Preface

The International Conference on Energy and Environmental Protection provides a forum for accessing to the most up-to-date and authoritative knowledge from both industrial and academic worlds, sharing best practice in this exciting field. The first ICEEP was successfully taken place in Hohhot during the period 23-24 June, 2012 and the 2nd ICEEP was held in Guilin, from 19 to 21 April 2013. Following the success of the previous two conferences, the third ICEEP2014, held in Xi'an during April 26-28, 2014, was organized in four simultaneous tracks: "Applied Energy Technology", "Advances in Environmental Technologies", "Thermal, Power and Electrical Engineering" and "Resources and Sustainable Development".

The present volumes contain the selected papers from many submissions for this conference and provide up-to-date, comprehensive and worldwide state-of-the art knowledge in this field. All papers included in this collection had undergone the careful peer-review by the experts of international and domestic of China before it is selected for publications. Studies presented in this book cover these topics: Materials and Processing Technology, Engineering Thermophysics, Thermal Engineering, Fluid and Air Engineering and Machinery, HVAC, Air Conditioning and Refrigeration, Electrical Theory and New Technology, Smart Grid Technology, High Voltage and Insulation Technology, Power System, Control and Automation, Motor and Electrical Research, Power Electronics and Power Drives, Power Machinery and Engineering, Power Systems Management etc.

We would like to take this opportunity to thank many people. First and foremost we want to express my deep appreciation to invited keynote speakers, invited session chairs, invited session organizers and reviewers for their efforts and kind help in this congress. Final thanks go to all authors and participants at ICEEP2014 for helping to make it a productive and interactive meeting.

The Organizing Committee of ICEEP 2014

2014 3rd International Conference on

Energy and Environmental Protection

(ICEEP 2014)

Organized by:

Keywords: Fluorescence immunoassay, Estradiol, FITC-labeled anti-E_2 antibody

Abstract. A new fluorescence immunoassay with high sensitivity, time-saving, good precision and reliablility was proposed for the determination of estradiol (E_2) in human urine. The complex of FITC-labeled anti-E_2 antibody was produced and regarded as a probe in this system. Ninety-six microplate was coated with ovalbumin conjugated E_2 antigen as solid phase for the immunoassay. The method parameters affecting the determination, such as the concentration of immunoreagents, pH, and other relevant variable conditions upon the immunoassay were studied and optimized systematically. Under the optimal experimental conditions, it was found that the proposed method exhibited high performance with the detection limit of 9.2 pg/mL, and the linear range of determination of 0.01-1000 ng/mL. The recoveries were 93.58-105.82% with the relative standard deviations (RSD) 5.52-7.09%. The proposed method has been used for the determination of E_2 in human urine with satisfactory results, and may be expected to find wide application in other environmental samples.

Introduction

With the development of industry, the pollution of the global environment due to various human activities is continuously increasing and becoming more and more complex. More and more attention was paid to the adverse effects of environmental endocrine which threaten endocrine systems of a great variety of organisms including our humans. Estrogens have been often identified as the major contributors to the endocrine-disrupting activity observed in environmental samples[1]. Since 17β-estradiol has the greatest estrogenic activity and even a very low concentration of exogenous estradiol can disturb the balance of it in vivo. So it is very necessary to establish a sensitive method for the detection of estradiol in the environment.

There were many analytical methods for the determination of estradiol in environmental samples. In contrast, immunoassay method[2] is highly sensitive and cost effective, so it is easy to use exhibiting good potential in widespread application. In recent years, radioimmunoassay (RIA)[3], enzyme-linked immunosorbent assay (ELISA)[4], fluoroimmunoassay (FIA)[5], chemiluminescence enzyme immunoassay (CLIA)[6] and electrochemical immunoassay (ECIA)[7] have been reported. FIA has been widely applied in environmental analysis, and the major advantages of FIA, as compared with conventional RIA, are the use of nonradioactive reagents, and increased reagent stability, and the short counting time, and the wide dynamic range[8].

The aim of this study was to establish a robust, reliable, speedy and sensitive fluoroimmunoassay method for the routine quantification of estradiol in urine sample, and the method can also be used for clinical diagnosis. In this study, it is reported that a FIA for the determination of estradiol based on indirect competitive reaction using E_2-OVA as solid phase and FITC-labeled anti-E_2 antibody conjugation as a probe, the FITC-labeled anti-E_2 antibody was produced in my laboratory. The competition assay took place in a conventional 96-well microplate. Up to now, the FITC-labeled primary antibody as direct detection signal has not been reported at home and abroad. Compared with other immunoassays, the proposed method has some advantages of simple steps, short detection time, high accuracy and sensitivity, and saving reagent. The reaction parameters of the present FIA were

studied and optimized. Applicability of the method was evaluated through analyzing human urine sample.

Experimental

Apparatus

All fluorescence intensity determinations were performed on a model M200 microplate reader (Tecan Genios, Switzerland). 96-well black polystyrene microplates (Costar) were purchased from Beijing Dingguo Biotech Co.. UV-Vis Spectrophotometer (UV2550, Shimadzu) was used for characterization. The pH values were controlled with pHs-3C precision acidity meter purchased from Shanghai Leici Apparatus Factory (P.R. China).

Chemicals and Immunoreagents

All chemical reagents used were of analytical grade. Estradiol, N,N-dicyclohexylcarbodiimide (DCC), N-hydroxysuccinimide (NHS), bovine serum album (BSA), ovalbumin (OVA) and fluorescein isothiocyanate (FITC) were purchased from Sigma Chemicals Co. (St. Louis, MO, USA). Dimethylsulfoxide (DMSO) was purchased from Tianjin Fuchen Chemical Reagent Factory (P.R. China). Tween-20 was purchased from Beijing bayer di biological Co.. Polyclonal anti-E_2 antibody and artificial antigen were obtained from my laboratory.

Buffers

Highly purified distilled and deionized water was used throughout this work. The coating solution was 0.01 mol/L carbonate buffer solution, pH 9.6. The dilution buffer (PBS) was 0.02 mol/L phosphate buffer solution containing 150 mmol/L NaCl, pH 7.4. The washing solution (PBST) was PBS containing 0.05% (v/v) Tween-20. The blocking buffer was PBST containing 0.4% (w/v) OVA.

Preparation of FITC-labeled Antibody Conjugates

Lyophilized antibody was dissolved in carbonate buffer solution (pH 9.2), and made it into 2 mg/mL solution. FITC was dissolved in dry dimethylsulfoxide (DMSO), and made it into 1 mg/mL solution. The antibody solution and a certain amount of FITC solution were mixed. The mixture was reacted at 4°C for 2 h in the dark. After that a certain amount of 1 M NH_4Cl was added to the above solution to 50 mmol/L and then incubated at room temperature for 2 h. The resulted solution was dialyzed with PBS (pH 7.4) under 4°C for 3-4 days until the dialysis fluid had no fluorescence, and then stored at 4°C for future use.

Sample preparation

The two urine samples were collected from the same pregnant woman. One sample is morning urine, another sample is the urine after meal three hours. Because the urine was packed with many other proteins, these proteins may seriously interfere with the detection of E_2, so it should be necessary to remove the proteins.The treatment process was as follows: 1 mL urine was added a little distilled water, and then added 2.5 mL 2 M HCl. The mixture was heated at 100°C for 30 mins, after that, cooled it at the room temperature. The obtained urine hydrolysate was added to 2.5 mL of 1 M sodium carbonate solution. After eliminating carbon dioxide, added HCl or Na_2CO_3 to adjust the pH value to 7.4, and then diluted the solution to 20 mL with PBS. The volume dilution ratio of urine was 1 : 20.

Fluorescence Immunoassay Procedure

The direct competitive fluorescence immunoassay procedure was shown as follows. 96-well polystyrene microplate was coated with 100 μL E_2-OVA in coating buffer. The microplate was kept at 4°C overnight and then washed three times with PBST. Then 150 μL blocking buffer was added to each well and incubated with gentle shaking at 37°C for 1 h in order to saturate the attachment sites on the microplate. After that, the microplate was washed as the described above. Then 50 μL serial dilutions of the E_2 or sample solution and 50 μL FITC-labeled anti-E_2 antibodies were added to the coated wells and incubated at 37°C for 1 h. And then the microplate was washed three times with PBST. An excitation wavelength of 485 nm and an emission wavelength of 525 nm were chosen to measure the fluorescence intensity.

Results and Discussion

The label ratio of FITC-labeled anti-E_2 antibody

The FITC-labeled anti-E_2 antibody was characterized by spectrophotometry using absorption bands at 280 nm and 495 nm. The single antibody has the characteristic absorption only in the 280 nm place, and the single FITC has the characteristic absorption only in the 495 nm place, but the conjugation of FITC-labeled antibody has two characteristic absorptions both in the 280 nm and 495 nm places. According to the change of characteristic absorption, the result of UV-Vis spectrum indicated that the conjugation of FITC-labeled anti-E_2 antibody was successfully produced. The absorbance ratio of FITC to antibody (A_{495}/A_{280}) can produce a big effect on the detection limit and linear range for the determination. In order to get a better ratio, the experiment synthetized three different FITC-labeled anti-E_2 antibody conjugations and compared with their impacts on the determination of the method. The three different label ratios were 0.53, 0.7 and 0.88 respectively.

Optimum Immunoassay condition

In general, the amounts of immunoreaction reagents are key parameter affecting the sensitivity and specificity of a competitive reaction. Therefore, in this experiment, the coating antigen and FITC-labeled anti-E_2 antibody concentrations were investigated and optimized. The fluorescence intensity increased gradually with increasing FITC-labeled anti-E_2 antibody concentration from 5 μg/mL to 60 μg/mL, and reached a plateau at 60 μg/mL. The fluorescence intensity showed a maximum at 20 μg/mL of the coating antigen. Finally, 20 μg/mL and 60 μg/mL were selected as the best concentrations of coating antigen and FITC-labeled anti-E_2 antibody respectively.

The non-specific adsorption can be reduced by adding blocking solution. Various concentrations of OVA solution were investigated and the result was shown that the fluorescence intensity showed a maximum at the concentration of 0.4%, so 0.4% was chosen as the optimum condition in this experiment.

pH of solution is one of the most important impact factors affecting the sensitivity of an immunoassay, which was investigated and the result was shown that the fluorescence intensity increased gradually to the peak, and then weakened with the increase of pH. The fluorescence intensity showed a maximum at pH 7.4. Therefore, in this experiment, pH 7.4 was selected as the optimum condition.

The label ratio of FITC-labeled anti-E_2 antibody is an important factor that influences the sensitivity and linear range of an immunoassay. Three different label ratios of FITC-labeled anti-E_2 antibody were investigated and the results were shown that the label ratio of 0.7 was shown greatly heightened sensitivity compared with the other two ratios. Thus the label ratio of 0.7 was used in this experiment.

Preparation of standard curve

Under the optimal conditions, the typical standard curve for E_2 with the proposed method was obtained. The calibration graphs were found to be linear over the concentration range 0.01-1000.0 ng/mL. The line equation for the calibration curve was $\Delta I = 198.3 \lg C_{E2} + 434.7$, the linearity of measurement resulted in a correlation coefficient of 0.9951, and the detection limit calculated from three times the standard deviation (SD) of the blank was 9.2 pg/mL.

Sample Analysis

To evaluate the application of the present method, one urine sample was investigated. Corresponding recoveries and the relative standard deviations (RSD) for urine samples at each concentration were presented. The recoveries were 93.58-105.82% with the relative standard deviations (RSD) 5.52-7.09%. It was found that the proposed method possessed high reproducibility, good precision, and was suitable for the detection of E_2 in urine and other environmental samples.

Conclusions

A new fluoroimmunoassay based on FITC-labeled anti-E_2 antibody was constructed to monitor E_2 in human urine samples. The label ratio of FITC-labeled anti-E_2 antibody has a large effect on the sensitivity of the proposed immunoassay. Under the optimal conditions, the linear range for

determination of E_2 was 0.01-1000 ng/mL, and the detection limit was 9.2 pg/mL. Compared with other methods, this technique only required small volumes of samples and did not need expensive equipment. This method has been shown to be advantageous in terms of sensitivity, accuracy, reliablility and simplicity of handling. The method could be further developed for determination of E_2 in other environmental samples, and may indicate its potential use in clinical diagnosis.

Keywords: Calcined bauxite, Physical and chemical properties, Thermal performance, Phase composition and microstructure

Abstract. In order to further broaden the application field of calcined bauxite, using XRF and other testing technology to study and analysis on the high temperature performance of calcined bauxite in this paper. The results showed that the sintering temperature range was 1300 ~ 1650℃, the firing line shrinkage, bulk density, bending strength, heat capacity and thermal conductivity was increased gradually, the water absorption and porosity was decreased, the water absorption, volume density and flexural strength of the sample fired at 1650℃ were 0.93%, 3.20 $g \cdot cm^{-3}$ and 182.23 MPa, the specific heat and thermal conductivity were 0.83 $kJ \cdot (kg \cdot K)^{-1}$ and 9.21 $W \cdot (m \cdot K)^{-1}$. Due to the thermal performance of calcined bauxite is optimal, and is expected to be used for the field of high temperature solar thermal heat storage material.

Introduction

Bauxite is the most important ore of aluminum which belongs to the family of lateritic rocks. It is characterized by the enrichment of aluminum hydroxide minerals, such as gibbsite [$Al(OH)_3$], boehmite [γ-AlO(OH)], and diaspore [α-AlO(OH)], together with the iron ore minerals hematite and goethite, the kaolinite and small amounts of anatase (TiO_2). The bauxite resource has been very scarce in recent years [4-7]. Therefore, it is necessary to improve the application value and further broaden the application field of the bauxite. In order to make full use of bauxite resource and improve utilization effectively, the bauxite must be pre-processed through sinter at high temperature. The bauxite is calcined at high temperature that is called calcined bauxite.

Bauxite was used as raw material for producing calcined bauxite by the following steps: Bauxite ores was crushed and dry milled to pass through a certain sieve, Then, the bauxite powdered sample was mixed with water as binder. After that, the obtained mixtures were packed into metal mould and processed into compacted shapes by a hydraulic pressing. The pressed samples were cured for some time. Finally, the samples were fired at high temperatures. The prepared calcined bauxite is a widely used homogenized synthetic clinker because of its good chemical stability and excellent physical properties, excellent homogeneous structure, dense microstructure, low thermal expansion coefficient and so on [8-10].

The objective of this study is to make better use of Xinmi bauxite through high-temperature calcination.

Experimental

Raw materials. Calcined bauxite was provided by Henan Xinmi. The total tonnage is more than 57 million tons and a further 0.3 billion tons can be estimated as possible resources with a mean value of Al_2O_3 content around 78.05%. The chemical compositions of the calcined bauxite is given in Table 1.

Table 1 The chemical composition of calcined bauxite（wt%）

Materials	SiO_2	Al_2O_3	Fe_2O_3	TiO_2	CaO	MgO	K_2O	Na_2O	I.L	Total
calcined bauxite	12.09	78.05	1.03	4.17	0.24	0.30	0.46	0.11	3.05	99.74

Experimental procedures. The calcined bauxite was ball milled in a zirconia pot with zirconia ball for 1 h and passed through 250 mesh sieve to get the desired powder. The ball to calcined bauxite weight ratio was kept at 2:1. Water mist was then added gradually to made the calcined bauxite homogenized. Then the sample was cured at room temperature for 24~48h. The samples were prepared by wet-pressing molding by using a NYL-500 pressing machine at 55 KN and 40KN, respectively (produced by Wuxi Machine Factory). Both rectangular bars (36 mm×6.5 mm×6.5 mm) and cylindrical pellets (30 mm in diameter and 4.5 mm in height) were made. Finally, the compacted samples were heated at various temperatures (1300-1650˚C) for 2 h.

Characterization techniques. The water absorbency（Wa）, apparent porosity（Pa）and bulk density（D）were measured by an AUY120 electronic analytical balance (Japanese Shimadzu) through Static Weighing methods. The bending strength of the samples were tested by using a computer-controlled electronic universal testing machine (REGER-4100, produced by Shenzhen Rui Geer).

Results and discussion

Physicochemical properties. In order to investigate the sintering property of calcined bauxite，the single calcined bauxite was studied through high-temperature calcination. The measured physicochemical properties (apparent porosity, Pa, water absorption, Wa, bulk density, D, bending strength, σ_b, and firing shrinkage coefficient, S_f) of the sintered samples were investigated over the temperature range 1300-1650˚C, and the results are shown in figures 1 and 2. It was shown that the water absorption and apparent porosity decreased with the sintering temperature increasing, on the contrary, the bending strength, bulk density and firing shrinkage coefficient increased with the sintering temperature increasing. After sintering at 1300˚C, the calcined bauxite had a higher water absorption and lower bulk density and bending strength, also had a little powder on the surface of the sample. That was because the main crystalline phases of the raw calcined bauxite were corundum and mullite, and there was no phase inversion or new phases were found when the sintering temperature reached 1300˚C. While the calcined bauxite was sintered at 1500˚C, there was no powder on the surface of the sample, the firing shrinkage coefficient was about 6%, the bulk density and bending strength reached 2.56g·cm^{-3} and 84.48MPa, respectively. When the sintering temperature reached 1650˚C, the water absorption of the sample could be reduced to 0.93%, the bulk density and bending strength reached 3.20g·cm^{-3} and 182.23MPa, respectively, and the firing shrinkage coefficient reached above 10%. It is because of the high - temperature resistance of raw calcined bauxite that it has enormous potential applications in the fire-resisting material industry and high-temperature ceramic field.

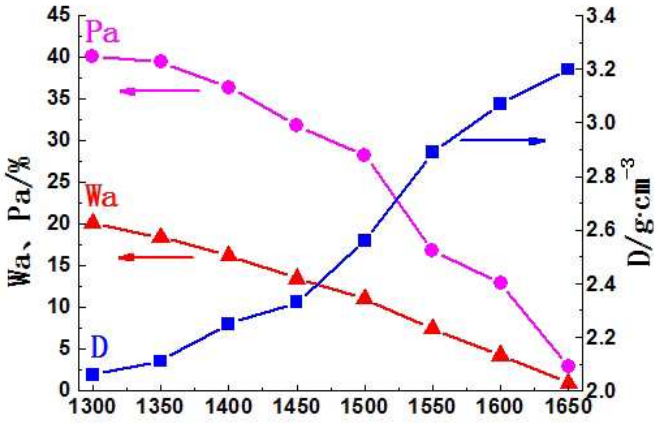

Fig. 1 Relationship of Pa, Wa, D and the firing temperature of samples

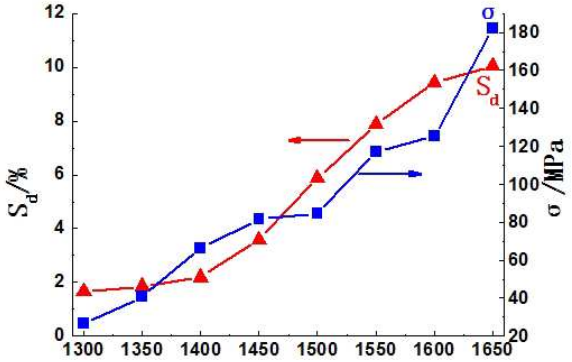

Fig. 2 Relationship of S_d, σ_f and the firing temperature of the samples

Thermophysical properties. The measured thermophysical properties of the sintered single calcined bauxite samples are listed in Table 2. It can be seen that the thermal conductivity coefficient increased from 0.61W/m·K to 2.02W/m·K at 600˚C, from 0.51W/m·K to 9.08W/m·K at 300˚C, from 7.93W/m·K to 8.15W/m·K at room temperature, respectively. With the temperature increasing from room temperature to 600˚C, the specific heat capacity increased from 0.37kJ·(kg·K)$^{-1}$ to 0.61kJ·(kg·K)$^{-1}$, from 0.31kJ·(kg·K)$^{-1}$ to 0.79 kJ·(kg·K)$^{-1}$ and from 0.55kJ·(kg·K)$^{-1}$ to 0.72kJ·(kg·K)$^{-1}$, respectively. Therefore, the calcined bauxite will be a promising material in the new energy resources ceramic field.

Table 2 The thermal properties test results of the samples

Firing temperature /˚C	Test temperature /˚C	Thermal diffusivity /cm^2·s^{-1}	Specific heat capacity /kJ·(kg·K)$^{-1}$	Thermal conductivity coefficient /W·(m·K)$^{-1}$
1400	25	0.02	0.55	1.93
	300	0.01	0.31	0.51
	600	0.01	0.37	0.61

	300	0.04	0.88	9.15
	600	0.02	0.71	3.24

Summary

(1) Results indicated that the main component of the calcined bauxite is Al_2O_3. The phase composition analysis shows that the main crystalline phases of the calcined bauxite samples are corundum and mullite, and the impurity content is low. Therefore, it has enormous potential applications in the fire-resisting material industry and high-temperature ceramic field.
(2) The results of investigations reveal that the calcined bauxite has high temperature resistance and the melting temperature could be above 1650˚C. With the increase of the sintering temperature, the main crystal phases of the calcined bauxite are corundum and mullite. With the temperature increased, the main crystalline phases of calcined bauxite are both corundum and mullite, and the the bulk density, bending strength, specific heat capacity, thermal conductivity coefficient are all increased gradually.
(3) After sintering at 1650˚C, the thermal conductivity coefficient of the calcined bauxite could reach 9.21 W/m·K (at room temperature), so the calcined bauxite would be expected to be used in the field of high-temperature solar thermal storage materials.

Study on Parrifine Removal Additive of High Wax Crude Oil

ZHANG HONG [1, a]

[1]Shanghai University of Engineering Science College of Chemistry and Chemical Engineering, Shanghai 201620, China

[a]zhanghonglindi@163.com

Keywords: high wax crude oil; parrifine removal additive; consist property;

Abstract. The consist property analysis of Shenbei and simulation high wax crude oil was carried on in the paper. The result showed the key factor of temperature lies in the wax crystal forming and growing. only when the heating temperature is high, the wax can be fully dissolved in crude oil drop dispersed, glial, asphaltene can be fully dissolved, agent and in crude oil.

Introduction

Most of China's crude oil are high waxy crude oil. According to the statistics, the wax content is higher than 10% in the 90% of total output of crude oil [1]. The high wax content of crude oil brings a lot of difficulties for the oil exploitation and transportation. The surface generates by wax deposition and attached on the pipe wall when the temperature access to the critical point. Also result to transport capacity greatly reduced, even serious blockage. It becomes the primary problem of oil transportation and exploitation [2]. At present, the chemical additive was added into the crude oil to solution the problem in the foreign countries use. The pour point depressant can change the original state of paraffin crystallization difficult to form network structure to improving the liquidity of the crude oil[3]. In China, research of the crude oil pour point depressant has made great progress and it has entered the practical using stage, such as, Lu Ning, Luo, Ma Huining long distance oil pipeline has been officially used crude oil pour point depressant [4].

The paper mainly aims at development of new high waxy crude oil pour point depressant. At the same time test the application the effect of improving the security of oil transportation and reducing the transportation and processing costs effectively.

Experiment

1.1 Simulation crude oil preparation

Paraffin wax (58# ~ 62#) with different proportion was added into n-octane, heating to melt to get simulation high waxy crude oil with different wax content.

1.2 Shenbei crude oil properties

Table 1 The crude oil properties

density	water	wax	pour point	wax precipitation
Kg/m³	（%）	（%）	℃	℃
839.1	0.30	24	44	49

1.3 Wax cleaning agent preparation

Preparation of long chain ester was got by ester reaction, distillation, solvent removal. Different long chain series was gained by transform different alcohols. The copolymer is prepared in the polymerization reaction, under the protection of nitrogen of polymerization was completed.

Results and discussion

2.1 Application performance testing

2.1.1 Additive on the depressive temperature effect

Temperature on the depressant effect has a great influence at the same additive conditions. The pour point depressant can change the crystalline morphology and coagulation function only above the wax precipitation temperature. The temperature is too low to prevent wax formation. So pour point depressant effect is unsatisfactory. However the temperature should not be too high the wax is dissolved, colloidal and other substances can be fully free. So pour point depressant can inhibit the three-dimensional network structure the low-temperature fluidity of crude oil was improved.

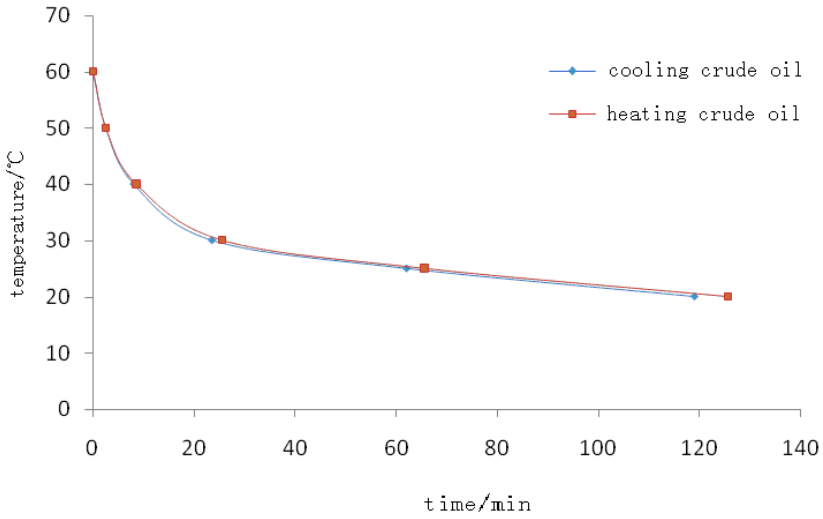

Fig. 1 Additive on the depressive temperature effect

In Figure 1 can be observed, whether cold or hot crude oil cooling preheating are quite fast from 60 ℃ to 40 ℃. It is slow cooling from 40 ℃ to 30 ℃ and below 30 ℃ more slowly. This is due to the thermal treatment temperature is an important factor of coagulation effect. Based on the theory of adsorption of eutectic, joining the intermediate temperature must be higher than the wax in the melt temperature, pour point depressant for crude oil pour point can effective better.

2.2 The solubility of wax in base oil

Wax solubility in crude oil is different with different composition of wax. The solubility of 54#, 56# and 62# three kinds of models of paraffin wax in base oil at different temperature were tested. The solubility change trend chart is as below fig. 2.

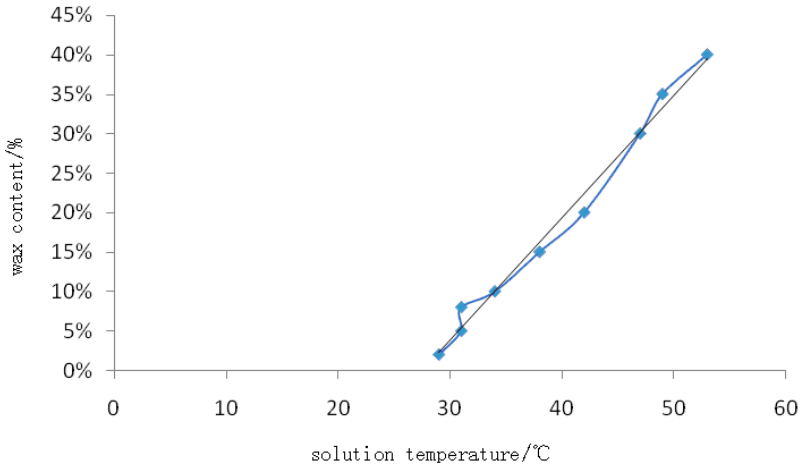

Fig. 2 The solubility of wax

The solubility of wax can been seen from graph 3 which increases the melting point of wax in crude oil with the solubility. On the other hand, for the wax was added to the base oil the wax melting point higher the wax precipitation at the same temperature will higher. Different molecular weight of alkane molecules in crude oil with different solubility, relative molecular mass is greater, the melting temperature is higher. Results also showed that solubility of wax and wax content are better conform to the exponential relationship.

Conclusion

Adding pour point depressant into crude oil the temperature factor is very important and the existence of a modified optimum range of heating temperature. This shows that only when the heating temperature is high, the wax can be fully dissolved in crude oil drop dispersed, glial, asphaltene can be fully dissolved, agent and in crude oil. Flow improver modification of wax crystal is better than that of the commercially available flow improver. Wax crystals have grow up and get well dispersed, which confirms the flow improver can enhance the crystalline wax wax crystals grow up point of view

Keywords: Carbon Fiber, Conductive Concrete, Electrical Resistivity, Produce Process

Abstract. This paper studied the produce process of carbon fiber concrete and the workability of carbon fiber conductive concrete (CFCC) by changing the fiber content as well. Based on a proper process, the electrical resistivity of CFCC in different CF continents was discussed and the percolation threshold was obtained.

Introduction

The research in the performance and application of conductive concrete has become a focus both at home and aboard in recent years.

Compared with the conventional concrete which has a high level of electrical resistivity about 10^5 - $10^9\Omega\cdot$cm, the conductive concrete has it much lower by adding some conductive materials such as carbon fiber, steel fiber and graphite. It is useful for cathodic protection, self monitoring of structure, deicing or snow-melting, etc. [1, 2]

Carbon fiber is widely considered the ideal conductive material，because of its high specific modulus, high rupture strength, fine corrosion resistance oxidation resistance and both high and low temperature resistance.

Carbon fiber conductive concrete (CFCC) is a new kind of intelligent concrete made by adding chopped carbon fibers into conventional concrete. It has a serious of fine properties as well. For example: electrical conductivity, compression sensitivity, thermo sensitivity.

On the other hand, it has been recognized as the most promising way for pavement deicing or snow-melting due to a good deal of advantages for instance: economic friendly, easy operation, high conductivity, good durability, etc.

In this paper, an advanced produce process is used to guarantee the CF can be fully dispersed. Besides, the workability and conductivity of CFCC is tested by changing the content of carbon fibers.

Experimental

1. Materials and electrode fabrication

1) Ordinary Portland cement was used.
2) Standard river sand was used as fine aggregates.
3) The largest stone size was 15 mm, the smallest was 5 mm, and the average stone size was 10mm.

4) The ratio of the high-range water-reducing agent to cement was 4% (by weight).
5) Hydroxypropyl Methyl Cellulose (HPMC) was used as dispersant in the amount of 0.1%-0.25% by weight of cement.
6) Defoamer was added to accompany HPMC; the defoamer-cement ratio was 0.3% by weight.
7) Carbon fibers of 7 μm in diameter and 10-15 mm in nominal length were used as the conductive filler. The carbon fibers were isotropic PAN-based and unsized. Other properties of CF are given in Table 1.

Table 1 Properties of CF

Tensile strength [MPa]	Tensile modulus [GPa]	Density [g/cm3]	Electrical resistivity[μΩ·m]	Content of carbon
2000-3000	175-215	1.74-1.77	30	93%

The electrode is made by 1 mm in thickness stainless steel plant in square ($130\times130mm^2$) with 9 circular holes in it which is shown in Fig.1. The diameter of the hole is 20mm, which is slightly larger than the aggregate particle size to ensure the electrical plate on both sides of the CFCC can be well connected.

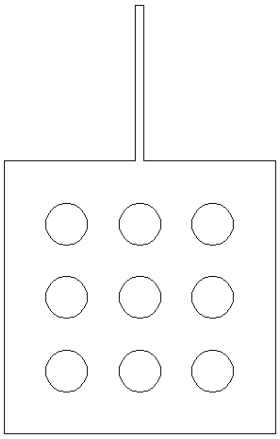

Fig.1 Electrode Plant

2. Mixing procedure

HPMC and defoamer were first added into water and stirred well for approximately 5 min. CF was then added into water and stirred gently. The rest of the mixing water was poured into the mixer followed by the high-range water-reducing agent.
Then the cement, sand and stones were added and stirred by a rotary mixer for 2 min. The mixer was stopped and the carbon fibers were spread into the mixer in several batches. Finally, ran the mixer for 5 min when all CF and mixed liquid were poured into the mixer.
The electrode was laid in oiled mold when fresh concrete was poured into an oiled mold. Then an external vibrator was used to facilitate compaction and decrease the amount of air bubbles. The samples were demolded after 24 hours and then cured at room temperature (temperature: 20℃; relative humidity: 50%). Fig.2 shows the samples were 150 mm length of side in cubes and $100 \times 100 \times 400\ mm^3$ in cuboids.

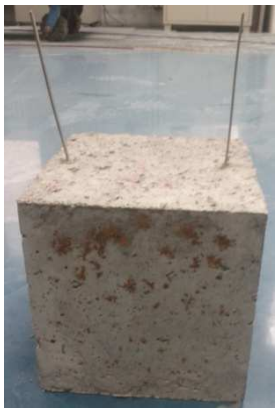

Fig.2 CFCC samples for electrical resistivity and rupture strength tests

Results and Discussion

1. The influence of carbon fiber content on workability

Slump was tested as an index of the workability of CFCC. The result proved the produce process in this paper is fantastic to guarantee the workability of CFCC. Since the increase of CF content and the water retention of HPMC, the fluidity of CFCC declined within a certain range.

2. The influence of carbon fiber content on rupture strength

Carbon fiber can prevent early plastic shrinkage crack of concrete from appearing and expanding, because CF fiber can absorb a part of tensile stress on the section, relieve the stress concentration of the concrete and thereby have good effect on rupture strength. When the crack appears, CF across the crack can still absorb and transfer tensile stress. It can not only delay the time of incipient crack, but also resist the expanding of crack. The experiment proved this idea well. Rupture strength was tested among samples in different CF content. All tests were taken after 28 days. The results are listed in Table 2

Table 2 Comparison of Rupture Strength and Slumps

Cement [kg/m$^{3]}$	Sand [kg/m^3]	Stone [kg/m^3]	Water [kg/m^3]	water-reducing agent [kg/m^3]	CF content (volume)	water cement ratio	28d rupture strength [MPa]	Slumps [mm]
500	525	1225	250	20	0.50%	0.50	5.49	177
500	525	1225	250	20	0.75%	0.50	6.24	149
500	525	1225	250	20	1.00%	0.50	6.63	143
500	525	1225	250	20	1.25%	0.50	7.03	132

3. The influence of carbon fiber content on concrete resistivity

The electrical resistivity of different CF contents was tested after 28d and the result was listed in the Fig.3. Each data is an average from 5 samples.

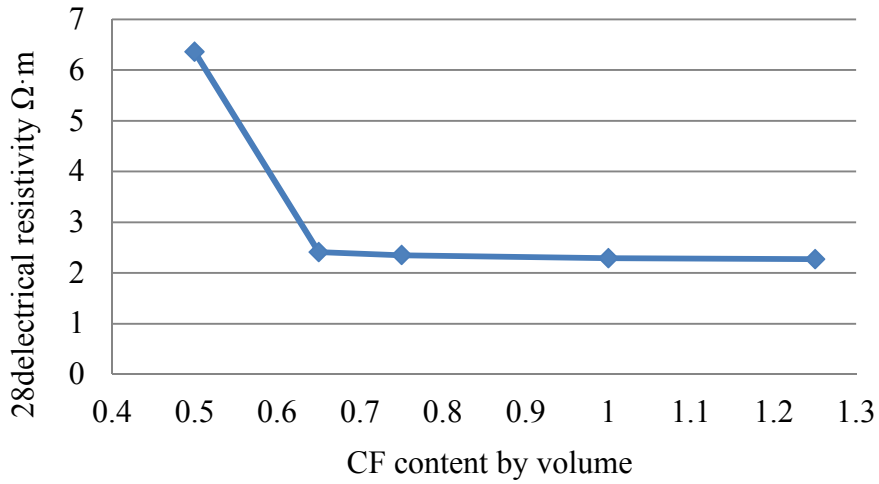

Fig.3 The effect of CF content on the electrical resistivity

Summing up the Fig.3, there is an obvious decrease in the electrical resistivity with the increasing CF content in the beginning stage. There is only a slight decrease in the electrical resistivity when the content varies from 0.65% to 1.25%.

It is concluded that low CF content in the beginning stage, the space between fibers is relatively large, so the fibers contribute less in electrical conduction than Ionic conduction in the concrete. While, a network of CF gradually formed with the increase of CF content, leading to an obvious decrease in the electrical resistivity.

When CF content was enough to form a stable conductive network, the electrical conductivity of CFCC became mainly depend on the CF network. The feature point of CF content is defined as the percolation threshold. After that, the electrical resistivity tends to be stable.

Fig.3 shows that the percolation threshold of CFCC is about 0.65%

Conclusions

The carbon fiber conductive concrete shows a good electrical conductivity and a superior mechanical strength. The workability of CFCC can be better since the CF content decreases in a certain range. CF content has an obvious influence on conductivity. When it reaches percolation threshold, the conductivity of CFCC tends to be stable. Percolation threshold of CFCC obtained is 0.65%

In this paper, CFCC of great workability, well fiber dispersion and stable electrical resistivity was produced, which laid a good foundation of CFCC practical application.

Keywords: Chemical composition; gold deposits; calcite; Jiaodong

Abstract. The largest gold district in China is the Jiaodong Peninsula. This study is based on chemical composition characteristics of calcite from gold deposits in Jiaodong. In this paper, a new formula was proposed to character the chemical composition characteristics of calcite in gold and silver deposits. The results showed that the chemical composition characteristics of calcite between gold and silver deposits were of great difference. And each data focused in each area. The spots of gold deposits located in the area of riched CO_2 areas. But the spots of silver deposits located in the area of riched CaO areas. The reason of these differences was mainly resulted from each different ore-forming condition.

Introduction

The Jiaodong Peninsula is the premier gold district in China with total measured gold reserves exceeding 1000t, and current annual production of over 30tonnes. There are conflicting views regarding the sources of ore-forming fluids in the Jiaodong gold province. the fact that most of the gold orebodies are hosted in 160 to 150 Ma Linglong-type biotite granite or 130 to 126 Ma Guojialing-type granodiorite has prompted a group of researchers to suggest that the ore-forming fluids were dominantly derived from granitic magma, which increasingly mixed with meteoric water during the late stages of hydrothermal activity[1,2]. Others, on the basis of stable isotope systematics and initial ratios of Sr isotopes, suggested that the major component of the ore-forming fluids was meteoric water, or that the meteoric water mixed with small amounts of magmatic fluid. Owing to the close spatial relationship between the orebodies and Cretaceous lamprophyre dykes, together with some evidence of mantle-derived components, other researchers argued that deep fluids or mantle-derived fluids were responsible for the gold deposits in the Jiaodong Peninsula.

One method to constrain the nature of ore-forming fluids is to study stable isotopes, such as those of hydrogen, oxygen, sulfur and nitrogen [3]. In the present work, a new formula was proposed to character the chemical composition characteristics of calcite in gold and silver deposits. The results showed that the chemical composition characteristics of calcite between gold and silver deposits were of great difference. The reason of these differences was mainly resulted from each different ore-forming condition in Jiaodong peninsula.

Regional geological setting

The Jiaodong peninsula is located along the southe-eastern margin of the North China carton and at the western margin of the Pacific Plate. It is bounded to the west by the NNE-trending Tanlu Fault zone that extends for thousands of km fom the Yangtze River north to Far East Russia. The peninsula is divided into two-Hurassic tectonic units: the Jiaobei terrane in the north and Sulu Terrane in the south. These terrane are separated by the Wulian-Yantai suture (Figure 1). The Sulu Terrane is at the eastern end of the Qinling-Dabie-Ulu diamond and coesite-bearing ultra-high pressure metamorphic belt. The Jiaobei Terrane consists of the Jiaobei uplift in the north and the jiaolai basin in the south.

The gold deposits can be classified into: 1) quartz vein type, as exemplified by the Linglong gold deposit; 2) altered-fracture type, as in the Jiaojia deposit, and interlayer slippage type as shown by the Dujiaya and Pengjiakuang deposits [4].

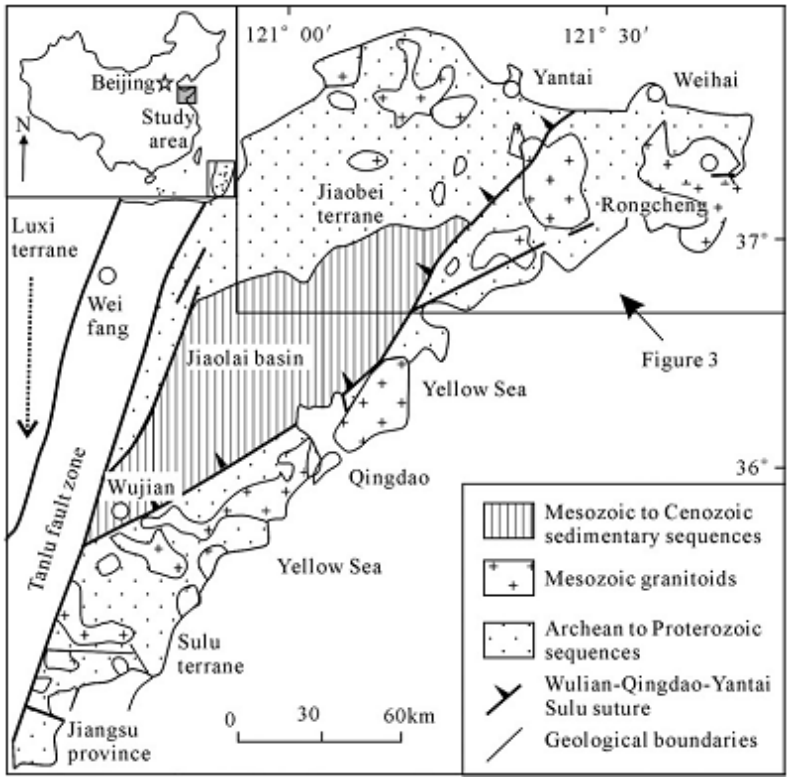

Figure 1 Simplified geological map of the Jiaodong Peninsula (according to [5])

Methods

The gold and silver chemical composition data is collected from the electronic probe analysis and previous literatures. And a new formula was proposed.

Results and Discussion

4.1 New formula of chemical composition characteristics of calcite in deposits

Until now, there are few method to character the chemical composition of calcite in gold and silver deposits. In this paper, a new formula was proposed as follows.

$$\delta CaO(\%) = \frac{100x - 52.0435}{52.0435} \times 100 \quad (1)$$

$$\delta CO_2(\%) = \frac{100y - 47.0565}{47.0565} \times 100 \quad (2)$$

x，y are signed for mass fraction of CaO and CO2。and δCO2

4.2 Chemical composition differences between gold and silver deposits

The calcite chemical composition data in Jiaodong gold and silver deposits are listed in Figure 2 and Table 1. Based on the data, the δCaO and δCO2 values changes little and have a narrow range of δCaO of -10.23 to -2.45 and of δCO2 of -0.07 to -5.69. The δCaO values changes bigger than the δCO2 values. The spots of gold deposits occupied riched δCO2 area. And the spots of silver deposits occupied reched δCaO area. The reason can be related to the ore-forming conditions between gold and silver deposits.

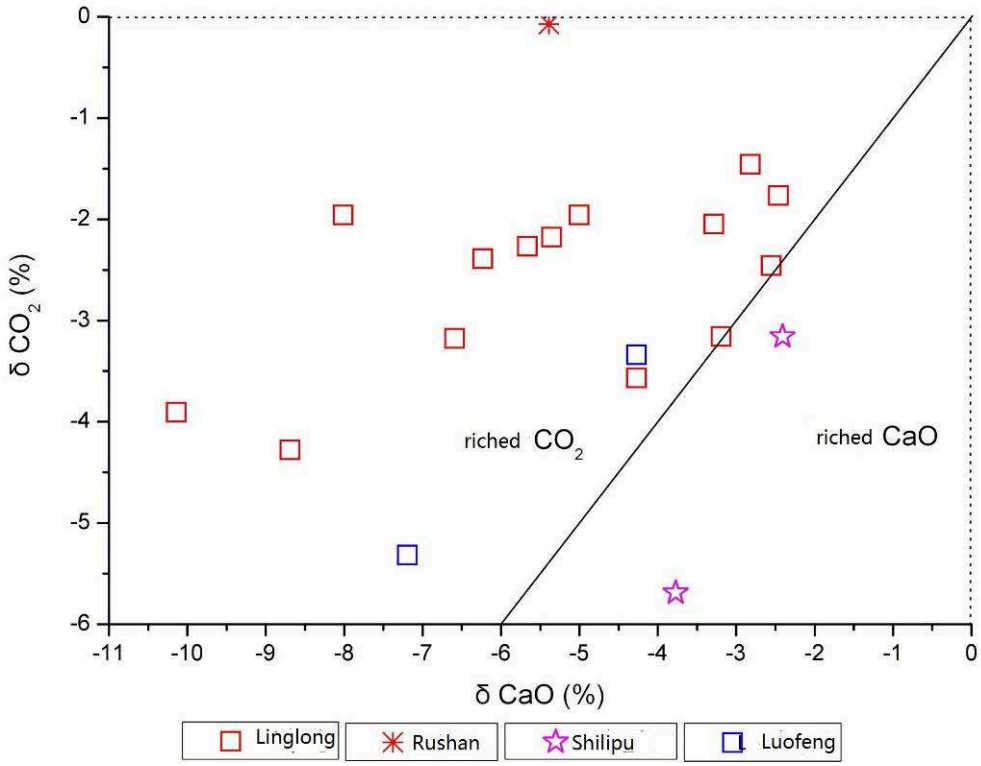

Figure 2 The spot of δ CaO— δ CO_2 of calcite in gold and silver deposits in Jiaodong. Red data stand for quartz-vein type gold deposit, blue data stand for alter type gold deposit, pink data stand for Shilipu silver deposit.

Keywords: life, hydrogen embrittlement, cycling.

Abstract. There are various types of structural components, which are subjected to hydrogen aggressive environment and cycling. Their unexpected failure occurs suddenly and may entail serious consequences such as emergency stop of equipment, failure of the structure etc. The special engineering models are developed to predict the crack kinetics in structure components, which are subjected both to hydrogen environment and to cycling simultaneously. These models enable estimation of structure component life. The paper considers some features of such empirically specified special model giving emphasis to the one of them, namely to the prevailing fracture mechanism transition from fatigue to hydrogen embrittlement and back in crack kinetics process.

Introduction

Each structure, apparently, may have different metallurgical defects (cracks initial length of L_0, for instance). An aggressive hydrogen environment influence is supposed to accelerate a precipitateness of the fatigue fracture process in the structure component containing defects.

Numerous catastrophic failures of the important structure components have been reported. Most of them concern the steels of high yield strength for tubing and casing although there are also accidents with low alloy steels used in pipelines and pressure vessels [1]. The paper describes kinetics of central crack length of L in infinite plate [2] kinetics in the specimen made from the high-strength steel AISI 4340 using two different models, i.e. hydrogen cracking (HC) model and fatigue cracking (FC) one. Authors suppose that influence of cycling in combination with hydrogen environment leads to appearing some features in crack kinetics. Crack kinetics described till unstable cracking (UC) becomes the prevailing fracture mechanism.

Hydrogen cracking model

Hydrogen penetrates into material through the material-environment interface due to diffusion process. Eq. 1 describes hydrogen penetration into material for unidirectional diffusion and tension of a specimen [3]. Boundary and initial conditions are presented below too.

$$\frac{\partial C}{\partial t} = D\frac{\partial^2 C}{\partial x^2} + f\left([\Psi]\right)\frac{\partial C}{\partial x}\frac{\partial \tilde{\sigma}}{\partial x};\ C(0,t) = C^0;\ C(x,0) = C^0 G(x), \tag{1}$$

where x is a coordinate from the crack tip, t is time, $C = C(x,t)$ is hydrogen distribution function, $\tilde{\sigma}$ is stress distribution near the crack tip, C^0 is the current hydrogen concentration in the material-environment interface, $f([\Psi])$ is a function of environment and material parameters.

Mechanical characteristics in the hydrogenated region differ from those of in another part of the same body [4]. Hydrogen penetration into material lattice, for instance, results in decreasing fracture toughness. Therefore, *conditional stress intensity factor* (CSIF) and conditional fracture *toughness* (CFT) $\tilde{K}_I$ and $\tilde{K}_{Ic}$ are introduced instead of K_I and K_{Ic} in the hydrogenated region near the crack tip, and a criterion of the crack propagation is described by Eq. 2

$$\tilde{K}_I\left(\tilde{\sigma}^{\infty},l\right)\geq\tilde{K}_{Ic}\left(\bar{C}_a\right) \tag{2}$$

where $\tilde{K}_I=Y\tilde{\sigma}^{\infty}\sqrt{\pi l}$, $\bar{C}_a$ is an average hydrogen concentration in a *prerupture region a(l)* of the material. This region is much smaller than the hydrogenated one.

Crack growth rate in hydrogenated material depends on a *specific pair*, i.e. *environment and material* used in different experiments. Therefore, authors have introduced a new material-environment characteristic Ω to relate the current hydrogen concentration in the crack tip C^0 (*environment, initial condition of Eq. 1*) to the maximum solubility of the hydrogen in material C^* (*material*), in other words $\Omega=C^0/C^*$ [5].

CFT $\tilde{K}_{Ic}$ versus $\bar{C}_a$ is described by the Eq. 3:

$$\left(\left(\tilde{K}_{Ic}-\tilde{K}^*_{Ic}\right)/\left(\tilde{K}^0_{Ic}-\tilde{K}^*_{Ic}\right)\right)^{\alpha_1}+\left(\Omega\cdot\bar{C}_a/C^0\right)^{\beta_1}=1 \tag{3}$$

where $\tilde{K}^*_{Ic}$ - CFT of the material with uniform hydrogen concentration equals to C^0/Ω, $\tilde{K}^0_{Ic}$ - CFT of the non-hydrogenated material, α_1,β_1 - constants.

A crack propagation process is discrete in the given model. It is divided into three main stages:

- The first (incubation) stage may last quite long. It means an initial accumulation of hydrogen near the crack tip in the initial prerupture region. The length of this area depends on the metal lattice.
- The second stage is a stable crack growth. Here, the stable crack growth proceeds till the initial average hydrogen concentration does not exceed the critical one in the current prerupture region. The current prerupture region is longer as compared to the initial prerupture region length (Fig.1).

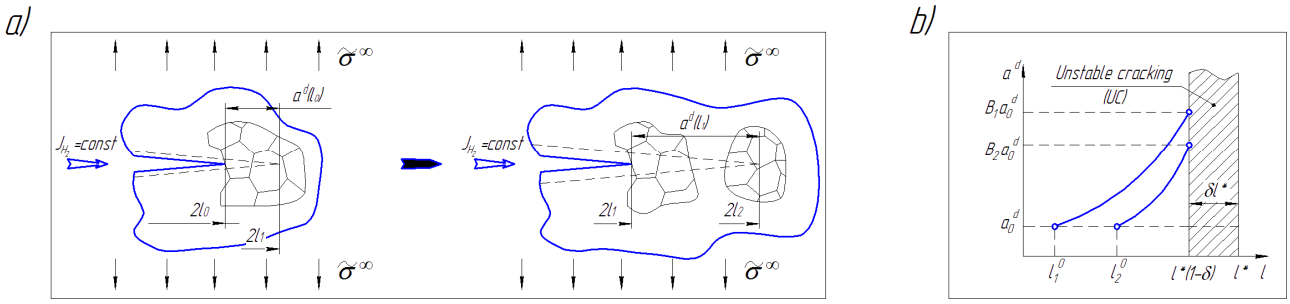

Fig. 1. (a) Crack growth; (b) The prerupture region length.

The length of initial prerupture region is supposed to be constant, and it does not depend on initial crack length. Eq. 4 describes a prerupture region length $a^d(l,\delta,l_0,l^*,a_0^d,A,\alpha_2,\beta_2)$ versus crack length l.

$$\left(\left[a_i^d-a_0^d\right]/\left[a_0^d\left(B-1\right)\right]\right)^{\alpha_2}+\left(\left[l^*\left(1-\delta\right)-l\right]/\left[l^*\left(1-\delta\right)-l_0\right]\right)^{\beta_2}=1 \tag{4}$$

where a_0^d is an initial prerupture region length, B,α_2,β_2 are parameters; l_0 is an initial half-length of the crack, l^*,δ are parameters, which defined below.

Using Eqs. 2-4 and a solution of Eq. 1 time $t^*(a_i^d)$ (i is a number of iterations) which is expanded to crack growth from l_i to $l_i+a_i^d(l_i)$, is defined as follows

$$t_d^*\left(a_i^d\right)=\frac{\int_{\Phi}\varphi(x)^2\,dx}{\int_{\Phi}\left(D\varphi''(x)\varphi(x)-\frac{\tilde{K}_I f\left([\Psi]\right)}{2\sqrt{\pi}}\frac{\varphi'(x)\varphi(x)}{x\sqrt{x}}\right)dx}\ln\left\{\frac{a_i^d\sqrt{1-\left(\frac{\tilde{K}_I-\tilde{K}^*_{Ic}}{\tilde{K}^0_{Ic}-\tilde{K}^*_{Ic}}\right)^{\alpha}}}{\Omega\int_0^{a_i^d}\varphi(x)\,dx}\right\} \tag{5}$$

where $\varphi(x)$ is a coordinate function, which appears after using Galerkin method with orthogonalizaiton of difference on the hydrogenated area $\Phi >> a_0$.

Crack growth rate $\dot{l}_{d\,i}$ at the i[th] regrowth caused both by hydrogen embrittlement of the material and by static loading is determined by the formula below

$$\dot{l}_{d\,i} \approx a_i^d \Big/ t_d^* \left(a_i^d\right) \tag{6}$$

- The third stage is an unstable cracking (UC). It occurs when the current initial average hydrogen concentration is greater than the critical one. In the other words, stable cracking lasts till the crack growth length L smaller than the L_{fr}^*:

$$L_{fr}^* = l^* \left(1-\delta\right) = \left[\left(\tilde{K}_{Ic}^0\right)^2 \Big/ \left(\pi \cdot Y^2 \cdot \tilde{\sigma}^{\infty 2}\right)\right] \cdot \left(1-\delta\right) \tag{7}$$

where $\delta = \delta(C)$ - parameter.

Fatigue cracking model

It is supposed that a crack growth rate is defined by two independent mechanisms. The first mechanism is accumulation of plastic strain near the crack tip due to cycling and another one is embrittlement structure component material especially near the crack tip caused by the aggressive hydrogen environment coming in contact with material. Also it is supposed that the incubation stage occurs only in case of hydrogen embrittlement and static loading. The Paris-Erdogan law, Eq.8, determines a crack growth rate due to fatigue:

$$\dot{l}_f = A\left(Y \Delta\tilde{\sigma}^{\infty} \sqrt{\pi l}\right)^n \tag{8}$$

where A, n are Paris-Erdogan constants, Y is a crack shape factor, $\tilde{\sigma}^{\infty}$ is a stress far from the crack. Time Δt_i^f a crack growth time from l_i to $l_i + a_i$ due to fatigue is defined by the formula below:

$$\Delta t_i^f = f^{-1} \cdot \Delta N_f \tag{9}$$

where f is a load frequency, ΔN_f is the number of cycles.

According to Eqs. 8 and 9, Eq. 10 determines the length of the crack regrowth a_i^f:

$$a_i^f = A \cdot \left(\Delta t_i^f \cdot f\right) \cdot \left(Y \Delta\tilde{\sigma}^{\infty} \sqrt{\pi l_i}\right)^n \tag{10}$$

The crack propagation in hydrogenating metal due to cycling

The Eq. 11 allows us to determine the crack growth rate $\dot{L}$ in structure components, which are subjected to cycling and hydrogen environment in case of $a_i^f = a_i^d = a_i$ [6].

$$\dot{L}_i \approx a_i \Big/ \min\left(\Delta t_i^f, \Delta t_i^d\right) = F\left([X],[Y],\tilde{\sigma}^{\infty}, l_0, t\right) \tag{11}$$

where Δt_i^d is the crack growth time from l_i to $l_i + a_i$ caused by the hydrogen embrittlement and static loading, $[X]$ and $[Y]$ are mechanical and environment parameters.

Diagram $L(t)$ and structure component life t^* is defined using Eq. 12.

$$L(t) \approx \int_0^t F\left([X],[Y],\tilde{\sigma}^{\infty},l_0,t\right)dt;\ L(t^*) = L^* \to t^* \tag{12}$$

Using Eqs. 11-12 is supposed to lead to appearing points $P\left(HC \xleftarrow{change} FC\right)$ to indicate the HC prevailing over FC (or vice versa). The curve to connect such points represents a borderline. The appeared borderline is a crack growth feature in hydrogenated material under cycling.

High-strength steel AISI 4340 has been examined using available empirically specified model. Table 1 gives specimen with the crack under mode I loading.

Table 1. Data for the specified specimen with crack under loading (mode I)

$\Delta\tilde{\sigma}^{\infty}$	f	A	n	$\tilde{K}^*_{Ic}$	$\tilde{K}^0_{Ic}$	α_1	β_1	a_0^d	α_2	β_2	B	δ	Ω	lg([Y])	L_0
[MPa]	[Hz]	$\left[\frac{\mathrm{m}\cdot\left(\mathrm{MPa}\cdot\sqrt{\mathrm{m}}\right)^{-n}}{\mathrm{cycle}}\right]$		$\left[\mathrm{MPa}\cdot\sqrt{\mathrm{m}}\right]$				[m]						$\lg\left[\frac{\mathrm{kg}\cdot\mathrm{m}}{s^2}\right]$	[m]
140	1.2	$1.095\cdot10^{-12}$	3.24	10	80	2	2	10^{-5}	2	2	10	0.05	1.5	-19.094	var.

Fig. 2 shows the crack growth versus life for various initial crack lengths. The initial crack length L_0 was varied beginning from $0.02\cdot l^*$ to L^*_{fr} in presented example.

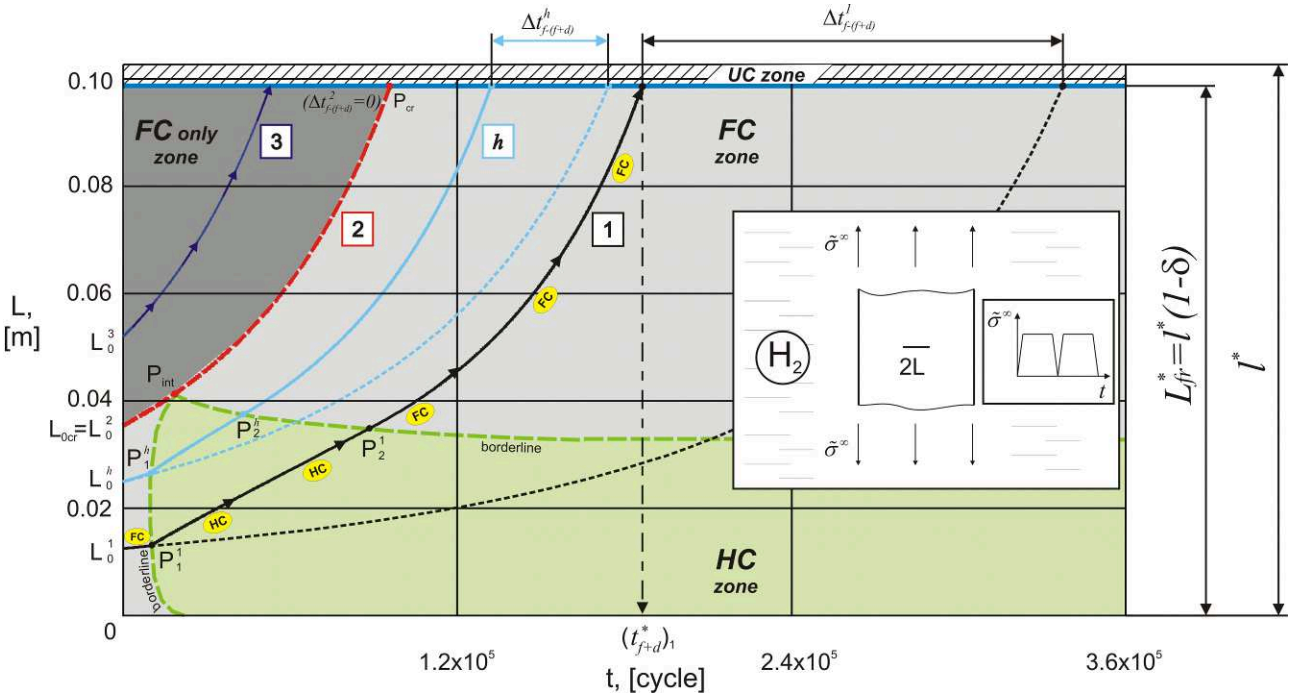

Fig.2. Crack kinetics features diagram (example)

The crack growth features description

Simulation results presented in Fig.2 illustrate appearing points P_i^j to indicate the HC prevailing over FC (or vice versa). A connecting these points borderline is shown in the diagram too. The mentioned borderline divides the diagram into two zones, namely the FC zone and the HC one.

The crack growth process with initial length L_0^1 is shown for two different loading conditions, i.e., hydrogen environment influence and cycling (solid curve 1) and only cycling (dashed curve 1). The growth process represented by the solid curve 1, starts due to fatigue. Then the crack continues growing to the point P_1^1. This point indicates that the prevailing fracture process changes, namely the mentioned solid curve transits to the HC zone. As time goes by the crack continue growing till it

reaches the point P_1^2 to indicate that the prevailing fracture process changes for fatigue. Afterwards, the solid curve 1 transits to the FC zone again. The proposed model allows us to follow the kinetic process till the moment when the crack reaches the value of $l^*(1-\delta)$; life t^*_{f+d} of the specimen under examination is exhausted. In other words, the crack growth process becomes unstable (UC zone).

Fig.2 presents the life difference of the specimen under two loading conditions mentioned above. Such difference $\Delta t^h_{f-(f+d)}$ is shown for curve h, which represents the crack growth with initial length $L_0^h > L_0^1$ under the same conditions. With increasing initial crack length the difference of the mentioned life $\Delta t^*_{f-(f+d)}$ decreases. The curve 2 describes the case, when life difference is zero ($\Delta t^2_{f-(f+d)} = 0$) thereby showing that the initial critical length L_{0cr} exists. Cracks with initial length $L_0 > L_{0cr}$ will grow just due to fatigue fracture process (only FC zone).

Summary

For high-strength steel AISI 4340 crack begins growing due to fatigue mechanism until hydrogen embrittlement does not prevail. As time goes by the fatigue mechanism becomes the prevailing one again. Borderline of HC zone in the diagram *L(t)* is defined by the proposed empirically-specified model. The determined zones could help to determine the prevailing fracture mechanism of the structure components with the cracks subjected to hydrogen environment influence and cycling.

Besides, the proposed empirically-specified model is a tool to define the life of the structure components under consideration.

Keywords: extrusion, stamping machine, contact finger, mould

Abstract. Extrusion process and mould design for contact finger by stamping machine is introduced in this paper. The structural design of the die is simple and practical, the productivity is improved significantly, the material consumption is reduced accordingly , the quality of products is very good and the production cost is low.

Introduction

As a near net shape technique, cold extrusion plays a more and more important role in the product manufacturing for its efficient high quality and low consumption characteristics .It can directly form the billet into net shape and near net shape products. Except for a small amount of mechanical processing, this technique does not need machining but just but also can improve the mechanical properties of the product and dimensional accuracy, and can improve the productivity. This paper introduces a technology using the cold extrusion to punch contact figure. Compared with the hydraulic press, it has high production efficiency, low cost, and high precision, good quality, and it has achieved good economic benefits.

The material of the contact finger is T2Y, which is a kind of hard copper. The part is as shown in Fig.1

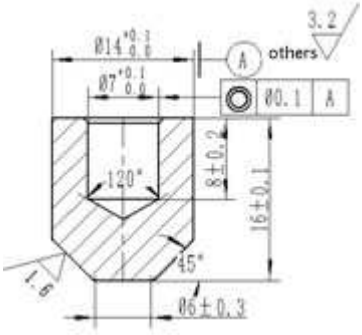

Fig.1 Part drawing

Process Analysis

From the shape of contact finger, this part belongs to the parts that are typical suitable for extrusion forming. On this occasion, if we use general lathe, drilling or some other methods for processing, the utilization rate of materials will be low and the labor time cost will be high. From the point of material characteristics, T2y copper's hardness is not high, which is suitable for cold extrusion forming. From the requirements of size tolerance, in addition to the requirements of the internal and external circular coaxial degree is high, which require the precision achieves 0.1, the general requirements are not high. After taking the appropriate measures, cold extrusion process can meet the requirements of the indicators. So the extrusion forming process is a better choice.

From the view of deflection, the deflection ε_A of backward extrusion hole in this contact is 25%, which is relatively smaller. While forward compression deformation condition also requires to being meet to fill the cone Ø6. The deflection ε_A of forward extrusion is 81.6%, which is relatively larger, but it is also within the decrement of 90~95% of forward extrusion allowable end face for fine copper. Thus it can be seen that the contact can be formed only once by using extrusion process.

The contact has holes of Ø7×8 and cone Ø6, the hole needs to be formed by backward extrusion and the cone needs forward extrusion, which is able to calculate forming extrusion force respectively. According to the algorithm of unit extrusion force diagram for nonferrous metals, unit extrusion force of backward extrusion hole can be figured out as p=965MPa, total extrusion force of backward extrusion hole as P=3.7T. Similarly, unit extrusion force of forward extrusion cone can be figured out as p=817MPa, total extrusion force of forward extrusion cone as P=12.6T.

Based on above forming forces, it can be judged that the backward extrusion forming of hole Ø7 has already completed prior to forward extrusion in pressure of 4T. However, after backward extrusion of forming hole, cone Ø6 is not able to completely take shape, which needs to control metal flow in direction of backward extrusion to force metal fill down. Finally, when the pressure reaches to 12T, the cone will form to required shape.

The extrusion forming force of contact finger is not much larger, as well as extrusion trip, equipment selection of hydraulic machine or punch is able to meet forming requirements. If extrusion forming is taken place in general oil press, mandrill can autonomously return after ejection, and the blank can be easily put in. and due to controllable pressure, the size of blank is not a big issue, this is just a matter of extrusion that whether it is longer or shorter. However, it is too slow in form by hydraulic machine to meet mass and low cost production requirements. Therefore, the punch is considered for production. Based on above calculations, the selection of punch 16t or 40 is favorable

In order to meet coaxiality of inner bore and encircle, some measures need to be taken to ensure coaxiality of 0.1when forming is completed in the punch with steeled terrace die.

According to the part drawing of finished products, we select the blank with a diameter of Ø 14. According to the principle of the invariability of volume constant in the process of compressional deformation, we can select the blank with a height of 12.5 mm and eventually determine the blank size for Ø14 x 12.5 mm.

Finite element software of DEFORM-3D will be used for simulation verification. Taking 1/12 blank to do numerical simulation and then getting the extrusion simulation diagram with intact forming (figure 2), its load curve of punch travel can be shown in Figure 3, and the total extrusion force is 15.36 T, which is close to the extrusion force calculated by algorithm of non-ferrous metal graph. Forming condition can be backward hole extrusion and meanwhile forward extrusion boss, but the hole accomplish forming in advance, and the boss accomplish forming later. At last, formed boss requires larger extrusion force.

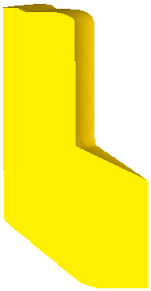

Figure 2: Mimetic diagram of the extrusion

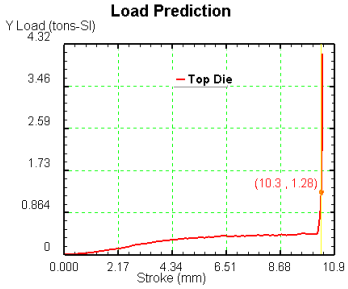

Figure 3: The lode curve of the punch

The mould structure and precision guarantee method

The mould structure formed by the extrusion of contact punch is shown in Figure 4. The mould structure has designed discharging mechanism consisting of guide sleeve for terrace die and kicker pin to ensure that after extrusion, extrusions can smoothly demould. Discharging mechanism is composed of Belleville spring 3, plate 4, plunger, kicker pin 5, and guide sleeve for terrace die 13. Lifter mechanism consists of kicker pin 21, pull rod 28, crown sheet 29, etc. which drives pull rod to lift upwards by return trip of punch sliding block. In order to ensure the accuracy requirement of coaxiality and parts for terrace die and die in the process of backward extrusion, guide sleeve 27 and guide pillar between up and down dies.

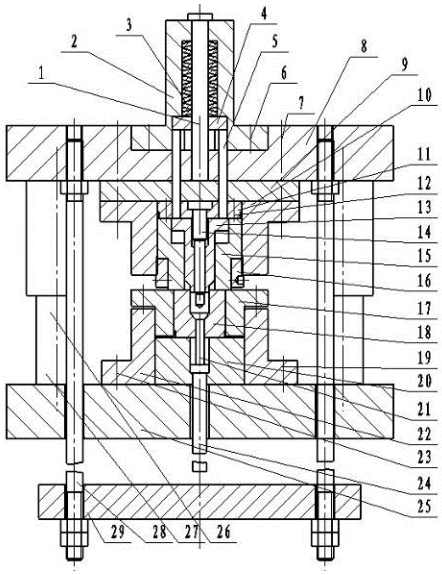

Fig.4 Structure schematic illustration of the die

n order to make it convenient to install mould in the punch, punch shank is used and mandril 5 inside of the punch shank uniformly configures by 120 °.

The die can be quickly replaced. Prestress circle of the die and the lower flange are connected by socket head cap screw, which is easy to assemble and unassembled, and the die replacement can be easier.

The extrusion is ejected by pull rod system [3], and the ejection distance should be strictly controlled within 17 ~ 19 mm. If the ejection distance is beyond the standard, the extrusion may knock terrace die or its guide sleeve; besides, another condition may be taken place that the next extrusion blank cannot put into the die cavity due to the overtop mandril. If the ejection distance is less than the standard, the ejected part of extrusion in the die cavity is too less to take the extrusion out.

Since the extrusion excircle doesn't process, while it directly require to reaching requirements of part, then only cavity Ø14 can be used. However bar-stock with negative tolerance of Ø14×12.5mm will be tense when putting into the die and the bar-stock will be easy to deflect resulting in punch broken when the punch is downriver in that the mandril places in a high position after ejection completion and little parts of the blank are put into the die. Besides the extrusion die is not flat but a sharp punch. The punch tends to partial, which makes the inner hole can not meet the requirement of the coaxiality. The way to solve this problem is to add a guide sleeve to the punch.

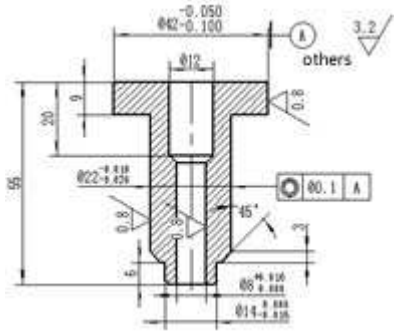

Figure 5: The punch guide sleeve

The punch guide sleeve as shown in figure 5, undeclared chamfer 1*45 degrees, unnoted fillet R2, materials GCr15, heat treatment requires HRC58~62. The punch guide sleeve in the mold structure played the following roles: (1) the punch guide sleeve extends a little beyond the tip, ensuring that before the semi-finished product is put into the die, it has already forced into the die cavity rough, which is used to avoid the punch guide sleeve partially slanting cut before entirely entrance. (2)The punch guide sleeve plays a role of guidance, which ensures coaxial requirements of the extrusion hole and ex-circle reach 0.1 degree. Since the inner hole is small, the head is cone, easily eccentric flow; pure reverse extrusion cannot guarantee the coaxial requirement of the contact finger. T he punch with the guide sleeve can ensure the requirements of it. (3) The punch guide sleeve plays a role of extruding punch when the backward extrusion finished, then it goes downward along with the hole punch to finish the Ø6 small platform extrusion forming. (4) The ex-circle of the punch guide sleeve is 1×45°,which can prevent the blank is so large that car will be stuffy, as well as releasing the excess metal to reach the design dimension when the blank volume is a little larger than the parts. (5) The punch guide sleeve ensures the extrusion release from the punch .In the interaction of the Belleville spring pressure and extrusion force, the punch guide sleeve retains the extrusion in the hollowing block and then push-out by the pull rod system.

It is simple and reliable by using the belleville spring to control the punch guide sleeve's movement. The application on the relatively smaller opening height of the punch is very convenient, because the belleville spring has the characteristics of big strength and compressible distance. It can not only ensure the mold, punch and extrusion part ejection, but also provide a lager pressure to force them into the blank.

Process experiment

The process flow diagram of this contact finger is as follows: cutting – cylinder deburring—smearing stearic acid zinc powder—extrusion forming—barrel burnishing—inspecting—warehousing.

Lubricant uses stearic acid zinc powder and the effect of lubrication is better when we use roller coated rather than use manual or simple rolling powder.

This method is feasible and can successfully produce qualified extruding contact finger, which has been proved by actual production, which is shown in the figure 6.

Figure 6: The part

Conclusions

(1)Using the forming technology of contact finger punching on extrusion is advanced feasible, and high efficient.
(2)It has reasonable extrusion process and high material utilization.
(3)The mould design is simple and practical. Besides it has reliable operation, long service life, and it can meet the requirement of mass production.

Keywords: Sweeteners, Qualitative Analysis, Micro-Laser Raman, Liquor and Wine

ABSTRACT. Efficient method was proposed for the qualitative detection of 6 illegal sweeteners in commercial liquor and wine by laser Raman spectroscopy. The method was based on the comparative analysis of Raman spectrogram of pure sweeteners and alcohol samples. For the 6 kinds of sweeteners tested, saccharin sodium, acesulfame potassium impurity and cyclamate, were present as additives in the samples. The results showed that the proposed method was fast and simple with high repeatability and sensitivity, and needed little samples and cost less.

Introduction

Laser Raman spectrometry, which uses laser as the powerful light sources, is theoretical based on Raman scattering. Raman spectrometry has been strongly applied in studying the composition and structure of material[1-5]. It was largely restricted due to the low sensitivity and weak signal processing techniques in the early stage of Raman. However, it has been quickly developed because of the introduction of laser, the improvement of weak signal processing techniques and the application of computers[6]. With the continuous development of Raman techniques, the application fields have been expanded from laboratory to storage and work site as a result of the appearance of portable Raman spectrometry, which is light and handy, more powerful and costs less on maintainance[6-8].

Micro-laser Raman spectrometry technology is a combination technology of microscopic analysis and Raman spectrum analysis. It adopts holographic CCD technology of high conversion efficiency, laser scanning confocal microscopy and low power laser in order to overcome the shortcomings of traditional laser Raman spectroscopy that had high powerful laser and low sensitivity. Micro-roman spectroscopy can do the in-situ testing, multiphase testing and microcosmic testing. It also has the advantages of high sensitivity, fast detecting, high spatial resolution and non-made sample technology, which allows it to achieve spectral information in different depth through point by point scanning[9].

Raman spectroscopy has been put into use in molecular biology[6], medicine[10], analytical chemistry[11] and nano-structure with the development of high sensitive analytical instruments, including in testing illegal and excess food additives[12]. Recently, Raman spectroscopy has been a significant instrument in qualitative determination of complex mixture[13]. The greatest difference of Raman spectroscopy from other analytical instruments is that it doesn't require dissolving or collecting samples, which simplifies the analysis procedure and shortens the time of analysis[1,12].

Sweetening agent is a kind of substance that can give food sweet taste and has high-sweetness but low heat and nutritional value. There are a large number of known intense sweeteners, but only

very few are allowed to be used in liquor and wine. The list of authorized artificial sweeteners varies from country to country[12]. It's reported that taking in high doses of artificial sweeteners can lead to the damage of liver and nervous system, even cancer[14]. However, many liquor-manufacturing enterprises add sweeteners into liquor to improve the taste regardless of the law, just because of the lack of detection methods of sweeteners in samples.

In this study, a rapid detection method of 6 illegal artificial sweeteners in liquor and wine was built by DXR micro-laser Raman, including Sodium cyclamate, Acesulfame potassium imputity, Aspartame, Saccharin sodium, stevioside and Neotame. The results show that the determination method is fast and simple with high repeatability and sensitivity and needs less samples and low costs.

Experimental

2.1 Instrumental

A DXR micro laser Raman spectrometer equipped with full scope grating, CCD array detector and auto-3D software was used to perform the measurements. The imaging software of OMNICTM AtlusTM was applied to collect and analyze imaging information.

Electronic balance (AR1140 from MET instruments) was used to weigh the solid sweeteners.

Electric heating water bath (DZKW-4) was employed to evaporate alcohols from liquid samples.

Ultrapure water polishing system (UPⅡ) was operated to obtain pure water.

2.2 Chemicals

Sodium cyclamate, Acesulfame potassium imputity, Aspartame, Saccharin sodium, stevioside and Neotame were of pharmacopoeial purity. The 10 kinds of liquor samples and 8 types of wine samples were bought at a local store. The liquid standard substance and samples were prepared using purified water.

2.3 Sample preparation

Sodium cyclamate, Acesulfame potassium imputity, Aspartame, Saccharin sodium, stevioside and Neotame were exactly weighed 50.08mg, 50.19mg, 50.23mg, 50.04mg, 50.03mg and 50.45mg in 6 volumetric flasks of 50mL respectively to prepare certain concentration solutions using pure water.

30mL of each samples were measured in 50mL beakers, and evaporated to a little solutions, then transferred to volumetric flasks of 5mL, volumed by pure water, then filtered through0.45μm filter membrane, contained in the vitric cuvette to be determined. In the full progress, alcohols were taken off from liquor and wine samples.

2.4 Determination of standard substances and samples

Solid reference sweeteners were tiled on the gold-plating glass sheet, which was put on the optical table of Raman spectrometer. Light should be hit exactly on the solid sweeteners by hand. The sample state would be clearly visible by coarse tuning and fine controlling to obtain Raman spectrograms of solid sweeteners. The wavelength of laser was 780nm under the power of 50mW, and the grating was 400gr/mm with 50μm slit.

The solutions contained in the vitric cuvette were put on the optical table, respectively and detected under the same conditions in the same way. The obtained Raman spectrograms were compared with the Raman spectrograms of solid reference sweeteners to confirm whether there was sweetener in liquor and wine samples.

Results and discussion

The qualitative analysis of sweeteners shows that 3 kinds of sweeteners, saccharin sodium, acesulfame potassium impurity and cyclamate, were present as additives. The Raman spectra of commercial samples in liquor and wine and the spectra of pure sweeteners (reference substance) are shown in the following figure.

3.1 Reference analysis

The spectrum of pure Sodium cyclamate, Acesulfame potassium imputity, Aspartame, Saccharin sodium, stevioside and Neotame, the Raman shift of which was revealed obviously, were shown in Fig.1-6. The 3075 cm^{-1} and 3058 cm^{-1} of Raman spectra were strongly expressed in saccharin sodium, aspartame and neotame, because of the stretching vibration of C-H in aromatic compound, and the signal of 1598cm^{-1} was powerful because of C=C. The signals of 1295 cm^{-1},1162 cm^{-1}, 1147 cm^{-1}, 1062 cm^{-1} and 1036 cm^{-1}were obvious in acesulfame potassium impurity, cyclamate and saccharin sodium owing to the structure of SO_2. And also there existed 1023 cm^{-1}and705 cm^{-1}(because of C=S) in saccharin sodium and 2968$cm^{-1}$and 2853 cm^{-1}(because of CH_2) in cyclamate and stevioside.

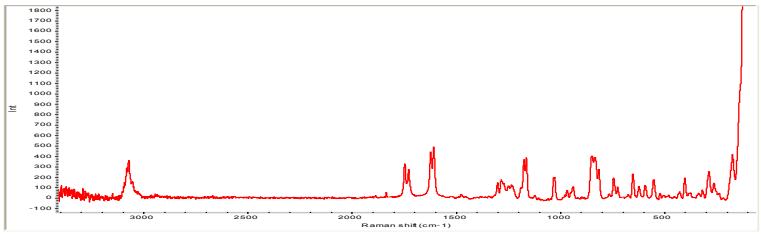

Fig.1 Raman spectrum of Sodium cyclamate (reference substance)

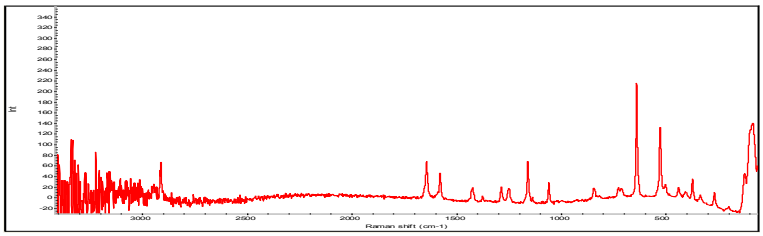

Fig.2 Raman spectrum of Acesulfame (reference substance)

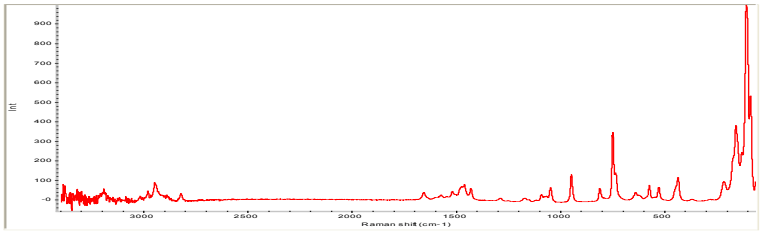

Fig.3 Raman spectrum of Aspartame (reference substance)

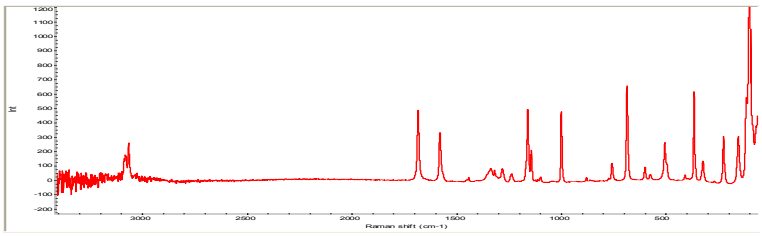

Fig.4 Raman spectrum of saccharin sodium (reference substance)

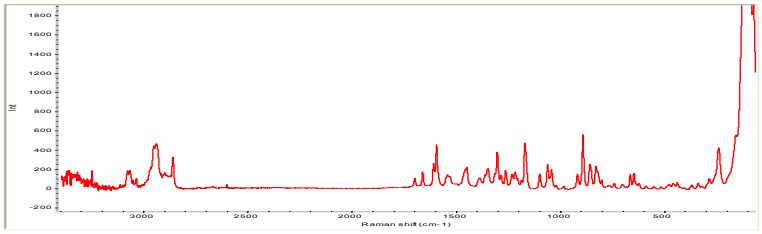

Fig.5 Raman spectrum of stevioside (reference substance)

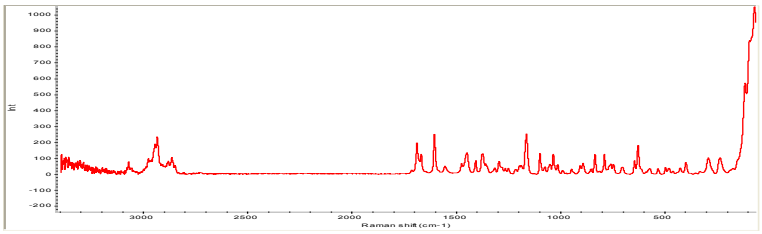

Fig.6 Raman spectrum of Neotame (reference substance)

3.2 The comparison of Raman spectra of reference substance and Liquor samples

The spectrum band width, the shift of spectral peak and the characteristic of peak shape is the obvious recognition information. According to the comparison of the Raman spectra of samples with that of pure sweeteners in the following figure, saccharin, sodium cyclamate, acesulfame were found in liquor and wine samples.

3.2.1 The comparison of Raman spectra of sodium cyclamate

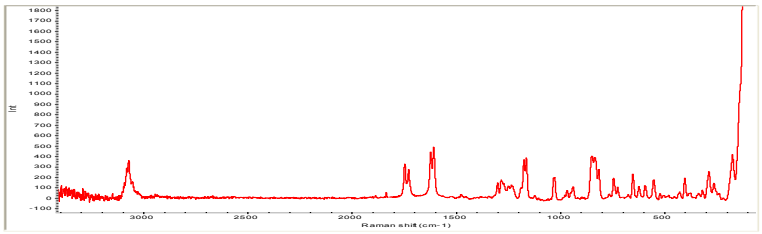

Fig.1 Raman spectrum of Sodium cyclamate (reference substance)

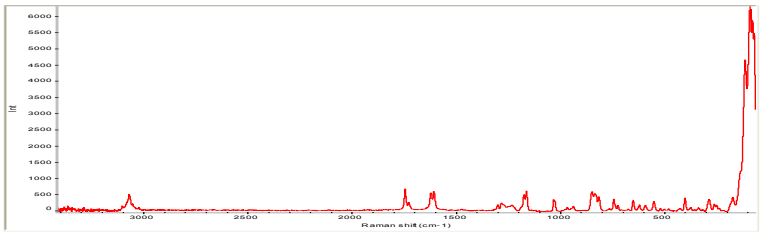

Fig.7 Raman spectrum of Liquor samples

According to the contrast of the Raman spectrun of reference(fig.1) and liquor samples(fig.7) of sodium cyclamate, the signals of 1295 cm^{-1}, 1162 cm^{-1}, 1147 cm^{-1}, 1062 cm^{-1} and 1036 cm^{-1} were both obvious because of the existence of SO_2. Also, there existed the signal of 2968cm^{-1} and 2853 cm^{-1} owing to the structure of CH_2. Therefore, Sodium cyclamate was obviously present in liquor samples, when compared the two Raman spectrums.

3.2.2 The comparison of Raman spectra of acesulfame

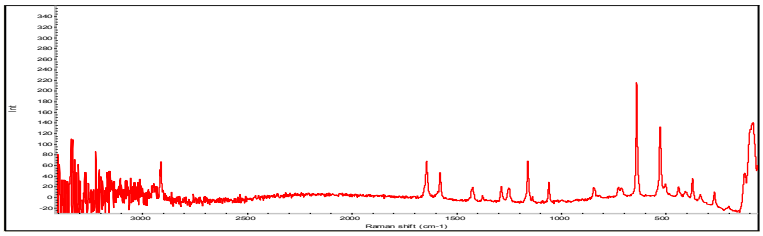

Fig.2 Raman spectrum of Acesulfame (reference substance)

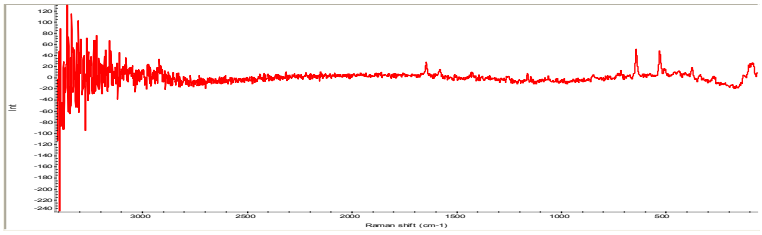

Fig.8 Raman spectrum of Liquor samples

The signals of 3075 cm^{-1} and 3058 cm^{-1} were strongly expressed in fig.2 and fig.8 because of the stretching vibration of C-H in aromatic compound, and the signal of 1598cm^{-1} was powerful because of C=C. Owing to the structure of SO_2, the signals of 1295 cm^{-1}, 1162 cm^{-1}, 1147 cm^{-1}, 1062 cm^{-1} and 1036 cm^{-1}were presented obviously. According to the comparative analysis of the Raman spectrum of acesulfame (Fig.2) and liquor samples (Fig.8), there exactly existed acesulfame in liquor samples.

3.2.3 The comparison of Raman spectra of saccharin sodium

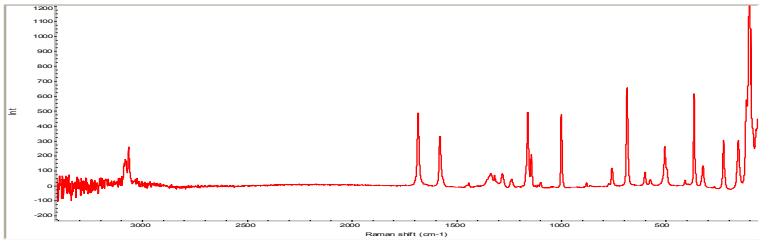

Fig.4 Raman spectra of saccharin sodium (reference substance)

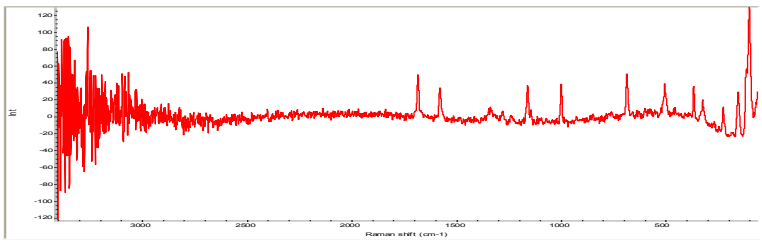

Fig.9 Raman spectra of liquor samples

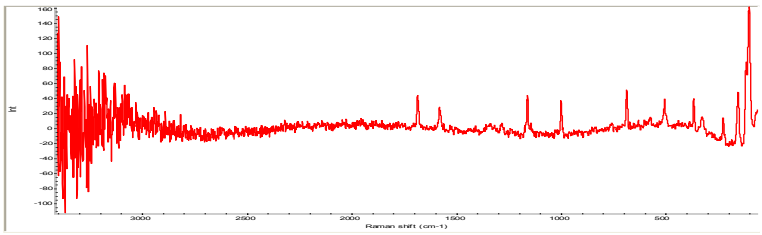

Fig.10 Raman spectra of wine samples

Based on the contrast of Raman spectra of liquor samples, wine samples and reference substance, there existed saccharin sodium in liquor samples and wine samples, respectively, according to the reasons below. Because of the stretching vibration of C-H and C=C in aromatic compound, the signals of 3075 cm^{-1} and 3058 cm^{-1} ,1598cm^{-1}were strongly conveyed respectively in fig.4, fig.9 and fig.10. And also there existed the signal of 1023 cm^{-1}and705 cm^{-1}(because of C=S) in saccharin sodium.

Conclusions

An method of rapid detection for sweeteners qualitative analysis via micro-laser Raman were presented in this paper. The proposed method can be a convenient alternative to the standard procedures of sweeteners qualitative determination[1]. In the 6 kinds of detected sweeteners, saccharin sodium, acesulfame potassium impurity and cyclamate were present as additives in liquor and wine samples. However there still remains the challenge of developing stable , reliable methods for the determination of artificial sweeteners in different kinds of liquor and wine. Analytical methods are essential to meet the needs of growing markets in quality control and consumer safety[12].

Keywords: reflectivity, microwave absorption, Ni-Fe fiber, stainless steel filament

Abstract. In order to develop flexible absorption fabric and study the effects of specifications on absorption properties, two-layer laminated fabrics were designed according to thickness matching and impedance matching. Stainless steel core-spun yarn fabrics were used as first layer which easily realized matching to the free space, Ni-Fe fiber consisted of second layer because its strong dielectric loss and magnetic loss. The reflectivity of fabrics were measured by the means of "arch testing method" in the range from 2~18 GHz. The results showed that the reflectivities of laminated fabrics can below -20 dB and the bandwidth <-10dB can reach 3.88 GHz with the change of fabric specifications**.**

Introduction

The wide application of electronic technology which has significant improved the quality of people's work and life, also produced a lot of negative effects at the same time, leading to electromagnetic pollution[1-3]. Absorbing material could transform the electromagnetic wave into other state of energy, not only can realize the stealth of aircraft, but also can use in electromagnetic pollution prevention which gained growing concern[4-5].

With technology development, metal fiber in textile level can be applied to the exploitation of flexible absorbing fabric because its anisotropic properties, and can be adjusted by its aspect ratio to achieve high absorption efficiency in wide range[6-7].

The main aim of this study is to optimum the design of flexible microwave absorption fabrics, which are fabricated by weaving technology with stainless steel filament and Ni-Fe fiber. And gain the good absorbing performances by optimizing fabric specifications.

Experiment

2.1 Theoretical background. Due to Ni-Fe fiber's low impedance, the difference between fabric wave impedance and free space impedance was larger when Ni-Fe fiber fabric as surface layer, and the reflection was high, unless the geometric structure designed specially such as pyramid. So, it needed to set a wave impedance between Ni-Fe fiber fabric and free space making the more electromagnetic wave into the absorption material.

$$Z_0 = \sqrt{\frac{\mu_0}{\varepsilon_0}} = 120\pi\Omega = 377\Omega \tag{1}$$

where Z_0 was the characteristic impedance of free space,

$$R = \frac{Z_L - Z_0}{Z_L + Z_0} \tag{2}$$

If the reflection coefficient was zero, medium impedance Z_L match with the free space wave impedance Z_0 was needed.

$Z_0 = \sqrt{\mu_0/\varepsilon_0}$,

$Z = \sqrt{\mu_r\mu_0/\varepsilon_r\varepsilon_0}$

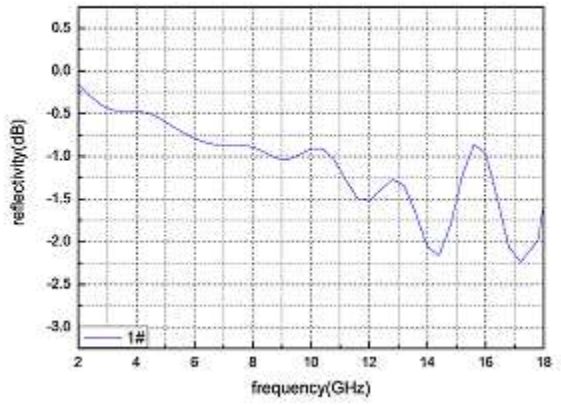
Where Z was absorbing interface wave impedance, μ_0 and ε_0 were magnetic permeability and dielectric constant of free space, μ_r and ε_r were relative permeability and relative dielectric constant. By the formula (2), it was easy to calculate ideal impedance matching conditions:

$\mu' = \varepsilon'$, $\mu'' = \varepsilon''$

Stainless steel filament fiber conducted electricity well, resistivity was only $10^{-6}\ \Omega \cdot$ cm, had been widely used in electromagnetic radiation shield fabric. Stainless steel filament in the center of core yarn reduced the overall conductivity of fabric, which was conductive to achieve impedance matching and reduce electromagnetic reflections. Ni-Fe fiber blended fabric was used as the second layer with a strong dielectric loss and magnetic loss characteristics.

2.2 Measurement. GJB2038-94 wave absorbing material reflectivity test method 102"RAM reflectivity arch testing method" was used. Microwave scanning signal source was HP83751B and obtained the results by HP8757E network analyzer in the frequency range of 2~18GHz.

2.3 Single layer fabrics design and test. Single layer Ni-Fe fiber and stainless steel filament fabrics were fabricated and tested respectively, the results were shown in Fig.1 and Fig.2.



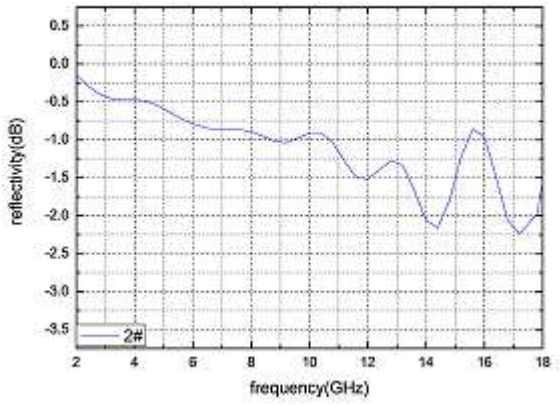


Fig.1 The reflectivity of stainless steel core-spun fabric Fig.2 The reflectivity of Ni-Fe fiber fabric

As shown in Fig.1 and Fig.2. , the reflectivity of designed single-layer were poor, because it was too thin to adjust electromagnetic parameters of single-layer fabric, difficult to meet the impedance matching.

2.4 Double layer fabrics design and test. According to absorbing material design principle, the single components was difficult to fully meet the "thin, light, wide, strong" and other requirements, double layer two-component absorption fabrics were designed. Ni-Fe fiber consisted of second layer due to its strong dielectric loss and magnetic loss, stainless steel core-spun yarn made up of first layer which easily realized matching to the free space.

In order to find the optimal laminated fabric, orthogonal experimental with three factors and three levels of the fabric specifications was shown in Tab.1. SU111-automatic sample loom was applied to fabricate 4 kinds of fabrics, the length and width were both of 30cm, the test results of absorbing properties were shown in Tab.2. Only one type of Ni-Fe fiber blended fabric was prepared as the underlayer, which blending ratio, warp density and weft yarn were 8.34%, 230/10cm and 18/10cm respectively.

Tab.1 Laminated fabric design

Levels	A The yarn core diameter （μm）	B warp density Pj(/10cm)	C Weft density Pw(/10cm)
1	18	260	210
2	28	280	230
3	34	300	250

Tab.2 The absorbing properties test

Number	The yarn core diameter（μm）	Pj (/10cm)	Pw (/10cm)	absorption peaks（GHz）	Minimum reflectivity R_L (dB)	bandwidth <-10dB f_w (GHz)
1	18	260	210	10.08	-13.68	2.02
2	18	280	230	11.24	-16.74	2.55
3	18	300	250	11.86	-14.50	2.35
4	28	260	230	14.56	-19.59	3.59
5	28	280	250	7.32	-28.50	4.10
6	28	300	210	16.32	-22.33	3.85
7	34	260	250	13.40	-20.02	3.88
8	34	280	210	7.48	-22.56	3.60
9	34	300	230	10.68	-23.12	3.16

Results and discussions

As shown in Tab.2, the optimal reflectivity of laminated fabrics can reach -21.10 dB and the bandwidth <-10dB was 3.08. The test results were studied with variance analysis method and shown in Tab.3. From the analysis, we can obtain that the yarn core diameter had significant influence on absorbing performance, the warp density and weft density also had effects on it.

Tab.3 The variance analysis of absorbing property of double composite fabric

（a）The variance analysis of minimum reflectivity

Variation source	deviation quadratic sum	freedom	variance	F	Fa	significance
core diameter	143.9606	2	71.980	13.9883	F0.05（2,6）=5.14335	**
Pj	61.1052	2	30.553	5.9375	F0.01（2,6）=10.9248	*
Pw	107.9054	2	53.953	10.485		*
null columns e*	26.0931	2	13.047	2.5354		
error	30.8746	6	5.146			
total	369.9389	8				

（b）The variance analysis of bandwidth of reflectivity less than -10dB

Variation source	deviation quadratic sum	freedom	variance	F	Fa	significance
core diameter	4.0178	2	2.009	23.260	F0.05（2,6）=5.14335	**
Pj	1.0592	2	0.530	6.132	F0.01（2,6）=10.9248	*
Pw	1.3072	2	0.654	7.568		*
null columns e*	0.3584	2	0.179	2.075		
error	0.5182	6	0.0864			
total	7.2608	8				

Conclusions

Different combinations of laminated fabrics were compared to find the main affect factors of absorbing performance. As the experimental results shown, the factors of yarn core diameter had significant effects, warp density P_j and weft density P_w both also had significant effects on absorbing performances. With optimized specifications, the fabrics can obtain good absorbing performances with a low areal density, wideband and thin characters.

Research new waterproof agent of the particleboard

Zhao yan

Beihua University, Jilin, 1320132

Keywords: Non wood shavings; Molded sheet; Process parameters; Mechanical properties

Abstract: Modern society,with the rapid development of economy,people living standard increasing, for the plate demand continues to grow. Because the forest resources dwindling, To make full use of waste bagasse, corn straw and non wood fiber materials to produce an artificial plate material instead of wood man-made board has be imperative.Corn straw shavings can realize the recycling of waste materials, bring the economic value, so this topic with corn straw shavings as raw material, in the laboratory preparation of melamine resin adhesive, pressing flake molded sheet.Melamine plastic using M (melamine):U (urea) :F (formaldehyde) =1∶0.6∶2.5, adhesive solid content is 54%, the sizing, hot pressing temperature, hot pressing time as three factors orthogonal experiment, pressed sheet. On the plate thickness swelling, internal bond strength and surface plate bending strength test, on the analysis and summarization of results, the optimum process parameters: sizing quantity20%, temperature 150 ˚C, hot pressing time25min. The corresponding optimum mechanical properties: the absorbing water thickness expansion rate (2H) 9.76%, inner strength, bend strength of17.49Mpa,0.45MPa.

Introduction

In particleboard production process, in order to enhance the waterproof performance particleboard, widely used in the production method of a waterproofing agent was added to the plate. Currently the most used is water repellent wax emulsion. The paraffin emulsion quality directly affect the waterproof performance. So many domestic researchers waterproofing agent on paraffin emulsion stability, water resistance, etc. conducted extensive research.

For a long time, particleboard production is mainly used as a waterproofing agent paraffin, particleboard production of basic addition method using molten paraffin, particleboard production in the use of paraffin emulsion. Particleboard using conventional solid wax emulsion has a low content (usually less than 30%) and high moisture content.

Shavings molded integrally molded flat this subject, the package can be avoided, in order to enhance the tear waterproof particleboard, loaded material, adding new water repellent - paraffin. The product board formation, its carrying capacity in line with national standards, fairly flat with ordinary wood. Due to the production process particleboard center temperature exceeds 105 ˚C, and the final moisture content of the product is less than 9%, so the product can resist insects and decay fungi erosion, without further processing can be achieved by any other international organization Plant Protection Convention at No. 15, the international standard for phytosanitary measures enacted in 2002——"Wood Packaging Material in International Trade Management Guidelines" (International Standard for Phytosanitary Measures 15, referred to as ISPM 15) in particleboard materials for export quarantine requirements [1-6].

Physical and mechanical properties of this material particleboard meet structural requirements; smooth surface, excellent performance, environmental protection, fumigation, the economy, the furniture market is to meet the needs of the most ideal products [7]:

Experiment

2.1 Physical and chemical properties of the test urea-formaldehyde glue

2.1.1Viscosity measurement

The Tu 4 cup viscometer cleaning and keep it dry, adjust the horizontal screw in a horizontal position so viscometer, viscosity cup placed beneath 250ml beaker, hand blocked drain holes, filling the glue viscosity cup, with a glass rod the design of bubbles and excess scraped into the groove, and then

release your finger out of, and immediately start the stopwatch, the time when the entire sample flowing from the drain mouth is coated specimen 4 cup measuring viscosity. The difference between the two measured values should not exceed 3% of the average.

2.1.2 Determination of solid content

Take three glass dish, washed with water and put it into the oven removed after drying, labeling, pick a good analytical balance to be cleared in advance, the glass dish on the analytical balance, note the glass dish weight after cleared; taken with plastic dropper dropping resin, drop by drop on a glass dish, when the value reaches a certain date, note the weight of the resin and the glass dish, and then the weight of the glass dish, and then put the glass dish into the constant temperature of the drying oven 100 ˚C, after about three hours to remove, removed after cooling in the oven for some time, and then weighed on an analytical balance, note values. Averaging the three values, namely the solid content of the melamine resin.[8]

Tab1 Solid content measurement data

No.	m1（g）	m2（g）	m（g）	R(%)
1	13.9747	15.0630	14.5640	54.50
2	15.0018	16.1850	15.6390	53.85
3	12.6683	13.7478	13.2466	53.57

Therefore, the solids content of urea-formaldehyde glue: $R=(R_1+R_2+R_3)/3=53.97\%$。

2.2 Orthogonal design

In the packing sheet repression experiment, due to take into account the amount of glue, pressing temperature, pressing time three factors, if we make a three experimental factors and three levels, according to a comprehensive test requirements shall be 3×3 = 27 combination of experimental and has not yet considered the number of repetitions of each combination, and therefore adopt high efficiency, quick and economical method of orthogonal experimental design to volume sizing, pressing temperature, pressing time for three factors are the main factors, 3 levels L9 (3^4) orthogonal experiment, bit-level factors are shown in Table 2-2.

Tab2 Orthogonal table

Test No.	Factor

1	10	130	4
2	10	140	5
3	10	150	6
4	15	130	5
5	15	140	6
6	15	150	4
7	20	130	6
8	20	140	4
9	20	150	5

Determination of thickness swelling of particleboard

3.1 Experimental principle, instruments, methods

(1) Principle: Make sure the specimen before absorbing increased thickness than the thickness of the absorbent.

(2) laboratory equipment: water bath pot calipers

(3) Specimen size: 50×50mm

(4) experimental procedures and methods:

(a) measuring the center of the test piece thickness h1, accurate to 0.01mm;

(b) the specimen placed on the shelf, immersed in water for 20±2˚C, so that the specimen surface is higher than 2cm, all specimens that do not float on water, do not sink to the bottom, either free expansion of the specimen;

(c) soaking two hours, remove the specimen, and then measuring the thickness of the original measuring point h_2;

$$D = \frac{h_2 - h_1}{h_1} \times 100$$

Where: D - specimen water swelling (%)

h_1 - before soaking the specimen thickness (mm);

h_2 - after soaking the specimen thickness (mm)

3.2 Experimental results and analysis

The results are shown in Table 3-1, where α = 0.05, F0.1 (2,2) = 4.460. Response curve shown in Figure 3-1.

Tab. 3 Intuitive adsorption expanding of orthogonal table

Test No.	Factor			Adsorption expanding/%

K1j	8.25	8.06	8.07	
K2j	7.96	7.88	7.98	
K3j	7.76	8.04	7.92	
Rj	1.46	0.56	0.44	

3.3 Experimental results and analysis

Table derived from visual analysis, static bending strength of the primary to the secondary factors as: the amount of glue, pressing temperature, pressing time. MOR optimal solution is: $A_3B_2C_2$, namely resin content of 20%, hot temperature of 140 ˚C, hot pressing time was 25min.[9-10]

ANOVA table can be drawn glue content, pressing time, pressing temperature were the significant factors. Effect curves can be drawn, the greater the amount of sizing, static bending strength increases; pressing temperature of 140 ˚C, hot pressing time 25min, the MOR maximum value. Pressing higher the temperature, the longer the pressing time, pallet board brittle, its bending strength decreases, the same as the above results and analysis. Therefore, the optimal process parameters $A_3B_2C_2$, namely resin content of 20%, hot temperature of 140 ˚C, hot pressing time was 20min.

According to GB / T 4897.1-2003, structural use in humid conditions required by board, the board thickness of 13 ~ 16mm, water expansion ratio less than or equal 8.0, because this time the water swelling of 7.40%, thus reaching the national standard.

Conclusion

Since the majority of particleboard in furniture applications, so it is important waterproof particleboard, adding waterproofing agent affect particleboard water swelling. Of water swelling, the resin content of 20%, pressing temperature 140 ˚C, when the pressing time 20min, its value reaches a minimum. From the table, when pressed to process parameters A3B2C2 particleboard, its water swelling, internal bond strength have reached the national standard.

In summary, pressed particleboard optimal process parameters A3B2C2, namely resin content of 20%, hot temperature of 140 ˚C, water repellent 6%. Mechanical properties of the corresponding value: 7.40% water swelling, internal bond strength 0.46MPa.

Keywords: albumin dialysis, artificial liver support system, protein-bound toxin, mass transfer

Abstract: The open-loop albumin dialysis mode (OLM) is usually used to remove protein-bound toxins from artificial liver support systems. However, there is still interest in closed-loop albumin dialysis mode (CLM) because this mode could enable the regeneration and reuse of albumin and minimize the physical size of liver support systems. In this paper, the two dialysis modes were theoretically compared under various theoretical conditions. Our results show that at the beginning of the dialysis period, in terms of detoxification efficiency, CLM is better. As the molar ratio of toxin to albumin in the blood (RTA) decreases, the overall performance of CLM approaches that of OLM in 4-hour dialysis. In certain cases, the clearance of albumin-bound toxins by CLM could be as effective as that by OLM; occasionally, CLM is even more effective.

Introduction

Liver failure, a common and serious public health problem, causes high mortality all over the world [1]. A shortage of donor organs is prompting the development of various extracorporeal artificial liver support systems [2-4].Currently, albumin dialysis is used in liver support systems, starting a new era of the treatment of liver failure [5].

Albumin dialysis is a detoxifying method that involves a hemodialysis system in which albumin solution is used as dialysate [6]. In the dialysis process, free toxins unbound to albumin are transferred out of fibers because of concentration and pressure differences across the fiber membrane, bind to albumin on the dialysate side and are eventually removed. Usually, there are two operating modes: one is called open-loop dialysis mode (OLM) [7, 8], the other is closed-loop dialysis mode (CLM) [9, 10]. For OLM, it requires a large volume of dialysate and is also not convenient for regenerating albumin. Therefore, there is still interest in closed-loop mode (CLM) for systems removing toxins only by albumin [11]. CLM is considered to be a possible way to help to reduce the use of dialysate (i.e., increasing the portability of devices) and to improve the regeneration of albumin (i.e., reducing the treatment cost), but there are still certain issues that need to be resolved in advance. The first issue is what factors affect the efficiency of CLM, the second is how to obtain a higher efficiency for CLM in practice, and the third is whether the efficiency of CLM is better than that of OLM.

In this work, CLM in albumin dialysis was investigated and then compared with OLM in term of their efficiency in removing albumin-bound toxins. The factors affecting the efficiency of CLM are also discussed. The results of this study are of great significance to the design of a portable extracorporeal artificial liver system.

Theory

In the solution, the concentration of the toxin is equal to the sum of the free toxin concentration and the albumin-bound toxin concentration. Under the condition of equilibrium, there exists an equilibrium binding constant k_B (l/mol) as follows [12]:

$$k_B = C_{a\cdot s} / (C_s \cdot C_a) \tag{1}$$

where the subscripts *a·s, s,* and *a* denote the albumin-toxin compound, the free toxin, and the free albumin, respectively; k_B (l/mol) the equilibrium constant; and C (mol/l) the concentration. For a given equilibrium constant, the above binding kinetic can be used to obtain the relationship of the free toxin concentration and the total toxin concentration.

According to the literature [13, 14], the equations for calculating the local ultrafiltration are:

$$dP_b / dz = -8\mu_b \cdot Q_b / (n\pi \cdot r_i^4) \tag{2}$$

$$dP_d / dz = 8\mu_d (R_M + nr_o)^2 \cdot Q_d / [\pi (R_M{}^2 - nr_o{}^2)^3] \tag{3}$$

$$dQ_b / dz = dQ_d / dz = -J_v \tag{4}$$

$$J_v = 2n\pi r_i \cdot L_P \cdot (P_b - P_d) \tag{5}$$

where the subscripts *b* and *d* denote the blood and dialysate sides, respectively; r_i (μm) the inner radius of hollow fibers; r_o (μm) the outer radius of fibers; Q (ml/min) the flow rate; P (P_a) the pressure;μ (N·s/m^2) the viscosity; L_P (cm/s/P_a)the hydraulic permeability; R_M (cm) the inner radius of the module; n the number of fibers; and J_v (ml/min/cm) the local ultrafiltration rate.

According to mass conservation, the mass transport of free toxins along the axial direction, considering the effect of local ultrafiltration, can be described as follows [15]:

$$d(Q_b \cdot C_{s,tl,b}) / dz = d(Q_d \cdot C_{s,tl,d}) / dz = [J_v (1-\sigma) f - kA / L] \cdot [C_{s,b} - C_{s,d}] - J_v (1-\sigma) C_{s,b} \tag{6}$$

where the subscript *tl* indicates the total amount; σ the toxin reflection coefficient; k (cm/min) the mass transfer coefficient; L (cm) the effective length of fibers; A (cm^2) the total membrane area and f a function of the Pe number: $f = 1/Pe\text{-}1/(e^{Pe}\text{-}1)$ and $Pe = Q_f \cdot (1\text{-}\sigma)/kA$ [15].

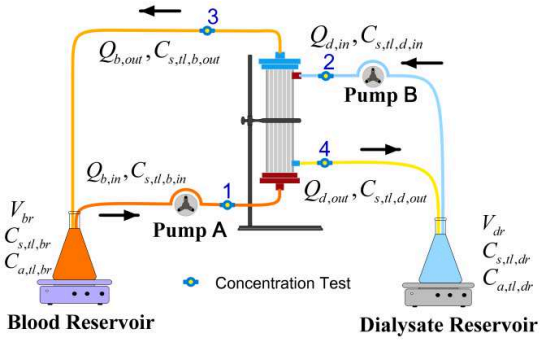

Fig. 1 Schematic of albumin dialysis in CLM

In the CLM experiment shown in Fig.1, the total toxin and albumin concentrations in blood and dialysate reservoirs are functions of dialysis time and can be written as

$$d(C_{s,tl,br} \cdot V_{br}) / dt = C_{s,tl,b,out} \cdot Q_{b,out} - C_{s,tl,b,in} \cdot Q_{b,in} \tag{7}$$

$$d(C_{s,tl,dr} \cdot V_{dr}) / dt = C_{s,tl,d,out} \cdot Q_{d,out} - C_{s,tl,d,in} \cdot Q_{d,in} \tag{8}$$

where the subscripts *br* and *dr* denote the blood and dialysate reservoirs, respectively; the subscripts *in* and *out* denote the inlet and outlet of a reservoir, respectively; and V (ml) is the solution volume.

In simulation, equations were solved by Runge-Kutta, and a regula-falsi method was used, according to the literature [13, 14]. A mesh refinement analysis was performed so that the error caused by the grids was less than 0.5%.

Results and Discussion

The Effect of Albumin Concentrations in CLM. In OLM, the concentration of albumin in the dialysate is low, and the volume of the dialysate is large; therefore, albumin regeneration is not convenient. However, CLM does not have such draw back. Fig. 2 shows the effect of albumin concentrations in dialysate on the clearance of toxins for a certain mass of albumin. If the albumin concentration is higher, more free toxins in dialysate will be bound to albumin molecules in dialysate, generating a higher driving force for the transport of free toxins from the blood side to the dialysate side. Therefore, a highly concentrated albumin dialysate results in a high toxin clearance.

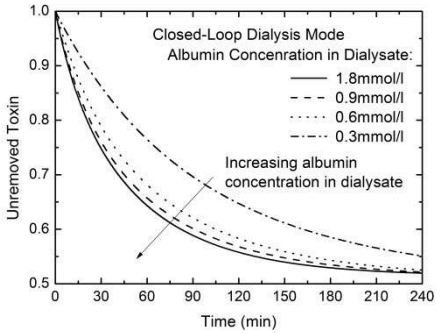

Fig.2 Effect of albumin concentrations in dialysate on toxin (k_B= 10^5 l/mol) removal in CLM with a fixed mass of albumin (1.8 mol) at Q_d= 30 ml/min, Q_b = 200 ml/min, and Q_f= 0 ml/min. Initial conditions: $V_{br}|_{t=0}$ = 3000 ml, $C_{a,tl,br}|_{t=0}$ = 0.6 mmol/l, $C_{s,tl,br}|_{t=0}$ = 0.684 mmol/l.

Comparison of Detoxification Efficiencies. In this work, we performed a comparison between CLM and OLM. To facilitate the comparison, the amounts of albumin used in both CLM and OLM were assumed to be equal, and the dialysis time was set at 4 hours. Our results show that the detoxification efficiency of CLM is higher than in OLM at the beginning and lower in the late stage (Fig. 3). If the molar ratio of toxin to albumin in the blood (λ) become smaller (Fig. 3 A vs. B and Fig.3 C vs. D), the difference in detoxification efficiency between CLM and OLM in the late stage could decrease. Based on the above analysis, there is possibly a turning point for λ for a certain toxin, under which CLM could be more effective and over which OLM could be more effective during 4 hours of dialysis. Both CLM and OLM have their own advantages and disadvantages; however, for the sake of albumin cost and the convenience of albumin regeneration, CLM is highly recommended.

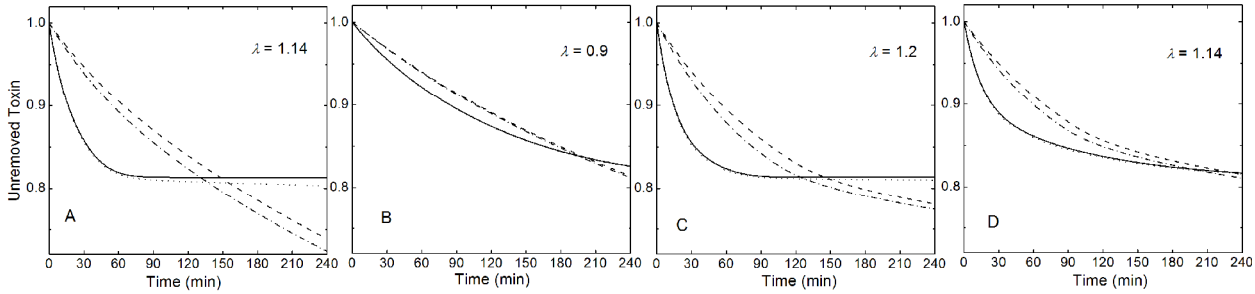

Fig. 3 Comparison of clearances for a toxin between CLM and OLM at Q_b = 200 ml/min(A, B: k_B = 10^6 l/mol; C,D: k_B = 10^7 l/mol)(Initial conditions: $V_{br}|_{t=0}$ = 3000 ml, $C_{a,tl,br}|_{t=0}$ = 0.6 mmol/l, $C_{s,tl,br}|_{t=0}$ = 0.684 mmol/l. In CLM, $V_{dr}|_{t=0}$ = 500 ml, $C_{a,tl,dr}|_{t=0}$ = 0.864 mmol/l, Q_d= 200 ml/min. In OLM, $C_{a,tl,dr}|_{t=0}$ = 0.06 mmol/l, Qd = 30 ml/min). Solid line: CLM, Q_f= 0 ml/min; dot line: CLM, Q_f= 10 ml/min; dash line: OLM, Q_f= 0 ml/min; dash-dot line: OLM, Q_f=10 ml/min.

Conclusions

The need for a large quantity of expensive albumin in albumin dialysis motivated us to find not only a more efficient but also a more economical mode of dialysis operation for artificial liver systems. In this work, the detoxification efficiencies for toxins in the blood in both CLM and OLM were compared theoretically. Our results show that for a fixed mass of albumin in CLM, a higher albumin concentration in the dialysate is helpful to remove toxins from the blood. As the molar ratio of toxin to albumin in the blood decreases, the overall performance of CLM approaches that of OLM in 4-hour dialysis. In certain cases, the clearance of toxins in CLM could be as effective as in OLM; occasionally, this clearance could be even better. Both CLM and OLM have their own advantages and disadvantages; however, due to the cost of albumin and the convenience of albumin regeneration, CLM is highly recommended. In addition, because a concentrated albumin solution is used, the volume of the dialysate is reduced, which will enable significant improvements in the design of portable extracorporeal liver supporting systems.

The research of high internal pressure forming process of variable cross-section elliptical tube

Jintao Wang, Jian Li

School of materials, Northwestern Polytechnical University, Shaanxi Xi' an China

15362282@qq.com

Keywords: TA2; high internal pressure forming; variable cross-section elliptical tube; finite element method

Abstract: Based on the ETA/DYNAFORM elastic-plastic explicit finite element platform, the finite element model of high internal pressure forming was established and the forming process was simulated. Through simulating, the forming process was researched. The distribution law of wall thickness, stress and strain was revealed in forming process. The results show that: the thinnest wall lies in the middle of forming part, and the thickest wall in the end of feeding areas. Both maximum equivalent stress and minimum equivalent strain lie in the forming fillet of the large elliptical cross-section. These play an important guiding significance on molding process.

Introduction

As a kind of advanced no-cutting plastic forming technology, high internal pressure forming has take more and more attention and development [1]. In recent years, Germany, the United States and Japan use the forming technology for the manufacture of machine parts, the forming pressure is generally greater than 500 MPa, sometimes more than 1, 000 MPa[2] .At present, it has been used in automobile, aviation and other machine manufacture field of practical production[3]. But on the other hand, it is a relatively new industry technology. Some key technical problems, such as forming mechanism of complex parts, have not been resolved and need further research. So, the research of high internal pressure forming technology has an important practical significance [4-7].

High internal pressure forming of variable cross-section elliptical tube is a complex multi-factor coupling deformation process ,including material, mould, process parameters, etc[5-9].In this paper, the internal high pressure forming process of varying cross-section elliptical tube is studied though the theoretical analysis and finite element numerical simulation. The forming law and deformation mechanism is revealed through stress and strain distribution, and laws of wall thickness development in the process of forming. These provide certain theoretical basis for the establishment of the forming process, thus reducing the time and cost for high internal pressure forming technology research and development, and increasing productivity and utilization rate of materials.

Build models

DYNAFORM pretreatment provides with modeling function. But because of its low efficiency, 3D modeling software UG is used to establish the geometric model. Here we only need to build mould, tube billet and punch on both ends. After building up the mold, output of IGES format file, and then input it to the former processor of DYNAFORM software. Because high internal pressure forming simulation usually adopt thin shell grid cell, block model is used in modeling. As shown in figure 1 is the geometry model.

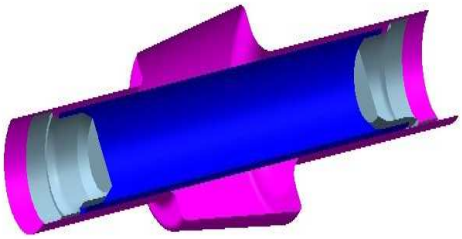

Figure1 Geometrical model

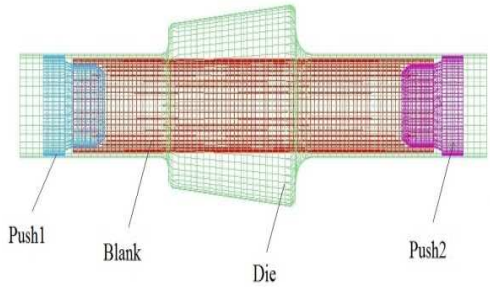

Figure2 The finite element model

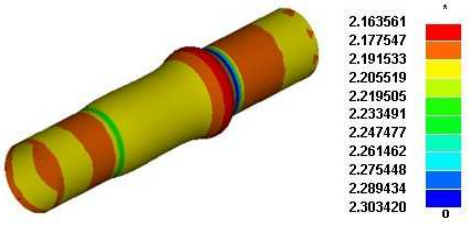
In the EAT/DYNAFORM MESH generator, TOOL MESH is chose to divide grid for die and punch, because this type of grid has the highest fitting precision to mold. PART MESH is chose to mesh for the pipe, as it can obtain more uniform fine grid, which is convenient to subsequent calculation. In the process of meshing, try to ensure that all units are quadrilateral element, and make the triangle element distribution on the edge, so that the accuracy of the calculation can be ensured .Finite element model is shown in figure 2, the tube billet is BT shell element and other tools are treated as rigid body unit.

The simulation results and analysis

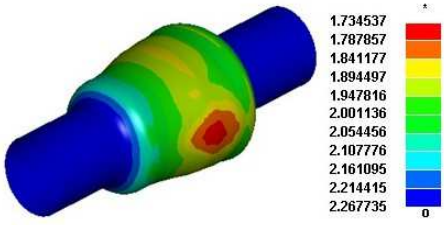
3.1 The variation law of wall thickness in the forming process

In the process of pipe high internal pressure forming, the stress distribution of each part is different. It will change with the increase of the swelling degree. Wall thickness distribution is an important indicator of internal high-pressure forming.

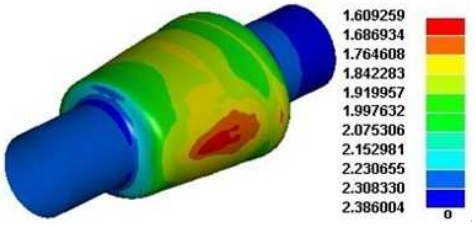
Figure 3 shows the distribution of wall thickness in four forming stages. As we can see: The wall thickness mainly thin in 0.04 ~ 0.05 s, because during this time, the materials of transition fillet accumulate, which causes materials flow into the mold cavity difficulty. At the end of the forming, the wall thickness of forming central area is thinnest, and the more to the sides, the thicker the wall thickness is, because internal pressure increases faster than the feeding speed; the feeding zone have a thickening , this is because of the friction between pipe material and mold. The wall thickness of large elliptical cross- section feeding area thickens bigger than small.



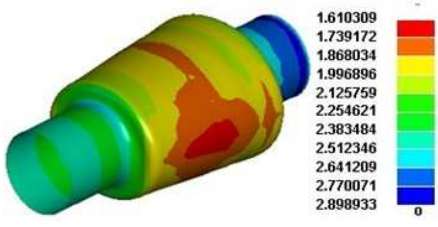
a) forming time 0.019s



b) forming time 0.04s



c) forming time 0.05s

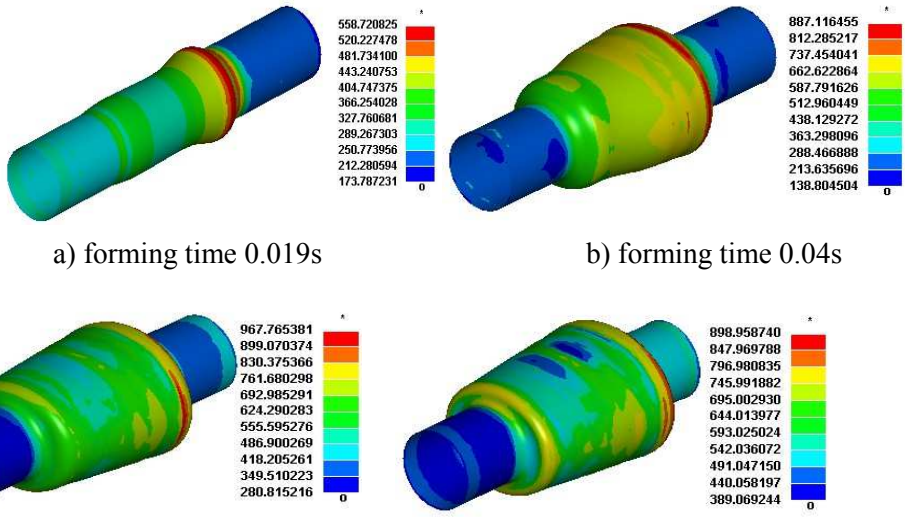


d) forming time 0.06s

Figure3 Thickness distribution of variable parameters elliptical Cross-section tube in internal high pressure forming (mm)

3.2 The distribution rule of equivalent stress

Assume that the pipe is a thin wall one, ignore the stress in the thickness direction, and only consider the axial and tangential stress, we can simplify stress state as a plane one. With the forming, the pipe of forming area bulges outward and stays at a two-way tensile stress state.



a) forming time 0.019s b) forming time 0.04s

c) forming time 0.05s d) forming time 0.06s

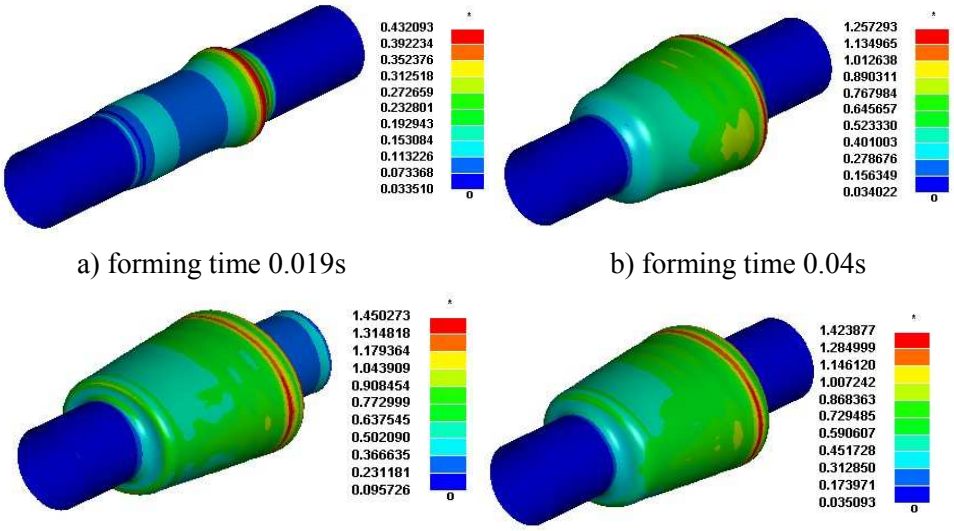
Figure4 Max equivalent stress distribution of variable parameters elliptical Cross-section tube in internal high pressure forming

As shown in figure 4 is equivalent stress distribution nephogram of forming process. at 0.019 s, the maximum equivalent stress locates in the forming rounded corner of large section, and forms a circular area; at 0.04 s, it is same with the previous stage but the area of maximum equivalent stress increases; at 0.05 s, the scope continues to increase, After the forming, the maximum equivalent stress still locates at the forming rounded corner of large section.

From above analysis we can see that in the whole forming process, the maximum equivalent stress always locates in the forming rounded corner of large elliptical cross-section, this is because the deformation of large cross-section forming rounded corner is maximum and deformation is most difficult.

3.3 The distribution rule of equivalent t strain

In forming process, the axial and tangential is tensile deformation, thick is compression deformation. As shown in figure 5 is equivalent strain distribution nephogram of forming process. At the beginning of forming, the equivalent strain presents a series of circular distribution, and the maximum equivalent strain locates in the forming rounded corner of large elliptical cross-section. Strain value of each part increases with the forming. At the end of the forming, the maximum equivalent strain still locates at the forming rounded corner of large section.



a) forming time 0.019s b) forming time 0.04s

c) forming time 0.05s d) forming time 0.06s

Figure5 Max equivalent strain distribution of variable parameters elliptical Cross-section tube in internal high pressure forming

From above analysis we can see that in the whole forming process, the maximum equivalent strain always locates in the forming rounded corner of large section. Deformation and flow are most sever in the maximum equivalent strain regions, so defects is easiest to appear in this place.

Conclusions

In this paper, through establishing the finite element model of TA2 varying cross-section elliptical tube high internal pressure forming, and simulating the forming process, we revealed the distribution rule of wall thickness, stress and strain in forming process:

1) The wall thickness mainly thin in 0.04 ~ 0.05 s. At the end of the forming, the wall thickness of forming central area thin and the more to the sides, the thicker the wall thickness is. The feeding zone thickens. The wall thickness of large elliptical cross- section feeding area thickens bigger than small.

2) The maximum equivalent stress and strain all locate at the forming rounded corner of large elliptical cross- section

Keywords: Environmental protection; Nano-tubes; Hydrogen storage capacity

Abstract. There are a series of problems existing in global issues, such as the increasing energy demand, environmental pollution, haze and global warming. Thus, the hydrogen energy attracts more attention of new energy industry. The materials of hydrogen storage are ideal renewable energy carrier; the combustion of hydrogen forms water is pollution-free for the environment and releases large amounts of heat. This paper systematically introduces the structure, preparation methods, and hydrogen storage capability of boron nitride nano-tubes. It also highlights the importance of boron nitride nano-tubes, which we believe will play a promoting role for the hydrogen storage materials.

Introduction

With global economic development, human demand for oil, coal, natural gas and other fossil fuels are increasing. According to the existing world oil reserves and mining velocity, global oil resources will be depleted till 2050 year, and humanity will face an energy crisis.[1] It is noteworthy that fossil energy release large amounts of harmful gases in the combustion process. Nowadays, we are suffering serious pollution and ecological destruction. In addition, global warming and its effects are only worsening. Therefore, the development of new clean renewable energy is imminent, because of high efficiency and environmentally friendly hydrogen, which is honored as green renewable energy. However, hydrogen storage has become a major bottleneck of hydrogen energy technology development. For example, compared with the same energy of gasoline, the volume of liquid hydrogen(under pressure of 100bar) is 30 times that of gasoline. If its volume continues to compress until it exceeds the volume of gasoline by 10, one would need to pay a high cost, and there is a significant safety risk during the practical operation [2]. Thus, solid-state hydrogen storage materials has increased in importance and as an issue that needs to be addressed. Based on adsorption theory, hydrogen storage materials is divided into two sections chemistry adsorption and physical adsorpti：
Chemisorption of hydrogen storage materials include light metal alloys [3-5] and lanthanide hydrogen storage alloys [6-8]. Physical absorption of hydrogen storage materials include carbon nano-tubes [9-11] and boron nitride nano-tubes [12-14]. The hexagonal planar network structure of boron nitride is similar to graphite, which makes the preparation of boron nitride nano-tubes become possible. Boron nitride also shows a higher chemical and thermal stability, and its electrochemical properties has nothing to do with its diameter or helicity. Therefore, boron nitride nano-tubes could be ideal hydrogen storage materials, along with light quality and stability.

The structure of boron nitride

The structure of boron nitride(BN) is similar to the graphite(C), especially the hexagonal boron nitride (h-BN), its structure almost same to the layered structure of graphite. The cell parameters of hexagonal boron nitride (a=0.2504nm, c=0.6660nm) and graphite(a=0.2464nm, c=0.6708nm) is almost the same, so hexagonal boron nitride is also named white graphite. The comparison of crystal structure between hexagonal boron nitride and graphite is shown in Figure 1.

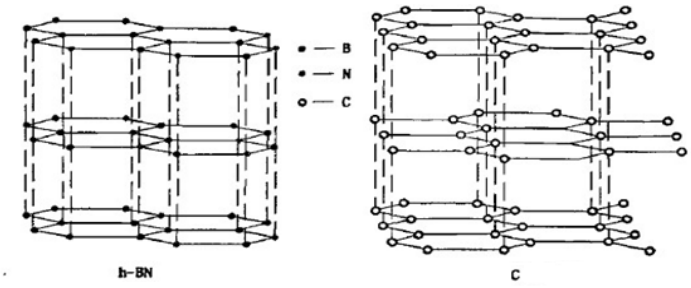

Figure1. The crystal structure of hexagonal boron nitride and graphite

The preparation of boron nitride nano-tubes

Currently, there are many different methods in preparing boron nitride nano-tubes, such as arc discharge method, laser evaporation method, arc melting method, and a carbon nano-tubes template method. Boron nitride nano-tubes were synthesized for the first time in a arc-discharged process[16]. Arc-discharge is a method to obtain nano-tubes by using a reactant as the electrode to discharge directly. In 1995, Chopra NG et al [16] made a bold improvement on the outer surface of a layer of BN coating, adding another refractory material(tungsten), and using tungsten as the positive electrode. With a water-cooled copper electrode as the anode electrode and helium as a buffer gas, multi-walled boron nitride nano-tubes are prepared by using a plasma arc method. Most of the pipe end of boron nitride nano-tubes have similar size and tube diameter of metal or metal boride particles by this method. Terrones et al.[17]. In addition, synthesized multi-walled boron nitride nano-tubes can be successful by using a similar method. Altoe et al.[18] This method can make the boron cast into ingots with a metal catalyst. Using these ingots as the electrode then can synthesize high-purity double-walled boron nitride nano-tubes. However, this method is too costly and it is almost impossible to apply it to industrialization.

Laser evaporation is a method of using laser that irradiates the block structure of boron nitride in the high pressure atmosphere of N_2 or Ar to prepare boron nitride nano-tubes. The diameter distribution of boron nitride nano-tubes prepared in this way is particularly small. In 1996, Golberg [19] used a 10Hz laser beam to prepare single-walled boron nitride nano-tubes, and D.P.Yu et al.[20] used 248nm laser beam to prepare single-walled boron nitride nano-tubes. Compared to other methods, boron nitride nano-tubes synthesized in this method show fewer layers, mostly single-walled tubes, and narrow the diameter distribution. However, the yield and purity of the boron nitride nano-tubes are not ideal.

The arc melting method is a way of preparing boron nitride nano-tubes in which the melting mixture of boron and the transition metal combine in a N_2 atmosphere. Tateo Oku et al.[21] Press the boron powder which is mixes Au and Fe_3O_4 into tablets, then the tablets are synthesized to boron nitride nano-tubes in the mixture atmosphere of Ar(0.025MPa) and N_2(0.025MPa). Recently, Zettl [22] wrote, using the non-equilibrium plasma arc method, melting BN ingots which mixed with cobalt and nickel, the current was 60A, the voltage was under the range of 30~45V, and then synthesized double layer of boron nitride nano-tubes. The inner diameter of the boron nitride nano-tubes was 2.2nm, and the outside diameter of the boron nitride nano-tubes was 2.9nm.

The carbon nano-tubes template method is also named carbon nano-tubes substitution method. This is because the preparation of carbon nano-tubes substitution method uses carbon nano-tubes as a template, replacing the boron atom of carbon nano-tubes with boron atom and nitride atom, and the boron nitride nano-tubes is formed. D. Golberg et al.[23] added when MoO_3 or V_2O_5 is mixed into the powder of the multi-wall carbon nano-tubes and B_2O_3, and then heat-treated at 1773℃ in nitrogen atmosphere, multi-walled boron nitride nano-tubes bundles are formed. SEM results showed that the top of the tube bundle is open, and the obtained tops are sealed when using the MoO_3 and V_2O_5 as raw material directly without the metal oxide inside.

Because of the higher reactivity, ammonia is envisaged to replace the nitrogen in reducing the reaction temperature. Deepak et al.[24] Does a lot of work on the ammonia and boric acid. The results showed that under the temperature of 1000~1300℃, an atmosphere with ammonia, and when mixture of boric acid and multi-walled carbon nano-tubes are heated, high yield boron nitride nano-tubes can be obtained, with close to a 100% conversion rate. When using arrayed carbon nano-tubes bundles as template, the boron nitride nano-tubes are also arrayed, indicating that the carbon nano-tubes template does play an important role during this reaction.

The hydrogen storage property of boron nano-tubes

The structure of boron nitride nano-tubes is very similar to that of carbon nano-tubes. Considering the chemical stability and thermal stability of boron nitride nano-tubes, boron nitride nano-tubes may become the most ideal lightweight hydrogen storage materials. Ma et al.[25] studied the hydrogen storage capacity of boron nitride nano-tubes. Studies have shown that, at room temperature, when pressure is gradually increased from 0 to 10MPa, boron nitride nano-tubes with hydrogen storage mass fraction corresponding increases. The mass fraction of hydrogen storage of multi-walled boron nitride nano-tubes and bamboo-like boron nitride nano-tubes are 118% and 216%. The mass fraction of hydrogen storage of bamboo-like boron nitride nano-tubes is higher than multi-walled boron nitride nano-tubes, which is due to the bamboo-like nanotubes that are composed of a variable diameter segment composition. With more defect structure, there are many openings edge layer around the outer surface, thus the mass fraction of hydrogen storage is much higher. The multi-walled boron nitride nano-tubes with capped ends hindered the entrance of the hydrogen molecules, thus the mass fraction of hydrogen storage is much lower. Tadao Sato[26] research group reported the hydrogen storage capability of boron nitride nano-tubes. When the boron nitride nano-tubes are placed between two platinum plates and then placed into a tube furnace, a heat treatment during hydrogen atmosphere at 1500℃, produces a vicious producet. Compared to the untreated boron nitride nano-tubes, the specific surface area of the treated boron nitride nano-tubes increased from 254.2 m^2/g to 789.1m^2/g. Through the thermal analysis, as the pressure increases, the ratio of the hydrogen storage increases. At the pressure of 10MPa, boron nitride nano-tubes collapse, the mass fraction of the collapsed hydrogen storage is 4.2wt%, which is higher than the traditional structure of multi-walled boron nitride nano-tubes. This may be due to the specific surface area of the boron nitride nano-tubes which is increased after heated-treating. In other words, after the heat treatment, the wall openings expand more hydrogen storage channels, thus, the boron nitride nano-tubes with surface defects shows a better hydrogen storage capacity.

Outlook

At present, the study of boron nitride nano-tubes is at the initial stage. Although there are many research achievements about the synthesis technology of boron nitride nano-tubes, the syntheses of highly pure and highly yield boron nitride nano-tubes are still difficult. Meanwhile, the growth mechanism of boron nitride nano-tubes is not very clear. The synthetic technology of highly pure, highly yield, and the growth mechanism of boron nitride nano-tubes will be the research emphases in future.

Boron nitride nano-tubes play an important role in the fields of structure materials for its potential advantages, and it also shows immeasurable advantages in the fields of functional materials, such as ferromagnetic materials, ferroelectric materials, piezoelectric semiconductors materials, and nano-superconducting materials. We believe that the application of boron nitride nano-tubes will make a significant contribution to the development of human civilization in the near future.

Keywords: copper doping, zinc oxide, micro/nanostructure, wetting.

Abstract. ZnO with different morphologies were formed on Zn foils immersed in various concentrations of CuSO4 solutions. Then the specimens were heated at temperature of 200~600℃ in air for 3h. The morphologies of as-prepared specimens were characterized by a scanning electron microscope (SEM). Water wetting angles on the specimens were measured. The results indicate that the morphologies of ZnO on the Zn foils relate to the CuSO4 concentration of in solutions. The morphologies on the specimens with dual-scale (nano and micro) structure have higher wetting angles than those with flat structure. The water wetting angles can reduce with the increase in annealing temperatures of immersed specimens. The water wetting angles increase with keeping immersed specimens at room temperatures. The change of the wetting angle is explained by absorption of organic carbon on specimen surface and the geometric structure of the surface.

Introduction

Wettability of solid surfaces is a very important property and is governed by both the chemical composition and the geometric structure of the surface [1]. In order to increase in wetting angle, some spectral materials, such as heptadecafl uorodecyl-trimethoxysilane, were used to modify the materials surface, based on chemical modification [2]. A simple and effective way to achieve high wetting angle is preparation of dual-scale (nano and micro) structure on materials surface, based on physical modification [3]. The surface is superhydrophobic when the wetting angle in a solid–water–air system is larger than 150°, hydrophobic when the wetting angle is between 90~150° and hydrophilic when the wetting angle (θ) is <90° [4]. In recent years, one of the extensive researches on the material surface is hydrophilic/hydrophobic.Hydrophilic surfaces have been widely used in biological, chemical, solar, bio chip etc. Surperhydrophobic surfaces have important practical applications, such as self-cleaning, lubricity, resisting water coalescence, etc [5]. A fast and low cost method to fabricate ZnO nanosheets has been reported in our previous paper [6]. The morphologies of ZnO nanosheets with micro/nano structures can be controlled with different concentrations of CuSO4 in aqueous solutions. The effects of annealing temperatures on the morphologies of ZnO nanosheets are also studied [7] in our paper. The effects of the different morphologies of ZnO nanosheet surfaces and annealing temperatures on the wettability are studied in this paper.

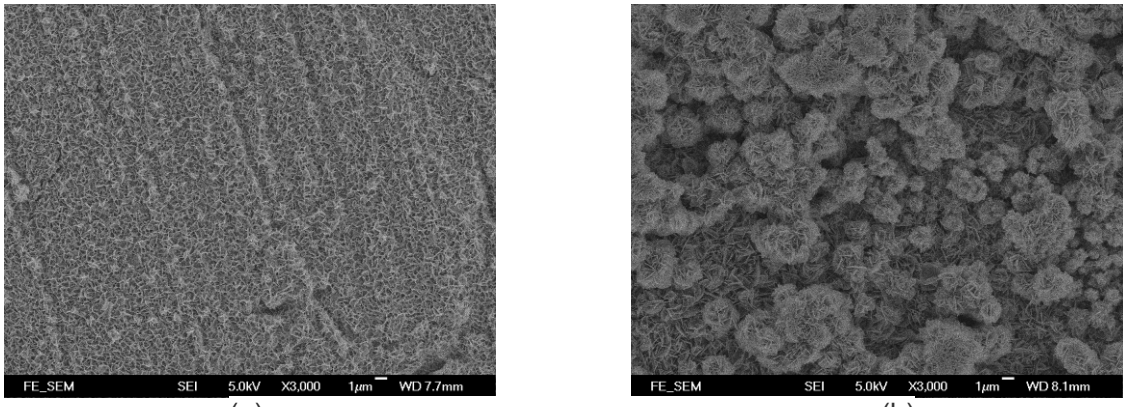
Experimental procedure

Commercial zinc foil (300 μm in thickness and 99.0% in purity) was ground on 1000# emery paper, cleaned in acetone, ethanol and distillation water for 5min, respectively, by an ultrasonic machine (SYS5200). Cleared zinc foils were immersed into 1%CuSO4 and 5%CuSO4 aqueous solutions for 3 seconds, and finally dried at ambient condition for about 20 min in order to obtain ZnO micro- / nano-structures on the surface of Zn foils. All the chemicals in the experiment, including acetone (99.5%), ethanol (99.7%), CuSO4(99%) are analytic grade reagents without further purification. The immersed specimens were heated in a SYS-G-Z-13 tube furnace at 200˚C, 300 ˚C, 400 ˚C, 500 ˚C, 600 ˚C in air for 3 hours, respectively. Water wetting angles (WA) on the specimens was measured and recorded after cooling specimens to room temperature immediately and after keeping the specimens at room temperature for 3 to 100 days. Water wetting angles were measured on the using

the sessile drop method by deposition of 4~6μL droplets of DI water on a horizontal surface, and under their observation in cross-section. Each drop was observed directly with an Olympus BX-41 microscope objective lens, whereas its image was digitally captured using a 1.4 mega pixel computer-controlled digital CCD camera. Five water drops were placed at different locations on a horizontal surface, and the derivation of the WAs measured was within 2°. The morphologies of as-prepared specimens were observed by a field emission scanning electron microscope (JSM-6335F).

Results and discussions

The morphologies of as-prepared specimens show in Fig. 1. Fig. 1a shows uniformly distributed nanosheets on the specimen immersed in 1%CuSO4 aqueous solutions. The width and thickness of the nanosheets are about 1μm and 80 nm, respectively. Quasi-flowers assembled with nanosheets can be formed on the specimens immersed in 5%CuSO4 aqueous solution in Fig. 1b. The diameters of quasi-flowers are in the range of 1~2 μm. Morphology change in Fig. 1 suggests fast chemical reaction rate between zinc and CuSO4 in high concentration solutions. With the increase in the concentration of CuSO4 in the solution, uniformly distributed nanosheets become quasi-flowers.



(a) (b)

Fig. 1 Morphologies of the specimens after immersing in (a) 1% and 5%CuSO4 aqueous solutions

Water wetting angles on the specimens were measured and recorded after immersing Zn foils in CuSO4 aqueous solution and drying immediately. Fig. 2 the exhibits a water wetting angle measured for the specimens with the morphologies in Fig. 1. The wetting angle on the specimen surface in Fig. 1a with uniformly distributed nanosheets (only nanostructure) is as small as 14.93°, as shown in Fig. 2a. The wetting angle on the immersed specimen in 5%CuSO4 solution with dual-scale (nano and micro) rough surfaces in Fig. 1b is 70.21°, as shown in Fig. 2b.

The combination of a dual-scale (nano and micro) roughness and an inherent low-surface energy coating material are an essential factors for the increase in water wetting angles on metallic surfaces. According to the Cassie model, increasing the proportion of water/air interfaces can greatly intensify the surface superhydrophobicity [8]. The Cassie wetting mechanism indicates that only the hills of the rough surfaces are wetted, while the water drop does not penetrate into the valleys. The morphology on the specimen immersed in 5%CuSO4 aqueous solution in Fig. 1b shows a dual-scale (nano and micro) roughness, which can trap more air, resulting in higher wetting angle 70.21°. There is low wetting angle 14.93° on the specimen immersed in 1%CuSO4 aqueous solution in Fig. 1b with nano structure only.

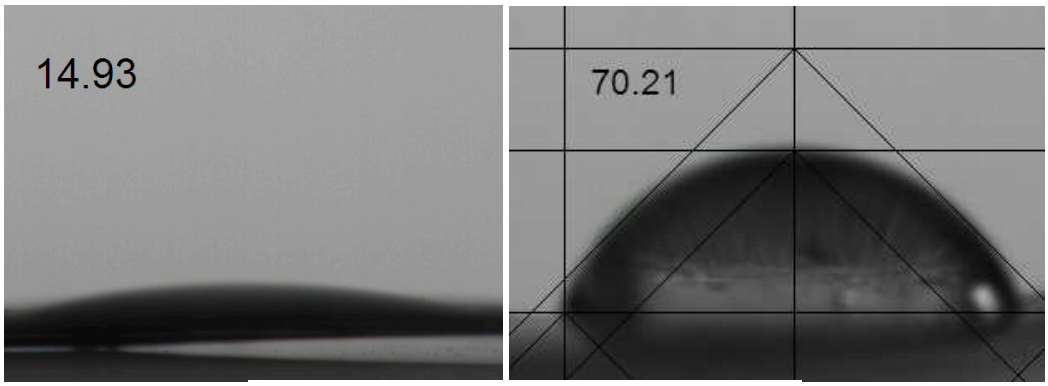


Fig. 2 Water contact angle measured on the specimens after immersing in (a) 1% and (b) 5%CuSO4 aqueous solutions

The immersed specimens were heated at different temperatures and wetting angle was measured on the specimens after cooling immediately. The results are shown in Fig. 3a. Generally, wetting angles decrease with the increase in temperatures. The reasons can be (1) the surface morphology changing form dual-scale (nano and micro) roughness to flat or (2) the changing chemical state on specimen surfaces. Based on our previous research, the surface morphologies nearly did not change after heating the specimens immersed in 1%CuSO4 aqueous solution at the temperatures less than 450˚C or after heating the specimens immersed in 5%CuSO4 aqueous solution at the temperatures to 600˚C [6]. This factor implies that the change in the chemical state on the specimen surface dominates the changing wetting angles.

Then the specimens after heating at 300˚C were kept at room temperature for various times (3, 17, 100 days) and wetting angles were measured as shown in Fig. 3b. Wetting angles increase with the increase in time. For the specimen immersed in 1%CuSO4 and heated at 300˚C, wetting angle increases form 12.8˚ measured at 0 day to 114.36˚ measured at 100 day.

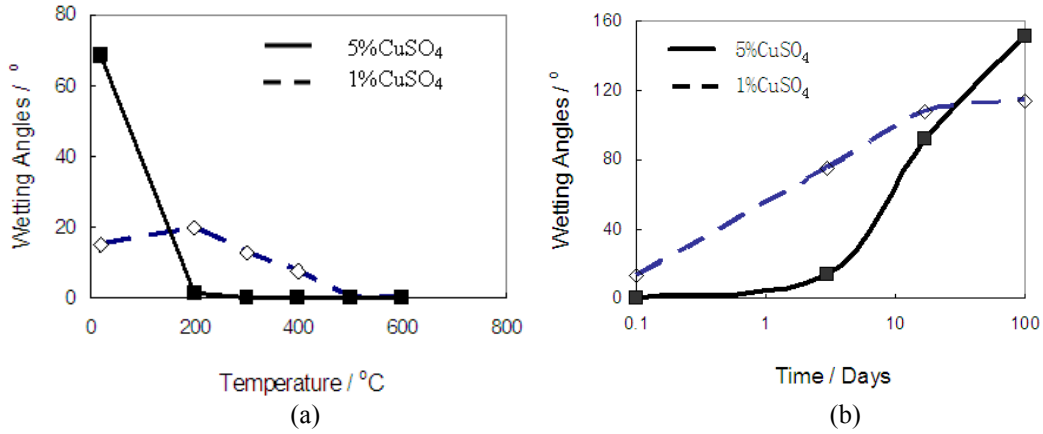

Fig. 3 Wetting angles versus of (a) annealing temperature and (b) time at room temperature

For the specimen immersed in 5%CuSO4 and heated at 300˚C, wetting angle increases form 0° measured at 0 day to 151.16° measured at 100 day. Theoretically speaking, ZnO is a hydrophilic material, wetting angle should be small. The samples can adsorb organic carbon in air and carbon is hydrophobic materials. The samples kept longer at room temperature and absorbed more carbon, resulting in the increase in wetting angle. When an annealed specimen at 300˚C was kept at room temperature for 17 days with the wetting angle of 107°, the wetting angle became 77° after specimen was heated again at 200˚C for 3 hour.

It can be concluded that ZnO surface can absorb organic carbon at room temperature and that heating specimen at high temperature can cause evaporation of organic carbon.

Conclusions

1. The morphology on the specimen immersed in 1%CuSO4 aqueous solutions shows uniformly distributed ZnO nanosheets with water wetting angle of 14.93°. The morphology on the specimen immersed in 5%CuSO4 aqueous solutions shows quasi-flowers assembled with ZnO nanosheets with water wetting angle of 70.21°.

2. Water wetting angles on the ZnO nanosheets decrease with the increase in temperatures of 200~600℃, due to evaporation of organic carbon.

3. After heating the immersed specimens at 300℃ and keeping the specimens at room temperature, the wetting angle on the specimen immersed in 1%CuSO4 increases form 12.8° measured at 0 day to 114.36° measured at 100 day and wetting angle on the specimen immersed in 5%CuSO4 increases form 0° measured at 0 day to 151.16° measured at 100 day.

Keywords: DeSOx filter, dry-desulfurization, amorphous citric acid complex method, base adducted complex material

Abstract. Sulfur dioxide (SO_2) including combustion exhaust gas is must be clarified because of its air pollutant in middle-scale facilities or marine ships. In this study, dry $DeSO_x$ filter is developed to capture SO_2 within diesel exhaust. $CaCO_3$ is focused on as SO_2 absorption material. However, SO2 absorption materials has to be improved low temperature activity below 723 K. To improve the low-temperature desulfurization performance, physically and chemically modified $CaCO_3$ was synthesized using the amorphous citric acid complex method and base adducted complex method. Development of $CaCO_3$ having high specific surface area of 169 m_2/g (HSSA $CaCO_3$) by the amorphous citric acid complex method was succeeded. Then, Li or Na doped complex $CaCO_3$ by HSSA $CaCO_3$ was synthesized by base adducted complex method. It is found that these Li -doped complex $CaCO_3$ have higher SO_2 absorption performance than conventional $CaCO_3$ and HSSA $CaCO_3$. Its performance is reached 0.31 $g_{SO2}/g_{material}$ at reaction temperature of 723 K by TG experiment, as a comparison, that of conventional $CaCO_3$ is 0.02 $g_{SO2}/g_{material}$.

Introduction

Sulfur dioxide (SO_2) from combustion exhaust gas is one of the main air pollutants, and it affects human being harmfully in its small amount under 100 ppm. Moreover, it is reported that SO_2 from diesel exhaust deteriorates NO_x catalyst [1,2]. However, sulfur as a chemical substance is largely demanded, for example, fertilizer, source of sulfuric acid and neutralization solution of alkaline. Emission of SO_2 is improved by upgrading of fuels and clarification from exhaust gas. Exhaust clarification device is used only large-scale facilities because of its big size. In the recent social situation of Japan, demand of medium-scale power generator such as diesel power plant is rapidly used. Compact size SO_2 purification device is need for middle-scale facilities. SO_2 clarification device becomes large size because of a lot of water use. The initial cost of SO_2 capture device become bigger. So, we have focused on dry $DeSO_x$ filter by sulfate reaction of alkaline metal oxide ($M_xO_y + ySO_2 + 0.5xO_2 \rightarrow M_x(SO_4)_y$). This method has potential to be small size because it does not demand water treatment process. The concept of our study is developing dry $DeSO_x$ filter having good SO_2 capture performance for downsizing, simple SO_2 capture materials for sulfur reuse. In our past study, $CaCO_3$ having good reaction with sulfur dioxide at 923K is found by our past research [3]. However, in the low temperature conditions, there is problem that sulfate reaction rate decreases. In this study, in order to develop DeSOx filter having low temperature activation, physically modification such as making high specific surface area and chemically modification such as making low activation energy is desired. In this study, the amorphous citric acid complex method is focused on as a physically modification of $CaCO_3$ [4]. Then, base adducted complex method is focused on the chemically modification of $CaCO_3$ [5]. $CaCO_3$ having more low temperature activation is proposed by

combining both method. Physically and chemically modified $CaCO_3$ is synthesized and evaluated material characterizations, then SO_2 absorption performance of these synthesized $CaCO_3$ is investigated by TG experiment.

Material preparation

Synthesis of $CaCO_3$ having high specific surface area

For the synthesis of calcium carbonate having high specific surface area, commercial calcium hydrate was used as a starting material and citric acid (Kanto Kagaku Co. Ltd.) as the organic acid. Calcium hydroxide ($Ca(OH)_2$) was mixed with aqueous citric acid solution in a beaker, through which carbon dioxide gas was passed, and the mixture was stirred for about an hour. The intermediate product was then introduced into the calcination reactor, which is shown in Fig.1. The molar ratio of citric acid molecules to Ca^{2+} ions is changed from 0 : 1 to 4 : 1 as a parameter of specific surface area or mean pore diameter. It was desiccated at 393 K. Then, extra moisture was removed from the solid substance by pre-calcination at 473 K under vacuum at 4.0 kPa in a vacuum firing furnace. Finally, these dried materials was calcinated by high temperature of 873 K. The target calcium carbonate materials were obtained by repeating this procedure.

Synthesis of base doped composite materials of $CaCO_3$ by base adducted complex method

In previous experiment, several alkaline materials and concentrations of sorbents were investigated as a preliminary validation, including LiOH, LiCl, KOH, KCl, NaOH and NaOH. From these previous examinations, $CaCO_3$ doped NaOH or LiOH have a good SO_2 absorption performance. So, NaOH or LiOH is focused on in this study as a base materials. These base materials were diluted with ultrapure water to generate from 0 to 2.0 Molar aqueous of these base materials solution at room temperature, and 100 mL of these solution was mixed with 50 mg of synthesized $CaCO_3$ by amorphous citric acid complex method. The solution mixture was dried and crushed at 393 K and classified as a $CaCO_3$-based composite materials, i.e., "Na doped $CaCO_3$" or "Li doped $CaCO_3$."

Experimental procedure

Evaluation of SO_2 absorption performance by using TG experiment

The effectiveness of SO_2 absorption performance of synthesized materials was measured by using TG (TGA-50, Shimadzu Co. Ltd., resolution of 10μg) measurement. Schematic drawing of the TG measurement is shown in Fig.2. The simulated exhaust-gas composition used in the TG experiment is that 500 ppmv of SO_2, 10 wt% of O_2, 6.0 wt% of CO_2, and N_2 base, then, total flow rate is 300 mL/min. Reaction temperature is 723 K. These conditions are simulated real diesel engine.

The SO_2 absorption performance in terms of the reaction rate per single particle, as well as the sulfate reaction rate, were evaluated. The SO_2 absorption performance per unit mass X is expressed by the following equation:

$$X = \frac{M_{SO_2}}{M_{SO_3} - M_{CO_2}} \cdot \frac{m_t - m_0}{m_0} \left[g_{SO_2} / g_{material} \right] \qquad (1)$$

X is the SO_2 capture performance per unit mass [g_{SO2} / $g_{material}$], M_i is the molar mass of i [g/mol], m_0 is the initial weight [g], and m_t is the weight after t seconds [g].

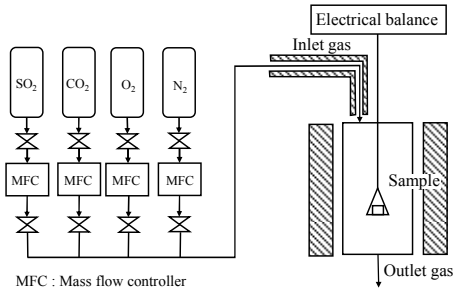

Fig.2 Schamatic drawing of TG experiment

Results and Discussions

Characterization of Na or Li doped composite $CaCO_3$ having high specific surface area

Pore distribution and BET specific surface area of synthesized $CaCO_3$ by amorphous citric acid complex method with changing citric acid concentration is shown Fig.3 .These characteristics were measured from BET method and BJH method by N_2 adsorption isotherm at N_2 melting point. From this result, $CaCO_3$ with a specific surface area of 169 m^2/g could be synthesized using the amorphous citric acid complex method with a molar ratio of organic acid molecules to Ca^{2+} ions of 4:1 and calcination temperature of 823 K. This $CaCO_3$ having high surface area is called "HSSA $CaCO_3$". However, mean pore diameter did no change in concentration of citric acid. It is thought that mean pore diameter depends on kind of doped acid. For comparison with influence of specific surface area, starting material of synthesis of composite $CaCO_3$ is selected two kind of $CaCO_3$ having different specific surface area having 16 and 169 m^2/g.

Then, Na or Li-doped $CaCO_3$ was synthesized with changing concentration of NaOH or LiOH aqueous solution. XRD patterns of synthesized composite $CaCO_3$ which concentration of each solutions is 1.0 M is shown Fig.4 and SEM photograph is shown in Fig.5. From the result of XRD pattern, it is found that main component is $CaCO_3$ however, Li-doped $CaCO_3$ is synthesized amalgam of Li_2CO_3 and $CaCO_3$, Na-doped $CaCO_3$ is synthesized $Na_2Ca(CO_3)_2$. It seems that these materials differ SO_2 absorption mechanism. From SEM photograph, $CaCO_3$ without citric acid mixing is formed cubic structure, on the other hands, $CaCO_3$ synthesized by amorphous citric acid complex method (HSSA $CaCO_3$) is formed complex surface structure. This complex surface structure increases specific surface area.

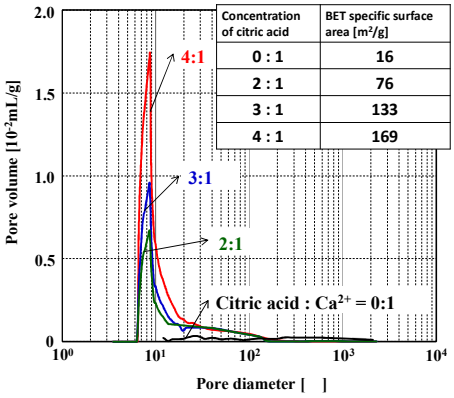

Fig.3 Pore distribution of $CaCO_3$ doped citric acid

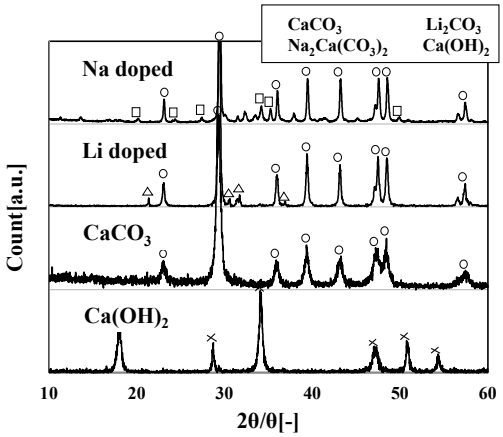

Fig.4 XRD patterns of chemically modifid $CaCO_3$

SO_2 absorption performance of Na or Li doped $CaCO_3$

The SO_2 absorption performance of Na or Li doped $CaCO_3$ was evaluated using TG. Influence of concentration of NaOH or LiOH aqueous solution and specific surface area of $CaCO_3$ against SO_2 absorption performance is investigated by using TG device. Result of Na doped $CaCO_3$ is shown in Fig.6 and that of Li doped $CaCO_3$ is shown in Fig.7. Summary of SO_2 absorption capacity after 2.0 h of TG experiment is shown in Fig.8. XRD analysis of products are also measured. From XRD analysis, products after SO_2 absorption of Li or Na doped material are all sulfate not including sulfite. From these results, SO_2 absorption performance of both doped $CaCO_3$ increase much more than that of $CaCO_3$. However, in Na doped $CaCO_3$, SO_2 absorption rate does not change with increasing specific surface area, but it does not change with increasing concentration of NaOH aqueous solution, on the other hands, in Li doped $CaCO_3$ it does not increase with increasing specific surface area, but it increase in high concentration

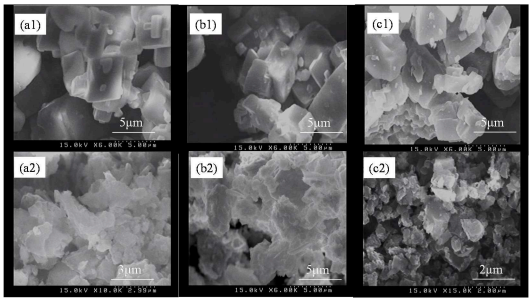

Fig.5 SEM photograph of chemically modifid $CaCO_3$
(a1) $CaCO_3$, (a2)HSSA $CaCO_3$,
(b1)Na doped $CaCO_3$, (b1)Na doped HSSA $CaCO_3$
(b1)Na doped $CaCO_3$, (b1)Na doped HSSA $CaCO_3$

of LiOH aqueous solution. In Li doped $CaCO_3$ synthesized by concentration of LiOH aqueous solution of 2.0 M, maximum performance which means SO_2 absorption capacity after 2.0 h in TG experiment at reaction temperature of 723 K is reached 0.31 $g_{SO2}/g_{material}$ as a comparison that of conventional $CaCO_3$ is 0.02 $g_{SO2}/g_{material}$. It is thought that SO_2 absorption mechanism of these materials is different. Na doped $CaCO_3$ is formed $Na_2Ca(CO_3)_2$ and $CaCO_3$, Li doped $CaCO_3$ is formed Li_2CO_3 and $CaCO_3$. Both materials increase SO_2 absorption capacity which is shown in Fig.8. Li^+ ions assist SO_2 absorption reaction in material surface at low temperature. For development of dry DeSOx filter, improvement of SO_2 absorption material is desired. Improvement of materials mean increase of SO_2 absorption rate and capacity. From this, Li doped $CaCO_3$ seems hopeful material for improving SO_2 absorption rate and capacity. In our future work, doping Li^+ ion will be focused on. Clarification of SO_2 absorption mechanism and roll of Li^+ ions will be investigated.

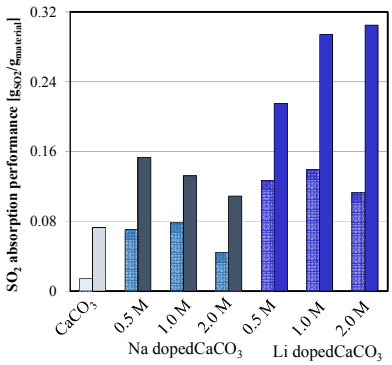

Fig.8 Summary of SO_2 absorption performance of physically and chemically modifid $CaCO_3$

Conclusions

Dry DeSOx filter is developed for purification of diesel engine exhaust. To improve SO_2 absorption material having more low temperature activation, physically and chemically modification of $CaCO_3$ is investigated. In this study, the following conclusions were obtained from this study.

- $CaCO_3$ with a specific surface area of 169 m^2/g could be synthesized using the amorphous citric acid complex method with a molar ratio of organic acid molecules to Ca^{2+} ions of 4:1 and calcination temperature of 823 K.
- Li-doped $CaCO_3$ is synthesized amalgam of Li_2CO_3 and $CaCO_3$, Na-doped $CaCO_3$ is synthesized $Na_2Ca(CO_3)_2$.
- SO_2 absorption performance of Na or Li doped $CaCO_3$ increase much more than that of $CaCO_3$.
- In Li doped $CaCO_3$ synthesized by concentration of LiOH aqueous solution of 2.0 M, maximum performance which means SO_2 absorption capacity after 2.0 h in TG experiment at reaction temperature of 723 K is reached 0.32 $g_{SO2}/g_{material}$.

Abstract. The effect of electron beam irradiation on permittivity of silicon dioxide insulate layer was investigated. Theoretical analysis indicates that electron beam irradiation will change the permittivity of SiO_2 through decreasing the molecular number per unit volume and increasing the polarizability of the sample. The escape of impurities during irradiation decreases the permittivity while the accumulation of space charge increases the permittivity. Simulation results show that with the change of permittivity, the electric field of the area irradiated by electron beam is strengthened locally and carbon nanotubes (CNTs) are more likely attracted to this area by dielectrophoresis. Therefore, the method could be used for precise positioning of CNTs for various applications in many areas including nano-electronics, sensors, and new energies.

Introduction

Due to their excellent electrical, thermal and mechanical properties, carbon nanotubes (CNTs) have become a candidate of nano materials for micro- and nano-sensors, energy storage and conversion devices, field emission displays, and many other applications [1-3]. Several approaches have been used to assemble CNTs such as utilizing directed CNT-growth techniques and by means of manual manipulations [4,5]. Dielectrophoresis (DEP) is a simple and efficient method for CNTs assembly since it does not require chemical reactions and expensive instruments [6]. However, there exist multiple influencing factors in DEP which include the magnitude of the applied voltage, the concentration of the CNT suspension, the duration of the electric field, the electrical properties of the CNTs and the dielectric liquid, and the geometry and spacing of the electrodes. Therefore, it is difficult to achieve precise positioning of assembled CNTs by DEP.

Several methods have been presented for precise positioning of CNTs such as using floating metal posts during DEP and chemically modifying substrates [7,8]. By using floating posts, it is possible to perturb and enhance the electric field in the vicinity of the posts, guiding the alignment of CNTs along the posts across the electrodes in the process of DEP assembly of CNTs [7]. In this paper, we will show an alternative way of precise positioning of CNTs by simulating the DEP force field with a change of permittivity of the dielectric layer on the selected area of the substrate after electron beam irradiation, which can strengthen electric field locally and attract CNTs to the irradiated area for precise positioning of CNTs by DEP.

Theory of Dielectrophoresis

During DEP, particles will be aligned to the field direction and attracted to the area of the highest DEP force [9]. When a particle is subject to an externally applied electric field, a dipole moment is induced. If the electric field is inhomogeneous, the DEP force acting on each side of the particle will be different, causing the particle to move with respect to the liquid medium [10]. The DEP force exerted by an electric field E on a particle is [11]:

$$F_{DEP} = \Gamma \cdot \varepsilon_m \operatorname{Re}\{K_f\} \nabla |E|^2 \tag{1}$$

where Γ is a factor depending on the geometry of the particle, ε_m is the permittivity of the suspending medium and E is the externally applied electric field. The factor K_f depends on the complex permittivities of both the particle and the medium.

In DEP manipulation, CNTs will be attracted to the area with the maximal field strength. When parallel electrodes are used, CNTs will tend to be evenly arranged between the electrode gap along the width of the electrodes. Electron beam irradiation on a selected area of the electrode gap will change the electrical properties of the substrate such as permittivity. A local permittivity change of the substrate could affect the distribution of the whole DEP electric field, strengthening the electric field locally and realizing a precise positioning of CNTs on the irradiated area. In order to explore the role of electron bean irradiation, we looked into the role of the electron beam and simulated the DEP force field respectively before and after irradiation.

Effect of Electron Beam Irradiation

When electron beam irradiates a dielectric material, the physical and chemical structure of the dielectric will change, leading to a change in its electrical properties. After electron beam irradiation, the relative permittivity of the dielectric ε_r is given by Clausius – Mossotti equation [12]:

$$\frac{\varepsilon_r - 1}{\varepsilon_r + 2} = \frac{N\alpha}{3\varepsilon_0}, \tag{2}$$

where N is the number of molecules per unit volume of the dielectric, ε_0 is the permittivity of a vacuum, α is the molecular polarizability of the dielectric. As shown in equation 2, ε_r is related to N and α, and only one or two polarizations among electronic polarization, ionic polarization, dipole polarization, and thermionic polarization dominate the magnitude of ε_r.

Impurities usually exist in dielectric materials such as SiO_2. After electron beam irradiation, these impurities would escape, causing some interspaces in the dielectric [13]. This implies that after irradiation the molecular number N in the dielectric would be decreased, causing permittivity ε_r decreased with it too. Another influence is that, after radiation, large number of negative charges will store in the SiO_2 substrate [14,15]. With the change of space charge distribution, the polarizability α is increased, causing ε_r increased too.

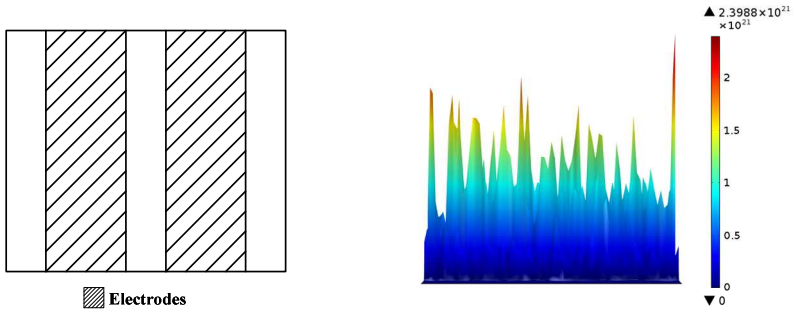
Simulation and Analysis

In order to evaluate the influence of local permittivity change of SiO_2 in the selected area due to electron beam irradiation on the CNT assembly by DEP, we calculated the DEP force distribution for parallel electrodes before and after electron beam irradiation by numerical simulation. Table 1 shows the electrical properties of the components of the DEP system in simulation.

Table 1 The electrical properties of the components in the DEP system for simulation

Components in the system	Conductivity [s/m]	Relative permittivity
Metallic CNT	1×10^{7}	1×10^{4}
IPA	6×10^{-16}	18.6
Aluminum electrode	3.774×10^{7}	1
Silicon dioxide	1×10^{-18}	3.8
Silicon	1.2×10^{-6}	11.7

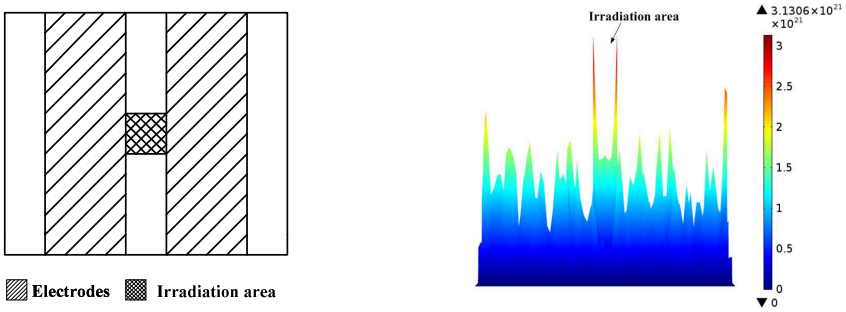
Fig. 1 shows the schematic of parallel electrodes in (a) and DEP force field distribution before irradiation in (b). As shown in Fig. 1 (b), the biggest DEP force appears at one corner of the electrodes. This means that CNTs will deposit firstly in the corner area during DEP.



(a) (b)

Fig. 1 Schematic diagram of electrodes (a) and DEP force field (b) before irradiation

Fig. 2 shows the area of electron beam irradiation on SiO_2 layer in (a) and DEP force field distribution with permittivity ε_r increased to 4.3 in (b). Compared to Fig. 1 (b), the largest DEP force appears at the irradiation area, instead of the electrode corner area. Therefore, CNTs will take precedence to deposit in this irradiated area and realize precise positioning. When permittivity ε_r is decreased to 3.8, similar results were obtained by simulation. This indicates that the permittivity change in the selected area of SiO_2 layer influences the whole DEP electric field. A local enhancement of the field in the irradiated area will attract CNTs to deposit there first.



(a) (b)

Fig. 2 Schematic diagram of electrodes (a) and DEP force field (b) after irradiation

Summary

The permittivity of the dielectric layer on the substrate has an impact on electric field distribution when manipulating CNTs by DEP. Two factors will affect the permittivity of a dielectric after electron beam irradiation: molecules number N and polarizability α. After irradiation, molecule number per unit volume will decrease, making the permittivity decrease too. On the other hand, due to electron injection the permittivity is increased. Although these two factors have opposite influence on the permittivity, simulation results indicate that DEP force can be enhanced in the irradiation area under the both cases. It is possible to achieve precise assembly of CNTs by DEP through electron beam irradiation on a selected position between the electrodes. However, the roles of electron beam irradiation have not been clearly understood and further studies are still needed.

Keywords: 4',4''(5'')di-tert-butyl-dicyclohexyl-18-crown-6; Bimetallic Rh-Fe catalyst; MgO support; Crown ethers hydrogenation

Abstract. For preparing 4',4''(5'')di-tert-butyl-dicyclohexyl-18-crown-6 with high yield under low H_2 pressure, the support, active component, promoter, reduction time and reduction temperature were studied. The catalyst structure and composition were characterized by XRD, TEM and EDS. The experimental results showed that MgO was the most suitable catalyst support because of its weaker acidity than other supports. The higher hydrogenation activity and selectivity were observed when Rh was used as the active component and Fe was used as promoter owing to the cooperative interaction. The optimum reduction temperature and the reduction time were 500 ºC and 3h, respectively. The specific surface area of Rh-Fe/MgO was 133m^2/g, and the Rh-Fe was well dispersed on MgO with the particle size about 20 nm. Under a low H_2 pressure (4 MPa), the 4',4''(5'') di-tert-butyldibenzo 18-crown-6 conversion was 78% and 4',4''(5'')di-tert-butyl-dicyclohexyl- 18-crown-6 yield was 53% catalyzed by Rh-Fe/MgO, which were higher than that catalyzed by single metal catalyst.

Introduction

Crow ether, which has a cavity with precise size, has been seen as a promising membrane material for liquid membrane [1-3]. Singh S.K. [1] and Walkowiak W[2] reported liquid membrane using crown ether for removal of metal ions from water. Mona M. Naim [3] prepared dibenzon 18-c-6 liquid membrane for the desalination of sea water. Among the crown ethers, 4',4''(5'')di-tert-butyl-dicyclohexyl-18-crown-6 (DTDCH18C6) is of particular interest for it similar cavity size with Cs ion and low solubility in water.

Generally, DTDCH18C6 was prepared by the di-tert-butyldibenzo 18-crown-6 (DTBB18C6) hydrogenation catalyzed by mono-noble metal catalyst. Predersen [4] synthesized dicyclohexyl 18-crown-6 by Ru/ at 10 Mpa, 100 °C with the conversion about 90% and the yield about 70%. Gula [5] synthesized DTDCH18C6 by Rh/Al_2O_3 at 10 MPa, 120 °C with the conversion about 90% and the yield about 60%. Liu [6] reported preparing dicyclohexyl 18-crown-6 with Rh/CNTs at 10 Mpa, 50 °C with the conversion about 60% and the about 80%.

Due to the cooperative interaction between two different metals [7], using bimetallic catalyst may increase the DTDCH18C6 yield under lower hydrogen pressure compared to monometallic catalyst, the active component and promoter thus were studied in this work. The catalyst support was investigated too because its structure and acidity also affected the DTDCH18C6 yield under lower hydrogen pressure. Moreover, the mass ratio of active component to promoter, reduction temperature, and time were researched to define the preparing conditions of this catalyst. At last, the catalyst structure and composition were characterized by XRD, TEM, and EDS.

Experiments

2.1. Catalyst preparation

The catalysts were prepared by an impregnation method using $H_2PtCl_6 \cdot 6H_2O$ (Aldrich) as the Pt precursor, $RhCl_2$ (Aldrich) as the Rh source, $RuCl_2$ (Aldrich) as the Ru source, $Co(NO_3)_2 \cdot 6H_2O$ (Aldrich) as the Co source, $Fe(NO_3)_3 \cdot 6H_2O$ (Aldrich) as the Fe source, and $NiNO_3 \cdot 6H_2O$ (Aldrich) as the Ni source, respectively. In a typical procedure, a certain quality of the support and the precursor (the total percentage of active component and promoter is 5%) were stirred in deionized water 4h and dispersed in ultrasound 2h. After the mixture was immersed 48h, it was dried in a vacuum oven 110 ° C. Then, the mixture was calcined under nitrogen (60 mL/s) at 400-500 °C for 2-4h, and reduced under hydrogen (60 mL/s) at 400-500 °C for 2-4h.

2.2. Catalyst characterization

The contents of Rh and Fe were estimated using the Scanning electron microscope (JSM-6700F, JEOL, Japan).X-ray diffraction (XRD) patterns were obtained with a powder X-ray diffractometer (X'Pert Pro, Panalytica, Holland), using Cu as α radiation (1.5406 Å) at 40 kV, 40 mA. The measurements were recorded with a count time of 1 s in the 2θ range of 0^o-80^o.

Results and Discussion

3.1. Catalyst characterization

Fig. 1 showed the XRD patterns of MgO, Rh/MgO and Rh-Fe/MgO. Peaks at 36.1^o and 61.5^o were assigned to MgO. Peaks at 41.2^o detected in the XRD patterns of Rh/MgO were assigned to Rh (111). However, this peak was not detected in the XRD pattern of Rh-Fe/MgO, which may be due to the effect of Fe on Rh.

The TEM patterns of Rh-Fe/MgO were shown in Fig. 2. As can been seen from the TEM pattern of Rh-Fe/MgO, the Rh and Fe were dispersed on the support well with the size about 20 nm.

EDS results show that the the mass percentage of the Rh was 4.46% and the Fe mass percentage was 1.32%, which was agreed with the design mass ratio of Rh (4%) and Fe (1%)

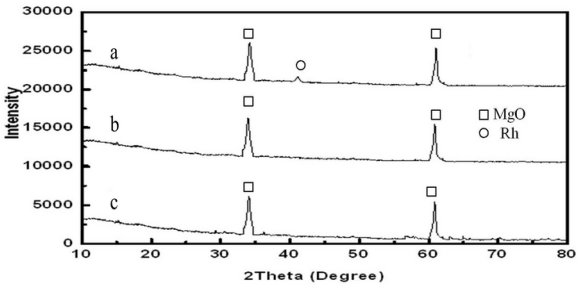

Fig. 1. XRD patterns of MgO, Rh/MgO and Rh-Fe/MgO

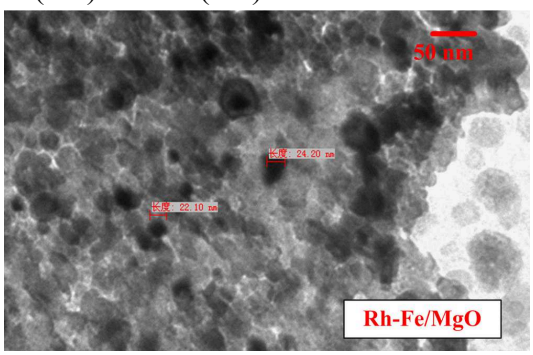

Fig. 2. TEM patterns of Rh-Fe/MgO

3.2. Catalyst activity and selectivity

3.2.1. The effect of the catalyst support on the reaction

Table 1 The effects of the catalyst support

Samples	ABET(m^2/g)	Pore Size (nm)	DTBB18C6 conversion	DTDCH18C6 yield
Rh/ Al_2O_3	238	22	75.3%	36.5%
Rh /MgO	133	43	72.2%	43.4%
Rh /TiO_2	108	15	49.6%	28.8%
Rh /CNTs	212	13	52.3%	33.4%

The effects of CNTs, TiO_2, Al_2O_3 and MgO as the catalyst supports were studied. As it shown in Table 1, owing to MgO can provide a more effective surface area and suitable pore structure than other supports, the DTBB18C6 conversion reached to 72.2% and the DTDCH18C6 yield was 43.4% when MgO was used as support. Although the activity of Al_2O_3 was slight higher than that of MgO, its selectivity was much lower than that of MgO. It may attribute to that Rh did not interact with Mg

and lose its catalytic activity when the catalyst was reduced by H_2 at high temperature [8]. Moreover, because the metal of group VIII was electron deficient, more strong adsorption bonds between reactants and active metal will formed and the reaction rate thus lowered if the metal was supported on an acidic support [9]. A strong interaction between the acidic sites of support and the reactants will also reduce the efficiency of the hydrogenation [10].

3.1.2. The effect of the active component on the reaction

Generally, the hydrogenation activity of the group VIII metals was highest than other group due to their lower chemical adsorption energy (100-120 kJ/mol). Therefore, Pt, Rh and Ru were selected in this work. Seen from Fig. 3, the following sequence for catalyst activity was founded: Pt>Rh>Ru**.** The selectivity was founded: Rh>Pt>Ru**.** It was believed that the metal activity was related to the arrangement of its outer electrons, and the activity sequence was 4d, 5d and 3d in succession[11]. The outer electrons arrangement of Pt, Rh and Ru are $5d^9 6s^1$, $4d^8 5s^2$ and $4d^7 5s^1$, respectively, which can explain the reason why the activity of Rh was higher than Ru and lower than Pt. In addition, some authors suggested that the hydrogenation activity of metal was associated with the acidity of the corresponding Lewis acid [11]. They indicated that the strong bond between a metal and reactants will be formed when the corresponding Lewis acid of this metal was hard acid, and weak bond will be formed if it was soft acid. The acidity of $RhCl_6^{3-}$ was lower than $PtCl_6^{2-}$, but higher than RuO_4^{2-}, that was why Rh showed a higher selectivity and activity for DTBB18C6 hydrogenation than Pt and Ru.

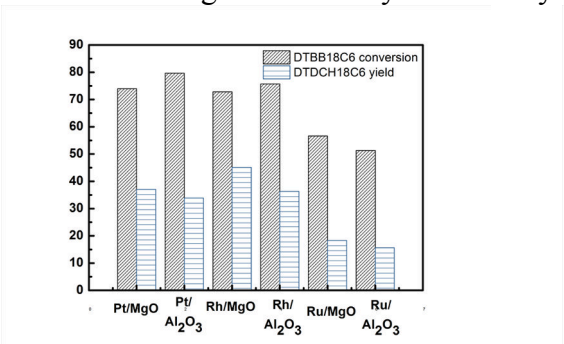

Fig. 3. The effect of the active component on the reaction.

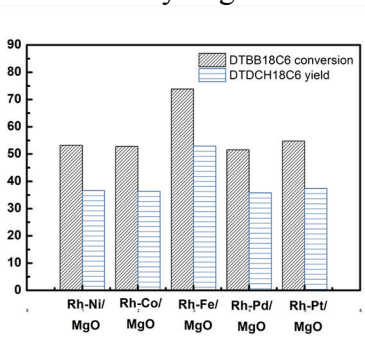

Fig. 4. The effect of promoter on the reaction.

3.1.3. The effect of promoter on the reaction

One role of promoter on the catalyst activity was group effect which can reduce the aggregation of the active component and improve its dispersity. Another was electronic effect which can affect the chemical bonds between the active component and the reactants. Ni, Co, Fe, Pd, and Pt were used as the promoter (its mass ratio to Rh was 1:4) in this works. As shown in Fig. 4, when Fe was used, DTDCH18C6 yield increased from 43% to 53%. Fe was able to influence the electron distribution of Rh d-orbital better than other metals, the Rh atoms were thus disordered on the crystal surface and the percentage of lattice defects was increased, which resulted the selectivity of catalyst increased.

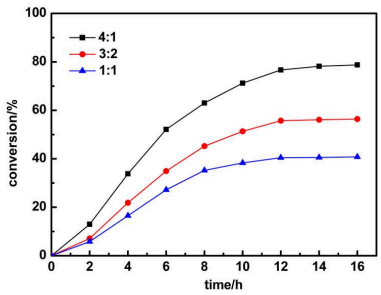

Fig. 5. The effect of Rh to Fe mass ratio on DTBB18C6 conversion

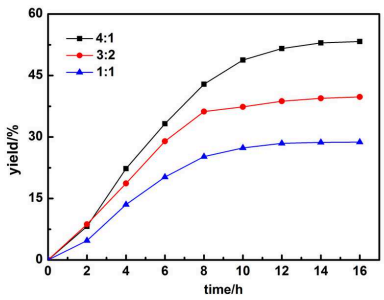

Fig. 6. The effect of Rh to Fe mass ratio on the DTDCH18C6 yield.

3.1.4. The effect of Rh to Fe mass ratio on the reaction

Since Fe was able to influence the electron distribution of Rh, the different mass ratio of Rh to Fe, the different electron distribution of Rh and different products yield, thus it was important to study the

mass ratios of Rh to Fe. Three different mass ratios of Rh to Fe (4:1, 1.5:1 and 1:1) were investigated, and the total mass percentage of Rh ang Fe was 5%. Seen from Fig. 5 and Fig. 6, the DTBB18C6 conversion (78%) and DTDCH18C6 yield (53%) both reached to its highest value when the Rh-Fe mass ratio was 4:1. The reason was that the mass percentage of an active component in a bimetallic catalyst must get to a certain value so as to ensure catalytic activity and the higher mass percentage of the active component the higher activity of catalyst generally. However, the selectivity of this catalyst was affect by the mass percentage of Fe, therefore Fe must be added moderately owing to the total mass percentage of Rh and Fe was constant.

3.1.5. The effect of impregnation sequence on the reaction

Rh and Fe were impregnated by three methods. As it Shown in Fig. 7 and Fig.8, the DTBB18C6 conversion and DTDCH18C6 yield were both highest when Rh and Fe were impregnated simultaneously. The reason was that the hydrogenation process carried out on the catalyst surface generally, if Rh and Fe were impregnated at different time, the two metals will easily form a structure similar to "core-shell" which was harmful to the surface reaction. While if Rh and Fe were impregnated simultaneously, the two metals may disperse randomly on the support surface and it was helpful for Fe influencing the *d*-orbital of Rh.

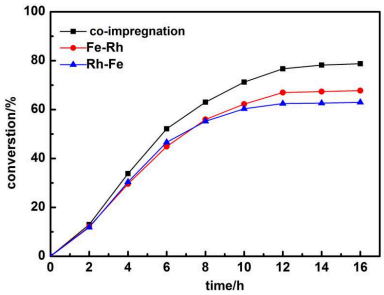

Fig. 7. The effect of Rh-Fe impregnation sequence on the DTBB18C6 conversion

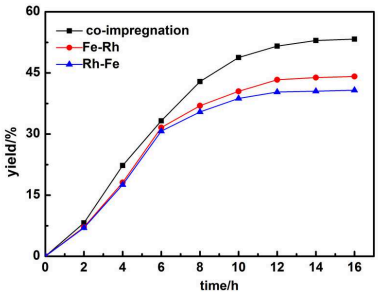

Fig. 8. The effect of impregnation sequence of Rh-Fe on the DTDCH18C6 yield.

3.1.6. The effect of reduction time on the reaction

Due to the large amounts of water vapor will be produced at a high reduction temperature, the active metal was easily oxidized and lost its activity if the reduction time was too long, the catalyst should be reduced as quick as possible. In this work, the catalyst was reduced for 2h, 3h and 4h， respectively. Shown in Fig. 9 and Fig. 10, although the activity of the catalyst reduced 3h was slightly higher than others, the activity difference of these catalysts was not distinguished. This result implied that the Rh^{+} and Fe^{3+} of the precursor could be completely reduced to Rh^{0} and Fe^{0} during 3h, and extending the reduction time was not helpful for increasing the catalytic activity under this condition.

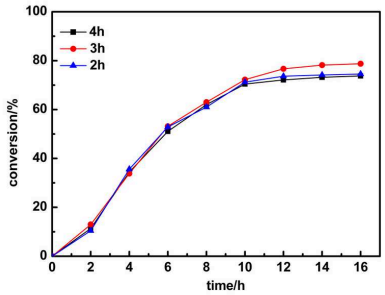

Fig. 9. The effect of reduction time on the DTBB18C6 conversion

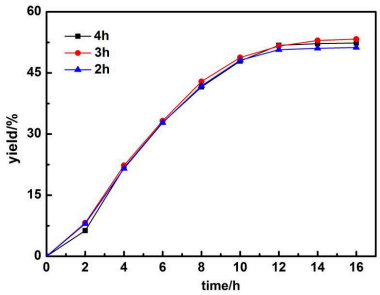

Fig. 10. The effect of reduction time on the DTDCH18C6 yield.

3.1.7. The effect of reduction temperature on the reaction

The reduction temperature directly affected the catalyst structure, and thus affected the catalyst activity. At low reduction temperature, the size of active metal particles was non-balance because of the gathering of water vapor on the metal surface. While at high reduction temperature, the metal

atoms rapidly diffused to the ligand center and its size was very stable due to the role of surface re-configuration [19]. However, if the reduction temperature was too high, the metal atoms will be sintered and lost its activity. The activity of catalysts reduced at 300 °C, 400 °C and 500 °C were studied. It can be seen from Fig. 9 and Fig. 10, the highest DTDCH18C6 yield and DTBB18C6 conversion were founded when the reduction temperature was 500 ^{o}C. Some papers reported that the relative percentage of the defects on Rh surface was less than 10^{-4} when the reduction temperature was below 500 °C, and the higher metal surface defects the higher catalyst activity.

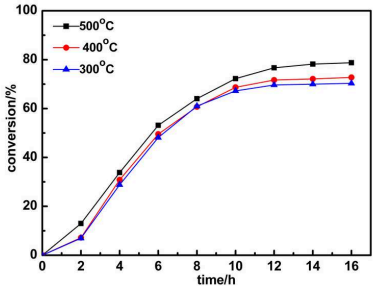

Fig. 11. The effect of reduction temperature on the DTBB18C6 conversion

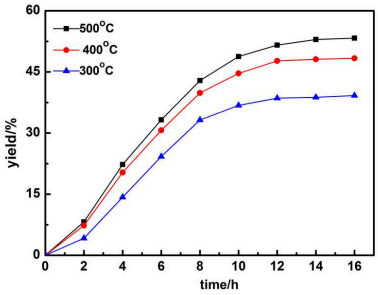

Fig. 12. The effect of reduction temperature on the DTDCH18C6 yield

Conclusion

The results of catalyst supports research indicated that the DTBB18C6 conversion and DTDCH18C6 yield were higher when MgO was used as a support. Pt, Rh and Ru were employed to study the use of active component, and it was founded that Rh was the proper active component for DTDCH18C6 preparation. When Fe was used as promoter, the DTDCH18C6 yield increased from 43% to 53%, which was the highest increase than other promoters. In addition, the optimal mass ratio of Rh to Fe was 4:1. When Rh and Fe were impregnated simultaneously, and reduced at 500 ^{o}C for 3h, the DTBB18C6 conversion and DTDCH18C6 yield reached to the highest values in this work. From the results of characterization, peak of Rh was not detected in the Rh-Fe/MgO XRD patterns which may be due to the effect of Fe on Rh. The EDS showed the mass ratio of the Rh (4.46%) to Fe (1.32%) was agreed with the design mass ratio of Rh (4%) to Fe (1%). The Rh and Fe were dispersed well on the support with the size about 20 nm from the TEM pattern of Rh-Fe/MgO.

Abstract: To study the influences of snowmelt agent to performances of asphalt,three snowmelt agents of NaCl，$CaC1_2$，$CH_3COONa·3H_2O$ were used to make asphalt sample and experiments about performances of high temperature and low temperature of asphalt were done.The results indicated that: temperature sensibility of 90# asphalt was reduced, softening point was increased ,dynamic viscosity was increased and ductility was reduced after being dealedwith snowmelt agent; Residual penetration ratio and residual ductility were also reduced after being dealedwith snowmelt agent.

As the development of the highway transportation, performances of roads are improved continuously[1]. However, snows of road hinder the normal transportation and also influence the traffic Safety, Even can cause a wide range of vehicles on the highway, Thus cause huge economic loss to the country. Therefore using the effective means to eliminate the road snow and ice quickly and maintain normal operation of transportation are very important. Snowmelt agent is the main way to snow melt in our country because of the low price and user-friendly control[2~3]。

Chlorine salt snowmelt agent is the most widely used snowmelt agent but which also can erode environment: Soil and groundwater, reinforced concrete structure and so on.The problems of chlorine salt snowmelt agent emergent after 1950s in the USA[4]. A large number of research reports of snowmelt agent impact on the environment and concrete structures at home and abroad has been reported but corrosion destruction to asphalt mixture do not form a unified understanding[5]. The influences of snowmelt agent to performances of asphalt was studyed in the paper to research the failure mechanism and degree to asphalt.

Test materials

Asphalt

SK90# asphalt was used,and the indexes is as table 1.

Table 1 The indexes of SK90# asphalt

Asphalt type	25℃needle penetration /0.1mm	10℃duc-tility /cm	softening point /℃	60℃dynamic viscosity/Pa·s	RTFOT (163℃,85min)		
					quality change /%	Residual penetration ratio /%	10℃Residual ductility /cm
SK90#	85.6	47	48.7	198.1	0.3	73.3	20.1

Snowmelt agent

three snowmelt agents of NaCl， $CaC1_2$， $CH_3COONa·3H_2O$ were used to make asphalt sample.

NaCl: white crystal, hygroscopy, can be dissolved in water and ethyl alcohol;

$CaC1_2$: white crystal, Strong moisture absorption, can be dissolved in water and ethyl alcohol;

$CH_3COONa·3H_2O$: white crystal, can be dissolved in water

Specimen preparation

1）NaCl,$CaC1_2$,$CH_3COONa·3H_2O$ of 0.2g/ml were made up in vessels and then heating and boiling it.;

2) Asphalt was heated to 155~165℃;

3)Heating ssphalt was poured into snow-melting Agent and then boiled 3min;

4) Thermal dehydration.

Test and results analysis

penetration index PI, softening point, dynamic viscosity, ductility,were done to test the performances of asphalt in high temperature, low temperature .

Temperature sensitive performance

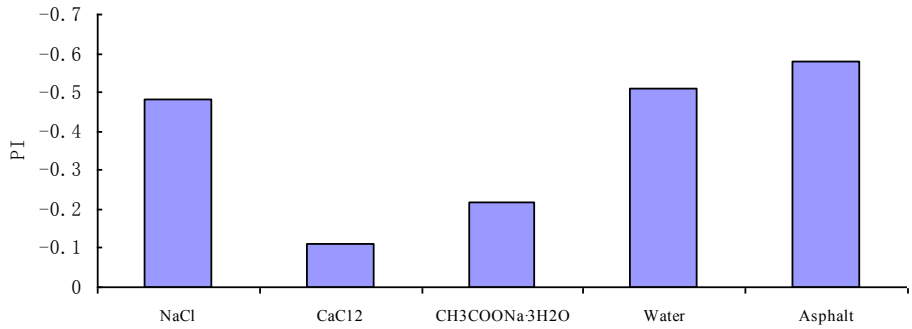

Fig. 1 The influences of snowmelt agent to temperature sensitive performanceof asphalt

The influences of snowmelt agent to temperature sensitive performanceof asphalt is shown like Fig. 1 which indicat that PI indexes of 90# matrix asphalt are increased after dealing with snowmelt agent.The order is that $CaC1_2$＞$CH_3COONa·3H_2O$＞NaCl.The reason is that snowmelt agent exist in asphalt as type of ionic crystal whiach share responsibility for temperature variation.

High-temperature behavior

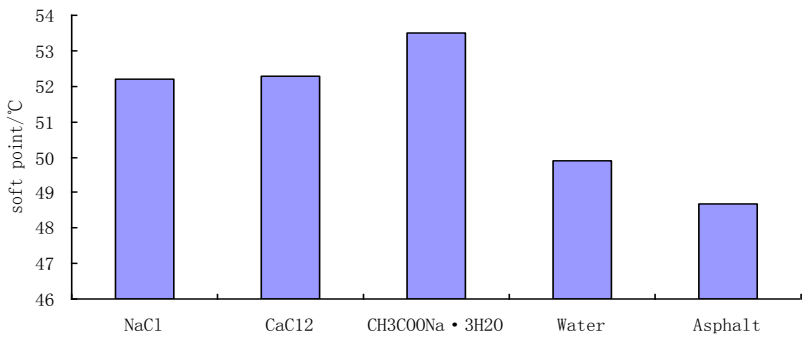

Fig. 2 The influences of snowmelt agent to softening point of asphalt

The influences of snowmelt agent to softening point of asphalt is shown like Fig. 2 which indicat that idexes of softening point are increased after dealing with snowmelt agent. The order is that $CH_3COONa \cdot 3H_2O > CaC1_2 > NaCl$.

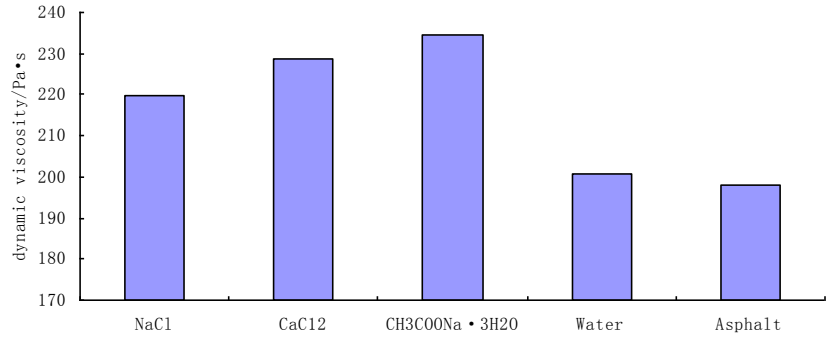

Fig. 3 The influences of snowmelt agent to dynamic viscosity of asphalt

The influences of snowmelt agent to dynamic viscosity of asphalt is shown like Fig. 3 which indicat that idexes of dynamic viscosity are increased after dealing with snowmelt agent. The order is that $CH_3COONa \cdot 3H_2O > CaC1_2 > NaCl$.The reason is that the molecular weight of asphalt is increased afte dealing with snowmelt agent which resulted in viscosity increased.

Low-temperature performance

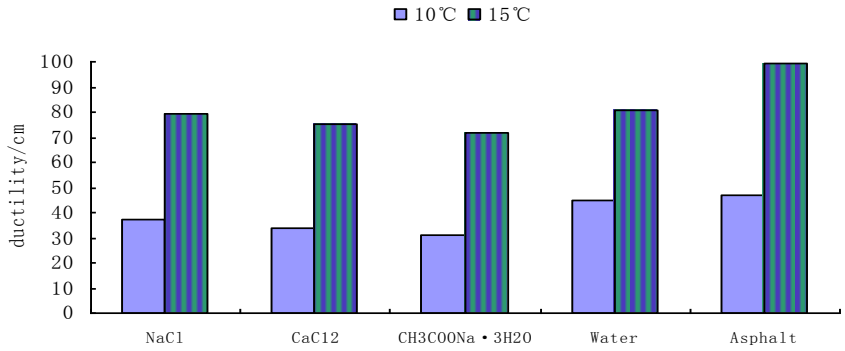

Fig. 4 The influences of snowmelt agent to ductility of asphalt

The influences of snowmelt agent to ductility of asphalt is shown like Fig. 4 which indicat that idexes of ductility are decreased after dealing with snowmelt agent. The order is that $NaCl > CaC1_2 > CH_3COONa \cdot 3H_2O$.

The influences of snowmelt agent to aging characteristic of asphalt

Residual penetration ratio

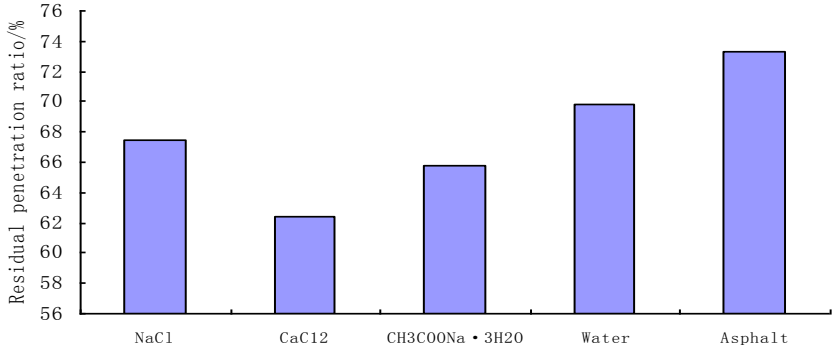

Fig. 5 Residual penetration ratio

Residual penetration ratio can reflect changes of asphalt after aging. the residual penetration ratio is greater ,the anti-aging performance of asphalt is the better. The influences of snowmelt agent to residual penetration ratio is shown like Fig. 5 which indicat that idexes of residual penetration ratio are decreased after dealing with snowmelt agent. The order is that NaCl＞ $CH_3COONa·3H_2O$＞$CaC1_2$.

Residual ductility

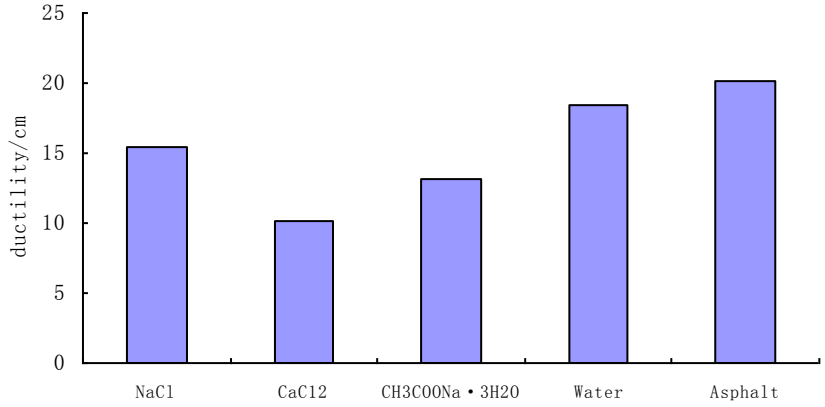

Fig. 6 10℃Residual ductility

The influences of snowmelt agent to 10℃residual ductility are shown like Fig. 6 which indicat that idexes of 10℃residual ductility are decreased after dealing with snowmelt agent. The order is that NaCl＞$CH_3COONa·3H_2O$＞$CaC1_2$.

Conclusion

The indexes of temperature sensibility are reduced, indexes of softening point are increased, dynamic viscosity are increased, ductility are reduced after the 90# asphalt dealing with snowmelt agent.

The indexes of residual penetration ratio and 10℃residual ductility are decreased after the 90# asphalt dealing with snowmelt agent which shows that aging characteristic of 90#asphalt is decreased by snowmelt agent.

Keywords: rock salt; CT scan; corrosion;

Abstract: The roadbed base of railway in Qarhan Salt Lake area entirely consists of brine saturated rock salt formations. However, low salinity brine would cause corrosion for roadbed and the stability of rock salt roadbed would be directly affected. In this paper, physical and mechanical properties of brine-dissolved rock salt have been studied, as well as Computer Tomography was used to scan and analyze the meso-structural changes in rock salt before and after corrosion. The results show that density of rock salt would be changed obviously in the process of corrosion.The deriving or closing of meso-fissures in rock salt could been found with rock salt immigrating and corrosion damage.

Introduction

The brine saturated rock salt formations is adopted as the roadbed base of the Qinghai-Tibet railway, which goes across the largest Saline Lake called Qarhan Salt Lake in China[1]. The phenomena of brine corrosion appear in freshwater or low salinity brine, the solution and salt crystallization conditions of rock salt will be changed under conditions such as rainfall and brine deposits mining, these will cause diseases in rock salt roadbed. Therefore, studying of percolation, salting and changes of mechanical properties of salt rock under dissolution has become the governing problem to ensure stability of railway roadbed in salt area.

A lot of research on rock salt corrosion problems have been in progress at home and abroad. Results of mechanical and corrosion experiment of rock salt shows that a significant correlation exists between damage evolution and corrosion of rock salt. The corrosion characteristics of rock salt are obviously different under conditions of stressed and unstressed [2,3].

The technique of CT has received extensive attention, because of its advantages such as low disturbance, real-time and nondestructive analysis which make up for the defects of electron microscopy and many other means for observation [4,5]. This article analyzed CT scans of rock salt before and after corrosion, the aim is to discuss the mechanism of corrosion damage of rock salt from the micro level, provide test data for studying the macro corrosion properties of rock salt and the stability of rock salt roadbed.

Test situation

The samples were collected from the K740+200 transmission channel in crystalline rock salt specimen halogen, specimen is cylindrical, machined specifications: height 100mm, diameter 50mm. The samples are numbered and brine infiltration directions are marked. Because water has great influence on rock salt, so the specimens are processed using dry milling methods.

PHILIPS Brilliance 16 spiral CT of CAS Lanzhou Institute of Glaciology and Frozen State Key Laboratory of Engineering was utilized in the CT scan experiment of the rock salt before and after corrosion. Experimental coefficients is shown in figure. The spatial resolution of PHILIPS Brilliance 16 spiral CT system is 0.208mm, density resolution is 0.3%. The parameters about this test of CT scan: the scanning voltage :90~140kV, scanning current (the tube current):30~500mA, scan time: 4~10s, a magnification of 1, slice thickness: 3mm. Several layers are scanned each time, selected three layers as the test layer in random. Corrosion device for rock salt is designed by the author. It mainly made up by three parts, the infiltration of halogen water, the tank to undertake halogen water and corroded pipe.

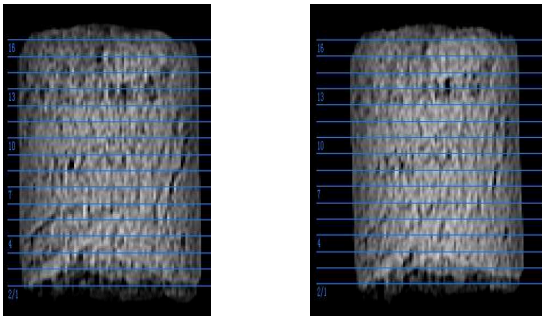
Fig. 1 PHILIPS Brilliance 16 spiral CT machine

Procedure of this test: in order to obtain initial damage of the internal structure before rock salt corrosion, firstly, progress the initial CT scanning of rock salt as the basis to contrast the change image that rock salt corrosion. Scanning for 3 slice, the thickness is 3mm. Select a certain concentration of brine to progress corrosion test according to the corrosion mechanism of rock salt. After a certain time, remove the samples of corrosion rock salt, progress the second scan after drying the rock salt, scanning layer and layer thickness were consistent with the first scanning, so as to make a comparison with same position of the meso-structure damage changes before and after corrosion.

Analysis of test results

Generally speaking, it is difficult to reflect the meso-structure characteristics from density information in a CT images. If the CT images about samples of the same layer in different states are compared, we can get the meso-structure evolution information of the tested samples easily. Therefore, the same layer of the salt rock sample was scanned respectively before and after corrosion. In other words, CT scanning the sample for the first time, then carry on the second scanning after the corrosion test of rock salt samples. Three samples and three layers of each sample are scanned totally, there are 18 CT images before and after corrosion in all, limited by the length of the article, only 6 CT images of rock salt sample 2 are shown in Figure 4, 5, 6.

Figure 2 and Figure 3 are CT scanning location maps of 2# rock salt sample before and after corrosion. The pure salt rock is white, while the 2# rock salt sample presents hoar, it was caused by the internal impurities of rock salt, the surface presents granular, with teeth marks, and there is a visible fracture.



(a) before corrosion (b) after corrosion

Fig. 2 The sample location map

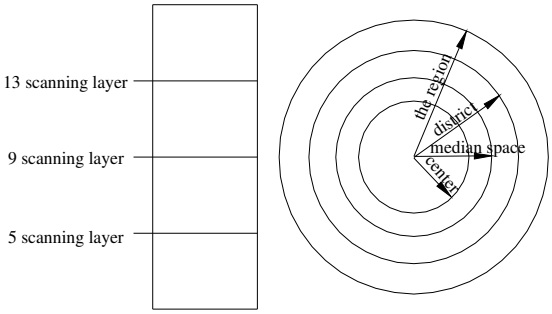


Fig. 3. 2# rock salt sample scanning horizon and measurement area

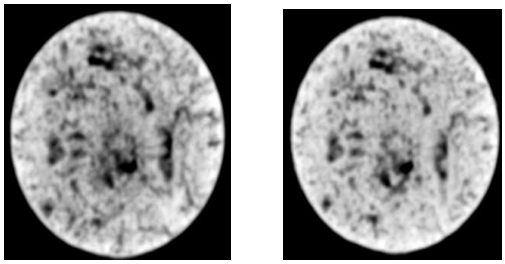
The CT images 5, 9, 13 layers of 2# rock salt sample before and after corrosion are shown in Figure 4-6, CT image is essentially a gray scale display of data image, and the gray values of each part can be displayed in the appropriate position of the image. In the course of rock salt dissolution, meso-evolutionary change will cause damage to the internal structure of the rock, which is expressed as diversification of gray values in CT images Gray shading indicates the gray size of CT images, the larger of the gray size, the higher the density of rock salt is, and vice-versa. The mean numbers and variances of CT image in each layer of 2# sample were given in Table 1, the mean number of the CT

image reflects the average density of all material points in the cross section, the variance value reflects the differences of density of material points in the cross section in degree. It reflects the structural strength of the rock salt rock salt indirectly.

The properties of CT images show that dark black region is low density area, which means in this area of the sample existing pores, cracks and other damage; bright white region in the image is high density area, in which rock salt particles are concentrated, which can be seen Figure 4~6. Three layers of 2# rock salt sample were taken before and after corrosion, each layer can be divided into four regions of interest (ROI) : respectively named the region, district, median space and center, the number of CT domain of interest is shown in table 1 and Figure 7.

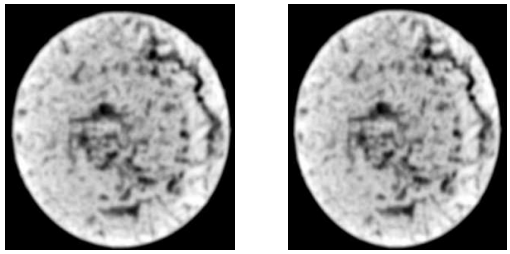
It can be seen from the relevant data in Figure 4,5, 6,7 and Table 1 that :

It can be concluded from 5, 9, 13 (the first layer scanning) images of 2# rock salt sample before corrosion in Figure 4, Figure 5 and Figure 6 that, brightness level of each layer in the image was obviously uneven distributed, gray of rock salt was evenly distributed in 5, 9 layers before corrosion, there is only a small amount of abnormal low density area and internal structural damage is lesser. However, the image of rock salt sample in 13 layer before corrosion shows that most regions are abnormal low density area, even appear "cavity", it's the internal large holes and cracks within rock salt, thus structure is quite fragile. Longitudinally compare the three layers before corrosion.



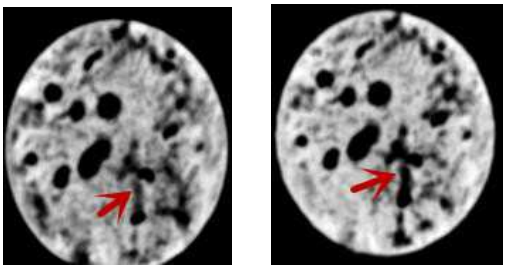
(a) before corrosion (b) after corrosion

Fig. 4 The 5 layer scanning corrosion image



(a)before corrosion (b)after corrosion

Fig. 5 The 9 layer scanning corrosion image



(a)before corrosion (b) after corrosion

Fig. 6 The13 layer scanning corrosion image

It can be found in CT images of 2# sample that the brightness of three different layers is markedly different , which means the density of rock salt sample in each layer is different ; it can be seen from Table 1 and Figure 7, the CT number of the same sample at different levels (Table 1) are different. In addition, the CT number within the same layer of each pixel is also different. Namely the density inhomogeneous distribution. It can be concluded that the internal structure of rock salt sample exists inhomogeneity before corrosion. Whole internal parts density of the rock salt shows a random distribution. That is to say, there is initial damage in rock salt.

In the course of rock salt corrosion test, brine which infiltrated into 2 # sample is unsaturated, internal meso-damage evolution of rock salt causes the internal structure changes which is shown as differences of gray values in CT images. It can be seen there's no significant change about integral gray scale of CT images on rock salt with corrosion from Figure 4, 5, and 6, abnormality only appears as increasing or decreasing in local areas of the rock salt. From Table 1 and Figure 7 we can see : ΔME increased in different regions of the three layers before and after corrosion, but the values added are extremely uneven. The number of value added in 13 layer is the smallest , SD increased greatly

and discrete is also increased among the three layers , the opening of the pores of areas in which indicated by the arrow is increased . We can conclude that integral density of rock salt increased but reduced in local areas, the phenomenon indicates that salt grow in rock salt in the course of corrosion integrally and corroded locally .

Table 1 2# rock salt specimen CT scanning CT number

CT number	5					9					13				
	ME		SD		ΔME	ME		SD		ΔME	ME		SD		ΔME
	B	A	B	A		B	A	B	A		B	A	B	A	
The region	1132	1278	406	368	146	1116	1262	410	382	145	843	991	593	631	148
district	1043	1193	387	361	150	1034	1176	387	366	141	774	909	598	652	135
Median space	928	1096	384	377	168	950	1104	339	343	153	760	848	618	685	88

Note : B mean before corrosion ;A mean after corrosion ;AR is fault measurement area ; ME : mean number of the measurement area ; SD : the measurement of regional CT value standard deviation ; △ME : variation of the mean value of CT before and after immersion .

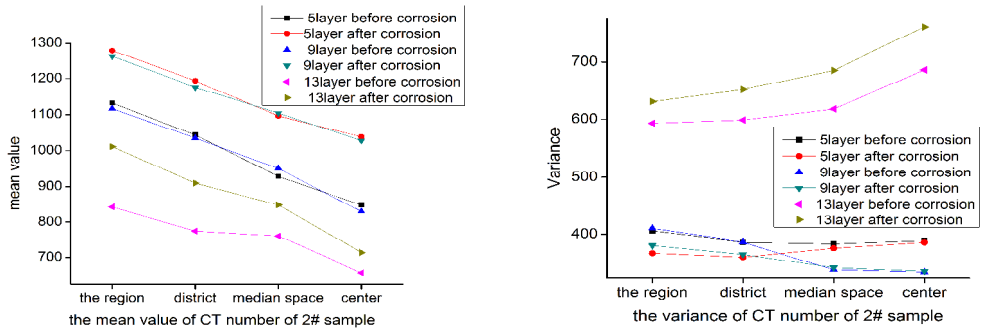

Fig. 7 Mean and variance of CT number of the 2# rock salt sample before and after corrosion

It can be seen from analysis the longitudinal of 5-9-13 layer: the brightness level of 5 and 9 layers of 2# sample changed little before corrosion, namely density is similar and tend to increase to the infiltration direction. Most of the regions in 13 layer are abnormal low density areas, while the low density band is essentially the micro crack development zone. A small amount of pores appear signs of rising and fracture began to run through after corrosion , shown as corrosion, part of rock salt soluble matter was taken away by brine and voids arise which is indicated by the arrow in figure 6. From table 1 and Figure 7, we can see that the mean CT values of each area have increased before and after corrosion, 5 layer and 9 layer show little fluctuation, and the 13 layers has a wider fluctuation range. The change of CT mean number is smaller but variance fluctuated greatly in the center of 13 layer before and after corrosion, especially in the core area. This demonstrates that the internal particles, they arrangements and fracture structures in 13 layer of rock salt are greatly uneven, and low density areas and dissolution increased the discretion of internal structure of rock salt that crack growth becomes possible, and all the results above are consistent with figure 6.

It can be seen in Figure 4 , 5 and 6: the higher brightness in the edge of the area it is, the higher density it will be . From Table 1, the initial means of CT value about 2 # rock salt sample decreased gradually from the region to center, which suggest that density of the edge of rock salt is bigger and more compact while density in center is smaller , the structure is more fragile. By comparing the differences of brightness of CT images about rock salt before and after corrosion, we can see that the gray-scale in each layer increased significantly in the edge region and changed a little in other areas. Comparing the 4 ROI, mean CT values decreased gradually from the edge to the center. It shows that the rock salt density reduced over the edge to the center, the marginal zone is fringe while the center

area is loosed texture. It can be seen from△ME of 5 layer and 9 layer in table 1. CT value increment increased from edge to center, Central areas the phenomenon of salt growth is obvious; In 13 layer mean CT value increment gradually reduced from edge region toward center zone, salt growth mainly occurred in edge of rock.

It can be seen from 6 CT images as well as in Table 1 and Figure 7: the mean CT values of 5 and 9 layers changed greatly, variances changed minimally, 13 layer CT number mean changed in large level and shows small change in the central area while the variance fluctuate dramatically. This illustrates materials moved into the edge in 5 and 9 layers of rock salt sample, so there appears salt growth ; but at the central and edge zone of 13 layer arises the phenomenon of local corrosion .

Conclusions

There are greater differences of meso-structure of rock salt sample and distribution unevenly. The internal particles and porosity of samples were arranged also unevenly. That means the internal structure of rock salt have initial damage, and fissure begin to develop.

The CT values changed regularly with corrosion, the values of CT were greater after corrosion. The growth rate is connected its internal micro-structure, solution concentration and immersion time. Solution migration occurs inside the sample when it was soaked. Then the external solution gets into the pore of the sample, a part of solution become crystallization, some remains in the pore, lead to density difference of samples and meso-structure changes.

The CT number of 2# sample increased in each layer after corrosion, showing that some substances moved into rock salt and caused increasing of the density in rock salt. The corrosion brine is unsaturated solution. The CT number of the 13 layer overall increased slightly after corrosion , but parts of the area occurs pore expansion and perforation which is shown that the CT number increased slightly, SD values increased obviously, which can account for the original crack of local area inside rock salt, with the new crack emergence, the amount of the fracture increased and connected,finally forming fissure network, namely produce corrosion phenomenon .

The corrosion liquid of 2# sample is unsaturated brine, the analyzed results show that 2# rock salt samples grow salt integrally and corrode locally. The probable reason should be that the concentration of unsaturated brine is too high, the local area fracture inside rock salt developed abnormally.

The density of rock salt is increased with the infiltration of saturated brine, internal cracks closed and holes were filled. The structure was repaired, but the structure that was repaired presents uneven distribution. The phenomenon of salt growth at the edge area of rock salt is obvious; However the phenomenon of salt growth is not appeared in the central area.

Effect of rare earth elements on Microstructure and Mechanical Properties of AZ91D Alloy

ZhichaoLiu[1], YaoLi[1,a,*] and JunjieYang[1]

[1]The school of electromechanical & architectural engineering, Jiang Han University, Wuhan, Hubei Province in China

[a,] *lylly111@sina.com

Keywords: AZ91D magnesium alloy; rare earth element; mechanical properties

Abstract: Rare earth Y, Gd, Nd were added to improve the tensile strength, elongation, hardness and microstructure of AZ91D magnesium alloy in this study. The investigation had been undertaken by 8 GWU type resistance furnace, RGM - 50 electronic machine , Vickers ,etc. Results show that a moderate amount of composite adding rare earth can effectively improve the tensile strength of AZ91D alloy, elongation, hardness and the organizational structure, as a rare earth content increased after the first performance decline. When rare earth content is 1.8%, the highest tensile strength up to 276.58mpa, 8.3% elongation. When rare earth content is 2.4%, the hardness is up to 99.36 HV1.96.

Introduction

In recent years，magnesium alloy has become the most commonly used light structural alloy, plays an important role in the automotive, aerospace, consumer electronics and so on. Magnesium alloy and the expansion coefficient of heat transfer is larger.AZ91D alloy is a kind of foundry magnesium alloy, it has high strength, good heat dissipation, etc. It is one of the hot topics in the study of magnesium alloy, and in terms of a large proportion in the use of magnesium alloy[1].

But in practice, AZ91D is difficult to completely replace the lightweight materials such as aluminum alloy. This is due to the strength and plasticity of magnesium alloys is difficult to meet the requirements of actual use. Existing research[2-4] shows that alloying of rare earth elements can make magnesium alloy get enough reinforcement.

This paper selects the AZ91D magnesium alloy and rare-earth yttrium, neodymium, gadolinium as research materials. With the aid of industrial production equipment, researched on compound added comprehensive effects of rare earth on microstructure and properties of AZ91D alloy.

Experimental materials and methods

Experiment chooses industrial AZ91D magnesium alloy ingot.Using mixed refrigerants YH134a and nitrogen gas,melting in 8 GWU type resistance furnace.Compound of adding different ratio of Mg - Y, Mg - Nd, Mg - Gd rare earth alloy and stirring When the temperature reached 690 ℃ ~ 720 ℃.Thermal insulation for 10 minutes,then making RE-AZ91 magnesium alloy experimental samples in the J1125B type of test die casting machine with a metal die-casting mold at 680 ℃~ 710 ℃.Die casting sample size and die casting process are according to the national standard GB/T 13822-13822 "die casting non-ferrous alloy specimen" regulation requirements.Tensile specimen size chart as shown in figure 1.The experiment using RGM-50 electronic universal testing machine,with tensile speed of 5 mm/min.

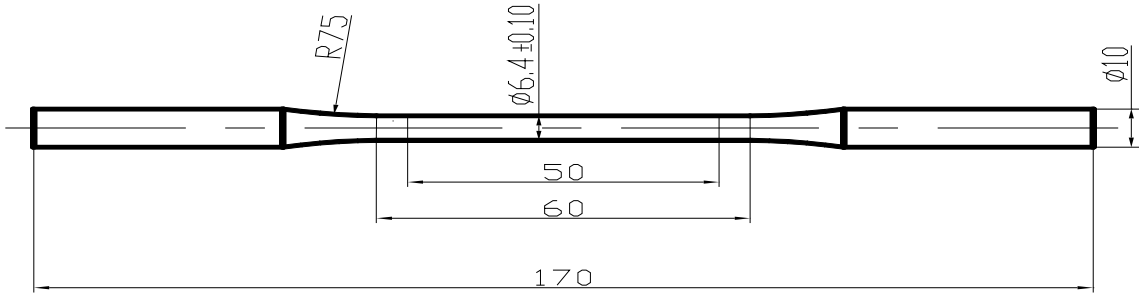

Fig.1 Tensile specimen size figure

Removed the burr of the sample surface, and numbered 10 groups of sample, each group contains three parallel samples. Zero group for not adding rare earth of AZ91D magnesium alloy, the rest of the group of rare earths such as shown in table 1.

Table 1 Adding rare earth elements table

number	Content of rare earth %			Amount of rare earth

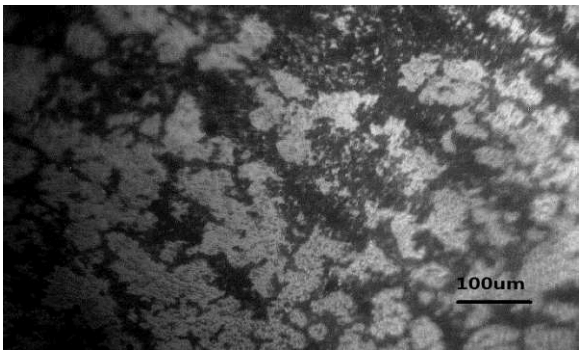
The experimental results and analysis.

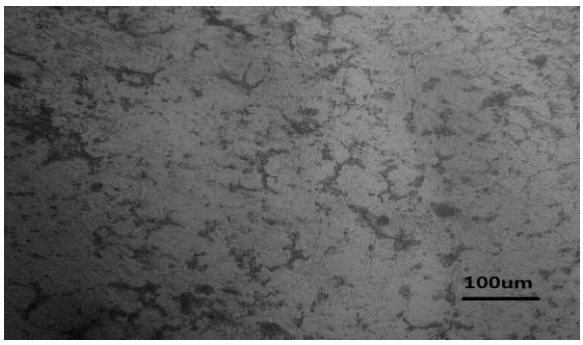
3.1Rare earth magnesium die casting organization and the performance impact

Figure 2 for the different content of rare earth 400 ratio of metallographic sample photos. Figure 2a is not adding rare earth alloy phase diagram, organized by figure known alloy by the matrix and eutectic of precipitation (Mg17Al12) phase. The alpha phase distribution uniformity, beta phase presents the coarse mesh intermittent or continuous irregular distribution, and a small amount of particulate matter exists. The figure 2b and 2c show that with the increase of the content of rare earth basic remains the same, alpha beta phase number, have great changes, and the distribution form by thick mesh gradient for the tiny granule. In addition, the organization of rare earth compounds, and the content is on the rise. By figure 2d, rare earth content is increased to a certain amount, the increase of the rare earths are not further promote the grain refinement, on the contrary make grain overgrowth of. In addition to the above two phase, after adding rare earth alloy, there is a new phase for rare earth compounds, its content increased with the increase of content of rare earth.

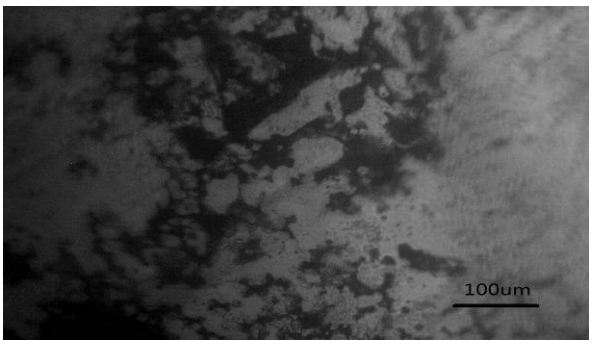


a 0%

b 1%



c1.8%



d 4%

Fig.2 Different content of rare earth 400 ratio photos

In addition to the above two phase, after adding rare earth alloy, there is a new phase for rare earth compounds, its content increased with the increase of content of rare earth. After adding rare earth magnesium alloy, because of the difference between element electronegativity, adding rare earth elements will be priority and Al element reaction, formation of rare earth compounds .The metallography theory shows that the new formation of the rare earth compounds from the elements affected the beta phase.

3.2Tensile experimental results.

The fig.3 shows that the RE (rare earth) content increased, the strength and elongation of the alloy were increased. With the increase of the content of rare earth alloy intensity present a first down later. When the adding amount of RE in the rang e of 1.8%, the strength of the alloy and elongation increase with the increase of rare earth, the highest can reach 276.58mpa and 8.3% respectively. Rare earth content is above 1.8%, , the alloy strength and elongation does not increase, instead of down.

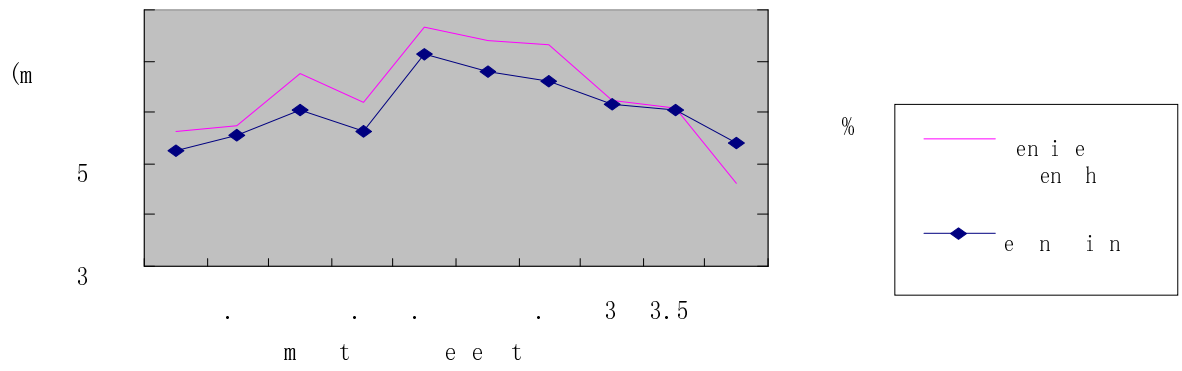


Fig. 3 Tensile strength and elongation of different rare earth content

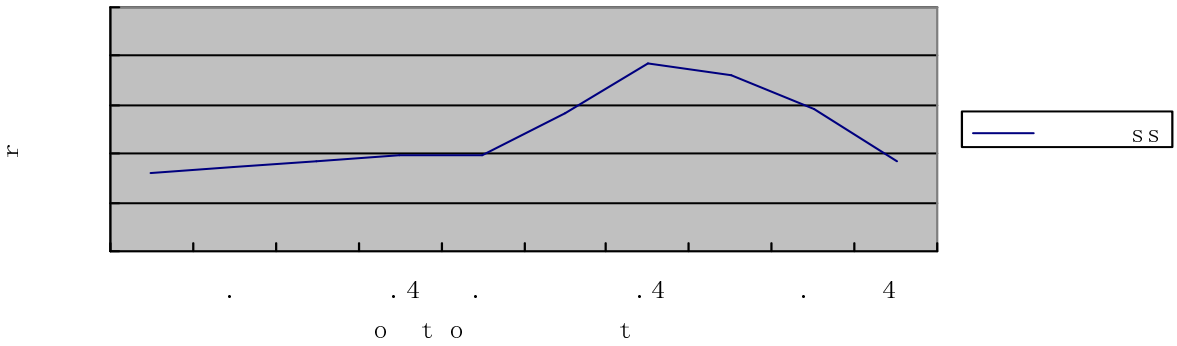

Fig. 4 Hardness

The hall-page formula shows that the size of the grain can affect the strength of the alloy. When adding rare earth alloy, organizations are obviously enhanced, the tensile strength and elongation were increased, surface hardness of alloy rose slightly. And when the organization fully refined grains and uniform distribution, the tensile strength of alloy achieves the best condition, it shows that the rare earth elements by influencing the grain size of the organization's size distribution and then change the performance of the alloy[5].When rare earth content continues to increase, the microstructure changed from spread evenly to part is linked together, and have obvious trend of bulky, the corresponding tensile strength and elongation decreased, and the hardness is increased. Can be thought that tensile strength and elongation are greatly influenced by grain size and distribution, and hardness are greatly influenced by content of rare earth compounds. When rare earth content continues to increase, alloy tensile strength and elongation decreased, and not as good as not adding rare earth, and the hardness and nominal tensile modulus when adding rare earth also dropped to less than not. The grain overgrowth of resulting in a decline in the tensile strength of the alloy at the same time reduce the hardness of the alloy.

Conclusion

1. Adding rare earth can be change alloy casting organization, with the increase of the content of rare earth group shows the tendency of refinement before coarsening.

2. The right amount of compound added rare earth magnesium alloys can be effectively increased the tensile strength, elongation, surface hardness. when rare earth content is 1.8%, the strength of the alloy and the highest elongation can be up to 276.58mpa and 8.3% respectively. When the content of 2.4%, up to 99.36 HV1.96 hardness.

3.Alloy strength and hardness increased with the increase of the content of rare earth were first after a downward trend, but the best rare earth content is different.

Keywords: Nano-SiO_2, Acetic Acid-Acrylate Copolymer, Situ Emulsion.

Abstract. Available nano-silica commercially was modified with silane coupling agent A-151, and then emulsion was synthesized with modified SiO_2, vinyl acetate, methyl methacrylate and butyl acrylate by polymerization reaction. Effects the amount of emulsifier, initiator and organic nano-SiO_2, etc factors on the performance of emulsion polymerization and latex film were investigated. The best test results of composite emulsion of SiO_2 and vinyl acetate-acrylate were obtained by theoretical research and experimental operation: modified nano-SiO_2 content of 3%, the content of 3% emulsifier OP, content of 0.5% potassium persulfate initiator.

Introduction

Vinyl acetate-acrylate emulsion as film forming material has low environmental pollution, good gloss, color retention and resistance to the aging, showing expansive prospects in many fields [1, 2] . However, its poor water resistance, cold resistance, storage stability and low drying rate had limited its development to some extent. It is necessary to study and solve these problems. Composite of nanoparticles/emulsion can improve the aspects of performance greatly. Because the added nano-materials could react with the monomer, emulsifier, and initiator, etc in situ polymerization process[3-6]. The way could allow a more uniform distribution of the nanoparticles in the polymer system. This could also allowa chemical effects and an interface interaction sufficiently and uniformly between the molecules of the polymer and nanoparticle, thus this would has an obvious effect of the performance of these polymers [7].

This paper has used the commercially available nano-SiO_2 modified by silane coupling agent A-151 to be added into the vinyl acetate, methyl methacrylate acrylate, and butyl acrylate, etc monomers and to synthesize vinyl acetate-acrylate emulsion by situ emulsion polymerization method. The effect of the amount of emulsifier, initiator and modifiednano-SiO_2 on performances of the emulsions was investigated.

Experimental Section

Experimental Materials and main test instruments. Toluene, Nano-SiO_2 (Q/RMHGI-2009), a silane coupling agent (A-151), ethanol, dilute hydrochloric acid, vinyl acetate, butyl acrylate, methyl methacrylate, polyvinyl alcohol, emulsifier(OP-10), potassium persulfate, ammonia. Electric mixer (JJ-1), shear emulsifying machine with high velocity(A300-70G-S), infrared spectroscopy (ALPHA), rotational viscometer (NDJ-1).

Preparation of modified SiO2. Nano-SiO2 with a silane coupling agent A-151 was modified at its surface. When content of the A-151 is 5%, effect of SiO2 air gel particle surface modification was the best.SiO_2 of 3 g was dispersed in 90 mL of toluene. A-151 of 5% content was dissolved in anhydrous ethanol of 6 mL. Then they were added into four-neck flask and ultrasonic dispersed by 10 min and stirred at 75 ˚C with constant temperature about 1.5 h. Finally they were cooled to room temperature,

and filtered. The precipitate was washed with ethanol and repeated 4 times to remove the excess of a-151 and byproducts and dried to obtain modified SiO_2.

Preparation of nano-SiO_2 and vinyl acetate-acrylate emulsion. Vinyl acetate of 12.5 mL, methyl methacrylate of 25 mL, butyl acrylate of 12.5 mLas monomers, emulsifier (OP-10, $C_8H_{17}C_6H_4O(CH_2CH_2O)_{10}H$), initiator(KPS, potassium persulfate). Distilled water of 400 mL (the ratio of it with monomer was 1:4), all of emulsifier, polyvinyl alcohol of 0.5 g, modified nano-SiO_2, and 1/5 of the monomer mixture were added into a beaker. They were dispersed about 15 min in a dispersion machine. When water bath is heated up to 80 ˚C, initiator was added to appear blue light. The remaining monomer mixture was added at 80-83 ˚Cdropwise. The reaction was warmed to 85 ˚C.After additional initiator of 0.1 g added, it was cooled to 40 ˚C. Using aqueous ammonia to adjust pH value as 7-8, the material was given out.

The types of experiments: 25% vinyl acetate, 50% butyl acrylate, 25% methyl methacrylate, emulsifier OP (contents of 1%, 2%, 3%, 4%, 5%, 6%), 0.5% initiator KPS and 3%modified nano-SiO_2.25% vinyl acetate, 50% butyl acrylate, 25% methyl methacrylate, 3% emulsifier OP, initiator KPS(contents of 0.3%, 0.4%, 0.5%, 0.6%, 0.7%) and 3%modified nano-SiO_2.25% vinyl acetate, 50% butyl acrylate, 25% methyl methacrylate, 3% emulsifier OP, 0.5% initiator KPS and 3%modified nano-SiO_2(contents of 0%, 1%, 2%, 3%, 4%).

Methods of analysis. Appearance is checked visually. Viscosity is measured by NDJ-1 rotary viscometer. Test method of stability of calcium ion: sample of 8mL composite emulsion was added into a tube with 10mL graduation. Then 3mL (concentration of $CaCl_2$ was 0.5%) added into solution. About 24h later, if lamination phenomena is not appeared, stability of calcium ion was considered as qualification. Condensation rate: after the reaction, the gel was collected, and dried to reach a constant temperature to calculate condensed material accounting mass percentage for monomer. Determination of solids content of the emulsion: approximately1.0gsample was placed in a small beaker to form an uniform film. The film was dried about 6hat100 ˚C and cooled to room temperature and weighed. The aqueous assay: take emulsion of 100 μL on glass pane to prepare dry film at 30 ˚C and then the dry film was soaked in deionized water, phenomenon was observed after a day. Film-forming: the prepared emulsion was coated on a clean glass surface at room temperature. The film formation conditions of the emulsion were observed.

Results and Discussion

Effect of the amount of emulsifier on properties and viscosity of the emulsion. From the table 1 it can be found that when the amount of emulsifier at 1% and 2%, the appearance of the emulsion would have a stratification phenomenon, mainly due to insufficient amount of the emulsifier, thus only a small part of the surface of particles of the monomer mixture was surrounded by emulsifier molecules. Less than enough emulsifier molecules were absorbed into surface of the monomer mixture particles, which cannot sustain a stable emulsion, and stability of the emulsion was not good and gloss of the liquid was not too good. The reactants were not fully reacted. When the amount of emulsifier is between 3% and 4%, sufficient emulsifier improved stability of the emulsion polymerization process. The polymerization rate became faster. Appearance of the resulting emulsion was uniform, good gloss, and no precipitation. Increasing the amount of emulsifier continuously to exceed 5%, emulsifier was too more, and the emulsions contained more coarse particles and agglomeration phenomenon, thus a little precipitate has formed.

Figure 1 shows that amount of the emulsifier increase the viscosity of the emulsion. An increase in the number of colloidal particles was caused by an increased probability of a single particle nucleation and decreasing of the large particle diameter, thus the surface area of the particles became larger, thus bind the particles together to increase the viscosity of the emulsion performance. However, when the viscosity is very large, the cohesion was increased, and stability of the emulsion was decreased. The optimum of amount of the emulsifier was 3%.

Effect of the amount of initiators on properties and viscosity of the emulsion. As shown in the table 2 and figure 2, when content of the initiator is at 0.3%, polymerization was not very stable, and the appearance of emulsion was gray. It was because of amount of the initiator was very less, and the

reaction rate would be smaller, and thus the conversion of monomers was low. The chemical reactions were not complete. The particles of the emulsion became unstable, thus resulted in the larger rate of aggregation. The amount of initiator of 0.7% produced violent polymerization. It was because more free radicals were formed to accelerate the rate of polymerization, thus the emulsion stability became lower. The amount of initiator at 0.5% made emulsion attain a best performance.

Table 1 Effect of the amount of emulsifier on properties of the emulsion.

Amount of emulsifier/%	Appearance	Viscosity	Gloss	Stability of Ca^{2+}
1	White, stratification	15	Poor	More precipitation
2	A little stratification	20	General	Little precipitation
3	White, blue	26	Good	No precipitation
4	White, blue	29	Good	No precipitation
5	White, a little blue	35	Good	Little precipitation

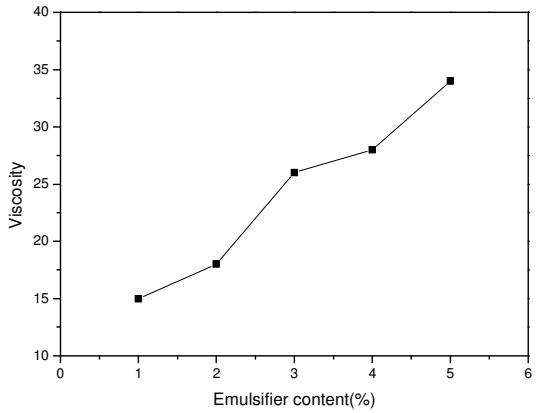

Figure 1 Effect of the amount of emulsifier on viscosity of the emulsion.

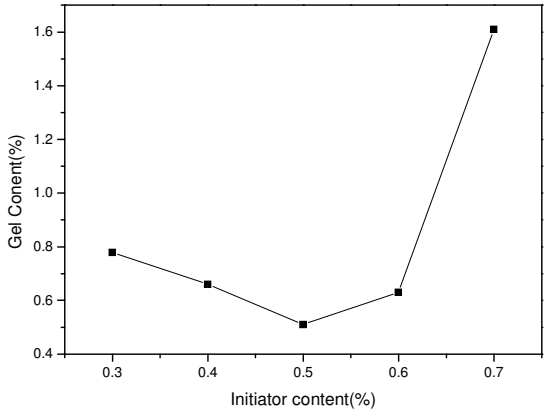

Figure 2 Effect of the amount of emulsifier on polymerization degree of the emulsion.

Table 2 Effect of the amount of initiators on properties of the emulsion.

The amount of initiator/%	Aggregation rate/%	Appearance
0.3	0.79	Gray
0.4	1.2	White
0.5	0.52	White, blue
0.6	0.67	White,a little blue
0.7	1.57	White, yellow

Effect of the amount of the modified SiO_2 on properties and solids content of the emulsion. Modifiednano-SiO_2 had better original dispersion to improve the properties of the emulsion. As can be seen from Table 3, with the increase of amount of the SiO_2 from 0 to 3%, water resistance changed better. When diameter of the SiO_2 particles is smaller, the surface area of the particles would be increased, thus chemical bind had more opportunities of binding between polymer chain and particles. However, excessive amount of SiO_2 led to worse water resistance. This was mainly result of agglomeration and lost of nano effects of air gel.

Table 3 Effect of the amount of nano-modified SiO_2 on properties of the emulsion.

Nano-modified SiO_2/%	Solid content/%	Water resistance	Film-forming
0	53.9	Better, white	Uniform, transparent
1	47.2	Well, white	Uniform, transparent
2	41.7	Well, white	Uniform, transparent
3	37.8	Well, no white	Uniform, transparent
4	32.5	Poor, no white	Fine lines, yellow

As can be seen from Figure 3, the solid content decreased with the increase of the use of SiO_2. The reason may be result of reactions of between the excessive charge on the surface of SiO2 and free radicals produced by the initiator. This decreased the efficiency of reaction of initiator. Usually for the polymer emulsion, the solids content is about 35%, latex particle size is prefer between 0.1 and 0.5 μm. If the polymer emulsion had an average particle diameter of 0.1μm, and an average particle diameter of the cores had 10μm, under suitable process conditions and the ratio of raw materials, and the reaction did not generate the new latex particles, the monomer would be seen as the seed particles of the polymerization. According to the theoretical calculation, the amount of SiO_2 as seeds should be less than0.14% of amount of the total monomers. The theoretical amount of SiO_2 as air gel should be less than 5% of amount of the total emulsion. Obviously, the amount of SiO_2 was too low to reflect the nano performance of it.

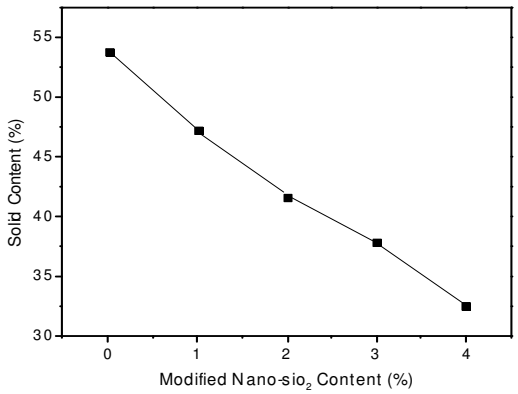

Figure 3 Effect of the amount of nano-modified SiO2 on solid content of the emulsion.

Analysis of IR spectrum. For understanding the change of structure and properties of vinyl acetate-acrylate emulsion, IR results them modified by nano-SiO2 before and after were characterized. After modification, at 1637 cm^{-1}, 1407cm^{-1}, 1115cm^{-1} and 544cm^{-1}, absorption peak moved to long wave direction respectively, showing structural change of the emulsion. At 3431 cm^{-1}, the absorption peak moved to 3449 cm^{-1}. The movement showed existence of -OH and -COOH groups and increased amount of them. Moreover, the absorption peak of 1115cm^{-1} approved existing of functional groups of –C=O and –C-O-C- etc.

Conclusions

When the amount of the silane coupling agent (A-151) is 5%, the effect of surface modification of surface of the SiO_2 was best and can achieve best dispersion effect in the emulsion, thus effectively prevent the occurrence of agglomeration of nano-SiO_2 particles with the effect of high surface energy.

In modified nano-SiO_2 and vinyl acetate-acrylate emulsion, under nano-SiO_2 content of 3%, emulsifier (OP-10) as 3% of total content, initiator of potassium persulfate as 0.5% of total content, the prepared vinyl acetate-acrylate emulsion showed good shiny, viscosity, solids content and stability and performance of emulsion had been significantly improved.

After modification by nano-SiO_2 based on the silane coupling agent (A-151), absorption peak moved to long wave direction respectively, showing structural change of the emulsion. Surface of modified emulsion were grafted by polymers.

Keywords: Qarham to Golmud expressway, saline soil, subgrade, technique of salinization prevention, Qarham salt lake

Abstract. Qarham to Golmud expressway is the first high-grade road in Qarham salt lake, which is regarded as the most enormous inland salt lake in China, moreover, it is the first expressway built on the inland salt lake in China. There is high and excessive saline soil distributed over this area whose thickness is no less than 20m, but the average subgrade height of the expressway is only 2m. A great many of measures are taken for the construction of the subgrade to prevent salt migrating from foundation to roadbed and pavement, which will cause disasters of secondary salinization in roadbed and pavement. By paving testing road at the site and detecting the efficiency of the measures in preventing salt, the paper put forward the technique of preventing subgrade from salinization for Qarham to Golmud expressway. The results of testing and detecting demonstrate that the height of salt migration is only 45cm in subgrade under the condition of brine supply, which is less than the height of subgrade. So it is efficient to keep the roadbed and pavement from the erosion of salt; The settlement of road surface was about 0~2mm among 3 months since the highways had been opened to traffic for two years, and uneven settlement and other diseases caused by the secondary salinization were not appeared, which showed that the measures of salinization prevention (salt resistance) were taken well to achieve the design purposes.

Introduction

Currently, the grades of domestic existing roads are limited to 2 to 3 in saline soil area, and the construction of high grade highway is lack of engineering practice and the corresponding support of technology. Qarham to Golmud expressway is the first high grade way in saline soil regions, while it is the first expressway in the field of inland salt lake in China. It used a variety of techniques of salinization prevention and achieved the desired effects, which provides practical experience and technical reference for the highway construction in saline soil regions.

The analysis of salt migration

In order to study the technique of salinization prevention of highway subgrade, we have to understand the migration of salt in subgrade and the factors that affecting this migration. According to massive relevant literatures[1-5], the primary methods of the migration involve that: 1) salt rises along with the rise of capillary water, the moisture evaporation or the temperature decrease, leading to the salt precipitation, which causes the secondary salinization; 2) the infiltration of surface water or rainfall leads to the invasion of salinity into roadbed; 3) salinity increasing is accompanied by

conflux rising, capillary water gathers from high temperature area to low temperature area, and moisture and salinity moves upward in embankment. The Qarham salt lake has a long time of droughts, with less rainfall, than which the evaporation is much greater. So the salinity move-up with capillary rise is overwhelmingly dominant.

The main factors that influencing the migration of capillary water (salinity)[6-9] include that: 1) soil particle size; 2) the salinity of capillary water; 3) types of salt.; 4) soil density. The greater the soil density, the smaller the migration of water and salt[10]; 5) The overlying conditions of surface [11]. In addition, soil permeability, temperature phase transition, and temperature gradients also have some effects on salt migration.

The measures of salinization prevention for subgrade in Qarham to Golmud expressway project

General situation of Qarham salt lake.

Qarham salt lake is the largest inland salt lake in China. The subsoil is mainly the chlorine excessive saline soil, and the salt content of topsoil is as high as 90%. The groundwater level is about 0 to 2.0m whose the salinity is 310 to 370g / L. The head height of pressurized brine layer is 2 to 5m, while the salinity of the water is 79 to 392g / L [12-13]. The embankment of Qarham to Golmud expressway is mainly low embankment, that the average filling height is 2.0m.

The measures of salinization prevention

Gravelly soil subgrade

Well-graded gravel soil reclamation was used as the subgrade filler in the Qarham to Golmud expressway, and the subgrade compaction was strictly controlled to reduce capillary water rising height. Subgrade filler adopted gravel soil, of which the natural moisture content was 1.4% to 1.6%, the optimum moisture content was 4.4% to 5.5%, and the maximum dry density was 2.22 to 2.30g/cm^3. The minimum intensity and maximum particle size of Subgrade were implemented according to the regulations in the " Specifications for design of highway subgrades " (JTG D30-2004)[14].

The analysis results of subgrade particle size are shown in Table 1. The particle size was mainly distributed among the range of 40mm ~ 2mm, which took up 70.4%, the uniformity coefficient Cu was 27.81> 5, and the curvature coefficient 1 <Cc was 1.7 <3; it was gravel type soil with good grading.

Table 1 Test results of particle size analysis of gravelly soil

Particle size range (mm)	100~60	60~40	40~20	20~10	10~5	5~2	2~1	1 0.5	0.5 0.25	0.25 0.075	≤0.075
Percentage (%)	0	3.20	58.00	3.50	4.30	4.60	3.60	5.80	12.90	2.80	1.30

The separation layer technique

In order to prevent capillary and gaseous capillary water rise, the gravel separation layer and impermeable geotextile barrier layer were set up between the embankment and roadbed.

The material selection of separation layer

The material selection of separation layer should be based on local materials, road grade, subgrade height and hydro-geological condition [15]. The gravel reserves are rich along the road that it is suitable for building the gravel separation layer. The particle analysis results of separation layer material are displayed in Table 2, the particle size was mainly distributed in the range of 2 mm

~ 40mm, which took up 99.06% and the uniformity coefficient Cu was 3.14 <5 , which was poorly graded gravel. The natural moisture content of gravel was 1.1%, the maximum dry density was 2.28g/cm3，and the void ratio was 1.38. The impermeable geotextile is laid in the top of separation layer, the indicators should be consistent with the specification [16].

Table 2 Test results of particle size analysis of gravel

Particle size range (mm)	100~60	60~40	40~20	20~10	10~5	5~2	2~1	<2
Percentage (%)	0.00	0.82	43.84	33.49	20.33	1.40	0.12	0.12

The separation layer set

The separation layer set and construction techniques were determined through a field trial road paving combining with the construction appropriate test in the barrier layer. The thickness of gravel separation layer was 30cm; the impermeable geotextile was laid on it, under which 10cm sandy gravel was laid as a protective layer. The separation layer set is shown in Fig.1.

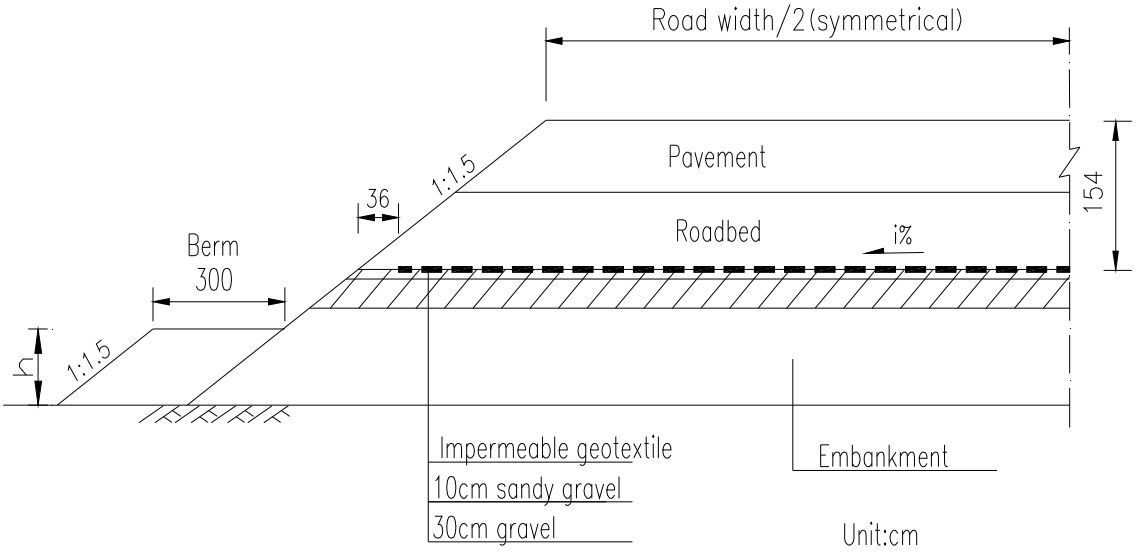

Fig.1. Separation layer set

The effect test of subgrade salt resistance

Subgrade soil was taken to measure the moisture and salinity after the embankment was completed, which as the initial value: the initial moisture was 0.4%, and the initial salt content was 1.321%. The period of the examination of salt resistance in roadbed was 2 years, the examination depth of subgrade was 0～1.5m.The test results of water and salt content of subgrade filling are shown in Table 3 and Fig.2.

Table 3 Test results of water and salt content of subgrade filling

Soil number	Height(cm)	Water content(%)	Salt content(%)
1—1	145	0.3	1.510
1—2	125	0.3	1.453
1—3	105	0.3	1.302
1—4	85	0.4	1.247
1—5	65	0.4	1.130
1—6	60	0.4	1.473
1—7	55	0.3	1.437
1—8	50	0.9	1.752
1—9	45	1.3	2.494

1—10	40	1.6	3.056
1—11	35	1.8	3.894
1—12	30	2.2	3.964
1—13	25	2.6	5.635
1—14	20	3.1	5.041
1—15	15	4.0	6.769
1—16	10	4.8	8.334
1—17	5	5.3	9.868

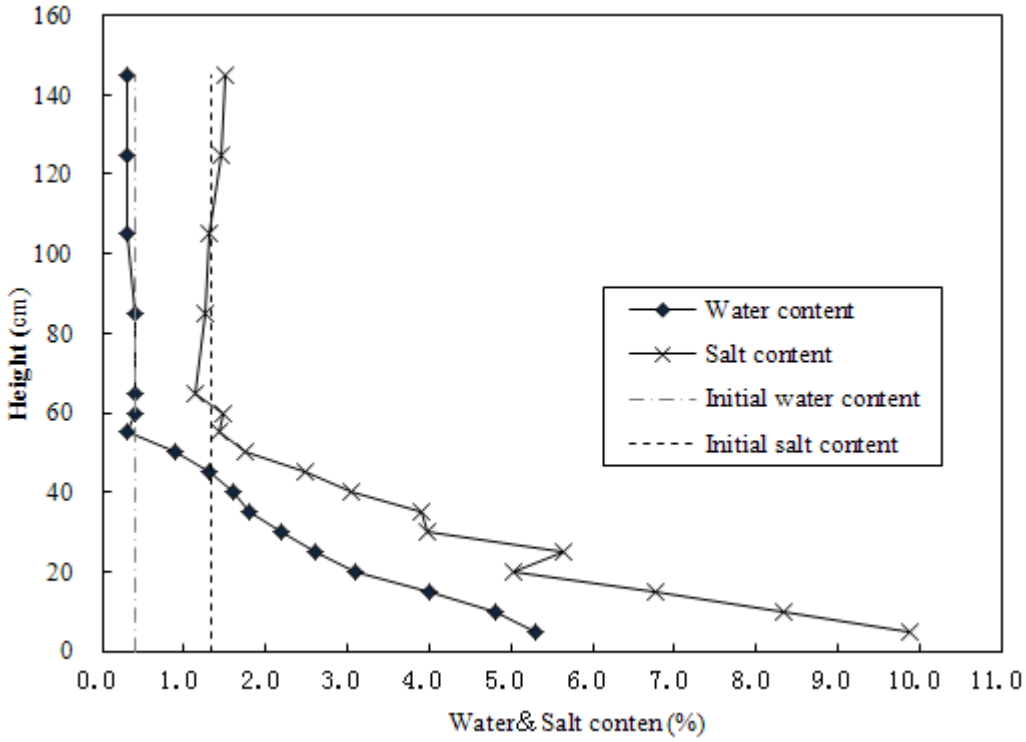

Fig.2. The height of rising capillary water and salt

(1) Moisture migration condition: As can be seen from the moisture curve, the water content decreased gradually from the bottom to up, and it was 0.9% at 50cm, 0.3% at 55cm. The curve come out a significant turning point at 50cm, and the height of capillary water rising was 50cm.

(2) Salt migration condition: As is shown in the salinity curve, the salinity decreased gradually from bottom to up, and at the height of capillary water rising, that is 50cm, the salt content was 1.752%, greater than the initial salt content, which illustrates that the capillary water rise brought out salt migration to make the salt content of the soil changed. The salt content was 2.494% at 45cm, greater than 2% of threshold salinity, which indicates that non-saline soil had been transformed into weak saline soil, and the critical height of salinization of good gravel was 45cm under the condition of brine supply.

Test results showed that: the internal migration height of water and salt were 50cm in gravel subgrade, the volume of migration gradually decreased with the height increasing, and the effect of salt blocking was obvious. The whole settlement of road surface was about 0~2mm among 3 months since the highways had been opened to traffic for two years, and uneven settlement and other diseases caused by the secondary salinization were not appeared, which showed that the measures of salinization prevention (salt resistance) were taken well to achieve the design purposes.

Conclusions

(1) The techniques of salinization prevention for highway subgrade were put forward depending on the project of Qarham to Golmud expressway: Coarse-grained materials such as gravel soil were used as subgrade filler; the gravel separation layer and geotextile barrier layer were set in subgrade structure;

(2) The separation layer trial road was built to finally determine the settings of the separation layer and the construction technology.

(3) According to the monitoring of road operation, the water and salt content within the scope of the structural layers were consistent with the initial value, the amount of settlement was small, and the salinization diseases were not found in the embankment since the highway was opened to traffic, which evidence that the measures of salinization prevention used in Qarham to Golmud expressway are effective.

(4) The research results can provide technical references and support for the new construction of expressway, the renovation and expansion project, the road maintenance and so on in saline soil area.

The current situation and development trend of Electroforming

Wuxin Yu[1], Shiqian Zhou[1,a]

[1]The school of electromechanical & architectural engineering, JiangHan University, Wuhan, Hubei Province in China

[a]zhoushiqian0225@163.com

Keywords: electroforming, overpotential, micro fabrication, nanocrystalline

Abstract: Electroforming technology is an important part of micro fabrication andfine parts and composite materials prepared by the electroforming technology has broad application prospects. This paper describes the principle and method of electroforming, introduces the development and the basic elements of electroforming, then concludes the research status and main research direction and trend of this technology.

Introduction

Electroforming is based on electrochemical principle,which electrodeposited metal layer on cathode mold, and then separated the layer from the original mold for electroforming layer.Since 1838, Russian professor Jacobi developed copper electroforming, 1842 German scientist Professor Boettger invented the nickel electroforming[1-2],Electroforming process has 170 years of history. In early times, electroforming process was used to produce exquisite and complex crafts or apply in printing industry, the range of application is narrow. With the increasing profound understanding of electroforming technology, research on electroforming process has been more and more deeply. In the last 50 years,the applications of electroforming technology has had a greater degree of expansion which extends to mold, automotive, electronics, materials, aerospace, weapons and other manufacturing fields.

In the machinery industry, electroforming is used to make complex shapes and high precision machining or otherwise difficult to hollow parts, injection mold cavity, and other fine surface profile , electroforming material can also expand from copper to nickel, iron and its alloys (or other alloys) for the high replication accuracy, surface finish.

Principles and characteristics of electroforming technology

Electroforming principle: use the pre-made original mold which is according to the desired shape as a cathode, use electroforming material as an anode , then put them together into appropriate metal salt solution, through DC. In electrolysis, the original mold surface gradually deposited metal electroformed layer. After reaching the desired thickness we removed it from the solution, and separated the electroformed layers from the original mold to obtain a shape corresponding to the original copy of a metal. Electroforming technology consists of four basic elements:an anode, a cathode (to be plated original mold), the electrolyte, and the power. As electroplating technology, both are belong to the ion adsorption behavior under current effect.The difference is, purpose of electroplating is forming coating on the material surface to protect or decorative raw materials, but the purpose of electroforming is obtaining manufacture parts which is hard to made by machining method, the final deposition of metal can form an independent structure.

From the results we can see some differences, the thickness of the electroplated coating is generally about 1 to 30 microns, the thickness of the electroformed layer often greater than tens of microns, even to the millimeter. Judging from the expected results, we hope to combine raw materials and electroplating coating very closely, they can not appear peeling phenomenon, but we hope electroforming layer can separated from the original mold easily.

Compared to other processing methods, electroforming method has the following three main features:①Can quickly replicate the complex shape, deformation processing of large or difficult to machine parts.②Higher copy accuracy which can achieve sub-micron level, far beyond the ordinary machining methods. ③ Processing costs are relatively low, there is no waste of materials processing[3].

Development of electroforming basic elements

2.1 Effect of power on electroforming

For electroforming experiment using DC in normal circumstances, under different power the quality of cast layer, electroforming speed, energy consumption are different.When using ordinary DC power electroforming complex shape castings，Because the electric field e effect between the cathode and anode, casting surface and edges generate a lot of buildup, electroforming has disadvantages of effective rate, higher consumption, in some cases it cannot meet the requirements.

Using current pulse is an effective means to improve the quality of electroforming layer.Pulse electrodeposition change original current to periodic pulses current, the pulse power impact on the quality and physical properties of the deposited layer greatly.There is close relationship between the metal crystalline morphology, growth patterns and cathodic polarization overpotential. Increase the overpotential during electroforming can lead to fine-grain and cast layer of dense.

At the same time within the pulse interval, metal ions can quickly add at the cathode interface and significantly reduce the concentration polarization. So we can achieve higher electrochemical polarization by using pulse current which has higher electric potential than conventional DC, ultimately makes the cast layer of grain refinement, improved densification[4~5]. In addition, the pulse current can improve the dispersion of the electrolyte, improve ability to both plating, it also changes physical and mechanical properties of the electrodeposited layer.

2.2 Effect of anode on electroforming

The anode materials commonly used today has two types: One is a metal material that containing the cation in the electrolytic solution，This anode material can add the depletion of cationic in the electrolytic solution ，this method is commonly used in the LIGA technique, used for the preparation of micro and small parts. The basic process includes steam plating, using the metal layers below the photoresist as electrode for electroforming, then filling metal into the void of the three-dimensional structure of photoresist，at last forming a stable concave-convex metal that convex complementary to photoresist pattern. Removed the photoresist and the substrate material attached to it when the electroformed layer has a certain thickness and strength. Then we can obtain the casting mold[6~7].As it shown in Fig.1, soluble metal anode are also used in pictographic-anode electroforming[8]. This method can make the clearance between anode and original model of each corresponding point basically consistent, It ensures more uniform electric field, thereby cathode deposition rate remain basically the same.

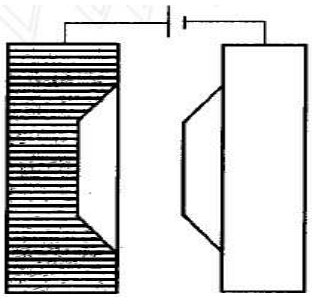

Fig.1 Soluble pictographic-anode Electroforming

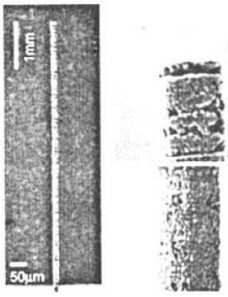

Fig.2 Electroforming of micro copper cylinder

The other is insoluble inert anode, typically platinum or graphite.It is commonly used to cast linewidth uniform, simple structure parts or do laboratory studies of metal ion electrodepositing behavior. For example：Dr.Said used a platinum wire anode to deposit fine copper cylinder in copper sulfate solution,the length diameter reached 282, the deposition rate reached 8 um/s(Fig.2)[9]。

2.3 Effects of electrolyte on electroforming

Usually electrolyte consist of the main salt, conductive salt, buffering agents, anode activator, complexing agents, additives, etc. Each components has different functions in electroforming process. Composition of electroforming liquid should not be too complex,for electroforming process is relatively long, the complex composition will easily change significantly, thereby increasing the difficulty of maintaining the solution.

For example, in nickel electroforming, we currently mainly use electrolytic solution of two types: Watt type and amino sulfonate type. Watt-type electrolyte solution has the advantages of low cost, easy maintenance, easy operation, but the disadvantage is coating of greater internal stress; electrolyte solution of amino sulfonate type has the advantages of less internal stresses, but the disadvantage is the higher cost of the electrolyte, a strong sensitivity to impurities.The solubility of nickel-sulfamate is much higher than nickel sulfate in aqueous solution, so that a high current density and high electrolyte concentration (300 ~ 650g / L) can be electroformed. Under these conditions, we can obtain electroformed casting that hardness range from HV200~750, strength up 340 ~ 1370MPa [10]。

Buffering agents effect mainly reflected in the stability of PH changes due to a variety of reactions during electroforming process, thereby stabilizing the electrode potential of each material. Such electroforming process lead to small change of current density and better quality of the electroforming layer.

Complex in electroforming has the following effects：

1. Promoting normal dissolution of the anode (soluble anode)
2. Preventing metal hydrolysis, stable plating solution
3. Increasing cathodic polarization,improving crystalline coating
4. Enhanced the activity of cathode surface
5. Masking metal impurities in plating solution

Additives have some influence on crystal grains size of the electroformed layer. By selecting appropriate additives and controlling the dosage can reach the objective of controlling the crystal grains size.

The development trends of electroforming process

Current research of electroforming technology to further the development of three aspects: 1. New materials and equipment of electroforming; 2. Explore the copy process for special type of parts; 3. Study of micro electroforming for precision and ultra precision machining.

In recent years, research of electroforming process mainly has following several aspects:Composite electroforming, Alloy electroforming and Nanocrystalline electroforming.

3.1 Composite electroforming

There are two types of composite electroforming：One is adding fine dispersed solid particles to the solution during electroforming,so that deposited metal layer is finally obtained with the fine solid particles,thereby increasing the hardness,strength and wear resistance of the electroforming metal,while improving the electroforming product's service life. Wang Xuran, Feng Xiaoming [11], et al. obtained composite electroforming layer of iron base SiC_p friction material on the surface of Q235 steel. They found that when the the concentration of SiCp is 35g/L, the current density is 3.5A/dm^2, the pH value is 1~1.5, temperature is 35 ℃, SiCp is uniformly dispersed in the composite electroforming layer(Fig3, Fig4), and crystallite size is more uniform.Composite electroforming friction layer's dry friction is 0.55 ~ 0.60, the wear rate is less than $0.42\times10\text{-}^7$ cm^3 / J, and the wear resistant property is good.

The second is winding high-strength fiber to the cathode of the original mold, so this high-strength fibers embedded in Electroforming metal layer ,thereby electroformed layer strength is greatly improved. High strength metal fibers, glass fibers and ceramic fibers are usually used as reinforcing fibers. Qian Wanghuan,Qu Ningsong[12] et al obtained composite nickel electroforming layer by using boron fiber. They found that when fiber volume fraction of 40%, the current density is 4A/dm^2, the tensile strength of the composite electroforming layer can reach 1255MPa at room temperature,Tensile strength relative to pure nickel electroforming layer (550Mpa) has improved significantly.

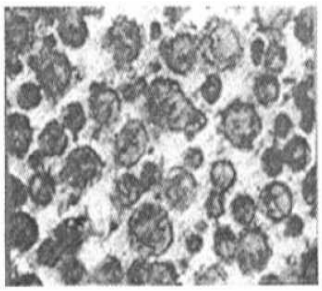

Fig. 3 Surface morphology of the composite electroforming layer650×

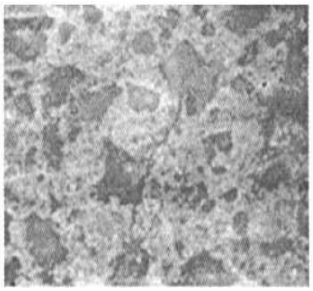

Fig. 4 Section morphology of the composite electroforming layer650×

3.2 Alloy electroforming

In alloy electroforming, there have been many research achievements on nickel-copper, nickel-iron, nickel-manganese,nickel-phosphorus and other binary alloy. The electroforming alloy often has many excellent properties, they are often used to product many important components. Nickel-copper, electroforming, for example, has been widely used in rocket nozzles cooling channels. There have been successful cases on rocket engine combustion chamber system by using electroformed Cu/ Re alloy with good weldability, high temperature resistance, high hardnessand high strength [13].

He Fengjiao, Zhang Yubin[14] studied the process of electrodeposition of iron-nickel alloy thin films and found that increasing the iron content or increasing the cathode rotational speed will both increase the iron content in the alloy film. The optimum process parameters for the preparation of iron nickel alloy: C_{Fe}=0.15mol/L, rotational speed V=300~800rpm, pH 2.5~3.0, complexing agents0.10-0.2mol/L, temperature 45-65℃, Boric acid 35-45g/l，current density15-25A/dm^2；In this case the iron content can reach 33-45%， the alloy films is smooth, bright, dense and of good flexibility.

Wang Ruiyong, Long Jinming[15] studied the electroforming process of copper content of 28 to 30% Ni-Cu alloys(Monel); Yang Dongfang, Pei Hezhong[16] used the response surface method to do further analysis of the factors influencing the Ni-Cu alloy electroforming coating grain size.

3.3 Nanocrystalline electroforming

Nanocrystalline electroforming is a research hotspot of domestic and foreign scientists. When the metal materials' grain refining to the nanoscale, they will have a quantum size effect, small size effect, surface effect and macroscopic quantum tunneling effect.

Canadian scientist Erb et obtained nano nickel, nickel-based alloys by using pulse current method with organic additives such in Watts electrolytic solution and studied the alloys' microstructure and properties[17]. Domestic research on nanocrystalline electroforming is relatively late. Zhu Di studied precision electroforming technology of nanocrystalline nickel, and obtained nanocrystals nickel electroforming layer at the size of 20 nm(Fig.5), inally studied the relationship between process parameters and microstructure of the electroforming layer[18]。

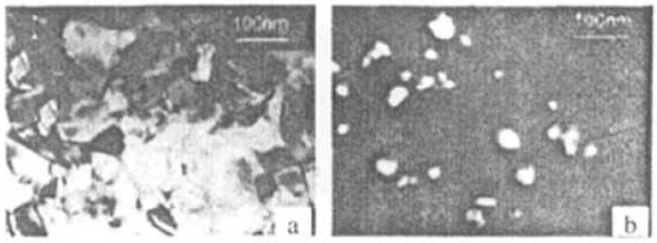

Fig.5 Electroforming nanocrystalline

Conclusion

Electroforming technology has been invented over 170 years. Electroforming materials have changed from copper, nickel, iron metal to today's composite, nano-crystalline alloy materials etc; From the early primary application, preparation of the print version, electroforming developed to various high-tech precision manufacturing and traditional manufacturing. With the continuous development of physical chemistry, materials science, mechanical engineering, electrical engineering, environmental science and other disciplines, will expand the application of electroforming and electroforming technology is bound to a further development.

Keywords: Al-based alloy, Si-content, Chemical composition, Microstructure, Erosion property

Abstract. In order to develop new protective materials for magnesium alloy, Al-based alloys with different Si-content were fabricated by copper mold casting. Microstructure, erosion properties of the ingot samples were characterized or tested by using spectrum analysis, optical imcroscope, salt testing machine etc, respectively. The results indicated that the microstructure of Al-1.9Si-1.32Mg-0.40Mn was mostly dendritic crystal. That of Al-13Si consisted of α-Al, flaky eutectic silicon and primary crystal silicon. That of Al-18Si-0.01%P was consistent of a large proporation of primary crystal silicon phase, a part of eutectic silicon phase and a little of α-Al phase. With Si-content increasing, anti-corrosion properties of Al-based alloy gradually improved, which could provide theoretical principle to determine chemical elements of protective materials for magnesium alloy.

Introduction

With outstanding performance, called 21st century green engineering materials, magnesium alloys have been applied in aerospace, automotive, military weapon and equipment etc[1]. However, owing to be prone to be severely corroded, large scale application of magnesium alloys was still restricted[2]. Therefore, the development of surface protective materials for magnesium alloy had become an international research hotspot among materials field. Now, surface protective materials used for magnesium alloys included mainly commercial pure aluminium, Zn-Al alloy, Al-12%Si, Al356 and Al-Al_2O_3 mixed powder etc[3-5]. Application of the powders mentioned above might improve wear-resistant properties or anti-corrosion properties of magnesium alloy at certain extent. However, its features such as bond strength and erosion property etc, could not meet the requirements used in high temperature, high humidity and high salt-fog environment.Therefore, new type protective materials for magnesium alloy should be exploit, which could deposit effevtively and generate excellent coating with superior performance.

In the present work, Influence of Si content on microstructure and erosion properties of Al-based alloy was investigated, which laid a foundation for the further development of protective powders and preparation of coating on magnesium alloy.

Experimental method

Industrial pure aluminum, industrial pure silicon and industrial pure magnesium utilized as raw materials to generate ingots. Industrial pure aluminum was melted firstly in graphite crucible equiped at intermediate frequency induction coil; then the other raw materials were added in turn. At certain temperature measured by K-type thermocouple, fused mass was poured into water-cooled copper mold and solid into ingot.

The samples prepared as follows: the casting ingot cutted into given size by band saw, machined by lathe, preparatory grinded, fine grinded and polished; Then etched using 30%HNO_3-40%HCl-30%H_2O. FOUNDRY-MASTER PRO optical spectrometer adopted to analyze chemical composition of the sample. Leicae DMI5000M optical microscope applied to observe its microstructure.

Salt-fog corrosion experiment conducted in DCTC1200P type test case. The 50+5 g/L corrosion fluid with PH value 6.5-7.2 adopted, which made from the sodium chloride consistent with GB1266 dissolved into distilled water.Then the samples placed into salt-fog case. Experimental temperature kept at 35±2 ℃ and mist spray 12 hour interval.

Experimental results and discussion

2.1Chemical composition test. Table 1 presented chemical composition spectral analysis results of the casting ingot samples including Al-1.9Si-1.32Mg-0.40Mn, Al-13Si and Al-18Si-0.01%P. The chemical composition of each casting ingot was within setting scope, which proved the excellent melting process control. The testing value of Si and Mn content in Al-1.9Si-1.32Mg-0.40Mn and Si content in Al-18Si-0.01%P was higher than that of theorical value. The main reason is that, considering elements burning loss during melting, addition actual amount of each element was slightly higher than the theoretical value in design. Due to melting titanium alloy cap and doped into aluminum alloy flux during addition of raw silicon materials, Ti-content increased significantly in Al-18Si-0.01%P.

Table 1.Chemical composition spectral analysis results of alloy

	Al	Si	Fe	Ti	Mn	Mg	P
Al-1.9Si-1.32Mg-0.40Mn	95.9	1.91	0.215	0.019	0.426	1.32	-
Al-13Si	86.6	13	0.186	0.03	-	-	-
Al-18Si-0.01%P	80.9	18.6	0.205	0.124	-	1.32	0.0084

2.2 Macrostructure observation. Fig.1 (a)-(c) exhibited macrostructure of Al-1.9Si-1.32Mg-0.40Mn,Al-13Si and Al-18Si-0.01%P alloy,respectively. It was founded that the grains in Al-1.9Si-1.32Mg-0.40Mn casting ingot was coarse and no obvious defects such as porosity and loose; There existed fine equiaxed grains at top layer, and columnar crystal region grown vertical to the die wall in the middle region, and equiaxed crystal region in the core. Superiorsurface layer of Al-13Si ingot was composed of a little short columnar crystal, and there existed a large proportion of uniform isometric crystal enclosed by black eutectic structure. Al-18Si-0.01%P casting ingot possessed an obvious columnar crystal area at the edge and isometric crystal region in the core. Due to the increasing Si-content, black area increased in the core of casting ingot increased.

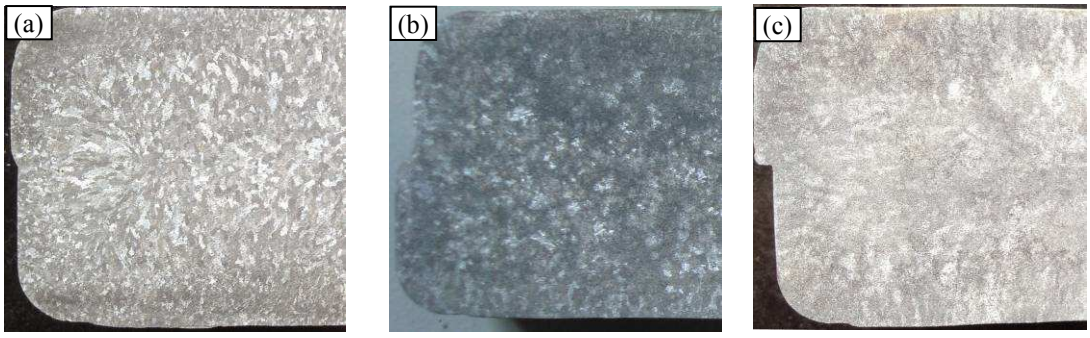

Fig.1. Macrostructure of different alloy

2.3 Microstructure observation. Fig.2 (a)-(c) displayed microstructure of Al-1.9Si-1.32Mg-0.40Mn casting ingot under different magnification. It was founded that the grains appeared rosette morphology and its size was about 200 um. Secondary dendrite arm spacing was smaller; and there existed an amount of strip mesophase. The most area was aluminum phase.

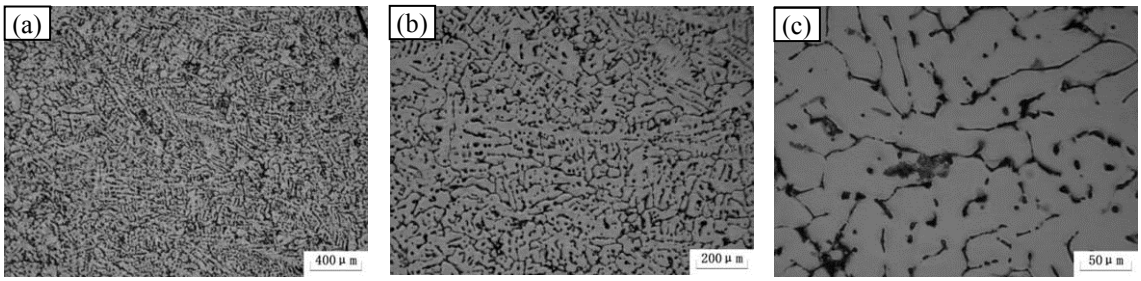

Fig. 2. Microstructure of Al-1.9Si-1.32Mg-0.40Mn casting ingot under different magnification

As seen in Fig.3 (a)-(c), The microstructure of Al-13Si casting ingot was composed of white bulky dendritic α-Al phase, black lamellar eutectic silicon phase and grey block primary silicon.Block primary silicon and lamellar eutectic silicon distributed around the dendritic α-Al. The area of aluminum phase decreased.

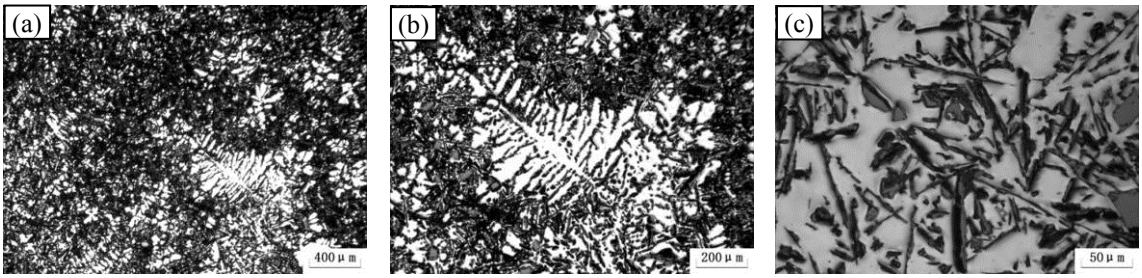

Fig.3. Microstructure of Al-13Si casting ingot under different magnification

Microstructure of Al-18Si-0.01%P ingot casting under different magnification, Fig.4 (a)-(c), depicts that there emerged a large proporation of block primary silicon, which presented grey, about 20μm, with irregular geometric shape and uniform distribution; while, there existed eutectic silicon phase and white α-Al phase. The area of white aluminum phases reduced furtherly.

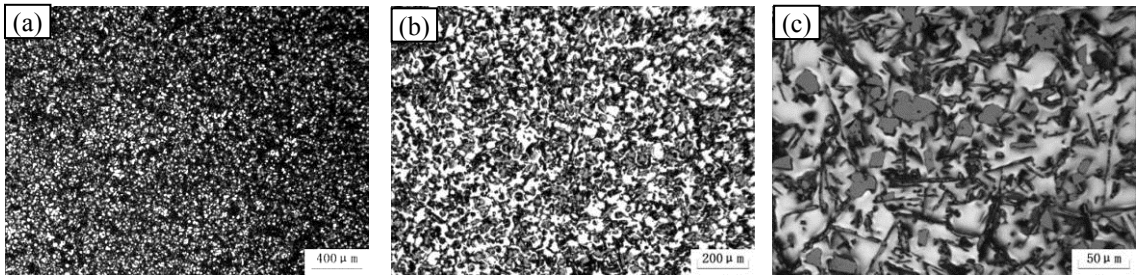

Fig.4.Microstructure of Al-18Si-0.01%P casting ingot under different magnification

2.4 Erosion properties test. Fig.5~Fig.7 presented the corrosion morphology of different aluminum alloy sample. It can be founded that the samples with difference Si-content educed different anti-corrosion properties. There emerged some deep corrosion pits on the surface of Al-1.9Si-1.32Mg-0.40Mn casting ingot attached by plenty of white grains. Al-13Si casting ingot sample had been covered entirely by a large number of white attachments, on which could not found any Al-substrate morphology. Al-18Si-0.01%P casting ingot sample exhibited excellent anti-corrosion properties, and emerging only a little of white flake induced by salt-fog corrosion.

Conclusions

(1) Al-1.9Si-1.32Mg-0.40Mn, Al-13Si and Al-18Si-0.01%P casting ingots were fabricated by water-cooled copper mold method. With the increasing percentage of Si-element, the sample exhibited different microstructure obviously. Microstructure of Al-1.9Si-1.32Mg-0.40Mn alloy was mianly dendritic crystal and most area was aluminum phase. That of Al-13Si alloy was composed of white dendritic α-Al phase, black lamellar eutectic silicon phase. Al-18Si-0.01%P possessed a large number of block primary silicon, eutectic silicon phase and a little of white α-Al phase.

(2) Erosion property was influenced seriously by Si-content in Al-based alloy. In the present work, with Si-content increasing, anti-corrosion properties of Al-based alloy gradually improved, which provided theoretical principle to determine chemical element of the protective materials for magnesium alloy.

Key word: composite fillers; morphology; synergistic effects; electrically conductive adhesives

Abstract. With the 'Synergistic Effects' such as 'Bridging' and 'Intercalating' between fillers with different morphologies, we can get the CF/CNTs/NanoG filled polyacrylate electrically conductive adhesives(ECA). Through the study, we found that the comprehensive properties of the electrically conductive PSA reach the best when the composite fillers are made up of CF 3wt%, NanoG 5wt% and CNTs 5wt%. The conductivity of the electrically conductive PSA reaches 3.0×10^{-2} S/cm, the 180^{o} peel strength is 0.38KN/m and the shear strength is 0.42MPa.

Introduction

In the electronic packaging industry, lead-based solder alloys are frequently used to produce manufactures such as flexible printed circuit boards (PCBs) [1]. However, with the enhancement of people′s environmental consciousness, the harm of lead-based solder alloys is gradually attracted people′s attention [2]. As the alternative of solder alloys, electrically conductive adhesives (ECA) have many advantages, such as environment-friendly, low packaging temperature and so on [3]. ECA are made up of polymer resin (such as, an epoxy or a polyacrylate) that provides mechanical properties and fillers (such as silver or carbonaceous fillers) which conduct electricity [4]. Currently, the ECA on the market are made up of single-morphology fillers, such as silver powder and the proportion of filler is more than 30 percent [5]. Nevertheless, the considerable adding of single filler would reduce the mechanical properties significantly and serious agglomeration appears [6].

For solving these problems, ECA can be prepared by acrylate resin and composite carbonaceous fillers with different morphology.The fillers with different morphology would form "Intercalating effect" and "Bridging effect" with each other.

Experimental

Materials. MA and BA were washed with 10 wt% NaOH solution to remove the polymerization inhibitor. The initiator 2,2-azodiisobutyronitrile(AIBN)was recrystallized twice before use. 2-Butanone (MEK), KH-570, Carbon Nanotubes (CNTs, chopped Carbon Fiber (CF), Carbon Black (CB) were purchased from commercial suppliers and used received.

Preparation. Preparation of acrylate pressure-sensitive adhesive (PSA):The thermoplastic acrylate pressure-sensitive adhesive was synthesized in a 250ml, four-necked flask equipped with a thermometer, a reflux condenser, an efficient stirrer and N_2 purge. First, half of the solvent was added into the flask, mixing for 15 min with the efficient stirrer at the rate of 150rad/min. When the temperature of solvent reached about 70~75^{o}C, all the monomers mixed with half of the initiator

were added into the flask, and the reactant was heated to the 80~85°C. After 2.0h of polymerization, the mixture of the remaining solvent and initiator was added to raise the degree of polymerization. The reaction processed continuously for another 2.0h.

Preparation of ECA: The ECA was prepared by mixing the solvent-based acrylate PSA with the composite fillers at room temperature. The acrylate PSA was diluted with MEK regent, and then the composite fillers were added into the PSA in an ultrasonic bath for 30 min.

Characterization. The internal morphology of the composite fillers based ECA was analyzed by the transmission electron microscope (TEM; H-600 model, Japan). Megohmmeter (ZC-36 model, China) and Desktop digital multimeter (UT61E model, China) were used to measure the conductivity(σ) of the acrylate resin and composite fillers based ECA. The peel strength at the angle of 180° and the shear strength of the ECA were measured with computer controlled electronic tensile testing machine (CMT-8502 model, China). The thermal property of the acrylate resin and the composite fillers based ECA were analyzed by thermogravimetric analysis (TGA; Q50 model, America) at a heating rate of 10 K/min in the range from 50°C to 700°C under environment atmosphere.

Results and discussion

The acrylate resin has poor conductivity; the value is 10^{-16} S/cm. Many groups of samples could be got by changing the constituent and proportion of the composite fillers, and measuring the conductivity of each sample (showing in Tab.1)

Tab.1 Relationship between the constituent and proportion of the compesite fillers in the ECA and the conductivity of the compesite fillers based ECA

Sample	CF (ωt%)	NanoG (ωt%)	CNTs (ωt%)	CB (ωt%)	Total fillers (ωt%)	Conductivity(σ) (S/cm)	lgσ
1	/	/	/	/	0	10^{-16}	-16
2	/	/	/	15	15	8.3×10^{-8}	-7.1
3	/	/	/	30	30	5.3×10^{-7}	-6.3
4	/	/	10	30	40	1.7×10^{-3}	-2.8
5	10	/	/	30	40	7.5×10^{-2}	-1.1
6	/	10	20	10	40	4.5×10^{-3}	-2.3
7	/	5	5	20	30	1.4×10^{-4}	-3.9
8	/	5	5	15	25	3.6×10^{-4}	-3.4
9	5	/	/	15	25	6.7×10^{-4}	-3.2
10	3	10	/	10	23	4.1×10^{-3}	-2.4
11	3	5	/	10	18	2.9×10^{-3}	-2.5
12	3	/	10	10	23	2.9×10^{-2}	-1.5
13	3	5	5	/	13	3.0×10^{-2}	-1.5

Comparing sample 1 and sample 2, the conductivity of PSA increased dramatically from 10^{-16} S/cm to 8.3×10^{-8} S/cm. The results show that the electrical fillers could improve the conductivity of acrylate resin significantly. Comparing simple 2 and simple 3, which indicate 15wt% CB has formed a conductive path within the adhesive.

Comparing simple 3 and simple 4, the conductivity to increase from 5.3×10^{-7} S/cm to 1.7×10^{-3} S/cm. The change can be explained by the "Bridging Effect" between the CB caused by the CNTs. More conductive chain means higher electrically conductivity. Replacing the 10 wt% CNTs by CF (simple 5), the conductivity is 43 times higher than the simple 4, which indicates CF has advantage than CNTs in improving conductivity. The reason is a) CNTs is apt to agglomerate, uneasy to mix in the matrix homogeneously, and b) CF has larger aspect ratio and superior "Bridging Effect" (Fig.1).

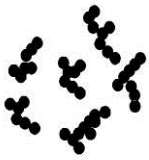

Fig.1(a) Imitative scattergram of CB15wt%

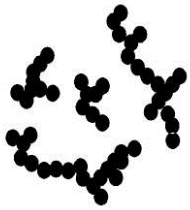

Fig.1(b) Imitative scattergram of CB30wt%

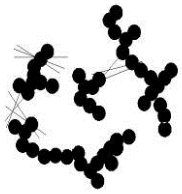

Fig.1(c) Imitative scattergram of CB+CNTs

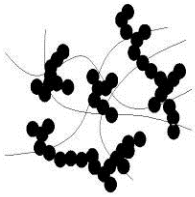

Fig.1(d) Imitative scattergram of CB+CF

The adding of 5wt% CF into the simple 2 lead the conductivity to increase; comparing simple 4 and simple 12, the tests show that 3wt% of CF is enough for bridging within the PSA. Comparing simple10 and simple 11, the decrease of NanoG to 5wt% has miniscule impact to the conductivity. The result indicates that 5wt% NanoG is enough to form the conductive chain within the PSA. There are bridging taking place in the PSA (Fig.2), and some CNTs intercalating into the NanoG(Fig.3). All the above weakens the agglomeration of CNTs and NanoG and promotes the conductive chains to form within the PSA.

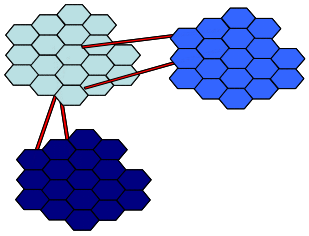

Fig.2 Bridging effect of NanoG+CNTs

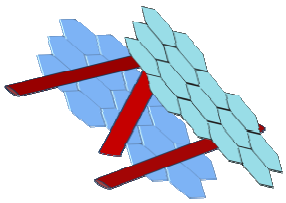

Fig.3 Intercalating effect of NanoG+CNTs

In the process of mixing within the PSA, owning to the “Bridging Effect” and “Intercalation Effect”, dissimilar fillers are apt to contact. Therefore hydrogen bonds form between the dissimilar fillers to prevent the agglomeration. Based on the experimental data(Tab.1), when the composite fillers are CF 3wt%, NanoG 5wt% and CNTs 5wt%, the conductivity of PSA is 3.0×10^{-2} S/cm, reaching the goal: low fillers(13%) and high conductivity(3.0×10^{-2} S/cm).

Fig.4 shows selected TEM image of ECA. The gray coshes, gray tubules, gray flakes represented the CF, CNTs and NanoG. The light coloring area was the acrylate resin. It can be seen from the TEM image that the composite fillers disperse among the acrylate resin homogeneously, less agglomeration can be observed obviously.

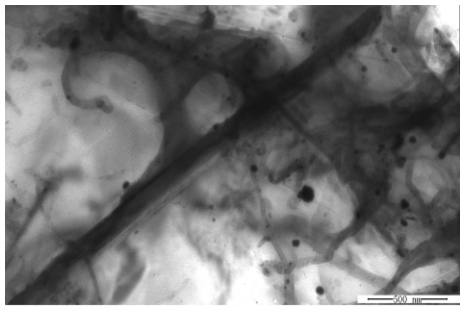

Fig.4 TEM micrograph of ECA

The tests of the 180° peel strength and shear strength of the ECA on the content of the fillers were shown in Tab.3. The 180° peel strength of ECA dropped down to 0.38 KN/m. The behavior is common for polymers filled with filler. The 180° peel strength is mainly related to the adhesion strength between the adhesive and the surface of the testing panel. The adding of filler to the PSA forms hydrogen bonds between acrylate molecular and filler, reducing the fluidity of polymer and wettability to the adherends. The adhesion strength between the adhesive and testing panel reduces sharply. Shear strength of ECA increased slightly which is in line with the other researchers' results [7]. As for shear strength, the shear strength is related to cohesive strength of the ECA. With the adding of composites fillers, the hydrogen bonds between acrylate molecular and filler strengthen the rigidity and cohesive strength of PSA.

Tab.3 Mechanical properties of the pure acrylate resin and composite fillers based ECA

Sample	180° peel strength from Al plate (KN/m)	180° peel strength from silicone rubber (KN/m)	Shear strength MPa）
Pure acrylate resin	0.70	0.42	0.35
ECA	0.38	0.38	0.42

The thermal stability is mainly dependent on the resin, but the addition of fillers would endow the composites with new characteristics. TG analysis is performed under air atmosphere at heating rate of 10K/min. Fig.5 shows the TG and DTG curves of the pure acrylate resin PSA and ECA. From the TG curve, it can be observed that both PSA and ECA show only one decomposition peak, they all start to decompose at 300°C which were as a result of the main-chain pyrolysis. The temperature of max weight loss rate for PSA and ECA were 405 °C and 433 °C. The reason is that a higher interaction between large numbers of surface atoms of composite fillers and acrylate molecule chains. The barrier character for the degradation of acrylate resin was then achieved.

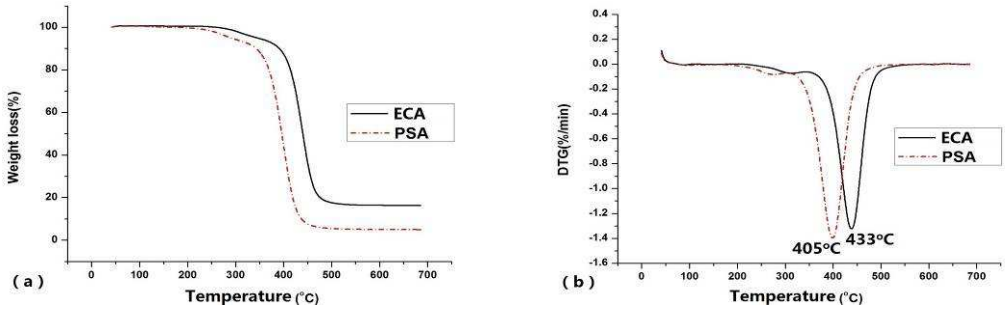

Fig.5 TG (a) and DTG (b) curves of the pure acrylate resin and composite fillers based ECA

Conclusions

A novel ECA consisted of acrylate resin and composite fillers with solution blending and ultrasonic dispersion method was obtained. The SEM and TEM images indicated a homogeneously dispersion of composite fillers in the acrylate resin and the "Intercalating effect" and "Bridging effect" were formed between the CF, CNTs and NanoG. The conductivity increased to 3.0×10^{-2} S/cm. The 180° peel strength was 0.38KN/m and the shear strength was 0.42 MPa. The thermal stability of ECA was also improved with acrylate resin from TGA.

Abstract: This paper studies extract as corrosion inhibitors extracted from garlic. The IR spectrum analysis of the extract shows that the main ingredient of extract is amino acids, and the better extracting condition is that 30˚C 50mL 10%$H_2SO_4$and 20g peeled garlic react for 120.0h, and composite amino acids content in the extract is 19.0mg/L. The result of corrosion inhibition performance using static weight loss shows that the dosage of the extract, temperature and concentration of acidic mediums have effect on corrosion inhibition remarkably. The corrosion inhibitive efficiency for A3 steel is 93.26% in 5% Hydrochloric acid and 79.2% in5% mud acid when the dosage of the garlic extract is 4.0%(V/V) and 6.0%(V/V),respectively. The investigated results of electrochemistry performance of the extract indicates that corrosion potential of A3 steel shift in negative direction both in Hydrochloric acid and in mud acid, which indicates that the extract are inhibitors of inhibiting cathodic corrosion, and circular-arc radius of alternating-current impedance spectroscopy increase notably in acidic medium, and corrosion inhibition effect is remarkable. Therefore, it is feasible to extract inhibitors from garlic.

Introduction

Using corrosion inhibitor is one of the best way to prevent corrosion. Along with the increasingly regard on the hazard which is produced by using chemicals, people have reduced the use of corrosion inhibitors of high-toxic or non-biodegradable. The researchers shifted their attentions to high efficiency, eco-friendly, low-toxic materials which called green corrosion inhibitors. The Chinese scholars Ying-Chu Tao[1],Zhi-Hu Guo[2],Zheng Lin [3],Wan-You Zhang[4] ,Zheng Liu[5],Xiu-Zhou Lin[6],Yan Li etc[7],Xiang-Hong Li[8], began the corrosion inhibitive performance evaluation research respectively from the plant stem and leaf extract, tea, camphor leaves, Chinese prickly ash, peel, orange peel, cork, baicalin, berberine, black pepper,

white pepper, tobacco and reed, water lotus, sweet potato, white magnolia, hibiscus rosa-sinensis, etc. The foreign researchers, like Salch[9], Farooqi etc[10], Vinod Kumar etc[11], Minha[12], Matamala etc [13], Martinez etc[14] , had studied the inhibitive efficiency and mechanism of the extract of the mango skin and aloe leaf , betel nut seed, plants of the genus eucalyptus leaves, pod jam of plant flowers and Jun Cao section plant and pine bark, gum Arabic tannins and chestnut tannin, natural plant extracts-hardwood alkaline, curcumin; another researchers, Xiu-Zhou Lin[6], Ying Han[15], Guang-Hua Zhang[16], Hai-Yan Du[17], also extracted the corrosion inhibitive components from waste rice bran, Chinese medicine residue, rapeseed meal, bean dregs bread. The literatures reveal that the effect of the corrosion inhibitor in different medium is remarkable. This paper will develop the study on the extract from garlics in acid medium for metal corrosion inhibition. Garlic Contains the active ingredient such as Diallyl Disulfide, Diallyl Trisulfid, amino acids, and the amino and carbonyl with more negative charge, can provide electrons to the empty orbital of metal, and adsorb the metal surface to form a protective film, which separated the metal surface and from corrosion medium and slow down the metal corrosion rate. To prepare inhibitor from garlic is low cost, non-toxic harmless, and no environmental pollution. The research in this field is seldom. Therefore, this research is significant for resource utilization, environment protection, and the development of green corrosion inhibitor.

Experimental section

Experimental material, reagent and instrument. Fresh garlic, concentrated hydrochloric acid, ninhydrin, dibasic sodium phosphate, potassium phosphate monobasic, sodium hydroxide, L-glutamic acid; A3 steel, soxhlet extractor, thermostat water bath, adjust electric heating set, electrothermal constant-temperature dry box, electronic balance, corrosion coupon instrument, electrochemical workstation (model:LK2005A1),Fourier transform infrared (FTIR) spectrograph.

Extraction and characterization. Taking a certain amount of peeled garlic, Mashed and soaked in 50ml certain concentration of H_2SO_4 at a certain temperature for 120.0h according reference[17], filtrating under suction, and the obtained filtrate storage standby, The concentration of the filtered liquor can be determined by colorimetric method according to the National Standard(GB/T8314-2002)[18]. With sodium hydroxide to adjust the pH of the filter liquor, then continue to add acetone until there are white precipitations in the solution. The solution was filtered, and the filter residue dried in electrothermal constant-temperature dry box at 60℃ to get the dry solid extractors which can characterizationed by Fourier transform infrared(model:UV2450) spectrograph.

Performance evaluation method. The experiment is on the basis of the standard of China petro and gas industry(SY/T5405-1996)[19],and reference[20,21]. Weight loss analysis were used for corrosion inhibition performance evaluation of the garlic extractors on mild steel in acid medium; the polarization and impedance studies of the system which consists of mild steel and acid medium(with or without extractors) were carried out by electrochemical workstation(model: LK2005A1),thereby we can discuss the mechanism of the corrosion inhibition. The acid medium is hydrochloric acid and mud acid with different concentration.

Results and discussion

Components analysis of amino acids in garlic extract. According to the GB8314-2002[18], we used the assay method of the free amino acid to determine the amino acid content. Firstly, 0.1g/L L-glutamic acid solution was prepared. Different volume of standard amino acid solutions mixed with 0.5mL Na_2HPO_4—NaH_2PO_4 buffered solution and 0.5mL ninhydrin. Put it into the

thermostat water bath 15min, then cool it at room temperature, transfer it to a 25mL volumetric flask and constant volume. After 15min, measure the absorbance with λ=570nm. The standard curve of the composite amino is A =20.957C+0.0625（r= 0.9979）. The amino acid content of the extract can be obtained using the equation after the absorbance of the garlic extracts was measured.

The effect of H_2SO_4 concentration on the extractor inhibition efficiency. Six copies of peeled garlic, each 20g, Mashed and soaked in 50ml different mass fraction H_2SO_4 at 30℃for 120.0h. The soaking solution was filtered, then operation according to the above method, the absorbance of 5ml filtrate was measured at λ=570nm ，according to the standard curve equation for calculating amino acid content in liquid, at the same time，Respectively taking extract，and adding to 50 ℃ 500ml 5% HCl by 1% (V/V), hanging pieces experiments was carried, hang time was 4.0h, calculate A3 steel corrosion rate and the corresponding inhibition rate, all results as shown in Fig.1.

Fig.1 show that with the increase of the H_2SO_4 concentration, and content of amino acid in the extract increased at first, then decreased. Due to the linear relationship between absorbance and amino acid concentration, When the H_2SO_4 mass fraction was 10%, the content of the amino acid in extractors is maximal, up to 19.0mg/L, At the same time, extract had the best corrosion inhibiting effect on A3 steel ， the inhibition efficiency was 89.08%. Therefore, it identified using 10% H_2SO_4 as extraction agent in the following experiment.

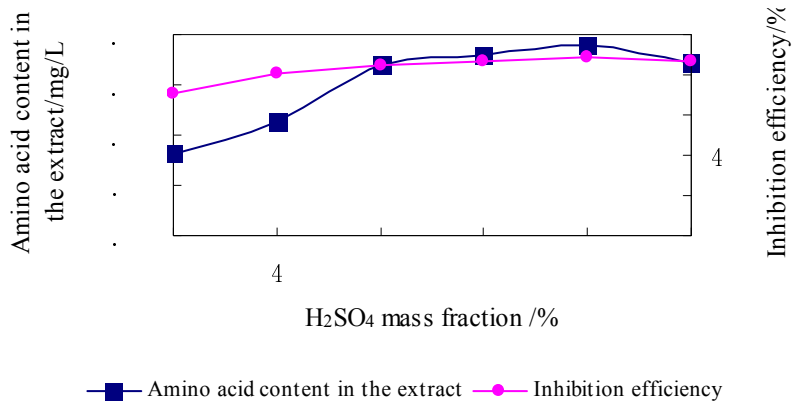

Fig.1 The effect of H_2SO_4concentration on the extractor inhibition efficiency

characterization of the extractors. The garlic leaching liquid with H_2SO_4 was filtered, sodium hydroxide is added to adjust the pH of the filter liquor, then continue to add acetone until there are white precipitations in the solution. and the filter residue dried in electrothermal constant-temperature dry box at 60℃ to get the dry solid extractors which can be characterizationed by Fourier transform infrared(model:UV2450) spectrograph. The results shown in Fig.2.

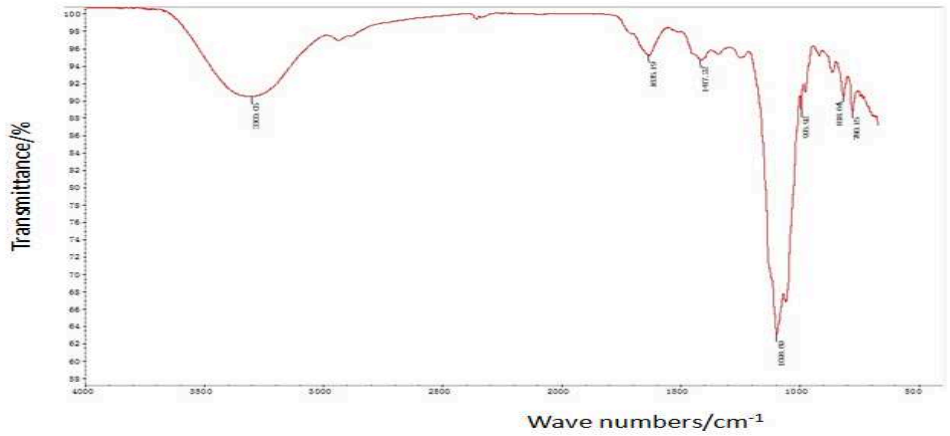

Fig.2 The infrared spectra of the extract

According to Fig.2,the infrared spectra absorption characteristic peak of the extract are3300.05cm^{-1} (V_{NH})，1635.19cm^{-1}($V_{C=O}$)，1098.69cm^{-1}(ν_{C-N})，995.92 cm^{-1},818.64 cm^{-1},780.15 cm^{-1}($V_{C=H}$).The result shows that the main ingredient of extractors from garlic is amino acids.

Corrosion inhibitive performance evaluation

The effect of dosage of the extractors on inhibitive efficiency. Three parallel specimens were completely immersed in an open beaker containing 500mL 5% HCl and mud acid with different dosages of extractors at 50℃for weight loss measurements, Respectively. For 4.0 h, take the specimens out, and wash and dry, and then weight accurately. The corrosion rate of A3 steel and corrosion inhibitive efficiency is presented in Fig.3 and Fig.4.

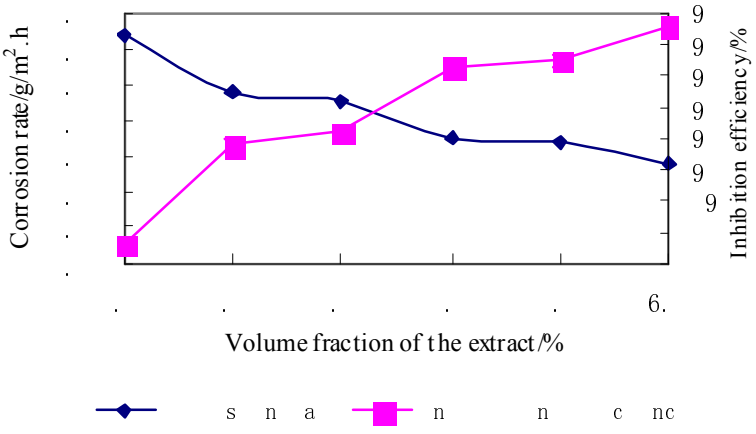

Fig.3 The effect of dosage of the extract on corrosion inhibitive efficiency for A3 steel in HCl

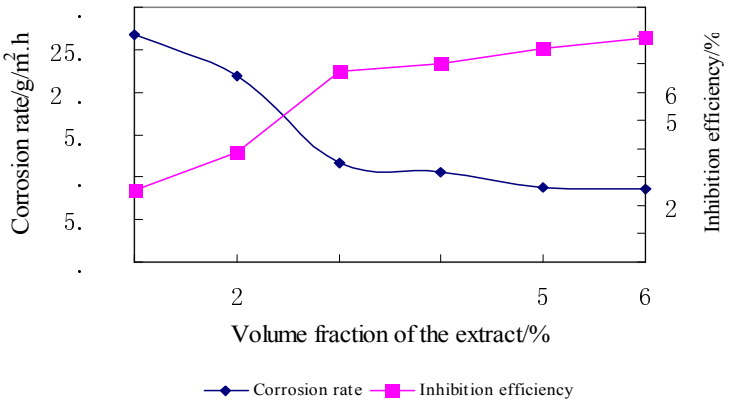

Fig.4 The effect of dosage of the extract on corrosion inhibitive efficiency for A3 steel in mud acid

Fig.3, Fig.4 shows, both in the medium of hydrochloric acid, or in the mud acid medium, garlic extract has good inhibition effect on the A3 steel in corrosion medium. The inhibition efficiency increase with the the dosage of extract increased. But the extract volume fraction is 4.0%-6.0% in the 5%HCl, the inhibition efficiency did not change significantly, therefore, the dosage of extract as corrosion inhibitor adding volume fraction is 4% in 5%HCl,and the inhibition efficiency is 93.26%,while the extract as corrosion inhibitor adding volume fraction is 6%in 5% mud acid, and the inhibition efficiency is 79.2%, therefore, adding extract corrosion inhibitor should follow appropriate amount principles.

Effect of temperatures on corrosion inhibitive efficiency. Three parallel specimens were completely immersed in an open beaker containing different temperatures 500mL 5% HCl and mud acid for 4.0h, when the dosage of the garlic extract is 1.0%(V/ V). The effect of corrosion inhibitive efficiency in different temperatures are given in Tab.1.

Tab.1 Effect of temperatures on corrosion inhibitive efficiency for A3steel in hydrochloric acid and mud acid

condition / index	The temperature of HCl/				The temperature of mud acid /			
	30	40	50	60	30	40	50	60
Corrosion rate/g/m^2·h	2.8298	7.0877	11.3985	16.002	8.9125	10.0497	11.6629	16.000
Inhibition efficiency/%	89.08	79.64	66.64	65.95	75.09	70.40	65.37	24.23

It is clear that (Tab.1) on increasing the temperature there is an increase in corrosion rate, so there is a decrease in inhibitive efficiency.

Effect of concentration of medium Three parallel specimens were completely immersed in an open beaker containing different concentration 500mL hydrochloric acid and mud acid at 50℃ for 4 h, when the dosage of the extract is 1.0%(V/ V). The results were given in Tab.2.

Tab.2 Effect of concentration of hydrochloric acid and mud acid on corrosion inhibitive efficiency for A3steel

condition / index	The concentration of HCl /%				The concentration of mud acid /%			
	5	10	15	20	5	10	15	20
Corrosion rate/g/m^2·h	4.4430	11.4778	17.4812	21.1837	8.4276	8.4968	8.6132	8.9125
Inhibition efficiency /%	76.79	51.36	22.23	20.91	75.09	60.89	16.86	15.68

Tab.2 present that with the rise of the concentration of hydrochloric acid and mud acid, the corrosion rate is increased and the corrosion inhibitive efficiency is decreased.

Evaluation of the electrochemical properties of extracts

(1) Polarization curve. An electrochemical workstation (model:LK2005A1) with a three-electrode assembly(platinum counter electrode(CE, Pt), saturated calomel electrode(SCE), working electrode(mild steel)) was used to study the corrosion inhibitive mechanical of the garlic extract at room temperature. The polarization curves for the A3 steel in the 5% hydrochloric acid and 5% mud acid when the dosage of the extract is 1.0%(V/V) are shown in Fig.5 and Fig.6,respectively.

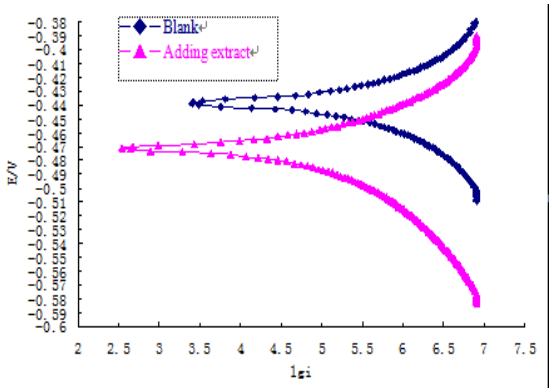

Fig.5 Polarization curve ofA3steel in 5%HCl solution with or without extract

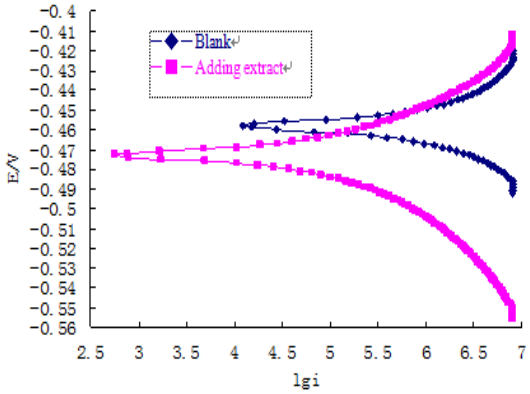

Fig.6 Polarization curve of A3 steel in 5%mud acid solution with or without extract

It is obvious from Fig.5 and Fig.6, that corrosion potential of A3 steel shifted in negative direction both in 5% hydrochloric acid and in 5% mud acid. It makes the Tafel slops increased, makes the cathodic polarization increased, and slows down the corrosion rate. This result is correspondence with the weight loss studies. Therefore, the garlic extract is cathodic corrosion inhibitor.

(2) Impedance analysis. In order to a further study on the corrosion inhibitive mechanical of the garlic extract,an electrochemical workstation (model:LK2005A1) was used to study the alternating-current impedance for the A3 steel in the 5% hydrochloric acid and 5% mud acid when the dosage of the extract is 1.0%(V/V). The electrochemical impedance spectroscopy (EIS) was carried out in the frequency range of 10^{-1} Hz to10^{5} Hz using a 10 mV peak-to-peak voltage excitation. The results are shown in Fig.7 and Fig.8.

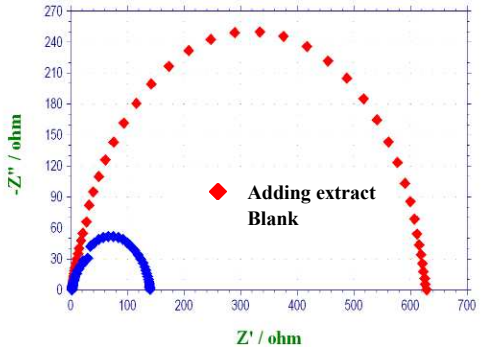

Fig.7 Impedance spectra of A3 steel in 5%HCl solution with or without extractors

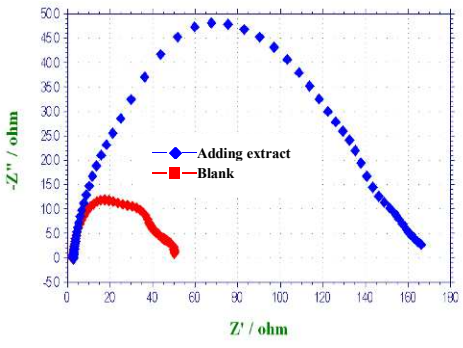

Fig.8 Impedance spectra of A3 steel in 5% mud acid solution with or without extractors

As it shown for us in Fig.7, Fig.8 , extractors make circular-arc radius of impedance spectroscopy increase notably for A3in acidic medium. The results indicate that after addition of the extract, the impedance increased, the corrosion current lower, and the corrosion inhibition effect is remarkable. Because of the semicircle is above the real axis, extract from garlic control the electrochemical process of the corrosion. This result is correspondence with the weight loss studies.

Conclusions

(1) The analysis IR spectrum of extract shows that the main ingredient of garlic extract is amino acids, and the better extracting condition is as follows: 30℃,50mL 10%H_2SO_4 and 20g garlic react 120.0h, and composite amino acids content in extract is19.0mg/L.

(2) The corrosion rate in 500mL 5% hydrochloric acid and mud acid decrease with the increase of the dosage of the garlic extract as inhibitor. The corrosion inhibitive efficiency for A3 steel is 93.26% in 5% Hydrochloric acid and 79.2% in5% mud acid when the dosage of the garlic extract is 4.0%(V/V) and 6.0%(V/V),respectively. On increasing the temperature and acidity, there is a increase in corrosion rate and a decrease in inhibitive efficiency.

(3) The corrosion potential shifted in negative direction both in hydrochloric acid and in mud acid after addition of the garlic extract. The results indicate that the garlic extract is cathodic corrosion inhibitors. The extract make circular-arc radius of impedance spectroscopy increase notably, which means that the impedance increased ,the corrosion current lower, and the corrosion inhibition effect is remarkable.

Keywords: alumina xerogel, alumina whisker, Nanocomposite, Solvothermal drying

Abstract. In this research, nano pore composite had an effect on enhancing thermal property and mechanical property. The nano pore composite maintained the pore structure and enhanced mechanical property. Al_2O_3 xerogel was collapsed after heat treatment over 1000℃ and they had weak mechanical strength because of pores. For maintenance of pore at high temperature and improvement of mechanical strength, Al_2O_3 whisker was hybridized. The Al_2O_3 whiskers in nano pore composite play the role of pillar during heat treatment. The mechanical property of Al_2O_3 xerogel was improved through complexation with Al_2O_3 whisker. The elastic modulus of nano pore composite increased 225 % from Al_2O_3 xerogel.

Introduction

A porous structure is known to interrupt the thermal conduction of materials. For this reason, porous structure can apply for an insulator at ultimate environment. Especially, ceramic materials that have outstanding heat-resisting property are more helpful for porous structure. And nano meter sized pores made the structure have excellent insulating property as shown in Fig. 1. It means that porous structure made by ceramic material is suitable for an insulator. [1]

Fig. 1. Excellent thermal insulation property of nano pore structure [2]

Thermal conduction is largely occurred by solid conduction and gas convection. But nano-sized pore of ceramic nano pore structure can reduce a mean free path of gas and efficiently prevent the gas convection. Also solid conduction can be controlled by higher porosity. [3]

Ceramic nano pore structures that can apply for an insulator are ordered mesoporous, aerogel, xerogel materials. And these structures are made by sol-gel process.[4] The materials are divided by external conditions like a target temperature. It is useful for economical side and efficient side. In other words, under 1100℃ of low temperature, Silica is most widely used. Especially, silica is a lowest-cost oxide. Under 1400℃ of mid temperature, alumina is most widely used and above 1700℃ of high temperature zirconia is most widely used for. And a research for finding another ceramic matrix material is widely progressed.[5,6]

But nano pore structure has a weak mechanical strength because of the pores. Therefore overcoming of mechanical strength weakening is very important for an application of ceramic nano pore structure. In order to overcome of mechanical strength weakening, I.-K. Jung et al. studied about nano pore composite, such as doping of nano particles or CNT with xerogel. The complexation brought about an improvement of mechanical strength. But it is still imperfect for commercialization due to some problems. [7]

In this study, Al_2O_3 whisker was chosen for overcoming mechanical weakening problem and Al_2O_3 xerogel hybridized with Al_2O_3 whisker. Al_2O_3 whisker is known to have outstanding thermal and mechanical property. The changes of structural and mechanical properties were observed after high temperature treatment between Al_2O_3 xerogel and Al_2O_3 xerogel hybridized with Al_2O_3 whisker.

Experimental procedure

Formation of Al_2O_3 xerogel. One of the alkoxide precursor Aluminum sec-butoxide (ASB) was used as a precursor for formation of Al_2O_3 xerogel. And solvent for formation of Al_2O_3 xerogel was ethanol. Acetic acid and H_2O were used as catalyst for hydrolysis reaction. After hydrolysis reaction, highly polar agent N,N-dimethylformamide (DMF) was added for inducement of condensation reaction. After adding of DMF, the solvent was exchanged with n-hexane and surface modification was proceeded using HMDS(5 vol% in n-hexane). The final Al_2O_3 xerogel was synthesized through solvothermal drying in the autoclave. The total procedure was shown at Fig. 2.

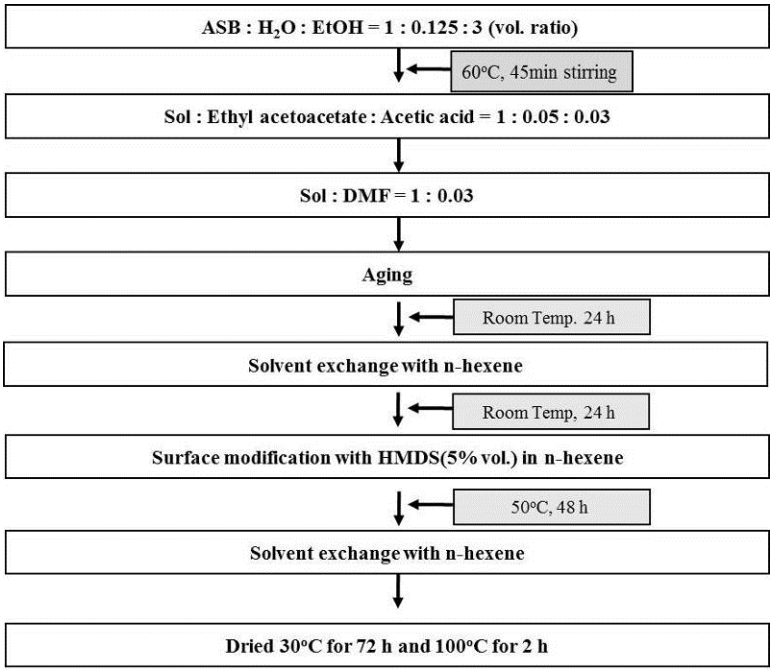

Fig. 2. Fabrication procedure of Al_2O_3 xerogel

Formation of Al_2O_3 whisker. Al_2O_3 whisker was synthesized using hot-wall chemical vapor deposition (CVD). The mixture of Al powder and Al_2O_3 powder was used as a source. During heating, evaporation and cooling process, Ar gas was flowed at 100 sccm for gas dilution and the pressure was fixed under 0.1 torr. At evaporation temperature 1400℃, reactant gas O_2 gas was flowed at 6 sccm during 10 m and cooled at room temperature. Scanning electron microscopy (SEM) image of Al_2O_3 whisker was shown in Fig. 3.

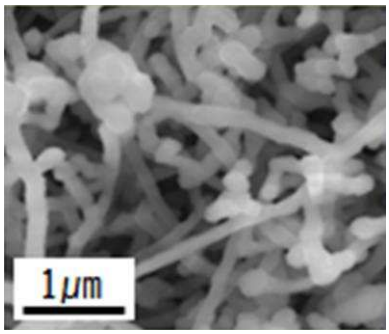

Fig. 3. Al_2O_3 whisker grown at 1400℃ [8]

Formation of nano pore composite. After formation of Al_2O_3 xerogel and Al_2O_3 whisker, the complexation was proceeded. For complexation of Al_2O_3 xerogel and Al_2O_3 whisker, Al_2O_3 whisker grown Al_2O_3 substrate was dip coated at Al_2O_3 xerogel solution during 15 m. After solvothermal drying at ambient pressure drying, the final composite was synthesized.

Results & discussion

The structural changes of composite after heat treatment. Al_2O_3 xerogel hybridized with Al_2O_3 whisker annealed at 1100℃ for 2 h. The structural analysis of composite was observed by SEM. The structural changes after exposing of high temperature were shown in Fig. 4. In the result of a comparison between Al_2O_3 xerogel and nano pore composite, Al_2O_3 xerogel has collapsed structure after heat treatment. It was confirmed that Al_2O_3 xerogel hybridized with Al_2O_3 whisker maintained pore structure after heat treatment at 1100℃. It was because that the existence of Al_2O_3 whisker increased thermal resistance of internal matrix for maintenance

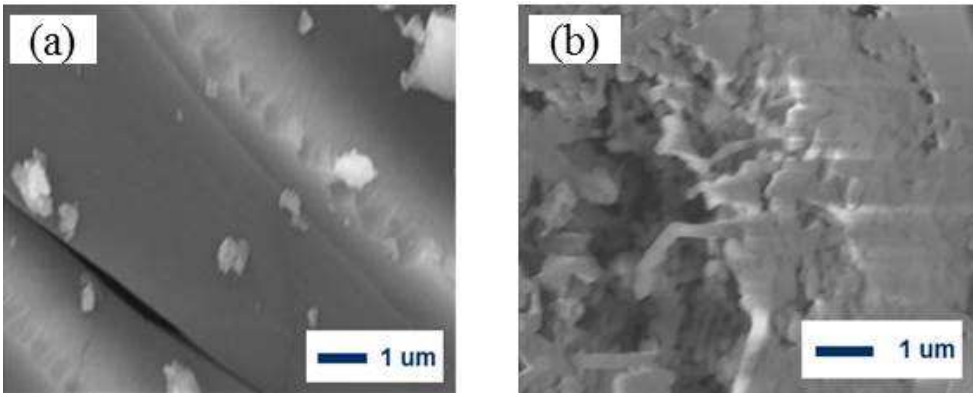

Fig. 4. SEM images after annealing of (a) Al_2O_3 xerogel, (b) nano pore composite

The mechanical changes of composite. The mechanical property of Al_2O_3 xerogel hybridized with Al_2O_3 whisker was analyzed using nano indentor. The result was shown in Table 1. In the mechanical properties of Al_2O_3 xerogel, the modulus of elasticity of Al_2O_3 xerogel was improved up to 225% after hybridization with Al_2O_3 whisker. The mechanical properties like modulus of elasticity and hardness coefficient of composite were even increased after heat treatment. Especially, composite of Al_2O_3 xerogel and Al_2O_3 whisker annealed at 1100℃, the composite had fine porous structure of xerogel and the modulus of elasticity was improved up to 114% after heat treatment. So it can be said that an improvement of thermal and mechanical property was obtained by complexation. With grain boundary densification occured at the interface, it was caused an increasing of the modulus of elasticity and hardness coefficient.

Table 1. Mechanical property of nano pore composite

	Modulus (GPa)	Hardness (GPa)
Al_2O_3 xerogel	0.4±0.2	0.02±0.01
Al_2O_3 xerogel+Al_2O_3 whisker before anneal	0.9±0.3	0.03±0.02
Al_2O_3 xerogel + Al_2O_3 whisker after anneal at 1000℃	1.15±0.5	0.03±0.02
Al_2O_3 xerogel + Al_2O_3 whisker after anneal at 1100℃	1.03±0.3	0.04±0.01
Al_2O_3 xerogel + Al_2O_3 whisker after anneal at 1200℃	2.3±0.2	0.06±0.01

Summary

In this study, a porous structure was formed by complexation of Al_2O_3 xerogel and Al_2O_3 whisker via solvothermal drying at ambient pressure. It was confirmed that nano pore composite had improved thermal stability with enhanced modulus of elasticity and hardness coefficient. As a result, it was verified that excellent mechanical property of Al_2O_3 whisker has an effect on the improvement of mechanical strength of Al_2O_3 xerogel.

Inhibition of corrosion by dithiocarbamate in Oilfield water injection

Zuohua Wang

Sinopec Petroleum Engineering Corporation (SPE), Dongying 257000, P. R. China. E-mail: messias1015@163.com

Keywords: dithiocarbamate (DTC), corrosion inhibition, oilfield wastewater.

Abstract In this work, corrosion inhibition in steel water pipes, used in Shengli oilfieldis studied in different corrosive media by adsorption of dithiocarbamate (DTC) on the surface of the pipes. Electrochemical impedance spectroscopy (EIS), linear polarization resistance (LPR) and potentiodynamic was applied to determine the effection of this dithiocarbamate. And the result shows that this dithiocarbamate has high corrosion inhibition up to 90%.

Experimental principle and method

Electrochemical impedance spectroscopy (EIS) is an transient electrochemical technique. The characteristics as follows, each half cycle duration is very short and can not cause serious concentration polarization and surface state change while the frequency is high enough because of using the small amplitude symmetrical alternating current(<10 mV) for polarization of electrode. The process of cathode and anode alternate on the electrode without causing the accumulation of polarized development, which can avoid excessive impact on system. Secondly, it can be measured in wide frequency range to get impedance spectroscopy. Therefore, EIS can get more electrode kinetics information and electrode interface structure information than other conventional electrochemical methods.

In this experiment, electrochemical impedance spectroscopy test were performed using the classic three-electrode system. All electrochemical experiments were carried out by using an PARSTAT 2273 (AMETEK, USA).Working electrodes with a surface area of 1cm^2 are carbon steel material, and non-working surface sealed with epoxy resin, and the surface of the electrode were polished by DTC metallographic sandpaper, and washed with water, and then degreased with alcohol and washed with deionized water to soak in the solution. The reference electrode is a saturated calomel electrode and the counter electrode is a platinum electrode. The EIS measurements were carried out over a frequency range from 0.05 Hz to 100 kHz with sinusoidal potential perturbation 5 mV in amplitude. All the potential values in this paper are relative to the saturated calomel electrode (SCE).

Experiment

Fig.1 shows the Nyquist plots of the carbon electrodes immersed in oilfield water injection solution with different concentrations DTC inhibitor for 4d. Where the abscissa Z ' represents the real part of the impedance, and where the vertical axis-Z '' represents the imaginary part of the impedance. Fig.1 shows a flattened semicircular, semicircle in the chord Z 'axis corresponds to the electrode polarization resistance Rp. And the greater the value of Rp, the better corrosion inhibition effect [1].Compared to blank electrode, the polarization resistance of carbon electrodes increased obviously after added DTC corrosion inhibitor, and the polarization resistance of electrodes

increases with increasing inhibitor concentration.. And the polarization resistance at 20mg /L is greater than at 10mg/L. Fig.2 shows the Bode plots of the carbon electrodes immersed in oilfield water injection solution with different concentrations DTC inhibitor for 1d.. Corrosion inhibition effect can also be characterized by the impedance modulus value $|Z|_{0.05}$ at the low-frequency electrode point (f = 0.05Hz). And the greater the value of $|Z|_{0.05}$, the corrosion inhibition effect is better. The value of the $|Z|_{0.05}$ also increases with the increasing inhibitor concentration. And the impedance modulus $|Z|_{0.05}$ at 20mg/L is greater than at 10mg/L. It is also easy to find out from Fig.3 the phase angle only appears a maximum value, which illustrate in the system of corrosion electrochemistry reaction there is only one time constant. In the presence of inhibitor, it can consider that the corrosion system composed by basement metal and inhibitor film as a protective film was formed on metal surface. But in the neutral interface, because of the diffusion of oxygen molecules, EIS will be partially covered, and phase angle only appears a maximum value at the Bode phase angle θ-logf figure (Rs is the solution resistance, Rp is Polarization resistance, C is the capacitance between the electrode and the solution).

Admittance of a C is given by (1) [3]:

$$C = 1 / (2\pi f\theta max \, |Z|\theta max) \quad (1)$$

Where $f\theta max$ and $|Z|\theta max$ is corresponding with maximum phase angle θmax and the Bode figure.

The inhibition efficiency η can be calculated according to the following equation (2) [4]：

$$\eta = (R_p - R_p^\circ) / R_p \times 100\% \quad (2)$$

Where Rp is the polarization resistance of the electrode with inhibitor and Rp° is the the polarization resistance of the electrode without inhibitor.

10	24.28	15476	399.0	87.56
20	25.51	18482	201.2	89.58

Table 1shows the $f_{\theta max}$and $|_{\theta max}$corresponding with maximum phase angle θ_{max} and the Bode figure of DTC inhibitor. Table 2 shows the fitted value of electrochemical impedance spectroscopy of carbon electrodes with DTC inhibitor. Table 2 shows that the polarization resistance of carbon electrodes increased obviously after added another DTC corrosion inhibitor. And polarization resistance also increased with increasing of the inhibitor concentration. Inhibition efficiency can up to 89.58% when the concentration of inhibitor is 20mg/L.

Conclusion

DTC inhibitor has corrosion resistance for carbon steel in oilfield water injection. Inhibition efficiency can up to 89.58%.when the concentration of DTC inhibitor is 20mg/L.

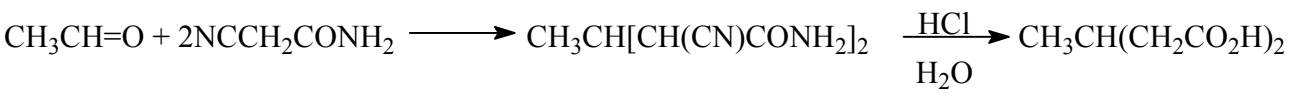
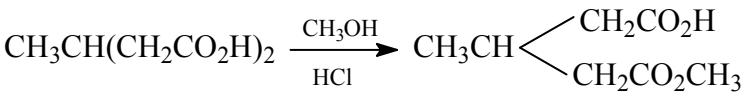
Keywords: monomethyl β-methylglutarate; musk ketone; methyl malonate; butene Ethyl;heteropoly acid

Abstract. Malonate ethyl ester of butene in the presence of sodium hydroxide was synthesized by addition reaction of 2-methyl propane-1,1,3 tricarboxylic acid ester, by hydrolysis decarboxylation heatingβ- methyl glutaric acid. First with excess of methanol into methyl metaplasiaβ- methyl dimethyl glutarate, and then itsβ- methyl glutaric acid methylation, get high yield of monomethyl β-methylglutarate.

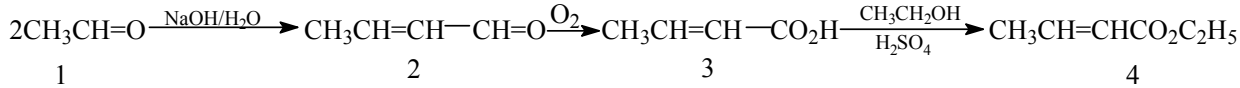
β-methyl glutaric acid monomethyl ester is an important intermediate by the stoll synthesized musk ketone [1]. Musk ketone is not only an excellent spice, but also is an important component of Chinese medicine musk. The natural musk contains musk ketone 1.2% to 1.4%,with exciting nerve center, respiratory center and heart, for the treatment of delirium, swelling pain, sore, bruises .

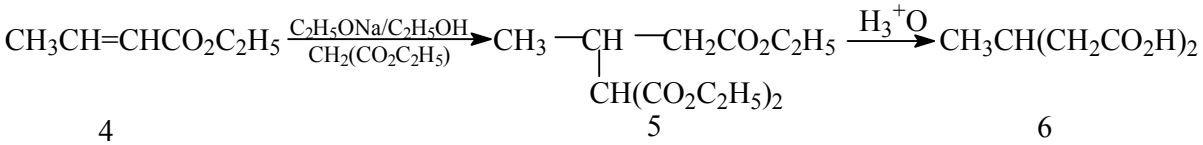
The method of synthesis of β-methyl-glutaric acid monomethyl ester as follows.

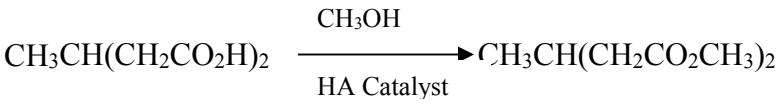


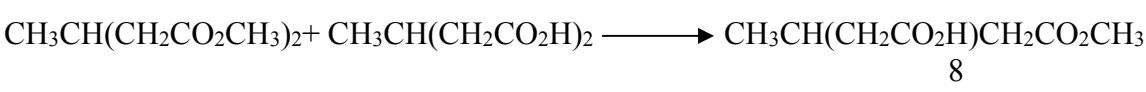


The total yield of this method is only 30%, ethyl cyanoacetate is bimolecular reactions, therefore, the total efficiency is only 15%.After repeated tests, we use the following route:









The reaction under mild conditions is less by-products, the unreacted raw materials are recovered, dimethyl malonate utilization rate is more than 90%. Heteropoly acid compound is a class of oxygen bridge polynuclear complexes, having the characteristics complex and a metal oxide, is a multifunctional catalyst. As catalyst of the esterification reaction, there must be sufficiently acidic, the weaker the oxidation. Experiments show, phosphotungstic heteropoly acid (PW) in organic solvent the acidity of $-8.2 \leq HO \leq -5.6$, while oxidation is very weak, is an ideal esterification catalyst,and load heteropolyacid has stronger catalytic activity in the reaction.

Experiment

1.1 Crotonic acid ethyl (2 - butenyl acetate) (4) Synthesis

Compound (2) according to the literature [5] synthesis, yield 72%, b•p 102~103℃, nD^{20} 0.8450 .compounds (3), according to the literature [6] synthesis, yield 50%, m•p 72 ℃. Compound (4) according to the literature [4] synthesis, yield 71%, b•p 137~140℃

1.2 2 - methyl-propane-1,1,3 - tricarboxylic acid ethyl ester (5) Synthesis

First,420 g (9.13 mol) of anhydrous ethanol was added 1 000 ml round bottom flask with stirrer and reflux apparatus, 35 g (1.52 mol) of pure sodium under stirring was added portionwise.Then, 220 g (1.50 mol) of diethyl and 161 g (1.50 mol) of ethyl crotonate malonate was gradually added .After 10 h of reflexing, the mixture was distilled off ethanol. The remaining liquid is cooled, addition of 50% sulfuric acid aqueous to acidic, separation of reservoirdistillation under reduced pressure, collecting fraction at 157~170℃/14 mmHg to obtain a colorless oily liquid 300 g, 73.0% yield. Elemental analysis: $C_{13}H_{22}O_6$ measured values (calculated value%): C, 56.68 (56.93); H, 8.10 (8.03), ^{1}HNMR, δ: 0.9 (d, 3H, CH_3); 1.3 (t, 9H, CH_2); 4.1 (q, 6H, 3 × CH_2)

1.3 β-methyl glutaric acid (6) Preparation

274 g (1.0mol) of 2 - methyl-propane-1 ,1,3 - 3-carboxylic acid ethyl ester and 280 g of 95% ethanol was added 1000ml round bottom flask with stirrer and reflux apparatus, was heated to reflux, 210 g of potassium hydroxide (content 82%, 3.0 mol) was gradually added . After 5h of reflexing, the mixture was distilled off ethanol. The remaining liquid was cooled, addition of 50% sulfuric acid aqueous to acidic, filtered potassium persulfate,dryed at 140 ℃ and pulverized. Extraction by 100 mL - acetone in five, the extract was distilled acetone. The remaining liquid was distilled under reduced pressure. Fractions was collected at 150~170℃/10mmHg. Recrystallized in ethyl acetate we get white solid 122.8 g was prepared, yield 83.0%, m•P 86 °C (literature values 86~87°C)

1.4 Synthesis of β-methyl glutaric acid monomethyl ester (8)

146 g (1.0 mol) of (6) and 192 g (6.0 mol) of anhydrous methanol, 200 g - anhydrous toluene, 5 g - heteropoly acid mixed , refluxed in flask 4 h, toluene and methanol was distilled off under reduced pressure, β-methyl glutaric acid dimethyl ester was prepared; 65.7 g (0.45mol) of (6) and 100g dioxane was added. After 2h of reflexing, dioxane was distilled off under reduced pressure.The remaining liquid was distilled under reduced pressure. Fractions was collected at 138~144℃/10mmHg and 148~152℃/10mmHg. The former was (7), obtained 81.8 g, bis esterification rate was 32.4%, and the latter was (8), obtained 132.9 g, single esterification rate was 60.0%. The conversion rate of (6) reached 90%. Elemental analysis:C7H12O4，measured values (calculated%)：C，52.15（52.17）；H，7.16（7.14）。^{1}HNMR，δ：0.96（d，3H，CH_3）；2.41（t，2H，CH_2）；2.53（q，2H，CH_2）；3.68（s，3H，CH_3）. B-methyl-glutaric acid

monomethyl esterβ-methyl glutaric acid dimethyl ester was prepared by the above method - main infrared spectroscopy σ is (liquid film method): 1146, 1740, 1450, 1326, 1170 cm-1, with the standard sample of the infrared spectra consistent σ. The product was confirmed by IR and 1HNMR data for the structure of β-methyl-glutaric acid monomethyl ester. The refractive rate of product was 1.440(nD^{20}), consistenting with the standard sample(nD^{20} 1.442).

Results and discussion

We found that synthesis of β-methyl-glutaric acid monomethyl ester (8) was the key step,so we focus on the step.

2.1 Orthogonal experiment

Selected five factors and four levels orthogonal experiment [10] table, - experiments are shown in Table 1:

Table 1 L16 (4^5) experimental factor level table

Reaction temperature /℃	acid and alcoholmolar ratio - mol/mol	Solvent	Reaction time /h	Catalyst
60	1:4	Benzene	2	PW
70	1:5	Toluene	3	CMA-PW
80	1:6	Tetrahydrofuran	4	C-PW
90	1:7	Dioxane	5	SiO_2-PW

By range analysis and Ri, We come to the influence factors on the experimental results: time> acid molar ratio > solvent> catalyst> temperature. L16 (4^5) orthogonal experimental results can - initially identified heteropoly acid catalyzed synthesis of β-methyl glutaric acid monomethyl ester optimal process parameters: reaction temperature: 80 °C; molar ratio: 1:6; solvent : toluene; reaction time: 4h; catalyst: CMA-PW.

2.2 Single factor experimental results

2.2.1 the effects amount of catalyst

Acid with methanol of the molar ratio was 1:6,200 ml of toluene as a solvent, the reaction temperature was 80 °C, the reaction time was 4h, in accordance with the synthesis method in reaction was carried out of the orthogonal experiments. CMA-PW were added to 3g, 4g, 5g, 6g, 7g as a catalyst. Analytical data of the drawing shown in Figure 1:

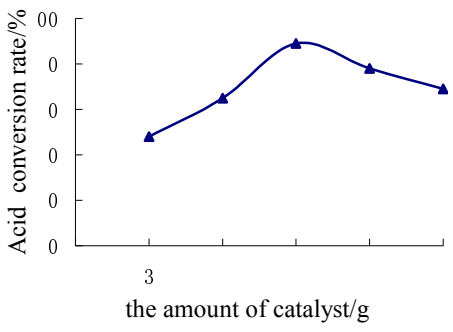


Fig.1 The effects of the amount of catalyst

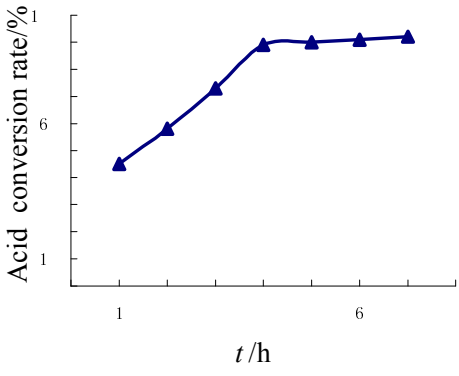

Fig.2 The effects of time

Figure 1 shows: the maximum of the catalytic efficiency is the amount of catalyst of 5g. When the the amount of catalyst less than 5 g, the catalyst amount the insufficient, not enough to make the reaction has reached the maximum reaction conversion rate; When the catalyst amount is more than 5 g, the conversion rate the diacid lower, may be due to the occurrence of side reactions. Therefore, the amount of catalyst 5 g is appropriate, that is 1.5% of the quality the the substrate.

2.2.2 Time factors

Acid with methanol of the molar ratio was 1:6,200 ml of toluene as a solvent, the reaction temperature was 80 °C, the reaction time was8h, in accordance with the synthesis method in reaction was carried out of the orthogonal experiments. When the reaction proceeds to 1h, 2h, 3h, 4h, 5h, 6h, 7h, 8h were measured by the conversion rate of the acid. Diacid conversion rate increasing with reaction time, it can be shown from Figure 2. But after 4h acid conversion rate rises slowly from 4 ~ 8 h reaction lasted for4 h, acid conversion rate rose only 5.0%. Consider of economic factors, reaction time is 4 h appropriately.

Conclusions

(1) Under basic conditions the addition reaction of crotonic acid ethyl ester and diethyl malonate to prepare β-methyl glutaric acid , the two sides are single molecule reactions, the relative production rate can be greatly improved, while also recovery to 20% of the reactants can be recycled.
(2) The use of β-methyl dimethyl glutarate and β-methyl glutaric acid reaction, single esterification rate can be improved. Diester can be recycled, so that of utilization rate of more of 90% of dicarboxylic acid.
(3) Optimal conditions of heteropoly acid catalyzed transesterification method is that acid and alcohol molar ratio of 1:6, solvent for anhydrous toluene, catalyst supported heteropoly acid dosage under of condition of 1.5% of of substrate, and the reaction time was 4h, of acid after of reactionof the conversion rate was 90%.
(4) All reaction conditions are mild, heteropoly acid catalyzed is reusable, non-corrosive, non-pollutant emissions, green line chemical cleaner production concept has important practical value.

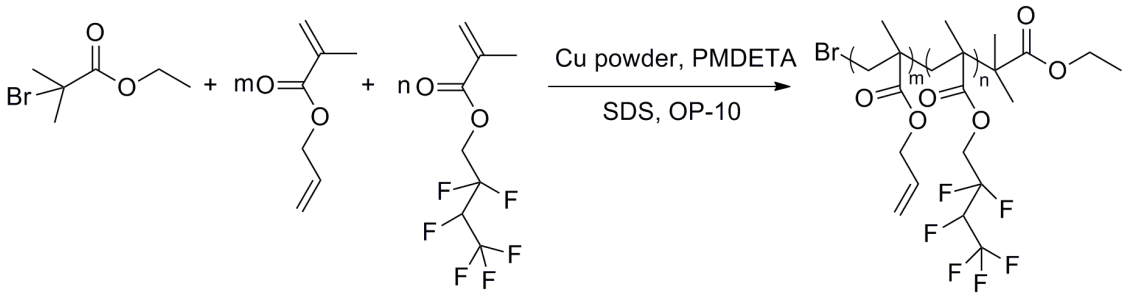
Keywords: fluorinate; thiol-ene; SET-LRP; UV curable

Abstract. Single electron transfer living radical emulsion polymerization (SET-LRP) of allyl methacrylate (AMA) coupled with 2,2,3,4,4,4-hexafluorobutyl methacrylate (HFBA) was investigated in the presence of Cu(0)/N,N,N',N'',N''-pentamethyldiethylenetriamine (PMDETA) as catalyst and ethyl 2-bromoisobutyrate (EBiB) as initiator. Solid content of the emulsion and the amount of the catalyst, initiator and emulsifier were discussed for the optimal reaction conditions. Then, the emulsion was combined with thiol capped polyurethane (SHPU) under UV to form the UV curable fluorinated films. Mechanical properties and contact angle of the UV cured films were studied.

Introduction

Living radical polymerization (LRP) has come into the spotlight for synthesis of well-defined polymers from a versatility range of vinyl monomers via a reversible activation-deactivation process [1]. A variety of LRP techniques have been developed, such as atom transfer radical polymerization (ATRP), reversible addition-fragmentation chain transfer (RAFT), nitroxide-mediated polymerization (NMP) and SET-LRP. Among them, SET-LRP has emerged as a robust technique for the ultrafast synthesis of tailored and multifunctional polymers with excellent control of molecular weight and molecular distribution [2]. Cu(0) powder and Cu(0) wire or Cu_2X (X= Te, Se, S, O) combined with diversity of disproportionating N-ligands are used as catalyst in SET-LRP [3-5]. A wide range of polar solvents such as DMSO [6], DMF [7], alcohols [8], and water [9] were confirmed to be feasible in this versatility channel. In this work, we report a SET emulsion polymerization of AMA and HFBA. Optimal reaction conditions for SET-LRP emulsion polymerization including solid content of the emulsion and the amount of the catalyst, initiator and emulsifier were investigated. The illustration for synthesis of PAMA-co-PHFBA was shown in Scheme 1. Afterward, SHPU was synthesized in our previous research [10] was used to react with double bond containing of PAMA-co-PHFBA under UV to obtain the UV cured films.



Scheme 1. SET emulsion polymerization of PAMA-co-PHFBA

Materials and methods

Allyl methacrylate (AMA), 2,2,3,4,4,4-hexafluorobutyl methacrylate (HFBA), 2-bromoisobutyrate (EBiB), sodium lauryl sulfare (SDS), polyoxy ethylene nonyl phenyl ether (OP-10) were purchased from Aladin China. photoinitiator 2959 (BASF), N,N,N',N'',N''-pentamethyldiethylenetriamine (PMDETA) (Alfa Aesar).

SET-LRP of PAMA-co-PHFBA. Cu(0) powder 0.15g, PMDETA 0.06g, SDS 0.01g, OP-10 0.02g and deinoized water 3g were charged into a 25mL three neck round flask, then the mixture was stirred vigorously with a speed of 1000rpm for 1h to obtain the emulsified catalyst system . On the other hand, AMA 0.755g, G02 1.5g, SDS 0.067g, OP-10 0.03g, EBiB 0.06g were charged into another 25 mL round flask, then the mixture was stirred vigorously for 30 min at 30°C under N_2 to obtain the pre-emulsion of the monomers. The emulsified catalyst system was transferred to the pre-emulsion with a stirring speed of 200rpm to initiate the polymer reaction. Conversion of the monomer was measured by weighting method.

Synthesis of UV curable films. UV cured films of PAMA-co-PHFBA and SHPU were prepared with the mole ratio of double bond and thiol of 1.5:1, 1:1, 1:2, 1:2.5 and 1:3, and the corresponding codes were 1, 2, 3, 4, 5 respectively, then the mixture was cured by UV in the presence of photoinitiator 2959.

Result and discussion

Optimal conditions for fluorinated SET emulsion. Solid content of the emulsions ranging from 10-30 wt% were investigated at the emulsifier content of 5 wt%, initiator loading of 1% and catalyst of 10% to the total monomer molar ratio, the results are shown in Fig.1. It was found that the shorter induction time of the polymerization was found in higher solid content, which may be ascribed to the higher monomer concentration in higher solid content system. However, in the solid content of 20%, the polymerization rate was much faster. Hence, solid content of 20 wt% was used in the next experiments. Effects of catalyst content on the conversion are revealed in Fig.2. Interestingly, 7% catalyst exhibited the fastest polymerization rate and 10% and 5% both prolong the induction time. This is due to reaction site is much less when polymerized at low catalyst and the generation of Cu(2)-ligand that lead to the passivation of the reaction, then 7% catalyst was used in the next experiments. Initiator content of 4%, 2%, 1%, 0.5% were studied and results are shown in Fig.3. It can found that the increment of initiator results in faster polymerization rate. However, at the point of 4%, the induction time became longer, which is attributed to the more activity centers were appeared and results in more time to obtain the same molecular weight. As a result, initiator of 1% was used in the next experiments. Emulsifier content of 3%, 5%, 7%, 9% were investigated and the results are shown in Fig.4. It can be figured out that emulsifier of 5% got the highest polymerization rate. This can be ascribed to the increased emulsifier resulted smaller particle size, which creates more particles and turn out to be faster polymerization rate. Thus 5% emulsifier was chosen as the best emulsifier content.

FT-IR. FT-IR spectras of PAMA-co-PHBA, SHPU, and UV cured film are shown in Fig.5. It can be noted that 3060 cm^{-1} and 1654 cm^{-1} are attributed to ally hydrogen characteristic absorption peaks. 1295 cm^{-1}, 974 cm^{-1}, 745 cm^{-1}, 682 cm^{-1} were due to the C-F absorption peaks. In the spectra of SHPU, 1738 cm^{-1} was ascribed to carbonate vibration absorption and 2570 cm^{-1} was due to the thiol characteristic absorption. As expect, in the spectra of UV cured film, absorption of ally at 3060 $cm^{-1}$and thiol characteristic absorption at 2570 cm^{-1} was disappeared and the C-F absorption peaks were retained, which confirmed the thiol-ene photopolymerization between SET emulsion of PAMA-co-PHFBA and SHPU.

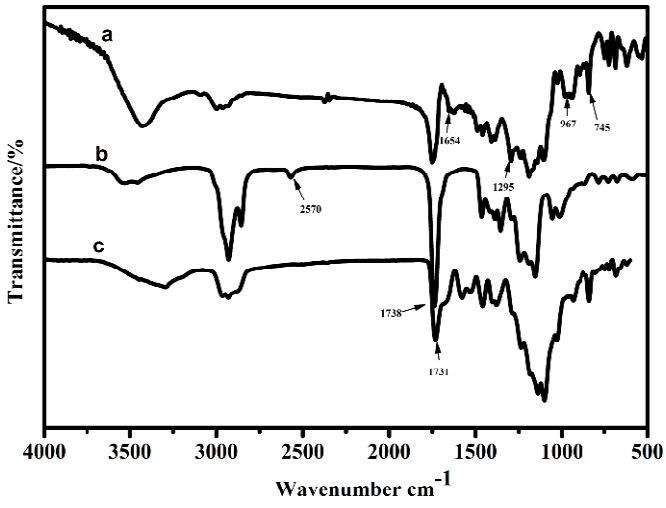

Fig. 5 FT-IR of a: PAMA-co-PHFBA, b: SHPU, c: UV cured film

Properties of UV cured films. Results of mechanical properties, gel rate and contact angle of UV cured polymer films are shown in Table 1. The gel rate of the films was inversely to the thiol and double bond ratio, which may be due to the high degree of crosslink between SHPU and PAMA-co-PHFBA when the double bond component was increased. In addition, pendulum hardness of film was also increase with the content of SET emulsion since PAMA-co-PHFBA was belongs to hard segment. Elongation at break and fracture deformation was increase followed by a little decline when thiol and double bond ratio increase, which may be attributed to the fact that SHPU was soft segment in UV curing films. The more composition of SHPU, the more flexible of the film was. As a result, tensile strength and elongation at break was increased. However, when SHPU was increased, the crosslink between thiol and double bond was saturated and the thiol residues was remained thus may impair the flexible of the final UV curing films. Contact angle of the UV curing films was decreased as thiol and double bond ratio increase, which can be ascribed to low surface energy fluorine atom in the PHFBA that can act as hydrophobic role in this UV curing films.

Table 1 Properties of UV cured polymers

Entry	1	2	3	4	5
Gel rate [%]	80.98	77.69	70.58	67.69	68.64
Pendulum hardness [s]	7.0	5.6	4.62	4.2	4.2
Elongation at break [%]	24.8	47.2	79.6	70	52.9
Fracture deformation [mm]	9.94	18.86	31.83	28.02	21.15
Contact angle [°]	83	81	80	78	75

Conclusions

SET emulsion polymerization of AMA coupled with HFBA were investigated in the presence of Cu(0)/PMDETA as catalyst and EBiB as initiator. Solid content of 20%, catalyst of 7%, initiator of 1% and emulsifier of 5% to the total monomer molar ratio was found to be the optimal reaction condition. And then the fluorated crosslink film were prepared under UV, Mechanical properties and contact angle of the UV cured films were investigated.

Keywords: Micro arc oxidation; Magnetism; Magnetic Field; Performance;

Abstract. Ceramic coatings were prepared on ZM5 magnetism substrate by micro-arc oxidation method with and without magnetism filed in silicate electrolyte. The morphology of the MAO coatings was investigated by scanning electron microscope (SEM). The friction coefficient of the MAO coatings prepared with magnetism is about 0.2 and more stable than the coatings prepared without magnetism. The polarization test indicated that the coating prepared with magnetism has better corrosion resistance.

Introduction

Micro-arc oxidation (MAO) is a complex thermo-chemical, electrochemical and plasma chemical process with combining concurrent partial processes of oxide film formation, dissolution and dielectric breakdown [1-3]. It is a new surface treatment technique developed from tradition anodic oxidation for aluminum, magnesium and titanium and their alloys to improve the performance of were resistant, corrosion, high temperature resistant and so on [4-6]. In recent years, vast investigations have studied on composition and concentration of electrolyte, oxidation time, electric parameters and it is with good performance of silicate solutions as environmental friendly electrolyte [7, 8]. Magnetic has the ability to increase the Lorentz force to affect particles in the electrolyte to move regularly [9, 10]. So this article is to investigate the MAO ceramic coatings performance with and without magnetism acting on both sides of the samples.

Experimental

A schematic of the experimental set-up used in this work is shown in Fig.1 (1-MAO power supply, 2-cyclied cooling water, 3-work sample, 4-electrolyte, 5- magnesium field, 6-insulate bracket). Samples made from a ZM5 magnesium alloy, which chemical composition is: 5.7% Al, 0.9% Zn, Fe, Si<0.01%, plus a small amount of rare metals with total surface area of 0.3dm^2. The samples were mechanically polished with waterproof abrasive paper up to 600 grits prior to micro-arc oxidation. The aqueous solution consists of 10g/l Na_2SiO_3 and adjusts pH to 10.5. An average current density of 1A/dm^2 was maintained on the surface with a frequency of 1200Hz and the duty of 10%. The oxidation process was conducted for 90min and electrolyte temperature for less than 40℃.

The surface morphologies of the oxide coatings were characterized by scanning electron microscopy (SEM, S2570). Friction and wear test was done on ceramic coatings produced by MAO with and without magnesium with CJS111B friction wear testing machine made by HIT. The relative grinding object is Si3N4 alloy with relative sliding speed of 0.377m/s and load of 1N. Friction coefficient is known directly on the testing machine. Potentiodynamic polarization was used to investigate the protective properties of the composite coatings and MAO film with CHI 660D at scan rate of 1mV/s in 3.5% NaCl solution.

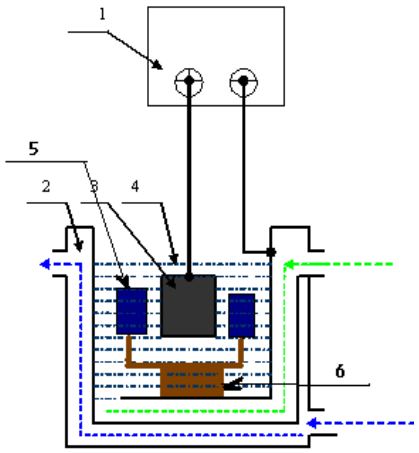

Fig.1 Typical arrangement of the equipment used for MAO treatment

Discussion

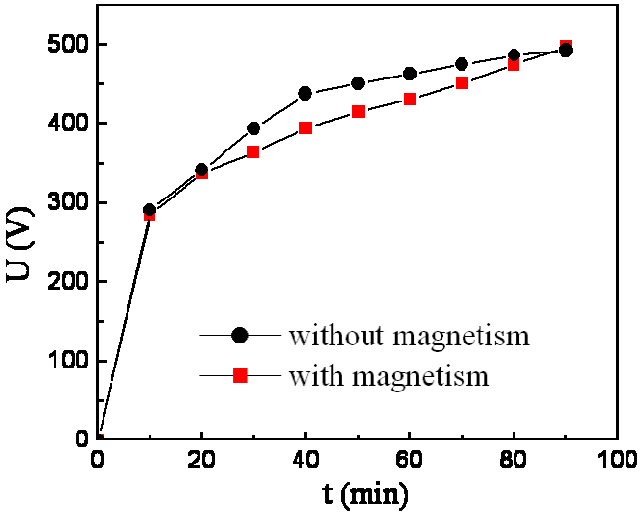

Fig.2 Voltage-time curves of MAO coatings progress

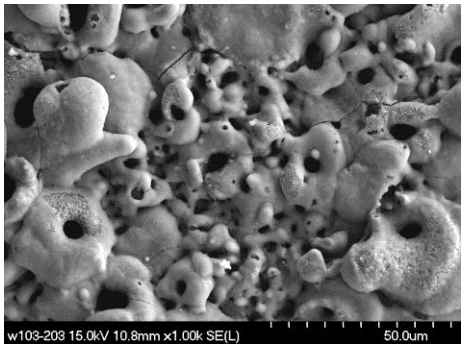
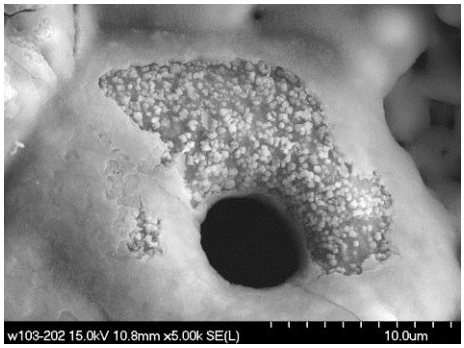
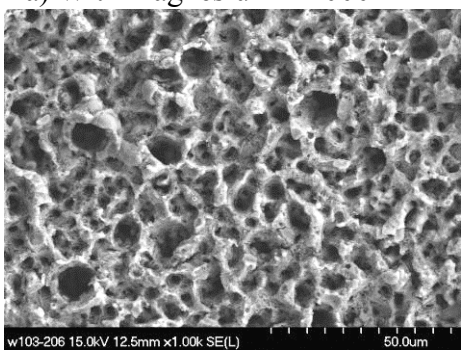
Fig.2 shows the voltage-time curves of ceramic coatings made with and without magnetism. From the picture it can be seen that the line with magnetism is smooth with voltage rising after 20min MAO course. This means as the increase of micro-arc oxidation time, conductive ions move intense disordered. The magnetism can lower the disordered movement of ions of the electrolyte but didn't affect the final voltage deeply. After 90min micro arc oxidation, the voltage without magnetism is 497V and with magnetism is 493V.



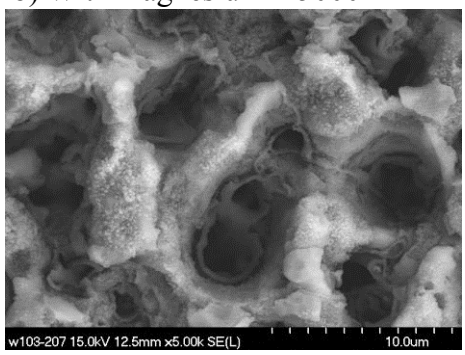
a) With magnesium×1000



b) With magnesium×5000



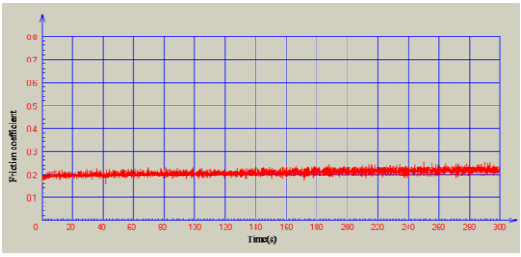
c) Without magnesium×1000



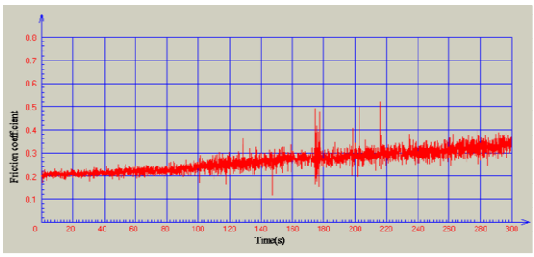
d) Without magnesium×5000

Fig.3 SEM images showing the surface morphology of MAO coatings prepared with and without magnetism

Fig.3 shows the picture of the surface morphologies of MAO coating prepared with and without magnetism. As can be seen in the picture, the ceramic coatings made with magnetism has lower porosity with a dense and flat outside layer and small particle as the inner layer. Compared to the magnetism sample, the samples without magnetism has relatively big pore as the net layer. So the magnetism has the ability to promote the good growth of ceramic coatings.



a) With magnesium



b) Without magnesium

Fig.4 Friction and wear testing of MAO coatings prepared with and without magnetism

Fig.4 shows the friction-wear tests of MAO coatings with and without magnetism field. Compared to the coatings without magnesium, the friction coefficient of MAO coatings prepared with magnesium is smaller and stable. According to SEM of the MAO structure, the coefficient is not a constant value due to the heterogeneous and inconsistency phases.

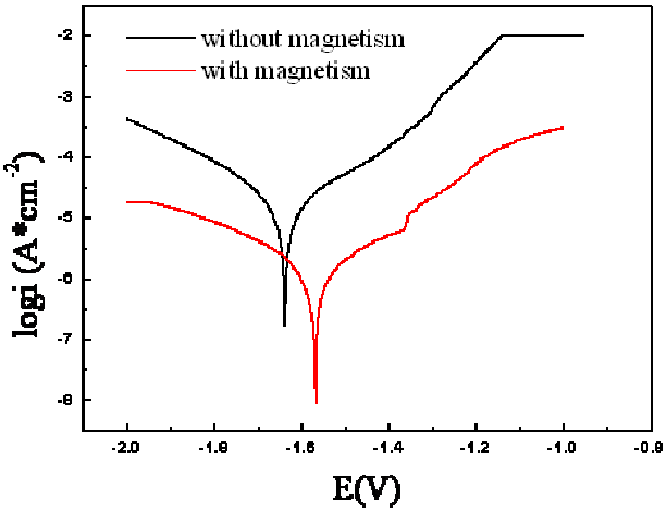


Fig.5 Potentiodynamic polarization curves of MAO films with different conditions

Fig.5 is the potentiodynamic polarization curves of MAO films with and without magnetism. With the same solution and same constant current density, MAO coating with the magnetism has the corrosion resistance with lower corrosion current 1.458×10^{-6} and higher corrosion resistance 31183.9Ωcm^2.

Table 1 Parameters of potentiodynamic polarization curves of

Samlpes	E_{corr}(V)	I_{corr}(A/cm^2)	R_p(Ωcm^2)
With magnetism film	-1.5683	1.458×10^{-6}	31183.9
Without magnetism film	-1.6389	1.533×10^{-5}	2578.0

Conclusions

In summary, we have demonstrated that magnetism has effect on the performance of MAO ceramic coatings of ZM5 magnetism alloys. The coating prepared with magnetism has small pore and a dense and flat outside layer. It has a better mechanical property and anti-corrosion performance of the MAO coatings prepared added in magnetism field.

Keywords: Organosilicon; epoxy esters resin; silane coupling agent; solution polymerization

Abstract. Organosilicon-modified epoxy esters resin was successfully prepared by solution polymerization and the effect of content of silica sol and silane coupling agent (KH560) on the resistance to water, acid, alkali and film dry, the polymerization mechanism, structure were studied, respectively. The results showed that: compared with the properties of resistance to water, acid, alkali and film dry of pure epoxy esters resin, to some extent, those of organosilicon-modified epoxy esters resin had been improved a lot. The properties of resistance to water, acid, alkali and aging increased at first and then changed little with the increase of the content of organosilicon. Especially, the comprehensive performance of composite resin was relatively excellent when the content of silica sol and KH560 was 10%, respectively.

Introduction

As a new type of high performance coatings, epoxy esters resin coating have developed rapidly in recent decades. However, pure epoxy esters resin has some defects, for example, it exists high viscosity , poor coating.These cause bad properties of acid resistance ,alkali resistance and aging resistance, its application range is also limited [1-3].

After modified by organosilicon, epoxy esters resin contained Si-O-Si bonds, Si-C bonds, the bond energy of Si-O bonds can be greater than the C-O. It could effectively solve the epoxy esters resin coating and silicon sol coating defects, achieving the complementary advantages in the performance [4-8].In addition, the weatherability of organosilicon modified epoxy esters resin coatings can be comparable to those containing fluorine resin coating, but its cost is only one third of the fluoride resin coating. So organosilicon modified epoxy esters resin has become one of hot research topic in the field of coatings.

Experiment

2.1 Experimental raw materials and equipment

Epoxy resin,Oleic acid,Zinc oxide, maleic anhydride, triphenylphosphine ,ethanol：Sinopharm Chemical Reagent Co. ,Lt d, KH560: Nanjing nengde chemical Co., Ltd , Hydrochloric acid: Shenyang economic development zone reagent factory, Deionized water: homemade, Digital display temperature control electric heating; motor stirrer, Four flask, Constant pressure drop funnel. Straight type reflux condenser pipe, Electronic balance, beakers, etc.

2.2 Preparation

According to the proportion of the molar ratio of TEOS: anhydrous ethanol: water 1:5:3 to put into four flask with hydrochloric acid to adjust pH between 2~4, insulation 6 h under 50~60℃. KH560 was dropped according to 1molTEOS/0.2mol KH560 ratio after the reaction, and then keep the temperature between 50~60℃ 6h reaction, at last modified silica sol was achieved.The fatty acids was added to the molten, hot resin, and the esterification reaction was continued. The esterification was carried out at high temperatures (220 to 240℃),until the acid number is low, usually less than 5mg of KOH per gram of resin. Cool to 110℃to maleic anhydride and dripped silica sol into it，tir and heat preservation 2~3h in 100~110 ℃ in order to make fully react. In the end, organosilicon-modified epoxy esters composite resin had been prepared.

3.1 Synthetic process and mechanism analysis of organosilicon modified epoxy esters resin

Ethyl orthosilicate (TEOS) reaction in acidic system is placid and easy to control, and silicon alkoxide groups can exist stably in acid solution, the stability could be improved in this way. Therefore, modified silica sol was prepared under acid condition.

The silane coupling agent KH560 could hydrolyze in a certain degree Under the same principle, and produced R_1-Si$(OCH_3)_2$(OH), R1-Si$(OCH_3)$$(OH)_2$ and R_1-Si$(OH)_3$ (R_1=CH_2=C(CH_3)-COO$(CH_2)_3$), eventually converted into R1-Si$(OH)_3$. At the same time of hydrolysis reaction, polycondensation among hydrolysis product of TEOS and KH560 generated silanol and other compounds containing -Si-O-Si-bonds or cross-linked R_1-[Si-O-Si] n-R under the condition of acid catalytic. Modified silica sol was achieved eventually.

$$Si(OC_2H_5)_4+xH_2O \rightarrow Si(OC_2H_5)_{4-x}(OH)_x+xC_2H_5OH \quad (x=1,2,3,4)$$

$$R_1\text{-}Si(OCH_3)_3+xH_2O \rightarrow R_1\text{-}Si(OCH_3)_{3-x}(OH)_x+xCH_3OH \quad (x=1,2,3)$$

$$R_1\text{-}Si(OCH_3)_{3-x}(OH)_x+Si(OC_2H_5)_{4-x}(OH)_x \rightarrow R_1\text{-}[Si\text{-}O\text{-}Si]_n\text{-}O\text{-}R_{11}+H_2O$$

3.2 Structure analysis of organosilicon modified epoxy esters composite resin

The structural of organosilicon modified epoxy esters composite resin was characterized by using Fourier infrared spectrum. Fig.1 showed the infrared spectrogram of epoxy esters resin and organosilicon modified epoxy esters resin. 770$cm^{-1}$and 843cm^{-1} vibration absorption peaks were characteristic peak of Si-C bond, 972cm^{-1} was characteristic peak of Si-O bond, absorption peak at the near 1070 cm^{-1} was the stretching vibration characteristic peaks of Si-O-C bond in the samples,1027 cm^{-1} was characteristic peak of Si-O-Si, This suggests that the epoxy esters resin polymer containing silicone group.

From figure 1 and the above analysis, Due to the synthesis of epoxy esters resin monomer is roughly same, so the skeleton structure of organosilicon modified epoxy esters resin is similar to that of pure epoxy esters polymer, Just only vibration absorption peak intensity was different because of the introduction of organosilicon containing Si-O bonds and Si-C bonds. Thus the organic silicon have been graft copolymerization on epoxy esters polymer molecules.

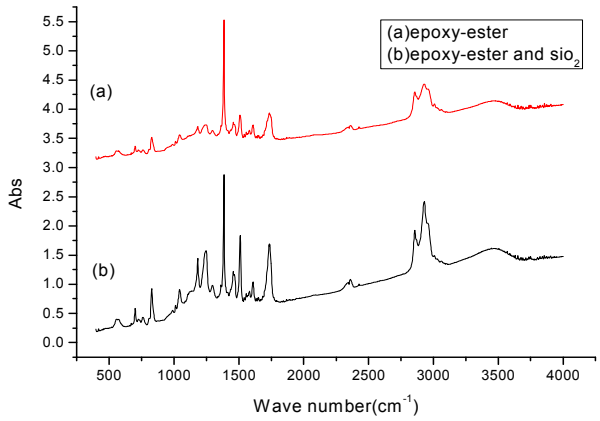

Fig. 1 The infrared spectrogram of the pure epoxy esters resin and organosilicon modified composite resin

3.3 Affect of silica sol content on the performance of composite resin coating

As is shown from tablel, Compared with pure epoxy esters resin coating, the performance of the organosilicon modified composite resin coating such as hardness, water resistance, acid resistance, alkali resistance and aging resistance had improved dramatically with the increase of silica content.

Table 1 Different silica sol content composite resin coating performance tests

Colloidal silica content	0%	5%	10%	15%
Hardness	HB	HB	HB	HB
Impact 500g cm	30	30	30	30
Water resistant 25	7h white	22h white	32h white	32h white
Acid resistant 0.05mol	9h white	15h white	48h normal	48h normal
Alkali resistant 0.1mol	3h hair bubbles	3h air bubbles	45h paint film falls off	50h paint film falls off
Film dry(h)	6	5	4	4

With the increase of organosilicon content water resistance, acid resistance, alkali resistance and aging resistance of composite resin showed a trend of first increases then changed little.Comprehensive consideration ,when colloidal silica content was 10%, the performance become better.

Conclusion

Compared with pure epoxy esters resin, water resistance, acid resistance, alkali resistance, ageing resistance, film dry and stability of organosilicon-modified epoxy esters resin had more improvement. When KH560 content remained invariant, water resistance, aging resistance and other comprehensive performance increased,but Especially, the comprehensive performance of composite resin was relatively excellent when the content of silica sol was 10%.

Corrosion resistance of CrSiN coatings by cathodic arc deposition with different arc currents

Wei-Yu Ho*, Po-Yi Tsou, Yen-Shuo Chang, Cheng-Liang Lin

Department of Materials Science and Engineering, MingDao University, Taiwan

weiyuho@mdu.edu.tw

Keywords: Cathodic arc deposition, arc current, bipolar plate, corrosion resistance

Abstract. Recently, metallic bipolar plates, particularly different grades of stainless steels, have been increasingly considered due to excellent properties. Metallic bipolar plates are coated with protective coating layers to avoid corrosion. The corrosion behavior of the nanostructured CrSiN coatings on the stainless steel was studied to be potential application for the bipolar plate. In this study, CrSiN coating deposited by a modulated pulsed current arc process was achieved using the cathodic arc deposition process. The crystallographic structure of the CrSiN coatings does not affect with the different cathodic arc currents. The interfacial electrical resistance of CrSiN coatings deposited on AISI 304 stainless steel substrates similar with the blank substrate was confirmed. The improved corrosion behavior can be obtained by using the cathodic arc current of 90/120and 90/150 A modulated type.

Introduction

Bipolar plate with multiple functions is one of the essential components of the PEMFC (Proton Exchange Membrane Fuel Cells) stacks. Recently, metallic bipolar plates, particularly different grades of stainless steels, have been increasingly considered due to relatively low cost, good corrosion resistance, sufficient stiffness and excellent flexibility in thin forms, and easy manufacturability [1-3]. However, the major concerns with the use of stainless steel alloys as bipolar plates are their corrosion resistance and interfacial electrical resistance under long operation conditions. Development of advanced ternary nitride coatings such as chromium silicon nitride (CrSiN) has attracted significant industrial interest in recent years [4-11]. Si addition of CrN to form CrSiN films were prepared by cathode arc ion deposition technique and magnetron sputter technique, in order to improve the characterizations of the coatings from structure to corrosion behaviors. It is reported that with the additional element of Si, the hardness and corrosion resistance of the CrSiN coatings can be greatly improved compared to that of the CrN coating. A direct link between the microstructure and mechanical properties of CrSiN coatings with varying Si contents was established [8]. With increasing Si content, the structure of CrSiN coating exhibited the transformation from a columnar-grained structure to a nanocomposite structure, consisting of CrN nanocrystallites embedded in an amorphous matrix. A maximum hardness of 26.6 GPa was found for CrSiN coating with Si content of about 6.7 at.%, while that of pure CrN was 19.4 GPa [6]. Up to now, the CrSiN is yet thoroughly investigated.

The goal of this paper is to report a study on the corrosion behavior of nanostructured CrSiN coatings on the stainless steel in the H_2SO_4 solution. The cathodic arc deposition technique with deposition condition of various pulsed arc currents was conducted.

Experimental

AISI 304 stainless steel used as substrates were cleaned in acetone and then in alcohol ultrasonically for 15 min before deposition. CrSiN coatings were deposited at the temperature of 300°C using a commercial cathodic arc deposition unit. Two kinds of targets, Cr and $Cr_{0.8}Si_{0.2}$ were used as cathodic arc sources. The process is designed as CrN as an adhesive layer and then CrSiN as the top layer. Different arc currents of 90A and modulating pulsed current of a duty ratio 90/120, 90/150 A were used. The duty cycle of the modulating pulsed current of 90/120, 90/150 A was set at 1 ms. The thickness of the coatings is about 2 μm.

X-ray diffraction (XRD; model PAN analytical X'pert PRD (MRD)) with Cu Kα radiation were used to specify the existent phases and the orientation of the CrSiN coatings. The Cu Kα line at 0.15405 nm was used as the source for diffraction pattern analysis. Scanning electron microscopy (SEM; model JOEL JSM-5600) was carried out to observe the surface morphology of the various samples. Thickness was measured from SEM observation of the fractured cross-sections of coated samples. A surface roughness tester was used to measure the surface roughness of the coating and substrate surfaces. A four point probe is used to measure the resistivity of the coated samples. Polarization test was conducted to distinguish the corrosive behavior of the CrSiN coated AISI 304 stainless steel. The corrosive medium of 1M H_2SO_4 solution was used to simulate the aggressive aqueous environment. The electrode potential was scanned from −0.8 to 0.8 V at the scanning rate of 1.0 mV/s. The corroded surface was then examined by using SEM.

Results and discussion

Fig. 1 shows the cross-sections of the CrSiN coatings deposited with modulated arc currents 90/120 A. The thickness of 2 μm was obtained from the Fig. 1. It is interesting that the thickness of the coatings is not related to the modulated pulsed arc current from 90 A to 90/120 and 90/150A, but is dependent on the deposition time. It is clearly observable that the deposited CrSiN coatings were equiaxed grain instead of columnar grain structure. Fig. 2 shows surface morphologies of the SEM observation of the CrSiN coatings deposited with modulated arc currents 90/120 A. The grain size of CrSiN coating is estimated about 1 μm of nanocomposite structure which are similar with the other work, consisting of CrN nanocrystallites embedded in an amorphous matrix [8].

Fig. 3 shows the surface roughness of the CrSiN coatings deposited with different arc currents. It is found that the surface roughness of the CrSiN coating decreases from 0.3 μm to 0.1 μm with an arc current from 90 A to 90/120 and 90/150A. The reason may be from the higher mobility result that the higher arc current causes the Cr ion to arrive at the desired location, resulting in a smoother surface [12].

Fig. 4 shows the XRD patterns of the CrSiN coatings with different arc currents. The (1 1 1), (2 0 0) orientation can be clearly observed for all the deposited films, indicating a NaCl-type crystal structure. The crystallographic structure of the CrSiN coatings does not therefore affect by the different cathodic arc currents.

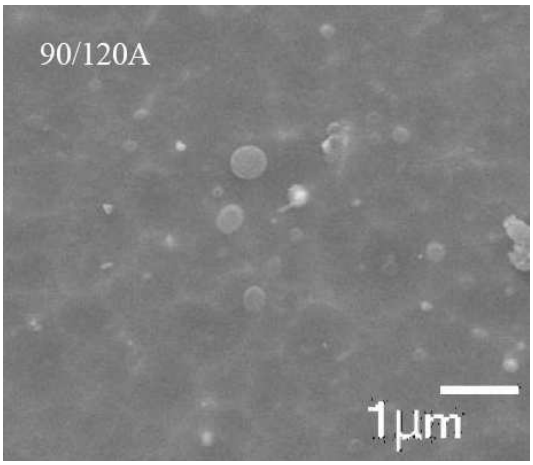

Fig. 2 SEM observation of the surface morphologies of CrSiN coatings deposited with modulated arc currents 90/120 A.

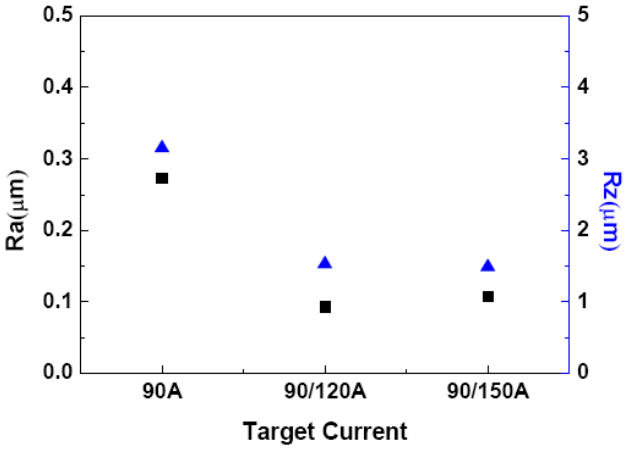

Fig. 3 Surface roughnes of CrSiN coatings with different arc currents.

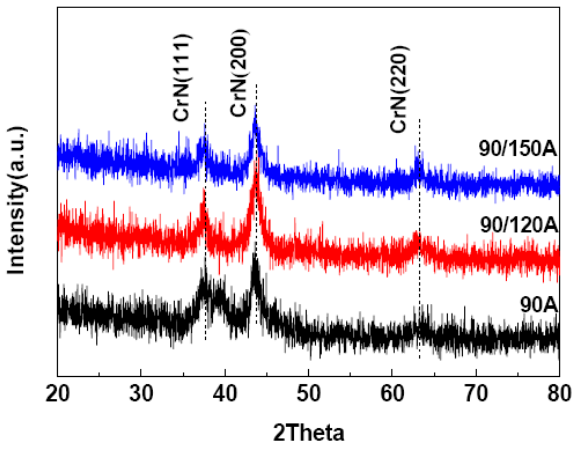

Fig. 4 XRD patterns of the deposited CrSiN coatings with different arc currents.

The interfacial electrical resistances of CrSiN coatings deposited on the AISI 304 substrates are examined by four-point probe measurement (Fig. 5). The CrSiN coatings are conductive and adhere to the base metal without exposing the substrate. The similar interfacial electrical resistance values of 2 $m\Omega.cm^2$ is observed for the CrSiN coating deposited at the different arc currents in this study. Generally, the CrSiN coatings have an average electrical resistance similar with the stainless steel substrate indicating electrical resistance low enough to meet the requirement of the bipolar plate for PEMFCs [13].

Polarization tests were carried out using 1M H_2SO_4 solution at room temperature. The polarization curves ($E_{corr.}$ vs. $I_{corr.}$) of CrSiN coated AISI 304 stainless steels are shown in Fig. 6. Compared with the blank stainless steel sample, the CrSiN coated specimens had evidently higher $E_{corr.}$ value. In particular, the film treated by 90/120 and 90/150 A showed a clear increase in $E_{corr.}$ value. A higher value implies that a stable electrode potential has been achieved, indicating an improvement in the corrosion resistance of the coated AISI 304 stainless steel. In addition, I_{corr} commonly utilized as an index of corrosion rate is determined by the extrapolation of cathodic Tafel lines. In this study, a significantly reduced I_{corr} was observed for the coatings with CrSiN deposition treated by 90/120 and 90/150 A. The treated specimens had an evident enhancement on the corrosion resistance as compared to the blank stainless steel and the one coated at 90A. It is expected that modulated pulsed arc current causes the reduction of defects in the coatings. A better corrosion resistance of the CrSiN coated AISI 304 stainless steel obtained by using the cathodic arc current of 90/120and 90/150 A is the potential application for the bipolar plate.

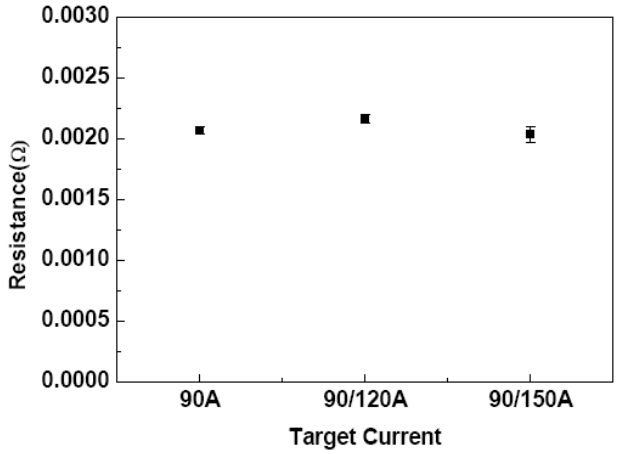

Fig. 5 Interfacial electrical resistances of CrSiN coatings deposited with different arc currents.

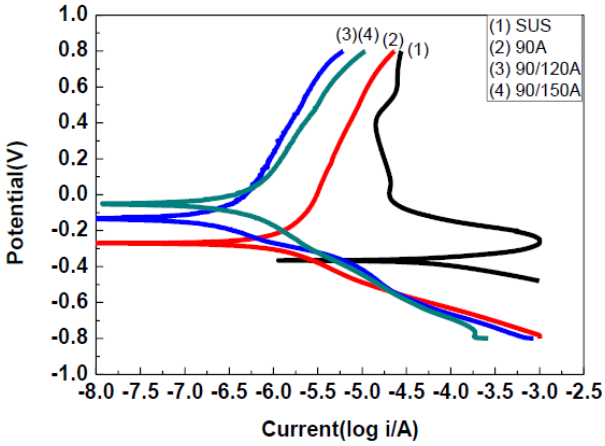

Fig. 6 Potentiodynamic curves for CrSiN coated stainless steel in 1M H_2SO_4 solution at room temperature.

Conclusions

CrSiN coating deposited by a modulated pulsed current arc process was achieved using the cathodic arc deposition process. The crystallographic structure of the CrSiN coatings does not affect with the different cathodic arc currents. The interfacial electrical resistance of CrSiN coatings deposited on AISI 304 stainless steel substrates similar with the blank substrate was confirmed. The improved corrosion behavior can be obtained by using the cathodic arc current of 90/120and 90/150 A modulated type.

Keywords: Zinc Oxide, Mesoporous structure, Sol-gel process, EISA process, pH value

Abstract. In this work, ordered mesoporous ZnO thin films was synthesized and gas sensor properties were introduced. Mesoporous ZnO thin films were successfully formed by sol-gel process. In ZnO structure, complex agent (MEA) was used for the hydration and condensation reaction. According to the change of MEA concentration, porosity and pore arrangement, specific surface area could be changed. As complex agent concentration decreased, pore ordering was increased and gas sensitivity has the high value (8.01).

Introduction

Mesoporous structures have pores with size ranging from 2 to 50 nm [1]. This pore structure causes low thermal conductivity, high specific surface area, and so on. Mesoporous structure could be used in gas sensor applications and thermoelectric devices, among many other applications. Metal oxide semiconductor gas sensor has merit due to their low cost and high sensitivity. Among many metal oxide semiconductors, zinc oxide (ZnO) was widely used for gas sensor application [2]. ZnO is an inexpensive, n-type semiconductor and it has been researched such as laser, thermoelectric, and gas sensor applications. ZnO thin films could be synthesized by RF sputtering, chemical vapor deposition (CVD), sol-gel process [3-5], and so on. In this work, sol-gel process was chosen because sol-gel process could be easily controlled the film thickness and composition. And, evaporation-induced self-assembly (EISA) process was progressed to synthesize ordered pore structure. In this paper, we investigated the effect of the molar ratio of MEA/Zn precursors on the formation of mesoporous ZnO thin films. Monoethanolamine (MEA) acts sol stabilizer and control pH value and viscosity. Because sol stability and pH could affect ZnO structure, pore arrangement and porosity could be affected by MEA addition. In this work, crystallization, pore structure, porosity, and gas sensing properties of mesoporous ZnO thin films were analyzed.

Experimental

Mesoporous ZnO thin films were synthesized by using sol-gel process. Zinc acetate dihydrate [$Zn(CH_3COO)_2 \cdot H_2O$], Brij-76, and n-propanol were used as ZnO precursor, surfactant, and solvent, respectively. MEA was used as complex agent that acts a ZnO sol stabilizer and pH controller. Addition of MEA to ZnO sol causes the ZnO matrix to adopt a rigid structure. So, because mesoporous structure could be changed by MEA addition, molar ratio of MEA/Zn precursors was changed from 0.8 to 1.2. In this work, the molar ratio of zinc acetate dihydrate : Brij-76 : MEA : n-propanol was 1: 0.05 : 0.8~1.2 : 34.5. MEA/Zn precursors molar ratios were 0.8, 1.0, and 1.2, which were indexed as MEA(0.8), MEA(1.0), and MEA(1.2), respectively.

Brij-76 was dissolved in n-propanol for solution preparation. After stirring for 1 hour, Zinc acetate dihydrate and MEA were added to the solution. The mixed solution was aged for 24 hours at room temperature to get stable solution. Mesoporous ZnO thin films were prepared by spin coating on SiO_2/Si substrate through the evaporation-induced self-assembly (EISA) process [6, 7]. After coating, thin films were preheated at 300°C for 10 min to pyrolysis of ZnO precursor and remove residual organics. After anneal at 450°C for 4 h under vacuum, mesoporous ZnO thin films were synthesized.

Pore arrangement could be confirmed by using small angle X-ray diffraction (SAXRD). SAXRD was performed with angles ranging from 1° to 5° using CuKα radiation (1.5418 Å). The refractive indices of mesoporous ZnO thin films were obtained by using an ellipsometer (Gatan L117 C, 632.8 nm He–Ne laser). Based on these refractive indices, the porosities were calculated using the Lorentz-Lorenz equation [8]. A gas sensor for sensing CO gas was fabricated using a SiO_2/Si substrate with 200 nm thick of Pt interdigitated electrodes (IDE) which electrode gap of 5 μm. IDE patterns were fabricated using photolithography and dry etching. The responses of the fabricated gas sensors to CO gas were measured at 350 °C by monitoring in change of sensor resistances with 100 ppm CO gas which was balanced with dry air. To eliminate interfering effects, a constant flow rate of 1000 sccm for dry air and the CO gas were used. Film resistance was measured under a DC bias voltage of 3 V using a source measurement unit (Keithley 2635A).

Results and discussion

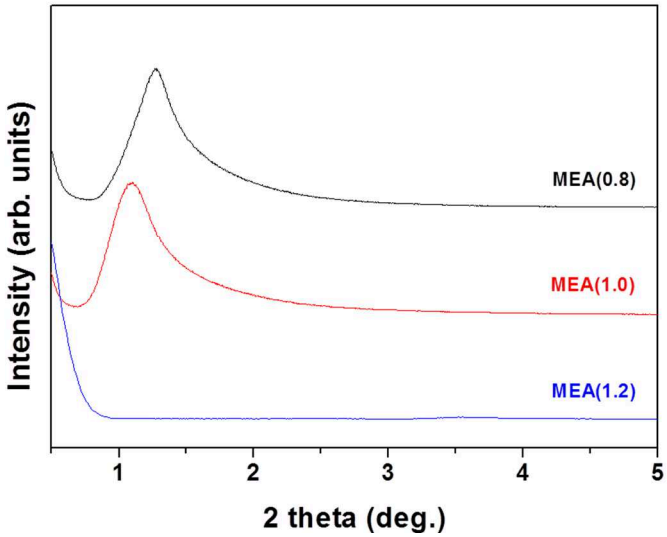

Fig. 1. SAXRD patterns of mesoporous ZnO thin films with various MEA/Zn concentrations.

Fig. 1 shows the SAXRD patterns of mesoporous ZnO thin films with various MEA/Zn precursor molar ratios. At SAXRD results, existence of diffraction peaks indicates a regular pore arrangement. As shown at Fig. 1, SAXRD peaks were observed at MEA (0.8) and MEA (1.0). However, in the case of MEA (1.2) sample, diffraction peak was not observed because ordered pore structure was collapsed. From the diffraction 2θ data, we confirmed that MEA concentration could affect regular pore arrangement. Because MEA has amine ligand and high viscosity, pH and sol viscosity were increased with MEA concentration. When MEA was added in excess, sol stability was decreased because hydration and condensation reaction rate was affected by pH value. It could affect pore structure arrangement, no diffraction peak was observed at MEA(1.2). Diffraction peaks were observed around 1.1 and 1.26° of 2θ for MEA (0.8) and MEA (1.0). From diffraction peaks, inter-planar distances were calculated as 8.03 and 7.01 nm for MEA (0.8) and MEA (1.0), respectively. From the SAXRD data, pore structure of mesoporous ZnO thin films could be analyzed. Crystallization of mesoporous ZnO thin films was shown in Fig. 2 of wide angle X-ray diffraction (WAXRD). As shown at Fig. 2, all mesoporous ZnO thin films have hexagonal wurtzite structure which diffraction peaks at 2θ of approximately 31.8°, 33.4°, and 36.2°. These WAXRD peaks could be indexed as (100), (002), and (101), respectively. Comparison of diffraction peak position and intensity, all samples has same crystallization although MEA concentrations affect pore arrangement.

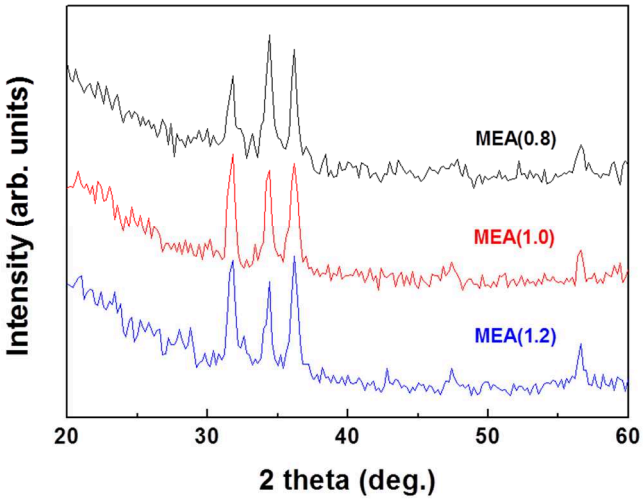

Fig. 2. WAXRD patterns of mesoporous ZnO thin films with various MEA/Zn concentrations.

$$1 - F_p = \frac{\frac{nf^2-1}{nf^2+2}}{\frac{na^2-1}{na^2+2}} \quad (1)$$

Fig. 3 shows the porosity behavior of mesoporous ZnO thin films with various MEA concentrations. Porosity was calculated by Lorentz-Lorenz equation (Eq. 1) where F_p is the pore volume fraction, n_f is the refractive index of the film, and n_a is the refractive index of air.

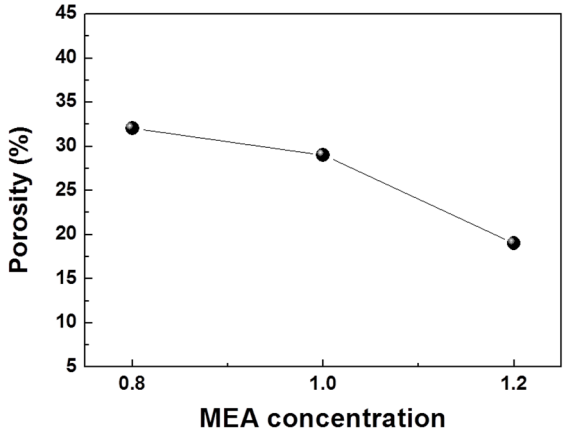

Fig. 3. Porosity behavior of mesoporous ZnO thin films with various MEA/Zn concentrations.

As shown at Fig. 3, porosity was decreased with increasing MEA concentration. The porpsity values of MEA (0.8) and MEA (1.0) were 32% and 29%, respectively and they were similar values. However, in the case of MEA (1.2) sample, porosity was decreased rapidly because ordered pore structure was collapsed as shown in Fig. 1. From Fig. 1 and Fig. 3, ordered mesoporous ZnO structure could be affected by an increase of MEA concentration.

Fig. 4 shows gas sensing properties of mesoporous ZnO thin films with various MEA/Zn precursors. During an exposure to 100 ppm CO at 350 °C, the sensor resistance decreased, which indicated that the ZnO thin films were n-type semiconductors. From the difference between the sensor resistance in air and the sensor resistance in CO, sensitivity of gas sensors could be calculated. Gas sensitivities of mesoporous ZnO with various MEA concentrations were 8.01, 5.64, and 4.41, respectively.

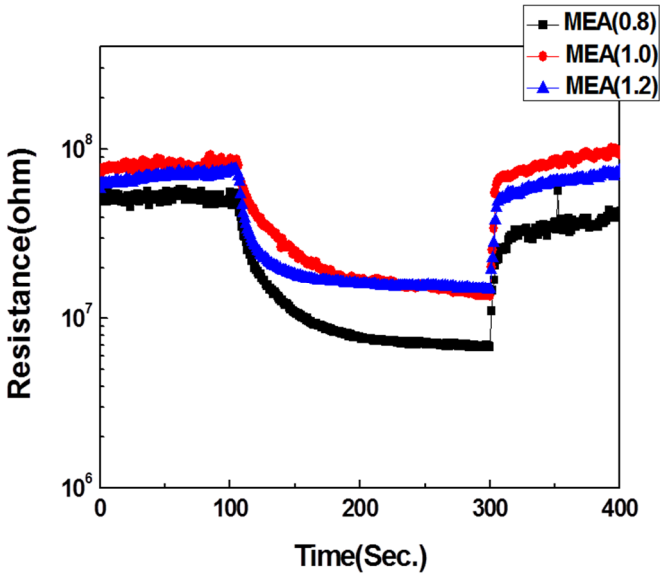

Fig. 4. Gas sensing properties of mesoporous ZnO thin films with various MEA/Zn concentrations.

As shown at Fig. 4, the sensitivity was decreased with increasing MEA concentration. The sensitivity of MEA(0.8) was higher than that of MEA(1.2) and this difference was followed by pore arrangement and porosity as MEA(0.8) has higher pore ordering and porosity.

Summary

In this work, mesoporous ZnO thin films were synthesized by using sol-gel and EISA process. Porosity of the thin films changed from 19% to 32% by adjusting the MEA/Zn precursors. Because pore arrangement and porosity were changed with MEA concentrations, specific surface area could be changed and gas sensor properties were also changed.

Keywords: Al base alloys; glass-forming ability; thermal stability; crystallization kinetics.

Abstract. Glass forming ability and crystallization kinetics of Al-Mg-Ni-La alloys have been investigated by X-ray diffraction (XRD) and differential scanning calorimetry (DSC). The maximum thickness achievable in glasses of $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ ribbons were 200 and 120 μm, respectively. The crystallization temperature and peak temperature indicated by DSC measurements displayed dependence on the heating rate during continuous heating, and were coincident with Lanoka's relationship. The activation energies for the crystallization reaction E_x were obtained from the Kissinger's equation. The results show the Mg addition is beneficial to the thermal stability of the amorphous phase.

Introduction

Multi-component Al-based metallic glasses (MGs) are of significant interest as low-density and high-strength alloys. The limited glass forming ability of the present Al-based metallic glasses, however, is the bottleneck to constrain their application. Tremendous work has been devoted to pursuing the higher glass forming ability of Al-based MGs since their discovery. Up to date, most of Al-based MGs have high Al content of 85 at. % more or less [1], which is very different from that of other system MGs, in which the content of the base element is in the range of 40-60 at.% [2]. Many studies show that the poor glass forming ability of Al-based MGs is related to the easy formation of f.c.c.-Al thermodynamically and kinetically. These works shed light on improving the glass forming ability of Al-based MGs by suppressing the precipitation of f.c.c.-Al. Recently, some progresses that bulk amorphous sample with the size of 1mm was successfully prepared in the Al-Ni-La system have been made [3]. The formation of f.c.c.-Al was effectively hindered through melt treatment [4].

In other MG systems, minor alloying of the element with a large size mismatch with the base element favors stabilizing the supercooled melt and suppressing the nucleation of the crystals, which leads to the enhancement of glass forming ability[5]. Similarly, in the Al-based MGs, minor alloying is used to improve the glass forming ability and enhance the thermal stability as aforementioned. However, the effect of glass forming ability improvement is limited [6,7]. Because the Al content as high as 85 at.% leads to the nucleation ease of f.c.c.-Al in most of the present developed Al-based MGs. From this aspect, reducing the Al content is probable to restrain the precipitation of f.c.c.-Al, leading to elevating the glass forming ability. Simultaneously, the alloying element with the replacement of Al cannot increase the density of MGs. Based on such a consideration, Mg is selected as alloying element because of the low density, the negative mixing enthalpy of Al-Mg along with the large size difference between Al and Mg[8] in the present work. The glass forming ability and crystallization kinetics of Al-Mg-Ni-La alloys were investigated. It shows that MG samples can be prepared in the investigated range of Mg content and Mg addition obviously enhances the thermal stability by suppressing the formation of f.c.c.-Al.

Experimental

Intermediate alloy with the composition of $Al_{50}Mg_{50}$ (in atomic percentage, at.%) was prepared firstly using induction melting method. The ingots of $Al_{(87-x)}Mg_xNi_8La_5$ (x=11,13,15,18,20, at.%) were obtained by melting the intermediate alloy and the rest elements in a graphite crucible under high purity argon atmosphere using induction melting in order to reduce evaporation of Mg. All the raw materials have the purity more than 99.9 wt.%. Proper amount of ingots were then remelted under high vacuum in a quartz tube and injected through a nozzle with 0.5-1 mm in diameter onto surface of rotational copper wheel at different speeds to obtain ribbons with 70 to 200 μm thickness. The structure of the ribbons was examined by X-ray diffractometry (XRD; Rigaku, D/Max-2500PC, Tokyo, Japan, Cu Kα). Thermal behaviors were analyzed by differential scanning calorimetry (DSC; Netzsch DSC 204C, Germany) at different heating rates of 5, 10, 15 and 20K/min.

Results and discussion

Figure 1 shows XRD patterns of melt-spun Al-Mg-Ni-La alloys. The thicknesses of all the ribbons are about 70 μm. It can be seen that only for $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ alloys, broad peaks characteristic of amorphous structure and no sharp Bragg diffraction peaks corresponding to crystalline phases are observed on the patterns, indicating that the samples are fully amorphous. For the other three alloys, some sharp peaks, which are not identified in the present work, are imposed on broad peaks, meaning that the samples consist of a mixture of crystalline phase and amorphous phase. These results suggest that $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ alloys exhibit relatively higher glass forming ability.

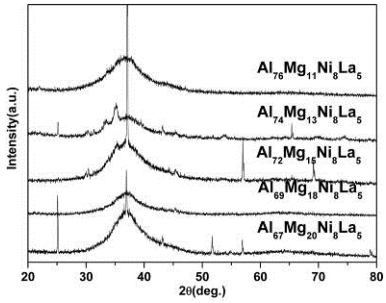

Figure 1 XRD patterns of melt-spun Al-Mg-Ni-La alloys with the thicknesses of 70 μm.

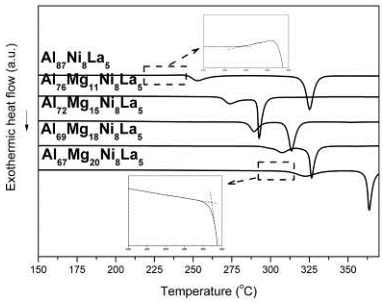

Figure 2 DSC curves of melt-spun Al-Mg-Ni-La alloys obtained at a heating rate of 20 K/min

The critical size for metallic glass formation was further examined for $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ alloys. For the $Al_{76}Mg_{11}Ni_8La_5$ alloy, when the sample thickness is 150μm or even 200μm, the patterns consist of only one broad diffraction peak, which shows the samples are in an amorphous state. When the sample thickness further reaches 220μm, some distinct diffraction peaks corresponding to crystalline phases are seen to appear on the XRD patterns, showing that the sample partially crystallized. This indicates that for $Al_{76}Mg_{11}Ni_8La_5$ alloy the critical thickness of glass formation is between 200 μm and 220 μm. For the $Al_{69}Mg_{18}Ni_8La_5$ alloy, it is found that the sample with a thickness of 140 μm contains some crystalline phase indicated by some sharp diffraction peaks imposed on a diffusive peak. That is to say, the critical size of the MG sample is smaller than 140 μm for this alloy. It indicates that the $Al_{76}Mg_{11}Ni_8La_5$ alloy shows a higher glass forming ability than the $Al_{69}Mg_{18}Ni_8La_5$ alloy.

Thermal properties of the investigated Al-Mg-Ni-La metallic glasses were evaluated using DSC measurements. Fig.2 shows the DSC curves obtained at a heating rate of 20 K/min. It clearly shows that the Mg addition obviously changes the thermal behaviors of the Al-based MGs. Although all the samples exhibit two-stage crystallization, the glass transition temperature (T_g) and on-set crystallization temperature (T_x) rise with the addition of Mg. With the increase of Mg content, T_g and T_x increase. It shows that Mg alloying favors thermally stabilizing the amorphous phase. The first crystallization peak on the DSC curve corresponds to the formation of f.c.c.-Al for $Al_{87}Ni_8La_5$

amorphous alloy. The rise of T_g and T_x with the Mg addition indicates that f.c.c.-Al is effectively suppressed. As aforementioned, it is beneficial to the improvement of glass forming ability. It is consistent with the results shown in Figure 1.

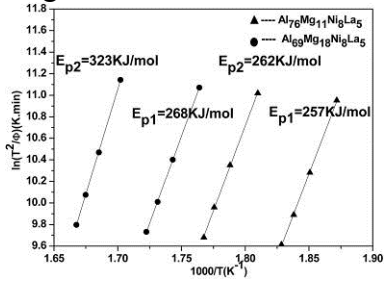

Figure 3 The Kissinger plots of crystallization peaks' temperatures for $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ alloys

Furthermore, the crystallization kinetics of $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ metallic glasses was studied. The continuous-heating DSC traces of $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ metallic glasses at heating rates of 5, 10, 15 and 20 K/min were tested. No clear glass transition phenomenon is observed in all DSC traces. Apparently, T_x and peak temperature T_{pi} of $Al_{69}Mg_{18}Ni_8La_5$ alloy are obviously higher than those of $Al_{76}Mg_{11}Ni_8La_5$ alloy, which indicates that the former should be more thermodynamically stable than the latter.The crystallization behavior is largely dependent on heating rate during continuous heating and presents kinetic nature. The activation energies E_x for crystallization reaction could be determined by Kissinger's equation [9],

$$\ln\frac{T^2}{\phi}=\frac{E_x}{k_BT}+C \tag{1}$$

Where k_B is Boltzmann's constant. The Kissinger plots of crystallization peaks' temperatures for $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ alloys are shown in Fig. 3. The E_{p1} and E_{p2} of $Al_{76}Mg_{11}Ni_8La_5$ are obtained to be 257 and 262 KJ/mol. For $Al_{69}Mg_{18}Ni_8La_5$, they are 268 and 323 KJ/mol, respectively. The E_{pi} of $Al_{76}Mg_{18}Ni_8La_5$ is higher than those of $Al_{69}Mg_{11}Ni_8La_5$, indicating that $Al_{76}Mg_{18}Ni_8La_5$ alloy has better thermal stability, which coincides with the case stated above.

As described by Inoue's three empirical rules for glass formation [10], Mg has a large size difference from Al, Ni and La, and the negative mixing enthalpy exists between them [8]. The Mg replacement of Al improves the atomic packing of the supercooled melt. The atom diffusion becomes harder in this case so that the competing crystals are difficult to form. In other words, the Mg alloying is expected to not only improve the thermal stability of the amorphous alloy, but also enhance glass formation. In the previous studies, the core-shell structure with the Al core and La-rich shell is formed when the f.c.c.-Al is formed in the Al-based metallic glass [11]. This structure shows that the atomic diffusion is needed in the process of f.c.c.-Al nucleation and growth. It is believed that the precipitated nanoscale Al crystal is the perfect one which will exclude other elements, such as Ni and La in the Al-Ni-La metallic glasses. Correspondingly, the similar process should occur upon the f.c.c.-Al formation in the Al-Mg-Ni-La system. From the Al-Mg binary phase diagram, the solubility of Mg in Al is quite small at room temperature [12]. In the precipitation of f.c.c.-Al, Mg should be rejected. Due to the high content and relatively large atomic size of Mg, this process is more difficult to occur. The higher activation energy is needed. As shown in Fig. 3, T_x is increased with the addition of Mg.

As shown in Fig. 2, without the addition of Mg, the $Al_{87}Ni_8La_5$ base alloy exhibits obvious glass transition, which is enlarged in the inset of Fig. 2. The width of supercooled region is about 30 K. With the addition of Mg, the alloys exhibit no clear glass transition phenomenon as shown by DSC traces in Fig. 2. Crystallization of metallic glasses is reported to be nucleation controlled or growth controlled. When crystallization of MGs is under growth control, the nuclei is supposed to be some small fraction of crystallization occurring initially in the rapid solidification process or atomic clusters with the size equivalent to the critical nucleation size retaining in the solidification process. In either case, once MG crystallizes upon heating, no nucleation is activated and the growth directly starts

based on the existing nuclei, which results in the coincidence of T_g and T_x. In this way, the addition of Mg changes the crystallization mechanism of the investigated Al-based MGs from the nucleation-controlled one to the grow-controlled one. As discussed above, the mixing enthalpy between Mg and Al is quite low. In the liquid state, Mg and Al tend to self-agglomerate, producing the atomic-scale chemical heterogeneities. Some Al-rich clusters with large size can serve as the nuclei in the crystallization of MGs upon heating, the further development of which is limited by the Mg-rich heterogeneities. This kind of chemical heterogeneities in the melt helps form the amorphous phase. At the same time, it helps stabilize the amorphous phase against heating, which is evidenced by the activation energy of crystallization of the present Al-Mg-Ni-La MGs higher than the base alloy. Furthermore, the atomic scale chemical heterogeneities are expected to benefit the mechanical properties of MGs, which makes Al-Mg-Ni-La metallic glasses in the present study exhibit good mechanical performance.

Conclusion

The glass forming ability, thermal properties and crystallization kinetics of Al-Mg-Ni-La MGs were investigated by using Mg partially replacing Al in the $Al_{87}Ni_8La_5$ alloy. The following conclusions can be drawn:

1. Among the investigated $Al_{87-x}Mg_xNi_8La_5$ (x=11, 13, 15, 18, 20) alloys, $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ have better glass forming ability. And the maximum thickness of $Al_{76}Mg_{11}Ni_8La_5$ and $Al_{69}Mg_{18}Ni_8La_5$ are 200 and 120μm.

2. The addition of Mg enhances the thermal stability though elevating the glass transition and onset crystallization temperature. The corresponding crystallization activation energies are calculated by Kissinger's plot and increases with the Mg addition. The values are 257 and 262 KJ/mol for $Al_{76}Mg_{11}Ni_8La_5$ amorphous alloy, and 268 and 323 KJ/mol for $Al_{69}Mg_{18}Ni_8La_5$ amorphous alloy.

Key words crystallization; microbubble; motion characteristics; force equilibrium

Abstract：The motion characteristics of microbubble in the water or solution have important influence to crystallization process. In the paper, the movement equation of single bubble was modeled based on force equilibrium, the mechanics factors influence on the single bubble motion were discussed, and the velocity of microbubble was analysed with the different bubble sizes. The results show that the velocity of microbubble in static water is increasing with time increasing, the influence of virtual mass force and Basset force caused by the acceleration on the velocity of microbubble must be considered in the initial stage of microbubble motion. In the processes of microbubble motion, compared with constant microbubble radius the variation laws of velocity fluctuations mean with microbubble radius changing are uniform.

Introduction

In recent years, people have made great progress in the relationship between crystallization, fluid mechanics and external factors intervention, and people have started to search all kinds of external factors to dynamically intervene crystallization process. Researches of plus ultrasonic strengthening water or solution crystallization are catching researcher's attention more and more[1-4]. Mathieu[3] studies the first nucleation process when a single bubble collapse into a plurality of microbubbles, the influence of the number of hole microbubbles on crystal nucleation in the nuclear. Therefore, there are still many hot issues in the study of ultrasonic cavitation to promote or reinforce water and solution crystallization.

As the microbubble widely exists in chemical industry, power plant, nuclear reactor, heat energy, biology, medicine and other fields, the research of motion law of microbubble has a great significance for actual production, fluid mechanics and development of multiphase. At present, the research of the bubble rising velocity, bubble distribution and gas-liquid mass transfer has been widely concerned by scholars both home and abroad. Chakraborty[5] researches on the coupling relationship of bubble radius change and upward movement, establishing the motion equation, and obtaining the influence of bubble radius change on the rising movement by numerical calculation. However researches mentioned above are still imperfect both in the influence of mechanical factors on the bubble rise process and in the influence of bubble radius change on the rising movement.

This paper researches the influence of various mechanical impact factors on the single bubble movement. The bubble velocity is discussed with the constant sizes or sizes changing by sine or sawtooth rule.

Simulation theory and Method

A. Motion control equation

1) Basical assumptions

Several simplified assumptions are adopted in the present analysis. a) Bubble keeps spherical state. b) The gas in the bubble keeps in constant temperature condition. c) The liquid keeps in stationary state.

2) Motion balance equation

Based on the above assumptions, analysis the forces of the bubble, we could obtain the motion balance equation for bubble:

$$m_b \frac{du}{dt} = F_g + F_b + F_d + F_A + F_B \tag{1}$$

Balance equations expression (1) could be rearranged as:

$$\int_0^t \frac{du/d\tau}{\sqrt{t-\tau}} d\tau = \frac{\Delta t}{2}(a(0) + 2\sum_{i=1}^{n-2} \frac{a(i\Delta t)}{\sqrt{t-i\Delta t}}) + \frac{3}{2} a(t-\Delta t)\sqrt{\Delta t} + \sqrt{\Delta t}\frac{du}{dt} \tag{2}$$

B. The calculation method of the equation

A singular point can be found from the basset force expression of the bubble motion differential equation (2), And when try to solve the differential equation, we need to deal with the generalized integral term properly. First estimate the convergence of generalized integral term, because when the acceleration of bubble is bounded, there will be a positive number $M < +\infty$, making $|du/dt| \leqq M$ establish. So according to the generalized integral limit review gathered method, this generalized integral item must be convergent.

$$\frac{du}{dt} = \frac{2(\rho_l - \rho_g)g}{\rho_l} - \frac{9u}{r}\cdot\frac{\mu}{\rho_l r}[1 + 0.168(\rho_l r u/\mu)^{0.75}] - \frac{9\sqrt{\pi\rho_l\mu}}{r\pi\rho_l}\left(\frac{\Delta t}{2}(a(0) + 2\sum_{i=1}^{n-2}\frac{a(i\Delta t)}{\sqrt{t-i\Delta t}}) + \frac{3}{2}a(t-\Delta t)\sqrt{\Delta t} + \sqrt{\Delta t}\frac{du}{dt}\right) \tag{3}$$

C. Solving method and parameter determination

In order to improve the accuracy of numerical results, the method is first to predict and second to correct, in other words it is modified Eular method. Then solve equation through the adaptive variable step size simultaneous. During solving the model, some key parameters are shown in table 1.

Table 1 Parameter determination

Parameter	Bubble density ρ_g [kg/m^3]	Water density ρ_l [kg/m^3]	Empirical coefficient K_m	Empirical coefficient K_B	Viscosity coefficient μ [Pa · s]	Radii R [m]
Value	1.29	1000	0.5	6	1.0042×10^{-3}	5×10^{-5}

Results and Analyses

A.The influence of force on the bubble rise process

Figure 1 is curve of the bubble rise velocity changing with time in the influence of force. We can see that the bubble rise velocity increases gradually with the time, and in late process bubble rising velocity tends to be stable. In the figure, black solid line expresses the curve of bubble rise velocity that considers virtual mass force and basset force , and the red dashed line expresses the curve that doesn't consider basset force. Contrast these two curves we can find that when not consider the basset force, the bubble rise velocity is bigger than that considers basset force. It makes clear that basset force not only continues to affect the movement of bubbles, but also plays the leading role. The virtual mass force on the influence of the bubble motion is very small in the late process. Meanwhile, when consider neither virtual mass force nor basset force and when just not consider virtual mass force, bubble rising velocity changes from 0 mutation to steady state velocity in the initial time.

B. The influence of particle size

1) The influence of constant particle size

Figure 2 shows bubble velocity changing with time when particle sizes are respectively taken 30μm, 50μm, 100μm, 200μm, 300μm in the rise process. From figure 2 we could see the bubble velocity is in increasing trend with time, and bubble velocity increases rapidly in the initial time. In

the late process bubble rise velocity tends to be stable. At the same time, bubbles of greater size has the greater velocity, conversely, bubbles of smaller size has the smaller velocity. In addition, the increasing trend of bubble velocity is not obvious with the increase in time when the bubble size is less than 50μm. According to figure 2, the bubble rise velocity is related directly with particle size, greater size bubble has the greater velocity. For the smaller size bubbles, for example bubble size is less than 50μm, if want to gain greater velocity, external force needs to be used.

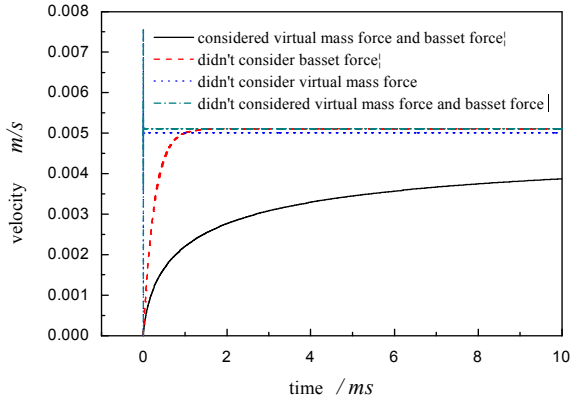

Figure 1. The influence of force during rising process

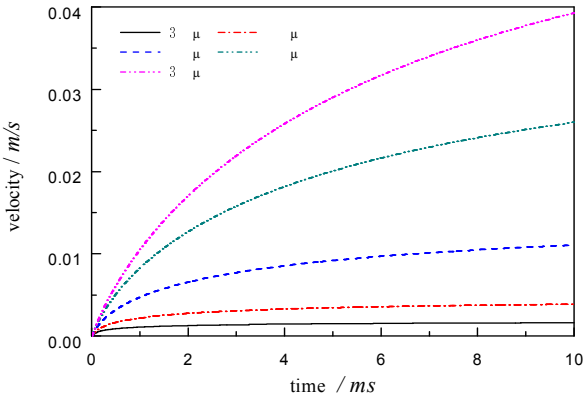

Figure 2. Velocity profile of constant size bubble

The table 2 is the experimental value and the simulation value of bubble velocity at the end of the rise motion. The experimental value could be obtained on literature[4].From table 2 we know that the changing rule of simulation value and experimental value is consistent. The error between experimental value and the simulation value is less than 8%. It demonstrates that the method proposed by this article is feasible.

Table 2 Experiment and simulation results

Item / Particle Size[μm]	experiment value [4] [m/s]	simulation value [m/s]	deviation [%]
30	0.0017	0.0016	5.9
50	0.0040	0.0039	2.5
100	0.0120	0.0111	7.5
200	0.0280	0.0260	7.1
300	0.0400	0.0393	1.7

2) The influence of changing particle size

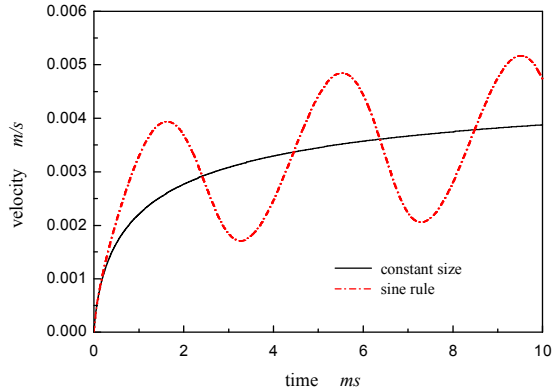

Figure 3 Velocity of bubble with sine rule

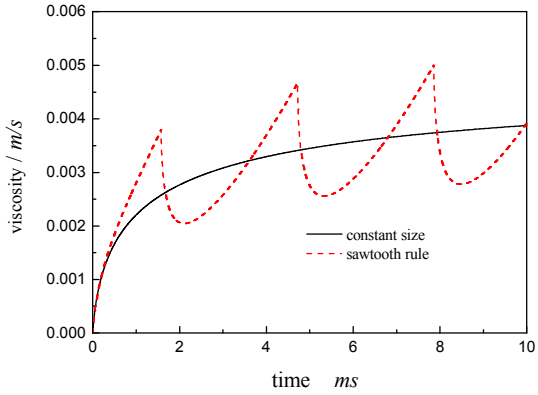

Figure 4 Velocity of bubble with sawtooth rule

Figure 3 shows the bubble rising velocity contrast curve. Where the red dashed line says the changing curve of bubble rise velocity when the bubble particle size changes in sine wave. Black solid line says the curve of bubble rising velocity when the size is constantly 50 μm . It is known

from figure 3 that when the bubble size changes in sine wave, the bubble rise velocity changing rule also presents the sine wave characteristic. The fluctuation mean is consistent with the changing rule of rising velocity for particle in 50μm size, and also has increasing trend. As time increases, rising velocity fluctuation amplitude and particle size changing by sine law has increase trend.

Figure 4 shows the bubble rise velocity contrast curve where the red dashed line says the changing curve of bubble rise velocity with the bubble particle size changing in sawtooth wave. Black solid line says the changing curve of rising velocity when bubbles are in constant size 50μm. It is known from figure 4 that when the bubble size changes by sawtooth law ,the bubble rise velocity change rule also presents the sawtooth wave characteristics. In a maximum size , the sawtooth changing law of bubble velocity is obvious, but in minimum size, the bubble velocity curve is more smooth. The fluctuation of mean is consistent with bubble rise velocity change rule when the particle size is 50μm, and also has an increasing trend. As time increases, the fluctuation amplitude of rising velocity for particles whose size change by sawtooth law has an increasing trend..

Conclusions

Velocity of the bubble increases gradually with the increase of time in static water, and the experimental values are consistent with the calculated values. The influence of virtual mass force and basset force caused by acceleration to float velocity in initial stage must be considered, When not consider the virtual mass force, float velocity has the characteristics of the shock and in late stage velocity tends to be stable .

In static water the greater size of bubbles has the greater velocity. When the bubble size changes in rising process by sine or sawtooth wave, the changing rule of bubble velocity fluctuation mean and the changing rule for bubbles in constant size, but in the turning point of the maximum radius the rising velocity changes abruptly and in minimum point the bubbles' rising velocity could change smoothly.

Keywords: preformed particle gel; emulsion microspheres; chromium gel; starch graft; fractures

Abstract. Several conformance control agents, including preformed particle gel, emulsion microspheres, continuous chromium gel and underground starch graft copolymer gel were evaluated. The properties such as gelation time and gel strength of gel, and expansion of particles and microspheres were tested at high temperature. Also, the injection pressure, plugging strength and resistance factor were measured using the artificial low permeability cores with fractures. It was shown that, for particle type conformance control agents, the particle size should be adaptable with the fracture width. Also, for continuous chromium gel, the added polymer concentration higher, the viscosity is higher, with higher plugging strength. The plugging and strength should be coordinated. The starch graft copolymer gel is easy to be injected into formation and has good plugging property. The results show that underground starch graft gel is more suitable for conformance control in low permeability formation with fractures.

Introduction

As for low permeability reservoirs with permeability under $50\times10^{-3}\mu m^2$ (Li, 1997), especially for the ultra-low permeability under $10\times10^{-3}\mu m^2$, it is common that there are fractures with high flow conductivity (Zhang, 2007). During water flooding, the water is prior flowing along fractures, leading to water breakthrough in short time (Hao et al., 2007; Pu and Yin, 2008). It has been proved that injecting chemical conformance control agents into formation to partly plug fractures is one of relatively effective and economic methods (Yang et al., 2006; An and Liu, 2004; Liu et al., 2012; Bai et al., 2013). Also, there are many challenges such as selection of agents with high plugging strength and good injectivity and injection parameters optimization (Yan et al., 2011), which are crucial for low permeability formation with low oil well production.

For preformed particle gels and emulsion microspheres, different sized particles/microspheres can plug fractures of different width (Tian et al., 2012). So, there is a need to study the adaptability of particle/microsphere size with fracture width. For continuous chromium gel, the added polymer concentration will affect the viscosity and plugging property of the gel (Perez et al., 2012). However, high polymer concentration will result in poor injectivity and high cost. Thus, it is important to coordinate the concentration and strength. Therefore, adaptability evaluation of the frequently-used conformance control agents in tight formation is essential for conformance control application.

Experiment

1.1 Materials

The formulation of continuous chromium gel includes polymer (0.3%~0.5%), cross-linker A (0.05%), cross-linker B (0.01%) and cross-linker D (0.3%). The underground starch graft copolymer gel basically consists of modified starch (2.5%~4%), cross-linker (0.05%-0.15%), control agent (0.1%~0.25%), unsaturated monomers (2.5%~4.0%), PAM (0.2%). The particle size of preformed particle gel KL-1 is 2~4mm, and the particle concentration is 5000mg/L. The polymer microspheres are of sub-millimeter, and the concentration is 3000mg/L. The experimental water used is produced water which can be used for sample preparation and water flooding after microfiltration.

1.2 Experimental methods

1.2.1 Static evaluation of chromium gel and underground starch graft copolymer gel

Put the formulated gel solutions into glass bottles, then place them in the constant temperature oven of 64℃. Measure the viscosity of gel solution using Brook Field viscometer at a regular time interval.

1.2.2 Dynamic performance evaluation

Different permeability sand-packs were filled in 100-cm or 50-cm long, 2.5-cm inside diameter tubes with different mesh sands to stimulate fractures. The core models were firstly vacuumed and saturated with formation water. Then, water was flowed into the core to calculate the absolute permeability of sand-pack. Next, conformance control agent was injected. At last, formation water was injected into the model until the pressure drop was stable. Thus, resistance factor, breakthrough pressure gradient and residual resistance factor were measured.

Results and Discussion

2.1 Static performance evaluation

Properties such as gelation time and gel strength of gel, and expansion of particles and microspheres were tested. The expansion time of preformed particle gel KL-1 is 3 days and the swelling ratio is more than 5(shown in Table1).

Table 1 Property of preformed particle gel KL-1

Particle Size and Roundness	Expansion Times	Expansion Velocity
2.0-4.0mm	≥5	6h-60%，24h-87%，48h-89%，72h-90%

The viscosity of continuous chromium gel with polymer concentration of 3000mg/L was measured. The results are shown in Figure 1. It can be seen that the viscosity of base fluid before gelation is only 423mPa•s, and the viscosity reaches maximum after 24 hours, then reduces slightly. So, the gelation time is about 24h, and the gel strength is more than 14000mPa•s.

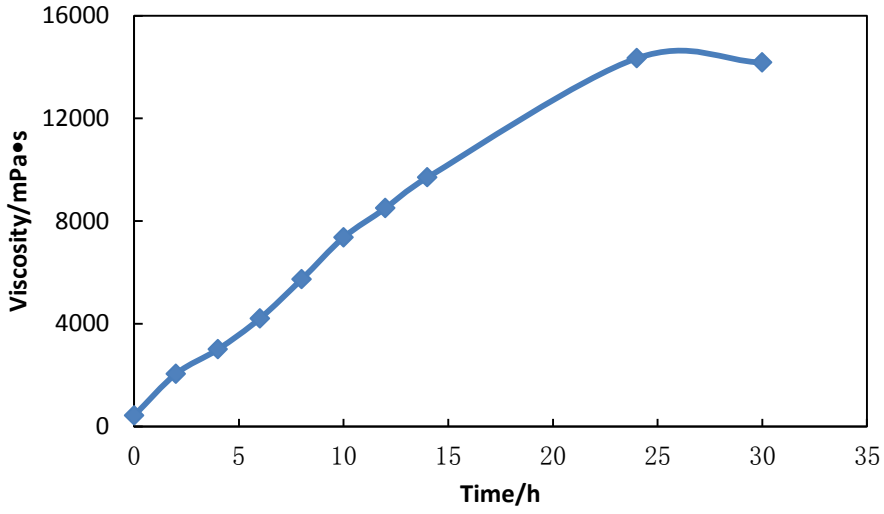

Figure 1 Viscosity of continuous chromium gel at different time

Figure 1 shows the viscosity of underground starch graft copolymer gel at different time. Note that the viscosity is very low before gelation, only 56.3mPa•s; after 8 hours, the viscosity sharply increases to 149871mPa•s. Then, viscosity changes very little. So, the gelation time is 8 hours, and the gel strength is more than 150000mPa•s.

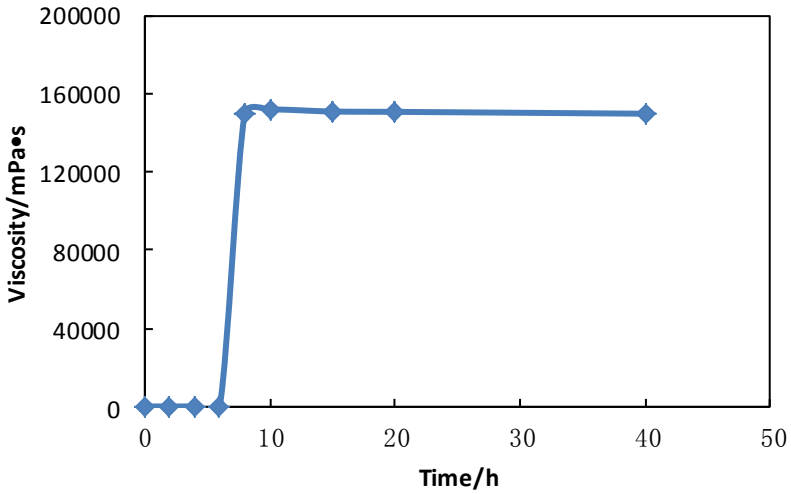

Figure 2 Viscosity of underground starch graft copolymer gel at different time

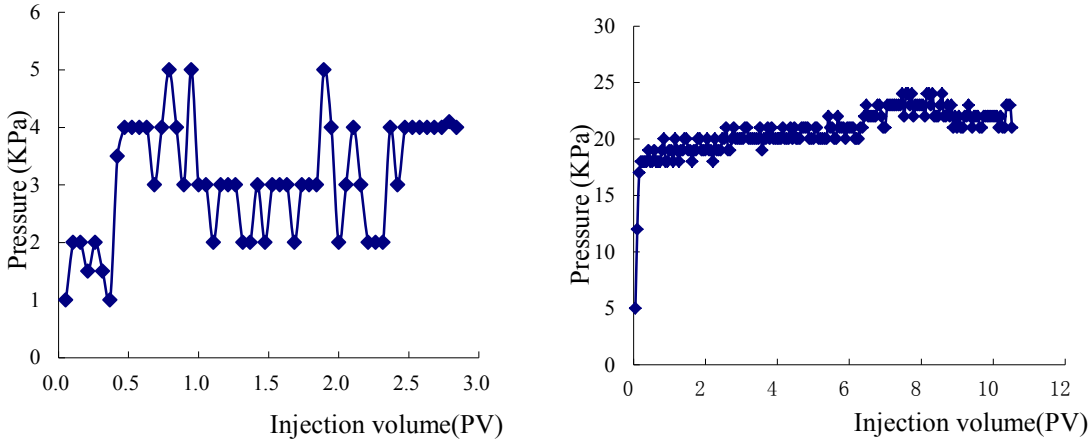
2.2 Dynamic Performance Evaluation

2.2.1 Preformed gel particles dynamic performance evaluation

The injection and plugging properties of preformed particle gels were studied in fractures of 10μm^2, 50μm^2 and 100μm^2. Figure 3(a) shows the injection pressure of preformed particle gel KL-1. After 3 days, the particles fully expanded; subsequently, the water was injected. Figure3 (b) is the water-flooding pressure curve. The resistance factor, residual resistance factor and plugging percentage are listed in Table 2. The results indicate that the particles have certain plugging property for these fractures, but the plugging ability is poor.



(a) (b)

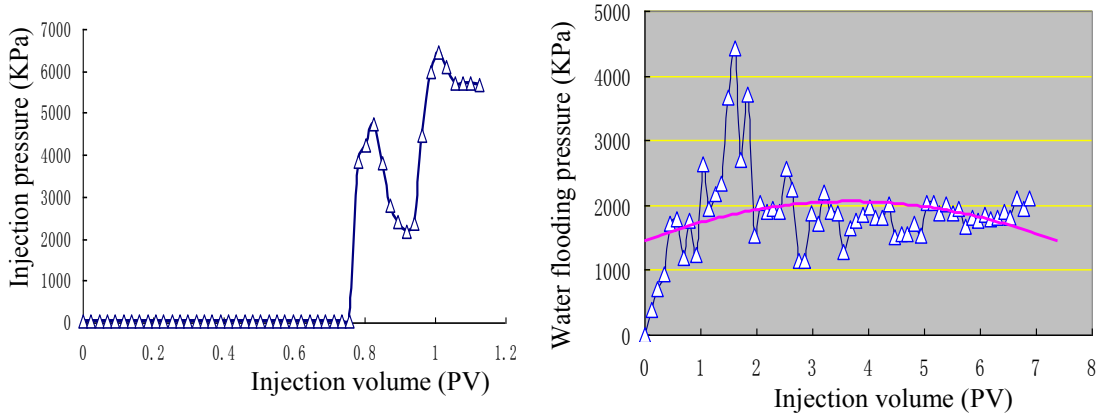
Figure 3 Injection pressure and water flooding pressure curves (10μm^2)

Table 2 Plugging property of KL-1

Particle size (mm)	Permeability of Fracture (μm^2)	Resistance factor	Residual resistance factor	Plugging percentage (%)
2~4	11.7	1	5.71	82.5
2~4	51.6	1	3.95	74.7
2~4	98.6	1	1.88	46.9
2~4	150	15	5.68	91.5

To further determine the adaptability between particle size and fractures, the core of 150μm^2 was studied. The obvious increase of injection pressure (shown in Figure4 (a)) indicates that the particle size and the fracture have begun to match. Also, the water flooding pressure curve (shown in Figure4 (b)) after fully swollen has an obvious breakthrough pressure peak and the final average injection

pressure can maintain at a high value. So, for the core of 150μm^2, the preformed particle gel has good plugging adaptability.



(a) (b)

Figure 4 Injection pressure and water flooding pressure curves (150μm^2)

2.2.2 Continuous chromium gel dynamic performance evaluation

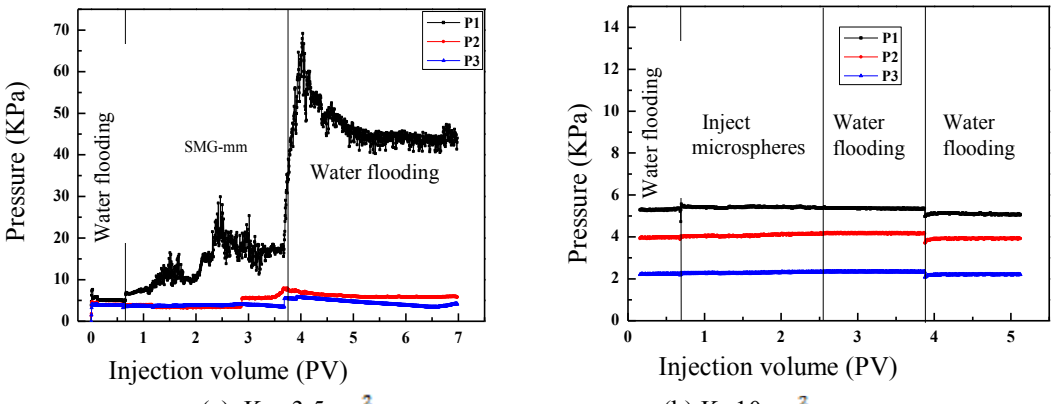
Two formulations were selected to study the continuous chromium gel, and the polymer concentration was 3000mg/L and 5000mg/L respectively. The results are listed in Table 5. It can be found that, for continuous chromium gel, the added polymer concentration higher, the viscosity is higher, with higher plugging strength.

Table 3 Plugging properties of chromium gel

Polymer concentration (mg/L)	Permeability of Fractures(μm^2)	Injection volume(PV)	Plugging percentage (%)	Breakthrough Pressure Gradient(MPa/m)
3000	10	0.1	88.10	0.075
3000	100	0.1	77.78	0.000
5000	10	0.1	93.29	0.160
5000	100	0.1	81.48	0.031

2.2.3 Emulsion microspheres dynamic performance evaluation

After 1-day swelling at 64℃, the sub-millimeter sized microspheres were injected into models of 2μm^2, 3.5μm^2, 5.6μm^2 and 10μm^2. The pressures curves are shown in Figure5. The results show that for cores of 2μm^2, 3.5μm^2, 5.6μm^2, the microspheres can form plugging, but the plugging property becomes poorer with the increase of permeability. Figure 5 (b) indicates emulsion microspheres system is completely unable to form plugging in the pores of 10μm^2. Also, the resistance factor and residual resistance factor both are 1.0. So, emulsion microspheres system is not suitable to the formation of 10μm^2 or more.



(a) K = 3.5μm^2 (b) K=10μm^2

Figure 5 Displacement pressures of different measuring points

2.2.4 Underground starch graft copolymer gel dynamic performance evaluation

The starch system was injected into different permeability models to test its resistance factor and residual resistance factor. The results are listed in Table 6 and the high residual resistance factor and high plugging percentage prove that the system has high plugging strength.

Table 4 Resistance characteristics of underground starch graft copolymer gel

Permeability of Fracture (μm^2)	Breakthrough pressure (MPa)	Resistance factor, Fr	Residual resistance factor, Frr	Plugging percentage (%)
213	7.06	2.2	54.3	98.16
196	28.28	13.8	73.4	99.03
88	30.77	14.4	106.3	97.22

Conclusions

(1) For the particle type water control agents, preformed particle gel KL-1(2~4mm) has good plugging adaptability to fractures of 150μm^2, while is not suitable for fractures of less than 100μm^2. The sub-millimeter emulsion microspheres system is not suitable to the formation of 10μm^{2}or more. So, the particle size should be adaptable with the fracture width.

(2) For continuous chromium gel, the added polymer concentration higher, the viscosity is higher, with higher plugging strength. Meantime, high polymer concentration will lead to poor injectivity (high viscosity on ground) and high cost. Therefore, the plugging and strength should be coordinated.

(3) The underground starch graft copolymer gel is easy to be injected into formation and has good plugging property.

(4) Underground starch graft copolymer gel is more suitable for conformance control in low permeability formation than the other three conformance control agents.

Key word V_2O_5-WO_3/ TiO_2; Cordierite; flue gas denitrification; NO_x; selective catalytic reduction (SCR)

Abstract: The V_2O_5-WO_3/TiO_2 honeycomb catalysts with cordierite modified were prepared by solid-liquid mixing method. Its thermal stability, crystal structure, abrasion resistance and activity were studied by XRD, abrasion equipment and simulated flue gas analyzer，respectively. The results indicated that V_2O_5-WO_3/Cordierite-TiO_2 honeycomb catalyst possessed a better thermal stability, mechanical property and activity at the higher temperature comparing to commercial catalyst. There was no rutile phase present after the catalysts were calcined at 700℃, and the vanadia and tungsten trioxide phases could be apparently visible on TiO_2.

Introduction

The selective catalytic reduction (SCR) of NOx by NH_3 is one of the most widely used methods of removing NOx from stationary sources of coal-fired power plant due to its efficiency, selectivity and economy [1-5]. V_2O_5-WO_3(MoO_3)/TiO_2 catalyst is well known for its high de-NOx activity, the good resistance against SOx and As poisoning[2-4]. Generally, SCR reactor is installed between the boiler economizer and air preheater, in which smoke ash content and temperature of the flow gas are both high, which inevitably makes the catalyst wore and tore easily and badly by smoke ash content and other impurities, thus its mechanical and chemical life are both shortened[4]. Accordingly if the thermal stability and corrosion resistance of the catalyst for SCR will be both improved, so is the catalyst's lifespan. It is reported that V_2O_5-WO_3(MoO_3)/TiO_2 supported on cordierite prepared by the coprecipitation method, the sol-gel method and the chemical vapor deposition have a large BET surface area and shows a remarkable acidity[6-14]. However, the stability and corrosion of the catalyst have not been investigated.

The purpose of this paper is to clarify the behavior of cordierite loaded with V_2O_5-WO_3/TiO_2 by XRD, mechanical properties and activity tested in comparison with commercial V_2O_5-WO_3/TiO_2.

Experiment

2.1. Catalyst preparation

Cordierite powder was immersed in sulfuric acid solution of 20 wt% at 60 ℃ for 6h and standby after 10h at 105 ℃ drying. Ammonium metatungstate and ammonium metavanadate were dissolved in a mixed aqueous of 10% oxalic acid at 80℃. The solutions, TiO_2 power and cordierite power mentioned above were thoroughly mixed under continuous addition of a suitable amount of distilled water, kneaded for a certain time and placed for 24h, then formed in an extrusion mold to produce a honeycomb monolith with 75mm×75mm in outer diameter. The obtained monolith was dried at 80℃ for 12h and then was calcined under the current of air at 600℃ for 4h.

The V_2O_5-WO_3/TiO_2 catalysts with cordierite contents (0.0, 5.0, 10.0, and 15.0wt. %) and 1%V_2O_5 and 7%WO_3 were obtained. This series of the catalysts are denoted as T, TC5, TC10 and TC15, respectively.

2.2. Characterization of catalysts

X-ray diffraction measurement (XRD) of the catalysts were carried out in the range of 2θ=10-90°at the scanning rate of 5°min^{-1} by a Spectris-diffractometer with Co Kα (Rigaku D/Max-2500pc). Mechanical properties (axial direction and lateral direction) of catalysts were examined by Shenzhen sans – at the rate of 0.7mm/min.

2.3. Abrasion performance of SCR honeycomb catalysts

The abrasion performance experiment was operated as follows. The catalyst samples (75mm×75mm×90mm) were placed into the tank of experimental sample and reference sample. And then quartz sand in the air was blown away by the blower and went through the samples in certain time. As a measure of weight change before catalyst was abrasion rate d . The definition of abrasion rate d is calculated by:

$$\delta = (1 - \frac{M2}{M1} \times \frac{M3}{M4}) / M5 \times 100\% \quad (1)$$

where M1 is the weight of the experimental sample; M2 is the weight of the experimental sample after being tested; M3 is the weight of the comparative sample; M4 is the weight of the comparative sample after testing; M5 is the weight of the collection of silica sand.

2.4. Catalyst performance measurement

Catalyst performance measurement for the SCR reaction of NO by NH_3 were carried out in a fixed bed reactor made of a stainless steel tube with 30mm×30mm in section orientation. The honeycomb catalysts samples were cut into a size of 9×9 cells and loaded in the reactor. The reaction gas mixture which consisted of 220 pm NO, 220 ppm NH_3, 1000ppm SO_2, 3.5% O_2, 10% H_2O (v/v) with N_2 as the carrier gas was fed into the reactor. The total flow through the reactor was 5Nm^3/h and the gas hourly space velocity (GHSV) was 15,000 h^{-1} for activity test of SCR reaction.

The inlet and outlet concentrations were measured by the CEMS NOx analyzer. The definition of NOx conversion is as follows:

$$\eta_{NO}(\%) = \frac{C_{NO,in} - C_{NO,out}}{C_{NO,in}} \times 100 \quad (2)$$

where η_{NO} is NO conversion rate; $C_{NO,in}$ is inlet NO concentration; and $C_{NO,out}$ is outlet NO concentration.

Results and discussion

3.1. XRD of catalysts

The XRD patterns of catalysts with cordierite contents, calcined at 600℃ and 700℃ are shown in Fig.1. The catalyst samples calcined at and below 600℃ possess only diffraction lines, such as 2θ=25°, 38°, 48° and 53°, all of which attribute to the phase of anatase. Although the calcinations temperature increases to 700℃, there is still no rutile TiO_2 appearing. Based on thermodynamic principles[15-18], the microcrystalline or crystalline material of V_2O_5 and WO_3 is not detected on TiO_2 due to the spontaneous heat, while at the high loaded of 15% V_2O_5 and WO_3, the vanadia and tungsten trioxide phases can be apparently visible on TiO_2. This indicates that V_2O_5, WO_3 are not changed or present a highly dispersion on supports as the increase of cordierite power. The catalyst samples overcome the deficiencies inherent due to the addition of whisker-like substance and then retain the crystal phase composition.

Fig.1 XRD spectra of catalytic samples

3.2. Mechanical properties

Tab.1 Mechanical properties of the catalysts

Catalysts	Transverse compressive strength (MPa)	Axial compressive strength (MPa)	Abrasion rate(%)
T	0.65	1.25	0.0650
TC5	0.45	0.79	0.0815
TC10	0.76	1.31	0.0559
TC15	0.56	0.37	0.0659

The mechanical properties of the catalysts were carried in the lab platform for commercial catalyst. The results are shown in Tab.1. It can be seen that transverse and axial compressive strength reaches a maximum when cordierite content is 10wt% while others decrease. Afterwards, the abrasion rate of catalysts slightly decreases.

It is well known that denitration catalyst is placed between the boiler economizer and air preheater, in which catalyst endure ash and high temperature erosion. Interspace of catalyst is filled by the addition of cordierite. Therefore, the ability of resistance of ash erosion should be improved. Meanwhile transverse and axial compressive strength of catalysts are also promoted. As cordierite content reaches 10%, mechanical properties of catalysts become lower. It seems that there are new defects on the surface of catalysts with cordierite content enhanced. Its mechanical properties will drop. It is considered that using 10 wt% cordierite and TiO_2 as a carrier of the catalyst can significantly resist ash and temperature erosion.

3.3. NO removal activity

It is well known that commercial SCR catalyst work between 300-400℃. The results of activity test are shown in Fig.2-4.

Fig.2 exhibits that NO conversation will be improved with the temperature ascend. NO conversation slightly increases at the higher temperature above 380℃(Formula 2). And at the temperature 450℃, NO conversation of commercial catalyst sharp drop in 52%. NO conversation of TC10 merely drop in 72%. It is reported NH_3 will occur oxidation reaction to NO or N_2O(Formula 3 and 4). Many other researchers[4]have reported that the content of N_2O in the atmosphere is very low, but the greenhouse effect of N_2O is 310 times of carbon dioxide.

Fig.3 shows that NO conversation increase with different molar ration of NH_3-NO. When molar ration of NH_3/NO is above 1, NO conversation has a slight increase. It is indicated that there are excessive NH_3 in the reaction mixture gas. Many researchers[19,20] have illuminated that the excess of NH_3 will react with SO_3 in the flue gas and generate a viscous substance ($(NH_4)_2SO_4$ or NH_4HSO_4). This substance is to be adhered to in the downstream equipment, making the system pressure increases and a bad effect on power plant operations.

The NO conversation is shown as a function of gas flow rate in Fig.4. When gas flow rate is gradually increases, the residence time of the reaction gas on the surface of the catalyst becomes short. The content of NH_4^+ or NH_2^- activated by active site is less corresponding; NO conversion rate is gradually falling off.

The reports suggest that cordierite added never change the N_2 selectivity of commercial catalyst. Therefore, it is considered that cordierite modified may be added into V_2O_5-WO_3/TiO_2 catalyst and replace a portion of TiO_2.

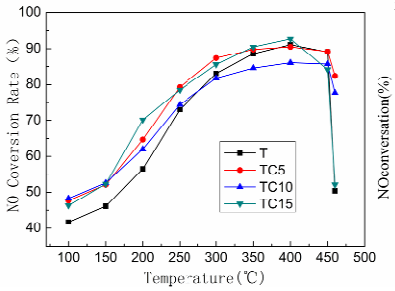

Fig.2 NO conversation vs. temperature

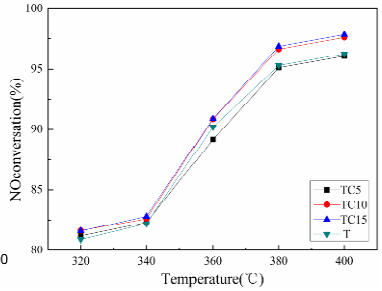

Fig.3 NO conversation vs. NH_3/NO

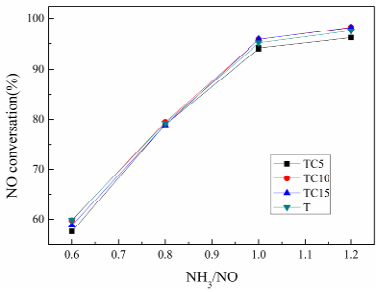

Fig.4 NO conversation vs. flow rate

Reaction condition O_2=6% C_{NO}=C_{NH3}=500PPM space velocity =10000H^{-1} N_2 =Balance gas

$$4NO + 4NH_3 + O_2 \rightarrow 2N_2 7 + 6H_2O \quad (2)$$

$$4NH_3 + 5O_2 \rightarrow 4NO + 6H_2O \quad (3)$$

$$2NH_3 + 2O_2 \rightarrow N_2O + 3H_2O \quad (4)$$

Conclusions

The TiO_2-cordierite support containing 10wt% of cordierite exhibits a good thermal stability ,activities and mechanical properties, as compared to TiO_2 support. With cordierite content increasing, the XRD spectra of V_2O_5/TiO_2-cordierite catalysts show anatase-TiO_2. V_2O_5 and WO_3 phases are not detected after catalyst samples were calcined at 700℃. The mechanical performance of V_2O_5/TiO_2-cordierite catalysts exhibits well as cordierite content increases.

The SCR activity and N_2 selectivity are found to be excellent over vanadia loaded on TiO_2 and cordierite carriers. In other words, cordierite addition will not change the dispersion of V_2O_5 and WO_3 on the support.

It is concluded that V_2O_5/TiO_2-cordierite is suitable as SCR catalysts for sulfur-containing coal and oil-fired SCR plants due to its lower abrasion, good mechanical performance and higher activity in SCR.

Keywords: Lotus effect, Super-hydrophobic surface, Dual-scale roughness, Silicon Wafer, TiZn-P, Al, Galvalume Steel.

Abstract. Si Wafer, pre-weathered TiZn alloy (TiZn-P), Aluminum (Al), and hot-dipped galvalume steel (G.L.) are chosen in this work for the study of hydrophobic coating to various substrates. Various amounts of TS-720 hydrophobic nano-particles were mixed into ITRI hydrophobic agent (H.A.), and this mixture liquid was applied onto different material surfaces by using a coating bar technique. High contact angle near 140^{o} are achieved in all samples with 2.5 wt% TS-720 in ITRI H.A. mixture.

Introduction

Lotus surface has a high hydrophobicity, which can significantly improve the ability of self-cleaning, anti-pollution and corrosion resistance by reducing the dielectric constant of the material surface, and decreasing the adhesion of dust [1 – 3]. The micro-nano dual-scale roughness surface structure is a crucial role for super-hydrophobic characteristic [4 – 6]. Coating bar (R.D.S. SUS304, No.5, wire diameter: 0.13 mm) is used to apply paint over metal substrate in coil coating industry. Cabot CAB-O-SIL® TS-720 is a medium surface area fumed silica which has been surface modified with polydimethylsiloxane, which diameter is 200 – 300 nm [7 – 9]. Zheng reported the ITRI, (C-B-HN-$(CH_2)_3$-$[A]_n$-$(CH_2)_3$-NH-B-C; $[A]_n$ is a composition of polysiloxane with fluoride oligomer, and B is isocyanate), which is a kind of hydrophobic agent (H.A.) [10], with the characteristics of high transparency, strong adhesion and abrasion resistance, that can be dissolved in the tetrahydrofuran (THF). This coating process study uses ITRI adding with TS720 as the hydrophobic composite agent in atmosphere condition, like the existing metal coil coating industry applying paints by using the coating-bar, achieves a surface with high hydrophobicity.

Experiment

There were various kinds of material chosen as the substrates, silicon wafer (MEMC), titanium-zinc (Ti-Zn alloy 710, 0.3 mm of thickness, with pre-weathered, TiZn-P), aluminum alloy (Al, 0.3 mm of thickness), and hot-dip galvalumed steel (GL, 0.3 mm of thickness). The substrates were degreased in ultrasonic with degreasing agent of 5 v% (Tanmax, No.928) at 50^{o}C for 5min, and rinsed with deionized water. In order to produce a surface with dual-scale roughness like lotus surface, we added the TS-720 nano-powder into ITRI H.A.

The ITRI/TS-720 composite was synthesized by two-step process. The first step, the ITRI THF solution was kept stirring for 30 min. The second step, various amount (0 – 2.5 wt %) of hydrophobic nano powder TS-720 were added into the ITRI THF solution, and dispersed by sonication for 5 min. We dripped the ITRI/TS-720 composite onto the cleaned si wafer and metal surfaces, and coated homogeneously by a coating bar (R.D.S. SUS304, No.5, wire diameter: 0.13 mm). The average thickness of wet film was 11.43μm, as shown in Figure 1 (a) – (c). The coated si wafer and metal substrates were dried in air for 20 s, and calcined at 130^{o}C for 5 min.

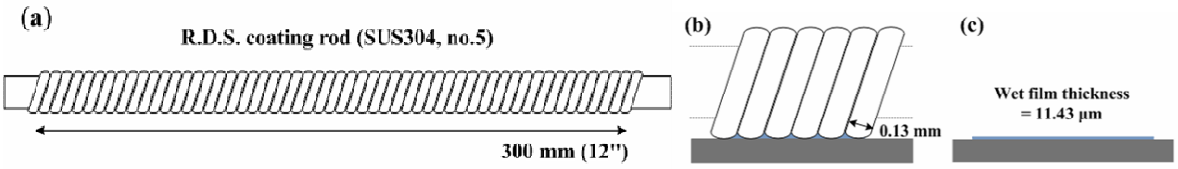

Fig 1 (a) Coating bar (R.D.S. SUS304, No.5, wire diameter: 0.13 mm), (b) The coating process by using coating bar, and (c) The wetted film thickness is 11.43 μm.

Schematic 1. The process of hydrophobic coating to a sample

Result and Discussion

The first experiment is using a Si wafer as the substrate. The morphology of the sample was via field-emission scanning electron microscope (FE-SEM, JEOL JSM-6500F). The specific contact angle of sample was calculated via static sessile drop method and contact angle goniometer (Sindatek, Model 100SB). Fig 2 demonstrates the SEM images of the Si wafer substrate when there is no hydrophobic coating, and the contact angle is 79.0°. Fig 3 demonstrates the SEM images of the Si wafer substrate coated with ITRI H.A. adding 2.5 wt% TS-720 which covered the Si wafer surface and observed a nanoporous structure, the inset fig presents the contact angle is 139.4°. After Si wafer coated with ITRI/2.5 wt% TS-720 composite, 60.4^{o} of contact angle is increased, with an enhancement of 76.5%.

The surface structure of sample was analysized by atomic force microscope (AFM, Veeco di-CP II). Fig 4(a) shows the 2D image of the wafer surface when there is no hydrophobic coating. Fig 4(b) shows the 3D image of wafer surface. The roughness was 2.5nm and the vertical height was 4.3nm, as shown in Fig 4(c). Fig 5(a) shows the 2D image of the wafer surface coated with ITRI H.A. adding 2.5 wt% TS-720. Fig 5(b) shows the 3D image of wafer surface coated with ITRI H.A. adding 2.5 wt% TS-720. The further observation of the surface morphology and roughness, the nanoparticle covered the entire sample surface. The roughness was 52.2nm and the vertical height was 228.5nm, as shown in Fig 5(c).

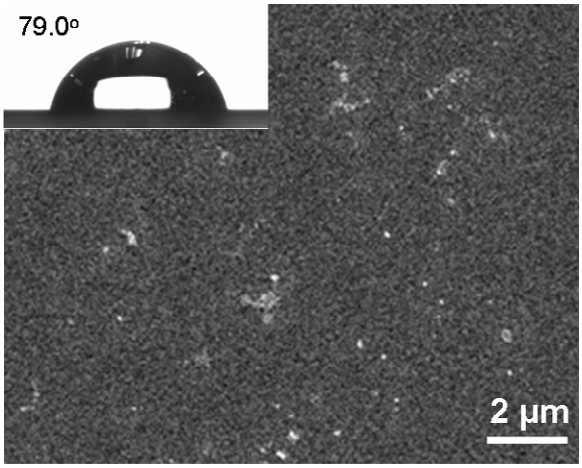

Fig 2 The morphology of Si wafer surface, and the inset presents the contact angle is 79.0° .

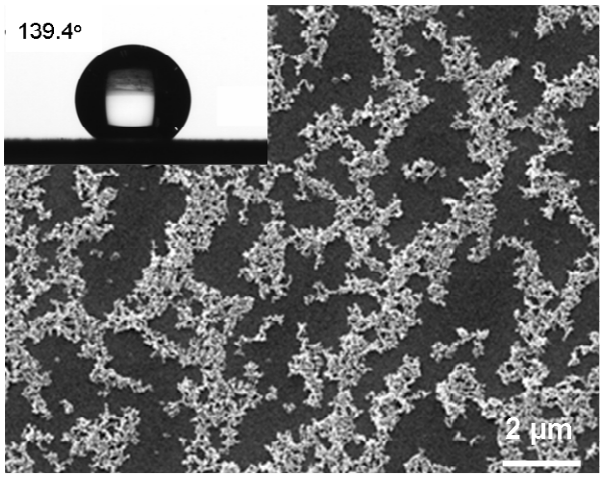

Fig 3 The morphology of Si wafer surface coated with ITRI H.A. adding 2.5 wt% TS-720, and the inset fig presents the contact angle is 139.4°.

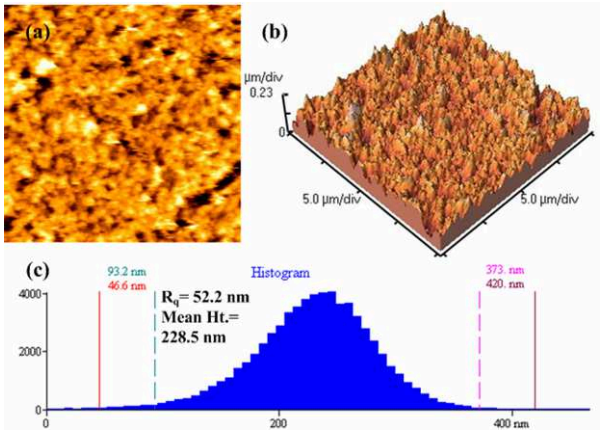

Fig 5. AFM image analysis of Si wafer surface coated with ITRI adding 2.5 wt% TS-720, (a) 2D image, (b) 3D image, and (c) the roughness and the vertical height curve.

Further experiment by using various metal substrates, the TiZn pre-weathered (TiZn-P), Al, and GL. Fig 6 demonstrates the SEM images of the TiZn-P surface with no hydrophobic coating and the contact angle is 97.6°. Fig 7 demonstrates the SEM images of the TiZn-P coated with the ITRI H.A. adding 2.5 wt% TS-720. The surface covered with microrods crystalline structure, and the TS-720 filled in the aggregate surface, and its contact angle is 142.1°. After TiZn-P coated with ITRI/2.5 wt%TS-720 composite, the contact angle increased 44.5°, with an enhancement of 45.6%.

Fig 8(a) shows the 2D image of the TiZn-P surface with no hydrophobic coating, . Fig 8(b) shows the 3D image of TiZn-P. The TiZn-P surface had micro crystalline structure, thus the surface roughness is higher. The surface roughness was 77.2nm and the vertical height was 329.0nm, as shown in Fig 8(c). Fig 9(a) shows the 2D image of the TiZn-P surface coated with ITRI H.A. adding 2.5 wt% TS-720. Fig 9(b) shows the 3D image of TiZn-P surface coated with ITRI H.A. adding 2.5 wt% TS-720. The further observation of the surface morphology and roughness, the nanoparticle fully covered the entire sample surface, and the aggregation of TS-720 can be observed clearly. The roughness was 107.5nm and the vertical height was 375.2nm, shown in Fig 9(c).

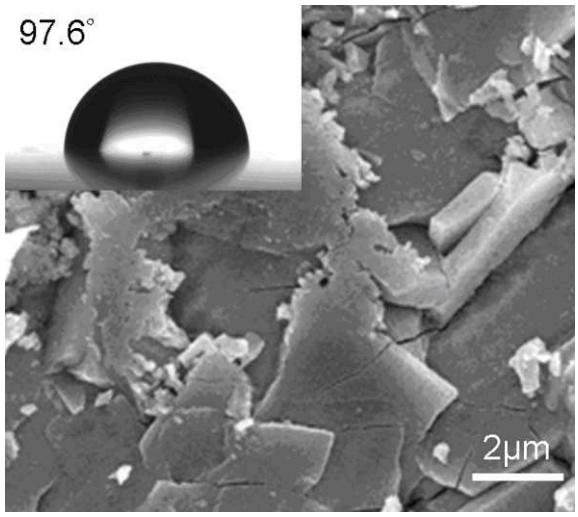

Fig 6 The morphology of TiZn-P surface, and the inset presents the contact angle is 97.6°.

Fig 10 demonstrates the SEM images of the Al substrate when there is no hydrophobic coating. There were some fixed directional linear 4 – 10 μm width scratches on the surface, which were the mirroring roll machining mark from coil rolling, and the inset fig presents the contact angle is 76.4°. Fig 11 demonstrates the SEM images of the Al substrate coated with ITRI H.A. adding 2.5 wt% TS-720 which covered the Al surface completely, and the nanoporous structure was observed, the inset fig presents the contact angle is 141.3°. After Al coated the ITRI/2.5 wt%TS-720 composite, the contact angle increased 44.5°, with an enhancement of 84.9%.

Fig 12(a) shows the 2D image of straight rolling scratches on the Al surface with no hydrophobic coating. Fig 12(b) shows the 3D image of Al surface. The roughness was 15.9nm and the vertical height was 116.7nm, as shown in Fig 12(c). Fig 13(a) shows the 2D image of the Al surface coated with ITRI H.A. adding 2.5 wt% TS-720. Fig 13(b) shows the 3D image of Al surface coated with ITRI H.A. adding 2.5 wt% TS-720. Through further observation of the surface morphology and roughness, the nanoparticle covered the entire sample surface. The roughness was 89.6nm and the vertical height was 445.2nm, as shown in Fig 13(c).

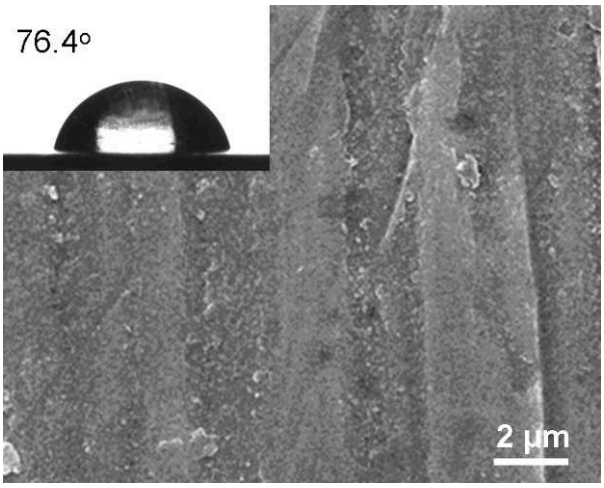

Fig 10 The morphology of Al surface, and the inset presents the contact angle is 76.4°.

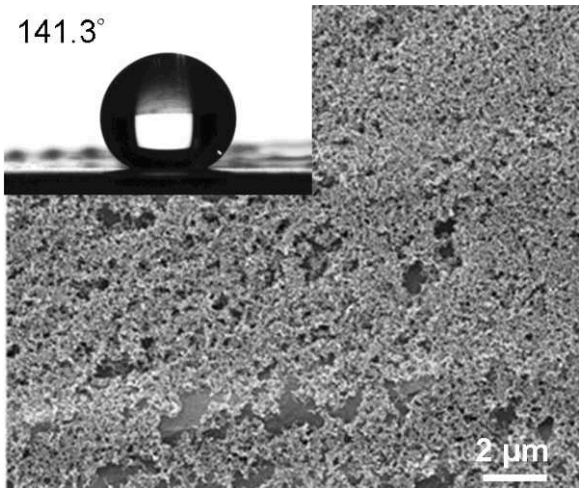

Fig 11 The morphology of Al surface coated with ITRI H.A. adding 2.5 wt% TS-720, and the inset fig presents the contact angle is 141.3°.

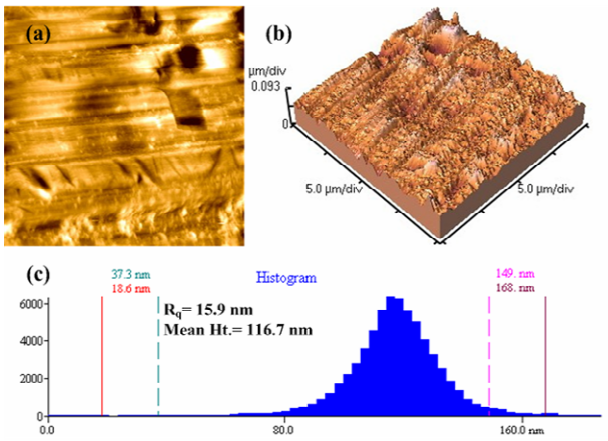

Fig 12. AFM image analysis of Al surface, (a) 2D image, (b) 3D image, and (c) the roughness and the vertical height curve.

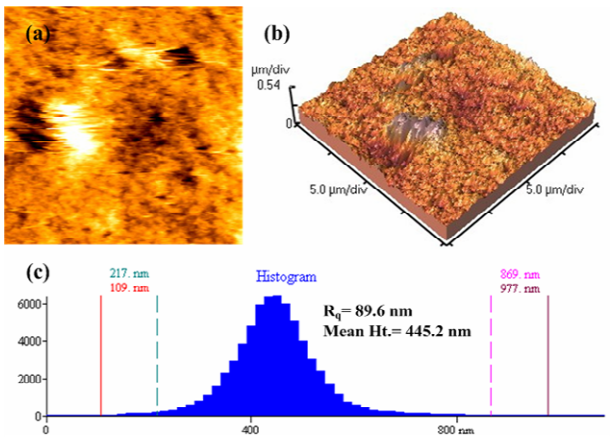

Fig 13. AFM image analysis of Al surface coated with ITRI adding 2.5 wt% TS-720, (a) 2D image, (b) 3D image, and (c) the roughness and the vertical height curve.

Fig 14 demonstrates the SEM images of the GL substrate with no hydrophobic coating. The island-like surface structure is from the hot-dipping galvalume (G.L.) process, which caused the zinc aluminum (Zn-Al) tends to the island-grow mode, the inset fig presents the contact angle is 93.6°. Fig 15 demonstrates the SEM images of GL coated with ITRI H.A. adding 2.5 wt% TS-720. The coated surface was covered by the TS-720 nanoparticle with an aggregation of nanoporous structure, the inset fig presents the contact angle is 138.6°. After GL coated the ITRI/2.5 wt%TS-720 composite, the contact angle increased 44.5°, with an enhancement of 48.1%.

Fig 16(a) shows the 2D image of the GL surface with no hydrophobic coating. Fig 16(b) shows the 3D image of GL surface. The GL surface roughness was 190.7nm and the vertical height was 1.121μm, as shown in Fig 16(c). Fig 17(a) shows the 2D image of the GL surface coated with the ITRI H.A. adding 2.5 wt% of TS-720. Fig 17(b) shows the 3D image of GL surface coated with the ITRI H.A. adding 2.5 wt% of TS-720. Through further observation of the surface morphology and roughness, the nanoparticle fully covered the entire sample surface. The roughness was 103.4nm and the vertical height was 380.0nm, as shown in Fig 17(c).

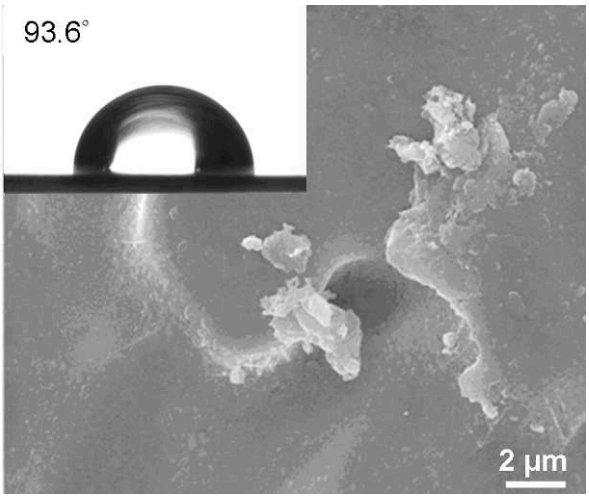

Fig 14 The morphology of GL surface, and the inset presents the contact angle is 79.0°.

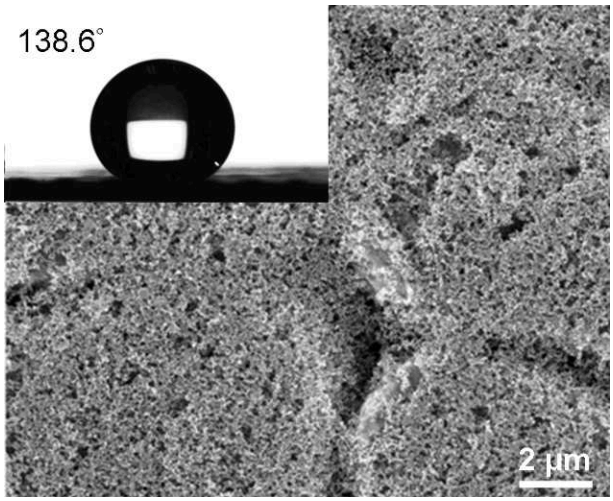

Fig 15 The morphology of GL surface coated with ITRI H.A. adding 2.5 wt% TS-720, and the inset fig presents the contact angle is 139.4°.

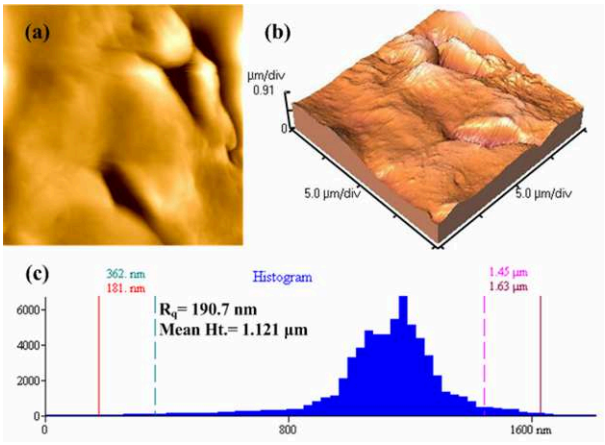

Fig 16. AFM image analysis of GL surface, (a) 2D image, (b) 3D image, and (c) the roughness and the vertical height curve.

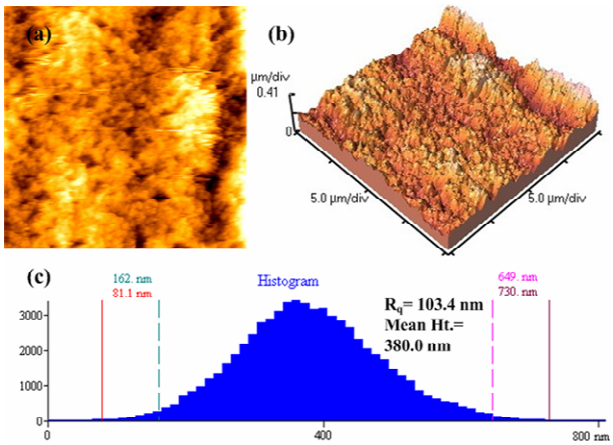

Fig 17. AFM image analysis of GL surface coated with ITRI adding 2.5 wt% TS-720, (a) 2D image, (b) 3D image, and (c) the roughness and the vertical height curve.

The original contact angles of various substrates were lower than 98° when the surface is without hydrophobic agent coating, which are shown on Table 1. After coating with the ITRI H.A. adding 2.5 wt% of TS-720, higher contact angles were generated which are between 138° – 142°. The enhancement of contact angle is above 45%. The best contact angle enhancement is from Al substrate (84.9%).

Table 1. The contact angle variation of various materials coated ITRI/TS-720 composite.

	Silicon Wafer	TiZn-P	Al	GL
No Coating	79°	97.6°	76.4°	93.6°
Coating ITRI/TS-720 Composite	139.4°	142.1°	141.3°	138.6°
Enhanced Contact Angle Ratio	45.6%	45.6%.	84.9%	48.1%

Conclusion

Making samples with a coating bar is an adopted mature process to current coil coating industry during color matching. This study, using the ITRI H.A. adding with TS-720 nanoparticle as the hydrophobic agent, operating the process in atmosphere parameters, demonstrates the possibility of using current facilities from coil coating industry to produce a hydrophobic surface with self-cleaning, anti-pollution and corrosion resistance for various substrates. Thus process is low cost and low technology threshold to current coil coating industry.

Keywords: Porous ceramic; Aluminum titanate; Thermal expansion; Porosity

Abstract: This paper described the properties of porous aluminum titanate (AT) ceramics. The AT samples with composition of 41 wt% Al_2O_3, 50 wt% TiO_2, 4.5 wt% MgO and 4.5 wt% Fe_2O_3 while 0~60 wt% graphite was used as pore former. The pore structures of the samples sintered at 1250~1350 ^oC were analyzed by scanning electron microscopy and Hg porosimetry, while the crystal phases of the aluminum titanate were analyzed by X-ray diffraction. After sintered at, the samples have open porosities of 25~51%, depending on the graphite amount and the sintering temperature. The porosity increases and the flexural strength decreases with the increasing amount of graphite.

Introduction

Aluminum titanate ceramic (Al_2TiO_5, AT) is promising material for many structural applications for their high melting point (1860 ^oCmatthew henrichsen), low thermal expansion coefficient (~1×10^{-6} $^oC^{-1}$), low thermal conductivity (0.9~1.5$Wm^{-1}K^{-1}$) and excellent thermal shock resistance.[1,2,3,4,5] However, its industrial applications are hindered by two drawbacks. One is the decompose into α-Al_2O_3 and TiO_2-rutile within the temperature range between 800 ^oC and 1280 ^oC.[6] The other is poor fractural strength due to microcracks.[7,8] In order to eliminate the drawbacks and improve the properties, much work has been done on doping additives into the raw materials.[9,10,11] This work is concerned with the fabrication of porous aluminum titanate ceramic materials using graphite as pore former, which endows the samples with different levels of porosity.

Experimental procedure

The raw materials were α-Al_2O_3(>99%, median particle size 53μm) and TiO_2(>99%, median particle size 0.8μm) powders on a molar ratio of 7:11 while 4 wt% MgO and 4 wt% Fe_2O_3 were added as additives. Then the mixtures were mixed with 25-55 wt% of graphite by planetary ball milling for 3 h. After that, the mixed powders with 5 wt% binder (PVA) was pressed uniaxially under a pressure of 3 MPa for disc samples (15mm diameter) and 15Mpa for rectangular samples (100 mm ×10 mm ×10 mm). Then, the dried samples were sintered at 1250 ^oC, 1300 ^oC, 1350 ^oC for 1h.

Linear dimensional changes of the sintered pellets were measured using a vernier caliper. The porosity and pore size distribution was measured by a mercury intrusion porosimeter (AutoPore IV 9500). Room temperature flexural strength was determined by the three-point bending method in a universal materials testing machine (CDW-5). The microstructure of the fracture surfaces of the

sintered samples was observed using a scanning electron microscopy (SEM, S440i). The linear thermal expansion coefficient were measured in a horizontal dilatmeter over the temperature range of 25-1100 °C at a heating rate of 10 °C /min. The phase composition was characterized using XRD (Cu Kα radiation; Rigaku DMAX-RB 12KW) for the sintered disc samples. The density of the specimens was measured using the Archimedes principle with water as medium. Thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) analysis were performed by TA instrument SDT 600 at a heating rate of 10 °C/min from 25 °C to 1350 °C.

Result and discussion

The XRD results (Fig. 1.) shows that the sintering at 1350°C for 1 h is enough to form nearly 100% Al_2TiO_5 with tiny Al_2O_3 and TiO_2 remnants, while the specimen sintered at 1250°C has a lot of Al_2O_3 and TiO_2 remnants.

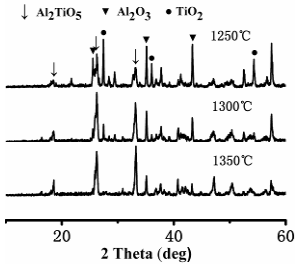

Fig. 1 XRD spectra of the samples sintered at 1250 °C, 1300 °C and 1350 °C for 1 h

Fig. 2 shows the linear shrinkage rate and bulk density as a function of the graphite content and the sintering temperature. Both the shrinkage rate and the bulk density increases with the increasing sintering temperature. The density decreases monotonically with the rise of the graphite amount, which tends to a steady value gradually. The shrinkage rate varies with graphite amount complexly. It decreases first, reaches a minimum at about 25wt% graphite, and then increases until 60wt% graphite. The thermal expansion curves of the samples with different graphite amount are shown in Fig. 3. The thermal expansion coefficient of the specimens varies between 0.76% and 0% in the temperature range 25~1100°C.

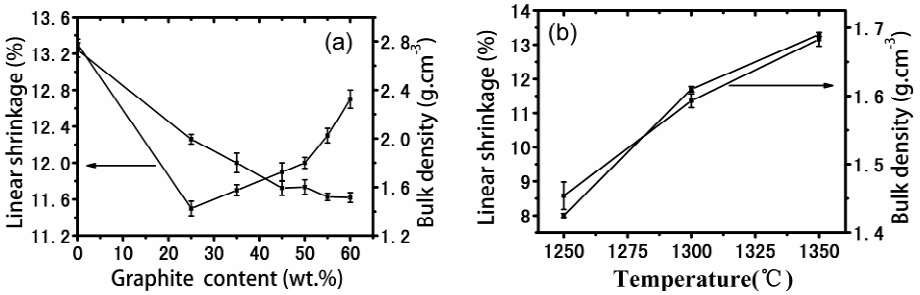

Fig. 2 Variation of linear shrinkage rate and bulk density of the porous AT ceramics with (a) graphite content (b) sintering temperature

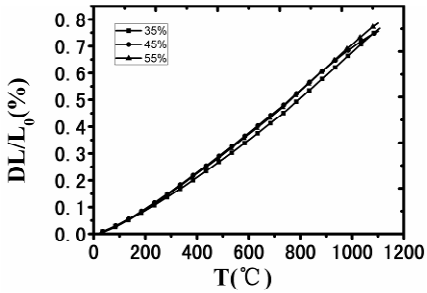

Fig. 3 Thermal expansion of the samples with 35-55 wt% graphite and sintered at 1300°C

The microstructures of the fracture surfaces of the porous AT ceramics are shown in Fig. 4(a-g). The specimens show obvious porous structure. The sizes of pores are in good agreement with the mercury porosimetry results. The pores of the sample without graphite addition are small. The number and size of the pores increase with the rise of graphite addition, while tends to steady as graphite amount is above 45wt%.

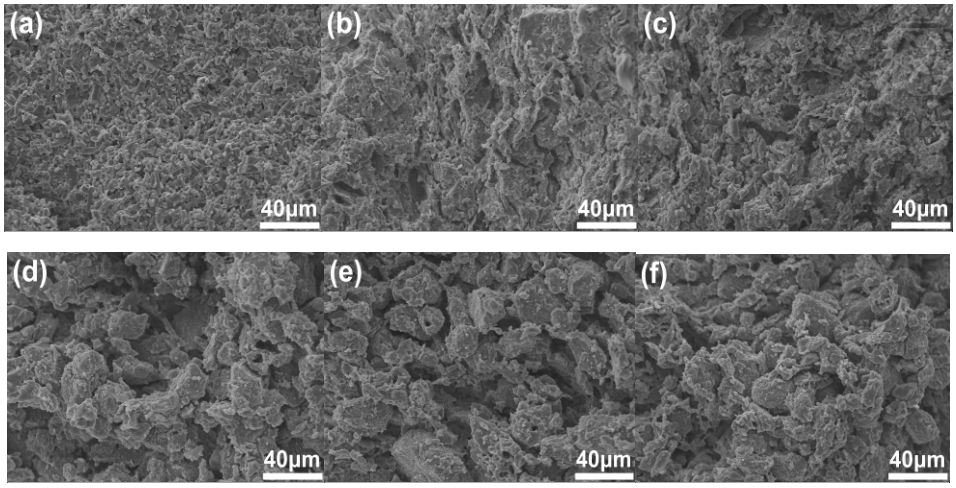

Fig. 4 SEM micrographs of the fracture surfaces of the porous AT ceramics with different graphite amount (a) 0 wt%; (b) 25 wt%; (c) 35 wt%; (d) 45 wt%; (e) 50 wt%; (f) 55 wt%

The open channels among pores result in an open porosity. Fig. 5 illustrated the effects of the graphite addition and the sintering temperature on the apparent porosity and median pore diameter. The apparent porosities increases from 25% to 51% as the amount of graphite increases from 0 wt% to 55 wt%. These results imply that the apparent porosity are determined by the amount of pore former. The apparent porosity and median pore diameter of the sample without graphite are 24.55% and 1.37μm, while those are 51.29% and 10.25μm for the sample with 55 wt% graphite. The median pore diameter increases with the rise of sintering temperature. The sample with 45 wt% graphite sintered at 1300°C has the highest apparent porosity and median pore diameter.

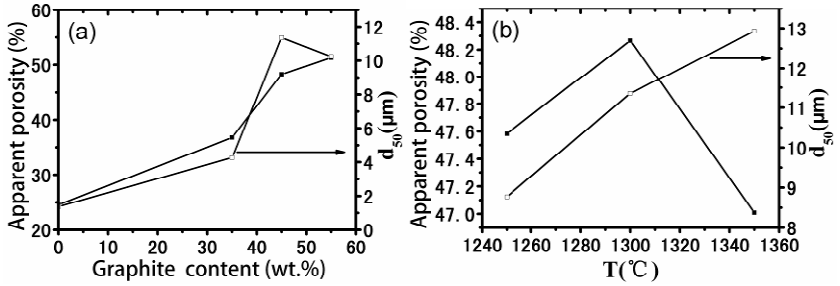

Fig. 5 (a) Influence of graphite content and (b) sintering temperature on the apparent porosity and the median pore diameter

Fig. 6 shows the pore size distribution for the samples with different graphite amount and sintered at different temperatures. The pore size distribution shows a sharp peak. The samples with 45 wt% and 55 wt% graphite have two types of pore size, one corresponding to the intrinsic pore size distribution and the other to those formed by burning-off of pore former[12]. he pore size distribution of the sintered samples is very uniform. With the rise of sintering temperature, median pore diameter is concentrated at 8.77μm, 11.35μm, and 12.94μm, respectively.

Fig. 7 shows the flexural strength of the sintered porous AT ceramics as a function of graphite amount. The strength decreases with the rise of graphite amount, especially from 25% to 35 wt%, because of the increase of porosity and pore size.

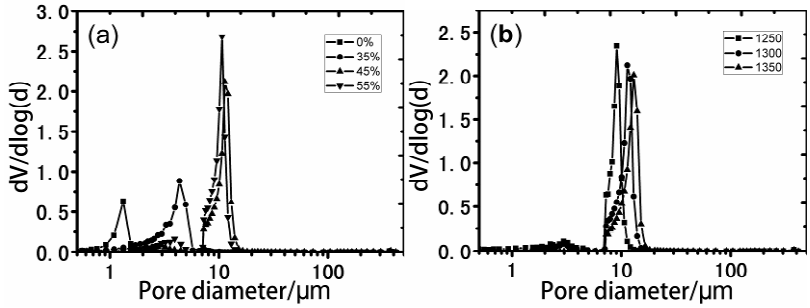

Fig. 6 Pore size distribution (a) different graphite amount (sintered at 1300°C for 1h); (b) different sintering temperatures (45 wt% graphite)

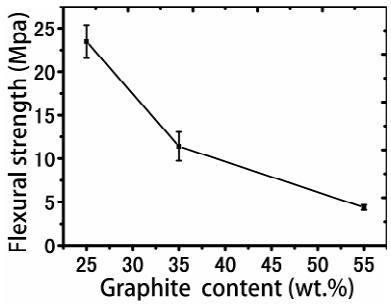

Fig. 7 The flexural strength of the porous AT sintered at 1300°C with graphite contents (25-55wt%)

Conclusions

The porosity increases and the flexural strength decreases with increasing graphite amount. The samples shows open porosities between 24.55% and 51.29% and median pore diameter between 1.37μm and 12.94μm with graphite within 0 wt% to 55 wt%. Flexural strengths of the samples with 25, 35 and 55 wt% graphite are 23.47±1.90, 11.41±1.66 and 4.38±0.29 MPa.

Keywords: Tilapia fishtail, byproducts, Chondroitin sulfate, Collagen, Simulation shark fin.

Abstract. The aim of this study is to investigate the changes of chemical compositions in the process of simulation shark fin. The simulation shark fin was produced by tilapia fishtail; whose main chemical compositions were collagen and chondroitin sulfate (CS). The study indicated that both of them had different change trend in the process of simulation. The process of softening had main effect on the content of collagen, the higher of ice acetic acid concentration, the lower of the level of collagen. The content of CS was related to the process of obtaining wings, and the high temperature would induce a reduction of CS. The content of collagen and CS could be maintained efficiently by improving the processing technology of simulation shark fin.

Introduction

In general, natural shark fin is made by shark's fin [1-2], and its main composition is protein, fat and minerals. With the improvement of people's living standard, there are more and more demands for shark fin. However, a large variety of sharks were slaughtered to get the shark fins. Therefore, it is essential to develop a technology of simulation shark fin to suppress the decline of shark. Nowadays, hybrid tilapias are used as the material of shark fin. At the same time, sodium alginate and gelatin are also used to make it [3].

The tilapia production in Hainan province accounted for 59% of all freshwater aquaculture production in China, which is the biggest export aquatic product. In the present, people focus their attention on the study of fish fillets and the extraction of pectin [4-9], and a large amount of byproducts are produced. Accumulating evidence suggested that tilapia fishtail could be used to prepare the simulation shark fin by the process of alkali treatment and acetic acid soften [10]. The simulated shark fin is similar to natural shark fin in appearance and taste, so this technology can take advantage of the tilapia byproducts effectively.

The utilization of byproducts can improve the additional value of products, whereas, the process of simulation shark fin will lead to the loss of collagen [11-15] and chondroitin sulfate[16-19], which is the main nutrients of fishtail. So it is critical to learn the tendency of nutrition change in the process of simulation, and it can provide theoretical basis for improving the quality of product.

Materials and methods

Materials. Tilapia(*Oreochromis niloticus*) fishtail was provided by Hainan Golden Spring Foods Co., Ltd. (China); standard chondroitin sulfate was purchased from Sigma-Aldrich (USA); compound protease (3.8×10^5 U/g) was bought from Novo. All the other reagents used in the experiment were analytical grade.

The tilapia fishtail were boiled in 80℃ water for 1h, removed the impurities and cleaned the bones, then dried in the constant temperature 65℃ for 4h, then stored at 4℃ in refrigerator until used.

Extraction of Collagen 0.5mL standard hydroxyproline added 1mL isopropyl alcohol, stir 2 minutes after added in oxidant A 0.2mL, placed 4 min after added chromogenic agent B 6.5mL at room temperature. Placed it under the condition of 60 ℃ keep 25 minutes, then cooled it to room temperature, determination the absorbance at 558 nm. Drawing standard curve with the Ammonia concentration (C) as the abscissa, absorbance (A) as the ordinate, the regression equation is that A=0.0355C+0.0024，R^2=0.9997.

The oxidant A was mixed by Sodium Citrate, Citric acid, Sodium acetate, and Isopropyl alcohol. Add the concentration of 7 g/100ml Chloramine-T, mixed them with the ratio of 1:4. The chromogenic agent B was mixed by p-dimethyl amino benzaldehyde and Isopropyl alcohol, with the ratio was 2:13. Put the samples (m_0) 4~6 mg in the block test tube, add 5mL, 6 mol/L HCl at 110 ℃ for 24 h, fix the capacity to 25mL with distilled water, using NaOH adjust pH value to 7, distilled water to 50mL. Take 0.2mL liquid sample under test, according to the standard curve of hydroxyproline in the standard liquid handling and measure its absorbance, the extraction rate of Collagen was calculated by the following formula:

$$\text{Collagen}(\%)=\frac{C\times V\times F}{m_0\times 1000}\times 100$$

Where C is the mass concentration of hydroxyproline; V was the volume of sample solution; F is 11.1; m_0 is the weight of raw materials. Every experiment was repeated three times, and averaged.

Extraction of Chondroitin Sulfate Take a certain volume chondroitin sulfate[20] standard or sample solution, put them in the two 10mL test tubes, respectively ,add distilled water to make the solution volume to 1.00mL, placed in ice water, then added 6 mL concentrated sulfuric acid, put in boiling water heating 20 min, then placed in ice water. One adds 0. 20mL carbazole solution, another one add 0.20mL ethanol without aldehyde as blank, put them in boiling water heating 15 min, then put in ice water to cool quickly. With blank solution for reference, determined the chondroitin sulfate's absorbance (A) under 520 nm, the regression equation is that A=1.2257C+0.0141, R^2=0.9942.

3.0g tilapia fishtail powder was soaked in 10mL petroleum ether for 5 minutes, poured out petroleum ether, add 10mL NaOH ultrasonic processing 25 min, then add 10mL again, extracted, put in water bath for 1h at 50℃(stirring once every 20 minutes). Adjusted the pH to 2~3, then adjusted it to 7 as soon as possible, filtered. Then it was necessary to measure the volume of the filtrate, added 2% compound protease into the filtrate, hydrolyzed it in water bath for 2h at 50℃. During that process keeping pH at 7.0, when the zymohydrolysis was accomplished, the solution would be heated to 85℃ for 5min to kill the enzyme, and decolorized with 2% activated carbon and removed protein and then filtered. Finally, the content of the chondroitin sulfate was measured by spectrophotometer. The extraction rate of CS was calculated by the following formula:

$$CS=\frac{C.N.V}{M\times 10^3}\times 100$$

Where C is the mass concentration of CS; N is the dilution time; V is the volume of sample solution; M is the weight of raw materials. Every experiment was repeated three times, and averaged.

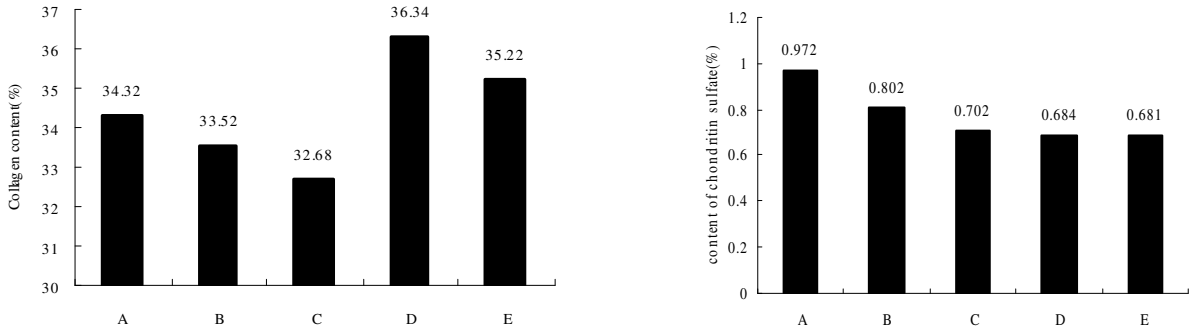
Experimental design Take 50g dry fish tail, take wing by NaOH solution, then dip in black tea, filtering, dry in 30℃ constant temperature for 2 h. Soften, soak in the collagen solution, increase the simulation the taste of shark fin [21].

Measure the variation of collagen and chondroitin sulfate in the tail material, NaOH take wing, collagen optimization, and ice acetic acid softening after optimized and rehydrated.

The content of collagen and chondroitin sulfate were reduced more in the process of softening, in order to ensure the simulation of the shark fin's chemical composition, research the influence of the process of ice acetic acid concentration, softening time, and temperature in the shark fin's chemical composition content.

Results and Discussion

The Effect of Changes of Chemical Compositions in the Simulation of Shark Fin Processing. It can be seen from Figure 1a, the content of collagen was gradually reduced as the process going until reached to the ice acetic acid softening, then the yield increased when it reached to the collagen soaking the optimized fin, and then decreased little in rehydration, this might was because that collagen were extracted by NaOH and ice acetic acid treatment from the simulation shark fin, which lead to a drop of collagen content. The content of collagen in the simulation shark fin soaking by collagen solution will improve significantly; it can absorb part of the same kind of collagen. After rehydration, the collagen on the surface of the simulation shark fin will be lost to the solution.



a **simulated process** **b** **simulated process**

Figure 1. Effects of simulated conditions on the chemical composition (a,collagen;b,chondroitin sulfate)

Figure 1 was the change of collagen content under different process conditions. A was the fish collagen content in the raw material; B was the collagen content in NaOH take wings; C was the collagen content in the ice acetic acid softening; D was the collagen content in soaking the optimized fin; E was the collagen content after product rehydration.

From figure 1b, the results showed that the content of chondroitin sulfate reduced greatly when it in the NaOH. It was because that the alkaline environment will extract part of the chondroitin sulfate[22] from the shark fin, resulted the decrease of chondroitin sulfate content in the shark fin. After softening technology, the content will reduce, too, this may be because part of chondroitin sulfate loss in the solution. Then it will remain stable in other conditions. It has no obvious change when it was soaked by collagen solution and rehydration. These results showed that the process of the ice acetic acid softening has the biggest change in these two chemical components.

The Effect of Concentration on Changes of Chemical Composition. When the time, temperature, ratio of solid to liquid were fixed at 120min, 45℃ and 1:20, respectively, the effect of different ice acetic acid concentration on change trend of chemical was showed in Figure 2.

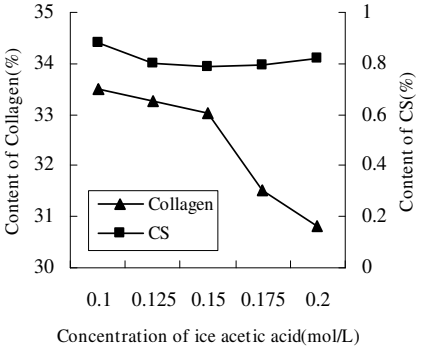


Figure 2. Effect of chemical composition content by different concentration

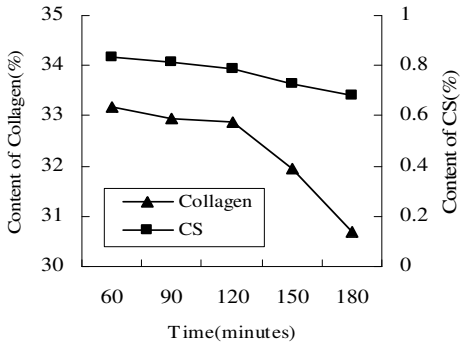

Figure 3. Effect of chemical composition content by different time

It reflected in Figure 2 that the content of collagen and chondroitin sulfate were significantly reduced with the increase of ice acetic acid concentration, and it showed a trend of rapid decline when the concentration higher than 0.15%, this is because that with the increase of acid concentration, the collagen will extracted from the shark fin, resulting in a loss of product in the content. The softening effect is better when the ice acetic acid concentration is higher than 0.1%, and the simulation of collagen in the shark fin will loss a lot when the concentration higher than 0.175%. In order to keep the chemical compositions of the simulation shark fin, and didn't damage the softening effect, we need to make sure the concentration of ice acetic acid is between 0.125% and 0.15%.

The Effect of Time on Changes of Chemical Composition. When the ice acetic acid concentration, temperature, ratio of solid to liquid were fixed at 0.15mol/L, 45℃ and 1:20, respectively, the effect of different time on change trend of chemical was showed in Figure 3. From the figure 3, the results showed that the content of collagen and chondroitin sulfate were significantly reduced. The content of collagen changed a little, but the content of CS declined rapidly when the time was higher than 120 min, this indicated that the increase of time would lead to a decrease of the nutrients in the stimulation shark fin, and the shark fin's softening effect has little change after 120 min, but the decrease of collagen is very obvious, this is not conducive to the production of the products.

The Effect of Temperature on Changes of Chemical Composition. When the ice acetic acid concentration, time and ratio of solid to liquid were fixed at 0.15mol/L, 120min and 1:20, respectively, the effect of different temperature on change trend of chemical was showed in Figure 4.

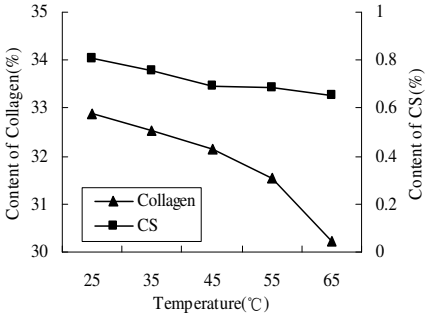

Figure 4. Effect of chemical composition content by different temperature

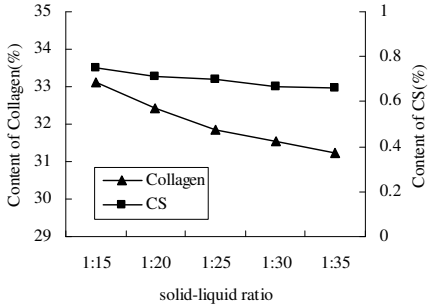

Figure 5. Effect of chemical composition content by different solid-liquid ratio

From the figure 4, the results showed that the content of collagen and chondroitin sulfate were significantly reduced. It kept stability when the temperature between 45 ℃ and 55 ℃. Collagen's downward trend is linear, which showed that the temperature will seriously affect the content of collagen, especially when the temperature is higher than 55 ℃.It showed that high temperature will lead to the dissolution of collagen in simulation shark fin. The content of CS is not obvious, when the temperature reached 45℃, it has a tread of steady. In order to keep the compositions, we need to keep the temperature less than 45℃, while the softening effect had no obvious change when the temperature higher than 45℃.

The Effect of Solid-liquid Ratio on Changes of Chemical Composition. When the ice acetic acid concentration, time and temperature were fixed at 0.15mol/L, 120min and 45℃, respectively, the effect of different ratio of solid to liquid on change trend of chemical was showed in Figure 5. From the figure 5, the results indicated that the content of collagen and chondroitin sulfate were significantly reduced. But the decline is not obvious, especially the change of CS, it's nearly without change, and the content of Collagen maintained a small amplitude stability reduce. While the softening effect was remain stable until the solid-liquid ratio is higher than 1:25. Generally speaking, the effect of solid-liquid ratio was not significant in the change of the content of chemical compositions.

Conclusion

The changes of the content of collagen and chondroitin sulfate were researched in the process of simulation shark fin. Results showed that: these two kinds of contents were decreased significantly in the process of ice acetic acid softening shark fin, the ice acetic acid concentration has the bigger influence in the content of collagen, when the concentration is higher than 0.15 mol/L, the content of collagen will decline rapidly. The time has the bigger influence in the content of CS, when the time is higher than 120 min, the content of CS will loss more. And the process of take wing has an effect on the content of CS, and the temperature has bigger influence, when the temperature is higher than 55 ℃, the content of CS drops rapidly.

Keywords: Magnesium Carbonate Tri-hydrate; magnesium oxide; optimal conditions; brine

Abstract. It is a kind of high efficiency and energy saving new method to prepare high purity magnesium oxide (MgO) with magnesium carbonate tri-hydrate ($MgCO_3 \cdot 3H_2O$) as intermediate. Our research group had already designed orthogonal experimental and got the optimal process conditions of $MgCO_3 \cdot 3H_2O$. The operating parameters such as temperature, pH and reaction time had been further optimized in this paper. Intermediate $MgCO_3 \cdot 3H_2O$ with high aspect ratio and good settling performance was synthesized at the optimal temperature 40-50°C， the optimal pH 8.8-9.0, the optimal reaction time70min, the optimal condition also applied to brine system.

Introduction

High purity active magnesium oxide (MgO) is an important chemical raw material. It is the necessary material in the production of high-temperature thermocouple, is the high quality material in made of refractory, is used as drilling mud additives and catalyst and desulfurizer in refining. What is more, it is widely used in the chemical industry, metallurgy, medical equipment, building materials; ceramics, etc [1-3].The production of MgO in our country is very large. However, High value-added production of magnesia products is very small and can't meet the requirements of the development of industrial production, which is long-term dependence on imports. Therefore, it is an urgent need to research new industrial production technology of high purity active MgO.

Magnesium brine resources are abundant in China. How to make rational utilization of the brine as raw material to produce high-grade magnesium series products are an important way for comprehensive utilization of brine resources. It not only is the strategic needs of national economic development, also is the need of protecting the environment sustainable development. Magnesium carbonate tri-hydrate（$MgCO_3 \cdot 3H_2O$）can be used as precursors for the preparation of high purity active MgO with low calcine temperature, energy and cost [4-5]. $MgCO_3 \cdot 3H_2O$ with high aspect ratio and good settling performance was synthesized in this paper.

Experimental Sections

2.1 Materials. $MgCl_2 \cdot 6H_2O$ and NH_4HCO_3 solution (reagent grade, Tianjin Guangfu fine chemical research institute) were used as starting materials. Also, ammonium water was used for the additive to control pH (reagent grade, Tianjin northern Tianyi chemical reagent factory).

2.2 Characterization

The morphology and size of particles obtained were observed by scanning electron microscope (SEM; Philips XL30ESEM). The crystal structures of as-prepared samples were characterized by X-ray diffraction (XRD; Rigaku D/max 2500v/pc, Cu Ka radiation).

Results and Discussion

Our research group had already designed orthogonal experimental and got the optimal process conditions: reaction temperature is 40-50°C, n (Mg^{2+}): n (HCO_3^-) =1:2.2, n (HCO_3^-): n ($NH_3 \cdot H_2O$) =1:1, stirring speed is 130 r/min; aging time is 3h. The optimization experiments were taken in this paper.

3.1 Effect of different reaction temperatures on crystal morphology

The reaction temperature parameters of crystal growth have a great effect on crystal morphology. The temperature of 25°C, 40°C, 50°C, 55°C, 60°C and 70°C was carried out respectively in the optimal conditions to the aim of optimize experiment. Different crystal morphologies of $MgCO_3 \cdot 3H_2O$ at different reaction temperatures are shown in Fig.1. XRD patterns are shown in Fig.2.

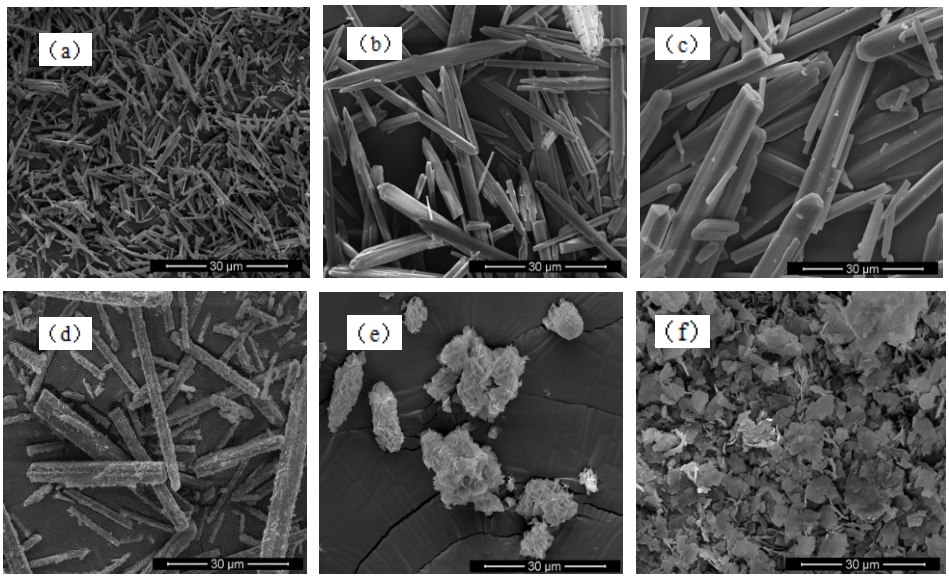

Fig.1 SEM images of $MgCO_3 \cdot 3H_2O$ with different temperature
(a)25°C,(b)40°C,(c)50°C,(d)55°C,(e)60°C,(f)70°C

It was possible to obtain different crystal morphologies of $MgCO_3 \cdot 3H_2O$ at different reaction temperatures. The reaction rate increased as the temperature rises. Only a few precipitations generated after 40 min in 25°C while a large number of precipitations generated after 15 min when the temperature was higher than 40°C. Needlelike or rod-like particles of $MgCO_3 \cdot 3H_2O$ were found to be formed when the temperature ranged from 40°C to 50°C [Figure 1(b) (c)]. $MgCO_3 \cdot 3H_2O$ deposited as a metastable phase in 55°C [Figure 1(d)], whereas no formation of $MgCO_3 \cdot 3H_2O$ was observed when the temperature was increased to 60°C.Figure 1(e) and 1(f) showed that flaky basic magnesium carbonate can be prepared at above 60°C.

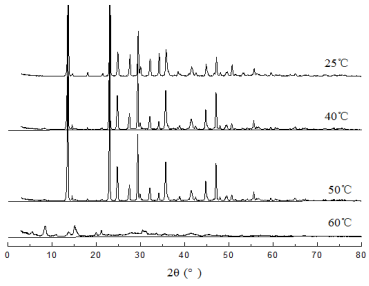

Fig.2 XRD patterns of $MgCO_3 \cdot 3H_2O$ with different temperature

Figure 2 showed that diffraction intensity of basic magnesium carbonate was far less than magnesium carbonate tri-hydrate.

3.2 Effect of different pH on the crystal morphology

The pH of 8.5, 8.8, 8.9, 9.0, 9.1, 9.3, 9.5, 9.8, and 10 was carried out respectively in the optimal conditions to the aim of optimize experiment. Different crystal morphologies of $MgCO_3 \cdot 3H_2O$ at different pH are shown in Fig.3. XRD patterns are shown in Fig.4.

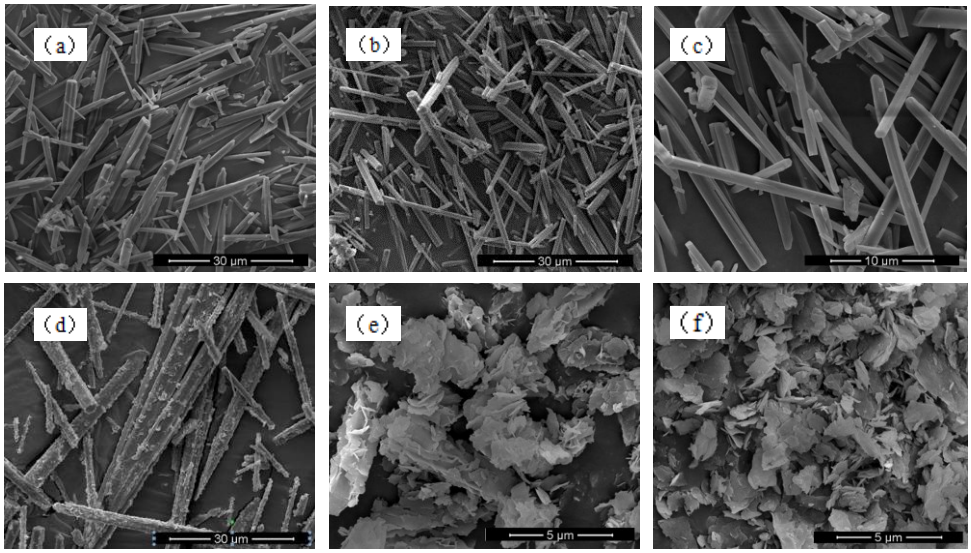

Fig.3 SEM images of $MgCO_3 \cdot 3H_2O$ with different pH
(a)pH=8.5,(b)pH=8.8,(c)pH=9.0,(d)pH=9.5,(e)pH=9.8,(f)pH=10

Observations were made on particles sampled at a specified period in the process of transformation from magnesium carbonate tri-hydrate to basic magnesium carbonate with pH range from 8.5-10 (Figure 3). The changing process of product morphology as the increase of pH value was: rod-like → needlelike → nest → flaky. There was no precipitation at pH=7.9-8.1 without adjust the solution pH value. The product was $MgCO_3 \cdot 3H_2O$ at pH=8.5-9.5 and was basic magnesium carbonate in pH=9.8-10. Especially in pH=9.8 could obtain $4MgCO_3 \cdot Mg(OH)_2 \cdot 5H_2O$ while in pH=10 could obtain $4MgCO_3 \cdot Mg(OH)_2 \cdot 4H_2O$. Aspect ratio of product could up to 29.60 while the section diameter was about 5-8μm in pH=8.8-9.0.

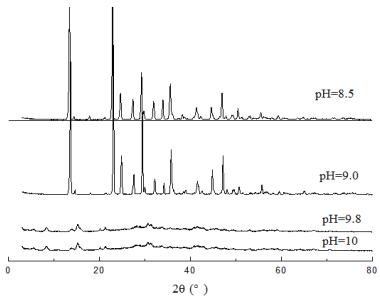

Fig.4 XRD patterns of $MgCO_3 \cdot 3H_2O$ with different pH

Regard to HCO_3^- ion, the ionization reaction ($HCO_3^- \rightarrow H^+ + CO_3^{2-}$) is greater than the hydrolysis reaction($HCO_3^- + H_2O \rightarrow H_2CO_3 + OH^-$) under the condition of weak alkaline, which contribute to form $MgCO_3 \cdot 3H_2O$. In conclusion, the optimal pH was 8.8-9.0.

3.3 Effect of different reaction time on the crystal morphology

The reaction time of 16.7min, 25min, 50min, 70min, and 100min was carried out respectively in optimal condition to the aim of optimize experiment. Different aspect ratio of $MgCO_3 \cdot 3H_2O$ at different reaction time is shown in Fig.5.

Table 5 Effect of reaction time on aspect ratio

Reaction time [min]	Dropping speed [ml·min^{-1}]	Aspect ratio
16.7	3	22.50
25	2	23.46
50	1	27.18
70	0.71	29.60
100	0.5	29.80

Table 5 showed that aspect ratio increased as the reaction time rose. However, unlimited extension of reaction time, the increasing of aspect ratio was not obvious. When reaction time was too short, namely titration speed too fast, it was possible to cause concentration super saturation partly and instantaneous nucleation in solution, crystal reunion and aspect ratio uneven. In contrast, the reaction time was too long, that was to say the titration speed too slow, the reaction efficiency was reduced. Aspect ratio of product could up to 29.60 while the section diameter was about 5-8μm in 70min.

SEM image of $MgCO_3 \cdot 3H_2O$ in optimum conditions is shown in Fig.5.

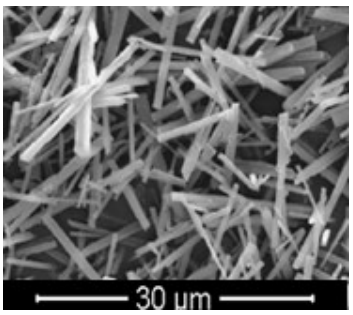

Fig.5 SEM image of $MgCO_3 \cdot 3H_2O$ in optimum condition

Conclusions

(1) The method of prepare high purity magnesium oxide (MgO) with magnesium carbonate tri-hydrate ($MgCO_3 \cdot 3H_2O$) as intermediate has very high popularization value. The process is reasonable and the conversion rate is higher.

(2) There are a lot of salt lake brine including carbonate salt lake, sulfate salt lake (including sodium sulfate and magnesium sulfate subtype), chloride salt lake in Tibet, xinjiang, qinghai and other regions in China. Resource utilization reasonable according to the intrinsic characteristics of each type of salt lake at the same time reduce the difficulty of the salt lake development alone is a new development direction of salt lake brine comprehensive utilization.

Keywords: Crosslinking Etherification Bagasse Xylan, Synthesis, Characterization

Abstract. The bagasse xylan is a polysaccharide that occurs in nature in enormous amount in various one year- and perennial plants. Versatile ways to generate bio-based functional polymers result from the chemical modification of this biopolymer. The crosslinking etherification bagasse xylan(CEBX) has been synthesized by using aqueous solution polymerization method. It implies the use of sodium hydroxide, chloroacetic acid as a carboxymethylating agent and epichlorohydrin as crosslinking agent. The DS values of Carboxymethylated xylan up to 0.59 can be controlled by adjusting the molar ratio in a two step syntheses. Crosslinking etherification bagasse xylan are water soluble at a DS of 0.3. The result showed that the final product had excellent surface activity. IR spectrometry were applied to characterize the carboxymethyl xylans in detail, and revealed characteristic absorption peaks at 1600, 1426 and 1324cm^{-1}.

Introduction

Xylans are the most abundant hemicelluloses. The hemicellulose xylan is most abundant in bagasse and other plants such as grasses, cereals, and herbs. Xylans of all higher plants possess β-(1→4) linked xylose units as the backbone, usually substituted with sugar- and *O*-acetyl groups. In the wood of dicots, only the typecontaining single side chains of 2-linked 4-*O*-methyl-α-D-glucopyranosyl uronic acid units was found[1]. In recent years, xylans as one of the most important renewable resources has received much attention because of its functional properties, such as antioxidant activity, anticomplementary activities, immunomodulating effects and anti-HIV activity[2]. Carboxy-methylation of polysaccharides is one of the most versatile functionalization procedures as it provides access to biobased materials with valuable properties like metal ion induced gel forming well studied for cellulose and starch.[3,4] Up to now, only a few papers describe carboxymethyl xylan (CMX) using AGX from corn cob, AX from oats and rice, and GX from beech wood with a degree of substitution(DS) lower than 1.0[5].

A problem that limits the use of xylans is their poor solubility. To get soluble polysaccharide derivatives, etherification in particular carboxymethylation, hydroxyalkylation, and methylation of the hydroxyl groups is a suitable way[6]. Carboxymethylation is one of the widest modified method of preparation of high-value biobased materials and seems to be an appropriate functionalization to get water-soluble products. [7~14]

The present paper describes the crosslinking etherification of bagasse xylans from bagasse applying different reaction conditions. Moreover, the derivative of xylan is water soluble. The aim of this work is the synthesis of crosslinking etherification bagasse xylan, as well as the characterization of this polymer by using spectroscopic and thermic analytical methods.

Experimental

Materials. Bagasse xylan was isolated from bagasse (all provided by Guilin institute of botany) washed with methanol. It had a water content of 6%. NaOH was obtained from Luoyang chemical reagent factory (Luoyang , China). Sodium monochloroacetate (SMCA) and epichlorohydrin were

obtained from Tianjin chemical reagent factory I (Tianjin, China). Ethylene diamine tetra acetic acid (EDTA) and Ammonia chloride were obtained from Xilong chemical plant (Shantou, China). Peroxyacetyl nitrate (PAN) was obtained from Kelong chemical reagent factory (Chengdu, China). Copper Sulfate was obtained from Xinyu chemical plant (Shantou, China). Ethanol, acetone, and acetic acid were reagent grade analyticals.

Measurements. The DS of the carboxymethyl groups was determined by complexometric titration using EDTA as the complexing agent and PAN as the indicator, according to carboxymethyl starch analysis.[15]

TG and DTG were performed with Netzsch STA 449C instrument. The measurements were recorded in an air atmosphere (flow rate: 20 mL/min). The sample mass was 20mg and it was heated from room temperature to 600 ℃at the heating rate of 10 ℃/min.

Complete Heterogeneous Synthesis of CEBX. For a typical synthesis of CEBX, 5.0g (38 mmole) of bagasse xylan was suspended in 25 mL 80% (v/v) aqueous ethanol. The reaction mixture was vigorously stirred at room temperature for 1 h, at the same time dropwise added NaOH solution (2.25 g, 56.7 mmole NaOH dissolved by 15 mL 80% (v/v) aqueous ethanol) slowly. Then SMCA solution (4.47 g, 47.25 mmole SMCA dissolved by 10 mL 80% (v/v) aqueous ethanol) and NaOH solution (3.02 g, 75.6 mmole NaOH dissolved by 20 mL 80% (v/v) aqueous ethanol) were dropwise added slowly and the temperature of the reaction bath was raised to 65℃. The etherification was performed for 3h. The product was filtered off, suspended in 80% (v/v) aqueous ethanol, neutralized with diluted acetic acid, and washed five times with 50 mL acetone. The product was dried at 60℃ in vacuum.

Effect of reaction parameters on crosslinking etherification

The xylan used is a commercial xylan isolated from sugarcane bagasse showing a yellow to brownish color. The molecular mass is 200,000 g/mole with a xylose content of 80% (related to the total sugar content). For the etherification of xylan a procedure according to the common method for carboxymethylation of the polysaccharides cellulose or starch was applied[7]. Thus, xylan was slurried in an aqueous ethanol followed by the addition of 15% NaOH solution and SMCA solution. The gelatinization was carried out for 2h at 45℃, and the etherification was reacted for 3h at 65℃(Table 1, sample 1~9). The epichlorohydrin as crosslinking agent was added to cross for 0.5h at 45℃.

Table 1 The compilation of reaction conditions used for the synthesis of CEBX

Sample	H_2O/solvent	$n_{NaOH}/n_{AGU(s)}$	$n_{SMCA}/n_{AGU(s)}$	DS
1	2/8	3.25	1.25	0.59
2	2/8	3.75	1.25	0.51
3	2/8	3.00	1.25	0.37
4	2/8	3.00	2.25	0.16
5	2/8	1.50	1.25	0.08
6	4/6	3.00	1.25	0.16
7	0.5/9.5	3.00	1.25	0.50
8	5/5	3.00	1.25	0.08
9	0/10	3.00	1.25	0.01

Infrared spectra

The infrared spectra of native and a representative CEBX derivative are presented in Fig. 1. The broad band between 3600 and 3000 cm^{-1} is assigned to O—H stretching and it is due to hydrogen bonding involving the hydroxyl groups on the xylan molecules. The band at 2925 cm^{-1} is assigned to C—H stretching vibrations. The band at 1643 cm^{-1} is attributed to the scissoring of two O—H bonds of water molecules, while the bands at ν = 860 and 767 cm^{-1} are due to skeletal stretching vibrations of xylan. The CEBX derivative revealed characteristic absorption peaks at ν = 1619, 1420 and 1320

cm^{-1}. These characteristic absorption peaks are assigned to carboxymethyl moieties and this indicates that the hydroxyl groups of xylan molecules were carboxymethylated. Besides, the band at 3430cm^{-1} grows wider due to the introduction of carboxyl enhancing the association of hydroxyl groups.

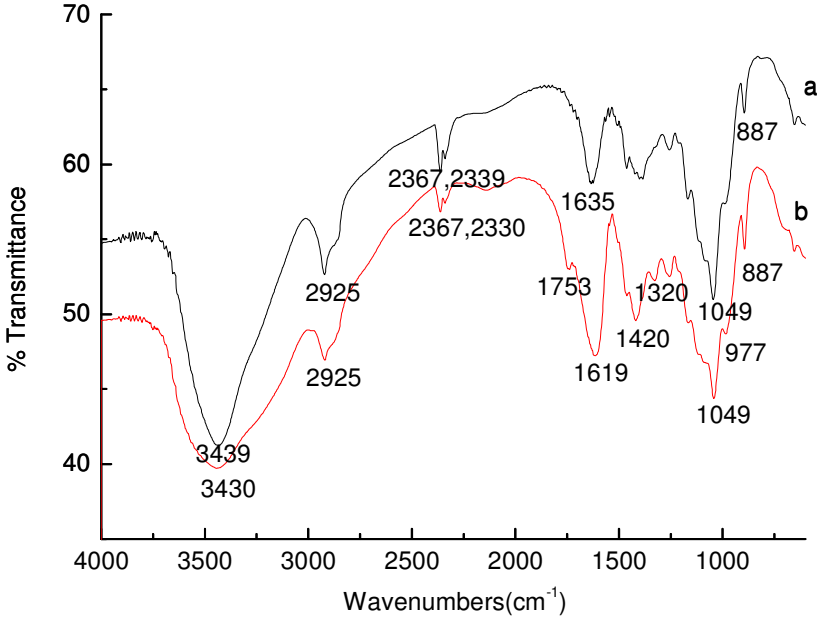

Fig.1 Infrared spectra of native and a representative CBEX (DS 0.59)

Thermogravimetry (TG) and derivative thermogravimetry(DTG)

Thermograms and derivatograms of native and a crosslinking etherification bagasse xylan are presented in Figs. 2 and 3, respectively. Native xylan showed a characteristic tow-step thermogram with 8.93% and 46.27% weight loss progressively. The derivatogram indicates that maximum decomposition occurred at the range 234~312 ℃. Representative CEBX showed tow decomposition stages with 9.72% and 30.58% progressively. In both native and carboxymethylated and crosslinking xyalns, the first thermal events are due to water evaporation. It is also instructive that only 32.64% of the total mass of the carboxymethyl starch was lost at 234~312 ℃ where maximum decomposition occurred. This is lower than 46.27% that was observed in the native starch within the same range. This information suggests that carboxymethylation and crosslinking improved the thermal stability of the xylan.

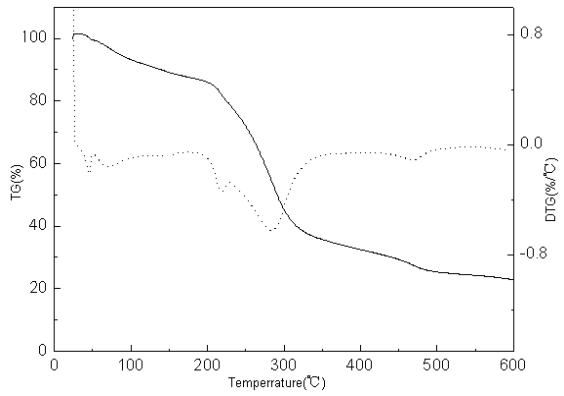

Fig. 2. Thermogravimetry (TG) and derivative thermogravimetry (DTG) of bagasse xylan.

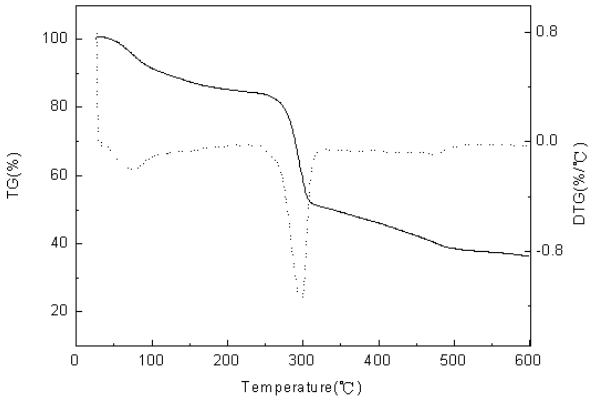

Fig. 3. Thermogravimetry (TG) and derivative thermogravimetry (DTG) of CBEX (DS 0.59)

A plausible explanation for this development is the replacement of the hydroxyl groups on the native xylan with carboxymethyl groups after modification. Since the main decomposition mechanism of xyaln is the dehydration reaction between xyaln hydroxyls, it is reasonable that the lower the amount of hydroxyl group that remained, the more the stability of the xyaln derivative.

Conclusions

In the present investigation, we report about the first synthesis of carboxymethylated and crosslinking bagasse xylan derivative. We investigated on the factors influencing the synthesis such as temperature, ratio of solvent to water in the reaction medium, amount of etherifying agent as well as the influence of the ratio of sodium hydroxide to xylan. All these are with a view to optimizing the synthesis conditions for high degree of substitution. The carboxymethylation and crosslinking of xylan represents a useful way to get water soluble bagasse xylans derivative with anionic functions.

The polymers contain more unsubstituted and di-*O*-carboxymethylated units and less mono-*O*-carboxymethylated units indicating a non-uniform distribution of the CEBX functions within the polymer chains. Further investigations will include some other derivatives in view of the biological activity, reactivity and the substitution pattern as well as the properties.

Keywords: magnetron sputtering; deposition rate; SiN.

Abstract. In this paper, the SiN film was deposited on Si wafer, and the deposition rate of the SiN film was discussed with different parameters such as the sputtering power, deposition temperature, deposition pressure and ratio of $N_2/(N_2+Ar)$. The result showed that the optimal parameter for SiN film were 60W, 300℃, 2.5% and 1Pa, respectively.

Introduction

The refractory metals and their nitrides were mostly polycrystalline structure, the grain boundary between the polycrystalline was become the rapid diffusion path to Cu atoms. To solve the problems, TaSiN, ZrSiN, WSiN and HfSiN et al[1-5] have become the hot topic for the barrier layer.

However, the resistivity of the ternary compounds constituting of Ta, Zr, W or Hf elements was 400μΩ·cm to 800μΩ·cm[1-5], which was not suitable for high speed operation of circuit. The barrier layer with low resistivity and good thermal stability has been demanded. The resistivity of CoSiN film is lower than 300μΩ·cm, and the crystal structure of CoSiN film were close-packed hexagonal at 350K, which were different with crystal structure of Cu. So the CoSiN film has become the research hot.

Magnetron sputtering[6] has been used to deposit various film on Si wafer. SiN film were deposited, which was benefited for depositing heterogeneity sandwich structure of $CoSiN/Cu/CoSiN/SiO_2/Si$[7]. In order to obtain the SiN film, the depositing parameter of sputtering power, depositing temperature, Ar pressure and the ratio of $N_2/(N_2+Ar)$ were discussed to analysis the SiN film.

Experimental

Si target with Ø60×5 was used to deposit SiN film, and the high purity N_2 and Ar with 99.999% were employed. Before depositing, the Si wafer was washed with HCl solution, ethanol, dilute HF solution and distilled water, respectively. The detail cleaning procedure was as follows. Firstly, the dilute HCl was used to remove the surface metal impurities, then the dilute HF was adopted to remove the surface organic impurities. Finally, distilled water was employed to wash the Si wafer under ultrasonic vibration, each process must be lasted 5min, the film can be deposited.

The cleaned Si wafer was shifted into the deposition chamber, and was placed onto the substrate. Then deposition chamber was turned off, and evacuated to a pressure of 1Pa by the mechanical pump, then the molecular vacuum pump was started to evacuate until the pressure under 9.0×10^{-4}Pa or less. At the same time, the substrate was heated, and the N_2 and Ar gases were imported into the chambers

with different proportions. After the gas flow was stable, the pre-sputtering of the target was started to remove the surface impurities or oxide, the process was lasted 10min.

After the pre-sputtering, the sputtering experiments were carried out with different depositing parameters, such as gas pressure, the ratio of $N_2/(N_2+Ar)$, sputtering power and substrate temperature, the detailed experimental parameters were in table 1. The samples can not take out immediately until the chamber pressure elevated to the Atmospheric pressure. And the samples have been sealed into a box to prevent film exposure to air and have been damaged.

Table 1 Deposition parameters

Experimental parameters					
Sputtering power/W	40	50	60	70	80
Deposition temperature/˚C	25	100	200	300	400
Ratio of $N_2/(N_2+Ar)$/%	2.5	5	10	15	20
Deposition pressure/Pa	1	2	3	4	5

Preparation of SiN films

The deposition rate is the important parameter for the film. The film thickness can be controlled by the deposition rate and the deposition time. The appropriate deposition rate and deposition time are in favor of the CoSiN film. The deposition rate are determined by the sputtering power, the ratio of $N_2/(N_2+Ar)$ and substrate temperature[7]. The film thickness of SiN was detected by SGC-10 measured thickness device.

Sputtering power for SiN film. In order to discuss the sputtering power for the film, five kinds of deposition power were explored to analyze the deposition rate. The deposition power were 40, 50, 60 and 80W, respectively. And the substrate temperature was 300˚C, the ratio of $N_2/(N_2+Ar)$ was 2.5%, and the deposition pressure was 1Pa. The deposition rate was calculated by the film thickness and deposition time, and the relationship of sputtering power and deposition rate of the SiN film was showed in figure 1.

From figure 1, it can be seen that deposition rate increased when the power enlarged from 40W to 60W. Then the power was further increased, the deposition rate decreased. At first, the sputtering power was increased, the ions amount of the target materials was enhanced, which was helpful for the film deposition. When the higher of deposition power, the greater of the Si ion power and the activity of the ion, the enhancer of the collision and the scattering of the ions, thereby the weaker the of deposition ions on the substrate.

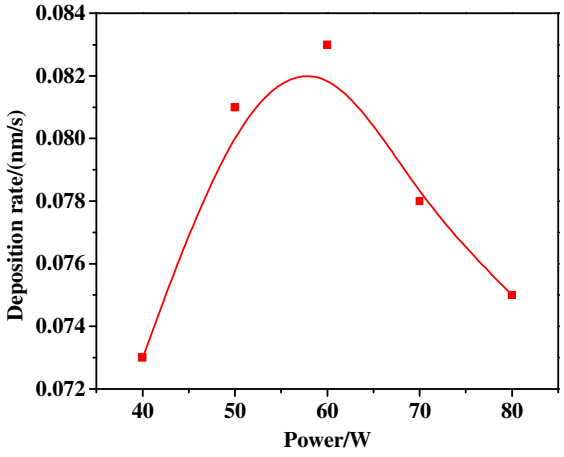

Figure 1 Relationship of the deposition rate of the SiN film and sputtering power

Deposition temperature for SiN film. In order to analyze the substrate temperature in the sputtering process, the SiN film was prepared at different substrate temperatures. And the deposition power was 50W, the ratio of $N_2/(N_2+Ar)$ was 2.5%, and the deposition pressure was 1Pa. The relationship of the substrate temperature and the deposition rate of the SiN film was showed in figure 2.

From figure 2, it can be seen that the deposition rate of the SiN film increased when the substrate temperature elevated from the room temperature to 300˚C, the deposition rate was descended while the substrate temperature further was increased. The highest of deposition rate appeared at 300˚C. The temperature was benefit for the growth of the film. When the substrate temperature increased, the surface diffusion of the adsorbed particles were increased, the number of the particle nucleation was enhanced, which were speeded up the deposition rate of the film. While increasing the substrate temperature was also raised the number of surface absorption and bonding capacity, which enhanced the film growth rate. On the other hand, the substrate temperature was proportional to the evaporation rate of the particle adsorption, the elevated temperature speeded up release of the target molecule in the surface reaction. The deposition rate of the film will fall if the substrate temperature was too high.

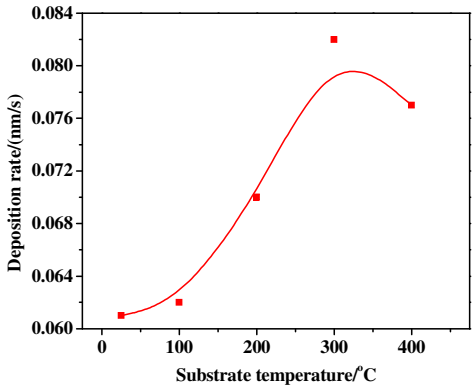

Figure 2. Relationship of substrate temperature and deposition rate of the film

Ratio of $N_2/(N_2+Ar)$ on SiN film. To explore the ratio of $N_2/(N_2+Ar)$ for the SiN film, the SiN film prepared by different ratio of $N_2/(N_2+Ar)$, and the sputtering power was 50W, the substrate temperature was 300˚C, the deposition pressure was 1Pa. The relationship of the deposition rate of the SiN film and the ratio of $N_2/(N_2+Ar)$ was showed in figure 3.

From figure 3, when increase of the ratio of $N_2/(N_2+Ar)$ from 2.5% to10.0%, the film deposition rate was elevated from 0.084nm/s to 0.092nm/s. If the ratio further increased, the deposition rate declined. At the stage of 2.5%-10%, the amount of the activity N_2 in the vacuum chamber enhanced, the phenomenon that the Si ion crashed with nitrogen ion has happened sharply, the deposition rate of the SiN film enhanced greatly. When the ratio of $N_2/(N_2+Ar)$ was greater than 10%, the amount of Ar was reduced, which caused the amount of the sputtered Si ion was declined gradually, and the deposition rate of the SiN film was decreased.

N_2 pressure on SiN film. In order to analyze the N_2 pressure influencing the SiN film, the different N_2 pressure was discussed, and the sputtering power was 50W, the substrate temperature was 300˚C, the ratio of $N_2/(N_2+Ar)$ was 2.5%. The relationship of the deposition rate of the SiN film and pressure was showed in figure 4.

It can be seen from figure 4, the deposition rate of the SiN film was reduced when the pressure was enlarged. If the pressure increased, the crash probability of the target ion and the residual gas was increased, the kinetic energy of the target ion decreased greatly, and the Si ion can not reached the substrate. The amount of Si ion on the substrate was reduced greatly, the deposition rate of the SiN film was decreased gradually.

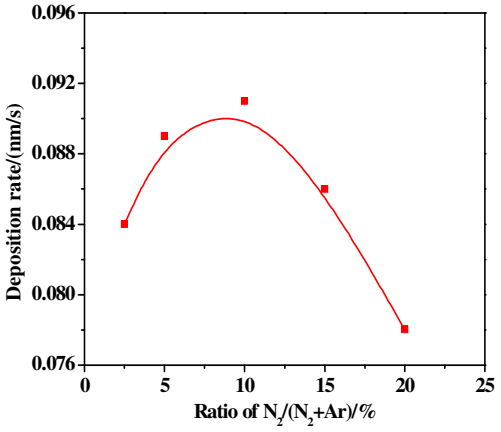

Figure 3 Relationship of deposition rate of SiN film and ratio of $N_2/(N_2+Ar)$

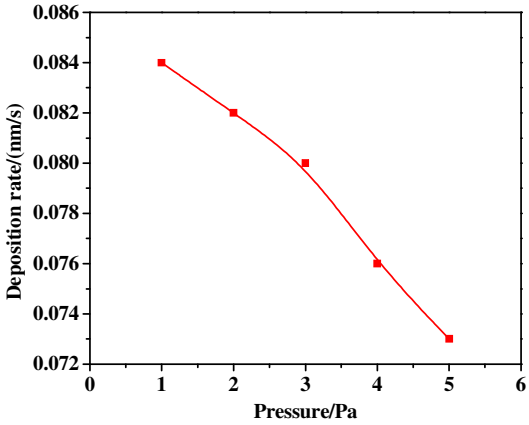

Figure 4 Relationship of deposition rate of the SiN film and the working pressure

Conclusions

The SiN film was deposited with different sputtering power, deposition temperature, ratio of $N_2/(N_2+Ar)$ and N_2 pressure. The deposition rate of the SiN film was increased and then decreased with increase of the deposition power, and the maximum deposition rate was 0.083nm/s. The substrate temperature was also seriously influenced the deposition rate of the SiN film, the deposition rate of the SiN film was enhanced when the temperature was below 400˚C. The ratio of $N_2/(N_2+Ar)$ was also affected the deposition rate of the film, the change trends o f the deposition rate was consistent with that of the ratio of $N_2/(N_2+Ar)$. The deposition rate of the film was declined with the N_2 gas pressure.

Keywords: tea saponin, cotton, pre-treatment, short process

Abstract. Combining the application of tea saponin in short pre-treatment of cotton fabric, the chemical reaction characteristics and mechanism of one-bath process were discussed. The impact of various parameters on the one bath process with tea saponin was analysed, and the optimum process prescription was obtained: tea saponin 40 g/L, penetrating agent JFC 5 g/L, scouring agent YS198 6 g /L and hydrogen peroxide stabilizing agent GJ-101 4 g/L. By tea saponin qualitative analysis, the action mechanism of tea saponin in one bath pretreatment was proposed.

Introduction

Tea saponin as a novel auxiliary for cotton fabric pretreatment of desizing-scouring-bleaching one-bath process was launched grandly in 2009. The tea soponin features replacing the caustic soda and hydrogen peroxide used in the conventional desizing scouring and bleaching three-step method, shortening the process, reducing the consumption of water and energy, decreasing wastewater BOD and COD emissions. It is an effective way to achieve high efficiency, energy-saving and environmentally friendly for low-carbon era cotton fabric pre-treatment process. If the role of the tea saponin is really as well as they said, this is undoubtedly a great reform for the cotton fabric pretreatment. However, this auxiliary is still in its beginning application period in pre-treatment, so its action mechanism, practical effect and operability need further research.

Experimental procedures

Materials and chemicals

Fabric: 122/127 cm 18.2tex * 18.2tex +19.5 tex 551 / 10cm * 315 pieces / cm cotton twill

Chemicals: 27.5% hydrogen peroxide (Xingtai Furunde Chemical), 395 g/L sodium hydroxide solution (Ji-heng Chemical stock company) , hydrogen peroxide stabilizing agent GJ-101 (around the city of Shijiazhuang biological), scouring agent YS198 (Xingtai Furunde Chemical), alkali resistant penetrating agent JFC (Shijiazhuang the Bang Ke-te Chemical), tea saponin (trade name Bugong tea saponin, Shanghai yuanna Fine Chemical Co., Ltd.)

Desizing-scouring-bleaching one-step process

Dipping and padding many times (at 50 ℃) → steaming (95-100 ℃，60 min) →hot water washing twice (100 ℃) → cold water washing →drying

Caustic soda and hydrogen peroxide one-bath prescription (g/L)

Hydrogen peroxide stabilizing agent GJ-101 4 g/L, sodium hydroxide solution 30 g/L, scouring agent YS198 6 g/L, alkali resistant penetrating agent JFC 5 g/L, 27.5% hydrogen peroxide 12 g/L.

Tea saponin one bath prescription(g/L)

Hydrogen peroxide stabilizing agent GJ-101 4 g/L, Scouring agent YS198 6 g/L, Alkali resistant penetrating agent JFC 5 g/L, Tea saponin 20 g/L.

Test procedure

Take a 20 cm×15 cm (warp and weft) cotton gray fabric, with a small amount of water wetting. After being squeezed, put into working bath to full wet. At about 50℃, dipping and padding many times (rolling over rate greater than 100%). After pad-batch, put the fabric on the surface of the dish, and

then put it on the pot grate, avoiding the cloth with the grates, pot wall and other metal contact. Steaming at 100 ℃ for 60 minutes, hot water (100 ℃) washing twice, followed by cold water washing, and then drying, reserved for semi-finished products index test.

Quality testing methods of semi-finished products

Whiteness

The whiteness of fabric after pretreatment is measured by the national standard FZ/T 01068-2009 on WD80 whiteness meter (Dong-guan City Wei-dun Test Equipment Co., Ltd.)

Capillary effect

By FZ/T01071-1999 standards with YGB871-capillary effect analyzer (the textile Wen-zhou city Da-rong instruments)

Strength

By ASTMD 50535-96 standards (strip method) with YGB026E-250 Electronic fabric strength tester (Wen-zhou Da-rong textile instruments)

Results and discussion

Effects of various process parameters on tea saponin one-bath process

Effects of tea saponin concentration

Respectively select tea saponin of 10, 20, 30, 40 and 50 g/l, to examine the effects of tea saponin dosage on pretreatment. The results were shown in table1.

Table1. Effects of tea saponin concentration

	1	2	3	4	5
Tea saponin concentration [$g.L^{-1}$]	10	20	30	40	50
whiteness	78.3	79.3	82.8	83.5	83.8
Capillary effect [cm]	7.3	7.4	10.1	10.0	9.7
Strength [N]	397	415	422	431	407

From Table 1, with the increase of tea saponin concentration, fabric whiteness and capillary effect and strength have increased. So select the tea saponin amount of 40 g / L better.

Effects of steaming time

Under the premise of the tea saponin dosage set at 40 g/L, respectively select steaming time as 40, 50 and 60 min, to examine the effects on pretreatment. The results were shown in Table2.

Table2. Effects of steaming time

	1	2	3
Steaming time [min]	40	50	60
whiteness	82.5	83.3	83.7
Capillary effect [cm]	8.7	9.3	9.8
Strength [N]	417	430	428

From Table2, with the change of steaming time, fabric whiteness, capillary effect and strength have hardly changed. Therefore, the steaming time can be chose between 50 to 60 minutes.

Effects of scouring agent

During tea saponin pretreatment found that oil processing effect was not very well. Scouring agent was added in tea saponin formulations, so as to achieve a better effect. The results were shown in Table3.

Table3. Effects of scouring agent

	1	2	3	4
Scouring agent [$mL.L^{-1}$]	2	4	6	8
whiteness	83.3	83.1	82.8	83.8
Capillary effect [cm]	9.7	9.8	11.1	11.0
Strength [N]	428	419	412	406

From Table3, adding scouring agent to tea saponin process, a better pretreatment effect can be achieved. The scouring agent improved the fabric capillary effect. Furthermore removes residual size, oil and the cotton fibers concomitant.

A better recipe of tea saponin steaming desizing –scouring-bleaching one bath process was elected by the above tests. Namely: the tea saponin 40 g/L, alkali resistant penetrating agent JFC 5 g/L, scouring agent YS198 6 ml/L,GJ101 hydrogen peroxide stabilizing agent 4 ml/L.

Comparative analysis of pure and composite tea saponin

Physical and chemical properties contrast

The pure tea saponin (Xin-yi City-imperial Chemical Co., Ltd., Fig.1) is light yellow solid, amorphous powder. It is easy to float so as to stimulate the nasal mucosa, making people sneezing. And it is insoluble in water, but after heating was dissolved in water and the aqueous solution was dark brown, pH value of 5-7. Composite tea saponin (Fig.2) as a white and small solid particles, is not soluble in cold water and heated gradually dissolved, the aqueous solution is strongly alkaline, pH value of 13-14.

Fig1. Pure tea saponin.

Fig2. Composite tea saponin.

One-bath pretreatment process test contrast

In accordance with the above process and the prescription concluded above. Respectively to do one bath pretreatment test with the two types of tea saponins and results were shown in Table 4.

Table 4. Pure and composite tea saponin semi-products test results

	Pure tea saponin			composite tea saponin		
whiteness	51.5	51.5	51.4	84.3	85.7	86.3
Capillary effect [cm]	6.8	6.9	6.1	8.9	9.3	8.6
Strength [N]	356	368	373	412	398	406

From Table 4, the gray fabric treated with pure tea saponin in whiteness, capillary effect and strength are far less than that treated with composite tea saponin. This shows that only the composite component was analyzed before understand the action mechanism of tea saponin in pretreatment.

Observed the cotton fabric treated with pure tea saponin found that it is some yellowing compared with gray fabric. After testing fabric whiteness, measured the data inTable 5.

Table 5. The whiteness contrast of gray fabric and pure tea saponin treated fabric.

	Whiteness		
Gray fabric	57.5	57.2	57.4

From Table 5, the cotton fabric whiteness treated with pure tea saponin but reduced, this indicated tea saponin almost no effect in bleached cotton fabrics.

Discussion of composite tea saponin action mechanism

(1) Composite tea saponin composition analysis

The composite tea saponin was reported to contain nano-TiO_2, tea saponin, chitosan and other materials. The above test shows that composite tea saponin contains strong alkali and bleaching materials.

A. Identification of the bleaching effect substances in composite tea saponin

Assuming the bleaching effect material is hydrogen peroxide. Then, added MnO_2 in tea saponin solution, the MnO_2 can catalyze H_2O_2 to produce oxygen.

Collect the gases produced and it can make the wood with spark resurgence. This shows that the composite tea saponin containing H_2O_2. But the composite tea saponin is solid, how the H_2O_2

presents in solid? By information knows that H_2O_2 and sodium carbonate can generate sodium percarbonate under certain conditions, which is commonly known as solid hydrogen peroxide. This substance is a white solid particle, dissolved in water and decomposition of hydrogen peroxide, which has bleaching effect.

Adding barium chloride in composite tea saponin solution, appearing precipitation, after added hydrochloric acid, precipitation disappeared, showing that composite tea saponin solution contains carbonate ions. Thereby further prove that bleaching effect substances should be sodium percarbonate.

B. Identification of the chitosan in composite tea saponin

Chitosan is the degradation products of chitin or chitosan, which is a oligomeric soluble sugars and linked by acetyl glucosamine or glucosamine through 1,4-glycosidic bond. The chitosan molecule containing amino and hydroxyl group, salting-out can occur. According to the salting-out nature, added a certain amount of salt in composite tea saponin solution, precipitate generated (Fig3). So preliminary concluded that composite tea saponin contains chitosan. To filter the precipitate and take its supernatant set aside.

To do pre-treatment using the salting tea saponin (the supernatant), and compared with the results of the composite tea saponin pretreatment. Test data were shown in Table 6.

Table 6. The test results of salting tea saponin and composite tea saponin semi-products

	whiteness		Capillary effect [cm]		Strength [N]
composite tea saponin process	85.6	83.9	84.4	9.7	420
after salting out of tea saponin process	84.3	83.7	83.8	8.6	415

From Table 6, the capillary effect of fabric treated with composite tea saponin is better than that treated with salting tea saponin in pre-treatment, and the whiteness and strength changes a little. This shown that the chitosan can improve the absorbency of the fabric in pretreatment.

C. Identification of the nano-TiO_2 in composite tea saponin

TiO_2 non-toxic, chemically very stable, hardly react with other substances at room temperature, not soluble in water, fatty acids and other organic acids and weak inorganic acid, slightly soluble in alkali and hot nitric acid, is an acidic amphoteric oxide. Only long time boiling can fully dissolve in concentrated sulfuric acid and hydrofluoric acid, the reaction of TiO_2 with sulfuric acid to produce $TiOSO_4$ precipitate. Add concentrated sulfuric acid, stirring results in white floc produced (Fig4.) in tea saponin after salting, indicating that the composite tea saponin containing TiO_2.

Fig3. The salting-out precipitation-chitosan.

Fig4. The white precipitation-$TiOSO_4$.

(2) Composite tea saponin action mechanism discussion

A. The role of sodium percarbonate

The case of sodium percarbonate in aqueous solution can be represented by the Eq.1 and Eq.2.

$$2Na_2CO_3 \cdot 3H_2O_2 = 2Na_2CO_3 + 3H_2O_2 \quad (1)$$

$$H_2O_2 = H_2O + [O]. \quad (2)$$

From the chemical equation, the sodium percarbonate has bleaching and alkaline dual nature; it is very suitable for scouring and bleaching process used in cotton.

B. The role of chitosan

According the test, chitosan can improve the moisture absorption capacity of the fabric in the pretreatment. And in theory, the chitosan has adsorbed flocculation function. Either by complexation and adsorbing the metal ions in the pretreatment liquid and thus play the role of the bleaching stabilizers, or by enclosing the flocculation of sizes and other impurities on the fabric serves to prevent secondary sizing pollution.

C. The role of TiO_2

Nanoscale titanium dioxide, the special catalytic action, removal of formaldehyde and other impurities, bactericidal antimicrobial effect, the health effects of the absorption of far infrared, ultraviolet shielding effect, so that it has a wide range of applications in a variety of areas, including textile printing and dyeing industry. In addition, TiO_2 has high reflectance, high opacity and whiteness. So it is speculated that TiO_2 may be used to improve the whiteness and glossiness of the cotton fabric in the pretreatment process, and is conducive to the removal of impurities.

D. The role of tea saponin

As the special chemical structure of tea saponin make its emulsifying, dispersing, wetting, foaming, foam stability, decontamination has good activity, and it is an excellent natural surfactant, so tea saponin can greatly enhance the absorption capacity of the cotton fibers, fabric luster and texture, and remove the fabric stain in the printing and dyeing pretreatment.

Conclusions

(1) The optimal formula of composite tea saponin in one step steaming pretreatment: Hydrogen peroxide stabilizing agent GJ-101 4 g/L, scouring agent YS198 6 g/L, alkali resistant penetrating agent JFC 5 g/L, tea saponin 40 g/L.

(2) The one step process of composite tea saponin steaming pretreatment:
Dipping and padding many times (at 50℃) → steaming (95-100℃, 50-60min) →hot water washing twice (100℃) → cold water washing →drying

(3) The speculated mechanism of composite tea saponin pretreatment: the alkali agent in the composite tea saponin has scouring effect; the sodium carbonate has bleaching effect; the chitosan has adsorption flocculation function, and can play the role of bleaching stabilizing agent; the real tea saponin has the function of emulsifying, dispersing, wetting, foaming, foam stabilization, decontamination effect. Pure tea saponin cannot replace caustic soda and hydrogen peroxide in the traditional pre-treatment process. It's the combined effect of each component in the composite tea saponin that makes the cotton fabric obtain a better whiteness, strength and capillary effect.

Keywords: p-choronitrobenzene; p-chloroaniline; hydrogenation; magnetic catalyst

Abstract. Ir/AlO(OH)/Fe_3O_4 catalyst has been prepared and applied for the hydrogenation of p-choronitrobenzene(p-CNB) to p-chloroaniline(p-CAN) at 35 ^oC and balloon hydrogen pressure in ethanol/water mixture. The experiment results indicated that the catalyst Ir/AlO(OH)/Fe_3O_4 showed excellent catalytic properties for the hydrogenation of p-CNB to p-CAN. A complete conversion of p-CNB was achieved with a selectivity of 97.2 % to p-CAN. The catalyst was quite stable and can be recycled at least seven times without loss of any activity. Moreover, the magnetic property of the catalyst facilated the separation of the used catalyst from the reaction system without filtration.

Introduction

Hydrogenation of chloronitrobenzenes to chloroanilines is of great concern in synthetic chemistry since chloroanilines are important chemicals which are widely applied as end products or intermediates for producing herbicides, dyes, drugs, pesticides and fine chemicals[1, 2]. Compared to the traditional synthesis routes, catalytic hydrogenation has been demonstrated as an alternative avenue for the reduction of chloronitrobenzenes from the view of environment because it is considered to be a simple, safe, and effective technology. Especially, liquid hydrogenation of chloronitrobenzenes catalyzed by heterogeneous catalysts using molecular hydrogen as a reducing agent has attracted intensively attention in recent years. Up to now, catalytic hydrogenation of CNBs has been successfully achieved using catalysts based on noble metals, such as Ru, Pt, Au, Ag and Pd, with this last being the most active[2-5]. Nevertheless, the selectivity to chloroanilines is very low due to the extensive dehalogenation of C-Cl bond in the starting materials or the final products[4]. Apart from the metals that have been mentioned above, catalytic hydrogenation of CNBs catalyzed by iridium nanoparticles supported on commonly used carriers such as active carbon and Al_2O_3 is an emerging process due to its comparable catalytic activity. However, the selectivity to CANs is still not satisfied enough even though large amount of additives and modifiers are introduced into the reaction systems[6]. Therefore, it is a tremendous challenge to develop iridium based catalysts for the clean synthesis of CANs.

In a previous work, we synthesized catalyst Ir/$ZrO_2 \cdot xH_2O$ by a co-precipitation method and applied for the hydrogenation of haloaromatic nitro compounds in ethanol/water mixture at room temperature and atmospheric pressure[6]. The catalyst showed both 99.9 % conversion of p-CNB and selectivity to p-CAN, which was probaly attributed to the the formation of hydrogen bond between p-CNB and the hydroxyl groups on the surface of Ir/$ZrO_2 \cdot xH_2O$ or solvent water,faciliating the activation of the N=O bond in nitro group. Although superior catalytic properties have been obtain, the separation of the catalyst from the reaction mixture should be conducted by centrifugation with high speed. In the present work, Ir/AlO(OH)/Fe_3O_4 catalyst were prepared and used for the selective hydrogenation of p-CNB to p-CAN at 35 ^oC and balloon hydrogen pressure in ethanol/water mixture. The as-prepared catalyst exhibited excellent catalytic performace for the selective hydrogenation of p-CNB to p-CAN.

It can be easily separated from the reaction system by a magnet and can be recycled at least seven times without loss of any activity.

Experiment

Materials. $IrCl_3.nH_2O$ was purchased from Kunming Borui Preclous Metals. $Al(O\text{-}sec\text{-}Bu)_3$ were purchased from Alfa Aesar. PEG-400 (PEG with an average molecular weight of 400), p-CNB, ethanol, and 2-butanol are analytical grade and used without further purification. Hydrogen (H_2) with a purity of 99.99% were used as delivered, water was distilled and deionized before use.

Catalyst preparation. Synthesis of iron oxide nanoparticles[7]: $FeCl_3 \cdot 6H_2O$ (540 mg, 2.00 mmol) and ethylene glycol (16.0 g) were added to a 100 mL round bottom flask equipped with condenser. The mixture was stirred at room temperature for 10 min, then sodium acetate (1.60 g) and poly(ethylene glycol) (Mn =400; 400 mg) were added to the reaction mixture and was heated up to 200 ^oC for 6 h and cooled to room temperature. The black nanoparticles were isolated by centrifugation and washed several times with ethanol, and dried under vacuum to give iron oxide nanoparticles(165mg).

Synthesis of $Ir/AlO(OH)/Fe_3O_4$: $IrCl_3$ (50.0 mg) and THF (1.0 mL) were added to a 50 mL round bottom flask. The mixture was stirred at 23 ^oC for 10 min. $Al(O\text{-}sec\text{-}Bu)_3$ (4.0 g) and 2-butanol (1.0 mL) were added to the reaction mixture and the mixture was heated at 50 ^oC for 20 min. Magnetite nanoparticles (100 mg) dispersed in ethanol (2.00 mL) was added to the resulting black suspension. The mixture was stirred for 10 min at 50 ^oC. Then, water (3.0 mL) was added to form black gel. The gel was isolated by filtration, washed with acetone, and dried at 120 ^oC for 5 h to give dark brown powder.

Catalyst Characterization. X-ray photoelectron spectroscopy (XPS, Kratos XSAM800) spectra was obtained by using Al Ka radiation (12 kV and 15 mA) as an excitation source (hv = 1486.6 eV) and Au (BE Au4f = 84.0 eV) and Ag (BE Ag3d = 386.3 eV) as reference. All binding energy (BE) values were referenced to C1s peak of contaminant carbon at 284.6 eV. A Fourier transform infrared (FT-IR) spectrum was recorded with a Nicolet 6700 (resolution 0.4 cm^{-1}) infrared spectrometer and samples were dispersed in potassium bromide and compressed into pellets. All hydrogenation samples were analyzed by gas chromatography (Agilent 7890A) with a FID detector and PEG-20M supelco column (30m×0.25mm, 0.25 um film) and nitrogen was used as a carrier gas. The vented gas was detected with Agilent 7890A equipped with a thermal conductivity detector (TCP) and a plot carbon sieve column (25m×0.53mm) and hydrogen was used as a carrier gas.

The catalytic hydrogenation of p-CNB was carried out in a 50 mL round flask equipped with a balloon. Typically, p-CNB (1.0 mmol), catalyst (20 mg), ethanol (5 mL), and water (2 mL) were indtroduced to the round-bottom-flask. The reactor was treated under vacuum and charged with pure hydrogen. After the designated reaction temperature (35 ^oC) was reached, the stirring rate was adjusted to 1200 rmp, and the reaction time was accounted.

Results and Discussion

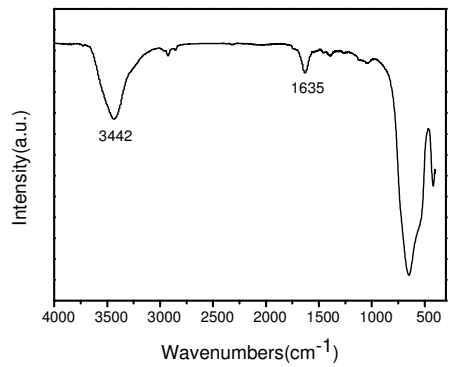

Fig.1 FT-IR spectrum of the catalyst $Ir/AlO(OH)/Fe_3O_4$

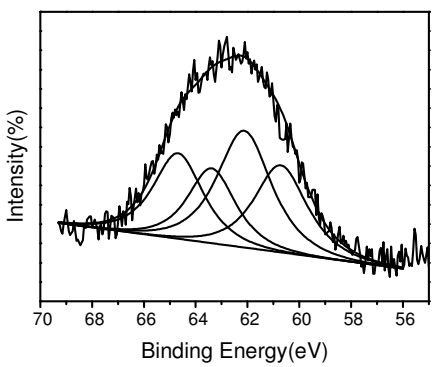

Fig.2 XPS pattern of the catalyst $Ir/AlO(OH)/Fe_3O_4$

The as-prepared catalyst Ir/AlO(OH)/Fe_3O_4 was firstly characterized by the FI-IR technique and the reuslt is shown in Fig.1. It can be seen that the intensive bands at 3442 cm^{-1} was blonged to the ν_{as}(Al)O-H stretching vibrations and the band at 1065 cm^{-1} was assigned to the δ_sAl-O-H mode of boehmite, respectively, indicating that the pre-prepared catalyst contained large amount of hydroxyl groups and structure water and can be dispersed well in ethanol/water mixture[8]. The band at 590 cm^{-1} was originated from the Fe-O bonds, confirming that Fe_3O_4 particles were sucessfully entrapped into the AlO(OH) matrix. In order to evaluate the electronic state of Ir in the Ir/AlO(OH)/Fe_3O_4 catalyst, the binding energy of Ir was determined and the reslut was illustriated in Fig.2. The peaks at 61.1 and 64.9 eV were assigned to the $4f_{7/2}$ and $4f_{5/2}$ peaks of metallic iridium, while the binding energy values at 62.7 and 65.8 eV were attributed to the $4f_{7/2}$ and $4f_{5/2}$ peaks of iridium dioxide, which was attributed to the oxidation of metallic iridium in the air or the incomplete reduction of Ir^{3+} ion[6]. However, the IrO_2 could be redcued by melecular hydrogen during the hydrogenation process and acted as the active sites for the hydrogenation of p-CNB.

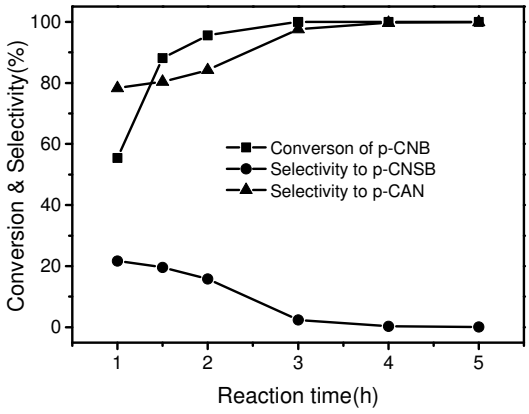

Fig.3 Hydrogenation of p-CNB catalyzed by Ir/AlO(OH)/Fe_3O_4

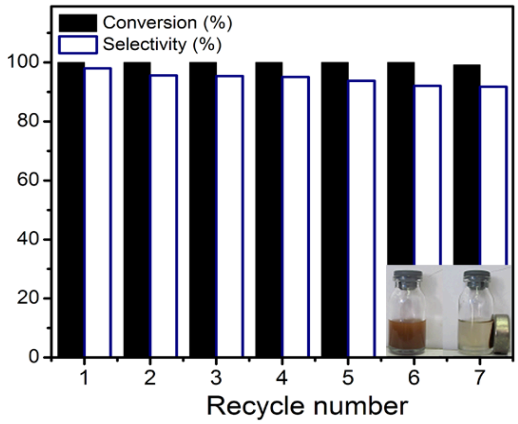

Fig.4 Reusability of Ir/AlO(OH)/Fe_3O_4 catalyst

Catalytic hydrogenation of p-CNB. The selective hydrogenation of p-CNB was employed as a model reaction to investigate the catalytic performance of the catalyst Ir/AlO(OH)/Fe_3O_4 and the results are illustrated in Fig.3. Blank test or the use of AlO(OH)/Fe_3O_4 as catalyst showed no conversion of p-CNB, showing that the iridium was indispensable for the high activity of the Ir/AlO(OH)/Fe_3O_4. During the reaction process, p-CAN, p-chloronitrosobenzene (p-CNSB), and a trace amount of aniline were detected as the main products. It can be seen that a complete conversion of P-CNB was obtained with a selectivity of 97.6 % to p-CAN in a reaction time of 3 h. Moreover, large amount of p-CNSB was detected as an intermediate at the beginning of the reaction; however it can be further hydrogenated to the desired product p-CAN with the elevation of reaction time. A high yield of 99.9 % can be observed at a reaction time of 5 h. The stability and reusability of the catalyst Ir/AlO(OH)/Fe_3O_4 was also studied and the reuslts are shown in Fig.4. Specifically, at the end of each run, the catalyst was separated from the reaction system by a magnet and the supernatant liquid was removed to determine the conversion of p-CNB and selectivity to p-CAN. The black catalyst was washed with ethanol three times and dried under vacuum at room temperature for 12 h for the next run. As shown in Fig.4, the catalyst Ir/AlO(OH)/Fe_3O_4 exhibited excellent catalytic activity and can be recycled at least seven times without loss of any acitivity with a slight decrease of the selectivity to p-CAN.

Summary

In summary, the magnetic nanocomposites Ir/AlO(OH)/Fe_3O_4 was synthesized and applied for the catalytic hydrogenation of p-CNB to p-CAN. The catalyst exhibited excellent catalytic properties at mild conditions in a ethanol/water mixture. Furthermore, it also exhibited showed substantial stability

and recyclibilty and can be easily separated from the reaction mixture by a extenal magnet and recycled at least seven times without loss of any activity

Abstract. Fe_xO_y@C nanocomposites were synthesized and used as carriers for depositing Pt nanoparticles. Catalytic properties of the nanocomposites were investigated for the hydrogenation of p-chloronitrobenzene at room temperature and balloon hydrogen pressure. The catalyst Pt/Fe_xO_y@C was extremely active for the hydrogenation of p-chloronitrobenzene. Completely conversion of p-chloronitrobenzene was achieved with a selectivity of 99.7 % in ethanol-water mixture in a reaction time of 40 min. Moreover, it can be reused four times without loss of any activity.

Introduction

Selective hydrogenation of p-chloronitrobenzene(p-CNB) to p-chloroaniline(p-CAN) has attracted widely attention in recent years because of their useful application in the field of synthetic organic chemistry. As an atom-efficient and environment-friendly approach, catalytic hydrogenation is seen as one of the most promising avenues for the production of p-CAN from the hydrogenation of p-CNB. To this end, liquid catalytic hydrogenation of p-CNB over heterogeneous catalysts such as Pt, Pd, Ru, Ir, and Ni based catalysts are studied in recent years.[1-8] Among these catalysts, Pd has the highest catalytic activity but always generates various kinds of by-products. Ru exhibits lower activity but is more selective for this reaction. In view of Pt-based catalysts, although higher catalytic activity was achieved, the side reaction of dechlorination through the break-up of C-Cl bond should be inhibited to obtain a high selectivity of the desired product. As a result, many methods such as the addition of additives and modifiers have been adopted in order to overcome this disadvantage. However, extra efforts are needed to avoid the secondary pollution due to the addition of additives or modifiers. Despite this advances, it is still remains a big challenge to synthesize Pt based catalysts with high activities and selectivities.

Recently, the preparation of functionalized supports for immobilizing Pt nanoparticles are widely concerned especially the carbon based nanocomposites with the advantages of good stability, accessibility and porosity[4]. However, these catalysts are not steady due to the lack of organic groups on the surface of these nanocomposites. Very recently, it has been reported that the carbon spheres made from the hydrothermal of glucose has large amount of functional organic groups which can be used as robust anchor to stabilize the catalytic centers on the surface of the catalyst [9]. It is desirable to explore such a material as a support for catalysis. To the best of our knowledge, no attempt has yet been exerted to develop the catalytic performance of the platinum catalysts for the reduction of p-CNB by using carbon sphere nanocomposites as a carrier. In this work, we reported a facile route to synthesize the Pt/Fe_xO_y@C catalyst and investigated its catalytic properties for the hydrogenation of p-CNB.

Experiment

Catalyst preparation. All aromatic compound (A.R.), solvents (A.R.), and reagents (A.R.) were used as received. Fe_xO_y@C was prepared according to the reported literature[10]. Typically, glucose(11.250 g) and $Fe(NO_3)_3 \cdot 9H_2O$ (13.635 g) were dissolved in 60 and 30 mL distilled water respectively. The two solutions were mixed together and introduced to an autoclave (120 mL), which was heated at different temperatures for 12 h. The resulting black solid was washed with water and ethanol several times, and dried at 60 ^oC under vacuum for 12 h. Finally, the black solid was caclined at 400 ^oC for 8 h and then used as carrier to deposit platinum nanoparticles. Specifically, 200 mg of the pre-prepared Fe_xO_y@C was transferred into a 50 mL round-bottom-flask, followed by the addition of an aqueous solution of $H_2PtCl_6 \cdot 6H_2O$(0.55 mL,9.844 mg/mL). Then the mixture was reduced by an excess amount of aqueous solution of $NaBH_4$. The resulting products were washed several times with water and ethanol, and dried at 60 ^oC under vacuum overnight.

Activity test. The catalytic property of the Pt/Fe_xO_y@C catalyst was tested as follow: 10.0 mg of catalyst and 0.5 mmol of p-CNB, a mixture of ethanol and water (7 mL, volume ratio of 6:1) were introduced into a 25 mL round-bottom-flask equiped with a balloon. The reactor was treated under vacuum in order to remover air and then purge with pure hydrogen. After the designated temperature (30 ^oC) was reached, the stirring rate was ajusted to 1200 rpm and the reaction time accounted.

Results and Discussion

Catalytic hydrogenation of p-CNB. The catalytic performance of the catalyst Pt/Fe_xO_y@C was investigated using the selective reduction of p-CNB as a model reaction and the results are listed in Table 1. No conversion of p-CNB was detected without catalyst or with Fe_xO_y@C as the catalyst, indicating that Pt was the active site for the hydrogenation of p-CNB. P-chloronitrosobenzene (p-CNSB), P-CAN and a trace amount of aniline were detected as the main products during the hydrogenation process. Specifically, the applied support of the catalyst Pt/Fe_xO_y@C was prepared by heating the mixture at 80 ^oC. From the results illustrated in Table 1, it can be seen that the conversion of p-CNB increased with the elevation of the reaction time. The Pt/Fe_xO_y@C catalyst achieved an 18.2 % conversion of p-CNB within 5 min with a selectivity of 83.1 % towards p-CAN. The conversion of p-CNB and selectivity to p-CAN reached 100 % and 99.4 % respectively when the reaction time was increased to 35 min. The increasing selectivity of p-CAN was contributed to the further hydrogenation of the intermediate p-CNSB to the desired product p-CAN.

Table 1 Effect of reaction time on the hydrogenation of p-CNB catalyzed by Pt-Fe_xO_y@C

Reaction time (min)	Conversion (%)	Selectivity (%)	
		p-CAN	p-CNSB
5	18.2	83.1	16.9
10	33.8	89.9	9.9
15	52.5	90.1	9.9
20	66.5	92.9	7.1
25	79.5	94.8	5.1
30	89.9	96.4	3.5
35	100.0	99.4	0.5

Reaction conditions: catalyst, Pt/Fe_xO_y@C(10 mg) p-CNB,0.5 mmol; temperature, 30 ^oC; solvent, ethanol/water=6:1(total volume was 7 mL)

The heating temperature for the synthesis of the support Fe_xO_y@C was also investigated and the results are shown in Table 2. It can be seen that the catalytic properties of the Pt/Fe_xO_y@C catalysts decreased with the increase of the heating temperature. The conversions of p-CNB decreased from 34.4 to 13.1 % with the increasing temperature from 80 to 140 ^oC. On the contrary, the selectivity to

p-CAN was not affected with the increase of the heating temperature since the selectivity to p-CAN was higher than 96 % in all the investigated temperatures. However, we can see that the catalytic activities of the catalysts are relative low and a long reaction time is required. In order to improve the catalytic activity of the catalyst, NaOH was added to deposit the Pt precursor before it was reduced by $NaBH_4$. From the results listed in Table 2, we can see that the addition of NaOH can significantly increase the catalytic properties of the Pt/Fe_xO_y@C catalysts. Especially, the conversion of p-CNB achieved 100 % when the support of the catalyst was heated 80 ^oC. However, it should be noted that the addition of NaOH resulted in a slight reduction of the selectivity to p-CAN.

Table 2 Effect of heating temperature on the catalytic activities of the catalysts Pt/Fe_xO_y@C

Temperature	NaOH	Conversion (%)	Selectivity (%)	
			p-CAN	p-CNSB
80	No	34.4	98.0	2.0
	Yes	100.0	95.5	0.0
100	No	30.1	97.6	0.7
	Yes	50.4	95.3	0.9
120	No	21.2	100.0	0.0
	Yes	44.2	98.0	0.5

	Yes	30.3	90.5	0.0

Reaction conditions: catalyst, 10 mg; temperature, 30 ^oC; H_2 pressure, 1 atm; solvent, ethanol/water mixture (volume ratio=3:4, total: 7 mL); reaction time, 4 h.

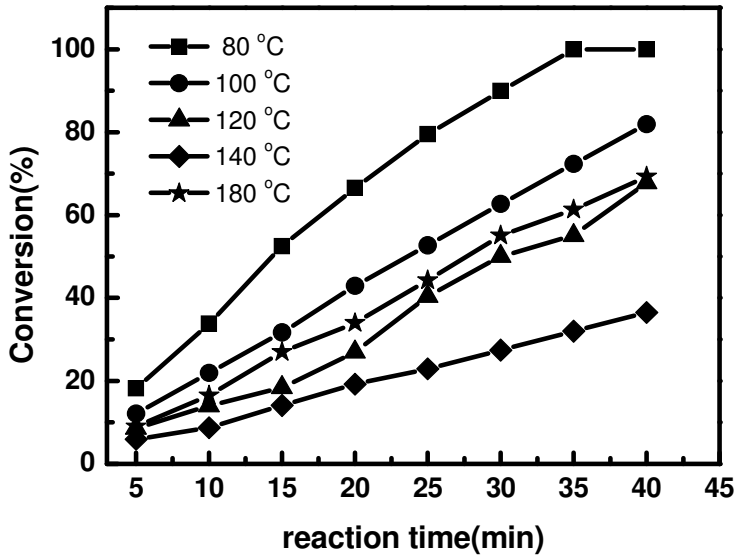

Fig.1 Hydrogenation of p-CNB catalyzed by the Pt/Fe_xO_y@C after calcination

Although the application of NaOH increased the activity of the catalyst to some extent, a long reaction time of 4 h was required to obtain a complete conversion of p-CNB. Therefore, the carriers were calcined at 400 ^oC to improve their crystallites with the aim of enhancing the catalytic activity of the catalysts. The results illustrated in Fig.1 showed that the catalytic activities of the catalysts were enhanced after the catalyst supports were treated. The conversion of p-CNB was 100 % within 35 min at the same reaction conditions compared to 34.4 % conversion of p-CNB within 240 min for the catalyst without calcination. Moreover, these catalysts also showed increased catalytic activities compared to the catalysts which were treated with NaOH during the procedure of catalyst reduction. For example, both of the catalysts (the carrier was obtained from heating mixture at 80 ^oC and the NaOH was used for depositing the Pt ion) achieved 100 % conversion of p-CNB, however the

reaction time for complete conversion was reduced 35 min with the catalyst support calcined at 400 ^{o}C compared to the catalyst treated with NaOH. From the results discussion above, it can be seen that the Pt/Fe_xO_y@C catalyst exhibits excellent catalytic activity and selectivity without the detection of any hydrodechlorination product. This advanced composite material provides a kind of novel and effective catalyst with great promise for catalytic hydrogenation of p-CNB in practical application.

Summary

Catalyst Pt/Fe_xO_y@C was prepared and used for the selective hydrogenation of p-CNB to p-CAN at 30 ^{o}C and balloon hydrogen pressure in ethanol/water mixture. The hydrothermal temperature played an important role in the catalytic performance of the catalyst. Furthermore, the calcination temperature also has a significantly effect on the catalytic activity of the Pt/Fe_xO_y@C catalyst. The complete conversion of p-CNB with a 99.4 % selectivity of p-CAN was achieved in a short reaction time of 35 min.

Keywords: Bimetallic Catalyst, Glyoxal, Glyoxylic Acid

Abstract. In this paper, Au/C and Au-Pd/C catalysts were prepared respectively. The catalytic performance for the oxidation of glyoxal to glyoxylic acid has been investigated. Furthermore, these catalysts were characterized by XRD and XPS. The results demonstrate that, the conversion of glyoxal was 58.9% and the yield of glyoxylic acid was 13.7% at the optimum reaction time of 20h, which implied the bimetallic catalyst showed higher performance than the monometallic catalyst obviously.

Introduction

Au-Pd/TiO_2 catalyst has been found to be particularly effective for the liquid-phase oxidation of primary alcohols by Enache et al[1] In addition, there are some studies indicated that Au-Pd bimetallic catalyst has shown good catalytic activity for selective hydrogenation of Nitro compounds[2] and selective oxidation of organic compounds in liquid phase[3-4] reactions. It has also been reported that the addition of another metallic element to the monometallic catalysts can give rise to catalytic activity and stability, when compared to their monometallic catalysts due to the synergistic effect and coordination effect. The experiments by Rossi et al[5-6] confirmed that for the selective oxidation of alcohols, the catalytic activity of bimetallic catalyst such as Au-Pd and Au-Pt supported on activated carbon is better than a single metallic catalyst. Landon et al[7-8] found that the yields of the synthesis of H_2O_2 reaction was significantly enhanced over Au-Pd alloys catalyst compared with the Pd or Au monometallic catalysts, which related with the Synergistic effect between Au and Pd.

According to the literature[9], Au/C catalyst has shown catalytic properties for the oxidation of glyoxal to glyoxylic acid, but there are some shortcomings such as low yields and poor stability of catalyst. In this paper the catalytic performance of Au-Pd/C for the oxidation of glyoxal to glyoxylic acid has been investigated and the structure of the bimetallic catalyst was characterized by XRD, XPS.

Experimental

Materials. Activated carbon is provided by sheng-miao industry of fine chemicals company, glyoxal is provided by sinopharm group chemical reagent co, $HAuCl_4$ is provided by Shang Hai reagent company, $PdCl_2$ is provided by Bei Jing reagent company.

Pretreatment of carbon. Before use, the carbon was suspended in HCl 2mol/L for 6h, then washed several times with distilled water until the pH of the solution reached values of 7. At the end the carbon was filtered off and dried under vacuum at 120℃.

Catalysts preparation. Au/C catalyst: A certain amount of carriers, 20mL of lysine solution(0.1mol/L) and solution of $HAuCl_4$(2.43mol/L) were mixed for 30min under vigorous magnetic stirring in the cone-shaped bottle. $NaBH_4$ solution (0.1mol/L) which was freshly prepared was added, then after 2min, HCl solution (0.3mol/L) was immediately added. The system was left to

stand for 24h, filtered, washed with a small amount of anhydrous ethanol, dried under vacuum at 100℃ in for 6h, calcined at 200℃ for 2h.

Au-Pd/C catalyst: An aqueous solution of $PdCl_2$(0.0385mol/L) was added under vigorous stirring to 100ml distilled water which contains a certain amount of above-mentioned Au/C catalyst and reacted for 0.5h, then $NaBH_4$ solution (0.1mol/L) which was freshly prepared was added. The solution was left to stand for 24h, filtered, washed with a small amount of anhydrous ethanol, dried under vacuum at 100℃ in for 6h, calcined at 200℃ for 2h.

Catalytic test. Glyoxal (2.5ml, 40%) and 0.2g catalyst were mixed with 200ml distilled water in a 4-mouth flask(500ml) provided with an electric stirrer and reflux condensing tube. The reactor was pressurized at the desired pressure of O_2 and at the constant temperature of 323k. The pH of the reaction mixture was kept at a constant value of 7.7 by addition of a solution of NaOH(0.05mol/L). After the end of reaction the catalyst was filtered and the organic products were tested. According to literature[10], spectrophotometry is used to analyse the concentration of glyoxal and glyoxylic acid.

Catalysts characterization techniques. XRD patterns were obtained with a philips RW-1729 diffractometer using the Cu Ka radiation (λ =0.15405nm). XPS was performed on an Escalab-210 spectrometer from VG Scitntific, using the Mg Ka radiation.

Results and discussion

Comparison of catalytic activity of Au/C and Au-Pd/C for the oxidation of glyoxal to glyoxylic acid. At the reaction temperature of 50℃, oxygen flow of 0.4L/min, pH value of 7.7 and the catalyst of 0.2g, the catalytic activity of Au/C and Au-Pd/C for the oxidation of glyoxal to glyoxylic acid was compared. From fig.1 we can see that Au/C catalyst showed high activity at the reaction time of 10h, the yield of glyoxylic acid reached 9.7%. However the highest activity was achieved over Au-Pd/C catalyst at the reaction time was 20h, with 58.9% conversion of glyoxal and 13.7% yield of glyoxylic acid. The catalytic activity of bimetallic catalyst is sure to win out over the monometallic catalyst. This is determined by synergistic effect between Au and Pd[6].

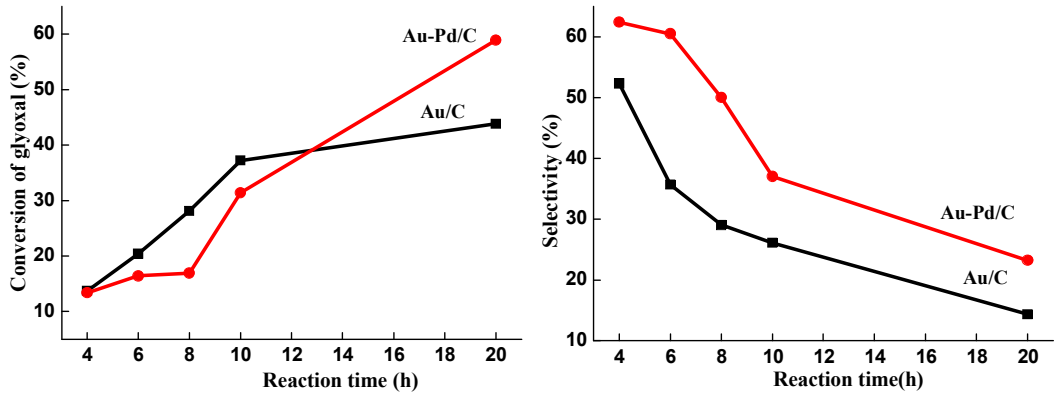

Fig.1 Comparing of the performance of Au/C and Au-Pd/C

XPS. In order to study the relationship between catalytic activity and active components of bimetallic catalyst, XPS test was used for Au/C and Au-Pd/C catalyst. We can see from Fig. 2, Au $4f_{7/2}$ binding energy of Au/C is 83.9eV which is similar to the reported literature[11], but Au $4f_{7/2}$ binding energy of Au-Pd/C is 84.3eV which is obviously increased. This means that the electronic structure of gold was changed because of introduction of Pd[12] and synergistic effect between these two metal elements. Yet, this result can impact the catalytic activity of bimetallic catalyst.

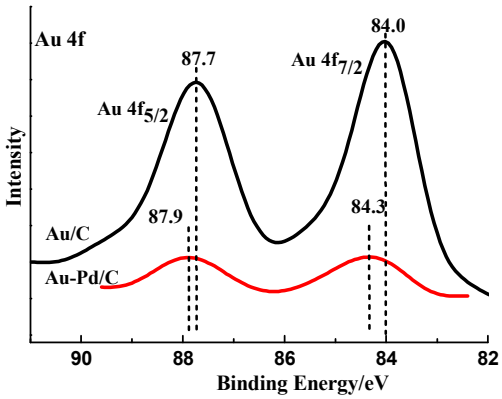

Fig.2 XPS spectra of Au4f in Au/C and Au-Pd/C

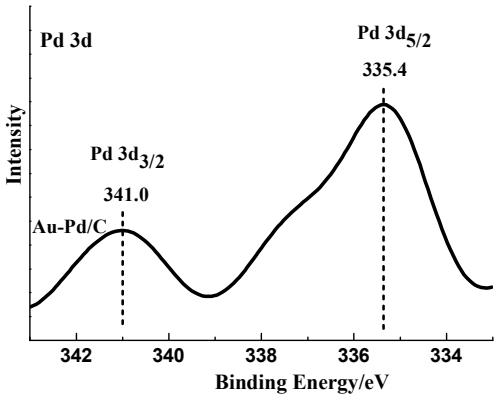

Fig.3 XPS spectra of Pd 3d in Au-Pd/C

Fig. 3 reports XPS spectra, in the Pd 3d region, of the Au-Pd/C catalyst. According to the literature reported[13], Pd $3d_{3/2}$ and Pd $3d_{5/2}$ binding energy of Pd^0 are 335.6eV and 341.3eV, respectively; Pd $3d_{3/2}$ and Pd $3d_{5/2}$ binding energy of PdO are 336.9eV and 342.3eV, respectively. Fig. 3 displays that Pd $3d_{3/2}$ and Pd $3d_{5/2}$ binding energy of Au-Pd/C catalyst are 335.4eV and 341.0eV which are consistent with Pd^0. This means that Pd existed as Pd^0 on the surface of Au-Pd/C catalyst.

XRD. Characteristic peaks of Au are normally considered as 2θ = 38.2°, 44.4°, corresponding to cubic Au crystal face of (111), (200). Pd characteristic peaks are considered as 2θ=40.2°, 46.3°, corresponding to Pd (111), (200). According to the literature[14-15], the characteristic peaks in the range of 38.18-40.18° and 44.20-46.35°should be attributed to Au-Pd alloy. If diffraction peak is close to 38.18° and 44.20°, Au-Pd alloy will be the rich gold alloy, if it is close to 40.18°and 46.35°, Au-Pd alloy will be rich of Palladium. XRD spectra of Au/C and Au-Pd/C are reported in Fig.4. We can find that there are diffraction peak of activated carbon besides characteristic peak of gold. This indicates the high dispersion of gold on carrier.

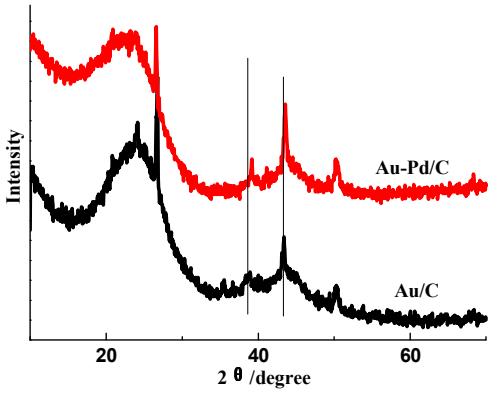

Fig.4 XRD patterns of Au/C and Au-Pd/C

Conclusion

In this paper we have shown that the Au-Pd/C catalyst was more active than the Au/C catalyst for the oxidation of glyoxal and glyoxylic acid. At the optimum reaction time of 20h. the conversion of glyoxal was 58.9% and the yield of glyoxylic acid was 13.7% over Au-Pd/C. This means that the synergistic effect between Au and Pd is better for this reaction.

Keywords: Inhibition efficiency, Copper, Polarization curves, Acid solutions.

Abstract. This paper is mainly to discuss that myclobutanil as corrosion inhibitor and its corrosion efficiency were evaluated via electrochemical impedance spectroscopy (EIS) and potentiodynamic polarization. The potentiodynamic polarization measurements showed that the inhibition efficiency increases sharply with the increasing of concentration of myclobutanil, and the highest inhibition efficiency of the myclobutanil reached 84.3% at 3.2×10^{-4} mol/L in 1 mol/L HCl. The result also indicated that myclobutanil belongs to the mixed type inhibitor. The results obtained from EIS measurements are in good agreement with that obtained from potentiodynamic polarization.

Introduction

Copper plays an indispensable role in daily life, but due to the characteristics of metal, when the copper is exposed in acid solution, corrosion will happen. It will cause huge economic loss. In recent years, corrosion inhibitor began raising concern as a new method for metal corrosion [1]. Now the most widely used inhibitor is benzotriazole (BTA). Thanks to its excellent corrosion resistance performance, BTA is used in the production of all aspects of life. But with the awareness of environmental protection rising, people are eager to find a more environmentally friendly corrosion inhibitor. Myclobutanil is a three azole compounds, and it has good biodegradation properties and low toxicity. In this work, the corrosion behavior of copper in 1mol/L HCl solution with addition of myclobutanil as inhibitor was investigated by EIS and potentiodynamic polarization.

Materials and methods

Materials

In this paper, the working electrode is a copper electrode, and the copper electrode is coated by epoxy resin with an exposed diameter of 3.0 mm. The structure of myclobutanil namely 2- (4-chlorophenyl) -2- (1H, 1, 2, 4- three -1- methyl) of adiponitrile are shown below (**Fig.1**). Before the experiment, the copper electrode need to be polished by metallographic sandpaper, then placed it in ethanol to ultrasound, acetone degrease, finally washed the electrode with deionized water. Corrosive medium used in this essay is 1mol/L HCl. Concentrations of myclobutanil are 0, 3.2×10^{-4}, 1×10^{-4}, 3.2×10^{-5}, 1.0×10^{-5}, 3.2×10^{-6}. The experiment was carried out in 293K water bath.

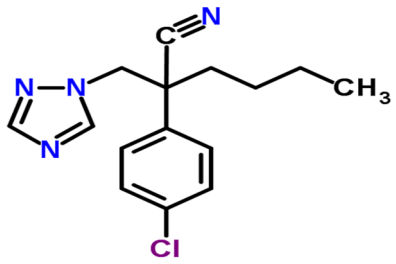

Fig.1 Molecular structure of the studied compound of myclobutanil

Methods

The experiment was conducted by using a three-electrode system with the electrochemical workstation CHI660D in this essay. The copper electrode is working electrode, reference electrode is saturated calomel electrode, a platinum foil of 1.5×1.5 cm as counter-electrode. The three electrodes are placed into a 250 mL solution for half an hour, and then measured the open circuit potential, the corrosion system is considered to have reached a steady state when the open circuit potential changes less than 2 mV in five minutes. In the measurement of polarization curve, the potential scan ranges from -250 to 250 mV SCE (relative to the open circuit potential), and the scanning rate is 0.5 mV/s. The frequency range of the measurements of EIS is 100 k Hz~10 mHz, and the excitation signal is a sine wave with its amplitude of 10mv. Then using specialized software analysis the measured data.

Results and discussion

Polarization curves

Fig. 2 shows the corrosion potentiodynamic polarization curves of copper electrode under different concentrations of the inhibitor in 293 K. From the picture, cathode and anode's potentiodynamic polarization curves with corrosion inhibitor have changed obviously, namely inhibitor has suppress both cathode and anode. And Tafel curve of cathode and anode move to the low current density area with the increase of the inhibitor concentration. That is, the inhibition efficiency increased with the concentration of the inhibitor.

The corrosion parameters of copper in 1mol/L HCl Solution with different concentrations of inhibitor determined by the Tafel extrapolation method- were listed in **Table**.1. From the charts, the corrosion current sharply reduced after adding the corrosion inhibitor, at the same time the concentration increased and corrosion current reduced, which also indicates that the inhibition efficiency increases with the concentration and the highest inhibition efficiency of the myclobutanil reached **75.9%**.Because the change of the open circuit potential is less than 85mV [2], myclobutanil belongs to mixed type inhibitor. The corrosion efficiency is calculated by the following formula [3]. $i_{coor(inh)}$ means the current density in the absence of myclobutanil.

$$IE\% = \frac{I_{coor} - I_{coor\ inh}}{I_{coor}} \times 100$$

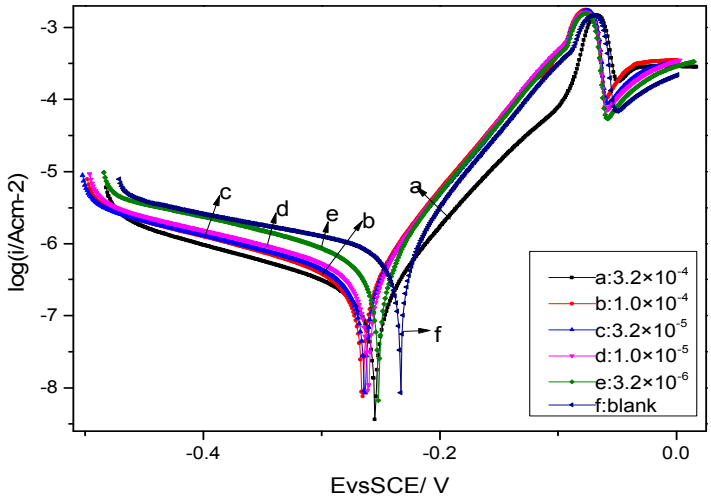

Fig.2. Potentiodynamic polarization curves of copper in 1mol/L HCl solution with different concentrations of myclobutanil

Table1 Potentiodynamic polarization parameters of copper in 1mol/L HCl solution with different concentrations of myclobutanil

Concentration (mol/L)	Ecorr (mV SCE)	Icorr (μAcm^{-2})	β c ($mVdec^{-1}$)	β a ($mVdec^{-1}$)	IE%

3.2×10^{-4}	3.045	1280.0	4026.o	0.755	4.68	0.1889	84.3

Conclusion

Myclobutanil is an effective inhibitor for corrosion of copper in acid medium at 293K.It can inhibit the copper corrosion by forming the adsorption protective film on metal surface [5]. The potentiodynamic polarization measurements showed that both cathodic and anodic processes of copper corrosion were suppressed and the myclobutanil acts as a mixed-type inhibitor. It is obviously that inhibition efficiency depended on inhibitor concentration and the corrosion efficiency reached the highest point at 3.2×10^{-4} mol/L in 1mol/L HCl solution.

Keywords: Selective catalytic reduction; NH_3; NO; coprecipitation method.

Abstract: CeO_2-Fe_3O_4/TiO_2 and CeO_2/TiO_2 catalysts were prepared by coprecipitation method, and their activities for selective catalytic reduction of NO with NH_3 were investigated. As can be seen from the experimental results, the CeO_2-Fe_3O_4/TiO_2 catalyst prepared showed the best SCR activity and SO_2 resistance. Based on the characterization results of BET, XRD, NH_3-TPD and XPS the excellent performance of CeO_2-Fe_3O_4/TiO_2 catalyst should be resulted from its large surface area, high NH_3 adsorption capacity and high concentration of surface chemisorbed oxygen.

Introduction

Selective catalytic reduction process is the main technique for controlling NO in the flue gas emitted from stationary sources such as coal fired boilers [1]. Now, vanadium based catalyst has been put into large scale commercial utilization. But the deactivation od this catalyst caused by dust and SO_2 in the flue gas make it necessary to develop low temperature SCR catalyst [2].

In recent years, much attention had been paid on Ce-Fe-based low temperature SCR catalysts because ceria oxides have high oxygen storage capacity and high activity and Fe have good SO_2 resistance in low temperature [3,7]. Fang et al. [4] found that highly dispersed CeO_2 on carbon nanotubes showed high NH_3-SCR activity and good SO_2 and H_2O resistance. Gu et al. [5] found that surface sulfation could enhance the NH_3-SCR performance of CeO_2 catalyst. Gao et al. [6] reported a Ce-Cu-Ti complex oxide catalyst with high activity and SO_2 resistance ability at the temperature lower than 350 ℃. However, very few reports on Ce-Fe-based catalysts over TiO_2 can be found in the literatures. It is well recognized that the difference of components and preparation conditions have great impact on the dispersion and existence state of active components[1,7], therefore, affecting the activity and SO_2 resistance of catalyst. So it is necessary to find the relationship between different components and the activity and SO_2 resistance of TiO_2 supported Ce-Fe-based catalysts.

In this study, CeO_2-Fe_3O_4/TiO_2 and CeO_2/TiO_2 catalysts prepared by coprecipitation method. The effect of different components on the SCR activity, SO_2 resistance and surface properties of catalysts samples was investigated and discussed.

Experimental

1.1 Catalyst preparation

The catalysts were prepared by coprecipitation method. Titanium sulfate (0.1 mol), ferric nitrate (0.05mol) and cerium nitrate (0.05mol) (or titanium sulfate (0.1 mol) and cerium nitrate (0.05mol)) were fully dissolved in deionized water(100ml), then ammonia solution(3mol/L) was added drop by drop into the solution under adequate mixing at room temperature until the pH value of the solution reached 11. After 3h, the sediment was filtered and washed throughly with deionized water. After dried at 100℃ in air for 12h, the sediment was calcined at 550℃ in air for 5h.

1.2 Characterization

The BET surface areas of the catalysts were measured N_2 adsorption at77 K on a Quantachrome Autosorb iQ instrument. The X-ray diffraction (XRD) measurement was performed on a Bruker D8advance X system with CuK α a radiation. The t temperature programmed desorption with ammonia (NH_3-TPD) was carried out on a chemisorption analyzer (ChemBET TPR/TPD, Quantachrome Instruments). The NH_3 signal was measured by a thermal conductivity detector.

1.3 Activity test

The SCR activity test was performed on a fixed bed reactor (13mm i.d.) with 2.4mL catalyst samples with particle size of 60-100 mesh. The simulated flue gas composition was as follows: 600ppmNH_3, 600ppm NO, 5%O_2, 200ppm SO_2(when used), and balance Ar. The concentrations of NOx before and after reaction was determined by a flue gas analyzer (Model 60 I, Thermo Fisher Scientific Inc.). X-ray photoelectron spectroscopy (XPS) was performed on an AXIS-NOVA (Kratos, Inc.) by using 300W AlK radiation.

Results and discussion

2.1 Characterizations

The textural properties of the catalyst samples are listed in Table 1. It is clear that Ce-Fe-TiO_2 and Ce-Fe-TiO_2-S(By Ce-Fe-TiO2 catalyst forming in the sulfur dioxide poisoning) is of the largest BET surface area and total pore volume among the three samples. And the difference in the average pore diameter is also obvious: Ce-TiO_2>Ce-Fe-TiO_2 and Ce-TiO_2-S(By Ce-TiO2 catalyst forming in the sulfur dioxide poisoning)>Ce-Fe-TiO_2-S. That is to say, different components catalysts have impact on the textural properties of catalysts .

Table 1. Textural properties of the catalyst samples

Samples	BET surface area (m^2/g)	Total pore volume (cm^3/g)	Average pore diameter (nm)
Ce-Fe-TiO_2	46.8713	0.035611	34.7913
Ce-TiO_2	31.5262	0.010775	38.9864
Ce-Fe-TiO_2-S	81.4939	0.246598	10.6511
Ce-TiO_2-S	80.0124	0.284306	12.7842

XRD patterns are shown in Fig.1. It is obvious that Ce-Fe-TiO_2 and Ce-TiO_2 is similar.So that the activity of Ce-Fe-TiO_2 and Ce-TiO_2 catalysts are similar.There are several peaks of CeO_2, Fe_2O_3,Fe_3O_4,rutile and TiO_2 can be observed in the spectrum of Ce-Fe-TiO_2 and Ce-TiO_2, but the Ce-Fe-TiO_2-S and Ce-TiO_2-S intensities are very low. Because, the surface of catalysts is encased by sulfur dioxide . As a whole, CeO_2, Fe_2O_3,Fe_3O_4 and rutile are well dispersed on the surface of TiO_2, which means strong interaction between the active components and the support. As for the two samples, the diffraction peaks of CeO_2, Fe_3O_4 and TiO_2 are more apparent compared , and the crystallinity of CeO_2, Fe_3O_4 and TiO_2 is very high. The amorphous CeO_2-TiO_2 and Fe-TiO_2 is believed to be beneficial to SCR reaction[6,7] .

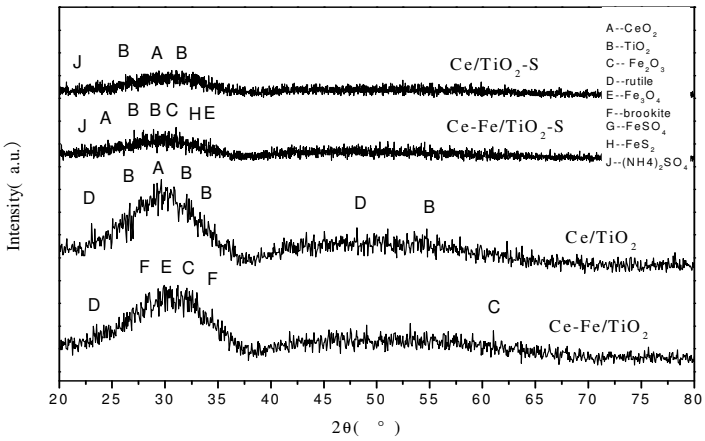

Fig.1 XRD Patterns of the Ce-Fe/TiO_2 and Ce/TiO_2 catalysts

NH_3-TPD profiles of the Ce-Fe/TiO_2 catalysts are shown in Fig.2. It is clear that there are different acid sites of different strength on each sample. Ce/TiO_2 has three desorption peaks, the first one centered at about 175℃ and the second one centered about 650℃ could be assigned to Brönsted acid sites[9]. And the third one may be linked to Lewis acid sites[5].As for Ce-Fe/TiO_2, desorption peaks belong to Brönsted acid sites and Lewis acid sites can also be observed in their NH_3-TPD profiles. In addition, the total surface concentration of acid sites of the two samples are calculated and the results are listed in Table 2. Table 2 shows that Ce-Fe/TiO_2 is of the strongest surface acidity, indicating its strongest NH_3 adsorption capacity. And high NH_3 adsorption capacity can promote SCR reaction[10].And the two catalysts have the similar characterizations after sulfur dioxide poisoning because of encased by sulfur dioxide.

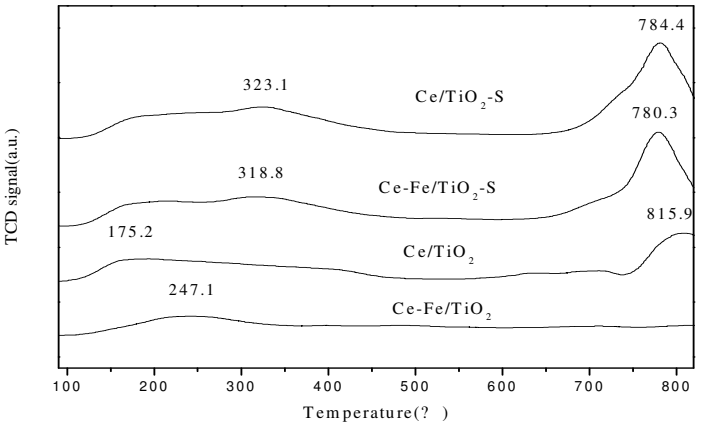

Fig.2 NH_3-TPD profiles of the Ce-Fe/TiO_2 and Ce/TiO_2 catalysts

Table 2. Surface acidity of the catalyst samples

Samples	Surface acidity(mmol/g)
Ce-Fe-TiO_2	5.57
Ce-TiO_2	4.97
Ce-Fe-TiO_2-S	8.69
Ce-TiO_2-S	8.38

H_2-TPR profiles of the four catalysts are shown in Fig.3. It could be seen that there is one reduction peak in the TPR profile of each catalyst sample. The reduction peak in the TPR profile of Ce/TiO_2 centers between 600-700℃ might be linked to the reduction of non stoichiometric ceria of type Ce^{3+}–O–Ce^{4+}[11]; the peak centered at about 500 ℃ in the profile of Ce-Fe/TiO_2 belongs to the

reduction of Fe_2O_3 and FeO. In addition, the Ce-Fe/TiO_2-S and Ce/TiO_2-S catalysts lead to a shift of reduction temperature to a higher value, which the process may be explained that sulfate species deposit on catalyst surface at low temperature, and catalytic active center is covered[12]. And the redox ability of the two catalyst samples is in the following order: Ce-Fe/TiO_2> Ce/TiO_2.

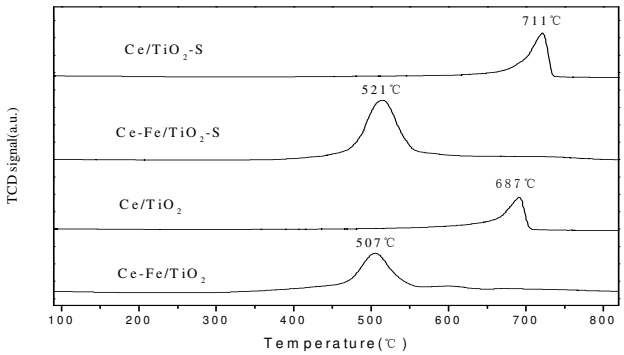

Fig.3 H_2-TPR profiles of the Ce-Fe/TiO_2 and Ce/TiO_2 catalysts

XPS:O1 s spectra of the two catalyst samples are shown in Fig.4. Fig.4 shows that the O1 s profiles of the two samples can all be fitted three peaks. The three peaks can be assigned to: lattice oxygen O_α (529.9-530.0eV), chemisorbed oxygen O_β (531.3-531.9eV) and hydroxyl groups O_γ (532.7-533.5eV)[13]. As can be seen from Fig.4, the concentration of chemisorbed oxygen is in the following sequence: Ce-Fe/TiO_2>Ce/TiO_2 . It has been reported that chemisorbed oxygen is of the highest activity among oxygen species in the SCR reaction[14]. The presence of so high concentration of chemisorbed oxygen in CCA(SG) would be helpful to enhancing its SCR performance.

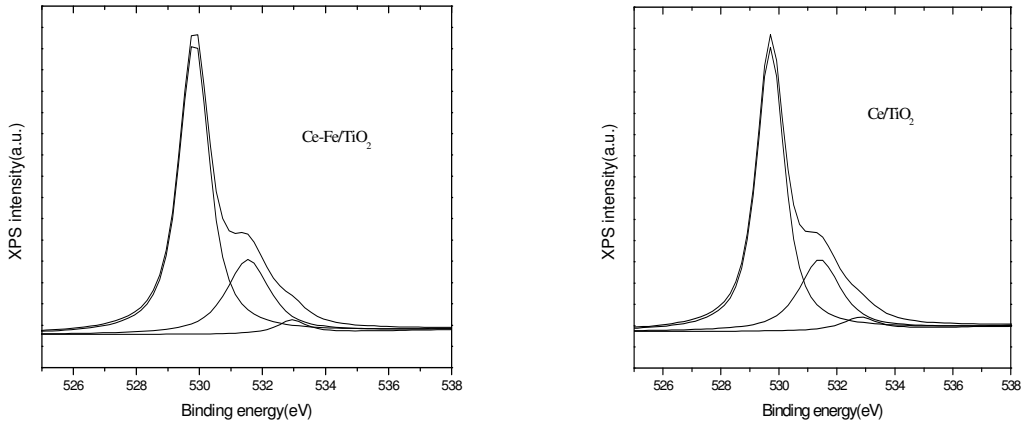

Fig.4 O1s spectra of the Ce-Fe/TiO_2 and Ce/TiO_2 catalysts

2.2 Catalytic activity

The NO conversions over the two catalyst samples at different reaction temperature are shown in Fig.5. It is obvious that the two catalyst samples show the best similar performance in the whole temperature range. And Ce-Fe/TiO_2 and Ce/TiO_2 , a decrease of NO conversion can be observed when the reaction temperature exceeds 330℃. A similar phenomenon was also found by Gao et al. [1] when they studied NO conversion over CeO_2/TiO_2 catalyst, which be may be caused by NH_3 oxidation to NO at high temperature. And the high NO conversion of the two catalyst samples maybe caused by CeO_2 ,and Fe_3O_4 maybe not influence the NO conversion. As shown in section 3.1, large surface area, well dispersion of CeO_2, high NH_3 capacity and high concentration of chemisorbed oxygen may be the main reasons for its best SCR performance.

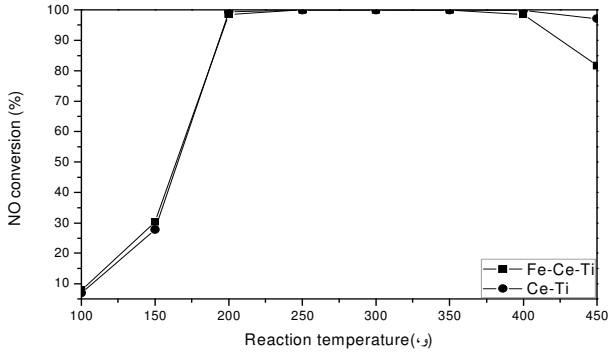

Fig.5 NO conversion as a function of reaction temperature for different catalysts
Reaction conditions: [NO]=[NH_3]=600ppm, [O_2]=5%, total flow rate =1L/min, GHSV=25,000h^{-1}

2.3 Effect of SO_2 on the catalytic activity

Effect of SO_2 on NO conversion over the two catalyst samples is shown in Fig.6. It is obvious that SO_2 has an inhibition effect on the performance of the catalysts, and the effect of SO_2 on the catalytic activities of the two samples is quite different. While Gao et al. [6] had reported that SO_2 can enhance the activity of Ce-Cu-Ti oxide catalyst, the difference may be caused by the presence state of Cu species in the catalysts. From Fig.6, it can be seen that NO conversion decreases about 41% in 5h for Ce/TiO_2, while the NO conversion of $Ce\text{-}Fe/TiO_2$ decrease after piped SO_2 between 60 and 90 minutes, after 90 minutes the NO conversion of $Ce\text{-}Fe/TiO_2$ rises to about 98%,and Liu et al.[7] had reported that the sulfate species was mainly formed on iron sites in a chelating bidentate conformation, resulting in the higher binding energies of Fe 2p and Ti2p due to the inductive effect of the S==O double bond . That is to say, $Ce\text{-}Fe/TiO_2$ has the best SO_2 resistance ability among the two sample. According to the results of BET and XRD, the inhibition effect of SO_2 on Ce/TiO_2 may be weakened by the strong interaction between active components.

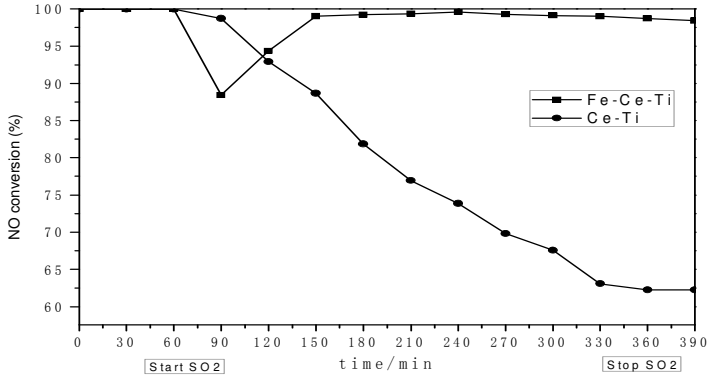

Fig.6 Effect of SO2 on NO conversion over different catalyst samples
Reaction conditions: [NO]=[NH_3]=600ppm, [O_2]=5%, [SO_2]=200ppm, total flow rate =1L/min, GHSV=25,000h^{-1}, reaction temperature 250℃

Conclusions

The performance of $Ce\text{-}Fe/TiO_2$ and Ce/TiO_2 catalysts were investigated and discussed based on the characterization results. It was found that the two catalysts showed the best SCR activity and $Ce\text{-}Fe/TiO_2$ showed the best SO_2 resistance. Large surface area, high NH_3 adsorption capacity and high concentration of surface chemisorbed oxygen should be the main reasons for its excellent performance.

Keywords: conglomerate reservoir, mobility, compatibility, injection parameters

Abstract. The conglomerate reservoir is provided with strong heterogeneity and complex pore structure. To study the matching relationship between polymer flooding system and pore throat of the conglomerate reservoir and set up the flow matching relationship plate, this paper conducted natural core flow experiments at the true flow rate of the site formation based on constant pressure flooding method, considering the shear of the borehole and the formation. And several suitable polymers for different reservoirs permeability were given. The experimental results indicated that a positive correlation between the flow properties and the viscosity of the polymer solution, but a negative correlation between the mobility and the permeability of reservoir. Such as the natural core with the permeability = $30\times10^{-3}\mu m^2$ was suitable for the viscosity$\leqslant$16.0 mPa·s of the polymer solution in the formation, the natural core with the permeability = $60\times10^{-3}\mu m^2$ was suitable for the viscosity$\leqslant$35.2mPa·s of the polymer solution and the natural core with the permeability = $120\times10^{-3}\mu m^2$ was suitable for the viscosity $\leqslant$ 102.4mPa·s of the polymer solution. Using compatibility relationship, quickly and easily choose the right injection parameters of the polymer based on the reservoir permeability, providing a theoretical basis for program preparation and parameters adjustment of the polymer flooding.

Introduction

Compared with sandstone reservoirs, conglomerate reservoir with features of complex structure and uneven distribution of pore[1,2], small diameter of throat and big throat to pore ratio has bad physical property. So study on the compatibility between displacement system and conglomerate reservoir becomes difficult. The traditional research methods were mathematical method, atomic force microscopy (SEM) and dynamic light scattering (DLS) [3,4], but the results obtained from them have some limitations. The block of displacement system in farther formation occurs frequently because of serious permeability differences however the displacing phase was injected into immediate vicinity of wellbore easily. In this paper, natural core flow experiments under the condition of deep formation pressure gradient based on constant pressure flooding method were conducted to study on the matching relationship between displacement system and the father

formation, providing guidance and research methods for field application to select suitable polymer system for reservoir with different permeability.

Experimental materials and equipment

1.1 The experimental materials and conditions

(1) Polymer: XinJiang oilfield using polymer, molecular weight are 600×10^4, 1000×10^4, 1500×10^4, 2000×10^4, 2500×10^4 respectively, the solid content is 90%;

(2) Xinjiang oilfield injection water, water salinity and ion composition are shown in table 1;

Table 1 Ion composition of dilution water

water quality	Cl^-	$SO4^{2-}$	HCO^{3-}	K^++Na^+	Ca^{2+}	Mg^{2+}	Total salinity(mg/L)
injected water	103.0	33.7	146.7	55.3	58.0	8.4	405.2

(3) Experimental model: use natural core, The size isΦ3.8×10cm, core permeability are $30\times10^{-3}\mu m^2$, $60\times10^{-3}\mu m^2$and $120\times10^{-3}\mu m^2$;

(4) The experimental temperature: 34.3℃.

1.2 Experimental apparatus

(1) FY-3 type constant temperature box, the control precision of +/-1℃;

(2) Waring blender, speed is divided into 7 files;

(3) Precision pressure regulator, the adjusting range of 0.05 to 0.4 MPa, 0.0008 MPa accuracy;

(4) Pressure sensor: the maximum range is 0.2 MPa, precision to 0.001 MPa;

(5) Brookfield DV-typeII+Pro BROOKFIELD viscometer;

(6) Cylinders, container, etc.

Experimental methods

2.1 Shear simulation

Before it is injected into the deep reservoir area, the polymer solution goes through the high-speed shear of wellhead and the near-wellbore. This study using Waring blender, design a shear simulator of the near-wellbore, with the shear strength of viscosity 50% lost after shear, which is the same shear strength as the spot water compounding water diluting molecular weight of polymer solution after the shear of wellhead and the near-wellbore. All the polymer solution involved in the experiment is shared by the simulator, in order to simulate the spot which the polymer solution was shared in the wellhead and the near-wellbore before entering the deep reservoir.

2.2 Determine the constant pressure method

Due to the match object is deep reservoir area with low and little change pressure gradient value,and approximate it constant, so we use the constant pressure gradient method.

2.3 Quantify stable flow velocity of the producted end

According to field experience, in deep reservoir area polymer solution actual flow velocity is 0.2m/d.

2.4 Calculate the actual pressure gradient in deep reservoir

According to field experience, the actual field with the well spacing 200m of reservoir deep area，the average pressure gradient is about 0.12MPa/m.

2.5 The determination methods of liquidity

Use The nature core with the constant pressure gradient 0.12MPa/m, inject the polymer solution for evaluation, record the outlet volume with the injection PV, then calculate the matching flow velocity in the formation.

Experimental result

3.1 The influence of polymer molecular weight on the mobility

The results of the core flow experiments showed that the greater the molecular weight of the polymer, the more difficult the polymer flowed in the core because the polymer solution was a kind of viscoelastic fluid, the ability flow into the throat became worth with the molecular weight of the polymer increased[5,6].

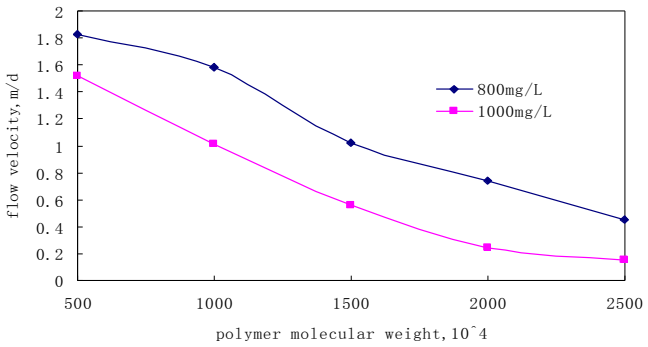

Figure1 Mobility experimental results in 100md cores

3.2 The influence of polymer concentration on the mobility

The results of the core flow experiments also showed that the greater the polymer concentration, the bigger the viscosity of the polymer solution was and the worse the ability of the polymer flowed into the throat was.

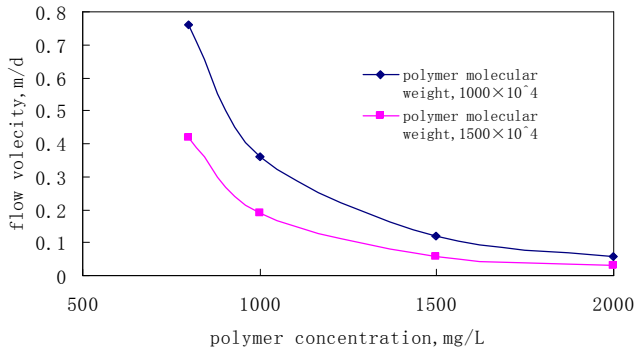

Figure2 Mobility experimental results in 50md cores

3.3 Establishing the matching relationship chart of the polymer system and reservoir permeability

Based on the real formation flow rate 0.2m/d, we establish the matching relation chart of different polymer system in effective permeability 30mD, 60mD and 120mD cores, with the polymer molecular weight of 600×10^4, 1000×10^4, 1500×10^4, 2000×10^4, 2500×10^4, at a concentration of 800mg/L, 1000mg/L, 1500mg/L, 2000mg/L, respectively. The result shows that Permeability of $30\times10^{-3}\mu m^2$ natural core requires polymer solution viscosity no more than 16.0mPa·s at formation, and the polymer solution viscosity should be equal or lesser than 35.2mPa·s at $60\times10^{-3}\mu m^2$ natural core, and the $120\times10^{-3}\mu m^2$ cores require polymer solution viscosity no more than 16.0mPa·s at formation, respectively. The results are shown in Table 2, Table 3, Table 4.

Table2 Different polymer system with $30\times10^{-3}\mu m^2$ mobility compatibility chart

water quality	Concentration, mg/L / Molecular weight, $\times10^4$	800	1000	1500	2500
injected water	600	1	1	0	0

	2000	1	1	0	0
	2500	1	1	0	0

(0 represents bad matching;1 represents good matching)

Conclusions

(1) To evaluation liquidity of flooding system in the core at the condition of deep formation, we adopt shear simulator and constant pressure gradient near wellbore area, which can better simulate the polymer solution flow state in deep reservoir.

(2) Under certain conditions of core permeability, with the increase of Polymer molecular weight and concentration, the mobility of polymer system turns bad. The mobility of polymer system depends on its molecular weight at a fixed permeability core.

(3) The matching relationship chart of the polymer system and reservoir permeability can guide the plan for polymer flooding program and adjustment of injection parameters, which can help to determine polymer injection parameters.

Keywords: Heterogeneity, Fuyu Reservoir, Chao 45 block, Remaining oil

Abstract. Based on analyzing and testing the core samples of three inspection wells, we research in-layer heterogeneity of the main types monosandbody; in order to build macroscopic analysis on the difference of physical properties in reservoir interbedded, we can also draw distribution diagram of the interbedded sandstone's average porosity and permeability through the physical property data in the study area, meanwhile it is necessary to use statistic data of physical parameters including variation coefficient, mutation coefficient and range to draw tables, which can show the degree of heterogeneity of monosandbody in the reservoir become much stronger from top to bottom; In addition, according to the study of plane microfacies and monosandbody, the information relating to the heterogeneity of the main monosandbody can be acquired. In conclusion, it is clear to know the distribution characteristics of remaining oil deriving from FuYu oil layer in the Chao 45 Block, and the distribution area of residual potential of microfacies by reducing the heterogeneity of reservoir to improve the connectivity, and then increase the mining effect.

Introduction

Reservoir heterogeneity is refers to the basic properties of the reservoir (lithology, physical property, electric property and oiliness, etc.) on the 3D spatial distribution of heterogeneity[1-6]. Under the influence of structure, diagenesis and reservoir sedimentary environment, the interior of the reservoir physical properties and spatial distribution of non-uniform changes, which make the underground oil, gas, water sports and oil and gas recovery factor affected, so studying the reservoir heterogeneity has an important significance on oil and gas drilling and the evaluation of reservoir remaining oil.

General situation in the study area

Chao 45 block is located in south Chaoyang block oil field in pure oil region, exploited horizon is fuyu oil reservoir, oil bearing area is 2.0 km^2, geological reserves is 184×10^4t. Fuyu reservoir is in Songliao basin in middle-late development which as a predominantly fluvial-dominated delta deposits , the upper delta front subfacies and lower delta distributary plain subfacies.

Reservoir heterogeneity

Heterogeneity in reservoir layer upon layer. Through core observation description and on the basis of single well facies analysis, we draw the conclusion: The development of Fuyu reservoir is delta front subfacies, delta distributary is plain subfacies, sand body reservoir is mainly distributary channel, at the same time, it develops sedimentary microfacies of crevasse-splays and natural levees, including fuyu oil layer stranded at the bottom of the underwater distributary channel deposits in this

area is mainly calcium nodules[7], controls the sand body vertical permeability is positive and negative are more complex rhythm, also often appear positive rhythm. The following is the area of backward and forward in the small layer composite rhythm to be analyzed.

Typical analysis of the heterogeneity in single sand layer. For the 103-55 Coring Wells on F Ⅰ 2^2 depositional time unit as an example, F Ⅰ 2^2 depositional time unit representative microfacies types are high sinuosity distributary channel microfacies, delta front is a typical microfacies types. Property vertical sequence of sequence is controlled by sedimentary and lithology , the field logging data, the permeability sand body as a whole for a f positive and negative in the layer composite rhythm, 45 block in fuyu reservoir is the distributary channel micro phase extremely typical type of rhythm. According to mechanical analysis, the interior is divided into seven secondary rhythm (figure 1), with the thinnest 52 cm, upper and lower porosity is the rhythm of negative and positive , lower and upper permeability is the rhythm of negative and positive, secondary rhythm thin interbedded easily identified from the log.

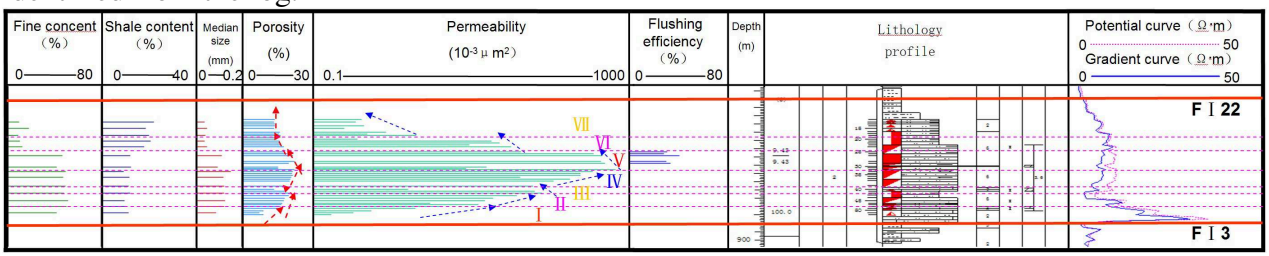

Fig. 1 Heterogeneity analysis of unit F Ⅰ 2^2

Within the depositional time unit, shale content showed a trend of positive and negative rhythm and silt content showed a trend of positive and negative rhythm and fine content was positively rhythm trend, medium sand content showed a trend of anyway, rhythm and the lower layer is thin coarsen and then gradually tapering upward, permeability showed a trend of anyway, a negative and positive rhythm, and the granularity has corresponding good rhythm, but no significant vertical variation of porosity, the layers of inner heterogeneity is strong.

The permeability in this layer shows the positive rhythm, water absorption on the lower layer is stronger than upper one in the permeability of positive rhythm on the above layer . Lots of injected water crashed into the lower part of the bottom quickly through the high permeability zone .At the same time, gravity and then put into the upper injection water sinks and more contributed to the level of the water flowing and water washing at the bottom of the reservoir . And the permeability of the in turn rhythm layer is Under the low high above , the layer of high permeability water absorption, upper infiltration gradually, but as a result of injected water by gravity makes less water washing to strengthen in the bottom of the reservoir .The result that the lower interval section water to wash up and down differences .In conclusion, the water in the small layer thickness distribution on the bottom, controlled by the heterogeneity, predict remaining oil throughout the layer on top of the underwater distributary channel.

Interlayer heterogeneity

Refers to the reservoir sand body on longitudinal and physical properties of the differences between distribution characteristics, on the other hand refers to the distribution and the change of the mudstone interlayer between each group .In the layers of mudstone interlayer distribution change law is not obvious, here we focus on physical differences between the study of sand body. The property differences between layers including the differences of porosity and permeability , the permeability differences between interlayer usually use parameters such as coefficient of permeability differential, coefficient of variation, dash coefficient to show[8]. The vertical distribution of oil and gas, the condition of water between the upper and remaining oil distribution are different due to the Interlayer heterogeneity.

Physical differences between the layers. Each layer of fuyu oil layer in the study area vertical relatively has little change of porosity, the average porosity is above 15%; Vertical permeability changes are very different, The property of two depositional time unit F Ⅰ 2^2 ,F Ⅰ 3^2 is best, Permeability in more than $20\times10^{-3}\mu m^2$, As the neutral pore of low permeability reservoir, Permeability of the adjacent vertical F Ⅰ 3^2 quickly reduced. The property the differences between the layers shows that F Ⅰ 2 and F Ⅰ 3 have a better ability to control the oil and gas gathering; The rest of the average permeability basic depositional time unit is less than $9\times10^{-3}\mu m^2$, as a neutral pore of low permeability reservoir. Depositional time unit property of F Ⅱ 1^1 is relatively poor, The average porosity is 13.3%, the average permeability is $4.9\times10^{-3}\mu m^2$,Under the influence of the neutral hole in the low permeability reservoir, by combining with valid for alloy layer sandstone thickness of the two vertical adjacent time units for the further investigation.

The main unit plane heterogeneity. Plane heterogeneity is due to the geometry of sand body, the size of continuity, porosity and permeability, the plane changes [9].Fuyu oil layer planar sand body and heterogeneity is mainly controlled by sedimentary microfacies distribution, so the characteristics of layer heterogeneity distribution basic consistent with the plane distribution of sedimentary microfacies, phased by the plane can further determine the distribution of remaining oil in the area of sedimentary units, which can be through the volume method to calculate geological reserves, residual oil reserves in the entire block, prediction and evaluation.

According to layer data of 103-55 well on Unite F Ⅰ 7^3 to make the contour map(figure 2).

Boundaries of the sand body is not necessarily strictly stuck in hierarchical boundary, the condition of the cross, this need split, sandstone finally get effective sandstone thickness 10.2 metres at the last(10C98-60 Wells), which is 4.56 meters thick, on average, value distribution in 3-5.2 meters, about 24%, low distribution at 0-0.8 m, about 15%, mainly distributed in 1.2-2.4 meters, about 61%. Figure sandstone in the high value area even lamellar distribution in all those places, 10C106-49, 10C106-50, 10C106-52, 10C106-54. Along the river, gradual trend, effective thickness change controlled by the river. Which can be further, effective sandstone thickness according to the channel boundary preliminary qualitative outlined the distribution of remaining oil in the sedimentary unit boundaries, to guide in the process of oilfield production, play an important role of remaining oil exploration and exploitation.

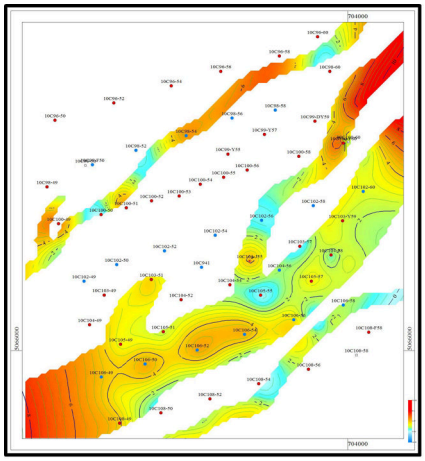

Fig. 2 Isogram of effective sand thickness with facies controlled on Unit F Ⅰ 7^3

Summary

The reservoir development of 45 block in Chaoyang ditch oilfield in delta front subfacies, delta distributary plain subfacies, reservoir mainly underwater distributary channel sand body. In which Fuyu oil layer stranded at the bottom of the underwater distributary channel deposits in this area is given priority to with calcium nodules, what controls the sand body vertical permeability is always backward and forward composite rhythm, also often appear forward rhythm. Thus controlled by the heterogeneity strongly, the remaining oil distribution in the top of the underwater distributary channel.

Intraformational heterogeneity of fuyu reservoir is mainly controlled by sedimentary facies, FⅠ oil reservoir group of delta front subfacies sand body heterogeneity is strongest. The other two reservoir group FⅡ and FⅢ delta distributary plain subfacies sand body heterogeneity more weak. Residual oil is generally a lot of focus on relatively strong heterogeneity and the horizon of relatively poor physical properties.Therefore, by the property differences between layer and interlayer heterogeneity parameters, The two layer FⅠ2, FⅠ7 is the main horizon of enrichment of remaining oil, as an important horizon for oilfields to explore.

For 103-55 wellblock on Unit FⅠ7^3 depositional time of sand body as an example, According to the purpose of effective sandstone layer logging data compiled river phased effective sandstone thickness contour map, depend on the river boundary and effective sandstone thickness boundary preliminary qualitative we can further outlined the distribution of remaining oil in the sedimentary unit boundaries, as the guidance in the process of oilfield production and remaining oil potential.

Aiming at Chaoyang ditch oilfield reservoir with characteristics of low porosity, low permeability and reservoir heterogeneity. such as fracturing, bentonite and separate injection measures should be taken, by lowering the reservoir heterogeneity, improving connectivity, we can improve the development effect.

Keywords: Sodium metatungstate, Rheological properties, Apparent viscosity, Herschel-Bulkley model.

Abstract. Sodium metatungstate (SMT) solution is an inorganic heavy liquid which is widely used in density fractionation. However, rheological properties of aqueous SMT solutions have never been fully researched. The objective of the present work was to study the rheological properties of aqueous SMT solutions and effects of temperature and density on the apparent viscosity. The steady flow experimental data was fitted using Herschel-Bulkley model. The results show that aqueous SMT solutions of different density are pseudoplastic fluids and the flow curves of SMT solutions were described by the Hershel-Bulkley equation. The apparent viscosity decreases monotonically with increasing temperature under the same density and increases exponentially with increasing density at the fixed temperature. Rheological properties of aqueous SMT solutions can be applied in the calculation of density fractionation efficiency and provides a theoretical basis for flow simulation.

Introduction

Sodium metatungstate (SMT) has the formula of $Na_6O_{39}W_{12}$ with a molecular weight of 2986.12 $g \cdot mol^{-1}$. It is extremely soluble in water giving neutral solutions and it is possible to achieve solution of very high density (3.12 $g \cdot cm^{-3}$ at 298.15 K). SMT solutions are nontoxic and tasteless inorganic heavy liquid with high stability [1]. SMT was started to be used in density fractionation of macromolecule in physical chemistry and cell separation in biological sciences from the mid-1980s [2,3], and then its application was expanded into various areas, such as density fractionation of organic matter in soil science [4-7], riverbed sediments in hydrology and water resources [8,9], marine microbes in marine science [10,11], and minerals in geology which is the most widely used application [12-15].

There are no special requirements on efficiency of density fractionation and the amount of SMT needed at the laboratory scale is very small. However, with the advancement of engineering in density fractionation and computer simulation of density fractionation, study on rheological properties of SMT solutions is becoming more and more important. The viscosity of aqueous solutions of SMT at the molalities (0.0055 to 1.73) $mol \cdot kg^{-1}$ were measured at 5 K temperature intervals from 288.15 to 308.15 K [16]. However, the measured viscosity values were dispersed and research on rheological properties of different substances in SMT solutions for their separation is far from enough. And rheological properties of SMT solutions were not researched in this paper as well.

In the present study, the rheological properties of SMT solutions were measured with Brookfield DV-Ⅱ+ viscosimeter and Ultra-low viscosity adapter. The effects of temperature and density of aqueous SMT solutions on the apparent viscosity were investigated. The research provides a theoretical basis for dynamic analysis in density fractionation process and flow field simulation of aqueous SMT solutions flowing in vessel and pipeline.

Experimental section

Materials. Sodium metatungstate hydrate 2.82 $g \cdot cm^{-3}$ density solution in water was obtained from J&K Chemical Ltd. Bidistilled water was used in all experiments.

Instruments. The rheological properties and viscosity were measured using Brookfield DV-Ⅱ Pro viscosimeter with ultra-low viscosity adapter. Accuracy of viscosity measurement was ± 1% of measurement range from 1 to 20 mPa·s and repeatability of viscosity measurement was ± 2%. The instrument has a built-in thermostat to maintain the temperature of solutions between -15 and 100 °C with a precision of ± 0.1 °C. The instrument required a liquid volume of about 16 ml and measured the viscosity after a thermal equilibration period of 10 min.

Densities were measured by Sartorius Cubis® MSA224S-000-DA electronic analytical balance, Shenzhen Ater DZF-6210 vacuum drying box, Blaubrand® volumetric flasks and transferpette® digital pipettor from Brand Tech Scientific Inc. The uncertainty of weighing data of balance is 0.1 mg and the repeatability and nonlinearity of balance is below 0.1 mg and 0.2 mg, respectively. Weighing capacity of balance is 220 g. Stability of temperature control to the volatility of vacuum drying box is within 1.0 ˚C from 10-250 ˚C in vacuum of below 133 Pa. The volumetric flask has a capacity of 10ml with the upper/lower mark is ± 0.07 ml. The pipettor has range of 5 ml with accuracy 30 μl and relative deviation 10 μl.

Preparation of aqueous SMT solutions. The mass of SMT and the volume of water in aqueous SMT solutions were calculated according to the data shown in Table 1 [17] and the volume of the desired aqueous SMT solutions. Firstly, distilled water was added to the SMT solution at a density of 2.82 $g \cdot cm^{-3}$ by stirring, and then the obtained aqueous SMT solutions were calibrated using the electronic analytical balance and the volumetric flask. A suitable amount of distilled water or stock solution might be added into the obtained solution according to the calibration to get the desired aqueous SMT solutions. The obtained desired SMT solutions of different density were stored in volumetric flasks. The density of the SMT solutions should be measured again before each use and distilled water or SMT solution might be added into the obtained solutions according to the measured density.

Table1
Composition of aqueous SMT solutions of different density

ρ/g·cm^{-3}	SMT/g	Distilled water/mL	ρ/g·cm^{-3}	SMT/g	Distilled water/mL
2.25	700	300	2.50	772	228
2.30	723	277	2.60	790	210
2.35	740	260	2.80	820	180
2.40	752	248	3.00	850	150

Rheological property testing. SMT solutions of different density were taken into low viscosity meter adapter outer cylinder. The desired temperature was adjusted in a water bath to maintain a constant temperature for at least 15 min. Then the rheological properties and viscosity were measured using Brookfield DV- Ⅱ Pro viscosimeter with ultra-low viscosity adapter.

Results and Discussion

Rheological curves and model of aqueous SMT solutions. The relationship between viscosity and shear rate of different fluids is various and thus the rheological curves are distinct as well. In the present work, a shear stress *vs.* shear rate plot for aqueous SMT solutions at different density and temperature is shown in Fig. 1.

Herschel-Bulkley model shown in Eq. (1) was adopted to fit the rheological curves in Fig. 1, where τ is shear stress (Pa), γ is shear rate(s^{-1}), τ_0 is the parameter defined as yield stress (Pa), K is consistency coefficient ($Pa \cdot s^n$), which indicates fluid flow property, and n is the flow property index. In general, a fluid is pseudoplastic fluid if its flow property index is less than 1.

$$\tau = \tau_0 + K\gamma^n \tag{1}$$

As shown in Fig. 1, the shear stress of SMT solutions of various density first increases sharply with the increase in shear rate, and then the rising rate is reduced gradually but still maintains positive in

the test shear rate range. Moreover, SMT solutions of greater density tend to have higher shear stress at the same shear rate, including when shear rate is zero. According to Fig. 1 and the above discussion, it can be concluded that SMT solutions exhibit the characteristics of pseudoplastic fluids.

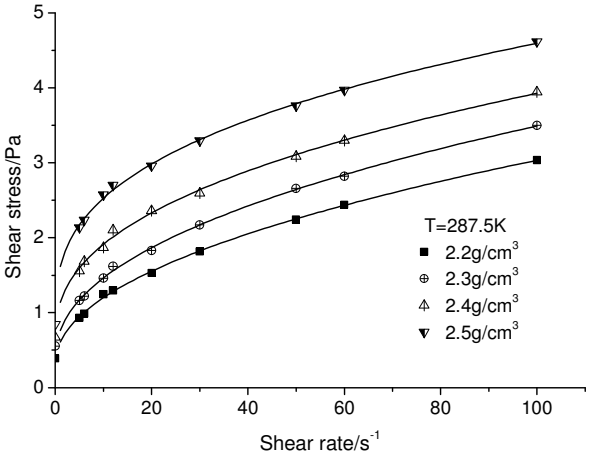

Fig. 1 Rheological curves of aqueous SMT solutions at different density

Using the measured shear stress and shear rate, fitting results of rheological curves in Fig. 1 of SMT solutions at 287.5 K can be obtained and are listed in Table 2. As can be seen from Table 2, the value of n decreases from 0.49132 to 0.35436 and the value of K increases from 0.28175 to 0.72461 with increasing density, which indicates that the non-Newtonian property of the system is intensified, the viscosity is higher and the mobility is worse. Due to the molecular attraction among molecules and ions in SMT solutions, the system is arranged in spatial structure. Only when fluid shear stress exceeds yield stress τ_0, intermolecular forces can be destroyed and the solution can flow. It can also be seen from Table 2 that the value of τ_0 for SMT solutions at different density is very small, which demonstrates that although molecular attraction exists in SMT solutions, the intensity of the formed spatial net structure is weak.

Table2
Fitting results of rheological curves of aqueous SMT solutions at different density at 287.5 K

ρ/g·cm^{-3}	$\tau_0 \pm \sigma_{\tau 0}$	$K \pm \sigma_K$	$n \pm \sigma_n$	r^2
2.20	0.03262±0.00086	0.28175±0.00473	0.49132±0.00304	0.99881
2.30	0.03909±0.00126	0.37097±0.00736	0.46106±0.00356	0.99839
2.40	0.06470±0.00247	0.48786±0.01576	0.41379±0.00558	0.99599
2.50	0.08892±0.00266	0.72461±0.01877	0.35436±0.00421	0.99768

Effects of temperature on the apparent viscosity of aqueous SMT solutions. The apparent viscosity was plotted against temperature in Fig. 2 and then the measured experimental data were regressed linearly respectively according to Eq. (2) to determine a, b parameters at each density studied. Linear fitting results are given in Table 3.

$$y=ax+b \tag{2}$$

It is observed from Fig. 2 that the temperature has a great influence on the apparent viscosity and the apparent viscosity decreases linearly with the increase in temperature. Moreover, the apparent viscosity increases with the increase in the density if the temperature is constant. As can be seen from the negative fitting straight slopes (parameter a) in Table 3, the greater the density, the faster the apparent viscosity falls with the increase in the temperature. It can also be seen from Fig. 2 that molecule structure or aggregate state in SMT solutions did not change in the range of test temperature. The decrease of the apparent viscosity resulted from the increase in intramolecular energy and the temperature, and the decrease of intermolecular forces.

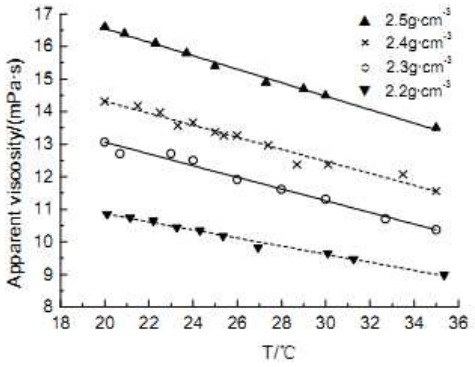

Fig. 2 Viscosity curves of aqueous SMT solutions at different density

Table 3
Linear fitting results of aqueous SMT solutions at different density and 287.5K

ρ/g·cm^{-3}	a	b	r^2
2.50	-20.6958±0.1457	0.2074±0.0055	0.994
2.40	-18.0409±0.2570	0.1846±0.0096	0.968
2.30	-16.6452±0.2454	0.1796±0.0091	0.980
2.20	-13.4168±0.1275	0.1308±0.0049	0.988

Effects of density on the apparent viscosity of aqueous SMT solutions. It is obvious from Fig. 3 that the density plays an important role in the apparent viscosity of SMT solutions. To be more specific, the apparent viscosity increases slowly first and then increases quickly with the increase in the density at different temperature. Additionally, if the density is fixed, the apparent viscosity decreases with the increase in the temperature, and the apparent viscosity decreases faster with the increase in the temperature at higher density. Fitting results of 5 curves in Fig. 3 are obtained and shown in Table 3 according to Eq. (2) using the measured experimental data;

$$y=a+bx^c \tag{2}$$

where a, b and c are the parameters.

From Table 3, it can be seen that the apparent viscosity grows exponentially with the increase in the density at the same temperature, and the apparent viscosity increases faster with the increase in the density at lower temperature based on the c parameter, which demonstrates that molecule structure or aggregate state in SMT solutions did not change in the range of test temperature, and the increase of the apparent viscosity resulted from the increase in the density and intermolecular forces, and the decrease in intermolecular distance.

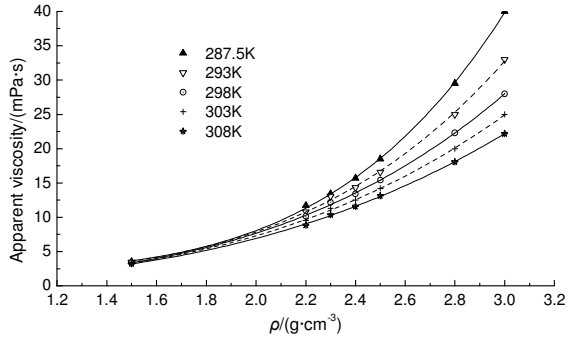

Fig. 3 Viscosity curves of aqueous SMT solutions at different temperature

Table 3
Fitting results of 5 curves ($y=a+bx^c$) in Fig. 2

T/K	a	b	c	r^2
287.5	2.0070	0.2628	4.5238	0.9983
293.0	1.5334	0.4134	3.9370	0.9942
298.0	0.7843	0.6543	3.3929	0.9994
303.0	0.6709	0.7200	3.2018	0.9994
308.0	0.5272	0.7879	3.0172	0.9996

Conclusions

Herschel-Bulkley model was adopted to fit rheological property curves of aqueous SMT solutions at different density with the fitting correlation coefficient r^2=0.99768~0.99881. Results show that SMT solutions at different density are pseudoplastic fluids.

At 287.5 K, the non-Newtonian property of SMT solutions increases with increasing density, the viscosity is higher and the mobility is worse. Molecules in SMT solutions attract each other and form spatial net structure of weak intensity.

The apparent viscosity of SMT solutions decreases with increasing temperature if the density is fixed and grows exponentially with increasing density if the temperature is constant.

Keywords: Pore-network; Digital core; Micro-CT; Maximal Ball algorithm; Pore-scale modeling

Abstract. In this paper, firstly, the X-ray micro computed tomography (micro-CT) is used for the analysis of internal structure of sand-packed beds. Binary data which are able to describe the pore structures of these beds were obtained from a series of imaging processing of rescaling, media filtering, and thresholding. Then a Maximal Ball (MB) algorithm is applied to these binary data to extract the equivalent pore networks. The parameters of the pore networks, such as radius, coordination number and shape factors of pore and throat are computed. The results demonstrate that the MB method can extract reasonable and faithful pore network of the different sand packed samples. Finally, the relative permeability and capillary pressure of drainage and imbibition cycle of water and oil are predicated. The numerical simulation results demonstrated good accordance with that of the experiments. Pore network simulation shows good results for two phase flow in porous media.

Introduction

The macroscopic properties of porous media such as porosity, permeability are related to their internal structures. In recent decades, pore network models that represent the void space of a rock by a lattice of pores connected by throats have been widely used as a platform of core analysis to predict multiphase flow. In this paper, an improved maximal ball method proposed by Dong et al. [1], has been used for pore network extraction. Because the parameters of extracted pore network have significant influence on the modeling of multiphase flow, it is necessary to investigate those influences of the pore network parameters. So this paper aims to compare the structure of pore networks of different sand packed samples, which are extracted from the micro-CT images using the maximal ball method. Through direct imaging, usually by micro-X-Ray computerized tomography (micro-CT), can obtain the pore-space geometry (i.e. digital cores) of rocks[2,3].The micro-CT imaging is considered the most direct and accurate way to construct pore geometry (digital core).Micro-CT allows samples a few millimeters across to be imaged nondestructively at a resolution of a few microns or submicron using nano-CT scanners[4].

Micro-CT scanning and imaging process

The parameters of samples are listed in Table 1.

Table 1 Parameters of four sand packed samples.

Samples	Diameter (mm)	Porosity (%)
BZ02	0.105-0.125	37.2
BZ04	0.350-0.500	37.5
BZ06	0.500-0.710	38.7

The images of samples are obtained through a desktop X-ray micro-CT. It is necessary to apply a series of filters to smooth the image, to reduce noise and improve the contrast between grain and void [5]. In this paper, the median filter is used to replace the gray scale value of a voxel by the median value of the nearest 26 surrounding cells. And then a threshold value based on the isodata algorithm

[6] is chosen to binarize or segment the gray scales into two phases: solid and void. At last, those black-white images are rescaled and normalize to be digital cores with the size of 248×248×248. The imaging process and all the reconstructed images of the three BZ sand packed samples and obtained digital cores from rescaling, median filtering, and segment are shown in Fig. 1.

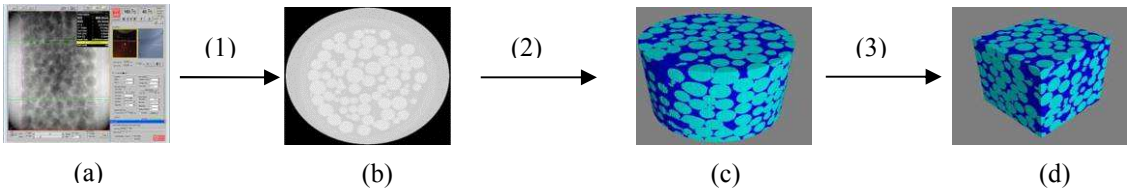

Fig. 1 The flow chart of image processing of BZ04 sand packed sample. (a) x-ray image, (b) CT image, (c) smoothing and segment, (d) rescaled digital core.

Pore-network extraction and flow simulation

In this study, the pore network extraction algorithm used to extract a topologically equivalent network of pores and throats from 3D micro-CT images is the Maximal Ball algorithm firstly used by Sillin et al. [7]. Flow simulation used to predicate the relative permeability and capillary pressure of the oil and water displacement is performed based on this pore network extraction[8]. The grade pore quasi static flow simulation model [9] was used for the flow simulation research. Pore-scale oil-water two phase flow simulation process is as follows: firstly, network model will be water saturated ,then oil drainage is performed until the experimental initial water saturation is reached; after the oil flooding process, oil and water contact angles of each pore and throat is adjusted, to simulate the changes of porosity wettability of cores after being invaded by oil. Finally, to simulate the process of water imbibition, inject water into the model, then calculate oil water relative permeability[10] .

In the simulation, single wetting system is used for all samples. To be specific, oil and water contact angles of all pores and throats are uniformly distributed. Decane is used in this flow simulation process. The parameters of two-phase fluid at room temperature are given in Table.2.

Table 2 Parameters of two-phase fluid in flow simulation

parameters	value
Water viscosity(cp)	1.005
Oil viscosity (cp)	0.93
Water density(kg/m^3)	998.2
Oil density(kg/m^3)	731.9
Interfacial tension(mN/m)	37.26*
Water wetting Angle	78.5*
oil wetting Angle	45.3*

* is laboratory measurements

Results and discussion

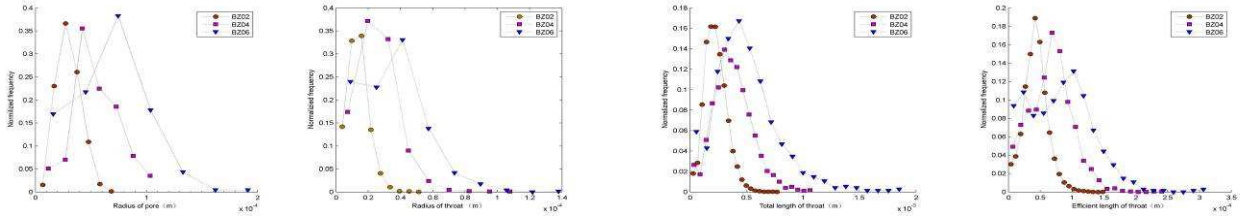
The properties of the extracted networks are listed in Table 3. In this part we compare the three samples in terms of connectivity (coordination number), size distributions (contains inscribed radii, volume, lengths of pores and throats), and shape factors.

Table 3 Properties of the pore networks extracted from four BZ sand packed samples.

Properties	Samples		
	BZ02	BZ04	BZ06
Porosity (%)	37.14	35.79	38.89
Ave. Coord. No.	7.60	6.86	6.20
Ave. pore radius 10^{-6}m	30.0	54.3	65.9
Ave. pore volume 10^{-12} m^3	1.36	6.96	16.7
Ave. pore shape facture (10^{-2})	2.28	2.11	2.22
Ave. throat radius 10^{-6}m	13.6	25.4	34.2
Ave. throat volume 10^{-15} m^3	37.4	230.0	489.0

By comparing Table 3 with Table 1, we can see that porosity of samples in pore-network extraction reaches basic agreement with results from CT scanning. Therefore, network modeling method established in this paper can preserve the fluid storage capacity ability of the core completely into the pore network model, which is of great significance in developing relative research based on network modeling with the aid of micro flow simulation technology (such as the remaining oil distribution, etc.).

Radii distribution of pore and throats for all the BZ samples are plotted in Fig. 2, respectively. There are two kinds of lengths of throat. The throat total length, is the distance measured form two pore centers that are linked by this throat. The throat efficient length is the length of a pure throat defined as equation calculated by Øren and Bakke [11]. Those two kinds of statistical data are shown in Fig. 3. The void space will become larger with the increase of diameters of sand packed samples. So the peaks of sizes (radii and length) of pores and throats have gradually shifted toward rights as the BZ02 to BZ06.

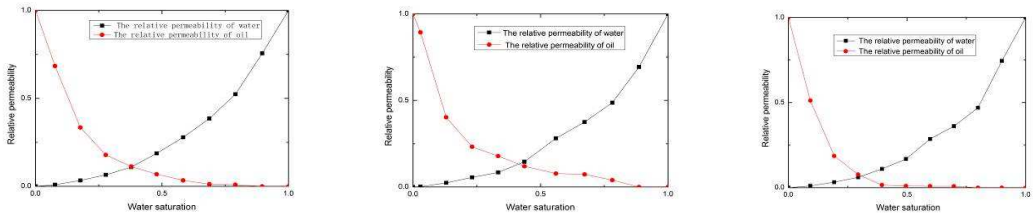


(a) (b) (c) (d)

Fig. 2 Distributions of inscribed radii of pores (a) and throats (b) for three BZ samples.

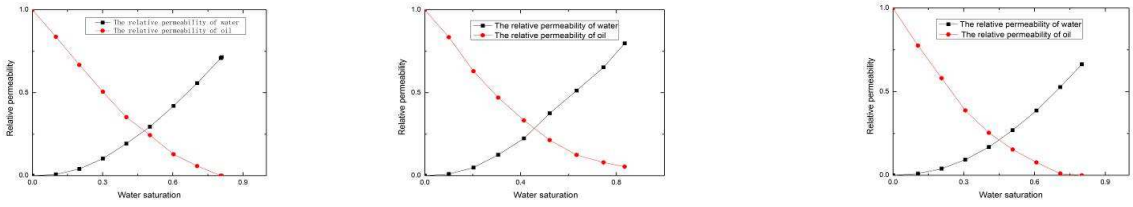
Fig. 3 Distributions of the total (c) and efficient (d) lengths of throats for three BZ samples.

The results of oil flooding and water flooding from pore scale flow simulation are listed in Fig. 4, Fig. 5 respectively. Capillary pressure of oil flooding and water flooding curved along with the water saturation are illustrated in Fig. 6(a) and Fig. 6(b) respectively.



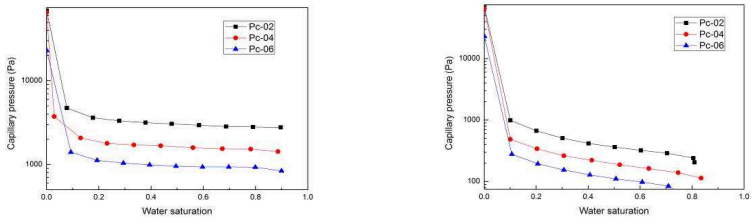
(a) BZ02 (b) BZ04 (c) BZ06

Fig. 4 Graphs of relative permeability (a), (b), (c) of oil flooding



(a) BZ02 (b) BZ04 (c) BZ06

Fig. 5 Graphs of relative permeability (a), (b), (c) of water flooding



(a) Capillary pressure of oil flooding (b) Capillary pressure of water flooding

Fig. 6 Graphs of Capillary pressure (a) and (b) of oil flooding and water flooding

As seen in the Fig. 4 and Fig. 5, the pore-network modeling established in this paper predicated the experimental relative permeabilityof three BZ sand samples, as well as giving the prediction of oil and water two phase relative permeability changing along with the water saturation within the whole interval, which indicates that pore-network modeling established in this paper can reflect the real structure , in terms of Topology and geometry characteristics of the digital cores.

Summary

Pore space images of three BZ samples with high resolution can be obtained through Micro-CT scanning based on X-ray. Development characteristics of the pore space, such as size of pore and throat, connectivity and morphological characteristics are analyzed to construct the pore-network based on those reconstructed CT images. By comparing and analyzing properties of samples, we can see that porosity of samples in pore-network extraction reaches basic agreement with results from CT scanning. Therefore, network modeling method established in this paper can preserve the fluid storage capacity ability of the core completely into the pore-network model. In the end, the relative permeability and capillary pressure of three BZ sand samples are predicated based on pore network extraction, which demonstrated that pore network extraction algorithm—Maximal Ball (MB) algorithm cited in this article could extract reasonable and reliable pore network of different BZ sand packed samples. This simulation technology has great utility value in oil recovery.

Keywords: Mercury Injection, Normalization, Petrophysics

Abstract. Study on Formation Type II is so few that affect on tapping the potential [2]. Analyzing petrophysics of Formation Type I and II by mercury injection curve normalization, it's vital to developing method choice on tapping the potential of Formation Type II.

Capillary pressure curves (Pc-curves) from conventional Mercury Injection are hard to analyze and compare because of various shapes. To get typical capillary pressure curves for Formation Type I and II, the curves from Mercury Injection is processed by Function J, and the J function curves and normalized Pc-curves for tabulated thin layers, tabulated thick layers and un-tabulated layers in Formation Type I and II, compare and analyze the influence of permeability on the shape of J function curves and normalized Pc-curves; compare the influence of different kinds of layers with the same permeability order of magnitude on the shape of J function curves and normalized Pc-curves, i.e. the influence of other factors except permeability, to get some visual identification methods and analyze the petrophysics difference between Formation Type I and II which is shown on Pc-curves.

Introduction

In mercury injection method each pressure point represents the pressure under which the mercury is injected into the pore with corresponding size [1]. The result of experiment shows that, the shape of Pc-curves is mainly determined by the wettability and pore structure property of the formation. The Pc-curves of formation with different permeability and porosity is different.

To get the J function curves and normalized Pc-curves for tabulated thin layers, tabulated thick layers and un-tabulated layers in Formation Type I and II, the Pc-curves from mercury injection is processed with J function; compare them and seek creative conclusion.

Principle of Normalized Pc-curves

Experiments proves that, the capillary pressure in the formation is the function of fluid saturation, which can be formulated as,

$$p_c = f(S_{Hg}) \tag{1}$$

The ratio of measured capillary pressure values and reference ones is defined as the J function of formation by M. C. Leverett, thus the expression of J function is gotten as following:

$$J(S_{wn}) = \frac{p_c}{\sigma}\sqrt{\frac{K}{\phi}} \tag{2}$$

Where, S_{wn} is the normalized saturation of core:

$$S_{wn} = \frac{S_{Hgmax} - S_{Hg}}{S_{Hgmax}}, \qquad 0 \le S_{wn} \le 1 \tag{3}$$

Where, S_{Hg} is core mercury saturation; S_{Hgmax} is the maximum mercury saturation.

Combining core data, the pc and S_{Hg} measured in laboratory is transformed to $J(S_{wn})$ function and data corresponding S_{wn} by equation (2) and (3). To get J (S_{wn}), the data can be fitting by least square method. The power function is chosen in fitting after observation on the Pc-curve features [3].

$$J(S_{wn}) = a\ S_{wn}^{b} \tag{4}$$

Where, a is dimensionless drainage pressure of J function; b is curve index of J function.
Solving the equations satisfied by the fitting curves, the expression of a, b is gotten.

$$c = \left[\sum_{i=1}^{m} \ln J_i \sum_{i=1}^{m} (\ln S_{wni})^2 - \sum_{i=1}^{m} S_{wni} \sum_{i=1}^{m} \ln S_{wni} \ln J_i\right] \Big/ \left[m \sum_{i=1}^{m} (S_{wni})^2 - \left(\sum_{i=1}^{m} \ln S_{wni}\right)^2\right] \quad (5)$$

$$b = \left[m \sum_{i=1}^{m} \ln S_{wni} \ln J_i - \sum_{i=1}^{m} \ln J_i \sum_{i=1}^{m} \ln S_{wni}\right] \Big/ \left[m \sum_{i=1}^{m} (S_{wni})^2 - \left(\sum_{i=1}^{m} \ln S_{wni}\right)^2\right] \quad (6)$$

$$a = e^c \quad (7)$$

Thus a, b of each core is calculated, substitute arithmetic mean of a, b values of all the core into equation (4), then the average J function curves of formation is determined. Average capillary pressure can be calculated from equation (8) and (9):

$$p_c(S_w) = \frac{\sigma}{\sqrt{K/\phi}} J(S_{wn}) = \frac{\sigma}{\sqrt{K/\phi}} a S_{wn}^b \quad (8)$$

$$S_{Hg} = S_{Hgmax}(1 - S_{wn}) \quad (9)$$

Where, P_c is average capillary pressure of formation, MPa, σ is the interfacial tension between oil and water, which is given as 0.033N/m, K is air permeability of core, μm^2, ϕ is porosity.
Based on the theory the core data from different type layers of Formation Type I and II is processed, from which their normalized Pc-curves are gotten and analyzed.

Pc-curves Normalization results

Contrast the capillary pressure and coring data according to depth, refer to net pay thickness, the core data is classified as tabulated thin layers（0<h<0.5）, tabulated thick layers(h≥0.5) and un-tabulated layers(h=0), which is taken normalization, from which normalized Pc-curves for different formation with different permeability. According contrasting between these curves, the relationship between shape of normalized Pc-curves and petrophysics of formation is discussed.
The normalization method for mercury withdrawal curve is revised. If small step length is given, the normalized mercury injection curve will meet with the normalized withdrawal curve, which is the same as original mercury curve.

Normalized Pc-curves with different permeability in Formation I

Thick layers in Formation I are analyzed by permeability magnitudes because of abundant coring.

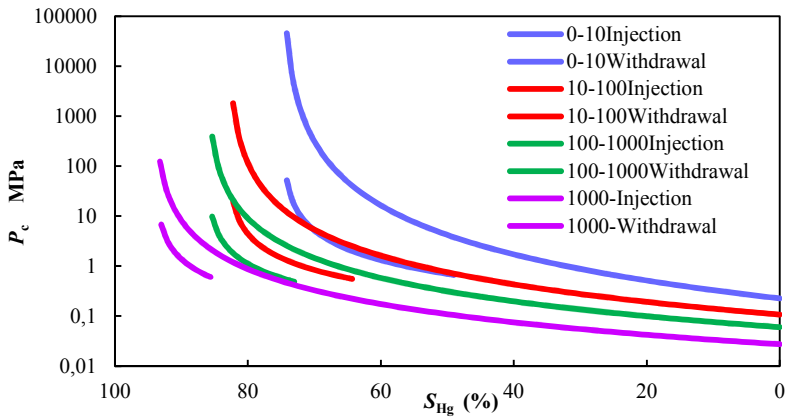

Figure 1 Normalized Pc-curves of thick layers with different permeability in Formation I

Larger is the permeability of thick layers in Formation I, Larger is the maximum mercury saturation and minimum mercury saturation in withdrawal curves, and the more normalized Pc-curve is closed to axis X and Y, which means better formation property.

Normalized Pc-curves with different permeability in Formation II

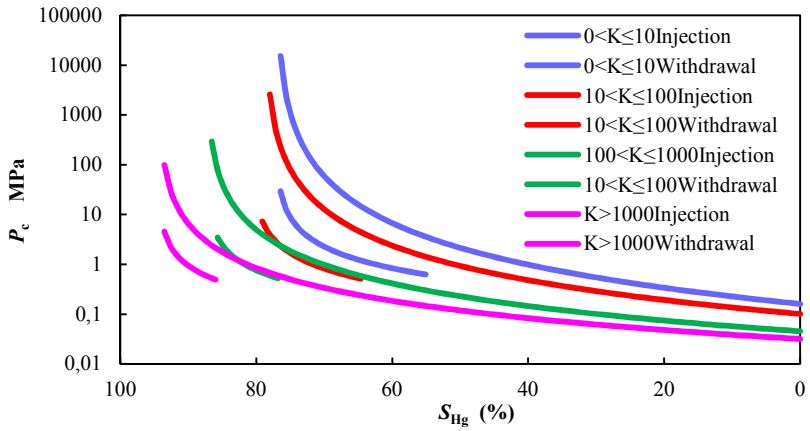

Figure 2 Normalized Pc-curves of thick layers with different permeability in Formation II

Normalized Pc-curves in Formation II follow the same law for permeability in Formation I. And it also can be seen that for different type of layers in Formation II, the shape of Pc-curves, that is the formation property, is different, from which provides visual means of distinguishing methods.

Normalized Pc-curves of thick layers in Formation I and II

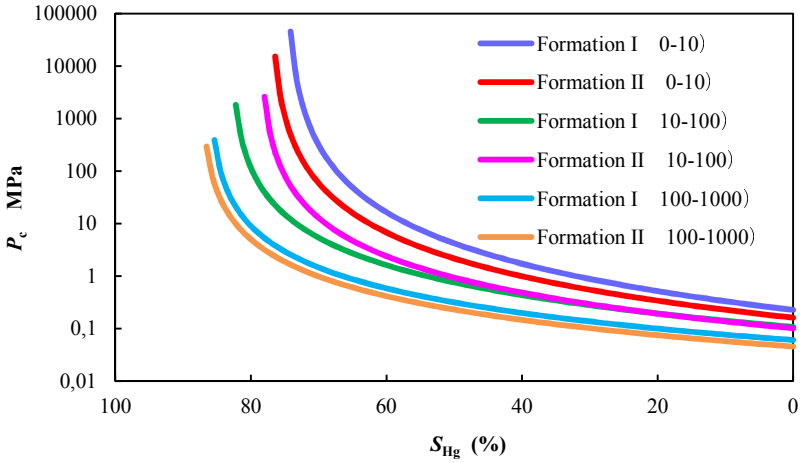

Figure 3 Normalized injection Pc-curves of thick layers in Formation I and II

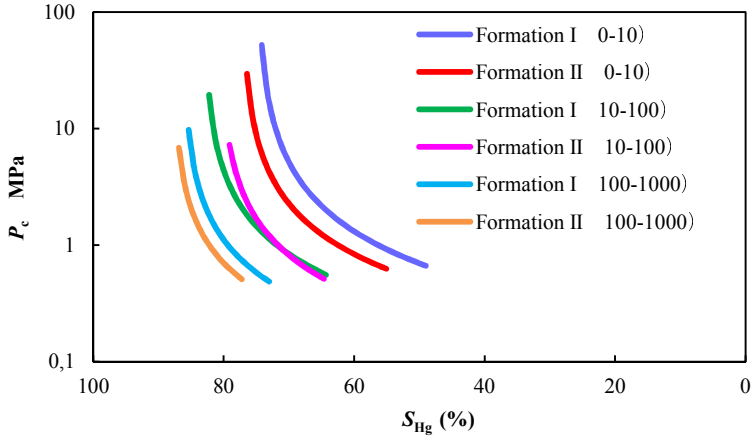

Figure 4 Normalized withdrawal Pc-curves of thick layers in Formation I and II

From Fig.3 and 4, it can be seen that in the permeability range (10-100) mD the property of Formation II is better than that of Formation I; while it's inverse for the other two ranges.

Summary

1. Normalization for original Pc-curve makes it easy to find and analyze the law of formation property;
2. Larger is the permeability of thick layers in Formation I, Larger is the maximum mercury saturation and minimum mercury saturation in withdrawal curves, and the more normalized Pc-curve is closed to axis X and Y, which means better formation property.
3. In the permeability range (10-100) mD, the property of Formation II is better than that of Formation I; while it's inverse for the other two ranges.
4. For the core in Formation I, higher is the permeability magnitude, smaller is the difference between the properties of cores with different permeability, that is, and more similar are the shapes of different cores.

Keywords: natural rubber, polyvinyl alcohol, blend, compatilizer.

Abstract. The natural rubber/polyvinyl alcohol (NR/PVA) blends containing various compatilizers grafted from NR were prepared using latex compounding techniques. The effects of various compatilizers on the morphology, mechanical properties and thermal behaviors were studied. The interface compatible performance of the blends were greatly improved with the presence of the compatilizers, and the phase dispertion of the blends achieved the best effect under the action of epoxidized natural rubber (ENR). The onset temperature of the thermal decomposition of ENR and graft copolymerization of methyl methacrylate (MMA) onto NR (NR-g-PMMA) increased obviously, but the maleic anhydride grafted onto NR (NR-g-MAH) drop obviously comparing to that of NR. The thermal stability of the blends were inferior to NR. With the presence of ENR, the tensile strength and elongation at break obtained great value which was ascribed the presence of the best phase dispertion, while the tear strength and shore A hardness obtained great value due to the addition of MAH-g-NR.

Introduction

With the development of modern science and technology, the wide range of material are required increasingly as the single material difficult to meet a variety of requirements, so the polymer blends have become indispensable a class important materials in industrial and agricultural production and life[1,2]. The interface modification technology is increasingly being studied for the performance of the blend to get the proper morphology and interfacial strength in order to obtain better properties of the blends.

The interface modification techniques developed after the 1970s, since then it facilitated numerous incompatible blends to achieve compatiblity, and a series of new polymer alloy were developed[3]. The natural rubber (NR) blends prepared based on NR and other polymers have been a very important modern industrial production technology in the modern industrial production of NR[4].

In this work, the natural rubber/polyvinyl alcohol (NR/PVA) blends containing various compatilizers grafted from NR were prepared using latex compounding techniques. The influence of various compatilizers on the morphology, mechanical properties and thermal behaviors were investigated systematically.

Experimental

Materials. Natural rubber latex, with dried rubber content (DRC) of 60 wt%, was obtained from Agricultural Processing Research Institute, Chinese Academy of Tropical Agriculture Science. Polyvinyl alcohol (PVA, molecular weigth of 13000～23000 and degree of hydrolysis 87～89 %) was supplied by Sigma-Aldrich company. Hydrogen peroxide(H2O2, 30 %), Benzoyl peroxide (BPO, minimum purity of 98 %), Patassium hydroxide (KOH) and sodium dodecylsulfate were obtained from Sinopharm Chemical Reagent Company. tert-butyl hydroperoxide (TBHP), Oleic acid and Ammonia solution (25 %) were obtained from GuangZhou Jinhuada Chemical Reagent Company. Formic acid was obtained from Guangzhou chemical reagent company. Maleic Anhydride (MAH) was supplied by Tianjin YongDa chemical reagent company. Tetraethylene pentamine (TEPA) was supplied by Tianjin Guangfu fine chemical research institute. Methyl methacrylate (MMA) was supplied by Xiya Reagent Company. Various additives such as the Peregal-O (99.5 %,), the sulfur, the zinc oxide (ZnO), and Zinc diethyl dithiocarbamaate (ZDC) were used as supplied. DI (deionized water) was used throughout.

Preparation of compatilizers.

Epoxidized natural rubber (ENR)[5]. 200 g of NR latex containing 30 % dried rubber content (DRC) was blended with the peregal-O as a non-ionic surfactant at ambient temperature while stirring for 1 h. The mixture was then acidified with 15 g of formic acid. After that, 100 ml of hydrogen peroxide was added at 30 °C within 10～15 min. The epoxidation process was carried out at 70 °C for 5 h and the resulting ENR processing a 30 % of epoxided content was used after calculation.

Graft copolymerization of methyl methacrylate (MMA) onto NR (NR-g-PMMA)[6]. NR latex (100 g, DRC 60 %) was placed in a reactor, and sodium dodecylsulfate (1 phr) was then added while stirring. The mixture was deoxygenated by passing through the nitrogen gas for approximately 15 min at room temperature. Oleic acid as the stabilizer was added. After 20 min of stirring, MMA monomer was then added continuously while stirring for 30 min to allow the latex particles to swell. The mixture was heated up to 60 °C. TBHP and TEPA were added at a ratio of 1:1. The reaction was then allowed to proceed for 8 h under continuous stirring to complete the polymerization. The final product could be determined by the Soxhlet extraction. The free natural rubber was extracted in a Soxhlet extractor by light petroleum ether for 24 h while free PMMA was extracted by acetone for 24 h. Then, the grafting rate was 61.4 % after calculation.

The maleic anhydride grafted onto NR (NR-g-MAH). The graft reaction was carried out in a three flask with reflux condensing tube and thermometer. NR latex (100 g, DRC 60 %) placed in the flask was blended with the peregal-O as a non-ionic surfactant. MAH and BPO were added in turn to the latex, respectively. The reaction was carried out by stirring the latex at about 60 rpm for 5 h at 80 °C. The final product was cast into a glass sheet and it was dried at 60 °C in a vacuum oven. The unreacted monomer and initiator were removed by using aceton for 24 h in a soxhlet apparatus. Then, the grafting rate was 44.3 % after calculation.

Preparation of NR/PVA blends. PVA was first dissolved into the saturated solution of 25 wt% at 90 °C, then the solution mixing with NR latex (DRC 60 %) was carried out in a beaker by stirring for 1 h at 35 °C. The compatilizer and vulcanizing system were added and then the blend was heated up to 55 °C to be precured for 2 h. After that, the blend was cast into the glass sheet to be molded into film which thickness was about 1～2 mm. The film was cured at 60 °C for 3 h after natural dring, and then taken to the next test after placed in the standard test environment for 16 h. The formulations shown in Table 1 were used in this study.

Tab 1 Sample composition and code of NR/PVA blends [phr]*

***ALL the components are in phr (weight per hundred weight of NR)**

Fourier Transform Infrared Spectroscopy Analysis (FT-IR). The FT-IR spectra of the samples were obtained from Perkin-Elmer (GX-1) measuring in the range of 4000-500 cm^{-1}. The samples were cut into strips of 50 mm, using attenuated total reflection (ATR) accessory, scanning 16 times.

Mechanical Testing. The tensile and tearing test were performed on Testing Mechine UT-2080 (Ucan Instrument, TaiWan) at a crosshead speed of 500 mm/min at room temperature. The dumbbell-shaped samples for tensile tests were cut from the molded sheets according to GB/T 528-2009. For the tearing test crescent-shaped die B were punched from the molded sheets according to GB/T 529-2008. Hardness of the samples was also measured using a Shore A durometer according to GB/T 531-1999.

Scanning Electron Microscope (SEM) Observation. The morphology of the NR/PVA blends was characterized by a Hitachi S 4800 SEM instrument. Molded samples were fractured in liquid nitrogen. Then the samples were dried under vacuum at 40 °C for 2 h. The samples were examined by scanning electron microscope after sputter coating with a thin film of gold.

Thermogravimetric Analysis. The thermogravimetry analysis was carried out in a NETZSCH STA449C (Germany) instrument. The sample was scanned from 25 to 700 °C at a heating rate of 10 °C min^{-1} in nitrogen atmosphere.

Results and Disscussion

Fourier Transform Infrared Spectroscopy Analysis (FT-IR). The FT-IR spectra of NR and comptilizers grafted from NR are shown in Fig 1. The absorptions at 876 and 1253 cm^{-1} from the ENR plot can be attributed to the epoxy group, and the weak absorption at 1735 cm^{-1} can be assigned to the carbonyl group of the easter. The absorption of the NR-g-PMMA is found at 1140 cm^{-1} (–C–O– stretching), 1390cm-1 (methy C–H deformation),and 1725 cm^{-1} (carbonyl group). The main peaks of NR-g-MAH shown at 3450 cm^{-1} which is strong and wide can be attributed to O–H stretching vibration (MAH hydrolyzate). The main peaks shown at 1630～1660 cm^{-1} and 1050～1250 cm^{-1} are attributed to carbon-oxygen double bond stretching and carbon-oxygen single bond stretching, respectively. The presence of characteristic peaks of the above describes MAH monomer has been grafted onto NR macromolecular chain.

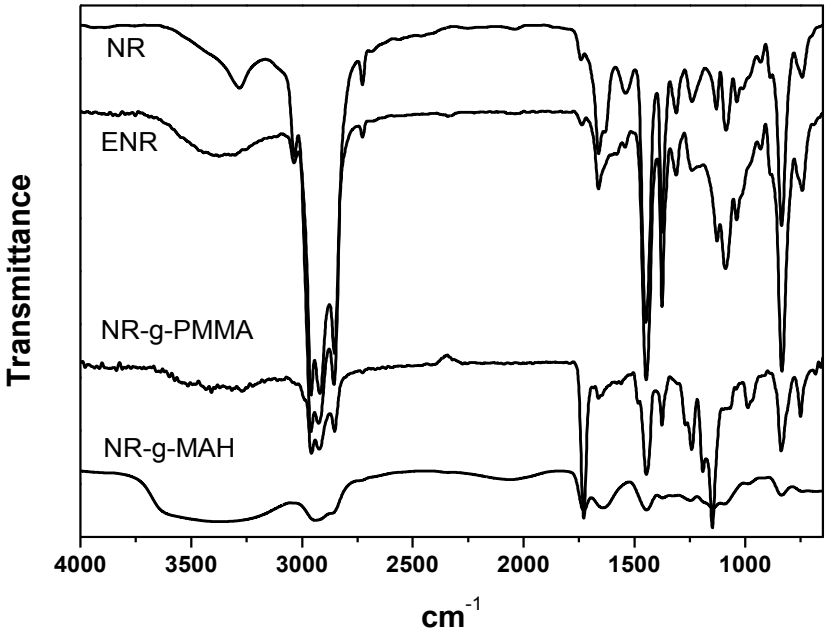

Fig.1. FT-IR spectra of NR, ENR, NR-g-PMMA and NR-g-MAH.

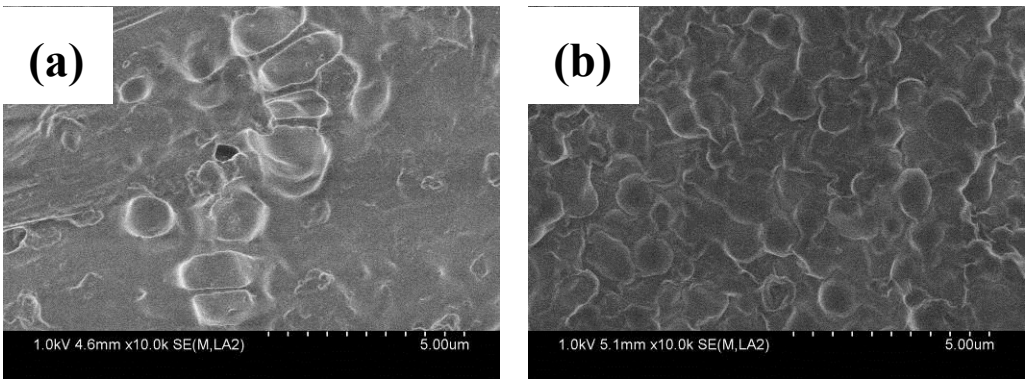
Phase Morphology. NR exists primarily as the matrix phase, and PVA exists primarily as the dispersed phase from NR/PVA blends composition. It can be found as shown at Fig 2 that the distribution of the dispersed phase disperses unevenly and the particles gather before the compatilizer added, while the distribution of the dispersed phase shows more regular domains after the compatilizer added. The interface compatible performance of the blends are greatly improved with the presence of the compatilizers, and the phase dispertion of the blends achieve the best effect under the action of ENR. Although the dispersed phase shows irregular shape in the NR-g-PMMA and NR-g-MAH blends, the dispersed phase presents a certain distribution due to the addition of the compatilizers. Thus, the compatilizer can greatly improve the interface compatibility of the NR/PVA blends.



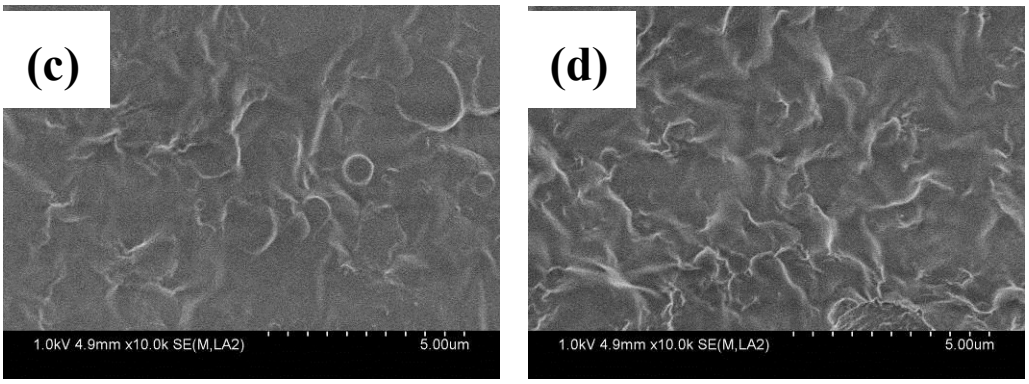


Fig.2. SEM micrographs of the NR/PVA blends:(a)sample 0#;(b)sample 1#;(c)sample 2#;(d)sample 3#.

Mechanical Properties. The effect of the compatilizers on the mechanical properties of NR/PVA blends are shown in Tab 2. The tensile strength, tear strength and hardness of the NR/PVA blends increase with the presence of the compatilizers. This is attributed to the compatilizers which results in the smaller particle size and improving the dispersion of the dispersed phase and enhancing the strength of the two-phase interface. With the presence of ENR, the tensile strength and elongation at break obtain great value which is mainly due to the presence of the epoxy group to active the adjacent double bonds, increasing the crosslink density, and thereby the mechanical properties increase. The tear strength and shore A hardness obtain great value due to the MAH-g-NR. The elongation at break of the blends decline after compatilizers added, which may be due to the compatilizers improving the toughness of the interface layer so that the elasticity of the material decreases.

Tab 2 Mechanical Properties of NR/PVA blends

Sample	Tensile strength [Mpa]	Elongation at break [%]	Tear strength [N/m]	Shore A hardness
0#	12.19	748.5	23.04	43
1#	18.27	716.0	36.28	52
2#	17.18	627.9	40.35	55
3#	15.84	574.4	52.16	55

Thermol behaviors. Thermograms results of the compatilizers are plotted in Fig 3. Thermograms and derivative thermograms results of the blends are plotted in Fig 4 and Fig 5. Both of the plots decomposed in one step.

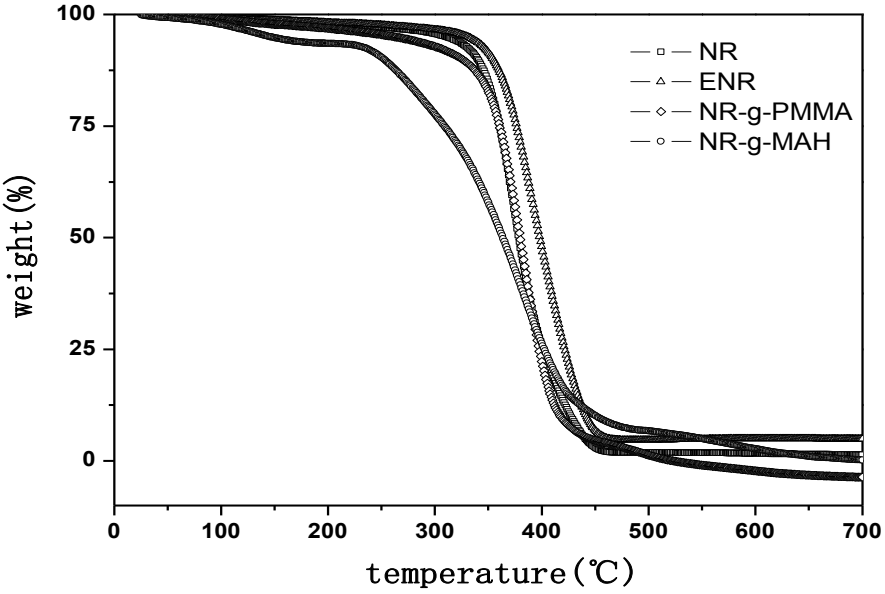

Fig.3. TG curve of the compatilizers

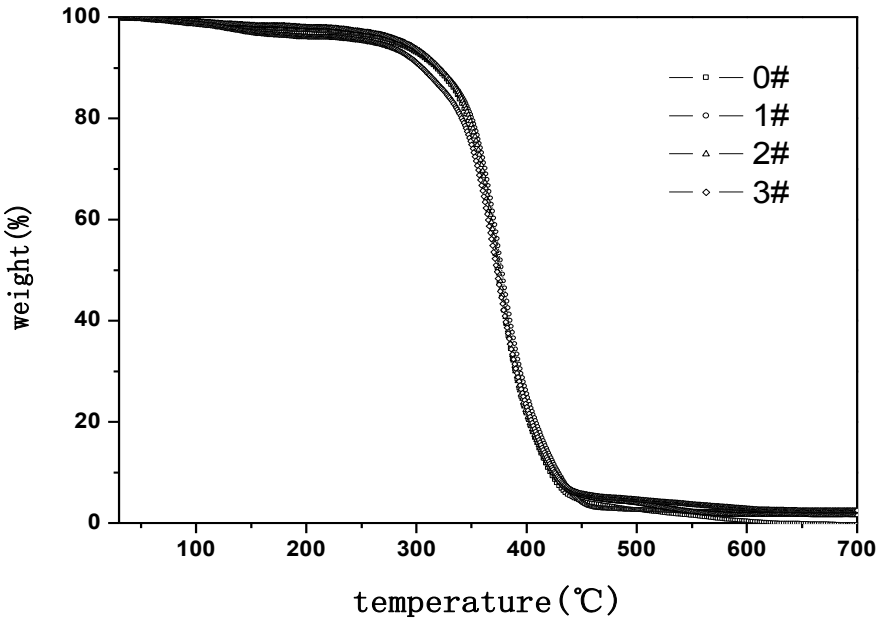

Fig.4. TG curve of NR/PVA blends

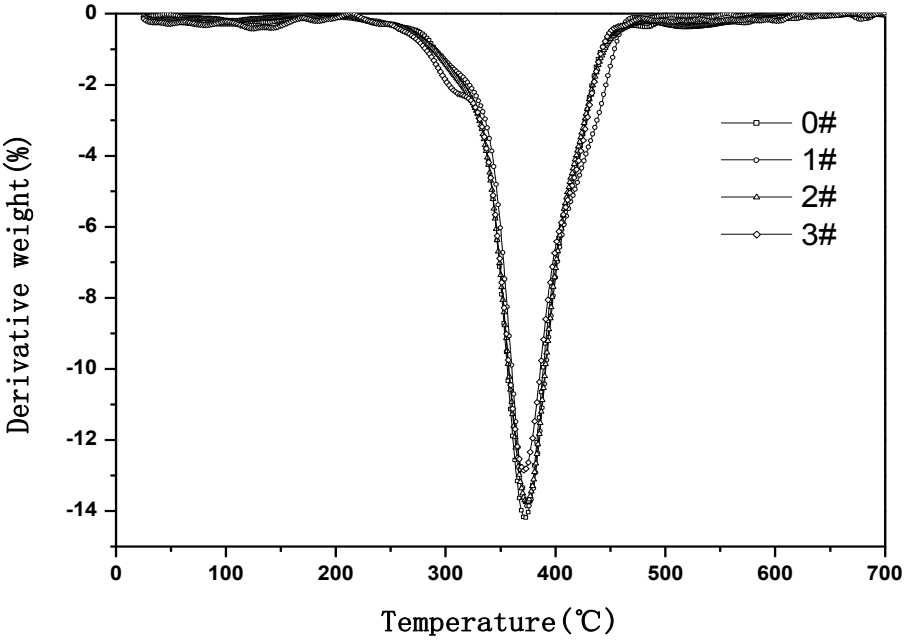

Fig.5. DTG curve of NR/PVA blends

The characteristics temperature of the thermol degradation process can be plotted through the double tangent curve method. The characteristics temperature of the thermol degradation process of the compatilizers and blends are summarized at Tab 3, of which To represents the onset temperature of the thermal decomposition, Tf representing the termination temperature of the thermol decomposition, Tp representing the temperature corresponding to the maximum rate of the thermal decomposition. The onset temperature of the thermal decomposition of ENR and NR-g-PMMA increase obviously, but that of the NR-g-MAH drops obviously comparing to NR. The thermal stability of the blends are inferior to that of the NR. This is due to the onset temperature of the thermal decomposition of the PVA is lower than that of the NR, so that the thermal stability decreases because of the oxidation induction time shortening. It can be observed that the temperatures corresponding to the maximum rate of the thermal decomposition show no significant change, indicating no significant effect on the temperatures corresponding to the maximum rate of the thermal decomposition after PVA added, but the maximum decomposition rate increasing gradually accelerates the thermal decomposition process.

Tab 3 Characteristic temperatures of compatiblizers and NR/PVA blends

Sample code	T_o [°C]	T_p [°C]	T_f [°C]
NR	347	374	411
ENR	358	392	438
NR-g-PMMA	351	382	411
NR-g-MAH	311	383	424
0#	341	372	406
1#	345	375	412
2#	343	374	407
3#	338	372	408

Conclusions.

The NR/PVA blends with various compatilizers were prepared and investigated. The interface compatible performance of the blends were greatly improved with the presence of the compatilizers, and the phase dispertion of the blends achieved the best effect under the action of the ENR. The onset temperature of thermal decomposition of ENR and NR-g-PMMA increased obviously, but that of the NR-g-MAH drop obviously comparing to NR. The thermal stability of the blends were inferior to NR. With the presence of the ENR, the tensile strength and elongation at break obtained great value which was ascribed the presence of the best phase dispertion, while the tear strength and shore A hardness obtained great value due to the addition of MAH-g-NR.

Keywords: scales; adsorption; EGCG

Abstract. Tilapia scale was used as the raw material to explore the preparation methods of EGCG adsorption material. Based on the results, the most reasonable interpretation of the data indicates that the EGCG adsorption material preparation process was as follows, particle size 0.30-0.45 mm , preparation temperature 110℃, pH 7, solid to liquid ratio (g/mL)1:6, time 20 min. Under this condition, the adsorption capacity of EGCG was 23.53mg/g.

Introduction

Epigalocatechin-3-gallate (EGCG) is one of the most important and main active ingredients derived from green tea, and has a broad spectrum of beneficial activity, for example strong antioxidant [1,2], tabacum [3], anticancer[4],antiaging[5],antiatherosclоresis[6,7]， antibacterial and antiinflammatory [8-10]activity in humans . EGCG is a natural antioxidant, has important applications in food industry, medicaments and chemical products for daily use. In generally, the conventional techniques for EGCG extraction are solvent extraction, precipitation and resin column chromatography [10], which are all limited by low extraction efficiency, large depletion of many kinds of reagents, heavy and complicated steps, high production costs and always using heavy metal salt as precipitator which pose some potential safety hazards. Therefore, recently, researches about safe and effective materials to extract and separate EGCG have received more and more attention from all over the world.

Tilapia is cultured as the main economic fish species in China and the yields in 2008 reached to 1.21 million tons [11] sharing 48.4% of the annual yield of Tilapia in the world. Hence there is a large number of fish head, fish skin, fishbone and fish scale and so on which are the waste of Tilapia processing. Hereinto, the amount of the fish scale accounts 2% allows an abundant and cheap source of biomaterial, such as extraction collage and hydroxyapatite. In present， the use of usually scales focus on the adsorption material research have reported less. This work used tilapia scales as raw materials, to prepare a new type of adsorption material with large adsorption capacity, low-cost, high security to extract and separate EGCG. More to the point, the preparation methods were investiged on EGCG adsorption of tilapia scale.

Experimental

Materials. The tilapia scales were provided by Hainan Golden Spring Foods Co., Ltd. EGCG (≥98%, Fu Zhou Corona Science & Technology Development Co., Ltd.). All other chemicals used in this study were of analytical grade.

Pretreatment of Tilapia scales. The raw tilapia scales were first washed in water to get rid of the surface impurity, and then contacted with 0.1mol/L NaOH solution for five hours. After that the scales was washed abundantly with deionized water until neutrality was reached and dried by naturally for reserve.

EGCG adsorption material preparation and appraisement. A certain amount of the pretreated scales treated with different griddle(below 0.30, 0.30-0.45, 0.45-0.90, 0.30-0.90mm), temperature(65, 80, 95, 110, 125℃), pH(3, 5, 6, 7, 9, 11), solid to liquid ratio（1:3, 1: 6, 1:12, 1:18, 1:24（g/mL））and time（10, 20, 30, 40, 50min） produced the adsorption materials.

When examined a single factor of the above, the factors as the variables, the others set as particle size 0.30-0.45 mm , preparation temperature 110℃,pH 7 , solid to liquid ratio (g/mL) 1:6, time 20 min. Then, the effect of the adsorption materials produced by different conditions determined by adsorption tests based on a batch reactor that 0.5g of the adsorption materials infused with 7mL of EGCG solution (0.004mol/L) at room temperature(25℃) was oscillated at 200r/min for 40min. Then after 10 min, the absorbance of supernatant was measured at 510nm by method for determining EGCG.

EGCG content test. The preparation of the sample liquid was produced by three steps. First, 1ml sample was immersed in 4 mL deionized water and 0.3ml 5% $NaNO_2$ for 5 min in a test tube. Second, adding 0.3 mL 10% $AlCl_3$ into that test tube and setting for other 1 min. At last, putting 2 mL 1mol/L NaOH into that test tube and adding enough deionized water making the volume of the liquid in the test tube reached exactly 10 mL. Then the absorbance of the sample liquid is measured at 510nm on the UV-4802.

Results and Discussion

Single factor experiment for EGCG adsorption material preparation. The results of the single factor experiment indicated that these facts are producing big influence on the adsorbance. The figure 1(a) shows, the material have the maximum adsorption capability with the particle size between 0.30 and 0.45 mm. That could be considered that the specific area of the scales is one of the key points for adsorption. When the particle size is too big the specific area is relatively small which counts against to adsorption. However, when the particle size is too small, the period of adsorption equilibria would be too long for the material to hold the EGCG that once adsorbed, hence, resulted in some of the adsorbed EGCG desorption, the final adsorbance is still decrease. So the particle size was set to 0.30-0.45 mm.

The figure1(b) shows, the adsorbance increased obviously with the temperature from 65℃ to 110℃. However, once the temperature exceed 110℃, the adsorbance would decrease. It could be own to the temperature which influenced the combinative state of the protein and hydroxyapatite of the scales. The fact is the materials prepared at 110℃ possess the optimal combination or existent pattern of ingredients in the scales to adsorb EGCG , therefore, the 110℃ is the optimal temperature in the preparation.

The figure1(c) indicated, with increasing of pH, the adsorbance for EGCG by the material increases first and then decrease.Under the pH value of 7, the scales had a maximum adsorbance for EGCG. Weak acids or weak bases environment are benefit for dissolving protein that is why the relationship between the rate that collagen to the scales decreased and the adsorbance being contacted like that. Therefore, we chose the pH 7 as the optimal processing pH value.

The figure1(d) shows, the material have a maximum adsorbance for EGCG, when the solid to liquid ratio (g/mL) is 1:6 to be used to processing the scales. And the adsorbance decreases with decreasing of solid to liquid ratio. This could be explain like this, for a certain amount of scales, the

increasing amount of the liquid could increase the apparent contact area for the scales and the liquid in the process, which would promote the dissolution of collagen, consequently, the amount of collagen has been occupied in forming a good structure to absorb EGCG would change too, so that the absorption level of EGCG by the scales has been influenced. So the solid to liquid ratio was set to 1:6.

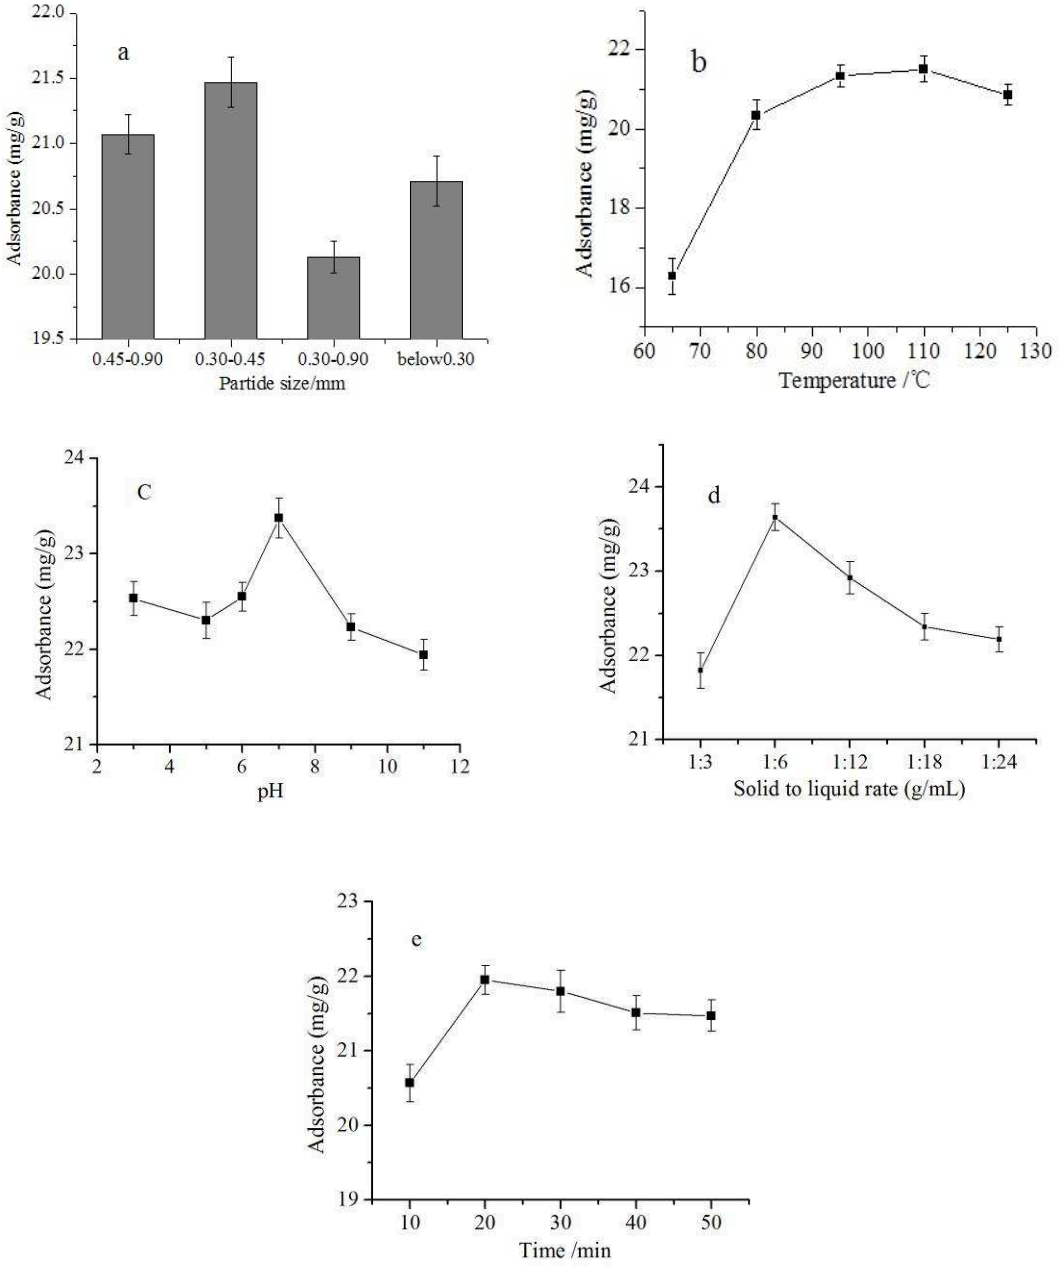

Fig.1 Variation curve of adsorption capacity vs sieve mesh(a) temperation(b) pH(c) solid to liquid ratio(d) time(e)

By figure1(e) knowable, there is little difference in adsorbance when the time of the scales preparation is longer than 20 min. By determination content of the protein dissolving from the scales we found the material achieved a dissolution balance for the collagen during the period, which indirectly demonstrated that the ingredients of the scales reached to a relatively stable state. Since the adsorbance of the scales for EGCG is relatively stable as long as the processing time surpassed 20 min, we chose the 20 min as the optimal processing time.

We did another experiment according the conditions of the particle size 0.30-0.45 mm , pH 7 , temperature 110℃, processing time 20 min, solid to liquid ratio (g/mL) 1:6. Under this condition,

the result showed the highest adsorbance for EGCG that is 23.53 mg/g, which is higher than the value that Wang RuiFang[12] and so on got though X-5, RA and RB resin. It demonstrated that tilapia scales possesses obvious potential to be as EGCG adsorption material. Since the tilapia scales have large adsorption capacity, low-cost, high security and easy to prepare, it would have a promising future applied in separation and purification of EGCG.

Summary

On the basis of above investigation of parameters in preparation of the scales material adsorption EGCG, it is confirmed that the tilapia scales process great ability to absorb EGCG and the optimal adsorption material preparation methods could be acquired when the particle size of 0.30-0.45 mm , pH of 7 , temperature of 110℃, processing time of 20 min, solid to liquid ratio (g/mL) of 1:6. Under this condition, we acquired the maximum adsorption capacity was 23.53mg/g.

Keywords: scale; classification; alumina; morphological structure

Abstract. The chemical composition, phase component and morphology characteristics of scale were researched by chemical analysis, XRD, SEM and TEM. The results show that the scale can be divided into iron minerals, silicon minerals, Ca-Ti-Mg minerals and aluminum hydroxide. Alumogoethite and micro-fine sodium-silicon slag fill in the gaps between the neat and bulky hematite crystals. Microgranular hydrated garnet and olivine fill in the gaps between the goethite crystals with a dense layered structure, accompanied by a small amount of galena and apatite precipitation particles. Perovskite and magnesium hydroxide have five periodic sedimentary cycles, forming an alternating sedimentary layer structure. Aluminum hydroxide forms thick scale and presents two kinds of typical structures, spherulitic and laminated. The research provides the theoretical basis for preventing and controlling scale in high-pressure digester group.

Introduction

In Bayer process of high pressure digestion of diaspore, various scales form inevitably. A large number of scale results in pipeline blocking, reducing heat transfer coefficient of heat exchanger severely, thereby reducing the output of equipment, increasing energy consumption and production cost. If it is serious, normal production will be affected [1,2].

Scholars at home and abroad have done a lot of work towards the scale forming in alumina production and put forward methods of scale prevention and treatment, mainly from property [3], formation mechanism and influence of scale. In general, methods of scale prevention and treatment mainly include three aspects [4,5]. The first is the pretreatment [6] which means strengthening the pre-desilication process to slow down scale formation. The second is the handling during the production which means optimizing process conditions to reduce scale formation, by using new digestion technology such as two-stream process and so on [7,8,9,10,11]. The last is the handling after the production which means cleaning scale up by use of machining, fire, high-pressure hydraulic, acid-base, magnetic field, electric field, ultrasonic and so on [12,13,14]. But these studies have not yet formed a set of effectively preventive, efficient, scientific and reasonable practice in scale prevention and treatment. The reason is that they are lack of systematic research and comparative analysis on the morphological structures of scale forming during every scaling step in the whole high pressure digestion unit. Therefore, this paper combines with high pressure digestion process in alumina production, studying the morphological structures of scale in the high- pressure-digestion single tube preheater, autoclave, staying ladle and flash type evaporator in turn, then classifying the scale, in order to provide theoretical and practical basis for scale prevention and treatment.

Methods and analysis instruments

We used chemical analysis and XRD to measure and analyze the main chemical composition and phase component of each sample of scale, adopt spectrum selection component analysis technique of scanning electron microscopy to analyze the micro-zone of component of scale, and used backscattered electron imaging analysis technique of SEM to study the internal structure characteristics of scale.

The chemical composition and phase component of scale

The chemical composition. The scale sample was taken from high-pressure digester group of a certain alumina plan. The results of its chemical composition are shown in Table 1. From the table, the chemical compositions of scale forming in different parts are quite different. The scale in the single tube preheator and stay ladle primarily contains Fe_2O_3, accounting for 60 %. The scale in the autoclave primarily contains TiO_2, accounting for 40 %. The scale in the flash type evaporator primarily contains Al_2O_3 and Fe_2O_3, accounting for 24.91 % and 27.51% respectively.

Table 1 Chemical composition of scale in different parts

Scale sample	Al_2O_3	Fe_2O_3	SiO_2	TiO_2	CaO	MgO	Na_2O	K_2O
Scale in single tube preheator	6.79	67.66	7.42	2.13	6.66	3.18	0.84	0.0059
Scale in autoclave	0.69	3.52	10.83	39.44	16.91	4.09	4.16	0.0053
Scale in stay ladle	10.84	61.12	6.62	3.08	2.21	4.77	1.50	0.0074
Scale in flash type evaporator	24.91	27.51	9.87	2.82	5.00	1.50	5.10	0.050

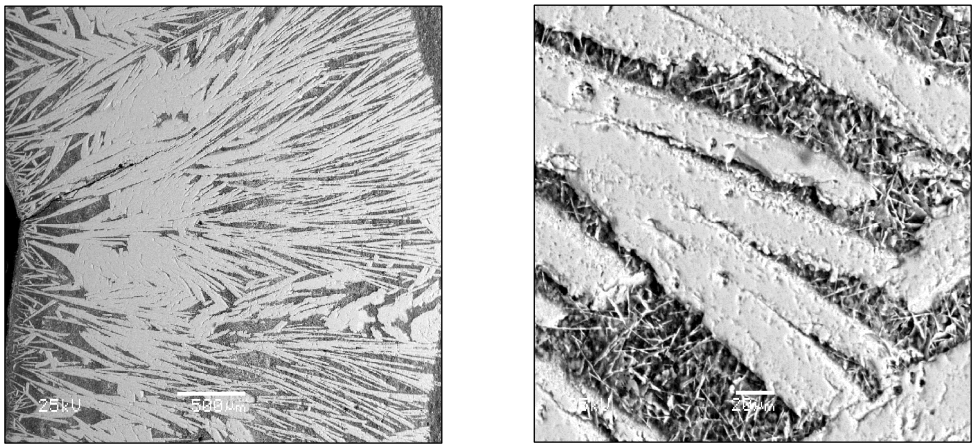
The phase components. Through XRD, we analyzed the phase component of scale. It's known that the scale in the single tube primarily contains sodium-silicon slag, hematite and aluminum goethite. The scale in the autoclave primarily contains perovskite and magnesium. The scale in stay ladle primarily contains hydrate garnet, olivine and goethite. The scale in the flash type evaporator primarily contains Al_2O_3($Al_2O_3 \cdot 3H_2O$) and calcium titanate iron. Along with alumina production process, scale has changed greatly.

The classification and morphological structure of scale

Scale in the high pressure digestion unit could be divided into iron mineral, silicon mineral, calcium titanium magnesium mineral and Al_2O_3 ($Al_2O_3 \cdot 3H_2O$) .

Iron mineral scale. Iron mineral scale contains hematite, aluminum goethite and goethite. Scale of hematite and aluminum mainly exists in single tube. Its SEM backscattered electron image is shown in Fig.1. Adopt spectrum selection component analysis technique of scanning electron microscopy to analyze Fig.1a. From the analysis result, it's knowable that the fillings are aluminum goethite and micro-fine sodium-silicon residue.

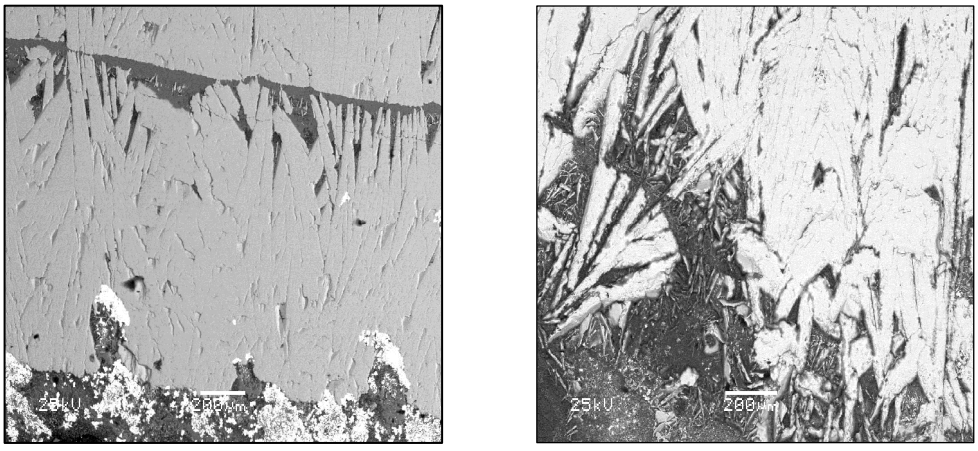
From Fig.1a, hematite grows along pipe wall, forming dense crystal clusters, crystals of which are regular and big, in forms of plate and column. Aluminum goethite is needle-like and tiny, filling in the gaps between the hematite crystals together with micro-fine sodium-silicon slag, as shown in figure 1b. Compared with original pulp material, the scale in the single tube is mainly the deposition of hematite, and that aluminum goethite and sodium-silicon slag form in the process of dissolving and preheating.



a b

Fig.1. SEM backscattered electron image hematite and aluminum scale

Scale of goethite mainly exists in stay ladle. The most important deposition is goethite containing aluminum and titanium. In the backscattered electron imaging of SEM, goethite appears to be gray-white contrast. Goethite crystals develop perfectly and big with columnar structure. The shape is clear and neat. A large number of goethite grows vertical to the pipe walls, forming thin scale with dense layered structure in the staying tank, as shown in Fig.2a. Use spectrum selective component analysis technique of scanning electron microscopy to analyze the material component in Fig.2b. The results show that aluminum and titanium accrete in the goethite, that the highest content of Al_2O_3 is up to 2.36% and that the highest content of TiO_2 is up to 6.49%. On the surface of scale and pipe walls, there is a small amount of particle-like deposition of bright white galena and gray apatite. Goethite crystal fillings primarily contains $Ca_3Al_2(SiO_4)_3$ and Mg_2SiO_4, also including a small amount of needle-like Na_2CO_3 and sodium silicate fillings.



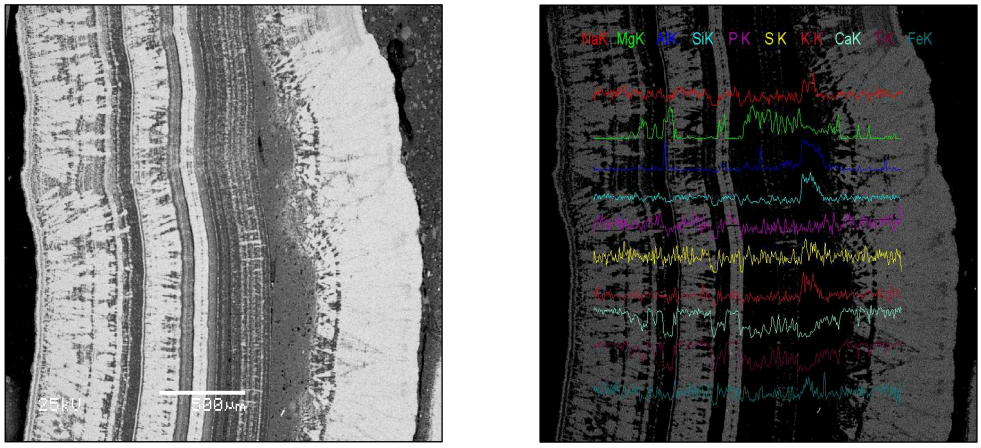
a b

Fig.2. Backscattered electron image of goethite and its fillings characteristic

Silicon mineral scale. Silicon mineral scale mainly composes of sodium-silicon residue ($Na_2O{\cdot}Al_2O_3{\cdot}xSiO_2{\cdot}nH_2O$), existing in single tube. Micro-fine sodium-silicon residue fills in the gaps between other scale crystals in the form of packing, as shown in Fig.1b. And silicon mineral scale has been forming during the whole alumina production process, as shown in Fig.2b.

Ca-Ti-Mg mineral scale. Ca-Ti-Mg scale mainly exists in autoclave. It's the deposition of titanium, calcium and magnesium. The most important is the deposition of titanium. Titanium separate out in the form of perovskite. Perovskite and magnesium hydroxide share five periodic cycles of sedimentation, forming sedimentary structure of perovskite and magnesium hydroxide in the form of layered alternation, as shown in Fig.3. Fig.3b is the element line distribution imaging

analysis of Fig.3, visually displaying the content change rule and correlation between elements which are Na, Mg, Al, Si, P, S, K, Ca, Ti and Fe in different sedimentary layers. The figure shows that the contents of Na, Mg, Al, K, Fe, P, S and Si is increasing in five depositions and that the content of Ca and Ti in the first deposition is significantly at lower level.



a. backscattered electron image b. element line distribution analysis image

Fig.3. Backscattered electron and element line distribution analysis image of Ca-Ti-Mg scale

Characteristics of five periodic sedimentary cycles of titanium are shown in Fig.4.

Perovskite which forms in the first cycle of sedimentation of titanium appears to be bright white contrast, and crystals are big and plate-like. The crystals of perovskite grow along the edge of pipe wall, forming perovskite crystal clusters which are perpendicular to the pipe walls. A large number of perovskite crystal clusters form dense structure. A little micro-fine calcium magnesium silicate scale deposits partially between interlamination.

Subhedral perovskite crystals which form in the second cycle of sedimentation of titanium are not only less than the one of the first deposition of titanium apparently, but also appear to be sparse, depositing in the micro-fine magnesium hydroxide matrix.

Dense enriched layers of perovskite form in the third cycle of sedimentation of titanium. In the early and advanced periods of the third cycle of sedimentation, fine-grained perovskite spread in the magnesium hydroxide.

The characteristics of enriched perovskite layer which forms in the forth cycle of sedimentation of titanium are similar to the one that forms in the first cycle of sedimentation of titanium. The crystals of perovskite are big in the form of dense crystal clusters which are perpendicular to sedimentary layer.

A large number of features of the last cycle of sedimentation of titanium appear to be platelike crystals of perovskite with euhedral and subhedral structure, locating in the fine-grained perovskite and magnesium hydroxide matrix, in the form of crystal clusters which are perpendicular to sedimentary layer.

The last sedimentation

Fig.4. Backscattered electron image of the five cycles sedimentation of Ti

$Al_2O_3(Al_2O_3 \cdot 3H_2O)$ scale. It exists in flash type evaporator and has two major kinds of typical structures, spherulitic and laminated. Their backscattered electron image and structure characteristics are shown in Fig.5 and Fig.6, respectively.

The Fig.5a shows the spherulitic structure. Spherulite appears to be gray contrast with the size of 400 microns to 1300 microns, in forms of elliptical or irregular granular state. The core of it is often hollow. Component analysis shows that, the spherulite is mainly composed of $Al_2O_3(Al_2O_3 \cdot 3H_2O)$, in symbiosis with a small amount of Na, Mg, Si, Co, Ca, Cr, Fe. Between spherulites, there are gray-white fillings. The fillings is mainly composed of Al_2O_3 $(Al_2O_3 \cdot 3H_2O)$. But in the fillings, there

are a lot of bright white calcium titanate iron [$CaFe(Ti_2O_6)$] and iron garnet in all size in symbiosis. It makes the contents of Si, Ca, Ti, Fe and other elements of fillings higher than that of spherulite in chemical composition. In addition, $Al_2O_3(Al_2O_3 \cdot 3H_2O)$t, the crystallinity of the main content of fillings, is higher than that of spherulite. $Al_2O_3(Al_2O_3 \cdot 3H_2O)$ in the fillings appears to be sheet-like and fibrous micro-crystal structures, while the one in the spherulite appears to be dense aphanitic texture. As shown in Fig.6a, the composition of crust layer and the composition of dark crust layer are both relatively pure aluminum hydroxide phase.The composition of the outside edge of crust layer is iron garnet which is bright white particle like triangle. The composition of fillings is calcium titanate iron [$CaFe(Ti_2O_6)$] phase.

In the laminated structure, gray-white laminae winds, bypassing gray contrast aluminum spherulite and aluminum clusters, with a characteristic of liquidity, as shown in Fig.5b, Through component analysis, gray-white laminae has two kinds of component characteristics. One is more Na, Si, S and K and less Al than gray aluminum spherulite. Gray-white laminae form when the mixture of micro-fine aluminum hydroxide phase and $Na_2Ca_3Si_3O_{10}$ phase flows through the edge of gray aluminum hydroxide. The other is rich in Ca, Ti, Fe. Under the SEM, there are a number of small bright contrast particles. They distribute in the interior of aluminum hydroxide phase with the size of less than 20 microns. The bright particles consist of calcium titanate iron [$CaFe(Ti_2O_6)$] phase. As shown in Fig.6b, the composition of bright laminae are $Na_2Ca_3Si_3O_{10}$ enrichment phase and pure aluminum hydroxide phase with round dark mass composition.

Analysis and discussion

Scale in single tube preheater mainly contains hematite, aluminum goethite and sodium-silicon slag. It could be reduced by strengthening the pre-desilication process, changing the flow velocity and flow condition of pulp reasonably, embalming the surface of steel composites to reduce the nucleation of iron, adding chemical scale inhibitors and so on. The most important material of scale in autoclave is the deposition of titanium. Build a detitanation pot in temperature area where reaction is rapid and precipitation is violent, and most of calcium titanate will separate out in staying ladle. The scale in staying ladle primarily contains goethite containing aluminum and titanium with dense layered structure. It is suitable for adopting alkali cooking after fire. Flash type evaporator mainly contains thick $Al_2O_3 \cdot 3H_2O$ scale. Higher solution alkalinity is conducive to deposition of $Al(OH)_3$. It is suitable for adopting hot alkali dissolving, before considering other mechanical or chemical methods.

Conclusions

The mineral composition and morphological structure of scale changed persistently in high pressure digestion process of alumina production. Formation of scale could be divided into early and advanced sedimentation. The early sedimentation is a chemical crystallization mainly with coarse crystalline of hematite, perovskite and goethite. The advanced sedimentation is an effect of physical deposition which are $Al_2O_3 \cdot 3H_2O$, Na_2CO_3 and sodium silicon slag in forms of micro-fine particles and aphanitic texture with loose structure and liquidity. Therefore, controlling the grow of hematite, perovskite and goethite crystal clusters is the key to scale prevention and treatment in high pressure digestion process.

Keywords: LCC analysis; Buried Corrugated Steel Culvert; Deterioration

Abstract. The characteristics of the corrugated steel culvert and the deterioration of the structure are analyzed. The Life Cycle Cost (LCC) approach is put forward to analysis the initial, maintenance and recycling cost of the different material culverts. The user delay costs are added to the typical LCC values considering the deterioration and the failure of structures. The analysis and the economic comparison results show that the total LCC values at the failure emergency situation is much larger than the situation when the deterioration is considered initiatively. Such economic analysis can help the project decision makers better understand the risks associated with deterioration and failure. The inspection and maintenance schedule should be formulated considering the culvert size, the environment in which the culvert is placed, and the characteristics of the soil and the backfill.

Introduction

As a pipe culvert structure with superior mechanical properties, buried corrugated steel culverts are getting more and more popular on roadway and drainage engineering [1]. They are more economical considering the Life Cycle Cost (LCC) compared to traditional concrete or masonry bridges and culverts [2]. It was widely built as highway structures in the USA, Canada, North Europe and such countries which have permafrost and deserts since 1950s and 1960s. In China, there were also many applications in highway engineering from the late 1990s [3]. Culverts were installed based on a 30-50 year expected life. In many western countries, many of these culverts have never been replaced and now their life expectancy is not only arrived but has passed in many locations and yet there are no plans for a replacement plan. However, corrosion protection is required for steel culverts to achieve their full-expected life. In some cases, corrosion will more than expected and this type of structure would not crack like concrete or masonry structure. Thus the deterioration of the buried corrugated culverts is relatively not easy to see. This is resulting in increased culvert failures and the replacements being handled haphazardly with emergency repairs often costing far more to replace and as an inconvenience to motorists than a scheduled repair would cost [4]. It can be a good reference for China to study the inspecting and maintenance strategies for this type of structures in these countries. With the increasing applications of buried corrugated steel structure in China recently, it is urgency to pay close attention to the deterioration of the structure and to avoid failure. In this paper, the economic analysis of the buried corrugated steel culverts considering the deterioration and the impact of the failure are present and some advice to the inspecting and maintenance strategies for this type of structures in China are proposed.

Deterioration of the Structure

The Durability is important for design and construction of all structures. The deterioration of the structure brought a lot of economic cost in many countries [5]. For pipe culvert structures, the United States Army Corps of Engineers identified recommendations on the design life by materials [6]:

Concrete: “Most studies estimated product service life for concrete pipe to be between 70 and 100 years. Of nine state highway departments, three listed the life as100 years, five states stated between 70 and 100 years, and one state gave 50 years.”

Steel: “Corrugated steel pipe usually fails due to corrosion of the invert or the exterior of the pipe. Properly applied coatings can extend the product life to at least 50 years for most environments.”

In many western countries, after nearly 90 years of practical experience with corrugated steel culverts installations, this type of structure has a proven durability for use as culverts and storm drains. Corrugated steel culverts can be designed for field conditions by using galvanizing, asphalt coating, paved inverts, and varying the metal thickness. Corrosion and abrasion are the major causes of corrugated steel culvert deterioration. Corrosion is a significant problem for underwater structures, particularly in environments where there are conditions that accelerate the process. Three dominant factors that cause deterioration of corrugated steel culvert are soil chemistry, water chemistry, and abrasion resistance of sediments. The abrasion potential of an environment can be evaluated by measuring the slope of installation, the velocity of the flow, and the size of the abrasive materials in the culvert. Erosion of corrugated steel culvert at the inverts can mechanically damage the invert surface. New Jersey Department of Transportation Maintenance has identified deterioration of corrugated steel culvert as a significant problem because many installed pipes are at or near the 30-year age mark. Most of these older culverts that are currently in the field exhibit 80-90% section losses, or in many cases 100% section losses at the inverts of the culvert [4]. If this deterioration is not addressed within the next several years, many areas will exhibit soil transfer from under the pipe resulting in erosion and/or collapse. A culvert collapse may result in the above roadway settling, or itself collapsing, which would prove very costly in terms of traffic delays and roadway repair. China is in the period of rapid applying this type of structure in highway engineering now. The design and construction specifications are most from the experience of abroad. The corrugated steel plates are generally galvanized to corrosion as the foreign standards. Although generally this method can avoid corrosion problems, the absence of in-depth study of durability for this type of structure will course extreme deterioration even the collapse after 10 or 20 years.

So not only the typical LCC, but also the structural deterioration or even failure must be considered when design (choose the materials) of the culvert. Such economic analysis can help the project decision makers better understand the risks associated with deterioration and failure. It would also help in identifying trends as well as quantifying the costs associated with failures. Based on this information, a risk factor could also be incorporated in future LCC calculations.

Economic Analysis Method

The concept of LCC is first proposed by the U.S. military in the 60s, 20th century. In 1980s, LCC method gradually applied to the road transport engineering [7]. For engineering, LCC models are used in business practice to determine an alternative by analyzing the structure type, the materials selected for it, the maintenance strategies and repair/rehabilitation engineering. From the analysis of various studies, the LCC analysis can be divided into two general categories: general LCC analysis model which using deterministic or probabilistic LCC approach and theoretical LCC analysis model which based on structural reliability approach. The theoretical LCC model can consider the risk (earthquake, typhoon, etc.) to structures that cannot be considered in a general LCC analysis model using time-invariant reliability or time-variant reliability. But it is more complicated. So the general LCC model is used more popular. However, it is difficult to determine whether a deterministic approach or a probabilistic approach is more accurate, as it is dependent on the type of the structure and cost-composition factors. For the large project that can be influenced by numerous environmental variables and has various cost-composition factors that are not clearly specified, probabilistic approach is more suitable. And for a specific structure, the cost-composition factors can be clearly specified, so the deterministic approach may be more accurate [8].

The deterministic approach is used to analyze the LCC of the culverts. Typical LCC mainly include three parts: that is the initial cost (design cost, supervise cost, construction cost, etc.), the maintenance cost and the recycling cost. The initial cost is assumed as happened at present and the maintenance

cost is assumed as happened in specific future points according to the usual maintenance strategies within the service life period of the culvert. The recycling cost is assumed as happened at the final points of the service life. So the total LCC present value of the culverts can be expressed as Eq. 1.

$$PV_{\mathrm{LCC}} = C_{\mathrm{ini}} + C_{\mathrm{mai}} - C_{\mathrm{rec}} \tag{1}$$

Where, PV_{LCC} is the present value of the LCC cost of the culvert, C_{ini} is the initial cost of the culvert, C_{mai} is the maintenance cost of the culvert and the C_{rec} is the recycling cost of the culvert.
The initial cost can be calculated according to the present standards and codes.
The maintenance cost can be calculated according to the ordinary cost of the maintenance and repair cost of the culvert and pavement. And then discount to present value. The maintenance cost can be expressed as Eq. 2.

$$C_{\mathrm{mai}} = \sum_{1}^{n} \frac{C_{\mathrm{mai1}}}{(1+q)^{y_n}} \tag{2}$$

Where, C_{mai1} is the cost of one ordinary maintenance and repair for the culvert and pavement, n is the number of times needed to be maintained and repaired during the service life, y_{n} is the years to the present when the maintenance and repair happened, q is the discount rate. Based on the general capitalization rate of the highway engineering in China, discount rate of the present value chooses 8%.

The recycling cost can be calculated according to the salvage value of the culvert. The salvage value is the value of the old material after demolition and take off the cost of the dismantle work. It always represent by a percent of the initial cost. Then it must be discount to the present value. So the recycling cost can be expressed as Eq. 3.

$$C_{\mathrm{rec}} = \frac{C_{\mathrm{ini}} \times q_{\mathrm{s}}}{(1+q)^{y}} \tag{3}$$

Where, q_{s} is the salvage value ratio, y is the expected service life of the culvert.

The traffic will be interrupted when the deterioration of the culvert needs to be fixed or the deterioration causing failure. The user delay costs (C_{ud}) are not considered in the LCC because user costs are experienced by traffic users and are not a direct expense to any agencies budget. However, these are in fact real costs and need to be considered in the economic analysis. Recent studies have shown that user delays are the primary benefit in the select of the structural and/or construction methods [9]. The cost of delay is experienced by the user during the culvert's re-installation. Such costs can be significant and consideration should be given to incorporate them in LCC. So the total LCC present value of the culverts should be expressed as Eq. 4.

$$PV_{\mathrm{LCC}} = C_{\mathrm{ini}} + C_{\mathrm{mai}} - C_{\mathrm{rec}} + C_{\mathrm{ud}} \tag{4}$$

The user delay cost C_{ud} can be expressed as Eq. 5.

$$C_{\mathrm{ud}} = \frac{1}{(1+q)^{y_d}} (C_{\mathrm{udd}} + C_{\mathrm{udi}}) \tag{5}$$

Where, C_{udd} is the direct cost of the user causing by the delay, C_{udi} is the indirect cost of the user causing by the delay, y_{d} is the years to the re-installation happened.

Generally, the direct cost of the user can be calculated using Eq. 6.

$$C_{\mathrm{udd}} = t \times u \tag{6}$$

Where, t is the increasing time for the delay or congestion when the culvert re-installation (in days), u is the unit cost of the user causing by the delay per day.

The unit cost can be expressed as Eq. 7.

$$u = u_{\mathrm{t}} + u_{\mathrm{d}} \tag{7}$$

Where, u_{t} is time cost of the user causing by the delay per day, u_{d} is detour cost of the user causing by the delay per day.

The u_{t} can be calculated according the local staff wage levers and the ud is relating to the cargo transportation costs and traffic flow of the road [10].

The indirect cost should consider the cost of the relevant industry sections and the social losses caused by traffic disruption. It is relate to the length of time and the generally correlation with the relevant industry sections. The calculation is more complex, generally can be derive using the analogy method under the same conditions [11].

Various types of culvert material have different life expectancies. A major concern is whether the road operating managers have a plan to monitor and replace culverts based on either inspection, or culverts reaching their expected life. Without a plan followed by action, failing culverts will have to be replaced at emergency rates instead of normal rates. The new relationship would likely include a risk factor cost as included in many risk assessment methodologies. So the total LCC present value of the culverts should be expressed as Eq. 8.

$$PV_{\mathrm{LCC}} = C_{\mathrm{ini}} + C_{\mathrm{mai}} - C_{\mathrm{rec}} + C_{\mathrm{eu}} \tag{8}$$

Where, C_{eu} is the cost of emergency.

It includes the emergency installation cost and emergency user delay cost. So the C_{eu} can be expressed as Eq. 9.

$$C_{\mathrm{eu}} = \frac{1}{(1+q)^{y_d}}[ERF \times C_{\mathrm{ini}} + (1+RF) \times C_{\mathrm{udd}}] \tag{9}$$

Where, ERF is emergency replacement factor for a certain culvert type, RF is the emergency user delay risk factor for a certain culvert type.

Obviously, the cost of installation in emergency situation when failure occurs would much larger than the normal situation. And the user delay cost, especially the indirect user delay cost also would much more than the planned arrangements in advance. The value of the factors ERF and RF should based on a national database. It also can be got using the analogy method if the database is not enough.

Example Analysis and Discussion of Results

The example is three reinforced concrete culverts with 5m span in Inner Mongolia changed design to the round corrugated steel culverts with the same span. According to the budget of the project, the initial cost of the reinforced concrete culverts are RMB 8 921 026 yuan. The initial cost of three corrugated steel culverts are RMB 9 774 155 yuan. The initial cost of the corrugated steel culverts is larger than the reinforced concrete because the corrugated steel is import from Korea. The import tariffs and the port charges is RMB 777 102 yuan. Subtract the import fee, if only the initial cost is considered, the cost increased by 0.9%.

But the reinforced concrete culvert need maintained or repaired regularly while the corrugated steel culvert hardly needs it. According to the Guidelines for Design of Highway Culverts of China [12], the design service life of culvert is 50 years. Assumed the ordinary cost of each maintenance or repair work is RMB 60 000 yuan for the three culverts, so the maintenance cost of the reinforced concrete culvert can be calculated using Eq. 2 and get the maintenance cost RMB 49 389 yuan.

The salvage value rate of the reinforced culvert is almost zero [13]. But the salvage value rate of the corrugated steel plate culvert is 80%, so the recycling cost of the corrugated steel culvert can be calculated using Eq. 3 and get the recycling cost RMB 166 717.6 yuan. Thus the typical total LCC present value of the reinforced culvert is: 8 921 026 + 49 389=8 970 415 yuan RMB. The total LCC present value of the corrugated steel culvert is: 9 774 155-166 717.6 =9 607 437.4 yuan RMB.

Taking off the import fee, the cost reduction of the corrugated steel culvert is 1.6%. So, it is can be seen that the cost is reduced when considering the typical LCC while it increased if only consider the initial cost as mentioned above.

But the above analysis has a prerequisite that all the culverts can achieve the design life. This is somewhat unrealistic. The deterioration of the corrugated steel culverts must be taken into account.

Now, considering the deterioration of the corrugated steel culverts, the user delay cost must be taken into account. Assuming the expected service life of the culvert is 25 years, the LCC cost during the design service life (50 years) can be calculated as follows:

The initial cost at 0 years is RMB 9 774 155 yuan; The recycling cost of the corrugated steel culvert at 25 years calculated using Eq. 3 is RMB 1 141 761.3 yuan; The initial cost at 25 years discount to present value is RMB 1 427 201.6 yuan; The recycling cost of the corrugated steel culvert at 50 years calculated using Eq. 3 is RMB 166 717.6 yuan.

The user delay is related to the population density and the economic develop lever of the district where the culvert constructed. Using the date of China from reference [14], for one breakage of the road, the direct cost of the user delay is RMB 2777.8 yuan per day, the indirect cost of the user delay is RMB 1111.1 yuan per day. The installation period of one corrugated culvert is about 20 days. So the user delay cost C_{ud} can be calculated using Eq. 5 and get the user delay cost RMB 102 212.8 yuan.

The total LCC value considering the deterioration initiatively is: 9 774 155-1 141 761.3+1 427 201.6-166 717.6+ 102 212.8= 9 995 090.5 yuan RMB.

But if the culvert not being replaced as it approaches its expected life, the failure may happen. According to reference [6], the re-installation cost in emergency is larger than the normal cost by times various from 4-140. Here we choose ERF =5 conservatively. According to reference [5, 11], the indirect cost of the user the delay in emergency is about 5-12 times as the direct cost. Here we also choose RF =5 conservatively. Thus the cost of emergency C_{eu} for corrugated steel culvert failure at the 25th service year can be calculated using Eq. 9 and get the cost of emergency RMB 7 574 065.4 yuan.

The total LCC value at emergency situation is: 9 774 155-1 141 761.3-166 717.6+ 7 574 065.4= 17 039 741.5 yuan RMB. It is much larger than 9 995 090.5, almost double the cost of considering the deterioration. The costs will much more if we take the risk factors larger. That is to say if agencies replaced culverts regularly once the expected service life was met, then most culvert failures could be prevented and the total LCC could be reduced. But this may best accomplished by initially constructing culverts with pipe materials with longer life expectancies and/or by providing an established inspection, maintenance, and replacement program.

Conclusions

According to the above analysis and the economic comparison, following conclusions can be obtained:

Deterioration of the corrugated steel culvert is objective. The inspection and maintenance schedule should be formulated considering the culvert size, the environment in which the culvert is placed, and the characteristics of the soil and the backfill.

The typical LCC approach can be used to choose the design plan. But the user delay cost should be added to the typical LCC value if the deterioration is considered.

The total LCC value at emergency situation is much larger than the situation when the deterioration is considered initiatively. Such economic analysis can help the project decision makers better understand the risks associated with deterioration and failure.

Keywords: endocrine disrupting chemicals (EDCs);nanofiltration;photocatalytic oxidation

Abstract: The potential hazard effects of Endocrine Disruptors (EDCs) are drawing growing attention from the public,and the traditional sewage water treat process works in an unstable way in the removal of EDCs and can be influenced by many factors.The membrane technology shows good interception efficiency of EDCs,and the photocatalytic oxidation,with its wide application range of different types of polluted water,can thoroughly convert EDCs to inorganic materials.The combination process of nanofiltration and photocatalytic oxidation can easily extract EDCs from the water at first step,and decompose the EDCs in the concentrated polluted water and the back fluch water collected at the second step.The combination process is a reliable,practical and effective methods for EDCs removal.

Since the 1990s, scholars have discovered that many chemicals have the ability to interfere with the endocrine system of the human body and the animals',those chemicals are generally called endocrine disruptors (EDCs).Because EDCs behave similarly to hormones,traces of them can cause negative effects on the reproduction and growth process,neural and immune system,and can lead to cancers and bring damages to the eco-system,etc.which poses great potential hazardous threats on the health of human and wild lifes.

Because EDCs usually exist in our life in very small amount[1] and damage the body slowly but continuously,it took a very long time for the public to take notice of their harms.In 1960,the publication of Silent Spring by Carson drew worldwide attention to environmental issues and aroused concerns about synthetic hazardous chemicals.With the increasing reports of abnormal growth of fishes, birds and frogs,etc. people are becoming increasingly aware of harms caused by EDCs.EDCs can be found in many places in our daily lives,for example,plastics,pesticides and pharmaceutical agents,etc. all of them contain EDCs or are themselves EDCs,what's more,even foods may contain EDCs such as phytohormone[2].

Current treatment process for EDCs

Because of lacks of relevant regulations,control criteria,public attention as well as the treatment technology and other reasons to fight against the soil and air pollution, the current pollution treatment methods focus mainly on water body,therefore,the EDCs controlling project should and can only begins from water treatment.Water body is one of the main place where EDCs exist,in wastewater,surface water, groundwater, and even drinking water,there have been EDCs detected,so the water body is the main target for EDCs removal and relevant studies[3].

Conventional water treatment processes for the removal of EDCs can generally be divided into three categories:physically,chemically and biologically.The major physical removal methods for EDCs are membrane method and absorbent charcoal method.The absorbent charcoal method shows great absorption ability in the removal of organic pollutants with small solubility,high hydrophobicity and weak polarity under the experimental conditions,however,this method can be seriously influenced by water conditions,especially in wastewater where diverse pollutants exist,and the adsorption capacity of the absorbent charcoal can deteriorate dramatically which will in the end make the processed water disqualified[4].Chemical methods such as photocatalytic oxidation,ozonation and chlorination can decompose EDCs to some extent,however,the hard to create and maintain working conditions,high costs and the possibility to generate new poisonous chemicals make it impractical in EDCs removal[5].Biological method performs unstable EDCs biodegradation,at the same time it

produces large amounts of toxic sludge treatment which makes the process even more complicated.Nie Yafeng[6] studied the EDCs removal efficiency of sewage treatment plants in many countries and found in some cases that the EDCs concentration in the processed water were unexpectedly doubled or more when compared with the primary sewage,concluding that the biodegradation process is much complex and can produce metabolites more toxic than the original pollutants [7].

As mentioned above,the sewage water contains pollutants that are both diverse and complicated,on the other hand,the conventional water treatment processes mainly focus on the demineralization,sterilization and turbidity reduction rather than EDCs removal of the polluted water,therefore,advanced treatment processes need to be established on the basis of conventional sewage treatment facilities in order to remove the conventional pollutants as well as EDCs.

Advanced combination treatment process for EDCs

Water body,even the domestic water we use daily,may carry kinds of pollutants such as heavy metals,disinfection by-products and EDCs which may be trace in amount but tremendous in their harms.How to wipe those pollutants out of everyday life is a question needs to be answered instantly for the long-term human health and development.

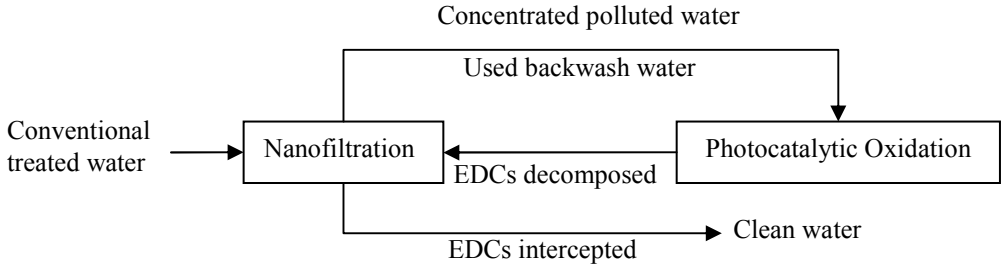

Fig.1 Advanced combination treatment process for EDCs

In order to remove the pollutants of trace amount from the water,an advanced treatment process is proposed as shown in Figure 1,this removal process can be interpreted as two steps:interception and decomposition.

2. 1 Interception

The interception of EDCs is necessarily the first step in the removal process,and in this step,the nanofiltration turns out to be effective and efficient with its unique advantages.As a membrane technology,nanofiltration performs better in the EDCs interception than ultrafiltration and microfiltration,and it needs lower operating pressure and is more energy saving than reverse osmosis,which makes it a ideal method for EDCs interception.

EDCs are mostly micromolecular organic pollutants,Figure 2 lists the relative molecular mass(MW) and dissolvability of 33 kinds of common EDCs,which are mostly pesticides,food additives and pharmaceuticals.

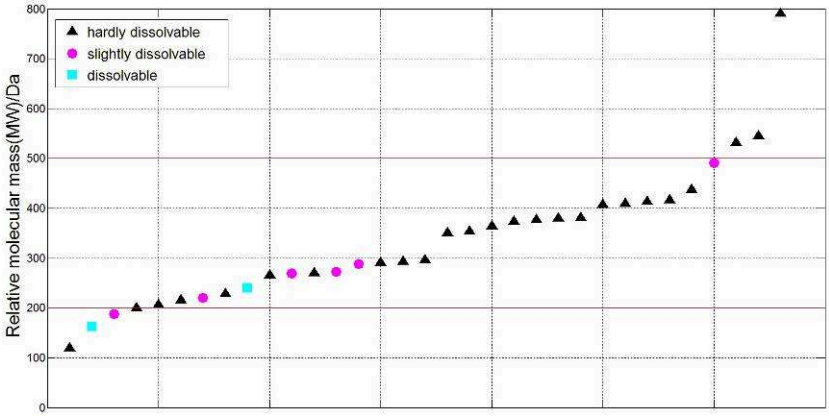

Fig.2 Features of 33 common EDCs

MWs of almost all the EDCs listed Figure 2 are greater than 200Da except 1,2-dibromoethane,methomyl and chloroform,and that of nearly 85 percent of the listed are ranging from 200Da to 500Da, according to the relationship between the Stokes radius and the MW of the organic molecules[8] [9]:

$$r_s = 0.0397 MW^{0.43}$$

It can be calculated that micromolecular organic pollutants with MW above 200Da have their stokes radius greater than 0.39nm,which are in the same order of magnitude with the nanofiltration membrane pore size.In fact,many studies have discovered that nanofiltration can effectively intercept the organic pollutants when their MWs are greater than 200Da,and sometimes the MW less than 200Da organic pollutants as well [10].

According to Figure 1,EDCs are mostly hydrophobic,and that many nanofiltration membrane are made from hydrophobic materials.It is similar to the principle 'like dissolves like' that adsorption occurs when the hydrophobic EDCs make contact with the surface of the membrane if it is also hydrophobic,and this adsorption reaction can be enhanced with the increase of the hydrophobicity of either the pollutant or the membrane[10].

The majority of EDCs are synthetic compounds that may be very possible to carry functional groups like amino and carboxyl,which can hydrolyze under certain pH condition so that the charged membrane surface will attract or repulse the ionized pollutants,for example,estriol,triadimefon and phthalate,etc.Other EDCs without hydrolysable functional groups may carry alcohol,aldehyde, ketone,ester or amine that can interact with the membrane due to the polar force.Thus,some of the EDCs are intercepted by nanofiltration.

In the light of the special properties of nanofiltration membrane and molecular characteristics of EDCs,it can be concluded that nanofiltration is an effective method in advanced sewage water treatment for EDCs interception.However,the membrane fouling will eventually happen during the working process due to concentration polarization and pollutants deposition,and this may lead to some serious problems such as disqualified processed water and shortened life span of the membrane, therefore,periodical backwash for the membrane is needed to ensure its proper functioning.The backwash water carries the pollutants away from the membrane so the membrane will be fresh again,then the used backwash water and the concentrated polluted water on the polluted side will be collected for further treatment to decompose the EDCs at last.

2. 2 Decomposition

The second step of EDCs removal process is decomposition.In this step, photocatalytic oxidation is applied to ensure the thorough decomposition of EDCs.It is a water treatment method using semiconductor as catalyst for the oxidation of pollutants.The semiconductor particles have energy band structure that consist of low-energy valence band (VB) filled by electrons and high-energy conduction band(CB) composition which is empty.When the light hit the semiconductor,photons in the irradiation light carrying certain energy also reach the surface of the semiconductor,and if the energy is greater than or equal to the energy the electrons needed for transition,electrons(e^-) in the VB will leap into the CB,leaving behind holes(h^+) in the VB.In the electric field,the holes will be ultimately transfered to the surface of the particle[11].Photocatalytic oxidation mechanism can be described by the following equations:

$$\text{semiconductor particle} \xleftrightarrow{h\nu} h^+ + e^-$$

$$H_2O + h^+ \longrightarrow \cdot OH + H^+$$

$$OH^- + h^+ \longrightarrow \cdot OH$$

$$O_2 + e^- \longrightarrow O_2^-$$

$$O_2^- + H_2O \longrightarrow \cdot OOH + OH^-$$

$$2 \cdot OOH \longrightarrow H_2O_2 + O_2$$

$$\cdot OOH + H_2O + e^- \longrightarrow H_2O_2 + OH^-$$

H_2O_2 and h^+ generated by the above process have very strong ability to steal electrons from the pollutants.These strong oxidizing intermediate products can snatch electrons of EDCs adsorbed on the surface of the semiconductor or in the water and make them completely decomposed.

TiO_2 is one of the most mommon photocatalysts applied in Photocatalytic oxidation,if the wavelength of the light strikes on TiO_2 is equal to 387.5nm or less, electrons will be motivated and leap into CB,creating the strong oxidizing holes and electrons structure.Nowadays,new techniques has made it possible for TiO_2 to be motivated by visible light,of which the wavelength is much longer than the 387.5nm ultraviolet light,these techniques include photosensitization and adding special reagents.Those techniques pave ways for the photocatalytic oxidation of pollutants under milder working conditions,making this water treatment method more practicable and easier to popularize.

Photocatalytic oxidation has many advantages over other methods in sewage water treatment.For example,it requires milder working conditions and it can be widely applied in different kinds of polluted water,most important of all,it can completely convert organic pollutants to CO_2 and H_2O,including recalcitrant and toxic chemicals[12].

The used backwash water and the concentrated polluted water collected from the nanofiltration facilities will be diverted directly to the photocatalytic oxidation facilities.In the coming period of a membrane backwash cycle,the EDCs and other contaminants in the water will be decomposed completely at last.Time is sufficient and chemical reaction is strong in this process,and that photocatalytic oxidation for EDCs removal is both effective and efficient.The decomposed water will then be delivered back to the nanofiltration facilities for recycling treatment,making sure that water coming out of the treatment plant will be clean water only.

Conclusions

From the theoretical standing point,the combination sewage treatment process of nanofiltration and photocatalytic oxidation,as an advanced treatment method,can work effectively in the control over EDCs.As for the selection of materials,the membrane with molecular weight cutoff 200Da and which is also hydrophobic is the optimum choice.Although to add advanced water treatment processes on the basis of conventional sewage treatment facilities will no doubt increase the operation cost and complicate the management,we should learn our lessons from the disadvantages of ‘economic development first,environmental protection second’ route,and take preventive measures before the crises emerge.In the long run,the advanced treatment program will benefit all the mankind.

The in-depth study of the EDCs control still has a long way to go,the comprehensive understanding and forward-looking research of EDCs is necessary and will certainly play a significant role in ensuring the cleaness of domestic water and safeguarding people’s the health. There arestill many questions of EDCs need to be answered now,before we solve all those problems,the most important things we can do right now are changing the way we lives,strengthening environmental protection consciousness,paying more attention to the way we produce life necessities especially pesticides and fertilizers and other chemical goods,encouraging cleaner production,safely usage and proper waste disposal,so as to prevent EDCs pollution.

Keywords: argon frost, cryogenic, helium adsorption, Grand Canonical Monte Carlo

Abstract. Fusion reactors require high-speed pumping of helium, deuterium and tritium while maintaining the inventory of tritium in the pumps at a low level. Cryopumping is potentially the most attractive method for this task. Cryosorption pump using rare-gas as sorbent is a good choice to satisfy the reactors for its special characters. Although a large number of works have been published in recent years on the properties of cryosorption pump using rare-gas as sorbent, it is hard to understand the behavior of fluid in a frost layer due to expensive and strict experiment conditions. Molecular modeling provides a convenient way to understand the principle of adsorption procedure in microscopic view. This paper applies the Grand Canonical Monte Carlo (GCMC) simulation method to study the adsorption behavior of Helium in argon frost. The HFD-B (HE) Aziz potential is used for the description of the interaction between two helium molecules. The adsorption behavior of helium in slit pore at T=4.3 K, 5 K, 6 K and 7 K is simulated. The simulation results show that the adsorption capacity increased rapidly as the bulk pressure smaller than 0.01 Pa, and the slop becomes slowly as pressure raised. The adsorption capacity is over 50% higher at lower temperature. The adsorption behavior agrees very well with experimental data in the public literature. The results show in this paper could be a guide for cryogenic workers to design cryosorption pump system. It is also provided a convenient method to predict the real adsorption procedure.

Introduction

Fusion power has the potential to provide sufficient energy to satisfy mounting demand with a relatively small impact on the environment. Fusion reactor which burn hydrogen isotopes (D/T) will produce neutrons and helium. It requires high-speed pumping of helium, deuterium and tritium while maintaining the inventory of tritium in the pumps at a low level. Cryopumping is potentially the most attractive method for this task. Cryosorption pump using rare-gas as sorbent is a good choice to satisfy the reactors for its special characters.

There are some gases, such as Ar, CO_2, SF_6 and N_2, exhibit large adsorption ability at low temperature for their porous structure [1]. The technology was applied in many large scientific projects. An argon frost continuous cryopumping system was carried out for Tokamak Fusion Test Reactor (TFTR) at the Princeton Plasma Physics Laboratory, and for DIII-D at General Atomics [2]. The TRAP (TRitium Argon frost Pump) was set up to study the performance of argon frost adsorption pump at Tritium Laboratory Karlsruhe in Germany [3].

Although a large number of works have been published in recent years on the properties of cryosorption pump using rare-gas as sorbent, it is hard to understand the behavior of fluid in a frost layer due to expensive and strict experiment conditions. The mechanism of the adsorption of gases on frost layers is best understood with computer simulation because detailed configurations of the adsorbed phase can be analyzed.

This paper applied the Grand Canonical Monte Carlo (GCMC) simulation method to study the adsorption behavior of spherical Helium molecule at 4.3 K, 5 K, 6 K and 7 K in argon frost pores.

Theory

The GCMC simulation is used to simulate the adsorption isotherms [4]. The slit pore model is used during the simulation (Fig. 1). The slit is bounded by argon walls of infinite area in the x-y plane. H is the internuclear distance (along the z-axis) between argon atoms in opposite walls. Δ is the internuclear distance of argon frost layers. Each pore wall comprises n parallel layers which represented the thickness of pore wall.

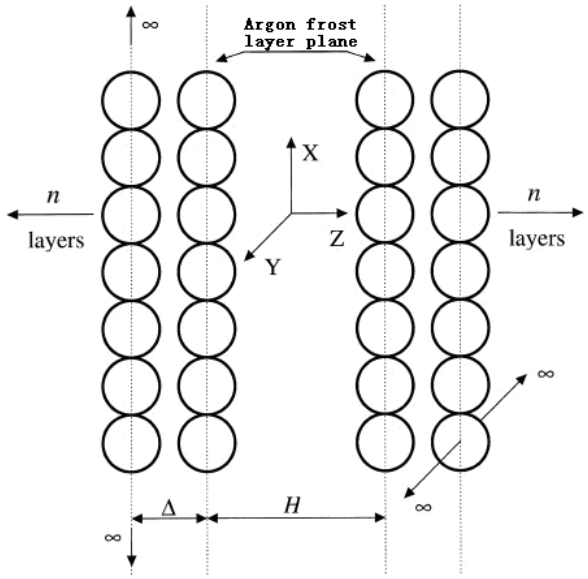

Fig. 1 The Schematic diagram of a slit pore

Periodic boundary conditions are applied in the x and y direction to simulate the infinite extent in that direction. Each of the equilibration and sampling stages has 50,000 cycles, with 3,000 steps in each cycle and equal probability between displacement, insertion and deletion.

Helium-Helium Potential Model. The HFD-B (HE) Aziz potential is adopted to represent the helium-helium interaction. The form of the HFD-B potential is [5]

$$U(r) = \varepsilon_{He} U^*(x) \tag{1}$$

where

$$U^*(x) = A^* \exp(-\alpha^* x + \beta^* x^2) - F(x)\sum_{j=0}^{2} c_{2j+6} / x^{2j+6} \tag{2}$$

with

$$F(x) = \begin{cases} \exp[-(\dfrac{D}{x} - 1)^2] & x < D \\ 1 & x \geq D \end{cases} \tag{3}$$

$$x = \frac{r}{r_m}$$

The parameters of the present potential are given in Table 1. ε_{He} is the depth of the potential minimum and σ_{He} is the collision diameter. The potential is cut off at a distance $r_c = 5.0\sigma_{He}$ during simulations to save computer time.

Table 1 HFD-B(HE) potential parameters

Parameter	Value	Parameter	Value
α	10.43329537	C_{10}	0.17473318
β	2.27965105	D	1.4826
C_6	1.36745214	r_m/A	2.963
C_8	0.42123807	A	184431

Argon-Helium Potential Model. The total interaction potential is the sum of the helium-helium interaction energy and the argon-helium interaction energy. This paper takes a simple model of surface, which is assumed to be homogeneous (structureless). The interaction potential energy between a helium molecule and the homogeneous flat argon frost wall is calculated by the well-known 10-4-3 Steele potential: [6]

$$U(z)=4\pi\rho\varepsilon_{sf}\sigma_{sf}^2\Delta\left\{\frac{1}{5}\left(\frac{\sigma_{fs}}{z}\right)^{10}-\frac{1}{2}\left(\frac{\sigma_{fs}}{z}\right)^{4}-\frac{\sigma_{sf}^4}{6\Delta(0.61\Delta+z)^3}\right\} \tag{4}$$

Where ρ is the volumetric argon atom density (27.5 nm^{-3}), and Δ is the spacing between two adjacent layers (2.628 A). The helium-argon molecular parameters are calculated from the Lorentz-Berthelot mixing rule with the values of $\varepsilon_{Ar}/k_B=119.8\,\mathrm{K}$ and $\sigma_{Ar}=0.34\,\mathrm{nm}$ for argon and $\varepsilon_{He}/k_B=10.948\,\mathrm{K}$ and $\sigma_{He}=0.26369\,\mathrm{nm}$ for helium. The cross collision diameter is:

$$\sigma_{sf}=(\sigma_{Ar}+\sigma_{He})/2 \tag{5}$$

The argon-helium interaction energy is:

$$\varepsilon_{sf}=\sqrt{\varepsilon_{Ar}\varepsilon_{He}} \tag{6}$$

Analysis of Simulation Data

The surface excess density is used to represents the adsorption amount. The excess amount is defined as the difference between the amount in the system and a hypothetical amount occupying the accessible volume of the system with adsorbate having the same density as the bulk gas phase.

$$\Gamma_{ex}=\frac{\langle N_{ex}\rangle}{A}=\frac{\langle N\rangle-N_G}{A} \tag{7}$$

where <> represents the ensemble average. N_G is the number of particles occupying the accessible volume of the system at the same density as the bulk gas phase. The accessible volume is the volume for which a molecule has a non-positive potential, and can be calculated by Monte Carlo method [7] as follows: a spherical helium particle is randomly inserted into the simulation model, and if its solid-fluid potential energy is negative or zero, it is counted as a success and then remove the particle from the box. This process is repeated 10 million times and the percentage of success is calculated and taken to be the ratio of the accessible volume to the simulation box volume.

Results and Discussions

Fig. 2 shows the isotherms of helium adsorption in argon frost at 4.3 K, 5 K, 6 K and 7 K. From the simulation results, it is seen that the adsorption capacity increased rapidly as the bulk pressure smaller than 0.01 Pa, and the slop becomes slowly as pressure rised. That's because the adsorption capacity increased with bulk pressure. It is difficult to adsorb more particles when the argon frost filled with

helium atoms. It is also seen that at the same helium pressure, the surface excess density increased as the temperature down. The adsorption capacity is over 50% higher at 4.3 K than that at 7 K. The results are in reasonable agreement with experiment conclusion in literature [8]. In the low pressure zone (less than 0.01 Pa), the higher the temperature the greater slop changed. As the temperature increased, the thermal motion of molecules makes it easer to release from the argon frost. So decrease the temperature of cryoplate can make the cryosorpsion pump more efficiet.

Keywords: Nanofluids; Nanoparticles; Convection heat transfer; Laminar flow

Abstract. This paper presents a numerical study on laminar flow and convective heat transfer of nanofluids in a circular tube under constant wall heat flux boundary condition. Single phase model is used for simulating the heat transfer and flow behaviors of three different nanofluids. The effects of nanoparticle concentrations, nanoparticle diameter, nanoparticle material and Reynolds number on the Nusselt number and wall shear stress of nanofluids are determined and discussed in details. The comparison of Nusselt number of CuO-EG/water, SiO_2-EG/water and Al_2O_3-EG/water nanofluids are presented. The results show that Nusselt number clearly increases with an increase in the nanoparticle concentration and flow Reynolds number, while the nanoparticle diameter has an opposite effect on the Nusselt number. Compared to SiO_2-EG/water and Al_2O_3-EG/water nanofluids, CuO-EG/water nanofluids give higher Nusselt number with the same nanoparticle concentrations. The results also show that wall shear stress increases with increasing nanoparticle volume concentration.

Introduction

As a type of colloidal suspensions of nano-sized solid particles, nanofluids named by Choi [1] in 1995 have attracted much attention since extensively greater thermal conductivity and heat transfer performance as compared to the base fluids [2]. Since a decade ago, there were several experimental and numerical studies about flow and convective heat transfer performance of nanofluids. In the experimental aspect, Xuan and Li experimentally studied the convection heat transfer and friction coefficient of nanofluids in both laminar and turbulent flows [3]. Wen and Ding investigated the convective heat transfer characteristics in Al_2O_3-water nanofluids along a copper tube [4]. Sharma et al. experimentally studied the convective heat transfer coefficient and pressure drop in the transient region for Al_2O_3-water nanofluids under a constant heat flux [5]. As for as the numerical simulations for flow and convection heat transfer of nanofluids is concerned, only very recently a few papers have published. He et al. numerically studied the convective heat transfer in TiO_2 nanofluids flow through a straight tube under the laminar conditions by using both single phase method and combined Euler and Lagrange method [6]. Izadi et al. numerically investigated laminar forced convection in Al_2O_3-water nanofluids in an annulus by the single phase approach [7]. Moraveji et al. simulated Al_2O_3-water nanofluids through a tube under constant heat flux [8]. They all found that the heat transfer coefficient increased by increasing the nanoparticle concentration and Reynolds number.

Ethylene glycol and water (EG/water) based nanofluids are required for application in cold regions, which have not been studied widely thus far. In this study, the forced flow and convective heat transfer of the laminar flow containing EG/water based nanofluids under constant heat flux is simulated using the Computational Fluid Dynamics (CFD) tools. Three different nanoparticles (CuO, Al_2O_3 and SiO_2) in an EG/water mixture are used to investigate the effect of nanoparticle concentrations, size and their properties on convective heat transfer and flow.

Mathematical modeling

Governing equations. Compared to the two phase model, the single phase model is simpler to implement and requires less computational time. For the nanofluids, nanoparticles are much smaller

than micro particles and the relative velocity decreases as the particle size decreases. The fluid phase and nanoparticles are in thermal equilibrium with zero relative velocity, which means the nanofluids may be considered as a conventional single phase fluid [9]. Therefore, single phase model is adopted to describe the laminar flow and heat transfer characteristics of nanofluids through a straight circular tube under constant wall heat flux in this study.

On the basis assumptions of single phase model, the governing equations for nanofluids are given in the following [9].

$$\iint \rho_{nf} \vec{V} \cdot d\vec{A} = 0 \tag{1}$$

$$\int_{\forall} \rho_{nf} \frac{\partial \vec{V}}{\partial t} d\forall + \iint \vec{V} \rho_{nf} \vec{V} \cdot d\vec{A} = -\iint p\vec{n} \cdot d\vec{A} + \iint \mu_{nf} \vec{\nabla} \vec{V} \cdot d\vec{A} \tag{2}$$

$$\int_{\forall} (\rho C_p)_{nf} \frac{\partial T}{\partial t} d\forall + \iint (\rho C_p)_{nf} T\vec{V} \cdot d\vec{A} = \iint k_{nf} \vec{\nabla} T \cdot d\vec{A} \tag{3}$$

where $\vec{V}$, p , T , t , $\forall$, $\vec{A}$ and $\vec{n}$ are the velocity vector, pressure, temperature, time, volume, cross-sectional area vector and normal unit vector, respectively. The subscript nf means the effective thermophysical properties of nanofluids which are temperature dependent under the operating conditions.

The density and heat capacity of nanofluids can be calculated by Buongiorno [10].

$$\rho_{nf} = \phi\rho_p + (1-\phi)\rho_{bf} \tag{4}$$

$$C_{pnf} = \frac{\phi\rho_p C_p + (1-\phi)\rho_{bf} C_{bf}}{\rho_{nf}} \tag{5}$$

The thermal conductivity of nanofluids can be calculated by Hamilton and Crosser [11].

$$\frac{k_{nf}}{k_{bf}} = \frac{k_p + (n-1)k_{bf} - (n-1)\phi(k_{bf} - k_p)}{k_p + (n-1)k_{bf} + \phi(k_{bf} - k_p)} \tag{6}$$

where the subscript p and bf mean the effective thermophysical properties of nanoparticle and base fluid, respectively. n is the shape factor and is equal to 3 for spherical nanoparticle.

The viscosity of nanofluids can be calculated by Namburu et al. [12].

$$\log \mu_{nf} = Ae^{-BT} \tag{7}$$

where two parameters A and B are determined according to the experimental data .

Boundary conditions and grid optimization. In order to simulate the nanofluids flow, circular tube geometry with 0.004 m in diameter and 2 m long is adopted according to the flow geometry in the experimental work of He et al. [6] as shown in Fig. 1. As for boundary conditions, the uniform velocity and temperature (T_{in}=293K) profile are assumed at the tube inlet section. At the outlet section, the flow and temperature fields are assumed fully developed ((L/D) > 10). Wall boundary condition is subjected to nonslip velocity and a uniform heat flux of 4000 W/m^2.

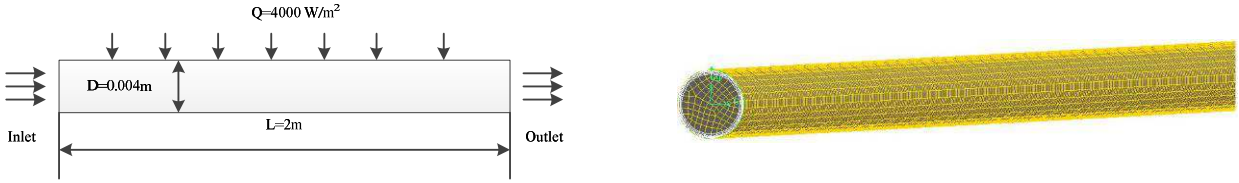

Fig.1 Flow geometry and numerical grid distributions

In order to identify the number of grid points that produce reasonably grid independent results, extensive computations have been performed. Fig. 2 presents the grid resolution effects on the axial variations of the centerline velocity and temperature for just four different mesh distributions. It is clear that both the grid 3 and grid 4 can resolve the velocity and thermal fields with reasonable accuracy. Considering computation time, grid 3 is used to describe the laminar flow and heat transfer characteristics of nanofluids in this study.

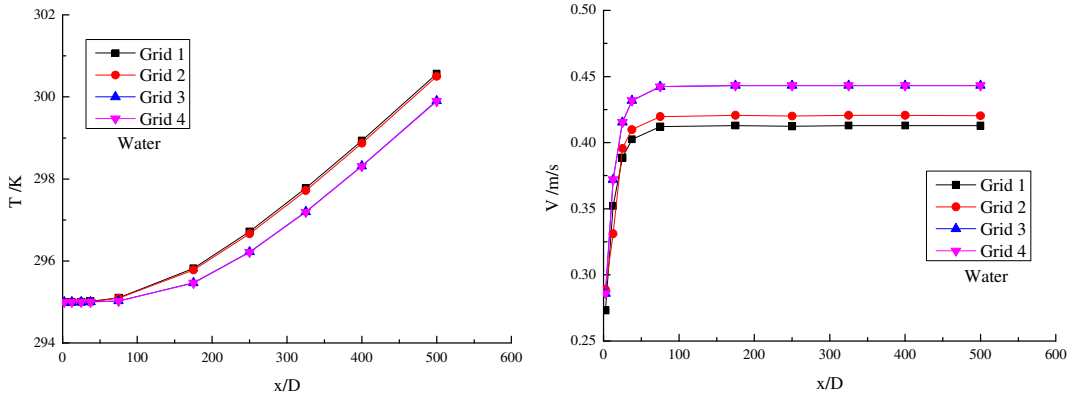

Fig.2 Axial variations of the centerline (a) velocity and (b) temperature of water for different grids at T_{in}=295K and Re=900

Results and discussion

Local heat transfer coefficient and Nusselt number are calculated using the following equations.

$$h(x)=\frac{Q}{T_w(x)-T_m(x)} \tag{8}$$

$$Nu(x)=\frac{h(x)D}{k_{nf}} \tag{9}$$

where T_w and T_m are tube wall temperature and nanofluids average temperature, respectively.

For checking the reliability and accuracy of the present numerical scheme, the numerical study is carried out on pure water firstly. As shown in Fig. 3, the axial variations of the local Nusselt number is compared with the experimental data of He et al. [6] and the results of the empirical expression by Shah [13]. It can be seen that reasonably good agreement is achieved.

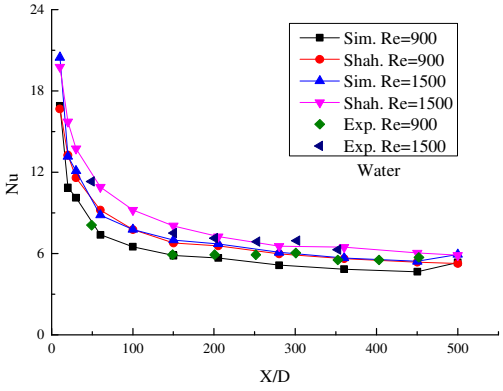

Fig.3 Comparison of axial variations of the Nusselt number with experimental data and empirical data

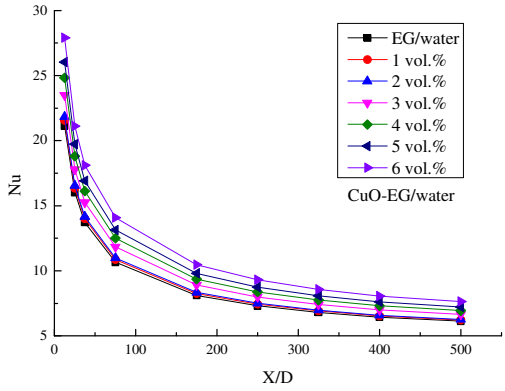

Fig.4 Axial variations of Nu for different nanoparticle volume concentrations

Effect of nanoparticle concentration on Nusselt number. Fig. 4 displays the effect of CuO nanoparticle (29nm) volume concentration on the Nusselt number along the tube for Reynolds number of 1000. The results indicate that the Nusselt number of nanofluids increases with increasing nanoparticle volume concentration. For example, in the case of 6 vol. %, the Nusselt number is about 24.76 % larger than EG/water at the end of tube.

Effect of nanoparticle diameter on Nusselt number. The effect of SiO_2 nanoparticle diameter (6 vol. %) on the Nusselt number along the tube for Reynolds number of 1000 is shown in Fig. 5. The results show that the nanofluids with larger nanoparticle diameter slightly decrease the Nusselt number as compared to the smaller nanoparticle diameter, especially at lower volume concentrations.

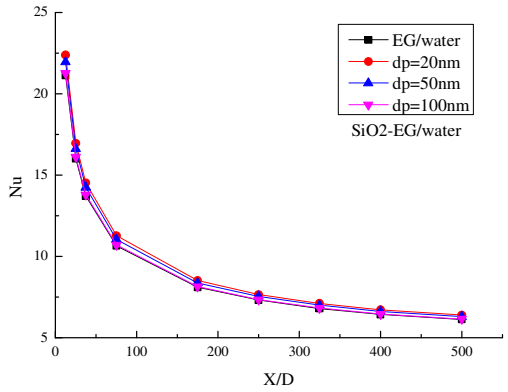

Fig.5 Axial variations of Nu for different nanoparticle diameter

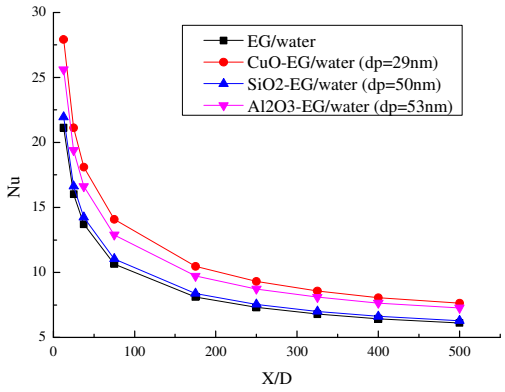

Fig.6 Axial variations of Nu for different nanoparticle material

Effect of nanoparticle material on Nusselt number. In order to study the effect of nanoparticle material, the Al_2O_3-EG/water and SiO_2-EG/water nanofluids are selected to compare with the results of the CuO-EG/water nanofluids. As shown in Fig. 6, CuO-EG/water nanofluids give higher Nusselt number than the Al_2O_3-EG/water and SiO_2-EG/water nanofluids with 6 vol. % nanoparticle concentration. This is because of the fact that the thermal conductivity of CuO nanoparticles is much larger than the thermal conductivity of Al_2O_3 and SiO_2 nanoparticles.

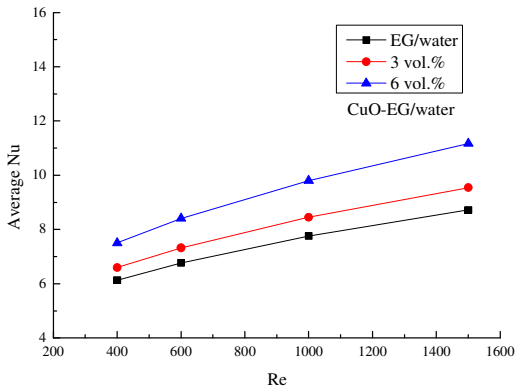

Fig.7 Variations of average Nu for different Reynolds number and nanoparticle concentrations

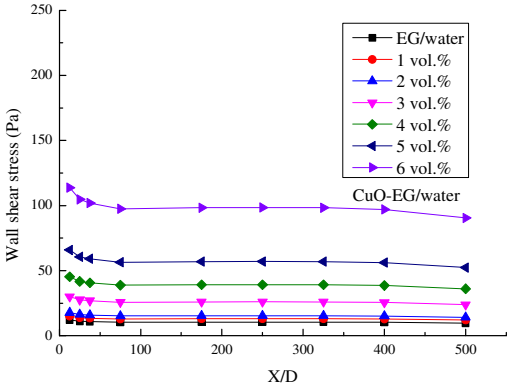

Fig.8 Axial variations of wall shear stress for different nanoparticle volume concentrations

Effect of Reynolds number on Nusselt number. Fig. 7 presents the effect of Reynolds number on the Nusselt number along the tube for CuO-EG/water nanofluid with nanoparticle diameter of 29 nm. The results indicate that the Nusselt number of nanofluid increases with increasing Reynolds number. This is due to the fact that higher Reynolds numbers lead to higher velocity and temperature gradients at the tube wall.

Effect of nanoparticle concentration on wall shear stress. Fig. 8 shows the numerical data obtained for the CuO-EG/water nanofluids with different nanoparticle (29nm) volume concentration on the wall shear stress along the tube for Reynolds number of 1000. From Fig. 8, it can be seen that wall shear stress increases with increasing nanoparticle volume concentration. Higher the wall shear stress, higher is the pumping power. Therefore, we should make a comprehensive decision the flow and convection heat transfer when selecting the nanofluids.

Conclusions

Numerical simulations have been performed by using a single phase model on the laminar flow and convective heat transfer of different nanofluids through a straight tube under constant wall heat flux boundary condition. The effects of some important parameters such as nanoparticle concentrations, nanoparticle diameter, nanoparticle material and Reynolds number on the Nusselt number and wall shear stress have been investigated. The results show that Nusselt number of

nanofluids increase with increasing in the nanoparticle concentration and flow Reynolds number and decreasing the nanoparticle diameter. At the Reynolds number of 1000, the Nusselt number for 6 vol. % CuO-EG/water nanofluids increases by 24.76 % over the base fluid at the end of tube. For the same nanoparticle concentrations of CuO-EG/water, SiO_2-EG/water and Al_2O_3-EG/water nanofluids, CuO-EG/water have highest heat transfer performance. The results suggest that we should make a comprehensive decision the flow and convection heat transfer when selecting the nanofluids because wall shear stress increases with increasing nanoparticle volume concentration.

Keywords: thin film, heat flux sensor, thermopile, thermocouple, dynamic response.

Abstract. A Cu-Ni thin film heat flux sensor had been fabricated on a 0.05mm thick polyimide film substrate by vacuum coating technology. The overall dimension of the sensor was 8 mm long and 4 mm wide. A thermopile and a thermocouple were arranged on the substrate to measure both heat flux and surface temperature. The thermopile had 18 thermocouple junctions which formed 9 pairs of differential thermocouples and were covered by two different thickness of thermal resistance layers. This research carried out static and dynamic tests of the thin film heat flux sensor. Seebeck coefficient of thermocouple is 19.3761μV/(˚C). Sensitivity of the thermopile is 0.010121μV/(W/m^2). Steady-state tests of the thermopile and the thermocouple were taken separately. Time constant of the thermocouple is about 0.26s, which is faster the thermopile of 1.57s.

Introduction

Various types of heat flux sensors have been developed due to its small volume, quick response and high sensitivity, including thin film thermocouple arrays and thin film Wheatstone bridge design. Liu selected silicon dioxide as the substrate to fabricate a six layers thin film heat flux sensor. Its sensitivity was 0.05062 μV/(W/m^2) [1]. Christopher et al developed a compound thin film heat sensor, which could measure both the surface temperature and heat flux. Materials of the sensor were Pt and Pt/Rh [2]. Using the same layout, Xiao et al made a high temperature thin film sensor. Results showed that response time of the heat flux sensor was 0.1s [3]. Experiment had indicated that the intrinsic strength and adhesion of the films to the substrate had a significant effect on sensor itself [4]. NASA used semiconductor materials - Al:ZnO and N:ITO to make thin film heat flux sensor. Placed on a 250 °C hot plate with an estimated maximum heat flux of 2200 W/m^2, the senor got a maximum output of 0.015μV, and the fluctuation was ±0.0035μV [5].

So far, research is mainly focus on single thin film thermocouple [6] or single thin film heat flux sensor. In this investigation, a thin film heat flux sensor, which can measure both heat flux and surface temperature, is designed, fabricated and calibrated.

Design of Thin Film Heat Flux Sensor

The thin film heat flux sensor was placed on polyimide film with a dimension of 8mm long, 4mm wide, and 0.05mm thick (Fig.1). Using vacuum coating technology, four layers were deposited on the substrate step by step - Cu layer (0.1μm), Ni layer(0.1μm), thermal resistance layer 1(0.2μm)

and thermal resistance layer 2(1.2μm). Silicon dioxide was applied as the two thermal resistance layers to create a temperature gradient in the vertical direction to the thermal resistance layers. To get a large output, 9 pairs of thermocouples were connected in series to form a thermopile. What's more, there was a single thermocouple beside the thermopile, which was used as a temperature sensor to measure the surface temperature. Leg A and leg B were the output of thermocouple and the thermopile output was read between leg C and leg D (shown in Fig.1).

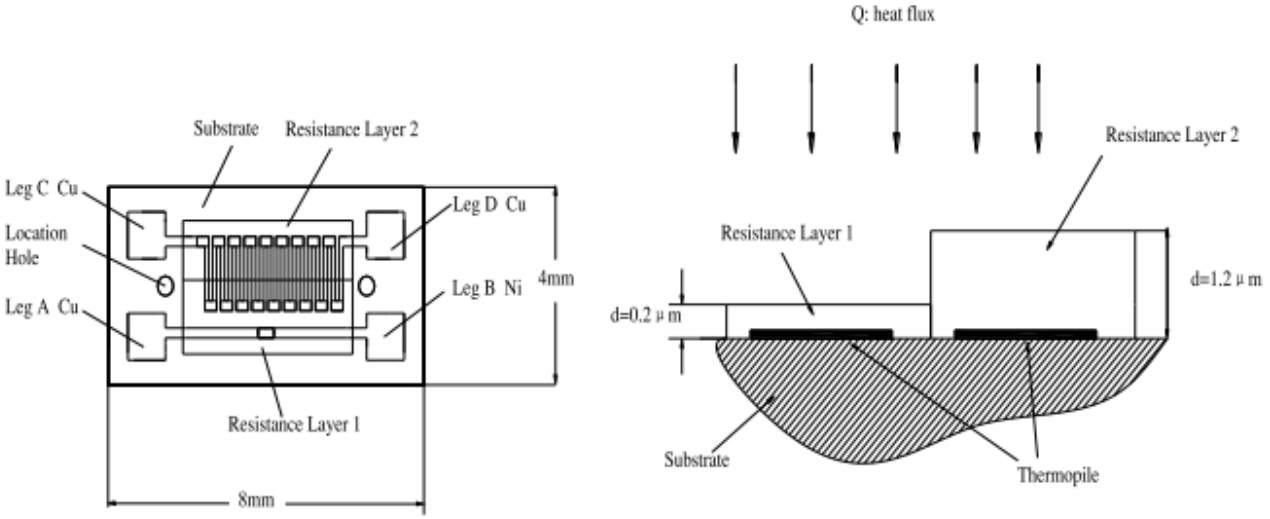

Fig. 1 Design layout of the thin film heat flux sensor

When a uniform heat flux is applied to the sensor, a temperature gradient will be created in the thermal resistance layer according to Fourier's conduction law. Therefore, the temperature difference measured by the thermopile is a function of the thickness of thermal resistance layer and the heat flux applied to the sensor, which can be shown s the following equation:

$$Q = \frac{\lambda}{d_1 - d_2}(T_1 - T_2) \tag{1}$$

Calibration of Thin Film Heat Flux Sensor

Static calibration is essential for the self-made sensor to obtain its sensitivity and performance. In fact, there are two sensors on the substrate: thin film heat flux sensor and thin film temperature sensor. Therefore, they have to be calibrated separately. First, the sensors were attached on the internal wall of a high-precision thermostatic water cabinet for temperature calibration. A K type thermocouple was placed at the same place. Output of the K type thermocouple is regarded as the reference temperature. The calibration was taken at a room temperature of 24.5˚C. Fig.2 shows the result of thermocouple's static calibration. As can be seen, correlation coefficient R is 0.94871.Result indicates that the output of thin film thermocouple has a relatively good linear relationship with the temperature. Moreover, Seebeck coefficient of the thin film thermocouple is 19.3761μV/(˚C), which is close to the standard Cu-Ni thermoelectric power 22.5μV/(˚C).

The heat flux calibration system is the same system with Liu [1]. The reason for choosing a halogen lamp as heat source is that it not only produce a wide range of heat flux values but also the heat flux values can be measured by a standard sensor. The standard heat flux sensor is HFM-201 in this paper. By adjusting the input power of halogen lamp we can get a series of heat flux values. Fig.3 is the calibration line between the heat flux and output voltage. Correlation coefficient R is 0.99759. The slope of the fitting line is 98.80643, thus the sensitivity is 0.010121μV/(W/m^2).

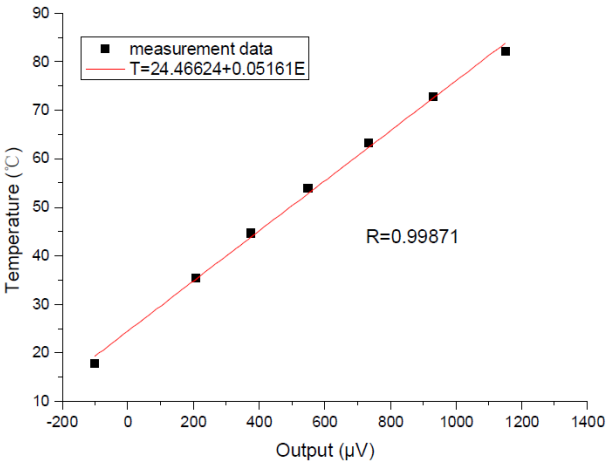

Fig.2 Static calibration of temperature

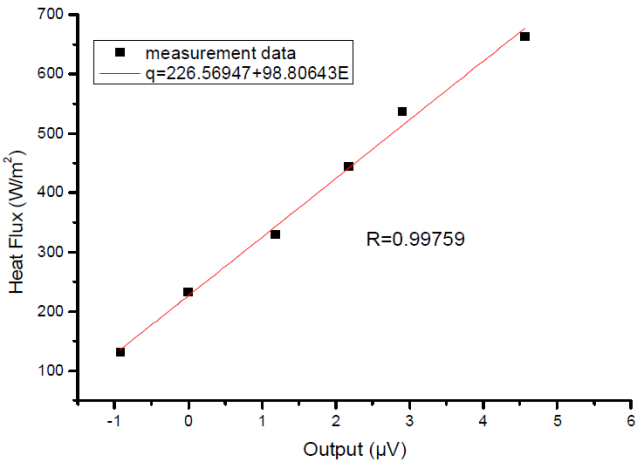

Fig.3 Static calibration of heat flux

Steady-State Response of Thin Film Heat Flux Sensor

To measure the steady-state response of the heat flux sensor, the halogen lamp is set at a constant output of 2kW and the sensor is irradiated until it reaches steady state. Results are show in Fig.4. It is observed that the heat flux increases rapidly when opening the circular shadow shield and stabilizes to an approximately constant value, same phenomenon emerges when heat source is disappeared. However, the temperature increases as a function of time. This behavior can be explained by that: the output of thermopile is the temperature difference between different thermocouples under different thickness of thermal resistance layers, while, the output of thermocouple is the temperature of substrate, which is increasing because of constant radiant heating during the test. Through this test, time constant of the thermopile can be calculated, which is 1.57s. In order to get the real dynamic response of the thin film thermocouple, we take the quickly throwing method as Yang [6] used. Fig.5 is the steady-state response of the thin film thermocouple when suddenly throwing the sensor into hot water. Time constant of the thermocouple is 0.26s, which is faster than the thermopile.

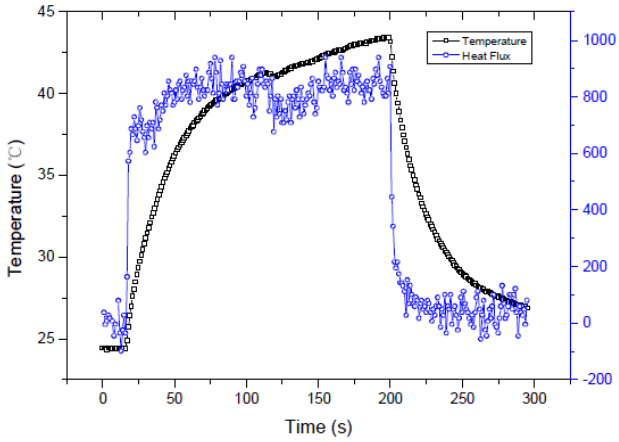

Fig.4 Steady-state responses of the sensor

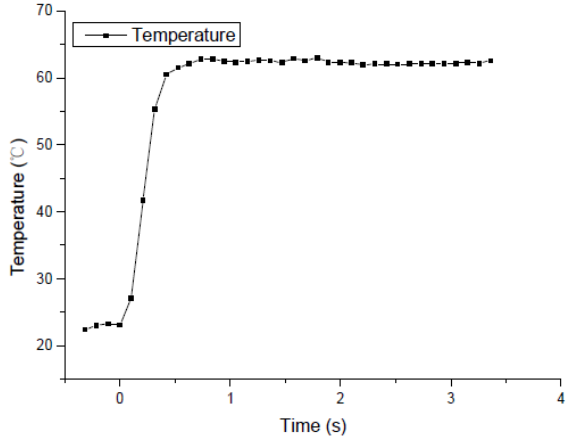

Fig.5 Steady-state responses of the thermocouple

Dynamic Response of Thin Film Heat Flux Sensor

During the dynamic calibration, the sensor get an intermittent heat flux by adjusting the circular shadow shield and the interval time is 10s. Dynamic response of the sensor is shown in Fig 6. As seen, responses of the thermopile and the thermocouple show two different tendencies. The heat

flux changes rapidly to the periodic heat flux. With a relatively high sensitivity of the heat flux sensor, its output fluctuates around a certain value. Surface temperature of the substrate is getting up and down when open and close the circular shadow shield. Different behaviors of heat flux and temperature once again demonstrate that heat flux has nothing to do with the substrate temperature.

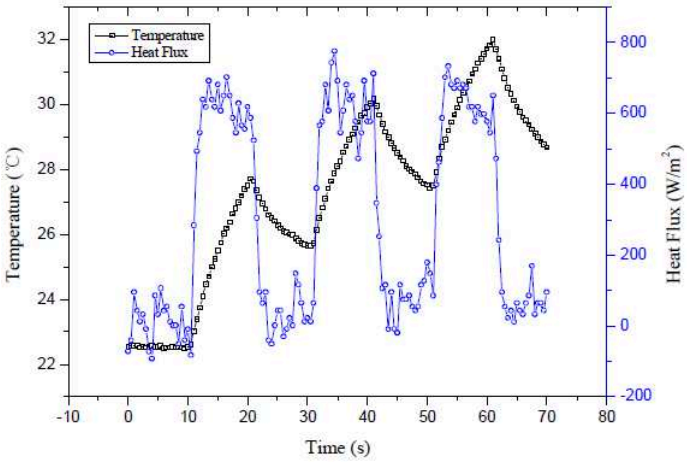

Fig.6 Dynamic response of the sensor

Conclusion

In this paper, a compound thin film heat flux sensor is developed and tested. It can measure both heat flux and temperature. Calibration results show that both thermopile and thermocouple have good linear relationship. Correlation coefficient R are 0.99759 and 0.99871, respectively. Using quickly throwing method, time constant of the thin film thermocouple is obtained and the value is 0.26s, which is faster than the thermopile. Dynamic test shows that the heat flux sensor responds fast to periodic radiant heat flux.

Keywords: Syngas, CO_2 capture, Renewable energy, Thermodynamic analysis, Sensitivity analysis

Abstract. Hydrocarbon fuel synthesis with renewable energy and captured CO_2 is a promising option for CCU and an important approach to sustainable energy. Like photosynthesis of plants, the technology of CO_2 direct captured from atmosphere with CO_2 utilization would close the carbon cycle thoroughly. Because of the dilute CO_2 in the atmosphere, the air capture process faces the challenge of high energy penalty. However, integrated with fuel synthesis process, the air capture process can take advantage of the waste heat produced by syngas production process and the transportation of CO_2 can also be avoided. In this study, a thermodynamic model of the fuel synthesis system is built through energy and exergy analysis. The thermodynamic contribution of three typical CO_2 capture technologies, moisture swing air capture, high-temperature swing air capture and traditional amine-based flue gas capture, is studied using the model built. Furthermore, by the sensitivity analysis of the critical parameters of the capture, electrolysis and heat exchange process, the influence of each process on the performance of fuel synthesis system is examined and the approach to improve the efficiency of the total system is proposed.

Introduction

CCU (Carbon Capture and Utilization)[1] is a new concept developed from CCS (Carbon Capture and Sequestration), which could evade the risk and uncertainty of CO_2 storage. Meanwhile, the conversion of CO_2 into high value products offsets high energy penalty and cost of capture process, which will accelerate the application of the technology.

As an option of CCU, hydrocarbon fuel synthesis with renewable energy and captured carbon dioxide has been widely studied[2]. Among the different carbon capture technologies, air capture is a more suitable technology for fuel synthesis as it can provide a CO_2 source without constraints from location, timing and transportation. Meanwhile, thermodynamic analysis has shown that the energy cost of an air capture device should not be much larger than that of a flue gas scrubber[3,4], although the CO_2 concentration of atmosphere is 400 times lower than that of flue gas.

A fuel synthesis system with renewable energy and captured CO_2 from ambient air was put forward in previous work[5]. And preliminary analysis shows that the fuel synthesis system is a promising approach to the utilization of CO_2 and renewable energy. To obtain additional insight about the energy flow and exergy reduction of the system, an energy and exergy analysis is conducted in this study.

The Fuel Synthesis System

For the sake of comparison, during all the thermodynamic calculations, electricity is converted from high temperature heat which could come from either concentrated solar energy or nuclear energy. Fuel synthesis using several typical CO_2 capture technologies: moisture swing air capture (low temperature process), temperature swing air capture (high temperature titanate causticization process) and amine-based flue gas capture, are evaluated.

Process Description. A diagram of three hydrocarbon fuel pathways with different approaches of CO_2 feeding is presented in Fig.1. The system has been described in detail in previous work[5], here gives a brief description.

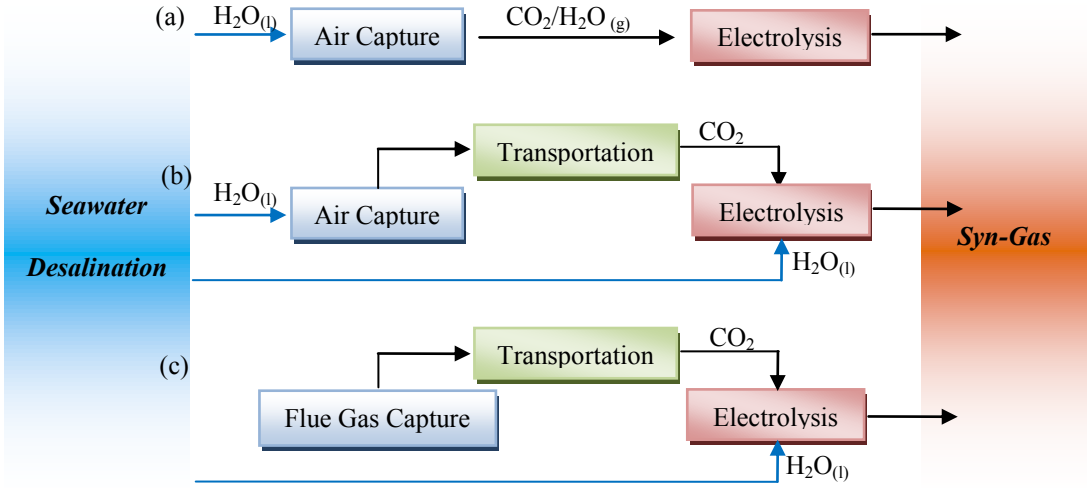

Fig.1 Hydrocarbon fuel synthesis from (a) integrated air capture, (b) transported CO_2 from air capture, (c) transported CO_2 from flue gas capture

The water consumed in the process of carbon capture and hydrogen production is provided from seawater desalination. As showned in Fig.1(a), the captured CO_2 from atmosphere could be directly fed to electrolysis process, which means the capture process is intergrated with eletrolysis process. As showned in Fig.1(b) and Fig.1(c), the captured CO_2 from atmosphere or flue is compressed, transported supplied to electrolysis process, which means the capture process is separated with eletrolysis process.

Efficient co-electrolysis under the same reversible potentials could avoid the excessive Joule heat production and the consequent complex heat management. The Gibbs free energy of dissociation corresponds to electrolysis reversible potential, which has the same value for CO_2 and H_2O at 850 ^oC. In this study, the SOEC (Solid Oxide Electrolyzer Cell), which is generally operated in the range of 700-1000 ^oC[6], is chosen for CO_2/H_2O dissociation and related thermodynamic analysis.

The MSAC (moisture-swing air capture) process employs an anionic exchange resin as the CO_2 sorbent, which absorbs CO_2 when dry and releases it when wet[7]. An optimum operating condition should consider the advantages from elevated temperature and the related energy penalty, which is about 45 ^oC[8] in this study. Since the partial pressure of regenerated CO_2 is on the order of several kPa, a vacuum condition for pure CO_2 production will be needed. In this study, liquid water is sprayed onto the sorbent to reduce the time for wetting. A moderate water consumption of 25 moles of water per mole of CO_2 is used[3].

Traditional high temperature processes for air capture is always energy intensive[9,10] and the temperature during the thermal decomposition process is usually at over 850 ^oC[11], which greatly reduces the feasibility of these technologies. However, since the regeneration temperature is close to the working temperature of high temperature electrolysis, the produced high temperature CO_2 gas could be directly fed to a HTE cell without additional heating. Nowadays, a titanate process technique developed by Mahmoudkhani et al.[10] requires a high-grade heat of 150 kJ/mol of CO_2, which is 50% less than conventional calcination. Considering the relatively low energy consumption, the titanate process with integrated high temperature electrolysis is analyzed as the other pathway for fuel synthesis.

Among the different post-combustion CO_2 capture technologies, systems based on amine solutions have been previously used industrially for more than half a century and are presently still one of the most suitable and widely employed technologies for high volume flue gas stream treatment[12]. The commonly used absorbents are typically 25–30 wt% aqueous solutions of alkanolamines such as monoethanolamine (MEA) and diethanolamine (DEA), which form carbamates and bicarbonates

with CO_2[13]. In this study, the amine regeneration is considered to have an energy requirement of 110 kJ/mol of CO_2 with 150 ^oC steam as the input heat source.

System and Parameters. Fig.2 shows the conceptual flow diagram of HTE for CO_2 and H_2O co-electrolysis and the gas parameters at the inlet and outlet of the heat exchangers and heater are given in Tab.1. System 1 is the fuel synthesis with integrated moisture-swing air capture (IFS-MSAC). Water vapor and CO_2 gas feeding to the electrolysis cell is provided simultaneously from the CO_2 stripper. System 2 is the fuel synthesis with integrated temperature-swing air capture (IFS-TSAC). High temperature CO_2 gas is generated through the 850 ^oC titanate process. High temperature water vapor is prepared in a separated heating device. System 3 is fuel synthesis with transported liquid CO_2 which could be captured from flue gas or ambient air. In systems 2 and 3, the exhaust steam is extracted from the turbine and then heated to 850 ^oC for electrolysis. By assuming the total electricity requirement of 1 MJ/Carbon for syngas generation, the steam consumption is around 0.13kg/kWh. The inefficiency of electricity generation due to low grade steam extraction should be insignificant.

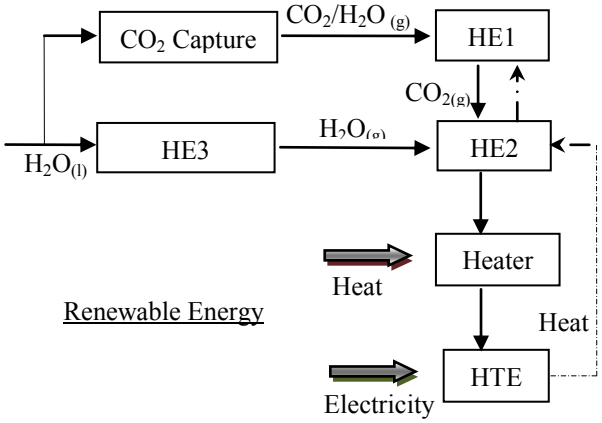

Fig.2 Conceptual flow diagram of HTE for CO_2 and H_2O co-electrolysis

	Production Gas (in)	102 ^oC	850 ^oC	--	--
	Production Gas (out)	70 ^oC	102 ^oC	--	--

[a] The feed gas (CO_2/H_2O : 1/2) is compressed to 100 kPa at 100 ^oC before entering HE2.
[b] The CO_2 gas is fed directly into the electrolyzer without additional heating.
[c] Water vapor for electrolysis is directly extracted from exhaust steam of turbine.

Thermal energy at 850 ^oC is provided from renewable energy to satisfy the heat requirement for power conversion, electrolysis and high temperature calcination. The modular helium reactor (MHR) and advanced high temperature reactor (AHTR) are candidate nuclear reactor technologies for achieving heat around or above 850 ^oC[14]. Solar thermal power plants with volumetric receivers have been successfully demonstrated to generate high temperature working fluids (800-1200 ^oC)[15]. Electricity is assumed to be converted at high efficiencies of 42-52% with current gas turbine technologies. The majority of the electricity is consumed by the electrolyzer, with the remainder

divided among desalination, CO_2 capture and CO_2 compression. A solid oxide electrolyzer cell is employed at an electrical efficiency of close to 100%[2]. Water vapor and CO_2 gas with a molar ratio of 2:1 are co-electrolyzed at 850 ^oC and 100 kPa. For fuel synthesis with isolated CO_2 capture, the CO_2 is compressed to liquid at 10 MPa for transportation. The net efficiency of heat exchangers or heater is designed as 70%.

Methodology

The energy analysis could be used to understand the energy flows in the system while exergy analysis could identify the components with high irreversibility. The reference environment for the gas phase process is taken to be 298 K and 100 kPa. The reference environment for seawater desalination is taken to be 298 K and 3.5% salinity. Thermodynamic parameters, such as heat capacity, standard change of enthalpy and entropy, are cited from literatures[16].

Energy Analysis. The first law of thermodynamics is the fundamental of the energy analysis. Five processes, including CO_2 capture, compression, heating, desalination and electrolysis, are considered to be main energy consumption processes. Reference [3] has discussed the required energy for MSAC process, whose data will be used for energy analysis in this study. The practical energy requirement for desalination is assumed to be 3.7 kWh/m^3 water[17]. The energy requirement for co-electrolysis could be considered as 780 kJ when 1 mole of CO and 2 moles of H_2 are produced at 850 ^oC. The compression process and heating process are basic thermal process, whose energy required could be calculated by corresponding formula.

Exergy Analysis. In thermodynamics, the exergy of a system is the maximum useful work possible during a process that brings the system into equilibrium with a reference environment[18]. The exergy ananlysis is based on the second law of thermodynamics, and the exergy reduction of a process is proportional to the entropy production of the process. The exergy could be divided into physical exergy and chemical exergy, which can be calculated by formula (1) and (2) respectively.

$$e_{ph} = (h_j - h_0) - T_0(S_j - S_0) \quad (1)$$

$$e_{ch,mix} = \sum_{i=1}^{n} X_i e_{ch,i} + RT_0 \sum_{i=1}^{n} X_i \ln X_i \quad (2)$$

where e_{ph} is physical exergy, h_j is enthalpy, S_j is entropy, h_0, S_0 are enthalpy and entropy in the reference environment respectively, $e_{ch,mix}$ is chemical exergy of mixture, X_i is mole percent of a certain component in mixture.

The exergy reduction could be calculated as the difference between inlet exergy and outlet exergy, which could be expressed as formula (3).

$$E_L = E_{in} - E_{out} \quad (3)$$

where E_L is exergy reduction, E_{in} is inlet exergy, E_{out} is outlet exergy.

Kinetic energy and potential energy are ignored in this study.

Results and Discussions

The thermodynamic analysis is based on parameters representative of typical industrial processes of electricity generation, heat exchange, CO_2 capture, electrolysis, etc (Tab.2).

Energy Analysis. Fig.3 shows the energy required in different processes when syngas is produced. As expected, the electrolysis dominates the total energy requirement. The implementation of air capture is evaluated to have significant uncertainty in economic assessments considering technique and market development[19,20]. However, from the thermodynamic point of view, it shows that the total energy requirement of fuel synthesis would not be sensitive to CO_2 capture technologies. Compared to separated fuel synthesis with moisture swing air capture (SFS-MSAC), the integrated fuel synthesis with moisture swing air capture (IFS-MSAC) has higher energy consumption on CO_2 capture, which is dominated by sorbent heating and enthalpy of water vaporization at 45 ^oC. The

required low grade heat can be provided from the waste heat during electricity generation (WH-1 in Fig.3). The WH-2 is the waste energy available from high temperature syngas at the exit of the electrolyzer. Due to the advantage of recycling low grade heat for CO_2 capture with the moisture swing process, the integrated fuel synthesis with MSAC technology has the highest energy efficiency. Compared to traditional high temperature process for air capture, TSAC of the titanate process has a relatively low energy consumption in the heating part. However, it still has a large high-temperature heat requirement of 150 kJ/mol of CO_2 during the capture process[10]. Moreover, due to the strong internal heat exchange in the titanate process, the dependence of energy consumption on heat recuperation efficiency is significant. In the long term, fuel synthesis utilizing a moisture-swing air capture technology could have greater potential because of the smaller energy cost and local CO_2 supply.

Tab.2 Parameters for thermodynamic analysis

Parameter	Deterministic Value	Uncertainty Distribution
Heat recuperator efficiency	70%	(60%, 80%)
Electrolyzer efficiency	90%	(80%, 100%)
Electricity generation efficiency	46%	(42%, 50%)
Water consumption (mol/mol CO_2)	25	(15, 35)
Electrolyzer conversion efficiency	50%	(40%, 60%)
Capture mode	IFS-MSAC	(SFS-MSAC, SFS-Amine)
Electrolyzer heat source	Electricity	Hybrid heat-electricity

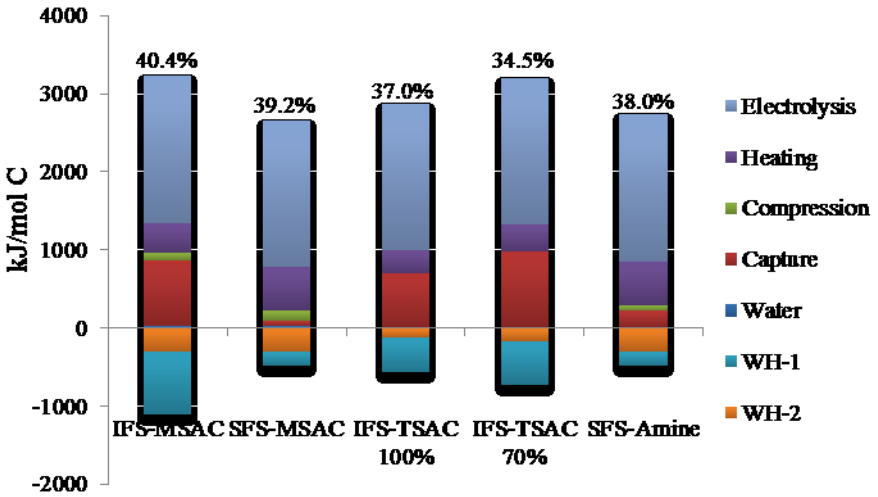

Fig.3 Energy requirement for fuel synthesis processes related to CO_2 capture technologies.

Exergy Analysis. The exergy analysis is based on three systems, IFS-MSAC, SFS-MSAC and SFS-Amine, with relatively lower energy consumption. Fig.4 shows the consumed exergy in the fuel synthesis processes. The minimum exergy requirement of the electrolysis is 780 kJ when producing 1 mole of CO and 2 moles of H_2 at 850 ^oC with electricity as the only input energy. The exergy output of syngas is 733 kJ with an ideal fuel cell at 25^oC. Fig.4 shows that the exergy consumption is dominated by the exergy output of syngas and exergy loss due to electricity generation. The electricity generation from high temperature heat consumes about one third of the total exergy requirement. From this point of view, for solar and nuclear energy, exploring fuel synthesis technologies with a lower electricity requirement (such as a hybrid sulfur cycle[21,22]) or direct chemical energy conversion without an electricity requirement (such as photosynthesis and phtoelectrolysis[23]) could be more exergy efficient.

The exergy consumptions related to CO_2 capture process, including the compression of CO_2, are listed in Tab.3. The moisture-swing air capture process generally has a larger energy consumption than that of an amine based flue gas capture as shown in Fig.3. However, the required exergy of MSAC could be smaller than that of an amine process. This is due to the consumption of high temperature steam when the amine sorbent is regenerated. The SFS-MSAC system has the largest

exergy consumption on CO_2 capture. For CO_2 transportation, additional electricity has to be consumed during air capture, such as water condensation and CO_2 compression. Waste heat is unavailable when air capture is isolated from the processes of fuel synthesis and electricity generation. Without the waste heat from electricity generation, the isolated moisture-swing air capture has to be conducted at room temperature rather than 45°C.

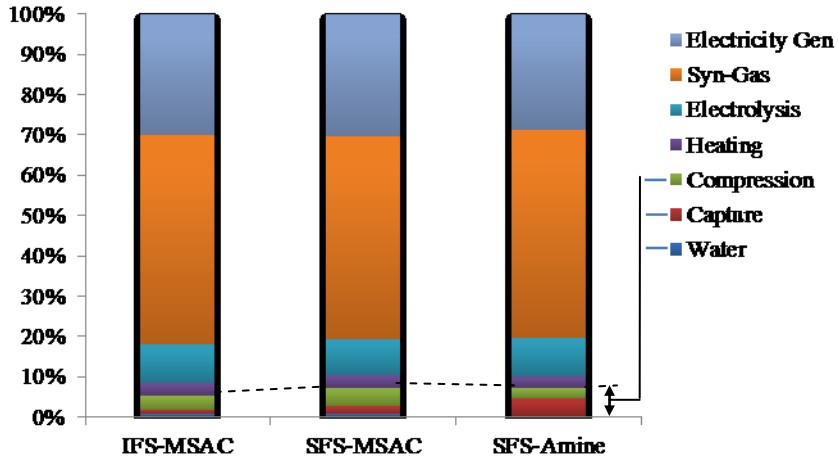

Fig.4 Exergy consumption and output for fuel synthesis processes related to CO_2 capture technologies.

Tab.3 Exergy consumption (kJ·mol^{-1} C) related to CO_2 capture

Parameter	IFS-MSAC	SFS-MSAC	SFS-Amine

Total Exergy	74.0	105.3	100.5
Exergy Efficiency	52.0%	50.4%	51.7%

Although the CO_2 capture technology or process has a minor effect on the total exergy efficiency due to the huge exergy requirement for electrolysis and electricity generation, this exergy analysis on CO_2 capture is helpful for other CO_2 utilization processes. Tab.3 shows that for moisture swing air capture technology, the exergy requirement is dominated by compression of CO_2 from several kPa to 10 MPa for the goal of transportation. For the moisture-swing air capture, water is used as the only fuel to drive the gas separation. The free energy is provided from water evaporation and the use of heat for sorbent regeneration can be avoided. Therefore, the production of clean and low partial pressure CO_2 can be energy efficient and attractive for in-situ CO_2 utilization or conversion processes. For example, at CO_2 partial pressures of 5-10 kPa, the microalgae generally have the maximum growth rates[24-26]. The weathering process of minerals on the surface of the earth, especially the ultramafic tailing, can be enhanced when CO_2 partial pressure is elevated from atmospheric level to several kPa[27].

Sensitivity Analysis. To assess the sensitivity of the energy and exergy consumption to changes in CO_2 capture technologies and parameters of energy conversion and transfer, uncertainties were assigned to several parameters. The integrated fuel synthesis with moisture swing air capture technology was selected to study due to several advantages of independence on CO_2 source, requirement of low grade heat and no requirement of CO_2 transportation. The energy conversion parameters of interest are the electricity generation efficiency, conversion efficiency of electrolyzer, electricity efficiency of electrolyzer and heating source of high temperature electrolyzer. The carbon capture parameters of interest include water consumption and technological processes, such as separated air capture and amine based flue gas capture. The parameters of the electrolyzer were determined based on the current technical development of a solid oxide electrolyzer cell[7,28]. Values of the input parameters for the sensitivity analysis are shown in Tab.2.

Energy and exergy efficiencies obtained with deterministic values in Tab.2 are 40.4% and 52.0% respectively. The energy efficiency and exergy efficiency have similar sensitivity to the studied

parameters, shown in Fig.5. Electricity efficiency of the electrolyzer and efficiency of electricity generation have the most significant impact on thermodynamic performance. It is interesting to find that both the energy and exergy efficiency are very sensitive to the source of high temperature heat for the electrolyzer. With current technologies of HTE, the high temperature heat is generally provided from the ohm heat by consuming electricity[2]. However, by supplying heat directly from a heat source rather than from electricity, the system efficiency increase could reach the same level as that with very high electricity generation efficiency. It implies that, for this fuel synthesis system, the process optimization can be as important as innovation of technologies of electrolysis or electricity generation. For example, in order to have similar energy or exergy efficiency enhancement, one has to increase the efficiency of electricity generation from 42% to more than 50%, which would be very difficult for current or advanced power plants.

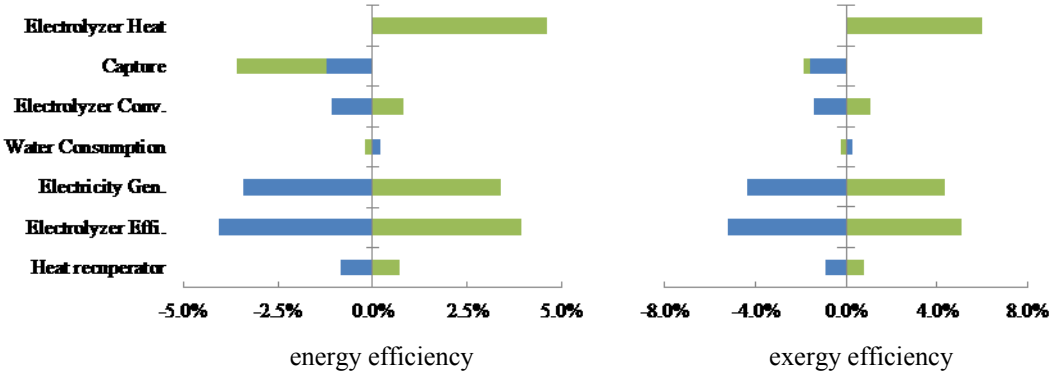

Fig.5 Sensitivity analysis on energy and exergy efficiency of the fuel synthesis system

The only exception, when comparing the sensitivities of energy efficiency and exergy efficiency, is the effect of the carbon capture process. As discussed above, the carbon capture process with amine has higher energy and exergy requirements compared to moisture swing air capture. However, the exergy efficiency is less sensitive to the CO_2 capture process due to heat consumption rather than electricity consumption when conducting amine based technology.

Conclusions

Energy and exergy analyses have been conducted to study the thermodynamic performance of fuel synthesis systems with heat from renewable energy, and CO2 captured from ambient air or flue gas. The results of the present investigation indicate that:

a) Compared to the energy consumed by electrolysis, the energy penalty from CO2 capture is insignificant. That is, the total energy requirement of fuel synthesis is not sensitive to CO2 capture technologies. This indicates the feasibility of air capture when integrated into the conversion of CO2 to high value products.

b) By choosing thermal energy, rather than electricity, from renewable energy as the direct heat source for high temperature electrolysis, the thermodynamic efficiencies could be enhanced greatly. This suggests the importance of process optimization for fuel synthesis with renewable energies. A system with lower electricity requirements is preferred, especially when using solar and nuclear energy.

c) Although energy and exergy analysis both show that fuel synthesis is not sensitive to CO2 capture technologies from the thermodynamic point of view, the advantages of direct air capture processes are still obvious, such as local CO2 capture and conversion. Moreover, the air capture unit can be integrated into renewable energy systems, both thermodynamically and physically.

Keywords: heat transfer coefficient, degree of turbulence, heat transfer correlations

Abstract. This article mainly makes a brief introduction about Microencapsulated Phase Change Material Slurries(MEPCMS) and its preparations， the research status and several correlations of heat transfer in turbulent flow of MEPCMS are also listed.The influencing factors of turbulent heat transfer are mainly the degree of turbulence, the mass fraction and wall heating rate,particle size effects weakly. Several heat transfer correlations under different degrees of turbulence are also presented.

Introduction

Energy is the motive force of social development and the foundation of human survival.With the development of science and technology and the increasingly prominent energy and environment problems, the problems of heat transfer,heat and cold storage have emerged in the fields of power, metallurgy, chemical engineering and technology.Since the limited heat transfer ability of ordinary fluid can not meet the actual needs, in this case, the functional fluids with higher heat transfer capability are needed[1，2].

Microencapsulated Phase Change Material(MEPCM) is the new material which is fabricated by the PCM(Phase Change Material) as core material and polymer as wall material[3，4].The diameter varies from 1μm to 1000μm. Microencapsulated particles can be mixed with fluids(water,ethylene glycol ect.) to form MEPCMS.Since they can store or reveal a lot latent heat and they have very large specific surface area, MEPCM can effectively hance the process of heat transfer.

Due to the complex heat transfer mechanisms of the MPCM slurry flow and narrow ranges of experimental conditions applied for each investigation.Only a few correlations were proposed to describe the melting heat transfer characteristics of MPCM slurry flows in a circular pipe.

The requirements of material

The MEPCM chosen should satisfy the following requirements:

1) High latent heat so that can be stored or released more heat in the phase change process ;

2) It has small reversibility and expansion shrinkage ratio,the same to the undercooling and overheating in the phase change process;

3) Appropriate phase change temperature can satisfy the need to control the specific temperature;

4) Large heat conductivity coefficient,density and specific heat;

5) It should be innocuous, non-corrosive,low costing and easily manufactured.

Compared with the traditional fluids,MEPCMS has higher heat transfer coefficient. The comparison of some microencapsulated PCMS from literature and prepared microencapsulated PCM are given in table 1.

Manufacturing

There are several methods which can be used to produce microencapsulated particles, such as spray-drying and fluidized bed process for physical approaches; and there are also chemical processes which can be used for microencapsulation, such as simple and complex coacervation, interfacial polymerization，in situ polymerization and so on.[5，6] The appearance is shown in fig 1.

Table 1 The comparison of some microencapsulated PCMS from literature and prepared MEPCM

Microcapsule shell	Core material	Encapsulation ratio wt%	Microcapsue diameter. μm	T_m	ΔH_m J/g	Method

Fig 1 The appearance of MEPCMS

Research status and heat transfer correlations

Several researchs have been conducted to explore the flow and heat transfer properties of MEPCMS.

Kasza and Chen[7] conducted an analytical study to investigate the heat transfer performance of solar energy or waste heat utilization system using phase change slurries and explored the potential benefits in reducing the pumping power and the storage tank size. They claimed that heat transfer performance of slurry flow in both laminar and turbulent conditions would increase because of the microconvective enhancement of thermal conductivity and latent-heat-induced heat capacity. Charunyaorn et al.[8] developed a model to predict the laminar MPCM slurry flow in a heated circular duct and showed about 2–4 times increase of the Nusselt number compared with single phase fluid flow. Goel et al.[9] conducted the heat transfer test of laminar MPCM flow in a heated circular pipe and confirmed the validity of numerical results of Charunyaorn et al. Other related numerical investigations of laminar MPCM slurries flow include the works of Zhang and Faghri,[10] Alisetti and Roy,[11] Hu and Zhang,[12] and Ho et al.[13]. All previous investigations in laminar MPCM slurry flow showed that the particle concentration and latent heat were dominating parameters in heat transfer enhancement, whereas the effects of specific heat ratio ($C_{P,P}/C_{p,f}$), thermal conductivity ratio k_p/k_f), and particle size were relatively weak.

Choi et al.[14] measured the local pressure drop and heat transfer coefficient of turbulent phase change emulsion flow (mixture of water and PCM with additive of emulsion) with 10% particle mass concentration in a horizontal tube with constant heating rates. They observed a significant enhancement in heat transfer performance because of the latent heat effect when PCM melted. They also found that both the local heat transfer coefficients and pressure drop along flow direction varied significantly when PCM melted, which made it difficult to determine the heat transfer coefficient. Yamagishi et al.[15] measured the pressure drop and local convective heat transfer coefficients of turbulent microencapsulated octadecane($C_{18}H_{38}$) slurry flow in a horizontal circular pipe with constant heating rates, and reported that heat transfer performance of MPCM slurry was influenced by the particle fractions, the degree of turbulence, and the heating rates on the tube wall.

Due to the reliable heat transfer data derived by former researchers in a horizontal circular pipe with constant heating rates. Several empirical correlations have been reported to predict the heat transfer characteristics of solid–liquid flow without phase change in the pipes.

Choi and Cho[16] calculated the local Nusselt number for the turbulent convective heat transfer of a single-phase fluid with combined thermal developing and hydraulic developed regions at the constant heating rates.

$$Nu_x = 0.00425\,\mathrm{Re}_{lb}^{0979}\,\mathrm{Pr}_{lb}^{0.4}(\mu_{1w}/\mu_{1b})^{-0.11} \tag{1}$$

where water dynamic viscosity μ_{1b} was evaluated based on the local mean temperature of the fluid and water dynamic viscosity, μ_{1w}, was calculated based on the local wall inner surface temperature.

Salamone and Newman [17] investigated the heat transfer of the water suspensions of solid particles of copper, carbon, chalk, and silica with various size ranges from 1.5 to 56 lm and with concentrations varying from 2.3% to 10.7% (by volume) in a horizontal pipe and derived the following correlation:

$$Nu = 0.131\mathrm{Re}^{0.62}\,\mathrm{Pr}^{0.72}(\frac{k_p}{k_f})^{0.06}(\frac{D}{d_p})^{0.05}(\frac{C_{P,P}}{C_{p,f}})^{0.35} \tag{2}$$

for 14,000≤Re≤140,000，3.4≤Pr≤12.7,0.53≤k_p/k_f≤12.7，282≤D/d_p≤10,500,and 0.09≤$C_{P,P}/C_{p,f}$≤0.22,where $C_{P,P}$ is the specific heat capacity of the MPCM particles, k_p is the thermal conductivity of the MPCM particles

Xichun Wang and Jianlei Niu [18]presented the heat transfer characteristics of MEPCMS flow in a horizontal tube,they proposed a new heat transfer correlation for the slurry under slightly turbulent condition.

$$Nu_m = 4.8527\times10^{-4}\,\mathrm{Re}_m^{0.7733}\,\mathrm{Pr}_m^{2.7941}\,Ste^{0.3159}\times[(L_1+L_2)/D]^{-0.333}(\mu_m/\mu_w)^{-2.4349} \tag{3}$$

for 2100<Re<3500，13<Pr<15，and 0.05<w_p<0.1,where w_p is the mass fraction of MPCM particles in the slurry, phase change region length $[(L_1+L_2)/D]$, μ_m is the average dynamic viscosity of the slurry in the phase change region and μ_w the average dynamic viscosity of water calculated based on the inner tube wall temperature.

Conclusions

Turbulent slurry flows are not only affected by the mass fraction and wall heating rate, but are greatly influenced by turbulent degree. About 1–2.5 times higher average Nusselt number relative to pure water was found for turbulent slurry flow, whereas a degradation of heat transfer performance was found at a higher particle load of the slurry.

Several turbulent heat transfer correlations were proposed by other researchers,which predicts the average heat transfer data. The new correlations, derived based on the series of experiments covering in both laminar and turbulent flow conditions, should be useful for the design of the new compact heat exchangers with MPCM slurry applications.

In adition, turbulent heat transfer correlations under different degree of turbulence should be proposed to meet the needs of practical engineering.

Keywords: microchannel, groove, shape factor, Catalytic combustion.

Abstract. This paper studied the methane/moist air combustion characteristics in smooth microtube and microtubes with five different shape grooves and proposed the microtube groove dimensionless shape factor $F=4\pi S/L^2$. The results show that the appearance of five grooves make combustion components and velocity occur jumping change and the vortex flow appears. The highest methane conversion rate is for the microtube with triangle grooves, which also indicates that the smaller shape factor is more in favor of methane conversion.

Introduction

At present, the micro-scale combustion problem has become the forefront of international research, the study has not only academic value, but a guiding significance for the corresponding areas[1]. Due to the decrease of the scale, the residence time of fuel in combustion chamber is sharply reduced, it is difficult to ensure that the fuel can complete combustion. What's more, the increased surface-to-volume ratio of micro-reactors leads to thermal and radical quenching of reactions and the heat loss is even serious. Catalytic microcombustor exhibits wider stability than homogeneous micro-combustor[2].The catalytic layer deposited on the reactor walls may sustain chemical reactions at lower temperatures and in the presence of higher heat losses, thus reducing the impact of thermal quenching.

Recently, most research activities in the field of catalytic combustion has emphasized on the use of methane, mainly for its nature of clean fuel, widely available world-wise. Nonetheless, methane is inherently the most stable, difficult-to-oxidize hydrocarbon with outstanding characteristics that its catalytic ignition occurs at relatively high temperature even on the most active and expensive PdO-based catalysts. Some strategies were proposed to overcome the shortcoming, such as preheating the fuel-air gas, adding hydrogen in methane-fuel and proposing new catalyst layout to improve hetero and homo-geneous reaction in a confined space. Undoubtedly, a proper combustor configuration and a well designed catalyst bed can improve the reaction and reduce heat and radical loss. Federici et al.[3]demonstrated that the thermal properties of reactor materials play a vital role in the overall thermal stability of micro-reactors. The reactor walls not only contribute to heat loss through conduction, but they are often responsible for the majority of heat transfer from upstream, which is necessary to preheat the feed to ignition temperature. Yueh-Heng Li et al.[4] proposed a configuration of catalyst segmentation with cavity to accelerate the methane conversion in a microreactor.

To extend the operation range and to study the interplay of methane/moist air reactions in microchannel-reactors, this paper simulated the methane/moist air catalytic combustion with fluent software in mirochannels with different wall shapes and analyzed the impact of different surface shape factors on the methane/moist air catalytic combustion .

Numerical Model and Chemical Mechanical

Physical Model. The physical model adopted diameter 1mm, long10mm microtubes with the wall owning different grooves. Fig.1 only shows a schematic diagram of a smooth tube and microtubes with five small groove of different shapes. The groove shapes and size are rectangular (0.1mm×0.2mm), triangle (two right-angle side: 0.1mm,0.2mm),isosceles trapezoid (bottom 0.2mm, lower base 0.1mm, height 0.1mm),respectively. The shape of each tube channel was calculated separately by groove number from zero to five, and the groove laid along the wall by way of groove spacing arithmetic increments, i.e. 0.5mm, 1.0mm, 1.5mm, 2.0mm. The wall thickness of each microtube is 1mm. To study the catalytic combustion of methane/moist air heterogeneous reaction, all of the walls were coated with Pt catalyst inside, ignoring its effect on the reactor volume.

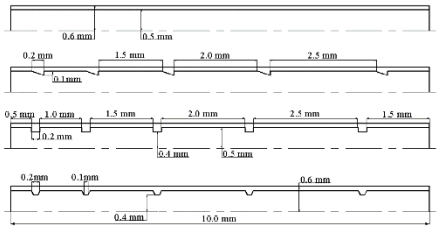

Fig. 1 Schematic diagram of a smooth tube and microtubes with five grooves of different shapes

Catalytic combustion mechanism. Surface catalytic reactions used a 24-step methane catalytic reaction mechanism on the Pt surface proposed by Deutschmann et al.[5], the mechanism includes nine kinds of gaseous components (CH_4, H_2, O_2, H_2O, CO_2, CO, O, H, OH) and eleven surface species (C(s), CH(s), CH_2(s), CH_3(s), CO(s), CO_2(s), H(s), H_2O(s), O(s),OH(s), PT(s)). The reaction mechanism has been widely used by numerical study of CH_4, H_2 and CO catalytic combustion,its accuracy has been demonstrated by literature[6].

Calculation methods and working conditions. According to the structure of the micro cavity, we used the structured grids and the grid size was taken as 0.01mm, the wall grids were handled with encryption processing. Grid sensitivity test should be carried out for combustion cases before the numerical simulation starts, the total number of mesh grid cells was 34033-35000 for microtubes with and without grooves. Laminar flow and species transport models were used and the solving method was the SIMPLE algorithm. Velocity inlet and pressure outlet boundaries were setted. The outer wall was insulating, while the inner wall surface was coupled with the flow region. This article is simulated at 573K, 0.1MPa environment, methane/moist air inlet equivalence ratio (0.5,0.8,1.0,1.2) and the inlet velocity (0.5m/s, 0.8m/ s, 1.0m/s, 1.2m/s) were changed separately in turn for different microchannels.

Results and discussion

To investigate the influence of different groove shape on the combustion characteristics of the microtubes, according to the microtube dimension characteristics, this article assumes microtube groove dimensionless shape factor $F=4\pi S/L^2$,where S is the area of a single groove, L is the

perimeter of a single groove. i.e., the shape factor of a single groove is a triangular groove F1=0.37,a rectangular groove F2=0.70, a trapezoidal groove F3=0.69, respectively.

Combustion characteristics of microtubes with different groove shapes.

When the methane/moist air equivalence ratio is 0.5 and inlet velocity of 1m/s, the combustion characteristics of smooth microtube and microtube with one single different groove are as follows:

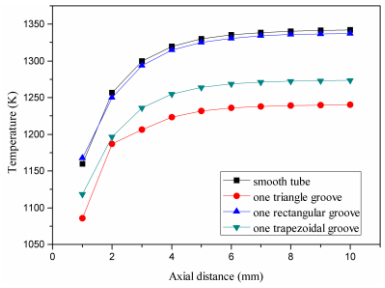

Fig. 2 Temperature along axial distance for smooth tube and tube with one groove

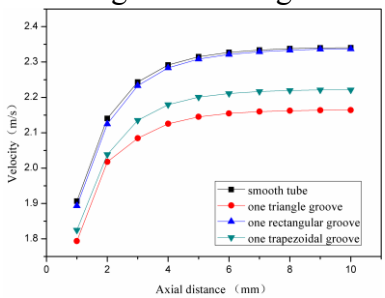

Fig. 3 Velocity along axial distance for smooth tube and tube with one groove

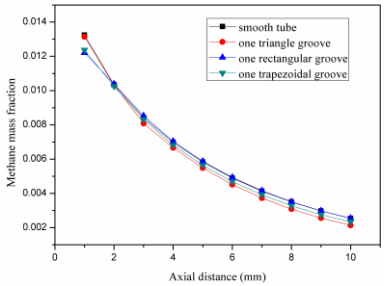

Fig. 4 Methane mass fraction along axial distance for smooth tube and tube with one groove

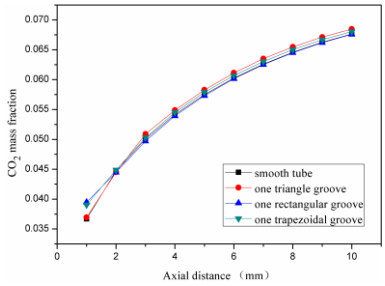

Fig. 5 CO_2 mass fraction along axial distance for smooth tube and tube with one groove

From Fig.2 and Fig.3 we can see that the variation tendency of methane/moist air combustion temperature and velocity along axial distance for different microchannels is basically the same. Fig.2 shows the outlet temperature is different: the smooth tube has the highest temperature of about 1350K, tube with a rectangular groove followed, and the tube with a triangular groove has the lowest temperature. This is because the groove in the microchannel increased wall roughness, thereby affecting the residence time of the combustion gas. Fig.3 shows that the velocity of smooth microtube is the maximum, and the microchannel with a triangular groove has the minimum velocity. As shown in Fig.4 and Fig.5, the average cross-sectional mass fraction of methane decreases along the axial distance, while the mass fraction of CO_2 is gradually increased. The methane mass fraction of the microchannel with a triangular groove is the lowest, which means small shape factor is in favor of methane conversion. A single groove on the overall average mass fraction of each component is not affected.

Impact of multiple grooves on catalytic combustion.

The paper studied the effects of multigroove microtubes (as shown in Fig.1) on the combustion characteristics under the inlet velocity is 1m/s and equivalence ratio is 0.5. Fig. 6 shows that the cross-section temperature gradually increased along the axial distance, the temperature of microtube with five triangular groove whose shape factor is also the lowest is still the lowest . As can be seen in the vicinity of 6mm occurs temperature jump because the appearence of grooves here makes the cross-sectional area decreases, the residence time is reduced and fuel combustion is not sufficient,

all of which lead to the temperature reduces. Fig. 7 shows that the appearance of five grooves make significant changes in the fuel flow lines, the horizontal velocity decreases near the grooves, increasing the vertical velocity, and the vortex flow appeares.

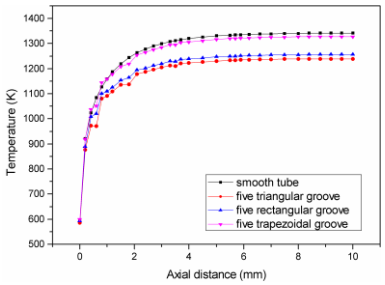

Fig. 6 Temperature along axial distance for smooth tube and tube with five grooves

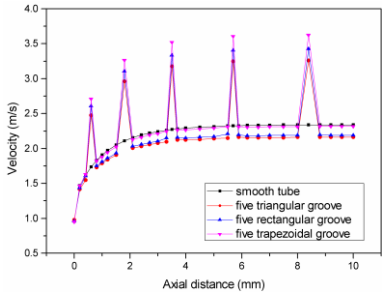

Fig. 7 Velocity along axial distance for smooth tube and tube with five grooves

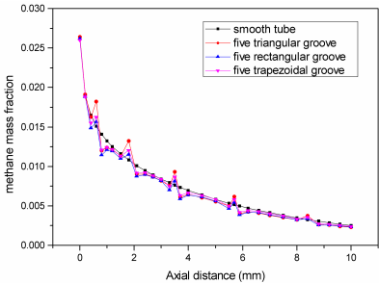

Fig.8 Methane mass fraction along axial distance for smooth tube and tube with five grooves

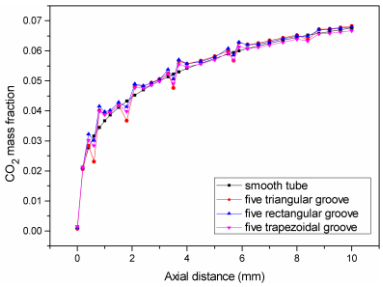

Fig.9 CO_2 mass fraction along axial distance for smooth tube and tube with five grooves

Fig.8 and Fig.9 show that the appearance of tiny grooves inside the microchannels making the combustion components occur jumping change, the overall trend is consistent of the smooth microtube. As for the tubes with five grooves, the area of fuel contact with the catalytic surface is increased, which promotes the methane conversion rate. The methane conversion of tube with five triangular groove (shape factor is the lowest) is the highest .

Effect of the shape factor on methane conversion rate.

Fig.10 and Fig.11 show methane conversion rate decreases with the increase of inlet velocity in the smooth microtube under the same equivalence ratio. When the inlet velocity increased, the residence time of fuel will be reduced, which leads to incomplete combustion and the methane conversion rate decreases. Methane conversion rate first decreases and then increases with the increase of equivalence ratio in the smooth microtube under the same inlet velocity. This is because the change of equivalent ratio leads to the change of mass fraction of inlet component, equivalent ratio less than 1 is oxygen-enriched combustion, the smaller equivalent ratio, the more oxygen, methane conversion rate is higher.

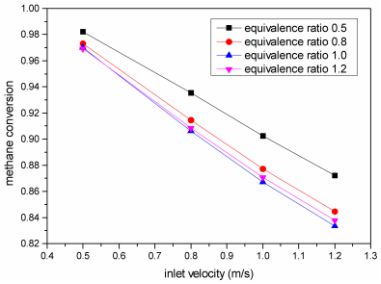

Fig.10 Schematic of methane conversion rate variation with inlet velocity in smooth tube

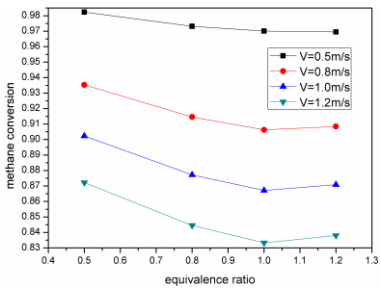

Fig.11 Schematic of methane conversion rate variation with equivalence ratio in smooth tube

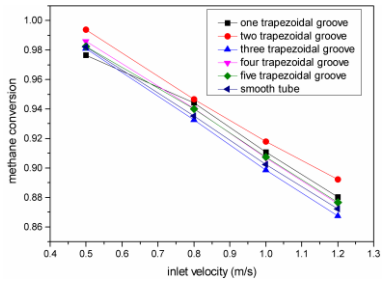

Fig.12 Influence of the groove number on methane conversion(equivalence ratio = 0.5)

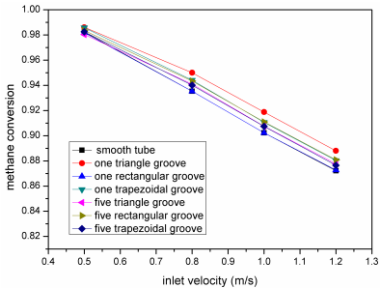

Fig.13 Influence of different shape factor on methane conversion (equivalence ratio = 1)

Fig.12 shows that the methane conversion rate decreases with the increasing of inlet velocity , and first increases then decreases with the decreasing of the groove number for the mirochannel with the same groove shape. The highest conversion rates is in microtubes with two trapezoidal groove. But the groove number has no significant impact on conversion rate.Fig.13 shows that for all of the microtubes, methane conversion rate decreases with the increasing of inlet velocity under the same equivalence ratio. That is the highest methane conversion occurs in the microchannels with the smallest shape factor (the microtube with a triangle groove), which indicates that the smaller shape factor is more favorable for the conversion of methane.

Conclusions

1.The variation tendency of combustion temperature and velocity along axial distance for different inner wall shape microchannels is the same. The mass fraction of methane decreases along the axial distance, while the mass fraction of CO_2 is gradually increased.

2.The appearance of five grooves makes significant changes in the fuel flow lines and it makes the combustion components occur jumping change, but the overall trend is consistent of methane and CO_2 mass fraction with the smooth microtube.

3.For all of the microtubes, methane conversion rate decreases with the increasing of inlet velocity under the same equivalence ratio. The smaller shape factor is more favorable for the conversion of methane.

Keywords: Rich-Lean Burner, Bias Current Stopper, Partition Plate, Concentration Ratio, Speed Difference.

Abstract. In order to solve the problem of that the boiler burns inferior coal but cannot guarantee the combustion stability, the rich-lean burner divides primary wind pulverized coal airflow into two stocks of airflows containing different amounts of pulverized coal and sends the airflows into coal-fired furnace for improving the ignition characteristics. By the numerical simulation of the pulverized coal flow characteristics in an elbow bias-oriented rich-lean burner, regarding the "concentration ratio" and "speed difference" as the standard of evaluating the separation characteristic of the burner, considering the influence of the partition plate length, bias current stopper height and primary wind velocity to the separation effect of pulverized coal so as to provide technical assistances for the elbow bias-oriented rich-lean burner's practical application and improvement.

Introduction

According to Chinese current energy policy, as far as possible the inferior coal used in coal-fired power plant, and now for the coal and coal blending system has many shortcomings, power plant boiler burning coal quality is difficult to guarantee, coal-fired variable and high ash content, calorific value has a tendency to decrease. Lower grade of coal lead to boiler combustion instability and caused not broken oil in boiler start-up and low load operation, even appear put out the flame [1]. Therefore, we should take effective measures to solve the problem of stability of the boiler burning inferior coal combustion.

For the corners of our country generally used direct flow burner arrangement tangential firing way, because of duct layout produce pulverized coal concentration differences in horizontal direction, and only two angles of burner can satisfy the conditions of pulverized coal strong combustion. Therefore, can be add partition plate and bias current stopper to adjust the pulverized coal flow direction in the other two angles of burner [2].

A power plant 2# furnace use HG - 670/140-7 boiler is a production of Harbin boiler factory. In the power plant unit overhaul in 2012, the two layers of middle burner were transformed into elbow bias-oriented rich-lean burner [3]. See Fig.1.In diameter of 480 *mm* wind pipe bending export add bias current stopper and 1/2 partition plate, make the primary air flow in the burner outlet is divided into two strands of airflow, two air flow deviate their respective stoichiometric ratio, and this form of pulverized coal on the rich side is ignition area "Three Highs" [4]. So rich-lean combustion on the horizontal direction is come true in the furnace, which is beneficial to improve the combustion stability and reduce NO_X formation.

The Mesh and Calculation Condition

Mesh. The model is divided into three regions, elbow and mixing chamber adopt Hex /Wedge mesh, main burner use Tet/Hybrid grid and encrypted. See Fig.2.The model use a lot of structured grids are helpful to speed up the operation and iteration convergence. Based on different order of magnitude of grid and grid sensitive independence test, determine the grid conform to the requirements of the calculation precision.

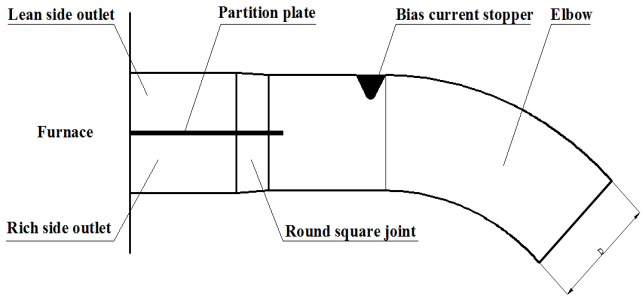

Fig.1 Structure diagram of the elbow bias-oriented rich-lean burner

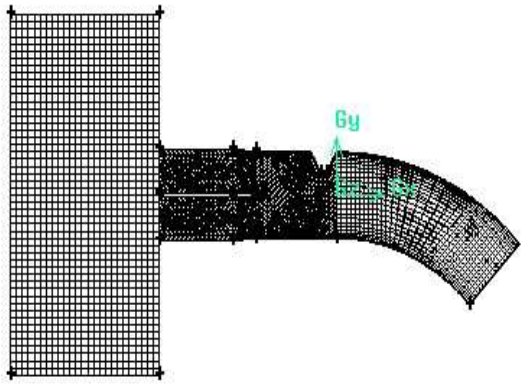

Fig.2 Schematic diagram of the mesh division of a burner

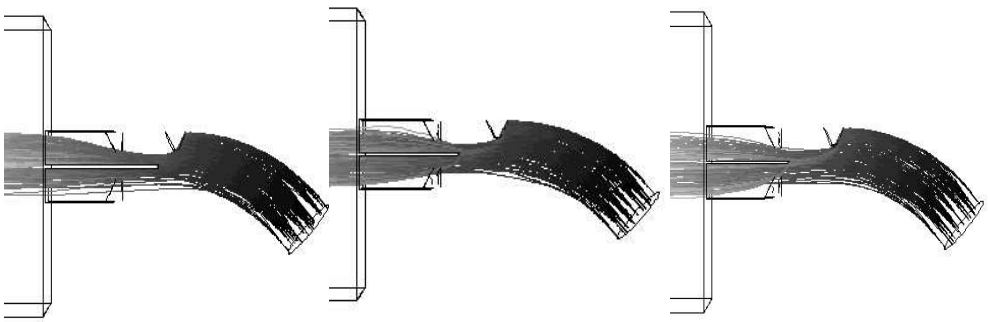
Calculation Condition

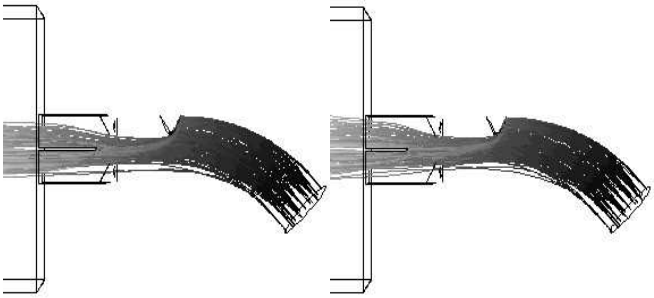
- Based on an equilateral triangle bias current stopper height of D/4 and angle 45 °of the elbow, add a partition plate from elbow (L)0.5D, 0.8D, D, 1.5D, 1.8D respectively, conduct particle trajectory tracking and numerical simulation analysis. Calculate conditions use the actual design conditions: the primary air velocity for 23*m/s*, the primary air pulverized coal concentration is 0.5 *kg*C/*kg*A, 60 μm of pulverized coal particle diameter, 1350 kg/m^3 of pulverized coal density.
- Based on distance elbow D partition plate, change the bias current stopper height of D/3 and D/4, conduct numerical simulation comparison.
- For the bias current stopper height of D/4 and partition plate from elbow length of D, simulate different primary air velocities effect on the separation result and contrast with the original design conditions of 23*m /s*.

Results and Discussion

Partition plate lengths effect on the separation result. No matter how far the partition plate distance elbow, the velocity of rich side outlet is always higher than the lean side outlet air flow, which is consistent with the result of the scene. Strong secondary flow of pulverized coal in the elbow generated by the centrifugal force, the mainstream high-speed fluid flow along the outside of the elbow, but the effect of the bias current stopper of the guide, high-speed air tent to concentrated side outlet and cause the rich side outlet flow velocity higher than the lean side. When the partition plate distance elbow length is 0.5D, pulverized coal of the rich side outlet is less than the lean side amount, which is due to the bias current stopper on the guiding role of coal particles is not fully realized, pulverized coal has separated by the partition plate, result in concentration ratio is less than 1. The result of particle phase movement trajectories at different partition plate lengths is shown in Fig. 3.



(a) (b) (c)



(d) (e)

Fig.3 Schematic drawing of the particle phase movement trajectories at different partition plate lengths

(a) L=0.5D*mm* (b) L=0.8D*mm* (c) L=D*mm* (d) L=1.5D*mm* (e) L=1.8D*mm*

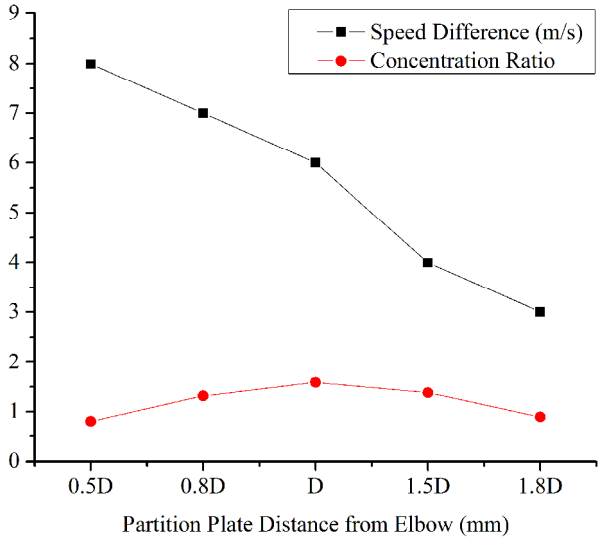


Fig.4 Law governing the change of speed difference and concentration ratio at the rich and lean outlet sides of burner with the plate lengths

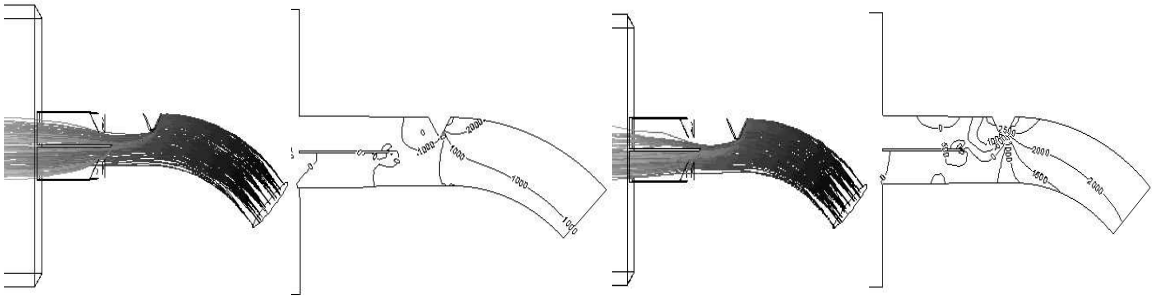
Fig. 4 shows that with increasing partition plate and elbow distance, the both sides of export airflow speed difference is decreased, concentration ratio is increased then decreased after the first, when partition plate from elbow for D, concentration ratio reaches a maximum. This is because the partition plate is too far from elbow, the pulverized coal restore to the lean side that after guiding role of bias current stopper has been tented to the rich side, so the pulverized coal amounts of rich side outlet is decreased and the both sides of export airflow speed difference is decreased too.

Bias current stopper heights effect on the separation result. The bias current stopper height of D/3, a large number of coal particles flow from the rich side exit, both sides pulverized coal concentration ratio as high as 1.975, but with increasing the height of bias current stopper, both sides outlet air speed difference would increase to 14 *m/s* and increase the resistance significantly. Resistance of the burner increases with the height of bias current stopper. When the bias current stopper height of D/3, burner pressure drop of 1500*Pa*, when the bias current stopper height D/4, burner pressure drop of only 1000*Pa*. Therefore, excessive bias current stopper height although can get better pulverized coal concentration ratio, but weakened the ability primary air pulverized coal flow capacity and the speed difference of burner outlet is bigger, which is unfavorable to improve the life of burner nozzles and coal combustion stability. The result is shown in Fig. 5.



(a) (b)

Fig.5 Schematic drawing of the particle phase movement trajectories and static pressure distribution chart at different bias current stopper heights (a)H=D/4*mm* (b)H=D/3*mm*

Primary air velocities effect on the separation result. By condition 1, condition 2 simulation results show that within the burner equipped with the partition plate from elbow D and bias current stopper height of D/4 is combined, which is the best to improve the comprehensive performance of burner. In this combination of conditions, adjust the primary air velocity. A relationship between primary air velocity and concentration ratio is shown in Fig. 6.

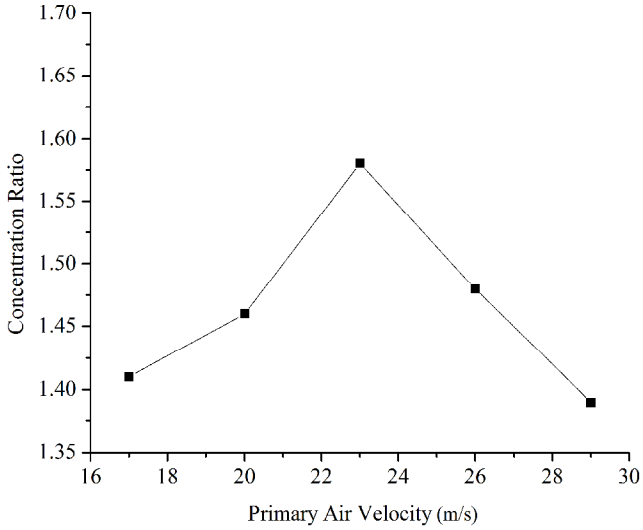


Fig.6 Law governing the change of the concentration ratio at the rich and lean outlet sides of burner with the primary air velocities

When the primary air velocity is less than 23*m /s*, coal particles momentum and inertia increase with the primary air velocity advances at the same time, and the airflow is better to follow. After the effect of bias current stopper adjust the airflow direction is easy to form a higher concentration ratio. Primary air velocity more than 23 *m/s*, concentration ratio would turn down, which is due to the different structure of the flow around the air flow when the air flows through the bias current stopper.

Conclusion

The partition plate from elbow too close will cause the both sides outlet of the burner speed difference bigger and pulverized coal concentration ratio less than 1, which is unable to guarantee the rich side pulverized coal combustion; the partition plate from elbow too far distance will lead to the rich side of pulverized coal to the lean side recovered and concentration ratio reduced, but the speed difference is decreased, which is conducive to protect the burner nozzle. The higher bias current stopper can enhance pulverized coal separation effect, but the burner resistance than normal run time increases by 500*Pa*, and the both sides outlet speed difference attains 14 *m/s*, which is disadvantageous to burner operation. Too low or too high primary air velocity will lead to poor

concentration ratio, when 23 *m/s* of primary air velocity for the design conditions, the pulverized coal concentration ratio than most, so should be as possible as to ensure sustained winds in the actual operation with the design value.

Keywords: Aviation Fuel; Hot Surface; Boiling pattern; Thermal ignition

Abstract. Fuel evaporation and ignition process on the high-temperature hot surface are difficult to be predicted accurately. The rule of fuel evaporation and ignition delay that various with hot wall temperature have been obtained by utilizing the simulated experiment to study the evaporation and ignition process of aviation fuel on hot surface. This study complements the related content of the fuel ignition mechanism on hot wall， at the same, reference method for fuel fire engineering practice has been provided.

Introduction

Fuel leaks onto the hot surface is quite a common fire accident of warship. Due to the damaged high pressure fuel pipe of diesel engine in the engine room, fire is caused by fuel sprays to high temperature of the body shell, etc[1]. A series of phenomena occur when aviation kerosene flows to the hot wall involving many theoretical problems in the field of engineering thermal physics: fuel film is formed after the flowing fuel expand on hot wall; fuel film conduct boiling heat transfer with the hot wall; the produced vapour flow and diffuse in the air and exchange heat with the surrounding air and occur ignition; etc.

According to the findings of the pool boiling heat transfer [2-4], when the hot wall temperature was different, the boiling pattern of fuel leakage on the hot wall was different, and heat that transferred from hot wall to liquid was also different. The boiling heat transfer can be divided into natural evaporation region, nucleate boiling region and film boiling region in accordance with the different temperature difference(or called degree of superheat, namely the temperature difference between the wall temperature and liquid saturation temperature)[5]. The ignition process of warship's fuel that leaked into the hot surface in engine-room was studied by Li Yuanlong, Lu Shouxiang, etc [6]. Furthermore, the evaporation pattern of leaked fuel on the hot surface was analyzed and the motion process of fuel vapour above the horizontal hot wall was described by them. Because of the complexity of fuel leakage conditions, it may generate all kinds of various boundary conditions. In addition, the space distribution and temperature distribution of fuel-gas that changed with time were caused by evaporation process. These factors make it difficult to predict the process of fuel evaporation and ignition. In this paper, the rule and the influence factors of the leaked aviation kerosene on horizontal hot wall were studied and analyzed through utilizing experiment to simulate the whole ignition process of the leaked aviation kerosene on horizontal hot wall.

Experimental platform

The thermal ignition experiment of aviation fuel could be carried out in early fire test platform. The platform was composed of environmental control system and data acquisition control system.

(1)Environmental control system

Environmental control was composed of simulation of high-temperature thermal environment, hot wall and atmospheric environment.

The conical electric heater above the combustion chamber was utilized to simulate high-temperature thermal environment. The radiant heat source of actual fire field could be simulated by conical electric heater. In this experimental platform, the conical electric heater could provide arbitrary heat radiation intensity ranging from 0 to 80kW/m2.

Hot surface was simulated by placing a copper plate at the bottom of combustion chamber. The area of the copper plate was 25 cm × 50 cm and the thickness was 3 cm. A control thermocouple and a 6 kW heat ring were embedded respectively in plate. The heat capacity of plate should be large so as to ensure the temperature have little changed after plate contacted with cold liquid. The temperature of hot plate was controlled by using a temperature controller to control the hot wall temperature. Temperature controller should adjust automatically and control temperature, ranging from 0 °C to 1000 °C. The resolution and temperature control precision was set as ± 2 °C. Furthermore, it had an automatic cold junction compensator with a thermocouple.

The atmospheric environment was controlled by a high pressure cylinder to connect the gas access to rotor flow meter. The flow meter was adjusted to connect the valve below pipeline for providing the requirement changes of atmosphere. Gas supply system of test platform could change the oxygen content of gas ranging from 0 to 21% arbitrarily.

(2)Data acquisition and control device

Test platform of early fire characteristics was mainly utilized to measure the characteristic parameters of combustible materials. The main measured parameters included: flame temperature, the shape and the size of flame, smoke composition, smoke temperature, smoke flow rate, smoke density, weight loss rate of sample, sample ignition temperature, thermal radiation temperature rise curve of sample surface, etc.

The full flame image acquisition and analysis system could be realized by installing industrial endoscope, CCD camera, optical system, filter, lens connecting, close-up lens and other optical measuring device on high-temperature hot wall. And then ignition temperature and ignition delay of fuel on high temperature hot wall could be analyzed.

Main performance parameters were shown in table 1

.

Table 1. Performance parameters of test bench

Shape size	600mm×800mm×2500mm
Gas composition	Atmospheric oxygen content 0～21% (random variable)
Gas flow rate	0～30L/s random variable
Experimental object	Solid, liquid fuel
Electronic balance weighing range	0. 01～3000g
Radiation heat flux	0～80kW/m^2 random adjustable
Maximum temperature limit of heater	1100^{0}C

Experimental results and test results

2. 1 Boiling pattern of aviation fuel on hot surface

From the experimental records, when the surface temperature of aviation kerosene ranged from 400K to 600K on horizontal hot wall , nucleate boiling dominated ;when the surface temperature of aviation kerosene ranged from 600K to 800K on horizontal hot wall, transition boiling dominated; when temperature was above 800K on horizontal hot wall surface, the film boiling dominated.

When the temperature of horizontal hot wall was approximately 600K, under this temperature condition, the boiling pattern of fuel sample was the most severe. At the same time, it also showed that heat transfer mechanism between nucleate boiling and transition boiling were not the same.

The temperature of fuel vapour surface could reflect the variation of heat flux density on hot surface from the other side. The fundamental reason lied in that heating region in the nucleate boiling stage was larger than that in the transition boiling stage. Because heating surface which was covered with film had a greater proportion, heat flux density from hot wall to fuel decreased when temperature was increased, resulting in the decline of vapour surface temperature.

According to the findings of Xiong and Yuen, the boiling pattern of diesel fuel is nucleate boiling below 356 °C ;that is transition boiling ranging from 356 °C to 440 °C ; that is film boiling above 440 °C . The boiling evaporation experiment that fuel sprayed into hot surface for twelve alkyl was conducted by Vaivids, etc [7]. The experimental results showed that nucleate boiling dominated

within 470K temperature for twelve alkyl. The boiling pattern was transitional boiling ranging from 470K to 550K. The boiling pattern is film boiling pattern in a higher temperature range for twelve alkyl. It can be seen that the experimental study that is carried out by utilizing aviation kerosene has a similar conclusion, only the transformation temperature of different boiling pattern is different.

2. 2 Ignition mode and ignition delay time

Through the analysis of 200 cases ignition experimental process, ignition mode could be divided into two types as following:

The first mode was when plume began to rise, fuel vapour formed a combustible mixture gas reaction through entraining the around oxygen mixture, and after a certain time, ignition occurred. With the increase of height, vapour accelerated entraining the around fresh air, and the maximum reaction rate of mixed gas was also moving up with the movement of plume and was almost near the position where the entrainment velocity was larger. This moment, the high temperature region of flammable vapour was located at the top of plume. Oxygen had also entered plume, and combustible gas mixture was formed at the top of plume, and the reaction rate had been accelerated to a certain value. Therefore, ignition occurred, called center ignition.

The second ignition mode usually occurred in the lower heat flux density condition, and ignition did not occur in the vapour just rising. However, after a period of time, it occurred in the full development of the plume. Furthermore, due to the mixed reaction between continuous flowing of vapour and air, ignition occurred when the condition was suitable. At the moment, the high temperature region distributed on the two sides of plume, while the vapour velocity was larger than that of the initial stage of plume. Combustible mixed gas could be formed through fast motion of vapour that entrained around air on both sides. If the mixed gas reaction rate was increased to a certain value, ignition occurred, called surrounding ignition.

Test records of ignition delay time, as shown in table 2:

Table 2. Ignition test records

Surface temperature（K）	660	670	680	690	700	710	720	730	740	750
Ignition delay time（S）	11	10. 9	10. 3	9. 7	8. 6	8. 5	8. 2	7. 9	7. 8	7. 8
Ignition height（mm）	1. 8	1. 9	2. 1	2. 5	2. 7	2. 7	2. 8	2. 9	2. 9	3
Surface temperature（K）	760	770	780	790	800	810	820	830	840	850
Ignition delay time（S）	8	8. 1	8. 3	8. 4	8. 4	8. 5	8. 6	8. 7	8. 9	9
Ignition height（mm）	3	3	2. 9	2. 7	2. 6	2. 5	2. 4	2. 3	2. 1	2

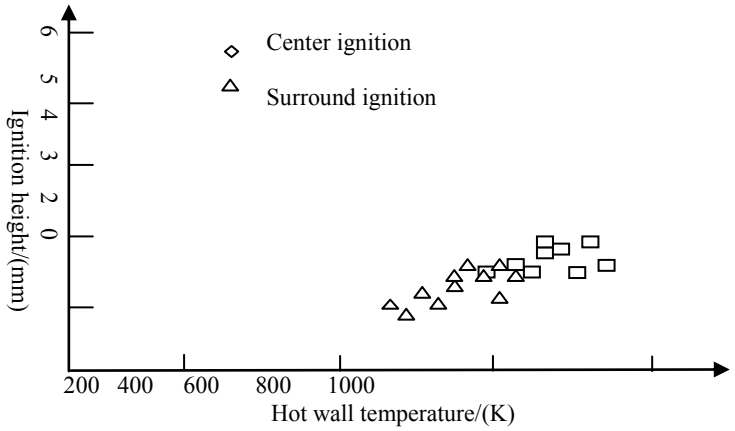

Fig. 1 Fuel ignition height under different surface temperature

Comparing the three kinds of boiling pattern, aviation kerosene could not be ignited within the nucleate boiling temperature range; within the transition boiling temperature range, ignition mode of aviation kerosene was mainly center ignition; while within the film boiling temperature range, ignition mode of aviation kerosene was mainly surrounding ignition. The average value of ignition

delay time was 9. 2S within the transition boiling temperature range. However, the average value of ignition delay was 8. 4S within the film boiling temperature range. As can be seen, the hot wall surface temperature had a direct relationship with the form of boiling evaporation; while the ignition morphology and ignition delay time mainly depended on the concentration and temperature distribution of combustible mixture vapour on hot wall.

Influence of boiling heat flux

After fuel leaked into the hot wall, the first occurrence was boiling heat transfer, then the generated vapour occurred ignition over the hot wall. Because there were a lot of key factors that influenced ignition delay over the hot surface, such as temperature, pressure, turbulent state, time scale, mixing degree between fuel and oxidizer , high temperature fuel pyrolysis and additional factors. The given factors of different literature such as ignition delay time definition, experimental equipment, experimental method were also different. Furthermore, the fitting relationship between ignition delay time and these parameters were also different. It may even appear more than one order of magnitude difference. The fitting relationship of ignition delay time was utilized in combustion chamber flow field calculation program, which provides possibility for ignition delay comparison under different parameters condition and also had a guiding significance for the selection of experimental conditions. Therefore, it was necessary to fit the ignition delay time. This paper attempted to analyze the key influence factors of ignition delay from experimental angle.

Based on the Arrhenius theory and Experimental Research on dynamic characteristics of aviation kerosene, the reaction system of aviation kerosene under the action of hot surface can be expressed as:

$$\tau_{ig} = A[Fuel]^{a}[O_2]^{\beta}[M]^{\gamma}\exp(\frac{E}{RT}) \quad . \tag{1}$$

where A is the pre-exponential factor. [Fuel], [O2], [M] are respectively the molar concentration of gas fuel, oxidant and other gas in air. α, β, γ are the impact factors. E is the activation energy. R is the universal gas constant. T is the ignition temperature.

Taking the logarithm of equation, there is:

$$1/\tau_{ig} = (M_{evap})^{1/4} C_1 + \ln[Fuel] + \frac{E}{RT} \quad . \tag{2}$$

In the Eq. (2), $\ln A$ is not related to temperature, while the atmospheric environmental is the natural environment under test condition. The oxygen concentration depends directly on the mixture concentration of combustible gas . Therefore, the formula can be simplified as:

$$\ln \tau_{ig} = C_1 + \ln[Fuel] + \frac{E}{RT} \quad . \tag{3}$$

Utilizing the Eq. (3) to attempt to fit out the relationship between ignition delay time and temperature are serious discrepancies with the experimental data. The reasons are because the above theories derivation foundation are based on some experimental data which are obtained through dynamic characteristics of aviation kerosene test, and the ignition conditions are obtained in a closed container. Furthermore, the temperature and concentration distribution are relatively consistent in reaction system. In this experiment, upward plume was generated for the combustible mixture gas and the surrounding air were mixed with each other. Fuel evaporation rate was also varying with the temperature, resulting in the complexity of distribution gradient of temperature and concentration above the liquid surface. Therefore, it cannot reflect the changes of ignition delay through the temperature this parameter.

The experimental results showed that boiling heat transfer size of hot wall was an important factor to influence ignition, however, boiling heat transfer leaded to a direct result that is the changes of the fuel surface heat flux density. Because the heat flux is not easy to be measured. So, the evaporation rate was utilized to express the changes of heat flux density in test. Fig. 2 shows the relationship between fuel evaporation rate and ignition delay time on hot wall surface. Through function fitting to make it meet:

$$1/\tau_{ig} = (M_{evap})^{1/4} \quad . \tag{4}$$

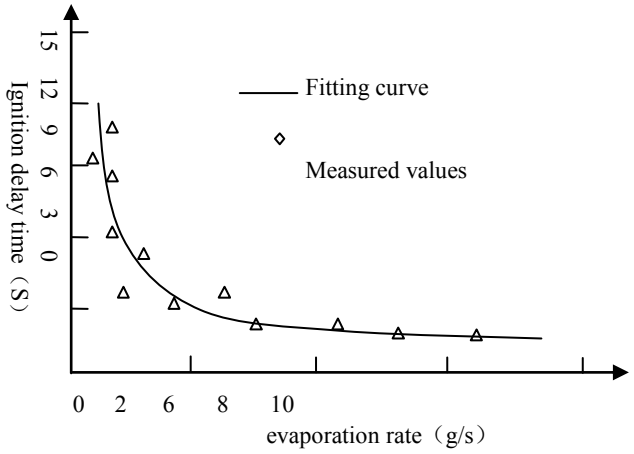

Fig. 2 Relationship between ignition delay and evaporation rate

Conclusions

Evaporation and ignition process of aviation kerosene on horizontal hot wall are studied, and the rule of ignition delay variation with hot wall temperature is obtained by utilizing the simulated experiment. The relationship between heat flux on hot wall and ignition delay time is analyzed and established to obtain the prediction model of ignition delay time by utilizing plume theory. This study not only complements the related content of hot wall fuel ignition mechanism, but also provides reference method for hot wall safety protection engineering practice.

Thermal transport in hotspots using the Lattice Boltzmann method with application to Silicon-on-insulator transistors

Y.D. Mao[a], M.T. Xu[*]

Department of Engineering Mechanics, School of Civil Engineering, Shandong University, Jinan, China

[a]maoyudong@aliyun.com, [*]mingtian@sdu.edu.cn

Keywords: hotspots, Lattice Boltzmann method, Silicon-on-insulator.

Abstract. Silicon-on-insulator (SOI) transistors have been widely used in the micro-electronic devices. The Lattice Boltzmann method (LBM) is employed to simulate the heat conductions of hotspots appeared in a SOI transistor. The results show that a thermal wave effect is appeared in micro-region, and it can not be found in Fourier prediction. Comparing the results obtained by the Fourier law and LBM, we find that the LBM solution shows approximately 22% higher energy density than the Fourier prediction. When two thermal waves form different hotspots meet together, a significant energy enhancement will be appeared.

Introduction

SOI devices are fabricated in a thin silicon layer that is electrically isolated by a buried oxide layer. It is well known that localized energy emission may result in hotspot with dimensions on the order of 10nm and it would challenge the stabilities and service life of devices [1, 2].

Thermal transport in semiconductor devices is modeled usually using diffusion theory based the Fourier law. However, some problems appear when the Fourier law is applied to micro-scale heat conductions, which has been mentioned in the past studies [3-5]. As a powerful tool, Boltzmann transport equation (BTE) is used to solve the thermal transport problems in micro-scale systems [6, 7]. However, it is too difficult to solve BTE by the direct mathematic methods because of its complex nonlinear integral item. Therefore the numerical methods are significant for us to resolve this problem. Having the obvious and delighted advantages in resolving the boundaries, achieving the programming and dealing with the complex multi-scale coupling problem, lattice Boltzmann method had been used to deal with the BTE in the last papers, and it has received considerable attention during the recent years [8-10].

In the present work, 2D heat conduction models based on LBM are built to simulate the energy distribution in hotspots of SOI transistors.

Theoretical analysis

In SOI transistors, phonon is the dominant energy carriers. Based on the BTE, 2D heat conduction model in hotspots can be expressed as Eq. (1)

$$\frac{\partial e_i}{\partial t} + v_i \nabla e_i = -\frac{e_i - e_i^0}{\tau} + S(x, y, t), i = 1, 2 \ldots \mathrm{m} \tag{1}$$

where e is energy density, e^0 is the equilibrium energy density, v is phonon group velocity, τ is the phonon relaxation time, and S is the energy source induced by hotspot. Here we consider a D_2Q_m lattice model with specular reflection boundary conditions and constant temperature initial condition, and define one-dimensional quantities in Eqs. (2-5).

$$x^* = x / L; \quad y^* = y / L; \quad t^* = t / \tau \tag{2}$$

$$e(T_0) = N_0 = C_v T_0 \tag{3}$$

$$e_i^*(x^*, y^*, t^*) = \frac{e_i(x, y, t) - N_0 / m}{N_0} \tag{4}$$

$$e^*(x^*, y^*, t^*) = \sum_{i=1}^{m} e_i^*(x^*, y^*, t^*) = \frac{e(x, y, t) - N_0}{N_0} \tag{5}$$

where L is the length of transistor medium, C_v is the volumetric heat capacity of silicon. Using LBM to discretize Eq. (2) and neglecting the high order terms, then the dominant equation can be written as Eq. (6)

$$e_i^*(x^* + \alpha\Delta x^*, y^* + \beta\Delta y^*, t^* + \Delta t^*) \approx (1-w)e_i^*(x^*, y^*, t^*) + we_i^{0*}(x^*, y^*, t^*) + \frac{w\tau}{N_0} S(x^*, y^*, t^*) \tag{6}$$

where $w = \Delta t^* = \Delta x^* / Kn$, $Kn = l / L$ is the Knudsen number, and l is the phonon mean free path. α and β are parameters which can be composed of a matrix B. For example, in the D_2Q_4 lattice model, the matrix B can be expressed as, $\mathbf{B} = [\boldsymbol{\alpha}, \boldsymbol{\beta}] = [1, 0; 0, 1; -1, 0; 0, -1]$.

Based on the Fourier law, the hotspots self-heating problem discussed above is described by the heat conduction equation with heat source expressed in Eq. (7):

$$C_v \frac{\partial T}{\partial t} = k_F \nabla^2 T + S \tag{7}$$

Introduce the notations in Eq. (2), the Fourier solution can be written as Eqs. (8-10)

$$e^*(x^*, y^*, t^*) = \sum_{n=1}^{\infty} \Gamma_n(t^*) \cos\alpha_n x^* \cos\alpha_n y^* \tag{8}$$

$$\Gamma_n(t^*) = \exp(-qt^*)\left[C + \int \exp(qt^*) \cdot 2\int_0^1\int_0^1 S(x^*, y^*, t^*) \cos\alpha_n x^* \cos\alpha_n y^* dx^* dy^* dt^* \right] \tag{9}$$

$$q = \frac{k_F \tau}{C_v L^2} \alpha_n^2, \quad \alpha_n = n\pi, \quad C = -2\int\int_0^1\int_0^1 S(x^*, y^*, t^*) \cos\alpha_n x^* \cos\alpha_n y^* dx^* dy^* dt^* \,|_{t=0} \tag{10}$$

Numerical results and Discussion

Now we consider a SOI transistor with the following parameters: $C_v = 1.66\times10^6$ J/m3K, $T_0 = 300$ K. The size of hotspot is *h*h*, and the proportion of *h* and *L* is kept 1:20. The phonon mean free path of silicon l is 40nm, and the phonon relaxation time τ is 6.53ps. The thermal conductivity of bulk silicon k_F is 148W/mK. In the following computation of LBM, the grid size Δx^* is taken as 0.01, and the time step $\Delta t^* = \Delta x^* / Kn$ which is required by the relation of the two parameter. The values of the parameters given above will be used throughout the following discussion, unless stated otherwise.

At first, the validity of LBM in solving macroscopic heat conduction problems is discussed by comparing with the Fourier law. We set the characteristic length value of transistor *L*=4000nm, then Knudsen number is equal to 0.01 and *h*=200nm. The hotspot is set at the center of transistor, and the system here is in diffusive region. Then the sectional view of comparison between Fourier law and LBM solutions at the middle of y-axis is present in Fig. 1. It can be found that the solution of LBM is very agreement with the prediction of Fourier law. Therefore, the LBM is verified to validate in dealing with macro-thermal transfer problems.

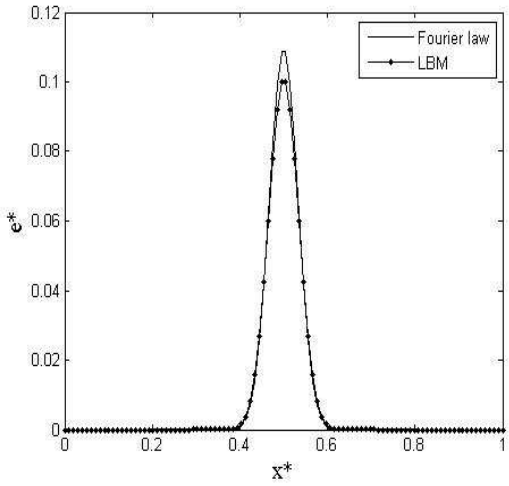

Fig. 1 Comparison between LBM solution and the Fourier law at the middle of y-axis

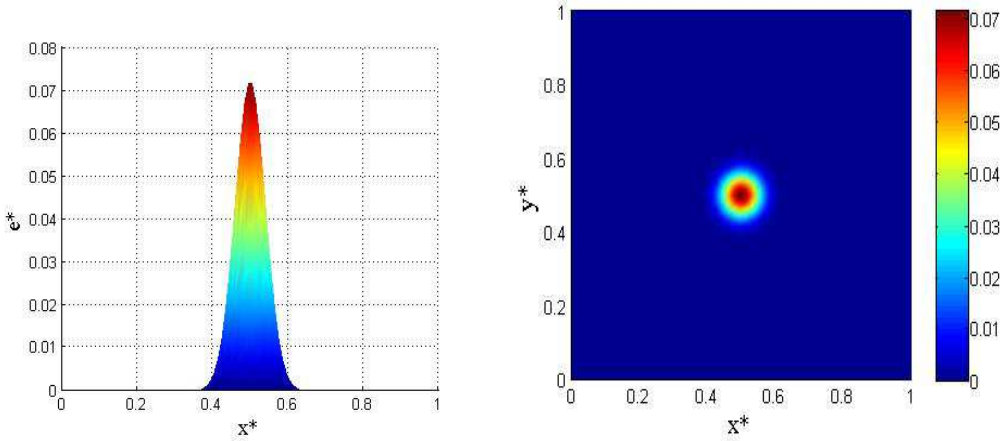
Energy density distributions obtained by Fourier law and LBM with $Kn=1$ are presented in Figs. 2 and 3. The system length

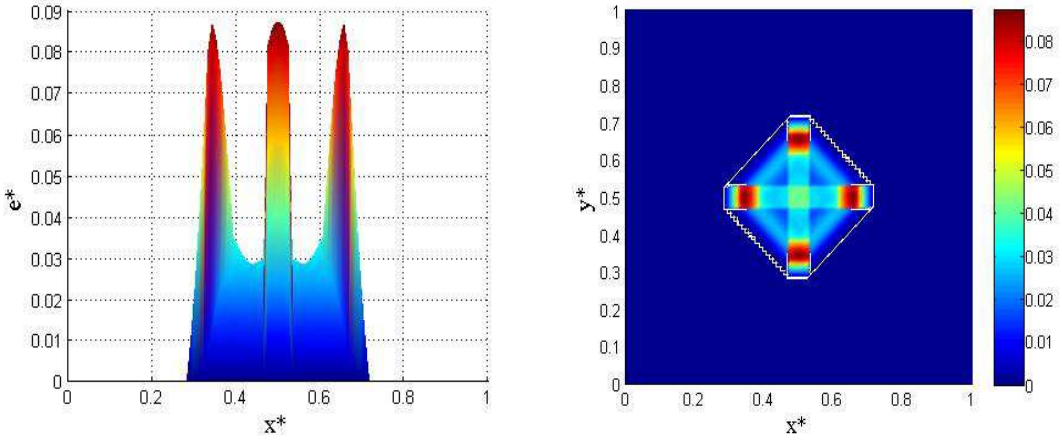
L here is 40nm, and the hotspot width h is 2nm. Thermal transport in ballistic region makes great difference between the Fourier law solution and LBM prediction. In Fig. 2, the energy density peak value obtained by Fourier law at the center of hotspot is 0.072. As illustrated in Fig. 2(b), the Fourier law only shows a diffusive energy propogation.



(a) (b)

Fig. 2 Energy density distribution obtained by the Fourier law with Kn=1, (a) X-O-Z lateral view, (b) X-O-Y bottom view.

However, the peak value in LBM solution is 0.088, as is shown in Fig. 3. This value is approximately 22% higher than which obtained by Fourier law. In Fig. 3(b), we can see that the energy are no longer abiding by diffusive track, but travels a wave-like movement from center to boundaries. This wave-like energy propogation can capture the ballistic characters with $Kn=1$. It is worth note that the energy in LBM prediction, not like the Fourier solution, no longer has its peak value in the center of hotspot. This means that the energy travels at a limited velocity.

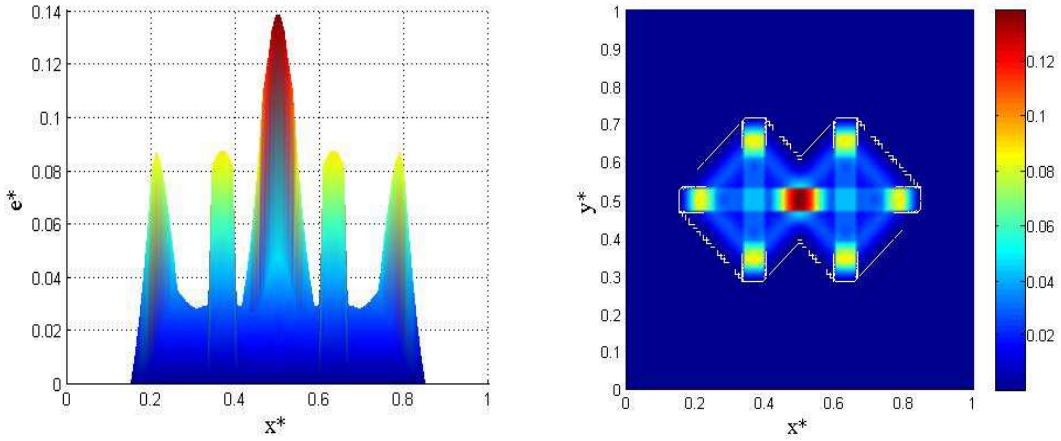


(a) **(b)**

Fig. 3 Energy density distribution obtained by LBM with Kn=1, (a) X-O-Z lateral view, (b) X-O-Y bottom view.

The energy density distribution of two hotspots in the transistor obtained by LBM is present in Fig .4. The conditions of this problem is same with which has been discussed in Fig. 3. Comparing the two graphs, one can see that when the thermal waves from different hotspots meet at the center of system, as is illustrated in Fig. 4, the energy has a significant enhancement. The peak value of

energy density at the middle of system is about 0.14 predicted in Fig. 4 (b), and it is approximately 60% higher than the peak value of one hotspot.



(a) (b)

Fig. 4 Energy density distribution of two hotspots obtained by LBM, (a) X-O-Z lateral view, (b) X-O-Y bottom view.

Conclusion

(1) The LBM is a valid method to simulate thermal transport problems in diffusive regions.
(2) In ballistic regions, the LBM solution can capture the thermal wave character, which can not be seen in the classical Fourier's solution.
(3) In the hotspot self-heating problems, the LBM solution illustrates about 22% higher energy density than the Fourier prediction.

Keywords: Twin swirl; Swirl number; Reverse flow rate; Numerical simulation

Abstract. An isothermal flow in a Twin Swirl Combustor (TSC) was simulated with the Renormalized Group (RNG) k-ε turbulence model. The swirling and recirculation intensity was studied under different structures and inlet conditions. The results confirmed that there was a significant negative correlation between the trend lines of the swirl number (S) and reversed flow rate (X_r). The gradient of reversed flow rate was larger in the front and middle parts of the combustor than that of swirl number. The end-surface-inlet structure had a better swirl and recirculation enhancement effect. With the end-surface-inlet structure, the internal swirl and reverse intensity could be flexibly adjusted by switching the swirl intensity of the primary air. Under the structure of staggered-inlet, there was a critical distance between primary and secondary air inlets. When exceeded, it would be more difficult to enhance the swirl and reverse flow effect by increasing the swirl intensity of the secondary air.

Introduction

Confined swirling flows are widely used in most the industrial instruments, i.e. internal combustion engines and industrial burners. A strong swirling airflow in the chamber will cause negative-pressure effects, generating internal recirculation zones (IRZ). The existence of recirculation is beneficial for both premix and non-premixed combustion. In pulverized coal combustion, it can help increase the gas recirculation for flame stabilization, and prolonging the travelling time of the coal particles, which is beneficial for reaching high-level burnout rate.

Many experiments have been done to better understand the flow properties of swirling and recirculation in pulverized coal burner. Wang [1] observed the gas-particle flow properties in a vertical-layout cyclone coal combustor using the visualization method and LDA system. The isothermal results showed there is strong internal recirculation in the spouting zone and strong swirling effect in the cyclone zone. A typical Rankine-vortex was observed in the cyclone zone. Li [2] and Chen [3] both studied the air-particle flows in a swirling pulverized coal burner in an isothermal condition with a three-dimension particle-dynamics anemometer(PDA). The experiment results revealed the relationships between the recirculation intensity and the air flux ratio. IRZ could generate while proper air flux ratio and swirl intensity were adopted.

Numerical simulation is another powerful method to better understand the properties of swirling flows, because there are always limitations for a few discrete positions for the sensors and cannot get the whole three-dimensional structure. This method also saves more time and is more cost-effective Weber [4, 5] used the RANS k-ε turbulence model and a second order Reynolds stress model (RSM) to simulate the isothermal expanding swirling flows into divergent burner with different expansions The results showed that anisotropic turbulent closure provided Reynolds stress transport model was better in the research case than that the k-ε model, due to the non-homogeneous and highly anisotropic turbulence in the swirling flows. Jawarneh [6] adopted the RANS RSM to simulate the strong confined swirling flow in a vortex chamber. The simulation results of velocities and pressure profiles were compared with the measurement data obtained from the experiment. The forced-vortex inside the core and the free-vortex outside the core were revealed by the mean tangential velocity profiles, which agreed well with the experiment data. Wang [7] used the Large Eddy Simulation (LES) to study the swirling air flow properties in a model dump combustor. The time averaged mean

velocity and Reynolds sheer stresses under three different swirling numbers were calculated and agreed well with the experiment data. LES succeed in simulating the vortex breakdown, the internal recirculation zones and the anisotropic turbulence structures in different levels of swirling intensity.

Hou [8] carried out a numerical simulation on a swirling flow tundish with different turbulence models. For the different treatment toward effective viscosity, the RNG k-ε is valid for both low and high Reynolds number flows. The standard k-ε however, was only for fully turbulent flows with high Reynolds number. The results prove that the RNG k-ε model is more suitable, because compared with standard k-ε model it has a faster convergence. Gupta [9] calculated the dynamics of the turbulent swirling flow in a cylinder with a tangential inlet and a tangential exit. The standard k-ε and RNG k-ε turbulence models were used and the simulation results were compared with the experiment data. The RNG k-ε model yield better results to the experiment because it modifies the standard k-ε model by adding a swirling factor into its model. It is better to use RNG k-ε model when simulating the flow under strong swirling conditions.

Comparisons between LES and RANS have proved LES predicts the flow properties more accurately, especially for transient and anisotropic flows, but tremendous time and calculation resources are required compared to RANS to get the result converged. While the RANS is still able to offer satisfied simulation results for the swirling flows with a reasonable calculation time, if modifications are adopted to the standard k-ε model.

It could also be concluded that the internal recirculation flow in the chamber is adjusted mostly by the outer swirling secondary air or the bluff body equipped inside the chamber, while the primary air is non-swirling. With the twin swirling air flow, both the primary and secondary air are swirling so that the recirculation and swirling intensity inside the chamber could be flexibly adjusted by either of them. The structure could be further simplified if no bluff body is installed in the chamber. While the interaction mechanism of recirculation and swirling between twin swirling flows is not clear yet, it is important to look inside the flowing characteristics in the chamber of the Twin Swirl Combustor (TSC).

In this paper, the renormalization group (RNG) k-ε model is used to predict the airflow in a confined TSC with a contraction in the rear, near the exit. Validation case has been implemented using RNG k-ε model on a swirling airflows in a smooth straight pipe done by Rocklage-Marliani [10], which is similar to the current chamber. A 2d mesh with an "axisymmetric swirling axis" is used according to the geometry and flow conditions. The results match favorably with the experiment data, which means the RNG k-ε model is qualified in predicting the internal swirling flow with appropriate mathematic method and high-quality 2d meshes (y^+<=1 for the grids adjacent to the wall and axis).

Case illustration

The properties of the co-axial swirling airflow in a dump combustor with a construction have been studied in this article. The simulation model setup is shown schematically in Fig.1. H is used as a scale and is equivalent to 0.125 m. The length of the chamber (L) is 8H, with an inner diameter (D) of 4H. The diameter of the exit is 2H. The primary air and secondary air enter the chamber through toroidal cross-sections respectively and then leave from the exit. Swirling airflow could be generated after travelling through the vanes equipped in the air inlets (not shown in the schematic Fig.1). The vane inclination for both inlets is 60°. The inner and outer diameters of the primary air inlet are 0.64H and 0.96H, and remain unchanged. The co-annular width is 0.16H for both primary and secondary air inlets. An IRZ can be generated in the vortex breakdown regions due to the swirling effect and the construction part [7].

The flux rate of the primary air remains at a constant of 0.02 m^3/s in all simulation cases, while that of the secondary air alters according to different flux ratios (β) between primary and secondary air. The structure of the model changes with different axial position (Δx) and radial position (α) of the secondary air inlet. Combining different flux ratio (β) between primary and secondary air, 4 simulation cases are calculated and analyzed, which is shown in Table 1. It is worth noting that when referring the end-surface-inlet structure, it means Δx=0, as is shown in Fig.2 (a); while the

staggered-inlet structure means $\Delta x \neq 0$, as are shown in Fig.2 (b) and (c). The inlet boundary conditions can be determined by the flux ratio β and the primary air flux, as well as the inclination angle of the vanes.

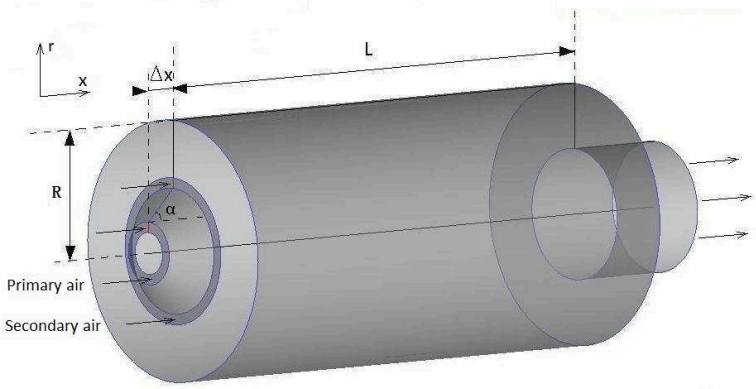

Fig.1 A schematic plot of the simulation model

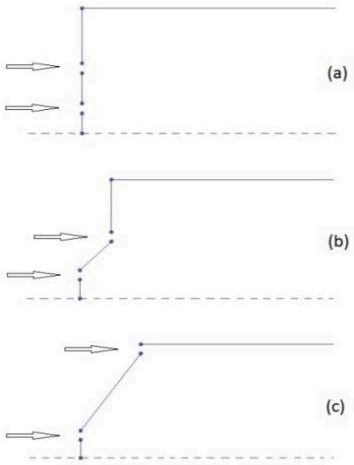

Fig.2 A schematic plot of the inlet structures

Table.1 Computational cases

Case	Δx	α (°)	β
C1	0	90	1:1
C2	0.48H	45	1:3
C3	0.48H	45	1:5
C4	0.96H	55	1:5

Note: in C1, the radial position for secondary air inlet is the same as that in C2 and C3

Numerical method

Governing Equations

The steady state Reynolds average Navier-Stokes continuity and momentum equations can be described as follows:

$$\frac{\partial U_i}{\partial x_i} = 0 \tag{1}$$

$$\rho \frac{\partial}{\partial x_j}\left(U_i U_j\right) = -\frac{\partial P}{\partial x_i} + \frac{\partial}{\partial x_j}\left[\mu\left(\frac{\partial u_i}{\partial x_j} - \rho\overline{u_i' u_j'}\right)\right] \tag{2}$$

Where ρ is the fluid density, U_i is a mean velocity component for the different direction X_i, P is the pressure, μ is the dynamic viscosity, and u' is a fluctuating component of velocity. The repeated indices represent summation from one to three for 3D problems and one to two for 2D problems.

The RNG k-ε model is based on the instantaneous Navier-Stokes equations using a mathematical technique called the "renormalization group" (RNG) methods. It contains modifications for the swirling flows by modifying the turbulent viscosity appropriately. The modification takes the following functional form:

$$\mu_t = \mu_{t0} f\left(\alpha_s, \Omega, \frac{k}{\varepsilon}\right) \tag{3}$$

Where μ_{t0} is the value of turbulent viscosity calculated without the swirl modification using the equations described above. Ω is a characteristic swirl number. α_s is a swirl constant, which equal to 0.07 while it's mildly swirling flows and can vary depend on the swirling intensity.

Mesh, boundary conditions and numerical methods

In the current simulation, 2D structured quadrilateral mesh cells are used according to the validation case. Three different numbers of grids (0.1 million, 0.2 million and 0.4 million) with the same meshing strategies have been implemented for the case C1 for the mesh independence check.

Results have proved that the predicted results match each other with few differences. So the minimum number of approximately 0.1 million is adopted. For other cases, the same meshing strategies are applied with a number of around 0.1 million in total. In the near-wall and near-axial regions, refined meshes are placed.

In this study, the commercial code ANSYS FLUENT 13.0 is used with the ICEM CFD for the mesh generation. The finite-volume method is applied while the governing equations are solved. The pressure based segregated solver solves the equations separately and sequentially. The SIMPLE scheme is applied for the pressure-velocity coupling. A second-order upwind scheme is used for spatial discretization of momentum, swirl velocity, turbulent kinetic energy and turbulent dissipation rate. Convergence criteria are set to five orders of magnitude reduction and at least 20,000 iterations have been carried out to insure the convergence.

The flowing parameters inside the chamber of TSC change with different structures and swirling intensities. It is hoped that from different cases, the characteristics of reverse and swirling flow under the condition of co-axial twin-swirl flow in a dump combustor could be better understood, and beneficial could be gained from the well-organized airflow structure for ignition and flame stabilization.

Results and Discussion

During coal combustion, the IRZ could be created by swirling air flow in the chamber. The combustion stabilization can be realized when appropriate swirl and reverse intensity is applied in the chamber. The intensity of swirling and flow reversals in the chamber will be analyzed, and the interaction mechanism will be illustrated below.

In the current research, the intensity of swirling in a given cross section can be evaluated by swirling number S. For any circular cross-section, S could be given by:

$$S = \frac{\int_0^R \rho u w \cdot 2\pi r^2 dr}{\int_0^R \rho u^2 \cdot 2\pi R r \, dr} \tag{4}$$

Here, R is the inner diameter of the chamber, ρ is the density of the fluid (here it is air), u is the axial velocity component and w is the tangential velocity component.

For any circular cross-section, the intensity of reverse flow can be assessed by reverse flow rate (X_r), given as follows,

$$X_r = \frac{|Q_{neg}|}{Q} = \frac{\left|\int_0^R u_{neg} \cdot 2\pi r dr\right|}{\int_0^R u \cdot 2\pi r dr} \tag{5}$$

Here, Q_{neg} is the net reflux through the cross-section, and Q is the flux in the given section. U_{neg} is the negative axial velocity component and u is the axial velocity component.

The swirling and recirculation features under the twin-swirl conditions

According to Eq. 4 and 5, the swirl number S and reverse flow rate X_r in different cross-sections which are perpendicular to axis x can be calculated by integration. Fig. 6 shows the trend lines of S and X_r in different simulation cases.

The interaction of inner and outer swirling flows make the internal swirl and reverse flow inside the combustion chamber more complicated than common single swirl cases, as is shown in Fig. 3. It is obvious to see that the trend lines change in a completely opposite way between swirl number S and reverse flow rate X_r, i.e., while S increases, X_r decreases; vice versa. When S increases to its local maximum or minimum, X_r is in its local minimum and maximum, correspondingly. The gradient of X_r is larger than S in the front and central of the chamber. In all 4 cases, the variance trends for both S and X_r are almost the same respectively, though different axial and radial inlet positions as well as the inlet flux ratio have been applied. In the front of the chamber, the swirl number S decreases initially and gets its global minimum at x/H=0.5 ~ 1.0. After that, it increases gradually along the axial direction downstream and gets its global maximum at x/H=6.5 ~ 7.0, then decreases rapidly as it approaches the end of the chamber.

Though the magnitude and range for the average S is almost the same, the X_r for C1 is notably larger than C2. A conclusion could be drawn that even though the flux ratio for C1 is smaller than C2 (which means the swirl momentum brought in by secondary air in C1 is smaller than that of C2), the recirculation effect for the end-surface-inlet structure (C1) is greater than staggered-inlet structure (C2). This is believed to be mainly due the fact that in the end-surface-inlet structure, the distance between primary and secondary inlet is smaller, which means that the mutual synergistic effect between primary and secondary air is better and the stronger swirling effect can be created under a greater negative pressure gradient and centrifugal forces.

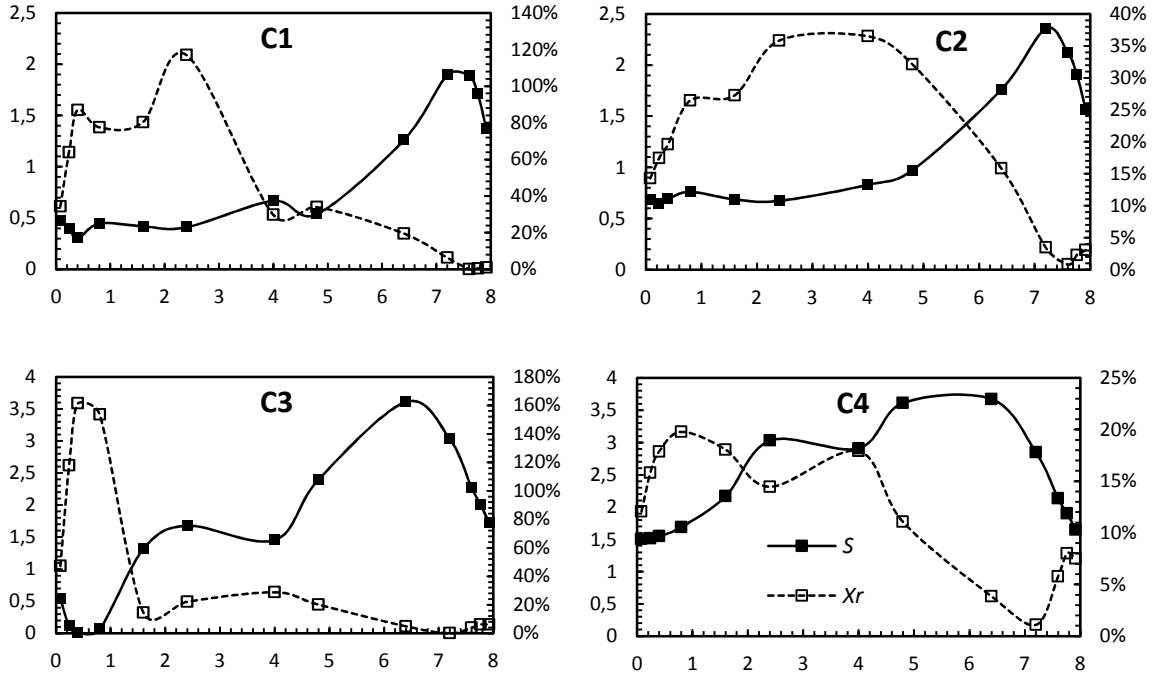

Fig. 3 Variances of S (straight lines with filled nodes) and X_r (dashed lines with unfilled nodes) in different axial positions (left vertical axis: S; right vertical axis: X_r)

With the same inlet structure (C2 and C3), when the flux ratio is increased (which means the secondary and total air flux are increased), both the swirl number S and reverse flow rate X_r increase. This can be explained that the swirl momentum brought in by the secondary air increases as the secondary air flux increases, which makes swirling effect inside the chamber enhanced. The stronger swirling airflow intensifies the reverse flow effect.

Even with the same air flow ratio while the distance between primary and secondary air inlets is further increased (C3 and C4), the range for the swirl number differs a little, while the reverse flow rate is significantly reduced. This is consistent with the former conclusion drawn from the comparison between C1 and C2. This comparison shows that increasing the distance will not help generating better recirculation effect. Besides, it is possible that there is a critical distance between primary and secondary air inlet. When exceeded, it would be difficult to enhance the recirculation effect by increasing the swirl intensity of the secondary air.

Comparative analysis on the swirling and recirculation features under the twin/single swirl conditions

The airflow in the TSC chamber can be flexibly adjusted and organized by both inner primary air and outer secondary air. For better understanding the influence of primary swirling air on the flow field in the chamber, a comparative analysis on the twin or single swirl was implemented. By turning the tangential velocity component of the primary airflow to zero while keep the axial velocity component unchanged, the former simulation cases C1 ~ C4 are named C1' ~ C4', respectively. The comparative results of swirl number S along the axis x for both twin and single swirl are illustrated in Fig. 4 (a) and (b), while those of the reverse flow rate X_r are shown in Fig. 4 (c) and (d).

As is shown in Fig 4 (a) and (c), the trend lines of swirl number S and reverse flow rate X_r are more similar between C2 and C2', compared with that of C1 and C1'. In most of the positions, both S and X_r in C1 are larger than C1'. This could attribute to the more "effective" enhancement of the swirling and recirculation in the twin swirl inlet conditions with the end-surface-inlet structure. When the primary air is turned from swirling into non-swirling, the average swirl number is slightly increased, while the average reverse flow rate is significantly decreased, which is not beneficial for combustion stability and intensification. As is mentioned before, with the end-surface-inlet structure, twin swirl airflows have a better superposition on swirling enhancement. When it comes to a single swirl, the enhancement effect is decayed so that the recirculation effect is receded correspondingly. When the staggered-inlet structure is applied in C2 and C2', the swirl number S in C2 is slightly smaller in the front chamber but marginally larger in the rear; while the reverse flow rate slightly enlarged, compared with C2'.

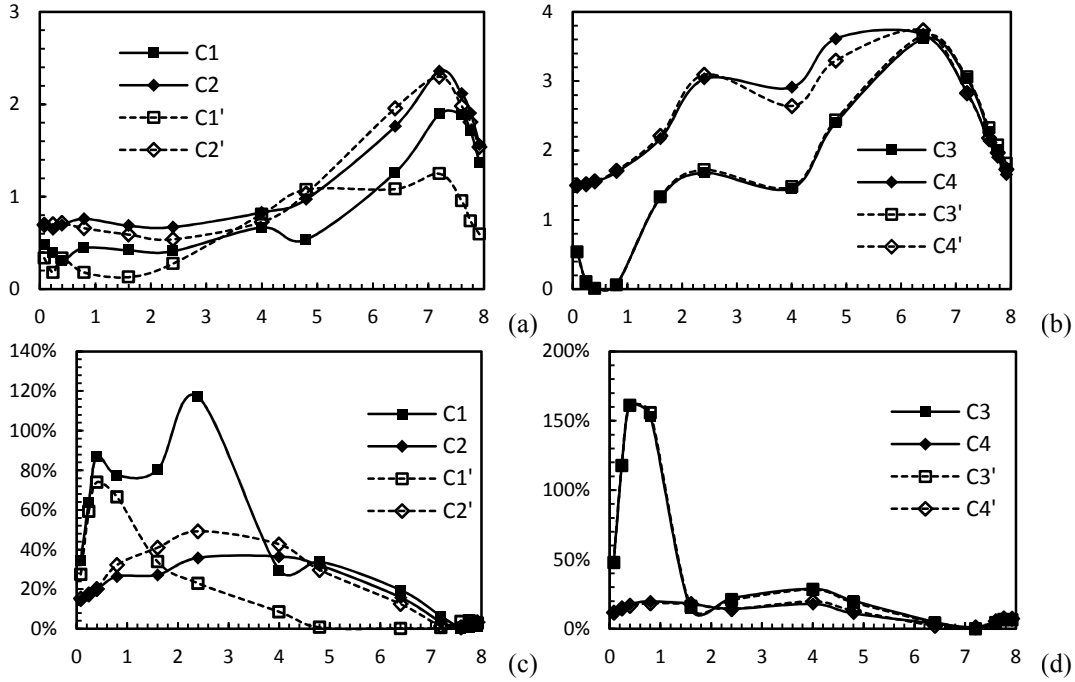

Fig. 4 Variances of S (straight lines with filled nodes) and X_r (dashed lines with unfilled nodes) in different axial positions (left vertical axis: S; right vertical axis: X_r)

Table 2 Average of swirl number $\bar{S}$ and reverse flow rate $\overline{X_r}$ for different cases

Cases	$\bar{S}$	$\overline{X_r}$ (%)	Cases	$\bar{S}$	$\overline{X_r}$ (%)
C1	0.9058	42.40	C3	1.5556	45.11
C1'	0.6103	23.42	C3'	1.5839	45.23
C2	1.2030	18.07	C4	2.3204	11.87
C2'	1.1721	20.64	C4'	2.3023	11.53

When the flux ratio β is further enlarged (C3 and C3'), and/or the distance between primary and secondary inlets is further increased (C4 and C4'), the differences of the trend lines for both swirl number and reverse flow rate between twin/single swirl are quite subtle, as it shown in Fig 4 (b) and (d). This could be explained by the relatively limited influence of the swirl momentum generated by the primary air, when β was changed from 1:3 to 1:5. Furthermore, the larger Δx weakens the swirl superposition effect. Compared with the secondary air, whether the primary air is swirling or not, there is less impact on the internal swirl flow and recirculation, with a relatively small β and large Δx.

The arithmetic means for both swirl number S and reverse flow rate X_r in 13 different axial positions are demonstrated in Table. 2. The dimensionless axial positions (x/H) for these cross-sections which perpendicular to the axis x are 0.24, 0.8, 1.6, 2.4, 4.0, 4.8, 6.4, 7.2 and 7.92. The quantitative analyses confirm the conclusions from the qualitative study of Fig. 7, as is mentioned above.

Conclusion

The confined swirling flow inside the chamber of the co-axial Twin Swirl Combustor (TSC) is studied with the RNG k-ε turbulence model. The validation case has proved that with qualified mesh and adequate mathematic method, RNG k-ε model is able to yield reliable results which could meet the requirements for industrial design and modifications. The swirling and recirculation characteristics in the chamber of TSC have been analyzed and discussed under different flux ratio of primary and secondary air, as well as the inlet structure. Conclusions can be made from the comparison on the trend lines of swirl number S and reverse flow rate X_r:

1) There is a notable negative correlation between the trend lines of swirl number (S) and reversed flow rate (X_r). The extreme values appear in the same axial location for S and X_r, when maximum or minimum is allocated to either of them.

2) The end-surface-inlet structure has a better swirl and recirculation enhancement effect when both the primary and secondary air are swirling. The gradient of reverse flow rate X_r is larger in the front and middle part of the combustion chamber than that of swirl number S. The swirl and recirculation intensity could be flexibly adjusted by regulating the swirling primary air.

3) With the staggered-inlet structure, the swirling and recirculation enhancement created by increasing the flux of swirling secondary air is not more notable than end-surface-inlet structure. Few differences are observed on the swirling and recirculation features inside the chamber when the primary air was turned from swirling to non-swirling. There is a critical distance between primary and secondary air inlets. When exceeded, it is more difficult to enhance the swirl and reverse flow effect by increasing the swirl intensity of the secondary air.

Keywords: Heat pipe; Orthogonal test method; Optimization levels; Heat transfer performance

Abstract. In order to study the influence of various factors on the heat pipe heat transfer performance, the heat transport limit was taken as test index, nine groups of heat pipe factors matching experiments were carried out based on the orthogonal test method. Four heat pipe internal factors including wick, work media, mass concentration and filling ratio were studied. The results show that the wick has the greatest influence, filling ratio ranks the second, while the work media and mass concentration are not so obviously; the wick and work filling ratio both have significant influences on test index, while work media and mass concentration have little significance.

Introduction

Working media and the wick are two important parts of heat pipe, which are closely related to the heat pipe heat transfer performance due to its structure and characteristics [1-4]. However, it is always confused to select the optimization factors and levels when study heat pipe heat transfer performance, such as the optimal combination among the wick, work media, mass concentration and filling ratio [5]. It must be considered how to find the optimal levels and main factors for heat pipe heat transfer performance with fewer test as possible.

In this paper, synthesizes the effects of heat pipe internal factors, such as wick, work media, mass concentration and filling ratio on heat transfer performance, and heat transport limit P was taken as test index in the test. The heat pipe tasted in this paper was copper tube (wall thickness 0.7 mm, outer diameter 12 mm).

The principle of orthogonal test method

Orthogonal test is a design method by using orthogonal table to arrange multi-factor and multi-level experiment [6]. Its core idea is through some typical combination to illustrate the information of the total test combination, and find out the optimal combination.

For example, a three factors three levels test, factor A have three levels: A 1, A 2, A 3; factor B have three levels: B 1, B 2, B 3; factor C have three levels: C 1, C 2, C 3, the possible combination is 27. As shown in Fig. 1, 27 points on the cube stand for the total test, 9 test points marked with "1" to "9" on the cube were selected by orthogonal table L_9 (34). Seen from the cube, each plane has three test points and each line has one test point, 9 test points are evenly distributed, every factor level has the same combination chance with other factor levels. These 9 points are very representative, can fully reflect the the total test characteristics and so reliable. According to the results and analysis of orthogonal test, the influence of various factors on the index, the significant, the optimal combination of different factors can be studied.

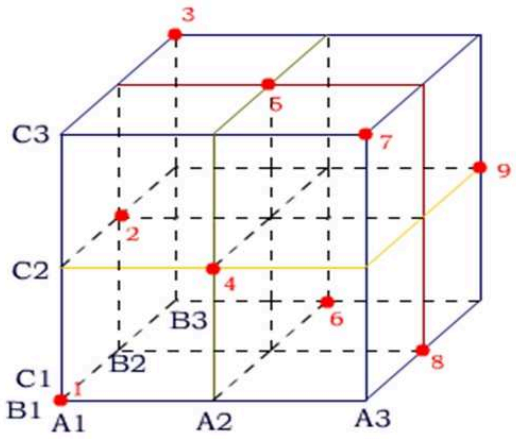

Fig. 1 The principle diagram of the orthogonal test

The orthogonal experiment design and arrangement

The wick, work media, mass concentration and work filling ratio are the major factors that influence heat pipe heat transfer. Different combination results in different heat transfer performance, we try to find the best combination of the four major factors to reach the maximum heat transfer potential: heat transport limit P. As show in Table 1, A stands for different wick form, PPI (pores per inch) is the porosity of the wick; B stands for filling ratio; C stands for work media; D stands for the mass concentration, 0% in the table means the work media is water. Each factors has three levels, regardless of the the factors interaction, an orthogonal $L_9(34)$ table [7-8] was used to find the best combination of heat transport limit. And the test plan and results was shown in Table 2.

Results and discussion

Range analysis and variance analysis are two common methods of orthogonal experimental design. Range analysis method can distinguish the primary and secondary order of various factors, and can find out the optimum level combination. But this method cannot distinguish the difference between the corresponding test results of difference factor level, also has no standard to make a judgement whether the factors have significant effect on the test index results,so variance analysis was uesd as a complement.

Range analysis. Range value reflects the changes of test index if a certain factor level changes, the more, the greater influence on index. Range analysis table is shown in Table 3. Attention: K_i is the sum value of the test index, k_i is the average value of the test index, R is the range of factors, is equal to the difference between maximum k and minimum k.

Table 1 Table of factor levels

Factors	Levels		
A: Wick	1(300 PPI mesh)	2(160 PPI copper foam)	3(160 PPI copper foam)
B: Filling ratio	1(40%)	2(50%)	3(60%)
C: Work media	1(SiO_2)	2(Al_2O_3)	3(CuO)
D: Mass concentration	1(0%)	2(0.3%)	3(0.5%)

Table 2 Analysis of the test data

Test number	Factor A	B	C	D	Index P
1	1 300 PPI mesh）	1(40%)	1(SiO_2)	1(0%)	105.8
2	1	2(50%)	2(Al_2O_3)	2(0.3%)	134.7
3	1	3(60%)	3(CuO)	3(0.5%)	126.3
4	2(160 PPI copper foam)	1	2	3	95.4
5	2	2	3	1	124.9
6	2	3	1	2	100.2
7	3(200 PPI copper foam)	1	3	2	136.3
8	3	2	1	3	156.4
9	3	3	2	1	136.4

Table 3 The table of ranges analysis W

Range	Factors A	B	C	D
K_1	366.8	337.5	362.4	367.1
K_2	320.5	416	366.5	371.2
K_3	429.1	362.9	387.5	378.1
k_1	122.3	112.5	120.8	122.4
k_2	106.8	138.7	122.3	123.7
k_3	143.0	120.9	129.2	126.0
R	36.20	26.20	8.37	3.67

As can be seen from Table 3, the maximum average index value of factor A is k_3(143.0 W), factor B is k_2(120.9 W), both factor C and D are k_3(129.2 W and 126.0 W). According to the results, 200 PPI copper wick has the greatest influence on heat pipe heat transfer limit, 160 PPI has the minimum influence; 50% filling ratio has the greatest influence on heat pipe heat transfer limit, 60% ranks second, while 40% has minimum influence; when compared the influence of work media, CuO- water nanofluids have a heat transfer advantages than that of other three work media; mass concentration has no obvious influence on heat transfer limit, but using nanofluids can make a difference on heat transfer limit, the value of 0.5% is the best. It can also be found that the influence on the heat transfer limit in the order of A>B>C>D. The conclusion can be reached from the discussion above: the important order of influence on test index is A B C D, Factors A 3, B 2, C 3, D 3's influence is the greatest. The optimal combination is A 3 B 2 C 3 D 3; that is, the wick 200 PPI copper foam, the filling ratio is 50%, work media is CuO-water nanofluids, mass concentration is 0.5%. When cooling water flow is 9 L/h, heat pipe heat transfer limit is the highest.

Variance analysis. The basic idea of variance analysis is total changes of test index value can be divided into two parts: changes caused by factors level, changes caused by test error. By F-statistics, significant effect of factors on test index shall be determined. Variance analysis of test results are listed in Table 4. And the principles of determine are as follows:(1)$F>F_{0.01}$, the factor has a very significant influence on the test index value, even a small changes in factor will results in big difference on test value; (2) $F_{0.01}>F>F_{0.05}$, the factor has a significant influence on the test index value; (3) $F<F_{0.05}$, the factor has little significant influence on the test index value.

Table 4 The table of variance analysis

Source	Sun of squares	Mean square	Freedom degree	F
A	1979.88	989.94	2	96.1
B	1069.67	534.8	2	51.9
C	120.87	60.43	2	5.8
D	20.6	10.3	2	1
Error	20.6	10.3	2	1

Check from the F statistic distribution table, $F_{0.05}$=19, $F_{0.01}$=99, while in this test, F_A=96.1, F_B=51.9, F_C= 5.8, F_D=1. According to the principle, factor A and B are the primary factors, have great significant influence on hear pipe heat transfer limit, factor A is more evidently than factor B; both factor C and D are secondary factors, have little significant influence on heat transfer limit.

Conclusions

(1)Various internal factors have influence on heat transfer performance, by orthogonal test, wick and filling ratio are the two primary factors, which have great significant influence on heat transfer limit .

(2) work media and mass concentration have little significant influence on heat transfer limit, but reasonable choice can also improve heat transfer performance.

(3) The optimal combination is: the wick is 200 PPI copper foam, the filling ratio is 50%, work media is CuO, mass concentration is 0.5%. When cooling water flow is 9 L/h, heat pipe heat transfer limit is the highest.

Keyword: Different materials; different times; the unit area of dry dirt mass; Growth pattern analysis

Abstract: This experiment wastewater treatment plant set up a device of researching different periods of dirt on the different heat exchanger tubes. The moisture test of dirt were derived from tubes of different materials (copper alloy tube, stainless steel pipe, polyethylene-aluminum composite pipe) is between 92.50% and 96.70%, This shows that the quality of per unit area of dry dirt to describe variation is feasible. The induction period of dirt on the copper alloy is between the 0d and 35d, the growth cycle is longer. In the mature period, the quality of per unit area of dry dirt is 2.031 mg/cm^2. The induction period of dirt on the stainless steel is between the 0d and 20d, the growth cycle is shorter. In the mature period, the quality of per unit area of dry dirt is 2.627 mg / cm^2. The induction period of dirt on the polyethylene-aluminum composite pipe is between the 0d and 35d, the growth cycle is shorter. In the mature period, the quality of per unit area of dry dirt is 2.863 mg/cm^2.

Foreword

The characteristics of heat transfer tube surface are different, the roughness, the surface free energy of the surface will affect the adhesion property of the dirt[1]. The literature mentioned in recent years, sewage source heat exchanger tubes are mainly three kinds, namely, copper alloy tube, stainless steel pipe, polyethylene-aluminum composite pipe [2]. In this experiment, the sewage is regarded as the heat source, combining the growth situation of three kinds of pipe , making dynamic experiments and comparative analysis.

Experimental introduction

In order to studying of three dirt's growth pattern, building three experimental pipe respectively, DN 20mm copper alloy tube, DN 20mm stainless steel pipe, the DN 20mm polyethylene-aluminum composite pipe, flow velocity V = 0.78m/s, a sewage influent water to plant secondary sewage effluent. The feed water come from a sewage treatment plant secondary effluent in changchun. According to the sampling date, name the experiment section numbers. Such as T - 12/06/04 for sampling date is on June 4, 2012 copper tube section. as shown in figure 1,put a row of experimental section as an example, the S0 valve is open, S1, S2, S3 valve is in the closed position, the sewage through the bypass valve and meter, loop through T3, T2, T1 and T1 ', T2 ', T3 ' ,flow to the next unit, sampling time period is t1,t2, t3 ••• tn, at the time when the t1 in, all of the experimental section's bio-film growth period is the t1 time. After t1 time ,close T0 valve, open the S1 valve, S2, S3 remain closed, removal the T1 number section, S0 valve, T1' number section for

sampling and analysis. When after t2 time, close S1 valve, open the t2 valve, the experimental section of bio-film growth within the t1 and t2 time, then use the same principle of regular sampling and records, to observe the different periods bio-film growth situation.

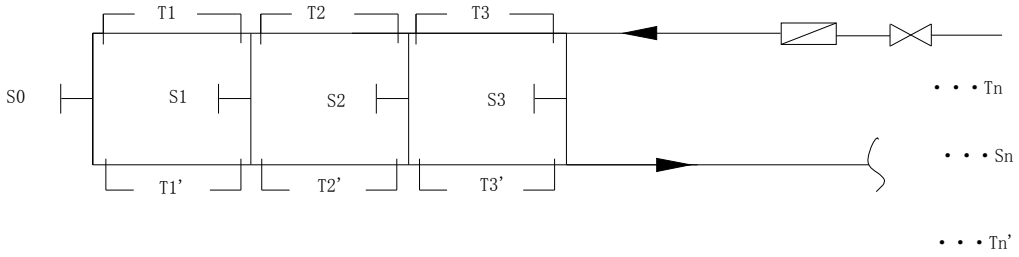

Figure 1 Experimental principle diagram

Moisture content analysis of the different dirt

Analysis result of moisture and burning weightlessness as table 1 shown, in 105 ~ 110 ℃ drying to constant weight loss is water. Moisture content at 92.50% ~ 96.60%,in the 550 ℃ burning to constant weight, the weight loss of the part is the biological sticky mud, combined water, organic matter [4]. In 950 ℃ calcination to constant weight, the weight loss part is CO2. The dirt in the 550 ℃ and 950 ℃ calcination weight value was 68.45% ~ 85.53% and 0.77% ~ 1.86%. Dirt moisture content is very high, dry dirt of the composition is mainly organic matter.

Table 1 The dirt moisture content and burning weightlessness analysis

Numbers	Sample quality	moisture (%)	550 ℃ calcination lost weight(%)	950 ℃ calcination lost weight(%)
T-11/06/19	1.0221	96.5689	72.896	0.7698
B-11/06/19	1.0125	92.4616	68.452	0.7952
L-11/06/19	1.0098	95.4212	85.527	1.8564

The different material exchanger pipe's dirt growth record

Respectively collect the three tube dirt samples, sample records such as table 1:

Table 2 Sampling site record

number	run days	scale sample description	dry biomass mg/cm2
T-11/04/20	5d	Smooth, no bio-film	0.221
B-11/04/20	5d	Smooth, no bio-film	0.398
L-11/04/20	5d	Smooth, little bio-film	1.232
T-11/05/05	20d	Smooth, no bio-film	0.245
B-11/05/05	20d	Smooth, no bio-film	0.532
L-11/05/05	20d	little bio-film	1.354
T-11/05/20	35d	Smooth, no bio-film	0.286
B-11/05/20	35d	Smooth, little bio-film	1.487
L-11/05/20	35d	thin, not easy peeling off	2.654
T-11/06/04	50d	thin	1.454
B-11/06/04	50d	thin, dense, not easy peeling off	2.627
L-11/06/04	50d	have fibrous macro creatures, thick,	2.863

		not easy peeling off	
T-11/06/19	65d	thick, dense, not easy peeling off	2.031
B-11/06/19	65d	have fibrous macro creatures, thick, easy peeling off	1.334
L-11/06/19	65d	have fibrous macro creatures, thin, easy peeling off	2.231

From the table 1, Because the quality of dry dirt keep increasingly, we know that copper tube dirt growth cycle period is longer than 65d. stainless steel tube's fouling growth cycle is about 65d, polyethylene-aluminum pipe's dirt growth cycle is almost 65d .The copper dirt growth cycle is long, polyethylene-aluminum tube dirt growth cycle is short. This is because:(1) copper tube surface is smooth, the crack is scattered and small, and polyethylene-aluminum tube surface crack arrange closely, heat transfer surface area is far greater than other pipe surface area; (2) copper tube surface is the presence of copper ion, which have certain inhibition function to the growth of microorganism.

Copper alloy tube fouling growth variation analysis

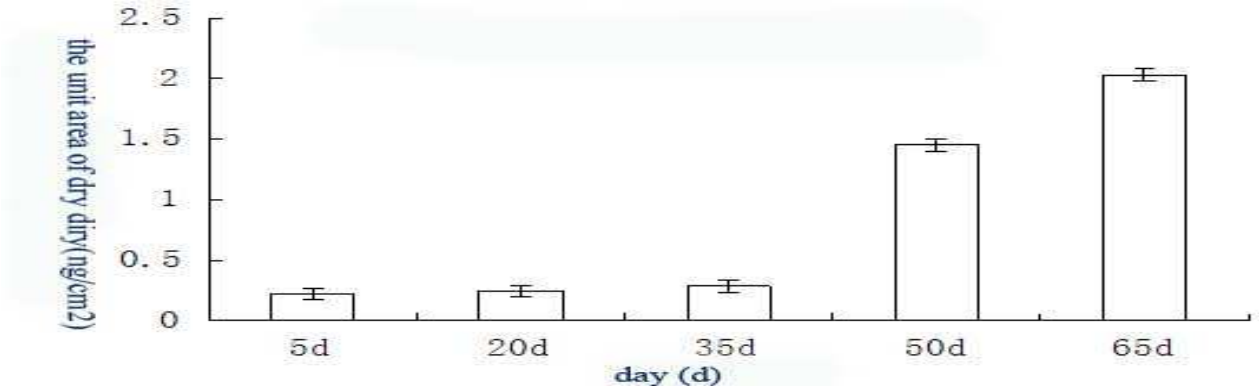

Figure 2 The increase regularity of copper alloy tube surface dirt

From Figure 2, the copper alloy tube fouling growth cycle is longer, the copper alloy tube fouling growth induction period is between 0d and 35d, 35d-65d is the logarithmic growth phase. The quality of dry dirt in induction period and maturity period is 0.286 mg / cm ^{2} and 2.031mg/cm ^{2}. This shows that the copper alloy tube is not easy to adhere dirt.

Stainless steel tube fouling growth variation analysis

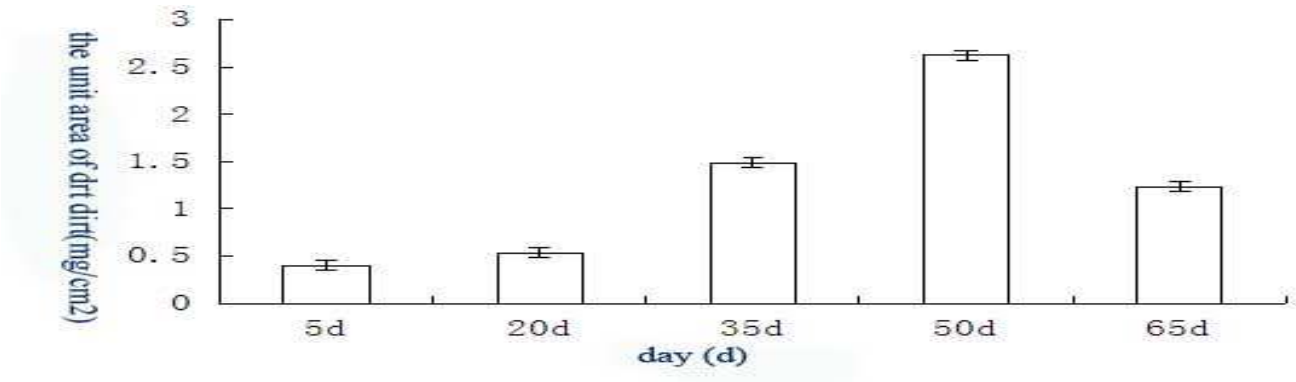

Figure 3 The increase regularity of stainless steel tube surface dirt

At the figure 3, the stainless steel surface dirt induction period is between 0d and 20d, the stain logarithmic growth phase is from the 20d to 50d. The amount of dirt shedding larger before the 65d, because stainless steel pipe surface is smooth, and have little adhesion of dirt.

Aluminum tube fouling growth variation analysis

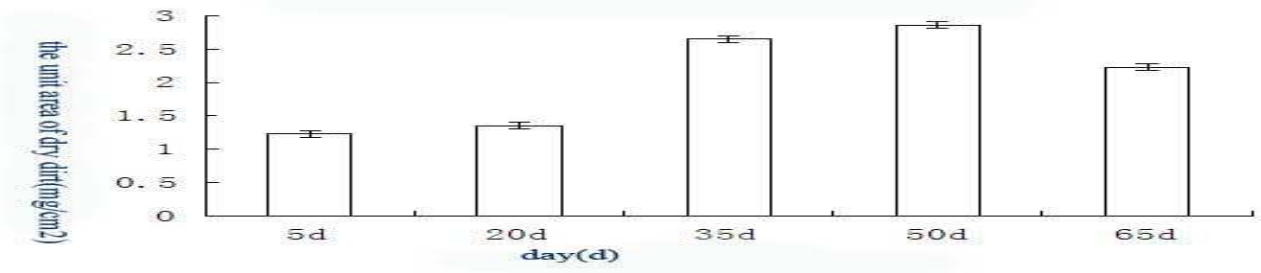

Figure 4 The increase regularity of the polyethylene-aluminum composite pipe surface dirt

Figure 4 shows that the growth cycle is short aluminum pipe. Induction period is from 0d to 20d, and the induction period is greater than 1mg/cm^2.this is because the specific surface area aluminum tube, resulting in the induction phase of the large surface dirt. Dirt grow into the stable period at 35d, and at 50d into the off period. The dirt on the maturity of the mass per unit area is more than 2.5mg/cm^2, and less dirt shedding, it is because of the larger surface area of the stain of solid foundation, can resist the erosion of sewage and shear force.

Conclusion

(1) The moisture content of the three pipes showed that the stain ignition moisture content 92.50% ~ 96.70%, the weight loss at this time is mainly water, the remain is compound water and organic matter. Dirt moisture is in a certain range, and keep stability. Therefore, the use of the area of the stain dry dirt to research quantity description rule is feasible.

(2) This experiment use urban sewage to be heat source. Dirt drawn copper alloy tube growth induction period between the 0d and 35d, stainless steel tube fouling induction period is at 20d. The aluminum tube induction period is at the 30d. Dirt within the copper alloy tube fouling growth cycle is longer, aluminum pipe dirt have a short growth cycle. Probably because the surface of the copper alloy tube is smooth, and copper ions give the dirt an early microbial growth inhibition, resulting in copper alloy surface dirt's growth cycle is longer.

(3) Copper alloy tube induction period and maturity dirt dry mass per unit area was 0.286 mg/cm^2 and 2.031mg/cm^2, stainless steel pipe induction period and maturity dirt dry mass per unit area were 0.532 mg/cm^2, and 2.627 mg/cm^2, aluminum tube induction period and maturity dirt dry mass per unit area was 1.354 mg/cm^2 and 2.863mg/cm^2.The specific surface area of copper alloy tube is much bigger than the specific surface on the polyethylene-aluminum composite pipe surface area, the uneven surface of copper alloy pipe provides habitat for microbial growth, resulting in a specific surface area become smaller than polyethylene-aluminum composite pipe's dirt.

Keywords: oil fire; temperature distribution; thermal radiation; gaseous pollutant component.

Abstract. The initial features of large scale oil fires were studied through combustion experiments in oil basins. Four basins were prepared, the diameters of two of them were 2.5m, and another two were 2m. Oil in the basins was ignited simultaneously, and the experiments were conducted twice. The thermal radiation, temperature distribution and components of pollutants were detected and analyzed. Then, some initial features and instructive rules of large scale oil fire disasters were concluded. Known from the experiments, the temperature is high in center areas and low around, in the vertical direction the temperature is high both in upper part and bottom and low in the middle. In addition, the density values of gas pollutants sampled during the experiments can reach to several hundred times of the standard values.

Introduction

Oil is a kind of important but flammable and explosive strategic resource, thus oil depot safety has always been the most concerned and urgent subject of relevant departments at all levels[1, 2].

Statistics show that noxious gas released from oil combustion is the key factor leading to casualties, thus the evaluation and forecast of gas components in fires are important subjects in the field of fire risk assessment. The analyzing methods and principles of gas composition based on Fourier transform infrared spectroscopy (FTIR) are introduced in literature [3]. Smoke extraction in case of fire in a tunnel is investigated experimentally in literature [4]. The producing mechanisms and the component detection methods of smoke are summarized in literature [5].

When oil depot fires break out, masses of oil catch fire and release lots of heat into the atmosphere, the heat extend outwards continuously in the form of radiation and convection. Suppose that there were combustible substances, trees and weeds for example, near the fire, they might be ignited simply by the energy delivered from heat radiation and convection, which results in worse situation and greater loses. Therefore, when evaluating the danger and pollution of oil fires, not only harmful gases and dusts in combustion need to be researched, but also the thermal pollution during combustion and the diffusion ability of the disaster need to be evaluated and analyzed[6, 7]. A systematic procedure for the quantitative assessment of the risk caused by domino effect is developed in literature [8]. The minimum fire suppression distance considering the safety of fire fighters is studied under the condition of 5 meter high flame and different critical heat radiation flux in literature [9]. The variation of flame temperature with time and height is studied in hydrocarbon pool-fires in literature [10]. Two synthetic 30 cm-diameter pool fires, generated from experimental data, are used to assess different radiative properties models in literature [11].

The literatures mentioned above have obtained certain achievements, but due to the complexity of fire itself; the difficulty in numerical modeling; great inaccuracy and weak similarity and different characteristics presented in different kinds of fires, more experimental data are needed

for further research. To this end, this article simulated the initial features of oil fire through experiments, collected the data of heat radiation, temperature, pollution components of the simulated fire, and concluded the initial features and rules of large scale oil fires.

The experimental system in this article mainly consists of experimental bench, data acquisition system and auxiliary experimental devices.

Experimental bench

The bench mainly consisted of oil basins, sampling system, supports of test devices, etc.

Oil basins. Oil basins were containers for the oil fire burning, welded from A3 steel plates with thickness of 3mm, including four basins with height of 0.3m, and the diameters of two of them were 2.5m, another two were 2m, some water was added into the basins before experiment for avoiding deformation caused by high temperature. Thin wire nettings were covered on the basins to ensure the homogeneity and constancy of burning. The arrangement plan of the experiment is shown in Figure 1.

Figure 1. Basins arrangement

Sampling system. The temperature of combustion products and atmosphere around the fire was so high after ignition that detection equipments could not get close to the fire and sampling could not be conducted directly. Thus the pollutants in high temperature needed to be cooled and sampled far away. The sampling system consisted of the sampling equipment, the cooling equipment, air pump and pipes. The sampling equipment consisted of Φ0.25×3m steel pipe and support, which could sample pollutant air in fixed points, high-temperature fields and flaming areas. The cooling equipment was a Φ0.08×1.5m brass pipe immersed in water, the air pump was a kind of diaphragm type air compressor pump, which could deliver sample gas into detection devices.

Data acquisition system. Data acquisition system mainly consisted of temperature online detection system, pollutant density test system, radiation heatflowmeter and live video capture system, etc.

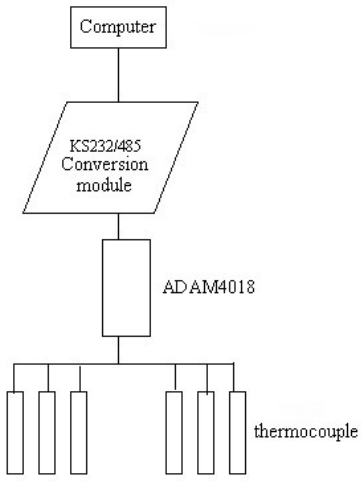

Figure 2. Structure of temperature online detection system

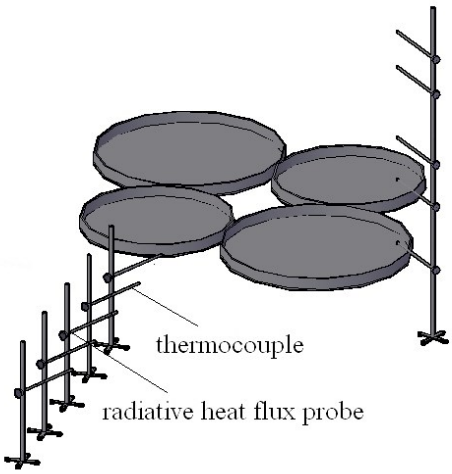
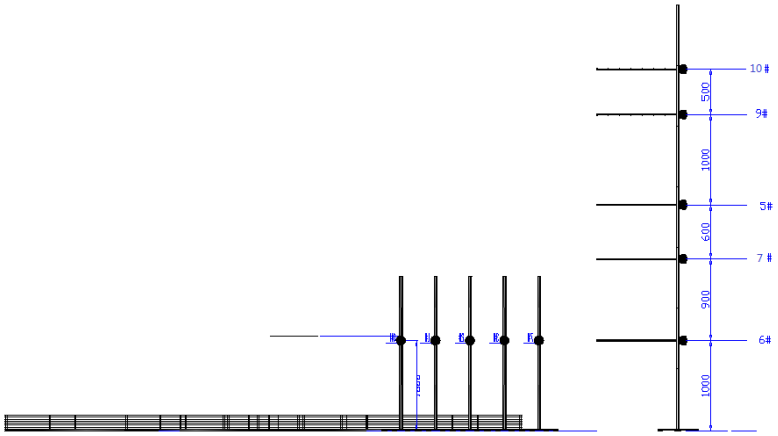
Individual protection facilities and emergency equipments. To meet the demand of close monitoring in experimental field simulating oil depot fires and handling sudden fire spread in emergency, protective and emergency equipments like fire-proof suit, fire-smothering blanket and fire extinguisher were prepared.

Experimental parameters and process

In the process of experiment, ten temperature and one thermal radiation measuring points were set around the fire to collect environment temperature and thermal radiation value during the burning process in real time, the arrangement plan of the temperature measuring points is shown in Figure 3.



(a) General arrangement of experimental field



(b) Temperature measuring points arrangement

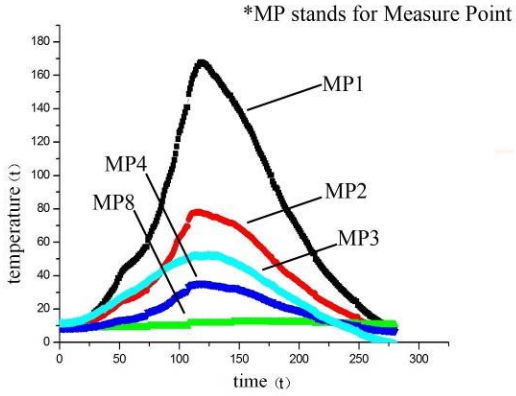
Figure 3. Experimental field and temperature measuring points arrangement

The environment temperature during the experiment was 11℃ and the atmospheric pressure was 98.6 kPa. The experiment was conducted twice, for each time every basin was filled with 25L $0^{\#}$ diesel separately, and 4 basins with 1L gasoline in total for the use of ignition. Wind speed in the first experiment was about 1.4～2 m/s, wind direction was about north by east 22.5～45 °. In the second experiment the wind speed was about 1.4～1.6 m/s and the wind direction was about north by east 0～30 °.

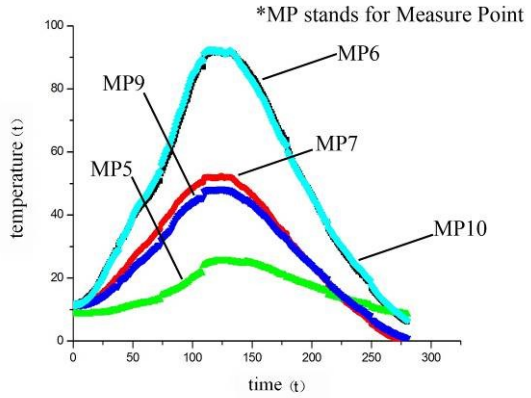
Data analysis

Thermal radiation and temperature data analysis. Experimental data from temperature measuring points and thermal radiation measuring points are shown in Figure 4. Seen from the graph,

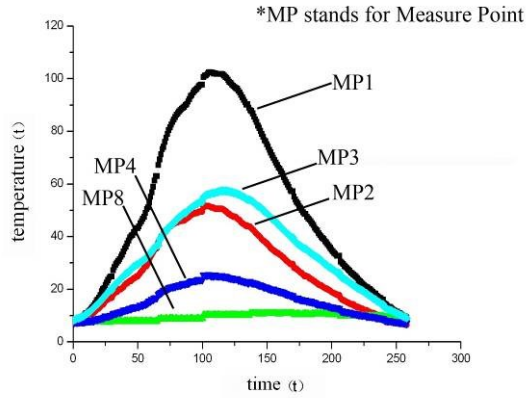
the temperature gradient in the horizontal direction gradually decreases as the distance increases, the temperature of the measuring point closest to the fire was far higher than the one of other points, but in the vertical direction the temperature did not decline progressively. Together with the position of sensors shown in Figure 3, we can see the temperature was high in top and bottom and low in middle. This was mainly decided by the shape of fire and smoke, as shown in Figure 5.



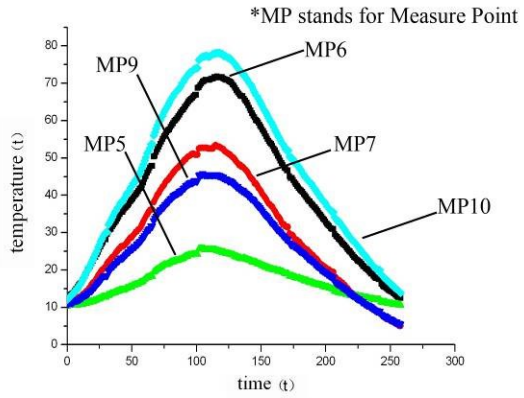
(a) Temperature data of the first experiment in the horizontal direction



(b) Temperature data of the first experiment in the vertical direction



(c) Temperature data of the second experiment in the horizontal direction



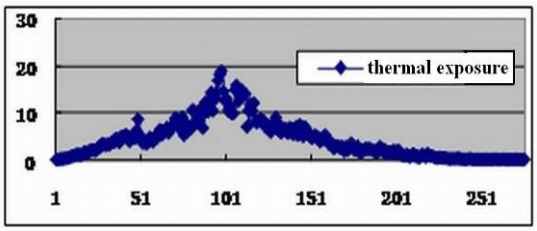
(d) Temperature data of the second experiment in the vertical direction

Figure 4. Experimental data of each temperature measuring points

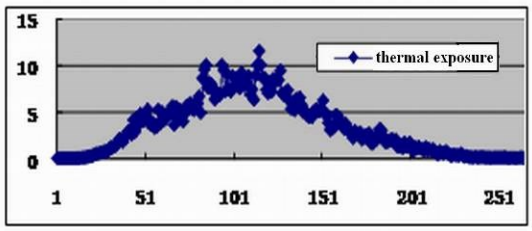
Figure 5. Shape of fire and smoke during combustion

It can be seen from the picture, the lower part of fire was naked flame and the upper part was dense smoke. Consider the temperature distribution in vertical direction, the flame in lower part released heat without limit, so the nearest measuring point, No.6, received more heat and which temperature was higher than the others. In middle part of the flame, dense smoke took in flux heat from flame and resulted in temperature rise, but the temperature and heat radiation of the smoke was far lower than that of the flame, so measuring points in the middle got less heat. In the upper part, measuring point No.10 was surrounded by dense smoke with the help of wind, in this condition, heat convection between smoke and the measuring point rose sharply, which resulted in similarly high temperature. In summary, in vertical direction, temperature was high in lower and upper part and low in the middle.

In terms of radiation, owing to the relatively large quantity of gasoline, the oil burned quickly, the radiation value reached its peak at 100 seconds or so, but the general level of radiation and its influence to temperature field were equivalent to former experiments, as shown in Figure 6.



(a) Radiation in the first experiment



(b) Radiation in the second experiment
Figure 6. Radiation data

Test result and Analysis of gas pollutants. Two experiments both lasted for about 5min and during which samplings lasted for 3min, samples were taken every 5s. Test results of gas pollutant components near the fire source in two experiments are shown as follows.

CO.As shown in Figure 7, the density of CO gradually rose after ignition, in the first experiment, release of CO reached its peak at about 1.5min after ignition, and in the second at about 2min, then the release value dropped with the abatement of fire after the peak. The same quantity of oil was burned in two experiments, the production law of CO agreed basically, the gas sampling process might be influenced by wind, which resulted in that the peak value of CO in the second experiment only equaled to a half of that in the first experiment.

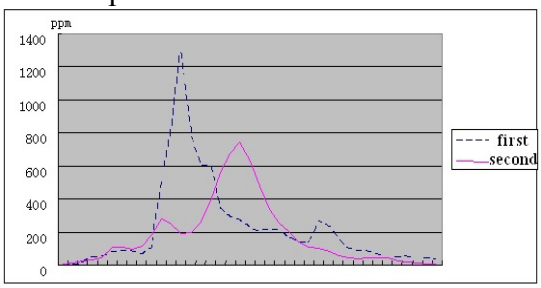


Figure 7. Density variation trend of CO

Known from results, the instantaneous maximum density of CO in the first experiment was 1290ppm, the average density during sampling process was 315ppm, comparing with the second level limit of average density of CO in one hour in *GB3095-2012 Ambient Air Quality Standard* [12], the instantaneous maximum density was 161 times of the standard value and the average density was 24 times of the standard value. The instantaneous maximum density in the second experiment was 744ppm, the average density during sampling process was 264ppm, the instantaneous maximum density was 93 times of the standard value and the average density was 19 times of the standard value.

NO. In both experiments, NO started to be detected at 0.5min after ignition, and its release peak appeared at about 1.5min, then release value dropped with the abatement of fire, this illustrated that NO had its regularity during burning process, as shown in Figure 8.

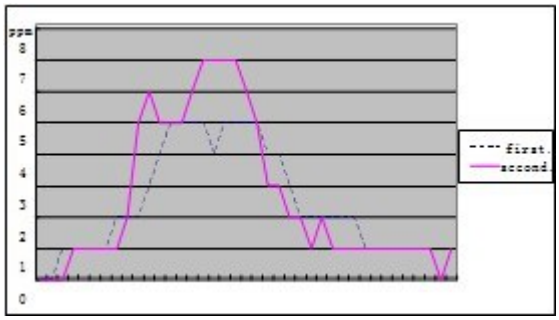

Figure 8**.** Density variation trend of NO

Known from results, the instantaneous maximum density of NO in the first experiment was 7ppm, the average density during sampling process was 2ppm, since NO can be quickly transformed

into NO_2 in air, the density of NO during the burning process can be seen as the density of produced NO_2, comparing with the second level limit of average density of NO_2 in one hour in GB3095-2012 Ambient Air Quality Standard, the instantaneous maximum density of NO_2 was 72 times of the standard value and the average density was 20 times of the standard value. The instantaneous maximum density of NO in the second experiment was 5ppm, the average density during sampling process was 2ppm, the instantaneous maximum density was 51 times of the standard value and the average density was 20 times of the standard value.

SO_2. In the first experiment, SO_2 started to be detected no long after ignition, and its release peak appeared at about 1.5min and reached 120ppm, then decreased rapidly, while in the second experiment, the density of SO_2 basically stabilized below 8ppm besides little rises and falls, as shown in Figure 9.

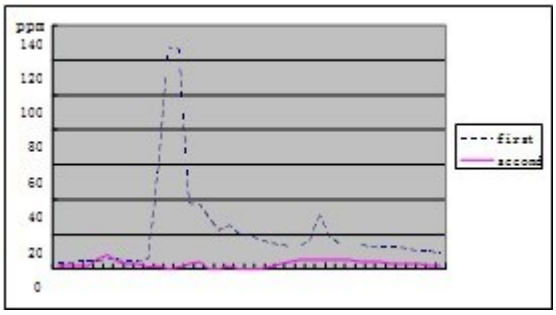

Figure 9. Density variation trend of SO_2

Known from testing results, the instantaneous maximum density of SO_2 in the first experiment was 127ppm, the average density during sampling process was 19ppm, comparing with the second level limit of average density of SO_2 in one hour in *GB3095-2012 Ambient Air Quality Standard*, the instantaneous maximum density was 725 times of the standard value and the average density was 108 times of the standard value. The instantaneous maximum density of SO_2 in the second experiment was 8ppm, the average density during sampling process was 3ppm, the instantaneous maximum density was 46 times of the standard value and the average density was 17 times of the standard value.

HC. In the first experiment, HC started to be detected no long after ignition, and its release peak appeared at about 1.5min and beyond 2200ppm, then release value decreased rapidly, while in the second experiment, HC density curve rose gently, and its release peak appeared at about 2min and reached 440ppm, as shown in Figure 10.

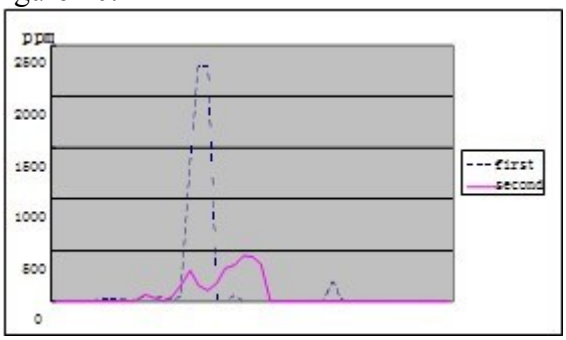

Figure10. Density variation trend of HC

Known from the results, at 1.5min after ignition the instantaneous density of HC reached the peak of 2298ppm in the first experiment, the average density during sampling process was 145ppm. At 2min after ignition, the instantaneous density of HC reached the peak of 436ppm in the second experiment, the average density during sampling process was 66ppm.

Under the condition of the same quantity of oil, the peak density values of all kinds of pollutants in the second experiment were apparently lower than that in the first experiment, it might result from some changes of wind direction meanwhile the location of inlet port of gas sampling

device was left unchanged, which leaded the peak density of pollutants during sampling to variation, but the variation trend of density agreed basically.

Conclusions

The experiments and research mentioned above can be concluded that:

- The temperature field around fire mainly influenced by heat radiation and convection, and direction of wind determines the location of fire radiation center. Temperature is centered by the center of flame radiation, which is regularly high in center areas and low in surroundings, and the temperature gradient gradually reduces from center to surrounding, in the vertical direction, the temperature appears high both in upper part and bottom and low in the middle.
- 2m away from radiation center, the heat radiation peak value reaches 10～20kW/m^2, it is mainly influenced by the oil burning velocity and has little to do with wind direction.
- Experiments indicate that with fire and explosion of oil depot, a great quantity of gas pollutants such as CO, NO, SO_2 and so on are produced, their instantaneous maximum density values far exceed the standard values, in dense smoke the density of CO is enough to stifle a man suddenly. In the initial period of fire, density of pollutants will rise rapaidly with the development of fire and diffuse to surroundings within several minutes, the release value usually reaches its peak 2min after ignition and then drops with the abatement of fire.

In experiments above, it lasted for about 5min from ignition to end, high level diffusion of pollutants lasted for about 3min. In real process of fire and explosion, burning usually lasts much longer than that in the experiment and production of pollutants is higher, as a consequence, its threat to man and environment is more conspicuous.

Keywords: thermal conductivity; temperature field; moisture content; porosity

Abstract. The ground coefficient of thermal conductivity is one of the most important parameters of simulating the ground temperature field. The ground coefficient of thermal conductivity of the severe cold region is investigated in this article. Firstly, calculating the ground thermal conductivity with considering the moisture content and porosity; then measuring the thermal conductivity of the 1.5 Meter depth; finally, simulating the unsteady heat transfer model of the shallow buried pipe and the ground with the Matlab software; it founded that the calculation data and the actual data differ only 0.31,but the corresponding ground temperature field vary widely. Thus, it can be concluded that the more precise temperature field of the ground can be simulated with the actual data of ground coefficient of thermal conductivity.

Introduction

Soil is a typical muti-phase medium, which consists of mineral substance, moisture and gases. The climate factor of the seasonal exchange and rainfall will induce the change of underwater level. With the variation of moisture content and porosity, the coefficient of thermal conductivity will change. Thus, it is necessary and important to carry out the investigation of the coefficient of thermal conductivity.

In past research, there are three mainly method to navigated the soil coefficient of thermal conductivity.

The heat probe method is applied to test the soil coefficient of thermal conductivity[2] ,the structure is shown in figure 1.With this experimental method, the values of it can be more accurate, but the initial investment of the engineering will increase.

It is believed that the values are constant, when assuming that: (1) soil is a semi infinite and uniform object ;(2) Ignoring the moisture migration ;(3)Ignoring the heat-moisture migration caused by moisture migration ; which is 1.2W/(m.k)～1.5 W/(m.k).

It is assumed that there is only exists porosity effect on coefficient of thermal conductivity but no heat transfer between the component of liquid and solid, whose calculation is below[3]:

$$\lambda = \varepsilon\lambda_f + (1-\varepsilon)\lambda s \tag{1}$$

Among that , λ_f and λ_s are representatively on behalf of soil coefficient of thermal conductivity with moisture and solid; ε is soil porosity. Because the soil structure is relatively complex, the influential factors include moisture migration, which results the heat-moisture migration, the type of soil and the porosity [4]. Thus, in order to simulate the soil temperature field more accurate, the factors above should be under consideration.

$$\lambda_{dry} = \frac{0.135\rho_b + 64.7}{2700 - 0.947\rho_b} \tag{2}$$

Among that: ρ_b is the density of bulk soil, kg/m^3.

Lu Sen semi-experience formula

LuSen improved Johansen O.'s mathematical model in 2007[5] ,mainly amended for Kersten coefficient and the thermal conductivity of dry soil.

$$K_e = \exp\{\alpha[1 - S_r^{(\alpha-1.33)}]\} \tag{3}$$

Among that, α is constant related to the soil geology, when soil sand content greater than 40%,the value adopt 0.96, whereas is 0.27.

$$\lambda_{dry} = -a\varepsilon + b \tag{4}$$

In the formula, a, b are empirical parameters values 0.56 and 0.51 respectivel

$$\lambda = \{[\lambda_q^{\alpha}\lambda_0^{1-\alpha}]^{1-\varepsilon}\lambda_w^{\varepsilon} + 0.56\varepsilon - 0.51\}\exp\{\alpha[1 - S_r^{(\alpha-1.33)}]\} - 0.56\varepsilon + 0.51 \tag{5}$$

Numerical calculation and experimental verification.

The test base of the group is located in Daqing City, Heilongjiang Province, the mainly soil components of the region are silver sand, light loam, loam and a handful of clay, the original porosity of the soil is 0.6～0.7, the dry density of soil is 1.5 g/cm ～1.6g/cm[6] the thermal conductivity of soil under the condition of unfrozen is 1.11 w/(m.k), saturated soil moisture content is 0.80, the initial moisture content is 0.2, the measured values of soil thermal conductivity[7] is shown in table one, Johansen O.semi-empirical formula are shown in figure 2 and figure 3.

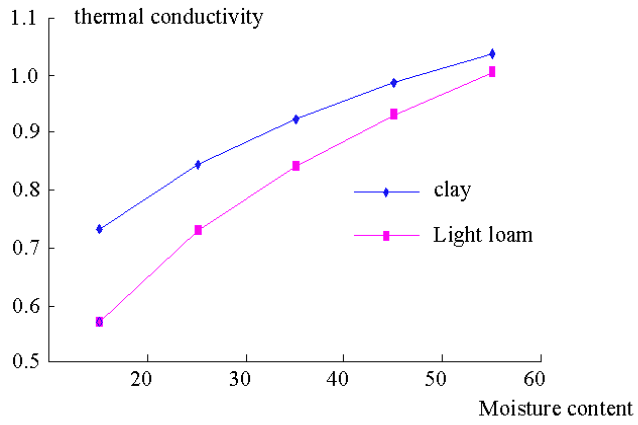

Fig. 2 Effects of moisture on the thermal conductivity

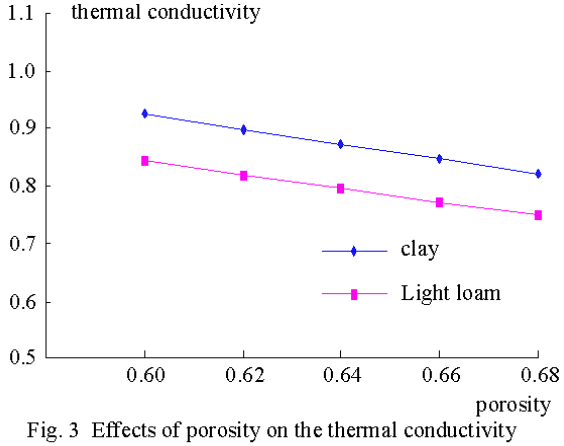

Fig. 3 Effects of porosity on the thermal conductivity

Table 1 The measured soil thermal conductivity

Sampling number	Wet soil density	Dry soil density	water content/%	saturation/%	Non-frozen soil thermal conductivity
1	1.7	1.34	26.5	70.4	1.3
2	1.84	1.46	26.1	82.2	1.5
3	1.91	1.57	21.8	80.7	1.43
4	1.47	1.23	20	44.6	1.32
5	1.73	1.31	32.3	80.8	1.49
6	1.73	1.35	27.6	74.3	1.38
7	1.66	1.42	17.3	51	1.25
8	1.48	1.28	15.9	38.3	0.98

The results with improved method of calculating of Lu Sen are shown in figure 4 and 5:

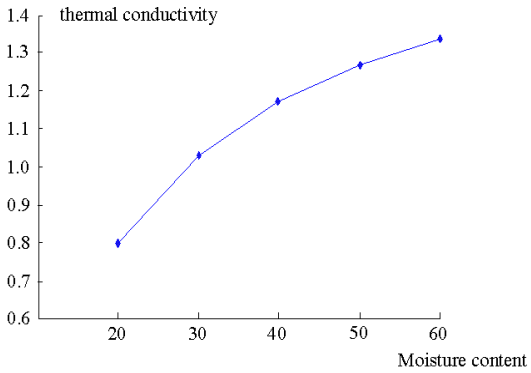

Fig. 4 Effects of moisture on the thermal conductivity

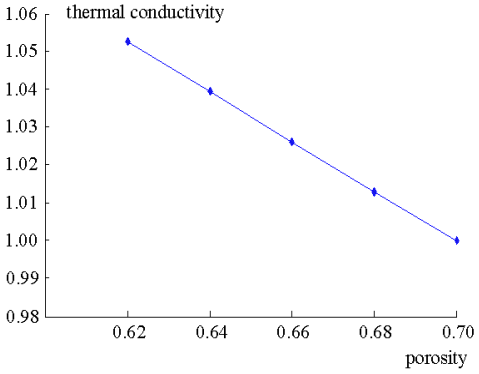

Fig. 5 Effects of porosity on the thermal conductivity

From above figures we can see, with the empirical formula of Johansen O, the calculated thermal conductivity of soil in Daqing area is 0.5w/(m.k)~1.1 w/(m.k), with an average of 0.8w/(m.k), with the empirical formula of Lu Sen , the calculated thermal conductivity of soil in Daqing area is 0.8 w/(m.k)~1.3w/(m.k), with an average of 1.05w/(m.k), the measured soil thermal conductivity is measured soil thermal conductivity, with an average of 1.24w/(m.k), Using matlab to simulate different coefficient of thermal conductivity of soil temperature field, as shown in figure6~figure8.

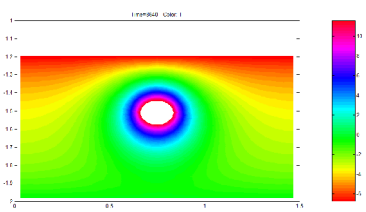

Fig. 6

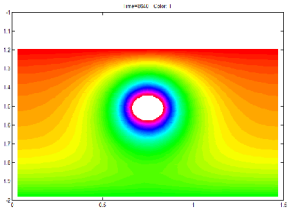

Fig. 7

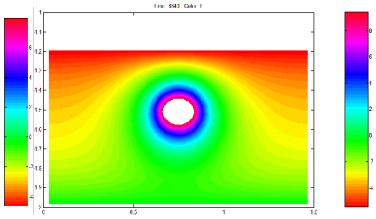

Fig. 8

Fig.6 soil temperature field around the DN100 pipeline when the thermal conductivity is 1.24w/(m.k);

Fig.7 soil temperature field around the DN100 pipeline when the thermal conductivity is 1.24w/(m.k);

Fig.8 soil temperature field around the DN100 pipeline when the thermal conductivity is 1.24w/(m.k).

Conclusion

(1)The soil thermal conductivity increase with the moisture content increase. This is mainly because the migration of moisture will induce the heat-moisture migration. Thus, soil in the region of long-term of rainfall has a good performance of good heat transfer conductivity.
(2) With the soil porosity increasing, the thermal conductivity shows a decreasing trend, because the increase of porosity leads to the increase of air content. The thermal conductivity of air is lower than soil, so that the thermal conductivity of the soil becomes small.

(3) In comparison with the measured values, the experimental results Obtained from the improved empirical formula of Lu Sen are close to the measured values. Therefore, when calculating the thermal conductivity of the soil ， It is recommended to use Lu Sen empirical formula. The larger the thermal conductivity, the greater the buried pipeline ambient temperature gradient, the greater the exchanged heat and moisture between soil.
(4) When the coefficient of thermal conductivity changing greatly, the temperature gradient around the buried pipeline will vary.

Dependence of the distribution law parameters of the annual run-off of rivers in Primorsky region on the soil thermal conductivity

S.A. Lobanov, E.E. Kholoden

Far-Eastern Federal University, Vladivostok, Russia

lobanov.sa@dvfu.ru

Key words: Watershed area, annual run-off, distribution law, statistical parameters, polymodality of distribution laws, thermal conductivity of watershed area soil.

Abstract

The empirical investigation of the dependence of the statistical characteristics of annual run-off of Primorsky region rivers - modulus of flow, variation coefficient, asymmetry ratio, polymodality degree – on the weighted average values of the soil thermal conductivity coefficients within their watershed areas was carried out. The physico-statistical interpretation of the general form of correlation dependences obtained is provided.

Problem statement

The thermal-physical properties of soils are the most important energy factor determining their water-thermal regime, microclimate of the surface layer of the atmosphere, character of thermal interaction of the land underlying surface with atmosphere on scale of synoptic processes. The soil cover transforms the absorbed solar radiation into its other kinds and, eventually, into the kinetic energy of atmosphere motion. It is characterized by high spatial nonuniformity of mechanical and mineralogical compositions, thermal conductivity, temperature conductivity and heat capacity and, as a result, conditions of forming the hydrometeorological processes. These questions were not adequately investigated and were reflected in the monograph [1]. The authors of this paper have developed a paleogeologic method of calculating the soil thermal conductivity coefficients [2]. Based on this method, a mapping of the thermal conductivity coefficients of the southern Russian Far East soils was executed [1]. The maps constructed provided a possibility to evaluate the effect of soil thermal conductivity on the water balance elements. As a result of researches performed, it was shown that the spatial variations of the long-time annual average values of evaporation, annual precipitation and annual run-off of rivers are determined, to a great extent, by the spatial variation of the soil thermal conductivity coefficient. The strongest correlation of the value of soil thermal conductivity is noted with modulus of annual flow (R = 0.94, Primorsky region), evaporation coefficient (R = -0.81, Khabarovsk region), annual precipitation (R = -0.85, Amur region) [3]. These and other results show that the soil thermal conductivity can be considered as the important climate forcing having a geological interpretation. The obtained dependences of the water balance equation components on the soil thermal conductivity coefficient offer the possibility to evaluate their mathematical expectations. Hereafter we propose also to consider the dependence of other parameters of the distribution law (DL) of the annual run-off of rivers – variation coefficient C_v, asymmetry coefficient C_s as well as polymodality degree Pl of the annual run-off of rivers DL on the soil thermal conductivity coefficient within the watershed areas of the Primorsky region rivers.

Materials and research methodology

In papers [1.3] in the course of investigating a dependence of the water balance elements on the soil thermal conductivity, the maps of the thermal conductivity of soils in the territory of the southern Russian Far East were placed in correspondence with maps of the water balance elements. At that, the territory was subdivided by the grade grid into cells. Then, the weighted average values

of the water balance elements and soil thermal conductivity were determined in each of these cells. Hereafter a correlation between the values of water balance elements and soil thermal conductivity for the cells having the same name was found. In this paper we propose to compare the soil thermal conductivity for the watershed areas and statistical characteristics of their annual run-off. For this purpose, the weighted average values λ of the soil thermal conductivity for the watershed areas were estimated with consideration for a weight proportional to an area f_i occupied by each value λ_i of the soil thermal conductivity for the watershed area:

$$\lambda = \frac{\sum_{i=1}^{m} \lambda_i f_i}{F}, \qquad (1)$$

where F is the watershed area.

The parameter values of the distribution laws of the annual run-off – long-time annual average modulus of run-off M, variation coefficient of the annual run-off C_v, asymmetry coefficient C_s as well as polymodality degree Pl of the DL of annual run-off – were determined using streamflow records in the main-stream station of watershed areas. A criterion Pl was calculated by formula

$$Pl = - lg (P_k), \qquad (2)$$

where P_k is the probability of accidental appearance of the identified empirical polymodality which is as follows [4-6]:

$$P_k = \frac{n!\, k_1!\, k_2!}{\prod_{i=1}^{k} m_i!} \prod_{i=1}^{k} p_i^{m_i}, \qquad (3)$$

where n is the sample size; ! is the factorial symbol; k_1 and k_2 is the number of intervals with reduced and, respectively, alternating increased density of points in them ($k_1+k_2=k$) ; k is the number of all identified intervals; Π is the product symbol; p_i is the probability of entry of the random variable into the identified interval with quantity m_i of the random points within it read from the analytic probability curve approximating the empirical curve. A writing of the polymodality criterion in the form of (2) was taken for the sake of convenience in order to avoid a cumbersome writing of small number in the demonstration form. The calculations of statistical parameters were carried out by the procedure recommended by the set of rules SR 33-101-2003 for determination of basic estimated hydrological characteristics [7]. For approximation of the empirical probability curves, the Pearson type III distribution curve was used. The coefficients of variation and asymmetry were determined using method of moments.

The study was carried out for the following rivers of Primorsky region (within the brackets the watershed area are shown in square kilometers): Avvakumovka river –Vetka village (1740), Arsenyevka river –Yakovlevka village (5180), Bikin river - Zvenyevaya village (21400), Bikin river - Krasny Yar village (13100) , Bolshaya Ussurka river - Melnichnoye village (6750), Zhuravlevka river - Zhuravlevka village (3190), Ilistaya river - Khalkidon village (4030), Malinovka river - Rakitnoye village (4730), Melgunovka river –Lugovoy settlement (3450), Partizanskaya river –Partizansk town (3120), Samarga river - Unty village (7280), Ussuri river – Kirovsky settlement (24400), Ussuri river –Koksharovka settlement (9340).

Results and discussion

Hereafter a non-linear correlation dependence of the long-time annual average modulus of annual run-off of the rivers under consideration on the weighted average coefficient of thermal conductivity for soils of watershed areas with the correlation ratio $\eta = 0.86$ is presented (Fig. 1). The similar dependence with coefficient of linear correlation $R = 0.94$ was obtained in paper [1] when determining a correlation between the modulus of run-off and thermal conductivity coefficient of soils for cells of grade grids. A closeness of the presented correlation measures points to the equal significance of these methodological approaches to examination of dependence of the distribution law parameters of the annual run-off on the thermal-physical properties of soils. A form

of dependence $M = f(\lambda)$ is determined by the following physical mechanism: the smaller is the soil thermal conductivity, the higher is a heating of its upper layer at the expense of the inflow of solar radiation and the more is approach of the evaporation value to the amount of precipitation.

The thermal conductivity of the soil cover, as the climate forcing, can influence not only on the long-time annual average value of the annual run-off but also determine other parameters of its distribution law. The most important of them is variation coefficient C_v. The inverse non-linear correlation dependence $C_v = f(\lambda)$ in Fig. 2 with correlation ratio $\eta = 0.78$ confirms the theoretically substantiated conclusion [8] that the variation coefficient is inversely proportional to the quantity of days in the year with the flood-forming rainfalls. The less is the soil thermal conductivity coefficient, the higher is the air temperature and the souther is the watershed, the less is the quantity of such days. Dependence $C_s=f(\lambda)$ does not reveal such high correlation due to great accidental errors when evaluating C_s.

A dependence of the polymodality degree Pl of the annual run-off DL on the soil thermal conductivity coefficient is emphasized by the high correlation ratio $\eta = 0.87$. It allows us to conclude that the DL polymodality has an especially wide occurrence in the areas with high air temperature and small amount of precipitation where an insignificant variety of the atmospheric circulation types with intense cyclones is observed. The similar result was also obtained in paper [9] where it was shown that the biggest inconsistency between empirical and analytic probability curves is observed on the southern European territory of Russia.

Conclusions

1. The close correlation dependences of the modulus and variation coefficient of the annual run-off as well as polymodality degree of its DL on the soil thermal conductivity in the watershed areas with correlation ratios of 0.86, 0.78 and 0.87 respectively were obtained.
2. The regression equations of these dependences can be used for evaluation of parameters of the DL of annual run-off of the rivers of Primorsky region in the absence of the hydrometric observation data.
3. The dependences of the values of the annual run-off modulus and variation coefficient on the watershed altitude and area are known but none of these physic-geographical characteristics determines the polymodality degree of the distribution laws. The exception is provided by the soil thermal conductivity.

Keywords: Cogeneration; Central heating; Comprehensive evaluation; Matter-element model

Abstract. In order to assess the operational efficiency of cogeneration heating system and measure the system's social, economic, energy-saving and environmental protection benefits in North China, an evaluation index system is built up after analyzing the influence factors which may impact the heating system operation. The association degree function of classical matter element method is improved. And then, an improved matter-element evaluation model is established, which not only can figure out the evaluation grade that heating system belongs to, but also can point out the direction of the further improvement work. Besides, the model has other merits, such as uncomplicated operation, good scalability and so on. Example indicates that this evaluation model has excellent applicability and operability.

Introduction

In the last decade, in order to protect human survival environment, voluntary environmental programs have increased considerably in number and scope in many countries in the world [1]. Today, energy conservation, emissions reduction and environmental protection gradually become the focus issues under the background of energy depletion and environmental degradation in China. At present, there are about 6.5 billion m2 heating areas in the north of China, of which about 70% using different types of central heating. China's exceptional national condition decides that cogeneration central heating will continue dominating city heating in the future. This paper mainly focuses on the evaluation of cogeneration central heating system operational efficiency. The evaluation of heating system efficiency is closely related to the related parties: for heat users, they hope to be able to get more high-quality services; for heating enterprises, they need to measure the heating system efficiency; for relevant supervision departments, they also hope to measure and sort the heating enterprises, so as to provide separate supporting policies. Therefore, it has very important practical significance to use accurate models and methods to evaluate the efficiency of cogeneration heating system, and assess the societal benefit, economic benefits, energy saving and environmental protection benefits of the heating system.

Now there are limited researches done regarding the heating system operational efficiency. Existing literature mainly focused on the economy and reliability of the heating system. Based on the particularity of the thermal power plant system, Zhang established a comprehensive economic quantitative mathematical model for thermal power plant, and solved the problem of simplified the process of partial quantitative analysis by introducing a concept of "generalized heating extraction"[2]. According to the characteristics of the secondary network load of heating systems, Zheng, et al., proposed the heat supply network system reliability index calculation method, and analyzed the effects of peak shaving heat sources to the reliability index of heat supply network [3]. Based on climate data, Gao, etc., analyzed the three principal energy saving measures (indoor temperature control, system climate compensation, variable flow rate systems running) of heat metering system respectively. The analysis results showed that the energy-saving benefits of metering heating are remarkable; reasonable heating price enabled users to benefit at the same time; heat metering shall abide by the principle of the market [4]. Jiang analyzed the reasons for low efficiency and high energy

consumption of the central heating system in China, and discussed the reform of heat metering and charging [5]. Zhang, et al., defined a comprehensive index, and applied it to the evaluation of heating system efficiency [6]. Ferreira, et al., presented an idea that in the building sector, an emerging pathway was the decentralized power production via small thermal units, and micro-cogeneration offered a valuable opportunity for studying the potential of Combined Heat and Power (CHP) production for the residential sector[7]. Rong, et al., presented an improved unit decommitment algorithm to research the relative cost-efficiency of CHP, considering the possibility to trade power on the spot market[8]. In addition, there are some literature concerning the heating efficiency, economic operation of heat and power system and other issues[9-14].

These studies mainly discussed the reliability of the heating system with a single index from the technical perspective. we improve the matter-element method, and establish a simple and practical evaluation model. Based on these, we can conduct a comprehensive analysis and discussion on the operational efficiency of central heating system.

Influence factors analysis

Heating system reliability（C1）

Stable operation of cogeneration heating system is the precondition of efficient evaluation, because only when the system reliably operates, the demand of all kinds of heat load can be met. The index values find themselves in the range of 0 ~ 100% and the optimum is 100%..

Heating system operation regulation abilities（C2）

In order to make the temperature of each user in a heating system meet the design requirements, the parameters of supply and return water temperatures and the circulating flow rate should be adjusted along with the change of outdoor temperature at any time. It will make the whole system more effectual in saving energy and reducing consumption on the premise of meeting the heating demands. The index values find themselves in the range of 0 ~ 100% and the optimum is 100%.

The qualified rate of room temperature（C3）

This index is measured with the specific value between the number of qualified household and the total number of tested household. It is the result of the heating piping on the imbalances, reflecting the heat distribution situation of a heating system. If the room temperature is lower than the specification requirements, then users need to use additional auxiliary heating methods. Therefore, inefficiency of thermal imbalance reflects at least in two aspects: in poor social benefit and poor energy saving benefit. So, we can think that the qualified rate of room temperature is the quantitative representation of the collective benefit and energy saving benefit. According to the relevant provisions, the qualified rate of room temperature should not be less than 97%.

Energy efficiency of heating（C4）

It refers to civilian residential heating floor areas that a ton of steam heating load (0.7 MW) can burden under the design condition. The index is utilized to measure the utilization ratio of the heating system. In accordance with the pertinent provisions, the technical standard of heating energy efficiency is 8000 ~ 10000 square meters per ton steam.

Coal consumption for heating（C5）

It is the principal index of the energy saving effect. It refers to the coal consumption quantity for unit quantity of heat, and it shows the thermal efficiency of the heat source or heat supply system. For a definite heating area, due to the constant heating period, the unit coal consumption of heating area can also be used as an evaluation index. In accordance with the related regulations, coal consumption amount should not be more than 19kg per heating area in a winter. The standard of coal consumption quantity is 17kg per square metre in Hohhot, Inner Mongolia, China.

Circulation flows（C6）

It refers to the circulating water quantity per heating area. The significance of this index is as follows: (1) increase the circulating pump power utilization; (2) is an essential means of overcoming the enormous flow operation; (3) can prevent the vertical imbalance of indoor thermal system. In accordance with the pertinent provisions, for 95/70 type of hot water heating system, the parameter value should be controlled in the range of 2-3kg per square metre per annum.

Perfect degrees of system operation and management（C7）

The index can be utilized to measure the operation and management level of the heating system. Stable and proficient operation of the heating system is due to the perfect rules and regulations. The value of this index is restricted in the range of 0 to 100%, and 100% means the optimal level of operation and management.

The matter-element evaluation model

Dividing the evaluation grades

According to the authentic situation, the system to be evaluated is divided into p kinds of evaluation grades. The following expression is used to denote the value intervals of these kinds of grades: $V=\{[a_{j1},b_{j1}],[a_{j2},b_{j2}],\cdots,[a_{jp},b_{jp}]\}$. In this paper, the heating system is separated into three kinds of evaluation grades, respectively is superior heating system, qualified heating system and unqualified heating system.

Constructing the matter-element evaluation model

Based on the above evaluation index system, the matter-element model is constructed as follows:

$$R_k=(N_k,C,V_{kj})=\begin{bmatrix} N_k & c_1 & V_{k1} \\ & c_2 & V_{k2} \\ & \vdots & \vdots \\ & c_n & V_{kn} \end{bmatrix}=\begin{bmatrix} N_k & c_1 & <a_{k1},b_{k1}> \\ & c_2 & <a_{k2},b_{k2}> \\ & \vdots & \vdots \\ & c_n & <a_{kn},b_{kn}> \end{bmatrix}$$

Where, N_k denotes the kth evaluation grade, C denotes the characteristic collection of the evaluation grade N_k, and V_{kj} devotes the value range of $c_j(j=1,2,\cdots n)$ in the evaluation grade N_k, which is the so-called classical domain.

The joint domain is described as follows:

$$R_p=\left[P,C,V_{pj}\right]=\begin{bmatrix} P & c_1 & v_{p1} \\ & c_2 & v_{p2} \\ & \vdots & \vdots \\ & c_n & v_{pn} \end{bmatrix}=\begin{bmatrix} P & c_1 & <a_{p1},b_{p1}> \\ & c_2 & <a_{p2},b_{p2}> \\ & \vdots & \vdots \\ & c_n & <a_{pn},b_{pn}> \end{bmatrix}$$

Where, P denotes the collection of all evaluation grades, v_{pj} denotes the value range of P with respect to the attribute $c_j(j=1,2,\cdots n)$.

The matter-element to be evaluated is described as follows:

$$R_0=\begin{bmatrix} P_0 & c_1 & x_1 \\ & c_2 & x_2 \\ & \vdots & \vdots \\ & c_n & x_n \end{bmatrix}$$

Where, P_0 is the system to be evaluated, x_j is the value of $c_j(j=1,2,\cdots,n)$.

Improving correlation functions of each grade

Here is the definition of general correlation function. The correlation degree of the ith evaluation object with respect to the jth index in the kth evaluation grade is described as follows:

$$\mu_{ijk} = \begin{cases} -\dfrac{\rho(x_{ij}, V_{jk})}{|V_{jk}|}, x_{ij} \in V_{jk} \\ \dfrac{\rho(x_{ij}, V_{jk})}{\rho(x_{ij}, V_{jp}) - \rho(x_{ij}, V_{jk})}, x_{ij} \notin V_{jk} \end{cases}$$

Where, $V_{jk} = [a_{jk}, b_{jk}], V_{jp} = [a_{j1}, b_{jp}]$, $\rho(x_{ij}, V_{jk}) = \left| x_{ij} - \frac{1}{2}(a_{jk} + b_{jk}) \right| - \frac{1}{2}(b_{jk} - a_{jk})$, $\rho(x_{ij}, V_{jp}) = \left| x_{ij} - \frac{1}{2}(a_{j1} + b_{jp}) \right| - \frac{1}{2}(b_{jp} - a_{j1})$.

In order to solve the illogical problems above, we the correlation function of the ith evaluation object with respect to the jth index in the kth evaluation grade should be corrected as follows:

$$\mu_{ijk} = \frac{\frac{1}{2}(b_{jk} - a_{jk}) - \left| x_{ij} - \frac{1}{2}(a_{jk} + b_{jk}) \right|}{\sqrt{(b_{jk} - a_{jk}) \left| b_{jp} - a_{j1} \right|}}$$

The larger the correlation degree, the closer to the midpoint of the classification interval the attribute value is. If the correlation degree is positive, then the attribute value is in classification interval; if the correlation degree is negative, then the attribute value is outside the classification interval; if the correlation degree is zero, then the attribute value is at the critical point of the classification interval.

Improving the weights of the original model

The index weights are treated equally in the original matter-element model, without considering the relative importance of different index. Therefore, in this paper, we consider using the analytic hierarchy process (AHP) to improve the original matter-element model, to the effect that we can get more reasonable index weights.

Analytic hierarchy process (AHP) can decompose various factors in the complex problem into an interconnected ordered hierarchies, and integrate the information, such as objective data, experts' advices, subjective judgement of analysts, et al., directly and effectively. Then, the relative importance of each index is quantified, and finally, the weights of all the indexes are determined.

Determining the evaluation grade

If the weight of the jth index is α_j, then the correlation degree of the ith evaluation object with respect to the kth evaluation grade is as follows:

$$\mu_{ik} = \sum_{j=1}^{n} \alpha_j \mu_{ikj} (i = 1, 2, \cdots, m)$$

If $\max_{1 \le k \le l} \mu_{ik} = \mu_{ik^*}$, then the ith evaluation object is belong to the k^* th evaluation grade. If for all values of k, $\mu_{ik} \le 0$, then the evaluation grade of the ith evaluation object is beyond the scope of all evaluation levels set in the research, and should be discarded.

Case analysis

Thinking certain thermal power plant in northern China, the maximum capacity of heating of each generating unit is to provide steam 200t/h, and total heating ability is 250MW(900GJ/h).

Peak-shaving boiler rooms in heating area are responsible for the gap between the maximum heat load of 328 MW (1182 GJ/h) and the maximum heating supply capacity. The information of peak-shaving boiler rooms is shown in TABLE1.

TABLE I. THE INFORMATION OF PEAK-SHAVING BOILER ROOMS

Number	Scale	Heating areas ($\times 10^4 m^2$)	Heating supply capacity (MW)
1	4×20t/h	12	56
2	4×10.5t/h	26	42
3	3×10.5t/h	40	31.5
Total		78	129

As can be seen from the table1, the heating supply capacity of three boiler rooms is up to 129.5MW, and can fully meet the needs of heating peak. During the outage of one boiler in the power plant, the maximum heating supply capacity of another boiler and that of the peak boiler can meet more than 65% of the maximum heat demand load. The thermalization coefficient is $C_5 = 250/328 = 0.76$. Here, we use the improved matter-element model to evaluate the performance of the heating systems.

Step1, the heating system is divided into three levels: excellent heating system, qualified heating system and unqualified heating system.

$$R_1 = \begin{bmatrix} \text{excellent} & c_1 & (98.0,100) \\ & c_2 & (96.0,100) \\ & c_3 & (97.5,100) \\ & c_4 & (9500,10000) \\ & c_5 & (16.0,17.0) \\ & c_6 & (2.00,2.40) \\ & c_7 & (98.0,100) \end{bmatrix}, R_2 = \begin{bmatrix} \text{qulified} & c_1 & (96.0,98.2) \\ & c_2 & (94.0,96.2) \\ & c_3 & (95.5,98.0) \\ & c_4 & (8500,9600) \\ & c_5 & (16.8,18.0) \\ & c_6 & (2.38,2.80) \\ & c_7 & (95.0,98.2) \end{bmatrix}, R_3 = \begin{bmatrix} \text{unqualified} & c_1 & (90.0,96.2) \\ & c_2 & (90.0,94.2) \\ & c_3 & (90.0,96.0) \\ & c_4 & (8000,8600) \\ & c_5 & (17.8,19.0) \\ & c_6 & (2.79,3.00) \\ & c_7 & (90.0,95.2) \end{bmatrix}$$

The joint domain of reliability of the heating system:

$$R_p = \begin{bmatrix} \text{efficiency} & c_1 & (90,100) \\ & c_2 & (90,100) \\ & c_3 & (90,100) \\ & c_4 & (8000,10000) \\ & c_5 & (16,19) \\ & c_6 & (2.0,3.0) \\ & c_7 & (90,100) \end{bmatrix}$$

Step2, determining the matter-element to be evaluated. The data of the evaluation index system is expressed in the form of matter-element as follows:

$$R_1 = \begin{bmatrix} \{p_0\} & c_1 & 98.5 \\ & c_2 & 97.3 \\ & c_3 & 98.3 \\ & c_4 & 9580 \\ & c_5 & 16.6 \\ & c_6 & 2.56 \\ & c_7 & 96.5 \end{bmatrix}$$

Step3, determining the correlation degree.

$$Q = \begin{bmatrix} \mu_{111} & \mu_{121} & \mu_{131} & \mu_{141} & \mu_{151} & \mu_{161} & \mu_{171} \\ k_{112} & \mu_{122} & \mu_{132} & \mu_{142} & \mu_{152} & \mu_{162} & \mu_{172} \\ k_{113} & \mu_{123} & \mu_{133} & \mu_{143} & \mu_{153} & \mu_{163} & \mu_{173} \end{bmatrix} = \begin{bmatrix} 0.112 & 0.206 & 0.160 & 0.080 & 0.239 & -0.253 & -0.335 \\ -0.067 & -0.174 & -0.060 & 0.020 & -0.116 & 0.285 & 0.335 \\ -0.514 & -0.490 & -0.460 & -0.980 & -0.693 & -0.364 & -0.291 \end{bmatrix}$$

Step4, using analytic hierarchy process (AHP) to determine the weight vector.

$\alpha = (\alpha_1, \alpha_2, \cdots, \alpha_7)^T = (0.058, 0.090, 0.178, 0.286, 0.290, 0.060, 0.038)^T$ After computation, the consequences passed the conformity test. Evaluation matrix was calculated as follows:

$$U = \left[u_{kj}\right]_{3\times 7} = \begin{bmatrix} 0.0065 & 0.0185 & 0.0285 & 0.0229 & 0.0670 & -0.0152 & -0.0128 \\ -0.0039 & -0.0157 & -0.0107 & 0.0057 & -0.0335 & 0.0171 & 0.0127 \\ -0.0298 & -0.0441 & -0.0819 & -0.2803 & -0.2009 & -0.0218 & -0.0111 \end{bmatrix}$$

Where, $u_{kj} = \mu_{1kj} \times \alpha_j$. As can be seen from the evaluation matrix, the cyclical flow control index and management level of this heating system have reached qualified level, and need to be further improved. The other five indexs are up to the excellent level, but it is not difficult to see that the index of heating energy efficiency will come back to the qualified level if not strengthen the management. In addition, the reliability of the heating system should also be strengthened. Moreover, $u_{3j} < 0 (j = 1, 2, \cdots, 7)$, so you can determine the heating system does not belong to the unqualified heating supply system.

Step5, the calculated correlation degrees corresponding to different grade are as follows:

$K = Q\alpha = (k_1, k_2, k_3)^T = (0.115, -0.028, -0.670)^T$

Obviously, 0.115 is the largest, so the heating system is rated as excellent heating system.

Conclusions

The improved matter-element model has many merits. For example, it does not need to consider the type of evaluation index (positive index, reverse index or moderate indexs); it does not need to do dimensionless treatment, its computation process is succinct; its calculation workload is very small, and et al. For the evaluation of complex structure with multiple indicators, it can be processed by a specialized computer program with higher efficiency.

It is worth mentioning that, although the matter-element model has its unique merits, but it is not a panacea by any means, so, in solving practical problems, you should choose the appropriate method based on the characteristics of the problem.

Abstract. In high temperature superconducting (HTS) magnet design, it well known that the critical current (I_c) is sensitive to the direction of the local magnetic field. The perpendicular magnetic field component to the face of tape have a larger effect on the I_c of a HTS tape than the parallel component. Thus in HTS magnet design, the magnetic field distribution is the first considering factor. This work presents a HTS magnet design using genetic algorithm to obtain the object. When the length of the tape is certain, the results show that the process gives the optimal number of the double pancake and the inner radius of the magnet.

Introduction

High temperature superconducting wire has provide a significant benefit from operating in liquid nitrogen, which lower the cost of the cryogenic facilities. However, the obvious anisotropy electromagnetic character makes the design of the HTS magnet is different with the LTS magnet design. It is well known that in HTS materials are more sensitive to magnetic fields perpendicular to the wide face of the HTS tape than to fields parallel to the wide face of the HTS tape [1].

For a HTS SMES magnet, the energy storage efficiency is crucial for the performance of the facilities. When the length of the tape is certain, the geometry of the magnet (number of the double pancake and the inner radius of the magnet) determines the I_c of the coils as well as the energy storage capacity. Fig.1 shows a cross section of a uniformed-current-density solenoid.

The magnet is optimized with the help of using genetic algorithm. After the optimization, the magnetic field distribution are calculated to confirm the result. At last, we using two different types of conductor in the same length in design, results shows the maximum energy storage capacity efficiency of the magnet.

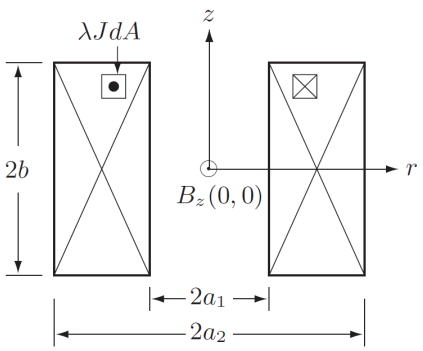

Fig.1 Cross section of a uniformed-current-density solenoid

Magnet Model

A SMES magnet consists single or multi solenoid magnet. Tape are winded as a double pancake coil type there insulation between each turn of the coil. Generally, the maximum magnetic field value is in the inner side center of the magnet and the perpendicular component maximum value is located in the top and bottom edge of the magnet.

The center magnetic field could be calculated by the equation (1)

$$B_0 = J\lambda\alpha F(\alpha,\beta) \tag{1}$$

$$F(\alpha,\beta) = \mu_0\beta\ln\{\frac{\alpha+\sqrt{\alpha^2+\beta^2}}{1+\sqrt{1+\beta^2}}\} \tag{2}$$

$$\alpha = a_2 / a_1, \beta = b / a_1 \tag{3}$$

As Fig. 1 shows, the a_1 is the inner radius and the a_2 is the outer radius. The b represents the total length of the magnet. The dimensionless number λ, is the space factor.

Conductor Characteristic

HTS materials are more sensitive to magnetic fields perpendicular to the wide face of the HTS tape than to fields parallel to the wide face of the HTS tape.

Fig. 2 illustrated the uniformed $I_c - B_\perp$ curve of the tapes in 20K. The Ic will be calculated by using this data and the load line of the magnet.

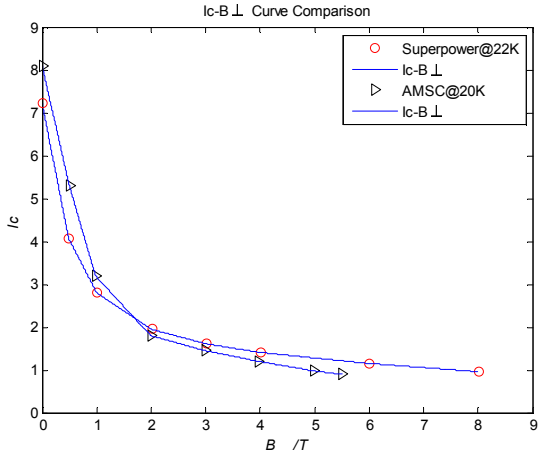

Fig. 2 Uniformed $I_c - B_\perp$ curve of the tapes

Optimization

Generally, due to there are many variables in a design problem, it can be very complex especially when they are interacted with each other. Many efforts have been made to find out an optimal solution investigation several approaches. Genetic algorithm is an efficient way to get the best results in multi variable condition.

The energy storage capacity efficiency is defined as follow:

$$\xi = \frac{E_{\max}}{V} = \frac{L\cdot I_{op}^2}{2V} \tag{4}$$

where the E_{max} is the energy storage capacity of the magnetic and the V represents the volume of the magnet by using $V = \lambda 2\pi a_1^3(\alpha^2-1)\beta$ to obtain. L is the inductance of the magnet and the I_{op} is the working current of the magnet.

The object of the optimization is find the maximum value of ξ. The Optimization Toolbox of the MATLAB is used to call the FEM software to obtain the perpendicular component of the magnetic field.

Fig. 3 shows the flow diagram of the optimization process as well as the program calling step in which the MATLAB is used as a optimize tool.

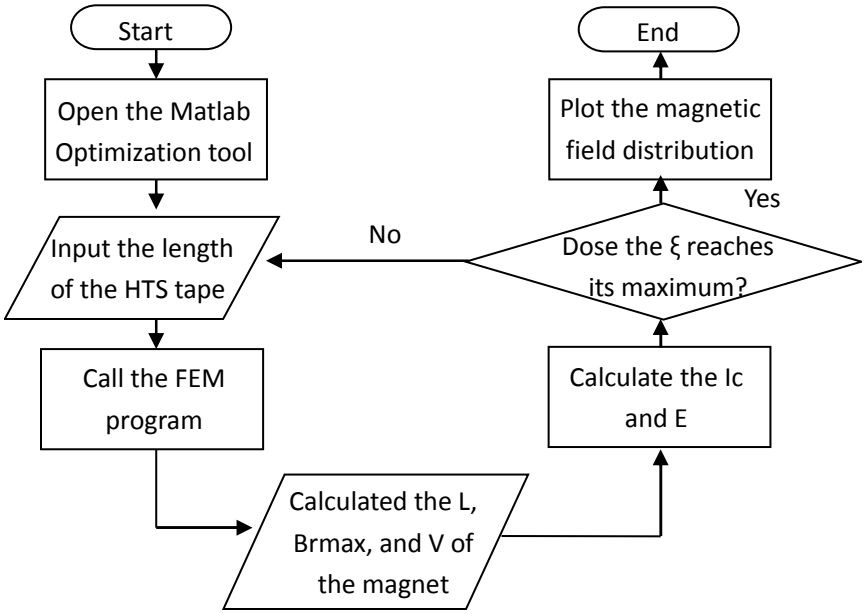

Fig. 3 The flow diagram of the optimization process

Result and Analysis

The result of the optimization has shown in Table 1. It suggests that in 20K and the same length of the tape, SCS4050 could get a larger ξ, which means for a SMES magnet, regardless the magnetic force sustainability the SCS4050 could be a better choice of the magnet.

Table 1 Parameters of the optimized magnet

	SCS4050	Amperium8501
Inner radius mm）	71	88
Outter radius mm）	192	228.7
Turns of each pancake	968	804
Energy Storage Capacity kJ）	41.929	39.331
Critical current A）	160.7	168
Working current A）	112.49	117.6
Inductance	6.627	5.688
ξ	4569.3	3085.7

Fig. 4 shows the magnetic field distribution of the optimized magnet. The magnet made by SCS4050 have a higher magnetic field because of the smaller inner radius as well as less thickness. Thus the energy storage capacity efficiency could be significant larger than the magnet make by Amperium8501.

(a) SCS4050, absolute value (b) SCS4050, racial component
(c) Amperium8501, absolute value (d) Amperium8501, racial component

Conclusions

In this paper, we presents a HTS magnet design using genetic algorithm to obtain the maximum value of the energy storage capacity efficiency. When the length of the tape is certain, the results show that the process gives the optimal number of the double pancake and the inner radius of the magnet. The result gives the parameter of the optimized magnet which made by SCS4050 and Amperium8501 respectively. It shows that regardless the magnetic force sustainability the SCS4050 could be a better choice of the magnet.

Integrated flat plate heat pipe-pulsation heat pipe for the high-flux electronics cooling

Y.P Zhang, J.G Wang,

School of Energy, Xi′an University of science and technology , Xi′an 710054, China

Keywords: Heat pipe; Heat dissipation, Thermal characteristic; Electronics cooling

Abstract. A trend towards increasingly dense and compact architectures has led to unmanageably high heat fluxes in electronic components. A novel heat pipe will be developed. Heat pipe designed is based on the flat plate heat pipe and pulsation heat pipe effective combination. Channel quantity is greatly increased ,as well as compact and homogeneous red copper pulsation plank is severed as the wick, dense and connected channels are served as the passage of the working fluid.

Introduction

As the power densities of power components continue to grow, thermal issues ars becoming extremely important and vital for the product quality. The primary causes of failures in electronic equipment are the excessive temperatures of the critical components, such as semiconductors and transformers. The current trend for increased integration, faster speed, and small die size means both increased raw power and power density resulting in greatly increased heat fluxes. Furthermore, the need for higher performance encourages the clustering of high power devices on a die. The collected electronic component have given rise to the hot spot in certain locations of a die far exceeding the surface-averaged heat flux. This complicates the adoption of cooling solutions in regards to placement of the cooling device on a die. This creates a challenge to provide the thermal solution without compromising the power module size and weight. The processor's die surface where most heat generated is usually small approximates 10mm×10mm. For effective cooling the heat must spread to a larger surface area and away from the processor. Extended surface devices, such as heat sinks, coupled with forced air convection are a reliable thermal solution for many applications. Heat sinks are a passive technology, simply manufactured and mass produced, requiring little to no maintenance and are relatively easily attachable to the desired components. These features have made the heat sink and fan a popular cooling system for many years, even though higher power dissipating options have been available. Heat pipe in phase change heat transfer bring new hope for the greater power electronics cooling since they make use of a circulating liquid-vapor phase change to transfer heat rather than generate heat. Its equivalent thermal conductivity can be several hundred times than that of a solid copper of the same dimensions [1]. Heat pipe are very effective heat transfer devices and can be used to raise the thermal conductive path in order to spread a concentrated heat source over a much larger surface area. The heat pipe has been widely used, and evidently acceptable to preserve. Because of the high ratio of heat transfer capacity to weight, the heat pipe takes a predominant position in the aeronautics and electronic cooling applications. Heat pipe emerged as the most appropriate technology and cost effective thermal solution due to its excellent heat transfer capability, high efficiency and its structure simplicity. It has many advantages compared to other cooling devices such as fans, thermoelectric module, liquid pump loop device are that it has simple structures, no moving parts and does not use electricity [2].

In the heat pipe development, the wick structure and material are of major concern. It is classified into four categories: convective heat pipe, flat plate heat pipe, separated liquid and vapor channel heat pipe and pulsating heat pipe. In addition, several novel heat pipe structure were developed at present. Yaxiong Wang et al.[3] presented a novel flat heat pipe to assist in meeting the high thermal design requirements in high power microelectronics, sintered copper screen mesh was used as the primary wicking structure, in conjunction with a series of parallel wires, which formed liquid arteries.

In this investigation, a novel heat pipe is proposed, The advantage of this kind of heat pipe is the integration of the plate heat pipe with pulsating heat pipe, which eliminates the existence of a thermal interface between the device and the cooling system.

Design heat pipe

A flat plate heat pipe has many advantages, such as flexible shape ,low resistance and lay out the heat source. However, dry out still occurs due to the opposing and interacting vapor and liquid flows, causing the same problems as suffered by convectional heat pipe.

A pulsating heat pipe(PHP) consists of a micro channel that meanders back and forth between a cooling section and heating section many times. After injection, the working fluid naturally forms liquid plugs and vapor bubbles distributed along the channel length. Pulsating flow enhances heat transfer because it breaks the thermal boundary layer on the channel wall, reducing thermal resistance [4]. Performance of a heat pipe improved with an increase in the number of channels. The heat pipes performed well at both the horizontal and vertical orientations. Heat pipe with smallest internal diameters is responded more quickly to change in the heat input. And therefore improving heat pipe performance by limiting the effect of the side channels should be an achievable goal. The channel diameter must be small enough to allow the vapor bubble, liquid plug configuration to develop. Akachi et al.[5] determined the maximum tolerable internal channel diameter (dmax) to be:

$$d_{\max} = 2\sqrt{\frac{\sigma}{g(\rho_l - \rho_v)}} \tag{1}$$

Where σ is the surface tension of the working fluid, g is the gravitational acceleration, and ρ is the density of the liquid/vapor. For internal diameters less than dmax surface tension dominates the stable liquid slugs' form. For internal diameters greater than dmax the working fluid will stratify and the meandering channel will function as an interconnected array of thermosyphons. In practice, internal channel diameters greater than dmax have resulted in slug formation in channels oriented vertically while stratifying in the horizontal orientation[6].Therefore this guideline on channel diameter is important for fabricating pulsating heat pipes that can function in any orientation. There have also been many observations of an increase in performance with an increase in internal diameter[7].This observation coupled with the requirement of a small enough channel diameter in order to form stable liquid slugs suggests the existence of an optimum channel diameter.

An argument for an optimum number of channels was made by Khandekar et al. [7]. Because of the small channel size, and small liquid inventory and thermal cross section per channel, increasing the number of channels reduces the heat load on any individual channel. Therefore, increasing the number of turns increases the performance of the pulsating heat pipe. Increasing the number of turns also increases the number of perturbations in the pulsating heat pipe which helps initiate and sustain the oscillating flow.

The most challenging aspect in convectional heat pipe design is the return of the liquid to the evaporator. Vertical, bottom heated heat pipe can use gravity for condensate return. A more effective mechanism is the use of a wick or micro-channels to induce capillary action. Capillary action is improved by increasing the surface area of the material which the fluid must travel relative to the volume of the fluid. Micro heat pipe arrays (MHPA) typically consist of a fine grooves machined into flat plates. Heat transport is improved because of the large quantity of fluid, and the plate geometry which allows better contact with the heat source. Construction and charging of MHPAs, however, is very complicated and thus cost prohibitive. A method of reducing the cost is to make the channels interconnected. This makes the charging of the channels much easier, as they can all be charged at once. Optical observations and theoretical studies of such arrays showed that the interconnection of the channels led to balance effects between the channels, resulting in even fluid distributions and even heat transport[8].

Heat pipe designed is based on the flat plate heat pipe and pulsation heat pipe effective combination. Channel quantity is greatly increased in the novel heat pipe structure. Compact and homogeneous red copper pulsation plank is severed as the wick, working medium is heated and then bubble generated in the evaporation face channel continuously expands, bring about working medium goes through the center pore ,arrive at the condensation section. Rapidly pass though the positive channel circulate the evaporation face and then finish the circulation, where air plug and liquid column were produced continually in the nature of excellent even heat transfer capacity (as shown in Fig.1). The novel heat pipe designed is integrated the micro channel of high heat transfer with phase change of even temperature.

The purpose of the heat pipe channels is to transfer heat from the evaporator to the condenser end with a minimal fluid temperature drop. It is expected that the thermal performance would increase as the number of capillaries increases because that the heat distributed to each capillary channel decreases as the number of capillaries increases. When the evaporator capillary channels is too big to transport a liquid back to the evaporator section by the capillary force in the channel, and the liquid in large capillaries might be depleted and caused bad evaporation performance. One can improve the design by reducing the channel size at the evaporator for the heat pipe. If the evaporation and condenser heat transfer coefficients in the capillaries are equal, then a vapor pressure drop would be the next factor to be considered. More capillaries would work to reduce the vapor pressure drop. Therefore, we adopt the dense and petty micro channel wick for the design of heat pipe.

Figure 2 is a configuration of the novel heat pipe. （1-Interconnected hole 2-Positive groove 3-Back groove 4- Screw hole 5-Rubber insert）.

The heat pipe was 99 mm in length, 83 mm in width, and 60 mm in height. The heat pipe walls were made of 1.5mm thick red copper plate. Attached to the inner surfaces of the heat pipe wall are porous wicks, In addition, vertical wicks are used to provide a secondary return mechanism for the condensate. 40 wide 1.5mm deep 1mm channel are layout separately in the wick of the front and back side,80 pylome are connected the close passage from beginning to end. The channel is layout denser in the evaporation side due to thermal resistance of heat pipe the evaporation side wick are the majority [14]. With the increase of heat flux, boiling and phase change take place and working medium is reflow rapidly, thus dry out limit is enhanced and pulsation channel make the condensation side temperature even in order to strengthen heat dissipation efficiency. Brazing welding was used to link fins and condensers. This technique can help reducing the contact thermal resistance between the evaporation

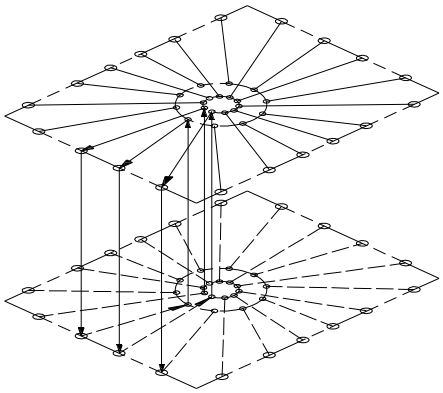

Fig.1. Working fluid passage

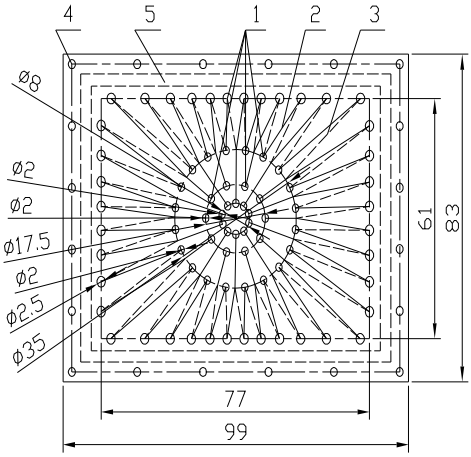

Fig.2. Heat pipe configuration

and the outside surfaces of the condenser. One of the main advantages of a heat pipe is that single or multiple heat sources can be located at any point on the evaporator surface, and generated heat would be spread out across the entire surface of the evaporator to achieve a near isothermal condition on the surface.

The features of the novel heat pipe are:

1) no contact resistance between the heat and the heat spreading plate;
2) quick-turn customization of the flow passage pattern to accommodate varying CPU location
3) combine flat plate heat pipe with pulsation heat pipe

dense channel is served as the passage of the working fluid in order to enhance the dry out limit. The wick structure is simple and high capillary force.

Conclusions

In the present heat pipe, which is designed on the base on the flat plate heat pipe and pulsation heat pipe effective combination. Channel quantity is greatly increased ,as well as compact and homogeneous red copper pulsation plank is severed as the wick, dense and connected channels are served as the passage of the working fluid. It makes temperature uniform distribution,corresponding improvement of the heat dissipation efficiency.

Keywords: Coal-fired Industrial Boiler, Non-pressure Heater, Heat Recycling, Boiler Efficiency

Abstract. A new non-pressure waste heat recycling system was designed and arranged on KHSS0.5-0.7-AⅡ industrial coal-fired boiler to decrease the exhausted gas temperature about 35℃, improve the boiler efficiency about 3.2%. Results showed that this system can avoid low-temperature sulfur corrosion and operate in normal and intermittent water supply condition safely and economically.

Introduction

There are about 550,000 unit coal-fired industrial boilers in china accounted for one-third of the total national annual coal consumption, and an objective fact is that the coal burned inefficiently in most of these boilers [1]. There are significant gaps between small industrial boilers and large industrial boilers, in terms of design efficiency, the operational level, the user's awareness of energy conservation, etc. which means great energy saving potential [2]. And one of the main reasons of low thermal efficiency of industrial boilers is that exhaust gas temperature is too high. According to statistics, a great number of general industrial boilers flue gas temperatures are nearly 200 ℃.

For example: According to 2010 statistics in Jining city Shandong province, there are about a thousand units coal-fired industrial boilers, in which 705 units' capacity are less than or equal to 4t / h, 257 units are more than 4t / h. We found that many boiler flue gas temperatures is designed as 160 ℃ during the daily inspection, while the actual exhaust gas temperature are close to 200 ℃, and to some small rated output boiler flue gas temperature is higher. Jining is the main coal producing areas with coal sulfur content typically 0.6%, yet most of the sulfur content of coal used are less than 1%. In order to avoid low temperature corrosion at tail heating surface area, its ideal exhaust gas temperature is preferably maintained at 130℃ [3].

Analysis of Industrial boiler status

Many reasons that cause high exhausted temperature problems are discussed as follows.

1.1 The poor adaptability of coal boiler

A particular coal boiler is generally designed for using a special coal and it can run under good operating efficiency [2]. The reality is that it is difficult to ensure stable quality for the vast majority of coal boilers. To meet the design requirements blending coal is necessary, yet for most coal-fired industrial boilers no proper blending system to qualify the calorific value, ash content etc. all of these makes the combustion conditions change, the combustion incomplete and the exhaust gas temperature high.

1.2 Poor operating conditions of boiler

To most coal fired low capacity industrial boilers, cleaning are not timely or convenient after boiler fouling because of lack boiler water treatment equipment. Serious fouling also makes boiler efficiency decreases, the exhaust gas temperature high.

1.3 Poor use of new technology

Energy-saving technologies and products that used in energy-saving industrial boilers include: condensing heat recovery technology, the transformation layer fired boiler combustion system, steam accumulator in the heating system and so on [4]. These technologies focused on the transformation of

the combustion system, furnace arch reconstruction, the use of new refractory materials, auxiliary transformation, optimized air distribution, regulation, and self-control. Some energy-saving technological transformation test running effects are good, but the transformation is more complex, with higher cost of renovation, more difficult reconstruction work, long recovery period, and the operating level of staff required which has failed to achieve the expected energy savings.

1.4 The existing reducing flue gas temperature methods

To reduce exhaust gas temperature, heat pipe technology, composite phase change heat transfer technology such as the installation of air preheater rehabilitation programs has been used in large oil boiler or large power station boiler [5]. As for the small boiler users the transform price is too high, the whole project is difficult to carry out and also the relatively complex operation, the long cycle energy recovery device which limited the application of these technologies.

For small industrial boilers, as managers, a simple low price and easy operating energy saving device is needed. To overcome the deficiencies of the higher exhaust temperature, providing a practical new industrial boiler energy-saving device is the main purpose of the project.

Research of Waste Heat Utilization on low-capacity Industrial Boiler

2.1 Selected samples

In Jining city, 73% boiler capacity is less than or equal to 4t / h. To make the experiment more typical, according to the current boiler situation of Jining city, one type of boilers KHSS0.5-0.7-AⅡ with horizontal tube, with economizer, forced ventilation is chosen. The economizer outlet water temperature is tested to compare the impact of the using of the new heat transfer equipment.

2.2 Parameters of KHSS0.5-0.7-AⅡ Horizontal boiler model:

Evaporation capacity: 0.5t / h
Design pressure: 0.7MPa
Working pressure: 0.5MPa
Designed exhausted Temperature: 158 ˚C
Design efficiency: 70%
Ventilation mode: induced draft fan

2.3 Tested data of operating sample boiler

The exhaust gas temperature, water temperature, water temperature, fan opening status of the normal operation of the boiler was tested and shown in Table 1.

Table 1. Data of the operating boiler (before transformation)

Serial number	Pump operating time		economizer（˚C）		Exhaust temperature	Water treatment operating	notes
	on	off	Inlet temperature	Outlet temperature			
1	9:10		20	65	221	on	Water tank area :1.76 m^2 Water tank height: 0.5m Induced draft fan: on Operating pressure: 0.5MPa
2	9:15		20	67	223		
3	9:20		20	67	223		
4	9:25		20	67	222		
5	9:30		20	68	223		
6		9:31	20	70	227	off	
7		9: 35	34	93	238		
8		9:40	50	115	245		
9	9:41		57	120	245		
10	9:45		24	77	238		
11	9:50		20	68	234		

From the test results, under stable and normal operating conditions, the exhaust gas temperature is about 223 ˚C, far above designed temperature 158 ˚C. The economizer outlet water temperature in normal operation is about 67 ˚C. However, if the pump stops, the water flow in the economizer stops, an over-temperature condition happened.

2.4 The design of non-pressure heat exchanger

The design efficiency of the small industrial boiler means enormous energy saving potential. The high exhausted gas temperature means a device can be used to reduce the heat exhaust. During the implementation of the project, to reduce the changing investment, the original boiler pressure structure was not changed; a non-pressure design heat exchanger is adopted. The water flowing after the heat exchanger was sent to the entrance of the pump directly which ensure the safety performance of the equipment, and avoid the risk of explosion. Considering the possible intermittent operation of industrial boilers, water in the tank was used to store the heat. Even the pump stops, the water was heated by the high temperature exhausted gas which is helpful to reduce exhausted gas temperature and also helpful to improve the boiler efficiency.

The flue gas flow chart of the waste Heat Utilization and the water flow chart are shown as follows. And the system is shown in Fig. 1.

Transformed flue gas flow is from furnace →Convection tubes →economizer → Non-pressure heat exchanger→ filter →draft fan→ chimney.

Water flow is from Water treatment equipment →water tank →Non-pressure heat exchanger → pump → economizer →boiler drum

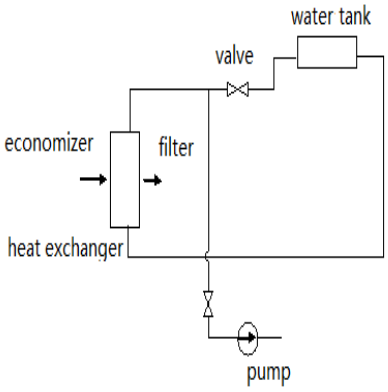

Fig. 1 Non-pressure energy-saving system

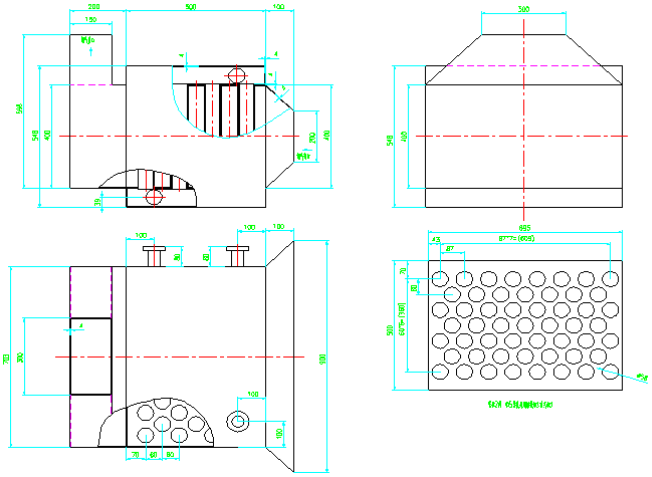

Fig. 2 The contracture of non-pressure heater

In this system, taking into account the normal use of industrial boilers with intermittent water supply, so that the valve connected the tank and the pump was designed as automatically open and close linkage. When the pump starts, the valve automatically shut off, the water was sucked by the pump, flow through the economizer and the non-pressure heat exchanger; when the pump stops the valve automatically open, the water tank, the cold water pipe, hot water pipes and non-pressure heat exchangers form a closed system, tank water cooling heat exchanger through natural circulation to reduce the exhaust gas temperature. Considering the sulfur content of Jining area coal, to avoid the low temperature area corrosion the heat exchanger area was designed to keep exhausted gas temperature as 173℃. After calculation non-pressure heater required transfer area is 3.9m^2. The actual design of the tube heat transfer area is 3.8m^2, and the tube sheet heat area is 0.4m^2.

In order to reduce the non-pressure heat exchanger manufacturing costs, and improve the heat transfer effect, in favor of the natural cycle principles, a vertical pipe structure for the staggered arrangement of the water flowing in the pipes up and down the tank tube sheet and plate has formed. The heater structure is shown in Fig. 2, to ensure the effective establishment of the natural cycle, the bottom of the tank is above the top of the heat exchanger. In the actual test unit the actual height of the tank bottom is flush with the top of the heat exchanger.

2.5 Results after use of waste heat utilization

2.5.1 Test Conditions

To demonstrate the feasibility and energy efficiency of the system, a stable load operating condition was considered. In order to compare the test results, reduce human error the operations are carried out by the same fireman. The test results are shown in table2. Operating conditions are: continuous water supply, fan operating, water treatment operating, the pressure stabilized at about 0.5MPa.

Table2 Test record in stable operation condition (after transformation)

num	Pump condi-tion	No pressure heat exchanger（˚C）				economizer（˚C）		Water treatment device condition	notes
	on	Inlet water temperature	Outlet water temperature	Flue gas inlet temperature	Flue gas outlet temperature	Inlet water temperature	Outlet water temperature		
1	9:00	24	61	195	165	67	116	on	Operat time:8:50 Stable operation
2	9:05	20	54	220	185	54	103		
3	9:10	20	52	231	189	52	97		
4	9:15	20	52	230	190	52	95		
5	9:20	20	52	229	189	52	95		
6	9:25	20	52	230	189	52	95		

Results and Discussion

Compare data shown in table1 and table2, the use of non-pressure waste heat device decrease the boiler exhaust temperature from 223 ˚C decreased to 189 ˚C, while the economizer outlet flue gas temperature increased which can protect the economizer form sulfur corrosion. The water temperature through the heater improves 32 ˚C. The water temperature flow into the economizer increase is 28 ˚C. The operating pressure is 0.5MPa, the saturated steam enthalpy is 2747.5KJ/Kg, the saturated water enthalpy is 640.115KJ/Kg, and the quality of the wet saturated steam is 4% by experience. The 20˚C feed water enthalpy is 84.476 KJ/Kg. The boiler efficiency improvement's about 3.2% and the coal saving rate is about 4.3% after the use of heater.

Conclusion

According to the results of the test and calculation, the evolution succeeded to achieve the expected energy savings. The temperature difference between the input and the output exhausted gas through is 41 ˚C deviate the design temperature difference 50 ˚C. The deviation is caused by the coal change, which means the actual gas enthalpy is lower than the calculated one. And also in the design calculation the ignored influence of the economizer inlet water change caused the bias. Actually if we want to modify the whole design, we can add 5~10˚C on non-pressure heater. If we give 10˚C modification to the non-pressure heater we tested, the outlet temperature will be 183˚C, very close to the actual tested value.

The flue gas resistance increased because of the improvement of boiler no pressure heat exchanger which will cause the power increased of the induced draft fan. And the calculation results is 23Pa, the actual test is about 40Pa. From the actual application perspective, the baffle opening of induced draft fan before transformation is 60%, after installation, no further adjustment is needed to the fan baffle opening which means the power increase of induced draft fan can be ignored.

To avoid boiling phenomena happen we must keep sufficient safety margins, keep the outlet temperature not close to the saturation temperature and in this project the temperature is 67 ˚C which is a reasonable choice.

To keep the pump safe operation we need consider the heat resist temperature which is 80 ˚C got form the pump factory manual. That means the pump can operate in the evolution project perfect. The following actual operation verified this.

Non-pressure heater can decrease the exhaust temperature and increase the efficiency of coal-fired industrial boilers. While the boiler feed water running intermittently, after the pump stops, the water in the tank can flow through economizer to absorb waste heat reducing the exhaust gas temperature. The heater run without pressure, so it is a safe, reliable, easy installation equipment which can also effectively reduce exhaust gas temperature, increase water temperature, saving energy. This non-pressure heater has been used in several industrial boiler and Tests data show that it can get a good energy saving effect.

Keywords: Optimization Boiler efficiency Excess air coefficient Fitting and interpolation Principal components analysis Correlative analysis

Abstract. This paper studies the problem of optimal operation of 300MW boiler. We combine the actual situation of the device and the theory of heat together, and improve the operating efficiency of the boiler through adjustment of device parameters, thus improving the economic benefit of thermal power plants. Firstly, according to coal characteristics and the theory of heat, we establish an improved utility model to calculate the heat loss of exhaust - gas, chemical incomplete combustion heat loss and heat loss of mechanical incomplete combusting. Then, we use fitting and interpolation, which is always applied to problems of Discrete Mathematical Statistics, to analyze discrete form of experiment data record, and give the relationship between 300MW boiler efficiency and excess air coefficient, which leads us to a new way to ascertain optimal excess air coefficient. And then, we use Principal Components Analysis (PCA) and Correlative Analysis (CA) to study the affection of operation parameters on boiler efficiency. Finally, we combine local optimization with global optimization, and establish an optimal operational model.

Background Information

In actual operation of the boiler, In order to ensure that the fuel completely combust, the amount of air supply is always greater than theory. Excess air coefficient refers to the ratio of tangible air volume to theoretical air volume. Excess air coefficient directly affects the heat loss of exhaust – gas (q_2), chemical incomplete combustion heat loss (q_3) and heat loss of mechanical incomplete combustion (q_4) [1].

When excess air coefficient increases, $q_2+q_3+q_4$ firstly increases and then decreases, and it has a minimum value. The excess air coefficient corresponding to this minimum value is called the optimal excess air coefficient. Because excess air coefficient has little effect on the chemical incomplete combustion heat loss, it can be regarded as constant. According to experiment, carbon content in fly ash (C_{fh}) is in one to one correspondence with excess air coefficient. Their relationship is given in Table 1.

Table 1: Excess air coefficient and carbon content in fly ash

α	1.1	1.15	1.2	1.25	1.3	1.35	1.4	1.45	1.5
C_{fh}/%	5.90	5.10	4.75	4.6	4.55	4.50	4.45	4.43	4.50

Sub problems to be solved

In this paper, on the basis of above background data and experimental results, following problems are put forward and solved.

Firstly, we have to determine the optimal excess air coefficient of boiler operation.

Secondly, we have to establish a model to describe the relationship between boiler efficiency and excess air coefficient.

Thirdly, we have to study the effect of boiler operation parameters on boiler efficiency.

Finally, we have to explore the method of optimal operation of 300MW boiler.

Model1: A simplified calculation model of mechanical incomplete combustion heat loss

The calorific value of coal is defined as the amount of heat evolved when a unit weight of the coal is completely burnt, which is divided into gross calorific value (GCV) and net calorific value(NCV) in practical application. GCV is applied when latent heat of vaporization which is generated by steam condenses is included. In this paper, we use Q_g^y on behalf of GCV, and we use Q_r on behalf of NCV.

In modern large capacity boiler, the water vapor in flue gas doesn't condense under atmospheric pressure, which means that latent heat of vaporization is not included. Therefore, NCV is used when it comes to calculation related to boilers. However, GCV is of great significance in practical application, so we give the relationship between GCV and NCV as follows:

$$Q_r = Q_g^y - 206H_{ar} - 23W^y . \tag{1}$$

In this equation, H_{ar} is Hydrogen content, and W^y is inorganic water content. We use Q_r to behalf NCV.

The conventional calculation formula to calculate heat loss of mechanical incomplete combustion (q_4) uses NCV. For certain coal, different ash and moisture will cause the change of NCV, which will be a great trouble when calculating. As a consequence, we introduce net calorific value on combustion basis (NCVB) to simplify calculating.

The relationship between NCV and NCVB is:

$$Q_r = Q_r^D(100 - A^y - W^y)/100 - 6W^y . \tag{2}$$

In this equation, we use Q_r^D to behalf NCVB.

Then, we introduce another parameter: dry ash content. Since NVCB has nothing to do with moisture, dry ash content is of great importance when it comes to correspondence. The relationship between dry ash content and ash content is

$$A^y = A^j(100 - W^y)/100 . \tag{3}$$

In this equation, A^j is dry ash content.

After arranging the above four equations, we come to a conclusion:

$$q_4 = a\frac{C_{fh}}{100 - C_{fh}} \bullet \frac{7.8A^j}{Q_r(B - A^j)} \bullet 10^5\% . \tag{4}$$

In this equation, B is an intermediate variable:

$$B = [100 - (1 + 600/Q_r)W^y]100/(100 - H_{ar}) . \tag{5}$$

This is the simplified calculation of mechanical incomplete combustion heat loss. For certain coal, different ash and moisture will cause the change of NCV, but it will not affect NCVB. Not like the traditional model, where we have to make a calorific analysis whenever the situation is changed,

in the simplified model, most of parameters stay unchanged. In this model, B is related to water content and net calorific value on combustion basis. Calculation shows that their effect on B is so little that it can be ignored. According to the actual situation, the value of B can be chosen as 99.5 [2]. Take experimental results for example, we get $Q_r = 24041.98KJ/kg$ [3].

After discussion above, we obtain the discrete mapping between excess air coefficient α and mechanical incomplete combustion heat loss (q_4), which is shown in Table 2.

Table 2 Discrete mapping between α and q_4

α	1.1	1.15	1.2	1.25	1.3	1.35	1.4	1.45	1.5
q_4	8.3672	7.1717	6.6550	6.4347	6.3614	6.2882	6.2151	6.1859	6.2882

Using exhaust enthalpy [4], we get the discrete mapping between excess air coefficient (α) and exhaust – gas heat loss (q_2), which is shown in Table 3.

Table 3: Discrete mapping between α and q_2

α	1.1	1.15	1.2	1.25	1.3	1.35	1.4	1.45	1.5
q_2	5.5511	5.7821	5.9643	6.1190	6.2542	6.3791	6.4930	6.5926	6.6710

We can see from the values of these discrete points that with α increasing, q_2 ascends monotonically. Under actual situation, the more air enters, the more smoke emissions, which increase heat loss. Moreover, the entry of cold air will also cause heat loss [5].

Model2: Calculation model of optimal excess air coefficient based on the least squares fit

As excess air has little effect on chemical incomplete combustion heat loss, it can be regarded as constant, according to actual situation, the value of q_3 can be chosen as 0.5. As a result,

$$q_2 + q_3 + q_4 = (100 - q_4)(h_{py} - \alpha h_{lk}) / Q_r + q_4 + 0.5 . \tag{6}$$

Then, we get $(q_2 + q_3 + q_4)_k$ at discrete points when α takes discrete values from 1.1 to 1.5, which is shown in Table 4.

Table 4: Discrete mapping between α and $q_2 + q_3 + q_4$

α	1.1	1.15	1.2	1.25	1.3	1.35	1.4	1.45	1.5
$q_2 + q_3 + q_4$	14.41	13.45	13.11	13.05	13.11	13.16	13.20	13.27	13.45

Using the least squares fit, we change discrete mapping into a continuous function:

$$f(\alpha) = 21.2155\alpha^2 - 56.5173\alpha + 50.6286 . \tag{7}$$

The function's minimum point is 1.33, so the optimal excess air coefficient is 1.33.

Model 3: Causal model of boiler efficiency and excess air coefficient

We use indirect balance method in this paper to estimate boiler efficiency. When this method is utilized, we need to know all kinds of heat loss that can't be ignored. Among them, radiation loss (q_5) and cinder heat loss (q_6) haven't been discussed yet.

When boiler rated evaporation increases, its fuel consumption is directly proportional to the increase, but the radiating area of boiler increases more slowly, which is equivalent to the reduction of radiating area .Therefore radiation loss increases as the amount of evaporation increases.

$$q_5 = 5.82(D)^{-0.38} \tag{8}$$

is used to determine q_5. In this formula, D represents the main steam flow of a 300MW boiler under rated operation. Since we can't get the data under rated operation exactly, we measure the main steam flow near rated point several times, and get D by interpolation. By applying the equations and conducting experiments, we get $q_5 = 0.4494$.

In actual situation, cinder heat loss can be neglected. So,

$$\eta_{gl} = \frac{Q_1}{Q_r} \times 100 = 100 \quad (q_2 + q_3 + q_4 + q_5 + q_6) = 100 - (21.2155\alpha^2 - 56.5173\alpha + 50.6286 + 0.4494). \tag{9}$$

When excess air coefficient is 1.33, efficiency of a boiler is the highest, with the value of 86.56%.

Model 4: Rational model of boiler operation parameters and boiler efficiency.

Boiler operating efficiency, different kinds of heat loss and specific operating parameters affect each other hierarchically [6].

According to background data, temperature of boiler water has little effect on boiler efficiency, which means that it can be neglected. With boiler mechanical parameters stay unchanged, there is a positive correlation between load and exhaust gas temperature, moreover, load and main steam flow are also positively related. That is to say, when load is given, exhaust gas temperature and main steam flow are fixed.

Exhaust gas temperature and heat loss of exhaust – gas are in positive correlation, while main steam flow and radiation loss are inversely correlated. So，load affects boiler efficiency in two distinct ways, and the trends in these two aspects are totally opposite. We use principal component analysis method, and extract two primary factors: excess air coefficient and load. We get the experimental data of a boiler when load is 298MW, 245.3MW, 215.8MW, and 192.3MW. Using methods and theory discussed above, we get four functions concerning boiler efficiency and excess air coefficient, which is shown in Fig.1.

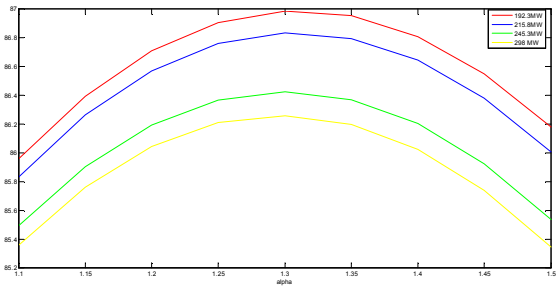

Fig.1: Functions of boiler efficiency and excess air coefficient

In summary, water temperature has negligible impact on boiler efficiency, while load and excess air coefficient have significant impact on the efficiency of the boiler. If load is given, main steam flow and exhaust temperature are fixed, and therefore the function of excess air coefficient and operating efficiency is also fixed. Furthermore, different values of the load result in different corresponding optimal excess air coefficient. Under the constant excess air coefficient, the more the load tends to 280MW, the higher the efficiency.

Model 5: Calculation of the most efficient operation based on layered optimization model

We combine local optimization with global optimization, and determine different variable in different layers.

On the basis of experimental data, we discuss such circumstances as loads are 298MW, 245.3MW, 215.8MW, 192.3MW and of 300MW. Using least squares fit, we change the discrete correspondence between excess air coefficient and carbon content in fly ash in Table 1 into a continuous function:

$$C_{fh} = 16.743\alpha^2 - 46.2271\alpha + 36.3229 . \tag{10}$$

With the help of enthalpy-temperature table, we use interpolation to obtain function of flue gas enthalpy and excess air coefficient under different load conditions. Then, we get

$$\eta_{gl} = 100 - [(100 - q_4)(h_{py} - \alpha h_{lk}) / Q_r + q_4 + 0.5 + q_5 + q_6] = f_k(\alpha) \text{ (k=1...5)} . \tag{11}$$

By derivation, we get the maximum values of the five functions, which are shown in Table 5.

Table 5: Loads and their corresponding optimal excess air coefficient of each load

Load	Corresponding optimal excess air coefficient of each load	Operation efficiency
192.3 [MW]	1.3103	85.9886
215.8 [MW]	1.3075	86.8362
245.3[MW]	1.3004	86.4248
298 [MW]	1.2971	86.2593
300 [MW]	1.2960	85.1952

It shows that different loads correspond to different optimal excess air coefficient, and when load increases, optimal excess air coefficient decreases.

Owing to the fact that we can't obtain experimental data under every load circumstances, we draw a function curve of load and boiler efficiency under its corresponding optimal excess air coefficient with the use of cubic spline interpolation, which is shown in Fig.2.

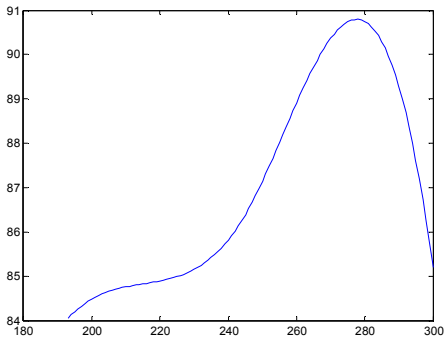

Fig.2: Function of load and boiler efficiency

When the load is 280MW, its efficiency is the highest, which is 90.79%. Its corresponding optimal excess air coefficient is 1.2982, and this is the result of global optimization.

With the help of models that have been discussed above, we get the optimal operation parameters, which are shown in Table 6.

Table 6: Optimal operation parameters

Load	280[MW]
Excess air coefficient	1.2982
Oxygen content	4.8238%
Main steam flow	789.3214[t/h]
Exhaust-gas temperature	136.5031[˚C]
Carbon content in fly ash	4.5282%
Exhaust – gas heat loss	5.89%
Incomplete combustion heat loss	2.36%
Radiation loss	0.46%
Operation efficiency	90.79%

Conclusions

It can be seen from Table 6 that layered optimization successfully improves the boiler efficiency. In this paper, a reasonable combination of the theory of heat and actual operational parameters is applied to establishing utility models of heat loss. Additionally, mathematical statistical methods are fully utilized to achieve a transformation of discrete domain to continuous domain.

ORC System Development Using Diesel Engine Waste Heat

DONG Junqi[a], WANG Jiangzhang and Zhang Rongyou

Zhejing Yinlun Machinery Co.,LTD, Zhejiang, China,

[a]dongjunqi2008@163.com

Keywords: Organic Rankince cycle（ORC）, engine, generator, exhaust gas

Abstract: Based on the waste heat characteristics of the coolant and exhaust gas from diesel engine, the Organic Rankine Cycle (ORC) commercial plant had been developed. The working fluid was the R245fa, and the plate type heat exchangers were used as the condenser and evaporator in the ORC systems. The performance of condenser and evaporator had been simulated and developed using the effective-NTU method. Using the engine jacket coolant as the heating media, the coolant absorbs the waste heat from the exhaust gas and engine cylinders. The ORC system and engine can stably run for a long time without frequent control acting. The ORC systems can bring the 14.6 kw electric energy in the stable condition. The efficiency based on the first law of thermodynamics is 7.2%; complete generating efficiency is 6.25%.

Introduction

The invention of the electric power is the core impetus of the second industrial revolution, and the steam Rankine cycle driven by fossil fuels is still the dominant power supply method. As is known to all, the accelerated consumption of fossil fuels has caused many serious environmental problems such as air pollution, global warming, ozone layer depletion and acid rain. Energy conservation and environmental protection have been the main issues in the word in the past twenty years [1]. How to effectively utilize low and medium temperature energy which is vast but undeveloped is one of the solutions to alleviate the energy shortage and environment pollution problems [2].

The organic Rankine cycle (ORC) in the past 10 years has gotten more and more attentions of the researchers, engineers and entrepreneurs for its obvious good characteristics [3-8], which lie in the absorption of low level temperature heat resource and simple structure. The ORC is similar to a typical Rankine cycle in principle structure, but it uses the organic fluid as the working fluid instead of water. Organic fluids are selected in the new Rankine systems (ORC) because their specific vaporization heat is much lower than that of water used in the classics Rankine cycle. This enables the ORC systems to produce electricity by using the low-temperature heat sources, with the temperature range 80~200℃. The technologies of ORC have been become more and more mature in the high power field in the past 15 years, such as the industry waste heat recovery, geothermy and biomass. Due to economic reason, the ORC power stations' ranges are almost the MW power level or more than 100kw power level. However, there very few ORC plants existing in the world with the kW power range [9].

And the development of higher efficiency ICE (internal combustion engine) will be most key task for the ICE researcher after the exhaust gas pollution problem has been solved. And the ORC technology will be one of methods in increasing engine efficiency because the engine have much waste heat and discharge to atmosphere, such as the in high temper exhaust gas, coolant and charge air. The waste heat discharged from the engine is about 60% in all the fuel energy [10-11]. However, there are very few ORC plants or systems using the ICE waste engine in the real products from the public literature or newspaper. There are some researchers doing the ORC plants using the ICE engine, but still in the testing and studying phase.

The authors developed the 10kw power range ORC commercialization of prototype based on the ICE waste heat in this paper. The waste heat is from the exhaust gas and coolant in the ICE.

ORC Principle

2.2 Thermo-physical property of the working fluid

Because affecting the efficiency of system, the size of the systems components, the design of expansion machine, the system stability and safety and environmental concerns, the selection of working fluids is very important for the ORC system performance economy. Except for the structural point of view and type of atoms in the fluid molecule, the working fluids could be categorized according to the saturation vapor curve. This saturation vapor curve is one of the most crucial charateristics of the working fluids in ORC. The character affects the fluid applicability, the system's efficiency and arrangement of the associated equipment in a power generation systems. As shown in the Fig.1, there are three types of vapor saturation curves in the temperature-entropy (T-S) diagram: a dry fluid with positive slopes, a wet fluid with negative slope, and an isentropic fulid with nearly infinitely large slope [2]. If the working fulid is the dry fluid, then the working fluid could not enter in the two-phase zone in the expander. This is very useful for the life of expander in ORC systems. If the working fluid beome the liquid or condense at the end of expaner, this is an unfavorable and unacceptable phenomenon for the expander during the ORC working process. While because the working fulid R245fa has the good thermo-physical property and has the dry fulid characterics, it has been accepted widely as one of working fulids in the ORC systems

Engine Waste Heat ORC systems development

3.1 ORC systems for Engine waste heat

In the engine, the fuel is the total heat source. One part is used to do useful work , which is about only 40% of total heat source, while the other part is rejected to atmosphere as various waste heat, such as exhaust gas, radiation and coolant heat in radiator. The Fig.3 give the ORC systems based on

the Engine waste heat, which is the high temper exhaust gas and coolant heat from the cyclinders. The Engine rate power is 200kw with 6 cylinders. In the engine, there is much waste heat rejected to atomosphere. This part of heat can be used as ORC heat source and generate electricity by ORC systems generator. At first, the coolant which is used to cool the engine cylinder is pumped to the exhaust gas heat recoverer from engine. In the recoverer, the coolant is heated by the high temperature exhaust and absorb the heat energy of exhaust gas, then the coolant enters the evaporator and engine. In the ORC system, the coolant is used as the media of heat source, which absorbs the heat energy from the engine cyclnder and exhaust gas.

The working fulid absorb the heat from the coolant in the evaporator, and then the vapor directly exnpand in the expander to do work and generate electricity. Other part are similar to the basic ORC systems, which include the pump, condenser, evaporator and expander,generator. At same time, the Fig.2 also gives the temperature and pressure sensor location. The temperature, pressure and mass flow parameters are very imporatnt for the systems analysis. The temperature sensor is the RTD type, whose accuracy is 0.1˚C.

3.2 Systems analysis for ORC

The temperature entropy diagram(T-S) is used to analyze the thermodynamic systems of ORC. The Fig.3 is the T-S diagram of the ORC working process, including the 4 main processes. 1-2 process is the working fulid expand in the expander, 2-3 process is the condensing in the condenser which the working fulid become the subcooled liquid from the superheat vapor; 3-4 process is the pressure raised by pump, in which frequency pump is used to adujst the working fluid flow rate according to the control order. The process 4-1 is the working fluid absorbing heat, evaporating and bringing phase exchange process. The working fluid become the high temperature and high pressure vapor which had much energy, and then enter in the expander. Then the whole Rankine cycle 4 basic processes are realized.

3.3 Data reduction and analysis

The whole ORC systems was taken for reaching the steady condition when all the sensors do not change. The test data are recordered by data acquisition systems, in which the sample rate is 0.2HZ. To more clear analyze the thermodynamic process, the data reduction are expressed by the list equation:

1）The total quantity of engine waste heat ,Q

$$Q=Q_w+Q_e \quad (1)$$

2）The working fluid absorb heat quantity, Q:

$$Q = m \times (h_1 - h_4) \quad (2)$$

3）The work expander do ,W：

$$W = m \times (h_1 - h_2) \quad (3)$$

4） Isentropic efficiency of expander ：

$$\eta s = \frac{h1-h2}{h1-h2s} \quad (4)$$

5) Heat rejection for the condenser, Qc：

$$Qc = m \times (h_3 - h_4) \quad (5)$$

6) Generating efficiency of ORC:

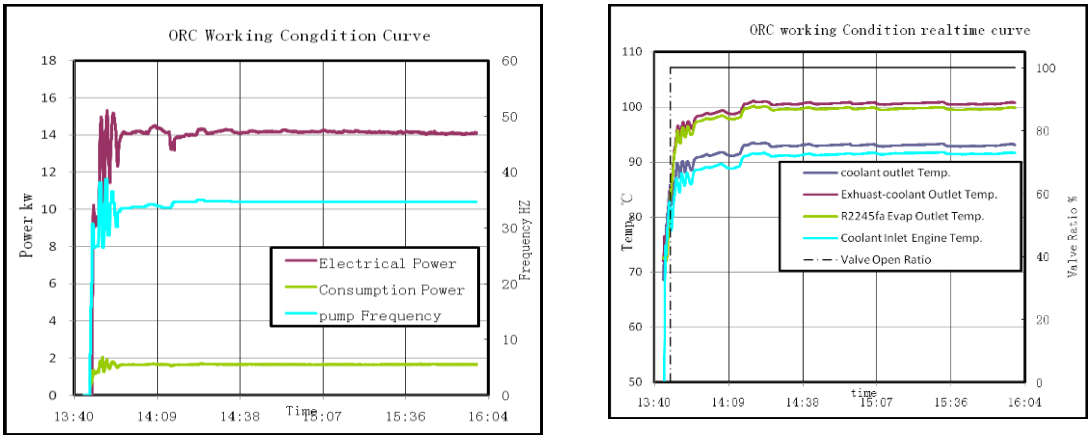
$$\eta = \frac{E}{Q} \quad (6)$$

7) Net generate efficiency of ORC systems

$$\eta_e = \frac{\dot{E} - E_1}{Q} \quad (7)$$

In the above equation, the Qw,Qe are the heat quantity of coolant and exhaust gas; the h_1, h_2, h_3, h_4, hs are respectively the enthalpy of the corresponding locations. In the Fig.3, the m is the mass flow rate of working fulid. The E and E1 are the elecrity of generation and consuming elecrity of ORC systems,such as the pump and control systems .

Test results and discussion



(a) (b)

Fig.4 The realtime working condition of ORC system

To clearly descibe the test process and working conditon of ORC systems and Egine. The Fig.4 gives the realtime working condition for the ORC systems and Engine. From the ORC systems beginning to generate elecrity to the steady condition, the test data recording time is about 2 hours and 24minutes. From the Fig4.(a), we can see the electricity generating power, consumtion power and pump frequency achieved a very stable condition after about 20 minutes. The steady elecric quantity of generator is about 14.6 kW, and the consumption power is about 1.9kw. And during the 2 hours, the speed of working fulid pumb almost no change, this shows the ORC systems based on the engine waste heat using the coolant as the media heat trasnfer is very right and effective. From the Fig.4(b), it can be seen that the engine coolant temper in the inlet and exit position are very stable, and it can control the suitable temperature according to the ORC systems effective and no frequently control is required from the control system of ORC.

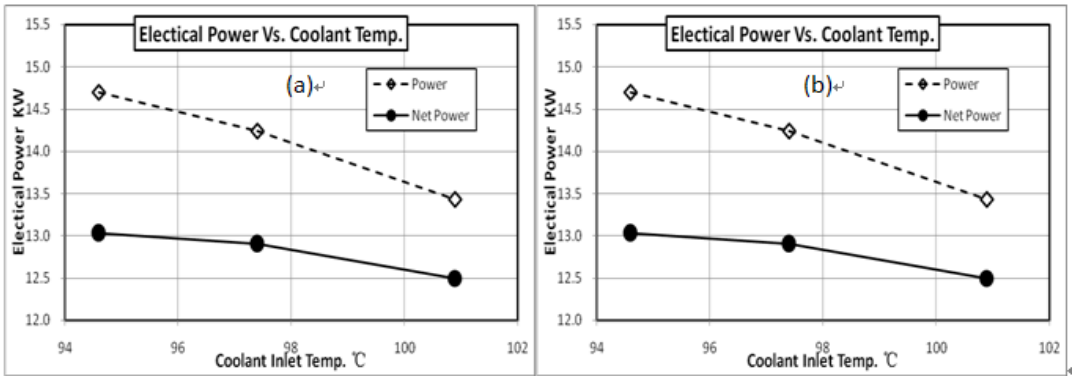


Fig.5 Generate Energy and Efficiency

Also, it can be seen clearly from the Fig.5 that the inlet and exit of engine coolant, and the exhaust gas valve open ratio have much effects on the R245fa temperature in expander inlet. The reason is the engine has a big thermal inertia, the control sofware of ORC systems must be considered.

Fig.5(a) give the curves for the generate electricity power and net power of ORC system under the different exit temperature of the engine coolant. From the plots change, we can see that the generator power reduces with the coolant exit temperature rising. However the net power has no obvious reducing with the coolant exit temperature rising. From the Fig.9(b), the generator electricity efficiency and Net power efficiency are respectively 7.4% and 6.4% under the coolant temperature with 94.4˚C; and the two efficiency are 6.7% and 6.2% under the coolant temperature with 100.9 ˚C

Conclusions

There are much waste heat is discharge in the engine and the ORC technology is a very attractive scheme in improving the engine efficiency and reduce fuel consumption ratio . In the study, the 10kw level ORC commercial plant had been developed based on the engine waste heat.

1. Using the engine coolant as the ORC heat source is a very right choice from the technology and economy point, which can make the ORC systems compact and reduce power consumption of whole ORC systems.
2. The condenser and evaporator are very imporatant components in the ORC systems. The thermal performance calculation are very key in the early development stage.
3. The control systems and control principle are very improtant for the ORC systems, especically for the ORC systems based on engine waste heat because the engine has much thermal inertia.
4. The big stable generator power is 14.6KW and the Net power is 13kw based on 200kw engine waste heat. The efficiency of ORC system is 7.4%.

Keywords: steam assisted gravity drainage (SAGD); waste heat recovery; heat exchanger; boiler feed water; fuel consumption

Abstract. In order to enhance the economy of steam assisted gravity drainage (SAGD) technology, researches were conducted on the technology for recovering heat from liquid produced from oil wells. In this study, spiral-plate heat exchanger has been chosen after comparison and analysis, which is used to recover the heat from the produced liquid and raise the temperature of the softened water used in steam injection boilers. The procedures are liquid produced from the wellhead enters a metering and transfer station for degasification and then enters a centralized heat exchanger station where its temperature is reduced to 100°C from 170°C and the temperature of softened water used as boiler feed water is increased to 110°C from 70°C. The result shows that the fuel gas consumption will drop by 907200Nm^3 for each boiler annually when the liquid heat recovery technology is adopted.

Introduction

Steam assisted gravity drainage (SAGD) is an effective technology to extract heavy oil petroleum. Steam is injected through vertical boreholes into the oil reservoir and forms a "steam chamber" that grows vertically and horizontally in the formation. The heat from the steam reduces the viscosity of the crude oil which allows it to flow together with condensate water down into the horizontal segments of the wellbore where it is pumped out [1]. Since 2004 SAGD technology trial has been conducted in Liaohe Oilfield, lots of significant breakthroughs were made so far and the current oil production can reach 150-300 t/d per well. As the SAGD technology matures, SAGD technology has already been an important technology to extract heavy oil petroleum after the steam flooding technique.

Although SAGD technology can improve the oil recovery efficiency substantially, it generates a large amount of waste heat [2]. Based on the current application of SAGD technology, the amount of high temperature produced liquid is 200-400 t/d for each oil well and its temperature can be 170°C, which contains a large amount of waste heat. If the energy of the high temperature produced liquid could be used, it may lower the energy consumption of oil exploitation and improve the economic benefit of SAGD technology.

The design of the process for recovering heat from liquid produced by SAGD Technology

In order to meet the needs of gathering and dehydration and lower the cost of SAGD technology, we can use high efficiency heat exchanger to recover the heat from the high temperature liquid produced from oil wells and raise the temperature of the softened water used in steam injection boilers.

The flow chart of using the produced liquid's heat is shown in Fig. 1. The liquid blended with heavy oil produced from the oil well enters a metering and transfer station for degasification and then enters a centralized heat exchanger station to undergo heat exchange. When its temperature is reduced to 100°C from 170°C, the produced liquid enters a multipurpose station and is dehydrated. While, the

softened water enters the centralized heat exchanger station from the softened water station and after its temperature rises through heat exchange, it's fed into the steam injection boiler as boiler feed water.

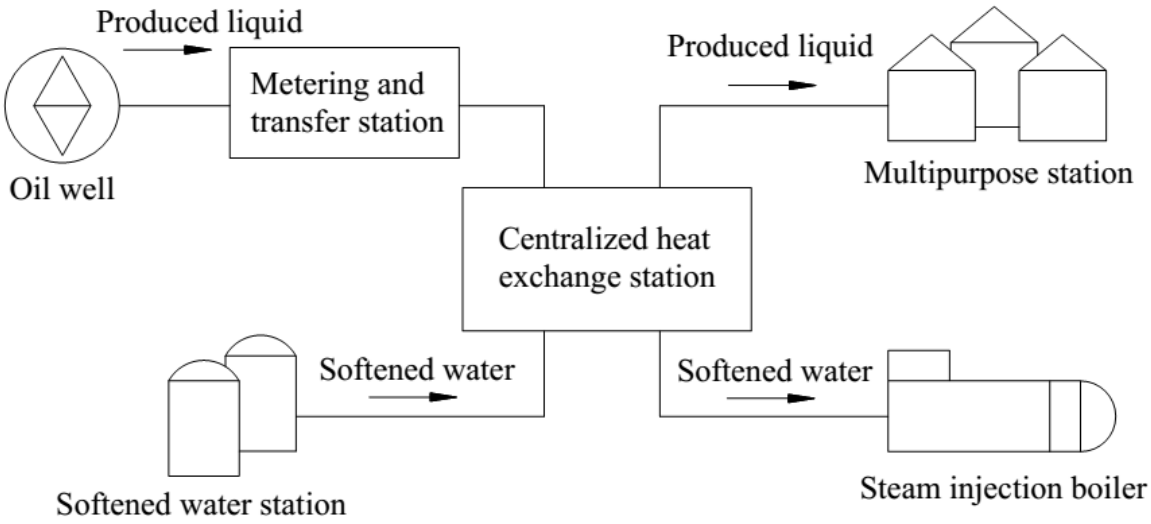

Fig. 1. The flow chart of using the heat of the produced liquid

The analysis on the physical and chemical properties of the produced liquid

In order to recover the waste heat of the liquid produced from oil well efficiently, we should measure and analyze physical and chemical properties of the liquid at first, which is the key to the design of the heat exchanger. So, we took samples of the liquid produced from the oil well in Liaohe Oilfield, which was measured and analyzed on the physical and chemical properties.

The analysis of physical properties. To design a proper heat exchanger, three characteristics (viscosity, specific heat at constant pressure and thermal conductivity) of the produced liquid was measured at two states at 1.6MPa with the temperature of 135°C and 170°C, respectively. The result is shown in Table 1.

Table 1. The result of physical properties analysis

State point	μ [Pa·s]	C_p [kJ/(kg·K)]	λ [W/(m·K)]
1.6MPa, 135°C	0.105	3.818	0.844
1.6MPa, 170°C	0.060	3.923	0.574

The analysis of chemical properties. Some researchers found that the heavy oil heat exchanger had serious corrosion [3]. Therefore, to avoid serious corrosion and reduce the economic loss as possible, the chemical properties analysis of the produced liquid is very important. The major ions in the high temperature produced liquid and the pH value were measured quantitatively. Before the test, oil was removed from the produced liquid. The quantitative analysis is mainly about pH of the produced liquid and the highly corrosive ions, such as Ca^{2+}, Mg^{2+}, Cl^-, HCO_3^-, SO_4^{2-}. The result is shown in table 2.

Table 2. The result of chemical properties analysis

Item	Ca^{2+} [mg/L]	Mg^{2+} [mg/L]	Cl^- [mg/L]	HCO_3^- [mg/L]	CO_3^{2-} [mg/L]	SO_4^{2-} [mg/L]	pH
Value	106	28	125	145.8	None	325	7.2

Comparison of alternative heat exchanger [4]

In Liaohe Oilfield, the pressure of the produced liquid ranges from 1 to 1.6MPa and the temperature is about 170°C when using SAGD technology. Considering the working condition of different heat exchangers and the needs of actual operation, the suitable heat exchanger can be plate heat exchanger or spiral-plate heat exchanger. The comparison and analysis about the characteristics of these two kinds of heat exchanger is shown as follows.

The characteristics of plate heat exchanger:

1) It has high heat-transfer coefficient, which can generate turbulence with low Reynolds number (Re=50-200). Generally speaking, its heat-transfer coefficient ranges from 3000-6000W/(m^2·K) which is 3-5 times to that of shell-and-tube heat exchanger.

2) Its logarithmic mean temperature difference is large and the terminal temperature difference is small.

3) It has compact structure so that it occupies a limited area. Its heat exchanger area per unit volume is 2-5 times to that of shell-and-tube heat exchanger.

4) It has long service life. It's punched with stainless steel sheet or titanium alloy sheet, so that it has high corrosion resistance against many working fluids.

5) Its operating pressure is less than 2.5MPa generally and the working temperature ranges from -40°C to 260°C.

6) The flow path is easily blocked due to the small space between sheet plates. Moreover, the flow path is more likely to be blocked when the working fluid contains large-size solid particle or fibrous matter.

The characteristics of spiral-plate heat exchanger:

1) It has high heat-transfer coefficient which is 1-3 times to that of shell-and-tube heat exchanger. When the hot and cold working fluids are both water, the maximal heat-transfer coefficient can reach 3000W/(m^2·K).

2) The spiral-plate heat exchanger is rolled of two stainless steel sheets so that two even spiral channels are formed and the both working fluids are flowing as complete counter current. So the mean temperature difference between the two working fluids can be as small as 1°C and the heat recovery efficiency may be over 99%.

3) It runs reliably. The sealing performance of non-detachable spiral-plate heat exchanger is fine. So it ensures that two working fluids will not be mixed.

4) It's free of clogging. Because of the spiral flowing, the dirt is not easy to be deposited, so it's easy to clean by using steam or alkali liquor as working fluid.

5) It has compact structure, small size and small external surface area. What's more, if the room temperature fluid flows in the outer channel, the thermal loss can be very low so that it doesn't need heat preservation.

Above all, plate heat exchanger is appropriate for operating when the pressure is lower than 2.5MPa and the temperature is not more than 260°C. It features compact structure and high heat-transfer coefficient. However, due to the narrow winding flow path (3-5mm) and a large amount of suspended solids and impurities mixed in the produced liquid, the flow path will be easily clogged. So, plate heat exchanger is inappropriate.

Not only does spiral-plate heat exchanger have the properties of compact structure, excellent seal and high heat-transfer coefficient, but also it's free of clogging and easily to clean without being disassembled. So, spiral-plate heat exchanger will be the best choice.

The results of design and calculation

The calculation results showed that, when the temperature of 12.5t/h of the produced liquid was reduced to 100°C from 170°C, the temperature of 18.5t/h of the softened water could be increased from 70°C to 110°C. During the design calculation of the spiral-plate heat exchanger, we denote the produced liquid's flow velocity as 0.6m/s and the softened water's flow velocity as 1.0m/s. The major

structures sizes of the spiral-plate heat exchanger are as follows: the produced liquid's passage interval is 10mm; the softened water's passage interval is 5mm; the plate width is 0.6m and the outer diameter is 1.32m. In addition, the overall heat transfer coefficient is 370W/(m^2·K) and the total heat exchange area is 59.7m^2.

In this process, the fuel consumption of the boiler will decrease with the increase of the boiler feed water's temperature. Referring to the report of SAGD project department of Liaohe Oilfield, the steam injection boiler uses natural gas as fuel and the original boiler feed water temperature is 70°C. According to our calculation, by adopting this process, the feed water temperature will be raised to 110°C. As a result, the gas consumption will be reduced to 1587Nm^3/h from 1713Nm^3/h, which means 2976Nm^3 of natural gas will be saved in one day. According to the local price of natural gas (3yuan/Nm^3), assuming the annual working time as 300 days, 2.72 million will be saved for each boiler per year.

Conclusions

1) This research shows that, by using spiral-plate heat exchanger to recover the waste heat of the liquid produced from the oil well, the temperature of the softened water will be raised to 110°C from 70°C which can meet the needs of the gas-fired boiler's technical specifications. So it is a feasible process to recover the waste heat of the produced liquid.

2) When this process is implemented, 3024Nm^3 of natural gas will be saved in one day corresponding that 2.72 million will be saved for each boiler annually. Therefore, this new technology has yielded remarkable economic and social benefits.

Keywords: flue gas; calculation of acid dew point;formula of acid dew point in the thermal calculation from the former U.S.S.R; sulfur dioxide

Abstract. At present, there are lots of calculation methods of acid dew point of flue gas; formula of acid dew point in the thermal calculation from the former U.S.S.R has been widely applied in China. But this formula still has some problems, such as the desulphurization ability of different fuels, classification of sulfur content in fuel and the factors of SO_2 transferred into SO_3.In order to solve these problems,the formula of the acid dew point in the thermal calculation from the former U.S.S.R is adjusted. It was found that the precision of A.G.O kkes formula is the highest by comparing several formulas. So the last will be the compilation of the new formula and A.G.O kkes formula, the former Soviet union formula and the calculation of burning lean coal,bituminous coal and lignite typical instance of 600 MW,it was found that the precision of new formula calculation has improved.

Foreword

So far ,there is sulfur (S) in the composition of the fossil fuels (coal, oil, natural gas, etc.)which the boiler used ,combustion of sulfur in the boiler produce SO_2,a few of SO_2 will generate SO_2 with the catalysis of Fe_2O_3 and V_2O_5,SO_2 and SO_3 combined with water vapor and produce sulfuric acid vapor,its dewpoint is the acid dew point of flue gas. When the temperature of the boiler heating surface is lower than that of acid dew point of flue gas, sulfuric acid vapor will be condenses on the surface heating surface and it has low-temperature corrosion on the heating surface[1].Therefore, calculate and determine the acid dew point of flue gas is significant to avoid the low temperature corrosion of heat exchangers and improving the boiler thermal efficiency. The acid dew point of flue gas is influenced by many factors (such as boiler combustion characteristics, sulfur content and ash content of fuel, moisture content, and excess air coefficient, etc), it is difficult to get accurate formula in theory.According to their own results of research, numerous research institutions get some empirical formula[2].As different starting point, they had different results.Therefore, analysis and comparison of the formula which frequently used to determine the applicable experience formula are necessary.

Commonly used calculation methods of the acid dew point of flue gas

Main methods follow:

(1)Formula of Japan Electric Power Research Institute[3]

$$t_{sld} = 20\lg\Phi_{so_3} + a - 80 \quad (1)$$

In the formula: Φ_{SO_3} is the volume fraction of SO_3 in the flue gas,%; a is water constant,when the volume of water constant in the flue gas is 5%,10% and 15%, a is 184,194 and 201.

(2)Formula of Experience method[3]

$$t_{sld} = 186 + 20\lg\Phi_{H_2O} + 26\lg\Phi_{SO_3} \quad (2)$$

In the formula: Φ_{H_2O} , Φ_{SO_3} is the volume fraction of Water vapor and SO_3 respectively,%.

(3)Muller curve[4]

$$t_{sld} = 116.5515 + 16.06329\lg V_{SO_3} + 1.05377(\lg V_{SO_3})^2 \quad (3)$$

In the formula: V_{SO_3} is the hundred million volume of SO_3 in the flue gas.

(4)A.G.Okkes formula[5]

According to experimental data,Dutch scholar A.G.Okkes put forward the following equation:

$$t_{sld} = 10.8809 + 27.6 \lg p_{H_2O} + 10.83 \lg p_{SO_3} + 1.06(\lg p_{SO_3} + 2.9943)^{2.19} \quad (4)$$

In the formula: p_{H_2O} is the partial pressure of water vapor in the flue gas,Pa; p_{SO_3} is the partial pressure of SO_3 in the flue gas,Pa.

(5)Formula of the acid dew point in the thermal calculation from the former U.S.S.R.1973[6]

$$t_{sld} = t_{ld} + \frac{\beta \bullet \sqrt[3]{S_n}}{1.05^{a_{fh} \bullet A_n}} \quad (5)$$

In the formula: t_{ld} is the dew point temperature of water vapor,℃; S_n is reduced sulfur content of fuel,10～kg / 4186． 8 kJ; A_n is the convert ash of fuel,10～kg / 4186． 8 kJ; a_{fh} is how many percent of fly ash in the convert ash of fuel,it generally takes 0.9 for domestic pulverized coal fired boiler; β is the coefficient about a'' (excess air coefficient at Chamber of furnace exit),when a''=1 ． 2～1． 5, $\beta = 121$～129.

(6)Correction formula of formula (5)[7]

$$t_{sld} = t_{ld} + \frac{1.1 \bullet \beta \bullet \sqrt[10]{S_n}}{1.05^{a_{fh} \bullet A_n}} \quad (6)$$

$$t_{ld} = -1.2102 + 8.4064 \bullet \phi_{H_2O} - 0.4749 \times (\phi_{H_2O})^2 + 0.01042 \bullet (\phi_{H_2O})^3$$

In the formula: ϕ_{H_2O} is the volume fraction of water vapor,%.

(7)Formula is based on the concentration of SO_2 in the flue gas[8]

$$t_{sld} = t_{ld} + \beta \bullet \sqrt[n]{4.2 S_n} \quad (7)$$

$$t_{ld} = -1.2102 + 8.4064 \bullet \phi_{H_2O} - 0.4749 \times (\phi_{H_2O})^2 + 0.01042 \bullet (\phi_{H_2O})^3$$

In the formula:n is conversion coefficient of SO_3, it takes 3 commonly,it can take 4-5 after installation of SCR denitration device; $S_n = S_{SO_2} / Q_{net.ar}$, $Q_{net.ar}$ is the low calorific value of fuel as received basis,MJ/kg; S_{SO_2} is sulfur content in fuel,%; $S_{SO_2} = 0.5 Q_V \bullet \rho_{SO_2} / B_M$, Q_V is the volume flow of flue gas, m^3 / s ; ρ_{SO_2} is the concentration of SO_2 of flue gas at desulfurization tower entry, mg / m^3 ; B_M is the amount of fuel,t/h.

Analysis on the calculation methods

Both formulae of Japan Electric Power Research Institute and the formula of Experience method need to measure the concentration of SO_3 in the flue gas. It is therefore difficult to measure accurately.These formulas are unfit for being applicable to the actual engineering.

Muller curve loses sight of the influence of water vapor,so it has certain limitations.

A.G.Okkes formula born of Muller data regression.It allowed for the impact of SO_3 and water vapor concentration in the acid dew point temperature.In the estimating of the acid dew point,it can be serve as a basis for the evaluation of other formula.

The current formula (5) is more widely applied in China,its data source (fuel element analysis and determination of calorific value)is easily got during the design and operation stages.This formula has the following problems:(1)It allowed for the influence of self-desulfurization of ash,but it is difficult to quantitatively the actual amount of desulfurization of fly ash ,different coal has different capacity of self-desulfurization[8];(2)The sulfur content in fuel was used in the calculation of this formula,actual sulfur content in fuel was divided into elemental sulfur, organic sulfur and sulfate sulfur and pyrite sulfur,organic sulfur also was divided into many kinds, there is a world of different between their releasing characteristics.For example,precipitation of SO_2 in the lean coal is divided into two stages:Stage one is produced by combustion of organic sulfur which easy to decompose and precalcining combustion of part of the pyrite sulfur(H_2S),stage two is produced by the organic sulfur which is difficult to decompose, pyrite sulfur and a small amount of sulfate sulfur[9].So the calculation of sulfur content is not accurate.(3)This formula loses sight of influence of SO_2 transferred into SO_3 to the acid dew point.

A large number of research results show that,acid dew point temperature rise accordingly when the generation of SO_3 increases.SO_3 in the flue gas usually accounts for 0.5%-5% of all SO_2,the flue gas which has different content of SO_3,its change of acid dew point temperature can reach 20 ℃[10].In this case, the consequences of formula (5) will be less than the actual acid dew point temperature.Literature [7] find the same conclusion after comparing with foreign acid dew point test measurements.

A new formula

According to the problems in the above formula,it put forward a method which uses the actual concentration of SO_2 in the flue gas to calculate the acid dew point on the basis of high precision correction formula. The methods follow:

(1)Fig.1 is the curve of acid dew point temperature change with the concentration of SO_3 comes in three kinds of formulas when the water vapor content is 8%.Among them,the Muller curve was verified by experiment[7].As we can see in the Fig.1,the calculation results of the former Soviet Union formula are quite far away from experimental data,and the slope of its curve is too large.So it changes the conversion coefficient from 3 to 10,and multiplies by 1.36 before $\Delta t(\Delta t = t_{sld} - t_{ld})$ to slow the increasing of the curve trend.

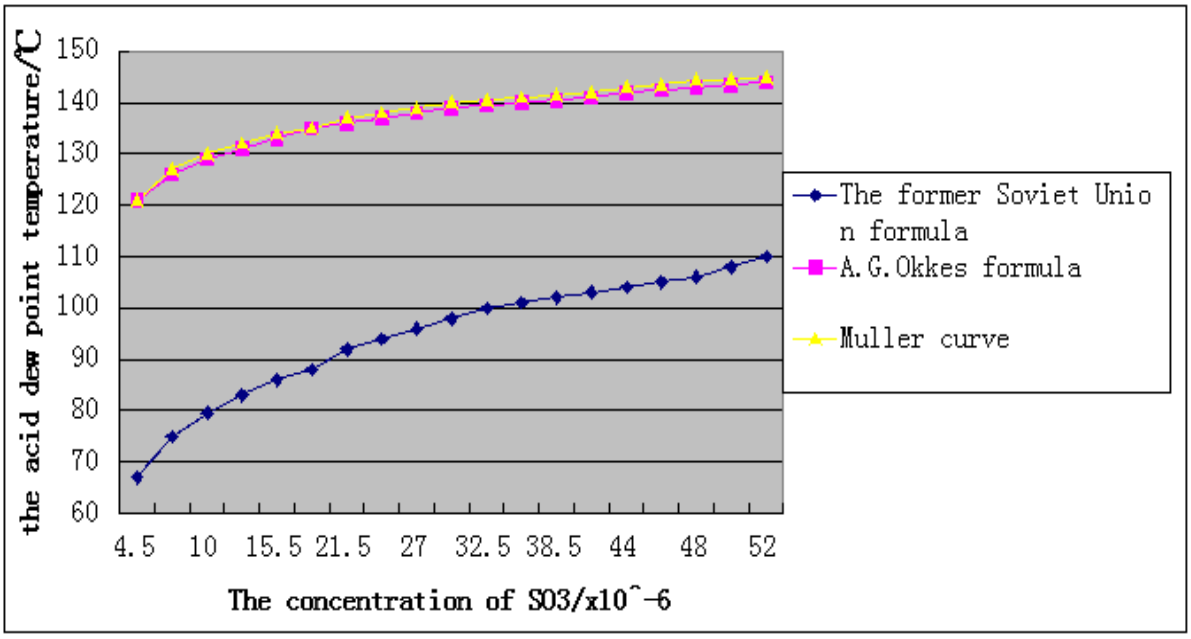

Fig.1 The curve about acid dew point temperature Change with the concentration of SO_3 when the water vapor content is 8%

(2)Based on the actual concentration of SO_2 in flue gas at desulfurization tower entrances(the smoke flow here is relatively stable and the difficulty of concentration of SO_2 measurement is smaller)[8],and combined with the actual boundary conditions to get the amount of actual flue gas,it gets the content of sulfur of SO_2 which is produced with coal in the grate.

(3)Changed type of coal have different ability of desulfurization and ash composition.The new formula performs the calculation of the actual concentration of SO_2 in flue gas.It needs not to reflect upon removal part of fly ash.

(4)Coal-fired power plants are widely equipped with SCR denitration system in recent years.The metal oxide of the main active ingredient in SCR catalysts will improve the proportion of SO_2 transferred into SO_3.Thus,improving the acid dew point of flue gas[11].Replacing the conversion coefficient of SO_3 is based on whether installed SCR denitration device.

The new formula is:

$$t_{sld} = t_{ld} + 1.36\beta\sqrt[n]{S_n}$$

$$t_{ld} = -1.2102 + 8.4064 \bullet \phi_{H_2O} - 0.4749 \times (\phi_{H_2O})^2 + 0.01042 \bullet (\phi_{H_2O})^3 \quad (8)$$

In the formula:n is conversion coefficient of SO_3, it takes 10 commonly,it can take 11-12 after installation of SCR denitration device; $S_n = S_{SO_2} / Q_{net.ar}$, $Q_{net.ar}$ is the low calorific value of fuel as received basis,MJ/kg; S_{SO_2} is sulfur content in fuel,%; $S_{SO_2} = 0.5Q_V \bullet \rho_{SO_2} / B_M$, Q_V is the volume flow of flue gas, m^3/s ; ρ_{SO_2} is the concentration of SO_2 of flue gas at desulfurization tower entry, mg/m^3 ;B_M is the amount of fuel,t/h.

Verification of formula

(1)Validated theoretically

In the estimating of the acid dew point,A.G.Okkes formula can serve as a basis for the evaluation of other formula.We get the Fig.2 after the comparation of the new formula,the former Soviet Union formula and A.G.O kkes formula,the change in trend of the new formula is slower than the former Soviet Union formula and its result is closer to the A.G.Okkes formula.

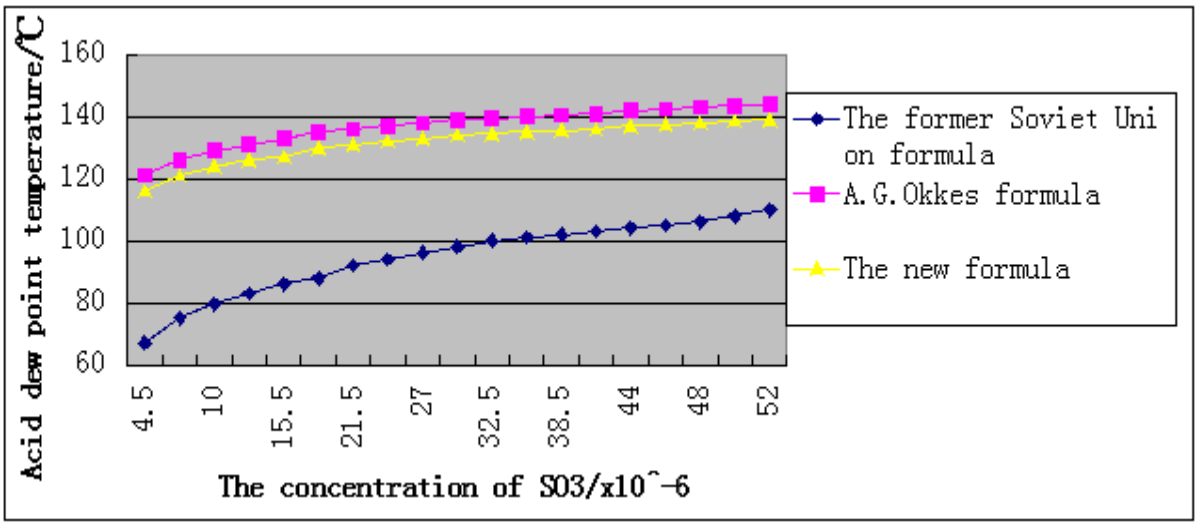

Fig.2 Comparison of the new formula,the former Soviet Union formula and A.G.O kkes formula

(2)Validated by calculation

According to the boundary conditions of the actual operation(Table 1),calculate the acid dew point temperature of the 600MW units firing lean coal,bituminous coal and lignite coal with the new formula.Specific steps are presented in Table 2.

We can see from Table 2:The result of the new formula is higher than formula(5) and formula(7),and close to the result of formula(6).The precision of the new formula can be guaranteed after the comparison with A.G.O kkes formula[7].

Table 1

Project		Lean coal unit	Bituminous coal unit	Lignite coal unit
Coal quality parameters	Carbon C_{ar}/%	55.15	62.41	32.74

Result of calculation of the former Soviet Union formula/°C	Formula(6)	177.0	171.4	166.7

Conclusions

(1)The acid dew point temperature in flue gas increase with the concentration of SO_3,in the formulas that considering the influence of SO_3,the former Soviet union formula after revised and A.G.Okkes formula are accurate.The error of former Soviet union formula and formula of Japan Electric Power Research Institute are large.There are still some certain errors in the formula based on the concentration of SO_2(formula (6)).

(2)The former Soviet Union formula loses sight of the influence of different desulfurization ability of different fuels,the classification of sulfur in coal and SO_2 transferred into SO_3 to the acid dew point of flue gas.Its result in low and slope of the curve is greater.

(3)The new formula which based on the actual concentration of SO_2 in the flue gas at desulfurization tower entrances combines with the actual boundary conditions to make calculations.It is more suitable for engineering application than the former Soviet Union formula without correction.

Keywords: Coal, Wood chips, Co-pyrolysis, Interaction

Abstract. As a clean, renewable energy, rational use of biomss can effectively solve the problem of energy shortage and environmental pollution. Co-combustion and Co-gasification of biomass and coal are important ways of biomass utilization. Co-pyrolysis reaction is one of the most important processes in the co-combustion and co-gasification. In order to study the different mix ways of coal and wood chips affections on the co-pyrolysis process, TGA was used to study the co-pyrolysis characters of wood chips and coal mixed by different methods with mass ratio 1:1. it is founded out that there is certain interaction between wood chips and coal by the comparison of TGA curves and calculation curves. There is promoting affection at the high temperature if wood chips and coal had been mixed up. There is inhibiting affection if wood chips and coal are tiering distributed.

Introduction

With the rapidly growth of energy consumption in our country, it is primary energy coal resources are sharply declining. According to the proved reserves and production capacity, China's coal mining life of just only 80 years the data shows. Therefore, it is urgent developing and looking for a new, clean renewable energy for need to sustainable development. Biomass resources are rich in our country, though the annual crop waste is equivalent to more than 600 million t of standard coal, and forestry waste of standard coal equivalent to about 300 million t. In burning power generation and use of renewable biomass to replace part of gasification coal can not only alleviate energy crisis, but also can reduce environmental pollution, implementation technology, economic and environmental win-win [1-2].

Although biomass which abundant in China, is a renewable energy, it's energy density low, separately used in the low temperature pyrolysis, and the process is not easy to control, equipment corrosion, generate the tar is much, not only reducing its efficiency, and may cause secondary pollution, so make the size of the individual pyrolysis is restricted. Mixing biomass with coal in a certain proportion pyrolysis already separately overcome various problems of biomass pyrolysis; also can make up for the shortage of coal resources, and biomass ashes metal and alkaline substance content is higher, can increase the reactivity of coal and the sulfur removal ability. So no matter from the angle of ecology and economics analysis, this is one of the feasible way so fusing [3].

Pyrolysis is coal and biomass thermal conversion process of the initial stage and with reaction, in the aspect of comprehensive utilization of coal and biomass in the foundation status. For coal and biomass pyrolysis process, scholars at home and abroad are analyzed under different operating conditions. Foreign scholars M.Yilgin etc. [4] by lignite with beet ratio 1:1 fast pyrolysis experiments show that the lignite pyrolysis with beet synergies; Wei ping Yan [5] by lignite and biomass pyrolysis research shows that in the process of biomass with coal pyrolysis, biomass mixing proportion, composition and properties and mineral composition of coal ash pyrolysis volatilization analysis the influence of both promotion and inhibition. When biomass adding amount of more than 50%, a large number of biomass can occur before the Samples volatilization of precipitation in coal softening melting, then adhesion, covering the surface of coal, coal blockage wool stoma, suppress the volatile evolution and diffusion, which play the role of inhibition of lignite pyrolysis; Wen Lee [6] in pressurized with non isothermal weight on the heat balance method for total biomass (sawdust, rice husk) and coal pyrolysis research, think of biomass with coal pyrolysis temperature difference is very big, so no interaction in the pyrolysis process. Thus, for biomass pyrolysis process with coal blend for how to influence and influence mechanism has not unified conclusion.

This experiment using thermogravimetric analyzer with 1:1 proportion, according to different methods of mixed with sawdust pyrolysis process of coal property research, for the coal and wood pyrolysis process design and operation to provide theoretical basis.

Experimental study

Raw material and the analysis of nature

Wood chips with high-speed multi-function crusher (BL - 100 type, voltage 220 v, power 650 w, rotating speed of 22000 r/min) grinding particle size was less than 0.2 mm samples, coal sample grain size is less than 0.105mm.Samples of industrial analysis, element analysis to see the table.1below.

Tab.1 Proximate analysis and ultimate analysis of samples

Samples	Proximate analysis/ %*				Ultimate analysis/ %				
	M_{ar}	V_{ar}	A_{ar}	FC_{ar}	C	H	N	S	O
Wood chips	4.942	79.848	1.128	14.082	41.9	5.17	0.19	0.16	46.51

Thermogravimetric analysis experiment

Experiment using TGA/DSC Switzerland Mettler Toledo - company - type 1 thermogravimetric analyzer, it analysis with high purity nitrogen as the carrier gas, flow rate of 60 ml/min, use PC - 85 MT type thermostatic bath cooling at low temperature. Experiments with each quantity of sample (10 + / - 0.1 mg), coal and wood chips under 1:1 ratio in three way mix, temperature range 50-1000˚C, the heating rate of 40˚C / min. Experiment explores different ways of mix influenced on coal pyrolysis characteristics with sawdust. Coal mixed with wood of three kinds of ways: 5 mg of coal sample with 5 mg sawdust by coal on sawdust, wood chips under coal mixed arrangement of stratification and the mixing coal and wood chips.

The results and discussion

Sawdust and coal pyrolysis alone

Figure1 and figure 2 respectively, sawdust and coal pyrolysis alone when the curve of the weight percentage change with temperature, Can be seen from the diagram, there are large differences in the process of pyrolysis between coal and wood chips alone; sawdust pyrolysis of coal pyrolysis temperature is higher; basic don't coincide with sawdust pyrolysis temperature range.

Sawdust pyrolysis process can be divided into three phases: preheating, volatile, analyzed a carbonized. From room temperature to 200 ˚C, sawdust mainly lose moisture, due to the moisture content in the wood is less, so the curve downward trend is not obvious. 200-400˚C is the main stage, the wood pyrolysis process of wood thermal decomposition under anoxic conditions, volatile precipitation, mass loss is as high as 70%. This phase of the important reactions include: dehydration reaction, decarboxylate and containing xylan of hemicellulose polymer. When the temperature is lower, coke formation reaction plays a leading role. As temperature rises, produce the sinistral glucan depolymerization reaction were dominated. The changes of biomass in low temperature pyrolysis have part of hemicellulose, lignin and cellulose decomposition (cellulose fiber shortening). Usually, hemicellulose decomposition during 200-250 ˚C, cellulose decomposition temperature range of 240-350 ˚C and lignin decomposition occurs in the within the range of 280-500, the decomposition rate of slow [1]. Hemicellulose and cellulose decomposing main produce volatile substances, and decomposition of lignin mainly for carbon [7]. Temperature of 400 ˚C above, mainly carbocoal decomposition is thought to be composed of C - C key and C - H key fracture caused by further, in this phase, sawdust volatile internal diffusion, slowly towards the outer quality change is relatively flat, a longer duration of [8]. Non-volatile solid residue into sawdust pyrolysis process carbocoal residue, generally does not generate gum body, and no bond phenomenon.

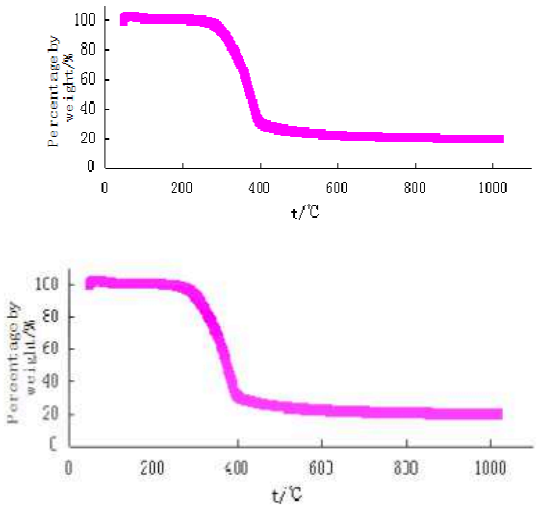

Fig.1 TGA curve of coal separate pyrolysis process

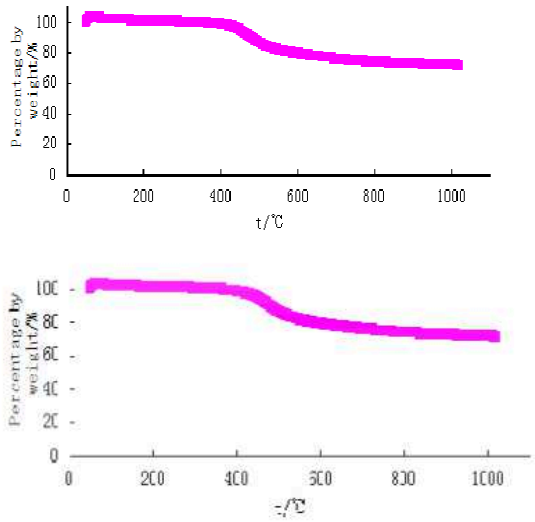

Fig.2 TGA curve of wood chips separate pyrolysis process

Coal compared with sawdust pyrolysis process, also has a powerful weightlessness, but the quality loss value are much smaller than wood, this industry analysis of volatile higher quality to score. With the increase of temperature, coal pyrolysis process is complex, gas during coal successively removing moisture and gap (350-400 ˚C); it is given priority to with depolymerization and decomposition reaction in a gas (400-550 ˚C); Polycondensation reaction gases and minerals decomposition gas (550-1000 ˚C), also known as secondary degassing [9]. Pyrolysis process of the TGA curve is consistent with the existing theory.

Sawdust mixed with coal pyrolysis

Analysis of coal mixed with sawdust pyrolysis synergy, need to draw the mixed pyrolysis process is the actual weight percentage and the difference between the theoretical values is calculated with the temperature change of the curve. Difference value greater than zero, the actual weight loss value is less than the theoretical value calculated, the pyrolysis process of mixing of coal and wood chips has played a certain inhibitory effect. On the other hand, the difference is less than zero, mixed with sawdust role to the improvement of the pyrolysis process of coal. Theoretical weight percentage of the total pyrolysis process is equal to the actual weight percentage of the coal and wood chips alone pyrolysis of 1/2, namely assume that when mixed with sawdust has no impact on the pyrolysis process of coal weight percentage.

Figure 3 to figure 5 for coal and wood chips in three different arrangement of mixed pyrolysis total actual weight percentage and the difference between the theoretical values is calculated with the temperature change of the curve, can be seen by the figure of coal mixed with sawdust in three ways, did not show obvious synergy before250 ˚C, after 250 ˚C inhibition enhanced obviously, peaked at about 350˚C, but far less evenly mixed inhibition enhanced amplitude fluctuation layered hybrid. The author concluded that produce inhibition to begin at about 250 ˚C was the main reason is that in the wood pyrolysis, volatile precipitation, at the same time a large number of biomass could occur in the coal volatile analysis before the softening melting, then adhesion, covering the surface of coal, coal blockage wool stoma, in both cases can inhibit the volatile matter in coal spillover and diffusion, which play the role of inhibition of coal pyrolysis [10]. Pyrolysis is a very complex physical and chemical reaction process, low temperature occurs mainly from coal pyrolysis decomposition, deployerization, generating a large amount of tar and gas. General bridge bond between the structural unit of coal when heated to above 250 ˚C are some weak bond began to break, with the increase of temperature, bond energy high bridge key will break. Bridge bond fracture generated on the basis of the structural unit of free radicals, is a kind of free radical molecules with unpaired electrons fragments, generally in bridge key on the breakup of a carbon atom, such as H +, CH3 -,

CH3CH2 - and C6H6 - etc. Temperature rises, the low temperature pyrolysis tar occurred secondary cracking, decomposed to solid carbon, gas, and free radicals reaction and most of these free radicals have the aromatic. Free radicals are unstable, baseband unpaired electrons has high reactivity, with adjacent unpaired electrons on the free radicals of pairs of trend, if these free radicals can not get hydrogen and its concentration is large, the free radical fragments will be combined with each other and generate greater molecular weight compounds and coke. Hydrogen atoms are the smallest and simplest of free radicals, rich in hydrogen atmosphere, free radicals hydrogenation can generate stable low molecular products (tar, a small amount of gas and water). In the process of pyrolysis of biomass and coal, biomass, ahead of coal pyrolysis, pyrolysis biomass pyrolysis release a large number of free radicals and small molecular hydrogen, makes coal pyrolysis of a large number of radicals stable low tar and gas molecules, speeding up the coal pyrolysis [11]. Due to the hierarchical hybrid coal mixed with sawdust even when fully contact, may offset the inhibition in a larger extent, so mixing showed inhibitory effect than layered mixed up and down.

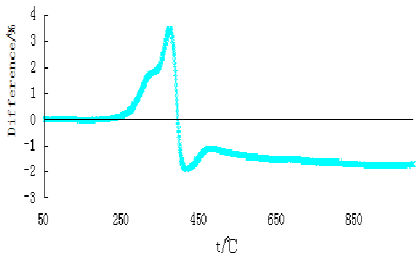

Fig.3 Differences of TGA measured value and calculated value with uniformly mix co-pyrolysis

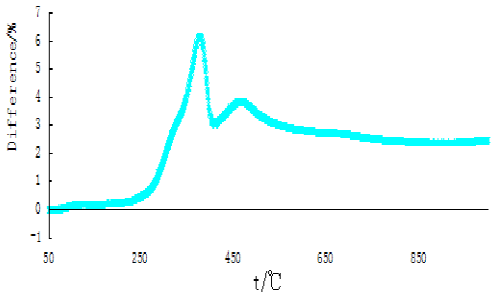

Fig.4 Differences of TGA measured value and calculated value with tiering distributed co-pyrolysis (toal in the upper

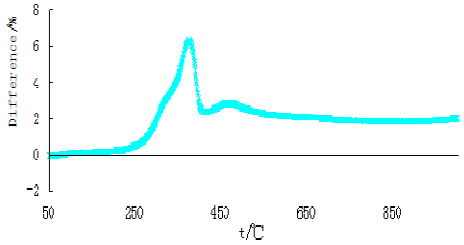

Fig.5 Differences of TGA measured value and calculated value with tiering distributed co-pyrolysis wood chips in the upper

Three ways that produce inhibitory effect began to decline after 350 ℃, it may on the one hand due to sawdust pyrolysis began to form the ash content, ash wood pyrolysis of alkali metal (K_2O, CaO,Na_2O) mass fraction is higher, the pyrolysis of coal play a catalytic role; Second, rice husk of H/C ratio greater than coal, pyrolysis process fracture C - H keys to produce hydrogen in part will be assigned to the coal carbon atoms, increase the quality of the coal pyrolysis process loss value. [8]At the same time it due to contact fully mixing, promoting effect is stronger, so the decline range is larger, after 400 ℃ has shown obvious role in promoting [1].

About 450 ℃, the curve has a modest rise, it may be due to the wood pyrolysis produced a large number of ash adsorption on the surface of coal particles, hindered the evolution of volatile matter in coal and diffusion, the pyrolysis process of coal to produce inhibition [12]. Using mixed coal on sawdust under stratified way, less ash wood pyrolysis will only part of the adsorption on contact with the underlying coal sample, and the rest of the coal samples pyrolysis has not been the impact of wood ash, compared with another two kinds of hybrid methods due to its smaller curve rises. After the curve of the three kinds of mixed mode relatively smooth, but there are varying degrees of decline, a longer duration. The authors concluded that may be because the adhesive on the surface of the coal, wood ashes and produce CO_2 reduction reaction occurred in the process of pyrolysis, reduced the

inhibitory effect of coal pyrolysis [13]. Using coal mixing way on the sawdust, sawdust pyrolysis of ash content accumulation in upper samples mostly, it is easier to contact fully with CO_2, there will be more adhesive on the surface of coal ash in response, so that this way of mixing the curve of the larger drop.

Conclusion

Through the above research and analysis to the following conclusion:

Coal mixture with sawdust pyrolysis rule is integrated embodiment of its single coal and wood pyrolysis regularity, but with sawdust pyrolysis characteristics of coal is not the simple sum of single coal and wood pyrolysis characteristics both in the process of coal pyrolysis with sawdust mixture has certain synergy.

Coal mixed with sawdust according to three different methods of TGA curves measured values compared with the theoretical value of curve trends are similar, but the range of the rise and fall is slightly different. When the temperature is higher, the mixing pyrolysis showed obvious synergy.

Coal mixed with sawdust pyrolysis of synergy and its hybrids, compared to the top and bottom layered hybrid, mixing may be more conducive to synergy.

Keywords: Thin film evaporation, heat transfer characteristics, Rectangular groove

Abstract. Thin film evaporation is a kind of high efficiency heat transfer. A thin film evaporator with rectangular micro groove has been designed, constructed and tested. The heat flux, superheat and thermal resistance of the thin film evaporator were investigated under different evaporating temperatures. Compared with the regular evaporator at the same condition, the thin film evaporator with rectangular micro groove has a better heat transfer performance and good temperature uniformity. The experimental investigation presented in this paper can be used as a reference to promote the engineering application and development of the thin film evaporator.

Introduction

With the rapid development of science and technology, instrument and equipment required total power and power density are significantly increasing. Thin film evaporation as a highly efficient heat transfer device has been concerned more and more. Fig.1 illustrates a schematic of an evaporating thin film formed in a rectangular micro groove. The heat transfer in the rectangular micro groove can be divided into two parts. Some of the heat is transferred through the bulk region, which is controlled by surface tension. While the rest of the heat through the thin film evaporating region, which is controlled by the disjoining pressure.

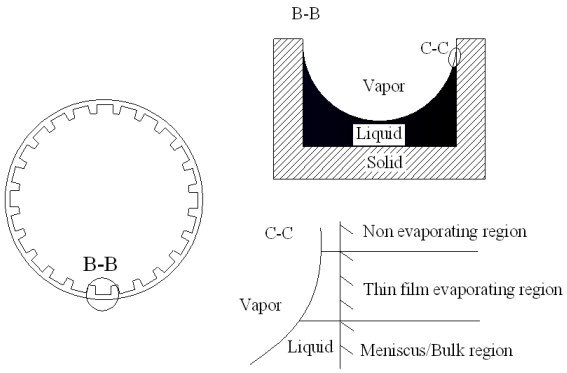

Fig.1 Schematic of an evaporating thin film formed in a rectangular micro groove

The description of the evaporation and fluid flow from an extended meniscus by expanding the Derjaguin-Landau-Verwey-Overbeek (DLVO) theory was reported by Potash and Wayner [1] as early as in 1972. Following this work, several investigations [2–5] were conducted to further understand the mechanisms of thin film evaporation, and found that thin film evaporation plays an important role in phase-change heat transfer. Xu and Carey [2] conducted investigations on the liquid flow in triangular grooves both theoretically and experimentally, and found the importance of disjoining pressure on the overall heat transfer. Ha et al. [3] investigated heat transfer in the evaporating thin film region in triangular micro grooves with non-uniform heat flux applied. It was found that the average and local heat transfer coefficients decreased as the ratio of film conduction resistance over ideal interfacial resistance increased. Still for triangular grooves, Ma and Peterson [4, 5] proposed a mathematical model involving the variation of heat transfer coefficient and temperature along the thin film region. They studied the thin film profile, heat transfer coefficient, and

temperature variation along the axial direction of a triangular groove with capillary induced liquid flow. All these investigations were limited to the evaporation and fluid flow in thin film regions occurring on a flat surface. More recently, Jiao et al. [6] proposed an analytical model which could predict the effects of contact angle on the thin film profile and meniscus radius within a micro-trapezoidal groove. It was found that the thin film evaporation governed the maximum heat transfer capability in a grooved heat pipe. Ma et al. [7] developed a mathematical model for the fluid flow and heat transfer in the thin film region, considering the effect of inertial force, disjoining pressure and temperature-dependent surface tension, which offered a better understanding of the thin film evaporation. Most recently, Cheng et al. [8] developed a mathematical model to determine heat transfer through both the thin film and bulk regions of a liquid in a rectangular micro groove. The result showed that the portion of heat transfer through the bulk region was found to be as high as 22%; hence heat transfer in this region should not be neglected. However, the temperature distribution within the meniscus bulk region was first found via a coordinate transformation and the Galerkin Method. Yan and Ma [9] proposed a mathematical model to predict heat transfer and film thickness in thin-film region. The analytical solutions show that the maximum dimensionless heat flux is constant which is independent of the superheat.

In the current investigation, a thin film evaporator with rectangular micro groove and a regular evaporator with regular pipe have been designed, constructed and tested in the same format and dimension. The evaporating temperature effects on the heat flux, superheat and thermal resistance were investigated for the two evaporators at the same condition. The experimental results presented in this paper will be used as a reference to promote the engineering application and development of the thin film evaporator.

Experimental Setup

The experimental setup is shown schematically in Fig. 2. The experimental system consists of an evaporator, a reservoir, a thermostatic water tank, a vacuum device and a NI-DAQ system. The evaporator is assembled by evaporation tubes, fins, inlet and outlet manifold and standard compression tube fittings. The fin pitch is 180 per meter. The length of the evaporation tubes is 330mm, the diameter is 10mm and wall thickness is 1mm. The total heat transfer area is 0.8822m^2. Two evaporators with different evaporation tubes were fabricated. One is the thin film evaporator, which use the rectangular grooved tubes. The other one is the regular evaporator, which use the regular tubes. The groove width and depth of the rectangular groove are 185μm and 320μm, respectively. The reservoir with a control valve is used for adjusting the flow rate into the evaporator. The thermostatic water tank was carefully wrapped by thermal insulation materials to eliminate the heat loss. The vacuum device was used to provide a certain degree of vacuum. Twenty T-type thermocouples (T1~T20) were placed at both inlet and outlet of the evaporator to monitor the temperature history and the accuracy of the T-type thermocouples is ±0.1 °C. The EJA310A type absolute pressure sensor was used for measuring the evaporation pressure of the evaporator. The range of the pressure sensor is 0~30kPa and the accuracy is 0.065%. The heating power of the thermostatic water tank was measured by the PZ200P-5K1 type wattmeter. The range of the pressure sensor is 0-2000W and the accuracy is 0.1%. A NI (National Instruments) high speed data acquisition system was used and a LabVIEW project was developed for the ejector test.

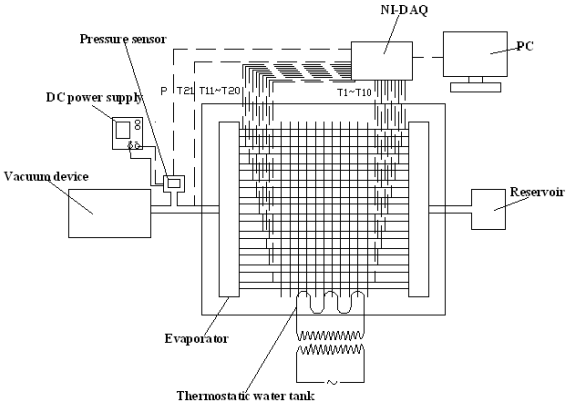

Fig.2 Schematic of thin film evaporation system

Results and Discussion

In this paper, the working fluid used in the test is water. The experimental contrast results of the heat transfer performance for the thin film evaporator and regular evaporator were shown in the Fig. 3 to Fig. 7.

Figure 3 illustrates the comparison result of the superheat at the inlet for the thin film evaporator and the regular evaporator under different evaporation temperature. The superheat at the inlet is defined as the temperature difference between the outer surface temperature at the inlet of the evaporator and evaporation temperature, $\Delta T_i = T_{i,w} - T_e$. Referring to Fig. 3, for the evaporation temperature at the range of 25～60℃, the superheat at the inlet of the thin film evaporator is 1.0~1.8℃. While the superheat at the inlet of the regular evaporator is 1.0~2.0℃. The superheat at the inlet of the two evaporators has less difference. The superheat at the inlet of the regular evaporator is a little bit higher than the thin film evaporator at some evaporation temperature.

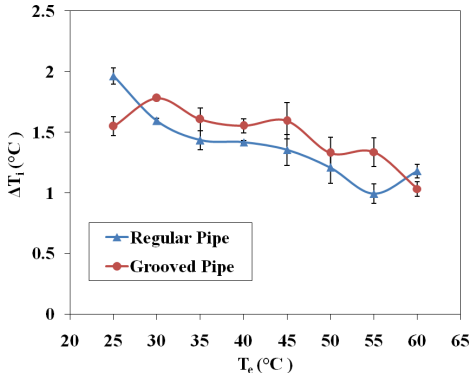

Fig. 3 The comparison result of the superheat at the inlet for two evaporator under different evaporation temperature

Figure 4 shows the comparison result of the superheat at the outlet for the thin film evaporator and the regular evaporator under different evaporation temperature. The superheat at the outlet is defined as the temperature difference between the outer surface temperature at the outlet of the evaporator and evaporation temperature, $\Delta T_o = T_{o,w} - T_e$. According to Fig. 4, for the evaporation temperature at the range of 25～60℃, the superheat at the inlet of the thin film evaporator is 1.3~2.0℃. While the superheat at the inlet of the regular evaporator is 1.8~3.0℃. The superheat at the outlet of the regular evaporator is much higher than the thin film evaporator.

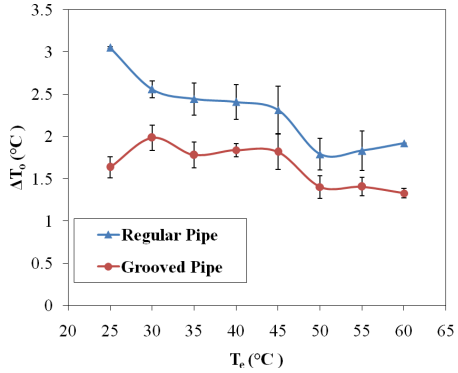

Fig.4 The comparison result of the superheat at the outlet for the thin film evaporator and regular evaporator under different evaporation temperature

Figure 5 shows the comparison result of the temperature difference between the inlet and outlet for the thin film evaporator and regular evaporator under different evaporation temperature. The temperature difference between the inlet and outlet is defined as the difference between the outer surface temperature at the inlet and outlet of the evaporator, $\Delta T_{i,o} = T_o - T_i$. From Fig. 5, it is clearly observed that the temperature difference between the inlet and outlet for the thin film evaporator is 0.1~0.3℃ for the evaporation temperature at the range of 25～60℃. While the temperature difference between the inlet and outlet for the regular evaporator is 0.7~1.1℃. The temperature difference between the inlet and outlet for regular evaporator is much higher than the thin film evaporator at the same evaporation temperature, which indicated that the thin film evaporator has good temperature uniformity.

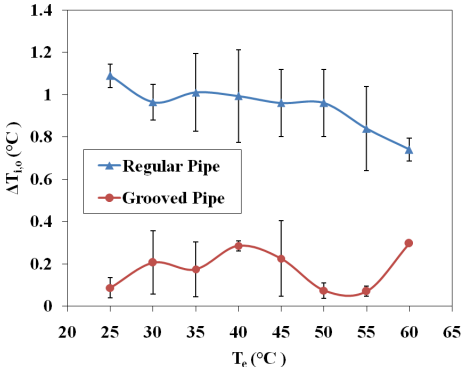

Fig.5 The comparison result of the temperature difference between the inlet and outlet for the thin film evaporator and regular evaporator under different evaporation temperature

Figure 6 shows the comparison result of the heat flux of the thin film evaporator and the regular evaporator under different evaporation temperature. In Fig. 6, the heat flux of the evaporator will increase with the increase of evaporation temperature, which is in a linear relation. From Fig. 9, it appears that the heat flux of the thin film evaporator increased from 193.6W/m2 to 827.3W/m2 for the evaporation temperature at the range of 25～60℃. While the heat flux of the regular evaporator increased from 173.2W/m2 to 501.1W/m2. The heat flux of the thin film evaporator is far above the regular evaporator at the same evaporation temperature, which showed that the thin film evaporator has a better heat transfer performance.

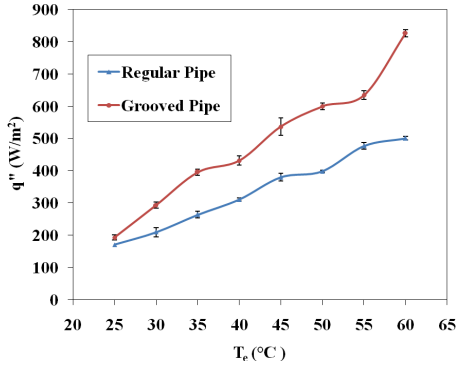

Fig.6 The comparison result of the heat flux of the thin film evaporator and regular evaporator under different evaporation temperature

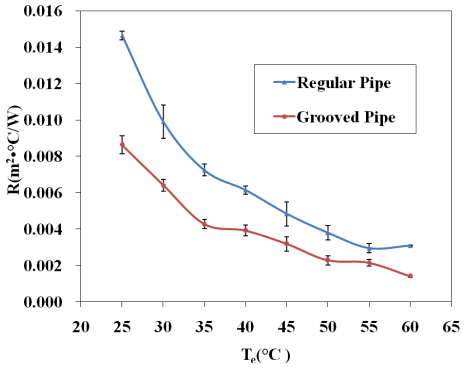

Fig. 7 The comparison result of the thermal resistance of the thin film evaporator and the regular evaporator under different evaporation temperature

The comparison result of the thermal resistance of the thin film evaporator and the regular evaporator under different evaporation temperature is shown in Fig. 7. The thermal resistance of the evaporator is defined as the ratio of temperature difference between the inlet and outlet into the heat flux, $R = \Delta T_{i,o} / q''$ .In Fig. 7, the thermal resistance of the evaporator will decrease with the increase of evaporation temperature, which is leveling off gradually. The thermal resistance of the thin film evaporator decreased from $0.086\,m^2 \cdot ℃/W$ to $0.0014\,m^2 \cdot ℃/W$ for the evaporation temperature at the range of $25 \sim 60$℃. While the thermal resistance of the regular evaporator decreased from $0.0146\,m^2 \cdot ℃/W$ to $0.0031\,m^2 \cdot ℃/W$. The thermal resistance of the thin film evaporator is lower than the regular evaporator at the same evaporation temperature, which showed that the thin film evaporator has a better heat transfer performance.

Conclusions

In the current investigation, a thin film evaporator with rectangular micro groove has been designed, constructed and tested. The evaporating temperature effects on the heat flux, superheat and thermal resistance were investigated. Compared with the regular evaporator at the same condition, the thin film evaporator with rectangular micro groove has a better heat transfer performance and good temperature uniformity. For the thin film evaporator, the heat flux increased from 193.6W/m^2 to 827.3W/m^2 and the thermal resistance decreased from $0.086\,m^2 \cdot ℃/W$ to $0.0014\,m^2 \cdot ℃/W$ for the evaporation temperature at the range of $25 \sim 60$℃. The experimental results presented in this paper will be used as a foundation to boost the engineering application and development of the thin film evaporator in the future.

Keywords: Submerged combustion vaporizer, LNG, Horizontal tube, Heat transfer, Large specific heat region.

Abstract. The submerged combustion vaporizer (SCV) is a new kind of vaporizer for liquefied natural gas (LNG). In this paper, a numerical study has been carried out to investigate the heat transfer characteristics of supercritical LNG in horizontal tubes. The thermo-physical properties of supercritical LNG were used for this study, and the influence of inlet LNG mass flow rate on heat transfer was investigated. Numerical results showed that the LNG flow in horizontal tubes included two stages. In the first stage, the surface heat transfer coefficients increased significantly with the increase of the fluid bulk temperature and reached a maximum value when the fluid bulk temperature equaled the pseudo-critical point. After the maximum, the surface heat transfer coefficients fell rapidly with the increase of the fluid bulk temperature. With increasing the inlet LNG mass flow rate, the surface heat transfer coefficients increased due to the increased fluid velocity in horizontal tubes.

Introduction

Natural gas (NG) owns the advantages of safety and cleanness, and its demand is expected to increase in future energy market considering the global energy crisis and the serious environment contamination worldwide. Liquefied natural gas (LNG) is practical approach for large quantity of NG transportation for its mass storage. NG volume can be reduced by about 1/600 by liquefaction, which allows long distance transportation using LNG carriers. Upon arrival at an LNG receiving terminal, LNG is stored in insulated atmospheric LNG storage tanks. The LNG must be vaporized to natural gas before it is used as fuel gas for industrial and domestic purposes. Therefore, efficient and reliable vaporizers for LNG receiving terminals are important. Four types of LNG vaporizers are mainly used in the LNG receiving terminals, namely, open rack vaporizer (ORV), super ORV, submerged combustion vaporizer (SCV), and intermediate fluid vaporizer (IFV) [1].

The SCV's have high thermal efficiency, easy start-up, and are capable of long-terms continuous operation. The structure of SCV is mainly composed of water tank, serpentine tube coils inside the water tank, and burner. The low-temperature NG and the boil off gas (BOG) from the LNG terminals are burned to flue gas as high-temperature heat source. The flue gas is injected into the water tank to keep the temperature of water bath constant, and the LNG is vaporized inside the serpentine tube coils located inside the water tank. The serpentine tube coils are mainly composed of horizontal circular tubes, and the thermal performance of supercritical LNG in horizontal circular tubes has not been reported.

Base on the above preview, the heat transfer performance of supercritical LNG in horizontal tubes were studied computationally in this paper. The influence of inlet LNG mass flow rate on heat transfer was investigated.

Mathematical models

Physical descriptions. The heat transfer of supercritical LNG in horizontal circular tubes is considered here. Fig. 1 shows the schematic diagram of the calculation model which consists of eight horizontal tubes. The outside diameter of the tube is 32 mm with a stainless steel wall thickness of 2.5

mm and the length of the tube is 6308 mm. This tube has been widely utilized in supercritical pressure treatment. In the present study, it was assumed that the working fluid was incompressible, and a constant pressure of 9.85 MPa was used for the physical properties since the pressure drop along the pipe was very small.

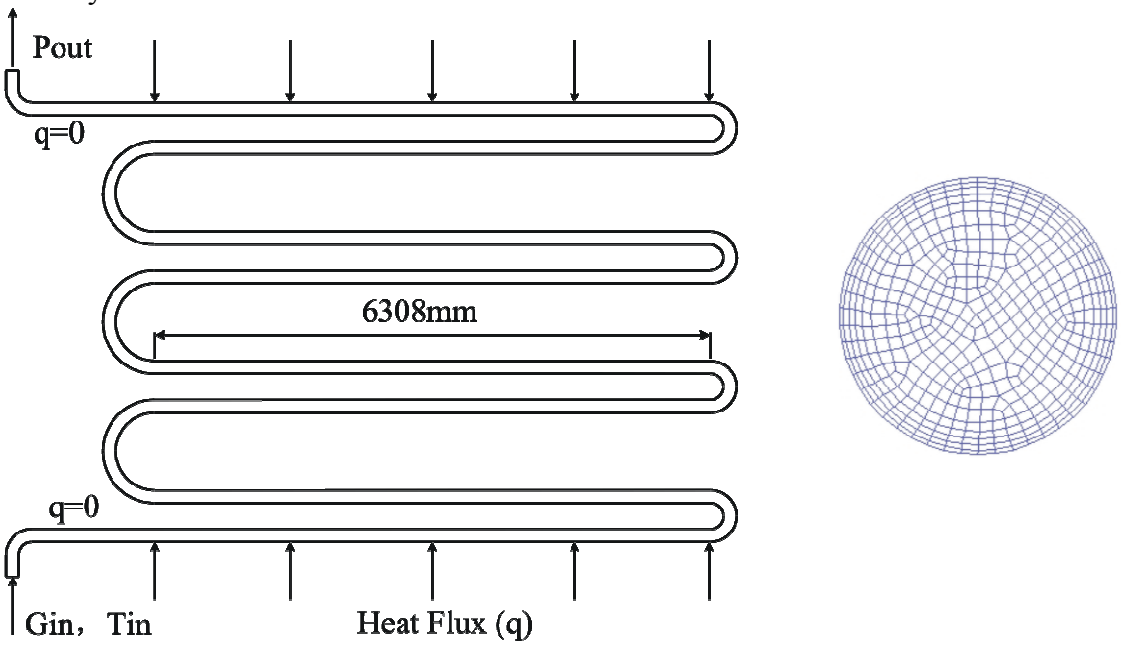

Fig. 1 Schematic diagram of the tubes and the grid configuration in the cross-sectional slice

Thermal properties of the working medium in SCV. Typical compositions of LNG or NG in the present study were (molar ratio): $Y_{CH_4}=89.39\%$, $Y_{C_2H_6}=5.76\%$, $Y_{C_3H_8}=3.3\%$, $Y_{C_4H_{10}}=1.44\%$, $Y_{N_2}=0.11\%$. Therefore, the thermal properties of mixture were used in the present study. The properties of working fluids varied with temperature and pressure. The thermal properties of each component of LNG or NG were calculated by the REFPROP developed by the National Bureau of Standards.

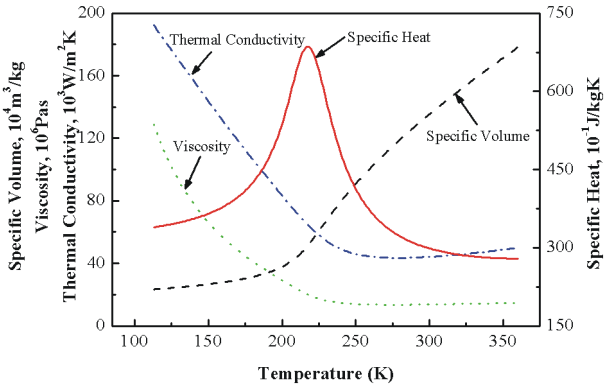

Fig.2 Thermo-physical properties variations of LNG at 9.85 Mpa

The major component of LNG or NG was methane. Fig. 2 shows the values of specific volume, viscosity, and specific heat and thermal conductivity of methane at a pressure of 9.85 MPa. It can be concluded from the variation trend of specific volume that the density decreased continuously with increased temperature, and the decreased trend was relatively significant near the critical temperature. However, the density variation was in the range of the same magnitude and no step variation was found. The specific heat changed sharply and had a maximum value near the critical point. The viscosity and thermal conductivity decreased with the increasing of temperature. The variation trends of thermal properties of other LNG components were as same as methane. The thermo-physical properties of the LNG were calculated by maxing-law based on the properties of each component.

LNG gasification differed from liquid evaporation, in which sharp density deduction and specific heat approaching infinite occurred with phase change. The LNG flow in tubes was consequently considered as single-phase flow rather than two-phase flow with reduced density.

Basic governing equations and Turbulence models. The governing equations of the continuity, momentum and energy [2] were used in the present study. The accuracy of numerical simulations of heat transfer in supercritical fluid may depend on turbulence models. Previous CFD study [3] using the Fluent code revealed the RNG $k-\varepsilon$ turbulence model gives reasonable results in predicting heat transfer of supercritical water, therefore the RNG $k-\varepsilon$ turbulence model was used in this study. **u** is the velocityvector, while u_i is velocity component in special direction $i(i=1,2,3)$. The transport equations for turbulence kinetic energy (k) and its dissipation rate (ε) are [4]:

$$\frac{\partial}{\partial t}(\rho k)+\frac{\partial}{\partial x_i}(\rho u_i k)=\frac{\partial}{\partial x_i}\left[\left(\alpha_k \mu_{eff}\frac{\partial k}{\partial x_i}\right)\right]+G_k+G_b-\rho\varepsilon-Y_M+S_k \tag{1}$$

$$\frac{\partial}{\partial t}(\rho \varepsilon)+\frac{\partial}{\partial x_i}(\rho u_i \varepsilon)=\frac{\partial}{\partial x_i}\left[\left(\alpha_\varepsilon \mu_{eff}\frac{\partial \varepsilon}{\partial x_i}\right)\right]+C_{1\varepsilon}\frac{\varepsilon}{k}\left(G_k+G_{3\varepsilon}G_b\right)-C_{2\varepsilon}\rho\frac{\varepsilon^2}{k}-R_\varepsilon+S_\varepsilon \tag{2}$$

where, G_k represents the generation of turbulence kinetic energy due to mean velocity gradients. G_b is the generation of turbulence kinetic energy due to buoyancy. Y_M represents the contribution of the fluctuating dilatation in compressible turbulence to the overall dissipation rate. The quantities α_k and α_ε are the inverse effective Prandtl numbers for k and ε, respectively. S_k and S_ε are user-defined source terms. The main difference between the RNG and standard $k-\varepsilon$ models lies in the additional term in the ε equation given by

$$R_\varepsilon=\frac{C_\mu \rho \eta^3\left(1-\eta/\eta_0\right)}{1+\beta\eta^3}\frac{\varepsilon^2}{k} \tag{3}$$

where $\eta=Sk/\varepsilon$, $\eta_0=4.38$, $\beta=0.012$. S is the modulus of the mean rate-of-strain tensor, $S=\sqrt{2S_{ij}S_{ij}}$. The effective viscosity μ_{eff} is determined by a differential equation:

$$d\left(\frac{\rho^2 k}{\sqrt{\varepsilon\mu}}\right)=1.72\frac{v}{\sqrt{v^3-1+C_v}}dv \tag{4}$$

where, $v=\mu_{eff}/\mu$, $C_v\approx 100$. In the high-Reynolds-number limit. Eq. (4) gives

$$\mu_t=\rho C_\mu\frac{k^2}{\varepsilon} \tag{5}$$

where $C_\mu=0.0845$.

Boundary conditions. Fig. 1 also shows boundary conditions of the computational domain. At the inlet of the tube, mass flow rate, temperature, turbulence intensity and hydraulic diameter were specified. The outlet boundary condition of the domain was specified as pressure-outlet, and the wall surfaces of tubes were set as heat flux boundary. In order to ensure a fully developed velocity profile before flowing into the heat transfer test section and also no backflow at the outlet, a certain length of tube wall surface was set to be adiabatic in the entrance and exit section. The inlet LNG mass flow rate varied in the range of 0.58-0.81 kg/s, and the inlet LNG temperature were kept constant of 118 K. The heat flux of the tube wall surface was 107 kW/m^2, and LNG outlet pressure was 9.55 MPa. The turbulence intensities at the inlet and outlet were both set to be 10%.

Numerical computations

Numerical methods. In this paper, a finite volume method [2] was used to solve all the governing equations above. Standard scheme was used for pressure treatment. A second-order upwind scheme was used for the discretization of the equations in the current work. The SIMPLE algorithm was used

for the velocity-pressure coupling. Numerical computations were carried out using the popular CFD package Fluent 6.3.26 [5]. For convergence monitoring, residual level for energy equation was less than 10^{-6} and for the other transport equations were less than 10^{-4}. Computations were stopped when all residuals became unchanged with iterations. Default under relaxation factor values were lowered to improve numerical stability. Global mass balances and LNG temperature at the outlet were also checked to ensure convergence.

Computational mesh. Gambit was used to generate the computational mesh as shown in Fig. 1. Most of the cells were of hex or wedge types with low skewness. To reduce computational cost, standard wall functions by Launder-Spalding [6] were utilized for turbulent flows. A further grid independence study has been carried out using several grid sizes. It was found a grid size of 1.5 million cells was fine enough to obtain grid-independent results, and the aspect ratio was 3.68. Using this grid size, all numerical computations were carried out using parallel computing techniques.

Results and Discussion

Heat transfer characteristics of supercritical LNG in horizontal tubes. Fig. 3 (a) shows the LNG

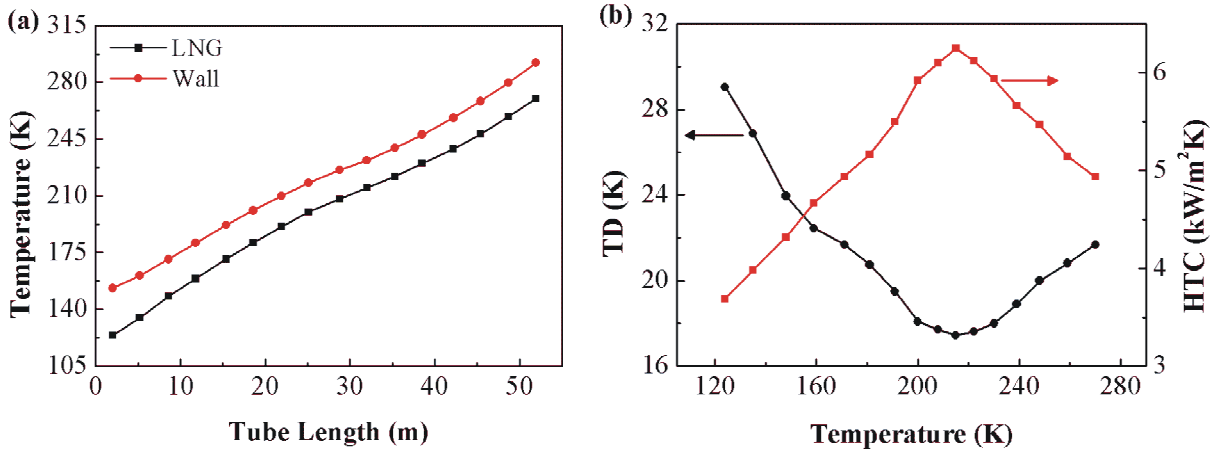

Fig. 3 Heat transfer characteristics of supercritical LNG in horizontal tubes, (a) LNG and inner wall temperature distributions along the ducts, (b) temperature difference between LNG and inner wall , and variation of HTCs with fluid bulk temperature.

and inner wall temperature along the ducts. The temperature of LNG increased along the ducts, and the LNG flow inside the tubes was composed of two stages, as shown in Fig. 3 (b). In the first stage, the temperature was below the critical point, whereas the pressure was above the critical point. The LNG flow was strictly supercritical flow in the second stage when the pressure and temperature were both above the critical point. The discharged NG was a supercritical fluid with large density, and only single-phase was encountered when the LNG was changed to NG during “gasification”. The temperature difference between LNG and inner wall showed different variation trends. The temperature difference decreased with increased fluid temperature when the fluid bulk temperature was below the pseudo-critical point T_{pc}, while the temperature difference increased when the fluid bulk temperature was above the pseudo-critical point T_{pc}, as shown in Fig. 3 (b). Fig 3 (b) also shows the influence of fluid bulk temperature on surface heat transfer coefficients. It can be observed that the surface heat transfer coefficients first increased and then decreased with the fluid bulk temperature, which reached a maximum value when the fluid bulk temperature equaled the pseudo-critical point T_{pc}. et alThe reasonable explain was that the physical properties of supercritical LNG varied sharply with the change of temperature and pressure in regions near the thermodynamic critical and pseudo-critical temperature. The specific heat of supercritical fluid at constant pressures in so-called large specific heat region was generally greater than that in other regions, which resulted in heat transfer enhancement, as previously described by other researches [7].

Influence of the inlet LNG mass flow rate. Fig. 4 shows the influence of the inlet LNG mass flow rate on the surface heat transfer coefficients. Increasing the inlet LNG mass flow rate can significantly improve the surface heat transfer coefficients in the horizontal tubes. The increased velocity of LNG caused by the increased inlet LNG mass flow rate contributed to the increasing of the surface heat transfer coefficients in the horizontal tubes. The surface heat transfer coefficients reached a maximum value in the pseudo-critical temperature point when the mass flow rate was kept constant.

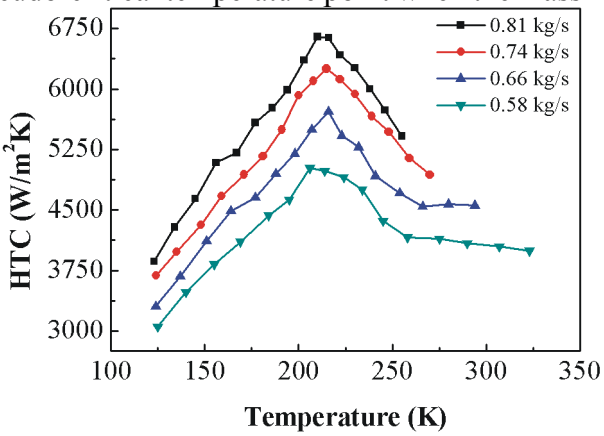

Fig. 4 Variation trends of surface HTCs with the inlet LNG mass flow rate

Conclusions

Three-dimensional computational fluid dynamics (CFD) based modeling and simulation have been conducted to investigate the influence of inlet mass flow rate on heat transfer of supercritical LNG in horizontal tubes. It has been found that the LNG flow in tubes included two stages, the surface heat transfer coefficients first increased and then decreased with the fluid bulk temperature. The surface heat transfer coefficients reached a maximum value when the fluid bulk temperature equaled the pseudo-critical point T_{pc}. Increasing the inlet LNG mass flow rate can significantly improve the surface heat transfer coefficients between supercritical LNG and the horizontal tubes.

Keywords: Submerged combustion vaporizer, LNG, Heat transfer, Supercritical pressure.

Abstract. The submerged combustion vaporizer (SCV) is a kind of equipment used for liquefied natural gas (LNG) vaporization. In order to get insights into the heat transfer of supercritical LNG, numerical simulations were carried out in this paper for investigating heat transfer of LNG in horizontal circular tubes under supercritical pressure. Numerical results showed that LNG temperature at the outlet under the design parameters was 276 K which met the demands of application. The velocity of LNG at the outlet was 12 m/s, and the pressure drop along the ducts was 120 kPa.

Introduction

Natural gas (NG) owns the advantages of safety and cleanness, and its demand is expected to increase in future energy market considering the global energy crisis and the rapid deterioration of the environment worldwide. Liquefied natural gas (LNG) is practical approach for large quantity of NG transportation for its mass storage. The LNG must be vaporized to natural gas before it is used as fuel gas for industrial and domestic purposes. Therefore, efficient and reliable vaporizers for LNG receiving terminals are important. Four types of LNG vaporizers are mainly used in the LNG receiving terminals, namely, open rack vaporizer (ORV), super ORV, submerged combustion vaporizer (SCV), and intermediate fluid vaporizer (IFV).

The structure of SCV is mainly composed of water tank, serpentine tube coils inside the water tank, and burner. The low-temperature NG and the boil off gas (BOG) from the LNG terminals are burned to flue gas as high-temperature heat source. The gas is injected into the water tank to keep the constant temperature of water bath, and the LNG is vaporized inside the serpentine tube coils located inside the water tank. The serpentine tube coils are mainly composed of horizontal circular tubes, and the thermal performance of supercritical LNG in horizontal circular tubes has not been reported.

Base on the above preview, heat transfer performance of supercritical LNG in horizontal circular tubes were studied computationally in this paper. The fields of LNG temperature, velocity and pressure along the ducts under constant inlet temperature, mass flux and wall heat flux were investigated.

Mathematical models

Physical descriptions. The heat transfer of supercritical LNG in horizontal circular tubes is considered here. Fig. 1 shows the schematic diagram of the calculation model which consists of eight horizontal tubes. The outside diameter of the tube is 32 mm with a stainless steel wall thickness of 2.5 mm and the length of the tube is 6308 mm. This tube has been widely utilized in supercritical pressure treatment. In the present study, it was assumed that the working fluid was incompressible, and a constant pressure was used for the physical properties since the pressure drop along the pipe was very small.

Basic governing equations and Turbulence models. The governing equations of the continuity, momentum and energy were used in the present study. The accuracy of numerical simulations of heat transfer in supercritical fluid may depend on turbulence models. Previous CFD study [1] using the Fluent code revealed the RNG $k-\varepsilon$ turbulence model gives reasonable results in predicting heat transfer of supercritical water, therefore the RNG $k-\varepsilon$ turbulence model was used in this study. **u** is the velocity vector, while u_i is velocity component in special direction $i(i=1,2,3)$. The transport equations for turbulence kinetic energy (k) and its dissipation rate (ε) are:

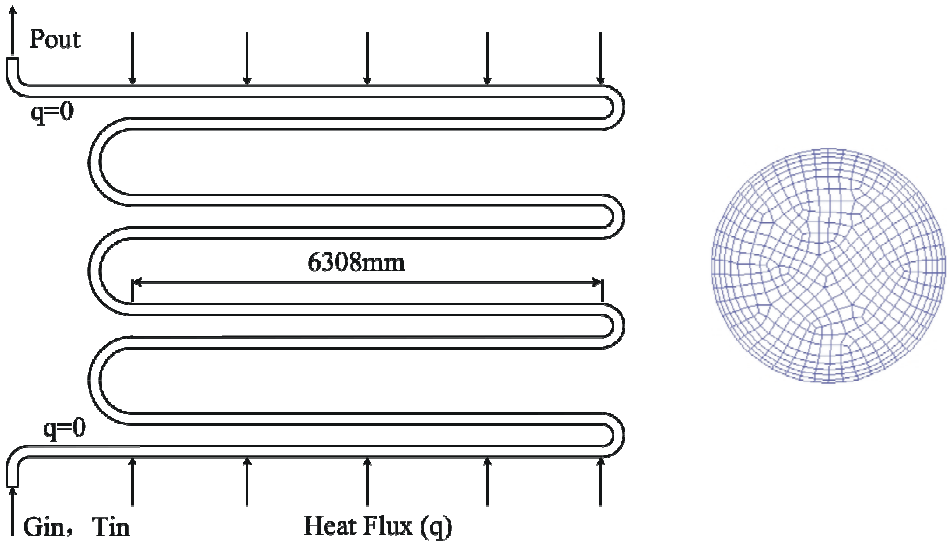

Fig. 1 Schematic diagram of the tubes and the grid configuration in the cross-sectional slice

$$\frac{\partial}{\partial t}(\rho k)+\frac{\partial}{\partial x_i}(\rho u_i k)=\frac{\partial}{\partial x_i}\left[\left(\alpha_k \mu_{eff}\frac{\partial k}{\partial x_i}\right)\right]+G_k+G_b-\rho\varepsilon-Y_M+S_k \tag{1}$$

$$\frac{\partial}{\partial t}(\rho \varepsilon)+\frac{\partial}{\partial x_i}(\rho u_i \varepsilon)=\frac{\partial}{\partial x_i}\left[\left(\alpha_\varepsilon \mu_{eff}\frac{\partial \varepsilon}{\partial x_i}\right)\right]+C_{1\varepsilon}\frac{\varepsilon}{k}(G_k+G_{3\varepsilon}G_b)-C_{2\varepsilon}\rho\frac{\varepsilon^2}{k}-R_\varepsilon+S_\varepsilon \tag{2}$$

where, G_k represents the generation of turbulence kinetic energy due to mean velocity gradients. G_b is the generation of turbulence kinetic energy due to buoyancy. Y_M represents the contribution of the fluctuating dilatation in compressible turbulence to the overall dissipation rate. The quantities α_k and α_ε are the inverse effective Prandtl numbers for k and ε, respectively. S_k and S_ε are user-defined source terms. The main difference between the RNG and standard $k-\varepsilon$ models lies in the additional term in the ε equation given by

$$R_\varepsilon=\frac{C_\mu \rho \eta^3(1-\eta/\eta_0)}{1+\beta\eta^3}\frac{\varepsilon^2}{k} \tag{3}$$

where $\eta=Sk/\varepsilon$, $\eta_0=4.38$, $\beta=0.012$. S is the modulus of the mean rate-of-strain tensor, $S=\sqrt{2S_{ij}S_{ij}}$. The effective viscosity μ_{eff} is determined by a differential equation:

$$d\left(\frac{\rho^2 k}{\sqrt{\varepsilon\mu}}\right)=1.72\frac{v}{\sqrt{v^3-1+C_v}}dv \tag{4}$$

where, $v=\mu_{eff}/\mu$, $C_v\approx 100$. In the high-Reynolds-number limit. Eq. (4) gives

$$\mu_t=\rho C_\mu \frac{k^2}{\varepsilon} \tag{5}$$

where $C_\mu=0.0845$.

Boundary conditions. Fig. 1 also shows boundary conditions of the computational domain. At the inlet of the tube, mass flow rate, temperature, turbulence intensity and hydraulic diameter were specified. The outlet boundary condition of the domain was specified as pressure-outlet, and the wall surfaces of tubes were set as heat flux boundary. In order to ensure a fully developed velocity profile before flowing into the heat transfer test section and also no backflow at the outlet, a certain length of tube wall surface was set to be adiabatic in the entrance and exit section. LNG inlet mass flux and temperature were 0.74 kg/s and 118 K, respectively. The heat flux of the wall surface was 107 kW/m^2, and LNG outlet pressure was 9.55 MPa. The turbulence intensities at the inlet and outlet were both set to be 10%. Typical compositions of the LNG at the inlet were (molar ratio): $Y_{CH_4} = 89.39\%$, $Y_{C_2H_6} = 5.76\%$, $Y_{C_3H_8} = 3.3\%$, $Y_{C_4H_{10}} = 1.44\%$, $Y_{N_2} = 0.11\%$.

Numerical computations

Numerical methods. In this paper, a finite volume method [2] was used to solve all the governing equations above. Standard scheme was used for pressure treatment. A second-order upwind scheme was used for the discretization of the equations in the current work. The SIMPLE algorithm was used for the velocity-pressure coupling. Numerical computations were carried out using the popular CFD package Fluent 6.3.26 [3]. For convergence monitoring, residual level for energy equation was less than 10^{-6} and for the other transport equations were less than 10^{-4}. Computations were stopped when all residuals became unchanged with iterations. Default under relaxation factor values were lowered to improve numerical stability. Global mass balances and LNG temperature at the outlet were also checked to ensure convergence.

Computational mesh. Gambit was used to generate the computational mesh as shown in Fig. 1. Most of the cells were of hex or wedge types with low skewness. To reduce computational cost, standard wall functions by Launder-Spalding [4] were utilized for turbulent flows. A further grid independence study has been carried out using several grid sizes. It was found a grid size of 1.5 million cells was fine enough to obtain grid-independent results, and the aspect ratio was 3.68. Using this grid size, all numerical computations were carried out using parallel computing techniques.

Results and Discussion

Temperature, velocity and pressure fields. Fig. 2 shows typical temperature fields of the horizontal tubes on symmetric plane under the design parameters. As can be seen from the figure, the temperature of LNG increased along the ducts, and the mass-weighted average temperature at the outlet was 276 K. Since the LNG temperature needs of industrial application is above 273 K, the design parameters are reasonable.

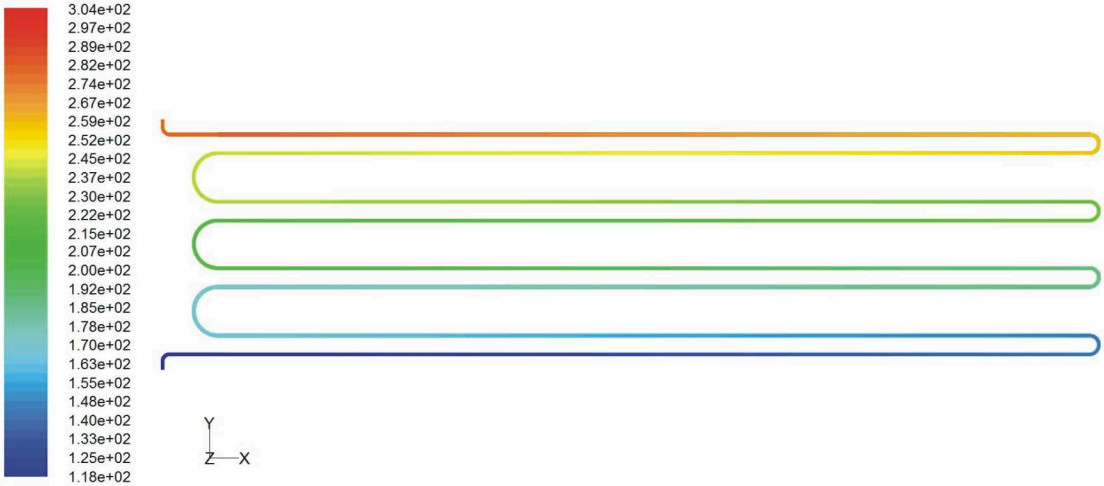

Fig. 2 Temperature distributions on the tube symmetric plane

Fig.3 shows the velocity fields on tube symmetric plane. It can be observed from the figure that the velocity of LNG increased from 3 m/s at the inlet to 12 m/s at the outlet under the constant inlet mass flow rate of 0.74 kg/s. The increasing of LNG velocity was attributed to the decreasing of supercritical fluid density caused by the increasing of temperature. Fig.4 shows the pressure fields on tube symmetric plane, which reveals the total pressure drop from inlet to outlet was 120 kPa.

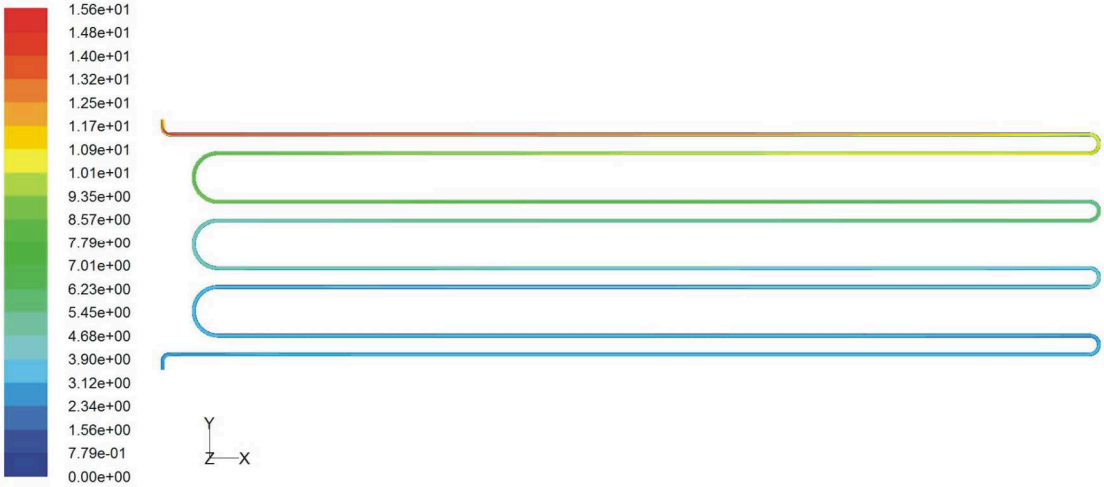

Fig. 3 Velocity distributions on the tube symmetric plane

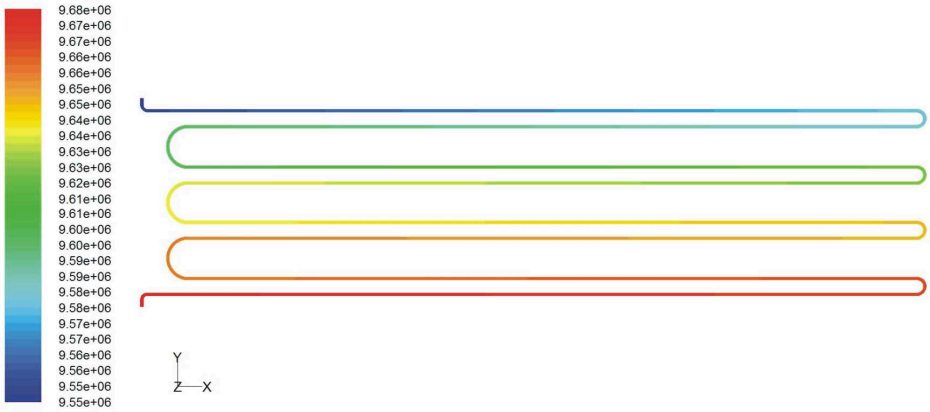

Fig. 4 Pressure distributions on the tube symmetric plane

Conclusions

Three-dimensional computational fluid dynamics (CFD) based modeling and simulation have been conducted to investigate the heat transfer and flow performances of supercritical LNG in the horizontal circular tubes for application in LNG vaporization. It has been found that LNG temperature increased from 118 K to 276 K under the design parameters, which met the requirements of application. The LNG velocity increased due to the decreasing of fluid density with the increasing of the temperature. The LNG velocity at the outlet was 12 m/s, and the pressure drop along the ducts was 120 kPa.

Keywords: Municipal solid waste, Pyrolysis, Characteristics, Kinetics analysis

Abstract. Wood-based materials from Municipal Solid Waste have the potential of covering a significant part of the future demand on gasification capacities. However, their pyrolysis kinetics and gasification behavior has not yet been fully investigated. This paper describes the pyrolysis characteristics of typing paper and Chinese parasol from municipal solid waste applying the non-isothermal thermogravimetric analysis, the apparent activation energy and the pre-exponential factor were obtained by kinetics analysis at the heating rate of 10/20/40 $^{o}C \cdot min^{-1}$.

Introduction

Municipal solid waste has become a serious environmental issue due to the increase of the produced waste quantities and the recently discovered limitations and impacts of the existing waste treatment concepts. In 2012, there are 160 million tons Municipal Solid Waste (MSW) being collected in a mixing way and cleaned out in China [1]. There are two major ways to dispose waste, which are landfill and incineration. A lot of flammable gases were generated in landfill, which led to explosions. The dioxins are inevitable under current techniques in combustion process of Chinese waste with high moisture content and complex substances. Concerning the usage of wastes as a substitute fuel for coal, it is important to have knowledge on its thermal properties and reaction kinetics.

Experimental

2.1 Materials. Materials tests included wood-based products, which represent two different qualities: typing paper and Chinese parasol. The biomass that was shattered to 74μm mainly consists of cellulose, hemicellulose and lignin. The pyrolysis and combustion processes of the cellulosic materials are complex because of the simultaneous degradation of the three components.

Table 1 Proximate analysis of Materials [wt. %, ad]

variety	moisture	volatile matter	ash	fixed carbon	Qgr.ad[$MJ \cdot kg^{-1}$]
Typing Paper	4.75	79.37	12.24	7.99	13.19
Chinese parasol	9.88	84.09	0.89	13.54	17.72

2.2 Apparatus and Procedures. Experiments were carried out in a TGA system (WCT-2C) produced by Beijing Optical Instrument Factory. The experimental apparatus is schematically shown in Fig. 1. The reactor consists of a quartz tube (22mm internal diameter) placed in an oven, which can be operated at a temperature up to 1400°C. The sample holders are two ceramic pans (5mm in diameter and 8mm in height). The inlet gas, of which the flow rate is controlled by a flow meter, is introduced to the reactor from the upper of the tube, whereas the outlet gas emits from the middle of the tube. The measurements of sample weight and reaction temperature are continuously recorded in a computer. A more detailed description of the apparatus can be found in [2].

In order to identify the behavior of selected fuels, thermo gravimetric tests were performed under inert atmosphere, at ambient pressure and different heating rates. The flow rate of inlet gas was kept at 60 ml·min^{-1}.

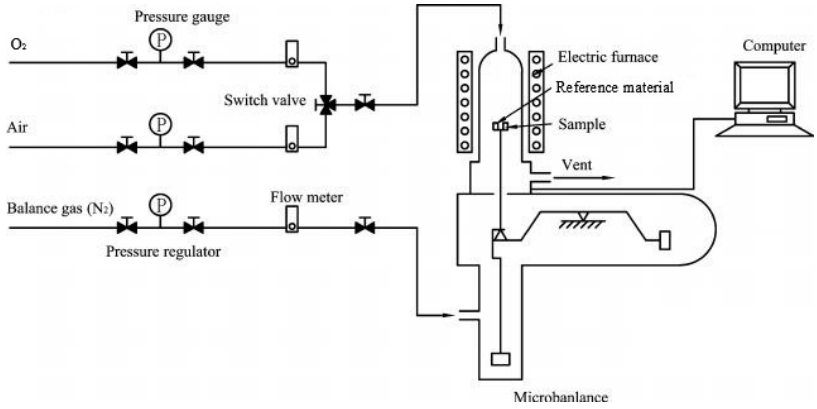

Fig. 1 Schematic diagram of the experimental apparatus

2.3 Evaluation Criteria. Pyrolysis involves a series of chemical and physical processes that contribute to the overall empirical weight loss in thermo gravimetric analysis. Differential method and integral method are two main methods to determine the apparent activation energy and pre-exponential factor. Coats-Redfern integral method is widely used to analysis the kinetic parameters of the non-isothermal pyrolysis process [3, 4, 5].

According to the Arrhenius law:

$$\frac{\mathrm{d}\alpha}{\mathrm{d}t} = A\exp(-E/RT)(1-\alpha)^n \tag{1}$$

where A and E are the apparent pre-exponential factor and activation energy, respectively. α is the conversion (reacted fraction) which can be expressed by:

$$\alpha = (m_0 - m)/(m_0 - m_\infty) \tag{2}$$

Where m_0, m_∞ and m represent the initial, ultimate and instantaneous mass of sample, respectively.

In the TGA experiments, $\beta = \mathrm{d}T/\mathrm{d}t$ represents the heating rate, so Eq. (1) can be transformed as follows:

$$\frac{\mathrm{d}\alpha}{(1-\alpha)^n} = \frac{A}{\beta}\exp(-E/RT)\mathrm{d}T \tag{3}$$

Coats-Redfern equation can be derived through integral transformation from Eq. (3) as follows [9]:

$$\text{if } n=1,\quad \ln\left|\frac{\ln(1-\alpha)}{T^2}\right| = \ln[\frac{AR}{\beta E}(1-\frac{2RT}{E})] - \frac{E}{RT} \tag{4}$$

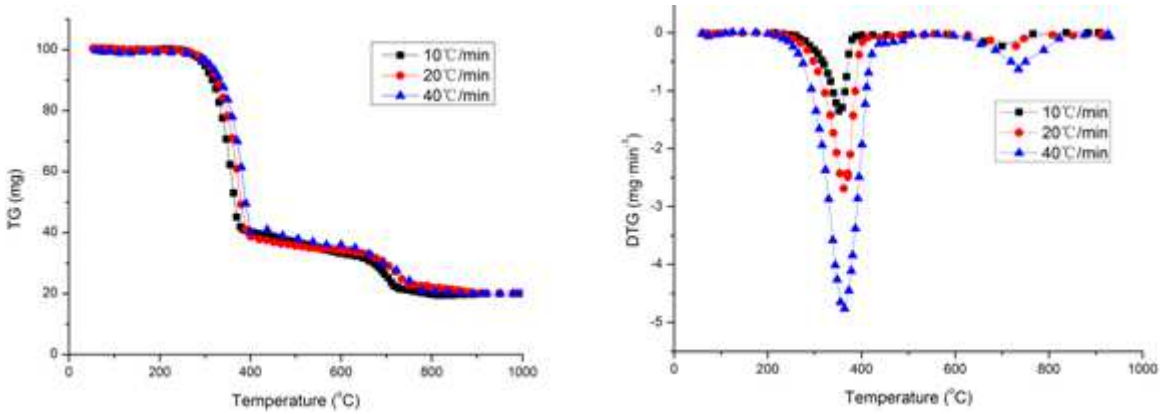
$$\text{if } n\neq 1,\quad \ln\left|\frac{1-(1-\alpha)^{(1-n)}}{T^2(1-n)}\right| = \ln[\frac{AR}{\beta E}(1-\frac{2RT}{E})] - \frac{E}{RT} \tag{5}$$

For the temperature range of reaction, $E/RT \gg 1$, so $\ln[AR/\beta E(1-2RT/E)]$ is almost constant. In order to obtain kinetic parameters, PVC and PP can be assumed as first-order reaction using the Coats-Redfern equation above to evaluate the apparent activation energy and per-exponential factor. Thus a plot of $\ln\left|\ln(1-\alpha)/T^2\right|$ versus $1/T$ should be result in a straight line with the slope equal to $-E/R$ for the first order kinetics.

Results and Discussion

3.1. Paper samples

Experiments were carried out in different heating rates. A comparative analysis of the obtained TG(weight loss)and DTG(weight loss rate) curves for paper samples is presented Fig.2.



(a)TG of Paper in N_2 atmosphere (b) DTG of Paper in N_2 atmosphere

Fig. 2 TG/DTG analysis curves of paper pyrolysis in different heating rates

The paper samples include many complex additives. Fig.2 shows the TG and DTG curves of typing paper. The decomposition pattern reveals two distinct peaks on the DTG curves: (1)low temperature regions (290-490℃), which could be volatile release from cellulose, hemicellulose and lignin and (2)medium temperature regions (650-750℃), which could be volatile from additives. Between the two reactions, no decomposition zone is observed.

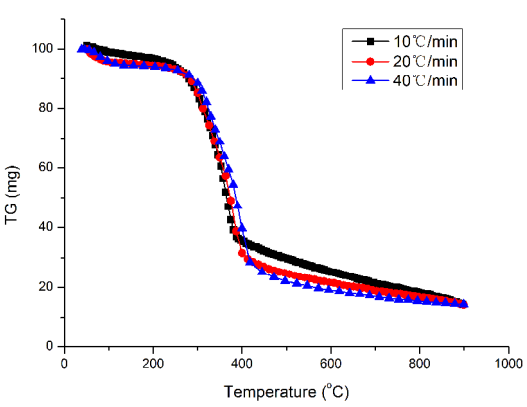
Fig.2 shows the effect of heating rate on the paper pyrolysis behaviors with the particle size of 74μm. It can be observed that, the derivative thermogravimetric (DTG) curves indicating the paper pyrolysis rate during the non-isothermal experiments shift to higher temperature zone with the increase of heating rate. This is due to more obvious thermal hysteresis at higher heating rate [6]. The characteristics of Typing Paper pyrolysis are presented in Table 2. With the increase of heating rate, the peak temperature and maximum DTG of both the two phase were increased.

Table 2 Characteristics of Typing Paper Pyrolysis

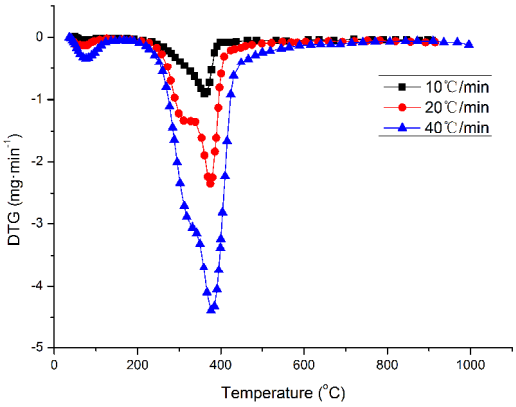
Heating rate[$^{o}C \cdot min^{-1}$]		10	20	40
First phase	Temperature range[^{o}C]	268-385	289-389	295-397
	Peak temperature[^{o}C]	352	362	364
	Maximum DTG[$mg \cdot min^{-1}$]	1.35	2.69	4.76
Second phase	Temperature range[^{o}C]	669-717	681-748	692-779
	Peak temperature[^{o}C]	700	730	735
	Maximum DTG[$mg \cdot min^{-1}$]	0.23	0.23	0.63
Total weight loss [%]		80.12	80.21	80.23

3.2. Chinese parasol samples

A comparative analysis of the obtained TG(weight loss)and DTG(weight loss rate) curves for Chinese parasol samples is presented in Fig.3. The major composition of Chinese parasol is volatile matter, which consists of cellulose, hemicellulose and lignin. It can be observed from Fig. 3(a, b) that the TG process of Chinese parasol consists of just one phase between 250-410℃, because of the simultaneous degradation of the three components. The total weight loss is about 85.7% for each test. The characteristics of Chinese parasol pyrolysis were presented in Table 3. Thermal hysteresis phenomenon also exists in pyrolysis of Chinese parasol in different heating rate as Typing paper, which is observed in the table 3.



(a)TG of Chinese parasol in N_2 atmosphere



(b) DTG of Chinese parasol in N_2 atmosphere

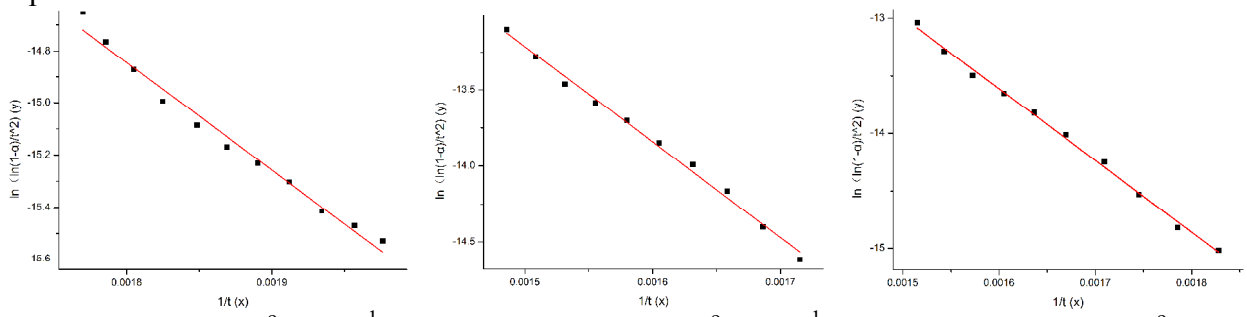
(f)The second phase at 40°C•min^{-1}

Fig.4. Arrhenius plots for typing paper pyrolysis

Table 4 Kinetic analysis of typing paper pyrolysis

Heating rate[°C·min^{-1}]	10				20				40			
	E[kJ·mol^{-1}]		A[min^{-1}]		E[kJ·mol^{-1}]		A[min^{-1}]		E[kJ·mol^{-1}]		A[min^{-1}]	
First phase	1.12	10^5	9.99	10^{11}	1.00	10^5	3.17	10^5	0.81	10^5	1.62	10^6
Second phase	2.28	10^4	7.77	10^{-8}	1.65	10^4	1.44	10^{-8}	1.25	10^4	2.21	10^{-8}

Fig.5 shows the straight line of Y-ln|ln(1-α)/t^2| versus X-1/t for two weight loss of Chinese parasol pyrolysis at different heating rates. The kinetic analysis results of Chinese parasol pyrolysis are presented in Table 5.



(a) The phase at 10 ^{o}C•min^{-1} (b) The phase at 20 ^{o}C•min^{-1} (c) The phase at 40 ^{o}C•min^{-1}

Fig.5. Arrhenius plots for Chinese parasol pyrolysis

Table 5 Kinetic analysis of Chinese parasol pyrolysis

Heating rate[^{o}C·min^{-1}]	10		20		40	
	E[kJ·mol^{-1}]	A[min^{-1}]	E[kJ·mol^{-1}]	A[min^{-1}]	E[kJ·mol^{-1}]	A[min^{-1}]
phase	34279	0.0002	51667	1.6790	52163	1.2212

It can be observed that both the apparent activation energy and pre-exponential factor stay at the same magnitude for one sample in different heating rates.

Conclusions

The pyrolysis of Typing paper and Chinese parasol were studied applying the non-isothermal thermogravimetric analysis. It is found that there are two weight loss phases in Typing paper TG curse, while Chinese parasol just one weight loss phase, which are in accordance with their composition. The DT curves indicating the wood-based samples pyrolysis rate during the non-isothermal experiments shift to higher temperature zone with the increase of heating rate. The peak temperature and maximum DTG of all phases were increased with the increase of heating rate.

Keywords: FCB, 35% bypass, Subcritical units.

Abstract. Power plant will be threatened in the blackout, a tiny carelessness could result in serious damage to the equipment. FCB (FastCutBack) refers to the function that during the normal operation, because of the internal fault or external fault the unit take the moment to get rid of all external power supply instantaneously, and keep the boiler continue running at the lowest load to supply the auxiliary power. In this paper, the new designed FCB control strategy has been applied in a 350MW subcritical coal-fired unit. Through some control logic optimization and debugging, the viable control parameters is obtained, the result of unit FCB function test is excellent and the safety of unit are effectively improved.

Introduction

With the rapid development of the national economy, the social demand for electric energy is increasing gradually. The grid is getting large day by day, and the security of electric network becomes important more and more. All over the world there have been some occurrence of severe balckouts, Natural disaster is a serious threat to the safe operation of power grid, and it may cause some power plant in the state of blackour in some areas[1].

During the state of the blackout, power plants will face a threat. A tiny carelessness may cause large damage of equipment, and the status and parameters of the unit will change dramatically, and the power of the cooling water, compressed air equipment will be lost. Most of the equipment of the unit will lost control. The safe operation of major equipment relies solely on the battery or backup diesel generators, and the safety factor of power plant decreased significantly. From the blackout accident of domestic power plant, we can find that there will be some bad effects on the equipments more or less, and even severe damage of the equipment. If the unit realize the FCB function, the unit could supply the auxilary power by itself in the most dangerous time, we can safely shutdown the unit or wait for the recovery of power grid. So there exist the following benefits for power plant[2] [3].

To unit security, FCB function can make the unit continuesly running after load rejection, and guarantee that system parameters will not exceed the limits in the whole process. The power plant can choose shutdown, or waiting for the recovery of grid, which inhance the security of the unit.

To reducing cost of unit, Comparing with the normal control strategy, the FCB can reduce times MFT, The boiler will be in the state of high parameters. After the cause of the accident is confirmed and solved, units can make a hot restart, so we can save a lot of time and energy, it is beneficial to reducing the operation cost.

When the unit realizes FCB function, the unit has the ability to supply the auxiliary power by itself. It could help the grid to return to normal as soon as possible, and also could safely shutdown the unit. So the FCB function has become an urgent topic of research.

Improvement of the difficulties of FCB functions

The overpressure of boiler. After the FCB action, turbine valve quickly turn down, while the boiler has larger inertia for the thermal storage, and the capacity of steam production will reduce slowly, which could cause the serious load imbalance of boiler and turbine [4]. Bypass capacity is only 35%,

so overpressure of boiler must happen. The solution is opening the bypass as soon as possible, quickly reducing the thermal load as much as possible. It is important to make short-term pressure relief with the PVC and safety, and then to use the bypass system to control pressure decreases slowly to a target value.

The rapid reduction of load of boiler. In the process of FCB, the bypass capacity is 35% , so it is needed to rapidly reduce of boiler load under 35%. Considering the unit characteristics, it is determined that during the FCB action two mills still run, rate of reduction load of boiler automatically changes to 100%/min, load target automatically changes to 35%. Considering the rapid reduction of the boiler load, furnace pressure fluctuation, and the unstable working condition of furnace, immediately boiler burner should be shut down from top to bottom automatically, and retained two coal mill running at least[5]. The FCB signal in fig. 1 is used by the load control system of the boiler.

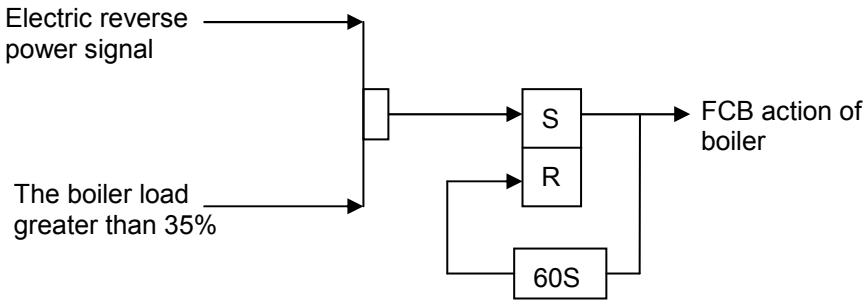

Fig. 1 FCB signal for boiler

DEH speed control. PLU is the function that when load rejection occurs, this circuit is used to avoid turbine overspeed. When the imbalance happens between turbine power and turbine load, it will cause overspeed of the turbine. When the PLU loop detect the situation, CV and CIV will be closed quickly to control the speed of turbine. ACC is acceleration control loop that When the turbine speed is greater than 3060rpm, the acceleration is greater than 49rpm, ACC will take an action to quickly close IV to control the speed of turbine.

Supplement of working fluid. After the FCB take an action, even if all the mills except 2 mills shut down, it still need some time to reduce the load to 35% for boiler, because the time delay of boiler and inertia of fuel system exit[6]. At this period, the surplus steam must be discharged by superheated steam safety valve and the PCV to the atmosphere. It caused a certain degree of imbalance of refrigerant cycle in perspective.

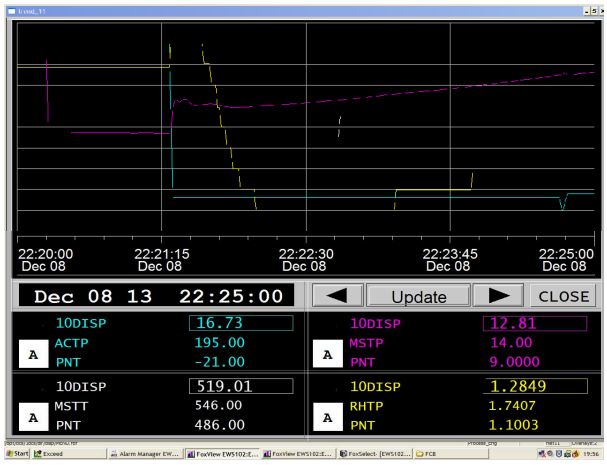
Switch of steam source of steam feedwater pump. During normal operation, steam source of feedwater pump is from four stage extraction of turbine. After load rejection, pressure of extraction steam falls. To maintain operation of feedwater pump, the steam source must quickly be cut into standby steam source. And it must meet 2 requirements during the steam source switch. One is the coal and water ratio imbalance is still within the allowable range, that is the overtemperature will not happen. The other is to maintain the hydrodynamic stability of boiler, that means superheat control of water cool wall is within the permitted value[7]. Switch to standby steam source can be in two ways, one is from four stage extraction of turbine to the auxiliary steam supply, the other is switch to the high pressure steam source from low pressure steam source

The logic of boiler, turbine and generator. The original design of the unit contains forward and reverses function that is boiler MFT action interlock ETS action, turbine ETS action interlock protection for generator; and generator protection action interlock turbine ETS action, ETS action interlock boiler MFT action (load greater than 35%). According to the purpose of FCB function, the reverse-power device to the generator protection circuit should be canceled.

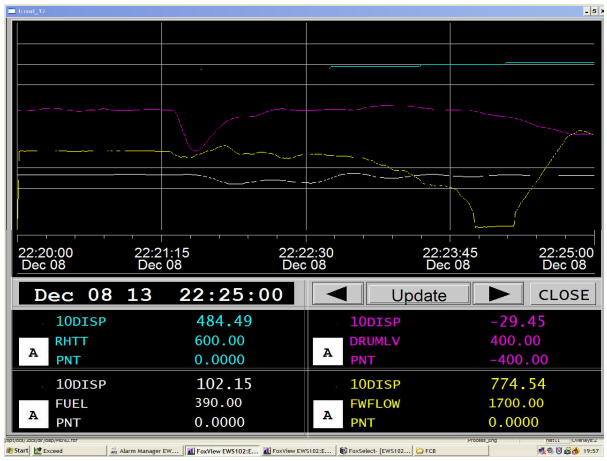
Engineering Application

In this paper, the new designed FCB control strategy has been applied in a 350MW subcritical coal-fired unit. Through some control logic optimization and debugging, the viable control

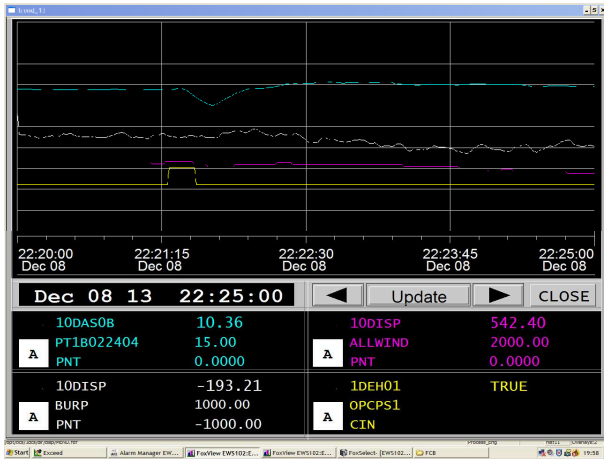
parameters is obtained, the result of unit FCB function test is excellent and the safety of unit is effectively improved. The curve of 50% FCB result is shown in Fig. 2. The curve of 100% is shown in Fig. 3.



(a)

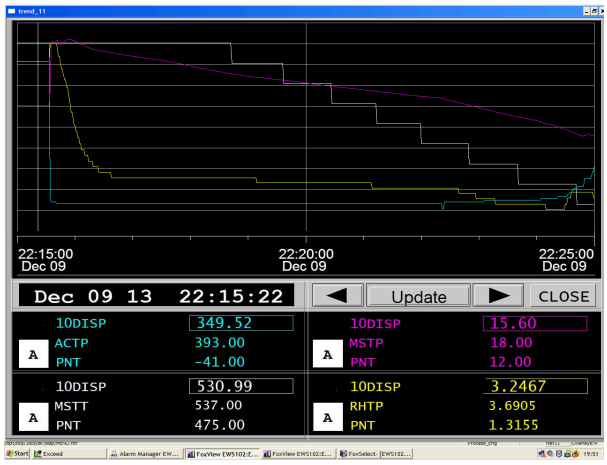


(b)

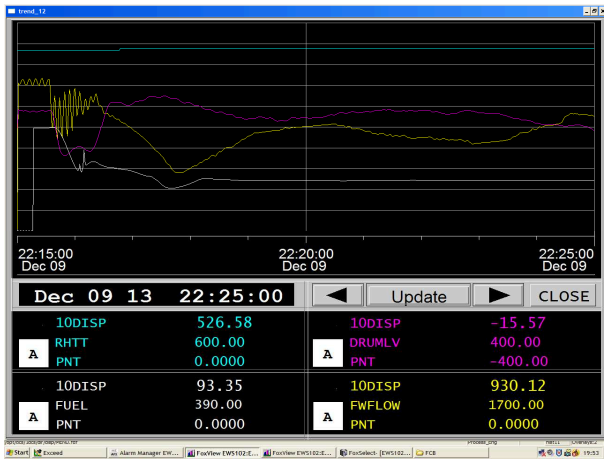


(c)

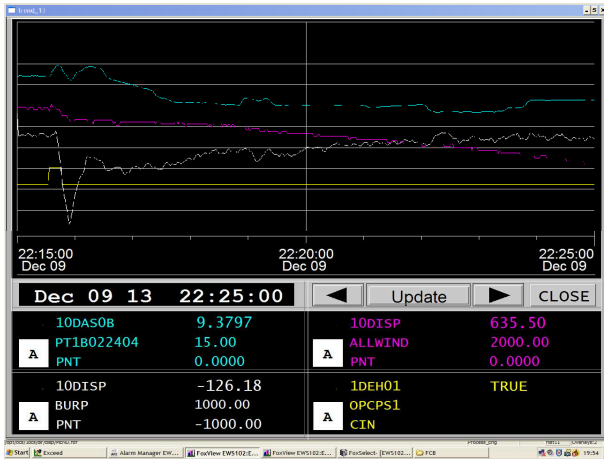
Fig. 2 50% FCB parameter curve



(a)



(b)



(c)

Fig. 3 100% FCB parameter curve

Conclusion

According to the result of the 50% load and 100% load FCB test, we can get the conclusion that in the process of the FCB test the 350MW unit with the bypass system of 35% BMCR could be stable at 3000rpm quickly through effective the control strategy. During the FCB test of 50% load and 100% load the OPC take action only once, and it effectively prevent the overspeed of the turbine. During the test all the main parameters are also in a stable state.

Keywords: micro-channel, flow boiling, experimental system

Abstract. To further deepen exploration of boiling in micro-channels a set of experiment system for micro-channel flow boiling is homemade, which includes experimental equipment required and experimental pieces of the design process. The channel is width of 100mm, length of 1200mm, and the groove depth of 95mm. The gasket thickness is 0.5mm, 1.0mm, 1.5mm or 2.0mm.

Introduction

Flow boiling phenomenon in micro-channels has aroused widespread concern of scholars home and abroad. After many efforts, scholars have got a lot of experimental data of flow boiling in micro-channels, which is about heat transfer, pressure drop and the identification. Due to the particularity of the micro-channels, the experiment is affected by many factors, such as the machining precision, measurement error, etc.. So the experiment conclusions of different scholar's will often be different or even opposite [1-8]. So far the research of boiling heat transfer and resistance properties about micro-scale flow, we still do not have a mature and consistent conclusion. In order to further deepen exploration of boiling in micro-channels, we have established a set of micro channel flow boiling experiment system.

The experimental system

We have established a set of experimental units, used to study the flow boiling heat transfer and pressure drop characteristics of vertical rectangular micro-channels. The experimental station apparatus is composed by many devices, such as metering pumps, filters, pre-heating means, the volumetric flowmeter, a thermocouple, pressure gauge, a differential pressure transmitter, data logger, computer, image processing apparatus, electrically heated sheet, condenser, accumulator, etc..

What we used the working fluid in this experiment is deionized water, which is boosted by diaphragm metering pump and is circulated in the system. The de-ionized water is preheated by pre-heating means and its temperature is stabilized at between 35℃~40℃. Through the flowmeter it enters the test section inlet, where absorbs heating of sides of the heating plate, the temperature of which increases up to a boiling state. The steam or steam - water mixture generated in the boiling process flows through the condenser and is condensed into a low-temperature water, which flows back to the tank and completes a cycle.

The flow boiling test section length is 1200mm, in which the effective heating length is 1100mm. In the course of experiments we adjust the inlet flow rate and the inlet temperature of the deionized water to observe different flow pattern. The two surfaces of the test section are transparent plexiglass plate of 5.0mm thickness to facilitate visualization observations.

The experimental section of the present experiment system is based on two-channel non concave relative composition. The channel is width of 100mm, length of 1200mm, and the groove depth of 95mm. Front and rear sides with plexiglass seal are to achieve the visual observation. Heating plate is added to the tank, which is length of 1100mm, width of 90mm, the maximum heating power of 500W per piece. By changing the thickness of the gasket of the channel end portion, we obtain the desired width of the channel. The gasket thickness is 0.5mm, 1.0mm, 1.5mm or 2.0mm. In order to meet the requirements of the experimental precision, the composed two faces of channel are strictly machined,

precisely grinding treated, after channel after surface treatment finish of 20 microns. Finish of the channel after surface treatment can be up to 20 microns. The range of parameters is shown in Table 1.

Table1. Microchannel flow boiling range of experimental parameters

Project and No.	Channel size (mm)	Left heating power (W)	Right heating power(W)	Volume flow L/h
Exp. pieces 1#	0.5	0~500	0~500	0~10
Exp. pieces 2#	1.0	0~500	0~500	0~13
Exp.l pieces 3#	1.5	0~500	0~500	0~16
Exp. pieces 4#	2.0	0~500	0~500	0~20

Laboratory instruments and precision required

FMC-8DLiquid volume flow meter. Hefei Forstar Measurement and Control Technology Co., Ltd.. 24V voltage supply, range:0~20L/h, the measurement accuracy of 0.2. In addition to the measurable general uniform fluid viscosity, also measured high viscosity fluid (honey, oil, pulp, etc.). It can measure not only a single solution of fluid parameters, and can also measure multiphase flow. Whether the medium is laminar or turbulent flow, and do not affect the measurement accuracy.

JWM20/1.0 Diaphragm metering pump (with pulse damper). The Shanghai RONGXING Pump Co., Ltd. production. Maximum displacement 20L / h, the itinerary can be in the range of 0 to 100% stepless adjustment. The transport medium maximum stroke measurement accuracy of ± 1%. Suitable for conveying a temperature of -30 to 120°C, a kinematic viscosity of 0.3 ~ 800mm2/s without solid particles of the medium.FMC8201Pressure transmitter. Hefei Forstar Measurement and Control Technology Co., Ltd.. It uses differential pressure-sensitive chips and other key components of Switzerland HUBA production, can be used to measure small pressure. Range: 0 to 50 kPa and an accuracy of ± 0.25% Operating temperature range: -10 to 120 ° C, resistance to static pressure up to 20MPa.

FLUKE2625A Data collection instrument. Fluke company. Built-in non-volatile memory can save up to 2000 scans data for stand-alone applications, with RS-232 interface, 21 analog input channels, ± 0.1 ° C resolution. XMX618 Smart single-channel communications controller. Beijing Huibang Technology Co., Ltd. production, the supply voltage of 24V with RS485 output, accuracy class 0.2. CT488 Vacuum pressure gauge. Zhuji City, Zhejiang Hongsen Machinery Co., Ltd. production, range 0 ~ 0.5MPa, an accuracy of ± 2.5%. T-type thermocouples. The homemade, base metal thermocouples, the temperature range of -200 to 400°C. Tube-fin air-cooled condenser. Boxing County Shandong Province Jn Yue refrigeration equipment factory production. Air volume 8.04m3/min. Temperature adjustable pre-heating device. The maximum heating power 2KW, the temperature can be adjusted between 0~100°C.

Experimental Procedure

Check various parts of the opening and closing of the correct state to open a total power. Start the refrigeration unit, to ensure the normal work of the condenser.Turned on each instrument, and start the data collection instrument and differential pressure transmitters.Start diaphragm metering pumps, and regulate the flow, observed each instrument is working in the expected value. Turn on the power of the heating plates, heating the test pieces of the microchannels. Stable when the expected value for a period of time required for recording data. Adjust parameters, enter the next condition. Repeat steps 1-7 until you have tested all conditions.

Measurement of the experimental parameters

5.1 The flow boiling experiments need to measure the following parameters

Water temperature in the preheater and experimental pieces of the import and export of the temperature of the working fluid. Axial wall temperature distribution along the test section.

Differential pressure and the pressure of the import and export of the test section. Electric heating power. Heating current and voltage. Volumetric flow rate of the working conditions.

5.2 Thermocouple arrangement

The measurement of the temperature of the wall is completed by uniformly arranged in both sides of the wall surface 10 of the thermocouple. The thermocouples are respectively arranged in a position of a distance entrance 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000 mm. Both sides of the wall surface at the same position disposed thermocouple is in order to prevent damage to the thermocouple measurement error and the heating process may occur. There are also two thermocouples used to measure the inlet and outlet of the test section temperature of the working fluid.

Because of the smaller channel size of this experiment, we directly in the flow channel into the thermocouple measurement will result in the destruction of the shape of the flow channel. Will also affect the distribution of gas-liquid two-phase flow. That it can not obtain accurate experimental results. Therefore, in the experimental process will thermocouple disposed in the inside of the channel concave. In order to ensure the system operating pressure and control the deformation of the test pieces, we used in the experiments of the channel having a thickness of 5.0mm. If the thermocouple is arranged directly on the inner surface of the recess for temperature measurement, and this is bound to cause a large temperature gradient, resulting in inaccurate temperature of the fluid in the measurement channel. In order to minimize the temperature gradient, we punch on the channel and then put into the thermocouple. In a predetermined place of the thermocouple location, we use the drill 4.0mm deep blind holes. First thermocouple probe into the hole, then solder thermocouple probe is close to the channel surface welding.

5.3 Heating uniformity test

Before the formal experiment, we first make heating uniformity testing of heat chip to ensure that the experimental results are accurate and reliable. The heated film is a self-made by heating wire evenly wound on mica. Mica sheet has a certain toughness, if its not close enough contact with the inner surface of the channel groove will form the thermal contact resistance, which leads to the heating effect can not meet experimental requirement. To avoid this situation, we must test for its heating uniformity.

Taking into account the inner surface of the channel groove finish is not enough to reduce the contact thermal resistance used in this experiment to ensure the tightness with the heater chip bonded smear high temperature thermal silica in the inner surface of the channel groove. After the completion of the heating plate laying, placed three aluminum silicate insulation materials for thermal insulation and fire retardant. The first installation of the cover, and then the insulation materials and heating plate is pressed against the inside surface of the channel groove.

After completion of the assembly of test pieces, test its heating uniformity. Heating with 220V AC power supply. Installation of leakage protection system to ensure the experiment safety. The test by FLUKE2625A. The data acquisition system has data-logging, real-time access to the temperature of the measuring point data. Some of the test data as shown in Table 2. Through the analysis table within the data, the maximum deviation of the temperature of 20 measurement points are located within ± 1.5℃, indicating that whether the heater chip mounting method or temperature measurement point arrangement are feasible.

5.4 System heat balance calculations

The heat loss in the experimental result is mainly due to the convective heat transfer between the test section and the environment. Despite insulation measures, this heat loss can not be ignored. To obtain reliable results, we must make the calculation of the heat balance. Taking into account the thermal equilibrium of multiphase flow calculation is more complicated, and many factors are difficult to determine, we have adopted a single-phase flow heat balance to calculate the heat loss Q_{loss} of the test section. Included in the heat flux heat loss formula is as follows.

$$q=(Q-Q_{loss})/A \ . \quad (1)$$

The boiling incipience is an important turning point in the flow boiling heat transfer and has an extremely important role for the study of the role of boiling heat transfer enhancement. Get to start boiling length is calculated as follows by thermal equilibrium.

$$C_pG(T_{L,sat}-T_{L,in})=q_SZ_{sat}\ . \quad (2)$$

Before boiling incipience of subcooled boiling phenomena have emerged. Through flow visualization method to determine the location of the cold boiling incipience Z_{ONB}.

According to the experimental data the rate of heat loss of the present experiment is about 9% by Formula 1 and Formula 2 calculations.

Table 2 Heating uniformity test temperature data recorded

Item No.	Temperature ℃

Key Words: SiO_2–TiO_2 nanocomposite; flue gas mercury; ratio of TiO_2 / SiO_2; UV irradiation

Abstract: SiO_2–TiO_2 nanocomposite was synthesized by an ultrasound-assisted pure physical method to oxidize elemental mercury (Hg^0) in simulated flue gas. Due to its low cost and photocatalytic ability, SiO_2 was used to dope TiO_2 to modify the TiO_2 photocatalyst. We put different ratio of TiO_2 / SiO_2 under the UV irradiation to get a low Ti/Si doping ratio and high flue gas mercury removal efficiency of SiO_2–TiO_2 nanocomposite catalyst. It was found that the photocatalytic activity of nanocomposite materials did not significantly improve, or even decline. This is mainly because that the presence of too much porous SiO_2 may affect TiO_2 on the effective absorption of light and direct adsorption of contaminants. When Ti: Si ratio was 2:1, SiO_2–TiO_2 nanocomposite catalyst reached its highest elemental mercury removal efficiency in the simulated flue gas.

Introduction

In recent years, with the rapid development of social economy, people's living standards frequently improves and people pay more and more attention to the influence of environment on the quality of life. Year after year all kinds of laws, regulations and policies on modern industrial pollutants emission standards has also improved, and the power plant emissions of heavy metal mercury is increasingly brought the attention of people. A lot of scholars have done much research on limiting the emissions of the metal mercury [1-4], In which photocatalytic technology is an emerging and rapid development in science and technology. At present, the materials in the field of photocatalytic technology adopted by the photocatalyst are N type semiconductor materials, such as TiO_2, ZnO, Fe_2O_3, SnO_2 and WO_3, etc.TiO_2 has been widely accepted because of its chemical and biological inertness, strong oxidizing power, non-toxicity and long-term stability against photo and chemical corrosion(Li et al,2011; Ghanbary et al,2012).

As the development of nanotechnology, titanium dioxide (TiO_2) nanocomposite has been widely used in photocatalysis field. Due to the character of nanomaterials (the surface effect, volume effect and quantum size effect and macroscopic quantum tunneling effect), make the nano TiO_2 have different physical and chemical properties compare to other block solid. It has big specific surface area, high density surface lattice defects, and high surface energy. What's more, because the nano SiO_2 [5] possesses small particle size, large specific surface area , carrying a small amount of catalyst active ingredients can achieve high catalytic activity, effectively reduce the cost of catalyst, improve the catalytic efficiency, and can extend the life of the catalyst. Such as TiO_2 - SiO_2 nanocomposite mixed with proper amount of SiO_2 is not only reduced the amount of TiO_2, reduces the cost but also to some extent improve the photocatalytic activity of TiO_2 [6-9]

In this paper, we make power plant flue gas emissions of mercury contamination can be reasonably and efficiently reduced as the research target. We design a method that it use TiO_2-SiO_2 nanocomposite materials to perform photocatalytic experiments in the simulated flue gas to achieve Hg^0 removal effect of simulated flue gas.

Experimental

Preparation of catalysts

A certain amount of TiO_2 and SiO_2 was dissolved in anhydrous ethanol and mixed in ultrasonic mixer for hours. The preparation of samples immersed in the processed glass fiber mat, dried in the oven and calcined in muffle furnace, to remove water and free alcohol of the gel adsorption. Six groups of sample set value as shown in table 1.

Catalytic activity measurement

The catalytic activities were evaluated using a bench-scale experimental system as shown in Fig1.The simulated flue gas was divided into two branches A and B and each of them passed through the mass flow controllers A and B. Mass flow controllers control the mass flow. The stream of B passed through a mercury generator to introduce the saturated Hg^0 vapor into the mixing tank and mixed with A. Gas after mixing valves are controlled by valves A and B into the main road or bypass. Valve A opens into the photocatalytic gantry system for photocatalytic reaction in the reactor; valve B opens into bypass. After leaving the reactor experiment, the gas went into mercury species conversion system and went through KCl fluid absorption, silica gel desiccant removal of oxidized Hg^{2+}, then entering the gas sampling system VM3000 mercury tester.

Special mercury generator generated certain concentration of elemental mercury Hg^0, carried by the simulated flue gas into the mixing tank whose flow controlled by a mass flow controller. Simulated flue gas is compressed air. TiO_2-SiO_2 and flow gas reacted in the photocatalytic reactor under UV light catalytic role. VM3000 mercury analyzer was used to test real-time measurement of the mercury concentration in flue gas.

Measurement of photocatalytic activity

Sample experiment time was 80 minutes in each group and was under the condition of 300W. The process for each experiment was 20 minutes of UV light, UV lamp close 20 minutes, 20 minutes of UV light, UV lamp closed for 20 minutes. Because before mercury into VM3000 tester installed KCl absorbing liquid, so finally only Hg^0 went into VM3000 mercury gas load, it can also be reflected on the line chart. When close the UV lamp, mercury value can back to the initial value.

Removal rate calculation formula

$$\eta_n = \frac{C_O - C_n}{C_O} \times 100\% \quad (1)$$

where C_0 is mercury initial value(μg/Nm^3); C_n is mercury instantaneous value(μg/Nm^3); η_n is removal rate(%).

Table 1 The sample set point

sample	Ti:Si	UV light intensity
1# sample	1:0	300W
2# sample	1:2	300W
3# sample	1:5	300W
4# sample	1:1	300W
5# sample	5:1	300W
6# sample	2:1	300W

Results and Discussion

Results

The removal rate of mercury under different ratio of Ti/Si is shown in Fig2 to Fig7.

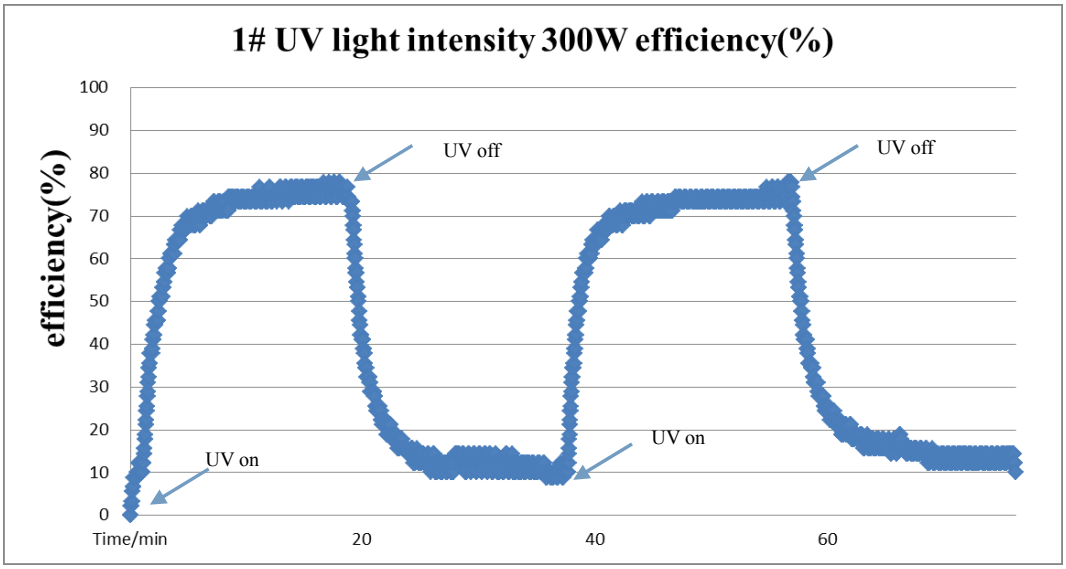

Fig 2 1#sample pure TiO_2

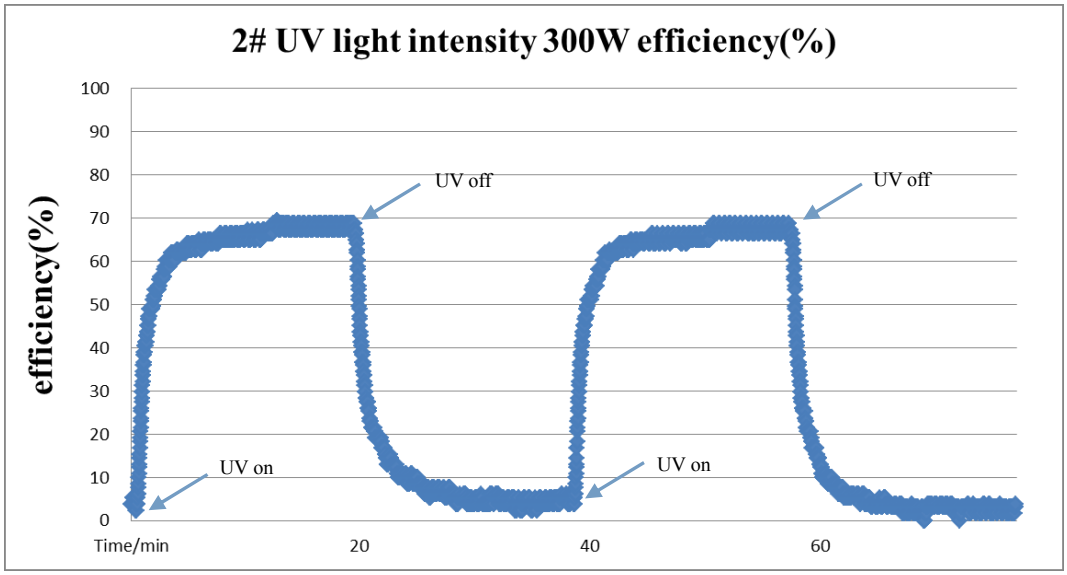

Fig3 2#sample Ti:Si=1:2

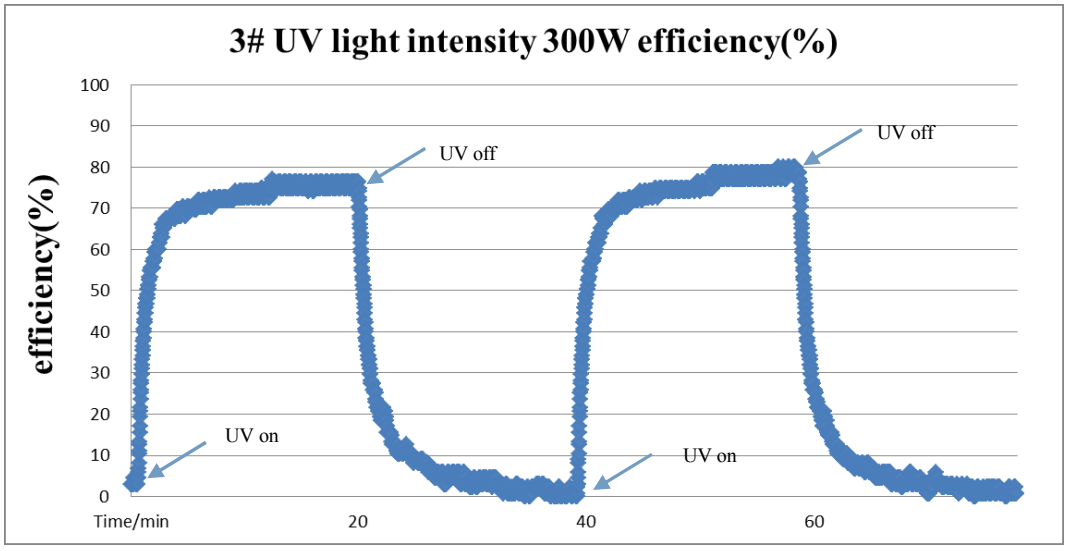

Fig4 3#sample Ti:Si=1:5

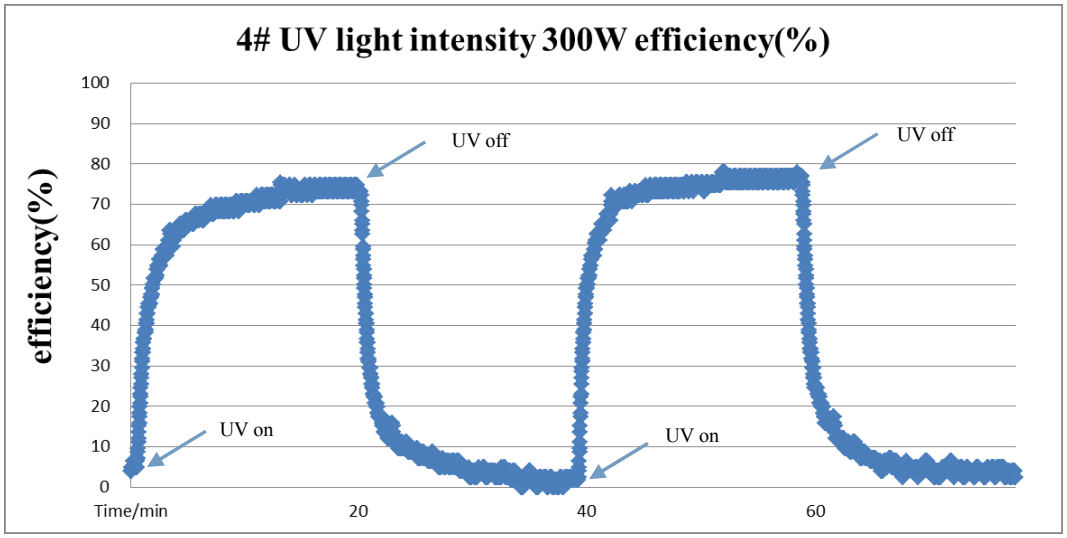

Fig5 3#sample Ti:Si=1:1

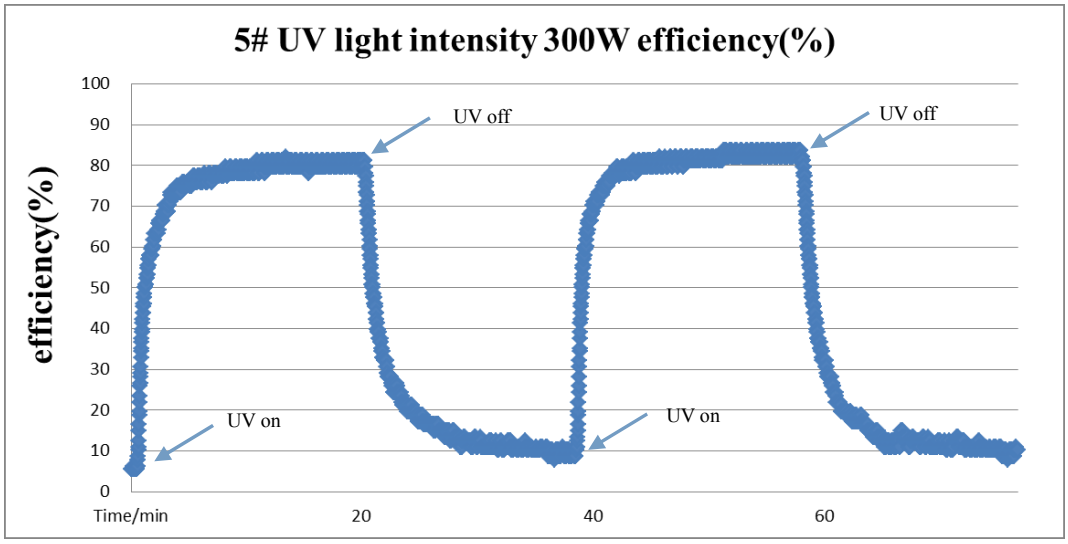

Fig6 5#sample Ti:Si=2:1

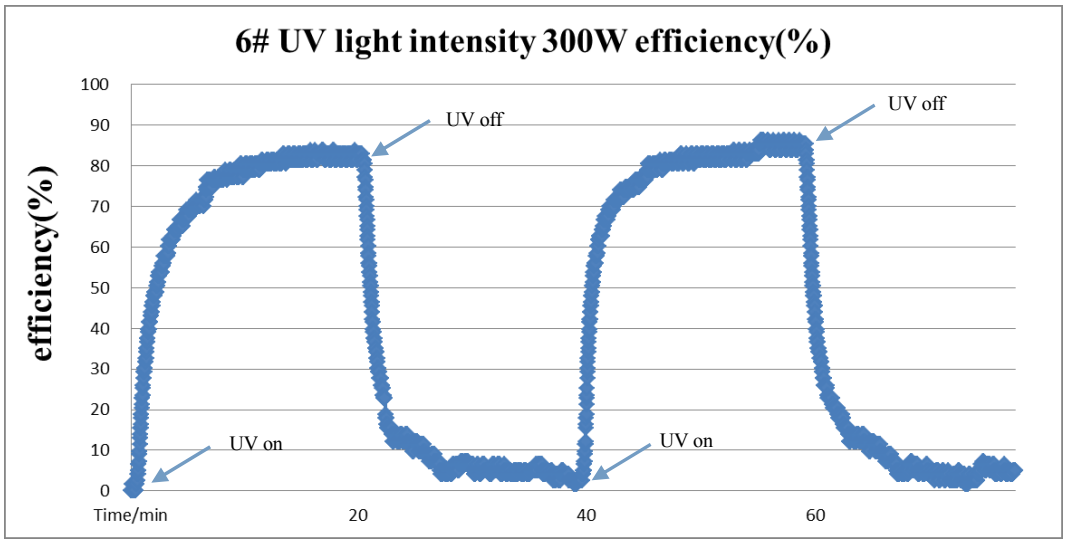

Fig7 6#sample Ti:Si=5:1

Discussion

The mercury removal efficiency of six samples was shown in Table 2, the results shown: the removal efficiency of Ti: Si ratio 1:0, 1:2, 1:5, 1:1, 5:1, 2:1 were 77.80%, 69.50%, 80.00%, 77.78%, 83.69%, 86.18% respectively. when Ti: Si ratio was 2:1,it reached the highest removal efficiency of elemental mercury.

The high photocatalytic nanoparticles of catalyst are mainly related with the anatase's high thermal stability and large specific surface. Porous SiO_2 on anatase TiO_2 nanocomposite surface effectively inhibit direct contact with TiO_2 nanocrystals. Thus significantly improve the thermal stability of anatase, and the improved thermal stability conducive to the crystallization of TiO_2 nano-titanium dioxide, thus contributing to the separation of photo-generated charge. Small crystallite size of TiO_2 and SiO_2 composite porous silica nanoparticles showed a larger surface area. However, preliminary results showed that: the photocatalytic activity of nanocomposite materials did not significantly improve, or even decline. This is mainly because that the presence of too much porous SiO_2 may affect TiO_2 on the effective absorption of light and direct adsorption of contaminants.

Table2 Experiment Results

sample	Ti:Si	Removal rate
1#sample	1:0	77.78%
2#sample	1:2	69.50%
3#sample	1:5	80.00%
4#sample	1:1	77.78%
5#sample	5:1	83.69%
6#sample	2:1	86.18%

Conclusion

This is based on the premise exploratory experimental studies and took into account the practical application, i.e, in view of the flue gas emissions from coal-fired power plants in the process of mercury removal process. Taking purely physical doping methods and draws close to the expected results of the experimental data. the results shown that the removal efficiency of Ti: Si ratio 1:0,1:2,1:5,1:1,5:1,2:1 were 77.80%, 69.50%, 80.00%, 77.78%, 83.69%, 86.18% respectively. When Ti: Si ratio was 2:1, it reached the highest removal efficiency of elemental mercury.

Keywords: WFGD, mercury, desulfurization slurry, flue gas, oxy-fuel

Abstract: Gaseous oxidized mercury (Hg^{2+}) in the flue gas is soluble in waterand can be captured effectivelyby Wet flue gas desulfurization (WFGD) system.But in some extent Hg^0 re-emission happens due to the reduction of absorbed Hg^{2+},and the pH of slurry is an important factor affecting Hg^0 re-emission. In this study, the theoretical formulas of slurry pH were derived through the conventional solution theoryand then were used to evaluate the factors determining the pH of slurry. A series oflaboratory experiments were carried out under N_2, CO_2 and O_2/N_2 atmosphere to measure the Hg^0 re-emission tendency at different pH values. The results show that the higher the pH, the less Hg^{2+} reduced by S(IV), resulting in the decrease of Hg^0 re-emission. Under N_2 atmosphere, the Hg^0 re-emission was mild at pH>4 while it was dramatic at pH<4. Under O_2/N_2 atmosphere, the addition of O_2 extended the time span of Hg^0 re-emission at low pH and increased Hg^0 re-emission unexpectedly in the latter part of the experiments at high pH. CO_2 atmosphere almost did not affect Hg^0 re-emission because of its little effect on the slurry pH.

Introduction

Mercury is one of the most toxic heavy metals in the environment. Coal-fired power plant is one of the largest stationary sources of anthropogenic mercury emission. Currently, mercury removal by existing air pollution control devices is the main strategy of mercury control in China. Wet flue gas desulfurization (WFGD) is the most widely used desulfurization unit which can simultaneously remove divalent mercury (Hg^{2+}) because of its water solubility. But the re-emission of Hg^0 generated by the reduction reaction of Hg^{2+} dissolved in the slurry, leading to atmospheric mercury pollution[1].

The slurry pH in WFGD not only influences the desulfurization efficiency, but also affects mercury removal efficiency[2]. The pH value is generally maintained at 5-6[3]. Previous studies showed that under N_2 or O_2/N_2 atmosphere Hg^0 release varied at different pH values. N.Omine, C.L.Wu and J.Schuetze[4-6]found that Hg^0 was re-emitted significantly at the higher pH values, which was completely opposite to the findings of R.Ochoa-González and J.J.Wo[7,8].J.J.Wo suggested that $Hg(OH)^+$ and $Hg(OH)_2$ inhibited Hg^0 release at high pH values[8], While J.Schuetze considered athigh pH values the reaction of $Hg(OH)_2$ with SO_3^{2-} and the $Hg_2(OH)_2$ decomposition led to Hg^0 re-emission[6].N.Omine found that the sulfite-Hg^{2+}reduction began to act at pH>5[4], but R.Ochoa-González thought $HgHSO_3^+$ formed at low pH was less stable than other S(IV)-Hg^{2+}complexes[7]. C.L.Wu considered at low pH the H^+ concentration was high so that Hg^{2+} reduction reaction could be inhibited[5]. Therefore, under N_2 or O_2/N_2 atmosphere the explanations of Hg^0 re-emission at different pH values are controversial and incomprehensive. Additionally, in their experiments $HgCl_2$was used as the source of mercury, the formed $ClHgSO_3^-$and $Cl_2HgSO_3^{2-}$could stabilize Hg^{2+}[9].In some of these experiments $CaCO_3$ or $CaSO_4$were added in the slurry, such solids introduced interfering substances[6]. Although O_2 had been contained in some

experimental atmospheres, there was no discussion about the effects of S(IV) oxidation by O_2 on the pH values and its further impact on the Hg^0 re-emission. On the other hand, because of adding fresh slurry, the pH of slurry in regionof circulationpumpsis above 6, oxidation and gypsum seed crystalscause abnormal decrease in pH values [10]. The pH of slurry changes under oxy-fuel flue gas condition[11], the pH of forced oxidation region may fluctuate. In all of these exceptional regions or circumstances Hg^0 re-emission is unclear.

In this study, the theoretical formulas of slurry pH were deduced to evaluate the decisive factor of pH values, and then the lab-scale experiments were performed under N_2, CO_2, O_2/N_2 atmosphere to test Hg^0 re-emission at different pH values. The objective of this work is to reveal the intrinsic mechanisms of Hg^0 re-emission from sulfur scrubbing slurry at different pH values, then provides some suggests for controlling Hg^0 re-emission in WFGDs.

Theory and experiments

Slurry pH theory

According to the solution chemistry theory, the pH value is directly determined by the concentration of H^+ ion generated by electrolyte ionization. The WFGD slurrypredominantly contains SO_4^{2-}, Ca^{2+}, SO_3^{2-} and HSO_3^-.Because SO_4^{2-} and Ca^{2+} are strong electrolyte ions which are hardly hydrolyzed, the pH value of slurry is mainly decided by weak electrolyte ions such as SO_3^{2-} and HSO_3^-. In order to study pH in single factor and conveniently, theoretical and experimental object of this study was the univariate solution consisting of SO_3^{2-} and HSO_3^-, which was abbreviated as S(IV)-H_2O solution.According to equilibration of S(IV)-H_2O solution[12], when the S(IV)consists of SO_3^{2-} and HSO_3^-,the formula (1) is used for calculating pH. When the S(IV) consists of H_2SO_3 and HSO_3^-, the formula (2) is used for calculating pH.

$$pH=lg[SO_3^{2-}]- lg[HSO_3^-]+(17780/T_0+1585T_1+114T_2+0.59T_0T_3)/R. \quad (1)$$

$$pH=lg[HSO_3^-]- lg[H_2SO_3]+(4604/T_0+7730T_1+118T_2+0.37T_0T_3)/R. \quad (2)$$

Where R=8.31448J/(mol·K), T_0=298.15K, $T_1=1/T_0-1/T$, $T_2=T_0/T-1+\ln(T/T_0)$ and $T_3=T/T_0-T_0/T-2\ln(T/T_0)$.

Experiment

A lab-scale scrubber was used to simulate a WFGD system, shown in Fig.1. The reactor containing S(IV)-H_2O solution was kept at 55℃in the water bath. A magnetic stirrer was put in the reactor and was kept stirring at the constant speed of 200r/min. The pH value was measured by a pH meter (PHS-3C, China). The concentration of Hg^0 at the outlet of the reactor was measured by an online mercury analyzer (VM3000, Mercury Instruments GmbH, Germany) based on cold vapor atomic absorption spectrometry (CVAAS). The detection limit of the mercury analyzer is 0.1 μg/m^3.

The experimental operational conditions were shown in Table 1. The reactive atmospheres were CO_2, N_2 and O_2/N_2. The total gas flow rate was set to 2 L/min by mass flow controllers. In preliminary experiments, 1N KCl and 4%$^W/_V$ $KMnO_4$ +10%$^V/_V$ H_2SO_4 were used for collecting Hg^{2+} and Hg^0 respectively, to evaluate mass balance of mercury.The results showed that the mercury recovery were between 79.95%and 106.94%, indicating the system was reliable.In the

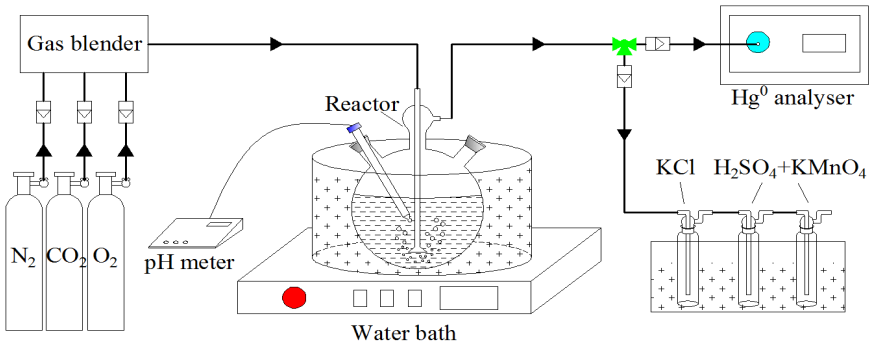

Fig.1 Schematic of lab-scale scrubber

formalexperiments, 1L 5mmol/L S(IV)-H_2O solution was added to the reactor and heated to 55℃. The pH value was adjusted to the expected value with 10% $^{V}/_{V}$ HNO_3 and 1mol/L NaOH. Afterwards, the standard mercury solution which composed of $Hg(NO_3)_2$ was added in the reactor. During the experimental process, the gas was continuously introduced in the solution in the reactor. When the Hg^{2+} was reduced to Hg^0 in the reactor, the gas would carry Hg^0out of the reactor.The Hg^0concentration in the outlet gas was recorded continuously.

Table 1 Experimental conditions

Experimental conditions	Parameters
O_2/N_2 [vol.%]	0/100,5/95
O_2/CO_2 [vol.%]	0/100
pH	3, 4, 6, 8
Hg^{2+} [μg/L]	100

Results and discussion

Simulation and experiments of S(IV)-H_2O solutionpH law

Relationship between theoretical pH and S(IV) species. The relationship between pH and S(IV)species in S(IV)-H_2O solution was calculated using the formula (1) and (2) , see Fig. 2. The total amount of S(IV) was 1mol, The temperature was 55℃. When pH is 2-5, S(IV)speciesare mainly in the form of HSO_3^- ions When pH is greater than 8, S(IV) speciesare mainly in the form of SO_3^{2-} ions. when pH is 5-8, S(IV) speciesare existed simultaneously as HSO_3^- and SO_3^{2-} ions.

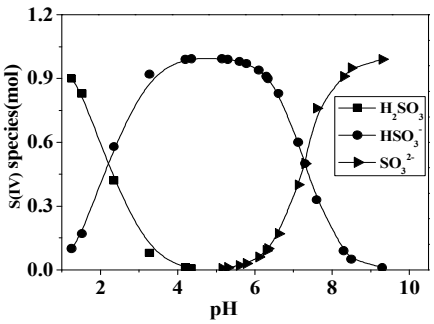

Fig.2 Relationship between pH with S(IV) species

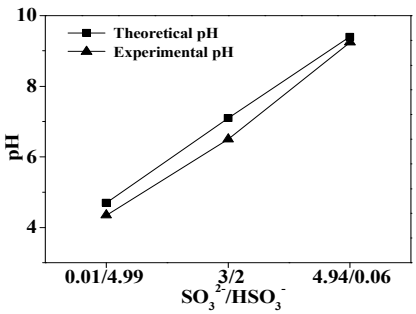

Fig.3 Comparison of experimental pH and theoretical pH(5mmol/L S(Ⅳ))

Comparison of experimental and theoretical pH. In order to evaluate the validity of the pH formulas, the pH values in the solutions with different SO_3^{2-}/HSO_3^- ratio were measured at 55℃. The experimental pH values are very close to the theoretical ones when the SO_3^{2-}/HSO_3^- ratio in the

solutions is the same (see Fig.3). The calculated pH value is less than 10% higher than the measured one. The comparison proved that the derived formulas could be used to judge the distribution ratio of S (Ⅳ)species in solutions at different pH value.

Relationship between pH and SO_3^{2-}/HSO_3^- ratio. The relationship between pH and SO_3^{2-}/HSO_3^- ratio is shown in Fig. 4. Seen from the simulation results the two curves were obtained at the same temperatures (25 or 55℃) are almost overlapped, showing that the S(IV) concentration has no effect on the pH values. At the same SO_3^{2-}/HSO_3^- ratio, the pH values slightly increase with the temperature increase from 25℃ to 55℃. Thetemperature has a little effect on the pH values. The pH values are strongly related with S(IV) species distribution ratio. Therefore, most likely it is the differentS(IV) species distribution ratio that causes the diversity of Hg^0 re-emission at different pH values.

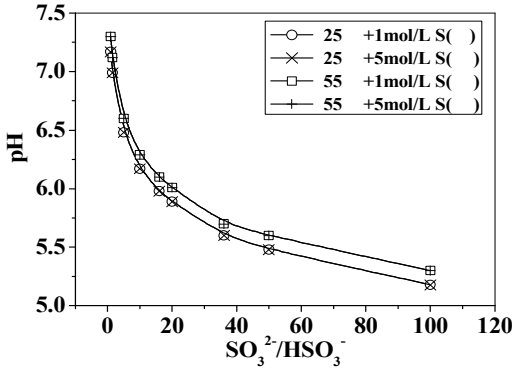

Fig.4 Relationship between pH and SO_3^{2-}/HSO_3^- ratio

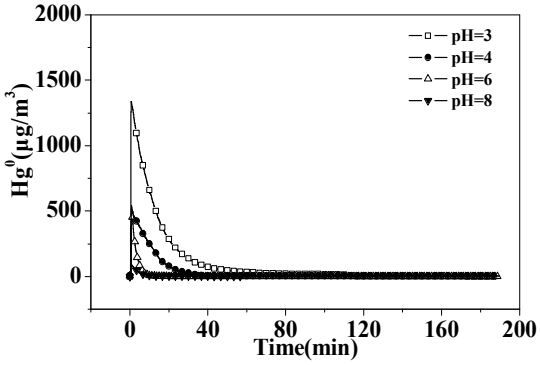

Fig.5 Hg^0 re-emission at different pH values under N_2atmosphere(5mmol/L S(Ⅳ))

Experimental study of the effects of pH on Hg^0 re-emission under different atmospheres

N_2 atmosphere. Fig. 5 shows the re-emission behavior of Hg^0 at different pH values under N_2 atmosphere. As shown in Fig.5, the lower the pH, the more Hg^0 reemitted under N_2 atmosphere.When the pH was 8, Hg^0reemitted gently. Although the peak height at pH 6 was much higher than that at pH 8, it decreased rapidly. Hence, the amount of Hg^0 re-emission was relatively small. Whereas the Hg^0 re-emission at pH 4 lasted for 30 minutes, which peak height was 541.2μg/m^3. When pH was 3, The Hg^0 re-emission sustained for about 50 minutes, which peak height was 1338.6μg/m^3. Therefore, under N_2 atmosphere when the pH is less than 4,Hg^0re-emissionis severe, Increasing the pH can remarkably inhabit the re-emission, lowering the peak height and shortening the time of duration.

The pH theory reveals that when the pH is between 5 and 8, S(IV)species are mainly in the form of HSO_3^- and SO_3^{2-}. SO_3^- is ready to react with Hg^{2+} and form $HgSO_3$. Because the concentration of SO_3^{2-} was much higher than Hg^{2+}, $HgSO_3$ which formedby the reaction of SO_3^{2-} and Hg^{2+} would further form $Hg(SO_3)_2^{2-}$ through the reactions expressed by Eq.(3) and (4). J. Munthe et al[13] demonstrated that $Hg(SO_3)_2^{2-}$ is relatively stable and difficultly hydrolyzed in the dynamics, so when the pH were 6 and 8, Hg^0 reemitted rarely. When pH is below 4, S(IV) species is in the form of HSO_3^- which can generate $HgSO_3$ and $HgSO_3H^+$ with Hg^{2+} through Eq.(5) and (6). $HgSO_3$ and $HgSO_3H^+$ are unstable resulting in increaseof Hg^0 re-emissionthrough Eq.(7) and (8), consistent with conclusion of R.Ochoa-González[7]. Because the pH of the plant WFGD is 5-6, once accidents of abnormal decrease in pH occur, the pH will be less than 5, the amount of Hg^0 re-emission should be increased.

$Hg^{2+}+SO_3^{2-}\leftrightarrow HgSO_3$. (3)

$HgSO_3+SO_3^{2-}\leftrightarrow Hg(SO_3)_2^{2-}$. (4)

$Hg^{2+}+HSO_3^{-}\leftrightarrow HgSO_3+H^{+}$. (5)

$Hg^{2+}+HSO_3^{-}\leftrightarrow HgSO_3H^{+}$. (6)

$HgSO_3+H_2O\rightarrow Hg^0+SO_4^{2-}+2H^{+}$. (7)

$HgSO_3H^{+}+H_2O\rightarrow Hg^0+SO_4^{2-}+3H^{+}$. (8)

O_2/N_2 atmosphere. Fig. 6 shows the re-emission behavior of Hg^0 at different pH values underO_2/N_2 atmosphere. Comparing the Hg^0 re-emission behavior curves in Fig. 5 with Fig. 6, great changes occurred when O_2 was added to the atmosphere. When the initial pH was 3, the time duration was extended from 50 minutes (under N_2 atmosphere) to about 90 minutes(O_2/N_2 atmosphere) due to the addition of O_2. When the initial pH was 6 or 8, the newly added O_2 caused a sudden increase of Hg^0 re-emission in the latter part of the experiments. The measured pH value decreased with the inflow of oxygen, once the pH was reduced to about 4, the outlet Hg^0 concentration began to rise.

The changes to the release behavior of Hg^0were possible due to the oxidation of the S(IV) species in solution by added O_2. According to previous study[14], the oxidation rate of S(IV) grows with the pH increases, which means the oxidation rate of SO_3^{2-} ions is greater than that of HSO_3^{-} ions. When pH was 6 or 8, through Reaction (9) and (10) the SO_3^{2-}ions were consumed faster than HSO_3^{-} ions, resulting in the decline of the ratio of SO_3^{2-}/HSO_3^{-}. The pH drop was caused by such SO_3^{2-}/HSO_3^{-}ratio decline, which was proved by the trend of pH curves in Fig. 6. Because the reactions (5) and (6) are reversible reactions in solution based on chemical equilibrium, When SO_3^{2-} concentration was reduced to the critical value for the maintenance of the chemical equilibrium, the reverse reactions would predominate. Finally the pH value dropped to less than 4, The insufficient SO_3^{2-} could not sustain the existence of $Hg(SO_3)_2^{2-}$. Then relatively stable $Hg(SO_3)_2^{2-}$ would be transformed into unstable $HgSO_3$ and $HgSO_3H^{+}$, resulting in the massive Hg^0 re-emission.

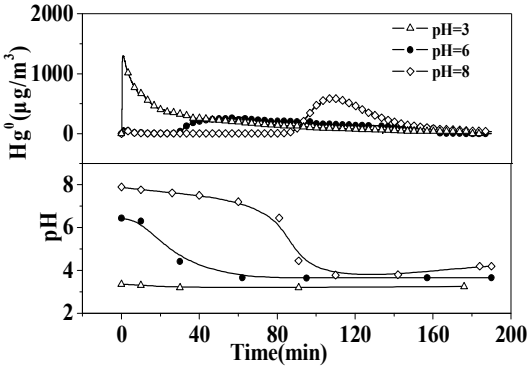

Fig.6 Hg^0 re-emission at different pH values under O_2/N_2 atmosphere (5mmol/L S(Ⅳ))

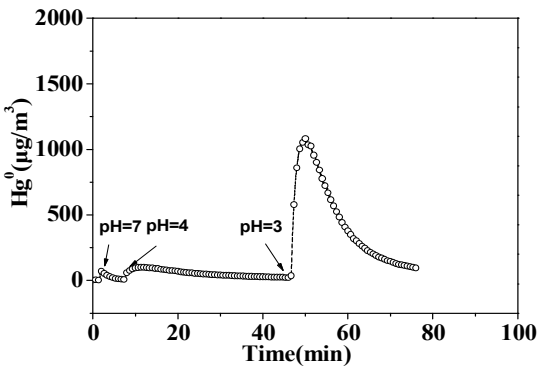

Fig. 7 Hg^0 re-emission at various pH values adjusted by HNO_3 (N_2,5mmol/L S(Ⅳ))

Direct oxidization of $Hg(SO_3)_2^{2-}$ by O_2 was another possible reason for Hg^0 re-emission. To exclude such a possibility, the effects of the pH drop on the Hg^0 re-emission under pure N_2 atmosphere were investigated by simply adjusting the pH value with $10\%^{V}/_{V}HNO_3$ (see Fig.7).

when the pH was adjusted down to 4, there was a Hg^0 re-emission peak which lasted for 15 minutes. when the pH was continuously adjusted down to 3, a high peak of Hg^0 re-emission turned up and sustained for more than 30 minutes. This indicated that no matter what O_2 exists or not, a large amount of Hg^0 will reemit as soon as the pH value of the solution decreases to less than 4. Hg^0 re-emission caused by O_2 addition was by consuming SO_3^{2-} to decrease the pH value. Therefore, massive Hg^0 re-emission may occur in the forced oxidation zone of WFGD system due to the unexpected low pH values produced by the sulfite oxidation during air bubbling.

$$O_2 + 2SO_3^{2-} \rightarrow 2SO_4^{2-}. \quad (9)$$

$$O_2 + 2HSO_3^{-} \rightarrow 2HSO_4^{-}. \quad (10)$$

CO_2 atmosphere. Fig. 8 shows that the Hg^0 re-emission at different pH values under CO_2 atmosphere. When the pH was 8, the behavior of Hg^0 re-emission under CO_2 atmosphere was similartothat under N_2 atmosphere which meant that CO_2 has no effect on Hg^0 re-emission. When the pH was 3, the peak of Hg^0 re-emission under CO_2 atmosphere was higher than that under N_2 atmosphere. The Hg^0 re-emission is sensitive to the pH values when the pH value is close to 3. CO_2 caused a little drop of the pH, leading to a slight increase of Hg^0 re-emission. The results are consistent with N. Omine's consequenceabout Hg^0 re-emission at different CO_2 concentration[4]. Because the solubility of CO_2 is low to0.017mol/L•atm at 50℃[15]and H_2CO_3 is weaker than H_2SO_3, CO_2 atmospherejust can slightly decrease the pH value of S(IV)-H_2O solution. As shown in Fig.8, when the pH is 3, for Hg^0 re-emissions underbothCO_2 and N_2 atmosphere, the durationisalmost identical and the amount has a little difference. As a result, no matter under CO_2 or N_2 atmosphere, Hg^0 re-emission is almost the same at same pH value. Based on above discussion, we believe that the enrichment of CO_2 in flue gas during oxy-fuel combustion has little effect on Hg^0 re-emission.

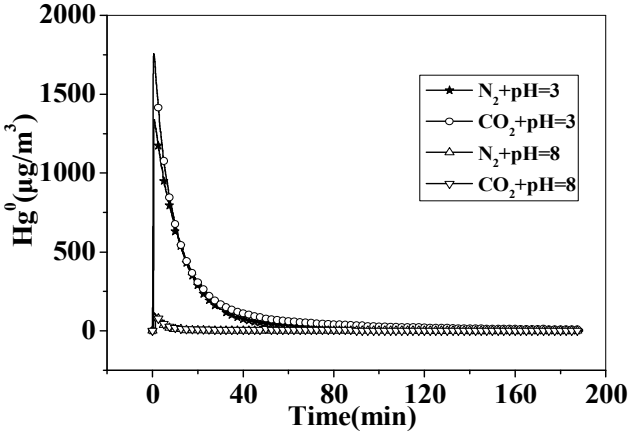

Fig.8 Hg^0 re-emission at different pH values under CO_2 atmosphere (5mmol/L S(Ⅳ)

Conclusions

A pH variation calculation method was established and a series of experiments were carried out to evaluate pH influences on Hg^0 re-emission in WFGD slurry under N_2,CO_2, O_2/N_2 atmosphere. The higher the pH value, the less Hg^{2+} reduced by S(IV), resulting in Hg^0 re-emission decrease. Under N_2 atmosphere,the Hg^0 re-emission wasmild at pH>4 while it was severe at pH<4.Under O_2/N_2 atmosphere, the addition of O_2extended the time span of Hg^0 re-emission at low pH and

increasedHg^0 re-emission unexpectedly in the latter partof the experiments at high pH.Hg^0 re-emission caused by O_2addition was to decrease the pH valueby consuming SO_3^{2-}. Under CO_2 atmosphere, CO_2 almost did not affect Hg^0 re-emission because of its little effect on the slurrypH.

Keywords: Shenhua coal; blending combustion; slagging; coal pulverizing system; operation parameter.

Abstract. Experimental study of changing and blending combustion of Shenhua coal on boiler operation was carried out, while the furnace slagging during the experiment, the coal pulverizing system adjustment and the boiler operation oxygen control issues were analyzed. The results show that: the boiler can operate in safety blending Shenhua coal and Zhungeer coal with the ratio of 7:3 based on the strengthening laboratory analysis of coal as fired, the safety and economy of the boiler and coal pulverizing system can be ensured with the pulverized coal fineness R90 in 30%, and selecting the lower mill combinations and setting the coal pulverizer outlet temperature at 73℃, the reasonable exhaust gas oxygen content should be 4.0%, and the boiler thermal efficiency has an 1% increase compared with the condiation of burning inferior Shanxi bituminous coal, the nitrogen oxide emissions are significantly reduced.

Introduction

Shenhua coal is the major steam coal of China. Cheng and Zhao studied the characteristics of coal quality, coal combustion and slagging of Shenhua coal, showed that Shenhua coal had the characteristics of high calorific value, high volatile matter, high calcium in ash, low ash content and low sulfur content, which determined the Shenhua with good ignition and stable combustion performance[1,2]. The economic analysis showed that boiler burning Shenhua coal presented great economy and environment protection of high thermal efficiency and low NOx, dust and SO2 emissions[3]. But it was found that the characteristics of low ash melting point and easy to slag would easily cause several issues directly affecting the unit safe operation, such as coal pulverizing system explosion and boiler slagging, which severely restricted the applications of Shenhua coal in power plant. Many scholars have conducted in-depth analysis of Shenhua coal slagging characteristics. Yu studied the fouling and slagging characteristics with coal reburning and injected calcium in 2.11 MW boiler with four-cornered combustor[4]. Zhou identified the morphology and mineralogy characteristics of deposits sampled at different loacations in the 0.25MW combustion facility furnace burning Shenhua coal using the SEM(SED) and XRD techniques, and presented two indices, viz. shedding periodicity of the deposition and the decaying amplitude of the heat flux to quantificationally evaluate the deposition propensity of differernt coals[5]. Zhang analyzed the slagging characteristics of 660MW supercritical boiler burning Shenhua coal[6]. Ren presented two methods to judge the slagging of large-capacity pulverized coal boilers burning Shenhua coal[7]. In practice, many plants improved the ash fusion temperature of coal as fired by blending the coal with high ash fusion temperature to reduce the boiler slagging. Li and Liang carried out the blending combustion simulation study of Shenhua coal and other difficult slagging coals on a 800MW supercritical swirling combustion boiler and a 1025 t/h double-furnace tangential drum boiler respectively, and analyzed the furnace temperature and speed distributions of different conditions, and verified by experiments[8,9]. Yan investigated the slagging performance of the blended heavy slagging coals for 100MW and 200 MW boilers, and predicted the main slagging parameters and tendency of the coal quality index of different blending ratios[10]. Chen analyzed the variation regularity of ignition, burnout, slagging and contamination of blended coals of Shenhua coal and other bituminous coals in different ratios systematically[11]. Gao carried out an experimental study

on the mixed combustion of Shenhua coal with Huolinhe lignite in a 1000 MW unit, and analyzed the effect of blending ratio on the maximum mill output, maximum unit output and the unit performance, and performed combustion optimization tests at an optimal blending ratio[12].

In recent years, with the increasing of coal prices year by year, the phenomenon of burning non-designed coal has been more common. The major coal of a power plant has been transferred from inferior bituminous coal of Shanxi province to Shenhua coal since 2012, and the blend program of Shenhua coal and Junger coal blended outside the furnace was used. Due to the obvious changes of coal feature, such as coal calorific value, ash and sulfur, the produced flue gas and cinder also change significantly, which will impact the boiler, dust collector and desulfurzation system operation probably. The experimental research of changing combustion of Shenhua coal was carried out in this boiler, the effects of changing combustion to boiler operation were analyzed in three aspect: slagging control, pulverizing system adjustment and furnace oxygen adjustment.

Set-up

It is a pulverized coal-fired boiler with sub-critical pressure, controlled circulation, single hearth, once reheat, and dry ash extraction, which adopts burner wiggling temperature adjusting, four corner arrangement, tangential firing, and direct blowing coal-pulverizing system with positive pressure. The primary and secondary air nozzles are spaced with the OFA secondary air nozzle at top. The burners are horizontal bias combustion pulverized coal burners using V blunt width adjustment ratio nozzle.

Table 1 shows the coal quality testing data of coals burning during the experiment, including inferior Shanxi bituminous coal, Shenhua coal, Zhungeer coal, blended coal of Shanxi coal and Zhungeer coal with the blending ratio 5:5 (blended coal 1) and blended coal of Shenhua coal and Zhungeer coal with the blending ratio 7:3 (blended coal 2).

Problems in changing combustion of Shenhua coal

Slagging problem

Any coal has a certain slagging tendency, but the slagging and fouling tendency of Shenhua coal are strong because of its coal characteristic, so more attention should be paid to slagging and fouling problems in changing combustion and blending combustion. As can be seen in the table 1, DT and ST temperatures of Shenhua coal are lower compared to Zhungeer coal, which indicate the strong slagging and fouling tendency, and the ash fusion temperatures of blended coals have a certain improvement compared to Shenhua coal.

Risk of pulverizing system explosion

The Shenhua coal is easy to fire and explosive because of its high volatile. Coal volatile and pulverized coal concentration are internal reasons of pulverizing system explosion, while running out of coal in coal mill, too high outlet temperature of coal mill, too small coal fineness, loose hot air

distributor and external ignition sources are external reasons. Measures should be taken to prevent pulverizing system explosion in changing combustion of Shenhua coal, such as eliminating accumulated pulverized coal, eliminating air leakage, controlling mill outlet temperature, controlling coal fineness, strengthening coal testing and controlling external ignition sources.

Boiler operation parameter control

Because of the great difference between the active coal and the original one, the original boiler operation control method requires a corresponding change, especially the furnace oxygen control.

Results and analysis

Furnace slagging analysis

To analyze the furnace slagging, the flame temperatures at different boiler elevations were measured through the hole on the furnace using an infrared pyrometer, while the furnace slagging conditions were also observed through the hole on the furnace. The flame temperatures of 36 points at 6 elevations were measured during the test, and averaging the temperatures of different points at the same elevation as the elevation temperature, and averaging the temperature of 6 elevation temperature as the furnace temperature. A serious furnace slagging situation was occurred during July 17 and July 18 when the blending ratio of Shenhua coal and Zhungeer coal was 7:3, resulting slag dragging machine stuck. The serious furnace slagging situation will be analyzed according to the furnace flame temperature test results as shown in Table 2.

Table 2 The furnace flame temperature test results during July 17 and July 18 [℃]

elevation	Condition 1	Condition 2	Condition 3	Condition 4	Condition 5
45m	1067.6	1056.1	1098.7	1134.3	1090.8
40.3m	1230.0	1183.5	1246.5	1247.0	1264.0
36m	1254.7	1216.0	1280.3	1279.0	1282.7
34.2m	1327.0	1287.8	1354.5	1361.8	1345.7
31m	1369.0	1348.4	1384.3	1390.9	/
28.6m	1408.3	1389.4	1415.0	1428.1	/
average	1276.1	1246.9	1296.6	1306.9	/

As shown in table 2, the furnace average temperature was 1276.1℃ in condition 1 in July 17 when the boiler operated normally and the load was 280 MW, while the test time was 4 hours after soot blowing. The flame temperatures of every elevation were reduced when soot blowing just ended in condition 2 in July 18, the furnace average temperature was reduced about 30℃, which showed that soot blowing had obvious effect on the control of slagging. At condition3, which was 3 hours after condition 2, comparison with condition 1, the flame temperatures of every elevation increased significantly, the furnace average temperature increased 20.5℃, especially in the elevation of 34m or more, the temperature rise 31.1℃ to about 1100℃ at elevation of 45m, which indicated that serious slagging was occurred at elevation of 34m or less, resulting in lower water wall reducing heat absorption, then flue gas temperature above 34m rise. The increasing 10℃ of inlet flue gas temperature of the air preheater and increasing 2℃ of boiler flue gas temperature also indicated the conclusion. At condition 4, which was 45 minutes after conditon3, the flame temperature at the elevation of 45m showed a rapid rise, the heating rate was close to 1℃/min, which showed the rapid growth of furnace slagging in the upper area. Although trying to reduce slagging by adjusting the air distribution and mill output, but the effect was not obvious. The load was reduced to 260 MW at condition 5 for safety, and then the furnace slag blocks fall. The flame temperature of every elevation showed significant decreasing trend, and the amount of slag increased sharply at the slag dragging machine, and then the slag dragging machine stuck. The cooling slag blocks were hard and bright black, and the visible veins of water wall heating surface indicated that some slags were adhered to the water wall heating surface in a molten state, which was extremely harmful to the safe operation of the boiler.

Comparison of the normal condition and the serious slagging condition showed that the boiler operation modes were basically the same, while the ash test results of Shenhua coal in July 18 were significantly different from the previous one, as shown in Table 3, and differences of the ash test results of blending Zhungeer coal in July 18 and the previous ones were small.

Table 3 Ash test results of previous Shenhua coal and Shenhua coal in July 18

coal	Ash composition[%]									Ash fusion temperature[℃]			
	SiO_2	Al_2O_3	TiO_2	Fe_2O_3	CaO	MgO	K_2O	Na_2O	SO_3	DT	ST	HT	FT
previous Shenhua coal	40.7	19.31	0.77	7.58	16.84	1.22	1.28	1.01	6.63	1180	1190	1200	1240
Shenhua coal in July 18	35.4	14.25	0.65	13.45	22.01	0.9	0.67	2.06	8.65	1080	1080	1090	1100

As shown in table 3, the softening temperature (ST) of Shenhua coal in July 18 was smaller than that of previous one, which indicated that the slagging characteristics of Shenhua coal was more serious, while the coal change was the key reason of the serious furnace slagging and slag dragging machine sticking in July 18. So in the future, it is necessary to strengthen the coal quality test of coal as received and coal as fired, especially the test of ash composition and fusion temperature. It is recommended that the Shenhua coal blending ratio reduced to no more than 40% encountering the similar one as that of July 18.

Adjustment of pulverizing system

Adjustment of coal fineness

Because of the high volatile of Shenhua coal, larger coal fineness was need to prevent pulverizing system from firing and exploding in view of security, and larger coal fineness could extend combustion distance, reduce heat load of burner area and slow slagging of burner area, but may result in the upper furnace and convection heating surface slagging in view of slagging. The coal fineness R90 was about 25% with burning the inferior bituminous coal of Shanxi province which was difficult to burn, while the coal fineness R90 increased to about 30% during the test. Table 4 shows the results of the coal fineness before and after adjustment.

Table 4 The results of the coal fineness before and after adjustment

Mill	Before adjustment		After adjustment	
	R_{90}[%]	Separator opening [%]	R_{90}[%]	Separator opening [%]
A	25.06	45	32.54	50
B	26.98	45	31.72	50
C	23.28	45	29.08	50
D	25.46	40	31.52	47
E	25.24	45	29.62	50

Adjustment of mill combination

By changing the mill combination mode and adjusting the input coals of every mill to change the burner load distribution of every layer, the burner region load will be distributed uniformly, and to avoid the problem of too high local heat load, the burner declination angle could be reduced, and ultimately the purpose of slowing the furnace slagging could be achieved. Table 5 shows the flame temperature distributions of several mill combinations.

Table 5 The flame temperature distributions of several mill combinations [℃]

elevation	Mill combinations					
	Condition 6 -ABCDE	Condition 7 -ABCE	Condition 8- ABDE	Condition 9 -ABCD	Condition 10 -ABCD	Condition 11 -ABCD
45m	1108.4	1104.6	1147.3	1068.3	1085.9	1084.1
40.3m	1235.0	1258.0	1289.0	1200.0	1220.0	1232.0
36m	1279.7	1277.0	1327.7	1263.3	1280.3	1291.0
34.2m	1355.2	1375.2	1416.7	1325.2	1345.7	1328.5
31m	1379.0	1401.9	1455.1	1358.0	1373.0	1368.4
28.6m	1409.5	1434.6	1493.5	1397.8	1412.0	1405.4
average	1294.5	1308.5	1354.9	1268.8	1286.1	1284.9

Conditions 6, 7 and 8 give out the furnace flame temperature results of three different mill combinations, and the interval of each test was 2 hours after soot blowing. As shown in the table, the flame temperatures of each condition were increased gradually, while the flame temperature of condition 8 was increased of 60℃ compared to condition 6, which increased the possible of slagging. Conditions 9, 10 and 11 give out the furnace flame temperature results under mill combination ABCD, and the interval of each test was also 2 hours after soot blowing. Under this combination, the center of furnace flame was lower, and furnace temperature decreased significantly, which was helpful to reduce the slagging tendency and exhaust gas temperature. So, it is recommended to choose the lower mill combination under normal situation of pulverizing system.

Control of mill outlet temperature

Increasing the mill outlet temperature could effectively improve the performance of pulverized coal ignition, while the Shenhua cola is easy to fire and explosive, so it is necessary to control the mill outlet temperature to prevent spontaneous combustion and explosion of pulverizing system. The mill outlet temperature should not exceed 75℃ according to the empirical formula. At first, the mill outlet temperature of burning Shenhua coal was decreased to 68℃ from 80℃ which was the temperature of burning inferior bituminous coal of Shanxi province. The mill outlet temperature was improved to 73℃ in condition 11. Comparing with the condition 10 and condition 11, it is found that the furnace flame temperature decreased, especially in the area of elevation 28.6m to elevation 34.2m, where the temperature decreased for about 10℃. The results showed that the pulverized coal into the furnace presented earlier fire trend. In addition, the hot primary air temperature and the exhaust gas temperature were both decreased for 3℃ based on the same primary air fan output, which indicated that the primary air into the air preheater was increased and the air preheater heat transfer efficiency was improved. So the moderate increase of mill outlet temperature could reduce exhaust gas temperature and improve boiler efficiency. After operating for one day in condition 11, setting the mill outlet temperature as 73℃ could guarantee the security and economy of the boiler.

Control of furnace oxygen

Generally the low oxygen combustion was considered to cause burner regions to be in a reducing atmosphere, which was not conducive to reduce boiler slagging trend, while the Shenhua coal belong to easily slagging coal, so most boilers firing Shenhua coal run with high oxygen. The higher oxygen for tangentially fired boilers may make tangentially larger and lead the primary air against the water wall, which will increase slagging. The higher oxygen operation mode will increase the power consumption of the fan and be conducive to control NOx concentration of the exhaust gas.

Some plans tried to adopt the operation mode of low oxygen combustion based on the above disadvantages of high oxygen combustion[13]. The results showed that low oxygen combustion had effect on reducing power consumption of air fans and NOx emission concentration on the premise of safe operation of the boiler, but it may cause incomplete combustion of coal or prolong the coal burn time, which may increase the combustion temperature and slagging trend of the upper region of furnace. So it is necessary to detect the co of exhaust gas and carbon content of fly ash timely to eliminate or reduce the reducing atmosphere in the furnace.

Table 6 shows the boiler operation parameters, the boiler thermal efficiency and NOx emission results of three kinds of coal.

Table 6 Boiler operation parameters, thermal efficiency and NOx emission results of three kinds of coal

Items	Shanxi province coal	Shanxi coal and Zhungeer coal	Shenhua coal and Zhungeer coal
Load [MW]	328.0	300.3	329.0
Duty[t/h]	1093.8	996.7	1098.6
Coal[t/h]	159	138.7	139
Inlet air temperature of forced draft fan[℃]	2.18	27.3	23.55
Atmospheric pressure[Pa]	100980	101700	101700
Relative air humidity[%]	69.66	32.53	72.51

Exhaust gas oxygen[%]	4.83	4.82	3.98
Exhaust gas co[ppm]	1	4	2
Exhaust gas temperature[℃]	138.09	150.83	144.28
carbon content of fly ash[%]	1.26	1.56	1.56
carbon content of slag[%]	2.38	7.62	1.73
Thermal efficiency[%]	92.06	92.38	93.04
NOx emission concentration [mg/Nm^3]	1040	1060	712

As can be seen from the table, the exhaust gas oxygen of burning blended coal of Shenhua coal and Zhungeer coal was smaller than that of the other two coals for 1%, but the co concentration of exhaust gas was also very small, while the boiler thermal efficiency was the highest, and the NOx emission concentration was the smallest. So setting the exhaust gas oxygen as about 4.0% at full load condition was reasonable to burn blended coal of Shenhua coal and Zhungeer coal.

Conclusions

The major coal of a power plant has been transferred from inferior bituminous coal of Shanxi province to blended coal of Shenhua coal and Zhungeer coal, which will challenge the safe and economic operation of the boiler and related systems. The boiler combustion adjustment research was carried out, the changes and adjustments of slagging characteristic, pulverizing system and furnace oxygen after burning the blended coals were analyzed to determine the reasonable operation parameters. The results showed that:

1) When burning blended coal containing Shenhua coal, it is necessary to strengthen the coal quality test of coal as received and coal as fired, especially the test of ash composition and fusion temperature, and the Shenhua coal blending ratio should be reduced encountering severely slagging Shenhua coal.

2) The coal fineness could be a little large when burning the Shenhua coal, the coal fineness R90 of 30% was suitable for blended coal of Shenhua coal and Zhungeer coal, and it is recommended to choose the lower mill combination under normal situation of pulverizing system, and setting the mill outlet temperature as 73℃ could guarantee the security and economy of the boiler.

3) When burning blended coal of Shenhua coal and Zhungeer coal, the furnace oxygen could be reduced, and setting the exhaust gas oxygen as about 4.0% at full load condition was reasonable.

Keywords: Ground-source heat pump; ground heat; thermal equilibrium;

Abstract. In order to study the issue of heat imbalance while the ground-source heat pump using in cold regions,this thesis adopts a technology with independent intellectual property rights which is called “thermal compensation control area partition method”.

Introduction

GSHP system as a reliable, efficient, economic and environmental protection air conditioning mode, cause the extensive concern of hvac industry in recent years, has become one of the frontier research topic in the field of building energy efficiency.[1-3] In cold region, however, due to the limitation of climate condition, soil source heat pump system in the operation process of "thermal imbalance" phenomenon, has become the bottleneck problem of its large-scale application.

In this thesis, A teaching in colleges and universities library in cold region Changchun heat pump project as an example, the project of six layers framework structure of large public energy saving building, a total construction area of about 27492 ㎡, the project adopts the "thermal compensation control area partition method" the winter use soil source heat pump system for heating of the building is 5000 ㎡, the rest of the use of city pipe network heating, in summer to building 10000 ㎡ (including winter heating area) and cooling way, to keep the soil source heat pump system take put the balance of heat from the soil, so as to maintain the stable operation of the heat pump system.According to using GAMBIT software to establish physical model for parts of the well group, and hourly simulate the 5 years operation of some heat exchanger of the well group by using FLUENT software, so that the simulation results of applicability of the thermal compensation method in severe cold area can be demonstrated.

Changchun natural conditions

Changchun City is located in the northern hemisphere mid latitude zone, east longitude 124 ° 18 ′ ~ 127 ° 02 ′, latitude 43 ° 05 ~ 45 ° 15 ′. Dry and windy spring, rainy summer, autumn is cool and windy, and the long cold winter are about the four seasons there. Changchun City, the annual average temperature of 4.8 ˚C, the highest temperature is 39.5 ˚C, the lowest temperature of -39.8 ˚C, belongs to the cold area[4]. HVAC design parameters of outdoor meteorological for Changchun are shown in Table 1.

Table1 , HVAC design parameters of outdoor meteorological for Changchun

The average temperature of heating period(˚C)	Heating period Z (d)	Degree days (˚C. d)	The annual average temperature (˚C)	Calculation of heating outdoor dry bulb temperature (˚C)	Calculation of the relative humidity of outdoor heating	The lowest temperature (˚C)
-8.3	170	4471	4.8	-23	69	-39.8

Underground penstock heat exchanger heat transfer model

Due to the underground heat transfer is a very complex process, the model of simplified assumptions are as follows:

1) The soil is uniform, the thermal properties of soil unchanged at the heat transfer process;

2) Ignore the soil moisture migration and influence of groundwater;

3) Ignore the surface temperature fluctuation effects on soil temperature, and soil temperature uniform;

4) Ignore the U type pipe wall and backfill, backfill material and the thermal contact resistance between the soils.

1 The determine of the heat conduction differential equation

$$\frac{\partial T_g}{\partial_t} = \frac{\lambda_g}{\rho_g c_g}\left(\frac{\partial^2 T_g}{\partial r^2} + \frac{1}{r}\frac{\partial T_g}{\partial r}\right) \quad (1)$$

In the way, T_g —The temperature of Soil,˚C; t—Time，S;

λ_g —Soil thermal conductivity/(m·˚C); ρ_g —Soil density, kg/m³; c_g —Specific heat capacity of soil, J/(kg·˚C); r—The radius of the U tube,m.

2 The determine of Equivalent diameter.

Cause of the Underground penstock with vertical U tube, tube spacing is close, and two adjacent wall will produce the influence each other, so the heat transfer surface and the soil is not uniform, in order to simplify the calculation, A equivalent tube instead of the equivalent radius of the U tube two.

$$r_{eq} = \sqrt{2}r \quad (2)$$

In the way, r- The radius of the U tube

3 Definite condition

(1) The initial conditions: the earth is regarded as isothermal body, according to the formation of thermal test measured initial ground temperature is 12 ˚C.

(2) Boundary condition: the equivalent pipe wall boundary conditions for the second boundary condition, when the heat pumps operation

$$-\lambda_g \frac{\partial T_g}{\partial_r}\Big|_{r=r_{eq}} = \frac{q}{2\pi r_{eq}} \quad (3)$$

In the way, q- The Unit amount of Borehole heat removal, W/m

When the heat pumps stop

$$-\lambda_g \frac{\partial T_r}{\partial r}\Big|_{r=r_{eq}} = 0 \quad (4)$$

Well drilling soil for adiabatic conditions

$$-\lambda_g \frac{\partial T}{\partial r}\Big|_{r=\infty} = 0 \quad (5)$$

4 The establish of the heat transfer model

The ground source heat pump project of the library according to the building in winter heat flux and soil heat exchanger calculation need heat hole 104, and then consider the drilling safety margin of 15%, the project for the heat transfer hole 120 single hole depth 100m, aperture 180mm, arrangement of hole spacing is divided into 4m, 5m, 6m. Heat pump in this project is show in Figure 2.

In this thesis, The total of 16 well group with the 5m distance will be simulated, and as shown in Figure 3, in a rectangular area is 35m * 35m, according to the 4 rows of 4 columns, evenly spaced 16 buried tube heat exchanger, drilling depth is 100m, the hole diameter 0.18m, buried pipe for 32mm, the heat exchanger spacing and heat exchanger and the soil boundary distance was 5m. Tube group drilling depth is 100m, aperture r=0.018m, equivalent radius of =0.025m, U type tube diameter is 32mm. Heat exchanger spacing and the heat exchanger and the soil boundary distance was 5m, initial ground temperature is 12 ˚C. By using CFD what is a special pre-processing software Gambit to

establish model and dividing grid as show in Figure 4, the simulation software to read the grid using Fluent heat pump operation, for five years the change of soil temperature field. The simulation runtime system physical parameters show Table 2**.**

Table 2, The thermal parameters of Ground-source heat pump system

The initial temperature of soil（˚C）	The initial temperature of soil W/(m·˚C)	Soil density (kg/m³)	Soil specific heat capacity J/(kg·˚C)	Thermal conductivity of water W/(m·˚C)	Water density kg/m3	Water specific heat capacity J/(kg·˚C)	The single well heat (w/m)

The simulation and analysis of dynamic

The simulation time of ground source heat pump system for five years, according to the characteristics of climate and load of the Building in Changchun City, operation process of every year is divided into four stages, the first stage for heating conditions (October 25th - April 15th), the second stage is the heating conditions after the end of the natural recovery (April 16th -5 months 31), the third stage is the cooling condition (June 1st -8 months 31), the fourth stage is the cooling after the end of the natural recovery (September 1st -10 months 24).The simulation and analysis of dynamic show figure5,figure6,figure7,figure8,figure9 and figure10.

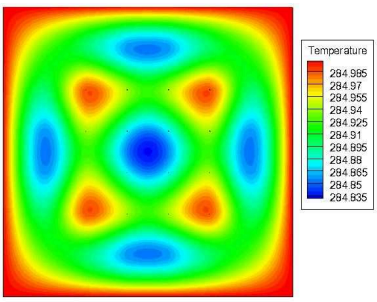

Fig.5, The temperature field Changes during one year

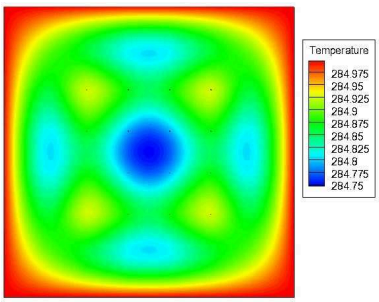

Fig.6, The temperature field Changes during two years

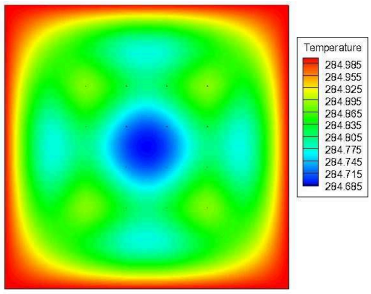

Fig.7, The temperature field Changes during three years

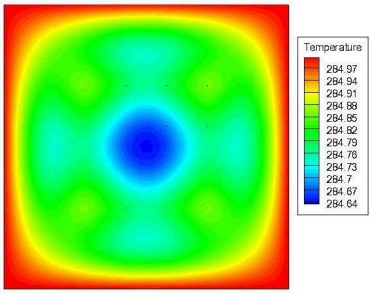

Fig.8, The temperature field Changes during four years

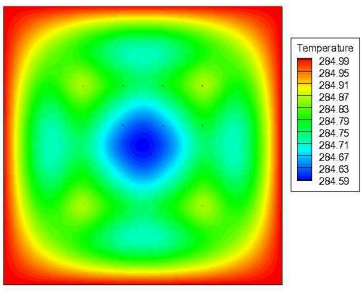

Fig.9, The temperature field Changes during five years

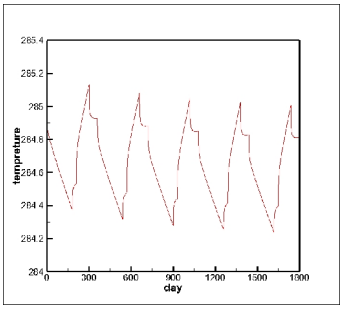

Fig.10, The average soil temperature variation

According to the simulation results, in the heat pump system after 1 years of operation, the soil after heating condition and the transition season in the heat exchanger will continue to absorb heat from the soil, the soil heat is not fully complementary, so the intermediate in the formation of the heat exchanger area cold accumulation, and well group Center "low temperature pit" is the heat exchanger area at low temperature in the soil is the most concentrated in a region. Through the heat pump system in operation, tube group around the soil temperature 0.15 ˚C lower than the initial soil temperature, soil temperature field system change after 2 years, the central area to reduce soil temperature 284.75K, 0.25 ˚C lower than the initial soil temperature. The system runs well group center temperature area expansion after 3 years, the central area to reduce soil temperature 284.68K, 0.32 ˚C lower than the initial soil temperature, the system to run for 4 years after the change of the soil temperature field, well group center soil temperature decreased, the temperature is lowered to 284.64K, than the initial soil temperature is 0.36 ˚C lower. Variation of system operation of soil temperature field in 5 year, reduce soil temperature well cluster center to 284.59K, 0.41 ˚C lower than the initial soil temperature. The soil temperature field can be balanced, and the soil temperature can be restored.

Conclusions

According to the simulation analysis on the operation of ground-source heat pump system: the soil temperature field has been basically balanced as the Ground-source heat pump system in 1 year operation, and as that proved the control area partition thermal compensation method for the proposed is feasible in severe cold regions. The system run for 5 years in the process of soil temperature decreased year by year, 5 years after the operation of the heat pump system, soil center temperature lower than the initial soil temperature as 0.41 ˚C,This shows, the thermal compensation method have a certain effect of resolving on the soil temperature which is used by the GSHP system, and this kind of mode is feasible.

Key words:field synergy principle; metal-wire inserts; heat transfer enhancement; experiment study

Abstract. Based on Field Synergy Principle and orthogonal experiment design, nine arranged metal-wire inserts(that is high porosity porous inserts) is determined to experiment. The results showed that heat transfer performance of the pipe that metal-wire inserts is rooted at the core region of pipe is better than the pipe that metal-wire inserts is rooted at the edge region of pipe., location and curve radian can impact heat exchange significantly. Under the given experimental condition, the heat transfer quantity increased by 120 - 520%, overall heat transfer coefficient increased by 126 - 610%. Through enhancing heat transfer performance evaluation criterion (PEC) comprehensive evaluation, it is concluded that when the Reynolds number Re changes in 338 ~ 6931, the PEC value of 0.89 ~ 5.97.The calculation formula of the drag coefficient is obtained by regression analysis.

Introduction

At present,more energy has been converted and used through heat energy,which has reached more than 90% in China.Heat exchangers accounted for more than 70% only in the equipments of petrochemical enterprise[1].Our country keep in a low level in energy utilization.How to improve the energy utilization and develop new energy become an important topic under the circumstances of the global energy crisis, Research of heat transfer enhancement of heat exchanger has become an important means of engineering energy-saving in China under the background in the "energy conservation and emissions reduction" and the construction of economical society. The disturbed flow device Which has been inserted into the tube has low cost relatively,meanwhile,it has simple process and easy cleaning,and is especially good for innovation of old equipment[2].This device can effectively prevent dirt generated, therefore this device has been widely applied in engineering.

Field Synergy Principle of inserts heat transfer enhancement.

Field Synergy Principle. At present, flowing and heat transfer of porous medium involves in many engineering application fields,which has become one of the forefront in the active research areas in the engineering of thermal physics discipline.Inserts which is rooted in the pipe is regarded as heat transfer enhancement of porous medium (porosity $\varepsilon \geqslant 95\%$) in the pipe. When flowing liquid in the tube through inserts, the dispersion effect obviously generate in the flow channel. Under the condition of low Reynolds number ($Re \geqslant 300$), the flowing of liquid in the tube change into turbulence by promotion of dispersion flowing[3]. Total thermal resistance of flowing liquid under

the condition of turbulence is minimum at all flow patterns. Because thermal resistance of flowing liquid in the tube under the condition of turbulence is very small, heat transfer coefficient (K) of heat exchanger will greatly increase. Under the condition of high heat transfer coefficient (K), the effect of inserts heat transfer enhancement will be very obvious.

Academician in China named Zengyuan Guo analysis the energy equation to the boundary layer flow,re-examined mechanism of convective heat transfer from the angle of mutual coordinate of velocity field and temperature field, and put forward Field Synergy Principle[4] of heat transfer enhancement.

For situation of Steady-state incompressible flowing, introducing variable into expression of convective heat transfer energy equation, thus obtain the equation:

$$Nu = \mathrm{Re}\,\mathrm{Pr}\int_0^1 \left(\left|\overline{U}\right|\left|\nabla\overline{T}\right|\cos\beta\right)d\overline{y} \tag{1}$$

Among them, β express the angle between velocity vector and heat flow vector.

We can see it is the effective measures of strengthening heat transfer by inducing this angle.

According to Field Synergy Principle, we can achieve the purpose of heat transfer enhancement by organizing flowing of fluid in the heat exchanger effectively to reduce included angle between velocity field and temperature field.Based on this principle,this paper insert meal-wire into heat exchange tube and reorganize flowing of fluid to achieve the purpose of heat transfer enhancement with smaller flow resistance increase.

The analysis of metal-wire inserts. For heat transfer of laminar flow in The tube, the drop of the temperature mainly occur at the radial direction of tube[5], included angle between velocity and temperature gradient close 90°, integral value close 0 by Eq.(1.1), so heat transfer ability is poorer. As long as we produce a smaller velocity along the radial direction of tube, it can influence heat transfer significantly.

Inserting metal-wire network structure of organization according to specific rules into tube, constructing large porosity porous inserts,which can construct porous aisle in the tube.However the fluid of porous medium inner have the dispersion effect, which is similar to eddy of turbulence, it makes fluid to mixing along the radial direction under low Reynolds number (Re ≥300), and makes temperature distribution of radial direction to uniform, which can enhance heat transfer. It is important that flow resistance increase is small.

Experimental research

The experimental device and Process. Test device is mainly composed of casing tube heat exchanger, cold and hot water tank and a series of measurement and control instrument, The main process is described as follow: hot water is supplied into tube from heating water tank by circulating pump, and return heating water tank through rotameter, electric heater offset heat loss of hot water in the water tank, which keeping the temperature of hot water constant. Running water is inducted into casing tube heat exchanger as cold water, exchanging heat with hot water, and is exhausted to sewer. Flow direction of hot and cold fluid is contrary, so the experiment is convective heat transfer.The experiment process is shown in Fig.1.

Comparing casing tube heat exchanger with metal-wire network structure to plain tube heat exchanger in the experiment, so that we can validate heat transfer performance of heat exchange tube with metal-wire inserts. Changing velocity of hot fluid in the tube in different experiments, Keep velocity of cold fluid larger, so that obtain relatively stable test section temperature.The

measured data include temperature both at the inlet and at the outlet of cold and hot fluid, and test section pressure drop. Get heat transfer performance coefficient of heat exchange tube with metal-wire inserts, and criterion equation of heat exchange by calculated.

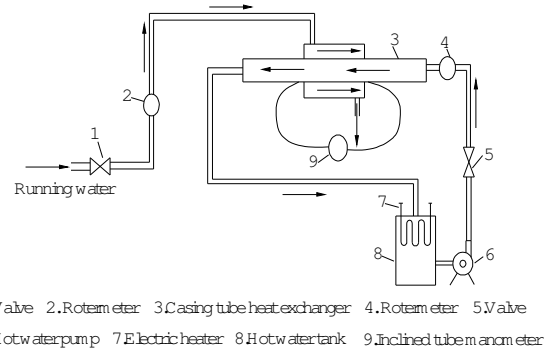

Fig. 1. Schematic drawing of experimental system

Results and analysis

Orthogonal experiment result analysis. By simulation analysis, this paper select 3 levels by location of metal-wire in the tube (A), metal-wire horizontal spacing (B) and curve radian (C). This paper make overall heat transfer coefficient K as experiment index and analyze orthogonal experiment[6] result of heat exchanger. We can get the most influential factor to experiment index and predict the optimal experiment combination. The range of 3 factors is obtained by orthogonal experiment range analysis, and demonstrated is shown in Fig.2,

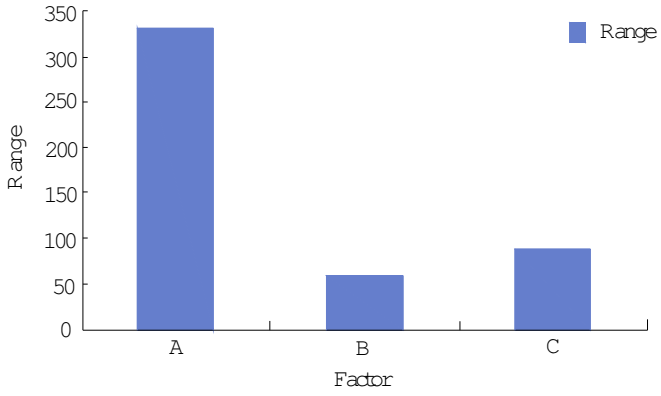

Fig. 2. The range of 3 factors

Through orthogonal design in the experiment,we summarize the poor and variance analysis to the 3 three parameters influence the heat pipe heat exchanger, The results show that location and curve radian can impact heat exchange significantly, the order according to ability of 3 factors impact heat exchange is: location > curve radian > spacing (A>C>B). Orthogonal experiment range analysis show that heat transfer performance of the pipe that metal-wire inserts is rooted at the core region of pipe is better than the pipe that metal-wire inserts is rooted at the edge region of pipe., this is because the full development period of equivalent thermal boundary layer is constructed in the tube, heat transfer enhancement main occur at the core region of flow.

Performance analysis of the heat transfer. Using the 50˚C hot water in the casing tube to exchange heat with constant 14˚C running water in the outer tube,taking average water temperature as qualitative temperature, When the heat hot water release equal to the heat cold water absorb (difference between the two<<5%), measuring temperature both at the inlet and at the outlet of fluid

and flow of cold and hot fluid. Getting convective heat transfer film coefficient of metal-wire porous tube by Wilson Principle, and criterion equation of heat exchange:

$$Nu = C \cdot \mathrm{Re}^{m} \cdot \mathrm{Pr}^{n} \tag{2}$$

the relation curve of overall heat transfer coefficient *(K)* and Nusselt number (*Nu*) versus Reynolds numbers (Re) are shown in Fig.3 and Fig.4.

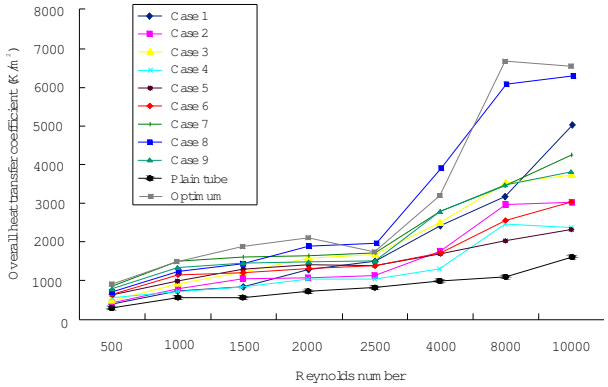

Fig. 3.Overall heat transfer coefficient versus Reynolds number

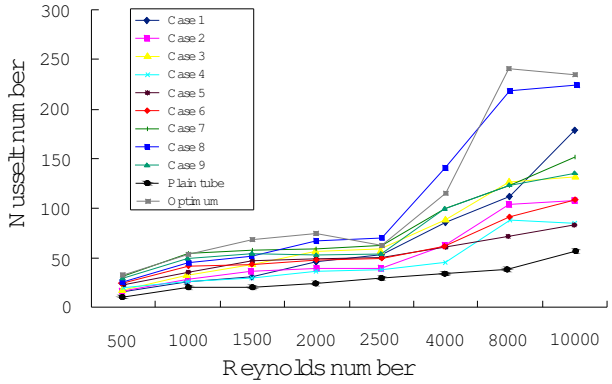

Fig. 4. Nusselt number versus Reynolds number

K and *Nu* gradually increase with increasing of Reynolds numbers, which consistent with change trend of plain tube. Under the same Reynolds numbers, overall heat transfer coefficient of tube with metal-wire is obviously bigger than plain tube, it show that metal-wire inserts can enhance heat transfer significantly. By calculating heat transfer quantity and overall heat transfer coefficient of tube with metal-wire, we know that heat transfer quantity increased by 120 - 520%, overall heat transfer coefficient increased by 126 - 610%.

Flow performance of heat exchanger analysis. Resistance coefficient of fluid in the tube is as follows:

$$f = \frac{2\Delta p}{\rho v^{2}} \cdot \frac{d_e}{l} \tag{3}$$

In the formula, $\triangle p$——the pressure drop of test section,Pa;

d_e——the hydraulic diameter of test section;

ρ ——heat density, kg/m^3;

v—— average flow velocity, m^2/s;

l—— the length of test section, m(200mm in the experiment).

We obtain the resistance coefficient by measuring pressure drop of test section, and draw resistance coefficient regression equation. The pressure drop $\triangle p$ versus Reynolds number Re is shown in Fig.5. As shown in the figures, pressure drop $\triangle p$ increase with increasing of Reynolds number Re, the pressure drop $\triangle p$ of tube with metal-wire is bigger than plain tube. It indicate that fluid resistance increase after metal-wire is inserted into heat exchange tube.

It can be seen from Fig. 5. After metal-wire is inserted into heat exchange tube, pressure drop $\triangle$p increase with increasing of Reynolds number Re, and the pressure drop $\triangle$p of tube with metal-wire is bigger than plain tube. It indicates that fluid resistance increase after metal-wire is inserted into heat exchange tube. The resistance coefficient is regressed, which obtain resistance coefficient regression equation:

$$f = 0.1476\,\mathrm{Re}^{-0.9653} \cdot \varepsilon^{-0.328} \tag{4}$$

Applicable conditions of the equation include: ① the hydraulic diameter of rectangular section tube is equal to 41.27; ② Re is among 300-1.3×10^4; ③ the porosity of metal-wire inserts ε is among 93.7-98.1

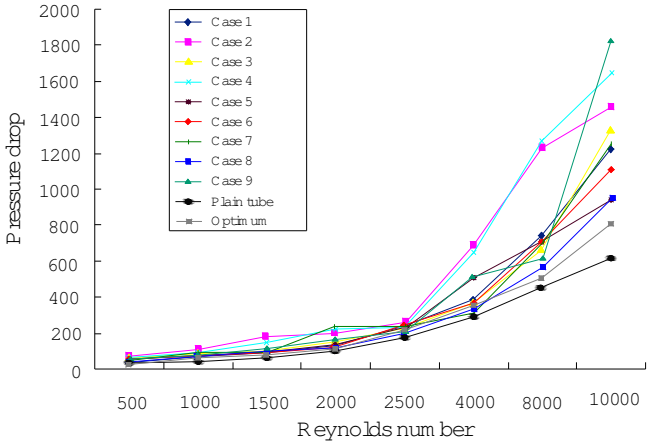

Fig. 5.Pressure drop versus Reynolds numbers

Comprehensive performance evaluation of heat exchanger. When heat exchanger is enhanced heat transfer, resistance will increase with increasing of heat exchange[7]. Some incremental of resistance is bigger than incremental of heat exchange, such measures is obviously unrealistic, we can also see that when the metal-wire inserted to enhance the heat transfer, Resistance is higher,So it is necessary that comprehensive evaluate heat transfer enhancement technology.

This paper adopt PEC as evaluation criteria of heat transfer enhancement performance according to paper[8]:

$$PEC = \left[\frac{Nu}{Nu_0}\right] \Big/ \left[\frac{f}{f_0}\right]^{\frac{1}{3}} \tag{5}$$

PEC>1 denotes that heat transfer enhancement is valid. The bigger PEC value, the better heat transfer enhancement effect. Comprehensive evaluation index PEC versus Reynolds number Re is shown in Fig.6. When $300 < Re < 1500$, the change of PEC value is small with increasing of Re; When $1500 < Re < 4000$, PEC value is monotonic rise with increasing of Re; When Re=6931, PEC value is maximum and up to 5.97; When Re=338, PEC value is minimum and up to 0.89. The heat transfer performance of all 9 cases experiment is enhanced, their heat transfer enhancement effect is obvious.

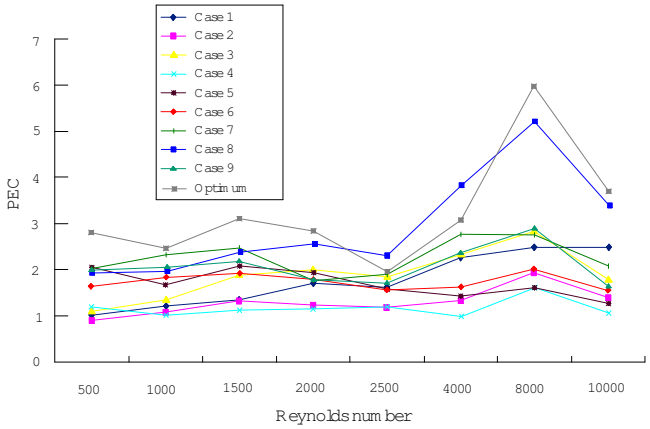

Fig. 6. PEC versus Reynolds numbers

Conclusions

(1) Orthogonal experiment range analysis show that heat transfer performance of the pipe that metal-wire inserts is rooted at the core region of pipe is better than the pipe that metal-wire inserts is rooted at the edge region of pipe., location and curve radian can impact heat exchange significantly, the order according to ability of 3 factors impact heat exchange is: location > curve radian > spacing.

(2) By calculating heat transfer quantity and overall heat transfer coefficient of tube with metal-wire, we know that heat transfer quantity increased by 120 - 520%, overall heat transfer coefficient increased by 126 - 610%. It show that metal-wire inserts can enhance heat transfer significantly.

(3) After metal-wire is inserted into heat exchange tube, pressure drop $\triangle p$ increase with increasing of Reynolds number Re, and the pressure drop $\triangle p$ of tube with metal-wire is bigger than plain tube. The resistance coefficient is regressed, which obtain resistance coefficient regression equation.

(4) When Re are change from 338 to 6931, PEC value also change from 0.89 to 5.97. The heat transfer enhancement effect of all 9 cases experiment is obvious.

Keywords: Ash conveying system for economizer ; Pneumatic ash handing ; Blockage;Technological retrofit

Abstract：The power economizer of 600MW boiler in ash pipeline system of ash clogging, vibration, resulting in problems of ash conveying device is not running, the causes are analyzed, put forward the optimization scheme. Transformation through a series of Economizer Ash Conveying System, effectively eliminate the ash conveying pipeline vibration, clogging problems, ensure the economizer ash conveying system.

Introduction

Economizer ash conveying system is an important part of the normal operation of the boiler, economizer unit pneumatic ash conveying system, will reduce the pollutant discharge of atmospheric pollution, ensure the stable and efficient operation of the follow-up equipment safety unit[1-2]。Economizer of boiler in a power plant 2×600MW unit pneumatic ash conveying system, the dense phase conveying compressed air. The system consists of the discharging water dome valve, pump, ash transport pipeline, dense phase air supply device, dry ash storage. 7 below the boiler economizer hopper, fly ash of large particles collected in flue gas, in the control of ash conveying control system, 7 pump a falling ash, uniform delivery to the dry ash storage. The grey rough and ash conveying system without fluidizing device, dense phase stabilizer frequent blockage, causing blockage ash pipeline economizer, causing the pipe vibration.

Transformation of the former system problems

The economizer. The main problem of the following respects grey system running in time:

(1)A large number of dense phase stabilizer air conveying system (every 3 meters set 1), dense phase stabilizer for quality, wear or compressed air quality low, lost the check function, so the ash pipeline ash clogging check valve, ash transport pipeline lose the compressed air supply, no method to complete the normal transportation.

(2)Ash bin pump using the AV pump, pump bottom without fluidizing device, economizer hopper for ash, crude ash grey, falling ash accumulation in the bin pump bottom, by ash blowing compressed air, dry ash easily in the bin pump to form embolism.

(3)Economizer Ash from line 24 meters vertically downward through the pipeline 6 meters high, the stent delivery to 350 meters far, 20 meter high dry ash storage. Because the ash conveying pipeline elbow, the gap between large, extremely easy to cause the ash in the pipeline settling and accumulate, form a blockage.

(4)The system adopts water cooling type dome valve, pneumatic seals with dome valve, to ensure that the seals are not hot cement burns, the ball using water-cooled cooling. Economizer hopper as low boiler the flue, construction of the remaining debris and heating surface falling components (welding rod, wire) stuck in dome valve, extremely easy to cause the wear of the sealing ring and the dome of the rock, grinding cooling waterway wear dome, can lead to the cooling water into the ash falling pipe, ash bucket, ash change caused by the ash wet, compaction; at the same time the wet ash into the ash conveying pipeline and the ash storehouse, causing ash pipeline blockage and ash silo unloading difficulties.

(5)No row blocking device of ash conveying system. Pipeline plugging, manual cleaning, through the pump on the small ash discharge valve pressure relief or along the pipeline on pipeline, find the choke point. High altitude operation danger and environmental pollution.

System optimization design

Economizer design points of Grey System Optimization:

(1)Design capacity. Considering the current coal supply, coal and ash conveying system, design output should be appropriately increased, prevent the undercapacity, ash bucket full of accidents. This works by coal-fired boiler 320t/h, calculation of ash content 35%, ash content is 112t/h, Economizer Ash (according to the total ash content 5% consider) for 5.6t/h.

(2)Pump capacity design. Pump should have sufficient capacity to minimize the valve action time, but also shoulds not be too big, economizer hopper volume is generally not more than $0.5m^3$, if the tank volume is too large, the charging time increased, will cause the instantaneous conveying capacity is too large and plugging. This system conveying tank volume is provided with $0.5m^3$, can satisfy the need of ash, do not change. Pipeline installation of 57 5mm in the bin pump at the bottom of the inner sleeve and the pump casing (double reference ash transport double casing), improve the stem initial liquidity ash.

(3)Valve selection. The economizer ash temperature up to 400 ℃, the transformation, the inlet valve, outlet valve selection using high temperature double metal seal valve, effectively improve the reliability of the equipment.

(4)Design of blanking pipe expansion volume. Economizer hopper downward expansion amount is 250mm, about the expansion 150mm. Three installation of expansion joint expansion to the pulverized coal ash, compensation in different directions.

(5)Pipeline design. Between the ash conveying pipeline to the economizer hopper dredging pipeline installation, and installed exhaust valve and draining pipe metal compensator (absorption economizer hopper hot when the downward expansion). Ash conveying pipe blockage can be opened when the line block valve, reduce the labor intensity of manual dredging the blockage of the pipeline, also with the blanking valve exhaust valve pump work[2]. Increased Paidu manipulator valve in the control room of CRT picture, discharging valve for manual control.

Conveyance ash system transformation of economizer

4.1 Selection of an ash conveying system

At present, economizer hopper of dry ash conveying system piping layout are: economizer hopper ash conveying to ESP entrance; ash conveying pipe economizer hopper ash transportation pipeline with esp an electric field or electric field of two common; economizer hopper ash through the ash pipeline separate to the ash storehouse.

Considering the wide source, power plant coal coal quality change, esp a field itself ash conveying pressure, the electric dust dry ash removal system into consideration, should not be economizer hopper ash conveying to ESP electric field; considered from the cost point of view, is still based on the original system, through the ash transportation pipeline, uniform delivery to the dry ash storage.

4.2 Ash conveying system

The specific reform areas:

(1) The ash storage pump pipeline pump is changed into a double casing, and at the same time, the reform of AV pump, pump bottom mounted inner casing, improve dry transport mobility gray early.

(2) Economizer tube ash pipeline transmission vertical downward and horizontal pipe elbow joint, installing a set of internal air supply device, improving liquidity in grey; ash silo pipeline, site bend, vibration blocking concentrated mounting an air supply device, reduce the blockage of the pipeline, the degree of oscillation.

(3) Discharge valve before the installation of a DN80 pipeline to the economizer 7, an ash conveying pipe in the economizer, as ash conveying system draining device.

(4) Blanking valve and outlet valve adopts high temperature double metal seal valve, replace water-cooled dome valve.

(5) The blanking pipe expansion serious, failure of the bellows expansion joints for three to replace coal compensator deformation section.

Conclusions

Ash conveying system in thermal control logic unchanged, an automatic operation or operation manual. The operating personnel by controlling the feeding time, falling blanking valve waiting time, feeding amount adjusting pump to guarantee output ash conveying system. Based on a series of grey system in transformation, Economizer Ash Conveying in normal operation, to achieve the desired results.

Keywords: Frozen soil foundation wall, automatic temperature measurement, wireless transmission.

Abstract: Supporting of deep foundation of ditch has become outstanding issues. As a kind of effective supporting measurement, independent development of automatic temperature measuring system and wireless transmission system. Foundation ditch and froze soil's retaining wall has been taken into account. According to study of automatic temperature measurement of foundation ditch and froze soil's retaining wall and system of wireless transmission, this paper gets its own result. It plays an important role in temperature in foundation ditch and froze soil's retaining wall and survey in change of froze soil's retaining wall. And at the same time, we can transfer information and reduce the possibility of damage wire in engineering site. Foundation ditch and froze soil's retaining wall is a kind of environmental. It has an important meaning in deducing cost of foundation ditch and environmental construction.

Preface

Frozen soil wall as special method that it used in foundation pit soil retaining wall method as used in the construction of the special method, freezing process lasts about to frozen section of the building structure has been completed, foundation pit soil retaining wall technology gradually began as a subject to be studied in the construction site, but due to the detection of line is overmuch, can cause damage, causing the construction the phenomenon of pause, so this research is foundation pit soil retaining wall automatic temperature measuring and wireless receiving system, independently developed a set of automatic temperature measurement system with wireless transmission system, reducing cost and construction time vandalism.

Multi point temperature measurement and wireless transmission into the 9 probe, a square stereo in three horizontal longitudinal three, a total of three row. The recorded data by wireless transmission equipment transmission, will display the data with other panel insert can directly read sensor light statistics of wireless transmission of data (through the wireless transmission of data effects is very small, neglected) changes, and the actual direct test results are compared, find out the deviation, and indirect test data are corrected.

Development of multi point automatic temperature measuring system and wireless transmission equipment

1.1 Multi point automatic temperature measuring system

Multi point automatic temperature measuring system comprises a main processor, a temperature sensor, LCD monitor, PC.the main processor is AT89S52 of processor made.

The digital temperature sensor DS18B20 temperature sensor is a new generation of single bus digital temperature sensor, the single bus is the address line, data line, the line of control in three for a signal line, a signal line for bidirectional data transmission, so that the maximum to minimize the number of communication lines, make the system more simple. The system is based on PC as a host computer, microcontroller as the core of data acquisition for PC, SCM needs only one port line can with multiple DS18B20 series connection and communication, microcontroller through the serial port and PC machine together, constituted distributed three-in-one control system. The system uses DS18B20 to complete the temperature sampling and conversion work, while the microcontroller 89C51 always control and communication function. When in use, multiple DS18B20 and single chip microcomputer is connected with a line, the formation of the multi-point temperature measurement.

Liquid crystal display chooses 1602 character LCD module, LCD monitor with its low power consumption, small size, show many advantages of rich content, thin and light, it is widely used in the portable instrument and low power application system.

Host computer using RS232 interface, its full name is "data terminal equipment (DTE) and data communications equipment (DCE) between serial binary data interchange standard interface technology". The standard DB25 connector using a 25 foot, each pin connector signal content to be defined, but also for various signal level to be provided. With the continuous improvement of equipment, the DB9 interface instead of DB25, now the RS232 interface called DB9.

The assembly of each component:

(1) The main processor program, nine probes also can measure temperature.

(2) In the upper computer, the need and software combination, using serial debugging genies degree.

(3) In the temperature sensor, should be waterproof, the temperature measurement system used in engineering field, must be waterproof.

(4) For liquid crystal displays, seriously each connection, to ensure that the correct.

1.2 wireless transmission equipment.

This design is the core of NRF9E5 radio frequency chip, NRF9E5 is composed of a core of 8051 and a 433/868/915 MHz wireless transceiver chip NRF905. The equivalent of enhanced MCU integrates the wireless transceiver chip.

Engineering practice in the field of complex environment, the wireless part must have strong anti-jamming capability and the data transmission efficiency. In general, in the data transmission distance of 100~200m construction. The wireless data transmission module (NRF9E5) can completely meet the transmission distance. In the device of sensor nodes and main control unit using NRF9E5. So that the sensor nodes and the main control unit is formed between the point to point link, and a plurality of sensor node and a main control unit for data transmission, the formation of a star network structure. Because each node has a unique address, the main control unit to select the corresponding nodes to communicate, so that each node in a controlled state, everything in good order and well arranged to transmit data.

For low power implementation of the main control unit, the system adopts 1.9~3.6 V power supply voltage, if only use two No. 5 batteries or 3V batteries can work for 1~2 years, fully meet the requirements of low power. The main control unit of the display part due to general I/O NRF9E5 module on the mouth is very limited, so this system uses DM12232F LCD module, its connection with MCU to serial mode, need only 3 data lines, effectively avoids the problem of insufficient port.

Each communication node and data monitoring module uses NRF9E5,NRF9E5 8051 kernel is enhanced 51 MCU cores, with 4 input 10 bit A/D converter 80ksps, the four A/D converters can be used to the standard signal conversion on the sensor nodes. Can fully meet the requirement of the design of the host computer data processing. The main module and each node using time division multiple access TDMA the way to avoid the point to multipoint wireless communication data collision, through RXD and TXD serial port settings, connected to each node of the data collected from the MAX232 level conversion and PC, and through the module sends control command and effective data for each node set of sensor nodes control.

This design is for the measurement and wireless transmission of permafrost retaining wall of low temperature expansion. To detect temperature must adopt appropriate sensor. The sensor task will transmit the data to the data acquisition system, and the data acquisition system transfers the data to the host computer for analysis and processing.

At present, the reliability measure is used in sensor performance is good, high reliability to use under the condition of sensor parts often work under the bad environment, such as thermocouple and thermal resistance often working in corrosive and fluid erosion environment requirements, temperature measuring element capable of continuous trouble free working time longer, and puts forward mounted on the measuring element in the design of the structure. In the recent twenty years, considering the possibility of replacement components without stopping the machine, because of platinum thermal resistance of the production technology has made a major breakthrough, the range of temperature measurement platinum thermal resistance increased from 650 ˚C to 850 ˚C, temperature measurement precision and reliability (life) have greatly improved, and prices significantly lower.

Through one corresponding key, the first key, the first light receiving end of the light, followed by the two, third, the receiving end lights are bright, enough to prove to the signal transmission in the past, after some of the procedures and A/D converter, the analog signal into a digital signal, it can realize the wireless transmission temperature. The spot has been test, distance is received in 100~200 meters.

Equipment connection

2.1Connect to a wireless transmitting equipment and measuring system

The wireless transmitting device plug and the connector can be connected to a wireless transmitter and temperature measurement system, connected to a wireless transmitting and receiving devices enter the program, so that it can be measured temperature transmission to the receiving modules, after obtaining the temperature value through equipment and computer wireless connection.

2.2 Connecting devices and computer wireless receiver

This is used by the PC machine as the position machine to realize data display, so to the communication interface appropriate system configuration is necessary. Communication of parallel communication and serial communication, parallel data communication transmission capacity, but requires a large number of wiring, not suitable for long distance transmission. The serial communication with the characteristics of convenient connection, widely used for remote communication. In the serial communication with RS232 and RS485, the most widely used.

NRF9E5 and PC to realize the hardware interface communication by RS232. Since the PC series microcomputer serial interface for RS232C standard interface, input and output are used, TTL level of 89C51 MCU inconsistencies in the interface specification, so converting to TTL level to RS232 interface level using AXIM Company’s MAX232 standard RS232 interface chip P02 for the simulation of the receiver.

Temperature field simulation experiment device and the measuring point

3.1 Temperature field simulation test device measuring point

Longitudinal tube of frozen wall temperature field control simulation test device is composed of 4 parts: model test chamber, temperature control system, control system and test system .In order to ensure the simulation boundary conditions and foundation pit engineering similarity model test, insulation box consists of 150 mm thick insulation effect of sand layer two 9mm thick organic glass plate combination, internal test space net size is 0.8 m× 0.8m×0.8 m. Vertical tube wall temperature field of frozen soil control simulation test device is composed of 4 parts: model test box, temperature control system, control system and testing system. In order to ensure the simulation boundary conditions and the foundation pit engineering similar sand model test, insulation box is composed of 150 mm thick insulation layer two 9mm thick organic glass plate, internal test space net size is 0.8 m × 0.8m × 0.8 m.

3.2 Select the point position

Mainly for multi-point temperature measurement in order to form a relatively well, taking the center of the model as a benchmark pipe freezing tube section hydraulic arrangement of 9 measuring points in the center of the frozen. Square three-dimensional into horizontal three vertical three, a total of three rows. Depth from surface calculated distance, horizontal distance of center pipe starting distance. (Figure 1)

Conclusions and suggestions

5.1Conclusions

By analyzing the data, we can be inferred from the rules:

The temperature is collecting temperature lower than measured temperature is the temperature is collected; in temperature must be higher than the measured temperature when negative. In fact, sampling and testing temperature difference, and repeated comparison of data, the correction results are: the measured temperature is positive, then on the basis of 0.5 °; the measured temperature is negative, then on the basis of minus 0.5 °.

5.2Suggestions

The test for the indoor test, due to limitations of the model device size, there are some differences in the foundation pit engineering thermal insulation and stratigraphic simulation and actual, not considering the influence of groundwater and geothermal, in future experiments suggest, can take the field of small pit simulation form, more practical.

Keywords: electric heating oil heater MCU temperature humidity

Abstract. An intelligent electric heating oil heater control system is designed in this paper. It takes the single chip microcomputer as the core controller; detects environmental temperature using the temperature sensor; controls opening and closing of electric heating oil heater according to the temperature user set; checks whether there is person indoor using the body detection sensor, if there is no, the oil heater is power off automatically; detects environmental humidity using the humidity sensor ,deciding whether the oil heater is turned on according to the current humidity sends out the alarm; detects oil heater placement using the angle sensor for detecting oil heater placement, Unable to start the oil heater. When the electric oil heater stands upside down or is set flat or inclined, it will send out the alarm. At the same time, the system is provided with keyboard and display circuit, which are used to set the various functions, such as setting the child lock and displaying the corresponding information.

Introduction

Oil heater is also called oil filled heater, is a space heater which is popular in recent years, its heat conduction oil is needed not to be changed and its long service life is also its advantage, besides, there is no noise, no light, no dust, no odor at the working state. However, at present, the control of the electric oil on the market is relatively simple and mainly using the switch and knob to control, the intelligent degree is low, unable to effectively save energy, and the security is low, unable to deal with the various things in family. We design and improve the system on the basis of this to improve the safety of electric heating oil heater then a multifunction and high security intelligent electric oil heater is designed.

The design of overall system

2.1 The design of the system function

2.1.1 Intelligent temperature control function

The control device can detect and display the current temperature indoor, adjust the heating power of electric oil heater automatically combining with the temperature the user set, which can effectively save energy;

2.1.2Auto induction of human body function

If there is some person in room, the oil heater works normally, otherwise, it will be Automatic power off, in order to achieve safe and energy-saving effect;

2.1.3The child lock function

The user can set the child lock function available, so that the children can't open the oil heater without the adults indoor;

2.1.4The dumping detection and control function

When the electric oil heater stands upside down or is set flat or inclined, it will not start and send out the sound and light alarm;

2.1.5 Humidity detection and control functions

Electric oil heater can't be used in the high-humidity environment, once the control device detects the environment humidity exceeds the limit range, oil heater will not start, and sends out the alarm.

2.2 System construction

Electric oil heater control system mainly consists of a main controller, a key detection module, body detection module, the ambient temperature detection module, humidity detection module, tilt angle detection module, LED display module, sound alarm module, heating control module, which collaborate with each other under the control of MCU to ensure the implementation of the various functions of the electric oil heater, the system construction is shown in Figure.1.

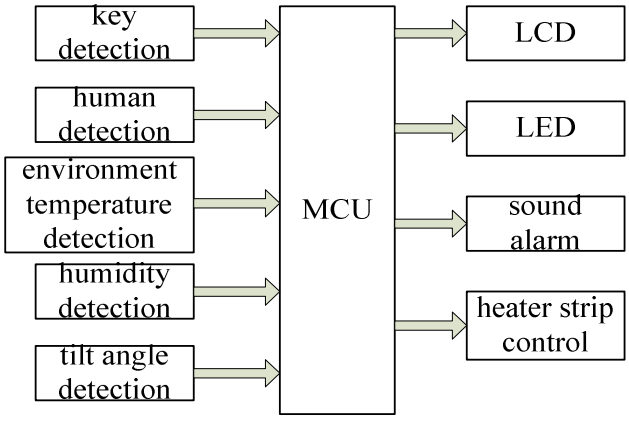

Fig.1 The block diagram of system construction

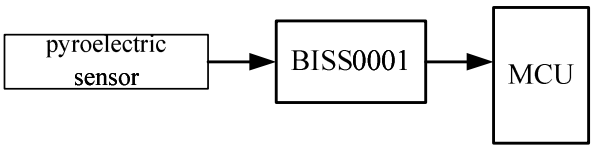

Fig.2The human detection diagram

The hardware design of the control system

3.1 The circuit of the MCU module

The controller of the electric heating oil heater uses STC12C5410AD microcontroller produced by domestic macro Crystal Technology Company, which has Wide 3.4V-5V working voltage range, 4K-FALSH program memory, 23 I/O ports, 2 16-bit timers, 4 PWM output. Based on the characteristics of the chip pins of STC12C5410AD, in actual design, human detection, temperature detection, humidity detection, angle detection, liquid crystal display, LED indicator, a voice alarm module are connected with the microcontroller I/O port and oil heater heating control module is connected with the MCU PWM port.

3.2 The human body detection

In this system, body detection is detected by the pyroelectric infrared sensor. Pyroelectric infrared sensor is mainly composed of a kind of high pyroelectric-coefficient material. Detecting signal of infrared radiation element is converted to the weak voltage signal, and then is output through the field effect transistor amplifier. The system uses the pyroelectric sensor BISS0001 as the processing chip, when there is some person, the pyroelectric sensor signal output high level after being treated by BISS0001, then is input an I/O port of the microcontroller, when the MCU detects that the falling edge of the signal, it shows that there is some person, the MCU decides whether the oil heater is started. Human body detection module schematic diagram is shown in figure 2.

3.3 The humidity detection module

Humidity detection module is used for detecting the environmental humidity oil heater located, when the humidity is greater than the threshold, the system will stop working. The system uses the HS1101 capacitance sensor as the humidity sensing element, HS1101 is placed in the 555 oscillation circuit, which transform the change of capacitance into voltage frequency signal inversely

proportional to it, and then the output signal is collected through the MCU. The circuit is shown in Figure 3.

The HS1101 and NE555 are connected to the circuit simultaneously. the function of NE555 circuit is summarized simply: When the pin 6 and the pin 2 is "1" at the same time, the pin 3 is output "0"; When the pin 6 and the pin 2 is "0" at the same time, the pin 3 is output "1". In this circuit, the 555 timer is used as multi state flip-flop output frequency signal just according to this function. When the power supply is switched on, the pin 6 and the pin 2 is input "0", then the pip 3 is output "1 ",because the voltage of the two ends of C1 is 0, C1 is recharge by VCC through R2 and R3. When the voltage of the two ends of C1 reached 2 /3VCC, the timer over reverses and is turned "0".Now, the base voltage of discharged BJT which is in the 555 timer is “1”, discharged BJT is conducted, so that the capacitor C1 discharge through R3 and internal discharged BJT, when the voltage of ends of C1 reduces to 1/3 VCC, the timer turns over again, and the output is "1", the internal discharged BJT is cut off, VCC begin charging on the C1 through R2 and R3, so go round and begin again, the oscillation is formed.

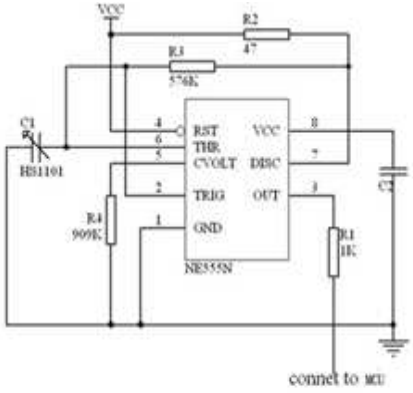

Fig.3The humidity detection circuit

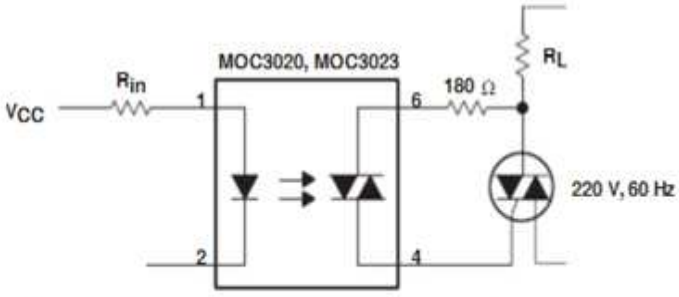

Fig. 4 The heating control module circuit

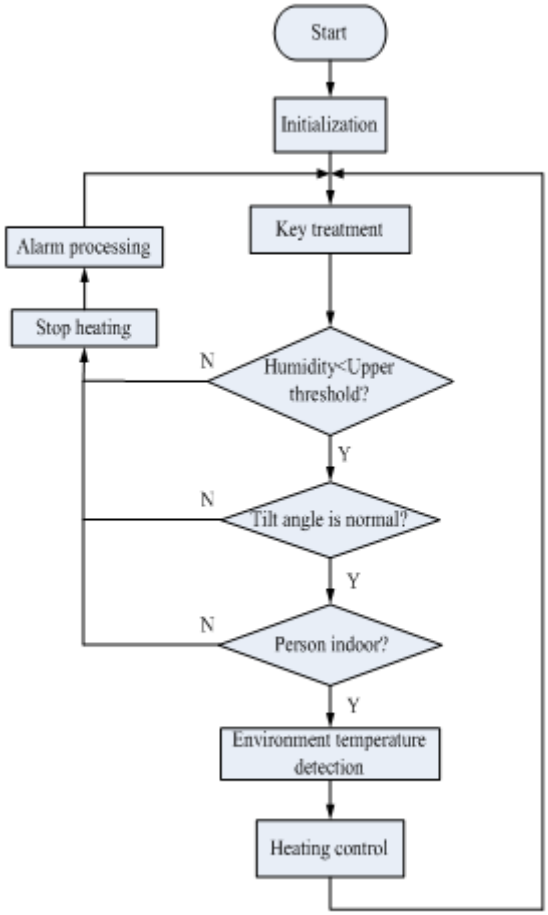

Fig.5 The flowchart of the software

The charging time in working cycle is T_h=0.7 (R2+R3) C1, the discharging time is T1= 0.7R3*C1, the duty cycle of the output pulse is q=(R2+R3)/(R2+2R3). In order to make the output pulse duty ratio is close to 50%, the R2 should be far less than R3. When the humidity changes outside, the capacitance value of both ends of the HS1101is changed, thus the output frequency of the timing circuit is changed. So as long as output frequency of 555 timer is measured, and according to the relationship between humidity and output frequency, we can obtain the humidity.

3.4 The temperature detecting module

The temperature detection module is used for detecting the temperature of the environment, and comparing to the temperature the user set to adjust the heating power of oil heater dynamically through the PID control algorithm. The system uses single bus temperature sensor

DS18B20 produced by DALLAS to detect the temperature, whose hardware circuit is very simple, here we say no more.

3.5 The heating control module

Oil heater uses the with heating wire heating, according to the different environment temperature detected ,combining with the temperature user set, adjusts heating power of the oil heater using PID algorithm dynamically, the circuit as shown in figure 4.

MOC3020 is the photoelectric coupler in figure. When the output of the SCM I/O is low-level, the photoelectric coupler is conducted, the port G of the bidirectional silicon controlled rectifier SCR1 gets trigger signals, the silicon controlled rectifier is conducted, and the voltage of two ends of the heating is 220V; When the output of the SCM I/O is high-level, the photoelectric coupler outputs no signal, the bidirectional silicon controlled rectifier is turned off, and the voltage of two ends of the heating is 0V. Accordingly, the PWM signal is output from n the SCM I/O ranging from low-level to high-level, conducted angle of the bidirectional silicon controlled rectifier can be changed by adjusting the duty cycle of the PWM signal, so as to achieve the purpose of regulating the heating power.

There are also the display module, keyboard module, and alarm module of hardware circuit in the system, which are much simpler, we say no more here.

The design of the hardware system

The design of System software follows the intelligent principle, when the control system is turned on, it is in the working status. The specific process is shown in figure 5. After power on, at first the system performs the initialization of program and variable, then tests whether the button is pressed, receives the information the user set (such as the setting of objective environment temperature),after this, it test whether the environment temperature and tilt angle is normal through the humidity sensor and angle switch. If the humidity value is over upper threshold or the angle switch is closed, it will stop heating program immediately, at the same time, send out the alarm. If the above are all normal, then it will test whether there is some person indoors. If there is someone, it will start the temperature detection sensor and collect the environment temperature, and then adjust the heating power through PID algorithm dynamically in order to the temperature maintain in the range of the value the user set. If there is no one indoors, it will stop heating the oil heater.

Conclusion

Intelligent electric oil heater control system designed in this paper, through testing and practical application, it is showed that the system has the characteristics of low cost, high intelligent degree and so on. Electric oil heater products have been applied in a company, the market reflects well. The system can accurately control the temperature according to the user set, provide a number of intelligent control and safety protection function for electric oil heater. It is the convenient to users at the same time saving electric energy to the full extent.

Key words: heat pump driven by steam turbine; irreversibility; optimal relation; thermal coefficient

Abstract: In this paper, a generalized irreversible heat pump driven by steam turbine cycle model was established by taking account of the heat resistances, heat leak and irreversibility due to the internal dissipation of the working substance. The heat transfer between the heat reservoir and the working substance is assumed to obey the linear (Newtonian) heat transfer law, and the overall heat transfer surface area of the assumed to be constant. The fundamental optimal relations between the heat load, the thermal coefficient of the system and the temperature difference of the evaporator are obtained. Moreover, the effects of the cycle parameters on the characteristics of the cycle are studied by numerical example. The results obtained herein have realistic significance and may provide some theoretical guidance for the performance improvements and optimizations of heat pumps driven by steam turbine.

Introduction

In recent years, the finite time thermodynamics has been developing rapidly, and many significant results have been obtained. Sahin and Kodal [1] have introduced a new finite time thermoeconomic performance criterion, defined as the cooling load for refrigerators and the heating load for heat pumps per unit total cost (total of investment and energy consumption costs). Based on this criterion, they investigated the economic design conditions of single stage and two stage vapor compression refrigerators and heat pumps [1–2].Some researchers established four-heat-reservoir absorption heat pump cycle with the loss of heat resistance and internal irreversibility [3], and with the loss of heat resistance, heat leakage and internal irreversibility [4,5]. In the studies of the internal irreversibility, almost just one internal irreversibility parameter is introduced, which could not distinguish the generator–absorber assembly and evaporator–condenser assembly.

Nomenclature

Q	heat transfer rate (kW)	A	heat transfer area (m^2)
k	heat transfer coefficient (kW/m^2)	T_H	the temperature of the steam input (K)
T_L	the temperature of the steam output (K)	T_c	the temperature of the condenser (K)
T_e	the temperature of the evaporator (K)	Q_L	rate of heat leak(kW)
K_L	heat leak coefficient(kW K)	a	heat exchange ratio
I	irreversibility factor		
Greek symbols			
τ	cycle period	π	the heat load(kW)
Ψ	the thermal coefficient		

In this paper, a generalized irreversible heat pump driven by steam turbine cycle model is established by taking account of the heat resistances, heat leak and irreversibility due to the internal dissipation of the working substance. At the condition of the total heat transfer area is constant, the fundamental optimal relations between the heating loads, the coefficient of the system's performance and the temperature difference of the evaporator are obtained.

System Model

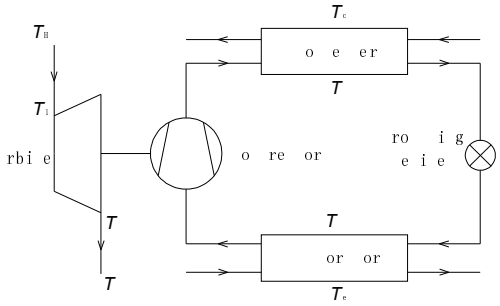

Fig.1 Schematic of heat pump system driven by turbine

It can be seen from Fig.1, the heat pump system driven by turbine is composed of two parts, the power cycle and the compression heat pump cycle, including the steam turbine, the compressor, the evaporator, the condenser and the throttling device. The temperature of the heat source and the working media in the cycle are shown in Fig.1.

According to the law of heat transfer, we can obtain:

$$Q_1 = k_1 A_1 (T_H - T_1)\tau, Q_2 = k_2 A_2 (T_2 - T_L)\tau, Q_3 = k_3 A_3 (T_3 - T_c)\tau, Q_4 = k_4 A_4 (T_e - T_4)\tau \quad (1)$$

Q_1, Q_2, Q_3 and Q_4 are the heat exchange on the high temperature side of the steam turbine, the low temperature side of the steam turbine, and in the condenser and the evaporator. k_1, k_2, k_3 and k_4 are the heat transfer coefficient and A_1, A_2, A_3 and A_4 are the heat transfer area respectively.

τ is the cycle time. According to the first law of the thermodynamics:

$$Q_1 + Q_4 = Q_2 + Q_3 \quad (2)$$

Introduce total heat transfer area A, which is determined by the following formula, and remains constant:

$$A = A_1 + A_2 + A_3 + A_4 \quad (3)$$

Define a as the heat exchange ratio between the condenser and the absorber,

$$a = Q_3 / Q_2 \quad (4)$$

Assume the thermal heat leakage between the space and the environment following the linear heat transfer law, the heat leakage can be expressed as:

$$Q_L = K_L (T_L - T_e + T_c - T_e)\tau \quad (5)$$

According to the second law of the thermodynamics, introduce the irreversible factor I, which is expressed as:

$$I = \frac{Q_2 / T_2 + Q / T}{Q_1 / T_1 + Q_4 / T_4} \geq 1 \quad (6)$$

When I=1, the cycle is reversible; I > 1, the cycle is irreversible.

Performance optimization

According to Eq.(6), we can obtain that

$$\frac{Q_1}{T_1} + \frac{Q_4}{T_4} - \frac{Q_2}{IT_2} - \frac{Q_3}{IT_3} = 0 \quad (7)$$

According to the definition of the heat load:

$$\pi=\frac{Q_3-Q_L}{\tau}=aA(\frac{(IT_2)^{-1}+a(IT_3)^{-1}-(1+a)T_4^{-1}}{k_1(T_1^{-1}-T_4^{-1})(T_H-T_1)}+\frac{1}{k_2(T_2-T_L)}+\frac{a}{k_3(T_3-T_c)}+\frac{(1+a)T_1^{-1}-(IT_2)^{-1}-a(IT_3)^{-1}}{k_4(T_1^{-1}-T_4^{-1})(T_e-T_4)})^{-1}-q_L \quad (8)$$

where $q_L=Q_L/\tau$.

The thermal coefficient of the system can be expressed as:

$$\psi=\frac{Q_1-Q_2}{Q_1}\cdot\frac{Q_3-Q_L}{Q_3-Q_4}=\frac{Q_3-Q_L}{Q_1}=\frac{Q_3}{Q_1}(1-\frac{Q_L}{Q_3})=a\frac{T_1^{-1}-T_4^{-1}}{(IT_2)^{-1}+a(IT_3)^{-1}-(1+a)T_4^{-1}}(1-\frac{q_L}{q_L+\pi}) \quad (9)$$

For the sake of convenience, let $T_L^*=IT_L$, $T_c^*=IT_c$, $k_2^*=k_2/I$, $k_3^*=k_3/I$, $x=T_4/T_1$, $y=T_4/IT_2$, $z=T_4/IT_3$, the heat load and the thermal coefficient can be written as:

$$\pi=aA(\frac{1-y+a(1-z)}{k_1(1-x)(T_H-T_4x^{-1})}+\frac{1}{k_2^*(T_4y^{-1}-T_L^*)}+\frac{a}{k_3^*(T_4z^{-1}-T_c^*)}+\frac{y-x+a(z-x)}{k_4(1-x)(T_e-T_4)})^{-1}-q_L \quad (10)$$

and

$$\psi=\frac{a(1-x)}{1-y+a(1-z)}(1-\frac{q_L}{q_L+\pi}) \quad (11)$$

Lagrangian functions are introduced:

$$L_1=\psi+\lambda_1\pi \quad , \quad L_2=\pi+\lambda_2\psi \quad (12)$$

Where λ_1 and λ_2 are two Lagrangian coefficients. Combining Eq. (12) and the extremal conditions $\partial L_1/\partial x=0$, $\partial L_1/\partial y=0$, $\partial L_1/\partial z=0$, $\partial L_1/\partial T_4=0$, $\partial L_2/\partial x=0$, $\partial L_2/\partial y=0$, $\partial L_2/\partial z=0$, $\partial L_2/\partial T_4=0$ yields a general relation

$$\sqrt{k_1}(T_Hx-T_4)=\sqrt{k_2^*}(T_4-T_L^*y)=\sqrt{k_3^*}(T_4-T_c^*z)=\sqrt{k_4}(T_e-T_4) \quad (13)$$

Let $u=T_e-T_4$,the thermal coefficient and the heat load after optimization are:

$$\pi=ak_4(b_1(T_eT_H^{-1}-(1-b_1)T_H^{-1}u)(1+a-T_eT_L^{*-1}-aT_eT_c^{*-1}+((1+b_2)T_L^{*-1}+a(1+b_3)T_c^{*-1})u)/((1-T_eT_H^{-1}+(1-b_1)T_H^{-1}u)u)+b_2(T_eT_L^{*-1}-(1+b_2)T_L^{*-1}u)/u+ab_3(T_eT_c^{*-1}-(1+b_3)T_c^{*-1}u)/u+(T_eT_L^{*-1}+aT_eT_c^{*-1}-(1+a)T_eT_H^{-1}-((1+b_2)T_L^{*-1}+a(1+b_3)T_c^{*-1}-(1+a)(1-b_1)T_H^{-1})u)/((1-T_eT_H^{-1}+(1-b_1)T_H^{-1}u)u))^{-1}-q_L$$

and

$$\psi=\frac{a(1-T_eT_H^{-1}+(1-b_1)T_H^{-1}u)}{1+a-T_eT_L^{*-1}-aT_eT_c^{*-1}+((1+b_2)T_L^{*-1}+a(1+b_3)T_c^{*-1})u}(1-\frac{q_L}{q_L+\pi}) \quad (14)$$

where $b_1=\sqrt{k_4/k_1}$, $b_2=\sqrt{k_4/k_2^*}$, $b_3=\sqrt{k_4/k_3^*}$.

Results and discussion

Numerical example is introduced to analyze the system. Conditions of the example are listed in Tab.1.

Tab.1 Parameters of the numerical example

k_i (kW/m^2)	A （m^2）	T_H(K)	T_I(K)	T_e(K)	T_c(K)
0.5	10	623	534	293	333

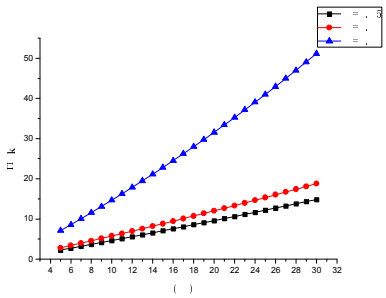

Fig.2 The effect of I on π

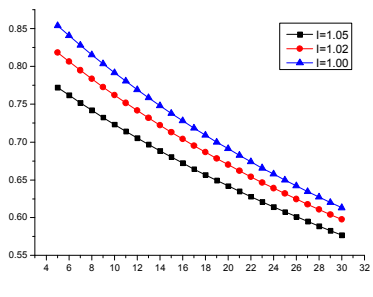

Fig.3 The effect of I on ψ

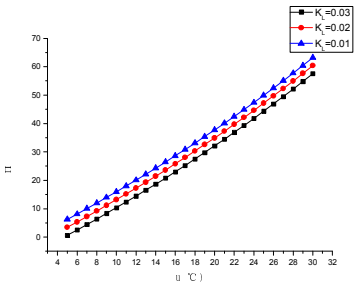

Fig.4 The effect of K_L on π

The Fig.2 and Fig.3 are the effect of I on π and ψ with the different of u when K_L=0, a=1. The heat load increases and the thermal coefficient decrease with the growth of u. When u is constant, the greater the irreversibility, the smaller the heat load and the thermal coefficient. As the temperature difference rises from 5℃ to 30℃(I=1), the heat load increase 6.21 times and the thermal coefficient decrease 28.22%, if I=1.05, the heat load increase 5.52 times and the thermal coefficient decrease 25.29%. When I = 1.05, compared to I=1.00, the heat load and the thermal coefficient decrease 69.34% and 7.39% at the temperature difference of 18℃.

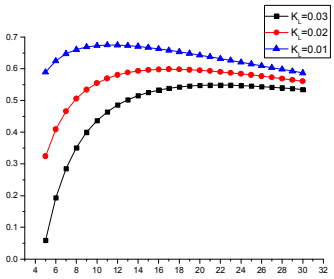

Fig.5 The effect of K_L on ψ

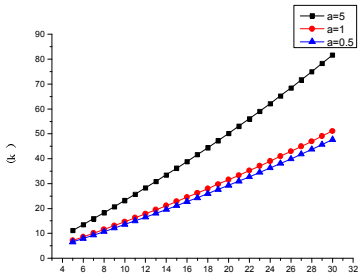

Fig.6 The effect of a on π

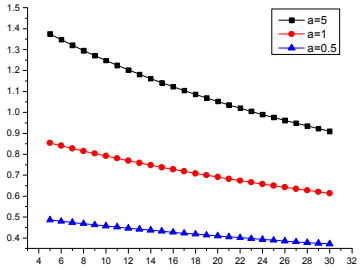

Fig.7 The effect of a on ψ

It can be seen from Fig.4, the heat load increases with the growth of u. When u is constant, the greater the heat leak, the smaller the heat load. As the temperature difference rises from 5℃ to 30℃(I=1,a=1), the heat load increase 16.56 times, when K_L=0.02. When the heat leak increases from 0.01 to 0.03, the heat load decreased 16.98% at the temperature difference of 18℃. The Fig.5 shows the thermal coefficient increases first then decreases with the increase of temperature difference in the presence of heat leakage. The thermal coefficient achieves maximum at u=15℃, u=17℃ and u=22℃, corresponding to K_L=0.01, K_L=0.02 and K_L=0.03, the maximum values are 0.667,0.599 and 0.549 respectively. The Fig.6 and Fig.7 show the heat load and the thermal coefficient increases with the growth of a(K_L=0，I=1). When the temperature difference rises from 5℃ to 30℃(a=5), the heat load increase 86.28% and the thermal coefficient decrease33.84%. When a= 5, compared to a=0.5, the heat load and the thermal coefficient increase 41.63% and 159.57% at the temperature difference of 18℃.

Conclusion

A generalized irreversible heat pump driven by steam turbine cycle model is established by taking account of the heat resistances, heat leak and irreversibility due to the internal dissipation of the working substance. Numerical example is introduced to analyze the effect of the cycle parameters on the heat load and the thermal coefficient. The heat load increases and the thermal coefficient decrease with the growth of u. The thermal coefficient increases first then decreases with the increase of temperature difference in the presence of heat leakage. The heat load and the thermal coefficient increases with the growth of a. These conclusions can provide some theoretical guidance for the improvement and the optimization of the heat pump driven by steam turbine.

Keywords: thermal power generation; generalized Weng model; electrical energy

Abstract. Since the 21st century, China's power industry has been developing very quickly, and the generated electrical energy has been growing rapidly. Although nuclear power, wind power, solar power generations have been increased, thermal power generation still accounts for more than 80% of the total generating capacity. Thermal power provides an important material basis for the development of the national economy. Therefore, the prediction research on China's thermal power generation trend is becoming a topic of great interest.

The fuel of thermal power generation-coal, is an exhaustible resource. Due to the exhaustible constraints the fuel, thermal power generation trend is bound to show a similar trend bell curve as the coal production trend, similar to a bell-shaped curve—a gradual increase to maximum output and then a short peak and a gradual decline. To get more accurate results of future thermal power generation, this paper applies the generalized Weng model to forecast China's thermal power generation peak and trend.

The result indicted that the peak of China's thermal power generation appears in 2022 with generating capacity of 51,702 TWh. The generating capacity of thermal power will decrease gradually after 2022. Based on the results, the paper proposes some policy recommendations for the sustainable development of China's electrical energy. China should decrease the percentage of the capacity which comes from thermal generation and reduce the dependence on thermal power generation. Moreover, nuclear, hydraulic, wind and solar power should be developed before the thermal power generation peak.

Introduction

The electricity industry, which is gaining more attention from various countries, has become the most important factor impacting the development of socioeconomic status worldwide. China's electricity industry has been developing very quickly, and the generated electricity energy has been growing fast with the rapid development of economy. Although nuclear power, wind power, solar power generations have increased in recent year, thermal power generation is still considered as the most important source of China. Since 1949, the average of annul increase rate of electricity generation has been 12.5%, similar to the annul average increase rate of thermal power generation[1].By the end of 2012, China's total electricity power generation had been 49,377 TWh and more than 80% of power generation was thermal (see Fig. 2) [1]. Therefore, accurate thermal power generation forecasting can provide a reliable basis for a reasonable plan for an adjustment of power policy and structures to avoid electricity shortages.

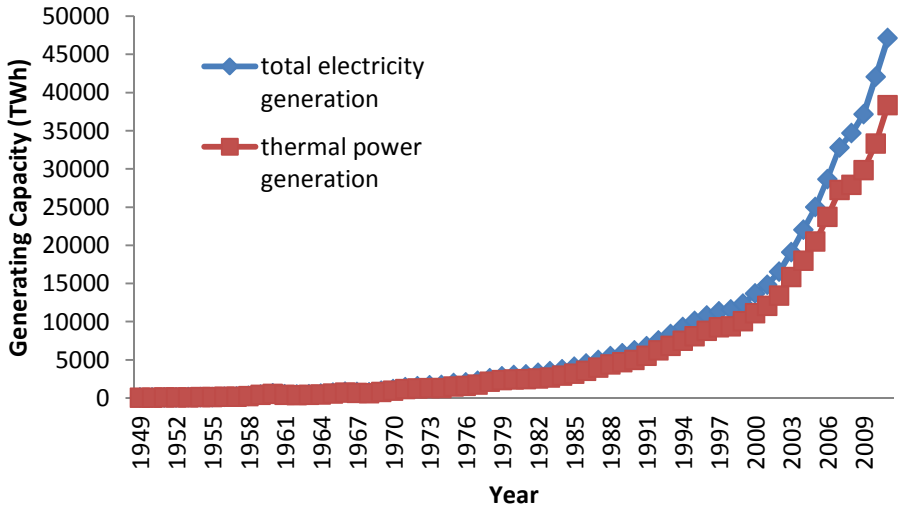

Fig. 1 China's historical Electricity generating capacity

Source:[1]

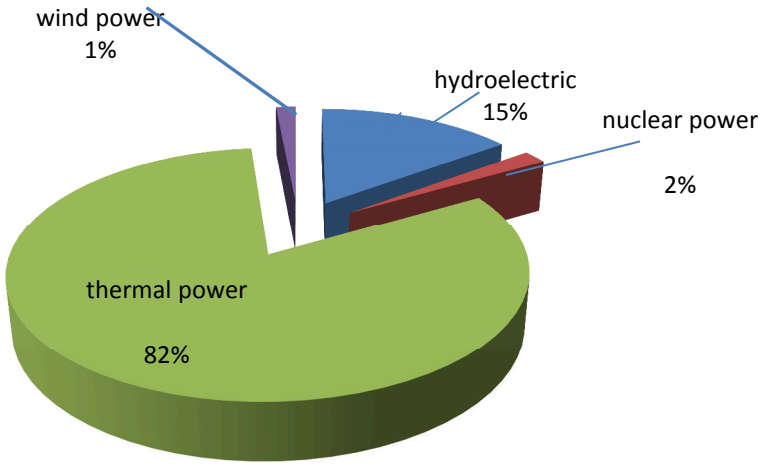

Fig. 2 The Source of China's Power Generation

Source: [1]

Different from the nuclear, wind and solar power generation, the major energy source of thermal power is coal, an exhaustible resource. Based on exhaustible property of the thermal power generation fuel, China's thermal power generation can also be seen as a kind of exhaustible resource. As most exhaustible resource production levels have already reached peaks or are approaching to peak levels, regardless of technological advances and price rising, China's thermal power generation peak which is based on coal-fired is inevitable. It is difficult to deny that a finite resource must at some point reach a maximum in extraction rate, after which production will decline [2].

Based on the production characteristics of nonrenewable resources, there are a number of commonly used forecasting techniques. Many scholars have adopted generalized Weng model (a typical bell curve model) which was first proposed by Chen [3] based on Weng model. Scholars have used the generalized Weng model to predict exhaustible resource supply trend and peak in China and obtained reasonable results [4-7].

The previous scholars have done a lot of research contributions by using Generalized Weng model.And the most of their study field is predictingthe peak production of oil and natural gas. Wang et.al,.[8] did some research on the production of China's natural gas by using Hubbert model and Generalized Weng mode and indicted that the gap between gas production and demand will reach 210.4 bcm by 2020.Feng et.al,.[9] did some research on the production of China's and world's oil by using Hubbert model and Generalized Weng model.Tang et al,. [10] researched on the peak production of oil in the North America, Central and South America, Europe, Middle East, Africa and Asia Pacific areas base on Generalized Weng model. And they pointed out hat the future oil pattern would become increasingly dependent on the Middle East, while Asia-Pacific region would become the most serious inbalanced between oil supply and demand. Feng Lianyong et al. [11] summarized the differences between domestic and foreign methods for predictingthe peak production of oil. As it can be seen in the development of predictive models, they considered that in foreign countries the methods are developed from a single-cycle model to a multi-cycle model, focusing on the vertical development of models; while in China the methods are developed from the Weng model to a series of predictive models, focusing on horizontal development of models. The study used the Generalized Weng model to predict the peak of world oil production, and indicated that the peak time would appear in 2020. Feng Lianyong et al [12] used Hubbert model, HCZ model and Generalized Weng model to predict the peak production of China's oil, without a reasonable plan for oil production.

In view of the exhaustibility of thermal power resources and the excellent performance of generalized Weng model in the field of exhaustible resource supply forecast, this paper proposes to use generalized Weng model to predict the thermal power generation in China and tries to provide some policy recommendations based on our forecasting results.

Methodology and Data Description

Methodology

Generalized Weng model is proposed by Chen Yuanqian [4] after deriving and expanding Weng model, which is proposed by Weng Wenbo [13], a Chinese famous geophysicist and member of Chinese Academy of Sciences.

$$Q_t = at^b e^{-(\frac{t}{c})} \quad (1)$$

The parameters referred in the equation include: the model predictive parameters a,b, c, and the time periods parameter t. The forecasting parameters of Generalized Weng model calculated by binary regression method is proposed by Zhao Lin, Feng Lianyong in 2009 [14]. It is calculated as follows:

The Equation (1) take the natural logarithm of both sides

$$\ln Q = \ln a + b\ln t - t/c \quad (2)$$

Set

$$Y = \ln Q \quad (3)$$

$$X_1 = \ln t \quad (4)$$

$$X_2 = t \quad (5)$$

$$B_0 = \ln a \quad (6)$$

$$B_1 = b \quad (7)$$

$$B_2 = -1/c \quad (8)$$

So Equation (12) can be written as

$$Y = B_0 + B_1X_1 + B_2X_2 \quad (9)$$

Using multiple linear regression we can obtain B_0, B_1, B_2, and after putting them into Equation (6), (7), (8), we can obtain B_0, B_1, B_2.

Table 1 Main Equations of Generalized Weng Model

Peak model	Basic Equations	Peak Production	Peak Time
Weng's Model	$Q = at^b e^{-t/c}$ $N_R = ac^{b+1}\Gamma(b+1)$	$Q_{max} = a(bc/2.718)^b$	$t_{max} = bc$

Data Sources

The historical data of China's thermal power generation 1949-2011 is taken from the *The National Bureau of statistics of PRC* [1].

Results and Disscussion

A systematic elaboration on the generalized Weng model has been presented previously in the paper. In this section, the generalized Weng model is employed to predict the trends and peaks of China's thermal power generation.

Results

Binary regression of the data from 2002 to 2011 was run on the EViews software according to Equation (19), and the reported F-test and DW test were all satisfying. In this way, we obtained B_0=-95.13, B_1=32.19, B_2=-0.44 (See Table 2). The prediction coefficients for the generalized Weng model were obtained from Equations (6), (7) and (8): a=4.83559E-42, b=32.19, c=2.27. Then a, b and c were substituted into the model, and predictions can thus be made.

The results which are predicted by generalized Weng model indicate that China's thermal power generation peak will appear in 2021 with the peak production 51,702 TWh.

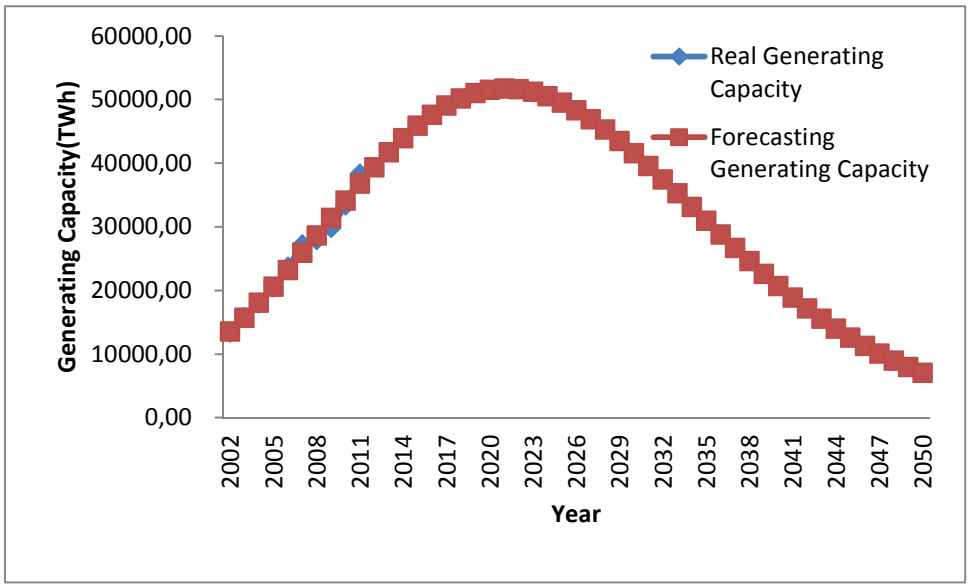

Fig. 3 China's Power Generation Forecasting

Discussion

This paper uses generalized Weng model to predict China's thermal power generation . The forecasting parameters of Generalized Weng model are calculated by binary regression method. In this paper, based on 2002-2011 China's thermal power annul generation data, we use the predictive parameter calculating method which is illustrated in last chapter to get the value of predictive parameter. The reason why we set the start year is 2002, because of the reformation of electric power system in the year of 2002. The power production and transmission are separated in the reformation. The aim of separation of power production and transmission is to break up the monopoly, to improve the efficiency, and to control the price of the electricity by impartial competition. Since then, the marketization of electric power in China is in a greater degree. Moreover, the data from market are more reliable than those from macro-control.

According to the comparison between the real generating capacity and forecasting generating capacity of thermal power from 2002 through 2011 in China, we find that the average difference rate is very small with the average difference rate of the results as less than 10%. R-squared is more than 99%. So we may judge that generalized Weng mode is considerable and suitable for China's thermal power generation forecasting.

Table 3 The Difference between Real and Forecasting Generating Capacity

Year	Real Generating Capacity	Forecasting Generating Capacity	Error
2002	13381.36	13513.39	0.99%
2003	15803.61	15708.54	0.60%
2004	17955.88	18066.94	0.62%
2005	20473.36	20567.17	0.46%
2006	23696.03	23182.53	2.17%
2007	27229.33	25881.56	4.95%
2008	27900.78	28628.79	2.61%
2009	29827.80	31385.69	5.22%
2010	33319.28	34111.63	2.38%
2011	38337.00	36765.10	4.10%

Conclusions and Recommendations

Conclusions

Electricity is indispensable energy in modern industry and society development. Thermal power generation account for about 80% of the total power generation in China. Based on the important position of China's thermal power generation in economy development, China's thermal power generation trends and peak prediction are increasingly the target of interest of researches. To achieve more accurate results, this paper applies the generalized Weng model to simulate China's thermal power generation peak and trends. Conclusions have been drawn based on the forecasting results.

(1) The generalized Weng model can be applied in the field of thermal power supply issues.

The generalized Weng model as a peak predictive model is widely used in forecasting exhaustible resource production peaks and trends. Because the coal of China's thermal power fuel is exhaustible, the thermal power in China also can be seen as an exhaustible resource. As an exhaustible resource, the curve of China's thermal power generation, a bell-shaped curve that is a gradual increase to maximum output and then a short peak and a gradual decline, is similar to other exhaustible resources. Once the output reaches the peak, regardless of efforts, thermal power generation cannot increase any more. In this study, the generalized Weng model is also used to study China's thermal power generation peaks and trends. According to the comparison between the real generating capacity and forecasting generating capacity of thermal power from 2002 to 2011 in China, we find that the average difference rate is less than 10%. We may judge from the small average difference rate that generalized Weng model is rational and suitable for China's thermal power generation forecasting.

(2) China's thermal power generation peak will appear by the year 2021.

According to the simulation, the peak of thermal power generation in China will occur in 2021 with peak generating capacity of approximately 51,702 TWh. Chinese thermal power generation will grow 7% annually before peaking and decrease afterwards.

Policy Recommendations

Based on the conclusions above, some policy suggestions are proposed as follow.

With the continuous development of China's macro-economy and urbanization, the demanding for electricity will rise. Nowadays, thermal power provides more than 80% China's electricity supply. However, the forecasting result indicates that China's thermal power generation will grow by 7% annually before peaking and decrease afterwards. If the electricity supply structure is still dominated by thermal power, then the gap between electricity supply and demand will certainly appear after peak generating capacity. The electricity shortage that may occur in the near future is certainly slowed down by China's economic and social development. Based on the consideration above, we suggest China's government, two major power grid companies and five major power generation companies adjust the structure of power supply as soon as possible to reduce the probability of electricity gap between supply and demand after thermal power generating peak.

Keywords: Dredger fill; Vacuum preloading consolidation; Self-weight consolidation

Abstract. At present, there are many methods of the dredger fill foundation treatment, in which the most widely used application of vacuum preloading method. The dredger fill for test was taken from the Tianjin Binhai new area center fishing port area, separately carried on the self-weight consolidation and vacuum preloading consolidation. Through the indoor test of soil test physical and chemical parameters, comparing the moisture content, soluble salt amount and component, caption exchange capacity, PH value and physical and chemical index. The results show that: the clay content of soil sample in the central fishing port area is higher, degree of aggregation is high, liquid limit is less than 60%, Ip is more than 10, belongs to the low liquid limit clay. Relative self-weight consolidation, soluble salt content of soil samples after vacuum preloading drainage treatment are low, but the particle size composition change less. It is said that parts of salt in the soil samples discharge with water discharge in vacuum preloading process, vacuum preloading effect is better.

Introduction

Because the developing demand of coastal cities and the scale of the project construction, the requirements for land resource are increasingly urgent, it is become one of the effective ways to relieve the tense of land resources using silt dredged out for sea reclamation. In the process of sea reclamation in Tianjin region, sand source is nervous, so take the silt of offshore as blow packing. However, reclaimed materials not only include sandy soil, also include cohesive soil. Its source difference is one of the main reasons which influence the project treatment [1]. The soil also have characteristics of the short deposit time, high water content, high compressibility and low strength, therefore strengthening the reclaimed land base has become inevitable difficult technical problems [2]. A large number of engineering practices found that: the reinforcement of dredger fill site still exist questions that the curing effect is not uniform, engineering geological properties are complex and post-construction settlement is large [3].

Based on these, take the dredger fill in the Center Fishing Port, Binhai District, Tianjin as the object, and make a general analysis about the grain size composition, physical chemistry properties of the dredger fill via different reinforcement methods, it also can provide a sharp mental basis for furthering study on the reinforcement mechanism of the dredger fill.

Testing program

Soil samples for testing were taken from two holes at Center Fishing Port, Tianjin, one of which was taken the vacuum preloading drainage treatment and the other was taken gravity consolidation. The depth of the drilled hole was 60 m, because the depth of the drainage board was about 12 m, so take the soil samples of this depth for analysis. The samples after the vacuum preloading drainage were labeled ZY01 - ZY04, and the others are labeled ZK11 - ZK14, with the depth of 4 m, 7 m, 10 m and 12 m, then tested the grain size composition, physical chemistry properties of the two groups of samples separately. By comparing the testing results, analyzing the changes of the properties in the dredger fill under different reinforcing conditions, so as to provide some solid basis for the study of the reinforcing mechanism.

Granulometric

The granularmetric measurement adopts the method of densimeter B and refers to the specification requirements [4]. Before the test, the samples need to be washed if the soluble salt content is greater than 5‰. Through the cumulative curve method, the variation of granularity ingredients can be found. And the testing of the total content of the soluble salt in the Center Fishing Port turns out that the content are all greater than 5‰, so the samples are totally to be washed. And the results are showed in Fig.1: the particle distribution curve, where the samples are within the dispersant, is obviously above the curve where those without the dispersant, and it turns out that the soil particles are affected by the dispersant greatly. Because of some clay particles which have flocculation to form greater particles in the soil, we call these "false particulates". After adding the dispersant into the samples, the false particulates will be restored to the normal particles and finally disappear. Due to the more false particulates in the soil which are assumed as hydrotropism in the engineering and its value is relatively lower compared with the granularmetric composition, the mineral composition and the organic matter, the soil in the study area can be solidified to be ideal foundation via the gravity consolidation method in which the drainage consolidation (vacuum preloading) can be in a very ideal state within a very short time. Therefore, this method is feasible in Tianjin Area.

The soil samples are mainly classified referred to the DT-92 Regulations of the Ministry of Geology, and the results of the experiment are shown in Table 1 (due to the fine-grained soil used in the testing, the content whose grain size lower than 0.25mm is listed. It can be seen that: the uniformity coefficients of the soil are totally higher than 5, which turns out that the particle grading composition is good [5]. And the distribution and composition of the soil reflect that the possibility of the pores decreasing after being compacted is greater. Because the geological properties in the soil engineering are the overall performance of the various fraction properties, the fraction which has more content will be in charge.

Table 1 Granum analysis data

Samples	Content of various fractions (%)			d60 / mm	d10 / mm	d60 / d10	Name
	0.075 ~ 0.25 mm	0.005 ~ 0.075 mm	< 0.005 mm

ZY14	7.054	51.66	41.16	0.029	0.0024	12.1	Powder light clay

Chemical composition

The chemical composition of the soil refers to the chemical elements, compound types and the relative content in the solid phase, liquid phase and the vapor phase in the soil [5]. The content of the soluble salts in the soil is high, and these salts are solid when the soil is dry which play the role of cementing soil particles; Containing more moisture in the soil, the soluble salts dissolve into ions, and interact with the charged soil particles, and meantime affect the engineering geological properties of the soil [6,7].

Ion exchange effect occurs between the anti-ion layer and the ions with the same symbol in the solution, which are totally called exchangeable ion. Because the ion composition determines the thickness of the thin film of water on the surface of the clay particles, and the film determines the degree of the consolidation of the soil drainage, the exchange capacity of the positive ion affect the efficiency of the consolidation and also the engineering geological properties.

In this experiment, mainly take the test of the amount of the soluble salts, PH, the exchange capacity of the ion. The specific results are shown in Table 3.

From the Table 3, the content of sodium and chloride is the highest in the vacuum preloading soil in the Center Fishing Port, and magnesium and sulfate higher while the others lowest. Generally speaking, the content of the soluble salts, chloride salt and the sodium salt decrease with the depth of the samples increasing, which is due to silt and sediment on the bottom of the ocean on the casing body, therefore, the content of the shallow soluble is higher; The PH of the sample consolidated via vacuum preloading is 6.83-6.97 with the soil acidic while the PH of that consolidated via gravity is 7.43-7.65 with the soil weak base.

Table 2 Chemical composition test results

Name	Testing methods	ZY01	ZY02	ZY03	ZY04	ZY11	ZY12	ZY13	ZY14
Soluble salt (‰)	Steam seasoning	15.52	12.12	8.51	7.22	31.70	21.94	10.29	9.28
Chloridion ion (‰)	Silver nitrate titration method	7.03	5.72	4.09	3.77	15.37	11.25	4.93	5.08
Bicarbonate radical (‰)	Hydrochloric acid titration method	0.27	0.18	0.14	0.12	0.31	0.37	0.43	0.55
Calcium ion (‰)	EDTA	0.13	0.10	0.07	0.08	0.15	0.12	0.13	0.16
Calcium and magnesium (‰)	EDTA	0.85	0.77	0.23	0.27	1.38	1.13	0.61	0.54
Sulfate radical (‰)	EDTA	2.57	2.59	2.13	1.33	2.77	2.71	2.50	2.65
Potassium ion (‰)	flame photometry	0.67	0.52	0.42	0.49	0.70	0.56	0.55	0.50
Sodion ion (‰)	flame photometry	6.84	5.52	5.04	5.99	7.07	5.87	5.75	6.15
PH	electrometric methods	6.93	6.97	6.83	6.83	7.46	7.43	7.65	7.64
CEC (mmol/100g)	Ammonium acetate leaching method	6.09	3.79	1.88	4.81	6.25	4.32	2.56	5.71

Fig.2 shows the contrast of the content of various ions of the two consolidation methods: whether the total amount or the respective component, the content of the soil via vacuum preloading drainage processing is lower, which means the vacuum preloading method is better for consolidation.

Physical properties

The physical properties of soil is properties of three-phase material that is shown in the mutual proportional relationship between the mass and volume or the mutual effect of Solid-liquid two-phase, That is the basic physical properties and hydrological properties. Based on soil test specification, Dry and wet conditions， consistency and plasticity of dredger fill that have Different consolidation modes are tested. The results are shown in Table 4. And it shows that: the moisture content of dredger fill that have the same consolidation mode decreases with increasing depth. The moisture of dredger fill that has the vacuum preloading drainage processing is lower than that is gravity consolidation. Eight groups of soil's plasticity index greater than 10, which are divided into low liquid limit clay according to plasticity chart. That can't be contrasted because different consolidation modes don't affect granulometric composition of dredger fill. Table 4 basic physical properties

Table 3 Physical property indexes

Samples	Moisture content	Liquid limit	Plastic limit	liquidity index	Plasticity index（%）	Designation
ZY01	0.347	0.490	0.238	0.432	25.2	Low liquid limit clay
ZY02	0.259	0.398	0.150	0.439	24.8	Low liquid limit clay
ZY03	0.252	0.268	0.164	0.846	10.4	Low liquid limit clay
ZY04	0.251	0.274	0.164	0.790	11.0	Low liquid limit clay
ZY11	0.371	0.429	0.230	0.497	19.9	Low liquid limit clay
ZY12	0.314	0.330	0.180	1.066	15.0	Low liquid limit clay
ZY13	0.239	0.290	0.142	1.104	14.8	Low liquid limit clay
ZY14	0.290	0.338	0.195	1.085	14.3	Low liquid limit clay

Conclusion

(1) Dredger fill in the areas of central fishing port of Tianjin is mainly cohesive soil. Due to the flocculation, a large number of cosmids get together and form "fake silt", a large number of "fake silt" show hydrophobicity in engineering, which is very low. Therefore, the soil in study area reaches ideal foundation by gravity consolidation. But it can reach ideal foundation by vacuum preloading in short time.

(3) Content of disguise salt is high in the areas of central fishing port of Tianjin and greater than 5 ‰ on average. Content of sodium salt and chloride salt is huge, magnesium salt and sulfate followed by. The single approach soluble salt content is decreasing with increasing depth, because the covering soil is silt and sediment of the bottom of the ocean. Comparing the content of the various ions in the two reinforcement manner, Soil samples of the vacuum preloading drainage processing is higher than soil samples of gravity consolidation processing. A part of soluble salt in the soil samples discharge along with water in the vacuum preloading process. This fully illustrated that reinforcement effect of vacuum Preload process is better than gravity consolidation drainage process.

(4) It can be seen from the plastically Figure, Selected soil samples are low liquid limit clay. Denominating the soil only through granularity can’t reflect engineering geological properties of dredger fill, and result of Joint use of the plasticity index and liquid limit (plastically Figure) is more accurate.

Therefore, it can be known that vacuum Preload process can shorten the consolidation time comparing with gravity consolidation drainage process, through researching physical and chemical properties of dredger fill in the areas of central fishing port of Tianjin. The researches of the physical and chemical properties provide the necessary foundation for the research of Consolidation.

Key Words: in-service welding, Software simulation, heat input, medium

Abstract: With the numerous applications of high-pressure pipeline, it is very important to simulate the in-service welding of the pipeline.The flow state of the medium in the pipeline can be analyzed, the temperature field and the stress field also can be simulated by applying sysweld software. The medium flow can reduce the welding residual stress and reduce welding stress range during in-service welding. Meanwhile, with the increase of flow rate of the medium, the maximum temperature of inner wall drops and the maximum weld residual stress increases by a slow growth. At the same time, the highest temperature of pipe wall increases rapidly with the increase of heat input, whereas the maximum residual stress of welded joint decreases by a slow trend.

Introduction

A type of high-pressure pipeline was used to transport the solid wastes(wet-ash) in JIANGSU JINMEI HENGSHENG Chemicals Co.Ltd. In order to guarantee the safe operation of the pipeline, we need to repair local corrosion of pipeline in-service. Obviously, the technology can ensure the continuity of the operation of the pipeline. Meanwhile, the repair time can be short. As a result the technology has a huge economic efficiency and broad application prospects. But because of the dangers of pipeline transport medium, guaranteeing the quality of welding in-service should be a priority. And numerical simulation of pipeline welding in-service is one of the necessities to ensure the welding quality[1-3].

Numerical analysis for fillet welding of transmission pipeline in-service

1.1 Establishment of the geometric model

Casing repair is the main method of pressure pipeline welding repair in service. This article uses the casing repair technology to illustrate, as shown in fig.1.

In the study, fillet welds of casing repairs is simulated, using pipe model symmetry build one-second when welding fillet welds, weld mesh refinement, other parts of mesh over the thick.

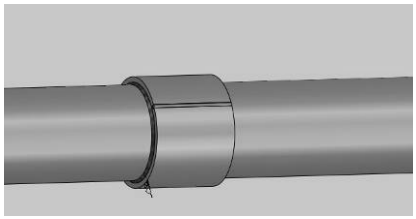

Fig.1 The diagram of Casing repair welded joints

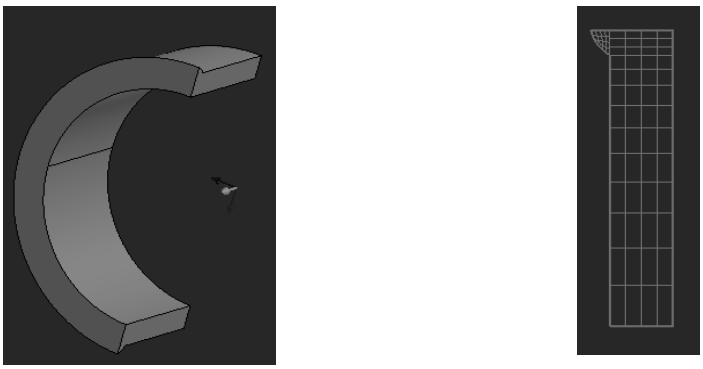
The study is only the simulating of the fillet weld for casing repair, taking advantage of the symmetry of 1/2 fillet weld model for pipe welding. Refining the weld grid, and the rest of the meshing is coarser[4]. Its mesh generation of two-dimensional and three-dimensional model section is shown in Fig.2.



(a) Three dimensional model **(b) Two-dimensional meshing**

Fig.2 Weld model and meshing

1.2 Thermo-physical properties and mechanical properties of pipeline steel

The material of this simulation is X70 pipeline steel, more details about material performance parameter refer to references [5].

1.3 Welding heat source model

In terms of manual arc welding, the authors make use of double-ellipsoidal power density distribution model[6-7] based on Gaussian-Distribution-Function, the mathematical expressions are as follows Eq.1 and Eq.2:

$$q_1(x,y,z) = Qf \bullet \exp\left(-\frac{x^2}{a_f{}^2}\right) \bullet \exp\left(-\frac{y^2}{b^2}\right) \bullet \exp\left(-\frac{z^2}{c^2}\right) \quad (1)$$

$$q_2(x,y,z) = Qr \bullet \exp\left(-\frac{x^2}{a_r{}^2}\right) \bullet \exp\left(-\frac{y^2}{b^2}\right) \bullet \exp\left(-\frac{z^2}{c^2}\right) \quad (2)$$

Where:

q1, q2: heat flux, J.m-2s-1

x, y, z: coordinates that are relative to the heat Center, dimensionless.

Qf: the energy density of heat in the front of hemisphere, J. m-2.

Qr: the energy density of heat in the back of hemisphere, J. m-2.

af, ar, b, c: shape parameter, mm.

1.4 Welding parameters

The welding simulation uses electric arc welding, and choose the thermal efficiency of 0.8.

1.5 Heat transfer boundary conditions

The heat transfer between the pipe wall and the fluid is mainly forced convection heat transfer fluid inside the tube, the heat transfer coefficient is as follow Eq.3:

$$\alpha = 0.027\frac{\lambda}{d}\mathrm{Re}^{0.8}\,\mathrm{Pr}^{1/3}\left(\frac{\mu}{\mu_u}\right)^{0.14} \quad (3)$$

Where:

λ: thermal conductivity of wet-ash, W·m-1K-1.

Re: Reynolds number of wet-ash, dimensionless.

Pr: Prandtl number of wet-ash, dimensionless.

μ: dynamic viscosity of wet-ash, N s·m-2.

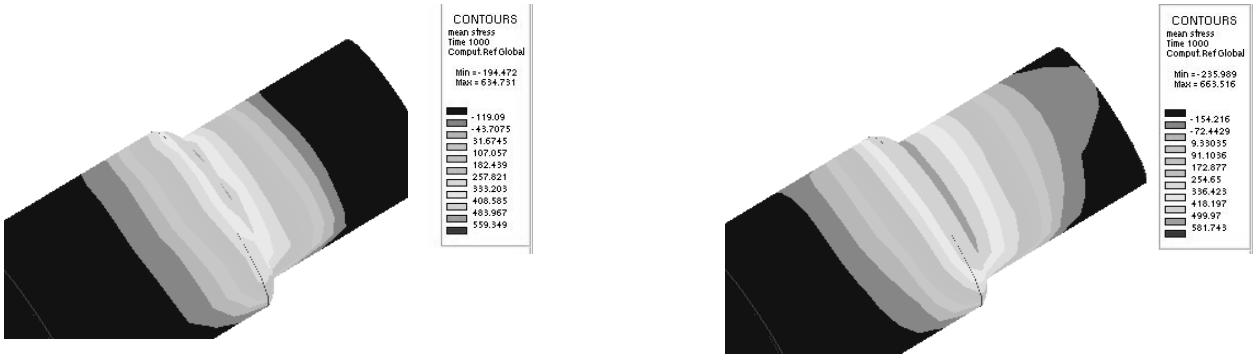
d: the inner diameter of the pipe, m.

μu: dynamic viscosity of wet-ash at wall temperature, N s·m-2.

Simulation results analysis

2.1 influence of the media

Fig.3 shows the welding residual stress distribution（MPa in SI units）. As can be seen, due to the forced convection of tube media, the stress distribution in-service area is small, and the welding stress reduces during the welding.



(a) with medium **(b) without medium**

Fig.3 Residual stress contours after welding

2.2 Effect of heat input

The heat input index of this simulation is welding heat input. Welding heat cycle area varies with the welding heat input, and leading to the change of welding thermal stress. When the pipe structure (the wall-thickness is 10mm) and medium flow rate (2m/s) remain the same at the medium temperature 200℃, taking 4 types of welding heat input respectively in Tab.1 to conduct simulation calculations, thus, different heat input acquisition versus the maximum temperature of inner wall, the maximum residual stress of welded joint, as shown in Fig.4.

Tab.1 Welding parameters

process planning	welding current I/A	welding voltage U/V	welding speed v/(cm·s-1)	heat input E/(J·cm-1)
A	85	28	4	595
B	110	28	3.3	933
C	130	29	3.4	1110
D	150	30	3.5	1320

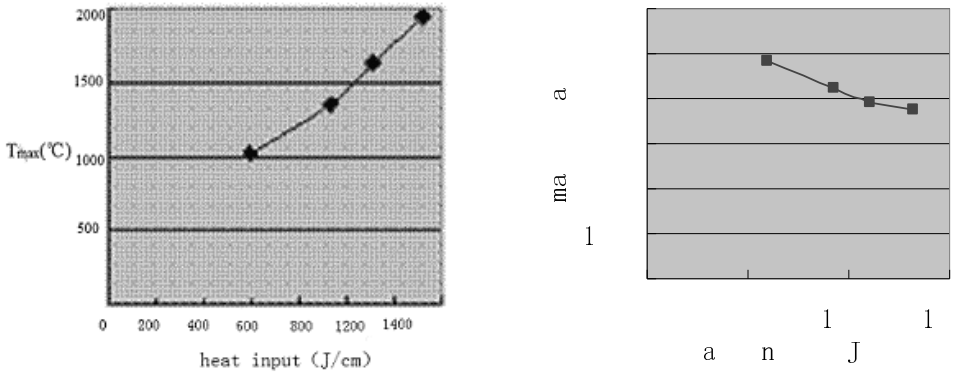


Fig.4 The maximum temperature of the inner wall and the maximum residual stress of welded joint at different line energy

The curve for maximum temperature of inner wall and welding heat input has a linear relation,and rising trend accelerated as welding heat input growth , as shown in Fig.4. However, the maximum residual stress of welded joint decreases with welding heat input growth, and at the same time, the descending trend slows. Therefore, low welding heat input should be input to prevent burn-through in the case of the welding residual stresses in not to exceed the yield strength during welding.

2.3 Influence of medium's velocity

The flow rate of the medium inner tube has a great influence on heat transfer coefficients during high-pressure pipeline in-service welding , and as a result, the welding thermal cycle will change, which also leads to the variation of welding thermal stress. Tab.2 shows the heat transfer coefficients between Medium and the pipe wall at different flow rate. The curses for different medium velocity versus the maximum temperature of inner wall and the welding residual stresses, as shown in Fig.5.

Tab.2 Heat transfer coefficient under different flow rates

flow rate/(m·s^{-1})	2	2.5	3	3.5	4	4.5
heat transfer coefficients /(W·m^{-2}℃$^{-1}$)	560.32	621.35	743.86	836.42	923.45	1053.96

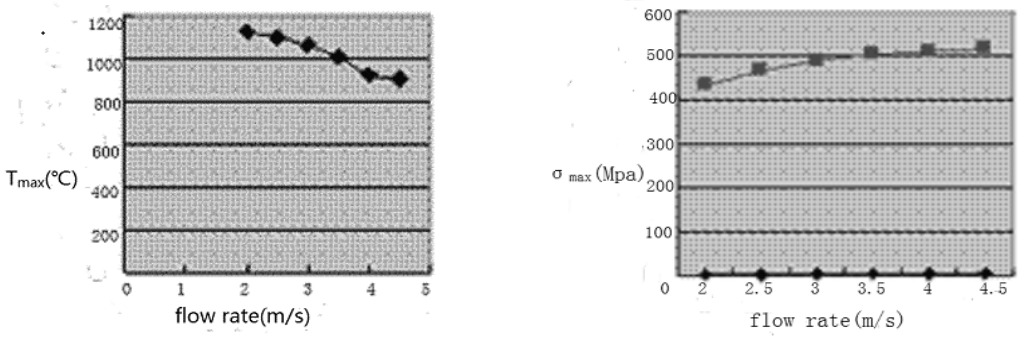

Fig.5 The maximum temperature of the inner wall and the maximum residual stress of welded joint at different medium flow velocity

It can be seen from Fig.5 that the maximum temperature of the inner wall falls with the medium flow rate increase, which is the result of the medium flow increases the convective heat transfer in tube that takes away the heat generated by the welding. And the increase of flow rate can lower the highest temperature of pipe wall in terms of preventing burn-through. As a consequence, the value of the welding heat input can be improved properly for high velocity pipeline welding in- service. The maximum residual stress of welded joint increases with an increase in medium flow rate is also shown in Fig.5, and the growth rate of the maximum residual stress slows down when it gets a fast speed, which indicates that the impact of flow rate on the maximum residual stress of welded joint will decrease gradually.

Conclusion

(1) Double ellipsoid heat source can be used for the fillet weld of high pressure transmission pipeline in-service, and the simulation has a good effect.

(2) The medium flow can reduce the welding residual stress and reduce welding stress range during in-service welding.

(3) With the increase of heat input, the highest temperature of pipe wall increases rapidly, whereas the maximum residual stress of welded joint decreases by a slow trend.

(4) With the increase of flow rate of the medium, the maximum temperature of inner wall drops and the maximum weld residual stress increases by a slow growth.

Numerical simulation of jet and cross-flow mixing in Tee pipe

Guobing Kang[1,a]

[1]Department of Packaging & Printing Engineering,

Guangdong Industry Technical College , Haizhu District, Guangzhou City, China

[a]kanggb@sina.com

Key words: Tee pipe; turbulent jet; mixing effect; numerical simulation

Abstract: In the present paper we investigated the mixing effect of uncompressible jet and cross-flow in Tee pipe based CFD, the model of Realizable $k-\varepsilon$ was employed as the tool to simulate the flow field, and the model was validated by experimental result of relative research. The mixing effect of jet and cross-flow in various configuration of Tee pipe at different inlet velocity of jet was discussed. The result shows jet and cross-flow mix quickly in near field of injection point, but in the downstream, the mixing effect keeps comparatively steady when $z>7d$, and there is power relation between the mixing parameter M and $r_1 \times r_2$. And r_1 is the ratio of jet pipe diameter to cross-flow pipe diameter, r_2 is the ratio of jet velocity to cross-flow velocity.

Introduction

Mixing processes in turbulent fluid motion are of fundamental interest in many engineering applications such as pollutant formation, heat and mass transfer and chemical reactions. The need for the efficiency of two kinds of fluid mixing systems and optimization of mixing processes has strongly increased. Transverse jets, or jets in cross-flow are generic flows which are often employed in technical applications where fast mixing is desired. In the chemical process industries jet and cross-flow mixing in Tee pipe are widely used for mixing miscible liquids.

Early stages of experimental work focused on the mixing effect for different combinations of flow parameters such as jet-to-cross-flow velocity ratios performed by SMITH and MUNGAL [1]. Fric and Roshko described the different vortical features of this flow in detail [2]. Flow phenomena resembling the interaction of a jet with a cross-flow such as ring-like vortices, interlocking vortex loops, shear layer structures, and vortex breakdown were observed [3-5]. Some numerical studies have been performed on two- or three-dimensional turbulent mixing with mass or heat transfer for simple geometries [6-7]. A round jet penetrating normally into a cross-flow is described through large-eddy simulation (LES) and the jet-to-cross-flow velocity ratio is 2.3 at a Reynolds number of 46,700, based on the jet bulk velocity and the jet diameter [8]. However, very few studies are available for dealing with the influence of the jet-to-cross-flow diameter ratio on the mixing effect. In this paper, we present a series of computational simulations of three-dimensional turbulent mixing in conditions of different jet-to-cross-flow diameter ratios and velocity ratios. In order to get the optimum mixing effect of the jet-to-cross-flow. The simulations are carried out with the ANSYS FLUENT software.

Turbulence model and verification

Turbulent flows are characterized by fluctuating velocity fields. These fluctuations mix transported quantities such as momentum, energy, and species concentration, and cause the transported quantities to fluctuate as well. Since these fluctuations can be of small scale and high frequency, they are too computationally expensive to simulate directly in practical engineering

calculations. Instead, the instantaneous (exact) governing equations can be time-averaged, ensemble-averaged, or otherwise manipulated to remove the resolution of small scales, resulting in a modified set of equations that are computationally less expensive to solve. For RANS (Reynolds Averaging Navier-Stokes equations), ANSYS FLUENT provides three choices of turbulence models: Standard k-ε turbulent model, Renormalization-group k-ε turbulent model and Realizable k-ε turbulent model. If just want to know the average physical quantity of flow field, the RANS is very effective [9]. The Realizable k-ε turbulent model was adopted to simulate mixing of jet-to-cross-flow successfully [10-13]. The current study uses Realizable k-ε turbulent model to simulate the mixing of jet-to-cross-flow.

In this study, the mixture model was adopted to investigate the mixing of jet-to-cross-flow. The mixture model is a simplified multiphase model that can be used in different ways. It can be used to model multiphase flows where the phases move at different velocities and the mixture model also can model n phases (fluid or particulate) by solving the momentum, continuity, and energy equations for the mixture, the volume fraction equations for the secondary phases, and algebraic expressions for the relative velocities [14]. The cross flow was defined as primary phase and the jet was defined as secondary phase. The materials of cross flow and jet both are liquid water.

The simulation was based on the following conditions: (1) the diameter of jet pipe is 10mm (d=10mm) and the diameter of cross-flow pipe is 60mm (D=60mm) ; (2) the materials are Non compressible fluid and there is no chemical reaction in flow field; (3) in mixture model, the primary phase and secondary are both defined as liquid water, there is no energy transfer and conversion during the process; (4) the velocity of jet is 847mm/s and the velocity of cross-flow is 277mm/s [5]. The configuration and grids of pipelines considered in this study are shown in Figure 1.

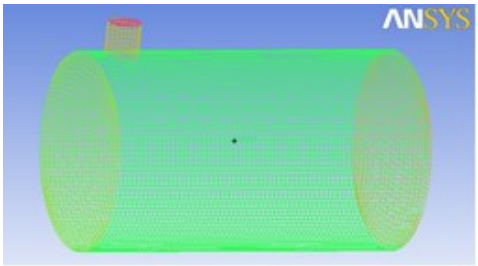

Fig.1 Configuration and grids of pipelines

Figure 2 shows examples of the side-view instantaneous concentration (mixture fraction) field on the center plane represented by 256 gray levels for this case. Figure 3 shows the contours of mean concentration of secondary phase on the center plane.

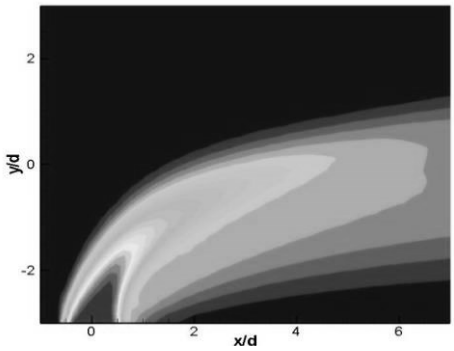

Fig. 2 Gray level images of the side-view instantaneous concentration field

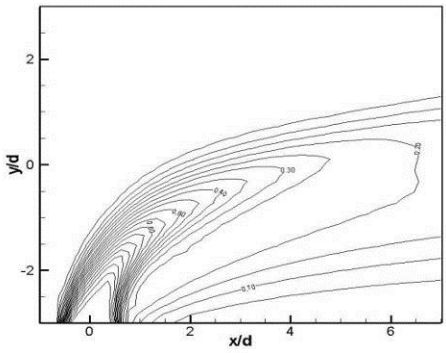

Fig.3 Contours of the side-view instantaneous concentration field (numerical simulation result)

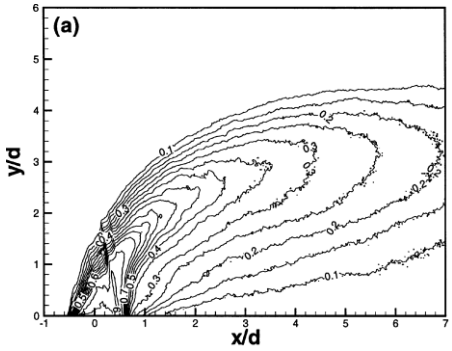

Fig.4 Contours of the side-view instantaneous concentration field (experimental result)

The result of numerical simulation shows a small difference as compared with the experimental result [5] showed in Figure 4, meaning that the turbulence model and simulation is effective.

Results and discussion

The mixedness of the flow can be computed for each cross-sectional plane. The average passive scalar $\bar{c}$ in a cross-sectional plane is defined by (1), its spatial variance σ_c by (2). The mixing parameter is M defined as the normalized square root of the spatial variance, as given by (3).

$$\bar{c} = \frac{1}{A}\int c dA \tag{1}$$

$$\sigma_c = \frac{1}{A}\int \left(c - \bar{c}\right)^2 dA \tag{2}$$

$$M = \sqrt{\sigma_c} / \bar{c} \tag{3}$$

The smaller the mixing parameter, the more homogeneous the mixture. If the spatial variance and hence the mixing parameter are zero, the mixture is perfectly homogeneous. The ratio of jet pipe diameter to cross-flow pipe diameter is defined as r_1, $r_1=d/D$. The ratio of jet velocity to cross-flow velocity is defined as r_2, $r_2=v_j/v_c$. Figure 5 shows the relation between the mixing parameter and distance of the measurement plane along the cross-stream line. In these cases, the diameter of jet pipe is 10mm and the diameter of cross-flow pipe is 60mm. The velocity ratios are 1, 2, 3 respectively (r_2=1,2,3). Figure 5 shows that the mixing parameter decreased slowly in the region where $z>3d$ especially $z>7d$ (z is the downstream distance from the injection point and d is the diameter of jet pipe). The relation between the mixing parameter and the product of r_1 and r_2 on the plane of $z=7d$.

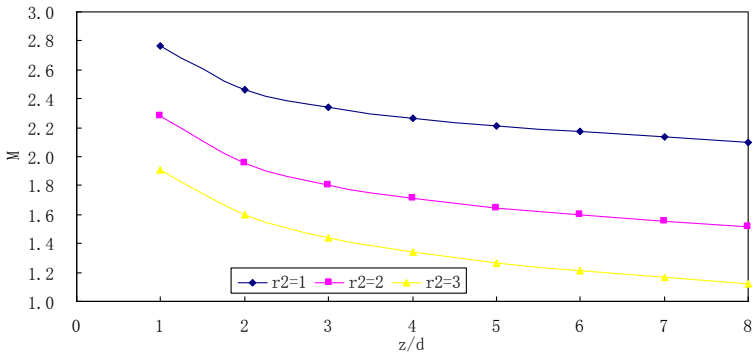

Fig.5 The mixing parameter on each cross-sectional plane

The data in the Table 1 are fitted by power function as showed in Figure 6.

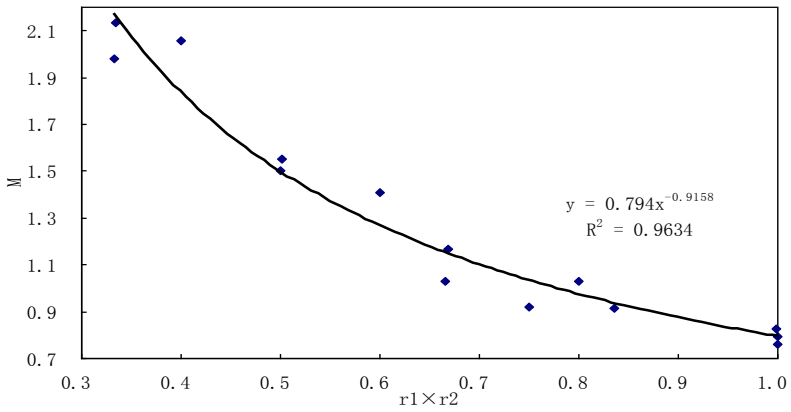

Fig. 6 The mixing parameter M on the plane of z=7d

Figure 6 shows on the plane of z=7d the mixing parameter M does eventually decline with the value of $r_1 \times r_2$. Further, the mixing parameter M has a power function to the product of r_1 and r_2. The power function can be expressed as :

$$M = a(r_1 \times r_2)^b \tag{4}$$

where a and b are linked to the downstream distance from the injection point.

Conclusion

In this paper, a numerical study of Tee pipe mixers has been conducted with the FLUENT software. To summarize, we obtain the following information pertaining to the design of the considered mixing arrangements:

1. Realizable *k-ε* turbulent model can be used to simulate the mixing of jet-to-cross-flow. The result of simulation does correspond with the existing experimental data.
2. The process of mixing happens quickly in zone of near the injection point, the mixing parameter decreased slowly in the region where z>3*d* especially *z*>7*d*.
3. In a certain plane where *z*>7*d*, the mixing parameter *M* has a power function to the product of r_1 and r_2. The power function can be expressed as $M = a(r_1 \times r_2)^b$.

Keywords: Air entrainment, Oxygen transfer, Dissolved oxygen concentration, Ejector, Design parameter.

Abstract. The objective of this study is to investigate the air entrainment and oxygen transfer characteristics of central-driven ejector with various ejector design parameters. The ejector design parameters are primary nozzle diameter, mixing tube length and diffuser angle. The entrainment ratio decreased with the primary nozzle diameter and diffuser angle, while the ratio increased with the mixing tube length. The trend of dissolved oxygen concentration with the diffuser angle and mixing tube length is equal to the result of entrainment ratio, however, the trend with the primary nozzle diameter is different to the result of entrainment ratio.

Introduction

An ejector works like a vacuum pump without usage of piston, rotor or any other moving components. In general, there are two configurations of ejector. The first is the central-driven ejector, in which the primary fluid passes through the inner nozzle inside the ejector and the suction fluid passes through the annular periphery surrounding the nozzle. The second is the annular-driven ejector, in which the suction fluid passes through the inner tube of the ejector and the primary fluid passes through the annular nozzle on the periphery of the suction tube [1-3].

Ejectors are being used as gas-liquid dispersion devices for many purposes in many industries since they have high mass transfer and mixing rate. Many reports have researched the gas-liquid flow and mixing in ejectors, but the results are different and have individual scope of application due to the different ejector geometries, study methods and the species of fluids [4,5].

There are many studies describing the hydrodynamic and mass transfer characteristics concerning multi-phase fluids with the conventional central-driven ejector [6]. The effects of various parameters such as primary nozzle area ratio, mixing tube length, diffuser angle and length on the ejector performance have been investigated by Sharma et al.[7], Kim et al.[8], Kumar et al.[9], Rogdakis and Alexis [10], Rainer et al. [1].

Mass transfer occurs in mixtures containing local concentration variation. Mass is transferred from one place to another under the influence of a concentration difference or concentration gradient in the system. Rate of mass transfer is directly proportional to the driving force for transfer, and the area available for the transfer process to take place. The solubility of oxygen within a water tank is very poor. Therefore, the enhancement of gas-liquid mass transfer during gas-liquid contacting processes is always put into priority. Mass transfer characteristics of ejectors using air or water as the primary fluid or the entrained fluid have been investigated by Park and Yang [11], Balamurugan et al.[12], Cramers and Beenackers [13] and Havelka et al.[14].

The development of new gas-liquid contacting systems for high-efficiency oxygen transfer at low operating costs is a very important issue in many applications. Because of the low solubility and transfer rate of oxygen, to achieve a higher oxygen transfer rate, it is necessary to have a large amount of entrainment air and to increase the contact time and area of the air-water bubbles by decreasing the

size of the entrained air bubbles. However, few experimental studies examining the effect of design parameter in central-driven on the flow and oxygen transfer characteristics have been reported in the literature [11]. The objective of this study is to investigate the flow and mass transfer characteristics of central-driven ejector with the primary nozzle diameter, diffuser angle and mixing tube length.

Experimental Setup and Method

The schematic diagram of central-driven ejector with screw pitch for movable primary nozzle is shown in Fig. 1, and the specifications of the ejector are listed in Table 1. The key components of the ejector are a primary fluid nozzle, a suction fluid tube, a parallel mixing tube, a diffuser and a screw apparatus. The primary fluid nozzle position could be adjusted by the screw apparatus. As the nozzle tip moves backward (as the screw pitch increases), the distance between the nozzle tip and the inlet of the parallel mixing tube increases. One pitch of the screw is 1.5mm. All experiments were carried out in a 0.48 m^3 (0.4 m wide × 1.5 m long × 0.8 m height) water tank system which was closed loop circulation type as shown in Fig. 2.

In the hydrodynamic experiments, the tank was filled with tap water which was circulated through the central-driven ejector by means of an electric motor-pump (Wilo, HL 8051-1). The volumetric water flowrate Q_p supplied by the motor-pump was regulated manually with a valve and measured by an electromagnetic flowmeter (Kometer, KTM-800) at the primary flow inlet with the accuracies of ±1.0% of full scale. The suction air flowrate Q_s was measured with an air flowmeter (Kometer, DPE-S) at the air suction inlet of the ejector with the accuracies of ±2.0% of full scale.

For the oxygen transfer measurements, the water in the water tank was deaerated by addition of sodium sulphite (Na_2SO_3) with a cobalt chloride($CoCl_2$) catalyst until the dissolved oxygen (DO) concentration fell to zero and then reaerated back to steady state (saturation) conditions. The total amount of sodium sulphite required for each test run was calculated based on the theoretical demand for sodium sulphite [11, 15]. The changes of the DO concentration with time were recorded until the water became saturated with air. The temperatures of the circulation water and the suction air were 14.3±1.0℃ and 14.4±0.5℃. The saturated dissolved oxygen concentration with the temperature of circulation water at standard atmospheric conditions is 10.24 mg/L. The dissolved oxygen concentration (C_t) was measured at 10 second time intervals with a DO meter (YSI model 5B). In each experiment, measurements were repeated three times at each operating condition. Percentage dissolved oxygen is defined by the ratio of actual dissolved oxygen concentration against saturated dissolved oxygen concentration at the water temperature.

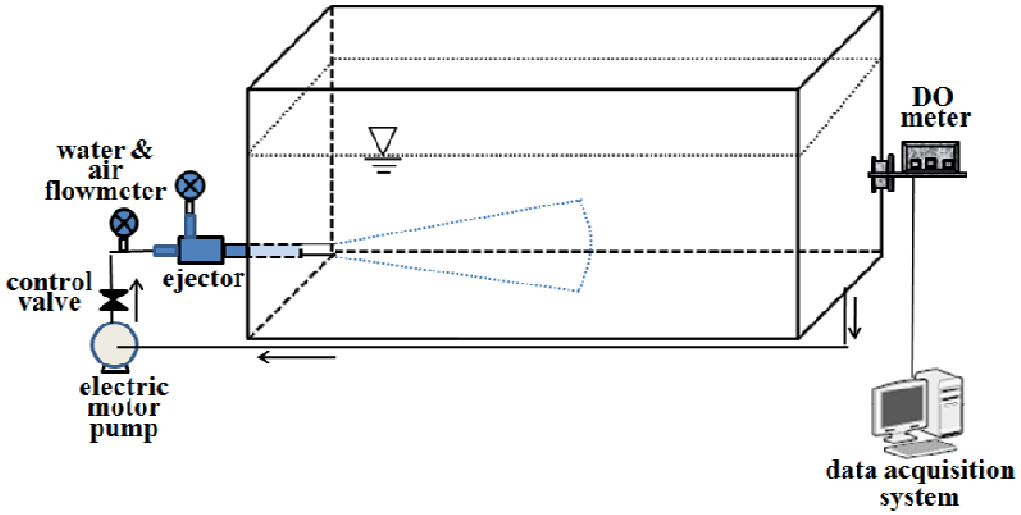

Fig. 2 Schematic diagram of experimental setup

Results and Discussion

The measured variables are the flow rates of the primary and suction fluids (water and air) and dissolved oxygen concentration. The entrainment ratio is the amount of suction air flow that can be sucked by a given primary flow. The entrainment ratio is calculated by $M=Q_s/Q_p$, where Q_s is the suction air flow rate and Q_p is the primary water flow rate.

Fig. 3 show the effects of primary nozzle diameter, diffuser angle and mixing tube length on the entrainment ratio with the screw pitch in the central-driven ejector. Generally, as the screw pitch increases (or as the nozzle exit tip is moved backward), the entrainment ratios increase. This is due to the fact that as the screw pitch increases the primary water flow rate is nearly constant, while the suction air flow rate increases. The nearly constant primary flow rate is owing to the constant primary nozzle area regardless of the screw pitch and the increasing suction air flow rate is owing to the variation of suction inlet vacuum pressure with the screw pitch. As the primary nozzle diameter reduces, the air entrainment ratio increases due to the increase of the vacuum pressure near the primary nozzle exit resulting from the increase of primary flow velocity. As the diffuser angle decreases, the entrainment ratio increases owing to decreasing vortical loss in the diffuser. As the mixing tube length decreases, the entrainment ratio reduces owing to the energy loss resulting from the incomplete mixing of primary fluid and suction air in the mixing tube and the vortical mixing in the diffuser.

Figs. 4, 5 and 6 show the effect of primary nozzle diameter, diffuser angle and mixing tube length on the percentage dissolved oxygen concentration with the aeration time at pitch 0, 7, 17 and 27 respectively. As can be seen in the percentage dissolved oxygen concentration results, dissolved oxygen concentrations increase with aeration time. The increase of dissolved oxygen concentration with aeration time may be attributed to the longer contacting time of air bubbles in aerating water [11].

As shown in Figs. 5 and 6, as the diffuser angle decreases and the mixing tube length increases, the dissolved oxygen concentrations increase with the aeration time. The trend is equal to the result of entrainment ratio as shown in Fig. 3. An increase in dissolved oxygen concentration with increasing the entrainment ratio may be ascribed to the increase in interfacial area between air bubbles and aerating water. At the minimum nozzle diameter the air entrainment ratios exhibit the highest values, however, the dissolved oxygen concentration exhibit the smallest values. This result may be attributed to the shorter persistence of air bubbles due to the increased buoyancy force resulting from their larger size.

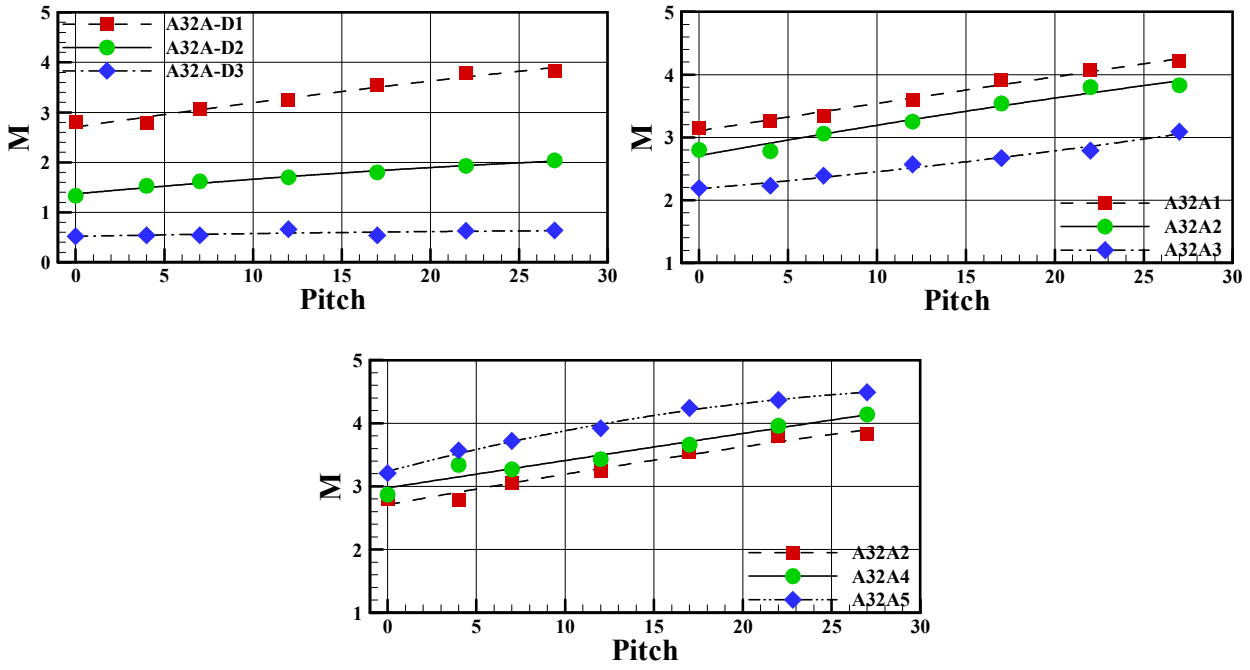

Fig. 3 Effect of design parameters (d_n, β, L_m) on the air entrainment ratio with screw pitch

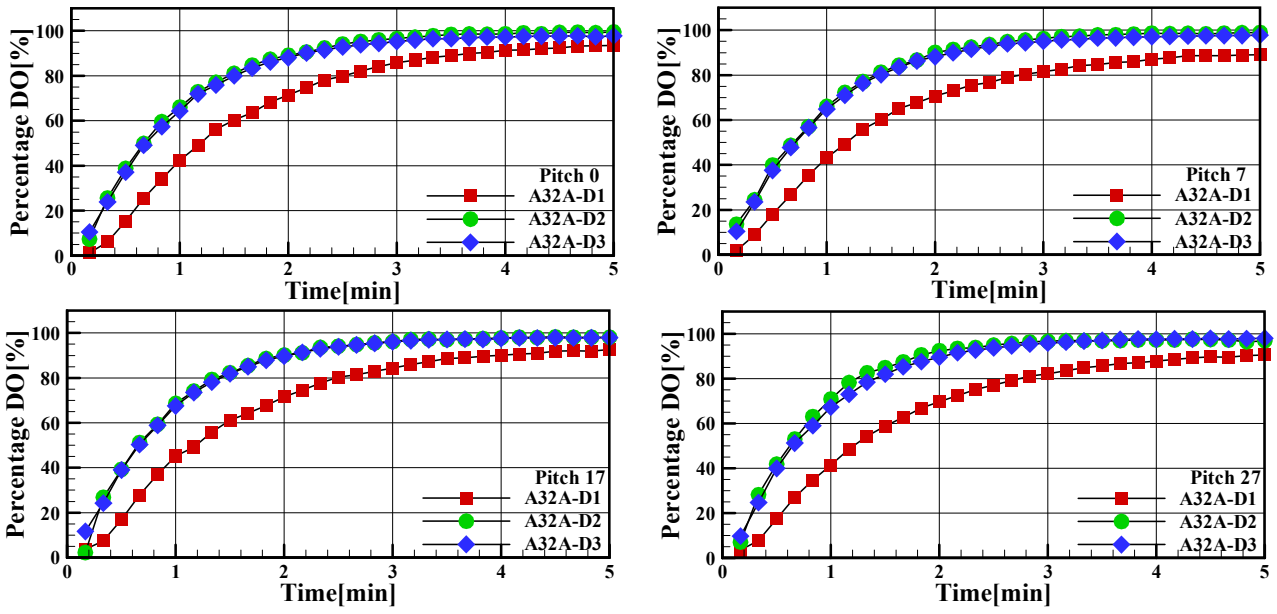

Fig. 4 Effect of primary nozzle diameter (d_n) on the percentage dissolved oxygen concentration with aeration time

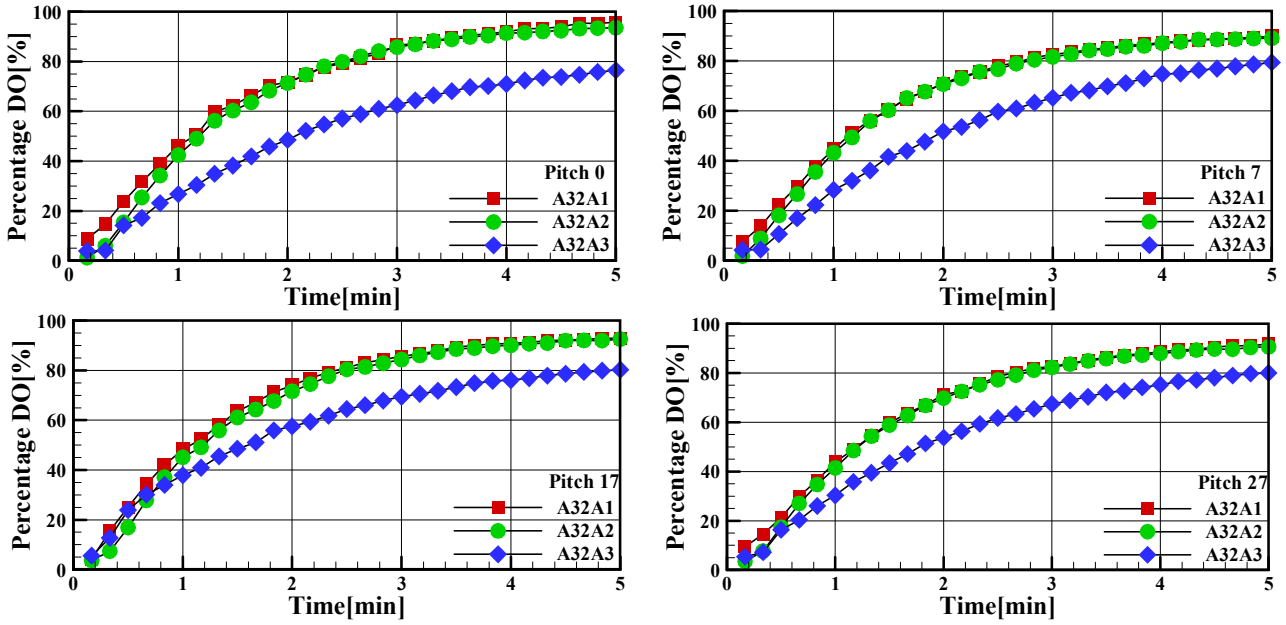

Fig. 5 Effect of diffuser angle (β) on the percentage dissolved oxygen concentration with aeration time

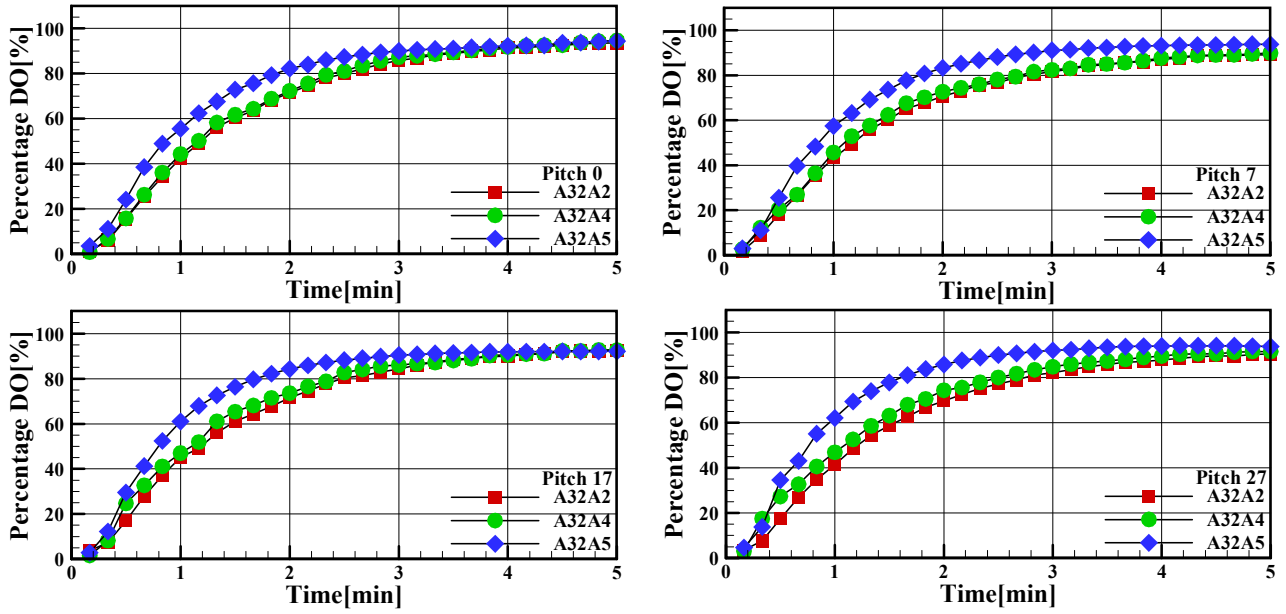

Fig. 6 Effect of mixing tube length (L_m) on the percentage dissolved oxygen concentration with aeration time

Conclusions

For the central-driven ejector, the entrainment ratios increase with the screw pitch. As the primary nozzle diameter reduces, the air entrainment ratio increases due to the increase of the vacuum pressure near the primary nozzle exit resulting from the increase of primary flow velocity. As the diffuser angle decreases, the entrainment ratio increases owing to decreasing vortical loss in the diffuser. As the mixing tube length decreases, the entrainment ratio reduces owing to the energy loss resulting from the incomplete mixing of primary fluid and suction air in the mixing tube. As the diffuser angle decreases and the mixing tube length increases, the dissolved oxygen concentrations increase with the aeration time. At the minimum nozzle diameter the air entrainment ratios exhibit the highest values, however, the dissolved oxygen concentration exhibit the smallest values due to the shorter residence time of air bubbles resulting from their larger size.

Keywords: pressure pipe diameter, upper room of surge chamber, the size of orifice, volute pressure

Abstract: For a long-distance convey tunnel hydropower station, the changes of its convey tunnel diameter will impact on the pressure at the turbine volute, due to the influence of upper room of surge chamber, surge pressure is difficult to be the controlling value of the pressure at volute, the results also indicate that the influence of pressure pipe diameter on the pressure is more significant than the diversion tunnel diameter. This paper focuses on the pressure pipe diameter by the calculation of a numerical example, the increasing of the pressure at volute caused by the reduction of pressure pipe diameter can be adjusted for security requirements by optimizing the orifice size of surge chamber. Combined with the calculation of the combinational conditions, optimization results are satisfactory. That will reduce the investment of pressure pipe, so it has a certain reference value to the project.

Introduction

With the rapid development of China water utilities, more and more hydropower projects are coming into the research and development. Due to geological and topographical constraints, some stations built diversion power plants. For the long-distance convey tunnel system, because the water inertia is large, wave cycle of the surge chamber is long, the attenuation is slow and the amplitude is large, so the maximum pressure at volute is controlled by water hammer pressure and surge pressure [1]. But when the surge chamber has an upper chamber, its surge pressure is difficult to become the controlling value, the maximum pressure at volute is decided by water hammer pressure. To reduce water hammer pressure for the purpose, we can reduce the water flexibility of the pressure pipe. However, its diameter is often larger than the economic pipeline diameter that is designed in the preliminary design stage by Peng Deschutes formula [2], it will increase the project investment. Reducing the pressure pipe diameter will increase the pressure at volute, but the increasing of the orifice size of surge chamber can effectively reduce the pressure at volute, combined with the interactional relationship of them, we present a viable optimization program, that can make the results meet the calculation range.

Numerical example

Water diversion system of a hydropower station is composed of diversion tunnel, throttled surge chamber with upper room and pressure pipe, the diversion way is that two units share a diversion tunnel. The length of diversion tunnel between water inlet and surge chamber is 6045.6m, the diversion tunnel diameter is 8.5m, the length of pressure pipe between surge chamber and units bifurcation point is 326.87m, the pressure pipe diameter is 7.5m, the orifice diameter of surge chamber is 4.0m, rated flow of two units is 111.2m^3/s, rated head is 176.5m, rated output is 178.61MW. Its layout diagram is shown in Figure 1.

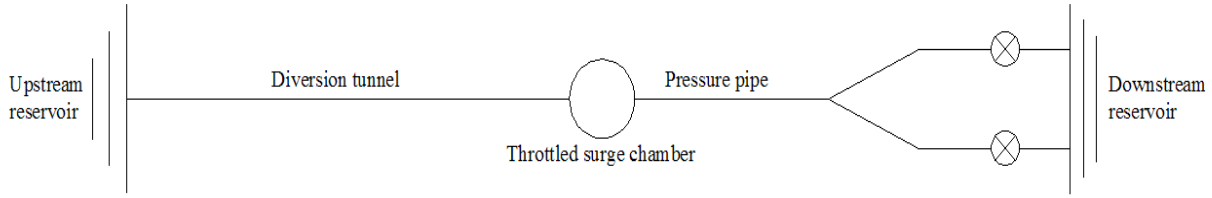

Fig. 1 Schematic of hydropower station layout

Effect of the water pipe diameter on the pressure in volute

Here, we have transitional process calculation for the numerical example, and respectively adjust the diameter of diversion tunnel and pressure pipe, then we can study its effects on the pressure at volute. Calculation condition is upstream reservoir high water level, the downstream reservoir normal tail water level, rated output, and two machines simultaneously loading rejection, this condition may be the controlled condition of the maximum pressure at volute, guide vanes turn off by straight at a fixed time. Diversion tunnel diameters are respectively taken 7.0m, 7.5m, 8.0m, 8.5m, 9.0m. Pressure pipe diameters are respectively taken 6.0m, 6.5m, 7.0m, 7.5m, 8.0m. The results are shown in Table 1, Table 2, Figure 2 and Figure 3.

Tab.1 Calculation results of the pressure at volute under different diversion tunnel diameters

Diameter of diversion tunnel (m)	7.0	7.5	8.0	8.5	9.0
Volute pressure (m)	264.13	265.50	265.05	264.38	264.37

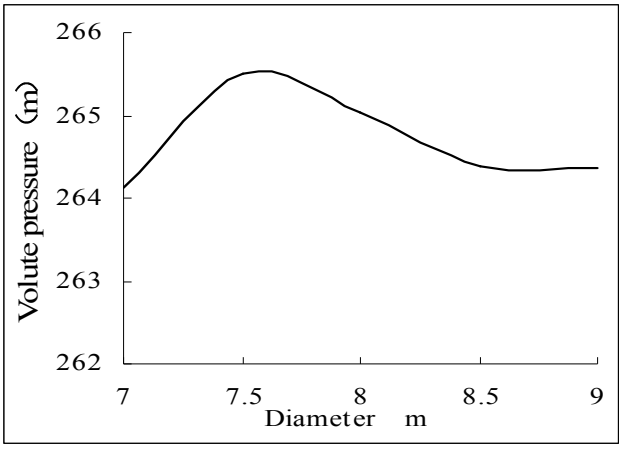

Fig.2 Relationship between the pressure at volute and diversion tunnel diameters

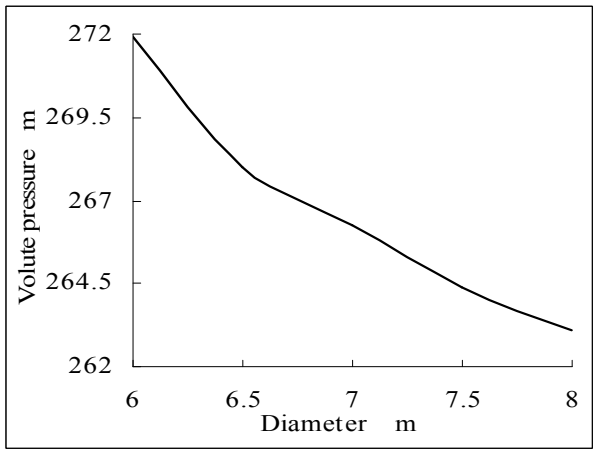

Fig.3 Relationship between the pressure at volute and pressure pipe diameters

Tab.2 Calculation results of the pressure at volute under different pressure pipe diameters

Diameter of pressure pipe (m)	6.0	6.5	7.0	7.5	8.0
Volute pressure (m)	271.96	267.97	266.25	264.38	263.12

We can see in Fig.2 the pressure at volute increases first and declines with the increasing of the diversion tunnel diameter, but the pressure amplitude changes little. In Fig.3, the pressure gradually decreases with the diameter increase of the pressure pipe, and the amplitude changes significantly. The reduction of diversion tunnel diameter makes its water inertia (∑LV) increased, the impact of the surge pressure on the volute will also increase. Due to the effect of the upper chamber, the flow rate rapidly decreases after water flowing into the upper room, it is difficult to form a higher surge to make it to be the controlling value of the maximum pressure at volute, so the change of the diversion tunnel diameter has little effect on the pressure at volute. Reduction of the pressure pipe diameter makes the water flexibility increased, the maximum pressure at volute is controlled by water hammer pressure so that it shows a significant change.

Effect of the orifice size of surge chamber on the pressure at volute

The water hammer wave reflectivity of the throttled surge chamber is not only related to the surge chamber diameter, but also its orifice area and throttle coefficients [3]. In general, the optimization of the surge chamber diameter only have an impact on the magnitude of the surge, compared to the orifice of surge chamber, its impact on the pressure at volute is not obvious. Keeping other parameters constant, we can study the impact of different diameters of the orifice of surge chamber on the pressure at volute. The results are shown in Table 3 and Figure 4.

Tab.3 Calculation results of the pressure at volute under different diameters of the orifice of surge chamber

Diameter of the orifice (m)	3.2	3.6	4.0	4.4	4.8	5.2
Volute pressure (m)	296.05	277.65	264.38	256.57	253.67	251.63

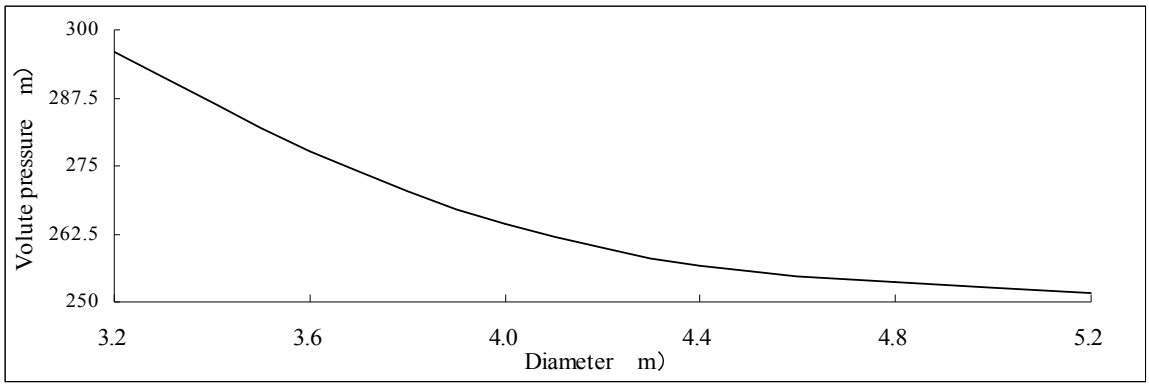

Fig. 4 The influence of different sizes of the orifice on the pressure at volute

By analyzing Table 3 and Figure 4, with the increasing of surge chamber orifice diameter, the pressure at volute gradually reduces. Thus, to increase the orifice diameter is an effective measure to reduce the water hammer pressure. While the curve in Figure 4 also reveals that when the orifice diameter increases to a certain extent, the reduced speed of the pressure at volute becomes slow. If we further increase the orifice diameter, its impact on the pressure will be getting smaller and smaller. In this case, increasing the area of the orifice will only lead to the increase of the surge and the adverse effect of delaying the decay time of the surge. Therefore, the orifice optimization is in a certain range.

Pressure pipe diameter and orifice size of surge chamber optimization

By the calculation above, reducing pressure pipe diameter will bring the rise of the pressure at volute, while increasing orifice diameter will effectively make the pressure reduced, combined with the optimization of them for their interactional relationship, so the pressure at volute is controlled in the calculation range that is possible. In general, at the feasibility study and preliminary design stage, the economic diameter of the pressure pipe is determined by Peng Deschutes formula [2], the formula is $D=(5.2Q^3_{max}/H)^{1/7}$, where, Q_{max} is the maximum design flow of the pressure pipe , H is the design head. The pressure pipe diameter of the example is 7.5m, but the calculated diameter is 6.12m by the Peng Deschutes formula in the same example, in comparison, to reduce the diameter of the original proposal has a certain space to explore. In the example, the design value of the pressure pipe diameter is 7.5m, the orifice diameter is 4.0m, the calculated value of the pressure at volute is 264.38m, we treat them as a benchmark, then the pressure pipe diameters are respectively taken 8.0m, 7.0m, 6.5m, 6.0m for the calculation of hydraulic transition process. To ensure the pressure is controlled in about 264.38m, orifice diameter is bound to be adjusted to meet the standard. The results are shown in Table 4.

Tab.4 Optimization of the orifice diameter of surge chamber under different pressure pipe diameters

Diameter of pressure pipe (m)	8.0	7.5	7.0	6.5	6.0
Diameter of the orifice (m)	3.96	4.00	4.06	4.30	4.90
Area of the orifice (m^2)	12.31	12.56	12.94	14.51	18.85
Volute pressure (m)	264.24	264.38	264.61	264.21	264.48

The following conclusions can be obtained by analyzing Table 4: the reduction of the pressure pipe diameter causes the increasing of the pressure at volute, with the increasing of orifice diameter, the reference value is controlled in about 264.38m by their interactional relationship. And when the pressure pipe diameter reduces at the same range, the orifice diameter only adjusts in a small extent to make the pressure controlled in the calculation range. So we can reduce the pressure pipe diameter without increasing construction costs, which provides a reference to reduce engineering investment. While the results in Figure 4 also reveal that when the orifice diameter increases to a certain extent, the effect of the reduction of the pressure at volute gradually becomes weak, thereby the orifice diameter is larger and larger with reducing the same diameter of the pressure pipe.

Combinational working conditions reviewing

Since the diversion tunnel of this hydropower station is long, the water inertia is large, wave cycle of the surge chamber is long, combinational working conditions often occur when the hydropower station works, so it may exacerbate the pressure at volute in the process of load shedding. Combined with conventional conditions, we draw up the following combinational conditions: upstream is the checking flood level and downstream is the normal tail water level, one unit is rated output, another unit normally starts to rated output, when the flow rate flows into the surge chamber to be the largest, two units suddenly load rejection, it may be the maximum pressure at volute. We select the original design (A-Program: pressure pipe diameter is 7.5m, orifice diameter is 4.0m) and two optimization programs (B-Program: pressure pipe diameter is 7.0m, orifice diameter is 4.06m;

C-Program: pressure pipe diameter is 6.5m, orifice diameter is 4.30m) to calculate in combinational working conditions. The results are shown in Table 5.

Tab.5 Check of combination conditions under different programs

Combinational program	The time of maximum flow (s)	The maximum volute pressure (m)
A-Program	237.44	275.38
B-Program	237.35	275.40
C-Program	236.02	270.15

By comparing the original program and the optimization programs in combinational conditions, the results indicate that the optimization programs have a good stability, even in C program, it achieves better results than the original program.

Conclusions

a. Due to the effect of the upper room of the surge chamber in the long-distance convey tunnel hydropower station, its surge is difficult to increase largely to be the controlling value of the maximum pressure at volute, and it leads to that the impact of diversion tunnel diameter on the pressure is also not obvious. With the function of the water flexibility in pressure pipe, the pressure at volute shows a growth trend by the decreasing of pressure pipe diameter.

b. With the increasing of the orifice diameter, the pressure at volute gradually decreases. But when the orifice diameter increases to a certain degree, its function on the pressure at volute gradually becomes weak.

c. By the interaction law between the pressure pipe diameter and orifice diameter, we reduce the pressure pipe diameter while increase the orifice diameter, so that the pressure at volute can be controlled within the scope of the guaranty calculation, that will be a feasible optimization program. And the optimization program has a good stability in combination conditions, so there will be a certain reference to the actual engineering design.

Keywords: Ejector; Structural parameters; Simulation; Dimensionless

Abstract. The effect of structure size on the flow field in the ejector was investigated by simulating structural parameters of ejector. Simulation results show that the shock occurred in the flow field of the ejector. The entrainment coefficient shows different trends as different structure parameters change. The effects of nozzle position, inlet diameter and nozzle exit ratio were studied respectively. The simulation result revealed that the structural parameters impact the performance of the gas ejector, having certain engineering application value.

Introduction

The ceramic filter has been considered to be one of the most promising technology of particle separation from gas at high temperature owing to its high filtration efficiency, heat-shock resistance, and gas erosion resistance[1-5] However, it has been pointed out that commercialization of these technologies is critically hindered by the problems with the dust removal system operating at high temperature and high pressure[6,7] The effect of the pulse cleaning system is one of the important factors influencing the stability of ceramic filter with long period. Excellent ejector design has an important impact on the quality of blowback effect. Therefore, to find the optimal structure dimension of venturi diffuser to obtain a larger injection coefficient and achieve better cleaning results. As the experiment restrictive and numerical simulation has the advantage that the distribution of the ejector flow field is displayed. Numerical simulations of full-size gas ejector using computational fluid dynamics software FLUENT carried [8,9].

Methods

An ejector is shown in Fig.1. The main structural member comprises work nozzle, tapered section, throat and diffuser. High pressure purge gas ejected from the nozzle. In the role of suction and shear stress of high pressure blowback gas surrounding gas was sucked into the mixing chamber volume. Then, they exchange momentum, energy with ejector airflow. Gradually uniform mixing and form a single gas stream. Mixed gas pressure begins to rise. In the diffuser, the mixing air pressure continues to rise, the speed is reduced. In the general, airflow pressure in the diffuser is higher than that in the reception room[8,9].

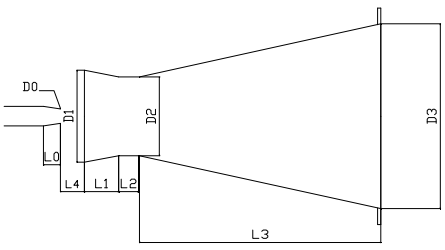

Fig.1 Schematic diagram of diffuser

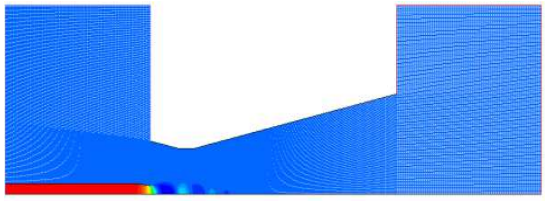

Fig.2 Schematic diagram of pressure distribution diffuser

Performance indicators used in this simulation is the injection coefficient. Referring to a certain conditions, Unit mass of high voltage pulse inverse blow air through ejector can inhale the quality of the low pressure gas. The entrainment coefficient is equal to the ratio of the low pressure gas mass flow Q_a to the mass flow Q_p of high pressure working gas.

The entrainment efficient can be calculated using the following equation:

$$n=Q_a/Q_p \quad (1)$$

Where n--Entrainment coefficient

Q_a--Low-pressure gas mass flow rate, kg/s

Q_p--High-pressure gas blowback mass flow rate, kg/s

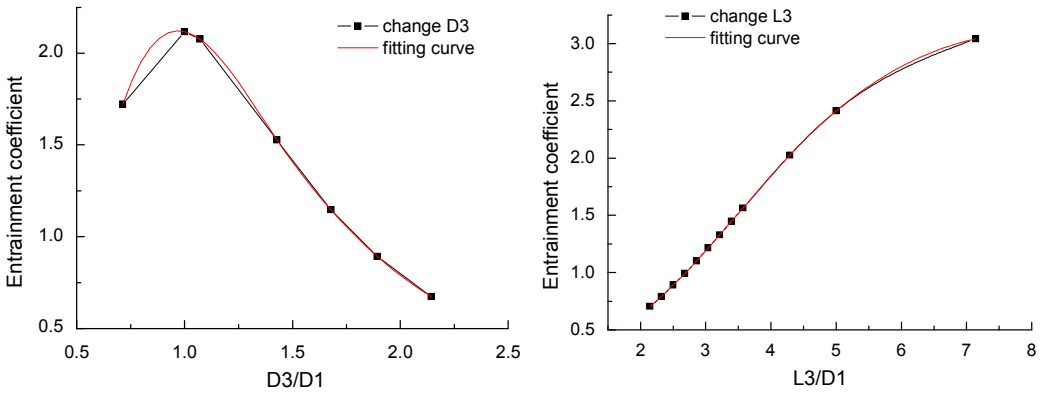
The turbulent flow was described by using standard k—ε model which has a high stability, economy, accuracy and wide range of applications considering the flow rate inside the ejector is likely to exceed the speed of sound and the emergence of shock waves, the fluid was set as ideal-gas. Its viscosity is calculated using the law Sutherland. All the walls is taken as a standard wall function; For Pressure, Momentum, Turbulent Kinetic Energy, Turbulent Dissipation Rate and so on, first use of a First-order upwind discretization, After about a hundred iterations changed to second order upwind. Blowing gas entrance is set as pressure-inlet, its value is 0.6Mpa;Low pressure gas entrance is also set as pressure-inlet boundary condition, the pressure value is also 101325Pa. Export is pressure-outlet, The same value of the pressure is taken as 101325 Pa. The structured grid was used to compute the discrete area.

The structure parameters of injector were changed to determine the optimizing structural parameters of the ejector which can have a larger entrainment coefficient.

Results and discussion

The pressure distribution was checked after calculating stability. Pressure distribution was shown in Figure Fig.2. It can be clearly seen from the fig.3 that internal flow field has emerged shock. It showed the accuracy of the simulation is qualified.

Taking into account the structural parameters of ejectors have a lot of size, the non-dimensional method was used to analysis the results of simulation to obtain the main influence factor. The inlet diameter is set as the characteristic length to make other length parameter dimensionless. The structure size of ejector was changed to determine their impact on the entrainment coefficient respectively by observing the change trend of ejector coefficient.



(a) (b)

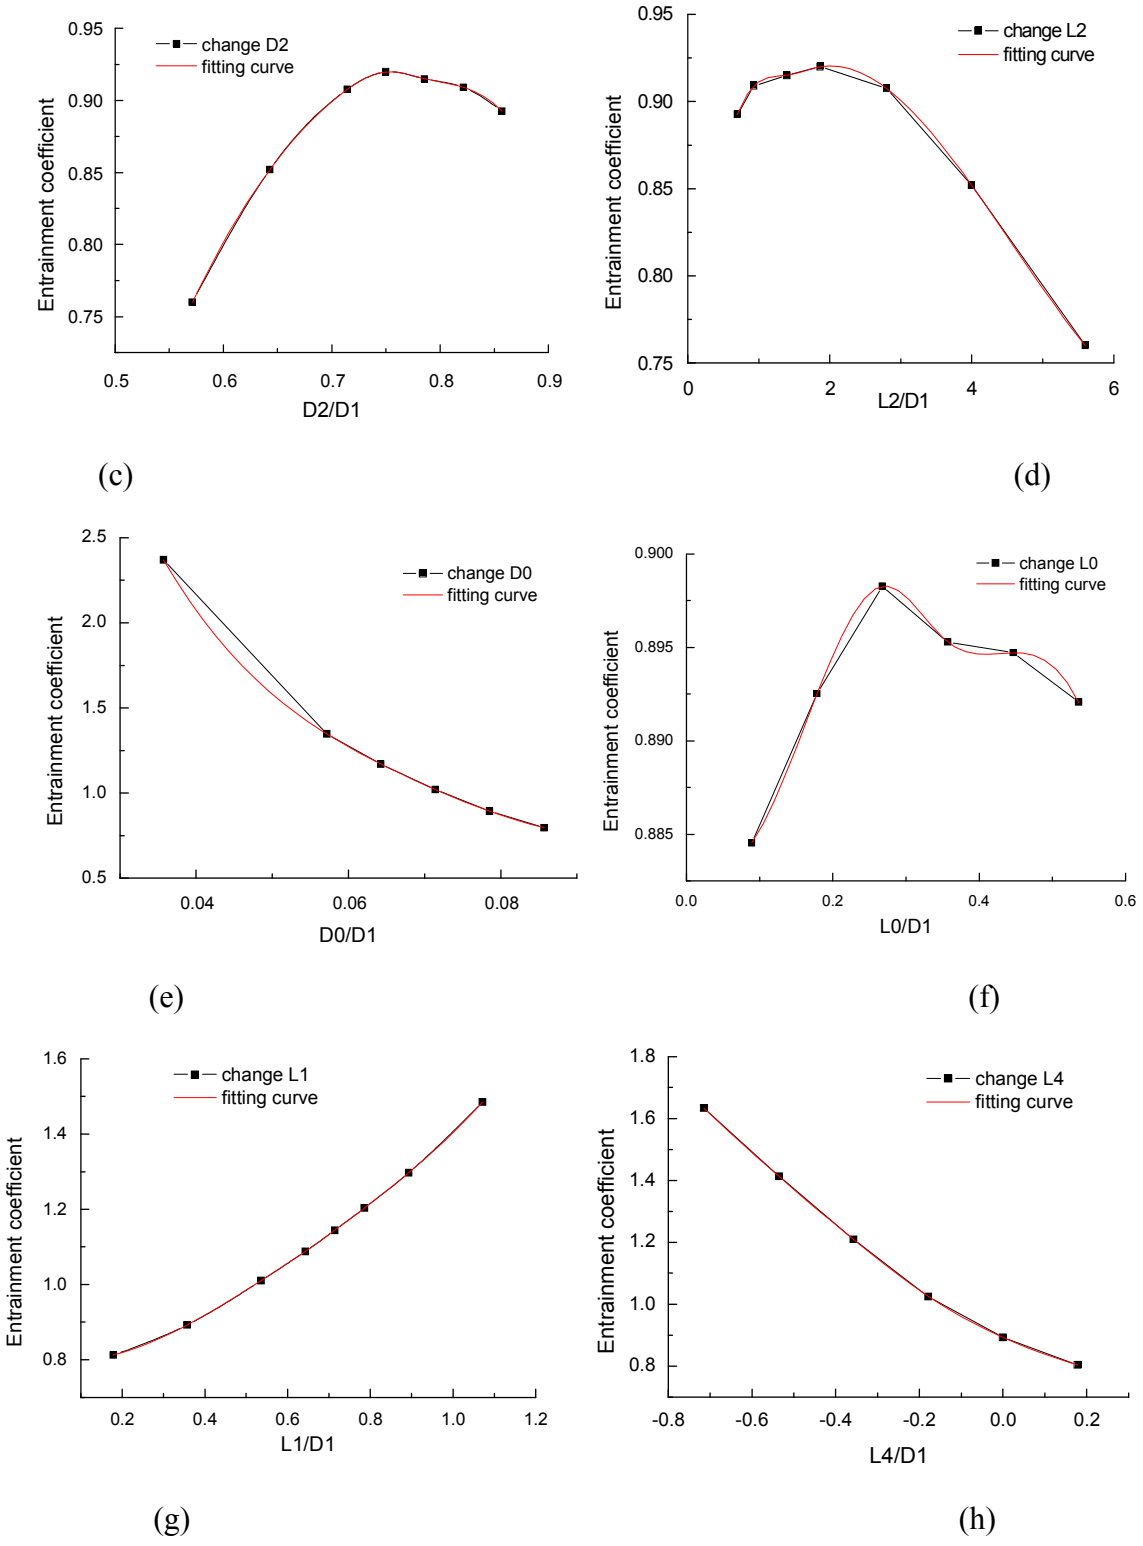


Fig.3 The variation of entrainment with the dimensionless length parameter

The length parameters were changed respectively, such as the ejector outlet diameter D3, the Diffuser length L3, the mixing chamber diameter D2, the mixing chamber length L2, the nozzle diameter D0, the nozzle length L0, contraction length L1 and the distance L4. The trend of the injection coefficient was observed to determine which structural parameter is the preferred. Figure 3 (a), (c), (d) and (f) show that entrainment coefficient variation with D3/D1, D2/D1, L2/D1, L0/D1 increase, but after the first increases and then decreases. The maximum value of 2.12172 occurred when the D3/D1 is 0.9663. The maximum value of 0.9198 occurred when D2/D1 is 0.75. The

maximum value of 0.92006 occurred when the L2/D1 is 2.1411. The maximum value of 0.89828 occurred when the L0/D1 is 0.2740. Furthermore, the slope of curve is sharper in the left side of the peak in figure 3 (a), figure 3 (c) and the right side of the peak in Figure 3(d). When design the value of D3/D1, D2/D1 and L2/D1 should be avoided in this interval when design ejector. This is to avoid the small change will cause a larger ejector coefficient changes.

Although in figure 3(b), (e), (g) and (h) did not appear peak value. Change trend clearly illustrates a situation. In the case of other conditions are met, L3/D1, L1/D1 should set as larger value and D0/D1, L4/D1 set as smaller values to get a larger coefficient ejector. Comparing figure 3(b), (e), (g), and (h), we can see that the slope of the curve is steeper in figure (e). This suggests that D0/D1 has a greater impact on entrainment coefficient. The value of the nozzle diameter D0/D1 should be key consideration in the design.

Conclusions

In this work, the relationship between the structure size and the coefficient of the ejector was obtained. Entrainment coefficient first increased and then decreased, along with the D3/D1, D2/D1, L2/D1, L0/D1 increase. The entrainment coefficient first increased and then decreased at first. While With the L3/D1, L1/D1 increase, it becomes larger. And it gradually becomes smaller as the D0/D1, L4/D1 increases. The ratio of the structure size should be taken to avoid the entrainment coefficient curve slope larger premises. Under the same condition, the part of the relatively steep curve should be considered in the design of ejector.

Keywords: steam jet pumps, calculation model, design method

Abstract. The use of steam steam ejector is formed in a Laval nozzle entrained flow speed airflow to the power unit of the body, has a simple structure, easy maintenance, stable and reliable, pumping capacity, etc.which is widely used in metallurgy, chemical, pharmaceutical , food and other industries. Based on the comprehensive domestic steam jet pump theory and design based on the results of its variety of design methods reviewed, and in accordance with design features and compare their design processes, raise steam jet pump design trends.

Introduction

Steam jet pump is a low pressure fluid using high pressure fluid pumping fluid machine, usually consists of four parts: Working nozzles, receiving room (absorption chamber), the mixing chamber and diffuser chamber (diffusion chamber). A working fluid energy (pressure and velocity) imported into the injector from the work, through the nozzle at sonic or supersonic flow after, a negative pressure near the exit of the nozzle, under the action of the pressure ejector (low pressure) fluid into the absorbent room, two different pressures stocks mixed fluid mixed in the mixing chamber, resulting in the exchange of mass and energy, and then enlarged mixed fluid pressure chamber pressurized flow. The structure shown in Figure 1:

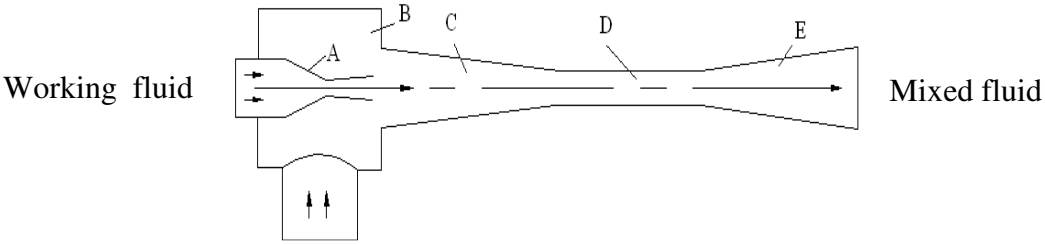

Fig.1 Ejector diagram. A—nozzle section, B—absorbing section, C—mixing section(conical), D—mixing section(cylinder) , E—diffuser section

Steam jet pump has no mechanical energy consumption, simple structure, no moving parts, low running costs, ease of operation and maintenance, and for toxic, flammable, corrosive and contain impurities or condensable gases entrained flow body apply. At home and abroad in the power, petrochemical, metallurgy, textile, refrigeration, industrial thermal engineering and other fields are widely used.

Steam ejector simple structure, but it involves the entrainment speed compressible flow, supersonic mixing, and the shock wave, boundary layer shear layer interactions, complex flow pattern, it is difficult to conduct a detailed flow process mathematical description. In industrial design, mostly used to check the chart method to determine injection coefficient, using the experience of rough estimation methods to determine the structure of the critical dimensions. Using this method injector design work often less than ideal performance, or even a vacuum degree of instability, thus affecting the stability of the entire production, continuity, security. Therefore, the structural design of steam ejector direct impact on the entire production process whether the normal and safe operation.

Calculation of Steam jet pump Model Research

One-dimensional Model. Keenan and Neumann section of a simplified without diffusion studied injector that the injector mixing process is a constant pressure , the injector is first given a complete theoretical analysis and experimental study , the formation of injector a wiki this theory . They assume that the working fluid and entrained flow body has the same molecular weight and the specific heat capacity of the working fluid and entrained flow body and the mixed fluid in any cross-section has a uniform physical distribution of the nozzle and the diffuser inside the process is such entropy process , without the wall resistance of the injector , without export of speed, ideal gas , based on the one-dimensional mass, momentum , and energy conservation equations , derived with a maximum compression ratio or the maximum coefficient of the injection jet geometric parameters optimization formulas and the ejector efficiency is defined as the actual and the ideal jet injection coefficient ratio coefficient . Keenan , also did not take into account the impact resistance , they were considered at constant pressure mixing phase working fluid in a very short distance to accelerate to supersonic speed , the impact resistance is negligible ; Similarly, when supersonic gas flows through the same pipe cross-section , the friction effect is extremely slight . Takashima In this method , based on the various parts of the jet pump friction loss calculations were classified and calculated according to this calculation the optimal performance parameters. However, these calculations are very complicated, and calculated and experimental values of the comparison is very narrow on the basis of the experimental results , it is not a large pressure range are able to set up , so that is not a perfect approach.

Obrine Simplified Model. Obrine put Keenan et al converted into a simple formula generalized equation , obtained by pumping gas is air , the working vapor steam (adiabatic index unchanged) , diffuser throat in the presence of shock steam jet pump design theory, the compression ratio and the entrainment ratio and the expansion ratio is a function . This model assumes that : (l) working steam and was pumping gas at the nozzle outlet to inlet diffuser throat between the isobaric mixing ; (2)ideal gas ;（3）one -dimensional flow . Wei Shiying first two based on the theory proposed by pumping gas is air , the working vapor is wet steam (steam during the expansion of the adiabatic index change), the shock diffuser throat more consistent with the presence of the actual operation of the steam jet pump design theory . Hayami Hui inferior water vapor jet pump also many theoretical problems have been studied , discussed the various factors that affect the pumping performance parameters as well as the state of the law on the pumping performance . Application of these theories is not only computationally intensive design calculations , but also in the practical application of the process by which some of the parameters , the coefficient is difficult to obtain exact values, resulting in theoretical calculations and the pump than the difference between the actual performance .

Cokonob Computational Model. Cokonob can summing the former Soviet Institute of Thermal Engineering Theory and practice based on the results of the working medium is pumped media with the states of matter, the different states of matter, as well as work in the process of change of state analysis of the situation, put forward a different compression ratio, the structural characteristics of the jet pump, design theory and design methods. Cokonob assumptions: (1) the mixing chamber pressure increases linearly; (2) ideal gas; (3) one-dimensional flow. Since the law does not consider the diffuser throat generate positive shock case, and did not fully consider the diverging section of the diffuser role in the calculation of the entrainment ratio decreases, thereby increasing the throat area ratio.

Design of a steam jet pump

Empirical Coefficient Method. Empirical coefficient method is the use of empirical coefficient and experimental investigations taking charts for injector design calculations . Because of this design method is simple , fast , many designers have taken this approach, but this method ah requires designers with rich experience in the design , such as different types, different structures and different working conditions ejector ejector coefficients are different , should the improper selection , it will seriously affect the working performance of the ejector can not even work properly.

Classical Thermodynamics. The first method is based on classical thermodynamics thermodynamics , second law -based , theory , be able to calculate the nozzle section humidity changes each case , but the compression ratio and the entrainment coefficient of the intrinsic link between not limited, can only rely on experience to solve, and classical thermodynamics method ejector key parts of the size , is also a major empirical approach to computing , it is difficult to get accurate results . However, after long-term improvements, part of his experience has been improved , the development has been more mature. Classical thermodynamic method is based on the fluid ejector thermodynamic process design calculation , calculation is relatively simple and convenient. But mostly based on classical thermodynamics law constant pressure hybrid model , simplifying the fluid mixing process, and multi-processing model based on adiabatic manner , and even ignored the impact of the model geometry , as is the mixing chamber and other cross-sectional hybrid model .

Gas Dynamics Function Method. Gas dynamics function method is based on kinetic theory of gases , according to the law of conservation of energy , the introduction of the relative pressure, relative hematocrit , converted isentropic speed dynamical functions , the theoretical analysis and empirical correction method perfected methods of calculation and solve the compression ratio and the entrainment ratio between the calculation of qualifying relationships, injector design calculations rationality has been greatly improved. However, this method are complex and cumbersome formula derivation , calculation of the gas injector is more accurate , but the saturated gas phase flow or humidity changes in the model can not resolve , calculation errors.

Computer Programming and Numerical Simulation. To improve water economy of the steam jet pump , the water vapor jet pump is necessary to optimize performance , and reduce the working steam consumption is particularly important. Current development of computer technology and the industry are closely related , in the steam jet pump jet pump theory based designers to work a minimum of steam consumption design objectives , and consider setting the condenser , condensate water flow and other factors, the compression ratio allocation to optimize the design to determine the objective function , using VB language, C language , Matlab and other writing optimized design process steam jet pump and two examples are calculated with the use of conventional design jet pump, can indeed save working steam .

As a new method of fluid flow , computational fluid dynamics (Computational Fluid Dynamics, CFD) in various industrial areas to be more widely used, at present , CFD methods have started to become enlarged engineering plant optimization and quantitative design tools. It not only gives approximate flow field within the device structure , but also provide some experimental information can not or difficult to measure . We can use existing models and CFD software flow jet pump the fluid simulation to simulate and study the different working media , was pumping gas state, the pump outlet conditions , gas mixing conditions and other factors on the jet pump performance effects and in-depth analysis of fluid flow within the jet pump status , according to the simulation results , and then the steam jet pump design optimization. Thus saving the financial and human resources and time investment. For the numerical simulation of steam jet pump the basic flow is (1) to establish computational model , formulating hypotheses ; (2) to establish the boundary conditions ; (3) for the discrete equations , numerical calculation .

Conclusion

Steam jet pump from the current domestic and international research status view, single-stage jet pump study design methods have matured, but multi-stage steam jet pump is not much research and application. The actual operation of the jet pump automatic detection automatic control needs to be improved. The jet pump theory, along with the continuous development of computer technology, CFD will become mainstream, its rich visualization predict the result will be complex fluid flow jet pump understanding of the issues and the analysis provides great help.

Air Pressure Reducer Modeling by CFD Methodology

Ranran Wu, Ding Fan

School of Power and Energy, Northwestern Polytechnical University, Xi'an 710072, China

wrr_1120@163.com

Key words: Air pressure reducer; computational fluid dynamics; CFD methodology; displacement-pressure characteristics; SST k-omega turbulence model

Abstract. In this paper, the computational fluid dynamics (CFD) methodology as well as the shear-stress transport (SST) k-omega turbulence model was adopted to model the air pressure reducer (APR). Changing the gas needle's displacement of APR continuously, the writer obtains the displacement-pressure characteristics of APR. In order to demonstrate the validity of these characteristics, a physical experiment was conducted, which generates another displacement-pressure characteristic. Comparing the two characteristics with a good agreement, it is indicated that the CFD methodology is suitable to study the displacement-pressure characteristics of APR.

Introduction

The APR, one key component of afterburner state control system of aero engine, plays a very important role in the afterburner state control system. It can regulate the turbine pressure ratio, making the aero engine operate steadily as expected. However, some problems are still sustained in design, production and manufacture of the APR. These problems hinder its normal use and performance improvement. Therefore, investigating the APR's characteristics is vitally necessary.

In the past decades, little research was carried on about the APR, especially the simulation studies. In this paper, the writer is going to split the computational domains, obtain the relationships between structure parameters and characteristic curves, and study the flow field characteristics. The experimental data obtained by physical experiment are employed to assess the CFD model.

Mathematical model

A 3-D CFD methodology is developed in this paper to investigate the displacement-pressure characteristics of the APR. The Reynolds averaged Navier-Stokes (RANS) equations with the SST k-ω turbulence model are adopted. In the present simulation, the shear-stress transport (SST) k-ω turbulence model is usually adopted as the turbulence model. This turbulence model has been demonstrated to have a better prediction generally in the flow conditions, including large normal strain, separating flow, strong acceleration, etc., which may occur in the flow characteristics of the APR [1,2].

Boundary condition

As shown in Fig. 1(a), the APR has only single inlet and single outlet. As the Mach number in the throat of Laval pipe reaches 1, and becomes greater later, the part of flow outlet as well as the working chamber can be removed, as shown in Fig. 1(b). The essential boundary conditions are listed in Table 1.

Table 1 Boundary conditions of the APR model.

Material Name	Air
Wall Roughness Constant	0.5
Total Pressure of Inlet [MPa]	1.674
Total Temperature of Inlet [K]	300
Specific Dissipation Rate [1/s]	1
Turbulent Kinetic Energy [m^2/s^2]	1
Gauge Pressure of Outlet [Pa]	101325
Backflow Total Temperature [K]	300
Backflow Turbulent Kinetic Energy [m2/s2]	1
Backflow Specific Dissipation Rate [1/s]	1

Mesh model and numerical treatment

Fig. 1(b) schematically shows the simplified mesh model for simulating the APR model. Considering the complexity of its structure, an unstructured mesh is adopted.

There are 1.5 million tetrahedral cells and 2.8 million nodes approximately. In order to simulate the model better, the cell size where the gradient of flow parameters are rather great is set to be shorter. Calculations with different mesh distributions and quantities are carried out to demonstrate that the simulation results are grid independent.

The mathematical model describing the SST k-ω turbulence model belongs to the partial differential equations (PDEs), which can be calculated after discretization. The density-based solver is chosen for the calculation, since it is more suitable to simulate the high velocity flow fluid than the pressure-based coupled solver [1,3]. The multigrid levels are set to 5, which contributes to iteration convergence dramatically [4,5]. The second order upwind scheme is adopted in the flow, turbulence kinetic energy and specific dissipation rate discretization.

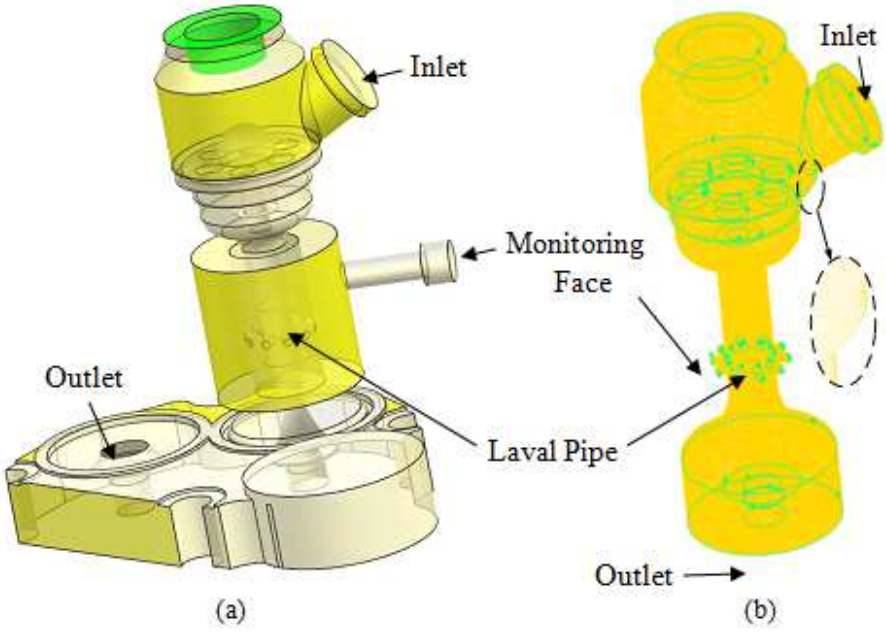

Fig. 1 Schematic of the APR model (a); Simplified mesh model (b)

Results and discussion

In order to validate the present CFD model, a physical experiment is conducted. Therefore, two sets of data are achieved, i.e., the measured data and the predicted data, as shown in Fig. 2. As seen in Fig.2, the predicted displacement-pressure characteristics show a good agreement with the measured'. The pressure monitored increases with an increase of the APR needle's displacement. When the needle's displacement is less than 5.6 millimeters, the pressure monitored increases linearly; then nonlinearly with a greater and changing increasing rate. This phenomenon can be explained by the characteristics of Laval pipe [6]. In addition, all the predicted data are slightly greater than the measured data, from the Fig. 2, since the heat transfer between the inside and outside of fluid field is omitted. Another reason is that, as known to all, there exists variance in the CFD simulation. However, the CFD methodology is often accepted, as long as it is utilized properly.

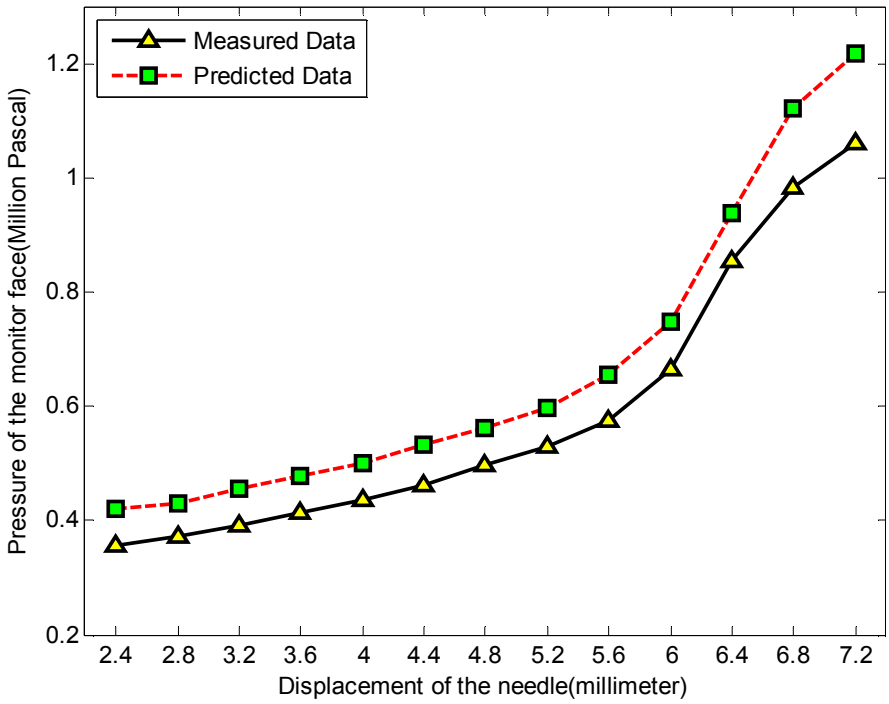

Fig. 2 Comparison of the displacement-pressure characteristics between measurements and predicts

The pressure nephogram and the Mach number nephogram of a symmetrical plane of the APR are obtained by TECPLOT software, as shown in Fig. 3. The air flows into the APR with a high pressure and low velocity. The parameters at the outlet of the top portion are almost the same as that at the inlet of the whole model. The flow fluid runs through the Laval pipe later, with the pressure from 1.6MPa to 0.1MPa, and the Mach number from 0.2 to 3.6. The Mach number reaches to 1 near the throat of the pipe. As the pressure of the outlet of the pipe is about 0.1MPa, which is slightly high, there is a shock wave before the fluid runs out of the pipe. The shock wave decreases the velocity of the fluid, but increases the pressure. The interface between the red color and the blue color in the Fig. 3(b) is the shock wave face. This indicates that the original outlet portion omitted is not essential. Near the outlet, there exist some small swirls.

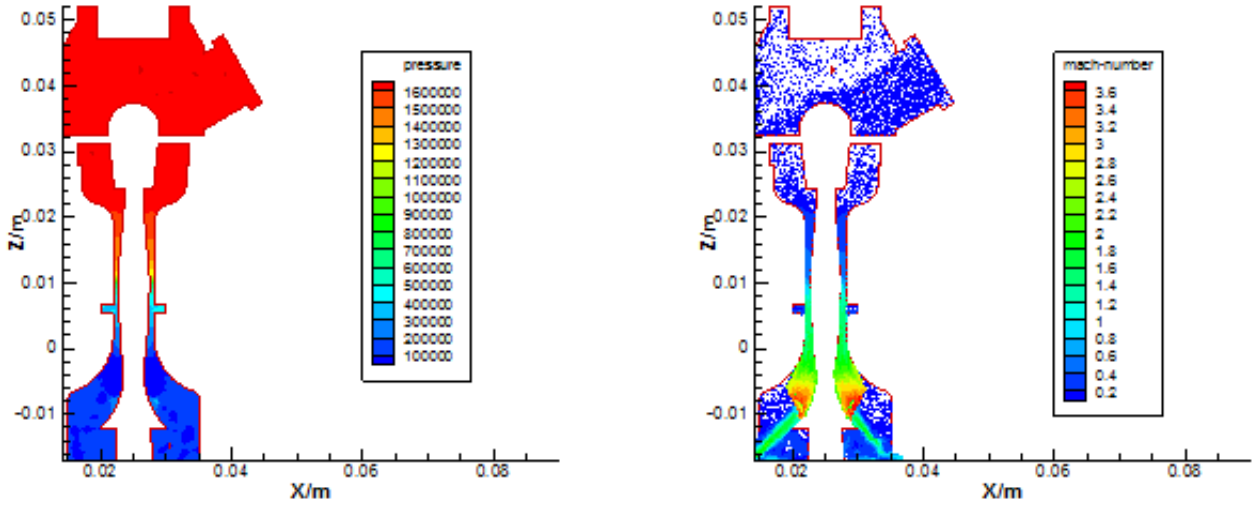

Fig. 3 The pressure nephogram of the APR (a); The Mach number nephogram (b)

Conclusions

In this paper, a 3-D CFD methodology is developed to simulate the displacement-pressure characteristics. A few conclusions can be drawn based on the simulation results and shown as follows:

1. Compared with the measured displacement-pressure characteristics, the present predicted results show a good result. These comparisons indicate that the RANS equation with the SST k-ω turbulence model can be adopted to reasonably simulate the flow behaviors for the APR.
2. The flow characteristics, including flow swirling as well as shock wave, can be reasonably captured by the RANS CFD model with the SST k-ω turbulence model.
3. The outlet portion which has no effect on pressure monitored, can be omitted when simulated.

Keywords: Micro-fluidcs, Couette flow,shear stress,velocity slip,temperature jump

Abstract. In this paper, Couette flow is mainly discussed by studying the general flow behaviour mechanism and importing the velocity slip and temperature jump boundary condition. By analyzing velocity, temperature and pressure profiles at different Knudsen numbers, we concluded that Couette flow is driven by shear stress. The shear stress lies in stream direction. Viscous heat causes the increasing of the fluid's temperature. With the increasing of Knudsen numbers, the increasing speed increases. It's in the beginning of transition region that the heat flux has the maximum.

Introduction

In recent years, an important feature of scientific research is the development direction of the micro scale. Because of the mean free path feature size and molecular flow system in the same order of magnitude, gradient change of macro parameters, the traditional theory of fluid dynamics based on the continuum assumption is no longer applicable, The flow and heat transfer in micro scale must be improved. The study of microscale gas flow including three kinds of methods such as the experimental study, numerical calculation and the theoretical analysis . Numerical simulation study mainly includes two aspects: the numerical solution of the Boltzmann equation and Direct simulation Monte Carlo method[1]. Direct solution of the analytical solution is difficult because of the presence of differential and integral complex on Boltzmann equation. Therefore, the theoretical framework of the flow and heat transfer in a suitable for the development of micro scale gas is very meaningful.

This paper mainly discusses a common flow system named Couette flow[2]. This flow system choice argon as flowing medium to calculate the rarefied gas in slip and transitional flow. This establishment of mathematical model based on the Navier-Stokes equations[3], the Fourier Heat transfer law[4] and the state equation of ideal gas[5] considering the rarefied gas effect and boundary conditions. The calculation results using the direct simulation Monte Carlo method (DSMC) to verify its effectiveness.

Control Equation

The calculation is concerned with the gas flow between infinite plates as shown in Fig.1. The distance between the two plates is 1 μm with upper plate is fixed, at the same time the lower plate movementlower plate moving at a certain speed. This flow is called the Couette flow.

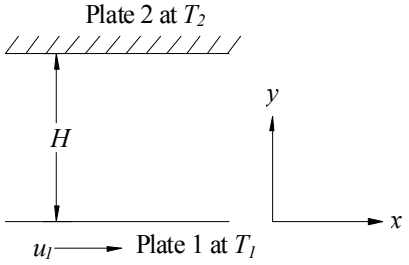

Fig.1 Couette Flow Coordinate Systerm

The flow can be considered as one-dimensional compressible steady flow，the suitable control equations is:

$$\frac{d}{d\tilde{y}}\left(\tilde{\mu}\frac{d\tilde{u}}{d\tilde{y}}\right)=0 \tag{1}$$

$$(\gamma-1)Ma^2\tilde{\mu}\left(\frac{d\tilde{u}}{d\tilde{y}}\right)^2+\frac{1}{\mathrm{Pr}_0}\frac{d}{d\tilde{y}}\left(\tilde{K}\frac{d\tilde{T}}{d\tilde{y}}\right)=0 \tag{2}$$

$$\tilde{p}=\tilde{\rho}\tilde{T} \tag{3}$$

In the formula: $\tilde{y}=\frac{y}{H},\tilde{u}=\frac{u}{u_0},\tilde{T}=\frac{T}{T_0},\tilde{p}=\frac{p}{p_0},\tilde{\rho}=\frac{\rho}{\rho_0},\tilde{\mu}=\frac{\mu}{\mu_0},\tilde{K}=\frac{K}{K_0}$

It will be occur velocity slip and temperature jump [6] phenomenon In the gas solid interface when the number of Kn exceeds 0.001. Schaaf and Chambre[7] indicates the dimensionless velocity slip conditions for single atomic gas:

$$\tilde{u}_s-\tilde{u}_w=\frac{2-\sigma_v}{\sigma_v}\lambda\left(\frac{d\tilde{u}}{d\tilde{y}}\right)_w \tag{4}$$

The dimensionless temperature jump boundary conditions is:

$$\tilde{T}_s-\tilde{T}_w=\frac{2-\sigma_t}{\sigma_t}\frac{2\gamma}{\mathrm{Pr}(\gamma-1)}\lambda\left(\frac{d\tilde{T}}{d\tilde{y}}\right)_w \tag{5}$$

The number of σ_v is a dimensionless quantity and its meaning the tangential momentum accommodation coefficient in the formula(4) . The numerical size of its representation momentum exchange between the degree of perfection of the incident gas molecules and wall: that is

$$\sigma_V=\frac{P_i-P_r}{P_i-P_w} \tag{6}$$

In the formula: the number of P_i is the incident to the wall surface of the momentum flux($kg.m/s^2$); the number of P_r is from the momentum flux wall reflection; the number of P_w as the momentum flux to the wall temperature out of the wall reflection.

The number of σ_t is a dimensionless quantity and its meaning the tangential energy accommodation coefficient in the formula(5). The numerical size of its representation energy exchange between the degree of perfection of the incident gas molecules and wall: that is

$$\sigma_t=\frac{E_i-E_r}{E_i-E_w} \tag{7}$$

In the formula: the number of E_i said the incident to the energy wall molecular flow(*J/s*); the number of E_r said from the molecular energy wall reflection out flow; the number of E_w said the molecular energy to wall temperature out of the wall reflection flow.

Numerical Method

The numerical methods used in this paper is the generalized differential quadrature method[8] (GDQ: Generalized Differential Quadrature Method): this method starting directly from the governing differential equation and take the node parameters as the corresponding time series In the time domain, also use the Lagrange polynomial approximation in the spatial domain to derive algebraic equations in the whole region. The amount of each time point were calculated independently and does not appear cumulative error in this method.

Rsults and Analysis

Velocity distribution. Fig.2 shows the Ma=1.0 under different Kn numbers speed distribution curve. The velocity distribution curve shows a linear distribution with a constant velocity gradient, it also shows shear stress is uniform along the groove height. With the increase of Kn number, the near the wall 2 (stationary flat) fluid velocity increases gradually, and the near the wall 1 (treadmill) fluid velocity gradually decreased. Because of as the Kn number increases, Knudsen layer would be thickened, and slip velocity is greater.

Temperature distribution. The curves of temperature distribution in Fig.3 shows clearly the dimensionless temperature elevation along the channel to the parabolic distribution. For the gas flow of Kn<1.2, the two kinds of model basically coincide. The figure also shows when the Kn number is increased, the more severe the temperature jump. The jump of the theoretical model and the DSMC model is the same to predict the temperature distribution when the Kn number is 0.01and 0.1. With the increase of Kn number, DSMC model to predict the temperature jump is bigger than predicted by the theoretical model.

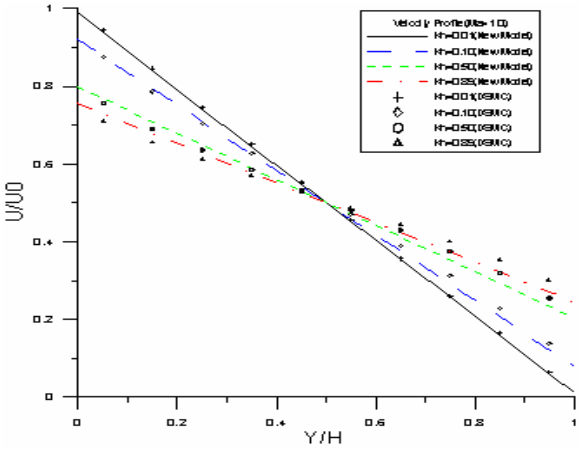

Fig.2 Velocity profiles at Mach 1.0

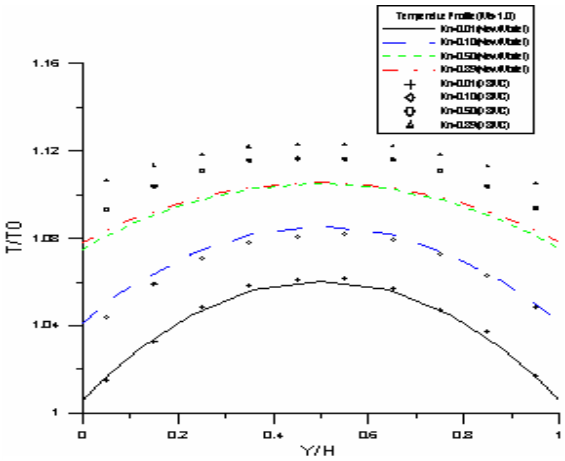

Fig. 3 Temperature profiles at Mach 1.0

Pressure distribution. Fig.4 shows the pressure distribution curve of pressure distribution curve of different under Kn. It shows that it exist larger error between the two models when the Kn number is larger. The DSMC model predicts an uneven pressure distribution, however the theoretical pressure hypothesis model distribution is uniform. And this difference increases gradually with the increase of Kn number.

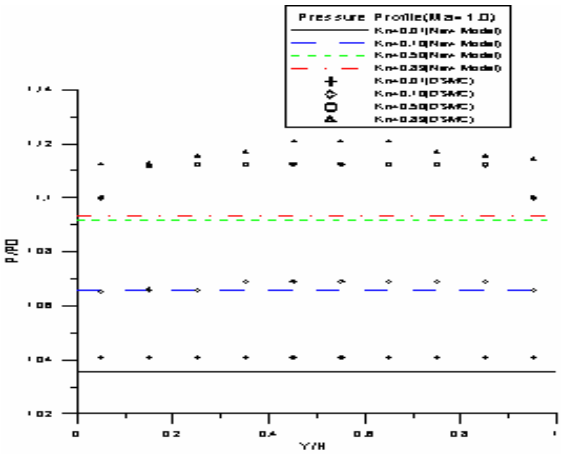

Fig. 4 Pressure profiles at Mach 1.0

Heat flow. The function relation between the dimensionless heat flux and Kn number of the new model and the DSMC model were plotted in Fig.5 and Fig.6. There is a big deviation about the dimensionless heat flux between the theoretical model and the DSMC model in the slip flow region and this deviation flow becomes more obvious when Kn>0.1 in transitional flow. This is because there is a corresponding deviation when use a slip velocity boundary and temperature jump boundary conditions to simulate the interface the actual velocity and temperature. The slip boundary condition was not applicable when Knudsen layer becomes thicker with the increase of Kn number. The prediction of flow line model in Kn>0.04 begins to bend in Fig.5. The deviation appeared in Kn>0.02 when the Maher number Ma=3.0 in Fig.6. With the increase of Kn number the molecules of a gas between two plates almost does not exist collision, so the heat conductivity between the molecules reduced to zero gradually, at the same time, heat transfer rely mainly on the radiation. The result of DSMC model showes that with the increase of Kn number, some characteristics of heat flux changes when the flow becomes more rarefied. The results of theoretical model and DSMC model are not very good agreement for the dimensionless heat flux.

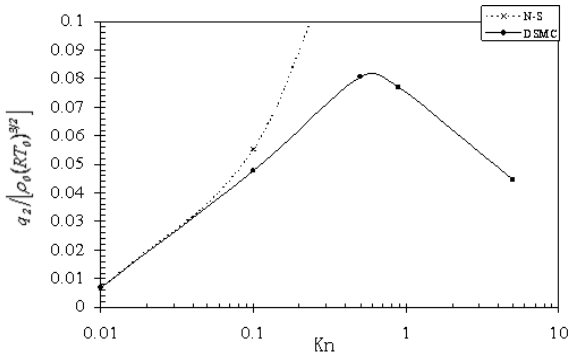

Fig.5 Non-dimensional shear stress at Mach 1.0

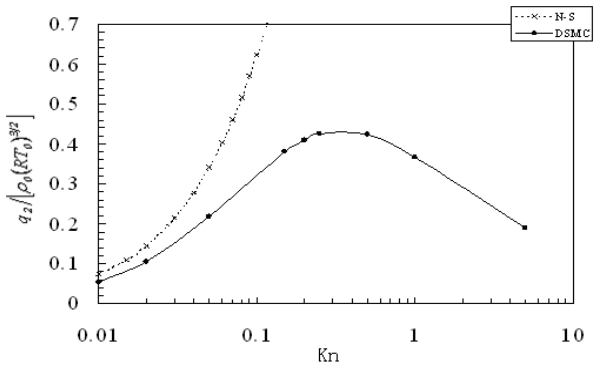

Fig.6 Non-dimensional shear stress at Mach 3.0

Conclusion

This paper discusses the physical mechanism of general micro flow use the macro method for simulation of gas flow and presents a mathematical model about the flow velocity,temperature and pressure distribution of rarefied gas micro Couette flow. This model is based on the N-S equation, also introduces the velocity slip and temperature jump boundary conditions. The theoretical model can be extended to the slip zone and the transition flow region based on the continuum hypothesis. The theoretical framework to analyze the micro Couette flow has been established. The precision of the model was verified through the contraction of direct simulation and Monte Carlo (DSMC). The comparison of the simulation results shows that: this model can reflect the change trend is consistent with DSMC model, but only can predict more accurately when Kn<1.2, the large deviation appears when *Kn*>1.2. Therefore it is still necessary to study the flow characteristics more in-depth about the flow mechanism of micro Couette flow.

Keywords: ground heat exchanger; fluid; temperature; power consumption

Abstract. In the paper, by studying the underground heat exchanger heat transfer mode, the computing platform for ground source heat pump system was established. Through a engineering case, the influence character of the fluid temperature at the outlet of ground heat exchange on the length of system, the fluid temperature in ground heat exchange, and the heat pump power consumption were analyzed, which provide an approach for engineering design and operation prediction, and for the thermodynamic analysis of performance of system year by year and prospective study to guide the engineering practice.

Introduction

Renewable energy is the inevitable choice for the future sustainable energy development, and earth energy utilization as well as its underground shallow as good heat reservoir to provide application space for heat pump technology, have aroused great attention in the world. Earth energy utilization is promising in fields of building HVAC (Heating, Ventilation and Air Conditioning) engineering, and melting snow and deicing in road traffic [1]. However, imbalance problem between cooling load and heating load in the HVAC system has long plagued heat pump engineering application of using earth energy in severe cold region. People have been seeking a solution for best efficiency.

In the paper, through a engineering case, the influence character of the fluid temperature at the exit of ground heat exchange on the length of system, the fluid temperature in ground heat exchange, and the heat pump power consumption were analyzed, which provide an approach for engineering design and operation prediction

The model

The fluid temperature in ground heat exchange. In the paper [2]**,** it systematically explored the establishment of modules, module scarf and coupling call based on Matlab/Simulink calculation control platform, established the basic analysis method of heat pump system. The calculation diagram of the fluid temperature at the outlet of ground heat exchange is shown in Fig.1. Eskilson developed an approach to determine the temperature distribution around a borehole based on a hybrid model combining analytical and numerical solution techniques called G function[3] [4]. The theory of G function of ground heat exchange is used to compute the borehole temperature and the thermal resistance of borehole by entering relevant parameter of ground heat exchange and thermophysical property date of ground, and output of the fluid temperature at the outlet of ground heat exchange.

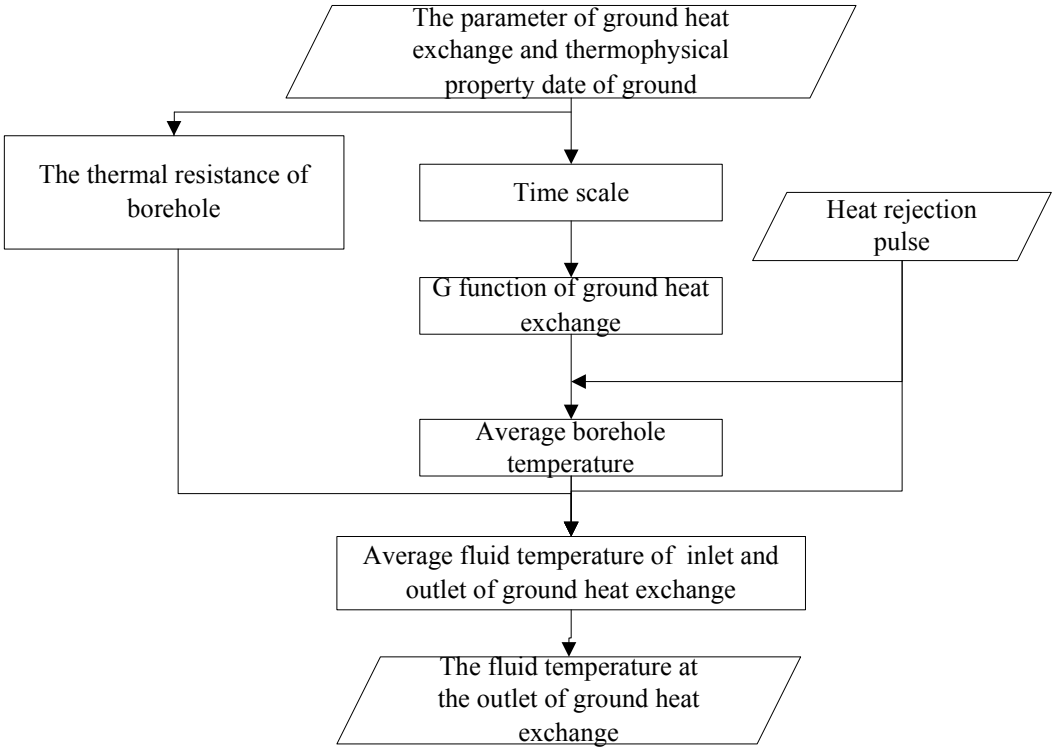

Fig. 1 The calculation diagram of the fluid temperature at the outlet of ground heat exchange

This provided hourly data for the space heating loads or cooling loads for the building in Changchun, China, a summary of the loads are shown in Fig.2. The purpose of this case is to research the influence character of the fluid temperature at the outlet of ground heat exchange on the length of system, the fluid temperature in ground heat exchange, and the heat pump power consumption for the space heating loads or cooling loads for 20 years.

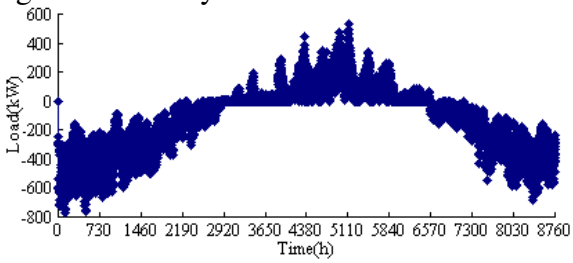

Fig. 2 Building loads

Results and discussion.

The design depth of borehole. The design depth of borehole is limited to the minimum fluid temperature at the outlet of ground heat exchange, and it decides initial cost and the life of project directly. In this case, we respectively select the minimum fluid temperature at the outlet of ground heat exchange of 0℃,-4℃,-6℃,-10℃. The deepest depth of borehole and biggest initial cost are caused by the increment of the minimum fluid temperature at the outlet of ground heat exchange. The longest life of project is caused by the decrement of the minimum fluid temperature under the same depth of borehole. In the Fig.3, a relationship diagram for the depth of borehole and the minimum fluid temperature at the outlet of ground heat exchange. Under this design conditions, we have to redesign the system for optimal solution for the minimum fluid temperature.

The average fluid temperature of GHE. As can be seen from the Fig.2, in Changchun, the heat load significantly greater than cooling load annual and the average fluid temperature of GHE declines year by year. After 20 years, we respectively select the minimum fluid temperature at the outlet of ground heat exchange of 0℃，-4℃，-6℃，-10℃ for the different depth as Fig.3. The average fluid

temperature of GHE can be calculated in Fig.4.After 20 years, the minimum average fluid temperature is -7.74℃ during operation time for when temperature is set at -10℃.

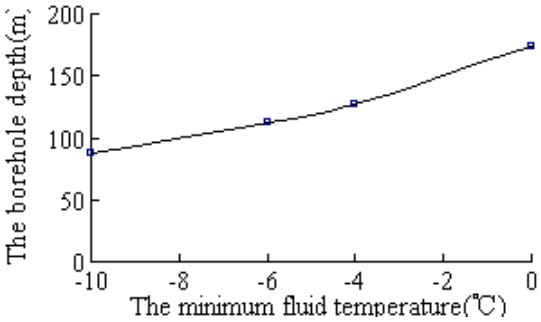

Fig. 3 The depth of borehole

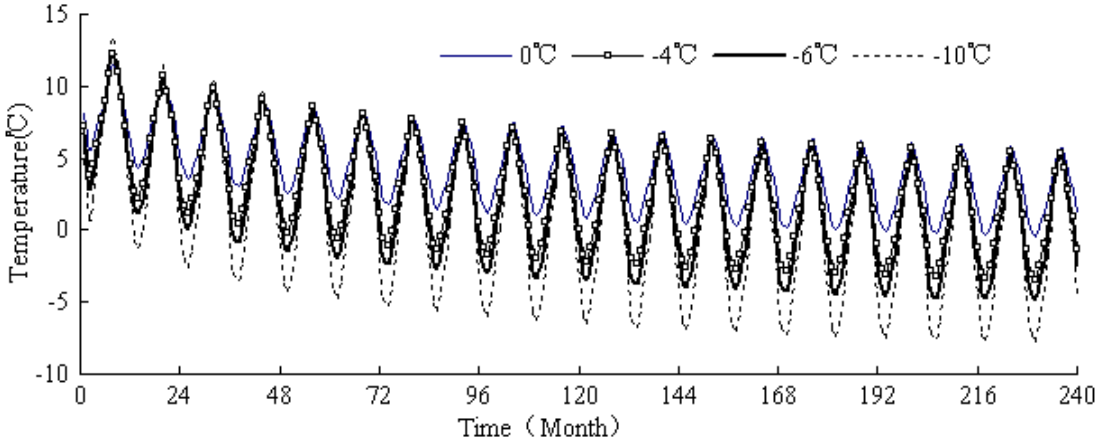

Fig. 4 The average fluid temperature of GHE

Power consumption. The power consumption for heat pump can be calculated in four conditions in Fig.5. In Changchun, the power consumption for heat pump is increase especially temperature is set at -10℃, due to the fluid temperature is low year by year. With lower fluid temperature, the energy consumption is increase. The power consumption only rises 4.25% when temperature is set at 0℃, after 20 years. When temperature is set at -10℃, because of the imbalance of heating and cooling load, the average fluid temperature of GHE decreases year by year, power consumption for heat pump rises 6.27% for 20 years.

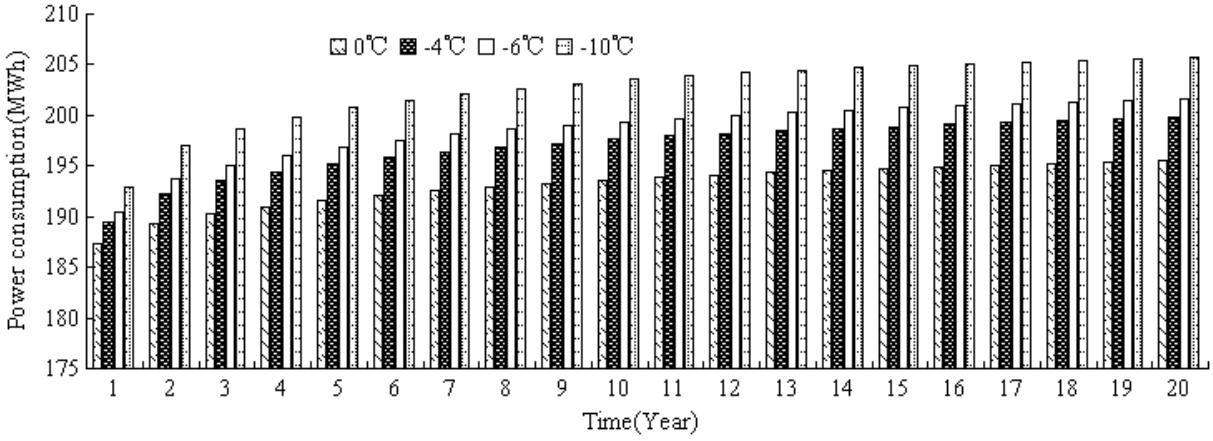

Fig. 5 Power consumption

Conclusion

In the paper, it is to study of underground heat exchanger heat transfer mode and calculate fluid temperature at the outlet of ground heat exchange. Through a engineering case, the influence character of the fluid temperature at the outlet of ground heat exchange on the length of system, the

fluid temperature in ground heat exchange, and the heat pump power consumption were analyzed, which provide an approach for engineering design and operation prediction

Keywords: Transmission and distribution energy consumption(TDEC), Optimization design, Variable Flow(VF), Constant Flow(CF)

Abstract. This paper deals with the study of transmission and distribution energy consumption (TDEC) optimization design about surface-water source heat pump system. Three mathematical model have been established. The fitted polynomials of *COP*, N_e, N_c were obtained by the MATLAB curve fitting toolbox according to datum from product samples. The differences between two operating states which are constant flow and variable flow were analyzed and compared. Under variable flow operating state it was found that there exists an maximum energy conversation rate12.68% of TDEC; the heat pump unit will consume more than average 8.41% energy, while *COP* will decline average 7.61%, the mean energy conversation rate of N_e and N_c are 49.38% and 38.86%, the average declination rate of t_{ein} and t_{cout} are 17.09% and 5.73% compared with constant flow operating state.

Introduction

With the rapid development of global economy, energy and environment problems are becoming more and more serious. In the whole energy consumption, building energy consumption possess a large proportion, and Heating Ventilation and Air Conditioning(HVAC) part occupies a lot[1]. As a kind of energy consumption and environment protection technology, SWSHP(Surface-water source heat pump) can greatly reduce air conditioning energy consumption, taking into consideration of a tendency that people pay more and more attentions to the indoor environment quality, SWSHP will get more and more applications. However in the current SWSHP systems there exist " two low and one high " phenomenons: low efficiency of heat pump units, low water pump efficiency and high operating energy consumption. In order to solve the above problems, it is necessary to optimize TDEC(transmission and distribution energy consumption) of SWSHP system so that it will truly realize energy saving and environment protection goal.

This paper will analyze the energy consumption difference between two operating conditions of SWSHP system: constant flow and variable flow. When heat pump unit keeps operating in a constant flow state, it will maintain high *COP* compared with variable flow state[2,3], however this will lead more pump energy consumption. Reference[4] put forward that under variable flow state it will be more energy efficient compared with constant flow state. It is filled with contradiction between high *COP* and low water pump energy consumption, the purpose of this paper is to solve this contradiction through optimization to TDEC by MATLAB optimization toolbox.

SWSHP system components

A integral SWSHP system contains there subsystems: Refrigerant cycle system, chilled water system, cooling water system, the flow chart of SWSHP system is shown in Fig.1.

- Refrigerant cycle system: it includes the following four components: compressor, condenser, evaporator, expansion value. The compressor needs to consume energy in order to maintain system cycle.

• Chilled water system: chilled water pump, evaporator and pipeline are the main components. Chilled water pump provides hydraulic press to overcome resistance of evaporator and pipeline.

• Cooling water system: cooling water pump, condenser make a loop through pipeline. The cooling water from surface water with lower temperature can absorb heat from high temperature refrigerant vapor so that the surface water can be regarded as one kind of environment protection heat sink.

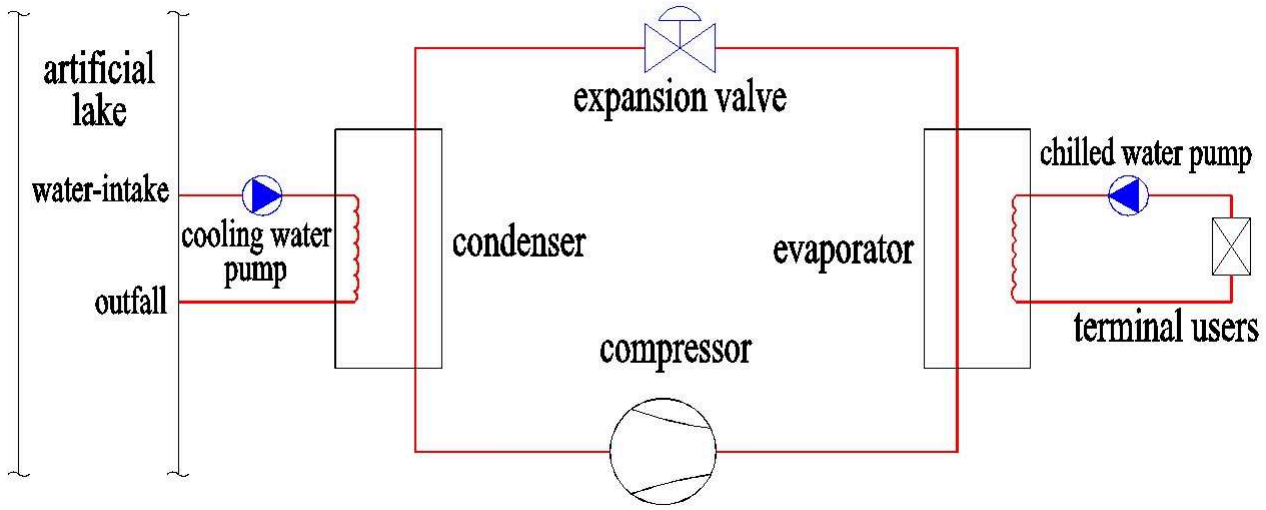

Fig.1 Flow chart of SWSHP system

Model establishment

Heat pump model. In summer air conditioning conditions, heat pump carries through reverse Carnot cycle, *COP* (Coefficient of performance) is proportional to t_0 and inverse proportional to t_k[5], when V_e and V_c keep constant, the mathematical model of *COP* can be described by formula (1):

$$COP_1 = \alpha_1 \exp(\alpha_2 t_0 + \alpha_3 t_k) + \alpha_4 t_0/t_k + \alpha_5. \quad (1)$$

When t_0 and t_k keep constant, *COP* can be described by formula (2):

$$COP_2 = \beta_1 \exp(\beta_2 V_e + \beta_3 V_c) + \beta_4 V_e/V_c + \beta_5. \quad (2)$$

Where, t_0 and t_k are chilled water outlet temperature and cooling water inlet temperature respectively, V_e, V_c are flow rate of chilled water and cooling water respectively, α_1-α_5 andβ_1-β_5 are fitted coefficients.

Under the actual operating conditions, the above parameters t_0, t_k, V_e, V_c are not always keep constant, their values can be changed according to load rate of users. Taking into account the variation of users' load rate–*R*, the mathematical model of *COP* can be described by formula (3):

$$COP = [\alpha_1 \exp(\alpha_2 t_0 + \alpha_3 t_k) + \alpha_4 t_0/t_k + \alpha_5] \cdot [\beta_1 \cdot \exp(\beta_2 V_e + \beta_3 V_c) + \beta_4 V_e/V_c + \beta_5]/\beta_6. \quad (3)$$

Where α_1-α_3 , β_1-β_6, represent fitted coefficients.

Chilled water pump model. In theory, energy consumption of chilled water system concludes water pump energy consumption, cooling loss etc. In order to simplify calculation, it can only consider the major energy consumption—chilled water pump energy consumption. In general, chilled water system is closed system. It needs a minimal differential pressure ΔH_{emin} to ensure that the most unfavorable terminal device can work normally. The pipeline characteristic curve, chilled water pump energy consumption and volume flow rate can be expressed respectively by formula (4), (5) and (6):

$$H_e = \Delta H_{emin} + S_e V_e^2. \quad (4)$$

$$V_{\mathrm{e}}=\frac{Q_{\mathrm{e}}}{\rho C_{\mathrm{p}}\left(t_{\mathrm{ein}}-t_0\right)}. \tag{5}$$

$$N_{\mathrm{e}}=\frac{\rho g V_{\mathrm{e}} H_{\mathrm{e}}}{\eta_{\mathrm{e}}}. \tag{6}$$

Where, H_{e}, N_{e}, η_{e} are lift, power and total efficient of chilled water pump respectively. Q_{e} is cooling load in the evaporator side. ρ and C_{p} are density and specific heat capacity of water. g is gravitational acceleration, S_{e} is impedance of chilled water pipeline. t_{ein} is inlet water temperature of evaporator.

For a given actual project, ΔH_{emim}, Q_{e} and S_{e} can be approximately regarded as constant, and it will satisfy the engineering demand. Meanwhile η_{e} is the function on V_{e}. Through above simplification it was found that N_{e} is only connected with V_{e}. So it is easy to get a polynomial of N_{e} on V_{e} through taking advantage of cftool (curve fitting toolbox) of MATLAB. The polynomial can be shown by formula (7):

$$N_{\mathrm{e}}=\gamma_0+\gamma_1 V_{\mathrm{e}}+\gamma_2 V_{\mathrm{e}}^2+\gamma_3 V_{\mathrm{e}}^3. \tag{7}$$

Where γ_0-γ_3 represent fitted coefficients.

Cooling water pump model. It is known that cooling water system is a open system, there exists a height difference ΔH_0 between water intake surface and water drainage surface. it is feasible that water pump energy consumption is only considered after ignoring energy dissipation and other loss. According to energy conservation principal the function of V_{c} on Q_{e} and COP can be deduced. The pipeline characteristic curve, chilled water pump energy consumption and volume flow rate can be expressed respectively by formula. The following formula(8), (9), (10),(11) can be used to calculate N_{c}:

$$H_{\mathrm{c}}=\Delta H_0+S_{\mathrm{c}} V_{\mathrm{c}}^2. \tag{8}$$

$$V_{\mathrm{c}}=\frac{Q_{\mathrm{e}}+W_{\mathrm{co}}}{\rho C_{\mathrm{p}}\left(t_{\mathrm{cout}}-t_{\mathrm{k}}\right)}. \tag{9}$$

$$W_{\mathrm{co}}=\frac{Q_{\mathrm{e}}}{COP}. \tag{10}$$

$$N_{\mathrm{c}}=\frac{\rho g V_{\mathrm{c}} H_{\mathrm{c}}}{\eta_{\mathrm{c}}}. \tag{11}$$

Where, H_{c}, N_{c}, η_{c} are lift, power and total efficient of cooling water pump respectively. S_{c} is impedance of cooling water pipeline. t_{cout} is outlet water temperature of condenser. W_{co} is energy consumption of heat pump unit.

For a given actual project, ΔH_0, Q_{e} and S_{c} can be approximately regarded as constant, and it will satisfy the engineering demand, meanwhile η_{c} is the function on V_{c}. Through above simplification it was found that N_{c} is only connected with V_{c}. The polynomial of N_{c} on V_{c} can be obtained by curve fitting toolbox of MATLAB. The polynomial can be shown by formula (12):

$$N_{\mathrm{c}}=\lambda_0+\lambda_1 V_{\mathrm{c}}+\lambda_2 V_{\mathrm{c}}^2+\lambda_3 V_{\mathrm{c}}^3. \tag{12}$$

Where λ_0-λ_3 represent fitted coefficients.

TDEC model. Through above three mathematical model TDEC of SWSHP system can be expressed by formula (13):

$$N_{\mathrm{t}}=W_{\mathrm{co}}+N_{\mathrm{e}}+N_{\mathrm{c}}. \tag{13}$$

Where N_t is the sum of heat pump unit, chilled water pump and cooling water pump energy consumption.

It is obvious that N_t is determined by six parameters: V_c, V_e, t_{ein}, t_0, t_k, t_{cout}, through analyzing formula (13), it is a multi-parameter function which includes some nonlinear and linear constraints such as mass conservation, energy conservation and flow limit of heat pump unit etc. And this optimization problem can be solved by MATLAB optimization toolbox.

Optimization function analysis. In the MATLAB optimization toolbox the fmincon function can solve such problems very well[6,7]. It contains four optimization algorithm: Trust region reflective, Active set, Interior point and SQP. It needs to create two M-file which stand for objective function and constraints respectively. The invoking format is shown as formula (14):

$$[x, fval, exitflag, output]=\text{fmincon}(@myfun, x0, A, b, Aeq, beq, lb, ub, @mycon). \quad (14)$$

Where, x represents variations, *fval* represents function value, *exitflag* represents the optimizing final state, *output* represents outputting the optimization message, *myfun* represents objective function expression, *x0* is a initial value so that the calculation can begin, A and b represent linear inequality, *Aeq* and *beq* represent linear equality, *lb* and *ub* represent the lower and upper bound, *mycon* represents nonlinear inequality.

Project case analysis. Here an actual project case was analyzed. This building which is used to office and dormitory is located in Qingdao China. In the northwest of the building there is an artificial lake whose dimensions are 80m long × 30m wide × 6m deep, annual mean water yield is roughly 8600 cubic meter, the maximum and minimum water temperature of the lakebed are 3℃and 28℃.

The total construction area of this project is 3750 square meter. Air conditioning cooling load is 300kW, the water-source heat pump unit is TECKA SRSW-90-1，the cooling water pump is KQB 80-125, and chilled water pump is KQB 80-160B.In the air conditioning water system variable flow primary pumps form is adopted, the terminal devices is fan coil. The design parameters of this SWSHP system are shown in Table.1.

Table.1 Design parameter

Parameter	Value	Parameter	Value
Q_e[kW]	300	Q_c[kW]	354.4
H_e[m]	22.17	H_c[m]	17.77
S_e[h^2/m^5]	0.0072	S_c[h^2/m^5]	0.0037
ΔH_{emin}[m]	3	ΔH_0[m]	4
t_0[℃]	7	t_k[℃]	27
t_{ein}[℃]	12	t_{cout}[℃]	32
V_e[m^3/h]	51.6	V_c[m^3/h]	61

According to formula (3) and correction coefficients Table.2 and Table.3 of heat pump unit sample, fitted values of α_i and β_i (i=1~6) were obtained as follow:the row vector of $\boldsymbol{\alpha}$=[-0.06178 -0.02769 0.1266 1.98909 5.455514], $\boldsymbol{\beta}$=[-5.9920 -0.02963 -0.00319 -0.6669 8.05699 5.511]. The variation tendency of COP_1 with t_0, t_k and COP_2 with V_c, V_e can be obtained which were shown in Fig.2 and Fig.3 respectively.

Table.2 Cooling performance correction coefficient table of variable temperature

Table.3 Cooling performance correction coefficient table of variable flow

V_e[m^3/h]	V_c[m^3/h]				
	31.04	43.45	55.87	68.28	80.70
28.96	0.9272	0.9839	1.0180	1.0417	1.0592
34.74	0.9693	1.0286	1.0642	1.0890	1.1073
40.25	1.0030	1.0643	1.1012	1.1268	1.1458
46.30	1.0303	1.0934	1.1312	1.1576	1.1770
52.09	1.0524	1.1168	1.1555	1.1824	1.2023

By observing Fig.2 and Fig.3 it was found that COP_1 will increase with increase of t_0, t_k, and COP_2 will increase with increase of V_c, V_e. It can be explain by that when flow rate increases, it can improve the fluid velocity, thus it will enhance heating transfer effect which is beneficial to improving *COP*.

According to the samples of chilled water pump and pipeline characteristic curve, the values ofγ_0-γ_3 can also be calculated, then put the results into formula (7):

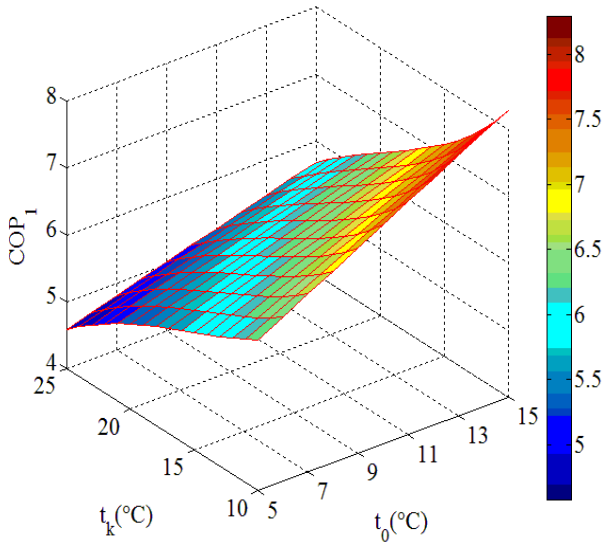

Fig.2 COP_1 with different t_0, t_k

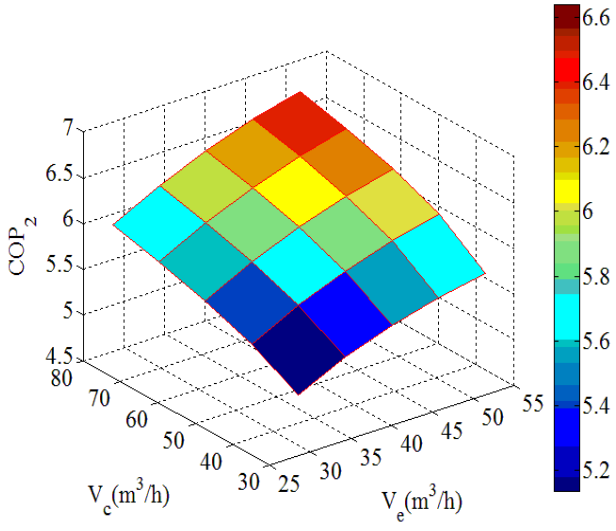

Fig.3 COP_2 with different V_e, V_c

$$N_e = 0.11 + 0.0066V_e + 0.00034V_e^2 + 2.6e-05V_e^3. \quad (15)$$

Similarly λ_0-λ_3 can be obtained by cooling water pump sample and pipe characteristic curve, then put the results into formula (12):

$$N_c = 0.11 + 0.012V_c + 0.00015V_c^2 + 1.4e-05V_c^3. \quad (16)$$

The variation tendency of N_e and N_c are shown in Fig.4.

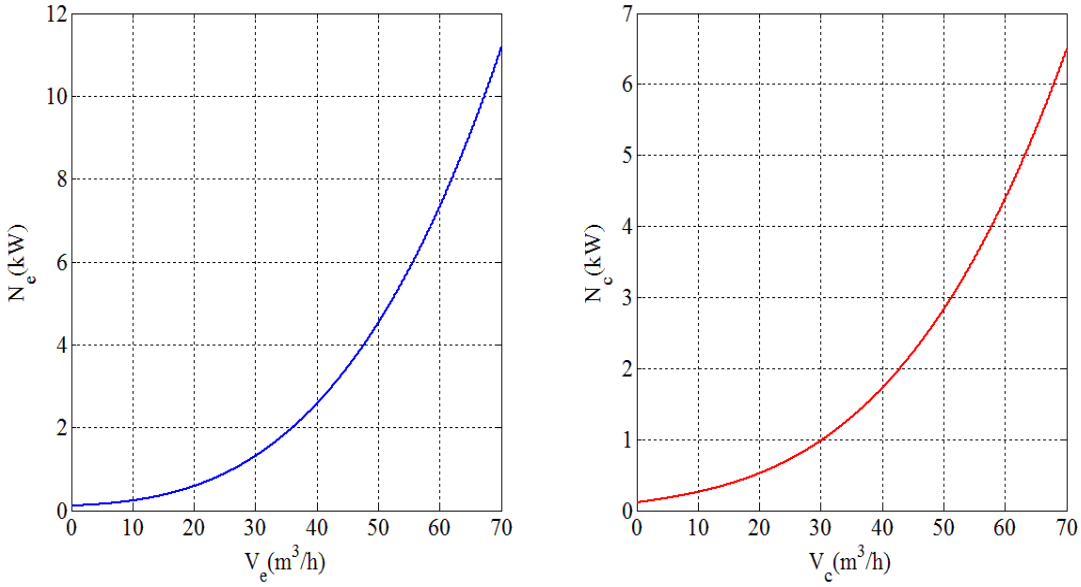

Fig.4 N_e and N_c with different V_e and V_c

It is obvious that both N_e and N_c reduce with the decrease of V_e and V_c respectively, it can illustrate that when variable flow condition was adopted there will save quite lots of energy consumption when terminal load of users begins to decrease.

Comprehensive optimization. According to above results, firstly it is necessary to create two M-file, then list various kinds of equality constraints and inequality constraints. The range of the six parameters V_c, V_e, t_{ein}, t_0, t_k, t_{cout} are shown in Table.4.

Table.4 Parameter range

Parameter	Range	Parameter	Range
V_c[m^3/h]	20-62	t_k[°C]	20-30
V_e[m^3/h]	15-52	t_{cout}[°C]	28-40
t_{ein}[°C]	8-15	t_{ein}- t_0[°C]	0-10
t_0[°C]	5-9	t_{cout}- t_k[°C]	0-11

COP, W_{co}, N_e, N_c under constant flow rate condition can be obtained by Table.1,and the energy consumption results are shown in Table.5.

Table.5 Energy consumption under constraint flow(CF)

R[%]	N_e[kW]	N_c[kW]	W_{co}[kW]	N_t[kW]
100	4.959	4.596	58.254	67.809
90	4.959	4.596	52.428	61.983
80	4.959	4.596	46.603	56.158
70	4.959	4.596	40.777	50.332
60	4.959	4.596	34.952	44.507
50	4.959	4.596	29.127	38.682
40	4.959	4.596	23.301	32.856
30	4.959	4.596	17.476	27.031

Taking into account of indoor temperature and humidity requirements t_0 and t_k should be regarded as constant whose values are 7°C and 27°C respectively, meanwhile the load rate R need to be 30% at least.

The optimization results are shown in Table.6.

Table.6 Energy consumption under variable flow(VF)

R[%]	N_e[kW]	N_c[kW]	W_{co}[kW]	COP	V_e[m^3/h]	V_c[m^3/h]	t_{ein}[ ]	t_{cout}[ ]	N_t[kW]
100	4.175	3.273	59.926	5.006	48.405	53.147	12.3	32.8	67.374

30	1.990	1.510	20.103	4.477	35.916	37.510	9.2	29.5	23.603

The differences between two operating conditions VF and CF are shown in Fig.5.

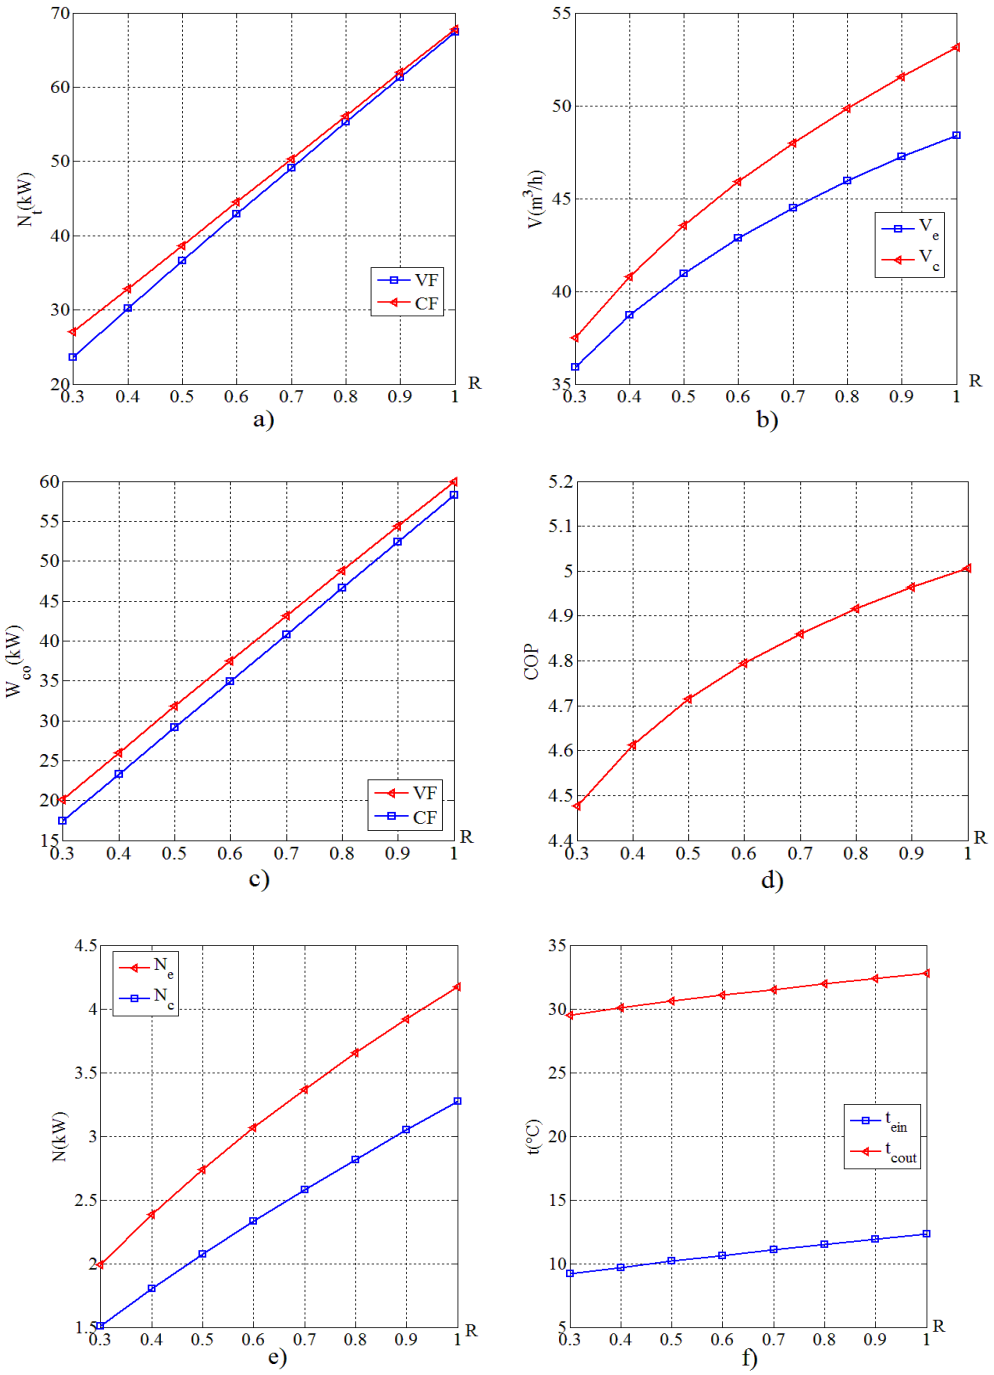

Fig.5. a)Comparison of N_t under constant flow and variable flow; b)The change of V_e and V_c with load rate R; c) Comparison of W_{co} under constant flow and variable flow; d)The change of COP with load rate R under variable flow; e)The change of N_e and N_c with load rate R; f)The change of t_{ein} and t_{cout} with load rate R.

Figure analysis. a)via optimization the total energy consumption of SWSHP system get a decrease compared with constant flow state, the maximun decrease percentage reaches 12.68%, it is proved that variable flow water system can save energy consumption; b)when load rate R reduces, V_e and V_c also go down which will lead a declination to heat exchange amount of evaporator and condenser so that the system can adapt the change of R; c), d)as load rate R reduces, it will lead a declination to COP, while W_{co} has a rising tendency, and it will consume more energy of heat pump unit compared with constant flow, it is because that when volume flow reduces, it will weaken heat-exchanging effect which will lead a declination to COP; e)as load rate R reduces, energy consumption of water pump will have a huge decrease, the smaller R is, the more energy will save, the reason is that both of N_e and N_c are proportion to V_e^3 and V_c^3 respectively; f)as load rate R reduces, both of t_{ein} and t_{cout} get reduced, this can be explained by that the temperature difference will reduce with the declination of water flow which is proportion to R.

Conclusions

In this paper, through the establishment of three mathematical model which are heat pump unit, chilled water pump and cooling water pump respectively, the curve fitting box was used to get fitted coefficients as well as an minimal TDEC through optimization tool box. Under the condition of that t_0 and t_k keep constant as 7℃ and 27℃ respectively, the results were shown as following:

(1)Under the variable flow operating state there exists an maximum energy conversation rate 12.68% of TDEC compared with the constant flow operating state, moreover with the decrease of R, it has more scope to save energy.

(2)With the reduction of R, under variable flow operating state the heat pump unit will consume more than average 8.41% energy, while COP will decline average 7.61% compared with constant flow.

(3)With the reduction of R both of the V_e and V_c will decrease so that there will have a energy saving of N_e and N_c.When R ranges from 30% to 100%, the mean energy conversation rate of N_e and N_c are 49.38% and 38.86%.

(4)With the reduction of R, both of t_{ein} and t_{cout} decrease due to the declination of temperature difference. When R ranges from 30% to 100%, the average declination rate of t_{ein} and t_{cout} are 17.09% and 5.73%.

Key words: filtration medium; pressure drop; numerical simulation; air filter; pleated structure

Abstract: In order to reduce pressure drop of filtration process and increase filtration area, filtration media would usually made into pleated shape. The designs of pleats numbers and pleats height in the unit length have greatly impacted on pressure drop of the filtration process. In this paper, filter pressure drop of pleated air filters were examined by theoretical, experimental and simulation studies. By solving pressure drop from the Navier-Stokes equation on basis of velocity function assumption, by using the concept of average pressure drop in wind gap width, pressure drop in pleated filters was calculated. The numerical simulation of pleated filtration media was developed via using FLUENT software package and flow field variation in gap of pleated media was simulated. The results of theoretical calculations were in agreement with experimental results. It was confirmed that reducing pleat spacing or increasing pleats height could increased the area of filtration media and reduce the overall pressure drop of filters, although structure pressure drop increased. There were best value between pressure drop of pleated air filters and pleat numbers in the unite length.

INTRODUCTION

Air quality has become the attention Hotpoint due to the worsening environmental pollution and people's awareness of environmental protection. Air filtration devices were widely used in various industrial and residential rooms [1]. In order to improve the performance of air filtration, most of the filter materials were made into pleated structures [2], this kind of structure such as pleated shapes was shown in Fig.1. It could increase the filtration area and the amount of dust accumulation via reducing filtration velocity of media. It may reduce the cost of operation [1].However, the air entering into or leaving out from the pleated and tilted filtration media, the gas flow direction varied rapidly, which will spin off the flow and flow, causing an additional loss of energy [2]. In this paper, the pressure drop of filter structure and tilted media were calculated via solving Navies-Stokes equations and air flow variation in the pleated filtration media was simulated by computer.

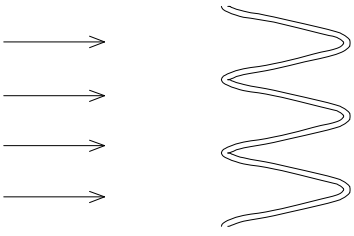

Fig. 1. Schematic of pleated air filter

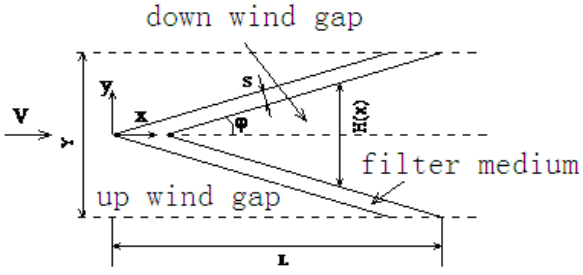

Fig.2. Schematic of pleat parameters

THE PRESSURE DROP OF PLEATED AIR FILTER

The pressure drop of pleated air filter was made up of two parts: that, is, structure pressure drop and media pressure drop. The structure pressure drop and media pressure drop were calculated as follows.

A. The pressure drop of pleated structure

The basic geometry and some of the parameters of pleated air filter was defined in Fig.2, Where, V is face flow velocity; Y is distance between two pleats, m ; L is pleats height, m ; s is filtration medium thickness, m ; j is pleats angle (angle between the center line and pleats); H (x) is distance between x and pleat. For the interest of simplicity, it is assumed for the pleated air filters that:

(1) Compressing of air was neglected, air density ρ is constant;

(2) The air dynamic viscosity μ is constant;

(3) No external force existed in x component direction (the direction of the pleat center line), according to the conservation of momentum equation:

$$V_x \frac{\partial V_x}{\partial x} + V_y \frac{\partial V_x}{\partial y} = -\frac{1}{\rho}\frac{\partial p}{\partial x} + \nu\left(\frac{\partial^2 V_x}{\partial^2 x^2} + \frac{\partial^2 V_x}{\partial^2 y^2}\right) \tag{1}$$

The pressure drop was obtained by solving equation (1) as follow:

$$\begin{aligned}\Delta p'_g = {} & \frac{\mu}{\rho V}\frac{\cos^2\varphi \sin\varphi}{s}\left[1-\left(\frac{s}{L\sin\varphi}\right)^3\right] + \frac{3\mu}{\rho V}\frac{\cos^2\varphi}{tg^2\varphi}\frac{\sin\varphi}{s}\left[1-\left(\frac{s}{L\sin\varphi}\right)\right] \\ & + \frac{1}{2}\cos^2\varphi\left(1+\frac{1}{2}\cos^2\varphi\right)\left[1-\left(\frac{s}{L\sin\varphi}\right)^2\right] - \frac{9}{40}\cos^4\varphi\left[1-\left(\frac{s}{L\sin\varphi}\right)^4\right] \\ & + \frac{1}{4}\cos^4\varphi\left[1-\left(\frac{s}{L\sin\varphi}\right)^3\right]\end{aligned} \tag{2}$$

$$\Delta p_g = \left|\ \Delta p'_g\ \right| \cdot \rho V^2 \tag{3}$$

B. Pressure drop caused by fluid across pleated medium

For Analysis calculation of the pressure drop of tilt filtration media, a microelement in tilt filtration medium was shown in Fig. 3 [2].

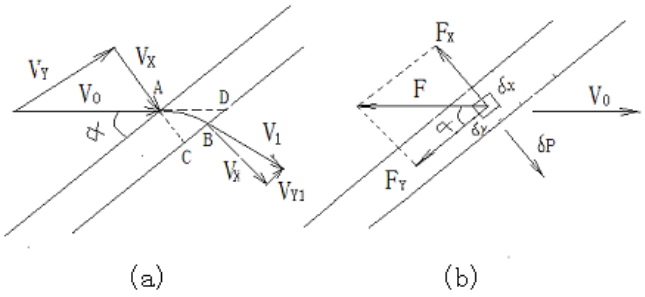

Fig. 3 Fluid flow and forced analysis of tilt filtration media

As the filtering occurs in low velocity flow, Darcy law was generally applicable, and pressure drop flowed across the tilt filtration medium could be expressed as [1]:

$$\begin{aligned}\Delta p_m &= \frac{\mu\cdot s}{K}V\sin\varphi\left[1+\left(\frac{1}{\sin^2\varphi}-1\right)\Big/\left(\frac{2\mu s}{K\rho V\sin\varphi}\right)\right] \\ &= \frac{\mu\cdot s}{K}V\sin\varphi\left(1+\frac{\cos^2\varphi K\rho V}{\sin\varphi 2\mu s}\right) \\ &= \frac{\mu\cdot s}{K}V\sin\varphi+\frac{\cos^2\varphi}{2}\rho V^2\end{aligned} \tag{4}$$

C. Overall pressure drop of pleated aerosol filters

The pressure drop of pleated air filters could be expressed as:

$$\Delta p = \Delta p_g + \Delta p_m = \left| \Delta p'_g \right| \cdot \rho V^2 + \Delta p_m \quad (5) \qquad \Delta p = f_1(\varphi, V, L, \mu, \rho, K, s) \quad (6)$$

Since $Y = \dfrac{1 - 2 \cdot s \cdot N}{N}$

The pleat angle in equation (6) could be expressed as ：

$$\varphi = arctg\left(\frac{Y}{2L}\right) = arctg\left(\frac{1 - 2 \cdot s \cdot N}{2LN}\right)$$

Therefore: $$\Delta p = f_2(N, V, L, \mu, \rho, K, s) \quad (7)$$

Where, K is permeability of filtration medium, m^2; α is tilt angle of filtration medium, V_0 is face flow velocity, m/s

PRESSURE DROP SIMULATION IN PLEATED FILTRATION MEDIUM

Fluid field flow was simulation calculated by CFD software package in this paper. In order to save computer resources, from the 80 pleats to select the four parts of them to conduct simulation. The filtration medium used triangle mesh to expressing porous region. The test parts used non-uniform rectangular grid. The total numbers of mesh were 2391.The results of the simulation do not changed with grid numbers increasing, that is, "grid independence." Selection of the calculation domain was considered as follows:

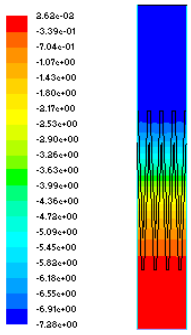
Inlet position (the position of experimental test points) was set in the distance which was less than 15 mm far to lower edge of filtration media, outlet position was set in the distance which was more than 67mm far to upper edge of filtration media. Boundary condition was velocity inlet, porous domain and freedom flow.

In order to minimize calculation errors, the impact of air leakage test was carried out and the velocity value was measured by the test and it was set up as entrance velocity of simulation calculation. Comparison of simulation results and experimental results was shown in table 1.The results of the simulation were different from the results of literature [3], but the simulation results were relatively close to results of experimental tests, it indicating that the simulation method of this paper was acceptable. It was found that the standard $k-\varepsilon$ turbulence model was a greater difference with results of the experimental test. The result of RNG $k-\varepsilon$ turbulence model was in agreement with result of RSM turbulence model and all of them were agreement with results of experimental test. However, RSM turbulence model was fitted better than RNG $k-\varepsilon$ turbulence model. This conclusion was in agreement with the literature [3].

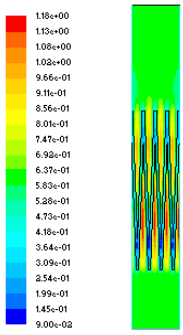
Table 1 Comparison of experimental test and simulation on pressure drop of pleated filtration media

Entrance velocity，m/s	Experimental pressure drop，Pa	Simulation pressure drop，Pa	Relative error
0.6	12.0	7.2	40%
1.1	24.8	16.9	32%
2.1	50.9	44.2	13%
2.8	68.3	69.0	-1%
3.1	73.9	81.5	-10.3%

From Table 2, it could be seen that pressure drop relative error of simulation and experimental induced firstly and then increased, there were air leakages in experimental test and smaller of entrance velocity causing measure error of hot-wire anemometer, which could lead to bigger error of experimental results and simulation result. When the entrance velocity increasing, the calculation error between experimental results and simulation results become larger, this may be due to amount of air leakage increasing.



(a) The static pressure at $V = 0.6 m/s$



(b) The velocity at $V = 0.6 m/s$

Fig. 4 Simulation result of static pressure and filtration velocity and pressure drop on 80 pleated filter

The static pressure chart was similar with velocity chart at different face flow velocity (Fig.4). The static pressure chart (a) shows that pressure drop was gradual changing like wave layers, and velocity chart (b) shows that fluid gradually expands when it's flowed cross the pleated medium. The filtration velocity increases firstly and then decreased to smaller value..

The three impact factors such as medium thickness, porosity and the average particle diameter, affected on medium pressure drop were studied through the orthogonal experimental tests. It could be seen that the bigger the porosity and particles diameters were, the smaller the medium thickness were and larger pressure drop were.

COMPARISON OF CALCULATION RESULTS AND EXPERIMENTAL RESULTS

Filtration Media parameters was described as follows:

$K = 11.89 \times 10^{-12} m^2$, $s = 0.406 \times 10^{-3} m$;Air parameters: $\mu = 18.40 \times 10^{-6} Pa \cdot s$, $\rho = 1.185 kg/m^3$

Structural parameters: $L = 40 \times 10^{-3} m$

The pleated numbers N were 333 pleat/m, 250 pleat/m, 200 pleat/m, which were remarked by F-1, F-2, F-3, respectively. The face flow velocity varied from 0.45m/s to 2.25m/s and the face flow velocity of the air filter rated flow was 1.50m/s in this experimental test.

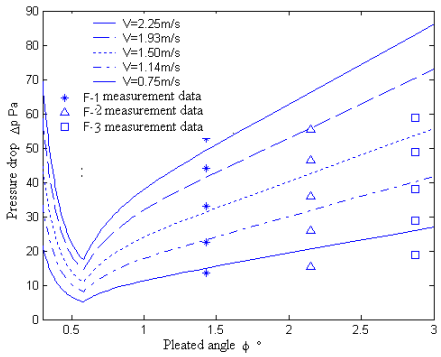


Fig.5. Comparison of pressure drop calculation results with experimental results

As shown in Figure 5: there was difference between theoretical results and experimental results, possible reason may be due to:
1. The fluid flowed into and leaved out from the filtration medium vertically was assumed, which made the path of flow into short, whereas the filtration velocity was calculated as average value.
2. The velocity was expressed by a special-second order polynomial.
3. Heterogeneity of the media and instability of media could cause measure error.

CONCLUSIONS

The pressure drop of pleated filtration medium was studied by experimental test and simulation in this paper. The factors such as filtration velocity, pleat numbers and pleat height impacting on pressure drop were discussed and main conclusions were described as follows:

1. The pressure drop of pleated air filters was obtained via solving the Navier-Stokes equation with concept of average velocity of gap width.
2. Calculation results were in agreement with results of experimental test.
3. The simulation results of RSM turbulence model were in agreement with results of experimental test.
4. There were best pleat numbers in unite length, minimum filtration pressure drop could be obtained according to this pleat numbers.

Keywords: hydro turbine model long term stability power system simulation hydraulic coupling; structure coefficient

Abstract. Based on the theoretical derivation of hydraulic coupling relationship between the hydropower units sharing long common tunnel，the non-linear hydro turbine model with sharing long diversion tunnel system is established and order-reduced in accordance with the demand of power system simulation. And according to the complex structure characteristics of surge tank，a method of correcting surge tank storage constant with surge tank structure coefficient is proposed. This hydro turbine model can reflect the influence of surge tank and sharing common tunnel in the power system long term process，the accuracy of model is proved by comparison of simulation results and actual recording data in power system.

Introduction

Special geographic conditions make some hydropower stations connecting to upstream reservoir with long tunnel, and sharing bifurcation pressure steel pipe at the end of tunnel. The hydro turbine's mechanical power is determined by water head and flow, so there's association between the mechanical power and regulating characteristics of hydroelectric units sharing common conduit. That will affect AGC control precision, safety control effect and some other long term stability process in power system.

Accurate analysis of hydro turbine's dynamic response and its influence on power system, must rely on the model accuracy of dynamic elements and control & protection equipment[1]. In some practical applications, it is important to model the hydraulic coupling process in the long common tunnel and surge tank. But it is still a lack of accurate calculation model for hydro turbine with sharing long common tunnel in power system stability analysis. The ideal turbine model and non-elastic water column turbine model in widely used power system transient simulation program are only suitable for hydro turbine with single tunnel[2]. Although IEEE working group, power system full dynamic simulation program and other literatures [3-6] provided some hydro turbine models with sharing common tunnel, but these models can't take account of surge tank effects, which may be critical in some long term stability process in power system.

Based on theoretical derivation, this paper puts forward a new nonlinear model for hydro turbines with sharing long common tunnel, which can accurately reflect the influence of surge tank and sharing common tunnel in the power system long term process.

Non-linear model of multiple penstocks and turbines supplied from common tunnel--Non-Elastic water column including surge tank effects

For any section of diversion pipe, considering the flexibility of pipe, the hydraulics equation[7] is

$$\begin{aligned} H_b &= H_a \sec h(T_e s) - Z_0 Q_b \tanh(T_e s) \\ Q_a &= Q_b \cos h(T_e s) + \frac{1}{Z_0} H_b \sinh(T_e s) \end{aligned} \tag{1}$$

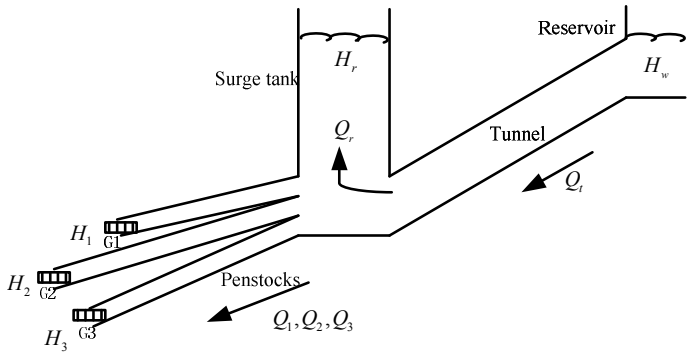

Fig.1 Hydraulic system sharing long common tunnel

Here, H_a, H_b are water head of the pipe; Q_a, Q_b are rate of flow, T_e is elastic time constant of pipe. So H_r in Fig.1 can be described in per unit as:

$$h_r = h_w \sec h(T_{eT}s) - Z_T q_T \tanh(T_{eT}s) \tag{2}$$

The water deviation of tunnel upstream side is zero, so h_w=1, then

$$h_r = 1 - Z_T q_T \tanh(T_{eT}s) \tag{3}$$

With n=0, tanh(T_s) can be expressed as:

$$\tanh(Ts) = \frac{1-e^{-2Ts}}{1+e^{-2Ts}} = \frac{sT\prod_{n=1}^{n=\infty}\left[1+(\frac{sT}{n\pi})^2\right]}{\prod_{n=1}^{n=\infty}\left[1+(\frac{2sT}{(2n-1)\pi})^2\right]} \approx Ts \tag{4}$$

That means ignoring elasticity of water column, so Eq.2 can be expressed as:

$$H_r = H_w - Z_T Q_T T_{eT} s \tag{5}$$

Considering the relationship between water head and flow in surge tank, as well as the flow relationship between tunnel, surge tank and penstocks, then

$$H_r = \frac{H_w - Z_T(Q_1+Q_2+Q_3)T_{eT}s}{1+Z_T T_s T_{eT} s^2} \tag{6}$$

The water head deviation of tunnel upstream side is zero, so

$$H_w - H_r = \frac{Z_T(Q_1+Q_2+Q_3)T_{eT}s}{1+Z_T T_s T_{eT} s^2} \tag{7}$$

For any penstock,

$$H_r - H_i = \frac{L_i}{S_i g}\frac{dQ_i}{dt} \qquad (i=1,2,3) \tag{8}$$

Here, Q_{i0}(i=1,2,3) is rate flow of penstocks, defining q_i(i=1,2,3) as per unit value for Q_i(i=1,2,3)

$$q_i = \frac{Q_i}{Q_{i0}} (i=1,2,3) \tag{9}$$

Then, from Eq.7, Eq.8 and Eq.9, we can see that

$$H_w - H_i = \frac{Z_T T_{eT} s}{1+Z_T T_s T_{eT} s^2}(Q_{10}q_1 + Q_{20}q_2 + Q_{30}q_3) + \frac{L_i}{S_i g} s(Q_{i0}q_i) \qquad (i=1,2,3) \tag{10}$$

Defining H_B as rate water head, and H_B=H_W, Eq. 10 divided by H_B, then

$$\begin{bmatrix} 1-h_1 \\ 1-h_2 \\ 1-h_3 \end{bmatrix} = \begin{bmatrix} \dfrac{T_{wT1}}{1+T_{wT1}C_{s1}s^2}+T_{wp1} & \dfrac{T_{wT2}}{1+T_{wT2}C_{s2}s^2} & \dfrac{T_{wT3}}{1+T_{wT3}C_{s3}s^2} \\ \dfrac{T_{wT1}}{1+T_{wT1}C_{s1}s^2} & \dfrac{T_{wT2}}{1+T_{wT2}C_{s2}s^2}+T_{wp2} & \dfrac{T_{wT3}}{1+T_{wT3}C_{s3}s^2} \\ \dfrac{T_{wT1}}{1+T_{wT1}C_{s1}s^2} & \dfrac{T_{wT2}}{1+T_{wT2}C_{s2}s^2} & \dfrac{T_{wT3}}{1+T_{wT3}C_{s3}s^2}+T_{wp3} \end{bmatrix} \begin{bmatrix} sq_1 \\ sq_2 \\ sq_3 \end{bmatrix} \tag{11}$$

Where T_{wti}, T_{wpi}, C_{si} represent the time constant of tunnel, penstock and surge tank.

$$\begin{aligned} T_{wTi} &= Z_T T_{eT} \frac{Q_{i0}}{H_B} \\ C_{si} &= T_s \frac{H_B}{Q_{i0}} \qquad (i=1,2,3) \\ T_{wpi} &= \frac{L_i Q_{i0}}{S_i g H_B} \end{aligned} \tag{12}$$

So, nonlinear hydro turbine model with sharing long common conduit can be described as

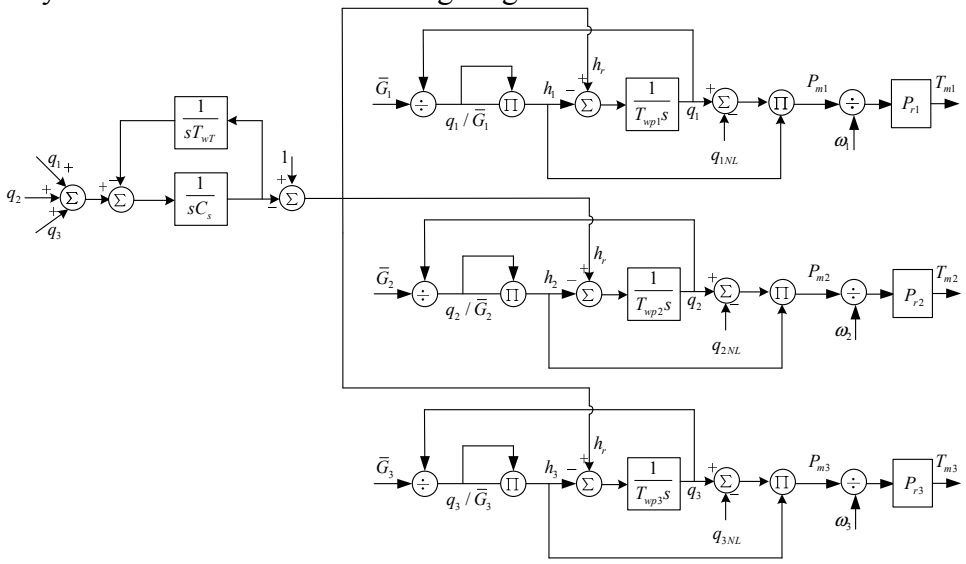

Fig.2 Nonlinear hydro turbine model with sharing long common conduit

Model of surge tank with complex structure

Some surge tank may consist of vertical shaft and upper chamber, where diameter of connecting pipe and shaft may be different, as shown in fig.3. Because the impedance orifice consumes some energy in hydraulic dynamic process, that can reduce water fluctuations amplitude in surge tank. But at the same time, the impedance may make tunnel under the influence of water hammer pressure.

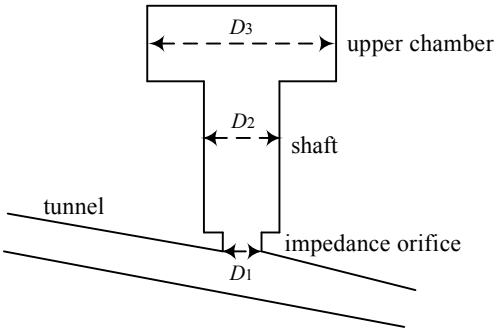

Fig.3 Impedance type surge tank model

Special structure makes it is difficult to calculate the impedance coefficient of surge tank, which is changing with flow and water level in the transition process. In hydraulic transient calculation, the surge tank impedance coefficient can be calculated by Gardel formula, model test or CFD[8-10]. For power system time domain simulation, using explicit formulation not only too complicated but also can't accurately represent some surge tank with special structures. Surge tank structure coefficient k is proposed in this paper, which can modify storage constant of surge tank according to the change of water head. The structure coefficient can simulate the pressure changing in tunnel which is caused by impedance orifice.

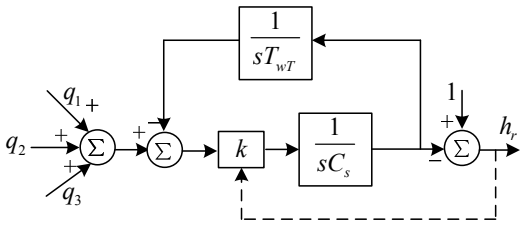

Fig.4 Tunnel and surge tank model with structure coefficient

The simulation model of tunnel and surge tank with structure coefficient is shown in fig.4. Where, C_s is the storage constant of shaft, accurate values of k can be gain by load rejection test or fluid mechanics calculation. Simplicity, we can use a piecewise function to approximate k:

$$k \approx \begin{cases} K_1 & (h \le h_1) \\ K_2 & (h_1 < h \le h_2) \\ K_3 & (h_2 < h) \end{cases} \tag{13}$$

Here, h_1 and h_2 respectively represent the water head at different cross-sectional area of surge tank.

Comparison of simulation results and recording data

Example 1: A hydraulic station with three units sharing long common tunnel, the rated head is 92m, rated flow of single unit is 62m^3/s, length of common tunnel is 22.975km, cross –section of tunnel is 45.3m^2, cylinder type surge tank diameter is 22m, pressure steel pipe inner diameter 5.8 m, total length is 391.3 m. The test operation condition is: Unit 3 was shutdown, governors of Unit 1 and 2 worked in opening regulation mode, primary frequency regulation was put into operation, Unit 1 AGC shutdown and Unit 2 AGC was put into closed-loop operation.

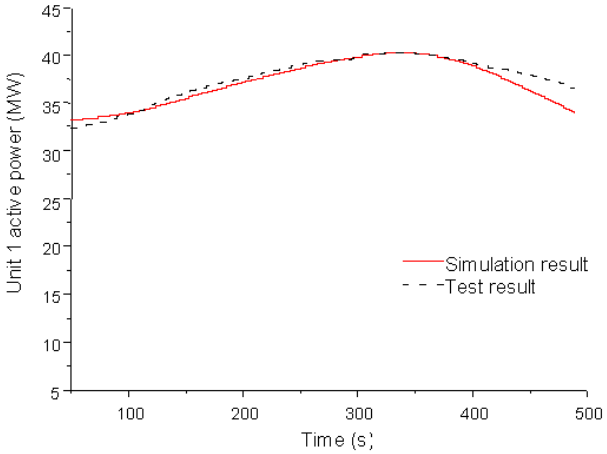

Fig.5 Active power curve of Unit 1

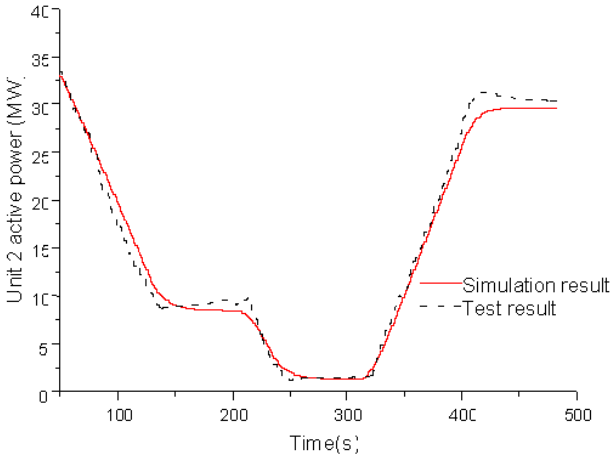

Fig.6 Active power curve of Unit 2

Because Unit 1 and Unit 2 sharing common tunnel, Unit 2 power reduction resulted in water pressure rising, then active power of Unit 1 increased almost 20% in opening regulation mode. Due to

AGC of this plant issued only one AGC command in active power regulation process, the active power closed-loop logic in monitoring and control system exit once actual power equals to command. So, the hydraulic correlation between turbines will affect AGC control precision.

Because primary frequency regulation didn't participate in active power adjustment, so the power curve in figure 5 can reflect dynamic characteristics of water diversion system and turbines. As shown in figure 5 and 6, simulation results are in good agreement with the measured curve.

Example 2: Another hydraulic station with two units sharing long common tunnel, the rated head is 288m, rated flow of single unit is 232.5m^3/s, length of common tunnel is 16.67km, cross –section of tunnel is 100.1m^2, vertical shaft diameter of its impedance type surge tank is 21m, pressure steel pipe inner diameter 6.5 m, total length is 584 m. This plant is a main power station of Jin-Su UHVDC, which special structure of tunnel and surge tank may have great influence on power system dynamic process.

The active power curve of Unit 1 after Unit 2 shutdown under the DC bipolar fault is shown in figure 7. Due to valve of Unit 2 was quickly closed, the hydraulic pressure of Unit 1 increase observably, that make active power increased almost 21%. Because of the status in system, the dynamic response characteristics of Unit 1 increased AC section power in the AC-DC hybrid power system after the accident. If Jin-Su UHVDC takes island operation mode, the dynamic process of the water diversion system may also have great influence on frequency stability in the island system.

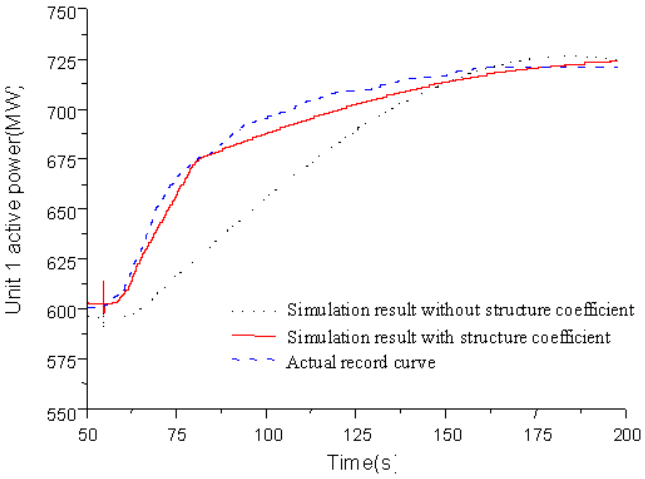

Fig.7 Active power curve of Unit 1

Tunnel and surge tank model considering structure coefficient which approximatively described by piecewise function was used in the simulation, and the simulation results and record curve are shown in figure 7. We can see that the simulation model has high precision. For the impedance type surge tank, if impedance coefficient of surge tank is ignored, although the active power fluctuation peak value is consistent, but the dynamic process will be different from the actual situation, as shown in figure 7.

Conclusions

(1) A nonlinear hydro turbine model for medium and long term power system stability analysis with sharing long common conduit was setup.

(2) For the difficult to determine impedance coefficient of surge tank with complex structure, the surge tank structure coefficient was put forward to dynamic correcting surge tank storage time constant. This method can improve accuracy of simulation model obviously.

(3) Contrast analysis with measured disturbance data shows that this model can correctly reflect the medium and long term process dynamic response of the hydro units sharing long common conduit.

(4) This model can be applied to prophase planning research and long term stability analysis in power system easily. And the water hammer constant testing in prime mover modeling test can improve the accuracy of this model further.

Keywords: DFIG; transient characteristics; voltage dip; power angle.

Abstract: Doubly-fed induction generator (DFIG) wind turbine has become a mainstream machine of wind generators in China. As the different operational characteristics between the DFIG and synchronous generator (SG), the large amount of DFIG-based wind generators installed in the grid may bring a series of impacts on the dynamic behaviors of power system. In order to study the DFIG transient characteristics on the condition of the voltage dips happening in the power system, a definition of the DFIG power angle is given and the effects of the converters on the DFIG power angle are discussed. On this basis, the transient angle characteristic of the DFIG is derived. The DFIG transient characteristics are performed by Matlab/Simulink software, the simulation results demonstrate that the DFIG has the resemble power angle characteristic of SG and prove the effectiveness of the derivation process, which lay a foundation for the study on the interactions between the DFIG and power system.

Introduction

In recent years, the variable-speed and constant frequency (VSCF) wind turbine has replaced the constant-speed one to be the most popular generator in the area of wind generation. As an important type of the VSCF, the doubly-fed induction generator (DFIG) has advantages of a smaller capacity voltage-source converter, lower cost and flexible power control, which has occupied a large proportion of the installed wind generation capacity.

Different from the SG, the DFIG utilized a wound rotor induction generator and realized independently control of the active and reactive power through vector excitation control strategy. It demonstrates different operational characteristics from the SG during the faults. With the increasing capacity of the DFIG-based wind generation in the grid, the power system dynamic characteristics which are mainly decided by the SG will get a change and undertake a challenge on the stability. And therefore, it is very necessary to study the transient characteristic of the DFIG.

Currently, most of the literatures on the DFIG transient characteristics are concentrated in the DFIG stator and rotor current transients [1-8] and its own electromagnetic transients[9-11] during the grid faults, however, the dynamic process of the DFIG external characteristics and the interactions between the DFIG and power system are merely studied. In reference [12] and [13], the author proposed a definition of the DFIG power angle and suggested that the wide variation of the DFIG angle cause the deep dip of the terminal voltage. However, the definition of the DFIG power angle is simply the direct transplant of the synchronous generator's concept of the power angle, which didn't consider the DFIG transients during the fault and the effects of the DFIG vector orientation control strategy. Hughes, F.M and Anaya-Lara, O[14] addressed the design and implementation of a novel control scheme for a DFIG which provided a DFIG-based wind farm with the similar characteristics with the conventional generator. The authors focused on the improvement of the DFIG control strategy but ignored the effects of the DFIG transients on the power system dynamic behaviors.

The paper gives a definition of the DFIG power angle through the theoretical derivation, explores the influence mechanism of the DFIG control system on the power angle and analyzes the angle's

dynamic process. The paper lays a foundation for the future study on the transient stability of the power system with large amount of the DFIG integrated.

The models of the DFIG

The DFIG utilizes a wound rotor induction generator with the rotor windings connected with grid through a back-to-back voltage-source converter. The converters and its control system can regulate the rotor currents to satisfy the DFIG with a large-scale operation. The positive reference directions of the stator and rotor windings are both in the light of motor convention. The models of the DFIG under the synchronous rotating coordinate system are as follows:

The voltage equations:

$$\begin{cases} u_{ds}=R_s i_{ds}-\omega_s \psi_{qs}+\dfrac{d\psi_{ds}}{dt} \\ u_{qs}=R_s i_{qs}+\omega_s \psi_{ds}+\dfrac{d\psi_{qs}}{dt} \\ u_{dr}=R_r i_{dr}-s\omega_s \psi_{qr}+\dfrac{d\psi_{dr}}{dt} \\ u_{qr}=R_r i_{qr}+s\omega_s \psi_{dr}+\dfrac{d\psi_{qr}}{dt} \end{cases} \quad (1)$$

The flux equations:

$$\begin{cases} \psi_{ds}=L_s i_{ds}+L_m i_{dr} \\ \psi_{qs}=L_s i_{qs}+L_m i_{qr} \\ \psi_{dr}=L_m i_{ds}+L_r i_{dr} \\ \psi_{qr}=L_m i_{qr}+L_r i_{qr} \end{cases} \quad (2)$$

Where the symbols u_{ds} and u_{qs} are stator voltages, u_{dr} and u_{qr} are stator voltages, i_{ds} and i_{qs} are stator currents, i_{dr} and i_{qr} are rotor currents; ψ_{ds} and ψ_{qs} are stator fluxes; ψ_{dr} and ψ_{qr} are rotor fluxes; R_s is stator resistance; R_r is rotor resistance; ω_s is synchronous rotating angular speed; s is rotor slip; L_s is stator inductance; L_r is rotor inductance; L_m is mutual inductance between the stator and rotor; the subscripts d, q, s and r respond direct-axis component, quadrature-axis component , stator and rotor components respectively.

The definition of the DFIG power angle

SG is the main generation form in the system and its characteristics have a tremendous impact on the gird. As a new generaion form, the DFIG demonstrates different characteristics. Making an deeply investigation of the DFIG operatioal theory is of huge sense.

The steady-state characteristics of the DFIG. When the DFIG operates at steady state, the stator fluxes maintain constant and the components of $d\psi_{ds}/dt$ and $d\psi_{qs}/dt$ are both zero. According to the equation (1), it can be derived the equation (3).

$$\begin{cases} \psi_{qs}=-\dfrac{u_{ds}-R_s i_{ds}}{\omega_s} \\ \psi_{ds}=\dfrac{u_{qs}-R_s i_{qs}}{\omega_s} \end{cases} \quad (3) \qquad \dot{\psi}_s = \frac{\dot{U}_s - R_s \dot{I}_s}{j\omega_s} \quad (4)$$

Choose the direct-axis as the real axis and quadrature axis as imaginary axis, the equation (3) can be transformed as the equation (4), where the symbols $\dot{\psi}_s$, $\dot{U}_s$ and $\dot{I}_s$ are flux , voltage and current of stator vectors respectively. Similarly, according to the fluxes equation (2), it can be derived the equation (5) and make the equation (5) substituted into the equation (4) we can get the equation (6).

$$\dot{\psi}_s = L_s \dot{I}_s + \frac{L_m}{L_r}(\dot{\psi}_r - L_m \dot{I}_s) \quad (5) \qquad \dot{U}_s = \left[R_s + j\omega_s \left(L_s - \frac{L_m^2}{L_r} \right) \right] \dot{I}_s + j\omega_s \frac{L_m}{L_r} \dot{\psi}_r \quad (6)$$

Then, make the replacement $x' = \omega_s (L_s - \dfrac{L_m^2}{L_r})$ and $E' = \omega_s \dfrac{L_m}{L_r} \psi_r$, where the symbol E' is the DFIG internal voltage and x' is its equivalent internal inductance. We can get the equation (7) and equaivalent circuit in the figure 1.

$$\dot{U}_s = (r_s + jx')\dot{I}_s + \dot{E}' \tag{7}$$

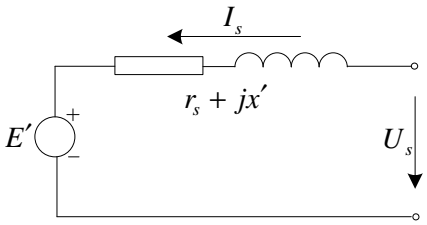

Fig. 1 DFIG steady-state equivalent circuit

The DFIG power angle. The SG is excited by a DC excitation system, which can produce a magnetic field that is stationary relatively to the rotor. When the rotor rotates at a synchronous speed under the dragging of the prime mover, a synchronous rotating magnetic field can be formed in the air gap of the generator and a constant 50 Hz AC voltage. As there is no relative motion between the rotor and the excitation magnetic field of the SG, the spatial position of the excitation field is the same as that of the direct axis of rotor. The vector diagram of the SG is shown in the figure 2, where the symbol δ_g is the relative angle between the internal voltage *E'* and the machine's terminal voltage U_s, φ is the power factor angle and ψ is the inner power factor angle.

However, the excitation currents through the DFIG rotor windings are a group of symmetrical three phase currents. According to the theory of AC motor, the equivalent excitation field rotates at a certain speed relative to the rotor with the speed determined by the frequency of the rotor currents. Similarly, under the adjustment fo the DFIG control system, a similar synchronous rotating field will appear in the air gap, whcih can induce a constant stator voltage with a frequency of 50Hz.

From the above literature we can conclude that the DFIG and SG are both have a synchronously rotating magnetic field in the air gap. So the DFIG can also be called an synchronous motor with an AC excitation.

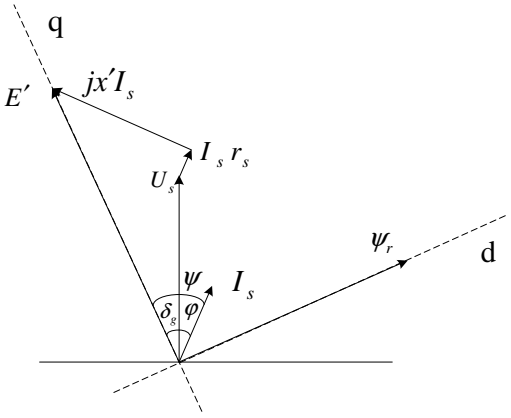

Fig. 2 The vector diagram of the SG

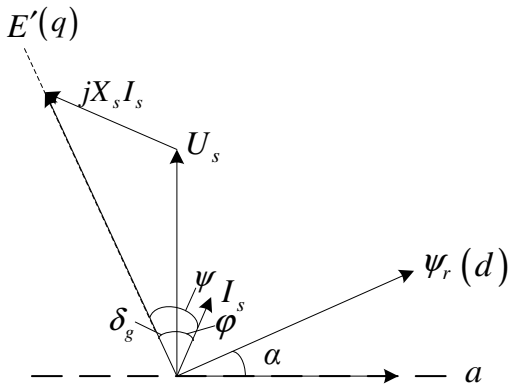

Fig. 3 The DFIG vector diagram

According to the AC motor theory, the magnitude and phase of the internal voltage E' is depended on the rotor flux ψ_r. With the consideration that the induced voltage is lead forward 90 space angle of the rotor flux, the real location of the SG internal voltage is the same with that of rotor's quadrant axis. However, for the DFIG, the real location of the rotor flux is not static relatively to the rotor. If making the location of the rotor flux as the imagined rotor direct axis, the DFIG vector diagram can be acquired in the figure 3. the angle α represents the relative angle between the space location of the rotor windings and the rotor flux vector. Ignore the effect of stator resistance on the DFIG power. The DFIG electric power can be expressed in the equation (8).

$$P_{em} = U_s I_s \cos\varphi = U_s I_s \cos(\psi - \delta_g) = U_s \cos\delta_g I_q + U_s \sin\delta_g I_d \tag{8}$$

Take the consideration of the equation (9), the equation (8) can be simplified to the equation (10).

$$\begin{cases} I_q = \dfrac{U_s \sin\delta_g}{x'} \\ I_d = \dfrac{E' - U_s \cos\delta_g}{x'} \end{cases} \quad (9) \qquad P_{em} = \frac{E'U_s}{x'} \sin\delta_g \quad (10)$$

Concluded from the equation (10) that the DFIG has the analogous power angle characteristics to the SG and its equivalent power angle is angle δ_g in the figure 3.

The effect of the converters on the DFIG power output

The DFIG has a back-to-back voltage-source converter (VSC), the rotor-side converter and the grid-side converter; the converters are important components in the doubly-fed wind generation system. With the controls of the DFIG converters, the DFIG realized the stable power output under the different wind velocity and the fast power exchange between the rotor windings and the power grid. The power flowing through the rotor windings can be illustrated in the equation (11).

$$\begin{cases} P_g = sP_s \\ Q_g = sQ_s \end{cases} \quad (11)$$

It can be conclude that the total exchange active power between the DFIG and the grid can be evaluated by the DFIG stator active power P_g.

Transient characteristics of the DFIG power angle

When the DFIG suffers a voltage dip by the faults happening in the power system, there will be a series of dynamic processes in the DFIG. The stator and rotor fluxes will both vibrant at a certain degree, which can affect the power angle of the DFIG. In order to make a detail analysis of the change rule of the DFIG power angle, it is very necessary to take the consideration of the flux vibrancy. The equation (6) can be expressed in the equation (12) during the transient process.

$$\dot{U}_s = \left[R_s + j\omega_s \left(L_s - \frac{L_m^2}{L_r} \right) \right] \dot{I}_s + j\omega_s \frac{L_m}{L_r} \dot{\psi}_r + \frac{d\dot{\psi}_s}{dt} \quad (12)$$

Thus, it can be derived the dynamic process of the DFIG internal voltage in the equation (13). Similarly, the dynamic stator voltage can also be expressed in the equation (14).

$$\dot{E}' = j\omega_s \frac{L_m}{L_r} \dot{\psi}_r + \frac{d\dot{\psi}_s}{dt} \quad (13) \qquad \dot{U}_s = j\omega_s \dot{\psi}_s + \frac{d\dot{\psi}_s}{dt} \quad (14)$$

By the comparison of the equation (13) and (14), the angle between the internal voltage *E'* and the terminal voltage U_s are as same as that between rotor and stator flux. So we can observe the angle α between the rotor and stator flux instead of the DFIG power angle. In addition, the equation (14) and (15) both have the component $d\psi_s/dt$, which represents the vibrant characteristics during the transient process. So the angle α can exactly substitute the DFIG power angle both in the steady and transient conditions. the total output power of the DFIG can be demonstrated in the equation (15).

$$P_G = (1-s) P_s = (1-s) \frac{E'U_s}{x'} \sin\alpha = \frac{(1-s)\omega_s L_m \psi_r \psi_s}{L_s L_r - L_m^2} \sin\alpha \quad (15)$$

Simulation example

To analyze the transient behaviors of the DFIG, a single machine and infinite bus system is modeled in the Matlab/Simulink environment. The diagram is showed in the figure 4. The established DFIG model includes two converters and its dual closed-loop control system model, the phase-locked loop model and flux observer model. Besides, the stator flux oriented control is utilized by the rotor-side converter control system. At the time 0.15 seconds, the terminal voltage of the DFIG suffers from voltage dips of 0.3 p.u, 0.5 p.u and 0.7 p.u respectively. The durations are both 0.1

seconds. After filtering stator flux oscillations, the simulation results are showed from the figure 5 to figure 9.

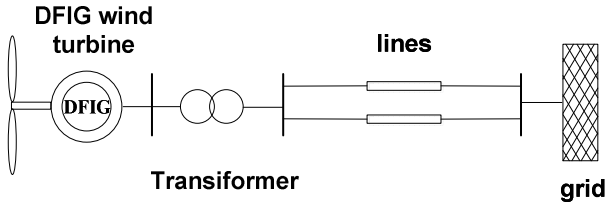

Fig. 4 Single DFIG infinite bus system

With the increase of the DFIG terminal voltage drop degree, the DFIG power angel also becomes greater, which is similar to the SG power angle. However, the DFIG power angel can restore to stability rapidly once the voltage dip disappeared, as shown from Figure 5 to Figure 6.

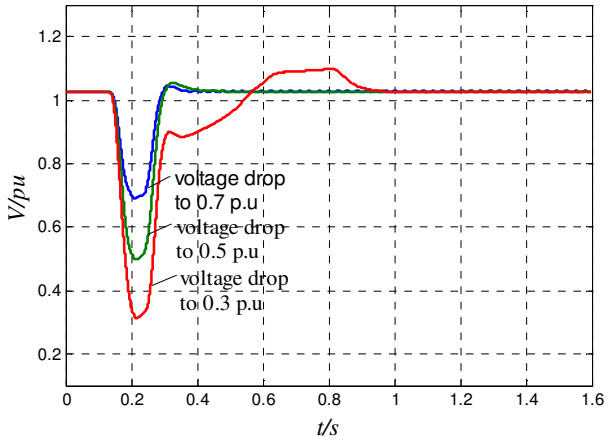

Fig. 5 The voltage dips of the DFIG stator terminal

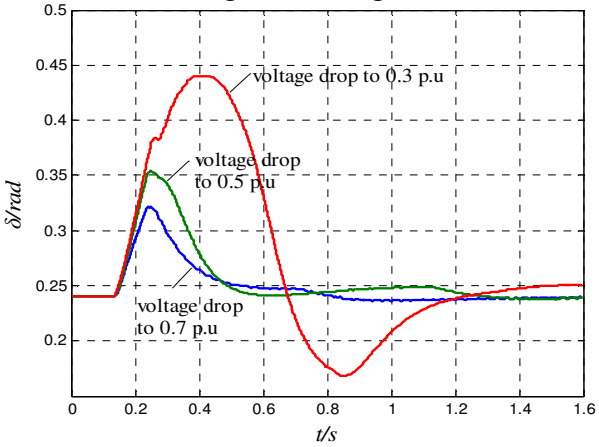

Fig. 6 The DFIG power angle under voltage dips

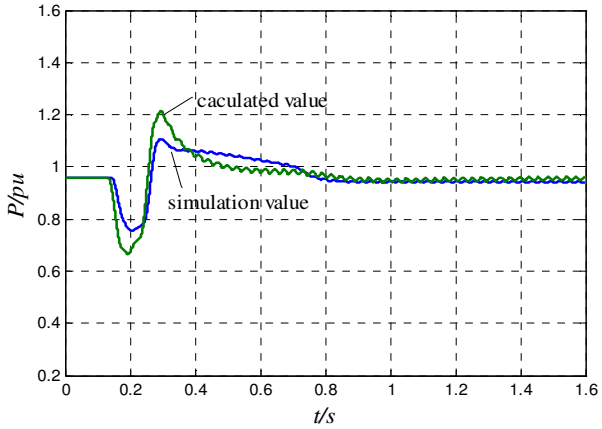

Fig. 7 The power output of the DFIG under 0.3 p.u voltage dip

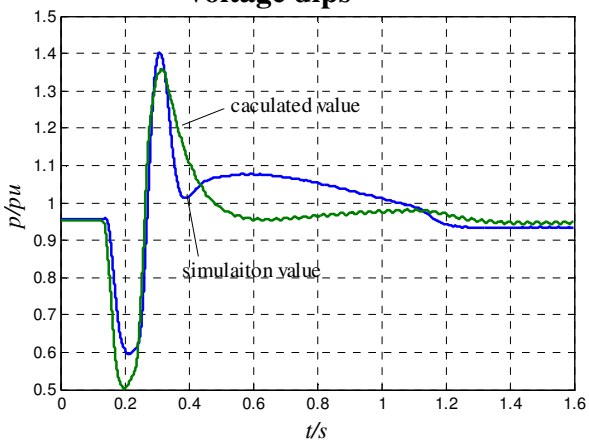

Fig. 8 The power output of the DFIG under 0.5 p.u voltage dip

Figure7 to8 demonstrates the comparison of the DFIG active power between the simulation result and the calculated active power defined on the basis of power angle characteristic equation 15. It can be seen from the Figures that the calculated power curve and the simulation curve are very close. The only difference is caused by the error and the time-delay of the regulation system. Wherefore, the DFIG power angle characteristics can make a better representation of the DFIG active power, which can illustrates the DFIG power angle defined in the paper are reasonable and accurate.

Summary

With the increasing capacity of the DFIG, the power system may appear a series of new features. The paper gives a definition of the DFIG power angle on the basis of its operational principle and

transients, analyzes the effects of the converters on the power angle and its transient characteristics. The study demonstrates that the DFIG has its own power angel characteristics. The simulation results verify the conclusions of this paper and prove the correctness of the derivation process.

Keywords: Rough Model Method, Pressurized conduit, circular pipe with benches, Turbulent flow, Discharge, Energy slope.

Abstract: The rough model method (RMM) is explained through its application to the design of a pressurized circular shaped conduit with benches, widely used in practice. The three basic equations of turbulent flow are firstly applied to define explicitly the geometric elements of a referential rough model characterized by an arbitrary assigned relative roughness value. The required linear dimensions of the studied conduit are then easily deduced by multiplying the homologues linear dimensions of the rough model by a non-dimensional correction factor. Friction factor is not indispensable when applying the RMM, unlike current design methods. Resulting RMM equations are not only explicit but are also valid in the entire domain of turbulent flow.

Introduction

In the field of hydraulic practice, the problem of designing pipes and channels is acute because current methods are laborious and difficult to handle for practical use [1, 2, 3]. For particular case of pressurized conduits, designing uses Darcy-Weisbach equation, expressing the energy slope, which is one of the three basic equations of turbulent flow. The major problem in this equation lies in the fact that it uses the friction factor which is himself implied regarding to Colebrook-White relationship [4, 5, 6]. The solution involves many trials and tedious computations or laborious graphical procedure due to the fact that linear dimensions of the conduit are unknown. To solve the problem, some authors have proposed in the past approximate relationships for designing conduits, especially circular pipe [7, 8, 9]. These relationships cause errors more or less acceptable, depending on the practical requirements. Despite the fact that the three basic relations of the turbulent flow are complete, they do not, however, allow an explicit solution to the design problem of conduits or channels. Referring to the literature, we can affirm that no explicit method is currently available for designing conduits, especially circular shaped conduit with benches subject of the present study, despite its extensive use in practice as water supply lines, sanitary sewers, culverts and storm drains or penstocks as well. For this reason, this article is a real enrichment of the literature by studying this type of conduit under pressurized condition of the flow. The problem of design will be solved by a rigorous theoretical development based on the three basic relations of the turbulent flow, especially Darcy-Weisbach relationship. To avoid the problem of friction factor, this relationship will be applied to a referential rough model whose friction factor is imposed in the rough turbulent domain. This helps provide explicit linear dimensions relationships of the rough model that are subsequently used to derive the required dimensions of the studied conduit, thanks to a non-dimensional correction factor of linear dimensions. This is the rough model method (RMM) that has been proven in recent past [10, 11] by its simplicity and effectiveness. We will observe that the equations resulting from the RMM are not only explicit but they are also applicable in the whole domain of the turbulent flow, corresponding to Reynolds number greater or equal to 2300 and relative roughness varying in the wide range [0; 0.05].

Basic equations

The relationships on which the study is based are simple well known hydraulic equations namely, Darcy-Weisbach equation, Colebrook-White equation and Reynolds number formula.
The energy slope of a conduit or channel is given by the Darcy-Weisbach relationship as:

$$J = \frac{f}{D_h}\frac{Q^2}{2gA^2}\cdot \quad (1)$$

where Q is the discharge, g is the acceleration due to gravity, A is the water area, D_h is the hydraulic diameter and f is the friction factor given by the well known Colebrook-White formula as:

$$\frac{1}{\sqrt{f}} = -2\log\left(\frac{\varepsilon / D_h}{3.7} + \frac{2.51}{R\sqrt{f}}\right)\cdot \quad (2)$$

ε is the absolute roughness and R is the Reynolds number which can be expressed as :

$$R = \frac{4Q}{P\nu}\cdot \quad (3)$$

ν is the kinematic viscosity and P is the wetted perimeter.

Geometric and hydraulic characteristics of the circular pipe with benches.

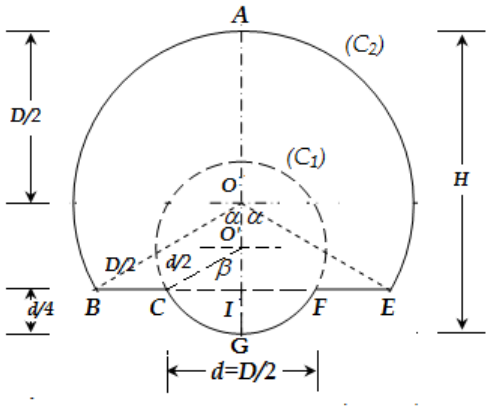

Fig. 1: Geometric elements of the pressurized circular pipe with benches

The circular pipe with benches is characterized by the vertical dimension H representing its height and the diameter D of the circle forming its top. The lower part is formed by a central circular culvert of diameter d and two benches of length $\overline{BC}$ and $\overline{FE}$.
The distance OO' between the two centers of the circle (C_2) of diameter D and the circle (C_1) of diameter d is equal to $D/4$. The diameter d of the circle (C_1) is the half of the diameter D of the circle (C_2).
From a geometrical point of view, Fig. 1 allows to write that:

$$\cos(\alpha) = \frac{\overline{OI}}{\overline{OB}} = \frac{0.5d}{0.5D} = \frac{d}{D} = 0.5\cdot$$

$$\cos(\beta) = \frac{\overline{O'I}}{\overline{O'C}} = \frac{0.25d}{0.5d} = 0.5\cdot$$

We can therefore deduce that: $\alpha = \beta = \pi/3$.
Moreover, one can write from Fig. 1:

$$tg(\beta) = \frac{\overline{CI}}{\overline{O'I}} = \frac{\overline{CI}}{0.25d}\cdot$$

Leading to:

$$\overline{CI} = 0.25\times d\times tg(\beta) = 0.25\times\frac{D}{2}\times\sqrt{3}\cdot$$

Or

$$\overline{CI} = \frac{D\sqrt{3}}{8}\cdot$$

$$tg(\alpha) = \frac{\overline{BI}}{\overline{OI}} = \frac{\overline{BI}}{0.5d} = 4\frac{\overline{BI}}{D}\cdot$$

Leading to :

$$\overline{BI} = \frac{D}{4}tg(\alpha) = \frac{D\sqrt{3}}{4}\cdot$$

The length of the benches is as:

$$\overline{BC} = \overline{BI} - \overline{CI} = \overline{FE} = \frac{D\sqrt{3}}{4} - \frac{D\sqrt{3}}{8} = \frac{D\sqrt{3}}{8}\cdot$$

The length of the arc $\widehat{BAE}$ is given by what follows:

$$\widehat{BAE} = D(\pi - \alpha) = D\left(\pi - \frac{\pi}{3}\right) = \frac{2\pi}{3}D\cdot$$

The length of the arc $\widehat{CGF}$ is as:

$$\widehat{CGF} = \frac{d}{2}(2\beta) = \frac{D}{4}\left(2\times\frac{\pi}{3}\right) = \frac{\pi}{6}D\cdot$$

The total water area A is calculated as follows:

$$A = A_0 - A_1 + A_2\cdot$$

Where:

A_0 is the area of the circular section of diameter D, given by :

$$A_0 = \pi D^2/4 = 0.7854D^2\cdot$$

A_1 is the area of the circular segment of the diameter D of center O and of central angle 2α. Hence:

$$A_1 = \frac{D^2}{4}\left[\alpha - \sin(\alpha)\cos(\alpha)\right] = \frac{D^2}{4}\left[\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right] = 0.1535D^2\cdot$$

A_2 is the area of the circular segment $\widehat{CIFGC}$ belonging to the circle of diameter d of center O' and of central angle 2β. Hence:

$$A_2 = \frac{d^2}{4}\left[\beta - \sin(\beta)\cos(\beta)\right] = \frac{D^2}{16}\left[\frac{\pi}{3} - \frac{\sqrt{3}}{4}\right] = 0.0384D^2\cdot$$

The total water area is then equal to:

$$A = A_0 - A_1 + A_2 = 0.7854D^2 - 0.1535D^2 + 0.0384D^2\cdot$$

Or :

$$A = 0.6703D^2\cdot \qquad (4)$$

On the other hand, the total wetted perimeter P can be written as :

$$P = P_0 + P_1 + P_2\cdot$$

Where:

P_0 is the length of the arc $\widehat{BAE}$, given by :

$$P_0 = \frac{2\pi}{3}D = 2.0944D\cdot$$

P_1 is the length of the segments $\overline{BC}$ and $\overline{FE}$, expressed as:

$$P_1 = 2\overline{BC} = 2\times\frac{D\sqrt{3}}{8} = \frac{D\sqrt{3}}{4} = 0.4330D\cdot$$

P_2 is the length of the arc $\overset{\frown}{CGF}$, given by :

$$P_2 = \overset{\frown}{CGF} = \frac{\pi}{6} D = 0.5236D \cdot$$

The total perimeter P is therefore:

$$P = P_0 + P_1 + P_2 = 2.0944D + 0.4330D + 0.5236D \cdot$$

Or :

$$P = 3.0510D \cdot \quad (5)$$

Accordingly, the hydraulic diameter D_h is:

$$D_h = 4A/P = 4 \times 0.6703/3.0510\, D \cdot$$

Or:

$$D_h = 0.8788D \cdot \quad (6)$$

According to Fig. 1, the height H of the conduit can be expressed as:

$$H = \overline{AO} + \overline{OO'} + \overline{O'G} = \frac{D}{2} + \frac{d}{4} + \frac{d}{2} = \frac{D}{2} + \frac{D}{8} + \frac{D}{4} = \frac{7D}{8} \cdot$$

Or:

$$H = 0.875D \cdot \quad (7)$$

Referential rough model

Both of geometric and hydraulic characteristics of the rough model are distinguished by the symbol "$\bar{}$". Thus, its height is representing by $\overline{H}$, its diameter is $\overline{D}$ and the wetted perimeter is $\overline{P}$…etc. The rough model we consider is a pressurized circular conduit with benches characterized by $\overline{\varepsilon}/\overline{D}_h = 0.037$ as the arbitrarily assigned relative roughness value. The selected relative roughness value is so significant that the prevailed flow regime in the model is fully rough. Thus, the friction factor is $\overline{f} = 1/16$ according to Eq. 2 for $\overline{R} = R$ tending to infinitely large value. Applying Eq. 1 to the rough model leads to:

$$\overline{J} = \frac{\overline{f}}{\overline{D}_h} \frac{\overline{Q}^2}{2g\overline{A}^2} \cdot \quad (8)$$

Bearing in mind that $\overline{D_h} = 4\overline{A}/\overline{P}$ and $\overline{f} = 1/16$, Eq. 8 can be rewritten as:

$$\overline{J} = \frac{1}{128g} \frac{\overline{P}}{\overline{A}^3} \overline{Q}^2 \cdot \quad (9)$$

Introducing Eq. (4) and Eq. (5) into Eq. 9, one may deduce:

$$\overline{J} = 0.0791 \frac{\overline{Q}^2}{g\overline{D}^5} \cdot \quad (10)$$

Let us assume $\overline{Q} = Q$ and $\overline{J} = J$, implying obviously $\overline{D} \neq D$. Thus, Eq. 10 gives:

$$\overline{D} = 0.6021 \left(\frac{Q^2}{gJ} \right)^{1/5} \cdot \quad (11)$$

Eq. 11 allows computing explicitly the diameter $\overline{D}$ of the rough model for the given values of the discharge Q and the energy slope J.

Non-dimensional correction factor of linear dimension

The RMM states that any linear dimension "L" of the conduit is related to its homologue "$\overline{L}$" of the rough model by the following fundamental relationship:

$$L = \psi \overline{L} \cdot \quad (13)$$

Where ψ is a non-dimensional correction factor of linear dimension, less than unity, which is governed by the following explicit relationship [1, 10]:

$$\psi = 1.35\left[-\log\left(\frac{\varepsilon/\overline{D}_h}{4.75}+\frac{8.5}{\overline{R}}\right)\right]^{-2/5}. \tag{14}$$

In which $\overline{R}$ is the Reynolds number characterizing the flow in the rough model, which can be simply expressed as:

$$\overline{R}=\frac{4Q}{\overline{P}\nu}. \tag{15}$$

Computation steps of the linear dimensions of the conduit

Knowing the discharge Q, the energy slope J, the absolute roughness ε and the kinematic viscosity ν, the following steps are recommended to compute the required value of the linear dimensions of the conduit:

1. Compute the diameter $\overline{D}$ of the rough model using Eq. 11.
2. Knowing $\overline{D}$, compute the wetted perimeter $\overline{P}$ and the Reynolds number $\overline{R}$ in the rough model, using Eq. 5 and Eq. 15 respectively.
3. Compute the hydraulic diameter $\overline{D}_h$ of the rough model using Eq. 6.
4. Applying Eq. 14, the non-dimension correction factor of linear dimension ψ is then worked out.
5. The required value of the diameter D of the conduit is finally $D=\psi\overline{D}$ according to Eq. 13.
6. Once the diameter D of the conduit determined, the diameter d is then $d=D/2$ and the height H is directly deduced from Eq. 7.

Example:

Compute the linear dimensions of the pressurized circular pipe with benches schematised in Fig. 1, for the following data: $Q=1.225\,m^3/s$, $J=4\times10^{-4}$, $\varepsilon=0.002m$, $\nu=10^{-6}m^2/s$

1. According to Eq.11, the diameter $\overline{D}$ of the conduit is:

$$\overline{D}=0.6021\left(\frac{Q^2}{gJ}\right)^{1/5}=0.6021\times\left(\frac{1.225^2}{9.81\times10^{-4}}\right)^{1/5}=1.9778\,m.$$

2. According to Eq. 5, the wetted perimeter $\overline{P}$ of the rough model is as:
   $\overline{P}=3.0510\overline{D}=3.0510\times1.9778=6.0343\,m.$
   Using Eq. 15, the Reynolds number $\overline{R}$ is then:
   $$\overline{R}=\frac{4Q}{\overline{P}\nu}=\frac{4\times1.225}{6.0343\times10^{-6}}=812025.$$
3. Applying Eq. 6, the hydraulic diameter $\overline{D}_h$ is:
   $\overline{D}_h=0.8788\overline{D}=0.8788\times1.9778=1.7381\,m.$
4. According to Eq. 14, the non-dimensional correction factor of linear dimension is given as:
   $$\psi=1.35\left[-\log\left(\frac{\varepsilon/\overline{D}_h}{4.75}+\frac{8.5}{\overline{R}}\right)\right]^{-2/5}$$
   $$=1.35\times\left[-\log\left(\frac{0.002/1.7381}{4.75}+\frac{8.5}{812025}\right)\right]^{-2/5}=0.8090.$$
5. Finally, the required diameter D of the conduit is given by Eq. 13 as:
   $D=\psi\overline{D}=0.8090\times1.9778=1.6\,m.$
6. Consequently, the diameter d is:
   $d=D/2=1.6/2=0.8\,m.$

Using Eq. 7, the height H of the conduit is then:

$$H = 0.875D = 0.875 \times 1.6 = 1.4\,m \cdot$$

We can continue the calculation by writing that the length of the benches is:

$$\overline{BC} = \overline{FE} = \frac{D\sqrt{3}}{8} = \frac{1.6 \times \sqrt{3}}{8} \cong 0.3464\,m \cdot$$

7. This step aims to verify the validity of the calculations. To do this, determine from Eq. 9 the energy slope $\overline{J}$ which must be equal to J for $\overline{Q} = Q$. Determine first the value of the water area $\overline{A}$ using Eq. 4:

$$\overline{A} = 0.6703\overline{D}^2 = 0.6703 \times 1.9778^2 = 2.6220\,m^2 \cdot$$

Hence:

$$\overline{J} = \frac{1}{128g}\frac{\overline{P}}{\overline{A}^3}\overline{Q}^2 = \frac{1}{128 \times 9.81} \times \frac{6.0343}{2.6220^3} \times 1.225^2 = 0.00040006 \cong 4 \times 10^{-4} \cdot$$

It is indeed the value of J given in the problem statement.

Conclusions

To explain the advantages of the rough model method in the design of hydraulic structures, the case of circular shaped conduit with benches was considered. This conduit is characterized by three linear dimensions that we have explicitly determined by a new theoretical rigorous approach. The theory is mainly based on the Darcy-Weisbach equation in which friction factor can not be directly determined without a laborious process. To avoid this drawback, a rough model was used to the sake of calculation. Its hydraulic characteristics have been previously defined in the rough domain, more particularly the friction factor whose value is constant. As a result, the Darcy-Weisbach equation has explicitly expressed the geometric diameter of the rough model which can easily be calculated from the known values of the discharge Q and the energy slope J. The required diameter of the studied conduit was simply obtained by multiplying the diameter of the rough model by a non-dimensional correction factor, in accordance with the fundamental relationship of the RMM. The others linear dimensions of the conduit, such as its height, were determined according to the same principle.

Keywords: Condensation, Refueling gas recovery, Turbo Brayton refrigeration

Abstract. Volatile organic compounds (VOCs) are emitted from the refueling of gasoline vehicles and trucks. Controlling these emissions has been an important issue since the late 2000s in China. We have recently developed a condensation refueling gas recovery system to recover the VOCs from gaseous wastes at a bulk gasoline terminal. In this system VOC vapor is condensed by a reversed turbo-Brayton cycle refrigerator. The recovery system has a capacity of 100 Nm^3/hr at the lowest condensation temperature of 190K. It has been put into use since 2008. The achieved recovery efficiency is 96% and the emission of VOCs is less than 8 g/m^3 at the exit of the recovery system.

Introduction

In China, there are more than 1500 bulk gasoline terminals, 90,000 gasoline filling stations and 20,000 tanker trucks until 2012. The emission of gasoline vapor containing volatile organic compounds (VOCs) from the filling, unloading and transportation of gasoline at the gasoline service stations is more than 600,000 tons per year. Controlling these emissions has been an important issue since the late 2000s in China. Several regulations have been enacted to limit the discharge of gasoline vapor to the environment. According to these VOC emission regulations and standards of China, the emission of total organic compounds loaded for gasoline storage and distribution facilities is specified to be less than 25g per cubic meter [1,2,3,4].

There are several techniques for recovering VOCs from gaseous wastes, such as activated carbon adsorption, condensation using refrigerants and membrane separation [5,6,7]. VOC-condensation processes use refrigerants to reduce the temperature of the emission stream to the level necessary for the VOCs to condense out of the stream. Two refrigeration cycles, the vapor-compression refrigeration cycle and Brayton refrigeration cycle, could be used to cool down the gasoline vapor. As compared with the vapor-compression refrigeration cycle, the Brayton refrigeration cycle can achieve very high recovery efficiencies. The reason is that it uses high efficiency turbo expanders to produce the necessary cooling power; the very low cooling temperature can be obtained by using different gas cryogen such as nitrogen, argon or dried air.

In order to meet the requirements of VOC emission regulations, Beijing Longyu Petroleum & Chemical Company had to develop a stage I vapor recovery system to control the VOC emissions during the transfer of gasoline from the cargo tank to the underground storage tank. This paper presents a condensation refueling gas recovery system based on turbo Brayton refrigeration technique.

Composition of VOC Vapor

In general, stage I vapors are created due to the high volatility of gasoline at atmospheric conditions. Emissions from the vent of underground storage tank include filling losses, breathing losses, and empting losses. The vapor evolved from the fuel tank contains a mixture of hydrocarbons and air. The concentrations of VOC vapors stream on user site are tested and listed in Table 1.

Table 1. Composition of VOCs vapors stream

compound	N_2	O_2	H_20	CO_2	C_2H_6	C_3H_8
Concentration (vol%)	62.1	16.5	1.1	0.8	1.1	2.3
compound	iC_4H_{10}	nC_4H_{10}	iC_5H_{12}	nC_5H_{12}	C_6H_{14}	C_7H_{16}
Concentration (vol%)	4.2	4.7	3.0	1.6	1.4	1.2

Condensation Temperature and Pressure

Owing to stringent environmental regulations imposed on the emission of VOCs, the gaseous wastes must be cooled to very low temperatures so as to condense the VOCs to the required level. Taking the VOC vapor with composition as listed in Table 1 as the inlet flow, the recovery efficiency of vapor gas of gasoline and the emission of VOCs by condensation is calculated based on the phase equilibrium theory. The simulation results are illustrated in Fig. 1 and Fig. 2. The results indicate that the values of percent removal of total VOCs of inlet gasoline vapor by condensation are about 89, 93, and 95.8 wt% at condensation temperature of 200, 190, and 180K, respectively. To reduce the VOC emissions to the level of 25g/m^3, the condensation temperature of less than 205K will be required at the pressure of 130 kPa. For the safety operation of VOC vapor, the low pressure of 130 kPa is considered as the condensation pressure, although the higher the condensation pressure (Pc) is, the higher the recovery efficiency may be achieved.

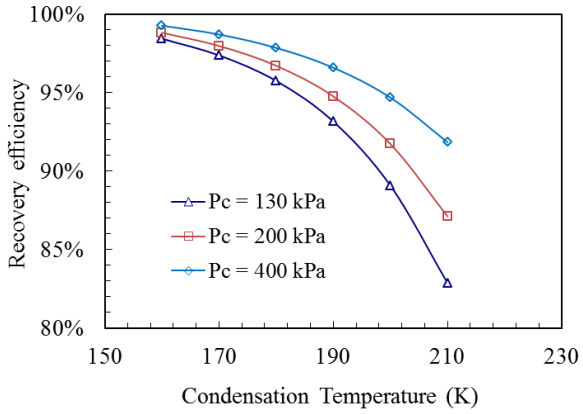

Fig. 1. Recovery efficiency at various condensation temperature

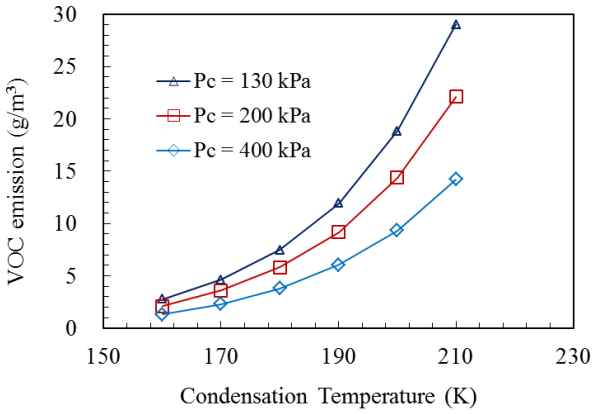

Fig. 2. VOC emissions at various condensation temperature

Condensation System Based on Reverse Turbo Brayton Refrigeration Cycle

Based on the above computation, we specified 190 K as the condensation temperature of the refueling gas recovery system. To condense the VOC vapor and remove the most VOCs at such low temperature, the reverse Brayton refrigeration technique was applied to the VOC condensation system.

As shown in Fig. 3, this system consists of a refrigeration loop and a VOC vapor flow loop. The refrigeration loop is a reverse Brayton refrigeration cycle, which is composed of a screw nitrogen compressor, an oil remove system, a gas nitrogen buffer tank, an air turbine expander and a two-stage aluminum plate-fin heat exchanger unit. The capacity of condensation recovery system is 100 Nm^3/hr at the lowest condensation temperature of 190K. The flow rate of the nitrogen compressor is 10 m^3/min, the discharge pressure is 800 kPa and the drive rated motor power is 55 kW. The high speed gas bearing turbine expander, working at 80000 rpm, is the key component to provide cooling capacity for the condensation of VOC vapor.

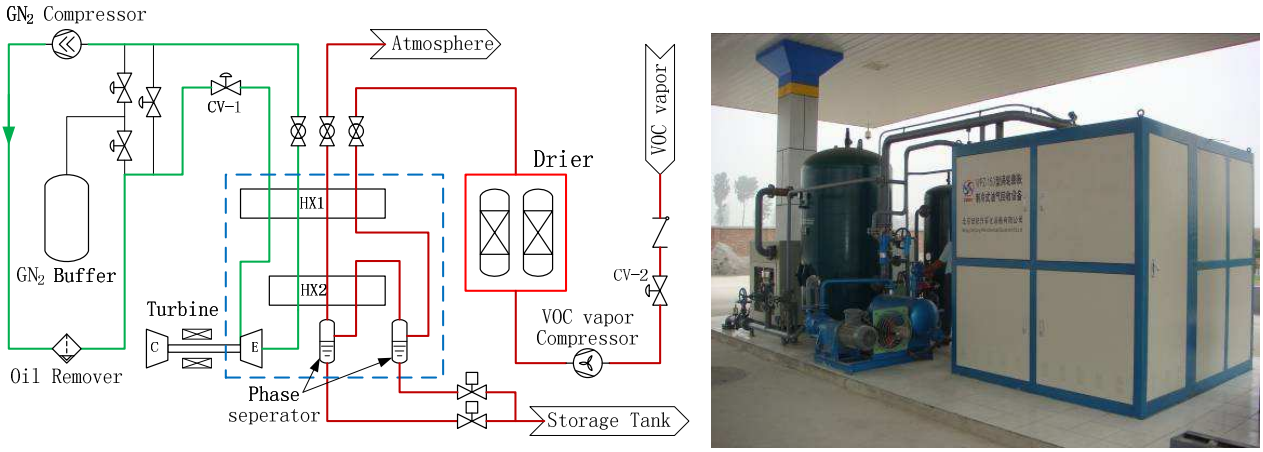

Fig. 3. Condensation recovery System

The VOC vapor flow loop is an isobaric heat exchanging process attached by phase separation at *the cold ends of heat exchangers, which includes a VOC vapor compressor, a VOC vapor dryer and* two gas-liquid phase separators. The condensation process occurs in the two-stage heat exchanger unit which avoids contamination due to the contacting of the VOC gas stream with other streams. The VOC vapor compressor is a liquid ring compressor equipped with a variable frequency drive and a control valve to match the VOC vapor flow and to avoid the subatmospheric pressure occurring inside the underground storage tank. The VOC vapor dryer consists of dual drying chambers alternately cycled through drying and regeneration.

Operation

This system has been put into use since 2008. The temperature at the outlet of the turbo-expander and the temperature at the outlet of the second stage phase separator are measured by two PT100 sensors which are located on the outside surfaces of pipes near the expander and phase separator.

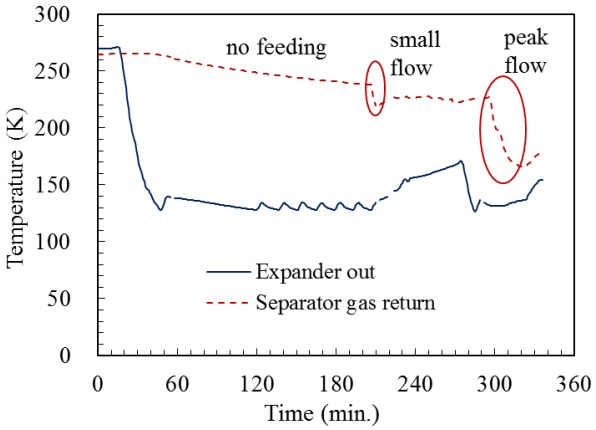

Fig. 4. Temperature change during Cool-down process

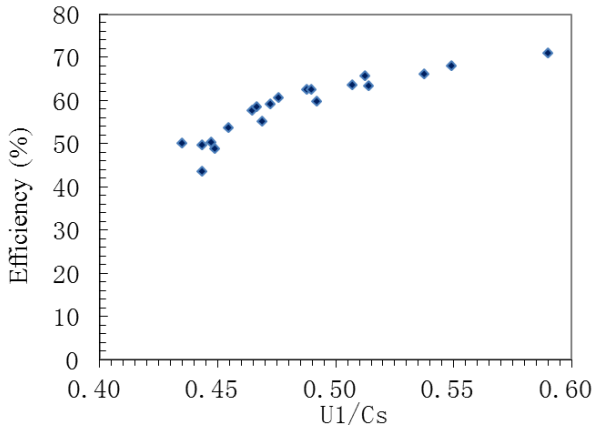

Fig. 5. Efficiency of turbo-expander at different isentropic velocity ratio

The variations of these two temperatures with the cool-down time are illustrated in Fig. 4. The cool-down time for the gas nitrogen refrigeration cycle as well as for the VOC vapor condensation loop is less than 30 minutes. Since the VOC vapor flow is not stable on the site of gasoline dispensing facility, the peak flow rate appears at heavy traffic period while the minimum flow rate is zero. The peak flow rate and a small flow rate are marked in the Fig. 4 with two ellipses. The condensation temperature at the peak flow is 170K which is lower than the design temperature. The reason is that the peak flow rate of VOC vapor is less than the capacity of condensation recovery system. In order to

match the lower peak flow rate, the working speed of turbo expander was controlled and adjusted to a lower speed. As a result, only the lower isentropic efficiencies had been achieved as shown in Fig. 5, the maximum efficiency of expander is about 70%.

The recovery efficiency of 96% and the VOC emission level of 8 g/m^3 at the exit of the recovery system had been detected and confirmed by authority in Nov. 2008.

Conclusion

The condensation refueling gas recovery system based on reverse turbo Brayton refrigeration technique was developed. The operation results indicate that such system meet the stringent requirement of VOC emission regulations of China. However, further work should be done to match the unstable flow of VOC vapor stream, and the cost effective analyses are expected to be carried out in details.

Key Words: Capillary, roof radiation, heating, Exergy Theory.

Abstract. This paper introduces the advantages of capillary roof radiant heating system, by using finite element numerical method, the indoor temperature distribution of capillary radiant roof and underfloor supply air composite system is simulated, using the theory of exergy to analysis the energy saving of the system, the result proves that the system can well satisfy indoor comfort requirements, and compared with the floor radiation heating system can saving energy 65.8%, has great research value.

Introduction

Existing air conditioning system through continuous improvement and perfection, but still has some problems such as: temperature and humidity coupling loss, difficult to adapt to changes in temperature and humidity, the cold surface mildew, convection wind feeling, coil air noise and indoor repeat installed two sets of environmental control system and so on[1]. Heating also have the problems such as the low heat exchange efficiency, nonuniform indoor temperature distribution, difficulty pipe installation and repair of the buried radiant floor heating system ,fouling and cleaning and other aspects etc. Therefore put forward higher request to the HVAC industry: in addition to the optimization of building periphery structure to strengthen heat preservation and heat insulation, research and development of high comfort, energy saving, low cost indoor environment control system is very necessary.

In twentieth Century 70 years scientists in Germany according to the principle of bionics invented the capillary radiation air conditioning system, but has not been seriously, while with the global energy crisis, environmental pollution and greenhouse effect is more serious, governments around the world to improve the energy-saving emission reduction standards, the capillary radiation heating refrigeration technology has become a hot research in recent years at air-conditioning industry.American Stanley A. Mumma[2] provides a design procedure of modern plane radiation air conditioning combined with ventilation system, and the system used in the commercial buildings are described. Stanley A. Mumma[3] discuss the dehumidifying measures in full consideration of capillary grille and displacement ventilation system investment and operation conditions. Wei Bing and Jiang Lu[4,5]of the North China Electric Power University studied model of capillary air-conditioning system, mainly for the numerical simulation of indoor thermal environment and micro environment between capillary tubes.

The advantage of capillary radiant ceiling

There was comprehensive study of cooling effect of capillary radiant ceiling at home and abroad, but the study of heating effect of capillary radiant ceiling is not enough . A complete air conditioning system which was propagable and energy-efficient must has the function of cooling and heating. In terms of human feelings, the capillary radiant ceiling is less comfortable than floor radiant heating, but it has its own advantage. For instance, in function, the capillary radiant ceiling system can both provides the function of heating and cooling; in installation, according to the structure of building the

capillary radiant ceiling system can be installed in the roof, wall, cylindrical and ground ;in energy saving effect, it used low grade energy, combined with heat pump it could save energy 40-70% ; in safety, even if destroyed, capillary diameter is small, no flooding accident, find the leak and repair is very simple.

Study on heating and energy saving

Calculation and analysis of the indoor temperature field in winter: In an office of Ji'nan city as an example, the room size is 4.85m×3m×3.9m, winter indoor temperature is 18℃, the average temperature of capillary radiant panel is 27℃, studies have shown that[7], using floor side air ways during winter, indoor vertical temperature difference is small, can well meet the requirements of comfort. According to the minimum fresh air and air speed 0.3m/s, determine the outlet size: 600mm×100mm, supply air temperature 21℃, office mesh as shown in Fig.1.

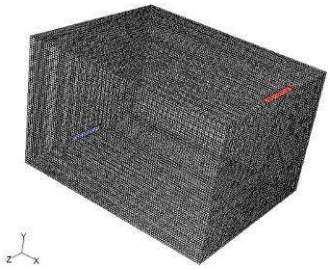

Fig.1 Room model meshing

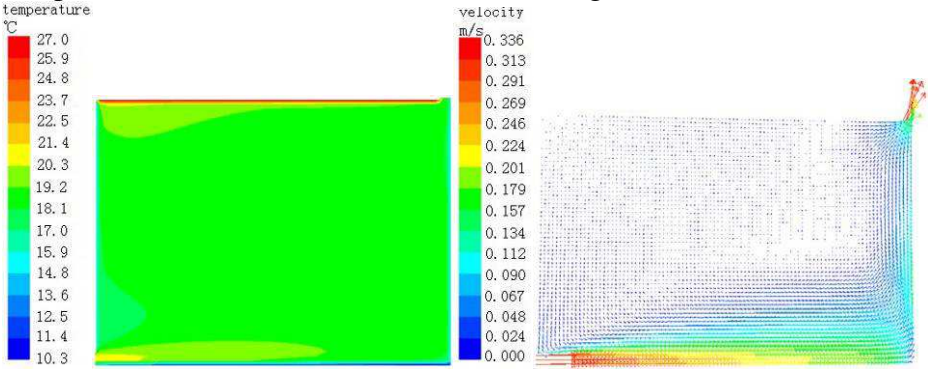

Fig.2 Temperature and velocity field of the Z = 1.95 cross-section

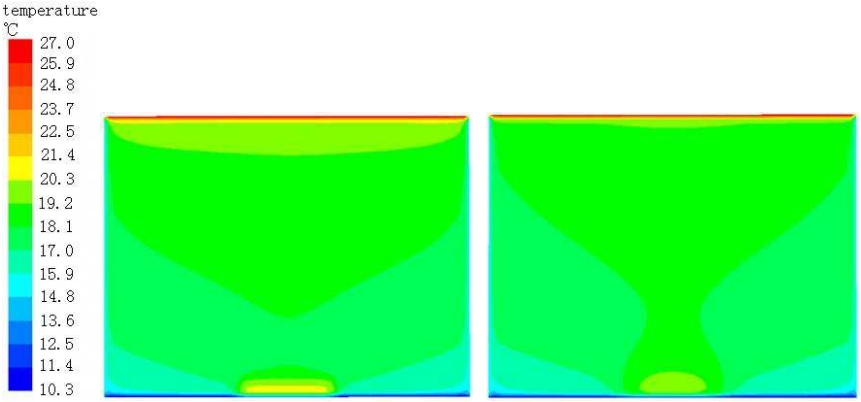

Fig.3 Temperature distribution of the X = 0.35m, X = 2m

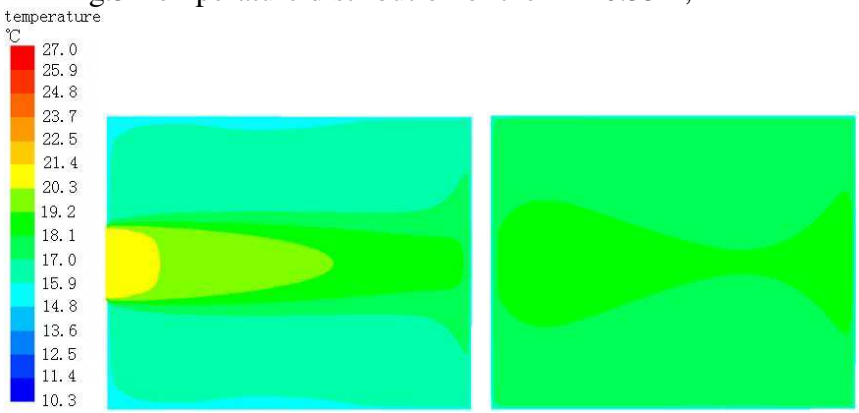

Fig.4 Horizontal temperature field of the Y = 0.1m, Y = 1.2m height

After the cross-section(Z=1.95) of heat source such as staff and computer, room temperature and velocity distribution as shown in Fig.2 when the outlet disposed on the ground. Fig.3 is the vertical temperature distribution close to the outlet(X=0.35) and the central(X=2) of the room, Fig.4 is the horizontal temperature distribution at a height of a human ankle(Y=0.1) and sitting(Y=1.2). In

addition to the outlet and close to the surface of the radiating plate, from the ankle (about 0.1m) to human activity area (2m or less), the indoor vertical temperature distribution is between 18.1℃ to 19.2℃, does not exceed 2℃. At the horizontal height of 0.1m close to the outlet, the temperature stratification, but not obvious, the horizontal temperature distribution at a height of 1.2m substantially consistent, the heating temperature reaches the set requirements and indoor temperature distribution is very uniform. Air flow in the room at 0.1m/s or less basically, no significant hair feeling, can well meet the requirements of comfort.

The results can be seen from the above simulation, capillary radiation plate has a good effect not only in terms of cooling, but also make the room temperature reaches requirements when heating, and have a high degree of comfort.

Exergy analysis theory: Seen by the thermodynamic principles: for 1kg working fluid, the maximum useful work for the opening lines of a steady flow from imports state into the state of the environment through the irreversible process is:

$$\mathrm{ex} = w_{\max} = (h-h_0) - T_0(s-s_0) = C_{\mathrm{p}}(T-T_0) - T_0\left(Cp\ln\frac{T}{T_0}\right) \tag{1}$$

Where, ex is the Exergy of the working fluid, kJ/kg; W_{max} is maximum useful work for the working fluid, kJ/kg; T_0 is the ambient temperature, K; T is working fluid inlet temperature, K; Cp is the specific heat, kJ/(kg • K).

Analysis of energy saving compared with floor heating

Capillary ceiling radiant heating and radiant floor heating are opening steady flow systems. Following as the radiant floor heating system and capillary ceiling radiant heating system example, supply water temperatures were 50℃and 30℃respectively, the temperature difference between supply and return water both were 5℃, calculation of the efficiency of the two systems is as follows (assuming the ambient temperature is 18 ℃):

Heat exergy for the supply water temperature of 50℃ is:

$$ex = 4.19\times(50-18) + (18+273)\times 4.19\times\ln\frac{18+273}{50+273} = 6.87kJ/kg \tag{2}$$

Heat exergy for the return water temperature of 45 ℃ is:

$$ex = 4.19\times(45-18) + (18+273)\times 4.19\times\ln\frac{18+273}{45+273} = 4.94kJ/kg \tag{3}$$

Heat exergy for the supply water temperature of 30℃ is:

$$ex = 4.19\times(30-18) + (18+273)\times 4.19\times\ln\frac{18+273}{30+273} = 1.01kJ/kg \tag{4}$$

Heat exergy for the return water temperature of 25 ℃ is:

$$ex = 4.19\times(25-18) + (18+273)\times 4.19\times\ln\frac{18+273}{25+273} = 0.35kJ/kg \tag{5}$$

Both are low-temperature radiant heating, and therefore take the two systems the same cooling load per unit area, the system's refrigerant mass flow rate can be calculated by the following formula:

$$Q = C_p m\Delta t \tag{6}$$

Mass flow ratio of the two systems working fluid is m1: m2 = 1:1.

For the radiant floor heating system 50/45℃, the exergy consumption for unit area of air conditioning per unit time is:

$$\Delta E_1 = m_1(ex_1 - ex_2) = m_1(6.87-4.94) = 1.93m_1 \tag{7}$$

For the radiant floor heating system 30/25℃, the exergy consumption for unit area of air conditioning per unit time is:

$$\Delta E_2 = m_2(ex_1 - ex_2) = m_2(1.01-0.35) = 0.66m_2 \tag{8}$$

Therefore, based on the same amount of heating, energy saving percentage of capillary roof radiant system are：

$$\eta = \frac{\Delta E_1 - \Delta E_2}{\Delta E_1} \times 100\% = \frac{1.93m_1 - 0.66m_2}{1.93m_1} \times 100\% = 65.8\% \quad (9)$$

Not difficult to see from the above results, on the basis of considering the heat "quality" and "amount", the capillary ceiling radiant heating system compared with radiant floor heating system can save energy about 65.8%. Capillary roof radiant energy saving system is reflected in saving not only the amount of energy, but also the high-grade energy. Thus, the capillary radiant system can take advantage of solar energy, geothermal energy and other low-grade renewable energy, better to reflect its energy efficiency superiority.

Conclusion

In this paper, an Office of Jinan City as an example, the indoor temperature and velocity field simulation shows that the use of capillary roof radiant heating, indoor temperature uniform, vertical temperature difference does not exceed 2 ℃, air velocity in addition of the outlet , were 0.1m/s or less, to meet the requirements of comfort. And use the exergy theory analysis the energy consumption of the system, the capillary radiant heating system can save 65.8% energy than radiant floor heating system at the same conditions, energy-saving effect is remarkable.

Although radiation capillary system has other conventional air conditioning systems incomparable advantages, but there are many problems, such as indoor dehumidification, cooling / heating capacity insufficient, air quality and other issues. This article only simulated and analyzed on the capillary heating and energy saving effect, without considering indoor air quality and other issues, I will continue to work in the relevant direction, get more valuable research results.

Keywords: buried pipe, variable temperature inflow, energy efficiency coefficient, coefficient of heat accumulation

Abstract. Taken as the carrier of heat extraction between rock-soil body and ground source heat pump systems, U-tubed pipe heat transfer efficiency was the key for ensuring the long-term and high-performance operation of ground source heat pump systems by means of improving the heat transfer effect. The efficiency coefficient, E, is defined as the ratio of the actual heat transfer capacity to the theoretically maximal heat transfer capacity from the U-tube into rock-soil body, which illustrated the effect of heat transfer ability and the variable heating or cooling loads. Aim at Variation characteristics of heat transfer coefficient of energy efficiency under the variable temperature inflow condition, decomposed into the product of the ratio of biggest buried tube heat transfer temperature difference φ and heat pump outlet water temperature difference σ. Use of u-shaped buried pipe three-dimensional heat transfer model which based on the multipole theory, the influence law of its change which caused by the construction load, buried pipe flow and the unit performance were analyzed, it can provide technical support to optimize the design of ground source heat pump system.

Introduction

Nowadays, in Ground source heat pump engineering, the calculation, design and equipment selection of the buried tube heat exchanger is usually based on the maximum cold or heat load of the building, due to the difference of building function and the ways of using, Difference would inevitably be generated. Even the design of ground source heat pump system is very reasonable, Because most of the time it running in the part load, the actual heat exchange of the buried tube heat exchanger in a rock mass will produce a great influence[1]. The heat transfer process of buried pipe is decided by the result of the changes between building load and geotechnical heat regenerative ability. As the change of inlet temperature of buried pipe, the heat exchange efficiency is decided by the result of many factors of the whole ground source heat pump system, and has its own characteristics and change rules.

When the loop fluid velocity stays the same, U-buried pipe outlet temperature not only reflects the heat exchange efficiency between buried pipe and the rock and soil mass, is also an important characteristic parameters of buried tube heat exchange process. Based on heat transfer coefficient of energy efficiency concept from literature [2] in which the inlet temperature remains constant, the rule indicates some typical conditions. The change rule of buried tube heat exchange efficiency characteristics under the variable temperature inflow which change with the construction load is analyzed close to the actual situation.

Heat Exchange Efficiency Characteristic Parameters of Buried Tube

Outlet Temperature Model of the Buried Pipe. During the heat exchange process of the buried tube, in order to realize the heat exchange, the Circulating fluid flow from a u-shaped tube to the

bottom of the drilling pipe, then flow out from another tube. According to the buried tube heat transfer model based on the theory of the multipolar, the two tube temperature distribution $T_{f1}(Z,t)$ and $T_{f2}(Z,t)$ can be expressed as follows[3]:

$$T_{f1}(Z,t)=T_{f1}(0,t)f_1(Z)+T_{f2}(0,t)f_2(Z)+\int_0^1 T_0(\eta,t)f_4(Z-\eta)d\eta \quad (1)$$

$$T_{f2}(Z,t)=-T_{f1}(0,t)f_2(Z)+T_{f2}(0,t)f_3(Z)-\int_0^1 T_0(\eta,t)f_5(Z-\eta)d\eta \quad (2)$$

In the formula: $f_1(Z)=e^{\beta Z}\left[\cosh(\gamma Z)-\delta\sinh(\gamma Z)\right]$ $f_2(Z)=e^{\beta Z}\frac{\beta_{12}}{\gamma}\sinh(\gamma Z)$

$$f_3(Z)=e^{\beta Z}\left[\cosh(\gamma Z)+\delta\sinh(\gamma Z)\right] \quad f_4(Z)=e^{\beta Z}\left[\beta_1\cosh(\gamma Z)-\left(\delta\beta_1+\frac{\beta_2\beta_{12}}{\gamma}\right)\sinh(\gamma Z)\right]$$

$$f_5(Z)=e^{\beta Z}\left[\beta_2\cosh(\gamma Z)+\left(\delta\beta_2+\frac{\beta_1\beta_{12}}{\gamma}\right)\sinh(\gamma Z)\right]$$

$$Z=\frac{z}{H} \quad \beta_1=\frac{H}{R_1^{\Delta}\rho_f c_f V_f} \quad \beta_2=\frac{H}{R_2^{\Delta}\rho_f c_f V_f} \quad \beta_{12}=\frac{H}{R_{12}^{\Delta}\rho_f c_f V_f} \quad \delta\ \frac{1}{\gamma}\left(\beta_{12}+\frac{\beta_1+\beta_2}{2}\right)$$

$$\beta=\frac{\beta_2-\beta_1}{2} \quad \gamma\ \sqrt{\frac{(\beta_1+\beta_2)^2}{4}+\beta_{12}(\beta_1+\beta_2)}$$

Where, ρ_f is the density of fluid; c_f is the specific heat of fluid; V_f is the volume flow of the fluid in the buried tube; R^{Δ}, R_2^{Δ} can be regarded as the Integrated thermal resistance between a branch of the fluid and he infinite boundary of the soil; R_{12}^{Δ} is the integrated thermal resistance between the two branch pipe.

By the boundary conditions $T_{fin}(t)=T_{f1}(0,t)$, $T_{f1}(1,t)=T_{f2}(1,t)$, the fluid outlet temperature of the u-shaped tube can be expressed as:

$$T_{fout}(t)=\frac{f_1(1)+f_2(1)}{f_3(1)-f_2(1)}T_{fin}(t)+T_0(t)\int_0^1\frac{f_4(\eta)+f_5(\eta)}{f_3(1)-f_2(1)}d\eta=\frac{\cosh(\gamma)-\frac{\beta_1}{\gamma}\sinh(\gamma)}{\cosh(\gamma)+\frac{\beta_1}{\gamma}\sinh(\gamma)}T_{fin}(t)+\frac{2\frac{\beta_1}{\gamma}\sinh(\gamma)}{\cosh(\gamma)+\frac{\beta_1}{\gamma}\sinh(\gamma)}T_0(t) \quad (3)$$

The basic simulation conditions can be found in table 1.

Table1. Properties related to the buried pipes

Heat Transfer Coefficient of Energy Efficiency under the Variable Temperature Inflow. In view of the u-shaped buried pipe structure and heat transfer characteristics, define the heat exchanger efficiency coefficient E, which is the ratio between actual heat exchange amount Q of the buried heat pipe heat exchanger and the biggest theory heat exchange amount Q ', its expression is [2]:

$$E=\frac{Q}{Q}=\frac{Gc(T_{in}-T_{out})}{Gc(T_{in}-T_0)}=\frac{T_{in}-T_{out}}{T_{in}-T_0} \quad (4)$$

In the formula, T_{in}, T_{out}, T_0 are inlet temperature of the u-shaped ground heat exchanger, outlet temperature and the initial temperature of geotechnical. G, c are Mass flow rate, specific heat capacity of buried pipe cycle medium.

Inlet temperature of the buried pipe water changes with the change of building air conditioning load, according to the commonly used Bury pipe side water temperature of the heat pump units

35℃, buried tube heat transfer coefficient of energy efficiency can be expressed as the product of the ratio of biggest buried tube heat transfer temperature difference φ and Heat pump outlet water temperature difference σ, that is:

$$E = \frac{Q}{Q} \quad \frac{T_{in} - T_{out}}{T_{in} - T_0} = \frac{T_{in} - T_{out}}{T_{35} - T_0} \times \frac{T_{35} - T_0}{T_{in} - T_0} = \phi \times \sigma \tag{5}$$

In the formula, type of T_{35} is the constant import water temperature 35℃ under design conditions[4].

As the instantaneous value of the dimensionless, parameters φ is related to the heat exchange performance of the buried tube, Characterization the capacity of the Import and export temperature difference of the buried tube heat exchange that can reach the maximum. Parameter σ is related to building air conditioning load and running efficiency of heat pump, which characterization of the impact of Building air conditioning load intensity and unit performance to buried tube heat exchange system. The two parameters common affecting the heat exchange coefficient of energy efficiency of the buried tube.

Model of Heat Pump Unit. Heat pump unit as the core component of ground source heat pump system, its' running conditions directly affect the performance of the heat pump system and energy consumption. For a given heat pump unit, inherent characteristics such as size, structure remains the same, the buried tube inlet water temperature T_{in} (the outlet water temperature of the Condenser) are mainly related to building air conditioning load and the unit performance coefficient, can be represented as:

$$T_{in} = \mathcal{F}(Q,\ COP) \tag{6}$$

Base on the experimental data of the ground source heat pump units product samples that use in actual project, the unit model under the summer conditions are fitting out, the expression is as follows:

$$COP = 0.001T_{out}^2 - 0.2016T_{out} + 10.108 \tag{7}$$

$$T_{in} = T_{out} + \frac{Q}{GC_p}\left(1 + \frac{1}{COP}\right) \tag{8}$$

Analysis of Heat Exchange Efficiency under Variable Temperature Inflow

Compared with constant buried pipe inlet fluid temperature, the generation of Variable temperature inflow conditions mainly depends on the change of building air conditioning load and the performance change of the heat pump unit, energy efficiency of heat transfer process also has its own characteristics, therefore it is necessary to analyze the influence law of buried tube heat exchange efficiency.

Influence of Structure Load Characteristics of Air Conditioning on Heat Exchange Efficiency. Building air conditioning load have big differences in load intensity and time because of the different use function, Selection of office buildings, hotels and residential air conditioning system which running 15 days in the summer as analysis object, the exhaust heat load of a single buried tube in a typical day shown in Fig.1, changes of buried tube heat exchange coefficient of energy efficiency, ratio of φ and σ under the variable temperature inflow are shown in Fig.2 ~ Fig.4.

It can be seen from Fig. 2 ~ 4, buried tube heat transfer efficiency E value, values of φ and σ changed with the cycle change of air conditioning load, the value of E and φ gradually reduce with the increase of running time, while the value of σ is increased. This is due to the increase of the geotechnical heat accumulation around the buried pipe which caused by the increases of the exhaust heat, this will reduce the thermal efficiency of the buried pipe. With the inlet water temperature of buried pipe gradually increased to design point (35℃), and then gradually greater than the design temperature, this will leads to the deterioration of the heat transfer condition; Although Increase the buried tube heat transfer temperature difference between water and rock mass around, to some

extent, can increase the heat exchanger (values of φ increase), the value of σ gradually weakened with the increase of time, therefore, the buried tube heat exchange effect reduced gradually with the increase of running time. Compared with office building and residential, load duration time of hotel building keep more intense, although at the beginning of the heat exchange, the coefficient of heat transfer efficiency keep basically the same, after five hours, the heat exchange efficiency of the hotel is below the offices and homes. And as there has no natural recovery time, long time running makes the thermal efficiency of the buried pipe lower. This suggests that the building load characteristics had a great influence on buried pipe heat exchanger, especially the projects which have long continuous running time. In order to ensure the running efficiency of the ground source heat pump system, it's need to guarantee a certain time to recover, so the composite ground source heat pump system is adopted.

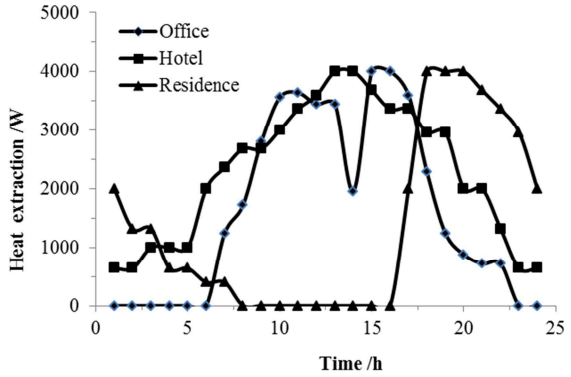

Fig.1 Characteristic curve of building air conditioning load

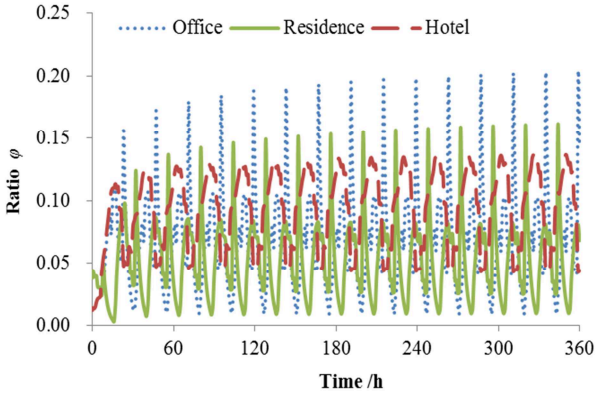

Fig.3 Effects of building load on values of energy efficiency φ

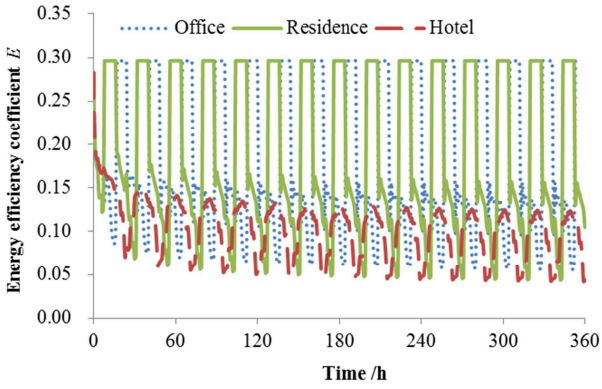

Fig.2 Influence of Building load to heat exchange efficiency of the buried pipe

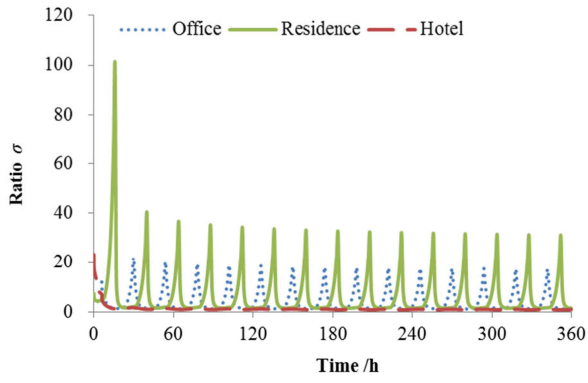

Fig.4 Effects of building load on values of energy efficiency σ

Influence of Flow on Heat Exchange Efficiency. In the process of buried pipe design, flow is one of the main parameters affecting the heat transfer effect. When the depth of the buried tube remains unchanged, the buried pipe inlet and outlet fluid temperature changed as the buried tube fluid flow changed. Fig.5 ~ Fig.7 shows the influence of circulating fluid flow velocity to the heat transfer coefficient, the ratio of φ and σ, the simulation operation condition is 0.6 m/s, 0.8 m/s and 1.0 m/s.

As can be seen from Fig.5 ~ Fig.7, the change rule of the buried tube heat exchange efficiency E value keep consistent under the conditions of velocity change, this is due to the change of velocity changing only import water temperature of the buried pipe, did not changes the heat resistance of the rock mass (different with the construction load intensity and duration time), it reveal the Consistent changing law with the literature [2].

The values of heat exchange efficiency φ gradually reduce with the increase of running time, while the value of σ is increased, this is due to the increase of the geotechnical heat accumulation around the buried pipe which caused by the increases of the exhaust heat, and the product is on the decline. When flow velocity under the working condition of 1.0 m/s, the water temperature that run

into the buried pipe is relatively low, the heat transfer temperature difference between buried pipe fluid and surrounding rock mass is reduced, the heat exchange intensity of buried tube is also weakened, the part of φ value is less than 0.6 m/s and 0.8 m/s conditions, and the part of σ value is on the contrary.

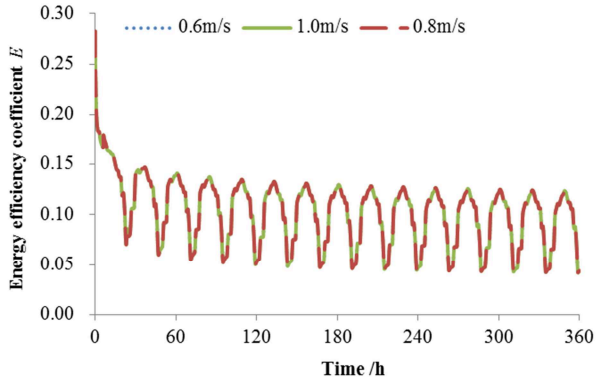

Fig.5 Velocity's influence on the buried tube heat exchange efficiency

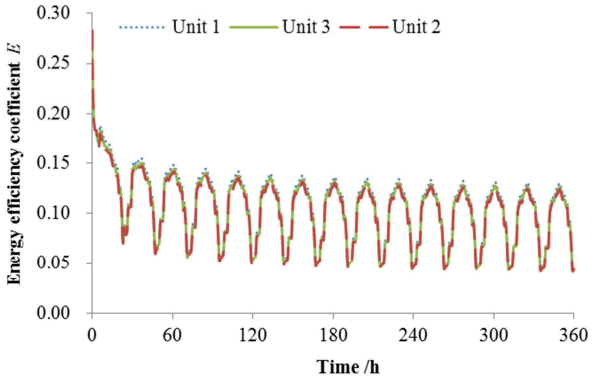

Fig.8 Unit performance's influence on the buried tube heat exchange efficiency

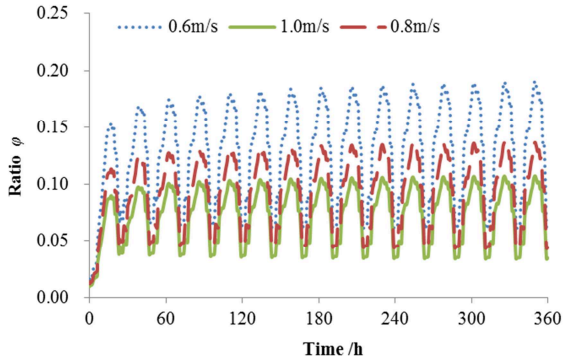

Fig.6 Velocity's influence on φ value of the energy efficiency

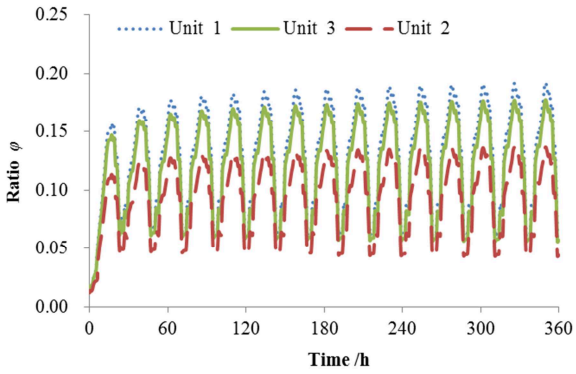

Fig.9 Unit performance's impact on φ value of energy efficiency

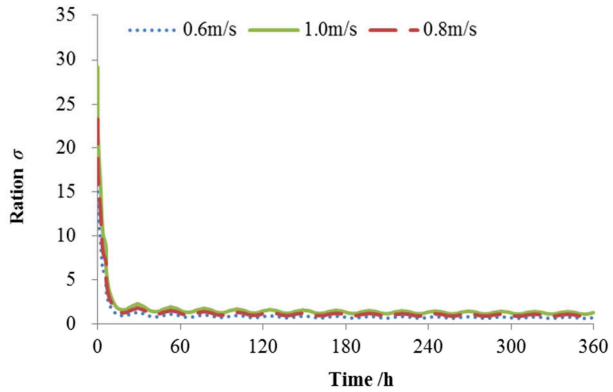

Fig.7 Velocity's influence on σ value of the energy efficiency

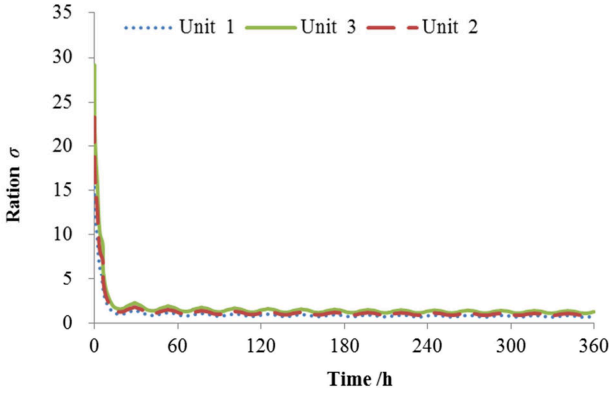

Fig.10 Unit performance's impact on σ value of energy efficiency

Influence of Heat Pump Unit Performance on Heat-Exchange Efficiency. Under different conditions of heat pump unit in type, cooling & heating capacity and manufacturer, its running efficiency is different, the buried pipe heat load are also different, which will affect the heat transfer process of buried pipe. Fig.8 ~ Fig.10 shows the influence of the performance of Heat pump unit on the heat transfer coefficient, the ratio of φ and σ, the simulation operation condition is unit 1: performance curve of formula (9), the unit 2: performance curve of formula (7), unit 3: performance curve of formula (10).

$$COP = 0.0012T_{out}^2 - 0.2347T_{out} + 11.768 \quad (9)$$

$$COP = 0.0009T_{out}^2 - 0.2346T_{out} + 11.763 \quad (10)$$

It can be seen from Fig.8 ~Fig.10, the change trend of the buried tube heat exchange efficiency E value keep consistent under the conditions of velocity change, but the values of the three conditions have small differences, this is due to the change of performance change the amount of the heat that released by buried pipe. For example, the changing of building load intensity and duration time change the heat resistance of the rock mass, this can lead to energy efficiency coefficient value is different. The values of heat exchange efficiency φ gradually reduce with the increase of running time, while the value of σ is increased, Just because the unit 1 is in better performance conditions, the heat transfer resistance of rock- soil is small, the heat transfer effect of buried tube Higher than that of unit 2 and unit 3 conditions are enhanced, so the unit performance is also the concerns during the design process of the buried tube heat exchanger.

Conclusion

Base on variation characteristics of heat transfer coefficient of energy efficiency under the variable temperature inflow condition, decomposed into the product of the ratio of biggest buried tube heat transfer temperature difference φ and heat pump outlet water temperature difference σ. Select the reasonable simulation conditions, three-dimensional heat transfer model of the u-shaped buried pipe that based on the theory of the multipolar are used to simulate the buried tube heat transfer process, the buried tube heat transfer coefficient, ratio of φ and ratio of σ main influence factors including the construction load, buried pipe flow, the unit performance are analyzed, and the changing rule with the time is also be study. The results show that the buried pipe flow does not affect the heat transfer coefficient of energy efficiency, only the ratio of φ and ratio of σ, and the intermittent changes of building air conditioning load, high efficiency of the unit can effectively enhance the heat transfer effect of buried tube, improve the running efficiency of ground source heat pump system.

Design of Virtual Corolla 1.6AT Automatic Air Conditioning Experiment Bench

Wenzi Gong

Wuxi Institute of Commerce Jiangsu Wuxi China 214153

gongwenzi1968@sina.com

Keywords: virtual; auto automatic air conditioning; experiment bench; working process; design

Abstract: This paper introduces a virtual experiment bench for automotive air conditioning. In the experiment bench based on the experiment bench for Corolla 1.6AT automatic air conditioning, the refrigeration, heating, gas distribution and other mechanical systems are removed and the electrical control system is reserved using the virtual and simulation theory. The experiment bench has the features, such as simple structure, low production and operation cost, safety and environmental protection; its main sensor signals are simulated through a variable resistance, the working processes of some actuators are shown by light bulbs, so that it is easy to operate the experiment bench, and the working process is visual and direct. The experiment bench can be self-developed, designed and produced by students under the guidance of teachers, thus to promote the comprehensive ability of students to use knowledge and innovate.

Introduction

With the wide application of electronic control technology in automobiles, automotive air conditionings in more and more automobiles, especially cars are controlled by microcomputer, and data transmission and communication between automobile control systems are done by buses, in order to achieve the coordinated operation of automotive air conditioning system and other systems [1]. At present, the experiment bench for automotive air conditioning is produced by real parts and components, not only including refrigeration, heating, gas distribution and control systems, but containing a motor system used to drive the compressor, so that the entire experiment bench is large, with high production costs, and has also an impact on the safety and environmental protection in experiment. The virtual experimental system can better address these problems above, and it is also easy to combine more than one system in a experimental platform, so that the interactive relationship between the systems can be clearly shown [2].

1 Basic working principle of microcomputer-controlled auto automatic air conditioning

Automotive air conditioning refers to the unit for control over the quality of air in cars. Its main function is to adjust the air temperature, humidity, flow rate, cleanliness, airflow pattern and intake patterns in cars, in order to improve comfort; its essential task is temperature adjustment. An automotive air conditioning is mainly composed of refrigeration system, heating system, gas distribution system and control system. The automotive air conditioning's refrigeration system enables the refrigeration medium stored in the confined refrigeration system through the engine driving the compressor to constantly circulate and makes its phase change to produce refrigeration effect, and each circulation has four processes: compression process, condensation process, expansion process, and evaporation process; in the condensation process, the refrigeration medium in the condenser turns into liquid from gas to dissipate heat outward; in the evaporation process, the

refrigeration medium in the evaporator turns into gas from liquid to absorb heat, thus reducing the temperature around the evaporator, while the blower blows the air through the evaporator into the car, so as to achieve the purpose of reducing the interior temperature [3]. The waste heat of the engine cooling water is generally used as a heat source of the automotive air conditioning's heating system; in buses or limousines, the waste heat from the engine cooling water and fuel or electrical interaction is used as a heat source, in order to improve the reliability of the heating system, and thus to achieve the purpose of quick heating.

The mechanical part of the microcomputer-controlled automatic air conditioning is consistent with ordinary air conditioning, and the main distinction is the control system of air conditioning. Its basic control theory is as follows: the interior set temperature, interior temperature, environment temperature, evaporator temperature, sun radiation strength, and pressure of the refrigeration system at high pressure end, engine water temperature and other signals are detected through various sensors or control panels; the displacement of the compressor at work (for electric controlled changed displacement compressor) or the pull-in and cutoff of compressor electromagnetic clutch is automatically controlled, and the blower speed and airflow way are regulated; meanwhile, data transmission and communication are completed through CAN-H line, CAN-L line and engine ECU and other control units, to enable the systems can coordinate, and thus to ensure that all the systems are in the optimum working conditions [4].

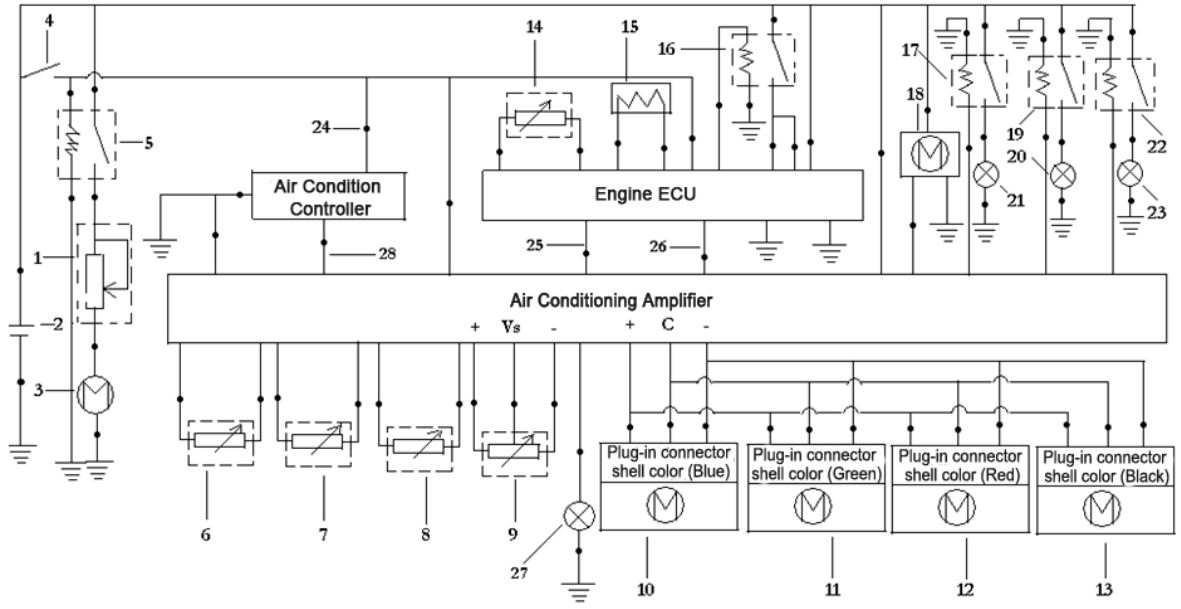
2 Overall programme and composition of the experiment bench

The experiment bench is a virtual integrated experiment bench for automotive air conditioning, and it is based on Corolla 1.6AT automatic air conditioning, without the complex mechanical systems such as refrigeration, heating and gas distribution, but with the air conditioning controller, engine ECU, air conditioning amplifier, sensors and actuators and other electrical components. The electrical components are installed at the positions as close as possible to the original places in cars, and a set of automotive air conditioning system with complete electrical systems and normal function displays is built. The entire system has the advantages, such as simple structure, small size, low costs, convenient detection and pollution-free[2].

As shown in Fig.1, this experiment bench is composed of slide rheostat 1, storage battery 2, DC motor 3, ignition switch 4, normally opened relay 5, indoor temperature sensor 6, air conditioning sunshine sensor 7, evaporator temperature sensor 8, pressure sensor 9, air mixing throttle servo motor with smart controller at driver side 10, air mixing throttle servo motor with smart controller at passenger side 11, vent throttle control servo motor with smart controller 12, intake throttle control servo motor with smart controller 13, water temperature sensor 14, speed sensor (crankshaft position sensor) 15, EFI main relay 16, No.1 PTC heating relay 17, blower motor with speed controller 18, No.2 PTC heating relay 19, No.2 PTC heater indicator light 20, No.1 PTC heater indicator light 21, No.3 PTC heating relay 22, No. 3 PTC heater indicator light 23, measuring terminal 24, CAN-H line 25, CAN-L line 26, air conditioning compressor indicator light with duty cycle controller 27, Lin line 28, air conditioner controller, engine ECU, and air conditioning amplifier[5]. The original installation positions of its main sensors and the roles are in the following: the pressure sensor 9 is installed on the high pressure end the refrigeration pipeline and is used for detection of the pressure of the refrigeration system at the high pressure end; the indoor temperature sensor 6 is installed inside the car and is used to detect the real temperature inside the car; the air conditioning sunshine sensor 7 is installed on the front windshield glass and is used to detect sunlight strength; the evaporator temperature sensor 8 is installed on the surface of the evaporator and is used to detect the temperature on the evaporator surface [5].

The indoor temperature sensor 6, air conditioning sunshine sensor 7, evaporator temperature sensor 8, pressure sensor 9, and water temperature sensor 14 are replaced by a variable resistor with an appropriate range of resistance value, and different resistor values can simulate corresponding signals. No.2 PTC heater working indicator light 20, No.1 PTC heater working indicator light 21, and No.3 PTC heater working indicator light 23 simulate the working process of the heater, and the heater is working when the lights are on. The air conditioning compressor indicator light with duty cycle controller 27 simulates the working process of the control electromagnetic valve of air conditioning compressor, and a different period of time for the indicator light in a cycle represents a different duty cycle. (Note: the compressor is an electrically controlled variable displacement compressor, the air conditioning amplifier controls the opening of the electromagnetic valve by the duty cycle, and different duty cycles enable the control electromagnetic valve to have a different opening, and the compressor has a different displacement.) CAN-H line 25 and CAN-L line 26 carry out data communication between the engine ECU and air conditioning amplifier; Lin 28 line conducts data communication between the air conditioning controller and air conditioning amplifier [5].

DC motor 3 turns through a homemade shaft-driven crankshaft signal gear, and the rotating crankshaft signal gear through the speed sensor (crankshaft position sensor) 15 provides the engine ECU engine with speed signal; the slide rheostat 1 is arranged below the throttle pedal, and interlocks with the throttle pedal; when stepping on the accelerator pedal, its resistance decreases, which in turn, its resistance increases, and the crankshaft signal gear speed that is, the engine speed rises; instead, its resistance increases, and the engine speed declines.



1-slide rheostat; 2-storage battery; 3-DC motor; 4-ignition switch; 5-normally opened relay; 6-indoor temperature sensor; 7-air conditioning sunshine sensor; 8-evaporator temperature sensor; 9-pressure sensor; 10- air mixing throttle servo motor at driver side; 11- air mixing throttle servo motor with smart controller at passenger side; 12- vent throttle control servo motor with smart controller; 13- intake throttle control servo motor with smart controller; 14-water temperature sensor; 15-speed sensor (crankshaft position sensor); 16-EFI main relay; 17- No.1 PTC heating relay; 18-blower motor with speed controller; 19- No.2 PTC heating relay; 20- No.2 PTC heater indicator light; 21-No.1 PTC heater indicator light; 22-No.3 PTC heating relay; 23-No.3 PTC heater indicator light; measuring terminal 24-; 25-CAN-H line 26-CAN-L line; 27-air conditioning compressor indicator light with duty cycle controller; 28-Lin line

Fig.1 Control schematic diagram

The air conditioning controller and the control panel with digital display are integrated, the function keys of the control panel are shown in Fig.2, and the information of the function keys is directly conveyed to the air conditioning controller and is transmitted to the air conditioning amplifier by the air conditioning controller through Lin line 28, to provide the air conditioning amplifier with driver's operating information; the related digital information is also transmitted by the air conditioning amplifier through Lin line 28 to the air conditioning controller and is displayed by the control panel with digital display[5].

Fig.2 Control Panel with digital display

3 Control functions of the experiment bench

This experiment bench takes Toyota Corolla 1.6AT automatic air conditioning as a template, by which the working processes of the automotive air conditioning systems and the intrinsic causal relationship between the systems can be displayed in an intuitive and eye-catching manner. It is very convenient to debug and detect this equipment, along with safety, economy and environmental protection.

3.1 Startup of the experiment bench

As shown in Fig.1, after the ignition switch 4 is closed, the engine ECU, air conditioning controller and air conditioning amplifier receive the signal of the ignition switch closed, and the control units begin to work. The engine ECU controls the switch touch of EFI main relay 16 to pull in, and to provide the engine ECU with working power supply; meanwhile, the switch touch of the normally opened relay 5 is pulled in, the DC motor 3 according to the position of throttle pedal turns with a certain speed, and the rotating crankshaft signal gear through the speed sensor (crankshaft position sensor) 15 provides the engine ECU engine with speed signal; the water temperature sensor 14 according to its adjusted resistance provides the engine ECU with engine water temperature signal. These signals above are passed to the air conditioning amplifier by the engine ECU through the CAN-H line 25 and CAN-L line 26.

3.2 Working process of the experiment bench

As shown in Fig.2, press down the AUTO key on the control panel and adjust the set temperature within the car through the TEMP key, and then the air conditioning controller through the Lin line 28 transmits the control key signal to the air conditioning amplifier; the indoor temperature sensor 6, air conditioning sunshine sensor 7, evaporator temperature sensor 8, and pressure sensor 9 according to their adjusted resistance provide the air conditioning amplifier with indoor temperature signal, sun radiation strength signal, evaporator temperature signal, and system pressure signal at high pressure end. According to the AUTO signal, TEMP control key signal and sensor signals, through analysis, calculation and processing, the air conditioning amplifier determines the optimal compressor displacement, temperature-regulated valve position, blower speed, airflow way, air intake mode and whether the heater works, and controls various actuators and indicator lights to work according to the set procedures, while the relevant digital information is displayed on the digital display on the control panel. Other keys on the control panel can shift from automatic mode to manual mode.

3.3 Measuring terminals are used for testing of relevant data, convenient for fault judgment, and detection and teaching needs[2].

Concluding remarks

This experiment bench takes Toyota Corolla 1.6AT automatic air conditioning as a template, the refrigeration, heating, gas distribution and other mechanical systems are removed and the electrical control system is reserved using the virtual and simulation theory. The experiment bench has the features, such as simple structure, low production and operation costs, and safety, environmental protection and economy in use; the main sensors are simulated with a variable resistance, so that it is more direct and convenient for teachers to teach and students to learn; light bulbs as actuators enable the whole process to be more visual and direct, thus improving the teaching effect [(2)]. Under the guidance of teachers, students participate in the design and production of the experiment bench, which can stimulate and improve students' innovative consciousness and ability.

Keywords: closed cooling tower; packing; structure; thermal performance

Abstract. Three different structural types of closed cooling tower (CCT) and two cooling water flow directions were considered. The experimental study were done on the cooling performance of influences of inlet air dry and wet bulb temperature, cooling water flow rate and inlet temperature, air flow rate and spray density. The experimental results show that the cooling performance of CCT with packing is obviously better than non-packing cooling tower in 7%~18.4%. And the cooling performance of CCT with packing on top and coil underneath is slightly better than CCT with coil on top and packing underneath in 4.9%. In the same conditions the cooling performance of CCT with packing under cooling water cocurrent-flow is better than that cooling water countercurrent-flow in 3.2%~9.6%. Therefore, the closed cooling tower structure with the cooling water path in bottom and out top, and with packing on top and coil underneath is recommended.

Introduction

Compared with other conventional heat transfer equipment, cooling tower is a relatively inexpensive and dependable heat rejection device combined with energy-saving water cooling type cooler and cooling tower. Therefore, it is widely used for dissipating heat from the system of water-cooledrefrigeration, air-conditioning, power plants and other industries[1.2.3].

The closed cooling tower (CCT) maintains an indirect contact between the cooling water and the atmosphere. Many researchers have made great progress in the theoretical and experimental study of CCT. Sarker et al.[4] hintedthatthe heat and mass transfer process in a CCT was dominated by the moisture exchange between water and air to give out the medium heat inside coil. A.Hasan and K.Sirén [5] claimedthat the heat and mass transfer coefficient of finned tubesin CCT was greater than that of plain circular tubes. A.Hasan and K.Sirén[6]also obtained the empirical formulas of mass transfer which were suitable for plain circular tube and oval tube in CCT. However most of the researches are about non-packing cooling tower, the related research literature about CCT with packing and coil is rare. P.J.Erens [7] added plastic packing into the evaporative type cooler and found that it could significantly enhance the thermal performance of evaporative type cooler with smooth round tubes. In comparison with conventional non-packing cooling tower, experimental study will be done on the performance of CCT with packing and coilin this paper.

Experimental apparatus and CCT structures

The schematic of the experimental installationis shown in Fig.1. It is mainly composed of air dispose system, experimental apparatus and automatic data acquisition system. The air dispose system supplies appropriate air parameters during experiment. It consists of surface air coolers, heater, fan, vapor humidifier and so on.

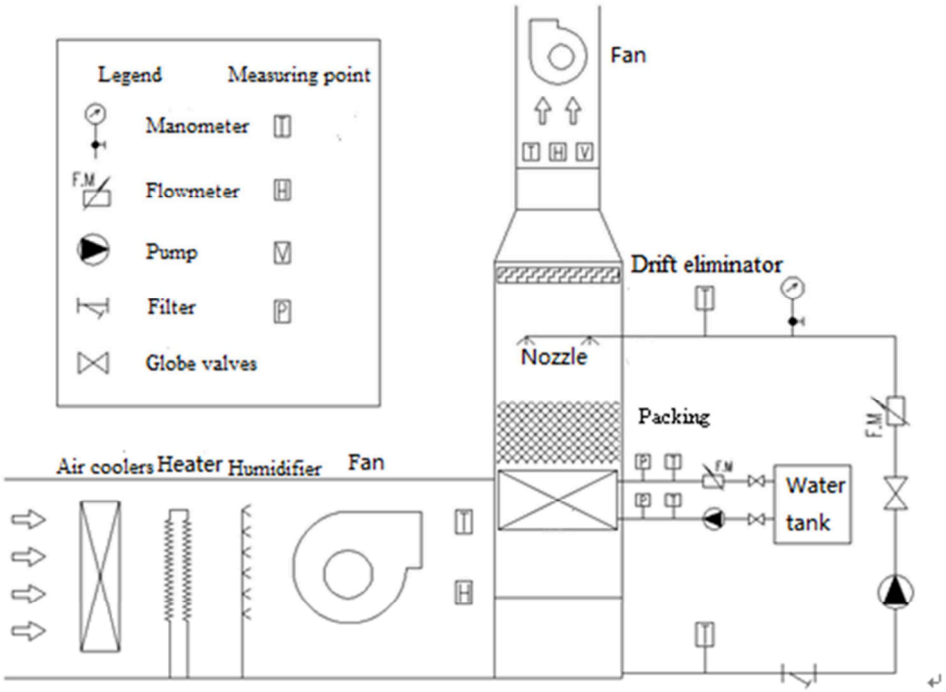

Fig.1 Principle diagram of the CCT experimental installation

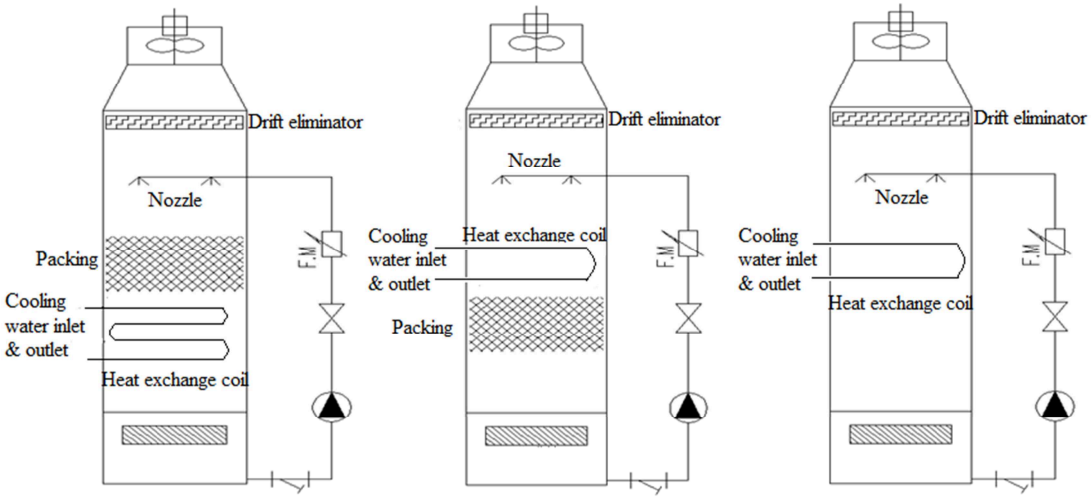
The shell of CCT unitwas made of transparent organic glass so that one can clearly observe water distribution and water film flows inside the CCT. In order to improve the heat and mass transfer efficiency, PVC plastic oblique wave alternating packing was chosen inthis experiment.

Three different structural types of CCT were discussed in the experiment. Shown in Fig.2,Tower 1 isCCT with packing on top and coil underneath, Tower 2 is CCT with coil on top and packing underneath, and Tower 3 is non-packing cooling tower.



(a) Tower 1 (b) Tower 2 (c) Tower 3

Fig.2 Three structural types of CCT

The heat exchange process of CCT is complex, involving heat and mass transfer and flow, which are affected by many factors.In this paper the influence of the factors such as the dry and wet bulb temperatures of inlet air, cooling water flow rate and direction and its inlet temperature, air flow rate, spray density on the process of CCT is investigated. The research method was that keeping other parameters constant and only set one of the varying parameters at different values.

Results and discussions

The effects of cooling capacityand cooling efficiency were investigated experimentally. Cooling capacity can be analyzed and calculated according to following equations:

$$Q_c=m_c c(t_{c,in}-t_{c,out}) \quad (1)$$

$$Q_a=m_a (h_{a,out}-h_{a,in}) \quad (2)$$

$$\varepsilon =(Q_c-Q_a)/Q_c \times 100\% \quad (3)$$

The heat balance of the apparatus could be claimed to be satisfactory whenthe thermal equilibrium error ε is inhered within ±15%.

The cooling efficiency is defined as following [8]:

$$\eta=(t_{c,in}-t_{c,out})/(t_{c,in}-t_{a,wet}) \quad (4)$$

The influence of air wet bulb temperature. The cooling water flow , air flow and spray density were kept inconstant, and the inlet temperature of cooling water was kept in 38.4℃,changing the air web bulb temperature, the cooling water outlet temperature, cooling capacity and cooling efficiency were observed. If inlet air relative humidity was kept in 76.7%, experimental results were shown in Fig. 3. If inlet air temperature was kept in 31.5℃,experimental results were shown in Fig.4.

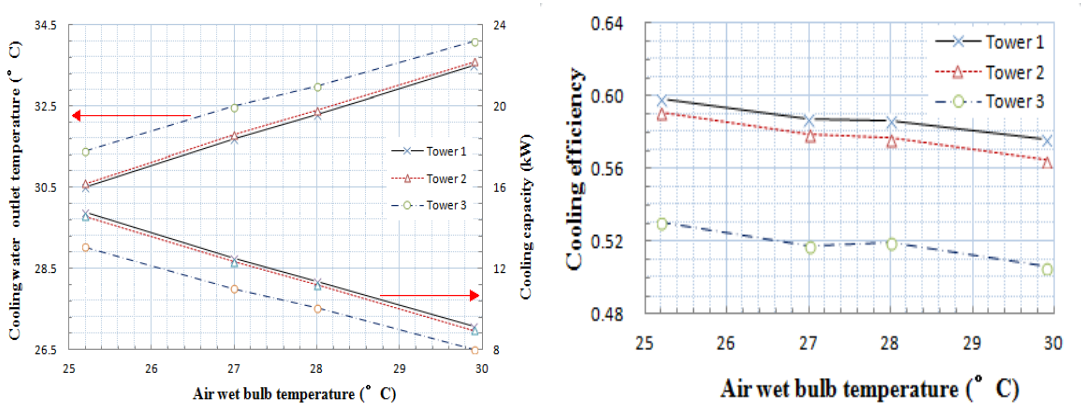


Fig.3 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. air wet bulb temperature (inlet air relative humidity constant)

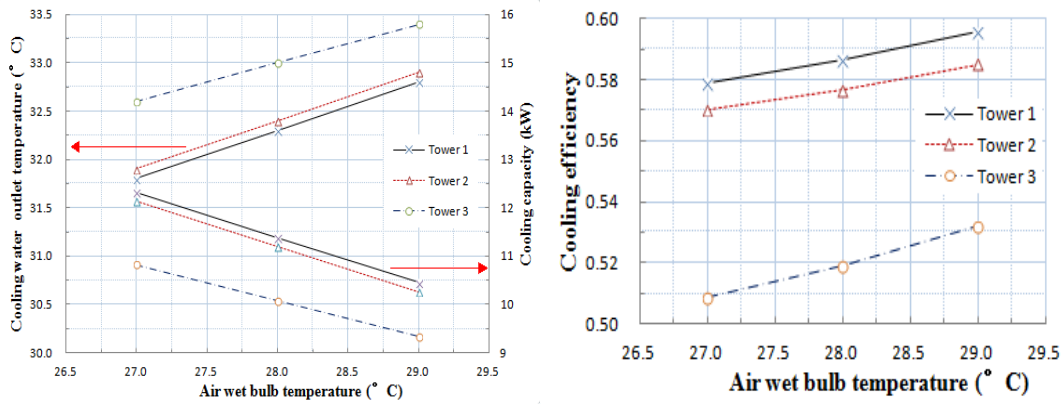

Fig. 4 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. air wet bulb temperature (inlet air temperature constant)

The influence of air dry bulb temperature. Keeping the air wet bulb temperature in 28℃. Other conditions same as above. Changing the air dry bulb temperature, the cooling water outlet temperature, cooling capacity and cooling efficiency were observed. Experimental results were shown in Fig.5.

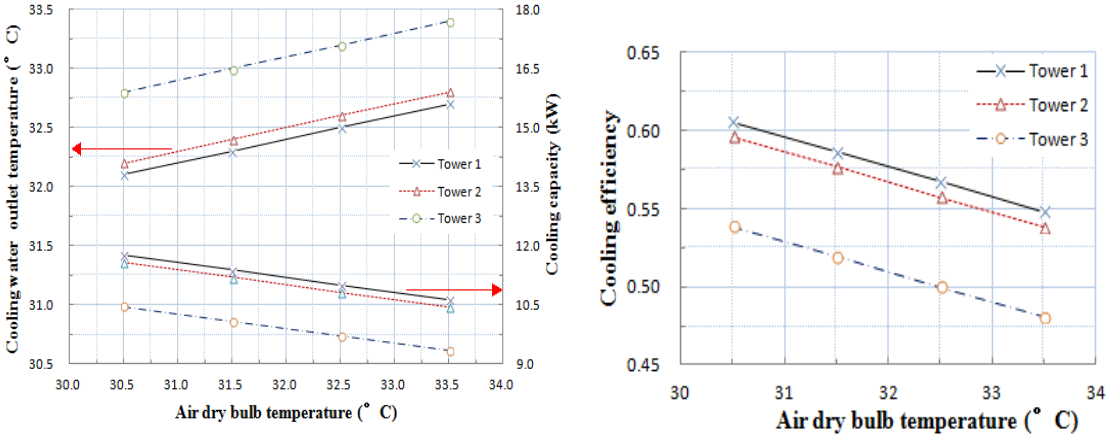

Fig. 5 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. air dry bulb temperature

The influence of cooling water flow rate and inlet temperature. Keeping the inlet air temperature in 31.5℃, air wet bulb temperature in 28℃. The cooling water flow rate and inlet temperature were changed respectively. Experimental results were shown in Fig.6 and Fig.7.

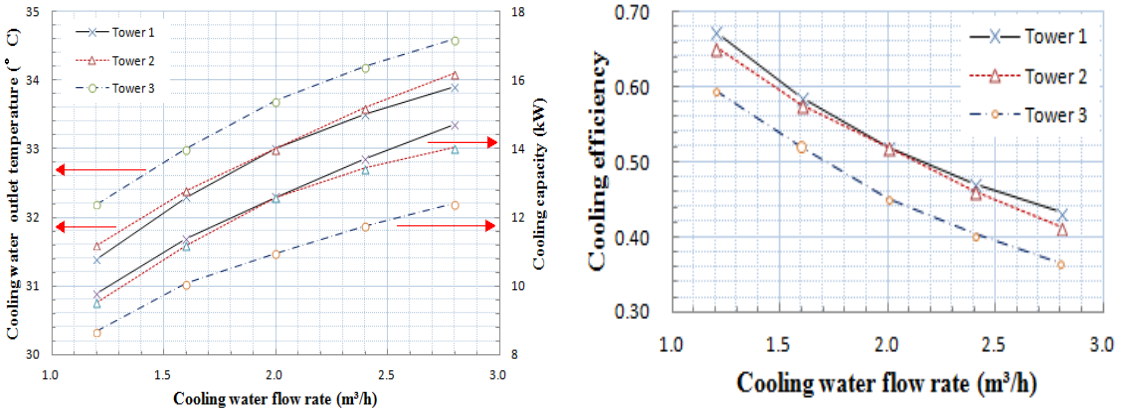

Fig. 6 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. cooling water flow rate

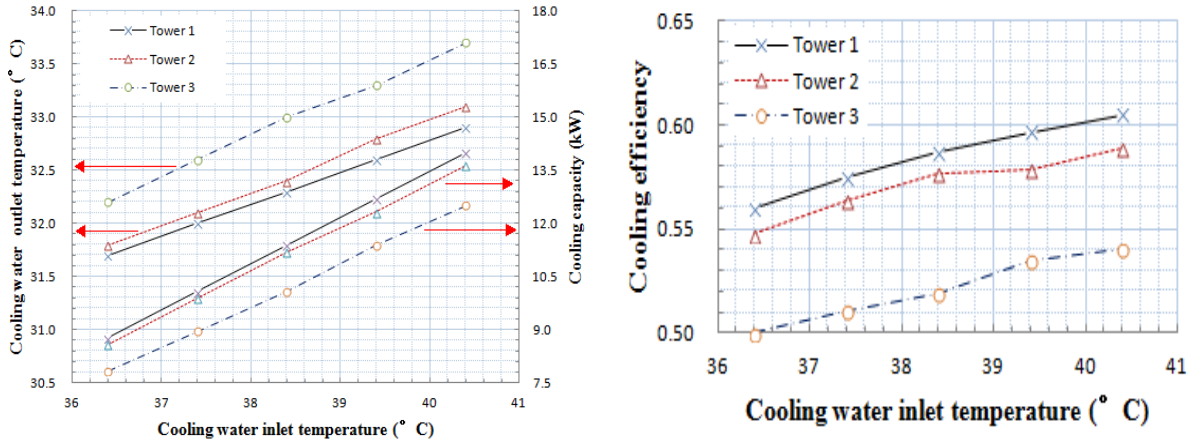

Fig. 7 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. cooling water inlet temperature

The influence of air flow rate. The air flow rate was changed by fan frequency changer. The other conditions were kept as the same as the above. Experimental results were shown in Fig.8.

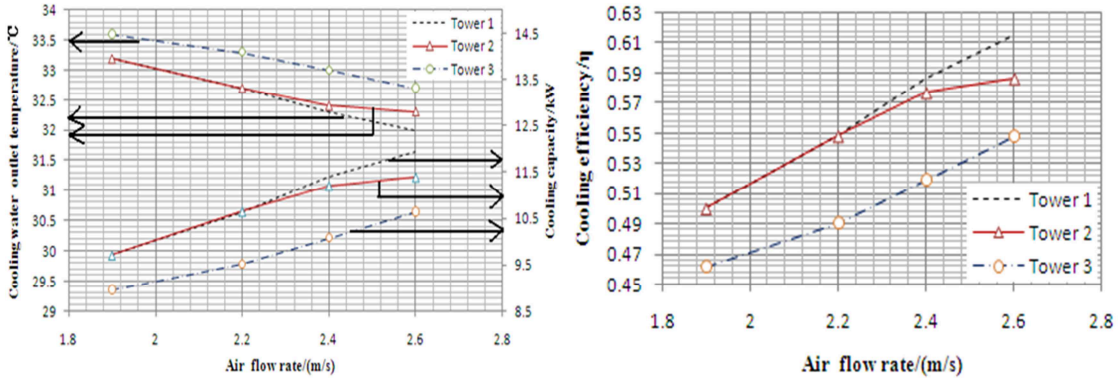

Fig. 8 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. air flow rate

The influence of spray density. The spray water was controlled by pump. The spray density was changed by changing pump frequency. The other conditions were kept as the same as the above. Experimental results were shown in Fig.9.

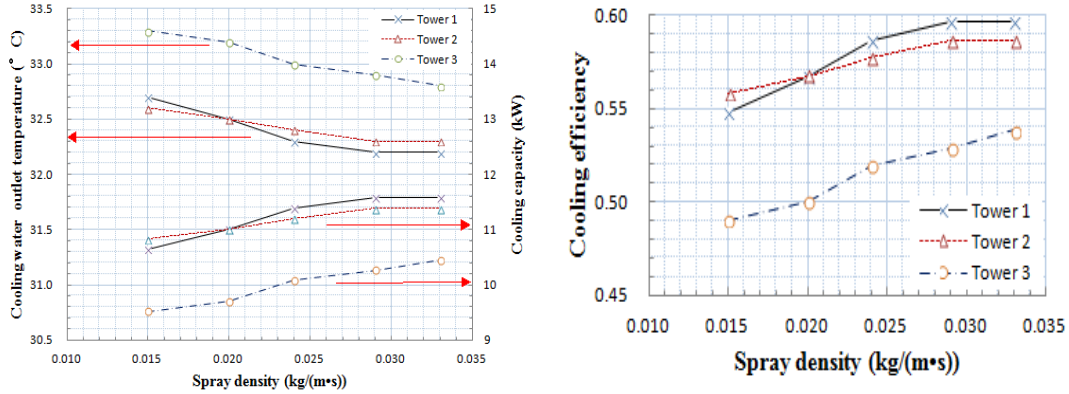

Fig. 9 Cooling water outlet temperature, cooling capacity, cooling efficiency w.r.t. spray density

Fig.3 to Fig.9 shows that decreasing the air dry and wet bulb temperature are good for enhancing the cooling capacity as well as cooling efficiency, while increasing cooling water inlet temperature, air flow rate and spray density. The air flow rate and air wet bulb temperature are the most important influence on cooling capacity.And the air dry bulb temperature is the least. As to the spray density, when it is low, the influence is relatively great, and with the spray density is increasing to an optimal value, the influence is getting to be neglected. The optimal spray density is about 0.025~0.035kg/m.s.

Fig.8 shows that the air flow rate is greater, the cooling performance of Tower 1 is better. But the fan power is also increased. Therefore air flow rate 2.5~3.5m/s is better.

It is worth noting that the cooling water outlet temperature, cooling capacity and cooling efficiency of Tower 1 and Tower 2 have alternating process, as shown in Fig.9. For example, when the spray density is 0.015 kg/(m·s), the cooling performanceof Tower 1 is slightly worse than that of Tower 2, when the spray density is about 0.020kg/(m·s), the cooling performance of Tower 1 and Tower 2 is approximately the same, but if the spray density goes on increasing, the cooling performance of Tower 1 is slightly better. Therefore, Tower 1 works better than Tower 2 when the spray density more than 0,020 kg/(m·s), and Tower 3 is the worst in all cases because of lack of packing.The cooling performance of Tower 1 and Tower 2 is better than Tower 3 in 7%~18.4%. And the cooling performance of Tower 1 is slightly better than Tower 2 in 4.9%. Therefore, Tower 1 is considered the best in cooling performance.

The influence of cooling water flow direction. According to the type of flow directions of thecooling water inside the heat exchange coil and air outside the coil, closed cooling tower can be divided into two types, i.e. countercurrent-flow and cocurrent-flow. Countercurrent-flow refers to the type that flow directionof cooling water is just the opposite of the air flow, so the cooling water pathway is of top in and bottom outas shown in Fig.2 Tower 1;while cocurrent-flow refers to the typethat cooling water and air flow in parallel with the same direction, andthe cooling water path is of bottom in and top out.

The influence of the cooling water flow direction on the cooling capacity is observed on Tower 1, under the condition of differentair dry and wet bulb temperature, cooling water flow rate, cooling water inlet temperature, air flow rate and spray density. The experiment is also operated in the sameexperiment platform, the experimental data of countercurrent-flowhas been obtained from the aboveexperiments, and the experimental results of cocurrent-flow were shown in Fig.10 ~ Fig.12.

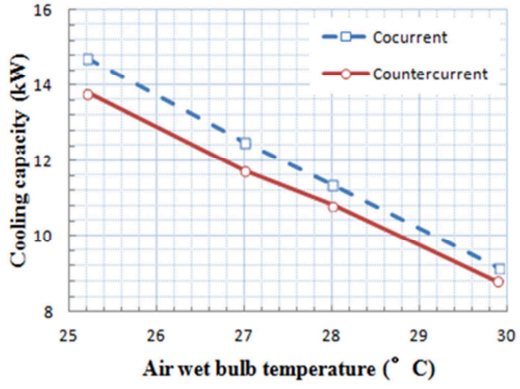

Fig. 10 The influence of air wet bulb temperature

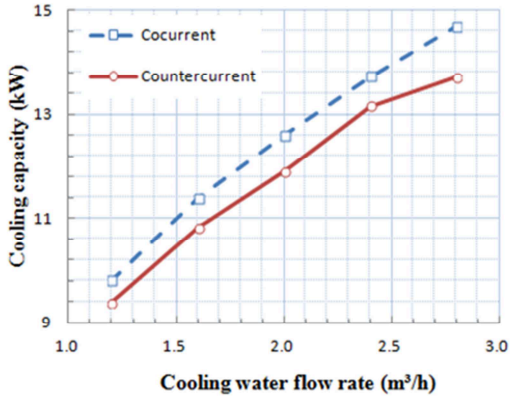

Fig.11 The influence of Cooling water flow rate

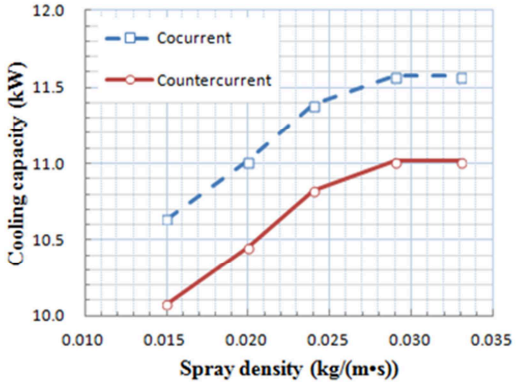

Fig.12 The influence of spray density

From Fig.10 to Fig.12 shows that, in the same conditions, the cooling capacity of concurrent-flow is greater than that of countercurrent-flow 3.2%~9.6%. Therefore, cocurrent-flow is better than countercurrent-flowfor enhancingcooling performance.

Conclusions

Based on three structural types of closed cooling tower, the effects of seven parameters on cooling performance are investigated. Theresults as follows:

a) To enhance the cooling performance in the three types of closed cooling tower, the air flow rate and wet bulb temperature contribute the most, and the air dry bulb temperature contributes the least. The optimal spray density is about 0.025~0.035kg/m.s. And 2.5~3.5m/s air flow rate is better.

b) The cooling performance of CCT with packing is obviously better than non-filler cooling tower in 7%~18.4%. And the cooling performance of CCT with packing on top and coil underneath is slightly better than CCT with coil on top and packing underneath in 4.9%.

c) The cooling water flow direction has a great influence on cooling performance. The cooling capacity of concurrent-flow is greater than that of countercurrent-flow 3.2%~9.6%.

Therefore, the best structure of closed cooling tower is the cooling water path in bottom and out top, and with packing on top and coil underneath.

Keywords: coal mine, air fully developed, air measuring station, numerical simulation

Abstract. The optimized air measuring station location of mine airway based on air fully developed was proposed and numerical tests were conducted with six models. The independence of air fully development and inlet velocity was analyzed which validated the models and the numerical methods. The results show that optimized air measuring station location in head entry is 132m-198m after the airway turning while 5.0m-10.1m before the airway turning in tail entry.

Introduction

Mine ventilation is one of the important technical means to ensure production safety of coal mine, in which the accurate determination of ventilation parameters is the basic work [1]. Air measuring uses the combination of artificial measuring with mechanical air flow meter and real-time monitoring with air velocity transducer in China's coal mines. In order to obtain the more accurate ventilation parameters, air measuring stations are installed in the main mine airways. According to the method described about air measuring station in reference [2], the main mine airways shall establish air measuring station, and air measuring station should be located in the flat airway; in order to ensure the measuring accuracy of air, the partial resistance may not be around the air measuring station within the range of 10m, such as obstacles, airway turning, etc.

Field air measuring show that some air measuring station' locations are not reasonable. Without any other changes, there have different results with the same air measuring worker in the different locations of an air measuring station. Fluid dynamics show that the flow parameters are changeless along the flow direction in the fully developed region. When the air measuring station is located in the fully developed region of the mine airway, there can obtain the consistent data in arbitrary cross section of the airway in air measuring, which can improve the measurement accuracy of air flow. Based on this idea, numerical tests of air measuring station location optimization in head entry and tail entry of coal face are conducted in order to obtain more reasonable air measuring station location.

Physical Models

The physical model based on some actual coal mine faces is shown in Fig.1. The model consists of two vertical airways, No.1 and No.2. When simulating the airway turning after the air measuring station, No.1 airway is regard as tail entry and No.2 airway as section outtake. When simulating the airway turning before the air measuring station, No.2 airway is regard as head entry and No.1 airway as section intake. The lengths of the two airways are 250m and 300m which are shown in Fig.1, and there have the same width (W) and height (H) of the two airways. Six models are designed, and whose sizes of width and height are shown in Table 1.

Table 1 Sizes of the six models

Model	Width[m]	Height[m]	Model	Width[m]	Height[m]
model 1	3	3	model 4	5	3.6
model 2	4	3	model 5	5	4.2
model 3	5	3	model 6	6	4

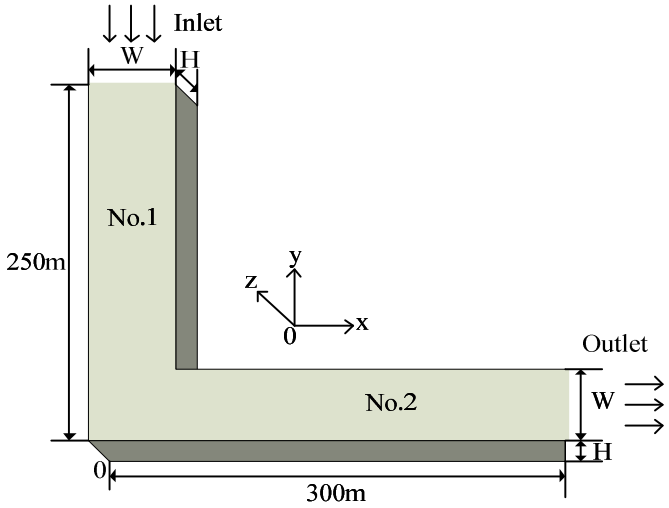

Fig.1 Schematic of physical model

Numerical Methods

Numerical tests are conducted using FLUENT software.

Mesh Generation. Mesh is generated by GAMBIT. A uniform structured grid with grid step 0.2m is used in airway cross section. A boundary layer non-uniform structured grid is used in air flow direction with the minimum grid step 0.2m, and the grid numbers in y and x direction are 250 and 300, respectively.

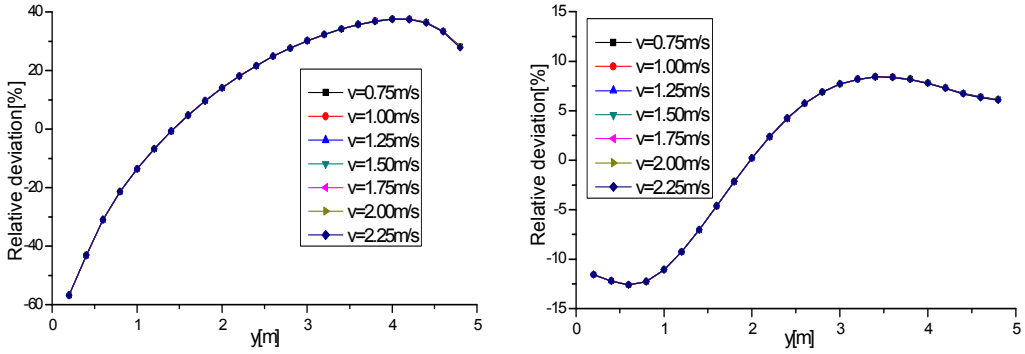
Parameter Setting. The fluid of the airway is air. Based on field testing data, the air density is set as 1.2kg/m^3 with the dynamic viscosity 1.44×10^{-5}kg/(m.s). The roughness height of the airway inner wall is set as 0.04m with roughness constant 0.8.

Boundary Conditions. Inlet condition: air velocity v=constant; Roof, floor and side wall of airways: wall; outlet condition: outflow.

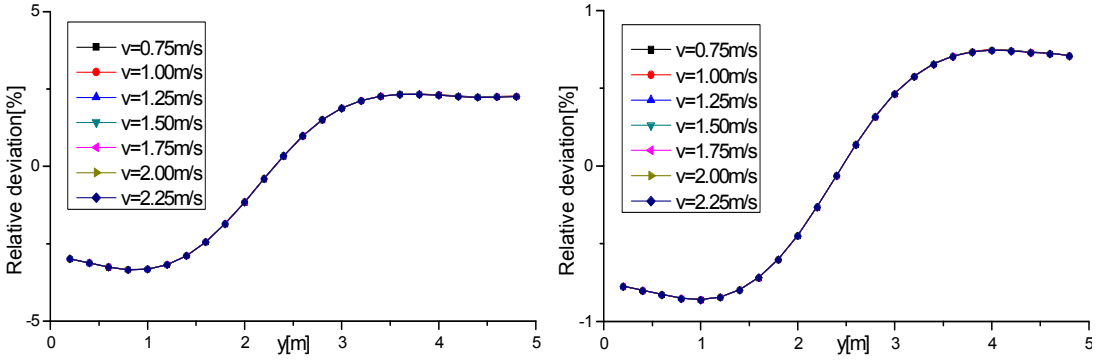
Computational Model and Algorithm. The k-e turbulence model is used in air flow computation. The coupling between pressure and velocity is implemented by the SIMPLE algorithm and the convection term is discretized by the SUD (Second-order Upwind Difference) scheme. The convergence criteria is residual values of all variables are reduced to less than 2×10^{-6}.

Model and Methods Validation

Numerical tests of model 3 are conducted at different inlet air velocity which are 0.75m/s, 1.0m/s, 1.25m/s, 1.5m/s, 1.75m/s, 2.0m/s, 2.25m/s. The horizontal center line's velocity gradient of each node at different airway cross sections(x=20m, x=70m, x=120m, x=170m, x=270m) in different inlet air velocity are extracted to analyze the results. Taking the results at x=270m as the benchmark (where in the fully developed region), the velocity gradients of same location's relative deviation comparison at different air inlet velocity are shown in Fig.2.



(a) x=20m (b) x=70m



(c) x=120m (d) x=170m

Fig.2 Relative deviation VS inlet air velocity

Fig.2 show that there have the consistent relative deviation at different inlet air velocity and the relative deviations decrease gradually along the air flow direction. The independence of air fully development in airway and inlet air velocity validates the physical model and the numerical methods.

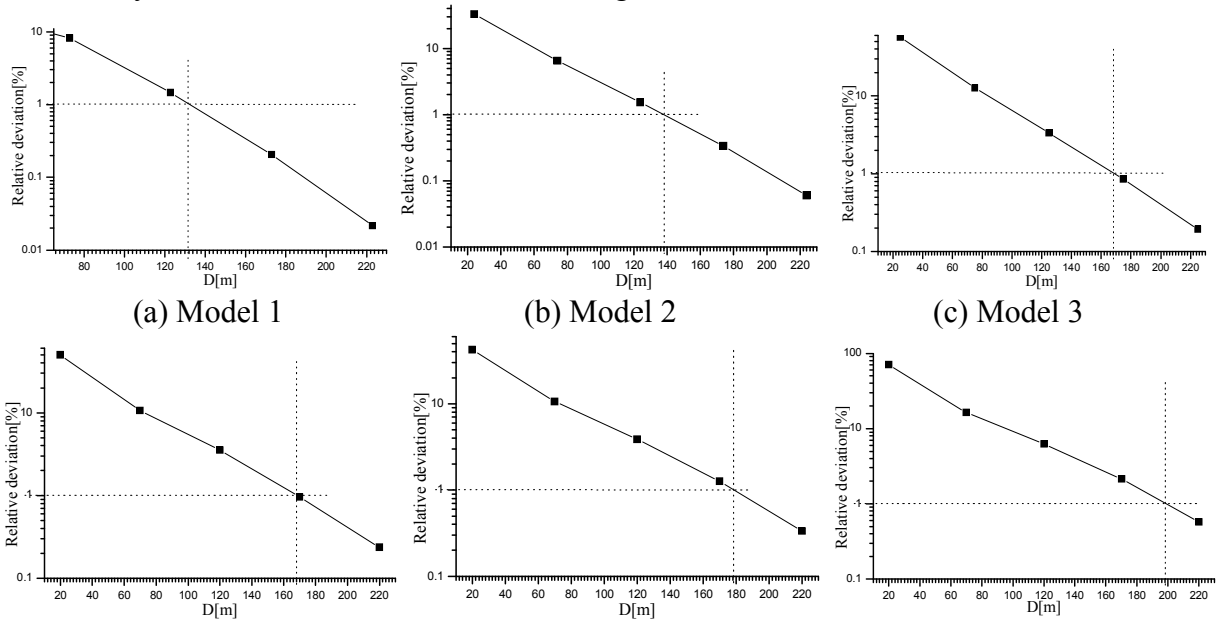
Results

Numerical tests are conducted with the inlet air velocity v=1.5m/s in different models. According to the actual situations of coal mine airway, air fully developed flow is defined as Eq.1.

$$|\max((vx-vf)/vf)|<1\%. \quad (1)$$

Where, vx is the velocity gradient of one of the node in analysis cross section, while vf is the corresponding node in reference cross section which in air fully developed region.

Results of head entry and tail entry are shown in Fig.3 and Fig.4, where the abscissa is the distance between analysis cross section and the corner in Fig.1.



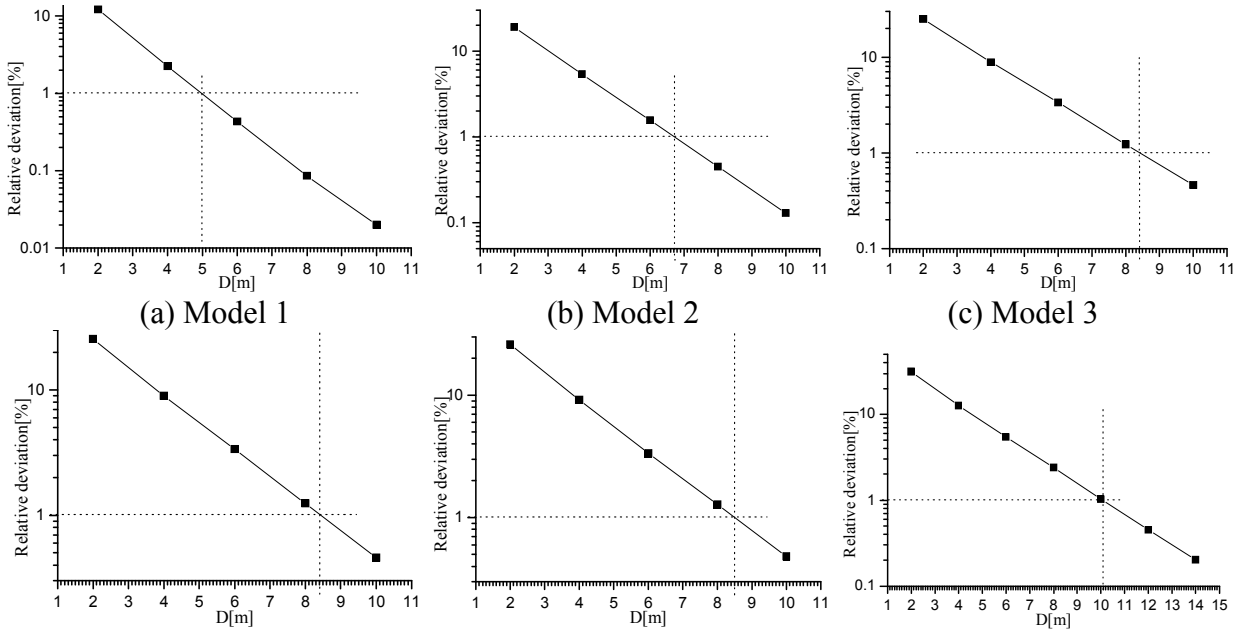
(a) Model 1 (b) Model 2 (c) Model 3

(d) Model 4 (e) Model 5 (f) Model 6

Fig.3 Results of air measuring station location in head entry

In Fig.3, the reference cross section is the cross section x=270m and the analysis cross sections are x=25m, x=75m, x=125m, x=175m and x=225m. In Fig.4, the reference cross section is the cross section y=70m and the analysis cross sections are y=7m, y=9m, y=11m, y=13m, y=15m, etc.

Fig.3 and Fig.4 show that the distance between the optimized air measuring station and air inlet/outlet increase with the increasing cross-sectional area, and air fully developed location at head entry in different models are range from 132m to 198m after the airway turning while range from 5.0m to 10.1m before the airway turning in tail entry.



(a) Model 1 (b) Model 2 (c) Model 3

(d) Model 4 (e) Model 5 (f) Model 6

Fig.4 Results of air measuring station location in tail entry

Conclusions

The major findings are summarized as follows.

1) The air measuring station of mine airway should be located in air fully developed region.

2) The optimized air measuring station location at head entry in computational models are range from 132m to 198m after the airway turning while 5.0m-10.1m before the airway turning in tail entry.

Keywords: UFAD, part-load, Fluent simulation, maximum (minimum) limit, optimal air parameters

Abstract. The air conditioning system did not run as the design conditions in most of the time. Therefore, how to rationally adjust air parameters under part-load conditions caused by changes in the outdoor environment is an important issue, which is crucial to people's comfort and energy systems. This paper introduces the part-load rate α to distinguish among different load-part conditions. And by taking the typical conditioned space of underfloor air distribution (UFAD) system in perimeter zone of New Tianjin Library as the object and using Fluent for simulation analysis, we get the conclusion that there is a maximum limit of supply air temperature and a minimum limit of supply air velocity under summer part-load conditions. For each condition, there is a set of optimal air parameters to make the indoor personnel achieve the most comfortable condition. Finally, we acquire this set of optimal air parameters by simulating and analyzing.

Introduction

In recent years, underfloor air distribution (UFAD) system has been widely studied and gradually used in office buildings, commercial buildings and other public buildings in China due to its advantages of high flexibility, comfort and energy efficiency. However, as the later application of this system in China and incomplete design specifications, there are still some problems in engineering design, operation of regulation and so on. This paper aims to estimate the best energy saving operational parameters of supply air and meanwhile ensuring comfort by simulating reasonable air parameters under part-load operating conditions with CFD simulation software. The simulation is carried out on a selected typical conditioned space of UFAD system which combines the actual project in Tianjin.

Typical room selection

Tianjin New Library is a comprehensive large public library. With consideration of the air conditioning energy efficiency and decorative effects, the library uses the UFAD air conditioning system in the study room, reading area and shared space in the public areas where are tall and diverse [1].

A typical conditioned room in the perimeter zone on the third floor was selected for simulation study. This room is a reading area, its east facade is glass curtain wall, and rest of the other walls is interior wall (adiabatic wall treatment). The master drawing of this room model is shown in Fig. 1, and the specific parameters are as follows:

The room is rectangular with dimensions of 10.2m × 10.2m × 5.85m (length × width × height); there are 20 air outlets on the floor, and the diameter D = 200mm; there are 2 air inlets in the ceiling with the size of 0.8m × 0.32m. The left air inlet is of 4.5m from the west exterior wall and 6.4m from the north exterior wall; the right air inlet is of 8m from the west exterior wall and 4m from the north exterior wall. We assume that there are total 15 staffs in the room: 10 people sit near eastern exterior wall and the other 5 people stand at the rest of the area. 10 fluorescent lamps have been situated at a height of 4.5m of the room. We also assume that the body heat quantity Q = 75W / person, and the fluorescent lamp heat quantity Q = 200W / light [2].

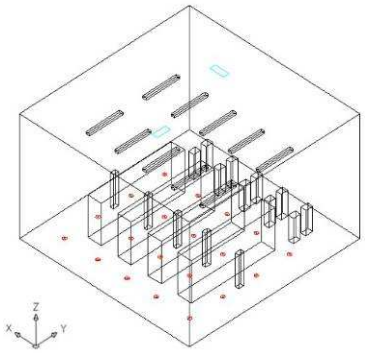

Figure.1 Master drawing of external room model

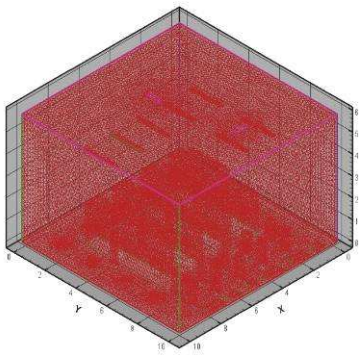

Figure. 2 Meshing Schematic of external room

Boundary conditions settings

It is difficult to build detailed models as the shapes of bodies, shelves and lamps in the actual room are complex. Therefore, in order to derive the simulation result, they are simplified to reduce the number of the mesh division to decrease computing cost and maintaining accuracy. The simplified models and the corresponding thermal boundary conditions are shown in Tab. 1.

Table.1 Simplified model and the thermal boundary layer settings

Type	Size	Setting boundaries	Remark
fluorescent lamp	2 m×0.2 m×0.1 m	q(heat flux)= constant	161.29 W/㎡
People standing	0.3 m×0.2 m×1.6 m	q = constant	45.18 W/㎡
People sitting	0.4 m×0.3 m×1.2 m	q = constant	41.67 W/㎡
Bookcase	5 m×0.8 m×2 m	q = constant	—
East exterior wall	—	q = constant	Setting based on the specific circumstances of different load
Interior wall	—	Adiabatic treatment	—

Establishment of radiation and numerical model

In the numerical simulation of the room, the radiation model is used to make the model closer to reality. DTRM model is used in this paper.

Tetrahedral mesh structure has been used to divide bodies, fluorescent lamps, air outlets and air inlets with refined mesh. Hybrid mesh has been used to divide the rest parts. The mesh division diagram of typical room at conditioned perimeter zone is shown in Fig. 2. As the problem in this study is incompressible flow problem, it can be solved with Segregated solver. Second Order Upwind format is used to deal with the discrete processing equation and SIMPLE algorithm is used to solve the discrete equations. Standard k-ε model, standard wall function and Bohemia Metalurh (Boussinesq) assumptions are also used. In the room model, boundary conditions of air outlets are velocity-inlet, and the air velocity of all the outlets are the same. Boundary conditions of air inlets are outflow. The rest of the facades are insulated walls. At the same time, each wall meets the no-penetration conditions and no-slip condition

Numerical simulation of summer part-load operating conditions

Under a certain load, the relationship between supply air volume and temperature difference of supply air is as follow：

$$V = \frac{Q_x}{c_p \rho \Delta t} \quad (1)$$

where V (m^3/h) is calculation supply air volume of the room; Q_x (kw) is calculation cooling load of the room; ρ (=1.2kg / m^3) is air density; c_p (=1.01 KJ/(Kg • ℃) is specific heat at constant pressure and Δt (℃) is the temperature difference between supply air and return air.

From the equation (1), it can be seen that there is a certain functional relation between supply air temperature and supply air volume. When outlet density and cooling load are determined, the change of supply air temperature can cause the change of supply air velocity. In summer, when the system is under part-load conditions, in order to meet the indoor environment and people's comfort when the load decreases, it is necessary to reduce supply air velocity to maintain the supply air temperature constant, or increase supply air temperature to maintain supply air velocity constant. And when maintaining supply air velocity as designing supply air velocity v_{design}, the correspond supply air temperature is the maximum supply air temperature t_{max} under this load condition; similarly, when maintaining supply air temperature as designing supply air temperature t_{design}, the correspond supply air velocity is the minimum supply air velocity v_{min}, under this load condition. The design supply air temperature of New Tianjin Library in summer is 19.2℃, the design supply air velocity in summer is 0.96m/s; based on these, this paper studies the effects of indoor environment and people's comfort under different supply air parameters and part-load conditions in summer.

Part-load operating conditions settings

In the study of system in part-load conditions, the part-load rate is used to distinguish among different load-part conditions, where the part-load ratio is the ratio of the actual running load and the design load, expressed by α, where $0 < \alpha \leq 1$. Assume that $0.4 \leqslant \alpha \leqslant 1$, operating point is established on each interval of 0.5 and there are total of 13 kinds of conditions. From equation (1), the maximum air supplying temperature t_{max} and the minimum air velocity v_{min} in the part-load conditions can be obtained. Then supply air parameter ranges in summer part-load can be also obtained, which is shown in Tab. 2.

Simulation parameters of supply air are chosen based on Tab. 2. Taking condition 7 for an example, supply air parameter is shown in Tab. 3, where the part-load factor α is set to be 0.70. The other 12 conditions are all set in the same way based on Tab. 2.

Table.2 Supply air parameter limits and ranges in summer part-load conditions

Conditions	Part-load ratio α	t_{max} (℃)	v_{min} (m/s)	Temperature ranges (℃)	Velocity ranges (m/s)
1	1.00	19.20	0.96	—	—
2	0.95	19.38	0.94	19.20—19.38	0.94—0.96
3	0.90	19.47	0.92	19.20—19.47	0.92—0.96
4	0.85	19.53	0.90	19.20—19.53	0.90—0.96
5	0.80	19.66	0.88	19.20—19.66	0.88—0.96
6	0.75	19.73	0.86	19.20—19.73	0.86—0.96
7	0.70	19.84	0.84	19.20—19.84	0.84—0.96
8	0.65	19.97	0.815	19.20—19.97	0.815—0.96
9	0.60	20.02	0.805	19.20—20.02	0.805—0.96
10	0.55	20.12	0.78	19.20—20.12	0.78—0.96
11	0.50	20.25	0.76	19.20—20.25	0.76—0.96
12	0.45	20.36	0.74	19.20—20.36	0.74—0.96
13	0.40	20.48	0.72	19.20—20.48	0.72—0.96

Simulation analysis of typical room under summer part-load operation

To be used as reference, temperature field and velocity field of the typical room under the design condition were firstly simulated. In order to facilitate the analysis of the flow field, profile of Y=4.2m is selected to analyze indoor temperature field and the result is shown in Fig.3. Profile of X=5.05m is selected to analyze indoor velocity field and the result can be seen in Fig.4.

Table.3 Supply air parameters setting of condition 7 (α=0.70)

Group number	Supply air temperature (℃)	Supply air velocity （m/s）
1	19.2	0.84
2	19.45	0.88
3	19.68	0.92
4	19.84	0.96

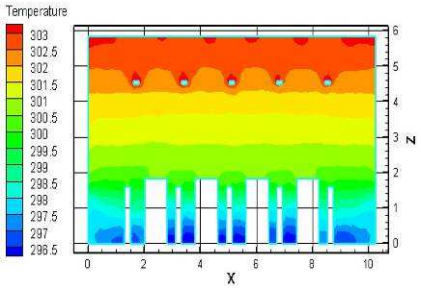

Figure.3 Temperature distribution profile of Y=4.2m under the design condition

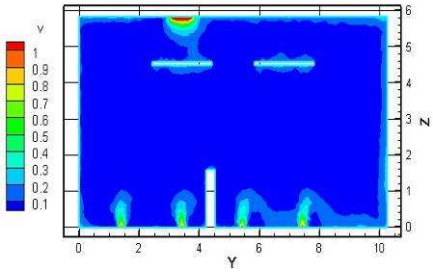

Figure.4 Velocity distribution Profile of X=5.05m under the design condition

In order to provide some guiding opinions to the actual adjust of the summer UFAD system, numerical simulation research is carried out to analyze changes of indoor air temperature field and velocity field under different supply air parameters based on the parameter combinations of condition 2 to condition 13. Supply air parameter combinations are represented with (t, v).

Research of correlation will be divided into the following three aspects:

1. Variable Air Volume conditions analysis

When the system is running under part-load conditions, with the load changing and the supply air temperature (t = 19.2℃) maintaining constant, only by changing the air outlet velocity (i.e.: supply air volume) can meet the indoor environment and people's comfort. Selected parameter combinations under 12 conditions are (19.20,0.94), (19.20,0.92), (19.20,0.90), (19.20,0.88), (19.20,0.86), (19.20,0.84), (19.20,0.815), (19.20,0.805), (19.20,0.78), (19.20,0.76), (19.20,0.74) and (19.20,0.72), respectively.

For comparative analysis, profile of Y=4.2m is selected to conduct temperature field analysis of various indoors conditions and profile of X = 5.05m is selected to conduct velocity field analysis of various indoors conditions. Taking the simulated figures of condition 2 with load factor α = 0.95 as an example, the profile of temperature field is shown in Fig. 5, and the profile of velocity field is shown in Fig. 6. Other simulation profiles of 11 conditions are omitted here.

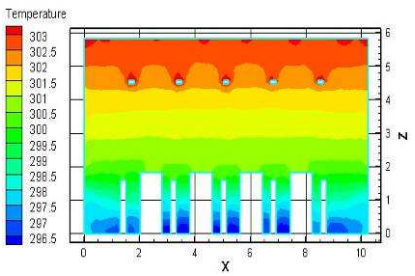

Fig.5 Temperature distribution profile of Y=4.2m under case 2

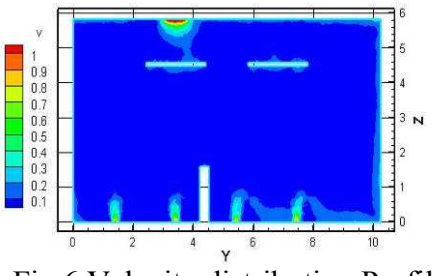

Fig.6 Velocity distribution Profile of X=5.05m under case 2

2. Constant air volume, variable temperature conditions analysis

When the system is running in part-load conditions, with the load change, maintaining the supply air velocity v = 0.96m / s constant, only by changing the air outlet temperature to meet the indoor

environment and people's comfort. Selected parameter combinations under 12 conditions are (19.38, 0.96), (19.47,0.96), (9.53,0.96), (19.66,0.96), (19.73,0.96), (19.84,0.96), (19.97,0.96), (20.02,0.96), (20.12,0.96), (20.25,0.96), (20.36,0.96）and（20.48,0.96), respectively.

For comparative analysis, temperature and velocity distribution profiles are selected in the same way as variable air volume conditions. The temperature distribution profile is shown in Fig. 7, and the velocity distribution profile is shown in Fig. 8. Other simulation profiles of 11 conditions are omitted here.

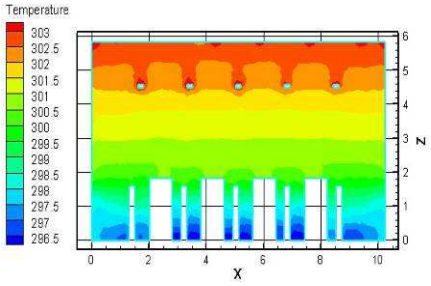

Figure.7 Temperature distribution profile of Y=4.2m under case 2

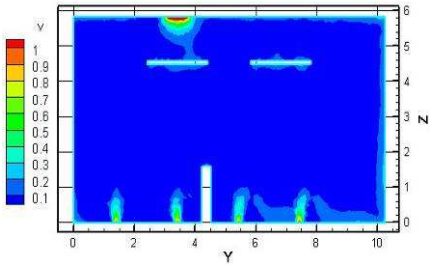

Figure.8 Velocity distribution profile of X=5.05m under case 2

3. Analysis of working conditions when air temperature and air volume change simultaneously

The impact of different supply air parameter sets for the indoor air environment and people's comfort have been analyzed when the system is under a certain part-load condition. Taking the condition 7 as an example, where the load factor α is set to be 0.70 and the supply air parameter combinations are shown in the Tab.3. Profiles of Y=4.2m are used to analyze the temperature and the results are shown in Fig. 9.

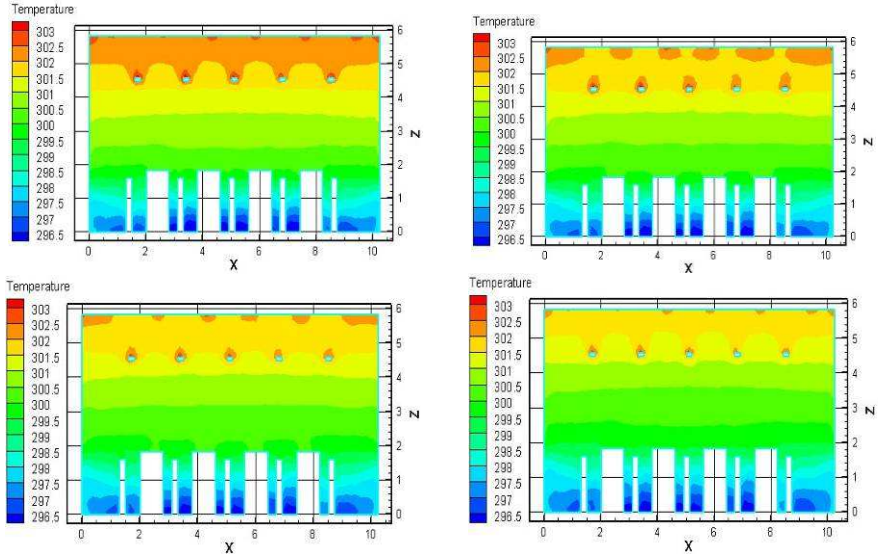

Figure.9 Temperature distribution profile of Y=4.2m under design condition

Analysis of the temperature and velocity distribution profiles in each condition, we can get the conclusions:

1)When the system is under part-load operations with changing load, it is feasible to maintain the supply air temperature t = 19.2 ℃ constant while only by changing the supply air velocity of the air outlet to meet the indoor environment and personnel comfort needs; it is also feasible to maintain supply air velocity v_{outlet} = 0.96m / s constant while only by changing the supply air temperature to meet the indoor environment and personnel comfort needs. The temperature and velocity distribution meet the requirements of ISO7730 [3], American Standard ASHRAE 55-1992[4] and Chinese specification [5]. Thus, as the indoor load reduces with the outdoor temperature declines in the summer, we can achieve the purpose of energy saving by changing the parameters of air supply.

2) For the summer part-load conditions, there is a maximum limit of supply air temperature and a minimum limit of supply air velocity. For a certain load condition, the design supply air velocity v_{design} should relate to the maximum limit of supply air temperature t_{max} and the design supply air temperature t_{design} should correspond to the minimum limit of supply air velocity v_{min}. Supply air parameter set (supply air temperature, supply air velocity) should satisfy the following relationship: t_{design} (19.2 ℃) $\leqslant t \leqslant t_{max}$, $v_{min} \leqslant v \leqslant v_{design}$ (0.96 m/s).

3) The average indoor temperature in work area and non-work area will both decrease in these three cases: Both of the two parameters of the supply air parameter set (air temperature and air velocity) increase; Supply air temperature maintains the design supply air temperature while supply air velocity decreases; Supply air velocity maintains design supply air velocity while supply air temperature increases.

4) The rational design of UFAD system can make people achieve a better comfortable condition [6].In the UFAD system, the indoor environment is more ideal, and the people's comfort is better in these conditions:

Average temperature of the indoor work area is closer to the design temperature;
Less temperature stratification of work area;
More temperature stratifications of non-work area;
Smaller height of the jet.

Therefore, for a certain summer part-load condition, there will be an optimum air parameter set to make the indoor environment most ideal, and to make people most comfortable. Through the above simulation analysis of each group, we can get that the first group of part- load parameter of each group (design supply air temperature t_{design}, the minimum supply air velocity v_{min}) is the best air parameter set. Therefore, variable air volume operation mode should be used in the actual operation of the project to achieve energy efficient operation, and to ensure the best comfort of the personnel.

Conclusion

A maximum limit of supply air temperature and a minimum limit of air velocity in the summer part-load conditions have been presented by simulation analysis. And it comes to the conclusion that for each condition, there is a set of optimal air parameters (t_{design} , v_{min}) to make the indoor personnel achieve the most comfortable condition. However, since the limited number of conditions, the α is not fully given. Therefore, there are some limitations of guidance for the actual operation of the complex working conditions. This section will be follow-up study in the future work.

Abstract. With the fast development of superconducting, nuclear-energy and high-energy physics, further requirement of the system of large-scale helium refrigeration is brought forward by some associated subjects. The present controlling system of the system abovementioned is not well able to deal with the interruption such as the heat pulse impact. Thus, it leads to a new challenge that must be confronted with by the system of large-scale helium refrigeration.This paper aims at the control of gas management panel (GMP) in compression station of large-scale helium refrigerator. The neural network PID control of GMP in the system is introduced and simulated.

Introduction

Large-scale helium refrigerators at 4.2 K are used to cool down superconducting magnet systems, nuclear-energy and high-energy physics. These superconducting magnetic systems generate heat load that are pulsed in nature and helium refrigerators have to handle such heat loads [1-3]. The proposed control scheme can be used to have precise control of every pressure in normal operation or to stabilize and control the cryoplant under high variation of thermal loads. The strategy intends to replace all the PID loops controlling the GMP, by neural network PID controller.

A refrigerator based on modified reverse Brayton cycle has been developed recently [4]. This refrigeration cycle consists of an oil lubricated screw compressor, a GMP, a buffer tank, a counter-flow heat exchanger, a heater (dummy user) and a turbine expander as shown in Fig. 1. In the commercial helium refrigerator control system, the usual PID controller is used. The control strategy for the existing plant is that the suction pressure (P1) is controlled by the bypass valve V1 and the outlet pressure (P2) for compressor is controlled by using V2, V3 [5] as shown in GMP part of Fig. 1. According to this control strategy, the control loops for P1 and P2 are independent, which can't satisfy the control purpose to the object sometimes. This paper will introduce a way to improve the PID control for the compression station of large-scale helium refrigerator.

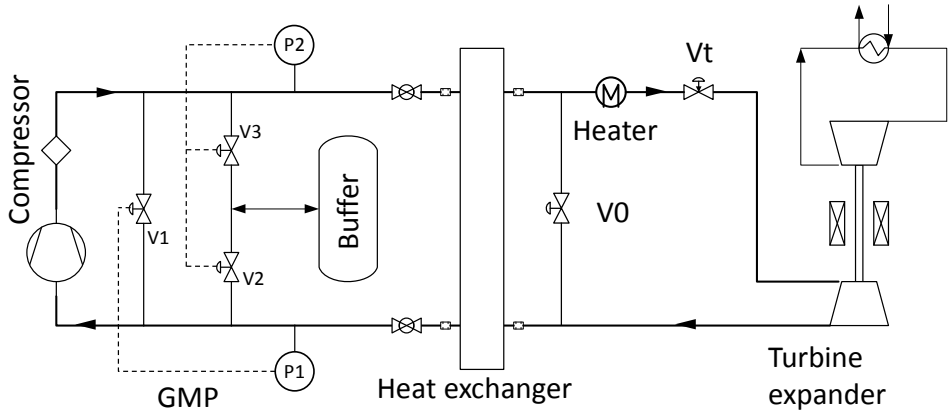

Fig. 1. Flow scheme of the modified reverse Brayton refrigerator.

Neuromorphic control structure

The function of V2 and V3 is charge valve and discharge valve, respectively. For the traditional control strategy, V2 and V3 can be opened at the same time, which is not rational in principle. In the new multivariable PID neural network (NN) control, the V2 and V3 will be considered as one regulator. When the system need more helium the V2 will be open and V3 will be closed. Conversely, when there is too much helium in the system the V3 will be open and V2 will be closed.

The multivariable PID neural network controller structure has been shown in Fig. 2. And the error1 is denoted by e1(t)=r1(t)-y1(t) where r1(t) is the desired signal of low pressure P1 and y1(t) is the actual P1; while the error2 is denoted by e2(t)=r2(t)-y2(t) where r2(t) is the desired signal of high pressure P2 and y2(t) is the actual P2. In the discrete-time control system, the PID algorithm can be given as Eq. 1:

$$u(t)=u(t-1)+K_P\left(e(t)-e(t-1)\right)+K_I e(t)+K_D\left(e(t)-2e(t-1)+e(t-2)\right) \tag{1}$$

where K_P, K_I, and K_D are respectively, the proportional, integral and derivative gains of PID controller which should be adjusted. The part of a NN block is build in order to adjust the gains of PID controllers adaptively by using the back propagation (BP) method with measurement data of u(t), y(t) and r(t).

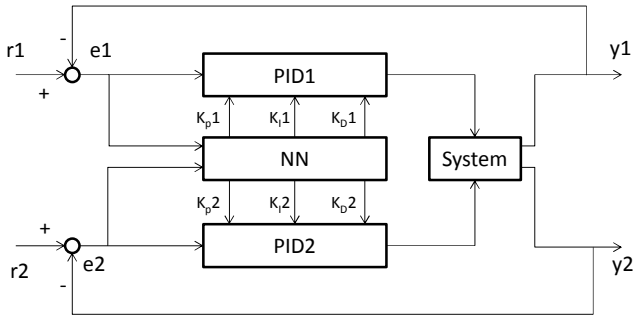

Fig. 2. Multivariable PID neural network controller structure.

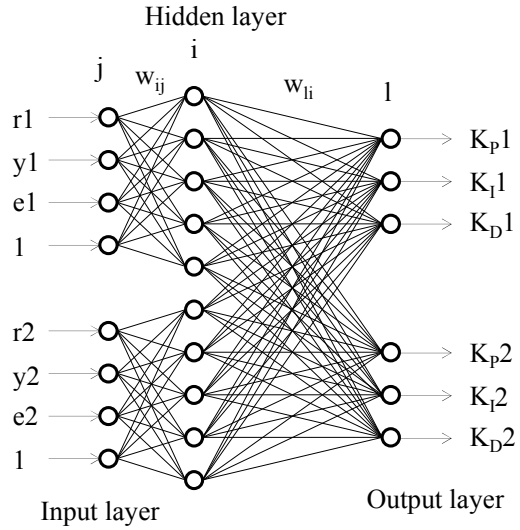

Fig. 3. Configuration of BP neural network.

The BP is a multilayered network which consists of an input layer, an output layer and several hidden layers of nonlinear processing elements [6]. For the new NN controller, the controller has three layers and the number of output layer neurons is K_P, K_I and K_D and the configuration of BP neural network is shown as Fig. 3. The input-output neurons relationship of BP NN can be expressed as follows:

$$net_p^{(m)}=\sum w_{pq}^{(m)}O_q^{(m-1)} \tag{2}$$

$$O_q^{(m)}=f\left(net_q^{(m)}\right) \qquad (pq=ij,li),(m=2,3) \tag{3}$$

where $w_{pq}^{(m)}$ is the weights of hidden layer, the upper number m = 1,2,3 denotes input layer, hidden layer, output layer, $net_p^{(m)}$ is the input of neuron p in the layer m, $O_q^{(m)}$ is the output of a neuron q,

$f(\cdots)$ is the neuron activation function, for hidden layer $f_1(x)=\tanh(x)$, for output layer $f_2(x)=\frac{1}{2}(1+\tanh(x))$. The learning goal of PID neural network is to minimize the average value of system output square error J which can be expressed as Eq. 4.

$$J=\frac{1}{2}\left(e_1(t)^2+e_2(t)^2\right) \tag{4}$$

where J is to modify the weights by the fastest descend mean, which is searched and tuned toward the negative gradient and added on a inertia coefficient to make faster constringency.

$$\Delta w_{li}^{(3)}(k)=-\eta\frac{\partial E(k)}{\partial w_{li}^{(3)}}+\alpha\Delta w_{li}^{(3)}(k-1) \tag{5}$$

where η is the learning rate and α is the smoothing coefficient. And Eq.5 can be rewrited as follows:

$$\begin{aligned}&\Delta w_{li}^{(3)}(k)=\eta\delta_l^{(3)}O_i^{(2)}(k)+\alpha\Delta w_{li}^{(3)}(k-1),\\&\delta_l^{(3)}=e(k)\operatorname{sgn}\left(\frac{\partial y(k)}{\partial u(k)}\right)\frac{\partial u(k)}{\partial O_l^{(3)}}f_2'\left(net_l^{(3)}\right),\qquad l=1,2,3.\end{aligned} \tag{6}$$

And the weights of hidden layser can be written as Eq. 7

$$\begin{aligned}&\Delta w_{ij}^{(2)}(k)=\eta\delta_i^{(2)}O_j^{(1)}(k)+\alpha\Delta w_{ij}^{(2)}(k-1),\\&\delta_i^{(2)}=f_1'\left(net_i^{(2)}(k)\right)\sum_l^3\delta_l^{(3)}w_{li}^{(3)}(k),\qquad i=1,2,3,4,5.\end{aligned} \tag{7}$$

Analysis and results

A dynamic simulator has been carried out, which provide a way to study and optimize control strategies of the refrigerator [7]. The numerical model comprises the typical components of the refrigerator: compressor, valves, heat exchangers, expander and heater. This simulator is based on the oriented-object approach and each component is represented by a set of differential and algebraic equations. The control logic of the refrigerator is also embeded in the simulator.

The initial pressure of the system is 0.2 MPa and the initial pressure in the buffer tank is 0.4 MPa. The setting pressure of high pressure is 0.55 MPa and that of low pressure is 0.105 MPa. The traditional PID parameters for V1 are $K_P = 2.0$, $K_I = 20$, $K_D = 0$; those for V2 and V3 are $K_P = 1.0$, $K_I = 30$, $K_D = 0$. For neural network PID in the simulation, the learning rate is 0.1 and the smoothing coefficient is 0.2 and the initial weights is the random number in the extent (-1,1).

The simulation results of nerual network PID control and traditional PID control in the starting stage have been obtained as shown in Fig. 4. The simulation results show that the high pressure and low pressure can be controlled to the setting point in shorter time by using NN PID control. It can be found that the overshooting of these two control loop is very similar, but the governing time of NN PID control is shorter than traditional PID control.

When the high pressure and low pressure is built up and kept to a steady state. The V0 should be turned on to start the self-circulation stage. The V0 is opened to 50 % at 400 s and then keep this opening. This operation is a typical disturbance to the GMP control system. Fig. 5 shows the simulation results of NN PID control and traditional PID control when V0 is turned on. The simulation results shows that the overshooting of the NN PID control is smaller than traditional PID control. And the governing time of NN PID control is much shorter than traditional PID control. The

simulation results indicate that the NN PID control can increase the performances and stability of the compressor station.

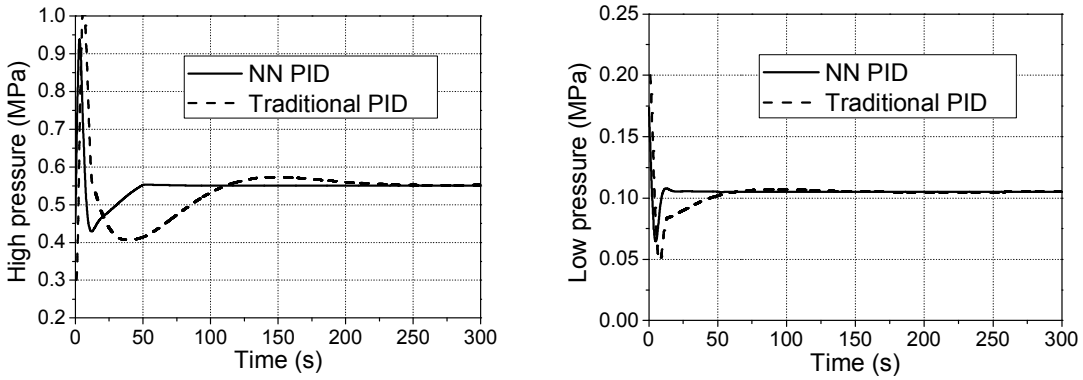

Fig. 4. Simulation results of NN PID control and traditional PID control in the starting stage.

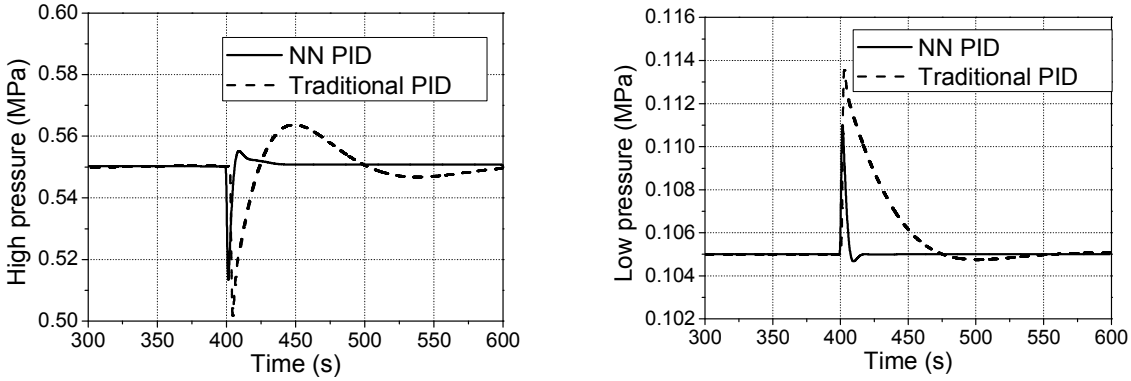

Fig. 5. Simulation results of NN PID control and traditional PID control when V0 is turned on.

Conclusions

A neural network PID controller, which is a method for adaptively adjusting the PID gains using a BP neural network, are introduced to GMP of the large-scale helium refrigerator. The neural network PID control has self-learning and self-adapting abilities. The neural network PID control and traditional PID control are applied to the pressure control for refrigerator. The simulation results indicate that the neural network control system has better robustness and higher precise than traditional PID control. For future work, the neural network PID controller will be applied to the control of turbine which is the key component of the helium refrigerator.

Abstract. More and more attentions have been paid on ice-storage low temperature air supply system because of its notable energy saving effects and comfort. The paper expatiate on that ice-storage low temperature air supply system brings a series of especial superiority to modern air-condition cause. The results show that low temperature air supply system can exert the potential advantage of ice-storage further. The combination of ice-storage and low temperature air supply system can obtain an “integrated approach”, which can save energy resources and improve human body comfort and indoor air quality.

Introduction

China's air-conditioned buildings total energy consumption account for 60% to 70% . In this energy shortage situation, ice-storage technology, as a power load management measure to effectively alleviate the power shortage and ease the contradiction between power distribution and load capacity ,has played a "peak load shifting" effect successfully .

With the ice-storage technology being more sophisticated, cold air can be applied in air-conditioning possibly. Cold air from the air-conditioning is the focus of processor for sending low-temperature primary air, after inducing air at the high end of the room air-conditioning unit into the air supply system. With the rise of ice-storage air-conditioning technology, the advantage of the ice-storage system to provide cold water, has low investment and operation cost, high efficiency, less demand for electricity and so on. More importantly, it can reduce indoor air humidity and improve indoor thermal comfort and air quality, so it can prevent "air-conditioning disease". In the meantime, because lower air temperature slows the growth of bacteria, people have a healthy space.

Ice-storage cold air distribution system not only can improve the effective utilization rate of building space, lower operating costs, but also improve indoor comfort and indoor air quality. Therefore, the development of low-temperature ice-storage air conditioning systems in China and the world has become a popular trend and the focus of research .Ice-storage cold air distribution system will also become widespread central air-conditioning system in the 21st century.

Low-temperature ice-storage air supply system and characteristics of classification.

Low-temperature ice-storage air supply system classification. Cold air, being usually based on the level of air temperature, can be divided into three categories: Super-cold air. Air temperature is 4 ~ 6 ℃; because the supply of such air is special, it is generally less recommended.

Lower air temperature. Air temperature is 6 ~ 8 □.Only when ice-storage air supply technology work closely together, it can get a better effect of air-conditioning and has good economic returns, so the best choice is to be a wide range of promotion and application.

Cold air distribution. Air temperature of 9 ~ 12 □, Cold air distribution. Air temperature of 9 ~ 12 ℃, the air supply of such ice-storage air-conditioning can also be combined with conventional air-conditioning, more flexibly, less access to economic benefits; it also has less ice in cold air conditioning system application.

Ice-storage characteristics of cold air distribution system. As the ice make full use of the frozen water of 1.1 ℃ to 3.3 ℃ , the combination of ice-storage and cold air distribution system often use the primary air which is 6.6 ℃ to 8.8 ℃. This system has a number of advantages:
Low-temperature air conditioning system, applying of ice-storage technology to achieve the success of "peak load shifting," reduces peak electricity demand.
The air temperature increases, making air supply reduce, reducing the air-handling equipment size, making power blower axis wind pipe size become smaller , can save building space, which is favorable for commercial high-rise building. Operating mode, as a result of the reduction of air flue, makes equipment reduce capacity, which reducing power consumption and improve the performance

Ice-storage air-conditioned indoor air quality

Ice-storage air-conditioned indoor air quality
With the deepening of the study, it finds that indoor air quality is different from indoor pollution. The pollutant level of the individual indicators can accurately reflect the indoor air quality. Low concentration of indoor pollutants is difficult to detect, so indoor air quality is also relate to temperature and humidity.

The impact of air flow to the human body comfort. At present, the cold air distribution technology is not widely applied in China. The main reason is that this not belongs to the length of cold jet, so that there is a sense of staff hair in room to reduce the volume of air. So that poor indoor air flow, results in the emergence of air trapping zone. International briefing on the effectively use of the main sense of cold air temperature on air conditioning systems performance evaluation. Effective temperature briefing include that the air temperature, relative humidity and air flow on the human body's physiological effects of a comprehensive. it can be expressed:

$$EDT = (tx-tc)-8(vx-0.15) \quad (1)$$

Where, EDT - a briefing for the effective temperature ℃;
t_x - a point of the indoor air dry bulb temperature ℃;
t_c - the average indoor dry bulb temperature ℃;
v_x - a point of the indoor air center wind speed m / s.

Comparing with conventional air conditioning systems, cold air distribution system has the following characteristics: first, because of reducing the air supply amount, leading to the room air flow rate is too low, it is possible to affect the indoor air quality. The second, it is caused by the low-temperature air supply device. Third, because air temperature goes down easily, people have a sense of cooling. To deal with the problem, take the following measures:
Low-temperature air mix with the indoor air before gets into the room.
A good performance converter scatters into the air indoors, to prevent the occurrence of the phenomenon of sinking.
Strengthen the pipeline insulation to reduce the amount of cold and prevent the loss of the condensation phenomenon.
At the same time, this also shows that: the indoor air flow rate, comfort are great relate to device structure. The apparatus is not only a very high degree of induction than the connection end portion in the same length of time long enough to improve indoor quality and comfort of air jets.

Low relative humidity of indoor air. Indoor air quality of the human body's feeling good or bad is mainly affected by indoor air temperature and humidity. When the indoor air temperature and relative humidity increase, air quality acceptability for the human body will markedly decline. Experimental results show: low humidity, the subjects feel more comfortable and cool. The fresh air determines indoor air quality, which is more acceptable. The cold air distribution system, it is precisely because of
its low relative humidity, which has a strong capacity dehumidifier, which makes an increase of fresh air and an increase of people's comfort.

Temperature impact the indoor air quality. As the cold air conditioning systems is relate to low temperature of the air supply, cold air of air-conditioning directly get into the region, causing cold air and heterogeneous indoor temperature drop, which affects the thermal comfort. If the air temperature has not been took any special measures, then sent it to the area below the dew point temperature of the air-conditioning, it is easy to produce the phenomenon of sending "fogging" or water and make indoor environmental damage. At present, for China's production induced device, this problem has been successfully solved. Essentially eliminating the "fogging" and "water", only ending the device's low degree of automation, it needs to further improve.

On the other hand, due to the cold air distribution system, ice-storage temperature is very low. It is able to effectively overcome the central air-conditioning syndrome, which is much better than the conventional air-conditioning.

The fresh air determines indoor air quality. Using the way of VAV air, the indoor cooling load in air flue can be decreased. When outdoor air has a certain minimum volume, with the reduction of air supply the amount of fresh air will decrease than to improve. In some cold air distribution system, when the cooling load is in a low state, the fresh air rate even close to 100%. As a result, the system design and selection，should use VAV way to determine a minimum volume of outdoor air, so as to improve the indoor air quality.

The overall evaluation of the indoor environment. Indoor air temperature, humidity and air distribution are the three major factors impacting indoor air quality and thermal comfort, which are interactional. Cold air distribution ice-storage air conditioning system reduces relative humidity and temperature of the region to improve the comfort of environment. Dry bulb temperature of coil exports can reach 5.5 ℃ and relative humidity can reach 36%, while the conventional system is 50% to 60%. Lower relative humidity and 25 ℃ indoor conditions can be used in the region making a cool and refreshing feeling . Jet attached at the end of the device to ensure a reasonable indoor air, air-conditioned rooms can maintain a good indoor environment.

Ice-storage air-conditioning has energy-saving effect. When cold air distribution system and ice-storage technology apply to the building's air-conditioning, the electricity supply will achieve the "peak load shifting "of the user side from its peak during the day shift to night-time. At the same time, it can reduce transmission and distribution facilities, so it can lower all the cooling system capacity requirements and capacity of mechanical and electrical equipment costs.

As the air temperature increasing, air flue and air power accordingly reduce significantly. At the same time, coil road and wind section size can be significantly reduced, thus the initial investment can be reduced. Also it accordingly reduces the floor area occupied and raises the utilization rate of the building. The ice-storage system with low temperature evaporation of the ice, leads to decline the COP which is usually higher than the energy storage system for non-ice systems. Ice-storage and using of a combination of cold air distribution system, due to the reduction of air supply volume and reduction energy consumption of fan, so the total energy consumption could be lower than the storage of non-conventional air supply system.

Cold air distribution system ,comparing to the general air supply system, reduces the temperature of air of air-conditioned room , which is usually 3 ~ 11 ℃. Because it sends the low-temperature air, it has significant energy-saving effect. Cold air distribution systems and air supply systems in all aspects of more conventional parameters list in the table below:

Table 1 Aspects of conventional parameters

Item	Cold air distribution system	Conventional air supply system
Air temperature (℃)	10 to 20	8 to 10
Air temperature (℃)	3 to 11	10 to 15
Air-conditioning units to reduce the size ratio (%)	20 to 30	0
Duct size reduction ratio (%)	30	0
Fan power to reduce the ratio (%)	30 to 50	0

From the above we can see: ice-storage cold air distribution system, although increases storage devices and accordingly increases investment, but the units, pumps and pipes accordingly reduce in size to a large extent ,which can make up for the increased costs. Due to the reduction of air supply, water pump and power unit can significantly reduce running costs. As a result, low-temperature ice-storage air supply system both in the way of investment and in the early running costs has significant energy-saving effect.

Conclusion

Not only in the energy-saving, but also to ensure indoor air quality and improve human comfort , the low-temperature ice-storage air supply system, particularly the low-temperature ice-storage air supply system outside the office building has become a popular air-conditioning program. China's scientific and technological workers who look at the technology research prove: cold air and ice-storage technology, which can transfer peak load electricity, save energy consumption and improve indoor air quality, have special advantages and far-reaching significance in promoting China's HVAC cause.

Abstract. In this paper, microcontroller is applied in the central air conditioning control system. Firstly, microcontroller controller is used as controlling core to control temperature and humidity of central air conditioning control system. Secondly, PID algorithm parameters are set up for improving traditional PID control principle. Lastly, input and output values can be set and displayed by LCD screen.

Introduction

At present, architecture consumption can account for about 70% of the total power consumption according to statistics. The architecture air-conditioning consumption can account for about 50% of the total architecture consumption [1-2]. Therefore, improving the management of central air conditioning is imperative. With the development of China's economy, people's living standards are improving. Their requirement for more comfortable air condition environment has become the first problem. How to control the air conditioner functioning to make its temperature within the human comfort range and how to improve the quality of system functioning to save operation energy consumption, has become a problem that should not be ignored [3]. This paper mainly elaborates the hardware of the central air-conditioning control system, PID parameter optimization problem and input and output problems.

The design of hardware of the central air-conditioning control system

Hardware selection. The hardware selection of this text mainly includes microcontroller, temperature and humidity sensor, regulating valve, frequency converter, air valve actuator and selection of related hardware. The list is shown in Table 1.

Table 1.The hardware list

sequence	type	hardware
1	micro controller	8051
2	temperature sensor	LM335
3	humidity sensor	HIH3610
4	regulating valve	V230
5	frequency converter	FR-A700
6	air valve actuator	CDH2019

Design principle. people can adjust the indoor temperature and humidity through remote control because of microcontroller inside instructions. Central air conditioning indoor temperature and humidity can make people get more comfortable office environment. 8051 microcontroller will drive the temperature sensor, humidity sensor to detect the air inlet temperature and humidity of new outlet.

When the control valve receives the feedback signal detection, it can automatically adjust the opening size. At this time, new entrants into the fresh air will be the same as the indoor return air mixing, forming a hybrid wind. When the wind pipe mixed air temperature is too high, the motor will drive the surface cooler for cooling treatment, hot and cold water will PID adjustment. In the precondition of ensuring the load demand, achieve the maximum energy saving central air conditioning. After A/D conversion, the humidity and temperature value is displayed on the LCD screen for people to confirm. The central air conditioning design principle is shown in Fig 1.

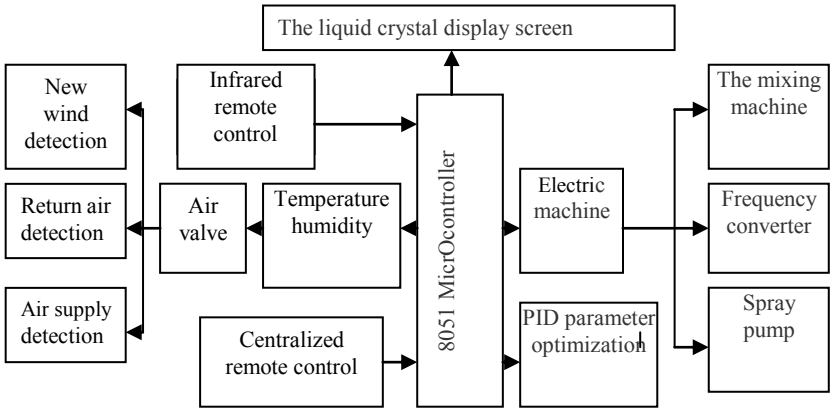

Fig 1. The design principle of central air conditioning

The PID parameter optimization

PID control algorithm is widely used in the intelligent architecture. The central air conditioning cold and hot water regulating control can also use PID control algorithm. The central air conditioning temperature and humidity sensor can build current signal of the fresh air temperature and humidity. The 8051 MCU and A/D conversion unit can transform the analog signal into digital signal. It can achieve PID control through software programming. Therefore, mixing unit for temperature and humidity treatment can satisfy the people' requirements. The fresh air is driven by single chip microcomputer. The traditional PID control principle is simple, strong robustness, adaptability. But the central air conditioning system is large, the control loop is more, the traditional PID algorithm parameters setting are difficult to meet their requirements. This design adopts the ant colony algorithm to optimize the parameters of PID control. Ant colony algorithm is a heuristic algorithm for discrete optimization problems. It is by a group of artificial ants cooperating to find the best solution. Its main part is the computer resource allocation to a group of relatively simple artificial ants, indirect communication between artificial ants through media. Ant colony algorithm with embedded operating system is the framework, after several times of iterative approaches the optimal results, the parameters of PID algorithm on the shortcomings of traditional setting lag, not precise. Application of PID in central air conditioning in the parameter optimization, the main algorithm is as follows:

First, Combinatorial optimization problems PID control parameters is transformed into the problem of ant colony algorithm applicable, Make a set of parameters(k_p, T_i, T_d),andA length of 15 digits correspond, The objective function is established:

$$J = \sum_{i=0}^{\infty} (w_1 |e(i)| + w_2 u^2(i) + w_4 |e(i)|) + w_3 t_w \tag{1}$$

Secondly, construct the desired path. Suppose that each artificial ant in the initial point($x_i - 1, y_i^{'}$),and in accordance with the probability of a random proportional rule behavior to choose rules, suppose climb to the next node(x_i, y_i),Until each ant at(15, $y_i^{''}$)as a cycle, The random proportional rule:

$$P_k(x_i,y_i,t)=\frac{\tau^{\alpha}(x_i,y_i,t)\eta^{\beta}(x_i,y_i,t)}{\sum_{j=0}^{9}\tau^{\alpha}(x_i,y_i,t)\eta^{\beta}(x_i,y_i,t)} \quad (2)$$

Finally, Conduct the pheromone update. Ants from the initial point to complete one cycle after the node information will change, Information update cable according to the following formula:

$$\tau(x_i,y_j,t+15)=\rho\tau(x_i,y_j,t)+\Delta\tau(x_i,y_j) \quad (3)$$

$$\Delta\tau(x_i,y_j)=\sum_{k=1}^{m}\Delta\tau_k(x_i,y_j) \quad (4)$$

$$\Delta\tau(x_i,y_j)=\frac{Q}{F_k} \quad (5)$$

The flow chart shown in Fig 2.

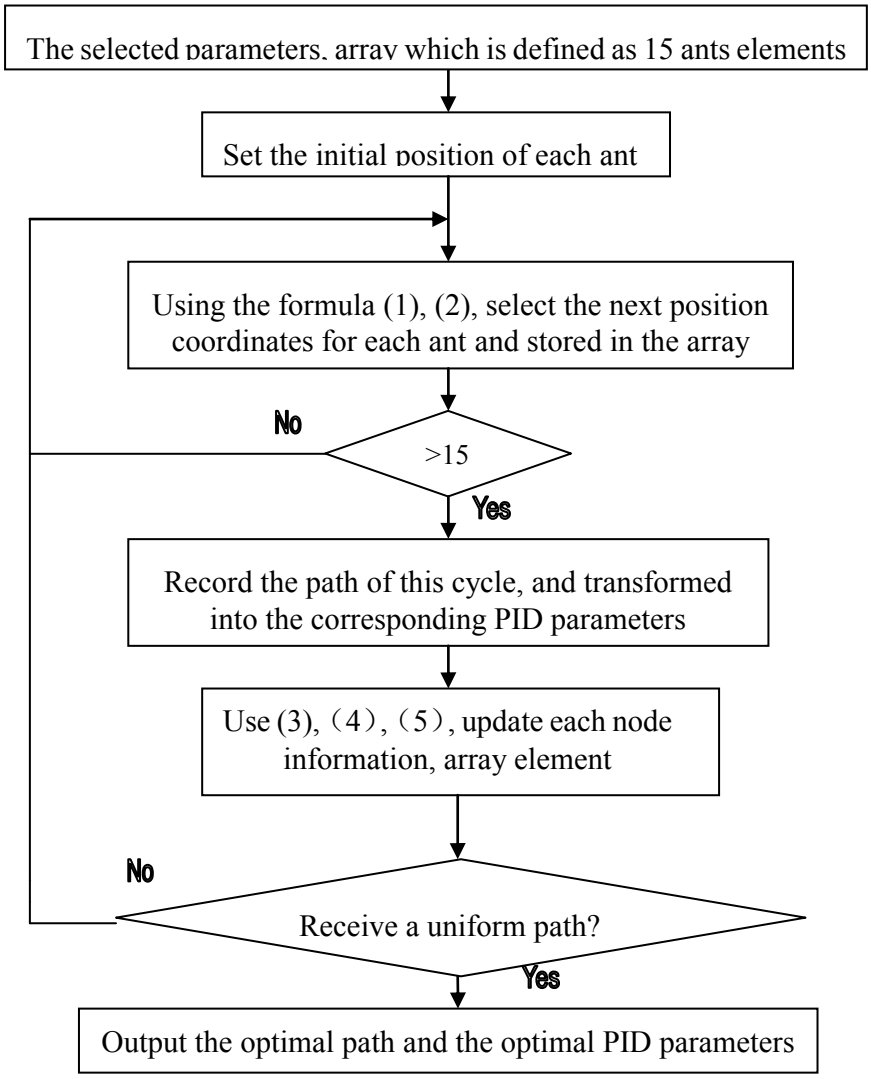

Fig 2. PID parameter optimization of ant colony algorithm

Design and display of input and output values

With the progress of society，more and more devices are equipped with remote control. The design of the infrared remote control can control the central air conditioning of 8051 single-chip operation. The motor can start and stop the temperature and humidity detection. Of course, the infrared remote control to be equipped with an infrared emission tube,when the electric infrared

receiving end to form on the radio state,then reach the remote control function. The infrared remote control by the 555 circuit generates a pulse signal, produced by the oscillating circuit characteristic frequency pulse through the drive signal of infrared emission tube emits the same frequency, complete the infrared control. The central air conditioning ventilation is good, the fresh air into the room. The temperature and humidity of air is displayed by LCD. LCD screen is composed of two plates, when an electric field is applied to the liquid crystal,then change the internal molecular arrangement,so that the droplets of liquid crystal layer formed in the pixel on the screen. This design allows the LCD display and the temperature and humidity detection circuit board, coordination the software can read the temperature and humidity of indoor. The temperature and humidity testing physical map is shown in Fig 3.

Fig 3. The physical map of temperature and humidity testing

Conclusions

This paper designs the hardware and software of the central air-conditioning control system using Siemens S7-200 programmable controller in the office. In the control algorithm, it adopts the traditional PID control and fuzzy control method to realize the combination of central air conditioning of the temperature and humidity and hot and cold water control. At the same time, it uses touch screen on the correlation parameter setting and information display. The central air conditioning system simulation control lays a certain theoretical basis for the intelligent central air conditioning.

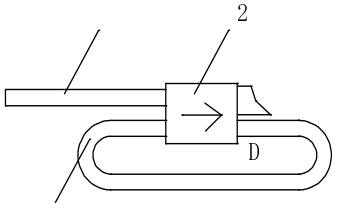
Keywords: stepped capillary tube, heat pump type air conditioner, flow characteristic, R410A

Abstract. A stepped capillary tube consisting of two serially connected capillary tubes with different diameters is invented to replace the conventional expansion device. The mass flow rate of refrigerant R410A in stepped capillary tubes with different size were tested. The model of stepped capillary tube is proposed, and its numerical algorithm for tube length and mass flow rate is developed. The experimental results show that the performance comparing between stepped capillary tube system and capillary tube assembly system, the cooling capacity is reduced by 0.3%, the energy efficiency ratio(EER) is equal to each other, the heating capacity is increased by 0.3%, the coefficient of performance(COP) is decreased by 0.3%. That is to say, the performance index of the two kinds of throttle mechanism is almost identical. It indicates that the stepped capillary tube can replace the capillary tube assembly in the R410A heat pump type air conditioner absolutely. The model is validated with experimental data, and the results show that the model can be used for sizing and rating stepped capillary tube.

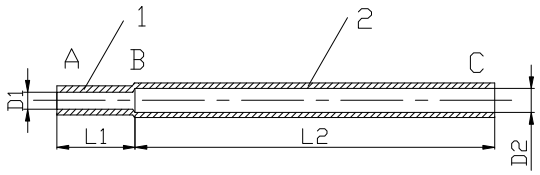
Introduction

The mass flow rate of refrigerant in heat pump type air conditioner is different under heatingand cooling mode. The mass flow rate of cooling mode is more than that of heating mode. In order to realize it, the capillary tube assembly is used in the heat pump type air conditioner. Fig.1 shows the the schematic diagram of the Capillary tube assembly. The length of capillary tubes are different under heating and cooling mode（for cooling mode, the refrigerant only goes through auxiliary capillary tube along the flow the path of A—B—E, for heating mode, the refrigerant goes through two capillary tubes sequentially along the flow the path of E—D—C—B—A）. The cost of capillary tube assembly is increased about $1 for adding the check valve. According to the performance of gas-liquid two phase flow in the capillary tube, Xu[1] invents a stepped capillary tube(as shown in Fig.2). It is composedof two tubes with different diameter, and it can replace the capillary tube assembly so as to reduce the expense as well as simplify the structure.



1-main capillary tube, 2-check valve, 3-auxiliary capillary tube

Fig.1 Capillary tube assembly



1-auxiliary capillary tube, 2-main capillary tube

Fig.2 Stepped capillary tube

Xu[1] performed the experiments of the stepped capillary tube replaced the capillary tube assembly in a heat pump type air conditioner (KFR-32GW) with R22. The ideal results were obtained, but the refrigerant R22 will be eliminated step by step due to the environmental problems. The refrigerant R410A as one of the most important substitute refrigerant will be applied to air conditioner widely[2]. Hence, the investigation on flow characteristic of stepped capillary tube for heat pump type air conditioner with R410A has an important significance.

Experimental program and equipment

Experimental program. The critical problem for stepped capillary tube replaces the capillary tube assembly is the matching problem of the stepped capillary tube in air conditioner. That is to say, how to design the pipe diameter and length of the capillary tube. At present, the theoretical and experiential models are used widely only for the structure size calculation of a constant diameter capillary tube[3-5]. The stepped capillary tube must meet the need of flow under heating and cooling mode. Two pipes diameter and length must be designed. On the one hand, the existing experiential models are not suitable for stepped capillary tube. On the other hand, the theoretical models have a low accuracy and a complicated calculation[6-8]. Hence, they are not suitable for the engineering application. In order to reduce the matching workload for stepped capillary tube used in R410A air conditioner, the experimental programs were set up as following.

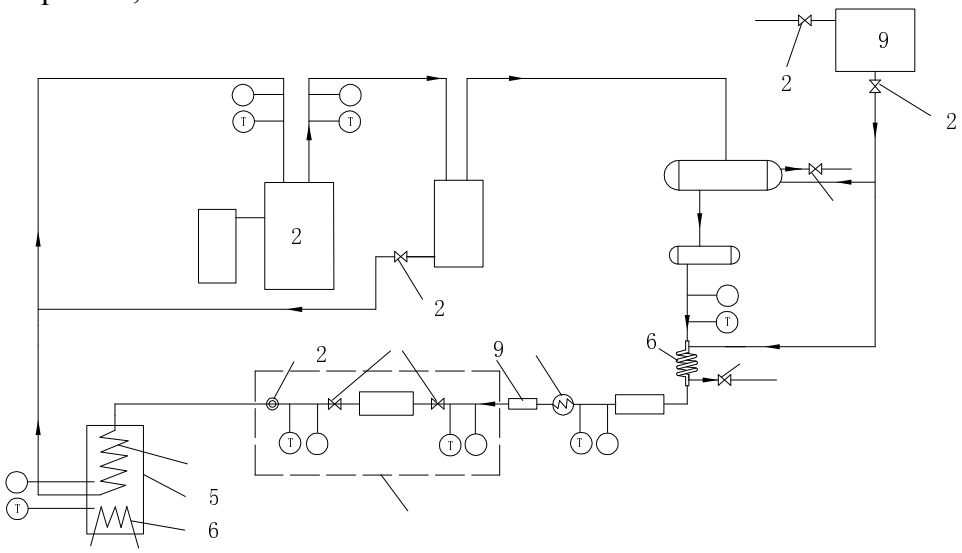
(1)The performance index (refrigerating capacity, heating capacity, EER and COP) and operation condition(condensing pressure, degree of supercooling, evaporating pressure, degree of superheat) of the R410A heat pump type air conditioner used the capillary tube assembly were tested in the standard environmental condition.

(2)The flow of R410A refrigerant under heating and cooling modes were tested with the capillary tube assembly on a test bench for measuring mass flow characteristics of the throttle mechanism.

(3)A few of stepped capillary tubes with different structures dimension were made. The flow of R410A refrigerant under heating and cooling modes were tested with those stepped capillary tubes on the same test bench. The experiential models were then set up.

(4) According to the experiential models, the initial configuration size of the stepped capillary tube was calculated. In the end, the configuration size of the stepped capillary tube was determined after the matching test on the air conditioner.

Experimental rig. The flow of refrigerant in the stepped capillary tube was tested on the experimental rig for measuring mass flow characteristics of the throttle mechanism. Fig.3 is the schematic of the experimental rig. This rig contained a compressor, an oil separator, a water-cooling condenser, an evaporator, a subcooler and a test section.



1.converter 2.compressor 3.oil separator 4.condenser 5.reservoir 6.subcooler 7. mass flow meter; 8.heater 9. dryer 10.stepped capillary tube 11.ball valve 12. sight glass 13.test section 14.evaporator 15. pressure vessel 16.electric heater; 17.control valve for condoner water flow 18. control valve for subcooler water flow 19.condensate water tank 20.float valve 21. ball valve

Fig. 3 Test rig for mass flow rate in step capillary tube

The condensing pressure was controlled by adjusting flow rate of water in the condenser, the evaporating pressure was controlled by adjusting the frequency of compressor, and the subcooling temperature was controlled by adjusting the water flow rate in the subcooler. The mass flow rate was measured by a Coriolis type mass flow meter with the uncertainty of ±0.2%. The inlet and outlet pressures of the test stepped capillary tube were measured by pressure sensors with the

uncertainty of ±0.2%, and the inlet and outlet temperatures were measured by T-type thermal couples with uncertainty of ±0.2 °C.

Flow experiment and modeling

Air conditioner performance test of capillary tube assembly. A heat pump type air conditioner with R410A(KFR-32GW) was chosen as the testing object. The inner diameter and length of the main capillary tube and auxiliary capillary tube are 1.6mm, 1350mm and 1.6mm, 400mm, respectively. Table.1 shows the air conditioner performance index and operation condition of the capillary tube assembly.

Table.1 Performance index and operation condition of the capillary tube assembly

Working mode	Environmental conditions		capacity W	COP	condensing temperature ˚C	supercooling temperature ˚C	evaporating temperature ˚C	Mass flow rate kg/h
	dry bulb/wet-bulb temperature indoor ˚C	dry bulb/wet-bulb temperature outdoor ˚C						
cooling	27/19	35/24	3250	3.26	46	41	7	70.8
heating	20/15	7/6	3630	3.40	47	43	4	63.1

Throttling characteristic model of stepped capillary tube

Foundation model. The flow resistance of the stepped capillary tube as shown in Fig.2 is composed of three portions. It includes the on-way resistance of the auxiliary capillary tube(ΔP_1), the main capillary tube(ΔP_2) and local resistance of the mutations place(ΔP_ξ). The local resistance is very small, so it can be ignored. When the pressure difference of import and export of the stepped capillary tube is a definite value, the dimensionless linear relationship between the mass flow rate and the structure size can be set up according to the impedance calculation under heating and cooling mode.

$$\begin{cases} a_1+b_1\left(\frac{L_1}{{D_1}^5}\right)+c_1\left(\frac{L_2}{{D_2}^5}\right)=\frac{1}{{G_C}^2} \\ a_2+b_2\left(\frac{L_1}{{D_1}^5}\right)+c_1\left(\frac{L_2}{{D_2}^5}\right)=\frac{1}{{G_H}^2} \end{cases} \quad 1)$$

Where a_1, a_2, b_1, b_2, c_1, c_2 is the non-dimensional coefficient. L_1, D_1 is the length and inside diameter of the auxiliary capillary tube, respectively, mm. L_2, D_2 is the length and inside diameter of the main capillary tube, respectively, mm. G_C, G_H is the mass flow rate under cooling and heating mode, respectively, kg/h.

Mass flow testing of stepped capillary tube. The orthogonal experiment scheme was adopted in this experiment. We made 16 stepped capillary tubes(D_1=1.2, 1.3, 1.4, 1.5mm，D_2=1.6, 1.7, 1.8, 1.9 mm，L_1=100, 200, 300, 400mm, L_2=300, 400, 500, 600mm). The mass flow of stepped capillary tubes were tested on the experimental rig for measuring mass flow characteristics of the throttle mechanism. The 16 mass flow values of cooling and heating were linear regressed. The experience calculation model for the physical dimension of stepped capillary tube is shown in Eq. (2).

$$\begin{cases} 62.5+0.953\left(\frac{L_1}{{D_1}^5}\right)+0.883\left(\frac{L_2}{{D_2}^5}\right)=\frac{10^6}{{G_C}^2} \\ 97.8+1.14\left(\frac{L_1}{{D_1}^5}\right)+0.59\left(\frac{L_2}{{D_2}^5}\right)=\frac{10^6}{{G_H}^2} \end{cases} \quad (2)$$

Model analysis. according to the Eq. (2), the cooling mass flow G_C and flow ratio G_C/G_H were calculated under different $\frac{L_1}{D_1^5}$ and $\frac{L_2}{D_2^5}$. The results were shown in Fig.4. It can be seen from Fig.4, the cooling mass flow G_C decreases with increasing $\frac{L_1}{D_1^5}$ and $\frac{L_2}{D_2^5}$, and the trend of decrease slow down. The influence of $\frac{L_1}{D_1^5}$ is greater than that of $\frac{L_2}{D_2^5}$. The flow ratio G_C/G_H decreases with increasing $\frac{L_2}{D_2^5}$ (when the $\frac{L_2}{D_2^5}$ is not more than 50), and the trend of decrease also slow down. But when the $\frac{L_2}{D_2^5}$ is more than 50, The flow ratio G_C/G_H increases with increasing $\frac{L_2}{D_2^5}$.

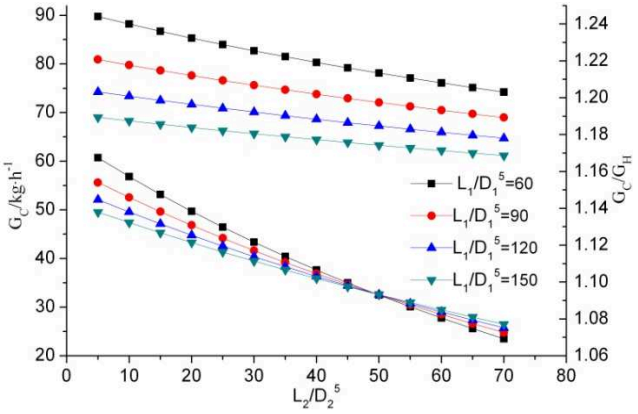


Fig.4 The calculated value of cooling mass flow and flow ratio

Case study on heat pump type air conditioner with stepped capillary tube

To study the effectiveness of stepped capillary tube in heat pump type air conditioner, the capillary tube assembly in a heat pump type air conditioner was replaced by a sized stepped capillary tube; and the air conditioner performances before and after replacement were experimentally tested. The mass flow of cooling and heating is G_C=70.8 kg/h and G_H=63.1 kg/h, respectively. In accordance with Eq. (2), $\frac{L_1}{D_1^5}$ is 123 and $\frac{L_2}{D_2^5}$ is 21.8. The length of capillarity tube is about in the range 500~1500mm, which in order to meet the need of working condition. Hence, the diameter of the auxiliary capillary tube and the main capillary tube is designed as 1.4mm and 1.8mm, respectively. The length of the auxiliary capillary tube and the main capillary tube is calculated as 661mm and 412mm, respectively. Based on these data, the further accurate match for stepped capillary tube can be carried out. In the case of D_1 and D_2 is a constant, the length of the auxiliary capillary tube (L_1)was chosen as 630, 660, 690mm, the length of the main capillary tube(L_2) was chosen as 380, 410, 440mm. All the 9 stepped capillary tubes with different size were tested in the air conditioner. The performance indicators of cooling and heating mode are shown in Fig.5 and Fig.6, respectively.

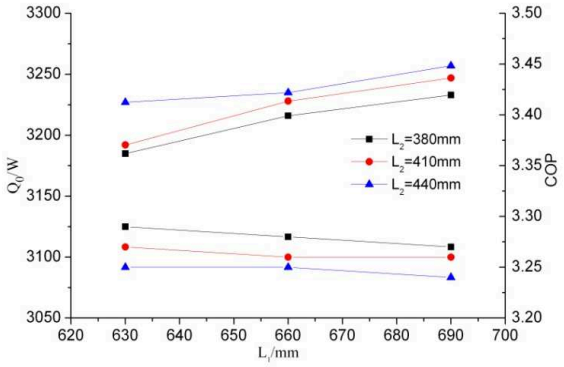

Fig.5 The performance indicators of cooling mode with different size stepped capillary tube

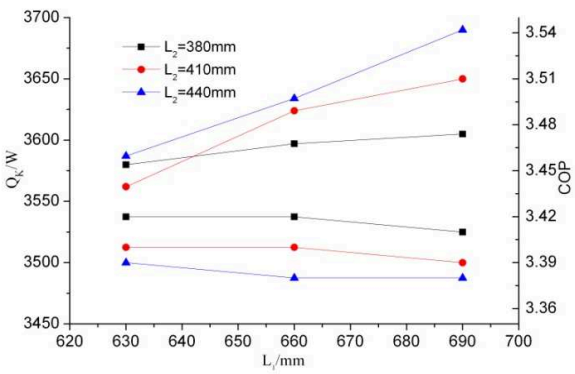

Fig.6 The performance indicators of heating mode with different size stepped capillary tube

The total cooling capacity change of the 9 stepped capillary tubes is 2.3%, and the change of EER is 1.5%. The total heating capacity change is 3.1%, and the change of COP is 1.7%. the experimental results show that the change of the capillary tube length has a less influence on the air conditioner performance. The structure size of the stepped capillary tube was confirmed after the testing, the diameter of the auxiliary capillary tube and the main capillary tube is 1.4mm and 1.8mm, respectively. The length of the auxiliary capillary tube and the main capillary tube is 690mm and 410mm, respectively. Table.2 shows the performance comparing between stepped capillary tube system and capillary tube assembly system.

As can be seen from Table.2, the performance comparing between stepped capillary tube system and capillary tube assembly system, the cooling capacity is reduced by 0.3%, the EER is equal to each other, the heating capacity is increased by 0.3%, the COP is decreased by 0.3%. As mentioned above, the performance index of the two kinds of throttle mechanism is almost identical.

Table.2 Performance comparing between stepped capillary tube system and capillary tube assembly system

Mode	Performance	Air conditioner with stepped capillary tube (NEW)	Air conditioner with capillary tube assembly (ORG)	Performance deviation (NEW-ORG)/ORG
Heating	Capacity W	3650	3630	0.5%
	COP	3.39	3.40	-0.3%
Cooling	Capacity W	3240	3250	-0.3%
	EER	3.26	3.26	0%

Conclusion

(1)The model of stepped capillary tube is proposed, and its numerical algorithm for tube length and mass flow rate is developed. The model is validated with experimental data, and the results show that the model can be used for sizing and rating stepped capillary tube.
(2)The change of the stepped capillary tube length has a less influence on the air conditioner performance.
(3) The performance index of stepped capillary tube system and capillary tube assembly system are almost identical, hence, the stepped capillary tube can replace the capillary tube assembly in the R410A heat pump type air conditioner absolutely.

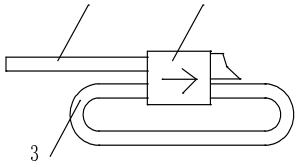
Keywords: R22, stepped capillary tube, throttle,model

Abstract. In order to calculate the structure size of stepped capillary tube, the experiments of flow characteristic of it were performed. The experience benchmark model of flow characteristics of R22 was set up through experimental method in specific reference conditions based on the impedance calculation method. The variable working condition model suitable for a range of conditions was obtained through fixing the condition based on the reference model. The mass flow rate of refrigerant R22 in two stepped capillary tubes with different size was tested. The experimental results show that the stepped capillary tube model has a high precision and working condition of certain flexibility. The deviation of cooling and heating flow between the calculated values and measured values are less than±10%. The model can meet the need of matching for stepped capillary tube on the heat pump type air conditioner with R22.

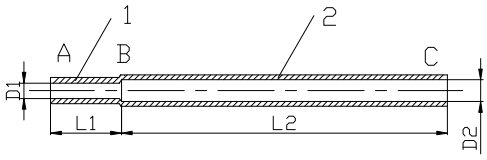
Introduction

The mass flow rate of refrigerant in heat pump type air conditioner is different under heating and cooling mode. The mass flow rate of cooling mode is more than that of heating mode. In order to realize it, the capillary tube assembly is used in the heat pump type air conditioner. Fig.1 shows the schematic diagram of the Capillary tube assembly. The length of capillary tubes are different under heating and cooling mode（for cooling mode, the refrigerant only goes through auxiliary capillary tube along the flow the path of A—B—E, for heating mode, the refrigerant goes through two capillary tubes sequentially along the flow the path of E—D—C—B—A）[1]. The cost of capillary tube assembly is increased about $1 for adding the check valve. According to the performance of gas-liquid two phase flow in the capillary tube, Xu[2] invents a stepped capillary tube(as shown in Fig.2). It is composed of two tubes with different diameter, and it can replace the capillary tube assembly so as to reduce the expense as well as simplify the structure.



1-main capillary tube, 2-check valve, 3-auxiliary capillary tube

Fig.1 Capillary tube assembly



1-auxiliary capillary tube, 2-main capillary tube

Fig.2 Stepped capillary tube

Xu[2] performed the experiments of the stepped capillary tube replaced the capillary tube assembly in a heat pump type air conditioner (KFR-32GW) with R22. The ideal results were obtained. The stepped capillary tube must meet the need of flow under heating (the flow direction of refrigerant is C—B—A) and cooling mode (the flow direction of refrigerant is A—B—C) in refrigeration system matching. Two pipes diameter and length must be designed. The workload of experiment will be very large if the structure sizes are confirmed only through the air conditioner matching test. Hence, in order to reduce the matching workload, the model for calculating the structure sizes of the stepped capillary tube should be set up.

Modeling and solving

The flow region of refrigerant in capillarity tube can be divided into supercooled liquid region, metastable liquid area, metastable gas-liquid two phase zone and thermal equilibrium state of gas liquid two phase zone. The throttling theoretical model is very complex. At present, the models for calculating the capillary are all based on the one-way flow and a single diameter. Their calculation error is general within ±10％[3-5]. Few researchers study the flow characteristic of stepped capillary tube. The theoretical and empirical models of stepped capillary tube are not appearing. If the theoretical model of stepped capillary tube was set up based on the model of capillarity tube, its difficulty will be larger, and calculation accuracy is limited[6-8]. Hence, we try to establish a semi-empirical model through experimental method, which can be suitable for specific refrigerant, a range of operating conditions and refrigerant mass flow rate. The aim is to solve the application problem of stepped capillary tube in practical engineering.

Reference model. The flow resistance of the stepped capillary tube as shown in Fig.2 is composed of three portions. It includes the on-way resistance of the auxiliary capillary tube (ΔP_1), the main capillary tube (ΔP_2) and local resistance of the mutations place (ΔP_ξ). The local resistance is very small, so it can be ignored. When the pressure difference of import and export of the stepped capillary tube is a definite value, the dimensionless linear relationship between the mass flow rate and the structure size can be set up according to the impedance calculation under heating and cooling mode. It is expressed in Eq. (1).

$$\begin{cases} a_1 + b_1\left(\frac{L_1}{D_1^5}\right) + c_1\left(\frac{L_2}{D_2^5}\right) = \frac{1}{Q_C^2} \\ a_2 + b_2\left(\frac{L_1}{D_1^5}\right) + c_1\left(\frac{L_2}{D_2^5}\right) = \frac{1}{Q_H^2} \end{cases} \quad (1)$$

Where a_1, a_2, b_1, b_2, c_1, c_2 is the non-dimensional coefficient. L_1, D_1 is the length and inside diameter of the auxiliary capillary tube, respectively, mm. L_2, D_2 is the length and inside diameter of the main capillary tube, respectively, mm. G_C, G_H is the mass flow rate under cooling and heating mode, respectively, kg/h.

Non-dimensional coefficient

Experimental parameter. The Eq. (1) is the mathematical model that the working conditions of stepped capillary tube and refrigerant type is given. The relevant data of cooling and heating flow with different structure size of stepped capillary tube can be obtained by experimental method. Then the specific value of dimensionless coefficient can be gained through linear regression. Under the standard working condition of refrigeration and heating of heat pump type air conditioner (KFR-32GW), the parameters of inlet and outlet of the capillary tube assembly were chosen as the working condition parameter of stepped capillary tube. Table.1 shows the benchmark condition parameters of stepped capillary tube. The cooling capacity of heat pump type air conditioner (R22 is as the refrigerant) is from 2000W to 5000W, and the corresponding mass flow rate of cooling and heating is from 40 kg/h to 100 kg/h. So the structure size of the stepped capillary tube is decided as follows: D_1=1.1, 1.2, 1.3, 1.4,1.5,1.6 mm, D_2=1.6, 1.7, 1.8,1.9, 2.0,2.2 mm, L_1 =50～1000 mm, L_2=300～1000 mm.

Table.1 Benchmark condition parameters of stepped capillary tube

Mode	P_{CO} kPa	T_{CO} ˚C	P_{EO} kPa	T_{EO} ˚C	T_{SCO} ˚C
Cooling	1770	46	622	7	5
Heating	1810	47	566	4	5

Where P_{CO}, P_{EO}, T_{CO}, T_{EO}, ΔT_{SCO} is the condensing pressure, kPa, evaporating pressure, kPa, condensing temperature,˚C, evaporating temperature and supercooling degree, ˚C, under benchmark conditions, respectively.

Experimental rig. The flow of refrigerant in the stepped capillary tube was tested on the experimental rig for measuring mass flow characteristics of the throttle mechanism. Fig.3 is the schematic of the experimental rig. This rig contained a compressor, an oil separator, a water-cooling condenser, an evaporator, a subcooler and a test section. The condensing pressure was controlled by adjusting flow rate of water in the condenser, the evaporating pressure was controlled by adjusting the frequency of compressor, and the subcooling temperature was controlled by adjusting the water flow rate in the subcooler. The mass flow rate was measured by a Coriolis type mass flow meter with the uncertainty of ±0.2%. The inlet and outlet pressures of the test stepped capillary tube were measured by pressure sensors with the uncertainty of ±0.2%, and the inlet and outlet temperatures were measured by T-type thermal couples with uncertainty of ±0.2 ºC.

Fig. 3 Test rig for mass flow rate in step capillary tube

Linear regression. The orthogonal experiment scheme(four factors, four level) was adopted in this experiment. We made 16 stepped capillary tubes. The mass flow of stepped capillary tubes was tested on the experimental rig for measuring mass flow characteristics of the throttle mechanism. The 16 mass flow values of cooling and heating were linear regressed. The experience calculation model for the physical dimension of stepped capillary tube is shown in Eq. (2).

$$\begin{cases} 115+1.77\left(\frac{L_1}{D_1^5}\right)+1.08\left(\frac{L_2}{D_2^5}\right)=\frac{10^6}{Q_C^2} \\ 187+1.54\left(\frac{L_1}{D_1^5}\right)+0.849\left(\frac{L_2}{D_2^5}\right)=\frac{10^6}{Q_H^2} \end{cases} \quad (2)$$

Variable working condition model. Throttling flow characteristic semi-empirical model of stepped capillary tube was set up by correction method of working condition. The variable working condition model is shown in Eq. (3).

$$\begin{cases} k_1\left[115+1.77\left(\frac{L_1}{D_1^5}\right)+1.08\left(\frac{L_2}{D_2^5}\right)\right]=\frac{10^6}{Q_c^2} \\ k_2\left[187+1.54\left(\frac{L_1}{D_1^5}\right)+0.849\left(\frac{L_2}{D_2^5}\right)\right]=\frac{10^6}{Q_H^2} \end{cases} \quad (3)$$

Where k_1, k_2 is the correction factor of cooling and heating mode, respectively. The change of condensing pressure, evaporating pressure and supercooling degree has a different sensitive degree of influence on the flow characteristic of the stepped capillary tube. Hence, the ratio of condensing pressure, evaporating pressure and degree of supercooling were introduced as the influence factor. Eq.(4)shows the correction factor of the working conditions.

$$k = m\left(\frac{P_C}{P_{CO}}\right)^r \cdot \left(\frac{P_E}{P_{EO}}\right)^s \cdot \left(\frac{\Delta T_{SC}}{\Delta T_{SCO}}\right)^t \quad (4)$$

Where m is the comprehensive effect coefficient of working condition. r, s, t is the influence factor of condensing pressure ratio, evaporating pressure ratio and supercooling degree ratio, respectively. P_C, P_E, ΔT_{SC} is the condensing pressure, kPa ,evaporating pressure, kPa, and supercooling degree, ˚C. The range of condensing pressure and supercooling degree of heat pump type air conditioner under cooling and heating mode with R22 is from 1600 kPa to 2200 kPa and from 3˚C to 9˚C, respectively. The corresponding condensing temperature is from 41.6˚C to 51.3˚C. The range of evaporating pressure is from 550 kPa to700 kPa and from 500 kPa to 650 kPa under cooling and heating mode, respectively. The corresponding condensing temperature is from 41.6˚C to 51.3˚C and from 0˚C～8.5˚C, respectively. The orthogonal experiment scheme was designed with the P_C, P_E, ΔT_{SC} as the influence factors. It can be seen from Table.2.

The stepped capillary tube (D_1=1.4mm，L_1=300mm，D_2=1.9mm，L_2=400mm) was chosen for testing. The cooling and heating capacity is 68.4 kg/h and 59.1 kg/h under the benchmark condition, respectively. 16 groups of cooling and heating mass flow data were obtained under 16 different cooling and heating conditions. The parameter of m, r, s, t is 0.983, -1.11, -0.0672, -0.284 under cooling mode, respectively, and 0.933, -1.12, -0.0319, -0.272, under heating mode, respectively, after the data regression processing. Thereby, the correction coefficient of working condition of cooling (k_1) and heating (k_2) flow is shown in Eq. (5) and Eq. (6).

$$k_1 = 0.983\left(\frac{P_C}{1770}\right)^{-1.11} \cdot \left(\frac{P_E}{622}\right)^{-0.0672} \cdot \left(\frac{\Delta T_{SC}}{5}\right)^{-0.284} \quad (5)$$

$$k_2 = 0.933\left(\frac{P_C}{1810}\right)^{-1.12} \cdot \left(\frac{P_E}{566}\right)^{-0.0319} \cdot \left(\frac{\Delta T_{SC}}{5}\right)^{-0.272} \quad (6)$$

As can be seen from Eq. (5) and Eq. (6), condensing pressure has a major effect on the mass flow rate, while evaporating pressure and supercooling degree has a little effect on it. But the change of the supercooling degree in air-conditioner is large, which make the supercooling degree has a obvious effect on the flow. This is accordance with literature [2]and [6].

Table.2 Testing program of cooling and heating mode

No	P_C kPa	P_E(Cooling) kPa	P_E(Heating) kPa	ΔT_{SC} ˚C
1	1600	550	500	3
2	1600	600	550	5
3	1600	650	600	7
4	1600	700	650	9
5	1800	550	500	5
6	1800	600	550	3
7	1800	650	600	9
8	1800	700	650	7
9	2000	550	500	7
10	2000	600	550	9
11	2000	650	600	3
12	2000	700	650	5
13	2200	550	500	9
14	2200	600	550	7
15	2200	650	600	5
16	2200	700	650	3

Solution of the variable working condition model. The model has no fixed results because there are four unknown numbers (D_1, D_2, L_1, L_2) in Eq. (3). It is suppose that the inner diameter of auxiliary capillary tube and main capillary tube are constant (D_1 is designed as 1.1,1.2,1.3,1.4,1.5,1.6 mm; D_2 is designed as1.6,1.7,1.8,1.9,2.0,2.2mm), then the length of tube can be acquired. If L_1 and L_2 are between 0 and 1000, so the value of D_1, D_2, L_1, L_2 are the needed results. If L_1 and L_2 is beyond the scope, then the value of D_1 and D_2 must be supposed again and recalculate until $L_1$and L_2 is in the scope of the above. If D_1, D_2, L_1, L_2 has no result in the range, which indicates that the stepped capillary tube can not be used on this heat pump type air conditioner.

Model verification

Flow verification of stepped capillary tube. Two kinds of stepped capillary tube were tested in the experiment. The diameter and length of the stepped capillary tube (D_1=1.5 mm, L_1=200 mm, D_2=2 mm, L_2=700 mm) is for "A" group. The parameter of "B" group is D_1=1.4 mm, L_1=500 mm, D_2=1.8 mm, L_2=500 mm. The testing program is in accordance with Table.2. The measured value and calculated value of cooling and heating flow for "A" type stepped capillary tube is shown in Fig.4a and Fig.4b. Fig.5a and Fig.5b show the results of "B" type stepped capillary tube. In the drawing, Q_c is the calculated value of flow, Q_t is the measured value of flow.

As can be seen from Fig.4 and Fig.5, the deviation of the measured value and calculated value for the two type stepped capillary tube is less than $\pm 10\%$, it indicates that the variable condition experience model has a high precision.

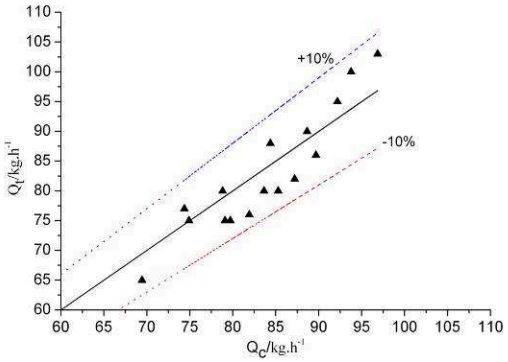

Fig.4a The measured value and calculated value of cooling flow for type "A"

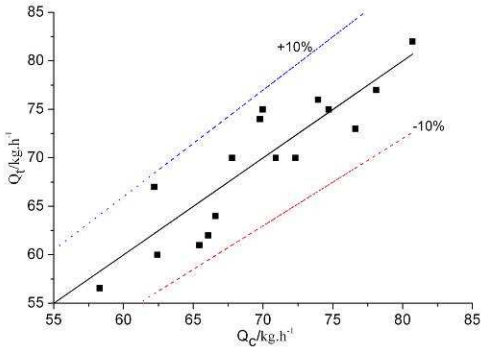

Fig.4b The measured value and calculated value of heating flow for type "A"

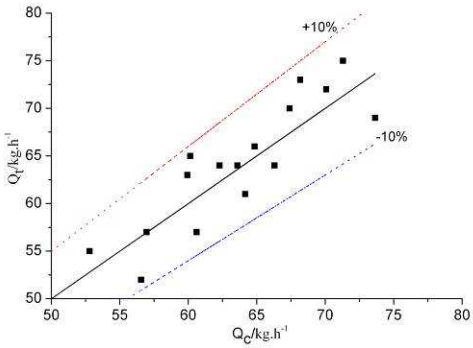

Fig.5a The measured value and calculated value of cooling flow for type "B"

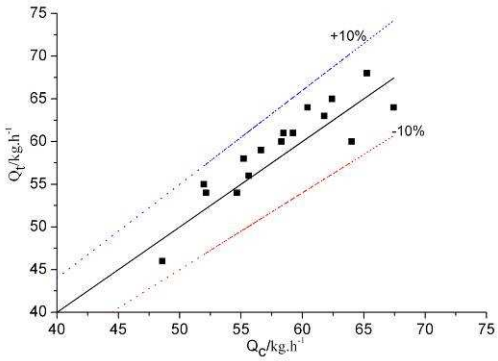

Fig.5b The measured value and calculated value of heating flow for type "B"

Conclusion

(1) The experience benchmark model of flow characteristics of R22 was set up through experimental method and based on the impedance calculation method. It has a high precision and working condition of certain flexibility. The deviation between the calculated values and measured values is less than±10%. The model can meet the need of matching for stepped capillary tube on the heat pump type air conditioner with R22.

(2) The condensing pressure has a major effect on the mass flow rate. The evaporating pressure and supercooling degree have a little effect on the mass flow rate. But the change of supercooling degree is larger in the design of air conditioner, which make the supercooling degree has a obvious effect on the mass flow rate.

Gas Load Characteristics and Calculation

Lei Zhao

Jilin Jianzhu University, Changchun, Jilin, China

Zhao0438@126.com

Keywords: Gas Load, Curve of Load Characteristics, Non-uniform Coefficient Method, Load Coefficient Method.

Abstract. Gas Load Characteristics of different users are analyzed in this paper. Different types of load charts which is drawn according to the statistical data may provide certain guidance for gas companies. Non-uniform coefficient method that continues to be used for calculation of gas load in China has limitations. It is more reasonable to calculate gas load with load coefficient method.

Introduction

China is in an age when gas demand is growing rapidly; in addition to gas consumed by residents and business users for cooking and industrial production, gas is applied more and more frequently in heating, air conditioning, vehicles and other fields. In particular, users for gas heating have stronger seasonal characteristics and their load characteristics are obviously different from other users. Load characteristics have a relatively big influence on gas storage and peak shaving measures adopted by urban gas transmission and distribution system, therefore it is necessary to carry out in-depth researches on load characteristics and their calculation methods.

Gas Load Characteristics

Gas Load Characteristics. Gas load is determined by gas consumption and there are different methods for classification of users based on the classification of gas consumption. Some countries classify gas consumption into gas for domestic use in residential houses, gas for commercial use and gas for industrial use and each of them includes gas for heating. In China, gas users are categorized into residents, users of commercial and industrial enterprises (excluding heating), heating users, air conditioning users, vehicle users, etc.

Residents and business users require continuous supply, so rule of load change is almost identical between them. For them, gas consumption is non-uniform in different seasons, days and hours, in which non-uniform gas consumption in different hours is relatively obvious and its obviousness is related to type and number of users, type and capacity of gas appliances used by users, structure of buildings where users live and their lifestyles. Generally, the more the users, the more uniform gas consumption will be.

Gas consumption for industrial production is less non-uniform than that for residents and business users, and non-uniformity mainly depends on shift systems of industrial enterprises.

Gas consumption of large-scale gas-fired boilers shows smaller fluctuation when there is no big change in air temperature, while gas consumption for household heating shows bigger fluctuation in one day. Number of such users is relatively small in China, so there is no complete statistical data about this aspect yet. Household heating is very common in America, Europe and other western countries and their experiences indicate that heating load peak often occurs between 6:00 and 9:00 a.m. in cold seasons and there exist obvious peak and valley. Daily load of gas heating is mainly influenced by outdoor temperature and wind speed, which is not generally a constant. However, it can be predicted by statistical data of urban climate unless extreme weather emerges.

Curve of Load Characteristics. For curve of load characteristics, time (month, day or hour) serves as horizontal ordinate, indicating changes of load in one or various user groups within one period. Load charts can be categorized into yearly, weekly and daily load chart, which are the basis for

designing gas transmission and distribution system. Different types of load charts may provide certain guidance for gas companies in production scheduling.

Figure 1 is the yearly load chart of 2001 in Huangpi District of Wuhan City. This figure indicates that there are four types of users in this region and their gas consumption in different seasons is non-uniform, in which the variation between winter and summer are most obvious. Gas supply plan can be worked out based on this figure. If gas supply units cannot increase or decrease gas supply according to seasonal variation, gas storage facilities are required to maintain the balance between supply and demand.

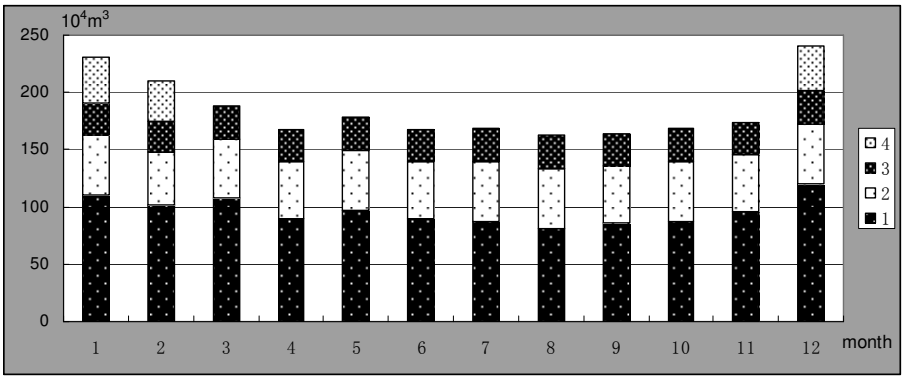

Figure 1 Yearly Load Chart of 2002 in Huangpi District of Wuhan City
1—Residents and business users 2—Industrial users
3—Vehicle users 4— Heating users

Figure 2 are respectively the hourly load chart in the week when gas consumption of residential users, business users and industrial users in Huangpi District of Wuhan City reaches the peak. This figure indicates that the largest gas consumption of residential users and business users doesn't occur in the same time period. Moreover, load characteristics in work days and holidays are also different because of lifestyles of residents.

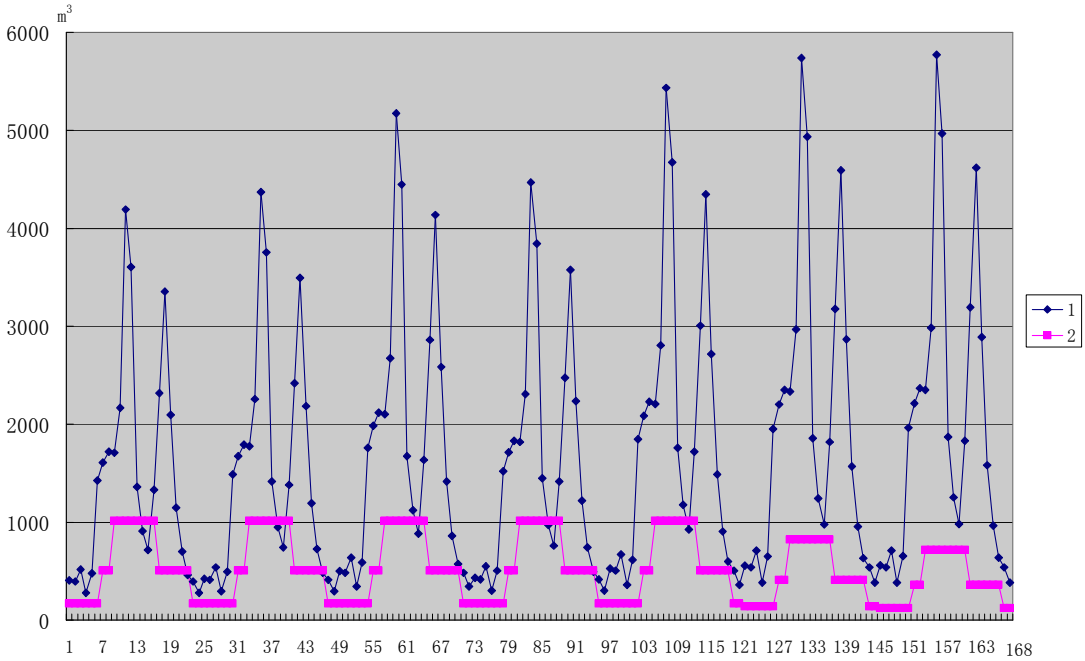

Figure 2 Daily Load Chart of users
1—Residents and business users 2—Industrial users

Heating is not taken into consideration in the above figures. When natural gas is applied in heating and such application reaches a certain scale, the maximum load of transmission and distribution system is often closely related to heating users. Therefore, it is very important to make a research on the load characteristics of gas heating and draw the load curve. There is a close relationship between

heating load and outdoor temperature. Figure3 is the daily load chart of heating users in a city in the US, in which different curves indicate different outdoor temperatures[1]. Although load increases along with decrease in outdoor temperature, the rule of load changes is basically identical.

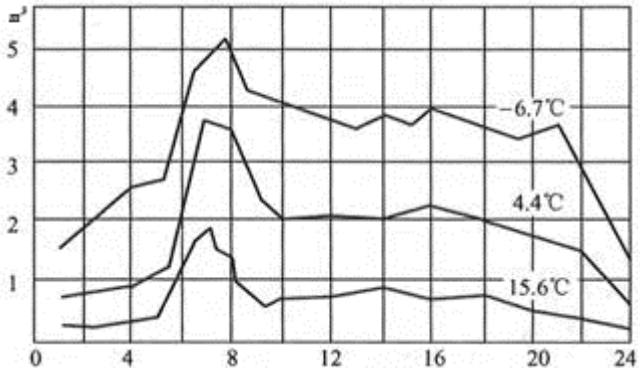

Figure3 Daily Load Chart of Heating users

Calculation of Gas Load

The method adopted by the former Soviet Union, namely non-uniform coefficient method, continues to be used for calculation of gas load in China, and changes in gas consumption of gas users are expressed with non-uniform coefficient. Firstly, yearly gas consumption of various types of users should be determined and then the peak hourly gas consumption can be calculated through three non-uniform coefficients, namely monthly, daily and hourly non-uniform coefficient. Herein, the month in which monthly non-uniform coefficient reaches the maximum is called month for calculation. Peak hour consumption is calculated as given blow[2].

$$Q_h = \frac{Q_y}{365\times 24} K_m^{\max} \bullet K_d^{\max} \bullet K_h^{\max} \tag{1}$$

Where, Q_h is hourly calculated flow (Nm^3/h), Q_y is yearly gas consumption (Nm^3/a), $K_m^{\max}$ is the maximum monthly non-uniform Coefficient, $K_d^{\max}$ is the maximum daily non-uniform Coefficient, $K_h^{\max}$ is the maximum hourly non-uniform Coefficient.

The premise for the formula being applicable is that the maximum daily peak coefficient occurs in the month for calculation, and the maximum hourly non-uniform coefficient and daily non-uniform coefficient occur in the same day, namely that month for calculation and peak day and peak hour coincide with each other. It is apparently that this assumption is unreliable.

In fact, gas companies in various regions draw yearly-daily load chart and yearly-hourly load chart based on statistical data in several years, in which the maximum daily gas consumption and maximum hourly gas consumption can be obtained. Many practices have proven that the concept of month for calculation is meaningless. For example, month for calculation of Changchun City in 2011 occurs in December, but the peak day occurs in January. Actually the maximum daily gas consumption in cities around China usually occurs on the New Year' Eve, so it is very important to ensure that sufficient gas can be supplied in this day. Therefore, data obtained through Formula (1) are inaccurate.

It is more reasonable to calculate gas load with load coefficient method. Load coefficient can be defined as the ratio of actual gas consumption in a certain period to the maximum short-term gas consumption in the same period.

Generally speaking, if load coefficient is based on Period a and Period b and Period b should be longer or cross Period a, then in the same climatic conditions, load coefficient can be expressed as

$$L_{a,b} = \frac{Q_{b,n}}{Q_{b,n}^{\max}} \tag{2}$$

If b stands for year and a stands for day, then daily load coefficient should be $L_{d,y}$, and herein $Q_{b,n}$ is annual average daily gas consumption and $Q_{b,n}^{\max}$ is the maximum of $Q_{b,n}$, namely the maximum daily gas consumption.If b stands for year and a stands for hour, then hourly load coefficient is $L_{h,y}$, $Q_{b,n}$ is annual average hourly gas consumption and $Q_{b,n}^{\max}$ is the maximum of $Q_{b,n}$, namely the maximum hourly gas consumption[3].

It can be known from definition of the two coefficients that non-uniform coefficient is always more than or equal to 1 and load coefficient is always less than 1. The larger the difference between 1 and these two coefficients, the more non-uniform the gas consumption will be.Table 1 can be filled out through an analysis on the statistical data of Changchun City in 2011 with the two methods.

Table 1 The statistical data of Changchun City in 2011

Type of Users	Residential Users	Business Users	Industrial Users	Vehicle Users
$K_m^{\max}$	1.65	1.65	1.0	1.1
$K_d^{\max}$	1.1	1.1	1.1	1.1
$K_d^{\max}$	2.2	2.2	1.5	1.5
$L_{h,y}$	0.35	0.40	0.89	0.50

It can be obtained through non-uniform coefficient method that peak hourly gas consumption is 145000m^3/h; it can be obtained through load coefficient method that peak hourly gas consumption is 126000 m^3/h; and the difference between them is 13%. It is obvious that the latter is more accurate. Therefore, adopting load coefficient method to calculate gas load can save project investment.

Conclusion

Heating users and non-heating users have different load characteristics and gas consumption peaks for them present different trends. Drawing curves of load characteristics for various types of users can better reflect characteristics of users and thus provide basic data for the optimization of urban gas transmission and distribution system. Climatic conditions, such as temperature and wind speed, have relatively big influence on heating user load.

Non-uniform coefficient method commonly used in China may lead to relatively big deviation, while load coefficient method doesn't require month for calculation to calculate peak hourly gas consumption. It is easier to obtain data for this method and its calculation results are accurate, so it is a method worth promotion.

Keywords: Central air-conditioning; STC11F08XE; PID optimization; Infrared control

Abstract: In this paper, hardware and software of the central air-conditioning control system is researched by STC series of enhanced 8051 microcontroller. The STC11F 08XE is the main control of the hardware part. Temperature and humidity sensor regulating valve and all kinds of motor are used as external equipment to complete the temperature and humidity of building the internal control of central air conditioner. In terms of software, the program is described by protel99SE software. Microcontroller program is compiled by Microcontroller development tools keil u and STC-ISP. The temperature and humidity control and optimization of central air conditioning are completed by PID parameters. Infrared control unit is operated and liquid crystal is displayed to show the operation results.

Introduction

Today's rapid development of intelligent building, central air conditioning is one of the main monitoring objects of building automation system. The reaction is slow, lagging more serious resulting in its annual power consumption accounts for about 50% -60% of the total electricity consumption of buildings [1-2]. Central air conditioning system is currently more widely, almost all large new buildings are equipped with central air-conditioning system, its development is more and more like energy, health, excessive. In this paper, According to the internal resources of traditional microcontroller less, performance and working slow defects, put to use the STC series enhanced 8051 microcontroller hardware design and software design of the central air conditioning.

The design of hardware of the central air-conditioning control system

Design principle. Central air conditioning indoor temperature and humidity make people get more comfortable office environment. When people adjust the indoor temperature and humidity through an infrared remote control for central air-conditioning inside the core of STC microcontroller instructions, STC microcontroller will mobilize the temperature sensor (18B20), humidity sensor (SHT11) to detect the new outlet, air inlet temperature and humidity. When the control valve receives the feedback signal detection, can automatically adjust the opening size. At this time, new entrants into the fresh air will be the same as the indoor return air mixing, forming a hybrid wind. When the wind pipe mixed air temperature is too high, the motor will drive the surface cooler for cooling treatment, hot and cold water will PID adjustment. In the precondition of ensuring the load demand, achieve the maximum energy saving central air conditioning. After A/D conversion, the humidity and temperature value is displayed on the LCD screen for people to confirm. The central air conditioning design principle is shown in Fig 1.

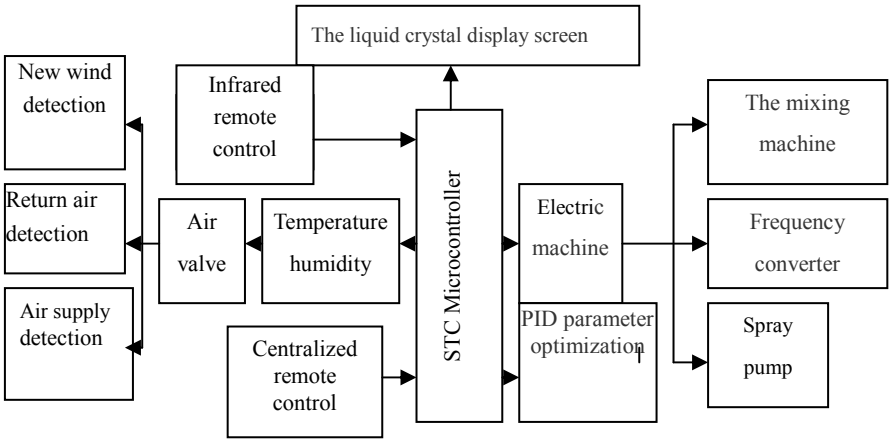

Fig 1. The design principle of central air conditioning

Hardware selection. The hardware selection of this text mainly includes micro controller, temperature and humidity sensor, regulating valve, frequency converter, air valve actuator and selection of related hardware. The list is shown in Table 1.

Table 1.The hardware list

sequence	type	hardware
1	micro controller	STC11F08XE
2	temperature sensor	DS18b20
3	humidity sensor	SHT11
4	regulating valve	Danfoss
5	frequency converter	MICROMASTER430
6	air valve actuator	GBB161.2E

The microcontroller used in this design is STC11F08XE. Resources on chip, performance and work speed have a great improvement compared with the traditional 8051 microcontroller core. Especially a Flash-based online system programming ISP technology is used. While the choice of on-chip resources is automatically follow the "good enough" principle to ensure the performance and reliability of the STC microcontroller system. STC11F08XE microcontroller incorporates enhanced 8051 CPU, 8KB Flash program memory, 1280 bytes of RAM, full-duplex asynchronous serial interfaces UART and MAX810 circuit and a dedicated hardware watch dog. Temperature sensor DS18b20 is all digital conversion and output temperature sensor. Having a single bus data communication of advanced, the highest resolution can reach 12. MICROMASTER430 inverter model has 6 programmable with potential isolation digital inputs, 2 analog inputs, 2 programmable analog output, 3 editable contact electrical output, has captured in the start-up and slip compensation function, senior PID built-in regulator.

The PID parameter optimization. PID control is widely used in the central air conditioning cold and hot water regulating control systems. When the central air conditioning temperature and humidity sensor built-in of the fresh air temperature and humidity, transformed into (4~20) mA current signal, through the STC11F08XE MCU A/D conversion unit, the analog signal into digital signal, and achieve PID control through software programming, thus mixing unit for temperature and humidity treatment to reach the people satisfied the requirements of fresh air is driven by single chip microcomputer. The traditional PID control principle is simple, strong robustness, adaptability. But the central air conditioning system is large, the control loop is more. The traditional PID algorithm parameters are difficult to meet requirements. This design adopts the ant colony algorithm to optimize the parameters of PID control. Ant colony algorithm is a heuristic algorithm for discrete

optimization problems. Its main part is the computer resource allocation to a group of relatively simple artificial ants, indirect communication between artificial ants through media.

Central air conditioning control system software design

The main part of the software design is to control the temperature and humidity of central air conditioner. The flow chart is shown in Fig 3 for motor control and analog digital conversion temperature and humidity detection software programming. Firstly, software design principle diagram mainly includes the main circuit part, USB download section, expanding pin part and power supply. Secondly, selection of the temperature and humidity control programming software Keil vision. They include temperature detection, humidity detection, PID regulation and each motor start stop. Finally, use ISP-STC burning software will be edited program recorded to calculate. The selected models in ISP-STC single chip microcomputer, click "open file" and in the dialog box to find the compiled program files to download, press the power switch to manual executable file write monolithic internal. The design of the software using C language and assembly language combining programming, the A/D conversion part of the program code is shown in Fig 2.

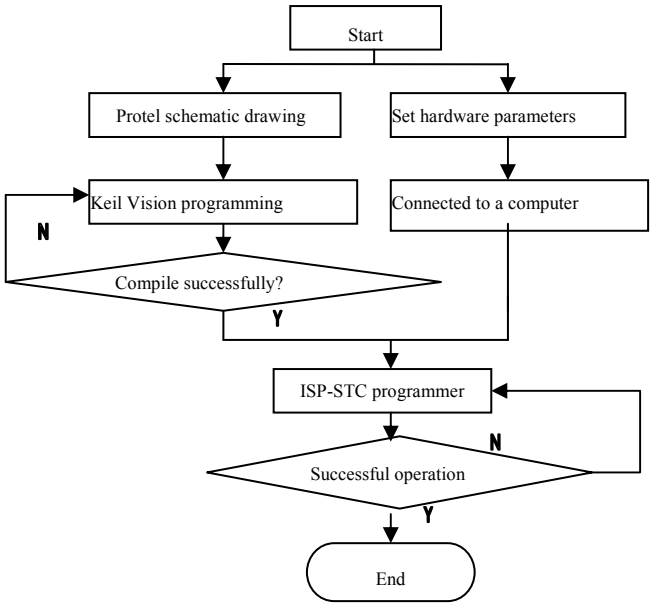

Fig 2. The software design flow chart of central air conditioning control system

Design and display of remote control

With the progress of society，more and more devices are equipped with remote control. The design of the infrared remote control to control the central air conditioning of STC11F08XE single-chip operation, it is the motor start and stop and the temperature and humidity detection. Of course, the infrared remote control to be equipped with an infrared emission tube, when the electric infrared receiving end to form on the radio state. The infrared remote control by the 555 circuit generates a pulse signal, produced by the oscillating circuit characteristic frequency pulse through the drive signal of infrared emission tube emits the same frequency, complete the infrared control. The design diagram is shown in Fig 3.

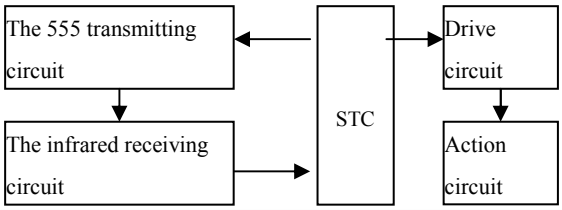

Fig 3. The design diagram of infrared remote control

Conclusions

The design is based on STC11F08XE single chip microcomputer as the control core. The design of hardware and software of central air conditioning are completed. The improved PID algorithm is adopted. The algorithm is combined with ant colony algorithm embedded traditional PID regulator. The control of hot and cold water of central air-conditioning temperature and humidity detection are completed. LCD screen display of central air-conditioning control results.

Keywords: High-temperature superconductor (HTS), controllable reactor, structure, reactive power

Abstract. The power equipments made of high-temperature superconductor (HTS) widely applied in power system in the recent years. A HTS adjustable reactor (HTS-AR) is a novel controllable reactor with the controllable windings made of HTS tapes. Shunt HTS-AR can regulate the reactive power of power and reduce the transmission loss. However, the leakage magnetic flux of the superconducting windings is relatively large, which may restrict the application of the HTS-AR in high-voltage transmission line. Basing on the research of the structure design for HTS winding, the characteristic analysis of magnetic and AC loss of HTS-AR with considering the structure of superconducting winding is shown in this study. The results show that the HTS winding with the ladder-like structure has a better performance compares with HTS winding with the solenoid structure.

Introduction

A controllable reactor can automatically and smoothly adjust its inductance and thus provide a continuous reactive power compensation to suppress system over voltage [1]. There are mainly two types of controlled reactors applied in power system: saturable reactor (SR) and thyristor controlled reactor (TCR). Reactance of SR is changed by regulating the DC flux component in core [2-3]. TCR is controlled by triggering the thyristor valve [4]. What's worse, most of traditional reactors have serious harmonic components which limit their application [2]. Hence, a new method of reactive power adjustment is proposed, which contains partly and step adjustment, thus the reactive power variation range is quite large [5-6].

With the development of high temperature superconductivity (HTS) technology, the power equipments made of HTS tapes are widely applied in power systems. A HTS adjustable reactor (HTS-AR) is a novel controllable reactor with the controllable windings made from HTS tapes [7]. A HTS-AR with two HTS controllable windings has been developed in [8]. However, the structure of the HTS windings is solenoid, which makes leakage magnetic flux and the AC loss of the HTS windings are large. So it is necessary to improve the structure of the HTS windings to improve the characteristic of the HTS-AR. Basing on the research of the structure design for HTS winding, the characteristic analysis of magnetic and AC loss of HTS-AR with considering the structure of superconducting winding is show in this study.

Structure and principle of HTS-AR

The HTS-AR has a gapless core, main winding, and two HTS windings. Both of the HTS windings are wound concentrically inside the main winding, as shown in Fig. 1. The main winding is connected to the AC power line. The leakage reactance of the HTS-AR is large, which mainly represent the reactance of this controllable reactor. The reactance can be adjusted by alternatively open and short HTS windings. The HTS windings are wound by Sumitomo BSSCO wire Type H [9]. Considering

both the HTS windings have the same structure and principle, the structure of one HTS windings is researched. Table 1 shows the parameters of the HTS-AR.

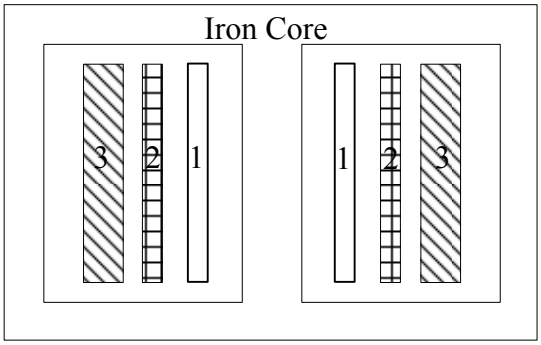

Fig. 1. Structure of HTS-AR
1-HTS-1 winding, 2-HTS-2 winding, 3-main winding

Table 1 The parameters of HTS-AR

rate voltage	380 V	Height of HTS winding	319.5 mm	Turns of HTS winding	426
rate current	100 A	Height of main winding	415 mm	Turns of main winding	190

Characteristic analysis of electromagnetic and AC loss

Calculation of magnetic and AC loss of HTS winding. The magnetic and current of HTS winding can be calculated by ANSYS [10]. Considering the anisotropy of BSCCO tape, we only research the vertical magnetic of HTS winding. The HTS winding of this HTS-AR is working in AC source. The HTS winding will generate AC loss, which will increase the cost of refrigeration and decrease the working reliability and safety. Based on equations provided by Carr [11], Muller [12], and simplified in [13], we use equations (1)-(5) to calculate the AC loss of HTS winding.

$$Q_{//} = \frac{2B_{a//}^2}{\mu_0}\left[\frac{i^3}{3\beta_{//}^2} + i\right] \qquad for \quad \beta_{//} \le 1 \tag{1}$$

$$Q_{//} = \frac{2B_{a//}^2}{\mu_0}\left[\frac{i^2}{\beta_{//}} + \frac{\beta_{//}}{3}\right] \qquad for \quad i \le \beta_{//} \le 1 \tag{2}$$

$$Q_{//} = \frac{2B_{a//}^2}{\mu_0}\left[\frac{3+i^2}{3\beta_{//}} - \frac{2(1-i^3)}{3\beta_{//}^2} + \frac{6i^2(1-i)^2}{3\beta_{//}^2(\beta_{//}-i)} - \frac{4i^2(1-i)^3}{3\beta_{//}^2(\beta_{//}-i)}\right] \qquad for \quad \beta_{//} \ge 1 \tag{3}$$

$$Q_{\perp} = \frac{2B_{a\perp}^2}{\mu_0}\frac{\pi w}{2\beta_{\perp} d}\left[\frac{2}{\beta_{\perp}}\ln(\cosh\beta_{\perp}) - \tanh\beta_{\perp}\right] \tag{4}$$

$$Q = Q_{//} + Q_{\perp} \tag{5}$$

Where $Q_{//}$ and $Q_{\perp}$ is the AC loss which is generated by the parallel magnetic and vertical magnetic of HTS winding, respectively. Table 2 shows the maximum vertical magnetic and AC loss of HTS winding with the parameter shown in Table 1.

Table 2 Magnetic and AC loss of HTS-AR

Maximum vertical magnetic	945 Gs	AC loss of parallel magnetic	54.33 W
AC loss of vertical magnetic	15.87 W	Total AC loss	70.20 W

Structure design of HTS Winding. A ladder-like structure of HTS winding is designed to analysis the characteristic of HTS-AR, as shown in fig 2. The current of HTS-AR, the leakage magnetic and AC loss of HTS winding are mostly affected by the parameters of the ladder-like structure. In Fig. 2, h_c is the total height of HTS winding, h_{c2} is the height of bulge, and $h_{c2}=h_c-2\times h_{c1}$. d_c is the total thickness of HTS winding, d_{cc} is the thickness of the bulge.

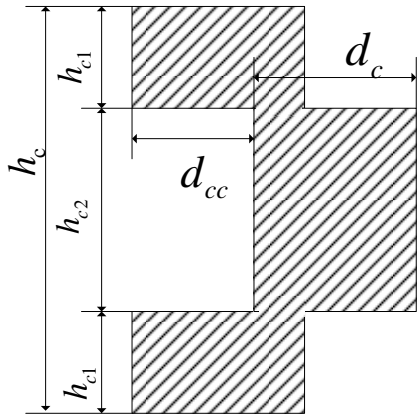

Fig. 2. The ladder-like structure of HTS winding

Electromagnetic characteristic analysis. The results of the electromagnetic characteristic of HTS-AR with ladder-like structure are shown in Figs. 3-4. Fig. 3. Shows the current of HTS-AR with h_{c1}/h_c is from 0.1 to 0.4 when d_{cc}/d_c is from 0.1 to 0.9. Fig. 4. Shows the maximum vertical magnetic field of HTS winding with h_{c1}/h_c is from 0.1 to 0.4 when d_{cc}/d_c is from 0.1 to 0.9.

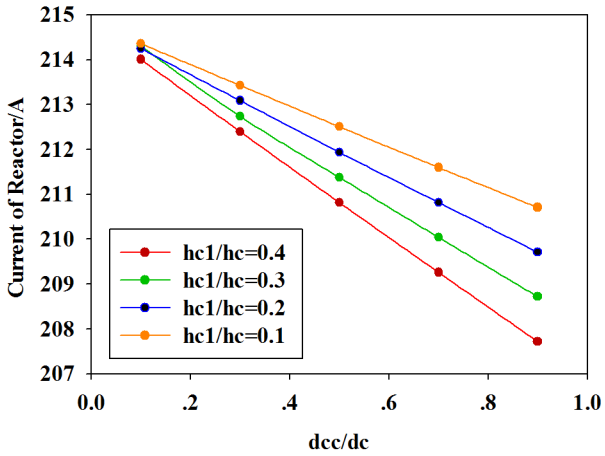

Fig. 3. The current of HTS-AR

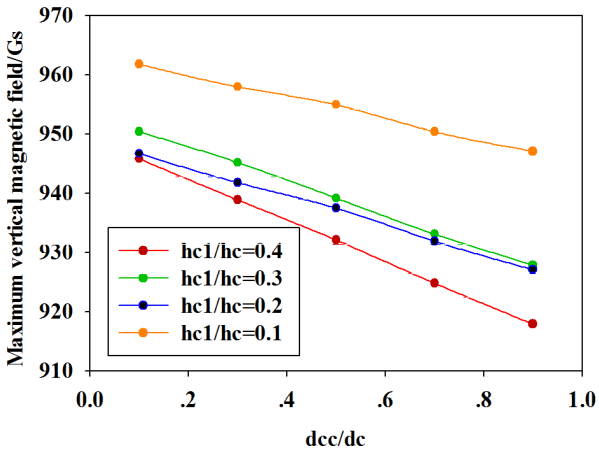

Fig. 4. The maximum vertical magnetic field

The current of HTS-AR is linearly reduces as d_{cc}/d_c increase from 0.1 to 0.9. When d_{cc}/d_c is 0.9, the current of HTS-AR reduce from 211 A to 207.5 A when h_{c1}/h_c is from 0.1 to 0.4. The attenuation rate is 1.66%. When d_{cc}/d_c is 0.1, the current of HTS-AR is almost no change. These results show that the height of the bulge will affect the work characteristic of HTS-AR when the thickness of the bulge is various. The effect will be weak when the thickness of the bulge is small. The effect will be strong when the thickness of the bulge is large. The effect caused by the height of the bulge will increase obviously when the thickness of the bulge increases.

The maximum vertical magnetic of HTS winding will linearly reduce when the thickness of the bulge increase. When d_{cc}/d_c is 0.9, the maximum magnetic of HTS winding reduce from 952 Gs to 917 Gs as h_{c1}/h_c is from 0.1 to 0.4. The attenuation rate is 3.68%. When d_{cc}/d_c is 0.1, the maximum magnetic of HTS winding reduce from 963 Gs to 946 Gs as h_{c1}/h_c is from 0.1 to 0.4. The attenuation rate is 1.76%. The maximum magnetic of the HTS winding will decrease when both the height and

thickness of the bulge increases. The attenuation rate of the maximum magnetic of HTS winding will slightly increase when the thickness of the bulge increases.

AC loss analysis of HTS winding. Figs. 5-7 show the total AC loss and AC loss in vertical magnetic, parallel magnetic of HTS winding. The total AC loss and the AC loss of vertical magnetic and the AC loss of parallel magnetic will nearly linearly decrease. When d_{cc}/d_c is 0.9, the total AC loss, the AC loss of vertical magnetic, and the AC loss of parallel magnetic reduce from 66.84 W, 15.03 W, and 51.8 W to 63.29 W, 14 W, and 49.27 W, respectively, as h_{c1}/h_c is from 0.1 to 0.4. The attenuation rate of the total AC loss, AC loss of vertical magnetic, and the AC loss of parallel magnetic is 5.31%, 6.85%, and 2.15%, respectively. When d_{cc}/d_c is 0.9, the total AC loss, the AC loss of vertical magnetic, and the AC loss of parallel magnetic are nearly no change. This indicates that the AC loss of HTS winding is mainly affected by the thickness of the bulge. The effect of AC loss caused by the height of the bulge is restricted by the thickness of the bulge. The attenuation rate rich the highest value when the height and the thickness of the bulge is large.

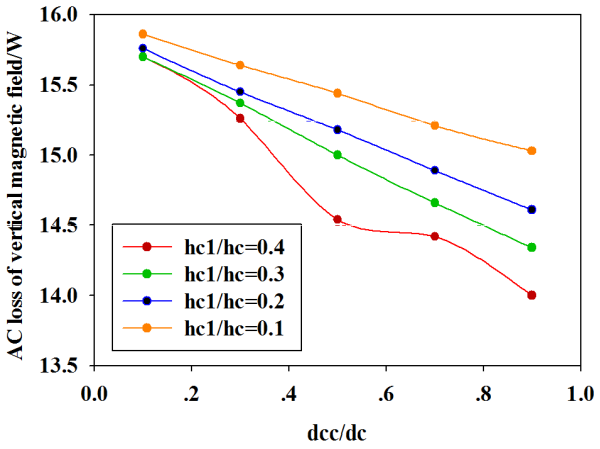

Fig. 5. AC loss of vertical magnetic field

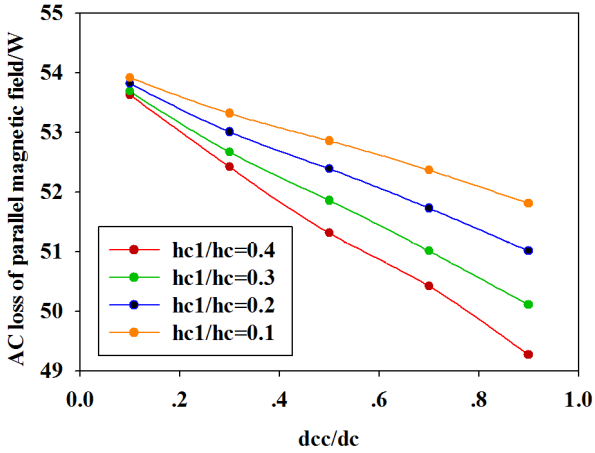

Fig. 6. AC loss of parallel magnetic field

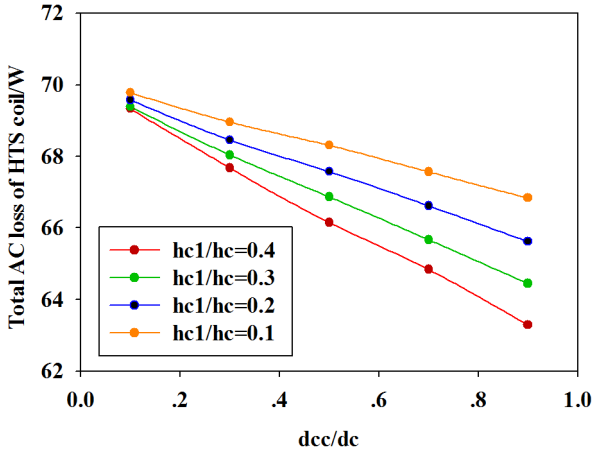

Fig. 7. The total AC loss of HTS winding

Conclusion

Basing on the ANSYS, the characteristic of electromagnetic and AC loss of a high temperature superconducting adjustable reactor (HTS-AR) with considering the structure of HTS winding is analyzed in this paper. The results show that the structure of the HTS winding will affect the work characteristic of HTS-AR, the maximum magnetic and the AC loss of the HTS winding. The current of main winding will reduce 1.66% when the sizes of the bulge are large. However, the attenuation rate of the AC loss is 6.85% when the sizes of the bulge are large. With the considering of the economy that the efficiency of the refrigerant is 0.05%, the larger AC loss will dramatically increased the cost of refrigeration and decrease the working reliability and safety. This indicates that the HTS

winding with the ladder-like structure has a better performance compares with HTS winding with the solenoid structure. The research in this study will provides some valuable reference for developing ultrahigh voltage and large capacity level HTS-AR.

Keywords: MEMS Geophone; Signal handing circuit; DC elimination;

Abstract. This paper aims at the problem that how to isolation the DC component of the MEMS geophone in the acquisition and processing of Seismic signal. Put forward to design a new circuit in the signal handing system. Design a new type of DC elimination circuit to eliminate the DC component through low-pass filter, reverse and other modules. The experiment result shows that, this new DC elimination circuit is easier to realize and has a large advantage than other existing DC elimination circuits.

Introduction

The sensors which were made by MEMS technology have a better performance than other traditional sensors. They have too many advantages such as the wider frequency band, the better LF response, lower noise, higher sensitivity, better linearity and so on. As result, researching the geophone base on the MEMS technology, improving the precision of the signal detection has important practical significance. The geophone base on the MEMS technology consists of the part of power supply, MEMS sensors and the signal handing circuits. What's more, the signal handing circuits consist of DC elimination, pre-amplifier, program control amplifier and filter circuit. Fig 1 shows the function diagram of this type of geophone.

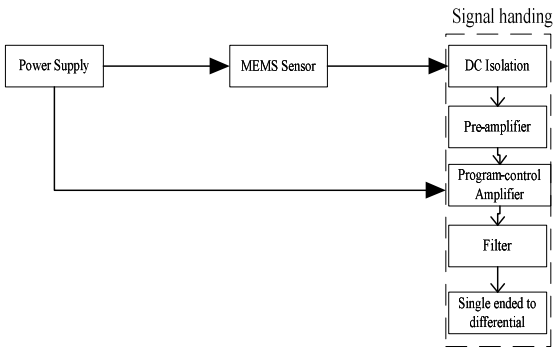

Fig. 1. Geophone function diagram

In the geophone system, signal handing circuit is the most important part of all. If the output error of any part in this circuit is larger than ever can inflect the later control system and the final seismic signal monitor and the system will affect the serious impact. As result, to design a reliable MEMS geophone's signal handing circuit occupies an important place in the whole system design. This

paper design a new type of DC elimination circuit apply to the Seismic acquisition and processing, this new type of DC elimination circuit has a lower response delay, higher precision and more reliable than other existing DC elimination circuit. It has a larger practicality and promotion value in Seismic signal processing.

Sensor, Amplifier and Transform Circuits Design

1.1 Sensor circuit design

This design chooses model1221L-002 accelerometer as the MEMS sensor, it manufacture by Silicon Designs Inc. it's a low noise capacitive accelerometer, its gravity block is the mobile heat convection nitrogen, it measure the acceleration by measure the inner temperature change cause by the acceleration. Model1221L-002 accelerometer owns a temperature sensor, which can measure the real temperature of the sensor inside; the senor is two way difference analog output, the difference analog output can eliminate the internal disturbance, reduce the impact cause by system error. In this design, if we let the sensor output the difference signal and use difference amplifier later, in that way, the signal in difference output unable to superposition. If we set it as in-phase input then there's none output signal, otherwise, if we set one output inverse and superimpose the output, then the DC offset will twice the value. In that way, it's very inconvenient in signal processing. So, this system must add a differential ended to single circuit to make the sensor output transform to single input of later signal handing circuit. We can see the detail circuit of sensor in figure 2.

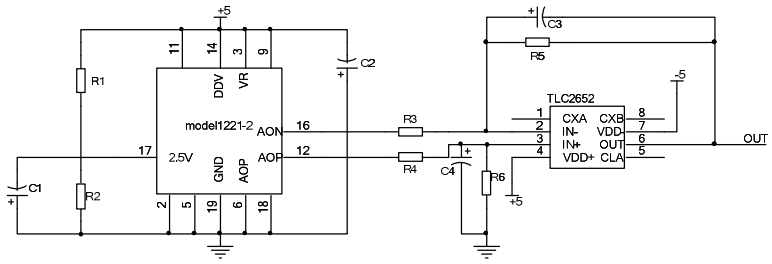

Fig. 2. Sensor circuit design

1.2 Pre-amplifier and signal transform circuits design

Analysis with exiting Seismic signal handing circuit, the circuit structure is almost the same. The signal processing circuits always use DC elimination part, pre-amplifier part and program-control amplifier part. Because of the follow-up ADC is differential output, so it must design a single ended to differential signal output to ADC. As result, this design use AD8138 chip and four same-arm resistances to transform the single signal output to differential output what the ADC needs.

In the signal handing circuit design, it use TLC2652 as the pre-amplifier and set the gain as 10 to amplifies the signal ten times in order to fit the PGA205 the program-control amplifier's picking request for the weak signal. Thus this paper underlines to analysis the new type of DC elimination circuit with existing circuits, so the follow-up handing circuits of all the experiment design as the same as above to obey the Single Variable Theory and analysis the different DC elimination result better.

DC Isolation Circuit Design

2.1 Existing DC Isolation Circuits analysis

There are two design methods of existing DC elimination circuit. The first is that using capacitance with pull-down resistor to eliminate the DC component of MEMS sensor; this design can basically complete the elimination work. But by the characteristic of the capacitance itself, the capacitance would bring the unexpected ripple wave noise to this system probably.

Reference [4] gives out a new method that using amplifier to complete the DC elimination work. It chooses instrumentation amplifier to isolation the DC component, because of the great performance in restrain the CMRR and the noise of instrumentation amplifier is small. So it selects AD620 to build up the DC elimination circuit and the gain is set to 1.because of it doesn't amplify the signal so the gain is 1. In accordance with the gain formula: $R_G = \frac{49.4\text{k}\Omega}{G-1}$ as we can conclude that, when the gain is set as to 1, the R_G goes to infinity so Pin1 and 8 set as dangling, Fig 3 shows the detail circuit of this method.

It must be informed that as we can conclude from the sensor character that when the sensor is vertical, there's 2V DC offset, but in experiment, it's hard to keep the sensor being absolute vertical, there must be a dip between the sensor and horizontal plane, so it cannot keep the offset value as 2V. Thus Pin2 must connect a potentiometer(R1) to precision fine adjust the input voltage to keep the DC offset as 2V in experimental stage.

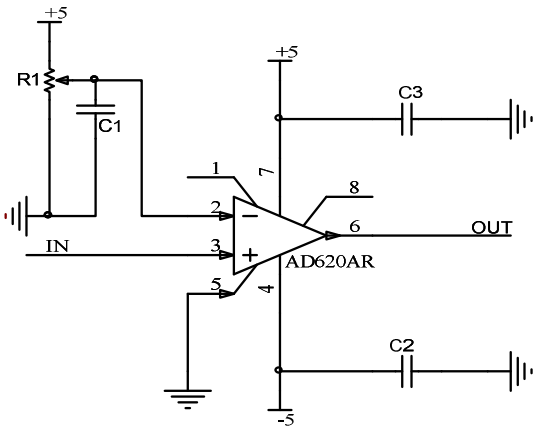

Fig. 3. AD620 DC elimination design

2.2 New Design of DC Isolation Circuit

In the condition of using MEMS technology in Seismic geophone signal processing, this paper comes up with a new type of DC elimination circuit. This design using four operation amplifiers which act as four different functions to complete the DC isolation work. The input signal will reduce the AC component through LPF(amplifier A); then back-ward processing by the invertor(amplifier B); the amplifier C act as a follower and output the input signal in the same potential; the amplifier D is a summator to sum the output of B and C. Then the DC component in the output signal of C will counteract by the B and complete the DC elimination work. The function diagram is Fig. 4.

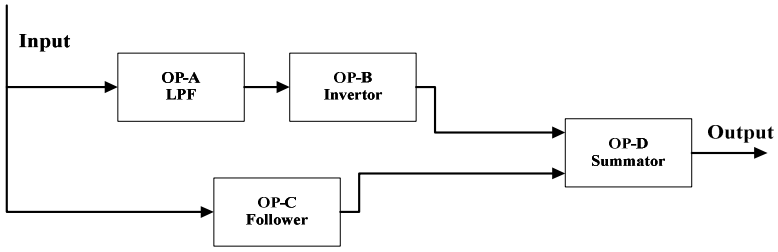

Fig. 4. Circuit function diagram

In the choice of operation amplifier, with the consideration of the complex of weak signal and the request of the signal handing. This circuit chooses OPA2735 from TI Inc as the four different function amplifier. This chip's zero offset is only 0.05μV/°C; maximum input offset voltage is 5μV. In the design of precision Seismic instruments, the request of offset voltage is 5μV max too, OPA2735 can fit the request of that. And OPA2735 is two operation amplifiers integrated in one chip, it can save the room in the circuit. Fig. 5 is the circuit diagram.

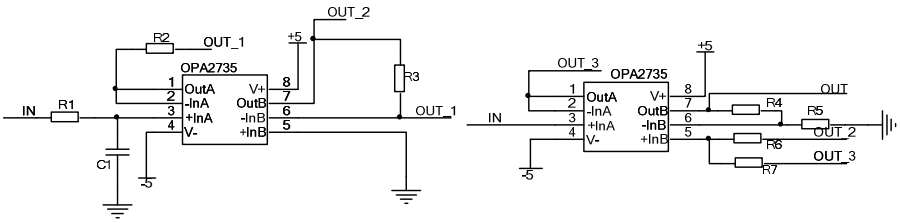

Fig. 5. Op-am DC elimination circuit diagram

Results Analysis and Conclusion

3.1 Result Analysis

Build the experiment circuits which consist of these three type of DC elimination methods, the sensor we choose Model1221L-002 to keep the input signal as the same. Using oscilloscope to observe the outputs of these three different DC elimination circuits when there's a slight shake.

For the DC elimination circuit which using AD620, Instrumentation amplifier notwithstanding has a great effect on CMRR but different types of the sensor the DC component of output is different, then this circuit need to adjust the potentiometer manually at the input (pin 2) to reset the reference voltage. If it need to satisfy the accuracy requirement or replace the sensor at the specific environment, we also need to adjust the potentiometer manually. It's very adverse for system automation of data collection and processing, and it's inconvenient to update the sensor type for this geophone.

As we can see, the DC elimination circuits build by four Op-Amps can avoid the problem what the AD620 DC elimination circuit brings, the result of this circuit is very perfect. But for the seismic transient signal, this momentary signal cannot make the capacitance saturated, then the output signal has a phase difference with the input signal, this phase difference is inevitable. Through analyzing low-pass filter amplitude-frequency characteristic we can launch that the filter instantaneous signal phase delay roughly 2ms. Then we use oscilloscope to observe the input and output signal showed in Fig. 6, we can conclude that the phase difference is almost 2ms, the calculated results approximately equal with the fact. And this phase difference is also within the range allowed by the system accuracy requirement.

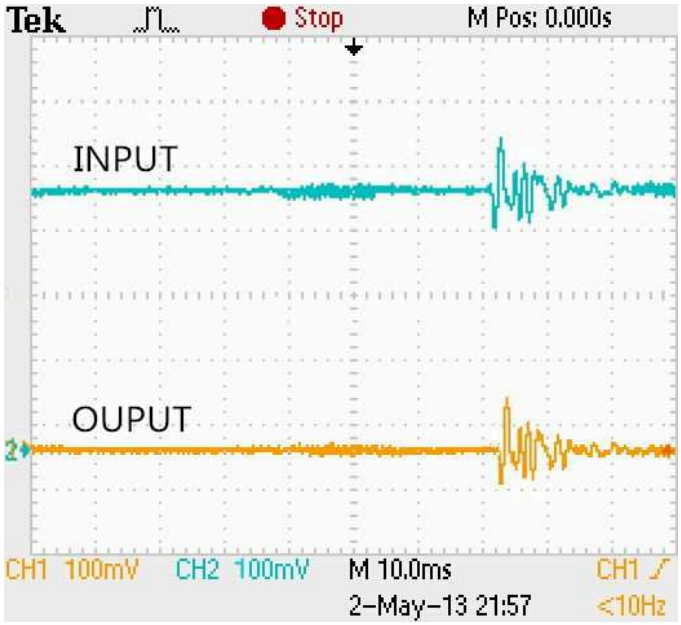

Fig. 6. Four op-ams DC elimination effect

3.2 Conclusion

This paper, based on the characteristic of the Seismic signal. Contrasts and analyzes the existing circuits of Seismic signal handing precisely, faces to the DC elimination problem to come up with a new circuit of DC elimination, breaks the traditional DC elimination method and solves the problems what the capacitance DC elimination circuit brings, using op-am to combine the circuit to finish the isolation work. Through the experiments contrast analysis, this new circuit of DC elimination has the advantages of better LP filter effect, short response delay, eliminate the DC component as much as possible in the condition of fitting the system requests. It has a great advantage by compared with other circuits. This design can widely be used in the further seismic instruments design and improve for production practice.

Keywords: AC+DC distribution network, Renewable energy, Simulink simulation, Z transformer

Abstract: The combined AC+DC distribution network in this study provides a coupling and decoupling strategy of renewable energy in DC mode by using zig-zag transformer, which makes each line transmit AC electrical power and DC power simultaneously. The proposed scheme is digitally simulated with the help of Simulink software package. Simulation results indicate lower line voltage drop and less active and reactive power loss in steady state; almost similar or even better transient effects in transient state, which demonstrates the feasibility of combined AC+DC distribution network of single line interconnected with renewable energy.

Introduction

Renewable energy witnesses rapid development in recent years. However, its lower utilization and uncertain interconnection with grid raises the study of about it. One of way to connect renewable energy into the grid is to construct a DC micro gird[1]. However, considering high economical investment and limited line corridor , its sparkling advantage remains open to question. H.Rahman and B.H.Khan have ever put forward a simultaneous AC+DC power transmission mode through a transmission line[2-4]. Their research mainly focused on the power upgrading by simultaneous AC+DC power transmission.

In this paper, the configuration of combined AC+DC distribution network interconnected with renewable energy is given. From theoretical analysis and simulation results, the feasibility of combined AC+DC distribution network of single line interconnected with renewable energy is demonstrated.

Combined AC+DC distribution network

System Configuration. As is shown in Fig 1, AC is required from AC system through zig-zag transformer, while renewable energy in DC mode is superposed on each distribution line from the neutral line of zig-zag transformer. DC chopper circuit is used to get needed DC voltage value.

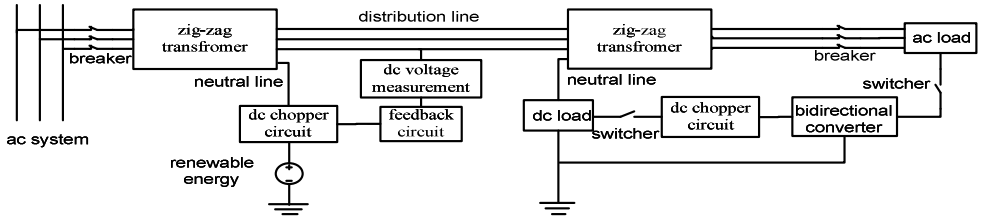

Fig.1 Configuration of combined AC+DC distribution Network interconnected with renewable energy

AC and DC power are separately supplied to AC load and DC load by zig-zag transformer. In order to guarantee reliability of power distribution to loads, bidirectional converter is used.

Zig-zag Transformer. Three-phase, nine windings transformer with six identical secondary windings can be used to zig-zag connection shown in Fig 2. Because of its special structure, on one hand, there is no zero-sequence flux in 3-phase core limb. On the other hand, the flux of 3-phase core limb doesn't change due to mutual offset of produced flux when DC current injects from neutral point.

DC Chopper Circuit and Control Strategy. In this study, the chosen DC chopper circuit is DC-DC full bridge chopper circuit with isolation shown in Fig.3.

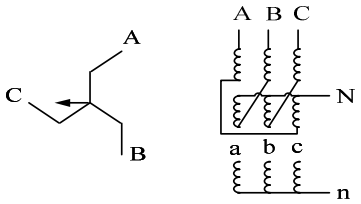

Fig.2 Zig-zag winding connection

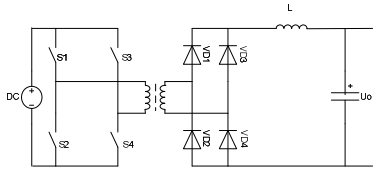

Fig 3. DC-DC full bridge chopper circuit

As is shown in Eq.1, the error of target value *ref* with output value e_r is integrated and then amplified by K times. Input current i_1 is amplified by f_1 times. The sum of two amplified value serves as input d (duty circle).

$$d = -f_1 i_1 + K\int (ref - e_r)dt \tag{1}$$

Theoretical Analysis

Steady State Analysis. Because DC component is superposed on 3 lines simultaneously, the line-to-line voltage remains unchanged. Line-to-ground voltage lifts to some extent. However, as long as the DC value is appropriate, the request of insulation margin of traditional AC distribution line can be meet. In order to simplify analysis, because of the symmetry of each line, the single line schematic diagram of AC+DC distribution is shown in Fig.4. The total power of node B of distribution line conforms to Eq.2.

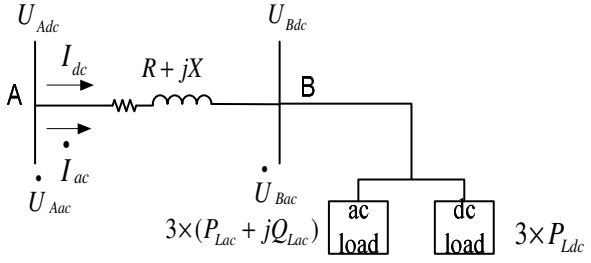

Fig.4 Single line schematic diagram of AC+DC distribution

$$S_B = P_B + jQ_B = 3\times(P_{Lac} + jQ_{Lac} + P_{Ldc}) \tag{2}$$

If provides S_B in traditional AC mode, the power loss ΔS_{ac} of distribution line and amplitude variation ΔU_{ac} of voltage vector of node A and B are as follows:

$$\Delta S_{ac} = \frac{3[(P_{Lac} + P_{Ldc})^2 + Q_{Lac}^2]}{U_{Bac}^2}(R + jX) \tag{3}$$

$$\Delta U_{ac} = U_{Aac} - U_{Bac} \tag{4}$$

If provides S_B in combined AC+DC mode, ΔS_{ac+dc} and ΔU_{ac+dc} are as follows:

$$\Delta S_{ac+dc} = \frac{3(P_{Lac}^2 + Q_{Lac}^2)}{U_{Bac}^2}(R + jX) + \frac{3P_{Ldc}^2}{U_{Bdc}^2}R \tag{5}$$

$$\Delta U_{ac+dc} = U_{Aac+dc} - U_{Bac+dc} \tag{6}$$

From Eq.2~6, $|\Delta Q_{ac+dc}| < |\Delta Q_{ac}|$, $|\Delta U_{ac+dc}| < |\Delta U_{ac}|$ can be get. Further, the theoretical analysis of comparison of active power is given. Supposing $\Delta P_{ac+dc} = k\Delta P_{ac}$, then get Eq.7:

$$U_{Bdc} = \frac{U_{Bac}}{\sqrt{k(1+2\frac{P_{Lac}}{P_{Ldc}}) + (k-1)\frac{P_{Lac}^2 + Q_{Lac}^2}{P_{Ldc}^2}}} \tag{7}$$

k is proportionality coefficient of active power loss, if $k \in (0,1)$, then $\Delta P_{ac+dc} < \Delta P_{ac}$. That means AC+DC distribution mode has less active loss.

Instance of Steady State and Transient State. Supposing a 10kV distribution line with AC load S_{ac}=3×(900+j240)=2700kW+j720kVar and DC load 3×300kW, if proportionality coefficient k is 0.8, U_{Bdc} is about 3kV from Eq.7. Distribution line is made of TJ70 sterepsinema. Resistance per unit length is r=0.28 Ω/km while reactance per unit length is x=0.37 Ω/km. Short-circuit fault occurs in 20km distance, then $R = 5.6\Omega$, $X = 7.4\Omega$.

Simulation Results

In this part, the simulation results are given by using simulink package of MATLAB. Model parameter uses the data of corresponding instance in last part.

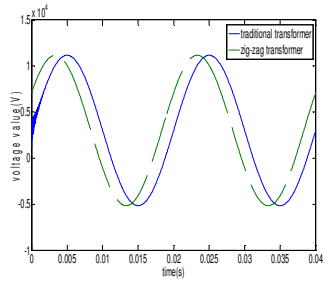

Fig.5 Comparison of zig-zag with traditional transformer

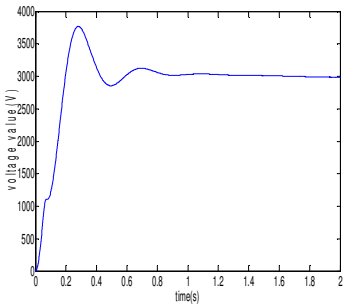

Fig.6 DC chopper circuit feedback result

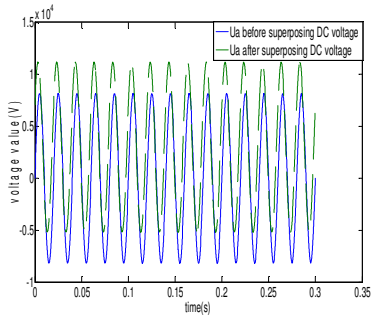

Fig.7 Comparison of u_a before superposing DC voltage with after

Fig.5 separately shows secondary side output voltage waveform by using zig-zag and traditional transformer. It can be seen that traditional transformer occurs saturation obviously while zig-zag transformer works properly. The simulation result of DC chopper feedback circuit is shown in Fig.6. The superposed DC voltage stabilizes 3kV effectively. Fig.7 shows that line-to-ground voltage of A phase uplifts after superposing 3kV DC voltage. The peak value is about 11160V, which corresponds to theoretical value.

From table 1, when works in AC+DC mode, active, reactive loss and voltage drop of distribution line are all less than AC mode, which corresponds to theoretical analysis. It can be seen from table 2 that the fault parameter of AC+DC distribution mode is similar to, or even better when three-phase symmetrical short-circuit occurs by adjusting parameter of zig-zag transformer. When other fault type occurs, simulation results also indicate the advantage of DC+AC distribution mode.

Table1 Comparison of steady state of two modes when R=5.6Ω ,L=0.02356H

	AC	AC+DC
Active loss（W）	6900	6200
Reactive loss（W）	9211	6030
Voltage drop（V）	116	115

Table 2 Comparison of three-phase symmetrical short-circuit impulse and RMS current when $L_{zig-zag}$ changed (A)

$L_{zig-zag}$ (H)	0.0445	0.05724	0.06996
i_{ac+dc}	960	907	865
I_{ac+dc}	609	591	580
i_{ac}	990		
I_{ac}	622		

Conclusion

The combined AC+DC distribution network realizes the coupling and decoupling of renewable energy. By using DC chopper circuit, the DC voltage can be kept to needed value. AC+DC distribution mode has lower line voltage drop and less active and reactive power loss in steady state; almost similar or even better transient effects in transient state, which demonstrates the feasibility of combined AC+DC distribution network of single line interconnected with renewable energy.

Keywords: AC/DC distribution network, distributed renewable energy, inductive filtering, core saturation

Abstract. With the rapid development of smart grids, the interconnection between the grid and distributed renewable energy is the inevitable trend of future study. Because of the existence of the DC source in the combined AC-DC distribution network, the transformer iron core is easily saturated generating lots of harmonics and increasing the loss of the transformer. This paper presents a novel method based on inductive filtering technology of core saturation suppression of the transformer in the combined AC-DC distribution network, this novel method can suppress the harmonics caused by the flux saturation and forbid the harmonics intruding into the ac grid. In the end we build the simulation model to prove the correctness and practicability of this novel method.

Introduction

With the rapid development of smart grid, the way that how to access the distributed renewable energy to the distribution network has attracted more and more attention [1]. There are many types of new energy including wind power, photovoltaic power, fuel cell, tidal power and so on, but it still can be summed up as two types, that is the ac power and dc power. Connecting the ac sources to the grid is relatively simple. The difficulties of the study lies in the integration of dc source of distributed energy. There are two main existing approaches, one is converting the dc source to ac source through the rectifier, another is to construct a micro grid [2, 3]. There are two impacts of these two methods, on one hand the cost is very high, on the other hand they will form a certain degree of impact to the power grid. Therefore, the need of combined AC-DC power transmission is more and more urgent.

Because of the existence of the ac source, the transformer iron core is easily saturated. When the iron core is saturated, it will course the distortion of the voltage and the current also it will course the raise of the iron core loss. These phenomena are referred to as ac magnetic bias [4]. DC magnetic bias makes the core flux saturation generating lots of harmonics. This paper presents a novel method of flux saturation suppression of combined AC-DC distribution network transformer based on inductive filtering technology. That is applying the inductive filtering transformer to the combined AC-DC power transmission system, through the use of superconductor flux conservation principle to suppress the core flux saturation of the transmission system.

The topology of the combined AC-DC power transmission

To apply the new mode of inhibiting the flux saturation based on inductive filtering, we need a new topology of combined AC-DC distribution network. This network contains ac source, dc source, inductive filtering transformer, boost chopper circuit and distribution line. The ac source and the inductive filtering transformer stands for the ac distribution network, the dc source stands for the distributed new energy sources. The schematic diagram is shown in Fig.1.

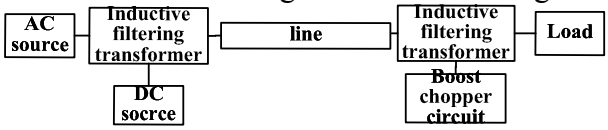

Fig.1 New topology of combined ac and dc distribution network

In Fig.1 the inductive filtering transformer is the special transformer used to inhibit the core flux saturation of the transmission system; the boost chopper circuit is a voltage conversion circuit.

Inductive filtering transformer. Inductive filtering transformer is a transformer with three windings, the LC filter is accessed to the third winding so as to inhibit the harmonic closing to the harmonic source. The spatial arrangement of the three windings and the number of the turns of the windings are all designed and arranged specially. The most important character of the special arrangement is that the equivalent impedance of the filtering winding is zero. The advantages of the inductive filtering transformer is that it can reduce the noise and vibration of the transformer and it can inhibit the harmonic coursed by the flux saturation [5].

The connection of the inductive filtering transformer windings and the connection of the inductive filtering device are shown in Fig.2.

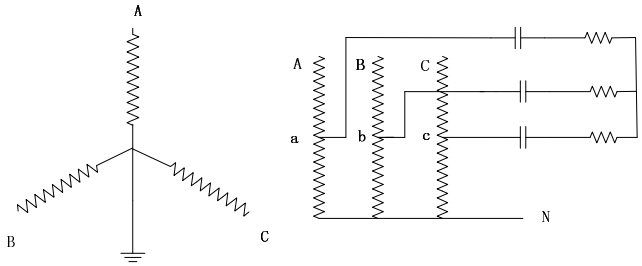

Fig.2 The connection of the inductive filtering transformer windings

The difference of the windings connection between the traditional transformer and the inductive filtering transformer is that the secondary is cut as two parts. Three taps a,b,c led out from the middle which is treated as public winding. We access the inductive filtering device in the light of the 2th,5th,7th,11th,13th harmonic to the three taps. The inductive filtering device can inhibit the harmonic right at the secondary side which can suppress the effect to the transmission line caused by flux saturation effectively.

Boost chopper circuit. Boost chopper circuit is a dc-dc conversion circuit whose output voltage is higher than input voltage. The angular phase difference courses the flow of the ac power, the voltage difference courses the flow of the dc power, so the voltage circuit is very necessary for maintaining the stability of voltage difference. In addition, boost chopper circuit unifying the rated voltage of every node of this topology in order to connect the ac source an ac load to the distribution network [6, 7].

Harmonic model and theoretical analysis

According to the connection of inductive filtering winding, the equivalent circuit diagram of the inductive filtering transformer is shown in Fig.3.

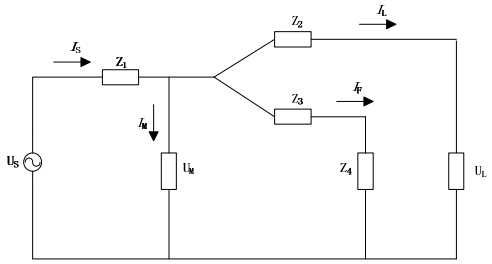

Fig. 3 Equivalent circuit diagram of the inductive filtering transformer

In this diagram, I_M contains a lot of 2th harmonic, I_L contains lots of 5th,7th,11th,13th harmonic, so the inductive filtering device accessed to this circuit is aimed at 2th,5th,7th,11th,13th harmonic.

According to the Kirchhoff law we can know:

$$\begin{cases} I_S = I_L + I_F + I_M \\ U_M = I_F(\mathrm{Z}_3 + \mathrm{Z}_4) \\ \mathrm{U_S} = \mathrm{I_S Z_1} + I_F(\mathrm{Z}_3 + \mathrm{Z}_4) \\ \mathrm{U_L} = \mathrm{I_F}(\mathrm{Z}_3 + \mathrm{Z}_4) - \mathrm{I_L Z_2} \end{cases} \tag{1}$$

In the above equations, U_S is the voltage source of the ac grid side, I_S is the current of the ac grid side, U_L is the voltage drop of the load, Z_1 is the impedance of the primary winding, Z_2 is the impedance of the secondary winding, Z_3 is the impedance of the inductive filtering winding, Z_4 is the impedance of the inductive filtering device.

We can get the current of the ac grid side I_S from the transform of the equations (1):

$$I_S = \frac{U_S}{Z_1 + Z_3 + Z_4} + \frac{I_L + I_M}{\frac{Z_1}{Z_3 + Z_4} + 1} \tag{2}$$

Also, we can get the current flowing through the inductive filtering winding branch I_F:

$$I_F = \frac{U_S}{Z_1 + Z_3 + Z_4} - \frac{I_L + I_M}{\frac{Z_3 + Z_4}{Z_1} + 1} \tag{3}$$

In this paper we have mentioned that through the special spatial arrangement the impedance of the inductive filtering winding $Z_3 \approx 0$, additionally under the specific harmonic frequency the impedance of the inductive filtering device $Z_4 \approx 0$. From the equations (2) and (3) we can know I_M and I_L are important elements of I_F but they have nothing to do with I_S which means the harmonic current is mostly shunted to the inductive filtering branch.

Meanwhile, we can get the current of the load side I_L from the change of equations (1) :

$$I_L = -\frac{U_L}{Z_2 + Z_3 + Z_4} + \frac{I_S - I_M}{\frac{Z_2}{Z_3 + Z_4} + 1} \tag{4}$$

We have known that $Z_3 + Z_4 \approx 0$, so the current I_L is only effected by U_L and the impedance of the windings.Through the harmonic shunting of the inductive filtering branch, the inductive filtering transformer achieve the target of inhibiting the iron core flux saturation.

Simulation and result analysis

In this paper we build the simulation model of combined AC-DC power transmission by matlab/simulink, and also we compare the result with the combined AC-DC distribution network applied with traditional transformer. In this model, the equivalent impedance of the load is 20+j31.4Ω. The rated capacity, voltage, frequency of the ac source is 100MVA, 10KV, 50HZ. The length of the line is 30km. The transformer ratio is 1:1. The rated voltage of the dc source is 3KV.

The simulation results are shown in Fig.4 and Fig.5:

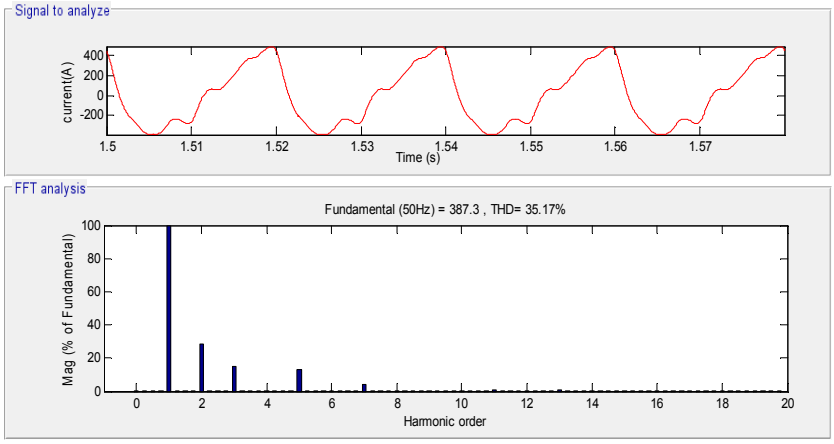

Fig.4 Current on line side in combined ac-dc distribution network with traditional transformer

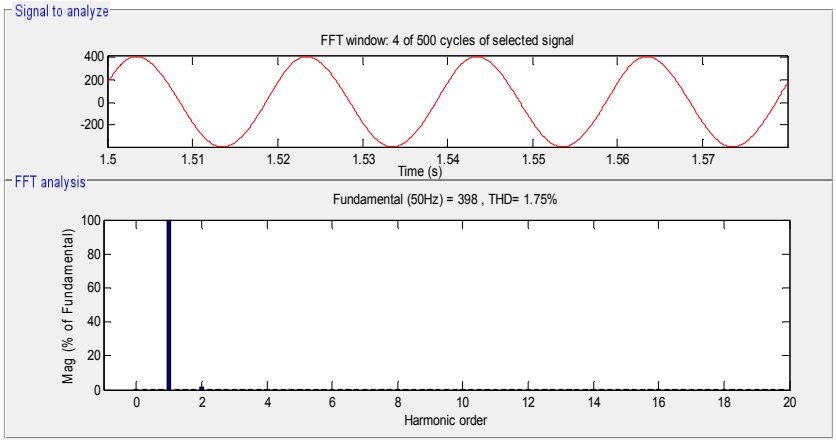

Fig.5 Current on line side in combined ac-dc distribution network with inductive filtering transformer

Fig. 4 and Fig. 5 show the simulation result of the current on line side in the two topologies of combined AC-DC power transmission. The waveform in Fig.4 has seriously distorted, meanwhile, the waveform in Fig.5 is much more smooth. From the two figures we can know:1. The core flux saturation generates many times of harmonic which leading to the distortion of the current on line side. The waveform in Fig.4 isn't asymmetrical, that is because of the effect of 2th harmonic generated by flux saturation. 2. When the inductive filtering transformer accessed to the combined AC-DC distribution network the current on line side becomes smooth and asymmetrical which means the inductive filtering transformer has good effect on the harmonic suppression.

Conclusion

Because of the existence of the dc source, the transformer of combined AC-DC distribution network is easily saturated. When the transformer is saturated it will generate many times of harmonics. When these harmonics intrude into the primary side, they will lead to the distortion of current on line side. The simulation result proves this phenomenon. This novel method of flux saturation suppression presented in this paper can suppress the harmonics on the secondary side. It can prevent the distortion of the current on line side caused by the flux saturation. The simulation result proves that this novel method has good effect on inhibiting the flux saturation. All of the theoretical analysis and the simulation results prove the correctness and practicability of this novel method.

Keywords: Controllable reactor, high temperature superconductor, reactive power compensation, electromagnetic design, DC critical current

Abstract. With the development of high voltage long distance transmission and expansion of the grid, continuous reactive power compensation devices, such as controllable reactor, become more and more important. This paper describes the design and prototype test of a high leakage reactance transformer-based high temperature superconducting controllable reactor (HLRT-HTSCR). Characteristics test results show the excellent impedance regulation characteristic of the prototype. DC critical current test of the superconducting winding shows that attention should be paid to the critical current of superconducting coil, avoiding over-current condition. This paper reveals the characteristics of HLRT-HTSCR by experiment, and will be of important practical significance to promote its development.

Introduction

As an important element of power system, controllable reactor has a broad application prospect, especially in the long-distance EHV/UHV transmission systems for the use of reactive power compensation [1]. Controllable reactor can adjust the line voltage and change the transmission power on condition that line voltage does not exceed the allowable value. The loss of traditional controllable reactor made of conventional materials is large in the case of high voltage and high current. Superconductor is a new type of material. Controllable reactor which is made of superconductor has the advantages of low loss, large capacity and rapid regulation and its characteristics are almost ideal [2]. High leakage reactance transformer-based HTS controllable reactor, which is one of the controllable reactor, has the characteristics of broad reactive power regulation range and very small output current harmonic and can be used in the occasion of high voltage level. This paper will analyze the characteristics of its operation by prototype experiments to promote the process of research and practicality.

Structure and principle

The structure and operation principle of HLRT-HTSCR is similar to the traditional power transformer [3]. It has a E-type core, main winding and two control windings which are made of high temperature superconducting (HTS) wire to reduce AC loss. Both of the two HTS windings are wound concentrically inside the main winding, as shown in Fig.1.

When HLRT-HTSCR works, the main winding is connected in parallel with the load on the line. By changing the operating state of HTS-A and HTS-B wingdings, capacity and the reactance of the reactor can be adjusted [4]. Here is the adjustment mechanism: HTS winding is shorted magnetic lines of flux is expelled from the HTS windings, then the flux area is reduced reactance decreases.

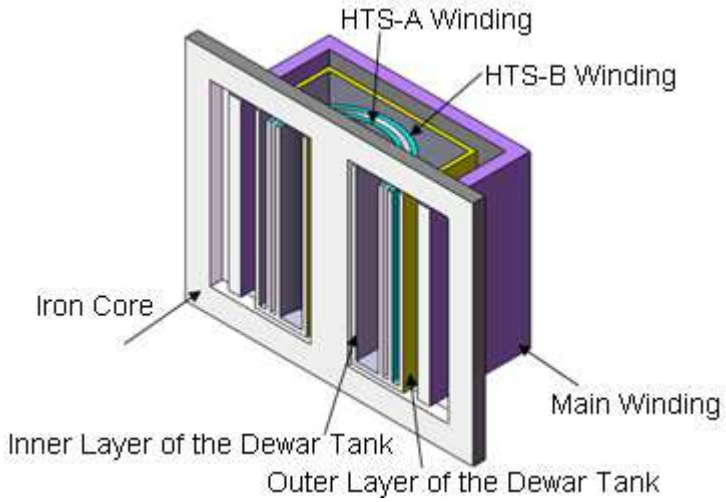

Fig.1. Structure of HLRT-HTSCR

Prototype design and calculation

A single-phase 380V/100A HLRT-HTSCR prototype is designed. The prototype has two superconducting windings, named HTS-A and HTS-B. Each of the windings has two operating modes. Therefore, the prototype has four operating states from M1 to M4, just as shown in the following table 1, where "0"represents open circuit and "1" represents short circuit.

Table 1. Operating modes of HLRT-HTSCR prototype

Mode	M1	M2	M3	M4
HTS-A	0	0	1	1
HTS-B	0	1	0	1

Prototype design includes the designs of windings, electromagnetic parameters, cryogenic system, control system and measurement and protection system. The following description focuses on the design of the electromagnetic parameters of superconducting windings, which is also the core of the prototype design.

Method of electromagnetic parameters design. The design principle is to fully consider the effect of the air gap length between superconducting winding and main winding, the superconducting winding parameters and space asymmetry coefficient on the reactor and electromagnetic characteristics of superconducting windings. The tool of analysis is ANSYS, using 2D symmetric electromagnetic unit to analysis the coupling field of magnetic and electric.

The flow chart of prototype electromagnetic design is shown in Figure 2. Use the methods of setting the parameters and then calculate and check whether the regulation performance of the reactor is good and whether there is enough critical current margin. If the check is not met, then correct the parameter to continue calculation and verification until meeting the requirements.

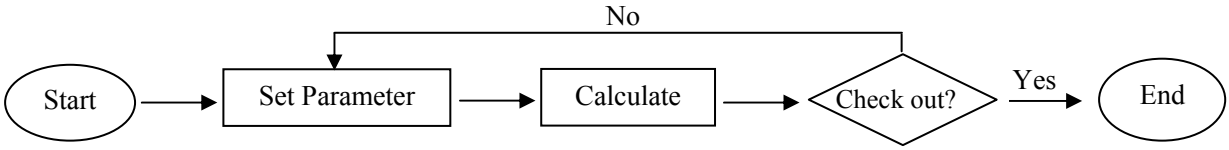

Fig.2 Flow diagram of the electromagnetic design

According to the design method in the previous section, a 380V/40kVar HLRT-HTSCR prototype is designed. Parameters and labels are shown in Table 2 and Figure 3:

Table 2. Parameters of HLRT-HTSCR prototype

Rated voltage /V			380	Rated Current /A			100	Turns of main winding			170
Turns of HTS-A winding			460	Turns of HTS-B winding			352	Height of iron core/mm			571
a/mm	85	a0/mm	45	a1/mm	55	a2/mm	75	a3/mm	125	a4/mm	129
a5/mm	160	a6/mm	168.8	a7/mm	185	a8/mm	205	a9/mm	215	a10/mm	285.5
a11/mm	310	h1/mm	50	h2/mm	220	h3/mm	80	h4/mm	410	h5/mm	450

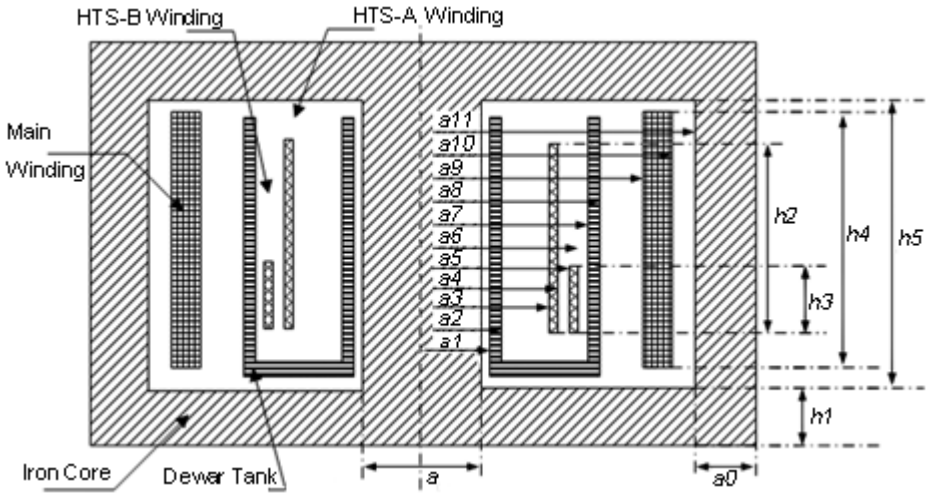

Fig.3. Marking of the electromagnetic parameters

Calculation of the reactance in M1-4. When the superconducting winding A and B are open, reactor can be seen as a conventional reactor which is made of iron core wound by normal conducting coils. In general, the relationship between reactor's inductance and structure size can be expressed by the following equation:

$$L_1=N^2A \tag{1}$$

$$A=\mu A_c/l_c \tag{2}$$

So，the reactance in M1 is given by Equation(3):

$$L_1=W^2\mu A_c/l_c \tag{3}$$

In order to approximately get the expression of inductance when the LFCR works from M2 to M4, we use the following approaches:1) The magneto motive force fully drops on reluctance of air space between short-circuit HTS winding and main winding;2) Leakage-flux density is homogeneous. So L2 is approximately represented by using the following equations:

$$\psi_2 =N\Phi_2 \tag{4}$$

$$\Phi_2 =B_2A_2 = \mu_0H_2A_2 = \mu 0N_iA_2/l_2 \tag{5}$$

$$L_2 =\psi_2/i = \mu_0N_2A_2/l_2 \tag{6}$$

The same as above, we use (7)–(8) to approximately represent L3 and L4, respectively.

$$L_3 =\mu_0N_2A_1/l_1 \tag{7}$$

$$L_4 =\mu_0N_2A_2/l_1 \tag{8}$$

Where,μ_0=4π×10^{-7}H/m; A_c: Equivalent flux area(m^2), l_c: Equivalent length of magnetic path(m).Ψ_2: flux linkage of main winding in M2; Φ_2: magnetic flux of LFCR in M2; N: turns of main winding; A_1:cross-section area between HTS-A and main winding; A_2:cross-section area between HTS-B and main winding; l_1:height of HTS-A winding; l_2:height of HTS-B winding.

Experiment and results analysis

Two relevant experiments are designed to test the performance of the prototype. Photograph of the prototype is shown in Fig.4&5.

Fig.4&5. Photograph of the prototyped HLRT-HTSCR

DC critical current test of the superconducting windings. This Experiment is to measure the maximum DC current which the prototype's superconducting windings can bear. Once the current exceeds this limit, the superconducting windings quenches. The measured data will be basis of the quench protection. The experimental data to be recorded is current and voltage of the two superconducting windings.

When the experiment starts, pay close attention to the data waveform of data acquisition system. Stop the experiment when the winding voltage offset exceeds the criterion (Taking 1uV/cm as a reference, the voltage offset is 35mV because the wire length of the superconducting winding is about 350 meters).

Since the acquisition of the voltage value includes superconducting coil voltage, superconducting coil induced voltage (current uniformly increases), and voltage drop across the welding point resistance and conventional wire resistance. We must subtract this part of the pressure drop when setting quenches criterion. This part of voltage drop increases linearly with the increase of current before superconducting coil quenches. Therefore, the voltage and current of the two loops of the superconducting coils A and B can be calculated and the voltage drop on the superconducting coil equals to the total voltage minus the linear-increasing voltage. The IV-curves are shown in Figure 6.

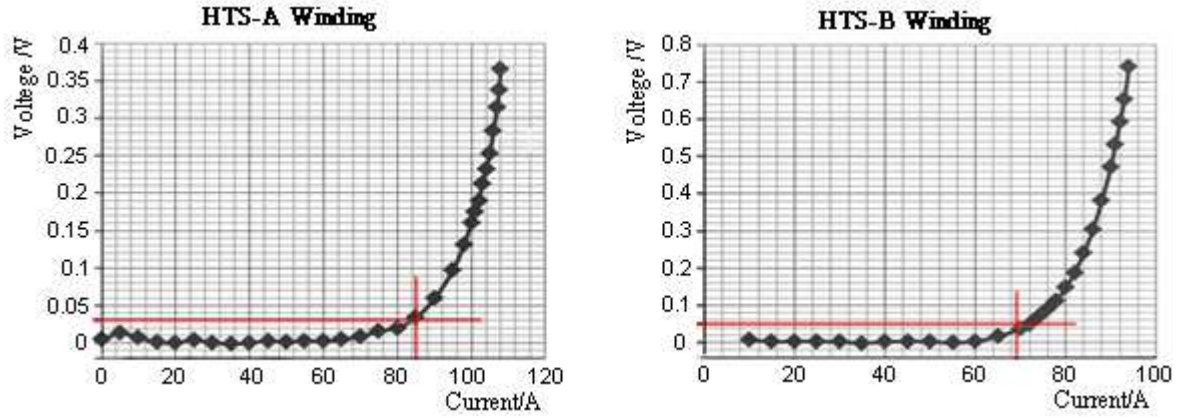

Fig.6. Processed volt-ampere characteristic curve

Making a judgment by 35mV offset voltage line, the DC critical current of HTS-A and HTS-B winding is 86A and 70A, respectively.

Test of reactance regulation. The test is to verify whether HLRT-HTSCR can realize four kinds of reactance adjustment rates in M1-4, and observe whether the adjusting effect is good enough.

The relationship between the main winding side current and voltage, which is worked out by original data, is shown in Figure 7.

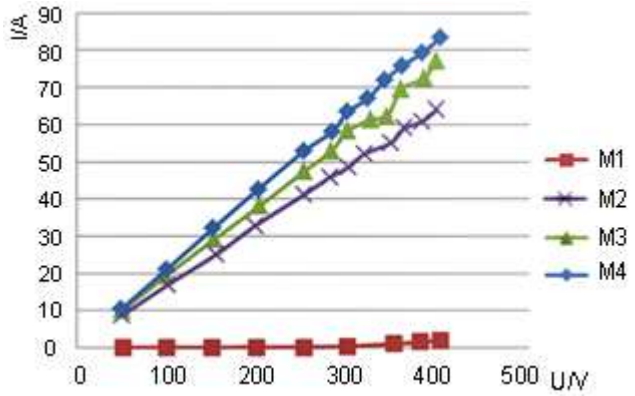

Fig.7. Characteristics of reactance regulation

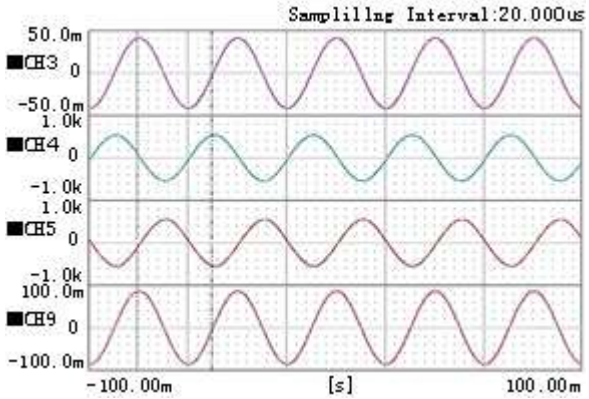

Fig.8. Waveforms of related U&I(M2,380V)

Fig 7 shows the main winding current harmonics and nonlinear relationship between the main winding voltage and current when HLRT-HTSCR works in M1. However, when a HTS winding is short-circuited, the voltage and current has good linearity. The ratio of main winding voltage and current can be considered the reactance. Because of the linearity, it can be considered that the reactance is constant in the test range of main winding voltage.

The prototype is rated at 380V/100A.It can be calculated that the four reactance adjustment rates is 1.94%, 76.6%, 91.7% and 100%. As can be seen from the results, the adjusting effect is good enough.

When the prototype works in M2 and the input voltage is 380V, the waveforms of main winding voltage(CH4), main winding current (CH9), HTS-A winding voltage (CH5), HTS-B winding current (CH3) are shown in Figure 8.It can be seen from Fig.8 that the harmonic is very small, calculated as THD=0.1%. Due to space limitations, waveforms in M1, M3 and M4 is not listed. Those waveforms are similar, containing very small harmonic components.

Experiment results analysis. Experimental results show that the HLRT-HTSCR can realize four kinds of reactance adjustment rates and has the characteristics of flexible control and small harmonic. So it can be used as reactive power compensation device to increase transmission capacity and improve grid stability and reliability.

Moreover, it is important to set the quench-protection action value according to the DC critical current of superconducting winding to avoid reactor damage caused by the quench. When measuring the DC critical current, attention should be paid to exclude the effects of the superconducting coil induced voltage and voltage drop across the welding point resistance and conventional wire resistance.

Conclusions

A single-phase 380V/100A HLRT-HTSCR prototype is developed. Based on the prototype test and analysis, the advantages of HLRT-HTSCR are summarized below:

1) Its structure is the same as traditional transformer, there are no problems on the production processes when used in the case of 500kV or 1000kV high voltage and large capacity;

2) The main reactance of HLRT-HTSCR is leakage reactance while the magnetizing reactance is very small. So, it has the advantages of fast response, stable reactance, no harmonic;

3) This type of reactor is controlled by thyristor-controlled secondary windings, so its response is very fast .As a result, it has the function of limiting line operation overvoltage.

The disadvantage is that the leakage flux is large at the ends of superconducting winding. So, there are strict requirements to the superconducting material. Overall, HLRT-HTSCR has many advantages, and there are a wide range of applications for it in the power system.

Keywords: microwire electrode; electrode tip; recording longevity; biocompatibility

Abstract. Electrodes are expensive consumables of electrophysiological experiments. Cheap and homemade microwire electrodes have been widely applied, but their implantation performance is not good. To fabricate low cost and acceptable performance of microwire electrode, first, we analyzed the key factors affecting the long-term recording performance and determined the direction of the enhancement of electrode. We improved the existing fabrication process through electrode fabrication and the electrode tip surface modification, and systematically evaluated its properties, signal acquisition ability and biocompatibility. The result shows that the improved electrode tip surface is smooth and tidy, and its impedance decreased by 56.1% on average; record signal-to-noise ratio is higher; recording longevity reached 45 days; biocompatibility is better. It can meet the use of the general electrophysiological experimental, and electrode fabrication cost is less than 58 yuan.

Introduction

The brain is the most complex organisms[1]. To study the brain to complete the complex mechanism of information processing, must obtain sufficient number of electrical activity information of neurons in the living brain environment. Microelectrode array recording technology can obtain a large number of electrical activity information of neurons[2].

Implanted electrodes are mainly silicon substrate electrode and the microwire electrode. The advantage of implanted electrode is its rich information bandwidth, but it has strong tissue reaction. The fabrication cost of silicon substrate electrode is complex and high, however, we can accurately control the electrode size, shape etc.. The fabrication cost of microwire electrode preparation is relatively simple. This paper uses nickel-cadmium alloy microwire electrode arrays by self-made.

Electrodes are expensive consumables. At present, there are 3 typical commercial electrodes price as follows: The Microprobe electrode is about $586, about $350 of the Michigan electrode, and the Plexon electrode is about 537 yuan. The homemade electrode fabrication cost is less than 58 yuan. Especially the cost is strictly limited circumstances ,self-made electrode is more significance. And the self-made electrode has the advantages of small volume, multiple recording points, stable and reliable performance, can meet the general electrophysiological experiments. In addition, from the literatures of recent years, the ability of long-term recording signal of microwire electrode is more than silicon electrode's [3].

However, after implantation of electrodes in vivo, as time increases, the recording performance of electrode will gradually become bad until failure. Using the operation scissors cutting electrode tip method, recording longevity of electrode is generally too short. Previous electrode problems mainly include two aspects: firstly, the uniformity can not be guaranteed, and the irregular increases implantation tissue damage and affects the long-term performance. Secondly, the tip can not guarante. Therefore, the urgent need is improvement of the performance of electrode. Mainly includes the fabrication of electrode and the electrode tip surface modification.

As a long-term implanted device in the brain cortex, the electrode need a stable electrode-tissue interface to ensure the selective neuronal population record, also need to avoid electrode or peripheral neural tissue degeneration. The study of its properties is related to the electrode and the electrode tissue. When the electrode was implanted into the brain tissue, it can cause injury or death of neurons and glial cells. And they stimulate the neighbor microglias and astrocytes[4,5,6,7]. At the

electrode-tissue interface, there is sustained inflammation, a lot of activated macrophages and damaged neurons[8]. The long-term reaction will reduce the recording performance of long-term application.

The electrode tissue interface has been studied many years. In 1968, DAVIDA proposed the equivalent model of the electrode tissue interface, and described the influence of the tip exposed of metal surface and platinum plating effect on electrode properties[9]. In 2003, L. A. Geddes selected for common electrode materials and insulating layer materials according to tissue reaction, allergic reaction, the electrode-tissue interface impedance[10]. Some literatures considered that electrode size, shape and cross-section affected tissue reaction[11]. But some studies keep skeptical, in 2003, Szarowski made different sizes, shapes, texture of the electrode compared to chronic experiment, and found the former 1-3 weeks of different electrode tissue reaction causes slight difference, and 6-12weeks of tissue reaction did not differ[12]. However, in 2011, Jonas Thelin's study showed that electrode size and fixed mode would strongly affect the nervous system tissue response [13]. In 2006, Sanchez J C studied the site and insulation layer damage of the electrode [14]. In 2011, Erin Patrick studied the electrode surface corrosion changing process of implantation process[15].

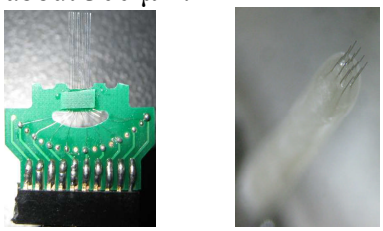
Review on the current status of the research can be found, the factors of affecting electrode chronically implanted performance included the electrodes and the tissue. In detail, there are the destruction of insulation layer, electrode tip corrosion, and the implantation site of acute and chronic tissue reaction. They pointed out our electrode improvement direction, so we should improve the tip. Another improvement is the arrangement of electrodes. Irregular arrangement will increase implanted tissue damage, the damage will affect their long-term performance, and we systematically evaluated its properties, signal acquisition ability and biocompatibility.

The design of experiment

The electrode fabrication. The electrode existing fabrication process: (a) Disinfect the experimental platform and the instruments. (b)Cut the wire. (c)Take the circuit board, fix, and glue. (d) Arranging the wire, punching, and welding. (e) The opposite side, repeat(c) and (d). (f)The circuit board welding pins and the Semtec pins are welded together, gluing electrode. (g)According to the need of experiment, the electrode was clipped to the appropriate length.

The fabrication process of modified electrode: (a) Disinfect the experimental platform and the instruments. (b) The micro-assembly: cut wire, into the ceramic piece, epoxy glue fixed, polyethylene glycol shaping. (c)Micro-welding (d) The opposite side, repeat (b). (e) Micro-cutting: according to the requirements, cut electrode wire with a professional tool.

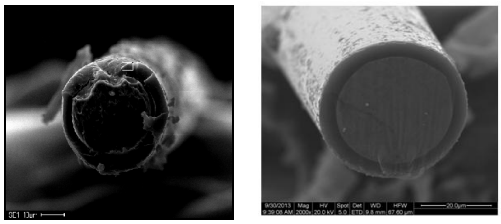
The home-made electrode material of the paper is nickel cadmium alloy wire, diameter of 40 μm, and electrode tip point size was about 706.5 μm^2. Fig.1 shows the 16 recording channel electrode array, and electrode axial space is about 300 μm.



(a) (b)

Fig.1 (a) The electrode of the existing fabrication (b) the electrode of the modified fabrication

The electrode tip as the measuring point, its impedance and morphology is closely related to electrode recording performance. Because of the electrode wire with a diameter of 40 μm, the tip of the electrode was not observed in ordinary optical microscope; therefore, the electrode tip was observed in the scanning electron microscope (SEM). Fig.2 shows the images of the electrode tips in the SEM.



(a) (b)

Fig.2 (a) Using the operation scissors cutting (b) Using micro-cutting

From Fig.2, when using the scissors cutting, it would appear adhesion around the electrode tip. Using micro-cutting, its surface is smooth and tidy and the insulating layer is good around the electrode tip. Compared with the scissors cutting, micro-cutting could improve the electrochemical performance of electrode; and improve the electrode stability and biocompatibility.

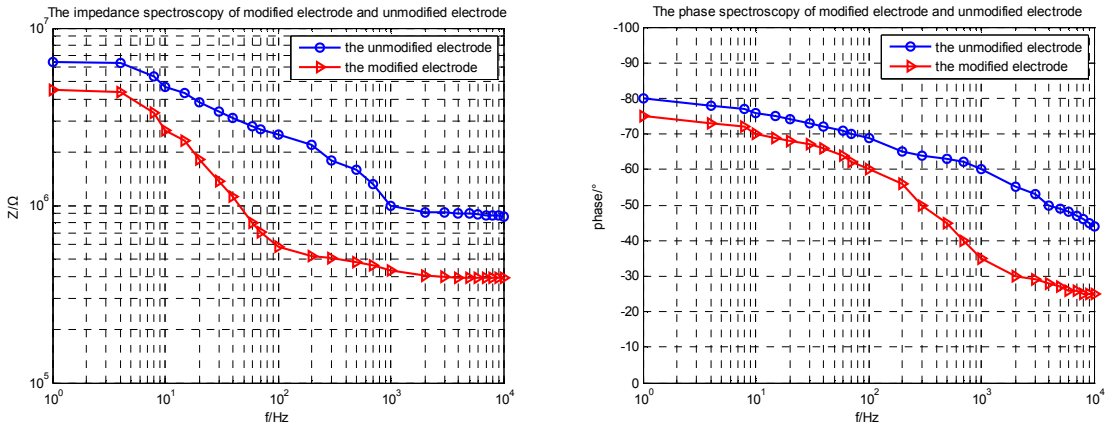
The electrode tip modification and impedance measuring in vitro. Conductive polymer polypyrrole has the advantages of good conductive performance and biocompatibility, using polypyrrole on electrode tip modification. Using the NeuroNexus niPOD coating modification on electrode tip and impedance measuring in vitro, and the electrode performance is modified. The modified electrodes include 5, respectively G1, G2, G3, G4, G5. The unmodified electrodes also comprise 5, respectively W1, W2, W3, W4, W5. The modified electrode and unmodified electrode have same material, fabrication process and cutting method. Impedance test experiment was carried out in standard saline solution, temperature control in 25 ℃, the impedances of modified electrodes and unmodified electrodes in the 1kHz value is shown in table1.

Table 1 The impedance values of modified electrodes and unmodified electrodes at 1 kHz [MΩ]

Channel number	1	2	3	4	5	6	7	8	9	10	11	12	13	14
unmodified electrodes	0.85	0.85	0.86	0.87	0.88	0.89	0.95	0.99	0.86	0.87	0.88	0.89	0.90	0.93
modified electrodes	0.37	0.38	0.38	0.39	0.39	0.40	0.42	0.45	0.37	0.38	0.39	0.40	0.40	0.41

The unmodified electrode all channels (80) impedance values at 1kHz and modified electrodes all channels (80) impedance values at 1kHz made t test, so H=1, $P=3.08 \times 10^{-15} < 0.05$, therefore, there is a significant difference between the modified electrode impedance and the unmodified electrode impedance. Modified electrode impedance decreased by 56.1% on average.

The electrochemical impedance spectroscopy[13] of the modified electrode and unmodified electrode is shown in Fig.3.



(a) (b)

Fig.3 (a) The impedance spectroscopy of modified electrode and unmodified electrode
(b) The phase spectroscopy of modified electrode and unmodified electrode

From Fig.3, as the frequency increases, the electrode impedance and phase decrease. Compared to the unmodified electrode, the impedance spectroscopy and the phase spectroscopy of modified electrode are lower. They are good for the modified electrode working.

Chronically implanted operation. The weights of 200-300 grams of LE (Long Evans) rats were used as experimental objects. The unmodified group and modified group electrodes (10) were implanted into the primary visual cortex (V1) of 10 rats. Each rat has the same sex and similar physical state. Inject anti-inflammatory drugs after operation.

The result of experiment

Signal acquisition and analysis. The ability of long-term acquisition signal electrode has important significance for evaluation of electrode performance. Using signal-to-noise ratio and recording longevity evaluates electrode signal acquisition ability.

After the implantation operation, after the rat body state recovery (about 1-2 weeks), we regularly (2-3 times per week) record signal by using Cerebus multi-channel data acquisition system .The modified electrode implantation signal acquisition situation is shown in Fig.4.

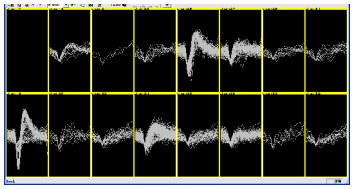


Fig.4 The modified electrode implantation signal acquisition graph

The signal-to-noise ratio (SNR) points out that the electrode differentiates the usable dynamic range of real neuron action potential from the random background noise. The signal-to-noise ratio is calculated by half of peak-to-peak of action potential divided by root mean square(RMS) of the noise base value[16]. The formula is as follows:

$$SNR = \frac{V_{P\_P}}{2V_{n\_std}} \tag{1}$$

Where, V_{P_P} represents the peak-to-peak of action potential, and V_{n_std} represents RMS of the noise base value. The SNR of the unmodified electrode and modified electrode recording signal is shown in Fig.5.

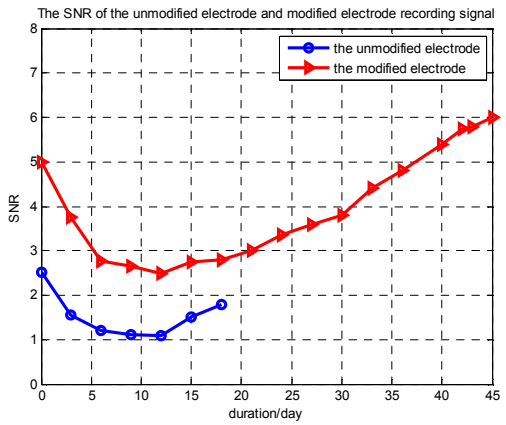

Fig.5 The SNR of the unmodified electrode and modified electrode recording signal

From Fig.5, as the duration increases, the changing trends of SNR of the unmodified electrode and modified electrode acquisition signal are first decreased and then increased. And the SNR of the modified electrode is higher than unmodified electrode's. Thus, the signal acquisition ability of modified electrode is better than unmodified electrode's.

The recording longevity of an electrode is the electrode recording a lot of action potentials duration[17]. The recording longevity of the unmodified electrodes and modified electrodes is shown in Fig.6.

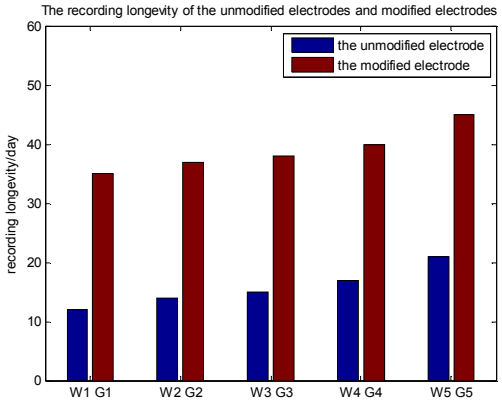

Fig.6 The recording longevity of unmodified electrodes and modified electrodes

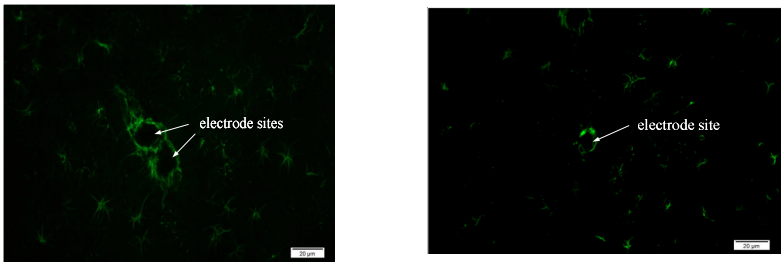
From Fig.6, the recording longevity of unmodified electrodes is shorter, the average is 17 days, and the recording longevity of modified electrodes is longer, the average is 40 days.

The electrode biocompatibility

The glial fibrillary acidic protein (GFAP) is a marker of astrocyte activation. When an electrode implanting into the brain regions, it will cause the astrocyte proliferation and accumulation. The brain tissues of modified electrode implanting rats and unmodified electrode implanting rats were separately labeled with GFAP. They were observed under the fluorescence microscope, as shown in Fig.7.



(a) (b)

Fig.7 (a) The unmodified electrode implanting rats GFAP labeled graph
(b) The modified electrode implanting rats GFAP labeled graph

From Fig.7, the aggregation degree of the unmodified electrode site surrounding glial cells is higher than the modified electrode's. So, the unmodified electrode to tissue damage is more serious than the modified electrode to tissue damage. It indicates that the compatibility of modified electrode is than the unmodified electrode's.

Conclusions

This paper improved the existing fabrication process through electrode fabrication and the electrode tip surface modification, and systematically evaluated its properties, signal acquisition ability and biocompatibility. The result shows as follow: (a) Compared to the unmodified electrode, the size of the modified electrode becomes smaller and electrode tip surface becomes smooth and tidy and its uniformity degree increases. (b) Compared to the unmodified electrode, the modified electrode impedance is reduced by 56.1% on average, increasing the recording SNR. (c) The recording longevity of modified electrode is up to 45 days and it is increased about 1.4 times compared to the unmodified electrode. (d)Modified electrodes implanted in the brain region, tissue reaction is smaller and they have better biocompatibility.

At present, the modified electrode fabrication cost is low, and its performance can meet the use of general electrophysiological experiment. But the recording longevity of modified electrode is not long. Factors which cause the electrode failure may be that electrode fabrication technology is not perfect, electrode tip modification is not good and the level implantation operation is low. Further, optimize the electrode design, and improve the level of electrode implantation. Thereby, improving the electrode performance and the recording longevity of electrode is the direction of next research.

Key words: low-frequency nanotesla, magnetic field, detection, high-permeability materials

Abstract. We report nanotesla resolution in a three-phase Metglas/FeNi/PZT-5A multiferroic composite with one end rigidly clamped operating in the first-order bending resonant mode for low-frequency magnetic field detection. Strong bending magnetoelectric(ME) couplings induced by the ununiform strain distribution in the free-clamped magnetostrictive beam are achieved without the benefit of nonmagnetic tip mass, and its natural resonant frequency is much lower than that in operating free-free mode. In addition, high-permeability materials Metgals are attached on the magnetostrictive beam for magnetic flux concentrating and resolution improvement. Experimental results reveal that the three-phase ferromagnetic/magnetostrictive/piezoelectric composite with a cantilever beam structure exhibits a high bending ME coefficient of ~32.17 V/cm·Oe at the resonant bending frequency of 819Hz under Hdc=175Oe. At the resonant excitation, the maximum resolution of 7nT is acquired under Hac=1Oe. The proposed ME cantilever structure with high resolution provideds a promising application in low-frequency magnetic transducer and sensors.

Introduction

Multiferroic composites composed of magnetostrictive and piezoelectric phases simultaneous have drawn significant focus in recent years due to their multifunctional applications, such as memory devices, resonators, energy harvesters, phase shifters and magnetic sensors[1,2] Among these multiferroic structures, magnetoelectric (ME) laminate composites exhibit a stronger ME coupling through the product property at room temperature than that of the single-phase ME materials[3] In general, the magnetostrictive/piezoelectric laminate composites can be divided into bilayer, trilayer and multilayer architectures[4], and these ME laminate composites may be symmetric (e.g., Terfenol-D/PZT/Terfenol-D trilayer laminates[5]) or asymmetric (e.g., Metglas/PVDF, Terfenol-D/PZT bilayer laminates[6,7]. It is established that both the symmetric and asymmetric ME composites all have improved sensitivity at the mechanical resonant frequencies, where the mechanical losses are the smallest and more mechanical variation energies are transferred from magnetostrictive layer to piezoelectric layer via strain between layers[8]. Generally, the natural longitudinal resonant frequencies of such symmetric composites are quite high, approximately hundreds kHzs. In comparison, the bending resonant frequencies in such asymmetric composites are as low as ~5kHz[9]. Moreover, the resonant frequency will be much lower in the thin-film structures, but ribbons of higher thickness are not available due to partial crystallization during synthesis and resulting degradation of magnetic parameters. In recent reports, to match the ambient operating vibration frequency, the ME composites have to work at the frequencies of just several Hz while with their resonant frequencies of several hundreds kHz[10] In this case, working at the nonresonant conditions result in an inefficient ME energy conversion as well as the sensitivity is severely limited. In view of this, the theoretical and experimental investigations bending resonant ME response have attracted an ever-increasing focus and triggered a great number of research activities for the low-frequency magnetic field detection[9,11]. Meanwhile, great efforts have been devoted to decreasing the bending resonant frequency by various solutions such as applied tunable load biases, resorting torque, changing dimensions and magnetic fields[12-15]. However, most of these schemes

with tip mass would greatly increase the volume in the expense of energy conversion efficient, which is disadvantageous and difficult to deploy in practical situations

Experiments and main Results

In this study, an asymmetric ME composites of Matglas/FeNi/PZT-5A with on end rigidly clamped operating at the bending resonant frequency is fabricated and characterized. In this scheme, FeNi plate is designed as a magnetostrictive cantilever beam with no mass by its robust rigidity over the commonly used PZT cantilever. With one end rigidly clamped. In our proposed ME cantilever, the bending frequency mode is easily chieved due to the ununiform strain distribution of the magnetostrictive beam. Consequently, the clamped-free ME laminate works in the bending mode, and a lower natural resonant frequency and a higher sensitivity at lower operating frequencies can be achieved. Therefore, the proposed architecture offers potentials of an ultrasensitive magnetic sensor at low frequencies.

Here, we provide experimental details of our studies on ME effects in the presented structure. Permalloy (alloy of FeNi) plates with high magnetostriction (~21ppm) and high piezomagnetic coefficient (~23nm/A) are selected as ferromagnetic phase in the composites, and the easy-magnetized axis oriented along its longitudinal direction with dimensions of 25×6×0.6mm3. We use transversely-polarized ceramics PZT-5A plates with high permittivity (~0.6) and resisitivity for the piezoelectric layer, which has dimensions of 25×6×0.2mm3. In order to concentrate more magnetic flux to FeNi plate and enhance the sensitivity, the high-permeability material of Metglas is used in our experiment with its 25×6×0.03mm3. Non-magnetic epoxy α-cyanoacrylate with thickness of ~10μm is used for bonding together between ferromagnetic and ferroelectric layers, and cured for more than 6h at room temperature is required. In experimental setup, an electromagnet was used to provide a dc bias from 0 to 1000Oe, and Helmholtz coil powered by a signal generator (Agilent 33220A, USA) is used to generate a small required ac magnetic field, which was superimposed on the dc bias. The ME voltage induced from the PZT plate was monitored by a lock-in amplifier (Stanford SR844, USA).

The dynamic properties of the proposed structure are characterized by measuring the vibration characteristics and the ME characteristics around resonant frequency. The end vibration amplitude of the FeNi beam in responds to ac magnetic field and its resonance frequency dependence of the end vibration amplitude are measured by using a laser Doppler vibrometry (Sunny Instrum LV-S01, Singapore). Fig. 1 shows the strain coefficient spectrum of the FeNi plate under optimal dc bias magnetic field of 200 Oe. In Fig.1, the induced vibration amplitude induced strain spectrum of the FeNi beam in response to Hac=1Oe for no mass attached at the free end. Under nonresonant excitation (1kHz) the strain coefficient d33 of ~ 0.2nm/A for the sample is obtained, which achieves 23.12nm/A at its natural resonance frequency of 84.8 kHz. The resonant strain coefficient exhibits approximately 116 times higher than the nonsonant coefficient.

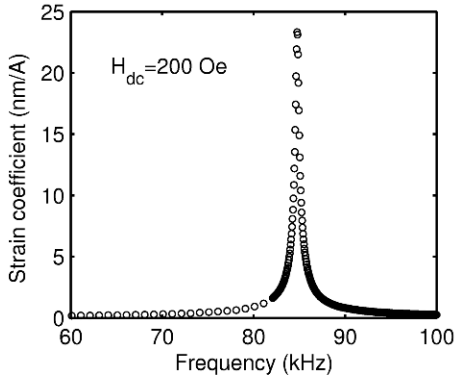

Fig. 1 Strain coefficient spectrum of the ferromagnetic alloy around resonant frequency.

Moreover, Fig. 2 shows the ME coefficient of the composite as a function of frequency at the bending resonant frequency, which is performed under the optimum dc bias magnetic field of 175 Oe.

The frequency dependence of ME coefficient is measured with the samples rigidly clamped at one end, and the optimum bias field is set to the values corresponding to maximum ME coefficient. The data show a resonance in ME vs f curve with a peak of ~32.17 V/cm·Oe for trilayers with Metglas, FeNi and PZT-5A, and the resonant frequency of 819 Hz occurs at the bending mode. The maximum ME response at such low frequencies exhibits ~0.6 times higher than that for 10Hz, which can be attributed mainly to the bending strain in a magnetic field associated with sample asymmetry. For a clamped-free cantilever composite, its natural resonant frequency is given as[16]

$$f_n = \frac{\pi d}{4\sqrt{3l^2}}\sqrt{\frac{\overline{E}}{\overline{\rho}}}\beta_n^2 \tag{1}$$

where d is the thickness of the cantilever, l is the length, $\overline{\rho} = v_m\rho_m + v_p\rho_p$ the average density, $\overline{E} = (v_m s_{33}^H + v_p s_{11}^E)/s_{33}^H s_{11}^E$ is the equivalent elastic modulus, and βn=n+0.5(n is the order of the bending mode). Taking advantage of the parameters list in Table.1, the first order bending mode resonance frequency can be estimated by Eq. 1 to be ~551Hz for the proposed cantilever. Predicted value is slightly lower than that of the experimental value, and this discrepancy at resonance mainly results from the decrease of the effective mechanical Q-factor of the clamped-free mode scheme.

Table.1 The material characteristics of FeNi and PZT-5A

Index	ρ_m or $\rho_p(kg/m^3)$	s_{33}^H or $s_{11}^E \times 10^{-12} m^2/N$	n_m or n_p	Q_m
FeNi	8000	5.22	0.6	1892
PZT-5A	7600	16.4	0.2	500

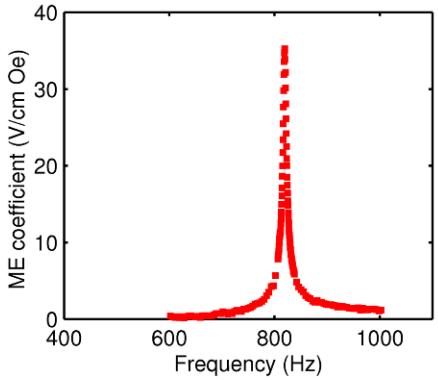

Fig. 2 ME coefficient as a function of frequency around bending resonance under 175Oe

The dependence of ME coefficient αv on Hdc at bending resonant frequency of 819Hz for the composite is demonstrated in Fig. 3. A rapid increase in αv with Hdc to its maximum value of ~32.17 V/cm·Oe is obtained and subsequent by a decrease to a minimum for higher bias fields. It is well known that the ME coefficients αv are directly proportional to the piezoelectric coefficient d33 (d33∞αv), hence we can predict that the H-variation in αv vs Hdc curve essentially tracks the change in piezoelectric coupling (d33=dλ/dH). In order to evaluate the capabilities of magnetic field detection by using our proposed architecture at low frequencies, the sample is placed in a μ-metal shield chamber for resolution measurement and superimposed with an alight ac magnetic field provided by Helmholtz coil. Figure 4 shows the induced ME voltage as a function of Hac under a magnetic bias. The induced ME voltage exhibits a linear function of Hac and increases progressively with applied ac field. The induced ME voltages at Hac=1Oe for 819Hz and 10Hz are 624mV and 0.7mV, respectively. The maximum resolution for detecting a small ac magnetic field is found to be 7nT under Hdc=175Oe at the first bending resonant frequency of 819Hz. When we change the

exciting frequency to the nonresonant frequency 10Hz, 400nT resolution is obtained under Hdc=175Oe at 10Hz.

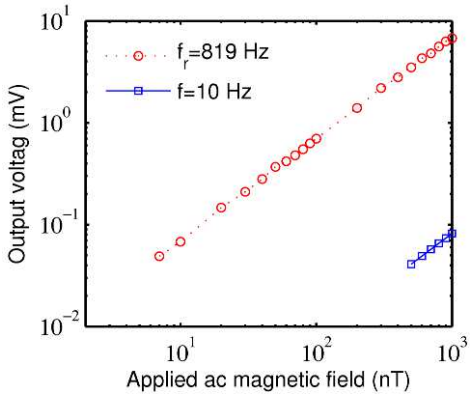

Fig. 4 The change in ME response with increasing applied ac voltage at resonant and nonresonant frequencies

Conclusions

In summary, a three-phase ferromagnetic/magnetostrictive/piezoelectric composite exhibiting high resolution for magnetic field detection at low frequencies is presented, which operates at the first bending resonant frequency with one end rigidly clamped. Without mass in our proposed ME cantilever, the bending frequency mode is easily realized due to the ununiform strain distribution of the magnetostrictive beam. In addition, more magnetic flux can be concentrated into the beam through the high-permeability materials of Metgals ribbons. Consequently, an enhancement of sensitivity and resolution can be achieved in the proposed structure for low-frequency magnetic field detection. Experimental results show that the ME coefficient and the resolution can reach 32.17 V/cm·Oe and 7nT at the first-order bending resonance frequency of 819 Hz, respectively. The strong bending-mode ME coupling with enhanced resolution in this three-phase composite will definitely offers a potential application in low-frequency magnetic transducer and sensors.

Keywords: Diagonal recurrent neural network; Fault diagnosis; Dissolved gas analysis; Recursive prediction error algorithm

Abstract. In recent years, improved three-ratio is an effective method for transformer fault diagnosis based on Dissolved Gas Analysis (DGA). In this paper, diagonal recurrent neural network (DRNN) is used to resolve the online fault diagnosis problems for oil-filled power transformer based on DGA. To overcome disadvantages of BP algorithm, a new recursive prediction error algorithm(RPE) is used in this paper.In addition, to demonstrate the effectiveness and veracity of the proposed method, some cases are used in the simulation. The simulation results are satisfactory.

Introduction

At present, DL/T2000 has recommended improved three-ratio method for the main transformer fault diagnosis method of internal fault [1] in china. It is one kind of fault diagnosis methods based on Dissolved Gas Analysis (DGA) [2,3]. DGA is an analysis method which is used to detect and diagnose different types of faults occurring in oil-filled power transformers. The method tests and samples the insulation oil of transformers periodically to obtain the different interpretations of dissolved gases in the mineral oil-insulation of such transformers. Now, in order to obtain online monitoring and fault diagnosis, transformer fault diagnosis requires an accurate model under fault conditions, particularly toward internal faults. Recently, many intelligence methods such as artificial neural network [4], Bayesian classifier and rough set [5], expert system [6], fuzzy theory and other some mixed new methods [7] have been investigated for transformer fault diagnosis and produced useful conclusions. Thus, in this paper, the diagonal recurrent neural network is used in the transformer fault diagnosis to increase diagnosis accuracy.

In recent years, the research of DRNN [8, 9] has made great development. Compared with BP neural network, DRNN is a dynamic neural network, it has simple structure. It can approximate any regular function and it has faster convergence speed. This faster convergence speed comes from the fact that DRNN has just three layers of weights and each layer can be determined sequentially. So DRNN is widely used in the fault diagnosis, functional approximation, modeling and classifying. In this paper, to further reduce the training time of DRNN, a new Recursive Prediction Error algorithm is used in this paper.

Diagonal recurrent neural network

DRNN is a dynamic neural network. It consists of three layers, one input layer , one middle layer and one output layer. The input layer corresponds to the input vector space and the output layer to the pattern classes. The architecture of DRNN is shown in Fig.1.

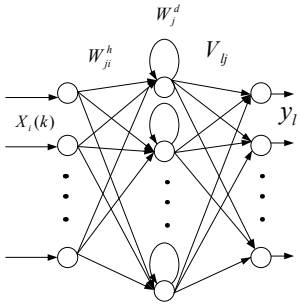

Fig.1 Architecture of DRNN

The DRNN equations between the input and output are as follows:

$$\begin{aligned} S_j(k) &= \sum_{i=1}^{M} W_{ji}^{h} * X_i(k) + W_j^d O_j(k-1) + b_{1j}(k) \\ O_j(k) &= f(S_j(k)) \\ y_l(k) &= \sum_{j=1}^{H} V_{lj} * O_j(k) + b_{2l}(k) \end{aligned} \tag{1}$$

Where, $X_i(k)$ is the input vector, $y_l(k)$ is the output, $S_j(k), O_j(k)$ are the input and output vectors of the hidden layer. W_{ji}^{h} is the weight vector between input layer and hidden layer. V_{lj} is the weight vector between output layer and hidden layer. W_j^d is weight of recurrent neuron. b_{1j} and b_{2l} are thresholds of hidden layer and output layer. $f(\bullet)$ is the excitation function of hidden neuron.

Recursive Prediction Error algorithm

The BP algorithm is a well-known method of training a multilayer feed-forward ANN. Although the algorithm is successful, it has some disadvantages. BP algorithm has a slow learning convergent velocity and easy convergence to local minima, which cannot be avoided. In addition, the selection of the learning factor and inertial factor affects the convergence of the BP neural network, which is usually determined by experience. To overcome disadvantages of BP algorithm, a Recursive Prediction Error algorithm is used. RPE algorithm is a method for parameter estimation based on the recursive prediction error minimizes principle.

Define the objective function:

$$\begin{aligned} E(\Theta) &= \frac{1}{2N} \cdot \sum_{k=1}^{N} [y_d(k) - \hat{y}(k)]^2 \\ &= \frac{1}{2N} \cdot \sum_{k=1}^{N} e^T(k,\Theta) \cdot e(k,\Theta) \end{aligned} \tag{2}$$

Where, e (k,Θ) is recursive prediction error vector. Θ is parameter vector(weights and thresholds of DRNN).

Then , the parameter vector revised formula is given :

$$\begin{aligned} &\Theta(k) = \Theta(k-1) + \alpha(k) \cdot \mu[\Theta(k-1)] \\ &\mu(\Theta) = -[H(\Theta)]^{-1} \nabla E(\Theta) \\ &\nabla E(\Theta) = -\frac{1}{N} \cdot \sum_{k=1}^{N} \psi(k,\Theta) \cdot e(k,\Theta) \\ &H(\Theta) = \sum_{k=1}^{N} \psi(k,\Theta) \cdot \psi^T(k,\Theta) \\ &\psi(k,\Theta) = [d\hat{y}(k,\Theta)/d\Theta]^T \end{aligned} \tag{3}$$

Where , $\alpha(k)$ is study velocity, μ(Θ)is the search direction of Gauss-Newton, ▽E(Θ) is gradient about Θ, H(Θ)is the Hessian array of E(Θ) .Then the RPE of DRNN can be given as follow functions.

$$\begin{aligned} &e(k) = y(k) - \hat{y}(k) \\ &P(k) = \frac{1}{\lambda(k)} \cdot \{P(k-1) + P(k-1) \cdot \psi(k)[\lambda(k) + \psi^T(k) P(k-1) \psi(k)]^{-1} \psi^T(k) \cdot P(k-1)\} \\ &\Theta(k) = \Theta(k-1) + \alpha(k) P(k) \psi(k) e(k) \\ &\lambda(k) = \lambda_0 \cdot \lambda(k-1) + (1-\lambda_0) \end{aligned} \tag{4}$$

Where, $\lambda(k)$ is forgetting factor.

Compared with the BP algorithm, RPE algorithm increases the amount of calculation for each-step training, but it uses second-order gradient effective accelerating the algorithm convergence speed, thus reduces overall training time. In addition, RPE algorithm of changed the algorithm adopted and the sensitivity of the initial momentum factors, and avoid the poor training effect of BP algorithm.

Improved three-ratio method

Among many DGA approaches, the normal three-ratio method is most commonly used because of its effective and convenient. It uses 3 gas ratios, C2H2/C2H4, CH4/H2 and C2H4/C2H6. Each ratio is quantized to a classification code 0, 1, or 2. So in total there is to be 27 possible combinations (fault types) but IEC 599 defines only 11 combinations leading to non-decision diagnosis, when falling within the invalid group of 16 remaining combinations. Improved three-ratio method overcomes the shortcomings of three-ratio method. Now, it is recommended fault diagnosis method based on DGA in china. Fault characters and fault diagnosis table of improved three-ratio method is given in Table 1.

Table 1. Improved three-ratio of DGA

Type of fault			
C_2H_2/C_2H_4	CH_4/H_2	C_2H_4/C_2H_6	Fault type code
$X_1<0.1$	$X_2<0.1$	$X_3<1$	1.Partial discharge
	$0.1<X_2<1$	$1 \le X_3<3$	2.Thermal fault with temperature(≤150℃)
	$1 \le X_2$	$X_3<1$	3.Thermal fault with temperature(150℃ 300℃)
	$1 \le X_2$	$1 \le X_3<3$	4. Thermal fault with temperature(300℃ 700℃)
	random	$X_3 \ge 3$	5. Thermal fault with temperature(≥700℃)
$X_1 \ge 3$	$X_2<1$	random	6.partial discharge with low energy density
	$X_2 \ge 1$	random	7.partial discharge with low energy density and thermal fault
$0.1 \le X_1<3$	$X_2<1$	random	8.Arc discharge
	$X_2 \ge 1$	random	9.Arc discharge and thermal fault

Neural network model and simulations

According to the improved three-ratio method, the structure of DRNN can be determined. The number of inputs of DRNN is three, respectively represent three inputs of C_2H_2/C_2H_4, CH_4/H_2 and C_2H_4/C_2H_6. The number of outputs of DRNN is nine, respectively represent nine different fault types (type 1-type 9). The nodes number of hidden layer is adaptive, meaning that the output of each node to the next node depends on the internal parameters pertaining to that particular node, which are modified during the learning process.

In order to evaluate the performance of the proposed algorithm, some simulation has been made. The diagnosis data of fault transformer contained 50 samples achieved from Jilin electrical science institute. With these samples, train the DRNN based on the RPE algorithm. Fig. 2 is the mean square error convergence curve of DRNN trained with RPE algorithm. Some fault diagnosis results with proposed method are list in the Table 2. From the simulation diagnosis results, it can be seen that the accuracy of this proposed method is satisfactory.

Conclusions

In this paper, a neural network fault diagnosis method based on DRNN is used to predict the internal fault for power transformers .In addition, to improve the convergence speed and improve the fault diagnosis accuracy, RPE algorithm is used. From the analysis of the results, it can be seen that the proposed method can provide an accurate approximation for fault diagnosis. It can detect the main fault type and provide useful information for future fault trends and multiple faults analysis systems.

Keywords: power quality; voltage flicker; cubic spline interpolation; envelope tracking

Abstract. Flicker envelope tracking is the key of analyzing voltage flicker signal. A novel method, i.e., cubic spline interpolation method is applied in the detection of the voltage flicker envelope. The typical flicker signals, such as one or multi-frequencies and frequency time-varying flicker signal are selected and analyzed by this method. Simulation results indicate that this method is effective in the detection of the envelope of voltage flicker signal. Results of one or multi-frequencies flicker signal simulation show that, when flicker frequency is less than 15Hz , the error of this method is quite tiny. The detection precision of this method is higher, especially in the scope of low frequencies of flicker and this method makes up for the disadvantage of square demodulation. Furthermore, results of frequency time-varying flicker signal simulation show that, the occurrence and recover time of voltage flicker signal can be accurately detected by cubic spline interpolation method.

Introduction

In various power quality problems, voltage fluctuation and flicker is considered as one of the major power quality disturbances [1-2]. With the development of the national economy, larger quantities of high-power impulsive, fluctuating and nonlinear loads, such as arc furnaces, arc welders, spot welders, resistance welders and repetitive operation machinery are used in power networks. The active power and reactive power change rapidly and violent during these equipments operate, which results in voltage fluctuation at the point of common coupling (PCC) [3]. In order to minimize voltage fluctuation, numerous reactive power compensation devices are applied in the power system. However, these devices are required to provide accurate tuning flicker parameters to make the right suppression decisions. The amplitude and frequency information of the voltage fluctuation is contained in the envelope of voltage flicker signal. Therefore, the key to analyze voltage flicker signal is the detection of flicker envelope. After separation of the flicker envelope, flicker-related parameters can be easily calculated according to selected criteria [4-5].

At present, square demodulation, rectifier detection and RMS detection are three main methods to be selected to detect voltage flicker by flicker meter at home and abroad [6]. However, these three methods are not suitable for detecting multi-frequency flicker signal and time-varying flicker signal. Especially, square demodulation is the method which based on the IEC recommended [7]. References [8-9] proposed that the error of square demodulation method to extract the envelope of flicker increases with the flicker frequency decreasing. In the vicinity of the most sensitive flicker frequency 8.8Hz, the detection error reduces to a minimum, and then increases again. In a word, the detection precision of square demodulation method is high, only in the scope of low frequencies.

The interpolation method is one of the important numerical approximation methods [10], which is based on the given variable value and function value to get the approximate value of unknown function. The task of interpolation is known by the observation points to set up a simple, continuous analytical model, in order to be able to deduce the physical quantities in the non observation points according to the characteristics of the model. However, in practice, there are many interpolation function curve with high smoothness. In the whole curve, curve can not be a turning point, but also can not have the mutation of curvature. Therefore, the interpolation functions must be continuous and constant micro No. two times; this requires cubic spline interpolation which has the best smoothness.

For this feature of cubic interpolation method, and considering the flicker signal characteristic, this method is used in this paper for the first time to track voltage flicker envelope.

The cubic spline interpolation method

The definition of cubic spline interpolation. For an interval $[a,b]$, $a=x_0<x_1<\cdots<x_n=b$, the corresponding function values are $y_0<y_1<\cdots<y_n$. If function $S(x)$ meets the following three conditions, $S(x)$ is called cubic spline interpolation on interval $a\le x_i\le b, i=0,1,\cdots n$.

(1) $S(x_i)=y_i$,$i=0,1,\cdots n$;(2)$S(x)$ is not more than three times polynomial on interval [x_{i-1}, x_i](i=1,2,…n);(3) $S(x)$ is continuous second-order derivative on interval $[a,b]$.

In constructing the cubic spline interpolation function, requiring $S(x)$ only determined a cubic polynomial on the each sub-interval [x_{i-1}, x_i], set:

$$S_i(x)=a_ix^3+b_ix^2+c_ix+d_i, i=0,1,\cdots,n \tag{1}$$

In which a_i,b_i,c_i,d_i are undetermined coefficients, and $S(x_i)=y_i$; $S(x_i-0)=S(x_i+0), i=1,2,\cdots,n-1$; $S'(x_i-0)=S'(x_i+0), S''(x_i-0)=S''(x_i+0), i=1,2,\cdots,n-1$ .There is 4n-2 conditions, so 4n coefficients need to be determined. To uniquely identify a cubic spline interpolation, additional two boundary conditions are also needed and they are usually given by the endpoints status of cubic spline interpolation in practical.

The construction of cubic spline interpolation function. Cubic spline interpolation function $S(x)$ approaches to the real function $y=f(x)$ through piecewise cubic polynomial, and satisfies three conditions mentioned above.

To make $M_i=S''(x_i)$, the interpolation condition $S(x_i)=y_i, i=1,2,\cdots,n$ and formula (2)

$$S''(x)=\frac{x-x_{i-1}}{h_{i-1}}M_i-\frac{x-x_i}{h_{i-1}}M_{i-1}, i=1,2,\cdots,n \tag{2}$$

By two continuous integration, you can get the cubic spline interpolation function $S(x)$ expressed as formula (3):

$$\begin{aligned}S(x)&=\frac{M_i}{6h_{i-1}}(x-x_{i-1})^3-\frac{M_{i-1}}{6h_{i-1}}(x-x_i)^3\\&+(\frac{y_{i-1}}{h_{i-1}}-\frac{M_{i-1}}{6}h_{i-1})(x_i-x)+(\frac{y_i}{h_{i-1}}-\frac{M_i}{6}h_{i-1})(x-x_{i-1})\end{aligned} \tag{3}$$

Where $x_{i-1}\le x\le x_i, i=1,2,\cdots,n$, $h_{i-1}=x_i-x_{i-1}, i=1,2,\cdots,n$.

The function $S(x)$ has a continuous second derivative at the sample point x_i , and according to cubic spline interpolation method principle, besides, increasing the natural boundary conditions:

$$\begin{aligned}S''(x_0)&=y_0''=0\\S''(x_n)&=y_n''=0\end{aligned} \tag{4}$$

Obtain the following equations represented by the matrix:

$$\begin{bmatrix}2 & j_0 & & & \\ \lambda_1 & 2 & j_1 & & \\ & \ddots & \ddots & \ddots & \\ & & \lambda_{n-1} & 2 & j_{n-1}\\ & & & \lambda_n & 2\end{bmatrix}\cdot\begin{bmatrix}M_0\\M_1\\\cdots\\M_{n-1}\\M_n\end{bmatrix}=\begin{bmatrix}J_0\\J_1\\\cdots\\J_{n-1}\\J_n\end{bmatrix} \tag{5}$$

Where $\begin{cases}j_i=\dfrac{h_{i+1}}{h_i+h_{i+1}}\\ \lambda_i=1-j\\ J_i=\dfrac{6}{h_i+h_{i+1}}(\dfrac{y_{i+1}-y_i}{h_{i+1}}-\dfrac{y_i-y_{i-1}}{h_i})\end{cases}$, and i=1， 2， …， n-1， j_0=0， J_0=0， λ_n=0.

To solve the equations above, obtained by M_i(i= 0, 1, 2,…,n) into formula (3), then get the cubic spline interpolation function on each sub-interval [x_{i-1},x_i](i= 1, 2,…,n).

The envelope tracking of voltage flicker based on this method

Voltage flicker is caused by voltage fluctuation. The analytical expression of periodic voltage flicker signal can be expressed by formula (6).

$$u(t) = A(1+\sum_{k} m_k \cos\Omega_k t)\cos(\omega t+\theta) \tag{6}$$

Where, A—the amplitude of power frequency carrier voltage;

ω—the angular frequency of power frequency carrier voltage;

m—the coefficient of amplitude modulation(AM) wave, i.e. AM wave voltage amplitude and power frequency carrier wave voltage amplitude ratio.

Ω_k—the angular frequency of amplitude modulation wave.

As power frequency voltage is the carrier of flicker signal, its peak value or root mean square voltage fluctuation component is modulated in amplitude as the waves, flicker frequency is generally between 0.5~25Hz. The amplitude and frequency information of the voltage fluctuation is contained in the envelope of voltage flicker signal. Therefore, the key to analyze voltage flicker signal is the detection of flicker envelope [11].

The steps of envelope tracking using cubic spline interpolation method are as follow:

1) For voltage flicker signal $u(t)$, high frequency sampling and the frequency of 3200Hz;

2) Determined all the coordinates of maximum points $p_i(x_i, y_i)$ and minimum points $q_j(x_j, y_j)$;

3) Regarded p_i and q_j as the interpolation nodes which have been known.

4) In order to avoid the end effect, adding the boundary condition and regarding the endpoints of flicker signal $u(t)$ as the maximum points.

5) Fitting the upper and lower envelope, respectively, using cubic spline interpolation.

6) The sum of the upper and lower envelope averaging to obtain the final envelope, i.e. to extract flicker envelope.

This method is simple and fast, just to get extreme points of flicker signal, you can quickly extract flicker envelope with a cubic spline interpolation method.

To reflect the cubic spline interpolation method to extract flicker envelope is valid, using the formula (7) to calculate the detection error of this method, which the relative error extracts flicker envelope is defined is:

$$e = \left|\frac{a(t)-a'(t)}{a(t)}\right| \times 100\% \tag{7}$$

In the formula (7), $a(t)$ is the real instantaneous amplitude, $a'(t)$ is the instantaneous amplitude extracted by cubic spline interpolation method.

Here the use of MATLAB software cubic spline interpolation method for programming method to extract flicker envelope, to verify the validity of this method. In the following case study, the voltage amplitude was represented by per-unit value. The extracted envelope is instantaneous amplitude of the results which the DC component has been filtered out.

Case study

Flicker signal with one frequency. In order to show test results more intuitively, set the example of the signal parameters calculated as follows: The frequency of AM wave: 8.8Hz, the coefficient m is 5%, carrier frequency:50Hz, Initial phase:0, sampling frequency: 3200Hz, sampling duration: 0.5s.

The example signal was shown as formula (8):

$$u(t) = (1+0.05\cos 17.6\pi t)\cos(100\pi t) \tag{8}$$

8.8Hz flicker signal waveform was shown in Figure 1, with cubic spline interpolation method to extract flicker envelope was shown in Figure 2. Figure 2 shows that the two envelopes are almost coincident. The method analyzing the detection error in this paper is that remove the anomalous data which in zero-crossing and endpoints and use the least squares to fit the data points. Take the average of fitting date as detection error of cubic spline interpolation method. Due to space limitations, only the results of a single frequency flicker detection error is shown in figure 3. Fitted by least-squares, it is a straight line parallel to the abscissa of the coordinate. The mean of detection error was 0.2772%.

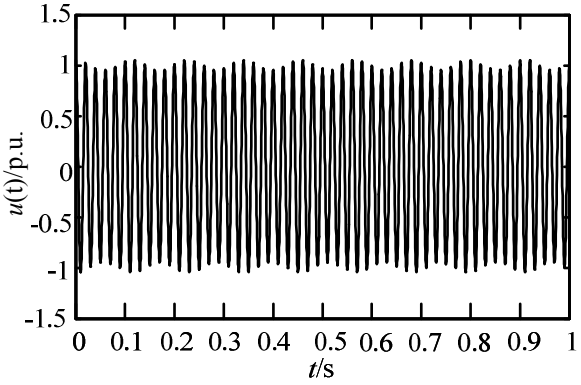

Fig.1 The one-frequency flicker signal

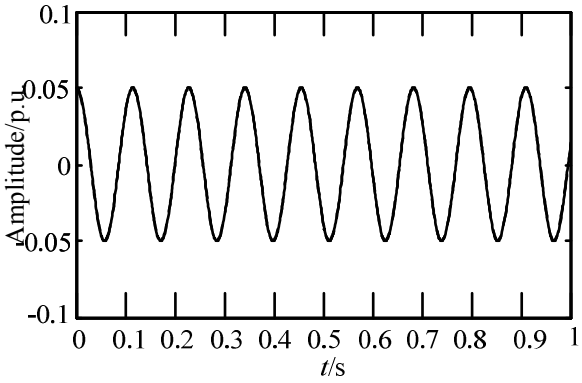

Fig.2 The detection result (dotted line) compare with real value (solid line) of multi-frequency

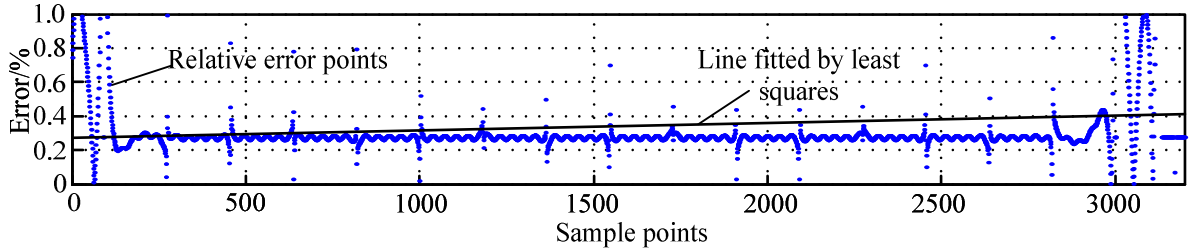

Fig.3 The relative value of detection errors

To get close to actual, take the voltage fluctuation parameters of instantaneous visual sensitivity $S(t)$=1 proposed in literature [6] for analysis. The errors detected by cubic spline interpolation method were shown in table 1.

Tab. 1 The detection errors of cubic spline interpolation method

f/Hz	Δ*V*/%	error/%	*f*/Hz	Δ*V*/%	error/%	*f*/Hz	Δ*V*/%	error/%	*f*/Hz	Δ*V*/%	error/%
0.5	2.340	2.2×10^{-6}	5.0	0.398	0.0241	**8.8**	**0.250**	**0.2772**	12.0	0.312	1.1900
1.0	1.432	3.5×10^{-5}	6.0	0.328	0.0518	9.5	0.254	0.3943	13.0	0.348	1.7692
2.0	0.882	5.6×10^{-4}	6.5	0.300	0.0730	10.0	0.262	0.4937	14.0	0.388	2.5771
3.0	0654	0.0029	7.0	0.280	0.1002	10.5	0.270	0.6268	15.0	0.462	3.6958
4.0	0.500	0.0095	7.5	0.266	0.1357	11.0	0.282	0.7817	**16.0**	**0.480**	**5.2105**

Analysis of the data in Table 1 shows that the detection error becomes larger and larger with flicker frequency increasing using the proposed method. When the frequency is greater than 15Hz, the error is more than a 5%. Using this method to extract the flicker envelope of which the frequency is below 12Hz, the detection error is small, maintained at 1.5%. And the lower the frequency is, the smaller the error is. In particular, when the flicker frequency is at 3Hz or less, the detection error is less than 0.003%. And this band is exactly in the test frequency range of low frequencies of IEC flicker meter. Literature [8] pointed out: IEC flicker meter for detection error of low-frequency flicker is large, so the cubic spline interpolation method is applicable to the detection of low-frequency flicker caused by wind power connected to grid (1~3Hz). Thus, this method is more suitable for flicker in low-mid frequency envelope detection.

Flicker signal with multi-frequencies. Formula (7) represents multi-frequency flicker signal.

$$u(t) = (1+0.075\cos 10\pi t + 0.05\cos 20\pi t + 0.025\cos 30\pi t)\cos(100\pi t) \tag{7}$$

The frequency of AM wave: 5Hz, 10Hz and 15 Hz; the coefficients are corresponding to 7.5%, 5% and 2.5%, respectively. Sampling frequency: 3200Hz, sampling duration: 0.5s.

Multi-frequency flicker signal waveform was shown in Figure 4, with cubic spline interpolation method to extract flicker envelope was shown in Figure 5. Since the endpoint effect, the two envelopes not coincide except for the envelope at the endpoint, and the rest almost coincide. Detection error is 1.2917% and the detection is ideal.

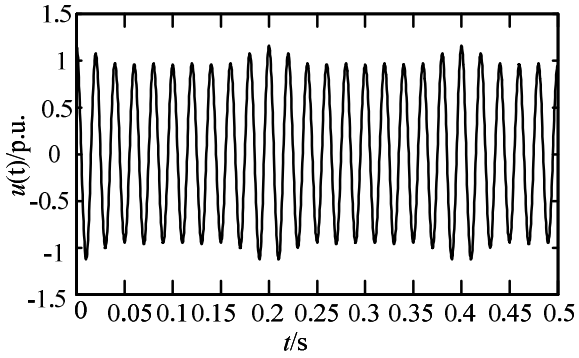

Fig.4 The multi-frequency flicker signal

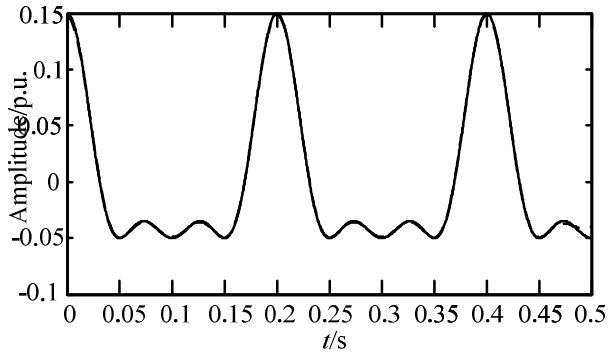

Fig.5 The detection result (dotted line) compare with real value (solid line) of multi-frequency

Flicker signal with time-varying frequency. EAF is one of the main equipment leading to voltage fluctuations and flicker. The frequency of each frequency component is roughly inversely proportional to the amplitude of the signal caused by it. Formula (7) simulates the flicker signal caused by EAF.

$$u(t)=\begin{cases}\cos(100\pi t); & 0\le t<0.3 \text{ or } 1.7\le t\le 2\text{s}\\ (1+0.1\cos(20\pi t))\cos(100\pi t); & 0.3\le t<1s\\ (1+0.075\cos(20\pi t)+ & \\ 0.05\cos(30\pi t))\cos(100\pi t); & 1\le t<1.7s\end{cases} \tag{7}$$

Time-varying frequency flicker signal waveform was shown in Figure 6, with cubic spline interpolation method to extract flicker envelope was shown in Figure 7.

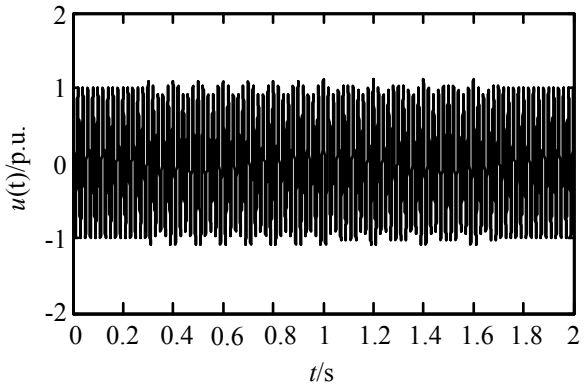

Fig.6 Time-varying frequency flicker signal

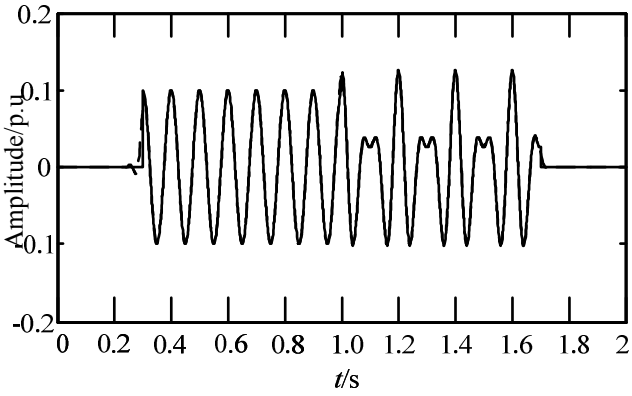

Fig.7 The detection result (dotted line) compare with real value(solid line) of Time-varying frequency

As shown in figure 7, Single frequency flicker occurred at moment 0.28s, changed into a multi-frequency flicker at 1.09s and continued to 1.73s, lastly changed into a power frequency signal. Thus this shows that this method can accurately detect the starting time and end time when flicker frequency component signal changes. Detection error is 1.5094% and the detection is ideal.

Conclusions

The key to analyze voltage flicker signal is to track envelope which contains the amplitude and frequency information of voltage fluctuation. The cubic spline interpolation method was applied in envelope tracking of voltage flicker and a new way was provided to analyze voltage flicker. Simulation examples show that the interpolation method in detecting single-frequency and multi-frequency flicker signal whose flicker frequency is 12Hz or less, the detection error is small. Especially in the low flicker frequency (0.5~3Hz), the error is smaller, making up for the disadvantage that the error is greater in detecting low frequency using square demodulation method.

Therefore, it is suitable for flicker envelope extraction caused by arc furnaces and grid connected wind power. Furthermore, results of frequency time-varying flicker signal simulation show that, the occurrence and recover time of voltage flicker signal can be accurately detected by this method.

Key words: power quality; harmonic contributions; partial linear method; background harmonic voltage

Abstract. The linear regression method which will be influenced by fluctuations could only calculate constant background harmonic voltage. To make up the limitation, this paper studies partial linear method. The method expands fluctuant background harmonic voltage at a time in accordance with Taylor series. On the basis of least sum of square error, the objective function selected by the method considers the influence of weight and uses bandwidth control each size of weight. This method can calculate fluctuant background harmonic voltage accurately. A case study based on the IEEE 14-bus test system is conducted and the results indicate that fluctuant background harmonic voltage can be obtained effectively and accurately by the proposed method.

Introductions

In recent years, some large-capacity and non-linear equipment, such as electric locomotives, electric arc furnaces etc, have caused a large number of harmonic problems [1-3]. In order to improve the level of harmonic management and control the harmonic pollution in the grid effectively, National quality supervision bureau promulgate the《Quality of electric supply Harmonics in public supply network》(GB/T 14549-93) in 1993. The standard provides specific provision about the threshold [4], but it can not scientifically settle the dispute between power supplies and consumers. In order to implement the principle of " who pollution, who control " , it is necessary to quantify harmonic contributions on both sides at the PCC.

The key to quantify the harmonic contributions at the point of common coupling is evaluating equivalent harmonic impendence of the system and background harmonic voltage at PCC accurately. Equivalent harmonic impendence is related with operation modes of electrical system and the topology of the grid, which can be approximated as a constant in short monitoring period. However, considering the fluctuation brought by non-linear loads at the PCC, background harmonic voltage can not regarded as a constant. In recent years，linear regression method become a research focus. On the basis of Norton equivalent circuit, linear regression method establishes corresponding functions. Scholars have proposed several linear methods such as binary linear regression method [5], robust regression method [6], partial least-square regression method [7] and complex least squares method [8]. From [5-7], we acquire that basically unchanged harmonic impendence and background harmonic voltage at the PPC is the premise of approaching ideal harmonic contributions caused by each harmonic source. Therefore, the limitations are as follows: If the background harmonic voltage is not a constant, the assessment of harmonic contributions is inaccurate. In view of fluctuating background harmonic voltage in the specific period, subdividing monitoring period into uniform pieces and taking each section as a constant has been proposed in [8-9].However, it is difficult to choose the agreeable scale to subdivide the period.

In order to qualify the harmonic voltage contributions, kernel estimation in partial linear method is applied in the mathematical model presented by [10]. Compared with common linear

method, the method can calculate fluctuant background harmonic voltage accurately without doing too much data processing.

The definition of harmonic voltage contribution

As is shown in Fig.1. Bus X is the concerned bus, which are respectively connected with the power system and several nonlinear loads.

If monitoring equipments detect that severe harmonic voltage distortion exists, it is necessary to determine the harmonic voltage contribution of each nonlinear load quantitatively. Without loss of generality, assuming that load A is of concern. $\dot{U}_{h\mathrm{X}}$ is the h-th harmonic voltage at bus X, $\dot{I}_{h\mathrm{A}}$ denotes *h*-th harmonic current injected by load A. $\dot{U}_{h\mathrm{X}}$ is composed of two parts, the one is background harmonic voltage expressed as $\dot{U}_{h0}$, which can be explained as a compound amount including the system and the other loads except A; the other is $\boldsymbol{Z}_{hX,A}\dot{\boldsymbol{I}}_{hA}$ provided by load A.

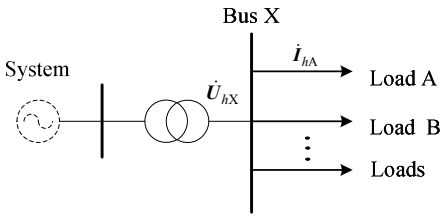

Fig. 1 Multiple loads connected with the same bus of concern

Due to the sampling measurement error, the relationship between $\dot{\boldsymbol{U}}_{h\mathrm{X}}$ and $\dot{\boldsymbol{I}}_{h\mathrm{A}}$ can be expressed in equation (1).

$$\dot{\boldsymbol{U}}_{hX} = \boldsymbol{Z}_{hX,A}\dot{\boldsymbol{I}}_{hA}+\dot{\boldsymbol{U}}_{h0}+\boldsymbol{\varepsilon} \tag{1}$$

Where $\boldsymbol{\varepsilon}$ is complex error. $\boldsymbol{Z}_{h\mathrm{X,A}}$ represents the *h*-th equivalent harmonic impendence, including the other loads and system side.

Detailed deduction about harmonic contribution calculation formula has been given in [10]. The final formula is shown in equation (2):

$$\mu_h = \frac{U_{h\mathrm{X}}^2 + \left|Z_{h\mathrm{X,A}}\right|^2 I_{h\mathrm{A}}^2 - U_{h0}^2}{2U_{h\mathrm{X}}^2} \tag{2}$$

From (2), we acknowledge that the essence of quantifying the harmonic contributions caused by concerned load is assessing equivalent harmonic impedance and background harmonic voltage accurately.

The paper attempts to apply a set of data $\dot{\boldsymbol{U}}_{h\mathrm{X}}$ and $\dot{\boldsymbol{I}}_{h\mathrm{A}}$ processed by Fourier transform and partial linear method to regress fluctuating background harmonic voltage $\dot{\boldsymbol{U}}_{h0}$ and equivalent harmonic impedance $\boldsymbol{Z}_{h\mathrm{X,A}}$.

Kernel estimation in partial linear method

Both $\dot{\boldsymbol{U}}_{h\mathrm{X}}$ and $\dot{\boldsymbol{I}}_{h\mathrm{A}}$ are plurals. Equation (3) can be derived by expanding complexes in equation (1).

$$\begin{cases} \boldsymbol{U}_{h\mathrm{X,r}} = R\boldsymbol{I}_{h\mathrm{A,r}} - X\boldsymbol{I}_{h\mathrm{A,x}} + \boldsymbol{U}_{h0,\mathrm{r}} + \boldsymbol{\varepsilon}_{\mathrm{r}} \\ \boldsymbol{U}_{h\mathrm{X,x}} = X\boldsymbol{I}_{h\mathrm{A,r}} + R\boldsymbol{I}_{h\mathrm{A,x}} + \boldsymbol{U}_{h0,\mathrm{x}} + \boldsymbol{\varepsilon}_{\mathrm{x}} \end{cases} \tag{3}$$

Subscript r and x respectively represent the real and the imaginary part of the complex. *R* is equivalent harmonic resistance, *X* denotes equivalent harmonic reactance.

Supposing there are n samples and taking the real part of voltage for example, we have:

$$\begin{cases} U_{hX,r}(1)=RI_{hA,r}(1)-XI_{hA,x}(1)+U_{h0,r}(1)+\varepsilon_{r1} \\ U_{hX,r}(2)=RI_{hA,r}(2)-XI_{hA,x}(2)+U_{h0,r}(2)+\varepsilon_{r2} \\ \vdots \\ U_{hX,r}(n)=RI_{hA,r}(n)-XI_{hA,x}(n)+U_{h0,r}(n)+\varepsilon_{rn} \end{cases} \tag{4}$$

The equation (4) can be described as follow:

$$\boldsymbol{U}=\boldsymbol{IZ}+\boldsymbol{U}_0+\boldsymbol{\varepsilon} \tag{5}$$

Where the elements R and X in matrix $\boldsymbol{Z}$ are constants while the elements in column vector $\boldsymbol{U}_0$ fluctuant with time. Therefore the mathematical mode is called partial linear model. The complex measurement error is ε_i which obeys normal distribution $N(0, \sigma^2)$.

Taking the background harmonic voltage at time t_k (k=1,2…， n) for example, $U_0(t)$ can be expressed approximately as follow at the time of t_k:

$$U_0(t)\approx U_0(t_k)+U_0'(t_k)(t-t_k) \tag{6}$$

Where $t_k=k$。For convenience, we assumed that $\alpha_k=U_0(t_k)$ and $\beta_k=U_0'(t_k)$. In order to calculate $U_0(t_k)$, the objective function selected by the method makes least square sum of error and considers the influence of weight.

$$\min\sum_{i=1}^{n}\left[U(t_i)-\boldsymbol{I}(t_i)\boldsymbol{Z}-\hat{\alpha}_k-\hat{\beta}_k(t_i-t_k)\right]^2K_b(x_i) \tag{7}$$

Where $\hat{\alpha}_k$ and $\hat{\beta}_k$ denote the estimation of α_k and β_k respectively, $K_b(x_i)=b^{-1}K(x_i/b)$, $x_i=(t_i-t_k)/n$. $K(x_i/b)$ represents kernel function which is a bounded symmetric density function. Parameter b represents bandwidth, a positive real number, which is associated with sample size. In this paper, we definite $b=n^{-1/5}$ [11]。Kernel function plays a role in weights which is controlled by parameter b.

Epanechnikov function is commonly used as optimal kernel function [12]:

$$K(x_i/b)=0.75\times\left(1-(x_i/b)^2\right)\qquad |x_i|\le b \tag{8}$$

The derivation shows that $\hat{\alpha}_k$ meets the equation (9):

$$\begin{bmatrix}\hat{\alpha}_k\\ \hat{\beta}_k\end{bmatrix}=\left(\boldsymbol{D}_{tk}{}^{\mathrm{T}}\boldsymbol{W}_{tk}\boldsymbol{D}_{tk}\right)^{-1}\boldsymbol{D}_{tk}{}^{\mathrm{T}}\boldsymbol{W}_{tk}(\boldsymbol{U}-\boldsymbol{IZ}) \tag{9}$$

Where:

$$\boldsymbol{D}_{tk}=\begin{bmatrix}1 & 1 & \cdots & 1\\ x_1 & x_2 & \cdots & x_n\end{bmatrix}^{\mathrm{T}},\qquad \boldsymbol{W}_{tk}=diag\left[K_b(x_1),K_b(x_2),\cdots,K_b(x_n)\right]$$

Therefore:

$$\hat{\alpha}_k=[1,0]\left(\boldsymbol{D}_{tk}{}^{\mathrm{T}}\boldsymbol{W}_{tk}\boldsymbol{D}_{tk}\right)^{-1}\boldsymbol{D}_{tk}{}^{\mathrm{T}}\boldsymbol{W}_{tk}(\boldsymbol{U}-\boldsymbol{IZ}) \tag{10}$$

According to earlier assumption $\hat{\alpha}_k=\hat{U}_0(t_k)$, $\hat{\boldsymbol{U}}_0$ can be described by equation (11):

$$\hat{\boldsymbol{U}}_0=\begin{bmatrix}[1,0]\left[\left(\boldsymbol{D}_{t1}{}^{\mathrm{T}}\boldsymbol{W}_{t1}\boldsymbol{D}_{t1}\right)^{-1}\boldsymbol{D}_{t1}{}^{\mathrm{T}}\boldsymbol{W}_{t1}\right]\\ \vdots\\ [1,0]\left[\left(\boldsymbol{D}_{tn}{}^{\mathrm{T}}\boldsymbol{W}_{tn}\boldsymbol{D}_{tn}\right)^{-1}\boldsymbol{D}_{tn}{}^{\mathrm{T}}\boldsymbol{W}_{tn}\right]\end{bmatrix}(\boldsymbol{U}-\boldsymbol{IZ})\triangleq\boldsymbol{S}(\boldsymbol{U}-\boldsymbol{IZ}) \tag{11}$$

Substituting (11) into (5), we have:

$$(\boldsymbol{E}-\boldsymbol{S})\boldsymbol{U}=(\boldsymbol{E}-\boldsymbol{S})\boldsymbol{IZ}+\boldsymbol{\varepsilon} \tag{12}$$

Where: $\boldsymbol{E}$ is unit matrix.

$\hat{\boldsymbol{Z}}$ can be obtained by least squares method.

$$\hat{\boldsymbol{Z}}=\left[\left((\boldsymbol{E}-\boldsymbol{S})\boldsymbol{I}\right)^{\mathrm{T}}(\boldsymbol{E}-\boldsymbol{S})\boldsymbol{I}\right]^{-1}\left((\boldsymbol{E}-\boldsymbol{S})\boldsymbol{I}\right)^{\mathrm{T}}(\boldsymbol{E}-\boldsymbol{S})\boldsymbol{U} \tag{13}$$

Case study

The proposed method is tested by the standard IEEE14 bus system shown in Fig.2. We select the 5th harmonic for explanation. Bus 11 which supplies three loads as our concern. HL1 and HL2 are nonlinear loads which could launch harmonic voltage into the concerned bus, and L3 is linear load. Without loss of generosity, we assume that load HL1 is of concern. Determining the harmonic impact of HL1 on bus 11 is commonly seen in engineering.

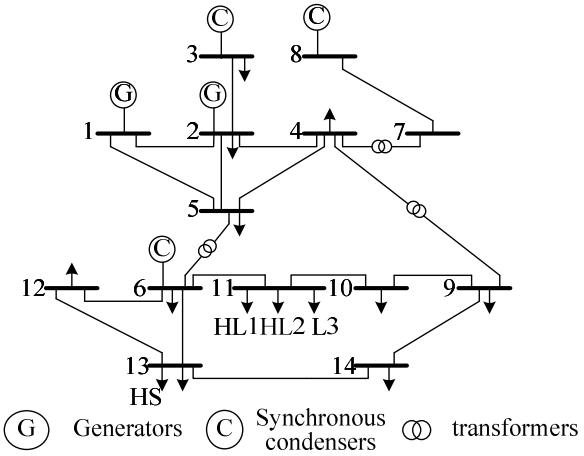

Fig. 2 IEEE14-bus system

Typical harmonic current spectrums given in [13] are used for HL1 and HL2 shown in Fig.3 andFig.4 respectively. Fluctuating background harmonic voltage is simulated by HL2. Harmonic source at system side is simulated by HS, which is a constant. The amplitude and initial phase angle is 114.80 amperes and -76.56 degrees. The background harmonic voltage is composed by HL2 and HS. The simulation process takes during a 24-h period, and each minute one sample is collected, resulting in 1440 data points for physical quantity that was measured.

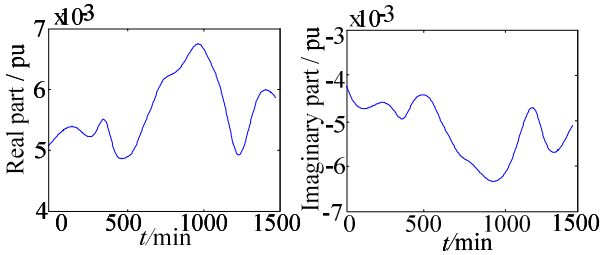

Fig.3 5th harmonic current injected by HL1

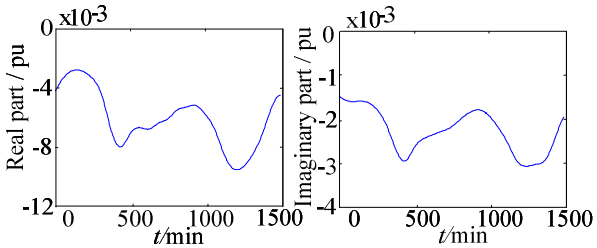

Fig.4 5th harmonic current injected by HL2

Curves of the effective value of the fifth harmonic voltage at bus 11 and effective value of the 5th harmonic current at bus 11 injected by HL1 are shown in Fig.5 and Fig.6.

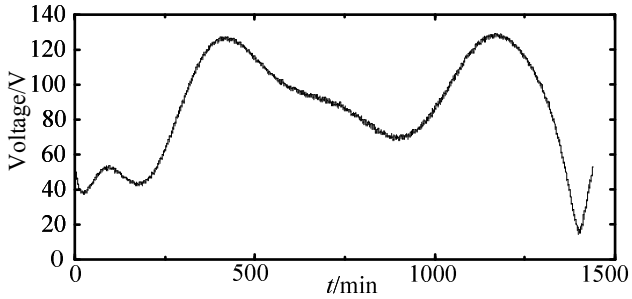

Fig.5 The 5th harmonic voltage at bus 11

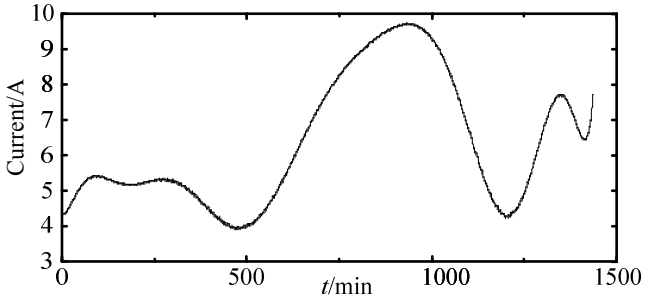

Fig.6 The 5th harmonic current injected by HL1

Kernel estimation in partial linear method is applied for calculating background harmonic voltage. The parameter bandwidth is 0.23. Comparing the real and imaginary part of the background harmonic voltage respectively with its true value achieved by case study is of importance. For the purpose of demonstrating the superiority of the method, we use the complex least squares

method to regress background harmonic voltage as well. Because of its nature that it could only regress constant coefficient, we subdivide the period of sampling time and regard that background harmonic voltage is unchanged in every piece of divided period. In this paper, the sampling time will be divided into 144 parts evenly. As is shown in Fig.6, the result has been compared among the true value and the two methods.

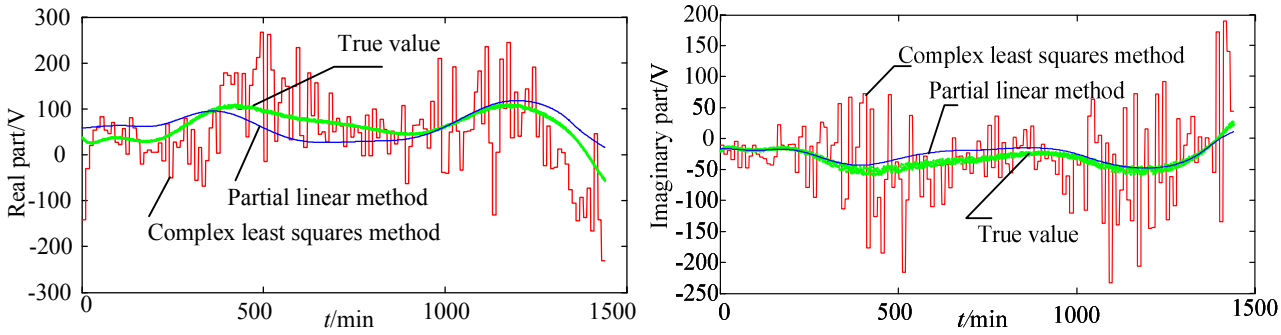

Fig.7 The real and the imaginary part of background harmonic voltage

Fig 7 shows that background harmonic voltage obtained by the method is close to the true value. Therefore, the complex least squares method can just return to the overall trend of the background harmonic voltage. Error analysis is displayed in Table 1. According to the data, equivalent harmonic impendence can be achieved by the two methods in the table 2.

Tab. 1 Error analysis of background harmonic voltage between the two methods

	Real part		Imaginary part	
	The absolute error /V	The relative error /%	The absolute error /V	The relative error /%
Complex least squares method	20.32	13.67	1.62	-72.49
Partial linear method	3.24	3.97	2.05	-1.46

Tab. 2 Error analysis of harmonic impedance results between the two methods

	Harmonic impedance/Ω	absolute error	relative error /%
True value	2.866∠79.75°	—	—
Complex least squares method	1.984∠173.06°	3.5784	124.86
Partial linear method	2.956∠70.70°	0.1650	5.76

Conclusions

For the purpose of solving fluctuant background harmonic voltage, this paper studies the kernel estimation in partial linear method, which is superior to linear method in several aspects. Kernel estimation in partial linear method can regress background harmonic voltage more accurately than complex least squares method in case of its fluctuation. Research for this article also requires the following instructions.

The equation (6) requires that background harmonic voltage is changing slowly. How to calculate the non-smoothing background harmonic voltage remains to be further studied.

Keywords: Simulation, Electrolytic cleaning, Cold rolled strip, Current efficiency

Abstract. The model of electrolytic cleaning for cold rolled strip was established, and the simulation of cleaning process was carried out in the finite element method with the software(Ansoft). The influence of processing parameters was investigated. The results show that, the processing parameters, such as the current efficiency, the electrode plate intervals and the insulation board have intense influence on current efficiency, which is significant for improving cleaning efficiency and energy conservation.

Introduction

Compared with traditional cleaning technologies, electrolytic cleaning is a rapid and effective cleaning technology in the pretreatment of the cold-rolled steel. Lots of studies have been done on the processing parameters, such as current density, electrolysis time, temperature and concentration of electrolyte and so on. At present, the parameters of processing are mainly chosen through experience, not only wasting the resources but also having a low efficiency[1-6].

In the process of electrolytic cleaning, the cold-rolled steel strip acts as electrode, experiencing cathodic and anodic cleaning respectively. the total input current(I_t) for the device can be divided into two parts: the first part (I_1)is from electrode to electrode, as shown in dotted lines in Fig.1, and the second part(I_2) is from electrode to steel strip, as shown in solid lines in Fig.1. Hydrogen or oxygen evolution reaction takes place on the surface of electrode and steel strip separately, and the gas evolution on the surface of cold-rolled steel strip plays the main role of cleaning, which means that only the current from the electrode of electrolytic cleaning device to cold-rolled steel is effective for cleaning.

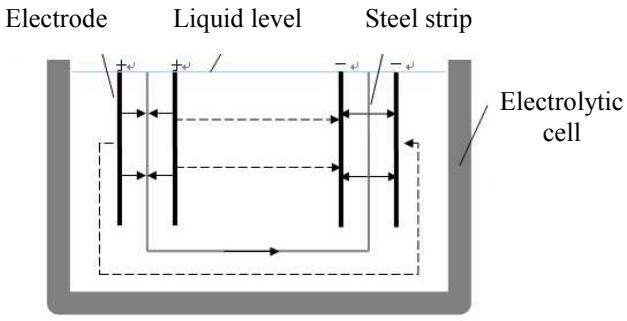

Fig.1 Current path in electrolytic cell

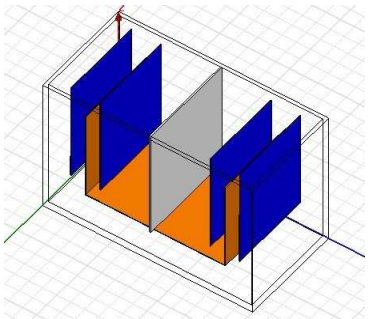

Fig.2 Simplied model of electrolytic cleaning

Up to now, there is no report studied on the distribution of electric current in the electrolytic cleaning device. In the paper, the current efficiency of electrolytic cleaning is defined as $\eta = \frac{i_2}{I_t}$, and the influencing factors were investigated in the method of simulation for the purpose of improving the efficiency of cleaning.

Establishment of Model and Simulation Principle

According to the process of electrolytic cleaning for cold rolled strip in practice, a simplified 3-dimention cleaning model with a insulation clapboard was established, which is shown in Fig.2. The conditions of boundary and initialization are set as follows:
Initial conditon:

$$\varphi_0 = C \tag{1}$$

φ is electric potential, and C is a constant.
Boundary condition:

$$\frac{\partial \varphi}{\partial n} = 0 \tag{2}$$

n is the normal line of the point on the electrolytic cleaning cell.
The distribution of electric potential in the cleaning cell can be calculated with laplace equation:

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} = 0 \tag{3}$$

Electric field intensity(E) and current density(j) can be obtained with such equations:

$$E = -\nabla \varphi \tag{4}$$

$$j = kE \tag{5}$$

∇ is laplacian, and k is the conductance.
The finite element software(Ansoft) was adopted for the calculation of electric field intensity(E). Using the values of current density(j), current can be calculated an follows:

$$I_e = \oiint_{S_e} j_e dS \tag{6}$$

$$I_s = \oiint_{S_s} j_s dS \tag{7}$$

I_s is the current through the surface of strip, which is useful for washing. I_e is the current through the electrode, which is equal to the total input current(I_t).
Then the current efficiency of electrolytic cleaning can be expressed as Eq.8:

$$\eta = \frac{I_s}{I_e} \times 100\% = \frac{\oiint_{S_s} j_s dS}{\oiint_{S_e} j_e dS} \times 100\% \tag{8}$$

Results and Discussion

Distribution of equipotential surface and current flow diagram calculated with Ansoft are shown in Fig.3 and Fig.4 respectively. It can be seen that, the equipotential surface and current density vary distinctly at the different part of the electrolytic cleaning cell. The distribution is most intensive in the areas close to the electric plate, and the potential reaches the maximum. The variance of electric potential and current density means there is leak current from electrode to electrode more or less, which would induce waste of electric energy.

The effect of processing parameters was investigated at different conditions, and the current efficiencies of electrolytic cleaning under different processing parameters were calculated with Eq.8, and contrasted separately.

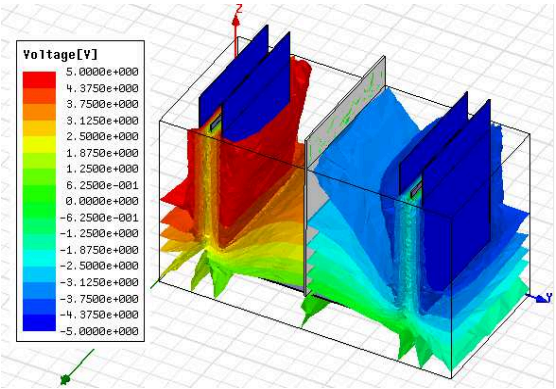

Fig.3 Stereogram of potential distribution

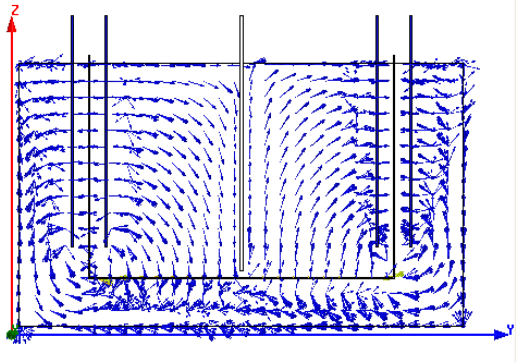

Fig.4 Current flow diagram

The influence of current density on current efficiency calculated at the conditions of different electrode plate intervals is shown in Fig.5. It can be seen that, the current density has remarkable effect on current density. The current efficiency increases almost 20% when the current density changes from 5A/dm^2 to 25A/dm^2. In addition, the larger is the electrode plate interval, the higher is the current efficiency with the same current densities(The current efficiency increases about 15% when the plate interval changes from 2.4cm to 6.4cm). It can be referred that, this is the reason that the high current density (beyond 100A/dm^2) electrolytic cleaning is more popular than ordinary current density (less than 50A/dm^2) electrolytic cleaning at present.

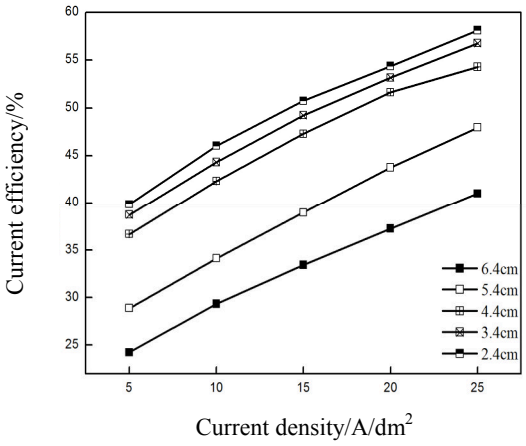

Fig.5 Current efficiency as a function of the current density

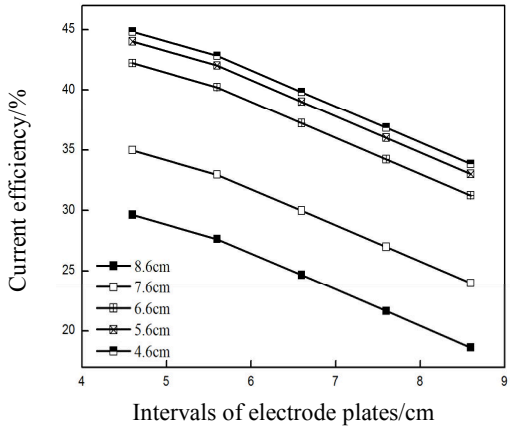

Fig.6 Current efficiency as a function of the electrode plate

Fig.6 illustrates the relationship among the current efficiency, the electrode plate interval and the length of electrode plate. It was shown that, there is a obvious decrease of about 10% of current efficiency when the interval changes from 4.5cm to 8.5cm. At the same time, the current efficiency reaches higher value when the length of electrode plate is shorter(There is a decrease of about 15% when the length of electrode plate increases from 4.6cm to 8.6cm). It can be inferred that, decreasing of electrode intervals can prevent the electric current from leaking to electrode plate directly.

The influence of insulation board on current efficiency with different current densities is presented in Fig.7. It indicates that, the insulation board is important for higher current efficiency. The current efficiency increases about 10% when the length of insulation board changes from 4.5cm to 8.5cm. It is

believed that the longer insulation board can separate the electrodes, which can significantly reduce the parallel discharge between positive and negative electrode, and induces a larger current focus flowing to the bottom of the strip.

Fig.8 reveals the relationship between the current efficiency and the electrolyte concentration. It can be learnt that, the current efficiency is unchangeable when the current density is fixed, and It can be learnt that, the current efficiency don't alter with electrolyte concentration. The reason is that, the electrolyte concentration can't induce the change of Electric field intensity(E). Though the conductance(k) increases with the concentration, the ratio of I_e to I_s would not alter according to Eq.4, Eq.5 and Eq.8. For the same reason, both the temperature and the conductance(k) have no effect on the current efficiency, which is confirmed by the results of simulation.

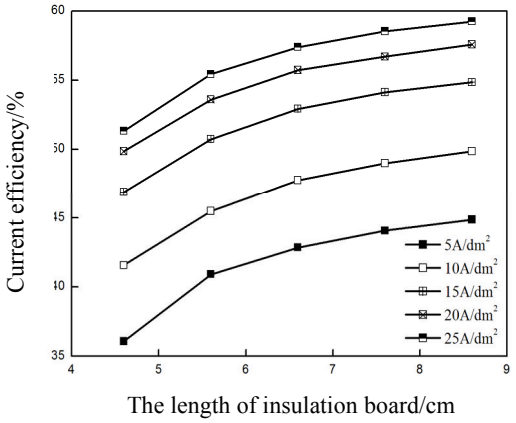

Fig.7 Current efficiency as a function of the length of insulation board

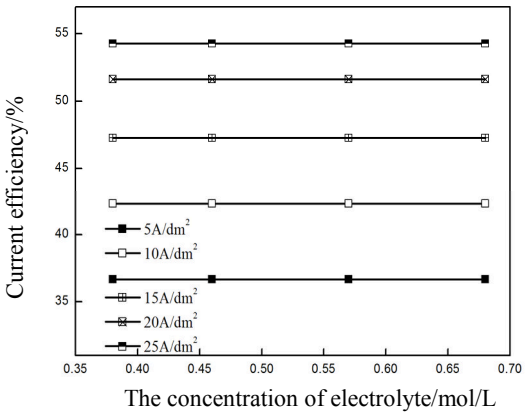

Fig.8 Current efficiency as a function of the concentration of electrolyte

Conclusions

Model of electrolytic cleaning for cold rolled strip was established, and the simulation of cleaning process was carried out with finite element method. The influences of processing parameters are studied, and the results show that:

(1) The current efficiency increases almost 20% when the current density changes from 5A/dm^2 to 25A/dm^2;

(2) The current efficiency decreases obviously with the increasing of the electrode plate intervals;

(3) The insulation board is important for higher current efficiency;

(4) The electrolyte concentration has no effect on current efficiency.

Keywords: Weak DC Current, Sensor, Magnetic Core Material, Ansoft,Simulation

Abstract. ZnMn ferrite, cold-rolled silicon steel, permalloy and nanocrystalline alloy can be used as magnetic cores of current sensors. And based on these four materials' inherent characters of electromagnetic, this paper presents closed loop simulation model of them using Ansoft which is a finite element analysis software. In simulation, the measuring currents are set to DC currents ranging from 0 to 1mA. And different amplitudes of variation of currents are set for each material. The simulation of each material produces 280 sets of data and with these data a series of curves of magnetic field changing with currents can be plotted using Matlab. The simulation results show that permalloy and nanocrystalline alloy have good characters of electromagnetic and they are suitable for detecting weak DC currents. When these two materials are used as magnetic cores of sensors, thetheoretical detecting accuracy can be up to 0.001mA, meanwhile, detecting accuracy of ZnMn ferrite is about 0.1mA to 0.01 mA.

Introduction

On-line monitoring ofinsulationand leakage current of electrical equipment has been a significant method through which can we find security risk timely and through which can we improve the reliability of electrical equipment. In the processing of monitoring, collecting data of leakage current is the most important aspect. Insulation leakage current of electrical equipment which is collected as important signal by on-line monitoring equipment is one of the main features which could reflect insulation ageing and flaw directly or indirectly [1-2]. As for detecting current, the key technique is to study current sensor with high performance which can be used in on-line monitoring [2]. Meanwhile we should consider various kinds, such as the variously strong noise around power substations and the small leakage current. When equipment is running well, the leakage current ranges from several tenths of a milliampere to decadesmilliamperes and about one thousandth of dielectric is lost. Taken together, the requirement of accuracy, angle error, stability and SNR of sensor is very high [2]. Therefore, the core material of sensor not only should have high resolving power and linearity, but also should have high sensitivity and strong antijamming capability. Selecting material of high differential permeability to make magnetic core is a method through we can reducemeasurement error efficiently. But we should also consider the strength of hysteresis effect of magnetic core when we are measuring low-frequency current [1-2]. As the requirement of precision of detection for current is improving continuously in the industry, many researches and comparison on permeability of different core material have sprung up [2]. But now, we will carry out a more quantitative study on permeability, resolving power, linearity of different magnetic core.

Analysis on Material Characteristics of Sensor

With the information industry developing constantly, performances and measurement accuracy of electric measuring instrument is improving continuously [4]. At present many materials, such as ZnMn ferrite, cold-rolled silicon steel, permalloy, nanocrystalline alloy and so on have been used as ferromagnetic materials widely. Comparison of typical parameters of ferromagnetic materials which is commonly used in the core of current sensors is shown in Table 1.

Table 1. Comparison of typical parameters of ferromagnetic materials

Basic parameters	ZnMn ferrite	Silicon steel	Nanocrystalline alloy	Permalloy
Saturation magnetic induction *Bs* *T*	0.5	2.0	1.25	0.75
Initial permeanceμ_0 $\mu H \cdot m^{-1}$	$2\sim2.5\times10^3$	$\sim10^3$	$4\sim8\times10^4$	$5\sim8\times10^4$
Maximum permeanceμ_m $\mu H \cdot m^{-1}$	5×10^3	4×10^4	6×10^4	6×10^4
Curie temperatureT ^{0}C	230	740	570	400
Density d g·cm^{-3}	4.8	7.65	7.25	8.75
CoercivityA/m	>4.4	>29.8	>0.8	>0.8

The value of magnetic induction of magnetic core materialsvaries with the magnetic field intensity. Meanwhile magnetic induction of magnetic core of sensor varies with the current of sensor. But in view of the small current which is needed to be detected and the value of which only ranges from several tenths of a milliampere to a dozen milliamperes. So we should consider the value of magnetic induction which ranges from 0 to 0.5T when we are selecting magnetic core materials [1]. We havesimulated four materials as sated above for seeking the best material which is suited for detecting weak DC Current very well.

Simulation Model and Theoretical Analysis

Based on inherent electromagnetic properties of permalloy and nanocrystalline alloy, we build closed loop simulation model with Ansoft Software.

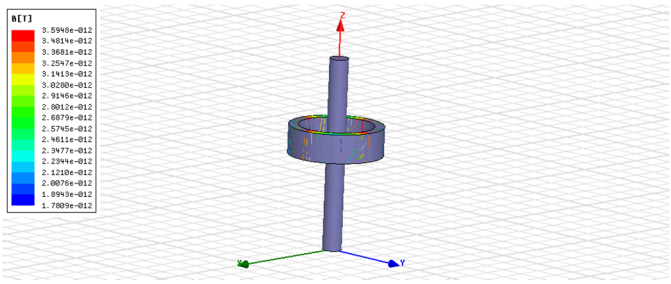

Fig. 1. Schematic diagram of Ansoft simulation model

Schematic diagram of Ansoft simulation modelis shown in Fig.1. We optimally choose magnetic ring's outer radius R2=25mm, inside radius R1=20mm and thickness h=5mm in Ansoft software. At center of the ring there is a cylindricalwire of which the diameter is 1mm and the length is 500mm and which is much larger than the thickness of the ring. In the model, the material of wire is copper. According to the references in Table 1, we put these four into material library of Ansoft. In this procedure, main parameters, such as differential permeability, coercivity, and state of materials should be set. As for ZnMn ferrite, we set the parameter of differential permeability to 5000, coercivity to –4.4A/m; for cold-rolled silicon steel, we set the parameter of differential permeability

to 10000, coercivity to –29.8A/m; for permalloy, we set the parameter of differential permeability to 200000, coercivity to –0.8A/m; for Nanocrystalline alloy, we set the parameter of differential permeability to 60000, coercivity to –29.8A/m. And we set the states of them to solid. Simulation result is shown in the left of the Fig. 1 through which we can see the magnetic induction B of different parts of the magnetic ring when a certain current is applied to the wire. From each time of simulation we can get 17 sets of data which respectively represent the magnitudes of magnetic induction of different parts between center and edge of the ring. We record the ninth set of data in order to make the mean value of magnetic inductionmore representative. In the processing of simulating, we set the range of current from 0.001mA to 1mA.

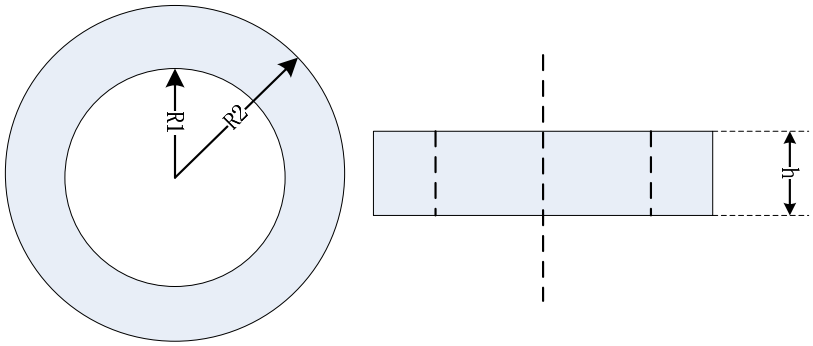

Fig.2. Schematic diagram of magnetic ring's structure

As Shown in Fig. 2, magnetic ring's outer radius is represented by R2; inside radius represented by R1; thickness is represented by h. Based on electromagnetic induction principle, when current flows in the center of the ring there should be magnetic induction B in the ferromagnetic material, and we have

$$\Phi = \int B.h.d_R (R_1 < R < R_2) \tag{1}$$

When the length of the wire is much larger than the thickness of the ring, the relationship between current and magnetic induction is approximately

$$B = \frac{\mu_r \mu_0 . I_0}{\pi \cdot (R_1 + R_2)} \tag{2}$$

Therefore, we can get corresponding relation of current and magnetic induction when we change the current magnitude in the wire and record corresponding magnitude of magnetic induction at the same time. And their relations are approximately linear.So as to determine whether we could detect various currents which range from 0.001mA to 1mA, we should set smaller step when we are collecting the data of small currents.

Simulation Results and Analysis

Among range of 0.00100–0.0100mA, we set step to 0.00005mA to collect 180 sets of data. Then we set step to 0.001mA to collect 90 sets of data among range of 0.01–0.1mA. Finally, we set step to 0.1mA to collect 10 sets of data among range of 0.1–1mA.Via this approach we could analyze whether the every material can reflect the various weak currents and determine the scope of accuracy. And in this way, we can make sure that the smallest current we detect is in our research scope. Because there always are electromagnetic interferences which produces higher magnetic induction than a 0.0005mA current does in the environment where the equipment is used.

3.1 Closed Loop Simulation Model of ZnMn Ferrite

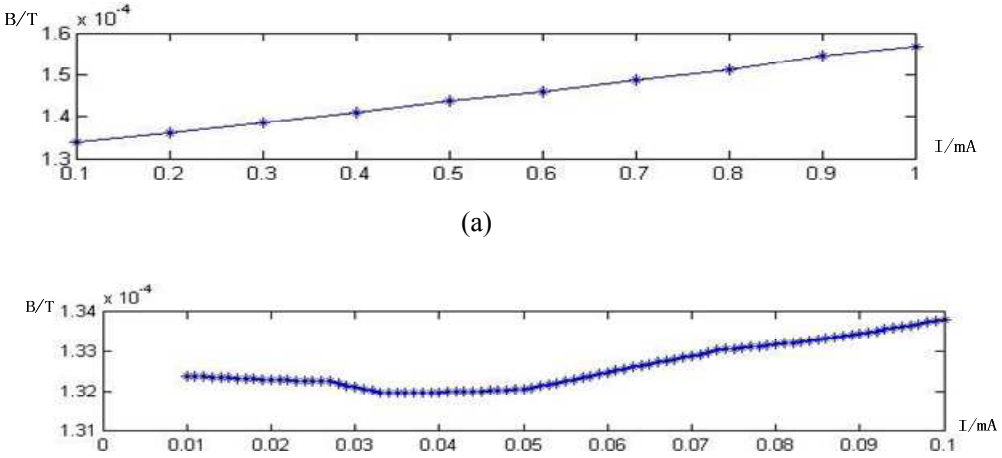

Fig. 3. ZnMn ferrite's change relation between magnetic induction and current

ZnMn ferrite's change relation between magnetic induction and current is shown is Fig. 3. When the step is set to 0.1mA, the relationship between magnetic field and current is approximately linear. And magnetic field can reflect variety of current as shown in Fig.3 (a). But when we set step to 0.01mA, we could find there is a nonlinear change of magnetic field in a certain scope as shown in Fig. 3 (b). Perhaps that phenomenon is led by hysteresis effect of ZnMn ferrite.

3.2 Closed Loop Simulation Model of Cold-rolled Silicon Steel

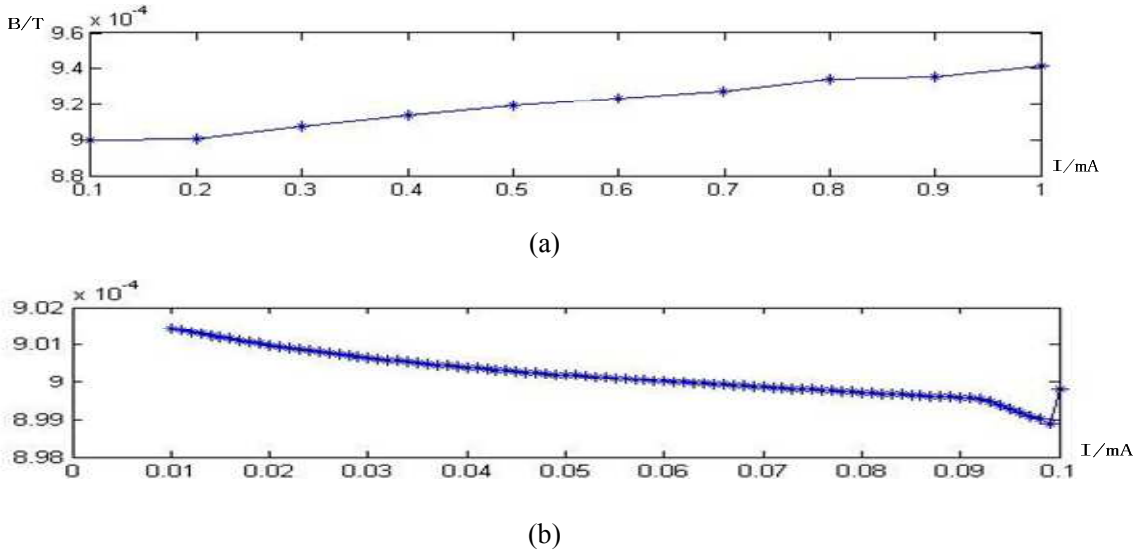

Fig. 4. Cold-rolled silicon steel's change relation between magnetic induction and current

Cold-rolled silicon steel's change relation between magnetic induction and current is shown in Fig.4. When the step is set to 0.1mA, the relationship between magnetic field and current is approximately less steadily linear. And magnetic field can reflect variety of current as shown in Fig. 4 (a). But when we set step to 0.01mA, we could find there is a nonlinear change of magnetic field which is led by variation of current in a large scope considering that ZnMn ferrite's nonlinear change only appears in a certain scope as shown in Fig. 4 (b). Perhaps that phenomenon is led by stronger hysteresis effect of cold-rolled silicon steel when we compare it with ZnMn ferrite.

3.3 Closed Loop Simulation Model of Permalloy (1J85)

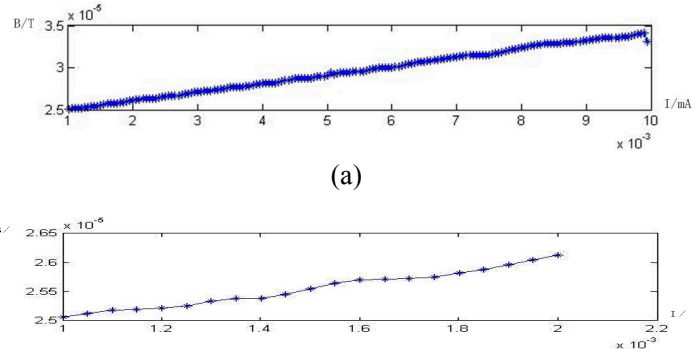

Fig. 5. Permalloy's change relation between magnetic induction and current

Permalloy's change relation between magnetic induction and current is shown in Fig.5. When the step is set to 0.1mA or 0.02mA, the relationship between magnetic field and current is steadily linear. When we set step to 0.01mA, the magnetic field has a relatively steady fluctuation with the change of current as shown in Fig.5 (a). Magnetic field can also reflect variety of current accurately. But when the step is set to 0.0005mA, the magnetic field has an unsteady fluctuation with the change of current as shown in Fig.5 (b). In this case magnetic field cannot reflect variety of current accurately. When we use permalloy (1J85) as the core material, the precision of detecting current is increased by at least two orders of magnitude comparing with ZnMn ferrite or cold-rolled silicon steel.

3.4 Closed Loop Simulation Model of Nanocrystalline alloy

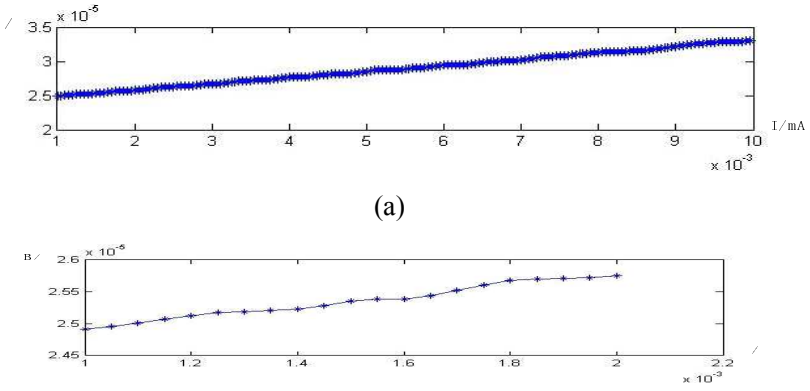

Fig. 6. Nanocrystalline alloy's change relation between magnetic induction and current

Nanocrystalline alloy's change relation between magnetic induction and current is shown in Fig.6. When the step is set to 0.1mA, 0.02mA or 0.001mA, the relationship between magnetic field and current is steadily linear similar to the relationship of permalloy. And magnetic field can reflect variety of current accurately as shown in Fig. 6(a). But when we set the step to 0.0005mA, the magnetic field has an unsteady fluctuation with the change of current as shown in Fig. 6 (d). In this case magnetic field cannot reflect variety of current accurately.

3.5 Simulation Analysis

In view of the closed loop simulation results of four materials, we could find that magnetic induction which are produced by different materials keep good linearities when the amplitude of variation of currents is 0.1mA. But when we reduce the amplitude of variation of currents by two

orders of magnitude (The step is 0.001mA), magnetic induction which is produced by ZnMn ferrite does not keep linearity because of its high coercivity and hysteresis effect. Similarly, the reason why cold-rolled silicon steel's magnetic induction appears abnormal is that it has the highest coercivity among four materials. At present, permalloy (1J85) and nanocrystalline alloy can keep their linearities of magnetic induction with the change of current well. But when the amplitude of variation of currents is set to 0.00005mA, with the change of current the magnetic field has an unsteady fluctuation which is not linear certainly.

Conclusions

Simulation data and analysis indicate that cold-rolled silicon steel can detect the variation of current which is smaller than 0.1mA and ZnMn ferrite can detect the variation of current which is smaller than 0.01mA. Permalloy (1J85) and nanocrystalline alloy can keep their linearities when magnetic induction is changing with smaller current relative to ZnMn ferrite and cold-rolled silicon steel. And when the measuring accuracy is set to 0.0001mA, these two materials can also keep good linearities. But when we set the measuring accuracy to 0.00005mA, the changing curve of magnetic induction of two materials is not linear. It is because differential permeability is not high enough and there exists coercivity and hysteresis effect. Hence, permalloy and nanocrystalline alloy is suitable for weak DC current sensors with high accuracy. By using the latter two materials, the highest accuracy of the sensor can be up to 0.0001mA without considering external interferences. But its real accuracy is less than 0.00005mA because of the deficiency of differential permeability and existence of coercivity and hysteresis effect. Considering that there are electromagnetic interferences of environment of which value is higher than this, so the detecting accuracy can reach 0.001mA in practical engineering field.

Influential Factors of suspension insulator AC Pollution flashover voltage: A Survey

SHEN Qing

School of Electrical Engineering, Wuhan University, Wuhan, China
d-q-j-0@163.com

Keywords: Insulator, Suspension, Pollution, Insulator structure, Pollution flashover voltage

Abstract: To make up insufficient of ESDD in insulator flashover voltage analysis, and A more comprehensive assessment of antifouling properties of insulators. This paper discusses the factors of suspension insulator flashover voltage of the AC, analyzed the influence of these factors on the flashover voltage, found the reason for large differences of the current test results of research institutions at home and abroad, and proposed future research directions.

Introduction

In recent years, with increased Pollution of industrial development, environmental degradation, the voltage increases, network expansion and interconnection of AC and DC, pollution flashover accident growing, threat to the safe operation of power transmission equipment. Therefore, the analysis of factors affecting the discharge of insulator flashover is conducive to seek administrative and technical measures to prevent flashover occurs, to minimize the occurrence of flashover accident. [1]~[3]

External insulation pollution discharge is a "product Pollution - wet - dry area and local arcing occurs - partial arc sent to flashover" [4]. The process is affected by filthy composition, degree of Pollution, insulator structure, weather conditions, and filthy uniform and so on.

The influence of the nature and amount of Pollution

The Pollution deposited on the insulator surface can be divided into industrial and natural. Whether it be industrial or natural filthy dirty, accumulate on the insulator Grimes actual solubles mainly is $CaSO_4$, $MgSO_4$, $ZnSO_4$ and $NaNO_3$, KNO3, KCl, NaCl etc. In these salts, $CaSO_4$ and NaCl influence the flashover voltage insulator pollution greater. The former makes flashover voltage rises. The latter makes flashover voltage decreases. Other salts such as $NaNO_3$, KNO_3, KCl, etc. can be incorporated in NaCl as Na salt. The little effect $MgSO_4$, $ZnSO_4$ and other salts of flashover voltage can not be considered [5].

Insulators withstand voltage or flashover voltage with different degrees of Pollution can be determined by artificial or natural Pollution experiment. Operating experience and a lot of test results show that flashover voltage insulators related to the degree of Pollution, its means that flashover voltage insulators related to salt density and non-soluble density.

According to a large number of experimental data, researchers establish a flashover voltage and salt density, non-soluble density equation:

$$U_f = K_{AB} S^{-a} G^{-b} \tag{1}$$

Where K_{AB} is the coefficient related with insulator string length, type and atmospheric conditions, and it can be calculated by the experiment.

Take the seven strings XP-160 insulators for example, the relationship between its flashover voltage and salt density, non-soluble density can be expressed as [7]:

$$U_f = 34.4S^{-0.237}G^{-0.139} \tag{2}$$

$$U_f(1) = 4.913S^{-0.237}G^{-0.139} \tag{3}$$

Analysis shows that, with the increase in salt and non-soluble density, U_f decreased; and U_f decreased rapidly when the salt and non-soluble density is small, with salt density and ash density increasing U_f decline slows, which are similar with the impact effected of salt and non-soluble density separately.

For composite insulators, Flashover voltage is much higher than the flashover voltage of the ordinary porcelain insulators; the non-soluble density impact characteristic index of composite insulators are not very different, and its salt density impact characteristic index is less than the non-soluble density impact characteristic index.

The influence of structure and the length of the insulator string

(1)The influence of structure

The Pollution situation of insulator surface depends primarily on the material and structure of the insulator.

Canadian theoretically derived that the insulator creepage distance is related with the insulator structural parameters and the degree of Pollution.

$$L_s = d_c D_e^{3r} SDD^r \tag{4}$$

Where, De is the average diameter of the insulator, cm; dc is vector constant; $r = n_a/(1-n_a)$, n_a is Static constant along the surface of the arc, $0 < n_a < 1$; SDD is the salt density, mg / cm2.

There are five main structure of anti-fog suspension insulator: Bell structure, ordinary suspension insulator with semiconductor glaze layer, flow lines umbrella structure, double or triple umbrella and large diameter, large creepage, lower height structure. Flashover Performance comparison of different types of insulators curve shows: In 0.1mg/cm^2 salt density, 70kN anti-fog insulator flashover voltage is 15% to 33% higher than the ordinary insulator flashover, and the double umbrella structure (XWPl-70) is 17% ~ 32% higher. Small height double umbrella structure(XWP2—70) is 15%～33%. Bell structure(XHPl-70) is 30%～60% higher. Meanwhile the 100kN or 160kN anti-fog insulator flashover voltage is similar. [8]

(2)The influence of the length

Whether a linear relationship is a very important unresolved issue between the insulator string length and AC flashover voltage. The problem for high voltage power transmission engineering filthy insulation design has important engineering significance. Since the test conditions, the test results are not uniform at home and abroad.
