df(3L)68C8-11;69A4-5* (Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25).

**rt<sup>2</sup>**

**origin:** Spontaneous.  
**discoverer:** Bridges, 25114.  
**phenotype:** Abdomen twisted, as is *rt*. Viability erratic, usually about 50% wild type. Male fertile; female not tested. RK2.

**\*rt<sup>w</sup>: rotated abdomen of Wallbrunn**

**origin:** γ ray induced.  
**discoverer:** Wallbrunn, 61i26.  
**references:** 1964, DIS 39: 59.  
**phenotype:** Like *rt*. RK2.

**\*rta: reduced tarsi**

**location:** 1-4.5.  
**origin:** Induced by methyl methanesulfonate (CB. 1540).  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 89.  
**phenotype:** Tarsi short and sometimes deformed. Body small. Eyes and wings small and abnormal. Bristles often waved or bent; postscutellars often held upright. Male sterile. RK2.

**rtv: retroactive**

**location:** 1-38.  
**origin:** Induced by ethyl-methanesulfonate.  
**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.  
**phenotype:** Recessive embryonic lethal; mouth parts darkly sclerotized. Embryo sometimes reversed in egg case (due to hyperactivity at late stages?). Zygotes from homozygous germ-line clones in females develop normally (Wieschaus and Noell, 1986, Roux's Arch. Dev. Biol. 195: 63-73).  
**alleles:** Allelism with Lefevre lethals reported by Perrimon, Engstrom, and Mahowald, 1989, Genetics 21: 333-52.

**rub: rubroad**

**location:** 2-5.0 (to the right of *dpp<sup>d-ho</sup>*).  
**origin:** Spontaneous.  
**discoverer:** Mohr, 31k20.  
**phenotype:** Eyes rough and kidney shaped. Wings broad and somewhat arclike. Abdomen short and bloated; tergites irregular. External genitalia of male rotated in varying degrees. Overlaps wild type. RK3.

**\*rub<sup>48d</sup>**

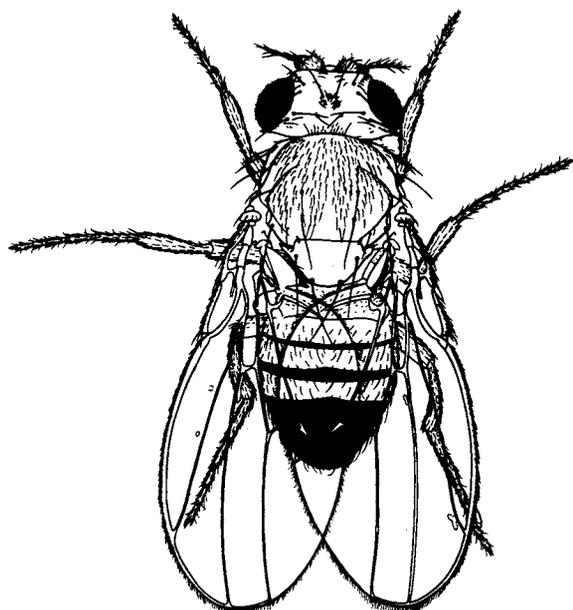

**origin:** Spontaneous.  
**discoverer:** Chute, 48d.  
**references:** Sturtevant, 1948, DIS 22: 56.  
**phenotype:** Like *rub*; wings also show slight network of extra veins and thickening between L3 and L4. RK3.

**rubb: rubbish (T. Schüpbach)**

**location:** 2-89.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.  
**phenotype:** Maternal effect lethal; embryos from homozygous mothers form a fragmented cuticle with variable holes and head defects.  
**alleles:** One: *rubb<sup>QD</sup> = rubbish<sup>1</sup>*.

**rubroad: see rub**

**ruby: see rb**

**rub: rubroad**

Edith M. Wallace, unpublished.

**rud: ruddle**

**location:** 1-3.3.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)aminophenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 74.

**phenotype:** Eye color dull reddish brown. Classification best in newly eclosed flies. Good viability and fertility. RK2.

**other information:** One allele each induced by CB. 1528, CB. 3026, and X rays.

**rudimentary:** see *r*

**rudimentary-like:** see *r-l*

**rue: ruffed eye**

**location:** 3- {47}.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kaufman.

**references:** Lewis, Kaufman, Denell, and Tellerico, 1980, Genetics 95: 367-81.

Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

**phenotype:** Roughened eyes and fine bristles at 25°; lethal at 28°.

**cytology:** Placed in 84C1-6 based on its inclusion in  $Df(3R)dsx2M = Df(3R)84C1-2;84E1$  and  $Df(3R)Antp-X2 = Df(3R)84B6-C1;84C5-6$ .

**rugose:** see *rg*

**rumpled:** see *rmp*

**run: runt**

**location:** 1- {65.8}.

**synonym:** *leg: legless*.

**references:** Nüsslein-Volhard and Wieschaus, 1980, Nature (London) 287: 795-801 (fig.).

Gergen and Wieschaus, 1986, Cell 45: 289-99 (fig.).

Gergen, 1987, Genetics 117: 477-85 (fig.).

Gergen and Butler, 1988, Genes Dev. 2: 1179-93.

**phenotype:** A pair-rule embryonic lethal; causes deletions of the dentical belts of the mesothoracic and the first, third, fifth, and seventh abdominal segments, extending through the more anterior naked cuticle and into the denticle belts of the next most anterior segments. Deleted regions appear to be replaced by mirror image duplications of the remaining more anterior pattern elements. Deleted regions exceed duplications in size, resulting in shorter embryos. The amount of material deleted varies among segments, alleles, and among animals with the same alleles. Hypomorphic alleles do not remove as much tissue as amorphs, and weak hypomorphic alleles produce occasional survivors missing methathoracic legs or halteres or both and are frequently missing one or more abdominal tergites. *run*<sup>31</sup>, among the weakest alleles, survives to adulthood. Deficiencies for *run* have discernable dominant effects on embryonic development; extra doses of *run*<sup>+</sup> produce anti-runt phenotype, i.e., 30% of males with two doses of *run*<sup>+</sup> display deletions of portions of the dentical belts of A6 and less frequently of A2 and A8; males with three *run*<sup>+</sup> alleles more severely affected with 70% penetrance. *run*<sup>+</sup> postulated to repress *eve* function and positively regulate *ftz*; *run* mutants show expansion of stripes of *eve* expression and premature disappearance of stripes of *ftz* expression in the embryo (Frasch and Levine, 1987, Genes Dev. 1: 981-95). *ftz*<sup>+</sup> expression in cellular blastoderm reduced in four anterior stripes; A5-A7 expression abnormal, possibly reflecting pattern duplication; nuclear shape abnormal [Carroll and Scott, 1986, Cell 45: 113-26 (fig.)]. For expression pattern later in development see Kania, Bonner, Duffy, and Gergen (1990, Genes Dev. 4: 1701-13). *run* is autonomous in gynandromorphs both for missing and for mirror-image duplicated phenotypes, suggesting that the duplication does not result from proliferation following cell death (Gergen and Wieschaus, 1985, Dev. Biol. 109: 321-35). Also, the earliest embryonic phenotypes are dosage compensated (Gergen, 1987). *run* embryos produced by homozygous ovarian clones not different from those produced by heterozygous mothers (Wieschaus and Noell, 1986, Roux's Arch. Dev. Biol. 195: 63-73).

Biol. 193: 296-307; 11 = Zusman, Coulter, and Gergen, 1985, DIS 61: 217-18.

**cytology:** Placed in 19E1-3 on the basis of its inclusion in the region of overlap of *Df(1)16.3.35 = Df(1)19D2-D3;E3* and *Df(1)B57 = Df(1)19E1-2;19F1* (Miklos, Kelly, Coombe, Leeds, and Lefevre, 1987, J. Neurogenet. 4: 1-19).

**molecular biology:** Gene cloned by transposon tagging; 50 kb cloned. Mutational lesions define a segment of at least 8.5 kb required for *run* function; transposition of a 14.5 kb segment that includes the 8.5 kb sequence elicits partial rescue of *run* mutants. Genomic sequences identify a 2.6 kb poly-adenylated mRNA on northern blots. Transcript uniformly distributed in early embryo; most abundant during blastoderm when it is expressed in the seven stripes characteristic of other pair-rule genes; switching to every-segment expression during gastrulation and showing expression in the head and proctodeal primordium at that time [Gergen and Butler, 1988, Genes Dev. 2: 1179-93 (fig.)].

Tully and Quinn, 1985, J. Comp. Physiol. 157: 263-77.  
Mariath, 1985, J. Insect Physiol. 31: 779-87.

**phenotype:** Mutant males and homozygous females impaired in several types of learning and memory; associative conditioning defective in tests using either reward (Tempel *et al.*, 1983) or aversive unconditioned stimuli (e.g. Dudai, 1983, Proc. Nat. Acad. Sci. USA 80: 5445-48; Dudai, Svi, and Segel, 1984, J. Comp. Physiol. 155: 569-76; Livingstone *et al.*), including tests of "classical" (e.g. Tully and Quinn, 1985) and "operant" conditioning (Mariath, 1985); able to learn in associative conditioning tests involving visual cues, but at subnormal levels (Folkers, 1982, J. Insect Physiol. 28: 535-39), and memory appears to be normal. Learning scores subnormal when measured immediately after certain types of training; then either scores decay rapidly with time (Tem-

pel *et al.*, 1983; Tully and Quinn, 1985) or there is no indication of memory (Mariath). Although defective in some aspects of learning, heterozygous females behave essentially normally in shock/odor tests (Dudai *et al.*, 1983). Courtship also defective; unlike wild-type males, *rut* males court inseminated and virgin females with equal vigor; they may be unable to distinguish them (Gailey *et al.*). In tests of non-associative conditioning, *rut* shows aberrant habituation and sensitization to sugar stimuli (Duerr and Quinn); *rut* males subnormal in learning to avoid courtship of immature males; and homozygous or hemizygous *rut* females defective in "priming" of mating behavior by prestimulations with artificial courtship songs; effects of such acoustical prestimulations decay more rapidly than normal (Kyriacou and Hall). In either the homozygous or heterozygous condition *rut* acts as a partial suppressor of the sterility of homozygous *dnc* females inversely related to degree of rescue, suggesting both a maternal and a zygotic role of *rut* (Bellen, Gregory, Olsson, and Kiger, 1987, Dev. Biol. 121: 432-44; Bellen and Kiger, 1988, Roux's Arch. Dev. Biol. 197: 258-68). Double mutant females mated to Canton-S males lay many eggs, but most of the eggs fail to hatch.

Biochemically, *rut* influences adenylate cyclase activity (Dudai *et al.*, Livingstone *et al.*); it seems to abolish a calcium or calmodulin stimulated component of adenylate cyclase activity (Livingstone, Dudai, and Zvi, 1984, Neurosci. Lett. 47: 119-24), while leaving intact a component of activity stimulated by guanyl nucleotides, fluoride, or monoamines, suggesting that *rut* may directly affect the catalytic subunit of the adenylate cyclase complex (Livingstone *et al.*, Dudai *et al.*, 1984); consistent with this hypothesis is the observation that cyclase activity in *rut* is lower than normal, even in the presence of forskolin (Dudai *et al.*, 1984; Dudai, Sher, Segal, and Yovell, 1985, J. Neurogenet. 2: 365-80). *rut* primarily affects total cyclase activity in the adult abdomen, with progressively milder effects on thoracic and head cyclase (Livingstone *et al.*, Dudai and Svi, 1985, J. Neurochem. 45: 355-64); reduction of abdominal adenylate cyclase activity of *rut*<sup>1</sup>>*rut*<sup>2</sup>>*rut*<sup>3</sup> (Bellen *et al.*); the majority of adenylate cyclase activity in wild type is in a particulate fraction, and *rut* lacks up to 35% of total particulate activity (Dudai and Zvi, 1985). That *rut* may in fact encode a component of the fly's adenylate cyclase catalytic subunit is suggested by altered Km of enzyme activity in mutant flies (*e.g.* Dudai *et al.*, 1983, 1985) and by the fact that hypoploidy of *rut*<sup>+</sup> in females leads to approximately half normal levels of that cyclase activity specifically affected by the *rut* mutations (Livingstone *et al.*), and hyperploidy for the normal allele leads to increased activity (Livingstone). The biochemical results suggest that *rut*<sup>1</sup> could be a null mutation.

**alleles:** Three alleles: *rut*<sup>2</sup> and *rut*<sup>3</sup> recovered as partial suppressors of the female sterility of homozygous *dnc* females.

**phenotype:** Eye color wine like.

**ry: rosy** (*A. Chovnick and colleagues*)**location:** 3-52.0.

**phenotype:** The structural gene for xanthine dehydrogenase [XDH (EC.1.2.1.37)]; it is a homodimer with subunit molecular weight estimated from its DNA sequence as 146,898 daltons (Keith, Riley, Kreitman, Lewontin, Curtis, and Chambers, 1987, *Genetics* 116: 67-73). Enzyme level responds to dose of *ry*<sup>+</sup> alleles (Grell, 1962, *Z. Indukt. Abstamm. Vererbungsl.* 93: 371-77). XDH is a molybdenum hydroxylase and requires the activity of *cin*<sup>+</sup>, *lxd*<sup>+</sup>, *mal*<sup>+</sup> for normal activity, though not for normal levels of CRM (Glassman, Shinoda, Duke, and Collins, 1968, *Ann. N. Y. Acad. Sci.* 151: 263-73). CRM (cross reacting material) contains bound molybdenum in the presence of *mal*; however, enzyme activity inhibited (Andres 1976, *Eur. J. Biochem.* 62: 591-600). Homozygotes for null alleles lack XDH activity (Forrest, Glassman, and Mitchell, 1956, *Science* 124: 725-26; Glassman and Mitchell, 1959, *Genetics* 44: 153-62; Hubby and Forrest, 1960, *Genetics* 45: 211-24) and have reddish brown eyes; accumulate enzyme's substrates, xanthine and 2-amino-4-hydroxypteridine as larvae plus hypoxanthine in the adult; precursors collect as solid granules in Malpighian tubules (Bonse, 1967, *Z. Naturforsch.* 22B: 1027-29); lack enzyme products uric acid and isoxanthopterin (Mitchell, Glassman, and Hadorn, 1959, *Science* 129: 268-69). Mutant homozygotes are also sensitive to administration of purine to the medium (Glassman, 1965, *Fed. Proc.* 24: 1243-51); survival on purine supplemented medium can be used to select for rare *ry*<sup>+</sup> recombinants (Chovnick, Ballantyne, Baillie, and Holm, 1970, *Genetics* 66: 315-29) and unequal crossovers producing tandem duplications (Gelbart and Chovnick, 1979, *Genetics* 92: 849-59). Hypomorphic alleles that have normal eye color are also sensitive to appropriate levels of purine supplementation; furthermore, both wild types and hypomorphs can be made to display mutant eye color by administration of appropriate levels of the XDH inhibitor, HPP (allopurinol) [4-hydroxypyrazolo-(3,4-d)pyrimidine] (Glassman, 1965, *Fed. Proc.* 24: 1243-51; Boni, DeLerma, and Parisi, 1967, *Experientia* 23: 186-87; McCarron and Chovnick, 1981, *Genetics* 97: s70-71); *in vitro* and *in vivo* complementation between *mal* and *ry* products was demonstrated by Glassman (1952, *Proc. Nat. Acad. Sci. USA* 48: 1491-97; Glassman and McLean, 1962, *Proc. Nat. Acad. Sci. USA* 48: 1712-18). Pigmentation is nonautonomous in *ry* eye disks trans-

planted into wild-type hosts (Hadorn and Schwink, 1956, *Nature* 177: 940-41). Enzyme levels climb from low levels in the zygote to a peak at puparium formation; the level then falls but increases again to a maximum a few days after eclosion (Chovnick, McCarron, Hilliker, O'Donnell, Gelbart, and Clark, 1978, *Cold Spring Harbor Symp. Quant. Biol.* 42: 1011-21). Enzyme derived from the paternal genome appears during gastrulation; activity at time zero is low in *ry*<sup>+</sup> zygotes produced by *ry*/+ females but undetectable in those produced by *ry* females (Sayles, Browder, and Williamson, 1973, *Dev. Biol.* 33: 213-17). Enzyme activity present in larval and adult fat bodies, larval and adult Malpighian tubules, and, in smaller amounts, in various regions of the larval and adult gut [Ursprung and Hadorn, 1961, *Experientia* 17: 230-31; Munz, 1964, *Z. Indukt. Abstamm. Vererbungsl.* 95: 195-210; Reaume, Clark, and Chovnick, 1989, *Genetics* 123: 503-09; Reaume (unpublished observations)]. XDH is not synthesized in the adult eye, but is transported there [Reaume *et al.*, 1989].

**alleles:** *ry* alleles have been detected by several criteria, including electrophoretic mobility of XDH, purine sensitivity, and rosy eye color, either in the absence or presence of allopurinol. Alleles are presented in two tables; the first table includes the wild-type variants, and the second the mutant alleles. Chovnick and his colleagues (Chovnick, Gelbart, and McCarron, 1980, *Cell* 11: 1-10) identify at least seven different electromorphs in laboratory stocks; using a highly discriminating series of gel conditions, Buchanan and Johnson (1983, *Genetics* 104: 301-15) identified, among 62 wild-type chromosomes isolated from nature, fourteen electromorphs, two of which corresponded to those contained among the earlier seven. Both induced mutations and natural variable sites are designated by the number of the + progenitor followed by specific derivative numbers, *e.g.* *ry*<sup>102</sup> is the second mutant derivative of *ry*<sup>+1</sup>. Not all mutants with allelic designations with values less than 100 are known to be derivatives of *ry*<sup>+0</sup>; however, those numbered from 3a to 54 (excepting 17, 20, and 21) are known to be so derived. However, those mutations discovered by Girton, Green, Daniels, Lewis, Spradling and Rubin do not use this system of nomenclature. Also, those alleles marked with an asterisk are no longer available. Finally, Chovnick's laboratory maintains several hundred mutants not reported here, including a group generated on a *ry*<sup>+11</sup> background.

<sup>α</sup> *ry*<sup>+</sup> allele designation refers to the entire rosy DNA sequence. Electrophoretic markers and control variants characteristic of a given allele represent only a few of the bp polymorphisms distinguishing one *ry*<sup>+</sup> allele from another. *ry*<sup>+</sup> alleles originated as iso-3 stocks from wild populations, with the exception of those marked (derivative) which are conversions to wild type of a unique rosy mutant allele. These may carry bp polymorphisms within the conversion segment not common to the original rosy mutant.

<sup>β</sup> Sequence data have been submitted to the EMBL/Gen Bank Data Libraries under the accession number Y 00307 and Y 00308. Data on other wild-type sequence are available (5, 6).

<sup>γ</sup> Polymorphic sites segregating in wild type alleles; the digits to the left of the slash bar represent the phenotype with respect to the 5' cis-acting control elements, 1005 and 409, with "0" indicating the CRM levels of *ry*<sup>+0</sup>, "+" representing higher CRM, and "-" indicating lower CRM. The remaining digits designate the electrophoretic charge relative to that of XDH produced by *ry*<sup>+0</sup> attributable to the amino-acid residues inferred to correspond to the three sites inferred from mapping and sequencing results; the sites are indicated in order and are located at +736, +1551, and +3557 in the gene sequence (5); "0" indicates the relative charge at the three sites of *ry*<sup>+0</sup>; "-" indicates a more negative charge, i.e. less anodically migrating; and "+" a more positive charge.

<sup>δ</sup> 1 = Buchanan and Johnson, 1983, Genetics 104: 301-15; 2 = Clark, Daniels, Rushlow, Hilliker, and Chovnick, 1984, Genetics 108: 953-68; 3 = Chovnick, Gelbart, and McCarron, 1980, Cell 11: 1-10; 4 = Coté, Bender, Chovnick, 1986, Genetics 112: 769-83; 5 = Curtis, personal communication; 6 = Curtis, Clark, Chovnick, and Bender, 1989, Genetics 122: 653-61; 7 = Gelbart, McCarron, Pandey, and Chovnick, 1974, Genetics 78: 869-86; 8 = Lee, Curtis, McCarron, Love, Gray, Bender, and Chovnick, 1987, Genetics 116: 55-66; 9 = McCarron, Gelbart, and Chovnick, 1974, Genetics 76: 289-99; 10 = McCarron, O'Donnell, Chovnick, Bhullar, Hewitt, and Candido, 1979, Genetics 91: 275-93.

<sup>ε</sup> The only extant non-derivative *ry*<sup>+0</sup> sequence is carried in the multiple break rearrangement *In(3LR)Ubx*<sup>A</sup>.

<sup>β</sup> +1 of the nucleotide sequence defined as the second base pair in an *EcoRI* site in the second exon; transcription from left to right.

<sup>γ</sup> Additional description below.

<sup>δ</sup> Adult eye color is not the same as in most null mutants. Some residual XDH activity may be present.

<sup>ε</sup> Leaky = hypomorph.

**cytology:** Placed in 87D8-12 based on *Df(3R)ry74 = Df(3R)87D4;87D12* and in 87D11-12 based on *in situ* hybridization with radioactively-labelled *ry* DNA probe (Lefevre, 1971, *DIS* 46: 40; Spierer, Spierer, Bender, and Hogness, 1983, *J. Mol. Biol.* 168: 35-50) and with biotin labelled *ry* DNA probe [Duttaroy, 1988, (unpublished results)].

**molecular biology:** Gene sequence originally included in a 315-kb walk in region 87D-E (Bender, Spierer, and Hogness, 1983, *J. Mol. Biol.* 168: 17-33). Location of *ry* restricted to region between the right breaks of *Df(3R)kar*<sup>1G27</sup> between coordinates -191 and -187 kb and *Df(3R)ry*<sup>36</sup> between -166 and -163.5 kb (Spiierer, Spierer, Bender, and Hogness, 1983, *J. Mol. Biol.* 168: 35-50). A group of *ry* mutants with molecular lesions were confined to 4 kb between -171 and -167 kb; 0 on the nucleotide map is within an *EcoRI* restriction site at -171 kb (Clark, McCarron, Love, and Chovnick, 1986, *Genetics* 112: 755-67; and Coté, Bender, Curtis, and Chovnick, 1986, *Genetics* 112: 769-83). The genomic sequence has been cloned and sequenced (Lee, Curtis, McCarron, Love, Gray, Bender, and Chovnick, 1987, *Genetics* 116: 55-66; Keith, Riley, Kreitman, Lewontin, Curtis, and Chambers, 1987, *Genetics* 116: 67-73). The gene is transcribed from the centromere (proximal to distal) and comprises four exons and three introns; exon one is at least 179 bp in length; it

contains the ATG codon and encodes the first fourteen amino acids. The codon for Lys<sup>14</sup> is followed by an 815 bp intron (coordinates -1365 to -551). Exon 2 begins at nucleotide -550 with the codon for Val<sup>15</sup> and extends for 2601 base pairs encoding 867 amino acids ending in Ser<sup>881</sup>. Intron 2 contains 281 base pairs from 2052 to 2332. Exon 3 is 1314 base pairs in length and encodes 438 amino acids from Val<sup>882</sup> to Leu<sup>1319</sup>. Finally, intron 3 extends from base pair 3647 through 3711 and is followed by the 3' exon beginning with Leu<sup>1320</sup> and terminating at the carboxyl end with Pro<sup>1335</sup> at nucleotide 3759. Seven conservative nucleotide substitutions noted between the Canton-S genomic sequence and Oregon-R cDNA sequences.

The molecular biology of *ry* alleles (listed according to their position on the DNA map of the locus) is summarized in the table on the next page.

**other information:** The locus has been extensively mapped by reciprocal recombination and conversion studies (see appended maps). Seven different classes of complementing or partially complementing alleles described; complementation map circular (Gelbart, McCarron, and Chovnick, 1976, *Genetics* 84: 211-32). *ry*<sup>+</sup> commonly used as a marker in P-element transformation experiments (Spradling and Rubín, 1982, *Science* 218: 341-47; Rubín and Spradling, 1982, *Science* 218: 348-53).

 $\alpha$  $\beta$ Positions are relative to the *EcoRI* site in exon 2.The molecular biology was referenced from one or more of the following: Curtis and Bender (unpublished results); Curtis, Clark, Chovnick and Bender, 1989, *Genetics* 122: 653-61; Gray and Bender (unpublished results); Lee, Curtis, McCarron, Love, Gray, Bender, and Chovnick, 1987, *Genetics* 116: 55-66. $\gamma$ 

Adult eye color is not the same as in most null mutants. Some residual XDH activity might be present.

**ry<sup>409</sup>**

**phenotype:** Designation applied to the site at -1145 in  $ry^{+4}$  that is responsible for the higher than normal XDH CRM of that allele (*i.e.*,  $ry^{409H}$  vs.  $ry^{409N}$ , the normal alternative; Curtis, Clark, Chovnick, and Bender, 1989, *Genetics* 122: 653-61). Enzyme activity two to three times that of other  $ry^{+}$  alleles (Chovnick, Gelbart, McCarron, Osmond, Candido, and Baillie, 1976, *Genetics* 84: 223-55); large tissue-specific increase in specific activity observed in late third-instar larval fat body, but not Malpighian tubules; mRNA levels 3.2 times higher than normal (Covington, Fleenor, and Devlin, 1976, *Genetics* 84: 211-32; see also Clark, Daniels, Rushlow, Hilliker, and Chovnick, 1984, *Genetics* 108: 953-68). Maps genetically to the right of  $ry^{1005}$  (Clark *et al.*, 1984).

**ry<sup>1005</sup>**

**phenotype:** Designation applied to the site at -1701 in  $ry^{+10}$  that is responsible for the lower than normal XDH CRM of that allele (*i.e.*,  $ry^{1005L}$  vs.  $ry^{1005N}$ , the normal alternative) (Curtis, Clark, Chovnick, and Bender, 1989, *Genetics* 122: 653-61). Enzyme levels 50% those of other normal alleles (McCarron, O'Donnell, Chovnick, Bhullar, Hewitt, and Candido, 1979, *Genetics* 91: 275-93); mRNA levels 52% normal (Covington, Fleenor, and Devlin, 1976, *Genetics* 84: 211-32). Maps genetically to the left of  $ry^{409}$  (Clark, Daniels, Rushlow, Hilliker, and Chovnick, 1984, *Genetics* 108: 953-68).

**molecular biology:**  $ry^{+10}$  sequenced from nucleotides -2105 to -260; 25 differences from the corresponding sequence of  $ry^{+5}$  noted; none could be associated with the difference in transcription levels (Lee *et al.*, 1987).

**s: sable****location:** 1-43.0.**discoverer:** Bridges, 12g19.**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 34.**phenotype:** Body color dark with prominent trident. Classification good at 19°, overlaps wild type increasingly with higher temperature. ERG normal (Hotta and Benzer, 1969, Nature 222: 354-56). Viability sometimes reduced. *s* is nonautonomous in gynandromorphs containing both *s* and + tissue (Lewis, 1955, DIS 29: 134). Tyrosinase formed in adult (Horowitz and Fling).  $\beta$ -alanine pools only 39% normal (Wright, 1987, Adv. Genet. 24: 127-222). *s/s*<sup>2</sup> easily classified. Females hemizygous for *s* very dark and sterile (Craymer and Roy, 1980, DIS 55: 200-04). Suppressed by *su(s)*. RK1 at 19°.**cytology:** Placed in 11F (Lefevre).**other information:** Neither transposable element 412 nor *roo* associated with *s* mutation as indicated in *in situ* hybridization experiments (Searles and Voelker, 1986, Proc. Nat. Acad. Sci. USA 83: 404-08).**s<sup>2</sup>****discoverer:** Bridges, 17e9.**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 234.**phenotype:** Body color less dark than *s* and trident more prominent. Expression best at 19°, overlaps wild type at 25° and 30°. Viability excellent. RK1 at 19°.**s<sup>eb</sup>: sable-ebonized****origin:** Induced by ethyl methanesulfonate.**discoverer:** Fahmy, 1956.**synonym:** *eb*.**references:** Fahmy, 1959, DIS 33: 86.**phenotype:** Fly heavily pigmented with trident pattern and scutellum very dark. Wings slightly shortened; membrane often slightly concave; wing tips occasionally truncate. Males viable and fertile; females sterile. RK2.**S: Star****location:** 2-1.3 (0.02 unit to the left of *ast*).**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 259 (fig.).

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

**phenotype:** Eyes slightly smaller and narrower than wild type; texture somewhat rough from rounded, irregular facets. Arrangement of hairs on surface of eye irregular. *S/ast* has small rough eyes; *S ast/+* + is like *S/+*. Enhanced by *E(S)*; partially suppresses *px* and *net* (Bedichak, 1936, DIS 5: 24; Lewis, 1945). Homozygote dies in late embryonic stage (Sivertzev-Dobzhansky, 1927, Wilhelm Roux's Arch. Entwicklungsmech. Organ. 109: 535-48; Sonnenblick and Huettner, 1938, Genetics 23: 169). A member of the so-called spitz group of mutants; embryos lack structures derived from ventral-lateral region of blastoderm. Denticle bands narrow and

ventral arms of head skeleton fused. Anal pads reduced. Transverse commissures of ventral nervous system reduced; Keilin organs, maxillary and antennal sense organs strongly reduced. Lethal in homozygous clones in female germ line (Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82; Mayer and Nüsslein-Volhard). RK1.

**alleles:** Many deficiencies formerly described as alleles listed under *Df(2L)S*.

Biol. 193: 283-95.**phenotype:** Embryonic lethal; no differentiation of cuticle or head skeleton; posterior of embryo condensed.**alleles:** Two.**cytology:** Placed in 86F7-87A7 based on inclusion in *Df(3R)E229 = Df(3R)86F6-7;87B1-2* but not *Df(3R)kar-D1 = Df(3R)87A7-8;87D1-2*.**safranin:** see **sf****sal: spalt****location:** 2-44.**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82. Jürgens, 1988, EMBO J. 7: 189-96.

Frei, Schuh, Baumgartner, Burri, Noll, Jürgens, Seifert, Nauber, and Jäckle, 1988, EMBO J. 7: 197-204.

**phenotype:** Embryonic lethal. Shows partial homeotic transformation of labium to prothorax and of A9 and 10 toward A8. Point mutants judged to be amorphic or nearly so judging from the phenotype of *sal/Df* compared with *sal/sal*. *sal; Abd-B*-double mutants exhibit thoracic structures in parasegments 14 and 15; similarly, *sal* and *Scr* seem to act independently on head structures in parasegments 2 and possibly 1.**alleles:**

<b>sal<sup>3</sup></b>	EMS	Anderson	<i>sal 445</i>	

<sup>α</sup> 1 = Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.**cytology:** Placed in 32F2-33A2 based on its inclusion in *Df(2L)esc-P2-0 = Df(2L)32F2-3;33A1-2* but not *Df(2L)esc10 = Df(2L)33A1-2;33B2-3* (Frei *et al.*).**molecular biology:** *sal* lies in the region of a chromosomal walk (Frei, Baumgartner, Edström, and Noll, 1985, EMBO J. 4: 979-87; Kilchherr, Baumgartner, Bopp, Frei, and Noll, 1986, Nature 321: 493-99); an early zygotic 0.8 kb transcript identified from the region between -385.25 and -377.5 of the walk (described under molecular biology of *prd*); injection of antisense RNA from this sequence is able to induce *sal* phenocopy formation. Transcript first appears at 0-2 h, is prevalentfrom 2-8 h after which it declines. Rescue of embryonic lethality by transformation requires 14 kb of 5' flanking sequence in addition to the 0.8 kb coding region; such transformants, however, do not complete larval development, implying later *sal* function. Sequencing reveals the presence of a single 57 base pair intron between codons 4 and 5 and that transcription is from left to right; the conceptual polypeptide comprises 142 amino acids and has a molecular weight of 14,533 daltons; the amino acid sequence reveals a series of three-amino-acid repeats and a high incidence of Gly residues; it consists of a larger hydrophobic amino-terminal and a hydrophilic carboxy-terminal part. *In situ* hybridization of labelled cDNA to sections of wild-type embryos reveals that *sal* transcript accumulates to high levels in the segmental Anlagen affected in mutant embryos but is also found in regions of the embryo where no functional requirement has been demonstrated. Homology detected in DNA of *D. simulans* and *D. orena*, but not of *D. hydei* or *D. virilis* (Reuter, Schuh, and Jäckle, 1989, Proc. Nat. Acad. Sci. USA 86: 5483-86).**salivary gland secretion:** see **sgs****sallimus:** see **sls****salmon:** see **g****Salmon:** see **Sa****sam: sperm amotile****location:** 1-3.7 (0.24 unit distal to *dnc*).**references:** Salz, Davis, and Kiger, 1982, Genetics 100: 587-96.**phenotype:** Males sterile with amotile sperm; homozygous females fertile.**alleles:** Two ethyl-methanesulfonate-induced alleles, *sam<sup>1</sup>* and *sam<sup>2</sup>*.**cytology:** Placed in 3D4; covered by *Dp(1;2)w<sup>+51b7</sup> = Dp(1;2)3C2;3D6-E1* but not *w<sup>+Y</sup> = Dp(1;Y)2D1-2;3D3-4*; also maps to the left of *dnc* in 3D4.**molecular biology:** Included in the chromosome walk around *dnc* (Davis and Davidson, 1984, Mol. Cell Biol. 4: 358-67). Molecular and genetic mapping data suggest that *sam* lies in the 79 kb intron that separates exons 1 and 2 of *dnc*. May be responsible for the 2.0-kb transcript from coordinates 17-20 (Chen, Malone, Beckendorf and Davis, 1987, Nature 329: 721-24).**sandpaper:** see **sdp****sas: stranded-at-second (D. R. Cavener)****location:** 3-{48}.**synonym:** *l(3)84Cd* and *rfd*.**references:** Cavener, Corbett, Cox, and Whetten, 1986, EMBO J. 5: 2939-48.

Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

Schneuwly, Kuroiwa, Gehring, 1987, EMBO J. 6: 201-6. Schonbaum, 1990, Ph.D. Dissertation, Vanderbilt University.

**phenotype:** Homozygous lethal; homozygotes die at the first to second instar molt or at second instar. Larvae do not grow and exhibit a segmentally repeated pattern of tanned spots on the ventral cuticle between the fourth and fifth row of setae and sometimes between the first and second row of setae. Tracheae are convoluted.

## alleles:

allele	origin	discoverer	synonym
<i>sas</i> <sup>11</sup>	EMS	Grigliatti	<i>l(3)3.6</i>
<i>sas</i> <sup>12</sup>	spont.	Green	<i>l(3)73b</i>
<i>sas</i> <sup>13</sup>	X ray	Denell	<i>l(3)d2</i>
<i>sas</i> <sup>14</sup>	EMS	Cavener	<i>l(3)g7</i>
<i>sas</i> <sup>15</sup>	EMS	R. Lewis	<i>l(3)r16</i>
<i>sas</i> <sup>16</sup>	EMS	R. Lewis	<i>l(3)r17</i>
<i>sas</i> <sup>17</sup>	EMS	R. Lewis	<i>l(3)r27</i>

**cytology:** Placed in 84C1-6 on the basis of *In(3R)Antp*<sup>73b</sup> being a *sas* allele and complementation tests with *Df(3R)Antp1* and *Df(3R)Scx2*.

**molecular biology:** Genomic clone (Cavener, *et al.*) and cDNA clone isolated (Schneuwly, Kuroiwa, and Gehring). *sas* RNA's are expressed at all stages of development in a variety of cuticle secreting ectodermally derived tissues. A 1348-amino-acid sequence (Schonbaum) is inferred for the *sas* protein. The inferred protein sequence is similar to a variety of cell receptor proteins. *In(3R)Antp*<sup>73b</sup> results in the formation of a fusion gene containing 5' exons of *sas* and the 3' end of *Antp*, beginning with exon 2 (Frischer, Hagen, and Garber, 1986, Cell 47: 1017-23).

**\*saw: sawtooth**

**location:** 1-0.0 (very close to right of *sc*).

**origin:** Ultraviolet induced.

**discoverer:** Edmondson, 51g.

**references:** 1952, DIS 26: 60.

**phenotype:** Hairs along wing edge arranged so that edge appears serrated. Wings may warp, especially in female. Fertility and viability excellent. Classification originally easy, but stocks apparently accumulate modifiers so that they came to appear nearly wild type. RK2.

**other information:** Not separated from *sc* in two crosses between *ac* and *sc* or in 60 crosses between *sc* and *pn*. Not covered by *Dp(1;2)sc*<sup>19</sup> = *Df(1;2)1B1-2;1B4-7;25-26*. Locus must be slightly to the right of *sc*.

**\*saw<sup>2</sup>**

**origin:** Ultraviolet induced.

**discoverer:** Edmondson, 51f.

**references:** 1952, DIS 26: 61.

**phenotype:** More extreme than *saw*. Wing margins as in *saw*, but wings are strongly warped up or down; thin textured, especially in female. Viability reduced. Fly often becomes stuck in food owing to warped wings. Fertility good; classification easy. RK2.

**sax: saxophone**

(*T. Schüpbach and E. Wieschaus*)

**location:** 2- {57}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, Genetics 121: 101-17.

**phenotype:** Maternal effect lethal, female sterile. Embryos from homozygous mothers gastrulate abnormally. The cephalic furrow is more pronounced than in wildtype. The phenotype is reminiscent of the zygotic embryonic lethal mutation twisted gastrulation (*twg*).

**alleles:** *sax*<sup>1</sup> and *sax*<sup>2</sup> originally *sax*<sup>WO</sup> and *sax*<sup>HB</sup>, respectively.

**cytology:** Placed in 41C1-43F8, since uncovered by *Df(2R)pk78s* = *Df(2R)42C1-7;43F5-8*.

**sb: soft brown**

**location:** 3-37.7.

**origin:** Spontaneous.

**references:** Aparisi and Nájera, 1987, DIS 66: 13-14. 1988, DIS 67: 4-5 and 5-6.

**phenotype:** Eye color soft brown, darkening with age.

*sb*: see *ml*

**Sb: Stubble**

**location:** 3-58.22.

**origin:** Spontaneous.

**discoverer:** Bridges, 23d21.

**references:** Dobzhansky, 1930, Z. Indukt. Abstamm. Vererbungsl. 54: 427-57 (fig.).

Beaton, Kiss, Fristrom, and Fristrom, 1988, Genetics 120: 453-64.

**phenotype:** Bristles of *Sb*/+ less than one-half normal length and somewhat thicker than wild type. Fiber bundles in bristle shafts smaller and more numerous than in wild type; occupy a third as much of the bristle cross-sectional area in *Sb* as in wild type (Overton, 1967, J. Morph. 122: 367-80). Developmental studies by Lees and Waddington [1943, Proc. Roy. Soc. (London), Ser. B. 131: 87-110 (fig.)] show that trichogen is shifted to lie more or less on the level of the tormogen. Most alleles viable as homozygotes; the only exceptions are *Sb*<sup>1</sup> and its derivative *Sb*<sup>v</sup>; they may be defective for an adjacent locus. Many homoallelic and heteroallelic combinations, involving both *Sb* and *sbd* alleles, display, in addition to shortened thickened bristles, what is termed by Beaton *et al.*, the malformed syndrome (Moore, 1935, DIS 3: 27); it consists of wings greatly reduced in size and short, thick, and twisted mesothoracic and metathoracic legs. *Sb* genotypes defective in elongation of appendage imaginal discs (Beaton *et al.*). This effect is exaggerated in a temperature-sensitive fashion in many genotypes that contain mutants in *BRC*; for example, females that are heterozygous both for *Sb*<sup>1</sup> or *Sb*<sup>63</sup> and any of a number of *br* alleles or a *br* deficiency display a strong enhancement of the short-wing deformed-leg syndrome. Similarly the malformed syndrome is engendered in *br*/Y males by the presence of *Sb*/+ (Beaton *et al.*). *Sb*<sup>1</sup>/*sbd*<sup>2</sup> more extreme than *Sb*<sup>1</sup>/+. *sbd*<sup>2</sup>/*Sb*<sup>1</sup> behaves as a recessive *sbd* allele but is homozygous lethal; rare escapers more extreme and easy to recognize (Davis, 1971, Mol. Gen. Genet. 113: 251-72). Classifiable in single dose in triploids. RK1.

**alleles:** Alleles differ in strength; phenotypes described at end of entry.

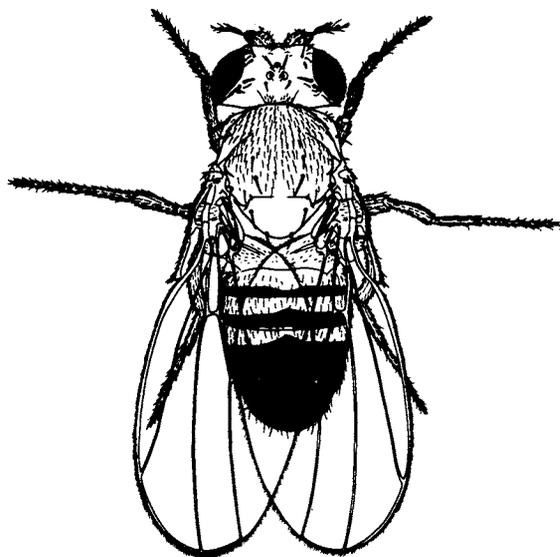

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments

<i>Sb</i> <sup>v</sup>	X ray	Lewis, 1948		2, 6	weak allele, homozygous lethal
<i>Sb</i> <sup>W</sup>	spont	Crow		4, 5	

<sup>α</sup> 1 = CP627; 2 = Beaton, Kiss, Fristrom, and Fristrom, 1988, Genetics 120: 453-64; 3 = Dobzhansky, 1930, Z. Indukt. Abstamm. Vererbungsl. 54: 427-57 (fig.); 4 = Friedenberg, 1963, Hereditas 50: 89-

115; 5 = Friedenber, 1964, Hereditas 51: 31-66; 6 = Lewis, 1948, DIS 30: 76-77; 7 = Moore, 1935, DIS 3: 27.

**cytology:** Salivary chromosomes normal (Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301). Placed in 89B4-5, probably in 89B4, by Lewis (1951, Cold Spring Harbor Symp. Quant. Biol. 16: 159-74). This probably corresponds to 89B9-10 on Bridges's revised map.

**other information:** *Sb* is pseudoallelic to and lies 0.01-0.03 unit to the right of *sbd*<sup>2</sup>. A gain-of-function mutation. Deficiency for the *Sb* locus produces no dominant phenotype (Lewis, 1951).

**Sb: Stubble**

Edith M. Wallace, unpublished.

**Sb<sup>63b</sup>**

**phenotype:** Bristles of *Sb*<sup>63/+</sup> somewhat shorter and thicker than *Sb*. Wings and legs normal. Homozygote shows reduced viability, short, thick bristles, small wings, and short deformed legs (Beaton *et al.*). *Sb*<sup>63b</sup>/*Sb* viable and fertile, more extreme than either heterozygote. RK1.

**other information:** Allelism inferred from failure to recover recombinants among 100 progeny of *Sb*<sup>63b</sup>/*Sb*.

**Sb<sup>Sp1</sup>: Stubble-Spike**

**phenotype:** Bristles of *Sb*<sup>Sp1/+</sup> about two-thirds normal length. Wings and legs normal. Bristles of homozygote one-fourth normal length. Wings reduced, crumpled, or blistered. Legs often short and bowed. *Sb*<sup>Sp1</sup>/*Sb* viability about 30% wild type. Bristles and wings shorter than homozygous *Sb*<sup>Sp1</sup>. RK1.

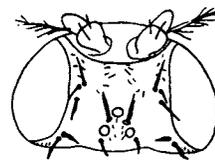

**Sb<sup>V</sup>: Stubble-Variigated**

**phenotype:** *Sb*<sup>V/+</sup> has mixture of wild-type and *Sb* bristles. In *X/X/Y* female and *X/Y/Y* male, bristles nearly all *Sb*. In *X/0* male, bristles usually all wild type. *Sb*<sup>V</sup>/*Sb* and homozygous *Sb*<sup>V</sup> are lethal. RK1A.

**cytology:** Associated with *T(2;3)Sb<sup>V</sup> = T(2;3)41A-C;88;89B*. Superimposed on *In(3R)Mo = In(3R)93D;98F2-6*.

**Sb<sup>W</sup>: Stubble-Wisconsin**

**phenotype:** Heterozygotes have short stout bristles; homozygotes die as larvae. Tends to persist in laboratory populations (Friedenberg and Chung, 1967, Genetics 57: 957-67).

**sbd: stubboid**

From Dobzhansky, 1930, Z. Indukt. Abstamm. Vererbungs. 54: 427-57.

**sbd: stubboid**

**location:** 3-58.2.

**synonym:** *stb*.

**references:** Beaton, Kiss, Fristrom, and Fristrom, 1988, Genetics 120: 453-64.

**phenotype:** Bristles short but usually slightly longer than in *Sb/+*. One or both wings often shortened and crumpled at base. Tibia and femur often shortened, thickened, and bowed. *sbd* genotypes interact synergistically with *br* genotypes to exaggerate reductions in wing length and short gnarled legs (Beaton *et al.*). Viability somewhat low. RK2.

**alleles:** *sbd*<sup>1</sup>, *sbd*<sup>2</sup>, and *sbd*<sup>20l</sup> homozygous viable; other listed alleles are recessive embryonic-larval-boundary lethals. Complementation for lethality but not *sbd* phenotype observed in some heteroallelic combinations; for example *sbd*<sup>32</sup> complements, at least partially, all lethal alleles except *sbd*<sup>47</sup>; *sbd*<sup>17</sup> fully complements all lethal alleles except *sbd*<sup>12</sup> and *sbd*<sup>47</sup>, which are partially complemented. *sbd* deficiencies listed under deficiencies.

Monte et al., 1989, Behav. Genet. 19: 267-83;

Lilly and Carlson, 1990, Genetics, 124: 293-302.

**phenotype:** Responds poorly, or apparently not at all, to a variety of volatile compounds; hence, may be generally olfaction defective, as opposed to responding poorly to only certain classes of synthetic or natural compounds; *sbl*<sup>1</sup> was isolated with respect to abnormal shock-avoidance learning tests of adults, which involve odor cues (Aceves-Piña and Quinn, 1979); *sbl*<sup>2</sup> was isolated with regard to odor response tests *per se* (Rodrigues and Siddiqi, 1978); *sbl*<sup>1</sup> and *sbl*<sup>2</sup> defective in larval olfaction (Aceves-Piña and Quinn, 1979; Monte et al., 1989) and fail to complement in this regard (Lilly and Carlson, 1990); the latter report showed *sbl*<sup>2</sup> to respond poorly to 3 separate odorants; both of these mutants also behave subnormally in tests of larval contact chemosensory responses, but each is normal in visually mediated larval behavior (Lilly and Carlson, 1990); *sbl*<sup>1</sup> and *sbl*<sup>2</sup> are temperature-sensitive near-lethals in 29° rearing tests, and they fail to complement in this regard (Lilly and Carlson, 1990); a post eclosion shift from 25° to the higher temperature does not appear to affect viability, but adults under these conditions have not been tested behaviorally--recall that *sbl*<sup>2</sup> flies are defective in odor responses (Rodrigues and Siddiqi, 1978; Gailey et al., 1986), and *sbl*<sup>1</sup> adults are as well (Aceves-Piña and Quinn, 1979; Tompkins et al., 1980; J. Carlson, unpublished--the latter determination used testing procedures as reported by Woodward, Huang, Sun, Helfand,

and Carlson, 1989, Genetics 123: 315-326). Other alleles are unconditionally lethal. In courtship experiments, *sbl*<sup>1</sup> (Tompkins et al., 1980) or *sbl*<sup>2</sup> (Gailey et al., 1986) males make little or no responses to pheromonal materials extracted from adult females; the former mutant, as a male, also performs subnormally in terms of quantitative measurements of overall courtship interactions with females (Tompkins et al., 1980) as well as by specification of individual elements of such sexual behavior (Markow, 1987). seemingly as a consequence, *sbl*<sup>1</sup> males exhibit mediocre mating success (Tompkins et al., 1980; Markow, 1987); the latter is observed when the mutant males are with females only (Tompkins et al., 1982) or are also in competition with wild-type males (Markow, 1987). *sbl*<sup>2</sup> males are rather wild-type-like, with respect to short-term monitoring of their behavior in presence of females and also in terms of mating success (Gailey et al., 1986); a *sbl*<sup>2</sup> male, however, makes almost no odor-mediated responses to a courtship object in his presence, as stimulated by a female placed nearby, whereas wild-type males are rather vigorously stimulated to court under these circumstances (Gailey et al., 1986). Females homozygous for *sbl*<sup>1</sup> (Tompkins et al., 1982; Markow, 1987) or *sbl*<sup>2</sup> (Gailey et al., 1986) exhibit relatively poor receptivity to male courtship/mating activities; this could be explained by the fact that they tend not to slow their movements in response to the courting male, whereas wild-type females do (Tompkins et al., 1982; Gailey et al., 1986). Courtship-experience-dependent after-effects, which appear to be in part mediated olfactorily, are subnormal or absent in tests of *sbl*<sup>1</sup> males with fertilized females (Tompkins et al., 1983). In experiments involving counts of post-eclosion mushroom-body fiber (axon) numbers in young imagoes, deantennated vs. intact *sbl*<sup>1</sup> flies were found to exhibit same degree of reductions in fiber numbers (Technau, 1984)--suggesting that deantennation, which leads to such decreases in wild-type adults, effects these anatomical changes because of sensory deprivation, instead of surgery-induced injury *per se*.

**location:** 1-32.6 [between 32.53 and 32.67 (Zhimulev *et al.*, 1981, 1982)].

**references:** Zhimulev, Belyaeva, Pokholkova, Kotchneva, Fomina, Bgatov, Khudyakov, Patzevich, Semeshin, Baritcheva, Aizenzon, Kramers, and Eeken, 1981, DIS 56: 192-96; 1982, DIS 58: 210-14.

Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, and Belyaeva, 1987, DIS 66: 194-97.

Zhimulev, Pokholkova, Bgatov, Umbertova, Solovjeva, Khudyakov, and Belyaeva, 1987, Biol. Zentralbl. 106: 699-720.

**phenotype:** Most alleles homozygous and hemizygous lethal; *sbr*<sup>1</sup> viable but displays reduced viability in hemizygous females. Bristles small, with one or more missing, especially scutellars and especially in hemizygous females (Zhimulev and Ilyina, 1980, DIS 55: 146). *sbr*<sup>16</sup> semilethal and male sterile; females sterile in heteroallelic combination with other lethal alleles. *sbr*<sup>9</sup> is a temperature-sensitive lethal; semilethal with small body at 25°, *sbr*<sup>1</sup>/*sbr*<sup>9</sup> viable and normal at 30°.

<sup>β</sup> Induced by male recombination factor, *MR*<sup>h12</sup> in *y mei9*<sup>a</sup> *mei41*<sup>D5</sup>.

**cytology:** Placed in 9F5-11 based on its inclusion in the region of overlap of *Df(1)v-LA = Df(1)9F5-6;10A1-2* and *Df(1)ras59 = Df(1)9E1;9F10-11*.

**\*sbs: stubs**

**location:** 1-0.9.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 90.

**phenotype:** Wing abnormalities vary from extreme reduction in size to partial incision of margin with L2 and L3 closer together. Eyes small and slightly rough. Male viable and fertile; female sterile. RK2.

*\*sbt*: see *sbr*<sup>2</sup>

**\*sby: small body**

**location:** 1-60.8.

**origin:** γ ray induced.

**discoverer:** Fahmy, 1958.

**synonym:** *sby-61*.

**references:** 1964, DIS 39: 58.

**phenotype:** Extremely small, lightly pigmented fly. Viability and fertility reduced. RK3.

**cytology:** Placed in salivary region 18A4 to 18B8 on the basis of its inclusion within deficiency resulting from recombining left end of *In(1)y*<sup>4</sup> = *In(1)1A8-B1;18A3-4* with right end of *In(1)sc*<sup>9</sup> = *In(1)1B2-3;18B8-9* (Norton and Valencia, 1965, DIS 40: 40).

*sc*: see *ASC*

**Sc: Scotched eye**

**location:** 1-4.5 (about 4 or 5).

**origin:** X ray induced.

**references:** Muller, 1946, DIS 20: 67.

**phenotype:** Ommatidia disarranged near posterior margin of eye. Resembles *spa*<sup>Cat</sup>. Good viability and fertility in heterozygous female. Male lethal. RK2.

**Sc<sup>2</sup>**

**origin:** X ray induced.

**discoverer:** Craymer, 1971.

**references:** 1980, DIS 55: 198.

**phenotype:** *Sc*<sup>2/+</sup> has glazed eyes, which are slightly reduced in size. Abdomen of female fails to expand with eggs; female seems to have impaired fertility. Hemizygous lethal. RK2.

**other information:** Allelism inferred from location (1-3 or 4) and phenotype.

**Sc<sup>2rv</sup>**

**origin:** Spontaneous.

**discoverer:** Craymer, 1977.

**references:** 1980, DIS 55: 199.

**phenotype:** Revertant of dominant phenotype of *Sc*<sup>2</sup>. Still recessive lethal.

*sc*: see *Scp*

*sc-Dp*: see *Dp(1,f)100*

*sc-Inh-3*: see *Su(sc)*

**sca: scabrous**

**location:** 2-66.7.

**origin:** Spontaneous.

**discoverer:** Ives, 34j2.

**references:** 1935, DIS 4: 10.

**phenotype:** Eyes large and rough. Ocellar bristles 85% absent at 25° and 10% absent at 18°. Postverticals occasionally missing. Bristle effect more extreme in male at 21° and in female at 28°. Most bristles subject to twinning. May be extra rows of acrostichal hairs. Mosaic experiments suggest that *sca* affects the spacing of R8 cells in the eye (Baker, Mlodzik, and Rubin, 1990, Science 250: 1370-77). RK1.

## alleles:

allele	origin	discoverer	ref <sup>α</sup>	comments
<b>sca</b> <sup>1</sup>	spont	Ives, 34j2	2	
<b>sca</b> <sup>2</sup>	spont	Ives, 65131	3, 4	no reduction in bristle number
<b>sca</b> <sup>dc</sup>	spont		1, 5	adds 3.5 bristles (scutellum); sternoplurals and third coxals reduced

<sup>α</sup> 1 = Frankham and Nurthen, 1980, DIS 55: 204; 2 = Ives, 1935, DIS 4: 10; 3 = Ives, 1967, DIS 42: 39; 4 = Ives, 1972, DIS 48: 16; 5 = MacBean, McKenzie, and Parsons, 1971, Theor. Appl. Genet. 41: 227-35.

**cytology:** Placed in region 49C2-D4 *Df(2R)vg*<sup>I</sup> = *Df(2R)49C2-D1;50A2-3* but not in *Df(2R)vg*<sup>B</sup> = *Df(2R)49D3-4;50A2-3* (Morgan, Bridges, and Schultz, 1938, Year Book – Carnegie Inst. Washington 37: 205).

**molecular biology:** *sca* cloned, the transcription unit identified, genomic DNA sequenced and putative amino acid sequence determined (Baker *et al*, 1990). The predicted protein of 774 amino acids appears to encode a secreted protein with similarity to the β and γ chains of fibrinogens in the carboxyl-terminal portion; also, the *sca* protein shows 39% identity to the protein encoded by a gene in the human adrenal medulla.

**scab:** see *scb*

**scal:** *scabrous like*

**location:** 2-11.7.

**origin:** Spontaneous.

**references:** Barker and Hollingdale, 1970, DIS 45: 39.

**phenotype:** Eyes rough, slightly bulging; increased numbers of abdominal and scutellar bristles; wings broad and curved with irregular L2 and posterior crossvein. Semilethal; females nearly sterile.

**scalloped:** see *sd*

**\*Scar:** *Scarred*

**location:** 2- or 3- (rearrangement).

**origin:** X ray induced.

**discoverer:** Yu, 48h.

**references:** 1949, DIS 23: 65.

**phenotype:** Eyes elliptical with indented, glassy posterior margin. Wings spread at 45° from body axis. Enhanced at 28°. Homozygous lethal. RK1A.

**cytology:** Associated with *T(2;3)Scar = T(2;3)27E;95A + In(3)91F;96A*.

**scarlet:** see *st*

**scarp:** see *scrp*

**Scarred:** see *Scar*

**scb:** *scab* (C. Nüsslein-Volhard)

**location:** 2-73.

**origin:** Induced by ethyl methanesulfonate.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

**phenotype:** Embryonic lethal. Embryos have small mid-dorsal hole with necrotic rim.

**alleles:** Four alleles *scb*<sup>1</sup> = IID; *scb*<sup>2</sup> = IIG; other two discarded.

**scd:** *sex comb distal* (J.A. Kennison)

**location:** 1-30.6.

**origin:** Spontaneous.

**discoverer:** Kennison, 1983.

**phenotype:** Exhibits 1-2 sex comb teeth on the second tarsal segment of the prothoracic leg in hemizygous males. Homozygous females viable and fertile. Interacts with *Sco* in that *scd;Sco*+/+ males have reduced viability and lack many bristles, including many of the sex comb teeth on the first tarsal segment of the prothoracic leg. Resembles description of rare *Sco* homozygotes.

**Sce:** *Sex combs extra*

**location:** 3-92.

**origin:** Induced by ethyl nitrosourea.

**references:** Breen and Duncan, 1986, Dev. Biol. 118: 442-56.

**phenotype:** A dominant enhancer of *Mcp* in the *BXC*. *Sce/Sce* zygotes from *Sce*+/+ mothers die as first instar larvae with weak posteriorly directed transformations, *i.e.*, A7 displays some A8 characteristics. Heterozygous offspring normal. *Sce/Sce* embryos from clones of homozygous oocytes produced by pole-cell transplantation display extreme posteriorly directed segmental transformation. Ventral setal belts of all abdominal and thoracic segments transformed toward A8; head involution blocked; abdominal type denticle belts also found anterior to T1 in the presumptive labial and maxillary segments; in addition an extensive belt of abdominal denticles of unknown derivation forms on the anterodorsal surface of the embryo. Keilin's organs and ventral pits suppressed in thoracic segments; wart-like sensilla normally found in A8 formed anteriorly as far as A2. Tracheal branches in A1-7 resemble those normally found more posteriorly. *Sce*+/+ offspring from homozygous germ line clones in the mothers may survive to adulthood or die as pharate adults; they show patches of tissue transformed toward A8.

**scg:** *scrambled-egg*

**location:** 3-{41}.

**references:** Berg and Spradling.

**phenotype:** Germ cell differentiation affected.

**cytology:** Located in 70C.

**\*sch:** *slender chaetae*

**location:** 1-21.1.

**origin:** Induced by D-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3026).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 90.

**phenotype:** Bristles thin and slightly shortened. Eyes slightly smaller and brownish. Body small. RK2.

**schlaff:** see *slf*

**schmal:** see *sim*

**Scm:** *Sex combs on midleg*

**location:** 3-48.5.

**phenotype:** Presumably *Scm*+/+ males form sex combs on the mesothoracic legs; does not appear to have been explicitly described. Homozygous embryos show posteriorly directed transformations; A1 resembles A2 and A2-7 transformed into more posterior segments, head and thorax normal. *Pcl Scm* double homozygotes exhibit

transformation of all segments toward A8; Keilin's organs retained in thoracic segments; head involution does not occur; prominent abdominal denticle band seen on dorsal surface of head. Homozygous embryos derived from transplanted homozygous maternal germ-cell precursors display A8 morphology in all thoracic and abdominal segments; head seems to resemble that of *Pcl Scm* double homozygotes produced by heterozygous mothers; heterozygous adults from homozygous oocytes show patchy transformations of A4 to A5 and of A6 and A7 to A8; similar transformation infrequently seen in heterozygous offspring of heterozygous mothers.

<sup>β</sup> Fuller description follows.

**cytology:** Placed in 85E1-10 based on its inclusion in *Df(3R)by62 = Df(3R)85D11-14;85F16* and *Df(3R)GB104 = Df(3R)85D11-13;85E10*, but not *Df(3R)by416 = Df(3R)85D10-12;85E1-3*.

**Scm K1**

**phenotype:** Strong dominant enhancer of the extra sex combs phenotype of *Pc* heterozygotes. Allelism to *Scm* inferred from phenotype and location.

**cytology:** Associated with *In(3R)85F;89AB*.

**\*Scn: Scutenick**

**location:** 4- [included in *Df(4)M*].

**discoverer:** Padoa, 1931.

**references:** Bridges, 1935, Biol. Zh. (Moscow) 4: 401-20. Padoa, 1938, Monit. Zool. Ital. 49: 279-84.

**phenotype:** Scutellum shortened, has nick at posterior edge; scutellar bristles missing. Ocelli reduced, has disturbed hairs and bristles. One or both eyes often small or absent. All characters overlap wild type. Eye effect is strongest at 19° but other effects weaker. Scutellum effect best at 28° but eyes normal. Homozygous lethal. Claimed by Robertson (1980, DIS 55: 130) to have been reisolated from a selection line for sternopleural-bristle number. RK2.

**cytology:** Placed in salivary chromosome region 101E through 102B16 on the basis of its inclusion in *Df(4)M = Df(4)101E-F;102B6-17*.

**Sco: Scutoid**

**location:** 2-51.0.

**origin:** X ray induced.

**discoverer:** Krivshenko, 56115.

**references:** 1959, DIS 33: 96.

1960, DIS 34: 55.

Ashburner, Tsubota, and Wooduff, 1982, Genetics 102: 401-20.

Ashburner and Harington, 1984, Chromosoma 89: 329-37.

**phenotype:** *Sco*+ flies exhibit the loss of 10-15 bristles, scutellars, notopleurals, upper humerals and anterior postalars being most frequently affected; removes both trichogen and tormogen cell derivatives. Homozygotes nearly lethal; rare homozygous or hemizygous escapers have only eight or so bristles per fly; eyes small and very rough. Escapers short lived and sterile. RK1A.

**cytology:** Associated with a pair of reciprocal transpositions that are tentatively postulated to result from a pair of inversions, one included within the other; i.e., *In(2L)34A4-5;35C5-D1 + In(2L)35B3-4;35C1-2*. Based on reversion analysis *Sco* postulated to result from the juxtaposition of *noc*<sup>+</sup> and *sna*<sup>+</sup> at the 34A5|35D1 junction.

**other information:** Numerous *Sco* revertants recovered; some are simple deficiencies and are listed under *Df(2L)Sco*, whereas others are rearrangements with a deletion for *Sco* associated with the breakpoint in 35D1-2 and are designated for example as *T(2;3)Sco*<sup>-</sup>; revertants without apparent loss of material are listed below. Breakpoints of the rearrangements indicated are superimposed on the four breakpoints of the original *Sco* chromosome; the rearrangements listed have in common a break in 35D1-2 at the proximal end of the *Sco* rearrangement.

**molecular biology:** Distal breakpoint of the *Sco* rearrangement occurs within the *noc* gene between components A and B; coordinate -107.8 from *noc* is brought to within 16 kb of *sna* by the realignment responsible for the *Sco* phenotype; the region from -107.8 to -102.3 is duplicated on opposite sides of the left-most breakpoint of the *Sco* rearrangement (McGill, Chia, Karp, and Ashburner, 1988, Genetics 119: 647-61) (coordinate 0 an *Eco*RI restriction site 1321 bp to the left of the start of transcription of the larval *Adh* transcript; positive values to the right).

**Scoop:** see *Scp*

**scooped:** see *scp*

**scooped thickvein:** see *sct*

**Scotched eye:** see *Sc*

**scp: scooped**

**location:** 1-19.3.

**discoverer:** Muller, 1926.

**phenotype:** Wings turn up slightly; classification fairly reliable. RK2.

**cytology:** Placed between 6A3-4 and 6F10-11 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book

– Carnegie Inst. Washington 41: 191).

**\*Scp: Scoop**

**location:** 3- (not located).

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Reddi.

**synonym:** *Sc* (preoccupied).

**references:** 1963, DIS 37: 53.

**phenotype:** Wing size reduced; proximal one-third of wing compressed laterally; distal two-thirds spoonlike. Three furrows run length of wing, and surface is wrinkled. Abdomen cylindrical and untapered posteriorly. Pigmented abdominal bands darkened. Excellent viability and fertility. RK3.

**\*scr: scruff**

**location:** 1-22.0.

**origin:** Spontaneous.

**discoverer:** Neel, 41b22.

**references:** 1942, DIS 16: 52.

1942, Genetics 27: 532.

**phenotype:** Hairs and bristles missing or doubled, and deranged. Eyes small and rough. Scutellum more convex than wild type. Wing margins, especially posterior, often incised. Wings occasionally blistered. All characters variable; a few flies appear normal. RK3.

**cytology:** Salivary chromosomes appear normal.

**Scr:** see **ANTC**

**scra: scraps (T. Schüpbach)**

**location:** 2 - {57}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Maternal-effect lethal. Embryos from homozygous females begin to cellularize at the blastoderm stage, but cellularization is often not completed; further development very abnormal; at final differentiation embryos form only fragmented pieces of cuticle.

**alleles:** *scra*<sup>1</sup> - *scra*<sup>6</sup> recovered as *HP*, *PB*, *PE*, *PQ*, *RS*, and *RV* respectively.

**cytology:** Placed in 42C1-43F8, since uncovered by *Df(2R)pk78s = Df(2R)42C1-7;43F5-8*.

**other information:** *scra*<sup>1</sup>, *scra*<sup>4</sup>, *scra*<sup>5</sup> are homozygous viable but lethal over the deficiency.

**scrambled-egg:** see **scg**

**scratched eyes:** see **sey**

**screw:** see **scw**

**scrp: scarp**

**location:** 2-74 (to the left of *c*; not an allele of *L*).

**origin:** Spontaneous.

**discoverer:** Hansen and Gardner, 1960.

**references:** 1962, DIS 36: 38.

1962, Genetics 47: 587-98 (fig.).

**phenotype:** Ventral one-third of eye flattened and separated from dorsal two-thirds by a furrow. Penetrance 80% at 30°; at 25°, eyes are wild type. Temperature-effective period from forty-second to sixty-eighth hour of development. RK3.

**scruff:** see **scr**

**\*sct: scooped thickvein**

**location:** 1-16.0.

**origin:** Induced by methyl methanesulfonate (CB. 1540).

**discoverer:** Fahmy, 1956.

**references:** 1960, DIS 34: 49.

**phenotype:** Wings short and scooped; inner margin frequently incised in several places; veins thickened. Eyes darker and slightly altered in shape. Abdominal tergites slightly ridged. Male sterile; viability about 40% normal. RK2?

**scute:** see **sc** under **ASC**

**scute Inhibitor on chromosome 3:** see **Su(sc)**

**Scutenick:** see **Scn**

**scutex:** see *sc*<sup>15</sup>

**Scutoid:** see **Sco**

**scw: screw**

**location:** 2-53.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *l(2)IG76*.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal; partially ventralized; cephalic furrow shifted dorsally with defects in germ band extension. Ventral denticles extended laterally; spiracles and two to three terminal segments retracted into embryo (Arora and Nüsslein-Volhard).

**alleles:** Five ethyl-methanesulfonate-induced alleles.

**cytology:** Placed in 13F (Daniels, McCarron, Love, and Chovnick, 1986, Genetics 109: 95-117) by *in situ* hybridization; in 14A by Lefevre [Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1a, p. 59].

**molecular biology:** A *P*[*ry+*] transposition into 13F associated with *sd*<sup>[*ry+*]</sup> (Daniels *et al.*, 1985) was the starting point of a 41 kb chromosomal walk. Molecular lesions associated with viable and lethal *sd* alleles were localized within a 15 kb region. Structurally related and developmentally regulated transcripts were detected in the genomic region where several *sd* lethal alleles were localized. 32 cDNA clones have been isolated from the region. Several are characterized that map across the 15 kb interval where *sd* lesions map. The strong possibility that these transcripts are products of the *sd* gene is being investigated. If true, the *sd* gene includes genomic sequences extending over at least 13 kb of the chromosomal walk described, and it appears to be subject to alternative splicing (Campbell, Duttaroy, Katzen and Chovnick, unpublished).

**sd:** scalloped

From Edith M. Wallace, unpublished.

*sd:* see *sprd*

**\*sd<sup>2</sup>**

**phenotype:** More extreme than *sd*. Wings small and scalloped. Like *vg* at high temperatures. Crossing over inhibited. RK2A?

**cytology:** Associated with *ln(1)sd*<sup>2</sup>; breakpoints unknown. No visible X-chromosome rearrangement in vicinity of 13F (Campbell, Duttaroy, Katzen, and Chovnick).

**\*sd<sup>56j</sup>**

**phenotype:** More extreme than *sd*. Expression enhanced by high temperature. Visible in prepupal wing buds. Interacts with *Bx* and *bi*. RK1.

**cytology:** No gross chromosomal abnormality.

**sd<sup>58d</sup>**

**phenotype:** Wings reduced to vestiges, like *vg*. Halteres and bristles also like *vg*. *sd*<sup>58d</sup>/*sd* has strap-shaped wing. Temperature sensitive; effects of temperature pulses at different developmental stages suggest that wing areas eliminated in a specific order (Simpson, Lawrence, and Maschat, 1981, Dev. Biol. 84: 206-11). RK2A.

**cytology:** Associated with *ln(1)sd*<sup>58d</sup> = *ln(1)11F;13F* (Campbell, Duttaroy, Katzen, and Chovnick).

**sd<sup>[ry+]</sup>**

**phenotype:** Extreme allele of *sd* associated with the insertion of a *P* element carrying *ry*<sup>+</sup> at 13F. In hemizygous males, wings reduced to mere vestiges similar to *vg*; in homozygous females the wings are narrow and strap-like. One or both scutellar bristles are sometimes truncated, and halteres appear somewhat reduced in males. Severity of wing defect may vary with temperature. Under dysgenic conditions, excision of the *P* element leads to the loss of *ry*<sup>+</sup> and amelioration of the *sd* phenotype (*i.e.*, wild type or nibbled wings); the molecular lesions of a number of such derivatives have been characterized (Daniels, McCarron, Love, and Chovnick, 1985, Genetics 109: 95-117). One derivative was used as a "tag" for cloning the *sd* region (Campbell *et al.*).

**\*sd<sup>s</sup>: scalloped-sterile**

**phenotype:** Wings divergent and slightly nicked. Male sterile. RK2.

**other information:** Allelism inferred from position and phenotype. No evidence of chromosome rearrangement.

**sd<sup>sp</sup>: scalloped-spatula**

**phenotype:** Wings cut at tips and along both margins. *sd*<sup>sp</sup> +/+ *Bx*<sup>r</sup> give slight nicking of wings. RK1A.

**cytology:** No gross rearrangement in addition to *ln(1)sc*<sup>SIL<sub>sc</sub>8R</sup> +dl-49 but possibly a local disturbance in pairing.

**sd<sup>ts</sup>**

**phenotype:** Wings vestigial-like at 29°; also capitellum of haltere extremely reduced; some crippling of legs. At 22° wings have parts of wing blade or wing margin or both missing; halteres normal. Viability and fertility good at 22°. Increases incidence of pattern duplications and deficiencies in *l(1)ts504*.

**\*sd<sup>UCI</sup>**

**phenotype:** Extreme vestigial-like wing (as in *sd*<sup>58d</sup>) with erect postscutellar bristles. Halteres greatly reduced in size. In some flies, outgrowths of tissue found on one side of the metanotum; in extreme cases, these outgrowths can be recognized as mirror-image pattern dupli-

cations of the notum and ventral hinge and reduction of the wing blade. Pupation delayed until about 168 hr after oviposition, with four days being spent as third-instar larvae. Average size of mature wing disk about 56% normal; reduction in size and pattern duplication attributable to extensive cell death in the wing imaginal disk. Wing margins of *sd<sup>UC1</sup>/Basc* females frequently incised; such females also produce significant numbers of patroclinous males. (Vyse and James, 1972, DIS 49: 39; James and Bryant, 1981, Dev. Biol. 85: 39-54).

### ***Sd*: Segregation distorter**

**location:** 2-54 (between *hk* and *pr*).

**origin:** Naturally occurring abnormality found at low levels in many natural populations.

**discoverer:** Hiraizumi.

**references:** Sandler, Hiraizumi, and Sandler, 1959, Genetics 44: 233-50.

Hartl and Hiraizumi, 1976, Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 615-66.

Ganetzky, 1977, Genetics 86: 321-55.

Brittnacher and Ganetzky, 1983, Genetics 103: 659-73.

1984, Genetics 107: 423-34.

**phenotype:** *Sd*-bearing second chromosomes are referred to as *SD*; they carry, in addition to *Sd*, other components of the segregation distortion system; they may carry inversions and recessive lethal alleles as well. The constitutions of various *SD* chromosomes are tabulated below. Other components of the segregation distortion system are *E(SD)* (Enhancer of *SD*) at the base of *2L*; and *Rsp* (Responder) at the base of *2R*; *St(SD)* (Stabilizer of *SD*) located more distally in *2R* appears to comprise several weak enhancers of distortion (Miklos, 1972, Genetics 70: 405-18). All naturally occurring *SD* chromosomes carry *Sd* and *E(SD)* but lack *Rsp* [sometimes said to carry *Rsp<sup>i</sup>* (Responder insensitive)]; most normal chromosomes carry a *Rsp* element. *SD*+/+ males transmit *SD*-bearing, to the virtual exclusion of +-bearing, homologues; as many as 99% of the functional sperm may carry *SD* (defined as  $k = .99$ ). The sex ratio of the minority class of offspring, in diverse crosses, is skewed in proportion to  $k$  in such a way as to indicate that within this class the probability of recovery of  $XY < X < Y$ -bearing  $< \text{null-X, null-Y}$  sperm (Denell, Judd, and Richardson, 1969, Genetics 61: 129-39; Denell and Miklos, 1971, Mol. Gen. Genet. 110: 167-77). Distortion by *Sd* requires heterozygosity at the *Rsp* locus; when *Rsp* is on the homologue, the *Sd*-bearing chromosome is preferentially recovered. and when *Rsp* and *Sd* are in coupling, the homologue is recovered preferentially. Extensive

electron microscopic studies of spermatogenesis (Tokuyasu, Peacock, and Hardy, 1972, Z. Zellforsch. 124: 479-506; 127: 492-525; 1977, J. Ultrastruct. Res. 48: 284-303) demonstrate that spermiogenesis of *SD*+/+ males is defective; chromatin in half of the spermatid nuclei fails to condense properly, leading in some cases to a failure of the spermatids to become individually invested in membrane, remaining syncytial instead, and in all cases to incomplete maturation of half the sperm. In addition, the transition from lysine-rich to sperm-specific arginine-rich histone, which normally occurs in late spermiogenesis, does not appear to take place in half the spermatids of *SD*+/+ males (Hauschteck-Jungen and Hartl, 1978, Genetics 101: 57-69). Temperature-sensitive period of distortion said to be in the primary spermatocyte (Mange, 1968, Genetics 58: 399-413); however, see Matthews and Mortin (1983, Canad. J. Genet. Cytol. 25: 662-67).  $k$  values also reported to increase with time of storage of sperm by females (Hartl, 1973, Genetics 74: 619-31), to decrease with the age of *SD*+/+ males (Hiraizumi and Watanabe, 1969, Genetics 63: 212-31), and to be influenced by the genotype of the female to which such males are crossed (Denell and Judd, 1969, Mol. Gen. Genet. 105: 262-74). Segregation distortion is subject to modification by numerous genetic factors throughout the genome; in addition various abnormal chromosome constitutions have been reported to reduce  $k$  values (Novitski and Erlich, 1970, DIS 45: 102; Enns, 1970, DIS 45: 136; Fowler, 1971, DIS 46: 74). Homozygous (when viable) and heteroallelic constitutions exhibit variably reduced male fertility, but the contribution of *Sd vis á vis* other components of the *SD* chromosomes involved not easily ascertainable. *SD* chromosomes without effect in females.

**cytology:** Placed in 37D2-5 based on reversions of *Sd* by  $Df(2L)Sd2 = Df(2L)37D1-2;38D2-E1$ ,  $Df(2L)Sd14 = Df(2L)37D1-2;38C1-2$ ,  $Df(2L)Sd57 = Df(2L)37D1-2;38C1-2$ , and  $Df(2L)Sd77 = Df(2L)37D1-2;38C1-2$ , but by neither  $Df(2L)hk39 = Df(2L)36F6-37A1;37D1-2$  nor  $Df(2L)pr26 = Df(2L)37D5-6;38C8-10$ , all of which were induced in *SD* chromosomes (Brittnacher and Ganetzky, 1983).

**molecular biology:** A 5 kb *Sd*-specific tandem duplication found in a restriction fragment that hybridizes at 37D5; an *Sd*-specific mRNA associated with the duplication (Powers).

**other information:** Analysis of the distribution of  $k$  values among and within genotypes by the use of probit transformation described by Miklos and Smith-White (1971, Genetics 67: 305-17) and by Miklos (1972, Genetics 70: 405-18).

**Sdh: Succinic dehydrogenase**

**location:** 2-89 [based on 199 *M(2)53-bw* recombinants].

**origin:** Identified by finding a naturally occurring isoallele that produced a slightly more temperature labile enzyme than that produced by other alleles.

**references:** Lawrence, 1981, J. Embryol. Exp. Morphol. 64: 321-32.

**phenotype:** The structural gene for succinic dehydrogenase (EC 1.3.99.1). Null mutations are homozygous lethal and lethal in heteroallelic combinations; however clones of homozygous cells survive and develop normally. Detected in clones by a cytochemical test for enzyme activity; cell autonomous with low perdurance; an excellent cell marker.

**alleles:** Mutant alleles show reduced or missing autonomous activity; some are heat sensitive.

**sdp: sandpaper**

**location:** 2-83 (based on 53 *pr-px* recombinants).

**origin:** Induced by ethyl methanesulfonate.

**references:** Garcia-Bellido and Dapena, 1974, Mol. Gen. Genet. 128: 117-30.

**phenotype:** Homozygous lethal, but survives as clones of homozygous cells; useful as a cell marker in the cuticle. Produces depigmentation and changes in trichome pattern only in tergites; extra processes per epidermal cell on tergite surface; densely packed uncombed. Not detectable in thorax.

**sdt: stardust**

**location:** 1-23.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307 (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Hypoderm almost totally absent; only small remains of cuticle found. *sdt*<sup>+</sup> function not required in female germline (Wieschaus and

Noell, 1986, Roux's Arch. Dev. Biol. 195: 63-73).

**alleles:** Six ethyl methanesulfonate-induced alleles recorded; two weak; one temperature sensitive.

**cytology:** Placed in 7D10-F2 based on its inclusion in *Df(1)RA2 = Df(1)7D10;8A45* but not *Df(1)KA14 = Df(1)7F1-2;8C6*.

**sdx: spreadex**

**location:** 1- (rearrangement).

**origin:** X ray induced.

**discoverer:** Muller.

**synonym:** *spx* (preoccupied).

**references:** 1965, DIS 40: 35.

**phenotype:** Wings spread widely apart and often directed somewhat downward, as in *Dichaete*. Abdomen of female tends to be narrow and shrunken. Fertility sufficient for maintaining homozygous stock. RK2A.

**cytology:** Associated with *In(1)sdx*; breakpoints unknown.

**se: sepia**

**location:** 3-26.0.

**phenotype:** Eye color brown at eclosion, darkening to sepia, and becoming black with age. Thought to be the structural gene for the enzyme PDA synthetase which catalyzes the conversion of 6-pyruvoyltetrahydropterin to 2-amino-4-oxo-6-acetyl-7,8-dihydro-3H,9H-pyrimido [4, 5, 6]-[1, 4] diazepine (=PDA), which is a precursor of the red drosoprotein pigments. The enzyme has been partially purified and has a molecular weight of 48,000 daltons (Wiederrecht and Brown, 1984, J. Biol. Chem. 259: 14121-27). Pigment of ocelli normal. Chromatographically, *se* eyes characterized by having no red pigment [e.g. drosoprotein and isodrosoprotein (McKay, 1972, DIS 48: 62)] and an accumulation of yellow pigment (Hadorn and Mitchell, 1951, Proc. Nat. Acad. Sci. USA 37: 650-65; Ziegler-Günder and Hadorn, 1958, Z. Vererbungslehre 89: 235-45). Three yellow pigments identified are 6- derivatives of 2-amino-4-hydroxy-7,8-

dihydropteridine; the most abundant is sepiapterin, the 6-lactyl derivative; minor species are isosepiapterin (Viscontini and Möhlmann, 1959, *Helv. Chim. Acta* 42: 836-41; Forrest, VanBaalen, and Myers, 1959, *Arch. Biochem. Biophys.* 83: 508-20) and neosepiapterin (Takikawa, 1973, *DIS* 50: 158; Sugiura, Takikawa, Tsusue, and Goto, 1973, *Bull. Chem. Soc. Jpn.* 46: 3312-13), which are the 6-propionyl and 6-acetyl derivatives respectively; the latter compound shown to be D-erythro-neopterin by Katoh and Arai (1974, *DIS* 51: 70). Other pteridines present in greater-than-normal amounts [*e.g.* isoxanthopterin II, xanthopterin I, and biopterin (McKay)]. Eye color autonomous in *se* eye disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936, *Genetics* 21: 230). *pn se* flies have 10% amount of sepiapterin of *se* alone (Lifschytz and Falk, 1969, *Genet. Res.* 14: 53-61); *dor se* displays reduced viability (Lucchesi, 1968, *Genetics* 59: 37-44). RK1.

**Segregation distorter:** see *Sd*

**seg:** *short egg*

**location:** 1- (proximal to *B*).

**synonym:** *l(1)SE*.

**references:** Wieschaus, 1978, *Symp. Soc. Dev. Biol.* 36: 23-43.

**phenotype:** Eggs of homozygous females 20% shorter and 10% wider than normal; volume and density of blastoderm nuclei unchanged. Defect in somatic tissue inferred from normal phenotype of germ-line clones (Wieschaus).

**sei:** *seizure* (J.C. Hall)

**location:** 2-106 [Ganetzky; probably a short distance (<1 m.u.) distal to this, as inferred from cytology].

**origin:** Induced by ethyl methanesulfonate.

**discoverers:** Wu and Ganetzky.

**references:** Jackson, Wilson, Strichartz, and Hall, 1984, *Nature* 308: 189-91.

Jackson, Gitschier, Strichartz, and Hall, 1985, *J. Neurosci.* 5: 1144-51.

Kasbekar, Nelson, and Hall, 1987, *Genetics* 116: 423-31.

**phenotype:** Paralyzed fairly rapidly at temperatures above 38°; adults seem to have a fit before becoming immobile, as opposed to immediately ceasing their movements;

increasing times of exposure to high temperature leads to progressively longer times necessary for recovery when temperature is lowered (Jackson *et al.*, 1985); *sei*<sup>1</sup> is recessive for heat-sensitive paralysis (Jackson *et al.*, 1985); *sei*<sup>2</sup> is semi-dominant in this respect, and behavior of hyperploid adults exhibits dose dependence: *sei*<sup>2</sup>/*sei*<sup>2</sup>/+ flies become paralyzed, at 40°, slightly less rapidly than homozygous mutants; *sei*<sup>2</sup>/+ paralyzed more slowly than *sei*<sup>2</sup>/+ but faster than wild-type (Jackson *et al.*, 1985); biochemically, head membrane extracts from *sei*<sup>2</sup> adults exhibit anomalously high K<sub>d</sub> of saxitoxin (STX) binding activity, and a different pH dependence of this activity from wild-type; these abnormalities observed when the incubations done at high, but not low, temperatures (Jackson *et al.*, 1984); in flies carrying three *sei* alleles, apparent reductions in the amounts of STX bound are observed, which are proportional to the relative number of mutant alleles (Jackson *et al.*, 1985); when these kinds of biochemical experiments are performed on head extracts from *sei*<sup>1</sup>, K<sub>d</sub> values are not appreciably different from wild-type at all assay temperatures, but the concentrations of STX binding activity are lower than wild-type under the influence of this allele, with such reductions being more marked at higher assay temperatures; recovery times, after exposure to high temperature and subsequent return to mild conditions, are shortened when *sei*<sup>2</sup> is combined with *nap*<sup>ts</sup> (Jackson *et al.*, 1985). Recordings of action potentials in the adult giant-fiber pathway reveal no decrement in *sei*<sup>2</sup> at 40° (Nelson and Baird, 1985, *Neurosci. Abstr.* 11: 313); at temperatures >40°, *sei*<sup>2</sup> causes spontaneous activity in recordings from dorsal longitudinal flight muscles, to appear coincidentally with the heat-induced paralysis (Kasbekar *et al.*, 1989); from "tight-seal whole-cell" recordings, using cultured neurons from *sei*<sup>1</sup> embryos, this mutation found to cause sodium current density to be about half-normal; yet, voltage dependence and channel-gating properties were not different from wild type (O'Dowd and Aldrich, 1988); for other aspects of *sei*-associated defects in physiology, see enhancer of seizure.

**alleles:** Two temperature sensitive alleles; *sei*<sup>1</sup> and *sei*<sup>2</sup>.

Some new ones recently isolated (Deak and Hall, 1989, *Neurosci. Abstr.* 15: 196), but not specified as to how many, the mutagenizing agent, or the allele names; certain of these, however, were found to be small deletions of the locus, which were used to generate apparently viable overlapping, *Df/Df* genotypes; these adults are paralyzed at 38°, suggesting that the null phenotype is temperature-sensitive paralytic (Deak and Hall, 1989).

**cytology:** Placed in 60A7-B10 based on its position between *Df(2R)bw-S46 = Df(2R)59D8-11;60A7* and *Df(2R)Px = Df(2R)60B8-10;60D1-2* (Jackson *et al.*, 1986; L.M. Hall, unpublished).

**other information:** Though some of the data mentioned above suggest *sei* might code for a voltage-sensitive sodium-channel component, this gene could not be colocalized with a known sodium-channel-encoding factor in 2R, which on the basis of clone and sequence plus *in situ* hybridization, maps within 60D-E (Salkoff, Butler, Wei, Scavarda, Griffen, Ifune, Goodman, and Mandel, 1987, *Science* 237: 744-749); see *NaCP*.

**sens(3)str: sensitivity (3) streptomycin**

**location:** 3-.  
**origin:** Spontaneous.  
**synonym:** *str*<sup>S</sup>.  
**references:** Duke and Glassman, 1968, Nature (London) 220: 588-89.  
**phenotype:** Homozygous larvae, but not adults, show 96% lethality when cultured on media containing 1% streptomycin, a concentration tolerated by wild type. Development of homozygotes arrested in early larval stages.

**sep: separated**

**location:** 3- (rearrangement).  
**discoverer:** Muller.  
**phenotype:** Most of posterior crossvein absent, one-third usually remaining attached to vein L5. RK2A.  
**cytology:** Associated with *In(3LR)sep = In(3LR)65D2-3;85F2-4* (Craymer, 1981, Genetics 99: 75-97).

**sepia:** see *se*

**Ser1: Serine protease 1**

**location:** 3-{101}.  
**references:** Yun and Davis, 1989, Mol. Cell. Biol. 9: 692-700.  
**phenotype:** Expressed abundantly in larval gut. Mutants *dnc*<sup>M11</sup> and *dnc*<sup>M14</sup> show lower levels of *Ser1* RNA than normal flies; levels of cAMP, however, are elevated in the mutants. The *Ser1*-related genes *Ser2* and *Ser3* (with same location and cytology) are not expressed differentially in *dnc* mutants.  
**cytology:** Located in 99C-D by *in situ* hybridization to salivaries.  
**molecular biology:** *Ser1*, *Ser2*, and *Ser3* cloned and their nucleotide and putative amino acid sequences determined (Yun and Davis, 1989); amino acid sequences homologous to serine protease enzyme family.

**sesA: stress-sensitive: A (J.C. Hall)**

**location:** 1-23.3 (Homyk).  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Homyk.  
**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.  
**phenotype:** Paralyzed briefly by mechanical shock, effected by banging a container of the flies (this barely,

or not at all, stuns wild-type flies); mutant's paralysis is accompanied by wing beating and followed by erratic movements; when stimulated to jump and fly, does so abnormally for short distances. Lethal when raised at 29°.

**sesB (J.C. Hall)**

**location:** 1-32.4 (Homyk).  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Homyk.  
**references:** Homyk and Sheppard, 1977, Genetics 87: 95-104.  
 Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

**phenotype:** *sesB*<sup>1</sup> causes adults to be extremely sensitive to mechanical shock (Homyk and Sheppard, 1977); paralysis lasts many seconds, and recovery is slow; the mutant is also generally inactive and uncoordinated; when stimulated to jump and fly, does so abnormally for short distances; when reared at 29°, after being raised at 22°, *sesB*<sup>2</sup> is not only stress-sensitive, but it also becomes debilitated after several bouts of induced to hopping and flying; in addition, *sesB*<sup>2</sup> is heat sensitive for female sterility (after rearing at low temperature).

**alleles:** Lack of complementation of lethal alleles and *sesB* alleles reported by Zhimulev, Pokholkova, Bgatov, Umbetova, Solovjeva, Khudyakov, and Belyaeva (1987, Biol. Zentralbl. 106: 699-720). Janca, Woloshyn, and Nash (1986, Genetics 112: 43-64) report lack of full complementation between *sesB*<sup>3</sup> and *l(1)9Ed* alleles.

**cytology:** Placed in 9E7-F4 based on its inclusion in the region of overlap between *Df(1)ras-P14 = Df(1)9E1-2;9F3-4* and *Df(1)v64f = Df(1)9E7-8;10A1-2* (Zhimulev *et al.*).

**sesC:** see *stn*

**sesD (J.C. Hall)**

**location:** 1-23.8 (Homyk and Pye, 1989).  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65;  
 Homyk and Pye, 1989, J. Neurogenet. 5: 37-48.  
**phenotype:** Paralyzed by mechanical shock; one allele (*sesD*<sup>2</sup>) causes constitutive inactivity, poor jumping and flying ability, abnormal landing responses, and feeble male courtship (Homyk *et al.*, 1980); this allele also leads to longer stress-induced paralysis than does *sesD*<sup>1</sup>; the latter is a heat-sensitive developmental lethal. In addition, *sesD*<sup>1</sup> is reversibly temperature sensitive for the following visual phenotype, shown by electroretinogram recordings (Homyk and Pye, 1989): at temperatures <30°, orange-light-elicited recovery from blue-induced prolonged depolarizing after potential (PDA) is slow, and

orange responses induced after recovery are aberrantly low-amplitude; at higher temperatures, orange-induced recovery from PDA involves incomplete repolarization, so that potential levels off below baseline extant before exposure to blue light; this persists even after continued orange stimulation or in the dark; under these conditions, orange light also leads to light-on and light-off ERG transient spikes with anomalously low amplitudes; these heat-induced effects are quickly reversible (to normal ERG/PDA-associated potentials) when temperature lowered to 25°.

**alleles:** Two alleles, *sesD*<sup>1</sup> and *sesD*<sup>2</sup>.

**cytology:** Maps within 7D13-14, based on assessment of ERG abnormalities of heterozygotes between *sesD*<sup>1</sup> and *Df(1)HA11 = Df(1)7D13-14;7D22*, which uncovers the defects and *Df(1)γa2 = Df(1)7D14;8A3*, which does not (Homyk and Pye, 1989).

**other information:** Complements adult-lethal-1, which maps nearby; rapid exhaustion does, too, but it maps to 7C1-3 (Homyk and Pye, 1989); mosaic analysis suggests stress-induced paralysis of legs associated with *sesD* maps to separate foci, since the individual appendages can be paralyzed independently in such gynandromorphs (Homyk, unpublished); *sesD*<sup>1</sup>'s developmental temperature-sensitive lethality originally said (Homyk *et al.*, 1980) to be caused by separate mutation on the X chromosome, but turned out not to be the case (Homyk, unpublished).

#### ***sesE* (J.C. Hall)**

**location:** 1-29.8 (Homyk).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Homyk.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

Homyk, Sinclair, Wong, and Grigliatti, 1986, Genetics 113: 367-89.

**phenotype:** Severely paralyzed by mechanical shock and also constitutively inactive; adults become hyperactive under crowded conditions (Homyk *et al.*, 1980). A heat-sensitive developmental lethal, with two temperature-sensitive periods, one primarily during second larval instar and another ranging from late third instar to early pupation (Homyk *et al.*, 1986); also an adult lethal, such that about half the flies are dead after five days exposure to 29° (Homyk *et al.*, 1986). From analysis of high-temperature-induced adult death and leg paralysis in mosaics, the foci of the former concluded to be diffuse, "domineering," and near posterior region of ventral blastoderm; regarding the behavioral phenotype, individual legs observed to be paralyzed, or not, in these gynandromorphs, and from these data it was also inferred that the paralysis foci are rather near that for lethality.

#### ***sesF* (J.C. Hall)**

**location:** 1-49.6 (Homyk).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Homyk.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

**phenotype:** Adults have small bristles and are heat-sensitive for death during development; temperature-sensitive period for lethality includes at least larval stages (Homyk); when cultures shifted to 29° after pupariation, adults eclose but are very uncoordinated (Homyk); the

originally stress-sensitive character seems to have vanished from the strain, though jumping ability of adults may still be impaired.

**cytology:** Placed in 12E1-13A5, on the basis of its inclusion in *Df(1)KA9 = Df(1)12E1;13A5* (Homyk, unpublished).

**other information:** Complements nearby *sesG* and *sesH* mutations.

#### ***sesG* (J.C. Hall)**

**location:** 1-50.8 (Homyk).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Homyk.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

**phenotype:** Flies become hyperactive when mechanically shocked, especially in crowded conditions; when in uncrowded containers, the adults tend to be inactive after coming to rest from flight.

**other information:** Complements the nearby *sesF* and *sesH* mutations.

#### ***sesH* (J.C. Hall)**

**location:** 1-51.7 (Homyk).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Homyk.

**references:** Homyk, Szidonya, and Suzuki, 1980, Mol. Gen. Genet. 177: 553-65.

**phenotype:** Briefly paralyzed after mechanical shock; during tethered flight, wing beating anomalously stops and starts again spontaneously; adults become hyperactive during various kinds of behavioral testings (*e.g.*, assessments of flying, climbing, running abilities; ability to hop when wings removed; landing responses; male tracking of, and vibration at, females).

**other information:** Complements the nearby *sesF* and *sesG* mutations.

Renfranz and Benzer, 1989, Dev. Biol. 136: 411-29.

Rubin, 1989, Cell 57: 519-20.

**phenotype:** Homozygotes and hemizygotes lack the R7 rhabdomere in all ommatidia; the R7 photoreceptor cell instead develops as an accessory lens-secreting cell, the equatorial cone cell (Tomlinson and Ready, 1986, 1987). Cell autonomous in mosaics (Harris *et al.*). Mosaic

analysis demonstrates that *sev*<sup>+</sup> product is required only in the presumptive photoreceptor 7 cell and is therefore involved in receiving signals from neighboring cells. Electroretinograms normal; defective in response to ultraviolet; in T-maze tests *sev* flies prefer visible to ultraviolet wavelengths and green light to darkness; slight preference for blue wavelengths over ultraviolet used in selecting mutant alleles (Gerresheim, 1988, Behav. Genet. 18: 227-46). In the presence of *Phb* the preference of green light to darkness is reversed for *sev*<sup>1</sup> and *sev*<sup>10</sup> but not for six other unspecified alleles; the absence of R7 is unaffected by *Phb* (Ballinger and Benzer, 1988, Proc. Nat. Acad. Sci. 85: 3960-64). Gene expression demonstrated by *in situ* hybridization and immune staining to take place in developing eye imaginal disc, near and posterior to the morphogenetic furrow, during ommatidial differentiation. Protein present transiently in at least nine cells in each developing ommatidium and is detectable before any overt differentiation of R7 observed (Tomlinson *et al.*, 1987; Banerjee *et al.*, 1987a). Transient expression of *sev*<sup>+</sup> by means of a transformed construct under control of the *Hsp70* promoter in a *sev* background results in a narrow stripe of ommatidia that contain photoreceptor cell 7 in eyes that are otherwise sevenless; the position and time of expression required for normal function are highly restricted (Bowtell, Simon, and Rubin, 1989, Cell 56: 931-36).

**cytology:** Placed in the right edge of the 10A1-2 doublet on the basis of its inclusion in *Df(1)ras-vCc8 = Df(1)9D1-2;10A2-3* but not *Df(1)sbr-K8 = Df(1)9B1-2;10A1-2* or *Df(1)v64f = Df(1)9E7-8;10A1-2* (Zhimulev, Semeshin, and Belyaeva, 1981, Chromosoma 82: 9-23).

**molecular biology:** Locus cloned by transposon tagging (Banerjee *et al.*, 1987b) and by microdissection followed by chromosome walking (Hafen *et al.*, 1987). cDNA sequencing (Hafen *et al.*, 1987; Basler and Hafen, 1988) reveals a gene with twelve exons, the first four of which are separated by long introns; exons 4-7 are short and separated by short introns; exon 8 contains the majority of the gene; exons 9-12 are again short and separated

from exon 8 and from each other by short introns. The conceptual amino-acid sequence indicates a protein of 2554 amino acids of calculated molecular weight 290 kd. Two putative membrane-spanning domains indicated-22 and 24 amino acids, beginning with residues 102 and 2124, respectively. These hydrophobic domains flank closely two short hydrophilic stretches (Basler and Hafen, 1988). The 2000 residues between the membrane-spanning domains are the extracellular domain (Bowtell, Simon, and Rubin, 1988). Transcription from right to left; produces an 8.2 kb mRNA, which is found in isolated third-instar imaginal eye discs, but not in wing discs or pre-third-instar discs, at low levels in adult heads, but not bodies, and in 5-12 h, but not 22-30 h pupae. The carboxy-terminal cytoplasmic domain shows homology with the tyrosine kinase domains of such proteins as *c-ras*, *v-src*, and the EGF receptor (Hafen *et al.*). A single amino acid substitution in the ATP-binding site of the putative kinase inactivates the gene as determined in transformation experiments (Basler and Hafen). Expression of *sev*<sup>+</sup>-β-galactosidase fusion protein confined to the apical surface of developing retina; expression not restricted to R7 cell; expressed in presumptive photoreceptor cells, cone cells, and possibly others. Protein localizes to all membrane of the apical tips and their microvilli, away from the bulk of the cell-cell contacts (Banerjee *et al.*, 1987a). 967 nucleotides of 5' promoter region capable of conferring the correct pattern but not level of *sev* expression on a *lacZ* reporter gene in some transformants. Enhancer sequences in the genomic segment comprising exons 2-7 able to confer both correct pattern and level of sevenless expression on either *sev* or heterologous promoters (Bowtell, Kimmel, Simon, and Rubin, 1989, Proc. Nat. Acad. Sci. USA 86: 6245-49). *sev* minigenes lacking introns expressed at low levels but in correct pattern (Bowtell *et al.*, 1988).

**sgg: shaggy**

**location:** 1-1.32.

**synonym:** *l(1)zw3*.

**references:** Simpson, El Messal, Moscoso del Prado, and Ripoll, 1988, Development 103: 391-401.

Ripoll, El Messal, Laran, and Simpson, 1988, Development 103: 757-67.

Simpson and Carteret, 1989, Development 106: 57-66.

Bourouis, Heitzler, El Messal, and Simpson, 1989,

Nature 341: 442-44 (fig.).

**phenotype:** Larval growth protracted, ceasing in the first [*sgg*<sup>2</sup>, *sgg*<sup>9</sup>], second [*sgg*<sup>5</sup>], or third [*sgg*<sup>3</sup> and *sgg*<sup>10</sup>] larval instar; death follows. *sgg*<sup>10</sup> may survive to puparium formation. Mutant cuticle tissue survives only in tergites; lacks bristles and appears etched; some deformed mutant wing tissue also observed in *sgg*<sup>3</sup>. *sgg*<sup>3</sup>, but no other allele produces viable and fertile males in combination with *Dp(1;4)w<sup>m65g</sup>* (Shannon, Kaufman, Shen, and Judd, 1972, Genetics 72: 615-38). *sgg*<sup>1</sup> and *sgg*<sup>10</sup> males exhibiting maternal-zygotic interaction with *Dp(1;4)mg* display deletion-mirror-image duplication homeotic transformation (eye-antenna, wing, and leg discs) (Robbins, 1983, Genetics 103: 633-48). Same noted in male tissue of gynandromorphs (Kaufman), *sgg*<sup>9</sup>, and *sgg*<sup>10</sup> (García-Bellido and Robbins, 1983, Genetics 103: 235-47). More recent studies with *sgg*<sup>32</sup>, an amorphic allele, (Bourouis *et al.*; Ripoll *et al.*; Simpson *et al.*; Simpson and Carteret) indicate that *sgg* is involved in the developmental choice between the epidermal pathway and that of the nervous system. In homozygous clones of *sgg*<sup>32</sup> formed 48 h or more before puparium formation all trichomes are replaced by chaetae in the ratio of one chaeta to four trichomes reflecting the number of cells involved in the elaboration of each structure; chaetae formed conform to positional information and genotype; *e.g.*, wing clones resemble dorsal or ventral costal bristles or triple or double row bristles depending on their position; clones are linear when near the margins and form clumps of chaetae when distant from the margins; adventitious veins often formed in association with wing clones. In the notum scutellar clones form macrochaetae in + but not *sc* genotypes and microchaetae in *h* but not + genotypes. Clones formed later than 48 h before puparium formation form trichomes, either more densely than normal (10-21 trichomes) or in normal density (up to 10 trichomes). *sgg* embryos from homozygous *sgg* female germ line cells exhibit delayed and disordered cellularization at blastoderm; gastrulation does not occur; no differentiation of ectoderm, mesoderm, or endoderm occurs; cell division continues and the embryo becomes filled with small round cells, most or all of which stain with neuronal-specific antibodies. *sgg*<sup>+</sup> embryos from *sgg* female germinal tissue show nearly normal blastoderm formation and gastrulation; however they are short with complete cuticles and neural hyperplasia as seen in neurogenic mutants; a lawn of hairs is seen dorsally, and ventrally most of the denticle belts are lacking. Two doses of *sgg*<sup>+</sup> in such embryos lead to more nearly normal cuticular development, but with odd-numbered denticle bands appearing before even-numbered ones. *sgg* progeny of females that carry *sgg*<sup>+</sup> in their germ lines die as defective larvae with underdeveloped central nervous systems; the degree of CNS development is positively correlated with the number of maternal doses of *sgg*<sup>+</sup>.

<sup>β</sup> MZI = maternal-zygotic interaction; demonstrated in males carrying mutant allele from heterozygous mother and variegating allele on a paternally derived duplication (Robbins, 1983, Genetics 103: 663-48).

<sup>γ</sup> Spontaneous in the paternal X chromosome of a cross between wild-type males and *mei9* females, such that the F1 females were *sgg/mei9*.

**cytology:** Placed in 3B1 based on its inclusion in *Df(1)64fl* = *Df(1)3A9-B1;3B2-3* but not *Df(1)62d18* = *Df(1)3B1-2;3C6-7*.

**molecular biology:** Cloning and sequencing indicates gene product to be homologous to serine-threonine proteases (Siegfried, Perkins, Capaci, and Perrimon, 1990, Nature 345: 825-29).

### **Sgs: Salivary gland secretion proteins**

A group of seven genes encoding proteins that are components of the secretion produced by the larval salivary glands during the third instar for the purpose of attaching the larva to the substrate preparative to pupariation. Initiation of transcription of these genes is coincident with the formation of the intermolt puffs in early to mid third instar (Korge, 1975, Proc. Nat. Acad. Sci. USA 72: 4550-54). The genes colocalize with the most prominent intermolt puffs. Synthesis of the glue proteins begins about 106 h after egg deposition and ceases abruptly within a few minutes after the glue is released 14 h later (Beckendorf and Kafatos, 1976, Cell 9: 365-73). Initiation of transcription, but not of intermolt-puff formation seems to depend on the presence of suitable levels of ecdysterone in early third instar larvae (Hansson and Lambertsson, 1983, Mol. Gen. Genet. 192: 395-401). The subsequent cessation of transcription and puff

regression also ecdysterone dependent (Crowley and Meyerowitz, 1984, Dev. Biol. 102: 110-21). Loci designated *Sgs1* and *Sgs3* through *Sgs8* in order of increasing electrophoretic mobility, except that *Sgs6* is out of order.

### **Sgs1**

**location:** 2-13.9 (based on 64 *dp-cl* recombinants).

**references:** Velissariou and Ashburner, 1980, Chromosoma 77: 13-27.

**phenotype:** Structural gene for the most slowly migrating of the salivary-gland glue proteins, SGS1 (Zhimulev and Kolesnikov, 1975, Wilhelm Roux's Arch. Entwicklungsmech. Org. 178: 15-28).

**alleles:** Nine electrophoretic variants designated *Sgs1<sup>a</sup>* through *Sgs1<sup>i</sup>*; no naturally occurring null alleles recorded.

**cytology:** Placed in region 25A2-D2 based on increased product in salivary glands of larvae carrying the duplication produced by combining elements of *T(Y;2;4)J96* = *T(Y;2;4)25A2-3* and *T(Y;2)D110* = *T(Y;2)25D1-2*. Associated with the intermolt puff in 25B3-7, which comes up coincidentally with the other glue-protein puffs.

### **Sgs3**

**location:** 3-35.0 (based on 100 *se-ri* recombinants; Kokoza, Kazakova, Karakin, 1982, DIS 58: 94-95).

**references:** Korge, 1975, Proc. Nat. Acad. Sci. USA 72: 4550-54.

Akam, Roberts, Richards, and Ashburner, 1978, Cell 13: 215-25.

Meyerowitz and Hogness, 1982, Cell 28: 165-76.

Garfinkle, Pruitt, and Meyerowitz, 1983, J. Mol. Biol. 168: 765-89.

**phenotype:** The structural gene for glue protein, SGS3. Dependence of initiation and cessation of *Sgs3* expression on ecdysterone levels studied by Crowley and Meyerowitz (1984, Dev. Biol. 102: 110-21). Expression of *Sgs3* as well as *Sgs7* and *Sgs8* does not take place in the presence of the nonpupariating lethal mutation, *npr*, which is a member of the Broad Complex, *BRC*; expression cannot be rescued by the administration of ecdysterone; *npr* does not inhibit formation of intermolt puff 67C, thus dissociating transcription from puff formation (Crowley, Mathers, and Meyerowitz, 1984, Cell 39: 149-56).

**alleles:** Four electrophoretic variants designated *Sgs3<sup>a</sup>* through *Sgs3<sup>d</sup>* identified by Akam *et al.*. In addition the allele from the Formosa wild strain produces a smaller polypeptide than other alleles.

**cytology:** Placed in 68C3-5 by in situ hybridization; associated with intermolt puff at 68C (Korge; Akam *et al.*).

**molecular biology:** Sequence recovered as a third-instar-salivary-gland-specific cDNA (Wolfner, 1980, PhD thesis, Stanford University). Hybridizes to an mRNA 1120 nucleotides in length (in Oregon R; smaller in some other strains; *e.g.*, Formosa). Nucleotide sequence and conceptual amino acid sequence of translation product of cDNA clone determined by Garfinkle *et al.*; 6751 nucleotides of genomic DNA, containing the coding sequences of the cluster, *Sgs3*, *Sgs7*, and *Sgs8*, were sequenced; The sequence encoding *Sgs3* extends from approximately nucleotide 4457 to 5646, with an intervening sequence of 73 nucleotides from nucleotides 4514 to 4586, between the first and second nucleotides of codon 10. The conceptual amino-acid sequence comprises three domains;

the first 23 amino acids are rich in hydrophobic residues and constitute a signal peptide which is removed from the mature polypeptide; the next 234 amino acids contain an amino terminal 49 amino acids of threonine-rich sequences followed by 185 amino acids that are composed entirely of 37 tandem repeats of minor variants of a five amino acid unit (basic unit = Pro-Thr-Thr-Thr-Lys); twenty of these repeats are deleted in the Formosa wild-type allele (Metzling, Bourouis, and Richards, 1985, Mol. Gen. Genet. 201: 265-68); the carboxy-terminal fifty amino acids of SGS3 are similar to those found in SGS7 and SGS8. *i.e.*, 19 identities including eight cysteines. The SGS3 polypeptide is heavily glycosylated (Beckendorf and Kafatos, 1976, Cell 9: 365-73), probably on the threonine residues (Garfinkle *et.al.*). Transformation experiments show that as little as 2.3 kb of 5' plus 1.1 kb of 3' sequence is sufficient for normal regulation of *Sgs3* expression (Crosby and Meyerowitz, 1986, Dev. Biol. 118: 593-607); 980 base pairs of 5' sequence allow for appropriate stage and tissue specificity of expression, but the levels of expression are greatly reduced; 27 5' base pairs are insufficient for *Sgs3* expression (Bourouis and Richards, 1985, Cell 40: 349-57). Finally, functional *Sgs7 Sgs8 Sgs3* inserts may form ectopic intermolt puffs, but they need not, thus separating puff formation from *Sgs* expression (Crosby and Meyerowitz).

### Sgs4

**location:** 1-3.0 (based on 97 *w<sup>a</sup>-rb* recombinants; Kokoza, Kazakova, and Karakin, 1982, DIS 58: 94-95).

**references:** Korge, 1977, Chromosoma 62: 155-74.

**phenotype:** Encodes the salivary-gland glue protein, SGS4; this protein not required for viability, since non producers eclose normally; it varies in size owing to a variable number of copies of a heptapeptide repeat in an N-terminal tandem array. Expression of the virtually inactive allele, *Sgs4<sup>H</sup>* increased four fold in trans heterozygotes with the normally active allele, *Sgs4<sup>OR</sup>*, and nine fold with a tandem duplication [*Dp(1;1)Co*] containing two copies of a normally active allele; neither *Sgs4<sup>H</sup>/Sgs4<sup>Ber</sup>* nor *Sgs4<sup>Ber</sup>/Sgs4<sup>OR</sup>* exhibits enhanced activity; enhancement decreased by disruption in pairing, *e.g.*, in *Sgs4<sup>H</sup>/FM6* (Kornher and Brutlag, 1986, Cell 44: 879-83).

**alleles:** So-called electrophoretic alleles, which are probably size variants, have been designated *Sgs4<sup>a</sup>*, *Sgs4<sup>b</sup>*, *Sgs4<sup>c</sup>*, and *Sgs4<sup>d</sup>* (see Korge, 1977); the correspondence between these designations and those tabulated below is not available.

allele	origin	ref <sup>α</sup>	express- ion (%) <sup>β</sup>	repeat number <sup>γ</sup>	5' sequences <sup>δ</sup>

<i>Sgs4<sup>OR</sup></i>	Oregon-R	2	100	19	
<i>Sgs4<sup>S</sup></i>	Seto	2	~2	28	-356 to -305 deleted
<i>Sgs4<sup>U</sup></i>	Urbana	2	100	27	

<sup>α</sup> 1 = McGinnis, Shermoen, Heemskirk, and Beckendorf, 1983, Proc. Nat. Acad. Sci. USA 80: 1063-67; 2 = Muskavitch and Hogness,

1980, Cell 29: 1041-51.

<sup>β</sup> mRNA level compared to Oregon-R.

<sup>γ</sup> The number of 21-base-pair repeats about 100 nucleotides downstream from the 5' end of coding sequence = seven-amino-acid tandem repeats near the amino-terminal end of polypeptide.

<sup>δ</sup> Comparison of upstream sequences with those of Oregon R; nucleotide 1 is the first base transcribed, the first T of an *EcoRI* restriction site.

**cytology:** Placed in 3C11-12 based on its inclusion in *Df(1)N-69h9* = *Df(1)3C6;3D1* but not *Df(1)N-5419* = *Df(1)3C5-6;3C10-11*; activity associated with formation of intermolt puff in same bands (Korge, 1977, Chromosoma 62: 155-74).

**molecular biology:** *Sgs4* resides within the first intron of *dnc* (Chen, Malone, Beckendorf, and Davis, 1984, Nature 329: 721-24). Transcription is from left to right. The entire *Sgs4* region cloned and the gene and its flanking regions sequenced (Muskavitch and Hogness, 1980, Proc. Nat. Acad. Sci. USA 77: 7362-66; 1982, Cell 29: 1041-51); gene contains no introns and is characterized by a tandem array of 21-base-pair repeats occupying the 5' 45% of the sequence. The repeating unit appears to be (Arg or Thr)-Cys-(Glu, Lys, or Arg)-Thr-Glu-Pro-Pro. The number of repeats is uncorrelated with gene activity; rather regions some 300 to 500 base pairs upstream of the start of transcription are abnormal or deleted in alleles with little or no activity. Fifteen transpositions of *Sgs4* with 2.6 kb of 5' and 1.3 kb of 3' sequences display normal expression with respect to quantity, stage and tissue specificity, and dosage compensation but not puff formation (Krumm, Roth, and Korge, 1985, Proc. Nat. Acad. Sci. USA 82: 5055-59); reduction of the 5' flanking sequences to -840 but not to -392 retains normal regulation (McNabb and Beckendorf, 1986, EMBO J. 5: 2331-40).

### Sgs5

**location:** 3- {60}.

**references:** Guild, 1984, Dev. Biol. 102: 462-70.

Guild and Shore, 1984, J. Mol. Biol. 179: 289-314.

Shore and Guild, 1986, J. Mol. Biol. 190: 149-58.

Shore and Guild, 1987 Genes Dev. 1: 829-39.

**phenotype:** The structural gene for the salivary-gland glue protein, SGS5, a polypeptide of 163 amino-acid residues, 13% of which are serine and threonine. SGS5 lightly glycosylated (Beckendorf and Kafatos, 1976, Cell 9: 365-73). The first 18 amino acids are highly hydrophobic as expected for a signal peptide.

**cytology:** Located in 90B3-8 by *in situ* hybridization; associated with the intermolt puff at 90B (Wolfner, 1980, PhD Thesis, Stanford University, Stanford, CA).

**alleles:** One null allele, *Sgs5<sup>nl</sup>*, found in a strain designated C2 from Wallace.

**molecular biology:** Genomic clone isolated; 1 kb including the *Sgs5* transcription unit sequenced; extends from nucleotide -173 to +839, with the transcribed region beginning at +1 and ending at the site of poly(A) addition at +769. Upstream sequences resemble those of other *Sgs* genes; information necessary for *Sgs5* expression contained within 109 base pairs upstream and 69 base pairs downstream of the transcribed region. Two introns, one extending from +302 to +357 and the other from +547 to +605; both introns interrupt a proline codon after the first nucleotide. *Sgs5<sup>nl</sup>* differs from wild type in seven base-pair substitutions between nucleotides -84 and

+75.

**Sgs6****location:** 3-42.0 (based on 42 *h-th* recombinants).**references:** Velissariou and Ashburner, 1981, Chromosoma 84: 173-85.**phenotype:** A component of the glue-protein mixture that is not present in all stocks. Electrophoretic mobility between that of SGS1 and SGS3, close to SGS3.**cytology:** Placed in 71C1-F5 based on dosage studies with segmental aneuploids involving  $T(Y;3)A60 = T(Y;3)71C1-2$  and  $T(Y;3)B99 = T(Y;3)71F3-5$ . Associated with intermolt puff at 71C3-4, which is absent in flies lacking SGS6.**Sgs7****location:** 3-35.0.**references:** Crowley, Bond, and Meyerowitz, 1983, Mol. Cell. Biol. 3: 623-34.**phenotype:** Encodes the 5481 kd salivary-gland glue protein, SGS7; the protein contains, in common with SGS3 and SGS8, a 23-residue amino-terminal signal peptide and a carboxy-terminal region of about 50 amino acids that shows considerable homology with that of SGS3 and SGS8; it is not glycosylated. Expressed coordinately with *Sgs3* and *Sgs8*.**cytology:** Placed in 68E3-5 by *in situ* hybridization.**molecular biology:** Cloned by Meyerowitz and Hogness (1982, Cell 28: 165-76); located approximately 2 kb distal to *Sgs3* and 500 base pairs to the right of *Sgs8*; transcribed from left to right, as is *Sgs3*. Has a small intervening sequence between the first and second bases of the tenth codon; mRNA contains 320 nucleotides. Expression absent in *su(f)<sup>ts67g</sup>* (rescuable by administration of ecdysterone) (Hansson and Lambertsson, 1983, Mol. Gen. Genet. 192: 395-401) and in *npr* flies (not rescued by ecdysterone) (Crowley, Mathers, and Meyerowitz, 1984, Cell 39: 149-56).**Sgs8****location:** 3-35.0.**references:** Crowley, Bond, and Meyerowitz, 1983, Mol. Cell. Biol. 3: 623-34.**phenotype:** Encodes the 5592 kd salivary-gland glue protein, SGS7; the protein contains, in common with SGS3 and SGS7, a 23-residue amino-terminal signal peptide and a carboxy-terminal region of about 50 amino acids that shows considerable homology with that of SGS3 and SGS8; it is not glycosylated. Expressed coordinately with *Sgs3* and *Sgs7*.**cytology:** Placed in 68E3-5 by *in situ* hybridization.**molecular biology:** Cloned by Meyerowitz and Hogness (1982, Cell 28: 165-76); located approximately 500 base pairs to the left of *Sgs7*; transcribed from right to left from the opposite strand transcribed by *Sgs7*. Has a small intervening sequence between the first and second bases of the tenth codon; mRNA contains 360 nucleotides. Expression absent in *su(f)<sup>ts67g</sup>* (rescuable by administration of ecdysterone) (Hansson and Lambertsson, 1983, Mol. Gen. Genet. 192: 395-401) and in *npr* flies (not rescued by ecdysterone) (Crowley, Mathers, and Meyerowitz, 1984, Cell 39: 149-56).**Sgs9****location:** 3-60.8 (based on eight *bx-sr* recombinants).**synonym:** *GP5*.**references:** Hoshizaki, Dlott, Joslyn, and Beckendorf, 1987, Genet. Res. 49: 111-19.**phenotype:** Controls the quantity of SGS9 (P5 of Beckendorf and Kafatos, 1976, Cell 9: 365-73), which migrates ahead of SGS5 in SDS polyacrylamide gel electrophoresis. Not demonstrated to encode SGS9. Protein levels inordinately sensitive to background genotype.**alleles:** A null allele exists in a stock labeled Stromsvreten 10; used in mapping experiments.**cytology:** Genetic mapping places it close to *Sgs5* and the intermolt puff at 90 B-C.**sh: short winged****location:** 3-56.**origin:** Spontaneous.**discoverer:** Bridges, 23d3.**synonym:** *short wing*.**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 235. 1935, DIS 3: 16.**phenotype:** Wings small; similar to *dy*. Appears to be epistatic to *vg* in that *vg sh* flies have *sh* phenotype; by same argument *px* epistatic to *sh* (Rudy and Duffy, 1972, J. Hered. 62: 387-88). RK2.**\*sh-5: short-5****location:** 3-93.2 (Koliantz, 1969, DIS 44: 52).**origin:** Spontaneous.**discoverer:** Spencer, 26j.**references:** 1934, DIS 1: 35.

1935, Am. Naturalist 69: 223-38.

**phenotype:** Wing veins L5 and L3 short and do not reach wing margin. Expression variable; overlaps wild type. RK3.**Sh: Shaker (M. Tanouye)****location:** 1-57.6.**origin:** X ray induced.**discoverer:** Catsch, 1944.**references:** Catsch, 1944, Z. Indukt. Abstamm. Vererbungslehre 82: 64-66.

Trout and Kaplan, 1973, J. Neurobiol. 4: 495-512.

Jan, Jan, and Dennis, 1977, Proc. R. Soc. London Ser. B 198: 87-108.

Tanouye, Ferrus, and Fujita, 1981, Proc. Nat. Acad. Sci. USA 78: 6548-52.

Salkoff and Wyman, 1981, Nature (London) 293: 228-30.

Tanouye, Kamb, Iverson, and Salkoff, 1986, Ann. Rev. Neurosci. 9: 255-76.

**phenotype:** Under moderate ether anesthesia, legs shake abnormally, antennae twitch, abdomen pulsates; wings scissor in some alleles; very little effect in deeply etherized flies; unetherized mutants twitch and shudder occasionally; severed legs shake (Kaplan and Trout, 1969, Genetics 61: 399-409; Trout and Kaplan, 1973; Tanouye, Ferrus, and Fujita, 1981; Ganetzky and Wu, 1982a, Genetics 100: 597-614; Tanouye and Ferrus, 1985, J. Neurogenet. 2: 253-71). Structural gene for several types of potassium channel (Iverson, Tanouye, Lester, Davidson, and Rudy, 1988, Proc. Nat. Acad. Sci. USA 85: 5723-27; Timpe, Schwarz, Tempel, Papazian,

Jan, and Jan, 1988, *Nature* 331: 143-45). Abnormal action potential repolarization of adult giant fiber; repetitive firing of action potentials in larval nerves; prolonged transmitter release at larval neuromuscular junction (Jan, Jan, and Dennis, 1977; Tanouye, Ferrus, and Fujita, 1981; Ganetzky and Wu, 1982b, *J. Neurophysiol.* 47: 501-14; Tanouye and Ferrus, 1985). Abnormal in one class of potassium channel (A channel) present in embryonic myocytes, larval and pupal muscle (Salkoff and Wyman, 1981; Salkoff, 1983, Cold Spring Harbor Symp. Quant. Biol. 48: 221-31; Wu and Haugland, 1985, *J. Neurosci.* 5: 2626-40; Timpe and Jan, 1987, *J. Neurosci.* 7: 1307-17; Haugland and Wu, 1990, *J. Neurosci.*). *Sh* mutations do not affect four other distinct potassium-channel types ( $K_D$ ,  $K_1$ ,  $A_2$ , Calcium-gated) (Salkoff and Wyman, 1981; Salkoff, 1983, *Nature* 302: 249-51; Wu, Ganetzky, Haugland, and Liu, 1983, *Science* 220: 1076-78; Solc, Zagotta, and Aldrich, 1987, *Science* 236: 1094-98; Solc and Aldrich, 1988, *J. Neurosci.* 8: 2556-70). Males carrying hemizygous deletions of *Sh* are viable (Tanouye, Ferrus, and Fujita, 1981). Abnormal associative learning in some paradigms (Tully); activity patterns high, but show normal circadian rhythmicity (Konopka). RK1.

Neurosci.* 7: 1307-17; 14 = Wu and Haugland, 1985, *J. Neurosci.* 5: 2626-40.

<sup>β</sup> *Sh* phenotype has been assessed in four ways: (a) abnormal leg shaking under ether anesthesia; (b) abnormal A-type potassium currents in larval muscle and/or pupal flight muscle; (c) abnormal action potentials in the adult cervical giant fiber; and (d) abnormal synaptic transmission at the larval neuromuscular junction and multiple firing of larval motoneurons. Numbers above indicate the tests that have been performed on each allele: 1 = a; 2 = a + b; 3 = a + b + c; and 4 = a + b + c + d. All tests performed produced mutant results.

**cytology:** Located in 16F1-8 (Tanouye, Ferrus, and Fujita, 1981). Associated with *T(1;Y)B55 = T(1;Y)16F1-4*, with *T(1;3)Sh15 = T(1;3)16F1-2;80*, and with *T(1;Y)W32 = T(1;Y)16F3-6*; covered by *Dp(1;3)16E2-4;17A-B,99D*.

**molecular biology:** Structural gene for a potassium channel cloned by chromosomal walking; large transcription unit spans >110 kb of chromosomal DNA with multiple transcripts generated by differential splicing; at least twelve different transcripts formed from at least 25 different exons; all transcripts contain a conserved central portion (863 bp) built from six common exons; the transcripts contain variable 5' and 3' domains; Northern blots show a heterogeneous pattern of transcripts with a broad band of 5.5-6.5 kb and major bands at 7.8, 8.5, and 9.5 kb (Kamb, Iverson, and Tanouye, 1987, *Cell* 50: 405-13; Baumann, Krah-Jentgens, Mueller, Mueller-Holtkamp, Seidel, Kecskemethy, Casal, Ferrus, and Pongs, 1987, *EMBO J.* 6: 3419-29; Papazian, Schwarz, Tempel, Jan, and Jan, 1987, *Science* 237: 749-53; Tempel, Papazian, Schwarz, Jan, and Jan, 1987, *Science* 237: 770-75; Kamb, Tseng-Crank, and Tanouye, 1988, *Neuron* 1: 421-30; Pongs, Kecskemethy, Muller, Krah-Jentgens, Baumann, Kiltz, Canal, Llamazares, and Ferrus, 1988, *EMBO J.* 7: 1087-97; Schwarz, Tempel, Papazian, Jan, and Jan, 1988, *Nature (London)* 331: 137-42).

Two forms of gene product are deduced: a small-protein form with three hydrophobic segments has unknown function; a larger form with six potential membrane-spanning segments has potassium channel function as demonstrated electrophysiologically by expression in *Xenopus* oocytes, mammalian cell lines, and insect cell lines; at least six different transcript variants express potassium channels with different physiological properties; the channel may be a tetramer formed from four *Sh* subunits; a heteromultimer may be indicated from results on heterozygous combinations and coinjections into *Xenopus* oocytes; conserved region may be responsible for voltage dependence of activation, voltage dependence of inactivation, potassium selectivity, and toxin sensitivity which are similar among all products; variable amino termini are responsible for different potassium channel inactivation rates; variable carboxyl termini are responsible for differences in inactivation recovery rates; a current loss in myotubes may be rescued by germline transformation (Iverson, Tanouye, Lester, Davidson, and Rudy, 1988; Timpe, Schwarz, Tempel, Papazian, Jan, and Jan, 1988; Timpe, Jan, and Jan, 1988, *Neuron* 1: 659-67; Leonard, Karschin, Jayashree-Aiyar, Davidson, Tanouye, Thomas, Thomas, and Lester, 1989, *Proc. Nat. Acad. Sci. USA* 86: 7629-33; Zagotta, Gerneraad, Garber, and Aldrich, 1989, *Soc. Neurosci. Abstracts* 15: 338; Iverson and Rudy, 1990, *J. Neurosci.*; Wu and Haugland, 1990; Iverson and Rudy; Stuhmer; Isakoff; Miller).

An S4 motif, consisting of 7 repeats of the triplet, R-X-X, where R is sometimes replaced by K, and X is a

hydrophobic residue, is present in all *Sh* channels and is highly conserved in virtually all other known voltage-gated ion channels; mutagenesis of S4 results in alterations of voltage sensitivity; the motif is thought to be a voltage-sensor (Tempel, Papazian, Schwarz, Jan, and Jan, 1987; Kamb, Tseng-Crank, and Tanouye, 1988; Pongs, Kecskemethy, Muller, Krah-Jentgens, Baumann, Kiltz, Canal, Llamazares, and Ferrus, 1988; Papazian, Timpe, Jan, and Jan, 1989, Soc. Neurosci. Abstracts 15: 337). A leucine-heptad repeat located adjacent to the S4 motif may participate in the channel gate; mutagenesis causes alterations in voltage sensitivity and subunit interactions (McCormack, Campanelli, Ramaswami, Mathew, Tanouye, Iverson, and Rudy, 1989, Nature 340: 103; McCormack, Ramaswami, Mathew, Tanouye, Iverson, McCormack, Rudy, 1989, Soc. Neurosci. Abstracts 15: 337).

A truncated product that acts as an antimorph is associated with *Sh*<sup>7</sup>; an amino acid substitution is associated with the *Sh*<sup>14</sup> product, which acts as an antimorph; an amino acid substitution in the leucine-heptad repeat motif is associated with the *Sh*<sup>5</sup> product; an alteration of a splice site is associated with the *Sh*<sup>9</sup> mutation; *Sh*<sup>16</sup> contains an insertion into coding sequence (Kamb, Iverson, Tanouye, 1983; Gisselmann, Sewing, Madsen, Mallart, Angaut-Petit, Mueller-Holtkamp, Ferrus, and Pongs, 1989, EMBO J. 8: 2359-64; Pongs; Gautam and Tanouye). The *Sh* product is highly homologous to three other potassium channel genes: *Shab*, *Shal*, and *Shaw*, isolated by DNA crosshybridization using *Sh* probes (Butler, Wei, Baker, and Salkoff, 1989, Science 243: 943-47).

Tissue *in situ* hybridization shows *Sh* transcript in the cell bodies of retina, optic lobe, central brain, thoracic ganglion, and muscle; antibody studies show a major polypeptide of about 70-80 kd; differential temporal and spatial expression may be indicated (Pongs, Kecskemethy, Muller, Krah-Jentgens, Baumann, Kiltz, Canal, Llamazares, and Ferrus, 1988; Tseng-Crank and Tanouye; Schwarz, Papazian, Carretto, Jan, and Jan, 1988, Soc. Neurosci. Abstracts 14: 454).

<sup>α</sup> Locations are relative to the *Sh* chromosomal walk in kb (Kamb, Iverson, and Tanouye, 1987). Amino acid changes are relative to the deduced H37 protein (Kamb, Tseng-Crank, and Tanouye, 1988).

<sup>β</sup> 1 = Gautam and Tanouye; 2 = Pongs; 3 = Gisselmann, Sewing, Madsen, Mallart, Angaut-Petit, Muller-Holtkamp, Ferrus, and Pongs, 1989, EMBO J. 8: 2359-64; 4 = Papazian, Schwarz, Tempel, Jan, and Jan, 1987, Science 237: 749-53; 5 = Kamb, Iverson, and Tanouye, 1987, Cell 50: 405-13; 6 = Baumann, Krah-Jentgens, Mueller, Mueller-Holtkamp, Seidel, Kecskemethy, Casal, Ferrus, and Pongs, 1987, EMBO J. 6: 3419-29.

**other information:** Some *Sh* phenotypes are suppressed by *nap* and *para* alleles; *i.e.*, in double mutant combinations,

abnormal leg-shaking, repetitive firing of larval action potentials, and transmitter release at larval neuromuscular junction are nearly normal; the interactions are not allele-specific (Ganetzky and Wu, 1982a,b). Some *Sh* phenotypes are enhanced by *eag*; *i.e.*, in double mutant combinations, abnormal leg-shaking, repetitive firing of larval action potentials, and transmitter release are more extreme; also, adults have down-turned wings, and dented-in thoraces at the sites of the dorsal longitudinal muscle insertions; the interactions are not allele-specific (Ganetzky and Wu, 1983, J. Neurogenet. 1: 17-28). Some *Sh* phenotypes are enhanced by *dnc*; *i.e.*, in double mutant combinations, abnormal leg-shaking is more extreme; abnormal spontaneous activity is seen in the giant fiber (Ferrus and Tanouye). The breakpoint of *T(1;3)B27 = T(1;3)16E3-5;36D-F*, induced in a *Sh*<sup>14</sup> background, causes an alteration in the pattern of leg-shaking (Tanouye and Ferrus).

**sha: shavenoid**

**location:** 2-62.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82. Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Trichomes missing or very short. Flies cannot fly or walk on glass. In larvae, the number of denticles is reduced with remaining denticles thin and bent. Hairs are largely absent, but sensory hairs not affected. Autonomous in nuclear transplants. Causes disoriented and abbreviated hairs on larval cuticle; useful as a larval-cuticle marker (Struhl and Lawrence, 1982, Cell 31: 285-92).

**alleles:** *sha*<sup>1</sup> and *sha*<sup>2</sup> (originally designated *IN* and *IIP*) plus two discarded alleles.

**cytology:** Placed in 47E3-48A6 based on its location in the area of overlap between *Df(2R)en-A = Df(2R)47D3; 48A5-6* and *Df(2R)en-B = Df(2R)47E3;48B2*.

**Shab: Shaker cognate b (J.C. Hall)**

**location:** 3- {15}.

**origin:** Isolated by screening a cDNA library with a *Sh* cDNA probe.

**references:** Butler, Wei, Baker, and Salkoff, 1989, Science 243: 943-47.

**cytology:** Mapped to 63A by *in situ* hybridization.

**phenotype:** Expression in *Xenopus* oocytes reveals a delayed-rectifier type of potassium current expressed by *Shab*; the rate of current activation in *Shab* is somewhat faster than in *Shaw*.

**molecular biology:** Isolated by screening a cDNA library with a *Sh* cDNA probe containing all of the presumptive membrane-spanning domains, which form the core of the potassium channel proteins encoded by *Sh*, and which thus very likely characterize the *Shab* gene product as well. Sequencing of six *Shab* cDNAs identifies alternatively spliced mRNAs from this locus; this involves, at least in part, the coding portion of the gene (*e.g.*, one cDNA contains an additional exon not found in two others). Sequencing data reveal, in addition to homologies to *Sh*, as expected, homologies to two other *Sh*-type genes, *Shaw* and *Shal*. Similarities among products of these four genes are greater than those between *D. melanogaster*'s *Sh* gene family and sodium or calcium channel proteins. *Shab* shares opa (poly-Gln) repeats with some of the alternatively spliced *Sh* products (rela-

tively near N- and C-termini of the respective proteins), and there are possible cAMP-dependent phosphorylation sites in one of the corresponding regions of the two gene products (C-terminal to the intramembrane portions of the proteins); in *Shab*, but not *Shaw* conceptual protein, there is a large sequence N-terminal to the first membrane-spanning region, which includes Ser-Gly and Thr-Gly repeats (possible sites of O-linked glycosylation); the "S4" region of *Shab*, which is the presumed voltage sensor of the channel, contains a string of five positive charges (*vs.* seven and four in *Sh* and *Shaw* proteins, respectively). *Shab* cDNA probes found to detect two late embryonic transcripts, 4.3 and 6.8 kb, the latter being more abundant; in pupae, relative abundances of these two switch; these RNA species not detected in adults.

**other information:** A rat potassium channel gene (*drkl*), isolated by expression cloning in a frog oocyte system, has greater sequence similarity to *Shab* than to *Sh* (Frech, VanDongen, Schuster, Brown, and Joho, 1989, *Nature* (London) 340: 642-645); *drkl* is not the same as two other mammalian K<sup>+</sup> channel genes, cloned by homology to *Sh*.

**shadow:** see *sad*

**shaggy:** see *sgg*

**shakA: shaking A (J.C. Hall)**

**location:** 1-38.2 (Homyk).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Homyk.

**references:** Homyk, Szidonya, and Suzuki, 1980, *Mol. Gen. Genet.* 177: 553-65.

**phenotype:** Vigorous shaking of legs when flies under ether; both mutant alleles cause temperature-sensitive phenotypes: *shakA*<sup>1</sup> exhibits generally hyperactive behavior (irrespective of anesthetic) when raised at 22°; after rearing at 29°, flying and jumping abilities severely subnormal, and males show abnormal wing usage in courtship; *shakA*<sup>2</sup> causes lethality when raised at 29°; after rearing at 22°, adults are hypoactive and uncoordinated.

**alleles:** Two alleles, *shakA*<sup>1</sup> and *shakA*<sup>2</sup>.

**shakB: shaking B (J.C. Hall)**

**location:** 1-64.

**synonym:** *nj-156: non-jumper; pas: passover.*

**references:** Homyk, Szidonya, and Suzuki, 1980, *Mol. Gen. Genet.* 177: 553-65.

Baird, Schalet, and Wyman, 1990, *Genetics* 126: 1045-59.

**phenotype:** Some of the *shakB* mutants are viable but defective in their neural phenotypes as homo-, hemi-, or

heterozygotes, but other mutants are homozygous lethals that may or may not complement the viable *shakB* alleles. The viable mutants have difficulty in controlling leg movements and show leg tremors under ether anesthesia (Homyk *et al.*, 1980). They show no escape response; the flies are unable to jump into the air and fly away at a light off stimulus (Thomas, 1980; Thomas and Wyman, 1984). Unlike the mutant *Sh*, the leg tremors of *shakB* are weak and end when the legs are severed from the body (indicating a central nervous system defect).

In wild-type flies, the thoracic muscles involved in the escape response are driven by the giant fiber (GF) neuron pathway connecting the brain and thoracic ganglia. In the mutant *shakB*, the synapse between the GF axon and the postsynaptic interneuron (PSI) or between the PSI and the dorsal longitudinal muscle (DLM) seems to be defective; thus the DLM does not respond to visual stimulation by depressing the wings in flight. The synapse between the GF axon and the motor neuron of the tergotrochanter muscle (TTM) also seems to be defective, resulting in a weak response or no response from the TTM, the muscle that extends the leg in jumping. The motor neurons "pass over" the midline of the thoracic central nervous system and send aberrant branches into each contralateral mesothoracic ganglion. The abnormal neural phenotype is more pronounced if *shakB* is uncovered by a deficiency (Wyman and Thomas, 1983; Baird and Hillis, 1985; Baird *et al.*, 1990). The muscles themselves and their neuro-muscular junctions are not abnormal (Thomas and Wyman, 1984).

Viable *shakB* mutants are also characterized by electroretinogram (ERG) abnormalities; the corneal negative component is reduced and the on- and off- transients are reduced or absent. Neurons in the brain are affected, as indicated by failure of one of the superoesophageal brain commissures to fill with cobalt when the antennal nerve is backfilled (Aceves-Piña).

*shakB*<sup>3</sup> (= *Pas*) is partially dominant to wild type in regard to the mutant's elimination of the jump response, but the other viable alleles are recessive. +/Df(1)16-3-35 and +/Df(1)A118 are behaviorally normal, but Df(1)16-3-35/Df(1)A118 females are *shakB* in phenotype.

**alleles:** A number of homozygous lethal alleles have been located in the *shakB* region. Six of them do not complement the *shakB* neural phenotype; two of the remainder have been tested and found to complement this neural phenotype, but do not complement the lethality of the other lethal alleles. The six noncomplementing lethals also fail to complement Df(1)16-3-35 (distal deficiency) and Df(1)A118 (proximal deficiency), while the two complementing lethals complement Df(1)A118 but not Df(1)16-3-35. 25 alleles, viables and lethals, are listed in the following table.

β Fails to complement *shakB<sup>2</sup>*.

γ Complements *shakB<sup>2</sup>*.

**cytology:** Placed in 19E3-4 based on the mutant neurological phenotype of heterozygotes for *Df(1)16-3-35 = Df(1)19D2-3;19E3-4* and *Df(1)A118 = Df(1)19E3-4;19E7-8* (Baird *et al.*).

**Shaker cognate:** see *Shab, Shal, and Shaw*

**shaking:** see *shak*

**Shal (J.C. Hall)**

**location:** 3- {45}.

**origin:** Isolated by screening a cDNA library with a *Sh* cDNA probe.

**references:** Butler, Wei, Baker, and Salkoff, 1989, Science 243: 943-47.

**phenotype:** Expression of *Shal* cDNA-derived mRNA in *Xenopus* oocytes (Wei, Covarrubias, Butler, Baker, Pak, and Salkoff, unpublished) leads to potassium currents intermediate in kinetic properties between those associated with *Sh* (using the heterologous egg system) and *Shaw* (same kind of experiment), *i.e.*, between very rapid activation/inactivation (*Sh*-encoded "A"-type channels) and quite slow kinetics (*Shaw*-encoded, delayed-rectifier-type channels).

**cytology:** Mapped to 76B by *in situ* hybridization.

**molecular biology:** Identified, as was *Shab*, via screening for *Sh*-like cDNAs; mixed probe of these two types plus a *Shaw* probe was used to isolate *Shal*. No structural details of the latter's coding sequence explicitly presented by the authors cited above, yet there are inferences about homology domains among the four known members of *Drosophila*'s *Sh* family, including *Shal*, *e.g.*, they are conserved at least insofar as each one's encoding of six similar putative membrane-spanning segments and the putative S4 voltage sensor. Also, whereas *Sh*, *Shab*, and *Shaw* conceptual proteins have strings of seven, five, and four positively charged amino acids in the presumed

gating charge region, *Shal* has five such charges.

**shaven:** see *svb*

**shaven baby:** see *svb*

**shavenoid:** see *sha*

**Shaw (J.C. Hall)**

**location:** 2- {10}.

**origin:** Isolated by screening a cDNA library with a *Shab* cDNA probe.

**references:** Butler, Wei, Baker, and Salkoff, 1989, Science 243: 943-47.

**phenotype:** In *Xenopus* oocyte mRNA injection experiment, protein encoded by *Shaw* transcripts leads to potassium currents with slow activation and inactivation kinetics (Wei, Covarrubias, Butler, Baker, Pak, and Salkoff, unpublished).

**cytology:** Mapped to 24B-C by *in situ* hybridization.

**molecular biology:** Identified by screening a cDNA library for *Sh*-like cDNAs, using a *Shab* cDNA probe. Sequencing the *Shaw* cDNA resulted in conceptual protein of approximately 500 amino acids (some 400 residues smaller than that deduced from *Shab*'s longest correctly spliced cDNA); hence *Shaw* polypeptide more similar in size to that of *Sh* than other putative potassium channel proteins; differs in length of charged amino acid string, in voltage-sensor region, from other members of the *Sh* family; for example, the position corresponding to the first (positive) gating charge in *Sh* occupied by negatively charged Asp in *Shaw* and *Shab*; *Shaw* also has a negative residue (Glu) at second position (defined by a positive amino acid in *Sh*). Northern blotting experiment using a *Shaw* cDNA probe showed one 4.9 kb transcript, which was similar in abundance in late embryos, pupae, and adults.

**\*shb: shortened bristles**

**location:** 1-39.0.

**origin:** Induced by S-2-chloroethylcysteine (CB. 1592).

**discoverer:** Fahmy, 1957.

**references:** 1959, DIS 33: 90.

**phenotype:** Bristles slightly short and thin. Wings broad, often convex or concave. Fly somewhat large. Male fertile; viability about 50% wild type. Female sterile. RK3.

**shd: shade**

**location:** 3-41.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

Roark, Mahoney, Graham, and Lengyel, 1985, Dev. Biol. 109: 476-88.

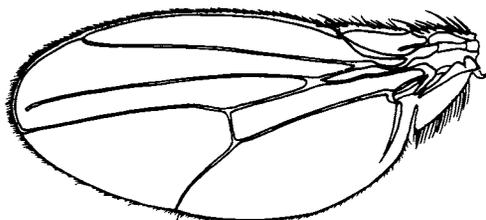

Tearle and Nüsslein-Volhard, 1987, Dis 66: 209-26.

**phenotype:** Embryonic lethal. No differentiation of cuticle or head skeleton.

**alleles:** *shd<sup>1</sup>*, *shd<sup>2</sup>*, and *shd<sup>3</sup>* (originally designated 6J, 7C, and 19K) plus two discarded alleles; all induced by ethyl methanesulfonate.

**cytology:** Placed in 70D-71C; covered by *Dp(3;Y)B162 = Dp(3;Y)65E;71A-C* but not by *Dp(3;Y)G145 = Dp(3;Y)68D;70D*.

**shd:** see *spl*

**\*she: sherry****location:** 3-0.**origin:** Kaliss, 36a13.**references:** 1937, DIS 8: 9.**phenotype:** Eye color sherry. Sterile *inter se* but both sexes crossfertilable. RK3.*Shell*: see *Cpl5***\*shf: shifted****location:** 1-17.9.**discoverer:** Bridges, 13a.**references:** Morgan and Bridges, 1916, Carnegie Inst. Washington Publ. No. 237: 63.**phenotype:** Vein L3 fails to reach wing margin and is shifted toward L4. Anterior crossvein usually lacking. Wings divergent. Postscutellar bristles small and erect. Body small. Viability 60% wild type. Female often sterile. RK2.**cytology:** Placed between 6A3 and 6F11 based on deficiency analysis using *shf*<sup>2</sup> (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book – Carnegie Inst. Washington 41: 191).***shf*<sup>2</sup>****origin:** X ray induced.**discoverer:** Oliver, 29j29.**references:** 1935, DIS 3: 28.  
1935, DIS 4: 10.**phenotype:** Veins closer together than in wild type. L3 and L4 tend to fuse near anterior crossvein; anterior crossvein shortened, knotted, or absent. Phenotypic effect visible in prepupal wing bud, the two longitudinal veins diverging at a smaller-than-normal angle [Waddington, 1940, J. Genet. 41: 75-139 (fig.)]. Eyes sometimes slightly rough. Scutellar bristles often absent. Scutellum short. Wings narrow and often warped downward. Fertility and viability good. RK2.**\*shf<sup>3</sup>****origin:** Spontaneous.**discoverer:** Curry, 37d26.**phenotype:** Like *shf*<sup>2</sup> but more extreme. Viability about 70% wild type. Frequently infertile. RK2.***shf*<sup>3</sup>: shifted-3**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 173.

***shf*<sup>ov</sup>: shifted-oval****origin:** Induced by P<sup>32</sup>.**discoverer:** Bateman, 1950.**references:** 1950, DIS 24: 55.**phenotype:** Eyes rough and narrow. First basal wing cell absent because L3 and L4 veins close. Wings narrow

and pointed. Viability and fertility low. RK2.

**other information:** On basis of phenotype and position, could be an allele of either *ov* or *shf* or both; not tested.***shg*: shotgun****location:** 2-92.**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Embryonic cuticle has many small holes with necrotic rims. Head grossly distorted. Weak alleles show head defects and irregular flaws in segmentation pattern.**alleles:** Two retained alleles, *shg*<sup>1</sup> and *shg*<sup>2</sup> (originally designated *IG* and *IH*) plus sixteen discarded alleles.***shi*: shibire (C. A. Poodry)****location:** 1-51.5.**discoverer:** Grigliatti, 1971.**references:** Grigliatti, Hall, Rosenbluth, and Suzuki, 1973, Mol. Gen. Genet. 120: 107-14.**phenotype:** The shibire locus is characterized by its temperature-sensitive alleles, which are reversibly paralyzed by exposure to 29°, but are essentially normal at 22° (Grigliatti *et al.*). Exposure of developing animals to the restrictive temperature for pulses of one to several hours leads to a plethora of developmental defects, which are specific for the stage treated (Poodry, Hall, and Suzuki, 1973, Dev. Biol. 66: 442-56) (see following table). Short exposures to restrictive temperatures at the time of delamination of the neuroblasts from the neurogenic ectoderm leads to excess neurogenesis at the expense of epidermogenesis, as seen in the neurogenic mutants (Poodry, 1990, Dev. Biol., in press). Differentiation of myoblasts and neuroblasts is inhibited in *shi*<sup>1</sup> embryonic cells *in vitro* at 30° (Buzin, Dewhurst, and Seecof, 1978, Dev. Biol. 66: 442-56). Embryonic neurons cultured at 30° show reduced adhesion to the substrate, retardation of growth cone formation and suppressed neuron formation and elongation; reversed by shift to permissive temperature (Kim and Wu, 1987, J. Neurosci. 7: 3245-55). Lethal embryos disorganized by the restrictive temperature can be cultured *in vivo* as tumorous masses (Poodry). Eye-antenna discs can also be cultured as tumorous masses for several transfer generations (Williams, 1981, DIS 56: 158-61). Primary *in vivo* culture of cut leg imaginal discs leads to an exceptionally high rate of transdetermination (Poodry).

temperature-sensitive period	developmental phenotype
1.5-3 hr	loss of pole cells
3-4 hr	fusion of cell membranes leading to syncytium
5-12 hr	disorganized proliferation of cells leading to transplantable tumorous masses
late third instar	stubby legs; joints missing;
12 hr heat pulse	clipped wings
48 hr before pupariation	eye scar (loss of pigment cells and cone cells). The later the heat pulse, the more anterior the position of the scar on eye
pupariation to pupation	animals die and fail to undergo pupation
14-24 hr after pupariation	supernumerary microchaetae on head and thorax; the temperature sensitive period for each bristle site precedes

temperature-sensitive period	developmental phenotype
	the final cell division of bristle precursor; loss of macrochaetae on head and thorax. Disruption of giant-fiber pathway development (Hummon and Costello, 1987, J. Neurosci. 7: 3633-38). Reduced numbers of dorsal-longitudinal flight muscles (Hummon and Costello, 1988, Roux's Arch. Dev. Biol. 197: 383-93)
24-36 hr after pupariation	loss of head and thoracic microchaetae; supernumerary abdominal macrochaetae and microchaetae
28-42 hr after pupariation	loss of abdominal macrochaetae and microchaetae
32-48 hr after pupariation	loss of abdominal microchaetae
48 hr after pupariation	scimitar-shaped bristles
adult	eggs fail to mature

The temperature-sensitive alleles differ in the severity of their paralysis, recovery period, the restrictive temperature for developmental effects, and in their viability as hemizygotes. They are all hypomorphs, being recessive and having a more extreme expression in combination with a deficiency than when homozygous. A wild-type paternal gene can rescue an egg from a homozygous mother only after 10 hr of development (Swanson and Poodry, 1976, Dev. Biol. 48: 205-11). Of the developmental effects tested, all are autonomous in mosaics generated by somatic recombination or in gynandromorphs (Poodry). The developmental effects on bristles is not enhanced or suppressed by the presence of temperature-sensitive alleles of *N*; *shi* is epistatic to *N* (Lujan, 1981, DIS 56: 86).

Physiological studies of *shi* have revealed the loss of transients in electroretinograms (Kelley and Suzuki, 1974, Proc. Nat. Acad. Sci. USA 71: 4906-09) and failure of neuromuscular transmission at the restrictive temperature (Ikeda, Ozawa, and Hagiwara, 1976, Nature 259: 489-91; Siddiqi and Benzer, 1976, Proc Nat. Acad. Sci. USA 73: 3253-57), though axonal conduction and muscle membrane excitability are unimpaired (Ikeda *et al.*). Exposure of *shi*<sup>1</sup> adults to 29° causes the depletion of synaptic vesicles from the neuromuscular synapse and their replacement with large cisternae (Poodry and Edgar, 1979, J. Cell Biol. 81: 520-27; Koenig, Saito, and Ikeda, 1983, J. Cell Biol. 96: 1517-22). Accumulation of acetyl choline is reduced at the restrictive temperature, not because of reduced synthesis but because of an abnormally rapid rate of release from the cell, which is not reduced by inhibiting tetrodotoxin-sensitive nerve activity (Wu, Merneking, and Barker, 1983, J. Neurochem. 40: 1386-96). Endocytosis is reversibly blocked in the nerve terminus (Kosaka and Ikeda, 1983, Neurobiol. 14: 207-25; Masur, Kim, and Wu, 1990, J. Neurosci.) and may limit the ability of nerves to regenerate synaptic vesicles. Neuromuscular transmission temperature is sensitive in mosaics in which the neuron but not the muscle is mutant, but not in the converse situation (Koenig and Ikeda, 1983, J. Neurobiol. 14: 411-19). During recovery from exposure to 30° *shi*<sup>ts1</sup> muscles display a multimodal distribution of miniature excitatory junction potential amplitudes never seen in wild type (Ikeda and Koenig, 1987, J. Physiol. 406: 215-23). Further, as the temperature is increased the amplitude of evoked excita-

tory junction potentials decreases; the numbers of vesicles per synapse displays a correlated decrease (Koenig, Kosaka, and Ikeda, 1989, J. Neurosci. 9: 1937-42). Endocytosis is also blocked in the garland cells (Kosaka and Ikeda, 1983, J. Cell Biol. 97: 499-507). Vesiculation of cell membranes results in fusion of blastoderm cells (Swanson and Poodry, 1981, Dev. Biol. 84: 465-70) and vesiculation of surface membranes accompanies secretion of protein epicuticle (Poodry).

**alleles:** The first alleles recovered were recognized as temperature-sensitive paralytic mutations. These show different temperature responses as summarized in the second table below.

**cytology:** Located in 13F to 14A (Austin and Poodry, 1991; Morgan, 1991).

**molecular biology:** Cloned and sequenced by van der Blik and Meyerowitz (1991, Nature 351: 411-14); homologous to rat dynamin.

**shifted genitals:** see *sgc*

**\*shi: shorter legs**

**location:** 1-36.3.

**origin:** Induced by 2-fluoroethyl methanesulfonate (CB. 1522).

**discoverer:** Fahmy, 1957.

**references:** 1959, DIS 33: 90.

**phenotype:** Small fly with short legs. Male viability and fertility low. RK3.

**shm: short macros**

**location:** 1-22.4.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1953.

**references:** 1959, DIS 33: 90.

**phenotype:** Bristles short and stiff. Eclosion delayed. Male sterile and viability reduced. RK2.

**shn: schnurri**

**location:** 2-62.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Embryos lack dorsal hypoderm. Internal organs appear normal and extruded through the open dorsal side of the embryo. Ventral hypoderm contracted.

**alleles:** Two ethyl-methanesulfonate-induced alleles *shn*<sup>1</sup> and *shn*<sup>2</sup> (formerly designated *IB* and *IM*), the latter being heat sensitive, and one hybrid-dysgenesis-induced allele, *shn*<sup>3</sup>, (formerly *TD5*) isolated by Gergen. In addition fifteen discarded alleles.

**cytology:** Placed in 47E3-48A6 based on its location to the area of overlap between *Df(2R)en-A = Df(2R)47D3; 48A5-6* and *Df(2R)en-B = Df(2R)47E3;48B2*.

**\*sho: shovel**

**location:** 2- (not located).

**origin:** Spontaneous in *In(2L)t*.

**discoverer:** GoodSmith, 49k.

**references:** Ives, 1952, DIS 26: 65.

**phenotype:** Wings short and rounded. Viability good. RK2A.

**shorter legs:** see *shl*

**shotgun:** see *shg*

**shovel:** see *sho*

**\*shp: shrimp**

**location:** 1-47.5.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 74.

**phenotype:** Small fly. Eclosion delayed. Male viability about 30% wild type. Both sexes fertile. RK3.

**shr: shrunken**

**location:** 2-2.3.

**discoverer:** Bridges.

**phenotype:** Body small and dark. Viability and fertility good. Overlaps wild type unless combined with *abb*, where mutual enhancement occurs. RK3.

**cytology:** Placed between 22A3 and 22B1 on the basis of its inclusion in *Df(2L)S2 = Df(2L)21C6-D1;22A6-B1* but not in *Df(2L)S5 = Df(2L)21C2-3;22A3-4* (Lewis, 1945, Genetics 30: 137-66).

**shrew:** see *sw*

**shrimp:** see *shp*

**shroud:** see *sro*

**shrunken:** see *shr*

**Shrunken thorax:** see *Sht*

**shrunken-3:** see *wz*

**\*sht: short tarsi**

**location:** 1-20.9.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1953.

**references:** 1959, DIS 33: 90.

**phenotype:** Legs extremely short; reduction in length most pronounced in metatarsal and tarsal regions. Some tarsi fused, others absent. Bristles thin and short. Adult short lived. RK3.

**Sht: Shrunken thorax**

**location:** 2-54.7 (2.8±0.4 map units to the left of *cn*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Kulkarni and Babu, 1981, DIS 56: 192.

**phenotype:** Heterozygotes exhibit an indentation across the dorsal mesothorax giving the appearance of shrunken thorax. Typically a groove runs across the thorax in a V shape. There is some variability in the expressivity; a small fraction of flies have only a marginal phenotype, but the penetrance is nearly complete. Newly emerged flies do not often show the phenotype or have only a faint line on the thorax; the groove becomes visible as the cuticle hardens. Mutant flies have good viability and fertility. Homozygous lethal.

**other information:** Possibly an allele of *Mhc*.

**shu: shut down (T. Schüpbach)**

**location:** 2-105.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females contain few developing egg chambers in their ovaries, which may contain abnormal numbers of nurse cells and usually degenerate before yolk uptake begins. Rarely a few very small and abnormal eggs are produced.

**alleles:** *shu*<sup>1</sup> and *shu*<sup>2</sup> recovered as *WQ* and *WM* respectively.

**cytology:** Placed in 59D8-60A2, since uncovered by both *Df(2R)bw-S46 = Df(2R)59D8-11;60A7* and *Df(2R)bw-D23 = Df(2R)59D4-5;60A1-2*.

**Shu: Shudderer (J.C. Hall)**

**location:** 1-55.1.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** R.L. Williamson.

**references:** Williamson, 1982, *Psychopharmacology* 76: 265-68.

**phenotype:** Sudden leg jerks are frequent and enough to topple the fly; negative geotaxis is sluggish and seemingly not a consequence of shuddering bouts during climbing toward top of glass vials; neither of these behavioral abnormalities is pronounced in young adults, but they become maximal after about a week of adult life; lithium or ammonium ions placed in medium on which the mutant is grown reduce the severities of the eventual adult phenotypes. Homozygous females are not observed.

**shut down:** see *shu*

**shv:** see under *dpp*

*shv:* see *svs*

*Shw:* see *Sh*<sup>4</sup>

**shy: shy (T. Schüpbach)**

**location:** 2-62.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal effect lethal. Embryos from homozygous mothers develop into larvae with no visible cuticular abnormalities, but which do not hatch out of the egg case.

**alleles:** *shy*<sup>RU</sup> = *shy*<sup>1</sup>.

**\*Si: Ski**

**location:** 2-36.

**discoverer:** Clausen, 1911.

**references:** Clausen and Collins, 1922, *Genetics* 7: 385-426.

Bridges and Morgan, 1923, *Carnegie Inst. Washington Publ. No. 327*: 149 (fig.).

**phenotype:** Homozygous or heterozygous *Si* combined with homozygous *si-3* produces wings with turned up tips. Double homozygote also has a crimped costal vein. Other genotypes wild type. RK3.

**\*si-3: ski-3**

**location:** 3-46.5.

**discoverer:** Clausen, 1911.

**references:** Clausen and Collins, 1922, *Genetics* 7: 385-426.

Bridges and Morgan, 1923, *Carnegie Inst. Washington Publ. No. 327*: 149.

**phenotype:** *si-3/si-3* fly has upturned wing tips when homozygous or heterozygous for *Si*, otherwise normal. RK3.

**sic: sichel**

**location:** 3-48.8.

**references:** Mayer and Nüsslein-Volhard, 1988, *Genes Dev.* 2: 1496-1511 (fig.).

Tearle and Nüsslein-Volhard, 1987, *DIS* 66: 209-26.

**phenotype:** Maternal effect lethal; embryos produced by homozygous mothers show narrow dentical bands and head skeleton with fused ventral arms. Embryos may also be normal and hatch or die early with irregular cell cleavage patterns. Distribution of syncytial blastoderm nuclei normal in some embryos and irregular in others. Germ line dependent but may also have a somatic component. Mutant expression autonomous in mutant pole cells transplanted into wild type recipients. Embryonic phenotypes of progeny of *sic/sic* and *sic/Df(3R)by10* are similar indicating null alleles.

**alleles:** Four ethyl methanesulfonate-induced alleles; all cold sensitive: *sic*<sup>1</sup> (weak allele), *sic*<sup>2</sup>, *sic*<sup>3</sup>, and *sic*<sup>4</sup> (originally designated 215, 256, 371, and 612).

**cytology:** Placed in 85D8-12 based on its inclusion in the region of overlap of the synthetic deficiency for 84F2-85E in *In(3R)Scr<sup>MscL</sup>Antp<sup>BR</sup>* and *Df(3R)by10 = Df(3R)85D8-12;85E7-F1*.

**side wings:** see *siw*

**sie: sieve (T. Schüpbach)**

**location:** 2-68.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal. Embryos from homozygous females show variable defects and irregularities at cellularization; at final differentiation embryos form only fragmented pieces of cuticle.

**alleles:** *sie*<sup>1</sup>, *sie*<sup>2</sup>, and *sie*<sup>3</sup> recovered as *HA*, *RF*, and *III E* respectively.

**cytology:** Placed in 49E7-50A3, since uncovered by *Df(2R)vgB = Df(2R)49D3-4;49F15-50A3*, but not by *Df(2R)vgC = Df(2R)49B2-3;49E7-F1*.

**other information:** *sie*<sup>3</sup> has a semi-dominant effect, causing 60-80% embryonic lethality when mother heterozygous.

**\*Sil: Skilike**

**location:** 2- (not located).

**discoverer:** Goldschmidt.

**references:** 1947, *J. Exptl. Zool.* 104: 216.

**phenotype:** Wings turned up at tips. Semidominant. Poor viability. RK3.

**other information:** Not an allele of *Si*.

**silver:** see *svr*

**silver tips:** see *stp*

**sim: single minded**

**location:** 3-52.2 (just distal to *pic*).

**synonym:** *l(3)S8; schm; l(3)87Ea*.

**references:** Hilliker, Clark, Gelbart, and Chovnick, 1981, *DIS* 56: 65-72.

Thomas, Crews, and Goodman, 1988, *Cell* 52: 133-41 (Fig.).

Crews, Thomas, and Goodman, 1988, *Cell* 52: 143-51 (Fig.).

Mayer and Nüsslein-Volhard, 1988, *Genes Dev.*

2: 1496-1511 (Fig.).

**phenotype:** Embryonic lethal. Denticle bands of all segments narrow. Both head skeleton ventral arms and anal plates fused. In the ventral nervous system, transverse commissures lacking entirely. Midline neurons and supportive mesectodermal cells missing. Germline viable with no maternal component. Deficiency test indicates that *sim*<sup>1</sup> is amorphic. In normal genotypes, transcript first noted at cellular blastoderm in a pair of longitudinal rows of cells at the interface between the presumptive mesoderm and the neurogenic ectoderm. At the end of gastrulation, the mesoderm has invaginated into the ventral furrow and the two rows of expressing cells have come together in the ventral midline and both transcript and protein expressed in a row of cells in the midline and in an annulus around the presumptive anterior midgut. By eleven hours of development, protein is found in the cell types missing in the midline of the central nervous system of mutant embryos, more in mesectodermal cells than neuronal elements, and in a subset of cells of the foregut. Antibody staining confined to nuclei.

<sup>α</sup> 1 = Hilliker, Clark, and Chovnick, 1980, Genetics 95: 95-110;  
2 = Hilliker, Clark, Gelbart, and Chovnick, 1981, DIS 56: 65-72;  
3 = Schalet, Kernaghan, and Chovnick, 1964, Genetics 50: 1261-68.

**cytology:** Placed in 87E1 based on its being between *Df(3R)ry75 = Df(3R)87D1-2;87D14-E1* and *Df(3R)l26c = Df(3R)87D14-E1;87E3-5*.

**molecular biology:** The 3' end of the gene has been cloned, a cDNA containing the 3' end sequence, and the conceptual sequence of 655 C-terminal amino acids determined. The only identity encountered in protein-sequence data bases is to the *Drosophila per* gene; a 239-amino-acid sequence exhibits 23% identity and contains two 51-amino-acid repeats separated by 115 amino acids in *sim* and 99 amino acids in *per*. The sequence contains no transmembrane, homeobox, or zinc-finger motifs. A transcript of 3.0 kb is present from 0-3 hr post fertilization, increases in 3-6 hr and then disappears; a 3.5 kb transcript appears strongly from 3-6 hr, declining over the next six hours, and then persisting at low levels throughout embryogenesis.

***sina*: seven in absentia (R. Carthew)**

**location:** 3-45.5.

**origin:** Induced with ethyl methanesulfonate.

**discoverer:** Carthew, 1988.

**phenotype:** Photoreceptor cell R7 of eye transformed into a cone cell, resulting in the absence of R7 in adult ommatidia. In amorphic alleles, 40% of ommatidia also missing an additional photoreceptor cell and 10% of ommatidia also missing two photoreceptor cells. Eyes weakly rough; ocelli appear normal. Adult bristles sometimes missing and sometimes duplicated, arising from a com-

mon socket; occasionally three bristles arise from a common socket. Wings sometimes held outstretched. Adults eclose normally but fail to survive after 24 h; display lethargic behavior and are not fertile, though mature sperm and ova are produced.

**alleles:** Six, designated *sina*<sup>1</sup> through *sina*<sup>6</sup>. *sina*<sup>1</sup>, *sina*<sup>4</sup>, *sina*<sup>5</sup>, and *sina*<sup>6</sup> hypomorphic; *sina*<sup>2</sup> and *sina*<sup>3</sup> amorphic based on the phenotypes of hemizygous [*sina/Df(3L)st-g18*] versus that of homozygous flies.

**cytology:** Located in 73D1-7 by deficiency mapping.

***sine oculis*:** see *so*

***singed*:** see *sn*

***singed wing*:** see *l(1)nfw*

***single minded*:** see *sim*

***sis-a*: sisterless a (T.W. Cline)**

**location:** 1-34.3 (based on 4496 *v-m* recombinants).

**origin:** Induced by ethyl methanesulfonate.

**references:** Cline, 1986, Genetics 113: 641-63, corrigendum 114: 345.

Cline, 1988, Genetics 119: 829-62.

**phenotype:** Homozygous females die but hemizygous males and heterozygous females fully viable; females die as embryos and larvae; rare morphologically normal and fertile escapers observed at lower temperatures. Single extant allele hypomorphic; locus also defined by dominant behavior of deficiencies and duplications. Dominant lethal for females simultaneously heterozygous for *sis-b*<sup>-</sup> or *Sxl*<sup>-</sup> or whose mothers are heterozygous for *da*<sup>-</sup>. Magnitude of female-lethal dominant synergism sensitive to genetic background, but can be very high. Lethal interactions are generally less severe at lower culture temperatures. Constitutive allele, *Sxl*<sup>M1</sup>, suppresses female lethality of *sis-a* homozygote or of any heterozygous combination of mutant alleles or deficiencies of these four genes. Duplication of *Sxl*<sup>+</sup> also suppresses, but less effectively. Female-lethal interactions between *sis-a* and *Sxl* mutations display remarkably similar *Sxl* allele specificity to those between maternal *da* and zygotic *Sxl* mutations, indicating that *da* and *sis-a* disrupt the same aspect of *Sxl* regulation. Oogenesis normal for homozygous *sis-a* germ-line clones induced by mitotic recombination; no maternal effect. Sexual phenotype of 2X:3A animals extremely sensitive to *sis-a*<sup>+</sup> dose (more male at lower temperatures), and like *da* and *Sxl*<sup>-</sup>, shows masculinizing interaction with autosomal male-specific lethal mutations but no increase in viability of escapers; nevertheless, sexual phenotype of homozygous *sis-a* clones generated by mitotic recombination normal. Female-lethal effects caused by decrease in *sis-a* function have their complement in male-lethal interactions caused by increase in *sis-a* function (duplications). Male lethality is increased as *Sxl*<sup>+</sup> dose or *sis-b*<sup>+</sup> dose is increased, and is suppressed by loss-of-function *Sxl* mutations. The dose-dependent interactions of this gene with *Sxl*<sup>+</sup> identify it as part of the numerator of what has been called the X/A balance, the primary sex-determination signal—a character it shares with *sis-b*.

**cytology:** Placed in extreme distal position in 10B4-9 based on its failure to complement *Df(1)N71 = Df(1)10B4-5;10D4* and its genetic position distal to *l(1)10Bb* and within <0.004 cM of *l(1)10Ba*.

**sis-b:** see under **Asc**

**\*siw: side wings**

**location:** 1-58.5.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1955.

**references:** 1958, DIS 32: 74.

**phenotype:** Wings rotated on long axis so that inner margin is higher than costal margin. Male sterile; viability about 50% wild type. jK2.

**sk: stuck (J.C. Hall)**

**location:** 4-?.

**origin:** Spontaneous.

**references:** Beckman, 1970, DIS 45: 36.

Hall, Siegel, Tompkins, and Kyriacou, 1980, Stadler Genet. Symp. 12: 43-82.

**phenotype:** Males become stuck in females after copulation; ca. 50% of such matings exhibit this phenotype (data shown in Hall *et al.*, 1980; Beckman, 1970, quoted 100% penetrance originally, which had fallen to 78% by the time of her report); stuck males not infrequently are able to disengage eventually on their own; if so, appendages of their terminalia are held in aberrantly protruding positions (Hall *et al.*, 1980); Beckman mentions anatomical abnormality in the strain (near time of isolation): affected males showing narrowing of abdomen (not observable in current versions of stock and was never consistent enough to allow discrimination of affected individuals from those who would behave normally); if mutant males are unable to withdraw after copulating, he and the female die within a few days (Beckman 1970, quotes 14% as mortality frequency for mated pairs); a stuck *vs.* non-stuck mating result is stochastic (as opposed to being a pure penetrance problem, as it were), given that (for example) re-testing a non-stuck case can readily lead to stuck outcome in a subsequent mating (Hall *et al.*, 1980); mutant male-female pairs are more difficult to separate (by vortexing) than are normal copulating pairs (Hall *et al.*, 1980); females unaffected by the genetic variant(s).

**other information:** Beckman (1970) reported that *sk* maps on chromosome 3; Hall *et al.* (1980) unable to confirm this, but their mapping to 4 was somewhat problematical, in that other factors in the strain seem necessary for full mutant phenotype to be realized.

**Sk: Streak**

**location:** 2-16.0.

**origin:** Spontaneous.

**discoverer:** Bridges, 12k27.

**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 222 (fig.).

**phenotype:** Dark streak extends down middle of thorax from neck to tip of scutellum. Wings may diverge and droop. Overlaps wild type. Enhanced by *b* or *e<sup>s</sup>*. Homozygous lethal. RK2.

**cytology:** Salivary chromosomes apparently normal (Bridges).

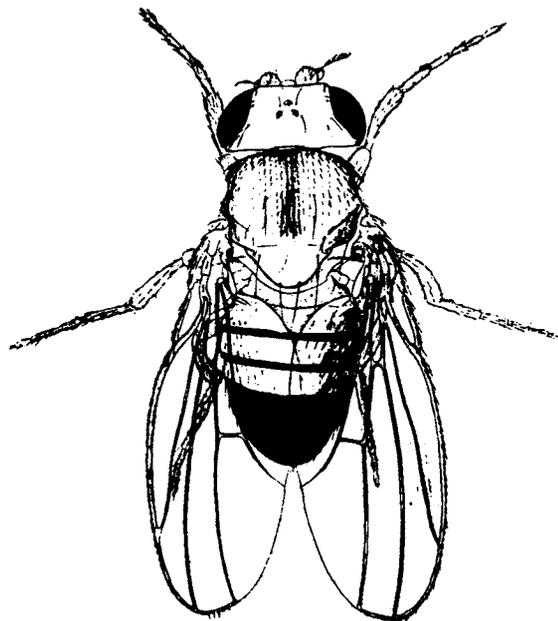

**skd: skuld (J.A. Kennison)**

**location:** 3-51.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1984.

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad.

**Sk: Streak**

From Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 216.

Sci. USA 85: 8136-40.

**phenotype:** Isolated as a dominant suppressor of *Pc* mutations. Associated with recessive lethality at the larval-pupal transition. Also interacts with *Pcl*, *Scr*, and *Ubx* mutations. May weakly suppress *Antp<sup>Ns</sup>*.

**alleles:** *skd<sup>1</sup>* induced by ethyl methanesulfonate and *skd<sup>2</sup>* induced by gamma irradiation.

**cytology:** Proximal to 87B15 on basis of exclusion from *Df(3R)ry615 = Df(3R)87B12-15;87E8-11*.

*Ski*: see *Si*

*ski-3*: see *si-3*

**Skilike:** see **Sil**

**skuld:** see **skd**

**sl: small wing**

**location:** 1-53.5.

**phenotype:** Wings about 80% normal length, straight edged, and blunt tipped. Crossveins rather close. Eyes large and slightly rough.

**alleles:**

allele	origin	discoverer	ref <sup>α</sup>	comments
<i>sl<sup>1</sup></i>	spont	Bridges, 15121		
<i>sl<sup>2</sup></i>	X ray	Dobzhansky, 31b3	2

<sup>α</sup> 1 = Schalet, 1986, Mutat. Res. 163: 115-44. 2 = Sivertzev-Dobzhansky and Dobzhansky, 1933, Genetics 18: 173-92.

**cytology:** Placed in 14B13 based on probable association of *sl<sup>3</sup>* with distal X break of *Tp(1;2)r<sup>+</sup>75c = Tp(1;2)14B13;15A9;35D-E*. *sl<sup>2</sup>/Tp(1;2)r<sup>+</sup>75c* and *sl<sup>2</sup>/Dp(1;2)r<sup>+</sup>75c* have small

wings and rough eyes; *sl<sup>2</sup>/Df(1)r75c* has very rough eyes. *sl<sup>2</sup>* has a normal phenotype in combination with *Dp(1;4)r<sup>+</sup> = Dp(1;4)14A1-2;16A1-2;102F2-3* (Schalet, 1986, Mutat. Res. 163: 115-44).

**\*Sl: Splotched**

**location:** 1-56.9 (to the right of *f*).  
**origin:** X ray induced.  
**discoverer:** Muller, 26111.  
**references:** 1935, DIS 3: 30.  
**phenotype:** Wing hairs disarranged in small patches. Male infertile. Viability excellent. RK1.

**sla: slimma**

**location:** 1-48.6.  
**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).  
**discoverer:** Fahmy, 1954.  
**references:** 1958, DIS 32: 74.  
**phenotype:** Fly slim with very narrow abdomen. Body length normal. Eclosion delayed slightly. Wings curve slightly. *sla/slb* and *sla/sld* wild type. Male fertile and viable. Female sterile; viability about 50% wild type. RK3.  
**other information:** Two alleles each induced by CB. 3007 and CB. 3025.

*slater*: see *tkv*

**\*slb: slim body**

**location:** 1-45.3.  
**origin:** Induced by ethyl methanesulfonate (CB. 1528).  
**discoverer:** Fahmy, 1956.  
**references:** 1958, DIS 32: 74.  
**phenotype:** Body narrow but of normal length. *slb/sla* and *slb/sld* wild type. Viability and fertility good in both sexes. RK3.

**slc: slim chaetae**

**location:** 1-3.6.  
**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1954.  
**references:** 1959, DIS 33: 90-91.  
**phenotype:** Bristles thin and short. Inner wing margins occasionally incised. Both sexes viable and fertile. RK1.

**sld: slender**

**location:** 1-50.1.  
**origin:** Induced by *p*-N,N-di-(2-chloroethyl)amino-phenylethylamine (CB. 3034).  
**discoverer:** Fahmy, 1957.  
**references:** 1959, DIS 33: 91.  
**phenotype:** Fly rather small and slim with narrow abdomen. *sld/sla* and *sld/slb* wild type. Male fertile but shows delayed eclosion and reduced viability. Female very inviable. RK3.  
**other information:** One allele induced by CB. 3025.

**\*sld<sup>pta</sup>: slender-pointed abdomen**

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).  
**discoverer:** Fahmy, 1956.  
**synonym:** *pta*.  
**references:** 1959, DIS 33: 88.  
**phenotype:** Fly small, has narrowed abdomen and slightly altered eye and wing shape. Male sterile; viability about

25% wild type. RK3.

**slender chaetae:** see *sch*

**slf: schlaff**

**location:** 2-15.  
**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.  
 Roarke, Mahoney, Graham, and Lengyel, 1985, Dev. Biol. 109: 476-88.  
 Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.  
**phenotype:** Embryonic lethal. Cuticular differentiation normal but arrangement of cuticle around embryo abnormal. Cuticle is detached from the body. Head skeleton tilted backwards. Posterior segments contracted, anterior segments stretched around egg tip.  
**alleles:** Two ethyl methanesulfonate-induced alleles retained, *slf<sup>1</sup>* and *slf<sup>2</sup>* (originally designated *IG* and *IJ*) plus four discarded alleles.

**slgA: sluggish-A (J.C. Hall)**

**location:** 1- {65}.  
**origin:** Induced by ethyl methanesulfonate.  
**discoverer:** Eichenberger and Benzer.  
**synonym:** *EE85*.  
**references:** Markow and Merriam, 1977, Behav. Genet. 7: 447-55.  
 Hall, 1978, Genetic Mosaics and Cell Differentiation, (W.J. Gehring, ed.). Springer-Verlag, Berlin, pp. 259-305.  
 Miklos, Kelly, Coombe, Leeds, and Lefevre., 1987, J. Neurogenet. 4: 1-19.

**phenotype:** Isolated as defective in fast phototaxis, using counter-current-distribution (CCD) machine; also turned out to have poor (negative) geotaxis in this machine; yet mutant males showed some positive optomotor responses and had a normal electroretinogram; hence termed sluggish (as opposed to phototaxis-defective *per se*); Markow and Merriam (1977) confirmed aberrant CCD phototactic response; in maze tests the mutant was found to be quite photonegative (more so than wild type) and seemingly normal in geotaxis (Markow and Merriam, 1977). *slgA* causes poor viability, as well as aberrant behavior in hemizygous females (Miklos *et al.*, 1987); in mosaics studied for sluggishness, a mutant leg seemed to be debilitated independently of behavior of other legs, with the six foci for such movement deficits mapping to the ventral blastoderm (A. Ghysen, cited in Hall, 1978).

**cytology:** Mapped to 19F4, along with *sol*, these two mutations being flanked by *l(1)19Fe* and *l(1)19Ff*; this determination (Miklos *et al.*, 1987) was based on the poor phototaxis of *slg* in heterozygous combination with *Df(1)GA104*, but not with *Df(1)16-129* or *Df(1)JA117*, none of which have breakpoints determined cytologically.

**molecular biology:** Gene located in a 25 kb subsegment of 19F. Three transcription units detected by Delaney *et al.* (unpubl.).

**other information:** Complements *sol* (Miklos *et al.*, 1987). Also complements *PC16*, another phototaxis/geotaxis-defective mutation in the region, isolated in laboratory of S. Benzer and studied by Markow and Merriam (1977).

**slgB** (J.C. Hall)

**location:** 1- {1}.

**origin:**  $\gamma$  ray induced.

**references:** Sharma, 1977, *Experientia* 33: 171-77.

**phenotype:** Isolated with regard to poor response to light in fast phototaxis tests; both sexes are sluggish in this regard. Males in this strain do not mate with females in darkness; in the light, males court and mate with females (40-50%, within 10 m) and other males with equal vigor; the latter behavior includes formations of chains and rings of intermale courters, as well as pseudo-copulation attempts; courters in these circumstances do not exhibit wing-flick repelling responses characteristic of wild-type males. Spectral sensitivity studies of the light-elicited courtship activities showed 420-515 nm to be effective (thus orange/red range ineffective); yellow light was perhaps the most stimulatory; quick turn-ons and turn-offs of intermale courtships could be effected by intermittent exposures to yellow and red light, respectively.

**cytology:** Associated with a reciprocal *T(1;3)*, whose *X* breakpoint is in 2C; appears to cause the aberrant behaviors; the other breakpoint is said to be in 97A10 (but also indicated as being in 3L in Sharma, 1977).

**other information:** *fru* causes somewhat similar courtship abnormalities, but its locus (polytene 90-91) is not near the third-chromosome breakpoint in this *T(1;3)*.

**sli: slit**

**location:** 2-77.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 267-82.

Rothberg, Hartley, Walther, and Artavanis-Tsakonas, 1988, *Cell* 55: 1047-59.

**phenotype:** Homozygotes die as embryos. Head involution abnormal. In the ventral nervous system, transverse commissures lacking entirely. Midline neurons and supportive mesectodermal cells missing. Gene expression confined to ectoderm in cellular blastoderm (*i.e.*, no expression in presumptive mesoderm) and to the midline neuroepithelium at gastrulation. Antibodies raised against a *TrpE* fusion protein fail to stain mutant embryos. More severe abnormality in *Df/sli* than *sli/sli* indicates that *sli* is hypomorphic in nature. In combination with *Pc*-like mutants abdominal transformations occur (Jürgens).

**alleles:** Two ethyl-methanesulfonate-induced alleles, *sli*<sup>1</sup> and *sli*<sup>2</sup> (originally designated *IG2 = IG23* and *IG7 = IG107*); also a *P*-induced allele mentioned by Rothberg *et al.*

**cytology:** Localized to 52D by *in situ* hybridization.

**molecular biology:** Isolated from genomic library using a 7 kb *EcoRI* fragment from the Notch locus that contains the epidermal-growth-factor-like repeats. A 2.5 kb *HindIII* genomic fragment sequenced; cDNA sequence indicates presence of 63 base-pair intron. Within exon sequence a single large ORF can code for six adjacent and one noncontiguous EGF-like repeat separated by 99 amino acids. EGF-like repeats show 59% identity to those of *N*.

**slip: slipshod** (T. Schüpbach)

**location:** 2-42.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal. Embryos from homozygous mothers do not hatch; in cuticle preparations they show irregular segmentation and variable segment fusions.

**alleles:** *slip*<sup>PX</sup> = *slip*<sup>1</sup>.

**slit:** see *sli*

**slm: slim**

**location:** 1-33.7.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1955.

**references:** 1958, *DIS* 32: 75.

**phenotype:** Small fly with narrow abdomen. Viability and fertility good. RK3.

**other information:** One allele induced by CB. 1506.

**\*sln: slimmer abdomen**

**location:** 1-53.5.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1959, *DIS* 33: 91.

**phenotype:** Rather small fly with narrow abdomen. Occasionally, wings slightly upheld and eyes small or misshapen. Male infertile; viability about 15% wild type. Female sterile. RK3.

**slo: slowpoke** (J.C. Hall)

**location:** 3-86.

**origin:** Induced by ethyl methanesulfonate.

**references:** Elkins, Ganetzky, and Wu, 1986, *Proc. Nat. Acad. Sci. USA* 83: 8415-19.

Elkins and Ganetzky, 1988, *J. Neurosci.* 8: 428-34.

**phenotype:** Isolated in screen for third chromosomal temperature-sensitive paralytic mutants (Elkins *et al.*, 1986); this one is uncoordinated and unable to climb when exposed to 38° but not completely paralyzed; four-minute exposure to that high temperature causes several minutes of motionlessness on return to 22°. Legs shake when under ether anesthesia, as in *Shaker* mutants but less extreme. Unconditionally defective in behavior (*e.g.*, diminished flight ability; tends to walk or fly in anomalous short hops when in large open container). Physiologically, the mutation abolishes Ca<sup>2+</sup>-dependent potassium current (*I<sub>C</sub>*), as shown, and analyzed further, in a variety of experiments involving recordings from dorsal longitudinal flight muscles (DLMs) of adults (Elkins *et al.*, 1986; Elkins and Ganetzky, 1988): DLM spikes abnormally broadened after stimulation of giant fiber nerve pathway (one of whose endpoints is DLMs) or of motor neurons synapsing on these muscles. From voltage clamp analyses, a peak of early outward current fol-

lowing a step pulse from -80 to -40 mV, as revealed by a *Sh* mutation, is absent in *slo*, though inward  $Ca^{2+}$  currents in same traces are normal; no early outward current seen when *slo* is treated with 4-aminopyridine (which phenocopies *Sh*) or combined with *Sh*<sup>14</sup>. (This double mutant has very low viability and severe impairment in locomotor activity); charybdotoxin, which blocks  $I_C$  channels in wild-type DLMs, had no effect on outward currents in *slo*; delayed excitation of DLMs, observed in response to depolarizing currents delivered to wild-type (or *Sh*), absent in *slo*, and spike amplitudes increased; these abnormalities phenocopied by reducing  $I_C$  in normal muscle by injecting EGTA into such cells or using low- $Ca^{2+}$  saline; the lengthened muscle action potentials in *slo* indicate importance of  $I_C$  in effecting repolarization of such potentials.

**alleles:** Several alleles; *slo*<sup>1</sup> and *slo*<sup>4</sup> have been mentioned (Atkinson, Robertson, and Ganetzky, 1989, Neurosci. Abstr. 15: 541).

**cytology:** Localization defined in part by *In(3R)slo*<sup>4</sup>, with one breakpoint in the *E(spl)* region (in 96F) and the other at or very near *slo* locus, which is indicated as proximal to *E(spl)* (Atkinson *et al.*, 1989).

**slope wing:** see *slw*

**sloppy paired:** see *slp*

**slow receptor potential:** see *slrp*

**slowpoke:** see *slo*

**slp: sloppy paired**

**location:** 2-8.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. Embryos lack parts of naked cuticle of T2, A1, A3, A5, and A7 in an irregular fashion. No effect of *ftz* expression (Carroll and Scott, 1986, Cell 45: 113-26).

**alleles:** Three ethyl methanesulfonate-induced alleles, *slp*<sup>1</sup> (weak) and *slp*<sup>2</sup> and *slp*<sup>3</sup> (both strong) (original designations *11M*, *L12*, and *7L*, respectively).

**cytology:** Placed in 24A3-D4 based on its being in the segment deleted by *Df(2L)ed1 = Df(2L)24A3-4;24D3-4*.

**slrp: slow receptor potential (J.C. Hall)**

**location:** 1-51.4 (Pak, 1975); 49.7 (Homyk and Pye, 1988).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Pak.

**references:** Pak, 1975, Handbook of Genetics (R.C. King, ed.). Plenum Press, New York, Vol. 3, pp. 703-33.

Homyk and Sheppard, 1977, Genetics 87: 95-104.

Homyk and Pye, 1989, J. Neurogenet. 5: 37-48.

**phenotype:** In electroretinogram recordings, there is an abnormally slow return of photoreceptor potential to baseline after stimulus is turned off; also, reduced light-on and light-off transient spikes; these phenotypes reported for the first three alleles isolated (Pak, 1975); action spectrum of mutant ERG (Pak, 1975) same as in wild-type; hence, opsins unlikely to be altered. Intracellular recordings reveal some penetrated photoreceptors to have potentials with abnormally slow decay and others to show normal receptor potentials (Pak, 1975). *slrp* mutants are generally hypoactive (Homyk, Pye, and Pak,

1981, Genetics 97: s50) and show ether-induced leg shaking, cold-induced leg paralysis, and the defects in ERG; *slrp*<sup>4</sup> exhibits, in its permissive temperature range (20°-30°), the phenotypes just listed; in addition it is difficult to arouse for flight, has abnormally short jumps elicited, and, as a male, shows abnormal courtship wing displays (Homyk and Sheppard, 1977); in the temperature range noted above, this allele causes ERG phenotypes like those associated with the original mutations (slow rate of repolarization, transient amplitude deficits); as the temperature is lowered from 20° to 15°, *slrp*<sup>4</sup> becomes (<17°) sensitive to mechanical stress (Homyk and Sheppard, 1977), and eventually completely paralyzed (Homyk and Pye, 1989); the ERG abnormalities are accentuated at these low temperatures (Homyk and Pye, 1989); for example, the off-transient spike can be completely eliminated in 15° recordings; this effect is reversed on raising the temperature (Homyk and Pye, 1989).

**cytology:** Maps to 13F10-14B1, based on inclusion of *slrp*<sup>4</sup> in both *Df(1)sd72b = Df(1)13F1;14B1* and *Dp(1;4)r<sup>+</sup> = Dp(1;4)13F10;16A1-2;102F2-3* (Homyk and Pye, 1988).

**sls: sallimus (J.A. Kennison)**

**location:** 3 (unmapped).

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Kennison, 1984.

**synonym:** *sam* (preoccupied).

**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.

**phenotype:** Dominant suppressor of the extra-sex-combs phenotype of heterozygous *Pc* alleles. Also suppresses the dominant extra-sex-combs phenotype of *Pcl* alleles.

**slt: slight**

**location:** 2-106.3.

**origin:** Spontaneous.

**discoverer:** Curry, 39b20.

**references:** 1939, DIS 12: 45.

**phenotype:** Fly small. Bristles short and thin. Enhances *px*. Viability and fertility good. RK3.

**sluggish: see slg**

*slv*: see *svr*

**\*slw: slope wing**

**location:** 1-51.2.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1958, DIS 32: 75.

**phenotype:** Wings usually slightly upheld or spread. Viability and fertility good. RK3.

**sm: smooth**

**location:** 2-91.5.  
**origin:** Spontaneous.  
**discoverer:** Bridges, 35c14.  
**phenotype:** Abdomen partially denuded of bristles and shrunken. Wings usually warped and semierect. Acrostichal hairs disarranged. Tendency for erect postscutellars. Male genitalia often disturbed. Anal protuberance of female bent down. Viability 30% wild type. Both sexes entirely sterile. RK2.

**sm<sup>2</sup>**

**references:** Frankham and Nurthen, 1980, DIS 80: 204.  
**synonym:** *2sm<sup>lab</sup>*: low abdominal bristle number.  
**phenotype:** Reduced numbers of abdominal bristles; alteration of abdominal bristle pattern and a reversal of the sexual dimorphism for abdominal bristle number. Temperature sensitive with a TSP in the pupal period. Both sexes fertile.

*sm*: see *smk*

**sma: smaller**

**location:** 1-29.9.  
**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1953.  
**references:** 1958, DIS 32: 75.  
**phenotype:** Body small. Eye color frequently dark. Viability and fertility good. RK2.  
**other information:** One allele each induced by CB. 1528, CB. 1540, CB. 2511, CB. 3007, CB. 3025, CB. 3026, CB. 3034. Two alleles induced by CB. 1414.

**smaller:** see *sma*

**smaller body:** see *srb*

**smaller eye:** see *sme*

**smaller thinner:** see *smh*

**smalloid:** see *smd*

**smb: slim bristle**

**location:** 1-23.1.  
**origin:** Induced by ethyl methanesulfonate (CB. 1528).  
**discoverer:** Fahmy, 1956.

**phenotype:** Bristles thin and rather short. Male viable and fertile; female sterile. RK2.  
**other information:** One allele induced by CB. 1540.

**smd: smalloid**

**location:** 1-61.1.  
**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).  
**discoverer:** Fahmy, 1954.  
**references:** 1958, DIS 32: 75.  
**phenotype:** Rather small body. Eyes frequently dark. Viability and fertility good. RK2.  
**cytology:** Placed in salivary chromosome region 18A4-18B8 on the basis of its inclusion within the deficiency resulting from recombining left end of *In(1)y<sup>4</sup>* = *In(1)IA8-B1;18A3-4* with right end of *In(1)sc<sup>9</sup>* = *In(1)IB2-3;18B8-9* (Norton and Valencia, 1965, DIS 40: 40).  
**other information:** One allele each induced by CB. 1414, CB. 1540, CB. 1592, and CB. 3007. Two alleles each induced by CB. 1506 and CB. 1528. Seven alleles induced by CB. 3025 and 10 by X rays.

**\*sme: smaller eye**

**location:** 1-68.9.  
**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1955.  
**references:** 1959, DIS 33: 91.  
**phenotype:** Small fly with small, round, and slightly dark eyes. Wings occasionally diverge. Male sterile; viability about 50% wild type. RK2.  
**other information:** One allele induced by CB. 3051.

**smell blind:** see *sbl*

**\*smh: smaller thinner**

**location:** 1-1.5.  
**origin:** Induced by methyl methanesulfonate (CB. 1540).  
**discoverer:** Fahmy, 1956.  
**references:** 1959, DIS 33: 91.  
**phenotype:** Rather small fly with thin bristles. Both sexes viable and fertile. RK2.

**\*smk: smoky**

**location:** 2-58.6.  
**origin:** Ultraviolet induced.  
**discoverer:** Edmondson and Meyer, 49d.  
**synonym:** *sm* (preoccupied).  
**references:** 1949, DIS 23: 61.  
**phenotype:** Body color dark, especially along sides of thorax. Similar to *e<sup>s</sup>* but somewhat lighter. At 27°, female sterile and male fertile; at 17°, both sexes fertile. Viability and classification good. RK2.

**\*sml: small**

**location:** 1-25.  
**origin:** Induced by P<sup>32</sup>.  
**discoverer:** Bateman, 1950.  
**references:** 1950, DIS 24: 56.  
**phenotype:** Body small; wings short; eyes small, rough, and bulging. Thoracic hairs irregular. Eclosion delayed. Ten percent normal viability. RK3.

**\*smn: small narrow**

**location:** 1-45.7.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 91.

**phenotype:** Fly weak and inviable, usually dies within 48 hr of eclosion. Wings frequently upheld slightly. Abdomen narrow. RK3.

**smo: smoothed**

**location:** 2-4.

**references:** Nüsslein-Volhard, Wieschaus, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 267-82.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. All denticles in abdominal segments point posteriorly. At 18° naked cuticle deleted and denticle belts of adjacent segments fused and locally arranged as mirror-image duplications.

**alleles:** Three ethyl-methanesulfonate-induced cold-sensitive alleles, *smo*<sup>1</sup>, *smo*<sup>2</sup>, and *smo*<sup>3</sup> (originally designated *IIG*, *IIX*, and *Q14*).

**smoky:** see *smk*

**smooth:** see *sm*

**smoothened:** see *smo*

**\*smp: small pallid**

**location:** 1-25.6.

**origin:** X ray induced.

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 91.

**phenotype:** Fly quite small and lightly pigmented. Bristles slightly thin. Occasional eye misshapen. Male viable and fertile. Female sterile. RK2.

**\*smt: small thorax**

**location:** 1-51.9.

**origin:** Induced by L-p-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 75.

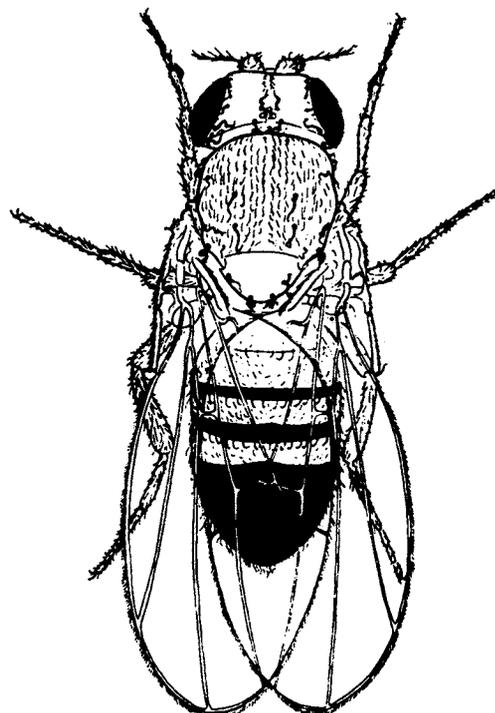

**phenotype:** Thorax and head small. Wings correspondingly short but of normal width and frequently wavy. Both sexes fertile. Viability about 50% wild type. RK2.

**sn: singed**

**location:** 1-21.0.

**references:** Bender, 1960, Genetics 45: 867-83.

**phenotype:** Macrochaetae deformed, from short and gnarled to wavy, depending on allele. Similarly, microchaetae may be straight or wavy. Electron-microscope examination of developing bristle shaft shows flattened fiber bundles around periphery, which occupy but 5% of cross-sectional profile, compared to wild type, which have fiber bundles that are circular in cross section and occupy 20% of cross-sectional area [Overton, 1967, J. Morph. 122: 367-80 (fig.)]. Females homozygous for the most extreme alleles are completely sterile; vitellogenesis defective. Eggs laid by *sn*<sup>f</sup> homozygotes are normal in number, but are short, blunt, and wrinkled with small blunt dorsal appendages [Mohr, 1922, Z. Indukt.

**sn: singed**

From Mohr, 1922, Z. Indukt. Abstamm. Vererbungsl. 28: 1-22.

Abstamm. Vererbungsl. 28: 1-22 (fig.)). Sterility autonomous in transplants (*sn*<sup>f</sup>; Clancy and Beadle, 1937, Biol. Bull. 72: 47-56; Perrimon and Gans, 1983, Dev. Biol. 100: 365-73). Heterozygotes between female-sterile and fertile alleles are fertile, between female sterile alleles are sterile.

**alleles:** The *sn* locus seems to be a very favorable site for *P*-element insertion; a number of the alleles listed below were isolated from natural populations in the USSR or are derivatives thereof. These alleles are highly mutable, generating innumerable derivative mutable normal-appearing and extreme singed alleles; some have been shown to carry *P*-element sequences at *sn* (Golubovsky, Ivanov, and Green, 1977, Proc. Nat. Acad. Sci. USA 74: 2973-75; Green, 1977, Proc. Nat. Acad. Sci. USA 74: 3490-93). Also some display slight increases in the rate of nondisjunction from *Basc* (Golubovsky, 1983, DIS 59: 40-42). Bender has classified *sn* alleles into four classes: class 1 = female sterile with gnarled macrochaetae and kinky microchaetae; class 2 = female fertile with kinky macrochaetae only; class 3 = female fertile with gnarled macrochaetae and kinky microchaetae; class 4 = female sterile with gnarled macrochaetae only. To these Golubovsky and Kozlovskaya (1978, DIS 53: 141-42) have added class 5 = kinky microchaetae only. Derivative alleles have sometimes been designated generically as *sn*<sup>f</sup>, *sn*<sup>m</sup>, *sn*<sup>s</sup>, and *sn*<sup>ex</sup>, for faint, moderate, strong, and extreme phenotypes; these symbols do not specify particular alleles (e.g., Zakharov and Golubovsky, 1984, Genetika 20: 1117-24). Unstable alleles also classed as *sn*<sup>A</sup> and *sn*<sup>B</sup>, *sn*<sup>A</sup> alleles mutating to normal and back to the original phenotype only and *sn*<sup>B</sup> alleles mutating to an array of intermediate states as well as to normal.

<sup>β</sup> Class according to Bender (1960); coordinates according to Roiha, Rubin, and O'Hare (1988).

<sup>γ</sup> More detailed information given below.

**cytology:** Placed in 7D1-2 by *in situ* hybridization (Spradling; Engels).

**molecular biology:** 40 kb cloned; from coordinates -15 to +25 with the origin at an arbitrary *EcoRI* site and positive values to the right. Six out of nine alleles tested have lesions between -1.9 and +10.5 kb. Three breakpoints [*Dp(1;2)sn*<sup>13a</sup>, *In(1)sn*<sup>B332.1</sup> and *In(1)sn*<sup>B337.2</sup> (Roiha,

Rubin, and O'Hare, 1988, Genetics 119: 75-83)] between -0.6 and +5.5; *P* element hotspot at -0.7 to 0.0 with at least four different insertion sites. Gene consists of six exons with three polyadenylation sites resulting in three sizes for the 3' exon and three sizes of RNA, 3.6, 3.3, and 3.0 kb. Structure of gene-exon 1 from -0.7 to 0.0 kb; exon 2 from 11.0 to 11.3 kb; exon 3 from 12.3 to 12.7

kb; exon 4 from 12.8 to 13.3 kb; exon 5 from 13.4 to 13.6 kb; exon 6 from 13.7 to 14.4 or 14.7 or 15.0 kb. A single 59-kd protein predicted.

**other information:** Locus divided into three recombinationally different sites from distal to proximal: (*sn*<sup>3</sup> and *sn*<sup>36a</sup>) (*sn*<sup>2</sup> and *sn*<sup>4</sup>) (*sn*<sup>1</sup>, *sn*<sup>5</sup> and *sn*<sup>50k</sup>) (Ives and Noyes, 1951, Anat. Rec. 111: 565; Hexter, 1955, Proc. Nat. Acad. Sci. USA 41: 921-25; Genetics 42: 376). Of these, *sn*<sup>3</sup> and *sn*<sup>36a</sup> show lesions between -0.9 and 0.0 kb, whereas *sn*<sup>2</sup> has a lesion between 8.0 and 10.5. The others show no detectable molecular lesions, and are presumed to be point mutations within the coding region between 11.1 and 13.8 kb.

***sn*<sup>36a</sup>**

**phenotype:** Macrochaetae gnarled in a fairly extreme manner. Microchaetae wild type. *sn*<sup>36a</sup> is only allele to cause pronounced reduction in replication of oocyte nurse cell DNA [King and Burnett, 1957, Growth 21: 263-80 (fig.)]. Also causes more extreme retardation of vitellogenesis than other female-sterile *sn* alleles (Bender). *sn*<sup>36a</sup> *sn*<sup>4</sup> homozygote has nearly normal bristles and is sterile. RK1.

***sn*<sup>49</sup>**

**phenotype:** A strong allele of *sn* recovered from a natural population. Associated with simultaneous mutation to club wing, *clw*, a defect in wing expansion with low penetrance. *sn*<sup>49</sup> is unstable, producing an array of derivatives that are in turn stable or unstable. and the expression of *clw* differs among them. It mutates to *sn*<sup>+</sup> and back at a rate of approximately 10<sup>-3</sup>; a rare moderate singed derivative exhibits an approximately ten-fold elevation in mutation frequency, mutating either back to the strong allele or to an unstable normal allele; a single extreme singed derivative of a normal derivative of the moderate allele produces strong-singed and non-singed derivatives, which can in turn revert to the extreme allele and in the case of the strong derivative to non singed (Yurchenko, Zakharov, and Golubovsky, 1984, Mol. Gen. Genet. 194: 279-85).

***sn*<sup>63-15</sup>**

**phenotype:** Moderate *sn* phenotype. Prototype type B mutable allele; mutation rate 0.1 to 1.2%. Produces both extreme singed and normal-appearing derivatives as well as an array of intermediate phenotypes. In addition strongly reversible alleles (25-50 x more mutable than parental allele) are produced. This allele also associated with increased rate of mutation to *fw*.

***sn*<sup>77-27</sup>**

**phenotype:** Extreme *sn* phenotype. Prototype type A mutable allele; mutates to an unstable *sn*<sup>+</sup>, which mutates back to extreme alleles; no intermediate alleles recovered.

***sn*<sup>cm</sup>**

**phenotype:** An allele of *sn* that is mutable in dysgenic but not in non-dysgenic genotypes. Mutation takes place in two directions; one is to apparent stable reversions and the other to a more extreme phenotype, *sn*<sup>ex</sup>, which is in turn unstable.

**molecular biology:** Contains a 628-bp defective *P* element inserted at coordinate -667. *sn*<sup>+</sup> derivatives characterized by precise or nearly precise excision of the element.

*sn*<sup>ex</sup> derivatives contain duplications of the defective *P* element located close to the right of the original *P* in inverted orientation.

***sn*<sup>w</sup>: singed-weak**

**phenotype:** Weak singed phenotype, probably class 2. Highly mutable in dysgenic genotypes; 40% to 60% of offspring are either normal (*sn*<sup>(+)</sup>) or extreme singed (*sn*<sup>e</sup>) in phenotype. These derivatives are in turn mutable, but at much lower levels. Completely stable in non-dysgenic genotypes.

**molecular biology:** Contains a pair of adjacent defective *P* elements of 0.95 kb and 1.15 kb inserted in head-to-head orientation between -0.589 and -0.582 kb. All *sn*<sup>e</sup> derivatives tested retain only the 1.15 kb element and all normal-appearing derivatives retain only the 0.95 kb element, thus the symbol *sn*<sup>(+)</sup>.

***sna*: snail**

**location:** 2-51.

**synonym:** *l(2)br28 = l(2)35Db*.

**references:** Simpson, 1983, Genetics 105: 615-32.

Grau, Carteret, and Simpson, 1984, Genetics 108: 347-60.

**phenotype:** Embryonic lethal. Partially dorsalized. In homozygotes for strong alleles, ventral furrow not formed at gastrulation; however, endoderm invaginates, cephalic furrow formed, and germ-band elongation takes place. Embryo has few if any mesodermally derived internal tissues. Homozygotes for weak alleles gastrulate normally, but die as late embryos without differentiating normal internal tissues. Many embryos make normal ectodermal derivatives: larval hypoderm with normal or reduced denticle belts, mouth hooks, and spiracles, but tracheae seen only in weaker alleles. Head involution abnormal and anterior end of embryo twisted in the egg owing to extra length. Some embryos fail to make normal cuticle and resemble long folded tubes filled with yolk. *sna* heterozygotes produced from mothers heterozygous for *dl* or a deficiency for *dl* show reduced viability; this effect is more extreme at elevated temperatures. Defect in *sna* embryos enhanced by heterozygosity for *Df(2L)75c* or *Df(2L)fn2*. No maternal effect in germ-line clones. No effect on pattern of *fz* expression (Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32). *sna*/+ embryos have delayed ventral furrow formation.

**alleles:** Alleles of varying strengths reported. Weak alleles appear to be hypomorphic based on their phenotypes over deficiencies versus in homozygotes. Strong alleles behave as amorphs. *Trans* heterozygotes of weak alleles produce few escapers, which may exhibit missing halteres or more rarely hemithorax.

**cytology:** Placed in 35C4-D2 based on its inclusion in *Df(2L)b80e4* = *Df(2L)35C4;35D1-2* but not in *Df(2L)osp18* = *Df(2L)35B1-2;35C4-5*.

**molecular biology:** Gene isolated from walk on the basis of DNA lesions identified in five independent *sna* alleles. Sequences from the region identify a 1.7 mRNA on Northern blots. A 1.7 kb cDNA of nearly full length cloned and sequenced; injection of antisense RNA into early embryos promotes phenocopy of *sna* development. Transcription from proximal to distal on 2L. cDNA contains a single open reading frame of 1,170 nucleotides, corresponding to 390 amino-acid residues with a calculated relative molecular mass of 43,000. The carboxy terminus of the conceptual polypeptide contains five zinc-finger motifs (Boulay, Dennefeld, and Alberga, 1987, Nature (London) 330: 395-98).

**other information:** The *Sco* transposition brings a portion of the *noc* gene into juxtaposition with *sna*; subsequent rearrangements with breakpoints within the *sna* gene are able to revert the *Sco* phenotype (McGill, Chia, Karp, and Ashburner, 1988, Genetics 119: 647-61).

**snake:** see *snk*

**snap:** see *snp*

*snb*: see *p<sup>snb</sup>*

***Snb*: Snow blind (B. Ondek)**

**location:** 3-104.7.

**origin:** Induced by ethyl methanesulfonate.

**discoverer:** Ondek and Hardy.

**phenotype:** Deep pseudopupil absent in white-eyed flies raised in either light or dark. Electroretinogram displays no receptor potential. Light and electron microscopy reveal no organized ommatidial structure; widespread degeneration and no apparent photoreceptor cells.

*snf*: see *fs(1)A1621*

***snk*: snake**

**location:** 3-52.1.

**references:** Anderson and Nüsslein-Volhard, 1984, Nature 311: 223-27.

Anderson and Nüsslein-Volhard, 1986, Gametogenesis and the Early Embryo, Alan R. Liss, Inc., pp. 177-94.

**phenotype:** Maternal effect lethal. Embryos produced by homozygous mothers show extreme dorsalized phenotype; only dorsally derived cuticle remains, resulting in a

hollow tube of dorsal ectoderm. No paternal rescue, even by two doses of *snk*<sup>+</sup>; dorsalizes the expression of *ftz* such that entire *ftz* stripes in the blastoderm exhibit the wide dorsal conformation and do not narrow ventrally as is normal (Carroll, Winslow, Twombly, and Scott, 1987, Development 99: 327-32). Responds most strongly of all maternal dorsalized mutants to rescue by injection of cytoplasm and poly A<sup>+</sup> RNA from wild-type embryos. Injection of wild-type cytoplasm or cytoplasm from other dorsalizing maternal-effect mutants into pre-pole-cell snake embryos fully restores the normal dorsal-ventral pattern, and more than 20% can develop into normal adults; the site of injection appears to be unimportant. Partial rescue also achieved by the injection of poly A<sup>+</sup> but not poly A<sup>-</sup> RNA isolated from cleaving embryos.

**alleles:**

allele	origin	discoverer	synonym
<i>snk</i> <sup>1</sup>	EMS	Rice	<i>mel(3)4, snk</i> <sup>073</sup>
<i>snk</i> <sup>2</sup>	EMS		<i>snk</i> <sup>229</sup>
<i>snk</i> <sup>3</sup>	EMS		<i>snk</i> <sup>233</sup>
<i>snk</i> <sup>4</sup>	EMS		<i>snk</i> <sup>rm4</sup>

**cytology:** Placed in 87D6-13 on the basis of the molecular observation that the right breakpoint of *Df(3R)ry36* interrupts the gene and it is to the right of the molecular deficiency associated with *ry*<sup>506</sup>. *Df(3R)ry36* is not detectable cytologically, but it includes *ry* but not *Hsc2* or *pic*.

**molecular biology:** Gene identified by finding a DNA segment capable of rescuing *snk* by germ-line transformation. This 13.5 kb segment begins and ends in the loci of *ry* and *Hsc2*, respectively. Northern blots of embryonic RNA probed with a 2.4 kb *EcoRI* internal fragment from the above segment reveal a 1.65 kb transcript; a slightly smaller pupal transcript that differs from the embryonic transcript at its N and C termini is recognized by the same probe. Transcription is from right to left, and the cDNA sequence predicts a protein of 430 residues. The conceptual sequence reveals homology to several known serine proteases over its 246 C-terminal amino acids; may also have a Ca<sup>2+</sup> binding site near its amino-terminus (DeLotto and Spierer, 1986, Nature (London) 323: 688-92).

***snl*: sonless**

**location:** 1-56.3.

**discoverer:** Paré, 1964.

**references:** Colaianne and Bell, 1970, Genetics 65: 619-25.

Colaianne and Bell, 1972, Genetics 72: 293-96.

Colaianne and Bell, 1972, DIS 48: 20.

**phenotype:** Maternal-effect recessive lethal or semilethal. *snl/snl* females crossed to normal males produce fewer than 10% of the expected number of sons. Lethality can be rescued by a paternally derived *snl*<sup>+</sup> allele as demonstrated by the survival of exceptional sons but not daughters (i.e., *snl*<sup>+/0</sup> but not *snl/snl/Y*) of the above mating. Lethality occurs during embryonic or early larval stages. *snl*<sup>+/+</sup> females crossed to *snl/Y* males produce normal offspring in a 1:1 sex ratio. Crosses between *snl* males and females are nearly sterile, producing extreme sex ratios favoring females among surviving offspring. Data indicate that homozygosity for *tra* enhances and for *dsx* reduces the lethality of sons of *snl* mothers.

**other information:** Complements both *r* and *fu*, nearby genes that also act as maternal-effect lethals.

**sno: strawberry notch**

**location:** 1-41.8 (based on mapping of *sno*<sup>4</sup>).

**synonym:** *g-l: glossy like*.

**references:** Lefevre and Peterson, 1972, DIS 48: 126-27.

Lefevre and Wright, 1976, Genetics 83: s44-45.

**phenotype:** Males and females homozygous for viable alleles have notched wings, thickened, Confluens-like wing veins with deltas at the junctions of the longitudinal veins and the margins, extra hairs on thorax and wings, shortened tarsal segments, and roughened, shiny bright, somewhat mottled eyes, closely resembling *fa*<sup>8</sup>. All macrochaetae thin and delicate. Phenotype almost completely suppressed by euchromatic duplications of the Notch locus, e.g., *Dp(1;2)51b = Dp(1;2)3C1-2;3D6-7;52E*. Insertions into heterochromatin, e.g., *w<sup>+</sup>Y*, are less effective in suppression. *fa sno* males and *fa sno/+* females have exaggerated phenotypes and are semi-lethal; *spl sno* less extreme. *sno*<sup>1</sup> does not survive when raised at 29° or in *Rpl1215<sup>Ubl</sup>/+* genotypes; exhibits slight dominance in *trans* heterozygotes with *Rpl1215<sup>Ubl</sup>* (Mortin and Lefevre, 1981, Chromosoma 82: 237-47).

**phenotype:** Ocelli always absent; eyes usually reduced to small groups of ommatidia, and occasionally missing; eye field sometimes in form of an eye stalk protruding from head with an irregular arrangement of ommatidia; heavy ommatidial disruption with many receptor cells missing. Optic lobes reduced in size, and many flies have no lamina. The reduced volume of adult optic lobes is due to accentuated degeneration of precursor neurons that occurs to a certain degree in normal pupal development (Fischbach, 1983); the increased severity in the mutant includes degeneration of axons in second optic chiasma (Fischbach and Technau, 1984); *sol* enhances this kind of degeneration, but acts on a separate set of precursors for columnar visual system neurons--as confirmed by anatomical analysis of *sol*; *so* double mutant, which ends up with tiny, rudimentary optic lobes (Fischbach and Technau, 1984); *sol*; *so* also leads to a central brain that is smaller than normal due to missing afferents from visual system (Fischbach and Technau, 1984); more specifically, there is a reduction in number of axons in anterior optic track in *so*, and combining *so* with *sol* causes a further reduction, but again, these two genes act independently on separate subsets of such axons (Fischbach and Lyly-Hünerberg, 1983). Histological studies reveal that the eye-antenna disc in third-instar larvae appears normal until differentiation begins, at which time cell death is observed (Hofbauer and Campos-Ortega). More extreme at elevated temperatures; lethal at 30°; temperature-sensitive period for eye defect in third instar. Survival sensitive to elevated temperature at all developmental stages (Ransom, 1980, DIS 55: 126). Mosaic studies demonstrate that *so* acts in developing eye tissue

and that the resulting reduction in retinal innervation leads to death of cells in the lamina and breakdown of medulla and lobula-complex neuropil (Fischback and Technau). Nonphototactic (Benzer, 1967, Proc. Nat. Acad. Sci. USA 58: 1112-19) and visual orientation almost absent (Bülthoff, 1982, DIS 58: 31). Studies of circadian rhythms in *so* show eclosion to be normally periodic (Engelmann and Honneger, 1966); adult activity rhythms are robust, in that *so*, even when thoroughly eyeless, responds to light:dark cues such that it entrains to these conditions (is periodically active vs. inactive, and anticipates the environmental transitions) and subsequently free-runs with obvious circadian periodicities in constant darkness (Helfrich and Engelmann, 1983; Dushay, Rosbash, and Hall, 1989); however, these behavioral rhythms are frequently aberrant, e.g., with "split" active components appearing after several days of free-run and with dual periodicities extractable from the locomotor data (Helfrich, 1986); nearly all adults are dual-period when *so* combined with *sol* (Helfrich, 1986).

Lee, Ayala, Misra, 1981, J. Biol. Chem. 256: 8506-09.

Lee, Misra, Ayala, 1981, Proc. Nat. Acad. Sci. USA, 78: 7052-55.

**phenotype:** The structural gene for Cu, Zn superoxide dismutase [Superoxide: superoxide oxidoreductase; SOD (EC 1.15.1.1)], a homodimer of 15,000 subunit molecular weight that contains two Cu<sup>++</sup> and two Zn<sup>++</sup> per molecule. Enzyme catalyzes the dismutation of the superoxide anion, O<sub>2</sub><sup>-</sup>, to H<sub>2</sub>O<sub>2</sub>, which in turn is converted into H<sub>2</sub>O by catalase and peroxidases. Enzyme purified by Lee, Ayala, and Misra (J. Biol. Chem. 256: 8506-09); shows homology to homologous mammalian enzymes but does not crossreact with anti-bovine-erythrocyte-SOD antibodies; specific activity 1.5 times that of other species. Amino acid sequence determined by Lee, Friedman, and Ayala (1985, Arch. Biochem. Biophys. 241: 577-89); 151 amino acid resi-

dues with molecular weight 15,750. Enzyme levels show little variation during development; slight rise in activity during adulthood (Graf and Ayala, 1986, Biochem. Genet. 24: 153-68).

**alleles:** Two electrophoretic variants, *Sod*<sup>F</sup> and *Sod*<sup>S</sup>, whose relative frequencies vary greatly among natural populations. *Sod*<sup>S</sup> alleles differ from *Sod*<sup>F</sup> alleles in having a lysine in place of asparagine at residue 96 (Lee and Ayala, 1985, FEBS Lett. 179: 115-19); fast alleles from California and Tunisia differ at two additional residues, tentatively California alleles have a serine and a glutamine or glutamic acid, where Tunisian alleles have a histidine and a proline. Slow forms of SOD have specific activity 2-3 times that of fast forms and they are more thermolabile (Lee, Misra, and Ayala, 1981). A low activity allele, *Sod*<sup>CA1</sup> isolated from a natural population in California exhibits 3.5% of normal CRM level; low level maps to *Sod* (Graf and Ayala). In addition to these naturally occurring alleles there is a single ethyl methanesulfonate-induced null allele, *Sod*<sup>nl</sup> (isolated as *l-108*; Campbell, Hilliker, and Phillips, 1986, Genetics 112: 205-15).

**cytology:** Placed in 68A8-9 by *in situ* hybridization (Kirkland and Phillips, 1987, Gene 61: 415-19).

**molecular biology:** Gene cloned and sequenced; cDNA clones have 458 base pairs of open reading frame, encoding 153 amino acids; N-terminal methionine and C-terminal valine do not appear in the mature polypeptide (Seto, Hayashi, and Tener, 1987, Nucleic Acids Res. 15: 5483). Genomic sequence contains a 725 base-pair intron between codons 21 and 22, which corresponds to the position of the first intron in the human SOD gene (Seto, Hayashi, and Tener, 1987, Nucleic Acids Res. 15: 10601).

### *Sod*<sup>nl</sup>

**origin:** Ethyl methanesulfonate-induced derivative of *Sod*<sup>F</sup>.

**references:** Phillips, Campbell, Michaud, Charbonneau, and Hilliker, 1989, Proc. Nat. Acad. Sci. USA 86: 2761-65.

**phenotype:** Originally recovered as a lethal mutation; homozygotes die in the process of eclosion; rare eclosing adults are completely sterile, are devoid of SOD activity and die within 2-3 days; however, some derived sublines show higher adult survival. Surviving homozygous males are sterile and homozygous females produce few if any offspring. Reduced life span and fertility attributed to reduced capacity of embryos, larvae, and pupae to protect developing preimaginal cells from O<sub>2</sub><sup>-</sup>-initiated cytotoxic damage. Homozygotes hypersensitive to the O<sub>2</sub><sup>-</sup>-radical-generating compound, paraquat (1,1'-dimethyl-4,4'-bipyridinium dichloride) and copper ions.

**soft brown:** see *sb*

### *sog*: short gastrulation

**location:** 1-53.

**references:** Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307. Zusman, Sweeton, and Wieschaus, 1988, Dev. Biol. 129: 417-27 (fig.).

**phenotype:** Embryonic lethal with weak ventralized phenotype. Invagination and subsequent closing of the posterior midgut and anterior midgut delayed; germ-band

extension incomplete; dorsal-most cells fail to assume normal amnioserosal fate; they are abnormally thick and fall into deep dorsal folds at the time of germ-band extension. Mosaic studies indicate that *sog* expression required only ventrally for normal development. No discernable maternal effect.

**alleles:** Six ethyl methanesulfonate-induced alleles, one of which is temperature sensitive, recorded by Wieschaus *et al.*; one isolated as *sog-92.31* designated *sog*<sup>1</sup> by Zisman *et al.* Allele *sog*<sup>M4</sup> here designated *sog*<sup>2</sup>; *XM* designated *sog*<sup>3</sup>. The remaining alleles designated *sog*<sup>4</sup> through *sog*<sup>6</sup>; identity of t.s. allele unknown. *sog*<sup>7</sup> ethyl methanesulfonate induced by Eberl and Hilliker (1988, Genetics 118: 109-20) as *EH628*.

**cytology:** Placed in 13D1-E7 based on its location between the breakpoints of *T(1;Y)B28 = T(1;Y)13D;YS* and *T(1;Y)W23 = T(1;Y)13E1-7;YL*.

***sol*: small optic lobes (J.C. Hall)**

**location:** 1- {65} (Fischbach and Heisenberg, 1981, and Helfrich, 1986, quote more distal and more proximal meiotic map positions, respectively); Fischbach and Lyly-Hünerberg mapped *sol* proximal to *car*.

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *PC79*; *w5000*.

**references:** Markow and Merriam, 1977, Behav. Genet. 7: 447-55.

Fischbach and Heisenberg, 1981, PNAS 78: 1105-09.

Helfrich, 1986, J. Neurogenet. 3: 321-43.

Coombe, 1986, J. Comp. Physiol. 159: 655-65.

Miklos, Kelly, Coombe, Leeds, and Lefevre, 1987, J. Neurogenet. 4: 1-19.

**phenotype:** Medulla, lobula, and lobula-plate optic ganglia reduced in volume and cell number (anatomical criteria on which several of the mutations, including the most studied allele *sol*<sup>1</sup>, were isolated by Heisenberg and Böhl, 1979, Z. Naturforsch. 34: 143-147); lamina seems unaffected; degree of reduction in the three more proximal visual-system ganglia is allele dependent; after isogenization the severity ranking of nine alleles was as follows: *sol*<sup>2</sup> = *sol*<sup>3</sup> (ca. 50% normal volume) > *sol*<sup>6</sup> = *sol*<sup>9</sup> = *sol*<sup>16</sup> > *sol*<sup>1</sup> = *sol*<sup>4</sup> = *sol*<sup>5</sup> = *sol*<sup>8</sup> (ca. 30% normal volume). Three *sol* mutants isolated on basis of fast phototaxis; Markow and Merriam (1977) showed that one such allele, *sol*<sup>4</sup>, causes flies to be anomalously photo positive and highly geonegative in maze tests. Anatomically, *sol* mutations cause specific cell types in medulla to be missing (Fischbach and Heisenberg, 1981); stratifications in outer medulla are missing; in general, however, mutant optic lobes are grossly well structured, and there are no disorders in the optic chiasma; special classes of transmedullary columnar neurons as well as intramedullary cells are absent; numbers of columns in the visual ganglia are normal, but numbers of neurons per column are reduced; certain neurons called T1 cells are present in each column in *sol*<sup>1</sup>, as usual; these reductions in cell numbers are caused by cell-type-specific degen-

eration of presumptive optic lobe neurons during pupation, with no degeneration apparent in neuropiles of these ganglia (Fischbach and Technau, 1984); the number of axons severely reduced in anterior optic track, and the combining of *so* with *sol*<sup>1</sup> showed that these two mutations act independently on nearly exclusive subsets of these axons (Fischbach and Lyly-Hünerberg, 1983). Mosaic study showed that aberrant morphology of visual ganglia is autonomous in these optic lobes (Fischbach and Technau, 1984); adult eye and lamina optic lobe appear normal. In combination with *rol* and *mnb* mutations, *sol* causes diminished amplitudes of light-on and light-off transient spikes in electroretinogram (Coombe, 1986); visual fixation behavior notably defective (Fischbach and Heisenberg, 1981) [e.g., in the walking mode, fixation behavior is actually reversed in all *sol* alleles (Fischbach)] as, to a lesser degree, are landing responses and "figure/ground" discrimination; on the other hand, optomotor *yaw* response is nearly normal (Fischbach and Heisenberg, 1981); orientation to spots in multiple Y-maze quite subnormal (Bülthoff, 1982a,b). Shock-avoidance learning of *sol*<sup>1</sup> (Heisenberg, Borst, Wagner, and Byers, 1985, J. Neurogenet. 2: 1-30) and color discrimination in *sol*<sup>1</sup>, *sol*<sup>2</sup>, and *sol*<sup>3</sup> (Fischbach) are normal; there are, however, deficits in visual plasticity (Götz, 1983, Dtsch. Zool. Ges. Gustav Fischer Verlag, Stuttgart, pp. 83-99) and in the flexibility that wild types can exhibit in optomotor flight control tests (Götz, 1985, Biol. Chem. Hoppe Seyler 366: 116-17). Circadian rhythms of adult locomotor activity basically normal (Helfrich and Engelmann, 1983; Helfrich, 1986), but when *sol*<sup>1</sup> combined with *so*, all flies tested showed complex periodicities, with a given behavioral record having one component at approximately 21 and another at approximately 26 h (Helfrich, 1986).

<sup>α</sup> 1 = Benzer and Merriam; 2 = Bülthoff, 1982, DIS 58: 31; 3 = Fischbach and Heisenberg, 1981, Proc. Nat. Acad. Sci. USA 78: 1105-09; 4 = Heisenberg and Böhl, 1979, Z. Naturforsch. 34: 143-47.

<sup>β</sup> Criterion used in selection of mutant.

**cytology:** Tentatively placed in 19F4, along with *slgA*, these two genetically separable mutations being flanked by *l(1)19Fe* and *l(1)19Ff*; this determination (Miklos *et al.*, 1987) was based the behavioral defects and anatomical abnormalities of *sol* in heterozygous combination with *Df(1)GA104*, but not by *Df(1)16-129*, located distally or *Df(1)JA117*, located proximally; none of the three

has cytologically determined breakpoints.

**molecular biology:** Maps within the distal 15 kb of a 40 kb interval defined by the proximal breakpoint of *Df(1)16-129* and the distal breakpoint of *Df(1)JA117*. This region is further subdivided by a breakpoint of a deficiency, *Df(1)2/19B*, which separates *sol* and *slgA*. Only one transcription unit has been detected within this 15 kb segment by Northern blotting (should contain both *l(1)19Fe* and *sol*); a 5.3 kb cDNA complementary to the one transcript has been isolated and sequenced (Delaney, Hayward, Fischbach, and Miklos, unpublished). The conceptual translation product is *ca.* 35% identical to human or chicken calcium-activated neutral protease (calpain); sequence data also reveal an opa repeat and cysteine repeats of the zinc-finger type. Spatial expression studies so far reveal *sol* transcript to be expressed in a few cells (probably glia) within the embryonic CNS (F. Barleben and K. F. Fischbach, unpublished), although there are no apparent anatomical defects in mutant embryos or larvae.

**other information:** In behavioral tests, *sol*<sup>1</sup> was complemented by alleles of *l(1)19Ff* and also by mutations at the nearby *slgA*, *uncl*, and *stm* loci (Miklos *et al.*, 1987).

**\*som: sombre**

**location:** 1-40.8.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 75.

**phenotype:** Pigmentation of body and eyes dark and dull. Wings occasionally divergent or blistered. Good viability and fertility. RK2.

**other information:** One allele induced by CB. 1414.

**sonless:** see *snl*

**sp: speck**

**location:** 2-107.0.

**references:** Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 128 (fig.).

Morgan, Bridges, and Sturtevant, 1925, Bibliogr. Genet. 2: 211 (fig.), 236.

**phenotype:** Axils of wings have black specks. Body color dark. In pupa, region of anal papilla is dark (Waddington). Displays a marked decrease in the amount of the A2 component of phenoloxidase; levels restored to normal in presence of *su(s)*<sup>2</sup> (Warner, Grell, and Jacobsen, 1975, Biochem. Genet. 13: 353-56). RK1.

**cytology:** Placed in 60B13-60C5 on the basis of its inclusion in the 2R<sup>PX</sup><sup>D</sup> element of *T(1;2)Bld = T(1;2)1C3-4;60B12-13* and *Df(2R)Px = Df(2R)60B8-10;69D1-2* but

not in *Df(2R)Px*<sup>2</sup> = *Df(2R)60C5-6;60D9-10* [Bridges, 1937, Cytologia (Tokyo), Fujii Jub., Vol. 2: 745-55].

**sp: speck**

From Bridges and Morgan, 1919, Carnegie Inst. Washington Publ. No. 278: 129.

*sp*: see *sd*<sup>sp</sup>

**Sp: Sternopleural**

**location:** 2-22.0.

**origin:** Spontaneous.

**discoverer:** M. (Mann) Lesley.

**synonym:** *Br: Bristled.*

**references:** 1923, Genetics 8: 27-36.

**phenotype:** Sternopleural bristles increased in number. At 19°, wild type; at 25°, overlaps wild type; at 28°-30°, no overlap. Apparently does not affect sternopleural bristles on metathoracic segment converted by *bx* to a mesothoracic segment (Waddington, 1939, Growth Suppl. 1, pp. 37-44). Homozygous lethal. RK2.

**cytology:** Placed in salivary chromosome region 27C1 to 28C1 (E. H. Grell). Salivary chromosomes apparently normal (Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301).

**Sp: Sternopleural**

Edith M. Wallace, unpublished.

*sp-w*: see *w*<sup>sp</sup>

**spa: sparkling**

**location:** 4- [probably most distal visible locus on chromosome 4 (Abrahamson, Herskowitz, and Muller, 1956, Genetics 41: 410-19)].

**origin:** Spontaneous.

**discoverer:** L. V. Morgan, 34k6.

**references:** 1941, DIS 14: 52.

1947, Genetics 32: 200-19.

Hochman, 1971, Genetics 67: 235-52.

Hochman, 1974, Cold Spring Harbor Symp. Quant. Biol. 38: 581-89.

**phenotype:** Eyes rough in varying degrees and somewhat bulging. Affected by genetic modifiers. More extreme at 17°-19° than at 22°-25°. Heterochromatin and sex affect expression so that  $X/0 > X/X > X/Y > X/X/Y$ ; also enhanced by *Df(2R)M41A10*; *spa* haplo-4s have an exaggerated phenotype. RK2.

**cytology:** Placed in 102D-F on the basis of the absence of *spa*<sup>+</sup> from the 4<sup>P</sup>2L<sup>D</sup> element of *T(2;4)b = T(2;4)25E;102C15-D1* (E. B. Lewis). Observations on its further location conflict. Fahmy restricts its location to 102D on the basis of its inclusion in *Df(4)M<sup>62e</sup> = Df(4)101E;102D13-E1*, whereas Hochman places it between 102E2 and 102F10 on the basis of its inclusion in *Df(4)11 = Df(4)102E2-10;102F2-10*.

**spa<sup>A</sup>**

**references:** Craymer, 1980, DIS 55: 197-200.

**phenotype:** Dominant rough-eye allele; more extreme than *spa<sup>Cat</sup>*. *spa<sup>A</sup>/spa<sup>pol</sup>* shows extreme poliart phenotype; *spa<sup>A</sup>/spa<sup>Cat</sup>* lethal. RK1A.

**cytology:** Associated with *T(3;4)Ubx<sup>A</sup>*, an extremely complex rearrangement with one breakpoint in 102E-F.

**spa<sup>Cat</sup>: sparkling-Cataract**

**origin:** X ray induced.

**discoverer:** Belgovskiy, 1936.

**synonym:** *Cat*.

**references:** 1937, DIS 8: 7.

Morgan, 1941, DIS 14: 52.

**phenotype:** Posterior third or half of eye of heterozygote rough; facets irregular and fused. Homozygous lethal. Stocks vary in expression, presumably because of genetic modifiers.  $X/X$  and  $X/0$  flies that are *spa<sup>Cat</sup>/spa* show the bulging eyes and roughening of *spa* and the posterior fused facets of *spa<sup>Cat</sup>*;  $X/X/Y$  and  $X/Y$  flies have only the *spa<sup>Cat</sup>* phenotype. *spa<sup>Cat</sup>/spa<sup>pol</sup>* has fusion of facets over entire surface of eye and roughness in posterior region of eye. *spa<sup>Cat</sup>/4-sim* is wild type. *spa<sup>Cat</sup>/+* more extreme than *spa<sup>Cat</sup>/+/+* (Davis, 1969, Genetics 61: 577-94). RK2.

**other information:** *spa<sup>Cat</sup>* behaves as a deficiency in that it fails to complement *l(4)102EFa*, *l(4)102EFb*, *l(4)102EFc*, and *l(4)102EFd*; complements *sv* and *l(4)102EFe*.

**spa<sup>e(lz)</sup>: sparkling-enhancer of lozenge**

**origin:** Spontaneous.

**discoverer:** H. A. Bender, 65b23.

**phenotype:** Homozygote wild type in absence of *lz*; eyes strongly roughened in presence of heterozygous *lz<sup>3</sup>*, *lz<sup>34</sup>*, *lz<sup>36</sup>*, or *lz<sup>D</sup>*. Slight eye roughening when both *spa<sup>e(lz)</sup>* and a *lz* allele are heterozygous. *spa<sup>e(lz)</sup>/spa<sup>pol</sup>* and *spa<sup>e(lz)</sup>/spa<sup>p65</sup>* have very rough eyes but normal tarsal claws and spermathecae. RK3.

**spa<sup>p61</sup>: sparkling-poliart type**

**origin:** Spontaneous.

**discoverer:** Sturtevant, 1961.

**phenotype:** Eyes small, rough, and glazed. More extreme than *spa<sup>pol</sup>* or *spa<sup>p65</sup>*. Nonpigmented tarsal claws. RK1.

**spa<sup>p65</sup>**

**origin:** Spontaneous.

**discoverer:** H. A. Bender, 65j11.

**phenotype:** Eyes somewhat reduced in size, rough and partially glazed. More extreme than *spa<sup>pol</sup>* but less so than *spa<sup>p61</sup>*. Tarsal claws unpigmented and possibly reduced; reminiscent of certain lozenge mutants. Pulvilli and accessory female reproductive structures appear normal. Heterozygote with *spa<sup>pol</sup>* and *spa<sup>p61</sup>* has affected tarsal claws as well as rough eyes. Heterozygote with *spa* has slightly roughened eyes at 25° but markedly roughened eyes at 18°; female somewhat more extreme than male. Viability and fertility good. RK1.

**spa<sup>pol</sup>: sparkling-pollert**

**origin:** Spontaneous.

**discoverer:** Hadorn, 51a.

**synonym:** *pol*.

**references:** Rickenbacher, 1953, DIS 27: 59.

1954, Z. Indukt. Abstamm. Vererbungslehre 86: 62-68 (fig.).

**phenotype:** Eyes rather small; surface smooth and glassy.

During second day of pupal life, retinula cells withdraw from other cells of eye disk. SEM studies show irregular disposition and morphology of ommatidial hairs as well as numerous necrotic pits over surface of eye [Oster and Crang, 1972, Trans. Am. Microsc. Soc. 91: 600-02 (fig.); Strum-Tegethoff and Dicke, 1974, Theor. Appl. Genet. 44: 762-65]. ERG absent [Grossfield, Handbook of Genetics (King, ed.). Plenum, New York, pp. 679-702]. *spa<sup>pol</sup>/spa<sup>Cat</sup>* has extreme phenotype; *spa<sup>pol</sup>/spa* slightly more extreme than *spa* (Sturtevant, 1961, DIS 35: 47). Homozygote has excellent viability and fertility. RK1.

**spd: spade**

**location:** 2-21.9 [to the left of *Sp* (E. H. Grell)].

**origin:** Spontaneous.

**discoverer:** Bridges, 30d15.

**phenotype:** Wings short and broad, pointed at tip, and warped at base. Effect on wing shape arises from excessive contraction of epithelium from inflated stage onward (Waddington, 1940, J. Genet. 41: 75-139). Overlaps wild type in existing stock. RK3.

**cytology:** Placed in 27D based on its inclusion in

*Df(2L)spd = Df(2L)27D-E;28C* (E. H. Grell) and location distal to *T(Y;2)A171 = T(Y;2)h3;27D* breakpoint (Kotar-ski, Pickert, and MacIntyre, 1983, Genetics 105: 371-86).

***spd<sup>1g</sup>: spade-flag***

**origin:** Spontaneous.

**discoverer:** Doane, 60f14.

**synonym:** *fg*.

**references:** 1960, DIS 34: 49.  
1961, DIS 35: 45-46.

**phenotype:** Wings about two-thirds the length and three-fourths the width of wild type, held tentlike over abdomen. Alulae absent or vestigial; proximal posterior wing margins often irregular with tendency to fold under about vein L4. Venation usually normal with occasional blistering. *spd<sup>1g</sup>/spd* has phenotype varying from slight shortening of wings to a shape midway between the two homozygotes. Excellent viability and fertility. RK1.

*spe*: see *lz<sup>s</sup>*

***αSpec: alpha Spectrin***

**location:** 3- {1.5}.

**references:** Dubreuil, Byers, Branton, Goldstein, and Kiehart, 1987, J. Cell Biol. 105: 2095-2102.

Byers, Dubreuil, Branton, Kiehart, and Goldstein, 1987, J. Cell Biol. 105: 2103-10.

**phenotype:** Structural gene for alpha spectrin, a 234 kd polypeptide that forms an elongated heterodimer with beta spectrin to form an important cytoskeletal component. Product crossreacts with antibodies against mammalian spectrins; can be shown to bind to beta spectrin subunits.

**cytology:** Placed in 62B1-7 by *in situ* hybridization to a single polytene site.

**molecular biology:** cDNA sequences isolated by antibody screening of an expression library prepared from Drosophila adult head polyadenylated RNA. Northern blots reveal a single homologous 8 kb messenger RNA. Derived probes bind to a single polytene region, suggesting the presence of a single Drosophila alpha spectrin gene. cDNA clones indicate *αSpec* contains a single open reading frame that encodes a polypeptide 2,415 residues long of molecular weight 278,364 daltons. Conceptual sequence indicates two stretches of nine 106-residue repeats separated by a short non-repetitive segment; the repeats are defined by a consensus sequence of 54 residues, 50 of which are shared by chicken *α* spectrin. Drosophila *α* spectrin is 63% identical with chicken brain *α* spectrin (Dubreuil, Byers, Sillman, Bar-Zvi, Goldstein, and Branton, 1989, J. Cell Biol. 109: 2197-2205).

***βSpec: beta Spectrin***

**location:** 1-{57}.

**references:** Byers, Hussain-Chishti, Dubreuil, Branton, and Goldstein, 1989, J. Cell Biol. 109: 1633-41.

**phenotype:** Structural gene for beta spectrin; The subunit of beta spectrin associates with the subunit of alpha spectrin, forming heterodimers which associate to form tetramers, presumably the most important functional state for spectrin.

**cytology:** Located in 16C1-4 by *in situ* hybridization to the salivaries (Byers *et al.*, 1989). A single polytene site was detected.

**molecular biology:** Drosophila *βSpec* cDNA clones were isolated from cDNA expression library using chicken alpha spectrin as a probe. These cDNAs express polypeptides that bind to alpha spectrin. Antibodies from fusion proteins expressed by these sequences react with Drosophila spectrin. Nucleotide and predicted amino acid sequences for the 5' end of spectrin determined; the amino acid sequence predicted for this region shows 62% identity to the deduced sequence for the erythrocyte beta spectrin in man. A single mRNA of about 8.0 kb was detected on Northern blots of poly A+ RNA from Drosophila heads (Byers *et al.*, 1989).

***spg: sponge***

**location:** 3-95.

**discoverer:** Rice.

**synonym:** *early-D*; *mat3(6)*.

**references:** Rice and Garen, 1975, Dev. Biol. 43: 277-86 (fig.).

Rickoll and Counce, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 245-51 (fig.).

**phenotype:** Maternal-effect lethal; embryos produced by homozygous females produce pole cells, but syncytial blastoderm fails to cellularize completely; cells form at the anterior and posterior ends of the embryo but are separated by a noncellular region comprising 70% of the embryo surface. Abortive gastrulation signified by formation of posterior midgut rudiment.

**alleles:** Five ethyl methanesulfonate-induced alleles; *spg<sup>1</sup>* through *spg<sup>5</sup>*, isolated as *145*, *242*, *805*, *842*, and *rm6*, respectively.

***sph: sparse hairs***

**location:** 1- {65}.

**references:** Schalet and Lefevre, 1976, The Genetics and Biology of Drosophila (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 16, pp. 847-902.

Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31.

**phenotype:** Thoracic hairs sparse, eye roughening variable, wings extended and margins incised. This phenotype observed in flies heterozygous for *Df(1)17-87*, *Df(1)22*, and *sph<sup>1</sup>*, *sph<sup>3</sup>*, or *sph<sup>4</sup>* (Schalet and Lefevre). No effect on central or peripheral nervous system in *sph<sup>5</sup>* or *sph<sup>6</sup>*; both alleles cell lethal in female germline clones (Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52).

Mayer and Nüsslein-Volhard, 1988, *Genes Dev.* 2: 1496-1511 (fig.).

**phenotype:** Embryonic lethal. Normal allele required for normal development of blastoderm cells just lateral to the ventral mesodermal precursors. Denticle bands narrower than normal; first row often missing; reversal of polarity between anterior and posterior rows not seen; irregular fusion in midline of adjacent denticle bands. Keilin's organs missing or strongly reduced. Labrum, antennal-maxillary complex and labial sense organ reduced in size; right and left halves of head skeleton fused to produce pointed appearance. Tail region normal. Right and left halves of ventral ganglia of the central nervous system closer together than normal resulting in shorter commissures. The cells in the CNS that stain with anti-*eve*<sup>+</sup> antibodies are closer together in *spi* than in wild type. *spi*<sup>+</sup> required in the female germ line; *spi* pole cells transplanted into normal embryos produce no progeny.

**alleles:** Three ethyl methanesulfonate-induced alleles, *spi*<sup>1</sup>, *spi*<sup>2</sup>, and *spi*<sup>3</sup>, isolated as *IIA*, *IIT*, and *IIIA*.

**cytology:** Placed in 37E2-38A1; in the region common to *Df(2L)E55 = Df(2L)37D2-E1;37F5-38A1* and *Df(2L)TW9 = Df(2L)37E2-F4;38A6-C1*.

**molecular biology:** spitz region cloned from 37F [Rutledge, Zhang, Perrimon, Bier, and Y. Jan, 1990 (Asilomar)].

**spindle:** see *spn*

**spineless:** see *ss*

**spiny legs:** see *spie*

**spir: spire (T. Schüpbach)**

**location:** 2- {54.5}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Manseau and Schüpbach, 1989, *Genes Dev.* 3: 1437-52.

**phenotype:** Maternal-effect lethal; homozygous females lay eggs which sometimes (5-10%) have a "peak" (spire) of dorsal appendage material sitting over the anterior end of the egg, instead of two distinct dorsal appendages. Such eggs are similar to eggs formed by the female-sterile mutation *fs(1)K10*, but the extent of dorsal appendage material on *spir* eggs is much more variable than that of *fs(1)K10* eggs. Mutant females produce embryos lacking polar granules, pole cells, and normal abdominal segmentation. In combination with *Bic-D*,

however, abdominal segmentation does develop in the anterior half of the embryo; improper localization of abdominal determinants also indicated by the lack of posterior localization of *vasa* protein. Cellularization of the blastoderm irregularly defective with nuclei of different sizes and densities. Resemble embryos formed by other grandchildless-knirps-like mutations, such as *vasa* or *tudor*, but in addition, some of the embryos from spire females appear also to be dorsalized.

**alleles:** Twelve alleles, presumably induced by ethyl methanesulfonate; *spir*<sup>1</sup> to *spir*<sup>6</sup> isolated as *RP*, *HP*, *HJ*, *QF*, *O3*, and *41*, respectively.

**cytology:** Placed in 38A6-C10, based on its inclusion in *Df(2L)pr21 = Df(2L)37E3-F1;38C6-10* but not *Df(2L)TW50 = Df(2L)36E4-F1;38A6-7*.

**spiracles:** see *gra*

**spire:** see *spi*

**spi:** see under *N*

**Spl: Splayed**

**location:** 3-51.6.

**references:** Lindsley, Sandler, Baker, Carpenter, Denell, Hall, Jacobs, Miklos, Davis, Gethmann, Hardy, Hessler, Miller, Nozawa, Parry, and Gould-Somero, 1972, *Genetics* 71: 157-84.

Tasaka and Suzuki, 1973, *Genetics* 74: 509-20.

Suzuki, Kaufman, and Falk, 1976, *Genetics and Biology of Drosophila* (Ashburner and Novitski, eds.), Academic Press, London, New York, San Francisco, Vol. 1a, pp. 208-51.

**phenotype:** Legs extended; movements awkward; some melanization of leg joints. Originally described as the phenotype of a heterozygous deficiency for region 81F-82A by Lindsley *et al.*; subsequently a temperature-sensitive lethal isolated by Tasaka and Suzuki that mapped to the region and which produced the same phenotype, presumably in homozygotes reared at permissive temperatures.

**alleles:** Only one mutant allele, *Spl*<sup>ts</sup>.

**cytology:** Placed in 81F-82A based on the phenotype of heterozygotes for the segmental deficiency produced from *T(Y;3)J139 = T(Y;3)80-81* and *T(Y;3)J17 = T(Y;3)82A*.

**splay wing:** see *splw*

**splc:** see *tor*<sup>11D</sup>

**spie: spiny legs**

**location:** 2-55.3 [between *pk* and *pwn* (Grau and Simpson, 1987, *Dev. Biol.* 122: 186-200)].

**origin:** Spontaneous.

**references:** Goldschmidt, 1945, *Univ. Calif. (Berkeley) Publ. Zool.* 49: 503-4, 521.

Gubb and Garcia-Bellido, 1982, *J. Embryol. Exp. Morph.* 68: 37-57.

Held, Duarte, and Devakhshanian, 1986, *Roux's Arch. Dev. Biol.* 195: 145-57 (fig.).

**phenotype:** Polarity of chaetae and trichomes on legs irregular; relations between bracts and bristles disrupted. High incidence of ectopic tarsal joints with inverted polarity, especially in tarsae 3 and 4; incomplete intersegmental membranes between tarsal segments, especially between segments 3 and 4; no extra sensilla companion-

mia despite extra joints. Chaetae on abdominal tergites turned toward midline instead of pointing posteriorly as in wild type; polarity of bristles on sternites disrupted as well.

**alleles:**

**cytology:** Placed in 42C1-43C7 based on its inclusion in the region common to *Df(2R)pk78r = Df(2R)43A1;43C7* and *Df(2R)pk78s = Df(2R)42C1-7;43F5-8* (Ashburner, Angel, Detweiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-91).

***sple*<sup>3</sup>**

**synonym:** Bristle orientation reversed.

**phenotype:** A low-temperature-sensitive allele. Legs of flies raised at 19° highly condensed with incomplete joints, haphazard bristle pattern, occasional increase in number of bristle rows, and absence of some prominent markers. Flies unable to walk and soon get stuck in food. In *sple*<sup>3</sup> flies raised at 28° 53% of legs, though apparently normal, display abnormalities such as swollen second, third, and fourth tarsal segments, abnormal tarsal joints and reversals in bristle orientation in the middle of every segment; such flies able to walk and breed. About 30% of legs show phenotype intermediate between the two phenotypes described above. Mutant phenotype expressed in the homeotic legs of *Antp* and *ss*<sup>a</sup>; also expressed in mitotic clones.

*spliced*: see *tor*<sup>IID</sup>

*split*: see *spl* under **N**

*split thorax*: see *spx*

*Plotched*: see *Sl*

***splw*: splay wing**

**location:** 1-58.6.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 75.

**phenotype:** Wings shortened and usually slightly divergent. Eyes small and occasionally rough and deformed. Body size reduced slightly. Emergence delayed. Male sterile; viability about 10% wild type. RK3.

**other information:** One allele induced by CB. 1246.

***spn-A*: spindle A**

**location:** 3-96.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Egg shape affected; in extreme cases dorsal appendages are lacking and eggs have little or no dorsal-ventral polarity; some eggs have one fused dorsal appendage. Low fecundity; eggs often slightly collapsed.

**alleles:** Four alleles designated as *spn-A*<sup>1</sup> through *spn-A*<sup>4</sup> isolated as 003, 050, 057, and 215, respectively.

***spn-B*: spindle B**

**location:** 3-52.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Similar to *spn-A* but normal eggs also recovered; eggs always unfertilized and abnormal eggs often long.

**alleles:** Three alleles designated as *spn-B*<sup>1</sup> through *spn-B*<sup>3</sup> isolated as 056, 153, and 225, respectively.

**cytology:** Placed in 88A10-C3 based on its inclusion in *Df(3R)red-P93 = Df(3R)88A10-B1;88C2-3*. However, not in 88B1-4 based on its not being uncovered by *Df(3R)red-52P = Df(3R)88A12-B1;88B4-5*.

***spn-C*: spindle C**

**location:** 3-17.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Similar to *spn-A*.

**alleles:** Three alleles designated as *spn-C*<sup>1</sup> through *spn-C*<sup>3</sup> isolated as 094, 422, and 660, respectively.

***spn-D*: spindle D**

**location:** 3-91.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Similar to *spn-A*; embryos sometimes hatch.

**alleles:** Two alleles, *spn-D*<sup>1</sup>, a weak allele isolated as number 150, and a strong allele with isolation number 349.

***spn-E*: spindle E**

**location:** 3-62.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Similar to *spn-A*.

**alleles:** Two alleles, *spn-E*<sup>1</sup> and *spn-E*<sup>2</sup>, isolated as 616 and 653.

***spn-F*: spindle F**

**location:** 3-100.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Maternal-effect lethal. Similar to *spn-A*.

**alleles:** *spn-F*<sup>1</sup>, the only allele, isolated as 234.

***spo*: spook**

**location:** 3-19.

**references:** Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984,

Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.

**phenotype:** Embryonic lethal. No differentiation of cuticle and mouthparts.

**alleles:** *spo*<sup>1</sup> and *spo*<sup>2</sup> isolated as 4G9 and 7J.

**\**spot*: spot**

**location:** 3- (not located).

**discoverer:** Hersh, 34h15.

**references:** 1935, DIS 4: 14.

**phenotype:** Dark spot appears below eye on posterior margin of head. Expression variable. RK3.

*spotted white*: see *w<sup>sp</sup>*

**spotty**: see *stt*

*spotty-tergum*: see *stt<sup>2</sup>*

**spr: spread wings**

**location**: 3- [right arm associated with *In(3R)P*].

**origin**: Spontaneous.

**discoverer**: Bridges, 36c16.

**phenotype**: Wings held out at wide angle. Both sexes sterile. RK3A.

**\*Spr: Spread**

**location**: 3- (rearrangement).

**origin**: X ray induced.

**discoverer**: Oliver, 32k21.

**references**: 1935, DIS 4: 15.

**phenotype**: Wings held outstretched perpendicular to body axis, droop in older fly. Homozygous lethal. Heterozygote viability somewhat low. Female fertile; male quite infertile. RK2A.

**cytology**: Associated with *In(3L)Spr*; breakpoints unknown.

**\*sprd: spread**

**location**: 3-65.

**origin**: Spontaneous in *In(3R)C*.

**discoverer**: Dexter, 13k.

**synonym**: *sd* (preoccupied).

**references**: Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 105.

**phenotype**: Wings spread at right angles to body. RK2A.

**other information**: Probably separable from *In(3R)C* = *In(3R)92D1-E1;100F2-3*.

**Spread**: see *Spr*

**spread wings**: see *spr*

**spreadex**: see *sdx*

*spready*: see *eg<sup>spy</sup>*

**sps: spastic**

**location**: 2-63.6.

**origin**: Ultraviolet induced.

**discoverer**: Edmondson and Meyer, 49d.

**references**: 1951, DIS 25: 73.

**phenotype**: Pupal and postpupal lethal. Fly that emerges from pupal case unable to walk or fly. Spastic contraction and jerking of leg and wing muscles. Fly becomes overturned and stuck; survives less than 24 hr; sterile. Muscles so relaxed in etherized fly that mutant indistinguishable from normal fly. RK3.

**spt: spermatheca**

**location**: 2-63.3.

**origin**: Spontaneous.

**discoverer**: Hadorn, 43e.

**references**: Hadorn and Graber, 1944, Rev. Suisse Zool. 51: 418-23.

Graber, 1949, Z. Indukt. Abstamm. Vererbungsl. 83: 106-35 (fig.).

**phenotype**: At 28°, female has two spermathecae but ducts partly fused; at 25°, only one enlarged spermatheca on one duct; at 18°, a duct with three branches, each bearing

a spermatheca. Temperature-sensitive period in third larval instar. Female fertility not greatly affected. RK3.

*spt*: see *stt<sup>2</sup>*

**\*spw: spur wing**

**location**: 3- (right arm).

**origin**: Spontaneous.

**references**: Wallbrunn, 1942, DIS 16: 54.

**phenotype**: Wings vary from normal to large fan-shaped structures with extra veins; often a spur-shaped lobe from costal margin. Penetrance better in female and in old cultures. RK3.

**spx: split thorax**

**location**: 1-22.6.

**origin**: X ray induced.

**discoverer**: Fahmy, 1956.

**references**: 1959, DIS 33: 91-92.

**phenotype**: In extreme manifestation, thorax split into two segments by longitudinal furrow; abdominal tergites also split along mid-dorsal line. Eyes deformed. In least abnormal fly, always a hairless stripe along the dorsal midline of thorax. Wings often slightly divergent. Occasionally, one or both palpi abnormal in position or structure. Viability and fertility rather low in male, very low in female. RK3.

**other information**: One allele each induced by CB. 2511 and CB. 3007. Two alleles induced by CB. 1528.

*spx*: see *sdx*

*spy*: see *eg<sup>spy</sup>*

**spz: spätzle**

**location**: 3-92.

**references**: Anderson and Nüsslein-Volhard, 1984, Nature (London) 311: 223-27.

1986, Symp. Soc. Dev. Biol. 44: 177-94.

Seifert, Müller-Holtkamp, Marcey, and Jäckle, 1987, Roux's Arch. Dev. Biol. 196: 78-82 (fig.).

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype**: Maternal-effect lethal. Embryos dorsalized, germline dependent. Phenotypic rescue achieved by injection of cytoplasm or poly(A)<sup>+</sup>RNA from wild-type embryos into young embryos produced by *spz* females; cytoplasm more effective than RNA (Seifert *et al.*). Temperature-sensitive period of *spz<sup>3</sup>* extends from oogenesis through fertilization until about the time of pole-cell formation. Strong alleles amorphic by deficiency testing. Pole-cell-transplantation studies indicate that *spz* acts in germ line and not soma of mother (Seifert *et al.*).

**alleles**: Four ethyl methanesulfonate-induced alleles: *spz<sup>1</sup>* (weak), *spz<sup>2</sup>* (strong), *spz<sup>3</sup>* (temperature sensitive), and *spz<sup>4</sup>* (strong), originally isolated as 145, 197, 670, and *rm7*, respectively.

**cytology**: Placed in 97D15-E4 based on its inclusion in *Df(3R)9Q-RX1* (breakpoints not given) but not *Df(3R)ro80b* = *Df(3R)97D1;97D15* or *Df(3R)D605* (breakpoints not given).

**\*sq: square**

**location**: 2-8.4.

**discoverer**: Bridges, 17h17.

**phenotype**: Wings truncated with squarish or oblique tip. Overlaps wild type. Viability erratic. RK3.

**\*Sq: Squat****location:** 2-38.**origin:** Spontaneous.**discoverer:** Bridges, 15k29.**references:** Bridges and Morgan, 1929, Carnegie Inst. Washington Publ. No. 278: 283-84 (fig.).**phenotype:** Wings short, broad, blunt, arched, and less transparent than normal. Thorax and head short and broad. Legs short and weak. Overlaps wild type. Homozygous lethal. RK3.**sqh: spaghetti squash (D. P. Kiehart)****location:** 1-14.**origin:** P element insertion.**references:** Chang, Edwards, and Kiehart, in prep.; Karess, Kulkarni, and Aguilera, unpublished.**phenotype:** The structural gene for cytoplasmic myosin light chain (Chang *et al.*) In the homozygous *sqh*<sup>1</sup> mutant, the normally diploid larval tissues (*e.g.*, brain, imaginal disc, and gonad) possess numerous polyploid cells resulting from an intermittent failure of cytokinesis. Repeated rounds of apparently normal mitosis without cytokinesis produce cells containing hundreds of chromosomes. The mutant is a late larval-early pupal lethal with an extended larval period (10-14 days), during which the brain grows to enormous size. Imaginal discs are small and poorly formed (Karess).**alleles:** *sqh*<sup>1</sup> (isolation number 569) was found among a collection of larval and pupal lethals generated by Denzell and Johnson. Probably a hypomorph.**cytology:** Located in 5D5-6 by *in situ* hybridization with cytoplasmic-myosin-regulatory light chain and P element probes. Uncovered by *Df(1)5D1,2;5E*.**molecular biology:** The gene was cloned independently by P-element tagging (Karess *et al.*) and oligonucleotides corresponding to partial peptide sequence of purified cytoplasmic myosin light chain (Chang *et al.*). The 2.1 kb transcription unit contains two introns, of 1 kb and 73 bp. It expresses transcript(s) of approximately 1.1 kb at all developmental stages. Sequenced cDNAs encode a 174 amino acid protein of 19.9 kd, which is more similar to vertebrate smooth muscle regulatory light chains (80% identity) than to the *Drosophila* muscle homolog *Mlc2*. *sqh*<sup>1</sup> has an 800 bp internally deleted P element inserted in the 5' untranslated region of the transcription unit, 48 bp from the first codon of the open reading frame.**sr: stripe****location:** 3-62.0.**references:** Craymer, 1980, DIS 55: 197-200.

Costello and Wyman, 1986, Dev. Biol. 118: 247-58 (fig.).

**phenotype:** Trident pattern on thorax replaced by broad light gray stripe at 25°; stripe is dark at 18° or in the presence of heterozygous or homozygous *b* or *e*. Homozygotes are flightless (Levine and Wyman, 1973, Proc. Nat. Acad. Sci. USA 70: 1050-54) and show a reduction in size of a specific indirect flight muscle, the dorsal longitudinal muscle (DLM). The DLM is absent from *sr/Df(3)sr* adults. Early development of the indirect flight muscles is normal, but in the thirty-five-hour pupa the DLM begins to degenerate leading to its absence in adults (Costello and Wyman).**alleles:** All alleles except *sr*<sup>1</sup> are homozygous lethal, and all but *sr*<sup>1</sup> and *sr*<sup>61j</sup> are associated with chromosome

rearrangements.

Bristles finer. Both sexes viable. Female fertility low. RK3.**cytology:** Not included in deficiency for 18A4-18B8 formed by combining left end of *ln(1)y*<sup>4</sup> = *ln(1)1A8-B1;18A3-4* with right end of *ln(1)sc*<sup>9</sup> = *ln(1)1B2-3;18B8-9*, although *sby* (1-60.8) is included (Norton).**Src1: Src proto oncogene sequence****location:** 3- {15}.**origin:** Isolated from genomic library using v-src probe.**synonym:** *Dsrc*.**references:** Shilo and Weinberg, 1981, Proc. Nat. Acad. Sci. USA 78: 67789-92.

Simon, Kornberg, and Bishop, 1983, Nature (London) 302: 837-39.

Lev, Leibovitz, Segev, and Shilo, 1984, Mol. Cell. Biol. 4: 482-84.

Simon, Drees, Kornberg, and Bishop, 1985, Cell 42: 831-40.

**phenotype:** Considered to be the *Drosophila* sequence homologous to mammalian c-src, based both on its origin and amino acid sequence as inferred from its nucleotide sequence. The polypeptide product as yet uncharacterized, but presumed to be a protein kinase; *Drosophila* extracts do exhibit tyrosine kinase activity (Simon *et al.*, 1983). In the region of the polypeptide responsible for kinase and transforming activity, *Drosophila* amino acid sequence 54% homologous with that from v-src, 100 base pairs beginning with the tryosine-416 codon 62% homologous with *Drosophila Abl* (Hoffman, Fresco, Hoffman-Falk, and Shilo, 1983, Cell 35: 393-401). *Src* transcripts abundant in early embryos and in adult ovaries. Level declines in later embryos and is low in males and ovariectomized females; inferred to be a maternally acting gene whose product is required for early embryogenesis (Wadsworth, Madhavan, and Bilodeau-Wentworth, 1985, Nucleic Acids Res. 13: 2153-70).**cytology:** Located in 64B by *in situ* hybridization (Simon *et al.*, 1983).**molecular biology:** Gene cloned and sequenced; concep-

tual sequence indicates a 62-kd C-SRC protein with 40% homology with vertebrate C-SRC protein (Simon *et al.*, 1985). Developmental Northern blots reveal homologous transcripts of 3.0, 4.4, and 4.8 kb [3.5, 5.0, and 5.5 kb according to Simon *et al.* (1985)]; the 3.0 and 4.4 kb transcripts are abundant in unfertilized eggs and early embryos; disappear in larval and pupal stages, reappearing in adults. 4.8 kb transcript undetectable in unfertilized eggs; starts accumulating 2-5 h after fertilization and is expressed continuously throughout development (Lev and Segev, 1986, *Biochim. Biophys. Acta* 867: 144-51); similar developmental profiles noted by Simon *et al.* (1985). After first eight h of development, *Src* RNA accumulates almost exclusively in neural tissue and differentiating smooth muscle (Simon *et al.*, 1985).

**Src2**

**location:** 2- [22].

**origin:** Isolated from genomic library using v-src probe.

**synonym:** *src4*, *Dsrc28C*.

**references:** Simon, Kornberg, and Bishop, 1983, *Nature* (London) 302: 837-39.

Wadsworth, Madhavan, and Bilodeau-Wentworth, 1985, *Nucleic Acids Res.* 13: 2153-70.

Gregory, Kammermeyer, Vincent, and Wadsworth, 1987, *Mol. Cell. Biol.* 7: 2119-27.

Vincent, Gregory, and Wadsworth, 1989, *Genes Dev.* 3: 334-47.

**phenotype:** *Src* transcripts abundant in early embryos and in adult ovaries; also found in imaginal disks. Level declines in later embryos and is low in males and ovariectomized females. Inferred to be maternally acting gene whose product is required for early embryogenesis (Wadsworth *et al.*). Monoclonal antibodies detect two protein products of *Src2*, a doublet of 66 kd and one of 55 kd; the 55 kd polypeptide appears to initiate at the third methionine codon of the sequence; a faint 95 kd band appears to track the 66 kd band in developmental Northern blots. Monoclonal antibodies that differentiate between the two protein products show that they are differentially regulated. The 66 kd polypeptide first appears at the periphery of cells of the cellular blastoderm; this staining is transiently resolved into 13 or 14 segmental stripes plus uncharacterized staining in the head region in the fully extended germ band; no 66 kd protein detectable after 12 h of development. The 55 kd polypeptide first appears at 4-6 h and is widely distributed in the central and peripheral nervous systems. Larvae transformed with constructs that produce either the 66 or the 55 kd products under *Hsp70* promoter action display cell-surface localization of the 66 kd protein and cytoplasmic localization of the 55 kd protein in third-instar salivary glands.

**cytology:** Placed in 28C (Simon *et al.*) by *in situ* hybridization.

**molecular biology:** cDNA sequence reveals a single open reading frame capable of encoding a 590 amino-acid 66 kd polypeptide. Comparison with genomic sequence indicates presence of at least 6 introns. Conceptual amino-acid sequence reveals considerable homology to C-SRC over 70% of its length; 54% identity between C-SRC residues 270 and 470; amino-terminal 140 amino acids unrelated to C-SRC sequence; *Src2* contains a 58 amino-acid N-terminal extension lacking in C-SRC N-

terminal third of polypeptide has a 27-amino-acid stretch with 74% glycine, including eight contiguous glycine residues.

**\*srd: small round**

**location:** 1-0.6.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 92.

**phenotype:** Fly small with slightly dark, rounder, small eyes. One or both postvertical bristles frequently missing. Both sexes viable and fertile. RK3.

**Srf: Surf wings**

**location:** 2-66.8.

**origin:** Spontaneous.

**references:** Kang and Park, 1971, DIS 46: 41 (fig.).

**phenotype:** In heterozygotes distal half of wings upturned about 40° from normal wing axis as in *Si* or *j*, but usually not divergent. Penetrance at 25° is 96% in females and 84% in males. Homozygous lethal; heterozygotes fully viable and fertile.

**sro: shroud**

**location:** 3-100.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal. No differentiation of cuticle and mouthparts.

**alleles:** Two ethyl methanesulfonate-induced alleles, *sro*<sup>1</sup> and *sro*<sup>2</sup>, originally isolated as 8A and 11C.

**cytology:** Placed in 99A-100A; covered by *Y<sup>P3</sup>DB172* from *T(Y;3)YL;95A+In(3R)93B-C;99A* but not by *Y<sup>P3</sup>DA113* from *T(Y;3)Xhy<sup>+</sup>;100A*.

**srp: serpent**

**location:** 3-58.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal; germ-band shortening incomplete.

**alleles:** Three ethyl methanesulfonate-induced alleles, *srp*<sup>1</sup>, *srp*<sup>2</sup>, and *srp*<sup>3</sup>, isolated as 288, 6G, and 9L.

**cytology:** Placed in 88A11-89B4 based on its being deleted by *Df(3R)sbd105 = Df(3R)88F9-89A1* but not by *Df(3R)Po4 = Df(3R)87F7-89A1;89A11-13* nor by *Df(3R)sbd45 = Df(3R)89B4;89B10* (Hughes, Nelson, Yanuk, and Szauter).

**srw: shrew**

**location:** 3-15±.

**origin:** Induced by ethyl methanesulfonate.

**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, *Wilhelm Roux's Arch. Dev. Biol.* 193: 283-95.

Tearle and Nüsslein-Volhard, 1987, DIS 66: 209-26.

**phenotype:** Embryonic lethal; embryos partially ventralized.

**alleles:** One isolated as 10K.

**Sry: Serendipity**

**location:** 3- {101}.

**references:** Vincent, Colot, and Rosbash, 1985, *J. Mol. Biol.* 186: 149-66.  
1986, *Dev. Biol.* 118: 480-87.  
Schweisguth, Lepesant, and Vincent, 1990, *Genes and Dev.* 4: 922-93.

**phenotype:** The *Sry* region comprises three independently transcribed genes arranged in tandem, transcribed in the same direction, and separated by less than a kilobase. These are, from left to right, *Sry-β*, *Sry-α*, and *Sry-δ*.

**cytology:** Placed in 99D4-8 by *in situ* hybridization (Roark, Mahoney, Graham, and Lengyel, 1985, *Dev. Biol.* 109: 476-88).

**molecular biology:** Genomic clones of *Sry* region isolated independently by Vaslet, O'Conner, and Izquierdo (1980, *Nature (London)* 285: 674-76) and Roark *et al.* Sequence determined by Vincent *et al.* (1985). Five mRNA's are detected on Northern blots; three correspond to *Sry-α*, *-β*, and *-δ* and two correspond to *β-α* and *α-δ* read-through transcripts, which contain the spacer sequence between the respective genes. *Sry-α* transcripts detected in all nuclei and cells, except pole cells, during syncytial and cellular blastoderm; disappear during gastrulation (James and Vincent, 1986, *Dev. Biol.* 118: 474-79). Deficiency homozygotes display cellularization defects resulting in multinuclear cells at blastoderm. The molecular biology of the individual genes described below. *α*, *β*, and *δ* are transcribed off of the same strand, but each in a different reading frame.

**Sry-α**

**molecular biology:** The middle gene in the Serendipity region. Transcription begins 183 base pairs downstream from the 3' terminus of the *Sry-β* transcript and terminates 331 base pairs upstream from the initiation of transcription of *Sry-δ*; transcript size is 1.9 kb. The conceptual amino acid sequence contains 530 amino acids and 58 kd molecular weight. Expressed exclusively at the blastoderm stage of development; mostly associated with invaginating membranes at cellularization.

**Sry-β**

**molecular biology:** The left-most gene in the Serendipity region. The transcript size is 1.0 kb; the conceptual amino-acid sequence indicates a polypeptide of 351 amino acids with a molecular weight of 41,000. The carboxy-terminal portion of the *Sry-β* sequence appears to contain six tandemly arranged repeats of 28 or 29 amino acids, each of which contains two invariant cysteine and two highly conserved histidine residues; this segment of the gene shows high identity to the corresponding region of *Sry-δ* (87/172 residue identity). *Sry-β*. mRNA abundant in oocyte; maternally inherited.

**Sry-δ**

**alleles:** Four recessive lethal alleles, *Sry-δ<sup>11</sup>*, *Sry-δ<sup>12</sup>*, *Sry-δ<sup>13</sup>*, and *Sry-δ<sup>14</sup>* isolated by Kongsuwan, Vincent, Lengyel, and Merriam (1986 Asilomar meeting).

**molecular biology:** The right-most gene in the Serendipity region. The transcript size is 1.5 kb; the conceptual amino-acid sequence indicates a polypeptide of 430 amino acids and molecular weight of 50,000. The identity to *Sry-β* in the region of the six repeated motifs has been discussed. Expression as detected by Northern blots

occurs throughout development, being high in oocytes and embryos and reduced during the rest of the life cycle.

**Sryc: Serendipity cognate**

**location:** 3- {99}.

**synonym:** *sry-h1*.

**references:** Vincent, Kejzlarová-Lepesant, Segalat, Yancostas, and Lepesant, 1988, *Mol. Cell. Biol.* 8: 4459-68.

**phenotype:** Structural gene for a protein of 868 amino acids with eight TFIIIA-like fingers. Developmental Northern blots reveal abundant transcript in adult females but not males and during the first four hours of embryonic development; low levels present in later embryos, larvae, and pupae. *In situ* hybridization to tissue sections shows that transcripts produced in nurse cells and beginning at stage 10 are transported to and accumulate in oocytes.

**molecular biology:** Gene recovered from genomic library by low-stringency hybridization with both *Sry-β* and *Sry-δ*. Probes derived from genomic clone detect a single mRNA of 3.2 kb. Genomic sequence comprises three exons and two introns, one between nucleotides 1263 and 1325 and the other between nucleotides 2528 and 2639. Three kilobases of genomic clone sequenced; conceptual amino-acid sequence contains 868 amino acids with calculated molecular weight of 96,000. The polypeptide contains two proline-rich domains in residues 141-213 and 593-669 and eight tandemly repeated 28- to 29-residue DNA-binding finger motifs in the central basic portion of the molecule; the first intron is in the loop of the third finger; an 11-residue polyalanine repeat resides 28 residues carboxy to the finger domain; also contains five potential glycosylation sites, three between residues 97 and 130. The 5' untranslated region contains five AUG codons, all followed shortly by in-frame stop codons.

**cytology:** Placed in 98E-F by *in situ* hybridization.

**ss: spineless**

**location:** 3-58.5.

**references:** Bownes, Bournias-Vardiabasis, and Spare, 1979, *Mol. Gen. Genet.* 174: 67-74.  
Struhl, 1982, *Genetics* 102: 737-49.

**phenotype:** Mutations at the spineless locus display three different phenotypes: (1) The spineless phenotype is characterized by the reduction in size of all bristles; (2) the aristapedia phenotype corresponds to the transformation of distal antennal segments, specifically the arista and the distal portion of the third antennal segment, into distal mesothoracic leg segments, *i.e.*, tarsal segments; and (3) leg-segment fusion manifested as fusion of tarsal segments on all eight legs. Homeotic tissue does not conform to developmental compartment boundaries; therefore, *ss* does not qualify as a selector gene (Struhl). Expression of these phenotypes varies among alleles. Some alleles show only the spineless phenotype. Aristapedia alleles, symbolized *ss<sup>a</sup>*, vary in expression; weak alleles show a swelling of the third antennal joint and rudimentary tarsal transformation of the base of the arista; as expression becomes more extreme, more tarsal joints are formed until in the most extreme alleles four tarsal segments and terminal claws are formed. Tarsal fusions are characteristic of extreme aristapedia alleles.

**cytology:** Placed in 89C1-2 (Lewis, 1963, Am. Zoologist 3: 33-56).

**other information:** *ss* and *ss<sup>a</sup>* to the left of both *ss<sup>a40a</sup>* and *ss<sup>ax</sup>* (Hexter, Lozner, and Bunn, 1967, Genetics 56: 565).

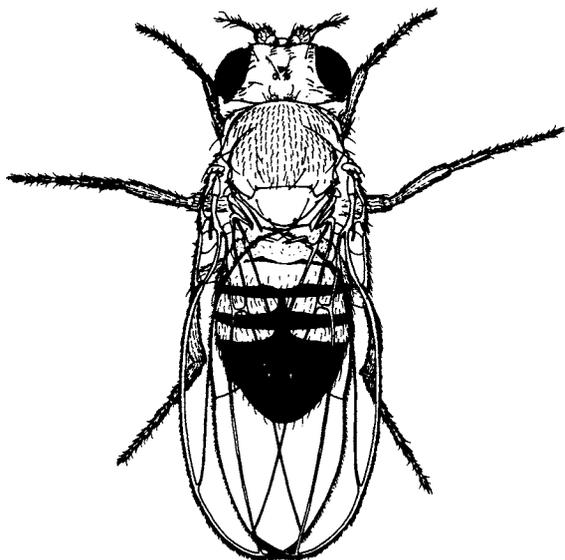

**ss<sup>1</sup>**

**phenotype:** Bristles only a little larger than hairs; dorso-centrals least reduced; postscutellars erect. No effect on legs or arista. Growth of bristles slows during development [Lees and Waddington, 1943, Proc. Roy. Soc. (London), Ser. B 131: 87-110]. Dominant to aristapedia phenotype of all *ss<sup>a</sup>* alleles. RK1.

**ss<sup>a</sup>: spineless-aristapedia**

**phenotype:** Antennae and arista tarsuslike; mean number of tarsal segments = 4.0; incidence of claws = 97.1% (García-Bellido, 1968, Genetics 59: 487-99); classified as an intermediate allele by Struhl. Third joint of antenna like parts of a tarsal row but with broad, flat, plate-like lobes below. Tarsal segments of legs display intermediate level of fusion (Struhl). Bristles like those of a medium to slight Minute. Frequent extra dorsocentral bristles. Transformed tissue is leg tissue in every attri-

bute tested. Transformed tarsi elicit behavioral response similar to that of normal legs when exposed to sugar solutions (Deak, 1976, Nature 260: 252-54). Regions of arista converted into tarsi not affected by mutants affecting arista (*e.g.*, *th* and *al*) but are affected by those operating on tarsi (*e.g.*, *ff*, *d*, *app*, and *ey*) [Waddington, 1939, Growth, Suppl. 1, pp. 37-44; Braun, 1940, Genetics 25: 143-49; Mglinetz and Ivanov, 1975, Genetika 11(#11): 27-33; 1976, Genetika 12(#12): 87-94]. Dissociated cells from *ss<sup>a</sup>* antennal disks aggregate with dissociated leg-disk cells but not with those from wild-type antennal disks (García-Bellido). Antennal disks from *ss<sup>a</sup>* larvae give rise to leg-like structures when transplanted into wild-type hosts as do both duplicated and regenerated antennal disks formed from eye-antenna-disk fragments (Gehring and Schubiger, 1975, J. Embryol. Exp. Morph. 33: 459-69); when disks are pretreated with colchicine, the developing structures are more arista-like (Vogt, 1947, Experientia 3: 156-59). Homozygous clones of *ss<sup>a</sup>* tissue produce antennal leg tissue when induced before (Roberts, 1964, Genetics 49: 593-98) but not after (Postlethwait and Girton, 1974, Genetics 76: 767-74) mid-third instar. Large clones conform to

**ss<sup>a</sup>: spineless-aristapedia**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 179.

anterior and posterior compartments comparable to those induced in normal mesothoracic legs [Morata and Lawrence, 1979, Dev. Biol. 70: 355-71 (fig.)]. No maternal effect; temperature independent.

**ss<sup>a40a</sup>**

**phenotype:** Cold sensitive; phenotype normal in flies raised at 29°; fully penetrant at 17° [mean number of tarsal segments = 2.8; incidence of tarsal claws = 1.3% as recorded by García-Bellido (1968, Genetics 59: 487-99) probably in flies raised at 25°]. Phenocritical stage in first half of third instar [Grigliatti and Suzuki, 1971, Proc. Nat. Acad. Sci. USA 68: 1307-11 (fig.)]. Shifts from 17° to 29° early in third instar restrict transformation to base of arista; distal extent of transformation increases as shift is effected later in development (Grigliatti and Suzuki). Opposite response to temperature for antennal transformation but not tarsal fusion reported by Mglinetz (1977, Genetika 13: 70-75). Developmental compartments demonstrated in antennal legs [Morata and Lawrence, 1979, Dev. Biol. 70: 355-71 (fig.)].

**ss<sup>aB</sup>: spineless-aristapedia of Bridges**

**phenotype:** Bristles of female like a slight Minute, especially postscutellars. At 25°, arista inconspicuously thickened at base, plumed or threadlike for rest of extent. At 18° penetrance is 7% and expression weak; at 14°, ss<sup>aB</sup> enhanced and resembles ss<sup>a</sup>; al causes reduction of ss<sup>aB</sup> arista at 25° but has no effect on transformed arista at 14° (Villem, 1943, J. Exp. Zool. 93: 75-98). Legs frequently have lumps at second joint of tarsi; more pro-

nounced in male and result in doubling of sex combs, which are strung along first and second fused joints. Eyes a little flattened. Except at low temperatures, all characters slight and may overlap wild type. ss<sup>aB</sup>/ss<sup>1</sup> has slight Minute phenotype but wild-type legs and arista. ss<sup>aB</sup>/ss<sup>asp</sup> like ss<sup>asp</sup> with large tarsal arista. RK2. Struhl (1982, Genetics 102: 737-49) and Posakony.

**\*ss<sup>aH</sup> (A. Hannah Alava)**

**phenotype:** Homozygous viable and fertile. Displays enlargement of base of arista. Increased number of sex-comb teeth on basitarsus of first leg in males (12-38 with mean of 24 teeth per leg).

**\*ss<sup>asnB</sup> (A. Hannah Alava)**

**phenotype:** Description incomplete. Extreme fusion of tarsal segments; basitarsus of male first leg has 20-50 sex-comb teeth (mean = 40); sex-comb teeth not uncommon on second leg.

ss<sup>A</sup>: see Antp<sup>R</sup>

ss<sup>Ar</sup>: see Antp<sup>LC</sup>

**ss<sup>C1</sup>**

**phenotype:** Reported to be homozygous lethal and lethal in combination with Df(3R)bxd100 (Bownes, Bournias-Vardiabasis, and Spare, 1979, Mol. Gen. Genet. 174: 67-74); however both of these combinations viable in the hands of

**\*ss<sup>iso53</sup>: spineless-isoallele**

**phenotype:** Homozygote is wild type. ss<sup>iso53</sup>/ss<sup>a</sup>, ss<sup>iso53</sup>/ss<sup>a63c</sup>, and ss<sup>iso53</sup>/ss<sup>a53e</sup> have thickened proximal segments of arista, like ss<sup>aB</sup>. RK3.

**ss<sup>V</sup>: spineless-variegated**

**phenotype:** Variegates for spineless character but completely mutant for aristapedia. Male sterile. RK2A.

**st: scarlet**

**location:** 3-44.0.

**phenotype:** Eyes bright vermilion, darkening with age. Ocelli colorless, even in old fly; a reliable trait for classifying st se. Eyes of bw; st white. Eye color autonomous in larval optic disks transplanted into wild-type hosts (Beadle and Ephrussi, 1936, Genetics 21: 230). Larval Malpighian tubes pale yellow (Beadle, 1937, Genetics 22: 587-611). Phenocritical period, as indicated by temperature-shift experiments utilizing st<sup>12</sup>, is 24-48 h after pupariation at 25° (Howells, 1973). Uptake of kynurenine by Malpighian tubules and eye disks severely deficient (Sullivan and Sullivan, 1975, Biochem. Genet. 13: 603-13). 3-hydroxykynurenine accumulates only in pupae; virtually undetectable in larvae and adults (Howells and Ryall, 1976, Biochem. Genet. 14: 1077-90). Activity of phenoxazinone synthetase, which is found in pigment granules and which catalyzes the bimolecular condensation of 3-hydroxykynurenine in the production of brown eye pigment, xanthommatin, markedly reduced in st (Phillips, Forrest, and Kulkarni, 1973, Genetics 73: 45-56). RK1.

<sup>α</sup> 1 = Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-90; 2 = Ashburner, Faithfull, Littlewood, Richards, Smith, Velissariou, and Woodruff, 1980, DIS 55: 193-95; 3 = Bridges, and Morgan, 1923, Carnegie Inst. Wash. Publ. 327: 172 (fig.); 4 = Carnegie Inst. Wash. Publication 627; 5 = Howells, 1979, Biochem. Genet. 17: 149-58; 6 = Marsh and Mock, 1985, DIS 61: 214; 7 = Meyer, 1954, DIS 28: 77; 8 = Richards, 1918, Biol. Bull. 35: 199-206; 9 = Tearle, Belote, McKeown, Baker, and Howells, 1989, Genetics 122: 595-606; 10 = Ward and Alexander, 1957, Genetics 42: 42-54.

<sup>β</sup> Molecular coordinates based on Tearle *et al.*; origin defined as the *HindIII* site nearest to the left breakpoint of *In(3LR)st-a27 = In(3LR)73A3-4;87D13-14*; polarity undefined.

<sup>γ</sup> Severe hypomorphs have yellow eyes in combination with *bw* and approximately 10% wild-type levels of xanthommatin; moderate hypomorphs have orange eyes in combination with *bw* and 25-45% wild-type levels of xanthommatin.

**cytology:** Placed in 73A3-4 by deficiency mapping (Ashburner, Angel, Detwiler, Faithfull, Gubb, Harrington, Littlewood, Tsubota, Velissariou, and Walker, 1981, DIS 56: 186-90); restricted to distal two-thirds of the 73A3-4 doublet by Tearle *et al.* on the basis of the *st*<sup>+</sup> phenotype of *Df(3L)tra*, which removes the proximal edge of the doublet.

**molecular biology:** The region of the gene has been cloned, restriction mapped, and partially sequenced; coordinates established from origin defined as *HindIII* site nearest to left breakpoint of *In(3LR)st-a27* (Tearle, Belote, McKeown, Baker, and Howells, 1989, Genetics 122: 595-606); transformation with a segment extending from -7.3 to +1.4 rescues *st* phenotype. Restriction site polymorphisms in vicinity identified. Northern blots probed with riboprobes made from restriction fragments in region identify a 2.3 kb polyadenylated mRNA transcribed from a genomic sequence containing a large intron in the N-terminal half of the gene. Transcript present with substantially lower abundance than *w* transcript, and level independent of genotype at *w* locus. Developmental Northern blots show the presence of transcript throughout development, but level about ten-fold higher during early to mid pupa. A segment of the sequence between -678 and -354 shows homology with a segment of the *w* gene; sequence determined by Tearle *et*

*al.* includes one of the putative ATP-binding sites of *w*, where 72% homology is observed.

***st*<sup>12</sup>**

**phenotype:** Scarlet eyes at 29°; normal eye color at 18°; xanthommatin levels 9% and 72% of wild type respectively (Howells, 1979, Biochem. Genet. 17: 149-58).

***st*<sup>sp</sup>: scarlet-spotted**

**phenotype:** Eyes scarlet with facets and groups of facets that appear wild type. Darkening spreads in old fly. Not a variegated position effect. *st*<sup>sp</sup>/*st* like *st*<sup>sp</sup>. Larval Malpighian tubules pale yellow and classifiable (Brehme and Demerec, 1942, Growth 6: 351-56). RK2.

**cytology:** Salivary chromosomes appear normal.

**\**St*: Stumpy**

**location:** 1-55.5.

**origin:** X ray induced.

**discoverer:** Muller, 2612.

**references:** 1935, DIS 3: 30.

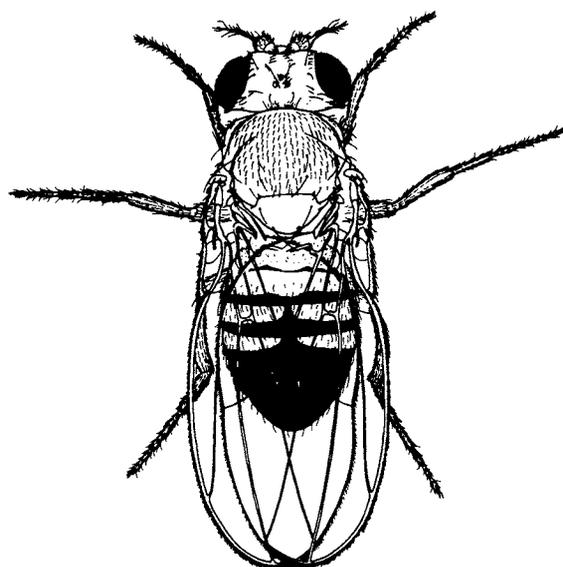

**phenotype:** Wings and abdomen short. Bristles Minute. Eyes rough. Male lethal. RK2.

***St*-*SD*: Stabilizer of Segregation Distorter**

**references:** Sandler and Hiraizumi, 1960, Genetics 45: 1269-87.

Miklos, 1972, Genetics 70: 405-18.

**phenotype:** Increases k value of *SD* chromosomes and by so doing decreases the male-to-male variability of k. Located to the right end of *2R* and affects k either in coupling or repulsion to *Sd*. Decreases fecundity and temperature response of *SD/+* males (Hartl, Hiraizumi, and Crow, 1967, Proc. Nat. Acad. Sci. USA 58: 2240-45; Hikawa, 1971, Jpn. J. Genet. 46: 75-82). Existence inferred from behavior of various recombinant *SD* chromosomes. Probit analysis by Miklos (1972) indicates that the phenotype results not from a single locus, but from the cumulative effects of several weak enhancers; variability in k values in *SD/+* genotypes lacking *St-SD* shown algebraically to be the consequence of reduced k values [see also Hartl, 1976, Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 615-66].

**sta: stubarista**

From Bridges and Brehme, 1944, Carnegie Inst. Washington Publ. No. 552: 180.

**sta: stubarista**

**location:** 1-0.3.

**phenotype:** Third joints of antennae short, blunt, free of hairs, and yellowish. Arista bases thickened, axes sometimes short, and branches irregular. All bristles and hairs extremely short and sparse. Eyes rotated on head slightly so that the long axis is vertical. Homozygous *sta*<sup>1</sup> females unable to oviposit; stage 14 oocytes appear normal (King, 1970, Ovarian Development in *Drosophila*, Academic Press, New York). Lethal allele (*sta*<sup>2</sup>) in combination with variegating translocation (*T(1;2)dor*<sup>var7</sup>) produces incised wing margins, small rough eyes with missing facets, and missing head macrochaetae [Demakova and Belyaeva, 1988, DIS 67: 21 (fig.)]. RK2A.

Schüpbach and Wieschaus, 1989, Genetics 121: 110-17.

**phenotype:** Maternal-effect lethal. Embryos from homozygous mothers exhibit a so-called "grandchildless-knirps" phenotype; all eggs lack polar granules and no pole cells are formed; most embryos show variable deletions of abdominal segments, whereby segment A4 is deleted most frequently; larger deletions may delete segments A2 through A7; in extreme cases, anterior parts of segment A1 become fused to posterior parts of segment A8, but telson elements are always present and relatively normal. In addition, embryos show deletions of the anterior-most head structures and the cephalic furrow is shifted anteriorly at gastrulation. Analysis of germline clones indicates that the mutation is germline autonomous (Schüpbach and Wieschaus, 1986, Dev. Biol. 113: 443-48).

*stb*: see *sbd*

**\**stb*: short bristle**

**location:** 1-14.6.  
**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).  
**discoverer:** Fahmy, 1955.  
**references:** 1958, DIS 32: 75.  
**phenotype:** Short, thin bristles. Viability and fertility good. RK2.

***std*: staroid**

**location:** 2-56.5.  
**origin:** Spontaneous.  
**discoverer:** E. M. Wallace, 31c26.  
**phenotype:** Eyes small, oval, and very rough. Bristles short. Wings slender, dusky, and warped; marginal veins irregular; gap in L4; L5 short. Body dwarfed. Thorax has dark streak. Male sterile; female semisterile. Viability variable. At 19°, eye character remains but other abnormalities disappear. RK2.

*std*: see *Bd*<sup>rl</sup>

***Ste*: Stellate**

**location:** 1-45.7.  
**references:** Meyer, Hess, and Beerman, 1961, Chromosoma 12: 676-716.  
 Hardy, 1980, DIS 55: 54-55.  
 Lovett, Kaufman, and Mahowald, 1980, Eur. J. Cell Biol. 22: 49.  
 Lovett, 1983, PhD Thesis, Indiana University, Bloomington, Indiana.  
 Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, Genetics 107: 591-610.  
 Livak, 1984, Genetics 107: 611-34.  
 Livak, 1990, Genetics Submitted.

**phenotype:** This locus is responsible for the appearance of crystals in the nuclei and cytoplasm of primary spermatocytes of *XO* males. Enzymatic treatments indicate that these crystals are proteinaceous in nature (Meyer *et al.*). The suppression of crystal formation by the *Y* chromosome is attributable to a sequence designated *Su(Ste)*.

**alleles:** Two forms of *Ste*, designated *Ste* and *Ste*<sup>+</sup>, can be distinguished; *Ste*<sup>+</sup>/*0* males produce needle-shaped crystals that are longer than cell diameters and thus curve to conform to cellular boundaries, whereas *Ste/0* males produce star-shaped aggregates of shorter crystals.

**cytology:** Placed in 12F1-2 by *in situ* hybridization (Lovett *et al.*).

**molecular biology:** The testes of *XO* males produce an abundant 750-base poly-A<sup>+</sup> transcript that is rare in *XY* testes; transcript also not found in male carcasses or in females. *XO*-cDNA-detected genomic clones were isolated by Lovett; Livak showed them to comprise tandem repeats of a 1250 base-pair sequence and estimates that there are 200 copies on *Ste*-bearing *X* chromosomes and low copy numbers in *Ste*<sup>+</sup>-bearing *Xs*; the *X* of *D. simulans* apparently lacks the sequence altogether. Sequence determinations by Livak (1990) reveals two major classes of Stellate repeats which differ by 150 base pairs in the 3' end of the gene. No TATA element associated with the

*Ste* promoter. The cDNA sequence reveals the presence of two introns, which are more efficiently spliced in *XO* than *XY* testes; the conceptual amino acid sequence suggests a 19,500-dalton protein that shares homology with the β subunit of casein kinase II (Henikoff). The fact that the *Ste* sequence is as similar to the bovine casein kinase sequence as it is to the *Drosophila* sequence suggests that the *Ste* and casein kinase sequences are probably not of recent common origin. A single *Ste* repeat sequence transposed into autosomal locations is regulated by the *Y* chromosome in the same way as are the endogenous sequences.

***Sternopleural*: see *Sp***

***stf*: stormfront**

**location:** 1-35.  
**origin:** Induced by ethyl methanesulfonate.  
**references:** Eberl and Hilliker, 1988, Genetics 118: 109-20.

**phenotype:** Sex-linked-recessive lethal. Hemizygous embryos exhibit failure of head involution and occasional defects in the ventral-denticle-belt pattern or the failure of germ-band retraction.

**cytology:** Placed in 10A7-11 based on its location between the proximal breakpoints of *Df(1)v-L3* = *Df(1)9F10;10A7-8* and *Df(1)9E1;10A11;56A*.

***stg*: string**

**location:** 3-99.  
**references:** Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95.  
 Edgar and O'Farrell, 1989, Cell 57: 177-87.

**phenotype:** Homozygous embryonic lethal; denticle bands reduced. First 13 nuclear divisions of zygote proceed on schedule; division 14 permanently arrested in G2 in homozygotes for strong alleles; no evidence of nuclear-envelope breakdown or chromosome condensation; division 14 severely impaired in weak alleles. DNA synthesis in arrested embryos confined to the polyploid amnioserosal cells. Gastrulation proceeds on schedule in *stg* embryos with but 5,000 cells, and markers ordinarily expressed in normal embryos with 50,000 cells also expressed in *stg* embryos. The only defect seems to be in the initiation of the first mitotic division that is under zygotic control. Clones of homozygous cells induced early don't survive; few late clones produced.

- $\alpha$  1 = Cooley, Kelley, and Spradling, 1988, Science 239: 1121-28; 2 = Jan (unpublished); 3 = Jürgens, Wieschaus, Nüsslein-Volhard, and Kluding, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 283-95; 4 = Edgar and O'Farrell, 1989, Cell 57: 177-87.
- $\beta$  These alleles are homozygous lethal and do not display a *stg* phenotype; however, they fail to complement completely strong *stg* alleles.
- $\gamma$  P insert detected in *EcoRI* fragment 5' to start of transcription.

**cytology:** Placed in 99A by *in situ* hybridization. Covered by 3<sup>P</sup>*Y*<sup>D</sup> from *T(Y;3)B172 = T(Y;3)YL;93B-C;95A;99A*, but not from *T(Y;3)B152 = T(Y;3)h3;98F*.

**molecular biology:** Region isolated by transposon tagging and plasmid rescue; 33 kb of flanking DNA cloned and restriction mapped. Probing of Northern blots reveals two transcripts of 2.8 and 3.0 kb, which are abundant during nuclear divisions 1-13 and 14-16 but not in post-division-16 cells. *stg*<sup>11</sup> has no detectable transcript during postblastoderm development. Conceptual amino-acid sequence indicates a protein with 479 amino acids, the C-terminal 187 amino acids of which exhibit 34% identity with *cdc25*, a mitotic initiator gene of *S. pombe*. The sequence has no introns. *In situ* hybridization to embryos reveals an uniform distribution of maternal transcript present throughout the first thirteen nuclear divisions; during the first 20-30 m of interphase 14 the maternal message is rapidly degraded and zygotic transcription begins 25-30 m before cells enter mitosis 14. Zygotic expression is not observed in strong *stg* mutants (e.g., *stg*<sup>11</sup>). During gastrulation the spatio-temporal pattern of *stg* expression anticipates rather exactly that of mitosis.

**\*sth: small thin**

**location:** 1-3.7.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 92.

**phenotype:** Fly small, has short thin bristles. Eyes frequently deformed and rough. Wing shape and position slightly atypical. Male ecloses late but is viable and fertile. Female sterile. RK3.

**sticking:** see *stk*

**stiff chaetae:** see *sfc*

**Stigmata:** see *Sta*

**stil: stand still (T. Schüpbach)**

**location:** 2-63.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females contain few developing egg chambers in their ovaries, which may contain abnormal numbers of nurse cells and usually degenerate before yolk uptake begins.

**alleles:** *stil*<sup>1</sup> and *stil*<sup>2</sup> recovered as WE and PS respectively.

**cytology:** Placed in 48D-49E, since uncovered by *Df(2R)vg135 = Df(2R)48D-E;49D-E*.

**stk: sticking**

**location:** 3- {47}.

**references:** Cavener, Otteson, and Kaufman, 1986, Genetics 114: 111-23.

**phenotype:** Undefined prepupariation effective lethal

phase; *stk/T(2;3)Ta*<sup>1</sup> fails to complete eclosion.  
**alleles:**

allele	origin	discoverer	synonym
<i>stk</i> <sup>1</sup>	EMS	Cavener	<i>l(2)g2</i>
<i>stk</i> <sup>2</sup>	EMS	Cavener	<i>l(2)g5</i>
<i>stk</i> <sup>3</sup>	EMS	R. Lewis	<i>l(2)r13</i>

**cytology:** Located in 84B1-C2 based on its inclusion in *Df(3R)Scx2 = Df(3R)84A4-5;84C1-2* but not *Df(3R)Win3 = Df(3R)84A4-5;84B1-2*. Also, not complemented by *T(2;3)Ta*<sup>1</sup> = *T(2;3)51E1-2;84B1-2*.

**stl: stall (T. Schüpbach)**

**location:** 2-102.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female-sterile; homozygous females often contain ovarian tumors; ovarioles filled with small undifferentiated cells, as well as egg chambers containing variable numbers of nurse cells and degenerating material. Occasional normal egg chambers take up yolk, but form abnormal, collapsing eggs which remain unfertilized.

**alleles:** Four alleles, *stl*<sup>1</sup>, *stl*<sup>2</sup>, *stl*<sup>3</sup>, and *stl*<sup>4</sup> - isolated as *WU, AWK, PA, and PH*.

**stm: stambh**

Three ethyl methanesulfonate-induced temperature-sensitive paralytic mutations at different loci on chromosome 2. Paralysis dependent on time and temperature of exposure; the recovery time is proportional to the severity of the paralyzing exposure.

**references:** Shyngle and Sharma, 1985, Indian J. Exp. Biol. 23: 235-40.

locus	location	comments
<i>stm-A</i>	2-56.8	paralyzed at 35°; rapid paralysis at 39°; larval paralysis; complements <i>nap</i> <sup>15</sup>
<i>stm-B</i>	2-97.6	paralyzed at 37°; slow paralysis at 39°; no larval paralysis
<i>stm-C</i>	2-59.4	paralyzed at 35°; rapid paralysis at 39°; no larval paralysis

**stm-A**

**phenotype:** Two-hour heat shocks applied throughout development show 0-8 h and 56-140 h to be highly sensitive, with no survival; 8-56 h and after 140 h show survival with normal phenotype. Early temperature shock leads to blastoderm arrest with no gastrulation. Embryos produced by homozygous *stm-A* mothers are exceedingly sensitive to a two-hour exposure to 36°; leads to complete lethality from 0-3 h irrespective of paternal contribution.

**stn: stoned (J.C. Hall)**

**location:** 1-66.3 (Grigliatti *et al.*, 1973) or 68.5 (Homyk and Pye, 1988).

**references:** Grigliatti, Hall, Rosenbluth, and Suzuki, 1973, Mol. Gen. Genet. 120: 107-14.

Kelly, 1983a, Cell. Mol. Neurobiol. 3: 127-41.

1983b, Cell. Mol. Neurobiol. 3: 143-49.

Miklos, Kelly, Coombe, Leeds, and Lefevre, 1987, J. Neurogenet. 4: 1-19.

Homyk and Pye, 1988, J. Neurogenet. 5: 37-48.

Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31.

**phenotype:** Exists as temperature-sensitive behavioral,

temperature-sensitive

lethal, and unconditionally lethal alleles. Severe behavioral debilitation is quickly induced by shift of adult *stn*<sup>6</sup> and *stn*<sup>7</sup> from 25° to 29°; abnormalities at high temperature include uncoordinated leg and wing movements, with complete paralysis never occurring (e.g., legs still move); *stn*<sup>6</sup> causes some debilitation at 22° (slow movements, occasionally falling over); whereas *stn*<sup>7</sup> is more nearly normal at low temperatures, and can even walk with difficulty at 29°; at permissive temperatures, *stn* (allele unspecified) causes unusual jump response to light-off stimulus, which is more pronounced in combination with *w* (Kelly, 1983b); associated with this abnormal jumping is an increase in amplitude of light-off transient spike of electroretinogram (ERG); in tests of light-adapted mutant, the jump response, as monitored by recordings from indirect flight muscles, habituates with increasing frequencies of light-off stimulation (Kelly, 1983b); combining *stn* with *tan*, which by itself leads to decreased amplitude of ERG on and off transients, leads to loss of anomalous jumping and partial restoration of light-off spike. In biochemical experiments, *stn* (allele unspecified) found to cause accentuation of *in vivo* phosphorylation of a protein from adult head synaptosomal fractions that is modified in this way by a cAMP-dependent protein kinase, with such phosphorylation being enhanced by exposure of flies to light, prior to extraction (Kelly, 1983a). A protein, which has same molecular weight as the one noted above, found to be phosphorylated *in vitro* by a fly-derived Ca<sup>2+</sup>-calmodulin-dependent protein kinase; *stn* causes increased levels of *in vivo* phosphorylation of this material (Kelly, 1983b). The temperature-sensitive lethal allele, *stn*, leads to brief paralysis, followed by sporadic movements, as a result of mechanical shocking (Homyk and Sheppard, 1977, Genetics 87: 95-104); other abnormalities include abnormally short jump and flight distances, apparent absence of on and off transients in ERG, and lethality when raised at 29°. Effects of three of the lethal alleles, *stn*<sup>1</sup>, *stn*<sup>11</sup>, and *stn*<sup>14</sup>, were examined during development for effects on gross anatomy of CNS or PNS; no obvious abnormalities were observed (Perrimon *et al.*, 1989).

**cytology:** Tentatively placed near bands 20B-C (Miklos *et al.*, 1987); by deficiency mapping placed between *l(1)20Bb* and *l(1)20Ca*. Also maps between right breakpoints of *Df(1)17-466* and *Df(1)17-439*; however, the cytology so close to the chromocenter is intractable and no observed breakpoints are given.

**\*sto: stocky**

**location:** 1-29.8.

**origin:** Induced by triethylenemelamine (CB. 1246).

**discoverer:** Fahmy, 1953.

**references:** 1958, DIS 32: 75.

**phenotype:** Fly short and stocky. Wings short but normal in width. Eyes large and pear shaped. Bristles slightly shorter than normal. Male sterile; viability about 50% normal. RK2.

**other information:** One allele induced by CB. 1528.

**\*sto<sup>tpw</sup>: stocky-tapered wings**

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**synonym:** *tpw*.

**references:** 1958, DIS 32: 76-77.

**phenotype:** Wings slightly shortened and broadened with tip pointed at L3 rather than being smoothly rounded. Eyes small and oval. Slightly dusky thorax. Both sexes viable; female rather infertile. RK2.

**stoned:** see *stn*

**stonewall:** see *snw*

**stop: stopped (T. Schüpbach)**

**location:** 2-76.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus.

**phenotype:** Female sterile; homozygous females often have underdeveloped ovaries that seem to lack germ cells altogether. In some females a small number of developing egg chambers are found that never develop beyond the first few stages of oogenesis.

**alleles:** Two alleles, *stop*<sup>7</sup> and *stop*<sup>2</sup> isolated as *W5* and *W6*.

**stormfront:** see *stf*

**\*stp: silver tips**

**location:** 1-46.1.

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**references:** 1959, DIS 33: 92.

**phenotype:** Fly slightly smaller than normal. Bristles thin, weak, and most are unpigmented; hairs unaffected. Male

sterile; viability low. RK3.

*Stp*: see *Mhc*<sup>15</sup>

**\*Stp-1: Strapped in chromosome 1**

**location:** 1-50.6 (not allelic with *sd*).

**origin:** Spontaneous.

**discoverer:** Hannah.

**references:** 1950, Genetics 35: 669.

**phenotype:** Expression limited to male. About 15% of *Stp-1*; *Stp-2*/+ males show some scalloping of wing margins. Most *Stp-1*; *Stp-2*/*Stp-2* males have some degree of scalloping, varying from a small nick to vestigial-like wings. Modified by both genetic and environmental factors. Without *Stp-2*, *Stp-1* has no effect. RK3.

**\*Stp-2: Strapped in chromosome 2**

**location:** 2- (right arm between *c* and *sp*).

**origin:** Spontaneous.

**discoverer:** Hannah.

**references:** 1950, Genetics 35: 669.

**phenotype:** Fifteen percent of *Stp-1*; *Stp-2*/+ and most *Stp-1*; *Stp-2*/*Stp-2* males show incising of wing margin. *Stp-2*/*Stp-2*/+ and *Stp-2*/*Stp-2*/*Stp-2* intersexes show scalloping in the presence or absence of *Stp-1*. RK3.

*str*: see *tkv*

*str(2)350*: see *mfs(2)350*

**\*Str: Stretched wings**

**location:** 2-67.

**discoverer:** Tanaka, 34a12.

**references:** 1937, DIS 8: 11.

**phenotype:** Wings divergent. Homozygous lethal. RK2.

*str-R*: see *Rst(1)str*

**Stretched wings:** see *Str*

**string:** see *stg*

**stripe:** see *sr*

**sts: streaked sterna**

**location:** 1-60.3.

**origin:** Induced by DL-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3007).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 92.

**phenotype:** Small fly with light body color. Brown areas on abdominal sternites often form two longitudinal lines. Eclosion delayed. Viability and fertility low. RK3.

**\*stt: spotty**

**location:** 1-34.3.

**origin:** Induced by *p*-N,N-di-(2-chloroethyl)amino-phenylethylamine (CB. 3034).

**discoverer:** Fahmy, 1955.

**references:** 1959, DIS 33: 92.

**phenotype:** Fly small. Wings slightly deformed. Small dark spots on anterior abdominal segments. In extreme cases, tergites broken and abnormally rejoined, and hairs deranged. Eyes rather small. Male sterile; viability about 50% wild type. RK2.

**\*stt<sup>2</sup>**

**origin:** Induced by 2-chloroethyl methanesulfonate (CB. 1506).

**discoverer:** Fahmy, 1956.

**synonym:** *spt*: *spotty-tergum*.

**references:** 1959, DIS 33: 91.

**phenotype:** Fly small; wings wrinkled or pleated. Darkly pigmented spots dispersed over abdomen, particularly on fourth tergite. Tergites occasionally ridged or broken. Bristles long and straggly. Male sterile; viability about 30% normal. RK2.

**other information:** Allelism inferred from similarity in phenotype and genetic location at 34.1.

**\*stu: small tumeroid**

**location:** 1-20.4.

**origin:** Induced by L-*p*-N,N-di-(2-chloroethyl)amino-phenylalanine (CB. 3025).

**discoverer:** Fahmy, 1954.

**references:** 1959, DIS 33: 92.

**phenotype:** Fly small, frequently has small melanotic pseudotumors. Viability 5% wild type. Male fertile. RK3.

<sup>α</sup> 1 = Meyer and Edmondson, 1951, DIS 25: 73; 2 = Morgan, Bridges, and Sturtevant, 1925, Bibliogr. Genet. 2: 237; 3 = Mossige, 1939, DIS 12: 47.

**cytology:** Placed in 41B or C on the basis of the pale body color of heterozygotes for the deficiency from 41B3 through 42A2 formed by combining left end of *In(2R)Cy* = *In(2R)42A2-3;58A4-B1* with right end of *In(2R)bw<sup>VDel</sup>* = *In(2R)41B2-C1;59E2-4* and inclusion of *stw* in several cytologically invisible deficiencies at base of 2R, e.g., *Df(2R)M41A* (Schultz).

***stw*<sup>2</sup>**

**phenotype:** Hairs pale yellow; bristles brownish with yellow tips. Wings pale yellow and somewhat thin and warped. Slightly more extreme than *stw*. Larval mouth parts straw colored at basal prongs and classifiable with difficulty in third-instar larvae (Brehme, 1941, Proc. Nat. Acad. Sci. USA 27: 254-61). RK2.

***stw*<sup>3</sup>**

**phenotype:** Hairs, bristles, wings, and wing veins straw yellow. Body yellowish with pronounced dark trident. Tyrosinase formed in adult (Horowitz). Wings thin and buckled. Hairs on wing cells incompletely chitinized (Waddington, 1941, Proc. Zool. Soc., Ser. A 111: 173-80). Puparium noticeably lighter than wild type. Larval mouth parts straw colored at basal prongs; classifiable in living larva (Brehme, 1941, Proc. Nat. Acad. Sci. USA 27: 254-61). RK2.

**other information:** Waddington found that irradiation of *stw*<sup>3</sup> homozygote 2 days before eclosion produces reverse mutations that appear as single wild-type wing hairs (1940, Nature 146: 335).

**\**stw*<sup>4</sup>**

**phenotype:** Body pale yellow. Legs almost colorless. Wings colorless, thin, and fragile. Black areas of abdomen still black but heavily sprinkled with pale spots. Larval mouth parts normal (Brehme, 1941, Proc. Nat. Acad. Sci. USA 27: 254-61). RK2.

***stw*<sup>5</sup>**

**phenotype:** Activation of the phenoloxidase at the time of melanization reduced in *stw*<sup>5</sup> homozygotes compared to wild type (Mitchell, 1966, J. Insect. Physiol. 12: 755-65). Electroretinogram normal (Hotta and Benzer, 1969, Nature 222: 354-56). Semilethal or associated with a closely linked semilethal. RK2.

***stw*<sup>6</sup>**

**phenotype:** Like *stw*. Viability low. RK2.

**\**stw*<sup>7</sup>**

**phenotype:** Bristles yellowish. Wing color pale, often overlaps wild type. Eclosion delayed. Poor viability. RK2.

**\**stw*<sup>D</sup>: straw-Dominant**

**phenotype:** Body and bristles of homozygote light yellow; wings thin, buckled, and curled. In heterozygote, wings less abnormal; body and bristles wild type. *stw*<sup>D</sup>/*stw*<sup>3</sup> like *stw*<sup>3</sup>. *stw*<sup>D</sup>/*Df(2R)M41A* has exaggerated *stw* phenotype. RK1.

**\**stx*: streakex**

**location:** 1- (rearrangement).

**origin:** X ray induced.

**discoverer:** Muller, 26k30.

**references:** 1935, DIS 3: 30.

**phenotype:** Dark streak down dorsal midline of thorax. Semilethal. RK3A.

**cytology:** Associated with *In(1)stx*; in the left end but breakpoints unknown.

*su*<sup>18</sup>: see *qs*<sup>2</sup>

*su*-: see *su*( )

**\**su(b)*: suppressor of black**

**location:** 1-0.1.

**origin:** Spontaneous.

**discoverer:** Plough, 23j28.

**references:** 1927, Proc. Intern. Congr. Genet., 5th., Vol. 2: 1193-1200.

Sherald, 1981, Mol. Gen. Genet. 183: 102-06.

**phenotype:** Suppresses *b* so that body color is only slightly darker than wild type. No dominant effect. Causes the level of β-alanine, which is ordinarily reduced, to return to normal in *b/b* flies; *su(b)*<sup>6</sup> in *b*<sup>+</sup> genotypes leads to 60% increase above normal β-alanine levels. *su(b)*<sup>6</sup> flies are unable to survive on 0.2 M β-alanine; apparently β-alanine ingested by females prevents *su(b)* embryos from hatching or the unhatched embryos from melanizing (Campbell and Sherald, 1987, DIS 66: 34). Also effects a return to normal of the fine structure of the puparial case in *su(b)*<sup>6</sup>; *b/b* individuals.

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments
<i>su(b)</i> <sup>1</sup>	spont	Plough, 23j28		1	frequently reverts fertility reduced

<sup>α</sup> 1 = Plough, 1927, Proc. Intern. Congr. Genet., 5th., Vol. 2: 1193-1200; 2 = Sherald; 1981, Mol. Gen. Genet. 183: 102-06; 3 = Sϕndergaard and Kolbak, 1987, DIS 66: 134.

**cytology:** Placed in 1B4-9 based on its being covered by the terminal deficiency, *Df(1)260-1 = Df(1)IA4-6* but not by *Df(1)yT4-12 = Df(1)IA7-9* (Sherald and Voelker,

1985, DIS 61: 155).

**Su(b): Suppressor of black**

**location:** 1-55.5 [ $1-2 \times 10^{-4}$  units distal to the distal end of the *r* locus; possibly a regulatory sequence (Søndergaard and Kolbak, 1987, DIS 66: 134)].

**references:** Pedersen, 1982, Carlsberg Res. Commun. 47: 391-400.

**phenotype:** A semidominant suppressor of *b*; homozygotes and hemizygotes in combination with *b* are slightly darker than wild type, whereas heterozygotes are intermediate between *b* and wild type in cuticle reflectance. *Su(b)* by itself has no visible phenotype. Although supplementation of the medium with 6-azathymine, an inhibitor of dihydrouracil dehydrogenase, results in a dark body color in wild-type flies, it does not darken the wild-type coloration of *Su(b); b*. The double-mutant combination, *Su(b) r*, does not suppress *b* (Bahn and Søndergaard, 1983, Hereditas 99: 309-10), whereas *su(r) Su(b); b* flies have enhanced black cuticle. Unlike *su(b); b*, the combination *Su(b); b* is not sensitive to dietary  $\beta$ -alanine (Campbell and Sberald, 1987, DIS 66: 34).

**cytology:** Placed in 15A1 based on its virtual inseparability from *r*.

**\*su(B): suppressor of Bar**

**location:** 2-94.

**origin:** Spontaneous.

**discoverer:** Steinberg, 361.

**synonym:** *m(B)*: modifier of *Bar*.

**references:** 1937, DIS 7: 20.

1937, DIS 8: 11.

1939, DIS 12: 49.

1940, Collecting Net 15: 173.

1941, Genetics 26: 325-46, 440-51.

**phenotype:** When homozygous, increases number of eye facets from about 75 to 220 in *B* male and to 140 in *B/B* female. Affects all *B* effects but not *ey*<sup>2</sup> or wild type. RK2.

**\*su(B)2: suppressor of Bar in chromosome 2**

**location:** 2-46 or -60 (7 units from *Tft*).

**origin:** Spontaneous.

**discoverer:** Gans.

**phenotype:** *su(B)2/su(B)2* causes *B/+* female to appear wild type. RK2.

**\*su(B)4: suppressor of Bar in chromosome 4**

**location:** 4- (not located).

**origin:** Spontaneous.

**discoverer:** Brehme, 39k.

**synonym:** *m(B)4*: modifier of *Bar* in chromosome 4.

**references:** 1942, DIS 16: 47.

**phenotype:** Facet number in eyes of *B* male increased, approaching that of *B/+* female. Effect increases with age of culture. *B/B* and *B/+* female not affected. RK3.

**Su(bw<sup>V1</sup>): Suppressor of brown-Variegated**

**location:** 2-105.2.

**origin:** Spontaneous.

**discoverer:** Kadel, 59b17.

**synonym:** *Su-Pm*: Suppressor of *Plum*.

**references:** 1959, DIS 33: 95.

**phenotype:** *Su(bw<sup>V1</sup>)/bw<sup>V1</sup>* has wild-type eye color with peppering of dark spots instead of the more or less uniform brown of *bw<sup>V1</sup>/+*. Effect on various *bw<sup>V</sup>* chromo-

somes varies from none for some to complete suppression for others. Pteridines of heads of *bw<sup>D</sup>/bw<sup>V1</sup>* heterozygotes increased to 28% of normal from 2.5% for *bw<sup>D</sup>/+* heterozygotes (Henikoff and Dreesen). Homozygous viable. RK2.

**cytology:** No gross aberration (Lindsley). *In situ* hybridization using *bw* cDNA probe shows a tandem duplication of the sequence, possibly including 59E2-F1 (Dreesen and Henikoff).

**other information:** *Su(bw<sup>V1</sup>)* is a tandem duplication of *bw<sup>+</sup>* and flanking sequences based on wild-type phenotype of *bw/bw Su(bw<sup>V1</sup>)* and *bw<sup>5</sup>/bw<sup>5</sup> Su(bw<sup>V1</sup>)* (Kadel and Wright). Homozygous *Su(bw<sup>V1</sup>)* female produces 0.3% reversions associated with crossing over in a manner analogous to reversions of *B*.

**su(Cbx): suppressor of Contrabithorax**

**location:** 1-30.

**origin:** Spontaneous.

**discoverer:** E. B. Lewis.

**references:** 1955, Am. Naturalist 89: 73-89.

**phenotype:** Almost completely suppressed *Cbx*; wings made virtually normal and segmental transformations strongly reduced. Without effect on the incidence of ether-induced *bx* phenocopies (Capdevila and García-Bellido, 1981, Wilhelm Roux's Arch. Dev. Biol. 190: 339-50). RK2.

**cytology:** Placed in 7F1-8C6 based on its inclusion in *Df(1)KA14* (Lefevre).

**Su(crc): Suppressor of cryptocephal (J.C. Sparrow)**

**location:** 2-54.7.

**origin:** Induced by ethyl methanesulfonate in *l(2)crc cn* chromosome.

**discoverer:** Sparrow, 1977.

**references:** Sparrow, J.C., 1981, Genet. Res. 38: 297-314.

**phenotype:** A dominant suppressor of *l(2)crc* lethality. Expression is temperature sensitive in *Su(crc) l(2)crc/l(2)crc* heterozygotes and *Su(crc) l(2)crc* hemizygotes with a temperature-sensitive period beginning before pupariation and ending at the time of pupation. The effective lethal period for the suppressor genotypes at 30°C is at the end of the pupal period, not during prepupal stages as is the case for *l(2)crc* homozygotes.

**cytology:** Located between 38A7-B1 and 39C2-D1 but separable by deficiency mapping from *l(2)crc* which has been localized to 39C2-D1 and therefore *Su(crc)* is not a revertant of *l(2)crc*.

**su(Cy)**

**location:** 3- not mapped.

**origin:** Natural population.

**phenotype:** Homozygotes without discernable phenotype except in the presence of *Cy*, in which case the curly-wing phenotype is suppressed.

**alleles:** Two independent isolations of chromosomes with this effect (Meyer and Temin, 1965, DIS 40: 62 and Kosuda, 1971, Jpn. J. Genet. 46: 41-52).

**Su(Cy): Suppressor of Curly**

**location:** 2- (not located).

**origin:** Spontaneous in *In(2LR)bw<sup>V1</sup>*.

**discoverer:** Thompson, 61e.

**references:** 1963, DIS 38: 28.

**phenotype:** *Su(Cy)/Cy* has wild-type wings. RK3.

**other information:** Separable from *In(2LR)bw<sup>V1</sup>*.

*Su(da)*: see *Sxl<sup>MI</sup>*

**\**su(dx)*: suppressor of *deltex***

**location:** 1-5.

**discoverer:** Bridges, 35c26.

**synonym:** *su<sup>X-dx</sup>*: suppressor in X chromosome of *deltex*.

**phenotype:** Reduces phenotype of and imparts male fertility to *dx<sup>st</sup>*. RK2.

***su(dp<sup>ov</sup>)*: suppressor of *dumpy-oblique vortex* (T. Kjaer)**

**location:** 1- (proximal half of chromosome).

**references:** Kjaer, 1986, DIS 63: 162.

**phenotype:** Suppresses phenotype of *dp<sup>ov1</sup>* to normal or nearly normal; also suppresses *dp<sup>ov-DG37</sup>* and *dp<sup>cm2</sup>* but does not suppress *dp<sup>vz2</sup>* or *dp<sup>olv</sup>*. Viability and fertility good.

**alleles:** Three non-complementing, ethyl-methane-sulfonate-induced alleles.

allele	synonym	comments
<i>su(dp<sup>ov</sup>)</i> <sup>1</sup>	<i>su(dp<sup>ov</sup>)</i> TK8-84	suppresses oblique and vortex
<i>su(dp<sup>ov</sup>)</i> <sup>2</sup>	<i>su(dp<sup>ov</sup>)</i> TK25-84	suppresses oblique only
<i>su(dp<sup>ov</sup>)</i> <sup>3</sup>	<i>su(dp<sup>ov</sup>)</i> TK26-84	suppresses oblique only

**\**Su(dx)*: Suppressor of *deltex***

**location:** 2- (not located).

**origin:** Spontaneous.

**discoverer:** Bridges, 31a3.

**references:** Morgan, Bridges, and Schultz, 1931, Year Book - Carnegie Inst. Washington 30: 410.

**phenotype:** *Su(dx)*+ reduces *dx<sup>st</sup>* to a slight but recognizable, fully fertile phenotype. *Su(dx)/Su(dx)* converts *dx<sup>st</sup>* to nearly wild type. RK3.

***Su(dx)*<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** Bridges, 31f1.

**references:** Morgan, Bridges, and Schultz, 1931, Year Book - Carnegie Inst. Washington 30: 410.

**phenotype:** Less effective than *Su(dx)* as a suppressor of *dx*. RK3.

**other information:** Found in *dx* stock, as was *Su(dx)*, along with *ed*. *Su(dx)*<sup>2</sup> may simply be *ed Su(dx)* or it may be of independent origin. Allelism inferred from phenotype alone.

*Su(en)28*: see *Dp(2;3)Su-en*

***Su(er)*: Suppressor of *erupt***

**location:** 2- (near *cn*).

**origin:** Present in many stocks.

**discoverer:** Glass, 1941.

**references:** 1944, Genetics 29: 436-46. 1957, Science 126: 683-89.

**phenotype:** Only effect is suppression of *er*. Semidominant. Exposure to 1000 r of X rays from shortly after

fertilization [8 min, according to Glass (1957), but not until 6 hr, according to Hildreth, 1968, Proc. Nat. Acad. Sci. USA 58: 1924-29] to middle of second larval instar inhibits *Su(er)*, and *er* is then manifested in about 98% of flies. Tryptophan fed to larvae has similar effect. Some related compounds have a lesser effect; kynurenine and indole acetic acid have little or no effect. RK3.

***su(f)*: suppressor of *forked***

**location:** 1-65.9 (adjacent to and to the left of *bb*).

**references:** Schalet and Lefevre, 1974, Chromosoma 44: 183-202.

Schalet and Lefevre, 1976, The Genetics and Biology of *Drosophila* (Ashburner and Novitski, eds.). Academic Press, London, New York, San Francisco, Vol. 1b, pp. 847-902.

**phenotype:** *su(f)* mutations are found with several levels of reduced expression, and some if not all mutant alleles are sensitive to temperature. The weakest exhibit no phenotype when raised at 25° other than modification of the expression of specific alleles at other loci; increasingly reduced expression leads to a specific phenotype, which variably includes Minute-like bristles, rough eyes with some anterior indentation, reduced or absent ocelli, missing ocellar and other head and thoracic bristles, irregular acrostichal rows, excessive melanization, especially on head, and some crippling of legs; also wings may be blistered, broader, with extra veins and may be held upward and outward (Grell, CP627; Schalet, 1968, DIS 44: 125). The most severely affected alleles are lethal, the lethal period becoming earlier with increasing severity. At least one instance of interallelic complementation has been reported by an allele which in surviving adults exhibits pale yellow thread-like chaetae. Viable alleles act as allele-specific but locus-nonspecific modifiers. The locus was recognized by the nearly wild-type bristle phenotype of *f su(f)*; some bristles slightly shortened or twisted at tips. Autonomous in gynandromorphs. *f* alleles fall into two classes: suppressible (*f<sup>1</sup>*, *f<sup>4</sup>*, and *f<sup>5</sup>*) and insuppressible (*f<sup>3</sup>* and *f<sup>3N</sup>*) (Green, 1959, Heredity 13: 303-15). Suppressible alleles are spontaneous and contain insertions of transposable sequences; such alleles are also frequently modified by mutations in other modifier genes. For example, among alleles with gypsy inserts, *su(f)* suppresses *ct<sup>k</sup>*, *lz<sup>1</sup>*, *f<sup>1</sup>*, *f<sup>5</sup>*, *bx<sup>34e</sup>*, but not *y<sup>2</sup>*, *Hw<sup>1</sup>*, *sc<sup>1</sup>*, or *ct<sup>6</sup>*; all are suppressed by *su(Hw)*. In addition, *su(f)* enhances the spontaneous mutants *w<sup>a</sup>* (*copia*) and *lz<sup>37</sup>*, but not *w<sup>e</sup>*, *lz<sup>34</sup>*, *lz<sup>k</sup>*, *s<sup>1</sup>*, or *v<sup>1</sup>* (412); all of these are affected by one or more other suppressor genotypes (Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97). Does not suppress the effect of *f* on the phenotype of *dvr*, i.e. crumpled wings (Lee, 1974, Aust. J. Biol. Sci. 27: 305-7).

**alleles:** Allele specific features are detailed at the end of the entry.

<sup>β</sup> Coordinates are from O'Hare; the origin is at a *saII* site close to the insertion of the *P* element used to clone the gene. Positive values are toward the centromere.

**cytology:** Placed in 20E-F by Lefevre (Schalet and Lefevre, 1973, Chromosoma 44: 183-202); polytene chromosomes in this region are refractory to analysis; however, it is generally accepted that *su(f)* is the most proximally located euchromatic gene on the *X* chromosome.

**molecular biology:** Region cloned by O'Hare by means of transposon tagging using the *P*-element insert in *su(f)*<sup>28</sup>. 50 kb (-32 kb to +19 kb) restriction mapped; coordinate 0 designated as *saII* site 1.1 kb to the left of the *P* insert; positive values are to the right, toward the centromere. The region comprises single-copy DNA interspersed with repeated sequences. Repeated DNA found from -32.0 to -29.4, from -23.4 to -19.9, from -10.2 to -7.8, from -7.4 to -6.6, from -5.0 to -2.0, and from +4.9 to +19.0. Three major RNAs identified by RNA blotting and cDNA analysis; they are transcribed from the interval -0.3 to +3.7; their sizes are 1.3 kb comprising 3 exons, and 2.6 kb and 2.9 kb, both containing the same eight exons, including the three from the smaller RNA; they predict two proteins. DNA lesions detected so far in *su(f)* mutations confined to the region from -5.0 to +5.0 kb (O'Hare). Transformation with -2.2 to +4.3 kb rescues lethality of *su(f)*<sup>2</sup>, *su(f)*<sup>5</sup>, *su(f)*<sup>6</sup>, *su(f)*<sup>19</sup>, and *su(f)*<sup>26</sup> at

25°; also covers suppression of forked-bristle phenotype in *f su(f)*<sup>1</sup> (Simonelig and O'Hare).

### *su(f)*<sup>1</sup>

**phenotype:** Wild type in appearance with normal viability and fertility when raised at 25°; however, both *su(f)* flies raised at 29-30° and *su(f)/Df(1)su(f)* flies raised at 25° display the Minute-like syndrome. The same phenotype is seen in combinations with *su(f)*<sup>2</sup> and *su(f)*<sup>6</sup> raised at 29°. *su(f)/Df(1)su(f)* is lethal when raised at 29°; viability also temperature sensitive in combination with *su(f)*<sup>3</sup> and *su(f)*<sup>5</sup> (Schalet and Lefevre, 1976). *su(f)* enhances *w<sup>a</sup>*; *w<sup>a</sup> su(f)* eyes nearly white at 25° and white at 18° but apricot in flies raised at 29°; suppresses *lz*<sup>1</sup> and enhances *lz*<sup>37</sup> at all temperatures. Increases the accumulation of *gypsy* transcript, suggesting that the wild-type allele represses *gypsy* (Parkhurst and Corces, 1986, Mol. Cell. Biol. 6: 2271-74); protein binding to a negative regulatory sequence of *gypsy* is reduced in nuclear extracts from *su(f)* pupae compared with those from wild type, again suggesting *gypsy* repression by *su(f)*<sup>+</sup> (Mazo, Mizrokhi, Karavanov, Sedkov, Krichevskaha, and Ilyin, 1989, EMBO J. 8: 903-11).

***su(f)*<sup>2</sup>**

**phenotype:** Homozygotes lethal at the larval stage; homozygous germ-line clones don't survive; no effect on development of peripheral or central nervous systems (Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31). Survives and suppresses *f* in combination with *su(f)*<sup>1</sup> at 25°, and exhibits *M*-like syndrome in flies raised at 18°. *w<sup>a</sup>* displays dilute apricot pigmentation in *su(f)*<sup>1</sup>/*su(f)*<sup>2</sup> flies raised at 25° but white eyes when raised at 18° (Schalet and Lefevre, 1976). *su(f)*<sup>2</sup> shown to be proximal to *su(f)*<sup>1</sup> by recombination (Schalet).

***su(f)*<sup>3</sup>**

**references:** Schalet, 1972, DIS 49: 36-37.

**phenotype:** Homozygous lethal. Fails to complement lethality of either *su(f)*<sup>3</sup> or *su(f)*<sup>5</sup>. In combination with *su(f)*<sup>1</sup> shows the *M*-like syndrome at 25° and is lethal at 29°.

***su(f)*<sup>4</sup>**

**references:** Schalet, 1972, DIS 49: 36-37.

**phenotype:** May be the only pale-bristle allele. One other allele of this type was found by Dale Grace as a sex-lined lethal (Schalet). Recovered originally as a sex-linked recessive lethal, but fully viable, though weak, and suppresses *f* when raised at 18°. Survivors exhibit pale-yellow, thread-like bristles, darker pigmentation dorsoanteriorly on thorax, and curled or wrinkled wings. Lethality at late pupal stage; homozygous germ-line clones show no maternal effect; also, no zygotic effects on development of peripheral or central nervous systems (Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31). Interactions of *su(f)*<sup>4</sup> with other *su(f)* alleles are as follows: *su(f)*<sup>1</sup>, same as *su(f)*<sup>1</sup> homozygotes at all temperatures; *su(f)*<sup>2</sup>, complementation for viability and bristle color and slight complementation for suppression of *f*; *su(f)*<sup>3</sup>, lethal at the time of puparium formation at 25°, fully viable with some chaetae of all individuals showing the pale-bristle phenotype and the texture of the wings appearing abnormal at 18°; *su(f)*<sup>5</sup>, fully viable and normal at 18°, variable viability with a broad streak of dark pigment on thorax, which sometimes is concentrated at dorsal anterior region, and wings which may extend upward and outward at 25°, lethal prior to puparium formation at 29°; *su(f)*<sup>6</sup>, fully viable and normal at 18° and 25° but exhibiting the *M*-like syndrome at 29°; *Df(1)su(f)*, lethal at the time of puparium formation at 25° and just prior to eclosion at 18°. Enhances *w<sup>a</sup>*; *w<sup>a</sup> su(f)* eyes white in flies raised at 25° and dilute apricot at 18°; also enhances *lz*<sup>37</sup> at 18°.

***su(f)*<sup>6</sup>**

**phenotype:** Homozygotes lethal at the larval stage; homozygous germ-line clones don't survive; no effect on development of peripheral or central nervous systems (Perrimon, Smouse, and Miklos, 1989, Genetics 121: 313-31). Lethal with *su(f)*<sup>3</sup> at 25° and with *su(f)*<sup>4</sup> at 29°. In combination with *su(f)*<sup>1</sup>, displays the *M*-like syndrome at 25° and lethal at 29°.

***su(f)*<sup>8</sup>**

**references:** Dudick, Wright, and Brothers, 1974, Genetics 76: 487-510.

**phenotype:** The first allele recovered specifically as a temperature-sensitive lethal; completely lethal at 29°; suppresses *f* at 25° but not at 18°. Temperature-sensitive

period for lethality from 50 to 140 h after oviposition, for *f* suppression coincident with bristle differentiation. Shift up to 30° before end of the second instar causes failure to pupariate; full-sized third instar larvae produced, which live 10-14 days; salivary-gland-secretion proteins specifically reduced or absent in these larvae, although the associated chromosome puffs appear normally; other proteins unaffected (Hansson, Lineruth, and Lambertsson, 1982, Wilhelm Roux's Arch. Dev. Biol. 190: 308-12); shift up prior to 70 h leads to little or no accumulation of *Sgs* transcripts as detected in Northern blots probed with sequences from *Sgs*<sup>3</sup>, *Sgs*<sup>4</sup>, *Sgs*<sup>7</sup>, and *Sgs*<sup>8</sup>, whereas a 48-h pulse beginning at 75 h is without effect on transcription or translation of *Sgs* genes (Hansson and Lambertsson, 1983, Mol. Gen. Genet. 192: 395-40). Shift up to 30° in early third instar blocks the increase in ecdysterone titer normally occurring at the end of L3; ecdysterone supplementation induces abortive pupariation and stimulates prepupal polypeptide synthesis (Hansson and Lambertsson, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 48-51); leg discs of such larvae unable to evert, either *in vivo* or *in vitro* (Fekete and Lambertsson, 1980, Hereditas 93: 169-76). Homozygous females raised under permissive conditions, when shifted up to 30° cease laying eggs and the ovarian oocytes degenerate; fertility recoverable after pulses of three but not eleven hours (Dudick *et al.*). Heterozygotes with *Df(1)su(f)* at 25°, *su(f)*<sup>1</sup> at 29°, and *su(f)*<sup>3</sup> at 30° exhibit the *M*-like syndrome. Enhances *M(3)67C*, as indicated by reduced viability of *su(f)*<sup>8</sup> versus *su(f)*<sup>+</sup> sibs that are *M(3)67C/+* (Girton, Langner, and Cejka, 1986, Roux's Arch. Dev. Biol. 195: 334-37). Enhances *gypsy* expression, more at 25° than at 18° (Parkhurst and Corces, 1986, Mol. Cell. Biol. 6: 2271-74).

***su(f)*<sup>9</sup>**

**references:** Voss and Falk, 1973, Mutat. Res. 20: 221-34.

**phenotype:** Recovered as a surviving son of *su(f)*<sup>3</sup>; still suppresses *f*, but is no longer lethal. *X/Y* males survive and have small rough eyes, broad outstretched wings and irregular abdominal pigmentation; homozygous females usually lethal with escapers showing the same phenotype as the males. *XXY* females survive and resemble *XY* males. *XO* males die. *su(f)*<sup>9</sup>/*su(f)*<sup>3</sup> never survives. Attributed by authors to a recessive variegated-position-effect suppressor of the lethality of *su(f)*<sup>3</sup>; locates to proximal extremity of the *X*; complements *bb*.

**cytology:** Salivary chromosomes normal; pseudolinkage not tested.

***su(f)*<sup>12</sup>**

**references:** Russell, 1974, Dev. Biol. 40: 24-39.

**phenotype:** Selected as a cell-autonomous, temperature-sensitive lethal. Relative survival is 85% at 22°, 75% at 25° and 1% at 29°; temperature-sensitive period from first larval instar to early pupa. Homozygous females become sterile after two days at 29°, whereas males so treated remain fertile. 23% of eggs laid at 29° fail to hatch; surviving larvae grow at subnormal rate and survive for up to twelve days, reaching the third instar; imaginal discs reduced greatly in size. 48-h pulses of 30° during late second and third instars results in considerable cell death in imaginal discs with a consequent deletion of some pattern elements and duplications of others in the head and legs; head duplications occur only in

association with deficiencies; leg duplications seen as simply and complexly branched appendages involving variable numbers of joints. Pulses applied to early pupae lead to failure of histoblast differentiation and applied later to the lack of chaetae (Russell, Girton, and Morgan, 1977, Wilhelm Roux's Arch. Dev. Biol. 183: 41-59). Extensive use made of leg duplications induced in *su(f)*<sup>12</sup> in investigations of pattern formation (Tiong, Girton, Hayes, and Russell, 1977, Nature 268: 435-37; Postlethwait, 1978, Wilhelm Roux's Arch. Dev. Biol. 185: 37-57; Girton and Russell, 1980, Dev. Biol. 77: 1-21; Girton, 1981, Dev. Biol. 84: 164-72; Girton and Russell, 1981, Dev. Biol. 85: 55-64). Enhances *M(3)67C*, as indicated by reduced viability of *su(f)*<sup>12</sup> versus *su(f)*<sup>+</sup> sibs that are *M(3)67C/+* (Girton, Langner, and Cejka, 1986, Roux's Arch. Dev. Biol. 195: 334-37).

### *su(f)*<sup>13</sup>

**references:** Jürgens and Gateff, 1979, Wilhelm Roux's Arch. Dev. Biol. 186: 1-25.

**phenotype:** A cell-autonomous, temperature-sensitive recessive allele. Phenotype similar to that of *su(f)*<sup>12</sup> except that trypan-blue staining provides no evidence of cell death resulting from heat shock at stages of development in which such treatment induces leg duplications. Authors postulate that *su(f)*<sup>12</sup> discs developmentally impaired by heat shock, giving rise to observed abnormalities. Temperature-sensitive period from late second instar until two hours into pupariation. Shifts from 22° to 29° during the first larval instar leads to inability to pupariate; shifts between 112 and 164 h arrests adult development; shifts within the first six hours after the temperature for lethality removes bristles from the tergites. Gynandromorphs and somatic clones formed normally at permissive temperatures, but are not observed in adults produced at 29°. Ecdysteroid level of larvae raised at 29° are less than one-tenth that of wild type; pupariation can be induced by ecdysterone supplementation (Klose, Gateff, Emmerich, and Beikirch, 1980, Wilhelm Roux's Arch. Dev. Biol. 189: 57-67).

### *su(f)*<sup>14</sup>

**references:** Wilson, 1980, J. Embryol. Exp. Morphol. 55: 247-56.

**phenotype:** Temperature-sensitive lethal allele. Temperature-sensitive period for lethality extends from the second larval instar until twelve hours after pupariation. Shifting adult females to restrictive conditions results in the gradual abolition of oviposition; during the first day normal appearing eggs, many of which hatch, are produced, on the second day the hatchability of the eggs is reduced, and by day four the eggs are small and misshapen and lack chorions; oviposition ceases on the fifth or sixth day after shift up; at this time the ovary is deficient in stage 8-11 oocytes and lacks follicle cells indicating a breakdown in vitellogenesis. Shift back down to 25° leads to resumption of egg laying after four days. Ovarian response is autonomous in ovarian transplants. Fertility of males irreversibly impaired by shift up to 29°.

### *su(f)*<sup>23</sup>

**references:** Girton, Langner, and Cejka, 1986, Roux's Arch. Dev. Biol. 195: 334-37.

**phenotype:** Homozygotes and hemizygotes survive at all

temperatures from 18° to 29°; complements the lethality of lethal alleles. The suppression of *f* is temperature sensitive, but the sensitivity is of opposite sign from that of other temperature-sensitive alleles; *f su(f)*<sup>23</sup> flies raised at 18° have suppressed forked bristles, whereas those raised at 29° are forked; the temperature-sensitive period sharply confined to the short interval at which bristle development is initiated. Does not appear to enhance *M(3)67C*.

### *su(f)*<sup>24</sup>

**phenotype:** Similar to *su(f)*<sup>1</sup>; enhancement of *w<sup>a</sup>*, however, seen only in *su(f)*<sup>1</sup>/*su(f)*<sup>24</sup>. Closely linked to or inseparable from a variable recessive abnormality giving small misshapen eyes.

### \**Su(f)*: Suppressor of forked

**location:** 2-74.

**origin:** X ray induced.

**discoverer:** Dobzhansky, 1931.

**synonym:** *Su<sup>D</sup>-f*: Suppressor of forked of Dobzhansky.

**phenotype:** Heterozygous *Su(f)* reduces expression of *f*; bristles blunt and wavy. Female fertility low. Homozygous lethal. RK3(A).

**other information:** Crossing over probably reduced.

### *su(fa<sup>swb</sup>)*: suppressor of facet-strawberry

**location:** 1-1.96 (0.46 cm to the right of *w<sup>a</sup>*).

**origin:** Spontaneous.

**references:** Welshons and Welshons, 1986, Genetics 113: 337-54.

**phenotype:** In the *cis* configuration with *fa<sup>swb</sup>* it causes a facet-like rather than a glossy-like phenotype. Deficiencies for the element, when in *cis* with *fa<sup>swb</sup>*, result in the complete suppression of *fa<sup>swb</sup>* (Welshons and Welshons, 1985, Genetics 110: 465-77). Furthermore *In(1)78b = In(1)3A2-3;3C3-5* also suppresses *fa<sup>swb</sup>* when in *cis* configuration.

**cytology:** Placed in 3C2-5 based on its genetic position between *w<sup>a</sup>* and *fa<sup>swb</sup>* and on the suppressive effect of *In(1)78b*.

### *Su(fu)*: Suppressor of fused

**location:** 3 (not mapped).

**origin:** Induced by ethyl methanesulfonate

**references:** Bussan, Limbourg-Bouchon, Mariol, Preat, and Lamour-Isnard, 1988, Roux's Arch. Dev. Biol. 197: 221-30.

**phenotype:** Dominant suppressor of both the wing phenotype and the maternally determined lethality of *fu* mutants.

**other information:** Four dominant partial suppressors observed in same experiment; not further characterized.

### *Su(Gl)27*: Suppressor of Glued

**location:** 1- {64}.

**origin:** Induced by ethyl methanesulfonate.

**references:** Harte and Kankel, 1982, Genetics 101: 477-501 (fig.).

**phenotype:** Males carrying *Su(Gl)27* in combination with *Gl/+* are virtually wild type in phenotype, both with respect to the eye and to the optic lobe, when raised at 29°; eye slightly reduced in size with some small facets scattered throughout the eye; facets not packed together as tightly as in wild type, some smooth pigmented material separating facets from one another. The optic

lobe is very nearly normal in appearance; the lamina cell body region is thicker than in wild type and the lamina neuropil is slightly irregular in contour, but the medulla rotation and gross fiber tract abnormalities of *Gl* are missing. Phenotype less nearly normal in flies raised at 18°. Phenotypes of females not given; presumably recovered in heterozygous females and therefore dominant. *Su(Gl)/Df(1)mal10* females exhibit outheld wings; probably not allelic to *ot*, which maps to the same region, since *ot* not included in *Df(1)mal10*.

**cytology:** Placed in 19A5-E1 based on its inclusion in *Df(1)mal10 = Df(1)19A5-6;19E1*.

***Su(Gl)57***

**location:** 1- (not mapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Harte and Kankel, 1982, *Genetics* 101: 477-501.

**phenotype:** Said to reduce the severity of *Gl/+* at both 18° and 29°, but genotypes not specified.

***Su(Gl)77***

**location:** 3- (between *ru* and *h*).

**origin:** Induced by ethyl methanesulfonate.

**references:** Harte and Kankel, 1982, *Genetics* 101: 477-501 (fig.).

**phenotype:** Reduces the severity of *Gl* in flies raised at either 18° or 29°. The most severe allele shows more normal facet arrays in the anterior than in the posterior part of the eye. The lamina cell body layer is thicker than normal in its posterior region and the lamina neuropil is somewhat misshapen, particularly anteriorly. The medulla is abnormally rotated, its posterior edge directly apposed to the lamina, but it is more normally organized than in *Gl*. The familiar abnormal projections from the posterior lamina through the medulla are present. The second optic chiasma is also divided into several tracts. In less extreme cases, the medulla is only slightly rotated and the second optic chiasma is normal.

**alleles:** Although allelism not established, three independent mutations numbered 57, 102, and 160 with suppressing effects on *Gl* map between *ru* and *h* and are presumed to be allelic and are designated *Su(Gl)77<sup>1</sup>*, *Su(Gl)77<sup>2</sup>*, and *Su(Gl)77<sup>3</sup>*, respectively. Of these *Su(Gl)77<sup>1</sup>* is the weakest *Su(Gl)77<sup>3</sup>* is intermediate and *Su(Gl)77<sup>2</sup>* is the strongest suppressor of *Gl*.

***Su(H): Suppressor of Hairless***

**location:** 2-50.8.

**synonym:** *E(H); l(2)br7*.

**references:** Nash, 1965, *Genet. Res.* 6: 175-189.

Nash, 1970, *Genetics* 64: 471-79.

Ashburner, 1982, *Genetics* 101: 447-59.

**phenotype:** Homozygous lethal; hemizygotes die in the pupal stage, between head eversion and the beginning of eye pigmentation. Heterozygotes in the absence of *H* are wild type in phenotype. Suppresses *H*; *Su(H)/+*; *H/+* have 7-10 more bristles than *H/+* alone; besides affecting the bristle phenotype of *H*, all alleles tend to enhance its wing-vein phenotype of shortening L4 and L5. *Su(H)* is without effect on the lethal phenotype of homozygous *H*. One homozygous-lethal allele acts as a dominant enhancer of *H*. Most alleles are amorphic or hypomorphic; heterozygous deficiencies for the locus also suppress, and duplications enhance *H* (Nash, 1970).

Enhanced genotypes have 10-15 fewer bristles and a far more extreme loss of microchaetae on the thorax than their unenhanced counterparts. The number of bristles in *H/+* flies is inversely related to the dose of *Su(H)<sup>+</sup>*, with the number of bristles varying from fewer than ten with four doses to approximately 35 with one dose. Some combinations of hypomorphic alleles produce occasional escapers; survivors have distinctive phenotypes, which are described under entries for specific alleles.

**cytology:** Placed in 35B3-C1 on the basis of its inclusion in *Df(2L)AR-R1 = Df(2L)35A3-4;35B9-C1* but not *Df(2L)fn31 = Df(2L)34D3;35B3-5*.

***Su(H)<sup>3</sup>***

**phenotype:** A leaky allele; trans heterozygotes with *Su(H)<sup>1</sup>* show 20% survival; almost viable with *Su(H)<sup>7</sup>*; semilethal with *Su(H)<sup>2</sup>*, *Su(H)<sup>4</sup>*, *Su(H)<sup>6</sup>*, and *Su(H)<sup>8</sup>*; lethal in combination with *Su(H)<sup>16</sup>*. Survivors have vestigial wings and halteres and eyes somewhat reduced and rough; bristles normal.

***Su(H)<sup>7</sup>***

**phenotype:** Homozygous lethal; in trans heterozygotes with other alleles produces rare escapers, which have an extreme mutant phenotype; wings and halteres similar to those of an extreme vestigial allele; eyes, although large, have rough glazed appearance and the flies are almost achaetous, having fewer than ten macrochaetae per fly; acrostichal hairs and other microchaetae reduced in number and disturbed in arrangement; tarsal claws also much reduced.

***Su(H)<sup>16</sup>***

**phenotype:** Homozygous lethal; acts as a dominant enhancer of *H*, with about the same effect as heterozygosity for a duplication for the locus.

***su(Hw): suppressor of Hairy wing***

**location:** 3-54.8.

**references:** Lewis, 1949, *DIS* 23: 59-60.

Klug, Bodenstein and King, 1968, *J. Exp. Zool.* 167: 151-56.

Klug, King, and Wattiaux, 1970, *J. Exp. Zool.*

174: 125-40.

Modolell, Bender, and Meselson, 1983, Proc. Nat. Acad. Sci. USA 80: 1678-82.

Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97.

**phenotype:** In homozygous condition (e.g.,  $su(Hw)^2/su(Hw)^2$  or  $su(Hw)^2/su(Hw)^7$ ) suppresses certain spontaneous alleles that contain *gypsy* inserts at a number of different loci, e.g.,  $y^2$ ,  $Hw^1$ ,  $sc^1$ ,  $sc^{D2}$ ,  $dm^1$ ,  $ct^6$ ,  $ct^K$ ,  $lz^1$ ,  $f^1$ ,  $f^5$ ,  $f^K$ ,  $B$ ,  $Bxd^2$ ,  $h^1$ ,  $bx^3$ ,  $bx^{34e}$ ,  $bx^{51j}$ ,  $bx^{55i}$ ,  $bx^K$ , and  $ci^1$ ; alleles without *gypsy* inserts are not suppressed (see Lewis, 1949). Apparent exceptions to the above generalizations are  $sc^{D1}$ , which is suppressed and reportedly X ray induced and  $r^{SP1}$  and  $r^{SP2}$ , both of which show temperature-sensitive suppression but no evidence of *gypsy* insertion. With the exception of  $lz^{37}$ , which is enhanced by  $su(Hw)$ , alleles not known, or known not, to contain *gypsy*, but which are modified by other suppressors are unaffected by  $su(Hw)$ . Two alleles,  $ct^K$  and  $f^K$ , exhibit suppression in heterozygotes for either  $su(Hw)$  or a deficiency for  $su(Hw)$ .  $su(Hw)$  causes accumulation of *f* transcript in flies carrying *f* alleles that ordinarily display low levels to return to wild-type levels (Parkhurst and Corces, 1985, Cell 41: 429-37); judging from results with  $y^2$ , this is caused by reduction of transcription from the associated *gypsy* element (Parkhurst and Corces, 1986, Mol. Cell. Biol. 6: 47-53). Females homozygous for  $su(Hw)^1$ ,  $su(Hw)^2$ ,  $su(Hw)^3$ , and  $su(Hw)^4$  are sterile; females homozygous for  $su(Hw)^8$  and transheterozygotes of  $su(Hw)^7$  with other alleles are fertile;  $su(Hw)^7/su(Hw)^2$  are fertile and, in fact, suppress the female sterility of *dm* and *lz* (Grell). In sterile combinations, vitellogenesis inhibited leading to smaller-than-normal cysts surrounded by multiple layers of follicle cells; nurse cell chromosomes remain condensed until stage 9, after which egg chambers degenerate; ovarian phenotype autonomous in transplants (Klug *et al.*, 1968, 1970). Reduced viability attributed to some alleles apparently caused by extraneous genes, since those alleles are perfectly viable in combination with  $su(Hw)$  deficiencies.

<sup>α</sup> 1 = Bridges, 1932, Proc. Int. Congr. Genet. 6th, Vol. 2: 12-14; 2 = Lewis, 1949, DIS 23: 59-60; 3 = Modolell, Bender, and Meselson, 1983, Proc. Nat. Acad. Sci. USA 80: 1678-82; 4 = Parkhurst, Harrison, Remington, Spana, Kelley, Coyne, and Corces, 1988, Genes Dev. 2: 1205-15; 5 = Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97.

**cytology:** Placed in 88A12-B5 based on its inclusion in  $Df(3R)red-P52 = Df(3R)88A12-B1;88B4-5$  [Lewis, 1981, Developmental Biology Using Purified Genes (Brown and Fox, eds.). Academic Press, New York, pp. 189-

208].

**molecular biology:** Region cloned and sequenced by Parkhurst, Harrison, Remington, Spana, Kelley, Coyne, and Corces (1988, Genes Dev. 2: 1205-15); normal allele produces a 3.3 kb message which is expressed throughout development, and is expressed in ovaries; transcription from right to left, i.e., from the tip of 3R toward the centromere. Genomic sequence comprises seven exons, separated by six introns, all but the first of which are short, in the range of 50-60 base pairs. Conceptual amino-acid sequence corresponds to a 109,000 dalton polypeptide; it contains twelve Zn finger motifs in the middle of the protein encoded by sequences contained in several of the miniexons and a highly acidic region (48% Asp + Glu) between amino acids 154 and 202 immediately preceding the first Zn finger; structure suggests a transcription factor. Nuclear extracts or partially purified protein from overexpressing *E. coli* or *Drosophila* cells bind to a 367 base pair DNA sequence containing twelve copies of PyPuTTGCATACCPy from the 5' untranslated end of *gypsy* between the 5' LTR and the initial ATG (Spana, Harrison, and Corces, 1988, Genes Dev. 2: 1414-23; Mazo, Mizrokhi, Karavanov, Sedkov, Krichvskaja, and Ilyn, 1989, EMBO J. 8: 903-11); footprinting indicates protection of a 55 bp domain by  $su(Hw)$  protein. Antibodies raised against the protein label 100 to 200 sites on polytene chromosomes (Spana *et al.*).

***su(lz<sup>34</sup>): suppressor of lozenge-34***

**location:** 3- (not located).

**origin:** Spontaneous.

**discoverer:** H. A. Bender.

**references:** Bender and Green, 1960, Genetics 45: 1563-66.

**phenotype:**  $lz^{34}$ ;  $su(lz^{34})$  eyes larger, less rough, and more normal in color than  $lz^{34}$  alone. Female distinctly more fertile with  $su(lz^{34})$  but still lacks parovaria and spermathecae. RK2.

***Su(M): Suppressor of Minute***

These are tandem duplications selected on the basis of their normal phenotype in heterozygous combination with a specific Minute. They are treated under  $Dp(2;2)M^+$  and  $Dp(3;3)M^+$ .

***su(msm1)***

**location:** 2- (not mapped).

**origin:** Induced by ethyl methanesulfonate.

**references:** Nishida, 1980, Jpn. J. Genet. 55: 427-39.

**phenotype:** Most males homozygous for  $su(msm1)$  and  $ms(3)ml$  have small spiral-shaped testes and motile sperm in their seminal vesicles, whereas those homozygous for  $ms(3)ml$  have rudimentary testes.

***Su(par): Suppressor of paralog***

**location:** 1- to the right of v.

**references:** Thierry-Mieg, 1982, Genetics 100: 209-37.

**phenotype:** Semidominant. In homozygous condition reduces the incidence of agametic *par/par* females from 95-100% to 51-61% and abdominal defects from 26-49% to 5-14%. No effect on fecundity at 29° or the frequency of cephalic defects caused by *par*. *par+/par Su(par)* females are 77% agametic. *Su(par)* homozygotes in the absence of *par* are normal.

**Su(Pc)37D: Suppressor-of-Polycomb-37D**

**location:** 2-{54}.  
**references:** Kennison and Tamkun, 1988, Proc. Nat. Acad. Sci. USA 85: 8136-40.  
**phenotype:** Suppresses *Pc*.  
**cytology:** Located at 37D2 to 38C1.

**su(pr): suppressor of purple**

**location:** 3-95.5.  
**references:** Schultz and Bridges, 1932, Am. Nat. 66: 323-34.  
 Rutledge, Mortin, Kelley, and Meselson, 1988, Genetics 119: 391-97.  
**phenotype:** Completely suppresses *pr*<sup>1</sup> but not *v*<sup>1</sup> both of which contain an insert of transposable element *412*, and both of which are suppressed by *su(s)*. Also suppresses both *lz*<sup>34</sup> and *lz*<sup>k</sup>; among alleles with *gypsy* inserts, *su(pr)* suppresses *ct*<sup>K</sup>, *f*<sup>1</sup>, and *f*<sup>5</sup>, enhances *Hw*<sup>1</sup>, *ct*<sup>K</sup>, *bx*<sup>3</sup>, and *bx*<sup>34e</sup>, but has no influence on the expression of *y*<sup>2</sup>, *sc*<sup>1</sup>, or *ct*<sup>6</sup>. No visible mutant phenotype. Abnormal phenotypes, low viability and sterility described for *su(pr)*<sup>1</sup> and *su(pr)*<sup>B</sup> extraneous to *su(pr)*, since *su(pr)*<sup>B</sup>/*su(pr)*<sup>1</sup> displays normal viability and fertility.

**su(r): suppressor of rudimentary**

**location:** 1-27.7.  
**references:** Bahn, 1972, DIS 49: 38 & 98.  
 Strøman, Bahn, Nørby, and Sick, 1973, Hereditas 73: 239-46 (fig.).  
 Strøman, 1974, Hereditas 78: 157-68.  
**phenotype:** Suppresses both the phenotypic effects and the female sterility of all *r* alleles; also suppresses the *r* phenocopying and lethal effects of 6-azauracil administration. Little or no dihydrouracil dehydrogenase (EC 1.3.99.11) activity. Thought to interfere with pyrimidine catabolism. Unable to degrade uracil and extremely sensitive to exogenous pyrimidine. Enhances the expression of *dp* and *net*, and causes *b* flies to have very black bodies, darker than wild type, especially along the wing veins; forms synthetic lethals in combination with *tt* and

*whd*.

**alleles:** Ten ethyl-methanesulfonate-induced alleles recorded; one by Bahn and nine by Falk and DeBoer (1980, Mol. Gen. Genet. 180: 419-24).

**su(s): suppressor of sable (R.A. Voelker)**

**location:** 1-0+ [rare crossovers occur between *y* and *su(s)*].  
**references:** Bridges, 1919, Anat. Rec. 15: 357-58.

 Jacobson, Grell, Yim and Gardner, 1982a, Genet. Res. 40: 19-32.  
 Jacobson, Yim, Grell and Wobbe, 1982b, Cell 30: 817-23.  
 Chang, Wisely, Huang and Voelker, 1986, Mol. Cell. Biol. 6: 1520-28.  
 Rutledge, Mortin, Schwarz, Thierry-Mieg and Meselson, 1988, Genetics 119: 391-97.  
 Searles and Voelker, 1986, Proc. Nat. Acad. Sci. USA 83: 404-08.  
 Voelker, Huang, Wisely, Sterling, Bainbridge and Hiraizumi, 1989, Genetics 122: 625-42.

**phenotype:** In hemizygous or homozygous condition suppresses certain spontaneous alleles that contain *412* insertions at several loci (e.g., *v*, *v*<sup>2</sup>, *v*<sup>k</sup>, *pr*, *pr*<sup>bw</sup>, *sp*) or hybrid dysgenesis-induced alleles that contain *P* element insertions (e.g., *sn*<sup>w</sup>, *y*<sup>76d28</sup>). *s* is suppressible but does not have a *412* insertion (Searles and Voelker, 1986). *bx* is caused by a *412* insertion but is not suppressed (Voelker *et al.*, 1989). Not all *su(s)* alleles suppress all suppressible alleles (Jacobson *et al.*, 1982a). Although reported as recessive, some alleles show a slight dominance (Shapard, 1960; Baglioni, 1960). No lethal alleles recovered in a lethal saturation screen of the *su(s)* region, but a number of X-ray-, EMS- and ENU-induced alleles exhibit sterility or reduced male fertility when reared at 18°C (Voelker *et al.*, 1989). Some alleles cause a slight spreading of the wings, especially in males. Suppression of *v* and *y*<sup>76d28</sup> occurs by elevating the levels of pseudo-wild-type, presumably translatable, message (Searles, Ruth, Pret, Fridell, and Ali, submitted; P. Geyer, V. Corces and M. Green, personal communication). Some alleles enhance some *gypsy*-caused mutations (Rutledge *et al.*, 1988). A duplication of *su(s)*<sup>+</sup> enhances suppressible *pr* alleles (Jacobson *et al.*, 1982b).

**cytology:** Placed in 1B10-1C1 (Hayman and Maddern, 1972; Chang *et al.*, 1986).

**molecular biology:** An 8 kb region that rescues *su(s)* mutations when reintroduced by *P* element-mediated transformation of embryos was sequenced (R. Voelker, W. Gibson, J. Graves, J. Sterling and M. Eisenberg, in preparation). A 7.8 kb primary transcript that is produced throughout the life cycle is transcribed telomere to centromere. It is processed to a ~5 kb mature message by splicing out five introns that range in size from 60 to 2053 nucleotides, the latter occurring within but near the 3' end of a ~500 nucleotide nontranslated leader. All eleven spontaneous mutations examined contain mobile element insertions within the 2053 nt intron. One dysgenesis-induced allele contains a *P* element insertion within that same intron, whereas four other alleles contain *P* element insertions within the nontranslated leader 5' to the large intron (R. Voelker, J. Graves, W. Gibson and M. Eisenberg, in preparation). The conceptual protein is a ~145,000 dalton polypeptide that contains an *opa*-like sequence and a highly charged region similar to regions of some RNA-binding/splicing proteins. The protein is located primarily in the nucleus.

### **Su(S): Suppressor of Star**

**location:** 2-3; based on cytological location between *shr* (2-2.3) and *dpp* (2-4.0).

**origin:** Synthetic.

**discoverer:** Curry, 37b.

**references:** Morgan, Bridges, and Schultz, 1937, Year Book - Carnegie Inst. Washington 36: 301. Lewis, 1945, Genetics 30: 154.

**phenotype:** *Su(S)/S* and *Su(S)/+* wild type. RK2A.

**cytology:** Associated with the deficiency for 22D1 to 22E1 or the deficiency for 33F to 34A9, or both, derived by combining the left end of *In(2L)Cy = In(2L)22D1-2;33F5-34A1* and the right end of *In(2L)t = In(2L)22D3-E1;34A8-9*. According to Lewis (1945), the region between 22D1 and 22E1 is more likely responsible.

### **\*Su(sc): Suppressor of scute**

**location:** 3-59.

**discoverer:** Payne.

**synonym:** *sc-Inh-3: scute Inhibitor on chromosome 3; Ext-sct-3*.

**references:** 1921, Genetics 5: 501-42.

Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 158.

Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 225, 235.

**phenotype:** Tends to restore bristles removed by *sc* in *Su(sc)/+* heterozygotes. RK3.

### **su(SD): suppressor of Segregation Distortion**

**location:** 1-49.5 [53/74 of the distance from *g* to *sd* (Waddle, Owens, and Petty)].

**references:** Sandler, 1962, Am. Nat. 96: 161-65.

Sandler and Rosenfeld, 1962, Can. J. Genet. Cytol. 4: 453-57.

Katakao, 1967, Jpn. J. Genet. 42: 327-33.

Waddle and Oster, 1977, DIS 52: 5.

**phenotype:** Several *X* chromosomes that reduce the *k* value in *SD/+* males from nearly 1.0 to a value closer to 0.5. Not clear that the various *X*-linked suppressors of distortion are related.

### **Su(sph): Suppressor of sparse hairs**

**location:** 2-24 or 25.

**synonym:** *Su-x4*.

**references:** Voss and Falk, 1973, Mutat. Res. 20: 221-34.

**phenotype:** Allele specific suppressor of *sph*. *Su(sph)* permits survival of *sph*<sup>4</sup> but not *sph*<sup>7</sup> males; both homozygous and heterozygous *Su(sph)* allow 50 to 60% control survival. *sph*<sup>4</sup> females are rescued by homozygous but not heterozygous *Su(sph)* to nearly 20% of control.

**alleles:** One spontaneous allele [*Su(sph)*<sup>1</sup>] and one induced by X rays [*Su(sph)*<sup>2</sup>].

**cytology:** Polytene chromosomes normal.

### **\*Su(ss): Suppressor of spineless**

**location:** 3-61 (between *bx* and *sr*).

**origin:** Spontaneous.

**discoverer:** Bridges, 22g15.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 236.

**phenotype:** *Su(ss)/+* converts *ss/ss* to wild type except for reduced and erect posterior scutellars. Homozygous lethal. RK2.

### **Su(ss)<sup>2</sup>**

**origin:** Spontaneous.

**discoverer:** E. B. Lewis, 1947.

**references:** 1950, DIS 24: 59.

**phenotype:** Homozygous or heterozygous *Su(ss)*<sup>2</sup> causes *ss* to have long bristles that are only slightly thin, like a mild Minute; however, the posterior scutellars remain greatly reduced as in un-suppressed *ss*. Temperature-sensitive allele; suppression more extreme at 29° than at

17°; temperature-sensitive period from 5-34 h after onset of puparium formation (Mglinetz, Ivanov, and Kostina, 1978, *Ontogenez* 9: 136-41). RK2.

**Su(ss)<sup>3</sup>**

**origin:** Spontaneous.

**discoverer:** Hexter, 1950.

**references:** 1953, DIS 27: 55-56.

**phenotype:** *ss Su(ss)<sup>3</sup>* homozygote wild type for all bristles; *ss Su(ss)<sup>3</sup>/ss* + intermediate between *ss* and wild type. *ss Su(ss)<sup>3</sup>/ss bx Su(ss)<sup>2</sup>* is wild type. RK2.

**Su(Ste): Suppressor of Stellate**

**location:** Y-between *kl2* and *kl1*.

**references:** Meyer, Hess, and Beerman, 1961, *Chromosoma* 12: 676-716.

Hardy and Kennison, 1980, DIS 55: 55.

Gatti, M. and S. Pimpinelli, 1983, *Chromosoma* 88: 349-373.

Hardy, Lindsley, Livak, Lewis, Sivertsen, Joslyn, Edwards, and Bonaccorsi, 1984, *Genetics* 107: 591-610.

Livak, 1984, *Genetics* 107: 611-634.

Livak, 1990, *Genetics* 124: 303-16.

**phenotype:** Designates the region of the Y chromosome whose presence decreases both abundance and splicing of the X-linked *Ste* transcripts. *Ste* males deficient for *Su(Ste)* display abundant star-shaped aggregates of needle-shaped crystals in the nuclei and cytoplasm of their primary spermatocytes; their spermatids contain micronuclei and nebenkerne of nonuniform size; and they are sterile. *Ste*<sup>+</sup> males deficient for *Su(Ste)* have one or more long needle-shaped crystals in their primary spermatocytes and micronuclei and irregular nebenkerne in their spermatids; these males are fertile and display irregular disjunction as follows: (1) both the sex chromosomes and the large autosomes undergo nondisjunction, (2) the fourth chromosomes disjoin regularly, (3) sex chromosome nondisjunction is more frequent in cells in which the second or third chromosomes nondisjoin than in cells in which autosomal disjunction is regular, (4) in doubly exceptional cells, the sex chromosomes tend to segregate to the opposite pole from the autosomes, and (5) there is meiotic drive; *i.e.*, reciprocal meiotic products are not recovered with equal frequencies, complements with fewer chromosomes being recovered more frequently than those with more chromosomes. Two smaller component deficiencies of the *Su(Ste)* deficiency display a normal meiotic phenotype in *Ste*<sup>+</sup> males and low levels of meiotic nondisjunction in *Ste* males.

**cytology:** Placed primarily in the Hoechst-dull region h11 of the Y chromosome, between the Y breakpoints of *T(1;Y)P7 = T(1;Y)h33;h11* and *T(1;Y)E15 = T(1;Y)h26-29;h12-13*.

**molecular biology:** Comprises approximately 80 copies of a sequence that is partly homologous to the *Ste* sequences on the X chromosome; actually the number of repeats varies over a three-fold range in Y's from natural populations (Lyckegaard and Clark, 1989, *Proc. Nat. Acad. Sci. USA* 86: 1944-48). The repeat length, however, is 2.6-2.8 kb compared to 1.15-1.25 for *Ste*. The majority of these sequences lie proximal to the breakpoint of *T(1;Y)P7 = T(1;Y)h33;h11*; and distal to that of *T(1;Y)E15 = T(1;Y)h26;h11*; all *Su(Ste)* sequences lie distal to the breakpoint of *T(1;Y)E15 = T(1;Y)h26-29;h12-13*. Dele-

tions for most or all of these sequences results in abundant spliced *Ste* RNA in the testes, compared the less abundant and largely unspliced transcripts detectable in XY males. Results from partial deletions more nearly resemble those from XY than from XO testes. Sequences of two *Su(Ste)* repeats show segments homologous to *Ste* and totally unrelated segments; the homologous regions show a number of single nucleotide substitutions, including one that alters a splice-acceptor site; the sequence also contains an insert of a variable number of AAC repeats.

**Su(stn): Suppressor of stoned**

**location:** 1-22 (between *sn* and *oc*).

**references:** Kelly, Hannan, and Petrovich, 1987, *J. Neurogenet.* 4: 144-45.

**phenotype:** Suppresses both the behavioral and the viability effects of *stn*.

**su(t): suppressor of tan**

**location:** 3-26.

**origin:** Spontaneous.

**discoverer:** Bridges, 22k2.

**phenotype:** Converts *t* to wild type. RK3.

**su(tu-bw): suppressor of tumor with brown**

**location:** 3- (not located but probably in 3L).

**origin:** Naturally occurring allele.

**discoverer:** Glass, 1941.

**references:** Glass and Plaine, 1952, *Proc. Nat. Acad. Sci. USA* 38: 697-705.

Glass, 1954, DIS 28: 74.

Burnet and Sang, 1964, *Genetics* 49: 223-35, 599-610.

**phenotype:** Reduces incidence of melanotic masses in *tu-bw* homozygote from 85-100% in *su(tu-bw)/+* to 5-10% in *su(tu-bw)* homozygote. Suboptimal ratios of pentose nucleotides, cholesterol deficiency, or excess L-tryptophan in the larval diet, as well as X irradiation of embryos, increase incidence of melanotic masses in *tu-bw*; *su(tu-bw)* homozygote. Glass and colleagues attribute this to an effect on *su(tu-bw)*, whereas Burnet and Sang believe the reaction controlled by *tu-bw* is affected. Does not suppress *tu-48* (Burnett, 1966, DIS 41: 161). RK3.

**Su(var): Suppressor of variegation**

A series of dominant suppressors of variegation, mostly selected on the basis of their ability to suppress the mottling of *In(1)w<sup>md</sup>*; where they have been tested, these mutations suppress variegated type position effects involving other loci as well. Two groups have performed extensive mutagenesis experiments, but there has apparently been no exchange of material nor any attempt to determine allelic relationships between the two samples of mutants. The Canadian group has designated its mutants as a *Su(var)200* series for second-chromosome mutations and a *Su(var)300* series for third-chromosome mutations. The German group uses *Su-var(3)1*, *etc.* to designate a series of suppressors on the third chromosome; we reconcile these terminologies but keep them separate by altering the second nomenclature to *Su(var)3-1*, *etc.* Despite the fact that some mutants from the two groups map to virtually identical positions, we choose to list them separately until appropriate complementation tests are performed. Most of these suppressors appear to be loss of function mutations and are frequently associated

with deficiencies; in addition variegation suppression is often produced by heterozygous deficiencies for their loci. Of these, several have been shown to enhance variegation when duplicated (Tartof, Bishop, Jones, Hobbs, and Locke, 1989, *Dev. Genet. (Amsterdam)* 10: 162-76).

Genet.* 191: 326-33; 10 = Spofford, 1967, *Genetics* 57: 751-56; 11 = Spofford, 1969, *Genetics* 62: 555-71; 12 = Szidonya and Reuter, 1988, *Genet. Res.* 51: 197-208; 13 = Tartof, Bishop, Jones, Hobbs, and Locke, 1989, *Dev. Genet.* 10: 162-76; 14 = Wustmann, Szidonya, Taubert, and Reuter, 1989, *Mol. Gen. Genet.* 217: 520-27.

<sup>β</sup> Phenotypes listed refer to homozygotes.  
<sup>γ</sup> Synonym: *Su(var)5401*.

**other information:** In addition to the tabulated mutations, deficiencies for 31C-32A, 38C6-D1, 47E3-48A6, 86C-D, and 99B-D and duplications for 26B, 33C-34A, 57D-58A, and 99C-D shown to suppress variegation of *In(1)w<sup>m4</sup>* (Wustmann, Szidonya, Taubert, and Reuter, 1989, *Mol. Gen. Genet.* 217: 520-27).

**phenotype:** Reduces variegated mutant effect (sometimes completely) of *w*, *rst*, *fa*, *spl*, *nd*, and *dm* in *Dp(1;3)N<sup>264-58</sup>*. Also reduces *w* variegation of *In(1)w<sup>m4</sup>*, *rst* variegation of *In(1)rst<sup>3</sup>*, and *sc* variegation of *In(1)sc<sup>8</sup>*. Enhances *sc* variegation of *In(1)sc<sup>4</sup>* and *y* variegation of *In(1)y<sup>3P</sup>*. Semidominant; heterozygote less suppressed than homozygote. Shows maternal effect; *Su(var)/+* offspring of *Su(var)/Su(var)* more nearly normal than *Su(var)/+* offspring of *Su(var)/+* mothers. Homozygote fertility slightly reduced. Viability excellent. RK2.

### *Su(var)2-1*

**phenotype:** *Su(var)2-1/+* but not *Su(var)2-1/+* display nearly normal amounts of eye pigment in *In(1)w<sup>m4</sup>* flies. Homozygous viable; females sterile; do not produce eggs. Survival reduced by the presence of the Y chromosome or by administration of sodium n-butyrate, an inhibitor of histone deacetylation (Reuter, Dorn, and Hoffmann, 1982, *Mol. Gen. Genet.* 188: 480-85). Exhibits significant hyperacetylation of histone H4 and increased accessibility of chromatin to endogenous nuclease, suggesting a defect in chromosome condensation (Dorn, Heymann, Lindigkeit, and Reuter, 1986, *Chromosoma* 93: 398-403).

**alleles:** Five alleles defining two complementation groups.

allele	origin	comments
<i>Su(var)2-1<sup>1</sup></i>	spont	noncomplementing
<i>Su(var)2-1<sup>2</sup></i>	EMS	complements <i>Su(var)2-1<sup>3</sup></i>
<i>Su(var)2-1<sup>3</sup></i>	X ray	complements <i>Su(var)2-1<sup>2</sup></i> and <i>Su(var)2-1<sup>4</sup></i>
<i>Su(var)2-1<sup>4</sup></i>	EMS	complements <i>Su(var)2-1<sup>3</sup></i>
<i>Su(var)2-1<sup>5</sup></i>	X ray	noncomplementing

### *Su(var)205*

**origin:** Induced by ethyl methanesulfonate.

**synonym:** *E(var)29A*.

**phenotype:** Encodes a nonhistone chromosomal protein, HP1, which by immunofluorescent staining of polytene chromosomes with a monoclonal antibody, is localized to  $\alpha$ ,  $\beta$ , and intercalary heterochromatin as well as chromosome 4 (James and Elgin, 1986, *Mol. Cell. Biol.* 6: 3862-72).

**cytology:** Placed in 29A by *in situ* hybridization.

**molecular biology:** Sequence isolated from an expression library; hybridizes to a broad band in polytene subdivision 29A. In Northern blots the sequence recognizes an abundant 1.2 kb RNA; furthermore an aberrant transcript is seen in *Su(var)205*-bearing flies; attributable to missplicing caused by G  $\rightarrow$  A transition at the first nucleotide

of the last intron (Eissenberg, James, Foster-Hartnett, Hartnett, Ngan, and Elgin, 1990, Proc. Nat. Acad. Sci. USA, 87: 9923-27). *Su(var)2-5*<sup>4</sup>, an allele of *Su(var)205*, shown to contain a nonsense mutation in the gene encoding HP1 (Eissenberg, Hartnett, and Reuter). The conceptual amino acid sequence specifies a 18,101 dalton hydrophilic polypeptide; basic-to-acidic amino acid ratio of 1.2; has a run of six glutamic acid residues in a row in a putative  $\alpha$ -helical stretch. No apparent similarity to published amino acid sequences (James and Elgin).

**other information:** Duplications for the locus cause enhancement of variegation (Tartof, Bishop, Jones, Hobbs, and Locke, 1989, Dev. Genet. (Amsterdam) 10: 162-76).

### ***Su(var)210***

**origin:** Induced by ethyl methanesulfonate.

**alleles:** Three alleles by complementation testing of lethal mutations: *Su(var)210*<sup>1</sup>, *Su(var)210*<sup>2</sup>, and *Su(var)210*<sup>3</sup> recovered as *Su(var)210*, *Su(var)214*, and *Su(var)216*, respectively.

### ***Su(var)3-1***

**alleles:** Six ethyl methanesulfonate-induced alleles, *Su(var)2-1*<sup>1</sup> to *Su(var)2-1*<sup>6</sup>.

### ***Su(var)3-2***

**alleles:** Three alleles: *Su(var)3-2*<sup>1</sup> and *Su(var)3-2*<sup>2</sup> induced by ethyl methanesulfonate; *Su(var)3-2*<sup>3</sup> by X rays.

### ***Su(var)3-3***

**location:** 3-46.6 (on 3L based on its absence from induced *C(3R)RM* derivatives of *Su(var)3-3*-bearing chromosomes).

**phenotype:** Homozygotes strongly semilethal in males; weakly so in females; homozygous females sterile; produce no eggs. Homozygous males have spread-wing phenotype and reduced fertility. Survival sensitive to the presence of the Y chromosome as well as to the presence of 0.1 M butyrate in the medium.

**alleles:** Twenty-five alleles: *Su(var)3-3*<sup>13</sup>, *Su(var)3-3*<sup>18</sup>, and *Su(var)3-3*<sup>19</sup> induced by X rays; the remainder by ethyl methanesulfonate.

### ***Su(var)3-4***

**alleles:** Six alleles: *Su(var)3-4*<sup>1</sup>, and *Su(var)3-4*<sup>6</sup> induced by X rays; the remainder by ethyl methanesulfonate.

### ***Su(var)3-5***

**origin:** X ray induced.

**phenotype:** Homozygotes strongly semilethal in males; weakly so in females; homozygous females sterile; produce no eggs. Homozygous males have reduced fertility. Survival sensitive to the presence of the Y chromosome as well as to the presence of 0.1 M butyrate in the medium.

### ***Su(var)3-6***

**alleles:** Three alleles: *Su(var)3-6*<sup>1</sup> ethyl methanesulfonate induced with normal cytology, *Su(var)3-6*<sup>2</sup> X ray induced, associated with *T(Y;3)15 = T(Y;3)87B5-7*, and *Su(var)3-6*<sup>3</sup> X ray induced, associated with *Df(3R)Su-var6 = Df(3R)87B1-2;87D9-11*. *Su(var)3-6*<sup>1</sup> shows some reduction in viability in trans heterozygotes with some alleles of *l(3)87Bg*; in one case a clear maternal

effect is noted.

**cytology:** Placed in 87B5-10 based on its inclusion in *Df(3R)E079 = Df(3R)86F1-2;87B8-10* but not *Df(3R)TE45 = Df(3R)86F1-2;87B5-6*.

### ***Su(var)3-7***

**origin:** X ray induced.

**cytology:** Identified by virtue of the variegation suppression of *T(Y;3)409 = T(Y;3)87E2-5*. Located between *Ace* and *l(3)87Ee* as indicated by its survival in combination with *Df(3R)ry1607 = Df(3R)87D4-6;87E1-2* but not *Df(3R)N42 = Df(3R)?;87E3-4* or *Df(3R)N78 = Df(3R)?;87E3-4*, the latter two deficiencies themselves suppressing variegation. Corresponds to the dominant suppressor function identified by Henikoff (1979, Genetics 93: 105-15) by deficiency analysis. Duplication for the locus causes enhancement of variegation (Wustmann, Szidonya, Taubert, and Reuter, 1989, Mol. Gen. Genet. 217: 520-27).

**alleles:** Complements all lethals in the region except *Ace*<sup>41</sup>; *Ace*<sup>41</sup> has a weak dominant variegation-suppression effect.

**molecular biology:** Genomic clone identified by transformation (Reuter, Giarre, Farah, Gausz, Spierer, and Spierer, 1990, Nature 344: 219-23). The sequence located in region 59-63 on chromosomal walk of Bender, Spierer, and Hogness (1983, J. Mol. Biol. 186: 17-33). cDNA clones isolated with transforming genomic clone sequenced; conceptual polypeptide has 932 amino acids with five widely separated zinc fingers, from 40-107 residues apart in the N-terminal half of the protein. The regions between and around the fingers are rich in acidic residues.

### ***Su(var)3-8***

**phenotype:** Homozygous lethal. One allele temperature sensitive; dies at 25° but not at 18°; homozygous flies raised at 18°, nevertheless, exhibit some suppression of position-effect variegation. Homozygous females sterile; lay eggs that fail to hatch.

**alleles:** Two ethyl methanesulfonate-induced alleles: *Su(var)3-8*<sup>2</sup> temperature sensitive.

### ***Su(var)3-9***

**alleles:** Thirteen alleles: *Su(var)3-9*<sup>7</sup> induced by X rays; the remainder by ethyl methanesulfonate.

**other information:** Duplications for the locus cause enhancement of variegation (Tartof, Bishop, Jones, Hobbs, and Locke, 1989, Dev. Genet. (Amsterdam) 10: 162-76).

### ***Su(var)3-11***

**origin:** X ray induced.

**cytology:** Identified by virtue of its association with *Df(3R)M95A = Df(3R)94D-95A3*. *M(3)95A*<sup>2</sup> does not suppress variegation, however.

### ***Su(var)3-12***

**origin:** X ray induced.

**cytology:** Identified by virtue of its association with *Df(3R)MSu2*, which is deficient in the region 100F3-5.

### ***Su(var)3-13***

**origin:** Induced by ethyl methanesulfonate.

**phenotype:** Heterozygote shows weak suppression of variegation; homozygote lethal.

**alleles:** Fails to complement alleles of *l(3)86Fc*; however, *l(3)86Fc*<sup>4</sup> and *l(3)86Fc*<sup>5</sup> fail to suppress variegation.

**cytology:** Placed in 86F4-7 based on its location between *Df(3R)TE7 = Df(3R)86F1-2;86F4-5* and *Df(3R)E229 = Df(3R)86F6-7;87B1-2*.

### **Su(var)3-14**

**cytology:** Gene inferred from the suppression of variegation seen in *Df(3R)cu = Df(3R)86C1-2;86D8* heterozygotes; no suppression observed in *Df(3R)M86D = Df(3R)86D1-2;86D4* heterozygotes.

### **su(ve): suppressor of veinlet**

**location:** 3 -0.1 (0.1 unit to the left of *ru*).

**origin:** Spontaneous.

**discoverer:** Curry, 37a.

**phenotype:** At 19°, suppression of *ve* is complete except tip of L2 occasionally missing. At 25°, suppression only partial with some overlap into range of unsuppressed *ve*. At 19°, *su(ve)/+* partially suppresses *ve*. RK2.

**cytology:** Not included in *Df(3L)D = Df(3L)61E2-F1;61A4-6* from *T(Y;2;3)D*; therefore, probably located in 61A-E.

### **su(vg): suppressor of vestigial**

**location:** 3-98.

**origin:** Spontaneous.

**references:** David, Javellot, and Tazet, 1970, DIS 45: 33.

**phenotype:** Temperature-sensitive recessive suppressor of *vg*. Suppression partial at 25°; wings and halteres intermediate in size between *vg* and +. Wings, halteres, and positions of scutellar bristles nearly normal in flies reared at 28° and above. Flies reared below 20° resemble *vg* alone. Slight effect of *su(vg)/f* on *vg* expression at 28°. *vg; su(vg)* lethal above 30° and below 13°; 30% mortality at 25°.

### **su(w<sup>a</sup>): suppressor of apricot**

**location:** 1-0.1.

**references:** Levis, O'Hare, and Rubin, 1984, Cell 38: 471-81.

Zachar, Davison, Garza, and Bingham, 1985, Genetics 111: 495-515.

Zachar, Garza, Chou, Goland, and Bingham, 1987, Mol. Cell. Biol. 7: 2498-2505.

Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97.

**phenotype:** Produces a darker, brownish eye color in *w<sup>a</sup>* flies. Suppresses *w<sup>a</sup>*, *w<sup>am</sup>*, *w<sup>a59k1</sup>*, and *w<sup>a59k9</sup>* but not *w<sup>a2</sup>*, *w<sup>a3</sup>*, *w<sup>a4</sup>*, *w<sup>aR84h</sup>*, *w<sup>sl0</sup>* or any other *w* allele tested by Green (1959, Heredity 13: 303-15). Enhances *w<sup>a60a5</sup>* and *w<sup>M</sup>*. Seems to act on *w<sup>a</sup>* by promoting transcription through the *copia* element that is inserted into the second intron in the same orientation as that of *w*; the level of a read-through transcript is elevated in *su(w<sup>a</sup>) w<sup>a</sup>* compared to *w<sup>a</sup>*. *su(w<sup>a</sup>)* is without effect on the phenotype of *w<sup>hd81b11</sup>*, which has *copia* inserted at another position and in the opposite direction (Zachar *et al.*, 1985). *su(w<sup>a</sup>)* also enhances the expression of a subset of alleles with *gypsy* inserts that are also enhanced by *su(s)* and suppressed by *su(f)* and *e(w<sup>e</sup>)*; it also enhances *lz<sup>34</sup>* and *lz<sup>k</sup>* (Rutledge *et al.*).

**alleles:** No *bona fide* amorphic alleles reported; however, *Df(1)sta*, which is deficient for *su(w<sup>a</sup>)* survives (Rayle

and Hoar, 1969, DIS 44: 94).

<sup>α</sup> 1 = Green, 1954, DIS 28: 74; 2 = Mount, Green, Rubin, 1988, Genetics 118: 221-34; 3 = Rayle, 1972, Genetics 71: s50; 4 = Rutledge, Mortin, Schwarz, Thierry-Mieg, and Meselson, 1988, Genetics 119: 391-97; 5 = Zachar, Garza, Chou, Goland, and Bingham, 1987, Mol. Cell. Biol. 7: 2498-2505.

**cytology:** Placed in 1E1-2 by Rayle (1972, Genetics 71: s50); transposed to chromosome 3 by *Tp(1;3)sta = Tp(1;3)1D3-1E1;2A;89B21-C4*.

**molecular biology:** Gene isolated by transposon tagging. Identity of the *su(w<sup>a</sup>)* transcription unit confirmed by transformation with a 6.2 kb fragment. Three overlapping mature transcripts of 3.5, 4.6, and 5.2 kb produced from the 6.2 kb region, the two larger ones drastically reduced in *su(w<sup>a</sup>)* animals. The transcripts produced at approximately the same level at all developmental stages, in all body parts, and in cultured *Drosophila* cells (Zachar *et al.*, 1987).

### **Su(w<sup>a</sup>)B1**

**location:** 1- (to the right of *w*).

**origin:** Recovered from hybrid-dysgenic cross.

**references:** Birchler, 1984, Genetics 107: s12.

**phenotype:** Heterozygotes, homozygotes, and hemizygotes display increased levels of pigment in *w<sup>a</sup>* eyes.

### **Su(w<sup>a</sup>)B2**

**location:** 2- (Just proximal to *c*).

**origin:** Recovered from hybrid dysgenic cross.

**references:** Birchler, 1984, Genetics 107: s12.

**phenotype:** Homozygous lethal. In heterozygotes causes an approximately two-fold increase in pigmentation of *w* alleles with lesions in the coding region. Without effect on four alleles that are not dosage compensated or on *w<sup>sp</sup>* alleles, whose lesions are 5' to the *w* transcription unit. Duplications for the locus reduce pigmentation of *w* alleles.

### **Su(w<sup>ch</sup>): Suppressor of cherry**

**location:** 2-4.0.

**discoverer:** Lewis.

**references:** Rasmusen, 1970, Hereditas 65: 83-96.

Rasmusen and Ljung, 1973, Hereditas 73: 71-84.

**phenotype:** Homozygous lethal; in heterozygotes leads to increased levels of eye pigmentation in *w<sup>ch</sup>*, *w<sup>e</sup>*, and *w<sup>a</sup>*; heterozygotes exhibit increased courtship activity leading

to mating advantage over wild type (Connally, Burnet, and Sewell, 1969, *Evolution* 23: 548-59).

***su(w<sup>h</sup>)*: suppressor of white honey**

**location:** 3- (not mapped).

**references:** Lee, 1972, *DIS* 48: 18-19.

**phenotype:** In homozygous *su(w<sup>h</sup>)* flies pigmentation of *w<sup>h</sup>* increased to a bright cherry color; *w<sup>a</sup>* and *w<sup>a4</sup>* show slight suppression. Without effect on *w*, *w<sup>a</sup>*, *w<sup>aM</sup>*, *w<sup>bl</sup>*, *w<sup>c</sup>*, *w<sup>cf</sup>*, *w<sup>col</sup>*, *w<sup>e</sup>*, *w<sup>i</sup>*, *w<sup>sat</sup>*, and *w<sup>t</sup>*.

***su(w<sup>sp</sup>)*: suppressor of white-spotted**

**location:** 1-0.16 (based on 19 *y-w* recombinants).

**discoverer:** Gelbart.

**references:** Chapman and Bingham, 1985, *DIS* 61: 48-49.

Davison, Chapman, Wedeen, and Bingham, 1985, *Genetics* 110: 479-94.

**phenotype:** Results in nearly wild-type pigmentation of *w<sup>sp1</sup>*, *w<sup>sp2</sup>*, *w<sup>sp3</sup>*, and *w<sup>sp4</sup>*, but not *w<sup>sp81d5</sup>*. No phenotypic effect seen on eight other tested *w* alleles. The lesions of the spotted alleles map 500 to 1000 base pairs 5' to the *w* transcription unit and are postulated to affect an enhancer sequence. The normal allele of *su(w<sup>sp</sup>)* is postulated to encode a repressor of this enhancing function; the combination of the repressor and defective enhancer produces the spotted phenotype; the mutant allele of *su(w<sup>sp</sup>)*, lacking repressor function, results in the derepression of the defective enhancers at the time of eye-pigment deposition, leading to increased pigmentation. *w<sup>sp81d5</sup>*, a molecular deletion extending more 3' than the other *w<sup>sp</sup>* alleles is postulated to be insensitive to the presence or absence of repression owing to loss of the site of interaction between the *su(w<sup>sp</sup>)* gene product and the *w* locus. Adult transcription of all *w* alleles, including *w<sup>+</sup>*, markedly increased by *su(w<sup>sp</sup>)*, apparently after pigment deposition, since with the exception of *w<sup>sp</sup>* alleles, eye color does not respond to *su(w<sup>sp</sup>)*. The latter observation implies a second site of repressor binding specific to adult transcription.

*Su-x4*: see *Su(sph)*

**\**Su(y<sup>3P</sup>)*: Suppressor of yellow-3 of Patterson**

**location:** 3-90.

**origin:** X ray induced.

**discoverer:** Parker, 48h.

**synonym:** *su-y<sup>31e</sup>*.

**references:** 1950, *DIS* 24: 62.

**phenotype:** *Su(y<sup>3P</sup>)/+* suppresses *y<sup>3P</sup>* to about normal color, except that wings remain yellowish. *y<sup>3P</sup>*; *Su(y<sup>3P</sup>)/Su(y<sup>3P</sup>)* is darker than wild type but wings remain yellow. May be suppression of variegation since extra Y chromosomes also suppress *y<sup>3P</sup>*. No effect on *y*, *y<sup>2</sup>*, *y<sup>2S</sup>*, *y<sup>3d</sup>*, *y<sup>4</sup>*, *y<sup>35a</sup>*, or *y<sup>id</sup>*. Homozygote has low viability and fertility; occasionally, wings held out from body. RK2.

***Su(z)2*: Suppressor 2 of zeste**

**location:** 2-67 (distal to *vg*; also distal to *Psc*).

**references:** Kalisch and Rasmuson, 1974, *Hereditas* 78: 97-104.

Persson, 1976, *Hereditas* 82: 111-20.

Wu, Jones, Lasko, and Gelbart, 1989, *Mol. Gen. Genet.* 218: 559-64.

Adler, Charlton, and Brunk, 1989, *Dev. Genet.* (Amsterdam) 10: 249-60.

**phenotype:** Dominant suppressor of the yellow eye color associated with the *z<sup>1</sup>* mutation. Can be detected in homozygous *z<sup>1</sup>* females and in males. Lethal in homozygous or hemizygous condition and in *trans*-allelic heterozygotes. Viability reduced in *trans* heterozygotes in some *Psc/Su(z)2* combinations, lethal in others. *Psc* and *Su(z)2* are both members of the *Su(z)2* complex.

**alleles:**

allele	origin	discoverer	synonym	ref <sup>α</sup>	comments

<sup>α</sup> 1 = Adler, Charlton, and Brunk, 1989, *Dev. Genet.* 10: 249-60; 2 = Gelbart, 1971, Doctoral dissertation, University of Wisconsin, Madison; 3 = Kalisch and Rasmuson, 1974, *Hereditas* 78: 97-104; 4 = Persson, 1976, *Hereditas* 82: 111-20; 5 = Wu, 1984, Doctoral dissertation, Harvard University, Cambridge; 6 = Wu, Jones, Lasko, and Gelbart, 1989, *Mol. Gen. Genet.* 218: 559-64.

**cytology:** Placed in 49E-F on the basis of its inclusion in *Df(2R)vg-B = Df(2R)49D3-4:49F15-50A2* and its exclusion from *Df(2R)vg-C = Df(2R)49B2-3:49E7-F1* and *Df(2R)vg-D = Df(2R)49C1-2:49E4-5* (Wu).

**molecular biology:** Reported to be distal to and transcribed from left to right, divergently from *Psc* (Adler *et al.*).

*Su(z)301*: see *E(z)*

*Su(z)302*: see *Scm*

**sub: subito (T. Schüpbach)**

**location:** 2-86.

**origin:** Induced by ethyl methanesulfonate.

**references:** Schüpbach and Wieschaus, 1989, *Genetics* 121: 101-17.

**phenotype:** Maternal-effect lethal or female sterile; homozygous females lay eggs which show no visible signs of development when observed under transmitted light in a stereo microscope. These eggs are defective in fertilization or very early embryonic development.

**alleles:** Two alleles, *sub<sup>1</sup>* and *sub<sup>2</sup>*, isolated as *PF* and *HM*.

**cytology:** Placed in 55A-F, since uncovered by *Df(2R)PC4 = Df(2R)55A:55F*.

**other information:** *sub<sup>2</sup>* females form rare syncytial-blastoderm embryos.

**Succinic dehydrogenase: see Sdh**

**Sucr: Sucrase**

**location:** 2- {37}.

**references:** Oliver and Williamson, 1979, *Biochem. Genet.* 17: 987-907.

**phenotype:** Thought to be the structural gene for sucrase [EC 3.2.1.26], a 100 kilodalton protein.

**alleles:** Thought to exist in two forms by isoelectric focusing.

**cytology:** Placed in 31C-F by changes in enzyme levels

associated with segmental aneuploids.

*sunburst*: see *p<sup>snb</sup>*

**\*sup: superwith**

**location**: 3- (not located).

**discoverer**: Morgan, 10k.

**references**: Bridges and Morgan, 1923, Carnegie Inst. Washington Publ. No. 327: 35.

**phenotype**: Trident pattern on thorax dark. RK3.

**supact: suppressor activated**

**location**: 1-0.0 (near *mul*; separable from *sc*).

**origin**: Spontaneous.

**references**: Lee, 1970, Austr. J. Biol. Sci. 23: 645-55.

**phenotype**: Recessive; bristle and eye abnormalities produced by over 95% of females that are homozygous for *su(Hw)*<sup>2</sup>. Abnormalities include irregular pattern of missing bristles (scutellars, dorsocentrals, vertical, post-verticals, and ocellars) and small granulated eyes. Restricted to females; not influenced by gene dosage or the presence of the Y chromosome, since neither XY nor X0 males homozygous for *su(Hw)*<sup>2</sup> are affected, nor are males with two doses of the *supact* region at the tip of the X. No effect of *supact* on flies raised at 30°; females but not males raised at 18° show enhanced eye effect, but no bristle effect.

**super sex combs**: see *sxc*

**Superabdominal**: see *Sab* under *BXC*

**Super-Bar**: see *B<sup>S3i</sup>*

**superwith**: see *sup*

**suppressor**: see *su()*

**Suppressor**: see *Su()*

**suppressor activated**: see *supact*

**Surf wings**: see *Srf*

**\*sv: shaven**

**location**: 4-3.0 [diplo-4 triploids (Sturtevant, 1951, Proc. Nat. Acad. Sci. USA 37: 405-7)].

**origin**: Spontaneous.

**discoverer**: Bridges, 20k14.

**references**: Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 235 (fig.).

Bridges, 1935, Biol. Zh. 4: 401-20.

**phenotype**: Bristles reduced, somewhat variably. Trichogen irregularly displaced and usually partly converted to socket (Lees and Waddington, 1942, DIS 16: 70). *sv/sv/sv* triplo-4 nearly normal. *sv* haplo-4 extreme shaven (Schultz, 1935, Am. Naturalist 69: 30-54). Expression depends on temperature: excellent at 19°, overlaps wild type at 25°, and entirely wild type at 30°. RK2.

**cytology**: Placed in region between 102E2 and 102F10 on the basis of its inclusion in *Df(4)11 = Df(4)102E2-10;102F2-10*.

*sv*<sup>2</sup>: see *sv<sup>n</sup>*

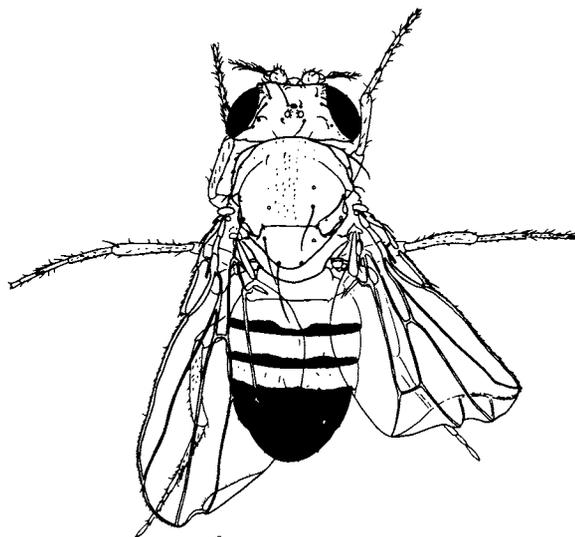

**sv<sup>35a</sup>**

**discoverer**: Ives, 35a18.

**references**: 1935, DIS 4: 11.

**phenotype**: Resembles *sv<sup>n</sup>* more than *sv*. Bristles fre-

quently reduced to stumps. RK2.

**sv<sup>de</sup>: shaven-depilate**

Edith M. Wallace, unpublished.

**sv<sup>de</sup>: shaven-depilate**

**origin**: Spontaneous.

**discoverer**: E.M. Wallace, 37a24.

**phenotype**: More extreme than *sv<sup>n</sup>*. Thorax denuded over large areas. Phenotype more severe than *H*<sup>2</sup>; bristleless sockets found on adult integumentary derivatives of all imaginal discs; nearly 100% penetrance on thorax. Shafts, where present, often bent, twisted, or forked; up to 97% of bristle organs on wing costa and distal leg segments fail to produce normal shafts. Bracts present when bristle normally formed; otherwise bracts missing (Tobler, Rothenbuhler, and Nöthiger, 1973, Experientia 29: 370-71). Both sexes sterile. RK2.

**sv<sup>n</sup>: shaven-naked**

**discoverer**: Mohr, 31j13.

**synonym**: *sv*<sup>2</sup>.

**references**: 1933, Hereditas 17: 317-22 (fig.).

**phenotype**: Extremely short bristles. Viability excellent. Trichogen irregularly displaced, becoming more or less converted into tormogen [Lees and Waddington, 1943, Proc. Roy. Soc. (London), Ser. B, 131: 87-110 (fig.)]. Polarity of microchaetae in vicinity of double sockets disrupted such that they form a whorl around socket [Toney and Thompson, 1980, Experientia 36: 644-45 (fig.)]. In triplo-4 *sv<sup>n</sup>/sv<sup>n</sup>/sv<sup>n</sup>*, the phenotype is more nearly normal than in diplo-4. RK1.

**other information**: Selective advantage for triplo-4 in stocks of *sv<sup>n</sup>* results in accumulation.

**svb: shaven baby**

**location**: 1-9.8.

**references**: Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

Gergen and Wieschaus, 1985, Dev. Biol. 109: 321-35 (fig.).

**phenotype**: Homozygous lethal. Many fewer denticles than wild type; remaining denticles small and with

characteristic morphology. Denticles arranged in belts in the abdominal segments; absent from thoracic segments. Cell autonomous in mosaics; useful in studying embryonic mosaics.

**alleles:**

<sup>α</sup> 1 = Eberl and Hilliker, 1988, Genetics 118: 109-20; 2 = Perrimon, Engstrom, and Mahowald, 1989, Genetics 121: 333-52; 3 = Wieschaus, Nüsslein-Volhard, and Jürgens, 1984, Wilhelm Roux's Arch. Dev. Biol. 193: 296-307.

**cytology:** Placed in 4E1-2 along with *ovo* based on the simultaneous loss of both functions in many *ovo*<sup>D</sup> reversions. Included in *Df(1)bi-DL5 = Df(1)3C7-12;4E1-2* and *Df(1)bi-D2 = Df(1)4B6-C1;4D7-E1*, both of which retain *ovo*<sup>+</sup> (Oliver, Perrimon, and Mahowald, Genes Dev. 1: 913-23).

**svp: seven up (Y. Hiromi)**

**location:** 3- {52}.

**references:** Gausz, Gyurkovics, Bencze, Awad, Holden, and Ish-Horowitz, 1981, Genetics 98: 775-89.

Mlodzik, Hiromi, Weber, Goodman, and Rubin, 1990, Cell 60: 211-24.

**phenotype:** Originally identified as recessive lethal mutations; independently identified by an enhancer-trap screen to be a gene expressed in a subset of neuroblasts in the embryonic CNS and also in a subset of photoreceptor-cell precursors in the developing compound eye. Mutant alleles die as embryos with normal cuticular morphology, but have alterations in numbers of *eve*-positive neurons in some neuroblast lineages. *svp*<sup>-</sup> clones in the eye produce abnormal ommatidia where photoreceptors R1, R3, R4, and R6 are transformed toward another photoreceptor R7. In addition, *svp*<sup>-</sup> ommatidia usually contain one to two extra photoreceptor cells. Mosaic studies show that transformation towards R7 is due to cell autonomous requirement in R1, R3, R4, and R6, whereas production of extra cell(s) is a secondary phenotype caused by lack of *svp*<sup>+</sup> function in other cells, most likely in R3 and R4. Formation of some, but not all, R7-like cells in *svp*<sup>-</sup> ommatidia is dependent on *sev*<sup>+</sup> function.

**alleles:** Of eight ethyl methanesulfonate-induced alleles listed by Gausz *et al.*, only two are now existent (*svp*<sup>1</sup> and *svp*<sup>2</sup>); *svp*<sup>3</sup> has an enhancer trap *P*-element insertion at the *svp* locus and expresses β-galactosidase in a pattern resembling the *svp* transcription pattern.

allele	synonym	comments
<b>svp<sup>1</sup></b>	<i>l(3)ck16<sup>e22</sup></i>	embryonic lethal
<b>svp<sup>2</sup></b>	<i>l(3)ck16<sup>e300</sup></i>	embryonic lethal
<b>svp<sup>3</sup></b>	<i>svp<sup>H162</sup></i>	embryonic lethal

**cytology:** Placed in 87B4-6 based on its inclusion in the region of overlap of *Df(3R)T45 = Df(3R)86E;87B5-6* and *Df(3R)kar-H10 = Df(3R)87B4;87D7-8*.

**molecular biology:** Walking from the enhancer trap *P*-element insert, a transcription unit was identified whose expression pattern is indistinguishable from the β-galactosidase expression pattern of the *P*-insertion allele. The conceptual amino-acid sequence from a *svp* cDNA

clone shows that *svp* is a member of the steroid receptor gene superfamily, and is likely to be the *Drosophila* homologue of the human transcription factor COUP.

**svr: silver**

**location:** 1-0.0.

**discoverer:** Bridges, 23g23.

**synonym:** *slv*.

**references:** Morgan, Bridges, and Sturtevant, 1925, Bibliog. Genet. 2: 235.

Morgan, 1940, DIS 13: 51.

**phenotype:** Color of legs, wings, veins, and integument pale and silvery. Bristles and trident pattern on thorax dark. Tyrosinase formed in adult (Horowitz). Wings of all males and some females pointed. Viability fair. Larval mouth parts normal in color. RK2.

**alleles:**

**cytology:** Locus placed at 1B5-6 (Demerec, Kaufmann, Fano, Sutton, and Sansome, 1942, Year Book - Carnegie

Inst. Washington 41: 191).

**other information:** Pointed alleles studied by Goldschmidt enhanced by *a<sup>ba</sup>*, *svr<sup>poi</sup>* and *svr<sup>poi-dish</sup>* reported to suppress *s* and *sp*.

**\*svs: shortened veins**

**location:** 1-24.6.

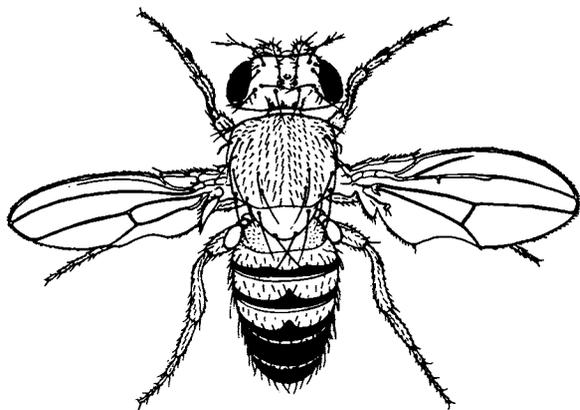

**origin:** Induced by ethyl methanesulfonate (CB. 1528).

**discoverer:** Fahmy, 1956.

**synonym:** *shv* (preoccupied).

**references:** 1959, DIS 33: 90.

**phenotype:** Wings highly abnormal, varying from small stubs to almost full size with inner margin cut away. Vein L4 often shortened and posterior crossvein absent. Eyes small and deformed. Male fertile; viability about 50% wild type. Female sterile. RK2.

**sw: short wing**

From Eker, 1935, J. Genet. 30: 357-68.

**sw: short wing**

**location:** 1-64.0 (to the left of *mel*).

**discoverer:** Eker, 32a12.

**references:** 1935, J. Genet. 30: 357-68 (fig.).

1939, J. Genet. 38: 201-27.

**phenotype:** Above 23°, most *sw<sup>1</sup>* flies have spread and incised wings with irregular veins; eyes reduced and roughened. Male expression more extreme than female. 15% of males eclose at 25°; show wing and eye abnormalities (Schalet, 1969, DIS 43: 128); above 31°, *sw* is lethal. At 17°, most flies are wild type; at 14°, all are wild type. *+Df(1)mal10* and *+sw* exhibit short-wing phenotype in presence of *Rp11215<sup>Ubl</sup>* (Mortin and Lefevre, 1981, Chromosoma 82: 237-47). RK2 at 28°.

**alleles:** Either this is a complex locus with *sw<sup>4</sup>* being the only noncomplementing allele or *sw<sup>4</sup>* is a double mutant and there are two loci. Numerous lethal alleles at this locus recovered from line containing a *P* element in 19C (Simmons, Raymond, Johnson, and Fahey, 1984, Genetics 106: 85-94).
